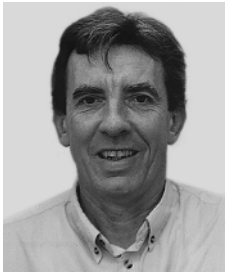
Keywords: One-dimensional multicomponent arrays / Energy- and electron transfer / Molecular motions / Ruthenium / Osmium / Terpyridines / Bis-terpyridines / Bis-cyclometallating ligands / Porphyrins / Copper(I) rotaxane

Transition metals are powerful three-dimensional templates, which can gather various functionalized ligands and orient them in a precise fashion so that complex multicomponent molecular systems can be obtained without constructing covalently-assembled edifices. The compounds thus prepared exhibit precise chemical or physical functions, which are governed by the design of the system. The construction of one-dimensional molecules around ruthenium(II) or osmium(II), using rigid ligands attached to the desired electroactive species, leads to systems that are able to undergo charge separation after photonic excitation. In other related compounds, a ruthenium(II)-based chromophore is, for example, connected to an osmium(II) complex by means of rod-like bridging ligand, thereby ensuring strict control over the Ru···Os distance. By tuning the length and the electronic properties of the bridge, one can control the efficiency of the electronic energy transfer between the two chromophores. In particular, the use of a bis-cyclometallating ligand is very conducive to energy transfer and allows the observation of this process up to a Ru..Os distance of ≈20 Å. By combining the building blocks of these inorganic systems with appropriate porphyrins, long-range (centre-to-centre distance between the donor and the acceptor porphyrins ≈30 Å) and relatively long-lived photoinduced charge separation has been demonstrated. Finally, with copper(I) as the template, compounds of the rotaxane family are obtained, which consist of a coordinating ring threaded by a string-like component. If this acyclic fragment is end-functionalized by two bulky stoppering groups and if it incorporates two different coordination sites (a bi- and a terdentate chelate site), novel dynamic properties are observed. The movement of a given fragment of the molecule is triggered by changing the metal oxidation state. This one-dimensional motion of the ring along the string on which it is threaded is controlled by redox manipulation, resulting in a primitive molecular machine.



Pablo Gaviña (top left) was born in Valencia, Spain, in 1966. He studied chemistry at the Universidad de Valencia, where he received his Ph. D. in 1994 with Professor R. Mestres, on dienediolates of unsaturated carboxylic acids and on the protection and controlled release of aldehydic pheromones. He then spent two years as postdoctoral fellow with Dr. J.-P. Sauvage, working on chemical topology and on electrochemically induced molecular motions. He is currently working with Professor G. Asensio in the Department of Organic Chemistry of the Universidad de Valencia on enantioselective protonation of prochiral enolates.

Valérie Heitz (bottom left) was born in Strasbourg, France, in 1966. After completing a Ph. D. with Dr. J.-P. Sauvage in 1992 on multiporphyrin systems performing photoinduced electron transfer, she did postdoctoral work with Dr A. Harriman at the Center for Fast Kinetic Research at the University of Texas at Austin. She obtained a position as "Maître de Conférences" at the University of Strasbourg in 1993 and carries out research work in the laboratory of J.-P. Sauvage. Her current interest concerns the synthesis of functional models of photosynthetic reaction centres.

Jean-Paul Collin (top right) was born in 1945 in Metz. After his Ph. D. in electrochemistry with Professor J. P. Schwing at the Louis Pasteur University, Strasbourg, he did postdoctoral work with Professor J.-M. Lehn on water photolysis. He is now a CNRS research director. He joined Dr J.-P. Sauvage's group in 1983 and his present research focuses on photoinduced charge separation in multicomponent molecular systems.

Jean-Pierre Sauvage (bottom right) was born in Paris in 1944. He obtained his Ph. D. from the University of Strasbourg, under the supervision of J.-M. Lehn. After postdoctoral research in Oxford (UK), with M.L.H. Green, he went back to Strasbourg, where the started his own research group in 1980. His interests span from models of the photosynthetic reaction centre to molecular topology.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

7. Conclusion and Prospects

1. Introduction

In complex multicomponent molecular systems, the control of physical properties related to electron- and energy-transfer or displacement of molecular fragments relies, to a large extent, on our mastery of the geometrical properties of the ensemble.

For several years, we have been interested in one-dimensional compounds, for which an axis along the largest dimension of the object can be clearly defined[1][2][3]. If rigidity can also be introduced during the design and synthesis steps, distances and, sometimes, angles between the various components located on the axis can be estimated to a good approximation.

Two distinct aspects of our research are discussed in the present review article: (i) electron- or energy-transfer, and (ii) molecular motions, related to "molecular machines", along an axis.

(i) The aims of the first and main topic are manifold. In the short term, it is important to improve our understanding of electron- and energy-transfer processes and to verify the current theories[4][5][6][7] by modifying at will the distances and orientations between the various chromophores and electrophores of the assembly, and by changing their electronic properties as well as those of the spacer groups used in the construction of the systems. An aspect of this approach is to build and study models[8][9][10][11][12] of photosynthetic reaction centres (RC), which function so efficiently in living organisms, and in particular in photosynthetic bacteria[13][14]. In the long term, it would of course be of great interest to build molecular systems or hybrid devices, containing molecules and organic or inorganic solids, capable of converting light energy into electrochemical or chemical energy[15][16][17]. In other words, the creation of artificial systems able to perform real photosynthesis is a special challenge.

(ii) The second line of research is more recent and is concerned with molecular machines and motors[18][19][20], i.e. molecular ensembles for which a large amplitude and reversible motion can be triggered simply by sending a signal to the molecule from outside. This signal is usually electrochemical (reduction or oxidation of an electroactive component) or photochemical. However, many other types of perturbations can be envisaged: magnetic or electric field, temperature or pressure jump, chemical signal (pH change), etc. In our case, the notion of axis and geometrical control is again essential. Scheme 1 illustrates, in a simplified fashion, the two facets of the work discussed herein.

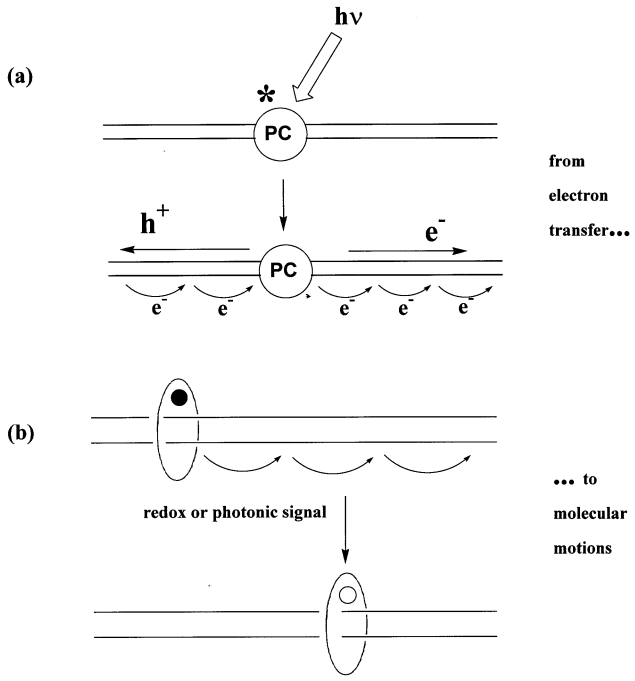
2. Complexes of Ruthenium(II) and Osmium(II) Covalently Linked to Electron Donor and Acceptor Groups

One of the key features of natural photosynthesis is the efficiency of charge separation. In a multistep procedure, light energy absorbed by a photoactive centre is converted into electrochemical energy with formation of a long-lived charge-separated state. This complex process relies on the subtle arrangement of energy levels for the excited or redox states involving the various chromophores, favouring a cascade-like sequence of electron-transfer steps leading to the charge-separated state.

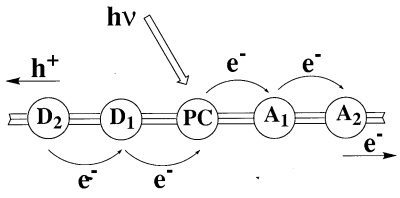
In the field of transition metal complexes, one can design multicomponent systems for which similar charge separation may occur, provided that the electronic properties of the various chromophores are controlled and selected in a precise fashion, and that there is strict control over the geometrical properties of the set of photo- and electroactive species (Scheme 2).

On the basis of their photochemical, photophysical and electrochemical properties, M(II) polypyridine complexes (M = Ru or Os) are, in principle, suitable photosensitizer components for use in multicomponent systems designed to permit efficient photoinduced charge separation[15][21][22][23][24]. However, with ligands such as 2,2′-bipyridine, the building up of multicomponent molecules

Scheme 1. In a one-dimensional multicomponent system, a photoactive centre (PC) is (a) first excited by a photon. The excited state is subsequently able to transfer an electron to an acceptor (on the right of the PC, not represented). This process induces a series of cascade-like electron-transfer steps the overall effect of which is to create a negative charge on the right-side and a positive hole on the left-side of the array. (b) A redox or photonic signal modifies the coordination requirements of a metal centre (black dot) incorporated in a rotaxane, triggering molecular motions. The shift of the ring and the metal is induced by modification of the metal centre coordination sphere

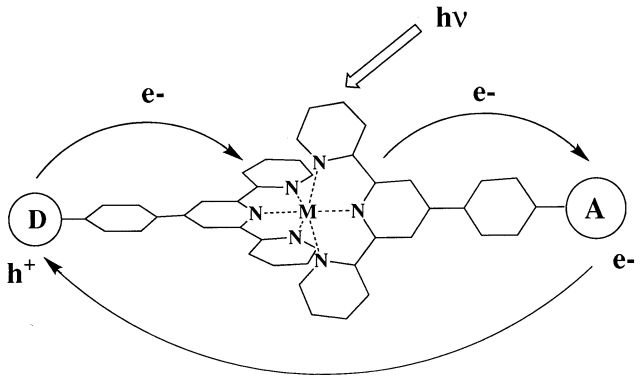


Scheme 2



leads to systems in which the acceptor or donor groups linked to the chromophore are relatively close to one another (*cis*-type configuration)[25]. In contrast, the geometry of terpyridine complexes offers the possibility of designing systems in which the D and A components lie in opposite directions with respect to the chromophore (*trans*-type configuration)[1]. In addition, bis-terpyridine complexes bearing substituents at the 4′-position do not lead to isomeric (enantio- and diastereomeric) mixtures, in contrast to the corresponding substituted bipyridine systems. Furthermore, the interposition of aromatic rings (Figure 1) affords a convenient means of increasing the A−D separation[26].

Figure 1. Schematic representation of the photochemically-induced electron-transfer step in an $M(tpy)_2^{2+}$ complex bearing acceptor (A) and donor (D) groups



2.1. Synthesis of Terpyridine Ligands

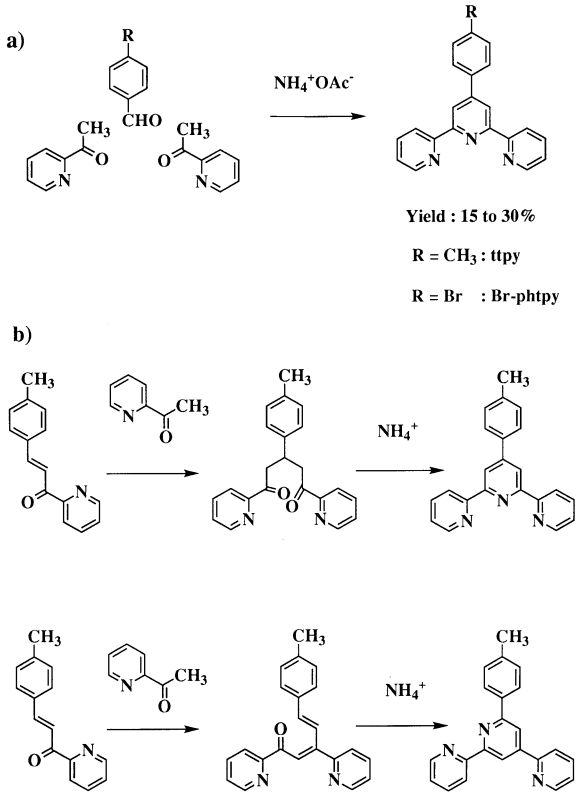
Since the first preparation of the 2,2′:6′,2"-terpyridine ligand 60 years ago by oxidative coupling of pyridine with $FeCl_3$ in an autoclave[27], other strategies involving the coupling of pyridine units (cross-coupling methodology)[28] or the formation of one or two pyridine rings from precursor functions have been developed. Certainly, the most commonly used methodology is the synthesis of the central pyridine ring. The pioneering works of Hantzsch[29], Tschitschibabin[30], Case[31], Kröhnke[32] and others using this principle, have been followed by new developments and improvements. In particular, the works of Constable[33], Potts[34] and Jameson′s group[35] allow the preparation of various substituted terpyridines. In order to obtain large amounts of the 4′-aryl-2,2′:6′,2″-terpyridine, the one-pot Hantzsch synthesis, developed by Case[31] and later by Calzaferri[36], was selected (Figure 2a).

The condensation of the aromatic aldehyde with two equivalents of 2-acetylpyridine gave a 1,5-diketone. Ring closure was achieved using ammonium acetate. In some cases, two terpyridine isomers[37] could be obtained following a 1,2- or 1,4-Michael addition on the unsaturated ketone intermediate (Figure 2b).

The separation of the terdentate ligand, arising from 1,4-addition, from the sterically hindered bidentate ligand was readily achieved by formation of the highly stable $Fe(terpyridine)_2^{2+}$ complex, as described by Constable et al.[33] The iron(II) complex, upon treatment with H_2O_2 in alkaline solution, yielded the free terpyridine in good yield.

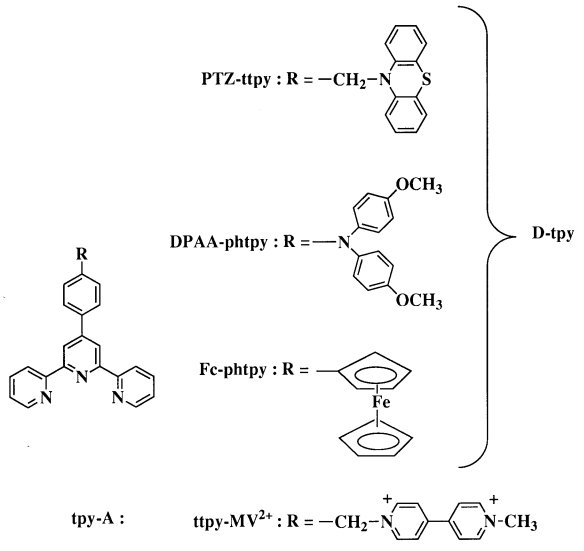
The terpyridine-bearing electroactive compounds could be prepared using one of two general strategies. In the first of these, the ligand is synthesized bearing a suitable functionality and the desired electrophore is then introduced in a second step[37][38]. The other possibility involves introduction of the electroactive function into the aromatic aldehyde prior to the terpyridine formation reaction[37]. Both routes have been explored and used, the method of choice being dictated by the chemical stability of the donor or the acceptor groups, since the second ap-

Figure 2. (a) Synthetic route to various substituted terpyridines. (b) Formation of 2,2′:6′,2″-terpyridine and its isomer (2,2′:4′,6″-) via 1,2- or 1,4-Michael addition



proach implies that the electrophore will have to resist the relatively harsh experimental conditions of the cyclisation reaction. Figure 3 depicts various ligands, containing either D or A units as pendant groups, prepared by these two strategies.

Figure 3. Various tpy derivatives used, with an electrophore rigidly attached to the chelate via a 1,4-phenylene spacer. PTZ = phenothiazine; DPAA = di-*p*-anisylamine; Fc = ferrocene; MV^{2+} = methylviologen



2.2. Synthesis of Diads and Triads Based on $Ru(tpy)_2^{2+}$ -Type Photosensitizers

The various ruthenium(II) complexes prepared and studied are listed in Table 1. The various ligands used are depicted in Figure 3.

Table 1. Preparation of the various ruthenium(II) diad or triad complexes[a] A: sequential method; B: statistical method

Complex	Method[a]	Yield (%)	Reference
(Fc-phtpy)Ru(ttpy)$^{2+}$	A	15	[38]
(Fc-phtpy)Ru(ttpy)$^{2+}$	A	5	[37]
(DPAA-phtpy)Ru(ttpy)$^{2+}$	A	37	[37]
(ttpy)Ru(ttpy-MV^{2+})$^{4+}$	B	8	[26][37]
(PTZ-ttpy)Ru(ttpy-MV^{2+})$^{4+}$	B	5	[26][37]
(DPAA-phtpy)Ru(ttpy-MV^{2+})$^{4+}$	B	8	[26][37]
(Fc-phtpy)Ru(ttpy-MV^{2+})$^{4+}$	B	18	[41]

They have been prepared either in a *sequential manner* (A) or by a *statistical method* (B):

(A): $Ru(ttpy)Cl_3 + tpy{-}D \xrightarrow{(i)} Ru(ttpy)(tpy{-}D)^{2+}$
(i): reflux in ethanol/water/triethylamine for 1 h

(B): "ruthenium blue" + L_1 + $L_2 \xrightarrow{(ii)}$ $Ru(L_1)_2^{2+} + Ru(L_1)(L_2)^{2+} + Ru(L_2)_2^{2+}$
(L_1)(L_2): (ttpy)(ttpy$-MV^{2+}$), (PTZ$-$ttpy)(ttpy$-MV^{2+}$), (DPAA$-$phtpy)(ttpy$-MV^{2+}$)
(ii): reflux in ethanol for 18 h

Method (A) was used for ligands bonded to an electron donor (tpy$-$D). However, it turned out not to be appropriate for the synthesis of complexes containing the ttpy$-MV^{2+}$ ligand. The triads and the electron acceptor diad Ru(ttpy)(ttpy$-MV^{2+})^{4+}$ were thus prepared according to the statistical procedure (B).

2.3. Synthesis of Diads and Triads Based on $Os(tpy)_2^{2+}$ -Type Photosensitizers

Although the coordination sphere of ruthenium is known to be relatively inert vis-à-vis substitution reactions, it is still very labile as compared to osmium. In fact, substituting ligands within the coordination sphere of osmium is notoriously difficult and requires either extremely harsh conditions or multistep procedures involving different metal oxidation states. Using the ligands shown in Figure 3, various osmium(II) complexes could be prepared[26][38][39][40][41]. Due to the chemical fragility of some of the ligands, the very drastic classical conditions, consisting of heating osmium salts and the ligands at very high temperature (typically, refluxing ethylene glycol) for long periods could not be systematically applied. Consequently, more elaborate, specific methods had to be developed. The two general routes used are indicated in Figure 4.

The series of osmium(II) diad and triad complexes prepared and investigated is listed in Table 2.

Importantly, since photophysical measurements are very sensitive to impurities, special care was taken in order to ensure the isolation of very pure samples of the various ruthenium(II) and osmium(II) complexes. For this purpose,

Figure 4. The two general routes to substituted bis(tpy)osmium(II) complexes

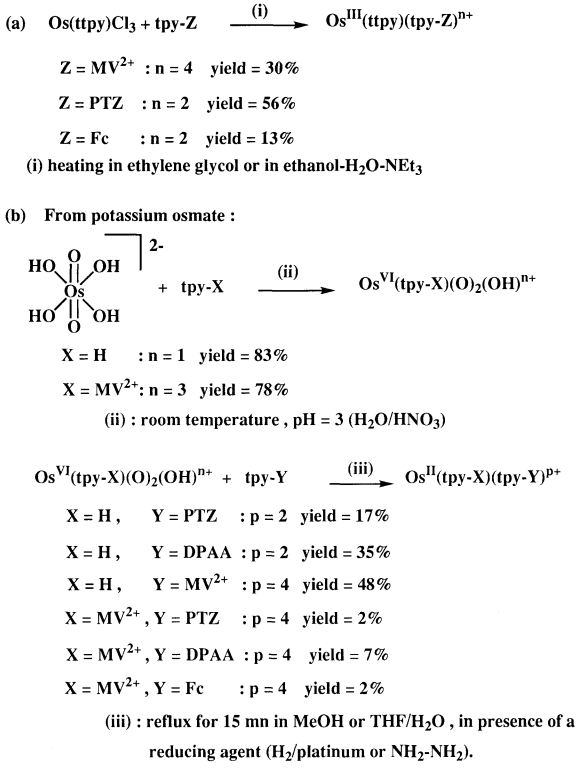


Table 2. The various multicomponent compounds prepared containing a bis-terpyridine osmium(II) central chromophore

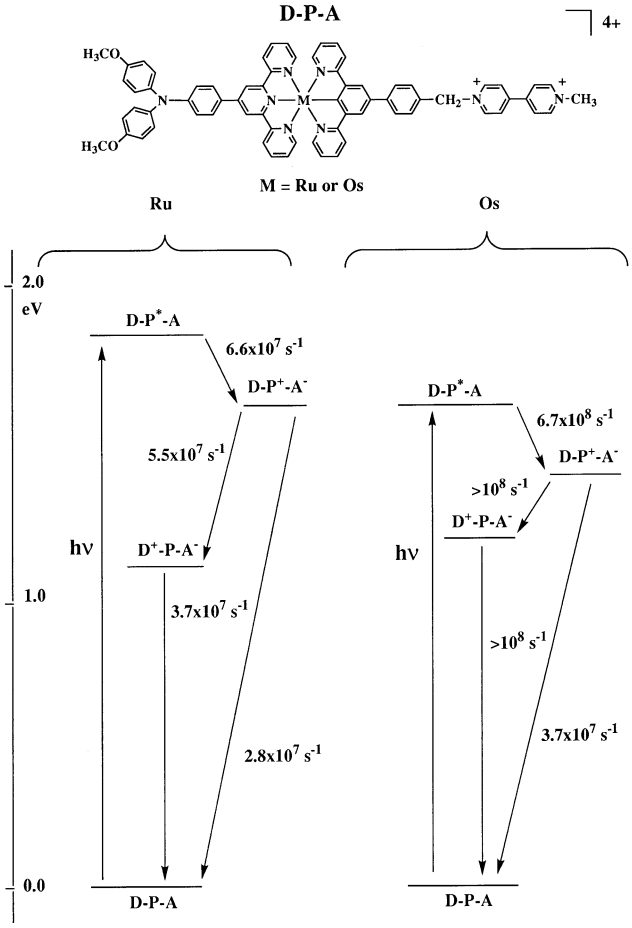
Complex	Method (see Figure 4)	Reference
$(ttpy)Os(ttpy\text{-}MV^{2+})^{4+}$	(a) or (b)	[26][40]
$(PTZ\text{-}ttpy)Os(ttpy)^{2+}$	(a)	[26][40]
$(Fc\text{-}phtpy)Os(ttpy)^{2+}$	(a)	[38]
$(DPAA\text{-}phtpy)Os(ttpy)^{2+}$	(b)	[40]
$(PTZ\text{-}ttpy)Os(ttpy\text{-}MV^{2+})^{4+}$	(b)	[39]
$(DPAA\text{-}phtpy)Os(ttpy\text{-}MV^{2+})^{4+}$	(b)	[39]
$(Fc\text{-}phtpy)Os(ttpy\text{-}MV^{2+})^{4+}$	(b)	[41]

all the compounds prepared were subjected to chromatography on silica gel, with a mixture of solvents (usually CH_3CN and H_2O) containing a salt (KNO_3, for instance) as eluent.

2.4. Photoinduced Processes in Diads and Triads Based on $Ru(tpy)_2^{2+}$ and $Os(tpy)_2^{2+}$-Type Photosensitizers

As is normal for ruthenium(II) and osmium(II) polypyridine complexes, light excitation in the spin-allowed MLCT bands eventually leads to population of the lowest energy ^{3}MLCT level[23][42], which is the state responsible for the observed electron-transfer processes. Since $Ru(tpy)_2^{2+}$ is practically non-emitting at room temperature, the experiments on this species and its derivatives were performed at 155 K[43]. For the compounds based on $Os(ttpy)_2^{2+}$, which is luminescent at room temperature, experiments were performed at both 155 K and 298 K[39]. The solvent used was butyronitrile. Detailed mechanisms of the photoinduced processes in these P−A diads and in the D−P−A triads have been given in a previous review article[1]. Photoinduced processes in the D−P−A triads are depicted in Figure 5. At 155 K, the lifetime of the fully charge-separated state D^+-P-A^- (P = Ru) is estimated to be 27 ns. For the Os-based triads, the deactivation via the fully charge-separated state D^+-P-A^- occurs with $k > 10^8\ s^{-1}$. In this case, the transient absorption spectrum of the D^+-P-A^- species is not detected because this species does not accumulate but rapidly reverts to D−P−A.

Figure 5. Photoinduced processes in the $DPAA-P-MV^{2+}$ triads at 155 K, where P is $Ru(ttpy)_2^{2+}$ or $Os(ttpy)_2^{2+}$



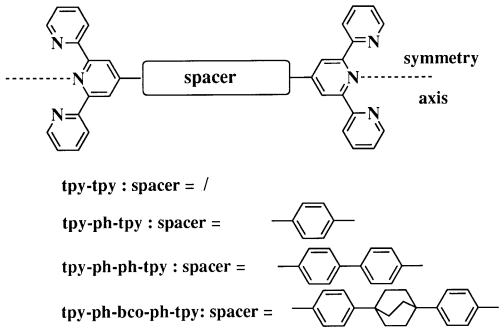
3. Rigid Rod-like Dinuclear Terpyridine-Type Complexes

Symmetrical rigid dinucleating ligands, the syntheses of which are versatile enough to allow modulation of the electronic and geometrical properties, are also promising. The family of compounds discussed in the following section allows us to evaluate the effect of metal-to-metal distance on the rate of energy- or electron-transfer between the donor subunit and the acceptor fragment, and also to assess the influence of the electronic properties of the spacer inserted between the two components.

3.1. Synthesis of Bridging Bis-terpyridine Ligands

By connecting two terpyridine units via a rigid spacer attached to their 4′-positions, bridging ligands displaying axial symmetry can be obtained. The compounds which have been synthesized and used further to make dinuclear complexes are illustrated in Figure 6.

Figure 6. Ligands used in the preparation of the heterodinuclear complexes



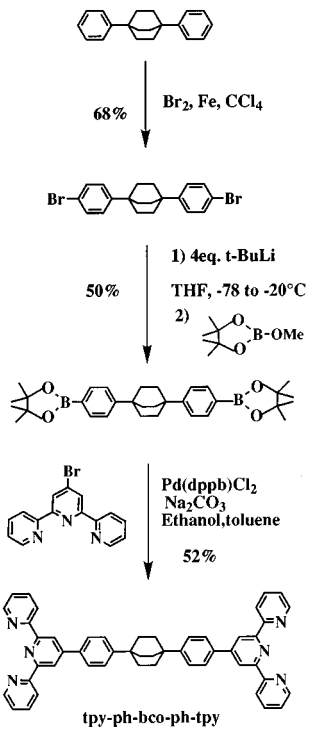
The bis-terpyridine ligand tpy−tpy was synthesized by reductive coupling of 4′-chloro-2,2′:6′,2"-terpyridine, following the methodology recently reported by Constable and Ward[44]. The phenyl-bridged bis-terpyridine ligand tpy−ph−tpy was obtained according to the method developed by Kröhnke et al.[32]. The same reaction has also been used more recently by others[45]. The principle is very general and can allow the preparation of virtually any compound containing several pyridine nuclei attached to aromatic rings. The biphenyl-containing ligand tpy−ph−ph−tpy was obtained by homo-coupling of 4′-*p*-bromophenyl-2,2′:6′,2"-terpyridine in the presence of Ni(0) triphenylphosphane complex and Zn dust in DMF. The yield was 60%, thus allowing preparation of the compound on a gram scale.

It should be noted that the bromo-terpyridine used as starting material is readily available from 2-acetylpyridine and 4-bromobenzaldehyde[36] (Figure 2). This functionalized terpyridine is the ideal precursor to a potentially bridging multi-terpyridine ligand. It should lead to bis-terpyridine systems with various aromatic or saturated spacers, as well as to bridging multi-chelates by connecting several such terpyridine units.

The preparation of the bridging ligand tpy−ph−bco−ph−tpy (bco = 2,2,2-bicyclooctane) was achieved using the multistep procedure shown in Figure 7.

The key intermediate, Br−ph−bco−ph−Br, was prepared following a modification of a procedure previously described by Zimmermann et al.[46]. Treatment of this dibromoarene with 4 equivalents of *t*-butyllithium and 2 equivalents of 2-methoxy-4,4,5,5-tetramethyl-1,3,2-dioxoborolane[47] afforded a diester derivative, which could be purified by crystallization. The successful cross-coupling of the 4′-bromo-2,2′:6′,2"-terpyridine with the diester using $Pd(dppb)Cl_2$ [dppb = 1,4-bis(diphenylphosphane)butane] as catalyst was performed following the methodology developed by Suzuki et al.[48] and recently applied to a water-soluble *p*-phenylene-containing polymer[49].

Figure 7. Reaction used in the synthesis of the bridging ligand tpy−ph−bco−ph−tpy



3.2. Synthesis and Photochemical Behaviour of Rigidly Bridged Heterodinuclear Complexes

The rigidly bridged ruthenium(II)-osmium(II)[50][51][52][53] and ruthenium(II)-rhodium(III)[54] complexes are depicted in Figure 8.

The general preparation of the heterodinuclear complexes requires, as a first step, the synthesis of the key complexes $(ttpy)Ru[tpy-(ph)_n-tpy]^{2+}$. These intermediate mononuclear compounds were obtained as follows: $Ru(ttpy)Cl_3$ and $AgBF_4$ were refluxed in acetone in order to remove the chlorine atoms from the metal. The complex obtained was added to a DMF solution of the bridging ligand and the mixture was refluxed for 1 h. After work-up and chromatography on alumina with CH_3CN as eluent, the compounds were isolated as their PF_6^- salts in good yields: $(ttpy)Ru(tpy-tpy)^{2+}$: 85%; $(ttpy)Ru(tpy-ph-tpy)^{2+}$: 77%; $(ttpy)Ru(tpy-ph-ph-tpy)^{2+}$: 76%. All the compounds described were characterized by standard techniques (^{1}H-NMR and FAB-MS). FAB-MS turned out to be particularly useful for these highly positively charged species. In each case, the molecular peak was sufficiently intense to eliminate any ambiguity concerning the structure of the compound.

3.2.1 Ruthenium-Osmium Complexes: The ruthenium complex bearing a free terpyridine site was allowed to react with crude $(ttpy)OsCl_3$ in refluxing *n*BuOH for 7 h. This very insoluble compound was prepared from $OsCl_3.xH_2O$

$(ttpy)Ru(tpy\text{-}ph\text{-}tpy)Rh(ttpy)^{5+}$: n = 1

$(ttpy)Ru(tpy\text{-}(ph)_2\text{-}tpy)Rh(ttpy)^{5+}$: n = 2

and ttpy and used without further purification. In fact, attempts to remove the chloride ions with Ag^+ were of questionable success. Depending upon the starting sample, other ruthenium-osmium complexes could be isolated in low yield[51]. The formation of these by-products seems to reflect the polymeric nature of the poorly-defined starting complex, $(ttpy)OsCl_3$.

Photophysical data (steady-state luminescence spectroscopy and time-resolved spectroscopy methods) indicate a very efficient energy-transfer process from the ruthenium chromophore to the osmium moiety[53][55]. This transfer takes place according to the exchange mechanism of Dexter[4]. Actually, the transfer of energy was found to occur with $k > 10^{10}$ s^{-1}, even for $d_{MM} = 20$ Å (d_{MM} is the intermetal distance). One concludes that the polyphenylene bridge behaves as an extremely good energy transducer. Insertion of a bicyclooctane (bco) unit leads to an internal separation of 24 Å and results in a dramatic decrease in the rate of energy transfer ($k = 4.4 \times 10^6$ s^{-1} as measured at 77 K). This effect is due to the increased internal distance as well as the electronically insulating properties of the saturated bco group. It is nevertheless remarkable that energy transfer still takes place at such a large distance and in spite of the presence of a central insulating group. Studies performed by other groups with systems incorporating ethynyl[56] or other rigid spacers[57][58][59] have led to similar results.

3.2.2. Ruthenium-Rhodium Complexes: The ruthenium complex bearing a free terpyridine site was allowed to react with $(ttpy)RhL_3$ (L = acetone) in refluxing ethanol for 4 h. The latter was obtained similarly to its ruthenium analogue, by replacing the chloride ligands of the complex $(ttpy)RhCl_3$ by solvent molecules using $AgBF_4$ in refluxing acetone. As in the case of ruthenium-osmium complexes, other multinuclear by-products were isolated. Their formation can be explained in terms of reduction of the rhodium(III) centre to rhodium(I) during the complexation reaction, followed by ligand scrambling[54]. Indeed, the coordination sphere of the rhodium(I) metal is labile and the ligand interchange can easily occur.

The photophysics of the binuclear complexes were investigated in 4:1 methanol/ethanol solution at 77 K (rigid glass) and 150 K (fluid solution) and compared with data for the mononuclear $Ru(ttpy)_2^{2+}$and $Rh(ttpy)_2^{3+}$ model compounds[54]. At 77 K, no quenching of the Ru(II)-based excited state was observed, whereas energy transfer from excited state Rh(III) to Ru(II) was observed for all the complexes. At 150 K, energy transfer from excited state Rh(III) to Ru(II) was again observed for all complexes, while quenching of the excited state of Ru(II) by *electron transfer* to Rh(III) was observed, but only in the complex with $n = 0$. The different behaviour between $n = 0$ and $n = 1$, 2 can be rationalized in terms of better suited electronic factors and smaller reorganizational energies for the former species. A number of ruthenium-rhodium diads have also been synthesized and studied in recent years[60][61][62][63]. These display a variety of intercomponent energy- and electron-transfer processes.

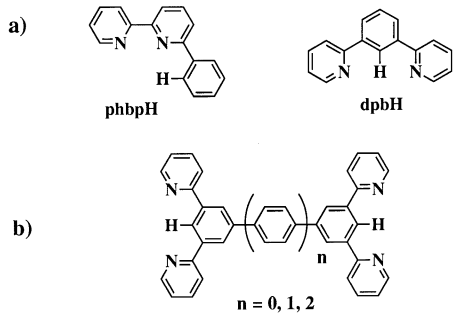
4. Rigid Rod-like Dinuclear Complexes with Bis-cyclometallating Terpyridine Analogues

Interestingly, the electronic properties of a multidentate ligand containing pyridine nuclei can be dramatically modified by replacing a nitrogen atom by a carbon atom (phenyl group). This procedure permits us to go from a moderate σ- and π-donating neutral species to a negatively charged ligand, provided that the metal can form a σ-bond to the deprotonated CH group of the phenyl ring. The new ligand would then be negatively charged and would, of course, be expected to behave as a strong donor and be able, for instance, to stabilize high oxidation states or to favour high field complexes. Since $Ru(ttpy)_2^{2+}$ is virtually non-luminescent at room temperature ($\tau = 0.96$ ns in CH_3CN), different approaches have been explored in order to overcome this difficulty. One possibility is to increase the ligand field (LF) or to diminish (to some extent) the metal-to-ligand charge-transfer (MLCT) energy level so that the MLCT and the LF states become well separated. In this context, cyclometallating ligands such as 6-phenyl-2,2′-bipyridine (phbpH) or 1,3-dipyridylbenzene (dpbH) (Figure 9a) have been combined with one terpyridine in heteroleptic complexes.

4.1. Synthesis of Cyclometallating and Bridging Bis-cyclometallating Ligands

Initially, dpbH was prepared according to a synthetic procedure described previously by Bönnemann for 2,2′-(1,4-phenylene)dipyridine[64][65]. A more convenient method employs the mild aromatic cross-coupling reaction originally described by Stille et al.[66]

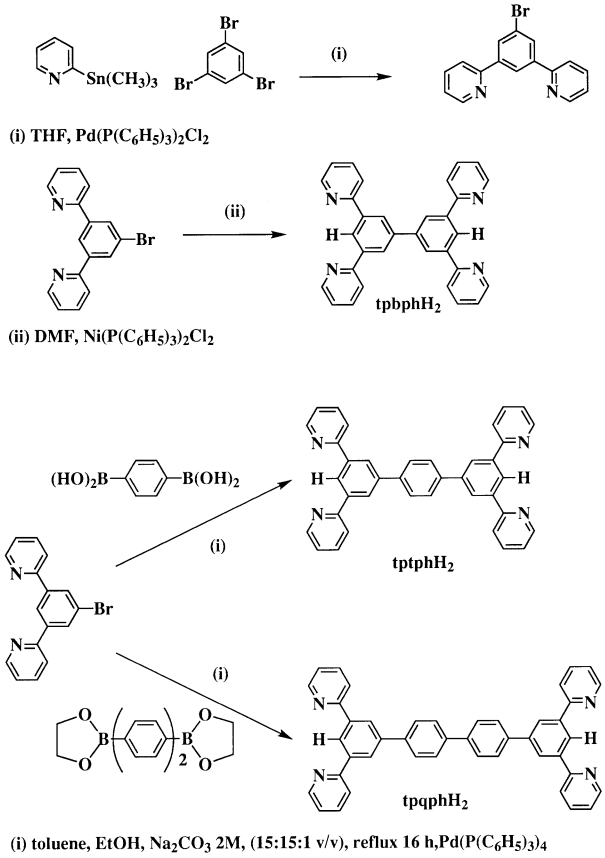
Figure 9. (a) Cyclometallating and (b) bridging bis-cyclometallating ligands



The design of multicomponent systems incorporating these new chromophores and electrophores requires the synthesis of rigid, symmetrical bis-cyclometallating ligands. Mild and efficient aromatic cross-coupling reactions catalysed by various transition metal complexes have recently been used in the synthesis of natural products, large organic receptors[67], dendrimers[68] and one-dimensional polymers[69]. Applied to suitable precursors, these methodologies have permitted the preparation of three bis-cyclometallating ligands (Figure 9b), in which aromatic spacers modulate the separation distance between sites[70]. The universal precursor 5-bromo-1,3-dipyridylbenzene (Figure 10) was obtained by reaction of the 2-trimethylstannylpyridine with 1,3,5-tribromobenzene in the presence of $Pd[P(C_6H_5)_3]_2Cl_2$. It was coupled using nickel(0) to afford a 70% yield of $tpbphH_2$ (tpbph denotes tetrapyridylbiphenyl).

The ligands ($tptphH_2$ and $tpqphH_2$; tph and qph denote terphenyl and quaterphenyl, respectively) with one and two phenylene spacers were prepared using Suzuki ′s cross-coupling procedure as depicted in Figure 10[48].

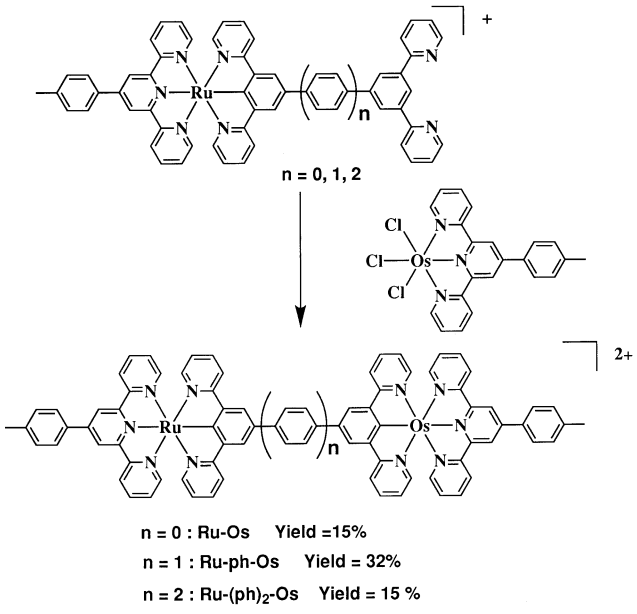
Figure 10. Synthetic steps leading to bis-cyclometallating ligands



4.2. Preparation and Properties of Rigidly Bridged Ruthenium-Osmium Cyclometallated Complexes

By using the bis-cyclometallating ligands depicted in Figure 10, ruthenium-osmium cyclometallated complexes were prepared with the aim of studying photoinduced energy-transfer processes between the two bridged complex subunits[3][71][72]. The synthetic strategy used was the same as that described for the analogous terpyridine-type complexes (3.2.1.). The mononuclear ruthenium precursors bearing a free cyclometallating site and the corresponding heterodinuclear complexes are represented in Figure 11.

Figure 11. Synthesis of ruthenium-osmium cyclometallated complexes



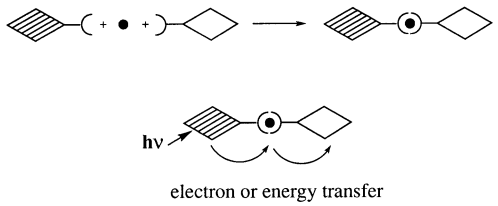
The binuclear complexes containing the dianionic ligands exhibit the same geometrical properties as the previous bis-terpyridine series, with the distance between the metal centres ranging from 11 to 20 Å, depending on the size of the phenylene spacer. For the cyclometallated series, the rate of Ru(II) to Os(II) energy transfer proved to be much slower than for the structurally identical series discussed in the previous section (3.2.1.). Thus, at room temperature, no energy transfer was observed, despite the fact that the ex-

cited state of the chromophore [Ru(ttpy)(dpb)$^+$] exhibits a lifetime of 4.5 ns in acetonitrile. At 77 K, the energy-transfer rate is affected to a large degree by the presence of the phenylene spacer. Energy transfer was found to take place according to a Dexter mechanism[4]. Comparison with analogous complexes containing non-cyclometallating bridging ligands, where the MLCT excited states involved in the energy transfer step are localized on the bridge and very fast energy transfer takes place ($k > 5 \times 10^{10}$ s^{-1}), suggests that the energy-transfer step in the cyclometallated complexes is slower because the involved MLCT excited states are directed toward the terminal ligands[3]. This apparently results in a longer transfer pathway. The main conclusions are that the phenylene spacers are very efficient in transmitting the intermetal electronic communication, but that an important role is also played by the spatial localization of the MLCT excited states involved in the excitation-transfer process (peripheral for the cyclometallated series and bridging for the non-cyclometallating family).

5. Multiporphyrin Linear Systems Assembled by Transition Metal Complexes

Multiporphyrin systems are of considerable interest in the fields of molecular electronics and artificial photosynthesis[15] with regard to converting light signals into high energy separated states. An attractive route to such systems is to use transition metals to assemble ligands, each bearing a porphyrin unit. This strategy, which uses coordination rather than covalent chemistry to interconnect the various components, offers several attractive features: (i) its high flexibility should allow easy preparation of multicomponent systems, and (ii) good geometrical control should be possible. The general concept and the synthetic principle are illustrated in Scheme 3.

Scheme 3. Strategy used to assemble asymmetrical bis-porphyrins around a central transition metal cation (black dot). The basic module consists of a porphyrin (lozenge) covalently attached to a chelate (arc of a circle). Provided the transition metal complex is resistant to ligand-exchange processes, stepwise electron- or energy-transfer can be envisaged after selective illumination of a porphyrin ring



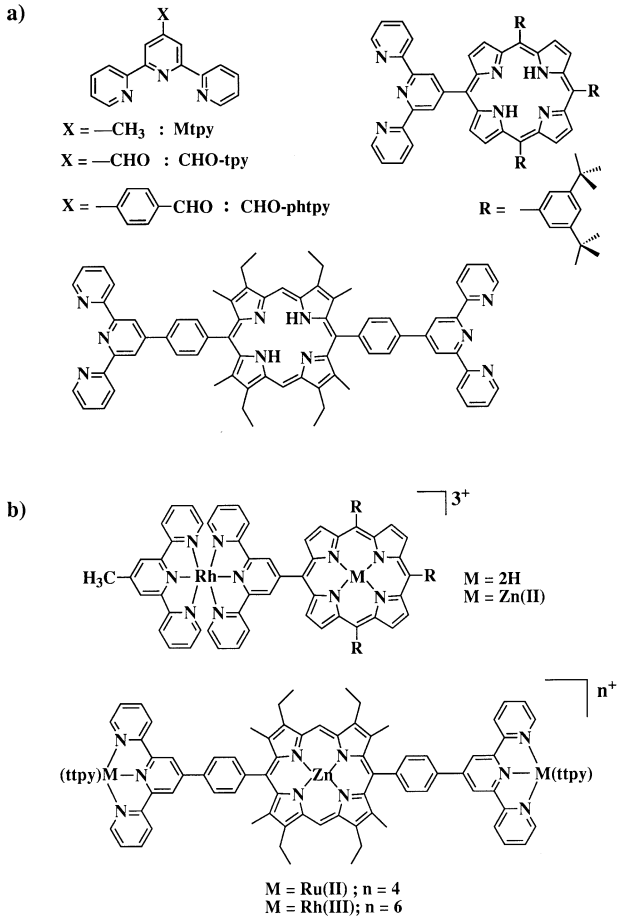
The role of the transition metal is manifold: (i) to gather and orient the system so as to have metallated porphyrins held rigidly at a fixed distance and to have asymmetrical systems able to undergo electron- or energy-transfer; (ii) to modulate the electronic coupling between the donor and acceptor porphyrins, and (iii) to form a complex which could act as a relay in electron transfer or as an antenna in energy transfer.

The ligand to be attached to each porphyrin and the binding mode used to assemble the two modules into the final conjugates are selected so as to facilitate strict stereochemical control, especially with regard to the distance between the porphyrins.

5.1. Synthesis of Porphyrin-Metal Bis-terpyridine Diads

5.1.1. Synthesis of the Ligands: The use of 2,2′:6′,2"-terpyridine as a chelate is indeed very appealing for the strategy outlined in Scheme 3, since substitution at its 4′-position leads to axially symmetric bis-terpyridine complexes. The ligands used in the preparation of the porphyrin-metal bis-terpyridine conjugates are shown in Figure 12a and their syntheses have been described[73].

Figure 12. (a) Structures of the various terpyridine ligands used for the synthesis of the diads. (b) The various terpyridine-porphyrin diads



Although the preparation of 4′-methyl-2,2′:6′,2"-terpyridine (Mtpy) is well-documented[74][75][76], we have developed a new route which gives high yields (87%) and allows the preparation of large amounts (10 g scale) of this compound. This alternative route to Mtpy involves the reaction of 4′-trifluoroacetyl-2,2′:6′,2"-terpyridine[74][77] with tetramethyltin, using the general procedure described by Stille[78]. 4′-Formyl-2,2′:6′,2"-terpyridine (CHO−tpy) was prepared from Mtpy by a modification of a procedure developed by Vismara et al.[79], while a Sommelet reaction applied to 4′-tolyl-2,2′:6′,2"-terpyridine led to the corresponding aldehyde (CHO−phtpy)[73] in 40% yield. The

monoterpyridine porphyrin was prepared following Adler's procedure[80] and was isolated in 7% yield. The synthetic strategy for the preparation of bisphenylterpyridine porphyrin is derived from MacDonald's methodology[81], using the improved procedure developed by Lindsey et al.[82] This ligand was obtained pure in 42% yield after two recrystallizations of the crude material.

5.1.2. Synthesis of the Complexes: The complexes synthesized are shown in Figure 12b.

The rhodium(III) and ruthenium(II) complexes were prepared following the same strategy. In the first step, a given substituted terpyridine ligand L was reacted with the metal trichloride according to a literature procedure[37], thereby yielding $MLCl_3$ [M = Ru(III) or Rh(III)]. In the second step, after dechlorination with $AgBF_4$, the solvated complex $ML(acetone)_3^{n+}$ [M = Ru(III) or (RhIII)] was reacted with the appropriate substituted terpyridine in refluxing alcohol (EtOH or *n*BuOH).

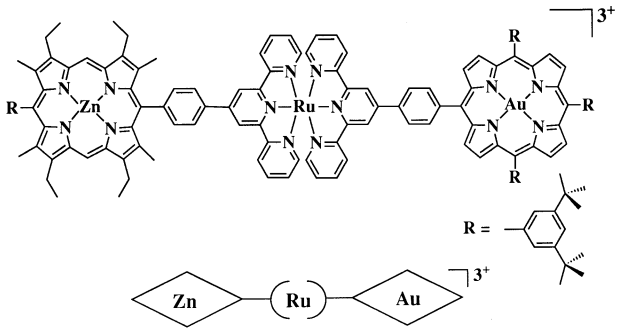
Metallation of the free-base porphyrins in the different compounds by zinc acetate is almost quantitative. The purity of each highly-colored complex was checked by thin-layer chromatography, UV/Vis spectroscopy, high resolution ^{1}H-NMR spectrometry and mass spectroscopy.

5.1.3. Photophysical Properties of the Diads: Photophysical properties have been measured for zinc and free-base porphyrins covalently linked to ruthenium(II) or rhodium(III) bis-terpyridine complexes using ultrafast transient absorption spectroscopy and the full study has been reported[73]. In each compound, the appended metal complex quenches porphyrin fluorescence. The quenching is attributed to intramolecular electron transfer from the excited singlet state of the porphyrin to the metal complex. For directly coupled systems, it appears that both forward and reverse electron-transfer steps are extremely fast, and such materials possess little attraction as building blocks. Insertion of a phenyl ring between the components has a profound effect on the dynamics of electron transfer, especially with regard to charge recombination. In particular, the relatively long lifetime (2 ns) of the charge-separated state of the zinc-porphyrin phenyl-bridged ruthenium(II) bis-terpyridine conjugate (Figure 12b) makes the ruthenium(II) complex attractive as a bridge in multicomponent systems. The ruthenium(II) bis-terpyridine-based system has the additional attraction that light absorbed by the complex is transferred to the triplet excited state of the porphyrin by way of an antenna effect.

5.2. Synthesis of a Bis-porphyrin-Ruthenium(II) Bisphenylterpyridine Triad

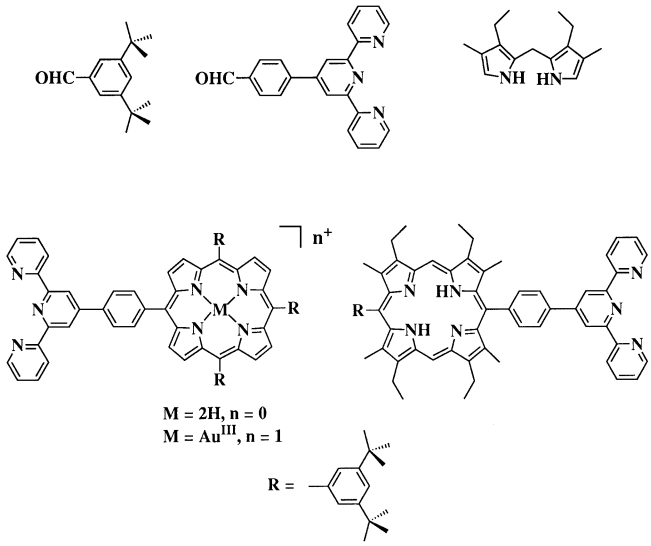
In order to perform long-range charge separation, the triad represented in Figure 13 was prepared[83][84]. It should be noted that it contains two differently substituted porphyrins, a zinc etioporphyrin-like donor and a gold(III) tetraarylporphyrin acceptor. The $-CH_3$ and $-CH_2CH_3$ substituents located at the periphery of the tetrapyrrolic donor increase the electron-donating ability of the singlet excited state (^{1}*PZn) and thus favour electron transfer to the central $Ru(tpy)_2^{2+}$ unit. On the other hand, the tetraarylporphyrin backbone metallated by a gold(III) centre is a better electron acceptor than the analogous gold(III) etioporphyrin.

Figure 13. The triad



5.2.1. Synthesis of the Ligands: The various precursors leading to the triad are depicted in Figure 14.

Figure 14. The various reagents and ligands used in the preparation of the triad

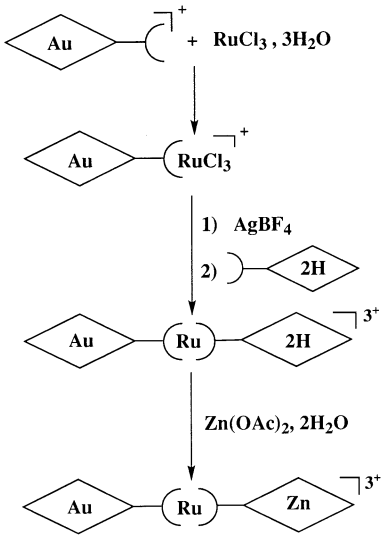


Synthesis of the octaalkyl diaryl porphyrin terpyridine was achieved in 20% yield following MacDonald's methodology[81] using Lindsey's conditions[82]: acid-catalysed condensation of dipyrrylmethane with 3,5-di-*tert*-butylbenzaldehyde and terpyridine benzaldehyde in a molar ratio of 6:5:1 in dichloromethane. The tetraaryl-porphyrin terpyridine was prepared using two different sets of conditions: (i) Using Adler's conditions[80], a mixture of 3,5-di-*tert*-butylbenzaldehyde, terpyridine benzaldehyde and pyrrole in a ratio of 18:1:19 was refluxed in propionic acid giving the desired compound in 13% yield after purification by column chromatography. (ii) Using Lindsey's conditions[82], a mixture of 3,5-di-*tert*-butylbenzaldehyde, terpyridine benzaldehyde and pyrrole in a molar ratio of 15:1:16 in dichloromethane containing trifluoroacetic acid was stirred at room temperature for 12 h. The resulting porphyrinogens were oxidized with tetrachloro-1,4-benzoquinone (chlor-

anil) in refluxing dichloromethane. The crude product was purified by column chromatography, giving pure phenylterpyridine porphyrin in 9% yield. Metallation of the free porphyrin site of this compound with gold(III) was achieved in 85% yield using $KAuCl_4$ and NaOAc in refluxing acetic acid.

5.2.2. Synthesis of the Complex: Stepwise formation of the asymmetrical ruthenium(II) complex from the gold(III) porphyrin phenylterpyridine and free-base porphyrin phenylterpyridine components was realized using a procedure similar to the one described in Section 5.1.2., which is shown schematically in Figure 15.

Figure 15. Stepwise formation of the triad

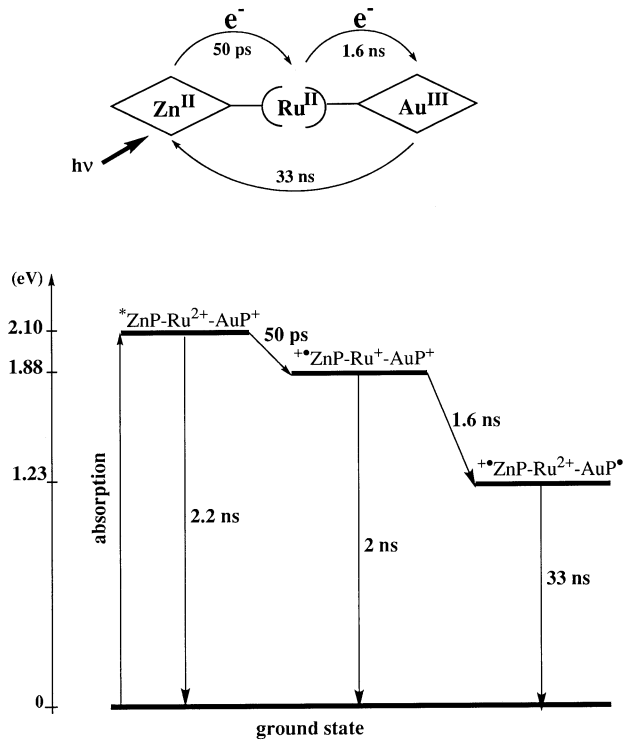


A pure sample of the triad was obtained in 35% yield by successive chromatography on silica gel, eluting with an acetonitrile/water/saturated aq. KNO_3 mixture. Metallation of the free porphyrin site was carried out with $Zn(OAc)_2$ in methanol and afforded the triad as an orange solid in 90% yield.

5.2.3. Electron-Transfer Properties of the Triad: Excitation of the terminal zinc porphyrin in the triad results in electron transfer to the central ruthenium(II) bis-terpyridine complex, which is followed by secondary electron transfer to the appended gold(III) porphyrin (Figure 16). Electron transfer occurs by two consecutive steps over a porphyrin centre-to-centre distance of ca. 30 Å.

Rate constants for the individual steps, as determined from laser photolysis studies[84], are indicated in Figure 16. The primary electron-transfer step leading to reduction of the central Ru(II) complex ($\Delta G° = -0.25$ eV) requires 50 ps and is essentially quantitative. The second electron-transfer process follows, resulting in reduction of the distant gold(III) porphyrin. The rate constant for this second step is found to be 6×10^8 s^{-1}. This process, for which there is a thermodynamic driving force of ca. 0.6 eV, is in competition with reverse electron transfer to restore the ground state. Subsequent charge transfer between the terminal porphyrinic subunits occurs with a rate constant of 3×10^7 s^{-1}

Figure 16. Energy level diagram showing the electron-transfer sequence for the triad



and leads to regeneration of the initial system. It is interesting to compare the lifetime of 33 ns for the ultimate charge-separated state in the triad with the value of 2 ns found for that in the corresponding diad (Section 5.1.3.); this illustrates the advantage of using a multistep electron-transfer pathway.

The salient features of this molecular triad may be summarized as follows: (i) there is rapid interporphyrin electron transfer between linear, fixed-distance subunits, (ii) the ultimate charge-separated state, which has a lifetime of 33 ns, retains almost 60% (1.2 eV) of a photonic input of 2.1 eV and, (iii) the modular synthetic approach is highly versatile, facilitating the preparation of many different $D-A_1-A_2$ triads and higher-order, linear oligomers.

6. A Copper(I) Rotaxane Incorporating Two Different Sites in a Thread: Molecules in Motion

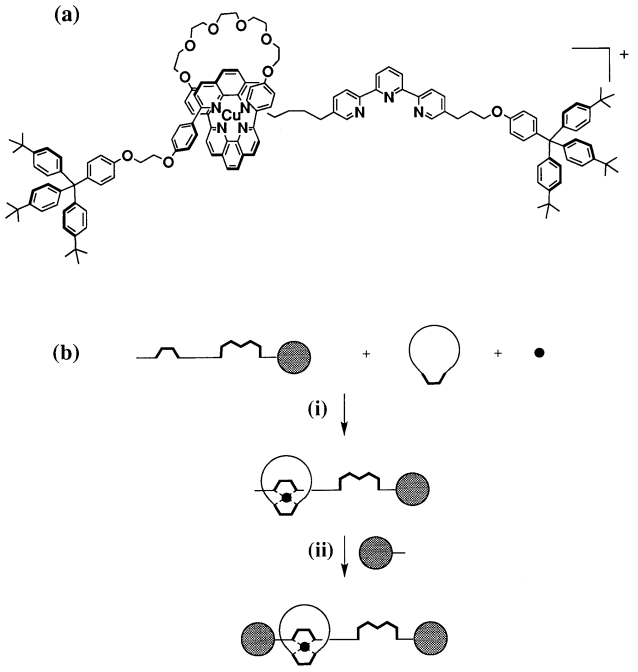
Molecular systems whose motions can be triggered by applying an external signal are currently of special interest, both as mimics of biological systems (redox proteins) and as potential bistable molecular devices[85][86][87][88]. Catenanes and rotaxanes are particularly well-suited in this context since reversible molecular motions using interlocked or threaded rings can be easily performed[18][89][90][91][92]. The use of transition metal-containing systems is also especially favorable since the stereoelectronic requirements of the metal can depend strongly on its oxidation state. This property can be exploited for switching a molecular system from a given geometrical arrangement, corresponding to the most stable coordination for the tran-

sition metal(s) involved, to a different geometry, simply by changing the metal oxidation state by chemical or electrochemical means, ultimately leading to the preferred coordination for the new redox state[93][94][95][96].

6.1 Synthesis of the Rotaxane

A [2]-rotaxane is a molecular system consisting of a ring threaded by a string, with two blocking groups attached at either end of the string in order to prevent dethreading[97]. Such compounds were first prepared long ago[98][99], but were largely considered as mere chemical curiosities. Recently, rotaxanes have undergone a notable revival due to the newly developed efficient procedures which make them relatively easy to make[100][101][102], as well as because of their electro- and photochemical properties[103][104][105] and their aptitude for undergoing controlled molecular motions[18][89][92]. Recently, we reported the synthesis of a copper(I)-assembled rotaxane[106] with a coordinating macrocycle containing a 1,10-phenanthroline (phen) moiety forming the ring, and a threaded fragment incorporating both a phen unit and a 2,2′:6′2″-terpyridine (tpy) coordination site (Figure 17a). The key feature of the system is its potentially dual complexing mode towards a metal, involving the phen or tpy moieties.

Figure 17. (a) Representation of the Cu(I)-rotaxane. (b) Construction principle of the Cu(I)-rotaxane

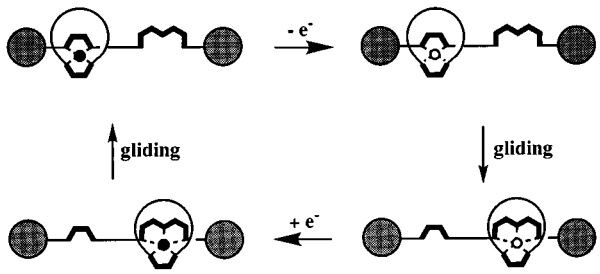


The synthetic strategy is illustrated in Figure 17b. A key step is the metal-directed threading process, often used in the past for making various catenanes and rotaxanes[107]. The bidentate chelate (phen, represented by an inverted U) and the terdentate unit (tpy, represented by a stylized M) are incorporated in an acyclic ligand, already bearing a bulky stopper at one end. The ring contains a phen nucleus. In the threading step (i) of Figure 17, copper(I) (represented by a black circle) forces the string to pass through the ring. Since copper(I) has a pronounced preference for tetracoordination, the threading reaction will selectively lead to the pseudo-rotaxane intermediate. The driving force behind this threading process is the great stability of the pseudotetrahedral bis-chelate complex between copper(I) and the two disubstituted 1,10-phenanthrolines[108]. The blocking reaction is performed by attaching a voluminous group at the other end of the coordinating string.

6.2. Electrochemically-Induced Molecular Motions

The principle of the process is explained in Figure 18. It is based on the difference of preferred coordination number for the two different redox states of the metal: 4 for copper(I) and 5 for copper(II). The electrochemical and chemical steps of the *square scheme* are analysed by a combination of cyclic voltammetry and controlled potential electrolysis experiments. The square scheme of *electron transfer induced* reactions[109] takes place, assuming that the chemical steps (motions of the ring from the phenanthroline to the terpyridine and *vice-versa*) are slow in comparison with the time scale of cyclic voltammetry. The voltammograms obtained demonstrate the perfect reversibility of the system, and also give the orders of magnitude of the rates of the chemical steps.

Figure 18. Square scheme in the copper rotaxane made in Figure 17



The stable 4-coordinate monovalent complex is oxidized to an intermediate tetrahedral divalent species. Due to the preference of copper(II) for a square-base pyramidal-type geometry, the ring moves to the terpyridine site to give the stable 5-coordinate copper(II) complex. Upon reduction, the 5-coordinate monovalent state is formed as a transient. Finally, the latter undergoes the reorganization process (opposite movement of the ring), thereby regenerating the starting complex [the shaded circle represents copper(I) and the white circle represents copper(II)].

Certainly, rotaxanes are very promising compounds with regard to electrochemically and photochemically induced molecular motions, due to the perfect chemical reversibility of the processes. Interestingly, the rates of the movements in the rotaxane are very different from those measured for related catenanes[19][90][91]. The conversion of copper(II) (4-coordinate state) to copper(II) (5-coodinate state) is much faster in rotaxane than in the interlocking ring systems described previously. This difference could reflect a greater ability of the copper(II) (4-coordinate state) in rotaxane to interact with solvent molecules or anions, the copper(II) centre being perhaps loosely bound to a fifth ligand, which

would thus stabilize intermediate states on the way to copper(II) (5-coordinate state). Interestingly, the sequence of electrochemical and chemical steps involved in the square scheme of Figure 18 is very different from the classical EC mechanism universally encountered in molecular electrochemistry since, in principle, it does not consume electrons.

7. Conclusion and Prospects

Although there may still be a long way to go from the design and synthesis of multifunctional molecules with predicted electrochemical or photochemical properties to the construction of real molecular devices, utilizable as artificial photosynthetic systems, photovoltaic devices or nanoscale components in electronics, the two last decades have nevertheless witnessed substantial progress as far as complex multicomponent molecules and molecular assemblies are concerned. In particular, the use of transition metals has contributed greatly to progress in the field. In this context, the role of the metal is twofold: (i) to gather ligands bearing various functional groups and thus allow the construction of compounds with a defined arrangement, the electro- and photoactive groups incorporated in the molecule being disposed in space with a good geometrical control, and (ii) to provide interesting functions related to electronic molecular motions and thus become operative parts of the system.

In the field of electron- and energy-transfer, in relation to artificial photosynthesis, terpyridine has been used extensively. The coordination geometry and the symmetry of its complexes has been used to good advantage in the construction of several families of compounds incorporating ruthenium(II) or osmium(II) centres connected to various other electro- or photoactive components. Photoinduced charge separation over a long distance (> 20 Å) has been demonstrated in a few instances. If porphyrins are used as building blocks in conjunction with bis-terpyridine ruthenium(II), long-range (30 Å) and long-lived charge separation takes place. Energy transfer between inorganic chromophores [ruthenium(II) and osmium(II) complexes] has also been shown to occur over more than 20 Å, the success of the process being attributable to the inherent rigidity of the bridging spacer used and, above all, to the electronic properties provided by its bis-cyclometallating nature.

Molecular machines constitute an emerging field and, again, strict control over the geometry of the ensemble used and over the trajectory of the fragment(s) set in motion will be essential. It is of course much too early to know whether molecular machines and nanoscopic motors will one day be used in imaging or as molecular information storage devices, but the search for such systems is important and allows the discovery of interesting properties related to molecular dynamics. The rotaxane discussed in the present review article also has a one-dimensional component since the movement observed is that of a ring gliding on a linear fragment on which it is threaded. Presently, the system is close to bistable, but in the future it should be generalized to less primitive molecular machines, with more complex mobility (2 or several fragments in motion) or several possible geometries.

This work was supported by the CNRS (France). Special thanks go to *Balzani*'s, *Barigelletti*'s and *Harriman*'s groups. Thanks are also due to all the members of our team who contributed to the work described in the present review article with so much skill and enthusiasm.

Keywords: Tetrapodal pentadentate ligand / Square pyramidal coordination cap / Pentaamine / Nickel(II) complexes / Magnetochemistry

The architecture of the tetrapodal pentaamine ligand 2,6-bis(1′,3′-diamino-2′-methylprop-2′-yl)pyridine (pyN_4, **1**) allows it to coordinate to nickel(II) as a square pyramidal coordination cap. The pyridine nitrogen atom occupies an apical position of the coordination octahedron, while four equivalent pendent primary amino groups occupy the equatorial positions, with a sixth coordination site remaining for a monodentate ligand. Exchange of this ligand is facile, and a series of complexes [(**1**)NiX]$^{n+}$ (X = OH_2, $OClO_3$, NCS, N_3, {Cl-Ni(pyN_4)}) has been prepared and characterised by elemental analysis, IR and UV/Vis spectroscopies (as applicable), and X-ray structure determination. While the solid state structures show varying degrees of distortion of the ligand cap **1** from C_{2v} symmetry, a polynucleating coordination mode has not been observed. The ligand enables the synthesis of dinuclear nickel(II) complexes containing a single bridging ligand, as exemplified by the singly μ-chloro bridged complex [(**1**)Ni–Cl–Ni(**1**)](PF_6)$_3$. This complex has an antiferromagnetically coupled ground state of total spin $S_T = 0$, as determined from variable-temperature magnetic susceptibility measurements.

Introduction

The objective of our work is to explore the potential of tetrapodal pentadentate ligands as mononucleating head groups in functional transition metal complexes. Ligands of this topology are virtually unknown. Specifically, we aim to create octahedral coordination compounds containing a square-pyramidal coordination cap (a pentadentate ligand) and a substrate (a monodentate ligand), which is bound at the sixth coordination site. Ideally, functional groups appended to the base of the coordination cap will provide an environment for the substrate in which it shows modulated reactivity. Such metal complexes would utilise the principles of simultaneous first- and second-sphere coordination[1][2].

In this context, we recently introduced a tetrapodal pentadentate ligand with an NN_4 donor set, consisting of a central pyridine and four equivalent primary amino nitrogen atoms (pyN_4, **1**)[3]. Structural characterization of a cobalt(III) chloro complex showed that the ligand provides the desired square pyramidal coordination cap. A square-pyramidally coordinating ligand of overall C_{2v} symmetry represents a novel structural motif in coordination chemistry since it has one central donor atom which occupies the apical position of a pyramid, while *four* equivalent pendent donor groups take the basal positions. In the case of octahedral complexes, such a coordination mode leaves a sixth site for the binding of a monodentate substrate. The tetrapodal pentadentate ligand **1** is particularly attractive in that it forces a sixth ligand to coordinate *trans* to a pyridine substituent. While this feature has been suggested to influence the overall reactivity with respect to ligand exchange in certain cases, experimental verification has so far been lacking[4]. A topological relative of **1** has recently been described[5], being virtually identical to a ligand previously used by Canty and co-workers in their studies of the coordination chemistry of palladium(II), where square-pyramidal coordination was not observed[6]. A different type of tetrapodal pentadentate ligand of C_2 symmetry involves a "superstructured"[7][8] porphyrin, *i. e.* the basal donor atoms are incorporated into a macrocyclic ring.[9]

As part of our studies directed toward the synthesis of functional metal complexes with a square-pyramidal coor-

1

dination cap, we have been exploring the coordination behaviour of the pyN_4 ligand **1** and the reactivity of a variety of complex fragments of the type [(**1**)M] (M = Co, Ni, Rh), as well as the further derivatization of this ligand in order to construct a concave ligand periphery and/or an enclosed coordination site. We now wish to report our findings relating to ligand exchange at the fragment $[(\mathbf{1})Ni]^{2+}$, for which we have used the aqua complex $[(\mathbf{1})Ni(H_2O)]Cl_2$ (**2**) as precursor. We were interested in the structural characterization of the aqua complex as well as a series of other complexes $[(\mathbf{1})Ni(X)]^{n+}$ (X = perchlorate, halide, pseudohalide), in order to assess the influence, if any, of monodentate ligands X upon the coordination mode of the pentadentate ligand, and to obtain a quantitative measure of the flexibility of the ligand in those cases where it does provide a square-pyramidal coordination cap.

Exchange reactions have yielded the mono- and dinuclear nickel(II) complexes $[(\mathbf{1})Ni(H_2O)]I_2$ (**4**), $[(\mathbf{1})Ni(OClO_3)](ClO_4)$ (**5**), $[(\mathbf{1})Ni(\mu\text{-}Cl)Ni(\mathbf{1})](PF_6)_3$ (**6**), $[(\mathbf{1})Ni(NCS)](PF_6)$ (**7**), and $[(\mathbf{1})Ni(N_3)](PF_6)$ (**8**). While the solid state structures of these compounds show different degrees of distortion of the ligand cap, the pentaamine ligand **1** does act as a podand in all cases, and a polynucleating coordination mode (which is undesirable in the light of the aims specified above) is not observed. Since the pentadentate ligand effectively blocks five coordination sites in a coordination octahedron, it allows the synthesis of dinuclear complexes containing a single bridging ligand. In view of the interest attached to such complexes, particularly with respect to their magnetic properties[10], we have undertaken the magnetochemical characterization of the dinuclear μ-chloro-bridged nickel(II) complex **6**.

Results and Discussion

Analytical data indicate the nickel(II) aqua complex $[(\mathbf{1})Ni(H_2O)]Cl_2$ (**2**) to be the primary species formed when an ammoniacal aqueous solution of the tetrakis(hydrochloride) salt **1** • 4 HCl (ref.[3]) is treated with one equivalent of $NiCl_2 \bullet 6\ H_2O$. Drying of the purple crystalline material in vacuo results in a colour change to bluish green which indicates removal of the aqua ligand. Addition of $NaClO_4$ to an aqueous solution of **2** and recrystallization of the resulting precipitate from water/methanol (1:1 v/v) gives a crystalline solid (**3**) with no conclusive elemental analysis and IR data. Preliminary X-ray structural data of this solid confirm the pyN_4 ligand to act as a square-pyramidal coordination cap and reveal the presence of at least one uncoordinated perchlorate anion, but do not allow the identification of the monodentate ligand at the sixth coordination site. The residual electron density is compatible with a ligand containing a single "heavy" atom, and both chloride and water are likely candidates, but neither enables further refinement. Hence, the possibility of this substance being a mixture of the chloro and aqua complexes cannot be ruled out.

$[(\mathbf{1})Ni(H_2O)]I_2$ (4)

Exchange of the monodentate ligand is facile in **2** and **3**, and the above results suggest chloride and water compete as ligands for the sixth coordination site. The aqua complex is formed exclusively as the iodide salt $[(\mathbf{1})Ni(H_2O)]I_2$ (**4**) upon recrystallization of **2** from water in the presence of an excess of sodium iodide. These conditions apparently prevent the coordination of chloride, while the large iodide ligand, if accommodated, would induce steric strain as a consequence of van der Waals interactions with the basal amino groups of the complex fragment $[(\mathbf{1})Ni]^{2+}$ (ref.[11]).

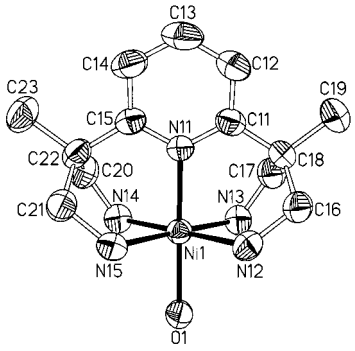
The spectroscopic characteristics of **4** resemble those determined for the other complexes in the present series (**5**, **6**, **7**, and **8**). All complexes contain octahedrally coordinated high-spin nickel(II), making ^1H NMR spectra of limited diagnostic value due to paramagnetically shifted and broadened resonances (an assignment is given below for the proton spectrum of **5**, based on approximate integration intensities and chemical shifts). The UV/Vis spectrum of an aqueous solution of **4** is characterized by an absorption attributable to a d-d transition at $\lambda = 543$ nm ($\varepsilon = 3.4\ dm^3\ mol^{-1}\ cm^{-1}$), in keeping with data obtained for other six-coordinate polyamine complexes of Ni(II)[12]. The spectrum is virtually identical to those of complexes **5**, **6**, **7**, and **8**, presumably due to the ease of ligand exchange at the sixth coordination site.

The IR spectrum of **4** shows bands characteristic of N−H, O−H, and skeletal vibrations of the ligand [in particular, the ν(C=C) and ν(C=N) in-plane vibrations of the pyridine ring]. The base peak in the FD mass spectrum is at $m/z = 436$ ($[(\mathbf{1})NiI]^+$), all other peaks having an intensity of less than 10%. In the FAB spectrum, the base peak is again at $m/z = 436$, with a fragment ion at $m/z = 309$ ($[(\mathbf{1})Ni]^+$, 45%). These results indicate that exchange of the aqua ligand for an iodo ligand does occur under the conditions prevailing in the mass spectrometer.

Compound **4** crystallises in the monoclinic space group $P2_1/n$. The molecular structure of the cation, which has no crystallographically imposed symmetry, is shown in Figure 1. The nickel(II) ion is coordinated by the pentaamine ligand **1** in pyramidal fashion, leading to the formation of six six-membered chelate rings, all of which adopt a boat conformation. The aqua ligand completes the Ni(II) coordination octahedron. It forms two weak hydrogen bonds to the two iodide counterions [d(O1···I1) = 3.406(4) A, d(O1···I2) = 3.405(3) A; sum of the van der Waals radii of O and I: 3.50 A[13]]. The arrangement of the equatorial nitrogen atoms around the nickel centre is trapezoidal rather than square planar, with two shorter and two longer $Ni-N_{eq}$ bond distances (Table 1). The angles $N_{eq}-Ni-N_{eq}$ in the NiN_4 plane have average values of 84.9(2)° and 95.2(2)° for diametrically opposite pairs, the smaller value representing the averaged "bite angle" of the 1,3-diaminoprop-2-yl substituents. These groups are displaced slightly

toward the equatorial NiN_4 unit, as indicated by the deviations of the angles at the *ortho* carbon atoms from their ideal values of 120° [N11−C11−C18 116.8(3)°; C12−C11−C18 122.7(4)°; N11−C15−C22 116.7(3)°; C14−C15−C22 122.8(4)°]. Whether this is a consequence of the ligand acting as a podand toward the central nickel ion cannot be said with certainty as similar deviations are observed for the corresponding angles in the tetrakis(hydrobromide) salt **1** • 4 HBr where the *ortho* substituents are not constrained by metal coordination[14]. However, the Ni−N_{ax} bond length at 2.050(3) A is shorter than the average Ni−N_{eq} bond length [2.090(4) A]. By way of comparison, the corresponding Ni−N_{py} bond lengths in the cation $[(H_2O)_5Ni(py)]^{2+}$ and in a Ni(II) cyclam complex with a pendent pyridyl group coordinated *trans* to an aqua ligand are 2.08(1) A[15] and 2.142(4) A[16], respectively, while the averaged Ni−N_{eq} bond length in the latter complex is 1.927(5) A. The nickel−oxygen bond length in **4** [d(Ni−O) = 2.133(3) A] is within the range of values found in both the pentaaqua and the cyclam complexes [*d*(Ni−O) = 2.05(1)···2.18(1) A[15], and *d*(Ni−O) = 2.166(3) A[16], respectively].

Figure 1. Molecular structure of the cation in **4** with thermal ellipsoids drawn at the 50% probability level; hydrogen atoms are omitted for clarity



As shown in the side-on view in Figure 2, the $[(pyN_4)Ni]^{2+}$ complex fragment in **4** is distorted from C_{2v} symmetry. The pyridine ring, itself a regular hexagon, is tilted to one side of the (pyN_4)Ni pyramid, inducing a slight bending of the N_{ax}−Ni−O axis relative to the equatorial NiN_4 unit (cf. Table 1 for relevant bond angles N_{ax}−Ni−N_{eq}). This unit shows minor tetrahedral distortion, with diagonally opposite N donor atoms 0.015(4) A above and, respectively, below the plane containing the nickel atom. For the purpose of comparison with the other structures reported in the present publication, the distortion of the ligand cap in **4** from C_{2v} symmetry may be quantified as follows (Table 2): a) The least-squares planes defined by the pyridine ring (N11, C11, C12, C13, C14, C15) on the one hand and the quaternary and methyl carbon atoms C18, C19, C22, C23 on the other do not coincide but form a dihedral angle of 15.4(4)°; b) the least-squares planes defined by the four methylene carbon atoms C16, C17, C20, C21 and the four equatorial amino nitrogen atoms N12, N13, N14, N15 are not parallel but at a dihedral angle of 8.0(1)°; c) one of the distances between pairs of equivalent methylene carbon atoms in the two 1,3-diaminoprop-2-yl groups [*d*(C16···C21)] is widened to a value of 5.399(7) A, while the other [*d*(C17···C20)] is compressed to 4.743(7) A. This distortion (see below for a unifying discussion of possible causes) attests to the flexibility of the ligand backbone. Except for the angles given in Table 1, all other angles in the carbon framework are close to the ideal values expected for sp^2 and sp^3 carbon and nitrogen atoms, respectively.

[(1)Ni(OClO$_3$)](ClO$_4$) (5)

Recrystallization of the ill-defined complex **3** from methanol in the presence of $NaClO_4$ yields single crystalline material whose IR spectrum is characterised by a triply split very intense band between 1088 and 1145 cm^{-1} (ClO_4 str). This is characteristic of unidentate perchlorate coordination (reduction of the local symmetry from T_d to C_{3v})[17] and points to the perchlorato perchlorate complex [(**1**)Ni(OClO$_3$)](ClO$_4$) (**5**). Its ^{1}H NMR spectrum ([D$_6$]DMSO, room temp.) shows paramagnetically shifted resonances over the range 0 to + 140 ppm which can be assigned on the basis of their approximate integration intensities and are in accord with C_{2v} symmetry of the pyN_4 ligand in the complex[18]. As expected, the protons closest to the nickel atom ($-NH_2$, $-CH_2-$) show the most pronounced paramagnetic shifts (128 and 100 ppm, respectively) and the largest line widths. The H^3 (*meta*), H^4 (*para*) and $-CH_3$ protons have signals at 43, 20, and 1 ppm, respectively, with line widths decreasing in this order, which mirrors the increasing remoteness of the proton locations with respect to the nickel center.

The X-ray structural study of **5** shows the cation to have C_1 symmetry in the solid state (Figure 2). The nickel atom is coordinated in distorted octahedral fashion by the pentadentate pyN_4 ligand and an oxygen atom of one of the perchlorate anions. While the diametrically related sets of bond angles N_{eq}−Ni−N_{eq} are comparable to the corresponding values in **4**, the N_{py}−Ni−O unit deviates significantly from linearity [N11−Ni1−O1 166.0(5)°]. However, the coordination cap in **5** is less distorted than in **4**, as is evident from the structural parameters listed in Table 2, which are closer to the ideal values. The Ni−N_{ax} bond is shorter still in **5** [Ni1−N11 2.015(4) A] than in **4** [2.050(3) A], while the average Ni−N_{eq} bond lengths are comparable [**5**: 2.09(1) A; **4**: 2.090(4) A]. The bond length in **5** between nickel and the oxygen atom of the coordinated perchlorate anion has a value of *d*(Ni1−O1) = 2.233(6) A which is shorter than the value found in the nickel(II) perchlorato complex of a pendant-arm macrocyclic ligand which also has an N_5 donor set [*d*(Ni−O) = 2.393(8) A][19]. The bond lengths and angles within both perchlorate anions are in the normal range.

[(1)Ni(μ-Cl)Ni(1)](PF$_6$)$_3$ (6)

Recrystallization of **2** from water in the presence of NH_4PF_6 gives a purple material, and analytical data suggest it is the bridged species [(**1**)Ni(μ-Cl)Ni(**1**)](PF$_6$)$_3$ (**6**). Its formation requires partial dissociation of the monodentate ligand in **2**, in accord with the observation that a vacant coordination site may be created in a complex by NH_4PF_6-induced loss of a labile ligand[20]. Compound **6**, once

Table 1. Selected bond lengths [Å] and angles [°] for **4**, **5**, **6**, **7** and **8** with estimated standard deviations in parentheses

formed and isolated, may be recrystallised from water. Whether or not the dinuclear species persists in aqueous solution is uncertain as the UV-Vis spectrum is not significantly different from that of the mononuclear aqua complex **4**. The X-ray structural analysis of **6** confirms the presence of a dinuclear chloro-bridged complex cation in the solid state, making it one of the very few structurally characterised complexes containing a single *unsupported* Ni(II)−X−Ni(II) halide bridge[21]. The compound crystallises in the tetragonal space group $I4_1cd$, and the two halves of the molecule are related by a two-fold rotation axis which bisects the Ni−Cl−Ni′ unit (Figure 3). The bridging chloro substituent (Cl1) and the phosphorus atom of one of the three PF_6^- counterions occupy special positions. The coordination mode of the pentaamine ligand **1** is again pyramidal. The chloro substituent functions as a bridge between two symmetry-equivalent nickel(II) ions, the angle subtended at the μ-chloro ligand by the bonds to Ni1 and Ni1′ being 165.5(3)°. Similar to **4** and **5**, the angles $N_{eq}-Ni-N_{eq}$ in the NiN_4 plane have average values of 85.5(5)° and 94.5(6)° for diametrically opposite pairs, leading to a rectangular rather than a square arrangement of the equatorial amino nitrogen atoms around the nickel centre (Table 1). The C_2 symmetry of the dinuclear ion causes the equatorial NiN_4 unit and its symmetry-related counterpart to adopt an eclipsed conformation. The $Ni-N_{ax}$ bond length (2.049(11) Å) is again shorter than the average $Ni-N_{eq}$ value [2.085(13) pm], but the higher standard deviations in this structure limit the usefulness of this comparison. The Ni−Cl bond length of 2.448(2) Å is appreciably shorter than in two other complexes containing octahedrally coordinated nickel(II) bridged by a single μ-chloro ligand [*d*(Ni−Cl) = 2.941(2) Å[22] and 2.712(4) Å (average)[23], respectively]. The capping pentaamine ligand is again distorted in the sense that the pyridine ring is tilted to one side of the $[NN_4]$Ni pyramid, the degree of distortion being comparable to that observed in **4** (cf. Table 2 for relevant distances and interplanar angles). The hexafluorophosphate counterions show thermal disorder but otherwise have normal structural parameters.

[(1)Ni(NCS)](PF$_6$) (7)

In view of the ready formation of a dinuclear complex from **2** by incorporation of a μ-chloro ligand under suitable conditions, we carried out substitution experiments with potentially bidentate polyatomic anions such as thiocyanate or azide in the anticipation of obtaining dinuclear species containing end-to-end coordinated, μ-(1,3)-pseudohalide bridges. Such complexes are of current interest with respect to their magnetic properties[24][25][26]. So far, however, even in the presence of NH_4PF_6, these reactions have yielded only the mononuclear complexes[27], which X-ray structural analyses have shown to contain terminally coordinated pseudohalide ligands.

The IR spectrum of the complex [(**1**)Ni(NCS)](PF_6) (**7**) is inconclusive with respect to the bonding mode of the SCN^- ligand. The X-ray crystal structure determination shows **7** to be the isothiocyanato complex, its cation having the expected octahedral symmetry. The distortion of the pyN_4 ligand in **7** (Figure 2) is much less severe than in complexes **4** and **6**, and comparable to that in **5**. The least-squares planes defined by the four methylene carbon atoms C16, C17, C20, C21 and the four equatorial amino nitrogen atoms N12, N13, N14, N15 form an angle of only 3.0(2)°, and the distances between pairs of equivalent methylene carbon atoms in the two 1,3-diaminoprop-2-yl groups

Figure 2. Molecular structures of the cations in **4** (top left), **5** (top right), **7** (bottom left), and **8** (bottom right); side-on views are shown in order to illustrate the differing degrees of distortion of the ligand caps; for clarity, ball-and-stick representations have been chosen, and all hydrogen atoms have been omitted; for all structures, the numbering of atoms in the pyridine ring is identical to that shown in Figure 1

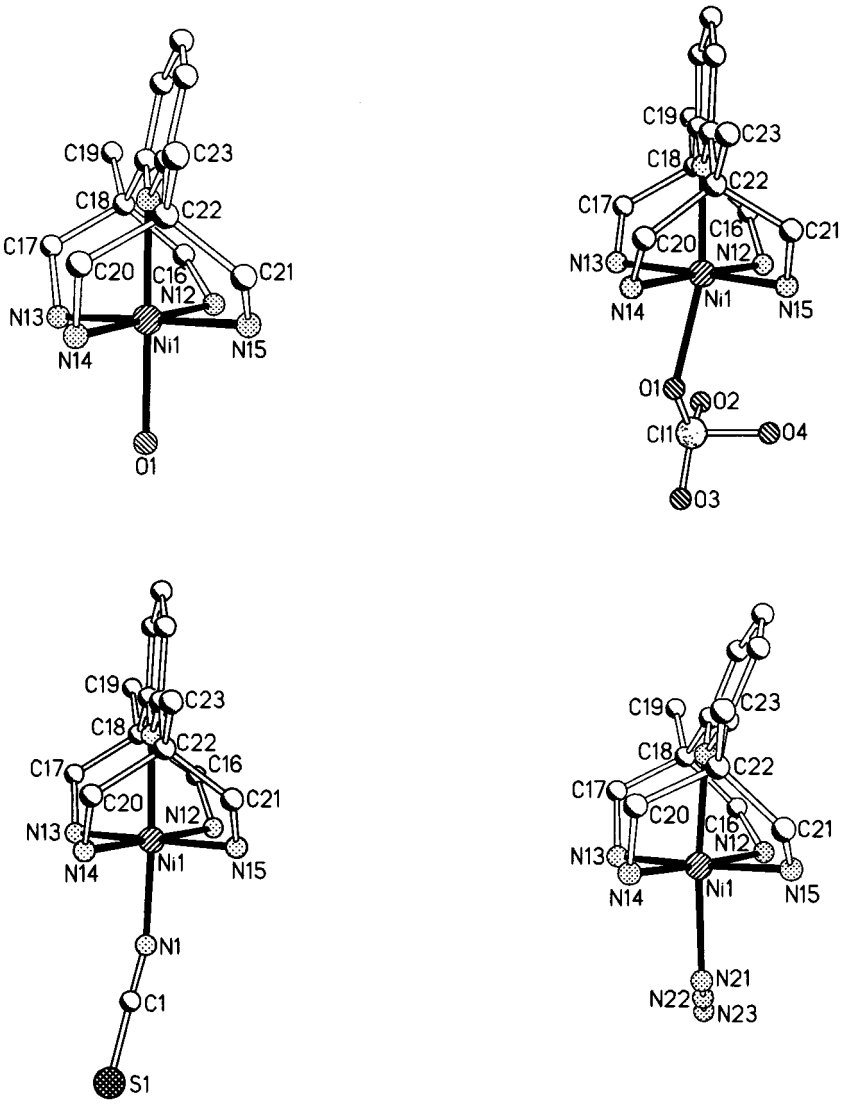

Table 2. Intramolecular angles [°] and distances [Å] illustrating the distortion of the ligand cap in complexes **4**, **5**, **6**, **7** and **8** (with estimated standard deviations in parentheses); see footnote and text for definitions of angles

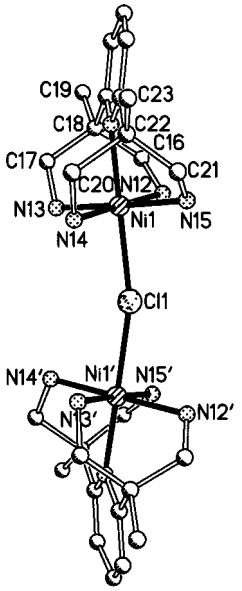
bond or angle	**4**	**5**	**6**	**7**	**8**
ε[a]	15.4(4)	1(1)	17(1)	5.0(3)	26.8(4)
ζ[b]	8.0(1)	1.3(3)	7.4(4)	3.0(2)	9.8(2)
η[c]	11.6(2)	3.1(6)	13.2(6)	4.0(2)	19.3(2)
d(C16···C21)	5.399(7)	5.18(2)	5.30(3)	5.28(1)	5.44(1)
d(C17···C20)	4.743(7)	5.01(2)	4.80(3)	5.06(1)	4.69(1)

[a] Angle ε between the least-squares planes defined by the pyridine ring (N11, C11, C12, C13, C14, C15) and the quaternary and methyl carbon atoms C18/C19/C22/C23. – [b] Angle ζ between the least-squares planes defined by the equatorial nitrogen atoms N12/N13/N14/N15 and the methylene carbon atoms C16/C17/C20/C21. – [c] Angle η subtended by the lines N11···C13 and N11–Ni1 at N11.

[*d*(C16···C21) and d(C17···C20)] have adjusted to 5.28(1) Å and 5.06(1) Å, respectively. On average, the Ni–N_{eq} bonds in **7** are slightly longer and the Ni–N_{eq}–C angles slightly larger than in the other complexes, and it appears that these differences, and possibly also solid state packing effects, allow the ligand to adopt a conformation closer to C_{2v} symmetry. The isothiocyanato ligand is linear [N1–C1–S1 = 177.8(6)°] and is coordinated to nickel at an angle of

Figure 3. Molecular structure of the cation in **6**; hydrogen atoms have been omitted for clarity; the numbering of atoms in the pyridine ring is identical to that shown in Figure 1



Ni1−N1−C1 = 165.9(5)°, with an Ni1−N1 bond length of 2.086(4) A. Corresponding values for an octahedral nickel(II) complex likewise containing a *trans* py−Ni−NCS unit are 159.0(3)° and 2.022(3) A, respectively[28].

[(1)Ni(N$_3$)](PF$_6$) (8)

The IR spectrum of the azide complex [(**1**)Ni(N$_3$)](PF$_6$) (**8**) shows, in addition to diagnostic bands due to the pyN$_4$ ligand and the hexafluorophosphate counterion, a sharp and very intense band at 2060 cm^{-1} due to the asymmetric stretching vibration of the coordinated azide ligand. Structural analysis reveals a complex cation (Figure 2) in which the distortion of the ligand cap is the most pronounced of all the complexes in the present series. While the Ni−N$_{py}$ bond length *trans* to the azide ligand [*d*(Ni1−N11) = 2.062(5) A] is identical to the corresponding value found in the isothiocyanate complex **7** (Table 1), the pyridine ring (which is planar to within 4 σ) is forced out of coplanarity with the quaternary and the exocyclic methyl carbon atoms of the ligand backbone by 26.8(4)° (Table 2). More significantly than in the other structures, the Ni−N$_{py}$ bond Ni1−N11 is bent from its vertical orientation relative to the NiN$_4$ plane, with relevant angles N$_{ax}$−Ni−N$_{eq}$ ranging from 85.5(2)° to 91.3(2)°. Further distances and angles are given in Table 1, and the complete set of parameters quantifying the ligand distortion in comparison to the other structures is given in Table 2. It is interesting to note that, despite the more serious distortion of the ligand in **8** with respect to the relative orientation of the pyridine ring, the bond angles in the carbon backbone (especially those at the methylene carbon atoms of the 1,3-diaminoprop-2-yl units, cf. Table 1) do not differ significantly from the corresponding values in the other structures. The terminally-coordinated azide ligand is linear [N21−N22−N23 = 177.9(7)°], and is bound to the nickel centre at an angle of Ni1−N21−N22 = 116.4(4)° (an angle approaching 120° is to be expected[29]; corresponding angles in other octahedral Ni(II) complexes containing terminal azide ligands span the range 123···138°[27][30][31][32][33][34]). The bond length *d*(Ni−N$_\alpha$) at 2.156(5) A is somewhat longer than in other terminal nickel(II) azide complexes (2.05···2.12 A)[27][30][31][32][33][34].

The Conformation of the Ligand Cap in 4, 5, 6, 7, and 8

The factors responsible for the varying degrees of distortion of the pentaamine ligand **1** in the solid state structures of **4**, **5**, **6**, **7**, and **8** are difficult to assess. The ligand has the topology of a podand, and hence is inherently more flexible than a macrocyclic or a cage-like arrangement of donor atoms, with their higher degrees of preorganization ("juxtapositional fixedness"[7]). The structures of complexes of **1** in the solid state are therefore expected to be more susceptible to packing effects, the significance of which will vary depending on the nature of the monodentate ligand and of the counterions. On a more subtle level, the *trans* influences ("static *trans* effects"[35][36]) of the monodentate ligands have to be considered. Perchlorate is weakly bound, and its complex has a shorter Ni−N$_{py}$ bond than the other complexes in the series. The tilt of the pyridine ring, however, is obviously unrelated to the length of the bond connecting it to the metal centre (i. e., the *trans* effect of the monodentate ligand). Thus, the isothiocyanato complex **7** and the azide complex **8**, while differing markedly in the degree of distortion of the ligand cap, have Ni−N$_{py}$ bond lengths which are identical within experimental error.

Magnetic Properties of 6

The magnetic behaviour of di- and polynuclear transition metal complexes is being studied extensively. The objective is to define the role played by the bridging ligands in mediating coupling interactions between the paramagnetic metal centers, and in particular to establish magneto-structural correlations[10]. Nickel(II) complexes, especially those containing chain-like one-dimensional arrangements of alternating metal atoms and bridging ligands, feature prominently in this context[29][32][37][38][39]. Bridging groups include carboxylato, nitrito, cyanide, cyanato, thiocyanato and, in particular, azido ligands, and complexes containing single, double, and triple bridges have been characterised[38][39][40]. The scarcity of polynuclear nickel(II) compounds containing an unsupported single halide bridge[21] led us to undertake the magnetochemical characterization of the μ-chloro bridged complex **6**.

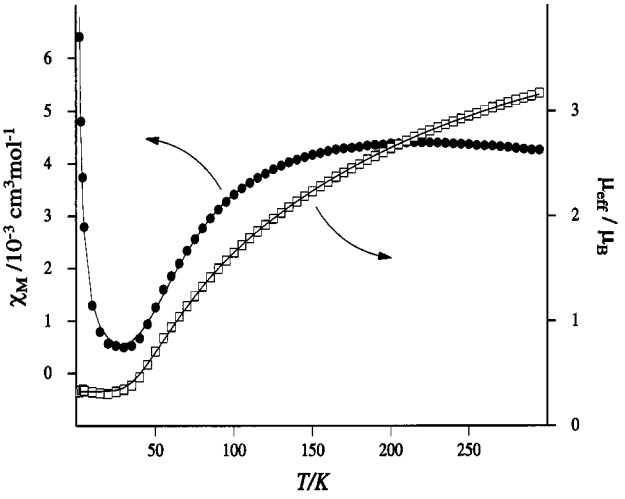
The solid-state magnetic susceptibility of **6** was measured at 1.0 T in the temperature range 2 to 295 K using a SQUID magnetometer (MPMS, Quantum Design). Figure 4 shows the variation of both the molar paramagnetic susceptibility χ_M and the effective magnetic moment μ_{eff} (per mol) with temperature. As temperature decreases, χ_M increases slightly, reaching a broad maximum at 225 K, and then decreases to reach a minimum at 30 K. The marked rise of χ_M for T < 20 K is attributed to the presence of a small amount of paramagnetic impurity, presumed to be a monomeric nickel com-

plex. As may be seen from the plot of μ_{eff} versus T, the value of the effective magnetic moment decreases steadily with decreasing temperature from the maximum value of 3.17 μ_B at 295 K ($\chi_M \cdot T = 1.256$ cm^3 K mol^{-1}), reaching a minimum of 0.32 μ_B ($\chi_M \cdot T = 0.013$ cm^3 K mol^{-1}) at temperatures below 25 K. The theoretical spin-only value of the magnetic moment μ_{SO} for two uncoupled Ni(II) spins $S_{Ni} = 1$ is 4 μ_B ($\chi_M \cdot T = 2$ cm^3 K mol^{-1}), which is higher than the experimental value of 3.17 μ_B at 295 K. The data are, however, consistent with strong antiferromagnetic exchange between the two nickel atoms through the bridging chlorine atom, resulting in a diamagnetic ground state with total spin $S_T = 0$. The residual value of μ_{eff} is indicative of the presence of a paramagnetic impurity. The experimental data of **6** have been analysed by a least-squares fit procedure using an isotropic Heisenberg-Dirac-van-Vleck (HDVV) exchange Hamiltonian $H = -2J\,\boldsymbol{S}_1 \cdot \boldsymbol{S}_2$, and taking account of Zeeman splitting as well as corrections for paramagnetic impurity (p) and temperature-independent paramagnetism (TIP)[41]. Diamagnetic correction is based on substracting the sample-holder signal and the contribution $\chi_D = -236 \times 10^{-6}$ cm^3 mol^{-1}, as determined from Pascal's constants[10], from the raw data. A good fit was achieved (solid lines in Figure 4) for isotropic exchange coupling $J = -74$ cm^{-1} between the two paramagnetic sites, average g value $g = 2.18$, paramagnetic impurity with spin $S = 1$ and relative amount $p = 2.7\%$, and TIP = $+171\times10^{-6}$ cm^3 mol^{-1} per nickel atom. It was further assumed that the paramagnetic impurity has about half the molecular weight and half the diamagnetic correction χ_D of **6**. The J value for **6** is considerably larger than the values typically found for antiferromagnetic coupling in Ni(II) chains containing single μ-(1,3)-azido bridges[29,38,42,43] or multiple bridges[44][45][46][47][48][49]. The reason for **6** having such a large J value is that its Ni(II)−X−Ni(II) angle comes closest to 180° of all the Ni(II) chains considered. The g value is as expected for octahedral nickel(II) complexes (cf. the typical value of $g = 2.25$ for $[Ni(H_2O)_6]^{2+}$ [50]). As far as we are aware, **6** is the first complex containing a single halogen bridge between two Ni(II) centres that has been characterised by a magnetochemical method.

Summary

The tetrapodal pentaamine ligand **1** acts as a square-pyramidal coordination cap towards nickel(II) ions in aqueous solution, leaving a sixth site for the binding of a monodentate ligand, which completes the coordination octahedron. Exchange of the monodentate ligand is facile, and the pentadentate ligand shows considerable conformational flexibility, as illustrated by the solid state structures of the aqua, perchlorato, isothiocyanato, and azido complexes. Since the pentaamine ligand effectively blocks five coordination sites in a coordination octahedron, dinuclear Ni(II) complexes containing a single bridging ligand may also be prepared. The ligand thus meets the requirements set out in the Introduction for the construction of coordination caps carrying a functional periphery. Work using the complex fragment $[(\mathbf{1})Ni]^{2+}$ as a template for the derivatization of the tetrapodal pentadentate ligand **1** is currently in progress.

Figure 4. Temperature dependence of the effective magnetic moment μ_{eff} (Bohr magnetons, μ_B) and of the molar magnetic susceptibility χ_M (10^{-3} cm^3 mol^{-1}) of **6**. Squares and dots represent the experimental data, whereas the solid lines are the calculated fits (see text). The scales at left and right have been chosen so as to avoid overlay of the curves.



We thank Professor *D. Sellmann* for generous support of this work and Dr. *F. Hampel* for establishing the crystallographic data set of compound **8**. Further, a Liebig-Stipendium from the *Fonds der Chemischen Industrie* (to A. G.) is gratefully acknowledged.

Experimental Section

CAUTION! Although no problems were encountered in this work, transition metal perchlorate and azide complexes with organic ligands are potentially explosive and should be handled with due precautions.

Materials and Instrumentation: 2,6-$C_5H_3N\{CMe(CH_2NH_2)_2\}_2$ (**1**) was prepared as described previously[3]. The aqua complex **2** was prepared by reacting equimolar amounts of **1** • 4 HCl and $NiCl_2$ • 6 H_2O in dilute aqueous ammonia solution and subsequent cation exchange chromatography on Sephadex SPC-25. The chromatography was performed as described in a published procedure[51]. Reagents were AR grade or better and were purchased from Merck, Fluka, and Aldrich. IR (KBr discs) and UV/Vis spectra (solvent: water) were recorded on Perkin-Elmer 16PC FT-IR and Shimadzu UV-3101 PC instruments, respectively. NMR spectra were measured on a JEOL JNM-EX 270 spectrometer, and mass spectra were obtained on a JEOL MSTATION 700 spectrometer. Elemental analyses were performed using a Carlo Erba Elemental Analyzer 1106. Magnetic measurements were carried out on a polycrystalline sample with a SQUID magnetometer (MPMS, Quantum Design).

X-ray Crystallography: Crystal data for compounds **4**, **5**, **6**, **7**, and **8** are given in Table 3, and selected distances and angles are listed in Table 1. The structures of the cations are presented in Figures 1, 2, and 3. Only the cation of **5** shows slight disorder (oxygen atoms of the perchlorato ligand). The structure of **4** was solved by direct methods and refined using the programme package SHELXTL 5.03[52]. An absorption correction (Ψ scans, 10 reflections, $T_{min} = 0.011$, $T_{max} = 0.032$) was carried out. All non-hydrogen atoms were refined anisotropically (full-matrix least-squares). All hydrogen atoms were located in a difference Fourier synthesis, and all hydrogen atoms except H1A and H1B (aqua ligand) were refined isotropically. Both the positional and the isotropic displace-

ment parameters of H1A and H1B were kept constant during refinement. The structure of **5** was solved by direct methods (SHELXS-86) and refined on F^2 using SHELXL 93[53][54]. The structure of **6** was solved by direct methods and refined using the programme package SHELXTL 5.03. For both **5** and **6**, the non-hydrogen atoms were refined anisotropically (full-matrix least-squares), and the hydrogen atoms were positioned geometrically. The structures of **7** and **8** were solved by direct methods and refined using the programme package SHELXTL 5.03. For both structures, all non-hydrogen atoms were refined anisotropically (full-matrix least-squares), and all hydrogen atoms were located in a difference Fourier synthesis and refined isotropically. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100 937. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code +44 (1223) 336−033; E-mail: deposit@ccdc.cam.ac.uk].

*[(**1**)Ni(H$_2$O)]I$_2$* (**4**): To a solution of **2** (0.94 g, 2.36 mmol) in water (50 ml) was added solid NaI (3.70 g, 24.69 mmol), and the mixture was stirred until all solid had dissolved. The solution was taken to dryness, the remaining solid taken up in as little methanol as possible, and the suspension filtered to remove NaI. Slow evaporation of solvent from the purple filtrate yielded a purple crystalline solid after several days. This was removed by filtration and air-dried. Yield: 0.40 g (0.69 mmol, 29%). Recrystallization from methanol gave single crystals suitable for an X-ray structure analysis. − IR (KBr): ν = 3272 cm^{-1} (br, OH/NH str), 2930 (CH str), 1594 (OH/NH def and C=C/C=N str), 1577 (OH/NH def and C=C/C=N str), 1463 (CH_2 asym def), 1397 (CH_2 sym def), 1024 (C−C skelet), 838 (NH def and CH_{pyr} oop def), 573 (C−C def). − UV/Vis (water): λ_{max} (ε) = 543 nm (3.4 dm^3 mol^{-1} cm^{-1}), 262 (1643). − MS (FD); *m/z* (%): 436 (100) [[(**1**)NiI]$^+$]; (FAB); *m/z* (%): 436 (100) [[(**1**)NiI]$^+$], 309 (45) [[(**1**)Ni]$^+$]. − $C_{13}H_{27}I_2N_5NiO$ (581.91): calcd. C 26.83, H 4.68, N 12.04; found C 26.66, H 4.26, N 11.98.

*[(**1**)Ni(OClO$_3$)](ClO$_4$)* (**5**): To a solution of **2** (0.42 g, 1.00 mmol) in water (5 ml) was added a saturated aqueous solution of $NaClO_4$ (5 ml). The resulting purple precipitate was centrifuged, washed with cold water, and dried in vacuo. Recrystallization from water/methanol (1:1 v/v) gave a crystalline solid (**3**) with no conclusive elemental analysis and IR data. A methanol solution of **3** (5 ml) containing $NaClO_4$ (0.50 g) was heated to reflux and cooled slowly to room temperature to give **5** in the form of single crystals suitable for an X-ray structural analysis. − IR (KBr): ν = 3263 cm^{-1}, 2964, 1576, 1464, 1145 (ClO_4 str), 1116 (ClO_4 str), 1088 (ClO_4 str), 1031, 1020, 822, 626. − ^{1}H NMR ([D$_6$]DMSO, room temp.; all signals paramagnetically broadened) δ = 1 (-CH_3), 20 (H^4), 43 (H^3), 100 (-CH_2-), 128 (-NH_2). − $C_{13}H_{25}Cl_2N_5NiO_8$ (508.99): calcd. C 30.68, H 4.95, N 13.76; found C 30.70, H 5.08, N 13.50.

*[(**1**)Ni(μ-Cl)Ni(**1**)](PF$_6$)$_3$* (**6**): To a solution of **2** (0.42 g, 1.00 mmol) in water (20 ml) was added a saturated aqueous solution of NH_4PF_6 (10 ml). The purple crystalline precipitate that formed was centrifuged, recrystallised from hot water, removed by filtration, washed with water, and air-dried. The resulting crystals were suitable for an X-ray structural analysis. Yield: 0.35 g (0.32 mmol, 64%). − IR (KBr): ν = 3374 cm^{-1}, 2967, 1603, 1579, 1469, 1397, 1084, 1020, 850 (PF_6), 559. − $C_{26}H_{50}ClF_{18}N_{10}Ni_2P_3$ (1090.52): calcd. C 28.64, H 4.62, N 12.84; found C 28.23, H 4.63, N 12.52.

*[(**1**)Ni(NCS)](PF$_6$)* (**7**): A solution of **2** (0.67 g, 1.68 mmol) in water (20 ml) was loaded onto a cation exchange column (Sephadex

SPC-25, ∅ 30 mm, length 190 mm), and the column eluted with water (200 ml). Gradient elution with an aqueous solution of NH_4SCN (0.1 M, 150 ml) removed a purple eluate which was concentrated to a volume of 20 ml. To this solution was added a saturated aqueous solution of NH_4PF_6 (10 ml). A single crystalline precipitate formed after several days. – IR (KBr): ν = 3274 cm^{-1}, 2979, 2091 (SCN), 1597, 1465, 1062, 1009, 850 (PF_6), 558. – $C_{14}H_{25}F_6N_6NiPS$ (513.13): calcd. C 32.77, H 4.91, N 16.38; found C 33.03, H 5.24, N 16.44.

*[(**1**)Ni(N$_3$)](PF$_6$)* (**8**): A solution of **2** (0.70 g, 1.75 mmol) in water (25 ml) was loaded onto a cation exchange column (Sephadex SPC-25, ∅ 30 mm, length 190 mm), and the column eluted with water (200 ml). Gradient elution with an aqueous solution of NaN_3 (0.1 M, 200 ml) removed a purple eluate which was taken to dryness. The remaining solid was taken up in methanol (50 ml), the suspension filtered to remove excess NaN_3, and the filtrate again taken to dryness. The residue was dissolved in water (10 ml), and the solution added to a concentrated aqueous solution of NH_4PF_6 (5 ml). The purple precipitate which had formed after several days was removed by filtration, washed quickly with a small amount of cold water, and air-dried. Single crystals suitable for an X-ray structural analysis were obtained by recrystallization from water. – IR (KBr): ν = 3256 cm^{-1}, 2962, 2060 (N_3), 1606, 1467, 1019, 834 (PF_6), 558. – $C_{13}H_{25}F_6N_8NiP$ (497.07): calcd. C 31.41, H 5.07, N 22.54; found C 30.94, H 4.88, N 20.52. Repeated recrystallizations gave samples which analysed consistently too low for N and, to a lesser extent, for C.

Keywords: Chromium / Organometallics / Homogeneous catalysis / Olefin polymerization / Polyethylene

Chromium-based heterogeneous catalysts are used extensively for the polymerization of olefins. There are few homogeneous model systems that allow investigation of the reaction mechanisms and unique characteristics of chromium catalysts. Coordinatively unsaturated paramagnetic chromium alkyls containing a $Cp^*Cr^{III}R$ fragment ($Cp^* = \eta^5\text{-}C_5Me_5$, pentamethylcyclopentadienyl) catalyze the polymerization of ethylene and α-olefins. Correlations between molecular structure and catalytic activity are reviewed.

Introduction

Polymers produced by homopolymerization and/or copolymerization of small olefins such as ethylene and propene are among the most widely used plastics. In 1996 worldwide consumption of polyethylene and polypropylene stood at 40×10^6 and 21×10^6 tons, respectively.[1] Except for so-called low density polyethylene (LDPE), which is made by a high temperature/high pressure radical process, these materials are the products of metal-catalyzed reactions conducted on an enormous scale. Two different kinds of catalysts are used commercially . One group utilizes group 4 metals (Ti, Zr) and can be traced to the Nobel prize-winning discoveries of Ziegler and Natta.[2] There has been much recent interest in this area, due to the development and application of so-called "metallocene" technology, i.e. catalysts based on sophisticated organometallic molecules that facilitate greater control of polymer structure and properties.[3] The second kind of catalyst is based on chromium and was discovered independently by Hogan and Banks at Phillips Petroleum Co.[4] Roughly one third of all polyethylene is currently produced with it, and it is notable for not requiring any cocatalyst (e.g. AlR_3 or methyl aluminoxane, i.e. MAO). Despite much investigative effort, much less is known about the mechanism and active site(s) of this catalyst, and it has not undergone innovations to match the "metallocene revolution". A large obstacle in this regard has been the lack of homogeneous model systems for chromium-based heterogeneous catalysts. This is now beginning to change, and this review covers the relevant organometallic chemistry of chromium, with particular emphasis on studies carried out in the author′s laboratory.

The Phillips catalyst is prepared by impregnation of silica with an inorganic chromium compound (e.g. CrO_3 or various Cr^{III} salts), followed by calcination in oxygen.[5] This leaves the chromium in the hexavalent state. Upon contact with ethylene, the metal is reduced, ultimately forming the catalytically active species. With carbon monoxide as an alternative reducing agent, the surface-bound chromium

Klaus H. Theopold was born in Berlin, Germany in 1954. With a "Vordiplom" from the University of Hamburg he moved to California where he received his Ph. D. in 1982 from the University of California at Berkeley. After a postdoctoral year at MIT, he began his academic career as asssistant professor at Cornell University in 1983. In 1990 he moved to the University of Delaware, where he is currently Professor of Chemistry. His research in synthetic organometallic and inorganic chemistry is aimed at the rational design of homogeneous catalysts for a variety of chemical transformations.

MICROREVIEWS: This feature introduces the readers to the authors′ research through a concise overview of the selected topic. Reference to important work from others in the field is included.

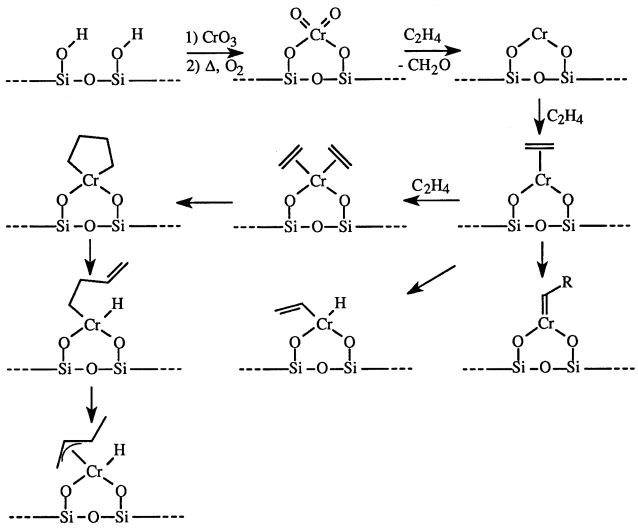
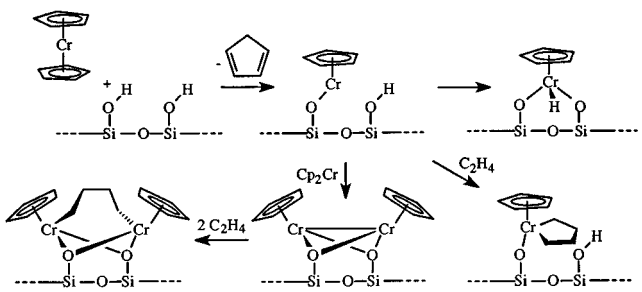
can be reduced to its divalent state (Cr^{II}), and this species will polymerize ethylene.[6] However, the chemical structure, valence state, and mechanism of formation of the active site, i.e. the chromium alkyl actually producing the polymer by repetitive insertion of ethylene, have been the subject of a longstanding controversy. Especially the valence (i.e. the formal oxidation state) of the catalytically active chromium has inspired much speculation, and almost every stable oxidation state of chromium has been held responsible for catalysis at one time or another. Scheme 1 depicts some of the proposed structures; several of the organometallic derivatives could in principle undergo ethylene insertion. Variations of these structures containing binuclear chromium sites (with and without metal−metal bonds) have also been proposed.

Scheme 1



Another chromium catalyst was discovered by Karapinka[7a] and developed by Karol et al.[7b] at Union Carbide in the early 60′s. It is prepared by impregnating dehydroxylated silica with chromocene (Cp_2Cr, Cp = η^5-cyclopentadienyl). While not in use industrially at present, the Union Carbide catalyst shares some of the advantages of the Phillips catalyst, namely high activity and absence of cocatalyst. It is different from the latter, however, in its high selectivity between ethylene and propene (no copolymerization) and its good response to hydrogen (H_2) for molecular weight control. There is little doubt that the reaction of the organometallic molecule with remaining hydroxyl groups on the silica surface results in loss of one cyclopentadienyl ligand and formation of a surface bound CpCr fragment (see Scheme 2). However, it is also clear that the remaining cyclopentadienyl group does not initiate the polymer chain growth; rather it stays coordinated to the chromium during catalysis. Thus there arises the same set of questions about the mechanism of the initiation, and the structure and valence of the active site. Scheme 2 shows some of the commonly proposed candidates for the active site.

Scheme 2



Homogeneous Model Systems

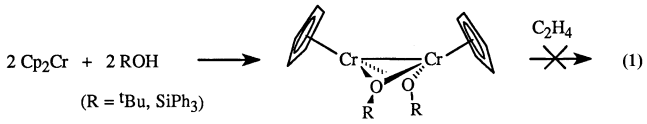
The proposed structures depicted in Schemes 1 and 2 have resulted from many spectroscopic investigations of heterogeneous catalysts combined with extrapolations from the now extensive body of known organometallic structures. However, the relevance of this "deluge of conjecture"[8] is highly questionable. Most of the analytical work utilized IR spectroscopy[9], with some EXAFS[10] and solid state ^1H NMR[11] results added relatively recently. Even for pure substances, most of these techniques can hardly be called definitive structural tools, and synthetic organometallic chemists would not base a detailed molecular structure solely on such results. Furthermore, the most careful studies of this type have come to the conclusion that the catalytically active sites represent only a very small fraction of the surface-bound chromium (< 1%!).[9b] Thus, whatever spectroscopic information is available probably pertains to those chromium species that are inactive. The proposals were further compromised by the fact that until recently the organometallic chemistry of chromium—i.e. the very metal of concern—did not offer realistic model compounds for any of the suggested species. As we have previously noted, "the known organometallic chemistry of said metal concerns low-valent carbonyl derivatives and/or diamagnetic complexes with 18-electron configurations. Such molecules are unlikely candidates for modeling highly reactive (coordinatively unsaturated) and oxide supported alkylchromium compounds".[12] This lacuna in the development of molecular chromium chemistry is largely due to the physical properties of relevant compounds. Chromium alkyls in the intermediate oxidation states of interest (II−IV) are typically "metallaradicals" featuring unpaired electrons. The associated paramagnetism makes characterization by NMR spectroscopy, the most important analytical tool of solution chemistry, more difficult and less informative.[13]

Nevertheless, we are convinced that homogeneous organometallic chemistry is in a position to make an important contribution both to the understanding of present-day heterogeneous catalysts and to the development of the next generation of chromium catalysts. To this end we must create functional models, i.e. well-defined chromium compounds that catalyze the polymerization of olefins in homogeneous solution. The preparation and catalytic activity of molecules incorporating the structural elements of Schemes 1 and 2 will be the best arbiter of their relevance. If a structurally characterized Cr^{IV} metallacycle, to name but one ex-

ample, does not polymerize ethylene in solution (see below), it is unlikely to do so on a silica surface. Conversely, if a class of coordinatively unsaturated $CpCr^{III}$ alkyls consistently exhibits catalytic activity, it must have some claim to being related to the catalytically active site of the Union Carbide catalyst. Let us then review the available homogeneous chemistry.

Cyclopentadienyl Chromium Catalysts

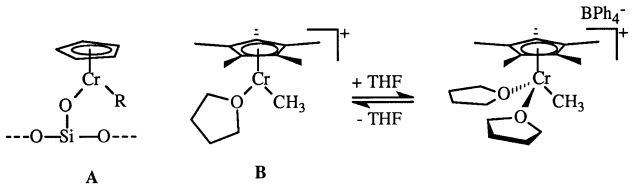
The Union Carbide catalyst is prepared by treatment of silica with chromocene. There have, of course, been attempts to model this reaction with surface hydroxyl groups in homogeneous solution by reaction of chromocene with alcohols or silanols.[14] The products of such reactions are invariably dinuclear Cr^{II} alkoxides (see eq. 1); they do not polymerize or even react with ethylene. One of the obvious advantages of surface-supported organometallics is "site-isolation", i.e. the inability of coordinatively unsaturated species to dimerize and thereby annihilate reaction sites. With respect to the initiation of catalysis, an investigation of the reactivity of a mononuclear complex of the type $CpCr^{II}-OR$ would be desirable; however, such a molecule has not been prepared. The closest we have come is the synthesis of mononuclear $Tp^{tBu,Me}Cr-OPh$ [$Tp^{tBu,Me}$ = hydrotris(3-*tert*-butyl-5-methylpyrazolyl)borato]; the sterically hindered tris(pyrazolyl)borate ligand is isoelectronic to the Cp ring, but its steric bulk prevents dimerization.[15] However, $Tp^{tBu,Me}Cr-OPh$ does not react with ethylene.



Chromocene by itself does not catalyze the polymerization of ethylene. However, in the presence of an excess of aluminum alkyl and at high ethylene pressure some polymer has been obtained. Under the same conditions, a variety of chromium π-complexes [including bis(arene)chromium$^{0/+}$, CpCr(acac)Br, and $CpCr(NO)_2X$] showed some activity.[16] Wilke et al. found that hexane solutions of tris(allyl)chromium polymerize ethylene under mild conditions[17]; although not a cylopentadienyl derivative, $Cr(\eta^3\text{-}C_3H_5)_3$ is chemically related to Cp_2Cr. The structure of the mixed ligand system $CpCr(\eta^3\text{-}C_3H_5)_2$ has been reported; its reaction with ethylene has not been described in the literature[18], but it is said to be active at modest ethylene pressure.[18c] Bis(indenyl)chromium, a dimeric complex featuring bridging $\mu\text{-}\eta^3$-indenyl ligands, is also a catalyst for ethylene polymerization.[19]

The generally accepted mechanism of polymer chain growth involves coordination of ethylene to a metal atom carrying an alkyl functionality, followed by migratory insertion of the olefin into the metal−carbon bond, thereby increasing the length of the alkyl chain by two carbons (Cossee mechanism).[20] Thus a minimum requirement for the active site is an alkyl group (or hydride) bonded to chromium. Keeping in mind the presence of the ancillary Cp ligand, and maintaining the link to the silica surface via an oxygen atom, one might suggest structure **A** (Scheme 3) as an active site of the Union Carbide catalyst.

Scheme 3



Based on this simple proposal, we began some time ago to explore the synthesis and reactivity of cyclopentadienyl chromium alkyls in the +III oxidation state.[21] For all the familiar reasons (e.g. solubility, stability) we opted for preparing the Cp* derivatives (Cp* = $\eta^5\text{-}C_5Me_5$, i.e. pentamethylcyclopentadienyl), but the qualitative differences caused by this substitution are expected to be minor.[22] Our first success was the synthesis and structural characterization of $[Cp^*Cr(THF)_2Me]BPh_4$ (THF = tetrahydrofuran).[12][23] In solution, this paramagnetic 15-electron cation exists in equilibrium with coordinatively unsaturated $[Cp^*Cr(THF)Me]^+$, via dissociation of a THF ligand (shown by ^1H NMR). Despite their electron deficiency (i.e. three electrons short of the 18-electron configuration), we consider three-legged piano stool complexes of the type Cp^*CrLX_2[24] "coordinatively saturated". If one considers the cyclopentadienyl ring (Cp*), a tridentate chelating ligand, to be occupying one trigonal face of an octahedron, then three additional ligands suffice to complete the octahedral coordination environment of the Cr^{III} ion, one of the most stable entities known to coordination chemists. We suggest that the 13-electron species (**B** in Scheme 3) is a good structural model of the proposed active site of the heterogeneous catalyst (i. e. **A**). Its positive charge may serve to discourage dimerization of the unsaturated species by electrostatic repulsion.

Solutions of $[Cp^*Cr(THF)_2Me]BPh_4$ in dichloromethane catalyzed the polymerization of ethylene at ambient temperature and pressure, without any added cocatalyst. Attempts to polymerize propene with $[Cp^*Cr(THF)_2Me]BPh_4$ were unsuccessful, however. In a typical experiment ca. 10 mg of the chromium compound dissolved in 50 ml CH_2Cl_2 ([cat] = 0.81 mM) produced 1−2 g of polyethylene before activity ceased. Ethylene uptake measurements showed an immediate onset of reaction upon addition of the catalyst. Although no induction period was observed, a slight increase in activity was noted during the initial phase of the reaction. At later times the catalytic activity slowly diminished and effectively ended after ca. one hour. In accord with the dissociation equilibrium depicted in Scheme 3, addition of external THF markedly inhibited the rate of polymerization, presumably by shifting the equilibrium to the coordinatively saturated, unreactive $[Cp^*Cr(THF)_2Me]^+$ cation. This interpretation was also supported by the observation that analogous complexes with more strongly bonded ligands, e.g. $[Cp^*Cr(Py)_2Et]PF_6$ (py = pyridine), were much less effective catalysts. ^1H NMR experiments

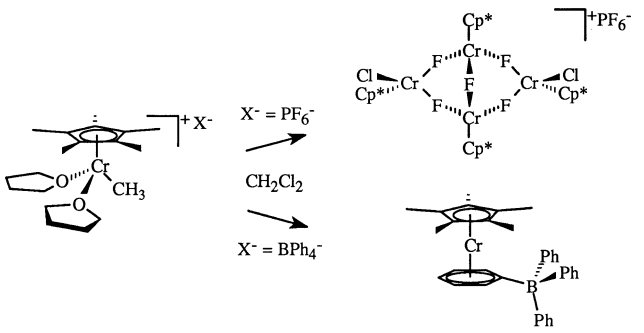
and measurements of the rate of polymerization in the presence of various concentrations of THF were used to establish the equilibrium constant for the ligand dissociation [K_{diss} = 1.0(2) M in CH_2Cl_2 at 19°C]. Based on this value, ca 60% of the chromium catalyst exists in the form of the catalytically active 13-electron species $[Cp^*Cr(THF)Me]^+$ under the conditions of the catalytic runs. Taking this into account, the maximum activity measured in these experiments was 1.1 turnover/sec or $>10^5$ g_{PE} $(mol_{Cr}\ h\ atm)^{-1}$, a value that is within an order of magnitude of the quoted activity of commercial catalysts. Measurements of the temperature dependence of the polymerization rate yielded an activation energy (E_a) of 8(1) kcal/mol, which also compares favorably with the value measured for Cp_2Cr/SiO_2 (E_a = 10.1 kcal/mol).[25]

The polymers so obtained were identified as high density polyethylene (HDPE) by IR spectroscopy and melting points (135−140°C). Molecular weight determinations by gel permeation chromatography (GPC) revealed relatively low molecular weights (M_w: 22000−77000; M_n: 14000−20000) and narrow molecular weight distributions (M_w/M_n: 1.9−4.6). The polymers are highly linear, showing no detectable sidebranches by ^{13}C NMR.

The eventual deactivation of the catalysts may be due to several factors. As noted above, the polymerization experiments were carried out without the addition of any cocatalysts. One of the benefits of the latter (typically aluminum alkyls) is their tendency to scrub the ethylene feed of detrimental impurities (e.g. H_2O, O_2), which may react with the catalyst. Without this protection the chromium alkyl will eventually be destroyed. Another possibility may be bimolecular deactivation pathways. β-Hydrogen elimination of a growing polymer chain would yield a Cr^{III} hydride. While such a species might start a new polymer chain (i.e. effect chain transfer) when fixed on a heterogeneous support, we have not been able to prepare a stable mononuclear hydride complex which might model such an intermediate. Attemps to do so have invariably led to reduction to Cr^{II}, presumably accompanied by formation of H_2.[26] Thus β-hydrogen elimination, followed by a binuclear reductive elimination of H_2, may seal the fate of the homogeneous catalyst. A third possibility involves irreversible reactions of the highly electrophilic chromium cation with the solvent or its counterion. In this vein, we have isolated and structurally characterized some unusual chromium complexes resulting from the metal attacking "innocent" anions (see Scheme 4).[12][27] Better noninteracting anions are now available,[28] but only the use of neutral catalysts completely circumvents these problems.

As part of a survey of the factors which are important for the activity of chromium catalysts, it was of interest to ascertain whether the cationic nature of the system described above is essential to the catalysis. After all, its charge is one of the subtle ways model complex **B** differs from the proposed active site **A** (see Scheme 3), which is envisioned as a neutral species. To this end we prepared the neutral dialkyl $Cp^*Cr(CH_2SiMe_3)_2$ (see eq. 2).[29] Although its crystal structure has not been determined yet, the magnetic behavior of the complex in the solid state is consistent with a mononuclear structure devoid of any metal-metal interactions. The effective magnetic moment of $Cp^*Cr(CH_2SiMe_3)_2$ is temperature independent and has a value of μ_{eff} = 3.9(1) μ_B, i.e. the expected spin-only moment for an isolated Cr^{III} ion.

Scheme 4

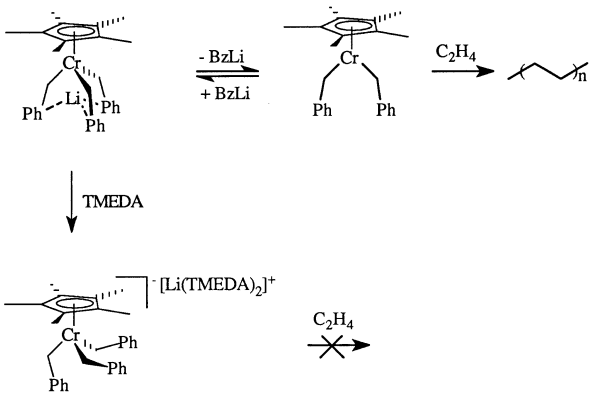


$$CrCl_3(THF)_3 \xrightarrow{Cp^*Li} [Cp^*CrCl_2]_2 \xrightarrow{Me_3SiCH_2Li} Cp^*Cr(CH_2SiMe_3)_2 \quad (2)$$

The steric bulk of the trimethylsilylmethyl groups apparently suffices to prevent dimerization, in contrast to the situation for smaller alkyl groups (see below). There is no spectroscopic evidence for an agostic[30] Cr···H···C interaction, and thus $Cp^*Cr(CH_2SiMe_3)_2$ is best described as a coordinatively unsaturated 13-electron complex. It is also a very good catalyst for the polymerization of ethylene. Hydrocarbon solutions (pentane, toluene) rapidly precipitated polyethylene at reaction temperatures ranging from 0 to −42°C [$Cp^*Cr(CH_2SiMe_3)_2$ slowly decomposes at room temperature]. The polymers had similar physical properties to those produced by $[Cp^*Cr(THF)_2Me]BPh_4$ (M_w: 20000−143000; M_n: 6000−20000; M_w/M_n 3.0−7.0). It is apparent that catalytic activity does not require the chromium alkyl to be positively charged. Indeed, we have found that even an anionic complex can serve as a catalyst precursor. Thus, the ate complex $Li[Cp^*Cr(CH_2Ph)_3]$ (see Scheme 5) polymerized ethylene.[13g] Its rate of polymerization was inhibited by addition of external benzyl lithium, however; presumably dissociation of $LiCH_2Ph$ from the complex generated coordinatively unsaturated $Cp^*Cr(CH_2Ph)_2$, a neutral complex much like $Cp^*Cr(CH_2SiMe_3)_2$. It is probably this intermediate which is responsible for the catalytic activity. Blocking the dissociative pathway, e.g. by sequestering the lithium ion with tetramethylethylenediamine (TMEDA), yielded a coordinatively saturated trialkyl complex, which did not show any polymerization activity. It is not known whether an anionic and yet coordinatively unsaturated Cp^*Cr^{III} alkyl might be active; to test this notion would require the use of a dianionic ligand {e.g. X^{2-} in $[Cp^*Cr^{III}(X)R]^-$}. Even if such a hypothetical 15-electron complex were available, it would still differ in an important way from $[Cp^*Cr(L)R]^+$ and Cp^*CrR_2, both of which exhi-

bit 13-electron configurations. We have not pursued this question.

Scheme 5

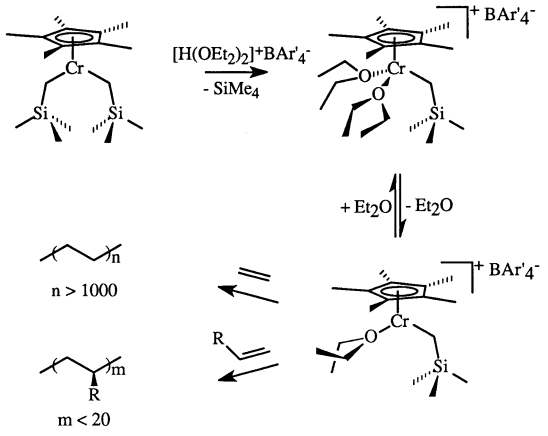


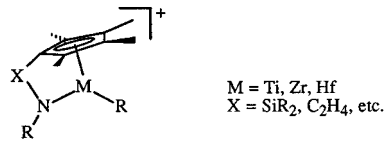
One of the characteristics of the Union Carbide catalyst (Cp_2Cr/SiO_2) distinguishing it from the Phillips catalysts is its pronounced selectivity between ethylene and higher olefins. Basically, it does not react with α-olefins and does not catalyze homopolymerization of the latter or even copolymerization of ethylene with α-olefins. The random incorporation of alkyl branches into the polymer chain gives rise to so-called "linear low density polyethylene" (LLDPE), a material of increasing commercial importance. Our model system seems to behave similarly in this respect as well. It has already been noted that $[Cp^*Cr(THF)_2Me]BPh_4$ failed to polymerize propene under mild conditions. In an attempt to facilitate reaction with α-olefins, and reasoning that the selectivity might be steric in origin, we have prepared chromium complexes with extremely labile ligands. While propene might not be able to compete effectively with THF for the empty coordination site of $[Cp^*Cr(THF)Me]^+$, it might be able to do so if the THF was replaced by a much weaker ligand. With this in mind, we have prepared chromium alkyls stabilized by dialkyl ethers, i.e. $[Cp^*Cr(OR_2)_2CH_2SiMe_3]BAr'_4$ [R = Me, Et, ^{i}Pr; Ar′ = 3,5-bis(trifluoromethyl)phenyl, see Scheme 6].[31] As an indication of the weakness of the chromium−ether bond, structurally characterized $[Cp^*Cr(OEt_2)_2CH_2SiMe_3]BAr'_4$ lost one equivalent of Et_2O when nitrogen gas was passed over the solid. It was also an extremely reactive catalyst, polymerizing ethylene even below its boiling point (b.p. −104°C).

$[Cp^*Cr(OEt_2)_2CH_2SiMe_3]BAr'_4$ also catalyzed the polymerization (or more appropriately, oligomerization) of α-olefins. Reactions of $[Cp^*Cr(OEt_2)_2CH_2SiMe_3]BAr'_4$ with propene and 1-hexene occurred at temperatures close to 0°C and yielded oily residues, which were analyzed by ^{1}H NMR and GC-MS. They were mixtures of oligomers with degrees of polymerization below 20. Finally, copolymerization experiments, in which the same catalyst was exposed to mixtures of ethylene and an α-olefin, yielded pure polyethylene without any indication (^{13}C NMR) of branching.

Because of the great interest in copolymerizations, we have made another attempt to tune the reactivity of chromium catalysts in that direction. So-called "constrained geometry" catalysts containing titanium are known to facilitate incorporation of large amounts of α-olefins into a copolymer.[32] The common structural element of these catalysts is an amido group covalently linked to the cyclopentadienyl ligand via a short bridge (1 or 2 atoms) as shown below.[33]

Scheme 6

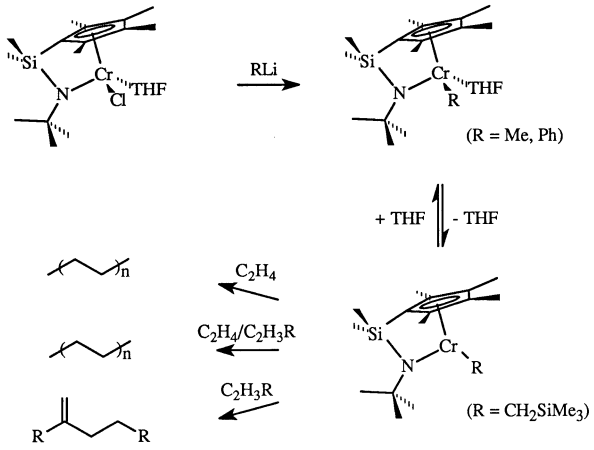




The open access to the metal alkyl is thought to be responsible for the lack of selectivity between different olefins. Hoping to capitalize on this effect, we have prepared isostructural chromium compounds.[34] Scheme 7 shows some of the molecules we have prepared and their reactions with olefins. The sterically demanding trimethylsilylmethyl ligand facilitated the isolation of $[\eta^5\text{-}(Me_4C_5)SiMe_2(N^tBu)]CrCH_2SiMe_3$, i.e. a coordinatively unsaturated Cr^{III} alkyl that has been structurally characterized. True to our expectations, this complex catalyzed the polymerization of ethylene. Remarkably, when the polymerization was carried out in 1-hexene instead of toluene as the solvent, the resulting polymer was still pure polyethylene without any indication of incorporation of the α-olefin. Finally, when the catalyst was presented with pure α-olefin (propene, hexene), a much slower reaction yielded the products of catalytic head-to-tail dimerization and isomerization of the olefin. In this system too, chromium exhibits significant selectivity, favoring ethylene by a wide margin over any other olefin.

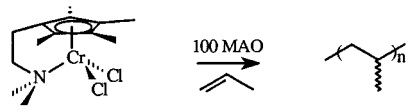
We conclude that the Cp^*Cr^{III} model system exhibits considerable selectivity for ethylene, much like Cp_2Cr/SiO_2. While it possesses some activity for the polymerization/oligomerization of α-olefins, the relative rates of polymerization make copolymerizations impractical. Our observations suggest that several factors limit the polymerization of α-olefins. First, the large difference in temperature at which the reactions commence (i.e. differences in rates) suggests that, for example, either the binding or the insertion

Scheme 7



step greatly favors ethylene over propene. On the other hand, the production of α-olefin oligomers of relatively low molecular weight (including dimers for the "constrained geometry" chromium catalyst) indicates that β-hydrogen elimination of a growing chain is much more facile for a Cp*Cr alkyl with tertiary hydrogen atoms. Whatever the underlying reasons for these preferences, they would appear to make cyclopentadienyl chromium systems unsuitable for α-olefin polymerization.

In this context it is appropriate, however, to mention some ambiguity in the available evidence. Jolly has recently reported that amino-substituted cyclopentadienyl chromium derivatives (see eq. 3), in the presence of methylaluminoxane (MAO:Cr = 100:1), polymerize propene (to atactic polypropylene) and copolymerize ethylene and norbornene to an alternating copolymer.[35] MAO is known to confer remarkable enhancements upon the catalytic activity of group 4 metallocene catalysts, and these observations may suggest that chromium systems will show a similar response. In keeping with the noted lack of cocatalyst requirements of heterogeneous chromium catalysts, we have not explored the effects of MAO on the Cp*Cr system. Conversely, based on our work with closely related compounds, a dialkyl or cationic monoalkyl containing the amino-substituted ligand shown in eq. 3 would not by itself be expected to polymerize propene effectively. This apparent ambiguity awaits further study.



(3)

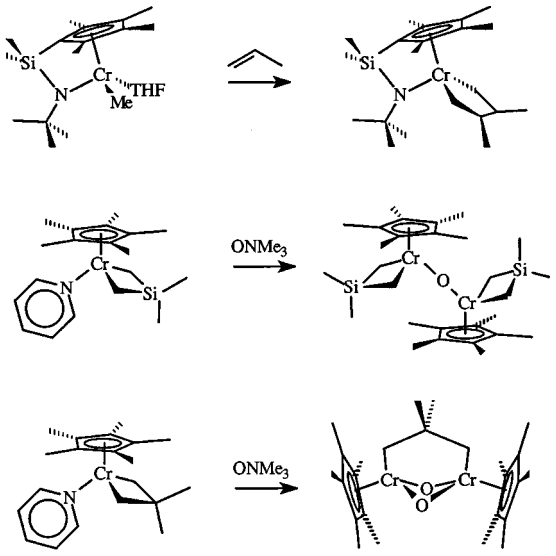
We conclude that *coordinatively unsaturated Cp*Cr*^{III} alkyls provide a credible structural as well as a functional model for the active site of the Union Carbide catalyst. Their reactivity characteristics parallel those of the heterogeneous catalyst. While the exact origin of the alkyl group in the latter remains unclear, the weight of the available evidence suggests that structure **A** of Scheme 3 is a good approximation of the chromium site in the act of chain propagation. Further support for this notion was provided by a recent theoretical study inspired by [Cp*Cr(THF)$_2$Me]BPh$_4$; its authors noted that the Cr^{III} system "displays many similarities to corresponding group IV systems".[36]

As noted in the introduction (see Scheme 3) many other types of organometallic structures have been proposed to account for the activity of the Union Carbide catalyst. Chief among these are various metallacycles, binuclear catalytic sites, and chromium compounds in formal oxidation states other than +III. During our wide-ranging exploration of the organometallic chemistry of Cp*-ligated chromium we have encountered many molecules which may serve as homogeneous models for such species. For the first time, their catalytic competency can thus be tested directly. If a particular structure does not exhibit any catalytic activity or reactivity with ethylene in homogeneous solution, simply grafting it onto a silica surface will not render it catalytically active. Attachment of a catalyst to a solid support has many advantages, but it is not a license for suspending sound chemical reasoning. Naturally, lack of catalytic activity is merely a negative datapoint, and it can always be argued that a model compound does not capture the actual species in detail. However, since we have described a fully functioning model system (see above), proponents of alternative structures now face the challenge of demonstrating that their candidates can actually do the job.

The proposal of a metallacycle is obviously connected to the desire to create an alkyl ligand via a precedented reaction of a metal site with ethylene. Reductive coupling of two ethylene units to a 1,4-butanediyl ligand is such a transformation, and accordingly metallacyclopentanes and dimetallacyclohexanes have often been considered as initiators of chain growth. Assuming, for the sake of the argument, that the lowest accessible oxidation state of chromium in Cp_2Cr/SiO_2 is +II, then coupling of two ethylene molecules on a mononuclear site would generate a Cr^{IV} metallacycle. This relatively rare oxidation state could be circumvented by considering cooperativity of two chromium sites, resulting in a dinuclear metallacycle with two Cr^{III} centers (see Scheme 2). Other, more complicated sequences of events are conceivable and might lead to any combination of ring size, nuclearity, and oxidation state. In any case, Scheme 8 shows some structurally characterized chromium metallacycles prepared as part of our studies.[37]

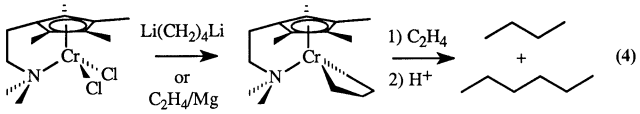
Most of these contain four-membered rings; however, it is unlikely that the slight difference in ring size would affect the insertion of ethylene. While the exact mechanism of formation of these molecules has not been determined in all cases, it seems probable that the Cr^{IV} metallacyclopentane with the "constrained geometry" ligand is the product of a reductive coupling of propene, i.e. the very reaction envisioned above for the formation of such structures. Its lack of any further reactivity with ethylene is thus all the more disappointing, if not entirely surprising. Indeed, none of the metallacycles depicted in Scheme 8 catalyzed the polymerization of ethylene. The most likely explanation for this lack or reactivity is the fact that all of the molecules are coordinatively saturated, i.e. in addition to the Cp* ligand they

Scheme 8



contain three ligands bonded to chromium. Interestingly, this objection was raised, and promptly dismissed, by one of the champions of a metallacycle intermediate.[9e] In any case, these observations certainly do not support the initiation of the catalysis via a metallacycle.

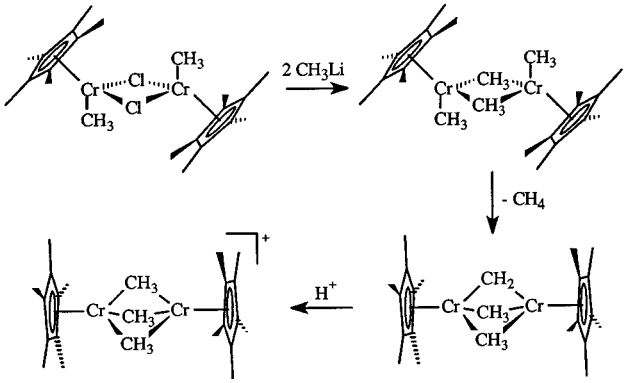
On the same topic, Jolly has reported the preparation of Cr^{III} metallacyclopentanes, inter alia by reductive coupling of ethylene (see eq. 4).[35] These react slowly with ethylene, and the work provides support for the intermediacy of such species in the chromium-catalyzed trimerization of ethylene to hexene.[38] However, activity for the polymerization of ethylene was noted only in the presence of an excess of MAO (100 equiv.). Under these conditions the fate of the metallacycle fragment is unclear.



(4)

Dinuclear chromium sites have often been suggested as the locus of catalytic activity. This may seem somewhat counterintuitive, as metal−metal bonding would be possible under these circumstances, which tends to attenuate the reactivity of metal complexes. The latter expectation seemed to be borne out by our experience with dinuclear chromium alkyls. For example, Scheme 9 shows a sequence of transformations of dinuclear complexes beginning with the synthesis of $[Cp^*(CH_3)Cr(\mu\text{-}CH_3)]_2$.[39] This complex is formally analogous to the catalytically active $Cp^*Cr(CH_2SiMe_3)_2$ (see eq. 2), but the lesser steric hindrance of the methyl groups and the electron deficiency of the metal result in dimerization via bridging alkyl groups. We have analyzed the extent of metal−metal bonding between the pseudooctahedral Cr^{III} atoms.[40] Their structures (d_{Cr-Cr}: 2.4−2.6 Å) and magnetic properties were consistent with some metal−metal interactions, which were also supported by EHMO calculations. Metal−metal bonding is rather unusual in Cr^{III} chemistry, and the interactions must certainly be weak. We noted that addition of even weak ligands (e.g. dissolution in THF) rapidly cleaved both $[Cp^*(CH_3)Cr(\mu\text{-}CH_3)]_2$ [to two equiv. of $Cp^*Cr(THF)(CH_3)_2$] and $[Cp^*_2Cr_2(\mu\text{-}CH_3)_3]^+$ {to $Cp^*Cr(THF)(CH_3)_2$ and $[Cp^*Cr(THF)_2CH_3]^+$}. Apparently the interaction with the cyclic ether is stronger than the Cr−Cr bond. However, ethylene binding was apparently not competitive. None of the molecules depicted in Scheme 9 exhibited any activity for the polymerization of ethylene under mild conditions. Thus we see no compelling advantage in postulating binuclear active sites.

Scheme 9



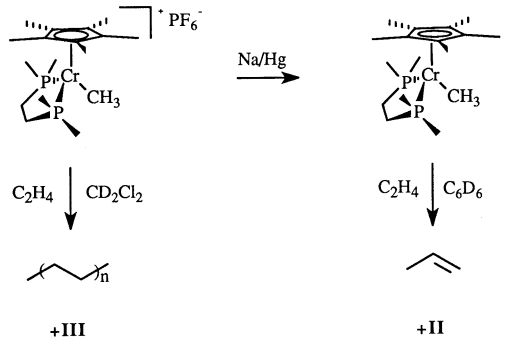
The remaining issue generating some difference of opinion is the valence state of the active chromium species. While even more contentious with regard to the Phillips catalysts, various formal oxidations states have been proposed for the Cp_2Cr/SiO_2 catalyst as well. In the words of its inventors, "it seems reasonable that the active site is an adsorbed, divalent chromium species which is still bonded to one cyclopentadienyl ligand".[7b] Our work points toward Cr^{III} rather than Cr^{II} as the active species, and even higher valence states have been contemplated.

Before describing our relevant observations some remarks of a general nature are perhaps in order. To begin with, we will consider an "active site" only a species which is actually producing polymer chains by repeated insertion of monomer. In general, this will require the presence of an alkyl (or hydride) ligand σ-bonded to chromium. Species that can be transformed into active sites by some reaction, including initiation of a chain via a reaction with ethylene, are merely "catalyst precursors". For example, the Cr^{VI} oxo sites of the calcined Phillips catalysts, or even the Cr^{II} centers resulting from reduction of the former with CO, are precursors rather than active sites. While they have the potential to catalyze the polymerization reaction, and will do so when exposed to ethylene, they are clearly missing an important attribute of the functioning catalyst, namely the growing macromolecule. While this distinction may seem rather restrictive, an unambiguous discussion of the evidence requires it. The initiation event may well change the oxidation state of the chromium (see Schemes 1 and 2), and the chemical situation is complex enough without introducing ambiguity due to ill-defined terminology.

Secondly, any argument about active vs. inactive valence states may be somewhat artificial, inasmuch as the "formal oxidation state" of a metal is a theoretical construct rather than a physical observable. Chromium complexes of the same oxidation state may have widely differing electron densities and partial charges on the metal center; the latter will ultimately determine the reactivity of any compound rather than a number based on willful neglect of any covalent contribution to metal−ligand bonding. As McDaniel put it regarding the Phillips catalysts, " it is ridiculous to speak of a particular valence state as if it were monolithic", and "the environment of the chromium, i.e., its type and arrangement of ligands, may be more important than the formal valence".[5] That said, it is probably overzealous to completely disregard valence as an important factor. There are, after all, good reasons while the concept remains in wide use in inorganic and organometallic chemistry. Furthermore, the coordination environment of the Cp_2Cr/SiO_2 catalyst is delineated fairly well. Thus, it may well be informative to ask which valence state of the metal will render a coordinatively unsaturated CpCr alkyl fragment catalytically active. In any case, in the following we will summarize our experimental observations on this matter.

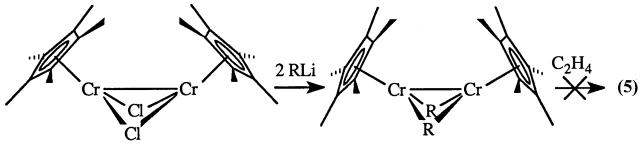
Our first experiment with respect to oxidation state was a direct comparison of the reaction of isostructural di- and trivalent chromium alkyls with ethylene. Thus, chemical reduction of [Cp*Cr(dmpe)Me]PF_6 [dmpe = bis(dimethylphosphino)ethane] yielded the neutral Cr^{II} alkyl Cp*Cr(dmpe)Me, which has been structurally characterized.[12] Scheme 10 shows the side-by-side comparison of the reactivity of these two compounds.

Scheme 10



As expected, the Cr^{III} complex catalyzed the polymerization of ethylene; the forcing conditions were presumably due to the presence of the chelating phosphine, which makes the opening up of a coordination site difficult. In contrast, the Cr^{II} alkyl reacted at ambient temperature, reflecting the known substitutional lability of divalent chromium. However, its reaction with ethylene produced propene along with small amounts of other olefins. The likely mechanism of formation of propene consists of insertion of ethylene into the chromium−methyl bond, followed by β-hydrogen elimination of the resulting propyl complex. There appears to be a clear dividing line between the reactivities of these two valence states, at least in this particular system. While the Cr^{III} alkyl repeatedly favors olefin insertion (i.e. chain growth) over β-hydrogen elimination (i.e. chain transfer), the Cr^{II} species exhibits the opposite selectivity. The choice of active oxidation state for polymerization catalysis is obvious.

The set of compounds described above differ from the actual catalyst in that they contain a phosphine ligand. To assess the polymerization activity of a divalent CpCr alkyl, it would be desirable to prepare the simplest such system imaginable, i.e. "CpCrR". We have done just that, however, the resulting species were of course not mononulear compounds with 12-electron configurations. Eq. 5 depicts the synthesis of the dinuclear chromium alkyls of the type [Cr*Cr(μ-R)]$_2$.[41] While of interest as a novel class of organochromium compounds and precursors to chromium hydrides, these complexes did not react with ethylene. This failure is probably due to the strong metal−metal bonding featured by these dimers. The short chromium−chromium distances {e.g. 2.26 Å in [Cr*Cr(μ-CH_3)]$_2$} signal the strength of this interaction, which is a well-precedented feature of Cr^{II} chemistry. Only one of the dinuclear complexes, namely a benzyl complex, catalyzed the polymerization. However, upon closer inspection, we found that isomerization to a mixed valence isomer (Cr^{I},Cr^{III}) was responsible for this activity.[42]

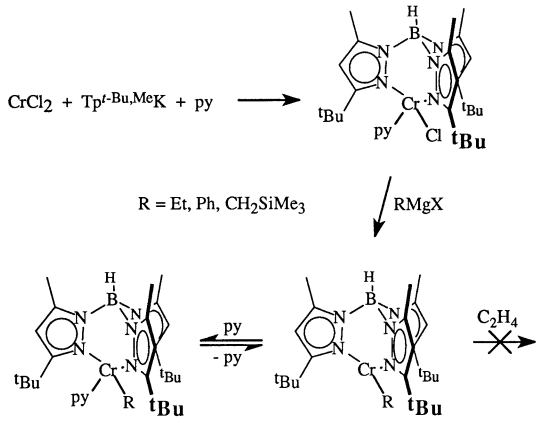


Dimerization of coordinatively unsaturated species has been noted as a "basic dilemma in attempting to model a heterogeneous reaction with compounds in solution".[14a] Thus the chemistry shown in eq. 2 is probably another good argument against the activity of dinuclear chromium sites (see above), but it falls short of ruling out mononuclear, coordinatively unsaturated Cr^{II} alkyls as active sites. However, we have recently obtained a set of compounds that address this question. Utilizing a sterically hindered tris(pyrazolyl)borate ligand, we have prepared divalent chromium alkyls of the type Tp$'^{Bu,Me}$CrR [Tp$'^{Bu,Me}$ = hydrotris(3-*tert*-butyl-3-methylpyrazolyl)borate; R = Et, Ph, CH_2SiMe_3], see Scheme 11.[43] The Tp ligand serves as an isoelectronic, yet sterically more demanding, replacement of the Cp ring. It effectively prevents dimerization, and accordingly the compounds feature mononuclear, four-coordinate Cr^{II}. Remarkably, they adopt an unusual "cis-divacant octahedral" coordination geometry, which leaves two coordination sites on chromium open for binding of the olefin substrate or other ligands.

None of these complexes reacted with ethylene, either at room temperature or upon heating. Indeed, Tp^{tBu,Me}CrEt eventually decomposed via β-hydrogen elimination.

In summary, the available evidence suggests that divalent chromium alkyls are not capable of catalyzing the polymerization of ethylene. They either fail to react with ethylene, or, if they do, the products undergo facile β-hydrogen elim-

Scheme 11



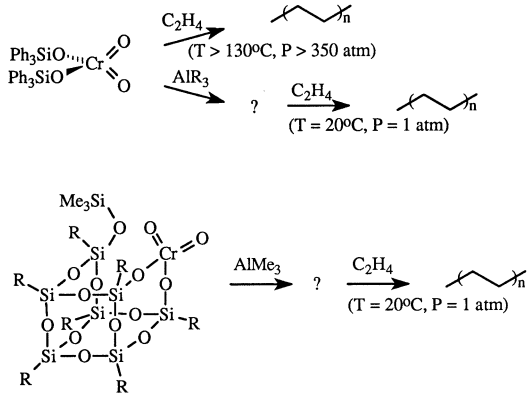
ination. Trivalent cyclopentadienyl chromium alkyls, on the other hand, when coordinatively unsaturated, consistently catalyze the polymerization, and the characteristics of the catalysis faithfully model the Union Carbide catalyst. Much less is known about the reactivity of CpCr alkyls in even higher oxidation states (IV−VI). None of the examples we[44], or others[45], have prepared have proven catalytically active, and it seems likely that the presence of several uninegative ligands beyond the Cp ligand and the polymer chain would render such complexes coordinatively saturated and hence inactive. Thus, based on the extensive available evidence from homogeneous model chemistry, we assert that the active sites of cyclopentadienyl chromium polymerization catalysts, including the Cp_2Cr/SiO_2 catalyst, are coordinatively unsaturated alkyls of trivalent chromium. To suggest otherwise would require experimental evidence in the form of a functioning homogeneous catalyst.

Other Chromium Catalysts

The most significant commercial chromium catalyst is the Phillips catalyst. It is usually prepared by impregnation of silica or silica/alumina with CrO_3, followed by calcination in air. The material resulting from this procedure is commonly thought to contain surface-bound chromate esters, i.e. Cr^{VI} species coordinated only by oxygen atoms (see Scheme 1). The oxidized form of the catalyst can be used for polymerizations. However, an induction period is observed, and products of olefin oxidation (formaldehyde) have been detected. Chromyl derivatives are known to be strong oxidants, which are reduced by olefins.[46]

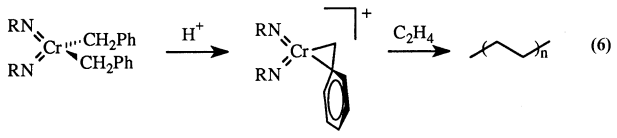
Attempts to model the activation of the Phillips catalyst in homogeneous solution have met with limited success, although without shedding much light on the detailed nature of the active site (see Scheme 12). Thus, cyclohexane solutions of bis(triphenylsilyl)chromate catalyzed the polymerization of ethylene at high temperatures (T > 130°C) and pressures (P = 350−1500 atm), even in the absence of a cocatalyst.[47] Addition of an aluminum alkyl caused "reduction of the chromium" and onset of ethylene polymerization at room temperature and atmospheric pressure. Similarly, Feher et al. have prepared and structurally characterized a chromate ester of a silasesquioxane, probably the best available structural model of the oxidized Phillips catalyst.[8b] Addition of two equivalents of $AlMe_3$ to benzene solutions of this compound produced dark orange solutions which polymerized ethylene under mild conditions (20°C, 1 atm). However, no further information about the oxidation state or chemical nature of the active catalyst(s) in these systems has been reported.

Scheme 12



It is apparent that the active site of the Phillips catalyst must contain chromium in a reduced state; however, the exact oxidation state of the metal remains unknown, despite much work and endless debate. Krauss and Stach showed some time ago that under favorable conditions the surface chromium can be reduced with carbon monoxide all the way down to Cr^{II}, and that the resulting coordinatively unsaturated species is indistinguishable in its polymerization behavior from the regular catalyst.[6] Based largely on these observations the catalytic activity of divalent chromium has become the prevailing dogma. However, the nature of the initiation step remains unclear, and the same ambiguities described for the Union Carbide catalyst (see above) exist here too. It is noteworthy that well-characterized Cr^{II} complexes, including coordinatively unsaturated alkyls, have failed to show any polymerization activity.[48]

The most promising recent development in this area has been Gibson's report of highly active homogeneous catalysts derived from bis(imido) chromium(VI) precursors (see eq. 6).[49] While the active species in this system have not yet been structurally characterized, the spectroscopic evidence seems consistent with cationic bis(imido)chromium alkyls featuring hexavalent chromium (Cr^{VI}). Based on the isolobal relationship between Cp- and imido ligands, and its putative d^0 configuration, this system resembles group IV metallocene chemistry (i.e. Cp_2MR^+) much more than any known heterogeneous chromium catalyst.



(6)

Conclusions

Coordinatively unsaturated Cp^*Cr^{III} alkyls represent the first well-characterized homogeneous ethylene polymerization catalysts based on chromium. These complexes model the Union Carbide catalyst (Cp_2Cr/SiO_2), and their chemistry may well be related to the Phillips catalyst (CrO_3/SiO_2) as well. Attachment of the compounds to inorganic oxide supports generates heterogeneous catalysts of considerable commercial potential. Looking to the future, this system may serve as the starting point for the design of new single-site catalysts containing chromium, and work toward that end is in progress in several laboratories.

Keywords: Bite angle / Catalysis / P ligands / Palladium / Allylic alkylation

The effect of the natural bite angle (β_n) of diphosphane ligands on catalyst selectivity and activity in the palladium-catalyzed allylic alkylation was investigated. The selectivity and rate of the reaction are mainly determined by steric hindrance induced by the diphosphane ligands. The steric hindrance at the palladium center increases as the natural bite angle of the ligand becomes larger. This results in an increasing selectivity at larger bite angles, but at very large bite angles the rate of the reaction drops. The ligand with the largest calculated bite angle, Xantphos, induced 100% selectivity but the reaction rate became low.

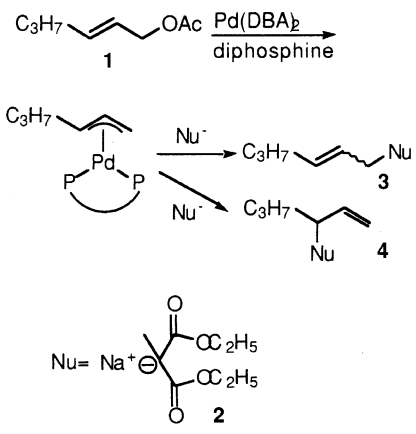
Catalyst selectivity and activity can be influenced by the steric and electronic properties of ligands. Additionally, a third ligand parameter, the bite angle of bidentate ligands,[1] seems to have a crucial effect on reactivity and stability of transition metal complexes. The bite angle can have a tremendous influence on catalyst behavior as shown for the hydroformylation[2][3][4][5] and hydrocyanation[6] reactions.

An intriguing reaction is the palladium-catalyzed allylic substitution reaction. After the discovery by Tsuji[7] further development of this reaction by Trost led to extensive use in organic synthesis.[8] A highly enantioselective palladium diphosphane catalyst was shown to have a large bite angle of 110.5°[9] which indicates that the bite angle can also be of importance in this reaction.

Most studies in this field focused on asymmetric induction and only little attention was paid to regioselectivity. Åkermark and coworkers investigated the influence of the steric bulk of bidentate ligands (substituted phenanthrolines) on the regioselectivity only very recently.[10] A detailed mechanistic and computational study by Bäckvall et al. showed the effect of the electronic properties of ligands on the regioselectivity of the reaction.[11] Steric factors had a large influence on the regioselectivity of this reaction. Recently, both experimental[12][13] and theoretical[14][15] studies were performed on the regioselectivity in the asymmetric allylic substitution, using ligands containing phosphorus and nitrogen donor atoms. Since steric interactions and electronic preferences can induce opposite effects, the involvement of an early or a late transition state remains under debate. All studies mentioned, however, ignored the effect of the bite angle of the ligands, although Trost found that enlarging the bridge of chelating chiral diphosphanes (and consequently increasing the bite angle of the diphosphane) led to higher asymmetric induction.[16]

Here we present a detailed systematic study on the effect of the bite angle of diphosphanes on catalyst activity and selectivity. The catalyst system we employed was prepared in situ using $Pd(DBA)_2$ (DBA = dibenzylidene acetone) and diphosphane in DMF. As a substrate we used 2-hexenylacetate (**1**) and the nucleophile was sodium diethyl methylmalonate (**2**), the same reagent used by Åkermark et al.[10] Only two products were observed: the linear product diethyl 2-(2-hexen-1-yl)-2-methylmalonate (**3**) and the branched product diethyl 2-(1-hexen-2-yl)-2-methylmalonate (**4**). The reaction is depicted in Scheme 1.

Scheme 1



The diphosphane ligands studied as catalyst components were dppe (1,2-bis(diphenylphosphanoethane), dppp (1,3-bis(diphenylphosphanopropane), dppb (1,4-bis(diphenylphosphanobutane), dppf (1,1′-bis(diphenylphosphanoferrocene), DPEphos, Sixantphos, and Xantphos (see Figure 1). The results are summarized in Table 1.

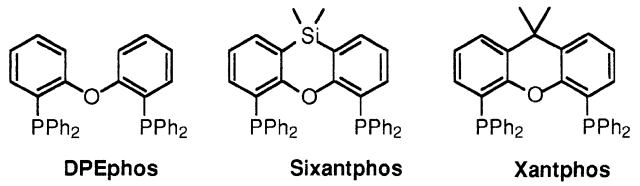
Figure 1. Diphosphanes with large bite angles



The bite angle of the diphosphane used affects both the activity and the selectivity of the catalyst. A sharp increase in catalyst activity (measured in initial turnover frequency) is observed in going from dppe to dppb. A further increase of the bite angle results in a decrease of the t.o.f.

Table 1. Alkylation of 2-hexenylacetate (**1**) with sodium diethyl methylmalonate (**2**) in DMF[a]

Ligand	Bite angle [°]	t.o.f. [mol/mol Pd/hr][b]	Reaction time [h]	Conversion [%][c]	**3** [%]	**4** [%]
dppe	78.1	82	5	98.5	96.2	3.8
dppp	86.2	111	5	97.9	96.6	3.4
dppb	98.6	393	1	98.0	97.7	2.3
dppf	99.07[d]	118	5	97.6	99.0	1.0
DPEphos	102.7	114	5	98.4	99.7	0.3
Sixantphos	106.5	91	20	97.5	99.6	0.4
Xantphos	110.0	22	20	92.1	100.0	0.0

[a] Conditions: 0.01 mmol $Pd(DBA)_2$, 0.02 mmol ligand, 1.0 mmol of **1**, 2.0 mmol of **2** in 3.0 ml DMF, T = 20°C. The 95% confidence interval of the mean measured values is ±0.1%. – [b] Initial turnover frequency, determined after 5 min. reaction time. – [c] Based on **1**; [d] P–Pd–P angle in X-ray of $(dppf)PdCl_2$.[17]

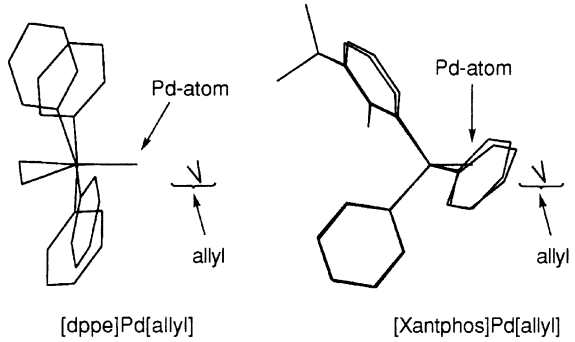
The selectivity of the reaction towards the linear product **3** increases regularly with an increasing bite angle (see Table 1). Using dppe 3.8% of product **4** is obtained, while dppf leads to 1%. When the Xantphos-type ligands are used, less than 1% of **4** is formed. The differences in amounts of **4** formed using Xantphos-type ligands are within the experimental error and will therefore not be discussed. It is noteworthy that when Xantphos is employed, 100% formation of **3** is observed, i.e. without any trace of **4**, which can prevent laborious purification of the desired product.

The selectivities reported were obtained at maximal conversion, which is nearly quantitative.

The formation of **4** is the result of a nucleophilic attack on the substituted carbon atom of the allyl moiety. In the transition state, the hybridization of this carbon atom changes from sp^2 to sp^3, which results in a bending of the R group towards the phosphane. This causes steric interference of the R group with the diphosphane ligand. A larger diphosphane bite angle results in larger steric interference and consequently less **4** is formed.

The steric interference was investigated by molecular modeling. The data from a P_2Pd[allyl] fragment (obtained from a recent X-ray crystal structure[18]) was superimposed on the structures of [dppe]Pd, the ligand with the smallest bite angle, and that of [Xantphos]Pd, the ligand with the largest bite angle (both taken from the natural bite angle calculations). The results are presented in Figure 2.

Figure 2. View through the P···P axes of [dppe]Pd[allyl] and [Xantphos]Pd[allyl]; H atoms were omitted for clarity



[dppe]Pd[allyl] [Xantphos]Pd[allyl]

In [dppe]Pd[allyl], the allyl fragment experiences no steric interference at all from the diphosphane ligand, while in [Xantphos]Pd[allyl] the allyl fragment interacts with the PPh_2 moieties of the ligand. This can be illustrated by the distances between the terminal allyl carbon atom and the *ipso* carbon atom of the phenyl rings. In [dppe]Pd[allyl] the $C\cdots C_{ipso}$ distances are 3.67 and 4.22 Å, whereas in [Xantphos]Pd[allyl] the $C\cdots C_{ipso}$ distances are 3.12 and 3.55 Å.

The increasing embracement of the allyl fragment at large bite angles not only dictates the regioselectivity, but it also hampers the reaction correspondingly. It is therefore not surprising that the initial turnover frequencies decrease when the natural bite angle of the diphosphane used becomes 100° or larger.

Since the ligand is completely symmetric, the regioselectivity cannot be induced by an electronic effect (trans influence).[12][13] The calculated structure of the complex has an approximate C_s symmetry as supported by crystal structure determinations[19] and solution structures[3] of other complexes. It is therefore unlikely that an electronic difference between the two Pd–C bonds results from steric effects, as suggested by Ward.[15] There is probably not much steric hindrance in the starting Pd allyl complex and the effect of increasing bite angle on the selectivity therefore points to a late transition state for this reaction.

In conclusion, the bite angle of a ligand has been shown to be a parameter of utmost importance for catalyst behavior. In the palladium-catalyzed allylic alkylation of 2-hexenyl acetate, regioselectivity increases with an increasing bite angle. The increased selectivity is induced by the increasing embracing of the allyl fragment by the diphosphane. This purely steric interaction inhibits the formation of the branched side product. The best selectivity with reasonably high reaction rates is obtained with DPEphos.

Experimental Section

Computational Details: All calculations were performed using CAChe WorkSystem software[20] on an Apple Power Macintosh 950 equipped with 2 CAChe CXP coprocessors. The Molecular Mechanics calculations were performed using the MM2 force

field.[21] Block-diagonal Newton-Raphson was used as optimization method. Natural bite angle calculations were performed using a method similar to that described by Casey and Whiteker[1], using a Pd−P bond length of 2.288 Å.[18][19]

For the ligands dppe, dppp and dppb, a starting geometry for the chelate ring resembling the appropriate cycloalkane was used. By this procedure, the global minimum resulting from excessive, stabilizing π-stacking interactions (and a too small a bite angle) was avoided. The geometry obtained this way agrees with geometries observed by X-ray crystallography.[22]

Palladium-Catalyzed Alkylation of Hexenyl Acetate. − General Procedure: To a Schlenk vessel was added $Pd(DBA)_2$, (5.8 mg, 0.01 mmol) and a diphosphane ligand (0.02 mmol), followed by 1 ml of a 1 M solution hexenylactetate (1.0 mmol) and 0.5 M decane (internal standard, 0.5 mmol) in DMF . The Schlenk vessel was kept at 20°C using a water bath and the solution was stirred for 5 min to ensure complete formation of the catalyst. Then 2.0 ml of a 1 M solution of sodium dimethyl malonate in DMF (2.0 mmol) was added. The reaction was monitored with GC at regular time intervals, by working up a small sample in H_2O and ether. The product distribution and the yield were determined using the internal standard.

Received July 9, 1997

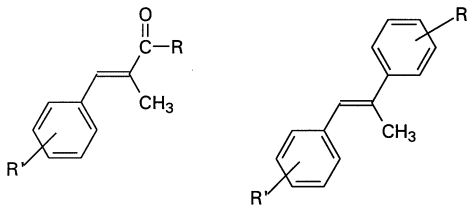
Keywords: Catalysis / Palladium / C−C coupling / Metallacycles / Trisubstituted olefins

The coupling reaction of 1,1-disubstituted olefins (α-methylstyrene, *n*-butyl methacrylate) with various aryl bromides (Heck reaction) has been studied as a new concept to synthesize trisubstituted olefins. Surprisingly, the nature of the base dramatically influences the product distribution. Thus, a systematic investigation on the role of base in Heck reactions of 1,1-disubstituted olefins was performed. Less coordinating bases like NaOAc, NaOBz or Na_2CO_3 yield a statistical distribution of regioisomers with the terminal olefin **10** as the major product. However, by using amines like Bu_3N or diisopropylethylamine (DIPEA) as base internal olefins can be synthesized with high selectivities. With phosphapalladacycle **3** as catalyst precursor, we were able to obtain catalyst turnover numbers up to 1000, while $Pd(OAc)_2/2PPh_3$ was one order of magnitude less active. Analysis of the reaction profile by kinetic investigations led to the postulation of a reduction and subsequent oxidative addition of the catalyst precursor **3** to form **12** as catalytically active intermediate.

Introduction

Trisubstituted, arylated olefins of the type **A** or **B** display interesting pharmacological or physical properties.[2]

Figure 1. Trisubstituted aromatic olefins



A **B**

In this respect derivatives of α-methylcinnamic acids display hypolipidemic activities.[2a] Further, the substructure is found in active substances such as the antibiotic hygromycin A.[2b] In addition, certain α-methylstilbenes can be used as nematic liquids[2c] with interesting retinoidal properties.[2d] Despite of their broad applications the stereodefined synthesis of trisubstituted alkenes is still a challenge of modern synthetic organic chemistry. Although a number of methodologies have been reported in the literature[3] the problems in synthesizing highly substituted alkenes, e.g. by Wittig reaction are well documented.[4] Thus, the search for alternative methodologies is ongoing.[5]

In this respect, the palladium-catalyzed Heck reaction is a powerful tool for the construction of aryl- and vinyl-substituted carbon−carbon double bonds as it does not interfere with a broad range of functional groups (for reviews see ref.[6]). Recently, we have developed cyclometallated palladium complexes as a new type of efficient catalysts for Heck and related reactions.[7][8] Obviously, olefins **A** or **B** should be available by Heck olefination. However, the low regioselectivity in the formation of the C=C double bond using disubstituted as well as aliphatic olefins is still a major disadvantage for the application of Heck reactions. The low regioselectivity can be explained either by unselective β-hydride elimination during the catalytic cycle, and/or by the tendency of the eliminated HPdX species to undergo readdition and subsequent β-hydride elimination to different hydrogen atoms, thus resulting in isomerization reactions.

As a concept for controlling regioselective olefin formation Tietze et al. have shown that silyl groups in allylsilanes act as terminating group in intramolecular Heck reactions enabling regio- and enantioselective construction of triple-substituted double bonds.[9] More recently, Ricci et al. reported a stereo- and regiocontrolled synthesis of di- and trisubstituted olefins starting from vinylsilanes by a Heck reaction and Pd-catalyzed desilylation reaction sequence.[10] Despite the high selectivities for specific double-bond isomers using silyl-substituted olefins it is obvious that control of the double-bond formation in Heck reactions using simple disubstituted alkenes by other means is a very attractive goal.

Results and Discussion

The interesting properties of α-methylcinnamic acid derivatives[2a][2b][11] prompted us to study regioselective Heck reactions of various aryl bromides **1** with *n*-butyl methacry-

[◇] Part 3: Ref.[1].

late (**2**) as model reaction.[12] Clearly, after insertion of the olefin into the Ar−Pd−Br complex there are two possibilities for β-hydride elimination: it can proceed towards the methyl or the benzylic methylene group. The former reaction leads to α-benzylacrylates **5** with a terminal double bond, the latter to α-methylcinnamic acid esters **4** with an internal double bond. Because of the reactivity of terminal olefins **5** the doubly arylated product **6** can subsequently be formed. In addition, *E* and *Z* isomers of **4** and **6** could be formed. Due to the importance of the β-hydride elimination for determining the double-bond selectivity we anticipitated that the nature of the base will be of major influence for the product distribution. Thus, various bases were examined for the reaction of *n*-butyl methacrylate with 1-bromo-4-fluorobenzene using the phosphapalladacycle catalyst **3** {*trans*-di(μ-acetato)bis[*o*-(di-*o*-tolylphosphanyl)benzyl]dipalladium(II)[13]}. The results are sumarized in Table 1.

Table 1. Heck reaction of *n*-butyl methacrylate with aryl bromides

10	4-Cl	Bu_3N	4	> 98	980	76	8	16

Reaction: 15 mmol of aryl bromide with 22.5 mmol of butyl methacrylate in the presence of 18 mmol of base and 0.1 or 0.01 mol% of phosphapalladacycle catalyst **3** in 15 ml of DMAc at 135−140°C. − [a] Conversions of the aryl bromides have been determined by GC with internal standard (diethylene glycol dibutyl ether). − [b] Selectivities have been determined by GC on the basis of area percentage.

Indeed, the nature of base significantly influences the regioselectivity of the double bond. Sodium acetate favors the formation of terminal olefin **5**, thus leading to a relatively large extent of doubly arylated products **6** (Table 1, run 1). In contrast, in the presence of 1.2 equiv. of tributylamine the internal olefin **4** is formed as major product (runs 2 and 3). Further improvement of selectivity towards the internal olefin **4** was achieved using the sterically hindered base *N,N*-diisopropylethylamin (DIPEA) which gives so far the best selectivities for this reaction (internal olefin/terminal products, 82:18, run 4). Interestingly, the productivity of the catalyst system is reduced by a factor of 3 in the presence of amines compared to NaOAc (0.01 mol% Pd, runs 1 and 2) which is explained by enhanced stabilization of Pd^{II} intermediates. While the selectivity in the presence of NaOAc is only moderate the catalyst productivity (TON = 8300) is about two orders of magnitude higher compared to previous data of similar reactions.[14]

In order to distinguish between thermodynamic or kinetic control of the double-bond formation the terminal olefin **5** was isolated and treated with NaOAc and Bu_3N under reaction conditions in the presence of the palladium catalyst. Only a negligable amount of isomerization of **5** to the more stable internal olefin **4** was detected. Thus, we assume that the formation of the double bond occurs under kinetic control.

Comparison of the phosphapalladacycle **3** with conventional palladium phosphane complexes which were tested as in situ catalysts shows the superiority of **3**. Significantly lower conversions (16% and < 5%) were obtained in the presence of tributylamine as base and 0.1 mol% $Pd(OAc)_2$/PPh_3 (1:2) or $Pd(OAc)_2$/P(*o*-tolyl)$_3$ (1:2), respectively.

In agreement with previous results[6] the electronic nature of the aryl bromide has dominating effect on the yield of the reaction (runs 5−10). Here, electron-withdrawing substituents enhance the productivity. It is noteworthy that, in all cases where amine is used as base, the ratio of internal olefin to terminal and doubly arylated olefin is approximately 80:20, while with NaOAc as base the ratio is about 40:60. Therefore, we conclude that the electronic nature of the aryl bromide has just a minor effect on the selectivity.

As a suitable candidate for further evaluation of the influence of base on the regioselectivity of Heck reactions with 1,1-disubstituted olefins we considered α-methylstyrene (**8**) which is available on large scale.[15] Here, the olefination of 1-bromo-4-chlorobenzene (**7**) was performed in the presence of 8 different bases. As shown in Scheme 1 five different Heck products can in principle arise from the reaction of **7** and **8** (both *E* and *Z* isomers are possible).

To suppress formation of doubly arylated Heck products an excess of α-methylstyrene **8** (5 equiv.) was used. The results of the model reaction are summarized in Table 2.

Using the phosphapalladacycle *trans*-di(μ-acetato)bis[*o*-(di-*o*-tolylphosphanyl)benzyl]dipalladium(II) (**3**) as catalyst under standard reaction conditions (dimethylacetamide, NaOAc, 0.1 mol% **3**, 135−140°C, 24 h; run 1) the coupling products were isolated in excellent yield (94%). Analogous to the reactions with *n*-butyl methacrylate the highest selectivity for the terminal olefin **10** is observed with NaOAc (**9**/**10**, 35:65). Only a small amount of the doubly arylated product **11** is formed (4% yield). Comparison of the phosphapalladacycle **3** with a classical catalyst system [0.1 mol% $Pd(OAc)_2$/2 PPh_3] gave similar results (run 10). The same regioselectivity (**9**/**10**, 37:63), albeit a lower total yield (66%) was obtained with sodium benzoate as base (run 2). Using inorganic salts such as sodium carbonate (run 3) or sodium hydrogen carbonate (run 4) excellent total yields (97% and 95%) were obtained, but the selectivity towards the terminal product is slightly lower (**9**/**10**, 38:62 and 46:54, respectively). On the other hand high selectivities up to 95:5 towards the internal olefin **9** are observed using tertiary amines as bases. Again, best results were obtained using the sterically hindered amine *N,N*-diisopropylethylamine (DIPEA, run 9, 65% total yield). A slightly lower regiose-

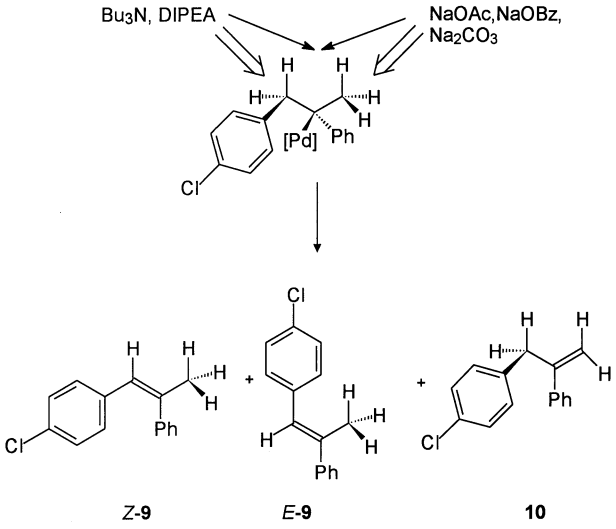
11	DIPEA	14	93	7	–	12	140

Reaction: 15 mmol of 4-bromo-1-chlorobenzene with 75 mmol of α-methylstyrene in the presence of 18 mmol of base and 0.1 mol% of phosphapalladacycle catalyst **3** in 15 ml of DMAc at 135−140°C. After 24 h, the reaction mixture was extracted and the solvent and not converted starting materials were removed in vacuo. The remaining reaction mixture was analyzed by GC, GC/MS, and ^{1}H NMR. − [a] Isolated yields. − [b] Selectivities have been determined by NMR of the isolated products. − [c] TON = mol product/mol catalyst. − [d] 1,8-Bis(dimethylamino)naphthalene.

lectivity (**9**/**10**, 89:11) is observed using tributylamine as base (66% total yield). Other bases or mixtures of bases gave results inbetween sodium acetate and DIPEA. No reaction is observed using chelating amines like TMEDA.

In the presence of amine as base the phosphapalladacycle catalyst **3** was found to be superior in productivity compared to classical catalyst precursors. Thus, the use of 0.1 mol% $Pd(OAc)_2$/2 PPh_3 led to a significantly lower total yields of **9** and **10** (14%, run 11). The selectivity towards the internal olefin is similar to the phosphapalladacycle catalyst **3** (**9**/**10**, 93:7), but there is a clear difference in the *E*/*Z* selectivity (*E*/*Z* = 12).

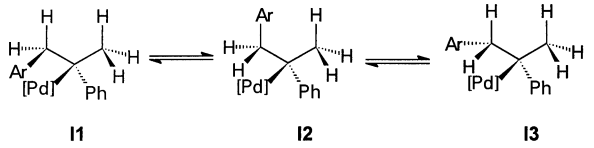
Scheme 2. Regiochemistry of the β-hydride elimination



Next we investigated whether an isomerization of the terminal olefin **10** to the internal olefin **9** in the presence of amine is possible. Neither heating of the terminal olefin **10** with catalyst **3** and DIPEA, nor heating of the internal olefin **9** with **3** and sodium acetate results in significant isomerization (< 10%). In addition, a thermodynamic isomerization would not explain the observed amount of the *Z* isomer *Z*-**9**. Thus, we propose a kinetic control for the reaction. In order to explain the different regio- and stereoselectivities (Scheme 2) we propose different mechanism for the proton abstraction (β-hydride elimination) depending on the base. Unfortunately, the β-hydride elimination and reductive elimination of HX from "H−Pd−X" have been scarcely investigated in the literature.[16] Based on simple conformation analysis the stereochemical outcome of the products is explained by β-hydride elimination from the possible intermediates **I1** (leading to **10**), **I2** (leading to *E*-**9** and **10**) and **I3** (leading to *Z*-**9** and **10**) (Scheme 3).

In the presence of less basic salts like NaOAc, NaOBz direct elimination of "H−Pd−X" will occur from inter-

Scheme 3. Conformational analysis of the β-hydride elimination



mediates **I1**, **I2** and **I3**. Because of the nearly statistical product ratio (terminal/internal, 3:2) we assume that the less coordinating bases are not involved in the elimination step of "H−Pd−X". However, the amine-assisted elimination takes place towards the most acidic protons (Scheme 2). A direct abstraction of the more acidic benzylic protons would explain for the low selectivity for the *E* isomer ***E*-9** because of a similar acidity of both benzylic protons. Thus, we believe that the base is involved in the β-hydride elimination by proton abstraction. Support for the direct abstraction of the proton may also result from the fact that the amine is blocking coordination sites on the metal centre, which are esssential for β-hydride elimination.

To obtain further mechanistic information about the system concentration vs. time diagrams for the reaction of 1-bromo-4-chlorobenzene (**7**) with α-methylstyrene (**8**) in the presence of NaOAc and DIPEA were compared (Figure 2).

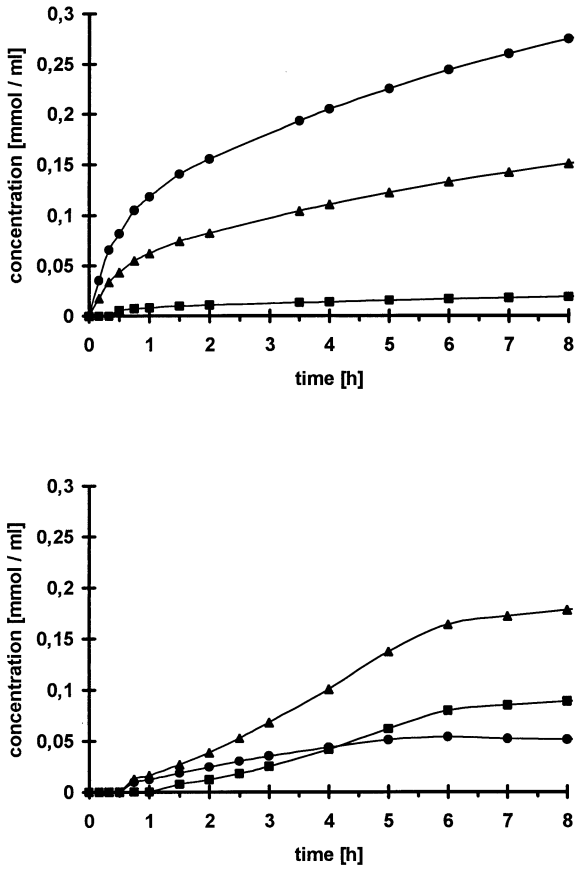
As shown in Figure 2 the base influences the reaction profile dramatically. In the presence of NaOAc the reaction starts immediately leading to the terminal olefin **10** as the major isomer. If the concentration of **10** is high enough (after ca. 5 h) the doubly arylated product **11** (not shown in Figure 2) is produced in small quantities by a consecutive Heck reaction. No initial catalyst activation is observed. However, the reaction with DIPEA as base (Figure 2, lower diagram) shows a sigmoidal concentration vs. time diagram indicating preformation of the active catalyst species. The induction period might be explained by a slowly occurring reduction of the phosphapalladacycle **3**[17] to a monophosphanepalladium(0) compound. Immediately, this species would undergo oxidative addition to 1-bromo-4-chlorobenzene (**7**) to give the palladium complex **12** (Scheme 4). To proof this assumption the oxidative addition product **12** was prepared independently from $Pd[P(o\text{-tolyl})_3]_2Cl_2$ and **7** in a total yield of 66% according to a procedure described by J. F. Hartwig et al.[18]

The concentration vs. time diagrams for the Heck reaction of 1-bromo-4-chlorobenzene (**7**) with α-methylstyrene (**8**) in the presence of 0.1 mol% **12** as catalyst with NaOAc and DIPEA as base are shown in Figure 3.

No induction period is observed in both cases! In the presence of NaOAc as base the reaction catalyzed by **12** starts faster compared to the reaction catalyzed by **3** and a similar product distribution is observed. Also using DIPEA as base the raction starts immediately. The ratio of products initially formed is comparable to the ratio of the different isomers obtained in the phosphapalladacycle-catalyzed reaction. However, after several hours ***E*-9** is formed preferentially with **12** as catalyst yielding in a higher *E*/*Z* ratio.

This findings are rationalized as follows: As shown in Scheme 4 the phosphapalladacycle **3** is reduced to a monophosphanepalladium(0) species. The nature of the reducing agent is not clear in detail. Coordination of amines stabilizes the phosphapalladacycle **3** slowing down the formation of a palladium(0) compound. This results in an induction

Figure 2. Concentration vs. reaction time diagrams; top: NaOAc as base; bottom: DIPEA as base; ● terminal olefin **10**; ■ **Z-9**; ▲ E-**9**[a]



[a] Reaction conditions: 15 mmol of 1-bromo-4-chlorobenzene, 75 mmol of α-methylstyrene, 18 mmol of base and 2 ml of diethylene glycol dibutyl ether were heated in 15 ml of DMAc at 135°C. At $t = 0$ a solution of 0.1 mol% of the phosphapalladacycle **3**, dissolved in 1 ml of DMAc, was added. The course of the reaction was monitored by removing 0.1-ml samples of the reaction mixture. These were washed with 5% HCl solution, then extracted with 1.5 ml of dichloromethane and analyzed by GC.

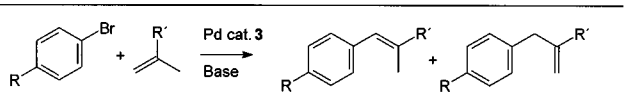
period for the proper catalyst. Furthermore, the rate of oxidative addition is decreased in the presence of amines by blocking of free coordination sites on the Pd^0 species. On the other hand it is known, that the coordination of NaOAc to phosphanepalladium(0) complexes increases the rate of oxidative addition for haloarenes.[19] This explains in general the higher catalyst activity in the presence of NaOAc.

Further evidence for the discussed transformation of the phosphapalladacycle **3** to **12** is obtained by comparing the *E*/*Z* ratio for the different catalysts (**3** and **12**) using DIPEA as base. As a matter of fact the *E*/*Z* ratio produced by **12** in the first hour is identical to that of the phosphapalladacycle **3** during the whole reaction time. Due to side-reactions in the formation of **12** from **3** the productivity of **3** is lower.

In order to demonstrate that the determination of the regiochemistry by the base is a general principle for Heck reactions of 1,1-disubstituted olefins we studied coupling reactions of **2** and **8** with various other aryl bromides (Table 3). As can be seen from Table 3 4-bromotoluene and 1-bromo-4-fluorobenzene behave in a similar manner as described for 1-bromo-4-chlorobenzene. In contrast to Table 1 the coupling reactions with *n*-butyl methacrylate were performed in the presence of five equivalents of the olefin. Thus, the amount doubly arylated products could be minimized.

Table 3: Heck reaction of 1,1-disubstituted olefins with various aryl bromides



Run	R	R'	Base	Yield[a] [%]	Internal[b] [%]	Terminal[b] [%]	Double[b] [%]	*E*/*Z*[b]	TON[c]

6	Cl	COOBu	DIPEA	84[d]	88[d]	7[d]	5[d]	23[d]	840

Reaction: 15 mmol of aryl halide with 75 mmol of olefin in the presence of 18 mmol of base and 0.1 mol% of phosphapalladacycle catalyst **3** in 15 ml of DMAc at 135−140°C (24 h). − [a] Total isolated yields. − [b] Selectivities have been determined by NMR of the isolated products. − [c] TON = mol product/mol catalyst. − [d] Determined by GC analysis.

In conclusion we have demonstrated that the nature of base significantly influences the regiochemistry of the double bond in certain types of Heck reactions. Based on this finding we have developed a new and general valid concept to determine the regiochemistry of Heck reactions of 1,1-disubstituted olefins simply by changing the added base. Moreover, by using phosphapalladacycle **3** as catalyst precursor we have been able to improve the catalyst productivity for Heck coupling reactions of 1,1-disubstituted olefins by at least one order of magnitude. Comparison of the concentration vs. time diagrams for Heck reactions with the phosphapalladacycle **3** and the oxidative addition product **12** as catalysts provides evidence that **3** is a catalyst precursor with **12** as active species.

Kühlein*, Dr. *H. Geißler* and Dr. *R. W. Fischer* (*Hoechst AG*) are thanked for many stimulating discussions.

Experimental Section

Chemicals were obtained from Aldrich and Fluka. NMR spectra (^1H,^{13}C,^{31}P) were recorded with a Jeol JMX-GX 400 or a Bruker AM 360 instrument. GC-MS spectra were measued with a Hewlett Packard gas chromatograph GC 5890 A equipped with a mass-selective detector MS 5970 B. Elemental analyses were carried out by the Microanalytical Laboratory at the TU München. Quantitative analyses were performed with a Hewlett Packard 6890 instrument using a HP-5 capillary column in conjunction with a flame ionization detector (GC/FID). − Except for the work-up of reaction mixtures, all operations were carried out under nitrogen. Solvents were carefully dried according to standard procedures.

1. *Heck Reactions with n-Butyl Methacrylate:* 15 mmol of aryl halide, 22.5 mmol of *n*-butyl methacrylate (3.58 ml), 18 mmol of tri-*n*-butylamine (4.29 ml), 0.1 mg of 2,6-di-*tert*-butyl-4-methyl-

phenol and 7.0 mg of the phosphapalladacycle **3** were dissolved in 15 ml of *N,N*-dimethylacetamide and stirred at 135−140°C (reaction time as indicated). After cooling, the reaction mixture was extracted with diethyl ether and 5% aqueous HCl for three times. The combined organic phases were neutralized with 10% aqueous $NaHCO_3$ and dried with $MgSO_4$. After removal of the solvent and starting materials in vacuo the products were isolated as colourless oils by distillation or by column chromatography.

n-Butyl 3-(4-Methoxyphenyl)-2-methylpropenoate: Isolated by column chromatography (ethyl acetate/hexane, 1:10, 20%). − ^{1}H NMR (360 MHz, 20°C, $CDCl_3$): δ = 7.64 (s, 1 H, C*H*=C), 7.37 (d, 2 H, $^3J_{HH}$ = 8.3 Hz, 2-Ph-H, 6-Ph-H), 6.91 (d, 2 H, $^3J_{HH}$ = 8.3 Hz, 3-Ph-H, 5-Ph-H), 4.18 (t, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH_2), 3.82 (s, 3 H, OCH_3), 2.13 (s, 3 H, =C−CH_3), 1.65 (tt, $^3J_{HH}$ = 6.6 Hz, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH$_2$CH_2) 1.44 (tt, $^3J_{HH}$ = 6.7 Hz, $^3J_{HH}$ = 7.4 Hz, 2 H, COOCH$_2$CH$_2$CH_2), 0.97 (t, $^3J_{HH}$ = 7.4 Hz, 3 H, CH$_2$CH_3). − MS (70 eV); *m/z*: 248 [M$^+$], 192, 146, 115, 91.

n-Butyl 3-(4-Chlorophenyl)-2-methylpropenoate: Isolated by distillation (55%, b.p. 120−125°C/1 mbar). − ^{1}H NMR (360 MHz, 20°C, $CDCl_3$): δ = 7.63 (s, 1 H, C*H*=C), 7.38−7.32 (m, 4 H), 4.23 (t, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH_2), 2.10 (s, 3 H, =C−CH_3), 1.74 (tt, $^3J_{HH}$ = 6.6 Hz, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH$_2$CH_2) 1.44 (tt, $^3J_{HH}$ = 6.7 Hz, $^3J_{HH}$ = 7.4 Hz, 2 H, COOCH$_2$CH$_2$CH_2), 0.98 (t, $^3J_{HH}$ = 7.4 Hz, 3 H, CH$_2$CH_3). − MS (70 eV); *m/z*: 252 [M$^+$], 196, 179, 150, 115, 89.

n-Butyl 3-(4-Nitrophenyl)-2-methylpropenoate: Isolated by column chromatography (ethyl acetate/hexane, 1:15, 75%). − ^{1}H NMR (360 MHz, 20°C, $CDCl_3$): δ = 8.25 (d, 2 H, $^3J_{HH}$ = 8.9 Hz, 3-Ph-H, 5-Ph-H), 7.70 (s, 1 H, C*H*=C), 7.54 (d, 2 H, $^3J_{HH}$ = 8.9 Hz, 2-Ph-H, 6-Ph-H), 4.25 (t, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH_2), 2.12 (s, 3 H, =C−CH_3), 1.72 (tt, $^3J_{HH}$ = 6.6 Hz, $^3J_{HH}$ = 6.6 Hz, 2 H, COOCH$_2$CH_2) 1.47 (tt, $^3J_{HH}$ = 6.7 Hz, $^3J_{HH}$ = 7.4 Hz, 2 H, COOCH$_2$CH$_2$CH_2), 0.98 (t, $^3J_{HH}$ = 7.4 Hz, 3 H, CH$_2$CH_3). − MS (70 eV); *m/z*: 263, [M$^+$], 207, 190, 161, 115, 89.

2. *Heck Reactions with α-Methylstyrene:* 15 mmol of the aryl bromide, 75 mmol of α-methylstyrene (8.86 g, **2**), 18 mmol of the base and 7.0 mg of the phosphapalladacycle **3** (0.1 mol% Pd) were dissolved in 15 ml of *N,N*-dimethylacetamide and stirred under a gentle stream of nitrogen at 135−140°C for 24 h. After cooling, the reaction mixture was extracted with dichloromethane and 5% aqueous HCl for three times. The combined organic phases were neutralized with 10% aqueous $NaHCO_3$ and dried with $MgSO_4$. The solvent and starting materials were removed in vacuo. The ratio of the regioisomers was calculated by the relative intensities of the typical signals in the ^{1}H-NMR spectrum ($CDCl_3$, TMS as internal standard). Total yields for different bases are given in Tables 2 and 3.

(E)-4-Chloro-α-methylstilbene (*E*-**4**): ^{1}H NMR (360 MHz, 20°C, $CDCl_3$): δ = 7.5−7.0 (m, 9 H, aromatic protons), 6.76 (s, 1 H, C= C*H*), 2.25 (s, 3 H, −CH_3). − MS (70 eV); *m/z*: 228, [M$^+$], 211, 193, 178.

Keywords: Tripodal P ligands / Rhodium / Water-soluble complexes / Immobilization / Biphasic hydroformylation

The synthesis of the water-soluble tripodal phosphane ligand *cis,cis*-1,3,5-$(PPh_2)_3$-1,3,5-$[CH_2(OCH_2CH_2)_xOCH_3]C_6H_6$ (x = 30−160) (**5**) has been achieved in a four-step reaction sequence. The alcohol $Mo(CO)_3$[*cis,cis*-1,3,5-$(PPh_2)_3$-1,3,5-$(CH_2OH)_3C_6H_6$] (**1**) is converted to the corresponding alcoholate **2**, which forms the polyethylene glycol derivative **3** in a polyaddition reaction with oxirane. After methylation of the end groups of **3**, the ligand **5** is obtained by a combined photochemical/oxidative demolybdenation reaction. The water-soluble tripodal phosphane **5** and the methoxymethyl functionalized tripodal ligand **6** react with $Rh(PPh_3)_3(CO)H$ to form the water-soluble and water-insoluble rhodium carbonyl hydrido complexes **5a** and **6a**, respectively. The catalytic activity of the rhodium complex **5a** in the hydroformylation of 1-hexene was found to be comparable in a single-phase system (1-hexene/methanol) with that in the biphasic system (1-hexene/water). Only traces of alcohol were found, which demonstrates that the catalyst **5a** displays higher selectivity in hydroformylation than in hydrogenation.

Simplification of process engineering in the field of biphasic homogeneous catalysts has spurred the successful industrial application of these systems.[1] For example, in aqueous biphasic oxo-catalysis, the reactants and the products stay in the organic phase while the catalyst remains in the aqueous phase.[1][2] Such a two-phase system exhibits low catalytic activity in the hydroformylation of higher olefins because of mass transfer limitations that result from the lower solubility of such longer-chain derivatives in water. Water solubility of transition metal complexes is generally achieved by using phosphane ligands that bear polar substituents such as $-SO_3Na$[1b][1f][3] or $-NR_3^+$.[4] It has been suggested that the problems encountered due to mass transfer limitations may be overcome by using phosphane ligands derivatized with polyalkylene glycol ether groups.[5] The inverse temperature dependence of the solubility of polyalkylene oxide oligomers in water[6] leads to a single-phase system at higher temperatures. In this way, at elevated temperature, the catalyst migrates from the aqueous phase into the organic phase and is available to perform homogeneous catalysis. Upon cooling the system, the catalyst migrates back into the aqueous phase and can be recovered by simple phase separation. Ethylene glycol moieties with various chain lengths have been introduced into several phosphane ligand systems.[5][7][8] Polyethylene glycol has also been used as a hydrophilic film in which water-soluble rhodium complexes were dissolved to act as immobilized homogeneous catalysts.[9]

Herein, we report on the synthesis of water-soluble tripodal phosphanes and their rhodium complexes, and present preliminary results of investigations into the catalytic activity of these complexes in the hydroformylation of 1-hexene. Our goal was to functionalize the cyclohexane backbone of the tripodal phosphane ligand *cis,cis*-1,3,5-$(PPh_2)_3C_6H_9$ (tdppcy)[10] with polyethylene glycol groups, in order to solubilize tdppcy-type ligands and their metal complexes in water.

Results and Discussion

In recent studies, it was demonstrated that the $Mo(CO)_3$ fragment serves as an excellent protecting group when modifying tripodal phosphane ligand systems with a cyclohexane backbone.[11] Thus, the thermally stable tris(hydroxymethyl) complex **1**[11] (Scheme 1) is an ideal starting material for the functionalization of the cyclohexane backbone with polyethylene glycol groups under the rather severe conditions of a base-catalyzed oxirane polyaddition reaction. In the first step, the triol **1** is converted into its corresponding trialcoholate **2** with stoichiometric amounts of NaH in hot THF.

Treatment of a solution of in situ generated **2** with oxirane at 170−185°C leads in a polyaddition reaction to the polymer trisodium alcoholate, which is then converted into the alcohol **3** with anhydrous NH_4Cl. The degree of polymerization can be controlled by adjusting the stoichiometric ratio of oxirane to **1** in the range 90:1 and 500:1. In Table 1, the stoichiometric ratios of oxirane to **1** used in typical polyaddition reactions are listed, together with the properties of the resulting homologous polymers of **3**, the calculated average molecular weights M_p, and degrees of polymerization P.

The parameters M_p and P were calculated independently from the mass balance of the reaction, as well as from the relative integrals of the ethoxy and the phenyl proton sig-

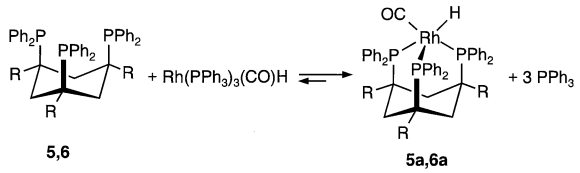
nals in the ^{1}H-NMR spectra.[12] According to Flory, the distribution of the molecular weight of polyethylene glycol ethers follows a Poisson distribution if (i) all the initiating groups are accessible at the beginning of the reaction, (ii) only the reaction of a polymer with a monomer occurs, and (iii) all the reaction steps are kinetically identical.[13] It has been shown that these criteria are met in the case of addition reactions of oxirane to monofunctional alcohols under the conditions of a stoichiometric polyaddition reaction used here.[14] When it is further assumed that the three chains in each molecule grow independently from one another, this leads to a Poisson distribution with an expectation value P for the degree of polymerization of the homologous polymers of **3**. The relation of the degree of polymerization P to the degree of polymerization X of a single chain attached to the cyclohexane backbone is then given by the equation $P = 3\ X$.

The hydroxylic end groups of the homologous polymers of **3** react smoothly with methyl iodide under Williamson ether synthesis conditions to form the corresponding triether complexes **4** (Scheme 1). Polymers **3** and **4** are miscible with water in any ratio when the degree of polymerization is approximately 90 or greater. They are also soluble in polar organic solvents such as THF, CD_2Cl_2, and $CDCl_3$, and swell in diethyl ether. Their properties are comparable with those of polyethylene glycols with similar degrees of polymerization. The local C_{3v} symmetry at the molybdenum centres of **3** and **4** is confirmed by spectroscopic data of the complexes, which are comparable with those of their monomeric counterparts.[11] The IR spectra display two sharp ν(CO) absorptions at 1936 and 1844 cm^{-1} for the $Mo(CO)_3$ fragment besides intense absorptions due to the polyethylene glycol ether chains. The ^{31}P{^{1}H}-NMR spectra show singlets at δ = 46.2 (**3**) and δ = 46.1 (**4**), respectively. In the ^{13}C{^{1}H}-NMR spectra, the ring methylene and the quaternary carbon atoms display complex multiplet patterns as a result of interactions with the phosphorus nuclei. Two multiplets are observed for the axial and equatorial cyclohexane ring protons in the ^{1}H-NMR spectra. Besides the intense absorptions attributable to the ethoxy protons, the hydroxylic end groups of **3** and the methyl end groups of **4** give rise to singlets in the ^{1}H-NMR spectra.

Liberation of the polyethylene glycol functionalized tripodal phosphane ligands **5** can be achieved by irradiating solutions of **4** in the presence of the mild oxidizing agent N_2O (Scheme 2).[11]



R = $CH_2(OCH_2CH_2)_xOCH_3$ (**5**), CH_2OCH_3 (**6**)

The solubility of **4** allows the reaction to be carried out in a mixture of THF and aqueous K_2CO_3, under which conditions the in-situ generated MoO_3 is converted into soluble molybdate, thereby facilitating easy separation. The homologous tripodal phosphane ligands **5** are obtained in high yields as colorless to off-white waxy materials. Their

Table 1. Average molecular weight (M_P), degree of polymerization (P) and properties of **3**[12]

1:C_2H_4O[a]	T[b] [°]	t[c] [h]	M_P[d]	P[d]	M_P[d]	P[e]	consistency	color	melting range [°C]

1:267.6	180	14	12206	256.8	12219	257.1	brittle	yellow, transparent	57–61
1:582.9	175	18	22621	493.5	–[f]	–[f]	brittle	pale-brown, transparent	62–65

[a] Ratio of **1** to oxirane. – [b] Reaction temperature. – [c] Reaction time. – [d] Average molecular weight (M_P), degree of polymerization (P), calculated from the mass balance of the reaction. – [e] Average molecular weight (M_P), degree of polymerization (P), calculated from the relative ^{1}H-NMR integrals of ethoxy and phenyl protons. – [f] Average molecular weight (M_P), degree of polymerization (P) cannot be calculated.

solubilities are comparable to those found for the molybdenum complexes **3** and **4**. The singlets in the $^{31}P\{^1H\}$-NMR spectra of the homologous polymers of **5** are shifted 15.5 ppm further upfield compared to those of the molybdenum complexes. The alkane regions of the $^{13}C\{^1H\}$-NMR spectra display triplets ($\delta = 34.18$, $^2J_{PC} = 18.07$ Hz) and doublets of triplets ($\delta = 42.06$, $^1J_{PC} = 21.57$, $^3J_{PC} = 9.35$ Hz), which result from interaction of the three methylene and the three quaternary carbon atoms with the phosphorus nuclei. In addition, the carbon atoms of the methyl end groups, the ethoxy carbon atoms and the exocyclic methylene carbon atoms attached to the cyclohexane ring are each observed as singlets. In contrast to the spectra of the molybdenum complexes **3** and **4**, the *ipso*, *ortho*, and *meta* carbon atoms of the phenyl rings of **5** are resolved into doublets. The non-equivalent ring methylene hydrogen atoms in the ^{1}H-NMR spectra of **5** give rise to doublets of triplets ($\delta = 1.93$, $^2J_{HH} = 13.61$, $^3J_{PH} = 10.13$ Hz) and broad doublets ($\delta = 2.26$, $^2J_{HH} = 13.61$, $^3J_{PH} < 5.0$ Hz).

When $Rh(PPh_3)_3(CO)H$ is treated with equimolar amounts of the tripodal ligands **5** or **6** at elevated temperatures in DMSO, the solutions become deep-red or orange in color, respectively. ^{31}P-NMR spectroscopic investigations confirm that an equilibrium is set up between the tripod ligands **5**, **6**, the complex $Rh(PPh_3)_3(CO)H$, and free PPh_3, leading to carbonyl hydrido species of the general composition $[Rh(\eta^{n,n+1}\text{tripod})(PPh_3)_{2-n}(CO)H]$, $n = 0-2$. The equilibrium can be shifted in favor of the carbonyl hydrido complexes **5a**, **6a** (Scheme 2) by continuously removing PPh_3 in a liquid-liquid extractor using *n*-hexane as the extracting solvent and DMSO as the reaction medium.[15] However, this reaction procedure has the disadvantage that the high boiling point of DMSO does not allow the complete removal of the solvent from the polyethylene glycol functionalized product **5a**. If, on the other hand, stoichiometric amounts of **5** are treated with $Rh(PPh_3)_3(CO)H$ in a melt at 80°C in vacuo, in the absence of solvent, the PPh_3 is removed by sublimation thereby affording **5a** quantitatively. The red-brown homologous polymers of the carbonyl-hydrido complexes **5a** are obtained as water-soluble waxy solids, while the yellow-orange methoxymethyl functionalized complex **6a** is soluble in polar organic solvents.

Apart from the IR spectroscopic data, which are very sensitive to changes in the functional groups at the *ipso*-position of the cyclohexane ring[16], the spectroscopic data of compound **6a** correspond to those of the polyethylene glycol functionalized complex **5a**. Two absorptions [1973, 1902 cm^{-1} (**5a**) and 1950, 1911 cm^{-1} (**6a**)] are observed in the IR spectra of the carbonyl hydrido complexes **5a**, **6a**, which are characteristic of metal hydride and carbonyl groups, respectively. Doublets in the $^{31}P\{^1H\}$-NMR spectra [$\delta = 40.3$, $^1J_{RhP} = 118.4$ Hz (**5a**), $\delta = 43.3$ $^1J_{RhP} = 117.3$ Hz (**6a**)] and doublets of quartets at $\delta = -8.97$ ($^2J_{PH} = 34.7$, $^1J_{RhH} = 12.9$ Hz) and $\delta = -8.28$ ($^2J_{PH} = 34.5$, $^1J_{RhH} = 12.9$ Hz) in the ^{1}H-NMR spectra of **5a** and **6a**, respectively, are what one would expect for dynamic pentacoordinate rhodium complexes (Scheme 2). Thus, only one set of resonances for the ring methylene and quaternary carbon atoms is observed in the $^{13}C\{^1H\}$-NMR spectra of both complexes. In addition, characteristic signals in the expected regions are found for the polyethylene glycol functions and the methoxymethyl groups.

Preliminary studies aimed at demonstrating the catalytic activity of complex **5a** have been conducted. The results are summarized in Table 2. The hydroformylation of 1-hexene catalyzed by **5a** ($P = 209.1$) was performed either in a single homogeneous phase with methanol as solvent, or in a biphasic system (water/1-hexene).

Table 2. Hydroformylation of 1-hexene with complex **5a** ($P = 91$) as catalyst[a]

product	single phase[b] amount [%]	biphase[c] amount [%]
n-hexane	–	–
1-hexene	4.3	3.5
2- and 3-hexene	26.5	20.5
2-methylhexanal	21.8	29.2
n-heptanal	47.3	46.4
2-methylhexanol	0.1	0.1
n-heptanol	–	0.3

[a] Conditions: 119°C, 2 h, 15 bar of CO, 15 bar of H_2, 1:5000 catalyst to substrate ratio. – [b] 1-Hexene/methanol, 10:3 (v/v). – [c] 1-Hexene/water, 10:3 (v/v).

The pressure of the synthesis gas (15 bar of CO, 15 bar of H_2) and the temperature (119°C) were kept constant during the whole reaction period. The organic products were separated from the catalyst by distillation (single phase) or by decantation of the clear, colorless organic phase from the clear, red-brown aqueous phase (biphase). The hydrocarbon- and aqueous phases were analyzed by $^{31}P\{^1H\}$-NMR spectroscopy. No detectable amounts of **5a** were found in the organic phase, whereas the aqueous phase contained **5a** and decomposition products. Both systems showed high activity, since only minor amounts of 1-hexene remained after a reaction time of 2 h. Catalyst **5a** displayed higher selectivities towards hydroformylation than hydrogenation. In neither medium was any hexane detected, and traces of heptanol were only observed in the biphasic system. The degree of conversion to *n*-heptanal was comparable in both systems, while the extent of hydroformylation of the isomerized hexenes was greater in the biphasic medium.

This work was supported by the *Fonds der Chemischen Industrie*, Frankfurt/Main, Germany, and the *University of Tübingen*. We thank *BASF AG* and *DEGUSSA AG* for loans of $Mo(CO)_6$ and $RhCl_3 \cdot 3\ H_2O$, respectively.

Experimental Section

General: All reactions were carried out under an atmosphere of dry argon using standard Schlenk techniques. Solvents were dried under argon; THF was distilled from Na/Ph_2CO; dichloromethane was distilled from CaH_2; methanol was distilled from Mg; water was degassed by the freeze-pump-thaw technique. Oxirane and N_2O were commercial and medical grade, respectively, and were used without further purification. The molybdenum complex **1**[11], the ligand **6**[11] and $Rh(PPh_3)_3(CO)H$[17] were prepared as described

in the literature. – ^{1}H-, ^{13}C{^{1}H}-, and ^{31}P{^{1}H}-NMR spectra were recorded on a Bruker DRX250 spectrometer operating at 250.13, 62.90, and 101.26 MHz, respectively. ^{1}H chemical shifts were referenced to the residual proton peaks of the solvents and are quoted in ppm downfield from TMS. ^{13}C chemical shifts were calibrated against the deuterated solvent multiplet are referenced to TMS. ^{31}P chemical shifts were measured relative to external 85% H_3PO_4 with downfield values taken as positive. In addition to a ^{13}C{^{1}H}-NMR spectrum, a ^{13}C-DEPT experiment was routinely performed for each compound. Infrared spectra were recorded on a Bruker ISF 48.

Tricarbonyl[cis,cis-1,3,5-tris(diphenylphosphanyl)-1,3,5-tris(hydroxypolyethoxymethyl)cyclohexane]molybdenum (**3**): A steel autoclave fitted with a Teflon inlet was charged with a suspension of 907 mg (1.0 mmol) of **1** and 72 mg (3.0 mmol) of NaH in 120 ml of THF. The suspension was heated to 100°C for 2 h, and then cooled to −20°C, whereupon the desired amount of oxirane was condensed into the autoclave. The reaction mixture was heated at 170°C for 18 h, and was then allowed to cool to room temp. The pale-yellow solution was transferred to a Schlenk tube and the autoclave was rinsed with two 25-ml portions of THF. The combined organic phases were reduced to a volume of 100 ml under reduced pressure so as to remove remaining traces of oxirane. Then, 177 mg (3.3 mmol) of anhydrous NH_4Cl was added. The resulting mixture was heated at 80°C for 2 h, the solvent was removed under reduced pressure at 50−60°C, and the remaining pale-yellow, viscous oil was dissolved in 100 ml of dichloromethane. The salts (NaCl and residual NH_4Cl) were filtered off by passage through a short column of SiO_2 (1 cm) and washed once with 25 ml of dichloromethane. The dichloromethane was removed from the combined solutions under reduced pressure and the pale-yellow residue was dried in vacuo (12 h at 60°C). Yield quantitative. – IR (KBr): $\tilde{\nu}$ = 3487 cm^{-1} ν(OH), 2883 ν(CH_2), 1936, 1844 ν(CO), 1113 ν(OCH_2). – ^{31}P{^{1}H} NMR (CD_3OD): δ = 46.2 (s). – ^{1}H NMR (CD_3OD): δ = 1.77−1.95 (m, 3 H, CHH_e), 2.48−2.81 (m, 3 H, CHH_a), 3.44−3.70 [m, 6 + 4×(*P* − 1) + 12 H, CH_2O(CH_2CH_2O)$_{P-1}$CH_2CH_2OH], 4.56 [br. s, 3 H, $CH_2O(CH_2CH_2O)_{P-1}CH_2CH_2O$*H*], 6.91−7.30 (m, 30 H, C_6H_5). – ^{13}C{^{1}H} NMR (CD_3OD): δ = 30.18−30.82 (m, CH_2), 39.85−40.00 (m, CP), 62.77 [s, $CH_2O(CH_2CH_2O)_{P-1}CH_2$*C*H$_2$OH], 71.29 [s, CH_2O(*C*H$_2$*C*H$_2$O)$_{P-1}$*C*H$_2$CH$_2$OH], 73.45 [s, *C*H$_2$O(CH$_2$CH$_2$O)$_{P-1}$CH$_2$CH$_2$OH], 128.41 (br. s, *meta*-C_6H_5), 129.79 (s, *para*-C_6H_5), 136.85 (br. s, *ortho*-C_6H_5), 138.00−138.51 (m, *ipso*-C_6H_5), 220.66−221.67 (m, CO).

Tricarbonyl[cis,cis-1,3,5-tris(diphenylphosphanyl)-1,3,5-tris(methoxypolyethoxymethyl)cyclohexane]molybdenum (**4**): A mixture of 1.0 mmol of a homologous polymer of **3** and 216 mg (9.0 mmol) of NaH in 150 ml of THF was heated in a sealed Schlenk tube at 80°C for 2 h. After cooling to room temp., 1.1 ml (18.0 mmol) of iodine-free methyl iodide was added dropwise via a syringe. The mixture was heated at 60°C for 16 h under exclusion of light, and was then reduced to a volume of 100 ml under reduced pressure. Subsequently, 481 mg (9.0 mmol) of anhydrous NH_4Cl was added. The resulting mixture was heated at 80°C for 2 h, the solvent was removed under reduced pressure at 50−60°C, and the remaining pale-yellow, viscous oil was dissolved in 100 ml of dichloromethane. The salts (NaCl and residual NH_4Cl) were filtered off by passage through a short column of SiO_2 (1 cm) and washed once with 25 ml of dichloromethane. The dichloromethane was removed from the combined solutions under reduced pressure and the pale-yellow residue was dried in vacuo (16 h at 60°C). Yield 98−100%. – IR (KBr): $\tilde{\nu}$ = 2883 cm^{-1} ν(CH_2), 1936, 1844 ν(CO), 1113 ν(OCH_2). – ^{31}P{^{1}H} NMR (CD_2Cl_2): δ = 46.1 (s). – ^{1}H NMR (CD_2Cl_2): δ = 1.77−1.93 (m, 3 H, CHH_e), 2.48−2.81 (m, 3 H, CHH_a), 3.31 [s, 9 H, $CH_2O(CH_2CH_2O)_{P-1}CH_2CH_2OCH_3$], 3.40−3.66 [m, 6 + 4×(*P* − 1) + 12 H, CH_2O(CH_2CH_2O)$_{P-1}$CH_2-CH_2OCH$_3$], 7.04−7.31 (m, 30 H, C_6H_5). – ^{13}C{^{1}H} NMR (CD_2Cl_2): δ = 29.15−29.73 (m, CH_2), 38.85−39.00 (m, CP), 58.77 [s, $CH_2O(CH_2CH_2O)_{P-1}CH_2CH_2OCH_3$], 69.86 [s, CH_2O(*C*H$_2$-*C*H$_2$O)$_{P-1}$*C*H$_2$*C*H$_2OCH_3$], 71.53 [s, *C*H$_2$O(CH$_2CH_2$O)$_{P-1}CH_2$-CH$_2OCH_3$], 127.34 (br. s, *meta*-C_6H_5), 128.84 (s, *para*-C_6H_5), 135.83 (br. m, *ortho*-C_6H_5), 136.84−137.33 (m, *ipso*-C_6H_5).

cis,cis-1,3,5-Tris(diphenylphosphanyl)-1,3,5-tris(methoxypolyethoxymethyl)cyclohexane (**5**): A solution of 0.5 mmol of **4** in 150 ml of THF and 5 ml of an aqueous solution of K_2CO_3 (2.0 M) were placed in a double-walled Duran Schlenk tube and the mixture was degassed by using the freeze-pump-thaw technique. The vigorously stirred solution was cooled to 15°C (cooling solvent: water) and dinitrogen monoxide (N_2O) was added (1.0−1.3 bar). Then, the reaction mixture was irradiated for 1.5 h with light from a TQ 150 W (Original Hanau) high-pressure mercury lamp, which was positioned 5 cm from the Schlenk tube. After 1.5 h, the progress of the reaction was monitored by ^{31}P{^{1}H}-NMR spectroscopy. If small amounts of the starting material were still present, irradiation was continued. After complete conversion, the brown solution was concentrated to a volume of 10 ml under reduced pressure. The brown, viscous residue was dissolved in 100 ml of dichloromethane, the aqueous layer was removed, and the organic layer was dried over 5 g of CaO (2 h). The CaO was then filtered off and washed with two 25-ml portions of dichloromethane. The solvent was removed under reduced pressure and the colorless to off-white, viscous oil was dried in vacuo (12 h at 60°C). Yield 88−92%. – ^{31}P{^{1}H} NMR (CD_3OD): δ = 30.8 (s). – ^{1}H NMR (CD_3OD): δ = 1.93 (dt, $^2J_{HH}$ = 13.61, $^3J_{PH}$ = 10.13 Hz, 3 H, CHH_a), 2.26 (br. d, $^2J_{HH}$ = 13.61, $^3J_{PH}$ < 5.0 Hz, CHH_e), 3.35−3.80 [m, 6 + 4×(*P* − 1) + 12 H, CH_2O(CH_2CH_2O)$_{P-1}$CH_2CH_2OCH$_3$], 3.41 [s, 9 H, $CH_2O(CH_2CH_2O)_{P-1}CH_2CH_2OCH_3$], 7.37−7.54 (m, 30 H, C_6H_5). – ^{13}C{^{1}H} NMR (CD_3OD): δ = 34.18 (t, $^2J_{PC}$ = 18.07 Hz, CH_2), 42.06 (dt, $^1J_{PC}$ = 21.57, $^3J_{PC}$ = 9.35 Hz, CP), 59.08 [s, $CH_2O(CH_2$-$CH_2O)_{P-1}CH_2CH_2OCH_3$], 71.21 [s, CH_2O(*C*H$_2$*C*H$_2$O)$_{P-1}$*C*H$_2$-*C*H$_2OCH_3$], 72.77 [br. s, *C*H$_2$O(CH$_2CH_2$O)$_{P-1}CH_2CH_2OCH_3$], 129.17 (d, $^3J_{PC}$ = 6.73 Hz, *meta*-C_6H_5), 129.90 (br. s, *para*-C_6H_5), 135.68 (d, $^1J_{PC}$ = 21.57 Hz, *ipso*-C_6H_5), 135.76 (d, $^2J_{PC}$ = 21.57 Hz, *ortho*-C_6H_5).

Carbonylhydrido[cis,cis-1,3,5-tris(diphenylphosphanyl)-1,3,5-tris(methoxypolyethoxymethyl)cyclohexane]rhodium(I) (**5a**): A stirred mixture of a homologous polymer of **5** (0.5 mmol) and 459 mg (0.5 mmol) of $Rh(PPh_3)_3(CO)H$ was heated at 90°C for 24 h under reduced pressure (0.1−0.5 mbar). The PPh_3 sublimed during the course of the reaction. The viscous, deep-red to brown, clear reaction mixture was then allowed to cool to room temp. to furnish a quantitative yield of **5a**. – IR (KBr): $\tilde{\nu}$ = 1973 cm^{-1} ν(RhH), 1902 ν(CO). – ^{31}P{^{1}H }NMR ([D$_8$]THF): δ = 40.3 (d, $^2J_{RhP}$ = 118.4 Hz). – ^{1}H NMR ([D$_8$]THF): δ = −8.97 (dq, $^2J_{PH}$ = 34.69 Hz, $^1J_{RhH}$ = 12.87, 1 H, RhH), 1.82−1.96 (m, 3 H, CHH_e), 2.29−3.18 (m, 3 H, CHH_a), 3.29 [s, 9 H, $CH_2O(CH_2CH_2O)_{P-1}$-$CH_2CH_2OCH_3$], 3.35−3.73 [m, 6 + 4×(*P* − 1) + 12 H, CH_2O-(CH_2CH_2O)$_{P-1}$CH_2CH_2OCH$_3$], 6.96−7.47 (m, 30 H, C_6H_5). – ^{13}C{^{1}H} NMR ([D$_8$]THF): δ = 31.54−31.84 (m, CH_2), 40.68 (d, $^2J_{PC}$ = 13.51 Hz, CP), 58.92 [s, $CH_2O(CH_2CH_2O)_{P-1}CH_2CH_2$-$OCH_3$], 71.17 [s, CH_2O(*C*H$_2$*C*H$_2$O)$_{P-1}$*C*H$_2$*C*H$_2OCH_3$], 72.73 [s, *C*H$_2$O(CH$_2CH_2$O)$_{P-1}CH_2CH_2OCH_3$], 127.59−127.72 (m, *meta*-C_6H_5), 129.81 (br. s, *para*-C_6H_5), 136.12−136.36 (m, *ortho*-C_6H_5), 134.38−140.92 (m, *ipso*-C_6H_5).

Carbonylhydrido[cis,cis-1,3,5-tris(diphenylphosphanyl)-1,3,5-tris(methoxymethyl)cyclohexane]rhodium(I) (**6a**): 385 mg (0.5 mmol)

of **6** and 459 mg (0.5 mmol) of $Rh(PPh_3)_3(CO)H$ were dissolved in 100 ml of DMSO at 100°C. After the reaction mixture had cooled to 60°C, it was extracted with *n*-hexane for 4 h in a liquid-liquid extractor. The reaction mixture was maintained at 60°C throughout the course of the extraction. DMSO was removed from the orange reaction mixture under reduced pressure at 60°C. The remaining orange solid was suspended in 100 ml diethyl ether, the orange solid was filtered off (P3), washed with five 25-ml portions of diethyl ether, and dried in vacuo. Yield 401 mg (89%), m.p. 221°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1950 cm^{-1} ν(RhH), 1911 ν(CO). – $^{31}P\{^1H\}$ NMR ([D$_5$]pyridine): δ = 43.3 (d, $^2J_{RhP}$ = 117.3 Hz). – ^1H NMR ([D$_5$]pyridine): δ = −8.28 (dq, $^2J_{PH}$ = 34.53 Hz, $^1J_{RhH}$ = 12.85, 1 H, RhH), 2.07−2.22 (m, 3 H, CH_eH), 2.47−3.28 (m, 3 H, CH_aH), 3.17 (s, 9 H, CH_2OCH_3), 3.86 (br. s, 6 H, CH_2OCH_3), 7.02−7.76 (m, 30 H, C_6H_5). – $^{13}C\{^1H\}$ NMR ([D$_5$]pyridine): δ = 31.08−31.39 (m, CH_2), 40.08−40.29 (m, CP), 58.44 (s, CH_2OCH_3), 77.32−77.48 (m, CH_2OCH_3), 127.63−127.71 (m, *meta*-C_6H_5), 128.44 (br. s, *para*-C_6H_5), 135.81−135.97 (m, *ortho*-C_6H_5), 139.92−140.43 (m, *ipso*-C_6H_5). – MS (FAB), *m/z*: 899.1 [M^+ − H], 871.2 [M^+ − H − CO]. – $C_{49}H_{52}RhO_4P_3$ (900.77): calcd. C 65.34, H 5.82; found C 65.13, H 5.58.

Hydroformylation: The hydroformylation of 1-hexene with **5a** as catalyst was performed in a 100-ml steel autoclave. During the reaction, the temperature and pressure were monitored electronically and were kept constant. The catalyst and the substrate were transferred into the autoclave under an argon atmosphere. After heating the autoclave to the reaction temperature, the gases CO and H_2 were introduced. After separation, the products were analyzed by gas chromatography and the catalyst residues by $^{31}P\{^1H\}$-NMR spectroscopy.

1-Hexene/Methanol (Single Phase): A mixture of 152.8 mg (0.015 mmol, P = 209.1) of **5a**, 9.4 ml (75 mmol) of 1-hexene, and 2.8 ml of methanol was pressurized with 15 bar of CO and 15 bar of H_2 at 119°C. After 2 h, the autoclave was allowed to cool to room temperature. The organic products were separated by vacuum distillation and analyzed by gas chromatography.

1-Hexene/Water (Biphase): A mixture of 152.8 mg (0.015 mmol, P = 209.1) of **5a**, 2.8 ml of water, and 9.4 ml (75 mmol) of 1-hexene was pressurized with 15 bar of CO and 15 bar of H_2 at 119°C. After 2 h, the autoclave was allowed to cool to room temperature. The clear, colorless organic solution was separated by decantation and distilled prior to gas chromatographic analysis.

Keywords: Asymmetric catalysis / Allylic alkylation / 1,5-Dimethylbarbituric acid / Palladium catalysts / Chiral phosphane imine ligands

Allylation of 1,5-dimethylbarbituric acid (**BS**) with allyl acetate using in situ catalysts of palladium(II) acetylacetonate and chiral phosphane imine ligands results in the enantioselective formation of 5-allyl-1,5-dimethylbarbituric acid (**ABS**) as the main product with up to 34% *ee* and 3,5-diallyl-1,5-dimethylbarbituric acid (**AABS**) as a possible by-product, also with up to 34% *ee*. This reaction is a type of allylic alkylation, the stereoselectivity of which is difficult to control because the new stereocenter is formed in the nucleophile attacking from the side opposite to the metal atom. Classical optically active ligands do not give any enantioselectivity in this palladium-catalysed reaction. Chiral phosphane imine ligands, however, are a successful class of compound, synthesized by Schiff base condensation of 2-formylphenyl(diphenyl)phosphane with optically active primary amines. An optimisation of this ligand type showed that the substituents at the stereogenic center in the imine part should be a hydroxymethyl group and a bulky alkyl group, with the best ligand being the L-*tert*-leucinol derivative. A screening of other types of chiral ligand, e.g. phosphane amines and phosphane trisimines, has also been performed. NMR experiments and a molecular modelling study of the cation $[(\eta^3\text{-allyl})\text{Pd}(\mathbf{2a})_2]^+$ were carried out (tripos force field). The enantioselectivity of the phosphane imine ligands is explained by an interaction of the chiral side arm of one of the ligands, which extends to about 3 Å above the allyl plane, with the incoming nucleophile.

Introduction

The enantioselective palladium-catalysed allylic alkylation is one of the most studied subjects in stereoselective synthesis[2][3][4][5]. Usually the new stereogenic center is formed at one of the carbon atoms of the allylic system. The enantioselectivity of this type of allylic alkylation can be controlled by optically active phosphane ligands bound to the Pd catalyst, which forms an intermediate η^3-allyl complex in the catalytic cycle. High optical inductions have been obtained for systems, in which the new asymmetric center is generated in the allylic moiety[2][3][4][5][6][7][8][9][10][11][12][13][14][15]. However, there is an unsolved problem in the palladium-catalysed allylic alkylation involving the creation of an asymmetric center in the nucleophile, usually a carbanion, which attacks the η^3-allyl system in the C−C bond forming step. Control of the enantioselectivity of this type of allylic alkylation is difficult because the nucleophile approaches the (η^3-allyl)Pd complex from the side opposite to the metal atom (and its optically active ligand). By using special nucleophiles, such as the benzophenoneimine of methyl glycinate[18][19] or 2-acetylcyclohexanone[3], enantioselectivities of 62 and 81% *ee*, respectively, were obtained in the alkylation of allyl acetate.

The enantiomers of chiral barbituric acids show different effects inside the organism[20][21][22][23][24]. These optically active barbituric acids are synthesized by the resolution of racemates[20][25][26] or by regioselective condensation of *N*-methylurea with optically active cyanoacetates[21][22][24]. Although interest in barbituric acids acting as sedative/hypnotic and antiepileptic agents is decreasing, this is not true for barbituric acids which function as short time anesthetics. An important example is Methohexital (Brevimytal®)[20][27][28][29][30][31][32][33][34], an allylated barbituric acid, the synthesis of which in principle could be attempted by stereoselective palladium-catalysed allylic alkylation. An achiral allylation of the unsubstituted barbituric acid has been reported[35].

As a model system for the synthesis of Methohexital by allylic alkylation, we chose the reaction of 1,5-dimethylbarbituric acid with allyl acetate as the allylic component, which we introduced in 1994 together with the pertinent enantiomer analysis[36]. In these previous studies we showed that classical ligands, such as (−)-Diop, (−)-Prophos and (−)-Norphos, only gave the allylated product 5-allyl-1,5-di-

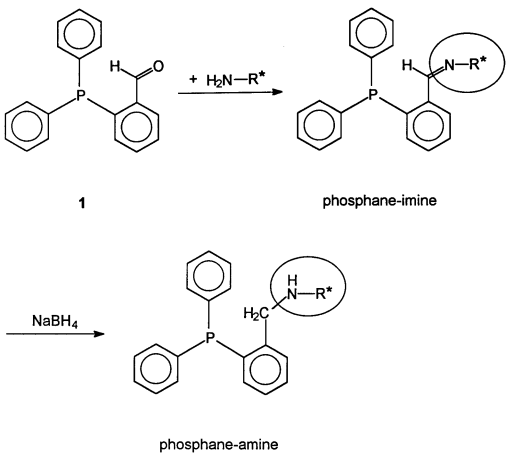
methylbarbituric acid in racemic form[36], whereas with the phosphane imine ligands **2a**, **2b**, and **11**, an enantiomeric excess of 10 to 13% was obtained[36].

In this paper we describe our investigations into the enantioselective palladium-catalysed allylation of 1,5-dimethylbarbituric acid with allyl acetate in which we varied the base, solvent, temperature, concentration, Pd/ligand ratio and ligand type[37]. In all, 134 different chiral ligands have been tested[37][38]. We present an explanation for the enantioselectivity of the phosphane imine ligands in the (η^3-allyl)Pd complex[37]. The preparation of new optically active phosphane imine, phosphane amine, and phosphane trisimine ligands is reported[37].

Synthesis of New Optically Active PN Ligands

In the previous studies the phosphane imine ligands **2a**, **2b,** and **11** had given the best results in the Pd-catalysed allylation of 1,5-dimethylbarbituric acid with allyl acetate[36]**.** The synthesis of the new PN ligands described here was carried out bearing in mind information gained from the enantioselectivities obtained in the catalytic model reaction between 1,5-dimethylbarbituric acid/allyl acetate. Schiff base condensation (Scheme 1) of 2-formylphenyl(diphenyl)phosphane **1**[39][40][41] with the optically active primary amines (*R*)-(−)-2-amino-1-butanol, (*S*)-(+)-2-amino-1-butanol, L-alaninol, L-valinol, L-leucinol, (2*S*,3*S*)-(+)-2-amino-3-methyl-1-pentanol (L-isoleucinol), (*S*)-(+)-2-amino-3,3-dimethyl-1-butanol (L-*tert*-leucinol), D-α-phenylglycinol, L-phenylalaninol, L-norephedrine, (1*S*,2*S*)-(+)-2-amino-1-phenyl-1,3-propanediol, L-*tert*-butyl *tert*-leucinate and (+)-dehydroabietylamine in refluxing methanol and dichloromethane, respectively, gave the corresponding phosphane imines **2**−**13** (Scheme 2). Recrystallisation of the dry residues from petroleum ether (boiling range 40−60°C) provided colourless or white-yellow crystals and powders, except in the case of **6**, which is a colourless oil.

Scheme 1. Synthesis of phosphane imines and phosphane amines



Reduction of the phosphane imines **2a** and **2b** with sodium borohydride at −10°C in methanol (Scheme 1) gave the phosphane amines **14a** and **14b** (Scheme 2).

The phosphane trisimines **15a** and **15b** (Scheme 2) were prepared by Schiff base condensation of tris(2-formylphenyl)phosphane[40][41][42] with an excess of (*R*)-(−)-2-amino-1-butanol and (*S*)-(+)-2-amino-1-butanol, respectively, in refluxing dichloromethane. **15a** and **15b** were isolated as yellow crystalline solids after recrystallisation from petroleum ether (boiling range 40−60°C). The crystals were suitable for X-ray analysis. Figure 1 shows the molecular struc-

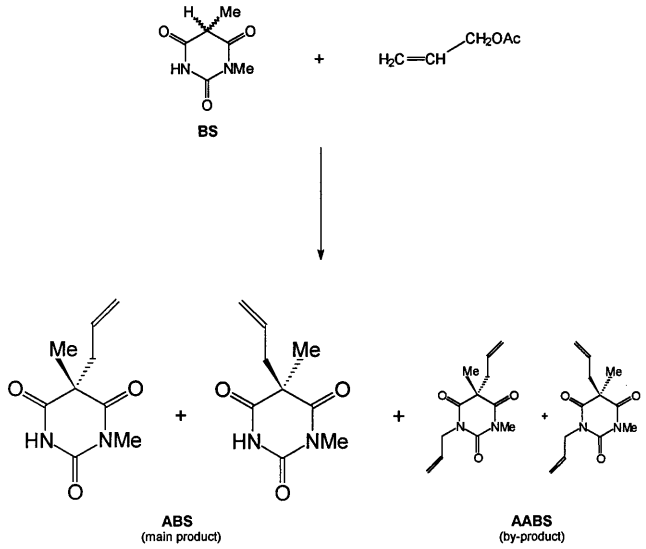
Standard Reaction: The Allylation of 1,5-Dimethylbarbituric Acid

In the catalytic model reaction, 1,5-dimethylbarbituric acid (**BS**) is allylated with allyl acetate to give 5-allyl-1,5-dimethylbarbituric acid (**ABS**) as the main product and 3,5-diallyl-1,5-dimethylbarbituric acid (**AABS**) as a possible by-product (Scheme 3).

Scheme 3. Enantioselective palladium-catalysed allylation of 1,5-dimethylbarbituric acid (**BS**) with allyl acetate



In dichloromethane **BS** is deprotonated with a small excess of a base, such as DBU or NEt_3. To the clear solutionwas added 1 mol% of palladium(II) acetylacetonate, $[Pd(acac)_2]$, 4 mol% of a monodentate optically active phosphane imine ligand and a mixture of dichloromethane and toluene. The addition of allyl acetate starts the reaction. Typically, the clear solution is stirred at 38°C for 24, 48 or 72 hours. A qualitative TLC test (silica 60, Merck; dichloromethane/acetonitrile 25:1) shows how much **ABS**, **AABS** and allyl acetate are present at a specific point of conversion (yellow spots after dipping into a dilute $KMnO_4$ solution). The reaction is stopped with 0.2 M hydrochloric acid. In ordert to remove the excess base, base/acetic acid adduct, and the unreacted **BS**, the organic layer is treated with 0.2 M hydrochloric acid and washed three times with water. Evaporation to dryness removes the excess allyl acetate. Due to the slight water-solubility of **ABS**, about 3% of the yield of **ABS** is lost in the work-up procedure described. This loss, however, cannot be avoided because repeated extraction of the organic layer with hydrochloric acid and water is necessary to remove **BS** quantitatively, as this compound would be detected as a broad peak below the (−)-**ABS** peak in the GC analysis with a Chirasil-Val-L column.

The enantiomeric excess of monoallylated barbituric acid **ABS** and diallylated barbituric acid **AABS** was determined by GC on a Chirasil-Val-L column and on a Lipodex E column, respectively. The first peak detected on the Chirasil-Val-L column was assigned to (−)-**ABS** (configuration unknown) by correlation with an enantiomerically enriched sample (see below). For **AABS**, the symbols (1.) and (2.),

respectively, indicate whether the first or the second detected peak of the two **AABS** enantiomers on the Lipodex E column was in excess. Chemical yields of **ABS** and **AABS** were determined on the same Chirasil-Val-L column using the internal standard benzil. In some cases, e.g. if the chemical yield was below 3%, the by-product 5-chloromethyl-1,5-dimethylbarbituric acid was detected. This compound results from the reaction of the carbanion of **BS** with the solvent dichloromethane[37].

Samples of optically active **ABS** dissolved in dichloromethane did not change their enantiomeric excess after half a year. In a racemisation test under standard catalytic conditions at 25°C, (+)-**ABS** (12.4% *ee*) was dissolved in dichloromethane and then [Pd(acac)$_2$] and PPh_3 were added. After 72 h a sample was examined by GC [12.2% *ee* (+)]. The base DBU was then added. After 48 h, work-up using the usual procedure gave 11.8% *ee* (+) (GC reproducibility about ±0.5% *ee*). Thus, **ABS** is configurationally stable during catalysis.

An enantiomerically enriched sample of (−)-**ABS** was obtained by recrystallisation from water/ethanol (175:1). After this recrystallisation the *ee* in crystals had diminished, whereas it increased in the mother liquor. A crystal of 17.4% *ee* (−)-**ABS** had the optical rotations $[\alpha]_D^{25} = -0.36$ and $[\alpha]_{436}^{25} = -2.4$ (c = 5, CH_2Cl_2). An extrapolation to optical purity gives $[\alpha]_D^{25} = \pm 2.1$ and $[\alpha]_{436}^{25} = \pm 13.8$ for the enantiomers of **ABS**.

The Diallylated 1,5-Dimethylbarbituric Acid AABS

The formation of **AABS** depends on the reaction conditions. When the catalysis is carried out with a 3-fold excess of the base DBU and a 21-fold excess of allyl acetate, **AABS** is produced in 98% yield in refluxing THF after 24 h. After 6 h a yield of 34% **ABS** and 32% **AABS** is obtained in this experiment. The formation of **AABS** depends on the ligand used in the catalyst, although a correlation between the ligand structure and the amount of **AABS** cannot be found. Under standard conditions (25°C or 38°C) the 134 ligands tested give the by-product **AABS** in yields ranging from 0 to 19%[37][38]. Ligands which form 7- to 9-membered chelate rings containing a dioxolane structural element[37][38] (e.g. Diop) give, in all cases, **AABS**, due to the high catalytic activity of their complexes. For example, with the ligand (1*S*,2*S*)-1,2-bis[2′-(diphenylphosphanyl)phenyl]-1,2-dimethoxyethane[43], the reaction was almost complete after 1 h, yielding 78% **ABS** and 8% **AABS**. However, in the case of the the phosphane imine ligand **2a**, formation of **ABS** and **AABS** had not even begun after 1 h[37]. Interestingly, a mixture of the starting material **BS** and the diallylated product **AABS**, in the absence of allyl acetate, under catalytic conditions gave the monoallylated product **ABS**, i.e. the formation of the diallylated product **AABS** is reversible[37].

Catalyses with the Ligand PPh_3

When the catalysis was attempted with [Pd(acac)$_2$] without a ligand, there was no turnover. Addition of triphenylphosphane in dichloromethane at 25°C (base DBU) gave 64% **ABS** and traces of **AABS** (Table 1, entry 1). Thus, the palladium-catalysed allylation of **BS** is an ideal example of a ligand accelerated catalysis[44]. Under the same conditions, but at −17°C, a yield of only 4% **ABS** was obtained after 72 h[37]. The use of [(η^3-allyl)PdCl]$_2$ in place of [Pd(acac)$_2$] afforded 60% **ABS** along with 11% **AABS**, the doubly allylated product (entry 2). Nickel dichlorophosphane complexes (1 mol% of catalyst) gave yields below 2% for **ABS**. With 10 mol%, yields of up to 29% for **ABS** were obtained[38]. Therefore, only Pd-catalysed reactions with 1 mol% of [Pd(acac)$_2$] were investigated further.

Variation of the base, i.e. replacement of DBU by triethylamine, at 38°C in dichloromethane yielded 98% **ABS**, and these conditions are close to those chosen as the standard conditions described later (entry 3). The use of BSA [*N*,*O*-bis(trimethylsilyl)acetamide] as the base in equimolar quantities with respect to **BS**, in dichloromethane at 25°C, gave 63% of **ABS** (entry 4), and this is comparable with the results obtained using DBU (entry 1). When a 1.5 M LDA·THF solution in cyclohexane was added to **BS** dissolved at −72°C in THF (colourless precipitate), low yields of **ABS** and **AABS** were obtained[37]. Stirring a mixture of **BS**, NBu_4OH, the catalyst, and allyl acetate in a two-phase system for 72 h at 25°C gave 59% **ABS** and 6% **AABS** (entry 5). Presynthesis of the tetrabutylammonium salt of **BS** (**NBu_4**BS) makes the addition of a base unnecessary[37]. Thus, **NBu_4**BS in a dichloromethane/toluene mixture (5:1) at 25°C (homogeneous solution) afforded a yield of 44% **ABS** and 1% **AABS** after 24 h (entry 6).

The optically active bases (−)-quinine, (+)-quinidine, (−)-cinchonidine and (+)-cinchonine, in combination with the achiral ligand triphenylphosphane, induced an enantiomeric excess of up to 6% *ee* in **ABS,** with the yields varying from 71 to 90% (entry 7)[37]. 2-Formylphenyldiphenylphosphane (**1**) is the parent compound of the imines **2**−**13**. As this compound could be formed on hydrolysis of these imines, it was tested as a ligand in the catalytic allylation. Indeed, **1** in combination with (−)-quinine as a base induced 6% *ee* (+) for **ABS** (81% yield) and 4% **AABS** (entry 8).

Catalyses with the Phosphane-Imine Ligands 2a and 2b

With a 1:2 ratio of [Pd(acac)$_2$]/**2a** in 10 ml of dichloromethane at 25°C, a yield of 14% and an enantiomeric excess of 8% of (+)-**ABS** was obtained (Table 2, entry 1). Increasing the Pd/ligand ratio to 1:4 and the amount of dichloromethane to 15 ml increased the enantiomeric excess to 10% *ee* and 13% *ee* for (+)-**ABS**, respectively (entries 2, 3). At a reaction temperature of 38°C the yield improved significantly to 63% **ABS** and 9% **AABS** without loss of enantioselectivity (entry 4). With 15 ml of a mixture of dichloromethane/toluene (2:1) as the solvent, the enantiomeric excess rose to 20% *ee* for (+)-**ABS** and 20% *ee* (2.) for **AABS** (entry 5), with the yield being 66% **ABS** and 12% **AABS** (typical standard conditions). The use of triethylamine and (−)-quinine as bases did not improve the enantiomeric excess[37]. Little or no enantioselectivity with ligand **2a** was observed in solvents such as acetonitrile, methanol, tetra-

8	**1**	(−)-quinine	10 CH_2Cl_2 + 5 toluene	38	24	81	6 (+)	4

[a] 1 Mol% [$Pd(acac)_2$] was used as procatalyst. − [b] Pd:ligand ratio = 1:4. − [c] Yields were determined by GC on a Chirasil-Val-L column, yields < 0.5% are given as 0%. − [d] The *ee* of **ABS** was measured by GC on a Chirasil-Val-L column. − [e] 0.5 Mol% [(η^3-allyl)PdCl]$_2$ was used as procatalyst. − [f] **BS**:BSA ratio = 1:1 + ≈ 1 mg KOAc.

hydrofuran, chloroform and hexamethylphosphoric triamide (base DBU)[37]. Thus, the best solvent for the allylation of **BS** is a dichloromethane/toluene mixture. As **BS** is only sparingly soluble in toluene, the toluene content is limited in order to keep the reaction mixture homogeneous.

The ligand **2b**, the enantiomer of **2a**, verified with 19% *ee* for (−)-**ABS** and 20% *ee* (1.) for **AABS** the reproducibility of the catalysis and the product analysis under the standard reaction conditions (entry 6). Double stereoselection came into play for the optically active base (−)-quinine in combination with the enantiomeric phosphane imines **2a** and **2b**. Thus, **2a** provided 16% *ee* (+)-**ABS** (78% yield) and **2b** 12% *ee* (−)-**ABS** (entries 7, 8). With (+)-quinidine in combination with **2a**, 3% *ee* was obtained for (+)-**ABS** under the standard conditions[37]. The bases (−)-cinchonidine and (+)-cinchonine, together with ligand **2a**, induced 9% *ee* and 10% *ee* (+)-**ABS** and yields of 87 and 82%, respectively, in a reaction which started as a suspension in a 6:1 mixture of dichloromethane and toluene and which became clear after 41 h under standard conditions. The bases BSA and LDA·THF with ligand **2a** afforded low **ABS** yields[37]. With **NBu_4**BS and the ligands **2a** and **2b**, 12% *ee* (+)- and (−)-**ABS** was obtained, but with a yield of only 20 and 17%, respectively, in a dichloromethane/toluene mixture of 5:1 under the standard reaction conditions[37].

Optimisation of the Lead Structure of 2a

As already mentioned, the phosphane imine ligand **2a** gave an enantioselectivity of 20% *ee* (+)-**ABS** and 20% *ee* (2.) **AABS** using the base DBU in the solvent mixture dichloromethane/toluene (Table 2, entry 5; Table 3, entry 1), and this is superior to all the classical ligands. Therefore, the structure of **2a**, which carries a hydroxymethyl group and an ethyl group at the stereogenic center in its imine substituent in the *ortho* position of one of its phenyl rings, seems to be a lead structure for catalytic allylation in which the new stereocenter is formed at the carbanionic center of the deprotonated nucleophile **BS**. Therefore, we set out to optimize this lead structure.

Ligand **3** is similar to ligand **2b**, having a methyl group instead of an ethyl group and the same hydroxymethyl group in the ligand side arm, and this gives rise to an enantiomeric excess of 9% for (−)-**ABS** with DBU (entry 2) and of 8% for (−)-**ABS** with triethylamine . Thus, a decrease in the size of the alkyl group in the ligand side arm reduces the enantioselectivity. Therefore, we increased the size of the alkyl group in the ligands **4**−**7**, a strategy which turned out to be successful. The phosphane imine **4**, carrying an isopropyl group instead of the ethyl group in **2b**, gave 21% *ee* for (−)-**ABS** and 21% *ee* (1.) for **AABS** with DBU

[a] 1 Mol% [$Pd(acac)_2$] was used as procatalyst. − [b] Yields were determined by GC on a Chirasil-Val-L column, yields < 0.5% are given as 0%. − [c] The *ee* of **ABS** was measured by GC on a Chirasil-Val-L column, *ee* of **AABS** was measured by GC on a Lipodex E column.

(entry 3), which is slightly better than the enantioselectivity of **2b** (Table 2, entry 6). Triethylamine and (−)-quinine, respectively, in combination with **4** afforded 18% *ee* for (−)-**ABS** with 89 and 75% yield, respectively[37]. Further enlargement of the alkyl group, i.e. to an isobutyl group in ligand **5**, provided 28% *ee* for (−)-**ABS** and 28% *ee* (1.) for **AABS** with DBU (entry 4). Triethylamine and (−)-quinine, respectively, together with **5** gave 24% *ee* and 23% *ee* for (−)-**ABS**[37]. The ligand **6**, bearing a *sec*-butyl group, gave a similar result for (−)-**ABS** with 26% *ee* with DBU (entry 5) and 20% *ee* with triethylamine (yield 97%)[37]. The best enantiomeric excess in the palladium-catalysed system **BS**/allyl acetate was obtained with the phosphane imine **7**, which contains a *tert*-butyl substituent. **7** induced 34% *ee* for (−)-**ABS** with 77% yield and 1% yield for **AABS** [(34% (1.)] with DBU (entry 6). Ligand **7** with triethylamine as a base afforded 29% *ee* and 89% yield of (−)-**ABS** and 1% yield of **AABS** with 30% *ee* (1.) (entry 7).

nantly (−)-**ABS**, whereas the ligands with the (*R*) configuration (**2a**, **8**) give (+)-**ABS** (bases DBU and triethylamine).

Screening of the Ligands 12−20

Under standard conditions, nitrogen, nitrogen/oxygen and nitrogen/sulfur ligands [e.g. 2,2′-bipyridine, (−)-sparteine, pyridine-oxazolines, etc.] only give yields below 1% for **ABS** in the Pd-catalysed allylation of 1,5-dimethylbarbituric acid[38]. Therefore, the ligand screening concentrated on phosphane ligands[37][38]. Here, we only report representative results.

The phosphane imines **12** and **13**, the phosphane amines **14a** and **14b**, the phosphane trisimines **15a** and **15b**, the phosphane octaimine **16**, the deltacyclanephosphane **17** and the phosphane oxazolines **18**−**20** (Scheme 2) were tested in the standard palladium-catalysed allyllation of 1,5-dimethylbarbituric acid (**BS**) with allyl acetate.

Table 3. Palladium-catalysed allylation of 1,5-dimethylbarbituric acid (**BS**) with allyl acetate using the phosphane imine ligands **2a**−**11**

[a] 1 Mol% [$Pd(acac)_2$] was used as procatalyst, Pd : ligand ratio = 1:4 at 38°C. − [b] Yields were determined by GC on a Chirasil-Val-L column, yields < 0.5% are given as 0%; [c] The *ee* of **ABS** was measured by GC on a Chirasil-Val-L column, *ee* of **AABS** was measured by GC on a Lipodex E column.

We subsequently replaced the alkyl group at the stereogenic center with a phenyl and a benzyl group while retaining the hydroxymethyl substituent (ligands **8** and **9**). Phosphane-imine **8** induced 12% *ee* and 13% *ee* for (+)-**ABS** with DBU (entry 8) and triethylamine, respectively. Similar results were obtained with the ligand **9** (entry 9). The results with the ligands **8** and **9** show that phenyl and benzyl substituents in the ligand side arm are not as efficient as alkyl groups. Ligand **10** differs slightly from ligand **3** in that it has a hydroxybenzyl group instead of a hydroxymethyl group, and this gave only 2% *ee* for (−)-**ABS** with DBU (entry 10) and 2% *ee* for (+)-**ABS** with (−)-quinine. Thus, the hydroxymethyl substituent, essential for the optical induction, cannot be replaced by a hydroxybenzyl substituent. With ligand **11**, which compared to **2b** contains a second hydroxy group and an additional phenyl substituent in its chiral side arm, no enantioselectivity was found for **ABS** using DBU[37]. With (−)-quinine and ligand **11**, 6% *ee* (+)-**ABS** was induced (entry 11).

Uniformly, within the phosphane imine ligand family **2**−**11**, the ligands with the (*S*)-configuration of their *N*-bound stereogenic center (**2b**−**7**, **9**−**11**) induce predomi-

Though resembling the phosphane imine ligands **2**−**11**, ligand **12**, a *tert*-butyl *tert*-leucinate, gave only 1% *ee* for (−)-**ABS** with DBU and triethylamine, respectively. Ligand **13** bears the alkylaromatic system of (+)-dehydroabietylamine with no hydroxy group in its side arm, and this afforded racemic **ABS** with DBU and 4% *ee* (+)-**ABS** with (−)-quinine. With 2−3% *ee* for (+)- and (−)-**ABS**, the phosphane amine ligands **14a** and **14b** were much less enantioselective than the corresponding phosphane imine ligands **2a** and **2b**. The change from one-arm phosphane imines **2a** and **2b** to the three-arm phosphane trisimines **15a** and **15b** did not lead to an improvement in the optical induction of **ABS**. With **15a** an enantiomeric excess of 6% *ee* and a yield of only 2% for (−)-**ABS** was found with the base DBU. Interestingly, with **15a** **ABS** was formed with the inverse configuration in comparison to **2a**. Ligand **15b** in combination with (−)-quinine provided (−)-**ABS** with 3% *ee* and in only 1% yield.

With the phosphane octaimine **16**[45], which bears D-alaninol in its eight side arms, an enantiomeric excess of 11% *ee* for (+)-**ABS** was obtained. The incorporation of (*R*)-(−)-2-amino-1-butanol, L-valinol, L-leucinol, L-phenylalan-

inol in the ligand arms and changing the ligand backbone to the 1,2-disubstituted phenylene bridge decreased the enantioselectivity for **ABS**[37]. The deltacyclanephosphane **17**[46] gave 8% *ee* for (+)-**ABS** with DBU. The combination of **17** with (−)-quinine led to an improvement to 11% *ee* for (+)-**ABS** (double stereoselection). The phosphane oxazoline ligands **18**−**20**[47][48] induced up to 99% *ee* in allylations in which the stereogenic center is formed in the allylic system and up to 13% *ee* in allylations in which the stereogenic center is formed in the nucleophile[49][50]. In the catalytic allylation of **BS** with allyl acetate, an enantiomeric excess of only about 1% *ee* for (+)-**ABS** was obtained. Phosphane-oxazoline **20** in combination with (−)-quinine provided 4% *ee* for (+)-**ABS**, probably an effect of (−)-quinine.

A Model for the Catalytically Active Phosphane-Imine Pd Complex

The in situ system consisting of the dimeric (η^3-allyl)palladium chloride and the phosphane imine **2a** was investigated by $^{31}P\{^1H\}$-NMR spectroscopy. In dichloromethane using a Pd/**2a** ratio of 1:1, signals at δ = 36.34 (broad) (0.6 P), 32.81 (0.1 P), 32.63 (0.1 P) and 21.82/21.74 (0.2 P) were observed, the most intense of which could be due to a Pd complex containing **2a** as a P−N chelating ligand similar to the Pd complexes of the phosphane oxazoline ligands[8][9][11][13]. On changing from a Pd/**2a** ratio of 1:1 to a ratio of 1:4, all the signals present in the 1:1 experiment disappeared. Two new doublets of equal intensity arose at δ = 45.86 and 18.67 (coupling constant 341.8 Hz), belonging to the complex [(η^3-allyl)Pd(**2a**)$_2$]Cl. Excess **2a** exhibited a singlet at δ = −9.92 with double the intensity compared to the signals of the coordinated **2a**. In addition there were small signals at δ = 33.28 (oxide of **2a**), 23.27 and 15.20 (broad) (CH_2Cl_2/CD_2Cl_2, external 85% H_3PO_4, 162 MHz, 21°C). After seven days the signal at δ = 15.20 had disappeared and that at δ = 33.28 had increased (increasing oxidation). Thus, using a Pd to ligand ratio of 1:4, a (η^3-allyl)Pd complex formed containing two inequivalent phosphane imine ligands **2a**.

Based on X-ray studies[51][52][53][54][55] and calculations[56] of (η^3-allyl)Pd complexes a molecular modelling study of an (η^3-allyl)Pd complex with two phosphane imine ligands **2a** was carried out using the tripos force field. Figure 2 shows a conformation of this complex obtained on energy minimisation.

The two phosphane imine ligands **2a** turn out to be different. The hydroxy group of one phosphane imine extends to about 3 Å above the allyl plane, whereas the hydroxy group of the other phosphane imine remains below the allyl plane in accord with their NMR inequivalence (Figure 2). Furthermore, a substituted and an unsubstituted phenyl ring, one from each of the two phosphane imines, form a π-stacking pair which participates in the conformational organisation of the two monodentate ligands. Taking into account this phenyl/phenyl interaction, the two monodentate ligands in the (η^3-allyl)Pd complex can be considered a ″chelating″ ligand. The hydroxy group, which is about 3 Å above the allyl plane, can influence the incoming 1,5-dimethylbarbiturate anion (Figure 2), e.g. by forming hydrogen bonds, thus differentiating the N−H and the N−Me side of the **BS** anion (Figure 3), which explains the enantioselectivity of long-arm ligands of the type **2a**.

Figure 2. Conformation of the (η^3-allyl)Pd complex containing two phosphane imine ligands **2a** after energy minimisation

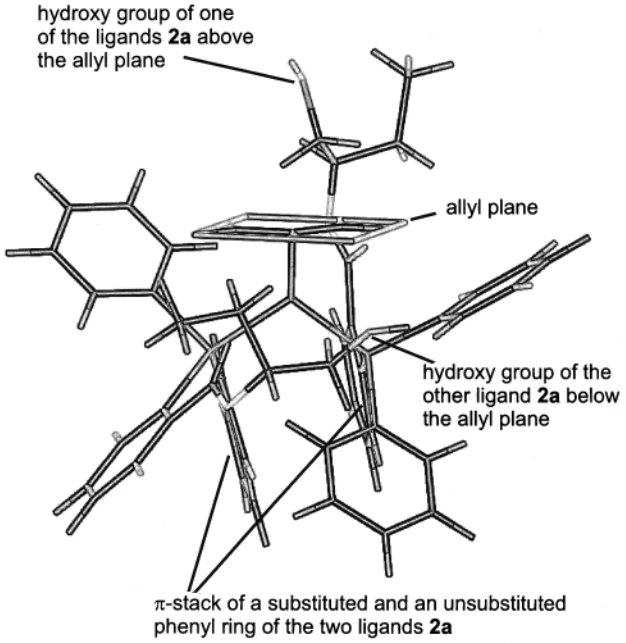

Figure 3. Differentiation between the N−H and the N−Me side of the incoming 1,5-dimethylbarbiturate anion in the formation of the new stereogenic center

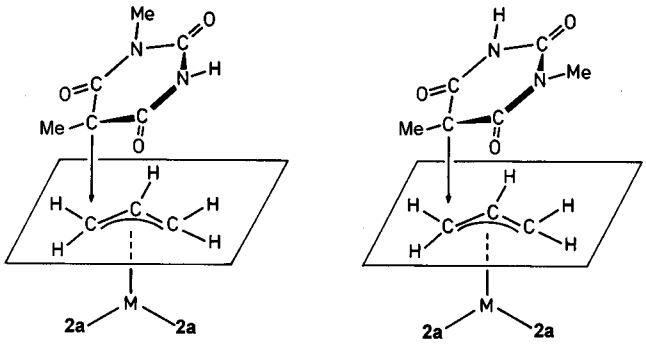

We thank the *Fonds der Chemischen Industrie* and the *BASF*, Ludwigshafen, for support of this work, and PD Dr. *S. Dove* for carrying out the force field calculations.

Experimental Section

NMR spectra were recorded on a Bruker WM 250 or on a Bruker ARX 400 instrument. Chemical shifts (δ) are reported in parts per million (ppm) vs. internal tetramethylsilane (TMS) (^1H) and external 85% H_3PO_4 ($^{31}P\{^1H\}$). − FD mass spectra were obtained on a Finnigan MAT 95, and for EI mass spectra a Varian MAT 311A was used. − Gas chromatography measurements were carried out on a Fisons Instruments GC 8000 series 8130. For integration of gas chromatograms a Spectra-Physics SP 4270 was used. − Infra red spectra were recorded on a Beckman Gitterspektro-

meter IR 4240. − Optical rotations were measured on a Perkin-Elmer polarimeter 241 (1-dm cell). − Melting points were obtained on a Büchi SMP 20 (uncorrected). The X-ray structure analysis was carried out on a AED II diffractometer.

(−)-Quinine, (−)-cinchonidine, and (+)-cinchonine were purchased from Merck, (+)-quinidine from Fluka, (*R*)-(−)-2-amino-1-butanol, (*S*)-(+)-2-amino-1-butanol, (1*S*,2*S*)-(+)-2-amino-1-phenyl-1,3-propanediol, (+)-dehydroabietylamine, L-*tert*-butyl *tert*-leucinate from Merck, L-alaninol, L-valinol, L-leucinol, D-α-phenylglycinol, L-phenylalaninol, L-norephedrine from Fluka, (2*S*,3*S*)-(+)-2-amino-3-methyl-1-pentanol (L-isoleucinol) from Aldrich, (*S*)-(+)-2-amino-3,3-dimethyl-1-butanol (L-*tert*-leucinol) from Sigma or Fluka and used without further purification. 2-Formylphenyl(diphenyl)phosphane (**1**)[39][40][41] and tris(2-formylphenyl)phosphane[40][41][42] were prepared as described in the literature. New analytical data are reported for **1**. The phosphane octaimine **16**[45], the deltacyclanephosphane **17**[46] and the osphane oxazolines **18**−**20**[47][48] were prepared using procedures described in the literature. All the syntheses and catalytic reactions were carried out with dried solvents under a nitrogen atmosphere using standard Schlenk techniques.

2-Formylphenyl(diphenyl)phosphane (**1**): Yellow crystals, m.p. 115−116°C. − IR (KBr): $\tilde{\nu}$ = 1701, 1679 cm^{-1} (C=O). − ^{1}H NMR ($CDCl_3$, 400 MHz): δ = 10.50 (d, ^4J_P = 5.4 Hz, 1 H, aldehyde), 7.97 (ddd, ^4J = 1.8 Hz, ^4J_P = 3.7 Hz, ^3J = 7.2 Hz, 1 H, Ar−H^3), 7.51−7.43 (m, 2 H, Ar−H^4 and Ar−H^5), 7.37−7.25 (m, 10 H, Ar−H), 6.99−6.95 (m, 1 H, Ar−H^6). − ^{31}P{^{1}H} NMR ($CDCl_3$, 162 MHz): δ = −10.99 (s). − $C_{19}H_{15}OP$ (290.30): calcd. C 78.61, H 5.21; found C 78.66, H 5.07.

General Procedure for the Preparation of the Phosphane Imines **2**−**13**. − *Variant A*: 3.45 mmol of the optically active primary amine was dissolved in 10 ml of methanol. 2-Formylphenyl(diphenyl)phosphane (**1**) (3.45 mmol; 1.00 g) and 10 ml of methanol were added to the above solution with stirring and the mixture refluxed for 3 h. After cooling to room temp. the methanol was removed and the resulting residue was dried and recrystallized as described for the individual phosphane imines.

Variant B: 3.45 mmol (or 4.14 mmol) of the optically active primary amine was dissolved in 30 ml of dichloromethane. 2-Formylphenyl(diphenyl)phosphane (**1**) (3.45 mmol; 1.00 g), 1 g of Na_2SO_4, and 10 ml of dichloromethane were added to the above solution with stirring and the mixture refluxed for 3 h. After cooling to room temp. the Na_2SO_4 was filtered off and washed with dichloromethane. The dichloromethane was removed and the resulting residue was treated as in variant A.

(+)-2-[N-(R)-1′-Hydroxybut-2′-ylcarbaldimino]phenyl(diphenyl)phosphane (**2a**): Variant A with 3.45 mmol (307 mg, 325 µl) of (*R*)-(−)-2-amino-1-butanol. Recrystallisation from 50 ml of petroleum ether (boiling range 40−60°C): colourless needles (1.02 g, 82%), m.p. 84.5−85°C. − $[\alpha]_D^{25}$ = +73 (*c* = 1, EtOH). − IR (KBr): $\tilde{\nu}$ = 1639 cm^{-1} (C=N). − ^{1}H NMR ($CDCl_3$, 400 MHz): δ = 8.68 (d, ^4J_P = 4.0 Hz, 1 H, azomethine), 7.80 (ddd, ^4J = 1.5 Hz, ^4J_P = 3.8 Hz, ^3J = 7.7 Hz, 1 H, Ar−H^3), 7.41 (pseudo dt, ^4J = 1.2 Hz, ^3J = 7.6 Hz, 1 H, Ar−H^4 or Ar−H^5), 7.35−7.20 (m, 11 H, Ar−H), 6.88 (ddd, ^4J = 1.2 Hz, ^3J_P = 4.5 Hz, ^3J = 7.6 Hz, 1 H, Ar−H^6), 3.52 (d, ^3J = 5.4 Hz, 2 H, NCH−C*H*$_2$−OH), 3.09 (ddt, ^3J = 4.8 Hz, ^3J = 8.5 Hz, ^3J = 5.4 Hz, 1 H, CHH′−NC*H*−CH$_2$), 1.82 (s br, 1 H, O*H*), 1.42 (dqd, ^3J = 4.8 Hz, ^3J = 7.4 Hz, ^2J = 13.7 Hz, 1 H, NCH−C*H*H′−CH$_3$), 1.30 (qdd, ^3J = 7.4 Hz, ^3J = 8.5 Hz, ^2J = 13.7 Hz, 1 H, NCH−CH*H*′−CH$_3$), 0.62 (pseudo t, ^3J = 7.4 Hz, 3 H, CHH′−C*H*$_3$). − ^{31}P{^{1}H} NMR ($CDCl_3$, 162 MHz): δ = −9.69 (s). − $C_{23}H_{24}NOP$ (361.42): calcd. C 76.44, H 6.69, N 3.87; found C 76.15, H 6.76, N 3.95.

(−)-2-[N-(S)-1′-Hydroxybut-2′-ylcarbaldimino]phenyl(diphenyl)phosphane (**2b**): Variant A with 3.45 mmol (307 mg, 325 µl) of (*S*)-(+)-2-amino-1-butanol. Recrystallisation analogous to **2a** (946 mg, 76%), m.p. 84.5−85°C. − $[\alpha]_D^{25}$ = −73 (*c* = 1, EtOH). − IR, ^{1}H NMR, ^{31}P{^{1}H} NMR analogous to **2a**. − $C_{23}H_{24}NOP$ (361.42): calcd. Synthesis of the Phosphane amines **14a** *and* **14b**: 750 mg (2.08 mmol) of **2a** (or **2b**) was dissolved in 30 ml of methanol at −10°C followed by the addition of 100 mg (2.64 mmol) of $NaBH_4$. The solution was allowed to come to room temp. within 4 h and heated for 2 h at 50°C. After removal of the methanol, 25 ml of water and 120 ml of dichloromethane were added to the residue. The dichloromethane layer was extracted twice with 25 ml of water and dried with Na_2SO_4. After filtration the dichloromethane was removed and the resulting oil was recrystallized with 20 ml of petroleum ether (boiling range 40−60°C) to give colourless crystals at −20°C. At room temp. the crystals of **14a** (or **14b**) became a highly viscous oil. Yield: 665 mg (88%).

(+)-N-[2-(Diphenylphosphanyl)benzyl]-N-[(R)-1′-hydroxybut-2′-yl]amine (**14a**): $[\alpha]_D^{25}$ = +11, $[\alpha]_{365}^{25}$ = +75 (*c* = 1, CH_2Cl_2). − ^1H NMR ($CDCl_3$, 400 MHz): δ = 7.41 (ddd, ^4J = 1.2 Hz, ^4J_P = 4.5 Hz, ^3J = 7.6 Hz, 1 H, Ar−H^3), 7.36−7.23 (m, 11 H, Ar−H), 7.18 (pseudo dt, ^4J = 1.2 Hz, ^3J = 7.6 Hz, 1 H, Ar−H), 6.92 (ddd, ^4J = 1.2 Hz, ^3J_P = 4.5 Hz, ^3J = 7.6 Hz, 1 H, Ar−H^6), 4.10 (s very br, 2 H, OH and NH), 3.98 (dd, ^4J_P = 1.6 Hz, ^2J = 12.6 Hz, 1 H, Ar−C*H*H′−NH), 3.95 (dd, ^4J_P = 1.2 Hz, ^2J = 12.6 Hz, 1 H, Ar−CH*H*′−NH), 3.60 (dd, ^3J = 3.8 Hz, ^2J = 10.9 Hz, 1 H, NCH−C*H*H′−OH), 3.24 (dd, ^3J = 5.9 Hz, ^2J = 10.9 Hz, 1 H, NCH−CH*H*′−OH), 2.51 (pseudo dq, ^3J = 3.8 Hz, ^3J = 6.3 Hz, 1 H, CHH′−NC*H*−CH_2), 1.36−1.27 (m, 2 H, NCH−CH_2−CH_3), 0.82 (t, ^3J = 7.4 Hz, 3 H, CH_2-CH_3). − $^{31}P\{^1H\}$ NMR ($CDCl_3$, 162 MHz): δ = −15.44 (s). − MS (FD, CH_2Cl_2); *m/z* (%): 363.1 (100) [M^+]. − $C_{23}H_{26}NOP$ (363.44): calcd. Synthesis of the Phosphane trisimines **15a** *and* **15b**: 3.79 ml (40.4 mmol, 3.60 g) of (*R*)-(−)-2-amino-1-butanol [or (*S*)-(+)-2-amino-1-butanol] was dissolved in 10 ml of dichloromethane and 1 g (7 mmol) of Na_2SO_4 was added. A solution of 0.70 g (2.0 mmol) of tris(2-formylphenyl)phosphane[40][41][42] in 10 ml of dichloromethane was added dropwise during 15 min. After 16 h reflux the yellow solution was filtered and the dichloromethane was evaporated. The excess amine was removed by heating under high vacuum at 100°C for 6 h. The resulting yellow oil was dissolved in 50 ml of dichloromethane, stirred for 15 min and filtered. The clear solution was evaporated to dryness. Recrystallisation from 90 ml of petroleum ether (boiling range 40−60°C) afforded yellow crystals of **15a** (or **15b**). Yield 0.90 g (80%).

(+)-Tris[2-(N-(R)-1′-hydroxybut-2′-ylcarbaldimino)-phenyl]phosphane (**15a**): M.p. 106.5−107°C. − $[\alpha]_D^{25}$ = +105 (*c* = 1, EtOH). − IR (KBr): $\tilde{\nu}$ = 1647 cm^{-1} (C=N). − ^1H NMR ($CDCl_3$, 400 MHz): δ = 8.45 (d, ^4J_P = 2.0 Hz, 3 H, azomethine), 7.65−7.59 (m, 3 H, Ar−H^3), 7.38 (pseudo dt, ^4J = 1.2 Hz, ^3J = 7.5 Hz, 3 H, Ar−H), 7.16 (pseudo t, ^3J = 7.4 Hz, 3 H, Ar−H), 6.92 (ddd, ^4J = 1.2 Hz, ^3J_P = 3.8 Hz, ^3J = 7.7 Hz, 3 H, Ar−H^6), 3.76 (s br, 3 H, OH), 3.51−3.37 (m, 6 H, NCH−C*H*H′−OH), 3.02−2.94 (m, 3 H, CHH′−NC*H*−CHH′), 1.25−1.10 (m, 3 H, NCH−C*H*H′−CH_3), 0.92−0.78 (m, 3 H, NCH−CH*H*′−CH_3), 0.41 (pseudo t, ^3J = 7.3 Hz, 9 H, CHH′−CH_3). − $^{31}P\{^1H\}$ NMR ($CDCl_3$, 162 MHz): δ = −10.12 (s). − MS (EI, 70 eV); *m/z* (%): 559.2 (100) [M^+], 486.3 (95) [$M^+ - C_4H_8OH$], 470.3 (39), 459.3 (15) [$M^+ - CHNC_4H_8OH$]. − $C_{33}H_{42}N_3O_3P$ (559.69): calcd. X-ray Structure Analysis of **15b**: $C_{33}H_{42}N_3O_3P$ (559.69); crystal dimensions 0.30 × 0.45 × 0.50 mm; two independent molecules in the unit cell; crystal system triclinic; space group *C*1/1, *P*1, (1); unit cell dimensions *a* = 10.068(6), *b* = 11.611(7), *c* = 15.125(9) Å, α = 88.08(5), β = 73.55(5), γ = 70.35(5)°, *V* = 1593.3 Å^3; *Z* = 2; density $d_{calcd.}$ = 1.17g/cm^3; μ(Mo-K_α) = 0.12 mm^{-1}; 3.0° < 2θ < 50.5°; total no. of reflections 8224, unique reflections 7653, unique reflections with $I > 2.5\sigma(I)$ 6037; *F*(000) = 600; diffractometer AED II; temp. −70°C. The structure was solved by direct methods using the SHELXTL PLUS version 4.2/800 program system. Hydrogen atoms were calculated by the HFIX program; R = 0.044; R_w = 0.033; residual electron density max. 0.36 e/Å^3, min. −0.39 e/Å^3. Further details of the crystal structure investigation may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository number CSD-407358.

1,5-Dimethylbarbituric Acid (**BS**): Handling of **BS** has been described in the literature[57][58][59][60], but a synthesis and characterisation was not given. 16.6 g (0.722 mol) of sodium was dissolved under reflux in 230 ml of absolute ethanol under a nitrogen atmosphere. After cooling to about 60°C, 25.9 g (0.350 mol) of *N*-methylurea and 20 ml of ethanol and, after 15 min, 59.8 ml (0.350 mol, 61.0 g) of methylmalonic acid diethyl ester were added (colourless precipitate). After 2 h reflux the solvent was removed. The dry residue was dissolved in 400 ml of hot water and, with vigorous stirring, 100 ml of conc. hydrochloric acid was added. After cooling to room temp. the precipitated product was filtered off and washed with 400 ml of cooled diethyl ether. Recrystallisation from 600 ml of absolute ethanol/methanol (3:1) provided colourless crystals, which were washed with petroleum ether (boiling range 40−60°C) and dried under high vacuum at 60°C for several days. Yield 34.7 g (63%), m.p. 170−171°C. − IR (KBr): $\tilde{\nu}$ = 1703 cm^{-1} (C=O). − ^1H NMR ([D$_6$]DMSO, 250 MHz): δ = 11.27 (s, 1 H, NH), 3.72 (q, ^3J = 6.9 Hz, 1 H, *H*CCH$_3$), 3.06 (s, 3 H, N−CH$_3$), 1.34 (d, ^3J = 6.9 Hz, 3 H, HCC*H*$_3$). − $C_6H_8N_2O_3$ (156.14): calcd. C 46.15, H 5.16, N 17.94; found C 46.21, H 5.18, N 17.90.

Enantioselective Palladium-Catalysed Allylation of 1,5-Dimethylbarbituric Acid (**BS**) *with Allyl Acetate:*150 mg (0.961 mmol) of **BS** and 1.01 mmol of base were dissolved in 10 ml of dichlorometh-

ane at 38°C under a nitrogen atmosphere. The following bases were used: DBU (150 µl, 153 mg), triethylamine (140 µl, 102 mg), BSA (247 µl, 205 mg), 1.5 M LDA·THF solution in cyclohexane (673 µl), NBu_4OH solution in methanol (12.5%) (2.59 ml, 2.10 g), (−)-quinine (328 mg), (+)-quinidine (328 mg), (−)-cinchonidine (297 mg) and (+)-cinchonine (297 mg). **BS** and base can be replaced by 382 mg (0.961 mmol) of **NBu_4BS**. After 5 min stirring 2.93 mg (0.0096 mmol) of palladium(II) acetylacetonate, 0.0384 mmol of a monodentate ligand or 0.0192 mmol of a bidentate ligand and 10 ml of a 1:1 mixture of methylene choride/toluene were added to the clear solution. After 2.0 min the reaction was started by the addition of 115 µl (1.07 mmol, 107 mg) of allyl acetate. The solution was stirred for 24, 48 or 72 h at 38°C. For work-up the solution was diluted with 10 ml of dichloromethane and extracted successively with 10 ml and 5 ml of 0.2 M hydrochloric acid and three times with 5 ml of water. The organic layer was dried with Na_2SO_4. The solid was filtered off and washed with 10 ml of dichloromethane. Removal of the solvent from the filtrate left the dry product ready for GC analysis. To the product was added about 25 mg of benzil (GC standard) and 6 ml of dichloromethane. This solution was used to determine the enantiomeric excess of **ABS** and the yield of **ABS** and **AABS** by GC on a Chirasil-Val-L column. Furthermore, a chromatographic analysis of 3 ml of the solution on alumina was carried out in a Pasteur pipette, in which only **AABS** and benzil eluted. The eluate was used for the determination of the enantiomeric excess of **AABS** on a Lipodex E column.

Conditions: 25 m *Chirasil-Val-L* fused silica capillary column (0.25 mm inner diameter, 0.12 µm film thickness, from Chrompack), column temp. 130°C, He pressure 1.2 bar, injector temp. 250°C, detector temp. 230°C [flame ionisation], retention times: (±)-**AABS** 4.24 min, standard benzil 17.10 min, (−)-**ABS** 19.09 min, (+)-**ABS** 20.33 min, separation factor $\alpha_{[(+)\text{-ABS}/(-)\text{-ABS}]} = 1.07$, resolution $R_{[(+)\text{-ABS}/(-)\text{-ABS}]} = 1.80$, mass correlation factors: $f_{\text{benzil/ABS}} = 1.77$ and $f_{\text{benzil/AABS}} = 1.50$; retention times for the enantiomers of 5-chloromethyl-1,5-dimethylbarbituric acid were 34.74 and 35.32 min, respectively. − 50 m *Lipodex E* fused silica capillary column (0.25 mm inner diameter, coated with octakis(2,6-di-*O*-pentyl-3-*O*-butyryl)-γ-cyclodextrine, from Macherey-Nagel), column temp. 110°C (after 45 min the column temp. was raised by 12°C/min to 170°C), H_2 pressure 2.07 bar, injector temp. 250°C, detector temp. 240°C (flame ionisation), retention times: (1.)-**AABS** 42.45 min, (2.)-**AABS** 43.84 min, standard benzil 65.0 min, separation factor $\alpha_{[(2.)\text{-AABS}/(1.)\text{-AABS}]} = 1.03$, resolution $R_{[(2.)\text{-AABS}/(1.)\text{-AABS}]} = 1.74$.

5-Allyl-1,5-dimethylbarbituric Acid (**ABS**): Main product of catalysis under standard reaction conditions. Maximum yield 184 mg (98%) (Table 1, entry 3). Recrystallisation from water/ethanol 175:1 provided colourless crystals, m.p. 131−131.5°C. − IR (KBr): $\tilde{\nu}$ = 1758, 1716, 1680 cm^{-1} (C=O). − ^1H NMR ($CDCl_3$, 400 MHz): δ = 9.03 (s, 1 H, NH), 5.60 (tdd, ^3J = 7.5 Hz, $^3J_{cis}$ = 10.1 Hz, $^3J_{trans}$ = 17.0 Hz, 1 H, $CH_2-CH{=}CHH$), 5.14 (md, $^3J_{trans}$ = 17.0 Hz, 1 H, $CH_2-CH{=}CHH_{trans}$), 5.11 (md, $^3J_{cis}$ = 10.1 Hz, 1 H, $CH_2-CH{=}CH_{cis}H$), 3.28 (s, 3 H, $N-CH_3$), 2.71 (d, ^3J = 7.5 Hz, 2 H, $CH_2-CH{=}CHH$), 1.57 (s, 3 H, $C-CH_3$). − GC-MS (EI, 70 eV); *m/z* (%): 195.9 (6) [M^+], 180.9 (100) [$M^+ - CH_3$], 41.0 (32) [$C_3H_5^+$]. − $C_9H_{12}N_2O_3$ (196.21): calcd. C 55.09, H 6.16, N 14.28; found C 55.09, H 6.23, N 14.09.

3,5-Diallyl-1,5-dimethylbarbituric Acid (**AABS**): By-product of catalysis under standard reaction conditions (yield 0−19%). To produce **AABS**, the standard catalysis was carried out with a 3-fold excess of the base DBU (450 µl) and a 21-fold excess of allyl acetate (2.20 ml) in refluxing THF (10 ml) with a reaction time of 24 h (ligand PPh_3). The THF was removed and 30 ml of dichloromethane was added followed by standard work-up. The resulting liquid was dissolved in dichloromethane and filtered through aluminia to remove traces of **ABS**. For further purification a bulb to bulb distillation was carried out to give a colourless liquid at 130°C and 3 Torr. Yield 222 mg (98%), b.p. ≈ 80°C at 3 Torr. − IR (film): $\tilde{\nu}$ = 1689 cm^{-1} (C=O). − ^1H NMR ($CDCl_3$, 400 MHz): δ = 5.82 (pseudo tdd, ^3J = 6.0 Hz, $^3J_{cis}$ = 10.2 Hz, $^3J_{trans}$ = 17.1 Hz, 1 H, $N-CHH'-CH{=}CHH$), 5.54 (tdd, ^3J = 7.5 Hz, $^3J_{cis}$ = 10.1 Hz, $^3J_{trans}$ = 17.0 Hz, 1 H, $C-CH_2-CH{=}CHH$), 5.28 (pseudo qd, $^{2/4}J$ = 1.3 Hz, $^3J_{trans}$ = 17.1 Hz, 1 H, $N-CHH'-CH{=}CHH_{trans}$), 5.21 (pseudo qd, $^{2/4}J$ = 1.3 Hz, $^3J_{cis}$ = 10.2 Hz, 1 H, $N-CHH'-CH{=}CH_{cis}H$), 5.10 (md, $^3J_{trans}$ = 17.0 Hz, 1 H, $C-CH_2-CH{=}CHH_{trans}$), 5.08 (md, $^3J_{cis}$ = 10.1 Hz, 1 H, $C-CH_2-CH{=}CH_{cis}H$), 4.50 (pseudo tdd, ^4J = 1.3 Hz, ^3J = 6.0 Hz, ^2J = 14.6 Hz, 1 H, $N-CHH'-CH{=}CHH$), 4.44 (pseudo tdd, ^4J = 1.3 Hz, ^3J = 6.0 Hz, ^2J = 14.6 Hz, 1 H, $N-CHH'-CH{=}CHH$), 3.30 (s, 3 H, $N-CH_3$), 2.69 (d, ^3J = 7.5 Hz, 2 H, $C-CH_2-CH{=}CHH$), 1.55 (s, 3 H, $C-CH_3$). − GC-MS (EI, 70 eV); *m/z* (%): 236.0 (100) [M^+], 221.0 (99) [$M^+ - CH_3$], 194.9 (17) [$M^+ - C_3H_5$], 138.0 (90), 41.0 (59) [$C_3H_5^+$]. − $C_{12}H_{16}N_2O_3$ (236.27): calcd. C 61.00, H 6.83, N 11.86; found C 60.95, H 7.04, N 11.63.

5-Chloromethyl-1,5-dimethylbarbituric Acid: Found in catalyses with yields of **ABS** <3%. − $C_7H_9ClN_2O_3$ (204.61). − GC-MS (EI, 70 eV); *m/z* (%): 204.0 (14) [M^+], 189.0 (30) [$M^+ - CH_3$], 169.0 (100) [$M^+ - Cl$], 155.1 (6) [$M^+ - CH_2Cl$], 69.0 (62), 40.9 (27).

Molecular Modelling: The calculations were carried out with the program Sybyl 6.1 using the standard tripos force field on a Silicon Graphics Indigo workstation (tripos metal file with standard geometries and van der Waals parameters of transition metal atoms). After establishment of the geometry of the (η^3-allyl)Pd system and the two P atoms, the P substituents were attached in their standard geometries, the *ortho*-substituent being oriented towards the allyl plane. A conformational analysis with energy minimisation was carried out.

Keywords: Arsaalkenes / Arsenic ligands / Carbonyl complexes / Chromium / Iron

Reaction of equimolar amounts of the metalloarsaalkene [(η^5-C_5Me_5)$(CO)_2$FeAs=C$(NMe_2)_2$] (**1**) with the carbonyl complexes [$Ni(CO)_4$], [$Fe_2(CO)_9$], and [{(*Z*)-cyclooctene}$Cr(CO)_5$], respectively, affords the adducts [(η^5-C_5Me_5)$(CO)_2$FeAs{$M(CO)_n$}=C$(NMe_2)_2$] with [$M(CO)_n$] = [$Ni(CO)_3$] (**2**); [$Fe(CO)_4$] (**3**), and [$Cr(CO)_5$] (**4**). These feature η^1 coordination of the arsaalkene ligand via the arsenic atom. The molecular structures of the complexes **3** and **4** have been determined by X-ray diffraction analyses.

Introduction

Recently, we reported on the reactivity of the ferriophosphaalkene [(η^5-C_5Me_5)$(CO)_2$FeP=C$(NMe_2)_2$] (**I**) towards [$Ni(CO)_4$], [$Fe_2(CO)_9$], and [{(*Z*)-cyclooctene}$Cr(CO)_5$][2]. The results were surprising in as much as the expected η^1-complex **II** was only obtained with [$Ni(CO)_4$]. Reaction of the metallophosphaalkene with the pentacarbonylchromium complex gave rise to the formation of the thermolabile black [$Cr(CO)_5$] adduct **III**, which in solution underwent an intramolecular condensation to give complex **IV**[2][3]. Upon exposure to [$Fe_2(CO)_9$], compound **I** was converted into the η^2-phosphanylcarbene complex **V** (Scheme 1).

It was intriguing to find out whether the chemistry of the ferrioarsaalkene [(η^5-C_5Me_5)$(CO)_2$FeAs=C$(NMe_2)_2$] (**1**)[4] would mirror that of its phosphorus analogue, i.e. furnishing an arsanylcarbene complex upon treatment with [$Fe_2(CO)_9$] and a condensation product analogous to **III** when treated with [{(*Z*)-cyclooctene}$Cr(CO)_5$].

Results and Discussion

Treatment of **1** with an equimolar amount of tetracarbonylnickel in *n*-pentane in the temperature range −50 to 20°C afforded the tricarbonylnickel adduct **2** as a red-brown air- and moisture-sensitive powder. The dark-red crystalline tetracarbonyliron complex **3** resulted from the reaction of **1** with [$Fe_2(CO)_9$] in *n*-pentane. Product formation was accompanied by effervescence owing to the liberation of carbon monoxide. Black-red **4** precipitated when a mixture of **1** and [{(*Z*)-cyclooctene}$Cr(CO)_5$] in *n*-pentane was allowed to warm from −30°C to ambient temperature. Purification of the obtained carbonylmetal adducts was achieved by recrystallization at −30°C. In the IR spectrum (Nujol) of complex **2**, intense bands at $\tilde{\nu}$ = 2035, 1956, and 1908 cm^{-1} can be assigned to the stretching modes of the terminal carbonyl ligands of the [$Ni(CO)_3$] unit. These absorptions are shifted to lower wavenumbers when compared with the analogous metallophosphaalkene complex [(η^5-C_5Me_5)$(CO)_2$FeP{$Ni(CO)_3$}=C$(NMe_2)_2$] [$\tilde{\nu}$(NiCO) (KBr) = 2034, 1957, 1917 cm^{-1}][2].

The donor strengths of the ferrioarsaalkene **1** and its phosphorus analogue resemble that of the phosphonium ylide $(C_6H_{11})_3P{=}CH_2$ in its [$Ni(CO)_3$] complex [$\tilde{\nu}$(NiCO) (cyclohexane) = 2030, 1955, 1936 cm^{-1}][5]. The terminal carbonyl ligands of the [$Fe(CO)_2$] unit give rise to strong valence absorptions at 1977 and 1936 cm^{-1}. In **1**, the respective υ(CO) bands are observed at $\tilde{\nu}$ = 1970 and 1921 cm^{-1}.

The $^{13}C\{^1H\}$-NMR spectrum of **2** shows a singlet at δ = 215.24 for the methylene carbon atom, which is close to the corresponding resonance in **1** (δ = 214.77). A singlet at δ = 200.96 can be assigned to the carbonyl groups of the [$Ni(CO)_3$] unit in **2**. In the phosphorus analogue this absorption was reported at δ = 199.5. The chemical shifts of the carbonyl signals of the [$Fe(CO)_2$] group in **1** (δ = 221.39) and of its nickel complex **2** (δ = 220.96) also compare well. These data clearly demonstrate that the molecular structure of **2** resembles that of the phosphorus analogue, in which the ferriophosphaalkene is η^1-ligated to the [$Ni(CO)_3$] fragment.

The observance of six intense carbonyl bands in the IR spectrum of the tetracarbonyliron complex **3** ranging from 2000 to 1888 cm^{-1} is consistent with a lowering of the local symmetry of the point group C_{3v} for the [$Fe(CO)_4$] unit with an axial ligand. Comparison with the υ(CO) stretching vibrations in [$Fe(CO)_4$ (PMe_3)] [$\tilde{\nu}$(CO) = 2051, 1977, 1936 cm^{-1}][6] further underlines the pronounced donor capacity of the arsaalkene ligand.

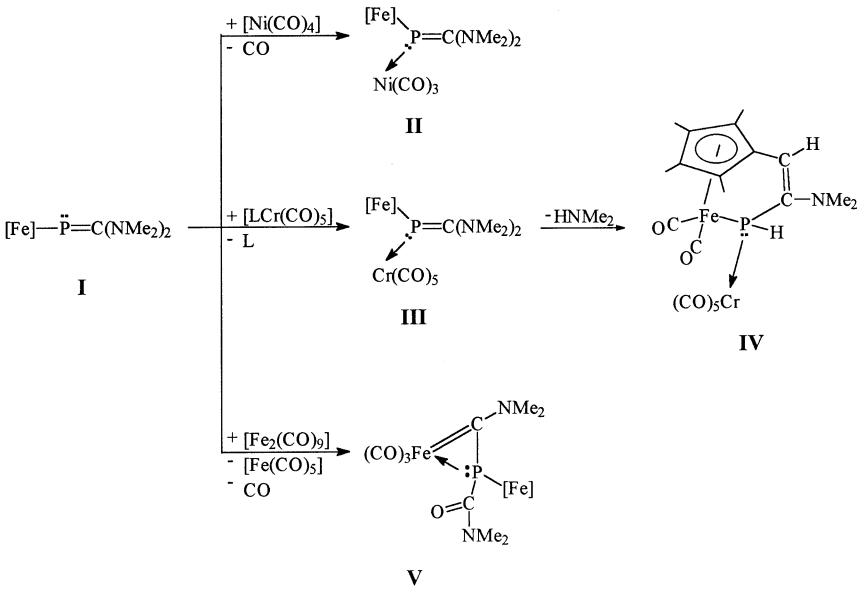
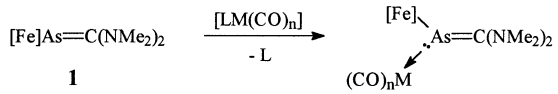
Scheme 1



[Fe] = [η^5-(C_5Me_5)$(CO)_2$Fe]; L = (*Z*)-cyclooctene.

Scheme 2



[Fe] = [η^5-(C_5Me_5)$(CO)_2$Fe]

Comp.	[M(CO)n]	L
2	[Ni(CO)3]	CO
3	[Fe(CO)4]	[Fe(CO)5]
4	[Cr(CO)5]	(Z)-C_8H_{14}

The $^{13}C\{^1H\}$-NMR spectrum of **3** shows a singlet at δ = 208.6 for the carbon atom of the As=C unit, while singlets at δ = 219.44 and 219.96 can be attributed to the carbonyl groups of the [Fe(CO)4] and the [$Fe(CO)_2$] fragments. These findings are in marked contrast to the reactivity of [(η^5-C_5Me_5)$(CO)_2$FeP=C$(NMe_2)_2$] towards [$Fe_2(CO)_9$], where phosphanylcarbene complex **V** was obtained as the sole phosphorus-containing product. It is conceivable that the formation of **V** is initiated by a tetracarbonyliron adduct analogous to **3**. A similar situation is encountered with the pentacarbonylchromium complex **4**, the phosphorus analogue of which, compound **III**, undergoes an intramolecular condensation to give **IV**.

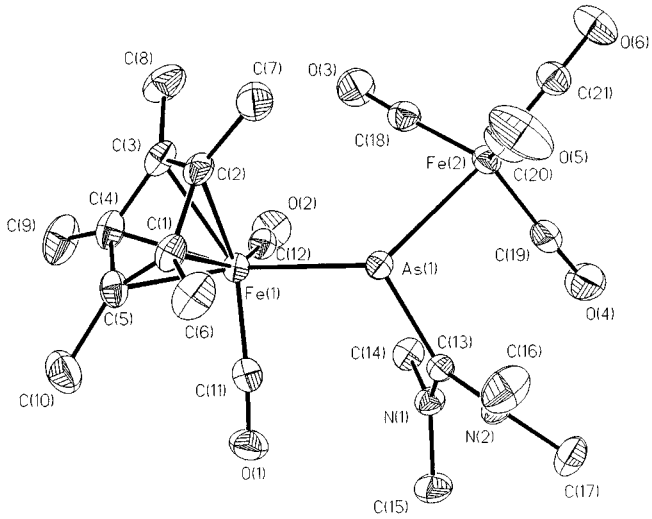
Strong carbonyl absorptions at $\tilde{\nu}$ = 2029, 1911, 1891, and 1858 cm^{-1} in the IR spectrum of **4** correspond to the υ(CO) bands in **III** [$\tilde{\nu}$(CO) (KBr) = 2033, 1915, 1897, 1860 cm^{-1}]. In the $^{13}C\{^1H\}$-NMR spectrum of **4**, the carbon atoms of the [$Cr(CO)_5$] unit give rise to singlets at δ = 222.36 (CO_{eq}) and 227.05 (CO_{ax}). A singlet at δ = 220.42 can be attributed to the iron-ligated carbonyl groups. Owing to the removal of electron density from **1** by the [$Cr(CO)_5$] group, this resonance is slightly shifted to higher field (Δδ = 1 ppm). The singlet of the methylene carbon atom of **4** (δ = 214.33) is close to the chemical shift of the free ligand **1** (δ = 214.77).

X-ray Structural Analysis of 3

An ORTEP drawing of **3** is shown in Figure 1; selected bond lengths and angles are given in the caption. The analysis shows that η^1 coordination of the ferrioarsaalkene **1** to the [$Fe(CO)_4$] fragment results in severe distortion of the organoarsenic ligand. In contrast to free **1**, which exhibits a slightly elongated As−C double bond of 1.876(8) Å[4] (theoretical value in $HAs=CH_2$: 1.79 Å[8]), the bond length between the pyramidally configured arsenic atom (sum of angles = 331.53°) and the trigonal-planar atom C(13) (sum of angles = 359.0°) amounts to 1.990(3) Å. This is comparable to the As−C single bonds in the 1,2-dihydroarsete PhAs[−C(Ph)=C(Ph)CH_2−] [1.989(6) and 1.949(4) Å][9].

The iron−arsenic bond lengths Fe(1)−As(1) [2.4559(8) Å] and Fe(2)−As(1) [2.5089(11) Å] differ markedly and are longer than those in precursor **1** [Fe(1)−As(1) = 2.443(2) Å] and in [(η^5-C_5Me_5)$(CO)_2$Fe−As=C(OSiMe_3)(*t*Bu)] [2.407(1) Å].[7] The bond angle Fe(1)−As(1)−C(13) [110.39(8)°] in complex **3** is compressed compared to that in **1** [116.2(3)°]. The presence of an As−C single bond in **3** is consistent with a zwitterionic structure, As^--C^+, which is stabilized by coordination to the [$Fe(CO)_4$] unit and by π conjugation with the lone pairs of electrons on the nitrogen atoms. In keeping with this, relatively short carbon−nitrogen bonds C(13)−N(1) [1.341(3) Å] and C(13)−N(2) [1.345(3) Å] were found in this structure. Both nitrogen atoms are planar [sum of angles at N(1): 359.8°; N(2): 358.5°]. The planes defined by the atoms Fe(1), As(1), C(13) and C(13), N(1), N(2) enclose a dihedral angle of θ = 141.9°. In free **1**, this angle is more obtuse (θ = 155.0°). The arsaalkene ligand occupies an axial position in a distorted

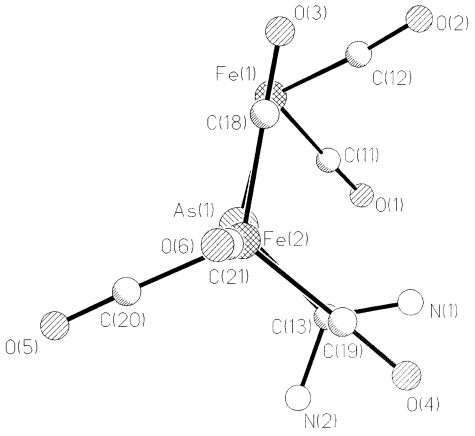
Figure 1. Molecular structure of **3**[a]



[a] Selected bond lengths [Å] and bond angles [°]: As(1)−C(13) 1.990(3), As(1)−Fe(1) 2.4559(8), As(1)−Fe(2) 2.5089(11), Fe(1)−C(11) 1.757(3), Fe(1)−C(12) 1.754(3), Fe(2)−C(18) 1.775(3), Fe(2)−C(19) 1.784(2), Fe(2)−C(20) 1.793(3), Fe(2)−C(21) 1.762(3), N(1)−C(13) 1.341(3), N(2)−C(13) 1.345(3); C(13)−As(1)−Fe(1) 110.39(8), C(13)−As(1)−Fe(2) 97.65(8), Fe(1)−As(1)−Fe(2) 123.49(3), C(12)−Fe(1)−C(11) 96.48(12), C(11)−Fe(1)−As(1) 87.60(6), C(12)−Fe(1)−As(1) 99.13(9), C(21)−Fe(2)−C(18) 91.40(14), C(21)−Fe(2)−C(19) 93.93(14), C(18)−Fe(2)−C(19) 119.08(14), C(20)−Fe(2)−C(21) 94.17(14), C(18)−Fe(2)−C(20) 123.2(2), C(19)−Fe(2)−C(20) 116.8(2), C(21)−Fe(2)−As(1) 171.93(10), C(18)−Fe(2)−As(1) 86.55(9), C(19)−Fe(2)−As(1) 93.89(10), C(20)−Fe(2)−As(1) 80.50(10), C(13)−N(1)−C(14) 122.3(2), C(13)−N(1)−C(15) 123.5(2), C(14)−N(1)−C(15) 114.0(2), C(13)−N(2)−C(16) 123.2(2), C(13)−N(2)−C(17) 122.2(2), C(16)−N(2)−C(17) 113.1(2), N(1)−C(13)−N(2) 117.3(2), N(1)−C(13)−As(1) 125.8(2), N(2)−C(13)−As(1) 116.9(2).

trigonal bipyramid. Fe(2) deviates by 0.0978 Å from the plane defined by the atoms C(18), C(19), and C(20) towards the opposite side of the arsenic atom. The bond angles between the vector Fe(2)−C(21) and carbon atoms of the equatorial CO groups range from 91.40(14) to 94.17(14)°, and the angle As(1)−Fe(2)−C(21) [171.93(10)°] clearly shows a deviation from linearity. A Newman projection along the vector Fe(2)−As(1) shows an almost eclipsed conformation with torsion angles C(18)−Fe(2)−As(1)−Fe(1) = 5.2° and C(19)−Fe(2)−As(1)−C(13) = 6.9° (Figure 2).

Figure 2. Newman projection of **3** with view along the Fe(2)−As(1) vector (the Cp* ring and the *N*-methyl groups are omitted for clarity)

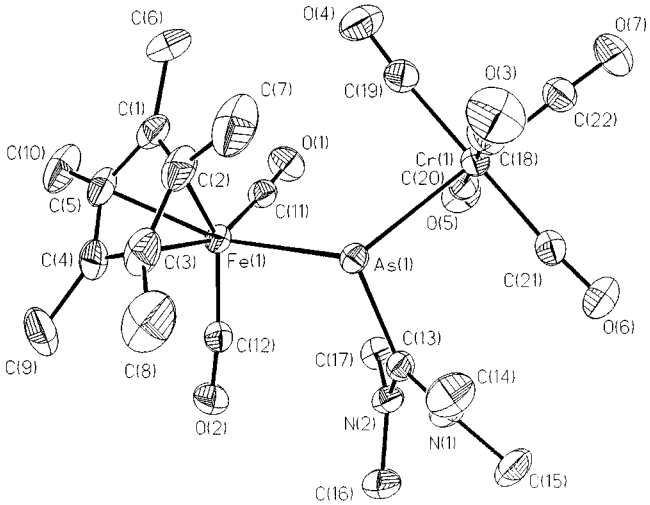


X-ray Structural Analysis of 4

An ORTEP drawing of **4** is shown in Figure 3; selected bond lengths and angles are given in the caption.

The molecule exhibits octahedral geometry. One coordination site is occupied by an η^1-ligated metalloarsaalkene. Again, the complexation of **1** to a carbonylmetal moiety causes a severe distortion of the organoarsenic compound. As in **4**, a single bond of 1.975(2) Å is found between the pyramidal arsenic atom (sum of angles 333.76°) and the planar carbon atom C(13) (sum of angles 359.9°). Both nitrogen atoms are planar (sum of angles 358.8 and 360.0°), and the dihedral angle between the planes defined by the atoms Fe(1), As(1), C(13)and C(13), N(1), N(2) is 142.2°.

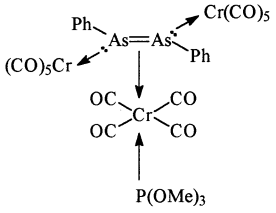
Figure 3. Molecular structure of **4**[5]



[a] Selected bond lengths [Å] and bond angles [°]: As(1)−C(13) 1.975(2), As(1)−Fe(1) 2.4589(5), As(1)−Cr(1) 2.6277(6), Fe(1)−C(11) 1.753(2), Fe(1)−C(12) 1.747(2), Cr(1)−C(CO)eq = 1.890(2) av., Cr(1)−C(22) 1.828(2), N(1)−C(13) 1.345(3), N(2)−C(13) 1.345(3); C(13)−As(1)−Fe(1) 111.81(6), C(13)−As(1)−Cr(1) 100.39(6), Fe(1)−As(1)−Cr(1) 121.56(2), C(12)−Fe(1)−C(11) 99.06(10), C(12)−Fe(1)−As(1) 91.61(7), C(11)−Fe(1)−As(1) 90.58(7), C(22)−Cr(1)−C(21) 88.72(10), C(22)−Cr(1)−C(20) 88.88(10), C(21)−Cr(1)−C(20) 89.55(10), C(22)−Cr(1)−C(19) 90.55(11), C(22)−Cr(1)−C(18) 91.81(11), C(22)−Cr(1)−As(1) 174.28(8), C(21)−Cr(1)−As(1) 90.52(7), C(20)−Cr(1)−As(1) 96.78(7), C(19)−Cr(1)−As(1) 90.39(7), C(18)−Cr(1)−As(1) 82.53(8), C(13)−N(1)−C(14) 123.2(2), C(13)−N(1)−C(15) 122.5(2), C(14)−N(1)−C(15) 113.1(2), C(13)−N(2)−C(17) 122.2(2), C(13)−N(2)−C(16) 123.7(2), C(17)−N(2)−C(16) 114.1(2), O(1)−C(11)−Fe(1) 176.4(2), O(2)−C(12)−Fe(1) 173.4(2), N(1)−C(13)−N(2) 116.7(2), N(1)−C(13)−As(1) 116.7(2), N(2)−C(13)−As(1) 126.5(2).

The bond length Fe(1)−As(1) [2.4589(5) Å] is comparable with that in **3**. The Cr−As bond [2.6277(6) Å] is shorter than the sum of the Cr^0−As covalent radii of Cr^0 [1.48 Å][10] and As [1.21 Å][11], but is considerably longer than Cr−As single bonds in related carbonylchromium complexes such as $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{Cr(CO)_5\}=C(SSiMe_3)_2]$ [2.524(1) Å][1], $[(\eta^5\text{-}C_5Me_5)(CO)_2\text{-}FeAs\{Cr(CO)_5\}=PMes^*]$ [2.494(1) Å][12], or [Mes*As=

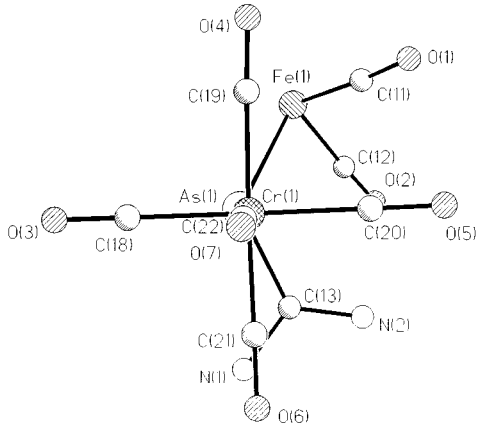
$As\{Cr(CO)_5\}CH(SiMe_3)_2]$ [2.454(1) Å][13]. The As−Cr separation in **4** is similar to the Cr−As π-bond length in the trinuclear complex **5**[14].



5

A view perpendicular to the $[Cr(CO)_4]$ plane indicates an almost staggered conformation with torsion angles C(19)−Cr(1)−As(1)−Fe(1) = 30.0° and C(21)−Cr(1)−As(1)−C(13) = 24.4° (Figure 4).

Figure 4. Newman projection of **4** with view along the Cr(1)−As(1) vector (the Cp* ring and the *N*-methyl groups are omitted for clarity)



Due to steric hindrance, the ideal C_{4v} symmetry of the $[Cr(CO)_5]$ group is perturbed, as is evident from the angles C(20)−Cr(1)−As(1) [96.78(7)°], C(18)−Cr(1)−As(1) [82.53(8)°] and C(22)−Cr(1)−As(1) [174.28(8)°]. It is also remarkable that the bond length Cr(1)−C(22) [1.828(2) Å] in a *trans* position with respect to the electron-donating ligand is significantly shortened as compared to the other Cr−C(carbonyl) bond lengths [1.881(2)−1.897(3) Å].

To sum up, arsaalkene derivatives are usually thermally less stable and more reactive than their phosphorus analogues[15]. However, here the opposite is encountered. The metalloarsaalkene complexes **3** and **4** are isolable compounds and can be conveniently studied in solution, whereas the corresponding phosphorus compound $[(\eta^5\text{-}C_5Me_5)(CO)_2FeP\{Cr(CO)_5\}=C(NMe_2)_2]$ undergoes a facile condensation with C=C bond formation. The complex $[(\eta^5\text{-}C_5Me_5)(CO)_2FeP\{Fe(CO)_4\}=C(NMe_2)_2]$ could not even be detected spectroscopically in the reaction between the ferriophosphaalkene and $[Fe_2(CO)_9]$.

Experimental Section

All manipulations were performed under dry, oxygen-free nitrogen using standard Schlenk techniques. Solvents were dried by standard methods and freshly distilled under argon prior to use. − Infrared spectra were recorded with a Bruker FT-IR IFS 66 spectrometer. − ^1H- and ^{13}C-NMR spectra were recorded in C_6D_6 at 22°C using Bruker AM Advance DRX 500, Bruker AC 250 P, and Bruker AC 100 instruments. Standards: $SiMe_4$ ($^{1\,H,\,13}C$). − Elemental analyses were performed in the microanalytical laboratory of the University of Bielefeld. − The metalloarsaalkene $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs=C(NMe_2)_2]$ (**1**)[4], $[\{(Z)\text{-cyclooctene}\}Cr(CO)_5]$[16], and $[Fe_2(CO)_9]$[17] were synthesized according to literature procedures. $[Ni(CO)_4]$ was purchased commercially (Strem).

Synthesis of $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{Ni(CO)_3\}=C(NMe_2)_2]$ (**2**): A portion of $[Ni(CO)_4]$ (0.24 g, 1.42 mmol) was added to a chilled solution (−50°C) of $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs=C(NMe_2)_2]$ (**1**) (0.60 g, 1.42 mmol) in 50 ml of *n*-pentane. The stirred solution was allowed to warm to ambient temperature over a period of 1 h and then the solvent and volatile components were removed. The residue was redissolved in *n*-hexane (30 ml) and the resulting solution was filtered. The filtrate was concentrated to ca. 15 ml and stored overnight at −30°C to afford 0.52 g (65%) of **2** as a red-brown powder. − IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 2035 [s, Ni(CO)], 1977 [s, Fe(CO)], 1956 [s, Ni(CO)], 1935 [s, Fe(CO)], 1908 [s, Ni(CO)]. − ^1H NMR: δ = 1.59 (s, 15 H, C_5Me_5), 2.71 (s, 12 H, NCH_3). − $^{13}C\{^1H\}$ NMR: δ = 9.61 [s, $C_5(CH_3)_5$], 43.99 (s, NCH_3), 95.04 [s, $C_5(CH_3)_5$], 200.96 (s, NiCO), 215.24 (s, As=C), 220.96 (s, FeCO).− $C_{20}H_{27}AsFeNiO_5$ (564.92): calcd. C 42.52, H 4.82, N 4.96; found C 41.89, H 4.85, N 4.64.

Synthesis of $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{Fe(CO)_4\}=C(NMe_2)_2]$ (**3**): Solid $[Fe_2(CO)_9]$ (0.3 g, 0.81 mmol) was added at 20°C to a stirred solution of 0.34 g (0.81 mmol) of **1** in 50 ml of *n*-pentane. The reaction proceeded with effervescence owing to liberation of CO. After stirring for 2 h at room temperature, the ^1H-NMR resonances of **1** had disappeared, and the solvent and volatiles were removed from the solution in vacuo. Drying at 10^{-3} Torr was maintained overnight. The black residue was then redissolved in 10 ml of diethyl ether, and the resulting solution was filtered. Storing at −28°C afforded black-red hexagonal crystals of **3** (0.28 g, 59%). − IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 2000 [s, $Fe(CO)_4$], 1974 [s, $Fe(CO)_2$], 1937 [s, $Fe(CO)_2$], 1927 [m, $Fe(CO)_4$], 1911 [m, $Fe(CO)_4$], 1888 [s, $Fe(CO)_4$]. − ^1H NMR: δ = 1.58 (s, 15 H, C_5Me_5), 2.62 (s, 12 H, NCH_3). − $^{13}C\{^1H\}$ NMR: δ = 9.09 [s, $C_5(CH_3)_5$], 44.63 (s, NCH_3), 96.17 [s, $C_5(CH_3)_5$], 208.6 (s, As=C), 219.44 [s, $Fe(CO)_4$], 219.96 [s, $Fe(CO)_2$]. − $C_{21}H_{27}AsFe_2N_2O_6$ (590.07): calcd. C 42.75, H 4.61, N 4.75; found C 42.56, H 4.50, N 4.37.

Synthesis of $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{Cr(CO)_5\}=C(NMe_2)_2]$ (**4**): A solution of $[\{(Z)\text{-cyclooctene}\}Cr(CO)_5]$ (0.15 g, 0.50 mmol) in 20 ml of *n*-pentane was added dropwise to a cooled solution (−30°C) of **1** (0.21 g, 0.50 mmol) in 30 ml of *n*-pentane. Warming to room temperature led to the formation of a black precipitate. After stirring for 1 h, this was filtered off. The filter cake was washed with *n*-pentane (30 ml), dried in vacuo, and then redissolved in 5 ml of toluene. Upon storing at −30°C, black-red crystals of **4** separated (0.22 g, 71%).− IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 2029 [s, Cr(CO)], 1964 [s, Fe(CO)], 1936 [s, Fe(CO)], 1911 [s, Cr(CO)], 1891 [s, Cr(CO)], 1858 [s, Cr(CO)]. − ^1H NMR: δ = 1.54 (s, 15 H, C_5Me_5), 2.69 (s, 12 H, NCH_3). − $^{13}C\{^1H\}$ NMR: δ = 9.16 [s, $C_5(CH_3)_5$], 44.78 (s, NCH_3), 95.61 [s, $C_5(CH_3)_5$], 214.33 (s, As=C), 220.42 [s, $Fe(CO)_2$], 222.36 [s, $Cr(CO)_{eq}$], 227.05 [s, $Cr(CO)_{ax}$]. − $C_{22}H_{27}AsCrFeN_2O_7$ (614.25): calcd. C 43.02, H 4.43, N 4.56; found C 42.46, H 4.55, N 4.28.

X-ray Structure Determination of [(η^5-C_5Me_5)(CO)$_2$FeAs{Fe(CO)$_4$}=C(NMe$_2$)$_2$} (**3**)[18]: Single crystals of **3** were grown from diethyl ether solution at −28°C. A black crystal of approximate dimensions 1.00 × 0.80 × 0.70 mm was examined on a Siemens P2(1) diffractometer using Mo-K_α radiation at 173 K. Crystal data and refinement details: Cell dimensions: a = 10.240(4), b = 14.922(6), c = 18.190(8) Å, β = 100.93(3)°, V = 2734(2) Å^3, Z = 4, $d_{calcd.}$ = 1.524 g cm^{-3}, μ = 2.302 mm^{-1}, space group $P2_1/n$, semiempirical absorption correction from Ψ scans, 8381 reflections collected, of which 7980 independent (R_{int} = 0.030), 6305 with $I > 2\sigma(I)$. Structure solution and refinement on F^2 with SHELXTL-PLUS and SHELXL-93. 331 parameters, anisotropic refinement for all non-hydrogen atoms, hydrogen atoms treated as riding groups with a 1.2-fold (1.5-fold for methyl groups) isotropic U value of the equivalent U value of the corresponding C atom. $R1$ = 0.059, $wR2$ = 0.097, $GooF(F^2)$ = 1.048, $w^{-1} = \sigma^2(F_o^2) + (0.0386 \cdot P)^2 + 2.32 \cdot P$, where $P = (F_o^2 + 2F_c^2)/3$, max./min. residual electron densities 0.4 and −0.5 eÅ^{-3}.

X-ray Structure Determination of [(η^5-C_5Me_5)(CO)$_2$FeAs{Cr(CO)$_5$}=C(NMe$_2$)$_2$} (**4**)[18]: Single crystals of **4** were grown from benzene at 4°C. A black crystal of approximate dimensions 1.00 × 0.70 × 0.30 mm was examined on a Siemens P2(1) diffractometer using Mo-K_α radiation at 173 K. Crystal data and refinement details: Cell dimensions: a = 9.131(2), b = 11.555(2), c = 14.009(2) Å, α = 100.680(10), β = 107.790(10), γ = 105.920(10)°, V = 1293.6(4) Å^3, Z = 2, $d_{calcd.}$ = 1.577 g cm^{-3}, μ = 2.292 mm^{-1}, space group $P\bar{1}$, semi-empirical absorption correction from Ψ scans, 7978 reflections collected, of which 7541 independent (R_{int} = 0.027), 6431 with $I > 2\sigma(I)$. Structure solution and refinement on F^2 with SHELXTL-PLUS and SHELXL-93. 317 parameters, anisotropic refinement for all non-hydrogen atoms, hydrogen atoms treated as riding groups with a 1.5-fold isotropic U value of the equivalent U value of the corresponding C atom. $R1$ = 0.042, $wR2$ = 0.084, $GooF(F^2)$ = 1.037, $w^{-1} = \sigma^2(F_o^2 + (0.0388 \cdot P)^2 + 0.72 \cdot P$, where $P = (F_o^2 + 2F_c^2)/3$, max./min. residual electron densities 0.5 and −0.4 eÅ^{-3}.

Keywords: Arsenic / Bioinorganic chemistry / Dihydrolipoic acid / Lipoic acid / S ligands

The arsenic(III) dithiolate [PhAs(HlipS$_2$)] (**1**, HlipS$_2^{2-}$ = reduced *rac*-lipoic acid) has been obtained via three different routes: (A) from (PhAsO)$_n$ and *rac*-dihydrolipoic acid, (B) from (AsPh)$_6$ and *rac*-lipoic acid, and (C) from PhAsO(OH)$_2$ and *rac*-dihydrolipoic acid. The latter method is also suitable for the preparation of [(4-NH$_2$C$_6$H$_4$)As(HlipS$_2$)] (**2**) from (4-NH$_2$C$_6$H$_4$)AsO(OH)$_2$. *rac*-Dihydrolipoic acid and Me$_2$AsO(OH) react to give [(Me$_2$As)$_2$(HlipS$_2$)] (**3**). These reactions indicate pathways by which mono- and diorganoarsenic compounds of various As oxidation states (I, III, and V) may inhibit enzymes that contain lipoic acid as a cofactor. X-ray structure analysis shows that **1** is a 2,4-disubstituted 1,3,2-dithiarsinane, i. e. a six-membered heterocycle. The phenyl group at the 2-position (As) adopts the axial orientation. (2*RS*,4*RS*)-**1**, which is the isomer found in the crystal, is thermodynamically more stable than the diastereomeric (2*SR*,4*RS*)-**1** by 4.3 ± 0.8 kJ/mol (25°C). In solution, the epimerization by inversion of configuration at the ψ-tetrahedrally coordinated As atom is faster than expected, with acid catalysis (COOH groups!) being a possible cause.

The toxicity of arsenic compounds has been known and used since classical antiquity[2]. In addition to its harmful effects on individuals, arsenic can cause severe public health problems, as a recent case of mass contamination has shown[3]. However, the underlying molecular mechanisms of action are still far from clear. It is assumed that the electronically soft species RAs^{2+} and R$_2$As$^+$ (R = e. g. alkyl, aryl) block biological sulphydryl groups; however, "the inhibition of thiol-enzymes by As^{III}, although widely quoted, is poorly understood"[4].

A probable biological target of arsenic(III) is enzyme-bound lipoic acid (α-lipoic acid, thioctic acid, 5-(1,2-dithiolan-3-yl)pentanoic acid, Hlip)[5][6]. This small biomolecule acts as a cofactor in some multienzyme complexes, namely the pyruvate dehydrogenase (and other α-keto acid dehydrogenases[7][8]) and the glycine cleavage system[9][10]. It has gained attention as a powerful biological antioxidant[11] and is approved in Germany for use as a therapeutic agent[12]. Lipoic acid can be reduced reversibly to dihydrolipoic acid (6,8-dimercaptooctanoic acid, Hlip(SH)$_2$; Scheme 1). This redox equilibrium is part of the enzymatic cycles[13].

It has repeatedly been demonstrated that lipoic acid-containing enzymes are strongly inhibited by As^{III} compounds such as arsenite[14] and organoarsoxanes (RAsO)$_n$[15]. However, only a few relevant low-molecular models have been examined; these were obtained from As^{III} starting materials in all cases[16][17][18]. In the present paper we show that such models are also accessible from compounds of *mono*- and *penta*valent arsenic related to the antimicrobial arsenicals, of which "Salvarsan" is the most prominent example[19]. In addition we report the crystal and molecular structure of [PhAs(HlipS$_2$)] (**1**), which to our knowledge is the first X-ray structure of an organoarsenic complex of a naturally occuring thiolate. A brief report on some of these results has appeared as a conference abstract[20].

Hlip Hlip(SH)$_2$

Reactions

In the human body, inorganic As^V is partly methylated to MeAsO(OH)$_2$ and Me$_2$AsO(OH), and it has been suggested that the intermediate formation of As^{III} is involved in the biomethylation pathway[21]. The accompanying redox processes are probably coupled to biological thiol/disulphide equilibria. A redox reaction also occurs in the metabolism of the aryl-As^I compound Salvarsan (see below) and results in an As^{III} species, which is thought to be the active form of this formerly used medicinal drug[22]. This

[◇] Part 1: Ref.[1].

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0061 $ 17.50+.50/0

prompted us to investigate the redox behaviour of some relevant organoarsenic compounds towards the dithiol dihydrolipoic acid [Hlip$(SH)_2$] and its oxidation product, the cyclic disulphide lipoic acid (Hlip, see Scheme 1).

In tetrahydrofuran (THF), phenylarsonic acid is smoothly reduced by Hlip$(SH)_2$ with the formation of the As^{III} compound [PhAs(HlipS$_2$)] (**1**) and lipoic acid (Eq. 1, method C under Experimental).

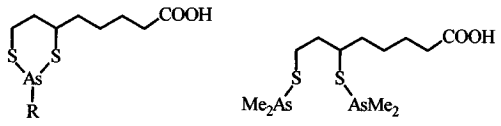
$$PhAsO(OH)_2 + 2\ Hlip(SH)_2 \xrightarrow[\text{room temp.}]{\text{THF}} \underset{\mathbf{1}}{[PhAs(HlipS_2)]} + Hlip + 3\ H_2O \quad (1)$$

1 is a disubstituted 1,3,2-dithiarsinane (Scheme 2). Its constitution was deduced from NMR data by Dill et al., who obtained **1** from $PhAsCl_2$ and Hlip$(SH)_2$ in solution but did not isolate the product[18]. The final proof of the structure of **1** comes from our crystal structure determination described below. Eq. 1 includes two reaction steps, namely the reduction of As^V and the subsequent complexation of the As^{III} formed. The second step determines the result of the overall reaction. Therefore, even with the appropriate ratio of phenylarsonic acid to Hlip$(SH)_2$, no phenylarsoxane is obtained (Eq. 2).

$$PhAsO(OH)_2 + Hlip(SH)_2 \not\longrightarrow {}^1/_n\,(PhAsO)_n + Hlip + 2\ H_2O \quad (2)$$

Instead, **1** is formed, and 50% of the $PhAsO(OH)_2$ remains unreacted.

Scheme 2



1: R = phenyl
2: R = 4-aminophenyl

3

Starting from phenylarsoxane, there is an alternative and more favourable route to **1** (Eq. 3, method A).

$${}^1/_n\,(PhAsO)_n + Hlip(SH)_2 \xrightarrow[\text{room temp.}]{\text{THF}} \underset{\mathbf{1}}{[PhAs(HlipS_2)]} + H_2O \quad (3)$$

As **1** is the only solid product of this reaction, separation problems, as in the case of method C (Eq. 1; similar solubilities of **1** and Hlip), are avoided. Triphenylarsane was also tested as a starting material. However, no reaction with dihydrolipoic acid was observed. This behaviour distinguishes $AsPh_3$ from $HgPh_2$, which under the same conditions yields the trinuclear complex $[Hg(PhHg)_2(HlipS_2)_2]$[23].

p-Aminophenylarsonic acid [arsanilic acid, (4-$NH_2C_6H_4$)$AsO(OH)_2$] was one of the first arsenicals to be used successfully. Ehrlich has already inferred from biological observations that this compound must be reduced in organisms in order to become active against pathogens[19b]. We have shown that (4-$NH_2C_6H_4$)$AsO(OH)_2$ is reduced by Hlip$(SH)_2$. The reaction, which was carried out in methanol, is analogous to that of $PhAsO(OH)_2$ (Eq. 1) and yields the crystalline As^{III} compound [(4-$NH_2C_6H_4$)As(HlipS$_2$)] (**2**). Spectroscopic data reveal that **2** is *not* zwitterionic, at least in the solid state and in $CDCl_3$, and that it has the same constitution as **1** (Scheme 2). The formation of **2** sheds light on the possible biochemical pathway of arsanilic acid and similar As^V arsenicals. It shows the facile reduction by a biological dithiol as well as the blocking of the coenzyme lipoic acid, which may be the cause or one of the causes of the antimicrobial activity.

The As^I arsenical Salvarsan is an aromatic ring-substituted (3-NH_2, 4-OH) derivative of hexaphenylcyclohexaarsane. While the parent compound is well-defined and forms cyclic $(AsPh)_6$ molecules[24], Salvarsan appears as mixtures of partly oxidized oligomeric and polymeric chains with strongly varying properties[25]. Both compounds contain As−As bonds. In Salvarsan these bonds are oxidatively cleaved under physiological conditions (see above). We used $(AsPh)_6$ as a model for Salvarsan to test whether lipoic acid acts as an oxidizing agent towards aryl-As^I and can accomplish the As−As bond cleavage. No reaction occurred in THF, toluene or diethylene glycol dimethyl ether at temperatures up to the boiling point of the respective solvent. However, when $(AsPh)_6$ and lipoic acid were melted together, compound **1** was formed quantitatively (Eq. 4, method B).

$${}^1/_6\,(AsPh)_6 + Hlip \xrightarrow[130°C]{\text{melt}} \underset{\mathbf{1}}{[PhAs(HlipS_2)]} \quad (4)$$

The need for quite drastic and thus nonphysiological conditions may be rationalized in terms of the different structures of $(AsPh)_6$ and Salvarsan, i.e. cyclic vs. open-chain. Bearing this difference in mind one can expect that in vivo, Salvarsan, after oxidation by a suitable biological disulphide (not necessarily lipoic acid), is able to inhibit lipoic acid dependent enzymes.

Finally, we studied the reaction of dihydrolipoic acid with a *di*organoarsenic(V) compound, namely dimethylarsenic acid [cacodylic acid, $Me_2AsO(OH)$]. Again reduction of As^V to As^{III}, accompanied by As^{III} complexation was observed (Eq. 5).

$$2\ Me_2AsO(OH) + 3\ Hlip(SH)_2 \xrightarrow[\text{room temp.}]{\text{THF}} \underset{\mathbf{3}}{[(Me_2As)_2(HlipS_2)]} + 2\ Hlip + 4\ H_2O \quad (5)$$

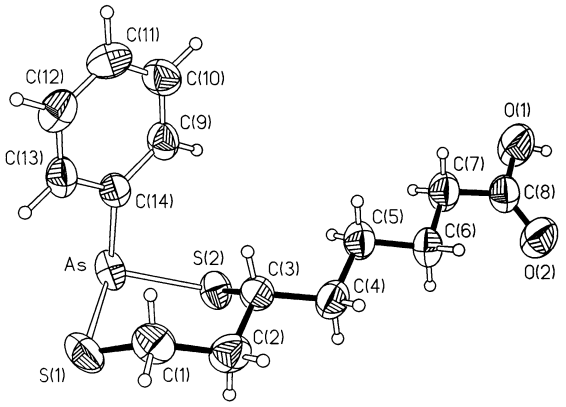
Attempted separation of $[(Me_2As)_2(HlipS_2)]$ (**3**, see Scheme 2) from the second nonvolatile product lipoic acid failed, although **3** was unambiguously identified by spectroscopic methods (^{13}C NMR, CI-MS) in the reaction mixture. The 1:2 molar ratio of **3** and Hlip expected from Eq. 5 was confirmed by ^1H-NMR spectroscopy. No unreacted starting material or other products were found. Pure **3** is accessible via reaction of Me_2AsCl with Hlip$(SH)_2$ in the presence of pyridine as a base[16]. Its formation from $Me_2AsO(OH)$ is, however, more relevant to bioinorganic and toxicological questions, because dimethylarsenic acid is a common biomethylation product of arsenate and arsenite[21]. Moreover, this compound is also a herbicide and a chemical weapon ("Agent Blue")[26].

We have shown that mono- and diorganoarsenic(V) compounds of the type $RAsO(OH)_2$ and $R_2AsO(OH)$, respectively, are easily reduced by dihydrolipoic acid. The logical extension of this, the reduction of R_3AsO by $Hlip(SH)_2$, has been studied by others for R = Me[27]. The only products observed were Me_3As and lipoic acid.

Crystal Structure of 1

Crystals of **1** consist of [PhAs(HlipS_2)] molecules (or complexes, to emphasize the semi*metallic* character of arsenic; see Figure 1). The molecules are arranged as symmetric hydrogen-bonded dimers. Each dimer is situated on a crystallographic centre of inversion and has a central eight-membered ring formed by the two carboxylic groups. The O···O distances within the two hydrogen bonds of the ring are 2.657 Å [O(1)···O(2′); 2 − *x*, 2 − *y*, 2 − *z*]. This motif is very common and has been found for the majority of monofunctional carboxylic acids in the crystalline state[28].

Figure 1. View of [PhAs(HlipS_2)] (**1**) in the solid state; non-hydrogen atoms are shown as thermal ellipsoids with 50% probability[a]



[a] Selected bond lengths [Å] and angles [°]: As−S(1) 2.230(1), As−S(2) 2.227(1), As−C(14) 1.964(4), S(1)−C(1) 1.817(5), S(2)−C(3) 1.848(4), C(1)−C(2) 1.530(6), C(2)−C(3) 1.521(5), C(3)−C(4) 1.529(6), C(4)−C(5) 1.515(6), C(5)−C(6) 1.510(6), C(6)−C(7) 1.509(6), C(7)−C(8) 1.485(6), O(1)−C(8) 1.297(5), O(2)−C(8) 1.208(5), S(1)−As−S(2) 99.41(5), S(1)−As−C(14) 99.49(11), S(2)−As−C(14) 100.51(11), As−S(1)−C(1) 102.55(14), As−S(2)−C(3) 104.56(13), S(1)−C(1)−C(2) 117.1(3), C(1)−C(2)−C(3) 115.9(3), S(2)−C(3)−C(2) 113.0(3), S(2)−C(3)−C(4) 106.5(3), C(2)−C(3)−C(4) 112.2(3), C(3)−C(4)−C(5) 113.9(3), C(4)−C(5)−C(6) 115.9(3), C(5)−C(6)−C(7) 111.1(4), C(6)−C(7)−C(8) 117.0(4), O(1)−C(8)−O(2) 122.0(4), O(1)−C(8)−C(7) 114.2(4), O(2)−C(8)−C(7) 123.8(4).

The [PhAs(HlipS_2)] molecule is a 1,3,2-dithiarsinane disubstituted at the 2-position (As) and the 4-position [C(3)], i.e. it is a 2-arsa-1,3-dithiacyclohexane derivative. The AsS_2C_3 six-membered ring adopts a chair conformation. While the 4-substituent has an equatorial orientation, the phenyl group is axially orientated. This axial conformational preference of a substituent at the As atom is not unexpected. It has been observed before in related molecules such as 2-phenyl-1,3,2-dithiarsinane (solution)[29] and 5-*tert*-butyl-2-phenyl-1,3,2-dithiaphosphinane (solution and solid state)[30] and seems to be a more general phenomenon. The consequences of the alternative equatorial conformation can be easily deduced from Figure 1. Changing the positions of the stereochemically active lone pair and the phenyl group at As [without rotation about the As−C(14) bond!] would cause severe repulsion between the phenyl *ortho*-H atoms and the four lone electron pairs at S(1) and S(2). Rotation about the As−C(14) bond would reduce this unfavourable energy contribution, but on the other hand it would move one of the *ortho*-H atoms towards the lone electron pair at As.

In the conformation of **1** that is actually adopted, *cis*-axial interactions probably occur between the phenyl group and the axial H atoms at C(1) and C(3). As suggested for substituted 1,3,2-dithiaphosphinanes and their dioxo analogues[30b][31], these van der Waals forces may be weakly attractive. In addition, hyperconjugative interactions in the S_2AsPh moiety, similar to those accepted as a basis for the anomeric effect[32], may contribute to the observed axial orientation of the phenyl group in **1**.

There are no intermolecular contacts to As smaller than the sum of the van der Waals radii. Thus the coordination number of As is three, and the geometry around this atom is pyramidal (ψ-tetrahedral). At least one related compound is known, in which, in contrast to **1**, the coordination sphere of the central atom is expanded by secondary As−S bonds. This compound is $[PhAs\{S_2P(OiPr)_2\}_2]$[33]. In **1** the metrical data of the C(14)AsS(1)S(2) part are unexceptional and fall within the ranges found for four other compounds having aryl-$As^{III}S_2$ moieties[34]: As−S 2.23−2.28, As−C 1.95−1.99 Å; S−As−S 92.7−102.1, S−As−C 94.0−101.3°. The As−S bond lengths in **1** lie marginally below the single-bond value calculated from the covalent radii and corrected for the electronegativity difference[35a].

Two chiral centres are present in [PhAs(HlipS_2)]: the one at C(3) belongs to the reduced lipoic acid and a second one at the arsenic atom. According to the numbering scheme for the 1,3,2-dithiarsinane ring, these are the 2- and the 4-position. The structure determination was performed on a crystal of the (2*RS*,4*RS*) racemate. Figure 1 shows the (2*R*,4*R*) enantiomer.

Stereoisomerism of 1

The crystalline products obtained by methods A and C (see Experimental Section) are (2*RS*,4*RS*)-**1** as found by X-ray structure analysis (see above) and spectroscopic comparison. A freshly prepared solution in $CDCl_3$ shows the expected number of 12 signals in the ^{13}C-NMR spectrum. On standing at room temp. for several days, the diastereomer (2*SR*,4*RS*)-**1** gradually forms in the solution. It gives rise to additional, weak signals in the ^1H- and ^{13}C-NMR spectra. Signals at the same positions are observed for the product prepared by method B, i.e. by melting together *rac*-lipoic acid and $(AsPh)_6$ at 130°C. A quantitative evaluation of the NMR spectra of this product gives a content of the minor isomer (2*SR*,4*RS*)-**1** of ca. 16%.

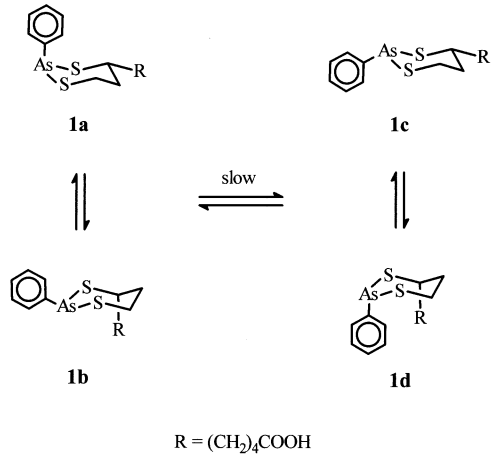
The establishment of equilibrium between the two isomers proceeds much faster in [D_4]methanol than in $CDCl_3$. Starting from pure (2*RS*,4*RS*)-**1**, it is about 90% complete after one day, and after 7 days the final ratio of ca. 85:15 is

attained. This ratio corresponds to $\Delta G = 4.3 \pm 0.8$ kJ/mol at 25°C for the equilibrium shown in Eq. 6.

$$(2RS,4RS)\text{-}\mathbf{1} \rightleftharpoons (2SR,4RS)\text{-}\mathbf{1} \qquad (6)$$

In other words, the (2*RS*,4*RS*) isomer, whose X-ray structure has been determined, is the thermodynamically more stable one. In contrast to **1**, solutions of the compound **2** in $CDCl_3$ exhibit NMR spectra compatible with the pure (2*SR*,4*RS*) isomer. Here further experiments were hampered by the low solubility.

Scheme 3



1a **1c** **1b** **1d**

The equilibrium of Eq. 6 is shown in more detail in Scheme 3. **1a** and **1b** are conformational isomers of (2*R*,4*R*)-**1**, while **1c** and **1d** correspond to (2*S*,4*R*)-**1**. The isomer **1a** is shown in Figure 1. (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** are not considered because they would merely give a mirror image of Scheme 3. In addition to the slow epimerization by inversion of configuration at the arsenic atom, two chair-chair equilibria (**1a/1b** and **1c/1d**) are included. As demonstrated above, (2*R*,4*R*)-**1** is thermodynamically favoured. Under the plausible assumptions that (i) conformations other than chair may be neglected and (ii) the $(CH_2)_4COOH$ substituent prefers the equatorial orientation, it can be concluded that **1a**, together with equal amounts of its enantiomeric form, is the major stereoisomer in solution. Thus, the conjecture that **1c** is most likely the major isomer[18] could not be confirmed.

From the early phase of the transformation of (2*RS*,4*RS*)-**1** into (2*SR*,4*RS*)-**1** in $CDCl_3$ the activation energy can be roughly estimated[35b] at ca. 110 kJ/mol at 25°C if the reaction is assumed to be monomolecular. Mislow and coworkers have found a correlation between the barriers to pyramidal inversion at arsenic and at phosphorus[36]. From this correlation and the activation energy reported for 5-*tert*-butyl-2-phenyl-1,3,2-dithiaphosphinane[30b], a $\Delta G^{\neq}$ value near 180 kJ/mol is expected for **1**. The large discrepancy of ca. 70 kJ/mol can only be accounted for by a mechanism other than a simple pyramidal inversion. Although we did not investigate this problem further, one can hypothesize that acid catalysis by the carboxyl group of **1** may be the determining step. The epimerization would then be self-catalyzed. A possible reaction mechanism involves cleavage of one of the As−S bonds accompanied by protonation of the S atom and $As-O_2C$ bond formation, rotation about the remaining As−S bond, and re-establishment of the first As−S bond by elimination of −COOH. Acid catalysis is consistent with the observed acceleration of the epimerization in [D_4]methanol. While in $CDCl_3$ hydrogen-bonded dimers like those observed in the solid state can be expected, in protic solvents monomers having more easily accessible protons should prevail.

Financial support from the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged. We thank *ASTA Medica AG* for generous donations of *rac*-lipoic acid, Dr. *H. J. Tritschler* for providing us with copies of refs.[11][38a], and Mr. *W. Saak* for helpful discussions and for collecting the diffraction data.

Experimental Section

General: Racemic lipoic acid was obtained as a gift from ASTA Medica AG. Dihydrolipoic acid was prepared by $NaBH_4$ reduction of lipoic acid[37]. The identity of the product and its purity (≥99% based on GC) were checked by high-resolution ^{13}C-NMR spectroscopy (125.8 MHz, $CDCl_3$): δ = 22.03 (C-8), 24.02 (C-3), 26.17 (C-4), 33.67 (C-2), 38.37 (C-5), 39.03 (C-6), 42.48 (C-7), 179.8 (C-1)[38]. Dihydrolipoic acid is a colourless oil which should be stored under nitrogen. Hexaphenylcyclohexaarsane was prepared and purified according to the method described in ref.[39]. All other chemicals were purchased from commercial sources and used without further purification. The solvents were reagent grade. The compounds **1**−**3** were prepared and handled in a glove box under an atmosphere of dry nitrogen. − IR: FT-IR spectrometer Bio-Rad FTS 7PC. − ^{1}H and ^{13}C{^{1}H} NMR: Bruker AM-300, Bruker ARX-500, chemical shifts relative to TMS, solvent signal as internal reference in the ^{13}C-NMR spectra ($CDCl_3$: δ_c = 77.00, [D_4]methanol: δ_c = 49.00). Asterisked signals belong to the minor isomer (2*SR*,4*RS*)-**1**. − MS: Finnigan MAT 212, Finnigan MAT 95. − Elemental analyses: Mikroanalytisches Laboratorium Beller, D-37004 Göttingen, Germany. − *Caution!* Arsenic compounds are highly toxic, and some of them are recognized as human carcinogens. They should therefore be handled with care to avoid exposure.

5-(2-Phenyl-1,3,2-dithiarsinan-4-yl)pentanoic Acid (**1**): *Method A*: 336 mg (2.00 mmol) of phenylarsoxane was added to a solution of 416 mg (2.00 mmol) of *rac*-dihydrolipoic acid in 40 ml of tetrahydrofuran. The solution was stirred for 24 h. Subsequently its volume was reduced in vacuo until an oil remained. From this residue colourless crystals of **1** separated over a two-week period at room temp. The crystals were collected on a glass filter, washed with a small amount of toluene and dried in vacuo. A second crop of crystals was obtained from the filtrate after evaporation. Total yield: 0.43 g (60%), m.p. 97°C. − IR (KBr): $\tilde{\nu}$= 3042 cm^{-1} (w, aryl-CH), 2942 (w, alkyl-CH), 2907 (w, alkyl-CH), 1707 (s, C=O), 1429 (m), 1250 (m), 1206 (m), 745 (m, phenyl group), 370 (m, AsS[40]). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.37−1.66 (m, 6 H), 1.89 (m, 2 H), 2.34 (t, 2 H, CH_2COOH), 2.65 (m, 1 H), 2.83 (m, 2 H), 7.36 (m, 1 H, Ph-*para*), 7.46 ("t", 2 H, Ph-*meta*), 7.87 ("d", 2 H, Ph-*ortho*), 11.5 (br., 1 H, COOH). − ^{1}H NMR (500 MHz, [D_4]methanol; after keeping the solution at room temp. for ca. 7 d): δ = 1.47 (m), 1.58 (m), 1.71 (m)*, 1.82−1.95 (m), 2.21 (m)*, 2.28 (t), 2.66 (m), 2.85 (m), 3.04−3.18 (m)*, 7.40 (m), 7.44 (m)*, 7.50 ("t"), 7.82 (m)*, 7.88 ("d"). − ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = 24.20, 25.07, 27.85, 33.80, 35.73, 38.75, 39.76, 128.7 (Ph-*para*), 129.2, 132.1, 139.2 (Ph-*ipso*), 179.7 (C=O). − ^{13}C NMR (125.8

MHz, [D_4]methanol; after keeping the solution at room temp. for ca. 7 d): δ = 25.58, 25.75*, 26.19, 26.98*, 28.77, 29.85*, 34.77, 36.99, 37.32*, 39.33*, 39.87, 41.01, 46.04*, 129.9, 130.3, 131.4*, 133.1, 133.6*, 140.2*, 140.5, 177.3, 177.4*. − MS (CI, isobutane); *m/z* (%): 359 (100) [MH^+], 341 (14) [$MH^+ - H_2O$], 207 (7) [$MH^+ - C_6H_5As$], 189 (35) [$MH^+ - H_2O - C_6H_5As$]. − $C_{14}H_{19}AsO_2S_2$ (358.4): calcd. C 46.92, H 5.34, As 20.91, S 17.90; found C 47.10, H 5.43, As 20.85, S 18.00.

Method B: An intimate mixture of *rac*-lipoic acid and hexaphenylcyclohexaarsane in a 6:1 molar ratio was heated to 130°C within 1 h. The mixture started melting at ca. 70°C. The clear, initially yellowish melt was kept at 130°C for 3.5 h before it was allowed to cool down to room temp. and to solidify. The reaction was quantitative and yielded a colourless product. − ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = 24.18, 24.28*, 25.04, 25.78*, 27.83, 29.29*, 33.82, 35.71, 36.11*, 38.19*, 38.72, 39.74, 44.84*, 128.7, 128.8*, 129.1, 130.3*, 132.0, 132.6*, 139.2, 179.9.

Method C: *rac*-Dihydrolipoic acid and phenylarsonic acid in a 2:1 molar ratio were dissolved in tetrahydrofuran. The solution turned light yellow due to the formation of lipoic acid. After stirring for 24 h, the solvent was removed in vacuo. Colourless crystals of **1** separated from the remaining oil within 2 weeks. Their IR spectrum was identical with that of the product prepared by method A.

5-[2-(4-Aminophenyl)-1,3,2-dithiarsinan-4-yl]pentanoic Acid (**2**): 434 mg (2.00 mmol) of *p*-aminophenylarsonic acid was added to a stirred solution of 833 mg (4.00 mmol) of *rac*-dihydrolipoic acid in 60 ml of methanol. The arsenic compound slowly dissolved, and after a few hours the yellow colour of lipoic acid emerged. After stirring for 24 h, removal of the solvent in vacuo resulted in the crystallization of small colourless needles of **2**. The product was isolated on a glass filter, washed with a small amount of chloroform and dried in vacuo. Yield 0.53 g (71%), m.p. 122°C. − IR (KBr): $\tilde{\nu}$= 3376 cm^{-1} (m, NH_2), 3302 (w, NH_2), 2932 (w, alkyl-CH), 2868 (w, alkyl-CH), 1707 (s, C=O), 1591 (m), 1495 (m), 1265 (m), 1169 (m), 1074 (m), 818 (m, aryl group), 511 (m), 374 (m, AsS[40]). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.39−1.77 (m, 7 H), 2.12 (m, 1 H), 2.34 (t, 2 H, CH_2COOH), 3.00−3.19 (m, 3 H), 5.6 (br., 3 H, NH_2 and COOH), 6.67 ("d", 2 H, aromatic H), 7.59 ("d", 2 H, aromatic H). − ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = 24.34, 25.71, 30.11, 33.70, 36.54, 38.50, 45.37, 115.1 (H_2NC*C*), 125.5 (AsC), 134.3 (AsC*C*), 148.7 (H_2NC), 178.9 (C=O). − MS (EI, 80 eV); *m/z* (%): 373 (1.4) [M^+], 93 (100) [$C_6H_7N^+$], 66 (50) [$C_5H_6^+$], 65 (37) [$C_5H_5^+$]. − $C_{14}H_{20}AsNO_2S_2$ (373.4): calcd. C 45.04, H 5.40, As 20.07, N 3.75, S 17.18; found C 45.14, H 5.52, As 19.56, N 3.75, S 17.44.

Formation of 6,8-Bis[(dimethylarsanyl)thio]octanoic Acid (**3**) *from Dimethylarsinic Acid and rac-Dihydrolipoic Acid:* 138 mg (1.00 mmol) of $Me_2AsO(OH)$ was added to a stirred solution of 312 mg (1.50 mmol) of *rac*-dihydrolipoic acid in 10 ml of tetrahydrofuran. After stirring overnight, the solvent was evaporated in vacuo. To remove tetrahydrofuran and water completely, the remaining oil was dissolved in dichloromethane, and the solvent was evaporated again. After drying in vacuo, a yellow oil was obtained, which consisted of **3** and lipoic acid in a 1:2 molar ratio. − ^{1}H NMR (500 MHz, $CDCl_3$): The intensities of the signals at δ = 1.24 ($AsCH_3$) and 2.27 (CH_2COOH from **3** and from lipoic acid) were used to determine the product ratio. − ^{13}C NMR (125.8 MHz, $CDCl_3$), **3**: δ = 13.88 ($AsCH_3$), 14.01 ($AsCH_3$), 24.09, 26.10, 28.78, 33.67, 37.04, 40.14, 45.30, 179.7 (C=O). The remaining signals were those of lipoic acid; no signals of unreacted dihydrolipoic acid were found (cf. ref.[38]). − MS (CI, isobutane); *m/z* (%): 416 (32) [M^+], 312 (100) [$MH^+ - As(CH_3)_2$].

X-ray Crystal Structure Analysis of **1**: A suitable single crystal of **1** was obtained from the reaction of *rac*-dihydrolipoic acid with phenylarsonic acid (similar to method C described above). $C_{14}H_{19}AsO_2S_2$, M = 358.36, colourless crystal, crystal size 0.42 × 0.29 × 0.10 mm, triclinic, space group $P\bar{1}$, a = 7.240(1), b = 8.526(1), c = 14.193(2) Å, α = 82.03(1), β = 82.84(1), γ = 67.72(1)°, V = 800.4(2) Å^3, Z = 2, $\rho_{calcd.}$ = 1.487 gcm^{-3}, $F(000)$ = 368, $\mu(MoK_\alpha)$ = 2.38 mm^{-1}. 3983 reflections were measured at 23°C on a Siemens/STOE AED2 diffractometer using graphite-monochromated MoK_α radiation. 5° ≤ 2Θ ≤ 50°, 0 ≤ h ≤ 8, −9 ≤ k ≤ 10, −16 ≤ l ≤ 16, ω/2Θ scans, empirical absorption correction, T_{min} = 0.1803, T_{max} = 0.2880. Structure solution by direct methods[41], refinement on F^2 values (full-matrix least-squares)[42], 2819 independent reflections (R_{int} = 0.0196) of which all were used in the final refinement, 173 parameters, S (on F^2) = 1.097, $R1$ (all data) = 0.0612, $wR2$ (all data) = 0.1079, $R1$ [$I > 2\sigma(I)$] = 0.0438, max. and min. electron density in final difference map: +1.13 and −0.25 eÅ^{-3}. Anisotropic thermal parameters were refined for all non-hydrogen atoms. H atoms were included on idealized positions and were given U values 1.5 (OH) and 1.2 times (CH, CH_2), respectively, the equivalent isotropic displacement factors of the atoms to which they were attached. The H atom of the OH group was allowed to rotate about the C(8)−O(1) bond (AFIX 87 instruction).

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (deposition no. 100410). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: int. code +44(0)1223/336-033, e-mail: deposit@chemcrys.cam.ac.uk).

Formation and Reactivity of Five-Coordinate Gallium Supported by Salen Ligands

Michael S. Hill and David A. Atwood*

Center for Main Group Chemistry, Department of Chemistry, North Dakota State University, Fargo, North Dakota, 58105-5516, USA

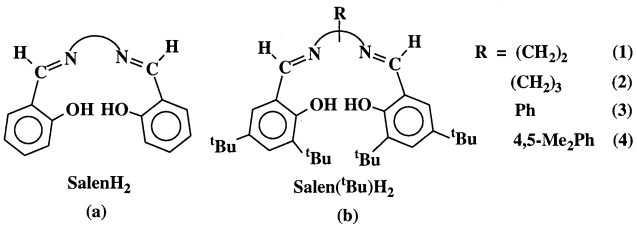
Received May 6, 1997

Keywords: Gallium / Pentacoordination / Salen(*t*Bu)

This work is an exploration into the synthesis and reactivity of five-coordinate gallium complexes of the ligands, Salen(*t*Bu)H_2 [*N,N′*-ethylenebis(3,5-di-*tert*-butylsalicylideneimine), (**1**)], Salpen(*t*Bu)H_2 [*N,N′*-propylenebis(3,5-di-*tert*-butylsalicylideneimine), (**2**)], Salophen(*t*Bu)H_2 [*N,N′*-phenylenebis(3,5-di-*tert*-butylsalicylideneimine), (**3**)], and Salomphen(*t*Bu)H_2 [*N,N′*-(4,5-dimethyl)phenylenebis(3,5-di-*tert*-butylsalicylideneimine), (**4**)]. Fully characterized examples include those of general formula LGaX, where L = **1**, X = Cl (**5**), Et (**6**); **3**, X = Cl (**7**), Et (**10**); **4**, X = Cl (**8**), Me (**9**) Et (**11**). X-ray structural data is presented for **6**, **7**, **9**, **10**, and **11**. The ability of these complexes to undergo either alkane or salt elimination reactions is described. In one reaction the unusual salt: [{Salophen(*t*Bu)Ga(MeOH)}$_2$]$^+$$BPh_4^-$ (**12**) is obtained.

Despite the fact that Salen ligand (Figure 1a) complexes of transition metals[1] have been known for over sixty years,[2] very little has been accomplished with regards to the main group elements. Until recently, monomeric group-13 derivatives of the form, SalenMX (where M = Al, Ga, In and X = halide or alkyl) were uncommon. The first example to be reported was SalpenAlEt.[3] Since that time more have appeared in the literature, including those of aluminum [Salen(*t*Bu)AlX; X = Me, Et, *i*Bu,[4] chloride[5]; SalcenAlEt[6]], indium [Salen(*t*Bu)InX; X = Me, Et, Cl, Br][7] and some aluminum alkoxides[8] and siloxides.[4] The solubilizing influence of the Salen(*t*Bu) ligand (Figure 1b) makes these compounds much more amenable to solution state studies than those of the underivatized Salen ligands (Figure 1a). They provide a unique opportunity to examine the formation and reactivity of the group-13 elements in a five-coordinate geometry. Depending on the nature of the ligand and the substituents on the group-13 element, either a square-pyramidal or trigonal bipyramidal geometry is observed. From these early studies it is clear that there are marked differences in reactivity of the elements in this geometry compared to the more traditional four-coordinate, tetrahedral geometry. The present work will add to this growing base of knowledge on five-coordinate group-13 elements with a description of the first gallium examples. These are of the form LGaX [where L = Salen(*t*Bu)].

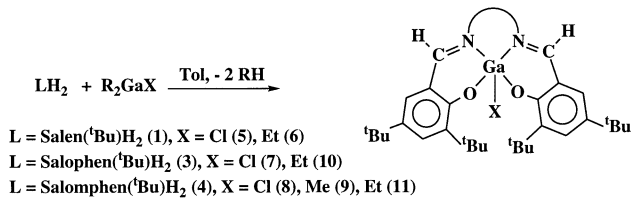
Figure 1. General depiction of the Salen (a) and Salen(*t*Bu) (b) classes of ligands



Results and Discussion

Combining one equivalent of Et_2GaCl with **1** or **2** leads to a mixture of predominantly LGaEt with some LGaCl. In the case of the derivatives obtained from **1**, these products (**5** and **6**) can be separated by fractional crystallization. Similar problems were observed in the formation of the analogous aluminum derivatives. In fact, ligands **1** and **2** most readily form open, bimetallic compounds of the sort $L(MR_2)_2$ (where M = Al, Ga and R = alkyl).[9] Use of the the ligands containing an aryl backbone, **3** and **4**, leads to high yields of the chloride derivatives, **7** and **8** without contamination from any LGaEt products. Likewise, the combination of these ligands with $GaEt_3$ leads to isolation of **10** and **11** in high yields.

Scheme 1. The general synthetic pathway for the preparation of **5**−**11**



Monomeric species are generally obtained in these types of reactions. For all of the compounds the *t*Bu resonances of the ligands are manifested as a pair of singlets in the region δ = 1.3−1.5. Dimeric derivatives normally show more complexity for these resonances. This is the case, for example with {Salen(*t*Bu)Al}$_2$O.[8] Furthermore, the derivatives of **4** contain only one resonance for the Me−Ph group. The Ga−Et groups are observed as well-defined

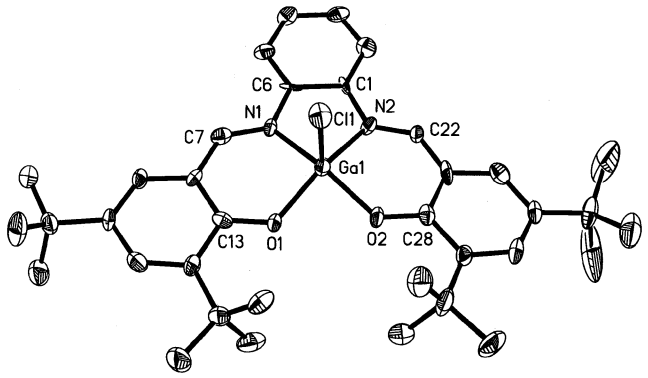
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0067 $ 17.50+.50/0

triplets and quartets. The aryl derivatives show greater deshielding of these groups with shifts in the range of $\delta = 0.2$ and 0.7. Compound **5** is marginally more shielded with values of $\delta = 0.26$ and 0.83.

The Me resonance of **9** occurs at $\delta = 0.59$. This can be compared to the same shift in the four-coordinate derivatives, $Me_3Ga-thf$ ($\delta = -0.3$)[10], $Me_3Ga-NH(iPr)_2$ ($\delta = 0.33$)[11], $Me_3Ga-PPh_3$ ($\delta = 0.17$)[12], and $(Me_3Ga)_2$-diphos ($\delta = 0.15$). From the limited amount of data that is available it would appear that the five-coordinate shifts occur at lower field than those observed for four-coordinate derivatives.

The five-coordinate environment around the gallium atoms was confirmed structurally for **6**, **7**, **9**, **10**, and **11**. The structure of **7** is the third reported for a group-13 halide bound by a Salen(*t*Bu) ligand (Figure 2).[7] The Ga atom is in a distorted square pyramidal geometry with the ligand occupying the basal plane at a $Ga-N_2O_2$ plane distance of 0.49 Å. The chloride occupies the apical site at a distance of 2.199(3) Å. A similar geometry is observed for the methyl derivative, **9** (Figure 3) which has a $Ga-N_2O_2$ plane distance of 0.63 Å. The Ga−O and Ga−N bond distances shorten by comparison to **7**. Compare, for instance, the Ga−O axial distances (ave = 1.87 Å for **7** and 1.90 Å for **9**). This is a result of the lessened inductive effect of the Me group when compared to Cl. The Ga−Me distance [1.939(5) Å] is fairly standard for four- and five-coordinate compounds.[9][10][11] For example this distance in $[Me_2GaNH(tBu)]_2$ and $Me_3Ga-NH_2(tBu)$ is 1.978(7) Å and 2.01(1) Å, respectively.[13] Compound **9** is actually dimeric in the solid state. The two monomeric units are held together by a relatively close Ga···H (from a Ph−Me group) contact of approximately 3.1 Å.

Figure 2. Molecular structure and atom numbering scheme for Salophen(*t*Bu)GaCl (**7**)



Compound (**6**) adopts a geometry that may best be described as distorted square pyramidal (Figure 4). It contains a fairly obtuse angle [O(2)−Ga(1)−N(1)] of 153.2(4)° that is indicative of a trigonal bipyramidal distortion. Compounds **10** and **11** are more ideally square-pyramidal as a result of the enforced planarity inherent to the aryl backbones of ligands **3** and **4** [a figure (Figure 5) is provided for **10** only]. The $Ga-N_2O_2$ plane distances for **6**, **10**, and **11** are close to one another with values of 0.67 Å, 0.63 Å, and 0.64 Å, respectively. The $Ga-CH_2$ distance does not vary substantially based upon the geometry of the gallium.

Figure 3. Molecular structure and atom numbering scheme for Salomphen(*t*Bu)GaMe (**9**)

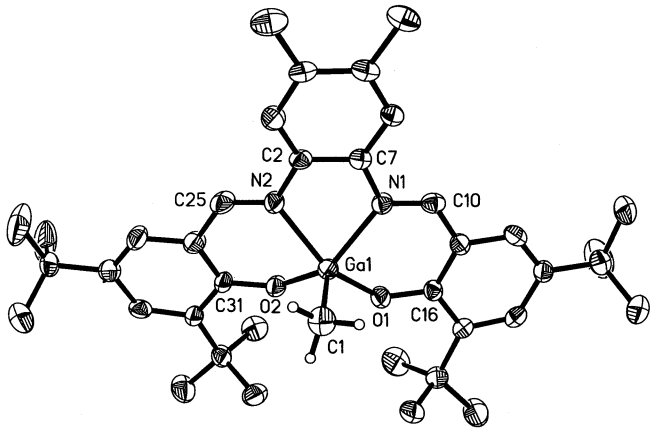


Figure 4. Molecular structure and atom numbering scheme for Salen(*t*Bu)GaEt (**6**)

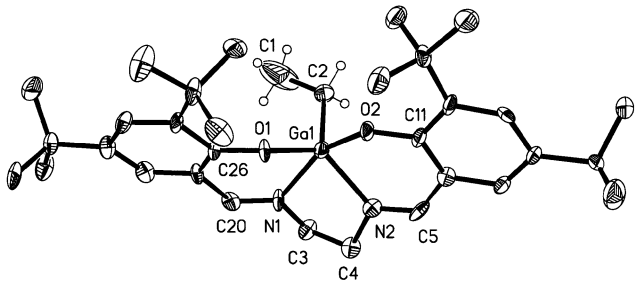

Figure 5. Molecular structure and atom numbering scheme of Salophen(*t*Bu)GaEt (**10**)

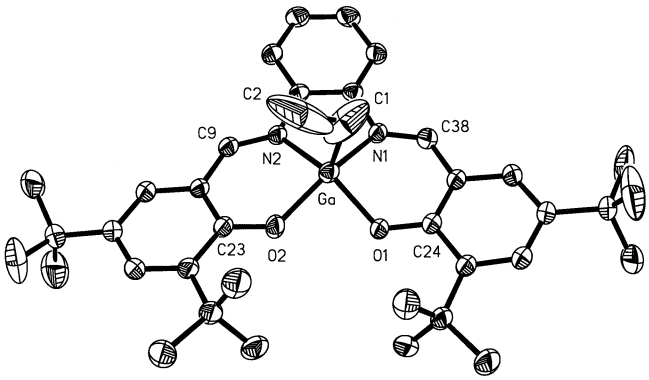
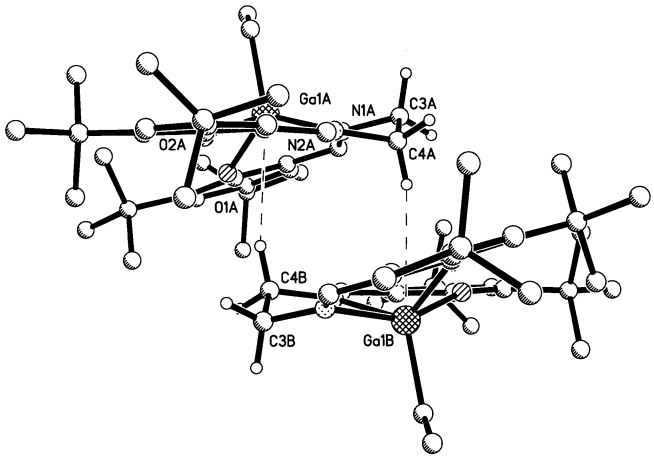


In a manner similar to compound **9**, one of the ethylene hydrogen atoms of **6** is close (3.15 Å) to the gallium atom of a second Salen(*t*Bu)GaEt unit (Figure 6). Dimerization through such close contacts is becoming commonplace in these types of structures.[7] They are also observed in square pyramidal indium derivatives. This may be an indication

that a sixth coordination site may be available, at least to small nucleophiles, in these compounds.

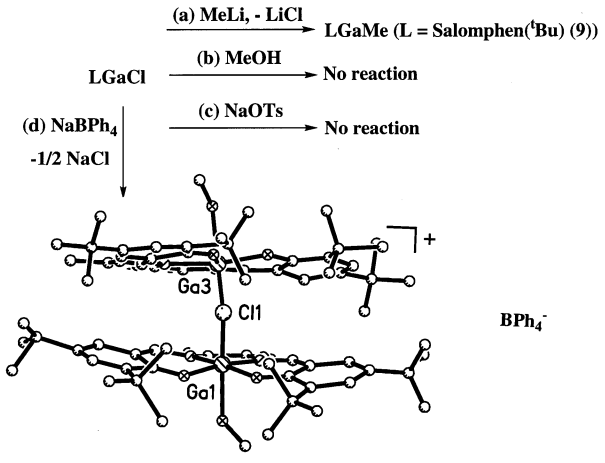
Figure 6. Dimerization of **6** through hydrogen contacts



Reactivity Studies

The gallium halide derivative **8** will undergo a salt elimination reaction with MeLi to form the methyl derivative, **9** [Scheme 2(a)]. The same type of product is obtained in the analogous reaction with indium.[7] However, the gallium halide complexes will not undergo halide displacement with Lewis bases such as MeOH [Scheme 2(b)]. This is in contrast to the same reaction for aluminum in which cationic complexes are formed (eg. $[SalenAl(MeOH)_2]^+Cl^-$).[14] Similarly, salt eliminations with the gallium halides and NaOTs (OTs = toluenesulfonic acid) do not occur [Scheme 2(c)] despite the fact that, for aluminum, a wide range of cations ($[SalenAl(base)_2]^+OTs^-$) can be accessed in this manner.[14] For these two reactions [Scheme 2(b) and (c)] gallium and indium behave identically.

Scheme 2. Reactions involving the five-coordinate halide derivatives



(12)

Cationic aluminum complexes can also be formed containing $[BPh_4]^-$ as the anion. While this reaction was not successful for indium, a new product can be isolated when using gallium. The product is the unusual salt comprised of a cation containing two gallium atoms and the BPh_4 counter-anion [Scheme 2(d)]. The ^{1}H-NMR data is complex and difficult to interpret. However, the results of a partial crystal structure determination and elemental analyses confirms the proposed formulation. Unfortunately, the structure is complicated by the presence of as many as five molecules of MeOH in the independent unit so the structure could not be satisfactorily refined.[15] It can be viewed as being an adduct between the cationic species, $Salen(t\text{Bu})Ga(MeOH)_2]^+$ and a neutral Salen(*t*Bu)GaCl molecule. Within the limits of the quality of the structure, both of the Ga−Cl distances are the same (ca. 2.0 Å) and form a Ga−Cl−Ga′ angle of 149°. That species like **12** may, in fact, represent a new class of bimetallic compounds is evidenced by the Ti^{III} compound, $[\{(acacen)Ti(NO_3)\}_2O]$ (acacen = *N,N′*-ethylenebisacetylacetoneiminato) which has been used to prepare a range of interesting oligomeric metal-chelate derivatives.[16] It will be interesting to see if compound **12** can be utilized similarly.

Gratitude is expressed to the *National Science Foundation* (Grant 9452892) and the donors of the *Petroleum Research Fund* (Grant 31901-AC3), administered by the *American Chemical Society*, for support. The receipt of an *NSF-CAREER Award* (CHE 9625376) is also gratefully acknowledged.

Experimental Section

General Considerations: All manipulations were conducted using Schlenk techniques in conjunction to an inert atmosphere glove box. All solvents were rigorously dried prior to use. − NMR data were obtained on JEOL-GSX-400 and -270 instruments at 270.17 (^{1}H) and are reported relative to $SiMe_4$ and in ppm. − Elemental analyses were obtained on a Perkin-Elmer 2400 Analyzer. − Infrared data were recorded as KBr pellets on a Matheson Instruments 2020 Galaxy Series spectrometer and are reported in cm^{-1}. The reagent 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde was prepared according to the literature.[17] − All of the X-ray data was collected on a Siemens SMART-CCD unit. A complete data set was collected (Θ = 55°) in each case although this number could be reduced to provide a better structure in the final stages of the structure determination. All of the hydrogen atoms were placed into calculated, idealized positions. The structures were solved with the Siemens SHELXTL-Plus suite of programs.

Reaction of Salen(tBu)H$_2$ and Et$_2$GaCl: To a stirred solution of Et_2GaCl, prepared in situ from triethylgallium (0.32 g, 2.03 mmol) and gallium trichloride (0.18 g, 1.02 mmol) in toluene (20 ml), was added Salen(*t*Bu)H_2 (1.50 g, 3.05 mmol). The resultant yellow solution was refluxed for a total of 14 h before removal of solvent in vacuo to yield a yellow solid. NMR analysis of this material indicated a single major product identified as Salen(*t*Bu)GaCl (ca. 60% by integration) and a number of minor products. Attempted fractional cystallisation from methanol solution yielded yellow crystals identified as Salen(*t*Bu)GaEt by single crystal X-ray analysis [0.10 g, 5.5% based on Salen(*t*Bu)H_2, m.p. 223 °C]. Attempts to isolate an analytically pure sample of Salen(*t*Bu)GaCl however were unsuccessful.

[a] All of the data sets were collected to 55°. The range was narrowed during refinement to improve the structure solution.

Salen(tBu)GaCl (**5**): ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.10 [s, 18 H, C(CH_3)$_3$], 1.40 [s, 18 H, C(CH_3)$_3$], 3.80−4.18 (m, ca. 4 H, CH_2CH_2), 6.72 (s, 2 H, Ar-*H*), 7.47 (s, 2 H, Ar-*H*), 8.50 (s, 2 H, Ar-C*H*).

Salen(tBu)GaEt (**6**): ^{1}H NMR (270 MHz, $CDCl_3$): δ = 0.26 (q, 2 H, CH_2Ga), 0.83 (t, 3 H, CH_2CH_3), 1.27 [s, 18 H, C(CH_3)$_3$], 1.50 [s, 18 H, C(CH_3)$_3$], 3.66−3.68 (m, 2 H, CH_2CH$_2$), 3.83−3.85 (m, 2 H, CH$_2$CH_2) 6.87 (s, 2 H, Ar-*H*), 7.40 (s, 2 H, Ar-C*H*), 8.27 (s, 2 H, Ar-*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2953 s, 2903 s, 2864 s, 1649 s, 1618 s, 1535 s, 1440 m, 1411 m, 1303 m, 1253 m, 1199 m, 1168 m, 1055 w, 979 w, 877 w, 831 w, 787 m, 742 m, 700 w, 667 w, 561 w, 462 w. − $C_{34}H_{51}GaN_2O_2$ (589.49): calcd. (found) C 69.30 (69.36), H 8.66 (8.37), N 4.76 (4.63).

Reaction of Salpen(tBu)H$_2$ and Et$_2$GaCl: An identical procedure to that described above, utilizing triethylgallium (0.319 g, 2.03 mmol), gallium trichloride (0.179 g, 1.02 mmol) and Salpen(*t*Bu)H$_2$ (1.544 g, 3.05 mmol) in toluene solution (20 ml), provided a pale green solid upon removal of the solvent. This was demonstrated to be a complex mixture of products by ^{1}H NMR and proved insensitive to further purification by fractional crystallization in a variety of polar and non-polar solvents.

Synthesis of Salophen(tBu)GaCl (**7**): This compound was synthesized utilizing a similar procedure to that described above, employing triethylgallium (0.194 g, 1.23 mmol), gallium trichloride (0.109 g, 0.62 mmol) and Salophen(*t*Bu)H$_2$ (1.00 g, 1.85 mmol) in toluene solution (20 ml). In vacuo removal of solvent afforded the title compound as a pale orange solid in stoichiometric yield which could be crystallized from methanol solution as pale orange crystals suitable for X-ray analysis (0.98 g, 82%) m.p. >260 °C. ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.33 [s, 18 H, C(CH_3)$_3$], 1.58 [s, 18 H, C(CH_3)$_3$], 7.14 (s, 2 H, Ar-*H*), 7.40 (m, 2 H, Ar-*H*), 7.62 (s, 2 H, Ar-*H*), 7.72 (m, 2 H, Ar-*H*), 8.92 (s, 2 H, Ar-C*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2959 s, 2906 m, 2868 m, 1614 s, 1583 s, 1533 s, 1465 m, 1388 m, 1359 m, 1315 w, 1257 m, 1026 w, 835 w, 785 w, 744 m, 540 w. − $C_{72}H_{92}Cl_2Ga_2N_4O_4$ (1287.84): calcd. (found) C 67.16 (67.37), H 7.15 (6.95), N 4.35 (4.17).

Synthesis of Salomphen(tBu)GaCl (**8**): This compound was synthesized by a similar procedure to that outlined above employing triethylgallium (0.276 g, 1.76 mmol), gallium trichloride (0.158 g, 0.88 mmol) and Salomphen(*t*Bu)H$_2$ (1.50 g, 2.64 mmol). In vacuo removal of the solvent produced an orange solid [containing ca.

in vacuo removal of solvent produced a red-brown solid which was recrystallized from methanol in air to yield the title compound as a dihydrate as orange crystals suitable for single crystal X-ray analysis (0.15 g, 65%) m.p. >260 °C. − ^{1}H NMR (270 MHz, $CDCl_3$): δ = −0.59 (s, 3 H, Ga-CH_3), 1.3 [s, 18 H, C(CH_3)$_3$], 1.52 [s, 18 H, C(CH_3)$_3$], 2.36 (s, 6 H, Ph-CH_3), 3.48 (br. s, 4 H, H_2O), 7.04 (s, 2 H, Ar-*H*), 7.40 (s, 2 H, Ar-*H*), 7.48 (s, 2 H, Ar-*H*), 8.66 (s, 2 H, Ar-C*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2962 s, 2918 m, 2874 m, 1616 s, 1591 s, 1465 w, 1398 m, 1259 m, 1172 m, 1016 m, 808 m, 787 w, 705 w, 491 w. − $C_{39}H_{57}GaN_2O_4$ (687.59): calcd. (found) C 68.35 (68.48), H 8.03 (8.17), N 4.09 (4.67).

Synthesis of Salophen(tBu)GaEt (**10**): A solution of $GaEt_3$ (0.29 g, 1.85 mmol) in toluene (5 ml) was added at room temperature to a stirred solution of Salophen(*t*Bu)H_2 (1.0 g, 1.85 mmol) in toluene (15 ml). The initial golden yellow solution was stirred for 2 h at which point the solvent was removed to yield a pale brown solid. NMR analysis of this material indicated a mixture of products. The solid was redissolved in a further 20 ml of toluene and refluxed for 15 h producing an orange/brown solution. Removal of solvent and subsequent recrystallisation from a hexane/toluene solution yielded the title compound as ruby-red rectangular crystals suitable for X-ray analysis. (1.00 g, 81%). m.p >260 °C. − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 0.23 (q, 2 H, CH_2Ga), 0.73 (t, 3 H, CH_2CH_3), 1.32 [s, 18 H, C(CH_3)$_3$], 1.54 [s, 18 H, C(CH_3)$_3$], 7.02 (d, 2 H, Ar-*H*), 7.34−7.36 (m, 2 H, Ar-*H*), 7.50 (d, 2 H, Ar-*H*), 7.61−7.64 (m, 2 H, Ar-*H*), 8,70 (s, 2 H, Ar-C*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2960 s, 2918 m, 2866 m, 1612 s, 1581 s, 1529 s, 1465 w, 1435 w, 1386 m, 1357 w, 1259 m, 1174 m, 1106 m, 1026 m, 866 w, 802 m, 748 m, 528 m. − $C_{38}H_{51}GaN_2O_2$ (637.53): calcd. (found) C 71.62 (71.31), 8.01 (7.75), N 4.40 (4.20).

5% Salomphen(*t*Bu)GaEt by NMR] which was recrystallized from hexane/toluene solution at −30 °C to yield the title compound as an orange microcrystalline solid (1.35 g, 76%) m.p. >260 °C. − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.33 [s, 18 H, C(CH_3)$_3$], 1.58 [s, 18 H, C(CH_3)$_3$], 2.36 (s, 6 H, Ar-CH_3), 7.14 (s, 2 H, Ar-*H*), 7.49 (s, 2 H, Ar-*H*), 7.60 (s, 2 H, Ar-*H*), 8.87 (s, 2 H, Ar-C*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2960 s, 2908 m, 2868 m, 1616 s, 1591 s, 1550 s, 1465 m, 1435 m, 1388 m, 1359 m, 1249 m, 1176 s, 1134 w, 1024 w, 839 m, 785 m, 746 w, 653 w, 538 w, 505 w. − calcd. (found) C 67.94 (67.51), H 7.45 (7.63), N 4.17 (3.97).

Synthesis of Salomphen(tBu)GaMe (**9**): Salomphen(*t*Bu)GaCl (0.25 g, 0.37 mmol) was dissolved in diethyl ether (20 ml) and stirred at −78 °C. MeLi (0.27 ml, 1.4 M in diethyl ether, 0.37 mmol) was added producing a deep brown solution. This was allowed to warm to room temperature before evaporation of the solvent to produce a brown solid. Extraction in toluene (15 ml), followed by

Synthesis of Salomphen(tBu)GaEt (**11**): This compound was synthesized by an identical procedure as that outlined for Salophen(*t*Bu)GaEt from $GaEt_3$ (0.28 g, 1.76 mmol) and Salomphen(*t*Bu)H_2 (1.00 g, 1.76 mmol), recrystallisation from a hexane/toluene solution yielding the title compound as an orange rectangular crystals suitable for X-ray analysis. (1.06 g, 87%). m.p. >260 °C. − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 0.19 (q, 2 H, CH_2Ga), 0.71 (t, 3 H, CH_2CH_3), 1.33 [s, 18 H, C(CH_3)$_3$], 1.54 [s,

18 H, C(CH_3)$_3$], 2.35 (s, 6 H, Ar-CH_3), 7.03 (d, 2 H, Ar-*H*), 7.40 (s, 2 H, Ar-*H*), 7.49 (s, 2 H, Ar-*H*), 8.67 (s, 2 H, Ar-C*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2962 s, 2910 m, 1618 s, 1593 m, 1548 m, 1410 w, 1261 m, 1174 m, 1089 m, 1018 m, 800 m, 534 w. − $C_{40}H_{56}GaN_2O_2$ (666.84): calcd. (found) C 72.21 (71.94), H 8.27 (8.25), N 4.21 (3.98).

Synthesis of {[Salomphen(tBu)Ga·MeOH]$_2$Cl}BPh$_4$ (**12**): Salomphen(*t*Bu)GaCl (0.30 g, 0.47 mmol) and sodium tetraphenylborate (0.16 g, 0.47 mmol) were stirred as a pale orange solution in methanol (15 ml) for 14 h. At this point the solution was reduced in volume to ca. 5 ml and allowed to crystallise by slow evaporation of the solvent. This produced the title compound as heavily solvated orange needles suitable for X-ray analysis. This material could be converted to a red unsolvated form by storage under vacuum for several hours (total yield, 0.41 g, 52%) m.p. 208−213 °C (dec). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 0.77−1.56 [complex multiplet, 72 H, C(CH_3)$_3$], 2.46−2.54 (m, 12 H, Ph-CH_3), 3.35 (s, 6 H, HO-CH_3), 6.43−7.60 (m, 32 H, Ar-*H*). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2960 s, 2906 m, 2872 m, 1614 s, 1587 m, 1533 s, 1465 m, 1435 m, 1390 m, 1359 m, 1251 m, 1180 m, 1081 m, 806 w, 702 w, 613 w, 540 w, 503 w. − calcd. (found) C 72.62 (73.02), H 7.47 (7.36).

Attempted Reactions:

Salophen(tBu)GaCl and NaOTs (in Dichloromethane): Sodium *p*-toluenesulfonate (0.1 g, 0.51 mmol) was added as a solid to a stirred solution of Salophen(*t*Bu)GaCl (0.25 g, 0.39 mmol) in 15 ml of CH_2Cl_2, thf, or MeO H, dichloromethane (15 ml). The resultant suspension was stirred for 14 h before filtration and evaporation of the solvent to yield an orange solid. This was demonstrated to be unreacted Salophen(*t*Bu)GaCl by ^{1}H NMR.

Crystallographic data (excluding the structure factor tables) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication CCDC-100614. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: int. code +44 (0)1223/336-033; E-mail: deposit@chemcrys.cam.ac.uk].

Water Soluble Phosphanes, IX[◇]

Nucleophilic Phosphanylation of Fluoroaromatic Compounds with Carboxyl, Carboxymethyl, and Aminomethyl Functionalities – an Efficient Synthetic Route to Amphiphilic Arylphosphanes

Martin Hingst, Michael Tepper, and Othmar Stelzer*

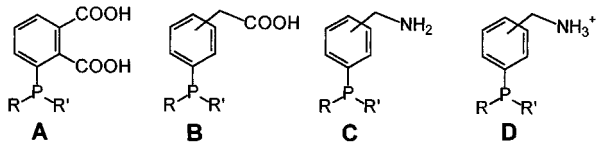
Received May 6, 1997

Keywords: Nucleophilic phosphanylation / Phosphanylphthalic acid / Phosphanylphenylacetic acid / Benzylaminophosphanes / Water solubility

Chiral- and multiply-carboxylated phosphanes and phosphanyl derivatives of benzoic and phthalic acids (**1**–**9**) are accessible in high yields by nucleophilic phosphanylation of potassium or lithium salts of commercially available fluorobenzoic and 3-fluorophthalic acids with Ph_2PH, Ph_2PK, $PhPLi_2$, $Ph(K)P-(CH_2)_3-P(K)Ph$ in superbasic media (DMSO/KOH) or in THF and DME. The hitherto unknown phosphanylphenylacetic acids (**10**–**13**) and phosphanylbenzylamines $RR'P-C_6H_4-CH_2-NH_2$ (**14**–**19**, R, R′ = H, Me, Ph) with unsubstituted amino groups were also synthesized by this method. The diphenylphosphanyl derivatives **14**–**16** (R, R′ = Ph) are accessible by an alternative method involving $LiAlH_4$ reduction of the phosphanylbenzonitriles (**20**–**22**), which were obtained in high yields by nucleophilic phosphanylation of the corresponding fluoro- or chlorobenzonitriles. The novel bidentate phosphanylbenzonitrile **23** has also been obtained using this synthetic route. All compounds were completely characterized by elemental analysis, NMR spectroscopy, and mass spectrometry.

Aromatic phosphanes with carboxylated side chains, e.g. $Ph_2P-(CH_2)_n-COOH$, $Ph_2P-C_6H_4-2$-COOH, have been extensively employed as components in catalysts for the oligomerization, polymerization, telomerization and hydroformylation of olefins[2a][2b][2c][2d]. Thus, the catalyst used for the two phase oligomerization of olefins in the "Shell higher olefin process" (SHOP)[2e] is prepared by reaction of bis(cyclooctadiene)nickel(0) with diphenylphosphanylacetic acid. Reduction/substitution reactions performed on pertechnate leads to neutral technetium(III) complexes with carboxylated phosphanes in which the phosphane ligands act as O,P-bidentate systems. The biodistribution of the corresponding ^{99m}Tc labelled species has been studied[2f].

The *o*-, *m*-, and *p*-isomers of diphenylphosphanylbenzoic acid have been reported earlier. These compounds are accessible by multistep[3a][3b][3c] or protective group synthesis[3d], but only in moderate overall yields. Despite the keen interest in these ligands, there are no reports in the literature so far on their higher carboxylated analogs (**A**) or derivatives containing CH_2 spacers between the aromatic ring and the COOH-groups ("phosphanylphenylacetic acids" **B**). Compounds of type **A**, which contain an additional set of hard donor atoms, should show enhanced solubility in water, and both of these factors are important for the application of these ligands in two-phase catalysis[4]. Ligands of type **B** contain activated CH_2 groups and, in addition, the carboxylate substituents are connected in a more flexible manner to the rigid aromatic ring systems. For the sake of comparison we have included phosphanylbenzylamines **C** in our study, and these systems contain aminomethyl groups. These groups can be protonated to give novel cationic water soluble phosphanes **D**. Ligands of this type, bearing quaternary ammonium groups, form palladium complexes with phase transfer properties. They are effective catalysts for the fluorocarbonylation of bromobenzene with CO and KF[4b].



Ligands with functionalized peripheries are of increasing interest[5a] because of their potential for further derivatization, e.g. by esterification with diols to give functionalized linear polymers suitable as insoluble supports for the immobilization of catalysts[5b].

As part of a project aimed at the development of tailor made water soluble phosphanes[6] for two-phase catalysis we have developed new synthetic procedures for these ligands based on nucleophilic phosphanylation of suitable functionalized fluoro-aromatic compounds under different conditions.

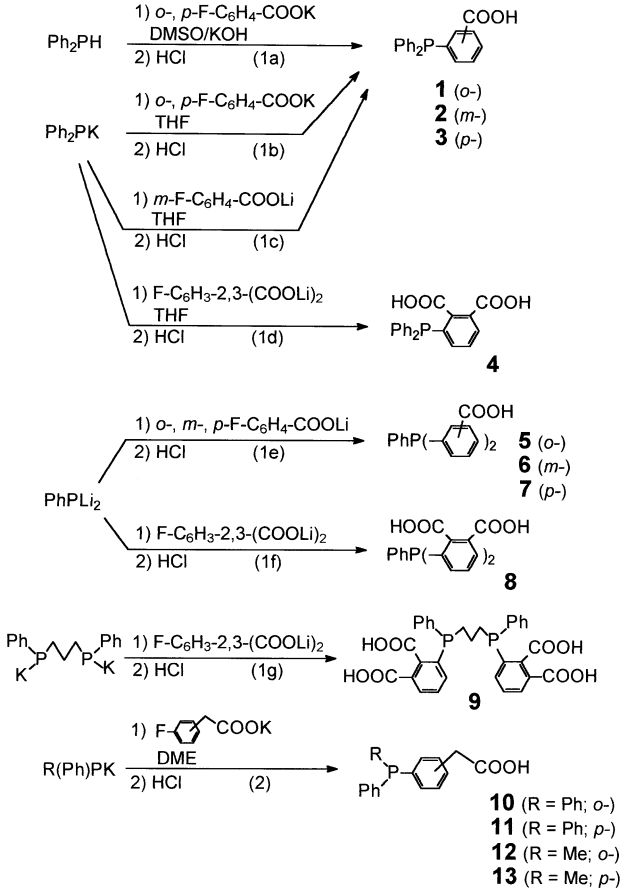
Nucleophilic Phosphanylation of Fluorobenzoic and Fluorophthalic Acids

Nucleophilic displacement of the halogen (X) in aromatic compounds X−C_6H_4−Z (X = F, Cl, Br; Z = NO_2, SO_3H, COOH) that contain electron withdrawing substituents (Z), proceeds much faster with the fluoro- than with the chloro- or bromo-compounds. This is well established for the halonitrobenzenes[7a][7b] and a variety of substituted aromatic amines has been obtained by making use of the pronounced reactivity of activated fluorobenzene derivatives towards nitrogen nucleophiles[7c]. The phosphanylation of the commercially available fluorobenzoic or fluorophthalic acids should in an analogous way lead to phosphanylbenzoic or phosphanylphthalic acids. This transformation can be performed in "superbasic" media[8], using secondary or primary phosphanes and solid KOH as the base in aprotic dipolar solvents (e.g. dimethyl sulfoxide). Alternatively, alkali metal phosphides such as Ph_2PK or $PhPLi_2$ can be employed for these nucleophilic aromatic substitution reactions in solvents like 1,2-dimethoxyethane (DME) or tetrahydrofuran (THF).



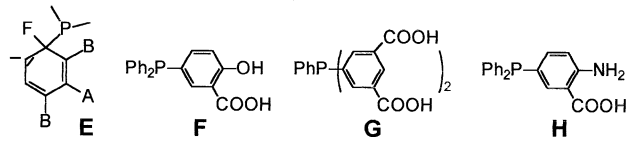
The nucleophilic phosphanylation of *p*-fluorobenzoic acid with Ph_2PH in the superbasic medium at 60 °C afforded the potassium salt of the phosphane **3** in a straightforward manner (eq. 1a). However, the corresponding reaction with the *o*-isomer gave only poor yields of **1**. Diphenylphosphane oxide $Ph_2P(H)O$[9a] and Ph_2PMe[9b] are formed by oxidation of Ph_2PH (Ph_2PK) with DMSO followed by subsequent dealkylation of the intermediate Me_2S with Ph_2PK[10] (eq. 3a,b). The potassium salt of *m*-fluorobenzoic acid did not react with Ph_2PH under these conditions. The COOK substituent in the *m*-position clearly does not activate the fluorine sufficiently for nucleophilic displacement to occur under these conditions.

$$Ph_2PH + Me_2SO \longrightarrow Ph_2P(O)H + Me_2S \quad (3a)$$

$$Me_2S + Ph_2PK \longrightarrow Ph_2PMe + MeSK \quad (3b)$$

If a solution of Ph_2PK in THF is used, then 2-F−C_6H_4−COOK could be phosphanylated to give the phosphane **1** in fair yield (eq. 1b). The *m*-isomer 3-F−C_6H_4−COOK, however, did not react at all even after prolonged reaction times. This might, at least in part, be due to the fact that 3-F−C_6H_4−COOK could not be obtained in a completely anhydrous form. 3-F−C_6H_4−COOK and 2-F−C_6H_4−COOK were prepared by neutralization of the corresponding acids with KOH in aqueous solution and heating the hydrates left after evaporation of water in vacuo at 100−120 °C for a couple of hours. The use of the anhydrous lithium salt 3-F−C_6H_4−COOLi instead of 3-F−C_6H_4−COOK resulted in phosphanylation with Ph_2PK in THF to afford **2** after work up of the reaction mixture (eq. 1c). Anhydrous 3-F−C_6H_4−COOLi can be obtained by deprotonation of the free acid with *n*BuLi or, preferably, $LiN(SiMe_3)_2$[11].

The bis(carboxyphenyl)phosphanes **5**−**7** are accessible, in an analogous way to that described above, by phosphanylation of the lithium salts of the corresponding fluorobenzoic acids with $PhPLi_2$ in THF (eq. 1e). In the case of the *m*-isomer of F-C_6H_4−COOLi, the nucleophilic aromatic substitution proceeds much slower than the corresponding reaction with the *p*- and *o*-isomers. This can be understood in terms of the different stabilization of the Meisenheimer type intermediate **E**[7b] by the COOH/COO^--substituents in the *m*- or *p*- and *o*-position to the fluoro substituent. The synthetic procedure developed for **5**−**7** can be extended to phthalic acid derivatives. Thus, nucleophilic phosphanylation of the Li-salt of 3-fluorophthalic acid with Ph_2PK or $PhPLi_2$ gave **4** or **8** after an acid workup procedure (eq. 1d,f). In the same way, Ph(K)P−$(CH_2)_3$−P(K)Ph was treated with 3-F−C_6H_3−1,2-$(COOLi)_2$ to yield the chiral bidentate tetracarboxylated phosphane **9** (eq. 1g).



The potassium salts of the phthalic acid derivatives obtained by neutralization of **4**, **8**, and **9** with KOH are highly soluble in water [0.8, 1.3, and 1.0 kg/kg water (20 °C), respectively].

Very recently we have found that carboxylated phosphanes (**1**−**7**) including salicylic, isophthalic, and anthranilic acid derivatives (**F**−**H**) can alternatively be synthesized by Pd-catalyzed P−C coupling reactions between primary

or secondary phosphanes and the corresponding functionalized iodo- or bromo-aromatic compounds[1,12].

The electron impact mass spectra of the phosphane ligands with monocarboxylated phenyl groups (**1**−**3**, **5**−**7**) all show the M^+ peak. Proximity effects[13] in the molecular ions of the *o*-carboxylated phosphanes (**1**, **5**) lead to the loss of CHO from the molecular ion. In the case of the phthalic acid derivatives **4**, **8**, and **9**, the peaks of highest *m*/*z* correspond to ions formed by loss of one or two molecules of H_2O.

Synthesis of Phosphanylphenylacetic Acids

The multiple functionality of the CH_2−COOR(H) group means that phosphanylphenylacetic acids and their esters should show an extended reactivity pattern (e.g. ester condensation) in comparison with benzoic and phthalic acid phosphanes of type **1**−**8**. This can be used for the design of tailor-made ligands with chiral backbones by the modular approach, as reported by Trost, van Vrancken and Bingel[14].

Nucleophilic phosphanylation of fluorophenylacetic acids in dimethoxyethane (DME) was employed for the synthesis of phosphanylphenylacetic acids. The intermediate of type **E**, formed in the rate determining step of these S_N2(Ar) processes, cannot be stabilized by the mesomeric effects of the substituents, and so the nucleophilic replacement is expected to proceed much slower than the analogous reaction of the fluorobenzene derivatives F−C_6H_4−Z [Z = CN (see below), COO^-, SO_3^-] with activating substituents. The weakly electron-withdrawing CH_2COO^- group can only activate the C−F bond in the *ortho* position due to its inductive effect. Thus, the reaction of the potassium salts of *o*- or *p*-fluorophenylacetic acid with Ph_2PK in DME requires 24 h reflux to give the respective isomers of diphenylphosphanylphenylacetic acid (**10**, **11**), after acidification of the reaction mixtures, in satisfactory yields (eq. 2). The P-chiral derivatives (**12**, **13**) can be prepared in an analogous way using Ph(Me)PK instead of Ph_2PK. Potassium fluorophenylacetate (*o*- or *p*-isomer) was obtained by neutralization of the appropriate free acids with a solution of KOH in methanol, followed by heating the solid left after evaporation of the solvent in vacuo (60 °C, 0.01 mbar)[15].

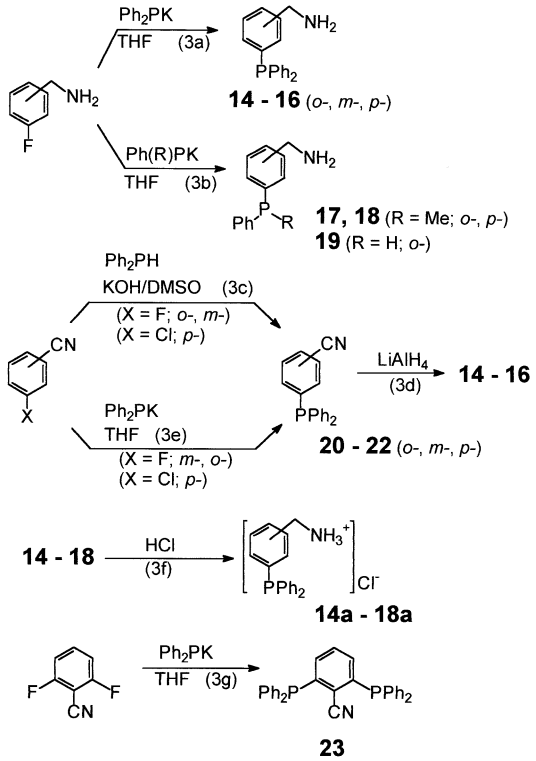
The molecular ion peaks in the mass spectra of the phosphanylphenylacetic acids are of high intensity (**10**) or represent the base peaks (**11**−**13**). The fragmentation pathway leads to the 9-phosphafluorenylium ions[16][17] at *m*/*z* = 183 or 197.

The solubilities of the alkali metal salts of the *p*-diphenylphosphanylphenylacetic acids in water (20 °C) are significantly higher than those of the corresponding *o*-isomers (e.g. Na^+ **10**: 130; Na^+ **11**: 750 g/kg water).

Synthesis of Phosphanylbenzylamines

Phosphanylbenzylamines with a primary amino group are of interest as starting materials for the synthesis of polymerizable phosphanes by acylation with acryl- or methacryloyl chloride[5a]. A new method for preparing water-soluble phosphanes by coupling of the phosphanylbenzylamine $Ph_2P-C_6H_4-CH_2$−4-NH(Me) to polyacrylic acid has very recently been reported[18]. Attempts to prepare phosphanylbenzylamines with a primary amino group by protective group synthesis via their 2,5-dimethylpyrrole derivatives or stabase (cyclic disilazane) adducts have so far been unsuccessful[5a].

We found, however, that phosphanylbenzylamines are accessible in a straightforward manner using a procedure analogous to that employed for the synthesis of the phosphanylphenylacetic acids **10**−**13**. Thus, reaction of *o*-, *m*-, or *p*-fluorobenzylamine with Ph_2PK in DME produced the phosphanes **14**−**16** in good yields. Chiral tertiary (**17** and **18**) and even secondary phosphanylbenzylamines (**19**) are accessible by this synthetic route if Ph(Me)PK or PhPHK are used instead of Ph_2PK (eq. 3a,b)[15].



The phosphanylbenzylamines **14** and **15** have been synthesized using an alternative route involving reduction of the cyanophenylphosphanes **20** and **21**[3b][3c][19] with $LiAlH_4$. The cyanophenylphosphanes are attractive starting materials since they can be obtained by a convenient method and in high yields by direct phosphanylation of the corresponding fluoro- or chlorobenzonitriles with Ph_2PH in the superbasic medium DMSO/KOH (eq. 3c,d). The same applies for the *m*-isomer **21**. Somewhat lower yields of the cyanophenylphosphanes (**20**−**22**) are obtained if the phosphanylation of the halobenzonitriles are performed with Ph_2PK in THF (eq. 3e). In both cases the nucleophilic aromatic substitution proceeds almost instantaneously, even at room temperature or below. The synthesis of the cyanophenylphosphanes **20**−**22** according to eq. 3c is therefore

superior to the methods reported in the literature[3b][3c][19].

o-Cyanophenyldiphenylphosphane (**20**) was obtained by nucleophilic phosphanylation of 2-F−C_6H_4−CN according to eq. 3c and 3e in a straightforward manner. However, attempts to synthesize this ligand by reaction of 2-Cl−C_6H_4−CN with Ph_2PM (M = Li, K) gave only very poor yields[19]. This clearly demonstrates the greater reactivity of aromatic C−F bonds towards nucleophiles in comparison with C−Cl bonds[7].The *p*-isomer (**22**) could, however, be obtained from 4-chlorobenzonitrile, indicating that the steric influence of the *o*-substituents may be decisive and override the important electronic effects. In the case of the reactive 2,5-difluorobenzonitrile, both fluoro-substituents in the *o*-positions can be replaced by the bulky Ph_2P-substituents on reaction with Ph_2PK, with the interesting bidentate ligand **23** being formed in high yield (eq. 3g).

Protonation of **14**−**18** at the amino group gives cationic phosphanes (**14a**−**18a**) (eq. 3f), and the water solublities of these compounds range from 5 to 970 g per kg of water at 20 °C. The *p*-isomers have much higher solubilities than the corresponding *ortho*-compounds. At higher temperatures thermal dissociation occurs to give the primary amines and HCl. The mass spectra obtained from **14a**−**18a** therefore show the M^+ peaks of the corresponding phosphanylbenzylamines along with that of HCl.

NMR Spectra of the Phosphane Ligands 1−23

The structural assignments given for **1**−**23** are based mainly on $^{31}P\{^1H\}$- and $^{13}C\{^1H\}$-NMR spectroscopy. ^1H-NMR spectra will only be discussed in certain cases.

Table 1. $^{31}P\{^1H\}$-NMR-spectroscopical data of **1**−**23**; chemical shifts δP relative to 85% H_3PO_4; coupling constants ^1J(PH) in Hz in parentheses[a]

1	−9.6	**10**	−15.0	**17**	−35.3
2	−7.9	**11**	−4.3	**17a**	−35.7
3	−6.9	**12**	−38.0	**18**	−23.0
4	−5.2	**13**	−22.8	**19**	−48.4
5	−1.5	**14**	−14.2		(223.0)
6	−1.4	**15**	−1.7	**20**	−12.8[c], −6.7[d]
7	−1.5	**15a**	−1.7	**21**	−5.6[c], −3.6[d]
8	−5.4	**16**	−4.3	**22**	−5.7[c], −2.5[e]
9[b]	−20.5, −21.2	**16a**	−2.3	**23**	−9.8

[a] Solvents: DMSO (**1**, **3**, **5**−**7**, **20**−**22**), THF (**2**, **4**, **8**), D_2O/KOD (**9**), $CDCl_3$ (**10**, **15a**, **23**), CD_2Cl_2 (**11**−**14**, **16**, **19**, **20**, **21**), [D_6]acetone (**13**, **18**), CD_3OD (**15**, **17**, **16a**, **17a**). − [b] Diastereoisomers. − [c] Solvent DMSO. − [d] Solvent CD_2Cl_2. − [e] Solvent $CDCl_3$.

The ^{31}P-NMR shifts of the triarylphosphane-type ligands (**1**−**8**, **10**, **11**, **14**−**16**, **20**−**22**) are within a narrow range (δP = −1.4 to −15.0), and the δP values of **9**, **12**, **13**, **17**, **18** are typical for alkyl-diaryl phosphanes[20] (Table 1). In both cases the degree of substitution and the nature of the substituents has little influence on the δP values. The resonances of the *o*-isomers are shifted, in most cases, to higher field compared with those of the corresponding *m*- and *p*-isomers (c.f. **10/11**, **14/15/16**, and **20/21/22**). The bidentate carboxylated ligand **9**, containing two asymmetrically substituted phosphorus atoms, is formed as a mixture of two diastereoisomers (meso form and racemate) as indicated by two very close $^{31}P\{^1H\}$-NMR signals. The changes in the $^{31}P\{^1H\}$-NMR shift values of **14**−**17** on protonation with HCl are very small, indicating that the addition of the proton occurs preferentially at the nitrogen atom. The same also applies in the case of the $^{13}C\{^1H\}$-NMR data (c.f. **17/17a**), with the exception of δC(2)(*C*−CH_2−NH_2) (**17**: 147.0, **17a**: 138.6) (Table 2).

The assignment of the $^{13}C\{^1H\}$-NMR signals of **1**−**23** (Table 2; for the numbering scheme of the carbon atoms see Figure 1a) was achieved by comparison of the ^{13}C-shift values with those found in a series of related compounds including Ph_3P[21], Ph_2PH and $PhPH_2$[22]. The assignments were further substantiated by analysis of the proton-coupled spectra, including DEPT spectra[23], and comparison of the relative intensities of the signals. Further support for a correct assignment comes from the relative magnitude of the coupling constants ^nJ(PC), which generally decrease within the series $^2J(PC) > {}^1J(PC)$ and $^2J(PC) > {}^3J(PC) > {}^4J(PC)$[23]. The ^{13}C-NMR spectra could be analyzed using a first order approximation with $^2J(CH) < {}^3J(CH)$ and ^4J(CH) ca. 0 Hz[23]. This is shown for **8** as a representative example in Figure 1c.

The introduction of one COOH, CH_2−COOH, or CH_2−NH_2 substituent into the *o*-, *m*-, or *p*-position of the aromatic ring system causes a shift to lower field of the $^{13}C\{^1H\}$-NMR signals of the corresponding carbon atoms in comparison with those of the unsubstituted carbon atoms in the corresponding isomers and the phenyl rings, the δC values of which may be taken as an internal reference for each compound. On going from the carbonic acids to the respective potassium or sodium salts the $^{13}C\{^1H\}$-NMR spectra do not change very much, as shown for **5** and Na-**5**. The δC values of the resonances assigned to C1 and C3−C6 remain constant within 1 ppm, whereas the signal of C2 is shifted significantly (by about 2 ppm). This is in agreement with the results obtained for benzoic acid and benzoates[23a].

The $^{13}C\{^1H\}$-NMR resonances of the carbon atoms bearing a CN-substituent in **20**−**22** are shifted to higher field by between 10 and 20 ppm in comparison with those of the corresponding unsubstituted carbon atoms in the Ph-groups. This shielding effect of the CN group is well established for mono-, di-, and trisubstituted benzonitrile derivatives[23a][24].

In comparison with the corresponding δC values in phthalic acid (*C*−COOH: δ = 131.4)[25], the $^{13}C\{^1H\}$-NMR resonances of C2 [in **4**: 148.8 (32.0), **8**: 146.5 (34.4) and **9**: 147.3 (34), 147.2 (34)] are shifted drastically to lower field on the introduction of the Ph_2P or PhP(Ar) groups, while those of C4 (δ = 128.8, 129.9 or 130.0 vs. 128.6) are not changed very much. The coupling constants ^2J[PC(2)] in the substituted aromatic ring systems of **4**, **8**, and **9** are significantly greater than those in **1**, **2**, **5**, and **6**. This may be due to the pronounced steric effect of the two COOH groups in *o*- and *m*-positions which favors a conformation of the P−$C_6H_3(COOH)_2$ unit with the phosphorus lone pair in close proximity to C2 (Figure 1b). In general ^2J[PC(2)] in related systems is large when the lone pair is close to the C atom and small when it is remote[23b][23c].

[a] Chemical shift δ(C) relative to TMS; coupling constants ^nJ(PC) in Hz in parentheses. – [b] Solvents: CD_2Cl_2 (**10**, **20**, **21**, **23**), D_2O (**8**), $CDCl_3$ (**12**, **14** − **16**, **18**, **22**), [D_6]acetone (**11**, **13**), CD_3OD (**17**, **17**·HCl), C_6H_6 (**19**); [D_6]DMSO (**1**−**4**, **6**, **7**, **9**). – [c] For an indication of the carbon atoms see Figure 1a. – [d] COOH substituent. – [e] Potassium salt; COO^- in the *o*-position. – [f] COO^- in the *m*-position to phosphorus. – [g] Diastereoisomers. – [h] $-CH_2-CH_2-CH_2$: 22.8, 22.2; $CH_2-CH_2-CH_2$: 29.5, 29.4 (13); diasteroisomers. – [i] CH_2-COOH: 39.7 (23.5). – [j] CH_2-COOH: 40.9. – [k] CH_2-COOH: 39.6 (24.1); P−*Me*: 12.4 (13.9). – [l] CH_2-COOH: 41.1; P−*Me*: 12.4 (13.9).– [m] CH_2-NH_2: 45.5 (22.1). – [n] CH_2-NH_2: 46.7. – [o] CH_2-NH_2: 46.3. – [p] CH_2-NH_2: 44.7 (22.7); P−*Me*: 12.2 (13.9). – [q] CH_2-NH_2: 46.3; P−*Me*: 13.0 (14.5). – [r] CH_2-NH_2: 48.2 (15.5). – [s] CN groups.– [t] N = ^nJ(PC) + ^mJ(PC) ; n = 1−3; m = 3−6.– [u] ^4J(PP) = 4.78 ± 0.22 Hz. – [v] C7: ^1J(PC) = 10.26, ^5J(PC) = 0.36 Hz; C8: ^2J(PC) = 20.30, ^{6}(PC) = 0.11 Hz; C9: ^3J(PC) = 7.30 Hz.

Seperate resonances are observed for the two COOH groups in the 2,3-positions in the phthalic acid derivatives. In the case of **4** and **8** the signal at δ ≈ 177.5 shows doublet fine structure [^3J(PC)] and can therefore be assigned to the COOH groups in the *o*-position with respect to the P atom. The bidentate ligand **9** is obtained as a mixture of two diastereoisomers (meso form and racemate, see above) and for this reason a doubling of the $^{13}C\{^1H\}$-NMR resonances of some of the aromatic carbon atoms (C1, C2, C6, C7, C8) is observed. Although the fine structure of the signals assigned to the terminal CH_2 groups of the $(CH_2)_3$ bridge (X-part of an ABX spin system, A and B = ^{31}P, X = ^{13}C) could not be completely resolved, two triplets [^2J(PC)] being observed for the medial CH_2 group.

The presence of two phosphorus atoms in **23** means that the C-atoms C1(3), C4(6), and C7−C9 represent the X-part of ABX spin systems (X = ^{13}C, A and B = ^{31}P; for the numbering scheme for the carbon atoms see Figure 3a). Higher order $^{13}C\{^1H\}$-NMR spectra appearing as doublets of doublets (C1, C3), five line (C9) and six line patterns

Figure 1. (a) Numbering scheme for the carbon atoms in mono- and disubstituted aromatic phosphanes; (b) conformation of the Ph(R)P-group with respect to the plane of the substituted aromatic ring; (c) ^{13}C-NMR spectrum of **8**

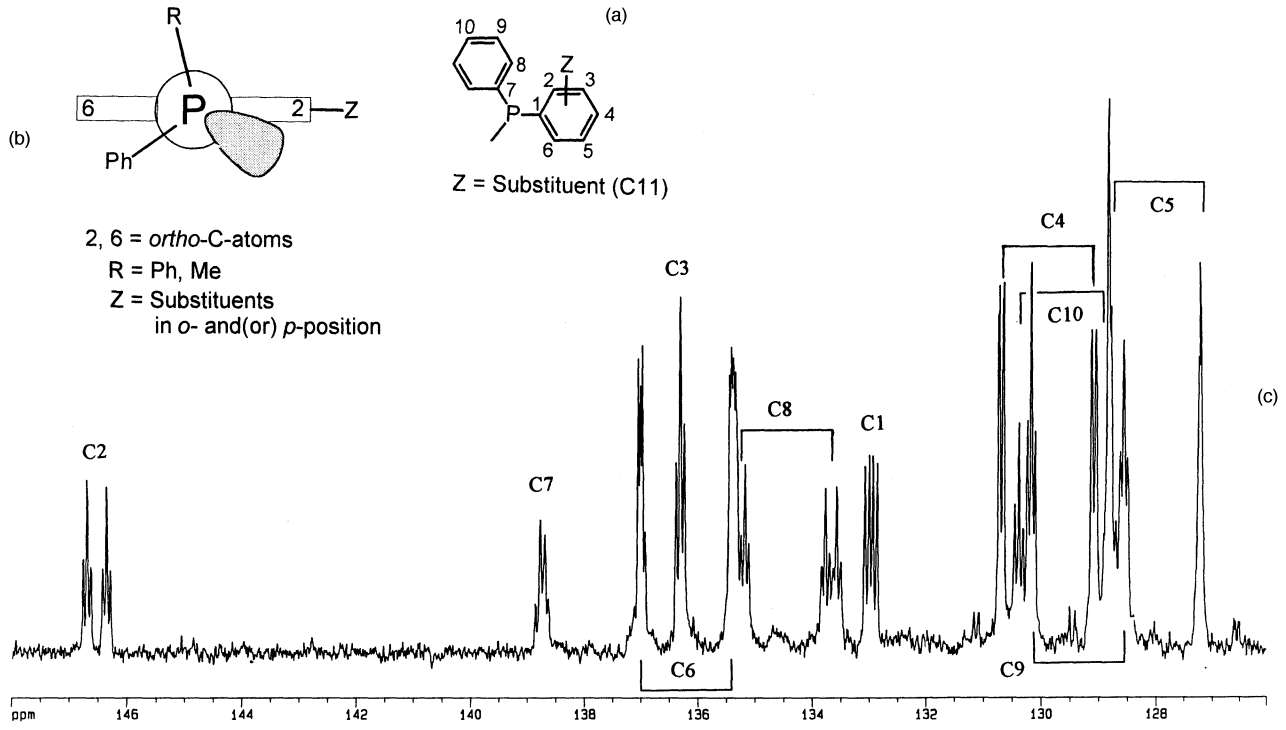

Figure 2. (a) Conformation of the CH_2-X group in **12** and **17**; (b) ^{1}H-NMR spectrum (CH_2-part) of **17**

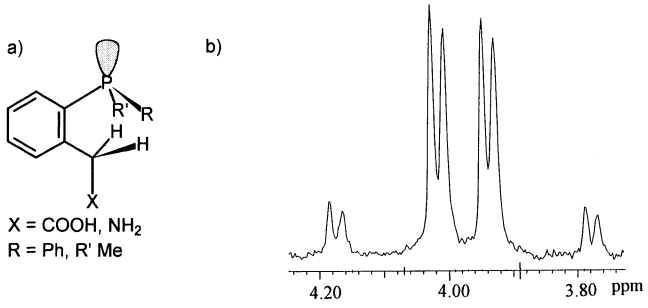

(C7, C8) are observed (Figure 3b). The analysis of the latter gave a value of around 4.8 Hz for the long range P-P coupling constant [^4J(PP)]. The resonances of C2 and C11 (X-parts of XA_2 spin systems) show first order triplet splitting, while singlets are obtained for C4(6) and C5.

The hydrogen atoms of the CH_2 groups in **12**, **17**, **17a**, **19**, and **19**·HCl are diastereotopic due to the asymmetric substitution at the phosphorus atoms (see Figure 2a). The ^{1}H-NMR spectra of these compounds therefore represent the AB part of an ABX spin system (A and B = ^{1}H, X = ^{31}P) and appear as an eight-line pattern in the cases of **17** (Figure 2b), **17a**, and **19**. The coincidence of lines means that a six-line pattern is observed for **19**·HCl and **12**.

Experimental Section

Experimental details are given in part VIII of this series[1]. Phenylphosphane, phenylmethyl- and diphenylphosphane were prepared according to literature methods[26]. 2-, 3-, and 4-Fluorobenzoic acid, 3-fluorophthalic acid, 2- and 4-fluorophenylacetic acid, 2-, 3-, and 4-fluorobenzonitrile, and 2- and 4-fluorobenzylamine were purchased from The Aldrich Chemical Company and used without further purification.

Preparation of **1** *by Phosphanylation of 2-F−C_6H_4−COOK with Ph_2PK:* To 20 ml of a 0.5 M solution of Ph_2PK (10.0 mmol) in THF was added 1.8 g (10.0 mmol) of 2-F−C_6H_4−COOK with stirring and the reaction mixture was heated at 60 °C for 20 h. After extraction with 20 ml of conc. KOH solution the aqueous phase was acidified with conc. HCl until a precipitate formed. The mixture was then extracted with 40 ml of diethyl ether and the extracts were dried over Na_2SO_4. Evaporation of the solvent in vacuo gave **1** as a colorless solid. Yield: 1.97 g (64%). − **1**: $C_{19}H_{15}O_2P$ (306.3): calcd. C 74.50, H 4.94; found C 74.20, H 4.96. − MS: (M^+: *m/z* = 306). − IR: ν(COOH): 1695, 1305 cm^{-1}.

Preparation of **2** *and* **4**−**8**: The lithium salts of the fluorobenzoic acids or 3-fluorophthalic acid were added at ambient temperature to either a THF solution of Ph_2PK or to a suspension of $PhPLi_2$ in THF (obtained by metalation of $PhPH_2$ with *n*BuLi in *n*-hexane in the presence of tetramethylethylenediamine at −40 °C), respectively (see Table 4). After the reaction mixtures were refluxed for 2 h the solvents were removed under reduced pressure (30 °C, 1 mbar). The remaining residues were dissolved in 100 ml of water and filtered through a fine porosity fritted funnel. On acidification of the filtrate the phosphanes precipitated as colorless powders which were further purified by recrystallization from methanol/water mixtures. In the cases of compounds **4** and **8** the filtrates

Preparation of **9**: 1.23 g (32 mmol) of potassium was added to a solution of 3.45 g (31 mmol) of phenylphosphane in 50 ml of THF and the reaction mixture was stirred for 2 h. The reaction mixture was refluxed under nitrogen for an additional 30 min in order to ensure completion of the reaction. Excess potassium was removed by decanting the solution. 3.00 g (15 mmol) of 1,3-dibromopropane was added and the yellow color of the solution disappeared. After

dilution with 30 ml of THF a further equivalent of 1.23 g (32 mmol) of potassium was added and the reaction mixture was again refluxed for 2 h. The lithium salt of 3-fluorophthalic acid was added and the color of the reaction mixture became dark red. After stirring for 12 h at 60−70 °C the color disappeared. All volatile components were then removed under reduced pressure (30 °C, 1 mbar). The residue obtained was dissolved in 200 ml of water and filtered through a fritted funnel. The filtrate was washed with three 50-ml portions of diethyl ether and then acidified with half conc. HCl. The white solid that precipitated was separated by filtration and recystallized from water/methanol. Yield: 4.1 g (41%). − **9**: $C_{31}H_{26}O_8P_2 \cdot 4H_2O$ (660.55): calcd. C 56.37, H 5.19; found C 55.51, H 5.33. − MS ($M^+ - 2\ H_2O$: *m/z* = 552. − IR: ν(COOH) = 1705, 1280 cm^{-1}.

Synthesis of **10**−**13**. − *General Procedure:* To a solution of Ph_2PK or Ph(Me)PK in DME [prepared by metalation of Ph_2PH or Ph(Me)PH with equimolar amounts of potassium] was added potassium 2- or 4-fluorophenyl acetate. The suspensions were refluxed until the yellow color of the potassium phosphides disappeared. The solvent was removed under reduced pressure (20 °C, 0.01 mbar) and, in each case, the solid obtained was dissolved in 50 ml of water. Unreacted phosphane was extracted with dichloromethane. After cooling to about 0 °C, the aqueous phase was acidified with conc. HCl. The phosphanylphenylacetic acids precipitated and were isolated by filtration through a fine porosity fritted funnel. A slurry was obtained by suspending the residue in 50 ml of water and 1 equivalent of KOH was added. The solution formed was filtered, cooled to about 0 °C and acidified with conc. HCl. The precipitate was isolated by filtration and dried in vacuo (20 °C, 0.01 mbar). The amounts of starting materials and yields are given in Table 4.

10: $C_{20}H_{17}O_2P$ (320.3): calcd. C 74.99, H 5.35; found C 74.33, H 5.56. − MS (M^+: *m/z* = 320). − IR: ν(COOH) = 1714 cm^{-1}.

11: $C_{20}H_{17}O_2P$ (320.3): calcd. C 74.99, H 5.35; found C 74.33, H5.49. − MS (M^+: *m/z* = 320). − IR: ν(COOH) = 1736 cm^{-1}.

12: $C_{15}H_{15}O_2P$ (258.3): calcd. C 69.76, H 5.85; found C 68.96, H 5.98. − MS (M^+: *m*/e = 258). − IR ν(COOH) = 1701 cm^{-1}.

13: $C_{15}H_{15}O_2P$ (258.3): calcd. C 69.76, H 5.85; found C 69.08, H 5.89. − MS (M^+: *m/z* = 258). − IR ν(COOH): 1712 cm^{-1}.

Preparation of **14**−**19** *by Phosphanylation of Fluorobenzylamines.* − *General Procedure:* In a typical procedure the fluorobenzylamines were added to a solution of Ph_2PK or Ph(Me)PK in DME with stirring. After heating the reaction mixtures at reflux for 24 h the solvent was evaporated under reduced pressure (20 °C, 0.01 mbar) and the residue obtained was washed with 100 ml of water. The crude products were dried in vacuo and isolated by distillation at 220−240 °C and 10^{-3} mbar. Starting materials, reaction conditions and yields are given in Table 5.

14: $C_{19}H_{18}NP$ (291.4): calcd. C 78.33, H 6.23, N 4.81; found C 77.24, H 6.23, N 4.81. − MS (M^+: *m/z* = 291). − IR: ν_{as}/ν_s-NH_2 = 3376, 3313 cm^{-1}.

15: $C_{19}H_{18}NP$ (291.4): calcd. C 78.33, H 6.23, N 4.81; found C 78.10, H 6.54, N 4.83. − MS (M^+: *m/z* = 291). − IR: ν_{as}/ν_s-NH_2 = 3371, 3298 cm^{-1}.

23	2,5-difluoro-benzonitrile 2.83 (20.3)	Ph_2PK[a] 9.13 (40.7)	THF 100	−78	1 min	7.76 (81)

[a] Prepared by reaction of equivalent amounts of Ph_2PH or Ph(Me)PH with potassium (in DME). − [b] Isolated as HCl adducts, for the preparation from the amines see below. − [c] Prepared by reaction of equivalent amounts of Ph_2PH with *n*BuLi (1.6 M solution in *n*-hexane) in stoichiometric ratios in THF.

Synthesis of **20**−**23** *by Phosphanylation of 2- or 3-Fluoro- and 4-Chlorobenzonitrile with Ph_2PM (M = Li, K):* Diphenylphosphane was dissolved in THF and metalated at 0 °C by the addition of the eqivalent amount of *n*BuLi (1.6 M solution in *n*-hexane). The red colored solution of Ph_2PLi was cooled to −78 °C and stoichiometric amounts of 2- or 4-fluorobenzonitrile were added at this temperature. After removal of the solvent in vacuo the oily residue was washed with water and recrystallized from ethanol. For the preparation of **22** and **23**, 4-chlorobenzonitrile or 2,6-difluorobenzonitrile, respectively, were used as starting materials along with Ph_2PK. Ph_2PK was prepared by reaction of equivalent amounts of Ph_2PH and potassium. The workup procedure was the same as that described above. The crude products were recrystallized from methanol. Starting materials, reaction conditions and yields are given in Table 5.

20: $C_{19}H_{14}NP$ (287.3): calcd. C 79.43, H 4.91, N 4.81; found C 79.05, H 4.89, N 4.88. − MS (M^+: *m/z* = 287). − IR: ν(CN) = 2219 cm^{-1}.

21: $C_{19}H_{14}NP$ (287.3): calcd. C 79.43, H 4.91, N 4.81; found C 79.41, H 4.88, N 4.84. − MS (M^+: *m/z* = 287). − IR: ν(CN) = 2225 cm^{-1}.

22: $C_{19}H_{14}NP$ (287.3): calcd. C 79.43, H 4.91, N 4.81; found C 79.02, H 4.84, N 4.86. − MS (M^+: *m/z* = 287). − IR: ν(CN) = 2225 cm^{-1}.

23: $C_{31}H_{23}NP_2$ (471.5): calcd. C 78.97, H 4.92, P 13.14; found C 79.01, H 5.04, P 13.07. − MS (M^+: *m/z* = 471).

Reduction of **20** *and* **21** *with* $LiAlH_4$: To a suspension of 0.38 g (10 mmol) or 0.13 g (3.6 mmol) of $LiAlH_4$ in 80 or 40 ml of THF was added over 15 min a solution of 2.87 g (10 mmol) of **20** or 1.00 g (3.5 mmol) of **21** in 20 or 10 ml of THF. After stirring for 0.5 h at ambient temperature the reaction mixtures were refluxed for 1 h. The precipitate formed on the addition of 20 or 50 ml of water, respectively, was separated by filtration and the solvent was removed in vacuo (20 °C, 0.01 mbar). The remaining crude reaction products were purified by vacuum distillation (220−240 °C, 10^{-3} mbar). Yields: 2.45 g (84%) of **14** and 0.82 g (80%) of **15**.

Protonation of **14** *with HCl:* 0.5 g (1.7 mmol) of diphenylphosphanylbenzylamine (**14**) was dissolved in diethyl ether. An etheral solution of HCl was added until no further precipitate was formed. The solid was filtered off using a coarse porosity fritted funnel and then dried in vacuo (20 °C, 0.1 mbar). Yield: 0.50 g (89%) of **14a**.

14a: $C_{19}H_{19}ClNP$ (327.8): calcd. C 69.62, H 5.84, N 4.27; found C 68.56, H 5.89, N 4.22. − MS (M^+ − HCl: *m*/*z* = 291).

Synthesis of **1**, **3**, **20**−**22** *in the Superbasic Medium. − General Procedure:* Diphenyl- or phenylphosphane were added to a suspension of powdered KOH (88%) in DMSO and the mixtures were stirred for 1 h at ambient temperature. After addition of the appropriate amounts of the fluoroaromatic compounds (see Table 6), the orange to red colored solutions were heated for 70 h at 60−70 °C in the cases of **1** and **3**. The reactions of the fluorobenzonitriles with the phosphanes were complete within a couple of minutes. For the isolation of **1** and **3** the reaction mixtures were first extracted with 200 ml of diethyl ether. After acidification with conc. HCl extraction was repeated with three 75-ml portions of diethyl ether. The organic extracts were washed with 30 ml of water and then dried over $MgSO_4$. The residue obtained after evaporation of the solvents in vacuo was recrystallized from methanol. **20**−**22** were precipitated from the reaction mixtures by addition of 30−40 ml of water and separated by filtration. Further purification was possible by recrystallization from methanol. **1**, **3**, **20**−**22** prepared by this route gave correct analyses. The compounds were identified by NMR spectroscopy (see above). Starting materials, reaction conditions and yields are given in Table 6.

Keywords: Phosphorus ylides / Bis(ylene)phosphoranes / Halogenophosphoranes / X-ray structure analysis

The iminophosphane (Me$_3$Si)$_3$C−P=N−Mes* (**1**) reacts with iodine to form the imino(methylene)phosphorane I−P(=N−Mes*)=C(SiMe$_3$)$_2$ (**2**). Upon subsequent treatment with AgCl, the corresponding chloro derivative **3** is obtained. Chlorine/bromine exchange in **3** with bromotrimethylsilane affords the bromo analogue **4**. The structures of **2**, **3** and **4** were confirmed by X-ray crystal structure analysis; each of the compounds features a trigonal-planar phosphorus atom.

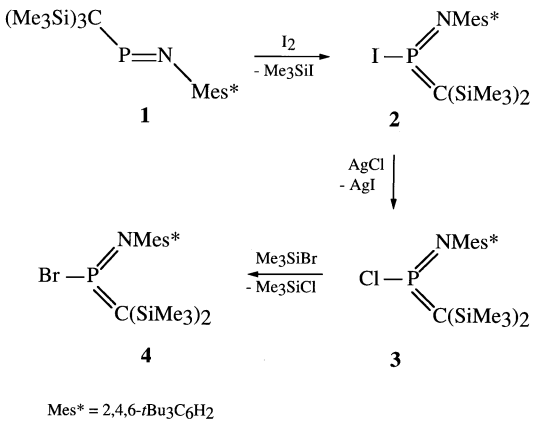
Introduction

The discovery of the first stable compound containing a trigonal-planar phosphorus(V) center in 1974[1] represents a landmark in organophosphorus chemistry. It opened the door to a rapid development of the chemistry of such compounds and structurally related derivatives[2] . Among these, bis(imino)-[3a] and bis(methylene)phosphoranes[3b] have attracted considerable attention, not only because they are valuable building blocks in organophosphorus and organometallic chemistry[4], but also because they are suitable precursors for monomeric metaphosphate analogues[5] and have found application in the catalysis of olefin polymerization[6]. In contrast, information concerning imino(methylene)phosphoranes, which feature both P−N- and P−C-pπ bonds, is comparatively sparse[3c]. Herein, we report on the synthesis and crystal structure analysis of the first *P*-halogeno(imino)methylenephosphoranes.

Results and Discussion

Treatment of the iminophosphane (Me$_3$Si)$_3$C−P=N−Mes* (**1**)[7], with iodine in THF at −40°C cleanly afforded the *P*-iodo(imino)methylenephosphorane **2**. Further reaction with AgCl in CH_2Cl_2 at 25°C resulted in I/Cl exchange of **2**, yielding the chloro derivative **3**. Subsequent reaction of **3** with Me$_3$SiBr led smoothly to the bromo derivative **4**. By crystallization from small volumes of *n*-hexane, compounds **2**−**4** were isolated as highly air- and moisture-sensitive, red (**2**), light-yellow (**3**), or orange (**4**) crystals (Scheme 1).

Scheme 1



The *P*-halogeno(imino)methylenephosphoranes **2**−**4** have been characterized on the basis of their elemental analyses and ^{1}H-, ^{13}C-, ^{31}P-NMR and mass-spectrometric data. Furthermore, the solid-state structures of compounds **2**−**4** have been determined by X-ray crystallography.

The ^{31}P-NMR chemical shifts of compounds **2**−**4** are observed at relatively low field values, which is typical for bis(ylene)phosphoranes[8]. The deshielding of the phosphorus nuclei on going from the iodo derivative **2** to the chloro analogue **3** [^{31}P: δ = 53.3 (**2**) < 65.2 (**4**) < 72.5 (**3**)] is a characteristic feature of tetracoordinated P^V compounds[9].

The ^{13}C-NMR signals of the methylene carbon atoms, which are observed at lower fields than in "classical" methylenephosphoranes, show the inverse trend. A stronger carbon shielding is found on going from compound **2** to **4** to **3**, i.e. on increasing the electronegativities of the substituents [^{13}C: δ = 68.0 (**2**) > 58.2 (**4**) > 51.7 (**3**)]. At the same time, a significant increase in the magnitude of ^1J(C,P) from 34.1 Hz (**2**) through 50.6 Hz (**4**) to 65.3 Hz (**3**) is observed. An inverse electronegativity effect on both ^{31}P- and ^{13}C-chemical shifts was also observed for substitution at the methylene carbon atom in imino(methylene)phosphoranes and was attributed to a polarization effect[10]. Similar trends in the δ^{31}P, δ^{13}C and ^1J(C,P) values were observed in the corresponding *P*-halogenobis(methylene)-phosphoranes[3a] and *P*-halogenobis(imino)phosphoranes (δ^{31}P)[11]. As compared to compounds **2**−**4**, the ^{31}P nuclei in the former are less shielded by 30 to 65 ppm, while those in the latter appear more shielded by 30 to 70 ppm com-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0083 $ 17.50+.50/0

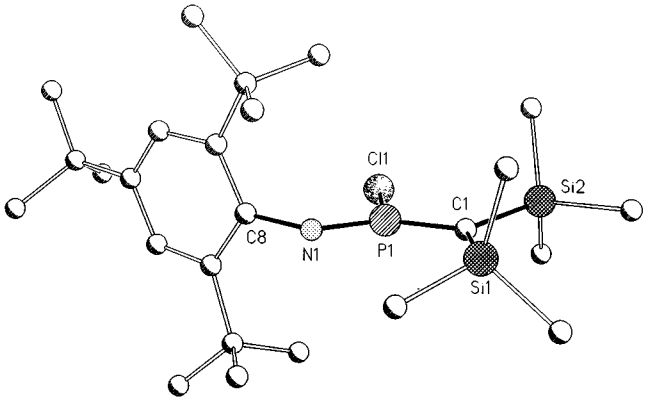
pared to the corresponding nuclei in the imino(methylene)phosphoranes. Furthermore, a detailed experimental and quantum-chemical study on the influence of phosphorus substituents on ^{15}N-NMR shifts in bis(imino)phosphoranes led to the conclusion that the substituent effects were transmitted by both inductive and mesomeric interactions, and revealed a correlation between increased shielding and higher ylidic character of the ylene bond[12].

Table 1. Representative NMR data of *P*-halogenobis(ylidene)phosphoranes X−P(=A)=B

	δ^{31}P	δ^{13}C(P=C)	$^1J_{PC}$ [Hz]
X = Cl; A = B = N	−18.5	–	–
X = Br; A = B = N	−30.2	–	–
X = I; A = B = N	−42.9	–	–
X = Cl; A = N; B = C	72.5	51.7	65.3
X = Br; A = N; B = C	65.2	58.2	50.6
X = I; A = N; B = C	53.3	68.0	34.1
X = Cl; A = B = C	136.8	83.3	38.6
X = Br; A = B = C	122.5	91.3	30.8
X = I; A = B = C	84.7	102.9	23.5

The constitutions of compounds **2**−**4** were further corroborated by single-crystal X-ray diffraction studies. The phosphorus and carbon atoms of the imino(methylene) moieties exhibit the expected trigonal-planar geometries (Figure 1). The atoms of the CSi_2 and P−N−C_{ipso} moieties are almost coplanar (dihedral angle 4.4−5.6°), while the aryl substituent is approximately orthogonal to the central π-bond system (angle between the plane P−N−C_{ipso} and the aryl plane: 88.8−91.7°). The P−N double bond adopts a (*Z*) configuration, as is observed in *P*-halogeno(imino)-phosphanes[13]. The P−halogen distances [**3**: 206.9(2), **4**: 223.1(1), **2**: 242.9(1) pm] are shortened in comparison with the corresponding bond lengths in bis(imino)phosphoranes[11], but are longer than those in bis(methylene)phosphoranes[14]. The P−N [151.8(3)−153.1(4) pm] and P−C [162.4(4)−164.2(4) pm] distances, as well as the central C−P−N valence angles [129.2(2)−130.5(2)°] represent typical structural features common to both bis(imino)- and bis-(methylene)phosphoranes[3a][3b]. The other bond lengths and angles show no peculiarities.

Figure 1. Crystal structure of the imino(methylene)phosphorane **3**[a]



[a] Selected bond lengths [pm] and bond angles [°]: **3**: P(1)−Cl(1) 206.9(2), P(1)−N(1) 152.7(4), P(1)−C(1) 162.4(4), N(1)−C(8) 142.6(5); Cl(1)−P(1)−N(1) 113.1(1), Cl(1)−P(1)−C(1) 116.3(2), N(1)−P(1)−C(1) 130.5(2), P(1)−N(1)−C(8) 127.0(3). − **2**: P(1)−I(1) 242.9(1), P(1)−N(1) 153.1(4), P(1)−C(1) 164.2(4), N(1)−C(8) 142.3(5), I(1)−P(1)−N(1) 112.0(2), I(1)−P(1)−C(1) 118.8(2), N(1)−P(1)−C(1) 129.2(2), P(1)−N(1)−C(8) 125.6(3). − **4**: P(1)−Br(1) 223.1(1), P(1)−N(1) 151.8(3), P(1)−C(1) 162.7(4), N(1)−C(8) 140.8(5); Br(1)−P(1)−N(1) 112.1(1), Br(1)−P(1)−C(1) 117.5(2), N(1)−P(1)−C(1) 130.4(2), P(1)−N(1)−C(8) 127.8(3).

Regarding the potential synthetic utility of these halogeno(imino)methylenephosphoranes, one can expect them to undergo nucleophilic displacement reactions as well as thermally induced β eliminations of silyl halide. Both of these strategies are currently under investigation.

Experimental Section

All experiments were carried out with the exclusion of air and moisture under argon. Solvents were purified and dried according to standard methods. Compound **1** was prepared according to a literature procedure[7]. − NMR: Bruker AMX 300 (^{31}P: 121.5 MHz, external standard 85% H_3PO_4; ^{1}H: 300.1 MHz, external standard TMS; ^{13}C: 75.5 MHz, external standard TMS). − MS: Kratos Instruments Concept 1 H, Kratos Instruments MS 50, VG Instruments VG 12-250. − Elemental analyses: Analytisches Laboratorium Pascher. − Melting points were determined in sealed glass capillaries and are uncorrected.

Iodo[(2,4,6-tri-tert-butylphenyl)imino][bis(trimethylsilyl)-methylene]phosphorane (**2**): To a solution of iminophosphane **1** (2.61 g, 5 mmol) in 20 ml of THF, an equimolar amount of iodine, dissolved in 20 ml of THF, was added at −40°C. The reaction mixture was then allowed to warm to room temp. under stirring. The solvent and all volatile components were removed in vacuo and the remaining residue was taken up in 30 ml of *n*-hexane. Storage of the resulting solution at 0°C led to the deposition of **2** in the form of red crystals, which were found to be suitable for X-ray structural analysis. − Yield 2.57 g (89.3%), m.p. 111−113°C. − ^{31}P NMR (C_6D_6): δ = 53.3. − ^{1}H NMR (C_6D_6): δ = 0.57 (s, 18 H, $SiMe_3$), 1.47 (s, 9 H, *p*-*t*Bu), 1.72 (s, 18 H, *o*-*t*Bu), 7.61 (d, $^5J_{HP}$ = 5.8 Hz, 2 H, C_6H_2). − ^{13}C NMR (C_6D_6): δ = 5.0 (d, $^3J_{PC}$ = 5.8 Hz, $SiMe_3$), 32.1 (d, J_{PC} = 4.2 Hz, *p*-CCH_3), 32.9 (d, $^5J_{PC}$ = 2.7 Hz, *o*-CCH_3), 35.3 (d, J_{PC} = 4.4 Hz, *p*-CCH_3), 37.2 (d, $^4J_{PC}$ = 4.7 Hz, *o*-CCH_3), 68.0 (d, $^1J_{PC}$ = 34.3 Hz, P=C), 123.0 (d, $^4J_{PC}$ = 11.8 Hz, *m*-Ar), 143.7 (d, $^3J_{PC}$ = 19.1 Hz, *o*-Ar), 145.7 (d, $^5J_{PC}$ = 14.1 Hz, *p*-Ar), 145.8 (d, $^2J_{PC}$ = 24.1 Hz, *ipso*-Ar). − MS (70 eV); *m/z* (%): 574 (49) [M^+], 290 (100) [$tBu_3C_6H_2NP^+$]. − $C_{25}H_{47}INPSi_2$ (594.7): calcd. C 52.15, H 8.22; found C 52.28, H 8.26.

Chloro[(2,4,6-tri-tert-butylphenyl)imino][bis(trimethylsilyl)-methylene]phosphorane (**3**): To a solution of imino(methylene)phosphorane **2** (1.44 g, 2.5 mmol) in 10 ml of CH_2Cl_2, AgCl (0.39 g, 2.7 mmol) was added at room temp. and the suspension was stirred for 12 h. The solvent and the volatiles were then removed in vacuo and the remaining residue was taken up in 20 ml of *n*-hexane. The insoluble silver salt (AgI) was separated by filtration. Storage of the filtrate at 0°C resulted in the deposition of **3** in the form of yellow crystals. − Yield: 1.05 g (86.7%), m.p. 81−82°C. − ^{31}P NMR (C_6D_6): δ = 72.5. − ^{1}H NMR (C_6D_6): δ = 0.40 (s, 9 H, $SiMe_3$), 0.60 (s, 9 H, $SiMe_3$), 1.45 (s, 9 H, *p*-*t*Bu), 1.73 (s, 18 H, *o*-*t*Bu), 7.63 (d, $^5J_{PH}$ = 3.3 Hz, 2 H, C_6H_2). − ^{13}C NMR (C_6D_6): δ = 4.2 (d, $^3J_{PC}$ = 7.0 Hz, $SiMe_3$), 4.6 (d, $^3J_{PC}$ = 2.0 Hz, $SiMe_3$), 32.1 (d, J_{PC} = 3.0, *p*-CCH_3), 32.2 (d, $^5J_{PC}$ = 2.3 Hz, *o*-CCH_3), 35.2 (d, J_{PC} = 3.4 Hz, *p*-CCH_3), 36.9 (d, $^4J_{PC}$ = 3.8 Hz, *o*-CCH_3), 51.7

(d, $^1J_{PC}$ = 65.3 Hz, P=C), 122.7 (d, $^4J_{PC}$ = 8.9 Hz, *m*-Ar), 140.8 (d, $^2J_{PC}$ = 23.3 Hz, *ipso*-Ar), 142.9 (d, $^3J_{PC}$ = 15.7 Hz, *o*-Ar), 145.0 (d, $^5J_{PC}$ = 10.7 Hz, *p*-Ar). − MS (70 eV); *m*/*z* (%): 483 (11) [M^+], 290 (100) [$tBu_3C_6H_2NP^+$]. − $C_{25}H_{47}ClNPSi_2$ (484.2): calcd. C 62.01, H 9.78; found C 62.22, H 9.84.

Bromo[(2,4,6-tri-tert-butylphenyl)imino][bis(trimethylsilyl)-methylene]phosphorane (**4**): To a solution of **3** (1.21 g, 2.5 mmol) in 10 ml of THF was added an equimolar amount of Me_3SiBr and the reaction mixture was stirred for 2 h at room temp. The solvent and the halosilanes were then removed in vacuo and the residue was crystallized from a small volume of *n*-hexane. The product was obtained as an orange, crystalline solid. − Yield 1.16 g (87.5%), m.p. 99−101°C. − ^{31}P NMR (C_6D_6): δ = 65.2. − ^{1}H NMR (C_6D_6): δ = 0.40 (s, 9 H, $SiMe_3$), 0.60 (s, 9 H, $SiMe_3$), 1.45 (s, 9 H, *p*-*t*Bu), 1.73 (s, 18 H, *o*-*t*Bu), 7.62 (d, $^5J_{PH}$ = 3.6 Hz, 2 H, C_6H_2). − ^{13}C NMR (C_6D_6): δ = 4.6 (s, $SiMe_3$), 5.0 (d, $^3J_{PC}$ = 5.7 Hz, $SiMe_3$), 32.1 (d, J_{PC} = 6.1 Hz, *p*-C*C*H$_3$), 32.5 (d, $^5J_{PC}$ = 2.6 Hz, *o*-C*C*H$_3$), 35.2 (d, J_{PC} = 3.8 Hz, *p*-*C*CH$_3$), 37.0 (d, $^4J_{PC}$ = 3.8 Hz, *o*-*C*CH$_3$), 58.2 (d, $^1J_{PC}$ = 50.6 Hz, P=C), 122.8 (d, $^4J_{PC}$ = 10.2 Hz, *m*-Ar), 142.0 (d, $^2J_{PC}$ = 24.4 Hz, *ipso*-Ar), 143.2 (d, $^3J_{PC}$ = 17.1 Hz, *o*-Ar), 145.3 (d, $^5J_{PC}$ = 12.2 Hz, *p*-Ar). − MS (70 eV); *m*/*z* (%): 527 (52) [M^+], 290 (100) [$tBu_3C_6H_2NP^+$]. − $C_{25}H_{47}BrNPSi_2$ (528.7): calcd. C 56.79, H 8.96; found C 56.98, H 9.04.

Crystal-Structure Analyses. − Crystal Data: **2**: $C_{25}H_{47}INPSi_2$, M_r = 575.7, red tablets, 0.60 × 0.50 × 0.35 mm; monoclinic, space group $P2_1/c$ (No. 14), *a* = 8.853(3), *b* = 33.25(1), *c* = 10.666(4) Å, β = 99.75(3)°, *V* = 3094(2) Å^3, *Z* = 4, D_x = 1.24 Mg m^{-3}, μ(Mo-K_α) = 1.18 mm^{-1}, *T* = 293(2) K, *F*(000) = 1200, number of reflections: 7843 (7145 independent, R_{int} = 0.025), *R*(*F*) = 0.054, *wR*(F^2 all data) = 0.153 (266 parameters, 50 restraints). − **3**: $C_{25}H_{47}ClNPSi_2$, M_r = 484.2, yellow blocks, 0.40 × 0.30 × 0.20 mm, monoclinic, space group $P2_1/c$ (No. 14), *a* = 8.902(2), *b* = 32.825(5), *c* = 10.516(1) Å, β = 98.95(1)°, *V* = 3035.4(9) Å^3, *Z* = 4, D_x = 1.06 Mg m^{-3}, μ(Cu-K_α) = 2.44 mm^{-1}, *T* = 293(2) K, *F*(000) = 1056, number of reflections: 4845 (4442 independent, R_{int} = 0.096), *R*(*F*) = 0.075, *wR*(F^2 all data) = 0.232 (266 parameters, 62 restraints). − **4**: $C_{25}H_{47}BrNPSi_2$, M_r = 528.7, orange blocks, 0.80 × 0.70 × 0.50 mm, monoclinic, space group $P2_1/c$ (No. 14), *a* = 8.851(2), *b* = 32.87(1), *c* = 10.556(4) Å, β = 99.15(3)°, *V* = 3032(2) Å^3, *Z* = 4, D_x = 1.16 Mg m^{-3}, μ(Mo-K_α) = 1.50 mm^{-1}, *T* = 293(2) K, *F*(000) = 1128, number of reflections: 5622 (5325 independent, R_{int} = 0.053), *R*(*F*) = 0.055, *wR*(F^2 all data) = 0.151 (266 parameters, 62 restraints). An absorption correction on the basis of Ψ scans was applied.

Structure Solution and Refinement: The structures were solved by direct methods and refined anisotropically on F^2 (program system: SHELXTL-Plus[15], SHELXL-93[16]). Non-hydrogen atoms were refined anisotropically; H atoms were refined using a riding model; the *tert*-butyl groups were found to be disordered. Full details of the crystal structure determinations (except structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100474 (**2**, **3**, **4**). Copies may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44(0)1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Imido complexes / Titanium / Heteroallylic ligands / Benzamidinate ligands / Diiminophosphinate ligands

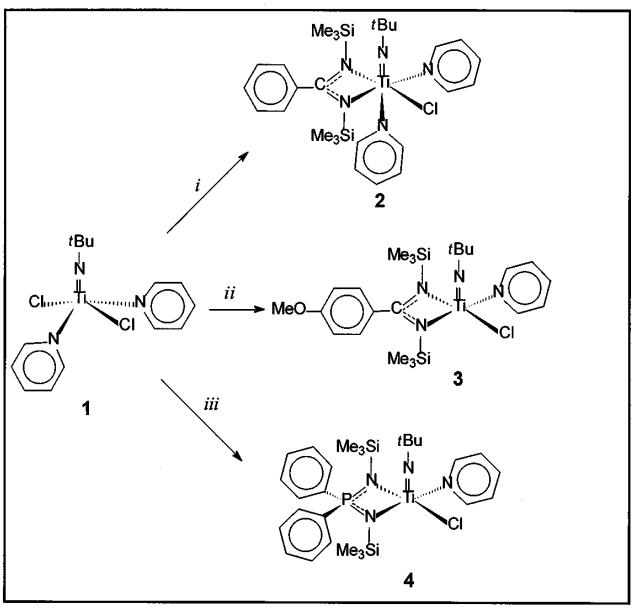
Treatment of $Ti(NtBu)Cl_2(py)_2$ (**1**, py = pyridine) with bulky heteroallylic ligands in a 1:1 molar ratio affords the monosubstituted derivatives $[PhC(NSiMe_3)_2]Ti(NtBu)Cl(py)_2$ (**2**), $[MeOC_6H_4C(NSiMe_3)_2]Ti(NtBu)Cl(py)$ (**3**), and $[Ph_2P(NSiMe_3)_2]$-$Ti(NtBu)Cl(py)$ (**4**). Similarly, 2:1 reactions afforded the disubstitution products $[PhC(NiPr)_2]_2Ti(NtBu)(py)$ (**6**) and $[Ph_2P(NSiMe_3)_2]_2Ti(NtBu)$ (**7**). The bis(pyridine) adduct $Ph_2P(NSiMe_3)_2Li(py)_2$ (**5**) was isolated as a by-product during the preparation of **4**. The molecular structures of **7** has been established by X-ray crystallography.

The chemistry of transition metal imido complexes continues to be an area of active research.[1−3] Such compounds are of interest as intermediates in organic syntheses as well as catalytically active species.[4−19] Just a few years ago, imidotitanium(IV) complexes were exceedingly rare. The first well characterized monomeric imidotitanium species were reported independently at the same time by Roesky et al. and Rothwell et al. in 1990.[20,21] Following the initial work, various other monomeric and dimeric imido derivatives of titanium have been prepared.[22−30] However, a general route providing straightforward access to a series of Ti=NR species was lacking. The recent preparation of readily accessible precursors such as $Ti(NtBu)Cl_2(py)_2$ (**1**, py = pyridine) and $Ti(NtBu)Cl_2(t\text{Bu-py})_2$ (*t*Bu-py = 4-*tert*-butylpyridine) has greatly facilitated the investigation of these compounds.[31] Various complexes derived from these starting materials have recently been reported by Mountford et al.[31−35] We describe here the synthesis and structural characterization of imidotitanium(IV) complexes containing bulky heteroallylic ligands. Related complexes have so far been reported only for vanadium(V) and niobium(V).[36] The bulky heteroallylic ligands used in this study include the benzamidinate anions $[PhC(NSiMe_3)_2]^-$, $[MeOC_6H_4C(NSiMe_3)_2]^-$, and $[PhC(NiPr)_2]^-$ as well as the diiminophosphinate anion $[Ph_2P(NSiMe_3)_2]^-$.[37−40] Chelating ligands of this type are currently being investigated as alternatives for cyclopentadienyl ligands in the design of novel "metallocene-like" homogeneous catalysts.[41−50]

Syntheses and Structures

Compound **1** is easily made be reacting $TiCl_4$ with *tert*-butylamine in the presence of pyridine.[31−35] Subsequent treatment of **1** with lithium salts of bulky heteroallylic anions in THF solution in a 1:1 molar ratio resulted in formation of the monosubstitution products **2**−**4** (Scheme 1).

Scheme 1. Reaction conditions: *i)* $Li[PhC(NSiMe_3)_2]$, 1 equiv., THF, 20°C; *ii)* $Li[MeOC_6H_4C-(NSiMe_3)_2]$, 1 equiv., THF, 20°C; *iii)* $Li[Ph_2P(NSiMe_3)_2]$, 1 equiv., THF, 20°C



The monosubstituted complexes **2**−**4** form orange crystalline solids, which are soluble in THF or toluene and only marginally soluble in hexane or acetonitrile. All three compounds were fully characterized by elemental analyses and spectroscopic methods. The benzamidinate derivative **2** is

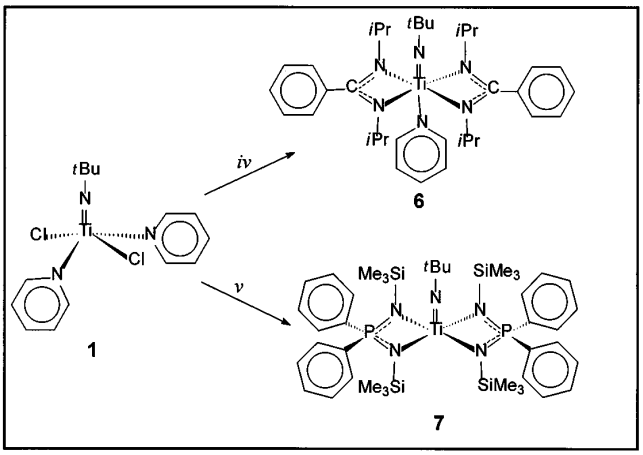
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0087 $ 17.50+.50/0

obtained as a bis(pyridine) adduct, while the complexes **3** and **4** contain only one additional pyridine ligand. In addition to the NMR spectroscopic results, the pyridine content of each compound was independently established by GC analysis of hydrolyzed samples. In the case of **2** X-ray quality crystals were grown from a saturated hexane solution. Unfortunately, due to the low quality of all examined crystals, the structure determination was not sufficiently accurate to allow a detailed discussion of bond lengths and angles. However, the crystallographic results confirm the overall structure of **2** as a monomeric *tert*-butylimidotitanium(IV) complex containing one silylated benzamidinate ligand and one chloro function (cf. Scheme 1).

The preparation of **4** from **1** and $Li[Ph_2P(NSiMe_3)_2]$[47–51] in THF solution is generally accompanied by the formation of the by-product $Ph_2P(NSiMe_3)_2Li(THF)_2$ (**5**), which can be isolated by fractional crystallization from hexane, in which it is less soluble than the titanium complex **4**.[51a] Compound **5** forms pale yellow, moisture sensitive crystals. Its molecular structure can be formulated in analogy to the crystallographically characterized THF adduct $Ph_2P(NSiMe_3)_2Li(THF)_2$.[51b] The presence of two pyridine ligands in **5** was further confirmed by a gas chromatographic analysis following hydrolysis of the material.

Similar treatment of **1** with two equivalents of heteroallylic ligands results in clean formation of the disubstituted derivatives **6** and **7** (Scheme 2).

Scheme 2. Reaction conditions: *iv)* $Li[PhC(NiPr)_2]$, 2 equiv., THF, 20°C; *v)* $Li[Ph_2P(NSiMe_3)_2]$, 2 equiv., THF, 20°C



Once again the composition of the products depends on subtle differences in the steric bulk of the heteroallylic ligands. The benzamidinate derivative **6** is obtained as the mono-pyridine solvate, while **7** is an unsolvated, pentacoordinated imidotitanium(IV) species. The complexes are isolated as nicely crystalline, orange or red materials, which are readily susceptible to hydrolysis in the presence of moist air. They exhibit a high solubility in non-polar organic solvents such as toluene or hexane. Both complexes were fully characterized by elemental analyses and spectroscopic methods.

The molecular structure of **7** (Figure 1) was determined by X-ray diffraction. Red single crystals of the compound were grown by slow cooling of a saturated solution in hexane to −20°C. The crystallographic investigation confirms the presence of a monomeric, pentacoordinated imidotitanium complex, in which the central titanium atom is coordinated only to nitrogen. A comparable coordination environment was found for *tert*-butylimidotitanium species containing the aza-macrocyclic ligands tetra- and octamethyldibenzotetraaza[14]annulene (Me4taa and Me8taa, respectively).[31] With 1.680(4) Å the Ti=N bond length falls in the typical range found for other crystallographically characterized imidotitanium complexes (1.672(7)−1.723(4) Å).[35] The Ti−N−C(*t*Bu) angle [175.9(3)°] is much closer to linearity than that in the macrocyclic imidotitanium derivative (Me8taa)Ti(N*t*Bu) [164.3(3)°].[31] The *tert*-butylimido ligand can thus be assumed to act as four-electron donor towards titanium.

Figure 1. Molecular structure of $[Ph_2P(NSiMe_3)_2]Ti(NtBu)$ (**7**)[a]

IR Studies

The compounds **2**−**4** and **6**, **7** have also been closely examined by IR and Raman spectroscopy. Assignment of the IR bands was made by spectra comparison as well as by inclusion of the Raman spectra and literature data. The N−C−N chelating units in **2**, **3**, and **6** give rise to a ν_{as} CN_2 band at 1523−1516 cm^{-1} as well as the ν_s CN_2 at 1377−1372 cm^{-1}.[52] The ν_{as} PN_2 vibration in **4** and **7** is assigned to the bands at 1090 and 1095 cm^{-1}, respectively.[53] The $SiMe_3$ groups in **2**−**4** and **7** are characterized by the following bands: δ_{as} CH_3 at 1407−1400 cm^{-1}, δ_s CH_3 at 1249−1245 cm^{-1}, and CH_3 rocking at 770−751 cm^{-1}.[54] Characteristic for the phenyl rings in all compounds are the ring valence vibrations at 1609−1600 cm^{-1} (only **7** shows no absorption in this region), 1592−1572 cm^{-1} and 1485−1477 cm^{-1} as well as the rocking vibrations at 1072−1062 cm^{-1} and at 1034−1028 cm^{-1}. A doublet at 1377−1372 and 1390−1385 cm^{-1} was assigned

to δ_s CH_3 of the *tert*-butyl group in the *tert*-butylimido ligand. In addition, the Raman spectra show at 653−651 cm^{-1} the ν_s (N)−CC_3 vibration of the N−$C(CH_3)_3$ unit.[55] ν Ti−py bands are observed in the spectra of **2**−**4** and **6** at 282−280 cm^{-1}.[56] In addition, the Raman spectra exhibit a ν CH band at 3082−3074 cm^{-1}, which can be assigned to pyridine. In the case of the monosubstituted complexes **2**−**4** the ν TiCl vibrations are observed at 323−321 cm^{-1} (IR) and 328−329 cm^{-1} (Raman), respectively. The isopropyl substituents in **6** give rise to the ν CH band at 1386 cm^{-1} in the IR spectrum as well as bands at 2926 cm^{-1} (ν CH), 2869 cm^{-1} (ν_s CH_3) and 480 cm^{-1} (δ CC_2) in the Raman spectrum.[55] Bands at 2838 cm^{-1} (ν_s CH_3), 1293 and 1040 cm^{-1} (ν CO) in the IR spectrum of **3** are typical for the *p*-methoxy substituent.[53]

Conclusions

In summary, we have shown that monomeric imidotitanium complexes containing bulky heteroallylic ligands can be synthesized starting from the readily accessible precursor Ti(N*t*Bu)Cl_2(py)$_2$ (**1**). Depending on the stoichiometry of the starting materials, 1:1- and 1:2 derivatives can be isolated. Bulky benzamidinate ligands as well as diiminophosphinate anions are equally suited to stabilize monomeric imidotitanium complexes.

We thank the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie* and the *Otto-von Guericke-Universität Magdeburg* for their continuing financial support.

Experimental Section

All reactions were carried out under purified nitrogen using standard Schlenk-line or dry-box techniques. Solvents were carefully dried over Na/benzophenone and freshly distilled under nitrogen prior to use. − Infrared and Raman spectra were recorded using a Perkin Elmer FTIR-2000 spectrometer equipped with a Raman facility. The IR measurements in the spectral range of 400−200 cm^{-1} were carried out using either Nujol mulls or with the pellet technique using RbBr as embedding medium. KBr pellets were used for spectra in the 4000−400 cm^{-1} range. For this purpose a metal bellow vessel was designed, which greatly facilitates the IR investigation of air-sensitive samples, especially in connection with the dry box technique. A diagram of the vessel is depicted in Figure 2.

The KBr die containing the air- and moisture-sensitive samples was placed under inert atmosphere in the dry-box into the evacuable metal bellow vessel made of steel. The metal bellow serves to level out the height difference of the vessel during power transmission from the hydraulic press onto the KBr die. The vessel is taken out of the dry box and evacuated to ca 10^{-2} mbar. After pressing the pellet the evacuated vessel is taken back into the dry box. The pellet holder containing the pellet is closed air-tight on both sides using IR cell windows and sealing rings, and then taken out of the dry box and inserted into the spectrometer. Very weak bands are not listed in the IR data. − NMR spectra: Bruker AM 250. − X-ray crystallography: Intensities were collected at −100°C on a Nonius CAD4 diffractometer with graphite-monochromated Cu-K_α radiation (λ = 1.54178 Å). The structure was solved by direct methods with SHELXS-86 and refined by full-matrix least-squares procedures using SHELXL-93.[57] A riding model was employed to refine the hydrogen atom positions. − The starting materials Ti(N*t*Bu)Cl_2(py)$_2$ (**1**),[31][35] Li[$RC_6H_4C(NSiMe_3)_2$] (R = H, MeO),[58] Li[PhC(N*i*Pr)$_2$][46] and Li[$Ph_2P(NSiMe_3)_2$][47,48] were prepared according to literature procedures.

*Reactions of Ti(NtBu)Cl_2(py)$_2$ (**1**) with Heteroallylic Ligands (General Procedure):* To a stirred solution of 1.74 g (5.0 mmol) of **1** in 20 ml of THF is added dropwise at room temperature a solution of 5.0 mmol of the ligand in 30 ml of THF (1:1 reactions). For the 1:2 reactions a solution of 10.0 mmol of the ligand in 60 ml of THF is employed. Stirring at room temperature is continued for 8 h and the mixture is evaporated to dryness. The residue is extracted with 40 ml of boiling hexane and filtered while hot through a thin layer of Celite filter aid. Cooling to −20°C for 24 h affords the crude product, which is purified by recrystallization from hexane.

[N,N'-Bis(trimethylsilyl)benzamidinato]-N-tert-butylimidochlorobis(pyridine)titanium(IV) (**2**): Red crystals, m.p. 107−109°C. Yield: 1.36 g (48%). − IR (cm^{-1}): $\tilde{\nu}$ = 2595 s, 2915 m, 2897 m, 1604 m, 1592 w, 1520 m, 1510 w, 1479 m, 1459 m, 1444 m, 1426 m, 1406 m, 1385 (sh) w, 1376 m, 1358 m, 1247 vs, 1027 w, 1042 m, 1029 w, 1013 m, 1002 m, 985 s, 921 s, 840 vs, 785 m, 759 s, 728 m, 700 s, 632 m, 526 m, 508 m, 492 m, 456 w, 392 w, 353 w, 302 w, 280 w. − ^{1}H NMR (C_6D_6): δ = 9.54 (m, 2 H, *p*-C_5H_5N), 8.70 (m, 4 H, *m*-C_5H_5N), 7.01 (m, 4 H, *o*-C_5H_5N), 6.90 (m, 1 H, *p*-C_6H_5), 6.65 (m, 4 H, *o,m*-C_6H_5), 1.35 (s br, 9 H, *t*Bu), 0.35 (s br, 18 H, $SiMe_3$). EI MS (70 eV); *m/z* (%): 567 (1) [M^+], 510 (2) [M^+ − C_4H_9], 263 (49) [$PhC(NSiMe_3)_2^+$], 103 (44) [$PhCN^+$], 73 (100) [$SiMe_3^+$]. − $C_{27}H_{42}ClN_5Si_2Ti$ (567.17): calcd. C 56.29, H 7.35, N 12.16; found C 55.83, H 7.82, N 11.88.

[N,N'-Bis(trimethylsilyl)-p-methoxybenzamidinato]-N-tert-butylimidochloro(pyridine)titanium(IV) (**3**): Red-brown crystals, m.p. 88−90°C. Yield: 1.34 g (51%). − IR (cm^{-1}): $\tilde{\nu}$ = 3069 w, 2954 m, 2897 m, 2838 w, 1609 s, 1583 w, 1516 m, 1489 m, 1477 m, 1459 m, 1443 s, 1425 (sh) s, 1400 m, 1390 (sh) m, 1377 m, 1350 m, 1300 (sh) w, 1293 m, 1249 s, 1171 m, 1108 m, 1071 w, 1040 (sh) m, 1034 m, 1016 s, 993 (sh) s, 983 s, 914 m, 839 vs, 756 s, 720 s, 695 s, 644 s, 633 s, 600 m, 543 m, 519 m, 502 w, 393 w, 389 w. − EI MS (70 eV); *m/z* (%): 527 (4) [M^+], 293 (6) [$MeOC_6H_4C(NSiMe_3)_2^+$], 73 (100) [$SiMe_3^+$]. − $C_{23}H_{39}ClN_4OSi_2Ti$ (527.09): calcd. C 52.41, H 7.46, N 10.63; found C 52.53, H 7.66, N 10.21.

N-tert-Butylimidochloro[P,P-diphenylbis(N-trimethylsilylimino)-phosphinato](pyridine)titanium(IV) (**4**): Orange crystals, m.p. 145−147°C. Yield: 2.61 g (88%). − IR (cm^{-1}): $\tilde{\nu}$ = 2956 m, 2895 m, 1604 w, 1591 w, 1485 w, 1438 m, 1403 w, 1390 w, 1377 w, 1353 w, 1257 s, 1247 s, 1212 m, 1138 s, 1115 vs, 1105 vs, 1090 vs, 1070 s, 1044 m, 1028 w, 1014 w, 999 w, 841 vs, 786 s, 751 s, 724 s, 696 vs, 660 s, 640 m, 626 m, 586 s, 532 vs, 509 s, 428 m, 366 m, 321 s, 297 m, 280 s, 248 m, 214 m. − ^{1}H NMR (C_6D_6): δ = 8,86 (m, 1 H, *p*-C_5H_5N), 8,63 (m, 2 H, m-C_5H_5N), 8,16-7,97 (m, 6 H, *m*,*p*-C_6H_5), 7,06 (m, 2 H, *o*-C_5H_5N), 1,52 (s, 9 H, *t*Bu), 0,33 (s, 9 H, $SiMe_3$), 0,10 (s, 9 H, $SiMe_3$). − EI MS (70 eV); *m*/*z* (%): 593 (2) [M^+], 578 (3) [$M^+ - CH_3$], 345 (100) [$Ph_2PN(SiMe_3)_2^+$], 73 (78) [$SiMe_3^+$]. − $C_{27}H_{42}ClN_4PSi_2Ti$ (593.14): calcd. C 54.68, H 7.14, N 9.45; found C 54.01, H 7.29, N 9.37.

Bis(pyridine)lithium P,P-Diphenylbis(N-trimethylsilylimino)-phosphinate (**5**): This compound was isolated as a by-product during the preparation of **4** and isolated as pale yellow crystals by fractional crystallization from hexane. All spectroscopic data (IR, ^{1}H NMR, ^{31}P NMR) were in good agreement with those of an authentic sample prepared directly by addition of pyridine to a hexane solution of $Li[Ph_2P(NSiMe_3)_2]$.[51] − $C_{28}H_{38}LiN_4PSi_2$ (524.72): calcd. C 64.04, H 7.30, N 10.68; found C 64.11, H 7.44, N 10.03.

N-tert-Butylimidobis[N,N-bis(isopropyl)benzamidinato](pyridine)titanium(IV) (**6**): Ochre, microcrystalline solid, m.p. 138−139°C. Yield: 1.45 g (48%). − IR (cm^{-1}): $\tilde{\nu}$ = 2964 s, 2920 s, 2890 s, 2862 s, 1645 m, 1635 m, 1616 w, 1600 s, 1576 m, 1523 s, 1505 s, 1480 s, 1441 s, 1386 s, 1372 s, 1345 s, 1336 s, 1243 s, 1221 s, 1213 s, 1203 s, 1168 s, 1135 s, 1120 s, 1112 s, 1070 s, 1039 s, 1030 (sh) m, 1007 vs, 949 m, 915 m, 798 m, 782 s, 757 s, 737 m, 701 vs, 631 m, 583 m, 525 s, 432 m, 300 m, 295 (sh) m, 282 m, 277 (sh) m. − ^{1}H NMR (C_6D_6): δ 7.34−7.06 (m, 10 H, C_6H_5), 3.58−3.35 (m, 4 H, *i*Pr-CH), 1.58−1.26 (m, 24 H, *i*Pr-CH_3), 1.01 (s, 9 H, *t*Bu). − $C_{35}H_{52}N_6Ti$ (604.72): calcd. C 69.52, H 8.67, N 13.90; found C 69.58, H 8.79, N 14.12.

N-tert-Butylimidobis[P,P-diphenylbis(N-trimethylsilylimino)-phosphinato]titanium(IV) (**7**): Red crystals, m.p. 130−132°C. Yield: 1.72 g (41%). − IR (cm^{-1}): $\tilde{\nu}$ = 3077 w, 3055 m, 2953 s, 2912 m, 2897 m, 1591 w, 1484 w, 1436 s, 1407 m, 1351 m, 1313 m, 1245 vs, 1209 m, 1181 w, 1153 (sh) m, 1115 vs, 1095 s, 1067 s, 1028 m, 999 w, 933 m, 840 vs, 770 s, 747 s, 731 s, 716 s, 695 s, 663 s, 655 (sh) s, 623 m, 615 m, 595 m, 529 s, 506 m, 489 m, 448 m, 409 m, 261 m, 239 m. − ^{1}H NMR (C_6D_6): δ 8.86 (m, 2 H, *m*-C_5H_5N), 8.65 (m, 1 H, *p*-C_5H_5N), 8.16−7.96 (m, 6 H, *m*,*p*-C_6H_5), 7.07 (m, 4 H, *o*-C_6H_5), 6.56 (m, 2 H, *o*-C_5H_5N), 1.52 (s, 9 H, *t*Bu), 0.33 (s, 9 H, $SiMe_3$), 0.10 (s, 9 H, $SiMe_3$). − $C_{40}H_{65}N_5P_2Si_4Ti$ (838.16): calcd. C 57.32, H 7.82, N 8.36; found C 57.42, H 8.04, N 8.30.

Crystal Structure Determination of **7**: $C_{40}H_{65}N_5P_2Si_4Ti$ (838.17), monoclinic, space group, a = 11.198(15), b = 22.055(26), c = 18.842(23) pm, β = 96.65(10)°, V = 4.6221(10) nm^3, Z = 4, d = 1.204 Mg/m^3, μ = 3.465 mm^{-1}, F(000) = 1792, crystal dimensions: 0.60 × 0.40 × 0.40 mm, 2θ range: 4−60°, number of measured reflexions: 6861 (5533 observed with $F^2 > 2\sigma F^2$), refined parameters: 487, goodness of fit: 1.058, R = 0.0772, wR = 0.1983. Further details of the crystal structure determination may be obtained from the Fachinformationszentrum Karlsruhe, Gesellschaft für wissenschaftlich-technische Information mbH, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository number CSD-380139, the names of the authors, and the journal citation.

Keywords: 2-Methyl-1,2,3,4-tetrazole-5-thiolates / 2-Phenyl-1,2,3,4-tetrazole-5-thiolates / Palladium / Platinum / Copper / Silver / Gold / Molecular structures

The molecular structures of nine transition metal tetrazolethiolates have been determined by X-ray structure determinations. The ligand is invariably coordinated through its sulfur atom to the metal center [M = Pd^{II}, Cu^{I}, Ag^{I}, Au^{I}, Au^{III}, and Hg]. The M−S−C bond angles vary considerably, but this cannot be correlated with variations in the C−S bond lengths. Intermolecular association occurs for $Ph_3PAu(SCN_4Me)$ via Au−S contacts, leading to dimeric strands in the solid state. The copper compound $(Ph_3P)_3Cu_4(SCN_4Me)_4$ (**5**), possesses a rather asymmetric structure: one Cu atom is tricoordinated by 3 sulfur atoms, the other three are tetracoordinated by P and N as well as by S atoms.

Introduction

It is well known that mercaptotetrazoles exist as their tetrazinethione tautomers[1]. Deprotonation leads to the tetrazolethiolate anion, which can be considered as a 6π-electron ring system[2]. It binds to metal atoms via its sulfur atom as is evident from IR spectra[3]. However, as shown for organotin complexes of mercaptotetrazoles, one of the nitrogen atoms of the tetrazole ring can also be involved in coordination[4]. This is not necessarily indicated by IR data. Therefore, X-ray structure investigations were necessary to complement other methods of structure analysis that we have performed on neutral and anionic palladium, platinum, copper, silver, and mercury complexes of 2-methyl- and 2-phenyl-1,2,3,4-tetrazole-5-thiolates. These compounds were first reported in 1977[3].

Neutral Complexes

Two types of transition-metal complexes of the mercaptotetrazole ligand have hitherto been described: (i) neutral complexes of the type $L_nM(SCN_4R)_m$ and (ii) anionic complexes $[M(SCN_4R)_m]^{n-}$, while cationic complexes with these ligands are as yet unknown. Neutral mercury, gold, silver, and copper complexes **1**−**5** were available for X-ray structure analyses.

$(Ph_3P)_2Hg(SCN_4Ph)_2$ **1** $(Ph_3P)AuSCN_4Me$ **2** $(Ph_3P)AuSCN_4Ph$ **3**

$(Ph_3P)_2AgSCN_4Ph$ **4** $(Ph_3P)_3Cu_4(SCN_4Me)_4$ **5**

The mercury complex **1** has a tetracoordinated metal center as shown in Figure 1. As has been suggested previously[3], only the sulfur atom of the tetrazolethiolate binds to the metal atom. In the case of compound **1**, the metal atom resides in a distorted tetrahedral environment. The mercury atom lies on a crystallographic twofold rotation axis and imposes C_2 point group symmetry on the molecule. There is a large variation in bond angles: the angle P1−Hg−P1a is rather wide [125.6(1)°] while the S1−Hg−S1a bond angle is compressed [95.7(1)°]. This reflects the larger steric requirement of the triphenylphosphane ligand. The two planes, P−Hg−P and S−Hg−S, are not perpendicular to one another; the twist angle is 78.9°. This is the result of an interaction between one phenyl group of the Ph_3P ligand and the tetrazole ring, which come into close contact and are oriented almost parallel to one another (interplanar angle: 18.4°). Moreover, the CN_4 plane is twisted with respect to the Hg1−S1−C1 plane by 17.8°, while the N-bonded phenyl group C2−C7 is in turn twisted by 125.6° with respect to the CN_4 plane.

[a] Bond parameters for only one tetrazolethiolate unit is given. Those of the other tetrazolethiolate groups are similar within esd's. – [b] S1–M–S1a.

Surprisingly, the Hg–P bond is shorter than the Hg–S distance. The opposite might have been expected considering the atomic radii of P and S atoms. Trends in the bonding parameters of the tetrazole thiolate ligand will be discussed later.

Amongst the coinage metal tetrazolethiolates, those of Au^I are the simplest ones. Two closely related compounds, $Ph_3PAuSCN_4R$ [R = Me (**2**); Ph (**3**)], have been investigated, which differ considerably as far as intermolecular interactions are concerned. The methyl compound **2** shows a dicoordinated gold atom and an almost linear array of the core atoms P, Au and S and angle 170.1(3)°, see Figure 2]. There is clearly very little steric strain in the molecule because the C–P–C bond angles lie in the narrow range from 105.5 to 107.2(3)°; the largest deviation from the ideal tetrahedral angle is only 4°. It should also be noted that the Au1–S1–C1 bond angle is rather small for that of a thiolate.

Figure 2. ORTEP representation of the molecular structure of the gold 2-methyltetrazolethiolate **2** in the crystal; hydrogen atoms are omitted for clarity

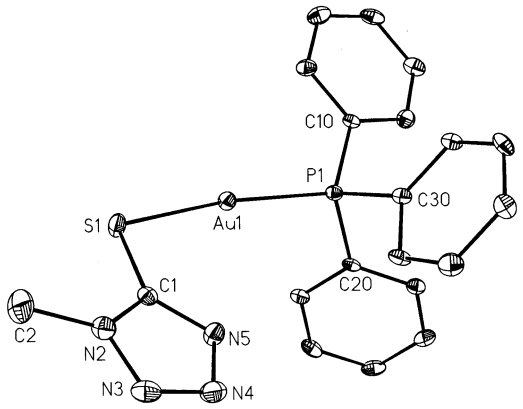

Figure 3. View of two associated molecules of **2** as present in the crystal

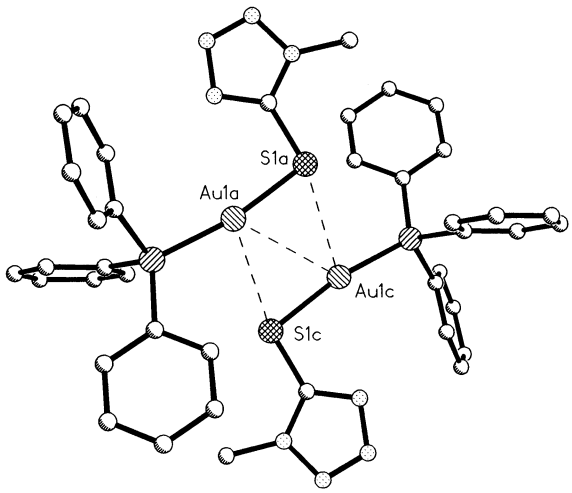


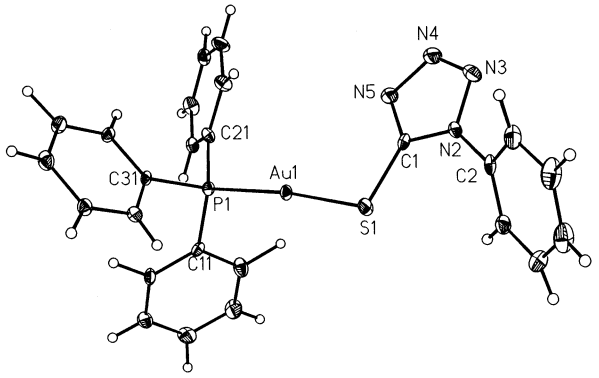
The tetrazole ring forms an angle of 13.2° with the P1–Au1–S1 plane. Interplanar angles between the phenyl groups range from 70.8 to 77.8°, and the C1–C6 plane is almost perpendicularly oriented to the P1–Au1–S1 plane. As in the case of compound **1**, we also observe a longer metal–S bond compared to the metal–P bond for the gold complex **2**, the difference between the bond lengths being

0.037 Å. This is, however, much smaller than that in **1** (0.066 Å).

In the lattice, the molecules of **2** are associated to dimers (see Figure 3) by weak intermolecular gold−sulfur contacts with a distance of 3.423 Å. However, the closest intermolecular Au−Au distance in **2** is 3.946 Å. Therefore, there is no bonding interaction between these atoms as is often found in gold(I) thiolates[5].

Although the overall molecular structure of the gold phenyltetrazolethiolate **3** (see Figure 4) resembles that of compound **2**, considerable differences become apparent upon close inspection. While the P1−Au1−S1 bond angles [172.68(5)°] and the C−P−C bond angles are very similar, the tetrazole ring is twisted out of the P1−Au1−S1 plane by 19.3°. More significant with regard to the packing of the molecules in the lattice is the effect of the phenyl group attached to the tetrazole ring. This group is twisted by 47.7° in relation to the nitrogen-containing ring. Compared with compound **2**, the Au−S bond is not significantly longer but at 105.3(2)° the Au1−S1−C1 bond angle is much wider. However, the most important difference between the two gold thiolates is the packing in the lattice: In compound **3** there are no intermolecular Au−S contacts. In fact, the shortest intermolecular distances between non-hydrogen atoms are between atom C16 of a PPh group and atoms C1, N2 and N3 (3.740, 4.014 and 4.165 Å, respectively).

Figure 4. ORTEP plot of the molecular structure of gold 2-phenyltetrazolethiolate **3**



In contrast to the gold complexes **2** and **3**, the silver 2-phenyltetrazolethiolate **4**, which crystallizes as $(Ph_3P)_2AgSCN_4Ph \cdot CH_2Cl_2$, coordinates to two triphenylphosphane ligands. This results in a planar P_2AgS structural unit (see Figure 6, sum of bond angles at Ag: 359.9°) with respect to which the CN_4 ring plane is twisted by 117.5°; the phenyl group bonded to the tetrazole ring forms an interplanar angle of 134.5° with the latter. The interplanar orientations of the phenyl rings of the phosphane ligands range from 88.0 to 97.0° for P1, and are 75.9, 94.4 and 114.0° for those at P2, the latter being much less evenly distributed than the former. Ag−P bond lengths are shorter by 0.08 and 0.05 Å for P2 and P1, respectively, compared to the Ag−S distance. Due to the rather acute Ag1−S1−C1 bond angle of 90.8(2)°, atom N5 comes relatively close to atom Ag1, the distance being 2.897 Å. This seems to be the reason why the two P−Ag1−S1 bond angles differ by 5.2°.

The copper methyltetrazolethiolate $Ph_3PCuSCN_4Me$ proved to be dimeric in solution suggesting a structure akin to type **A**[3]. However, crystals obtained from dichloromethane solution were shown by X-ray structure analysis to have a different composition: $Cu_4(SCN_4Me)_4(PPh_3)_3$ (compound **5**). Thus, one triphenylphosphane ligand is lost out of 4 monomeric units. The molecular structure of the tetranuclear complex **5**, which crystallizes with one molecule of CH_2Cl_2 per molecule of **5**, is depicted in Figure 7.

The assembly of the core atoms of **5** is rather asymmetric. Three copper atoms are tetracoordinated and one (Cu4) is only tricoordinated if Cu−Cu interactions are neglected [Cu4−Cu1: 2.745(1), Cu4−Cu3: 2.850(1) Å]. Atom Cu4 is the only one that has no triphenylphosphane as a coordination partner. It *only* coordinates to sulfur atoms. The S−Cu4−S bond angles range from 87.76(5) to 116.51(6)°. This corresponds to a strongly distorted trigonal-pyramidal array. A similar distortion is found for atom Cu1, where the tetrahedral angles span a range from 96.7(1) to 121.3(1)°. Deviations from tetrahedral symmetry are much smaller for atom Cu3 [103.5−121.5(2)°] and are smallest for atom Cu2 [101.6(1)−113.0(2)°]. Atoms Cu1 and Cu3 have one P, one N, and two S atoms as coordination partners, while atom Cu2 is surrounded by one P, one S, and two N atoms. The Cu−P bond lengths are different in terms of the 3σ criterion although the range (2.22−2.27 Å) does not suggest significant differences. This is not the case for the Cu−S bonds, which vary markedly (2.24−2.40 Å). Much less variation is observed for the Cu−N bond lengths [2.029−2.074(5) Å] and only the N atoms in the 5-position are found to be involved in bonding, as suggested previously (Formula **A**)[2].

Figure 8 gives a better perspective of the core structure of compound **5** than Figure 7. It represents a view almost down the Cu−S axis of the unique CuS_3 unit. One notes 5 six-membered rings and one eight-membered ring. The structure of this compound must be regarded as being rather unique.

Anionic Complexes

The anionic metal tetrazolethiolates **6**−**9** have in common a tetraphenylarsonium cation. Their AsC_4 core has a symmetry close to the point group T_d, which does not hold for the whole cation. In the tetraphenylarsonium salt of **6**, the As atom is located on a crystallographic twofold axis, but for all the other compounds the arsenic atom is found in a general position.

The mercury atom of the anion **6** (see Figure 9) resides in a general position, and out of the four Hg−S−C bond angles only two are equal [100.5(3)°] while the other two are 98.1(3)° and 103.0(4)°. This asymmetry becomes even more evident when one inspects the interplanar angles that the tetrazole rings form with the respective Hg−S−C planes: these range from 73.1° for S1 to 110.3° for S2 and 71.8° for S3, to finally 138.9° for S4. Two of the methyltetrazolethiolate units are mutually oriented in a "*syn*"

[a] Additional selected bond lengths [Å] and bond angles [°]: Cu2−N5 2.074(5), Cu2−P2 2.270(2), Cu2−N17 2.053(4), Cu2−S4 2.395(2), Cu3−P3 2.242(2), Cu3−S5 2.384(2), Cu3−S7 2.398(2), Cu4−S4 2.250(2), Cu4−S1 2.290(2), Cu4−S5 2.316(2), S4−C3 1.729(6), S5−C5 1.713(6), S4−C3 1.729(6); P1−Cu1−N13 121.3(1), S1−Cu1−N13 98.5(1), S1−Cu1−S7 113.47(5), S7−Cu1−N13 96.7(1), N17−Cu2−N5 112.8(2), N16−Cu2−P2 107.0(1), N5−Cu2−P2 111.4(1), N17−Cu2−S4 113.0(1), N5−Cu2−S4 101.6(2), S5−Cu3−S7 95.89(5), P3−Cu3−S7 104.42(6), P3−Cu3−S5 121.76(7), N9−Cu3−S5 103.5(2), S4−Cu4−S5 117.18(6), S1−Cu4−S7 103.66(5), S5−Cu4−S7 87.76(5), S4−Cu4−S7 112.92(6), S1−Cu4−S5 116.50(6).

fashion (S2 and S4), while the other two (S1 and S3) adopt an "*anti*" orientation. It is, therefore, not surprising that the four Hg−S bond lengths are not equal [range 2.507(2)−2.595(3) Å]. There is no correlation between the Hg−S bond length and the Hg−S−C bond angle.

The Pd atom of the anion **7** (see Figure 10) lies on a center of inversion. Its tetrazole units are twisted with respect to the PdS_4 plane by 71.9 and 75.8° (S1 and S2), respectively. Hence, the point group symmetry for this anion approaches S_4. Bond angles at the sulfur atoms are 108.3(1) and 106.9(1)°, and the corresponding Pd−S bond lengths are 2.332(1) and 2.339(1) Å.

As in the case of the Pd^{II} complex anion **7**, we also find a planar geometry around the gold(III) atom in the complex anion **8** (see Figure 11). This anion also has a symmetry close to point group S_4 since its metal atom resides on an inversion center. In this case, the tetrazole units are oriented almost perfectly orthogonally to the AuS_4 plane, with interplanar angles of 89.4 and 89.7°. However, the Au−S−C planes are not coplanar and the plane Au1−S1−C1 forms an angle of 11.3° with the plane Au1−S2−C2. It is interesting to note that the bond angles Au−S−C are rather wide at 107.2(2) and 106.8(2)°, and that, like the angles, there is no significant difference between the Au−S bond lengths [2.356(1) and 2.358(1) Å].

A rather unusual geometry is observed for the Au^{I} anion **9** (see Figure 12). There is an almost linear arrangement of atoms S1−Au1−S2 [175.15(7)°]. The tetrazole units form grossly different interplanar angles with the S1−Au1−S2

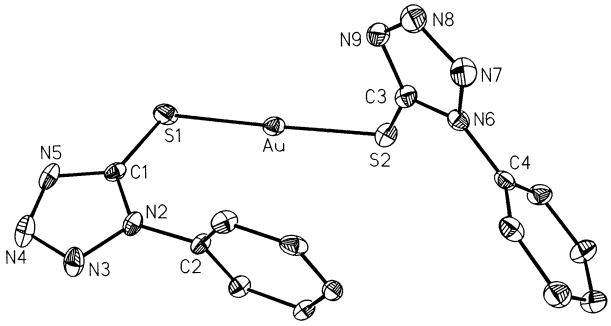
plane: 33° for tetrazole C1, and 114.8° for tetrazole C3. At least as different are the orientations of the planes of the phenyl groups in relation to the respective tetrazole rings. Interplanar angles are 92.2° and 130.8°, respectively. This leads to a molecular arrangement in which one of the two phenyl groups comes close to the gold center. In spite of this orientation, it is apparent that the Au−S1−C bond angle is wider [110.1(2)°] than the comparable angle at atom S2 [102.6(2)°]. If there were an η^6 interaction of a phenyl ring with the gold atom, one would expect that this phenyl group would be that with the more acute bond angle at the sulfur atom. This is obviously not the case.

Figure 12. The molecular structure of the bis(2-phenyltetrazolethiolato) aurate(I) (**9**), depicted in an orientation that shows the steric shielding of the gold atom by one phenyl group



Discussion

The present study on the molecular structures of 2-substituted metal tetrazolethiolates, as determined by X-ray structure analysis, confirm those suggested previously except in the case of the silver and copper compounds. All except the copper compound **5** show that the sulfur atom of the tetrazolethiolate coordinates to the metal center in accord with the hard/soft concept of acids and bases. Within the coinage group, compound **5** is also the only one in which nitrogen atoms are also involved in coordination, and this also fits with theory because the copper atom is the hardest in the coinage metal group. Moreover, the Cu−Cu atom distances calculated for **5** are too long to sug-

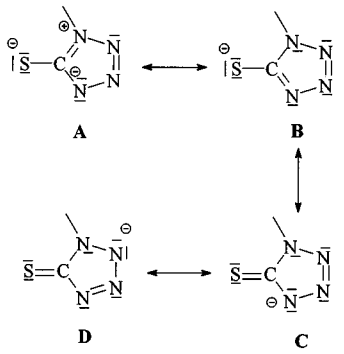
gest metal−metal bonding. Also, there are no close Au−Au contacts in **2**, although significant Au−Au interactions have been found in a related compound, $Ph_3PAuSPh$, which forms pairs in the crystal via Au−Au contacts [Au−Au 3.135(3), Au−S 2.30(1), and Au−P 2.26(1) Å][3].

The structural parameters obtained for complexes **1**−**9** show that there is *no* correlation between the magnitude of the M−S−C bond angle and the C−S bond length. It is, however, interesting to note that the M−S−C bond angle varies considerably. For the neutral complexes, the range covered is 97.5−106.9°, while for the anionic species it is 100.5−110.1°. There is also a range from 1.698(5)−1.740(4) Å for the C−S bond lengths found for the neutral complexes and a somewhat smaller range [1.72(1)−1.746(9) Å] for the anions. These bond lengths correspond to those found for thiourea [1.71(1)][6], thioacetamide [1.713(6)][7] and 3-hydrazino-5-mercapto-1,2,4-triazole [1.74(1)][7], but are definitely longer than the C=S double bond in CS_2 [1.555(1) Å]. Therefore, they are intermediate between the C−S single (1.82 Å) and C=S double bond lengths (see also the discussion in ref.[9]). Consequently, the bonding in this ligand is best described by the canonical formulae **B** to **D**.



Although the tetrazole ring can be considered as a 6π-electron heterocycle, the electron distribution is obviously not uniform because the N3−N4 bond is significantly shorter than the two other N−N bonds, let alone the C−N bonds[9]. Most notably, the N4−N5 bond is distinctly longer than the N3−N4 bond. This indicates that the canonical formulae **B** and **D** make the largest contributions to the ground state.

A comparison of the M−S bonds to the same metal center in neutral and anionic species reveals that these

bonds are *longer* in the neutral complexes than in the anionic species, e.g. by 0.01 Å for M = Hg and by 0.05 and 0.03 Å, for M = Au^{I}. The longer Au−S bonds for the aurate anion **7** are clearly the consequence of the higher coordination number. However, the Au−S bond lengths for **2**, **3**, **8**, and **9** fall into the range observed for many other complexes with Au−S bonds (2.28−2.79 Å), while the Cu−S bond lengths of **5** are best compared with those in $(Me_4N)_2Cu_5(SPh)_7$ [2.159(3) Å][10].

The copper complex **5** demonstrates that the Cu−S bond lengths to the tetrazolethiolate units are elongated when the N5 atom is involved in coordination to the copper atoms. Thus, the canonical forms **B** and **C** become more significant in this situation. In contrast, the trimeric tetrazolethiolato complex $Me_3Sn(SCN_4Ph)$, where association occurs via the N3 atom, shows a shortening of the N4−N5 bond [1.35(2) Å] and a lengthening of the N3−N4 bond [1.35(2) Å]. This indicates that in this situation formula **D** makes a significant contribution to the ground state. It remains to investigate structures of tetrazolethiolates with truly hard acids in order to find out whether the hard cation will only bind to nitrogen and/or to sulfur as well. The only compound reported to date is the potassium crown compound (12-crown-4)$KSCN_4Me$[9], in which the S and one N atom coordinate to the potassium ion. In addition, there is a fairly short distance between the potassium ion and the ring carbon atom, but this cannot be considered as a potassium−carbon bond.

We are grateful to the *Fonds der Chemischen Industrie* and *Chemetall GmbH* for generous support. Also, we are indebted to Dr. *I. Krossing* for recording the data set of compound **4**.

Experimental Section

The compounds used for the X-ray structure determinations were the original samples[3]. Only the Cu complex **5** had to be crystallized from dichloromethane, and the structure determination showed the loss of a triphenylphosphane ligand.

All compounds were mounted on a glass fibre with a small amount of perfluoroether oil. After optical alignment at 193 K on a Siemens P4 diffractometer equipped with a Siemens CCD area detector, the unit cells were determined from the reflections of four sets of 15 frames each recorded at four different χ settings by changing ϕ by 0.3° between each frame. Data were recorded from a total of 1200 frames with 10-s exposures and changes in φ by 0.3° at two different χ settings. Data reduction was performed with the program SAINT, and an empirical absorption correction was applied using all data with esd′s larger than 20. The structures were solved by the heavy-atom method; the model was complemented by difference Fourier synthesis and refined by using the programs SHELXL-93 and -97[10]. All non-hydrogen atoms were refined with anisotropic temperature parameters. Although many or all hydrogen positions could be located, the positions of hydrogen atoms were calculated and included as a riding model in the final cycles of the calculations. The crystallographic data are compiled in Table 2. Thermal ellipsoids in the figures represent a 25-% probability level. Further information on the crystal-structure determinations has been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100802 and may be obtained from CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax (internat.): + 44 (0)1223/336033; e-mail: deposit@.cam.ac.uk].

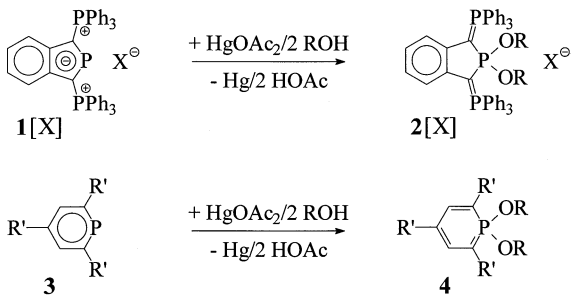
Bis(phosphonio)isophosphindolide iodide **1**[I] reacts with an equimolar amount of I_2 to yield the trihalide **1**[I_3], while treatment of **1**[X] (X = Br, OTf) with excess Br_2 furnishes the dibromophosphonium salt **6c**[X]. The bromo-substituted bis(phosphonio)isophosphindolide cations **5a** and **5b** are identified as intermediates in this reaction; **5b**[Br] is also obtained in pure form by reaction of **6c**[Br] with Zn or NEt_3. Reaction of **1**[OTf] with one equivalent of $PhICl_2$ (**7**) affords the dichlorophosphonium salt **8a**[OTf], which undergoes further substitution reactions in the presence of excess **7** and reacts with Me_3SiI to give a mixture of **1**[OTf] and I_2 rather than a substitution product **9**[OTf]. The results of a crystal-structure determination of **8a**[OTf] are reported and the mechanistic aspects of the different oxidation/substitution reactions are discussed.

In the course of our investigation of the coordination chemistry of bis(phosphonio)isophosphindolide ions, we found that the cation **1**[1] easily undergoes oxidative alcoholysis reactions in the coordination sphere of Hg^{2+} or Pd^{2+} ions to yield dialkoxy-substituted phosphonium ions **2** (Scheme 1)[2]. This reaction is related to the conversion of σ^2,λ^3-phosphinines **3** into 1,1-dialkoxy-σ^4,λ^5-phosphinines **4** (Scheme 1), which takes place under similar conditions[3]. In looking for a way to achieve oxidation of bis(phosphonio)isophosphindolides without the assistance of transition metals, we investigated the behaviour of the salts **1**[X] (X = halide, triflate) towards halogens, anticipating that a similar reaction as the oxidative halogenation of σ^2,λ^3-phosphinines[3] should occur. The results of these studies are presented here. The studies revealed, however, a more complex reactivity pattern which is characterised by competition between the expected oxidation with substitution reactions at the fused ring system.

Scheme 1. (X = Br, OTf)



Results

Reactions

Treatment of a CH_2Cl_2 solution of **1**[I] with an equimolar amount of I_2 produced almost instantaneously a brown solution. While ^1H- and ^{31}P-NMR data indicated the presence of the unchanged cation **1**, UV/Vis and Raman spectra showed bands attributable to I_3^- anions [UV/Vis: λ_{max} = 361, 294 nm (ref.[4]: 360, 290 nm); Raman: $\tilde{\nu}$ = 112, 145 cm^{-1} (ref.[5]: 52, 114, 145 cm^{-1})], suggesting the formation of a salt **1**[I_3] by electrophilic attack of iodine on the halide anion of the starting material (Scheme 2). The crude product was isolated as a dark brown, highly moisture-sensitive solid after evaporation of all volatiles, but decomposed during attempts to achieve any further purification by recrystallisation.

Reaction of **1**[Br] or **1**[OTf] with a substoichiometric amount of Br_2 (0.5 to 0.9 equiv.) in CH_2Cl_2 produced, according to a ^{31}P-NMR-spectroscopic assay, a mixture of the unreacted cation **1** with two further products which displayed ABX or A_2X patterns with $\delta^{31}P$ and $^2J_{PP}$ values very similar to those of **1**. Analysis of (+)-FAB mass spectra and two-dimensional $^1H,^{31}P$-HMQC/HMQC-TOCSY NMR spectra of the product mixture allowed the identification of the reaction products as the bromo-substituted bis(phosphonio)isophosphindolide ions **5a** and **5b**. This suggests that a bromination at the fused ring system of **1** with conservation of the two-coordinate phosphorus atom had occurred.

Addition of more Br_2 did not result in further conversion of **1** into **5a** and **5b**, but rather in the formation of two new species whose ^{31}P-NMR signals displayed ABX or A_2X patterns with much smaller values of $^2J_{PP}$ and a marked up-

field shift of the P^X resonance. On this basis the new species were found to be the oxidation products **6b** and **6c**. Complete conversion of all intermediates into **6c** was finally observed after four equivalents of Br_2 had been added. Evaporation of the solution formed gave a brown, highly moisture-sensitive residue of crude **6c**[X] which contained approximately 3−5% of nonphosphorus-containing compounds as impurities. Although attempts towards further purification failed because of decomposition of the highly reactive dihalo-phosphonium moiety, the constitution of the cation was unambiguously confirmed by means of multinuclear NMR investigations.

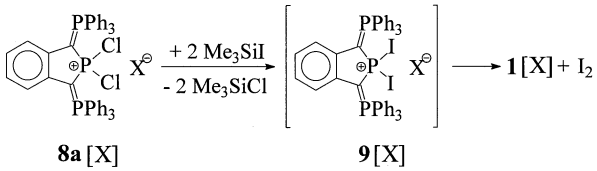
A further chemical proof of the identity of **6c** was obtained from its reactions with Zn or, alternatively, with excess NEt_3, which afforded the dibromo-substituted bis-(phosphonio)isophosphindolide **5b** by selective reduction of the Br_2P unit. The salt **5b**[Br] was isolated in analytically pure form as a white solid that was fairly stable to both air and moisture and was characterised by NMR spectroscopy. The monobrominated cation **5a**, which was not accessible in preparative amounts by this procedure, was formed as the main product (70% of phosphorus-containing species) in the reaction of a mixture of **6b** and **6c** (prepared in situ from the reaction of **1**[OTf] with 2.5 equiv. of Br_2) with an equimolar amount of **1**[OTf]. Chromatographic workup produced a small quantity of crude **5a**[OTf] which, although still contaminated by small amounts of **1** and **5b**, proved sufficient for an unambiguous NMR-spectroscopic structure elucidation.

Reaction of **1**[X] (X = Cl, OTf) with an equimolar amount of $PhICl_2$ (**7**), which was chosen as a chlorinating agent because of its superior handling as compared to elemental Cl_2, furnished selectively the oxidation products **8a**[X]. The triflate salt **8a**[OTf] was precipitated by addition of ether and isolated after recrystallisation as a light yellow, moisture-sensitive solid which is readily soluble in aprotic dipolar solvents such as CH_2Cl_2 or THF. The product was characterised by means of NMR spectroscopy and an X-ray crystal-structure determination.

Further reaction of **8a**[X] with an excess of **7** in the presence of NEt_3 as an acid scavenger was found to proceed in a more complicated way than the reaction with Br_2 and yielded a mixture of several species rather than a single final product. Attempts towards isolation of single components remained unsuccessful, but inspection of ^{31}P-NMR spectra of the mixtures allowed the identification of two species which displayed ABX and A_2X coupling patterns with very similar values for $\delta^{31}P$ and J_{PP} as **8a** and were tentatively formulated as the chlorinated cations **8b** and **8c**. The additional presence of a singlet resonance attributable to $[ClPPh_3]^+$, together with several unidentified AX-type multiplets, suggested that in addition to the H/Cl exchange, partial decomposition of the molecular skeleton by cleavage of an exocyclic phosphonio substituent had also occurred. Initial formation of **8b** and **8c** as the main products was likewise observed upon treatment of **1**[OTf] with an excess of **7** in pure CH_2Cl_2, but the products were found to decompose completely during the further course of the reaction.

Reaction of **8a**[OTf] with two equivalents of Me_3SiI proceeded with quantitative formation of **1**[OTf] and I_2. No evidence for the formation of a substitution product **9**[OTf] was obtained; this compound is presumably unstable with respect to disproportionation (Scheme 3). A slow, but selective conversion of **8a** into **1** was also observed upon addition of pyridine or NEt_3 to CH_2Cl_2 solutions of **8a**[OTf] and keeping the resulting mixtures for several days; in this case, the nature of the oxidation products was not elucidated.

Scheme 3. (X = Cl, OTf)



NMR-Spectroscopic Investigations

The $\delta^{31}P$ values for the two-coordinate phosphorus atoms in the cations **1** and **5a** and **5b** are shifted to lower field with increasing number of Br substituents, while the resonances of the nuclei in the phosphonio groups and those of the quaternary C-1/C-3 carbon atoms remain essentially unchanged (Table 1). Likewise, the values of both $^2J P^A P^X$ and $^4J P^A P^B$ are very similar for all three compounds. The position of the bromine atom in **5a** follows immediately from the $^1H\{^{31}P\}$-NMR spectrum; the resonances of the hydrogen atoms at the central ring appear as an AMX-type pattern whose middle proton shows a splitting by a large and a small coupling which is characteristic

of a 1,2,4-substituted benzene moiety. The $^1H\{^{31}P\}$-NMR spectrum of **5b** displays a singlet for the protons adjacent to the bromine atoms which splits into an apparent doublet in an undecoupled spectrum. A correlation peak with the upfield ^{31}P resonance in a $^1H,^{31}P$-HMQC spectrum revealed that the splitting must arise from coupling with the two exocyclic phosphorus nuclei rather than the single endocyclic phosphorus nucleus. The magnitude of the $^nJ_{HP}$ couplings [J = +(−)3.3 and −(+)1.7 Hz] which were determined by iterative analysis suggested attachment of the hydrogen atoms in the 4,7 rather than in the remote 5,6 positions of the fused ring system. This hypothesis was further corroborated by a strong correlation peak connecting the 4-H/7-H and C-1/C-3 signals in a $^1H,^{13}C$-HMBC spectrum which is in accord with the presence of a three-bond coupling pathway.

Table 1. ^{31}P-NMR and selected ^{13}C-NMR data of **1, 5a, 5b, 6b, 6c**, and **8a−c**; chemical shifts are given in ppm, coupling constants in Hz; P^A, P^B, and P^X denote the phosphorus nuclei in ABX- or A_2X-spin systems, respectively

	$\delta^{31}P$				$\delta^{13}C$	J_{PC}	
	P^A, P^B	P^X	$^2J_{P^A,P^BP^X}$	$^4J_{P^AP^B}$	C-1/C-3	$^1J_{PC}$	$^3J_{PC}$

8c	11.4	51.7	43.2	−	−	−	−

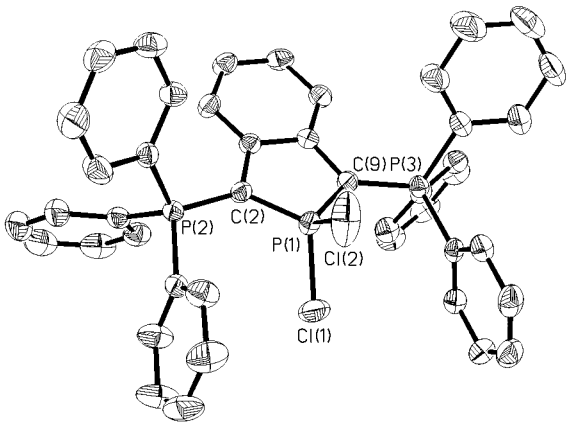
[a] $\delta^{31}P$, $\delta^{13}C$, and $^2J_{PP}$ from ref.[1]. − [b] Signs of coupling constants were determined from a two-dimensional $^{31}P,^{13}C$ shift correlation. − [c] Values of $^4J^{P^AP^{A'}}$ were obtained from analysis of appropriate ^{13}C satellites in the ^{31}P-NMR spectra.

The $\delta^{31}P$ values of the endocyclic phosphorus atoms in the oxidation products **6b** and **6c** range between those of acyclic dichlorophosphonium salts ($\delta^{31}P$ = 66−104[6]) and 1,1-dichloro-λ^5,σ^4-phosphinines ($\delta^{31}P$ = 7−17[7]), while formal replacement of Cl by Br in **8b** and **8c** induces a comparable upfield shift of $d^{31}P$ as in the cyclophosphazene system[8]. The magnitudes of $^2J^{P^AP^X}$ and $^4J^{P^AP^B}$ are about half as large as in **1**, **5a** and **5b**. The ^{13}C-NMR signals of the quaternary C-1/C-3 atoms in **6c** and **8a** reveal similar upfield shifts with respect to **1**, **5b** as were previously found for the 1,1-dialkoxy-substituted cations **2**[2], suggesting a pronounced ylidic character for the exocyclic P−C bonds. As in **5b**, the resonance of the 4-H/7-H atoms of **6c** and **8c** appears as a singlet in the $^1H\{^{31}P\}$-NMR spectrum and splits to a triplet in the undecoupled spectrum due to coupling with the two exocyclic ^{31}P nuclei.

Molecular Structure of 8a

Crystalline **8a**[OTf] consists of discrete anions and cations and contains an additional solvent molecule per formula unit. No contacts closer than van der Waals distances are exhibited by any of the single components. As in **1**[9], the fused ring system in the cation **8a** (Figure 1) is planar, with a standard deviation of the ring atoms and the two exocyclic phosphorus atoms from the mean plane of 0.030 Å. The difference between endocyclic [1.695(4), 1.697(4) Å] and exocyclic P−C bond lengths [1.723(4), 1.729(4) Å] is similar to **1**[9], but both types of bonds are somewhat shorter than there. The two P−Cl bonds [1.991(2), 2.063(2) Å] differ in length. Both exceed the bond length of 1.91 Å in $[PCl_4][FeCl_4]$[10] and lie between the values of equatorial and axial bonds in PCl_5 (2.02, 2.14 Å[10]). The central P(1) atom displays a distorted tetrahedral coordination, with the C(2)−P(1)−C(9) [99.5(2)°] and Cl(1)−P(1)−Cl(2) angles [97.4(1)°] being significantly more acute than the ideal angle of 109.4°. Interestingly, the two chlorine atoms exhibit a slightly asymmetric arrangement with respect to the plane through P(1), C(2), and C(9), with the longer P(1)−Cl(2) bond showing a larger tilt angle with respect to this plane. Regarding, however, the large thermal ellipsoid at Cl(2) (Figure 1), it remains uncertain if this effect indicates a real structural distortion or is merely the consequence of larger librational motion of the chlorine atom.

Figure 1. ORTEP view (50-% probability ellipsoids) of the cation in crystalline **8a** [OTf][a]



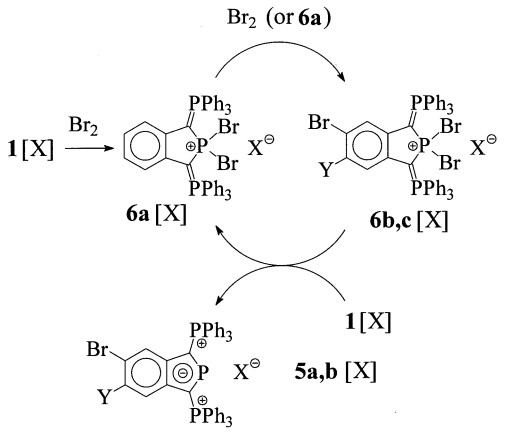
[a] Selected bond lengths [Å] and angles [°]: Cl(1)−P(1) 1.991(2), Cl(2)−P(1) 2.063(2), P(1)−C(2) 1.695(4), P(1)−C(9) 1.697(4), C(2)−P(2) 1.729(4), C(9)−P(3) 1.723(4); Cl(1)−P(1)−Cl(2) 97.4(1), C(2)−P(1)−C(9) 99.5(2), C(2)−P(1)−Cl(1) 116.2(1), C(2)−P(1)−Cl(2) 115.1(2), C(9)−P(1)−Cl(1) 116.9(1), C(9)−P(1)−Cl(2) 112.8(1).

The oxidation of the bis(phosphonio)isophosphindolide cation **1** to the 1,1-dihalogeno derivatives **6b, 6c** and **8a**, as well as the corresponding retro reaction (that is reduction of the formed products to give **1, 5a** and **5b**, respectively) resemble similar reactions of phosphinines[3][7]. The bonding in the products **6** and **8** may be described, as is suggested by the drawings in Scheme 2, in terms of a bis-ylide which receives additional electronic stabilisation by negative

hyperconjugation into the central dihalophosphonium moiety[11]. The instability of the corresponding 1,1-diiodo derivative **9** which becomes evident both in the failure to observe oxidation of **1** with I_2 as well as in the formation of **1** and I_2 after treatment of **8a** with Me_3SiI, reflects the lower oxidative power of the heavier halogen.

The reaction of **1** with Br_2 in which the formation of the substituted bis(phosphonio)isophosphindolides **5a** and **5b** precedes the formation of the oxidation products **6b** and **6c** deserves some further comment. In principle, **5a** and **5b** may be generated by either of two mechanisms: (a) direct electrophilic substitution of **1**, or (b) a multistep pathway (Scheme 4) involving initial oxidation of **1** to **6a**, subsequent substitution of the oxidation product to give **6b** and **6c**, and final reaction of these species with **1** under formation of **5a** and **5b** and regeneration of **6a** (because of the recursive nature of the overall reaction, **6a** needs to be present only in a catalytic quantity).

Scheme 4. Proposed mechanism for the formation of **5a** and **5b** during the reaction of **1** with Br_2 (X = Br, OTf; Y = H, Br)



The available experimental results do not allow a definitive determination of the reaction mechanism to be made; however, we favour the second alternative because it allows an explanation of the observed reactions of **1** with Br_2 and $PhICl_2$ in terms of a common mechanism. Moreover, this mechanism is equivalent to the "indirect" electrophilic substitution of λ^3-phosphinines[3], and all crucial steps in the sequence had been verified independently. Thus, reduction of a 1,1-dibromobis(phosphonio)isophosphindolide by **1** is involved in the conproportionation of **6a** and **1** to give **5a** (see above). Furthermore, it was recently shown by Schmidpeter[12] that ylide substituents may activate aromatic ring systems for electrophilic substitution so that a particularly high reactivity for the double ylide substituted benzene moieties in **6a** (and **8a**) is expected. Considering the *o*-/*p*-directing capability of ylide groups[12], exchange of all four hydrogen atoms in **6a** should in principle be possible. The observed regioselectivity indicates a higher reactivity at the 5,6 positions, while tri- and tetrasubstitution are presumably prevented by the deactivating influence (−I effect) of the halide substituents. The failure to observe **6a** in significant concentration beside the substitution products **6b** and **6c** suggests that either electrophilic substitution of **6a** occurs at a much higher rate or that **6a** exhibits a higher tendency for reductive debromination than **6b** and **6c**; both explanations again highlight the importance of deactivation of the aromatic system by halide substituents. The difference in the reactions of **1** with Br_2, where the formation of the substitution products **5a** and **5b** apparently precedes that of the oxidation product, and with **7**, where this is not the case, may be attributable to a higher kinetic lability and/or lower thermodynamic stability of **6a** as compared to **8a**. This is also in accord with the observed different rates of amine-induced reductive elimination reactions, and was predicted by the lower stability of 1,1-dibromo- as compared to 1,1-dichlorophosphinines[4].

Financial support of this work by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

General: All manipulations were carried out under dry argon. Solvents were dried using standard procedures. − NMR spectra: Bruker AMX 300 (^{1}H: 300.13 MHz, ^{13}C: 75.46 MHz, ^{31}P: 121.5 MHz). ^{1}H,^{31}P(^{13}C)-HMQC- and HMQC-TOCSY spectra were measured using standard pulse sequences from the Bruker Pulse Program library. Spectra of samples in nondeuterated solvents were recorded with suppression of the solvent resonances by presaturation. Chemical shifts were referenced to ext. TMS (^{1}H and ^{13}C) and 85% H_3PO_4 (^{31}P, Ξ = 40.480747 MHz); a positive sign denotes a shift to lower frequencies. Coupling constants are given as absolute values. The atoms in the isophosphindole ring system are denoted by C-1 to C-7a and 4-H to 7-H, and atoms within the C_6H_5 substituents by C(H)^{para}, C(H)^{meta}; the assignment of the resonances was derived from 2D ^{1}H,^{13}C-HMQC/HMBC spectra. For ^{13}C-NMR signals which are the X part of AA′MX- or AA′X-spin systems, ΣJ denotes the absolute value of the sum of the couplings to the exocyclic phosphorus nuclei, and J_M the coupling to the endocyclic phosphorus atom. − UV/Vis: Uvikon 860. − Raman Spectra: Bruker RFS 100. − MS: Kratos Concept 1 H, Xe-FAB, *m*-nitrobenzaldehyde matrix; molecular masses refer to the most abundant isotopes. − Melting points were determined in sealed capillaries. − Elemental analyses: Heraeus CHNO-Rapid or Mikroanalytisches Labor Pascher, Remagen.

Reaction of **1**[I] *with* I_2*:* To a solution of 0.63 g (0.81 mmol) of **1**[I] in 20 ml of CH_2Cl_2 was added 0.21 g (0.81 mmol) of I_2, and the mixture stirred for 30 min at ambient temperature until a clear solution was obtained. Removal of all volatiles in vacuo produced a brown, highly moisture- and air-sensitive solid whose ^{1}H- and ^{31}P-NMR spectra were identical with those of **1**[I]. UV/Vis and Raman spectroscopy (for data see text) indicated the presence of I_3^- ions, suggesting the formation of **1**[I_3^-]. Attempts at recrystallisation of the product from CH_2Cl_2/Et_2O mixtures failed due to the onset of extensive decomposition reactions.

Reaction of **1**[Br] *with* Br_2*:* A solution of 4.86 g (30.4 mmol) of Br_2 in 70 ml of CH_2Cl_2 was added dropwise within 2 h to a solution of 5.60 g (7.60 mmol) of **1**[Br] in 30 ml of CH_2Cl_2. Interrupting the reaction at different stages and subjecting an aliquot of the reaction mixture to ^{1}H- and ^{31}P-NMR-spectroscopic analysis allowed the identification of cations **5a, 5b** and **6b** as reaction intermediates. The red-brown solution resulting at the end of the reac-

tion was concentrated to dryness and the residue redissolved in CH_2Cl_2. Inspection of ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra revealed the presence of **6c** as the only phosphorus-containing component, together with small amounts (3−5% by integration of ^{1}H-NMR spectra) of nonphosphorus-containing impurities which were not analysed further. Attempts to purify the crude product by recrystallisation from different solvent mixtures were unsuccessful and promoted increasing decomposition of **6c**.

6b: ^{1}H NMR (CH_2Cl_2): δ = 7.9−7.7 (m, 30 H, C_6H_5), 6.47 (m, 1 H, 6-H), 6.23 (m, 1 H, 4-H), 6.07 (m, 1 H, 7-H). − ^{1}H{^{31}P} NMR (CH_2Cl_2): δ = 7.9−7.7 (m, 30 H, C_6H_5), 6.47 (dd, J_{HH} = 8.3, 1.9 Hz, 1 H, 6-H), 6.23 (d, J_{HH} = 1.9 Hz, 1 H, 4-H), 6.07 (d, J_{HH} = 8.3 Hz, 1 H, 7-H).

6c: ^{1}H NMR (CH_2Cl_2): δ = 7.88−7.75 (m, 18 H, H^{meta}, H^{para}), 7.71 (m, 12 H, H^{ortho}), 6.30 (t, ΣJ = 3.6 Hz, 2 H, H-4,7). − ^{1}H{^{31}P} NMR (CH_2Cl_2): δ = 7.88−7.75 (m, 18 H, H^{meta}, H^{para}), 7.71 (m, 12 H, H^{ortho}), 6.30 (s, 1 H, 4,7-H). − ^{13}C NMR (CH_2Cl_2): δ = 137.48 (m, ΣJ = 18.7 Hz, J_M = 31.2 Hz, C-3a,7a), 134.74 (m, ΣJ = 2.5 Hz, C^{para}), 134.51 (m, ΣJ = 10.9 Hz, C^{ortho}), 130.03 (m, ΣJ = 13.2 Hz, C^{meta}), 121.49 (m, ΣJ = 3.7 Hz, J_M = 18.3 Hz, C-4,7), 119.69 (m, ΣJ = 95.5 Hz, $^3J_{PC}$ = 3.0 Hz, C^{ipso}), 113.3 (d, J_{PC} = 2.5 Hz, C-5,6), 49.53 (ddd, $^1J_{PC}$ = 119.3, 123.7 Hz,$^3J_{PC}$ = 8.1 Hz, C-1,3).

Reduction of **6b and 6c**: To a stirred solution of crude **6c**[Br], which was prepared as described above, was added 3.64 g (36.0 mmol) of dry NEt_3. After continued stirring for 30 min, the reaction mixture was concentrated to dryness, the remaining solid redissolved in 40 ml CH_2Cl_2, and the resulting solution extracted twice with 25 ml of water. The organic phase was separated and dried with Na_2SO_4. Slow addition of 30 ml of ether produced a yellow precipitate which was collected by filtration and washed twice with 20 ml of ether. Recrystallisation from CH_2Cl_2/Et_2O gave 4.48 g of **5b**[Br]·CH_2Cl_2 (60%) as a light yellow powder, m.p. 186°C. For the preparation of compound **5a**, 1.00 g of **1**[OTf] and 50 mg (3 mmol) of Br_2 were treated as described above. To the resulting solution, which contained according to an ^{31}P-NMR-spectroscopic analysis approx. 70% of **6b**, was added with stirring 1.00 g (1.24 mmol) of **1**[OTf]. Chromatographic workup (silica gel, eluent: CH_2Cl_2) furnished 100 mg of a white solid which consisted of a mixture of **5a** (60%), **5b** (35%), and **1** (5%) according to an NMR-spectroscopic assay. No further separation by fractional crystallisation was achieved, and NMR-spectroscopic characterisation of **6b** was performed with the crude product mixture.

5a[OTf]: ^{1}H NMR ($CDCl_3$): δ = 7.72−7.55 (m, 30 H, C_6H_5), 7.03 (br. d, J_{HH} = 1.8 Hz, 1 H, 4-H), 6.95 (dd, J_{HH} = 1.8, 8.7 Hz, 1 H, 6-H), 6.80 (dd, J_{HH} = 8.7 Hz, ΣJ_{PH} = 2 Hz, 1 H, 7-H). − ^{1}H{^{31}P} NMR ($CDCl_3$): δ = 7.72−7.55 (m, 30 H, C_6H_5), 7.03 (d, J_{HH} = 1.8 Hz, 1 H, 4-H), 6.95 (dd, J_{HH} = 1.8, 8.7 Hz, 1 H, 6-H), 6.80 (d, J_{HH} = 8.7 Hz, 1 H, 7-H). − ^{13}C NMR ($CDCl_3$): δ = 146.6 (m, C-3a), 144.12 (m, C-7a), 134.52 (s, C^{para}), 134.48 (s, C^{para}), 133.9−133.7 (m, C^{ortho}), 130.20−129.9 (m, C^{meta}), 124.49 (br. s, C-4), 124.47 (br. s, C-6), 122.67 (ddd, J_{PC} = 92/3/3 Hz, C^{ipso}), 122.01 (br. m, C-7), 121.90 (ddd, J_{PC} = 92/2/1 Hz, C^{ipso}), 117.85 (s, C-5), 110.5 (ddd, $^1J_{PC}$ = 110/56 Hz,$^3J_{PC}$ = 14 Hz, C-1,3), 110.3 (ddd, $^1J_{PC}$ = 112/57 Hz,$^3J_{PC}$ = 15 Hz, C-1,3).

5b[Br]: $C_{44}H_{32}Br_3P_3$·CH_2Cl_2 (895.39): calcd. C 55.13, H 3.70; found C 55.41, H 3.88. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε_{max}) = 370 (sh), 345 (4.1), 274 (sh), 261 (4.5) nm. − ^{1}H NMR ($CDCl_3$): δ = 7.77−7.57 (m, 30 H, C_6H_5), 7.12 {m, iterative analysis as an $[AX]_2$ spin system gave J_{PH} = +(−)3.4, −(+)1.7 Hz, J_{HH} = 0.9 Hz, 2 H, 4,7-H}. − ^{13}C NMR ($CDCl_3$): δ = 144.49 (m, ΣJ = 24.0 Hz, J_M = 2.7 Hz, C-3a,7a), 135.02 (m, ΣJ = 2.3 Hz, C^{para}), 134.23 (m, ΣJ = 9.9 Hz, C^{ortho}), 130.503 (m, ΣJ = 20.2 Hz, C^{meta}), 124.79 (br. m, C-4,7), 121.90 (m, ΣJ = 92.6 Hz, $^3J_{PC}$ = 2.8 Hz, C^{ipso}), 120.52 (q, J_{FC} = 320.2 Hz, CF_3SO_3), 118.09 (s, C-5,6), 112.00 (ddd, $^1J_{PC}$ = 96.9, 58.2 Hz,$^3J_{PC}$ = 13.7 Hz, C-1,3).

Reaction of **1**[OTf] *with* $PhICl_2$: To a stirred solution of 1.50 g (1.86 mmol) of **1**[OTf] in 20 ml of CH_2Cl_2 was added dropwise a solution of 0.51 g (1.86 mmol) of $PhICl_2$ in 20 ml of CH_2Cl_2. Subsequent dropwise addition of 15 ml of Et_2O to the yellow fluorescing solution produced a yellow precipitate which was collected by filtration, washed with Et_2O and dried in vacuo to give 1.48 g of **8a**[OTf]·CH_2Cl_2 (91%), m.p. 201°C. The same product was obtained when the reaction was conducted in the presence of 0.55 ml of NEt_3. Reaction of **1**[OTf] with an excess of $PhICl_2$ (1.5 to 4 equiv.) under the same conditions produced, according to ^{31}P-NMR-spectroscopic analysis, complex product mixtures which contained beside unreacted **8a** various amounts of the supposed substitution products **8b** and **8c** and several components whose resonances appeared as singlets or AX-type patterns. With the exception of a singlet at δ = 63.4 which was assigned to $[ClPPh_3]^+$ by comparison with an authentic sample, none of these products was identified. Separation of the mixtures and isolation of individual compunds proved not to be feasible.

8a[OTf]: $C_{45}H_{34}Cl_2F_3P_3SO_3$·$CH_2Cl_2$ (960.58): calcd. C 57.52, H 3.78; found C 56.98, H 3.66. − ^{1}H NMR ($CDCl_3$): δ = 7.74−7.57 (m, 30 H, C_6H_5), 6.41 (m, 2 H, 5,6-H), 6.21 (m, 2 H, 4,7-H). − ^{13}C NMR ($CDCl_3$): δ = 135.69 (m, ΣJ = 18.7 Hz, J_M = 33.5 Hz, C-3a,7a), 134.86 (m, ΣJ = 3 Hz, C^{para}), 134.72 (m, ΣJ = 10.7 Hz, C^{ortho}), 130.33 (m, ΣJ = 13.0 Hz, C^{meta}), 121.36 (q, J_{FC} = 320.9 Hz, CF_3SO_3), 119.76 (d, J = 2.5 Hz, C-5,6), 118.66 (m, ΣJ = 4 Hz, J_M = 19.8, C-4,7), 121.38 (m, ΣJ = 92.7 Hz, $^3J_{PC}$ = 3.2 Hz, C^{ipso}), 46.18 (ddd, $^1J_{PC}$ = 142.2, 126.2 Hz,$^3J_{PC}$ = 7.7 Hz, C-1,3).

Crystal-Structure Determination of **8a**[OTf] *at 200(2) K:* $[C_{44}H_{34}Cl_2P_3][CF_3SO_3]$·$CH_2Cl_2$, M = 960.52, yellow plates, crystal size 0.30 × 0.23 × 0.20 mm, monoclinic, space group $P2_1/c$ (no. 14): a = 12.4581(4), b = 22.5518(6), c = 16.5854(6) Å, β = 104.852(4)°, V = 4504.0(2) Å^3, Z = 4, $\rho_{calcd.}$ = 1.416 Mg m^{-3}, F(000) = 1968, μ(Cu-K_α) = 4.28 mm^{-1}. 8443 reflections (8143 independent reflections with R_{int} = 0.032) were collected with an Enraf-Nonius MACH3 diffractometer (Cu-K_α radiation, graphite monochromator, 2θ/ω scans) in the range 3° ≤ θ ≤ 68° (−14 ≤ h ≤ 14, −27 ≤ k ≤ 0, 0 ≤ l ≤ 19). Of these, 8142 were used for structure solution (direct methods) and refinement (full-matrix least squares on F^2, 542 parameters and 82 restraints, nonhydrogen atoms anisotropic, hydrogen atoms with a "riding" model); wR_2 = 0.176 {$R_1[I > 2\sigma(I)]$ = 0.066}. A semiempirical absorption correction on the basis of ψ scans and an extinction correction were applied. Crystallographic data (excluding structure factors) have been deposited at the Cambridge Crystallographic Data Centre under the number CCDC-100692. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: internat.+44(1223)336-033, E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Silicon / Aminosilanes / Aziridine / Azetidine / Molecular conformation / Configuration determination / Nitrogen

In a continuation of structural investigations of poly(amino)-silanes, a series of silicon derivatives of aziridine and azetidine have been prepared. Analogies with the isoelectronic phosphorus ylide species and the high barrier to inversion at nitrogen in small N heterocycles were suggestive of steeply pyramidal and rather rigid configurations at the N atoms in the title compounds. Tetrakis(*N*-aziridino)silane (**1**) and tetrakis(*N*-azetidino)silane (**2**) have been synthesized from $SiCl_4$ and $LiN(CH_2)_x$ (x = 2, 3). Compound **1** is also formed when $LiN(CH_2)_2$ and $HSiCl_3$ are used as starting materials, but with free aziridine a non-volatile product (**1a**) is obtained. In neither case could any trace of $HSi[N(CH_2)_2]_3$ be detected. In contrast, $RSiCl_3$ (R = Me, Ph) could readily be converted into the corresponding tris(*N*-aziridino)silanes (**3**, **4**) by treatment with excess aziridine. Tris(*N*-azetidino)silane (**5**) was accessible from $HSiCl_3$ and excess azetidine, but the product was found to contain an unknown impurity. In order to determine the local symmetry and the dynamics of the aziridine rings, ^{1}H-NMR spectra were recorded at low temperature (−80°C). No splitting of the signals was observed, indicating that the inversion barriers are extremely low, even in the highly strained three-membered heterocycles. Nevertheless, single-crystal X-ray diffraction studies of the *N*-triphenylsilyl derivatives of aziridine (**6**) and azetidine (**7**) revealed an aziridinyl group with a steeply pyramidal configuration at nitrogen in **6** (sum of the angles at N 313.32°), and an azetidinyl group with a flat geometry in **7** (sum of the angles at N 350.96°). The Si−N bond is significantly shorter in **7** as compared to that in **6**.

Introduction

Aziridine derivatives of *phosphorus* have been extensively studied owing to their widely established application in pharmacology and agriculture.[1][2][3] The most important variants of this usage are based on cyclic phosphazene compounds in which all the phosphorus atoms are exclusively bound to nitrogen. In order to trace the physiological effects to structural parameters, the molecular structures of several representative examples have been investigated.[4][5][6][7][8] *Azetidine* derivatives of *phosphorus* are less well investigated. Only a limited selection of compounds of this family have been described in the literature, for which no comparable chemotherapeutic or agrochemical uses are discernible.[9]

The taxonomy of related *N-silylated aziridines* and *azetidines* is far less developed[10][11] and no systematic investigation has been made of their properties and structural characteristics.[12] This is particularly true for compounds based solely on silicon-nitrogen frameworks, with only one example appearing in the patent literature.[13] Fundamental representatives, such as tetrakis(*N*-aziridino)- or tetrakis(*N*-azetidino)silane (**1**, **2**), have not hitherto been described.

As part of an ongoing investigation of poly(amino)silanes[14][15] we have recently initiated a study of silicon derivatives of aziridine and azetidine, mainly oriented towards a full structural characterization of prototype compounds, and an account of our results is given in the present paper.

Our previous investigations had centered on tetrakis(*N*-pyrrolidino)- and tetrakis(*N*-morpholino)silanes, which are the higher members of the homologous series of *N*-silylated, saturated N-heterocycles, albeit with strain-free five- and six-membered rings, respectively. While these and other standard dialkylaminosilanes typically possess the much debated planar configuration at nitrogen,[14] the aziridine or azetidine substituents are the only analogs where a steeply pyramidal configuration can be expected. This is also suggested by findings for the isoelectronic phosphorus ylide species, which were shown to have pronounced pyramidality at the ylidic carbon atoms of the cyclopropylide and cyclobutylide groups, respectively.[16][17]

In view of the good leaving-group properties of silicon substituents, the silylated heterocycles reported herein are expected to be useful aziridinating/azetidinating agents, which might be employed as substitutes for the rather hazardous free heterocycles.[18][19][20][21]

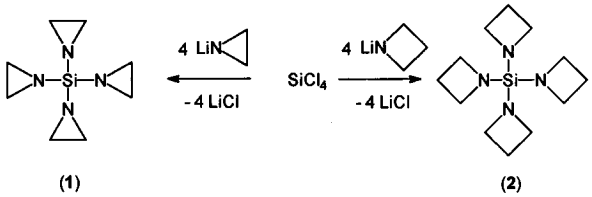
Results

Preparative Results

Tetrakis(*N*-aziridino)silane (**1**) and tetrakis(*N*-azetidino)-silane (**2**) have been prepared by the reaction of silicon tetrachloride with slightly in excess of four equivalents of the appropriate lithiated heterocycles in diethyl ether at low temperature (−60°C). Compound **1** was obtained as a colorless, distillable liquid, solidifying at 8°C, while the homolog **2** was obtained as a crystalline solid at room temperature, melting at 45°C. All attempts to grow single crystals of **1** and **2** were unsuccessful owing to pertinacious twinning, regardless of the method employed (from the melt, from

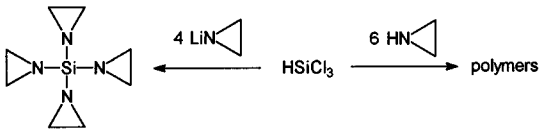
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0107 $ 17.50+.50/0

solution or by sublimation). Characterization of the compounds is therefore wholly based on the analytical and spectroscopic data (Experimental Section).



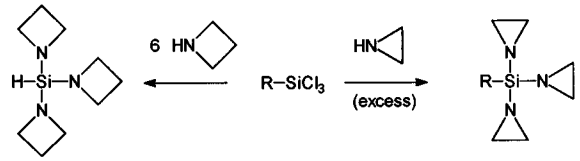
(1) (2)

Compound **1** was also generated in the reaction of *tri*-chlorosilane with lithium aziridinide, probably through an amide-catalyzed redistribution of the substituents [H/Cl/$N(CH_2)_2$] at silicon and/or hydride-induced aziridine ring opening. With $HSiCl_3$ and free aziridine in an organic solvent at −60°C, large amounts of a non-volatile, probably polymeric material were obtained. In neither reaction was any trace of the expected compound $HSi[N(CH_2)_2]_3$ detected.



(1) (1a)

Trichloro(*methyl-* and *-phenyl*)silane are readily converted to the corresponding tris(*N*-aziridino)silanes (**3**, **4**) upon treatment with excess aziridine.

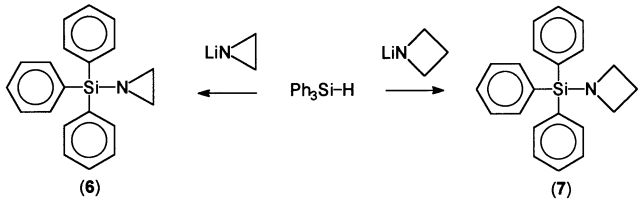


R = H (**5**) R = CH_3 (**3**)

Ph (**4**)

Tris(*N*-azetidino)silane (**5**) could be prepared from $HSiCl_3$ and excess azetidine, but purification of the product was not fully satisfactory. The analytical data seemingly indicate a rather pure product, but the values given in the Experimental Section nevertheless refer to a compound containing an unknown impurity. The MS and NMR data can be interpreted in terms of the presence of two isomers $\{HSi[N(CH_2)_3]_3\}_n$, but the nature of these isomers is not clear. Dimerization by azetidine ring-opening appears to be the most likely possible process.[22]

Because no poly(*N*-aziridino)- or poly(*N*-azetidino)silanes proved amenable to the growth of single crystals for structure determination, the *N-triphenylsilyl derivatives of aziridine* (**6**) and *azetidine* (**7**) were also prepared. Compound **6** has previously been synthesized from triphenylsilane, aziridine and alkali metals as catalysts in a dehydrocondensation reaction.[23] In the present study, **6** and **7** were obtained by the reaction of triphenylsilane with the appropriate lithiated heterocycles.



(6) (7)

Both compounds could be obtained in pure form, and single crystals of acceptable quality were readily grown from their solutions [m.p. 104°C (**6**), 86°C (**7**)].

NMR Spectroscopy

Assignment of the general patterns of the $^{29}Si\{^1H\}$- and $^{13}C\{^1H\}$-NMR spectra of the new silanes was largely straightforward. Regarding the ^1H-NMR spectra, however, the aspects of local symmetry of the aziridine rings and their dynamics have to be considered: A flat configuration at nitrogen, or a rapid inversion at this atom, would render the hydrogen atoms above and below the ring equivalent [(virtual) local symmetry with two perpendicular mirror planes, point group C_{2v} (on the NMR time scale)], while a rigid pyramidal configuration or a very slow inversion requires non-equivalent hydrogen atoms at the CH_2 groups (point group C_S). This also applies to the azetidine homologs, where additionally a flexible puckering of the four-membered ring has to be taken into account.

All compounds investigated in the present study exhibit only singlet ^1H resonances for the aziridine rings or show only multiplets characteristic of C_{2v}-symmetrical azetidine rings in solution at room temperature. Because it is implausible to assume a fully planar ground state for the aziridine/azetidine nitrogen atom, this result indicates a low barrier to nitrogen inversion. It is even more surprising that the pseudo-symmetry of the aziridinyl and azetidinyl groups is retained at temperatures as low as −80°C in all cases. This is in contrast to the "rigidity" of other simple organic derivatives of these heterocycles, which were found to have much higher barriers to inversion.[24] It therefore appears that the presence of silicon as the N-substituent atom has a marked effect on the inversion energetics. As found for other pairs of alkyl- and silylamines, even for strained small-ring amines, there is clearly a very significant lowering of the energy of the transition state for inversion.

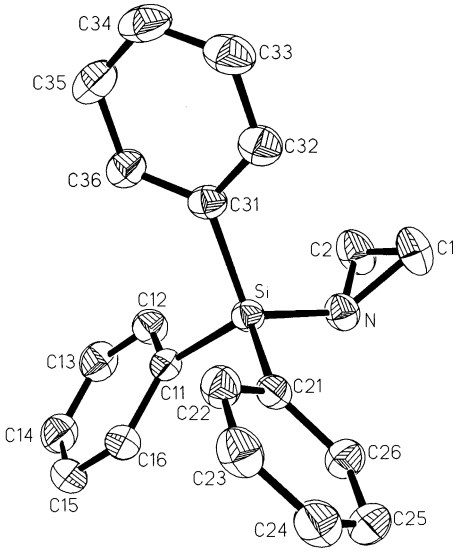
Unfortunately, the coalescence/splitting temperature of the signals of the hydrogen atoms above and below the ring planes could not be attained, and therefore the energy of activation can only be estimated. Assuming chemical shift differences $\Delta\delta$ of less than 1 ppm, the barrier must be lower than 8.5 (± 2.5) kcal/mol, and is thus less than half of that determined for *N*-alkyl- or *N*-arylaziridines.[24] When evaluating this result it should be kept in mind that for unstrained tri-, di- and monosilylamines, completely flat ground-state geometries were found experimentally, and that state-of-the-art theoretical calculations have confirmed this unusual geometry and predict extremely flat energy profiles for pyramidalization.[14][15] This general pattern is

still reflected in the most strained example of the silylaziridines.

Crystal Structures

Crystals of *N-triphenylsilylaziridine* (**6**) are triclinic, space group $P\bar{1}$ with $Z = 2$ formula units in the unit cell. The molecules have no crystallographically imposed symmetry owing to a propeller-type arrangement of the three phenyl groups at silicon (Figure 1).

Figure 1. Molecular structure of compound **6** (ORTEP drawing with 50% probability ellipsoids, H atoms omitted for clarity)[a]

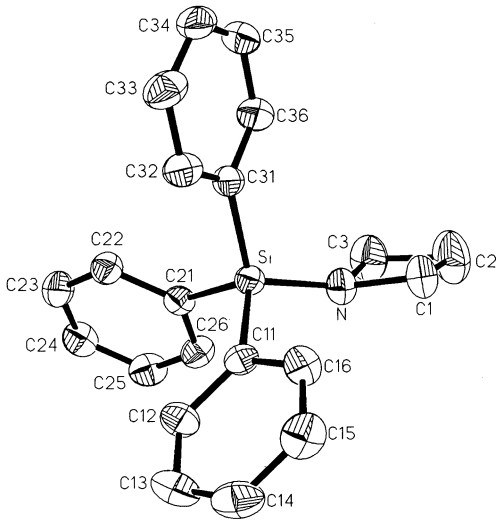


[a]Selected bond lengths [Å] and angles [°]: Si−N 1.7308(11), Si−C11 1.8658(13), Si−C21 1.8655(14), Si−C31 1.8744(13), N−C1 1.462(2), N−C2 1.456(2), C1−C2 1.470(2); N−Si−C11 105.94(6), N−Si−C21 105.81(6), N−Si−C31 114.28(6), C11−Si−C21 111.74(6), C11−Si−C31 109.59(6), C21−Si−C31 109.44(6), Si−N−C1 127.16(10), Si−N−C2 124.63(10), C2−N−C1 60.48(10), N−C1−C2 59.55(9), C1−C2−N 59.97(9).

The most important result of this structure determination is the geometry of the aziridinyl group, with its steeply pyramidal configuration at nitrogen. The plane of the three-membered ring forms an angle of 132.8° with the Si−N vector, and the sum of the angles at nitrogen amounts to only 312.3°. The conformation of the molecule with regard to the relative orientation of the $SiPh_3$ group and the $N(CH_2)_2$ unit, with its lone pair of electrons at the nitrogen atom, is staggered. The phenyl group *trans* to the lone pair at N has the largest N−Si−C angle [N−Si−C31 = 114.28(6)°]. The two remaining N−Si−C angles are almost equal, with individual values of N−Si−C11 = 105.94(6)° and N−Si−C21 = 105.81(6)°. The silicon atoms thus adopt a distorted tetrahedral geometry with bond lengths Si−N and Si−C in the range expected for standard single bonds (captions to Figure 1 and Table 1). The dimensions of the aziridine ring are also not unusual.

Crystals of *N-triphenylsilylazetidine* (**7**) are monoclinic, space group $P2_1/c$, with $Z = 4$ formula units in the unit cell. The molecules have no crystallographically imposed symmetry because of an adverse orientation of the phenyl rings at silicon (Figure 2).

Figure 2. Molecular structure of compound **7** (ORTEP drawing with 50% probability ellipsoids, H-atoms omitted for clarity)[a]



[a]Selected bond lengths [Å] and angles [°]: Si−N 1.7059(14), Si−C11 1.871(2), Si−C21 1.869(2), Si−C31 1.873(2), N−C1 1.481(2), N−C3 1.477(2), C1−C2 1.523(3), C2−C3 1.522(3); N−Si−C11 107.79(7), N−Si−C21 107.03(7), N−Si−C31 113.54(7), C11−Si−C21 109.74(7), C11−Si−C31 107.48(7), C21−Si−C31 111.17(7), Si−N−C1 127.63(11), Si−N−C3 131.76(12), N−C1−C2 89.6(2), C1−C2−C3 88.3(2), C2−C3−N 89.7(2), C3−N−C1 91.60(14).

The nitrogen atom of the azetidinyl group has a rather flattened pyramidal configuration, which can be quantified by the angle between the plane through the atoms N, C1 and C3 and the Si−N vector (156.2°), and by the sum of the angles at nitrogen (351.0°). As expected, the geometry at the nitrogen in **7** is much closer to planar than at that in **6**, but is nevertheless still distinctly non-planar.

The azetidine is folded, with an angle of 170.3° between the planes N−C1−C3 and C1−C2−C3, representing a flat butterfly structure. As in compound **6**, the conformation of the molecule is staggered with a wide angle N−Si−C31 = 113.54(7)° and two very similar angles for N−Si−C11 [107.79(7)°] and N−Si−C21 [107.03(7)°]. The bond lengths at silicon and in the four-membered ring show no anomalies (captions to Figure 2 and Table 1). It should be noted, however, that the Si−N bond is significantly shorter in **7** as compared to that in **6**, while there are no differences in the Si−C bond lengths. This difference may reflect a strengthening of the Si−N bond as the geometry at nitrogen is flattened, in agreement with the traditional concept of (p−d)π bonding, which, although now widely abandoned, is also consistent with the presently accepted (p−σ*)π model.[25]

Discussion and Conclusions

The structural investigations of a silylaziridine and of a silylazetidine have provided valuable reference data for a comparison with the isoelectronic phosphonium ylides.[16][17] From Table 1, it appears that the lattices of neither of the two pairs of compounds are isomorphous, but that the individual molecules share the same structural motifs with regard to the configuration at the functional atom

(nitrogen and ylidic carbanion, respectively) and the conformation. In the staggered rotamers, the lone pair of electrons at N or C is clearly "stereochemically active" and co-determines the overall structure. However, the carbanions show more pronounced pyramidalization than the amine nitrogen atoms and give rise to large deviations of the phosphorus atoms from the plane of the heterocycle. This is strong evidence for the "ylide" model of bonding with a highly polar P−C function, which should definitely be favored over the "ylene" form with P=C multiple bonding. For $Ph_3PC(CH_2)_2$, the non-equivalence of the hydrogen atoms above and below the cyclopropane plane could be demonstrated by a splitting of the ^{1}H-NMR resonances in solution at −80°C. For $Ph_3SiN(CH_2)_2$, this low-temperature limit was not sufficient to observe the same phenomenon, which indicates that the silylamine is more flexible than the phosphonium ylide.

The comparatively flat geometries of the silylaziridine and the silylazetidine are probably a consequence of the much greater difference in electronegativity of silicon and nitrogen (relative to phosphorus and carbon), which makes an Si−N linkage a strongly polar bond. The energy profile of such inherently polar bonds has been correctly predicted to be rather insensitive e.g. to deformations of bond angles,[26] and this is borne out by the present family of silazanes with their enormous flexibility: Although the ground-state geometries are rather steep, the activation energies for inversion at nitrogen are still sufficiently low to make these molecules fluxional on the NMR time-scale (see above).

It has been noted previously in theoretical studies of phosphonium cyclopropylides, as well as of silylamines, that inversion at carbon or nitrogen, respectively, has to be accompanied by P−C/Si−N bond rotation in order to regenerate the ground-state geometry.[27] This should be a minor contribution as compared to inversion, however, because rotation about Si−N and P−C bonds is known to be associated with very low barriers indeed, generally not in excess of 1 kcal/mol.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. The authors are grateful to Prof. *N. Rösch* and Ms. *K. Albert* for providing results of theoretical calculations prior to publication and to Mr. *J. Riede* for determining the X-ray data sets.

Experimental Section

All experiments were carried out under dry, pure nitrogen. Solvents and glassware were treated accordingly. Standard equipment was used throughout. Aziridine[28] and azetidine[29] were prepared according to literature procedures. Due to the method of preparation, the sample of azetidine contained benzene, which was quantified by ^{1}H-NMR spectroscopy. All other starting materials were commercially available. − NMR: Jeol GX 400 and Jeol GX 270, solutions in C_6D_6 at 23°C unless otherwise stated. − MS: GC/MS with mass-selective detector HP 5971 A (EI, 70 eV) and MAT 311 A (EI, 70 eV). − IR: Perkin-Elmer 1650 FT-IR.

Lithium Amides: In a typical reaction, *n*-butyllithium (1.7 M in hexane) was added dropwise to a solution of aziridine or azetidine in diethyl ether at −60°C. The reaction mixture was allowed to warm to room temperature and was stirred for 0.5 h. Then, the suspension was cooled to −60°C once more and used immediately in the subsequent reactions.

Tetrakis(N-aziridino)silane (**1**): A solution of silicon tetrachloride (0.86 ml, 7.5 mmol) or trichlorosilane (1.00 ml, 10 mmol) in 20 ml of diethyl ether was added dropwise to a suspension of lithium aziridinide [35 mmol, from 2.00 ml (39 mmol) of aziridine and 20.6 ml (35 mmol) of a 1.7 M solution of *n*-butyllithium in hexane] in 50 ml of diethyl ether at −60°C. After stirring the reaction mixture at room temperature for 15 h, the precipitate was separated, the solvent was removed from the filtrate in vacuo, and the remaining residue was extracted with pentane. **1** was separated from the extract by distillation (30°C, 0.05 mbar). Colorless liquid, 0.93 g (63%), m.p. 8°C. − ^{1}H NMR: δ = 1.77 (s, 24 H, CH_2). − ^{1}H NMR ([D$_8$]toluene, 23°C): δ = 1.73 (s, 24 H, CH_2). − ^{1}H NMR ([D$_8$]toluene, −80°C): δ = 1.77 (s, 24 H, CH_2). − ^{13}C{^{1}H} NMR: δ = 19.8 (CH_2). − ^{13}C NMR ([D$_8$]toluene, 23°C): δ = 19.6 (CH_2). − ^{29}Si{^{1}H} NMR: δ = −24.6. − ^{29}Si NMR: δ = −24.6 (m, $^3J_{Si,H}$ = 5 Hz). − ^{29}Si NMR ([D$_8$]toluene, 23°C): δ = −24.4 (m, $^3J_{Si,H}$ = 5 Hz). − ^{29}Si NMR ([D$_8$]toluene, −80°C): δ = −22.9 (m, br.). − ^{15}N NMR: δ = −390.2 (quint, $^2J_{N,H}$ = 2 Hz). − MS (EI, 70 eV) *m/z*: 196 [M$^+$], 154 [M$^+$ − $N(CH_2)_2$], 112 [154 − $N(CH_2)_2$], 70 [112 − $N(CH_2)_2$]. − IR (film): $\tilde{\nu}$ = 3041 m (ν NC_2H_4), 2983 m, 2900 m, 1276 s, 945 s, 683 s. − $C_{12}H_{24}N_4Si$ (196.32): calcd. C 48.9, H 8.2, N 28.5; found C 49.2, H 7.9, N 29.1.

Reaction of Trichlorosilane with Aziridine as Free Base (**1a**): 6 equiv. of aziridine (3.07 ml, 60 mmol) in 20 ml of diethyl ether was added dropwise to a solution of trichlorosilane (1.00 ml, 10 mmol) in 50 ml of diethyl ether at −60°C over a period of 15 min. After the reaction mixture had warmed to room temperature, stirring was continued for 1 h. The suspension was then filtered, the solvent was removed in vacuo, and a sample was prepared in C_6D_6 for NMR spectroscopy. − ^{1}H NMR: δ = 2.74 (m), 3.04 (m). − ^{13}C{^{1}H} NMR: δ = 42.7, 47.8. − ^{29}Si{^{1}H} NMR: δ = −34.6.

Tetrakis(N-azetidino)silane (**2**): A solution of silicon tetrachloride (0.22 ml, 2.0 mmol) in 10 ml of diethyl ether was added dropwise over a period of 5 min to a suspension of lithium azetidinide [10 mmol, from 2.00 ml (14.6 mmol) of a solution of azetidine, containing 42 mol-% of benzene and 5.9 ml (10 mmol) of a 1.7 M solution of *n*-butyllithium in hexane] in 50 ml of diethyl ether at −60°C. After stirring the reaction mixture at room temperature for 10 h, the precipitate was separated, the solvent was removed from the filtrate in vacuo, and the remaining residue was purified by distillation (40°C, 0.05 mbar). The crude product was crystallized from pentane at −60°C. Colorless crystals, 0.18 g (36%), m.p. 45°C. − ^{1}H NMR: δ = 2.24 (quint, 8 H, $^3J_{H,H}$ = 7 Hz, CCH_2), 3.94 (t, 16 H, $^3J_{H,H}$ = 7 Hz, NCH_2). − ^{13}C{^{1}H} NMR: δ = 21.8 (CCH_2), 49.4 (NCH_2). − ^{29}Si{^{1}H} NMR: not detected. − MS (EI, 70 eV) *m/z*: 252 [M$^+$], 196 [M$^+$ − $N(CH_2)_3$], 140 [196 − $N(CH_2)_3$].

Tris(N-aziridino)methylsilane (**3**): To a solution of trichloro(methyl)silane (1.17 ml, 10 mmol) in 50 ml of diethyl ether, 6 equiv. of aziridine (3.07 ml, 60 mmol) in 20 ml of diethyl ether was added dropwise over a period of 15 min at −60°C. After stirring for 20 h at room temperature, the reaction mixture was filtered and the solvent was removed in vacuo. The remaining oil was purified by distillation (50°C, 0.05 mbar). Colorless liquid, 1.12 g (66%). − ^{1}H NMR: δ = 0.11 (s, 3 H, CH_3), 1.70 (s, 12 H, CH_2). − ^{13}C{^{1}H} NMR: δ = −7.9 ($SiCH_3$), 19.7 (CH_2). − ^{29}Si NMR: δ = −4.5. − MS (EI, 70 eV) *m/z*: 169 [M$^+$], 127 [M$^+$ − $N(CH_2)_2$], 85 [127 − $N(CH_2)_2$]. − $C_7H_{15}N_3Si$ (169.30): calcd. C 49.7, H 8.9, N 24.8; found C 49.0, H 8.8, N 25.5.

Tris(N-aziridino)phenylsilane (**4**): Analogously to the preparation of **3**, **4** was prepared from 1.60 ml (10 mmol) of trichloro(phenyl)silane and 3.58 ml (70 mmol) of aziridine. After purification by distillation (100°C, 0.05 mbar), a colorless liquid was obtained. Yield 1.27 g (55%). − ^{1}H NMR: δ = 1.76 (s, 12 H, CH_2), 7.21 (m, 3 H, 3/4/5-H), 7.79 (m, 2 H, 2/6-H). − ^{13}C{^{1}H} NMR: δ = 20.1 (CH_2), 127.8 (C-2/6), 130.3 (C-4), 132.2 (C-3/5), 134.7 (C-1). − ^{29}Si{^{1}H} NMR: δ = −19.0. − MS (EI, 70 eV) *m/z*: 231 [M^+], 189 [$M^+ - N(CH_2)_2$]. − $C_{12}H_{17}N_3Si$ (231.37): calcd. C 62.3, H 7.4, N 18.2; found C 61.8, H 7.5, N 17.6.

Tris(N-azetidino)silane (**5**): To a solution of 7 equiv. of azetidine (2.00 ml of a solution of azetidine containing 42 mol-% of benzene, 14.6 mmol) in 50 ml of diethyl ether, trichlorosilane (0.20 ml, 2 mmol) in 10 ml of diethyl ether was added dropwise over a period of 15 min at −60°C. After the reaction mixture had warmed to room temperature, stirring was continued for 1 h. After filtration, the solvent was removed in vacuo and the remaining oil was distilled (100°C, 0.05 mbar) to give a colorless liquid. Yield 0.11 g (28%). − ^{1}H NMR: δ = 2.17 (quint, 6 H, $^3J_{H,H}$ = 7 Hz, CCH_2), 3.80 (t, 12 H, $^3J_{H,H}$ = 7 Hz, NCH_2), 4.36 (s, 1 H, SiH). − ^{13}C{^{1}H} NMR: δ = 21.9 (CCH_2), 48.7 (NCH_2). − ^{29}Si NMR: δ = −39.0 (d, $^2J_{Si,H}$ = 148 Hz). − MS (EI, 70 eV) *m/z*: 197 [M^+], 141 [$M^+ - N(CH_2)_3$], 85 [141 − $N(CH_2)_3$].

(N-Aziridino)triphenylsilane (**6**): A solution of triphenylsilane (1.04 g, 4 mmol) in 20 ml of diethyl ether was added dropwise to a suspension of lithium aziridinide [10 mmol, from 0.82 ml (16 mmol) of aziridine and 6.00 ml (10 mmol) of a 1.7 M solution of *n*-butyllithium in hexane] in 50 ml of diethyl ether at −60°C. After stirring the reaction mixture at room temperature for 15 h, the precipitate was separated, the solvent was removed from the filtrate in vacuo, and the remaining solid was extracted with pentane. **6** crystallized from this solution at 0°C. Colorless crystals, 1.48 g (61%), m.p. 104°C. − ^{1}H NMR: δ = 1.69 (s, 4 H, NCH_2), 7.20 (m, 9 H, 3/4/5-H), 7.77 (m, 6 H, 2/6-H). − ^{13}C{^{1}H} NMR: δ = 21.0 (NCH_2), 128.1 (C-2/6), 130.0 (C-4), 134.3 (C-3/5), 136.0 (C-1). − ^{29}Si{^{1}H} NMR: δ = −9.1. − MS (EI, 70 eV) *m/z*: 301 [M^+], 259 [$M^+ - N(CH_2)_2$], 182 [259 − C_6H_5], 105 [182 − C_6H_5]. − $C_{20}H_{19}NSi$ (301.46): calcd. C 79.7, H 6.4, N 4.7; found C 79.5, H 6.5, N 4.5.

(N-Azetidino)triphenylsilane (**7**): To a suspension of lithium azetidinide [5 mmol, from 1.00 ml (8 mmol) of a solution of azetidine containing 28 mol-% of benzene and 3.00 ml (5 mmol) of a 1.7 M solution of *n*-butyllithium in hexane] in 50 ml of diethyl ether, a solution of triphenylsilane (1.04 g, 4 mmol) in 20 ml of diethyl ether was added dropwise at −60°C. After stirring the reaction mixture at room temperature for 15 h, the precipitate was separated, and the filtrate was concentrated in vacuo. From this solution, compound **7** crystallized at −30°C. Colorless crystals, 0.61 g (48%), m.p. 86°C. − ^{1}H NMR: δ = 2.12 (quint, 2 H, $^3J_{H,H}$ = 7 Hz, CCH_2), 3.83 (t, 4 H, $^3J_{H,H}$ = 7 Hz, NCH_2), 7.21 (m, 9 H, 3/4/5-H), 7.71 (m, 6 H, 2/6-H). − ^{13}C{^{1}H} NMR: δ = 21.4 (CCH_2), 49.8 (NCH_2), 128.1 (C-2/6), 129.8 (C-4), 135.4 (C-3/5), 136.0 (C-1). − ^{29}Si{^{1}H} NMR: δ = −17.9. − MS (EI, 70 eV) *m/z*: 315 [M^+], 259 [$M^+ - N(CH_2)_3$], 182 [259 − C_6H_5], 105 [182 − C_6H_5]. − $C_{21}H_{21}NSi$ (315.49): calcd. C 80.0, H 6.7, N 4.4; found C 79.3, H 6.8, N 4.4.

Crystal Structure Determinations: Specimens of compounds **6** and **7** of suitable quality and size were mounted in glass capillaries and used for measurements of precise cell constants and intensity data collection on an Enraf-Nonius CAD4 diffractometer [Mo-K_α radiation, λ(Mo-K_α) = 0.71073 Å]. During data collection, three standard reflections were measured periodically as a general check of crystal and instrument stability. No significant changes were observed. The structures were solved by direct methods (SHELXS-86)[30] and refined by full-matrix least-squares techniques against F^2 (SHELXL-93)[31]. The thermal motion of all non-hydrogen atoms was treated anisotropically. All hydrogen atoms of compounds **6** and **7** were found and refined with isotropic contributions. Further information on crystal data, data collection and structure refinement is summarized in Table 1. Selected interatomic distances and angles are given in the corresponding figure captions. Anisotropic thermal parameters, tables of distances and angles, and atomic coordinates have been deposited at the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, Germany. The data are available on request on quoting the depository numbers CSD-407949 (**6**) and CSD-407950 (**7**).

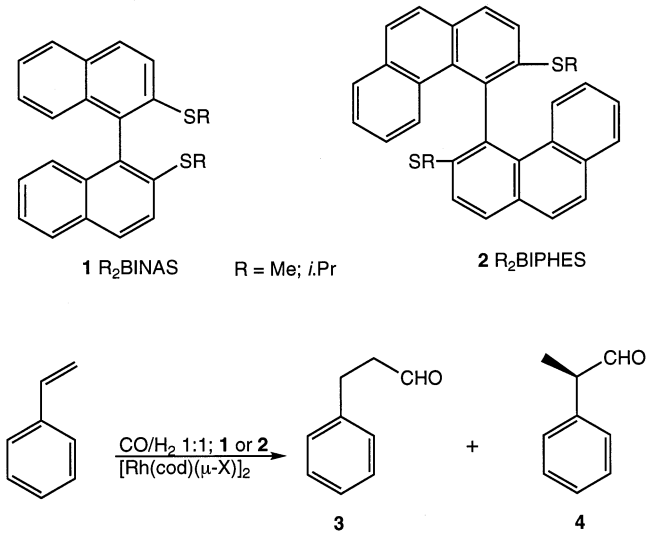
Keywords: S ligands / Transition metals / Fluxionality

The preparation and characterization of Rh^{I}, Pd^{II}, and Pt^{II} complexes with chiral C_2-symmetrical dithioether ligands derived from 1,1′-binaphthalene-2,2′-dithiol (BINAS) are reported. All complexes are fluxional in solution at room temp. Interconversion between the stereoisomers can take place through conformational equilibration of the chelate ring, and/or inversion of configuration at the stereogenic sulfur. In the solid state the palladium derivative of Me_2BINAS shows a twisted chair conformation of the chelate ring, with both methyl groups in equatorial positions.

Recent investigations by our groups have shown that, in the hydroformylation of styrene[1], rhodium(I) complexes with the atropisomeric dithioethers **1** and **2** (Scheme 1), either preformed or prepared in situ by addition of the appropriate amount of the sulfur donor ligand to a suitable rhodium diolefin precursor $[Rh(cod)(\mu\text{-}X)]_2$ (cod:1,5-cyclooctadiene; X:Cl; MeO), are endowed with a high catalytic activity. Quantitative conversions of the substrate, with complete chemoselectivity in the formation of the aldehydes **3** and **4** (Scheme 1), are easily attained; even at room temp. and for a fairly wide range of carbon monoxide/hydrogen (1:1) pressures.

Scheme 1. Atropisomeric dithioether ligands



As these catalysts favour carbon monoxide insertion into the more substituted vinylic carbon, the major product is the branched isomer **4**, which, in the most favourable cases, can account for more than 95% of the reaction mixture. This regioselectivity, which is among the highest recorded in the hydroformylation of styrene, prompted us to exploit the potential of the enantiopure derivatives **1** and **2** in enantioselective hydroformylation. Transfer of chirality from the ligand to the product does take place, but the efficiency is quite low and the best enantiomeric excess (e.e.) obtained so far is only slightly greater than 20%. Albeit low, this value is in the range of the e.e.′s normally obtained in this reaction after more than twenty years of experimentation using rhodium catalysts containing diphosphane ligands as chiral modifiers[2].

A notable feature of the dithioether ligands **1** and **2** is that upon coordination to the metal they can give rise to different diastereomeric complexes, since the two sulfur donors become stereogenic centers. This fact is expected to

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0101−0113 $ 17.50+.50/0

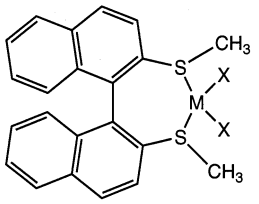
significantly affect the asymmetric bias of enantioselective hydroformylation, as the possibility of matching or mismatching combinations of the original stereogenic element of the ligand, the chiral biaryl backbone, and the newly established stereocenters, can easily be envisaged.

The formation of an unfavourable mixture of diastereomeric rhodium complexes, each one featuring its own stereodifferentiating ability, may well account for the low e.e. obtained in the hydroformylation of styrene. Alternatively this may be due to the configurational lability of the S-stereocenters under hydroformylation conditions.

In order to direct our research in this field on a more rational basis, we were interested to gain further information on the stability and the stereochemistry of the complexes used as catalysts. For this reason we investigated in more detail the coordination chemistry of the atropisomeric dithioethers **1** and **2** with d^8 transition metal centers.

Here we report on the preparation, structure and dynamic behaviour of the cationic and neutral complexes **5**, **6** and **7** obtained from the binaphthyl derivative **1** (R = Me; Me_2BINAS).

Figure 1. Me_2BINAS complexes



5 M = Rh; 2X = 1,5-cyclooctadiene
6 M = Pd; X = Cl
7 M = Pt; X = Cl

Results and Discussion

Preparation of the Complexes: The reaction of **1** with $[Rh(cod)_2]^+X^-$ (X = ClO_4; BF_4) **8** in CH_2Cl_2 solution proceeded, with the displacement of one 1,5-cyclooctadiene ligand, to afford the cationic complexes $[Rh(cod)(Me_2BINAS)]^+X^-$ **5**, isolated in high yield after the addition of diethyl ether. When the reaction was performed in the presence of a moderate excess of ligand **1**, the occasional formation of a byproduct, apparently a rhodium complex containing two units of dithioether ligand, was noticed. This product has not yet been fully characterized.

The chelate Pd complex **6** was obtained by the reaction of $[PdCl_2(PhCN)_2]$ **9** with an equimolar amount of the dithioether **1** in methylene chloride. The complex separated as a red solid upon the addition of diethyl ether. Under these conditions, the corresponding Pt complex $[PtCl_2(PhCN)_2]$ **10** does not react with the ligand **1** at room temp. However under UV irradiation at 254 nm in $CHCl_3$, chelate complexation of the dithioether ligand to the platinum center, with displacement of the ancillary benzonitrile ligands, takes place and is completed in a few hours. Addition of hexane leads to the precipitation of the complex **7** as a pale yellow solid.

Attempts to prepare complexes of binaphthalene thioethers **1** with a more demanding substituent on the sulfurs, such as isopropyl, have been so far unsuccessful since no reaction occurred at room temp.

Molecular Structure of [$PdCl_2(Me_2BINAS)$], (**6**): The molecular structure of **6** has been determined by X-ray diffraction analysis. A view of the molecule is given in Figure 2 and the most significant bond angles and lengths are listed in Table 1.

Figure 2. PLUTON[16] view of the molecular structure of $[PdCl_2(Me_2BINAS)]$ (**6**)

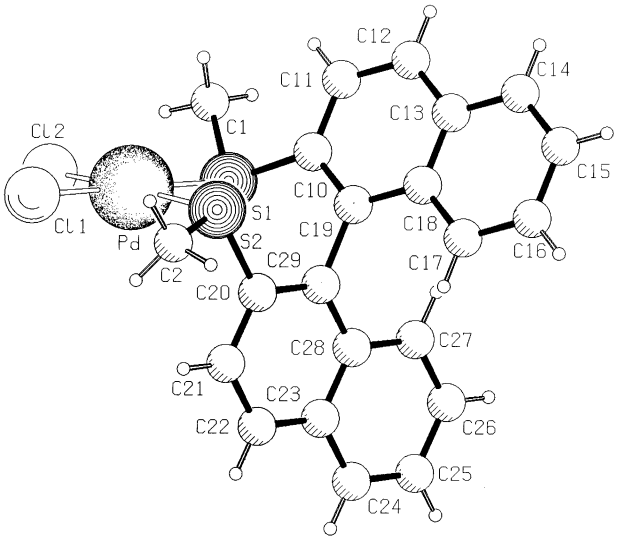


Table 1. Selected bond lenghts (Å) and angles (°) for complex $[PdCl_2(Me_2BINAS]$ (**6**)

Bonds (Å)		Angles (°)	
Pd-S1	2.316(2)	S1-Pd-S2	89.55(6)
Pd-S2	2.297(2)	Cl2-Pd-S2	175.73(6)
Pd-Cl1	2.285(2)	Cl2-Pd-S	187.57(6)
Pd-Cl2	2.305(2)	Cl1-Pd-S2	92.45(6)
C1-S1	1.805(9)	Cl1-Pd-S1	177.76(6)
S2-C2	1.791(7)	Cl1-Pd-Cl	290.38(7)
		Pd-S1-C1	107.29(26)
		Pd-S2-C2	112.19(25)

The crystal contains discrete mononuclear units of **6** in which the dithioether acts as a chelate ligand in a seven-membered ring with a highly distorted twisted chair conformation. Both the methyl groups are located in a pseudo-equatorial position giving the structure an overall C_2-symmetry, where the Pd atom is located on a two-fold axis. Both S-stereocenters display a pyramidal geometry and have the same relative configuration, whereas the binaphthyl moiety has the opposite chiral notation. As expected, the naphthyl rings are significantly bent and with a dihedral angle of 110.9(1)° between their planes, which allows the opposing hydrogens at C17 and C27 to be located at a comfortable distance apart (2.830(6) Å). These data suggest that the chiral diaryl backbone is, basically, free from torsional strain.

On the contrary, fairly short distances have been calculated between the hydrogen at C11 and two hydrogen atoms

of the C1-methyl (2.108(9) and 2.333(9) Å), and between the hydrogen at C21 and one hydrogen atom of the C2-methyl (2.189(9) Å). This may cause some destabilization of the diequatorial structure with respect to those structures with the methyl group(s) in an axial disposition.

The coordination around the Pd atom is essentially square planar. The Pd−S bond distances (2.297(2) and 2.316(2) Å) are comparable with those observed in other Pd complexes with diaryl[3] or aryl alkyl[4] sulfide ligands (2.293 and 2.288 Å, respectively). The Pd−Cl bond lengths (2.285(2) and 2.305(2) Å) are in the normal range for Pd chlorides with a *trans*-thioether donor[5], but are some seventy standard deviations shorter than those in *trans*-phosphane complexes (2.362 and 2.367 Å)[6]. This difference gives a measure of the weaker *trans* influence of the sulfur as compared to the phosphorus donor. The remaining bond distances and angles within the structure of the dithioether ligand are unexceptional.

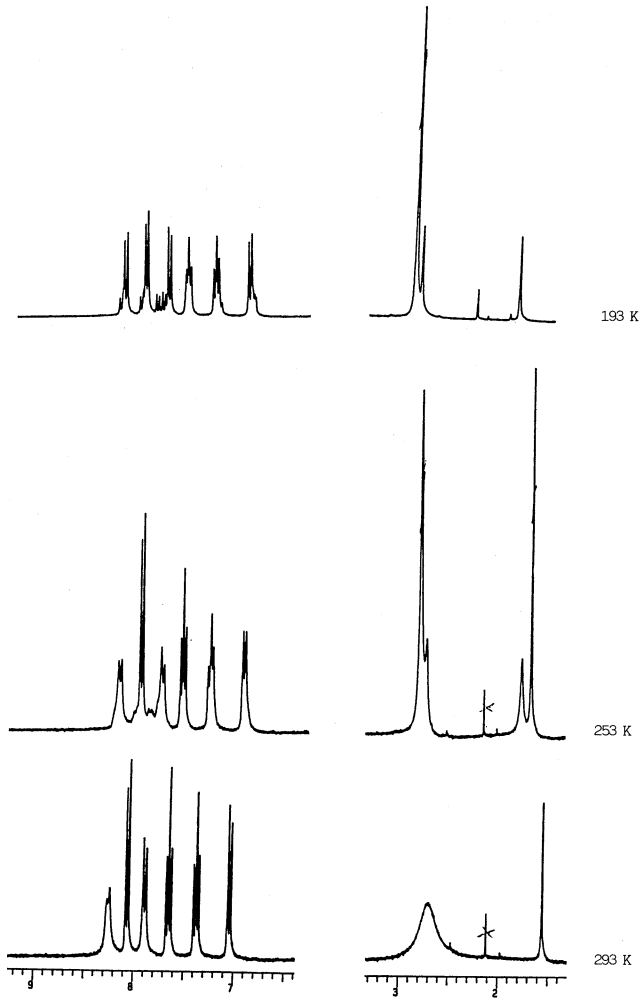
Of the possible stereoisomers of the complex **6**, which differ either in the conformation of the chelate ring or in the spatial arrangement of the *S*-methyl substituents, this one is expected to be the most stable because both methyl groups are located in equatorial positions of the energetically favoured twisted chair conformation[7]. Although its preferential separation in the crystalline form obtained from the solution does not necessarily depend on a higher inherent stability, but may only reflect small differences in solubility or in crystal packing energy, NMR evidence is in keeping with the view that this isomer corresponds to the main product present in solution at low temperature.

Variable-Temperature NMR Characterization: The proton NMR spectrum of the rhodium complex **5** (X = ClO_4) shows, in the non aromatic region, two multiplets (4 H) at δ = 4.76 and 4.36, two broad signals (2 H) at δ = 2.47 and 2.10 and a singlet (6 H) at δ = 2.42 for the *S*-methyl protons. The first four resonances can be attributed to the *exo*- and *endo*-olefinic protons and to the methylene groups of the coordinated cyclooctadiene, respectively. The aromatic part of the spectrum is characterized by the presence of six peaks in the range δ = 8.21−7.00, roughly four doublets (2 H) and two triplets (2 H), which corresponds to the typical pattern of a C_2-symmetrical 2,2′-disubstituted binaphthalene. The shape of the NMR spectrum is not affected when the sample is cooled down to 193 K. In particular, the methyl resonance at δ = 2.42 does not show any apparent splitting.

The variable-temperature proton NMR spectrum of the palladium complex **6** is shown in Figure 3. At room temp. **6** shows a C_2-symmetrical pattern for the aromatic protons of the binaphtalene backbone and a broad singlet at δ = 2.7 corresponding to both the *S*-methyl substituents.

A less significant, but not negligible line broadening is also apparent in two aromatic peaks in the low field region of the spectrum. At 253 K, the two aromatic and the *S*-methyl resonances resolve into two different signals in an approximate 4:1 ratio, and a new peak appears at about 1.7 ppm. From 233 K down to 193 K this last new signal is quite sharp and shows the same intensity as the lower intensity peak arising from the splitting of the original *S*-methyl resonance (Figure 3).

Figure 3. variable temperature ^{1}H-NMR spectrum of [$PdCl_2$(Me$_2$-BINAS)] (**6**)

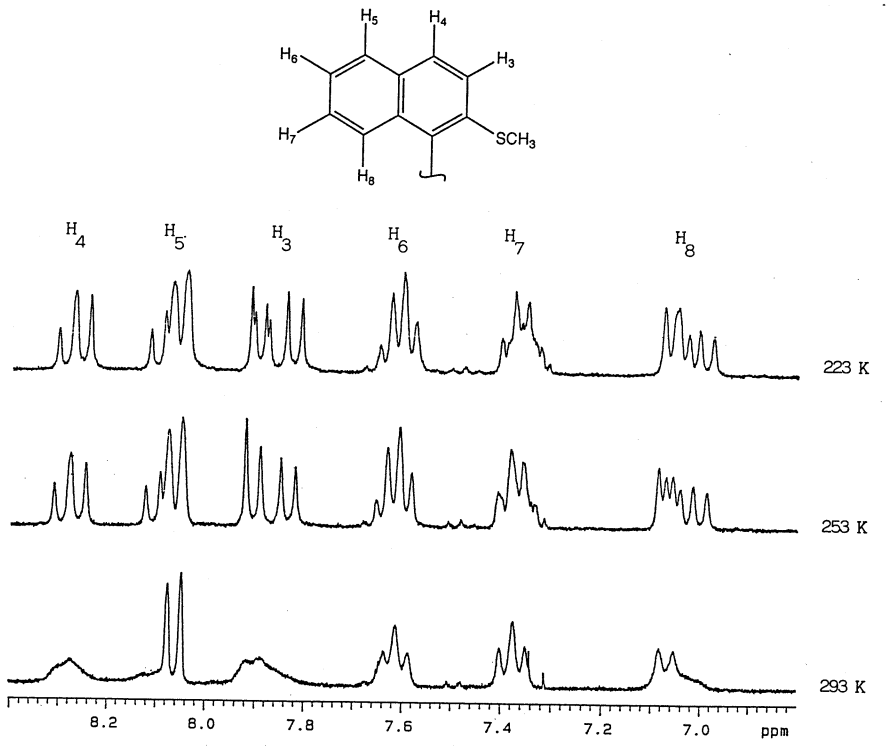


Since several stereoisomers with different spatial arrangements of the *S*-methyl substituents and different conformations of the seven-membered chelate ring are expected for the complex **6**, in principle this temperature dependent NMR spectrum may well reflect the presence of a dynamic equilibrium between two of these. An approximate energy barrier of 55 kJ mol^{-1} can be calculated for this process by line shape analysis of the variable temperature ^{1}H-NMR spectra, applying the coalescence temperature method[8].

The variable temperature ^{1}H-NMR spectra of the aromatic part of the platinum complex **7** is shown in Figure 4. The attributions to the protons have been assigned on the basis of selective decoupling and NOE experiments.

At room temp. the aromatic region shows six resonances with a pattern consistent with a C_2-symmetrical binaphthalene derivative. A significant line broadening is observed for the signals of three protons which apparently are close to the low exchange limit at room temp., while the remaining three protons give fairly sharp peaks. At 253 K all the aromatic protons give partially overlapping, sharp multiplets

Figure 4. Variable-temperature ^{1}H-NMR spectrum of [$PtCl_2(Me_2BINAS)$], (**7**): Aromatic part



indicative of the presence of a mixture of two C_2-symmetrical species in ratio of about 3:2. At a lower temperature the more abundant of these isomers undergoes a further dynamic process which leads to the formation of an additional product. Some resonances, in particular the one attributed to H_3, are further split into two separate sets of signals. The emerging stereoisomer at 223 K is apparently devoid of C_2-symmetry, as indicated by the number of observable peaks. Unfortunately, due to the poor solubility of the complex, the NMR spectra could not be recorded at temperatures lower than 223 K. These data show that at room temp. two diastereomeric platinum complexes are slowly interconverting and that the major one is involved in a further dynamic process at lower temperatures.

At room temp., the *S*-methyl groups give rise to three broad singlets at δ = 2.82, 2.72 and 1.80, of roughly the same intensity, which do not collapse even at 320 K. These peaks are all accompanied by Pt satellites, confirming the chelate coordination of the sulfur centers to the metal. At 253 K the approximate values of the $^3J_{Pt-H}$ of these couplings, from the most shielded to the most deshielded signal, are 38 Hz, 44 Hz and 41 Hz, respectively. These values are substantially constant in the range of temperature explored.

Correlated spectra indicate that the two resonances at higher field belong to the same product. This suggests that the predominant stereoisomer of **7** has two unequivalent methyl substituents resonating at δ = 2.72 and δ = 1.80, while the less abundant one has a C_2-symmetrical structure with two equivalent methyl groups resonating at δ = 2.82.

Irradiation of this peak causes a significant NOE enhancement of the H_3 proton on the naphthalene ring, which is consistent with an equatorial location for this methyl group. This indicates that the minor isomer has both methyl groups in equatorial position and the seven membered chelate ring in chair or twisted chair conformation, in order to fulfill the condition of C_2 symmetry.

When the methyl signal of the minor isomer at δ = 2.82 is under irradiation, it is apparent that also the resonances of the methyl groups of the major species at δ = 2.72 and 1.80 experience NOE and, vice versa, irradiation of these peaks shows a similar effect on the δ = 2.82 peak. These NOE experiments also indicate that the less shielded methyl resonance of the major isomer belongs to an equatorial methyl group, whereas the more shielded methyl resonance belongs to an axial group. From these data the major isomer of the platinum complex **7** can be assigned to having an ax-eq disposition of the methyl substituents.

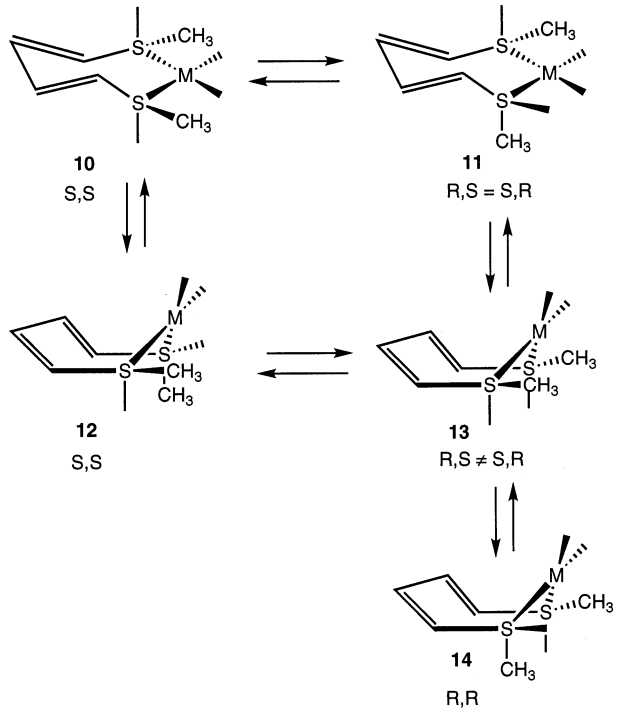
The peaks of the aromatic part of the NMR spectrum of the Pt complex are too close together and not appropriately shaped for a reliable determination of the activation energy of the dynamic processes to be achieved. However, the presence of well separated methyl resonances at room temp. indicates that this complex is less fluxional than the Pd counterpart and that the activation energy for the first equilibrium should be higher than the 55 kJ mol^{-1} found for the Pd complex.

Aside from the relative diastereomeric ratio and equilibration rates, the overall pictures emerging from the dynamic NMR investigation of the platinum and the palladium complexes are quite similar, with the basic difference that, unlike the platinum case, in the palladium complex it is the major species which has the eq−eq methyl groups.

Discussion

The dynamic behaviour shown by the Pd and Pt complexes indicates that different species are present in solution and that the interconversion among them is a fast process on the NMR timescale at room temp. Scheme 2 summarizes the interplay among the possible stereoisomers (diaxial species are omitted).

Scheme 2. Possible stereoisomers of Me_2BINAS complexes; the absolute configuration of the stereogenic sulfur centers are indicated; the binaphthalene backbone (R configuration) and the additional ligands at the metal are omitted for clarity



For the interconversion between these species three different hypothesis can be formulated: 1) interconversion between two different conformations of the seven membered chelate ring of comparable stability; 2) epimerization at the stereogenic sulfur through dissociation-recombination; 3) pyramidal inversion at the stereogenic sulfur in the bound state with no dissociation. In the first hypothesis the configurations at both the sulfur atoms are preserved during the dynamic process, while the second and the third transformations are accompanied by a net inversion of configuration at one or both stereogenic sulfur(s).

The fact that the position of the chemical shifts of the methyl substituents and the values of the relevant $^3J(^{195}Pt,^1H)$ coupling constants of the Pt complex are invariant in the temperature range scanned rules out the second hypothesis, and lends better support to the view that dissociation of the S donors is not occurring at any time.

From the NMR spectra of the platinum complex **7** two species can be univocally identified. The minor isomer has two equatorial *S*-methyl substituents and an overall C_2-symmetry. These conditions are met only by compound **10** having the seven membered chelate ring in a twisted chair (or chair) conformation, but not by the corresponding boat conformer **13**. The same chair structure can be attributed to the major isomer of the palladium complex which shows the same NMR pattern. Thus, the structure shown in the solid state by the Pd complex **6** corresponds to the structure of the predominant isomer in solution.

The second species identified by NMR has an equatorial-axial disposition of the methyl groups and is the predominant one in the Pt complex, even at room temp. Three different structures are conceivable for this isomer: one which mantains the twisted chair conformation and the C_2-symmetry (**11**) and two with a twisted boat conformation of comparable stability and C_1 symmetry (**12** and **14**). The ^{1}H-NMR spectra at −20°C suggest a C_2-symmetrical structure for this compound. While this condition is met by the chair conformer **11**, it cannot be overlooked that an apparent C_2 symmetry can result from a fast interconversion of two C_1-symmetrical stereoisomers such as **12** and **14**.

Actually, at −50°C a further dynamic process causes the C_2-symmetrical pattern of the aromatic resonances to be broken down. Notably, chemical shifts and shapes of the signals due to the methyl groups do not show any apparent change at this stage. As the surroundings of the methyl substituents are quite similar in **12** and **14**, both these facts seem to us to lend better support to the second assumption.

We can confidently conclude that in the case of the platinum complex **7**, the eq-eq chair conformer **10** is slowly interconverted at room temp. into the ax-eq boat conformers **12** and **14** which, under the same conditions, are rapidly interconverting. The same is probably true for the palladium derivative **6**, which is more fluxional than the Pt counterpart.

For the equilibration between **10** and **12** (or **14**) to occur, both changes in the chelate ring conformation and inversion of configuration at one stereogenic sulfur are required. The available data do not allow us to envisage which process is occurring first, but it is known that they are both feasible and can even take place simultaneously[9].

The structures having both the methyl groups equatorial are expected to be more stable, but this is not the case for the platinum complex where the predominant species has an axial methyl substituent. Actually, a non-bonding interaction is present between the hydrogen at the aryl carbon 3 (adjacent to that bound to the sulfur) and the equatorial methyl substituent. This is evidenced by a short contact distance in the solid state structure of the Pd complex (ca. 2.1 Å) and should be even more severe in the case of the Pt derivative due to the larger ionic radius. In keeping with this, the equilibrium of the platinum complex is shifted towards the ax-eq isomer.

Nothing can be said about the dynamics of the rhodium complex **5** which is probably highly fluxional over the range of temperatures scanned.

Conclusions

The dithioether complexes reported here are all fluxional at room temp. This dynamic behaviour is extremely pronounced in the case of rhodium(I) derivatives whose dia-

stereoisomers did not show isolated NMR resonances even at −80°C. Due to this property, Rh complexes with Me_2BINAS do not seem well suited for use in enantioselective catalysis where high e.e.'s should not be expected.

This work was carried out within the framework of the COST D2 program of the C.E.C. "Selective synthesis". Financial support from *the Italian Ministero dell' Università e della Ricerca Scientifica e Tecnologica* (MURST 60% and 40%), the *Spanish CICYT* (Ministerio de Educacion y Ciencia) and *CIRIT* (Generalitat de Catalunya), Proj. QFN-95-4725-C03 and the *Hungarian Research Fund* (OTKA 25525) is gratefully acknowledged. L. K. would like to thank dr. *Gabor Szalontai* (NMR Laboratory, University of Veszprem) for many NMR experiments on the Pt complex and for useful discussions. S. G. likes to thank Prof. *Dieter Sellmann* (University of Erlangen-Nürnberg) for reading and commenting on the manuscript.

Experimental Section

Melting points are uncorrected. Infrared spectra were recorded in KBr pellets on a BIO-RAD FTS-7PC spectrophotometer. ^{1}H and ^{13}C spectra were recorded on a Varian VXL 5000 spectrometer at 300 and 75.5 MHz, respectively, in CD_2Cl_2 and $CDCl_3$. Chemical shifts of protons and carbons are reported in ppm referred to TMS as an internal standard. Elemental analyses were performed with a Perkin Elmer Analyser 240 B. Commercial chemical reagents were used as received and solvents were dried by standard procedures and stored over molecular sieves under an inert atmosphere. $[Rh(cod)_2]^+X^-$[10], $PtCl_2(PhCN)_2$[11] and $PtCl_2(PhCN)_2$[12] were prepared according to the literature.

Preparation of [Rh(cod)(Me$_2$BINAS)]ClO$_4$ (**5**): The ligand Me_2BINAS (99.3 mg, 0.29 mmol) was added to a solution of $[Rh(cod)_2]ClO_4$ (100 mg, 0.24 mmol) in dichloromethane (5 ml). After stirring at room temp. for 15 min, diethyl ether was added to give a yellow precipitate of $[Rh(cod)(Me_2binas)]ClO_4$ which was filtered off and dried in vacuo (147.8 mg, 94% yield). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 1096 s, 625 m. − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.21 (d, *J* = 9 Hz, 2 H, ArH); 8.04 (d, *J* = 8.2 Hz, 2 H, ArH); 7.76 (d, *J* = 8.5 Hz, 2 H, ArH); 7.58 (t, *J* = 7.6 Hz, 2 H, ArH); 7.34 (t, *J* = 8.2 Hz, 2 H, ArH); 7.00 (d, *J* = 9 Hz, 2 H, ArH); 4.76 (br. m, 4 H, CH cod); 4.36 (br. m, 4 H CH, cod); 2.42 (s, 3 H, CH_3); 2.10 (d, *J* = 9.3 Hz, 4 H, CH_2 cod); 1.80 (br. m, 4 H, CH_2 cod). No splitting is observed at low temperatures. − ^{13}C NMR ($CDCl_3$): δ = 133.9, 132.6, 130.2, 129.7, 129.1, 127.0, 124.6 (Ar); 82.0 (CH cod); 79.9 (CH, cod); 34.2 (CH_2, cod); 15.9 (SCH_3). − $RhC_{30}H_{30}S_2ClO_4$ (657.0): calcd. C 54.9, H 4.5, S, 9.7; found C 55.0, H 4.5, S 9.7.

Preparation of [PdCl$_2$(Me$_2$BINAS)] (**6**): The ligand Me_2BINAS (50 mg, 0.144 mmol) was added to a solution of $[PdCl_2(PhCN)_2]$ (50 mg, 0.13 mmol) in dichloromethane (5 ml). After stirring at room temp. for 20 min, diethyl ether was added to give a red precipitate of **6** which was filtered off and dried in vacuo (54.1 mg, 73.1% yield). − ^{1}H NMR ($CDCl_3$): see text. − Mass spectrum (FAB); *m/z*: 523 (M^+), 489 (M − Cl), 452 (M − 2 Cl), 346 (Me_2binas). − Conductivity in CH_2Cl_2: 0.041 S·cm^2·eq^{-1}. − $C_{22}H_{18}Cl_2PdS_2$ (523.8): calcd. C 50.4, H 3.4, S 12.2; found C 50.6, H 3.3, S 12.1.

Preparation of [PtCl$_2$(Me$_2$BINAS)] (**7**): The ligand Me_2BINAS (172 mg, 0.5 mmol) was added to a solution of $[PtCl_2(PhCN)_2]$ (235 mg, 0.5 mmol) in chloroform (45 ml) and the solution was irradiated (254 nm) at 35°C for 11 h. The chloroform was evaporated and the yellow residue was taken up with benzene (20 ml). The yellow precipitate was filtered off and dried in vacuo (160 mg, 53% yield). − ^{1}H NMR ($CDCl_3$): see text. − $C_{22}H_{18}Cl_2PtS_2$ (612.5): calcd. C 43.11, H 2.96; found C 43.11, H 2.96.

X-ray Structure Determination and Refinement of [PdCl$_2$(Me$_2$BINAS)] (**6**): X-ray quality crystals of the complex **6** were grown by slow diffusion of diethyl ether into a CH_2Cl_2 solution. $C_{22}H_{18}ClPd_2S_2$, *M* = 523.81. Monoclinic, *a* = 8.144(2), *b* = 27.416(7), *c* = 9.416(2), β = 92.98(2), V = 2099(1) Å^3 (by least-squares refinement on diffractometer angles for 25 automatically centred reflexions, λ = 0.71069 Å), space group $P2_1/c$ (No. 14), *Z* = 4, D_x = 1.657 g cm^{-3}. Yellow, air stable crystals, μ(Mo-K_α) = 13.42 cm^{-1}. CAD4 diffractometer, ω/2θ mode with ω scan width = 0.80 + 0.35 tan θ, ω scan speed 1.3−5.5° min^{-1}, graphite-monochromated Mo-K_α radiation. Reflection ranges for the data collection were 1° < θ < 25° and −9 ≤ *h* ≤ 9, 0 ≤ *k* ≤ 32, 0 ≤ *l* ≤ 11. 3690 unique reflections (Lp and empirical absorption correction from ψ scans[13], minimum/maximum transmission = 0.786:0.999), 2634 observed reflections with $I > 2\sigma(I)$. Direct methods (SHELXS-86 program)[14] and full-matrix least-squares refinement on F^2 for all the reflections (SHELXL-93 program)[15] were applied.

Naphthyl groups were refined as rigid groups because some of their geometrical parameters were not sensible, and at the end of refinement were close to standard values. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions with isotropic temperature factors fixed at 1.2 times (naphthyl H) or 1.5 times (methyl H) U_{eq} for the corresponding carbon atoms. The weighting scheme was $w = 1/[\sigma^2(F_o^2) + (0.1075P)^2]$ where $P = [\max(F_o^2,0) + 2F_c^2)]/3$. Final R(*F*) and $R_w(F^2)$ values were 0.047 and 0.148 for reflections with $I > 2\sigma(I)$. Thermal parameters, a complete list of bond lengths and angles and further details of **6** are available from Fachinformationzentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, on quotation of the depository number CSD-407608.

Keywords: Arene complexes / Catalysis / Diazadiene complexes / Iron / Metal vapour

Two different routes to novel [(diene)(η^6-2,6-dimethylpyridine)Fe] complexes are reported, both of which utilize metal vapour reactions. The presence of two small substituents on the 2,6-position of pyridine is essential for the η^6-coordination of the heterocycle. Investigations on the reactivity and stability of the [(diene)(η^6-arene)Fe] complexes are presented, including those of the benzene, phosphinine, and pyridine derivatives. These investigations give some hints to the relevant factors for determining the interaction between an iron atom and a π-coordinated neutral arene ligand, and their modification by a nitrogen or a phosphorus atom. Selective substitution of the 1,5-cyclooctadiene (COD) ligand of [(COD)(η^6-arene)Fe] complexes by some 1,4-diaza-1,3-diene (DAD) derivatives is possible in the case of the benzene or phosphinine arene ligands, and [(DAD)(η^6-arene)Fe] complexes are formed, but all DAD derivatives tested so far cause the complete disintegration of [(COD)(η^6-2,6-dimethylpyridine)Fe]. [(DAD)(η^6-arene)Fe] complexes exhibit a catalytic potential, which was evaluated by experiments on the catalytic cyclodimerization of 1,3-butadiene in the presence of [$(Et_2AlOEt)_2$] as a co-catalyst. This reaction yields up to 92% of 1,5-cyclooctadiene, and an almost quantitative butadiene conversion is possible in the presence of less than 0.1% of the catalyst. Structural investigations on [(*N*,*N*′-bis(cyclohexyl)ethylenediimine)(η^6-toluene)Fe] **5a** reveal some details of the Fe-DAD interaction. An effective electron back-donation from occupied iron d-orbitals into the π*-LUMO of the DAD is indicated.

Diazadienes (DAD, **1**) exhibit a rich coordination chemistry[1], as they can formally act as 2-, 4-, 6-, or 8-electron donors. Metal coordination of the heterodiene is possible in different conformations since rotation of the central C−C-bond is only slightly energetically hindered (20−28 kJmol^{-1}). The most frequent case is coordination in the end-on chelate ligating mode, where the σ-lone pairs of the two nitrogen atoms are donated to a metal atom. A high catalytic potential has been found for such σ-diazadiene iron complexes in connection with unsaturated hydrocarbons. For example [$(DAD)_2$Fe] (**2**) derivatives[2] are catalysts for the cyclodimerization of 1,3-dienes in the presence of alkyl aluminium co-catalysts, to form vinylcyclohexene and 1,5-cyclooctadiene derivatives. [(DAD)$FeCl_2$] is activated by Grignard reagents. It allows efficient cyclodimerization, or co-dimerization, reactions of dienes and alkenes under mild conditions, and a Diels-Alder type reaction of 1,3-dienes with alkynes[3].

Both catalytically active species have the 12 valence electron (VE) fragment [(DAD)Fe] in common, which is believed to be part of the true catalyst[4]. With the aim of finding new catalytically active species with complementary properties to the known ones, and as the influence of the leaving ligand of a pro-catalyst may be decisive for such a process, we are interested in (DAD)Fe complexes with labile co-ligands.

On the basis of our own work on arene iron complexes, we have some knowledge about the conditions necessary to replace an arene ligand by other substrates at ambient or slightly elevated temperatures[5], and thus we decided to prepare the novel [(η^6-arene)(DAD)Fe] complexes. Attempts to prepare this class of compounds have been reported, but no full evidence was presented[6]. We found convenient synthetic routes for their preparation, including the iron complexes of heteroarenes. Some initial experiments on their catalytic potential demonstrated the merits of the concept.

Our synthetic approach to these complexes is that of an alkene ligand exchange reaction by diazadiene derivatives, which are allowed to react with [bis(alkene)(η^6-arene)Fe] or the corresponding diene complexes. Such compouds are known for benzene[7] and phosphinine[8] derivatives acting as the η^6-arene ligand, but no report about a pyridine derivative of this type has yet appeared in the literature. As

pyridine derivatives are believed to be decisively different in their π-ligand properties in respect to the other arenes, [(diene)(η^6-pyridine)Fe] complexes were our first synthetic goal. As for the phosphinines, the σ-lone pair of the hetero atom has to be shielded by one, or better two, *o*-substituents attached to the ring ligand in order to prevent the kinetically preferred σ-coordination[9][10]. The most simple pyridine derivative fulfilling this condition is 2,6-dimethylpyridine, which we therefore included in our studies.

The diazadiene derivatives **1a–g** used in this study are shown in Table 1.

Table 1. Diazadiene derivatives used

1a – g 
	R^1	R^2
1a	Cyclohexyl	H

1c	*tert*-Butyl	H
1d	*p*-Tolyl	Me
1e	*p*-Tolyl	Ph
1f	*p*-Anisyl	Me
1g	2,6-Dimethylphenyl	Me

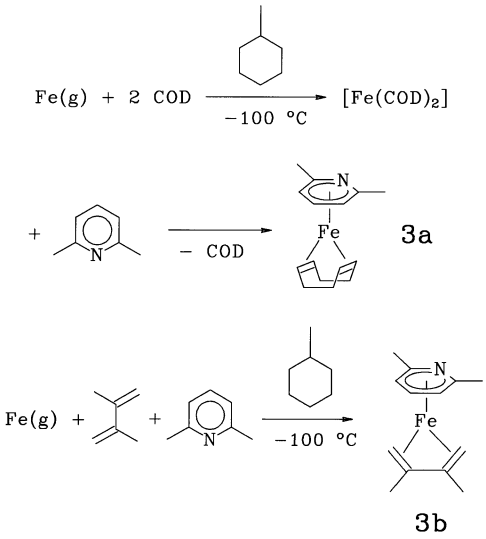
[(Diene)(η^6-2,6-Dimethylpyridine)Fe] Complexes and their Reactivity Towards Diazadienes

Highly reactive [(COD)$_2$Fe] was prepared in situ by reacting 1,5-cyclooctadiene (COD) with iron atoms in a metal vapour reaction[11]. Addition of 2,6-dimethylpyridine to the mixture at low temperatures results in the substitution of one COD ligand, and the desired product [(COD)(η^6-2,6-dimethylpyridine)Fe] **3a** is formed in a moderate yield. The same experiments have been performed with [(COD)$_2$Fe] and 2-trimethylsilylpyridine, 2,6-bis(trimethylsilyl)pyridine, or 2,6-bis(chloromethyl)pyridine. According to NMR studies of the crude product, the monosilylated heterocycle gave around a 5% yield of the corresponding [(COD)(η^6-2-trimethylsilylpyridine)Fe]. Due to the small amounts formed, no workup was attempted. The other pyridine derivatives failed completely to produce any observable π-complexes.

[(2,3-Dimethylbutadiene)(η^6-2,6-dimethylpyridine)Fe] **3b** is accessible directly, but only in poor yield, by a three-component reaction of stoichiometric quantities of iron vapour, 2,3-dimethylbutadiene and 2,6-dimethylpyridine. To the best of our knowledge, **3a** and **3b** represent the first examples of (η^6-pyridine)iron complex derivatives.

3a and **3b** are soluble in polar and apolar organic solvents, but strong donor solvents, such as acetonitrile, rapidly destroy the COD complex **3a**. Solutions of **3a** decompose slowly even in apolar solvents at room temp., whereas **3b** is stable under these conditions, probably due to the stabilizing effect of the conjugated diene ligand. Therefore the NMR spectroscopic characterization of **3a** has to be done at −10°C or lower. This problem does not exist for **3b**.

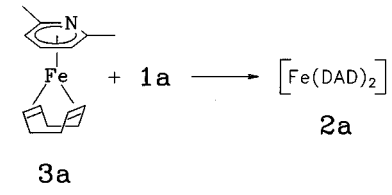
Scheme 1



Both compounds exhibit all the characteristics of π-complexes. There is no hint of σ-coordination of the nitrogen atom. For example the NMR data of **3a** and **3b** are closely related to those of their carbacyclic analogues [(COD)(η^6-toluene)Fe] and [(2,3-dimethylbutadiene)(η^6-toluene)Fe], respectively[12]. The observation of high-field coordination shifts for all ring nuclei investigated are a proof for the π-coordination of the heterocycle in both cases. In contrast to the otherwise much more reactive arene iron species [(ethene)$_2$(η^6-toluene)Fe] (**4**) (vide infra), the reaction of 2,6-dimethylpyridine complex **3a** and *N*,*N*′-bis(cyclohexyl)ethylenediimine **1a** results in a complete exchange of ligands and [(*N*,*N*′-bis(cyclohexyl)ethylenediimine)$_2$Fe] (**2a**) is formed as the only isolable species. This a known compound[2][4].

As expected, the reactivity of the η^6-coordinated 2,6-dimethylpyridine ligand of the iron atom is different from that of the carbacycle toluene. As hoped for, it is enhanced, but to such an extent that the replacement of the heterocycle by **1a** occurs parallel with the desired substitution of the diene ligand. [(DAD)(η^6-2,6-dimethylpyridine)Fe] complexes cannot therefore be made in this way.

Scheme 2

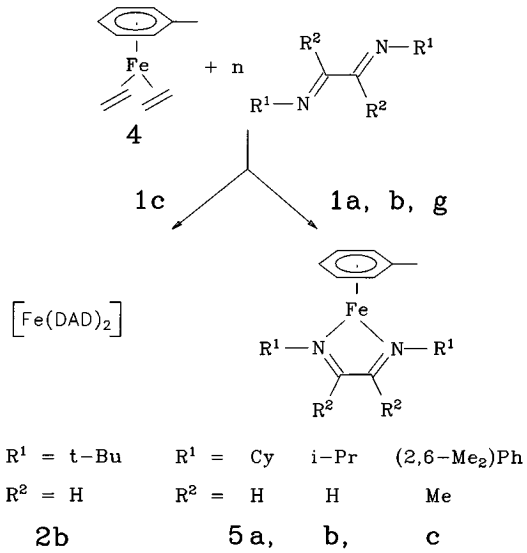


[(DAD)(η^6-Toluene)Fe] Complexes

[(Ethene)$_2$(η^6-toluene)Fe][7] **4** is well known as a highly reactive starting material which gives convenient access to many (η^6-toluene)Fe complexes, or FeL$_n$ species, at low temperatures, depending on the reaction partners[5][13]. In contrast to the significantly more stable pyridine π-complex **3a** only the two ethene ligands of **4** are substituted by **1a**,

b, and **g** around −20°C, and [(DAD)(η⁶-toluene)Fe] derivatives **5a−c** are formed in satisfactory to good yields.

Scheme 3



To our surprise, the complete coordination sphere of **4** was substituted under the same reaction conditions by the bis(*tert*-butyl) species **1c**, and the corresponding [(DAD)$_2$Fe] derivative **2b**[4] is the only isolable product of this reaction. Finally, the tolyl compounds **1d**, **e** and the anisyl derivative **1f** produce multicomponent reaction mixtures, which we have not been able to work up yet. Compared to the others, which substitute only the ethene ligands of **4**, **1c** contains bulkier *N*-alkyl substituents, but the increase in bulk is small compared to the cyclohexyl substituents of **1a**, and the 2,6-dimethyl phenyl substituents of **1g.** Therefore, the reason for this selective reactivity of DAD derivatives towards **4** is not yet clear and this point is currently under investigation.

Solid or dissolved **5a−c** are stable at room temp. and the solutions start decomposing around 40°C. Workup by column chromatography, however, requires low temperatures in order to prevent heavy losses. As was the case for **3a** and **b** the interpretation of the spectroscopic data of **5a−c** is straightforward and the desired products are definitely formed.

As **5** represents only the second class of compounds observed where arene iron fragments are combined with N-donor co-ligands in stable complexes, we are interested in more detailed information about the bonding situation between the metal and its ligands. In particular the Fe-DAD interaction is of interest. This fragment should be closely related to the active species of the diene dimerization (DAD)Fe catalysts.

An X-ray structure determination of crystalline [(*N,N′*-bis(cyclohexyl)ethylenediimine)(η⁶-toluene)Fe] **5a** was accomplished. The molecular structure in the solid state is shown in Figure 1 and some selected bond lengths are summarized in Table 2.

There are no unusually short intermolecular distances detectable in the unit cell. As a consequence, the details of the molecular structure have to be discussed mainly on the basis of intramolecular considerations. In full accord with the spectra, the DAD ligand acts as a chelate ligand, donating its N-lone pair electrons to the iron atom, and all ring carbon atoms of the planar toluene ligand are within bonding distance to the metal. The variation of the Fe−C bond lenths is small (208−210 pm), thus the metal is symmetrically bonded to the carbacycle. The Fe-DAD chelate ring is also planar, and both rings are oriented perpendicular to each other (90.4°). The bond distances within the ferradiazacyclobutadiene substructure of **5a** reflect the bonding situation between the iron atom and the DAD ligand, which is our main point of interest in this context. There is only one study dealing with related structural and electronic features of an arene iron complex. The authors who investigated [(2,2′-bipyridyl)(η⁶-toluene)Fe] **6**[14] point out the significant role of back-donation of π-electron density from the iron atom into the π*-orbitals of the bipyridyl ligand which they deduced from C−C- and C−N bond length variations within the bipyridyl ligand. This effect reduces the d-electron density of the occupied orbitals of the metal involved in this interaction.

If we compare the bond lenghts between free[15] and coordinated **1a** within **5a,** the distance C26−C36 is reduced by 7.8 pm, whereas the average of the distances C26−N1 and C36−N2 is increased by 4.3 pm. Exactly the same trends are observed for the corresponding parts of the molecule **6,** but the effect is slightly smaller (−7.3 and +3.9 pm, respectively)[14]. As a consequence the same interpretation seems to be appropriate for both compounds and we have to state that there is a slightly stronger electron back-donation from the iron atom of **5a** into the π*-LUMO of **1a**, which is antibonding in respect to the C=N double bonds, but bonding in respect to the central C26−C3 single bond. This synergetic metal−ligand interaction creates a partial

Figure 1. Molecular structure of **5a** in the solid state

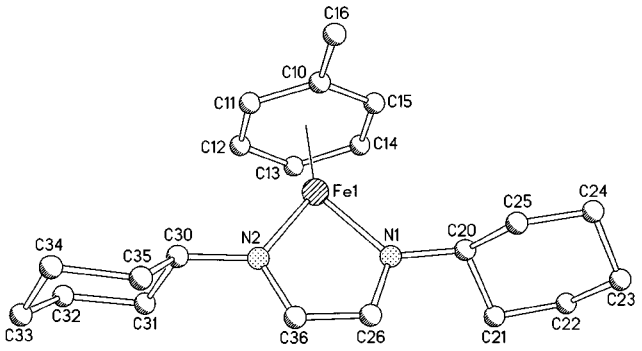


Table 2. Selected bond lenghts (pm) of **5a**

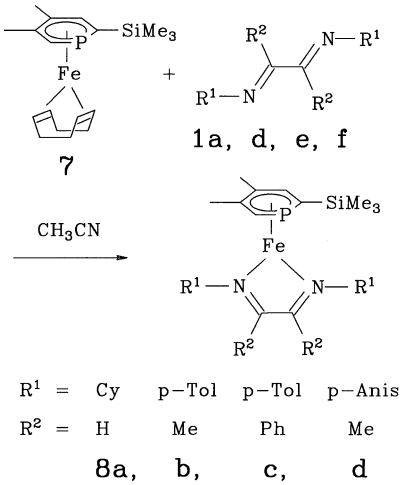
Fe−C10	208.1(3)	Fe−C11	209.4(3)
Fe−C12	208.7(3)	Fe−C13	208.9(3)
Fe−C14	210.0(3)	Fe−C15	210.1(3)
Fe−N1	189.9(2)	Fe−N2	190.1(2)
N1−C20	146.6(3)	N2−C30	146.4(3)
N1−C26	134.4(4)	N2−C36	133.6(4)
C26−C36	137.9(4)		

double bond character of the Fe−N bonds as well, which manifests itself in extremely short Fe−N bonds in the case of **5a** and **6** in relation to other examples of N-donor ligands complexed to iron[14]. We can thus classify the DAD as a very good π-acceptor of Fe d-electrons, and this interpretation is confirmed by independent NDDO calculations[16]. The decisive role of back-bonding for complexes of the type [(arene)(N−N−donor)Fe] is demonstrated by the experiments which aimed to produce [(toluene)(TMEDA)Fe], but which resulted in a completely different chemistry[17]. Being the formal hydrogenation product of a DAD derivative, the saturated N−N donor ligand TMEDA forms a closely related chelate ring with a complexed metal atom, but it completely lacks an appropriate π*-orbital and therefore cannot act as an π-acceptor.

[(DAD)(η⁶-2-Trimethylsilyl-4,5-Dimethylphosphinine)Fe] Complexes

From earlier work we know about the activating role of nitriles in initiating reactions of stable [(COD)(η⁶-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] **7**, which require the dissociation of the Fe−COD π-bond[8]. Because of a close relation between imine and nitrile N-donor ligands, DAD derivatives have first been reacted with **7** in the absence of nitriles. The reaction works, but requires elevated temperatures and the yields, as well as the purity of the products obtained, are not convincing. Running the same reaction with acetonitrile as the solvent, the substitution of COD by the DAD derivatives **1a, d, e, f** takes place at room temp. and moderate yields of the desired products are obtained. The [(DAD)(η⁶-2-trimethylsilyl-4,5 dimethylphosphinine)Fe] derivatives **8a−d** have been prepared in this way.

Scheme 4



8a−d are much more robust than the other π-complexes reported in this paper. Workup by column chromatography, for example, is possible at room temp. without losses.

Some Considerations on the Stability of Arene Iron Complexes

The preparative results of this study give an improved insight into the relative stability and reactivity of π-arene iron complexes of pyridine, benzene, and phosphinine derivatives. All three allow the preparation of [(arene)(diene)Fe] complexes[18]. Their stability as pure compounds, as solvated complexes in solution, or during workup by chromatography always increases in the sequence: pyridine < benzene < phosphinine.

In reacting such complexes with DAD derivatives, the same order is reproduced. The pyridine complex is disintegrated completely by DADs, even at temperatures below room temp. In spite of the fact that we did not react a diene, but the bis(ethene)Fe complex **4,** with different DADs, we can state that there is a differentiated behaviour, depending on the DAD substituents. However, in several cases the DAD derivative substitutes the ethene ligands in the presence of a π-toluene spectator ligand. The phosphinine complex **7**, however, requires either elevated temperatures, or the presence of nitriles as activating solvents, for the desired substitution reaction. Up to now, we found no indication of a substitution of the P-heterocycle of **7** parallel to the replacement of the COD ligand.

Without thermochemical data it is difficult to differentiate between thermodynamic and kinetic factors of complex stabilization. We believe in the predominance of the first factor, as the accessibility of the iron atom is not very different for the investigated substances.

Details of the electronic structures of the free arenes have been investigated for the unsubstituted rings[19] and these data have been used for comparing the π-ligand properties of benzene and phosphinine. Phosphinine is an equivalent π-donor but is the better π-acceptor ligand for transition metal atoms compared to benzene[20]. The two highest occupied orbitals of phosphinine are energetically close to the degenerate HOMO (e_{1g}) of benzene, but the LUMO (b_1) of phosphinine is significantly stabilized with respect to the LUMO (e_{2u}) of benzene. For pyridine the situation is different. Due to the higher electronegativity of the nitrogen atom combined with good π-orbital overlap, the LUMO (a_2) of pyridine is stabilized, but the HOMO is closer in its energy to the HOMO of benzene[19]. Consequently pyridine can be classified as a weaker π-donor, but a comparable π-acceptor ligand, with respect to benzene. From the combined data, we can rank the donor and acceptor capabilities of the arenes as follows:

π-Donor strength: phosphinine ≅ benzene > pyridine.

π-Acceptor potential: phosphinine > benzene ≅ pyridine.

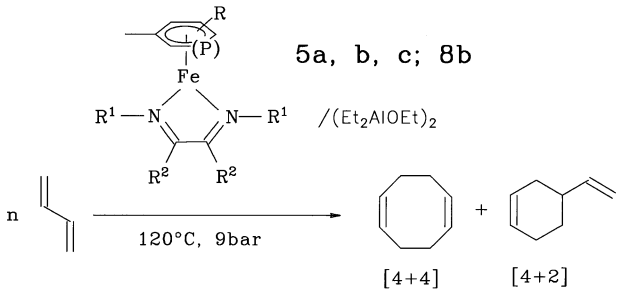
For electron-rich transition metals such as iron, the combination of both factors determine the bonding energy of the metal to the π-ligand of such complexes. Thus the experimental findings, and this interpretation of the bonding situation of arene iron complexes, are in a good agreement.

Catalytic Properties

The catalytic potential of the [(DAD)(arene)Fe] complexes was tested by experiments on the catalytic cyclodimerization of 1,3-butadiene. For the purpose of comparison analogous reaction conditions to those for the [$(DAD)_2$Fe] catalysts were initially chosen, including the use of the [$(Et_2AlOEt)_2$] co-catalyst[4]. The cyclodimerization of 1,3-buta-

diene yields two main products, and [4 + 2] and [4 + 4] cyclic addition reactions are the favoured processes, which result in the formation of vinyl cyclohexene (VCH) and COD, respectively.

Scheme 5



5a−c and **8b** have been tested as catalysts for this reaction and control experiments have been carried out with [(COD)(toluene)Fe][12]; all in the presence, as well as in the absence, of the $[(Et_2AlOEt)_2]$ co-catalyst. To rule out an independent role for $[(Et_2AlOEt)_2]$, this also was used (without an iron complex). Product analysis was done by gas chromatography. Some selected data are summarized in Table 3.

Table 3. Selected data of catalytic cyclodimerization of 1,3-butadiene

Experiment No.	Catalyst / mmol	$[(Et_2AlOEt)_2]$ / mmol	COD TON[a]	VCH TON[a]	Selectivity % COD[c]
1	**5a** / 0.062	0.4	972[b]	240	80.2
2	**5a** / 0.062	0.8	503	159	76.0
3	**5a** / 0.062	0.2	455	166	73.3
4	**5c** / 0.062	0.4	1479[b]	130	91.9
5	**8a** / 0.062	0.4	94	54	63.7

[a] TON = Turnover number, mole product per mole catalyst. − [b] Almost quantitative butadiene conversion. − [c] Percentage of the volatile products COD + VCH.

As hoped for, **5a−c** and **8b**, all in combination with the co-catalyst only, are cyclodimerization catalysts for the formation of COD and smaller amounts of VCH, whereas the combination [(COD)(toluene)Fe]/$[(Et_2AlOEt)_2]$ yields only a little VCH. Product yield and chemoselectivity of the [(arene)(COD)Fe] catalysts are closely related to those of the other (DAD)Fe systems[2][3][4], a first indication of comparable catalytic processes for the complete family of catalysts. The main difference is the lower reactivity of the [(arene)-(DAD)Fe] complexes. The optimal temp. here is 120°C, whereas $[DAD)_2Fe]$ requires less elevated temperatures, and the in situ reduction of $[(DAD)FeCl_2]$ results in the formation of an active species which already transfoms butadiene at room temp. A strong argument for the (DAD)Fe fragment to be part of the catalytically active species is deduced from the control experiments. Neither [(COD)(toluene)Fe] or $[(Et_2AlOEt)_2]$ alone, nor a mixture of both components, are able to induce the formation of COD, the main product of the catalytic reaction. As mentioned above, the presence of the co-catalyst in the reaction mixture is essential. The best results have been obtained with a molar ratio of catalyst/co-catalyst ≅ 2:13. In some experiments the butadiene was almost completely converted into the products, thus the maximal number of turnovers is most probably higher than the greatest number given in Table 3. Complete reaction of butadiene was also found, in some cases, with the other (DAD)Fe catalysts[21].

Toluene complexes **5,** and the phosphinine species **8b,** differ slightly in their selectivity of COD formation. Depending on the reaction conditions, 76−92% COD are formed by the derivatives of **5**, whereas **8b** produces 64% COD, but the difference in their reactivity is much more pronounced. Under the same conditions the catalysts **5** act approximately ten times faster than **8b**. We believe the higher turover frequency of the toluene complexes to be the main reason for their almost quantitative butadiene conversion.

The much higher reactivity of the complexes **5a−c** nicely parallels our findings on the substitution reactions of iron complexes with toluene or phosphinine π-arene ligands (vide supra). Obviously, the stronger Fe−phosphinine interaction hampers the generation of the true (DAD)Fe catalyst from the pro-catalyst **8b**. On the other hand, closed shell 18 valence electron (VE) species like **5a−c** are relatively stable. In contrast to the paramagnetic 16 VE $[(DAD)_2Fe]$ derivatives, for example, hydrolysis does not play a role here. Thus the reactivity of the catalytically active systems follows the stability of the different types of (DAD)Fe complexes, another hint that there are analogous reaction mechanisms in all cases.

We thank the *Fonds der Chemischen Industrie* and the *Deutsche Forschungsgemeinschaft* for financial support, Prof. Dr. *D. Sellmann*, Erlangen for providing X-ray structure facilities, and Dr. *F. Heinemann*, Erlangen for substantial help in evaluating the X-ray data.

Experimental Section

All reactions were carried out under a dry, oxygen free, nitrogen atmosphere. Solvents were purified by conventional methods, distilled and stored under nitrogen. − Unless otherwise stated, NMR spectra were recorded around room temp. on a Jeol FT-JNM-EX 270 spectrometer (269.6 MHz for ^1H, 67.7 MHz for ^{13}C, and 109.4 MHz for ^{31}P NMR), using dimethylpolysiloxane and solvent signals as internal standards for ^1H and ^{13}C, and 85% H_3PO_4/water as an external standard for ^{31}P NMR. The degree of substitution of the C-atoms was determined by DEPT spectra. − Mass spectra were recorded on a varian MAT 212 spectrometer (EI, 70 eV). − Microanalyses were peformed at the analytical department of the institute, using a Carlo Erba Elemental Analysers Mod. 1106. − Gas chromatography was done with a Philips PYE UNICAM PU 4500 chromatograph equipped with a supelcowax 10 capillary column l = 60 m, dia. = 0.75 mm. Column chromatography (15 × 1 cm) was accomplished with neutral degassed alumina or silica (Merck), deactivated with 5% degassed water. − Metal vapour reactions were carried out in a locally constructed rotating metal atom reactor[22], which uses resistively heated alumina crucibles in tungsten baskets as metal evaporators. The reactor allows low temp. reactions of metal vapours with liquid substrates, or solutions of substrates in low melting point solvents, and the transfer of cold solutions with complete exclusion of air and moisture.

The following starting materials have been prepared according to published procedures: DAD derivatives **1a**[23a], **1b**, **c**[23b], **1d**, **e**, **f**[23c], **1g**[23d], [(ethene)$_2$(η^6-toluene)Fe] **4**[7] , and [(COD)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] **7**[8]. All other substances have been purchased from commercial sources in synthetic quality and have been purified by distillation and saturation with pure nitrogen gas. Prior to use, 1,3-butadiene was condensed from a gas cylinder in a Schlenck tube at −78°C and stored there for several hours on a molecular sieve (0.5 nm).

[(COD)(η^6-2,6-dimethylpyridine)Fe] (**3a**): 8 g of iron gas (0.14 mol) was distilled into a mixture of 26,4 g of 1,5-*cis*-*cis*-cyclooctadiene (COD) (0.24 mol) and 300 ml of methylcyclohexane. During the course of reaction the gas pressure and the temp. of the liquid phase were held below 10^{-2} Pa and −100°C, respectively. The colour of the reaction mixture turned to dark green, while [(COD)$_2$Fe] was formed[11]. After completion of the metal vapour reaction, the cooling bath was removed. When close to −50°C the mixture was transferred to a round bottom flask and 921 mg 2,6-dimethylpyridine (8.6 mmol) was added at −40°C. It was then stirred and allowed to warm up slowly in air. Around −5°C the colour turned to red and the reaction was completed by stirring for 3 h at room temp.. Solvent and excess of COD were stripped off in vacuum and the residue was diluted in light petroleum ether (PE). Column chromatography (−30°C; alumina/5% water) resulted in two red fractions eluted by PE and toluene/THF (1:2), respectively. The toluene/THF solution contained red **3a**. Removal of the solvents and recrystallization from *n*-pentane yielded 716 mg (30,7%) of the dark red crystalline solid. − ^{1}H NMR ([D$_8$]toluene, −10°C): δ = 5.45 (d, J_{HH} = 10 Hz, 2 H, CH-pyr.), 3.05 (m, 1 H, CH-pyr.), 2.85 (m, 4 H, CH-COD), 2.55 (m, 4 H, CH$_2$-COD/*endo*); 2.35 (s, 6 H, CH$_3$-pyr.), 1.85 (m, 4 H, CH$_2$-COD/*exo*). − ^{13}C{^{1}H} NMR ([D$_8$]toluene, −10°C): δ = 115.8 (C-pyr.), 86.2 (CH-pyr.), 78.2 (s, CH-pyr.), 68.0 (CH-COD), 31.4 (CH$_2$-COD); 20.4 (CH$_3$-pyr.). − MS (70 eV) *m/z*: 271 [M$^+$], 163 [M$^+$ − COD]. − $C_{15}H_{21}FeN$ (271.10): calcd. C 66.44, H 7.81, N 5.17, found: C 66.50, H 7.90, N 5.03.

Reaction of **3a** *with DAD* **1a**: 222 mg of **3a** (0.82 mmol) was added to a solution of 180 mg of *N,N′*-bis(cyclohexyl)ethylenediimine **1a** (0.82 mmol) in 30 ml of toluene at −10°C. The mixture was stirred for 15 h without cooling, thus the temp. increased slowly to room temp.. Then the resulting dark suspension was filtered at −60°C through 3 cm alumina on a frit and a red solution was obtained. After removal of the solvent and recrystallization from *n*-pentane 123 mg (64.1%) of analytically pure, dark crystalline [bis(*N,N′*-bis(cyclohexyl)ethylenediimine)iron] was afforded. Within the experimental limits, all data on this compound are identical with those published in the literature[4].

[(η^4-2,3-Dimethylbutadiene)(η^6-2,6-dimethylpyridine)Fe] (**3b**): 8 g of iron gas (0.14 mol) was distilled into a mixture of 11.7 g of 2,3-dimethylbutadiene (0.14 mol), 15.3 g of 2,6-dimethylpyridine (0.14 mol), and 300 ml of methylcyclohexane as described before. The reaction mixture darkened until it was finally almost black. After completion of the metal vapour reaction, the cooling bath was removed to allow slow warming up. At −25°C the mixture was filtered through 3 cm alumina/5% H_2O on a frit, the alumina was extracted with toluene/THF, the liquid phases united, and the solvent removed in vacuo. Redilution in PE and column chromatography (−30°C; alumina/5% water) resulted in the formation of two red fractions (PE and toluene/THF, 1:4). The second fraction contained the desired product **3b**. Recystallization from *n*-pentane gave 584 mg (1,7%) of red needles. − ^{1}H NMR ([D$_6$]benzene): δ = 5.12 (m, 1 H, CH-pyr.), 4.57 (m, 2 H, CH-pyr.), 2.30 (s, 6 H, CH$_3$), 1.93 (s, 6 H, CH$_3$), 1.04 (s, 2 H, CH$_2$-butad.), −0.53 (s, 2 H, CH$_2$-butad.). − ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 113.4 (C-pyr.), 91.2 (CH-pyr.), 84.7 (s, CH-pyr.), 78.9 (C-butad.), 39.8 (CH$_2$-butad.), 23.3 (CH$_3$), 19.3 (CH$_3$). − MS (70 eV) *m/z*: 245 [M$^+$], 163 [M$^+$ − butad.], 138 [M$^+$ − pyr.]. $C_{13}H_{19}FeN$ (245.14): calcd. − C 63.69, H 7.81, N 5.71, found: C 63.76, H 7.75, N 5.52.

[(N,N′-Bis(cyclohexyl)ethylenediimine)(η^6-toluene)Fe] (**5a**): 292 mg of *N,N′*-bis(cyclohexyl)ethylenediimine (**1a**) (1.33 mmol) was suspended by stirring in 50 ml of toluene (1.35 mmol), and a solution of 275 mg of (1.35 mmol) [(ethene)$_2$(η^6-toluene)Fe] **4** in 10 ml of toluene was added, both were at −40°C. A badly isolated cooling bath (three plastic bowls of the same size, one put into the other) containing ca. 200 ml of ethanol at a temp. of , originally, ca. −40°C, allowed a slow increase in the temp. At −20°C the reaction mixture turned dark. The reaction was completed by stirring overnight at room temp.. After removal of the solvent, the residue was dissolved in PE. Column chromatography (−30°C; alumina) yielded two fractions (PE and PE/toluene, 3:1). The second fraction contained the desired red brown product **5a**. It was recrystallized twice, from acetonitrile and *n*-pentane, yielding 234 mg (47.7%) of dark crystals. − ^{1}H NMR ([D$_6$]benzene): δ = 6.76 (s, 2 H, CH-imine), 5.58 (t, *J* = 6 Hz, 1 H, CH-tol.), 5.20 (t, *J* = 6 Hz, 2 H, CH-tol.), 5.11 (d, *J* = 7 Hz, 2 H, CH-tol.), 4.47 (m, 2 H, CH-cy.), 2.30 (s, 3 H, CH$_3$-tol.), 2.24 (s, 4 H, CH$_2$-cy.), 1.55 (m, 14 H, CH$_2$-cy.), 1.10 (m, 2 H, CH$_2$-cy.). − ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 133.9 (CH-imine), 92.2 (C-tol.), 80.9 (CH-tol.), 79.4 (CH-tol.) 79.3 (CH-tol.), 70.0 (CH-cy.), 35.5 (CH$_2$-cy.); 27.1 (CH$_2$-cy.), 26. 5 (CH$_2$-cy.), 21.4 (CH$_3$-tol.). − MS (70 eV) *m/z*: 368 [M$^+$], 276 [M$^+$ − **1a**]. − $C_{21}H_{32}FeN_2$ (368.19).

[(N,N′-Bis(2-propyl)ethylenediimine)(η^6-toluol)Fe] (**5b**): Preparation as described for **5a** from 266 mg (1.90 mmol) of **1b** and 387 mg (1.90 mmol)of **4**. Recrystallization from *n*-pentane yielded 315 mg (57.6%) of **5b**. − ^{1}H NMR ([D$_6$]benzene): δ = 6.75 (s, 2 H, CH-imine), 5.55 (t, *J* = 6 Hz, 1 H, CH-tol.), 5.08 (t, *J* = 6 Hz, CH-tol.), 5.01 (d, *J* = 6 Hz, 2 H, CH-tol.), 4.80 (sept, *J* = 6 Hz, 1 H, CH-isopr.), 2.27 (s, 3 H, CH$_3$-tol.), 1.40 (d, *J* = 7 Hz, 12 H, CH$_3$-isopr.). − ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 133.4 (CH-imine), 92.8 (C-tol.), 81.1 (CH-tol.), 79.8 (CH-tol.), 79.7 (CH-tol.), 60,4 (CH-isopr.), 24,6 (CH$_3$-isopr.), 21.8 (CH$_3$-tol.). − MS (70 eV) *m/z*: 288 [M$^+$], 196 [M$^+$ − **1b**]. − $C_{15}H_{24}FeN_2$ (288.21).

[(N,N′-Bis(2,6-dimethylphenyl)-2,3-butanediimine)(η^6-toluene)Fe] (**5c**): Preparation as described for **5a** from 316 mg (1.08 mmol) of **1g** and 265 mg (1.30 mmol) of **4**. Recrystallization from *n*-pentane yielded 161 mg (33.9%) of **5c**. − ^{1}H NMR ([D$_6$]benzene): δ = 7.2 (m, 6 H, CH-phenyl), 5.30 (t, *J* = 5 Hz, 1 H, CH-tol.), 4.52 (t, *J* = 5 Hz, 2 H, CH-tol.), 4.46 (d, *J* = 5 Hz, 2 H, CH-tol.), 2.26 (s, 12 H, CH$_3$-phenyl), 1.95 (s, 3 H, CH$_3$-tol.), 1.00 (s, 6 H, CH$_3$-imine). − ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 157.1 (C-phenyl), 141.6 (C-phenyl), 131.0 (CH-phenyl), 129.2 (C-imine), 124.5 (CH-phenyl), 94.5 (C-tol.), 82.0 (CH-tol.), 81.3 (CH-tol.), 80.7 (CH-tol.), 20,1 (CH$_3$-tol.), 18,3 (CH$_3$-phenyl); 15,6 (CH$_3$-imine). − MS (70 eV) *m/z*: 277 [**1g**$^+$−CH$_3$]. − $C_{25}H_{32}FeN_2$ (368.19).

[(N,N′-Bis(cyclohexyl)ethylenediimine)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] (**8a**): 179 mg (0,81 mmol) of **1a**, 293 mg (0,81 mmol) of [(COD)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] **7** and 50 ml of acetonitrile were mixed at room temp. and stirred for 20 h. The orange reaction mixture slowly darkens and finally was nearly black. After removal of the solvent in vacuo the residue was dissolved in PE and subjected to column chromatography on silica/5% water. PE eluted some unreacted **7** and free phosphinine, whereas PE/toluene (1:1) gave a dark red fraction. Removal of the solvent and recrystallization afforded 146 mg (28.1%)

of dark red **8a**. – ^{1}H NMR ([D$_6$]benzene): δ = 6.75 (s, 2 H, CH-imine), 5.43 (d, J_{PH} = 10 Hz, 1 H, CH-phosp.) 4.70 (d, J_{PH} = 36 Hz, 1 H, CH-phosp.), 4.25 (m, 2 H, CH-cy.), 2.55 (m, 5 H, CH-cy. + CH_3 -phosp.), 2.35 (s, 3 H, CH_3 -phosp.), 2.00 (m, 2 H, CH-cy.), 1.52 (m, 14 H, CH-cy.), 1.06 (m, 2 H, CH-cy.), 0.45 [s, 9 H, $Si(CH_3)_3$]. – ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 137,8 (CH-imine), 99.0 (d, J_{PC} = 12 Hz, CH-phosp.), 95.2 (d, J_{PC} = 8 Hz, CH-phosp.), 93.6 (d, J_{PC} = 78 Hz, C-phosp.), 90.0 (d, J_{PC} = 8 Hz, C-phosp.), 89.2 (d, J_{PC} = 68 Hz, CH-phosp.), 69.8 (CH-cy.), 43.6 (CH_2-cy.), 34.6 (CH_2-cy.), 27.0 (CH_2-cy.), 26.8 (CH_2-cy.), 26.4 (CH_2-cy.), 23.4 (CH_3-phosp.), 22.4 (CH_3-phosp.), 1,4 [$Si(CH_3)_3$]. – ^{31}P{^{1}H} NMR ([D$_6$]benzene): δ = –17.7. – MS (70 eV) *m/z*: 472 [M$^+$]. – $C_{24}H_{41}FeN_2PSi$ (368.19).

[(N,N′-Bis(4-tolyl)-2,3-butanediimine)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] (**8b**): Preparation as described for **8a** from 279 mg (1.06 mmol) of **1d** and 381 mg (1.06 mmol) of **7**. Recrystallization from *n*-pentane, yielded 219 mg (30.4%) of dark red **8b**. – ^{1}H NMR ([D$_6$]benzene): δ = 7.75 (d, J_{HH} = 8 Hz, 2 H, CH-tolyl), 7.10 (d, J_{HH} = 8 Hz, 2 H, CH-tolyl), 7.0 (m, 4 H, CH-tolyl), 5.05 (d, J_{PH} = 9 Hz, 1 H, CH-phosp.), 3.99 (d, J_{PH} = 36 Hz, 1 H, CH-phosp.), 2.50 (s, 3 H, CH_3-phosp.), 2.24 (s, 3 H, CH_3-phosp.), 2.22 (s, 6 H, CH_3-tolyl), 1.00 (s, 6 H, CH_3-imine), 0.36 [s, 9 H, $Si(CH_3)_3$]. – ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 157.1 (C-tolyl), 146.1 (C-tolyl), 134.0 (C-imine), 125.6 (CH-tolyl), 124.3 (CH-tolyl), 99.0 (d, J_{PC} = 13.5 Hz, C-phosp.), 97.3 (d, J_{PC} = 6.6 Hz, CH-phosp.), 96.6 (d, J_{PC} = 77.9 Hz, C-phosp.), 91.2 (d, J_{PC} = 67.7 Hz, CH-phosp.), 90.2 (d, J_{PC} = 10.1 Hz, C-phosp.), 23.1 (CH_3-phosph.), 22.6 (CH_3-phosph.), 21.1 (CH_3-tolyl), 17.7 (CH_3-imine), 1.4 [$Si(CH_3)_3$]. – ^{31}P{^{1}H} NMR ([D$_6$]benzene): δ = –12.85 (s). – MS (70 eV) *m/z*: 516 [M$^+$], 320 [M$^+$ – phosp.]. – $C_{28}H_{37}FeN_2PSi$ (516.18).

[(N,N′-Bis(4-tolyl)-1,2-diphenylethylenediimine)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] (**8c**): Preparation as described for **8a** from 870 mg (2.23 mmol) of **1e** and 792 mg (2.20 mmol) of **7**. Chromatography was done with PE/toluene (3:1) and toluene. Toluene eluted the product. Recrystallization from PE yielded 270 mg (19.1%) of dark red **8c**. – ^{1}H NMR ([D$_6$]benzene): δ = 8.13 (dd, J_{HH} = 7 / 1 Hz, 2 H, CH-aryl) 7.05 (dd, J_{HH} = 7 / 1 Hz, 2 H, CH-aryl), 6.88 (dd, J_{HH} = 8 / 1 Hz, 2 H, CH-aryl), 6.70 (m, 6 H, CH-aryl), 6.60 (m, 6 H, CH-aryl), 5.48 (d, J_{PH} = 10 Hz, 1 H, CH-phosp.), 4.43 (d, J_{PH} = 34 Hz, 1 H, CH-phosp.), 2.55 (s, 3 H, CH_3-phosp.), 2.15 (s, 3 H, CH_3-phosp.), 2.03 (s, 6 H, CH_3-diimine), 0.25 [s, 9 H, $Si(CH_3)_3$]. – ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 157.0 (C-aryl), 152.4 (C-aryl), 138.9 (C-aryl or C-imine), 133.6 (C-aryl or C-imine), 130.4 (C-aryl or C-imine), 127.3 (C-aryl), 126.9 (C-aryl), 126.0 (C-aryl), 125.6 (C-aryl), 103.2 (br., C-phosp.), 99.6 (br., C-phosp.), 99.0 (br., C-phosp.), 94.5 (br., C-phosph.), 90.6 (br., C-phosph.), 22.8 (CH_3-phosph.), 22.7 (CH_3-phosph.), 21.0 (CH_3-tolyl), 1.2 [$Si(CH_3)_3$]. – ^{31}P{^{1}H} NMR ([D$_6$]benzene): δ = –11,7 (s). – MS (70 eV) *m/z*: 641 [M$^+$]. – $C_{38}H_{41}FeN_2PSi$ (640.21): calcd. C 71.24, H 6.45, N 4.37, found C 71.12, H 6.81, N 3.94.

[(N,N′-Bis(4-anisyl)-2,3-butanediimine)(η^6-2-trimethylsilyl-4,5-dimethylphosphinine)Fe] (**8d**): Preparation as described for **8a** from 241 mg (0.81 mmol) of **1f** and 290 mg (0.87 mmol) of **7**. Recrystallization from *n*-pentane yielded 145 mg (32.5%) of dark red **8d**, which was always contaminated with traces of a second uncharacterized product. – ^{1}H NMR ([D$_6$]benzene): δ = 7.75 (d, J_{HH} = 8 Hz, 2 H, CH-anisyl), 7.01 (d, J_{HH} = 8 Hz, 2 H, CH-anisyl), 6.88 (d, J_{HH} = 8 Hz, 2 H, CH-anisyl), 6.79 (d, J_{HH} = 8 Hz, 2 H, CH-anisyl), 5.05 (d, J_{PH} = 9 Hz, 1 H, CH-phosp.), 4.01 (d, J_{PH} = 31 Hz, 1 H, CH-phosp.), 3.40 (s, 6 H, CH_3-anisyl.), 2.50 (s, 3 H, CH_3-phosp.), 2.20 (s, 3 H, CH_3-phosp.), 1.03 (s, 3 H, CH_3-imine), 0.35 [s, 9 H, $Si(CH_3)_3$]. – ^{13}C{^{1}H} NMR ([D$_6$]benzene): δ = 157.3 (C-anisyl), 152,6 (C-anisyl), 146.3 (C-imine), 126.0 (CH-anisyl), 125.1 (CH-anisyl), 99.1 (d, J_{PC} = 12 Hz, C-phosp.), 97.3 (d, J_{PC} = 8 Hz, C-phosp.), 96.5 (d, J_{PC} = 78 Hz, C-phosp.), 91.2 (d, J_{PC} = 68 Hz, C-phosp.), 90.1 (d, J_{PC} = 9 Hz, C-phosp.), 55.0 (CH_3-anisyl), 23.1 (CH_3-phosp.), 22.7 (CH_3-phosp.), 17.7 (CH_3-imine, 1,4 [$Si(CH_3)_3$]. – ^{31}P{^{1}H} NMR ([D$_6$]benzene): δ = –13.4 (s). – MS (70 eV) *m/z*: 546 [M$^+$]. – $C_{28}H_{37}FeN_2O_2PSi$ (548.17).

General Procedure of Catalytic Cyclodimerization and Gas Chromatographic Product Analysis: Ca. 30 ml of purified 1,3-butadiene was condensed at –20°C into a glass tube, and defined solutions of catalyst and co-catalyst in a few ml of toluene are added. In some of the experiments 15 ml of additional solvents (toluene or diethylether) have been used with negligible effects on product formation. The tube was then put into a 250-ml stainless steel autoclave which contained an argon atmosphere. After closing the autoclave, the bottom half of it was placed in an oil bath and heated up to the reaction temp. for 3 h, whilst butadiene built up a gas pressure inside. At 80°C reactor temp. the volatile components of the reaction mixture were transferred in vacuo into a cold (77 K) trap and the content of the trap was analysed by gas chromatography later.

The volatile components butadiene, COD, VCH, and toluene of the product mixture were separated by the capillary down to the base line. For quantitative determinations defined amounts of THF were added. A complete calibration procedure was done for the integrated peaks of COD and THF and the VCH was then related to the COD. In all cases a linear correlation was observed. The data allow us to relate the molar amounts of product formed to the amounts of catalysts used in the experiments. These results are presented as the "turnover number of substrate molecules per molecule catalyst" (TON). The precise ratio of butadiene conversion, however, was undeterminable in our experimental setup, as the exact amounts of butadiene which have had contact with the catalysts remained unknown. In cases where we detected only traces of remaining butadiene in the product mixture, an almost quantitative conversion is assumed. Higher oligomers of butadiene are formed to some extent, but no analysis was attempted. An summary of the experimental data is given in Table 3.

Crystal Structure Determination: Suitable crystals of **5a** were grown in *n*-pentane at –40°C. The data were collected on a Sie-

mens P4 diffractometer with Mo-K_α radiation (λ = 0.71073 Å) and a graphite monochromator (Table 4.). The crystal structures were solved by direct methods (SHELXS-86[24]) and refined by SHELXL-93[25]. Non-hydrogen atoms were refined anisotropically; the hydrogen atoms were taken from a difference fourier calculation and included as fixed contributions in the final stages of a least squares refinements. Other experimental details are given in Table 4. Crystallographic data (excluding structure factors) for the structure report in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary pubilication no. CCDC-100543. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, GB-Cambridge CB12 1EZ [Fax: (internat.) + 44(0)1223/336-033, E-mail: deposit@ccdc.cam.ac.uk].

$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ (**1**) and ethylene (**A**) react when irradiated with UV light at 253 K predominantly to $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{1:4}\text{-}C_4H_5)(\mu\text{-}H)]$ (**3A**), $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-}C_4H_6)]$ (**4A**), and thermolabile $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\eta^4\text{-}C_4H_6)]$ (**5A**). Similarly, propene (**B**), 1-butene (**C**), and (*E*)-2-butene (**D**) yield mixtures of $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}H)(\mu\text{-}\eta^{1:4}\text{-}1,3\text{-dien-1-yl})]$ (**3B**, **3 C, 3D**), $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-}C_4H_5R]$ (**4B**, **4C**), and $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-}\eta^{1:2}\text{-}CO)(\eta^4\text{-}1,3\text{-diene})$ (**5B**, **5 C, 5D**). With **B** and **C** also thermolabile $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)(\eta^2\text{-}C_2H_3R)]$ (**2B**, **2C**) are formed. A by-product of the reaction of **1** with **D** is $[W(\eta^5\text{-}C_5H_5)(CO)(H)\{\eta^4\text{-}(E)\text{-}C_5H_7CH_3\}]$, which is generated in two diastereomeric forms (**6**, **6′**). In contrast, **1** yields no complexes with (*Z*)-2-butene (**E**) which contain ligands formed from coordinated acetylene and the olefin. From the reaction mixture only trinuclear $[W_3(\eta^5\text{-}C_5H_5)_3(CO)_5(\mu\text{-}\eta^{1:2}\text{-}C_2H_3)]$ (**7**) was isolated, an alicyclic complex with a W−W single and a W−W triple bond. The crystal and molecular structures of **5D** and **7** were determined by X-ray structure analysis. The constitutions of the other complexes were ascertained by IR and ^{1}H-NMR spectroscopy.

Introduction

Unsaturated hydrocarbons like alkenes or alkynes react in different ways with transition metal complexes. Oligomerisation, cyclooligomerisation and polymerisation are well-known reactions catalysed by transition metal complexes. Pre-requisite for a linkage of unsaturated hydrocarbons by C−C bond formation is the coordination of the substrates at one or two adjacent metal centres. Binuclear complexes offer after a suitable activation the possibility for a simultaneous coordination of two alkenes or alkynes followed by a C−C bond formation between the coordinated hydrocarbons. Examples for these types of reactions are the thermal oligomerisations of alkynes[2][3][4] at $[M_2(\eta^5\text{-}L)_2(CO)_4]$ complexes (M = Cr, Mo; L = C_5H_5, C_9H_7)[5][6][7][8], which proceed stepwise via $[M_2(\eta^5\text{-}L)_2(CO)_4(\mu\text{-}\eta^{2:2}\text{-alkyne})]$ as intermediates[9]. We have been able to show, that acetylene reacts photochemically with $[M_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ (M = Mo, W) predominantly to yield $[M_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-}\eta^{1:3:3:1}\text{-}C_6H_6)]$[10].

By light-induced CO cleavage $[M_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ complexes are generated at low temperatures with potentially free coordination sites, well suited to coordinate unsaturated hydrocarbons. Not only acetylene, but also alkenes are coordinated and linked with the acetylene ligand when $[Mo_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ or $[Mo_2(\eta^5\text{-}C_9H_7)_2(CO)_3(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ is reacted with ethylene or alkenes[11][12]. This system allows a specific generation of hydrocarbons by codimerisation of acetylene and alkenes. In order to study the reaction behaviour of simple alkenes at binuclear complexes also the tungsten homologue $[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)]$ was allowed to react with ethylene and some simple alkenes. The results of these investigations will be discussed in the following.

Preparative Results

The photoreaction of (μ-$\eta^{2:2}$-acetylene)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**1**) was carried out at 253 K with the olefins ethylene (**A**), propene (**B**), 1-butene (**C**), (*E*)-2-butene (**D**), or (*Z*)-2-butene (**E**) in petroleum ether/THF or ether/THF. The progress of the reaction is monitored by IR spectroscopy using the υCO stretching bands in the region from 2200 to 1700 cm^{-1}. Immediately after the bands of **1** have vanished the irradiation is stopped and the solvent is removed from the reaction mixture. The residue is separated by column chromatography on alumina at 253 K into its components, the isolated compounds are re-crystallised from ether. The complexes were characterised with IR and ^{1}H NMR spectroscopy and by C,H elemental analyses.

The photoreaction of **1** with ethylene (**A**) is conducted in petroleum ether/THF (1:1). By column chromatography of the reaction mixture three binuclear complexes can be isolated: (μ-$\eta^{1:4}$-1,3-butadien-1-yl)tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)ditungsten(*W*−*W*) (**3A**) (μ-$\eta^{1:3}$-2-butene-1,1-diyl)tetracarbonylbis(η^5-cyclopentadienyl)-

ditungsten(*W*−*W*) (**4A**) and (η^4-1,3-butadiene)tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**5A**).

$$\mathbf{1} + C_2H_4 \xrightarrow[243\ K]{h\cdot\nu} [W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{1:4}\text{-}C_4H_5)(\mu\text{-}H)]\ (\mathbf{3A})\ (3\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-}C_4H_6)]\ (\mathbf{4A})\ (2\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\eta^4\text{-}C_4H_6)]\ (\mathbf{5A})\ (2\%)$$

Propene (**B**) and 1-butene (**C**) react with **1** to analogous compounds. In addition to the dienyl bridged hydrido complexes **3B**, **3C** and the related 2-pentene-1,1-diyl and 2-hexene-1,1-diyl complexes **4B**, **4C** the η^4-diene compounds **5B**, **5C** with bridging μ-$\eta^{1:2}$-CO ligands and the very thermolabile substitution products with olefin acetylene ligands **2B**, **2C** were isolated from the reaction mixtures. The olefin complexes **2B**, **2C** rearrange at room temperature readily into the corresponding dienyl hydrido complexes **3B**, **3C**.

$$\mathbf{1} + C_2H_3R \xrightarrow[243\ K]{h\cdot\nu} [W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}\eta^{2:2}\text{-}C_2H_2)(\eta^2\text{-}C_2H_3R)]\ (\mathbf{2B}, \mathbf{2C})\ (4\%, 5\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}H)(\mu\text{-}\eta^{1:4}\text{-}C_4H_4R)]\ (\mathbf{3B}, \mathbf{3C})\ (4\%, 6\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-}C_4H_5R]\ (\mathbf{4B}, \mathbf{4C})\ (1\%, 1\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-}\eta^{1:2}\text{-}CO)(\eta^4\text{-}C_4H_5R)]\ (\mathbf{5B}, \mathbf{5C})\ (5\%, 5\%)$$

$$R = CH_3, C_2H_5$$

With (*E*)-2-butene (**D**) one mononuclear and three binuclear complexes are obtained after chromatography. No simple olefin complex has been detected in this case. Again a dienyl-bridged hydrido complex **3D** and a diene complex **5D** are formed. The generation of **4C** must be explained with an isomerisation of the olefin prior to the C−C bond formation. The mononuclear complex **6** contains like **5D** the η^4-(*E*)-3-methyl-1,3-pentadiene ligand. When **3D** is warmed in solution it rearranges into **5D**.

$$\mathbf{1} + C_4H_8 \xrightarrow[243\ K]{h\cdot\nu} [W_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-}H)(\mu\text{-}\eta^{1:4}\text{-}C_5H_6CH_3)]\ (\mathbf{3D})\ (5\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-}C_3H_3C_3H_7]\ (\mathbf{4C})\ (1\%)$$

$$[W_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-}\eta^{1:2}\text{-}CO)(\eta^4\text{-}C_5H_7CH_3)]\ (\mathbf{5D})\ (7\%)$$

$$[W(\eta^5\text{-}C_5H_5)(CO)(H)(\eta^4\text{-}C_5H_7CH_3)]\ (\mathbf{6})\ (1\%)$$

The photolysis of **1** in presence of (*Z*)-2-butene (**E**) yields no products with ligands, formed from acetylene and the olefin. Possibly, the steric demand of the *Z*-standing methyl groups causes this distinct differences of the reactivity. The starting material **1** is consumed only after 300 min and mainly decomposed into insoluble material. By column chromatography a trinuclear vinyl-bridged complex was isolated in addition to traces of other not yet characterised compounds.

$$\mathbf{2} + C_4H_8 \xrightarrow[243\ K]{h\cdot\nu} [W_3(\eta^5\text{-}C_5H_5)_3(CO)_5(\mu\text{-}\eta^{1:2}\text{-}C_2H_3)]\ (\mathbf{7})\ (1\%)$$

^{1}H-NMR Spectra

The ^{1}H-NMR spectroscopic data of the isolated complexes **2B**−**7** are given in the Experimental Section. For the binuclear complexes **2B**−**5D**, two singlets of the chemically different η^5-cyclopentadienyl ligands and additional signals due to ligands formed from acetylene and the olefins **A**−**D** are observed. The chemical shifts and the coupling constants of these signals together with the IR data allow justified suggestions for the constitutions of the complexes.

The photoreactions of **1** with propene (**B**) or 1-butene (**C**) yield the two η^2-olefin compounds **2B** and **2C**. Both are very temperature sensitive and can not be isolated in a pure state therefore. Two doublets in the ^{1}H-NMR spectra at δ = 2.35, 4.02 (**2B**) and δ = 2.33, 4.06 (**2C**) with coupling constants of 2 Hz are assigned to the bridging acetylene ligand. Four resonances in the spectrum of **2B** between δ = 1.03 and 2.30 with the relative intensities of 1:1:3:1 correspond to the η^2-coordinated propene ligand. Analogously, in the spectrum of **2C** a triplet and two multiplets for an ethyl group and three signals of single intensity between δ = 0.96 and 2.29 of the vinyl group were found. In solution **2B** and **2C** rearrange already at 273 K quickly into the μ-$\eta^{1:4}$-dienyl-μ-hydrido complexes **4B** and **4C**. Decomposition under formation of the starting material **1** is also observed.

The ^{1}H-NMR spectra of the μ-$\eta^{1:4}$-dienyl-μ-hydrido complexes show a strongly high-field shifted signal, typical for bridging hydrido ligands. The signals of the binuclear tungsten compounds **3A**, **3B**, **3C** and **3D** are accompanied by two pairs of ^{183}W satellites by which the bridging function of the hydrido ligands is further proved.

Five signals of **3A** with single intensity are related to each other by spin-spin couplings have to be assigned to the μ-$\eta^{1:4}$-1,3-butadien-1-yl ligand. The coupling constant J_{23} = 4.5 Hz is indicative for an *s-cis* conformation.

The ^{1}H-NMR spectra of **3B** and **3C** show two AB-spin systems each. Two doublets represent H1 and H2 with vicinal coupling constants of 6.0 Hz. Two doublets at higher field are due to H4 (*E*) and H4 (*Z*) with geminal coupling constants of 3.0 and 2.0 Hz. A singlet for **3B**, and two double quadruplets and a triplet for **3C** prove a methyl and an ethyl group at C3.

In the ^{1}H-NMR spectra of **3A**−**3D** a second hydrido signal of low intensity is found, which indicates the presence of a second isomer. Spin saturation experiments for **3B** and **3D** prove an exchange process between the two isomers. The increase of temperature causes first broadening of the signals of H1 and H2. At 303 K, they start narrowing again. Simultaneously the conversion to the corresponding η^4-diene complexes **5B** and **5D** is observed.

The tetracarbonyl complexes with μ-$\eta^{1:3}$-2-alkene-1,1-diyl ligands **4A**−**4C** were isolated only in low yields form the reactions of **1** with **A**−**D**. In the case of **D** as olefin component, an isomerisation to **C** has to be assumed prior CC bond formation. The complexes **4A**−**4C** are stable at room temperature.

The characterisation by ^{1}H-NMR spectroscopy is quite simple. Typical for all of these complexes is the resonance

of H1 at low field δ = 9.35 (**4A**, **4B**) and δ = 8.97 (**4C**). In the region of the proton resonances of coordinated olefins two signals for H2 and H3 are obtained. The vicinal coupling constants between H1, H2 and H3 reach from 8.5 to 10 Hz. The complexes differ according to the signals of the alkyl substituents (methyl, ethyl, propyl) in 3*E* position.

The ^{1}H-NMR spectra of the tricarbonyl-η^4-diene complexes **5A**, **5B**, **5C** and **5D** show at 243 K or 253 K the typical signal patterns for η^4-coordinated 1,3-butadiene, 2-methyl-1,3-butadiene, 2-ethyl-1,3-butadiene and (*E*)-3-methyl-1,3-pentadiene ligands. According to the stereochemistry of the complexes with the diene ligand in *ortho* orientation to the adjacent cyclopentadienyl ring, proved for **5D** with an X-ray structure analysis, four different stereoisomers (two pairs of enantiomers) are reasonable for such complexes with unsymmetrically substituted diene ligands. There is no evidence for the presence of a second pair of enantiomers in the spectra of **5B**, **5C** and **5D**. Obviously the energy difference between the pairs of enantiomers is too large to a allow a detectable population of the less favoured isomers.

The ^{1}H-NMR spectra of the complexes **5A**−**5D** were measured at variable temperatures between 223 and 283 K. Like the corresponding η^4-2,3-dimethyl-1,4-butadiene dimolybdenum complex for which an enantiomerisation was proved[13], **5A** shows signal broadening, although the dynamic behaviour could not be studied completely due to its thermal sensitivity. In contrast **5B**−**5D** show no dynamic effects.

The mononuclear complex **6**, **6′** is obtained only in minor amounts as a mixture of stereoisomers. The ^{1}H-NMR spectrum of **6**, **6′** contains two sets of eight signals with a proportion of 85:15. Two signals at δ = −9.65 and −6.13 with ^{183}W satellites of 76 and 74 Hz are assigned to the hydrido ligands. In each case three double doublets, a quadruplet, a singlet, and a doublet, the two latter of threefold intensity correspond with the (*E*)-3-methyl-1,3-pentadiene ligands of the two species. The chemical shifts of the (*E*)-3-methyl-1,3-pentadiene ligands in the two isomers are quite similar, the largest differences are found for H1 *E* and $CH_3$4 *E*. As a consequence of the asymmetric tungsten atom, and the asymmetrically substituted diene, two diastereomeric pairs of enantiomers are possible. When *o*-orientation is assumed on the basis of the observed chemical shifts for both isomers, the hydrido ligand is in one diastereomer in the vicinity of C1, in the other in the vicinity of C4. The large difference of the chemical shifts of the hydrido ligands is well understood on the basis of this assumption.

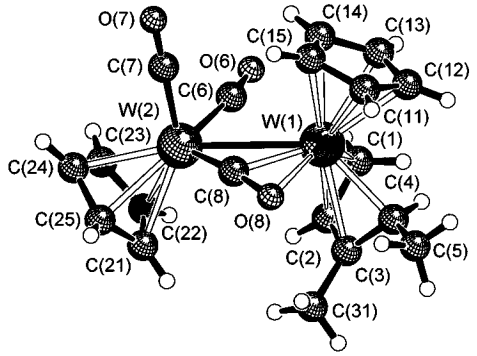
The trinuclear complex **7** is unexpectedly formed when **1** is irradiated in presence of (*Z*)-2-butene and is isolated in form of red-brown crystals in reasonable yield. Only three cyclopentadienyl singlets and three double doublets of single intensity at δ = 7.04, 4.72, 1.79 are observed in the ^{1}H-NMR spectrum. The double doublets are indicative for a bridging vinyl ligand. The spectrum is in accord with the molecular structure of **7** determined by X-ray structure analysis.

Crystal and Molecular Structures of 5D and 7

Reddish brown crystals of tricarbonylbis(η^5-cyclopentadienyl)[η^4-(*E*)-3-methyl-1,3-pentadiene]ditungsten-(*W*−*W*) (**5D**) are obtained in reasonable yields when **1** is allowed to react with (*E*)-2-butene. The complex crystallises in the monoclinic space group $P2_1/n$ with constants of the unit cell of *a* = 1089.3(2), *b* = 1240.5(3), *c* = 1303.7(2) pm, and ß = 95.914(14)°. The molecular structure of **5D** resembles to that of tricarbonylbis(η^5-methylcyclopentadienyl)(η^4-2,3-dimethyl-1,3-butadiene)dimolybdenum-(*Mo*−*Mo*)[12]. The W1−W2 bond length in the binuclear complex is found with 311.69(8) pm, typical for a W−W single bond[14]. The distances of the cyclopentadienyl ligands from the tungsten centres differ slightly from each other, W1 being somewhat closer with 196.9 pm than W2 with 202.1 pm. The (*E*)-3-methyl-1,3-pentadiene is η^4-coordinated to W1 and adopts *ortho* orientation[15]. The diene is originated by C−C bond formation between the acetylene ligand and the olefin **D**. Remarkably, the methyl groups being in *E* position in **D** are now in *Z* position to each other in **5D**. While W1−C1 = 221.3(10) pm and W1−C4 = 222.8(9) pm are of similar length, W1−C2 = 233.0(9) pm is found distinctly shorter than W1−C3 = 239.4(9) pm. Like in other η^4-diene complexes the C−C bond lengths of the diene entity are equal within experimental error. From the three CO ligands coordinated to W2, one is found in a normal terminal bond situation. The second CO ligand is semibridging to W1 with W1−C6 = 290.8(9) pm and W2−C6−O6 = 166.2(9)°. The third one forms a bridge between the two tungsten centres by a side-on coordination to W1 and shows only a slight bending with W2−C8−O8 = 169.1(11)°. By this type of coordination the CO ligand donates four electrons to the two tungsten centres. Examples for bridging, 4e-donor CO ligands are known for homo binuclear complexes[13][16][17][18] but especially for heteronuclear complexes[19][20][21][22][23][24].

The brown, trinuclear tungsten complex **7** crystallises in the monoclinic space group $P2_1/n$ with constants of the unit cell of *a* = 780.61(7) pm, *b* = 2197.1(3) pm, *c* = 1403.80(11) pm, and ß = 100.753(6)°. It shows noticeably different W−W bond lengths with W1−W2 = 304.65(11) pm and W2−W3 = 254.07(10) pm. They are in accord with W−W single[14] and triple bonds[25][26][27]. The three cyclopentadienyl ligands have similar distances to the pertinent metal centres with 201.0, 204.2, and 202.6 pm. Three of the five CO ligands are normal terminal ones. In contrast the CO ligands 5 and 6 are found in a special stereochemical situation. This kind of bond situation for CO ligands was observed for the first time in tetracarbonylbis(η^5-pentamethylcyclopentadienyl)dichromium[28], a binuclear complex with Cr−Cr triple bond and with four only slightly bent CO ligands, although heavily inclined toward the adjacent metal centres. Similar molecular geometries were also found for tetracarbonylbis(η^5-cyclopentadienyl)dimolybdenum[5], tetracarbonylbis(η^5-cyclopentadienyl)dichromium[29] and tetracarbonylbis(η^5-indenyl)dimolybdenum[8].

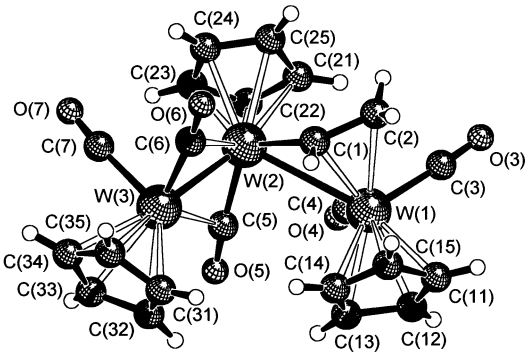
Figure 1. SCHAKAL projection of the molecular structure of **5D**; selected bond lengths [pm] and bond angles [°][a]; M(1) centre of C(11)−C(15), M(2) centre of C(21)−C(25)



[a]W(1)−W(2) 311.69(8), W(1)−M(1) 196.9, W(2)−M(2) 202.1, W(1)−C(1) 221.3(10), W(1)−C(2) 233.0(9), W(1)−C(3) 239.4(9), W(1)−C(4) 222.8(9), W(1)−C(6) 290.8(9), W(1)−C(8) 212.2(9), W(1)−O(8) 220.3(6), W(2)−C(6) 196.7(11), W(2)−C(7) 193.9(11), W(2)−C(8) 190.3(10), C(6)−O(6) 115.7(12), C(7)−O(7) 115.7(12), C(8)−O(8) 124.5(11); M(1)−W(1)−W(2) 116.1, M(2)−W(2)−W(1) 141.6, W(1)−W(2)−C(6) 65.3(4), W(1)−W(2)−C(7) 94.0(5), W(1)−W(2)−C(8) 41.9(4), W(2)−C(6)−O(6) 166.2(9), W(2)−C(7)−O(7) 178.2(9), W(2)−C(8)−O(8) 169.1(71).

Complex **7** can be considered to contain two subunits. The first one is related to (η^3-allyl)dicarbonyl(η^5-cyclopentadienyl)metal complexes of group 6[30], the second to tetracarbonylbis(η^5-cyclopentadienyl)dichromium[28].

Figure 2. SCHAKAL projection of the molecular structure of **7**; selected bond lengths [pm] and bond angles [°]; M(1) centre of C(11)−C(15), M(2) centre of C(21)−C(25), M(3) centre of C(31)−C(35)[a]



[a]W(1)−W(2) 304.65(11), W(2)−W(3) 254.07(10), W(1)−M(1) 201.0, W(2)−M(2) 204.2, W(3)−M(3) 202.6, W(1)−C(1) 221(2), W(1)−C(2) 230(2), W(2)−C(1) 210(2), W(2)−C(5) 194(2), W(2)−C(6) 253(2), W(3)−C(5) 236(2), W(3)−C(6) 192(2), W(3)−C(7) 202(2); W(1)−W(2)−W(3) 110.47(3), M(1)−W(1)−W(2) 125.5, M(2)−W(2)−W(1) 116.0, M(2)−W(2)−W(3) 132.8, M(3)−W(3)−W(2) 159.2, W(2)−C(5)−O(5) 168(2), W(3)−C(6)−O(6) 168.3(14), W(3)−C(7)−O(7) 175(2).

The bonding situation of the first subunit can be compared with those in the well-known (η^3-allyl)dicarbonyl(η^5-cyclopentadienyl)metal complexes. Formally W2, which is bonded to C1 and W1, replaces a sp^2-methylene group. In the second entity, vice versa, W1 and C1 replace in a formal sense a terminal CO ligand. In contrast to tetracarbonylbis(η^5-cyclopentadienyl)dichromium and the related compounds with all four CO ligands inclined to the adjacent metal centres, in complex **7** only two of them show this special type of coordination. This result is a good evidence for the assumption, that the inclination of only slightly bent CO ligands to a second metal centre and long metal−oxygen bonds is primarily due to steric and not due to electronic reasons. While for the two independent units of tetracarbonylbis(η^5-cyclopentadienyl)dichromium the angle Cr−Cr−M (M centre of the cyclopentadienyl ligand) is found with 158.7 and 165.0°, respectively, and in tetracarbonylbis(η^5-cyclopentadienyl)dimolybdenum close to 180°, the corresponding angles in **7** are W3−W2−M2 = 132.8(9)° and W2−W3−M3 = 159.2(9)°.

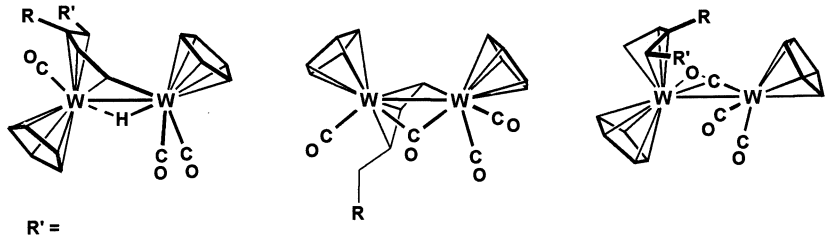
In complex **7** the three W atoms show an angular arrangement with W1−W2−W3 = 110.4(1)°. The plane defined by the three tungsten atoms is more or less perpendicular to the planes of the three cyclopentadienyl ligands with dihedral angles of 88.6, 82.2, and 82.9°. Remarkably, the two CO ligands 4 and 7 deviate only slightly from this plane and the C−W bonds penetrate the plane with 4.1 and 6.9°. W2, W3, C5 and C6 form an idealised parallelogram which is folded along the line W2, W3 with 162.4°. The distances W2−C5 and W3−C6 are short and amount 194(2) pm and 192(2) pm. The distances W2−C6 and W3−C5 are distinctly longer with 253(2) pm and 236(2) pm. The angles at C5 and C6 are found with 71.7(9) and 68.1(8)°, at W2 and W3 with 104.9(10) and 112.0(10)°. The sum of this angles is 356.7° as a consequence of the folding.

Complex **7** is also related to dinuclear complexes with μ-$\eta^{2:1}$-vinyl-bridging ligands[31][32]. It is an interesting example for a trinuclear complex with formal electron numbers of 17, 14, and 15 at the three tungsten centres. W−W single and triple bonds have to be considered for this trinuclear, angular 46 electron complex taking into account the 18 electron rule.

Discussion

The photoreaction of (μ-$\eta^{2:2}$-acetylene)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**1**) with ethylene yields at 253 K three complexes, [$W_2(\eta^5$-$C_5H_5)_2(CO)_3(H)(\mu$-$\eta^{1:4}$-1,3-butadien-1-yl)] (**3A**), [$W_2(\eta^5$-$C_5H_5)_2(CO)_4(\mu$-$\eta^{1:3}$-2-butene-1,1-diyl)] (**4A**), and [$W_2(\eta^5$-$C_5H_5)_2(CO)_3(\eta^4$-1,3-butadiene)] (**5A**) which are closely related to each other and allow conclusions about the reaction behaviour of unsaturated hydrocarbons in the coordination spheres of two tungsten centres. All products contain C_4 ligands, which result from a C−C bond formation between acetylene and ethylene and successive H shifts.

Binuclear complexes become accessible by photochemically induced formation of C_4 ligands from acetylene and ethylene which are only partially formed when 1,3-butadiene is reacted directly with [$M_2(\eta^5$-$C_5H_4CH_3)_2(CO)_6$] complexes (M = Mo, W)[33]. With [$Mo_2(\eta^5$-$C_5H_4CH_3)_2$-$(CO)_6$] 1,3-butadiene yields [$Mo(\eta^5$-$C_5H_4CH_3)$-$(CO)_2\{\eta^3$-(*E*)-2-butenyl}], [$Mo(\eta^5$-$C_5H_4CH_3)(CO)_2\{\eta^3$-(*Z*)-2-butenyl}], [$Mo_2(\eta^5$-$C_5H_4CH_3)_2(CO)_3(\eta^4$-butadiene)], and [$Mo_2(\eta^5$-$C_5H_4CH_3)_2(CO)_2(\mu$-$\eta^4$-butadiene)][13]. In the case of the photoreaction of [$W_2(\eta^5$-$C_5H_4CH_3)_2(CO)_6$] with 1,3-butadiene the only isolable product is [$W_2(\eta^5$-



R =	R' =			
H	H	**3A**	**4A**	**5A**
CH_3	H	**3B**	**4B**	**5B**
C_2H_5	H	**3C**	**4C**	**5C**
CH_3	CH_3	**3D**		**5D**

$C_5H_4CH_3)_2(CO)_4\{\mu\text{-}\eta^{1:3}\text{-}(E)\text{-2-butene-1,1-diyl}\}]$,[18] the analogue to **4A**.

Examples of C−C bond formations between small molecules in the coordination sphere of metals have been observed already in the past. $[Ru_2(\eta^5\text{-}C_5H_5)_2(CO)_2(CH_3CN)(\mu\text{-vinyl})]^+$ reacts with ethylene to $[Ru_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-H})(\mu\text{-}\eta^{2:2}\text{-1,3-butadiene})]^+$ and by deprotonation to $[Ru_2(\eta^5\text{-}C_5H_5)_2(CO)_2(\mu\text{-}\eta^{2:2}\text{-1,3-butadiene})]$[34]. Similarly, binuclear complexes with alkylidene bridges like $[M_2(\eta^5\text{-}C_5H_5)_2(CO)_3(\mu\text{-ethylidene})]$ (M = Fe, Ru) react with alkynes to the correspondingly substituted $\mu\text{-}\eta^{1:3}$-alkenediyl complexes[35][36].

Closely related to ($\mu\text{-}\eta^{1:4}$-1,3-butadiene-1-yl)tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)ditungsten(*W*−*W*) (**3A**), one of the products of the photoreaction of **1** with **A** is $[Mo_2(\eta^5\text{-}C_5H_4CH_3)_2(CO)_3(H)(\eta^{1:4}\text{-1,3-cycloheptadien-1-yl})]$, which is obtained when $[Mo_2(\eta^5\text{-}C_5H_4CH_3)_2(CO)_4]$ is irradiated in presence of 1,3-cycloheptadiene. The cyclic, $\eta^{1:4}$-coordinated dienyl and the hydrido ligand form bridges between the two metal centres[37]. Comparable bonding situations are also found in $[Rh_2\{(i\text{-}C_3H_7)_2PCH_2CH_2P(i\text{-}C_3H_7)_2\}_2(\mu\text{-H})(\eta^{1:4}\text{-1,3-butadiene-1-yl})]$, a product of the reaction of $[Rh_2\{(i\text{-}C_3H_7)_2PCH_2CH_2P(i\text{-}C_3H_7)_2\}_2(\mu\text{-H})_2]$ with 1,3-butadiene[38]. In both cases the diene is transformed into a dienyl ligand by hydrogen shift to the metal centre.

(η^4-1,3-Butadiene)tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**5A**) belongs to a group of complexes with side-on-coordinated, bridging CO ligands, donating 4 electrons to the metal centres. $[M_2(\eta^5\text{-}C_5H_4CH_3)_2(CO)_3(\eta^4\text{-diene})]$ complexes (M = Mo, W) are generated photochemically from $[M_2(\eta^5\text{-}C_5H_4CH_3)_2(CO)_4]$ with certain dienes[13][18]. They may be considered as derivatives of $[Mo_2(\eta^5\text{-}C_5H_5)_2(CO)_5]$ which is stabile only in matrix[39]. Of special interest is the 4-electron carbonyl bridge with a υCO band around 1600 cm^{-1}[13][18].

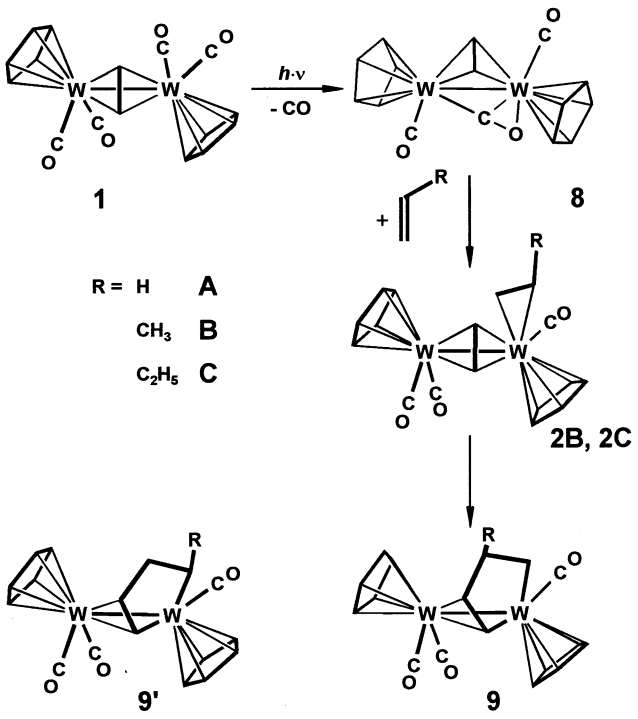
($\mu\text{-}\eta^{1:3}$-2-Butene-1,1-diyl)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**4A**) contains a 1,3-metalladiene core. Complexes of this type are generated under quite different conditions. $[Mo_2(\eta^5\text{-}C_5H_5)_2(CO)_4]$ reacts thermally with 3,3-dimethylcyclopropene by ring opening to $[Mo_2(\eta^5\text{-}C_5H_5)_2(CO)_4(\mu\text{-}\eta^{1:3}\text{-3-methyl-2-butene-1,1-diyl})]$[40][41]. The photoreaction of $[W_2(\eta^5\text{-}C_5H_4CH_3)_2(CO)_4]$ with 1,3-butadiene yields the analogous 2-butene-1,1-diyl complex[18]. 1,3-Metalladiene complexes may adopt *s-cis*[30][41] or *s-trans* configurations[42][43]. The ^{1}H-NMR-spectroscopic data of **4A** are in accord with the *s-cis* configuration.

Also with propene (**B**), 1-butene (**C**), or (*E*)-2-butene (**D**) hydrido-dienyl, 2-alkene-1,1-diyl and 1,3-diene complexes are formed. With **B** and **C** in addition the thermolabile, simple substitution products ($\mu\text{-}\eta^{2:2}$-acetylene)tricarbonylbis(η^5-cyclopentadienyl)(η^2-propene)ditungsten(*W*−*W*) (**2B**) and the corresponding 1-butene complex (**2C**) can be isolated and characterised by IR and ^{1}H-NMR spectroscopy. At room temperature **2B**, **2C** rearrange readily into the hydrido-dienyl complexes **3B**, **3C**.

The isolated products give good evidence for the route of the photochemical reaction when ($\mu\text{-}\eta^{2:2}$-acetylene)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**1**) is irradiated in the presence of olefins. In a primary step one CO ligand is cleaved from **1**. In contrast to mononuclear, electronically and coordinativly unsaturated carbonylmetal complex fragments with 16 electrons, the 32 electron intermediate, ($\mu\text{-}\eta^{2:2}$-acetylene)tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**8**), is probably stabilised by formation of a 4-electron carbonyl bridge like in the diene complexes **5A**−**5D**. This stabilisation would prolong the life time of **8**, but it might also delay the coordination of the olefin.

Addition of an olefin to **8** yields (η^2-acetylene)tricarbonylbis(η^5-cyclopentadienyl)(η^2-olefin)ditungsten(*W*−*W*) (**2**) which is moderately stable with propene or 1-butene as olefin component. In **2** two unsaturated hydrocarbon ligands are coordinated to a metal centre, a pre-requisite for a C−C bond formation. Insertion of the olefin into a W−C bond of the $W_2C_2H_2$ core yields the intermediate ($\mu\text{-}\eta^{1:2:1}$-1-butene-1,4-diyl)tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**9**).

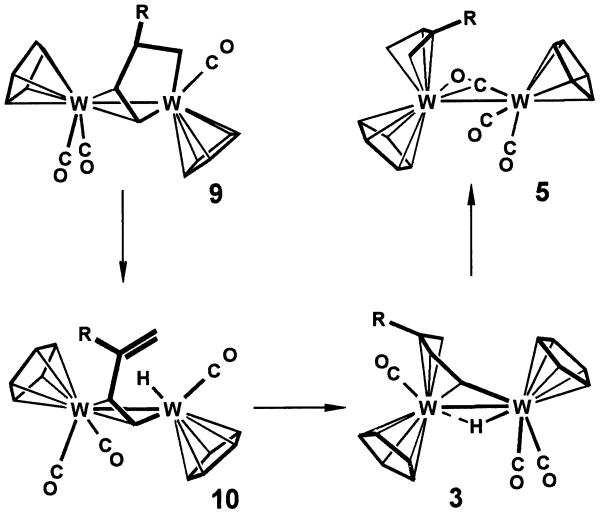
In a formal approach the $W_2C_2H_2$ fragment can be classified as a ditungstatetrahedrane and the WC_2H_4 entity as a tungstacyclopropane. By using this approach, the C−C bond formation is a kind of reductive elimination or reductive rearrangement, because it is accompanied by the cleavage of two W−C bonds. Also the electron deficit in **9** is possibly compensated by a 4-electron carbonyl bridge.



Unsymmetrically substituted olefins like **B** or **C** may form up to four different stereoisomers of **9**.

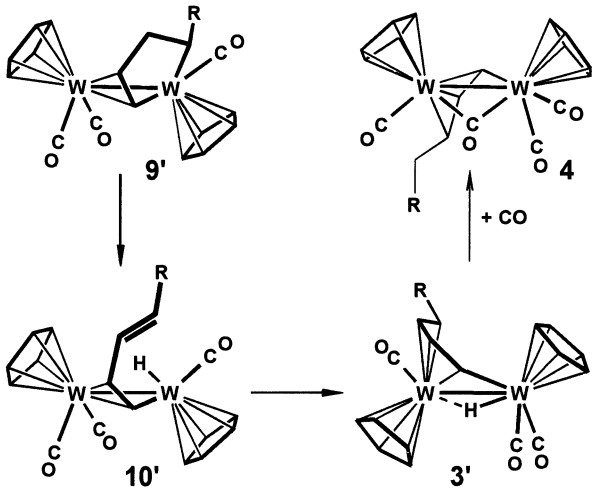
The 1-alkene-1,4-diyl ligands in **9** contain in β-position methylene or methine groups, which are susceptible to a β-elimination. This elimination leads immediately to the (μ-$\eta^{1:4}$-diene-1-yl)tricarbonylbis(η^5-cyclopentadienyl)-hydridoditungsten(*W*−*W*) complexes **3A**−**3D**.

In general, the complexes **3** rearrange at room temperature by H shift to C1 of the diene-1-yl ligand quickly into the (diene)tricarbonylbis(η^5-cyclopentadienyl)ditungsten complexes **5**. This reaction can also be interpreted as a reductive rearrangement, leading to 32-electron complexes.



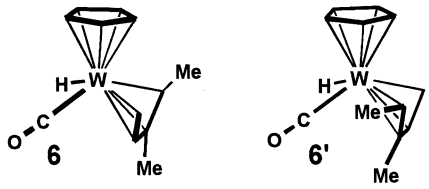
In addition to the hydrogen transfer to C1 also a transfer to C4 of the 1,3-butadiene-1-yl ligand and the coordination of carbon monoxide is possible which generates the (μ-$\eta^{1:3}$-2-alkene-1,1-diyl)tetracarbonylbis(η^5-cyclopentadienyl)-ditungsten(*W*−*W*) complexes **4A**, **4B** and **4C**.

Interestingly, the complexes **3B**−**3D** and **5B**−**5D** contain branched hydrocarbon ligands which are formed from acetylene and the olefins by C−C bond formation between acetylene and C2 of the olefins. Although the methyl groups in **D** are in *E* position, in the products **3D** and **5D** they are found in *Z* position, therefore a rotation around the C3−C4 bond has to be considered while intermediate **9** rearranges into **3**.



No branched hydrocarbon ligands are found in **4B** and **4C,** so the C−C bond formation involves C1 of the olefins. Furthermore, no corresponding dienyl-hydrido or diene complexes are observed. Obviously, the dienyl-hydrido precursor complexes **9** rearrange faster and are not detectable therefore. Small amounts of **4C** are also isolated from the reaction mixture of **1** and **D**. There are two explanations for this result. Either the olefin **D** contains impurities of **C** or the olefin is isomerised under the reaction conditions prior the C−C bond formation.

The by-product of the reaction of **1** with **D**, carbonyl(η^5-cyclopentadienyl)hydrido{η^4-(*E*)-3-methyl-1,3-pentadiene}-tungsten is generated in the two diastereomeric forms **6**, and **6′**. In addition to the centre of chirality at the tungsten atoms, the unsymmetrically substituted 1,3-diene ligand is planar chiral. Therefor diastereomers have to be expected and are obtained in a ratio of 0.85:0.15.



Finally, it should be mentioned, that (*Z*)-2-butene (**E**) does not form hydrocarbon ligands with acetylene at all. The only product obtained is the trinuclear tungsten complex **7** with a W−W single and a W−W triple bond and a vinyl bridge.

Experimental Section

All treatments and reactions were performed under dry, oxygen-free nitrogen. Solvents were dried with sodium/benzophenone or phosphorus pentoxide and saturated with nitrogen. − For column chromatography neutral alumina (Macherey, Nagel & Co KG, Düren) was heated in vacuum at 423 K and deactivated with 5% of water, saturated with nitrogen. − Photolysis reactions were conducted using a high-pressure mercury lamp (TQ 718, Heraeus Noblelight GmbH, Kleinostheim) operating at 700 W, which was immersed into a 750-ml vessel of Duran® with a cooling jacket. − C,H elemental analyses: Perkin-Elmer microanalyser 240. − IR (2200−1500 cm^{-1}): Perkin-Elmer Model 881. − ^1H NMR: Puls-FT-NMR-Spektrometer AMX 400 (Bruker) at 400.13 MHz. Chemical shifts are given relatively to TMS calculated from the solvent as internal standard. − (μ-$\eta^{2:2}$-Acetylene)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**1**) was prepared according to literature procedures[6][9]. All other reagents were commercial products.

1. *Photoreaction of (μ-η²:²-Acetylene)tetracarbonylbis(η⁵-cyclopentadienyl)ditungsten(W−W)* (**1**) *with Ethylene* (**A**): 1.6 g (2.5 mmol) of (μ-$\eta^{2:2}$-acetylene)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**1**) was dissolved in 750 ml of petroleum ether/THF (1:1). The solution was cooled to 243 K, and for 10 min ethylene (**A**) was condensed into it. During the photolysis nitrogen was bubbled through the solution and the progress of the reaction was controlled by IR spectroscopy in regular intervals. Irradiation was continued until the υCO bands of **1** had vanished. The solvent was removed in vacuo at 253 K and the residue was separated by column chromatography on alumina into two main fractions. The residue of the first main fraction was dissolved in 10 ml of ether and was subject of a further chromatography.

1st Fraction (pentane/ether 2:1): Starting material **1**.

2nd Fraction (pentane/ether 2:1): Pink solution; after removal of the solvent and crystallisation from ether, thermolabile (η^4-1,3-butadiene)tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**5A**) was obtained as red powder. Due to the thermal sensitivity of **5A** only a spectroscopic characterisation was possible (2%). − IR: $\tilde{\nu}$ = 1905 (s), 1825 (s), 1555 (m) cm^{-1}. − ^1H NMR (CD_2Cl_2, 213 K): δ = 5.41 (ddd, *J* = 7.5, 7.0, 7,0, 1 H, H2), 3.23 (ddd, *J* = 7.5, 7.0, 7.0 Hz, 1 H, H3), 2.92 (dd, *J* = 7.0, 4.0 Hz, 1 H, H4 *E*), 2.15 (d, *J* = 7.0, 2.0 Hz, 1 H, H1 *E*), 1.47 (dd, *J* = 7.0, 2.0 Hz, 1 H, H1 *Z*), 1.43 (dd, *J* = 7.0, 4.0 Hz, 1 H, H4 *Z*); 5.43 (s, 5 H, C_5H_5), 5.07 (s, 5 H, C_5H_5).

3rd Fraction (pentane/ether, 2:1): Orange solution. During the removal of the solvent, orange crystals of (μ-$\eta^{1:4}$-1,3-butadien-1-yl)tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)ditungsten(*W*−*W*) (**3A**) started to precipitate. The solid residue was crystallised from ether (3%). − IR: $\tilde{\nu}$ = 1925 (sh), 1910 (s), 1835 (s) cm^{-1}. − ^1H NMR (CD_2Cl_2, 243 K): δ = 4.52 (dd, *J* = 6.5, 1.0 Hz, 1 H, H1), 4.19 (dd, *J* = 6.5, 4.5 Hz, 1 H, H2), 4.00 (dddd, *J* = 9.0, 7.5, 4.5, 1.0 Hz, 1 H, H3), 2.00 (dd, *J* = 7.5, 3.0 Hz, 1 H, H4 *E*), 1.42 (dd, *J* = 9.0, 3.0 Hz, 1 H, H4 *Z*), 5.46 (s, 5 H, C_5H_5), 5.20 (s, 5 H, C_5H_5), 17.62 [s, $^1J(^{183}W-^1H)$ = 46, 54 Hz, 1 H, W−H]. − $C_{17}H_{16}O_3W_2$ (636.01): calcd. C 32.1, H 2.5; found C 31.9, H 2.5.

4th Fraction (ether): Bright green solution, which turned red during removal of the solvent. By crystallisation of the residue from ether (μ-$\eta^{1:3}$-2-butene-1,1-diyl)tetracarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**4A**) was isolated as red crystalline powder (2%). − IR: $\tilde{\nu}$ = 1945 (vs), 1900 (s), 1840 (s), 1775 (m) cm^{-1}. − ^1H NMR (CD_3COCD_3, 253 K): δ = 9.35 (dd, *J* = 9.0, 1.0 Hz, 1 H, H1), 6.24 (dd, *J* = 9.0, 9.0 Hz, 1 H, H2), 1.47 (dqd, *J* = 9.0, 6.0, 1.0 Hz, 1 H, H3), 1.80 (d, *J* = 6.0 Hz, 3 H, H4), 5.53 (s, 5 H, C_5H_5), 5.46 (s, 5 H, C_5H_5).

2. *Photochemical Reactions of* **1** *with Propene* (**B**): According to Procedure 1, 2.0 g (3.15 mmol) of **1** and propene (**B**) in 750 ml of ether/THF (6:1) were irradiated at 253 K for 85 min. After removal of the solvent, the residue was separated by column chromatography.

1st Fraction (pentane/ether 3:1): Starting material **1**.

2nd Fraction (pentane/ether 3:1): Orange solution, which contains a mixture of **1** and (μ-$\eta^{2:2}$-acetylene)tricarbonylbis(η^5-cyclopentadienyl)(η^2-propene)ditungsten(*W*−*W*) (**2B**) (4%). Even after repeated chromatography complex **2B** could not be obtained in a pure state. − IR: $\tilde{\nu}$ = 1957 (m), 1914 (s), 1826 (s) cm^{-1}. − ^1H NMR (C_7D_8, 233 K): δ = C_3H_6 1.03 (dd, *J* = 9.5, 2.0 Hz, 1 H, H1 *E*), 1.82 (dd, *J* = 11.0, 2.0 Hz, 1 H, H1 *Z*), 2.30 (ddq, *J* = 11.0, 9.5, 6.0 Hz, 1 H, H2), 1.85 (d, *J* = 6.0 Hz, 3 H, H3); C_2H_2 2.35 (d, *J* = 2.0 Hz, 1 H, H1), 4.02 (d, *J* = 2.0 Hz, 1 H, H2); 4.98 (s, 5 H, C_5H_5), 4.95 (s, 5 H, C_5H_5).

3rd Fraction (pentane/ether 2:1): Red solution, which already yielded tricarbonylbis(η^5-cyclopentadienyl)(η^4-2-methyl-1,3-butadiene)ditungsten(*W*−*W*) (**5B**) as red, microcrystalline powder (5%). − IR: $\tilde{\nu}$ = 1899 (s), 1806 (m), 1551 (m) cm^{-1}. − ^1H NMR (C_7D_8, 243 K): δ = 2.71 (dd, *J* = 4.0, 1.5 Hz, 1 H, H1 *E*), 1.36 (dd, *J* = 4.0, 2.0 Hz, 1 H, H1 *Z*), 1.34 (s, 3 H, 2-CH_3), 4.96 (dddd, *J* = 7.0, 7.0, 2.0, 1.5 Hz, 1 H, H3), 2.90 (dd, *J* = 7.0, 2.5 Hz, 1 H, H4 *E*), 1.57 (dd, *J* = 7.0, 2.5 Hz, 1 H, H4 *Z*), 5.07 (s, 5 H, C_5H_5), 4.91 (s, 5 H, C_5H_5). − $C_{18}H_{18}O_3W_2$ (650.04): calcd. C 33.26, H 2.79; found C 33.4, H 2.8.

4th Fraction (pentane/ether 1:1): Yellow-orange zone; after removal of the solvent and crystallisation from ether, tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)(μ-$\eta^{1:4}$-3-methyl-1,3-butadien-1-yl)ditungsten(*W*−*W*) (**3B**) was isolated as orange powder (4%). − IR: $\tilde{\nu}$ = 1924 (sh), 1909 (s), 1831 (s) (υCO); 1961 (w) (υMH) cm^{-1}. − ^1H NMR ($CDCl_3$, 243 K): δ = 4.39 (dd, *J* = 6.0, 2.0 Hz, 1 H, H1), 4.03 (d, *J* = 6.0 Hz, 1 H, H2), 2.11 (s, 3 H, 3-CH_3), 1.89 (d, *J* = 3.0 Hz, 1 H, H4 *E*), 1.59 (d, *J* = 3.0 Hz, 1 H, H4 *Z*), 5.45 (s, 5 H, C_5H_5), 5.11 (s, 5 H, C_5H_5), −17.38 (d, *J* = 2.0 Hz, $^1J^{183}W-^1H$ 46, 56 Hz, 1 H, W−H). − $C_{18}H_{18}O_3W_2$ (650.04): calcd. C 33.26, H 2.79; found C 32,2, H 2,6.

5th Fraction (pentane/THF 1:1): The residue of the red-brown solution was crystallised from ether. Tetracarbonylbis(η^5-cyclopentadienyl)(μ-$\eta^{1:3}$-2-penten-1,1-diyl)ditungsten(*W*−*W*) (**4B**) was obtained as red-brown crystals (1%). − IR: $\tilde{\nu}$ = 1948 (vs), 1905 (s), 1848 (s), 1775 (m) cm^{-1}. − ^1H NMR (CD_3COCD_3, 283 K): δ = 9.35 (dd, *J* = 8.5, 1.0 Hz, 1 H, H1), 6.20 (dd, *J* = 10.0, 8.5 Hz, 1 H, H2), 1.50 (dddd, *J* = 10.0, 10.0, 3.5, 1.0 Hz, 1 H, H3), 1.65 (ddq, *J* = 14.0, 10.0, 7.5 Hz, 1 H, H4), 2.10 (dqd, *J* = 14.0, 7.5, 3.5, Hz, 1 H, H4′), 1.01 (t, *J* = 7.5 Hz, 3 H, H5), 5.52 (s, 5 H, C_5H_5), 5.46 (s, 5 H, C_5H_5). − $C_{19}H_{18}O_4W_2$ (678.05): calcd. C 33.66, H 2.68; found C 33.4, H 2.8.

3. *Photochemical Reactions of* **1** *with 1-Butene* (**C**): According to Procedure 1, 1.6 g (2.5 mmol) of **1** and 1-butene (**C**) were irradiated in 750 ml of ether/THF (6:1) for 90 min with UV light. Column chromatography on Al_2O_3 yielded four characterised products.

1st Fraction (pentane/ether 3:1): Yellow zone, very small amount of substance, discarded.

2nd Fraction (pentane/ether 3:1): Starting material **1**.

3rd Fraction (pentane/ether 3:1): Orange solution; after removal of the solvent, a mixture of **1** and (μ-$\eta^{2:2}$-acetylene)(η^2-1-butene)-tricarbonylbis(η^5-cyclopentadienyl)ditungsten(*W*−*W*) (**2C**) was isolated as orange powder (5%). Even by repeated chromatography, **2C** could not be isolated in pure form. − IR: $\tilde{\nu}$ = 1965 (m), 1921 (s), 1834 (m) cm^{-1}. − ^1H NMR (C_7D_8, 233 K): C_4H_8: δ = 0.96 (dd, *J* = 9.5, 2.5 Hz, 1 H, H1 *E*), 1.75 (dd, *J* = 11.0, 2.5 Hz, 1 H, H1 *Z*), 2.29 (m, *J* = 11.0, 9.5, 4.0 Hz, 1 H, H2), 1.20 (m, *J* = 14.0, 7.0 Hz, 1 H, H3), 2.02 (m, *J* = 14.0, 7.0, 4.0 Hz, 1 H, H3′), 1.41 (t, *J* = 7.0 Hz, 3 H, H4); C_2H_2: δ = 2.33 (d, *J* = 2.0 Hz, 1 H, H1), 4.06 (d, *J* = 2.0 Hz,1 H, H2); 4.96 (s, 5 H, C_5H_5), 4.90 (s, 5 H, C_5H_5).

4th Fraction (pentane/ether 2:1): Red solution, after removal of the solvent tricarbonylbis(η^5-cyclopentadienyl)(η^4-3-methylene-1-pentene)ditungsten(*W*−*W*) (**5C**) was obtained as red, crystalline powder (5%). − IR: $\tilde{\nu}$ = 1900 (s), 1806 (m), 1551 (m) cm^{-1}. − ^1H NMR ($CDCl_3$, 253 K): δ = 2.60 (d, *J* = 4.0 Hz, 1 H, H1 *E*), 1.39 (d, *J* = 4.0 Hz, 1 H, H1 *Z*); 2-C_2H_5: δ = 0.89 (m, *J* = 7.0 Hz, 2 H), 0.99 (t, *J* = 7.0 Hz, 3 H); δ = 4.85 (dd, *J* = 7.0, 7.0 Hz, 1 H, H3), 2.42 (dd, *J* = 7.0, 2.5 Hz, 1 H, H4 *E*), 1.58 (dd, *J* = 7.0, 2.5 Hz, 1 H, H4 *Z*), 5.39 (s, 5 H, C_5H_5), 5.08 (s, 5 H, C_5H_5). − $C_{19}H_{20}O_3W_2$ (664.07): calcd. C 34.37, H 3.04; found C 34.5, H 3.2.

5th Fraction (ether): Yellow-orange solution, from which after removal of the solvent tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)(μ-$\eta^{1:4}$-3-methylene-1-penten-1-yl)ditungsten(*W*−*W*) (**3C**) results as an orange powder (6%). − IR: $\tilde{\nu}$ = 1924 (sh), 1909 (s), 1830 (s) (υCO); 1961 (w) (υMH) cm^{-1}. − ^1H NMR ($CDCl_3$, 243 K): δ = 4.43 (d, *J* = 6.0 Hz, 1 H, H1), 4.06 (d, *J* = 6.0 Hz, 1 H, H2); 3-C_2H_5: δ = 1.84 (dq, *J* = 16.0, 7.0 Hz, 1 H), 1.72 (dq, *J* = 16.0, 7.0 Hz, 1 H), 1.24 (t, *J* = 7.0 Hz, 3 H); δ = 1.87 (d, *J* = 2.0 Hz, 1 H, H4 *E*), 1.53 (d, *J* = 2.0 Hz, 1 H, H4 *Z*), 5.44 (s, 5 H, C_5H_5), 5.09 (s, 5 H, C_5H_5), −17.37 [s, $^1J(^{183}W-^1H)$ = 47, 53 Hz, 1 H, W−H]. − $C_{19}H_{20}O_3W_2$ (664.07): calcd. C 34.37, H 3.04; found C 34.7, H 3.0.

6th Fraction (pentane/THF 1:1): From the red solution tetracarbonylbis(η^5-cyclopentadienyl)(μ-$\eta^{1:3}$-2-hexene-1,1-diyl)-ditungsten(*W*−*W*) (**4C**) was obtained after recrystallisation in form of red crystals (1%). − IR: $\tilde{\nu}$ = 1945 (vs), 1901 (s), 1842 (s), 1771 (m) cm^{-1}. − ^1H NMR ($CDCl_3$, 253 K): δ = 8.97 (d, *J* = 9.0 Hz, 1 H, H1), 5.90 (dd, *J* = 9.0, 9.0 Hz, 1 H, H2), 1.72 (m, *J* = 9.0, 3.5 Hz, 1 H, H3), 2.12 (m, *J* = 3.5 Hz, 1 H, H4), 1.45 (m, *J* = 7.0 Hz, 3 H, H5), 0.89 (t, *J* = 7.0 Hz, 3 H, H6), 5.35 (s, 5 H, C_5H_5), 5.23 (s, 5 H, C_5H_5).

4. *Photochemical Reactions of* **1** *with (E)-2-Butene* (**D**): According to Procedure 1, 1.6 g (2.5 mmol) of **1** and (*E*)-2-butene (**D**) were irradiated with UV light in 750 ml of ether/THF (6:1) for 85 min. The reaction mixture was separated into its components by column chromatography.

1st Fraction (pentane/ether, 3:1): Yellow zone of small intensity; after crystallisation of the residue from pentane, few yellow crystals of carbonyl(η^5-cyclopentadienyl)hydrido[η^4-(*E*)-3-methyl-1,3-pentadiene]tungsten (**6**, **6′**) were isolated (1%). − IR: $\tilde{\nu}$ = 1927 cm^{-1}. − ^1H NMR (CD_2Cl_2, 253 K): Major isomer (0.85): δ = −0.12 (dd, *J* = 9.0, 4.0 Hz, 1 H, H1 *Z*), 1.49 (ddd, *J* = 8.0, 4.0, 3.0 Hz, 1 H, H1 *E*), 4.07 (dd, *J* = 9.0, 8.0 Hz, 1 H, H2), 2.37 (s, 1 H, 3-CH_3), 0.42 (q, *J* = 6.0 Hz, 1 H, H4 *Z*), 1.91 (dd, *J* = 6.0, 1.0 Hz, 3 H, H5), 4.87 (s, 5 H, C_5H_5), −6.13 [dd, *J* = 3.0, 1.0, Hz, $^1J(^{183}W-^1H)$ = 74 Hz, 1 H, W−H); minor isomer (0.15): δ = −0.04 (dd, *J* = 7.0, 3.5 Hz, 1 H, H1 *Z*), 1.49 (ddd, *J* = 7.0, 3.5, 1.0 Hz, 1 H, H1 *E*), 4.44 (dd, *J* = 7.0, 7.0 Hz, 1 H, H2), 2.46 (s, 1 H, 3-CH_3), 0.70 (q, *J* = 6.0 Hz, 1 H, H4 *Z*), 1.41 (d, *J* = 6.0 Hz, 3 H, H5), 4.87 (s, 5 H, C_5H_5), −9.65 [d, *J* = 1.0, Hz, $^1J(^{183}W-^1H)$ = 76 Hz, 1 H, W−H).

2nd Fraction (pentane/ether 3:1): Starting material **1**.

3rd Fraction (pentane/ether, 2:1): Red-brown solution, already during removal of the solvent red-brown crystals of tricarbonylbis(η^5-cyclopentadienyl)[η^4-(*E*)-3-methyl-1,3-pentadiene]-ditungsten(*W*−*W*) (**5D**) precipitated (7%). − IR: $\tilde{\nu}$ = 1901 (s), 1810 (m), 1548 (m) cm^{-1}. − ^1H NMR (C_7D_8, 253 K): δ = 2.88 (dd, *J* = 7.0, 3.0 Hz, 1 H, H1 *E*), 1.55 (dd, *J* = 7.0, 3.0 Hz, 1 H, H1 *Z*), 4.81 (t, *J* = 7.0, 7.0 Hz, 1 H, H2), 1.23 (s, 3 H, 3-CH_3), 1.66 (q, *J* = 6.0 Hz, 1 H, H4 *Z*), 2.03 (d, *J* = 6.0 Hz, 3 H, H5), 5.08 (s, 5 H, C_5H_5), 4.79 (s, 5 H, C_5H_5). − $C_{19}H_{20}O_3W_2$ (664.07): calcd. C 34.37, H 3.04; found C 34.3, H 2.9.

4th Fraction (pentane/ether 2:1): Orange fraction, which yielded after removal of the solvent an orange mixture of **5D** and tricarbonylbis(η^5-cyclopentadienyl)(μ-hydrido)[μ-$\eta^{1:4}$-(*E*)-3-methyl-1,3-pentadien-1-yl]ditungsten(*W*−*W*) (**3D**) (5%). Even by repeated chromatography **3D** was not obtained in a pure state. − IR: $\tilde{\nu}$ = 1923 (s), 1902 (s), 1834 (s) cm^{-1}. − ^1H NMR ($CDCl_3$, 243 K): δ = 4.54 (dd, *J* = 6.5, 1.5 Hz, 1 H, H1), 3.93 (d, *J* = 6.5 Hz, 1 H, H2), 2.05 (s, 3 H, 3-CH_3), 2.26 (q, *J* = 6.5 Hz, 1 H, H4 *Z*), 1.37 (d, *J* = 6.5 Hz, 3 H, H5), 5.47 (s, 5 H, C_5H_5), 5.12 (s, 5 H, C_5H_5), −18.14 [d, *J* = 1.5 Hz, $^1J(^{183}W-^1H)$ = 47, 56 Hz, 1 H, W−H). − $C_{19}H_{20}O_3W_2$ (664.07): calcd. C 34.4, H 3.0; found C 34,6, H 2,8.

5th Fraction (pentane/THF 4:1): Bright-red zone, after recrystallisation red crystals of **4C** (1%).

5. *Photochemical Reactions of* **1** *with (Z)-2-Butene* (**E**): According to Procedure 1, 1.8 g (2.8 mmol) of **1** and (*Z*)-2-butene (**E**) were irradiated with UV light in 750 ml of ether/THF (6:1) for 300 min. The reaction mixture contained large amounts of insoluble decomposition products. It was filtered through compressed filter flakes and brought to dryness at 253 K.

1st Fraction (pentane/ether 3:1): Starting material **1**.

2nd Fraction (pentane/ether 3:1): Yellow-orange solution, discarded.

3rd Fraction (ether): Red-brown solution; after partial removal of the solvent and cooling to 198 K, red-brown crystals of pentacarbonyltris(η^5-cyclopentadienyl)(μ-$\eta^{1:2}$-vinyl)tritungsten-(*W*−*W*−*W*) (**7**) were formed (1%). − IR: $\tilde{\nu}$ = 1925 (sh), 1910 (vs), 1849 (s), 1840 (sh) cm^{-1}. − ^1H NMR ($CDCl_3$, 253 K): δ = 7.04 (dd, *J* = 11.0, 11.0 Hz, 1 H, H1), 4.72 (dd, *J* = 11.0, 1.0 Hz, 1 H, H2 *E*), 1.79 (dd, *J* = 11.0, 1.0 Hz, 1 H, H2 *Z*), 5.43 (s, 5 H, C_5H_5), 5.37 (s, 5 H, C_5H_5), 4.88 (s, 5 H, C_5H_5). − $C_{22}H_{18}O_5W_3$ (913.93): calcd. C 28.91, H 1.99; found C 30.3, H 2.4.

6. *X-ray Structural Analysis of* **5D**[44]: $C_{19}H_{20}O_3W_2$, *M* = 664.05 $g \cdot mol^{-1}$, monoclinic space group $P2_1/n$, *a* = 1089.3(2), *b* = 1240.5(3), *c* = 1303.7(2) pm, β = 95.914(14)°, *V* = 1.7522(6) nm^3, *Z* = 4, ρ(calcd.) = 2.517 $g \cdot cm^{-3}$. Crystal size 0.40 × 0.25 × 0.05 mm, *T* = 293 K. Using a CAD4 diffractometer (Enraf Nonius), radiation Mo-K_α, wavelength λ = 71.073 pm, scan type ω-$^1/_3$q, 4487 reflections were collected in the θ range 2.27−22.45°. After data reduction, 2267 symmetry-independent reflections (R_{int} = 0.0512) were obtained. The structure was solved by direct methods using SHELXS-86[45] and refined by full-matrix least-squares against F^2 with SHELXL-93[46]. 232 parameters were refined to $R[I > 2\sigma(I)]$ = 0.0281, *wR*2(all data) = 0.0750. The hydrogen atoms of the cyclopentadienyl ligands and the methyl groups were located geometrically. All the other hydrogen atoms were detected. For the refinement the C−H distance was set to 97 pm, and the tempera-

ture factors of the hydrogen atoms were fixed at 1.2 times U_{eq} of the corresponding carbon atoms.

7. *X-ray Structural Analysis of* **7**[44]: $C_{22}H_{18}O_5W_3$, M = 913.91 g·mol^{-1}, monoclinic space group $P2_1/n$, a = 780.61(7), b = 2197.1(3), c = 1403.80(11) pm, β = 100.753(6)°, V = 2.3654(4) nm^3, Z = 4, ρ(calcd.) = 2.566 g·cm^{-3}. Crystal size 0.62 × 0.30 × 0.03 mm, T = 293 K. Using a CAD4 diffractometer (Enraf Nonius), radiation Mo-K_α, wavelength λ = 71.073 pm, scan type ω-θ, 4426 reflections were collected in the θ range 1.74−24.99°. After data reduction, 3880 symmetry-independent reflections (R_{int} = 0.099) were obtained. The structure was solved by direct methods using SHELXS-86[45] and refined by full-matrix least squares against F^2 with SHELXL-93[46]. 280 parameters were refined to $R[I > 2\sigma(I)]$ = 0.0491, $wR2$(all data) = 0.1245. The hydrogen atoms of the cyclopentadienyl ligands were located geometrically. All the other hydrogen atoms were found. For the refinement the temperature factor of the hydrogen atoms was set to the 1.2-fold value of that of the related carbon atom. The data set was modified using PLATON-92[47] to account for a multiply disordered ether molecule on a centre of inversion.

☆ Dedicated to Professor Dr. *Gottfried Huttner* on the occasion of his 60th birthday.

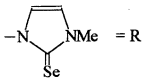
Keywords: Bromine / Imidazoline-2-selone / Hypervalent Se compounds / Dications

The oxidative addition of Br_2 to the imidazoline-2-selone derivatives **1a**−**c** has been studied by spectrophotometric and conductometric techniques. The experimental results clearly indicate that this reaction involves the dications **2a**−**c**, containing an Se−Se bond, as intermediates in the formation of the hypervalent 10-Se-3 selenium compounds **3a**−**c** containing the Br−Se−Br group. The crystal structure of 1,2-bis(3-methyl-4-imidazolin-2-ylium dibromoselenanide)ethane (**3c**), a new stable hypervalent 10-Se-3 compound, is also reported.

Introduction

In recent years, a great deal of synthetic and structural characterization work has been carried out on the products of the reactions of the donors **1a**−**c**, containing the imidazoline-2-selone ring, with acceptors such as diiodine,[1] interhalogens (IBr and ICl)[2] and unsaturated polynitriles (TCNQ).[3]



CH_3-R	(**1a**)
R-CH_2-R	(**1b**)
R-$(CH_2)_2$-R	(**1c**)

A variety of products has been obtained including neutral adducts, dications containing the Se−Se bridge, and hypervalent 10-Se-3[4] compounds containing the I−Se−I group.

While addition of I_2 to **1a** and **1c** quantitatively produces the I−Se−I insertion derivatives, the corresponding reaction of Br_2 with **1a** has recently been reported[5] to give the analogous Br−Se−Br insertion derivative **3a** with a 1:1 **1a**/Br_2 molar ratio and an ionic compound with a 1:0.5 **1a**/Br_2 molar ratio. This latter has been hypothesized to be 2,2′-diselenobis(1,3-dimethyl-4-imidazolinium) dibromide (**2a**) on the basis of previous studies carried out by Arduengo and Burgess[6] on the oxidative addition complexes of the sulfur analogue of **1a** with Br_2. However, we have previously obtained **2a** by reacting **1a** with IBr in a 1:1 molar ratio and have reported its structural characterization.[2] In order to ascertain whether **1b** and **1c** show the same behavior as **1a** in the reaction with bromine, and whether dications containing the Se−Se bridge are intermediates in the formation of the hypervalent compounds, a spectrophotometric and a conductometric study of this reaction has been undertaken. The X-ray crystal structure of 1,2-bis-(3-methyl-4-imidazolin-2-ylium dibromoselenanide)ethane (**3c**) is also reported.

Results and Discussion

Upon reaction of **1a**−**c** with 0.5 equiv. of molecular bromine in CH_3CN, ionic compounds consisting of dications containing the Se−Se bridge and Br^- counterions (**2a**−**c**) are obtained. When 1 equiv. of Br_2 per selenium atom is used, hypervalent selenium compounds featuring the Br−Se−Br group (**3a**−**c**) are produced.

As mentioned above, we have previously obtained compound **2a** by the reaction of **1a** with IBr and have reported its X-ray structural characterization.[2] The crystal structure of **3a** was recently determined by Williams et al.[5] while this study was being carried out. The reported data are consistent with the crystal data of the sample isolated by us.

Single crystals suitable for X-ray studies have also been obtained for **3c**. The crystallographic data are given in Table 1, the geometrical parameters are listed in Table 2. The structural data of **3c** are in good agreement with those of the corresponding iodo derivative.[1][7][8] In fact, the molecule (Figure 1) shows a pseudo two-fold axis and a *gauche* conformation [N(11)−C(41)−C(42)−N(12) 59(1)°]; the Br−Se−Br fragments are asymmetric [Se(11)−Br(11) 2.662(2), Se(11)−Br(21) 2.521(2), Se(12)−Br(12) 2.650(3), Se(12)−Br(22) 2.531(4) Å], essentially linear [Br(11)−Se(11)−Br(21) 175.7(1)°, Br(12)−Se(12)−Br(22) 172.1(1)°], and roughly perpendicular to the corresponding imidazoline ring [the values of the Br−Se−C−N torsion angles are in the −101(1) to 78(1)° range]. The dihedral angle between the two imidazoline rings is 46.6(5)°. The Se atoms show a roughly square-planar coordination due to the very appreciable interactions Se(11)···Br(21) (x, $-y$, $z - 1/2$) 3.344(3) Å and Se(12)···Br(22) (x, $-y$, $1/2 + z$) 3.754(3) Å. These interactions are responsible for the formation of chains in the directions of c through the axial glide plane. The chains are held together by weak interactions of the type Br···C and C···C (Figure 2). The structure shows considerable similarities with those of **2a**[5] and $SeBr_2tmtu$[9].

In the low-frequency region, the FT-Raman spectra of **3a**−**c** each show two strong peaks at 187 ± 6 and 152 ± 6 cm^{-1}, attributable to υ_{as} and υ_s of the Br−Se−Br three-body system, respectively.[5][9][10] Similarities are also ob-

served in the FT-Raman spectra of **2a** and **2c**; thus, the peaks at 248 and 189 cm^{-1} for **2c** must be in part associated with the υ(Se−Se) vibration, in accordance with the findings for **2a** and other dications.[2] The FT-Raman spectrum of **2b** is more complicated and, in addition to the peaks at 250 and 187 cm^{-1} (the intensities of which are reversed compared to those found for **2a** and **2c**), shows one strong peak at 176 cm^{-1}. This spectrum could be explained by hypothesizing that in **2b** some dication units interact strongly with Br^- ions forming an Se−Se−Br three-body system, which could be vibrationally described as a Br_3^- unit. In fact, for an only slightly asymmetric Br_3^- anion, the symmetric stretching vibration υ_1 is found near 160 cm^{-1} and the antisymmetric υ_3 near 190 cm^{-1}.[10][11] From this, it follows that the peak at 176 cm^{-1} could be assigned to the υ_1 mode of the Se−Se−Br group, while the increased intensity of the peak at 187 cm^{-1} is most likely attributable to the contribution from the υ_3 antisymmetric vibration of the Se−Se−Br group.

In order to ascertain whether the aforementioned dications are intermediates in the formation of the hypervalent selenium compounds, we have investigated the oxidative addition of Br_2 in CH_3CN solution by UV/visible spectroscopy and conductometric measurements.

The addition of increasing amounts of Br_2 to CH_3CN solutions of **1a**, **1b** or **1c** produces a drastic change in the electronic spectra of the free ligands; the main features are similar in the three cases and, as shown in Figure 3a for **1c**, two well-defined isosbestic points are observed at 291 and 301 nm indicating an initial conversion of the free ligand into a new species up to a 1:1 **1c**/Br_2 molar ratio and subsequent transformation of this species once its formation is completed. A spectrum identical to that recorded for the 1:1 **1c**/Br_2 solution is obtained from a CH_3CN solution of **2c**; thus, the formation of the dication is unequivocally proven when working at this molar ratio. The dication undergoes a further transformation upon increasing the amount of bromine to a 1:2 **1c**/Br_2 molar ratio, leading to **3c** as shown by the UV/Visible spectrum of **3c** compared with that recorded on the 1:2 **1c**/Br_2 solution. The spectral features of **3a**−**c** are very similar to those of a tribromide due to the great similarity of the chromophores Br−Se−Br and $[Br-Br-Br]^-$.[12] In Figure 3b, a plot of the absorbance at 260 nm versus the **1c**/Br_2 molar ratio is depicted; it shows that the formation of **2c** and subsequently of **3c** is quantitative. A similar plot is observed for **1b**, whereas for **1a** less evident equivalence points at the 1:0.5 and 1:1 **1a**/Br_2 ratios might suggest that the formation of the dication and of the hypervalent compound are equilibrium reactions. In order to further support the hypothesis that dications **2a**−**c** are intermediates in the formation of the hypervalent compounds **3a**−**c**, another experiment was carried out in which increasing amounts of Br_2 were added to CH_3CN solutions of **2a**−**c**; the resulting UV/visible spectra indeed showed that the hypervalent compounds were formed.

The oxidative addition of bromine to **1a**−**c** has also been investigated by conductometric measurements. The conductivities of CH_3CN solutions of the free ligands were monitored during stepwise Br_2 addition. Figure 4 shows plots of the molar conductivities versus the Br_2/**L** molar ratios; formation of an ionic species is clearly evident from the increase in the conductivity values up to a 1:1 Br_2/**L** (1:0.5 for **1a**) molar ratio. This species disappears upon the addition of further Br_2 and conductivity reaches a minimum value at a 2:1 Br_2/**L** (1:1 for **1a**) molar ratio. The UV/visible spectra of the solutions at the 1:1 and 2:1 Br_2/**L** (**L** = **1b**, **1c**) molar ratios, respectively, showed the corresponding dications and hypervalent compounds to be the only species present. The conductometric titration of **1a**, on the other hand, indicates an equilibrium reaction between the three species **1a**, **2a** and **3a**, in line with the spectrophotometric evidence.

Figure 3. 3a: UV/Vis spectra at 293 K in a 0.1-cm silica cell of CH_3CN solutions containing fixed amounts of **1c** ([**1c**] = 2.5 × 10^{-4} mol l^{-1}) and variable Br_2 concentrations in the ratios: (a) 1:0; (b) 1:0.2; (c) 1:0.4; (d) 1:0.6; (e) 1:0.8; (f) 1:1; (g) 1:1.2; (h) 1:1.4; (i) 1:1.6; (l) 1:2. − 3b: Plot of the absorbances of the same CH_3CN solutions of **1c** and Br_2 as in (3a) versus [**1c**]/[Br_2] molar ratios at λ = 260 nm. The increase in absorbance over the 1:2 **1c**/Br_2 molar ratio could be attributed to the presence of Br_3^- in the Br_2 solution used for the titration. In fact, in Br_2 solutions with concentrations ranging from 1 × 10^{-3} to 2.5 × 10^{-3} mol l^{-1}, about 1−2% of Br_3^- is observed

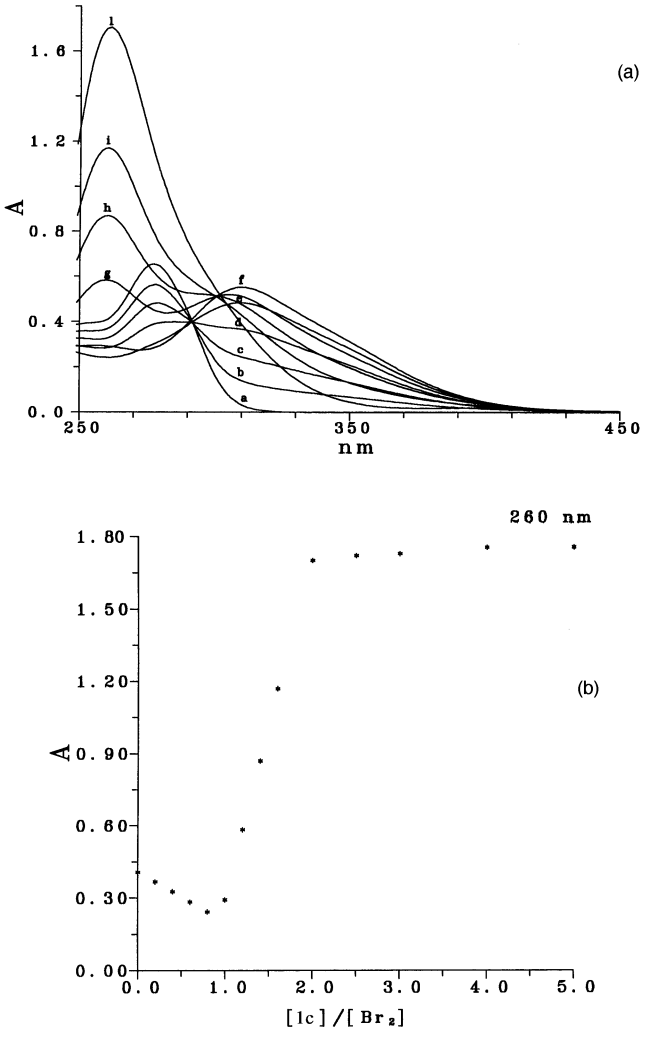

Figure 4. Plots of the molar conductivities recorded during the titrations of **1a**−**c** {[**1a**] = 2.16 × 10^{-3} mol l^{-1} (□); [**1b**] = 1.06 × 10^{-3} mol l^{-1}(○); [**1c**] = 1.99 × 10^{-4} mol l^{-1}(◆)} with Br_2 ([Br_2] = 9.61 × 10^{-3}; 1.04 × 10^{-2} ; 1.93 × 10^{-3} mol l^{-1} for **1a**−**c,** respectively) versus the [Br_2]/[L] molar ratios

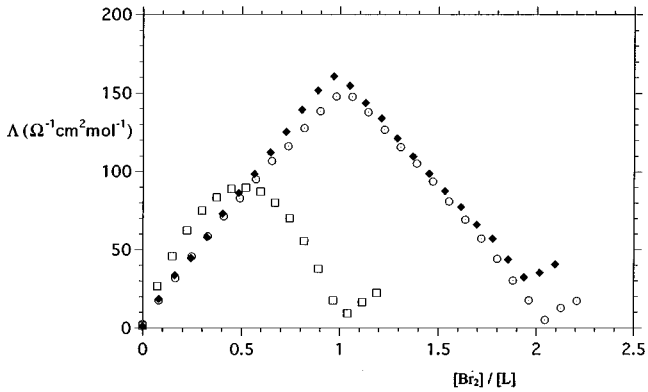

The observed reactions of **1a**−**c** with Br_2 are in good agreement with their electrochemical behavior. To confirm the tendency of the three ligands to undergo oxidation we also carried out an electrochemical study in CH_2Cl_2 solution (**2a**−**c** and **3a**−**c** are also obtained using CH_2Cl_2 as the solvent instead of CH_3CN; the electrochemical measurements were performed in CH_2Cl_2 for solubility reasons). In fact, cyclic voltammograms scanned in the anodic direction and reversed at +1.0 and −0.2 V to the starting potential (0.0 V), show two irreversible oxidations and one irreversible reduction for **1a** and **1c**, while only one broad oxidation peak and one reduction peak are observed for **1b** (see Table 3). When the scans are performed in the cathodic direction, the reduction peak does not appear for all ligands. This peak could therefore be attributed to the reduction of the oxidation products. The two oxidation peaks may be related to a two-step process involving the initial oxidation of one Se atom, which then interacts with either the unoxidized Se atom of the same molecule in the case of **1b** and **1c**, or with the Se atom of a different molecule in the case of **1a**. Subsequently, according to a simplified molecular orbital description for the Se−Se bond formation, this intermediate has one electron in the antibonding molecular orbital, which is removed in the second oxidation step to give the Se−Se dication.

Table 3. Anodic peak (*Epa*) and cathodic peak potentials (*Epc*) determined by cyclic voltammetry in CH_2Cl_2 for **1a**−**c** (1 × 10^{-3} mol l^{-1}). Pt electrode *vs.* SCE (saturated calomel electrode) in the presence of Bu_4NBF_4 (1 × 10^{-1} mol l^{-1}). Scan rate: 100 mV s^{-1}

L	Epa_1 (V)	Epa_2 (V)	*Epc* (V)[a]
1a	+0.57	+0.75	+0.08
1b	+0.60	+0.73	+0.24
1c	+0.50	+0.66	+0.04

[a] These peaks do not appear when scanning is started in the cathodic direction.

Conclusions

In this paper, we have reported the structure of the hypervalent Se compound obtained by oxidative addition of Br_2 to **1c** (**3c**). Hypervalent 10-Se-3 compounds of this type are quite uncommon, **3a**,[5] 1,3-diisopropyl-4,5-dimethyl-4-imidazolin-2-ylium diiodoselenanide[7] and the diiodoselenanides obtained from **1a** and **1c**[1] being the only such compounds structurally characterized to date. We have also demonstrated that the reactions of **1a**−**c** with bromine leading to the hypervalent compounds are two-step oxidation processes involving as intermediates the dications (**2a**−**c**), which contain Se−Se bridges. It is relevant that such dications are not formed in the reaction of **1a**−**c** with diiodine,[1] neither in solution nor in the solid state, whatever the molar ratio of reactants used. Only in the case of the reaction of diiodine with the saturated analogue of **1a**, i.e. *N*,*N*′-dimethylimidazolidine-2-selone, was formation of the corresponding dication observed; the solid product was found to be a mixed-valence compound containing equimolecular amounts of the CT complex and the dication having two triodides as counterions.[13] Finally, while **1a**−**c** show the same behavior in the reaction with bromine, the reaction with diiodine is more selective since different products are obtained from these rather similar donors.

The *Ministero della Università e Ricerca Scientifica e Tecnologica of Italy* (MURST 40%, Reattività e Catalisi) is acknowledged for support in this research.

Experimental Section

Materials: Reagents and solvents of reagent grade purity were used as received from Aldrich. The compounds **1a**−**c** were prepared as described previously.[1]

Compounds **2a**−**c** *and* **3a**−**c***:* The compounds **3a**−**c** were prepared by leaving to stand CH_3CN solutions of the ligands and Br_2 in a 1:1 (for **1a**) or 1:2 (for **1b** and **1c**) molar ratio at room temperature. After several days, well-shaped yellow-orange crystals of **3c** suitable for X-ray diffraction studies and yellow-orange crystals of **3a** and **3b** were obtained. Yields of each compound were typically 70%. The compounds **2a**−**c**, obtained as yellow microcrystals, were prepared analogously using a 1:0.5 (for **1a**, yields 88%) or 1:1 (for **1b** and **1c**, yields 90%) molar ratio. Elemental analysis data and FT-Raman spectra for **2a** and **3a** have been reported previously.[2]

2a: Electronic spectrum (250−550 nm): λ_{max} (ε) = 275 (22280), 312 nm (20480 l mol^{-1} cm^{-1}).

2b: $C_9H_{12}N_4Br_2Se_2$: calcd. C 21.88, H 2.45, N 11.34; found C 22.09, H 2.52, N 11.39. − Raman (500−50 cm^{-1}): $\tilde{\nu}$ = 290 (2.0), 250 (5.2), 218 (1.9), 187 (7.6), 176 (10), 135 (3.0), 128 (5.0), 92 (3.4), 74 (3.4). − Electronic spectrum (250−550 nm): λ_{max} (ε) = 292 nm (28200 l mol^{-1} cm^{-1}).

2c: $C_{10}H_{14}Br_2N_4Se_2$ × 0.5 CH_3CN: calcd. C 25.00, H 2.96, N 11.93; found C 25.19, H 3.15, N 12.06. − Raman (500−50 cm^{-1}): $\tilde{\nu}$ = 282 (1.0), 248 (10.0), 189 (1.3), 87 (1.1). − Electronic spectrum (250−550 nm): λ_{max} (ε) = 310 nm (19900 l mol^{-1} cm^{-1}).

3a: Electronic spectrum (250−550 nm): λ_{max} (ε) = 260 nm (32600 l mol^{-1} cm^{-1}).

3b: $C_9H_{12}Br_4N_4Se_2$: calcd. C 16.54, H 1.85, N 8.57; found C 16.77, H 1.90, N 8.64. − Raman (500−50 cm^{-1}): $\tilde{\nu}$ = 193 (10.0),

153 (7.5), 137 (3.0), 107 (2.8), 85 (2.7). − Electronic spectrum (250−550 nm): λ_{max} (ε) = 262 nm (58000 l mol^{-1} cm^{-1}).

3c: $C_{10}H_{14}Br_4N_4Se_2$: C 17.99, H 2.11, N 8.39; found C 18.11, H 2.17, N 9.26. − Raman (500−50 cm^{-1}): $\tilde{\nu}$ = 184 (10.0), 146 (9.4), 64 (2.5). − Electronic spectrum (250−550 nm): λ_{max} (ε) = 260 nm (56400 l mol^{-1} cm^{-1}).

X-ray Data Collection and Structure Refinement: Crystallographic data are given in Table 1. The diffraction measurements were made on a Philips PW 1100 diffractometer with graphite-monochromated Mo-K_α radiation (see Table 1); the data were collected using the θ−2θ scan technique. During the data reduction, intensities were corrected for Lorentz and polarization effects. A correction for absorption was applied: maximum and minimum values for the transmission factors were 1.000 and 0.514.[14][15] Solution by direct methods (SHELX-86),[16] full-matrix least-squares refinement, and anisotropic thermal parameters for all non-hydrogen atoms were used. The H-atoms were introduced in calculated positions and refined "riding" on the corresponding atoms with unique isotropic thermal parameters [U = 0.0725(166) Å^2]. The weighting scheme $w = k/[\sigma^2(F_o) + gF_o^2]$ was applied, with k = 1.5042 and g = 0.001495. Scattering factors were taken from ref.[17]. The final difference density map showed a minimum peak of −1.40 Å^{-3} and a maximum peak of 1.29 Å^{-3}. Structure refinement and final geometric calculations were carried out with the SHELX-76[18] and PARST[19] programs. The drawing was produced using ORTEP[20] and PLUTO.[21]

Spectroscopic Measurements. − FT-Raman Spectra: FT-Raman spectra (resolution ± 4 cm^{-1}) were recorded on a Bruker RFS100 FTR spectrometer fitted with an indium-gallium arsenide detector (room temp.) and operating with an excitation frequency of 1064 nm (Nd:YAG laser). The power level of the laser source was tuned between 20−40 mW. The solid samples, in the form of powders or crystals, were packed into suitable cells and then fitted into the compartment designed for use with a 180° scattering geometry. No sample decomposition was detected during the experiments. The values given in parentheses represent the intensities of the peaks relative to the strongest, which is given a value of 10.

UV/Visible Measurements: Electronic spectra were recorded of solutions in CH_3CN (freshly distilled from CaH_2) using a Cary 5 spectrophotometer equipped with a temperature probe accessory connected to a thermostatted multi-cell block. The CH_3CN solutions of Br_2 were standardized with a standard aqueous $Na_2S_2O_3$ solution (0.1000 mol l^{-1}) according to traditional methods.

1a: A set of 11 solutions containing a fixed concentration of the ligand (2.50 × 10^{-4} mol l^{-1}) and variable Br_2 concentrations ranging from 2.50 × 10^{-5} to 5.00 × 10^{-4} mol l^{-1} (in the ratios [**1a**]:[Br_2] = 1:0; 1:0.1; 1:0.2; 1:0.3; 1:0.4; 1:0.5; 1:0.6; 1:0.8; 1:1; 1:1.5; 1:2), was prepared. Spectra were recorded at T = 20°C, in the 250−550 nm range, using 0.1-cm path length silica cells.

1b: A set of 15 solutions containing a fixed concentration of the ligand (2.50 × 10^{-4} mol l^{-1}) and variable Br_2 concentrations ranging from 5 × 10^{-5} to 1.25 × 10^{-3} mol l^{-1} (in the ratios [**1b**]:[Br_2] = 1:0; 1:0.2; 1:0.4; 1:0.6; 1:0.8; 1:1; 1:1.2; 1:1.4; 1:1.6; 1:2; 1:2.4; 1:2.6; 1:3; 1:4; 1:5) was prepared. Spectra were recorded at T = 20°C in the 250−550 nm range using 1-cm path length silica cells.

1c: A set of 14 solutions containing a fixed concentration of the ligand (2.50 × 10^{-4} mol l^{-1}) and variable Br_2 concentrations ranging from 5.00 × 10^{-5} to 1.25 × 10^{-3} mol l^{-1} (in the ratios [**1c**]:[Br_2] = 1:0; 1:0.2; 1:0.4; 1:0.6; 1:0.8; 1:1; 1:1.2; 1:1.4; 1:1.6; 1:2; 1:2.5; 1:3; 1:4; 1:5), was prepared. Spectra were recorded at T = 20°C, in the 250−550 nm range, using 1-cm path length silica cells.

Conductiometric Titrations: Conductometric titrations were carried out at T = 25°C in a standard thermostatted cell using solutions in CH_3CN (freshly distilled from CaH_2), with a Model 120 microprocessor conductivity meter "Analytical Control". The k cell (1.23 cm^{-1}) was determined by measuring the conductivity of three solutions of kiln-dried (12 h) KCl (0.1, 0.01 and 0.001 mol l^{-1}, respectively) in doubly-distilled deionized water at T = 25°C. The conductivity values were corrected for the dilution error using the multiplicative factor $f = (V + V_o)/V_o$, where V_o is the starting volume (30 ml) of the **1a**, **1b** and **1c** solutions and V is the volume of the added Br_2 solution. Conductivity was recorded 5 minutes after each Br_2 addition in order to let the temperature equilibrate to 25°C.

Electrochemistry: Cyclic voltammetry experiments were performed using a conventional three-electrode cell, consisting of a Pt counter electrode and a Pt micro-working electrode *vs.* SCE (saturated calomel electrode). The experiments were performed at room temperature in anhydrous CH_2Cl_2. The solution was 1 × 10^{-3} mol l^{-1} in **L** (**1a, 1b, 1c**) with Bu_4NBF_4 (1 × 10^{-1} mol l^{-1}) as the supporting electrolyte. A stream of argon was passed through the solution prior to the scan. Data were recorded on a computer-controlled EG&G (Princeton Applied Research) potentiostat-galvanostat model 273 EG&G, using Model 270 electrochemical analysis software. The scan rate was 100 mV s^{-1}.

Keywords: Azaboranes / Six-coordinate nitrogen / Deltahedral clusters / Cluster opening / Cluster closure

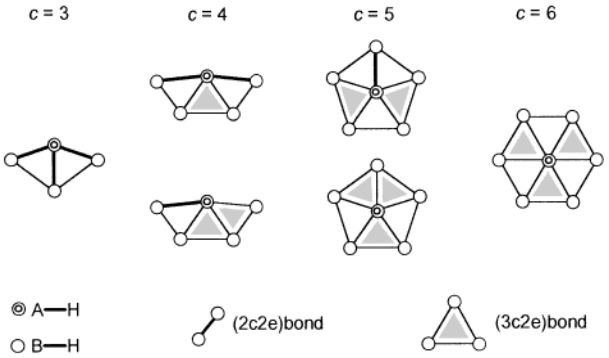
In the majority of known azaboranes $N_aB_bH_c$ and their derivatives, the coordination number of the nitrogen atoms within the cluster does not exceed the classical values of 3 or 4. In the azaboranes *closo*-NB_9H_{10}, *nido*-$NB_{10}H_{13}$, and *closo*-$NB_{11}H_{12}$ and in their derivatives, however, the nitrogen atoms are 5- or 6-coordinate and thus represent a novel bonding situation. The synthesis, structure, and reactivity of these azaboranes are reviewed in this article.

Introduction

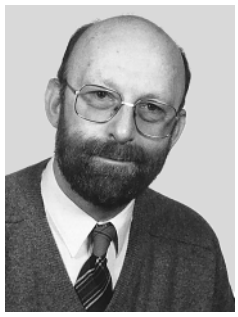
Azaboranes $N_aB_bH_c$ are closed deltahedral borane clusters or fragments thereof, in which at least one BH vertex is replaced by an NH vertex. Azaborates are the corresponding anions $[N_aB_bH_c]^{n-}$. Derivatives of azaboranes are formed by the addition of Lewis bases L to give $N_aB_bH_cL_d$ or by the substitution of hydrogen atoms by anionic groups X to give $N_aB_bH_cX_d$ (X = F, OR, NR_2, R etc.). Heteroazaboranes $S_aN_bC_cB_dH_eM_f$ are those azaboranes in which BH vertices have been replaced by S, CH, M etc.; the symbol M in this context means the fragment of a transition-metal complex with the metal atom being incorporated into the cluster skeleton.

If the bonding within borane clusters is described in terms of localized bonds, then electron deficiency makes it necessary to take skeletal three-centre, two-electron [(3c,2e)] bonds into account in addition to the more usual two-centre, two-electron [(2c,2e)] bonds. The skeletal coordination number, called *connectivity* (c), may exceed the value $c = 3$; this value would allow a skeletal atom to form four traditional (2c,2e) bonds, including one radial (2c,2e) bond between the skeletal atom and its *exo* ligand. Values of $c = 3-5$ are usually encountered in borane clusters, and $c = 6$ is found in a few cases. With $c > 3$, (2c,2e) bonds are no longer sufficient for the description of bonds. It may be de-

Figure 1. Localized bonds for a skeletal atom A with different connectivities of A



Peter Paetzold, born in 1935, received his doctoral degree on his work with Egon Wiberg at the Ludwig-Maximilians-Universität in Munich in 1961. He became Professor of inorganic chemistry and Director of the Institut für Anorganische Chemie at the Rheinisch-Westfälische Technische Hochschule in Aachen in 1968. He focused his interest on synthetic, structural and mechanistic aspects of boron chemistry. Due to his work, major progress was achieved in the chemistry of azidoboranes (the analogues of carbonic azides), iminoboranes (the analogues of alkynes, presenting a BN triple bond), boron-nitrogen ring compounds (the analogues of cyclobutadiene, benzene, Dewar benzene, and cyclooctatetraene), azadiboriridines (the analogues of cyclopropenyl cations, presenting a BB bond of unexpected basicity), and azaborane clusters (the analogues of dicarbaborane clusters, presenting five- and six-coordinate nitrogen). The analogy of the couples BN and CC, also of the couples BO and CN, is the common thread running through his work.



MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0143 $ 17.50+.50/0

Table 1. Formal charge $\delta_F(A)$ of skeletal atoms A = B, C, N, depending on the number t of (3c,2e) and y of (2c,2e) bonds at A (see Figure 1)

c	3	4	4	5	5	6
t/y	0/3	1/2	2/1	2/1	3/0	3/0
$\delta_F(B)$	−3/3	−2/3	−1/3	−1/3	0	0
$\delta_F(C)$	0	+1/3	+2/3	+2/3	+3/3	+3/3
$\delta_F(N)$	+3/3	+4/3	+5/3	+5/3	+6/3	+6/3

duced from Figure 1 that for c = 4−6 at least one, two or three (3c,2e) bonds are necessarily present, respectively, provided the atom A obeys to the octet rule. (Note that connectivities c = 3−6 correspond to overall coordination numbers of 4−7 by inclusion of the *exo* ligand.)

The discovery in 1963 that carbon atoms within the icosahedral C_2B_{10} skeleton of the carbaborane $C_2B_{10}H_{12}$[1] exhibited a connectivity c = 5 (coordination number = 6) changed the traditional view of the bonding situation of

carbon-containing molecules. Whereas the formal charge of boron changes from −1 to the more favourable value of 0 as a result of an increase in its connectivity (Table 1), the formal charge of carbon may become +1 with a connectivity of $c = 6$ or even $c = 5$. Since carbon is more electronegative than boron and its real charge is less positive than that of boron, the B−C skeletal bonds must be highly polarized, and actually the border case $c = 6$ is not observed for carbon. Indeed, there is a strong tendency in the reactions of icosahedral carbaboranes to reduce the connectivity of carbon. The more electronegative nitrogen shows a formal charge of at least +4/3 or +5/3, when incorporated into a cluster skeleton with $c = 4$ or 5, respectively. Hence, a very large bond polarisation must be expected in corresponding azaboranes. Nevertheless, the carbaborane $NC_2B_8H_{11}$ with $c(N) = 4$ was synthesized as early as 1974[2], followed in 1986 by the closed cluster molecule NB_9H_{10}[3], and finally, the icosahedral cluster molecule $NB_{11}H_{12}$ in 1991. The discovery of $NB_{11}H_{12}$, which is isoelectronic with $C_2B_{10}H_{12}$, represented the first observation of the connectivity $c(N) = 5$[4]. Certainly, the reactivity of the highly coordinated azaboranes is governed by their tendency to reduce the connectivity at nitrogen.

A great number of small azaboranes and heteroazaboranes clusters with $c(N) = 2$ and larger ones with $c = 3$ are known. The skeletal nitrogen atoms in these azaboranes are bonded in a way that may be interpreted only in terms of (2c,2e) bonds. A survey is given in Figure 2 and Table 2. In terms of Wade′s rules, *nido*, *arachno*, and *hypho* clusters are present, although no *closo* species are found. Note that the same structural pattern, an icosahedral fragment, holds for all the molecules and anions **11**−**34**. Note also that in cases of $c(N) = 2$ (**1**−**5**, **7, 8, 13**, **29**, **32**, **33**) π bonds need to be taken into account in order to provide the nitrogen atom with an electron octet.

A much smaller number of azaboranes and heteroazaboranes with $c(N) = 4$, 5 have been described; Table 3 and Figure 3 present a synopsis. All these clusters are derived from three parent azaboranes, all of which are well-characterized: *closo*-NB_9H_{10} (**35**), *nido*-$NB_{10}H_{13}$ (**38**), and *closo*-$NB_{11}H_{12}$ (**43**). It is intended here to review the synthesis, structure, and reactivity of these azaboranes with 5- and 6-coordinate nitrogen centres. Part of this chemistry has already been reviewed[50][51][52][53]. We start with a section about synthetic procedures that still includes all of the azaboranes.

Synthesis

The commercially available decaborane, $B_{10}H_{14}$, is the starting material for the synthesis of the azaboranes **8**−**45**, presented in this section. The synthesis of the azaboranes **1**−**7**, which starts from the azadiboriridine NB_2R_3 or from iminoboranes RB(NR′), will not be discussed here. There are three synthetic possibilities that include a change of skeletal atoms: the addition (*insertion*) or the removal (*degradation*) of a skeletal atom or both (*degradative insertion*). In addition, there are two possibilities that involve a change only in the skeletal *arrangement*, and which go hand in hand with a transformation in the direction *arachno* → *nido* → *closo* (*closure*) or vice versa (*opening*). Changes in the ligand sphere or in the hydrogen bridge area (e.g. deprotonations) are not considered in this section.

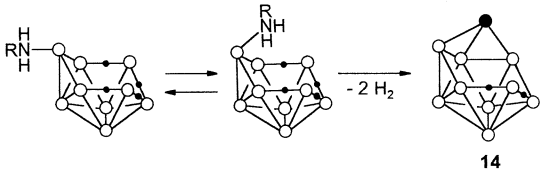
Insertion

We describe here the insertion of sulphur S (into azaboranes), nitrenes NH or NR (into boranes), metal-complex fragments M (into azaboranes), and borylenes BH (into azaboranes). The insertion of elemental sulphur transforms the *nido* anion **15** into the *arachno* anion **27**, the sulphur atom contributing four electrons to the cluster [Eq. (1)]. The anion **15** is easily available from RNB_9H_{11} (**14**) by applying the base 1,8-bis(dimethylamino)naphthalene (*proton sponge*)[30].

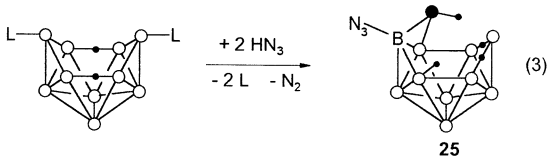
$$[RNB_9H_{10}]^- + 1/8\ S_8 \rightarrow [S(RN)B_9H_{10}]^- \quad (1)$$

The insertion of a nitrene unit NR into a B_9 skeleton can be achieved by first transforming $B_9H_{13}(SMe_2)$ into $B_9H_{13}(NH_2R)$ followed by a dehydrogenation in boiling xylene to give products of type **14** [Eq. (2)][13][21]. [Note the identity of the structures **14** given in Eq. (2) and in Figure 2].



(2)

The insertion of a unit NH (from HN_3) into $B_{10}H_{12}L_2$ (L = SMe_2) to give **25** with a bridging NH_2 group [*c*(N) = 2] is accompanied by an H/N_3 ligand exchange [Eq. (3)][31].



(3)

25

The reaction of CB_8H_{14} first with $NaNO_2$ and then with hydrochloric acid yields NCB_8H_{13} (**21**); the stoichiometry of this insertion of an NH vertex is unknown[28]. The insertion of metal cations into azaboranes, on the other hand, follows a clear cut stoichiometry. The 10-vertex *nido* species NB_9H_{12} (**14**) is transformed into an 11-vertex species either of the *closo* type [**37**; M = CpCo[19], (cymene)Ru[41]; Eq. (4)] or the *nido* type (**42**; X = Cl, M = Cp*Ir[46]). The 11-vertex *nido* species $[NB_{10}H_{12}]^-$ (**39**) and $[NB_{10}H_{11}]^{2-}$ (**40**) are transformed into the 12-vertex *closo* species $NB_{10}H_{11}M$ [**44**; M = $(Ph_3P)_2HRh$[43], $(C_6Me_6)Ru$, $(Ph_3P)_2Ni$[44]; Eqs. (5), (6)] or $[M(NB_{10}H_{11})_2]^-$ (**45**; M = Co[44]). The *arachno* 9-vertex species NB_8H_{13} (**11**), finally, gives the *nido* species $NB_8H_{11}M$ [**23**; M = $(Me_2PhP)_2Pt$[24]; Eq. (7)].

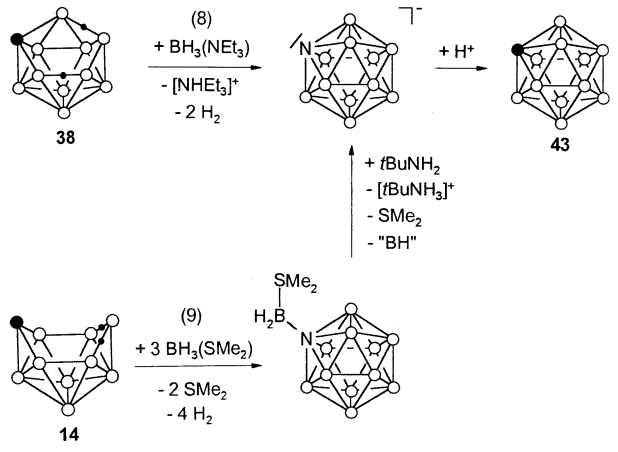
$$NB_9H_{12} + 1/2\ [(C_{10}H_{14})RuCl_2]_2 \rightarrow NB_9H_{10}[Ru(C_{10}H_{14})] + 2\ HCl \quad (4)$$

$$[NB_{10}H_{12}]^- + (Ph_3P)_3RhCl \rightarrow NB_{10}H_{11}[RhH(PPh_3)_2] + PPh_3 + Cl^- \quad (5)$$

$$[NB_{10}H_{11}]^{2-} + 1/2\ [(C_6Me_6)RuCl_2]_2 \rightarrow NB_{10}H_{11}[Ru(C_6Me_6)] + 2\ Cl^- \quad (6)$$

$$NB_8H_{13} + [(PhMe_2P)_2PtCl_2] \rightarrow NB_8H_{11}[Pt(PMe_2Ph)_2] + 2\ HCl \quad (7)$$

The insertion of a BH unit into azaboranes plays an important role in the synthesis of the icosahedral species $NB_{11}H_{12}$ (**43**). It is possible to start from the *nido* clusters $NB_{10}H_{13}$ (**38**) or NB_9H_{12} (**14**) and insert one or two BH units, respectively [Eq. (8)[4] and (9)[48]]. The thermal dehydrogenation (140°C) of **38** or **14** in the presence of BH_3 yields the *closo* anion $[NB_{11}H_{11}]^-$, either directly [Eq. (8)[4]] or via *closo*-$(Me_2SBH_2)NB_{11}H_{11}$ [Eq. (9)[48]; the anion can then easily be protonated to give **43**.



The synthesis of the *N*-organo *closo* 12-vertex derivative $RNB_{11}H_{11}$ can be achieved in one step from RNB_9H_{11} (**14**) [Eq. (10)][21].

$$RNB_9H_{11} + 2\ BH_3(SMe_2) \rightarrow RNB_{11}H_{11} + 2\ SMe_2 + 3\ H_2 \quad (10)$$

The insertion of a molecule BH_3 without loss of H_2 should transform a *nido* into an *arachno* species, exemplified by the formation of the anion **24** from the anion **15** [Eq. (11)][29][30].

$$[RNB_9H_{10}]^- + BH_3(thf) \rightarrow [RNB_{10}H_{13}]^- + thf \quad (11)$$

Both a carbyne unit and a nitrene unit are inserted when nitriles R′CN are added to the anions $[B_{10}H_{13}]^-$ or $[C_2B_8H_{11}]^-$ to give the 12-vertex *arachno* clusters $[N(R'C)B_{10}H_{13}]^-$ (**32**) and $[NC_2(R'C)B_8H_{11}]^-$ (**33**), respectively[37].

Degradation

The *nido* cluster NB_9H_{12} (**14**) is sensitive towards protic agents. One boron atom is removed by the attack of water in the presence of an acid to give *arachno*-NB_8H_{13} (**11**) [Eq. (12)][15].

$$NB_9H_{12} + 3\ H_2O \rightarrow NB_8H_{13} + B(OH)_3 + H_2 \quad (12)$$

One boron vertex is removed from *closo*-RNB_9H_9 and recovered in the borazine $(HBNR')_3$, when primary amines are applied, either according to Eq. (13) in polar THF or according to Eq. (14) in less polar, noncoordinating dichloromethane giving the *nido* anion **9** or the *arachno* species **12**, respectively[13].

$$RNB_9H_9 + 2\ R'NH_2 \rightarrow [R'NH_3][RNB_8H_9] + 1/3\ (HBNR')_3 \quad (13)$$

$$RNB_9H_9 + 2\ R'NH_2 \rightarrow RNB_8H_{10}(NH_2R') + 1/3\ (HBNR')_3 \quad (14)$$

The elimination of a BH_3 unit from the anions $[NB_{10}H_{14}]^-$ and $[NB_{10}H_{13}(N_3)]^-$ (**24**) on protonation may be accompanied by a cluster closure and is therefore mentioned in a later section.

Degradative Insertion

The first production of an azaborane with *c*(N) = 3 dates back to 1967, when two products, including the *arachno* cluster **19** (X = H)[25], were isolated from the reaction of decaborane and a thionitrosyl amine [Eq. (15)]. The fate of the expelled B atom is not known.

$$B_{10}H_{14}/Me_2NNS \rightarrow [SB_{10}H_{11}]^-/[(Me_2N)NB_9H_{12}]^- \quad (15)$$

Going from thionitrosyl to nitrosyl made a series of azaboranes available by the application of $NaNO_2$ in acidic media[54]. The transformation of the carbaborate $[C_2B_9H_{12}]^-$ into a mixture of $NC_2B_8H_{13}$ (**26**) and $NC_2B_8H_{11}$ (**41**) marked the starting point for this method in 1974[2], followed by the synthesis of NB_9H_{12} (**14**) in 1975;

the workup can be done with conc. H_2SO_4 [Eq. (16)][15] or with iodine, giving a 57% yield[19].

$$B_{10}H_{14}/NaNO_2/H_2SO_4 \rightarrow NB_9H_{12} \quad (16)$$

The diazaborane $N_2B_8H_{12}$ (**20**) can be prepared from NB_9H_{12} (**14**) by the same method. More stoichiometric clarity is achieved when the ionic nitrite is replaced by alkylnitrites [Eq. (17)][39]. The expelled boron vertex is then identified as trialkoxyborane.

$$B_{10}H_{14} + 3\ EtONO \rightarrow NB_9H_{12} + B(OEt)_3 + H_2 + NO + NO_2 \quad (17)$$

The thiaborane SB_9H_{11} was transformed by the action of BuONO into a mixture of SNB_6H_{11} (**8**) and SNB_8H_{11} (**22**)[12], and $B_{18}H_{22}$ into $NB_{17}H_{20}$ (**34**)[38].

We formally consider the nitrogen atoms of bridging amino groups to be skeletal atoms with $c = 2$ throughout this review article; the alternative position would be to view such groups as having the same functionality as two skeletal ligands, one of which contributes one and the other two electrons. The very first synthetic route to a larger azaborane was by the degradative insertion of an NHEt vertex by reacting $B_9H_{13}(SEt_2)$ with NH_2Et. The *hypho* cluster **13** (L = NH_2Et) was synthesized by this method in 1962[55] and was structurally identified in 1963[17]. The expelled boron vertex was presumably incorporated into a borazine [Eq. (18)].

$$B_9H_{13}(SEt_2) + 3\ NH_2Et \rightarrow (EtHN)B_8H_{11}(NH_2Et) + SEt_2 + 2\ H_2 + 1/3\ (HBNEt)_3 \quad (18)$$

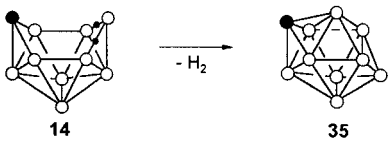
The 10% yield of NB_7H_9M [**10**; M = $Ir(PMe_3)_3$] from the action of N_2H_4 on $B_8H_{12}M'$ [M′ = $Ir(CO)(PMe_3)_2$] is formally the result of a degradative insertion[14].

A metal rather than a nitrogen vertex may be inserted under expulsion of a boron vertex. For example, $NB_8H_{11}M$ [**17**; M = $(C_6Me_6)Ru$] may be formed from NB_9H_{12} (**14**) and $[MCl_2]_2$[24] and azadirhoda-*closo*-decaborane **36** (M = Cp*Rh) from the *hypho*-borane **13** and $[MCl_2]_2$ [Eq. (19)][40].

$$(EtHN)B_8H_{11}(NH_2Et) + [Cp^*RhCl_2]_2 + 4\ NaH \rightarrow (EtN)B_7H_7(RhCp^*)_2 + BH_3(NH_2Et) + 4\ NaCl + 3\ H_2 \quad (19)$$

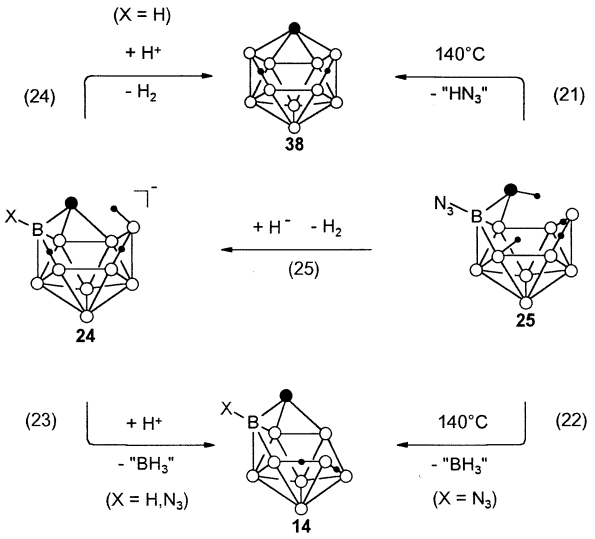
Closure

Thermal dehydrogenation of *nido*-NB_9H_{12} at 375−400°C makes *closo*-NB_9H_{10} available [Eq. (20)][3], and the dehydrogenation of RNB_9H_{11} follows the same pattern to give RNB_9H_9[13].



(20)

The *arachno* species $NB_{10}H_{14}(N_3)$ (**25**) undergoes an elimination of HN_3 in boiling xylene to give the *nido* cluster **38** [Eq. (21)]; the degradation product **14**, however, is the predominant product component [Eq. (22)][31]. Upon protolysis, the 11-vertex *arachno* anions of type **24,** $[RNB_{10}H_{13}]^-$ [from **15** by the insertion of BH_3, Eq. (11)] or $[NB_{10}H_{13}(N_3)]^-$ (from **25** by deprotonation[20]), are also predominantly degraded to give products of type **14** [Eq. (23)][20][29][30]; in the case of $[NB_{10}H_{14}]^-$, the *nido* species **38** is the concurrent closure product [Eq. 24)][29]. The deprotonation of **25**, according to Eq. (25)[20], represents a closure process that transforms one *arachno* structure (**25**) into another (**24**). Note that the skeleton of **24** can formally be derived from the corresponding *nido* skeleton of **30** or **31** by the removal of a vertex with $c = 4$, thus increasing the pentagonal aperture of **30** and **31** by one vertex; a vertex of $c = 5$ needs to be removed in order to transform **30** or **31** formally into **25** with a heptagonal aperture.



Opening

The opening of the *closo* species RNB_9H_9 (**35**) and $RNB_{11}H_{11}$ (**43**) by protic agents HX, neutral bases L, or anionic bases X^- gives *nido* products of the type $RNB_9H_{10}X$ (**16**), $RNB_{11}H_{11}L$ (**30**), or $[RNB_{11}H_{11}X]^-$ (**31**), respectively, as discussed in a later section. The *nido* clusters RNB_9H_{11} (**14**) are transformed into the *arachno* clusters $RNB_9H_{11}L$ (**18**) by the addition of Lewis bases L; the term "opening" has only an electronic meaning in this case, since the topology of the 10-vertex cluster skeleton is the same for *nido* and *arachno* species.

Structure

The geometry of the parent aza-*closo*-boranes NB_9H_{10} (**35**) and $NB_{11}H_{12}$ (**43**) have been determined from Hartree-Fock SCF calculations with 3-21G an 6-31G* basis sets as well as from X-ray (**35**) and electron diffraction work (**43**) (Table 4). The structures represent a C_{4v} distorted bicapped tetragonal antiprism and a C_{5v} distorted icosahedron, respectively, as expected from Wade′s cluster rules. We denote the three types of symmetrically equivalent boron atoms as *ortho*, *meta*, and *para* with respect to their distance from the nitrogen vertex. Typically, the nitrogen vertex of

NB_9H_{10} is in one of the two capping positions with $c = 4$. The highly symmetric structures, calculated for NB_9H_{10} and $NB_{11}H_{12}$ and observed for $NB_{11}H_{12}$ in the gas phase, are also present in solution, according to NMR data; they are slightly distorted in crystalline NB_9H_{10} and in two crystalline derivatives of $NB_{11}H_{12}$ (Table 4). Although the skeletal distances of the free molecules are in general longer than those in the crystal, the sequence is the same when going through the five zones of equivalent distances for C_{4v} or C_{5v} symmetry. The BN bonds, the shortest in both *closo* clusters, are distinctly shorter in the NB_9 than in the NB_{11} skeleton, a phenomenon that is apparently related to the different connectivity of the nitrogen atom. A smaller effect of the same type and origin is observed for the boron atoms in the *antipodal* position, i.e. the apex opposite to the nitrogen atom.

A typical feature of both polyhedra is the short distance between the nitrogen atom and the polyhedral centre, if compared to the boron atoms. The penetration of the nitrogen atom into the cluster widens the B−B distances in the upper pyramidal basis making them the largest in the skeleton. In addition, the four (five) B−H bonds in the upper pyramidal basis are shifted away from the radial direction towards the nitrogen atom, thereby shielding it considerably.

six-coordinated nitrogen atoms ($c = 5$) into the skeletons of the *closo* 12-vertex species.

Although the formal charge of the nitrogen atom is highly positive, the real atomic charge is expected to be most negative at the electronegative nitrogen atom of NB_9H_{10} or $NB_{11}H_{12}$, whereas the most positive positions should be the nitrogen-bound hydrogen atom and the boron atoms adjacent to the nitrogen atom (*ortho* position, *o*-B). This is confirmed by ab initio calculations of the atomic charges, which are quantitatively different depending on whether calculated according to the methods of either Mulliken or Löwdin (Table 5). Qualitatively, however, the results of the two calculations are in accord and indicate that the boron atoms in the *meta* position (*m*-B) are the most negatively charged ones, the antipodal boron atoms (*para* position, *p*-B) range between *o*-B and *m*-B, and the least positively charged hydrogen atoms are the antipodal ones. The large calculated dipole moments of ca. 5.1 (**35**) and 4.6 D (**43**) are oriented with their positives ends towards the negatively charged nitrogen atoms, demonstrating that all the 20 (24) atoms and particularly the hydrogen atoms on the symmetry axis contribute to the dipole moment.

The sequence $m > p > o$ for the charge densities at the boron atoms (Table 5) does not parallel the ^{11}B-NMR chemical shifts, which form a series $m > o > p$ with decreas-

The structures of the azametalla-*closo*-boranes $NB_7H_8(RhCp^*)_2$ (**36**)[40], $NB_{10}H_{11}[RhH(PPh_3)_2]$[43], and $NB_{10}H_{11}[Ru(C_6Me_6)]$ (**44**)[44] have also been investigated in the crystalline phase and represent typical 10- or 12-vertex *closo* structures, respectively.

The azametallaboranes **37**, $NB_9H_{10}(CoCp^*)$[19] and $NB_9H_{10}[Ru(cymene)]$[41], represent the rare case of a 11-vertex *closo* species for which the structure has been confirmed. Typically, the metal atom is in the unique position with $c = 6$; this position is unfavourable for boron and impossible for nitrogen.

The *nido* 11-vertex molecules $RNB_{10}H_{12}$ (R = $NB_2Ht Bu_3$; **38**), $NC_2B_8H_{11}$ (**41**), and $NB_9H_{11}Cl(IrCp^*)$ (**42**) can be described as the expected icosahedral fragment structures with a pentagonal aperture, which is confirmed by crystal structure analysis[42][45][46].

There is no doubt that five-coordinated nitrogen atoms ($c = 4$) are incorporated into the borane cluster skeletons of the *closo* 10-, *closo* 11- and *nido* 11-vertex species and

ing field [in CD_2Cl_2, standard $BF_3(OEt_2)$]: −21.7, −5.6, 62.4 (NB_9H_{10})[39] and −11.9, −9.8, 2.7 ($NB_{11}H_{12}$)][4]. The downfield shift of *p*-B, particularly with NB_9H_{10}, is called the *antipodal effect*. It has been compared to the corresponding antipodal effect exhibited by the isoelectronic species XB_9H_9 and $XB_{11}H_{11}$ with X = AlH^{2-}, BH^{2-}, CH^-, S etc. The antipodal effect for NB_9H_{10} has been described as greatly influenced by the paramagnetic part of the chemical shielding; the HOMO−LUMO energy difference is also an important factor, as are the tangential p_x, p_y orbitals at the *p*-B atom, which are called *NMR-active*[57][58][59]. Since precise calculated geometrical data are available, computational methods such as IGLO allow the calculation of ^{11}B-NMR data which are in good accord with experimental results[47].

An analysis of the charge distribution in clusters should provide an understanding of which vertices will be attacked by electrophiles and which by nucleophiles. The products of ligand substitution, opening, and even degradation reac-

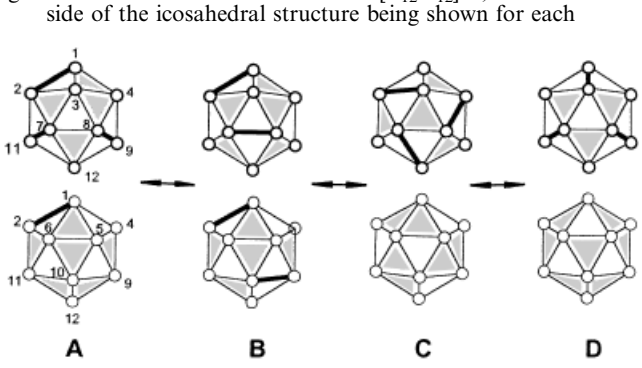
NB_9H_{10}	(a)	−1.073	0.184	−0.068	0.092	0.434	0.000	0.027	−0.024
	(b)	−0.234	0.062	−0.135	−0.077	0.291	0.030	0.040	0.031
$NB_{11}H_{12}$	(a)	−1.065	0.097	−0.054	0.009	0.443	0.037	0.037	0.029
	(b)	−0.222	0.027	−0.123	−0.078	0.295	0.040	0.048	0.038

tions may be predicted, provided that the first step of the reaction determines the products and that the ground-state polarities determine the transition state of that first step. In the case of NB_9H_{10} and $NB_{11}H_{12}$, one would expect nucleophiles to attack the *ortho* position and electrophiles the *meta* position. Such an expectation is met for nucleophiles, which exclusively attack at the *ortho* belt, whereas electrophiles attack either in the *para* or in the *meta*, but never in the *ortho* position (see following sections).

The binding electrons in closed boranes are delocalized over the whole skeleton in a way that is strongly suggestive of the π electrons in benzene-type molecules, and closed boranes have therefore been denoted as aromatic systems. In this context, azaboranes may be compared to pyridine. In the old-fashioned valence-bond description of benzene, the delocalization of the π electrons is achieved by introducing resonance between structures built up by localized (2c, 2e) π bonds. Such a procedure can also be applied to boranes, where the resonating structures are built up by localized (2c,2e) and (3c,2e) bonds[60]. The icosahedral dodecaborate $[B_{12}H_{12}]^{2-}$ is given as an example. This anion may be built up by y (2c,2e) bonds and t (3c,2e) bonds. The 24 atoms contribute 60 valence orbitals and 50 valence electrons. From the balances $60 = 3t + 2y$ and $50 = 2t + 2y$, we find $y = 15$ and $t = 10$. There are twelve B−H (2c,2e) bonds leaving three (2c,2e) and ten (3c,2e) bonds to build up the cluster skeleton. Four resonance structures of different energy can be constructed (Figure 4). Each of the structures **A** and **B** of C_1 symmetry is related to 120 degenerate resonance structures, the structure **C** (C_3 symmetry) allows 40 and the structure **D** (C_{3v} symmetry) 20 degenerate structures, which altogether sum up to 300 resonating structures. (Note that the number of degenerate structures is equal to the ratio of the order of the group I_h to the order of the corresponding subgroup.) The number of structures would be increased if we allowed those which (a) contain also open instead of only closed (3c,2e) bonds, (b) contain edges without bonding interaction, (c) contain vertices not obeying the octet rule. In going from $[B_{12}H_{12}]^{2-}$ to the isoelectronic $NB_{11}H_{12}$ the degeneracy decreases and structures in which the nitrogen atom adopts one of the (2c,2e) bonds become favourable.

Figure 4. Resonance formulae **A**−**D** of $[B_{12}H_{12}]^{2-}$, front and rear side of the icosahedral structure being shown for each



Reactivity

Little is known about the reactivity of the azametalla-*closo*-boranes with either an NB_7M_2 (**36**), NB_9M (**37**), or $NB_{10}M$ skeleton (**44**, **45**). The same is true for the reactivity of the *nido* 11-vertex clusters $NC_2B_8H_{11}$ (**41**) and $NB_9H_{11}ClM$ (**42**). More is known about the reactivity of *closo*-NB_9H_{10} (**35**), *closo*-$NB_{11}H_{12}$ (**43**), and *nido*-$NB_{10}H_{13}$ (**38**).

Redox Reactions

The *N*-alkyl derivatives RNB_9H_9 and $RNB_{11}H_{11}$ are stable towards iodine and bromine, even if dissolved in liquid bromine[49]. A mixture of $RNB_{11}H_{11}$ and liquid chlorine may be kept for a while at low temperature, but can undergo a spontaneous violent reaction. No doubt BN, $BHal_3$ and HHal are the thermodynamically stable products from a mixture of $NB_{11}H_{12}$ and excess Hal_2, but such a mixture is more or less metastable. Strong reduction agents like alkali metals do not react with $RNB_{11}H_{11}$.

Brønsted Acid/Base Reactions

The skeleton of the *closo* species RNB_9H_9 and $RNB_{11}H_{11}$ is stable if dissolved in strong acids such as triflic acid F_3CSO_3H[49]; a proton/proton exchange cannot be excluded, however. The nitrogen-bound protons of the parent molecules NB_9H_{10} and $NB_{11}H_{12}$ can be easily removed by bases, in the case of $NB_{11}H_{12}$ even with the weak base NEt_3, to give the anions $[NB_9H_9]^-$ and $[NB_{11}H_{11}]^-$. These anions can easily be alkylated by RI and RO_3SCF_3, respectively, if R represents an α-unbranched alkyl group[3][21][36]; bulky alkyl and aryl groups R cannot be fixed to the nitrogen atom of the anions, but such derivatives RNB_9H_9 and $RNB_{11}H_{11}$ are available from RNB_9H_{11} by either dehydrogenation [Eq. (20)] or insertion of two BH units [Eq. (10)], respectively.

The *nido* cluster $NB_{10}H_{13}$ (**38**) can be deprotonated once or twice by hydride bases, depending on the stoichiometric amount of base. The protons are removed from the bridging positions, not from the NH group. The corresponding anions $[NB_{10}H_{12}]^-$ (**39**) and $[NB_{10}H_{11}]^{2-}$ (**40**) are isoelectronic with the anions $[C_2B_9H_{12}]^-$ and $[C_2B_9H_{11}]^{2-}$ and, like these, they offer a pentagonal open face which is isolobal with $C_5H_5^-$ and is ready, therefore, to form pentahapto bonds with transition-metal species M^{2+}. A third proton cannot be removed from $[NB_{10}H_{11}]^{2-}$. Interestingly, the *nido*-azadicarbaborane $NC_2B_8H_{11}$ (**41**) which is isoelectronic with $NB_{10}H_{13}$ can be deprotonated at the nitrogen atom, since bridging hydrogen atoms are absent; applying K_2CO_3 and MeI consecutively gives the corresponding *N*-

methyl derivative[32][45]. Nevertheless, the terminal nitrogen atom and not one of the bridging protons becomes active when $NB_{10}H_{13}$ is added to the azadiboriridine NB_2tBu_3 to yield $(NB_2HtBu_3)NB_{10}H_{12}$[42].

Electrophilic Substitution

The *closo* clusters RNB_9H_9 (R = *p*-ClC_6H_4) and $RNB_{11}H_{11}$ (R = Me) react neither with triflic acid (as mentioned above) nor with methyl triflate. A mixture of one of the clusters, with methyl triflate as the solvent and triflic acid as a catalyst, however, results in a five- and six-fold methylation after four hours [Eqs. (26), (27)][49].

$$NB_9H_9 + 5\ MeOTrf \rightarrow RNBH_4Me_5 + 5\ HOTrf \quad (26)$$

$$RNB_{11}H_{11} + 6\ MeOTrf \rightarrow RNB_{11}H_5Me_6 + 6\ HOTrf \quad (27)$$

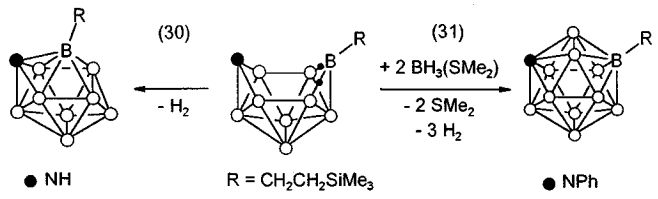
As expected from the cluster charge distribution, the *ortho* positions remain unattacked by the electrophile, whereas the *meta* and *para* positions are completely substituted. The same procedure transforms the *ortho*-dicarbaborane $C_2B_{10}H_{12}$ into $C_2B_{10}H_2Me_{10}$; all boron vertices in this product carry methyl groups, even those adjacent to carbon[61]. If the methylation of the aza-*closo*-boranes is prolonged by 16 hours, one of the methyl groups in each of the products is replaced by a triflate group [Eqs. (28), (29)].

$$RNB_9H_4Me_5 + HOTrf \rightarrow RNB_9H_4Me_4(OTrf) + CH_4 \quad (28)$$

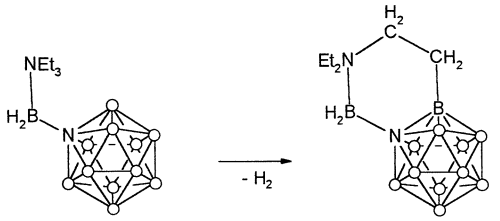
$$RNB_{11}H_5Me_6 + HOTrf \rightarrow RNB_{11}H_5Me_5(OTrf) + CH_4 \quad (29)$$

The triflate group is fixed to a *meta* position in the 10-vertex product, but to a *para* position in the icosahedral species. An electrocyclic mechanism via a six-membered cyclic transition state has been proposed for the reactions (28) and (29)[49].

Although *ortho*-alkyl derivatives of NB_9H_{10} are not available by electrophilic alkylation, they are available, if one starts from $NB_9H_{11}R$ with the group R in the 9 position. The thermal dehydrogenation yields NB_9H_9R with R in *ortho* position [Eq. (30)]. The starting material can be synthesized from NB_9H_{12} and the corresponding alkenes by hydroboration[22]. As expected, the 9-alkyl derivative $PhNB_9H_{10}R$ gives the *meta*-alkyl derivative $PhNB_{11}H_{10}R$ on ring closure with $BH_3(SMe_2)$ [Eq. (31)][30].



A singular alkylation at the *ortho* belt of the closed NB_{11} skeleton is observed when the synthesis of $NB_{11}H_{12}$ from NB_9H_{12} is performed with $BH_3(NEt_3)$ instead of $BH_3(SMe_2)$, according to Eq. (9). At 200 °C the product, expected from Eq. (9), is apparently not stable, and undergoes a further dehydrogenation; a B−C bond is formed from a CH_3 and a BH moiety [Eq. (32)][48]. An intermolecular dehydrogenation of this type has never been observed; the loss in entropy would be too great.



The bromination of the same *closo* species that were used for the methylation, yields either a fivefold-brominated or a monobrominated product when $AlBr_3$ acts as a Friedel−Crafts catalyst [Eqs. (33), (34)][49].

$$RNB_9H_9 + 5\ Br_2 \rightarrow RNB_9H_4Br_5 + 5\ HBr \quad (33)$$

$$RNB_{11}H_{11} + Br_2 \rightarrow RNB_{11}H_{10}Br + HBr \quad (34)$$

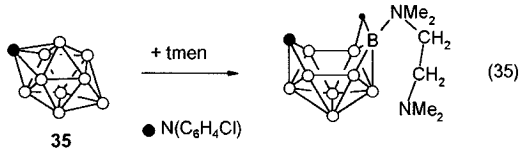
As expected, the bromination takes place in the *meta* and *para* position of the NB_9, but exclusively in the *para* position of the NB_{11} skeleton. Iodination in the presence of $AlCl_3$ stops at the diiodination to give $RNB_9H_7I_2$, with iodine in the *meta* and *para* position, or at the moniiodation to give the *para* product $RNB_{11}H_{10}I$.

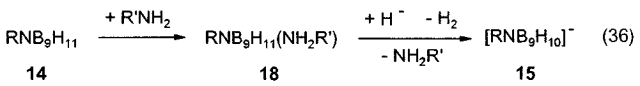
There is some similarity in the halogenation of the azaboranes RNB_9H_9 and $RNB_{11}H_{11}$ on the one hand and of the isoelectronic thiaboranes SB_9H_9 and $SB_{11}H_{11}$ on the other; these can be halogenated once, twice or three times, preferably in the *meta*, also in the *para*, but not in the *ortho* position[62][63][64]. The isoelectronic carbaborates $[CB_9H_{10}]^-$ and $[CB_{11}H_{12}]^-$ also undergo a similar electrophilic halogenation to give $[CB_9H_9Hal]^-$ (Hal = Cl, Br, I, in the *meta* position) or $[CB_9H_5Hal_5]^-$ (Hal = Cl, Br, in the *meta* and *para* positions)[65][66][67] and to give $[CB_{11}H_{11}Hal]^-$ (Hal = Cl, Br, I, in the *para* position) or $[CB_{11}H_{10}I_2]^-$ (I in the *meta* and *para* position) or $[CB_{11}H_6Hal_6]^-$ (Hal = Cl, Br, in the *meta* and *para* position)[68][69][70].

Cluster Opening by Bases

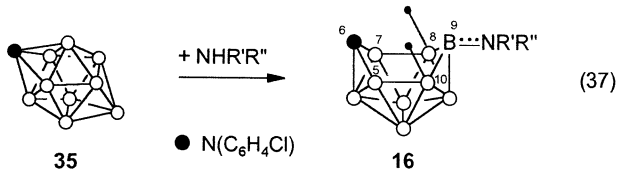
The 10-vertex aza-*closo*-borane RNB_9H_9 (**35**) can be opened by amines. Whereas simple tertiary amines like NEt_3, N*i*Bu_3 do not react with RNB_9H_9 (R = *p*-ClC_6H_4), the bifunctional tertiary amine $Me_2N-CH_2-CH_2-NMe_2$ (tmen) gives a 1:1 adduct via one of the basic nitrogen atoms, which attacks one of the *ortho* positions. The *closo* species is transformed into a *nido*-NB_9 skeleton that contains an unsymmetric hydrogen bridge without fluxional behaviour, according to NMR data at room temperature [Eq. (35)][23]. The same type of hydrogen bridge is present in the anions $[RNB_9H_{10}]^-$ (**15**; R = Ph, $PhCH_2$), which are formed from RNB_9H_{11} (**14**) by the addition of $R'NH_2$ (R′ = *t*Bu) and subsequent deprotonation of the adduct (**18**) by hydride [Eq. (36)][23]. The difference in reactivity

between ordinary tertiary amines and tmen is not understood.





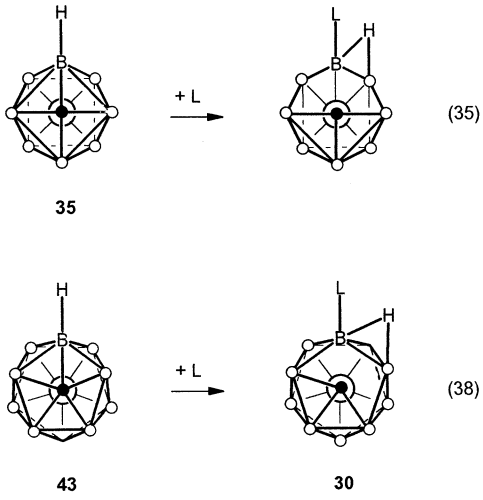
The *closo* species RNB_9H_9 is degraded when an excess of primary or secondary amine is applied. A secondary amine like $NHEt_2$ or $NHiPr_2$ and even a primary amine with a bulky group like NH_2tBu simply opens RNB_9H_9 without degradation, when an excess of amine is avoided. The hydrogen atoms of the reacting moieties BH and NH are found in the open face of the product [Eq. (37)]. Bridging positions B8−B9 and B10−B9 would be expected if the product $RNB_9H_{10}(NR'R'')$ was a *nido* cluster, whereas bridging positions B5−B10 and B7−B8 would indicate an *arachno* cluster. An electron count, according to Wade's rules, predicts a *nido* product $RNB_9H_{10}X$ (**14**) if the ligand X behaved like a hydrogen atom, but would give an *arachno* product if X acted as a three-electron ligand, forming a σ and a dative π bond, due to a lone pair of X. The two non-*exo*-hydrogen atoms of the product, Eq. (37), were found by NMR methods to be predominantly in an *endo* position at B8 and B10, i.e. a position inbetween those typical for *nido* and *arachno* 10-vertex clusters. Such an electronic-hybrid situation was also concluded from the ^{11}B-NMR data[23] apparently because of weak BN π bonding between the amino ligand and the cluster.



In the case of the *closo*-borane $RNB_{11}H_{11}$ (**43**), simple tertiary amines such as NEt_3 are added to the *ortho* position to give the *nido* cluster **30** by the migration of the former terminal hydrogen atom into a neighbouring bridge position in the open pentagonal face (R = Ph) [Eq. (38)][35].

$$PhNB_{11}H_{11} + NEt_3 \rightarrow PhNB_{11}H_{11}(NEt_3) \quad (38)$$

The similarity of the steric course of reactions (35) and (37) is elucidated by observing the *closo* clusters along the main axes. The reduction of the connectivity at the nitrogen atom to $c = 3$ involves the opening of one B−N bond in reaction (35), but of two B−N bonds in reaction (38). No B−B bond is opened during reaction (38), whereas three B−B bonds are opened and one B−B bond is closed during reaction (35), which can be considered to be the reverse of the dehydrogenation, Eq. (30), with respect to the skeletal changes.



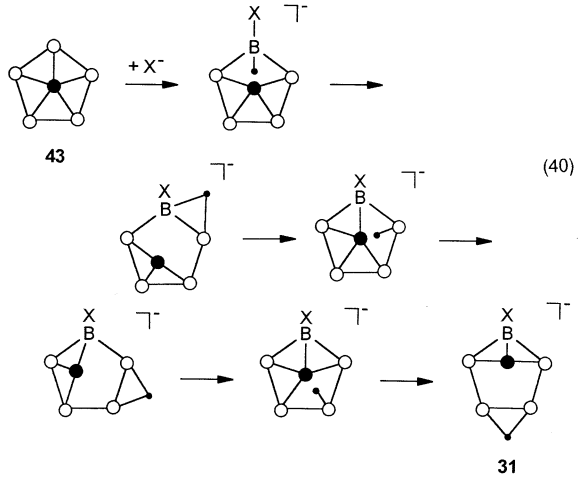
nido products of type **31** are formed when anions X^- are added to *closo*-$RNB_{11}H_{11}$ [Eq. (39)][35]. Substances MX as different as LiMe, LiBu, K[O*t*Bu], $[N(PPh_3)_2]Cl$, $[S(NMe_2)_3][Me_3SiF_2]$ (X = F by elimination of Me_3SiF), and $K[BHEt_3]$ (X = H by elimination of BEt_3) have been allowed to react with $MeNB_{11}H_{11}$.

$$MeNB_{11}H_{11} + MX \rightarrow M[MeNB_{11}H_{11}X] \quad (39)$$

In the case of protic agents such as HOMe, the anion MeO^- is added to $RNB_{11}H_{11}$ (R = H, Me, Et, Ph), and the proton, the corresponding cation, is dissolved in the organic medium, e.g. CH_2Cl_2. Efforts to isolate the free acid $H[RNB_{11}H_{11}(OMe)]$ resulted in a complete degradation of the cluster. The cluster anion can be precipitated, however, from solutions of the free acid by adding salts such as $[N(PPh_3)_2]Cl$, leaving HCl in the solvent[36]. No deuterium is incorporated into the cluster if DOMe instead of HOMe is applied, proving that the bridging hydrogen atom in the anion **31** is one of the hydrogen atoms of the starting material **43** and that there is no hydrogen/deuterium exchange between the anion **31** and DOMe[36]. A secondary amine such as the protic agent $HNEt_2$ yields the salt-type product $[H_2NEt_2][RNB_{11}H_{11}(NEt_2)]$[35].

We assume that the mechanism of the formation of anions **31** from **43** is best described by the reaction sequence (40), which starts with the addition of X^- to **43**, followed by a series of rearrangements of a hydrogen atom from an *endo* into a bridging position and vice versa. The second intermediate in this sequence corresponds to the isolated neutral adduct $RNB_{11}H_{11}(NEt_3)$ (**30**). [Only the 6-vertex upper halves of the 12-vertex polyhedral anions are drawn in sequence (40).]

The anions $[RNB_{11}H_{11}X]^-$ (**31**) are remarkably stable in protic media including aqueous acids and bases. Efforts have failed to deprotonate the anion $[PhNB_{11}H_{11}(OH)]^-$ in order to study the oxo-ligand in the expected dianion $[PhNB_{11}H_{11}O]^{2-}$, even though the strongest bases have



been applied. A degradation of the anions **31** has never been observed.

To summarize the findings on cluster opening: The closed NB_9 and NB_{11} skeletons of **35** and **43** are stable toward oxidation and reduction and toward Brønsted and Lewis acids. The *closo*-NB_{11} skeleton is opened by anionic or neutral bases to give a *nido*-NB_{11} skeleton with a nonplanar pentagonal aperture; this *nido* skeleton is stable towards degradation by bases. This is in striking contrast to the behaviour of the isoelectronic C_2B_{10} skeleton, which undergoes a degradative opening with bases to give the *nido*-C_2B_9 skeleton, whose planar pentagonal aperture is the basis for the synthesis of so many dicarbametalla-*closo*-dodecaboranes. The isoelectronic *nido*-NB_{10} clusters are not available from *closo*-NB_{11} systems and have to be synthesized by an alternative method. The *closo*-NB_9 skeleton can be opened by amines, if no excess is applied, but will be opened and degraded by protic bases in excess.

Degradative Opening of *closo*-RNB_9H_9

The *closo*-NB_9 skeleton is transformed into the *nido*-NB_8 skeleton in a sufficiently polar, aprotic medium such as thf as has been shown for RNB_9H_9 with R = *p*-ClC_6H_4, *p*-MeC_6H_4, $PhCH_2$[13]; the *nido* anion $[RNB_8H_9]^-$ (**9**) is the product. The expelled boron atom is found in a borazine molecule $(HBNiPr)_3$, if *i*$PrNH_2$ is the attacking base [Eq. (13)], but will be detected in the anion BF_4^-, if fluorides such as $[NBu_4]F$ or $[S(NMe_2)_3][Me_3SiF_2]$ are the degrading agents, according to reactions of unknown stoichiometry. The reaction of RNB_9H_9 with *i*$PrNH_2$ or other primary amines in the less polar solvent CH_2Cl_2, on the other hand, yields the *arachno*-NB_8 species $RNB_8H_{10}(NH_2R')$ [**12**; Eq. (14)][13].

Applications of Azaboranes

The nitrogen-bound amino group in the anion $[(Me_2N)NB_9H_{12}]^-$ [**19**; Eq. (15)] can be treated with MeI to form $(Me_3N)NB_9H_{12}$[25]. This product and similar ones are reported to be useful as blowing agents, in electrical resistors, and as reducing agents[71].

Received July 3, 1997

Keywords: Bite angle / Catalysis / P ligands / Palladium / Cross-coupling

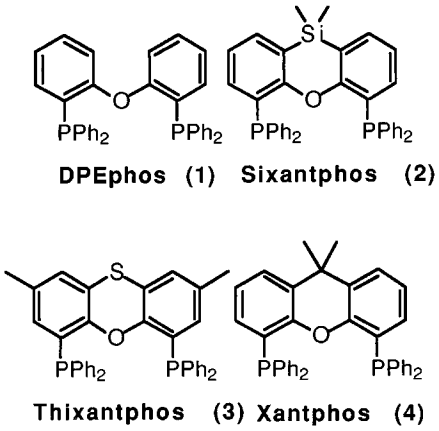
The effect of the natural bite angle (β_n) of diphosphane ligands on catalyst selectivity and activity in the palladium-catalyzed cross-coupling of *sec*-butyl magnesium chloride with bromobenzene was investigated. The calculated natural bite angles range from 78° for dppe (1,2-bisdiphenylphosphanoethane) to 110° for Xantphos. The natural bite angle of diphosphane ligands has a large effect on catalyst selectivity and activity. Both rate and selectivity of the cross-coupling reaction increase with increasing bite angle and reach a maximum value with DPEphos (β_n = 102.7°). Larger bite angles of the diphosphane ligands result in a decreased selectivity and activity.

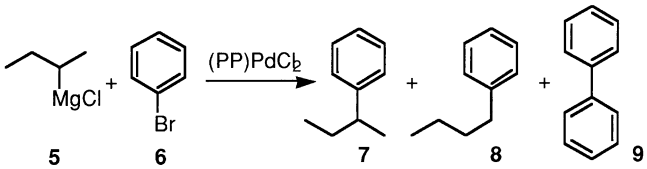
Transition metal catalyzed carbon−carbon bond formation is an important tool for organic chemists and a challenging area of research in homogeneous catalysis. Nickel and palladium catalysts with tailored phosphane ligands have been applied successfully in the cross-coupling reaction. The influence of the type of (di)phosphane used is very large, although the effect is not yet fully understood.[1][2] One of the steric parameters for diphosphanes is the bite angle induced by the ligand.[3] Hayashi et al. found that dppf [1,1′-bis(diphenylphosphanoferrocene)], a diphosphane with a large P−Pd−P bite angle of 99.1° in [dppf]$PdCl_2$, has the highest activity and selectivity of a range of (di)phosphane ligands. Furthermore, comparison of different diphosphanes revealed an increase of selectivity with an increasing bite angle.[4][5]

We have developed a new group of diphosphanes capable of enforcing large bite angles (see Figure 1).[6] According to our calculations, these ligands have natural bite angles varying from 102° to 110° (for palladium complexes). Recent studies on hydroformylation,[6] hydrocyanation,[7] and allylic alkylation[8] showed that changes in the bite angle of these ligands have a strong influence on catalyst selectivity. Since the steric and electronic properties of these ligands are the same, all effects on selectivity or activity can be attributed to the bite angle. Here we present a study on the effect of the bite angle of chelating diphosphanes on the activity and selectivity in the palladium-catalyzed cross-coupling reaction.

We prepared mononuclear, *cis*-(P-P)$PdCl_2$ (**1−4a**) complexes of the Xantphos-type ligands (see Figure 1) and the analogous (diphosphane)$PtCl_2$ complexes (**1−4b**). The platinum(II) complexes showed large Pt−P coupling constants of 3640−3800 Hz, indicative of square planar *cis* coordination. The palladium complexes were utilized as catalysts in the coupling of *sec*-butylmagnesium chloride with bromobenzene (see eq. 1, Table 1).[4][5]

Figure 1. Diphosphanes with large bite angles





Homocoupling, an important competing reaction in the cross-coupling reaction,[9] was not taken into account in Hayashi's study. We therefore applied their best catalytic system, dppf$PdCl_2$, under identical conditions and analyzed the product mixture for the presence of **9**, the homocoupled product. An amount of 3% was observed, which has a small effect on the overall selectivity of this catalyst system. The initial turnover frequency was 79 mol (mol Pd)$^{-1}$ h^{-1}

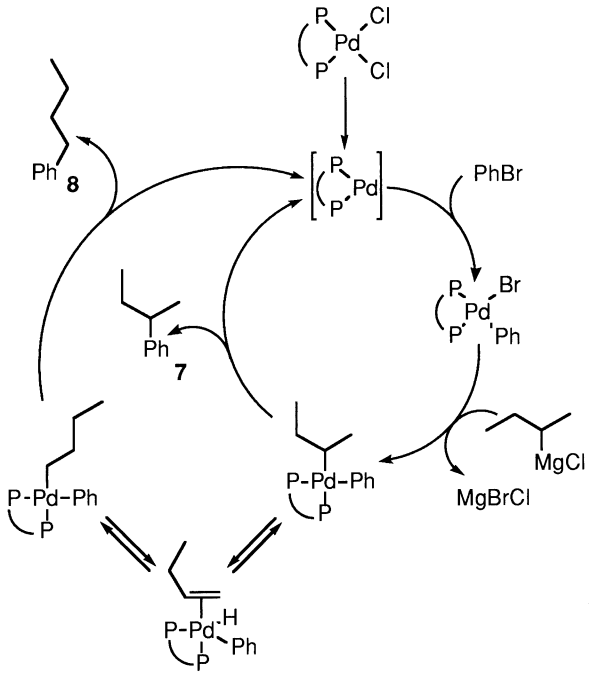
Thixantphos	107.2	24	16	36.5	51	17	32
Xantphos	110.0	24	16	23.6	41	19	40

Conditions: 0.04 mmol catalyst, 8 mmol **5** and 4 mmol **6** in 20 ml ether, T = 20°C. The 95% confidence interval of the mean measured values is ±1.1%. – n.d.: not determined – [a] Initial turnover frequency, determined after 5 min. of reaction time. – [b] Conversions based on **6**. – [c] Results from reference[5], dppe = 1,2-bis(diphenylphosphano-ethane), dppp = 1,3- bis(diphenylphosphano-propane), dppb = 1,4-bis(diphenylphosphano-butane). – [d] Since we are not able to model the ferrocene-unit accurately, the natural bite angle for dppf is taken as 99.1°, the P–Pd–P angle from the X-ray structure of (dppf)$PdCl_2$[5].

Scheme 1



The catalyst containing DPEphos, β_n = 102.7°, was even more active and selective than the one with dppf. The cross-coupling product **7** was obtained in a selectivity of 98% (compared to 95% for dppf), with only 1% of the homocoupled **9**, and 1% of **8**. The observed initial turnover frequency is 181 mol (mol Pd)$^{-1}$h^{-1}, which is 2.3 times as high as the initial t.o.f. we observed for dppf.

Increasing the β_n of the diphosphane resulted in a decrease of both catalyst activity (an initial t.o.f. of 36 mol/mol/h using Sixantphos) and selectivity. The amount of cross-coupling product **7** decreased, whereas the homocoupled **9** and the sideproduct **8** were formed in larger amounts. At still larger bite angles the amount of homocoupling product **9** increased to a level of 40%.

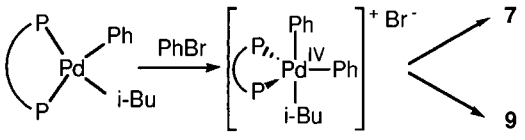
Which step in the catalytic cycle is rate determining, is still under debate. Evidence has been presented that the rate-determining step can be either one of the following steps: the oxidative addition,[10][11] the transmetallation,[12][13] or the reductive elimination step.[14][15]

Brown and Guiry studied the effect of the P–Pd–P bite angle on the rate of reductive elimination. Both experimental work and extended Hückel calculations showed that the P–Pd–P angle increased along the reaction pathway. To investigate this effect they prepared a ruthenium analogue of dppf in order to increase the bite angle to 105–110°. The ruthenium-based ligand exhibited a slightly larger reactivity for reductive elimination than dppf, but the effect was marginal.[16]

An increasing P–Pd–P angle results in a decreasing R–Pd–R′ angle in the intermediate of the catalytic cycle. This smaller R–Pd–R′ angle accelerates reductive elimination. The optimum is reached at a P–Pd–P angle of ca. 102°. The reaction rates of [DPEphos]$PdCl_2$ and [dppf]$PdCl_2$ are similar, which seems to imply that DPEphos still induces a distorted square planar coordination. When the P–Pd–P angle increases further, the Pd(II) species will no longer have a square planar geometry. We propose that this distortion leads to an increasing R–Pd–R′ angle, which results in a decreasing relative rate of reductive elimination. This might explain the decrease of the rate of reaction when going from DPEphos to Xantphos.

An explanation for the formation of *n*-butylbenzene (**8**) can be the increased tendency to form trigonal bipyramidal intermediates with an increasing bite angle. The large bite angle induced by the Xantphos-type diphosphanes stabilize trigonal bipyramidal geometries, and the phosphorus donor atoms will be coordinated in the equatorial plane. This may lead to an increased rate of β-hydride elimination and reinsertion (see Scheme 1). The 1-alkyl palladium intermediate can react further to yield **8**. The ligands that are most suitable for stabilizing trigonal bipyramids, Sixantphos, Thixantphos, and Xantphos give rise to the formation of large amounts of **8**. Additionally, oxidative addition of a second molecule of bromobenzene results in the formation of a trigonal bipyramidal [(diphosphane)$Pd^{IV}(Ph)_2Bu]^+$ Br^- complex.[14] Stabilization of this complex by ligands inducing larger bite angles can explain the increasing amounts of homocoupled product **9** (see Scheme 2). The alternative mechanism of transmetallation between isobutylmagnesium chloride and bromobenzene, however, cannot be excluded.

Scheme 2



In conclusion it was found that in the (diphosphane)$PdCl_2$-catalyzed cross-coupling of 2-butylmagnesium chloride with bromobenzene, the selectivity reaches the highest value when the natural bite angle of the diphosphane used is ca. 100°. The rate of the reaction is also maximal at this value. The best selectivity and activity are obtained for DPEphos, a diphosphane with a natural bite angle of 102°. We propose that diphosphanes with larger bite angles stabilize trigonal bipyramidal intermediates leading to 1-butyl-benzene and homocoupled biphenyl.

Experimental Section

Computational Details: All calculations were performed using CAChe WorkSystem software[17] on an Apple Power Macintosh 950 equipped with 2 CAChe CXP coprocessors. The Molecular Mechanics calculations were performed using the MM2 force field.[18] Block-diagonal Newton-Raphson was used as optimization method. Natural bite angle calculations were performed using a method similar to that described by Casey and Whiteker[3] using a Pd−P bond length of 2.288 Å.[5][19]

For the ligands dppe, dppp and dppb, a starting geometry for the chelate ring resembling the appropriate cycloalkane was used. By this procedure, the global minimum resulting from excessive, stabilizing π-stacking interactions (and having a too small a bite angle) was avoided. The geometry obtained in this way is in agreement with geometries observed by X-ray crystallography.[20]

Synthesis: The diphosphane ligands were prepared according to literature procedures.[6]

Complex Synthesis: In a typical experiment, ligand (0.121 g, 0.225 mmol) and $(PhCN)_2PdCl_2$ (0.087 g, 0.225 mmol) ware placed in a Schlenk flask, and flushed with N_2. THF (10 ml) was added, and the reaction mixture was stirred overnight at room temp. The solvent was removed in vacuo, the resulting yellow powder was washed 3 times with 10 ml of diethyl ether, then dried in vacuo.

(DPEphos)$PdCl_2$ (**1a**): Yield: 0.198 g (0.251 mmol, 98%) of yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 19.3.

(DPEphos)$PtCl_2$ (**1b**) Yield: 0.162 g (0.201 mmol, 95%) of yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 2.0 ($J_{Pt\text{-}P}$ = 3795 Hz).

(Sixantphos)$PdCl_2$ (**2a**):Yield: 0.150 g (0.251 mmol, 86%) of yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 24.8.

(Sixantphos)$PtCl_2$ (**2b**): Yield: 0.161 g (0.187 mmol, 88%) of yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 7.6 ($J_{Pt\text{-}P}$ = 3663 Hz).

(Thixantphos)$PdCl_2$ (**3a**): Yield: 0.256 g (0.330 mmol, 91%) yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 25.3.

(Thixantphos)$PtCl_2$ (**3b**): Yield: 0.163 g (0.189 mmol, 89%) offwhite powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 8.4 ($J_{Pt\text{-}P}$ = 3641 Hz).

(Xantphos)$PdCl_2$ (**4a**): Yield: 0.140 g (0.185 mmol, 82%) yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 22.7.

(Xantphos)$PtCl_2$ (**4b**): Yield: 0.149 g (0.176 mmol, 83%) pale yellow powder. − $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ = 6.6 ($J_{Pt\text{-}P}$ = 3695 Hz).

Palladium-Catalyzed Cross-Coupling of Bromobenzene with sec-Butylmagnesium Chloride. General Procedure: The catalyst (0.04 mmol) was placed in a 50 ml Schlenk flask equipped with a stirring bar. Diethyl ether (10 ml)was added, and the reaction mixture was kept at the desired temperature using a water bath (20° C). Bromobenzene (0.42 ml, 4 mmol) and *n*-decane as an internal standard (0.8 ml, 4.1 mmol) were added, followed by 10 ml of a solution of *sec*-butylmagnesium chloride (0.8 M in ether). Samples were hydrolyzed with 10% hydrochloric acid, the organic layer was separated, and analyzed by GC.

$Ti_9O_8(OPr)_4(methacrylate)_{16}$ was obtained by the reaction of $Ti(OPr)_4$ with an excess of methacrylic acid and analyzed by X-ray diffraction. The compound consists of a ring of nine $[TiO_6]$ octahedra linked by six μ_2- and only two μ_3-oxide bridges.

When metal alkoxides are treated with carboxylic acids, β-diketones, or related compounds, the alkoxide groups are replaced to some extent by the corresponding bidentate anionic ligands (BL^-).[1] There are three main objectives in using compounds of the type $E(OR)_y(BL)_x$ as precursors in sol-gel chemistry: (i) they have a lower reactivity than the parent alkoxides, (ii) organic functions can be introduced in the derived materials,[2] and (iii) the size of the primarily formed oxo particles can be controlled.[1] The primary hydrolysis products are the building blocks for organically modified non-silicate sol-gel materials. Chemical "nano-engineering" of sol-gel materials is only possible when several fundamental structural issues concerning the oxo clusters are understood and eventually controlled: (i) the coordination number of the central atom, (ii) the kind of linkage of the coordination polyhedra (vertex-, edge-, face-sharing), (iii) the number of shared vertices, edges, or faces, and (iv) the coordination mode of the organic ligands.

Carboxylates are often used as the bidentate ligands. One particular advantage of such compounds is that they allow the easy introduction of functional substituents. We recently succeeded in characterizing a coherent series of oxozirconium carboxylate clusters derived from the corresponding alkoxides.[3] The structures of $Zr_6(OH)_4O_4(OMc)_{12}$ (OMc = methacrylate), $[Zr_6(OH)_4O_4(acrylate)_{12}]_2$ and $Zr_6(OH)_4O_4(OOCR)_{12}(PrOH)$ [R = C(Me)=CH_2, C_6H_5] are highly condensed, with a $Zr_6(\mu_3\text{-}OH)_4(\mu_3\text{-}O)_4$ cluster core and octacoordinate zirconium atoms. When the Zr/bidentate ligand ratio is increased from 1:2 to 1:3, the structures open up, as in $Zr_4O_2(OMc)_{12}$ with a distorted butterfly structure (hepta- and octacoordinate Zr atoms)[3] or polymeric $[Zr(OnPr)(O_3SMe)_3]_\infty$ (heptacoordinate Zr atoms).[4] A high degree of substitution by bidentate ligands is possible because of the high coordination numbers of the zirconium atoms.

In contrast to the compounds discussed above, the maximum coordination number of titanium is 6. This restricts the maximum carboxylate/titanium ratio (x) of oxotitanium carboxylates to 2, i.e. to the composition $TiO(OOCR)_2$ (provided that all carboxylate ligands are bidentate). In oxotitanium carboxylate *alkoxide* derivatives x must be < 2 to accommodate the OR ligands. The maximum value of x found in structurally characterized oxotitanium carboxylate alkoxides to date is 1.33 in $Ti_6O_4(OR)_8(OOCR')_8$ [R′ = Me: R = Et, *n*Bu, *i*Pr;[5] R′ = C(Me)=CH_2: R = Et[6]]. Smaller degrees of substitution were found in $Ti_6O_4(OR)_{12}(OOCR')_4$ [R′ = Me: R = *i*Pr; R′ = μ_3-$CCo_3(CO)_9$: R = Et] and $Ti_4O_4(OR)_4[OOC{-}CCo_3(CO)_9]_4$ (R = *i*Pr, Ph).[7] The titanium atoms are octahedrally coordinated in all derivatives, and the carboxylate ligands are bridging. The linkage of the octahedra shows variations with the main difference between the cluster types being the ratio between shared vertices and edges.

Results

We have isolated a crystalline derivative of composition $Ti_9O_8(OPr)_4(OMc)_{16}$ (**1**) with $x = 1.78$. This compound was obtained by treating $Ti(OPr)_4$ with a 4-fold excess of methacrylic acid. The water for the hydrolysis of the OPr groups was generated in situ by esterification of methacrylic acid with the cleaved alcohol. We do not currently have any information regarding the sequence of the substitution and hydrolysis reactions necessary to convert $Ti(OPr)_4$ to **1**. We would like to emphasize that we did not intend to identify all products formed in this particular reaction. Instead, our goal was to gather additional structural information on carboxylate-substituted oxotitanium compounds as potential building blocks in titania-based inorganic-organic hybrid materials. The unusual structure of **1** is shown in Figure 1.

The compound consists of a ring of nine $[TiO_6]$ octahedra linked by six μ_2- and only two μ_3-oxide bridges. All titanium atoms are octahedrally coordinated and all methacrylate groups are bridging, as in the known oxotitanium carboxylates. However, the higher degree of substitution by

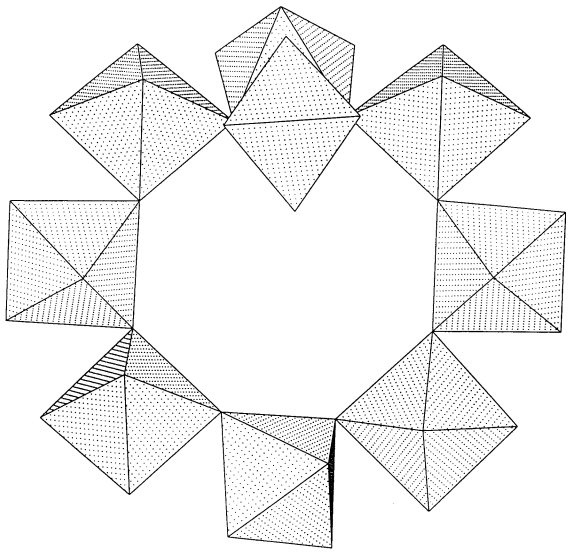
the bidentate carboxylate ligands forces the structure to become less condensed, since a coordination number larger than 6 (as in the Zr structures) is not possible. Unlike the less substituted derivatives, which are known, only two of the octahedra [Ti(8) and Ti(9)] share an edge, while the other octahedra [Ti(1)−Ti(7)] share *cis* vertices (Figure 2), i.e. only two oxygen atoms [O(215) and O(217)] are μ_3, while the remaining six oxygen atoms are μ_2.

All but two pairs of neighboring Ti octahedra are bridged by two methacrylate ligands. Ti(8)/Ti(9) and Ti(2)/Ti(3) are connected by only one methacrylate bridge, the second bridge is replaced by two OPr ligands (one at each Ti atom). This makes the macrocycle asymmetric with regard to the OPr substitution. There is a remarkable alternation in the bond distances of the μ_2-O bridges. With the exception of O(210), which bridges the OPr-substituted metal atoms Ti(2) and Ti(3), each μ_2-O bridge exhibits a long (190.1−193.4 pm) and a short (171.5−173.7 pm) Ti−O distance, although the *trans* substituent is the same (carboxylate bridge). The asymmetric Ti−O−Ti distances are compensated for by asymmetric carboxylate bridges, i.e. the Ti−O(carboxylate) distance *trans* to a short Ti−O(bridge) distance is lengthened [208.8−215.5 pm vs. 197.1−210.8 pm for the other Ti−O(carboxylate) distances].

Figure 2. Linkage of the coordination octahedra in $Ti_9O_8(OPr)_4(methacrylate)_{16}$ (**1**)



The overall structure is a balance between the sum of all coordination numbers and charges (c.n. 6 and charge +4 per titanium atom). The structural features in **1** can be understood by first considering a hypothetical structure of $[TiO_{2/2}(OOC-R)_2]_n$ with two bridging carboxylate ligands and one μ_2-oxide per formula unit. If two bridging carboxylate ligands are replaced by four monodentate OR groups, the sum of all c.n. is maintained, but there are two additional negative charges. These must be compensated for by the loss of one oxide. This, on the other hand, creates two empty coordination sites, which is compensated for by two other μ_2-oxygen atoms becoming μ_3. $[Ti(\mu_2\text{-}O)(OOCR')_2]_n$ is thus converted into $Ti_n(\mu_2\text{-}O)_{n-3}(\mu_3\text{-}O)_2(OR)_4(OOCR')_{2n-2}$. In all known oxotitanium alkoxide structures,[8] including the carboxylate-substituted derivatives mentioned above,[5][6][7] most $[TiO_6]$ octahedra share edges, and there is a substantial number of μ_3-oxygen atoms, characteristic of the rutile structure. In the structure of **1**, only one pair of octahedra shares an edge and, as a consequence, there are only two μ_3-oxygen atoms. This is an alternative way of expressing the above statement that a high value of x results in more open (= less condensed) structures.

The consequence for sol-gel processing is that for the first-row transition elements the bidentate ligand:metal ratio (x) should not be forced to high values if sufficiently condensed oxo structures are desired. A "natural" limit appears to be $x = 1.33$, as has been found in the structures of the $Ti_6O_4(OR)_8(OOCR')_8$ derivatives. Higher values of x result in polymeric rather than condensed structures. Only if the metal center can increase its coordination number beyond 6 do higher values of x still give condensed oxo clusters.

This work was supported by the *Fonds zur Förderung der wissenschaftlichen Forschung* (FWF).

Experimental Section

Preparation of **1**: 2.5 g (29 mmol) of methacrylic acid (Aldrich, as received) was mixed under Ar with 2.07 g (7.3 mmol) of $Ti(OPr)_4$ (Aldrich, as received) and stored in a closed Schlenk tube at ambient temperature. An orange solid (2.98 g) precipitated during 7 d, consisting of an approximate 1:1 mixture of an amorphous powder and colorless crystals. A suitable crystal was selected for X-ray structure analysis.

X-ray Structure Analysis for **1**: Monoclinic, space group *Ia*, a = 2357.24(5), b = 1855.37(1), c = 2610.62(6) pm, β = 112.933(1)°, $V = 10515.2(3)\cdot10^6$ pm^3, $d_{calcd.}$ = 1.362 g cm^{-3} for Z = 4. $F(000)$ = 4456, μ(Mo-K_α) = 0.727 mm^{-1}, λ = 71.073 pm, T = 203 K, crystal size = 0.14 × 0.10 × 0.08 mm. A crystal was sealed in a glass capillary and mounted on a Siemens SMART diffractometer with a CCD area detector. A hemisphere of data was collected by a combination of three sets of exposures (24943 reflections). Each set had a different ϕ angle for the crystal, and each exposure took 15 s and covered 0.3° in ω (2.8° ≤ 2Θ ≤ 46.0°). The data were corrected for polarization and Lorentz effects, and an empirical absorption correction (SADABS) was applied (10712 unique reflections). The structure was solved by direct methods (SHELS86). Refinement was carried out with the full-matrix least-squares method based on F^2 (SHELXL93) with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were inserted in calculated positions and refined riding with the corresponding atom. Refinement converged at R_1 = 0.069 [for 7062 reflections with $I > 2\sigma(I)$], wR_2 = 0.150 $\{w = [\sigma^2(F_o)^2 + (0.0887P)^2 + 17.77P]^{-1}$, where $P = (F_o^2 + 2F_c^2)/3\}$; final GOF = 1.064. The final difference map showed no peak larger than +0.942 e^{-3} and no hole larger than −0.359 e Å^{-3}.[9]

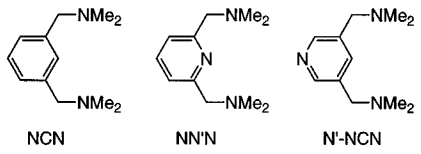
Keywords: Pyridine ligands / Bidentate bridging ligands / Palladium / Platinum / N ligands

The synthesis of the new potentially tridentate ligand 3,5-bis(dimethylaminomethyl)pyridine (**3**) is described. Coordination chemistry of this ligand has been investigated with Pd^{II} and Pt^{II} precursor compounds. Both a bidentate bridging bonding motif and a monodentate bonding mode is observed. The latter compounds incorporate **3** by coordination through the pyridinic N atom only. The former complexes contain ligand **3** bonded to 2 metal centres by bridging through coordination of one trialkyl N donor atom and the pyridinic N atom. The solid-state structure of a ligand bridged Pd dimer has been elucidated by single-crystal X-ray diffraction and corroborates with the solid-state IR data that suggested a *trans*-$PdCl_2$ unit was present.

Introduction

Organometallic and main-group complexes containing the terdentate ligand $[2,6\text{-}(Me_2NCH_2)_2C_6H_3]^-$ (NCN: "pincer" ligand; Scheme 1) have been extensively investigated in this laboratory over the past decade.[1][2] This work has involved a systematic study of the reactivity of these compounds with a concurrent investigation of their catalytic and electronic characteristics. Recently, we have begun to expand this chemistry to include functionalized versions of the NCN ligand containing synthetically useful groups in the *para* position of the arene ring. This has enabled the attachment of organometallic compounds to a variety of polymeric[3] and dendrimeric supports.[4] *para*-Substituted NCN ligands have also provided a convenient gateway into bi- and trimetallic systems,[5][6][7][8][9][10] and to hydrogen-bonded transition-metal networks ("molecular wires").[11][12] The introduction of a heteroatom in the aromatic ring, as in the case of the pyridine compound [2,6-$(Me_2NCH_2)C_5H_3N$] (NN′N; Scheme 1), represents a neutral version of the NCN ligand and results in modified reactivity of the resulting complexes incorporating this so-called "pyridine pincer".[13] Recent work has demonstrated that derivatives of NN′N containing a d^6 Ru^{II} metal centre present interesting structural and catalytic properties.[14]

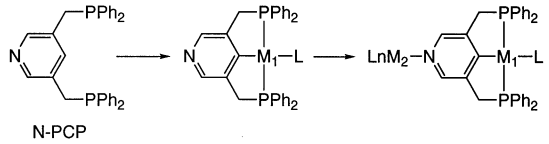
Scheme 1



Milstein and co-workers have recently described several rhodium and palladium complexes containing the related monoanionic diphosphanylpyridine ligand [3,5-$(Ph_2PCH_2)_2C_5H_2N]^-$ (N-PCP; Scheme 2). Subsequent coordination of the palladium compound [(N-PCP)PdCl] through the pyridinic nitrogen atom to a second metal center (M_2) was shown to influence the electron density of the coordinated Pd atom.[15a]

The reactivity of structurally similar pyridinium salts (specially of those derived from 3,5-pyridinediamides) towards various nucleophiles to form 1,2- and 1,4-dihydropyridines has also attracted recent attention. These compounds serve as models for NAD/NADH systems.[16] In this respect, the study of a ligand system derived from a 3,5-disubstituted aminopyridine presents an additional reason for investigation.

Scheme 2



We report herein the synthesis of the neutral pyridine-based ligand $[3,5\text{-}(Me_2NCH_2)_2C_5H_3N]$ (N′-NCN: **3**; Scheme 1), a potentially bridging ligand, and examine its coordination properties towards platinum and palladium in the 2+ oxidation state. Several coordination motifs are possible for this neutral N′-NCN ligand. Here the effect of the different Lewis basicity of the donor atoms (i.e. pyridine N vs. trialkyl amine N) towards various palladium and platinum precursors is investigated. Coordination through the trialkyl N atoms of the pincer "arms" or through the pyridinic N have been achieved depending on the reaction conditions. We have combined different NCN-based ligands in the same molecule, and have studied the reactivity of NCN-N′-metalated species (pyridinium ions) towards other metal precursors.

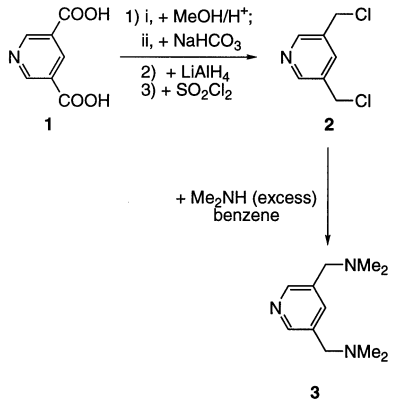
Results and Discussion

Ligand Synthesis

The starting compound 3,5-$(ClCH_2)_2C_5H_3N$ (**2**) was prepared from 3,5-$[HOC(O)]_2C_5H_3N$ (**1**) by a modified version of a previously published method (see Experimental).[16][17][18] The dimethyl ester of **1** was first reduced with excess of $LiAlH_4$ to the diol 3,5-$(HOCH_2)_2C_5H_3N$, which upon boiling with $SOCl_2$ gave compound **2** in 33% overall yield. The ligand 3,5-$(Me_2NCH_2)_2C_5H_3N$ (**3**) was synthesized in 90% yield by a reaction of **2** and an excess of Me_2NH in benzene (see Scheme 3). After subsequent drying ($MgSO_4$) and solvent evaporation, compounds **2** and **3** were assessed to be of sufficient purity by GC/MS, and ^{1}H- and $^{13}C\{^1H\}$-NMR spectroscopy for further synthetic applications.

Scheme 3



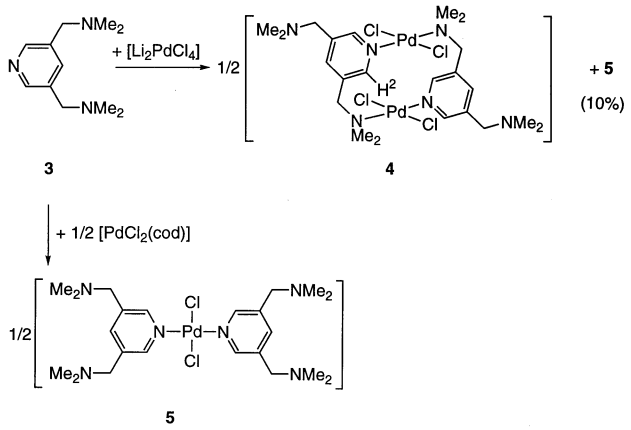
N′-NCN Coordination Compounds

With the aim of synthesizing orthometallated palladium complexes containing ligand **3**, the reaction between equimolar amounts of **3**, Li_2PdCl_4 and NaOAc in MeOH solution was investigated. Deprotonation of ligand **3** did not occur[15b] and immediate precipitation of compound **4** as a yellow solid took place (ca. 60% yield). Compound **4** could also be prepared in slightly higher yield by treating **3** with Li_2PdCl_4 (1:1) in MeOH. Small amounts of a second compound **5** were obtained in both these reactions (Scheme 4). This complex is the N(Py)-coordinated compound *trans*-$[Pd(N'\text{-}NCN)_2Cl_2]$ and was isolated in low yield (10%) from the mother liquor of the reactions. A high-yield synthesis of **5** is possible by using $PdCl_2(cod)$ (cod = cycloocta-1,5-diene) and excess **3**.

The ^{1}H-NMR spectra of compounds **4** and **5** show pronounced downfield shifts for hydrogen atoms assumed to be in close proximity to the metal atom compared with the corresponding values of free ligand **3**.

The ^{1}H-NMR spectrum at room temperature of compound **4** presents four singlets for the CH_2 and CH_3 groups. These are assigned to the non-coordinated arm (δ = 3.45, 2.22) and at lower field to the coordinated one [δ = 3.85 (br.), 2.66]. The signals of the three pyridine protons appear as three singlets at δ = 11.51, 8.47, and 7.58 (2-H, 6-H, and 4-H, respectively). It is assumed that a fast flip of the 12-membered ring that contains the two Pd atoms occurs in solution on the NMR timescale. This would explain the chemical shift equivalence between both diastereotopic protons of the CH_2 and CH_3 groups of the coordinated arm. The pronounced downfield shift observed for pyridine 2-H atoms upon coordination (Δδ = 3.1) contrasts with the small shift of the 6-H protons (Δδ = 0.06; Table 1). Such a high deshielding may be due to the proximity of this proton with respect to both a Cl and a Pd atom, as indicated by the short H···Cl and H···Pd interactions present in the solid-state structure (vide infra). Large downfield shifts of protons situated close to a d^8 metal center and above the bonding plane (pseudoaxial position) have been described in the literature and are attributed to the paramagnetic anisotropy of the metal atom[19] or to the presence of weak CH···M agostic interactions.[20] A deshielding effect is also expected for H atoms involved in short C−H···Cl contacts or in hydrogen bonds. The $^{13}C\{^1H\}$-NMR spectrum of **4** does not present any unusual features, revealing only four singlets for the two inequivalent CH_2 and NCH_3 groups and five singlets for the aromatic C atoms, in support of the above discussion (Table 2). The IR spectrum of **4** contains a band at 343 cm^{-1} that is assigned to the Pd−Cl stretching vibration of *trans*-dichloride ligands.

Scheme 4



The pyridinic 2,6-H and 4-H in compound **5** resonate as a doublet and a broad singlet at δ = 8.63 and 7.81, respectively in the ^{1}H NMR. The same resonances appear at δ = 8.41 and 7.62 in free **3**. The CH_2 and NCH_3 groups in **5** (singlets at δ = 3.45 and 2.26) have similar chemical shifts to those of **3** (Table 1). The $^{13}C\{^1H\}$-NMR spectrum of **5** presents five singlets of the coordinated ligand (Table 2). The *trans* configuration of compound **5** was supported by the presence of a single IR absorbance at 345 cm^{-1}, assigned to the Pd−Cl stretching vibration as in **4**.

(NCN)Pt(N′-NCN) Complexes

Previous publications have described the synthesis and reactivity of stable Pt complexes containing the monoanionic $[NCN]^-$ ligand. These compounds possess a variety of interesting properties involving the oxidative addition of halogens and alkyl halides (**6** and **7**: Scheme

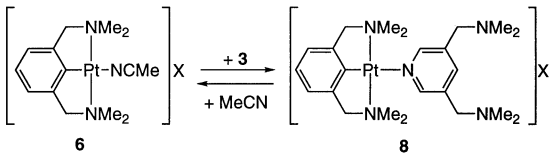
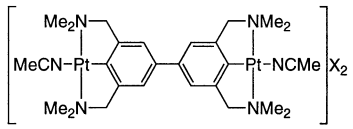
5).[1][10] Replacement of the coordinated MeCN ligands in complexes **6** and **7** by ligand **3** was therefore examined.

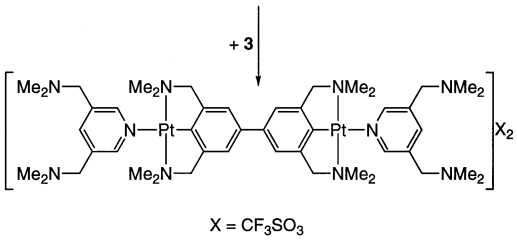
The starting compound **6** was prepared in situ by the reaction of the known complex PtCl[$(Me_2NCH_2)_2C_6H_3$][25] (**10**) with $Ag(O_3SCF_3)$ in MeCN (see Experimental Section). Compound **3** was then reacted separately with the cationic platinum complexes **6** and **7** in dry acetone to give the corresponding products **8** and **9** (Scheme 5). Displacement of MeCN by **3** takes place only when an excess of the latter is used. The structure proposed for compounds **8** and **9**, in which the ligand **3** coordinates to platinum through the pyridinic nitrogen atom, was confirmed by ^{1}H- and $^{13}C\{^1H\}$-NMR spectroscopy. These spectra show similar features to those of the parent compounds **7** and **10**, in addition to the resonances expected for coordinated **3**. Appropriate downfield shifts of the pyridinic 2,6-H and 4-H atoms with respect to **3** is observed, in addition to the presence of ^{195}Pt satellites associated with the resonance assigned to the 2,6-H of the pyridine ring (Table 1).

The addition of a drop of MeCN to a solution of **8** in [D_6]acetone resulted in partial conversion of **8** into the starting complex **6**, with liberation of free ligand **3**. This was observed in situ by ^{1}H-NMR spectroscopy. Compounds **8** and **9** are moisture-sensitive as slow ligand exchange processes between **3** and H_2O have likewise been observed (^{1}H NMR).

Scheme 5







The high lability of ligand **3** in compounds **8** and **9** made it difficult to draw conclusions concerning the subsequent coordination of **3** through the N atoms of the "arms". Thus, reaction of **9** with 2 equivalents of $PtCl_2(SEt_2)_2$ in dry acetone gave, among other non identified compounds, the neutral complex [ClPt(NCN−NCN)PtCl][10] which precipitated from the reaction mixture and was identified by its ^{1}H-NMR spectrum in $CDCl_3$.

In a subsequent reaction, ligand **3** and compound **8** were allowed to react with 1 equiv. of $[Pd(MeCN)_4](BF_4)_2$ in

[D_6]acetone. After 15 min, the ^{1}H-NMR spectrum of the reaction mixture showed the presence of at least three compounds. The most abundant product being complex **6**. Unfortunately, the minor components of the mixture could not be unequivocally assigned.

An ORTEP diagram representing the solid-state molecular structure of compound **4** in the crystal is depicted in Figure 1. Selected bond lengths and angles are listed in Table 3. The molecule of **4** has an inversion center at the center which is also a crystallographic inversion center. A distorted square-planar coordination at the Pd metal centre is observed. The value of the angles N1−Pd1−N3a are smaller than 180° [174.51(4)° and 172.9(1)°, respectively] and N3a is positioned significantly (0.24 Å) out of the plane determined by Pd1, Cl1, Cl2, and N1 (mean plane deviation 0.001 Å). This plane forms an angle of ca. 53° with the pyridine ring. The Pd1−Cl (average) and Pd1−N1 atom distances in complex **4** are 2.298(1) and 2.031(3) Å, respectively, and lie within the range observed in other *trans*-dichloropalladium(II) complexes containing pyridine ligands: 2.289−2.310 Å and 2.024−2.043 Å respectively.[21] The Pd1−N3a atom distance in **4** [2.102(3) Å] is similar to that found in related aryldimethylaminopalladium complexes.[10][22]

Figure 1. An ORTEP diagram (50-% probability level) of the molecular structure of complex **4** showing the adopted numbering scheme

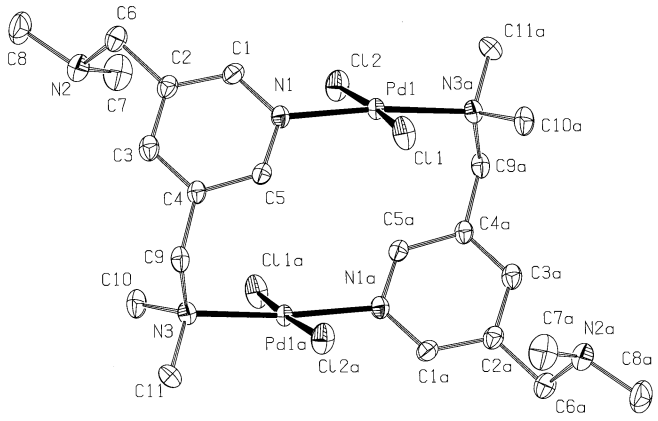


Table 3. Selected bond lenghts [Å] and angles [°] of compound **4**

Pd(1)−Cl(1)	2.2882(11)	Cl(1)−Pd(1)−Cl(2)	174.51(4)
Pd(1)−Cl(2)	2.3086(11)	Cl(1)−Pd(1)−N(1)	87.73(9)
Pd(1)−N(1)	2.031(3)	Cl(1)−Pd(1)−N(3a)	94.74(9)
Pd(1)−N(3)a	2.102(3)	Cl(2)−Pd(1)−N(1)	86.78(9)
		Cl(2)−Pd(1)−N(3a)	90.69(9)
		N(1)−Pd(1)−N(3a)	172.92(14)

The 12-membered ring containing the Pd atoms adopts a strained zigzag "chair"-like conformation which brings H51 close to both the Pd1a and the C11 atoms with H···Cl [2.73(3) Å] and H···Pd [2.69(2) Å] interatomic distances considerably shorter than the sum of the corresponding Van der Waals radii[23] (indicated by dotted lines in the Figure). Similar short Pd···H contacts have been identified in other Pd^{II} complexes.[19a][21b][21c][24] The C5−H51···C11 angle in complex **4** [109.6(19)°] is too far from linearity as to be considered a typical hydrogen bond. The intramolecular Pd···Pd distance [4.5997(8) Å] is virtually identical to the sum of their contact radii (4.6 Å).[23] Some of these features are comparable to those observed in other dipalladium ring systems described by Constable et al., e.g. [Pd_2Cl_4-{$Me_2N(CH_2)_nNMe_2$}$_2$] (n = 5, 7)[25] and [Pd_2Cl_4{Me_2NN=$CH(CH_2)_3CH$=$NNMe_2$}$_2$].[25b] The higher thermodynamic stability of these 16- and 20-membered cyclic systems with respect to their open-chain analogues has been explained in terms of entropy and conformational effects. Such influences can be derived from the presence of bulky NMe_2 groups occupying "corner positions" in the ring, the existence of double bonds in the ligand system, and/or the formation of short H···H and H···Pd attractive transannular interactions (e.g. 2.4 Å and 2.6−2.7 Å, respectively in [Pd_2Cl_4{$N(NMe_2)$=$CH(CH_2)_3CH$=$N(NMe_2)$}$_2$]).[25b] In spite of the obvious similarities between both our ligand system and complexes **3** and **4** and those studied by Constable et al., we suggest that short intramolecular interactions present in complex **4** (a more rigid system) may be due to geometrical contraints within the molecule, and not to forces of attractive nature. However, it is noticeable that although a certain degree of flexibility of the ring at room temperature in solution has been shown by ^{1}H-NMR spectroscopy (vide supra), short H···Cl and/or H···Pd contacts still appear to be important in solution.

Conclusions

It has been demonstrated that the potentially multidentate ligand 3,5-bis(dimethylaminomethyl)pyridine (**3**) can be synthesized in good yield from the corresponding bis(chloromethyl)pyridine. The coordination versatility of **3** has been shown in complex **4**, where N_{py}−Pd and Me_2N−Pd bonds are present, and in complexes **5**, **8**, and **9** in which only bonding through N_{Py} are observed. The three latter complexes represent a linear geometry of the NCN and N′-NCN ligands and thus are a potential starting point for the synthesis of organometallic chains. Our attempts to ligate the free NMe_2 groups of **8** and **9**, and hence to increase the number of metal centres, has not so far been successful. This may be a manifestation of the inherit lability of the N_{py}−M bond in these compounds.

This work was supported in part (A. L. S. and W. J .J. S.) by the *Netherlands Foundation of Chemical Research (SON)* with financial aid form the *Netherlands Organisation for Scientific Research (NWO)*. Mr. *Bert T. G. Lutz*, Department of Analytical Molecular Spectrometry, Faculty of Chemistry, Utrecht University is gratefully acknowledged for the infrared analyses of compounds **4** and **5**. Pruiksma* for assistance in the preparation of this manuscript.

Experimental Section

General: All experiments were conducted under dry nitrogen using standard Schlenk techniques. Solvents were dried over appropriate materials and distilled prior to use. − Elemental analyses were performed by Dornis und Kolbe, Mikroanalytisches Labora-

torium (Mülheim, Germany). – ^{1}H- and ^{13}C{^{1}H}-NMR spectra were recorded at 298 K with a Bruker AC200 or AC300 spectrometers. – Infrared spectra were recorded as Nujol mulls deposited on disposable polyethene substrates (700–100 cm^{-1}) with a Perkin Elmer Model 2000 FT-IR spectrometer equipped with a MIRTGS (for MIR) and FIRTGS (for FIR) detector. The instrument was flushed with nitrogen and connected to a PC under SPECTRUM software. – Melting (decomposition) points were measured using a Büchi melting-point apparatus. The boiling point of compound **3** was determined by the Siwoloboff method. – GC/MS analyses were recorded with a Unicam Automass instrument using electron impact (EI, 70eV). – Starting materials: $[Li_2PdCl_4]$[26] and $[PdCl_2(cod)]$[27] were prepared according to literature procedures. $Ag(O_3SCF_3)$ was purchased from Aldrich and $C_5H_3N(CO_2H)_2$-3,5 (**1**) from Avocado.

Synthesis of 3,5-(ClCH$_2$)$_2$C$_5$H$_3$N (**2**):[28] To a suspension of $LiAlH_4$ (1 g, 26.3 mmol) in Et_2O (25 ml) was added 3,5-$[MeO(O)C]_2C_6H_3N$ (1.7 g, 8.7 mmol).[29] The resulting yellow mixture was stirred for 15 h and MeOH (50 ml) was then added slowly to destroy excess $LiAlH_4$. The solvent was then removed in vacuo and the residue extracted in a Soxhlet apparatus with MeOH (12 h). The solution was subsequently concentrated to to give 3,5-$(HOCH_2)_2C_5H_3N$ as a yellow oil [^{1}H NMR (CD_3OD, 300 MHz), δ = 8.42 (s, 2 H, 2,6-Py*H*), 7.82 (s, 1 H, 4-Py*H*), 4.66 (s, 4 H, C*H*$_2$)]. Thionyl chloride (150 ml) was then added to the oil and the mixture refluxed for 18 h yielding a brown suspension. Excess of $SOCl_2$ was distilled off (vacuo) and the flask placed in an ice bath. Aqueous NaOH (100 ml; 4 M) was added slowly to the residue. The aqueous layer was then extracted with CH_2Cl_2 (4 × 25 ml) and the combined organic layers were dried with $MgSO_4$. The solvent was then removed in vacuo to give **2** as an off-white solid (2.9 g, 47% yield based on the starting ester). Mp: 86°C. – MS (EI, 70 eV); *m/z* (%): 175 (22.1) [M$^+$], 140 (100), 104 (11.0), 77 (25.0), 51 (16.3).

Synthesis of 3,5-(Me$_2$NCH$_2$)$_2$C$_5$H$_3$N (N′-NCN; **3**): A three-necked round-bottom flask was placed in an ice bath and charged with benzene (20 ml) and Me_2NH (17 ml, 255 mmol). A solution of **2** (2.4 g, 13.8 mmol) in 200 ml of benzene was then added via a dropping funnel during 30 min. The reaction mixture was allowed to reach room temperature and then stirred for 1 h yielding a yellow suspension which was concentrated in vacuo to ca. 100 ml and subsequently filtered. The filtrate was concentrated to dryness to give the product **3** as an orange liquid, which was dissolved in pentane and dried with $MgSO_4$ overnight (yield: 2.4 g, 90%). Bp: 178–180°C.[24] – MS (EI, 70 eV); *m/z* (%): 193 (3.8) [M$^+$], 150 (100), 105 (73.1), 77 (40.4), 58 (99.0).

Synthesis of μ-[{η^1-N,N′-3,5-(Me$_2$NCH$_2$)$_2$C$_6$H$_3$N}(PdCl$_2$)]$_2$ (**4**): To a solution of $[Li_2PdCl_4]$ (0.19 mg, 0.724 mmol) in MeOH was added **3** (0.14 mg, 0.724 mmol). The resulting yellow suspension was stirred overnight and then filtered. The solid thus obtained was then washed with MeOH and Et_2O and subsequently dried in vacuo. Compound **4** was isolated as a yellow solid, which was recrystallized from CH_2Cl_2 /Et_2O and dried on P_2O_5 (yield: 0.18 g, 67%). Mp: 179–180 (dec.)°C. – IR [υ(PdCl)]: $\tilde{\nu}$ = 343 cm^{-1}. – $C_{22}H_{38}Cl_4N_6Pd_2$: calcd. C 35.65, H 5.16, N 11.34; found: C 35.31, H 5.23, N 11.08.

Synthesis of trans-[{η^1-3,5-(Me$_2$NCH$_2$)$_2$C$_6$H$_3$N}$_2$PdCl$_2$] (**5**): To a solution of $[PdCl_2(cod)]$ (63 mg, 0.22 mmol) in CH_2Cl_2 was added an excess of **3** (172 mg, 0.891 mmol). After 30 min, the solution was concentrated in vacuo to approximately 2–3 ml and Et_2O was then added to precipitate the product (**5**) as a pale yellow solid. This was washed with Et_2O and dried (yield 70 mg, 60% yield). Mp: 110°C (dec). – IR [υ(PdCl)]: $\tilde{\nu}$ = 345 cm^{-1}. – $C_{22}H_{38}Cl_2N_6Pd$: calcd. C 46.86, H 6.79, N 14.90; found: C 46.53, H 6.92, N 14.47.

Synthesis of [{η^1-3,5-(Me$_2$NCH$_2$)$_2$C$_6$H$_3$N}Pt{η^3-NCN-2,6-(Me$_2$NCH$_2$)$_2$C$_6$H$_3$}](CF$_3$SO$_3$) (**8**): To a solution of [(η^3-NCN-2,6-{Me_2NCH_2}$_2$C$_6$H$_3$)PtCl][18] (96.4 mg, 0.228 mmol) in MeCN was added $Ag(O_3SCF_3)$ (64.4 mg, 0.250 mmol). The resulting suspension was stirred for 10 min and then filtered through a plug of Celite. The filtrate was concentrated to dryness and washed with Et_2O to give compound **6** as a colorless solid. Complex **6** was then dissolved in dry acetone and **3** (74 mg, 0.38 mmol) was added to the solution. Upon addition of Et_2O to the reaction mixture, compound **8** precipitated as a colourless solid, which was filtered, washed with Et_2O, and dried in vacuo (yield: 140 mg, 85%). Mp: 165°C (dec). – $C_{24}H_{38}F_3N_5O_3PtS$: calcd. C 39.56, H 5.26, N 9.61; found C 39.32, H 5.36, N 9.42.

Synthesis of [{η^1-3,5-(Me$_2$NCH$_2$)$_2$C$_6$H$_3$N}Pt{η^3-NCN-2,6-(Me$_2$NCH$_2$)$_2$C$_6$H$_2$}](CF$_3$SO$_3$)$_2$ (**9**): To a solution of **7** (51.9 mg, 0.045 mmol)[10] in dry acetone was added an excess of **3** (80 mg, 0.41 mmol). The resulting yellow solution was stirred at room temperature for 30 min. The solvent was then removed in vacuo and the residue washed with Et_2O (2 × 5 ml) to give **9** as a pale yellow solid (yield: 50 mg, 76%). Mp: 137–140°C (dec). – ^{19}F{^{1}H} NMR [$(CD_3)_2CO$, 200 MHz], δ = –77.9 (s, C*F*$_3$SO$_3$). – $C_{48}H_{74}F_6N_{10}O_6Pt_2S_2$: calcd. C 39.61, H 5.12, N 9.62; found C 39.54, H 5.04, N 9.46.

X-ray Structure Determination of Complex **4**: X-ray data were collected for an orange needle-shaped crystal at 150 K with an Enraf-Nonius CAD4T on rotating anode. Numerical data on the structure determination are collected in Table 4. The unit-cell parameters were derived from the 25 SET4[30] setting angles. The structure was solved with automated Patterson techniques using DIRDIF96[31] and refined on F^2 using the program SHELX96.[32] All other calculations (including the ORTEP illustration) were done with PLATON.[33]

Keywords: Ligand field spectra / Phosphonate complexes / X-ray structures

The synthesis and characterization of transition-metal coordination compounds containing the ligand diethyl 2-quinolylmethylphosphonate (2-qmpe) is described. Complexes of Co^{II}, Mn^{II}, Ni^{II}, Cd^{II}, and Zn^{II} were found to be mutually isomorphous according to their X-ray powder diffraction patterns and IR spectra. The new coordination compounds were identified and characterized by elemental analysis, magnetic measurements, infrared and ligand-field spectra. The crystal structures of the complexes $[M(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$ (M = Ni, **1**; Mn, **2**) reveal six-coordinate $[M(2\text{-qmpe})_4(H_2O)_2]$ cations with the qmpe ligand coordinating via the oxygen rather than via the nitrogen atom, as well as lattice perchlorate anions. The metal ion is octahedrally surrounded by the four oxygen atoms of the four organic ligands. The non-participation of the pyridine nitrogen atom is unusual. The two water molecules occupy the fifth and the sixth coordination sites in a *trans* configuration. The coordinated water molecules are strongly hydrogen-bonded to the pyridine nitrogen atom of the 2-qmpe, further stabilizing the solid-state structure. The geometry of the metal ion can be described as distorted octahedral. For the Cu^{II} complex, a hydroxo-bridged dinuclear structure of the type $[Cu(2\text{-qmpe})_2(OH)(H_2O)_2]_2(ClO_4)_2$ is proposed, based on its spectroscopic and magnetic properties. Ligand-field spectra of the Co and Ni compounds were found to be in agreement with the tetragonally distorted octahedral geometry.

Introduction

During the last decade there has been a great increase in interest in ligands containing a phosphoryl group and a heterocyclic ring[1]. Organophosphorus derivatives of pyridine and quinoline with the phosphonic chain *ortho* or *para* with respect to the endocyclic nitrogen atom have been shown to possess significant bactericidal and herbicidal activity. Coordination compounds of phosphonic acids and their esters with transition-metal ions have been the subject of several studies due to the fact that complexes of such compounds exhibit biological activity[1][2][3][4][5][6][7][8][9][10][11][12][13][14]. In recent years, platinum(II) complexes of phosphonate ligands have attracted attention as a result of their significant antitumor activity[8]. Phosphonate ligands bearing a heterocyclic ring have some interesting features with regard to their coordination chemistry; they contain two potential donor atoms, the heterocyclic nitrogen and phosphoryl oxygen atoms, in a suitable orientation for chelation. Over the years, we have studied in detail the complex-forming properties of phosphonate ligands towards transition-metal ions. The coordination behaviour of pyridylmethylphosphonate ligands was examined by single-crystal X-ray structure determinations, which showed that various coordination modes are possible[10][28]. In a previous study, the results of spectroscopic and magnetic studies on transition-metal complexes with diethyl 2- and 4-pyridylmethylphosphonate ligands (2-pmpe, 4-pmpe), as well as the structures of high-spin $[Co(4\text{-pmpe})_4(H_2O)_2](ClO_4)_2(H_2O)_2$, where the ligand bridges the cobalt ions with both ends of the molecule coordinating to a different metal ion forming infinite chains, and of $[Co(2\text{-pmpe})_2Cl_2]$, where the 2-pmpe acts as a bidentate N,O-bonded chelate ligand, were reported[10]. As the biological activity of coordination compounds depends on the presence of metal ions[6], we have studied the biological properties of complexes with pyridylmethylphosphonate ligands. Preliminary investigations have shown that 2-pyridylmethylphosphonic acid labelled with technetium (^{99m}Tc) forms a complex, which when administered to rats shows a high re-

nal clearance value[15a]. Recently, we investigated the effect of *cis*-$[PtCl_2(4\text{-pmpe})_2]$ and *cis*-$[PtCl_2(NH_3)_2]$ on murine mast cells[11] and on the aggregation of platelet-rich plasma[12]. Both of the complexes tested were found to activate mast cells so as to secrete histamine by a non-cytotoxic, active secretory process[11]. *cis*-Platinum complexes incorporating diethyl 2-, 3-, or 4-pyridylmethylphosphonate ligands showed in vivo cytostatic activity against mice Sa180 sarcoma solid tumours[13] and were found to exhibit alkylating activity in vitro[14]. In order to broaden the scope of this work and to determine the effects of the additional benzene ring, we have now extended our studies to the diethyl 2-quinolylmethylphosphonate ligand (2-qmpe). The 2-qmpe ligand, which has the desired 2-quinolyl group as well as a phosphonate group, can act either as a monodentate N-bonded, as a monodentate O-bonded, or as a bidentate N,O-bonded chelate ligand in forming coordination compounds with transition-metal ions. In the present work, we report on a modification of a previously[15] reported synthesis of diethyl 2-quinolylmethylphosphonate that simplifies the procedure and results in improved yields. We also report on the synthesis, spectroscopic and magnetic properties of coordination compounds of the 2-qmpe ligand with several transition-metal ions and perchlorate ions. These were investigated with regard to their structural and magnetic properties, which provide a chemical basis for the biological activity. The representative compounds $[Ni(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$ (**1**) and $Mn(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$ (**2**) were chosen for X-ray crystallographic studies in an attempt to determine which of the potential binding sites of the 2-qmpe ligand, N or O, is attached to the metal centre, as well as to allow comparison with the previously published crystal stucture of $[Co(4\text{-pmpe})_2(H_2O)_2](ClO_4)_2(H_2O)_2$. The structure of **2** is described in detail.

Results and Discussion

General

The condensation of 2-chloromethylquinoline with triethyl phosphite affords diethyl 2-quinolylmethylphosphonate (2-qmpe). The synthesis of 2-qmpe from 2-chloromethylquinoline by the reaction with diethyl sodium phosphite has been reported previously[15]. In the present investigation, we modified a previously reported[15a] synthesis of 2-qmpe, resulting in a simplified procedure and increased yields. The ligand was synthesized by the phosphorylation of 2-chloromethylquinoline with triethyl phosphite and checked for purity by spectroscopic and analytical methods.

The 2-qmpe system is a powerful ligand able to form coordination compounds of the types $[M(2\text{-qmpe})_4(H_2O)_2]_2(ClO_4)_2$, [M = Co^{II}, Ni^{II}, Mn^{II}, Cd^{II}, or Zn^{II}] and $[Cu(2\text{-qmpe})_2(OH)(H_2O)_2]_2(ClO_4)_2$. The structures of the complexes were unambiguously confirmed by a combination of NMR and IR experiments and by elemental analyses. Analytical data are reported in Table 1. A hydroxo-bridged structure is proposed for the Cu^{II} compound, which is supported by chemical and physical evidence. Dinuclear copper compounds having one or two OH groups as bridging ligands are known[16] and are magnetically interesting.

Table 1. Analytical[a] data for the diethyl 2-quinolylmethylphosphonate complexes

No.	Complex	Analysis (%)					M.p.
		M	H	C	N	P	[°C]
1	$[Co(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$	4.21 (4.18)	5.35 (5.43)	47.33 (47.67)	3.66 (3.97)	8.85 (8.78)	122−125

[a] Calculated values are given in parentheses.

Spectroscopic Studies

Ligand-field spectra (Table 2) of the nickel(II) compound exhibit three spin-allowed bands which, in order of decreasing energy, are assigned to the $^3T_{1g}(P) \leftarrow {}^3A_{2g}$ (υ_3), $^3T_{1g}(F) \leftarrow {}^3A_{2g}$ (υ_2), and $^3T_{2g} \leftarrow {}^3A_{2g}$ (υ_1) transitions[17]. In addition, a shoulder at ca. 21050 cm^{-1} in-forbidden [$^1T_{2g} \leftarrow {}^3A_{2g}$ (υ_5)] and a weak absorption at 15750 cm^{-1} [$^1E_g \leftarrow {}^3A_{2g}$ (υ_4)] are observed. The origin of the υ_4 band has been discussed elsewhere[17][18]. The υ_1 band shows weak signs of a splitting, which can be attributed to the lower, tetragonal symmetry of the nickel(II) compound. A complete assignment of the components in D_{4h} symmetry was not considered as meaningful, in view of the broad bands. The calculated value for D_q is in the lower range for Ni^{II}, reflecting the weak ligand field for phosphoryl ligands. Spectroscopic studies dealing with spectral and magnetic characterization of the nickel compounds have recently been reported[19].

The electronic spectra of the cobalt(II) compound exhibit three spin-allowed bands, corresponding to the $^4T_{2g} \leftarrow {}^4T_{1g}(F)$ (υ_1), $^4A_{2g} \leftarrow {}^4T_{1g}(F)$ (υ_2), and $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$ transitions. The υ_2 transition usually appears as a weak peak, so that accurate determination of the band maximum is not possible. A shoulder at ca. 21000 cm^{-1} on the high-energy side of the visible band is assigned to spin-orbit components and to a spin-forbidden transition[20]. The asymmetric near-IR band υ_1 gives evidence for octahedral stereochemistry, albeit tetragonally distorted[17]. The crystal-field parameters B and D_q were calculated using well-known methods[20]. The relatively high values of the ligand-field Racah parameter B might reflect the deviation from octahedral geometry[17].

The copper(II) complex exhibits one broad asymmetric d-d band at 13200 cm^{-1}, associated with the $^2T_{1g} \leftarrow {}^2E$ transition in O_h symmetry. The position and shape of this band indicate tetragonally elongated octahedral geometry[21][22].

The extremely low values of the intensities of the bands for the octahedral manganese(II) complex are not unusual[17]. The spectrum shows bands as shoulders on a high-energy ligand or CT band at ca. 25000 cm^{-1} and ca.

19000 cm^{-1}, which can be assigned to $^4A_{1g}$, $^4E_g(G) \leftarrow {}^6A_{1g}$ and $^4T_{1g}(G) \leftarrow {}^6A_{1g}$ transitions, respectively. The other characteristic bands for d-d transitions are masked by UV absorption and are difficult to recognize in the complex and thus the ligand-field parameters cannot be calculated.

In general, the IR spectra of all the complexes appear complicated and a complete assignment of each spectrum is difficult. Only some observations concerning the major bands will therefore be discussed. The IR spectra of the complexes of Co^{II}, Ni^{II}, Mn^{II}, Cd^{II}, and Zn^{II} are very similar with respect to band positions, shapes, and relative intensities, indicating a similar conformation for the five compounds. X-ray powder patterns also showed these five complexes to be mutually isomorphous. The IR spectrum of the Cu^{II} compound, however, indicates quite different structural features.

Evidence for the presence of ClO_4^- was obtained from the infrared spectra. All of the perchlorate compounds show a strong band near 1100 cm^{-1} (asymmetric stretch), a sharp band at 625 cm^{-1} (asymmetric bend) and a very weak absorption at 930−935 cm^{-1} (symmetric stretch), indicative of uncoordinated perchlorate anions[23][24].

The absorption bands attributed to the C=C and C=N of the quinoline ring, observed in the region 1600−1500 cm^{-1} in the free ligand, remain unchanged upon complex formation, confirming non-involvement of the quinolyl nitrogen atom in the metal coordination. In the far-IR region, no metal−nitrogen stretching vibrations are observed.

The absorption band at 1255 cm^{-1}, which corresponds to the P=O stretching of the ligand, is shifted by ca. 15−20 cm^{-1} towards lower frequencies in the spectra of all the complexes, in agreement with coordination of the phosphoryl group to the metal(II) ion[25].

In all the complexes, coordinating water is present. The δ(H−O−H) bending vibrations of coordinated water are observed at 1600−1650 cm^{-1}, whereas the O−H stretching bands are observed around 3400−3600 cm^{-1}. In the spectrum of the Cu^{II} compound, bands at 884 cm^{-1} and 530 cm^{-1} are assigned to H_2O rocking and wagging modes, respectively. On the other hand, the band observed at 440 cm^{-1} is attributable to Cu−O (for coordinated water) stretching vibrations[23]. A very sharp infrared peak at 3540 cm^{-1} can be assigned as the υ(OH) stretching frequency of the hydroxo bridge[26]. Furthermore, the investigated complex exhibits the bridging (Cu−OH) bending mode at 950 cm^{-1}. Support for the assignment of the bridge between two copper centres comes from the absorption at about 520 cm^{-1}, which appears as a doublet (asymmetric and symmetric modes) due to υ(Cu−O) copper−oxygen stretching OH vibrations[27].

^{1}H-NMR spectroscopy is a useful tool for the investigation of complexes of methylphosphonate ligands with N-heterocyclic rings, since coordination of the metal ion via N gives rise to a characteristic downfield shift of the proton signals of the CH_2−P methylene group[28] and this seems to be a general trend in such complexes[2]. We observed[28] a remarkable downfield shift for *trans*-dichlorobis(diethyl 2-pyridylmethylphosphonato-*N*)palladium(II), [Pd(2-pmpe)$_2$Cl$_2$]. Most notable is the downfield shift of 1.17 ppm for the CH_2 signal, which may be explained by the decrease in electron density in the pyridine ring caused by the coordination to the metal ion. In fact, a crystal-structure determination[28] of *trans*-[Pd(3-pmpe)$_2$Cl$_2$] confirmed that the metal ion is bound in a monodentate fashion to the pyridine-N. Comparison of the chemical shifts of the cadmium(II) (**5**) and zinc(II) (**6**) coordination compounds with those of the free 2-qmpe ligand enables us to make an assignment of the ^{1}H-NMR signals. The ^{1}H-NMR spectra of complexes **5** and **6** show the signals hardly shifted in comparison with those of the free ligand. The signal that appears as a doublet due to ^{31}P-^{1}H coupling is assigned to the CH_2−P protons and is not shifted upon coordination to the transition-metal centre. This clearly implies a lack of electron transfer from the quinoline to the metal centre and indicates that the pyridine nitrogen atom does not participate in coordination.

The effective magnetic moments (Table 2) of the cobalt(II), nickel(II), and manganese(II) complexes are within the usually observed ranges of experimental values for high-spin complexes in octahedral configurations[29]. Cadmium(II) and zinc(II) complexes are diamagnetic. Variable-temperature (4.2−294 K) magnetic susceptibility measurements (Table 2, Figure 1) of the Cu^{II} complex clearly indicate a magnetic interaction between the paramagnetic centres, suggesting a hydroxo-bridged [Cu(2-qmpe)$_2$(OH)(H$_2$O)$_2$]$_2$(ClO$_4$)$_2$ dinuclear structure. The susceptibility curve for this compound increases with decreasing temperature until a maximum is reached at 73 K. Below 73 K, the susceptibility χ_M (and μ_{eff}) decreases markedly with decreasing temperature. The μ_{eff}(Cu) at 294 K is 1.91 B.M., which is in the range expected for an octahedral Cu^{II} ion. In the molecular antiferromagnetics under study, the magnetic interactions are limited to two magnetic centres, the singlet-triplet separation defined as 2*J* being a measure of this effect. This parameter was determined by fitting the results to the modified Bleaney-Bowers expression[30]

$$\chi_{Cu}^{corr} = \frac{Ng_{av}^2\beta^2}{3kT}[1 + 1/3(e^{-2J/kT})]^{-1}(1-x) + (\frac{Ng_{imp}^2\beta^2}{4kT})$$

where $\chi_{Cu}{}^{corr}$ is the molar magnetic susceptibility calculated per copper(II) ion, *J* is the exchange parameter in the Heisenberg-Dirac-van Vleck Hamiltonian ($H = -2JS_1S_2$), *p* is the percentage of monomeric form of the complex, and other symbols have their usual meaning. In the least-squares fitting procedure, two parameters were calculated, the singlet-triplet 2*J* energy gap and *g*; these values amounted to −80 cm^{-1} and 2.34, respectively. The agreement factor *R* was found to be 3.97×10^{-3}, where $R = \Sigma_i[(\chi_i{}^{exptl} - \chi_i{}^{calcd})^2 / (\chi_i{}^{exptl})^2]$

The EPR X-band powder spectrum of the Cu^{II} compound does not exhibit absorption, suggesting a strong

magnetic interaction, e.g. as in a dinuclear unit. Such interactions can be transmitted by hydroxy ligands, resulting in an EPR-silent spectrum[31].

The nickel compound does not exhibit an X-band EPR spectrum. The cobalt compound shows no lines at room temperature, but one line is seen at 77 K at $g = 5.80$. The EPR spectrum of the Mn^{II} complex consists of a single, broad, asymmetric line. A hyperfine structure (6 lines) typical for a $^{55}Mn^{II}$ ion is not resolved, and only some fine-structure due to zero-field splitting is visible, which is not uncommon for Mn^{II}[32].

Crystal Structure Determination

Relevant bond-length and bond-angle information for $[Ni(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$ (**1**) is given in Table 3. The Ni atom has crystallographically imposed inversion symmetry and is in a distorted octahedral environment, of which the equatorial coordination sphere is formed by the four O-donor atoms of the phosphoryl groups of the 2-qmpe ligands. The axial ligands are two water molecules. The molecular structure is stabilized by hydrogen bonds donated by these water molecules to the quinoline nitrogen atoms (see Table 4). The isomorphous Mn compound **2** displays the same molecular structure and crystal packing. The molecular structure of $[Mn(2\text{-qmpe})_4(H_2O)_2](ClO_4)_2$ is shown in Figure 2. The water molecules bound to the manganese ion are also hydrogen-bonded to the nitrogen atom at a very short distance O−H···N = 2.799 Å. The structure as a whole is stabilized by intramolecular hydrogen-bond interactions.

Conclusions

A number of new coordination compounds with the diethyl 2-quinolylmethylphosphonate ligand have been synthesized. To the best to our knowledge, the results described herein show for the first time that, unexpectedly, the ligand 2-qmpe coordinates to M^{II} through the oxygen atom of the phosphonate group, and not through the pyridine nitrogen atom. This may be attributable to steric factors. Intramolecular O−H···N hydrogen bonds from H_2O toward N seem to stabilize the complexes. The complexes of Co^{II}, Ni^{II}, Mn^{II}, Cd^{II}, and Zn^{II} are six-coordinate, having four 2-qmpe ligands and two *trans* water molecules in a tetragonally elongated octahedral stereochemistry (MO_6 chromophore), as revealed by the crystal-structure determinations. The non-participation of the pyridine group is unusual. A contribution of the pyridine nitrogen atoms was observed in related ligands in an earlier study[10][28], when the reactivity of pyridylmethylphosphonate ligands towards transition-metal ions was studied. For the Cu^{II} compound, a hydroxo-bridged dinuclear structure is proposed, i.e. $[Cu(2\text{-qmpe})_2(OH)(H_2O)_2]_2(ClO_4)_2$; this is supported by chemical analysis and the antiferromagnetic coupling evident from the magnetic susceptibility data.

In summary, we have demonstrated that the P=O donor atom in the 2-qmpe ligand has a very high affinity towards divalent transition-metal ions. These observations may have important consequences, as subsequent studies will deal with platinum pyridyl- and quinolylmethylphosphonate complexes, which can be regarded as antitumour agents.

and at 77 K (liquid nitrogen). Solid diphenylpicrylhydrazyl (dpph) was used as the reference and magnetic fields were calibrated with proton and lithium NMR probes. − NMR: ^{1}H-NMR spectra were recorded with a Bruker MSL-300 spectrometer employing a frequency of 300 MHz, TMS as internal standard. − ^{31}P-NMR spectra were recorded with a Bruker MSL-300 instrument at 121.496 MHz with 85% phosphoric acid as external standard. − Magnetic susceptibility measurements: See below.

2-Chloromethylquinoline: 1.0 g (5.0 mmol) of 2-chloromethylquinoline hydrochloride was dissolved in 75 ml of water and the solution was brought to pH ≈ 8 by the addition of Na_2CO_3. The yellow product was filtered and dried in vacuo. Yield: 0.7 g (84%), m.p. 43−45°C (petroleum ether). − IR (KBr): $\tilde{\nu}$ = 700−900 cm^{-1} (CH), 1400−1700 (C=N), 3000−3800 (CH). − ^{1}H NMR ($CDCl_3$): δ = 4.82 (s, 2 H, CH_2Cl), 7.52−8.20 (m, 6 H, aromatic H).

Diethyl 2-Quinolylmethylphosphonate: A mixture of 2-chloromethylquinoline (1.77 g, 1·10^{-2} mol) and triethyl phosphite (25 ml, 1.4·10^{-1} mol) was stirred under reflux for 24 h. After this period, TLC analysis indicated complete phosphorylation. The excess triethyl phosphite was then evaporated yielding a yellow oil. Colorless diethyl 2-quinolylmethylphosphonate was obtained by distillation in vacuo. Yield: 2.2 g (78%). − ^{1}H NMR ($CDCl_3$): δ = 1.23 (t, $^3J_{HH}$ = 7 Hz, 6 H, 2 POCH$_2$CH_3), 3.63 (d, $^2J_{HP}$ = 22 Hz, 2 H, CH_2P), 4.13 (dq, $^2J_{POCH}$ = 7 Hz, $^3J_{HH}$ = 7 Hz, 4 H, 2 POCH_2CH$_3$), 7.36−8.23 (m, 6 H, aromatic H). − ^{31}P{^{1}H} NMR ($CHCl_3$): δ = 24.53.

Preparation of the Complexes: The coordination compounds were synthesized by addition of the appropriate hydrated metal perchlorate (1 mmol), dissolved in 10 ml of water, to a solution of 2-qmpe (4 mmol) in 20 ml of ethanol. The resulting solutions were filtered to remove any insoluble material. Following evaporation of the solvent at room temperature, the compounds crystallized after a few days. Crystals of **1** and **2** suitable for single-crystal X-ray diffraction studies were grown from saturated ethanolic solutions of the complexes at room temperature. The Mn, Ni, Co, Cd, and Zn compounds are isomorphous, as shown by X-ray powder diffraction experiments.

Magnetic Measurements: Magnetic susceptibility measurements (80−300 K) were carried out using the Gouy method on a sensitive Cahn RM-2 electronic balance at a magnetic field strength of 9.9 kOe. Over the temperature range 4.2−300 K, measurements were made by the Faraday method, using a Cahn RG-HV electrobalance and a magnetic field of 5.25 kOe. The standard employed for calibration was $HgCo(NCS)_4$, for which the magnetic susceptibility was taken as 16.44·10^{-6} cm^3 g^{-1}. Corrections for diamagnetism of the constituent atoms were made by using Pascal constants. The effective magnetic moments were calculated from μ_{eff} = 2.83 $(\chi^M T)^{1/2}$, after corrections for temperature-independent paramagnetism of 60·10^{-6} (Cu^{II}) and 220·10^{-6} cm^3 mol^{-1} (Ni^{II}).

X-ray Crystallography: Crystals of **1** and **2** (both colorless) suitable for X-ray diffraction were glued to the tip of a Lindemann glass capillary and transferred to an Enraf-Nonius CAD4 diffractometer on a rotating anode (for **1**) or in a sealed tube (for **2**). Crystals of **1** were of limited quality, as indicated by highly structured broad reflection profiles. Accurate unit-cell parameters and an orientation matrix were determined by least-squares refinement of the setting angles of a set of well-centered reflections (SET4)[33] in the range 9.84° < θ < 13.75° and 4.12° < θ < 12.83° for **1** and **2**, respectively. Reduced-cell calculations did not indicate higher lattice symmetry[34]. Crystal data and details of the data collection and refinement are given in Table 5. Data were corrected for Lp effects and for observed linear decay of the reference reflections. An empirical absorption/extinction correction (DIFABS)[35] was applied for both compounds. The structures were solved by automated Patterson methods and subsequent difference Fourier techniques (DIRDIF-92[37] and SHELX-86[36] for **1** and **2**, respectively). Both compounds were refined on F^2 by full-matrix least-squares techniques (SHELXL-93)[38]; no observance criterion was applied during refinement. 14 deviating reflections displaying an unequal background were omitted during the final refinement cycles of compound **1**. Hydrogen atoms were included in the refinement in calculated positions riding on their carrier atoms, except for water hydrogen atoms of both compounds, which were located on a difference Fourier map and subsequently included in the refinement. Two ethyl groups of compound **2** proved to be disordered; a disorder model consisting of two alternative sites and occupation factors was included in the refinement. Weak bond constraints had to be introduced on this moiety in order to obtain a reasonable geometry. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were refined with a fixed isotropic thermal parameter related to the value of the equivalent isotropic thermal parameter of their carrier atoms by a factor amounting to 1.5 for the water and methyl hydrogen atoms, and 1.2 for the other hydrogen atoms, respectively. The relatively high R value for **1** is attributed to the rather poor quality of the available crystals. Neutral atom scattering factors and anomalous dispersion corrections were taken from the International Tables for Crystallography[39]. Geometrical calculations and illustrations were performed with the PLATON package[40]; all calculations were performed on a DEC station 5000 cluster. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100672. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44 (0)1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

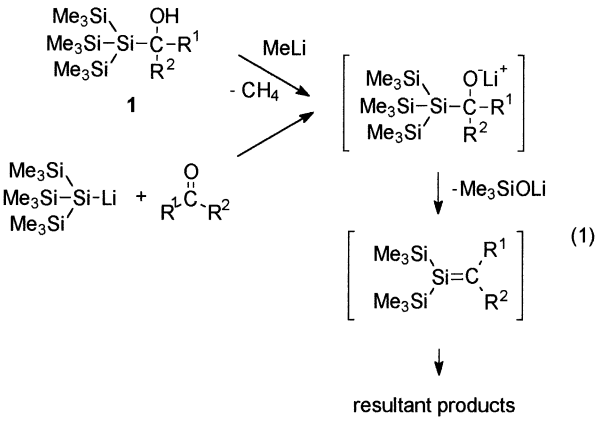
Keywords: Silanes / Rearrangements / Polysilanes / Hypersilylalcohols / 1,2-Trimethylsilyl migration

In the presence of strong acids, such as HCl or H_2SO_4, 1-hydroxyalkyltris(trimethylsilyl)silanes $(Me_3Si)_3Si-C(OH)R^1R^2$ (**1a–f**) isomerize by 1,2-Me_3Si/OH exchange to give the trimethylsilylmethylsilanols $(Me_3Si)_2Si(OH)-C(SiMe_3)R^1R^2$ (**4a–f**) [R^1,R^2: **a**: Me, Me; **b**: H, 4-MeC_6H_4; **c**: H, 4-*i*PrC_6H_4; **d**: H, Mes; **e**: H, 2-$Me_2NC_6H_4$; **f**: H, 2,4,6-$(MeO)_3C_6H_2$]. A mechanism for the isomerization is proposed. In the case of the reaction of **1d** with sulfuric acid, the silylsulfate $(Me_3Si)_2Si(OSO_3H)-C(SiMe_3)HMes$ (**5**) was isolated. **5** is the intermediate in the H_2SO_4-catalyzed isomerization of **1d** and was converted in situ with methanol, acetic anhydride, HF or HCl to give the respective methoxysilane **6**, acetoxysilane **7**, fluorosilane **8**, or chlorosilane **9**. Deprotonation of **4a, d, f** with sodium hydride causes a further rearrangement, a 1,3-C,O-trimethylsilyl migration, to give the siloxanes $(Me_3Si)_2(Me_3SiO)Si-CHR^1R^2$ (**11a, d, f**).

The base-induced elimination of trimethylsilanolate from 1-hydroxyalkyltris(trimethylsilyl)silanes (**1**) proved to be a suitable method for the synthesis of silaethenes. The mechanism of the process is interpreted as a variation of the Peterson reaction, in such a way that a carbon atom in the original Peterson product is replaced by a silicon atom. The polysilanylalcohols **1** are readily available by the addition of tris(trimethylsilyl)silylmagnesium bromide to the carbonyl group of aldehydes or ketones[1], and the isolated polysilanylalcohols are deprotonated with organolithium compounds, initiating the elimination of trimethylsilanolate to give transient silenes, which were characterized by trapping reactions and as different kinds of dimers (Eq. 1)[2]. The generation of silenes by the Peterson mechanism can also be performed in an in situ reaction from $(Me_3Si)_3SiLi$ and carbonyl compounds[3], and recently Apeloig et al. successfully applied this method to the synthesis of new stable silenes[4].

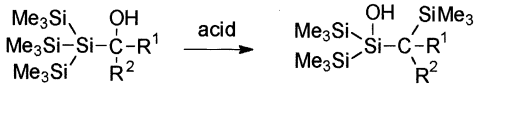


(1)

The Peterson reaction, originally the formation of olefins by a base-induced elimination of trimethylsilanol from 2-trimethylsilyl alcohols, can also be performed under acidic conditions[5]. During the course of our studies on the synthetic utility of 1-hydroxyalkyltris(trimethylsilyl)silanes (**1**) we therefore explored their conversion by strong acids which, in contrast to the base-promoted sila-Peterson reaction, did not give elimination and silene formation but an interesting rearrangement of the hydroxyalkylpolysilanes **1** into 1-trimethylsilylalkylsilanols **4**.

The Reaction of 1-Hydroxyalkyltris(trimethylsilyl)silanes (1) with Acids

Strong acids, such as hydrochloric acid in ether, cause the 1-hypersilylalcohols **1a–f** to rapidly undergo a rearrangement to afford the bis(trimethylsilyl)-1-trimethylsilylalkylsilanols **4a–f**. The silanols **4a–f** are colorless solids. Their structures were elucidated on the basis of their IR, NMR and MS data (see Experimental Section).



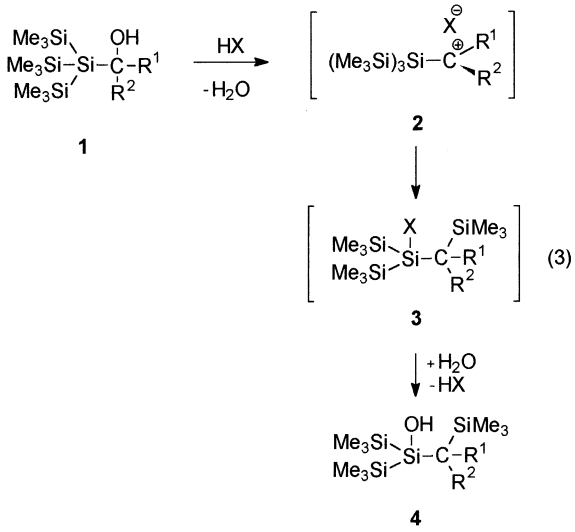
(2)

a: R^1 = R^2 = Me
b: R^1 = H; R^2 = 4-Me-C_6H_4
c: R^1 = H; R^2 = 4-iPr-C_6H_4
d: R^1 = H; R^2 = Mes
e: R^1 = H; R^2 = 2-Me_2N-C_6H_4
f: R^1 = H; R^2 = 2,4,6-$(MeO)_3C_6H_2$

The proposed pathway for the conversion of **1a–f** into **4a–f** is outlined in Eq. 3. The acid-catalyzed elimination of water from the alcohols **1a–f**, affording the carbenium ions **2a–f**, is followed by a migration of one trimethylsilyl group

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0177 $ 17.50+.50/0

from the central silicon atom to the neighboring carbon atom and attack of X^-, the conjugate base of the acid used as the catalyst, at the electrophilic silicon. Hydrolysis of the Si−X bond of **3a−f** by the eliminated water gives the silanols **4a−f**.



(3)

As the subject of some mechanistic studies we have chosen compound **1d**. The kinetic control of its conversion into **4d** (^{1}H NMR, solvent - [D_6]acetone, equimolar quantities of trifluoroacetic acid) revealed that the consumption of the alcohol **1d**, as well as the generation of the silanol **4d**, is a first-order process. Additional water in the reaction mixture does not increase the rate of formation of **4d**. Thus, a bimolecular reaction, involving a direct attack of water at the central tetracoordinated silicon atom of **2d** facilitating the trimethylsilyl shift and increasing the rate of the silanolate formation, can be excluded − at least in the rate-determining step of the reaction.

1,2-Migrations of alkyl, aryl and also trimethylsilyl groups from a tetracoordinated silicon center to a neighboring carbenium center appear to be common and have been described in the literature. Kumada et al. studied the $AlCl_3$-catalyzed rearrangement of chloromethyldisilanes into chlorosilanes[6]. They suggested a mechanism involving a slow rate-determining step consisting of the ionization of the carbon-chlorine bond, followed by a fast step involving synchronous nucleophilic attack by the halide on silicon and migration of a Me_3Si group from silicon to carbon. A similar mechanism was reported by Brook et al.[7] for the closely related reaction, the boron trifluoride-induced rearrangement of (hydroxymethyl)silicon compounds to give fluorosilanes. The BCl_3-induced conversion of methoxymethyltris(trimethylsilyl)silanes $(Me_3Si)_3Si-CH(OMe)R$ into the chlorosilanes $(Me_3Si)_2Si(Cl)-CH(SiMe_3)R$, described by Märkl et al., is similarly discussed as a synchronous process[8].

Isomerizations of silyl-substituted carbenium ions with the simultaneous generation of a silylium-ion intermediate or transition state have been described more recently[9]. An important contribution to this area was made by Apeloig and Stanger, who provided evidence of a direct, solvent-unassisted 1,2-methyl migration of a solvolytically produced α-trimethylsilyl carbenium ion[10]. These experimental observations confirm expectations deduced from theoretical work, according to which α-silyl carbenium ions should generally be less stable than the isomeric silylium ions[10][11]. In our particular case the 1,2-trimethylsilyl shift is probably favored by the fact that the hyperconjugative stabilization of the silylium-ion transition-states by the $CR^1R^2SiMe_3$ groups is more effective than the stabilization of the carbenium ions **2a−f** by the hypersilyl substituent. Whereas an α-silyl group at a carbenium ion center destabilizes the system relative to a methyl group[11], trimethylsilylmethyl groups cause a small but significant stabilization of a silylium ion[12].

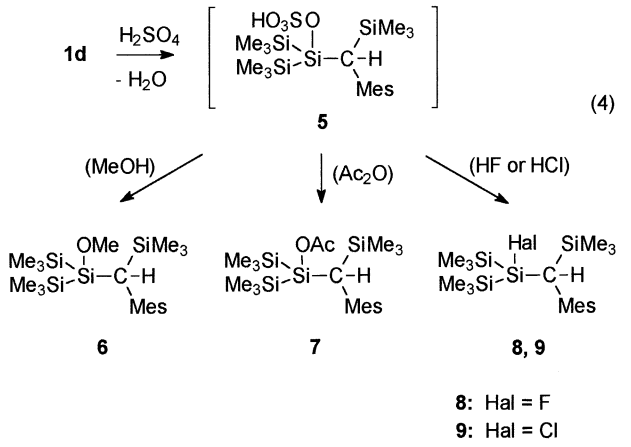
Both mechanisms, the synchronous process involving X^- in the trimethylsilyl shift and that involving a silylium-ion intermediate, fit the experimental results and agree with the proposed reaction path of the conversion of **1a−f** into **4a−f**. However, detailed information on the nature of the intermediates cannot be obtained from the data available and, in particular, the question of the existence of a silylium-ion intermediate remains unanswered.

Recently we became aware of a related rearrangement, the conversion of trimethylsiloxymethyl-chlorosilanes $(Me_3Si)_2Si(Cl)-C(OSiMe_3)R_2$ via chloromethyldisiloxanes $(Me_3Si)_2Si(OSiMe_3)-C(Cl)R_2$ into trimethylsilylmethylchlorodisiloxanes $Me_3Si(Me_3SiO)Si(Cl)-C(SiMe_3)R_2$, and it is very likely that this proceeds along a similar reaction path[13].

The polysilanylalcohols **1e** and **1f** were included in our studies with the aim of stabilizing the intermediate carbenium ion by introducing electron-donating substituents and thus preventing the 1,2-Si,C-trimethylsilyl shift. However, as demonstrated in Eq. 2, **1e** and **1f** follow the same isomerization pattern and give the silanols **4e** and **4f**, respectively.

When concentrated sulfuric acid is used as the catalyst for the rearrangement of **1a−f**, the water eliminated from the alcohols is not available and other nucleophiles present in the mixture can attack the electrophilic silicon center of **3a−f** to give the functionalized silanes **6−9**. For these experiments we have chosen to study **1d**. Thus, the addition of several drops of concentrated H_2SO_4 to a solution of **1d** in methanol results in the formation of the methoxysilane **6**. Under the same conditions **1e** and **1f** give **6e** and **6f**, respectively. The reaction of **1d** with sulfuric acid in acetic anhydride affords the acetoxysilane **7**. Similarly, when a mixture of HF and H_2SO_4 is added to an ethereal solution of **1d**, the fluorosilane **8** is formed almost quantitatively. The chlorosilane **9** is obtained by passing gaseous HCl through a solution of **1d** and H_2SO_4 in ether (Eq. 4).

All these reactions proceed through the silylsulfate **5**, and **6−9** are formed by replacement of the HSO_4 group of **5** by the appropriate nucleophile. This was demonstrated by the reaction of **1b** with sulfuric acid in ether in the absence of further nucleophiles, which allowed the isolation of **5** in the

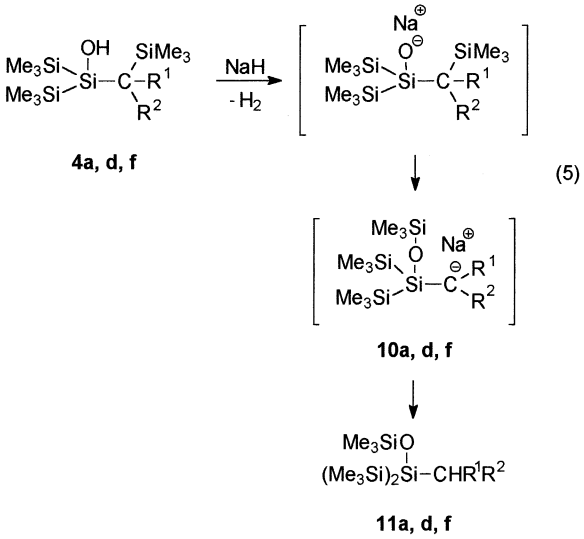


form of a colorless, crystalline, highly moisture-sensitive compound.

The structures of **4**–**9** were elucidated by a full spectral analysis [IR; ^{1}H-, ^{13}C- and ^{29}Si-NMR spectroscopy, MS and elemental analyses (see Experimental Section)].

The Base- Induced Rearrangement of the 1-Trimethylsilylalkylsilanols 4 into the Disiloxanes 11

Deprotonation of the silanols **4** with sodium hydride leads to a further rearrangement, with one trimethylsilyl group migrating from carbon to oxygen. The reaction was performed with **4a**, **4d** and **4f**, producing the disiloxanes **11a**, **11d** and **11f**, respectively (Eq. 5).



Such 1,3-C,O-trimethylsilyl migrations are well known, e.g. they are probably part of the Peterson olefination process[5]. Interestingly, the conversion of **4a, d, f** into **11a, d, f** is easily achieved by treatment with NaH in THF. In ether the reaction proceeds very slowly, and after deprotonation of **4a, d, f** with organolithium reagents, the silanols were recovered unchanged. This demonstrates the dependence of the nucleophilicity of the silanolate oxygen atom on the counter ion and the solvent. In the course of the Peterson reaction, the 1,3-Si,O-trimethylsilyl migration is followed by a trimethylsilanolate elimination to establish the olefinic double bond. In contrast, in the case of **10a, d, f** the high energy of the silicon oxygen bond, as expected, prevents a silanolate elimination and silaethene formation.

We gratefully acknowledge the support of our research by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie.* We thank Dr. *M. Michalik,* Dr. *W. Baumann* and Prof. *N. Stoll* for recording the NMR and mass spectra.

Experimental Section

All reactions involving organometallic reagents were carried out under purified argon. – NMR: Bruker AC 250 or Bruker ARX 300, tetramethylsilane as internal standard. – IR: Nicolet 205 FT-IR. – MS: Intectra AMD 402, chemical ionization with isobutane as the reactant gas. – $(Me_3Si)_3SiLi \cdot 3$ THF[14], **1a**[1], **1c**[15], **1d**[1] and **1e**[2] were prepared as reported in the literature. – All yields given refer to amounts obtained after chromatographic separation and purification. – The syntheses and the spectral data characterizing the structures of **4a**, **4c**, **4d**, **6** and **8** were described previously[15].

Synthesis of the 1-Hydroxyalkyltris(trimethylsilyl)silanes **1b** and **1f**: As described previously[1], **1b** and **1f** were prepared by the reaction of tris(trimethylsilyl)silylmagnesium bromide, made from 14.7 g (0.03 mol) of $(Me_3Si)_3SiLi \cdot 3$ THF and an equimolar quantity of $MgBr_2$ and 3.6 g (0.03 mol) of 4-methylbenzaldehyde or 5.89 g (0.03 mol) of 2,4,6-trimethoxybenzaldehyde, respectively.

1b: The product was purified by column chromatography (silica gel, heptane/ethyl acetate 20/1) and recrystallization from acetonitrile; yield 7.2 g (65%), m.p. 78°C. – IR (nujol): $\tilde{\nu}$ = 3518.5 cm^{-1} (OH). – ^{1}H NMR ([D$_6$]benzene): δ = 0.26 (s, $SiCH_3$, 27 H), 1.12 (d, ^3J = 2.74 Hz, OH, 1 H), 2.12 (s, *p*-CH_3, 3 H), 4.81 (d, ^3J = 2.74 Hz, CH, 1 H), 6.97 (m, ArH, 2 H), 7.16 (m, ArH, 2 H). – ^{13}C NMR ([D$_6$]benzene): δ = 1.8 ($SiCH_3$), 21.0 (*p*-CH_3); 69.2 (CH), 125.8, 129.1 (arom. CH), 135.6, 145.0 (quart. arom. C). – ^{29}Si NMR ([D$_6$]benzene): δ = −13.1 ($SiMe_3$), −67.7 (*Si*$SiMe_3$). – MS: *m/z* (%) = 351 (100) [M^+ − OH], 295 (4) [M^+ − $SiMe_3$], 277 (6) [M^+ − $C_6H_4CH_3$], 247 (16) [$Si(SiMe_3)_3^+$], 121 (15) [M^+ − $Si(SiMe_3)_3$]. – $C_{17}H_{36}OSi_4$ (368.81): calcd. C 55.36, H 9.84; found C 55.13, H 9.81.

1f: Recrystallized from heptane, yield 12.0 g (90%), m.p. 115°C. – IR (nujol): $\tilde{\nu}$ = 3579.8 cm^{-1} (OH free), 3455.0 (OH ass.). – ^{1}H NMR ([D$_6$]benzene): δ = 0.31 (s, $SiCH_3$, 27 H), 3.23 (s, *o*-OCH_3, 6 H), 3.34 (s, *p*-OCH_3, 3 H), 3.45 (d, OH, 1 H, ^3J = 10.98 Hz), 5.93 (d, CH, 1 H, ^3J = 10.98 Hz), 6.0 (s, ArH, 2 H). – ^{13}C NMR ([D$_6$]benzene): δ = 1.7 ($SiCH_3$), 54.7 (*o*-OCH_3), 54.9 (*p*-OCH_3), 59.0 (CH), 127.6 (arom. CH), 115.6, 157.4, 160.1 (quart. arom. C). – ^{29}Si NMR ([D$_6$]benzene): δ = −12.6 ($SiMe_3$), −73.1 (*Si*$SiMe_3$). – MS: *m/z* (%) = 444 (0.6) [M^+]; 371 (3) [M^+ − $SiMe_3$]; 197 (100) [M^+ − $Si(SiMe_3)_3$]. – $C_{19}H_{40}O_4Si_4$ (444.87): calcd. C 51.30, H 9.06; found C 51.14, H 9.22.

Isomerization of **1b**, **1e** *and* **1f** *into the Silanols* **4b**, **4e** *and* **4f**:

4b: To an ethereal solution of 0.5 g (1.35 mmol) of **1b** was added an equimolar quantity of ethereal HCl at room temperature and the mixture was stirred for 5 h. After addition of aqueous $NaHCO_3$ solution, the organic phase was separated, dried and the solvent evaporated. Kugelrohr distillation and chromatographic purification (silica gel, heptane/ethyl acetate 20/1) of the residue gave 0.25 g (50%) of colorless crystals, m.p. 48°C. – IR (nujol): $\tilde{\nu}$ = 3647 and 3676 cm^{-1} (OH), 3427 (OH ass.). – ^{1}H NMR ([D]$_6$benzene): δ = 0.12, 0.14 and 0.18 (3 s, $SiCH_3$, 3 × 9 H), 2.05 (s, CH, 1 H), 2.10 (s, Ar−CH_3, 3 H), 6.93 (m, ArH, 4 H). – ^{13}C NMR

([D$_6$]benzene): δ = −0.4, 0.0 and 0.6 ($SiCH_3$), 20.9 ($ArCH_3$), 30.1 (CH), 129.4, 129.5, 133.3 and 138.6 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −19.2 and −18.7 (Si*Si*Me$_3$), 1.9 ($CSiMe_3$), 10.4 (SiOH). − MS: *m/z* (%) = 368 (3) [M$^+$], 353 (5) [M$^+$ − CH_3], 295 (40) [M$^+$ − $SiMe_3$], 279 (80) [M$^+$ − Me_3SiOH], 73 (100) [$SiMe_3^+$]. − $C_{17}H_{36}OSi_4$ (368.81): calcd. C 55.36, H 9.84; found C 56.10, H 10.20.

4e: 0.04 ml (0.75 mmol) of conc. H_2SO_4 was added to a solution of 0.3 g (0.75 mmol) of **1e** in heptane and the mixture was stirred for 3 h. Workup as described above and chromatographic purification (silica gel, heptane/ethyl acetate 10/1) gave 0.12 g (40%) of a colorless solid, m.p. 60°C. − IR (nujol): $\tilde{\nu}$ = 3613 and 3655 cm^{-1} (OH), 3400 (OH ass.). − ^{1}H NMR ([D$_6$]benzene): δ = 0.04, 0.23 and 0.24 (3 s, $SiCH_3$, 3 × 9 H), 0.92 (br. s, OH, 1 H), 2.45 (s, NCH_3, 6 H), 3.12 (s, CH, 1 H), 6.92−7.35 (m, ArH, 4 H). − ^{13}C NMR ([D$_6$]benzene): δ = −0.5, −0.3 and 1.3 ($SiCH_3$), 22.8 (CH), 45.3 (NCH_3), 120.6, 124.4, 125.1, 130.5 139.6 and 151.9 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −19.5 and −19.2 (Si*Si*Me$_3$), 2.3 ($CSiMe_3$), 14.0 (SiOH). − MS: *m/z* (%) = 397 (100) [M$^+$], 353 (3) [M$^+$ − NMe_2], 338 (100) [M$^+$ − NMe_2 − CH_3]. − $C_{18}H_{39}NOSi_4$ (397.86): calcd. C 54.34, H 9.88, N 3.52; found C 54.52, H 9.94, N 3.60.

4f: As described for **4e**, 0.3 g (0.67 mmol) of **1f** and 0.04 ml (0.75 mmol) of H_2SO_4 gave, after chromatographic separation (silica gel, heptane/ethyl acetate 5/1), 0.2 g (66%) of colorless crystals, m.p. 53°C. − IR (nujol): $\tilde{\nu}$ = 3557 and 3675 cm^{-1} (OH), 3390 (OH ass.). − ^{1}H NMR ([D$_6$]benzene): δ = 0.08, 0.24 and 0.33 (3 s, $SiCH_3$, 3 × 9 H), 1.54 (s, OH, 1 H), 2.70 (s, CH, 1 H), 3.24, 3.34 and 3.39 (3 s, OCH_3, 3 × 3 H), 6.06 and 6.10 (2 d, ^4J = 2.45 Hz, ArH, 2 H). − ^{13}C NMR ([D$_6$]benzene): δ = −0.5, −0.3 and 1.6 ($SiCH_3$), 16.1 (CH), 54.5, 54.9 and 55.2 (OCH_3), 90.9, 91.3, 112.8, 157.4, 158.2 and 158.2 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −19.5 and −19.3 (Si*Si*Me$_3$), 2.3 ($CSiMe_3$), 11.8 (SiOH). − MS: *m/z* (%) = 445 (1) [M$^+$ + H], 429 (5) [M$^+$ − CH_3], 371 (100) [M$^+$ − $SiMe_3$]. − $C_{19}H_{40}O_4Si_4$ (444.87): calcd. C 51.30, H 9.06; found C 51.16, H 9.02.

Reaction of **1d** *with Sulfuric Acid*: 0.1 ml (1.9 mmol) of conc. H_2SO_4 was added to a solution of 0.3 g (0.75 mmol) of **1d** in 30 ml of ether at room temperature. After 3 h the solvent was evaporated and the colorless, slowly crystallizing residue was washed with pentane to give 0.26 g (72%) of **5**; m.p. 84−88°C. − IR (cap.): $\tilde{\nu}$ = 2224 and 2477 cm^{-1} (SOH), 840 (SO_2 symm.), 941 (SO_2 asymm.). − ^{1}H NMR ([D$_6$]benzene): δ = 0.21, 0.24 and 0.36 (3 s, $SiCH_3$, 3 × 9 H), 2.10, 2.31 and 2.39 (3 s, $ArCH_3$, 3 × 3 H), 2.77 (s, CH, 1 H), 6.75 (s, ArH, 2 H). − ^{13}C NMR ([D$_6$]benzene): δ = 0.2, 0.3 and 2.0 ($SiCH_3$), 20.7, 22.6 and 23.2 ($ArCH_3$), 25.0 (CH), 129.7, 130.0, 133.6, 135.7 136.0 and 137.3 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −15.1 and −14.1 (Si*Si*Me$_3$), 3.6 ($CSiMe_3$), 32.6 ($SiOSO_3H$). − MS: *m/z* (%) = 475 (35) [M$^+$ − H], 379 (100) [M$^+$ − HSO_4], 403 (25) [M$^+$ − $SiMe_3$], 306 (40) [M$^+$ − HSO_4 − $SiMe_3$]. − $C_{19}H_{40}O_4SSi_4$ (476.93): calcd. C 47.85, H 8.45, S 6.72; found C 47.26, H 8.36, S 6.28.

Synthesis of the Methoxysilanes **6e** and **6f**: A 2.5-fold molar excess of H_2SO_4 was added to a solution of **1e** or **1f** in methanol at room temperature. After 5−8 h the solvent was evaporated and the residue was separated by column chromatography.

6e: A solution of 0.3 g (0.75 mmol) of **1e** and 0.1 ml (1.9 mmol) of H_2SO_4 in 30 ml of methanol gave, after evaporation of the solvent and chromatographic purification (silica gel, heptane/ethyl acetate 20/1), 0.2 g (65%) of a colorless solid, m.p. 125−130°C. − ^{1}H NMR ([D$_6$]benzene): δ = 0.05, 0.26 and 0.30 (3 s, $SiCH_3$, 3 × 9 H), 2.47 (s, NCH_3, 6 H), 3.09 (s, CH, 1 H), 3.38 (s, OCH_3, 3 H), 6.93−6.98 and 7.39−7.42 (2 m, ArH, 4 H). − ^{13}C NMR ([D$_6$]benzene): δ = 0.5, 0.6 and 1.1 ($SiCH_3$), 21.9 (CH), 45.2 (NCH_3), 53.7 (OCH_3), 120.5, 124.1, 124.9, 127.5, 139.7 and 150.0 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −19.8 and −19.5 (Si*Si*Me$_3$), 2.9 ($CSiMe_3$), 18.4 (SiOMe). − MS: *m/z* (%) = 410 (1) [M$^+$ − H], 396 (20) [M$^+$ − CH_3], 338 (100) [M$^+$ − $SiMe_3$]. − $C_{19}H_{41}NOSi_4$ (411.88): calcd. C 55.41, H 10.03, N 3.40; found C 55.07, H 9.85, N 3.35.

6f: 0.3 g (0.67 mmol) of **1f** and 0.01 ml (1.7 mmol) of H_2SO_4 in methanol gave, after chromatographic purification, 0.22 g (70%) of colorless crystals, m.p. 121°C. − ^{1}H NMR ([D$_6$]benzene): δ = 0.20, 0.27 and 0.28 (3 s, $SiCH_3$, 3 × 9 H), 3.00 (s, CH, 1 H), 3.33, 3.35, 3.39 and 3.50 (4 s, OCH_3, 4 × 3 H), 6.08 and 6.10 (2 d, ^4J = 2.4 Hz, ArH, 2 H). − ^{13}C NMR ([D$_6$]benzene): δ = 0.3, 0.8 and 1.3 ($SiCH_3$), 14.0 (CH), 53.8, 54.4, 54.8 and 55.0 (OCH_3), 90.7, 90.8, 110.9, 157.6, 158.3 and 158.4 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −18.9 and −18.8 (Si*Si*Me$_3$), 2.2 ($CSiMe_3$), 14.9 (SiOMe). − MS: *m/z* (%) = 458 (40) [M$^+$], 443 (10) [M$^+$ − CH_3], 427 (100) [M$^+$ − OMe], 385 (50) [M$^+$ − $SiMe_3$]. − $C_{20}H_{42}O_4Si_4$ (458.89): calcd. C 52.35, H 9.23; found C 52.42, H 9.14.

Reaction of **1d** *with Sulfuric Acid in Acetic Anhydride:* 0.3 g (0.76 mmol) of **1d** and 0.1 ml (1.9 mmol) of conc. H_2SO_4 were dissolved in 30 ml of acetic anhydride and the solution was refluxed for 10 h. After evaporation of the acetic anhydride, chromatographic separation (silica gel, heptane/ethyl acetate 5/1) gave 0.27 g (82%) of **7**, m.p. 125°C. − IR (KBr): $\tilde{\nu}$ = 1712 cm^{-1} (CO). − ^{1}H NMR ([D$_6$]benzene): δ = 0.10, 0.16 and 0.31 (3 s, $SiCH_3$, 3 × 9 H), 1.78 (s, $OCOCH_3$, 3 H), 2.13 and 2.27 (2 s, Ar-*o*-CH_3, 2 × 3 H), 2.36 (s, Ar-*p*-CH_3, 3 H), 2.60 (s, CH, 1 H), 6.77 and 6.78 (2 s, Ar-H, 2 × 1 H). − ^{13}C NMR ([D$_6$]benzene): δ = 0.3, 0.5 and 2.0 ($SiCH_3$), 20.7, 21.2 and 22.2 ($ArCH_3$), 22.8 (CH), 129.6, 130.1, 133.2, 135.5, 135.6 and 138.2 (arom. C), 149.2 (OCO*C*H$_3$), 171.2 (O*C*OCH$_3$). − ^{29}Si NMR ([D$_6$]benzene): δ = −16.0 and −15.2 (Si*Si*Me$_3$), 2.9 ($CSiMe_3$), 12.9 ($SiOCOCH_3$). − MS: *m/z* (%) = 438 (100) [M$^+$], 423 (40) [M$^+$ − CH_3], 365 (100) [M$^+$ − $SiMe_3$], 233 (80) [$(Me_3Si)_2$-$SiOC(O)CH_3^+$]. − $C_{21}H_{42}O_2Si_4$ (438.91): calcd. C 57.47, H 9.65; found C 57.23, H 9.44.

Synthesis of **9**: Gaseous HCl was passed through a solution of 0.3 g (0.76 mmol) of **1d** and 0.1 ml (1.9 mmol) of H_2SO_4 in 30 ml of ether. The reaction was monitored by TLC and continued until all the alcohol **1d** had been consumed. The solvent was evaporated and the ether was replaced by pentane. After the addition of Na_2CO_3 the solution was filtered and the pentane evaporated to give a colorless solid, 0.19 g (60%), m.p. 45°C. − IR (cap.): $\tilde{\nu}$ = 690 cm^{-1} (SiCl). − ^{1}H NMR ([D$_6$]benzene): δ = 0.16 (s, $SiCH_3$, 18 H), 0.19 (s, $SiCH_3$, 9 H), 2.09, 2.20 and 2.33 (3 s, $ArCH_3$, 3 × 3 H), 2.65 (s, CH, 1 H), 6.72 (s, ArH, 2 H). − ^{13}C NMR ([D$_6$]benzene): δ = −0.6, 0.1 and 2.0 ($SiCH_3$), 20.7, 22.6 and 23.6 ($ArCH_3$), 24.0 (CH), 129.7, 130.0, 133.6, 135.2, 135.5 and 137.6 (arom. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −21.8 (Si*Si*Me$_3$), 4.0 ($CSiMe_3$), 13.1 (SiCl). − MS: *m/z* (%) = 414 (10) [M$^+$], 399 (30) [M$^+$ − CH_3], 379 (2) [M$^+$ − Cl], 341 (60) [M$^+$ − $SiMe_3$]. − $C_{19}H_{39}ClSi_4$ (415.31): calcd. C 54.95, H 9.47, Cl 8.54; found C 54.36, H 9.42, Cl 8.20.

Isomerization of the Silanols **4a, d, f** *into the Disiloxanes* **11a, d, f**: A two-fold molar excess of sodium hydride was added to a solution of the appropriate silanol in THF at room temperature. After stirring for 3−8 h (monitored by chromatography) water was added and the product was extracted with ether. After drying with $MgSO_4$ the ether was evaporated and the residue was purified by column chromatography (silica gel, heptane/ethyl acetate 20/1).

11a: 0.3 g (1.0 mmol) of **4a** and 0.05 g (2 mmol) of NaH gave 0.19 g (65%) of a colorless oil. − IR (cap.): $\tilde{\nu}$ = 1050 cm^{-1} (SiOSi). − ^1H NMR ([D_6]benzene): δ = 0.28 (s, $SiSiCH_3$, 18 H), 0.31 (s, $OSiCH_3$, 9 H), 1.15 (d, ^3J = 6.7 Hz, CCH_3, 6 H), 1.31 (sept, ^3J = 6.7 Hz, CH, 1 H). − ^{13}C NMR ([D_6]benzene): δ = 1.3 ($SiSiCH_3$), 2.7 ($OSiCH_3$), 21.0 (CCH_3), 23.0 (CH). − ^{29}Si NMR ([D_6]benzene): δ = −20.4 (Si*Si*Me_3), 6.1 and 6.3 (*Si*$SiMe_3$ and $OSiMe_3$). − MS: *m*/*z* (%) = 306 (42) [M^+], 305 (100) [$M^+ - CH_3$], 263 (15) [$M^+ - C_3H_7$]. − $C_{12}H_{34}OSi_4$ (306.74): calcd. C 46.99, H 11.17; found C 46.76, H 11.12.

11d: 0.3 g (0.75 mmol) of **4d** and 0.04 g (1.7 mmol) of NaH afforded 0.15 g (50%) of a colorless oil. − IR (nujol): $\tilde{\nu}$ = 1054 cm^{-1} (SiOSi). − ^1H NMR ([D_6]benzene): δ = 0.12 (s, $SiSiCH_3$, 18 H), 0.13 (s, $OSiCH_3$, 9 H), 2.18 (s, *p*-$ArCH_3$, 3 H), 2.26 (s, *o*-$ArCH_3$, 6 H), 2.45 (s, CH_2, 2 H), 6.80 (s, ArH, 2 H). − ^{13}C NMR ([D_6]benzene): δ = −1.1 ($SiSiCH_3$), 2.3 ($OSiCH_3$), 20.9 (*p*-$ArCH_3$), 21.6 (CH_2), 22.0 (*o*-$ArCH_3$), 129.1, 133.2, 134.6 and 135.8 (arom. C). − ^{29}Si NMR ([D_6]benzene): δ = −19.5 (Si*Si*Me_3), 3.3 (*Si*SiMe_3), 6.9 ($OSiMe_3$). − MS: *m*/*z* (%) = 396 (40) [M^+ − H], 381 (95) [$M^+ - CH_3$], 323 (75) [$M^+ - SiMe_3$], 307 (20) [M^+ − $OSiMe_3$], 277 (100) [$M^+ - C_6H_2Me_3$]. − $C_{19}H_{40}OSi_4$ (396.87): calcd. C 57.50, H 10.16; found C 57.24, H 10.10.

11f: 0.3 g (0.7 mmol) of **4f** and 0.035 g (1.5 mmol) of NaH gave 0.22 g (75%) of a colorless oil. − IR (cap.): $\tilde{\nu}$ = 1062 (SiOSi). − ^1H NMR ([D_6]benzene): δ = 0.22 (s, $SiSiCH_3$, 18 H), 0.29 (s, $OSiCH_3$, 9 H), 2.73 (s, CH_2, 2 H), 3.39 (s, *o*-OCH_3, 6 H), 3.42 (s, *p*-OCH_3, 3 H), 6.12 (s, ArH, 2 H). − ^{13}C NMR ([D_6]benzene): δ = −1.2 ($SiSiCH_3$), 2.3 ($OSiCH_3$), 12.9 (CH_2), 54.8 (*o*-OCH_3), 54.9 (*p*-OCH_3), 90.6, 109.1, 157.9 and 158.8 (arom. C). − ^{29}Si NMR ([D_6]benzene): δ = −19.6 (Si*Si*Me_3), 0.9 (*Si*Si*Me*$_3$), 6.3 ($OSiMe_3$). − MS: *m*/*z* (%) = 445 (10) [M^+ + H], 429 (35) [$M^+ - CH_3$], 371 (100) [$M^+ - SiMe_3$], 355 (10) [$M^+ - OSiMe_3$]. − $C_{19}H_{40}O_4Si_4$ (444.87): calcd. 51.30, H 9.06; found C 51.22, H. 9.14.

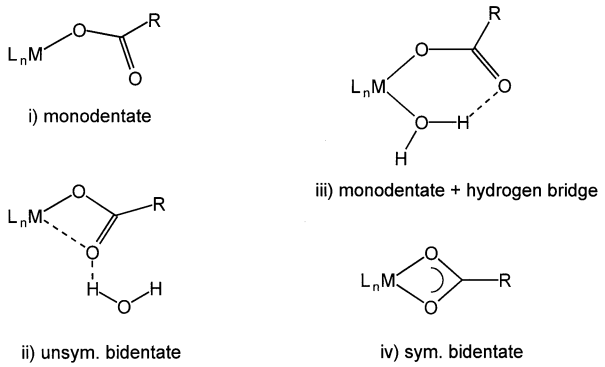
Keywords: Tripodal ligands / Cobalt complexes / Bridging ligands / Exchange coupling

Weak antiferromagnetic exchange interactions are observed in two Co^{II} dimers of the general formula $[\{(triphos)Co\}_2(\mu\text{-dicarboxylato})](BF_4)_2$ where the dicarboxylate is the dianion of fumaric acid [**3**·$(BF_4)_2$] or terephthalic acid [**4**·$(BF_4)_2$] and triphos is the tridentate phosphorus ligand 1,1,1-tris(diphenylphosphanomethyl)ethane. In these complexes the metal ions are separated by 8 and 10 Å, as determined by X-ray crystallography. Insight into the interaction pathway is gained through molecular orbital calculations performed on model compounds. The influence of bridging-ligand distortions and the stereochemistry around the two cobalt centres is discussed.

Introduction

Magnetic exchange interactions between two paramagnetic centres have attracted considerable interest from inorganic chemists.[1][2][3] The investigations have mainly been focused on the simplest case where two electrons at two d^9-Cu^{II} centres ($S_1 = S_2 = \frac{1}{2}$) are separated by an organic spacer leading to new good quantum numbers of $S = 0$ (singlet state) and $S = 1$ (triplet state) for these systems.[1][2][3] Factors that govern the nature of the interaction such as orbital topology and orbital overlap are quite well understood and are used to design antiferro- and ferromagnetically coupled systems[4][5] although it is not yet possible to use theory to make quantitative explanations and predictions.[2] In the case of two interacting spins at two copper centres the interaction is mediated through the σ-framework of the bridging unit.[2] Maximum overlap between the bridging-ligand orbitals and the copper orbitals which leads to a stabilisation of the singlet state is obtained for a $d_{x^2-y^2}$ ground state of the copper ion in a square-planar or square-pyramidal geometry as opposed to a trigonal-bipyramidal situation.[2][7] With this favourable electronic configuration, antiferromagnetic exchange interaction is observed even with Cu···Cu separations larger than 10 Å.[6][7][13] The organic spacers employed for obtaining large intramolecular distances are dicarboxylic acids (or the dianions derived from them) with a rigid, usually conjugated, core. However, the coordination mode of carboxylates at metal centres can vary drastically (Scheme 1) and has a large influence on both the coordination geometry around the metal and the magnetic exchange interaction. A relatively large interaction is found if the carboxylate coordinates in a monodentate fashion with an additional hydrogen-bridge system (Scheme 1, iii);[6][7] an interaction is also predicted for the symmetrical bidentate coordination mode (Scheme 1, iv).[8] In other cases the magnetic interaction is small and may instead be *inter*molecular in nature.[8][9][10][11][12] One exception is the complex $[\{(bpy)(H_2O)Cu\}_2(\mu\text{-terephthalato})](ClO_4)_2$, although its structure has not so far been determined.[13]

Scheme 1. Binding modes of carboxylates R−COO^- at metal centres



We have focused our attention on a cobalt(II) system with the tridentate ligand triphos [1,1,1-tris(diphenylphosphanomethyl)ethane]. This ligand induces a fivefold coordination around the cobalt centre providing two free *cis*-coordination sites[14][15][16] needed for a bidentate coordination mode of the carboxylate (Scheme 1, iv). The phosphorus donor set usually splits the metal-d orbitals such that a low-spin configuration (d^7) with one unpaired electron is obtained.[14][15] Furthermore the three bulky diphenylphosphano groups insulate the individual complex molecules from each other leaving no *inter*molecular interaction pathway accessible. This often represents a severe problem in the study of *intra*molecular interactions especially over large distances.[2][6]

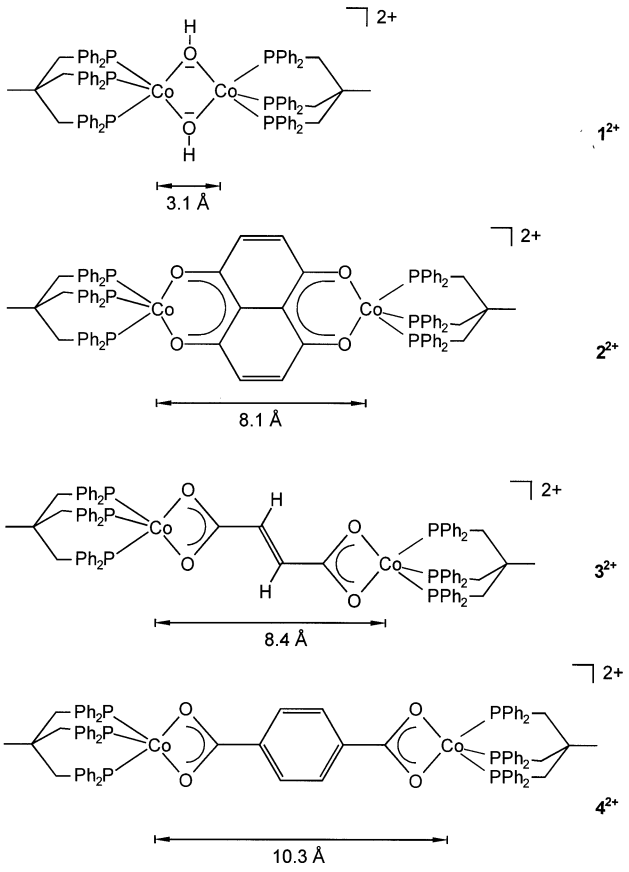
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0202−0183 $ 17.50+.50/0

In order to address the questions concerning magnetic exchange interactions (i) within a d^7/d^7 system and (ii) over distances up to 10 Å we describe here the syntheses, solid-state structures and magnetic behaviour of dinuclear triphos−Co^{II} complexes bridged by the dianions of fumaric and terephthalic acid. In addition, we describe molecular orbital calculations which qualitatively explain the interaction pathway.

Results and Discussion

Preparation of Complexes: The reaction of triphos with $Co(BF_4)_2 \cdot 6\ H_2O$ and the appropriate dicarboxylic acid in THF/ethanol in the ratio 1:1:0.5 yields red-brown solutions from which the complex salts [{(triphos)Co}$_2$(μ-fumarato)]$(BF_4)_2$ [**3**$\cdot(BF_4)_2$] and [{(triphos)Co}$_2$(μ-terephthalato)]$(BF_4)_2$ [**4**$\cdot(BF_4)_2$] were isolated (Scheme 2).

Scheme 2. Dinuclear triphos−Co^{II} complexes



The UV/Vis spectra of the solutions are almost identical and are similar to that of the mononuclear complex [{(triphos)Co}(η^2-acetate)](BPh_4),[17] suggesting an analogous coordination environment and geometry. The absorptions observed can be assigned to d-d transitions of a square-pyramidal d^7-low-spin complex.[18][19] The dinuclear composition of $\mathbf{3}^{2+}$ and $\mathbf{4}^{2+}$ is confirmed by the observed M^+ peaks in the FAB mass spectra with correct isotopic distributions as well as signals for dications M^{2+} at *m*/2*e*. The IR spectra show the typical bands for the triphos ligand,[20] as well as the broad absorption of the tetrafluoroborate counter ions at 1055−1059 cm^{-1}. Unfortunately the $\tilde{\nu}_{as}(CO_2^-)$ and $\tilde{\nu}_s(CO_2^-)$ absorptions could not be identified as they overlap with the $\tilde{\nu}$(C=C) and δ(C−H) absorptions of the aromatic rings of the triphos ligand. For **4**$\cdot(BF_4)_2$ a medium strong band is observed at 1514 cm^{-1} which is tentatively assigned to the $\tilde{\nu}$(C=C) vibration of the aromatic ring of the bridging terephthalato ligand. In the cyclic voltammogram (CH_3CN, vs. SCE) both complexes show only quasi- and irreversible oxidation and reduction waves (see Experimental Section).

Crystal Structures: The complexes **3**$\cdot(BF_4)_2$ and **4**$\cdot(BF_4)_2$ crystallise in the monoclinic, centrosymmetric space groups $P2_1/c$ and $P2_1/n$, respectively. Table 1 summarises selected bond lengths and angles. The crystal structures consist of centrosymmetric discrete dinuclear dications (Figures 1 and 2), BF_4^- counterions and solvent molecules.

Figure 1. View of the dication of **3**$\cdot(BF_4)_2$

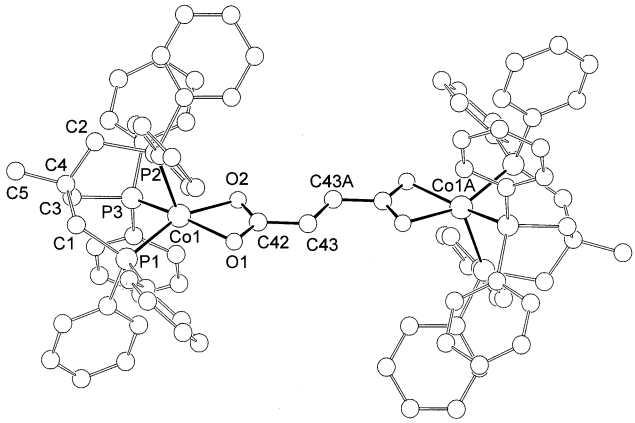


Figure 2. View of the dication of **4**$\cdot(BF_4)_2$

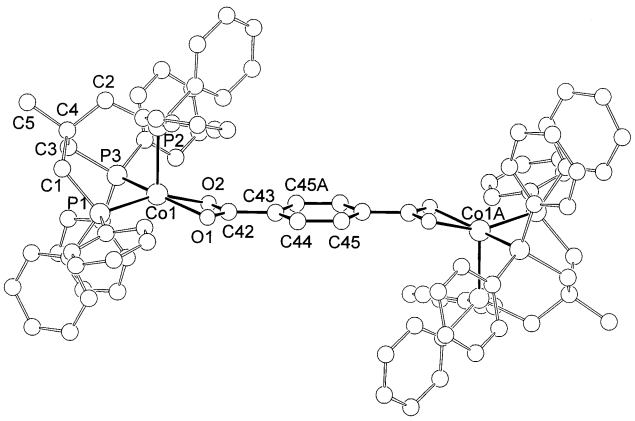

The packing of the molecules is such that no short intermolecular contacts arise: Co···Co(intermolecular) 11.8 Å [**3**···$(BF_4)_2$], 11.6 Å [**4**···$(BF_4)_2$], Co···F 7.6−10 Å [**3**···$(BF_4)_2$], 9−11 Å [**4**···$(BF_4)_2$] which provide perfect magnetic insulation of the dimeric cations. The geometry around the metal centres can be described as distorted square-pyramidal with the P2 atom occupying the axial coordination site (Figures 1 and 2). The carboxylates coordinate in a symmetric bidentate fashion with almost equal

			O1−C42−O2	118.1(3)	118.5(5)

[a] Estimated standard deviations of the least significant figures are given in parentheses.

Co−O and C−O bond lengths (Table 1). The small angle O−Co−O is similar to that found in monocarboxylate complexes of the triphos−Co^{II} fragment.[16][17][21] The distance between the carbon atom of the carboxylate fragment and the central -system (double bond in $\mathbf{3}^{2+}$, aromatic ring in $\mathbf{4}^{2+}$) is that of a $C(sp^2)-C(sp^2)$ single bond.[22] The carboxylate groups and the plane of the central π-systems are almost coplanar, the tilting angle being 7.8° ($\mathbf{3}^{2+}$) and 4.2° ($\mathbf{4}^{2+}$). The intramolecular Co···Co separations are 8.37 Å ($\mathbf{3}^{2+}$) and 10.31 Å ($\mathbf{4}^{2+}$).

Magnetic Susceptibility: Variable-temperature magnetic susceptibility data for the two complexes were measured in the temperature range 7−290 K using a Faraday balance (Figures 3 and 4). These data were fitted to the Bleaney−Bowers equation[2] and the result is represented by the solid lines in Figures 3 and 4.[23] From these fits the singlet−triplet splittings are estimated as $2J = -36$ cm^{-1} [$\mathbf{3}\cdots(BF_4)_2$] and -16 cm^{-1} [$\mathbf{4}\cdots(BF_4)_2$]. *Inter*molecular interactions (vide supra) can be safely excluded and the observed antiferromagnetic exchange coupling must therefore be *intra*molecular in nature. The results are compiled in Table 2 along with the results of EPR measurements. Also included are the data of two previously described dinuclear triphos-Co^{II} complexes with oxygen donor coligands, [{(triphos)Co}$_2$(μ-OH)$_2$]$(BPh_4)_2$ [$\mathbf{1}\cdots(BPh_4)_2$][17] and [{(triphos)Co}$_2$(μ-1,4,5,8-tetraoxonaphthaleno)]$(BF_4)_2$ [$\mathbf{2}\cdots BF_4)_2$][24] (Scheme 2).

The EPR spectra in solution at 295 K and in a THF−CH_2Cl_2 glass at 100 K show only broad unresolved signals centred at $g = 2.12$ which is a typical value for low-spin Co^{II} complexes.[24][25][26][27][28]

Molecular Orbital Calculations: To gain insight into the possible interaction pathway, molecular orbital calculations on idealised and simplified model compounds were performed at the SCF level of theory. The frontier molecular orbitals of the complexes are depicted in Figures 5 and 6. The symmetry labels *g* and *u* refer to the inversion centres of the molecules. According to Hoffmann[3] the splitting of the singlet and triplet state is related to the energy difference

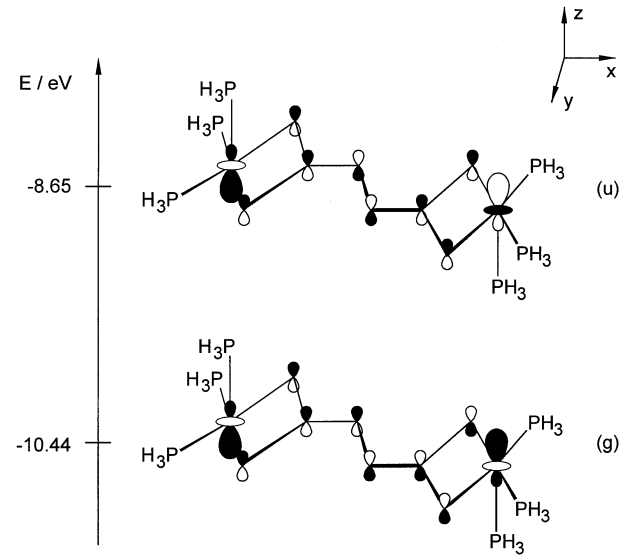
$\mathbf{4}^{2+}$	16	1.82	2.12	this paper

of the two frontier molecular orbitals $\varepsilon_1 - \varepsilon_2$ through $-2J = E_T - E_S = -2K_{ab} + (\varepsilon_1 - \varepsilon_2)^2\cdot(J_{aa} - J_{ab})^{-1}$ where K_{ab} is the two-electron exchange integral and J_{aa}, J_{ab} are the one- and two-centre coulomb repulsion integrals. Assuming that K_{ab}, J_{aa}, and J_{ab} vary only slowly in closely related compounds the energy difference of the *spin states* is proportional to the square of the splitting of one-electron *energy levels*.

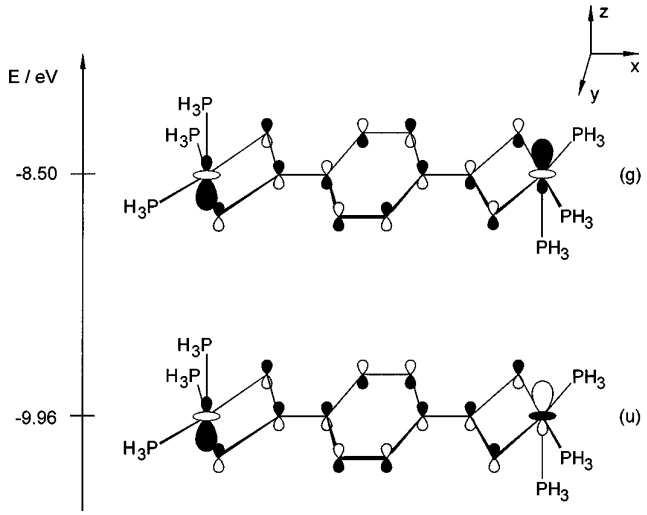
As expected from simple ligand-field theory[29] the unpaired electron of each cobalt centre in a square-pyramidal coordination geometry occupies a d_{z^2} orbital (with an ad-

Figure 5. Orbital splitting and orbital symmetry of the model complex of $\mathbf{3}^{2+}$ [a]



[a] The contribution of ligand orbitals is exaggerated. The composition is approximately 77% metal, 20% PH_3 and 3% bridging ligand.

Figure 6. Orbital splitting and orbital symmetry of the model complex of $\mathbf{4}^{2+}$ [a]



[a] The contribution of ligand orbitals is exaggerated. The composition is approximately 77% metal, 20% PH_3 and 3% bridging ligand.

mixture of 5% s and 9% p_z). The highest occupied orbitals of the dimer are the symmetric and antisymmetric combinations of these monomer orbitals. In the fumarato complex ($\mathbf{3}^{2+}$) the in-phase combination (*g*, Figure 5) is lower in energy than the out-of-phase combination (*u*, Figure 5), while the reverse is true for the terephthalato complex ($\mathbf{4}^{2+}$) (Figure 6). The qualitative level ordering of the ligand orbitals follows the expected trend from nodal structure: one (HOMO) and two (LUMO) nodal planes for the ligand-MOs of $\mathbf{3}^{2+}$ and two (HOMO) and three (LUMO) for $\mathbf{4}^{3+}$ (Figures 5 and 6).

As opposed to the d^9/d^9 case (Cu^{II}/Cu^{II}) the magnetic orbitals of the cobalt centres (d_{z^2} + p_z) are orientated almost perpendicular (*z* axis) to the plane of the carboxylato group (*xy* plane). This orientation precludes any interaction through the σ-framework of the bridging ligand but provides a pathway over the π-system of the bridge. The magnetic exchange coupling mediated by the π-system of the ligand is expected to be much smaller than an interaction through the σ-system (better orbital overlap) and the experimental results (small splitting in the cobalt case and larger splitting in the copper case) seem to support this expectation. However, inspite of the large distances between the metal centres and the poorer overlap between the metal and the ligand orbitals, a weak antiferromagnetic exchange is observed which is more than two orders of magnitude larger than the calculated singlet−triplet energy gap ($2J$ = -0.1 cm^{-1}, d_{M-M} = 10.3 Å) based on a statistical analysis.[2] Thus even switching from the σ-interaction pathway in Cu−Cu dimers to a π-interaction in Co−Co complexes does not prevent a magnetic coupling of the two metal centres separated by 10 Å.

In order to relate the singlet−triplet energy gap to the energy difference between the highest one-electron energy levels the HOMO−LUMO gaps of model compounds of $\mathbf{3}^{2+}$ and $\mathbf{4}^{2+}$ were calculated; also included in the calculation were models of the complexes $\mathbf{1}^{2+}$ and $\mathbf{2}^{2+}$.[17][24] The results are summarised in Table 3. In fact, the simple calculation reflects the correct ordering of decreasing antiferromagnetic interaction $\mathbf{1}^{2+} > \mathbf{2}^{2+} > \mathbf{3}^{2+} > \mathbf{4}^{2+}$ (Tables 2 and 3).

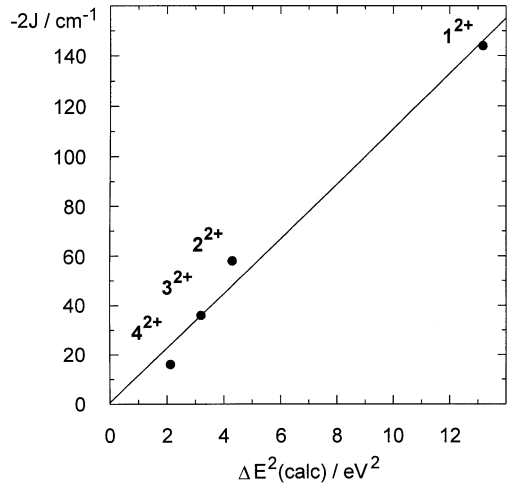
Table 3. Orbital energies and orbital energy splitting values

compound	ε_1/eV	ε_2/eV	$\Delta E^2=(\varepsilon_1-\varepsilon_2)^2$	Co···Co/Å
$\mathbf{1}^{2+}$	−12.232	−8.602	13.18	3.07
$\mathbf{2}^{2+}$	−10.533	−8.459	4.30	8.11
$\mathbf{3}^{2+}$	−10.438	−8.649	3.20	8.37
$\mathbf{4}^{2+}$	−9.958	−8.500	2.13	10.31

Furthermore the square of the calculated energy difference $\Delta E^2 = (\varepsilon_1 - \varepsilon_2)^2$ correlates well with the experimental singlet−triplet splitting $-2J$ ($-2J$ [cm^{-1}] = 11.0 × ΔE^2 [eV^2] + 0.61; r^2 = 0.982) (Figure 7) showing that even this simple and qualitative model can explain the observed antiferromagnetic interaction in d^7/d^7 dinuclear complexes.

Encouraged by these results the influence of distortions within the dinuclear complex on the singlet−triplet energy gap was studied. In the first study the central phenyl ring of the model complex $\mathbf{4}^{2+}$ was rotated around the x-axis (Figures 6 and 8). The dihedral angle between the plane of the phenyl ring and the basal planes of the metal-surrounding square pyramids was varied from 0 to 90°. Qualitatively the overlap between the p-orbitals at the carbon atoms C42 and C43 (Figures 2 and 8) should decrease and at the 90° distortion they should be strictly orthogonal leading to a vanishing HOMO−LUMO gap, ΔE, and thus to a zero antiferromagnetic interaction. With the employed calculation method the highest molecular orbitals become degenerate at a dihedral angle of 70°. However, too much significance should not be ascribed to the computed angle since the value is dependent on the choice of exponents for

Figure 7. Correlation of the experimental S/T gap ($2J$) and the the square of the calculated HOMO−LUMO gap (ΔE^2)



the carbon p-orbital. A similar situation was encountered in the study of the Cu−O−Cu angle variation in di-μ-OH copper dimers.[2][3] Experimentally this distortion could be achieved by attaching large substituents onto the phenyl ring of the bridging ligand; this is currently being attempted.

Figure 8. Distortion of the ligand π-system

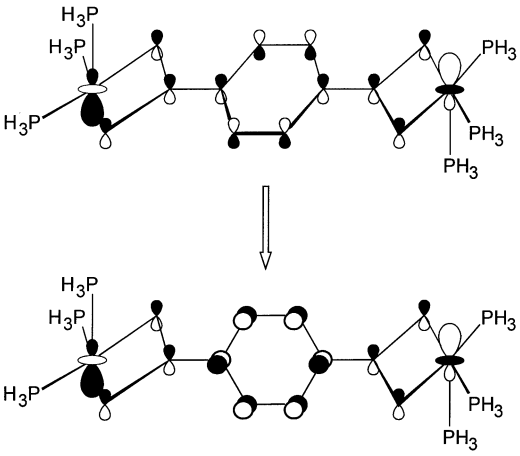


Figure 9. Square pyramid−trigonal bipyramid distortion

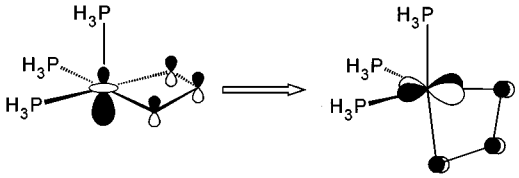

The second distortion possible in five-coordinate complexes is the transformation of the coordination polyhedron from square pyramidal to trigonal bipyramidal. This can be achieved by rotating the carboxylate chelating ligand out of the basal plane (xy plane) into the xz plane while maintaining the geometry of the $(PH_3)_3Co$ fragment (Figure 9). The hybridisation of the cobalt centres changes from d_{z^2} (+s and p_z) to almost pure d_{xy} (+p_y) (in this coordinate system) as has been shown previously.[29] The calculations show than this distortion has only a very small effect on the HOMO−LUMO energy gap; the π-type overlap of the metal d-hybrid orbitals with the oxygen p-orbitals obviously remains almost constant during the distortion. The small energy difference and activation barrier between square-pyramidal and trigonal-bipyramidal distorted triphos−Co complexes has been experimentally shown by EPR[24][25][26][27][28] and NMR spectroscopy[30][31][32] as well as by the fact that in one case both conformational isomers have been isolated in the solid state.[33] This is consistent with the assumption that neither the total energy nor the energy gap of the frontier orbitals change significantly during the distortion. Therefore unlike the Cu−Cu dimers[2][7] the singlet−triplet splitting in Co−Co dimers of the type described in this work appears relatively insensitive towards this geometrical distortion.

In summary, this work has shown that intramolecular antiferromagnetic exchange coupling occurs in dinuclear triphos−Co^{II} complexes up to a metal−metal distance of 10 Å. The interaction is transmitted through the π-system of the bridging ligand. The experimental results can be explained within a simple MO approach at the SCF level of theory. Distortions within the π-system of the bridging ligand are predicted to decrease the HOMO−LUMO gap and thus the antiferromagnetic coupling while distortions from a square-pyramidal to a trigonal-bipyramidal geometry around the metal centre are predicted to have a negligible influence on the HOMO−LUMO gap.

This work received support from the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie*, and the *Volkswagenstiftung*.

Experimental Section

Computational Details: Calculations were performed on an Apple Macintosh IIfx with the CACHe/ZINDO program Version 3.6 (M. C. Zerner 1990−1994) with INDO/1 parameters. Orbital energies were obtained from an SCF calculation of the singlet state without symmetry constraints. The geometry of the molecules was idealized to a square pyramidal polyhedron around the metal centre and a planar bridging ligand. The triphos ligand was replaced by three isoelectronic PH_3 groups. Distances and angles were as follows: Co−P_{eq} 2.19 Å, Co−P_{ax} 2.26 Å, Co−O 2.00 Å, P−H 1.38 Å, O−Co−O 65.8°, P−Co−P 90.0°, O−C−O 118.0°.

General Methods: Unless noted otherwise all manipulations were carried out under an inert atmosphere by means of standard Schlenk techniques. All solvents were dried by standard methods and distilled under inert gas. − NMR: Bruker AC 200 at 200.13 MHz (^{1}H). − IR: Bruker FTIR IFS-66, as CsI disks. − UV/Vis/NIR: Perkin Elmer Lambda 19. − MS: Finnigan MAT 8230. − EPR: Bruker ESP 300 E, X-band, standard cavity ER 4102, temperature control unit Eurotherm B-VT 2000, external standard diphenylpicrylhydrazyl (DPPH). − Elemental analyses: microanalytical laboratory of the Organisch-Chemisches Institut, University of Heidelberg. − Melting points: Gallenkamp MFB-595 010, melting points are not corrected. − Cyclic voltammetry: Metrohm "Universal Meß- und Titriergefäß", Metrohm GC electrode RDE 628, platinum electrode, SCE electrode, Princeton Applied Re-

search potentiostat Model 273, 10^{-3} M in 0.1 M nBu$_4$NPF$_6$/CH$_3$CN. – Magnetic measurements were carried out on a Faraday type magnetometer in the temperature range 7–290 K. The magnetic field applied was 10 kG. Mercury tetrakis(thiocyanato)cobaltate was used as a susceptibility standard. Corrections for diamagnetism were estimated using Pascal's constants[34] as $915 \cdot 10^{-6}$ [**3**·(BF$_4$)$_2$] and $955 \cdot 10^{-6}$ cm^3 mol^{-1} [**4**·(BF$_4$)$_2$]. Magnetism of the samples was found to be field-independent. The effective magnetic moment was calculated by using the equation $\mu_{eff} = 2.83\ (\chi_M\ T)^{1/2}$, whereas the exchange parameters J and g_{mag} were obtained by a least-squares fitting of the susceptibility data to the Bleaney-Bowers equation for dinuclear complexes with $S_1 = S_2 = 1/2$, where $2J$ is the energy difference between the singlet and the triplet states ($H = -2J \cdot S_1 \cdot S_2$). A further parameter p, representing the percentage of a mononuclear impurity with $S = {}^3/_2$ (high-spin Co^{II}), was introduced although the exact nature of the actual impurity (oligomer, polymer) was unknown: p = 6.7% [**3**·(BF$_4$)$_2$], 5.7% [**4**·(BF$_4$)$_2$]. The variations in g_{mag} values are not significant and result from the fitting method. Magnetic measurements in solution (CD$_2$Cl$_2$) were conducted according to the method of Evans.[35] Diphenylpicrylhydrazyl (DPPH) was used as a susceptibility standard.

Chemicals: 1,1,1-Tris(diphenylphosphanomethyl)ethane, CH$_3$C(CH$_2$PPh$_2$)$_3$[36], Co(BF$_4$)$_2$·6 H$_2$O[37].

Crystallographic Structure Determinations: The measurements were carried out on a Siemens P4 (Nicolet Syntex) R3m/v four-circle diffractometer with graphite-monochromated Mo-K_α radiation. All calculations were performed using the SHELXT PLUS software package. Structures were solved by direct methods with the SHELXS-86 program and refined with the SHELX93 program.[38] Graphics were prepared using XPMA and ZORTEP.[39] An absorption correction (ψ scan, $\Delta\psi = 10°$) was applied to all data. Atomic coordinates and anisotropic thermal parameters of the nonhydrogen atoms were refined by a full-matrix least-squares calculation. Table 4 is a compilation of the data for the structure determinations. Further details of the crystal structure determinations may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository numbers CSD-407616 [**3**·(BF$_4$)$_2$], and CSD-407617 [**4**·(BF$_4$)$_2$].

(μ-Fumarato)bis[{1,1,1-tris(diphenylphosphanomethyl)-ethane}cobalt] Bis(tetrafluoroborate) [**3**·(BF$_4$)$_2$] *and (μ-Terephthalato)bis[{1,1,1-tris(diphenylphosphanomethyl)ethane}-cobalt] Bis(tetrafluoroborate)* [**4**·(BF$_4$)$_2$]: A solution of Co(BF$_4$)$_2$·6 H$_2$O (341 mg, 1 mmol) in EtOH (10 ml) was added to a solution of the triphos ligand (624 mg, 1 mmol) in THF (15 ml). Addition of the dicarboxylic acid [fumaric acid for **3**·(BF$_4$)$_2$; 58 mg, 0.5 mmol; terephthalic acid for **4**·(BF$_4$)$_2$; 83 mg, 0.5 mmol] to the orange-coloured solution caused a slow colour change to red-brown. After the solution had been stirred for two hours it was filtered and the solvents were evaporated. The solid residue was washed with Et$_2$O, dissolved in CH$_2$Cl$_2$ and filtrated over 2 cm of Kieselgur. The clear, red solution was concentrated in vacuo until the complex started to precipitate. Precipitation was completed by adding 10 ml of Et$_2$O. Recrystallisation from CH$_2$Cl$_2$/Et$_2$O yielded 356 mg (43%) of **3**·(BF$_4$)$_2$ and 410 mg (48%) of **4**·(BF$_4$)$_2$, respectively. Vapour diffusion of Et$_2$O into a concentrated solution of the complex [**3**·(BF$_4$)$_2$ in acetone; **4**·BF$_4$)$_2$ in CH$_2$Cl$_2$] afforded red needle-shaped crystals suitable for X-ray crystallographic analysis.

3·(BF$_4$)$_2$: M.p. 250°C (decomp.). – IR (CsI): $\tilde{\nu}$ = 3058 cm^{-1} (m), 1485 (m), 1436 (s), 1283 (m), 1093 (s), 1055 (br), 999 (m), 829 (w), 738 (s), 692 (s), 513 (s). – MS (FAB); *m/z* (%): 1599 (18) [M$^+$ + F], 1480 (11) [M$^+$], 875 (38) [M$^+$ – triphos-Co + Ph + 1], 797 (40) [M$^+$ – triphos-Co], 740 (5) [M^{2+}], 683 (52) [triphos-Co$^+$], 547 (43) [triphos-Ph$^+$]. – UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 489 nm (3550 M^{-1} cm^{-1}), 966 (1030). – CV (CH$_3$CN): $E_{1/2}$ = –0.30 V (qrev.), +0.35 V (qrev.). – μ_{eff}(CD$_2$Cl$_2$): 3.5 μ_B. – C$_{86}$H$_{80}$B$_2$Co$_2$F$_8$O$_4$P$_6$ (1654.9): calcd. for **3**·(BF$_4$)$_2$·3 CH$_2$Cl$_2$: C 55.98, H 4.54; found C 55.11, H 5.04.

4·(BF$_4$)$_2$: M.p. 240°C (decomp.). – IR (CsI): $\tilde{\nu}$ = 3059 cm^{-1} (m), 1514 (m), 1485 (m), 1434 (s), 1409 (m), 1279 (w), 1096 (s), 1059 (br), 998 (m), 854 (s), 833 (w), 738 (s), 694 (s), 514 (s). – MS (FAB); *m/z* (%): 1549 (42) [M$^+$ + F], 1530 (21) [M$^+$], 925 (74) [M$^+$ – triphos-Co + Ph + 1], 847 (71) [M$^+$ – triphosCo], 765 (8) [M^{2+}], 683 (56) [triphosCo$^+$], 547 (72) [triphos-Ph$^+$]. – UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 474 nm (3130 M^{-1} cm^{-1}), 650 (230), 963 (880). – CV (CH$_3$CN): E_p = –0.37 V (irr.), $E_{1/2}$ = +0.27 V (qrev.). – μ_{eff}(CD$_2$Cl$_2$): 3.1 μ_B. – C$_{90}$H$_{82}$B$_2$Co$_2$F$_8$O$_4$P$_6$ (1705.0): calcd. for **4**·(BF$_4$)$_2$·1 CH$_2$Cl$_2$: C 61.07, H 4.73; found C 60.56, H 5.03.

Keywords: Polynuclear complexes / Carbene complexes / Bridging ligands / Alkynyl complexes

The sequential reaction of two equivalents of the dimethylamino(ethynyl)carbene complexes [$(CO)_5M{=}C(NMe_2)C{\equiv}CH$] [M = W (**1a**), Cr (**1b**)] with two equivalents of *n*BuLi and one equivalent of a transition metal dichloride, [$Cl_2M'(L_n)$], affords trinuclear biscarbene complexes of the type [$(CO)_5M{=}C(NMe_2)C{\equiv}C{-}M'(L_n){-}C{\equiv}CC(NMe)_2{=}M(CO)_5$] [$M'(L_n)$ = $Ni(PEt_3)_2$ (**2a**, **b**), $Pd(PEt_3)_2$ (**3a**, **b**), $Pt(PEt_3)_2$ (**4a**, **b**), $Fe(dmpe)_2$ (**6a**), Hg (**8a**), $Ti(\eta^5\text{-}C_5H_5)_2$ (**9a**, **b**)] [dmpe = 1,2-bis(dimethylphosphino)ethane]. Treatment of **1a** with equimolar amounts of first *n*BuLi and then [$Cl_2M'(L_n)$] results in the formation of the monosubstitution products [$(CO)_5W{=}C(NMe_2)C{\equiv}CM'(L_n)$] [$M'(L_n)$ = *trans*-$Pd(PEt_3)_2Cl$ (**5a**), *trans*-$Fe(dmpe)_2Cl$ (**7a**)]. Additionally, the synthesis of the heterobimetallic ethynylcarbene complex [$(CO)_5W{=}C(NMe_2)C{\equiv}CPd(PEt_3)_2C{\equiv}CH$] (**10a**), starting from **1a** and [$ClPd(PEt_3)_2C{\equiv}CH$], is described. When three equivalents of **1a** are treated, first with three equivalents of *n*BuLi and then with one equivalent of the trihalides PCl_3 or BBr_3, the novel tris(ethynylcarbene) complexes [$\{(CO)_5W{=}C(NMe_2)C{\equiv}C\}_3E$] [E = B (**11a**), P (**12a**)] are obtained. The reaction of four equivalents of **1a**, **b** with four equivalents of *n*BuLi, followed by addition of one equivalent of a group 14 tetrachloride [$M'Cl_4$], yields the novel tetrakis(ethynylcarbene) complexes [$\{(CO)_5M{=}C(NMe_2)C{\equiv}C\}_4M'$] [M' = Si (**13a**, **b**), Ge (**14a**), Sn (**15a**, **b**)]. The complexes **8a**, **9a**, **12a**, and **15a** were characterized by X-ray structural analyses. All spectroscopic and structural data suggest that the carbene fragments and the central transition metal or heteroatom in these new bis-, tris-, and tetrakis(ethynylcarbene) complexes interact only weakly.

Introduction

Polynuclear transition metal complexes with π-conjugated carbon bridges have recently attracted considerable interest due to their potentially useful chemical and physical properties. An application as materials for nonlinear optics has been proposed[1]. In addition, π systems, such as highly ethynylated organic and organometallic compounds, have been intensively studied since they represent viable monomers for the synthesis of high carbon polymers. Transition metal σ-acetylide complexes[2] and ethynyl-substituted half sandwich complexes can be considered as building blocks in the synthesis of linear[3], star-shaped[3d][4], and spherical[5] structures.

A wide range of π-conjugated acetylide transition metal complexes of the type [$L_nM{-}(C{\equiv}C)_x{-}M'L'_{n'}$] have already been reported[1a]. Examples for conjugated bis(Fischer carbene)complexes of the type [$L_nMC(YR)\mathbf{C}_c(RY)CML_n$] (with $\mathbf{C}_c$ = conjugated carbon bridge, Y = O, NR) are also known. Symmetrical complexes containing phenyl[6][7], biphenyl[8], binaphthyl[7], anthracene[9], 1,6-methano[10]annulene-2,7-diyl[10], alkenyl,[11] or ammonium pentadienide[12] bridges are readily accessible. By contrast, apart from our results on the synthesis of the C_4HgC_4-bridged complex [$(CO)_5W{=}C(NMe_2)C{\equiv}CC{\equiv}CHgC{\equiv}CC{\equiv}CC(NMe_2){=}W(CO)_5$][13], examples of π-conjugated metal-bridged trinuclear biscarbene complexes are unknown[14]. Nevertheless, all these systems may represent suitable substructures for the construction of two- and three-dimensional networks.

Previously, we reported on the efficient preparation of bimetallic ethynylcarbene complexes by nucleophilic substitution of a lithiated ethynyl- or butadiynylcarbene complex for the halide X in metal monohalides [$XM'(L'_m)$][13][15]. In this paper we report on a general synthetic route to a wide range of π-conjugated metal-bridged bis-, tris-, and tetrakis(Fischer carbene) complexes. These carbene complexes can be considered as a new type of monomeric polyacetylenic organometallic building blocks for the synthesis of two and three dimensional structures.

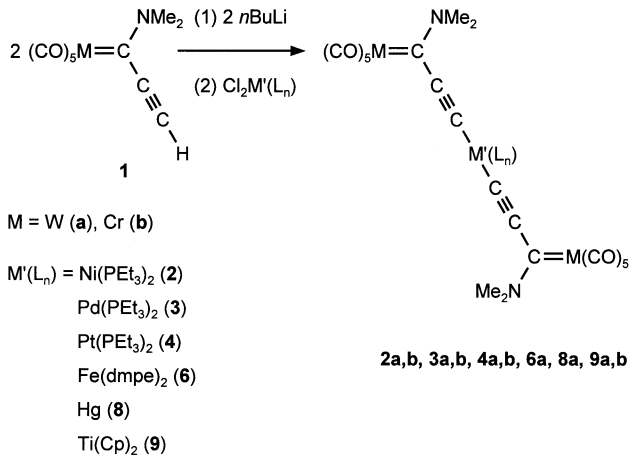
Results and Discussion

Extension of the concept of coupling a L_nMC_3 with a $M'L_m$ fragment to the treatment of the dimethylamino(ethynyl)carbene complexes of tungsten and chromium with different metal dihalides afforded metal-bridged biscarbene complexes of the general type [$(CO)_5M{=}C(NMe_2)C{\equiv}C{-}M'(L_m){-}C{\equiv}CC(NMe_2){=}M(CO)_5$]. The dimethylamino(trimethylsilylethynyl)carbene complexes [$(CO)_5M{=}C(NMe_2)C{\equiv}CSiMe_3$] (M = W, Cr) proved to be suitable precursors for the L_nMC_3 fragment. Desilylation with KF/THF/MeOH[15], followed by deprotonation with *n*BuLi, gave the lithiated acetylide [$(CO)_5M{=}C(NMe_2)C{\equiv}CLi$] (M = W, Cr). Treatment of two equivalents of this tungstate (or chromate) in situ with one equivalent of the metal dichloride [$Cl_2M(PEt_3)_2$] (M = Ni, Pd, Pt) resulted

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0191 $ 17.50+.50/0

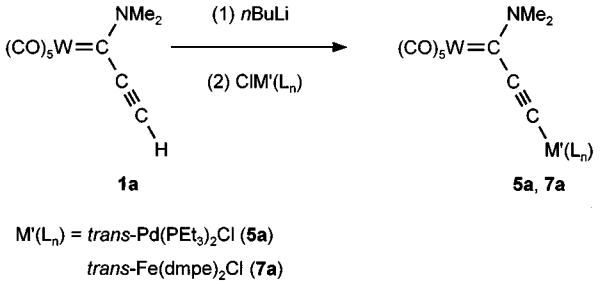
in formation of the pale yellow *trans*-bis(ethynylcarbene) complexes **2**–**4** in yields, after chromatography, of 66–72% (Scheme 1).

Scheme 1



As expected, the reaction of equimolar amounts of the lithiated complex $[(CO)_5W{=}C(NMe_2)C{\equiv}CLi]$ and a metal dichloride under the same conditions led to the formation of a monosubstituted product. Thus, when **1a** was treated at −80°C, first with *n*BuLi and then with the equimolar amount of $[Cl_2Pd(PEt_3)_2]$, chromatographic work up of the reaction mixture afforded the complex **5a** in a yield of 61% (Scheme 2).

Scheme 2



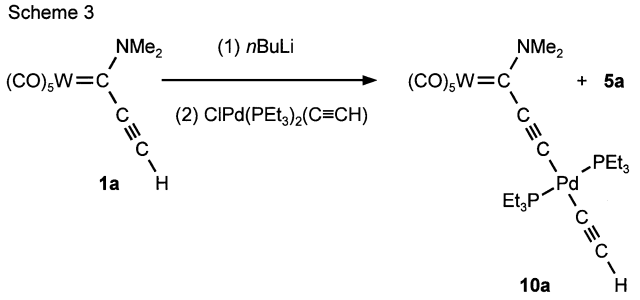
Analogous reaction sequences were carried out with the iron dichloride $[Cl_2Fe(dmpe)_2]$ [dmpe = 1, 2-bis(dimethylphosphino)ethane]. Addition of an equimolar amount of *n*BuLi to two equivalents of **1a**, followed by addition of one equivalent of the metal dichloride, gave the linear *trans*-substituted trinuclear complex **6a** in a yield of 35% (Scheme 1). The reaction of equimolar amounts of the educt complexes resulted in the formation of the bimetallic ethynylcarbene complex **7a** in a yield of 29% (Scheme 2).

Similar to **2**–**4**, and **6**, treatment of two equivalents of deprotonated ethynylcarbene complex **1a** and one equivalent of the dichloride $HgCl_2$ resulted in the formation of a linear biscarbene complex (Scheme 1). Chromatographic work up of the reaction mixture afforded compound **8a** in a yield of 57%. This *trans*-coordinated complex represents the only trinuclear complex without any coligands at the central metal in this series.

A tetrahedrally coordinated trinuclear biscarbene complex was obtained, when two equivalents of the lithiated complexes **1a**, **b** were treated with one equivalent of the dichloride $[Cl_2Ti(\eta^5\text{-}C_5H_5)_2]$ (Scheme 1). The red biscarbene complexes **9a**, **b** were obtained in yields of 67% (**9a**) and 68% (**9b**), respectively. Tweezer compounds such as the bisalkynyl substituted titanocene complexes of the type $[(\eta^5\text{-}C_5H_4R)_2Ti(C{\equiv}CR')_2]$ are well known[16][17][18]. The formation of monoalkynyl substituted titanocenes $[(\eta^5\text{-}C_5H_4R)_2TiCl(C{\equiv}CR')]$ by reaction of equimolar amounts of an acetylide and a metal dihalide could also be observed[16]. Efforts to prepare an analogous monosubstituted ethynylcarbene complex $[(CO)_5W{=}C(NMe_2)C{\equiv}CTiCl(\eta^5\text{-}C_5H_5)_2]$ starting from **1a** failed. Only a small amount of the disubstituted product **9a** was isolated.

Apart from **2**–**4**, and **8a** the synthesis of asymmetrically π-conjugated linear systems was intended. Treatment of the deprotonated complex **1a** with $[ClPd(PEt_3)_2C{\equiv}CH]$ afforded the light yellow ethynyl propynylidene palladium complex $[(CO)_5W{=}C(NMe_2)C{\equiv}CPd(PEt_3)_2C{\equiv}CH]$ **10a** in rather moderate yield (23%) (Scheme 3). The monosubstitution product **5a** was obtained as a by-product in a yield of 19%. Obviously, the ethynyl chloro palladium complex was contaminated with small amounts of $[Cl_2Pd(PEt_3)_2]$, which reacted with deprotonated **1a** to yield **5a**. Further investigations, in order to optimize the synthesis of **10a** and to apply this compound as starting material for polynuclear complexes with longer π-conjugated metal–carbon systems, are presently under way.

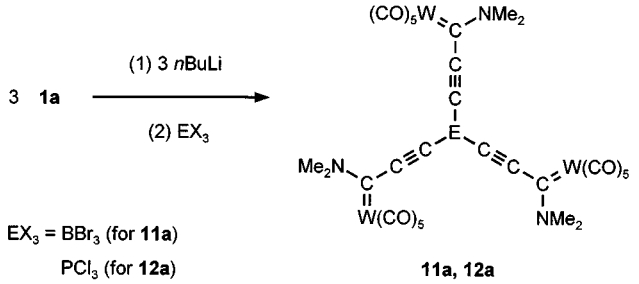
Scheme 3



The nucleophilic substitution of complexes **1a** and **1b** is not restricted to transition metal halides, but can also be applied to halides of main group elements. By the reaction of three equivalents of the deprotonated ethynylcarbene complex **1a** with one equivalent of either the group 13 trihalide BBr_3, or the group 15 trihalide PCl_3 tris(ethynylcarbene) complexes of the general type $[\{(CO)_5W{=}C(NMe)_2C{\equiv}C\}_3E]$ were obtained in good to high yield [E = B: 61% (**11a**), P: 81% (**12a**)] (Scheme 4).

Tetrahalides of the main group metals can also be employed for analogous nucleophilic substitution reactions with the lithiated complex **1**. When four equivalents of the deprotonated ethynylcarbene complex **1a** were treated with one equivalent of a group 14 tetrachloride $M'Cl_4$, pentanuclear tetrakiscarbene complexes $\{[(CO)_5W{=}C(NMe)_2C{\equiv}C]_4M'\}$ were obtained in good yield [M′ = Si: 60% (**13a**), Ge: 59% (**14a**), Sn: 76% (**15a**)] (Scheme 5). In the case of silicium and tin the corresponding chromium

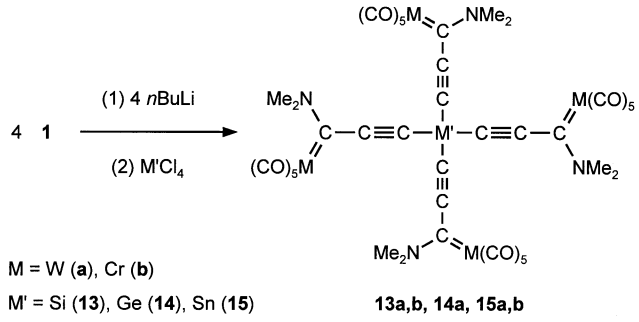
Scheme 4



complexes were prepared in a similar manner with yields of 54% (**13b**) and 71% (**15b**), respectively.

All complexes **13**−**15** are stable in the solid state and in solution, when carefully dried solvents are used. In the series Sn → Ge → Si the tin compounds are the most stable. By comparison, the M−C bond of the silicium and germanium derivatives is easily cleaved by hydrolysis or by contact with silica. Therefore, complexes **14a** and **15a**, **b** can only be filtered over cellite, whereas **14a**, **b** can be purified by column chromatography on silica.

Scheme 5



All other new complexes are stable at room temp. Compounds **2**−**15** were characterized by spectroscopic means and elemental analyses. The positions of the ν(CO) absorptions of the pentacarbonyl metal moiety in complexes **2**−**4**, **8a**, and **9** are only slightly influenced by variation of the propynylidene metal substituent M′(L_n). In contrast, the absorptions of the two iron-substituted complexes **6a** and **7a** are found at lower wavenumbers. The unsymmetrically substituted compounds **5a** and **10a** show absorptions similar to those of the *trans*-biscarbene complex **3a**. However, the A^1(*trans*) and the E absorptions of all complexes **2**−**10a** are at significantly smaller wavenumbers than those of the corresponding educt complexes **1**, indicating the π-basic properties of M′(L_n) in [$(CO)_5M{=}C(NMe_2)C{\equiv}C{-}$M′-($L_n$)$-C{\equiv}CC(NMe_2){=}M(CO)_5$] or [$(CO)_5M{=}C(NMe_2)$-$C{\equiv}$CM′($L_n$)], respectively. This tendency is less pronounced for the tris- and tetrakis(ethynylcarbene) complexes **11a**, **12a**, and **13**−**15**.

The two carbene fragments of the linear trinuclear biscarbene complexes **2**−**4**, **6a**, and **8a** can be regarded as π-conjugated. The ethynyl groups can mutually interact through metal d_{xy} and d_{yz} orbitals. For *trans*-coordinated square-planar dialkynyl complexes [$(Et_3P)_2M(C{\equiv}CR)_2$] (M = Ni, Pd, Pt), showing the same D_{2h} symmetry, π-conjugation involving the metal d-orbitals has already been discussed[19].

The stretching frequencies of the carbon−carbon triple bonds in the complexes **2**−**4** are significantly smaller than those of the unsubstituted ethynylcarbene complexes **1** [$\tilde{\nu}$(C≡C) = 2118 cm^{-1}]. This is commonly observed with σ-acetylenic transition metal complexes, and can be considered as evidence for the increase in polarity of the acetylenic bond upon coordination to the metal[17][20]. In the series **2** → **3** → **4** the ν(C≡C) absorptions shift to higher wavenumbers due to the increasing donating capacity of the M′$(PEt_3)_2$ moiety, and thus to the increasing polarity of the C≡C bond. For alkynyl complexes of group 10 metals an analogous order of ν(C≡C) frequencies has been noted[20]. In this case the M←CCR bond polarity, and not the M→CCR π-backbonding[20], was found to exert the dominating influence on the ν(C≡C) frequency.

For the two inequivalent *trans*-ethynyl moieties in **10a** only one ν(C≡C) absorption was observed [$\tilde{\nu}$(C≡C) = 2036 cm^{-1}]. Compared to **3a** and **10a**, complex **5a** shows a ν(C≡C) absorption band at significantly higher energy [$\tilde{\nu}$(C≡C) = 2032 cm^{-1} (**3a**), 2045 cm^{-1}(**5a**)]. The *trans*-position of the chloride ligand is known to cause a decrease in the polarity of the M−C≡ bond[21] thus leading to the observed shift of the ν(C≡C) absorption. The same tendency has already been observed for the disubstituted complex [$PhC{\equiv}CPd(PPh_3)_2C{\equiv}CPh$] [$\tilde{\nu}$(C≡C) = 2110 cm^{-1}][22] and the monosubstituted derivative [$ClPd(PPh_3)_2C{\equiv}CPh$] [$\tilde{\nu}$(C≡C) = 2125 cm^{-1}][23]. Compared to the phenyl substituted ethynyl complexes [$PhC{\equiv}CM(PEt_3)_2C{\equiv}CPh$] (M = Ni, Pd, Pt)[22], [$PhC{\equiv}CFe(dmpe)_2C{\equiv}CPh$][24] and [$ClFe(dmpe)_2C{\equiv}CPh$][25] the ν(C≡C) band of complexes **2**−**4**, **6a**, and **7a** is at lower wavelength, indicating that the $(CO)_5M{=}C(NMe_2)$ fragment acts as a stronger donor than the phenyl group. The IR spectrum of **8a** shows no ν(C≡C) band although a ν(C=C) absorption can be observed for the phenyl substituted complex $[Hg(C{\equiv}CPh)_2]$[26]. Similarly, but in contrast to $[(\eta^5\text{-}C_5H_4R)_2Ti(C{\equiv}CR')_2]$ (R′ = alkyl, aryl, $SiMe_3$)[16c], no ν(C≡C) absorption was observed for the complexes **9**.

Complex **11a** shows a very weak ν(C≡C) absorption at $\tilde{\nu}$ = 2126 cm^{-1}. However, no ν(C≡C) absorption was observed for **12a**, in contrast to $P(C{\equiv}CR)_3$ with R = H, Me, or Ph[27][28][29]. The frequencies of the ν(C≡C) absorption of the tetrakiscarbene complexes **13**−**15** decrease in the series **13** → **14** → **15** [$\tilde{\nu}$(C≡C) = 2132 cm^{-1} (**13a**, **14a**), 2118 cm^{-1} (**15a**)]. A similar tendency is observed for [M′$(C{\equiv}CH)_4$] [$\tilde{\nu}$(C≡C) = 2062 cm^{-1} (M′ = Si, Ge), 2042 cm^{-1} (M′ = Sn)][30], but the opposite trend is observed for the biscarbene complexes **2**−**4**.

The resonance of the carbene carbon atom in the ^{13}C-NMR spectra of the complexes **2**−**15** is at rather high field (δ = 238−250 for M = Cr and δ = 218−231 for M = W). This compares well with the shifts usually observed for simple aminocarbene complexes. As expected from the trend in the IR spectroscopic data of **1** and **2**−**9**, substitution of M′(L_n) for H in compounds of the type [$(CO)_5M{=}C(NMe_2)C{\equiv}CR$] [R = H, M′($L_n$)] results in an upfield shift of the C(carbene) resonance. A similar trend is

observed for the tris- and tetrakis(ethynylcarbene) complexes **11a**, **12a**, and **13**−**15**.

The ethynyl $^{13}C_\alpha$ and $^{13}C_\beta$ resonances of complexes **2**−**4** were unambiguously assigned on the basis of the coupling constants $J_{^{13}C,^{31}P}$ and in the case of **4** additionally on the basis of the coupling constants $J_{^{13}C,^{31}P}$. As a rule, the relationship $|^2J_{^{13}C,^{31}P}| > |^3J_{^{13}C,^{31}P}|$ was used in analogy to the assignment of the C_α and C_β resonances of the corresponding bisalkynyl complexes $[RC_\beta{\equiv}C_\alpha M(PEt_3)_2C_\alpha{\equiv}C_\beta R]$[21].

The shielding of the C_α and the C_β atom increases with increasing radius of the central metal (Ni < Pd < Pt). This observation has already been made for alkyl- or aryl-substituted bisalkynyl complexes of these metals[21] and is consistent with the IR spectroscopic data of **2**−**4**.

The difference $\Delta = \delta(C_\alpha)-\delta(C_\beta)$ in the ethynyl resonances for **3** [Δ = 41.04 ppm (**3a**), 45.0 ppm (**3b**)] and **4** [Δ = 35.01 ppm (**4a**), 38.98 ppm (**4b**)] is much more pronounced than for the phenyl-substituted bisalkynyl complexes $[PhC{\equiv}CM(PEt_3)_2C{\equiv}CPh]$ [M = Pd: Δ = 0.3 ppm, δ = 111.7 (C_α), 111.4 (C_β)[21]; M = Pt: Δ = −1.7 ppm, δ = 108.3 (C_α), 110.0 (C_β)][31] which indicates an increased polarity of the C≡C bond in the biscarbene complexes **2**−**4** when compared to bisalkynyl complexes. This can be explained with the stronger π-basic capacity of the $(CO)_5M{=}C(NMe_2)$ fragment relative to the phenyl group.

As already discussed, the π-backbonding of the central metal to the acetylide ligand is more pronounced in the halide-substituted complex **5a** than in the biscarbene compounds **2**−**4**. This tendency is reflected in the highfield shift of the C_α and C_β resonance of **5a** [δ = 149.51 (C_α), 118.68 (C_β)] when compared to **3a** [δ = 163.88 (C_α), 122.84 (C_β)]. The same trend has been found in the ^{13}C- and ^{31}P-NMR spectra of comparable bisalkynyl complexes $[RC{\equiv}CM(PEt_3)_2C{\equiv}CR]$[21] and alkynyl complexes $[ClM(PEt_3)_2C{\equiv}CR]$[21].

Compared to **2a**−**4a**, the $Fe(dmpe)_2$-substituted complexes **6a** and **7a** show a significant lowfield shift of the ethynyl resonances. Therefore, the $Fe(dmpe)_2$ fragment seems to have a stronger π-backbonding capacity than the $M(PEt_3)_2$ fragment (M = Ni, Pd, Pt). In contrast to **3a** and **5a**, the substitution of $(CO)_5W{=}C(NMe)_2C{\equiv}C$ in **6a** for Cl in **7a** does not result in a significant shift of the ethynyl resonances [**6a**: δ = 195.33 (C_α), 135.10 (C_β); **7a**: δ = 194.81 (C_α), 140.29 (C_β)]. However, the ^{13}C- and ^{31}P-NMR spectra of $[PhC{\equiv}CFe(dmpe)_2C{\equiv}CPh]$[25] and $[ClFe(dmpe)_2C{\equiv}CPh]$[24a][24c] are rather consistent with the results found for **3a**/**5a**.

As expected, the bisethynyl complex $[(CO)_5W{=}C(NMe_2)C_\beta{\equiv}C_\alpha Pd(PEt_3)_2C_{\alpha'}{\equiv}C_{\beta'}H]$ (**10a**) shows two different pairs of resonances for the ethynyl carbons [δ = 166.59 (C_α), 122.86 (C_β), 103.35 ($C_{\alpha'}$), 96.41 ($C_{\beta'}$)]. The assignment of the C_α, $C_{\alpha'}$, C_β, and $C_{\beta'}$ resonances is based on the comparison with $[HC{\equiv}CPd(PEt_3)_2C{\equiv}CH]$[21] and **3a**. As a result, the chemical shifts indicate a stronger π-basicity for the $(CO)_5W{=}C(NMe_2)C{\equiv}C$ than for the C≡CH fragment.

The ^1H- and ^{13}C-NMR spectra of complexes **8a**, **b** exhibit only one singlet for the cyclopentadienyl rings implying that the protons and the carbons of both rings are equivalent. In contrast, free rotation of the cyclopentadienyl rings is hindered for bulky substituents R [R = $CH_2C(Ph)_2H$ or $CH_2C(Ph)_2CN$] in $[(\eta^5\text{-}C_5H_5)_2Ti(C{\equiv}CR)_2]$[17]. Obviously, the carbene fragment in **8a**, **b** is small enough to avoid a similar effect.

Due to the nuclear spin I = 3/2 of boron the ethynyl resonances in the ^{13}C-NMR spectrum of **11a** appear as quartets. The identification of C_α (δ = 147.07) and C_β (δ = 101.39) is based on the decreasing size of the J_{BC} coupling constants ($^1J_{BC}$ = 71.2 Hz, $^2J_{BC}$ = 14.4 Hz). Whereas the ^1H-NMR spectrum of complex **11a** shows two distinct resonances for the NMe_2 group that of **12a** shows a doublet at δ = 3.77 ($^6J_{PH}$ = 1.2 Hz) and a singlet at δ = 3.61. The doublet is assigned to the methyl group in the *cis*-position with respect to the $W(CO)_5$ fragment at the N−C(carbene) bond. A similar homoallyl coupling between $C{-}CH_3$ and *cis*-$N{-}CH_3$ has already been observed for $[(CO)_5Cr{=}C(Me)NMe_2]$ ($^5J_{HH}$ = 0.9 Hz)[32]. Both ethynyl resonances of **12a** appear as doublets. In contrast, $P(C{\equiv}CC_6H_5)_3$ shows a doublet at δ = 109.5 ($^1J_{PC}$ = 18 Hz) and a singlet at δ = 82.3[27]. The C_α and C_β NMR resonances of complex **12a** were unambiguously assigned on the basis of the $^{13}C,^{31}P$ coupling constants. The doublet at higher field (δ = 107.15) with the larger coupling constant $^1J_{PC}$ = 11.4 Hz was therefore attributed to C_α and that at lower field (δ = 115.17), with the smaller coupling constant $^2J_{PC}$ = 8.1 Hz, to C_β. Compared to $P(C{\equiv}CPh)_3$ the C_β resonance of **12a** is downfield suggesting that the $(CO)_5W{=}C(NMe_2)$ fragment acts as a stronger acceptor than the phenyl group. The resonance in the ^{31}P-NMR spectrum of **12a** (δ = −98.92) resembles that of $P(C{\equiv}CPh)_3$ (δ = −85.1)[27] rather than that of $P(C{\equiv}CH)_3$ (δ = +91)[33] or $P(C{\equiv}CMe)_3$ (δ = +87)[28].

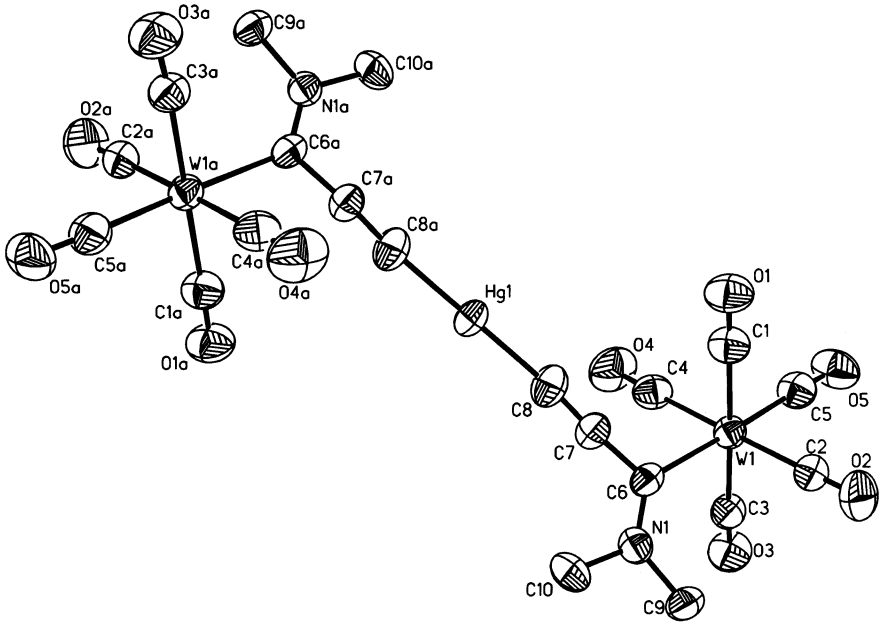
The $^{13}C_{(\alpha,\beta)}$ resonances of **15a**, **b** were assigned on the basis of J_{SnC} coupling constants with $^1J_{^{117}SnC,^{119}SnC}$ = 1169.5 Hz, 1118.2 Hz and $^2J_{^{117}SnC,^{119}SnC}$ = 218.9 Hz, 209.5 Hz. In contrast to **2**−**4**, the resonances of the C_α and C_β carbons of **13a**, **b**, **14a**, and **15a**, **b** are almost independent of the central metal atom [C_α, C_β: 118.73, 106.14 (**13a**); 117.66, 105.11 (**14a**); 119.47, 109.59 (**15a**)]. Compared to $[M'(C{\equiv}CPh)_4]$[34] or $[M'(C{\equiv}CMe)_4]$[34][35] the C_α resonances of complexes **13a**, **b**, **14a**, and **15a**, **b** are downfield.

In summary, the C_α resonance in the NMR spectra of the complexes **2**−**16** is at significantly lower field when compared to the corresponding phenyl-substituted ethynyl complexes[18][21][24c][25][31][36] and the difference $\Delta = \delta(C_\alpha)-\delta(C_\beta)$ is much more pronounced. These two trends can be explained by the stronger π-basicity of the $(CO)_5W{=}C(NMe_2)C{\equiv}C$ fragment when compared to that of the phenyl group, which gives rise to an increase in the polarity of the C≡C bond in the direction $M{-}C(\delta+){\equiv}C(\delta-)$.

Structures of 8a, 9a, 12a, and 15a

The structures of the complexes **8a**, **9a**, **12a**, and **15a** were also established by X-ray structural analyses (Figures 1−4). Within error limits the $(CO)_5W{=}C(NMe)_2C{\equiv}C$ unit of the

Figure 1. ORTEP plot of complex **8a** (ellipsoids drawn at 50% level, hydrogens omitted)[a]

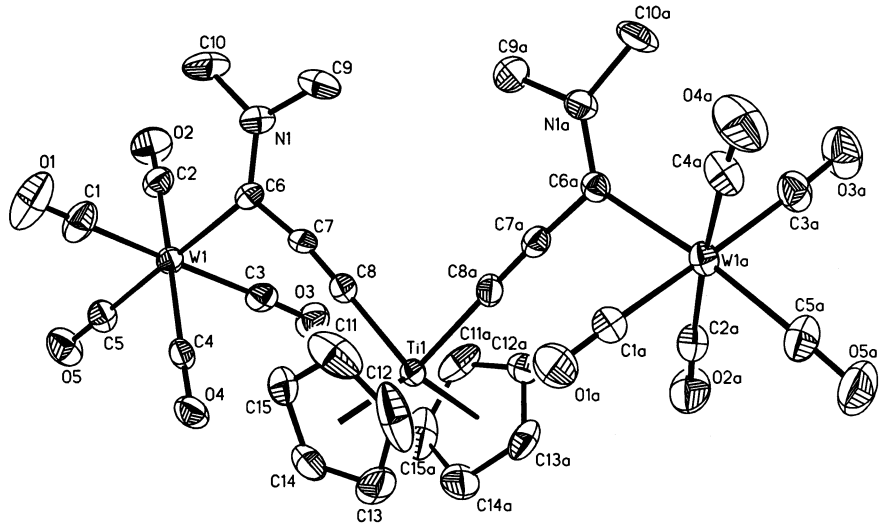


[a] Selected bond lengths [Å] and bond angles [deg]: Hg(1)−C(8) 1.994(9), C(8)−C(7) 1.20(1), C(7)−C(6) 1.43(1), C(8a)−Hg(1)−C(8) 180.0(1), Hg(1)−C(8)−C(7) 175(1), C(8)−C(7)−C(6) 175(1).

complexes **8a**, **9a**, **12a**, and **15a** is identical to that of the heterobimetallic ethynylcarbene complexes $[(CO)_5M{=}C(NMe)_2C{\equiv}CM'L_n]$ discussed previously[15]. The carbene carbon atoms (sum of angles: 359.2°−360.0°) as well as the nitrogen atoms (sum of angles: 359.9°−360.0°) of **8a**, **9a**, **12a**, and **15a** are trigonal planar coordinated. The rather long W−C(carbene) distance of the trinuclear complexes **8a** and **9a** [2.237(9) Å (**8a**), 2.244 and 2.250(7) Å (**9a**)], and the rather short C(carbene)−N bond [1.31(1) Å (**8a**), 1.32 and 1.33(1) Å (**9a**)], indicate a considerable double-bond character for the C(carbene)−N bond, similar to $[(CO)_5M{=}C(NMe)_2C{\equiv}CM'L_n]$ [W−C(carbene): 2.249(6) to 2.266(5) Å, C(carbene)−N: 1.298(6) to 1.323(8) Å][15]. This double-bond character is also reflected in the two distinct ^{1}H- and ^{13}C-NMR NMe resonances.

In the crystal, complex **8a** shows a centrosymmetric geometry with the Hg(1) atom as the center of symmetry, resulting in a *trans*-coordination of Hg(1) [C(8a)−Hg(1)−C(8): 180.0(1)°] (Figure 1) and a *trans*-configuration of the two bulky $W(CO)_5$ fragments. Also the

Figure 2. ORTEP plot of complex **9a** (ellipsoids drawn at 35% level, hydrogens omitted)[a]



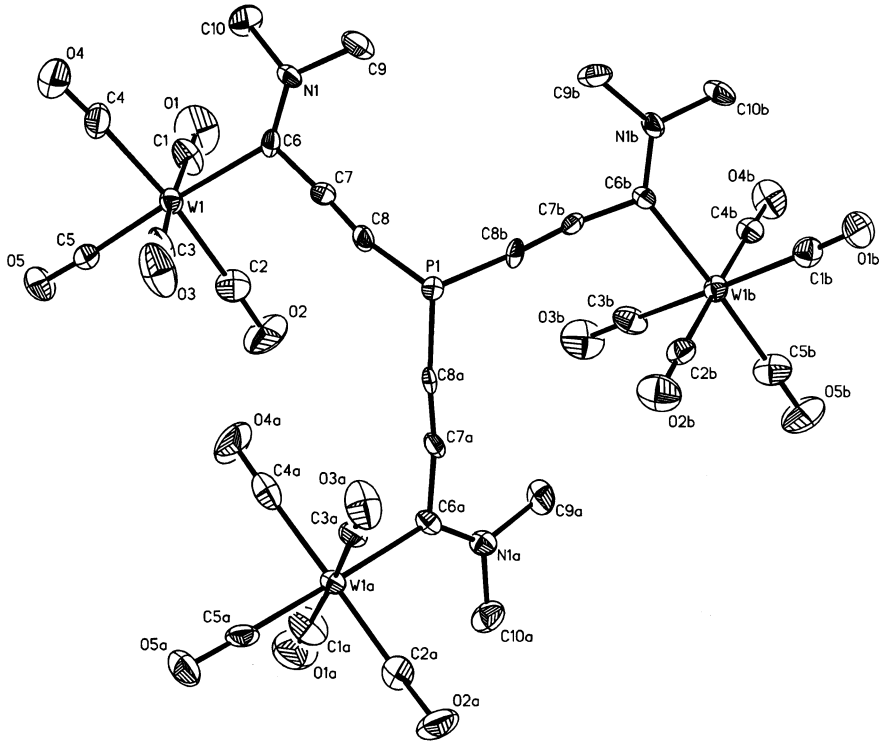
[a] Selected bond lengths [Å] and bond angles [deg]: Ti(1)−C(8a) 2.081(7), Ti(1)−C(8) 2.080(8), C(8a)−C(7a) 1.22(1), C(8)−C(7) 1.22(1), Ti(1)−D(1) 2.029, Ti(1)−D(1a) 2.038, C(7a)−C(6a) 1.41(1), C(7)−C(6) 1.40(1), D(1)−Ti(1)−D(1a) 135.3, Ti(1)−C(8a)−C(7a) 179.1(7), Ti(1)−C(8)−C(7) 178.7(8), C(8a)−C(7a)−C(6a) 176.4(8), C(8)−C(7)−C(6) 172.0(8), C(8a)−Ti(1)−C(8) 97.0(3) [D(1) and D(1a) denote the centroids of the cyclopentadienyl rings].

Hg−C≡C−C(carbene) unit of each σ-ligand is nearly linear [Hg(1)−C(8)−C(7): 175(1)°, C(8)−C(7)−C(6): 175(1)°], similar to the noncentrosymmetric bis(phenylethynyl)mercury-1,10-phenanthroline adduct [$Hg(C{\equiv}CPh)_2{\cdot}C_{12}H_8N_2$] (170, 176° and 173, 176°)[37]. The Hg(1)−C(8) distance and the C≡C distance of **8a** [1.994(9) Å and 1.20(1) Å] resemble those of [$Hg(C{\equiv}CPh)_2{\cdot}C_{12}H_8N_2$) (2.05, 2.03 Å and 1.17, 1.18 Å[37]).

Figure 2 shows that the ethynyl ligands of **9a** are twisted against each other, with the bulky $W(CO)_5$ fragments on the external sides. The two η^5-C_5H_5 ligands are staggered. The CpTiCp angle is typical for many group IV bent metallocene complexes with D(1)−Ti−D(1a) = 135.3°, where D(1)/D(1a) denote the centroids of the cyclopentadienyl rings {for comparison [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CSiMe_3)_2$]: 134.7°[38], [$(\eta^5$-$C_5H_4SiMe_3)_2Zr(C{\equiv}CMe)_2$]: 132.6°[39]}. The bite angle C(8)−Ti(1)−C(8a) in **9a** [97.0(3)°] resembles that in [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CC{\equiv}CFc)_2$] (Fc = ferrocenyl) [97.2(3)°][40] or in [$([\eta^5$-$C_5H_4]_2SiMe_2)Ti(C{\equiv}CSiMe_3)_2$] [100.8(5)][41]. The atoms W(1), C(6), N(1), C(7), C(8), Ti(1), C(8a), C(7a), C(6a), N(1a), and W(1a) nearly lie within a plane. The deviations from the plane through C(6), Ti(1) and C(6a) are less than ±0.08 Å. The σ-ethynyl ligands exhibit an almost linear carbon framework [C(8)−C(7)−C(6): 172.0(8)°, C(8a)−C(7a)−C(6a): 176.4(8)°]. The C≡C distances in **9a** [C(8)−C(7): 1.22(1) Å, C(8a)−C(7a): 1.22(1) Å] do not significantly deviate from typical C≡C bond lengths in similar titanocene or zirconocene complexes such as [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CSiMe_3)_2$] [1.203(9), 1.214(6) Å][38], [$(\eta^5$-$C_5H_4SiMe_3)_2Zr(C{\equiv}CMe)_2$] [1.206(4) Å][39] or [$\{(\eta^5$-$C_5H_4)_2SiMe_2\}Ti(C{\equiv}CSiMe_3)_2$] [1.20(2), 1.21(2) Å][41], or ethynylcarbene complexes such as **1a** (1.196 Å)[42] or [$(CO)_5CrC(OMe)C{\equiv}CPh$] [1.19(3) Å][43]. The Ti(1)−C(8) and Ti(1)−C(8a) distances in **9a** [2.080(8), 2.081(7) Å] are similar to those found in [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CSiMe_3)_2$] [2.124(5), 2.103(5) Å][38] or [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CC{\equiv}CFc)_2$] (Fc = ferrocenyl) [2.099(7), 2.090(7) Å][40], but are remarkably shorter than those in titanocene complexes with sp^3-hybridized carbon atoms, e.g. such as [$(\eta^5$-$C_5H_5)_2Ti(CH_2Ph)_2$] [2.239(6), 2.210(5) Å][44], [$(\eta^5$-$C_5H_5)_2TiMe_2$] [2.170(2), 2.181(2) Å][45] and [$(\eta^5$-$C_9H_7)_2TiMe_2$] [2.21(2) Å][46]. In the case of [$(\eta^5$-$C_5H_4SiMe_3)_2Ti(C{\equiv}CSiMe_3)_2$] this is regarded as evidence for some π-conjugation between the acetylide ligands and the d^0-configurated 16-valence electron titanocene fragment[38].

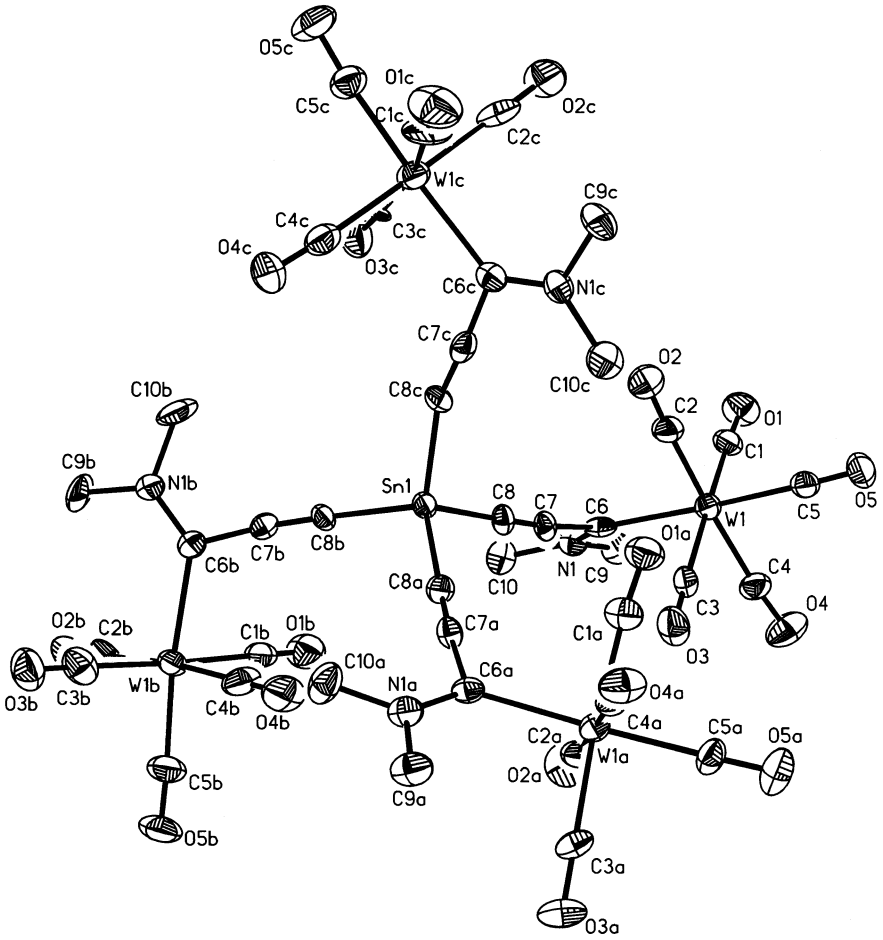
The X-ray structural analyses of **12a** and **15a** also unambiguously establish their structure (Figures 3 and 4). The phosphorus atom in **12a** is pyramidally coordinated, similar to $P(C{\equiv}CPh)_3$[47] or $P(C{\equiv}CH)_3$[48], and the three bond angles at the phosphorus atom [C(8)−P(1)−C(8a): 106.2(7)°, C(8a)−P(1)−C(8b): 102.5(7)°, C(8)−P(1)−C(8b): 103.5(6)°] are similar [$P(C{\equiv}CPh)_3$: 100.7(0.5)°[47], $P(C{\equiv}CH)_3$: 102, 102, 99°[48]]. However, in contrast to the propeller like arrangement of the three phenyl rings in the $P(C{\equiv}CPh)_3$, complex **12a** is not C_3-symmetric in the crystal. In **15a** the bond angles of the central Sn atom are between 107.9(6)° and 111.9(7)° and resemble those of $Sn(C{\equiv}CSiMe_3)_4$ [107.9(1)° to 112.4(3)°][49].

Figure 3. Plot of complex **12a** (ellipsoids drawn at 35% level, hydrogens omitted)[a]



[a] Selected bond angles [deg]: C(8)−P(1)−C(8a) 106.2(7), C(8a)−P(1)−C(8b) 102.5(7), C(8)−P(1)−C(8b) 103.5(6).

Figure 4. Plot of complex **15a** (ellipsoids drawn at 25% level, hydrogens omitted)[a]



[a] Selected bond angles [deg]: C(8)−Sn(1)−C(8a) 108.7(7), C(8a)−Sn(1)−C(8b) 109.2(6), C(8a)−Sn(1)−C(8c) 107.9(6), C(8)−Sn(1)−C(8b) 109.8(7), C(8)−Sn(1)−C(8c) 109.2(6), C(8b)−Sn(1)−C(8c) 111.9(7).

Due to the poor quality of the data set and consequently the large standard deviations of the bond lengths a detailed discussion of the interatomic distances is not feasible.

Conclusions

The coupling of ethynylcarbene complexes $[(CO)_5M{=}C(NMe)_2C{\equiv}CH]$ (M = W, Cr) with metal halides to form heteronuclear complexes with π-conjugated C_3 propynylidene bridges is not restricted to metal monohalides $[XM'(L_n)]$[15] but can also be applied to metal polyhalides $[X_mM'(L_n)]$ (m = 2−4). Thus, a wide range of novel π-conjugated tri-, tetra-, and pentanuclear complexes $[\{(CO)_5M{=}C(NMe)_2C{\equiv}C\}_mM'(L_n)]$ are readily accessible by nucleophilic substitution of the lithiated ethynylcarbene complex $[(CO)_5M{=}C(NMe)_2C{\equiv}CLi]$ (M = W, Cr) for the chlorides in $[Cl_mM'(L_n)]$. Transition metals, main group metals as well as other main group elements can be employed as the central linking atom M′.

In *trans*-biscarbene complexes interaction of the two carbene fragments through the ethynyl triple bonds and the d_{xy} and d_{yz} orbitals of the central metal is conceivable. However, the IR and NMR spectra indicate that the mesomeric interaction between the carbene fragments and the central metal is rather small. The central metal $M'(L_n)$ fragment acts as a weak π-donor. With increasing π-donor properties of the $M'(L_n)$ fragment the mesomeric interaction also increases. However, in all cases the influence of the $M'(L_n)$ fragment is inferior to that of the strong π-donor substituent NMe_2 at the carbene carbon.

π-Interaction between the central metal and the acetylide ligands in the pyramidally coordinated complex **12a**, the probably trigonal-planar complex **11a**, and the tetrahedrally coordinated tetrakiscarbene complexes **13**−**15**, is even less pronounced than in the biscarbene complexes.

The π-conjugated polymetallic complexes described here can be considered as monomers for the synthesis of organometallic systems with extended two and three dimensional π-conjugated metal-carbon networks.

Support of this work by the *Fonds der Chemischen Industrie* is gratefully acknowledged. We thank *B. Weibert* for collecting the data sets for the X-ray structural analyses.

Experimental Section

All operations were performed under argon by using standard Schlenk techniques. Solvents were dried by refluxing over CaH_2 (CH_2Cl_2) or sodium/benzophenone ketyl (pentane, Et_2O, THF)

and were freshly distilled prior to use. The yields refer to analytically pure substances and were not optimized. Silica gel used for column chromatography (Fa. J. T. Baker, silica gel for flash chromatography) was argon-saturated. For the synthesis of **1a**, **b** by desilylation of $[(CO)_5M{=}C(NMe_2)C{\equiv}CSiMe_3]$[42] (M = W, Cr), KF/THF/MeOH[15] was used instead of Bu_4NF/H_2O[42]. The complexes $[Cl_2Ni(PEt_3)_2]$[50], $[Cl_2Fe(dmpe)_2]$[51], $[Cl_2Ti(\eta^5\text{-}C_5H_5)_2]$[52], and $[ClPd(PEt_3)_2\ C{\equiv}CH]$[53] were prepared according to literature procedures. $[Cl_2Pd(PEt_3)_2]$ and $[Cl_2Pt(PEt_3)_2]$ were purchased from Aldrich. − NMR: Bruker AC 250, Bruker WM 250, Bruker DRX 600, and Jeol JNX 400; chemical shifts are reported relative to internal TMS (^1H and ^{13}C) or external H_3PO_4 (^{31}P). Unless mentioned otherwise, NMR spectra were recorded in $CDCl_3$ at room temperature. Abbreviations: vt = virtual triplet, dvt = double virtual triplet, tvt = triple virtual triplet, vquint = virtual quintet. − IR: Biorad FTS 60. − MS: Finnigan MAT 312. The peaks *m/z* are based on the following isotopes: ^{48}Ti, ^{52}Cr, ^{56}Fe, ^{58}Ni, ^{74}Ge, ^{106}Pd, ^{120}Sn, ^{184}W, ^{195}Pt, ^{202}Hg. − Elemental analyses: Heraeus CHN-O-RAPID.

General Synthetic Route to Compounds **2a**, **b**−**4a**, **b**: 2.00 mmol of *n*BuLi (1.25 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 2.00 mmol of **1a** (0.81 g) or **1b** (0.55 g) in 20 ml of Et_2O. On stirring for 30 min at −80°C, the yellow solution turned cloudy. Then, 1.00 mmol of $[Cl_2M(PEt_3)_2]$ [M = Ni (0.37 g), Pd (0.41 g), Pt (0.50 g)] and 5 ml of THF were added and the dark yellow solution was stirred for 30 min at room temp. The solvent was evaporated in vacuo, the residue dissolved in 5 ml of THF and chromatographed with pentane/THF [4:1 (**2a**,**b**), 7:2 (**3a**,**b**, **4a**,**b**)] at −40°C on silica. Light yellow bands were eluted, which afforded, after removal of the solvent in vacuo and recrystallization from CH_2Cl_2/pentane [3:1 (**2a**,**b**, **3a**,**b**), 4:1 (**4a**,**b**)], the complexes **2a**,**b**−**4a**,**b** as light yellow crystals.

trans-Bis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]bis(triethylphosphane)nickel (**2a**) *and trans-Bis[pentacarbonyl(1-dimethylaminopropynylidene)chromium]bis(triethylphosphane)nickel* (**2b**): **2a**: Yield: 0.74 g (67%, based on **1a**), m.p. 122°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2058 cm^{-1} w, 1965 w, 1920 vs, 1900 m, $\tilde{\nu}$(C≡C) = 2008 cm^{-1} w. − ^1H NMR: δ = 1.15 (tvt, $^{3/5}J_{PH} = {}^3J_{HH}$ = 8.0 Hz, 18 H, CH_2CH_3), 1.77−1.89 (m, 12 H, CH_2), 3.50 (s, 6 H, NCH_3), 3.67 (s, 6 H, NCH_3). − ^{13}C NMR: δ = 8.31 (CH_2CH_3), 16.52 (vt, $^{1/3}J_{PC}$ = 14.6 Hz, CH_2), 44.08 (NCH_3), 51.00 (NCH_3), 131.88 (C_β), 168.40 (t, $^2J_{PC}$ = 38.8 Hz, C_α), 199.45 (s and d, $^1J_{WC}$ = 127.1 Hz, *cis*-CO), 203.88 (*trans*-CO), 223.54 (W=C). − ^{31}P NMR: δ = 22.71. − MS (FAB, NBOH); *m/z* (%): 1102 (7) [M^+], 962 (6), 906 (7) [$M^+ - n$ CO, *n* = 5, 7]. − $C_{32}H_{42}N_2NiO_{10}P_2W_2$ (1103.0): calcd. 3-{trans-Bis[1',2'-bis(dimethylphosphino)ethane]chloroferrio}-1-dimethylaminopropynylidene(pentacarbonyl)tungsten (**7a**): 2.00 mmol of *n*BuLi (1.25 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 2.00 mmol (0.81 g) of **1a** in 20 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, a white precipitate was formed. After 2.00 mmol (0.85 g) of $[Cl_2Fe(dmpe)_2]$ and 10 ml of THF were added, the dark red solution was stirred for 30 min at room temp. and then the solvent was removed in vacuo. The residue was dissolved in 5 ml of CH_2Cl_2 and chromatographed at −40°C on silica. With pentane/CH_2Cl_2 (7:2) an orange band was eluted, which afforded the complex **7a** as an analytically pure orange solid, after evaporation of the solvent in vacuo. Yield: 0.46 g (29%, based on **1a**), m.p. 135°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2053 cm^{-1} w, 1913 vs, 1891 sh, $\tilde{\nu}$(C≡C) = 1942 cm^{-1} m. − ^{1}H NMR: δ = 1.43 (br. s, 12 H, PCH_3), 1.52 (br. s, 12 H, PCH_3), 1.94 (br. s, 8 H, CH_2), 3.29 (s, 3 H, NCH_3), 3.53 (s, 3 H, NCH_3). − ^{13}C NMR: δ = 13.91 (vquint, $^{1/3}J_{PC}$ = 5.4 Hz, PCH_3), 16.63 (vquint, $^{1/3}J_{PC}$ = 6.5 Hz, PCH_3), 30.13 (vquint, $^{1/2/3}J_{PC}$ = 12.6 Hz, CH_2), 43.08 (NCH_3), 51.11 (NCH_3), 140.29 (C_β), 194.81 (m_c, C_α), 200.19 (s and d, $^1J_{WC}$ = 127.9 Hz, *cis*-CO), 203.10 (s and d, $^1J_{WC}$ = 128.9 Hz, *trans*-CO), 217.82 (W=C). − ^{31}P NMR: δ = 63.79. − MS (FAB, NBOH); *m/z* (%): 795 (36) [M^+], 760 (10) [M^+ − Cl], 739 (8), 711 (19), 683 (81), 655 (22) [$M^+ - n$ CO, n = 2−5]. − $C_{22}H_{38}ClFeNO_5P_4W$ (795.6): calcd. C 33.21, H 4.81, N 1.76; found C 33.23, H 4.91, N 1.80.

Bis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]mercury (**8a**): 4.00 mmol of *n*BuLi (2.50 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 2.00 mmol (1.62 g) of **1a** in 40 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, the formation of a white precipitate was observed. 2.00 mmol (0.54 g) of $HgCl_2$ and 10 ml of THF were then added and the dark yellow solution was stirred for 30 min at room temp. The solvent was evaporated in vacuo and the residue was dissolved in 8 ml of CH_2Cl_2 and chromatographed at −40°C on silica. With pentane/CH_2Cl_2 (3:1) a yellow band was eluted. Evaporation of the solvent in vacuo and recrystallization from 30 ml of Et_2O/pentane (5:2) afforded yellow crystals. Yield: 1.15 g (57%, based on **1a**), m.p. 109°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2062 cm^{-1} w, 1972 w, 1926 vs, 1909 sh. − ^{1}H NMR: δ = 3.62 (s, 6 H, CH_3), 3.76 (s, 6 H, CH_3). − ^{13}C NMR: δ = 46.69 (CH_3), 51.72 (CH_3), 106.42 (C_β), 158.67 (C_α), 198.56 (s and d, $^1J_{WC}$ = 128.3 Hz, *cis*-CO), 203.93 (s and d, $^1J_{WC}$ = 88.3 Hz, *trans*-CO), 230.77 (s and d, $^1J_{WC}$ = 130.1 Hz, W=C). − MS (FAB, NBOH); *m/z* (%): 1010 (57) [M^+], 982 (10), 954 (15), 898 (24) [$M^+ - n$ CO, n = 1, 2, 4], 642 (100), 614 (32), 586 (26), 558 (15) [$M^+ - n$ CO − Hg, n = 6−9]. − $C_{20}H_{12}HgN_2O_{10}W_2$ (1008.6): calcd. C 23.82, H 1.20, N 2.78; found C 23.90, H 1.23, N 2.87.

Dicyclopentadienyl{bis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]}titanium (**9a**) *and Dicyclopentadienyl-{bis[pentacarbonyl(1-dimethylaminopropynylidene)chromium]}-titanium* (**9b**): 4.00 mmol of *n*BuLi (2.50 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 4.00 mmol of **1a** (1.62 g) or **1b** (1.10 g) in 40 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, a white solid precipitated. After 2.00 mmol (0.50 g) of $[Cl_2Ti(Cp)_2]$ and 10 ml of THF were added, the dark red solution was stirred for 30 min at room temp. The solvent was evaporated in vacuo. The residue was dissolved in 8 ml of CH_2Cl_2 and chromatographed with pentane/CH_2Cl_2 [4:1(**9a**), 7:2 (**9b**)] at −40°C on silica. A red band was eluted, which gave red crystals after removal of the solvent in vacuo and recrystallization from 50 ml of Et_2O/pentane [4:1(**9a**), 5:2 (**9b**)].

9a: Yield: 1.32 g (67%, based on **1a**), m.p. 142°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2058 cm^{-1} w, 1969 w, 1924 vs, 1906 sh. − ^{1}H NMR: δ = 3.40 (s, 6 H, CH_3), 3.65 (s, 6 H, CH_3), 6.33 (s, 10 H, C_5H_5). − ^{13}C NMR: δ = 45.64 (CH_3), 50.60 (CH_3), 112.27 (C_5H_5), 134.87 (C_β), 199.03 (s and d, $^1J_{WC}$ = 127.1 Hz, *cis*-CO), 203.95, 204.05 (*trans*-CO, C_α), 220.06 (W=C). − MS (FAB, NBOH); *m/z* (%): 986 (32) [M^+], 958 (4), 930 (20), 902 (10), 874 (15), 846 (25), 818 (100), 790 (18), 762 (41), 734 (25), 706 (21) [$M^+ - n$ CO, n = 1−10]. − $C_{30}H_{22}N_2O_{10}TiW_2$ (986.1): calcd. C 36.54, H 2.25, N 2.84; found C 36.38, H 2.43, N 2.69.

9b: Yield: 0.98 g (68%, based on **1b**), m.p. 131°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2049 cm^{-1} w, 1969 w, 1927 vs, 1908 sh. − ^{1}H NMR: δ = 3.43 (s, 6 H, CH_3), 3.73 (s, 6 H, CH_3), 6.34 (s, 10 H, C_5H_5). − ^{13}C NMR: δ = 46.99 (CH_3), 48.40 (CH_3), 112.09 (C_5H_5), 132.85 (C_β), 207.19 (C_α), 217.84 (*cis*-CO), 223.94 (*trans*-CO), 238.34 (Cr=C). − $C_{30}H_{22}Cr_2N_2O_{10}Ti$ (722.4): calcd. C 49.88, H 3.07, N 3.88; found C 49.96, H 3.03, N 3.87.

Pentacarbonyl{1-dimethylamino-3-[ethynyl-trans-bis(triethylphosphane)palladio]propynylidene}tungsten (**10a**): 3.00 mmol of *n*BuLi (1.88 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 3.00 mmol of **1a** (1.22 g) in 30 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, the formation of a white solid was observed. 3.00 mmol (1.21 g) of $[ClPd(PEt_3)_2C{\equiv}CH]$ {contaminated with small amounts of $[Cl_2Pd(PEt_3)_2]$} and 10 ml of THF were then added. The dark yellow solution was stirred for 30 min at room temp. and then the solvent was evaporated in vacuo. The residue was dissolved in 6 ml of THF and chromatographed at −40°C on silica. With pentane/THF (4:1) first a light yellow band containing **10a** was eluted. With pentane/THF (7:2) a further light yellow band containing **5a** was eluted. Evaporation of the solvent in vacuo gave complexes **5a** and **10a** as light yellow solids. **5a**: Yield 0.44 g (19%, based on **1a**). − **10a**: Yield: 0.52 g (23%, based on 1**a**), m.p. 87°C (dec.). − IR (THF): $\tilde{\nu}$(CO) = 2059 cm^{-1} w, 1966 w, 1920 vs, 1898 m, $\tilde{\nu}$(C≡C) = 2034 cm^{-1} w. − ^1H NMR: δ = 1.08−1.21 (m, 18 H, CH_2CH_3), 1.90−2.02 (m, 12 H, CH_2), 2.19 (t, $^4J_{PH}$ = 1.8 Hz, 1 H, ≡CH), 3.51 (s, 3 H, NCH_3), 3.67 (s, 3 H, NCH_3). − ^{13}C NMR: δ = 8.38 (CH_2CH_3), 16.76 (vt, $^{1/3}J_{PC}$ = 14.5 Hz, CH_2), 44.01 (NCH_3), 51.05 (NCH_3), 96.41 ($C_{\beta'}$), 103.35 (t, $^2J_{PC}$ = 17.4 Hz, $C_{\alpha'}$), 122.86 (C_β), 166.59 (t, $^2J_{PC}$ = 16.6 Hz, C_α), 199.52 (s and d, $^1J_{WC}$ = 126.9 Hz, *cis*-CO), 204.23 (*trans*-CO), 226.32 (W=C). − ^{31}P NMR: δ = 19.29. − MS (70 eV); *m/z* (%): 771 (9) [M^+], 743 (4), 715 (5), 687 (7), 659 (16), 631 (14) [$M^+ - n$ CO, n = 1−5]. − $C_{24}H_{37}NO_5P_2PdW$ (771.8): calcd. C 37.35, H 4.83, N 1.81; found C 37.47, H 4.87, N 1.93.

Tris[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]boron (**11a**): 3.00 mmol of *n*BuLi (1.88 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 3.00 mmol (1.22 g) of **1a** in 30 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, the yellow solution turned cloudy. After 1.00 mmol of BBr_3 (1.00 ml of a 1.0 M solution in hexane) was added, the solution was stirred for 30 min at room temp. The solvent of the brown solution was evaporated in vacuo, and the residue was dissolved in 6 ml of CH_2Cl_2 and chromatographed at −40°C on silica. With pentane/CH_2Cl_2 (3:1) a yellow band was eluted, which afforded, after removal of the solvent in vacuo, the complex **11a** as an analytically pure beige solid. Yield: 0.75 g (61%, based on **1a**), m.p. 126°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2062 cm^{-1} w, 1980 w, 1925 vs, 1900 sh, $\tilde{\nu}$(C≡C) = 2126 cm^{-1} vw. − ^1H NMR ([D_6]acetone): δ = 3.64 (s, 9 H, CH_3), 3.77 (s, 9 H, CH_3). − ^{13}C NMR ([D_6]acetone): δ = 45.42 (CH_3), 51.55 (CH_3), 101.39 (q, $^2J_{BC}$ = 14.4 Hz, C_β), 147.07 (q, $^1J_{BC}$ = 71.2 Hz, C_α), 199.59 (s and d, $^1J_{WC}$ = 128.2 Hz, *cis*-CO), 205.54 (*trans*-CO), 227.86 (W=C). − $C_{30}H_{18}BN_3O_{15}W_3$ (1222.8): calcd. C 29.47, H 1.48, N 3.44; found C 29.30, H 1.57, N 3.31.

Tris[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]phosphorus (**12a**): 3.00 mmol of *n*BuLi (1.88 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 3.00 mmol (1.22 g) of **1a** in 30 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, a white precipitate was formed. 1.00 mmol (0.14 g) of PCl_3 was then added and the solution stirred for 30 min at room temp. After the solvent of the orange solution was evaporated in vacuo, the residue was dissolved in 6 ml of CH_2Cl_2 and chromatographed with pentane/CH_2Cl_2 (4:1) at −40°C on silica. An orange band containing **12a** was eluted. After removal of the solvent in vacuo and recrystallization from 30 ml of Et_2O/pentane (3:1) the complex **12a** was obtained as orange crystals. Yield: 1.01 g (81%, based on **1a**), m.p. 135°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2064 cm^{-1} w, 1977 w, 1934 vs. − ^1H NMR : δ = 3.61 (s, 9 H, CH_3), 3.77 (d, 9 H, $^6J_{PH}$ = 1.19 Hz, CH_3). − ^{13}C NMR: δ = 47.66 (CH_3), 51.60 (CH_3), 107.15 (d, $^1J_{PC}$ = 11.4 Hz, C_α), 115.17 (d, $^2J_{PC}$ = 8.1 Hz, C_β), 197.86 (s and d, $^1J_{WC}$ = 127.2 Hz, *cis*-CO), 203.46 (s and d, $^1J_{WC}$ = 128.9 Hz, *trans*-CO), 226.32 (s and d, $^1J_{WC}$ = 87.0 Hz, W=C). − ^{31}P NMR: δ = −98.92. − MS (FAB, NBOH); *m/z* (%): 1243 (17) [M^+], 1103 (5), 1047 (8), 1019 (11), 991 (11), 963 (10), 935 (9), 907 (17), 879 (18), 851 (10), 823 (13) [$M^+ - n$ CO, n = 5, 7−15]. − $C_{30}H_{18}N_3O_{15}PW_3$ (1243.0): calcd. C 28.99, H 1.46, N 3.38; found C 29.03, H 1.38, N 3.36.

Tetrakis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]silicon (**13a**) *and Tetrakis[pentacarbonyl(1-dimethylaminopropynylidene)chromium]silicon* (**13b**): 4.00 mmol of *n*BuLi (2.50 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 4.00 mmol of **1a** (1.62 g) or **1b** (1.10 g) in 40 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, a white solid precipitated. 1.00 mmol (0.17 g) of $SiCl_4$ was then added, and the solution stirred for 30 min at room temp. The orange solution was filtered over 10 cm of cellite with 200 ml of Et_2O. After evaporation of the solvent in vacuo and recrystallization from 60 ml of Et_2O/pentane (4:1) complexes **13a**, **b** were obtained as orange crystals. **13a**: Yield: 0.99 g (60%, based on **1a**), m.p. 135°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2064 cm^{-1} w, 1979 w, 1935 vs, $\tilde{\nu}$(C≡C) = 2132 cm^{-1} vw. − ^1H NMR : δ = 3.58 (s, 12 H, CH_3), 3.76 (s, 12 H, CH_3). − ^{13}C NMR: δ = 47.51 (CH_3), 51.77 (CH_3), 106.14 (C_β), 118.73 (C_α), 197.89 (s and d, $^1J_{WC}$ = 128.4 Hz, *cis*-CO), 203.82 (s and d, $^1J_{WC}$ = 128.5 Hz, *trans*-CO), 229.28 (s and d, $^1J_{WC}$ = 88.2 Hz, W=C). − MS (FAB, NBOH); *m/z* (%): 1644 (3) [M^+], 1532 (4), 1392 (4), 1364 (4), 1336 (5), 1308 (5), 1224 (4), 1140 (6), 1112 (6), 1084 (7) [$M^+ - n$ CO, n = 4, 9−12, 15, 18−20]. − $C_{40}H_{24}N_4O_{20}SiW_4$ (1644.1): calcd. C 29.22, H 1.47, N 3.41; found C 29.30, H 1.69, N 3.27.

13b: Yield: 0.60 g (54%, based on **1b**), m.p. 115°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2056 cm^{-1} w, 1981 w, 1938 vs, $\tilde{\nu}$(C≡C) = 2130 cm^{-1} vw. − ^1H NMR : δ = 3.64 (s, 12 H, CH_3), 3.89 (s, 12 H, CH_3). − ^{13}C NMR: δ = 48.81 (CH_3), 49.60 (CH_3), 104.12 (C_β), 122.28 (C_α), 216.64 (*cis*-CO), 223.94 (*trans*-CO), 249.88 (Cr=C). − $C_{40}H_{24}Cr_4N_4O_{20}Si$ (1116.7): A correct analysis of **13b** has not yet been obtained.

Tetrakis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]germanium (**14a**): 4.00 mmol of *n*BuLi (2.50 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 4.00 mmol (1.62 g) of **1a** in 40 ml of Et_2O. On stirring the yellow solution for 30 min at −80°C, the yellow solution turned cloudy. After 1.00 mmol (0.21 g) of $GeCl_4$ was added, the solution was stirred for 30 min at room temp. Then the orange solution was filtered over 10 cm of cellite with 200 ml of Et_2O. Removal of the solvent in vacuo afforded the complex **14a** as an orange solid, which gave orange crystals after recrystallization from 60 ml of Et_2O/pentane (9:2). Yield: 1.00 g (59%, based on **1a**), m.p. 138°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2064 cm^{-1} w, 1980 w, 1935 vs, $\tilde{\nu}$(C≡C) = 2132 cm^{-1} vw. − ^1H NMR : δ = 3.58 (s, 12 H, CH_3), 3.77 (s, 12 H, CH_3). − ^{13}C NMR: δ = 47.40 (CH_3), 51.80 (CH_3), 105.11 (C_β), 117.66 (C_α), 197.95 (s and d, $^1J_{WC}$ = 127.2 Hz, *cis*-CO), 203.82 (s and d, $^1J_{WC}$ = 128.6 Hz, *trans*-CO), 229.23 (W=C). − MS (FAB, NBOH); *m/z* (%): 1690 (10) [M^+], 1578 (8), 1438 (21), 1298 (16), 1270 (13), 1214 (14), 1158 (24) [$M^+ - n$ CO, n = 4, 9, 14, 15, 17, 19]. − $C_{40}H_{24}GeN_4O_{20}W_4$ (1688.6): calcd. C 28.45, H 1.43, N 3.32; found C 28.51, H 1.51, N 3.26.

Tetrakis[pentacarbonyl(1-dimethylaminopropynylidene)tungsten]tin (**15a**) *and Tetrakis[pentacarbonyl(1-dimethylaminopropynylidene)chromium]tin* (**15b**): 4.00 mmol of *n*BuLi (2.50 ml of a 1.6 M solution in hexane) was added at −80°C to a solution of 4.00 mmol of **1a** (1.62 g) or **1b** (1.10 g) in 40 ml of Et_2O. On stirring

the yellow solution for 30 min at −80°C, the formation of a white precipitate was observed. 1.00 mmol (0.26 g) of $SnCl_4$ was then added and the solution stirred for 30 min at room temp. The solvent of the orange solution was evaporated in vacuo, and the residue was dissolved in 8 ml of CH_2Cl_2 and chromatographed at −40°C on silica. With pentane/CH_2Cl_2 [4:1(**15a**), 7:2 (**15b**)] an orange band was eluted, which afforded after removal of the solvent in vacuo complexes **15a**, **b** as analytically pure orange solids. Recrystallization from 30 ml of Et_2O/pentane [3:1(**15a**), 5:2 (**15b**)] gave orange crystals**. 15a**: Yield: 1.32 g (76%, based on **1a**), m.p. 136°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2064 cm^{-1} w, 1979 w, 1933 vs, $\tilde{\nu}$(C≡C) = 2118 cm^{-1} vw. − ^{1}H NMR : δ = 3.59 (s, 12 H, CH_3), 3.76 (s, 12 H, CH_3). − ^{13}C NMR: δ = 47.32 (CH_3), 51.74 (CH_3), 109.59 (s and 2 d, $^2J_{^{117}Sn C,^{119}Sn C}$ = 218.9 Hz, 209.5 Hz, C_β), 119.47 (s and 2 d, $^1J_{^{117}Sn C,^{119}Sn C}$ = 1169.5 Hz, 1118.2 Hz, C_α), 198.07 (s and d, $^1J_{WC}$ = 128.4 Hz, *cis*-CO), 203.89 (s and d, $^1J_{WC}$ = 128.7 Hz, *trans*-CO), 229.41 (s and d, $^1J_{WC}$ = 88.2 Hz, W=C). − MS (FAB, NBOH); *m/z* (%): 1736 (10) [M$^+$], 1512 (3), 1484 (6), 1456 (7), 1428 (8), 1400 (12), 1372 (14), 1344 (17), 1316 (13), 1288 (17), 1260 (12), 1232 (13), 1204 (13), 1176 (13) [M$^+$ − n CO, n = 8−20]. − $C_{40}H_{24}N_4O_{20}SnW_4$ (1734.7): calcd. C 27.70, H 1.39, N 3.23; found C 27.80, H 1.43, N 3.15.

15b: Yield: 0.86 g (71%, based on **1b**), m.p. 112°C (dec.). − IR (Et_2O): $\tilde{\nu}$(CO) = 2057 cm^{-1} w, 1982 w, 1937 vs, $\tilde{\nu}$(C≡C) = 2115 cm^{-1} vw. − ^{1}H NMR : δ = 3.65 (s, 12 H, CH_3), 3.88 (s, 12 H, CH_3). − ^{13}C NMR: δ = 48.65 (CH_3), 49.56 (CH_3), 107.68 (s and 2 d, $^2J_{^{117}Sn C,^{119}Sn C}$ = 219.9 Hz, 210.3 Hz, C_β), 123.05 (s and 2 d, $^1J_{^{117}Sn C,^{119}Sn C}$ = 1167.5 Hz, 1115.7 Hz, C_α), 216.84 (*cis*-CO), 223.97 (*trans*-CO), 250.09 (Cr=C). − $C_{40}H_{24}Cr_4N_4O_{20}Sn$ (1207.3): calcd. C 39.79, H 2.00, N 4.64; found C 39.67, H 2.19, N 4.64.

X-ray Structural Analyses of **8a**, **9a**, **12a**, *and* **15a**: Single crystals were grown from pentane/Et_2O [2:5 (**8a**), 1:4 (**9a**), 1:3 (**12a**, **15a**)], respectively, and mounted in a glass capillary. All crystal data were collected on a Siemens P4 diffractometer (Wyckoff scan, scan range 4° < 2θ < 54°, scan speed variable: 4 to 30° min^{-1} in ω) with a graphite monochromator (Mo-$K\alpha$, λ = 0.71073 Å). Semi-empirical absorption corrections were employed (ψ-scans with 10 reflections). The structures were solved with Patterson methods using the Siemens SHELXTL PLUS program package. The positions of the hydrogen atoms were calculated by assuming ideal geometry (d_{C-H} = 0.96 Å), and their coordinates were refined together with the attached carbon atoms as a "riding model". The positions of all other atoms were refined anisotropically by full-matrix least-squares techniques. Complete lists of atom coordinates and thermal parameters were deposited[54].

☆ Dedicated to Professor *Warren Roper* on the occasion of his 60th birthday.

Keywords: Gallium(III) halides / Indium(III) halides / Phosphanes, polydentate / Complexes / Crystallography / Lewis acid catalysis

The reactions of gallium and indium trihalides with 1,2-bis-(diphenylphosphanyl)benzene (DP) and bis[(2-diphenylphosphanyl)phenyl]phenylphosphane (TP) lead to a variety of molecular and ionic complexes. Treatment of $InCl_3$ with DP results in $[(DP)_2InCl_2]^+[InCl_4]^-$ (**1**). With $InBr_3$ or InI_3 molecular 1:1 complexes $(DP)InX_3$ (**2**: X = Br, **3**: X = I) and ionic 1:2 complexes $[(DP)InX_2]^+[InX_4]^-$ (**4**: X = Br, **5**: X = I) are obtained. With $GaBr_3$ and GaI_3 only the ionic complexes $[(DP)GaX_2]^+[GaX_4]^-$ (**6**: X = Br, **7**: X = I) are generated. According to single-crystal X-ray analyses the environment of the metal center is octahedral in the cation of **1**, square pyramidal in **3**, and tetrahedral in the cations of **5** and **7**. The reactions of TP with GaI_3 or InI_3 afford ionic complexes $[(TP)MI_2]^+[MI_4]^-$ (**8**: M = Ga, **9**: M = In). As shown by ^{31}P-NMR studies and X-ray analyses, TP acts as a bidentate ligand in both complexes. The central phosphorus atom is not engaged in coordinative bonding. The ^{31}P resonances of all compounds appear at higher field as compared to the free ligand. This phenomenon calls for further investigations and a detailed theoretical treatment.

Introduction

Traditional Lewis acid catalysis has been dominated for a long time by the use of boron and aluminium halides.[1] It is only very recently that the analogous compounds of the heavier congeners in group 13, gallium and indium, have also been employed for this purpose.[2] Prominent examples are the $InCl_3$ catalysis of the Mukayama aldol reaction or special variations of the Diels-Alder reaction,[3] but also the $GaBr_3$-mediated methyl transfer of alkylsilanes and -siloxanes.[4] In most of these reactions the anhydrous binary halides EX_3 are employed, but there is growing interest in a mediation of the catalytic effect by the introduction of neutral or cationic donor/acceptor complexes, X_3E-L_n and $[X_2EL_n]^+$, respectively. The soft donor ligand L is expected to be reversibly displaced by the substrate of the reaction. It can also serve as a component which enhances the solubility and stability of the Lewis acid catalyst EX_3.

The formation of donor/acceptor complexes of gallium and indium halides is known for a wide variety of neutral donor ligands L.[5] Among these the cationic species are of special interest, because analogous cationic complexes of boron and aluminium are already well established as active catalysts in the living polymerization of propylene oxide and in Diels-Alder reactions.[6] Structurally characterized ionic species derived from gallium or indium trihalides in previous work are limited to O or N donors like pyridine, bipyridyl, methylpyrazole, or a crown ether, but also dimethyl sulfoxide, triphenylphosphane oxide, dimethylglycol, or hexamethyl phosphoric triamide etc.[7]

Complexes of gallium and indium halides with tertiary phosphanes have been considered only sporadically, and very little information is available on the stoichiometry and structure of such coordination compounds.[8] This is true in particular for complexes with polydentate phosphanes, for which a large variety of structural concepts can be conceived.[8a][8b][8c]

We have therefore initiated a systematic investigation of this chemistry, and in the present paper we report a first set of results obtained for ligands based on a phenylenebis(diphenylphosphane) skeleton.

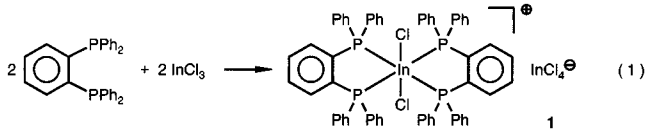
Preparative Results

In order to secure chelation of the metal trihalides, a bidentate ligand was chosen in which the two donor centers are fixed in a *cis* position at a rigid backbone. 1,2-Bis-(diphenylphosphanyl)benzene (DP) is the most common prototype for this kind of ligands, and in bis[(2-diphenylphosphanyl)phenyl]phenylphosphane (TP) the same structural principle is extended to give a tripodal tertiary phosphane.

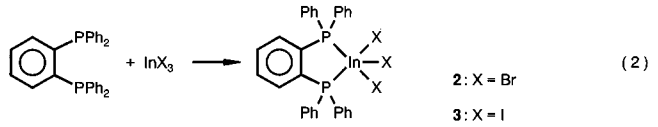
Anhydrous $InCl_3$ reacts with equimolar quantities of DP to give almost quantitative yields of an air-stable but moisture-sensitive crystalline product (**1**, 91% yield, m.p. 243°C), soluble in di- and trichloromethane [Eq. (1)]. Solvation in THF causes decomposition indicated by the release of phosphane ligand. The crystal structure analysis has shown that this compound is not a molecular 1:1 complex (below). Instead the reaction is associated with a halide redistribution between two indium atoms to give an ionic product

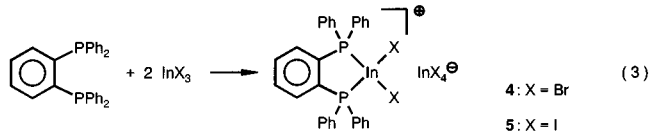
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0203 $ 17.50+.50/0

containing an $[InCl_4]^-$ anion and a bis-chelated cation $[(DP)_2InCl_2]^+$ with hexacoordinated indium atoms. Addition of excess $InCl_3$ has no effect regarding the nature of the product, and no complexes of the stoichiometry $(DP)(InCl_3)_2$ or $[(DP)InCl_2]^+$ $[InCl_4]^-$ can be isolated. The NMR spectra of solutions of $[(DP)_2InCl_2]^+[InCl_4]^-$ in $CDCl_3$ are consistent with fully symmetrically bound ligand molecules as suggested by only one set of phenyl and phenylene resonances (^1H,^{13}C). The singlet ^{31}P resonance also supports the proposed molecular symmetry, but the phosphorus nuclei are strongly shielded ($\delta P = -26.6$ in $CDCl_3$) which is very unexpected for tetracoordinated phosphorus atoms.



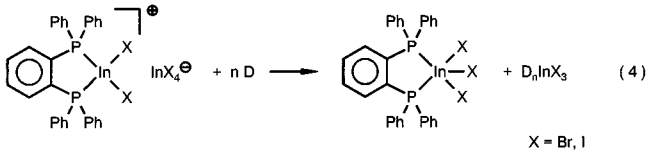
Unlike the results obtained with $InCl_3$, the nature of the product of the reaction of DP with $InBr_3$ and InI_3 depends on the molar ratio between the phosphane and the indium halide [Eq. (2) and (3)]. The 1:1 addition compound of DP with $InBr_3$ is assigned a molecular, non-ionic structure (**2**, 89% yield, m.p. 268°C, $\delta P = -26.9$) with a pentacoordinated indium atom. The compound is stable towards THF and its ^{13}C-NMR spectrum resembles that of $(DP)InI_3$, for which the non-ionic structure was confirmed by a crystal structure analysis (below, **3**, 75% yield, m.p. 239°C, $\delta P = -31.7$). The redistribution of halide anions as observed for **1** is excluded in both cases, because of serious steric congestion of the larger halogen atoms at a hexacoordinated metal center.





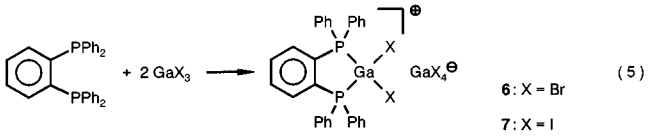
If the same components are allowed to react in the molar ratio of 1:2, ionic products are obtained, in which the $[InX_4]^-$ anion is accompanied by a cation $[(DP)InX_2]^+$ with tetracoordinated indium atoms (**4**, X = Br, 95% yield, m.p. 251°C, $\delta P = -20.0$; **5**, X = I, 87% yield, m.p. 199°C, $\delta P = -27.9$). The structure of **5** has also been determined by X-ray crystallography. The ^{13}C-NMR data of **5** show a distinct similarity with those of the bromo analog **4**.

In order to investigate whether an addition of nucleophiles to the tetracoordinated cationic indium complexes **4** and **5** is possible, reactions with THF, acetone and $OPPh_3$ were carried out. The reaction was found to transform the cationic complexes into the corresponding molecular 1:1 complexes [Eq. (4)].

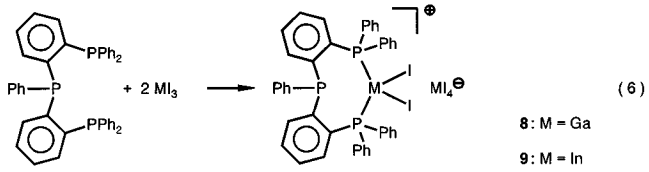


Cationic complexes of the type $[(DP)GaX_2]^+[GaX_4]^-$ with X = Br, I were also obtained with the lighter congener gallium [**6**, X = Br, 81% yield, m.p. 259°C, $\delta P = -22.1$; **7**, X = I, 95% yield, m.p. 219°C, $\delta P = -29.3$; Eq. (5)]. The ionic structure of the iodo compound with tetracoordinated gallium atoms in both the cation and the anion was confirmed in X-ray structure analysis (below).

Attempts to synthesize molecular gallium complexes analogous to **2** or **3** have failed.



Treatment of GaI_3 with TP in the molar ratio of 2:1 gives the ionic complex $[(TP)GaI_2]^+[GaI_4]^-$ in 83% yield [**8**, m.p. 267°C; Eq. (6)]. Earlier work with boron halides and a number of transition-metal salts has shown, that TP represents a potent tripodal ligand.[9] As derived from ^{31}P-NMR studies and X-ray analysis (below), in the present case TP acts only as a bidentate ligand, however, and the central phosphorus atom remains uncoordinated.



The reaction with InI_3 produces the indium analog of **8** in 88% yield (**9**, m.p. 259°C), for which the analytical and structural data (^{31}P NMR, X-ray diffraction) prove tetracoordinated metal centers. No molecular complex $(TP)InI_3$ could be obtained from equimolar quantities of TP and InI_3. The ionic complex **9** was again formed and half of the TP ligand applied (2:1 molar ratio!) remained unaffected.

NMR-Spectroscopic Investigations

The ^1H- and ^{13}C-NMR spectra of the complexes are characterized by complex multiplets and by a large number of phenyl/phenylene resonances, respectively, which were not analyzed any further because the δ and J data are not expected to be relevant to the discussion of structure and bonding in the individual species.

The ^{31}P-NMR spectra of the *DP complexes* show only one resonance with a large half width (ca. 80 Hz) owing to quadrupole broadening originating from interactions with the ^{115}In and $^{71/69}Ga$ nuclei which all have high quadrupole

moments. This line broadening is of course proof for the coordinative bonding of the phosphorus donors to the metal acceptors. It is very surprising, however, that the chemical shifts δP of the complexes are all in the range from −20 to −35 and hence upfield from the resonance of the free DP ligand (δP = −13.1 in $CDCl_3$). It is generally true for most phosphane complexes of main-group as well as transition metals that there is a downfield "coordination shift" between the free ligand and the corresponding complex. In the present cases this "coordination shift" is inverted. There is no straightforward explanation for this phenomenon, although it is tempting to ascribe the effect to the very low electronegativity of the heavy group 13 elements. Further experimental work and − more importantly − theoretical studies are required to clarify this point.

In the two *TP complexes* the resonances of the phosphorus atoms show marked differences: While the signals of the two terminal phosphorus atoms have a severe line broadening with poorly resolved (if any) splitting, the resonance of the central phosphorus atom is rather sharp and has the expected splitting for the A part of an AB_2 spin system (Figures 1 and 2). The implications of the two spectra are threefold:

1) The lack of quadrupole broadening of the signal of the central phosphorus atoms is proof that this atom is not strongly coordinated to indium or gallium, respectively. For the Ga compound this is clearly ruled out completely by the narrow line width, while for In there is discernible broadening, but still much less than for the terminal phosphorus atoms. (The same conclusions can be drawn from the crystal structure studies below.)

2) The *J*(P,P) coupling constants of the complexes are larger than in the free ligand, indicative of the change of hybridization at phosphorus upon complexation (from p to sp^3) as suggested by the Fermi contact mechanism.

3) There is no downfield shift of the resonance of the terminal or central phosphorus atoms upon complexation. On the contrary, all resonances are again (as for DP, above) shifted strongly *upfield* as compared to free TP.

Figure 1. $^{31}P\{^1H\}$-NMR spectrum of **8** in CD_2Cl_2 at 20°C; chemical shifts (δ values)

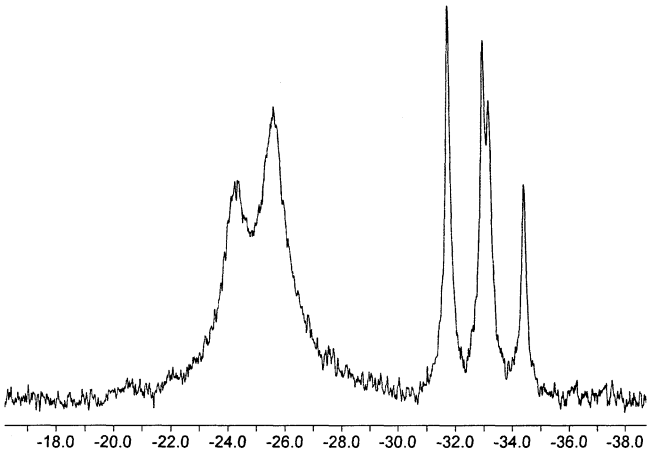


Figure 2. $^{31}P\{^1H\}$-NMR spectrum of **9** in CD_2Cl_2 at 20°C; chemical shifts (δ values)

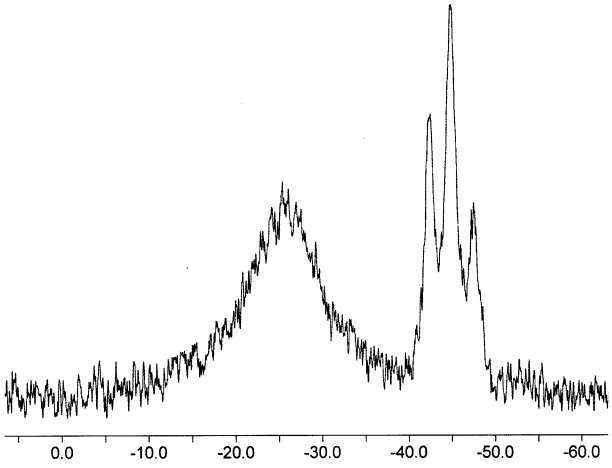
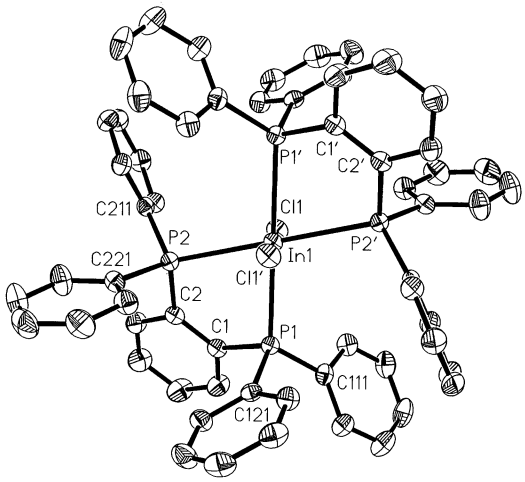


Structural Investigations

Complexes of 1,2-Bis(diphenylphosphanyl)benzene (DP): The compound with the net formula $(DP)InCl_3$ (**1**) was found to have the ionic structure $[(DP)_2InCl_2]^+[InCl_4]^-$. The complex crystallizes in the triclinic space group $P\bar{1}$ with two formula units in the unit cell. The asymmetric unit contains two crystallographically independent halves of the cation and one anion. The *anion* with In3 as the central atom has a standard tetrahedral structure with bond lengths and angles in the ranges documented in the literature. The two *cation* halves are complemented by their second halves which are related by crystallographic centers of inversion (Figure 3). As shown by a schematic superposition (Figure 4), the two cations are structurally very similar, and in a discussion of the details both cations can be treated together.

Figure 3. Molecular structure of the cation in **1** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, only one of the two crystallographically independent cations is shown, hydrogen atoms omitted for clarity)[a]



[a] Selected bond lengths [Å] and angles [°]: In1−Cl1 2.4822(5) [2.4838(6)], In1−P1 2.6648(6) [2.6849(6)], In1−P2 2.7133(6) [2.7374(6)]; Cl1−In1−Cl1′ 180.0 [180.0], Cl1−In1−P1 85.35(2) [85.50(2)], Cl1−In1−P2 82.77(2) [85.39(2)], P1−In1−P2 76.14(2) [73.29(2)]. The data in brackets refer to the second independent cation accordingly.

Figure 4. Superposition of the two crystallographically independent cations in **1**

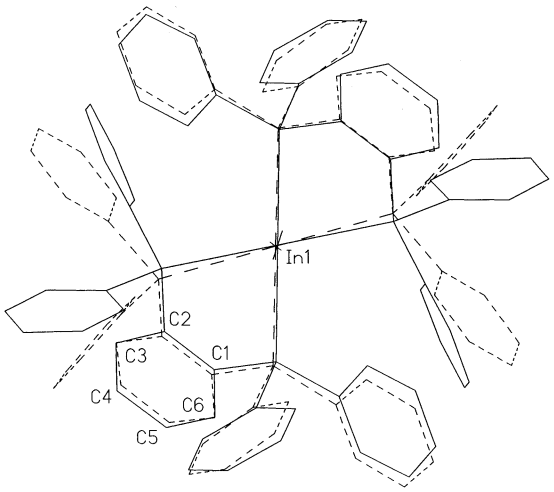


Figure 5. Molecular structure of **3** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, hydrogen atoms omitted for clarity)[a]

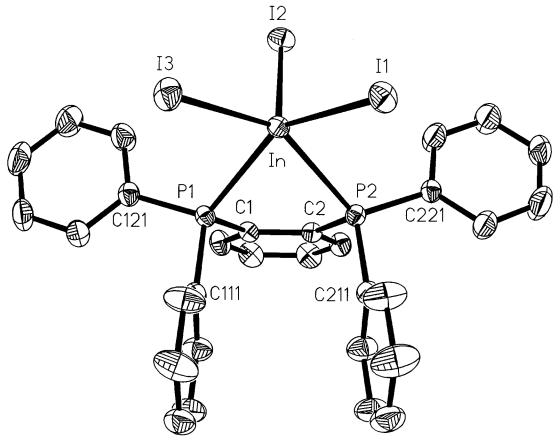


[a] Selected bond lengths [Å] and angles [°]: In−I2 2.7134(4), In−I1 2.7729(4), In−I3 2.7875(5), In−P1 2.7140(9), In−P2 2.7569(9); I3−In−I1 95.306(13), I1−In−I2 109.336(14), I2−In−I3 108.045(14), I1−In−P2 89.66(2), I3−In−P1 89.37(2), I2−In−P1 99.82(2), I2−In−P2 97.99(2), P1−In−P2 71.44(3).

The indium atoms in the cations are in an octahedral environment with two chloride ligands in the apical positions and two chelate ligands spanning equatorial edges. The angles at In1 and In2 are all close to 90 or 180°. The In1/In2−Cl bond lengths in the octahedra [average 2.4830 Å] are significantly longer than the In3−Cl bond lengths [average 2.3487 Å] in the tetrahedral anion. This result is in agreement with previous observations for two different polyhedra with a common central element having the same ligands.

The four chelate rings are in envelope conformations with the metal atoms out of the plane containing the phenylene rings and the phosphorus atoms. In both cases the geometry of the rings and their substituents is very close to mirror symmetry, the individual mirror planes passing through Cl1−In1−Cl1′/Cl2−In2−Cl2′ and bisecting the phenylene rings (Figures 3 and 4).

The compound with the net formula $(DP)InI_3$ (**3**) was found to be a molecular, non-ionic species. It crystallizes in the triclinic space group $P\bar{1}$ with two formula units in the unit cell. The individual molecules have no crystallographically imposed symmetry, but the molecular geometry follows very closely mirror symmetry as related to a plane passing through the In−I2 unit and bisecting the phenylene ring (Figure 5).

The indium atom is pentacoordinated in a quasi square-pyramidal environment, where I2 occupies the apical position and the ligand spans one edge of the basal square plane and with the other two iodine atoms at the remaining basal vertices. The chelate ring has an envelope conformation as already noted for $[(DP)_2InCl_2]^+$. The In−I2 distance (apical) is significantly shorter [2.7134(4) Å] than the In−I1/I3 distances [basal, average 2.7802 Å]. This deviation corresponds to two different sets of I−In−I angles, a smaller one for I1−In−I3 [95.306(13)°] and two larger ones for I1−In−I2 [109.336(14)°] and I2−In−I3 [108.045(14)°].

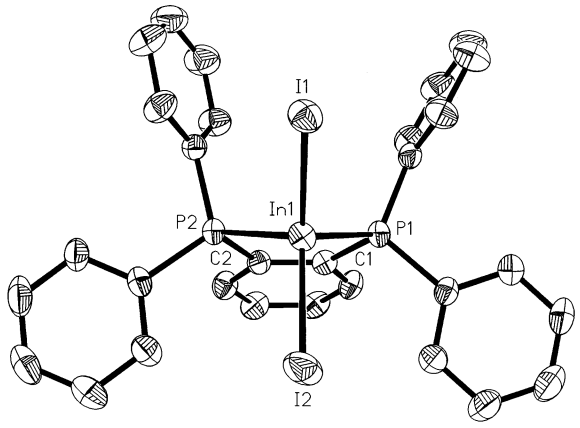
The compound of the stoichiometry $(DP)(InI_3)_2$ (**5**) has an ionic structure $[(DP)InI_2]^+[InI_4]^-$. It crystallizes in the triclinic space group $P\bar{1}$ with two formula units in the unit cell. The anion has a slightly distorted tetrahedral geometry at the central indium atom (In2) with standard bond lengths. The geometry of the cation (Figure 6) deviates only slightly from mirror symmetry. The indium atom In1 is in a tetrahedral environment and part of a chelate ring with an envelope conformation. Following a very general rule, the In−I distances are significantly shorter in the cation [average 2.6570 Å] than in the anion [average 2.6993 Å]. Both distances are shorter, however, than the bond lengths for pentacoordinate indium (above), and this reduction also applies to the In−P bonds in the tetra- as compared to the pentacoordinate species (see captions to figures).

The gallium analog of the composition $(DP)GaI_3$ (**7**) has the same structure $[(DP)GaI_2]^+[GaI_4]^-$ like its indium counterpart (Figure 7). The crystals are also triclinic, space group $P\bar{1}$, $Z = 2$, but are not isomorphous with the indium compound. The general description can be adopted from $[(DP)InI_2]^+$ $[InI_4]^-$. Where variations appear, these are only associated with the difference in the covalent radii of gallium and indium.

Complexes of Bis[(2-diphenylphosphanyl)phenyl]phenylphosphane (TP): The complexes $(TP)(InI_3)_2$ (**9**) and $(TP)(GaI_3)_2$ (**8**) have ionic structures $[(TP)MI_2]^+[MI_4]^-$ with M = In, Ga. The crystals are isomorphous (space group $P\bar{1}$, $Z = 2$) with very similar cell dimensions (Table 2). The anions are tetrahedral tetraiodometallate moieties with structural details closely comparable to those of the DP complexes (above).

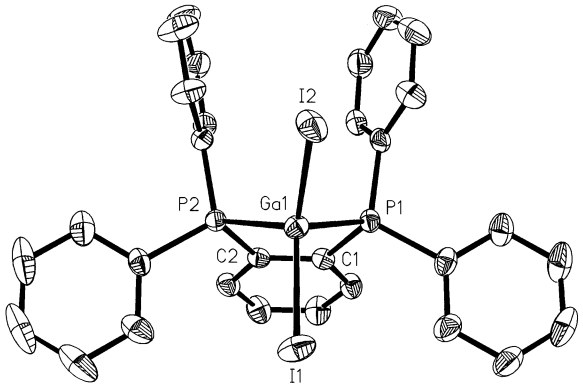
The metal atoms of the cations are also tetracoordinated with bond angles I−M−I and P−M−P at 103.02(2)/

Figure 6. Molecular structure of the cation in **5** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, hydrogen atoms omitted for clarity)[a]



[a] Selected bond lengths [Å] and angles [°]: In1−I1 2.6644(6), In1−I2 2.6497(5), In1−P1 2.5862(11), In1−P2 2.5635(11); I1−In1−I2 118.12(2), I1−In1−P1 116.22(3), I1−In1−P2 113.78(3), I2−In1−P1 111.02(3), I2−In1−P2 110.47(3), P1−In1−P2 81.61(4).

Figure 7. Molecular structure of the cation in **7** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, hydrogen atoms omitted for clarity)[a]

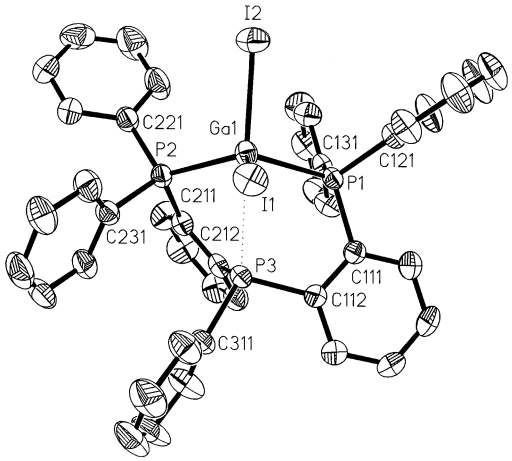


[a] Selected bond lengths [Å] and angles [°]: Ga1−I1 2.4904(6), Ga1−I2 2.4912(7), Ga1−P1 2.3976(13), Ga1−P2 2.4085(12); I1−Ga1−I2 115.02(2), I1−Ga1−P1 110.84(4), I1−Ga1−P2 110.05(4), I2−Ga1−P1 112.64(4), I2−Ga1−P2 119.90(4), P1−Ga1−P2 84.49(4).

113.11(3)° for In and 103.43(3)/113.71(5)° for Ga, respectively (Figures 8 and 9). Deviations from the regular tetrahedral angle are thus very small and not indicative of *tri*-podal action of the ligand. Bond lengths M−I and M−P are also similar to those in the DP complexes (above).

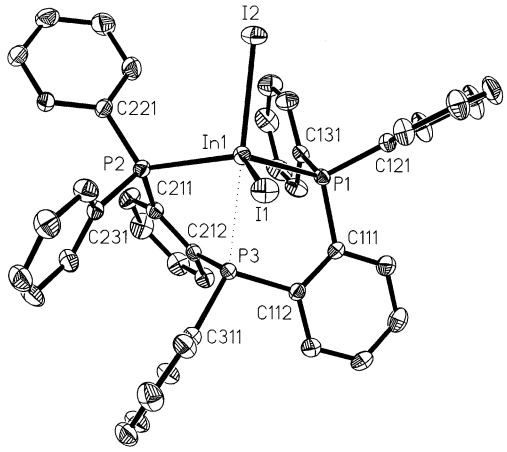
Closer inspection of the structural diagrams shows, however, that the distance In1−P3 [2.8933(10) Å] in the indium compound is not that much larger (about 10%) than the distances In−P1 [2.6239(10) Å] and In1−P2 [2.5982(10) Å]. This observation suggests that coordinative bonding of the middle phosphorus atom (P3) of the TP ligand to In1 cannot a priori be ruled out. In fact, the rather rigid geometry of the ligand leaves no choice and virtually forces the third phosphorus atom into the bonding region of the metal atom.

Figure 8. Molecular structure of the cation in **8** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, hydrogen atoms omitted for clarity)[a]



[a] Selected bond lengths [Å] and angles [°]: Ga1−I1 2.5473(8), Ga1−I2 2.5818(8), Ga1−P1 2.435(2), Ga1−P2 2.420(2), Ga1−P3 2.905(2); I1−Ga1−I2 103.43(3), I1−Ga1−P1 113.05(4), I1−Ga1−P2 118.84(4), I2−Ga1−P1 100.36(4), I2−Ga1−P2 104.55(4), P1−Ga1−P2 113.71(5), Ga1−P3−C112 103.3(3), Ga1−P3−C212 96.6(2), Ga1−P3−C311 137.2(3).

Figure 9. Molecular structure of the cation in **9** with atomic numbering (ORTEP drawing, 50% probability ellipsoids, hydrogen atoms omitted for clarity)[a]



[a] Selected bond lengths [Å] and angles [°]: In1−I1 2.7092(5), In1−I2 2.7376(5), In1−P1 2.6239(10), In1−P2 2.5982(10), In1−P3 2.8933(10); I1−In1−I2 103.02(2), I1−In1−P1 115.35(2), I1−In1−P2 119.96(2), I2−In1−P1 98.19(2), I2−In1−P2 102.94(2), P1−In1−P2 113.11(3), In1−P3−C112 106.13(12), In1−P3−C212 98.36(12), In1−P3−C311 132.91(13).

A simple geometrical calculation of the orientation of the lone pair of electrons at P3 (taking this atom as a pseudo-tetrahedral center) leads to the conclusion, however, that this vector is not pointing towards the metal atom, but into a direction where In1−P3 interaction is rather poor. This is e.g. borne out by the large spread of the angles from In1−P3−C212 = 98.36(12)° and In1−P3−C112 = 106.13(12)° to In1−P3−C311 = 132.91(13)°. The difference of the In−I distances in the cation and the anion of **9** are surprisingly small (only a few percent).

The situation is very similar in the structure of the gallium analog **8**, where the distance Ga1−P3 is 2.905(2) Å and thus almost equal to In1−P3 (above), but much larger as compared to Ga1−P1 [2.435(2) Å] and Ga1−P2 [2.420(2) Å]. The angles Ga1−P3−C112/ C212/C311 vary over a range of 40°, with individual values of 103.3(3)/ 96.6(2)/137.2(3)°, respectively, and are not in agreement with tetrahedral coordination of the phosphorus atom P3.

From the structural data it thus appears that neither the indium nor the gallium atom in the $[(TP)MI_2]^+$ cations of **8** and **9** (M = In, Ga) is pentacoordinated by the two halogen atoms and the potentially tripodal ligand. Although the inflexibility of the TP ligand holds the central phosphorus atom in close proximity of the metal atom, the bonding interaction is poor in spite of the sub-van-der-Waals distance of only ca. 2.90 Å. It is gratifying that this result is in full agreement with the essence of the NMR data regarding in particular the line widths and the coupling pattern of the ^{31}P-NMR resonances, although the chemical-shift parameters are much more difficult to evaluate. More comprehensive data sets are clearly needed in order to allow a deeper understanding of the chemical-shift increments responsible for non-classical signal displacements in the NMR spectra of main-group metal complexes.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. The authors are grateful to Mr. *J. Riede* for establishing the X-ray data sets.

Experimental Section

General: All experiments were carried out routinely in purified dry nitrogen. Solvents were dried and kept under nitrogen, and glassware was oven-dried and filled with nitrogen. 1,2-Bis(diphenylphosphanyl)benzene[10] and bis[(2-diphenylphosphanyl)phenyl]-phenylphosphane[9a] were prepared according to literature procedures, all other starting materials were commercially available. Gallium and indium trihalides were stored and handled in a glove box.

[1,2-Bis(diphenylphosphanyl)benzene]$_2$InCl$_2^+$ InCl$_4^-$ (**1**): Indium trichloride (99 mg, 0.45 mmol) is added to a solution of 1,2-bis(diphenylphosphanyl)benzene (202 mg, 0.45 mmol) in 10 ml of toluene and stirred for 2 h at 80°C. The white precipitate is collected and recrystallized from chloroform/pentane. Yield 273 mg (91%), colorless crystals, m.p. 243°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 7.78–7.11 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 128.8, 132.1, 135.3 (AXX′, phenylene); 125.8, 129.2, 131.6, 134.2 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −26.6 (br. s). – $C_{60}H_{48}Cl_6In_2P_4$ (1335.30): calcd. C 53.97, H 3.62; found C 53.31, H 3.65.

[1,2-Bis(diphenylphosphanyl)benzene]InBr$_3$ (**2**): As described for compound **1**, with indium tribromide (95 mg, 0.268 mmol) and 1,2-bis(diphenylphosphanyl)benzene (120 mg, 0.268 mmol). Yield 191 mg (89%), colorless crystals, m.p. 268°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 7.74–7.09 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 131.9, 135.2, 135.4 (AXX′, phenylene); 126.3, 129.1, 131.4, 134.3 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −26.9 (br. s). – $C_{30}H_{24}Br_3InP_2$ (801.00): calcd. C 44.99, H 3.02; found C 44.53, H 3.05.

[1,2-Bis(diphenylphosphanyl)benzene]InI$_3$ (**3**): As described for compound **1**, with indium triiodide (126 mg, 0.255 mmol) and 1,2-bis(diphenylphosphanyl)benzene (114 mg, 0.255 mmol). Yield 180 mg (75%), colorless crystals, m.p. 239°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 7.65–7.12 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 131.7, 135.4, 135.8 (AXX′, phenylene); 127.1, 129.0, 131.1, 134.2 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −31.7 (br. s). – $C_{30}H_{24}I_3InP_2$ (942.00): calcd. C 38.25, H 2.57; found C 37.63, H 2.81.

[1,2-Bis(diphenylphosphanyl)benzene]InBr$_2^+$ InBr$_4^-$ (**4**): As described for compound **1**, with indium tribromide (190 mg, 0.536 mmol) and 1,2-bis(diphenylphosphanyl)benzene (120 mg, 0.268 mmol). Yield 293 mg (95%), colorless crystals, m.p. 251°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 7.94–7.30 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 131.6, 134.9, 136.8 (AXX′, phenylene); 121.3, 130.5, 133.9, 134.2 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −20.0 (br. s). – $C_{30}H_{24}Br_6In_2P_2$ (1155.53): calcd. C 31.18, H 2.09; found C 30.89, H 2.02.

[1,2-Bis(diphenylphosphanyl)benzene]InI$_2^+$ InI$_4^-$ (**5**): As described for compound **1**, with indium triiodide (394 mg, 0.795 mmol) and 1,2-bis(diphenylphosphanyl)benzene (178 mg, 0.40 mmol). Yield 495 mg (87%), colorless crystals, m.p. 199°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 8.02–7.28 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 131.2, 135.2, 136.9 (AXX′, phenylene); 120.9, 130.4, 133.8, 134.1 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −27.9 (br. s). – $C_{30}H_{24}I_6In_2P_2$ (1437.53): calcd. C 25.07, H 1.68; found C 25.20, H 1.73.

[1,2-Bis(diphenylphosphanyl)benzene]GaBr$_2^+$ GaBr$_4^-$ (**6**): As described for compound **1**, with gallium tribromide (151 mg, 0.448 mmol) and 1,2-bis(diphenylphosphanyl)benzene (109 mg, 0.224 mmol). Yield 210 mg (81%), colorless crystals, m.p. 259°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 7.76–7.14 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 133.9, 135.9, 136.9 (AXX′, phenylene); 119.0, 130.6, 134.2, 134.5 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −22.1 (br. s). – $C_{30}H_{24}Br_6Ga_2P_2$ (1065.33): calcd. C 33.82, H 2.27; found C 33.48, H 2.14.

[1,2-Bis(diphenylphosphanyl)benzene]GaI$_2^+$ GaI$_4^-$ (**7**): As described for compound **1**, with gallium triiodide (201 mg, 0.446 mmol) and 1,2-bis(diphenylphosphanyl)benzene (100 mg, 0.223 mmol). Yield 285 mg (95%), colorless crystals, m.p. 219°C. – ^{1}H NMR ($CDCl_3$, 20°C): δ = 8.02–7.28 (m, Ph). – ^{13}C{^{1}H} NMR (v. s.): δ = 131.2, 135.2, 136.9 (AXX′, phenylene); 120.9, 130.4, 133.8, 134.1 (AXX′, Ph). – ^{31}P{^{1}H} NMR (v. s.): δ = −29.3 (br. s). – $C_{30}H_{24}I_6Ga_2P_2$ (1347.33): calcd. C 26.74, H 1.80; found C 26.48, H 1.75.

{Bis[(2-diphenylphosphanyl)phenyl]phenylphosphane}GaI$_2^+$-GaI$_4^-$ (**8**): As described for compound **1**, with gallium triiodide (219 mg, 0.485 mmol) and bis[(2-diphenylphosphanyl)phenyl]phenylphosphane (153 mg, 0.243 mmol). Recrystallization of the white precipitate from methylene chloride/pentane yielded 309 mg (83%) of colorless crystals, m.p. 267°C. – ^{31}P{^{1}H} NMR (CD_2Cl_2, 20°C): δ = −33 (A_2B, J = 213 Hz, $P^{cent.}$), −25 (A_2B, $P^{term.}$). – $C_{42}H_{33}Ga_2I_6P_3$ (1531.51): calcd. C 32.94, H 2.17; found C 32.58, H 2.09.

{Bis[(2-diphenylphosphanyl)phenyl]phenylphosphane}InI$_2^+$-InI$_4^-$ (**9**): As described for compound **8**, with indium triiodide (253 mg, 0.511 mmol) and bis[(2-diphenylphosphanyl)phenyl]phenylphosphane (161 mg, 0.255 mmol). Yield 364 mg (88%), colorless crystals, m.p. 259°C. – ^{31}P{^{1}H} NMR (CD_2Cl_2, 20°C): δ = −45 (A_2B, J = 282 Hz, $P^{cent.}$), −26 (A_2B, $P^{term.}$). – $C_{42}H_{33}Ga_2I_6P_3$ (1621.71): calcd. C 31.11, H 2.05; found C 30.78, H 2.04.

Reactions of **4** *and* **5** *with Oxygen Donors:* [(DP)$InBr_2$]$^+$ [$InBr_4$]$^-$ (**4**, 100 mg, 0.086 mmol) is dissolved in 5 ml of THF and layered with pentane. The colorless crystals obtained show the same analytical data (mp, EA, NMR) as compound **2**. [(DP)InI_2]$^+$[InI_4]$^-$ (**5**, 100 mg, 0.069 mmol) is dissolved in 10 ml of $CHCl_3$ and 0.1 ml of acetone is added. After heating to reflux, a colorless solid is precipitated with pentane. The product shows the same analytical data as compound **3**. Similar results are obtained with $OPPh_3$ (50 mg, 0.18 mmol).

Crystal Structure Determinations: Specimens of suitable quality and size of compounds **1**, **3**·2 $CHCl_3$, **5**·CH_2Cl_2, **7**, **8**, and **9** were mounted in glass capillaries and used for measurements of precise cell constants and intensity-data collection on an Enraf Nonius CAD4 diffractometer [Mo-K_α radiation, λ(Mo-K_α) = 0.71073 Å]. During data collection, three standard reflections were measured periodically as a general check of crystal and instrument stability. No significant changes were observed for either compound. Lp correction was applied and intensity data were corrected for absorption effects. The structures were solved by direct and Patterson methods (SHELXS-86), respectively, and completed by full-matrix least-squares techniques against F^2 (SHELXL-93). The thermal motion of all non-hydrogen atoms was treated anisotropically. All hydrogen atoms were placed in idealized calculated positions and allowed to ride on their corresponding carbon atoms with fixed isotropic contributions ($U_{iso(fix)}$ = 1.5 × U_{eq} of the attached C atom). Further information on crystal data, data collection, and structure refinement are summarized in Tables 1 and 2. Important interatomic distances and angles are shown in the corresponding figure captions. Anisotropic thermal parameters, tables of distances and angles, and atomic coordinates have been deposited with Fachinformationszentrum Karlsruhe, Gesellschaft für wissenschaftlich-technische Information mbH, D-76344 Eggenstein-Leopoldshafen. The data are available on request on quoting CSD-407907 (**1**), -407908 (**3**), -407905 (**5**), -407906 (**7**), -407904 (**8**), -407903 (**9**).

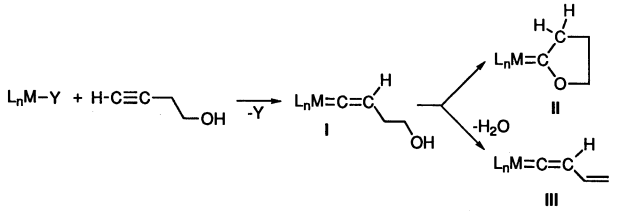
Keywords: Rhenium / Oxacyclocarbene complexes / Vinylidene complexes / Alkynols / Tripodal ligands

Various β-, γ-, and δ-alkynols have been reacted with the 16e$^-$ fragment $[(triphos)Re(CO)_2]^+$ generated in situ by H_2 elimination from $[(triphos)Re(CO)_2(\eta^2\text{-}H_2)]BF_4$ [triphos = $MeC(CH_2PPh_2)_3$]. Irrespective of the length of the alkyl chain between the C≡C and OH functional groups in the ω-alkynol, 2-oxacyclocarbene complexes are obtained. These include the 2-oxacyclopentylidene derivatives $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2O\}]BF_4$ and $[(triphos)Re(CO)_2\{=CCH_2CH_2CH(Me)O\}]BF_4$, the 2-oxacyclohexylidene derivatives $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2CH_2O\}]BF_4$ and $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2CH(Me)O\}]BF_4$, and the 2-oxacycloheptylidene complex $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2CH_2CH_2O\}]BF_4$. The latter compound contains a unprecedented seven-membered oxacarbene ring. The rhenium-assisted δ-alkynol to 2-oxacyloheptylidene rearrangement proceeds via the hydroxybutylvinylidene kinetic intermediate $[(triphos)Re(CO)_2\{C=C(H)CH_2CH_2CH_2CH_2OH\}]BF_4$, which has been characterized in both the solid state and solution. An X-ray analysis has been carried out on a single crystal of $[(triphos)Re(CO)_2\{=CCH_2CH_2CH(Me)O\}]BF_4$. The structure of this complex consists of $[(triphos)Re(CO)_2\{=CCH_2CH_2CH(Me)O\}]^+$ cations and tetrafluoroborate anions with no interspersed solvent molecules. A *facial* triphos ligand, two *cis*-disposed carbonyl groups and a 2-oxacyclopentylidene ligand coordinate the Re centre in a slightly distorted octahedral environment.

Introduction

The reaction of alkynols with unsaturated metal fragments provides a convenient synthetic route to 2-oxacyclocarbene complexes,[1] that are receiving increasing attention as organometallic synthons in several catalytic and stoichiometric elaborations.[2][3] The most widely studied of these, are the reactions of β-alkynols to give 2-oxacyclopentylidene derivatives, and various complexes with ruthenium,[4][5][6][7] osmium,[8] manganese,[9] rhenium,[9a] and metals of the chromium group[1][10] have recently been described. The β-alkynol to oxacyclocarbene rearrangement has been shown to proceed via preliminary metal-assisted 1-alkyne to vinylidene tautomerization.[1][10b][11] For β-alkynols, the formation of cyclic Fischer carbene implies the generation of hydroxyethylvinylidene derivatives (**I**), which have been intercepted spectroscopically in a few cases (Scheme 1).[5] Vinylidenes are highly polarized C_2 ligands and both experimental[12][13] and theoretical studies[14] show the C_α atom to be an electrophilic centre susceptible to attack by almost any sort of nucleophile (alcohols, water, amines, thiols, phosphanes, etc.).[12] In case of β-hydroxyethylvinylidene ligands, the oxacarbene ring forms via intramolecular attack by the OH group of the dangling hydroxyalkyl substituent at the C_α atom. When this happens it is implicit that the ring-closure reaction affording the Fischer carbene (**II**) is favored over the equally possible elimination of water to give the vinylvinylidene derivative (**III**).[15]

Scheme 1. Reactions of 3-butyn-1-ol with metal-ligand systems



It has been observed experimentally that the intramolecular attack by the hydroxy group is increasingly disfavored as the number of CH_2 spacers between the triple bond and the OH group in the alkynol increases. Indeed, 2-oxacyclohexylidene complexes derived from metal-assisted rearrangements of γ-alkynols are quite rare compounds,[1][8a][10b] while no example involving δ-alkynols has yet been reported.[16][17] In actuality, δ-alkynols are still reactive substrates towards transition metal fragments. Due to the length of the pendant hydroxyalkyl tail, however, their activation results in the preferential formation of stable hydroxybutylvinylidene complexes.[8][18] In no case was the hydroxybutylvinylidene intermediate seen to convert to the 2-oxacycloheptylidene isomer.

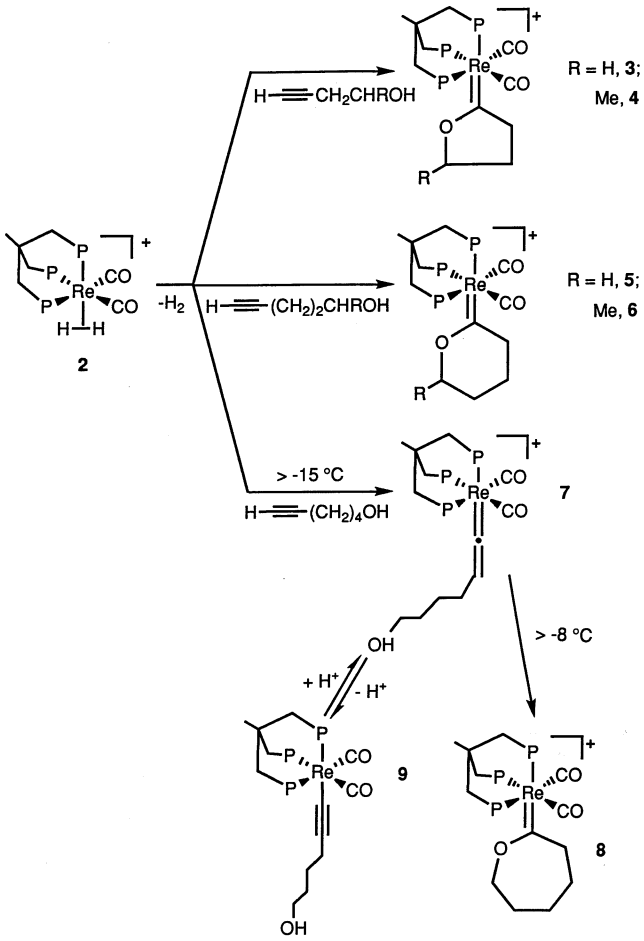
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0211 $ 17.50+.50/0

Stimulated by the idea that a comparative study involving the reaction of a unique metal fragment with different ω-alkynols could have provided additional information on the mechanism of formation of 2-oxacarbene complexes as well as their chemistry, we decided to examine the reactions of various β-, γ-, and δ-alkynols with the kinetically inert organometallic support $[\{MeC(CH_2PPh_2)_3\}Re(CO)_2]^+$.[19] We were gratified to find that Fischer carbene complexes are selectively formed, via kinetic hydroxyvinylidene intermediates, irrespective of the number of CH_2 spacers. The hydroxyvinylidene complex has exclusively been intercepted with the δ-alkynol 5-hexyn-1-ol and its conversion to the thermodynamic 2-oxacycloheptylidene product has been studied.

Results and Discussion

The preparations and principal reactions reported in this article are summarized in Scheme 2. Selected spectroscopic data (IR and NMR) are collected in Table 1, or are provided in the Experimental Section. The total and unambiguous assignment of all the hydrogen and carbon resonances for all rhenium complexes was obtained by a combination of 1D- and 2D-NMR spectroscopy including $^1H\{^{31}P\}$, DEPT-135, $^1H,^1H$-COSY, $^1H,^1H$-NOESY, and $^1H,^{13}C$-HETCOR experiments.

Scheme 2. Reactions of $[(triphos)Re(CO)_2]^+$ auxiliary with ω-alkynols



Synthesis and Characterization of 2-Oxacycloalkylidene Complexes: In earlier work,[19] we have shown that [(triphos)Re(CO)$_2$H] (**1**) reacts with $HBF_4\cdot OMe_2$ in CH_2Cl_2 to give $[(triphos)Re(CO)_2(\eta^2\text{-}H_2)]BF_4$ (**2**) which contains a weakly bound dihydrogen ligand.[19] We have now found that **2** in CH_2Cl_2 reacts with 3-butyn-1-ol yielding the 2-oxacyclopentylidene complex $[(triphos)Re(CO)_2\{=CCH_2\text{-}CH_2CH_2O\}]BF_4$ (**3**). The selective formation of this Fischer carbene complex takes place already at −10°C, and proceeds with no detectable intermediate on the NMR timescale. The room-temperature $^{31}P\{^1H\}$-NMR spectrum consists of an AM_2 pattern with chemical shifts and coupling constants in line with those reported for other cationic carbene complexes of the general formula $[(triphos)Re(CO)_2\{CRR'\}]Y$.[20] The magnetic equivalence of the two phosphorus atoms lying *trans* to the two carbonyl ligands is consistent with a rapid rotation of the oxacyclopentylidene group about the Re=C bond. The oxacarbene ligand continues to rotate freely even at −80°C. A very low-energy barrier to rotation is typical of carbene and vinylidene groups bonded to the $[(triphos)Re(CO)_2]^+$ fragment,[19][20] and it is also commonly encountered in carbene complexes with other transition metals.[9b][21] The most direct spectroscopic evidence of the presence of a carbene ligand in **3** is provided by the $^{13}C\{^1H\}$-NMR spectrum which contains a doublet of triplets centred at δ = 293.4 ($J_{CPtrans}$ = 35.0 Hz, J_{CPcis} = 8.9 Hz).[12][13] The other oxacyclopentylidene carbon atoms resonate at δ = 85.3, 62.7, and 22.8, consistent with this type of ligand, while the two carbonyl carbon atoms appear as a second-order multiplet at δ = 197.0. This may properly be computed using an AXX′Y spin system (A: carbonyl C atom, X and X′: P atoms *trans* to the CO ligands, Y: P atom *trans* to the carbene ligand; see Table 1).[19][20][22] The proton NMR spectrum correlates well with the spectra of various 2-oxacyclocarbene metal complexes containing three methylene groups in the ring.[4] A cyclic oxacarbene ligand in **3** is finally supported by the IR spectrum displaying a medium intensity ν(COC) band at 1194 cm^{-1} and two strong ν(CO) absorptions at wavenumbers (1962 and 1912 cm^{-1}) that are typical of $[(triphos)Re(CO)_2\{=CRR'\}]Y$ carbene compounds.[20]

Replacing 3-butyn-1-ol with (±)-4-pentyn-2-ol in the reaction with **2** affords the substituted 2-oxa-3-methyl-cyclopentylidene complex $[(triphos)Re(CO)_2\{=CCH_2CH_2CH\text{-}(Me)O\}]BF_4$ (**4**) as air-stable orange crystals. As expected, the presence of a stereogenic carbon atom in the oxacarbene ring differentiates the spectroscopic characteristics of **4** from those of **3**. For example, the $^{31}P\{^1H\}$-NMR spectrum of **4** consists of an AMQ spin system, while the carbonyl carbons appear in the $^{13}C\{^1H\}$-NMR spectrum as a well-resolved doublet of triplets (δ = 198.6, $J_{CPtrans}$ = 45.5 Hz, J_{CPcis} = 5.7 Hz). The stereocenter in the 2-oxacyclopentylidene ring also leads to the chemical and magnetic nonequivalence of the methylene protons. For this reason, the resonances of the oxacarbene-ring protons could only be unambiguously assigned by means of 2D-COSY and 2D-phase sensitive NOESY NMR spectra. In particular, the

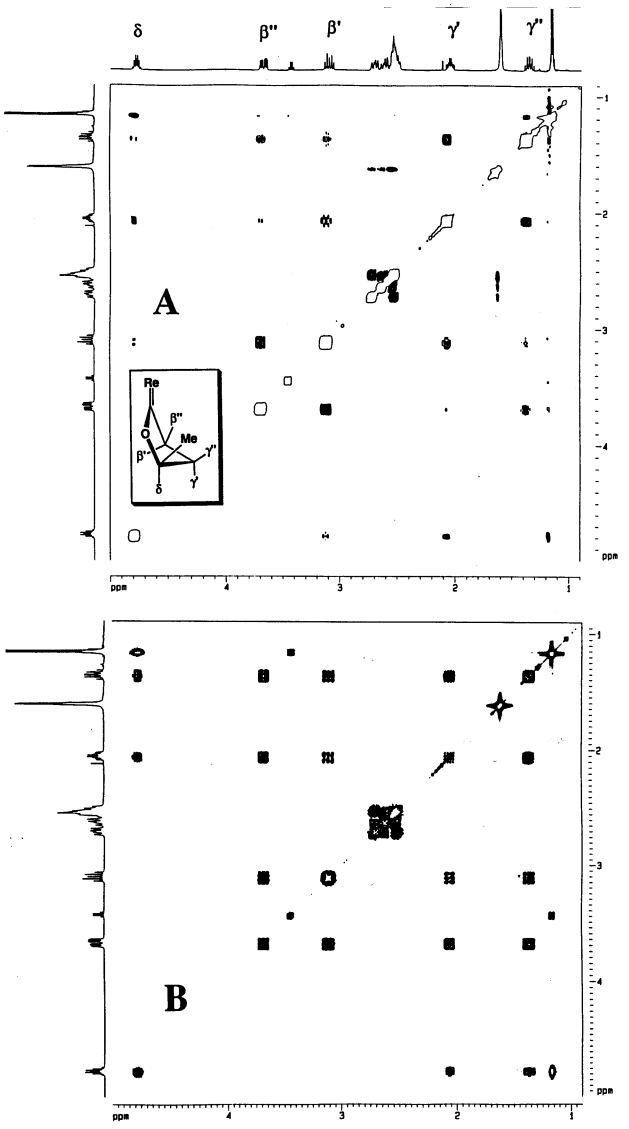
latter experiment allowed us to establish the spatial relationships between the H_δ proton at $\delta = 4.77$ (which correlates with the CH carbon at $\delta = 98.5$ in the 2D-^{1}H,^{13}C-HMQC NMR experiment) and the signal at $\delta = 2.05$ of the opposite $H_{\gamma'}$ proton. Following this assignment, the remaining proton and carbon resonances were readily and reliably identified. Significant sections of the NOESY and COSY spectra are presented in Figure 1.

Figure 1. (**A**) Section ($\delta = 5.00 - 0.90$) of the phase-sensitive 2D-^{1}H NOESY spectrum of **4** (500.13 MHz, CD_2Cl_2, 25°C, τ_{mix} 800 ms) showing the negative cross-peaks between the protons of the 2-oxa-3-methyl-cyclopentylidene ring. (**B**) Contour plot of a section ($\delta = 5.00-0.90$) of the 2D-^{1}H COSY spectrum of **4** (500.13 MHz, CD_2Cl_2, 25°C) showing the scalar couplings for the protons of the 2-oxa-3-methyl-cyclopentylidene ring



The solid-state structure of the 2-oxa-3-methyl-cyclopentylidene complex (**4**) has been determined by a single-crystal X-ray analysis. A view of the complex cation is shown in Figure 2, while selected bond lengths and angles are given in Table 2.

The structure of **4** consists of $[(triphos)Re(CO)_2\{=CCH_2CH_2CH(Me)O\}]^+$ cations and tetrafluoroborate anions with no interspersed solvent molecules. A *facial* triphos ligand, two *cis* disposed carbonyl groups and an oxacyclopentylidene ligand co-ordinate the Re center in a slightly distorted octahedral environment. The $Re-C_{carbene}$ bond length [$d_{Re=C} = 2.02(2)$ Å] is shorter than that found in the alkoxycarbene complex $[(triphos)Re(CO)_2\{=C(OEt)CH_3\}]BF_4$ [$d_{Re=C} = 2.071(8)$ Å],[20] but longer than that reported for the vinylidene complex $[(triphos)Re(CO)_2\{=C=C(H)Ph\}]BPh_4$ [$d_{Re=C} = 1.925(6)$ Å].[20] Noticeably, the present $Re-C_{carbene}$ distance is also shorter than that found in $(CO)_5Re=CCH_2CH_2CH_2O$ [$d_{Re=C} = 2.125$ Å][9a] and in $Br(CO)_4Re=COCH_2CH_2O$ [$d_{Re=C} = 2.135$ Å].[23] The oxacyclopentylidene ring adopts an "envelope" conformation with small deviations from the mean plane defined by the rhenium atom, and by the O3 and C8 to C12 atoms. The largest deviation affects the C10 atom (−0.0201 Å) in β-position with respect to O3. Deviations from planarity are often encountered in this class of oxacyclocarbene complexes and deformations ranging from

Figure 2. ORTEP Drawing of the complex cation $[(triphos)Re(CO)_2\{=CCH_2CH_2CH(Me)O\}]^+$ in **4-BF$_4$**. Only the *ipso* carbons of the phenyl rings of the triphos ligand are shown for the sake of clarity

practically planar systems to significantly distorted rings have been reported.[24][25] A comparable distortion has been reported for the molybdenum complex $[MoI(CO)_2\{=COCH_2CH_2CH_2\}(\eta^5\text{-}C_5H_5)]$.[26] The C8−O3 distance and the other metrical parameters pertaining to the carbene ligand fall into the range determined for related complexes.[5][9][23][24][25][26]

Reactions of **2** *with γ- and δ-Alkynols:* When either 4-pentyn-1-ol or (±)-5-hexyn-2-ol are allowed to react with a CH_2Cl_2 solution of **2** at room temperature, the Fischer carbene complexes $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2\text{-}CH(R)O\}]BF_4$ (R = H, **5**; R = Me, **6**) are obtained in good yields (Scheme 2). To the best of our knowledge, known examples of oxacyclohexylidene metal complexes are limited to the chromium complex $(CO)_5Cr\{=CCH_2\text{-}CH_2CH_2CH_2O\}$ described by Dötz,[1] the manganese compound $Cp(CO)(PPh_3)Mn=C\{OCH_2C(Me)_2CH_2CH(Me)\}$ synthesized by Geoffroy and coworkers,[9b] the molybdenum derivative $[Mo\{=CH_2(CH_2)_2CH_2O\}(dppe)(\eta\text{-}C_7H_7)]PF_6$ (dppe = $Ph_2PCH_2CH_2PPh_2$) reported by Whiteley and co-workers,[10b] and the indenyl osmium complex $[(\eta^5\text{-}C_9H_7)Os\{=CCH_2CH_2CH_2CH_2O\}(PPh_3)_2]$ described by Gimeno.[8a]

The presence of oxacyclohexylidene rings in **5** and **6** is shown by the $^{13}C\{^1H\}$-NMR spectra which exhibit four different methylene resonances (singlets at δ = 16.7, 21.6, 55.6, and 75.0), while the carbene carbon atoms resonate at δ = 303.0 (**5**: dt, $J_{CPtrans}$ = 36.8 Hz, J_{CPcis} = 9.5 Hz) and at δ = 305.3 (**6**: dt, $J_{CPtrans}$ = 36.9 Hz, J_{CPcis} = 8.6 Hz). As expected the NMR properties of **6** are similar to those of **4**, which analogously contains a stereogenic carbon atom in the ring.[27]

Monitoring the reactions between **2** and 4-pentyn-1-ol [or (±)-5-hexyn-2-ol] by multinuclear NMR spectroscopy in the temperature range from −50 to +20°C showed no intermediate species in the course of the conversion of **2** to **5** (or **6**). In contrast, V. T. NMR spectroscopy has revealed that the hydroxybutylvinylidene complex $[(triphos)Re(CO)_2\{=C=C(H)CH_2CH_2CH_2CH_2OH\}]BF_4$ (**7**) is an intermediate to the oxacarbene thermodynamic product $[(triphos)Re(CO)_2\{=CCH_2CH_2CH_2CH_2CH_2O\}]\text{-}BF_4$ (**8**) when **2** is reacted with a δ-alkynol such as $HC\equiv CCH_2(CH_2)_2CH_2OH$. The hydroxyvinylidene complex is stable in solution below −10°C. Above this temperature it slowly but selectively transforms into the 2-oxacycloheptylidene isomer **8** (Scheme 2). The conversion is fast at room temperature. Nonetheless, the stability at low temperature allows **7** to be unambiguously characterized in solution and isolated in the solid state as well.

Bands in the IR spectrum of **7** at 1663 (C=C) and ca. 3550 cm^{-1} (OH), diagnose the presence of a hydroxyvinylidene ligand. These absorptions are not present in the IR spectrum of **8**, in which the stretching frequencies of the two CO′s are at lower energy (1960 and 1900 cm^{-1}) compared to those of **7** (2008 and 1946 cm^{-1}) due to the greater π-acceptor character of the hydroxyvinylidene ligand.[14][20] In keeping with this electronic effect, the phosphorus resonances of **8** (δ_A = −17.14, δ_M = −11.49, J_{AM} = 20.9 Hz) are shifted to low field with respect to those of **7** (δ_A = −19.41, δ_M = −15.82, J_{AM} = 23.2 Hz). The $^{13}C\{^1H\}$-NMR spectrum of **7** displays the characteristic low-field resonance of the vinylidene C_α atom (δ = 343.9), while the resonance of the C_β atom appears at higher field (doublet of triplets at δ = 111.0).[12][13][21] Four signals, spanning from δ = 52.1 (C_ζ) to δ = 19.8 (C_γ) are assigned to the CH_2 carbon atoms of the δ-hydroxybutyl substituent in the vinylidene ligand. In the proton NMR spectrum of **7**, the vinylidene hydrogen resonance appears as a well-resolved triplet of pseudoquartets at δ = 3.53 which collapses into a triplet of 8.3 Hz in the broad-band phosphorus-decoupled spectrum.

Further experimental evidence of the vinylidene nature of the organyl ligand in **7** is provided by the reaction of the latter compound with Brønsted bases, such as NEt_3, which remove the vinylidene hydrogen atom, leading to the clean formation of the σ-alkynyl complex $[(triphos)Re(CO)_2\text{-}\{C\equiv CCH_2CH_2CH_2CH_2OH\}]$ (**9**).[12][20] This reaction is reversible and **9** re-generates **7** by treatment with protic acids. The alkynyl derivative **9** has been isolated and authenticated spectroscopically by comparison with several Re^I alkynyls of the formula $[(triphos)Re(CO)_2(C\equiv CR)]$.[20]

A careful and complete analysis of the $^{13}C\{^1H\}$-NMR spectrum was carried out for the unambiguous identification of **8**. Key features are a doublet of triplets at δ = 310.8, assigned to the carbene carbon atom, and five methylene resonances assigned to the five CH_2 groups of the 2-oxacycloheptylidene ring. The presence of five methylene resonances was of crucial importance for ruling out a vinyl-vinylidene structure which might have been formed via the alternative water-elimination pathway (Scheme 1). Of the five methylene resonances, only those of the C_ζ (δ = 78.6) and C_β (δ = 60.1) carbons, proximal to the oxygen and to the carbene carbon atoms, respectively, appear as doublets with small phosphorus-carbon couplings. The remaining CH_2 resonances (between δ = 29.1 and 21.5) are singlets with no discernible coupling.

Fischer carbene complexes containing oxacycloheptylidene rings are extremely rare. To the best of our knowledge, the only example reported in the literature is the dinuclear dimanganese complex $[(CO)_5Mn-Mn(CO)_4\{=CO\text{-}CH_2CH_2CH_2CH_2CH_2\}]$.[16] This, however, was prepared by the alternative reaction of the bistriflate $TfOCH_2CH_2CH_2CH_2CH_2OTf$ with the carbonyl metalate salt $K[Mn(CO)_5]$ in THF, and not by δ-alkynol activation.[16][17]

Conclusions

Our study of the reactions of the $16e^-$ $[(triphos)Re(CO)_2]^+$ support with different β-, γ-, and δ-alkynols has shown that cyclic carbenes are formed irrespective of the separation between the triple bond and the hydroxy functional group. We have also demonstrated that this cyclization reaction occurs via the hydroxyalkylvinylidene complexes. For the particular case of the δ-alkynol 5-hexyn-1-ol the kinetic hydroxybutylvinylidene intermediate has been intercepted in solution and isolated in the solid state. Its thermal rearrange-

ment to the thermodynamic 2-oxacycloheptylidene product has been observed, showing that the intramolecular nucleophilic attack by the OH group at the vinylidene C_α atom may still be favored over H_2O elimination to give vinylvinylidene products. The same should be true for long-chain ω-alkynols. Studies are currently in progress to scrutiny the chemistry of this new family of rhenium 2-oxacarbenes.

Thanks are due to Prof. *A. Medici* (University of Ferrara, Italy) for a gift of (±)-5-hexyn-2-ol and to Prof. *J. Gimeno* (University of Oviedo, Spain) for communicating some preliminary results prior to publication.

Experimental Section

General Procedure: Tetrahydrofuran (THF), *n*-hexane, and diethyl ether were purified by distillation over sodium/benzophenone under a nitrogen atmosphere. Dichloromethane and ethanol were purified by distillation under nitrogen over calcium hydride. The ligand $CH_3C(CH_2PPh_2)_3$ (triphos)[28] and the complexes [(triphos)-$Re(CO)_2H$] (**1**)[19] and [(triphos)$Re(CO)_2(\eta^2\text{-}H_2)]BF_4$ (**2**)[20] were prepared as described in the literature. All the alkynols were purchased from Aldrich except for (±)-5-hexyn-2-ol which was provided by Prof. A. Medici (Department of Chemistry, University of Ferrara). The purity of all alkynols was checked by ^{1}H-NMR spectroscopy, and, when necessary, they were distilled under inert atmosphere prior to use. All the other reagents and chemicals were reagent grade and, unless otherwise stated, were used as received from commercial suppliers. All reactions and manipulations were routinely performed under a dry nitrogen atmosphere by using standard Schlenk-tube techniques. CD_2Cl_2 for NMR measurements (Merck and Aldrich) was dried over molecular sieves (4 Å). – ^{1}H- and $^{13}C\{^1H\}$-NMR spectra were recorded on Varian VXR 300, Bruker AC200, or Bruker AVANCE DRX 500 spectrometers operating at 299.94, 200.13, or 500.13 MHz (^{1}H) and 75.42, 50.32, or 125.80 MHz (^{13}C), respectively. Peak positions are relative to tetramethylsilane and were calibrated against the residual solvent resonance (^{1}H) or the deuterated solvent multiplet (^{13}C). ^{13}C-DEPT, and gated $^{13}C\{^1H\}$-decoupled NMR experiments were run on the Bruker AC200 spectrometer. ^{1}H,^{13}C-2D HETCOR NMR experiments were recorded on either the Bruker AC200 spectrometer using the XHCORR pulse program or the Bruker AVANCE DRX 500 spectrometer equipped with a 5-mm triple-resonance probe-head for ^{1}H detection and inverse detection of the heteronucleus (inverse correlation mode, HMQC experiment) with no sample spinning. The ^{1}H,^{1}H-2D COSY NMR experiments were routinely conducted on the Bruker AC200 instrument in the absolute magnitude mode using a 45° or 90° pulse after the incremental delay. The ^{1}H,^{1}H-2D COSY NMR experiments on the racemate complexes **4** and **6** were acquired on the AVANCE DRX 500 Bruker spectrometer using the phase-sensitive TPPI mode with double quantum filter. ^{1}H,^{1}H-2D NOESY NMR experiments were conducted on the same instrument in the phase-sensitive TPPI mode in order to discriminate between positive and negative cross peaks. – $^{31}P\{^1H\}$ NMR spectra were recorded on either the Varian VXR 300 or Bruker AC200 instruments operating at 121.42 and 81.01 MHz, respectively. Chemical shifts were measured relative to external 85% H_3PO_4 with downfield values taken as positive. The proton NMR spectra with broad-band phosphorus decoupling were recorded on the Bruker AC200 instrument equipped with a 5-mm inverse probe and a BFX-5 amplifier device using the wideband phosphorus decoupling sequence GARP.[29] – Computer simulations of NMR spectra were carried out with a locally developed package containing the programs LAOCN3[30] and DAVINS.[31] The initial choices of shifts and coupling constants were refined by iterative least-squares calculations using the experimental digitized spectrum. The final parameters gave a satisfactory fit between experimental and calculated spectra, the agreement factor *R* being less than 1% in all cases. – Infrared spectra were recorded in KBr pellets on a Nicolet 510 P spectrometer operating in the FT mode, or as Nujol mulls on a Perkin–Elmer 1600 series FT-IR spectrometer between KBr plates. – Conductivities were measured with an ORION model 990101 conductance cell connected to a model 101 conductivity meter. The conductivity data were obtained at sample concentrations of ca. $1\cdot10^{-3}$ M in nitroethane solutions at room temperature (21°C). – Elemental analyses were performed with a Carlo Erba model 1106 elemental analyzer.

Synthesis of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$O}]BF$_4$ (**3**): A dichloromethane (5 ml) solution of the complex [(triphos)-$Re(CO)_2(\eta^2\text{-}H_2)]BF_4$ (**2**) was prepared in a 25-ml Schlenk-flask by treating [(triphos)$Re(CO)_2H$] (**1**) (0.25 g, 0.26 mmol) with $HBF_4.OMe_2$ (33 µl, 0.27 mmol) at −20°C under nitrogen.[19] To this solution, a slight excess of 3-butyn-1-ol (23 µl, 0.30 mmol) was added with stirring, and the solution was slowly brought to room temperature. During this time, the color of the resulting solution changed from pale yellow to orange. After the reaction mixture was allowed to reach room temperature, stirring was continued for additional 30 min. The solvent was removed under reduced pressure and the solid residue washed with 2 × 2 ml of ethanol and 2 × 3 ml of diethyl ether. The crude reaction product was recrystallized from dichloromethane/diethyl ether (1:1, v/v) to yield orange crystals of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$O}]BF$_4$ (**3**). Yield 80%. – $C_{47}H_{45}BF_4O_3P_3Re$: calcd. C 55.14, H 4.45; found C 55.20, H 4.55.– ^{1}H NMR (CD_2Cl_2, 22°C, 200.13 MHz): (the numbering scheme for the hydrogen and carbon resonances of this complex as well as all the other new complexes described in this paper is given in Table 1) δ = 1.62 (q, J_{HP} = 3.1 Hz, $CH_{3(triphos)}$, 3 H), 1.73 (quint, J_{HH} = 7.8 Hz, H_γ, 2 H), 2.54 (d, $J_{HP\,axial}$ = 8.8 Hz, CH_2P_{axial}, 2 H), 2.70 (m, CH_2P_{equat}, 4 H), 3.28 (td, J_{HH} = 7.7 Hz, J_{HP} = 0.6 Hz, H_β, 2 H), 4.06 (t, J_{HH} = 7.6 Hz, H_δ, 2 H). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 22°C, 50.32 MHz): δ = 293.4 (dt, $J_{CP\,trans}$ = 35.0 Hz, $J_{CP\,cis}$ = 8.9 Hz, C_α), 197.0 (m, CO), 85.3 (d, J_{CP} = 3.2 Hz, C_δ), 62.7 (d, J_{CP} = 5.7 Hz, C_β), 40.3 (q, J_{CP} = 9.9 Hz, $CH_{3(triphos)}$), 39.7 (q, J_{CP} = 3.5 Hz, $MeC_{(triphos)}$), 35.1 (td, N = $J_{CP\,equat'}$ + $J_{CP\,equat''}$ = 14.0 Hz, $J_{CP\,axial}$ = 4.5 Hz, CH_2P_{equat}), 32.4 (dt, $J_{CP\,axial}$ = 23.5 Hz, $J_{CP\,equat}$ = 4.4 Hz, CH_2P_{axial}), 22.8 (s, C_γ).– $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 22°C, 81.01 MHz): AM_2 spin system, δ_A = −15.90, δ_M = −11.86, J_{AM} = 22.1 Hz. $-\Lambda_{M(nitroethane)}$ = 80 Ω^{-1} cm^2 mol^{-1}.

Recrystallization of **3** from dichloromethane/ethanol in the presence of 2 equiv of $NaBPh_4$, yielded the corresponding tetraphenylborate salt (**3′**) in ca. 90% yield. – [(triphos)Re(CO)$_2$-{=CCH$_2$CH$_2$CH$_2$O}]BPh$_4$ (**3′**, $C_{71}H_{65}BO_3P_3Re$): calcd. C 67.89, H 5.21; found C 67.19, H 5.01. – $\Lambda_{M(nitroethane)}$ = 53 Ω^{-1} cm^2 mol^{-1}.

Synthesis of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH(Me)O}]BF$_4$ (**4**): The methyl-substituted oxycarbene complex **4**, was obtained as described above for **3** using (±)-4-pentyn-2-ol (24 µl, 0.26 mmol) instead of 3-butyn-1-ol. The reaction was complete after stirring the mixture at room temperature for 1 h. Work-up as above gave [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH(Me)O}]BF$_4$ (**4**) as orange microcrystals. Yield 85%. – $C_{48}H_{47}BF_4O_3P_3Re$: calcd. Synthesis of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH$_2$O}]BF$_4$ (**5**): A slight excess of 4-pentyn-1-ol (40 µl, 0.37 mmol) was added with stirring to a solution of **2** (0.26 mmol) prepared as described above. Usual work-up gave pale orange crystals of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH$_2$O}]BF$_4$ (**5**). Yield 80%. – $C_{48}H_{47}BF_4O_3P_3Re$: calcd. C 55.55, H 4.56; found C 55.49, H 4.50. – ^1H NMR (CD_2Cl_2, 25°C, 500.13 MHz): δ = 1.50 (m, H_γ + H_δ, 4 H), 1.68 (q, J_{HP} = 3.0 Hz, $CH_{3(triphos)}$, 3 H), 2.48 (d, $J_{HPaxial}$ = 8.8 Hz, CH_2P_{axial}, 2 H), 2.70 (m, CH_2P_{equat}, 4 H), 3.28 (t, $J_{H\beta H\gamma}$ = 6.8 Hz, H_β, 2 H), 3.44 (t, $J_{H\varepsilon H\delta}$ = 6.0 Hz, H_ε, 2 H). – $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 22°C, 50.32 MHz): δ = 303.0 (dt, $J_{CPtrans}$ = 36.8 Hz, J_{CPcis} = 9.5 Hz, C_α), 198.0 (m, CO), 75.0 (d, J_{CP} = 2.5 Hz, C_ε), 55.6 (d, J_{CP} = 3.8 Hz, C_β), 40.3 (q, J_{CP} = 10.4 Hz, $CH_{3(triphos)}$), 39.7 (q, J_{CP} = 3.8 Hz, $MeC_{(triphos)}$), 32.5 (td, N = $J_{CPequat'}$ + $J_{CPequat''}$ = 14.0 Hz, $J_{CPaxial}$ = 4.4 Hz, CH_2P_{equat}), 32.5 (dt, $J_{CPaxial}$ = 22.9 Hz, $J_{CPequat}$ = 4.3 Hz, CH_2P_{axial}), 21.1 (s, C_δ), 16.7 (s, C_γ). – $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 22°C, 81.01 MHz): AM_2 spin system, δ_A = –16.71, δ_M = –10.70, J_{AM} = 21.4 Hz. – $\Lambda_{M(nitroethane)}$ = 82 Ω^{-1} cm^2 mol^{-1}.

Synthesis of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH(Me)O}]BF$_4$ (**6**): A two-fold excess of (±)-5-hexyn-2-ol (54 µl, 0.55 mmol) was syringed into a dichloromethane solution of **2** (0.026 mmol) prepared as described above. Orange microcrystals of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH(Me)O}]BF$_4$ (**6**) were obtained in ca. 65% yield after usual work up. – $C_{49}H_{49}BF_4O_3P_3Re$: calcd. C 55.88, H 4.69; found C 55.90, H 4.72. – ^1H NMR (CD_2Cl_2, 25°C, 200.13 MHz): δ = 1.01 (d, $J_{MeH\varepsilon}$ = 6.3 Hz, $CH_{3(carbene)}$, 3 H), 1.35 (m, $H_{\beta'}$ + $H_{\delta'}$, 2 H), 1.60 (m, $H_{\gamma'}$ + $CH_{3(triphos)}$, 4 H), 1.96 (m, $H_{\delta'}$, 1H), 2.40 – 2.70 (m, $H_{\gamma''}$ + $CH_{2(triphos)}$, 7H), 3.92 (ddd, $J_{H\beta''H\beta'}$ = 17.1 Hz, $J_{H\beta''H\gamma'}$ = 5.8 Hz, $J_{H\beta''H\gamma''}$ = 3.6 Hz, $H_{\beta''}$, 1 H), 4.14 (m, H_ε, 1H). – $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 20°C, 50.32 MHz): δ = 305.3 (dt, $J_{CPtrans}$ = 36.9 Hz, J_{CPcis} = 8.6 Hz, C_α), 197.1 (dt, $J_{CPtrans}$ = 44.5 Hz, J_{CPcis} = 7.6 Hz, CO), 83.9 (d, J_{CP} = 2.2 Hz, C_ε), 55.8 (dt, $J_{CPaxial}$ = 4.5 Hz, $J_{CPequat}$ = 1.3 Hz, C_β), 39.7 (q, J_{CP} = 10.1 Hz, $CH_{3(triphos)}$), 39.5 (q, J_{CP} = 3.2 Hz, $MeC_{(triphos)}$), 35.7 (td, N = $J_{CPequat'}$ + $J_{CPequat''}$ = 5.0 Hz, $J_{CPaxial}$ = 2.5 Hz, CH_2P_{equat}), 35.1 (td, N = $J_{CPequat'}$ + $J_{CPequat''}$ = 5.0 Hz, $J_{CPaxial}$ = 2.4 Hz, CH_2P_{equat}), 32.8 (dt, $J_{CPaxial}$ = 22.2 Hz, $J_{CPequat}$ = 4.8 Hz, CH_2P_{axial}), 28.7 (s, C_δ), 20.3 (s, $CH_{3(carbene)}$), 16.9 (s, C_γ). – $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 22°C, 81.01 MHz): AMQ spin system, δ_A = –12.80, δ_M = –14.00, δ_Q = –16.56, J_{AM} = 20.1 Hz, J_{AQ} = 23.5 Hz, J_{MQ} = 20.7 Hz. – $\Lambda_{M(nitroethane)}$ = 85 Ω^{-1} cm^2 mol^{-1}.

In Situ NMR Studies: Reactions of [(triphos)Re(CO)$_2$(η^2-H$_2$)]BF$_4$ (**2**) *with 3-Butyn-1-ol, (±)-4-Pentyn-2-ol, or 4-Pentyn-1-ol:* Deoxygenated CD_2Cl_2 (0.8 ml) was transferred under nitrogen into a 5-mm NMR tube previously charged with **1** (0.025 g, 0.028 mmol). The addition of 3.3 µl of HBF4·OMe2 dissolved the monohydride **1** within a few minutes to give a solution of **2** which was cooled down to –78°C. After 2.3 µl (0.030 mmol) of 3-butyn-1-ol was syringed into the tube, this was flame-sealed under nitrogen at –78°C and then introduced into the NMR probe of the spectrometer precooled to –50°C. The progress of the reaction was followed by variable-temperature (V.T.) $^{31}P\{^1H\}$- and ^1H-NMR spectroscopy. No reaction occurred until the temperature was raised to about –10°C. At this temperature, the molecular hydrogen complex started converting to the oxycarbene derivative **3.** Within 1 h at –10°C, **3** was the only product detectable by ^{31}P-NMR spectroscopy.

In analogous experiments, (±)-4-pentyn-2-ol or 4-pentyn-1-ol were substituted for 3-butyn-1-ol. Monitoring the reaction by V.T.-NMR spectroscopy showed no intermediate species for the transformation of **2** into **4** or **5**.

In Situ NMR Studies: Reaction of [(triphos)Re(CO)$_2$(η^2-H$_2$)]BF$_4$ (**2**) *with 5-Hexyn-1-ol:* To a dry-ice/acetone cooled solution of **2** (0.050 mmol) in CD_2Cl_2 (0.8 ml), prepared in a 5-mm NMR tube from **1** and $HBF_4 \cdot OMe_2$, was added 6.3 µl (0.055 mmol) of 5-hexyn-1-ol. The tube was flame-sealed and the reaction progress was monitored by V.T.-NMR spectroscopy. A reaction between **2** and the alkynol already occurred at –15°C to give the vinylidene complex [(triphos)Re(CO)$_2${=C=C(H)CH$_2$CH$_2$CH$_2$CH$_2$OH}]BF$_4$ (**7**) as the only new rhenium-containing product. A complete transformation of **2** into **7** was observed after 6 h at –15°C. Heating the NMR tube to room temperature caused the transformation of **7** into the carbene [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH$_2$CH$_2$O}]BF$_4$ (**8**) at ca. –8°C. The formation of **8** was complete after the sample was heated to 20°C for 1 h.

NMR Data for **7**: ^1H NMR (CD_2Cl_2, –16°C, 500.13 MHz): δ = 1.43 (psquint, $J_{H\delta H\gamma} \approx J_{H\delta H\varepsilon}$ = 7.4 Hz, H_δ, 2 H), 1.61 (m, H_ε, 2 H), 1.67 (q, J_{HP} = 3.0 Hz, $CH_{3(triphos)}$, 3 H), 2.38 (psq, $J_{H\gamma H\beta}$ = 8.3 Hz, $J_{H\gamma H\delta}$ = 7.4 Hz, H_γ, 2 H), 2.46 (d, $J_{HPaxial}$ = 9.3 Hz, CH_2P_{axial}, 2 H), 2.54 (m, CH_2P_{equat}, 2 H), 2.73 (m, CH_2P_{equat}, 2 H), 3.53 (tpsq, transforms into a triplet in the $^1H\{^{31}P\}$-NMR spectrum, $J_{H\beta H\gamma}$ = 8.3 Hz, $J_{HPA} \approx J_{HPM}$ = 2.8 Hz, $H_{\beta(vinylidene)}$, 1 H), 3.64 (br t, $J_{H\zeta H\varepsilon}$ = 6.1 Hz, H_ζ, 2 H); the resonance of the OH proton was not observed. – $^{13}C\{^1H\}$ NMR (CD_2Cl_2, –16°C, 50.32 MHz): δ = 343.9 (dt, $J_{CPtrans}$ = 32.1 Hz, J_{CPcis} = 11.6 Hz, C_α), 191.7 (m, CO), 111.0 (dt, $J_{CPtrans}$ = 12.7 Hz, J_{CPcis} = 2.5 Hz, C_β), 52.1 (s, C_ζ), 39.7 (q, J_{CP} = 10.2 Hz, $CH_{3(triphos)}$), 39.2 (br s, $MeC_{(triphos)}$), 36.9 (m, CH_2P_{axial}), 32.4 (m, CH_2P_{equat}), 31.5 (s) and 27.6 (s) (C_δ and C_ε), 19.8 (s, C_γ). – $^{31}P\{^1H\}$ NMR (CD_2Cl_2, –16°C, 81.01 MHz): AM_2 spin system, δ_A = –19.41, δ_M = –15.82, J_{AM} = 23.2 Hz.

NMR Data for **8**: ^1H NMR (CD_2Cl_2, 22°C, 200.13 MHz): δ = 1.41 (m, H_ε, 2 H), 1.66 (q, J_{HP} = 2.9 Hz, $CH_{3(triphos)}$, 3 H), 1.7 (m, partially masked by triphos CH_3 resonance, assigned by 2D-^1H,^1H-COSY NMR experiment, H_γ + H_δ, 4 H), 2.53 (d, $J_{HPaxial}$ = 8.7 Hz, CH_2P_{axial}, 2 H), 3.57 (m, H_β, 2 H), 3.91 (t, $J_{H\zeta H\varepsilon}$ = 4.6 Hz, H_ζ, 2 H). – $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 22°C, 75.42 MHz): δ = 310.8 (dt, $J_{CPtrans}$ = 38.4 Hz, J_{CPcis} = 8.6 Hz, C_α), 198.1 (AXX′Y spin system, J_{AX} = 7.0 Hz, J_{AY} = 5.8 Hz, $J_{AX'}$ = –8.2 Hz, $J_{XX'}$ = 26.8 Hz, CO), 78.6 (d, J_{CP} = 2.9 Hz, C_ζ), 60.1 (d, J_{CP} = 5.2 Hz, C_β), 40.2 (q, J_{CP} = 10.1 Hz, $CH_{3(triphos)}$), 39.7 (q, J_{CP} = 4.1 Hz, $MeC_{(triphos)}$), 35.6 (td, N = $J_{CPequat}$ + $J_{CPequat'}$ = 14.0 Hz, $J_{CPaxial}$ = 4.4 Hz, CH_2P_{equat}), 32.7 (dt, $J_{CPaxial}$ = 22.3 Hz, $J_{CPequat}$ = 4.8 Hz, CH_2P_{axial}), 29.1 (s), 28.2 (s), and 21.5 (s), (C_γ, C_δ and C_ε). – $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 25°C, 81.01 MHz): AM_2 spin system, δ_A = –17.14, δ_M = –11.49, J_{AM} = 20.9 Hz. – $\Lambda_{M(nitroethane)}$ = 80 Ω^{-1} cm^2 mol^{-1}.

Synthesis of [(triphos)Re(CO)$_2${=C=C(H)CH$_2$CH$_2$CH$_2$CH$_2$-OH}]BF$_4$ (**7**): A slight excess of 5-hexyn-1-ol (60 µl, 0.55 mmol) was added to a stirred solution of **2** (0.26 mmol) prepared as described above and maintained at −15°C. The resulting solution was stirred for 15 min, then the solvent was removed under reduced pressure to give a raspberry-colored powder. The solid residue was washed with diethyl ether before being dried under vacuum. NMR spectroscopy showed it to contain **7**, occasionally contaminated by some **8** (usually less than 10%). − $C_{49}H_{49}BF_4O_3P_3Re$: calcd. C 55.88, H 4.69; found C 55.70, H 4.74.

Synthesis of [(triphos)Re(CO)$_2${=CCH$_2$CH$_2$CH$_2$CH$_2$-CH$_2$O}]BF$_4$ (**8**): A solution of **7** obtained by reacting **2** with 5-hexyn-1-ol as described above, was slowly warmed to room temperature with stirring. Within 30 min, the reaction mixture became pale yellow. Evaporation of the solvent under reduced pressure gave **8** as yellow microcrystals. Yield 90%. − $C_{49}H_{49}BF_4O_3P_3Re$: calcd. C 55.88, H 4.69; found C 55.92, H 4.75.

Synthesis of [(triphos)Re(CO)$_2${C≡CCH$_2$CH$_2$CH$_2$CH$_2$OH}] (**9**): To a Schlenk-tube charged with the vinylidene complex **7** (0.19 g, 0.20 mmol) in CH_2Cl_2 (5 ml) at −15°C, a three-fold excess of neat NEt_3 (85 µl, 0.60 mmol) was added with stirring. An immediate reaction took place to give a pale yellow solution. The reaction mixture was stirred for 1 h at room temperature. After the solvent was removed in vacuo, the pale yellow residue was washed with water (2 × 1 ml), ethanol (2 × 1 ml) and diethyl ether (2 × 2 ml) before being dried under vacuum. Yield 80%. − $C_{49}H_{48}O_3P_3Re$: calcd. C 60.98, H 5.02; found C 60.70, H 5.1. − ^{1}H NMR (CD_2Cl_2, 25°C, 200.13 MHz): δ = 1.3 − 1.6 (m, H_δ+ H_γ, 4 H), 1.77 (q, J_{HP} = 3.4 Hz, $CH_{3(triphos)}$, 3 H), 2.3 − 2.7 (m, $CH_{2(triphos)}$ + H_γ, 8 H), 3.60 (t, $J_{H\zeta H\varepsilon}$ = 6.5 Hz, 2 H); the resonance of the OH proton was not observed. − ^{31}P{^{1}H} NMR (CD_2Cl_2, 22°C, 81.01 MHz): AM_2 spin system, δ_A = −6.55, δ_M = −20.30, J_{AM} = 17.2 Hz.

Reaction of **9** *with HBF·OMe$_2$:* A 5-mm NMR tube was charged with a CD_2Cl_2 solution (0.8 ml) of **9** (0.020 g, 0.02 mmol), and cooled to −78°C. Addition of one equiv of HBF4·OMe2 (25 µl, 0.20 mmol) selectively regenerated **7** as shown by ^{31}P{^{1}H}-NMR analysis at −20°C.

X-ray Diffraction Study of [(triphos)Re(CO)$_2${=CCH$_2$-CH$_2$CH(Me)O}]BF$_4$ (**4**): A summary of crystal and intensity data is presented in Table 3. Experimental data were recorded at room temperature (20°C) on an Enraf-Nonius CAD4. A set of 25 carefully centered reflections in the range 6.5° < θ < 8.5° was used for determining the lattice constants. As a general procedure, the intensity of three standard reflections were measured periodically every 200 reflections for orientation and intensity control. This procedure did not reveal an appreciable decay of intensities. The data were corrected for Lorentz and polarization effects. Atomic scattering factors were those tabulated by Cromer and Waber,[32] with anomalous dispersion corrections taken from ref.[33]. An empirical absorptions correction was applied by using the program XABS2[34] with transmission factors in the range 0.631−1.425. The computational work was carried out by intensively using the program SHELX93.[35] Final atomic co-ordinates of all atoms and structure factors are available on request from the authors and are provided as supplementary material.

Pale orange crystals of **4** were grown in air from a dilute dichloromethane/ethanol solution. A parallelepiped crystal with dimension 0.25 × 0.20 × 0.11 mm was used for the data collection. The structure was solved by direct methods using the SIR92 program.[36] Refinement was done by full-matrix least-squares calculations, initially with isotropic thermal parameters then with anisotropic thermal parameters for Re, P, and C atoms of the triphos skeleton. The phenyl rings were treated as rigid bodies with D_{6h} symmetry, and the hydrogen atoms were allowed to ride on the attached carbon atoms. Crystallographic disorder was detected in the region of the tetrafluoroborate anion resulting in a double image of the four fluorine atoms. The two sets of fluorines were assigned a population factor of 0.6 and 0.4 respectively.

Table 3. Summary of crystal data and structure refinement for **4-BF$_4$**

Formula	$C_{48}H_{47}BF_4O_3P_3Re$		
Formula weight	1038.23	Crystal size [mm]	0.20×0.15×0.25
Crystal System	monoclinic	Space group	*P* 21/*n* (No. 14)
a [Å]	10.689(2)	*α* [deg]	90
b [Å]	17.921(4)	*β* [deg]	94.54(2)
c [Å]	23.175(5)	*γ* [deg]	90
V [Å^3]	4425(2)	*Z*	4
ρ(calcd) [gcm^{-3}]	1.558	Abs. coeff. [mm^{-1}]	2.912
F(000)	2080		
θ range [deg]	2.74−22.47		
Index ranges		$-11 \le h \le 11$, $0 \le k \le 19$, $0 \le l \le 24$	
Reflections collected		5763	
Independent reflections		5763 [*R*(int) = 0.0000]	
Refinement method		Full-matrix least squares on F^2	
Data/constraints/parameters		5763/0/234	
Goodness-of-fit on F^2		1.016	
Final *R* indices [$I > 2\sigma(I)$]		*R*1 = 0.0611; *wR*2 = 0.1226	
R indices (all data)		*R*1 = 0.1577; *wR*2 = 0.1564	
Largest difference peak [eÅ^3]		0.861 and −0.796	

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (deposition number 100775). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax (internat): +44(0)123/336-033, e-mail: deposit@chemcrys.cam.ac.uk].

Keywords: Polysilanes / Polysilyl anions / Silylpotassium / Silicon

A method is presented for the synthesis of tertiary, secondary, and primary polysilylpotassium compounds. Reaction of potassium *tert*-butoxide, in either DME or THF, with a suitable precursor molecule, proceeds by cleavage of a trimethylsilyl–polysilanyl bond, and formation of trimethylsilyl *tert*-butyl ether and a polysilanylpotassium compound. This route allows easy and flexible access to a number of novel polysilanylpotassium compounds, avoiding the hitherto common use of poisonous mercury compounds.

As is known from the pioneering work of Gilman and coworkers tetrakis(trimethylsilyl)silane can react with methyllithium to form tetramethylsilane and tris(trimethylsilyl)-silyllithium.[2]

$$(Me_3Si)_4Si + MeLi \rightarrow (Me_3Si)Me + \underset{\mathbf{1}}{(Me_3Si)_3SiLi} \quad (1)$$

The latter compound has been rapidly accepted as a prototype of a bulky nucleophilic polysilyl anion and, only recently, has been referred to as "hypersilyl" group.[3] It has been used for the synthesis of transition metal silyl compounds,[4] for the generation of silenes by means of sila-Peterson reaction,[5] and for a number of other purposes.[6] However, it is noticeable that this reagent, although so widely accepted, has rarely been the subject of variation. Only very recently have Klinkhammer[7] and Oehme[8] reported on the synthesis of the potassium and magnesium analogs, however the isotetrasilanyl moiety has almost never been varied. Nevertheless, Apeloig et al. have recently shown that variation of this moiety can be of some advantage. They have been able to show that an increase in the size of ligand gives rise to the formation of stable silenes.[9][5g]

Although it would be interesting to have a set of bulky polysilyl groups differing in reactivity and, especially, in size,[10] in order to achieve different degrees of steric hindrance, this problem has not so far been systematically addressed. The reason for this becomes obvious if one looks at a fact that was first pointed out by Gilman,[11] and then recently studied in more detail by Apeloig et al.,[12] namely that if polysilanes with "inner" Si–Si bonds react with methyllithium there is a pronounced tendency for these "inner" Si–Si bonds to undergo scission. This means that, for example, hexakis(trimethylsilyl)disilane yields **1** and tris(trimethylsilyl)methylsilane in the reaction with methyllithium (Eq. 2).

$$(Me_3Si)_6Si_2 + MeLi \rightarrow \underset{\mathbf{1}}{(Me_3Si)_3SiLi} + MeSi(SiMe_3)_3 \quad (2)$$

The results described in this paper show that this is not a primary limitation, and that it can be easily overcome by the correct choice of the transmetalating agent.

Results and Discussion

Our studies on the synthesis of dendritic and branched polysilanes[13] led to the investigation of some aspects of the chemistry of polysilyl anions. In reactions directed towards the formation of polysilanes with monosilyl anions and silyl halides we often found that the use of the potassium compound was superior to the use of lithium anions. So it was reasonable to also address the use of lithium vs. potassium in the case of the "hypersilyl" anion. Although this compound was already known from the work of Klinkhammer,[7] transmetalation from the corresponding bis-"hypersilyl" mercury, zinc, or cadmium compounds with potassium did not seem to be a real alternative to the use of the readily available "hypersilyllithium" **1**.[2] We felt that a really competitive synthesis must introduce the potassium in as easy a fashion as the lithium. So the obvious reagent of choice was potassium *tert*-butylate, which very effectively transforms dodecamethylcyclohexasilane into the corresponding undecamethylcyclohexasilanylpotassium.[14]

Indeed initial experiments showed that the conversion of tetrakis(trimethylsilyl)silane with *tert*-butylate in DME or THF, in a clean and almost quantitative reaction, gives "hypersilylpotassium" **1a** accompanied by the formation of trimethylsilyl *tert*-butyl ether (Eq. 3).

$$(Me_3Si)_4Si + KO\mathit{t}Bu \rightarrow \underset{\mathbf{1a}}{(Me_3Si)_3SiK} + (Me_3Si)O\mathit{t}Bu \quad (3)$$

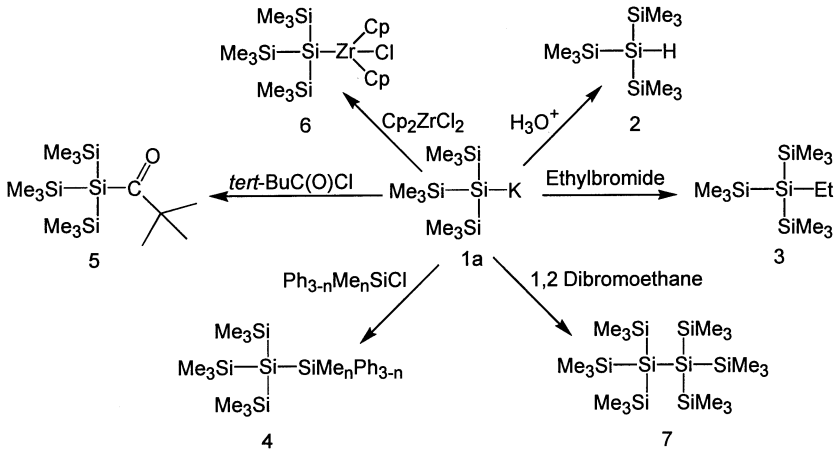
Changing the solvent to toluene or pentane gives **1a** as a crystalline compound, with one or two molecules of the

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0202–0221 $ 17.50+.50/0

etheral solvent still present, as can be seen from ^{1}H- and ^{13}C-NMR data. This synthesis of **1a** can be regarded as a significant improvement, avoiding the use of poisonous heavy metal compounds which are in turn prepared from **1** or tris(trimethylsilyl)silane.[7] It is an interesting alternative to use **1a** instead of **1** because the reactivities are comparable, the potassium compound being slightly more reactive. We found that the stoichiometry of the potassium reaction is easier to control dealing with potassium *tert*-butylate, which is a weightable solid, compared to methyllithium solutions which may have more or less well defined concentrations.

Treatment of **1a** with a variety of electrophiles proceeded as smoothly as expected (Scheme 1). Reaction with aqueous sulfuric acid gives the hydrosilane **2**, reaction with ethyl bromide yielded the ethylated product **3**, and silylation with a number of phenylated silyl chlorides was easily achieved (**4a,b,c**). Syntheses of an acylsilane (**5**),[15] and of the known zirconocene hypersilyl chloride (**6**),[16] can be achieved in a straightforward manner. The reaction of **1a** with 1,2-dibromoethane at −78°C proceeds in an analogous manner to that of the corresponding lithium compound **1**, and yields the dimerisation product **7**.

Scheme 1



4a can be converted quantitatively to the corresponding bromosilane **8** by a protodesilylation reaction in neat hydrogen bromide at −78°C. The reaction of **8** with another equivalent of **1a** gives bis-"hypersilyl"-dimethylsilane **9** (Eq. 4). The latter compound was found first by Sakurai et al. as one of the products in the aluminum trichloride catalyzed isomerisation of linear permethylnonasilane,[17] and was recently synthesized by Apeloig et al.[12][18]

$$\underset{\mathbf{4a}}{(Me_3Si)_3SiSiMe_2Ph} + HBr \rightarrow \underset{\mathbf{8}}{(Me_3Si)_3SiSiMe_2Br} \rightarrow \underset{\mathbf{9}}{[(Me_3Si)_3Si]_2SiMe_2} \quad (4)$$

Compounds **7** and **9** were chosen to test the reaction with potassium *tert*-butylate for its ability to differentiate between "inner" and "outer" Si−Si bonds. From Gilmans work it is known that the reaction of **7** with methyllithium leads to the formation of **1** and tris(trimethylsilyl)methylsilane.[11] Similarly Apeloig et al. also found, in the reaction of **9** with methyllithium, exclusive cleavage of one of the "inner" Si−Si bonds.[12]

In contrast to these findings the reaction to give the potassium polysilanyl, using potassium *tert*-butylate, exhibits the opposite selectivity, splitting exclusively one of the "outer" Si−$SiMe_3$ bonds (**10**, **11**).

$$RSi(SiMe_3)_3 + KO\mathit{t}Bu \rightarrow RSi(SiMe_3)_2K + (Me_3Si)O\mathit{t}Bu \quad (5)$$

R = $(Me_3Si)_3Si$ **7** **10**
R = $(Me_3Si)_3SiSiMe_2$ **9** **11**

These results open the door for the synthesis of higher polysilyl anions. Both of the anions **10** and **11** are already known as lithium analogs. The lithium analog of **10** was observed by Gilman in the reaction of **7** with **1**.[11] The lithium derivative of **11** was found by Apeloig et al. in a reaction that they describe as the addition of methyllithium to a disilene.[12]

The polysilyl anions **10** and **11** are candidates for experiments in which the polysilyl moiety is required to be of increased size compared to the "hypersilyl" unit in order to fulfill its stabilizing function. It also should be mentioned that in both cases we attempted to obtain the dianionic species by the addition of another equivalent of potassium *tert*-butylate, but failed under normal reaction conditions. However, experiments to obtain such compounds are still in progress in our laboratory. The results reported so far have demonstrated that the potassium polysilanyls are serious competitors to their lithium analogs when higher polysilyl anions are required. The following section will show that this chemistry is also able to yield smaller polysilyl anions.

When ethylated **3** was subjected to standard treatment with potassium *tert*-butylate the reaction proceeded as expected and secondary potassium trisilane **12** was formed.

$$\underset{\mathbf{3}}{(Me_3Si)_3SiEt} + KO\mathit{t}Bu \rightarrow \underset{\mathbf{12}}{(Me_3Si)_2Si(Et)K} + (Me_3Si)O\mathit{t}Bu \quad (6)$$

As **12** can as easily be treated with electrophiles, as was demonstrated for **1a**, the sequence: tetrakis(trimethylsilyl)si-

lane → $(Me_3Si)_3SiK$ (**1a**) → $(Me_3Si)_3SiE$ (**3**) → $(Me_3Si)_2Si(E)K$ (**12**) → $(Me_3Si)_2Si(E)E'$ offers an interesting method of access to 2,2′-disubstituted trisilanes.[19]

Even more interesting, but unfortunately less selective, is the conversion of **2**. Under analogous conditions a secondary potassium trisilane **13** was formed with hydrogen and potassium attached to the same silicon atom. The reaction is accompanied by the formation of **1a**, which seems to be the result of a deprotonation reaction. The ratio of these two products is about 7:3 in favor of **13**.

$$\underset{\mathbf{2}}{(Me_3Si)_3SiH} + KO\mathit{t}Bu \rightarrow 0.7\ \underset{\mathbf{13}}{(Me_3Si)_2Si(H)K} + 0.3\ \underset{\mathbf{1a}}{(Me_3Si)_3SiK} + 0.7\ (Me_3Si)O\mathit{t}Bu + 0.3\ HO\mathit{t}Bu \quad (7)$$

While it has been shown so far that tertiary and secondary potassium silanyls are easily available from the reaction of suitable precursors with potassium *tert*-butylate, and it is also known that monosilyl potassium compounds are accessible from disilanes by reaction with C_8K,[20] primary potassium silanyls are not so easy to obtain.

The reaction of octamethyltrisilane with potassium *tert*-butylate in DME shows some rather complex chemistry, which we are currently studying in more detail, but which does not provide a suitable route to pentamethyldisilanylpotassium. Since 1,1-diphenyltrimethyldisilanyl alkali compounds are known to form from the reaction of 2,2-diphenylhexamethyltrisilane with methyllithium or sodium potassium alloy,[21] it was decided to test our reaction conditions on 2-phenylheptamethyltrisilane. However addition of one equivalent of potassium *tert*-butylate to the latter gave not only the desired disilanylpotassium compound **14**, but also a substantial amount of trimethylsilylpotassium, which was detected by ^{29}Si NMR. Changing the solvent to THF slowed down the reaction rate and did improve the ratio, but only slightly. It was finally found that optimum reaction conditions could be achieved by gradual addition of potassium *tert*-butylate to a THF solution of the starting material.

Analysis of ^{29}Si-NMR data from the experiments described and from the literature (see Table 1) shows some interesting details. Comparison of the shift values of the silicon atom with a trimethylsilyl substituent and the analog bearing a negative charge shows a high field shift of about 60 ppm, for tertiary alkali silanyls (entries 1−3), and of 33 ppm for the generation of a secondary potassium silanyl compound with one alkyl group (entry 4). Interestingly the substitution of a trimethylsilyl group by hydrogen (cf. entry 5) also gives a $\Delta\delta_{Si}$ value similar to the tertiary alkali silanyl (entry 1). Comparison of the known ^{29}Si-NMR value of H_3SiK (entry 10) with that of the respective trimethylsilylated compound shows that even a trihydrogenated silicon atom shifts some 60 ppm to higher field when the trimethylsilyl substituent is replaced by potassium.

While the change from secondary alkali silanyls to primary ones (entry 4 vs. 6) is not so pronounced, the influence of a phenyl group on the silicon atom bearing the negative charge is indicative, as can be seen by comparison of entries 6 and 7. In the case of the permethylated molecule (entry 6) a 26 ppm higher field shift is observed, while the molecule with one phenyl group shows only a 16 ppm shift. Obviously some of the negative charge can be transferred onto the phenyl group, resulting in a weaker deshielding effect. A very similar case is that of the monosilyl alkali compounds. While trimethylsilylpotassium shows an even weaker shift (only 14 ppm) compared to hexamethyldisilane (entry 8), dimethylphenylsilyllithium (entry 9) shows the weakest shift in the entire series (about 6 ppm) compared to the trimethylsilylated compound.

Table 1. Comparison of ^{29}Si-NMR shift values of polysilyl alkali compounds with the respective trimethylsilylated molecules

Entry	Oligosilane	$\delta_{Si-SiMe_3}$	Alkali silanyl	δ_{Si-M}	$\Delta\delta_{Si}$
1	$(Me_3Si)_4Si$[a]	−135.6	$(Me_3Si)_3SiK$[a]	−195.8	60.2
2	$(Me_3Si)_3SiSi(SiMe_3)_3$[a]	−129.5	$(Me_3Si)_3SiSi(SiMe_3)_2K$[a]	−192.7	63.2
3	$(Me_3Si)_3SiSiMe_2Si(SiMe_3)_3$[a]	−117.8	$(Me_3Si)_3SiSiMe_2Si(SiMe_3)_2K$[a]	−187.0	69.2
4	$(Me_3Si)_3SiEt$[a]	−78.6	$(Me_3Si)_2EtSiK$[a]	−111.7	33.1
5	$(Me_3Si)_3SiH$[a]	−115.4	$(Me_3Si)_2HSiK$[a]	−181.1	65.7
6	$Me_3SiSiMe_2SiMe_3$[b]	−48.7	$Me_3SiSiMe_2Li$[c]	−74.9	26.2
7	$Me_3SiSiMePhSiMe_3$[d]	−46.0	$Me_3SiSiMePhK$[d]	−62.9	16.9
8	$Me_3SiSiMe_3$[b]	−20.5	Me_3SiK[e]	−34.4	13.9
9	$PhMe_2SiSiMe_3$[b]	−21.7	$PhMe_2SiLi$[b]	−27.3	5.6
10	Me_3SiSiH_3[f]	−97.7	H_3SiK[b]	−165.0	67.3

[a] Measured in DME. − [b] Value taken from ref.[26]. − [c] Value taken from ref.[27]. − [d] measured in THF. − [e] Value taken from ref.[22]. − [f] A sample of Me_3SiSiH_3 was kindly provided by Dr. Robert Zink.

From the comparison of these data it is evident that the silicon atom bearing the negative charge can gain a release of charge which depends on the kind of substituents attached. While hydrogen and silyl groups, in accordance with their respective electropositive characters, do not take a great deal of the charge, charge can be transferred to methyl and, to an even greater extent, to phenyl groups,[22] which in turn leads to smaller values of $\Delta\delta_{Si}$.

One should mention here that analysis of these NMR data has to be undertaken with some caution with respect to the solvents used in the measurement. While the shifts of the uncharged compounds are relatively independent of solvent effects the silyl potassium compounds show a rather pronounced dependence on the solvent. Compared to the reported ^{29}Si-NMR data of $\delta = -185$ for **1a** in deuterobenzene, we found that a complexing solvent such as DME causes an additional upfield shift of 11 ppm, indicating a less covalent character for the Si−K bond. Formation of **1a** in THF results in a signal at −194 ppm. Subsequent crystallization from pentane shows the presence of two molecules of THF in the ^{1}H-NMR spectrum, and a value of $\delta = -189.5$ in the ^{29}Si-NMR spectrum. So we can observe, for one compound, a difference in the shift value of some 10 ppm depending on the solvent. However, it was considered that, as the data compared in Table 1 always refer to compounds in etheral solvents, this comparison was valid. Also the tendencies discussed are so pronounced that the solvent effects are relatively small.

The author wants to express his gratitude to the late Prof. *Hengge* for his encouragement and support, and for stimulating discussions. The *Wacker AG*, Burghausen, kindly provided chlorosilanes as starting materials. CHM is the recipient of an APART (Austrian Program for Advanced Research and Technology) scholarship of the *Austrian Academy of Science*, Vienna which is gratefully acknowledged.

Experimental Section

All reactions were carried out in flame-dried glassware under an inert atmosphere of dry argon or nitrogen. Solvents were distilled prior to use from either sodium or sodium potassium alloy. Starting materials tetrakis(trimethylsilyl)silane[23] and 2-phenylheptamethyltrisilane[24] were prepared according to literature procedures. $PhMe_2SiCl$, $Ph_2MeSiCl$, Ph_3SiCl, potassium *tert*-butylate, 1,2-dibromoethane, and ethyl bromide were used without further purification.

^1H-, ^{13}C-, and ^{29}Si-NMR spectra were recorded on a Bruker MSL 300 at the indicated frequencies. ^{29}Si-NMR spectra were measured either in C_6D_6 or directly from the reaction mixture using a D_2O capillary providing an external lock signal. In all cases, except for **2** and **13**, the INEPT pulse sequence was employed. − GC/MS was performed on an HP 5890/II gas chromatgraph with an HP 5971/A MSD, an HP1 (Cross-linked methyl silicone) column and helium as a carrier gas. − Elemental analyses of the branched polysilanes were done using a Heraeus elementar vario EL apparatus. For some reason the carbon values found in the elemental analyses are too low when certain compounds were analyzed with quarternary silicon atoms. While the hydrogen values correspond nicely to the calculated numbers we attribute the low carbon values to the formation of silicon carbide, which seems to be very favorable in the cases of the compounds mentioned.

General Procedure: Starting material and one equivalent of potassium *tert*-butylate were mixed together in a flask and either DME or THF added. Almost immediately the solution turned yellow and, after some time, sometimes orange. Completion of the reaction was detected either by ^{29}Si-NMR spectroscopy (D_2O capillary as external lock) and/or by obtaining a derivative and subsequent GC/MS or GC analysis. The derivative was obtained by adding a 20-µl sample of the reaction mixture into a solution of 100 µl of ethyl bromide in 2 ml of ether, or by addition of the sample into the etheral phase of a 2 ml ether/2 ml 2 M H_2SO_4 mixture followed by mixing of the layers.

Tris(trimethylsilyl)silylpotassium (**1a**): In a typical experiment tetrakis(trimethylsilyl)silane (3.10 g, 9.66 mmol) was treated with *tert*-BuOK (1.14 g, 10.14 mmol) in 5 ml of either DME or THF following the general procedure. While the conversion in DME was usually complete within 10 min the use of THF sometimes required reaction times up to 60 min. − ^{29}Si NMR (59.6 MHz, DME, D_2O lock): δ = −3.93, −195.83, (59.6 MHz, THF, D_2O lock): δ = −4.55, −194.10.

A sample of **1a** prepared in THF on the same scale as described above, which was isolated by removal of solvent in vacuo and crystallization from toluene and pentane (3.20 g, 7.71 mmol, 80%), was identified by ^1H NMR and ^{13}C NMR as a complex containing two molecules of THF. − ^1H NMR (300 MHz, C_6D_6): δ = 3.42 (m, 8 H), 1.47 (m, 8 H), 0.47 (s, 27 H). − ^{13}C NMR (75.4 MHz, C_6D_6): δ = 68.33, 25.93, 7.67. − ^{29}Si NMR (59.6 MHz, C_6D_6): δ = −5.35, −189.56.

Tris(trimethylsilyl)silane (**2**): **1a** was generated in THF from tetrakis(trimethylsilyl)silane (1.00 g, 3.11 mmol) following the general procedure. After complete conversion the solution of **1a** in THF was slowly poured into a mixture of ethyl ether (30 ml), aqueous H_2SO_4 (1 M solution, 50 ml), and ice. The organic layer was dried over Na_2SO_4 and evaporated in vacuo. The remaining oil (720 mg, 2.90 mmol, 93%) was pure by GC/MS. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ −10.92, −115.36 (d, J = 156 Hz). − MS (70 eV): *m/z* (%): 248 (33) [M^+], 233 (27) [M^+ − Me], 174 (82) [M^+ − $HSiMe_3$], 160 (100) [M^+ − $SiMe_4$], 159 (88) [MH − $SiMe_4$], 73 (80) [$SiMe_3$]. − IR, ^1H and ^{13}C NMR data in accordance to the literature.[25]

Tris(trimethylsilyl)ethylsilane (**3**): Compund **3** was prepared from tetrakis(trimethylsilyl)silane (2.00 g, 6.22 mmol) by essentially the same method as for **2** with the difference that the solution of **1a** was poured into a mixture of ethyl ether (30 ml) and ethyl bromide (5 ml). After complete addition the solution was stirred for 5 min at room temp. and aqueous H_2SO_4 (1 M solution, 50 ml) was added. The workup was the same as for **2**. The remaining white solid (1.43 g, 5.17 mmol, 83%) was found, using GC/MS and NMR, to be pure. An analytical sample was recrystallized from ethanol (mp: 136−138°C). − ^1H NMR (300 MHz, $CDCl_3$): δ = 1.10 (t, J = 8.0 Hz, 3 H), 0.82 (q, J = 7.9 Hz, 2 H), 0.17 (s, 27 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 13.11, 1.39, 0.00. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ −12.35, −78.81. − MS (70 eV): *m/z* (%): 276 (20) [M^+], 261 (4) [M^+ − Me], 203 (19) [M^+ − $SiMe_3$], 188 (30) [M^+ − $SiMe_4$], 175 (27) [M^+ − $EtSiMe_3$], 73 (100) [$SiMe_3$]. − $C_{11}H_{32}Si_4$ (276.72) calcd. C 47.75, H 11.66; found C 47.46, H 11.71.

1,1,1-Tris(trimethylsilyl)dimethylphenyldisilane (**4a**): **1a** was prepared from tetrakis(trimethylsilyl)silane (3.10 g, 9.66 mmol) and *tert*-BuOK (1.14 g, 10.1 mmol) in THF by the general procedure. After complete reaction the solvent was removed in vacuo and toluene (15 ml) was added. The mixture was cooled to −78°C and chlorodimethylphenylsilane (1.81 g, 10.6 mmol) was added in toluene (10 ml) gradually over 5 min. The reaction was stirred for further 12 h at room temp.. The workup was done by the addition of aqueous H_2SO_4 (1 M solution, 20 ml), extraction of the aqueous phase with two portions of ether, and drying of the combined organic phases over Na_2SO_4. After removal of the solvent by evaporation the white residue was crystallized from ethanol to give **4a** (3.00 g, 7.83 mmol, 81%) as white crystals (mp: 156−157°C). − ^1H NMR (300 MHz, $CDCl_3$): δ = 7.56 (m, 2 H), 7.36 (m, 3 H), 0.54 (s, 6 H), 0.18 (s, 27 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 141.46, 134.32, 128.68, 127.86, 3.02, 1.42. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −8.92, −12.48, −133.23. − MS (70 eV): *m/z* (%): 382 (14) [M^+], 367 (7) [M^+ − Me], 294 (4) [M^+ − $SiMe_4$], 232 (93) [$Me_2Si_2(SiMe_3)_2$], 135 (79) [$SiMe_2Ph$], 73 (100) [$SiMe_3$]. − $C_{17}H_{38}Si_5$ (382.92) calcd. C 53.32, H 10.00; found C, 53.04 H 9.93.

1,1,1-Tris(trimethylsilyl)methyldiphenyldisilane (**4b**): **4b** was prepared following the procedure for the synthesis of **4a**, and on the same scale, using methyldiphenylchlorosilane (2.47 g, 10.6 mmol) as an electrophile. White crystals of **4b** (3.06 g, 6.88 mmol, 71%) were isolated after crystallization from ethanol (mp: 161−164°C). − ^1H NMR (300 MHz, $CDCl_3$): δ = 7.56 (m, 4 H), 7.33 (m, 6 H), 0.79 (s, 3 H), 0.14 (s, 27 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 138.90, 135.41, 128.97, 127.86, 3.10, 0.58. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −8.95, −11.95, −132.84. − MS (70 eV): *m/z* (%): 444 (4) [M^+], 429 (2) [M^+ − Me], 294 (4) [M^+ − $PhSiMe_3$], 232 (100) [$Me_2Si_2(SiMe_3)_2$], 197 (75) [$SiMePh_2$], 135 (34) [$SiMe_2Ph$], 73 (47) [$SiMe_3$]. − $C_{22}H_{40}Si_5$ (444.99) calcd. C 59.38, H 9.09; found C 59.32, H 9.01.

1,1,1-Tris(trimethylsilyl)triphenyldisilane (**4c**): **4c** was prepared following the procedure for the synthesis of **4a**, and on the same

scale, using triphenylchlorosilane (3.13 g, 10.5 mmol) as an electrophile. White crystals of **4c** (3.74 g, 7.37 mmol, 76%) were yielded after crystallization from ethanol (mp: 263−266°C). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.52 (m, 6 H), 7.37 (m, 9 H), 0.18 (s, 27 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 137.71, 136.71, 129.26, 127.99, 3.19. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −9.17, −10.22, −130.84. − MS (70 eV): *m/z* (%): 297 (1) [M^+ − $SiPhMe_2$ − $HSiMe_3$], 282 (8) [M^+ − $SiPhMe_2$ − $SiMe_4$], 259 (93) [$SiPh_3$)], 232 (100) [$Me_2Si_2(SiMe_3)_2$], 135 (28) [$SiMe_2Ph$], 73 (47) [$SiMe_3$]. − $C_{27}H_{42}Si_5$ (507.06) calcd. C 63.96, H 8.35; found C 63.81, H 8.39.

Tris(trimethylsilyl)silylpivaloate (**5**): **1a** was generated following the general procedure from tetrakis(trimethylsilyl)silane (3.00 g, 9.35 mmol) in THF. After removal of the solvent toluene (10 ml) was added and the solution was added slowly to an ice cold solution of pivaloyl chloride (1.16 g, 9.63 mmol) in toluene (10 ml). After complete conversion, which was checked by GC/MS, the reaction mixture was poured into an ice/sulfuric acid mixture (10%). The aqueous layer was extracted with ether (2 × 20 ml) and the combined organic layer dried over Na_2SO_4. After removal of the solvent final purification was achieved by chromatography on silica with toluene/heptane, 10:1. Spectral data of the compound (2.17 g, 6.52 mmol, 70%) were in accordance with the literature.[15]

Tris(trimethylsilyl)silylchlorozirconocene (**6**): **1a** was generated following the general procedure from tetrakis(trimethylsilyl)silane (2.00 g, 6.23 mmol) in DME. After complete conversion the solution was added, using a syringe pump, over a period of 40 min to a suspension of Cp_2ZrCl_2 (1.82 g, 6.22 mmol) in pentane (10 ml). Complete conversion was detected by ^{29}Si NMR after another 60 min stirring at room temp. Crystallization was achieved by removal of the solvent, addition of 20 ml of pentane and storage at −75°C. Extremely air-sensitive red crystals (3.12 g, 5.78 mmol, 93%) were obtained. − Spectral data in accordance to literature values.[16]

Hexakis(trimethylsilyl)disilane (**7**): **1a** was generated following the general procedure from tetrakis(trimethylsilyl)silane (5.00 g, 15.6 mmol) in THF. After complete conversion the solution was cooled to −78°C and 1,2-dibromoethane (1.63 g, 8.67 mmol) in ethyl ether (30 ml) was added dropwise over a period of 30 min. The solution then was allowed to come to room temp. and was poured into an ice/aqueous H_2SO_4 mixture. The organic layer was dried over Na_2SO_4 and the solvent removed in vacuo. The remaining white crystals (3.80 g) were shown by ^{29}Si NMR to be 90% pure **7**, with tetrakis(trimethylsilyl)silane being the only impurity. Sublimation (120°C, 1 mbar) removed about 300 mg of tetrakis(trimethylsilyl)silane. Finally pure **7** was obtained by recrystallization from acetone and ethanol which gave **7** (3.16 g 6.38 mmol, 82%) as white crystals. − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.20 (s). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 4.60. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −9.04, −129.49. − MS (70 eV): *m/z* (%): 406 (0.2) [M^+ − $SiMe_4$], 247 (6) [M^+ − $Si(SiMe_3)_3$], 232 (29) [M^+ − $MeSi(SiMe_3)_3$], 73 (100) [$SiMe_3$].

1,1,1-Tris(trimethylsilyl)dimethylbromodisilane (**8**): A flask equipped with a reflux condenser cooled to −80°C and charged with a sample of **4a** (2.40 g, 6.27 mmol) was cooled to −80°C and approx. 10 ml of hydrogen bromide was condensed on under a pressure of 200−500 mbar. After 30 min the cooling bath was removed and the solution of **4a** in hydrogen bromide was refluxed for 90 min. Then hydrogen bromide was removed in vacuo and pentane was distilled onto the residue (10 ml). The solution was filtered over a plug of glass wool and the solvent of the filtrate was removed in vacuo. The remaining white powder of **8** (2.40 g, 6.22 mmol, 99%) was pure by GC and NMR. − ^{1}H NMR (300 MHz, C_6D_6): δ = 0.71 (s, 6 H), 0.26 (s, 27 H). − ^{13}C NMR (75.4 MHz, C_6D_6): δ = 8.08, 2.90. − ^{29}Si NMR (59.6 MHz, C_6D_6): δ = 25.81, −9.61, −127.92; MS (70 eV): *m/z* (%): 369/371 (4/5) [M^+ − Me], 311/313 (1/2) [M^+ − $SiMe_3$], 232 (45) [M^+ − $BrSiMe_3$], 73 (100) [$SiMe_3$]. − $C_{11}H_{33}BrSi_5$ (385.71) calcd. C 34.25, H 8.62; found C 33.97, H 8.57.

1,1,1,3,3,3-Hexakis(trimethylsilyl)dimethyltrisilane (**9**): A solution of **1a** [prepared from tetrakis(trimethylsilyl)silane (1.66 g, 5.17 mmol) in DME] in toluene (5 ml) was added slowly at −50°C to a solution of **8** (1.81 g, 4.70 mmol) in toluene (5 ml). The reaction was allowed to reach room temp. and was followed by ^{29}Si NMR. After complete conversion a workup was performed by the addition of aqueous H_2SO_4 (1 M solution, 20 ml), extraction of the aqueous layer with two portions of ether, and drying of the combined organic layers over Na_2SO_4. Solvent was removed in vacuo and the residue was subjected to Kugelrohr distillation (1 mbar, 250°C) to remove volatile components. Finally crystallization of the remaining solid was achieved from ethanol/ethyl acetate to yield **9** (1.62 g, 2.92 mmol, 62%) as white crystals (mp: 168−171; ref.[17] 170−172°C). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.50 (s, 6 H), 0.23 (s, 54 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 5.81, 4.10. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −8.64, −25.19, −117.70. − MS (70 eV): *m/z* (%): 537 (1) [M^+ − Me], 305 (97) [M^+ − $Si(SiMe_3)_3$], 232 (100) [$Me_2Si_2(SiMe_3)_2$], 73 (95) [$SiMe_3$]. − $C_{20}H_{60}Si_9$ (553.47) calcd. C 43.40, H 10.93; found C 41.94, H 10.92.

Pentakis(trimethylsilyl)disilanylpotassium (**10**): Compound **10** was prepared from **7** (200 mg, 0.40 mmol) and *tert*-BuOK (44 mg, 0.40mmol) in DME following the general procedure. The only product after complete consumption of **7**, as detected by NMR and GC/MS of derivatives of the samples, was **10**. − ^{29}Si NMR (59.6 MHz, DME, D_2O lock): δ = −5.58, −10.68, −128.92, −192.62. − H_3O^+ quench: ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.81 (s, 1 H), 0.33 (s, 18 H), 0.32 (s, 27 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 3.74, 3.54. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −11.84, −13.38, −118.02, −135.04. − MS (70 eV): *m/z* (%): 407 (3) [M^+ − Me], 348 (18) [M^+ − $HSiMe_3$], 333 (2) [M^+ − $HSiMe_4$], 259 (4) [M^+ − $H_2Si_2Me_7$], 73 (100) [$SiMe_3$]. − Ethyl bromide quench: ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.13 (t, *J* = 7.0 Hz, 3 H), 0.97 (q, *J* = 7.0 Hz, 2 H), 0.26 (s, 27 H), 0.24 (s, 18 H). − ^{13}C NMR (75.4 MHz, $CDCl_3$): δ = 13.52, 5.11, 4.18, 3.01. − ^{29}Si NMR (59.6 MHz, pentane, D_2O lock): δ = −8.94, −11.73, −68.92, −130.43. − MS (70 eV): *m/z* (%): 377 (6) [M^+ − $SiMe_3$], 275 (4), [M^+ − 2 $SiMe_3$, − Et], 232 (26) [$Me_2Si_2(SiMe_3)_2$], 73 (100) [$SiMe_3$]. The experiment was repeated in THF with essentially the same results. Removal of solvent and crystallization from pentane gave white crystals solvated with two molecules of THF in an almost quantitative yield (220 mg, 0.37 mmol, 93%). − ^{1}H NMR (300 MHz, C_6D_6): δ = 3.41 (m, 8 H), 1.46 (m, 8 H), 0.51 (s, 18 H), 0.46 (s, 27 H). − ^{13}C NMR (75.4 MHz, C_6D_6): δ = 68.28, 25.94, 8.82, 4.78.

1,1,3,3,3-Pentakis(trimethylsilyl)-2,2-dimethyltrisilanylpotassium (**11**): Compound **11** was prepared from **9** (95 mg, 0.17 mmol) and *tert*-BuOK (19 mg, 0.17 mmol) in DME following the general procedure. The reaction was followed directly by ^{29}Si NMR and GC/MS of the quenched samples. Conversion was complete after 60 min. Addition of another equivalent of *tert*-BuOK (19 mg, 0.17 mmol) did not result in a second splitting reaction but led to the slow decomposition of the product after two days. − ^{29}Si NMR (59.6 MHz, DME, D_2O lock): δ = −3.21, −8.80, −16.12, −127.09, −186.99. − H_3O^+ quench: MS (70 eV): *m/z* (%): 480 (0.1) [M^+], 406 (3) [M^+ − $HSiMe_3$], 305 (63) [M^+ − $HSi(SiMe_3)_3$], 231 (25) [$Me_2Si_2(SiMe_3)_2$ − H], 73 (100) [$SiMe_3$]. − Ethyl bromide quench:

MS (70 eV): *m/z* (%): 493 (0.2) [M^+ − Me], 305 [M^+ − EtSi(SiMe$_3$)$_2$], 232 (30) [$Me_2Si_2(SiMe_3)_2$], 188 (24) [EtSi(SiMe$_3$) − Me], 73 (100) [SiMe$_3$)].

Bis(trimethylsilyl)ethylsilylpotassium (**12**): Compound **12** was prepared from **3** (89 mg, 0.36 mmol) and *tert*-BuOK (40 mg, 0.36 mmol) in DME following the general procedure. The reaction was followed directly by ^{29}Si NMR and GC/MS of the quenched samples. It was found to be complete after 25 min. − ^{29}Si NMR (59.6 MHz, DME, D_2O lock): δ = −6.82, −111.68. − H_3O^+ quench: MS (70 eV): *m/z* (%): 204 (14) [M^+], 189 (7) [M^+ − Me], 161 (8) [M^+ − SiMe$_3$], 130 (29) [M^+ − HSiMe$_3$], 102 (65) [M^+ − EtSiMe$_3$)], 73 (100) [SiMe$_3$]. − Ethyl bromide quench: MS (70 eV): *m/z* (%): 232 (12) [M^+], 159 (16) [M^+ − SiMe$_3$], 131 (27) [MH^+ − EtSiMe$_3$], 73 (100) [SiMe$_3$]. Repeating the experiment the same scale in THF led to the same results with some increased reaction time. Removals of solvent and crystallization from pentane gave white crystals (56 mg, 0.20 mmol, 56%), which were shown by NMR to contain half a molecule of THF coordinated to the silyl potassium compound. − ^{1}H NMR (300 MHz, C_6D_6): δ = 3.37 (m, 2 H), 1.37 (m, 2 H), 1.24 (t, *J* = 7.8 Hz, 3 H), 0.86 (q, *J* = 7.8 Hz, 2 H), 0.32 (s, 18 H). − ^{13}C NMR (75.4 MHz, C_6D_6): δ = 68.42, 25.82, 19.57, 5.03, 3.69.

Bis(trimethylsilyl)silylpotassium (**13**): Compound **13** was prepared from **2** (775 mg, 3.11 mmol) and *tert*-BuOK (385 mg, 3.43 mmol) in DME following the general procedure. The reaction was followed directly by ^{29}Si NMR and GC/MS of the quenched samples. Complete conversion was reached after 2 h and gave **13** and **1a** in a ratio of about 7:3. − IR $\tilde{\nu}$: 1891 cm^{-1} (Si−H). − ^{29}Si NMR (59.6 MHz, DME, D_2O lock): δ = −4.02, −181.14 (d, *J* = 82 Hz). − H_3O^+ quench: MS (70 eV): *m/z* (%):, 176 (11) [M^+], 161 (16) [M^+ − Me], 101 (9) [M^+ − H_2SiMe_3], 88 (21) [M^+ − SiMe$_4$], 73 (100) [SiMe$_3$]. − Ethyl bromide quench: MS: vide supra. The experiment was repeated in THF on larger scale and gave essentially the same results. Removal of the solvent and crystallization from pentane gave a mixture of **13** and **1a** with THF coordinated to the alkali silanyl compounds. − ^{1}H NMR (300 MHz, C_6D_6): δ = 3.51 (m), 1.38 (m), 1.29 (s, 1 H), 0.47 (s, 18 H), 0.43 (s, 27 H).

1-Phenyltetramethyldisilanylpotassium (**14**): Compound **14** (200 mg, 0.75 mmol) was prepared from 2-phenylheptamethyltrisilane in THF following the general procedure, with the variation that *tert*-BuOK (85 mg, 0.75 mmol) was added in several portions over two hours. − ^{29}Si NMR (59.6 MHz, THF, D_2O lock): δ = −12.33, −62.96. − H_3O^+ quench: MS (70 eV): *m/z* (%): 194 (21) [M^+], 179 (15) [M^+ − Me], 135(83) [M^+ − HSiMe$_2$], 121 (21) [M^+ − SiMe$_3$], 105 (28) [M^+ − HSiMe$_4$], 73 (100) [SiMe$_3$]. − Ethyl bromide quench: MS (70 eV): *m/z* (%): 222 (20) [M^+], 207 (4) [M^+ − Me], 193 (14) [M^+ − Et], 149 (39) [M^+ − SiMe$_3$], 135 (44) [SiPhEt], 121 (100) [HSiPhMe], 105 (17) [SiPh], 73 (27) [SiMe$_3$].

Received September 22, 1997

Keywords: Hydrostannylation / Phosphaalkynes / 1,2-Dihydro-1,3-diphosphetes / Homocubanes / Carbonyl complexes

The hydrostannylation of phosphaalkynes **8** with tin hydrides **1** depends on the stoichiometry employed: Thus, the 1,2-dihydro-1,3-diphosphetes **10** are isolated when an excess of phosphaalkyne **8** is used. On the other hand, an increase in the tin hydride concentration favors the formation of the phosphanes **11** and **12**. Synthesis of the 1,2-dihydro-1,3-diphosphetes **14** and **16** was achieved by the use of diorganotin hydrides **13** or chloro(organo)tin hydrides **4**, respectively. An isolated and characterized by-product of the latter reaction was the phosphorus-carbon-tin cage **17**. Furthermore, the following reactions of the 1,2-dihydro-1,3-diphosphetes **10** were performed: isomerization reactions, complexation reactions with transition-metal complexes, and substitution of the hydrogen atom by iodine.

Introduction

Addition reactions of organotin compounds to unsaturated systems have been known for a long time[2]. Following the hydrostannylation of alkenes which, as a consequence of the mild reaction conditions and high selectivity, has found wide-ranging applications, the first 1,2-addition of triorganotin hydrides to acetylenes was achieved in 1959[3][4]. In comparison to the hydrostannylation reactions of the corresponding olefins, the additions to C−C triple-bond systems proceed more readily. The vinyltin compounds **2** are the primary products of these reactions which then undergo, albeit somewhat delayed, addition of a second equivalent of the triorganotin hydride **1** to furnish the ditin compounds **3**. Modification of the organotin hydride by the introduction of a halogen atom to give the diorgano(halo)tin hydrides **4**[5] provides further new possibilities for the synthesis of numerous mixed substituted organotin compounds **5**[6].

We recently reported on hydrostannylation reactions in the chemistry of low-coordinated phosphorus, namely the selective 1,2-addition of organotin compounds to Becker-type phosphaalkenes **6** to furnish the stannylphosphanes **7**[7].

The central theme of the present work is the reactivity of organotin hydrides and organo(halo)tin hydrides towards kinetically stabilized $\lambda^3\sigma^1$-phosphaalkynes and the related question of whether the primary products of the 1,2-addition of tin hydrides to the P−C triple-bond system will be sufficiently stable to permit their isolation.

Reactions with Triorganotin Hydrides 1

Reactions of the tin hydrides **1** with an excess of the phosphaalkynes **8a−c** in *n*-pentane at room temperature for 2 weeks gave rise to the 2-stannyl-substituted 1,2-dihydro-1,3-diphosphetes **10** in good yields. The reaction of tributyltin hydride (**1a**) with 1-adamantylphosphaalkyne (**8b**) required heating at 60°C for 4 hours for completion.

The natures of the 1,2-dihydro-1,3-diphosphetes **10a−f** were deduced from their analytical and spectroscopic data. The valency vibrations at 2160−2340 cm^{-1} in the IR spectra provided the first evidence for the presence of the PH function. A doublet of doublets at $\delta = 6.78-7.8$ with $^1J_{H,P}$ coupling constants of between 163 and 168 Hz was found in the ^{1}H-NMR spectra for these protons, which were originally bonded to the tin atoms. The splitting into a doublet of doublets and the integration values of the signals clearly demonstrate that compounds **10** are 1:2 adducts formed from one equivalent of the tin hydride **1** and two equiva-

lents of the phosphaalkyne **8**. The proposed compositions of the products were further supported by elemental analyses or high-resolution mass spectrometry. The ^{31}P-NMR spectra each reveal the typical AX spin system for 1,2-dihydro-1,3-diphosphetes[8][9]. The signals for the $\lambda^3\sigma^2$-phosphorus atoms occur in the expected low-field positions (δ = 369−376) while those of the $\lambda^3\sigma^3$-phosphorus atoms are found at $\delta = -5$ to +3. Both signals experience $^2J_{P,P}$ couplings of 35 to 44 Hz and appear as doublets. Thus, the existence of the structurally isomeric 1,4-dihydro-1,2-diphosphetes can be excluded on the basis of the small P,P couplings[10]. In the proton-undecoupled ^{31}P-NMR spectra the signals for the $\lambda^3\sigma^3$-phosphorus atom are further split by $^1J_{P,H}$ couplings and those of the $\lambda^3\sigma^2$-phosphorus atoms by $^3J_{P,H}$ couplings to give a doublet of doublets. A comparison of the measured values with those of previously known 1,2-dihydro-1,3-diphosphetes[8][11][12] supports the proposed constitutions. The ^{13}C-NMR spectra provide further diagnostic evidence. The doublet of doublets with large (ca. 50 Hz) and small (ca. 20 Hz) $^1J_{C,P}$ coupling constants observed at low field is characteristic for the skeletal sp^2 carbon atoms[13]. The second skeletal carbon atoms give rise to signals in the typical sp^3 region with appreciably smaller $^1J_{C,P}$ coupling constants. The varying chemical shifts of the tin atoms in the ^{119}Sn-NMR spectra can be rationalized in terms of the differing substitution: The tin atoms of the tributyl-substituted derivatives give rise to signals in the region typical for tetraalkyl-substituted tin compounds[14] while increasing phenyl substitution results in a stepwise shift to higher field[15].

A more careful consideration of the structures of compounds **10** reveals the presence of two centers of chirality: In addition to the asymmetric carbon atom C2 the phosphorus atom P1 should be chiral and configurationally stable . However, only one set of signals was observed in all of the NMR spectra and therefore it must be assumed that only one diastereomer is formed in each case. An exact assignment to one of the possible isomers is not possible on the basis of the spectroscopic data.

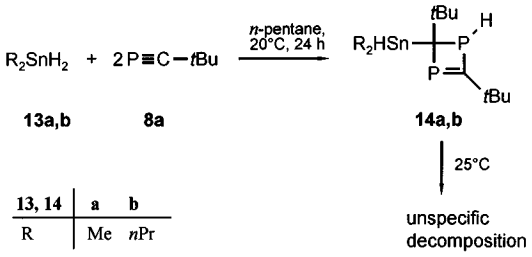
An increase in the tin hydride concentration favors the increased formation of the phosphanes **11** and **12**. When triphenyltin hydride (**1b**) was used in excess the phosphanes **11** were formed in yields exceeding 75%, while the isomeric compounds **12** were only observed as by-products (yields: < 5%). In comparison to triphenyltin hydride (**1b**), the lower hydrostannylation activity of tributyltin hydride (**1a**)[17] was not sufficient to alter the reaction course decisively in the direction of the phosphanes **11** and **12**; accordingly, the reaction mixtures contained appreciable amounts (60%) of the dihydrodiphosphetes **10** and a separation of the individual components was not possible.

The ^{31}P-NMR and ^{1}H-NMR spectra are of particular diagnostic value for the structural elucidation of the distannyl-substituted phosphanes **11**. The ^{31}P-NMR spectra of **11** each contain a singlet in the region typical for stannyl-substituted phosphanes[7] with $^1J_{P,^{117,119}Sn}$ coupling constants of ca. 720 Hz. In the proton-coupled ^{31}P-NMR spectra these signals are split into doublets by $^1J_{P,H}$ couplings of ca. 200 Hz. In the ^{1}H-NMR spectra doublet signals at δ = 3.03−3.32 with appropriate $^1J_{H,P}$ coupling constants are observed for the PH function while the protons added to carbon atoms give rise to signals at δ = 2.86−2.94. The $^2J_{H,P}$ coupling constants of about 4 Hz are very small. Integration of the individual signal groups clearly shows the 1:2 ratio of phosphaalkyne **8** to tin hydride **1b**. The presence of the PH function is further supported by a valency vibration at 2240 cm^{-1} in the IR spectra. The presence of two nonequivalent tin atoms is also apparent from the ^{119}Sn-NMR spectra. The triphenylstannyl groups directly bonded to phosphorus give doublet signals at $\delta = -73/-75$ with $^1J_{Sn,P}$ coupling constants of ca. 730 Hz, while the signals of *C*-bonded tin atoms appear as singlets at $\delta = -104$. Identification of the phosphanes **12a−c**, which were not isolated, was based on direct ^{31}P-NMR-spectroscopic investigation of the reaction solutions. The chemical shifts of $\delta = -136.4$ (**12a**), −143.7 (**12b**), and −138.1 (**12c**), as well as the $^1J_{P,H}$ coupling constants [198.1 Hz (**12a**), 198.8 Hz (**12b**), 216.6 Hz (**12c**)], support the proposed structures.

The phosphaalkenes **9** may be postulated as reactive intermediates in these stoichiometry-dependent reactions. These species then undergo stabilization either in a formal [2 + 2] cycloaddition to give the 1,2-dihydro-1,3-diphosphetes **10** or by renewed 1,2-addition of a further equivalent of tin hydride **1** to furnish the phosphanes **11** and **12**. The preferential formation of the phosphanes **11** over **12** can be rationalized in terms of both steric and electronic factors.

Reactions with Diorganotin Dihydrides

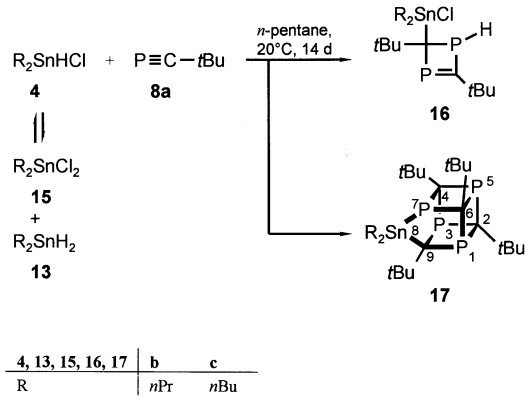
When the diorganotin dihydrides **13a**, **b** are allowed to react with an appreciable excess of the phosphaalkyne **8a** the primary products are the 1,2-dihydro-1,3-diphosphetes **14a**, **b**. However, these species undergo an unspecific decomposition so that their isolation is not possible. Even so, they can be characterized by ^{31}P-NMR and IR spectroscopy through termination of the reaction after 24 hours and removal of the volatile tin hydrides **13a**, **b** together with the excess phosphaalkyne **8a** under vacuum (oil pump).



The spectroscopic data of these compounds are in good agreement with those of the 1,2-dihydro-1,3-diphosphetes **10** discussed above. Therefore the constitutions of these hydrostannylation products may be considered as certain. One special feature resulting from the presence of the tin hydride function should be mentioned: The IR spectra contain SnH valency vibrations at 1790/1800 cm^{-1} in addition to the PH valency vibrations. This tin hydride function is presumably the cause of the unspecific decomposition reactions.

Reactions with Chlorodiorganotin Hydrides

Reactions of the chlorodiorganotin hydrides **4** with the phosphaalkyne **8a** proceed much less selectively than those with the triorganotin hydrides **1**. In addition to the 1,2-dihydro-1,3-diphosphetes **16b**, **c** formed as main products, numerous by-products are observed by ^{31}P-NMR-spectroscopic monitoring of the reaction solutions. One of these by-products is the cage compound **17**. Product **17b** cannot be isolated, while **17c** has been isolated in pure form by crystallization from pentane at −20°C and completely characterized. Complete separation of the reaction mixtures into their components by either column chromatography or bulb-to-bulb distillation was not possible.



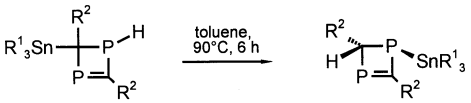
The ^{1}H-, ^{13}C-, ^{31}P-NMR, and IR data for the 1,2-dihydro-1,3-diphosphetes **16b**, **c** were taken from the crude reaction solutions and are in good agreement with those of the 1,2-dihydro-1,3-diphosphetes **10**. Thus, a detailed discussion of these data and the mechanism of the formation of the products is unnecessary in the light of the information given in the previous section.

The constitution of the cage compound **17c** was supported by mass spectrometry and elemental analysis. Linkage of the four phosphaalkyne units gives rise to an A_2MX spin system in the ^{31}P-NMR spectrum. As a consequence of the C_S symmetry, the phosphorus atoms P1 and P3 are magnetically equivalent (δ = 221). The signals for P5 and P7 appear at δ = 184 and δ = −72. The unusually low-field signals for the $\lambda^3\sigma^3$-phosphorus atoms P1, P3, and P5 are, in fact, not surprising when one considers that the pentacyclic compound **17c** is formally derived from tetraphosphacubane, which gives a ^{31}P-NMR signal at δ = 257[18]. These values can be explained on the basis of the bonding model derived for tetraphosphacubane, which reveals a strong interaction between the lone elctron pairs of the phosphorus atoms and the phosphorus-carbon σ bonds of the cubane skeleton. This effect is responsible for the dramatic low-field shifts of the phosphorus signals as well as the extreme high-field shifts of the signals for the skeletal carbon atoms in the ^{13}C-NMR spectrum[19]. A further indication in favor of the proposed structure is given by the tin satellite lines in the ^{31}P-NMR spectrum: P7 exhibits a characteristic $^1J_{P,Sn}$ coupling of 744 Hz, clearly demonstrating that P7 and tin are directly adjacent[20]. Tin satellites with $^3J_{P,Sn}$ coupling constants of 109 Hz are observed for the signal of P5. Accordingly, the ^{119}Sn-NMR signal for the tin atom (δ = 328) is split into a doublet of doublets ($^1J_{P,^{119}Sn}$ = 784 Hz, $^3J_{P,^{119}Sn}$ = 113 Hz). As a consequence of the C_S symmetry the ^{1}H-NMR spectrum contains only three signals for the four *tert*-butyl groups, with an intensity ratio of 1:2:1. For the same reason the skeletal carbon atoms C4 and C6 are magnetically equivalent in the ^{13}C-NMR spectrum (pt, δ = 37.6, $^1J_{C,P}$ = 13.5 Hz). Carbon atom C2 gives, as required by the discussed bonding model, a signal at extremely high field (δ = −17.2) (cf. skeletal carbon atom signals of tetraphosphacubane: δ = −29.1)[18][19]. Finally, the skeletal carbon atom C9 produces a ^{13}C-NMR signal at δ = 22.7.

From a mechanistic point of view, the formation of the cage compounds **17** may be considered as a cyclooligomerization of the phosphaalkyne **8a** in the coordination sphere of tin. Since the reaction of the 1,2-dihydro-1,3-diphosphete **16c** with an excess of the phosphaalkyne **8a** does not lead to the formation of the homocubane **17c**, the existence of the 1,2-dihydro-1,3-diphosphete **16c** as an intermediate can be discounted. Similarly, subsequent attempts to introduce the stannyl unit into a skeletal bond of tetraphosphacubane[18] by reaction of the latter with dibutyl(chloro)tin hydride (**4b**) were unsuccessful. Thus, a plausible mechanism involves the stepwise construction of the P/C skeleton by oligomerization of the phosphaalkyne units at tin.

Thermal Isomerization of the 1,2-Dihydro-1,3-diphosphetes 10

After heating of the 1,2-dihydro-1,3-diphosphetes **10a−d** in toluene at 90°C for 6 hours, quantitative isomerization of the original 2-stannyl-substituted 1,2-dihydro-1,3-diphosphetes into the 1-stannyl-substituted derivatives **18a−d** is observed.



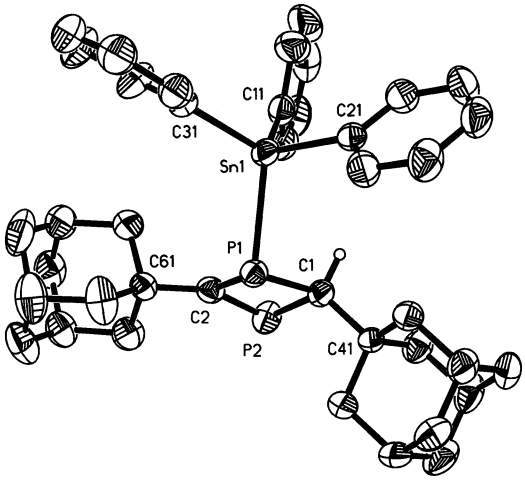
10 **18**

10, 18	a	b	c	d
R^1	*n*Bu	Ph	*n*Bu	Ph
R^2	*t*Bu	*t*Bu	1-Ad	1-Ad

The natures of the 1,2-dihydro-1,3-diphosphetes **18** obtained were unequivocally demonstrated by mass spectrometry and elemental analysis. Evidence for the arrangement of the substituents was provided by analysis of the NMR spectra in comparison with the data for the starting compounds **10a−d**. Thus, the ^{31}P-NMR signals of the $\lambda^3\sigma^2$-phosphorus atoms experienced high-field shifts of almost 20 ppm, while the signals of the $\lambda^3\sigma^3$-phosphorus atoms changed only slightly (δ = 2−3). The direct adjacency of tin to phosphorus is apparent from the tin satellites at the signal of P1 with $^1J_{P,^{117,119}Sn}$ coupling constants of more than 1000 Hz and the markedly smaller $^3J_{P,^{117,119}Sn}$ coupling constants of 170 Hz at P3. The same couplings also appear in the ^{119}Sn-NMR spectra. Because of the migration of the hydrogen atom from phosphorus to carbon the ^{1}H-NMR signal of this proton experiences a pronounced diamagnetic shift from δ = 7.5 to 2.6 and, instead of the original splitting into a doublet of doublets, appears merely as a doublet with a small $^2J_{H,P}$ coupling of 1.4 Hz. The magnitude of this $^2J_{H,P}$ coupling can be interpreted as evidence for the *trans* arrangement of **18**[21]. In the ^{13}C-NMR spectra the skeletal carbon atoms C4 give the expected doublet of doublet signals at low field (δ = 238.1−240.4; $^2J_{C,P}$ = 53/40 Hz) while the signals of the second skeletal carbon atom appear as doublets ($^1J_{C,P}$ = 22 to 24 Hz) at δ = 36.4−39.1 in the typical sp^3 region. An X-ray crystallographic analysis of product **18d** (Figure 1) supplied final confirmation of the *trans* orientation of the adamantyl group and the triphenylstannyl group. Since only one isomer was obtained from each experiment and since the $\lambda^3\sigma^3$-phosphorus atoms should be configurationally stable[16], the same arrangement of the substituents can also safely be assumed for the compounds **18a−c**.

The four-membered diphosphacyclobutene ring deviates slightly from planarity (sum of internal angles: 358.9°). The dihedral angle between the planes C(1)−P(1)−C(2) and C(1)−P(2)−C(2) amounts to 10.7°. The P(2)−C(2) bond length of 169.7 pm is in the typical range for P−C double bonds[22], whereas the P(1)−C(2) single bond is somewhat shortened to 181.5 pm. The tin atom exists in a distorted tetrahedral environment.

Figure 1. Molecular structure of **18d**[a]

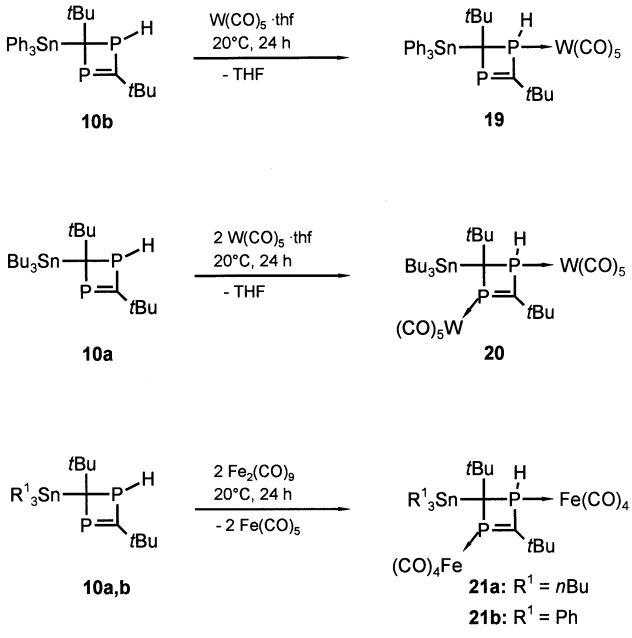


[a] Selected bond lengths [pm] and angles [°]: P(1)-C(2) 181.5(4), P(1)-C(1) 188.7(4), P(2)-C(2) 169.7(4), P(2)-C(1) 187.1(4), Sn(1)-C(21) 214.5(4), Sn(1)-C(31) 214.2(4), Sn(1)-C(11) 215.1(4), Sn(1)-P(1) 252.84(12); C(2)-P(1)-C(1) 82.2(2), C(2)-P(2)-C(1) 85.9(2), P(2)-C(1)-P(1) 91.2(2), P(2)-C(2)-P(1) 99.7(2), C(41)-C(1)-P(1) 118.1(3), C(41)-C(1)-P(2) 118.7(3), C(61)-C(2)-P(1) 130.0(3), C(61)-C(2)-P(2) 130.0(3), C(11)-Sn(1)-P(1) 115.27(12), C(21)-Sn(1)-P(1) 103.33(10), C(31)-Sn(1)-P(1) 113.14(10).

Complexation Behavior of 10

Phosphane ligands have found a wide range of applications in organometallic chemistry[23][24]. A common method for the preparation of phosphorus-containing transition-metal complexes comprises of a ligand-exchange reaction between phosphorus compounds and carbonyl transition-metal complexes.

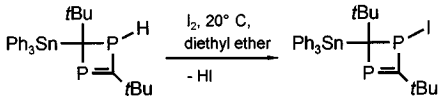
In the case of the 1,2-dihydro-1,3-diphosphetes **10**, both complexation of one phosphorus atom (→ **19**) and complete complexation of both phosphorus atoms (→ **20**) are possible using $W(CO)_5$·THF. Reactions of the 1,2-dihydro-1,3-diphosphetes **10a, b** with excess $Fe_2(CO)_9$ furnish the doubly complexed derivatives **21a**, **b**.



The spectroscopic characterization of the complexes **19**, **20**, and **21** is relatively simple. For the pentacarbonyltungsten complexes **19** and **20** the η^1 coordination of the metal fragment at P1 (for compound **19**) or at P1 and P3 (for compound **20**) is impressively demonstrated by the characteristic P-W couplings[25] in the ^{31}P-NMR spectra. The complexation has only a minor influence on the ^{13}C-NMR data of the starting materials with additional characteristic signals being observed at low field for the carbonyl groups (see Experimental Section). Furthermore, CO valency vibrations appear in the IR spectra of compounds **19**, **20**, and **21**. The compositions of the products were further substantiated by mass spectrometry and elemental analysis.

Reaction of 10 with Iodine

Conversion of the PH function of the 1,2-dihydro-1,3-diphosphete **10b** into a PI function can be achieved by treatment of **10b** with a solution of iodine in diethyl ether at room temperature.



10b **22**

The degradation of the PH function is immediately demonstrated by the absence of the corresponding signal in the ^{1}H-NMR spectrum. Also, no P,H couplings can be seen in the proton-coupled ^{31}P-NMR spectrum. In comparison to that of the starting material the ^{13}C-NMR signal for C2 experiences a shift of almost 20 ppm to lower field. Finally, the increases in the $^1J_{C,P}$ coupling constants are noteworthy. The composition of the 1,2-dihydro-1,3-diphosphete **22** was substantiated by mass spectrometry and elemental analysis.

We thank the *Fonds der Chemischen Industrie* for generous financial support. We are also grateful to the *Deutsche Forschungsgemeinschaft* (Graduate College *Phosphorus as Connecting Link Between Various Chemical Disciplines*) for generous financial support and a post-graduate grant (to M. S.).

Experimental Section

General: All experiments were carried out under argon (purity: > 99.998%) in previously evacuated and oven-dried Schlenk vessels. The solvents were anhydrous and stored under argon. – Melting points: Mettler FP 61 (heating rate: 3°C/min), uncorrected. – Elemental analyses: Perkin-Elmer EA 240. – ^{1}H NMR: Varian EM 360 (60 MHz), Bruker AC 200 and AMX 400; chemical shifts are relative to the solvent signals, and converted to TMS. – ^{13}C NMR: Bruker AC 200 and AMX 400; chemical shifts are relative to the solvent signals. – ^{31}P NMR: Bruker AC 200, external standard H_3PO_4. – MS: Finnigan MAT 90 (70 eV). – IR: Perkin-Elmer 16 PC FT-IR and Perkin-Elmer 1310. – Chemicals: Triphenyltin hydride (**1b**) was prepared from triphenyltin chloride[26], dimethyltin dihydride (**13a**)[27], dipropyltin dihydride (**13b**)[28], dibutyltin dihydride (**13c**)[29], dipropyltin dichloride (**15b**)[30], and the phosphaacetylenes **8a**[31], **b**[32], **c**[31] were prepared as described in the literature. All other starting materials were purchased from commercial suppliers.

1,2-Dihydro-1,3-diphosphetes **10**. – *General Procedure:* To a solution of phosphaalkyne **8** in pentane was added the tin hydride **1**. The mixture was stirred for two weeks at room temperature and the solvent removed under vacuum. The residue was purified by chromatography or crystallization.

2,4-Di-tert-butyl-2-tributylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10a**): From **8a** (800 mg, 8 mmol) in pentane (3 ml) and **1a** (873 mg, 3 mmol); chromatography on aluminum oxide (5% H_2O) with pentane yielded **10a** (413 mg, 28%) as a yellow, non-distillable oil. – ^{1}H NMR (C_6D_6): δ = 0.65–1.94 (m, 45 H, Bu-H and *t*Bu-H), 6.73 (dd, $^1J_{H,P}$ = 164.7 Hz, $^3J_{H,P}$ = 21.5 Hz, 1 H, P–H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 13.5 (s, $^1J_{C,^{117/119}Sn}$ = 315.7 Hz, Sn–*C*H$_2$), 13.9 (s, Sn–[CH$_2$]$_3$–*C*H$_3$), 28.0 (s, SnCH$_2$*C*H$_2$), 29.7 [dd, $^3J_{C,P}$ = 10.1/5.8 Hz, C(*C*H$_3$)$_3$], 30.0 (s, *C*H$_2$CH$_3$), 30.8 [d, $^3J_{C,P}$ = 5 Hz, C(*C*H$_3$)$_3$], 36.4 (dd, $^1J_{C,P}$ = 39.2/5.5 Hz, C2), 37.1 [d, $^2J_{C,P}$ = 7.7 Hz, *C*(CH$_3$)$_3$], 39.8 [d, $^2J_{C,P}$ = 6.3 Hz, *C*(CH$_3$)$_3$], 222.56 (dd, $^1J_{C,P}$ = 52.1/23.2 Hz, C4). – ^{31}P{^{1}H} NMR (C_6D_6): δ = 0.7 (d, $^2J_{P,P}$ = 39.1 Hz, P-1), 375.6 (d, $^2J_{P,P}$ = 39.1 Hz, P-3). – ^{119}Sn{^{1}H} NMR (C_6D_6): δ = 3.85 (s). – IR (film): $\tilde{\nu}$ = 2940, 2910, 2860, 2200 (P–H), 1455, 1355, 1210, 1110, 840 cm^{-1}. – MS; *m/z* (%): 492 (13) [M$^+$], 291 (39) [SnBu$_3^+$], 235 (76) [HSnBu$_2^+$], 179 (100) [H$_2$SnBu$^+$], 57 (38) [C$_4$H$_9^+$]. – $C_{22}H_{46}P_2Sn$ (491.26): calcd. C 53.8, H 9.4; found C 53.6, H 9.3.

2,4-Di-tert-butyl-2-triphenylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10b**): From **8a** (4 g, 40 mmol) in pentane (5 ml) and **1b** (3.43 g, 9.8 mmol); crystallization from 3 ml of pentane at –20°C yielded **10b** (2.6 g, 48% based on **1b**) as a yellow solid with m.p. 68°C. – ^{1}H NMR (C_6D_6): δ = 1.16 (s, 9 H, *t*Bu-H), 1.65 (s, 9 H, *t*Bu-H), 7.42–7.48 (m, 9 H, *m*-, *p*-C$_6$H$_5$), 7.57 (dd, $^1J_{H,P}$ = 166 Hz, $^3J_{H,P}$ = 18.6 Hz, 1 H, P–H), 8.05–8.08 (m, 6 H, *o*-C$_6$H$_5$). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 29.9 [d, $^3J_{C,P}$ = 3.6 Hz, C(*C*H$_3$)$_3$], 30.3 [d, $^3J_{C,P}$ = 9.0 Hz, C(*C*H$_3$)$_3$], 37.4 [d, $^2J_{C,P}$ = 7.2 Hz, *C*(CH$_3$)$_3$], 39.2 (dd, $^1J_{C,P}$ = 38.2/4 Hz, C2), 39.6 [d, $^2J_{C,P}$ = 5.4 Hz, *C*(CH$_3$)$_3$], 128.7 (s, $^2J_{C,^{117/119}Sn}$ = 49.4 Hz, *o*-C), 129.2 (s, *p*-C), 138.0 (s, $^3J_{C,^{117/119}Sn}$ = 35.0 Hz, *m*-C), 141.6 (s, $^1J_{C,^{117/119}Sn}$ = 471.2/492.8 Hz, *ipso*-C), 224.4 (dd, $^1J_{C,P}$ = 51.6/22.9 Hz, C4). – ^{31}P{^{1}H} NMR (C_6D_6): δ = 2.5 (d, $^2J_{P,P}$ = 35.8 Hz, P-1), 372.1 (d, $^2J_{P,P}$ = 35.8 Hz, P-3). – ^{119}Sn{^{1}H} NMR (C_6D_6): δ = –99.75 (pt, $^2J_{^{119}Sn,P}$ = 24.4 Hz). – IR (KBr): $\tilde{\nu}$ = 3040, 2920, 2180 (P–H), 1450, 1410, 1350, 1100, 840 cm^{-1}. – MS; *m/z* (%): 552 (5) [M$^+$], 351 (100) [SnPh$_3^+$], 197 (24) [SnPh$^+$], 57 (18) [C$_4$H$_9^+$]. – $C_{28}H_{34}P_2Sn$ (551.23): calcd. C 61.0, H 6.2; found C 61.3, H 6.2.

2,4-(Diadamant-1-yl)-2-tributylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10c**): From **8b** (360 mg, 2 mmol) in pentane (2 ml) and **1a** (291 mg, 1 mmol); after stirring the reaction mixture for two weeks at room temperature the solution was heated to 60°C for 4 h; chromatography on aluminum oxide (5% H_2O) with pentane yielded **10c** (150 mg, 23%) as a yellow, non-distillable oil. – ^{1}H NMR (C_6D_6): δ = 1.10–2.62 (m, 57 H, Ad-H and Bu-H), 6.81 (dd, $^1J_{H,P}$ = 164 Hz, $^3J_{H,P}$ = 22 Hz, 1 H, P–H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 13.8 (s, $^1J_{C,^{117/119}Sn}$ = 313.8 Hz, Sn–*C*H$_2$), 13.9 (s, Sn–[CH$_2$]$_3$–*C*H$_3$), 28.1 (s, $^2J_{C,^{117/119}Sn}$ = 63.0 Hz, SnCH$_2$*C*H$_2$), 29.2 (s, C-c), 29.5 (s, C-c), 30.2 (s, $^3J_{C,^{117/119}Sn}$ = 35.3 Hz, *C*H$_2$CH$_3$), 37.0 (s, 2 × C-d), 37.4 (d, $^1J_{C,P}$ = 30.5 Hz, C-2), 38.9 (d, $^2J_{C,P}$ = 6.3 Hz, C-a), 41.2 (br. d, $^3J_{C,P}$ = 7.6 Hz, C-b), 42.1 (d, $^2J_{C,P}$ = 5.7 Hz, C-a), 43.5 (d, $^3J_{C,P}$ = 3.8 Hz, C-b), 222.6 (dd, $^1J_{C,P}$ = 51/22.4 Hz, C-4). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –5.2 (d, $^2J_{P,P}$ = 43.6 Hz, P-1), 373.3 (d, $^2J_{P,P}$ = 43.6 Hz, P-3). – IR (film): $\tilde{\nu}$ = 2920–2800, 2160 (P–H), 1440, 1320, 1270, 1140 cm^{-1}. – MS; *m/z* (%): 649 (36) [M$^+$], 291 (46) [SnBu$_3^+$], 135 (100) [Ad$^+$]. – $C_{34}H_{58}P_2Sn$ (647.49): calcd. C 63.1, H 9.0; found C 63.4, H 8.9.

2,4-(Diadamant-1-yl)-2-triphenylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10d**): From **8b** (300 mg, 1.7 mmol) in pentane (5 ml)

and **1b** (296 mg, 0.8 mmol); evaporation of the solvent and washing of the residue with pentane yielded **10d** (198 mg, 35%) as a yellow solid with m.p. 92°C. – ^{1}H NMR (C_6D_6): δ = 1.38–2.63 (m, 30 H, Ad-H), 7.20–7.41 (m, 9 H, *m*-, *p*-C_6H_5), 7.44 (dd, $^1J_{H,P}$ = 168 Hz, $^3J_{H,P}$ = 21 Hz, 1 H, P–H), 7.87–8.09 (m, 6 H, *o*-C_6H_5). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 28.9 (s, C-c), 29.2 (s, C-c), 36.5 (s, C-d), 36.7 (s, C-d), 39.1 (d, $^2J_{C,P}$ = 6.5 Hz, C-a), 41.6 (br. d, $^3J_{C,P}$ = 10.0 Hz, C-b), 41.9 (d, $^2J_{C,P}$ = 5.6 Hz, C-a), 42.1 (d, $^3J_{C,P}$ = 5.6 Hz, C-b), 128.7 (s, $^2J_{C,^{117/119}Sn}$ = 49.0 Hz, *o*-C), 129.0 (s, *p*-C), 138.2 (s, $^3J_{C,^{117/119}Sn}$ = 35.3 Hz, *m*-C), 142.2 (s, $^1J_{C,^{117/119}Sn}$ = 467.4/489.1 Hz, *ipso*-C), 223.9 (dd, $^1J_{C,P}$ = 50.2/21.3 Hz, C-4), the C-2 signal could not be detected because of signal overlap. – ^{31}P{^{1}H} NMR (C_6D_6): δ = –4.1 (d, $^2J_{P,P}$ = 43 Hz, P-1), 369.2 (d, $^2J_{P,P}$ = 43 Hz, P-3). – ^{119}Sn{^{1}H} NMR (C_6D_6): δ = –101.43 (s). – IR (KBr): $\tilde{\nu}$ = 3030, 2940, 2865, 2818, 2180 (P–H), 1432, 1413, 1330, 1295, 1249, 715, 685 cm^{-1}. – MS; *m/z* (%): 708 (6) [M^+], 351 (100) [$SnPh_3^+$], 135 (47) [Ad^+]. – $C_{40}H_{46}P_2Sn$ (707.5): calcd. C 67.9, H 6.6; found C 67.6, H 6.5.

2,4-Di-tert-pentyl-2-tributylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10e**): From **8c** (357 mg, 3.13 mmol) in pentane (5 ml) and **1a** (407 mg, 1.4 mmol); chromatography on aluminum oxide (5% H_2O) with pentane yielded **10e** (540 mg, 74%) as a yellow, non-distillable oil. – ^{1}H NMR (C_6D_6): δ = 0.86–1.59 (m, 45 H, *t*Pent-H and Bu-H), 6.78 (dd, $^1J_{H,P}$ = 163.04 Hz, $^3J_{H,P}$ = 20.27 Hz, 1 H, P–H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 8.0 (s, $^1J_{C,^{117/119}Sn}$ = 341.3 Hz, Sn–*C*H_2), 9.2 (s, CH_2CH_3), 9.6 (s, CH_2CH_3), 13.5 (s, Sn–[CH_2]$_3$–*C*H_3), 24.7 [br. d, $^3J_{C,P}$ = 6.4 Hz, C(*C*H_3)$_2$], 25.8 [br. d, $^3J_{C,P}$ = 8.0 Hz, C(*C*H_3)$_2$], 27.1 (s, $SnCH_2CH_2$), 29.9 [s, $^3J_{C,^{117/119}Sn}$ = 21.7 Hz, Sn(CH_2)$_2$*C*H_2CH$_3$], 34.7 (dd, $^3J_{C,P}$ = 9.2/4.4 Hz, *C*H_2CH$_3$), 35.4 [d, $^2J_{C,P}$ = 7.2 Hz, *C*(CH$_3$)$_2$CH$_2$CH$_3$], 36.1 (dd, $^3J_{C,P}$ = 7.2/4.0 Hz, *C*H_2CH$_3$), 38.4 (d, $^1J_{C,P}$ = 40.2 Hz, *C*2), 39.2 [d, $^2J_{C,P}$ = 6.4 Hz, *C*(CH$_3$)$_2$CH$_2$CH$_3$], 221.0 (dd, $^1J_{C,P}$ = 52.2, 24.1 Hz, C-4). – ^{31}P{^{1}H} NMR (C_6D_6): δ = 1 (d, $^2J_{P,P}$ = 41 Hz, P-1), 379 (d, $^2J_{P,P}$ = 41 Hz, P-3). – IR (pentane): $\tilde{\nu}$ = 2942, 2912, 2880, 2340 (P–H), 1644, 1456 cm^{-1}. – MS; *m/z* (%): 520 (5) [M^+], 291 (100) [$SnBu_3^+$], 235 (59) [$HSnBu_2^+$], 177 (60) [$SnBu^+$], 71 (44) [$C(CH)_3CH_2CH_3^+$], 57 (16) [$C_4H_9^+$]. – HR-MS: $C_{24}H_{50}P_2Sn$: calcd. 520.2409; found 520.2385.

2,4-Di-tert-pentyl-2-triphenylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**10f**): From **8c** (422 mg, 3.7 mmol) in pentane (5 ml) and **1b** (123 mg, 0.35 mmol); evaporation of the solvent and washing of the residue with pentane yielded **10f** (70 mg, 34%) as a yellow solid with m.p. 86°C. – ^{1}H NMR (C_6D_6): δ = 0.70 (t, $^3J_{H,H}$ = 7.24 Hz, 3 H, CH_2CH_3), 0.82 (t, $^3J_{H,H}$ = 7.87 Hz, 3 H, CH_2CH_3), 0.86 [s, 3 H, C(CH$_3$)$_2$], 0.88 [s, 3 H, C(CH$_3$)$_2$], 1.27 [s, 3 H, C(CH$_3$)$_2$], 1.29 [s, 3 H, C(CH$_3$)$_2$], 7.10–7.18 (m, 9 H, *m*, *p*-C_6H_5), 7.27 (dd, $^1J_{H,P}$ = 166.59 Hz, $^3J_{H,P}$ = 19.98 Hz, 1 H, P–H), 7.73–7.82 (m, 6 H, *o*-C_6H_5). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 9.1 (s, CH_2CH_3), 9.5 (s, CH_2CH_3), 24.8 [br. s, C(*C*H$_3$)$_2$], 25.1 [br. s, C(*C*H$_3$)$_2$], 35.2 (br. s, *C*H_2CH$_3$), 35.8 (br. s, *C*H_2CH$_3$), 39.7 (d, $^1J_{C,P}$ = 6.7 Hz, C2) , 41.3 [s, *C*(CH$_3$)$_2$CH$_2$CH$_3$], 42.5 [s, *C*(CH$_3$)$_2$CH$_2$CH$_3$], 128.4 (s, *o*-C), 128.8 (s, *p*-C), 137.8 (s, $^3J_{C,^{117/119}Sn}$ = 34.4 Hz, *m*-C), 141.6 (s, *ipso*-C), 222.7 (dd, $^1J_{C,P}$ = 52.0, 22.4 Hz, C-4). – ^{31}P{^{1}H} NMR (C_6D_6): δ = 3 (d, $^2J_{P,P}$ = 40 Hz, P-1), 376 (d, $^2J_{P,P}$ = 40 Hz, P-3). – IR (pentane): $\tilde{\nu}$ = 2990, 2199 (P–H), 1468, 1429, 1261, 1072, 1021, 807, 726 cm^{-1}. – MS; *m/z* (%): 580 (1) [M^+], 351 (100) [$SnPh_3^+$], 274 (20) [$SnPh_2^+$], 197 (62) [$SnPh^+$], 77 (20) [$C_6H_5^+$], 71 (13) [$C(CH_3)_2CH_2CH_3^+$]. – HR-MS: $C_{30}H_{38}P_2Sn$: calcd. 580.1470; found 580.1465.

1,2-Bis(triphenylstannyl)phosphanes **11a**, **b**. – *General Procedure:* To a solution of phosphaacetylene **8** in pentane was added triphenyltin hydride (**1b**). The mixture was stirred for one week at 20°C, the solvent removed under vacuum, and the residue washed several times with pentane.

[tert-Butyl(triphenylstannyl)methyl]triphenylstannylphosphane (**11a**): From **8a** (0.4 g, 4 mmol) in pentane (5 ml) and **1b** (6.32 g, 18 mmol) to furnish **11a** (2.6 g, 81%) as a pale yellow powder with m.p. 154°C. – ^{1}H NMR (C_6D_6): δ = 1.04 (s, 9 H, *t*Bu), 2.94 (d, $^2J_{H,P}$ = 4.5 Hz, 1 H, PC–H), 3.32 (d, $^1J_{H,P}$ = 196.2 Hz, 1 H, P–H), 7.05–7.13 (m, 18 H, *m*-, *p*-C_6H_5), 7.47–7.49 (m, 6 H, *o*-C_6H_5), 7.62–7.66 (m, 6 H, *o*-C_6H_5). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 28.8 (d, $^1J_{C,P}$ = 36.1 Hz, P*C*H, ^{1}H coupl.: $^1J_{C,H}$ = 129.3 Hz), 32.4 [d, $^3J_{C,P}$ = 10.4 Hz, C(*C*H$_3$)$_3$], 35.4 [d, $^2J_{C,P}$ = 17.7 Hz, *C*(CH$_3$)$_3$], 129.26 (s, *o*-C), 129.30 (s, *o*-C), 129.4 (s, *p*-C), 129.6 (s, *p*-C), 137.9 (s, *m*-C), 138.1 (s, *m*-C), 139.1 (d, $^2J_{C,P}$ = 4 Hz, *ipso*-C), 140.2 (s, *ipso*-C). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –170 (s, $^1J_{P,^{117,119}Sn}$ = 716 Hz). – ^{119}Sn{^{1}H} NMR (C_6D_6): δ = –73 (d, $^1J_{^{119}Sn,P}$ = 732 Hz, P–Sn), –104 (s, PC–Sn). – IR (KBr): $\tilde{\nu}$ = 3030, 2920, 2240 (P–H), 1460, 1410, 1350, 1320, 1285, 1250, 1210, 1180, 1060, 1010, 985, 855, 750, 715, 685 cm^{-1}. – MS; *m/z* (%): 802 (0.2) [M^+], 451 (2) [M^+ – $SnPh_3$], 351 (100) [$SnPh_3^+$], 197 (18) [$SnPh^+$], 57 (9) [$C_4H_9^+$]. – $C_{41}H_{41}PSn_2$ (802.14): calcd. C 61.4, H 5.2; found C 61.4, H 5.2.

[Adamant-1-yl(triphenylstannyl)methyl]triphenylstannylphosphane (**11b**): From **8b** (0.3 g, 1.66 mmol) in pentane (5 ml) and **1b** (3.16 g, 9 mmol) to furnish **11b** (1.01 g, 75%) as a colorless powder with m.p. 185°C (dec.). – ^{1}H NMR (C_6D_6): δ = 1.2–1.9 (m, 15 H, Ad-H), 2.86 (d, $^2J_{H,P}$ = 3.7 Hz, 1 H, PC–H), 3.03 (d, $^1J_{H,P}$ = 198.4 Hz, 1 H, P–H), 6.9–7.25 (m, 18 H, *m*-, *p*-C_6H_5), 7.3–7.8 (m, 12 H, *o*-C_6H_5). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 31.3 (s, C-c), 31.4 (d, $^1J_{C,P}$ = 39.4 Hz, P*C*H, ^{1}H coupl.: $^1J_{C,H}$ = 127.7 Hz), 38.2 (d, $^2J_{C,P}$ = 15.2 Hz, C-a), 38.6 (s, C-d), 46.7 (d, $^3J_{C,P}$ = 11.1 Hz, C-b), 130.7 (s, *o*-C), 130.9 (s, *o*-C), 131.0 (s, *p*-C), 131.2 (s, *p*-C), 139.4 (s, *m*-C), 139.7 (s, *m*-C), 140.9 (d, $^2J_{C,P}$ = 3.3 Hz, *ipso*-C), 142.8 (s, *ipso*-C). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –175 (s, $^1J_{P,^{117,119}Sn}$ = 724 Hz). – ^{119}Sn{^{1}H} NMR (C_6D_6): δ = –75 (d, $^1J_{^{119}Sn,P}$ = 731 Hz, P–Sn), –104 (s, PC–Sn). – IR (KBr): $\tilde{\nu}$ = 3030, 2910, 2840, 2240 (P–H), 1480, 1425, 1310, 1100, 1070, 1020, 1000, 890, 730, 700 cm^{-1}. – $C_{47}H_{47}PSn_2$ (880.25): calcd. C 64.1, H 5.4; found C 64.0, H 5.3.

1,2-Dihydro-1,3-diphosphetes **14a**, **b**. – *General Procedure:* To a solution of phosphaalkyne **8** in pentane was added the diorganotin dihydride **13** and the mixture stirred at room temperature for 24 h. The solvent, unreacted phosphaalkyne **8**, and tin hydride **13** were removed under vacuum. Further purification by distillation, chromatography, or crystallization was not possible.

2,4-Di-tert-butyl-2-hydridodimethylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**14a**): From **8a** (800 mg, 8 mmol) in pentane and **13a** (452 mg, 3 mmol) to furnish **14a** (70 mg, 7%) as a yellow oil. – ^{31}P{^{1}H} NMR (C_6D_6): δ = 1.9 (dd, $^1J_{P,H}$ = 161.5 Hz, $^2J_{P,P}$ = 40.9 Hz, P-1), 371.5 (dd, $^2J_{P,P}$ = 40.9 Hz, $^3J_{P,H}$ = 18.5 Hz, P-3). – IR (film): $\tilde{\nu}$ = 2930, 2910, 2170 (P–H), 1790 (Sn–H), 1450, 1350, 1250, 1240, 1050, 1010, 860, 830, 760, 620 cm^{-1}.

2,4-Di-tert-butyl-2-hydridodipropylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**14b**): From **8a** (800 mg, 8 mmol) in pentane and **13b** (620 mg, 3 mmol) to furnish **14b** (110 mg, 9%) as a yellow oil. – ^{31}P{^{1}H} NMR (C_6D_6): δ = –0.4 (dd, $^1J_{P,H}$ = 163 Hz, $^2J_{P,P}$ = 41 Hz, P-1), 369.7 (dd, $^2J_{P,P}$ = 41 Hz, $^3J_{P,H}$ = 21 Hz, P-3). – IR (film): $\tilde{\nu}$ = 3000, 2980, 2920, 2900, 2160 (P–H), 1800 (Sn–H), 1350, 1250, 1240, 1050, 1010, 860, 830, 770, 750 cm^{-1}.

1,2-Dihydro-1,3-diphosphetes **16** *and Homocubane* **17**. – *General Procedure:* Diorganotin dichloride **15** was dissolved in toluene (3 ml) and pentane (3 ml) and cooled to 0°C. Diorganotin dihydride

13 was added and the reaction solution was stirred for 15 min. Phosphaalkyne **8** was added. After a few hours the color of the reaction solution changed to red-brown and after 14 d the solvent was removed under vacuum. The residue was taken up in pentane (10 ml). Unreacted diorganotin dihydride **13** was crystallized at −20°C, further crystallization at −20°C yielded the homocubane **17**. Compound **17b** could not be isolated. It was not possible to purify the oils which contained the 1,2-dihydro-1,3-diphosphetes **16** as main products.

2,4-Di-tert-butyl-2-chlorodipropylstannyl-1,2-dihydro-1λ³,3λ³-diphosphete (**16b**): From **15b** (690 mg, 2.5 mmol), **13b** (520 mg, 2.5 mmol), and **8a** (1600 mg, 16 mmol) to furnish **16b** (ca. 85%). − ^{1}H NMR (C_6D_6): δ = 0.85−1.9 (m, 32 H, Pr-H and *t*Bu-H), 6.82 (dd, $^1J_{H,P}$ = 166 Hz, $^3J_{H,P}$ = 20 Hz, 1 H, P−H). − ^{13}C{^{1}H} NMR (C_6D_6): δ = 18.8 (s, CH_2CH_3), 20.4 (s, $SnCH_2CH_2$), 23.1 (s, $SnCH_2$), 29.7 [dd, $^3J_{C,P}$ = 9.6/4.8 Hz, C(*C*H$_3$)$_3$], 30.6 [br. d, $^3J_{C,P}$ = 4.8 Hz, C(*C*H$_3$)$_3$], 37.1 [br. d, $^2J_{C,P}$ = 8.0 Hz, *C*(CH$_3$)$_3$], 40.2 [br. s, *C*(CH$_3$)$_3$], 43.2 (dd, $^1J_{C,P}$ = 39.0/6.0 Hz, C-2), 227.6 (dd, $^1J_{C,P}$ = 53.8/24.1 Hz, C-4). − ^{31}P{^{1}H} NMR (C_6D_6): δ = −5.5 (d, $^2J_{P,P}$ = 43.1 Hz, P-1), 365.7 (d, $^2J_{P,P}$ = 43.1 Hz, P-3). − IR (film): ṽ = 2930, 2842, 2200 (P−H), 1450, 1380, 1350, 1208, 1103, 1055 cm^{-1}.

Received October 10, 1997

Keywords: Titanium complexes / Amido−cyclopentadienyl ligand / Titanium alkyl / Intramolecular coordination / Ethene polymerization

Titanium complexes containing a linked isopropyl- or benzylamido(tetramethylcyclopentadienyl) ligand $C_5Me_4SiMe_2NR$ (R = *i*Pr, CH_2Ph,) and one bidentate organyl group $C_6H_4(CH_2NMe_2)$-2, $CH_2C_6H_4(NMe_2)$-2, and {η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5) were prepared by salt metathesis of the corresponding dichloro complex Ti(η^5:η^1-$C_5Me_4SiMe_2NR)Cl_2$ with the lithium organyl. Single crystal X-ray structural analysis of Ti(η^5:η^1-$C_5Me_4SiMe_2NCH_2Ph$)-{$C_6H_4(CH_2NMe_2)$-2}Cl and of Ti(η^5:η^1-$C_5Me_4SiMe_2N$*i*Pr)-{$CH_2C_6H_4(NMe_2)$-2}Cl revealed the presence of intramolecular coordination with square pyramidal geometry around titanium. In the ferrocenyl derivative Ti(η^5:η^1-C_5Me_4-$SiMe_2NCH_2Ph$)[{η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5)]Cl the NMe_2 group is not bonded at the titanium atom. Ethene polymerization catalyzed by these complexes upon activation with methylaluminoxane was examined.

Introduction

Homogeneous polymerization catalysts based on titanium complexes with the linked amido−cyclopentadienyl ligand $C_5Me_4SiMe_2N$*t*Bu[1a][1b][1c] have recently gained enormous technological importance for the efficient synthesis of novel copolymers of ethene with α-olefins such as 1-octene and styrene[2]. The initial design of this ligand system by Bercaw and Shapiro[1a][1b][1c] was guided by the increased Lewis acidity of the metal complexes that would accommodate the bulkier comonomers more easily, compared to *ansa*-metallocenes containing a linked bis(cyclopentadienyl) ligand. Because of the great industrial interest not many detailed studies on structure−activity relationships of this class of complexes have so far appeared in the open literature[3]. In particular the influence of each of the ligand moieties on the polymerization performance remains unknown. We have synthesized and characterized several titanium complexes containing a linked amido−cyclopentadienyl ligand with different amido and cyclopentadienyl substituents[1d][1h][1i][1j][4a]. More recently, the influence of a donor-functionalized amido side chain on the Lewis acidity of the titanium center has been investigated in some detail[4]. In continuation of these studies we describe here the synthesis and characterization of some new titanium complexes with this ligand system and assess their activity towards ethene polymerization. In particular we focus on those systems that contain a bidentate organyl group, since they may give a clue to the possible polymerization of functionalized monomers.

Results and Discussion

The established synthetic route to titanium dichloro complexes containing a linked amido−cyclopentadienyl ligand $C_5Me_4SiMe_2NR$ is the metathesis of $TiCl_3(THF)_3$ with the dimetallated ligand $[C_5Me_4SiMe_2NR]^{2-}$, followed by chlorination with $PbCl_2$[1h][1i][1j]. However, in the case of the prototypical ligand system $C_5Me_4SiMe_2N$*t*Bu, the yield of the isolated crystalline product Ti(η^5:η^1-$C_5Me_4SiMe_2N$*t*Bu)Cl_2 (**1**)[5] was invariably low in our hands, never exceeding 40%. Obviously, the nature of the amido substituent R in the ligand $C_5Me_4SiMe_2NR$ critically influences the yield of Ti(η^5:η^1-$C_5Me_4SiMe_2NR)Cl_2$ and we suspected that a tertiary amido substituent causes significant steric hindrance during coordination of the bidentate ligand to the titanium center. Thus, the reaction of the doubly deprotonated ligand $Li_2[C_5Me_4SiMe_2NAd]$ (Ad = 1-adamantyl) resulted only in a yield of 30% for the titanium dichloro complex Ti(η^5:η^1-$C_5Me_4SiMe_2NAd)Cl_2$ (**2**). Low yield was also encountered during the preparation of Ti(η^5:η^1-$C_5Me_4SiMe_2NCMe_2$-CH_2*t*Bu)Cl_2 (**3**), derived from the inexpensive 1,1,3,3,-tetramethylbutylamine. However, the analogous reaction with $Li_2[C_5Me_4SiMe_2N$*i*Pr] gave the yellow crystalline isopropylamido derivative Ti(η^5:η^1-$C_5Me_4SiMe_2N$*i*Pr)Cl_2 (**4**) in excess of 70% yield (Scheme 1). Analytical and spectroscopic characterizations of **1**−**4** are straightforward. In the ^{1}H-NMR spectrum of **4**, a low field shift of the methine proton (δ = 5.55) is observed which is typical for all related complexes with secondary amido groups [Ti(η^5:η^1-$C_5H_4SiMe_2N$-*i*Pr)Cl_2: δ = 5.69[1j]; Ti{η^5:η^1-$C_5Me_4(CH_2)_nSiMe_2N$*i*Pr}Cl_2: δ = 5.92 (*n* = 2), δ = 6.57 (*n* = 3)[6]].

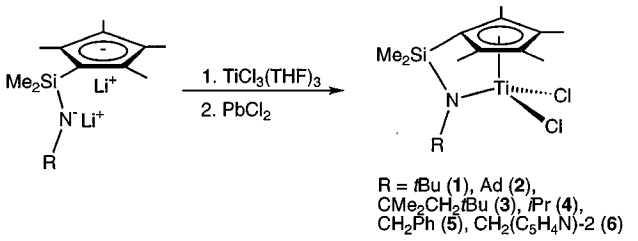
Scheme 1



R = *t*Bu (**1**), Ad (**2**), CMe_2CH_2tBu (**3**), *i*Pr (**4**), CH_2Ph (**5**), $CH_2(C_5H_4N)$-2 (**6**)

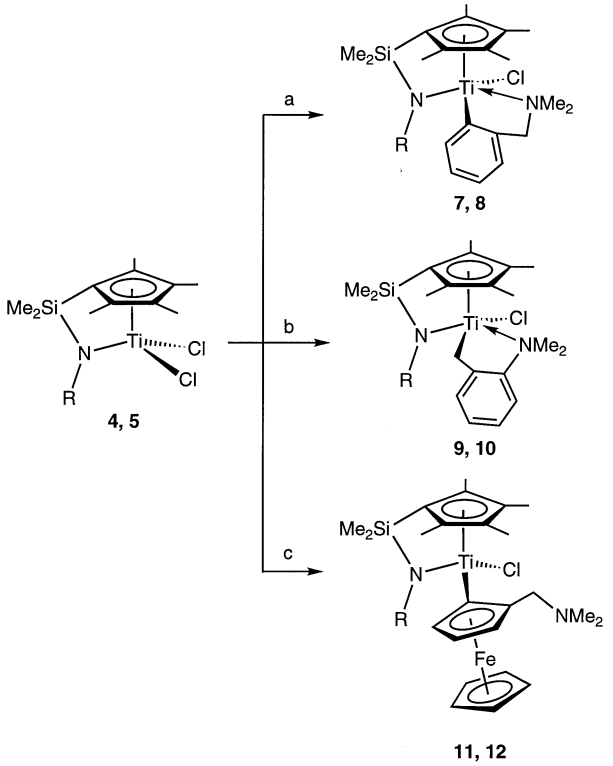
Yet another limitation to the complexation of the $C_5Me_4SiMe_2NR$ ligand was noted, when (2-pyridyl)methyl-amido as a "hetero-benzylamido" ligand was introduced. Previously we had synthesized the benzylamido complex $Ti(\eta^5{:}\eta^1\text{-}C_5Me_4SiMe_2NCH_2Ph)Cl_2$ (**5**) without any difficulty[1j]. However, after tedious workup, $Ti\{\eta^5{:}\eta^1\text{-}C_5Me_4SiMe_2NCH_2(C_5H_4N)\text{-}2\}Cl_2$ (**6**) was recovered only in 30% yield as orange crystals. The NMR data indicate the existence of a mirror plane and do not allow the distinction between a rigid intramolecular interaction of the pyridyl group at the titanium center and a fluxional complexation. However, in the the ^{1}H-NMR spectrum of **6** the *ortho* proton of the pyridyl group at $\delta = 9.40$ is remarkably shifted to low field compared to that in the ligand precursor $(C_5Me_4H)SiMe_2NHCH_2(C_5H_4N)$-2 ($\delta = 8.59$).

We successfully introduced each of the organyl ligands with an appended *N*,*N*-dimethylamino donor group 2-(*N*,*N*-dimethylaminomethyl)phenyl, 2-(*N*,*N*-dimethylamino)benzyl and {2-(*N*,*N*-dimethylamino)methyl}ferrocenyl by substituting one chloro ligand in **4** and **5** through salt metathesis. This type of bidentate organyl ligands were reported to be capable of stabilizing extremely sensitive monomeric, paramagnetic bis(cyclopentadienyl)titanium(III) derivatives[7]. Attempts to obtain compounds with two organyl groups failed so far, presumably due to the steric repulsion ot these bulky groups. As summarized in Scheme 2, the complexes **7**−**10** were obtained in good yields by the reaction in toluene of the dichloro precursors **4** and **5** with one equivalent of lithium{2-(*N*,*N*-dimethylaminomethyl)-phenyl} and lithium{2-(*N*,*N*-dimethylamino)benzyl}, respectively. The complexes **7** and **8** were isolated as yellow, **9** and **10** as red crystals, sensitive to air and moisture. They were fully characterized by NMR spectroscopy, mass spectral and elemental analysis.

Complexes **7**−**10** are soluble in toluene and THF, but only slightly soluble in aliphatic hydrocarbons. In contrast to the dichloro complexes **4** and **5**, the ^{1}H-NMR spectra reveal four signals for the methyl groups at the cyclopentadienyl ring as well as two for the methyl groups at the silicon due to the asymmetric titanium metal center. All methylene protons of the various CH_2 groups in **7**−**10** are diastereotopic, each giving rise to an AB spin pattern. The chemical shift differences between the two doublets for the CH_2NMe_2 group in **7** and **8** with $\Delta\delta > 1.1$ ppm are unusually large[8]. In **9** and **10**, the resonances due to the CH_2 group at titanium are centered around $\delta = 2.3$.

At room temperature, a single resonance is observed for the methyl groups of the *N*,*N*-dimethylamino group for

Scheme 2



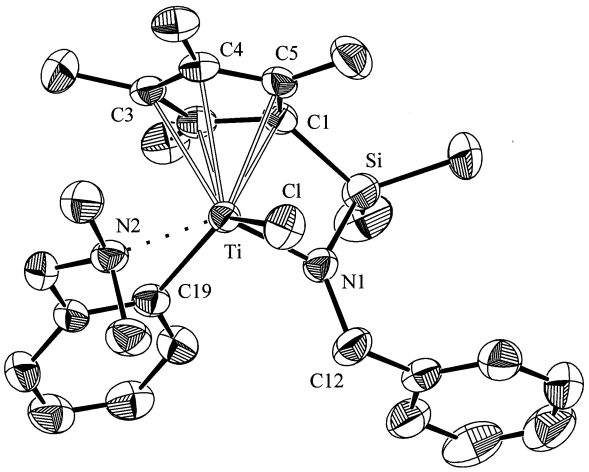
a) $Li\{C_6H_4(CH_2NMe_2)\text{-}2\}$; b) $Li\{CH_2C_6H_4NMe_2)\text{-}2\}$; c) $Li[\{\eta^5\text{-}C_5H_3(CH_2NMe_2)\text{-}2\}Fe(\eta^5\text{-}C_5H_5)]$

7−**10** in both the ^{1}H- and ^{13}C-NMR spectra. The diastereotopic methyl groups are rendered equivalent through the fast inversion at the nitrogen atom. This finding suggests that the *N*,*N*-dimethylamino function in these complexes is either not coordinated at the titanium or undergoes a rapid association−dissociation equilibration process on the NMR time scale. Temperature dependent ^{1}H-NMR measurements of **9** down to −50°C in $CDCl_3$ only resulted in slight changes in the chemical shifts and no decoalescence of the NMe_2 signal was observed. Based on what we have learned from the titanium complexes with the potentially tridentate ligand system $[C_5R'_4SiMe_2NCH_2CH_2NMe_2]^{2-}$ ($C_5R'_4 = C_5H_4$, C_5H_3tBu, C_5Me_4)[4a][4b], the latter scenario appears to be more probable, in particular in view of the crystal structures of **8** and **9** (vide infra). Likewise, a similar bonding situation can be found for the trichloro complexes of the type $Ti(\eta^5\text{-}C_5H_4CH_2CH_2NRR')Cl_3$[9a][9b].

According to single crystal X-ray structural analysis, the structures of **8** and **9** in the solid state unequivocally reveal the presence of a Ti−NMe_2 interaction (Figure 1 and 2). In the 2-(*N*,*N*-dimethylaminomethyl)phenyl derivative **8** the titanium−amino nitrogen bond length is 240.1(3) pm, whereas in the benzyl derivative **9** the corresponding bond distance is 254.0(1) pm. Nitrogen−titanium bond lengths in tetravalent titanium complexes range from 226 to 245 pm[9], estimated titanium−amine distances are in the range of 196 to 197 pm[10]. The bond distances observed in **8** and

9 are clearly longer than average. In Ti(η^5:η^1:η^1-$C_5H_4SiMe_2NCH_2CH_2NMe_2$)$Cl_2$ a bond length of 241.8(7) pm was observed[4b]. Interestingly, the titanium(III) complex (η^5-C_5H_5)Ti{($C_6H_4(CH_2NMe_2)$-2} shows Ti−N bond distances of 298.9(4) pm[11]. The coordination geometry for each complex **8** and **9** can be best described as square pyramidal, where the atoms N1, N2, Cl, and C15(C19) define a plane and the cyclopentadienyl ring resides perpendicular to this plane. In both **8** and **9**, the *N*,*N*-dimethylamino group adopts the coordination site trans to the amido ligand. This coordination avoids the amido and the benzyl/phenyl ligand from competing for the same metal-derived orbitals. The amido nitrogen atoms have almost planar geometry in agreement with all structurally characterized Ti(IV) complexes containing the linked amido−cyclopentadienyl ligand[12]. There is no α-agostic interaction for the benzyl group in **9**, as was observed in the crystal structure of Ti(η^5:η^1-$C_5Me_4SiMe_2NCH_2Ph$)$(CH_2Ph)_2$[1j]. Both the Ti−C15 of 217.1(2) pm and Ti−C15−C16 of 112.83(9)° are within the expected range.

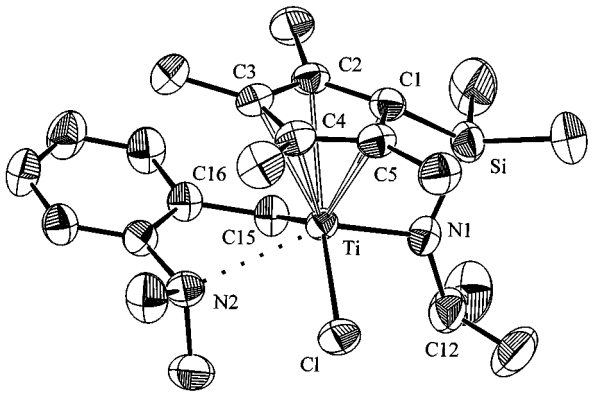
Figure 1. ORTEP diagram of the molecular structure of Ti(η^5:η^1-$C_5Me_4SiMe_2NCH_2Ph$){$C_6H_4(CH_2NMe_2)$-2}Cl (**8**); thermal ellipsoids are drawn at 50% probability level; hydrogen atoms are omitted for the sake of clarity[a]



[a] Selected bond distances [pm] and angle [°]; Cp denotes the cyclopentadienyl centroid: Ti−N1 194.1(3), Ti−Cl 238.40(11), Ti−N2 240.1(3), Ti−Cp 209.9(4), Ti−C1 229.9(4), Ti−C2 239.5(4), Ti−C3 253.1(4), Ti−C4 250.4(4), Ti−C5 237.3(4), Ti−C19 219.5(4), Cp−Ti−N1 105.5, Ti−N1−Si 106.3(2), Ti−N1−C12 123.5(3), Si−N1−C12 130.1(3), Cl−Ti−N1 90.3(1), Cl−Ti−N2 79.42(9), N1−Ti−N2 139.7(1).

The reaction of the dichloro complexes **4** and **5** with Li[{η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5)], generated in situ by lithiation of {2-(*N*,*N*-dimethylamino)methyl}ferrocene with *n*-butyllithium, gave the mono(ferrocenyl) derivative **11** and **12** as hydrocarbon-soluble, violet crystals in yields of 43 and 48%, respectively (Scheme 2). In the ^{1}H- and ^{13}C-NMR spectra of **11** and **12**, the asymmetry of the molecule can be easily detected by the occurence of diastereotopic resonances. The presence of the ferrocenyl moiety is obvious from the sharp singlet due to the η^5-C_5H_5 group at δ = 4.46 and 4.39 for **11** and **12**, respectively, as well as a set of three resonances around δ = 4.0 for the η^5-$C_5H_3(CH_2NMe_2)$-2 part. As in the case of **7**−**10**, only one

Figure 2. ORTEP diagram of the molecular structure of Ti(η^5:η^1-$C_5Me_4SiMe_2NiPr$){$CH_2C_6H_4(NMe_2)$-2}Cl (**9**); thermal ellipsoids are drawn at 50% probability level; hydrogen atoms are omitted for the sake of clarity[a]



[a] Selected bond distances (pm) and angle (°); Cp denotes the cyclopentadienyl centroid: Ti−N1 192.57(12), Ti−Cl 237.27(7), Ti−N2 254.03(13), Ti−Cp 208.4(2), Ti−C1 229.5(2), Ti−C2 241.4(2), Ti−C3 251.9(2), Ti−C4 247.5(2), Ti−C5 233.8(2), Ti−C15 217.2(2), Cp−Ti−N1 105.6, Ti−N1−Si 105.81(6), Ti−N1−C12 122.2(1), Si−N1−C12 131.3(1), Cl−Ti−N1 93.66(4), Cl−Ti−N2 78.39(3), N1−Ti−N2 139.35(5), Ti−C15−C16 112.83(9).

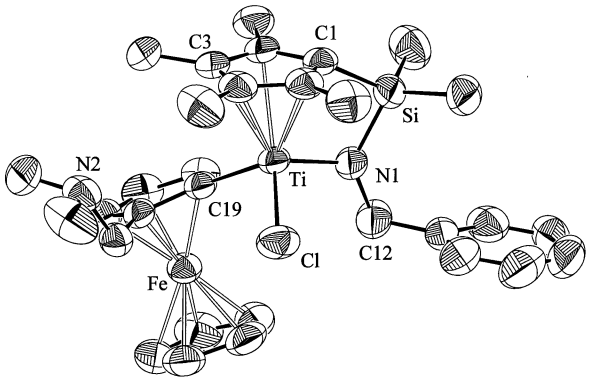
signal for the *N*,*N*-dimethylamino group is recorded in the ^{1}H- and ^{13}C-NMR spectra, excluding a rigid coordination of the *N*,*N*-dimethylamino group at the titanium center in solution.

The single crystal X-ray structure analysis of **12** (Figure 3) reveals a monodentate 2-(*N*,*N*-dimethylamino)ferrocenyl ligand in which the *N*,*N*-dimethylamino group is directed away from the titanium atom. Somewhat shorter Ti−N1, Ti−Cp and Ti−Cl distances as compared to **8** were found. The Ti−C19 distance of 210.5(3) pm is shorter. The bonding mode of **12** does not differ from that found in the titanocenes Ti(η^5-$C_5H_5)_2Cl_{(2-n)}$[{η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5)]$_n$ (n = 1, 2)[13], whereas in the half-sandwich complex Ti(η^5-C_5H_5)Cl_2[{η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5)][9c] a bidentate ferrocenyl ligand was observed. The well-known significantly stronger inductive effect of the ferrocenyl group in comparison to the phenyl group may be responsible for the bonding mode observed in **12**[14].

The intense color the ferrocenyl derivatives **11** and **12** exhibit are due to the presence of low-energy charge-transfer bands. For instance, the UV/Vis spectrum of a hexane solution of **12** exhibits absorptions at λ = 525 nm (ε = 340) and 406 nm (ε = 1270) besides a strong band at 225 nm (ε = $2.9 \cdot 10^4$). According to cyclovoltammetric studies in 1,2-dimethoxyethane solutions, these complexes show a rather complicated electrochemical behavior: One reversible oxidation wave at an electrode potential (E_p = 0.485 V for **11**, 0.524 V for **12**) can be attributed to the oxidation of the ferrocenyl moiety. Other oxidation waves observed are irreversible. Furthermore, the complexes **11** and **12** exhibited only irreversible reduction waves, with no reversible reduction of the titanium(IV) center being detectable.

Ethene polymerizations catalyzed by the complexes using methylaluminoxane (MAO) as cocatalyst were examined in

Figure 3. ORTEP diagram of the molecular structure of Ti(η^5:η^1-$C_5Me_4SiMe_2NCH_2Ph$)[{η^5-$C_5H_3(CH_2NMe_2)$-2}Fe(η^5-C_5H_5)]Cl (**12**); thermal ellipsoids are drawn at 50% probability level; hydrogen atoms are omitted for the sake of clarity[a]



[a] Selected bond distances [pm] and angle [°]; Cp denotes the cyclopentadienyl centroid: Ti−N1 191.3(3), Ti−Cl 227.61(11), Ti−Cp 204.4(3), Ti−C1 230.8(3), Ti−C2 236.9(3), Ti−C3 243.7(3), Ti−C4 240.6(3), Ti−C5 234.0(3), Ti−C19 210.5(3), Cp−Ti−N1 105.5, Ti−N1−Si 107.2(1), Ti−N1−C12 124.1(2), Si−N1−C12 128.7(2), Cl−Ti−N1 105.7(9).

a preliminary manner, as summarized in Table 1. Compared to the activity of the prototypical catalyst **1** with a *tert*-butylamido or **2** with the adamantyl, the isopropylamido substituent complex **4** is less active, whereas the benzylamido complex **5** exhibits the highest activity. The substitution of one chloro ligand by a bidentate organyl group influenced the activity in a different manner. **8** shows only moderately decreased activity, suggesting that the cationic active species formed by the action of MAO from both **5** and **8** are identical. However, the introduction of the ferrocenyl group as in **12** results in a catalyst that produces low yields of polyethene under the same conditions. The melting temperatures of the isolated polyethenes, as determined by DSC, range between 134 and 142°C.

Table 1[a]

Financial support of this work by the *Fonds der Chemischen Industrie*, the *Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie*, and *BASF AG* (Kunststofflaboratorium) is gratefully acknowledged. We thank the *Freiburger Materialforschungszentrum* (Prof. *R. Mülhaupt*) for DSC measurements and Mr. *O. Schiemann* and Prof. *C. Elschenbroich*, Marburg, for helping us with cyclovoltammetry. *WITCO GmbH*, Bergkamen, kindly supplied us with MAO solutions.

Experimental Section

General: All manipulations were performed under argon using standard Schlenk techniques. Solvents were purified, dried, and distilled under argon. − ^{1}H and ^{13}C NMR: Bruker AC 200 or Bruker AM 400. − Mass spectra: Finnigan 8230. − UV/Vis: Zeiss spectrophotometer DM4. − Elemental analyses: Microanalytical laboratory of the university. − The following reagents were synthesized using literature procedures: $C_5Me_4H(SiMe_2Cl)$[1c], $TiCl_3(THF)_3$[15], Ti(η^5:η^1-$C_5Me_4SiMe_2NCH_2Ph$)Cl_2[7], {2-[(*N*,*N*-dimethylamino)-methyl]phenyl}lithium[16], [2-(*N*,*N*-dimethylamino)benzyl]lithium[17], {2-[(*N*,*N*-dimethylamino)methyl)]ferrocenyl}lithium[17].

N-[Dimethyl(tetramethylcyclopentadienyl)silyl](1-adamantyl)-amine: (C_5Me_4H)$SiMe_2Cl$ (2.38 g, 11.1 mmol) was added to a suspension of Li(NHAd) (1.74 g, 11.1 mmol) in 70 ml of hexane at −78°C. The reaction mixture was allowed to warm to room temp. and stirred for 14 h. Filtration of the resulting suspension and removal of all volatiles in vacuo gave (C_5Me_4H)$SiMe_2NHAd$ as a yellow oil, yield 2.01 g (55%). − ^{1}H NMR (C_6D_6): δ = 0.27 (s, 6 H, $SiCH_3$), 1.06 (s, 1 H, NH), 1.66 (s, 6H, CCH_3), 1.74 (br d, 3 H, CH_2, Ad), 1.83 (s, 6H, CCH_3), 1.99 (br s, 3 H, CH, Ad), 2.04 (br d, 6 H, CH_2, Ad), 2.17 (br s, 3 H, CH, Ad), 2.92 (s, 1 H, C_5Me_4H). − ^{13}C{^{1}H} NMR (C_6D_6): δ = 4.0 ($SiCH_3$), 11.4, 15.0 (CCH_3), 30.5 (3-Ad), 36.7 (4-Ad), 47.6 (2-Ad), 53.9, 57.2 (*ipso*-Ad, C_5Me_4H at Si), 133.3, 135.4 (C_5Me_4).

Dichloro{η^5:η^1-N-dimethyl(tetramethylcyclopentadienyl)silyl](1-adamantyl)amido}titanium (**2**)**:** Crude $Li_2(C_5Me_4SiMe_2NAd)$ (1.41 g, 4.1 mmol), obtained by deprotonation of (C_5Me_4H)$SiMe_2NHAd$ with 2 equiv. of Li*n*Bu in hexane, was dissolved in 20 ml of THF and added dropwise to a suspension of $TiCl_3(THF)_3$ (1.53 g, 4.1 mmol) in 40 ml of toluene at −60°C. After warming to room temp., the green reaction mixture was stirred for 2 h and treated with $PbCl_2$ (1.15 g, 4.1 mmol). After stirring for 12 h, the solvent was removed under vacuum and the residue was extracted with 50 ml of a toluene/hexane mixture (2:1). Filtration of the extracts, followed by concentrating the filtrate and cooling to −20°C afforded in several crops Ti(η^5:η^1-$C_5Me_4SiMe_2NAd$)Cl_2 as yellow crystals, yield 0.57 g (31%); by-product: Ti(η^5:η^1-C_5Me_4H)Cl_3. − ^{1}H NMR (C_6D_6): δ = 0.61 (s, 6 H, $SiCH_3$), 1.64 (br dd, 6 H, CH_2, 4-Ad), 2.09 (br s, 3 H, CH, 3-Ad), 2.14, 2.16 (s, 6H, CCH_3), 2.22 (br d, 6 H, CH_2, 2-Ad). − ^{13}C{^{1}H} NMR (C_6D_6): δ = 5.9 ($SiCH_3$), 13.1, 16.2 (CCH_3), 30.7 (3-Ad), 36.3 (4-Ad), 45.6 (2-Ad), 63.8 (*ipso*-Ad), 104.1 (C_5Me_4 at Si), 137.9, 140.6 (CCH_3). − EI MS; *m*/*z* (%): 445 (88) [M^+], 414 (31) [M^+ − Me], 390 (33) [M^+ − C_4H_7], 356 (100) [M^+ − C_4H_9Cl], 324 (27) [M^+ − $C_6H_6Cl_2$], 297 (21) [$C_{11}H_{19}Cl_2SiTi^+$], 237 (27) [$C_5H_{17}Cl_2Ti^+$], 197 (35) [$C_{11}H_{23}NSi^+$], 159 (33) [$C_{10}H_{11}Si^+$], 149 [$C_9H_{13}Si^+$]. − $C_{21}H_{33}Cl_2NSiTi$ (446.4): calcd. C 56.51, H 7.45, N 3.14; found C 55.29, H 7.55, N 4.38.

N-[Dimethyl(tetramethylcyclopentadienyl)silyl](1,1,3,3-tetramethylbutyl)amine: (C_5Me_4H)$SiMe_2Cl$ (3.00 g, 14.0 mmol) was added to a suspension of Li($NHCMe_2CH_2tBu$) (1.89 g, 14.0 mmol) in 60 ml of hexane at −78°C. The reaction mixture was allowed to warm to room temp. and stirred for 14 h. Filtration of the resulting suspension and removal of all volatiles in vacuo gave crude (C_5Me_4H)$SiMe_2NHCMe_2CH_2tBu$ which was distilled at 95°C and $8\cdot10^{-3}$ mbar to give a yellow oil, yield 2.15 g (50%). − ^{1}H NMR (C_6D_6): δ = 0.34 (s, 6 H, $SiCH_3$), 0.51 (s, 1 H, NH), 1.08 [s, 9 H, $C(CH_3)_3$], 1.24 [s, 6 H, $C(CH_3)_2$], 1.42 (s, 2 H, CH_2), 1.81 (s, 6 H, CCH_3), 1.94 (s, 6 H, CCH_3), 2.80 (s, 1 H, C_5Me_4H). − ^{13}C{^{1}H} NMR (C_6D_6): δ = 2.9 ($SiCH_3$), 11.4, 14.9 (CCH_3), 31.9 [$C(CH_3)_3$,

$C(CH_3)_3$], 33.6 [$C(CH_3)_2$], 53.2, 56.8 [$C(CH_3)_2$, C_5Me_4H at Si], 58.9 (CH_2), 133.4, 135.3 (CCH_3). − EI MS; *m/z* (%): 307 (27) [M^+], 236 (15) [$C_{14}H_{26}NSi^+$], 186 (100) [$C_{10}H_{24}NSi^+$], 121 (10) [$C_9H_{13}^+$], 114 (13) [$C_8H_{18}^+$], 105 (11) [$C_6H_9^+$], 74 (42) [$C_2H_8NSi^+$], 59 (10) [$C_2H_7Si^+$], 55 (5) [$C_2H_3Si^+$]. − $C_{19}H_{37}NSi$ (307.6): calcd. C 74.19, H 12.12, N 4.55; found C 73.72, H 12.12, N 5.03.

Dichloro {η⁵:η¹-N-dimethyl(tetramethylcyclopentadienyl)-silyl](1,1,3,3-tetramethylbutyl)amido}titanium (**3**): Crude $Li_2(C_5Me_4SiMe_2NCMe_2CH_2tBu)$ (1.86 g, 5.8 mmol), obtained by deprotonation of $(C_5Me_4H)SiMe_2NHCMe_2CH_2tBu$ with 2 equiv. of Li*n*Bu in hexane, was dissolved in 40 ml of THF and added dropwise to a suspension of $TiCl_3(THF)_3$ (2.16 g, 5.8 mmol) in 30 ml of toluene at −60°C. After warming to room temp., the green reaction mixture was stirred for 2 h and treated with $PbCl_2$ (1.61 g, 5.8 mmol). After stirring for 12 h, the solvent was removed under vacuum and the residue was extracted with 80 ml of a toluene/hexane mixture (2:1). Filtration of the extracts, followed by concentrating the filtrate and cooling to −20°C afforded $Ti(\eta^5{:}\eta^1\text{-}C_5Me_4SiMe_2NCMe_2CH_2tBu)Cl_2$ as yellow crystals; yield 0.47 g (19%). − ^{1}H NMR (C_6D_6): δ = 0.62 (s, 6 H, $SiCH_3$), 1.10 [s, 9 H, $C(CH_3)_3$], 1.75 [s, 6 H, $C(CH_3)_2$], 1.87 (s , 2 H, CH_2), 2.13 (s, 6 H, CCH_3), 2.14 (s, 6 H, CCH_3). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 6.0 ($SiCH_3$), 13.0, 16.2 (CCH_3), 31.7 [$C(CH_3)_3$], 31.7 [$C(CH_3)_2$], 31.8 [$C(CH_3)_3$], 57.3 (CH_2), 67.0 [$C(CH_3)_2$], 104.1 (C_5Me_4 at Si), 138.2, 140.5 (CCH_3). − EI MS; *m/z* (%): 408 (7) [M^+ − Me], 352 (100) [M^+ − CH_2CMe_3], 296 (17) [M^+ − $NCMe_2CH_2CMe_3$], 261 (4) [M^+ − $NCMe_2CH_2CMe_3$, − Cl], 243 (3) [$C_{15}H_{21}NSi^+$], 203 (2) [$C_{12}H_{17}NSi^+$], 177 (9) [$C_{11}H_{17}Si^+$], 161 (6) [$C_{10}H_{13}Si^+$], 148 (4) [$C_8H_{12}Si^+$], 119 (2) [$C_9H_{11}^+$], 57 (16) [$C_2H_5Si^+$]. − $C_{19}H_{35}Cl_2NSiTi$ (424.4): calcd. C 53.78, H 8.31, N 3.30; found C 52.76, H 8.40, N 5.06.

N-[Dimethyl(tetramethylcyclopentadienyl)silyl]isopropylamine: $(C_5Me_4H)SiMe_2Cl$ (4.83 g, 22.5 mmol) was added to a suspension of Li(NH*i*Pr) (1.46 g, 22.5 mmol) in 60 ml of hexane at −78°C. The reaction mixture was allowed to warm to room temp. and stirred for 14 h. Filtration of the resulting suspension and removal of all volatiles in vacuo gave crude $(C_5Me_4H)SiMe_2NHiPr$ which was distilled at 70°C and $8\cdot10^{-3}$ mbar to give a yellow oil; yield 4.30 g (80%). − ^{1}H NMR ($CDCl_3$): δ = 0.01 (s, 6 H, $SiCH_3$), 0.30 (s, 1 H, NH), 1.05 (d, $^3J_{HH}$ = 7 Hz, 6 H, $CHCH_3$), 1.83 (s, 6 H, CCH_3), 1.98 (s, 6 H, CCH_3), 2.88 (s, 1 H, C_5Me_4H), 3.04 (sept, $^3J_{HH}$ = 7 Hz, 1 H, $CHCH_3$). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = -1.6 ($SiCH_3$), 11.1, 14.5 (CCH_3), 27.9 ($CHCH_3$), 43.2 ($CHCH_3$), 56.9 (C_5Me_4H at Si), 133.0, 135.5, (CCH_3). − EI MS; *m/z* (%): 237 (16) [M^+], 196 (3) [MH_2^+ − C_3H_7], 179 (2) [$C_{11}H_{20}Si^+$], 164 (100) [$C_5H_{15}NSi^+$], 73 (9) [$C_2H_7NSi^+$]. − $C_{14}H_{27}NSi$ (237.5): calcd C 70.81, H 11.46, N 5.90; found C 70.77, H 11.33, N 6.04.

Dichloro {η⁵:η¹-N-dimethyl(tetamethylcyclopentadienyl)silyl]-isopropylamido}titanium (**4**): Crude $Li_2(C_5Me_4SiMe_2NiPr)$ (3.75 g, 15.0 mmol), obtained by deprotonation of $(C_5Me_4H)SiMe_2NHiPr$ with 2 equiv. of Li*n*Bu in hexane, was dissolved in 40 ml of THF and added dropwise to a suspension of $TiCl_3(THF)_3$ (5.57 g, 15.0 mmol) in 80 ml of toluene at −60°C. After warming to room temp., the green reaction mixture was stirred for 2 h and treated with $PbCl_2$ (4.18 g, 15.0 mmol). After stirring for 12 h, the solvent was removed under vacuum and the residue was extracted with 100 ml of a toluene/hexane mixture (2:1). Filtration of the extracts, followed by concentrating the filtrate and cooling to −20°C afforded $Ti(\eta^5{:}\eta^1\text{-}C_5Me_4SiMe_2NiPr)Cl_2$ as yellow crystals, yield 3.75 g (70%). − ^{1}H NMR (C_6D_6): δ = 0.47 (s, 6 H, $SiCH_3$), 1.13 (d, $^3J_{HH}$ = 6 Hz, 6 H, $CHCH_3$), 2.09 (s, 6 H, CCH_3), 2.10 (s, 6 H, CCH_3), 5.45 (sept, $^3J_{HH}$ = 6 Hz, 1 H , $CHCH_3$). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 4.7 ($SiCH_3$), 12.9, 16.0 (CCH_3), 24.0 ($CHCH_3$), 55.6 ($CHCH_3$), 102.0 (C_5Me_4 at Si), 135.8, 140.1 (CCH_3). − EI MS; *m/z* (%): 353 (10) [M^+], 338 (100) [M^+ − Me], 318 (2) [M^+ − Cl], 296 (36) [M^+ − N*i*Pr], 283 (5) [M^+ − 2Cl], 204 (4) [$C_{12}H_{18}NSi^+$], 177 (10) [$C_{11}H_{17}Si^+$], 163 (4) [$C_{10}H_{15}Si^+$], 119 (3) [$C_9H_{11}^+$], 97 (2) [$C_4H_7NSi^+$], 73 (2) [$C_2H_7NSi^+$]. − $C_{14}H_{25}Cl_2NSiTi$ (354.2): calcd. Crystal Structure Determination of **8**, **9 and 12**: X-ray data were collected with an Enraf-Nonius CAD4 diffractometer at room temperature by using Mo-K_α radiation and ω scans. The structures were solved by direct methods (SHELXS-86) and refined by full-matrix least squares (SHELXL-93) against F^2. Non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located in difference Fourier maps and refined isotropically, except for **12** where the hydrogen atoms of the methyl groups are included in calculated positions. For **8** and **9**, isotropic temperature factors were refined. Crystallographic data are summarized in Table 2[18].

Polymerization: A 0.5 l Büchi reactor was charged with 200 ml of toluene and at constant ethene pressure of 3 bar (c = 0.432 mol/l) a mixture of 1.25 ml of catalyst (c = 4 mmol/l) and 1.5 ml of MAO ($c \approx$ 1.658 mol/l) was added at the pressure of 3.5 bar and stirred for 2 h at 23°C. After the reaction mixture was drained into 0.5 l of methanol acidified with 10 ml of concentrated aqueous HCl, the polymer was collected by filtration, washed with methanol, and dried to constant weight. Melting points were determined by DSC.

Keywords: Alkylamines / Arylamines / Zinc / Cadmium / Mercury / X-ray diffraction

Homoleptic intramolecularly stabilized organozinc, -cadmium, and -mercury compounds MR_2, with R bearing an amino function, have been synthesized from the corresponding metal dichlorides MCl_2 and the lithium salts $LiC_6H_4CH_2NEt_2$-2 (**1**), $LiC_6H_3(CH_2NMe_2)_2$-2,6 (**2**), $LiC_6H_3(CH_2NEt_2)_2$-2,6 (**3**), $(LiCH_2CH_2CH_2)_2NMe$ (**4**), and $LiCH_2CH_2CH_2NC_5H_{10}$ (**5**). The crystal structures of $Hg(C_6H_4CH_2NEt_2\text{-}2)_2$ (**1c**), $[M(CH_2CH_2CH_2)_2NMe]_2$ [M = Zn (**4a**), Hg (**4c**)], and of $M(CH_2CH_2CH_2NC_5H_{10})_2$ [M = Zn (**5a**), Cd (**5b**)] have been determined by X-ray diffraction. **4a** and **4c** form dimers with an unusual coordination number (three) of the central metal.

Introduction

Diorganometal compounds of the group 12 elements are of increasing interest in connection with the development of MOVPE techniques (**M**etal **O**rganic **V**apor **P**hase **E**pitaxy) for the generation of type II-VI semiconductors. In particular, the dimethyl or diethyl derivatives of zinc, cadmium, and mercury have been used as precursors[1a][1b][1c]. Unfortunately, these compounds are highly water sensitive and, with the exception of the zinc compounds, extremely toxic. It was to be expected that the use of *N*-donor functionalized ligands, which are able to coordinate intramolecularly with the metal center by formation of chelate rings, should result in a considerable increase in the stability of such organometallic derivatives. Although numerous dialkyl-metal compounds of the group 12 elements are known which are intermolecularly stabilized by mono-, bi-, and tridentate amines, e.g. by NMe_3, NEt_3, py[2], 2,2′-bipy[2][3][4][5][6][7][8][9][10], 1,10-phen[2][3][4][10], tmeda[6][7][11], *N*,*N*,*N*′,*N*′-tetraethylethylenediamine (teeda)[2][4], (−)-sparteine[12], and triazines $(RNCH_2)_3$ (R = Me, Et, *i*Pr)[13], only a few intramolecularly *N*-stabilized species are known. $Zn(CH_2CH_2CH_2NMe_2)_2$, synthesized by Boersma et al. in 1978, was the first and, to date, the best investigated compound of this type[14][15][16]. The corresponding cadmium species and the corresponding diethylamino derivative of zinc were prepared by Thiele et al.[16], the diorganozinc, -cadmium, and -mercury compounds bearing 2-$Me_2NC_6H_4CH_2$- and/or 2-$Me_2NCH_2C_6H_4$- as arylamino ligands by Atwood et al.[17], van Koten et al.[18], and O′Brien et al.[19]. Deacon et al. succeeded in synthesizing bis[2-(pyridin-2′-yl)phenyl]mercury and bis[2-(pyrazol-1′-yl)phenyl]-mercury[20]. A comprehensive paper concerning the structure of organomercury compounds and their secondary interactions has been published by Kuz′mina and Struchkov[21].

In this paper we present some interesting new homoleptic compounds of the group 12 elements with alkyl- and arylamine ligands.

Results and Discussion

1. Intramolecularly Stabilized Arylamino Compounds

The reaction of two equivalents of $LiC_6H_4CH_2NEt_2$-2 (**1**)[22][23][24][25], $LiC_6H_3(CH_2NMe_2)_2$-2,6 (**2**), or $LiC_6H_3(CH_2NEt_2)_2$-2,6 (**3**)[22][26] with one equivalent of MCl_2 (M = Zn, Cd, or Hg) gave the corresponding diorganozinc compounds **1a**, **2a**, **3a**, the diorganocadmium compounds **1b, 3b**, and the diorganomercury compounds **1c**, **2c**, **3c** in yields of 64 to 85% (Scheme 1). The lower yields obtained for **1b**, **3b**, and **2c** were caused by some decomposition accompanied by precipitation of metallic cadmium or mercury. With the exception of **3c**, which is a highly viscous liquid, all other derivatives are colorless solids at room temperature.

Within each group of compounds, the ^{1}H-NMR signal of the methyl protons and the ^{13}C-NMR signal of the phenyl carbon atom bound to the metal center shift to lower fields on going from the zinc to the mercury species. In the spectra of the cadmium and mercury derivatives **1b**, **2c**, and **3c**, ^{1}H- and ^{13}C-metal coupling was observed. The coupling constants of **1b** [$^3J(^1H,^{111/113}Cd)$ = 26, 19 Hz and $^{2,3}J(^{13}C,^{113}Cd)$ = 20, 12 Hz] are in the expected range[27][28]. The coupling constants of **3c** [$^{1,2,3}J(^{13}C,^{199}Hg)$ = 714, 22, 42 Hz] demonstrate that the usual relationship $^1J > {}^3J > {}^2J$ is also valid for the spin pair ^{13}C,^{199}Hg[29], while the absolute values ^2J and ^3J of **3c** and ^3J of **2c** (40.5 Hz) are somewhat smaller than those given in the literature[26][27]. The appearance of one NMR signal for both of the amino functions of each ligand in **2a**−**2c** and **3a**−**3c** indicates a dynamic behaviour of these complexes in solution. Selected NMR data of the arylamino compounds are summarized in Table 1.

The mass spectra of **1a**, **1b**, **1c**, **2c**, **3a**, and **3c** show the peak for the corresponding molecular ion, whereas the spectra of the zinc and cadmium species **2a** and **3b** show only ligand fragments.

Crystallization of **1c** from Et_2O/*n*-pentane afforded crystals suitable for X-ray structure determination. The molecular structure of **1c** is depicted in Figure 1a, and selected bond lengths and bond angles are listed in Table 2. The structure may be compared with that of the corresponding methylamine derivatives $M(C_6H_4CH_2NMe_2\text{-}2)_2$ (M = Cd[19] and Hg[17]). The angle C1−M−C1′ becomes larger with increasing radius of the central metal. This angle is 174° in $Cd(C_6H_4CH_2NMe_2)_2$, exactly 180° in $Hg(C_6H_4CH_2NMe_2)_2$ and nearly 180° in **1c** [176.7(1)°]. The same trend is observed for the angle N−M−N′ {$M(C_6H_4CH_2NMe_2)_2$: M = Cd (116.12°), Hg (180°); **1c** [151.2(2)°]}. Accordingly, the geometric arrangement of the ligands around the metal atom changes from a distorted trigonal bipyramid with one vacancy in the equatorial plane for $Cd(C_6H_4CH_2NMe_2)_2$, to a square planar system in **1c** and $Hg(C_6H_4CH_2NMe_2)_2$. The bond distance Hg−C1 in **1c** [206.9(4) pm] is similar to that in $Hg(C_6H_4CH_2NMe_2)_2$ (210 pm) and other mercury diaryl compounds[20][21][30][31]. The Hg−N distance [294.2(3) pm] is only slightly longer than that in the *N*-methyl derivative (289 pm), but it is still in the same range as other comparable Hg−N interactions[20][21][32]. The Hg···Hg distance [349.3(3) pm] in **1c** is remarkably short at just over twice the van der Waals radius of mercury (173 pm[32]). Figure 1b shows that two molecules of **1c** are situated very close to one another, resulting in a slight bend of the phenyl groups out of the phenylmercury plane away from the Hg···Hg axis. One of the two ethyl substituents at each nitrogen atom avoids close contact by being situated in the same direction, whereas the second ethyl group remains in the plane. A similar effect

Symmetry transformations used to generate equivalent atoms: ′: $-x$, $1/2-y$, z. − ″: $1/4-y$, $1/4+x$, $5/4-z$.

was observed in the analogous compound $Cd(C_6H_4CH_2NMe_2)_2$ with a Cd···Cd distance of 317.6 pm and this is probably caused by weak crystal packing forces[19]. The arrangement of the molecules in terms of the metal···metal axis differs: it is staggered for **1c** with an angle of 90° and eclipsed for the cadmium derivative. Surprisingly, this phenomenon of crystal packing with short metal···metal contacts was not detected in $Hg(C_6H_4CH_2NMe_2)_2$[17].

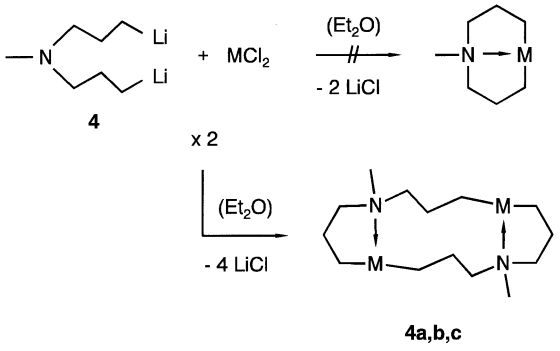
Unfortunately, it was not possible to obtain crystals suitable for X-ray investigations of **2a**, **2c**, **3a**, **3b**, and **3c** in which the appropriate metal is bonded to tridentate amino ligands. However, we also solved the crystal and molecular structure of the starting material $LiC_6H_3(CH_2NEt_2)_2$-2,6 (**3**)[33] which has recently been published by Hey-Hawkins et al.[34].

2. Intramolecularly Stabilized Alkylamino Compounds

We used tridentate bis(3-lithiopropyl)methylamine, $(LiCH_2CH_2CH_2)_2NMe$[35] (**4**), and bidentate 3-(*N*-piperidino)propyllithium, $LiCH_2CH_2CH_2NC_5H_{10}$[36] (**5**), for the synthesis of compounds **4a** to **4c**, and **5a** to **5c**.

The 5,13-diaza-5,13-dimethyl-1,9-dimetallacyclohexadecanes **4a**−**c** were prepared by treating equimolar amounts of MCl_2 (M = Zn, Cd, Hg) with $(LiCH_2CH_2CH_2)_2NMe$ in Et_2O at ambient temperatures (Scheme 2). The colorless and moisture sensitive compounds were isolated with yields of 75% for the Zn compound **4a** and 72% for the Hg derivative **4c**. The yield of the Cd species **4b** was only 49% due to decomposition during the reaction and precipitation of metallic cadmium. As indicated by the mass spectra of **4b** and **4c**, and as proved by X-ray structural analysis of **4a** and **4c**, the compounds **4a** to **4c** form dimers consisting of sixteen-membered rings.

Scheme 2



M = Zn **4a**, Cd **4b**, Hg **4c**

Treating MCl_2 (M = Zn, Cd, Hg) with a twofold amount of $Li(CH_2)_3NC_5H_{10}$ in Et_2O produced the bis(3-*N*-piperidino)propylmetal compounds **5a** to **5c** (Scheme 3) with yields of 76%, 65%, and 58%, respectively. The reaction with $HgCl_2$ was accompanied by the elimination of some metallic mercury. **5a** and **5b** are colorless crystalline solids which melt at 80°C or decompose above 90°C, respectively. **5b** changes color to yellow on exposure to light. **5c** forms colorless prisms at −20°C, but is a liquid at room temperature. The mass spectra of the three compounds show the molecular ion peak, but only with very low intensity. The first step in the fragmentation of **5b** and **5c** is the separation of the ligand as a whole, a process which could not be observed for **5a**.

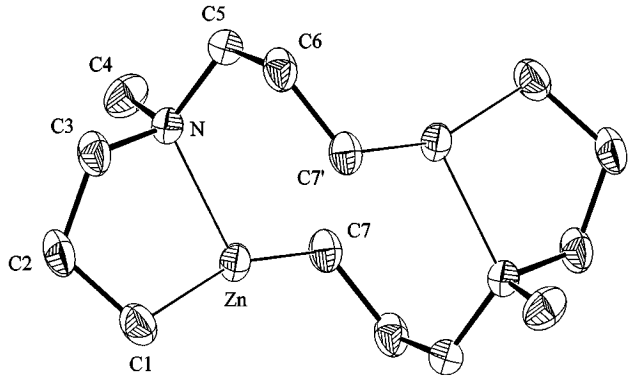

Figure 3. ORTEP plot of the molecular structure of **4c**

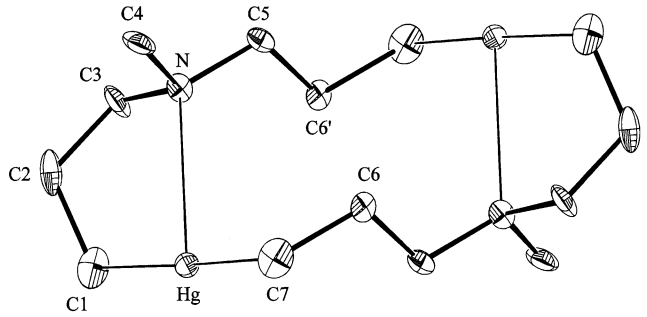

In a similar way to other homoleptic dialkyl complexes of the group 12 elements[13][37], comparison of the ^{1}H- and ^{13}C-NMR spectra of the alkylamino compounds shows a shift in the signals due to the metal-bonded CH_2 groups to lower fields on going from the zinc to the appropriate mercury derivative (Table 3).The NMR spectra of **4a, 4b** and **4c** show only one signal for the two different methylene groups bonded to the metal centers indicating a dynamic behaviour in solution. X-ray structure determinations performed on the metallacyclohexadecanes **4a** and **4c** (suitable crystals were obtained from *n*-pentane) prove the dimeric nature of the molecules in the solid state (Figures 2 and 3, Table 4). Each of the two metal atoms is coordinated to two carbon atoms belonging to different ligand molecules and one nitrogen atom. The sum of the angles C1−M−C7, C1−M−N, and C7−M−N is 356° for **4a** and **4c**, and this indicates that the four atoms essentially lie in a plane with a

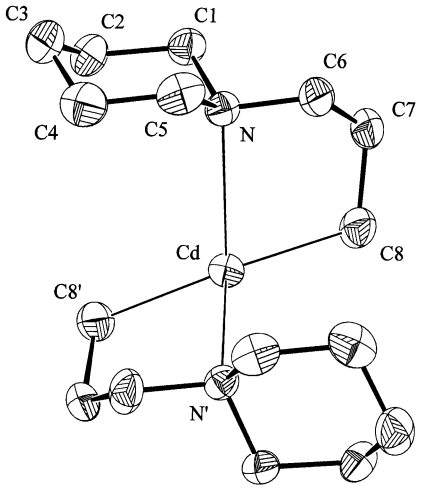
Figure 5. PLUTON plot of the molecular structure of **5b**



more or less T-shaped ligand arrangement around the metal atoms. Thus, the linear arrangement of the ligands usually found in dialkylzinc and -mercury compounds is not changed to a significant extent by the additional coordination of the nitrogen atom, indicating only a weak interaction [C1−Zn−C7 156.38(13)°; C1−Hg−C7 176.7(5)°]. This agrees with the relatively long M−N distances [Zn−N 221.6(2) pm; Hg−N 277.4(11) pm]. The M−C1 distances [Zn−C1 197.9(3) pm; Hg−C1 209(2) pm] are in the normal range for comparable complexes[9][11][12][15][31][38][39]. The triple coordination of the metal atoms is extremely unusual for group-12 elements.

The molecular structures of **5a** and **5b** (crystals suitable for X-ray structural analysis were obtained by crystallization from *n*-pentane) show the metal atom to be tetracoordinated by the binding methylene carbon and the nitrogen atom of each of the two ligands (Figures 4 and 5, Table 5). The intramolecular stabilization of the metal center by the nitrogen atom seems to be as weak in **5a** and **5b** as it was in the case of the metallacyclohexadecanes **4a** and **4c** because the distances Zn−N [240.4(2) pm] and Cd−N [264.2(2) pm] are also quite long. Furthermore, as in **4a** and **4c** and also in the comparable tetracoordinated $Zn(CH_2CH_2CH_2NMe_2)_2$[15], the C8−M−C8′ angle is closer to 180° [**5a** Zn: 155.5(2)°; **5b** Cd: 166.2(2)°] than to a tetrahedral angle. Similar long M−N distances and large C8−M−C8′angles are known in some intermolecular amine-stabilized dialkylmetal species, e.g. $[M(CH_2CMe_3)_2{\cdot}tmeda]$ (M = Zn: 241.1 pm, 148°; M = Cd: 264.2 pm, 157°)[11]. In a similar way to $Cd(C_6H_4CH_2NMe_2)_2$[19], comparable donor stabilized cadmium[11][40] and zinc complexes $Zn(CH_2CH_2CH_2X)_2$ (X = NMe_2, PPh_2, OMe, SMe)[15][38][41], the coordination sphere around the metal center is more accurately described as a distorted trigonal bipyramid with one vacancy in the equatorial plane than as a tetrahedron. The piperidyl rings in **5a** and **5b** have a chair conformation turning away from the metal center.

Conclusion

Aryl- and alkylamino metal compounds of the group-12 elements have been synthesized and the molecular structure of some representative examples investigated. In comparison to the linear structure of pure diaryl or dialkyl compounds of group-12 elements, the intramolecular metal−nitrogen coordination through chelate ring formation has only a weak influence on the geometry of the molecules, a situation which is similar to that in intermolecularly *N*-stabilized diorgano metal derivatives of these elements.

Experimental Section

1. General: The starting anhydrous metal chlorides (Merck) were dried under vacuum and stored under an argon atmosphere. The aryl- and alkylamine ligand systems and their lithium compounds (**1** to **5**) were prepared using known procedures. All reactions yielding organometallic species were performed using standard Schlenk techniques under dry argon and in dry solvents distilled from sodium/benzophenone. − Melting points and thermal decomposition temperatures were determined in sealed capillaries under argon with an HWG-SG 2000, HWS Mainz, and are uncorrected. − NMR (Bruker ARX 200): ^1H NMR (200 MHz): ext. TMS; $^{13}C\{^1H\}$ NMR (50.26 MHz): ext. TMS; ^{113}Cd NMR (400 MHz): ext. $Cd(CH_3)_2$. − MS (Varian MAT 311 A) analyses were carried out using electron impact ionisation with 70 eV. − Elemental analyses: Perkin-Elmer Series II CHNS/O analyser 2400.

2. Crystal Structure Determinations: Crystals of **1c**, **4a**, **4c**, **5a**, and **5b** were mounted on glass fibers and transferred to an Enraf-Nonius CAD4 four circle diffractometer (Mo-K_α radiation) equipped with a low temperature device. Data for all compounds were collected with ω-2θ scans. Intensity data were monitored after every 200 reflections through the measurement of three standard reflections. Raw data were corrected for Lorentz, polarization, and for absorption effects (DIFABS)[42]. The structures were solved using Direct Methods (SHELXS-86)[43] and the refinement of the molecules was performed using difference-Fourier methods (SHELXL-93)[44]. The older program, SHELX-76[45], was also used to prepare the data for DIFABS. All non-hydrogen atoms were refined anisotropically, whereas hydrogen atoms were placed at calculated positions with d_{CH} = 98 pm and U_{iso} = 8 pm^2. Molecular plots were obtained using the programs ZORTEP[46] and PLUTON[47]. Further details on crystals, data collection, and refinement are listed in Table 6.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary communication no. CCDC-100487. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: int code +44(0)1223/336-033, e-mail: deposit@chemcrys.cam.ac.uk).

3. Synthesis of the Complexes

Bis(2-diethylaminomethylphenyl)zinc (**1a**): 2-Diethylaminomethylphenyllithium (**1**) (4.06 g, 24.0 mmol) was dissolved in Et_2O (100 ml) and a solution of $ZnCl_2$ (1.64 g, 12.0 mmol) in Et_2O (40 ml) was added dropwise. The mixture became pale orange, was warmed up slightly, and a white precipitate formed. After stirring for 14 h at room temperature the Et_2O was removed in vacuo. The remain-

ing pale yellow solid was suspended in *n*-hexane. The reaction mixture was filtered through a fine glass frit and the filtrate volume was reduced to about 50 ml. Storing at −20°C yielded 3.98 g (85%) of colorless crystalline **1a**, m.p. 40°C. – ^{1}H NMR (C_6D_6): δ = 0.64 (t, ^3J = 7.2 Hz, CH_3), 2.52 (q, ^3J = 7.2 Hz, CH_3CH_2), 3.52 (s, CH_2C_{aryl}), 7.10-8.02 (m, $C_{aryl}H$). – ^{13}C NMR (C_6D_6): δ = 8.75 (CH_3), 45.25 (CH_3CH_2), 61.79 (CH_2C_{aryl}), 125.1 (*C*-3), 126.16 (*C*-5), 126.22 (*C*-4), 139.38 (*C*-6), 146.73 (*C*-2), 157.75 (*C*-1). – MS; *m/z* (%): 388 (5) [M(^{64}Zn)$^+$], 316 (8) [M$^+$ − NEt_2], 226 (8) [$ZnC_6H_4CH_2NEt_2^+$], 162 (89) [$C_6H_4CH_2NEt_2^+$], 148 (58) [$C_6H_4CH_2NEtMe^+$], 91 (100) [$C_7H_7^+$], and others. – $C_{22}H_{32}N_2Zn$ (389.90): calcd. C 67.77, H 8.27, N 7.18; found C 67.60, H 8.06, N 7.41.

Bis(2-diethylaminomethylphenyl)cadmium (**1b**): In a similar way to **1a**, $CdCl_2$ (2.93 g, 16 mmol) and **1** (5.41 g, 32 mmol) yielded 4.12 g (59%) of colorless crystalline **1b**, m.p. 62°C. Although the mixture was protected from light during the reaction, the formation of cadmium metal was observed. – ^{1}H NMR (C_6D_6): δ = 0.77 (t, ^3J = 7.2 Hz, CH_3), 2.43 (q, ^3J = 7.2 Hz, CH_3CH_2), 3.44 (s, CH_2C_{aryl}), 7.09-7.40 (m, $C_{aryl}H$), 7.94 [dd, sat.,^3J = 6.6 Hz, ^4J = 1.3 Hz, ^3J(^{1}H,$^{111/113}$Cd) = 26/19 Hz, C-6*H*]. – ^{13}C NMR (C_6D_6): δ = 10.33 (CH_3), 45.90 (CH_3CH_2), 62.07 [sat., ^3J(^{13}C,^{113}Cd) = 12 Hz, CH_2C_{aryl}], 126.31 (*C*-3), 126.40 (*C*-5), 126.91 (*C*-4), 140.30 [sat.,^2J(^{13}C,^{113}Cd) = 20 Hz, *C*-6], 147.21 (*C*-2), 160.72 (*C*-1). – ^{113}Cd NMR (C_6D_6): δ = −163.10. – MS; *m/z* (%): 439 (3) [M(^{114}Cd)$^+$], 365 (7) [M$^+$ − NEt_2], 274 (8) [$CdC_6H_4NEt_2^+$], 114 (5) [Cd$^+$], and others, as for **1a**. – $C_{22}H_{32}CdN_2$ (436.91): calcd. C 60.48, H 7.38, N 6.41; found C 60.89, H 7.59, N 7.12.

Bis(2-diethylaminomethylphenyl)mercury (**1c**): In a similar way to **1a**, $HgCl_2$ (2.71 g, 10 mmol) and **1** (3.38 g, 20 mmol) yielded 4.37 g (83%) of colorless crystalline **1c**, m.p. 74°C. – ^{1}H NMR (C_6D_6): δ = 1.09 (t, CH_3), 2.69 (q, CH_3CH_2), 3.68 (s, CH_2C_{aryl}), 7.24−7.97 (m, $C_{aryl}H$). – ^{13}C NMR (C_6D_6): δ = 11.21 (CH_3), 46.39 (CH_3CH_2), 61.60 (sat., CH_2C_{aryl}), 126.79 (*C*-3), 127.09 (*C*-5), 129.19 (*C*-4), 138.86 (sat., *C*-6), 148.03 (sat., *C*-2), 171.10 (*C*-1). – MS; *m/z* (%): 526 (6) [M(^{202}Hg)$^+$], 497 (5) [M$^+$ − Et], 453 (2) [M$^+$ − NEt_2], 202 (<1) [Hg$^+$], and others as for **1a**. – $C_{22}H_{32}HgN_2$ (525.10): calcd. C 50.32, H 6.14, N 5.33; found C 50.80, H 6.38, N 5.35.

Bis[2,6-bis(dimethylaminomethyl)phenyl]zinc (**2a**): A solution of 2,6-bis(dimethylaminomethyl)phenyllithium (**2**) (0.23 g, 1.16 mmol) in Et_2O (30 ml) was mixed in portions with $ZnCl_2$ (0.079 g, 0.58 mmol). The mixture was stirred for 12 h and during this time a white precipitate formed. The suspension was chilled and filtered through a fine glass frit. The pale yellow filtrate was stored at −20°C and gave 0.19 g (73%) of colorless crystalline **2a**, m.p. 94°C. – ^{1}H NMR ([D$_8$]THF): δ = 2.16 (s, CH_3), 3.36 (s, CH_2), 6.96−7.27 (m, $C_{aryl}H$). – ^{13}C NMR ([D$_8$]THF): δ = 45.60 (CH_3), 65.00 (CH_2), 128.10 (*C*-3,5), 130.00 (*C*-4), 140.30 (*C*-2,6), 159.10 (*C*-1). – MS; *m/z* (%): 192 (33) [$C_6H_4(CH_2NMe_2)_2^+$], 149 (100) [$C_6H_4(CH_3)CH_2NMe_2^+$], and others. – $C_{24}H_{38}N_4Zn$ (447.99): calcd. C 64.35, H 8.55, N 12.51; found C 64.19, H 8.44, N 12.62.

Bis[2,6-bis(dimethylaminomethyl)phenyl]mercury (**2c**): In a similar way to **2a**, $HgCl_2$ (0.25 g, 0.93 mmol) and **2** (0.37 g, 1.87 mmol) yielded 0.31 g (57%) of colorless fine crystalline **2c**, m.p. 139°C. The mixture was protected from light; although during the reaction, the formation of mercury metal was observed. – ^{1}H NMR ([D$_8$]THF): δ = 2.19 (s, CH_3), 3.41 (CH_2), 7.02-7.18 (m, C$_{aryl}H$). – ^{13}C NMR ([D$_8$]THF): δ = 48.25 (*C*H$_3$), 71.58 [sat., $^3J(^{13}C,^{199}Hg)$ = 40.5 Hz, *C*H$_2$], 129.20 (*C*-3,5), 130.60 (*C*-4), 150.80 (sat., *C*-2,6), 176.00 (sat., *C*-1). – MS; *m/z* (%): 584 (<1) [M(^{202}Hg)$^+$], 202 (1) [Hg$^+$], and others as for **2a**. – $C_{24}H_{38}HgN_4$ (583.19): calcd. C 49.43, H 6.57, N 9.61; found C 49.21, H 6.33, N 9.48.

Bis[2,6-bis(diethylaminomethyl)phenyl]zinc (**3a**): A solution of **3** (1.07 g, 4.2 mmol) in Et_2O (40 ml) was mixed in portions with $ZnCl_2$ (0.29 g, 2.1 mmol). The reaction mixture warmed up slightly. After stirring for 16 h at room temperature the solvent was removed in vacuo. The remaining solid was suspended in *n*-pentane. The mixture was filtered through a fine glass frit, and the filtrate volume was reduced to about 20 ml. Storing at −20°C yielded 0.82 g (70%) of colorless fine crystalline **3a**, m.p. 102°C. – ^{1}H NMR (C_6D_6): δ = 0.85 (t, ^3J = 7.1 Hz, CH_3), 2.63 (q, ^3J = 7.1 Hz, CH$_3$CH_2), 3.74 (s, CH_2C$_{aryl}$), 7.29-7.43 (m, CH_{aryl}). – ^{13}C NMR (C_6D_6): δ = 10.35 (*C*H$_3$), 46.09 (CH$_3$*C*H$_2$), 63.42 (*C*H$_2$C$_{aryl}$), 124.85 (*C*-3,5), 126.68 (*C*-4), 147.54 (*C*-2,6), 158.44 (*C*-1). – MS; *m/z* (%): 558 (15) [M(^{64}Zn)$^+$], 529 (3) [M$^+$ – C_2H_5], 310 (17) [ZnC$_6$H$_3$(CH$_2$NEt$_2$)$_2^+$], 247 (100) [C$_6$H$_3$(CH$_2$NEt$_2$)$_2^+$], and others. – $C_{32}H_{54}N_4Zn$ (560.20): calcd. C 68.61, H 9.72, N 10.00; found C 68.40, H 9.69, N 10.11.

Bis[2,6-bis(diethylaminomethyl)phenyl]cadmium (**3b**): In a similar way to **3a**, $CdCl_2$ (0.21 g, 1.14 mmol) was mixed with **3** (0.58 g, 2.28 mmol) and yielded 0.43 g (62%) of colorless crystals of **3b**, m.p. 137°C. Although the mixture was protected from light during the reaction, the formation of cadmium metal was observed. – ^{1}H NMR (C_6D_6): δ = 0.86 (t, ^3J = 7.2 Hz, CH_3), 2.61 (q, ^3J = 7.1 Hz, CH$_3$CH_2), 3.49 (s, CH_2C$_{aryl}$), 7.08-7.33 (m, C$_{aryl}H$). – ^{13}C NMR (C_6D_6): δ = 10.27 (*C*H$_3$), 45.81 (CH$_3$*C*H$_2$), 63.52 (sat., *C*H$_2$C$_{aryl}$), 124.51 (*C*-3,5), 126.01 (*C*-4), 147.54 (sat., *C*-2,6), 163.69 (*C*-1). – ^{113}Cd NMR (C_6D_6): δ = −182.58. – MS; *m/z* (%): 246 (2) [C$_6$H$_3$(CH$_2$NEt$_2$)$_2^+$ – H], and others as for **3a**. – $C_{32}H_{54}CdN_4$ (607.21): calcd. C 63.30, H 8.96, N 9.23; found C 63.08, H 8.94, N 9.51.

Bis[2,6-bis(diethylaminomethyl)phenyl]mercury (**3c**): In a similar way to **3a**, $HgCl_2$ (0.86 g, 3.17 mmol) and **3** (1.61 g, 6.33 mmol) yielded 1.41 g (64%) of colorless crystals of **3c** which melt below room temperature. – ^{1}H NMR (C_6D_6): δ = 0.92 (t, ^3J = 7.1 Hz, CH_3), 2.58 (q, ^3J = 7.1 Hz, CH$_3$CH_2), 3.70 (s, CH_2C$_{aryl}$), 7.16 (t, ^3J = 7.4 Hz, C-3,5*H*), 7.36 (d, ^3J = 7.2 Hz, C-4*H*). – ^{13}C NMR (C_6D_6): δ = 10.13 (*C*H$_3$), 45.41 (CH$_3$*C*H$_2$), 61.17 [sat., $^3J(^{13}C,^{199}Hg)$ = 42 Hz, *C*H$_2$C$_{aryl}$], 125.57 (*C*-3,5), 126.56 (*C*-4), 146.60 [sat., $^2J(^{13}C,^{199}Hg)$ = 22 Hz, *C*-2,6], 171.74 [sat., $^1J(^{13}C,^{199}Hg)$ = 714 Hz, *C*-1]. – MS; *m/z* (%): 696 (<1) [M(^{202}Hg)$^+$], 623 (2) [M$^+$ – NEt_2], 247 (100) [C$_6$H$_3$(CH$_2$NEt$_2$)$_2^+$], 202 (1) [Hg$^+$], and others as for **3a**. – $C_{32}H_{54}HgN_4$ (695.40): calcd. C 55.27, H 7.83, N 8.06; found C 54.84, H 8.00, N 8.07.

(5,13-Diaza)-5,13-dimethyl-1,9-dizincacyclohexadecane (**4a**): **4** (2.04 g, 16.05 mmol) was dissolved in Et_2O (150 ml) and mixed in portions with $ZnCl_2$ (2.19 g, 16.05 mmol). The reaction mixture warmed up slightly and a white precipitate formed. After stirring at room temperature for 12 h the solvent was removed in vacuo. The remaining solid was suspended in *n*-pentane and filtered through a fine glass frit. The filtrate volume was reduced to about 50 ml. Storing at −20°C yielded 2.15 g (75%) of large colorless crystals of **4a**, m.p. 71°C. – ^{1}H NMR (C_6D_6, *T* = 338 K): δ = 0.32 (t, ^3J = 7.1 Hz, ZnCH_2), 1.85 (quint, ^3J = 6.9/6.6 Hz, CH_2), 1.86 (s, CH_3), 2.23 (t, ^3J = 6.4 Hz, CH_2N). – ^{13}C NMR (C_6D_6): δ = 8.46 (Zn*C*H$_2$), 25.87 (*C*H$_2$), 41.87 (*C*H$_3$), 61.17 (*C*H$_2$N). – MS; *m/z* (%): 177 (6) [1/2 M(^{64}Zn)$^+$], 149 (13) [1/2 M$^+$ – CH_2CH_2], 84 (100) [$C_5H_{10}N^+$], and others. – $C_{14}H_{30}N_2Zn_2$ (357.19): calcd. C 47.08, H 8.47, N 7.84; found C 46.93, H 8.42, N 7.89.

(5,13-Diaza)-5,13-dimethyl-1,9-dicadmacyclohexadecane (**4b**): In a similar way to **4a**, $CdCl_2$ (1.20 g, 6.53 mmol) and **4** (0.83 g, 6.53 mmol) yielded 0.72 g (49%) of colorless fine crystalline **4b**, m.p. 89°C. Although the mixture was protected from light during the reaction, the formation of cadmium metal was observed. – ^{1}H NMR (C_6D_6): δ = 0.67 (t, ^3J = 7.0 Hz, CdCH_2), 1.89 (s, CH_3), 2.01 (quint, ^3J = 6.9/6.6 Hz, CH_2), 2.25 (t, ^3J = 6.5 Hz, CH_2N). – ^{13}C NMR (C_6D_6): δ = 12.14 (Cd*C*H$_2$), 32.56 (*C*H$_2$), 41.93 (*C*H$_3$), 61.89 (*C*H$_2$N). – MS; *m/z* (%): 454 (<1) [M(^{114}Cd)$^+$], 227 (3) [1/2 M(^{114}Cd)$^+$], 114 (3) [Cd$^+$], and others as for **4a**. – $C_{14}H_{30}Cd_2N_2$ (451.21): calcd. C 37.27, H 6.70, N 6.21; found C 37.01, H 6.58, N 6.34.

(5,13-Diaza)-5,13-dimethyl-1,9-dimercuracyclohexadecane (**4c**): In a similar way to **4a**, $HgCl_2$ (0.14 g, 0.51 mmol) and **4** (0.065 g, 0.51 mmol) yielded 0.23 g (72%) of colorless crystalline **4c**, m.p. 97°C. – ^{1}H NMR (C_6D_6): δ = 0.99 (t, ^3J = 6.9 Hz, HgCH_2), 1.91 (s, CH_3), 2.06 (quint, ^3J = 6.9/6.5 Hz, CH_2), 2.25 (t, ^3J = 6.5 Hz, CH_2N). – ^{13}C NMR (C_6D_6): δ = 27.58 (Hg*C*H$_2$), 37.56 (*C*H$_2$), 41.95 (*C*H$_3$), 62.20 (*C*H$_2$N). – MS; *m/z* (%): 627 (<1) [M$^+$], 315 (<1) [1/2 M(^{202}Hg)$^+$], 202 (4) [Hg$^+$], and others as for **4a**. – $C_{14}H_{30}Hg_2N_2$ (627.59): calcd. C 26.79, H 4.82 N, 4.46; found C 26.68, H 4.80, N 4.73.

Bis[3-(N-piperidino)propyl]zinc (**5a**): $ZnCl_2$ (0.43g, 3.19 mmol) was added portionwise to a suspension of **5** (0.85g, 6.38 mmol) in Et_2O (50 ml). The cloudy reaction mixture was stirred at room temperature for 18 h. After removing the solvent and addition of *n*-pentane, the mixture was filtered through a fine glass frit. The pale yellow filtrate was concentrated to a volume of about 30 ml and yielded, after storing at −20°C, 0.77 g (76%) of colorless crystalline **5a**, m.p. 80°C. – ^{1}H NMR (C_6D_6): δ = 0.48 (t. ^3J = 7.1 Hz, ZnCH_2), 1.29 (m, ^3J = 5.5 Hz, ZnCH$_2$CH_2), 1.52 [quint, ^3J = 5.6 Hz, N(CH$_2$CH_2)$_2$CH$_2$], 2.01 [m, ^3J = 6.2 Hz, N(CH$_2$CH$_2$)$_2$CH_2], 2.19 (t, ^3J = 5.6 Hz, CH_2N), 2.27 [t, ^3J = 5.4 Hz, N(CH_2CH$_2$)$_2$CH$_2$]. – ^{13}C NMR (C_6D_6): δ = 8.22 (Zn*C*H$_2$), 24.82 [*C*H$_2$CH$_2$N(CH$_2$*C*H$_2$)$_2$CH$_2$], 25.37 [N(CH$_2$CH$_2$)$_2$*C*H$_2$], 55.05 [N(*C*H$_2$CH$_2$)$_2$CH$_2$], 64.06 (*C*H$_2$N). – MS; *m/z* (%): 316 (<1) [M(^{64}Zn)$^+$], 127 (8) [$C_5H_{10}N(CH_2)_2CH_3^+$], 98 (100) [C$_5$H$_{10}$NCH$_2^+$], and others. – $C_{16}H_{32}N_2Zn$ (317.84): calcd. C 60.46, H 10.15, N 8.81; found C 60.37, H 9.97, N 9.24.

Bis[3-(N-piperidino)propyl]cadmium (**5b**): In a similar way to **5a**, $CdCl_2$ (0.805 g, 4.39 mmol) and **5** (1.17 g, 8.79 mmol) yielded 1.04 g (65%) of large colorless crystals of **5b**, m.p. > 90°C (dec.). – ^{1}H NMR (C_6D_6): δ = 0.59 (t, ^3J = 6.9 Hz, CdCH_2), 1.31 (m, ^3J = 5.1 Hz, CdCH$_2$CH_2), 1.56 [quint, ^3J = 5.6 Hz, N(CH$_2$CH_2)$_2$CH$_2$], 2.04 [m, N(CH$_2$CH$_2$)$_2$CH_2], 2.14-2.19 [m, CH_2N(CH_2CH$_2$)$_2$CH$_2$]. – ^{13}C NMR (C_6D_6): δ = 13.29 [sat., $^1J(^{13}C,^{111/113}Cd)$ = 307/294 Hz, Cd*C*H$_2$], 24.94 [N(CH$_2$CH$_2$)$_2$*C*H$_2$], 25.88 [N(CH$_2$*C*H$_2$)$_2$CH$_2$], 26.31 [sat., $^2J(^{13}C,^{113}Cd)$ = 15.4 Hz, CdCH$_2$*C*H$_2$), 55.38 [N(*C*H$_2$CH$_2$)$_2$CH$_2$], 64.30 [sat., $^3J(^{13}C,^{113}Cd)$ = 14.7 Hz, *C*H$_2$N]. – MS; *m/z* (%): 366 (<1) [M(^{114}Cd)$^+$], 240 (5) [$C_5H_{10}N(CH_2)_3Cd^+$], and others as for **5a**. – $C_{16}H_{32}CdN_2$ (364.85): calcd. C 52.67, H 8.84, N 7.68; found C 53.28, H 8.51, N 8.36.

Bis[3-(N-piperidino)propyl]mercury (**5c**): In a similar way to **5a**, $HgCl_2$ (1.09 g, 4.01 mmol) and **5** (1.07 g, 8.03 mmol) yielded 1.06

g (58%) of colorless crystalline **5c**, which melts below room temperature. Because of the formation of fine mercury metal in the mixture, the reaction time was shortened to 4 h. – ^{1}H NMR (C_6D_6): δ = 1.08 (t, ^3J = 6.7 Hz, $HgCH_2$), 1.34 (m, br., $HgCH_2CH_2$), 1.55 [quint, ^3J = 5.7 Hz, $N(CH_2CH_2)_2CH_2$], 2.12 [m, ^3J = 6.3 Hz, $N(CH_2CH_2)_2CH_2$], 2.21 (t, ^3J = 6.0 Hz, CH_2N), 2.25 [m, br., $N(CH_2CH_2)_2CH_2$]. – ^{13}C NMR (C_6D_6): δ = 25.08 ($HgCH_2$), 26.36 [$N(CH_2CH_2)_2CH_2$], 27.03 [$N(CH_2CH_2)_2CH_2$], 36.72 ($HgCH_2CH_2$), 55.16 [$N(CH_2CH_2)_2CH_2$], 63.36 (NCH_2). – MS; *m/z* (%): 454 (2) [$M(^{202}Hg)^+$], 327 (2) [$C_5H_{10}N(CH_2)_3Hg^+$], 202 (20) [Hg^+], and others as for **5a**. – $C_{16}H_{32}HgN_2$ (453.04): calcd. C 42.42, H 7.12, N 6.18; found C 42.17, H 7.05, N 6.38.

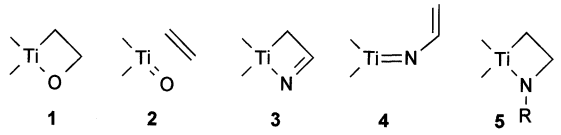
Received August 5, 1997

Keywords: Titanium / Vinylidene complexes / [2+2] Cycloaddition / Metallacycles / Azatitanacyclobutanes / Clathrates

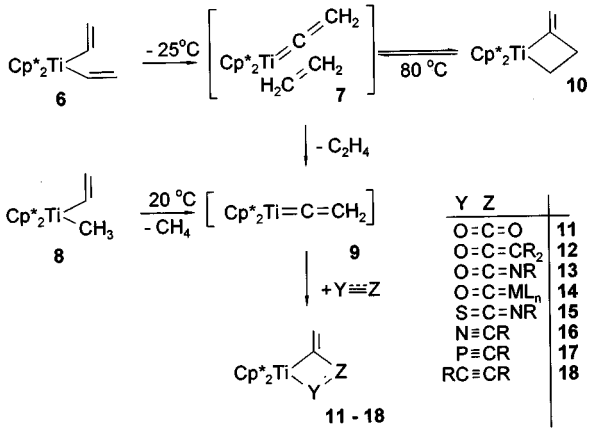
The titanocene vinylidene intermediate [$Cp^*_2Ti{=}C{=}CH_2$] (**9**) reacted with the carbodiimides R−N=C=N−R [R = *p*-$CH_3C_6H_4$ (**19a**), C_6H_{11} (**19b**)] to give the N=C-cycloaddition products [$Cp^*_2Ti\{-NR-C(=NR)-(C=CH_2)-\}$] [(R = *p*-$CH_3C_6H_4$ (**20a**), C_6H_{11} (**20b**)]. The X-ray structure of **20a** in form of a surprisingly stable *n*-hexane clathrate is presented. The azatitanacyclobutane [$Cp^*_2Ti\{-NPh-C(Ph)(H)-(C=CH_2)-\}$] (**22**) was formed from the reaction between **9** and benzylidene aniline [PhN=C(Ph)H (**21**)]. Reactivity studies showed that azatitanacyclobutanes are unreactive upon typical ring-enlargement reactions as observed for other four-membered titanacycles.

Oxatitanacyclobutanes (**1**) and azatitanacyclobutenes (**3**) are under discussion as intermediates in reactions of Ti=CR_2 with carbonyl compounds or nitriles. The high electrophilicity of the metal centre has generally prevented the isolation and characterization of oxa- and azatitanacyclobutenes: spontaneous ring opening reactions afford carbonyl olefination (**1**→**2**), or products of vinylimido intermediates (**3**→**4**).[1] The present paper deals with the formation of azatitanacyclobutane complexes (**5**) prepared by [2+2] cycloaddition of a Ti=C and N=C units.



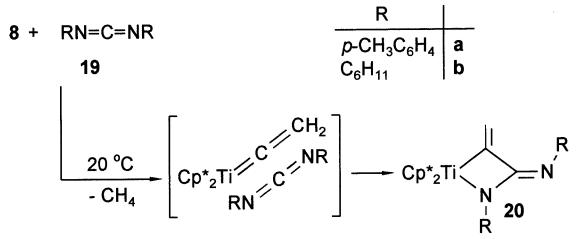
1 **2** **3** **4** **5**

From the thermally generated titana-allene intermediate $Cp^*_2Ti{=}C{=}CH_2$ (**9**), formed by ethane or methane elimination from $Cp^*_2Ti[-CH_2CH_2(C=CH_2)-]$ (**10**) or $Cp^*_2Ti(CH{=}CH_2)(CH_3)$ (**8**), a wide range of four-membered titanacycles (**11**−**18**) can be produced.[2][3][4][5][6][7][8] The high thermal stability of these titanacycles is the major advantage of using **9** instead of titanium methylene intermediates.[2a]



Results and Discussion

The vinylmethyl derivative **8** reacts with one equivalent of the carbodiimide RN=C=NR (R = *p*-$CH_3C_6H_5$ **19a**, R = C_6H_{11} **19b**) at room temperature in *n*-hexane as solvent with evolution of methane to give a dark green solution, from which the azatitanacyclobutane complexes **20** are obtained as green crystals (**20a**) or as a green oil (**20b**). These compounds are formed nearly quantitatively (NMR) and can be isolated in 92% (**20a**) and 88% (**20b**) yield. The mass spectra show the expected molecular peaks. For **20b**, a cycloreversion with formation of **9** can be detected from the fragmentation pattern, whereas for **20a**, the liberation of a C_5Me_5 ligand is the main fragmentation step, indicating a higher stability of the azatitanacyclobutane unit.



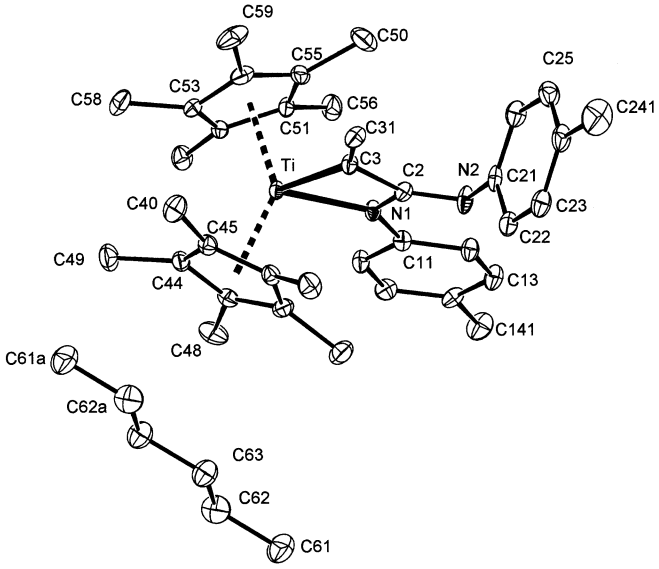
The two chemical shift signals in the ^{1}H-NMR spectra for the protons of the *exo*-methylene group in **20** (**20a** δ = 4.13, 5.87; **20b** δ = 4.52, 6.32) appear to be a distinguishing feature of the new complexes and similar metallacycles. In addition, the chemical shifts of the ring carbon atoms in the ^{13}C-NMR spectra are in accordance with a σ titanium-bonded sp^2 carbon atom (**20a** δ = 202.5; **20b** δ = 202.0). The eight ring proton signals of the two *p*-tolyl substituents in **20a** are detectable upon cooling to −80°C [ring A: (C11−C16, assignment according to Figure 1) δ = 4.63 (d, 1 H), 9.81 (d, 1 H), 6.68 (d, 1 H), 7.10 (d, 1 H); ring B: (C21−C26) 7.26 (m, 4 H)]. The low field shift of one proton signal in ring A (δ = 9.81) is attributed to a hydrogen bridge between the N2 and the H atom at C12, as concluded from

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0202−0253 $ 17.50+.50/0

comparison of δ values in NH compounds.[9] Indeed, in the X-ray structure the distance C12−N2 (2.875 Å) was found to be short. The rotation of ring A is probably blocked in solution at lower temperatures, as indicated by ^{13}C NMR: three *ortho* C signals (δ = 120.1, 121.6, 123.3) of the two aromatic rings are detectable, whereas at room temperature, only two ortho carbon resonances (δ = 121.6, 122.1) are present. Surprisingly, only six of the eight expected protons are detectable at room temperature [δ = 7.09 (m, 4 H), 6.85 (d, 2 H)], similar to the observation of other *N*-phenyl ligands in samarium complexes.[10]

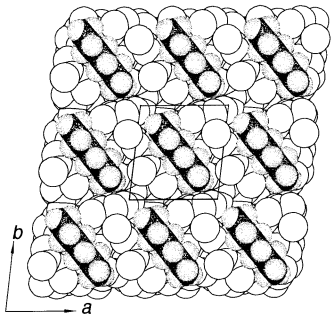
The structure of **20a** was confirmed by X-ray structure determination. The PLATON plot[11a] is shown in Figure 1, and relevant bond lengths and angles are given in Table 1. The azatitanacyclobutane is obtained as a surprisingly stable clathrate $2[Cp^*_2Ti\{-N(p\text{-}CH_3C_6H_4)C(=N-p\text{-}CH_3C_6H_4)(C=CH_2)-\}] \cdot n\text{-}C_6H_{14}$. It crystallizes in space group $P\bar{1}$ with complex molecules in general position (2*i*) and *n*-hexane on the crystallographic inversion centers (1*e*) (s. Figure 2). The atoms of the aliphatic chain exhibit small displacement parameters, and all hydrogen atoms of the *n*-hexane molecule could be located in a Fourier difference synthesis. Bond length and angles are in good agreement with a previous report.[11c] The cocrystallization of the *n*-hexane molecule illustrates in an excellent manner the highly organophilic character of permethylated metallocene complexes of the type $Cp^*_2TiX_2$.

Figure 1. PLATON drawing[11a] of 2 $[Cp^*_2Ti\{-N(p\text{-}CH_3C_6H_4)C(=N-p\text{-}CH_3C_6H_4)C(=CH_2)-\}\cdot n\text{-}C_6H_{14}]$ (**20a** · 0.5 C_6H_{14}) (30% ellipsoids) (two titanocene molecules and one molecule *n*-hexane are present in the unit cell)



The azatitanacyclobutane ring is planar. The *p*-tolyl ring A (C11−C16) is localized in the plane of the four-membered ring, whereas ring B (C21−C26) is orientated perpendicular to the equatorial plane. The sum of the angles at N1 is approximately 358°, which means that the nitrogen ring atom must be sp^2 hybridized with the lone pair located in a vacant p-orbital perpendicular to the ring plane.

Figure 2. SCHAKAL drawing[11b] of molecular packing of 2 $[Cp^*_2Ti\{-N(p\text{-}CH_3C_6H_4)C(=N-p\text{-}CH_3C_6H_4)C(=CH_2)-\}\cdot C_6H_{14}]$ (**20a**· 0.5 C_6H_{14}) view on *ab*-plane; hydrogen atoms of **20a** omitted, hexane molecules shaded



Compared to the azatitanacyclobutene **16** (R = *t*Bu) the Ti−N1 distance in **20a** was found to be significantly longer, resulting from the hybridization of the nitrogen atom. In contrast with **16**, in **20** a pϕ−dϕ interaction is no longer possible, due to the perpendicular orientation of the lone pair at the titanium-bonded nitrogen to the Cp^*_2Ti-acceptor orbitals in **20**.[12] This behaviour is in accordance with the general observation that reactivity of bent titanocene complexes is determined by the electron-deficient character of the metal centre, in combination with the orientation of the acceptor orbitals in the equatorial plane of the metallocene fragment.[13] The N1−C2 distance in **20** is in accordance with a N−C single bond, as expected.[12] To summarize, the structural data suggest that the reactivity of **20a** should differ from that of **16**. The short C3−C2 distance in **16** [1.485(3) Å] indicates a stronger C−C bond than that found in **20a** [1.505(4) Å]. Electrocyclic ring-opening reactions are indeed observed for **16**, whereas cycloreversion reactions are expected for azametallacyclobutanes, and are observed in the mass spectrometric fragmentation behaviour of **20b**, and the dynamic properties of other azametallacyclobutanes derived from $[Cp_2Zr{=}NR]$[15] or $[(tBu_3SiO)_2Ti{=}NR]$[16] intermediates and olefins.

Table 1. Selected bond lenghts [Å] and angles [deg] in 2 $[Cp^*_2Ti\{-N(p\text{-}CH_3C_6H_4)C(=N-p\text{-}CH_3C_6H_4)C(=CH_2)-\}\cdot n\ C_6H_{14}]$ (**20a**·0.5 *n* C_6H_{14}) and the azatitanacyclobutene $[Cp^*_2TiN{=}C(tBu)C{=}CH_2]$ (**16**)[6], assignment according the figure

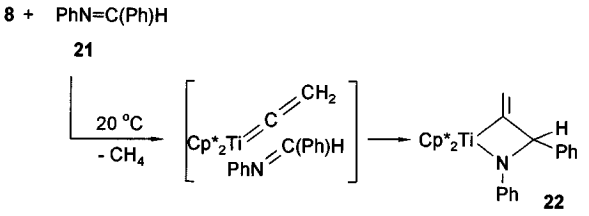
When **8** reacts with *N*-benzylidene aniline, the azatitanacyclobutane derivative **22** is formed by cycloaddition of **9** with **21**. Compound **22** was isolated in 30% yield as thermally stable (mp 158°C, dec.) red crystals. The expected molecular peak is found in the mass spectrum, and fragmentation occurs mainly with formation of a $Cp^*_2Ti{=}NR$ fragment (40.7%). Attempts to use this reactivity pattern for preparative purposes, e. g. in reaction with acetone, have until now been unsuccessful.



Proton transfer reactions leading to azavinylidene derivatives $Cp^*_2Ti(N{=}CPh_2)CH{=}CH_2$ occur when Schiff bases with nitrogen bearing an acidic hydrogen atom are used.[17] In the case of *N*-benzylidenemethylamine, the fulvene complex $Cp^*(\eta^5{:}\eta^1\text{-}C_5Me_4CH_2)TiCH{=}CH_2$ is formed instead of the metallacyclic cycloaddition product.

To compare the reactivity of **20** to that of the other four-membered titanacycles **10**−**18**, different reactions were carried out. With isonitriles, a fast and selective insertion into the Ti−C σ-bond is observed for **10**[18] and **18**[7a] (Ti−C bond opposite to the *exo*-CH_2 group) as well as for the oxetanes **11**−**14**,[8a][19]. The azatitanacyclobutanes **20** are however inert to ring enlargements with small molecules (RNC, R = *t*Bu, C_6H_{11}). Especially fast reactions take place between **16** and nitriles to form six-membered rings.[6] However, in the case of **20** no reactions are detectable. These reactions are summarized in Scheme 1. The azatitanacyclobutane **20** also appears to be inert in the presence of protic agents (PhC≡CH, PhOH, MeOH). Only with HCl/Et_2O the formation of $Cp^*_2TiCl_2$ is observed.

Scheme 1. Ring enlargement reactions of small titanacycles

Experimental Section

General: The preparation and handling of compounds were performed with rigorous exclusion of air and moisture under a nitrogen atmosphere, using a standard vacuum line and Schlenk techniques. All solvents were dried with the appropriate drying agents and distilled under a nitrogen atmosphere. Deuterated solvents were degassed by freeze-pump-thaw cycles and dried over molecular sieves (3 or 4 Å) prior to use. − ^{1}H- and ^{13}C-NMR spectra were recorded on a Varian Unity 500 spectrometer. Chemical shifts are reported in ppm with reference to residual protons in deuterated solvents ([D_6]benzene, δ = 7.15 for ^{1}H-NMR spectroscopy; [D_6]benzene, δ = 127.96 for ^{13}C-NMR spectroscopy). − Mass spectroscopic analyses were performed on a Finnigan MAT 95 mass spectrometer. − Infrared spectra were recorded as KBr pellets on a Perkin−Elmer 1720X FT-IR spectrometer. − Elemental analyses were carried out at the Analytische Laboratorien in Lindlar, Germany. − The titanocene complex $[Cp^*_2Ti(CH{=}CH_2)CH_3]$ (**8**) was prepared by literature procedures.[4] The Schiff bases were purchased from Aldrich.

Preparation of **20a**: To a solution of **8** (200 mg, 0.55 mmol) in 30 ml of *n*-hexane was added di-*p*-tolylcarbodiimide (**19a**) (0.12 g, 0.55 mmol) at −20°C. The mixture was stirred and warmed to 25°C over 4 h, forming a dark green solution, from which **20a** precipitates. Recrystallization from *n*-hexane at −20°C, yields **20a** as dark green crystals (210 mg, 67%) − mp 150−153°C (dec.) − ^{1}H NMR (C_7D_8, 500 MHz, −80°C): δ = 1.56 [s, 30 H, $C_5(CH_3)_5$], 2.19 (s, 3 H, CH_3), 2.32 (s, 3 H, CH_3), 4.06 (s, 1 H, =CH*H*), 5.79 (s, 1 H, =C*H*H), 4.63 (d, 1 H, *J* = 7.9 Hz), 6.68 (d, 1 H, *J* = 7.6 Hz), 7.10 (d, 1 H, *J* = 7.3 Hz), 7.26 (m, 4 H), 9.81 (d, 1 H, *J* = 7.9 Hz). − ^{1}H NMR (C_7D_8, 500 MHz, 25°C): δ = 1.68 [s, 30 H, $C_5(CH_3)_5$], 2.19 (s, 3 H, CH_3), 2.30 (s, 3 H, CH_3), 4.08 (s, 1 H, = CH*H*), 5.76 (s, 1 H, =C*H*H), 6.85 (d, 2 H, *J* = 6.4 Hz), 7.09 (m, 4 H). − ^{13}C{^{1}H} NMR (C_7D_8, 125 MHz, −80°C) δ = 12.7 [$C_5(CH_3)_5$], 21.2 (CH_3), 21.2 (CH_3), 118.7 (=CH_2), 120.1, 121.6, 123.3, 128.6, 128.7, 130.2, 146.0, 152.1 (Ph, 2 signals hidden), 140.5 (N-C=N). 201.5 (TiC), 125.4 [$C_5(CH_3)_5$]. − ^{13}C{^{1}H} NMR (C_7D_8, 125 MHz, 25°C) δ = 12.7 [$C_5(CH_3)_5$], 21.0 (CH_3), 21.1 (CH_3), 118.4 (=CH_2), 121.6, 122.1, 128.3, 128.4, 129.9, 146.1, 151.8 (Ph, 1 signal hidden), 140.3 (N-C=N), 202.5 (TiC), 125.7 [$C_5(CH_3)_5$]. − IR (KBr): $\tilde{\nu}$ = 2909 (m), 2854 (m), 1608 (w), 1590 (w), 1541 (s), 1504 (s), 1497 (s), 1453 (m), 1434 (m), 1335 (s), 1303 (s), 819 (s) cm^{-1}. − EI-MS (70 eV) *m/e* (*I*rel) 566 (57) [M^+], 459 (19), 461 (2), 432 (60), 384 (19), 318 (26). − $C_{37}H_{46}N_2Ti$ (566.67): calcd. C 78.42, H 8.18, N 4.94; found C 78.69, H 8.10, N 4.89.

Preparation of **20b**: To a solution of **8** (200 mg, 0.55 mmol) in 30 ml of *n*-hexane was added dicyclohexylcarbodiimid (**19b**) (110 mg, 0.55 mmol) at −20°C. The mixture was stirred and warmed to 25°C over 12 h. The solvent was removed to dryness, yielding **20b** as a dark green oil. (220 mg, 73%) − ^{1}H NMR (300 MHz, C_6D_6) δ = 0.88−2.14 (m, 20 H, C_6H_{11}), 1.75 [s, 30 H, $C_5(CH_3)_5$], 4.04 (tt, J_{HH} = 4.0 and 5.4 Hz, 1 H, N−CH), 4.44 (tt, J_{HH} = 3.4 and 11.4 Hz, 1 H, N−CH), 4.52 (s, 1 H, =CH_2), 6.32 (s, 1 H, = CH_2). − ^{13}C NMR (C_6D_6, 75 MHz): δ = 12.7 [$C_5(CH_3)_5$], 25.9, 26.9, 27.3, 27.5, 33.6, 37.7, 55.7, 56.2 (C_6H_{11}), 112.0 (=CH_2), 124.3 [$C_5(CH_3)_5$], 139.6 (N−*C*=N), 202.0 (Ti−C). − EI-MS (70 eV) *m/e* (%): 550 (10) [M^+], 453 (5) [M^+ − N − C_6H_{11}], 416 (14) [M^+ + H − $C_5(CH_3)_5$], 344 (91) [M^+ − $C_{13}H_{22}N_2$], 318 (100) [M^+ − $C_{15}H_{24}N_2$]. − $C_{35}H_{54}N_2Ti$ (550.8): calcd. C 76.32, H 9.90, N 5,09; found C 73.65, H 10.22, N 5.09.

Preparation of **22**: To a solution of **8** (300 mg, 0.83 mmol) in 30 ml of *n*-hexane was added N-benzylideneaniline (**21**) (150 mg) at −20°C. The mixture was stirred and warmed to 25°C over 12 h.

After filtration, the solvent was concentrated to 50%. After cooling to −78°C **22** was formed as red crystals (130 mg, 30%): − mp 158°C, dec. − ^{1}H NMR (300 MHz, C_6D_6, TMS): δ = 1.67, 1.80 [each 15 H, $C_5(CH_3)_5$], 3.89 (1 H, C*H*Ph), 4.69 (d, 1 H, =CH_2, *J* = 3.0 Hz); 6.05 (d, 1 H, =CH_2, *J* = 2.4 Hz); 5.84, 6.15, 6.58, 6.86 (each 1 H, PhH); 7.09, 7.26, 7.37 (each 2 H, PhH). − $^{13}C\{^1H\}$ NMR (75 MHz, C_6D_6, TMS): δ = 12.7, 13.0 [$C_5(CH_3)_5$]; 47.9 (CHPh); 107.7 (=CH_2); 114.8, 116.5, 118.7 (arom. C); 123.9, 124.2 [$C_5(CH_3)_5$]; 125.8, 128.2, 129.1 (arom. C); 139.2 (C−*C*ipso); 154.1 (N−Cipso); 217.8 (Ti−C). MS: *m/z* (%): 525.5 (9.5) [M^+], 343.3 (5.8) [$M^+ - C_{13}H_{12}N$], 318.2 (9.1) [$M^+ - C_{15}H_{13}N$], 274.3 (40.7) [$M^+ - C_{19}H_{23}$], 115.0 (100). − $C_{35}H_{43}NTi$ (525.67): C 79.96, H 8.26, N 2.67; found: C 79.58, H 8.17, N 2.70.

Structure Determination and Refinement of **20a**: Geometry and intensity data were collected on a ENRAF-Nonius CAD4 diffractometer with graphite-monochromated Mo-K_α radiation. Crystal data, data collection parameters, and convergence results are compiled in Table 2. After Lorentz and polarization corrections, an empirical absorption correction based on azimuthal scans[20] was applied, before averaging symmetry related intensity data. **20a** was crystallized from *n*-hexane in the composition 2 [Cp*$_2$Ti{−N(*p*-$CH_3C_6H_4$)−C(=N−*p*-$CH_3C_6H_4$)−C(=CH_2)−}]·*n*-C_6H_{14}. The structure was solved by direct methods,[21] refined with the SDP program system.[22] In the final refinement cycles, hydrogen atoms were included in riding geometry with fixed isotropic displacement parameters [d_{C-H} = 0.98 Å, U_{iso}(H) = 1.30 U_{eq}(C)]. Further details of the crystal structure investigations are available on request from the Cambridge Crystallographic Data Centre, on quoting the depository number CCDC-100571.

[13] Differences in Ti−N bond distances, depending on the orbital orientation are illustrated in Cp*$_2$TiNR^{1}R^2 complexes: if there is no steric hindrance, the substituents on the nitrogen atom R^1 = R^2 = H[14a], R^1 = H , R^2 = Me[14b] will be rotated out of the equatorial plane of the Cp*$_2$Ti fragment to maximise dπ−pπ overlapping and short Ti−N distances are found [1.944(2) A, 1.955(2) A]. In the case of larger substituents R^1 = Me, R^2 = Ph the R groups are now located in the equatoraial plane, and consequently dπ-pπ-interaction is no longer possible so that longer Ti−N distances are found [2.054(2) A].[14c] − R. Chemistry of 2*H*-Azaphosphirene Complexes, 8[◇]

Synthesis and Spectroscopic Data of *para*-Substituted (3-Phenyl-2*H*-azaphosphirene)tungsten Complexes☆

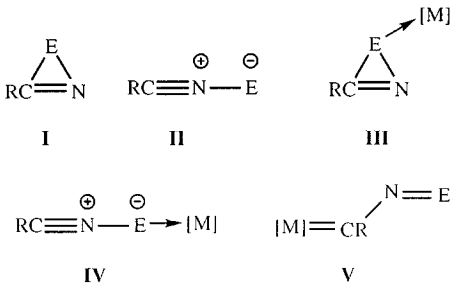
Keywords: Phosphorus heterocycles / 2*H*-Azaphosphirene complexes / Carbene complexes / Tungsten / Cyclizations

High-yield synthesis of *para*-substituted pentacarbonyl(3-phenyl-2*H*-azaphosphirene)tungsten complexes is reported, using a multi-step rearrangement reaction. Spectroscopic and mass-spectrometric data of these heterocyclic complexes are discussed; the ^{31}P-NMR-chemical shifts clearly reflect the electronic influence of the *para*-phenyl substituents and the correlation with Hammett σ^{p}-constants is almost linear.

2*H*-azirenes and their heterocyclic analogs (**I**), containing a ring system with a C=N moiety and a further heteroatom, are of current theoretical and synthetic interest.[2] The latter heterocycles are expected to suffer from destabilizing effects due to interaction of the lone pair(s) of the E fragment with the π electrons of the C=N double bond. Such is the case with 1*H*-diazirenes (E = NR)[3] and 1*H*-thiazirenes (E = S).[4] The former rearranges, if it is transiently formed, even at low temperatures to give 3*H*-diazirenes[5] or ring-expanded products[6] and the latter yields nitrile sulfides[7] (**II**: E = S, Scheme 1). Recently, a marked increase in stability of a 1-phosphonio-substituted 1*H*-diazirene derivative was observed[8] and a negative hyperconjugation was proposed to explain this phenomenon.[8][9] Interestingly, neither 2*H*-azaphosphirenes nor 1*H*-oxazirenes exist, even in matrices at low temperatures. The latter have been subjected to a theoretical study, in which an asymmetric bonding of the oxygen with respect to the geometric center of the imine bond was predicted, thus minimizing the electronic destabilization.[10] The former has only been mentioned as plausible intermediate.[11] Because of the relationship of the isolobal fragments RP and S, 2*H*-azaphosphirenes should be of particular interest. Moreover, to the best of our knowledge as yet uninvestigated is the influence of coordinating such heteroazirenes and their acyclic zwitterionic isomers, the 1,3-dipoles, to a metal-complex fragment via the "apical"- (**III**) and "terminal"-bonded atom E (**IV**, E = O, S, NR, PR; Scheme 1).

Recently, we reported the first synthesis of coordinated 2*H*-azaphosphirenes (**III**: E = PR), which was also the first access to heteroazirene complexes in general. We explained the product formation by a multi-step rearrangement reaction of transiently formed metal carbene complexes involving metallaheterobutadienes (**V**), which are isomeric to **III**, as key intermediates.[12] Even more recently, we obtained the first evidence for a nitrilium phosphane ylide complex (**IV**: E = PR). The transient formation of such a complex was achieved by thermal ring opening of a 2*H*-azaphosphirene complex.[13]

Scheme 1. Unsaturated three-membered heterocycles containing nitrogen and a second heteroatom and their zwitterionic acyclic isomers, the 1,3-dipoles (propargylic resonance structure). − **I**, **II**: E = CR_2, NR, PR, O, S. − R, R′ = alkyl, aryl. − **III**, **IV**, **V**: E = NR, PR, O, S. − R, R′ = alkyl, aryl. − [M] = metal complex fragment



In order to exploit this synthetic route to 2*H*-azaphosphirene complexes and to study the rearrangement cascade, we have now reacted a variety of *para*-phenyl-substituted (aminocarbene)tungsten complexes **1a**−**c**, **d**,[14] **e**−**h** with [bis(trimethylsilyl)methylene]chlorophosphane (**2**)[15] in the presence of triethylamine (Scheme 2). The reaction proceeded smoothly to the (2*H*-azaphosphirene)tungsten complexes **3a**−**h**, and, as in our first approach, we observed neither long-lived intermediates nor side products. Complexes **3a**−**g** were obtained in good yields, after low-temperature column chromatography, whereas complex **3h** showed some decomposition upon chromatography.

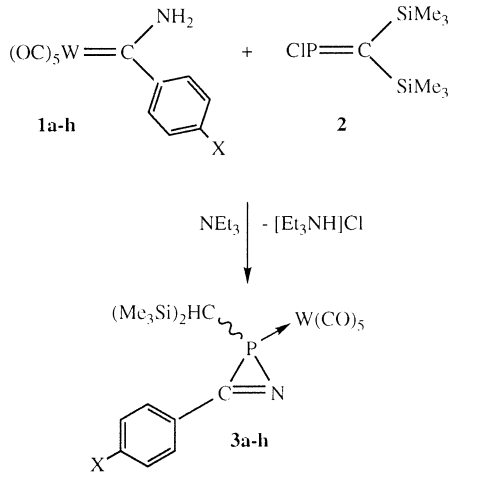
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0202−0257 $ 17.50+.50/0

Scheme 2. Synthesis of (2*H*-azaphosphirene)tungsten complexes **3a−h**



X	1a,3a	1b,3b	1c,3c	1d,3d	1e,3e	1f,3f	1g,3g	1h,3h
	CF_3	Br	Cl	H	F	Me	OMe	NMe_2

With respect to the ring formation reaction, all carbene complexes employed in this study behave approximately equivalently. Nevertheless, longer reaction times were observed for **3e−h**, which bear more electron-releasing *para* substituents. Doubling the reaction time led to the formation of small amounts of [{$(Me_3Si)_2HCP(H)Cl$}$W(CO)_5$]. This product resulted, at least formally, from the ring-cleavage reaction of the (2*H*-azaphosphirene)tungsten complexes **3a−h** with triethylammonium chloride. This has been verified for complex **3d**, which was treated in pure form with triethylammonium chloride under similar reaction conditions.[16]

From the spectroscopic data of these complexes, the phosphorus and carbon nuclear magnetic resonances are the most significant. The phosphorus and carbon resonances as well as the phosphorus-tungsten coupling constants clearly reflect the electronic influence of the *para* substituent of the phenyl group on the three-membered ring. Moreover, the correlation of $\delta^{31}P$ with the Hammett σ^p-constants[17] (Table 1) is almost linear. This should be useful for extrapolations of ^{31}P-NMR chemical-shift values of unknown (2*H*-azaphosphirene)tungsten complexes. EI mass-spectrometric experiments have shown that the (2*H*-azaphosphirene)tungsten complexes **3a−h** undergo predominantly ring cleavage subsequent to the ionization process, yielding aryl nitriles and the terminal (phosphanediyl)-tungsten complex radical cation.

The molecular structure of complex **3d** was confirmed by X-ray crystallography (Figure 1).[18] One very characteristic feature is the three-membered ring with a short C−N distance [1.272(7) Å] and a very acute endocyclic angle at the phosphorus atom [41.9(2)°]. The observation that the endocyclic P−C and P−N bond lengths of **3d** are similar [1.759(5) and 1.795(4) Å], is remarkable. This becomes even more obvious, if the structural data of **3d** are compared to

Table 1. ^{13}C- and ^{31}P-NMR data of the ring atoms of the 2*H*-azaphosphirene ringsystem of **3a−h** (in $CDCl_3$, [*] in C_6D_6) and Hammett σ^p-constants

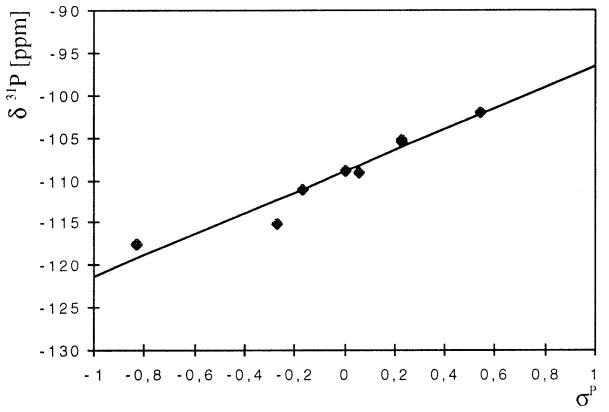

Figure 1. Molecular structure of **3d** in the crystal (ellipsoids represent 50-% probability levels, hydrogen atoms are omitted for clarity)[a]

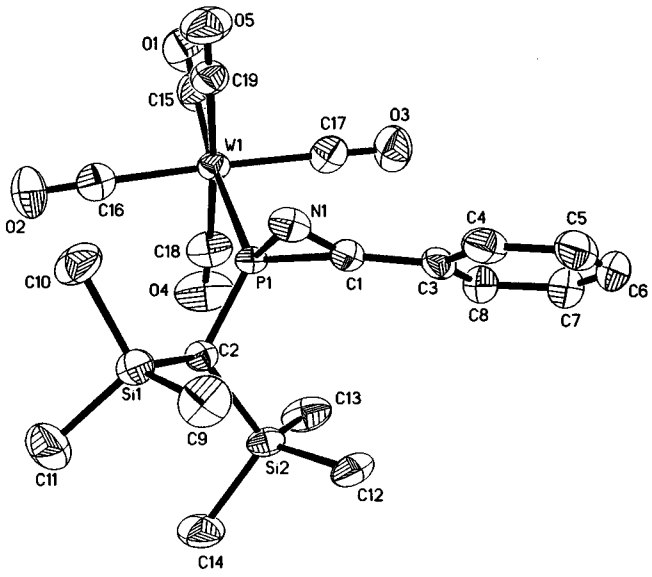

[a] Selected bond lengths [Å] and angles [°]: P(1)−C(1) 1.759(5), P(1)−C(2) 1.808(5), P(1)−N(1) 1.795(4), W(1)−P(1) 2.470(2), N(1)−C(1) 1.272(7), C(19−C(3) 1.457(7); C(2)−P(1)−W(1) 1.243(2), C(1)−P(1)−N(1) 41.9(2), N(1)−C(1)−P(1) 70.6(3), C(1)−N(1)−P(1) 67.5(3), N(1)−C(1)−C(3) 134.2(5)

those of a related (azaphosphiridine)tungsten complex[19] in which the bond lengths of the saturated three-membered P−C−N ring were determined to P−C 1.835(4), C−N 1.478(5) and P−N 1.728(3) Å. As in the molecular structure of **3g**,[12] **3d** reveals a coplanar arrangement of the two ring moieties (interplanar angle 2°), thus enabling an effective p_π-p_π-electron interaction.

Support by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

General: All operations were carried out under deoxygenated dry nitrogen as inert gas, solvents were dried according to standard procedures. − NMR spectra were recorded on a Bruker AC-200 spectrometer (200 MHz for ^{1}H; 50.3 MHz for ^{13}C; 188.3 MHz for ^{19}F; 81 MHz for ^{31}P) using [D$_6$]chloroform and [D$_6$]benzene as solvent and internal standard; shifts are given relative to tetramethylsilane (^{1}H,^{13}C), $CFCl_3$ (^{19}F), and 85% H_3PO_4 (^{31}P). − MS: Finnigan Mat 8430 (70 eV). − Elemental analyses: Carlo Erba analytical gaschromatograph. − IR: Biorad FT-IR 165.

General Procedure for the Preparation of {[Amino(aryl)carbene]pentacarbonyltungsten} Complexes: The ethoxy(aryl)carbenetungsten complexes were prepared according to ref.[20] and reacted, without purification, with ammonia. A gentle flow of ammonia was bubbled through a solution of 5 mmol of the ethoxy(aryl)carbenetungsten complexes in 60 ml of diethyl ether until a yellow color persisted and thin-layer liquid chromatography (SiO_2) indicated that all starting material had reacted. All volatile compounds were removed under reduced pressure (0.1 mbar) and the yellow residue was washed twice with a little pentane and subsequently dried in vacuo or, if necessary, purified by column chromatography.

[{Amino(4-trifluoromethylphenyl)carbene}pentacarbonyltungsten(0)] (**1a**): 2.1 g of **1a** (84%) was obtained as a yellow powder after low-temperature chromatography (SiO_2, −10°C; hexane/diethyl ether 10:1). General Procedure for the Preparation of Pentacarbonyl(2H-azaphosphirene)tungsten Complexes: To a solution of 1.5 mmol of amino(aryl)carbenetungsten complexes **1a−h** in 15 ml of diethyl ether 0.34 g (1.5 mmol) of **2** and 5 ml of NEt_3 was added at 0°C. The reaction mixture was stirred at ambient temp. until **2** was consumed (^{31}P-NMR control). The yellow-orange reaction mixture was evaporated to dryness under reduced pressure (0.1 mbar). The residue was extracted with 30 ml of pentane and filtered. The filtration residue was washed twice with 5 ml of pentane, the organic phases combined and the solvent removed under reduced pressure. The residue was purified, if necessary, by low-temperature column chromatography on silica gel.

Keywords: Zinc complexes / Pyrazolylborate ligands / Phosphate ligands / Hydrolytic cleavage / Condensation

Five different (pyrazolylborate)zinc hydroxide complexes Tp*Zn−OH (**1**) were used as hydrolytic reagents towards esters of various acids of phosphorus. Trimethyl phosphate and trimethyl phosphite could not be cleaved. Dimethyl and diphenyl phosphite yielded $Tp^{tBu,Me}Zn-OPHO(OR)$ (**2**, **3**). Triphenyl phosphate reacted slowly producing moderate yields of $Tp^*Zn-OPO(OPh)_2$ (**4**). Tris(*p*-nitrophenyl) phosphate was cleaved rapidly, forming $Tp^*Zn-OPO(OC_6H_4NO_2)_2$ (**5**) and $Tp^*Zn-OC_6H_4NO_2$ (**6**). Alkylbis(*p*-nitrophenyl) phosphates showed intermediate reactivity, losing *p*-nitrophenolate upon hydrolysis and producing $Tp^*Zn-OPO(OR)(OC_6H_4NO_2)$ (**7**, **8**). When phosphorus acid diesters were employed, condensation between the Zn−OH and P−OH functions occurred. This proved to be the convenient way of preparing the organophosphate complexes $Tp^*Zn-OPO(Ph)_2$ (**9**), $Tp^*Zn-OPO(OPh)_2$ (**4**), and $Tp^*Zn-OPO(OC_6H_4NO_2)_2$ (**5**). Six structure determinations showed the structural variability of the resulting complexes.

One of the largest group of enzymes are those which catalyze phosphate transfer[1]. Many of them are metalloenzymes[2], quite often having two or three metal ions in the active center[3]. Of the metals involved (Mg, Fe, Mn, and Zn) zinc plays an important role, being present for instance in alkaline[4] and acid[5] phosphatases, nucleases[6][7], phospholipases[8], phosphotriesterases[9], and DNA and RNA polymerases[10]. All these latter enzymes are involved in the making and breaking of phosphate ester (P−OR) linkages in their various biological occurrencies.

The importance of the subject and the ease of modelling the biological substrates by simple phosphoric acid esters like tris(*p*-nitrophenyl) phosphate has attracted organic chemists and coordination chemists early on. Research groups which have investigated the metal (specifically zinc) ion or complex catalyzed phosphate ester hydrolysis are, among others, those of Breslow[11], Chin[12], Brown[13], Kimura[14], Bianchi[15], and Yashiro[16]. Stoichiometric reactions and structural models for zinc complexes were provided, among others, by Krebs[17], Kitajima[18], Fenton[19], Lippard[20], and ourselves[21]. A typical characteristic of the model mechanisms or structures is the involvement of bidentate phosphate, being coordinated via two of its oxygen atoms to either one or two metal ions. Monodentate coordination is the exception, and to date just one structure of a mononuclear zinc complex bearing a phosphate only as a monodentate ligand has been published[21].

We are interested in exploiting the hydrolytic activity of zinc-bound water molecules or hydroxide groups in an isolated situation, i.e. one where the kind and number of other ligands on zinc leaves just one coordination site for H_2O or OH^-, thereby encapsulating it in an enzyme-like manner. The purpose is to make the reacting zinc complexes strictly monofunctional and allowing only monodentate coordination for the substrate too. We have so far tested it for zinc model complexes of tripodal N,N,N [e.g. tris(benzimidazolylmethyl)amine][22] and N,N,O (e.g. dipicolylglycine)[23] ligands. In our hands the substituted (pyrazolylborate)zinc hydroxides Tp*Zn−OH turned out to be the best nucleophiles, being active in the hydrolysis of esters[24], amides[24], CO_2[25][26] and similar systems with cumulated double bonds[27]. We have also briefly communicated the hydrolytic cleavage of phosphate esters and diphosphates by them[28].

This paper starts a series of publications on the cleavage of phosphate-containing materials by Zn−OH and $Zn-OH_2$ complexes. In order to lay a preparative and structural basis for further work, simple esters of various acids of phosphorus were treated with the five Tp*Zn−OH complexes **1a**−**e**. The reaction conditions were chosen such that one ester group each could be cleaved off, and due to the insolubility of the Tp*Zn−OH complexes in water the reactions were meant to be stoichiometric rather than catalytic.

"Small" Phosphates and Phosphites

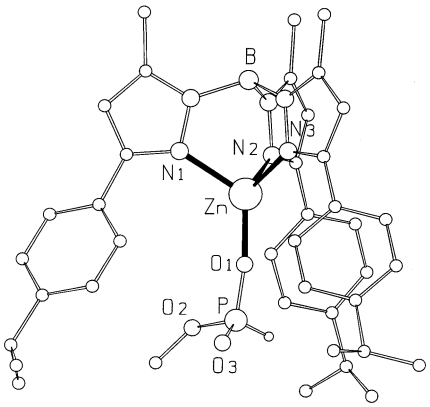
The first attempts at ester cleavage were made with trimethyl phosphite and trimethyl phosphate. Both turned out to be unreactive toward the Tp*Zn−OH reagents. Although, being small molecules, they allow easy access of a nucleophile to phosphorus, their alkyl ester functions seem to be too inert. Making them even smaller led to success, however. Dimethyl phosphite [$HPO(OMe)_2$] reacted with **1a** and **1c**, diphenyl phosphite [$HPO(OPh)_2$] reacted with **1a** producing in very good yields the zinc-phosphate complexes **2a**, **2c**, and **3a** as the products of the hydrolytic removal of one OR group. Both the liberated methanol and phenol did not show up in the form of zinc complexes, in accord with our experience that they don't react with Tp*Zn−OH[29]. One attempt at using an ester of methylphosphonic acid, namely $MePO(OMe)_2$, was also met with failure.

$Tp^{R,Me}Zn-OPHO(OMe)$
2a: R = *t*Bu
2c: R = Cum

$Tp^{tBu,Me}Zn-OPHO(OPh)$
3a

The spectroscopic identification of complexes **2a**, **2c**, and **3a** was easy due to their simple ^{1}H-NMR spectra containing the very typical P-H doublet. Confirmation of their constitutional assignment was obtained by a structure determination of **2c** (see Figure 1). The structure shows the expected pseudotetrahedral coordination of zinc with a symmetrical attachment of the $Tp^{Cum,Me}$ ligand and the Zn−O bond very close to the trigonal axis of the Tp*Zn unit. As such it provides no unusual features for a Tp*Zn−OX complex. The bonding situation of its phosphite ligand is discussed below.

Figure 1. Molecular structure of **2c**[a]



[a] Coordination environment of zinc: Zn−O1 1,825(5), Zn−N1 2.016(5), Zn−N2 2.026(5), Zn−N3 2.016(5) A; O1−Zn−N1 123.0(2), O1−Zn−N2 122.0(2), O1−Zn−N3 122.3(2)°. − In the crystal one methanol molecule is attached to O3 by a hydrogen bond.

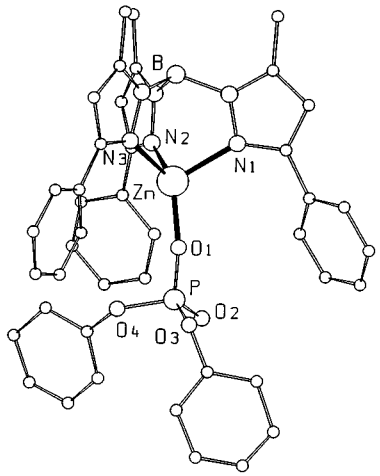
Triphenyl Phosphate

Aryl phosphates are more amenable to hydrolytic cleavage than trialkyl phosphates, yet they are not typically used for model studies for which *p*-nitrophenyl phosphates are the favourites. It turned out that our Tp*Zn−OH reagents are aggressive enough to remove one phenolate ligand from them, especially when applied in large excess for kinetic studies[30]. Stoichiometric reactions were relatively slow and led to product mixtures containing some starting material and side products which were not easy to separate. Thus **1d** and $PO(OPh)_3$ gave only traces of **4d**. Both **1b** and **1c** underwent relatively clean reactions with $PO(OPh)_3$ as evidenced by ^{31}P-NMR spectroscopy. After isolation, the products **4b** and **4c** were of moderate yield. Samples were also obtained of **4b** by condensation (see below) and of **4c** by hydrolytic cleavage of tetraphenyl diphosphate[31].

$Tp^{R,Me}Zn-OPO(OPh)_2$
4a: R = *t*Bu
4b: R = Ph
4c: R = Cum
4d: R = Py

The spectroscopic identification of complexes **4** rests mainly on the ^{1}H-NMR data of their Tp* ligands and the ^{31}P-NMR and υ(P=O) IR data of their phosphate ligands. The assignment was rounded off by a structure determination of **4b** (see Figure 2). It shows a less symmetrical arrangement around the zinc ion as evidenced by the Zn−N bond lengths and the O−Zn−N angles.

Figure 2. Molecular structure of **4b**[a]



[a] Coordination environment of zinc : Zn−O1 1,854(2), Zn−N1 2.009(3), Zn−N2 2.019(2), Zn−N3 2.060(2) A; O1−Zn−N1 114.6(1), O1−Zn−N2 130.8(1), O1−Zn−N3 119.5(1)°.

Tris(*p*-nitrophenyl) Phosphate

As expected, tris(*p*-nitrophenyl) phosphate reacted fast and cleanly with the Tp*Zn−OH reagents. It was, in our hands[30] like in others, the substrate of choice for kinetic measurements. We used it for stoichiometric reactions with **1b** and **1c**. In order to achieve complete consumption of the phosphate, two equivalents of the zinc complex had to be used. The reason for this is fast reaction of the liberated *p*-nitrophenol with the zinc−hydroxide unit in terms of a condensation reaction leading to the *p*-nitrophenolate complexes **6**, as we have described before[29]. Thus the hydrolytic cleavages of the phosphate yielded equimolar mixtures of

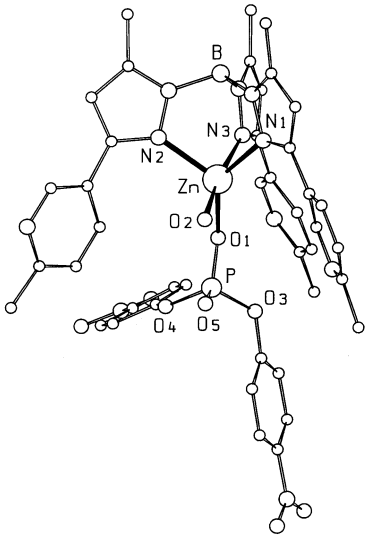
the phosphate complexes **5b**, **c** and the phenolate complexes **6b**, **c** which were separated.

$Tp^{R,Me}Zn-OPO(OC_6H_4-p\text{-}NO_2)_2$
5a: R = *t*Bu
5b: R = Ph
5c: R = Cum
5e: R = Pic

$Tp^{R,Me}Zn-OC_6H_4-p\text{-}NO_2$
6b: R = Ph
6c: R = Cum
6e: R = Pic

The spectroscopic identification of **5b** and **5c** rests on the ^{1}H-NMR data for the Tp* ligands and the υ(P=O) and δ(^{31}P) values again. Compounds **6b** and **6c** which we have described before[29] were identified spectroscopically. Crystals suitable for a structure determination were obtained of **5e** (see below). They turned out to contain hydrated **5e** with five-coordinate zinc (see Figure 3). Five-coordination of zinc seems to be the rule rather than the exception in zinc complexes of tris(3-pyridyl-3′-pyrazolyl)borato ligands[31][32][33]. In **5e** the geometry at zinc is that of a distorted trigonal bipyramid [angle O2−Zn−N3 170.8(1)°, angles between apical and equatorial ligands 85−96°, angles between equatorial ligands 97−139°]. The zinc-bound water molecule is connected via a hydrogen bond to the P=O oxygen (2.69 Å). The phosphate attachment is discussed below.

Figure 3. Molecular structure of **5e** · H_2O[a]



[a] Coordination environment of zinc: Zn−O1 1.996(2), Zn−O2 2.082(2), Zn−N1 2.070(3), Zn−N2 2.072(3), Zn−N3 2.202(3) Å.

Alkylbis(*p*-nitrophenyl) Phosphates

The alkylbis(*p*-nitrophenyl) phosphates contain two ester functions of quite different lability. It could therefore be predicted that they would lose only one *p*-nitrophenolate unit upon hydrolysis by Tp*Zn−OH. This was verified for ethylbis(*p*-nitrophenyl) phosphate with **1b**, **1c**, and **1e** as well as for cyclohexylbis(*p*-nitrophenyl) phosphate with **1e**. Reaction products were the zinc phosphate complexes **7b**, **7c**, **7e**, and **8e** together with the *p*-nitrophenolate complexes **6b**, **6c**, and **6e**, some of which were again difficult to separate. The various steps of the workup procedure resulted in partial hydrolytic destruction in case of **7b** and **7e**, liberating the free pyrazole which was then coordinated to zinc giving the addition products **7b′** and **7e′**. The presence of the additional pyrazole ligands in these complexes was found by ^{1}H-NMR spectroscopy. Otherwise the spectroscopic data of complexes **7** and **8** are in accord with their constitutions and quite similar to those of the related complexes with other phosphate ligands.

$Tp^{R,Me}Zn-OPO(OEt)(OC_6H_4-p\text{-}NO_2)$
7b: R = Ph
7c: R = Cum
7e: R = Pic

7b · 3-methyl-5-phenylpyrazole **7b′**

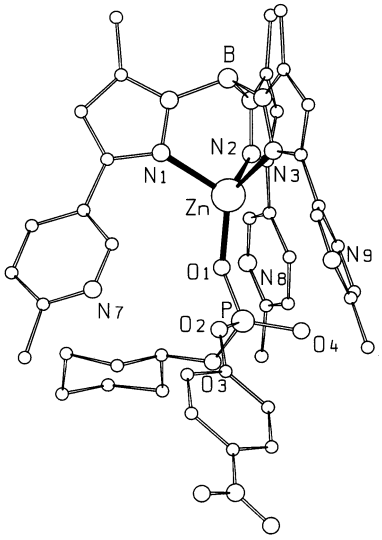
7e · 3-methyl-5-picolylpyrazole **7e′**

$Tp^{Pic,Me}Zn-OPO(OCy)(OC_6H_4-p\text{-}NO_2)$
8e

Of these complexes, one each with fourfold (**8e**) and fivefold (**7b′**) coordination at zinc was chosen for a structure determination. An unusual feature of all complexes **7** and **8** is the presence of phosphorus atoms with four different substituents. The crystals of **8e** and **7b′** are, however, not enantiomerically pure but belong to the centrosymmetric space group P−1.

Complex **8e** (see Figure 4) shares with complex **2c** the symmetrical attachment of the Tp* ligand to zinc. However, unlike the situation in **2c** the Zn−O bond is bent away significantly from the trigonal axis of the Tp* ligand, making the phosphate attachment in **8e** more like that in **4b**.

Figure 4. Molecular structure of **8e**[a]

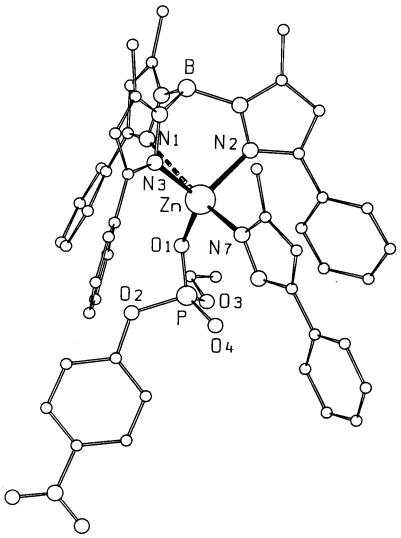


[a] Coordination environment of zinc: Zn−O1 1,854(2), Zn−N1 2.028(3), Zn−N2 2.030(2), Zn−N3 2.033(2) Å; O1−Zn−N1 118.8(1), O1−Zn−N2 116.4(1), O1−Zn−N3 131.8(1)°.

The coordination of zinc in complex **7b′** (see Figure 5) is quite unusual. The attachment of the free pyrazole molecule exerts a kind of a trans effect, pushing one of the Tp* pyrazole donors away on the opposite side of the zinc ion. The result is a very unsymmetrical coordination of the Tp* ligand to zinc, with the Zn−N1 distance (2.90 Å) practically outside a bonding range. The symmetry about the zinc ion can, however, best be described as trigonal-bipyramidal

with N7 and N1 in the apical positions (angle 172°). The angles between the axial and equatorial donors range from 77 to 105°, those between the equatorial donors between 101 and 125°. On the other hand all angles between N7 and the equatorial donors are much larger than 90° (maximum N7−Zn−O1 with 105°), indicating that the four donors O1, N2, N3, and N7 also define a flattened tetrahedron. It seems that electronic preferences favour tetrahedral coordination for **7b′** but the geometrical restraints of the Tp* ligand don′t allow to completely remove the fifth donor, resulting in the observed intermediate type of coordination.

Figure 5. Molecular structure of **7b′**[a]



[a] Coordination environment of zinc: Zn−O1 1.912(3), Zn−N1 2.897(4), Zn−N2 2.022(3), Zn−N3 2.003(3), Zn−N7 2.082(4) Å.

Condensation Reactions

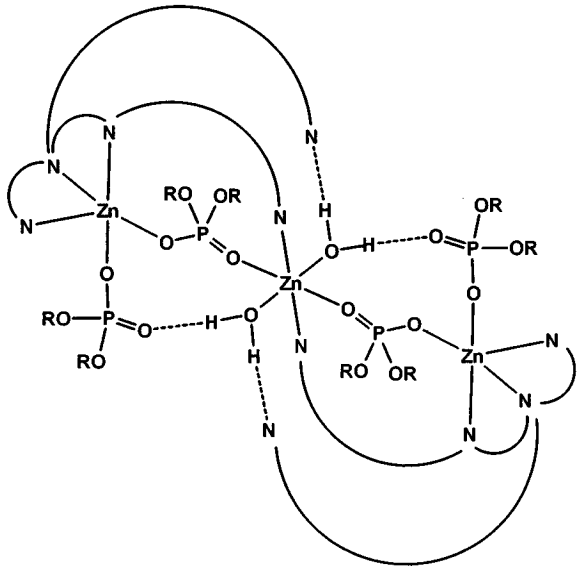
In addition to the phosphoric acid triesters we also tried to find out about the hydrolytic cleavage of phosphoric acid diesters. These are of course acids themselves and as such capable of destroying the pyrazolylborate ligands hydrolytically. To our surprise, however, their main reactivity towards the Tp*Zn−OH complexes consisted in a condensation reaction producing the corresponding diesterphosphate complexes. We then learnt that every $X_2P(O)OH$ compound undergoes this reaction yielding Tp*Zn−O-$P(O)X_2$.

In the context of this paper we applied the condensation reaction to **1a** and diphenylphosphinic acid, giving a good yield of **9a**. Similarly, **1a** with diphenyl phosphate and bis(*p*-nitrophenyl) phosphate yielded **4a** and **5a**, **1b** with both reagents yielded **4b**, **5b**, and **1e** with bis(*p*-nitrophenyl) phosphate yielded **5e** (which was used for the structure determination, see above).

$Tp^{tBu,Me}Zn-OP(O)Ph_2$
9a

The destructive power of the acidic phosphoric acid diesters came to effect in only one case, the reaction between **1d** and bis(*p*-nitrophenyl) phosphate. In the course of this reaction one of three Tp*Zn units was lost liberating zinc ions in a way which is unclear as yet. The combination of two Tp*Zn units, one zinc ion, four phosphate anions, and two water molecules then resulted in the formation of complex **10d**, the constitution of which became only clear by a structure determination. The schematic drawing of **10d** (see Figure 6) shows a octahedral zinc ion in the center and two five-coordinate zinc ions in the periphery. On both sides one phosphate each is bridging the zinc ions while the other is terminal. One pyridyl substituent of each $Tp^{Py,Me}$ ligand is used as a donor toward the central zinc ion as observed before in $[(Tp^{Py,Me}Zn)_2(\mu\text{-}H_3O_2)]^+$ [32]. Hydrogen bridging stabilizes the structure which is unique as a whole but comprised of established structural units.

Figure 6. Schematic drawing of complex **10d**[a]



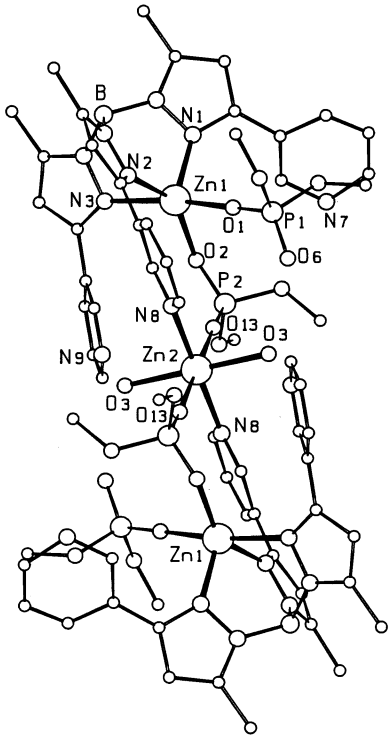
[a] R = *p*-nitrophenyl, the three interconnected N atoms bound to the outer Zn ions represent $Tp^{Py,Me}$ ligands, the four long curves represent one pyridyl substituent each of $Tp^{Py,Me}$.

Figure 7 displays the molecular structure of **10d**, with all atoms except the α-C of the *p*-nitrophenolate units omitted for clarity. The molecule is centrosymmetric. The central zinc ion is in a nearly ideal octahedral ZnN_2O_4 environment with Zn−O and Zn−N distances (2.12−2.14 Å) typically longer than those in all other zinc complexes of this paper. The peripheral zinc ions have a distorted trigonal-bipyramidal ZnN_3O_2 environment comparable to that in **5e** (*trans* angle O1−Zn1−N3 168°, *cis* angles 81−100°, equatorial angles 98−141°). The double-bridged linkage between Zn1 and Zn2 via one phosphate and one pyridylpyrazole unit represents a 10-membered heterocyclic ring.

Discussion of the Zinc−Phosphate Interactions

All the phosphite and phosphate complexes obtained here are molecular compounds soluble in nonpolar organic solvents. This implies that their zinc−phosphate interactions are covalent, as is also evidenced by the structure determinations. We became aware that this may be a questionable statement when observing that the Zn−O−P angles

Figure 7. Molecular structure of **10d**[a]



[a] Coordination environments of the zinc ions: Zn1−N1 2.034(5), Zn1−N2 2.070(5), Zn1−N3 2.224(5), Zn1−O1 2.067(4), Zn1−O2 1.960(4), Å Zn2−N8 2.140(7), Zn2−O3 2.125(6), Zn2−O13 2.128(5) Å.

are never close to the tetrahedral angle to be expected for covalent oxygen and that the formal single bonds P−O(Zn) are almost as short as the formal double bonds P=O. The data related to this are assembled in Table 1 which also includes values from two complexes in the accompanying paper[31].

Table 1 Bonding parameters for the zinc−phosphate interactions

4e·H_2O[a]	1.95	1.50	1.46	139	118

[a] Structures described in ref.[31]. − [b] Only the terminal phosphate is considered.

The table shows that in all cases there is an almost complete equalization of the formal single and double P−O bonds. Although the "double" bonds are shorter throughout, their shortening amounts to a maximum of 0.04 Å. When referenced against the P−O(R) bond lengths of truely single bonds in the same compounds (1.57−1.60 Å) or the standard value for a true P=O double bond (ca. 1.45 Å[34]) it becomes clear that both P−O bonds in the phosphate complexes described here have close to double bond character as is also observed in various ionic phosphates[34]. This relation to ionic phosphate is underlined by the quite constant and normal values of the O−P=O angles.

The Zn−O bond lengths cannot be used as a measure of the zinc−phosphate interactions. They simply reflect the coordination number of zinc, as made visible by the grouping of compounds in the table. For each of the three groups the range of Zn−O bond lengths is typical, increasing with the coordination number, and all of them are shorter than the value for octahedral zinc (2.15−2.20 Å). Conversely the bond lengths and angles of the P−O entities under consideration do not reflect the coordination number of zinc.

The most variable structural detail in this context is the Zn−O−P angle, showing a spread from 136 to 178°. As the individual values of this angle cannot be related to other bond lengths or angles in the corresponding complexes, they cannot reflect electronic situations, i.e. they must be determined by geometric constraints. This is, however, only obvious for **2c** where the phosphite ligand is "compressed" by the *tert*-butyl substituents of the Tp* ligand. In the other cases it must reflect a combination of intramolecular forces. Altogether the softness of the Zn−O−P angle is the second strong indicater for the rather polar nature of the zinc−phosphate interactions. As such it is reminiscent of the Si−O−Si linkage in silicates and siloxanes which has been discussed in similar terms in the light of modern MO theory[35].

Conclusions

The nucleophilic strength of the "enzyme models" Tp* Zn−OH has been demonstrated for a wide range of esters of phosphorus acids as well as for Tp* ligands of varying polarity and steric bulk. In a favourable case even an alkyl ester could be cleaved. Phenyl esters were of moderate, *p*-nitrophenyl esters of high reactivity. This work has lain the preparative basis for kinetic studies aimed at elucidating mechanistic details of the cleavage reactions.

In terms of enzyme modelling the reactions of the alkyl esters are the only ones of relevance. Phosphate transfer from mononucleotides or phospholipids involves the cleavage of aliphatic phosphate esters, i.e. those which are most difficult to hydrolyze. We have shown that this is in principle possible with Tp*Zn−OH. When an alkyl and a *p*-nitrophenyl ester group are present in a phosphoric acid ester, it is exclusively the latter which is cleaved off. Cleavage reactions of this kind have led here to the new class of metal phosphate complexes containing chiral phosphorus centers.

All cleavage reactions by Tp*Zn−OH have shown that a single zinc ion (or Zn−OH, or Zn−OH_2 unit) is sufficient to perform the hydrolysis. The rates of the cleavage reactions observed here are also not smaller than those reported for some dinuclear model complexes, irrespective of the fact that our reactions are stoichiometric rather than catalytic. All reactions end with the formation of phosphate complexes, allowing the mechanistic conclusion that the metal

ion and the phosphate are in contact during the ester cleavage.

The structure determinations of the zinc phosphate complexes have yielded two important pieces of information. Firstly they indicate that the bonding between zinc and phosphate is quite polar in nature. Secondly they show a variety of coordination geometries and ligand arrangements around zinc which is puzzling at first glance. We are optimistic, however, that a systematic analysis of the structures of all odd-shaped Tp*Zn(X)(Y) complexes will allow a superposition yielding a reaction trajectory for the nucleophilic transformation of substrates by Tp*Zn−OH. We are in the course of further structural and basic kinetic work with the aim of finding this trajectory.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. We thank Dr. *W. Deck* and Mr. *B. Müller* for help with the NMR and X-ray work.

Experimental Section

General experimental methods and measuring techniques see ref.[36]. The Tp*Zn−OH complexes[25][27][33][37] and the alkylbis(*p*-nitrophenyl) phosphates[38] were prepared according to published procedures. All other reagents were obtained commercially. Solvents were air- and water-free. − IR data (cm^{-1}) were recorded from KBr pellets. − ^{1}H- and ^{31}P-NMR data (δ in ppm, int. TMS, ext. H_3PO_4) were recorded from $CDCl_3$ solutions. All compounds are characterized in Table 2.

2a: 200 mg (0.395 mmol) of **1a** and 43.5 mg (0.395 mmol) of dimethylphosphite in 20 ml of dichloromethane were stirred for 16 h. The solvent was removed in vacuo and the residue crystallized from methanol. Yield 210 mg (90%) of **2a**. − IR: 2554m (BH), 1252vs (P=O). − ^{1}H NMR: 1.41 [s, 27 H, *t*Bu], 2.39 [s, 9 H, Me(pz)], 3.72 [d, J = 12.1 Hz, 3 H, OMe], 5.84 [s, 3 H, H(pz)], 7.10 [d, J = 647 Hz, 1 H, PH]. − ^{31}P NMR: −0.6.

2c: 1.00g (1.44 mmol) of **1c** and 1.20 g (10.9 mmol) of dimethyl phosphite in 30 ml of toluene were stirred for 2 h. The solvent was removed in vacuo, the residue washed with 2 ml of cold methanol and then crystallized from methanol. Yield 0.92 g (81%) of **2c**. − IR: 2537m (BH), 1246s (P=O). − ^{1}H NMR: 1.23 [d, J = 6.9 Hz, 18 H, Me(*i*Pr)], 2.50 [s, 9 H, Me], 2.94 [sept, J = 6.9 Hz, 3 H, CH(*i*Pr)], 3.19 [d, J = 11.8 Hz, 3 H, OMe], 6.21 [s, 3 H, CH(pz)], 6.27 [d, J = 654 Hz, 1 H, PH], 7.31 [d, J = 8.2 Hz, 6 H, Ph(3,5)], 7.60 [d, J = 8.2 Hz, 6 H, Ph(2,6)]. − ^{31}P NMR: 1.0.

3a: As before from 500 mg (0.988 mmol) of **1a** and 231 mg (0.988 mmol) of diphenylphosphite. Repeated crystallization from acetonitrile yielded 430 mg (67%) **3a**. − IR: 2558m (BH), 1259s (P=O). − ^{1}H NMR: 1.41 [s, 27 H, *t*Bu], 2.40 [s, 9 H, Me(pz)], 5.86 [s, 3 H, H(pz)], 7.09 [m, 1 H, Ph], 7.30 [m, 4 H, Ph], 7.38 [d, J = 664 Hz, 1 H, PH]. − ^{31}P NMR: −5.0.

General Procedure for the Cleavage of Aryl Phosphates: Two equivalents of the Tp*Zn−OH complex and one equivalent of the aryl phosphate were stirred in a solvent at room temp. All volatiles were removed in vacuo. Treatment of the residue with acetonitrile or ethanol yielded a solution of the phosphate complex and a residue of the phenolate complex. When already known, the phenolate complex was discarded. Otherwise it was recrystallized and characterized (see below). The solution of the phosphate complex was evaporated to dryness in vacuo and the product recrystallized.

4b: From 300 mg (0.530 mmol) of **1b** and 86.5 mg (0.265 mmol) of triphenyl phosphate in 20 ml of CH_2Cl_2 for 3 d. Crystallization from acetonitrile yielded 73.5 mg (36%) of **4b**. − IR: 2549m (BH), 1230s (P=O). − ^{1}H NMR: 2.52 [s, 9 H, Me(pz)], 6.25 [s, 3 H, H(pz)], 6.86 [d, J = 7.3 Hz, 4 H, Ph(phos(2,6))], 6.89−7.27 [m, 9 H, Ph], 7.24 [m, 6 H, Ph(3,5)], 7.64 [d, J = 7.4 Hz, 6 H, Ph(2,6)]. − ^{31}P NMR: −16.6.

4c: From 300 mg (0.433 mmol) of **1c** and 70.7 mg (0.217 mmol) of triphenyl phosphate in 20 ml of CH_2Cl_2 for 4 d. Crystallization from acetonitrile yielded 91 mg (45%) of **4c**. − IR: 2552m (BH), 1282s (P=O). − ^{1}H NMR: 1.04 [d, ^3J = 6.9 Hz, 18 H, Me(*i*Pr)], 2.53 [s, 9 H, Me(pz)], 2.70 [sept, ^3J = 6.9 Hz, 3 H, H(*i*Pr)], 6.26 [s, 3 H, H(pz)], 6.68 [d, ^3J = 7.5 Hz, 4 H, Ph(phos(2,6))], 6.95 [m, ^3J = 7.5 Hz, 6 H, Ph(phos(3,4,5))], 7.13 [d, ^3J = 8.1 Hz, 6 H, Ph(3,5)], 7.62 [d, ^3J = 8.1 Hz, 6 H, Ph(2,6)]. − ^{31}P NMR: −16.6.

4d: From 500 mg (0.879 mmol) of **1d** and 143 mg (0.438 mmol) of triphenyl phosphate in 40 ml of CH_2Cl_2 for 16 h. Several recrystallizations from acetonitrile were necessary to yield 35 mg (5%) of **4d**. − IR: 2553m (BH), 1261s (P=O). − ^{1}H NMR: 2.57 [s, 9 H, Me(pz)], 6.27 [s, 3 H, H(pz)], 6.56 [d, ^3J = 8.1 Hz, 4 H, Ph(2,6)], 7.05 [m, 6 H, Ph(3,4,5)], 7.05 [dd, ^3J = 7.9 Hz, ^3J = 4.6 Hz, 3 H, Py(5)], 8.11 [d, ^3J = 7.9 Hz, 3 H, Py(6)], 8.21 [d, ^3J = 4.6 Hz, 3 H, Py(4)], 8.67 [s, 3 H, Py(2)]. − ^{31}P NMR: −14.9.

5b: From 300 mg (0.530 mmol) of **1b** and 122 mg (0.265 mmol) of tris(*p*-nitrophenyl)phosphate in 5 ml of CH_2Cl_2 for 24 h. Two recrystallizations from acetonitrile yielded 37.3 mg (16%) of **5b**. − IR: 2554m (BH), 1548s, 1344s (NO), 1256s (P=O). − ^{1}H NMR: 2.56 [s, 9 H, Me(pz)], 6.27 [s, 3 H, H(pz)], 6.71 [d, ^3J = 7.3 Hz, 4 H, Nitr(2,6)], 7.20 [m, 3 H, Ph(4)], 7.35 [m, 6 H, Ph(3,5)], 7.63 [d,

^3J = 7.3 Hz, 6 H, Ph(2,6)], 7.89 [d, ^3J = 7.3 Hz, 4 H, Nitr(3,5)]. − ^{31}P NMR: −18.9.

5c: From 300 mg (0.433 mmol) of **1c** and 70.7 mg (0.217 mmol) of tris(*p*-nitrophenyl)phosphate in 10 ml of CH_2Cl_2 for 2 d. Two recrystallizations from acetonitrile yielded 22 mg (10%) of **5c**. − IR: 3130w (H_2O), 2561m (BH), 1553m, 1344s (NO), 1258m (P=O). − ^{1}H NMR: 1.06 [d, ^3J = 6.8 Hz, 18 H, Me(*i*Pr)], 2.55 [s, 9 H, Me(pz)], 2.73 [sept, ^3J = 6.9 Hz, 3 H, H(*i*Pr)], 6.24 [s, 3 H, H(pz)], 6.69 [d, ^3J = 8.2 Hz, 4 H, Nitr(3,5)], 7.21 [d, ^3J = 8.2 Hz, 6 H, Ph(3,5)], 7.57 [d, ^3J = 8.2 Hz, 6 H, Ph(2,6)], 7.87 [d, ^3J = 8.2 Hz, 4 H, Nitr(2,6)]. − ^{31}P NMR: −19.4.

7b′: From 500 mg (0.884 mmol) of **1b** and 168 mg (0.442 mmol) of ethylbis(*p*-nitrophenyl) phosphate in 10 ml of $CHCl_3$ for 24 h. Recrystallization from methanol/acetonitrile (1:1). Yield 129 mg (31%) of **7b′**. − IR: 2551m (BH), 1544s, 1343s (NO), 1251s (P=O). − ^{1}H NMR: 0.99 [t, ^3J = 7.1 Hz, 3 H, Me(OEt)], 2.49 [s, 12 H, Me(py), Me(pz(a))], 3.65 [dq, ^3J = 7.1 Hz, ^3J = 7.1 Hz, 2 H, CH_2(OEt)], 5.82 [s, 1 H, H(pz(a))], 6.26 [s, 3 H, H(pz)], 7.04−7.57 [m, 16 H, Ph], 7.59 [d, ^3J = 7.3 Hz, 6 H, Ph(2,6)], 8.00 [d, ^3J = 7.2 Hz, 2 H, Nitr(3,5)]. − ^{31}P NMR: −8.2.

7c: From 233 mg (0.336 mmol) of **1c** and 62.0 mg (0.168 mmol) of ethylbis(*p*-nitrophenyl) phosphate in 5 ml of $CHCl_3$ for 48 h. Crystallization from acetonitrile yielded two crystal fractions which had to be sorted manually (**6c** and **7c**). Yield 43 mg (28%) of **7c**. − IR: 2551m (BH), 1550m, 1344s (NO), 1256s (P=O). − ^{1}H NMR: 0.84 [t, ^3J = 7.1 Hz, 3 H, Me(OEt)], 1.15 [d, ^3J = 6.9 Hz, 18 H, Me(*i*Pr)], 2.55 [s, 9 H, Me(pz)], 2.79 [sept, ^3J = 6.9 Hz, 3 H, H (*i*Pr)], 3.46 [dq, ^3J = 7.1 Hz, ^3J = 7.1 Hz, 2 H, CH_2(OEt)], 6.23 [s, 3 H, H(pz)], 6.74 [d, ^3J = 7.2 Hz, 2 H, Nitr(2,6)], 7.29 [d, ^3J = 8.2 Hz, 6 H, Ph(3,5)], 7.61 [d, ^3J = 8.2 Hz, 6 H, Ph(2,6)], 7.84 [d, ^3J = 7.2 Hz, 2 H, Nitr(3,5)]. − ^{31}P NMR: −12.0.

7e′: From 312 mg (0.550 mmol) of **1e** and 101 mg (0.275 mmol) of ethylbis(*p*-nitrophenyl) phosphate in 5 ml of $CHCl_3$ for 48 h. Recrystallization from acetonitrile. Yield 107 mg (46%) of **7e′**. − IR: 2537m (BH), 1545m, 1342s (NO), 1248s (P=O). − ^{1}H NMR: 1.02 [t, ^3J = 7.1 Hz, 3 H, Me(OEt)], 2.34 [s, 12 H, Me(py), Me-(py(a))], 2.55 [s, 12 H, Me(pz)], 3.67 [dq, ^3J = 7.1 Hz, ^3J = 7.1 Hz, 2 H, CH_2(OEt)], 5.91 [s, 1 H, H(pz(a))], 6.29 [s, 3 H, H(pz)], 7.08 [d, ^3J = 8.0 Hz, 3 H, Py(5)], 7.12 [d, 1 H, Py(5(a))], 7.25 [d, ^3J = 7.2 Hz, 2 H, Nitr(2,6)], 7.64 [dd, ^3J = 8.0 Hz, ^4J = 2.2 Hz, 1 H, Py(6(a))], 7.93 [dd, ^3J = 8.0 Hz, ^4J = 2.1 Hz, 3 H, Py(6)], 8.13 [d, ^3J = 7.2 Hz, 2 H, Nitr(3,5)], 8.55 [d, ^4J = 2.1 Hz, 1 H, Py(2(a))], 8.59 [d, ^4J = 2.1 Hz, 3 H, Py(2)]. − ^{31}P NMR: −8.3.

8e: From 500 mg (0.818 mmol) of **1e** and 175 mg (0.414 mmol) of cyclohexylbis(*p*-nitrophenyl) phosphate in 20 ml of CH_2Cl_2 for 16 h. Recrystallization from acetonitrile/dichloromethane (4:1). Yield 278 mg (75%) of **8e**. − IR: 2570m (BH), 1544m, 1340s (NO), 1251s (P=O). − ^{1}H NMR: 0.91 [m, 2 H, Cy(4)], 1.28 [m, 4 H, Cy(3), C(5)], 1.36 [m, 4 H, Cy(2), Cy(6)], 2.44 [s, 9 H, Me(py)], 2.56 [s, 9 H, Me(pz)], 3.61 [m, ^3J = 7.6 Hz, 1 H, Cy(1)], 6.31 [s, 3 H, H(pz)], 7.09 [d, ^3J = 9.1 Hz, 2 H, Nitr(2,6)], 7.27 [d, ^3J = 8.0 Hz, 3 H, Py(5)], 8.03 [dd, ^3J = 8.0 Hz, ^4J = 2.1 Hz, 3 H, Py(6)], 8.09 [d, ^3J = 9.1 Hz, 2 H, Nitr(3,5)], 8.63 [d, ^4J = 2.1 Hz, 3 H, Py(2)]. − ^{31}P NMR: −11.3.

General Procedure for the Condensation Reactions: The reagents were combined in 20 ml of dichloromethane and stirred for one day. The solvent was removed in vacuo and the residue crystallized from acetonitrile.

9a: From 500 mg (0.988 mmol) of **1a** and 215 mg (0.988 mmol) of diphenylphosphinic acid. Yield 620 mg (88%) of **9a** which was not analytically pure and could not be purified by repeated crystallizations. − IR: 2547m (BH), 1218vs (P=O). − ^{1}H NMR: 1.26 [s, 27 H, *t*Bu], 2.37 [s, 9 H, Me(pz)], 5.81 [s, 3 H, H(pz)], 7.32 [m, 6 H, Ph], 8.05 [m, 4 H, Ph]. − ^{31}P NMR: +17.8.

4a: From 200 mg (0.395 mmol) of **1a** and 98.7 mg (0.395 mmol) of diphenyl phosphate. Yield 260 mg (88%) of **4a**. − IR: 2552m (BH), 1290vs (P=O). − ^{1}H NMR: 1.41 [s, 27 H, *t*Bu], 2.39 [s, 9 H, Me(pz)], 5.84 [s, 3 H, H(pz)], 7.03 [m, 2 H, Ph], 7.19 [m, 8 H, Ph]. − ^{31}P NMR: −17.3.

5a: From 200 mg (0.395 mmol) of **1a** and 134 mg (0.395 mmol) of bis(*p*-nitrophenyl) phosphate. Yield 290 mg (75%) of **5a**. − IR: 252m (BH), 1537s, 1345s (NO), 1302vs (P=O). − ^{1}H NMR: 1.38 [s, 72 H, *t*Bu], 2.41 [s, 9 H, Me(pz)], 5.88 [s, 3 H, H(pz)], 7.42 [d, J = 8.9 Hz, 4 H, Ph], 8.17 [d, J = 8.9 Hz, 4 H, Ph].

4b: From 300 mg (0.530 mmol) of **1b** and 133 mg (0.530 mmol) of diphenyl phosphate. Yield 368 mg (87%).

5b: From 250 mg (0.442 mmol) of **1b** and 150 mg (0.442 mmol) of bis(*p*-nitrophenyl) phosphate. Yield 310 mg (79%).

5e: From 500 mg (0.818 mmol) of **1e** and 278 mg (0.817 mmol) of bis(*p*-nitrophenyl) phosphate. Yield 694 mg (91%) of **5e**. − IR: 3378w (H_2O), 2554m (BH), 1518s, 1344s (NO), 1258m (P=O). − ^{1}H NMR: 2.36 [s, 9 H, Me(py)], 2.58 [s, 9 H, Me(pz)], 6.31 [s, 3 H, H(pz)], 6.92 [d, ^3J = 9.1 Hz, 4 H, Nitr(2,6)], 7.13 [d, ^3J = 8.0 Hz, 3 H, Py(5)], 7.89 [dd, ^3J = 8.0 Hz, ^4J = 2.3 Hz, 3 H, Py(6)], 8.02 [d, ^3J = 9.1 Hz, 4 H, Nitr(3,5)], 8.66 [d, ^4J = 2.3 Hz, 3 H, Py(2)]. − ^{31}P NMR: −17.2.

Preparation of **10d**: 500 mg (0.879 mmol) of **1d** and 299 mg (0.879 mmol) of bis(*p*-nitrophenyl) phosphate in 40 ml of CH_2Cl_2 were stirred for 16 h. The solvent was removed in vacuo, the residue picked up in 50 ml of hot acetonitrile, filtered hot and left to crystallize at room temp.. After 3 days 330 mg (44%) of **10d** had precipitated. − IR: 2551m (BH), 1517s, 1345s (NO), 1257m (P=O). − ^{1}H NMR: 2.55 [s, 18 H, Me(pz)], 6.56 [s, 6 H, H(pz)], 7.35 [d, ^3J = 9.3 Hz, 16 H, Nitr(3,5)], 7.54 [dd, ^3J = 7.9 Hz, ^3J = 4.8 Hz, 6 H, Py(5)], 7.97 [ddd, ^3J = 7.9 Hz, ^4J = 2.2 Hz, ^4J = 1.6 Hz, Py(6)], 8.15 [d, ^3J = 9.3 Hz, 16 H, Nitr(2,6)], 8.64 [dd, ^3J = 4.8 Hz, ^4J = 1.6 Hz, 6 H, Py(4)], 8.79 [d, ^4J = 2.2 Hz, 6 H, Py(2)]. − ^{31}P NMR: −13.4.

Structure Determinations[39]: Diffraction data were recorded with the ω/2θ technique on a Nonius CAD4 diffractometer fitted with a molybdenum tube (K_α, λ = 0.7107 Å) and a graphite monochromator. No absorption corrections were applied. The structures were solved with direct methods and refined anisotropically with the SHELX program suite.[40] Hydrogen atoms were included with fixed distances and isotropic temperature factors 1.2 times those of their attached atoms. Parameters were refined against F^2. The R values are defined as $R_1 = \Sigma F_o - F_c/\Sigma F_o$ and $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2/\Sigma[w(F_o^2)^2]\}^{1/2}$. Drawings were produced with SCHAKAL.[41] Table 3 lists the crystallographic data.

Hydrolytic Cleavage of Diphosphates, Sulfonatophosphates, and Disulfonates by (Pyrazolylborate)zinc Hydroxide Complexes☆

Karl Weis and Heinrich Vahrenkamp*

Institut für Anorganische und Analytische Chemie der Universität Freiburg,
Albertstrasse 21, D-79104 Freiburg, Germany

Received September 27, 1997

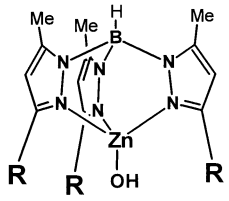
Keywords: Zinc complexes / Pyrazolylborate ligands / Hydrolytic cleavage / Diphosphate / Sulfonatophosphate / Disulfonate

Three (pyrazolylborate)zinc hydroxide complexes Tp*Zn−OH were used as hydrolytic reagents to cleave the P−O−P, P−O−S, and S−O−S linkages of organic diphosphates, sulfonatophosphates, and disulfonates. The resulting complexes of the types Tp*Zn−OPO(OR)$_2$ and Tp*Zn−O-SO$_2$R could also be obtained by condensation reactions between Tp*Zn−OH and HO−PO(OR)$_2$ or HO−SO$_2$R. Two of them were characterized by structure determinations.

Among the many phosphate transferring enzymes, an important class are those which cleave the P−O−P linkages of oligophosphates, e.g. ADP, ATP, or inorganic pyrophosphate[1][2][3]. As a rule these are metalloenzymes, quite often containing two or three metal ions in the active center, typically magnesium, manganese or zinc[4]. In all cases the labile coordination positions on the metal ions are occupied by water molecules in the resting enzymes and by the reacting phosphate entities in the working enzymes. Here like in other hydrolytic metalloenzymes the essential nucleophile is likely to be a M−OH unit[5].

While the modelling of enzymes cleaving phosphate esters by metal coordination compounds is very well established (see preceding paper[6] and references cited therein), we are not aware of related studies concerning the cleavage of P−O−P or related systems[7]. We therefore started such a study using our established "enzyme model" in the form of the highly nucleophilic pyrazolylborate zinc hydroxide complexes Tp*Zn−OH[8][9][10][11][12][13]. Following our preliminary communication on a P−O−P system, i.e. an anhydride of a phosphoric acid[14], we extended the studies to a S−O−S system, i.e. an anhydride of a sulfonic acid, and a P−O−S system, i.e. a mixed anhydride. The latter bears relevance in relation to adenosine-3′-phosphate-5′-phosphosulfate (PAPS), a sulfate resource of various organisms[15]. Our main interest was to find out how efficient our Tp*Zn−OH complexes would be for the cleavage of these anhydride systems.

As the "enzyme models" we used the three Tp*Zn complexes **1a**−**c**. Their "substrates" were chosen to be molecular rather than ionic species, i.e. containing fully esterified phosphate units [(RO)$_2$P(O)O] or sulfate units (RSO$_2$O). The purpose of this was to locate the reactivity in the anhydride linkages rather than the acidic P−OH or S−OH functions and to ease reaction with the Tp*Zn−OH complexes which are not water-soluble. As a result the reactions were predetermined to be stoichiometric rather than catalytic.



1a (Tp^{tBu,Me}Zn-OH) : R = t-butyl

1b (Tp^{Cum,Me}Zn-OH): R = p-cumenyl

1c (Tp^{Pic,Me}Zn-OH) : R = 5′-picolyl

Reactions and Products

It was found that of the three Tp*Zn−OH complexes **1a** does not react with diphosphates. The steric bulk of the *tert*-butyl groups seems to be too high. The other attempts at diphosphate cleavage went smoothly and produced the cleavage products in high yields. Tetraethyl diphosphate and **1b** yielded **2b**, tetraphenyl diphosphate upon reaction with **1b** and **1c** yielded **3b** and **3c** of which **3b** was obtained before by cleavage of PO(OPh)$_3$ with **1b**[6]. Upon recrystallization from acetonitrile which was not fully dried both **3b** and **3c** were converted to adducts, as found out by the subsequent structure determinations. Of these **3b′** results from partial hydrolytic destruction of the Tp^{Cum,Me} ligand while **3c′** simply involves addition of a water molecule.

Tp^{Cum,Me}Zn−OPO(OEt)$_2$ **2b**

Tp^{R,Me}Zn−OPO(OPh)$_2$

3b: R = Cum
3c: R = Pic

(Tp^{Cum,Me})(3-methyl-5-cumenyl-pyrazole)Zn−OPO(OPh)$_2$ **3b′**

(Tp^{Pic,Me})(H$_2$O)Zn−OPO(OPh)$_2$ **3c′**

The S−O−S system employed was the anhydride of *p*-toluenesulfonic acid (SOS). It reacted easily with **1c**, forming **4c** in good yields which was crystallized as a hydrate again. As the mixed anhydride we used that of diphenylphosphate and *p*-toluenesulfonic acid (POS). Its reaction with **1c** at room temperature was complete within about half a day. The product mixture consisted of an equimolar

mixture of **3c** and **4c** as evidenced by IR and ^{1}H- as well as ^{13}C-NMR spectroscopy. The separation of this mixture proved to be too cumbersome, however.

$Tol-SO_2-O-SO_2-Tol$ (SOS) $(PhO)_2PO-O-SO-Tol$ (POS)

$Tp^{R,Me}Zn-OSO_2-Tol$

4a: R = *t*Bu
4b: R = Cum
4c: R = Pic

The first step of the hydrolytic cleavages of the anhydrides by Tp*Zn−OH must result in the liberation of one equivalent of the corresponding acid while the other half of the anhydride becomes attached to zinc as in complexes **2**−**4**. Following the reactions spectroscopically gave no evidence, however, for the free acids $(RO)_2POOH$ or TosOH. Instead only the complexes **2**, **3**, or **4** were observed. This means that the free acids react quickly with excessive Tp*Zn−OH by means of a condensation reaction. Accordingly, employing a 1:1 stoichiometry for Tp*Zn−OH and anhydride resulted in only half-consumption of the anhydride. Therefore a 2:1 stoichiometry was applied for the preparations.

It could then be shown that the formation of the zinc phosphate and sulfonate complexes by condensation is indeed a fast reaction. It worked for the diorganophosphates yielding **3a** and **c** (see preceding paper[6]). It worked for all three Tp*Zn−OH complexes with *p*-toluenesulfonic acid, resulting in complexes **4a**−**c** of which **4a** has already been described by us[16]. For preparative purposes this condensation reaction is the method of choice to obtain complexes like **3** and **4**.

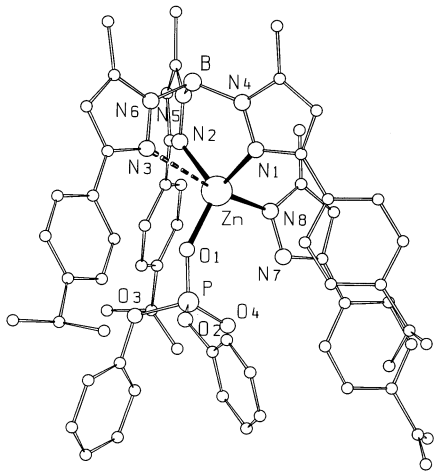
The identification of the Tp*Zn phosphate and sulfonate complexes consisted mainly in the structure determinations described here and in previous papers. The spectral data (see Experimental Section) are in agreement. Specifically the IR bands of the BH, P=O, and S=O functions, the ^{1}H-NMR resonances of the Tp* ligands, and the ^{31}P-NMR resonances are of diagnostic value.

Structure Determinations

The basic structural information on the complex types **2**, **3**, and **4** was already available due to the structure determinations of **4a** and various $Tp^*Zn-OPOX_2$ compounds[6][16][17]. In addition to this, the X-ray analyses of **3b′** and **3c′** were worthwhile because they yielded coordination patterns of zinc which differ from the usual tetrahedral Tp*Zn−X arrangement. In both cases, despite the steric bulk of the pyrazoles′ 3-substituents (Cum, Pic) and despite the presence of the voluminous phosphate ligand, a further ligand (the pyrazole in **3b′** and the water molecule in **3c′**) can exist in the ligand sphere of zinc. This finally breaks the rule that the sterically demanding Tp* ligands are "tetrahedral enforcers". In a later paper we will discuss the mechanistic implications arising from a comparison of the very variable geometry at the five-coordinated zinc ion in Tp*Zn(X)(Y) complexes.

Complex **3b′** (see Figure 1) contains the two coligands (phosphate and pyrazole) close to each other [angle O1−Zn−N8 103.1(2)°] and connected by a hydrogen bond between O4 and N7 (2.78 Å). The coordination of the Tp* ligand to zinc is very unusual. While the pyrazole nitrogen atoms N1 and N2 are attached at normal distances, N3 is practically nonbonding. Thus the geometry of **3b′** is intermediate between a flattened tetrahedron with N8 at the apex and an elongated trigonal bipyramid with N8 at the "short" and N3 at the "long" apex. In terms of a S_N2 substitution at a tetrahedral center this represents a situation close to the final state, i.e. with the entering group (N8) almost firmly bound and the leaving group (N3) almost completely removed. Complex **3b′** is, after $Tp^{Ph,Me}$(3-methyl-5-phenylpyrazole)Zn−OPO(OEt)(OC_6H_4−*p*-NO_2)[6], the second example of this kind of Tp*Zn complexes with a coordination intermediate between four- and fivefold.

Figure 1. Molecular structure of **3b′**[a]

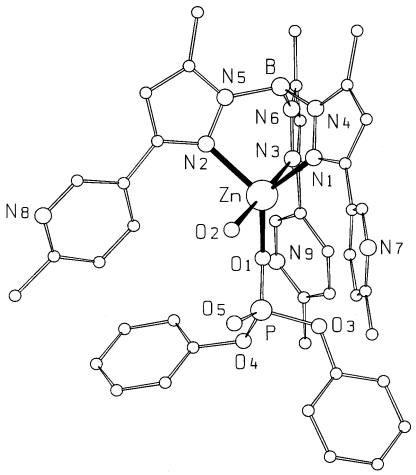


[a] Selected bond lengths [Å] and angles [°]: Zn−O1 1.905(4), Zn−N1 1.983(5), Zn−N2 2.004(5), Zn−N3 3.090(5), Zn−N8 2.080(5), P−O1 1.486(4), P−O4 1.467(4), N8−Zn−N3 171.9(2), Zn−O1−P 147.3(3).

The pyrazole ligand and the phosphate ligand in **3b′** display no unusual features. The Zn−O bond is relatively short, but typical for Tp*Zn−O compounds[6][8][9][10][11][12][13][14]. The phosphate ligand shows the typical equalization of the "single" and "double" P−O bonds P−O1 and P−O4 that we have observed previously[6][18]. Together with the rather large P−O−Zn angle it must reflect a partly ionic nature of the Zn−O bond. Similar observations hold for the Zn−O, P−O, and P−O−Zn interactions in complex **3c′** (see Figure 2). Zinc phosphate complexes not bearing Tp* ligands normally have longer Zn−O bonds, as evidenced by the two examples bearing diphenylphosphate ligands[19][20].

Like in **3b′**, the two coligands in **3c′** (water and phosphate) are linked by a hydrogen bond (O2−O5 2.77 Å). Otherwise there is no similarity between **3b′** and **3c′**. However, **3c′** is a close analogue of the complex $Tp^{Pic,Me}(H_2O)$-Zn−OPO(OC_6H_4−*p*-NO_2)$_2$ which was obtained by phosphate ester hydrolysis[6]. The Tp* ligand in **3c′** is bound in a symmetrical fashion, and the coordination geometry about the zinc ion is strictly trigonal-bipyramidal with one pyrazole nitrogen and the water oxygen on the apical posi-

Figure 2. Molecular structure of **3c′**[a]



[a] Selected bond lengths [Å] and angles [°]: Zn−O1 1.947(3), Zn−N1 2.065(4), Zn−N2 2.069(4), Zn−N3 2.200(4), Zn−O2 2.102(3), P−O1 1.496(3), P−O5 1.464(4), N3−Zn−O2 178.9(1), Zn−O1−P 138.6(2).

tions. The bond lengths at zinc are larger than in tetrahedral Tp*Zn−O complexes[6][8][9][10][11][12][13][14], reflecting the increase in coordination number, and typically the bonds holding the two apical atoms are elongated. A comparison of **3b′** and **3c′** in terms of bond lengths shows that all comparable ligand donor atoms except N3 are closer to zinc in **3b′**, thus qualifying **3b′** as tetrahedral rather than trigonal-bipyramidal.

Conclusions

The work in this paper has shown that the hydrolytic prowess of the Tp*Zn−OH "enzyme models" extends to the cleavage of the E−O−E links in inorganic polyacids. Part of the driving force of the hydrolytic cleavages seems to be the capturing of the resulting anionic fragments as O-bound ligands. These are not replaceable by water or other donor ligands. Instead these can be bound as additional ligands in five-coordinate Tp*(L)Zn−OPO(OR)$_2$ complexes.

Experimental Section

General experimental methods and measuring techniques see ref.[21]. The Tp*Zn−OH complexes[8][10][22], the diphosphate[23] and the sulfonatophosphate[24] were prepared according to the published procedures. All other reagents were obtained commercially. Solvents were degassed but not dried. IR data (cm^{-1}) were recorded from KBr pellets, ^{1}H- and ^{31}P-NMR data (δ in ppm, int. TMS, ext. H_3PO_4) were recorded from $CDCl_3$ solutions.

Hydrolytic Cleavages: *Tetraethyl Diphosphate and* **1b**: 138 mg (0.200 mmol) of **1b** and 29.0 mg (0.100 mmol) of tetraethyl diphosphate in 20 ml of dichloromethane were stirred at room temp. for 16 h. The solvent was removed in vacuo. Recrystallization from acetonitrile at −25°C yielded 110 mg (66%) of **2b**, m. p. 184°C. − $C_{43}H_{56}BN_6O_4PZn$ (828.1): calcd. C 62.36, H 6.82, N 10.15; found C 61.55, H 6.68, N 9.96. − IR: 2550m (BH), 1252s (P=O). − ^{1}H NMR: 0.85 [t, J = 7.0 Hz, 6 H, Me(OEt)], 1.24 [d, J = 6.9 Hz, 18 H, Me(*i*Pr)], 2.52 [s, 9 H, Me(pz)], 2.92 [sept, J = 6.9 Hz, 3 H, CH(*i*Pr)], 3.44 [dt, J = 7.0 Hz, 7.0 Hz, 4 H, CH_2(OEt)], 6.22 [s, 3 H, CH(pz)], 7.35 [d, J = 8.2 Hz, 6 H, Ph(3,5)], 7.66 [d, J = 8.2 Hz, 6 H, Ph(2,6)]. − ^{31}P NMR: −2.0.

Tetraphenyl Diphosphate and **1b**: As before with 500 mg (0.722 mmol) of **1b** and 174 mg (0.361 mmol) of tetraphenyl diphosphate in 40 ml of CH_2Cl_2. When the reaction and workup were performed under strictly anhydrous conditions, they resulted in 620 mg (93%) of **3b**[6].

Recrystallization of 300 mg (0.325 mmol) of **3b** from hot undried acetonitrile resulted in the formation of 237 mg (86%) **3b′**, m. p. 191°C. − $C_{64}H_{72}BN_8O_4PZn$ (1124.5). calcd. Diphenylphosphato-p-toluenesulfonate (POS) and **1c**: 500 mg (0.818 mmol) of **1c** and 167 mg of POS in 40 ml of CH_2Cl_2 were stirred under anhydrous conditions for 16 h at room temp. The solvent was removed in vacuo and the residue picked up in $CDCl_3$. ^{1}H- and ^{31}P-NMR spectra showed that the starting materials had disappeared and the solution contained an equimolar mixture of **3c** and **4c**.

Condensation Reactions (for **3a** and **c** see preceding paper[6]): **4b**: 276 mg (0.400 mmol) of **1b** and 76.0 mg (0.400 mmol) of *p*-toluenesulfonic acid hydrate in 20 ml of dichloromethane were stirred at room temp. for 8 h under strictly anhydrous conditions. Removal of the solvent in vacuo and recrystallization from carefully dried acetonitrile yielded 265 mg (78%) of **4b**, m. p. 158°C. − $C_{46}H_{53}BN_6O_3SZn$ (846.2): calcd. C 65.29, H 6.31, N 9.93; found

C 64.42, H 6.07, N 9.46. – IR: 2552m (BH), 1292s (S=O). – ^{1}H NMR: 1.12 [d, J = 6.9 Hz, 18 H, Me(*i*Pr)], 2.53 [s, 9 H, Me(pz)], 2.78 [sept, J = 6.9 Hz, 3 H, CH(*i*Pr)], 6.21 [s, 3 H, CH(pz)], 6.86 [d, J = 7.9 Hz, 2 H, CH(Tos)], 7.02 [d, J = 7.9 Hz, 2 H, CH(Tos)], 7.12 [d, J = 8.1 Hz, 6 H, Ph(3,5)], 7.56 [d, J = 8.1 Hz, 6 H, Ph(2,6)].

4c: 500 mg (0.818 mmol) of **1c** and 141 mg (0.819 mmol) of *p*-toluenesulfonic acid hydrate in 40 ml of CH_2Cl_2 were stirred at room temp. for 16 h. Removal of the solvent and recrystallization from acetonitrile/dichloromethane (5:1) under non-anhydrous conditions yielded 583 mg (91%) of **4c**·H_2O·1/2 CH_2Cl_2.

Structure Determinations[25]: Crystals of **3b′** and **3c′** were obtained from undried acetonitrile. Diffraction data were recorded at room temperature with the ω/2θ technique on a Nonius CAD4 diffractometer fitted with a molybdenum tube (K_α, λ = 0.7107 Å) and a graphite monochromator. Semiempirical absorption corrections based on ψ scans were applied. The structures were solved with direct methods and refined anisotropically with the SHELX program suite.[26] Hydrogen atoms were included with fixed distances and isotropic temperature factors 1.2 times those of their attached atoms. Parameters were refined against F^2. The R values are defined as $R_1 = \Sigma F_o - F_c / \Sigma F_o$ and $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2 / \Sigma[w(F_o^2)^2]\}^{1/2}$. Drawings were produced with SCHAKAL.[27] Table 1 lists the crystallographic data.

Keywords: Molybdenum / Peroxo complexes / Hydrogen bonds / Catalysis

The ring-opening reaction of epoxycyclohexane with 2-[3(5)-pyrazolyl]pyridine results in the formation of racemic *trans*-2-[3-(2-pyridyl)-1-pyrazolyl]cyclohexanol (**1**). Kinetic resolution with lipase B from *candida antarctica* gives the (1*S*,2*S*) enantiomer of **1**, the solid-state structure of which was determined by X-ray crystallography, as an enantiomerically pure tridentate ligand. Investigation by NMR spectroscopy of the corresponding oxodiperoxomolybdenum complex **2**, where **1** acts as a bidentate chelate, proves the formation of a weak intramolecular $Mo^{VI}(O_2)\cdots HO-C$ bridge in $CHCl_3$ solution. This H bonding is broken by solvents such as acetone, THF or DMF, which are capable of forming hydrogen bonds to alcohols. Intermolecular hydrogen bonds between the OH groups and molybdenum peroxo moieties are also found in the solid-state structure of **2**, leading to a helical arrangement of the peroxo complexes.

Peroxo complexes of high-valent transition metals are used as catalysts or stoichiometric reagents for the oxidation of organic and inorganic substrates[2]. We have investigated the role of seven-coordinate oxodiperoxomolybdenum complexes in the catalytic epoxidation of olefins[1] and have focused on bidentate *N*-alkylated 2-[3(5)-pyrazolyl]pyridine ligands, first described by H. Brunner et al.[3]. This ligand system allows the introduction of long alkyl side chains, leading to excellent solubility of the derived molybdenum catalysts in organic solvents, and a variation of the donor strength by the inclusion of electron donating and withdrawing groups attached to the heteroaromatic rings. The latter feature enables a correlation of electronic ligand properties with epoxidation activities of the catalysts[1]. From spectroscopic and kinetic investigations on peroxo complexes bearing olefinic side chains, we postulated a new reaction mechanism for the catalytic olefin epoxidation with seven-coordinate peroxomolybdenum complexes. In this mechanism the oxidizing agent (e.g. *tert*-butyl hydroperoxide) is activated by the Lewis acidic transition-metal center, resulting in an oxygen transfer from the hydroperoxide, and not from the η^2-coordinated peroxo ligands, to the olefin[4].

One crucial point of this mechanism is a proton transfer from the hydroperoxide to one of the peroxo ligands. NMR investigations (^1H,^{13}C,^{17}O NMR) on the reactivity of peroxomolybdenum complexes in the presence of strong Lewis and Brønsted acids, showed that the peroxo ligands are preferentially protonated while the oxo ligand is a poor proton acceptor[5]. These spectroscopic findings are in agreement with the results of Extended Hückel calculations on the model complex $(NH_3)_2MoO(O_2)_2$, which proved that the three highest occupied molecular orbitals of such compounds possess mainly π^* character at the peroxo ligands and only low σ^* and π^* character at the oxo ligand. From a mechanistic point of view, this proton transfer should start with the formation of a hydrogen bond between the hydroperoxide and an η^2-peroxo ligand. Since we were never able to prove such interactions between the weak Brønsted base η^2-O_2 and weak Brønsted acids like hydroperoxides or alcohols by means of spectroscopy, the energies of these bonds should be low. To overcome this problem, we synthesized new *N*,*N*-donor ligands of the pyrazolylpyridine type bearing OH functions in the side chain, which should lead to the formation of an intramolecular hydrogen bond. In the present paper, we describe the synthesis of such ligands and the corresponding peroxomolybdenum complexes, along with the NMR- and IR-spectroscopic evidence for a weak intramolecular $Mo^{VI}(O_2)\cdots H-OR$ interaction in solution.

Results and Discussion

The *N*-alkylation of 2-[3(5)-pyrazolyl]pyridines is usually carried out by a deprotonation (NaH) alkylation (RX, X = Br, I) sequence with THF as the solvent[6]. According to this procedure, primary linear alkyl substituents can be introduced with high regioselectivities and high yields. From geometric considerations, intramolecular hydrogen bonding would require a 2-hydroxyethyl or a 3-hydroxypropyl group, which can easily be attached to the pyrazole moiety of the

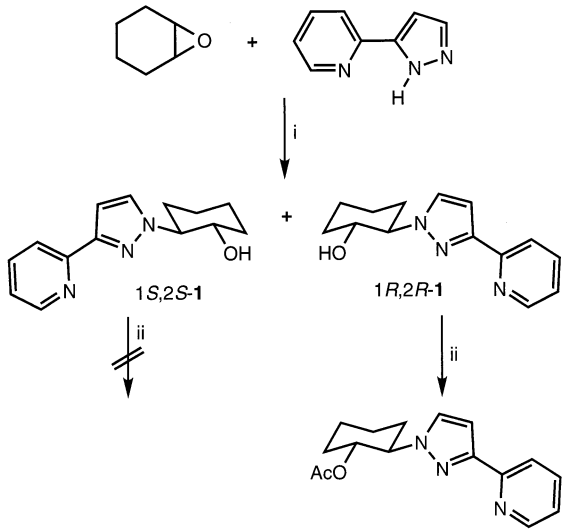
chelate ligand by nucleophilic ring opening of oxiranes or oxetanes. For synthetic reasons we focused on the ring opening of epoxycyclohexane with pyrazolylpyridine, generating a 1,2-disubstituted cyclohexane ring, which would also be expected to increase solubility of the desired peroxo complexes.

Heating a 1:1.5 mixture of 2-[3(5)-pyrazolyl]pyridine and epoxycyclohexane for 4 h at 170°C in a pressure tube[7] gives *rac-trans*-2-[3-(2-pyridyl)-1-pyrazolyl]cyclohexanol (**1**) in more than 90% yield (Scheme 1).

Scheme 1. i. 160°C, 4 h, pressure tube; ii. isopropenyl acetate, molecular sieve 4 A, lipase B from *candida antarcica*, 37°C, 4 h



As the resonances of the two protons connected to the substituted cyclohexane carbon atoms are observed at almost identical δ values, the conformation of the aliphatic ring system cannot be determined by means of NMR spectroscopy. However, we expect the cyclohexane ring to occupy the thermodynamically favored chair conformation with both substituents oriented in an equatorial position, as found in similar compounds[8].

Since we are interested in such compounds as enantiomerically pure ligands for enantioselective catalysis and as starting material for the synthesis of chiral ligands[9], we investigated the kinetic resolution of **1**[10]. Acylation of **1** with isopropenyl acetate in the presence of lipase B from *candida antarctica*[11] selectively leads to the formation of the acetate with the (1*R*,2*R*) configuration (Scheme 1), which can be separated from (1*S*,2*S*)-**1** by preparative MPLC. The absolute configuration of the non-acylated derivative was determined by X-ray-crystallographic methods (see below). For the corresponding 2-pyrazolylcyclohexanol, an identical stereoselectivitiy of the enzymatic esterification was found[10]. Figure 1 shows the molecular structure of (1*S*,2*S*)-**1** in the solid state, along with characteristic bond lengths and angles. Further crystallographic and experimental details are given in Table 1 in the Experimental Section.

(1*S*,2*S*)-**1** crystallizes from diethyl ether at 4°C in the monoclinic space group $P2_1$ with one additional molecule

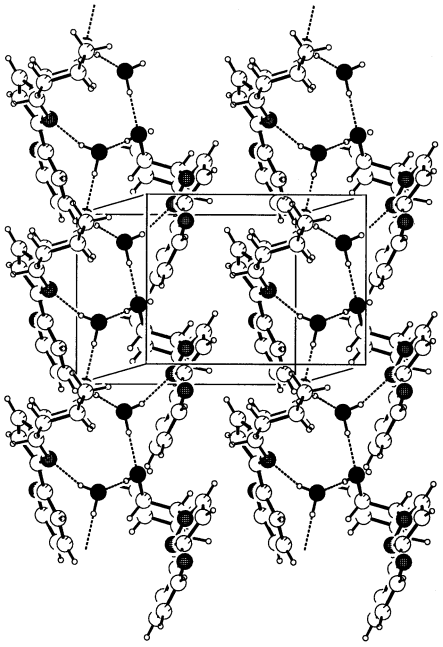
of water per formula unit. In the solid state structure of enantiomerically pure 2-pyrazolylcyclohexanol[10], the molecules are linked by hydrogen bonds between the hydroxy groups and the pyrazole moieties, resulting in a helical arrangement. In the case of (1*S*,2*S*)-**1**, this kind of molecular organization is hampered by the bulky pyridyl ring. Therefore, an additional molecule of water is incorporated, forming a new system of hydrogen bonds, which includes the OH group of the cyclohexanolyl fragment as proton donor and acceptor and the pyrazolyl moiety (N2) of (1*S*,2*S*)-**1** as an acceptor site (Figure 2).

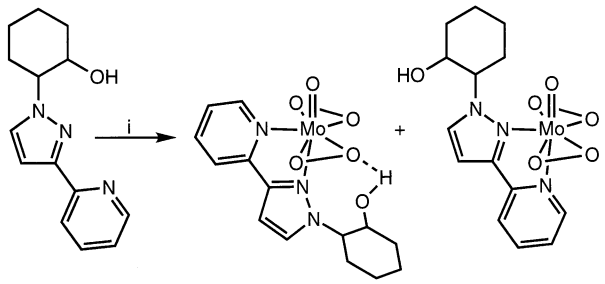
Figure 2. PLUTON plot[12] showing the hydrogen-bonding system, which builds the solid-state structure of (1*S*,2*S*)-**1**



The structure is best described by an arrangement of water molecules around the crystallographic 2_1 axis, linking the (pyridyl)pyrazolylcyclohexanol molecules to form infinite columns. For reasons of optimization of electronic interaction between the pyridine and the pyrazole ring and steric repulsion between the protons at C4/C7 and the lone pairs at N1/N2, the heteroaromatic rings are twisted by about 10° from coplanarity. All intra- and intermolecular bond lengths and angles were observed as expected. The absolute structure was determined by refinement of the Flack parameter $\chi = -0.061(0.2)$[13]. The refinement of the enantiomorphic structure model with (1*R*,2*R*)-**1** resulted in higher *R* values ($R_1 = 0.035$, $\omega R_2 = 0.098$) and a Flack parameter $\chi = 1.003(0.2)$.

The treatment of *rac*-**1** and (1*S*,2*S*)-**1** with an excess of molybdic acid (hydrated MoO_3), dissolved in H_2O_2, results in the formation of the seven-coordinate peroxo complexes *rac*-**2** and (1*S*,2*S*)-**2** (Scheme 2).

Scheme 2. i. $MoO_3 \cdot (H_2O)_x$, H_2O_2, room temp., 4 h



1 **2A** **2B**

Owing to the two different donor centers of the pyrazolylpyridine ligands, the seven-coordinate peroxomolybdenum complexes can exist in two isomeric forms (**A** and **B**). By means of NMR spectroscopy it was found that these isomers are in equilibrium in solution[14]. In a detailed study, we recently showed that the isomer ratios correlate with the individual donor properties of the heterocyclic ring systems[1].

Solutions of *rac*-**2** and (1*S*,2*S*)-**2** show the same behavior, which does not depend on the electronic properties of the ligand, but on the nature of the solvent. In chloroform, only isomer **A** can be detected, whereas in donor solvents capable of forming hydrogen bonds with alcohols, like acetone, the isomers **A** and **B** can be observed as expected in a 2:1 ratio. Thus, the electronic characteristics of the chelate ligand cannot be the reason for the special structural feature of **2** in solution in $CHCl_3$. We therefore believe an intramolecular hydrogen bond to be responsible for this behavior.

From investigations on the isomer ratios (**A**:**B**) of peroxomolybdenum complexes bearing pyrazolylpyridine ligands with electron-withdrawing and -donating substituents[1], we can estimate the enthalpy of the intramolecular hydrogen-bond formation to be at least −8 kJ/mol, which corresponds to data from the literature on the thermodynamics of hydrogen bonds between alcohols and ketones ($\Delta G \approx -12$ to −24 kJ/mol)[15].

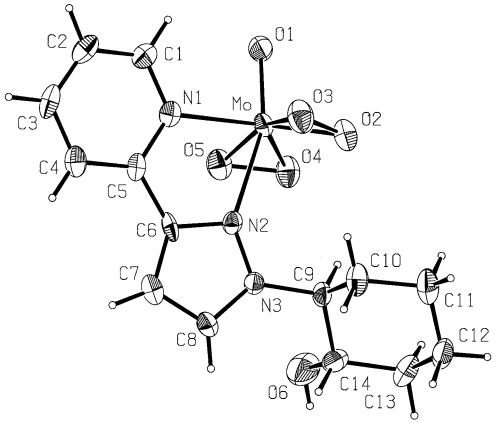
Infrared-spectroscopic investigations at low concentrations (3 mM) in solution support the formation of an intramolecular hydrogen bond: cyclohexanol gives a sharp O−H absorption at 3611 cm^{-1} in chloroform, but a shift of about 100 cm^{-1} towards lower wave numbers is observed in acetone solution, leading to a broad band at 3514 cm^{-1}, typical for associated O−H groups. In contrast to these findings, the IR spectra of **2** in solution, which again show broad O−H absorptions, differ only slightly on a change in the nature of the solvent [chloroform: ν(O−H) = 3491 cm^{-1}; acetone: ν(O−H) = 3509 cm^{-1}]. This fact provides strong evidence for the formation of hydrogen bonds in both cases: intramolecular in chloroform and intermolecular [OH···O=C$(CH_3)_2$] in acetone solution. The intramolecular hydrogen bond could alternatively be formed between the OH group of the chelate-ligand side chain and the oxo or one of the η^2-O_2 ligands coordinated to molybdenum. In acetone solution, **2** shows two Mo=O stretching vibrations: one at 956 cm^{-1} and an intense shoulder at 950 cm^{-1}, which can be assigned to the two isomers **A** and **B**. The asymmetric and symmetric O−O stretching vibrations are observed at 877 and 868 cm^{-1} for both isomers. In $CHCl_3$, the M=O absorption at 950 cm^{-1} almost vanishes, while the other M=O vibration is shifted to 962 cm^{-1}, indicating an almost selective formation of one isomer. The two O−O absorptions are shifted to lower wave numbers (875 and 865 cm^{-1}), indicating slightly weakened O−O bonds, which would agree with hydrogen bonding to a η^2-O_2 ligand. A reduction in the donor capability of the peroxo ligands can be compensated by increased π-backbonding from the oxo ligand to the molybdenum center, as confirmed by the shift of the Mo=O stretching frequency to higher wave numbers. However, hydrogen bonding to the oxo ligand would weaken the Mo=O bond and therefore shift the Mo=O absorption to lower wave numbers. The Mo=O and O−O absorptions of peroxomolybdenum complexes bearing pyrazolylpyridine ligands with unfunctionalized alkyl side chains, like [2-(3-butylpyrazol-1-yl)pyridine]oxodiperoxomolybdenum(VI)[6], which cannot participate in any intramolecular hydrogen bonding, show only weak solvent dependences [acetone: 962, 957 cm^{-1} ($2 \times \nu_{Mo=O}$), 877, 868 cm^{-1} ($2 \times \nu_{O=O}$); $CHCl_3$: 963, 956 cm^{-1} ($2 \times \nu_{Mo=O}$), 878, 866 cm^{-1} ($2 \times \nu_{O=O}$)].

From these results, it is clear that the intramolecular hydrogen bond should be formed between the OH group (H^+ donor) and one η^2-O_2 ligand (H^+ acceptor) in $CHCl_3$ solution, and this is in agreement with spectroscopic investigations of peroxomolybdenum complexes in the presence of strong Lewis and Brønsted acids[5]. This interaction would favor an orientation of the pyrazole moiety *trans* to the oxo ligand (isomer **A**, Scheme 2). However, this geometry is not in accordance with the assignments of the spectra of these complexes, which we published in previous papers[1][4][5][6], a contradiction which had to be clarified.

Crystallization of *rac*-**2** from chloroform gives yellow needles and a small amount of yellow plates (< 5%). Investigations of the needle-like material by X-ray crystallography indicated the solid-state structure of *rac*-**2**, which

crystallizes in the orthorhombic and acentric space group $Pca2_1$. Figure 3 shows the molecular structure of *rac*-**2** along with bond lengths and angles. Further crystallographic and experimental details are given in Table 1 in the Experimental Section.

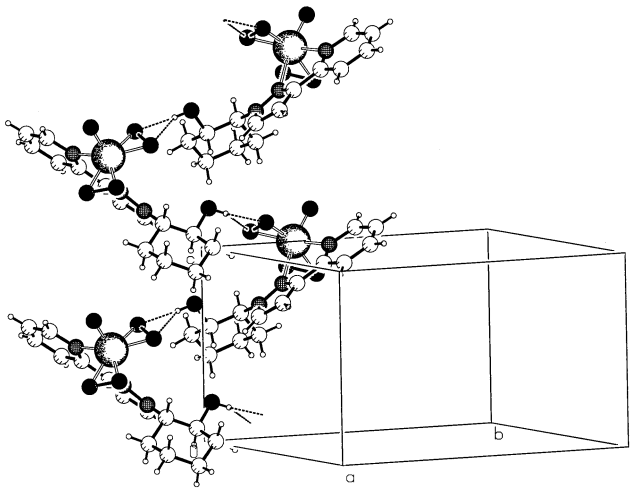
Figure 3. PLATON plot[12] of the asymmetric unit of *rac*-**2**; thermal ellipsoids are at the 50-% level[a]



[a] Bond lengths [Å] angles [°] and dihedral angles [°]: Mo−O(1) 1.675(5), Mo−O(2) 1.898(3), Mo−O(3) 1.951(5), Mo−O(4) 1.899(4), Mo−O(5) 1.955(4), Mo−N(1) 2.224(3), Mo−N(2) 2.347(4), O(2)−O(3) 1.457(5), O(4)−O(5) 1.467(5), O(6)−H(6A) 0.820, O(6)−C(14) 1.419(7), O(4)−H(6A) 2.532, O(5)−H(6A) 2.010; O(1)−Mo−O(2) 105.1(2), O(1)−Mo−O(3) 102.0(2), O(1)−Mo−O(4) 104.9(2), O(1)−Mo−O(5) 98.9(2), O(1)−Mo−N(1) 90.2(2), O(1)−Mo−N(2) 160.3(2), O(2)−Mo−O(3) 44.5(2), O(4)−Mo−O(5) 44.7(2), N(1)−Mo−N(2) 70.3(2), O(6)−H(6A)−O(4) 139.0, O(6)−H(6A)−O(5) 171.4; C(6)−N(2)−N(3)−C(8) 0.5(5).

Only isomer **A** is found in the solid-state structure, with pyrazole *trans* to the oxo ligand, like it is observed in $CHCl_3$ solution. However, in the solid state the hydrogen bond is not *intra*- but *inter*molecular between the OH group and an η^2-O_2 ligand, linking two peroxomolybdenum complexes and finally leading to the formation of a helical arrangement (Figure 4). The crystals include helices of opposite chirality.

Figure 4. PLUTON plot[12] of the helical arrangement formed by hydrogen bonding in the solid-state structure of *rac*-**2**



Clearly, intermolecular hydrogen bonding is energetically favored in the solid state with respect to the intramolecular mode observed in solution. Besides the OH···O_2 bond, which has previously been observed in the solid-state structure of only one other high-valent transition-metal peroxo compound[16], *rac*-**2** shows the typical structure of a molybdenum oxodiperoxo fragment coordinated to a bidentate *N*,*N*′-ligand[4][6][17]. Owing to the *trans* influence of the oxo ligand, the distance Mo−N2 is about 12 pm larger than Mo−N1. The peroxo ligands are bent with respect to the oxo ligand, leading to a distorted pentagonal-bipyramidal coordination geometry.

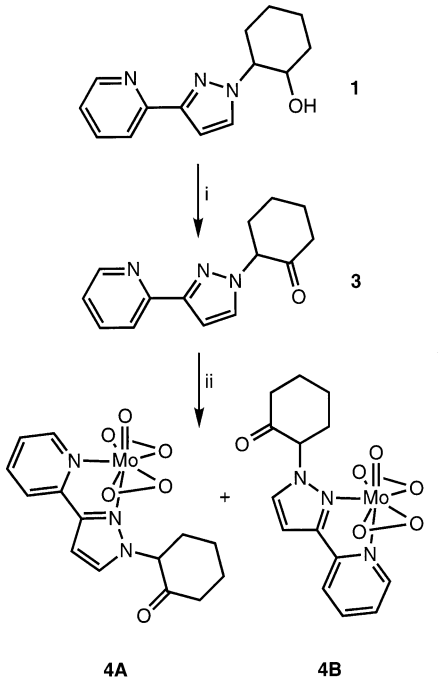
An analogous structure was found for the second type of crystalline material (yellow plates) in which pyrazole is *trans* to the oxo ligand. Owing to the poor crystal quality and a severe problem of disorder concerning the orientation of the OH group at the cyclohexane ring relative to the mirror plane of the $MoO(O_2)_2$ fragment, it was not possible to finish the structure refinement with acceptable *R* values (R_1 = 0.0993, $\omega R2$ = 0.2780)[18].

For the final assignment of the spectroscopic data of **2**, we carried out powder-diffraction and solid-state NMR experiments. Powder diffraction of the solid material, either crystalline or microcrystalline, can be correlated with the crystal data of the single-crystal diffraction experiment (space group $Pca2_1$) and, in addition, ^{13}C CPMAS experiments gave only one set of resonances. Therefore, the NMR spectra of the peroxo complexes in solution can now be assigned correctly (see Experimental Section). As shown in Scheme 2 the pyrazole fragment in isomer **A** is oriented *trans* to the oxo ligand.

The peroxo complexes **2** catalyze the epoxidation of olefins in the presence of *tert*-butyl hydroperoxide. Detailed investigations on the epoxidation of prochiral olefins with (1*S*,2*S*)-**2** unequivocally showed that racemic epoxides are formed under standard conditions (50 °C, $CHCl_3$). The hydroxy group of the ligand remains unaffected during these reactions, which is in agreement with findings in the literature that neutral peroxomolybdenum complexes do not catalyze the oxidation of alcohols. In contrast, alcohols are preferentially oxidized to the corresponding ketones in the presence of anionic peroxomolybdenum complexes[19]. However, conversion of the OH function of **1** into a carbonyl group can be achieved quantitatively by Swern oxidation[20]. Oxidation of enantiomerically pure (1*S*,2*S*)-**1** yields a racemic mixture of **3** under these conditions. We are interested in such compounds as building blocks for chiral multidentate ligands and are therefore currently working on the resolution of *rac*-**3**. The corresponding peroxomolybdenum complex **4** is available in a similar way to **2** by simply stirring a peroxidic solution of molybdic acid with a solution of **3** in dichloromethane (Scheme 3).

NMR spectroscopy shows that the peroxo complex **4** exists in chloroform solution as a 4.5:1 mixture of the two isomers **A** and **B**. This gives an indication of the slightly stronger electron-withdrawing properties of the β-oxo group compared to the β-hydroxy group of **1**, favoring the population of isomer **A**. The corresponding peroxo complex

Scheme 3. i. $(CH_3)_2SO$, $(COCl)_2$, NEt_3, −72°C, CH_2Cl_2; ii. $MoO_3{\cdot}(H_2O)_x$, H_2O_2, room temp., 4 h



4 catalyzes the epoxidation of olefins in the presence of *tert*-butyl hydroperoxide, showing an activity comparable to that of other peroxomolybdenum complexes[6].

Conclusion

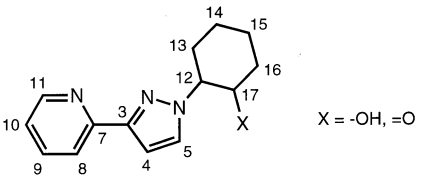
Proton-transfer reactions play an important role in many organic transformations catalyzed by high-valent transition-metal centers. From a mechanistic point of view, hydrogen-bond formation can be considered as the primary step in such reactions. With the synthesis of *trans*-2-[3-(2-pyridyl)-1-pyrazolyl]cyclohexanol (**1**), we succeeded not only in establishing a new chiral polydentate ligand system with potential applications in enantioselective catalysis, but were also able to obtain thermodynamic information on the strength of an $Mo^{VI}(\eta^2\text{-}O_2)\cdots HO{-}C$ interaction. Such an interaction in solution has never been described in detail before. Owing to the low Lewis basicity of the peroxo ligand coordinated to a high-valent transition-metal center this interaction is weak and can therefore be broken by Lewis-basic solvents. In the solid state, this hydrogen bond is no longer intramolecular but intermolecular. The formation of the intramolecular hydrogen bond in solution allowed a new assignment of the NMR data of pyrazolylpyridine peroxomolybdenum complexes. A simple and high-yield transformation of the secondary alcohol **1** into the ketone **3** led to a new chiral building block for multidentate ligand systems. The potential of such a system as a metal-complexing agent was proved by the formation of the corresponding peroxo complex **4**.

The authors wish to thank Prof. *W. A. Herrmann,* the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* for support of this work, and *Henricke Heise* for performing the CPMAS experiments.

Experimental Section

2-[3(5)-Pyrazolyl]pyridine was synthesized according to a published procedure[3]. Immobilized lipase B from *candida antarctica* was a generous gift from Novo Nordisk. All other starting materials were purchased from Aldrich. Isopropenyl acetate was distilled from K_2CO_3 before use. The NMR (Bruker DPX 400), infrared (Perkin-Elmer 1600 Series FTIR) and mass spectra (GC MS: Hewlett-Packard gas chromatograph HP 5890 and mass selective detector HP 5970), and all elemental analyses were carried out at the *Anorganisch-chemisches Institut der TU München*. The numbering of the NMR spectra is carried out according to Scheme 4.

Scheme 4. Labeling scheme for the assignment of NMR data



rac-[3-(2-Pyridyl)-1-pyrazolyl]cyclohexanol (*rac*-**1**): A mixture of 2-[3(5)-pyrazolyl]pyridine (2.0 g, 13.9 mmol) and epoxycyclohexane (2.0 g, 2.1 ml, 20.8 mmol) was heated for 4 h at 170°C in a pressure tube (Aldrich Z18,108-0). The dark-colored product was dissolved in dichloromethane and treated with 5.0 g of silica gel. The solvent was removed in vacuo and the powdery product transferred to a Soxhlet extractor. Extraction with diethyl ether and removal of the solvent yielded **1** (3.1 g, 92%) as a pale yellow oil. − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3382 s, br. Crystallographic Structure Determination and Structure Refinement of (1*S*,2*S*)-**1** · H_2O *and rac*-**2**: The crystals were fixed inside a Lindemann glass capillary. The intensity data were obtained at 293 K with graphite-monochromated Mo-K_α radiation using a STOE IPDS[21] in the case of *rac*-**2** and at 193 K with graphite-monochromated Cu-K_α radiation using an Enraf Nonius CAD4[22] diffractometer in the case of (1*S*,2*S*)-**1**. A combined absorption and decay correction, using the program DECAY[21] (smooth factor 8) was applied on the data set of *rac*-**2**. During the data collection for (1*S*,2*S*)-**1**, three standard reflections lost 12% of intensity, which was corrected with the program MolEN[22]. Preliminary positions of heavy atoms were found by direct methods (SIR92[23]), while positions of the other non-hydrogen atoms were determined from successive Fourier difference maps coupled with an initial isotropic least-squares refinement (SHELXL93[24]). The hydrogen atoms of (1*S*,2*S*)-**1** were all located in the difference Fourier maps and refined with isotropic temperature parameters. In the case of *rac*-**2** all hydrogen atoms were placed in calculated positions, included in the structure-factor calculation, but were not refined. Additional crystal data, data collection and refinement parameters are presented in Table 1.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (CCDC-100572). Copies of the data may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: int. code +(1223)336-033; e-mail: deposit@ccdc.cam.ac.uk].

X-ray Powder Diffraction: The X-ray diffraction pattern was recorded with a Huber Guinier diffractometer 642 with Ge mono-

Keywords: Gold / Chalcogenide / Flux reaction / Structure determination / Metal-metal bonding

The novel compounds K_2AuPS_4 (**1**), Tl_2AuPS_4 (**2**), K_2AuAsS_4 (**3**), and $KAu_5P_2S_8$ (**4**) have been synthesized by direct reaction of the elements with a molten alkaline polythiophosphate(arsenate) flux at 550°C. The crystal structures of these compounds have been determined by single-crystal X-ray diffraction techniques. **1**, **2**, and **3** crystallize in the monoclinic space group $P2_1/m$. The structures of **1**, **2**, and **3** consist of infinite, one-dimensional anionic chains running along the crystallographic *b* axis. The chains are separated by potassium or thallium ions. Neighbouring Au atoms are bridged by MS_4^{3-} tetrahedra (M = P, As) in a *trans* orientation. Compound **4** crystallizes in the space group $P2_1/c$. The anionic chains of **4** are built up from linear AuS_2 dumbbell units and PS_4^{3-} tetrahedra. The chains extend along the $[1\bar{1}0]$ and $[1\bar{1}0]$ direction and are separated by charge balancing K^+ cations. Each of the compounds was investigated by differential thermal analysis, FT-IR, and solid-state UV/Vis diffuse reflectance spectroscopy.

Introduction

Most transition metals react with chalcogen or chalcogen-containing compounds to give transition-metal chalcogenides. These compounds have been the subject of numerous studies during the past decades because of their intriguing electronic and chemical properties such as superconductivity[1], charge-density wave behavior[2] and intercalation chemistry[3], which are imparted by the low-dimensional character of the early transition-metal compounds. On the right-hand side of the Periodic Table, transition-metal chalcogenides prefer three-dimensional structures akin to those of pyrites or marcasite. Several papers on this matter have recently been published[4], while a general explanation for these observations was advanced long ago by Hoffmann and Zheng[5]. When we move across the transition series, the d bands decrease in energy and become narrower. At the same time, the band filling increases. These two competing factors determine the trend in the Fermi level: It falls as one moves to electron-rich transition metals. If bands of Q−Q (Q = chalcogen) σ and σ* character are superimposed on these transition-metal d bands, the Fermi level will be above the bands with Te−Te σ* character for the early transition metals, i.e. on the left-hand side of the Periodic Table, but below for the late transition metals, i.e. on the right-hand side. The result is a gradual increase of Q−Q bonding in metal chalcogenides as we move across the transition-metal series from left to right. Compounds at the crossover point are most interesting from a theoretical point of view, because in these cases a straightforward prediction of their electronic properties by a formal assignment of oxidation states becomes impossible. In the simple binary compounds, one can reach the crossover point by varying the metal or the chalcogen components. As far as the metals are concerned, chalcogenides of the coinage metals are definitely such borderline cases. For gold tellurides such as $AuTe_2$, a compound with a very distorted CdI_2 structure, even more ambiguities arise, as now the metal (Pauling elec-

tronegativities: Au 2.2, Te 2.1) is the more electronegative partner compared to the chalcogen atom.

Metal−metal bonding is an additional point of interest in many coinage metal systems (M = Cu, Ag, Au)[6]. If the geometrical constraints of the ligand or the structure allow, many compounds show a tendency to cluster or polymerize. Such behaviour has been observed in many binary cluster compounds of the general types $[Au_m(PR)_{3m}]^{x+}$ and $[Au_{m+1}(PR_3)_m]^{y+}$[7], molecular alkylcopper compounds[8a], pentaazenidocopper complexes[8b], Hartl's iodocuprates[9], and in multinuclear copper chalcogenide clusters of the $Cu_{2n}Q_n(PR_3)_x$-type reported by Fenske and co-workers[10]. In many of these compounds, the metal−metal distances are comparable to, or are sometimes considerably shorter than, the M−M separations in the elemental metals. Thus, the obvious question arises[11] as to the nature of the interactions between metal centers at such short distances.

We have been intrigued by these questions and have studied the ternary and quaternary systems A/Au/Q (A = alkali metal; Q = S, Se, Te) and A/Au/B/Q (B = group 14 or 15 element). The use of electropositive cations such as alkali metal ions permits the stabilization of gold compounds with the relatively electronegative elements sulfur[12] and

phosphorus. Thus, no ternary thiophosphates of Au exist. In contrast, for the lighter metals numerous compounds belonging to the ternary Ag−P−S[13] family have been reported in the literature, and some compounds of the type Cu−P−S[14] are known. Being itself rather electronegative, the usual, preferred chemistry for gold is through "soft" interactions with metalloids such as Te[15] and Bi[16].

In this paper, we report on two new thiophosphates of gold and an isostructural thioarsenate. A short account of this work has appeared elsewhere[17]. The compounds are K_2AuPS_4 (**1**), Tl_2AuPS_4 (**2**), K_2AuAsS_4 (**3**), and $KAu_5P_2S_8$ (**4**). During the preparation of this manuscript, one of the compounds presented here, K_2AuPS_4, was reported in the literature[18]. The compounds were prepared from Au, A_2S, S, and P_2S_5 or As_2S_3. The alkaline polythiophosphate or polythioarsenate forms a flux in situ. Kanatzidis and coworkers have used this feature to good advantage in the synthesis of metal thiophosphates such as $A_2AuP_2Se_6$ (A = K, Rb)[19], $A_2MP_2Se_6$ (A = K, Rb; M = Mn, Fe)[21], $A_2M_2P_2Se_6$ (A = K, Cs; M = Cu, Ag)[20], $A_3M(PS_4)_2$ (A = Rb, Cs; M = Sb, Bi)[20], as well as several main-group derivatives[21][22][23][24].

The structures of the title compounds have been determined by single-crystal X-ray diffraction techniques. Thermal and optical properties have also been investigated. One possible application of such compounds of the late transition metals stems from the fact that they have direct optical band gaps. Thus, they may be of interest in infra-red sensing. Also of interest is the observation of short Au−Au contacts in one of the compounds reported here.

Results and Discussion

Crystal Structures of K_2AuPS_4, K_2AuAsS_4, and Tl_2AuPS_4

Compounds **1**, **2**, and **3** are isostructural. Their structures consist of anionic columns separated by potassium cations, as shown in Figure 1. Selected distances and angles are compiled in Table 1. The $[AuPS_4]^{2-}$ columns run parallel to and are centered about the b axis. In these chains, neighbouring Au^I atoms are linked by PS_4^{3-} tetrahedra in a *trans* orientation. The distances in **1** are as follows: The Au−S distance is 2.298(2) Å, comparable to that in KAuS [2.305(6) Å][12a], Na_3AuS_2 [2.301(7) Å][12b], and $K_4Au_6S_5$ [2.295(6) Å][12c]. The PS_4 tetrahedra are slightly distorted.

The average P−S distance is 2.047 Å, with the individual P−S distances ranging from 2.014 to 2.080 Å. The S−P−S angles fall in a narrow range between 103.7 and 115.7°. Two crystallographically distinct K^+ cations K(1) and K(2) are situated between the anionic fragments and are surrounded by 6 and 9 S atoms, respectively, with an average K−S distance of 3.347 Å.

In **2**, the mean As−S distance is 2.165 Å. The AsS_4 units are slightly distorted with S−As−S bond angles ranging from 103.3 to 115.7°. The Au−Au distance (3.43 Å) is slightly longer than that in the thiophosphate. All other distances and angles are in the same range as those in the thiophosphate.

$KAu_5P_2S_8$

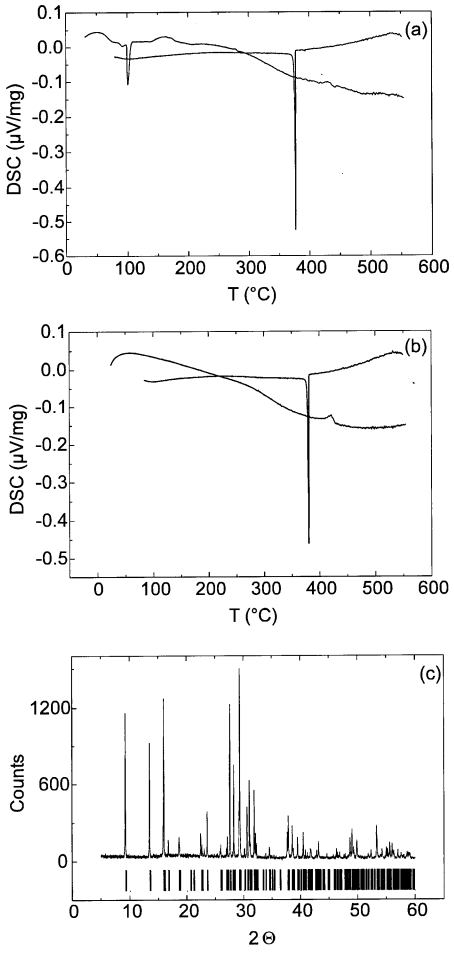
Compound **4** crystallizes with a structure that is characterized by infinite anionic $[Au_5P_2S_8]^-$ chains and isolated K^+ cations. The angular chains extend along the [110] and [1$\bar{1}$0] direction, as shown in Figure 2. The anionic framework is built up from linear AuS_2 dumbbell units and PS_4^{3-} tetrahedra, as shown in Figure 3. The edges of two PS_4^{3-} tetrahedra are alternately connected by two and three Au^+ ions, to form eight-membered $P(SAuS)_2P$ rings. Each PS_4^{3-} tetrahedron is linked to neighbouring tetrahedra by 5 Au atoms, so that S(4) and S(7) are coordinated by two Au atoms. These anionic chains interact with each other through close Au−Au d^{10}−d^{10} contacts [Au(1)−Au(3) 2.961 Å, Au(2)−Au(3) 3.043 Å]. This is not the case in **1**, which has Au−Au contacts of 3.364 Å. The short Au−Au distances are remarkable, since no sulfide bridging ligands or other steric effects are present that might account for this behaviour. The Au−Au short contacts are classical d^{10}−d^{10} interactions, which are also observed in KAuS[12d]. The intra-chain Au−Au distances are short, ranging from 3.035(2) [Au(1)−Au(3)] to 3.204(2) Å. A theoretical interpretation of the Au−Au bonding in terms of the electron localization function (ELF)[26] will be presented in a separate communication[27]. The Au atoms have a different number of homoatomic contacts. Au is almost linearly coordinated (∡ S−Au−S: 174.1−175.5°); the mean Au−S bond length is 2.31 Å, which is normal for linear AuS_2 fragments[12].

The structure contains two crystallographically distinct P sites. The PS_4^{3-} tetrahedra have a slightly distorted geometry, with bond lengths varying from 2.0−2.15 Å [P(1)−S] and 2.0−2.12 Å [P(2)−S]; bond angles range from 104−116° for [∡ S−P(2)−S] and from 105−120° for [∡ S−P(1)−S]. The distortion arises because one edge of the PS_4^{3-} tetrahedra has two Au neighbours, resulting in a longer P−S distance. The K^+ ions fill the voids in the structure. They are highly coordinated by seven K−S contacts in the range between 3.2 and 3.7 Å. Selected bond lengths and angles for **4** are given in Table 2.

Properties − Thermal Analysis

Differential thermal analysis (DTA) showed that **1**, **2**, and **4** melt congruently at 386, 412, and 394°C, respectively. Figure 4(a) shows the DSC trace obtained upon heating and cooling of the starting materials (polysulfide, As_2S_3, elements). The sharp exotherm near 100°C corresponds to the reaction leading to the clean product K_2AuAsS_4. The sharp exotherm at 386°C obtained upon cooling thus corresponds to the crystallization of molten K_2AuAsS_4. For comparison, Figure 4(b) shows the DSC trace (heating and cooling) of pure K_2AuAsS_4. Figure 4(c) shows the powder diffractogram of the products obtained from the in situ reaction in the DSC cell. The vertical lines mark expected peak positions of the K_2AuAsS_4 structure obtained from the single-crystal study.

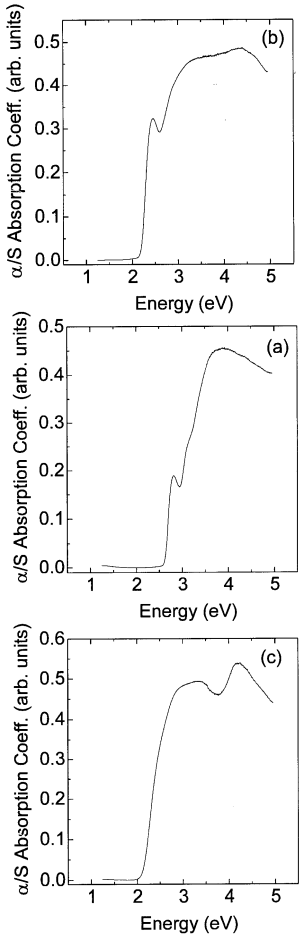
Figure 4. a) DSC diagram of the starting compounds of K_2AuAsS_4 (**2**), b) DSC diagram of K_2AuAsS_4 (**2**), c) powder pattern after the DSC experiments



The optical absorption properties of the compounds **1**, **3**, and **4** were assessed by studying their UV/vis-near IR reflectance spectra. The spectra confirm the semiconducting nature of the materials by revealing the presence of abrupt optical gaps, as can be seen in Figure 5. The band gaps of **1** and **2** are 2.63 and 2.20 eV, respectively. Higher energy absorptions are readily resolved in these spectra and are assigned to electronic S→Au charge-transfer transitions. The band gap of **4** is found to be 2.14 eV.

The infrared spectra of the compounds are shown in Figure 6. The spectrum of **1** displays absorptions at ca. 613, ca. 557, ca. 521, ca. 471, ca. 397, ca. 370, ca. 272, ca. 245,

Figure 5. Plots of absorbance (arbitrary units) vs. energy (eV) for a) K_2AuPS_4 (**1**), b) K_2AuAsS_4 (**2**), and c) $KAu_5P_2S_8$ (**4**)



and ca. 228 cm^{-1}. The vibrations can mainly be assigned to PS_4 stretching modes by analogy with $Na_3PS_4 \cdot 8\ H_2O$[28]. The far-IR spectrum of **2** displays absorptions at ca. 459, ca. 430, ca. 401, ca. 392, ca. 353, ca. 314, ca. 293, and ca. 216 cm^{-1}. These values are shifted to lower energies in comparison with those of the thiophosphate because of the greater mass of As. Compound **4** exhibits absorptions at ca. 660, ca. 552, ca. 459, ca. 395, ca. 326, and ca. 236 cm^{-1}.

This research was supported by the *Fonds der Chemischen Industrie.* The donation of quartz tubes from *Heraeus Quarzschmelze* Hanau (Dr. *Höfer*) and of gold from *Degussa AG* is gratefully acknowledged. We are indebted to Dr. *Ram Seshadri* for fruitful discussions and a critical reading of the manuscript.

Experimental Section

Synthesis: Starting materials were gold metal powder, P_2S_5 (Fluka, 99.99% purity, Alfa), As_2S_3 (Alfa, 99.998%), K_2S and S powder (Riedel, 99.999%).

Potassium Gold Thiophosphate, K_2AuPS_4 (**1**): A mixture of Au powder (0.164 g, 0.833 mmol), K_2S (0.092 g, 0.833 mmol), P_2S_5 (0.093 g, 0.417 mmol), and S (0.013 g, 0.417 mmol) was loaded into a silica tube in a glovebox. The tube was evacuated and sealed in vacuo. The mixture was heated to 550°C over a period of 12 h and maintained at this temperature for 4 d. It was then allowed to cool slowly to room temperature at a rate of 4°C/h. The yellow, plate-like crystals thus obtained were found to be stable in air and insoluble both in water and in common organic solvents. The collected material was washed with water and then dried by rinsing with diethyl ether.

[a] The isotropic equivalent displacement parameter is defined as one-third of the trace of the orthogonalized U_{ij} tensor.

Thallium Gold Thiophosphate, Tl_2AuPS_4 (**2**): Au powder (35 mg, 0.178 mmol), Tl_2S (79 mg, 0.355 mmol), P_2S_5 (78 mg, 0.178 mmol), and S (57 mg, 1.778 mmol) were heated to 700°C over a period of 12 h and maintained at this temperature for 4 d. The mixture was then slowly cooled to room temperature at a rate of 4°C/h. The long, red plates thus obtained were found to be both air- and water-stable.

Potassium Gold Thioarsenate, K_2AuAsS_4 (**3**): Pure material was obtained by heating a mixture of Au powder (0.123 g, 0.625 mmol), K_2S (0.069 g, 0.625 mmol), As_2S_3 (0.077 g, 0.312 mmol), and S (0.03 g, 0.937 mmol) in analogy to the procedure described for **1**. Orange, plate-like crystals were formed, which were found to be slightly air-sensitive and which decomposed in water.

Potassium Gold Thiophosphate, $KAu_5P_2S_8$ (**4**): 0.123 g (0.62 mmol) of Au, 0.034 g (0.31 mmol) of K_2S, 0.069 g (0.31 mmol) of P_2S_5, and 0.04 g (1.25 mmol) of S were heated as described above. Red, needle-shaped crystals were collected from the charge under inert atmosphere and were washed with anhydrous diethyl ether. The crystals were found to disintegrate in water or after exposure to air for 1 d.

Structure Determination: Crystal structures were determined from single-crystal X-ray diffraction data at 294 K for **4** and at 200 K for the other two compounds. A Siemens P4 diffractometer was used for the data collection. After Lorentz and polarization corrections, absorption corrections were made by acquiring Ψ scans and using the program XEMP in the SHELXTL package[29]. The structures were solved in the different space groups using direct methods with the package SHELXTL. Refinements were performed against F_o^2.using SHELXL-93[30]. Final refinement cycles included anisotropic thermal parameters on all atoms. Details of the data collection and refinement are given in Table 3. The final atomic and equivalent thermal parameters are listed in Tables 4−7. Further details of the crystal structure determinations may be obtained from the Fachinformatioszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository numbers CSD-407912 (K_2AuPS_4), -407910 (Tl_2AuPS_4), -407913 (K_2AuAsS_4), and -407911 ($KAu_5P_2S_8$).

Physical Measurements − Thermal Analysis: Differential thermal analyses were performed with a Netzsch STA 429 thermal analyzer. Typically, samples of 30 mg of ground crystalline material were heated in quartz ampoules in vacuo. An empty quartz ampoule of equal mass was used as a reference. The samples were heated to the 600°C at a rate of 3°C/min and were then cooled to 50°C at the same rate. The DTA samples were examined by powder X-ray diffraction (D5000, Siemens) after the experiments.

Optical Spectra: UV/Vis/NIR spectra were acquired with a CARY 5 G (Varian) in the reflectance mode using a diffuse reflectance integrating sphere. The samples were diluted with $BaSO_4$.

Infrared Spectra: FT-IR spectra of samples pressed into KBr pellets were recorded with a Galaxy-2030 FT-IR spectrometer (Mattson Instruments).

Keywords: Boron / Iron / Boryl complexes / η^1-Coordinated borazine

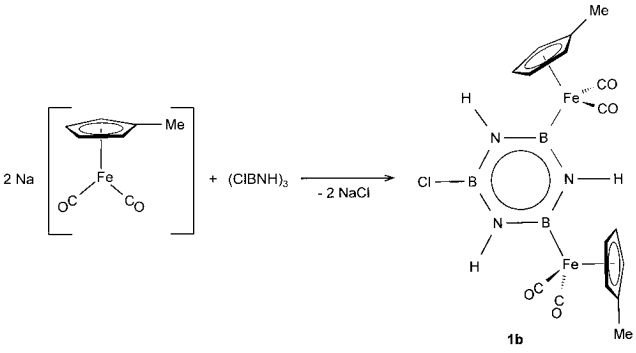
A series of η^1-borazine complexes were obtained by the reaction of trichloroborazine with $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$. The compounds $[\{(C_5R_5)(CO)_2Fe\}_nCl_{3-n}B_3N_3H_3]$ (**1a**, n = 1, R = Me; **1b**, n = 2, C_5R_5 = C_5H_4Me; **1c**, n = 3, R = H) have one to three iron−boron σ bonds and Fe−B π-interactions can be ruled out from the spectroscopic and structural results. All new borazine complexes were isolated as orange crystalline solids and characterized by multinuclear NMR methods and IR spectroscopy. The structure of **1b** in the crystalline state was also determined by a single-crystal X-ray study.

Introduction

The chemistry of borazine and its derivatives, in terms of their role as ligands in transition-metal complexes, is restricted to a few examples, such as $[(EtBNEt)_3Cr(CO)_3]$[1a][1b]. In these compounds, which are mostly derived from peralkylated borazines, the $(RBNR)_3$ ligand always shows η^6 coordination similar to the corresponding benzene complexes[2][3]. η^1-Coordinated borazines with a boron−transition metal bond are believed to play an important role in the $[RhH(CO)(PPh_3)_3]$-catalyzed hydroboration of acetylenes with $(HBNH)_3$. This reaction yields a variety of alkenyl-substituted borazines which are suitable precursors for conversion into ceramic materials[4]. The similarity between this reaction and the rhodium-catalyzed hydroboration with boranes[5] suggests the oxidative addition of a borazine B−H bond to the metal center with formation of a boryl complex. However, there is no spectroscopic evidence for the formation of such a compound. Structurally characterized boryl complexes have, in most cases, been obtained from catecholborane and its derivatives[6a][6b][6c][6d][6e][6f][6g]. As a consequence of our investigations of alternative transition metal complexes of boron[7a][7b], we report here the synthesis and structure of the first η^1-coordinated borazine complexes having boron−transition metal σ bonds.

Results and Discussion

The reaction of $(ClBNH)_3$ with two equivalents of $Na[(C_5H_4Me)Fe(CO)_2]$, as shown in Eq. 1, gives a borazine derivative with two boron−iron bonds, $[\{(C_5H_4Me)Fe(CO)_2\}_2ClB_3N_3H_3]$ (**1b**) as orange needles in 29% yield. The structure of **1b** in solution can be elucidated from the NMR and IR spectra. The compound shows two broad resonances at δ = 5.53 and δ = 6.20 (2:1 ratio) in the ^{1}H-NMR spectrum, corresponding to the nitrogen-bound hydrogen atoms, along with characteristic ^{11}B-NMR signals in a 1:2 ratio for the Cl- and Fe-substituted boron atoms, respectively, at δ = 27.2 and δ = 53.1. The relative high field shift of 68 ppm for the second signal compared to that of $[CpFe(CO)_2BPh_2]$[6c] is largely due to the B−N multiple bond character in the borazinyl ring. There is no evidence for an Fe−B π-interaction, which has been established for $[CpFe(CO)_2BCat]$ (Cat = OC_6H_4O)[6c] in solution, and evidence for this is provided by the CO stretching frequencies of **1b** (1996 and 1937 cm^{-1}) that match the IR data of the methyl complex $[(C_5H_4Me)Fe(CO)_2Me]$ (1995 and 1935 cm^{-1})[8].

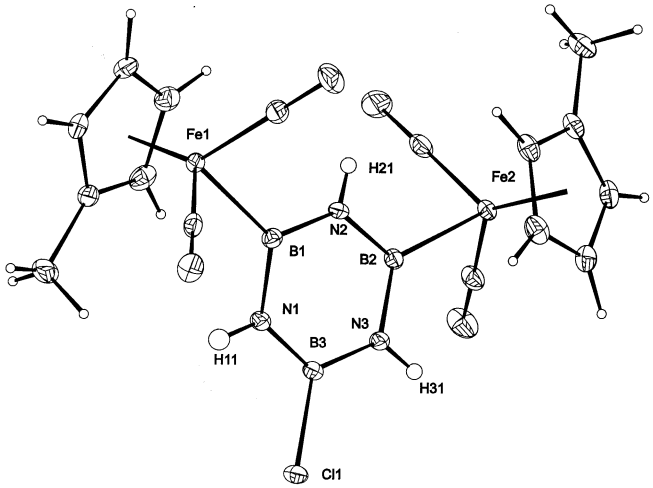


In the crystal (Figure 1) **1b** adopts C_1 symmetry. Fe-B π-interactions in the solid state can be excluded because of the orthogonal arrangement of the N−B−N planes with respect to the Cp centroid−Fe−B planes (90.6° and 94.5°)[6c][9]. The Fe−B distances of 2.041(1) and 2.045(1) Å, respectively, can be compared with the value of 2.034(3) Å found for $[CpFe(CO)_2BPh_2]$, which shows a similar geometry in the crystal in terms of the dihedral angle between the Cp centroid−Fe−B and C−B−C planes (75°)[6c]. The replacement of two Cl atoms by the more bulky $[(C_5H_4Me)Fe(CO)_2]$ moieties has no significant influence on the geometry of the central six-membered B−N core, as shown

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0202−0291 $ 17.50+.50/0

by the B−N bond distances [1.414(2)−1.442(2) Å] and N−B−N angles [115.3(1)−120.5(1)°] which resemble the corresponding values in the parent compound $(ClBNH)_3$; the planarity of the $(B-N)_3$ ring of **1b** is also preserved[10].

Figure 1. Structure of **1b** in the crystal (ellipsoids at 50% probability, drawing package CAMERON[14]).



Selected distances (Å) and angles (°): Fe1−B1 2.041(1); Fe2−B2 2.045(1); B1−N1 1.441(2); B3−N1 1.410(2); Fe1−centroid 1 1.721; Fe2−centroid 2 1.716; Fe1−B1−N1 123.10(9); Fe2−B2−N2 120.64(9); N1−B1−N2 115.3(1), N2−B2−N3 115.4(1)

Apart from **1b**, the corresponding borazine complexes containing one or three boron−iron bonds, respectively, were obtained by similar methods. In the case of the monosubstituted derivative $[\{(C_5Me_5)Fe(CO)_2\}Cl_2B_3N_3H_3]$ (**1a**) the best results were obtained from the reaction of $(ClBNH)_3$ with one equivalent $Na[(C_5Me_5)Fe(CO)_2]$, while $[\{CpFe(CO)_2\}_3B_3N_3H_3]$ (**1c**) is obtained with three equivalents of $Na[CpFe(CO)_2]$. In order to obtain the crystalline compounds **1a,b** it was necessary to employ the alkylated Cp derivatives, whereas the parent compound, $Na[CpFe(CO)_2]$, always led to oily products containing impurities. The structures of **1a**,**c** in solution can be deduced from the similarity between the IR- and NMR-spectroscopic data and the results obtained for **1b**. All compounds proved to be extremely air-sensitive and showed signs of decomposition after storage at room temperature under a nitrogen atmosphere for a few days.

Conclusion

The first η^1-borazine complexes have been obtained by the reaction of trichloroborazine with $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$, extending the scope of borazine in transition-metal chemistry. Depending on the borazine-to-iron ratio employed, the mono-, di- and trisubstituted compounds $[\{(C_5R_5)(CO)_2Fe\}_nCl_{3-n}BNH_3]$ (**1a**, n = 1, R = Me; **1b**, n = 2, $C_5R_5 = C_5H_4Me$; **1c**, n = 3, R = H) were obtained as crystalline solids. These complexes show, both in solution and in the crystal, iron−boron σ bonds with no further π stabilization, which was proved by NMR and IR spectroscopy as well as by X-ray studies.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*.

Experimental Section

All manipulations were carried out under a dry nitrogen atmosphere in Schlenk glassware. Solvents and reagents were dried by standard procedures, distilled, and stored under nitrogen and over molecular sieves. $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$[11] and $(ClBNH)_3$[12] were synthesized according to the literature procedures. − NMR: Varian Unity 500 at 499.843 (^{1}H, internal standard TMS), 150.364 (^{11}B, external standard $BF_3\cdot OEt_2$ in C_6D_6), 125.639 MHz (^{13}C{^{1}H}, APT, internal standard TMS); all NMR spectra were recorded in C_6D_6 as solvent. − Elemental analyses (C, H, N): Carlo-Erba elemental analyzer, model 1106. − IR: Perkin-Elmer FT-IR 1720x.

[2,4-Dichloro-6-{(η^5-pentamethylcyclopentadienyl)dicarbonyliron}borazine] (**1a**): 0.86 g (3.18 mmol) of $Na[(C_5Me_5)Fe(CO)_2]$ was suspended in 20 ml of benzene and a solution of 0.58 g (3.18 mmol) of $(ClBNH)_3$ in 15 ml of benzene was added dropwise at ambient temperature. After stirring for 45 min all volatile materials were removed under high vacuum (25°C/0.001 torr) and the solid residue was treated with 40 ml of hexane and filtered. 0.25 g (20%) of **1a** was recovered from the filtrate at −30°C as yellow needles. − ^{1}H NMR δ = 1.33 (s, 15 H, Me), 4.68 (s, 1 H, ClBNHBCl), 5.52 (s, 2 H, ClBNHBFe). − ^{11}B NMR: δ = 28.44 (s, 2 B, BCl), 58.99 (s, 1 B, BFe). − ^{13}C NMR: δ = 9.55 (Me), 94.66 (C1−C5, C_5Me_5), 217.55 (CO). − IR (hexane): $\tilde{\nu}$ = 1995, 1935 cm^{-1} (CO). − $C_{16}H_{17}B_3ClFe_2N_3O_4$ (494.91): calcd. C 38.83, H 3.46, N 8.49; found C 38.48, H 3.51, N 8.53.

[Chloro-4,6-bis{(η^5-methylcyclopentadienyl)dicarbonyliron}borazine] (**1b**): As described for **1a**, $Na[(C_5H_4Me)Fe(CO)_2]$ (0.90 g, 4.20 mmol) was reacted with $(ClBNH)_3$ (0.39 g, 2.10 mmol) and 0.30 g (29%) of $[\{(C_5H_4Me)Fe(CO)_2\}_2ClB_3N_3H_3]$ (**1b**) was recovered from the filtrate at −30°C as orange crystals. − ^{1}H NMR: δ = 1.51 (s, 6 H, Me), 3.92−4.05 (broad, 8 H, C_5H_4), 5.53 (s, 2 H, ClBNHBFe), 6.20 (s, 1 H, FeBNHBFe). − ^{11}B NMR: δ = 27.15 (s, 1 B, BCl), 53.05 (s, 2 B, BFe). − ^{13}C NMR: δ = 12.97 (Me), 81.50, 84.31 (C2−C4, C_5H_4), 99.86 (C1, C_5H_4), 217.19 (CO). − IR (hexane): $\tilde{\nu}$ = 1996, 1937 cm^{-1} (CO). − $C_{12}H_{18}B_3Cl_2FeN_3O_2$ (395.48): calcd. C 36.45, H 4.59, N 10.56; found C 36.33, H 4.60, N 10.56.

[2,4,6-Tris{(η^5-cyclopentadienyl)dicarbonyliron}borazine] (**1c**): As described for **1a**, 1.29 g (6.45 mmol) of $Na[CpFe(CO)_2]$ suspended in 30 ml of benzene was reacted with 0.40 g (2.15 mmol) of $(ClBNH)_3$ and 0.37 g (28%) of **1c** was obtained as orange needles. − ^{1}H NMR: δ = 4.28 (s, 15 H, C_5H_5), 6.03 (s, 3 H, NH). − ^{11}B NMR: δ = 49.69 (s). − ^{13}C NMR: δ = 83.10 (C_5H_5), 217.46 (CO). − IR (hexane): $\tilde{\nu}$ = 1988, 1928 cm^{-1} (CO). − $C_{21}H_{18}B_3Fe_2N_3O_6$ (606.36): calcd. C 41.46, H 2.98, N 6.91; found C 41.08, H 3.02, N 6.86.

Crystal Data for **1b**: $C_{16}H_{17}B_3ClFe_2N_3O_4$, M = 494.91 g mol^{-1}, unit cell dimensions: a = 13.682(1) Å, b = 7.163(1) Å, c = 20.504 Å, V = 2009.3 Å^3, β = 90.864(1)°, $P2_1/n$, Z = 4, D_{calcd} = 1.636 cm^{-3}, μ = 16.05 cm^{-1}. The data were collected using an Enraf-Nonius DIP2020 image plate diffractometer at 150 K with Mo-K_α radiation, λ = 0.71069 Å. 26825 reflections were measured giving 3954 reflections with $I > 3\,\sigma(I)$. The images were processed with DENZO and SCALEPACK programs[14]. All non-hydrogen atoms were refined in anisotropic and all nitrogen-bound hydrogen atoms in isotropic approximation. The carbon-bound hydrogen atoms were placed geometrically and included in the final refinement with fixed positional and thermal parameters. A correction for second-

ary extinction was applied and refinement completed using a Chebyshev weighting scheme with parameters 4.09, 3.54, and 3.18[15]. Refinement on F converged at $R = 0.032$, $R_w = 0.048$, and GOF = 0.86. A final difference Fourier synthesis showed minimum and maximum residual electron densities of -0.71 and 0.63 e Å^{-3}. Further details of the crystal-structure investigations can be obtained from the Cambridge Crystallographic Data Centre (CCDC, 12 Union Road, GB-Cambridge CB2 1EZ; Tel.: Int. +7247/808-205, Telefax: Int. +44(0)1223/336-033; E-mail: deposit@chemcrys.-cam.ac.uk; World Wide Web: http://www.ccdc.cam.ac.uk) on quoting the depository number 100374.

Keywords: Conjugate addition / Enones / Steroids

The transmetallation of arylmagnesium halides or aryllithium with Me_2AlCl results in the formation of aryldimethylaluminum compounds. These arylaluminum compounds are useful reagents for conjugate additions to enones in the presence of $Ni(acac)_2$ as a catalyst. 3-Aryl ketones are obtained in good yields in these catalytic reactions. Starting from the 3-oxo-$\Delta^{1,4}$-steroids this method gives access to 1α-arylsteroids.

The addition of organometallic compounds to enones is one of the most important reactions in organic synthesis for C−C bond formation, and various synthetic methods which focus on this problem have been developed[1]. Organocuprates are widely explored in stochiometric as well as in catalytic reactions[2]. In connection with the conjugate addition reactions of organoaluminum compounds to enones we have reported the following: (a) the 1,4-addition reaction can be catalysed by copper salts for the transfer of alkyl groups[3a]; (b) under the catalysis of nickel the method is efficient for the transfer of a methyl group, even in the case of highly sterically hindered enones[3b]. To investigate the transition metal catalysed transfer of an aryl group we have studied the possibility of using mixed aryldialkylaluminum compounds in the conjugate addition of an aryl group to α,β-unsaturated enones.

Organoaluminum compounds are useful reagents for organic syntheses[4a] in both catalysed and non-catalysed reactions. Amongst these the triarylaluminum compounds are reported to react in a conjugate addition with nitroalkenes[4b][4c], diarylaluminum chlorides exhibit conjugate addition to acrylamides when irradiated[4c], and arylaluminum halides add to enones in the absence of a catalyst[4d]. Triarylaluminum compounds react with aryl iodides in the presence of a palladium catalyst to produce unsymmetrical diaryl ketones[5a], and are also useful for the synthesis of aryl-substituted *o*-allylphenols[5b]. Arylaluminum complexes are helpful in the oxirane ring opening of *trans*-2,3-epoxy alcohols as described by K. H. Ahn[5c][5d].

The conjugate addition of aryl groups to enones can be achieved in general by molar and catalytic copper reactions[1][2], or by arylzinc compounds in sonication reactions[6a][6b]. In a recent paper we studied the nickel-catalysed 1,4-arylation of enones by aryltitanate complexes[7].

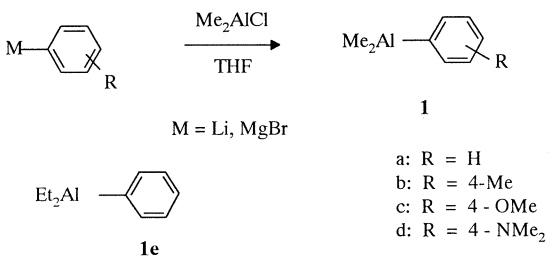
Nickel salts catalyse not only the addition of trimethylaluminum to enones[8a][8b], but also, as reported by J. Schwartz[8c], the transfer of an alkinyl group from dialkyl(alkynyl)aluminum to enones in good yields. The conjugate addition of an aryl group of mixed dialkyl(aryl)alanes has not so far been reported.

Results

In 1,4-addition reactions the use of molar organocopper reagents is often necessary, or the assistance of Lewis acids is required to give good results[9]. Cuprates are "softer" reagents than aryllithium or arylmagnesium halides, which are the reagents in transition metal catalysed reactions in the Kharasch procedure. The latter reagents lead mainly to a carbonyl attack when the enones are sterical hindered or when the cross-conjugated dienone **12** is the substrate, which results in undesired 1,2-adducts.

The authors were looking for a general catalytic method for the transfer of an aryl group to an enone in a simple manner, and therefore tested mixed aryldimethylaluminum compounds. Dialkyl(aryl)aluminum compounds are prepared by transmetallation of organolithium compounds with dimethylaluminum chloride in tetrahydrofuran[5a][5c].

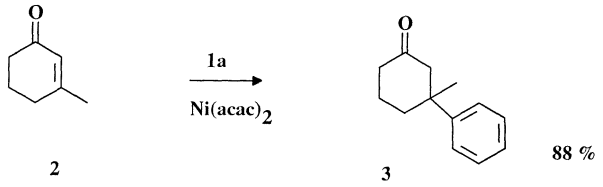
Surprisingly it was found that the dialkyl(aryl)alanes **1a−e** are suitable reagents for the transfer of an aryl group to enones.



In the presence of 5 mol-% of the catalyst $Ni(acac)_2$ a clean conversion of the alane **1a** with the enone **2** was ob-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0202−0295 $ 17.50+.50/0

served. After workup, the β-aryl ketone **3** could be isolated in 88% yield.



2 3

Furthermore, in the addition of the alane **1a** to 3,5,5-trimethylcyclohex-1-en-3-one (**4**) the yield of the product **5a** was 83%. The alanes **1c** and **1d**, with different substituents at the aryl group, were used in the addition to carvone **4**. It is promising that the addition to sterically hindered enones is possible. Also the conversion of 4-methylpent-2-ene-3-one (**6**) gave high yields of the products **7a−b**. In general, the aryl group is selectively transferred and no alkyl transfer has been observed[10].

The alanes **1a** and **1b** were prepared from commercially available aryllithium compounds. **1c** was prepared from 4-methoxyphenylmagnesium bromide. **1d** was prepared from 4-dimethylaminophenyllithium which was prepared from 4-dimethylaminophenyl bromide and *sec*-butyllithium by halogen/metal exchange. The reaction of the alanes **1d** with **4** gave **5d** in a yield of 65%. This shows that the method is sucessful for the addition to sterically hindered enones. The addition of an aryl group to the less hindered enone **6** gave the products **7** in high yields. The conversion of pulegone **8** with **1a** resulted in the formation of the ketone **9a** in a 85:15 ratio of two diastereomers. When **1e** (prepared from Et_2-AlCl and PhLi) was tested in the reaction with **4** the formation of **5a** was observed in a yield of 85%. Further examples are given in Table 1.

In testing the nucleophilic properties of mixed aryldimethylaluminum compounds versus a carbonyl group it was found that the alane **1a** gave, in the reaction with isophorone (**4**) under typical conditions (4 h, 0°C) without a catalyst, less than 1% of the 1,2-addition product **4a**. This indicates that the solvent THF has a reduced tendency for a 1,2-addition of a methyl or a phenyl group to the carbonyl group. This low 1,2-addition rate is a good assumption to make for a catalytic process. In comparison with the $Ni(acac)_2$-catalysed reaction the conversion was low, the main compound identified (98%) was the starting material **4**.

J. Y. Satoh et. al. report the introduction of a 1-phenyl group to a Δ^1-steroid by a copper-catalysed reaction in a yield of only 49%[11]. In our experiments the steroidal enone **10** reacted with the alane **1a** to give the product **11**, in a yield of 81%, without cleavage of the 17-acetate group. This is an example of the selective reaction conditions.

Less is known in the literature about conjugate additions of arylmetals to 3-oxo-$\Delta^{1,4}$-steroids of type **12,** in either stochiometric or catalytic reactions[3a]. The introduction of a phenyl group to position 1 of the steroid **12** was attempted in our laboratory using common catalytic methods. The result was a simple carbonyl attack; phenylmagnesium bromide in the presence of catalytic copper bromide yielded

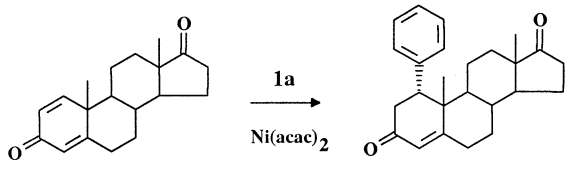
only the 1,2-addition product. In contrast to this the reaction of **12** with two equivalents of high-order cuprate ArThCuCNLi[9] was sucessful with molar copper reagent, and gave the 1,4-adduct **13a** in a yield of 65%.



12 13a

The experiments using the enone **12** and the alanes **1a−d** in the nickel-catalysed reaction gave the products **13a−d** in good to excellent yields. This is similar to the PhLi/Me_2-AlCl system in the nickel-catalysed reaction, and shows that Et_2AlCl is also useful. In the reaction of **1a** with **12** only 3% of 5β-methylandrost-4-ene-3,17-dione, which originates in the methylation of **12** in a side reaction, were produced. In the reactions of the alane **1d**, prepared from the Grignard reagent (*p*-Me_2N-ArMgBr), the yield was somewhat lower than in the experiment where **1d** was derived from 4-dimethylaminophenyllithium. This was prepared from the bromo compound by metal exchange with *n*-butyllithium in THF (see Experimental Section).

In the absence of the catalyst $Ni(acac)_2$ no reaction was observed. Optimal yields of conjugate addition product were obtained when 1.2−1.3 equivalents of aryldimethylaluminum was used. A small excess of arylalane was necessary to produce optimal yields, otherwise the unreacted starting material is methylated in a side reaction. When the aryl groups in the reagent are consumed, it seems that the starting compound is methylated by the dimethylaluminum enolates as methyl source under the catalysis of a nickel salt.

In the experiments the catalyst [$Ni(acac)_2$] was used in the commercial form without initial activation, similar to the use of DIBAH[8c]. It was found that the alane **1d** from phenylmagnesium bromide reacts faster with the enones **4** and **12** than the alane **1d** prepared from aryllithium, and that it also gives a better yield. A small amount of biaryl is usually isolated in the reactions. This comes from the biaryls in the aryllithium or arylmagnesium solutions.

5 mol-% of the catalyst gave a satisfactory yield, the optimal amount of the catalyst is in the range 2−5%. There were no advantages in the use of [$Ni(PPh_3)_4$] and [$Ni(PPh_3)_2Cl_2$] over the less expensive catalyst [$Ni(acac)_2$]. The alane **1a** and the enone **4** did not show a selective aryl transfer with the catalysts CuBr, CuCN and CuCl. The result was a statistical mixture of methylated and arylated product in the copper-catalysed reactions.

Conclusion

These experiments have demonstrated that dimethylaluminum chloride is a versatile carrier for aryl groups in transmetallation reactions, from arylmagnesium or -lithium compounds to arylalanes. This can be exploited for a chemoselective 1,4-aryl transfer to enones and cross-conjugated steroidal dienones catalysed by Ni^{II} salts.

Experimental Section

All reactions were carried out in capped vials under nitrogen. The products were isolated from the reaction mixture by preparative chromatography on silica gel (Merck F 254s) with ethyl acetate/hexane as eluent. The analysis of the products was carried out on a gas chromatograph, fitted with a 25 m × 0.2 mm CP Sil 19 CB fused capillary column. The detector signal was integrated. The column temp. was programmed to rise from 150 to 250°C at 10°C/min. Phenyllithium, *p*-tolyllithium, $Ni(acac)_2$ (95%), and the ketones **2**, **4**, **6**, **8**, were purchased from Aldrich. Dimethylaluminum chloride was used as a 1 M solution in hexane from Aldrich. 4-Dimethylaminophenyllithium was prepared from *p*-dimethylaminophenyl bromide by transmetallation with a *n*-butyllithium solution (1.6 M in hexane) in THF at 0°C/30 min, *p*-methoxyphenylmagnesium bromide was prepared from *p*-bromoanisol and magnesium in THF in a standard procedure[5c]. All solvents were used in commercial grade without any further purification.

General Procedure: 13 mmol [6.5 ml of a 2 M solution of phenylmagnesium bromide (or phenyllithium)] was added to 12 mmol of dimethylaluminum chloride (12 ml of a 1 M solution in hexane) at −20°C. The mixture was stirred for 10 min at −20°C. Then 10 mmol of the enone in 15 ml of THF was added at −20°C, followed by 0.5 mmol (0.128 g) of [$Ni(acac)_2$]. The reaction mixture was then stirred for 1−4 h at 0°C, during this time the solution was allowed to warm up to the temp. shown in Table 1. The reaction mixture was quenched with aqueous NH_4Cl solution and stirred for 15 min. The product was then extracted using ethyl acetate and dried with Na_2SO_4. Chromatography of the reaction product on silica gel and elution of the product with ethyl acetate/hexane gave the 3-aryl ketones in the yields shown in Table 1. All reactions described in the text and in Table 1 were performed on a 10-mmol scale.

Keywords: Calix[4]arenes / Calix[4]arene complexes / Molybdenum / Tungsten / Metal-metal bonding

Addition of *p-tert*-butylcalix[4]arene LH_4 to the dinuclear compounds $M_2(NMe_2)_6$ (M = Mo, W) results in the formation of $[NH_2Me_2]_2[L_2M_2]$ **1** (M = Mo) and **2** (M = W). Both compounds have been characterized by spectroscopic methods and single-crystal X-ray diffraction. The metal–metal distances of **1** and **2**, of 2.194(1) Å and 2.293(1) Å, respectively, are consistent with the retention of the M≡M triple bond. Both "ate" complexes contain a $[M{\equiv}M]^{6+}$ dimetal core, supported by two bridging μ_2-κ^2O,κ^2O-calix[4]arene ligands in the solid state. These compounds are the first examples of a formally fourfold deprotonated calix[4]arene acting as a μ_2-κ^2O,κ^2O bridging ligand for two transition metal centres. The calix[4]arenes in **1** and **2** are distorted from a *cone* conformation in the uncomplexed ligand, to an *elliptical cone* section. ^{1}H-NMR data at variable temperatures suggest fluxional behaviour of **1** and **2** in solution.

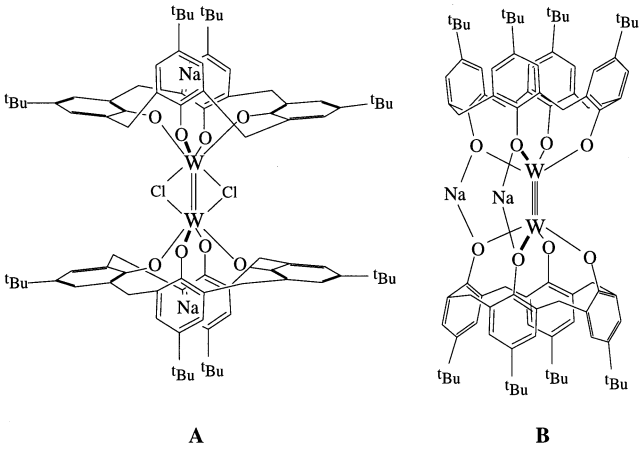
Introduction

Calixarenes and related macrocycles have received considerable attention for their host–guest chemistry, and their ability to bind metals.[1] There is currently much interest in the synthesis and structural characterization of new metallocalixarenes.[2][3][4][5] The simplest of the calixarenes, the calix[4]arene system, usually binds in an tetradentate fashion, and retains its *cone*-like appearance. In recent examples, it has been found that the calix[4]arene is capable of adopting alternative conformations in binding to metal centres, for example in an alkali-metal constrained *elliptical cone* conformation, in which the calixarene oxygen atoms adopt mutually *cis*- and *trans* sites in an octahedral geometry.[2h] There has also been an example of an *elliptical* calixarene arrangement in the absence of alkali-metal ions for mononuclear complexes.[2c]

These terminal ligating forms of the *p-tert*-butylcalix[4]arene ligand (L) have also been reported for dinuclear complexes, strongly dependant on alkali metal binding sites. C. Floriani and co-workers have recently published studies on the reduction of $LWCl_2$ in the absence of σ-donor/π-acceptor ligands.[2g] Two dinuclear species, $[Na(py)(thf)]_2[L_2W_2(\mu\text{-}Cl)_2]$ **A** and $[\mu\text{-}Na(py)_3][\mu\text{-}Na(py)_2][L_2W_2]$ **B** were structurally characterized in the course of this investigation (see Scheme).

In the former molecule (**A**), the calix[4]arene ligand adopts an *elliptical cone* arrangement, in which the sodium ions are ligated within the calixarene cavity. Each alkali-metal ion of this dinuclear ditungsten(IV) complex interacts with two oxygen atoms and two arene entities of the phenoxide groups of the calix[4]arene ligand.

The X-ray structure analysis of the ditungsten(III) species (**B**) reveals a tetragonal prismatic environment for the



$[W{\equiv}W]^{6+}$ metal core, spanned by two terminal calix[4]arene ligands in their *cone* conformations. Each sodium atom bridges two oxygen atoms of the calix[4]arene ligands. The reported tungsten–tungsten bond length at 2.313(1) Å is in range for tungsten–tungsten triple bonds.

We herein report our preliminary findings concerning the reaction of *p-tert*-butylcalix[4]arene LH_4 with dimolybdenum- and ditungstenhexamid $M_2(NMe_2)_6$ (M = Mo, W), which resulted in the isolation and characterization of two complexes $[NH_2Me_2]_2[L_2M_2]$ **1** (M = Mo) and **2** (M = W). The central $[L_2M_2]$ moieties in **1** and **2** are isoelectronic but not isostructural to the formally double negatively charged $[L_2W_2]^{2-}$ entity of **B**. Whereas in **A** and **B**, the macrocycles are terminally coordinated to each tungsten centre, the metal-metal multiple bonds in **1** and **2** are supported by bridging calix[4]arene ligands.

Results and Discussion

The reactions of *p-tert*-butylcalix[4]arene LH_4 with the dimetallahexamides $M_2(NMe_2)_6$ in toluene at 100°C gave $[NH_2Me_2]_2[L_2M_2]$ (M = Mo, **1**; M = W, **2**) after work-up in good to excellent yields, although the formation of small quantities of side products was observed. Some of these minor products have been structurally characterized.[6] Dissolution of the main products in acetonitrile on warming up to 80°C, and then cooling to room temperature afforded a crop of dark green crystals suitable for X-ray analysis. Each compound crystallizes in the monoclinic space group $P2_1/c$, with six non-coordinated molecules of acetonitrile. Figure 1 and Figure 2 show SCHAKAL plots of the solid state structure of the dianions of **1** (Figure 1) and **2** (Figure 2). Selected bond lengths and bond angles are given in the captions.

Figure 1. SCHAKAL drawing of the solid state structure of **1** (only the anion is depicted), showing the atom labeling scheme. Hydrogen atoms are omitted for clarity[a]

ligands [O(1)−O(4)] and leaving the other one uncoordinated (not shown in Figure 1 and 2). The C−N vector of the acetonitrile molecule is pointing out of the calix[4]arene pocket [O(5)−O(8)]. This orientation is similar to that of a previously studied inclusion complex of acetonitrile by a calix[4]arene macrocycle, tetraethyl *p-tert*-butylcalix[4]arenetetracarbonate]·MeCN.[7] The C−N−C planes of the dimethylammonium ions inside the calix[4]arene cavities of **1** are almost parallel to the planes defined by the oxygen and C_{ipso} carbon atoms of the O(3),O(1) [3.4(5)°], and O(6),O(8) [2.4(5)°] phenoxide moieties. The acute angle between the C−N−C plane, and the corresponding planes of the O(5),O(7) phenoxide entities of **2** is 14.7(9)°. The smallest (calculated) distances of a calix[4]arene oxygen atom to a hydrogen atom of the ammonium counterion are 2.67 Å to O(8) in **1**, and 2.34 Å to O(3) in **2**.[8]

The metal-metal bond lengths of 2.194(1) Å (Mo−Mo) in **1**, and of 2.293 (1) Å (W−W) in **2** are in the range expected for molybdenum−molybdenum or tungsten−tungsten triple bonds.[9] The coordination sphere of the [M≡M]

unit is a distorted tetragonal prismatic (partly staggered). The smallest angles of intersection between the planes defined by O−M(1)−M(2) and O−M(2)−M(1) come to approximately 30° in **1**, and 20° to 30° in **2**. A similar $[M_2O_8]$ structural type was reported for d^3-d^3 dimers in the "ate" complexes $K_2[M_2(OCH_2tBu)_8]$ (M = Mo, W) by M. H. Chisholm and co-workers.[10]

The X-ray single crystal structure determinations show that **1** and **2** contain a $[M{\equiv}M]^{6+}$ dimetal core, supported by two bridging μ_2-κ^2O,κ^2O-calix[4]arene ligands. The complexes **1** and **2** are, to the best of our knowledge, the first examples of a formally fourfold deprotonated calix[4]arene acting as a μ_2-κ^2O,κ^2O bridging ligand for two transition metal centres. These compounds are probably best compared to $LH_2Mo_2(OAc)_2$[3b], where a similar bridging mode was reported for the doubly deprotonated calix[4]arene ligand. In this compound, the hydrogen atoms form bonds to the phenoxide oxygen atoms of the calix[4]arene ligand, which retains the *cone* conformation and bridges two metal-metal quadruple bonded molybdenum atoms.

Both macrocyclic ligands of the molybdenum complex (**1**) are symmetrically distorted from the *cone* conformation. Each bridging calix[4]arene shows two opposing phenoxide rings − those of the oxygen atoms O_{inside} [O(1), O(3), O(6), and O(8)] − pushed away from the macrocycle and two − those of the oxygen atoms $O_{outside}$ [O(2), O(4), O(5), and O(7)] − towards the macrocycle. Thus, they define an *elliptical cone* section, along the O(1)−O(3) and O(6)−O(8) axis. As a result of this distortion, the bond distances $M{-}O_{inside}$ are slightly shorter, e. g. 1.942(2) Å for Mo(2)−O(1) vs. 2.016(2) Å for Mo(2)−O(7), and the bond angles $O_{inside}{-}M{-}M'$ are close to 90°. Consequently, the $O_{inside}{-}M{-}O_{inside}$ angles of approximately 175.5° are much larger than the corresponding $O_{outside}{-}M{-}O_{outside}$ angles of approximately 155.5°.

The angle of intersection between the least square planes through the carbon atoms of the methylene bridges and the least square planes through a phenoxide moiety, defined by the oxygen atom and the C_{ipso} and C_{ortho} carbon atoms, can serve as a good measurement for the tilting of the phenoxide entities of the calix[4]arene ligand. We calculated these angles for the $O_{outside}$ phenoxide moieties to be in a range between 74.3(2)° and 76.5(2)°, and for the O_{inside} phenoxide entities between 26.9(2)° and 37.9(2)°. The appropriate angles of the mononuclear calix[4]arene complex LMoNMes (Mes = mesityl),[11] in which the calix[4]arene ligand retains the *cone*-like shape might be a good reference. We calculated for this compound an angle of 59.0(1)° on average, with values ranging from 56.7(1)° to 61.4(1)°.

The bridging calix[4]arene ligands of the tungsten compound **2** are also heavily distorted from the *cone* conformation of the parent calix[4]arene LH_4. In contrast to the symmetrical tilting in **1**, only one phenoxide group per ligand − those of O(2) and O(5) − is pushed away from the macrocycle. The angles between the planes of these moieties and the corresponding reference plane through the methylene carbon atoms are 27.0(3)° and 28.8(3)°, respectively. We attribute this difference between the ligand systems in **1** and **2** in the solid state structure to steric reasons, resulting from the slightly longer bonding distance of the tungsten−tungsten triple bond. However, in solution we could observe signals due to two different types of phenoxide groups in the low temperature ^{1}H-NMR spectrum for **1** and **2**. Both compounds show a splitting of the signals of the *tert*-butyl hydrogen atoms and aromatic protons of the *p-tert*-butylcalix[4]arene ligand at low temperatures. At room temperature, we observe, for example, a sharp signal for the *tert*-butyl protons of **2**, and a broadened singlett in the case of **1**. These signals split on cooling to two sharp singletts at low temperatures. The coalescence temperature for this process is 252 K for the ditungsten compound **2**, and 282 K for the dimolybdenum compound **1**. These NMR data suggest fluxional behaviour of the μ_2-κ^2O,κ^2O bridging calix[4]arene ligand in solution, i.e. an interconversion of the O_{inside} and $O_{outside}$ phenoxide rings of the dinuclear compounds **1** and **2**. We calculated free activation enthalpies of 59.0 kJ/mol (**1**) and 52.2 kJ/mol (**2**) for this process. Details on the ^{1}H-NMR investigations at variable temperatures, on the characterization of side products, and on the reactivity of **1** and **2** will be given elsewhere.[6]

Fenske* is gratefully acknowledged. We would like to thank *Dr. G. Baum* and *Dr. A. Eichhöfer* for helpful discussions as well as *Fa. H. C. Starck GmbH*, Goslar, for a gift of metal chlorides.

Experimental Section

General: All reactions and subsequent manipulations involving organometallic reagents were performed under argon atmosphere using standard Schlenk techniques. The preparation of samples for spectroscopy was accomplished by using a glove box Braun MB 150 BG-I. Solvents were dried according to standard procedures, stored over activated 4 Å molecular sieve and degassed prior use. Deuterated solvents were obtained from Aldrich Inc. (all 99 atom% D), dried according to standard procedures and stored over activated 4 Å molecular sieves. − NMR spectra were recorded on a Bruker AC 250. ^{13}C-NMR spectra are broad-band proton decoupled (^{13}C{^{1}H}). Standard DEPT-135 experiments were recorded to distinguish -CH_3 and -CH type carbons from -C or -CH_2 type carbons in the ^{13}C-NMR spectrum. NMR data are listed in parts per million (ppm) and are reported relative to tetramethylsilane. Coupling constants are quoted in Hertz. Residual solvent peaks used as internal standards were as follows: $CDCl_3$, δ = 7.24 (^{1}H) or natural-abundance carbon signal at δ = 77.0; C_7D_8, δ = 2.09 (^{1}H). − EI-MS spectra were recorded on a Varian MAT 3830 (70 eV). − Elemental analyses were performed by the microanalytical laboratory of the author's department. − Infrared spectra were recorded as KBr pellets on a Bruker IFS 28 and are reported in cm^{-1}. − *p-tert*-butyl-calix[4]arene,[12] $Mo_2(NMe_2)_6$,[13] and $W_2(NMe_2)_6$,[14] were prepared as described in the literature. All other reagents were purchased from commercial sources and purified by standard techniques.

Preparation of Bis(dimethylammonium) Di-μ_2-κ^2O,κ^2O-p-tert-butylcalix[4]arenedimolybdate(III) (**1**): A solution of 250 mg (0.55 mmol) of $Mo_2(NMe)_6$ and 812 mg (1.10 mmol) of *p-tert*-butylcalix[4]arene−toluene adduct in 40 ml of toluene, was stirred for 8 h at

100°C. All volatiles were removed in vacuo, the yellow-greenish residue was washed with 20 ml of hexane and collected. Yield: 737 mg, 85%. Crystals suitable for X-ray analysis were grown in a saturated acetonitrile solution. m.p. 368°C (dec.). – IR (KBr): $\tilde{\nu}$ = 3129 vs, 2959 vs, 1743 w, 1597 m, 1552 m, 1449 vs, 1391 m, 1361 m, 1290 vs, 1206 s, 1121 m, 910 s, 873 m, 828 s, 801 m, 763 m, 745 s, 730 m, 694 m, 542 vs, 467 m, 430 m, 404 m. – ^{1}H NMR ($CDCl_3$, 298 K) δ = 7.15 (s, br, 4 H, aromatic *H*), 6.87 (s, 4 H, aromatic *H*), 5.85 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.37 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 2.94 (s, 4 H, C*H*$_2$), 2.57 [br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 1.19 [s, br, 36 H, C(C*H*$_3$)$_3$], 0.75 [t, 6 H, $^3J_{HH}$ = 5.2 Hz, H$_2$N(C*H*$_3$)$_2^+$]. – ^{1}H NMR (C_7D_8, 333 K): δ = 7.26 (d, 4 H, $^4J_{HH}$ = 2.6 Hz, aromatic *H*), 6.94 (d, 4 H, $^4J_{HH}$ = 2.6 Hz, aromatic *H*), 6.30 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.51 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.17 (d, 2 H, $^2J_{HH}$ = 13.4 Hz, C*H*$_2$), 2.90 [br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 2.88 (d, 2 H, $^2J_{HH}$ = 13.4 Hz, C*H*$_2$), 1.20 [s, 36 H, C(C*H*$_3$)$_3$], 0.86 [t, 6 H, $^3J_{HH}$ = 5.5 Hz, H$_2$N(C*H*$_3$)$_2^+$]. – ^{1}H NMR (C_7D_8, 233K): δ = 7.36 (d, 2 H, $^4J_{HH}$ = 2.0 Hz, aromatic *H*), 7.23 (d, 2 H, $^4J_{HH}$ = 2.3 Hz, aromatic *H*), 6.94 (d, 2 H, $^4J_{HH}$ = 2.0 Hz, aromatic *H*), 6.91 (d, 2 H, $^4J_{HH}$ = 2.3 Hz, aromatic *H*), 6.44 (d, 2 H, $^2J_{HH}$ = 12.4 Hz, C*H*$_2$), 3.63 (d, 2 H, $^2J_{HH}$ = 12.4 Hz, C*H*$_2$), 3.24 (d, 2 H, $^2J_{HH}$ = 13.9 Hz, C*H*$_2$), 2.88 (d, 2 H, $^2J_{HH}$ = 13.9 Hz, C*H*$_2$), 2.70 [br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 1.29 [s, 18 H, C(C*H*$_3$)$_3$], 1.17 [s, 18 H, C(C*H*$_3$)$_3$], 0.76 [br, 6 H, H$_2$N(C*H*$_3$)$_2^+$]. – ^{13}C NMR ($CDCl_3$, 298 K): δ = 31.79 [s, C(*C*H$_3$)$_3$], 33.31 (s, *C*H$_2$), 33.87 [s, *C*(CH$_3$)$_3$], 34.84 (s, *C*H$_2$), 37.99 [s, N(*C*H$_3$)$_2$], 123.85, 125.12 (s, aromatic *C*H), 128.97, 131.66 (s, aromatic *C*), 139.46 (s, aromatic *C*^{t}Bu), 164.55 (s, aromatic *C*O). – EI/MS (70 eV) *m/z* (%): 1481(63) ([L_2Mo_2 – H]$^+$), 1426(36) ([L_2Mo_2 – C_4H_8]$^+$). – $C_{92}H_{120}O_8Mo_2N_2$ (1576.7) calcd.: C 70.02, H 7.67, N 1.78; found: C 69,55, H 7.92, N 1.80.

Preparation of Bis(dimethylammonium) Di-μ$_2$-κ^{2}O,κ^{2}O-p-tert-butylcalix[4]areneditungstate(III) (**2**): A solution of 250 mg (0.40 mmol) of $W_2(NMe)_6$ and 590 mg (0.80 mmol) of *p-tert*-butylcalix[4]arene–toluene adduct in 40 ml of toluene was stirred for 8 h at 100°C. All volatiles were removed in vacuo, the green residue was washed with 20 ml of hexane and collected. Yield: 630 mg, 90%. Crystals suitable for X-ray analysis were grown from a saturated acetonitrile solution. m.p. 446°C (dec.). – IR (KBr): $\tilde{\nu}$ = 3132 vs, 2967 vs, 1742 w, 1598 s, 1553 s, 1480 vs, 1361 vs, 1312 s, 1210 s, 1120 s, 1026 m, 1008 w, 912 vs, 874 s, 829 vs, 800 s, 763 s, 729 s, 694 m, 538 vs, 463 m, 425 m, 396 m. – ^{1}H NMR ($CDCl_3$, 298 K) δ = 7.21 (d, 4 H, $^4J_{HH}$ = 2.2 Hz, aromatic *H*), 6.95 (d, 4 H, $^4J_{HH}$ = 2.2 Hz, aromatic *H*), 5.95 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.40 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.27 (d, 2 H, $^2J_{HH}$ = 13.4 Hz, C*H*$_2$), 3.08 (d, 2 H, $^2J_{HH}$ = 13.4 Hz, C*H*$_2$), 2.33 [s, br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 1.23 [s, 36 H, C(C*H*$_3$)$_3$], 0.66 [t, 6 H, $^3J_{HH}$ = 5.3 Hz, HN(C*H*$_3$)$_2^+$]. – ^{1}H NMR (C_7D_8, 298 K): δ = 7.28 (d, 4 H, $^4J_{HH}$ = 2.5 Hz, aromatic *H*), 6.95 (d, 4 H, $^4J_{HH}$ = 2.5 Hz, aromatic *H*), 6.41 (d, 2 H, $^2J_{HH}$ = 12.1 Hz, C*H*$_2$), 3.56 (d, 2 H, $^2J_{HH}$ = 12.1 Hz, C*H*$_2$), 3.48 (d, 2 H, $^2J_{HH}$ = 13.5 Hz, C*H*$_2$), 3.03 (d, 2 H, $^2J_{HH}$ = 13.5 Hz, C*H*$_2$), 2.58 [br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 1.21 [s, 36 H, C(C*H*$_3$)$_3$], 0.69 [t, 6 H, $^3J_{HH}$ = 5.2 Hz, H$_2$N(C*H*$_3$)$_2^+$]. – ^{1}H NMR (C_7D_8, 213 K): δ = 7.36 (s, 2 H, aromatic *H*), 7.23 (s, 2 H, aromatic *H*), 6.96 (s, 2 H, aromatic *H*), 6.93 (s, 2 H, aromatic *H*), 6.53 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.67 (d, 2 H, $^2J_{HH}$ = 12.2 Hz, C*H*$_2$), 3.54 (d, 2 H, $^2J_{HH}$ = 13.1 Hz, C*H*$_2$), 3.02 (d, 2 H, $^2J_{HH}$ = 13.1 Hz, C*H*$_2$), 2.45 [br, 2 H, *H*$_2$N(CH$_3$)$_2^+$], 1.31 [s, 18 H, C(C*H*$_3$)$_3$], 1.17 [s, 18 H, C(C*H*$_3$)$_3$], 0.62 [br, 6 H, H$_2$N(C*H*$_3$)$_2^+$]. – ^{13}C NMR ($CDCl_3$, 298 K): δ = 31.60 [s, C(*C*H$_3$)$_3$], 32.77 (s, *C*H$_2$), 33.63 [s, *C*(CH$_3$)$_3$], 35.44 (s, *C*H$_2$), 37.65 [s, N(CH$_3$)$_2$], 123.65, 125.13 (s, aromatic *C*H), 129.14, 131,77 (s, aromatic *C*), 138,95 (s, aromatic *C*^{t}Bu), 162.39 (s, aromatic *C*O). – $C_{92}H_{120}O_8N_2W_2$ (1748.8) calcd.: C 63.16, H 6.91, N 1.60, found: C 62.98, H 7.01, N 1.42.

Crystal Structure Analysis of **1**: Stoe-IPDS diffractometer (Mo-K_a radiation), T = 200(2) K; data collection and refinement: SHELXS-90[15] and SHELXL-96[16]; monoclinic, space group $P2_1/c$; lattice constants a = 26.393(5), b = 17.607(4), c = 23.468(5) Å, β = 114.59(3), V = 9917(3) Å^3, Z = 4, μ(Mo-K_α) = 0.31 mm^{-1}, $2\Theta_{max}$ = 52°; 18104 independent reflections measured, of which 14857 were considered observed with $I > 2\sigma(I)$; max./min. residual electronic density 2.172 and –1.439 e/Å^3. 1088 parameters (C, O, N, Mo anisotropic, the positions of the H atoms were calculated for idealized positions); R_1 = 0.0659, wR_2 = 0.1798.

Crystal Structure Analysis of **2**: Stoe-STADI IV diffractometer (Mo-K_a radiation), T = 203(2) K; data collection and refinement: SHELXS-90[15] and SHELXL-96[16]; monoclinic, space group $P2_1/c$; lattice constants a = 23.840(8), b = 15.500(7), c = 21.935(8) Å, β = 100.85(3), V = 10015(6) Å^3, Z = 4, μ(Mo-K_α) = 2.35 mm^{-1}, $2\Theta_{max}$ = 50°; 17236 independent reflections measured, of which 13273 were considered observed with $I > 2\sigma(I)$; max./min. residual electronic density 3.046 and –2.061 e/Å^3. 1118 parameters (C, O, N, W anisotropic, the positions of the H atoms were calculated for idealized positions); R_1 = 0.048; wR_2 = 0.1203. – Further details of the crystal structure investigation are available from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany) on quoting the depository number CSD-407859 and CSD-407860, the names of the authors and the journal citation.

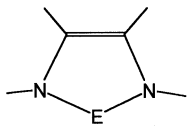
Keywords: Ab initio calculations / Carbene homologues / Boron / Isoelectronic analogues / Heterocycles

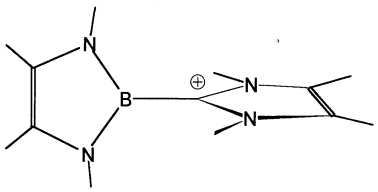
While Arduengo-type carbenes are now well established for the Group IVa elements carbon, silicon and germanium, they are experimentally unknown for the isoelectronic anions with the Group IIIa elements boron, aluminum, gallium, and indium. In the present quantum chemical investigations, the bonding features of this class of compounds are explored. As a result, they are predicted to be stable species with sizeable singlet-triplet energy separations and electron affinities. Hence, they may be considered as valid targets for experimental investigations. An analysis of the electron density distribution in the case of boron and aluminum reveals a strongly polar B−N bond for the former, and a half Al−N bond with positive charge at the aluminum, emphasizing the donor-acceptor formulation for the latter.

Introduction

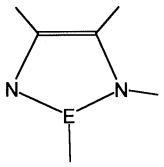
Since the pioneering studies of Wanzlick on nucleophilic carbenes[1], their successful isolation as stable species became prominent in the reports of Arduengo et al.[2][3] on the imidazo-2-ylidene, **1** (E = C).



1



2



3

Subsequent experimental studies included the preparation of the analogous silylene[4], **1** (E = Si), and germylene[5], **1** (E = Ge), derivatives. In order to gain insight into the peculiar stability of the Arduengo-type carbenes, various quantum chemical calculations have been performed on **1**[6][7][8][9][10][11][12][13][14]. Furthermore, investigations of their photoelectron spectra[9] and a detailed analysis of their chemical shielding tensors have been reported[10].

Meanwhile, the enormous stability of the valence isoelectronic diaminophosphenium cation is a well established matter in phosphorus chemistry[15][16], in particular in ring systems analogous to **1**[17][18][19][20]. The halogen precursors of the latter dissociate spontaneously into the cyclic cation and a halide anion[17]. In contrast, Arduengo-type carbenes with Group IIIa elements are as yet unknown. If these compounds are considered as being isoelectronic with the Arduengo-type carbenes, they would bear a negative charge at the Group IIIa element. The capability of Group IIIa elements to stabilize a negative charge has nevertheless been demonstrated by experimental and theoretical studies on B−B and Al−Al bonded systems[21][22][23][24][25][26][27][28][29]. For boron, one-electron [24][25][26] as well as two-electron[21][22] reductions have been observed. In contrast, for the Al−Al bond, only one-electron reduction has been found[27][28][29]. These findings indicate that it might be feasible to prepare Arduengo-type carbenes in which E (= C, Si, Ge) is replaced by a valence isoelectronic Group IIIa element bearing a negative charge.

We report herein on an exploration of the bonding properties of Arduengo-type carbenes, **1**, with E = $B^{(-)}$, $Al^{(-)}$, $Ga^{(-)}$, $In^{(-)}$. A first experimental approach to this class of compounds has recently been undertaken in the synthesis and structural elucidation of **2**[30]. This structure is found to contain the diazaborolyl unit. In addition, we include in our investigations the 1,2-shifted structural isomers **3**.

Methodology

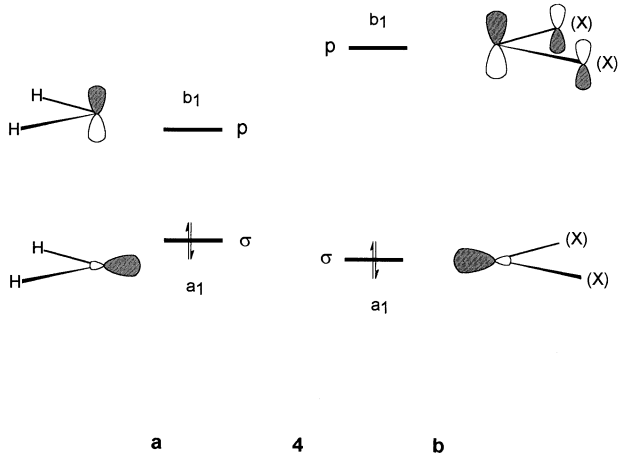
The geometries of the various molecular structures were energy optimized at the density functional theory level[31][32], utilizing Becke's three-parameter functional[33] with local and non-local electron correlation contributions. For the optimization of the geometries, the 6-31++g(d,p) basis set was used for carbon and hydrogen, as well as for boron, aluminum, and gallium[34]. One set of diffuse s,p-functions[35] and polarization functions[36] were added. Alterna-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0305 $ 17.50+.50/0

tively, the relativistic pseudopotentials of Basch and Krauss[37], with a double-ζ description for the valence space, were employed for the evaluation of structures in the homologous series containing boron to indium. For these cases, the basis sets were again augmented by one set of polarization functions (at all atoms) and one set of diffuse sp-functions (at all atoms). The coefficients for the supplementary functions were chosen according to the recommendations made for the utilization of the Gamess program[38]. Single point calculations were additionally performed (for the cases of boron and aluminum) at a triple-ζ level, with the 6-311++g(d,p) basis set[39] and with the MP4SDTQ(fc) approximation[40] for the electron correlation correction treatment. For the evaluation of the energies in the open-shell cases (doublets), the spin-projection technique of Schlegel[41] was applied. Zero-point vibrational energies were included in the relative energies, unless noted otherwise. All stationary points were verified by calculation of the corresponding Hessian matrices. For the calculations, we used the Gaussian-94[42] and Gamess[43] programs. The electron distributions in the various molecular structures were examined within the natural bond orbital (NBO) partitioning scheme[44].

Results and Discussion

Qualitative Considerations: The stabilities of the carbene structures are determined by (a) the singlet-triplet energy separations, and (b) the electron affinities in **1** (E = $B^{(-)}$, $Al^{(-)}$, $Ga^{(-)}$, $In^{(-)}$). If the singlet-triplet energy separations are small, the carbene-type structures will not be stable and will be capable of facile radical reactions (with solvents, etc.). The electron affinities, on the other hand, give a quantitative measure of the anion stabilities. If the electron affinities are large, then the possibility of preparing the anion can be considered as being realistic. In practice, however, the anions are surrounded by cations (e.g. as lithium salts). Hence, their stabilities will be mediated by crystal effects[45].

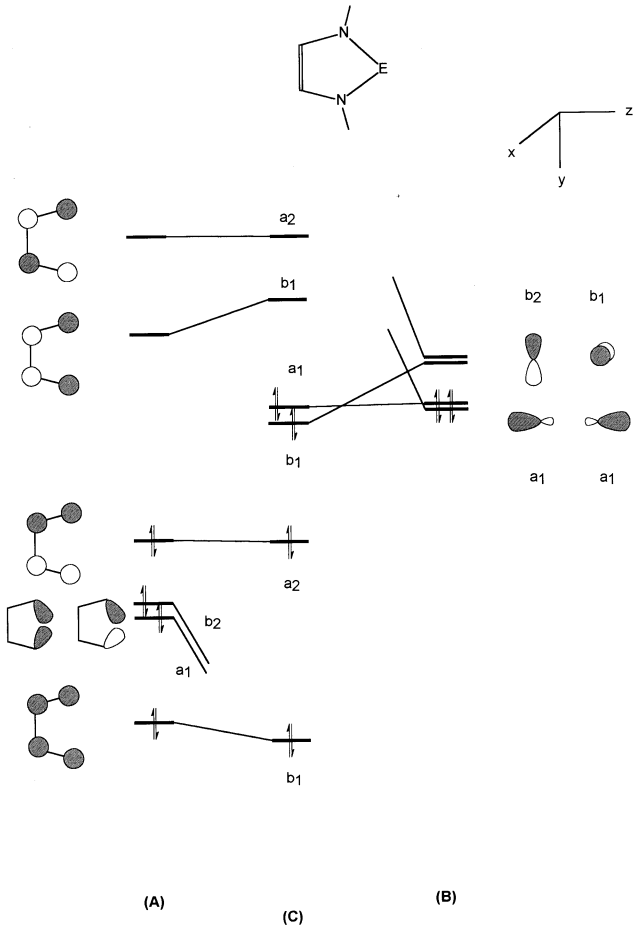


a **4** **b**

The frontier orbitals of methylene, **4a**, are given by the lone pair orbital at the central atom, σ, and the p-orbital[46]. Within C_{2v} symmetry they are confined to a_1 and b_1 representations. Both orbitals are energetically in close proximity to each other, hence a triplet ground state $^3B_1$ is preferred[47]. In a stabilized carbene, **4b** (X = NH_2, halogens), a similar sequence of orbitals is present[48]. Since the energy splitting between HOMO (σ) and LUMO (p) becomes larger for these structures, a singlet ground state results[49].

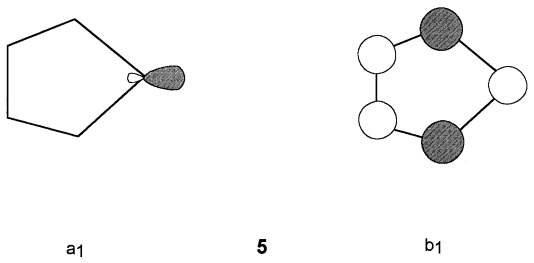
The frontier orbital system of **1** can be viewed in a similar manner, as a mutual interaction between the orbitals of the diene unit (A) and the orbitals at E (B). The composition of the orbital system is given in (C) [= (A)−(B), Figure 1].

Figure 1. Diagram showing schematic interaction between a diene unit (A) and E (B), resulting in the cyclic compound (C) [= (A)−(B)]



The p_y-orbital forms two linear combinations with the s-orbital ($s \pm p_y$), of which one ($s + p_y$) remains non-bonding upon interaction with the corresponding orbitals at (A). On the other hand, the other combination ($s - p_y$) can strongly overlap with the a_1 orbitals at fragment (A). Similarly, the b_2 orbital at (B) strongly interacts with the antibonding lone pair combination b_2 at (A). In addition, π-type interaction occurs among the b_1 orbitals, between (A) and (B). Consequently, the relevant occupied frontier orbitals at (C) can be depicted as in formula **5**.

As mentioned above, the stabilities of the anions are determined by their electron affinities, i.e. the tendency to retain their negative charge. Consequently, it is necessary to examine the anions, the corresponding neutral doublet



states, and the energy differences between the two species. The resulting Slater determinants for the singlet ground state of the anion and the two relevant doublet states are given as follows:

$\Psi\ (^1A_1) = ...(b_1)^2(a_1)^2 >$

$\Psi\ (^2A_1) = ...(b_1)^2(a_1)^1 >$

$\Psi\ (^2B_1) = ...(a_1)^2(b_1)^1 >$

The relevant triplet states for **1** are described by the following Slater determinants:

$\Psi\ (^3B_1) = ...(a_1)^1(b_1)^1 >$

$\Psi\ (^3A_1) = ...(b_1)^1(b_1)^1 >$

The first of these ($^3B_1$) refers to the lowest-energy triplet state, as has been evaluated for the classical Arduengo carbene[7]. All the states in question were examined by the quantum chemical calculations.

It should be noted that **1** is not the only feasible molecular structure. It might well be possible that it undergoes a 1,2-hydrogen shift with formation of species **3**. Consequently, we also included these possible structural isomers for the species in question in our evaluations.

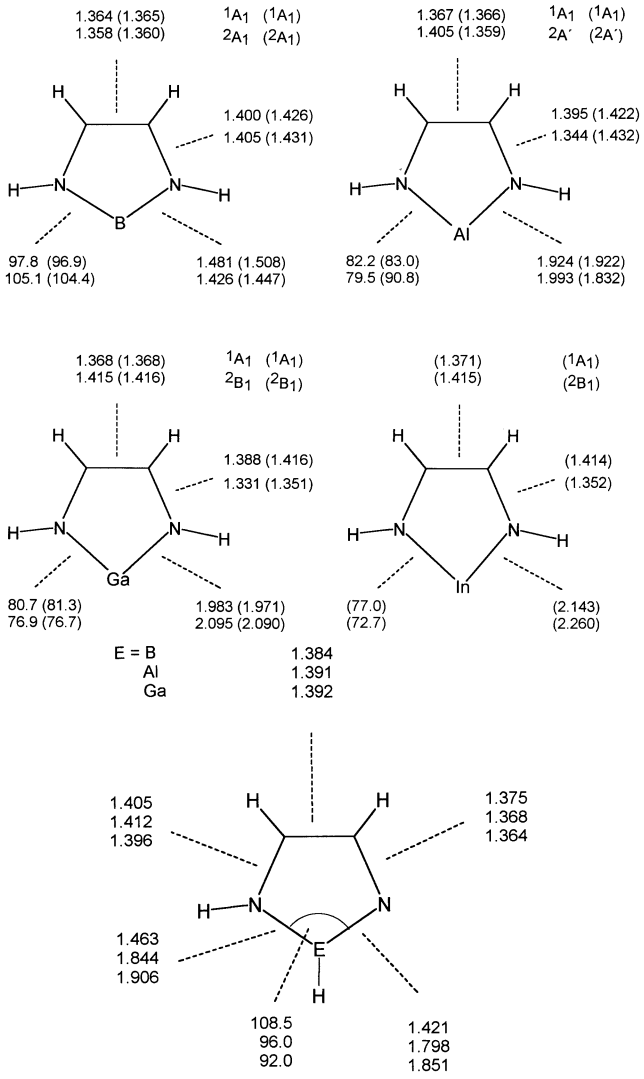
Equilibrium Geometries: The equilibrium geometries of all these structures, **1** and **3**, (bond lengths in Å, bond angles in degrees) are collected in Figure 2.

Minimum-energy structures were established by (3N − 6) positive vibrations of each species. The geometries were obtained with (a) all-valence basis sets, or alternatively with (b) effective core potential methods (ECP's, values in parentheses) (for details, see the Methodology section). All structures were obtained at the DFT level.

The anions of **1** invariably adopt C_{2v} symmetry. The valence angle at E ranges from 97.8° [X = $B^{(-)}$] to 77° [X = $In^{(-)}$]. This indicates that the equilibrium geometries of these ring systems are largely determined by the angle strain due to the first-row atoms C and N.

The bonding situation is somewhat more complicated in the doublet states. Interestingly, the doublet states undergo a change in their electronic (ground) state in the sequence E = B to In. In the case E = B, a $^2A_1$ ground state is observed, while for E = In it becomes $^2B_1$. An intermediate case is **1**, E = Al. Here, both states, $^2A_1$ and $^2B_1$, mingle with each other with concomitant Jahn-Teller interactions[50]. Symmetry breaking occurs to give C_s symmetry, through induction of b_1 vibration within C_{2v} symmetry. For this case (E = Al), the five-membered ring is tilted out of the plane (∡ CNNAl = 14.2° for $^2A'$). We acknowledge

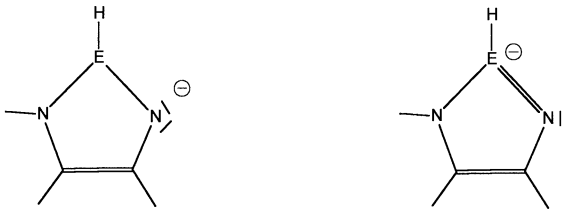
Figure 2. Equilibrium geometries of lowest-energy singlets (first entry) and doublets (second entry) of **1** (E = B, Al, Ga, In) and **3** (E = B, Al, Ga), at all-valence electron (ECP) level



that a more rigorous approach for the study of the Jahn-Teller phenomena in the (neutral) doublet states would require elaborate MCSCF calculations with subsequent multi-reference CI calculations. For the case at hand, a detailed study of the crossing of the electronic hypersurfaces of the various doublet states was not attempted.

The rearranged structures **3** invariably adopt C_s symmetry. Again, all species possess (3N − 6) positive vibrations in their equilibrium geometries. Thus, they correspond to energy minima on the electronic hypersurfaces. In general, the E−N bonds in **3** are shorter than those in the structures **1**. Notably, the E−N bond to the twofold coordinated nitrogen atom is always shorter than that to the substituted nitrogen. This can be rationalized in terms of two prominent resonance structures, which contribute to bonding in the ground states.

In canonical structure **a**, the negative charge is localized at the nitrogen atom, while in **b** it is shifted towards E (= B, Al, Ga) with formation of a (partial) double bond. The



a b

predominance of canonical structure **b** over **a** is determined by the electronegativity of E and the gain in π-energy. Although it is difficult to assess both factors quantitatively, one would expect that **3** becomes increasingly stabilized over (the singlet ground state) **1** in the order X = In < Ga < Al < B. As will be shown in the following section, this is indeed the case.

Energy Considerations: The electron affinities and singlet-triplet energy separations are the specific properties that determine the stabilities of the various species **1**. These are presented in Table 1.

Table 1. Electron affinities (in kcal/mol) [first entries] and singlet-triplet energy separations [second entries] for structure **1** (E = B to In); values in parentheses are derived from ECP calculations

Atom E		DZP[a]	DZP/ZPE[b]	TZP[c]	MP4[d]
B	($^1A_1 \rightarrow {}^2A_1$)	7.0 (9.3)[e]	8.4	7.2	3.3 (2.8)
	($^1A_1 \rightarrow {}^3A_1$)	20.2 (22.6)	20.9	20.4	23.1 (23.5)
Al	($^1A_1 \rightarrow {}^2A'$)	32.5 (34.3)	33.1	33.4	34.5
	($^1A_1 \rightarrow {}^3B_1$)	41.3 (50.5)	41.5	42.4	45.3
Ga	($^1A_1 \rightarrow {}^2B_1$)	27.0 (32.1)	28.1	26.7	39.3
	($^1A_1 \rightarrow {}^3A_1$)	52.0 (47.9)			
In	($^1A_1 \rightarrow {}^2B_1$)	(27.0)			
	($^1A_1 \rightarrow {}^3A_1$)	(38.8)			

[a] b3lyp/6-31++g(d,p). – [b] Method [a] plus zero-point vibrational energy correction (unscaled). – [c] b3lyp/6-311++g(d,p)//b3lyp(6-31++g(d,p). – [d] MP4SDTQ(fc)/6-31++g(d,p)//b3lyp/6-31++g(d,p). – [e] b3lyp/ECP-31++g(d,p).

For the cases X = B to Ga, they were explored with the all-valence electron basis set methods, and also with the ECP's (at times within the DFT procedure). For E = In, our considerations rely solely on the results of the ECP calculations. For the structures where the results of both quantum chemical procedures are available (all-valence electron basis sets and ECP's), the different approaches are seen to yield similar energy quantities. On closer inspection of the data, it can be seen that for E = B the electron affinity is found to be rather small. The value is only marginally changed by zero-point vibrational energy corrections or at an improved triplet-ζ basis set level. On the other hand, for all cases the singlet-triplet energy separations are sizeable. Thus, a singlet ground state of all structures is ensured. The electron affinity, and hence the stability of the anion, is increased for the higher element homologues. In essence, for all higher element homologues, the electron affinities are larger than those for the first-row element boron. Again, zero-point energy vibrational correction as well as explicit CI methods, such as the MP4SDTQ approach, yield comparable energy quantities.

To evaluate the feasibility of the synthesis of **1**, it is necessary to have knowledge of the relative energetic ordering of **1** and **3**, given the same element E. Corresponding energy quantities were evaluated at various levels of sophistication for the cases E = B, Al and Ga, and are listed in Table 2.

Table 2. Energy differences (in kcal/mol) between **1** and **3**, at various levels of sophistication

Atom E	DZP[a]	DZP/ZPE[b]	TZP[c]
B	−40.8	−42.4	−40.7
Al	17.6	13.9	17.9
Ga	23.9		

[a] b3lyp/6-31++g(d,p). – [b] Method [a] plus zero-point vibrational energy correction. – [c] b3lyp/6-311++g(d,p)//b3lyp/6-31++g(d,p).

The trends in the energies are obvious. For E = B, the 1,2-hydrogen shifted structure is the lowest-energy alternative. In the other cases, **1** is more stable than **3**. It should be noted, however, that in the case of carbenes it has been recently demonstrated that although 1,2-hydrogen migrations are very exothermic, their occurrence is highly unlikely from a kinetic point of view[51].

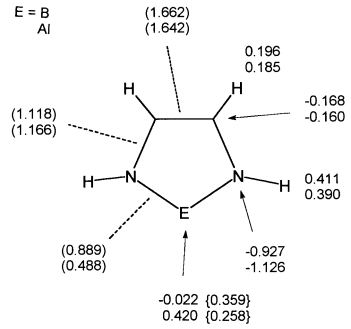
Improvement of the basis set (level C) or the inclusion of zero-point vibrational energy contributions (level B) does not significantly alter the situation. There is a clear-cut tendency of enhanced stability of **1** over **3**, with increasing atomic number of E. The case E = In was not further explored, but it seems reasonable to assume that it is at least as stable as the case E = Ga (**1** in relation to **3**).

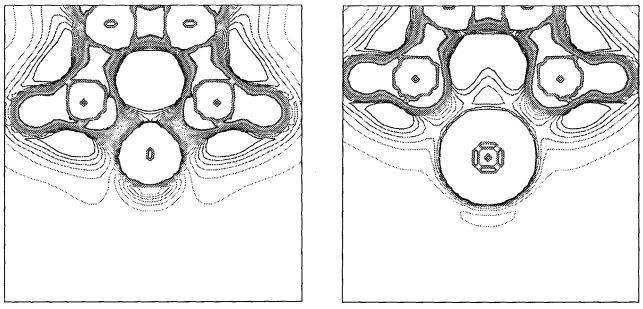
Electron Density Distributions: It is informative to analyze the electron distributions in **1** and **3**. The relevant values were computed within the natural bond orbital (NBO) scheme[44]. For the cases E = B and Al, these are displayed in Figure 3.

The electron distributions in E = B and E = Al reveal fundamental differences. For **1**, E = B, the E−N bond is almost a single bond, while it is almost a half bond for E = Al. Simultaneously, E releases electron density towards the neighbouring, more electronegative nitrogen atoms, with a concomitant strengthening of the E−N bonds. Similar trends are also observed in the Ga and In analogues, although detailed populations are not given here. Considering the data in more detail, the s/p ratio (atomic populations for the valence electrons) for the lone pair amounts to 1.378/0.918 for E = B and 1.660/0.536 for E = Al. (The corresponding π-populations of valence electrons are given in brackets in Figure 3).

Evidently, a fundamental change in the bonding is observed on going from E = B to E = Al. The Laplacians of the electron density for these two cases (as determined by the method of "atoms in molecules"[52], are shown in Figure 3b. For E = B, a non-bonding lone pair orbital (at E) is present. It is diminished in the case E = Al, in favour of an increased p-electron density at the neighbouring nitrogens. Furthermore, in the latter case (E = Al), the electron

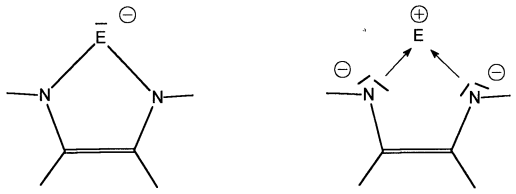
Figure 3. (a) NBO analysis (natural atomic charges with π-occupancies in curly brackets), in parentheses Wiberg bond indices (in the NAO basis) and (b) Laplacians of the electron densities for **1**, E = B and Al





E = B E = Al

density is more concentrated at the nitrogens compared with the former (E = B). All these findings are in accord with the predominance of canonical structure **c** for E = B, and a donor-acceptor formulation **d** for E = Al. For the higher element homologue E = Al, a cyclic delocalization of electrons does not occur.



c **d**

The structure **d** is dominant if E represents an electropositive element (as compared with nitrogen) and becomes increasingly so in the order X = Al < Ga < In.

Conclusions

The results of our quantum chemical study can be summarized as follows:

1. Arduengo-type carbene structures in which an isovalent electronic species E = $B^{(-)}$, $Al^{(-)}$, $Ga^{(-)}$, $In^{(-)}$ constitutes the divalent center are stable species. They possess singlet ground states and adopt C_{2v} symmetrical structures.

2. Although the central atom is relatively electropositive as compared with its neighbouring nitrogen atoms, the species possess bound states; i.e. they have a strong tendency to retain the negative charge. In other words, the corresponding doublet states have a strong electron affinity.

3. This is due to the enhancement of a chelate-type structure, in which the electropositive element E (In > Ga > Al) can release its formal negative charge to the more electronegative neighbouring nitrogen atoms.

4. Furthermore, with increasing atomic number of E, a possible 1,2-hydrogen rearrangement, which results in the formation of a "classical" structure becomes disfavored.

On the basis of our quantum chemical considerations, cyclic carbene structures of the Arduengo-type containing the Group IIIa elements should be interesting targets for synthetic verifications.

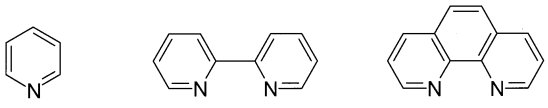
Ligands containing aromatic nitrogen heterocycles play a leading role in the molecular self assembling processes that lead to macromolecular architectures. The inductive effect of various metal fragments on those building blocks has not yet been studied systematically. To evaluate this effect we synthesized the homologous series of Group-13 metal complexes $[Me_2AlPy_2N]$ (**1**), $[Me_2GaPy_2N]$ (**2**), $[Me_2InNPy_2]_2$ (**3**), and $[Me_2TlNPy_2]_\infty$ (**4**) (Py = 2-NC_5H_4), and characterized them by low-temperature X-ray structure analysis and ^{15}N-NMR spectroscopy in solution. The electronic equivalence of the central and the ring nitrogen atoms leaves the energetic hyperface of the anion quite flat, and the electron density is polarized according to the requirements of the metal. In the aluminum and the gallium complexes **1** and **2** the metal center is coordinated exclusively through the nitrogen atoms within the pyridyl rings. The complexes with these hard metals are close-contact ion pairs. In the indium complex **3** the *cis-cis* orientation gives rise to a dimeric structure, while the unprecedented *cis-trans* arrangement in the thallium compound **4** leads to a polymeric structure. The complexes **3** and **4** have to be regarded as separated ion pairs of Me_2M^+ cations and Py_2N^- anions without any covalent bonds between the anionic moiety and the dimethylmetal cations, even in the solid state. The series of complexes proves the bis(2-pyridyl)amide to be an excellent self-adapting ligand. These findings are substantiated by NMR-spectroscopic studies in solution. Not only do the steric requirements of N heteroaromatic ligands have to be considered in molecular self-assembling processes but also the inductive effect of the different metal fragments.

Introduction

The use of aromatic nitrogen heterocycles has given a great impetus to metal coordination chemistry.[1] Due to the low-energy π* orbitals pyridine and its derivatives are valuable σ donors and π acceptors in the bonding synergism of transition-metal complexes.[2] Classical N-heteroaromatic donor ligands are pyridine, 2,2′-bipyridine and 1,10-phenanthroline.

Scheme 1



pyridine 2,2'-bipyridine 1,10-phenanthroline

In metal-induced molecular recognition processes various linkages of the simple building blocks yield polydentate macromolecular ligands tailored to the steric requirements of the nanomolecular architectures present. Helical arrangements with transition-metal centers are one focus of interest.[3] A spheric palladium polymacrocycle containing triazine bridgeheads has also been synthesized,[4] and metallo carotenate molecular wires containing pyridyl or bipyridyl ends coordinated to metal centers combine the electronic or photochemical properties of a metal fragment and the conjugated electron system of the carotenes.[5]

Over the last years our work has been concerned with the design and fine tuning of monoanionic ligands, containing N-heteroaromatic rings, which show a different coordination behavior towards soft and hard metals.[6] In these systems a single p block element in a low oxidation state links two or three pyridyl (Py) or pyrazolyl (Pz) rings. Metal coordination is achieved by the ring nitrogen atoms but never by the bridgehead atom. Anionic systems studied so far are the pyridyldiphenylmethyl,[7] dipyridylmethyl,[8] dipyridylphosphide and -arsenide,[9] tripyrazolylgermanate and -stannate.[10] These ligands are formally carbanions, phosphides and arsenides but in metal coordination they behave as amides. For instance the phosphorus or arsenic(III) center is only two-coordinate to both *ipso*-carbon atoms and the structures do not comprise any short M−P or M−As bonds. The negative charge in the anions is located almost entirely on the nitrogen atoms of the pyridyl substituents.

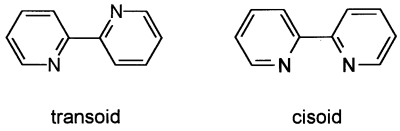
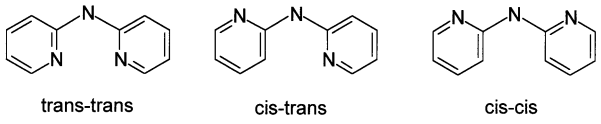
group, the P or the As bridgeheads by a nitrogen atom. In this paper a systematic study of the coordination behavior of the Py_2N^- anion, in both the solid state and solution, towards Group-13 metals is presented. The relationship between the geometry of a coordinated and an uncoordinated ligand system in solution and in the solid state is of special interest in the study of self-assembling systems.[11] The dipyridylamide ligand is anticipated to permit a *transoid* orientation in the uncoordinated form in solution, as found in 2,2′-bypiridine[12] and shown in Scheme 3.

Scheme 3. The *transoid* versus *cisoid* coordination of 2,2′-bipyridine



Because of electrostatic repulsion between the N lone pairs and the weak attraction between N and CH sites in antiparallel orientation of the N sites, they should favor the *transoid* over *cisoid* arrangement. A priori one can think of three different coordination modes.

Scheme 4. Feasible coordination modes of the dipyridylamide ligand



In the known complexes of neutral bis(2-pyridyl)amine the *trans-trans* coordination mode to both ring nitrogen atoms is observed [$(HNPy_2)CuHal_2$ (Hal = Br[13a], Cl[13b])], [$(HNPy_2)_2Cd-(ONO)_2$[13c], $(HNPy_2)M(CO)_4$ (M = Cr, Mo, W)].[13d] In the monomeric $M(Py_2N)_2$ (M = Cu[14a], Ru, Pd[14b][14c]) complexes *trans-trans* arrangements of both ring nitrogen atoms coordinated to the metal center are found, while in $(Py_2N)W(CO)_5$,[15] the tungsten atom apparently is exclusively coordinated to the central nitrogen atom. A *cis-cis* arrangement and coordination to all three nitrogen atoms is found in the dimer of $[(Py_2N)Tl(C_6F_5)_2]_2$.[16] This coordination is emulated in the polymeric complexes of $[Cu(Py_2N)]_n$[17], $[M_3(Py_2N)_4Hal_2]_n$ (M = Cu[18a], Ni[18b]). It seems worthy to note that until now a *cis-trans* coordination of the dipyridylamide ligand has not been observed.

To study the coordination behavior of the bis(2-pyridyl)-amide anion systematically in both the solid state and in solution the Group-13 metal complexes $[Me_2AlPy_2N]$ (**1**), $[Me_2GaPy_2N]$ (**2**), $[Me_2InNPy_2]_2$ (**3**), and $[Me_2TlNPy_2]_\infty$ (**4**) have been synthesized and characterized by low-temperature X-ray structures as well as by ^{15}N-NMR spectroscopy in solution.

Results and Discussion

Preparation of 1−4

Compounds **1**−**3** were synthesized by adding trimethylmetal compounds to a solution of bis(2-pyridyl)amine (eq 1).

$$n\,HNPy_2 + n\,Me_3M \longrightarrow [Me_2MPy_2N]_n + n\,MeH \quad (1)$$

1: M = Al; –10 °C in diethyl ether; $n = 1$

2: M = Ga; –78 °C in toluene; $n = 1$

3: M = In; 1 h reflux in toluene; $n = 2$

To obtain the compound **4** trimethylthallium has to be synthesized first in situ by adding methyllithium to a solution of dimethylthallium iodide in ether.[19] The second step is the addition of one equivalent of bis(2-pyridyl)amine (eq. 2).

$$n\,Me_2TlI \xrightarrow[2.\ +\ n\ HNPy_2\ ,\ -\ MeH]{1.\ +\ n\ MeLi,\ -\ n\ LiI} [Me_2TlNPy_2]_n \quad (2)$$

4 $n = \infty$

^{15}N-NMR-Spectroscopic Experiments

To gain information about the coordination behavior of the bis(2-pyridyl)amide ligand in the complexes **1**−**4** in solution we recorded NMR spectra. Particularly informative are the results of the ^{15}N-NMR-spectroscopic experiments. The spin of the ^{15}N nucleus is 1/2 and this gives sharp signals in the NMR experiments. Therefore, this method is particularly suitable to compare non-equivalent nitrogen atoms in solution. The chemical shift of the nucleus is correlated to its electronic shielding.

The neutral bis(2-pyridyl)amine gives rise to two signals which differ considerably with respect to their chemical shifts (assignment in analogy to similar systems[20]) because of the magnetically non-equivalent nitrogen sites (Table 1). In the aluminum and the gallium complexes **1** and **2** the signals of both nitrogen atoms display very similar chemical shifts, demonstrating the electron density to be shifted from the central nitrogen atom (the signal is more than 80 ppm downfield relative to that of the starting material) to the ring nitrogen atoms (where there is more than a 70 ppm upfield shift). These findings are further substantiated by the ^{1}H- and ^{13}C-NMR experiments. The two ^{15}N-NMR-spectroscopic shifts of both nitrogen sites in **3** and **4** differ by about 100 ppm and show a similar deviation of the signals as does the neutral system. Furthermore, in the ^{1}H- and the ^{13}C-NMR spectra of **4** the coupling of the related nuclei with the thallium nucleus are resolved ($^2J_{H-Tl}$ = 396.7, $^1J_{C-Tl}$ = 2574.7 Hz). There has no Tl−N coupling been detected. The coupling constants are in good agreement with separated linear dimethylthallium cations in solution.[21] Thus, the indium and the thallium compounds **3** and **4** are solvent-separated ion pairs in THF solution, while the aluminum and gallium complexes **1** and **2** are stable contact ion pairs, even in THF solution. To investi-

gate the nature of these complexes in the solid state, the crystal structures were determined.[22]

Crystal Structure of Me_2AlPy_2N (1) and Me_2GaPy_2N (2)

As in in the structures of Me_2AlPy_2CH,[8] Me_2GaPy_2CH,[8] Me_2AlPy_2P,[9] Me_2GaPy_2P[9] and Me_2AlPy_2As[9] **1** and **2** form monomers in the solid state (Figure 1). Despite the electronic competition between the deprotonated central nitrogen atom and the ring nitrogen atoms in **1** and **2** the metal center is chelated by the two ring nitrogen atoms without any contact with the central nitrogen atom (Figure 1). The anion shows *trans-trans* coordination (Scheme 4).

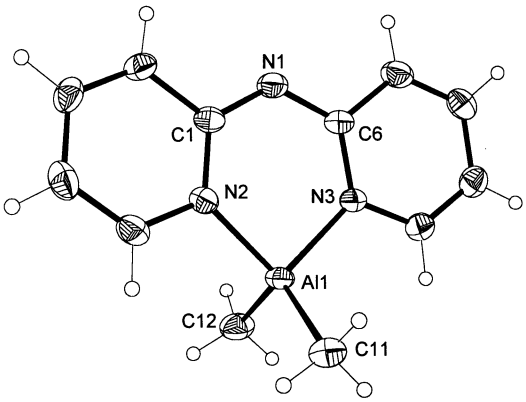
The Al−N distances of 191.5 pm in **1** are in good agreement with the literature values for aluminum amides,[23] but are about 15 pm shorter than the Al−N donor bonds to neutral 2,2′-bipyridyl[24a] or pyridine.[24b] The Al−C bond lengths (195.0 pm) are comparable with the distances in Me_3Al.[25] The N−Al−N angle (93.5°) is more acute than in the related bis(2-pyridyl)methyl derivative[8] (97.1°), and the aluminum atom is not in the plane of the ligand but is 28.3 pm out of the mean plane of the Py_2N^- ligand. These phenomena are due to the different "bite" of the amide ligand compared to that of the methyl ligand. The N···N distance (279.1 pm) is 7 pm shorter than in the bis(2-pyridyl)-methyl ligand. In contrast to the bis(2-pyridyl)methyl ligand the amide is not strictly planar, but the pyridyl rings are twisted by 10.4° with respect to each other. The basic structural parameters of the central nitrogen atom N1 (av. N−C 134.3 pm and C−N−C 125.5°) show that this atom is sp^2-hybridized. The expected C−N−C bond angle of 120° for an unstrained system is widened by the coordinated aluminum atom. Obviously, no electron density is accumulated at the central nitrogen atom.

The gallium atom in **2**, like the aluminum atom in **1**, is coordinated to the ring nitrogen atoms (Figure 1b). It is 32.1 pm out of the plane of the anion. The two pyridyl rings are twisted by 12.1°. The slightly longer Ga−N bonds of 197.5 (N2) and 196.9 (N3) pm reflect the decrease in the covalent contribution to the metal−nitrogen bonds from aluminum to gallium, but are in good agreement with the literature values for gallium amides.[23] The Ga−C distances (Ga1−C11 194.2 and Ga1−C12 195.6 pm) are similar to the distances found for Me_3Ga in the gas phase.[26]

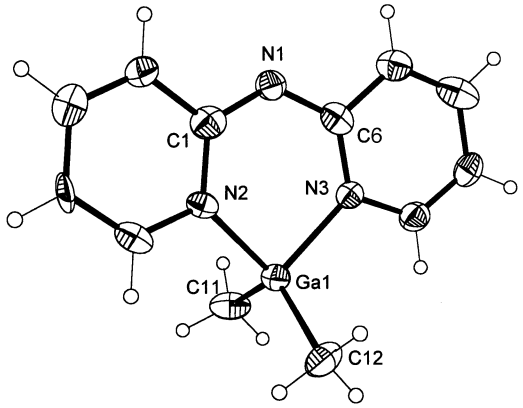
Crystal Structure of 3

To study the change in coordination behavior of the bis(2-pyridyl)amide anion to larger and softer cations, the bis(2-pyridyl)amine was treated with 1 equiv. of freshly prepared Me_3In.[27] The dimethylindium bis(2-pyridyl)amide (**3**) forms a dimeric structure in the solid state (Figure 2).

Figure 1. Solid-state structure of Me_2AlPy_2N (**1**) (a) and Me_2GaPy_2N (**2**) (b); anisotropic displacement parameters are depicted at a probability level of 50%

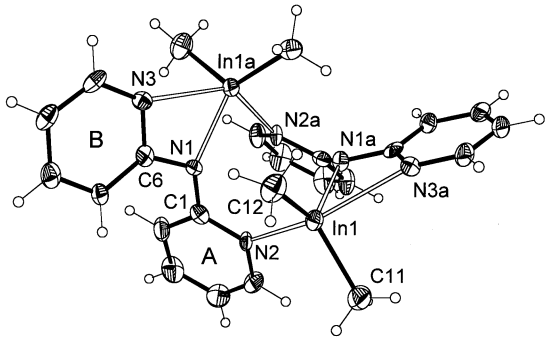


a



b

Figure 2. Solid-state structure of $[Me_2InNPy_2]_2$ (**3**); anisotropic displacement parameters are depicted at a probability level of 50%



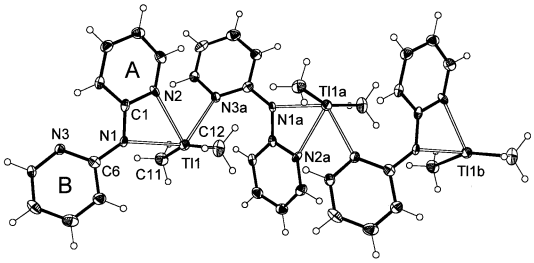
The dimer shows C_2 symmetry with the two-fold axis in the center of the molecule. The metal atom is coordinated by the pyridyl nitrogen atoms, but they are coordinated to different metal centers, providing the links in the dimer. Additionally each indium atom is coordinated by the depro-

tonated central nitrogen atom. All three nitrogen atoms of the ligand are pointing in the same direction, hence, the ligand coordinates in the *cis-cis* fashion (Scheme 4). The five atoms at each metal center form a distorted trigonal-bipyramidal coordination polyhedron. C11, C12, and N1A occupy the equatorial positions (sum of the angles 355.5°) while N2 and N3A reside in the axial positions (N2−In1−N3a 138.1°). The distance of the indium atom to the central nitrogen atom (220.4 pm) is considerably shorter than that to the ring nitrogen atoms (In1−N2 236.6 and In1−N3A 261.1 pm). These distances are found in $Me_3In \cdot$N-donorbase adducts like $Me_3In \cdot$tetramethylpiperidine (250.2 pm) and have to be regarded as dative bonds[28]. Only the In1−N1 distance is in good agreement with In−N bond lengths in indium amides (av. 223.3 pm in [Me_2InN-methylpiperazinyl]$_2$[29]). The indium−carbon distances (213.3 and 215.1 pm) are in good agreement with the literature values of trimethylindium adducts[28] and of dimethylindium complexes[29]. In **3** the distribution of the electron density must be notably different to that in the molecules of **1** and **2**. The anionic system is less planar than in **1** and **2**. The pyridyl rings are twisted by 58.3° with respect to each other to prevent full conjugation. The bond lengths of the central nitrogen atom differ (N1−C1 138.5 and N1−C6 135.9 pm) and are longer than in **1** and **2**.

Crystal Structure of 4

In the solid-state structures of **1**−**3** the tendency to greater isolation of the dimethylmetal cation moieties Me_2M^+, (M=Al, Ga, In) in the complexes can be ascertained. These phenomena should be even more pronounced in the dimethylthallium bis(2-pyridyl)amide complex. The dimethylthallium cation is known to be a very stable fragment that often forms separated linear cations.[21] To see whether this is valid with the dipyridyl amide ligand as well, we synthesized the thallium derivative **4** from freshly synthesized trimethylthallium[19] and bis(2-pyridyl)amine. **4** crystallizes as a polymer (Figure 3).

Figure 3. Solid-state structure of [Me_2TlNPy_2]$_\infty$ (**4**); anisotropic displacement parameters are depicted at a probability level of 50%

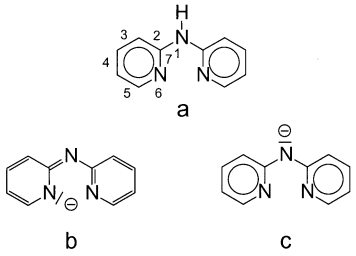


The helical polymer is made up by a crystallographic 2_1-screw axis. The thallium atoms are coordinated by the two methyl carbon atoms and three nitrogen atoms of the anionic ligand, but it seems arbitrary to assign any coordination polyhedron to the metal atom. It seems worth noting that in **4** the *cis-trans* arrangement (Scheme 4) of the bis(2-pyridyl)amide ligand is observed for the first time. The central, as well as one ring nitrogen atom (N1 and N2 in Figure 3), coordinate to the same metal center (Tl1), while the second ring (B in Figure 3) turns about the central N−C bond and coordinates to a second metal center (Tl1a) providing the polymeric link. The pyridyl rings are twisted by 38.2° with respect to each other to prevent full conjugation of the Py_2N^- anion. In contrast to **3** the shortest M−N distance is not found to be to the central nitrogen but to one ring nitrogen atom (Tl1−N2 248.1 pm). The other two are considerably longer (Tl1−N1 259.2; Tl2−N3a 268.9 pm). However, all three Tl−N contacts have to be regarded as weak donor bonds, since Tl−N bonds in thallium amides are normally shorter.[30] The Tl−C bonds are similar in length to those determined for the Me_2M^+ cations[21], but about 8 pm shorter than the shortest Tl−C contact in Me_3Tl.[31] The Me_2M^+ cation is almost linear (C11−Tl1−C12 158.3°), only bent slightly by the additional weak coordination of the three nitrogen atoms to the open side.

Structural Comparison

As mentioned above, the MMe_2 fragment in the complexes approaches linearity as the Group-13 metal gets heavier. The C−M−C angle widens from 116.9 (M = Al) to 120.8 (M = Ga), 126.1 (M = In) and finally to 158.3° (M = Tl). Hence the Me_2M^+ cationic character is most pronounced in the In and Tl complexes. The contacts to the Py_2N^- anion in the aggregates of **3** and **4** are only weak, while the hard metals, aluminum in **1** and gallium in **2**, induce metal amide bond lengths on the molecular level.

Table 2. Bond lengths [pm] of the Py_2N^- anion in **1**−**4** compared to the starting material



Compound	1	2	3	4	5	6	7

3 A[a]	138.5	140.6	137.3	137.5	135.8	135.9	134.0
3 B[a]	135.9	140.4	137.2	137.9	136.9	134.1	136.1
4 A[a]	136.2	143.0	137.5	139.2	137.1	132.3	135.1
4 B[a]	134.8	140.6	133.7	140.3	135.8	134.5	137.1

[a] A and B refer to the ring labeling in Figures 2 and 3.

The bis(2-pyridyl)amide ligand itself reveals different coordination behavior toward small hard and large soft cations in solution and in the solid state. In the compounds with the hard aluminum and gallium cations the anion exclusively coordinates the metal centers through the two ring nitrogen atoms. This coordination mode has previously

been observed in aluminum and gallium complexes of the bis(2-pyridyl)methyl anion.[8] Coordination of the ring nitrogen atoms and the ^{15}N-NMR-specroscopic shift lead the negative charge in **1** and **2** to be accumulated at the ring hetero atoms. In **3** and **4** the NMR experiments in solution, and the coordination through the central nitrogen atom in the solid state, indicate an accumulation of negative charge at this position. This different electronic situation has to induce structural differences in the Py_2N^- anion. Close inspection of the solid-state structures should be decisive in determining whether the resonance form **b**, with the charge at the ring nitrogen atom and localized double bonds in the rings, or the mesomeric form **c**, with the charge at the central nitrogen atom and delocalized rings, contributes most to the description of the structures (Table 2).

All experiments prove that **b** is the form which contributes most for **1** and **2**. Unlike the neutral system[32] described in **a** the double bonds are localized in positions 1, 3, and 5. The bonds 6 and 7 of the pyridyl nitrogen atom are lengthened significantly, also indicating as well an accumulation of the negative charge on these nitrogen atoms. In **3** and **4** the bonding situation is more complex. The pyridyl rings are not coplanar and both are involved in a different coordination. The notation A and B refers to the two different rings in Figures 2 and 3, respectively. Ring A in **3** is similar to the delocalized rings of bis(2-pyridyl)amide. Ring B, however, exhibits significant deviations from the neutral molecule. The bond in position 1 is shortened by 2.1 pm, and that in position 7 is lengthened by 2.6 pm, relative to the amine. Coupling of the central nitrogen atom to ring B and the marginal shift of electron density from the original place of deprotonation to the pyridyl ring B are established in this structure. Both nitrogen atoms are members of the azaallyl system coordinated to the same indium atom to give an InN_2C four-membered ring. In **4** significant shift of electron density to ring B can be detected. The bond in position 1 is shortened by 3.2 pm and there is partial localization of double bonds in the positions 3 and 5. As a consequence the $Tl-N_{ring}$ bond is more than 11 pm shorter than the $Tl-N_{central}$ bond. The nitrogen atom of the delocalized ring A provides the longest metal donor bond (about 21 pm longer).

Conclusion

The bis(2-pyridyl)methyl and the bis(2-pyridyl)phosphide anions coordinate metal atoms exclusively through the nitrogen atoms within the pyridyl rings. Due to the electropositive bridgehead atoms these ligands behave like amides with the electron density accumulated at the ring nitrogen atoms. The bis(2-pyridyl)amides discussed here show a higher coordination flexibility towards metals. The electronic equivalence of the central and the ring nitrogen atoms leaves the energetic hyperface of the anion quite flat and the electron density is polarized according to the requirements of the metal. In the complexes with the hard metal aluminum (**1**) and gallium (**2**) the coordination is the same as that observed in the bis(2-pyridyl)methyl and -phosphide ligands. With the soft metals indium and thallium the system changes its coordination behavior to suit the larger, and easier to polarize, cations. In these complexes the deprotonated nitrogen atom participates in the coordination and the ligand forms a bridging group. In the indium complex **3** the *cis-cis* orientation gives rise to a dimeric structure, while the unprecedented *cis-trans* arrangement in the thallium compound **4** leads to a polymeric structure in the solid state. In the aluminum and the gallium complexes **1** and **2** the metal−nitrogen bond lengths are in good agreement with literature values for metal amides. In the indium and thallium complexes most metal−nitrogen distances are too long for metal amides, partly due to their higher aggregation. They approach separated Me_2M^+ and Py_2N^- residues, even in the solid state. In solution the Al and Ga complexes are close contact ion pairs while the In and Tl complexes dissolve as solvent-separated ion pairs. Hence, not only the steric requirements of N-heteroaromatic ligands have to be considered in molecular self-assembling processes, but also the inductive effect of different metal fragments (like in any complexation).

Experimental Section

All manipulations were performed under dry nitrogen with Schlenk techniques or in an argon drybox. Solvents were dried over Na/K alloy and distilled prior to use. NMR spectra were obtained with a Bruker MSL 400 or AM 250 instrument. All NMR spectra were recorded in C_6D_6 or [D_8]THF with $SiMe_4$ (^{1}H, ^{13}C), CH_3NO_2 (^{15}N) and $AlCl_3$ (^{27}Al) as external standards. EI mass spectra were measured with Finnigan MAT 8230 or Varian MAT CH 5 instruments.

1: 1.00 g (5.8 mmol) of $HN(2\text{-}NC_5H_4)_2$ in 25 ml of Et_2O was treated with an equimolar amount of Me_3Al (2.90 ml of a 2.0 M solution) at −10°C. Stirring for 12 h at room temp. gave a yellow solution with a little of a yellow precipitate. Addition of 5 ml of THF gave a clear solution. Crystallization from this solution at −35°C yielded crystals suitable for X-ray diffraction. Yield 0.78 g (80%), m.p. 146°C. − ^{1}H NMR ([D_8]THF, room temp.): δ = −0.66 (s, CH_3), 6.68 (ddd, $^3J_{5,4}$ 6.8 Hz, $^3J_{5,6}$ = 6.1 Hz, $^4J_{5,3}$ = 1.2 Hz, 5-H), 6.93 (ddd, $^3J_{3,4}$ = 8.8 Hz, $^4J_{3,5}$ = 1.2 Hz, $^5J_{3,6}$ = 0.9 Hz, 3-H), 7.54 (ddd, $^3J_{4,3}$ = 8.8 Hz, $^3J_{4,5}$ = 6.8 Hz, $^4J_{4,6}$ = 1.9 Hz, 4-H), 7.74 (ddd, $^3J_{6,5}$ = 6.1 Hz, $^4J_{6,4}$ = 1.9 Hz, $^5J_{6,3}$ = 0.9 Hz, 6-H). − ^{13}C NMR (THF/C_6D_6, room temp.): δ = −10.5 (s, CH_3), 112.9 (s, C-5), 124.8 (s, C-3), 139.2 (s, C-4), 140.5 (s, C-6), 158.6 (s, C-2). − ^{15}N NMR (THF/C_6D_6, room temp.): δ = −181.1 (s, NC_5H_4), −184.5 (s, N_{center}). − ^{27}Al NMR (THF/C_6D_6, room temp.): δ = 150. − MS (70 eV); *m/z* (%): 227 (14) [$Me_2Al(NC_5H_4)_2N$], 212 (100) [$MeAl(NC_5H_4)_2N$], 197 (10) [$Al(NC_5H_4)_2N$], 120 (10) [$Al(NC_5H_4)N$], 106 (14) [$Al(NC_5H_4)$].

2: 4.00 g (34.8 mmol) of Me_3Ga in 50 ml toluene was treated with 5.96 g (34.8 mmol) of $HN(2\text{-}NC_5H_4)_2$, dissolved in 20 ml of toluene, at −78°C. Stirring for 12 h at room temp. gave a yellow solution. Crystallization from this solution at −35°C for 3 d yielded crystals in the form of pale yellow needles suitable for X-ray diffraction. Yield 7.48 g (80%), m.p. 134°C. − ^{1}H NMR ([D_8]THF, room temp.): δ = −0.10 (s, CH_3), 5.97 (ddd, $^3J_{4,5}$ = 6.8 Hz, $^3J_{4,3}$ = 6.0 Hz, $^4J_{4,6}$ = 1.3 Hz, 4-H), 6.83 (ddd, $^3J_{5,6}$ = 8.8 Hz,

$^3J_{5,4}$ = 6.8 Hz, $^4J_{5,3}$ = 2.0 Hz, 5-H), 7.05 (ddd, $^3J_{3,4}$ = 6.0 Hz, $^4J_{3,5}$ = 2.0 Hz, $^5J_{3,6}$ = 0.8 Hz, 3-H), 7.09 (ddd, $^3J_{6,5}$ = 8.8 Hz, $^4J_{6,4}$ = 1.3 Hz, $^5J_{6,3}$ = 0.8 Hz, 6-H). – ^{13}C NMR (THF/C_6D_6, room temp.): δ = −7.5 (s, CH_3), 112.4 (s, C-5), 124.7 (s, C-3), 138.2 (s, C-4), 141.1 (s, C-6), 158.6 (s, C-2). – ^{15}N NMR (THF/C_6D_6, room temp.): δ = −181.5 (s, *N*C_5H_4), −189.8 (s, N_{center}). – MS (70 eV); *m/z* (%): 269 (14) [$Me_2Ga(NC_5H_4)_2N$], 254 (100) [$MeGa(NC_5H_4)_2N$], 238 (24) [$Ga(NC_5H_4)_2N$].

3: 1.80 g (11.3 mmol) of Me_3In in 10 ml of toluene was treated with 1.93 g (11.3 mmol) of HN(2-$NC_5H_4)_2$, dissolved in 10 ml of toluene at room temp. Stirring for 24 h at room temp. gave a colorless precipitate. Heating under reflux for 1 h gave a clear solution. Colorless needles crystallized upon cooling the solution slowly to room temp. These crystals were suitable for X-ray diffraction. Yield 3.10 g (89%), m.p. 208°C. – ^{1}H NMR (C_6D_6, room temp.): δ = 0.24 (s, CH_3), 6.11 (dd, $^3J_{5,4}$ = 7.2 Hz, $^3J_{5,6}$ = 5.0 Hz, 5-H), 6.68 (d, $^3J_{3,4}$ = 8.2 Hz, 3-H), 6.92 (dd, $^3J_{4,3}$ = 8.2 Hz, $^3J_{4,5}$ = 7.2 Hz, 4-H), 7.77 (d, $^3J_{6,5}$ = 5.0 Hz, 6-H). – ^{13}C NMR (C_6D_6, room temp.): δ = −5.3 (s, CH_3), 113.5 (s, C-5), 114.0 (s, C-3), 138.7 (s, C-4), 147.1 (s, C-6), 163.2 (s, C-2). – ^{15}N NMR (THF/C_6D_6, room temp.): δ = −120.7 (s, *N*C_5H_4), −230.2 (s, N_{center}). – MS (70 eV); *m/z* (%): 315 (20) [$Me_2InN(NC_5H_4)_2$], 300 (100) [$MeInN(NC_5H_4)_2$], 285 (68) [$InN(NC_5H_4)_2$], 170 (78) [$N(NC_5H_4)_2$], 145 (24) [Me_2In].

4: 2.00 g (5.5 mmol) of Me_2TlI in 30 ml of *n*-hexane was treated with 3.44 ml (5.5 mmol) of a 1.6 M solution of MeLi in Et_2O at room temp. After stirring for 2 h, a solution of 0.95 g (5.5 mmol) of HN(2-$NC_5H_4)_2$ in 20 ml of Et_2O was added. This reaction mixture was stirred for 24 h at room temp. The solvent was removed under vacuum and the precipitate was suspended in toluene and the LiI was removed by filtration. Colorless needles crystallized from the clear solution at room temp. These crystals were suitable for X-ray diffraction. Yield 1.12 g (50%), m.p. 179°C. – ^{1}H NMR (C_6D_6, room temp.): δ = 0.82 (d, $^2J_{Me-Tl}$ = 396.7 Hz, CH_3), 6.35 (ddd, $^3J_{5,4}$ = 7.0 Hz, $^3J_{5,6}$ = 5.1 Hz, $^4J_{5,3}$ = 1.0 Hz, 5-H), 7.10 (ddd, $^3J_{3,4}$ = 8.5 Hz, $^4J_{3,5}$ = 1.1 Hz, $^5J_{3,6}$ = 0.9 Hz, 3-H), 7.22 (ddd, $^3J_{4,3}$ = 8.5 Hz, $^3J_{4,5}$ = 7.0 Hz, $^4J_{4,6}$ = 2.0 Hz, 4-H), 8.06 (ddd, $^3J_{6,5}$ = 5.1 Hz, $^4J_{6,4}$ = 2.0 Hz, $^5J_{6,3}$ = 0.9 Hz, 6-H). – ^{13}C NMR (THF/C_6D_6, room temp.): δ = 8.7 (d, $^1J_{Me-Tl}$ = 2574.7 Hz, CH_3), 112.1 (s, C-5), 112.9 (s, C-3), 137.4 (s, C-4), 147.3 (s, C-6), 161.1 (s, C-2). – ^{15}N NMR (THF/C_6D_6, room temp.): δ = −117.3 (s, *N*C_5H_4), −215.8 (s, N_{center}). – MS (70 eV); *m/z* (%): 405 (26) [$Me_2TlN(NC_5H_4)_2$], 390 (36) [$MeTlN(NC_5H_4)_2$], 375 (90) [$TlN(NC_5H_4)_2$], 235 (18) [Me_2Tl], 205 (100) [Tl], 170 (20) [$N(NC_5H_4)_2$].

X-ray Measurements of **1**–**4**: All data were collected at low temperatures using an oil-coated shock-cooled crystal[33] on a Stoe-

[a] $R1 = \Sigma\|F_o| - |F_c\|/\Sigma|F_o|$. – [b] $wR2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$. – [c] $w = 1/[\sigma^2(F_o^2) + (g1 \cdot P)^2 + g2 \cdot P]$; $P = (F_o^2 + 2F_c^2)/3$.

Siemens AED diffractometer with Mo-K_α (λ = 71.073 pm) radiation. A semiempirical absorption correction[34] was employed for structures **2**−**4**. The structures were solved by direct methods using SHELXS-90[35] and refined with all data on F^2 with a weighting scheme using SHELXL-93.[36] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the molecules were geometrically idealized and refined using a riding model. Refinement of an inversion twin parameter[37] [x = −0.008(61) (**3**), 0.003(22) (**4**) where x = 0 for the correct absolute structure and +1 for the inverted structure] confirmed the absolute structures of **3** and **4**. Selected bond lengths and angles of **1**−**4** can be found in Table 3, relevant crystallographic data for **1**−**4** are presented in Table 4. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100792. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) + 44(1223)336-033; e-mail: deposit@ccdc.cam.ac.uk].

Keywords: Palladium / Platinum / Bidentate nitrogen ligands / *p*-Quinone / Alkenes

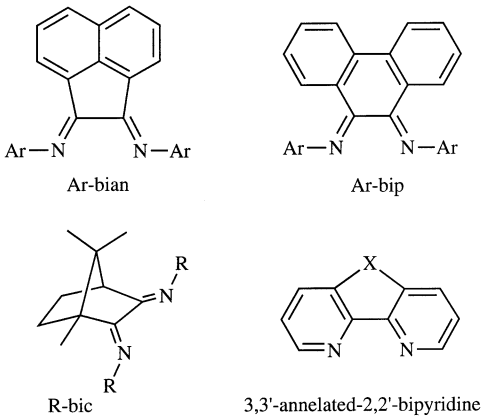
Compounds of the type M(N∩N-κ*N*)(nq)$_2$ and M$_2$(μ^2-N∩N)-(μ^2-pbq)$_2$, in which nq = 1,4-naphthoquinone, pbq = 1,4-benzoquinone, and N∩N is a monodentate or bridging ligand of the α-diimine type, were obtained from reactions of Pd(dba)$_2$ in toluene with the 3,3′-annelated-2,2′-bipyridines: 4,5-diazafluoren-9-one (dafo) and 4,5-diazafluorene (dafe) in the presence of the appropriate *p*-quinone. In the corresponding reactions with 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen), 2,2′-bipyrimidine (bpym), *N*,*N*′-dicyclohexyl-1,4-diaza-1,3-butadiene (chex-dab), bis[*N*-(*o*,*o*′-diisopropyl)phenylimino]acenaphthene (*o*,*o*′-*i*Pr$_2$-bian) and 5,6-dihydro-1,10-phenanthroline (dh-phen) only complexes of the type M(N∩N-κ^2*N*)(Q) were formed (Q = nq, pbq). The structures of the complexes have been established by NMR in solution and by X-ray diffraction in the solid state; crystal structures of Pd(bpy-κ^2*N*)(η^2-pbq) (**1**) Pd(dafo-κ*N*)(η^2-nq)$_2$ (**14**) and Pd$_2$(μ^2-dafo)(μ^2,η^2:η^2-pbq)$_2$ (**16**) have been determined. Of the ligands, dafo and dafe are the only ones apt to form complexes containing a monodentate or bridging N∩N ligand. This behaviour is ascribed to the geometrical constraints of dafo and dafe; the annelation by one carbon atom at the 3,3′-positions in these ligands causes an increase in bite angle from approximately 77° to 82°.

Introduction

The chemistry of complexes containing an alkene coordinated to a low-valent metal from the platinum group has received considerable attention and studies have been particularly aimed at trigonal planar zerovalent platinum and nickel complexes of general formula ML$_2$(alkene) where L is a phosphane[1][2][3]. Zerovalent palladium complexes containing nitrogen ligands have received relatively little attention.[4][5][6] We have previously reported about compounds consisting of organopalladium or -platinum fragments (where the metal has the formal oxidation state II or IV) and a rigid bidentate nitrogen ligand (RBN), such as bis(*N*-arylimino)acenaphthene (Ar-bian)[7], bis(*N*-phenylimino)camphane (Ar-bic), bis(*N*-arylimino)phenanthrene (Ar-bip)[8], see Figure 1, as well as those containing zerovalent palladium and an electron-deficient alkene[6].

These and similar compounds are versatile catalysts in e.g., catalytic (multicomponent) C-C coupling reactions[9][10][11], in homogeneous catalyzed hydrogenation of alkenes[12] and as models for copolymerization and as active catalysts in polymerizations of alkenes[13][14]. The rigid bidentate ligands employed sofar by us have bite-angles of about 77°.

Figure 1. Rigid bidentate nitrogen ligands



In many cases, bidentate ligands may dissociate one ligating atom (if only temporarily) during a reaction sequence, or undergo elongation of one of the metal-to-ligand bonds, as has been shown for an increasing number of cases, not only those involving hemi-labile ligands[15]. Monodentate coordination has e.g. been observed for phenanthrolines[16]

and for an Ar-bian ligand in the case of an(η^3-allyl)Pd^{II} compound[17], but not for complexes of Pd^0. Despite these observations, there is a clear tendency of the Ar-bian and similar rigid ligands to remain bidentate coordinated to the metal centre, which is partly caused by the favourable bite-angle of about 77°.

It was anticipated that a slight increase of the bite-angle, while maintaining rigidity, would lead to reduced overlap between relevant metal and ligand orbitals and hence to an enhanced aptitude for dissociation of one of the donor atoms. To this end we have turned to members of the series of 3,3′-annelated-2,2′-bipyridines, for which the bite angle as well as the planarity of the ligand system varies with the number of methylene groups in the bridge[18] especially 4,5-diazafluoren-9-one (dafo)[19] and 4,5-diazafluorene (dafe)[20], see Figures 2 and 3.

Figure 2. Ligands and abbreviations

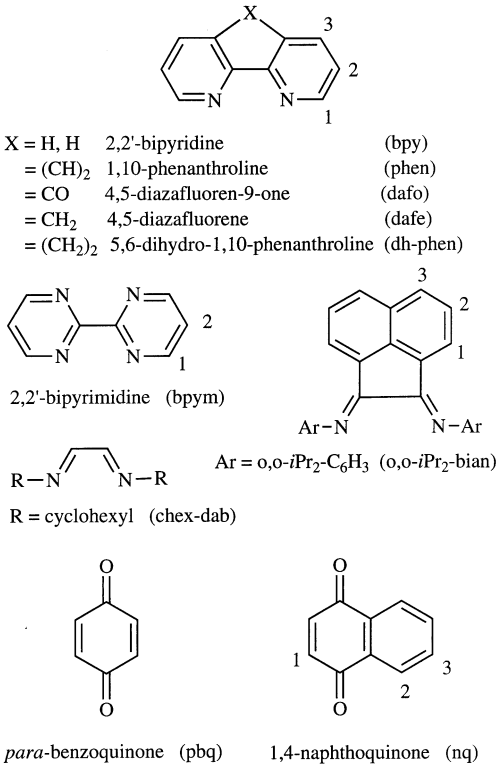

Figure 3. Decreasing orbital overlap between the metal atom (M = Pd, Pt) and a bidentate coordinating α-diimine ligand going from bipyridine (α = 77°) to dafo (X = CO) and dafe (X = CH2; β = 82°)

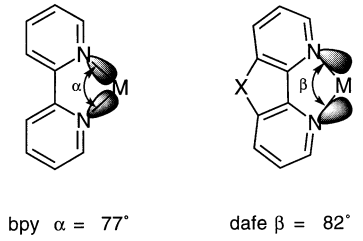


For dafo and dafe the bite-angle is 82°[18]. Consequently, one may expect that the altered lone-pair orientation on the nitrogen donor atoms of dafo and dafe, as illustrated in Figure 3, would facilitate the monodentate or bridging coordination mode for these ligands. In order to substantiate our expectations, we have decided to undertake a study of coordination compounds of zero-valent Pd and Pt containing the bidentate nitrogen ligands mentioned and suitable alkenes. For comparison, we employed a series of other rigid and flexible α-diimine ligands, such as 2,2′-bipyridine, 1,10-phenanthroline, 2,2′-bipyrimidine, 1,4-diaza-1,3-butadiene, and Ar-bian (Figure 2). In keeping with previous studies[21][22][23][24][25][26][27][28][29][30][31][32][33][34][35][36][37], stabilization of the zerovalent metal center by employing the strong π-acceptor *p*-quinone (Q) ligands *para*-benzoquinone (pbq) and 1,4-naphthoquinone (nq) was anticipated. Since *p*-quinones are potentially bidentate ligands, the ML_2Q complexes could be tetrahedral although it is well known that Pd^0 shows a tendency to be trigonal planar[38]. Furthermore because of the bisalkenic function of the *p*-quinones, it was foreseen that these might also support the formation of dinuclear complexes with bridging ligands[25][31][32][34].

In this paper the propensity of the 3,3′-annelated-2,2′-bipyridine ligands to stabilize compounds in which the bisnitrogen ligand coordinates in a monodentate way, i.e., $M(N\cap N\text{-}\kappa N)(\eta^2\text{-nq})_2$, or in which both the bisnitrogen ligand as well as *p*-benzoquinone are bridging between two metal centers, i.e., $M_2(\mu^2\text{-}N\cap N)(\mu^2,\eta^2\text{:}\eta^2\text{-pbq})_2$, is demonstrated. The structural and bonding features of these unique complexes have been elucidated, both in the solid state and in solution.

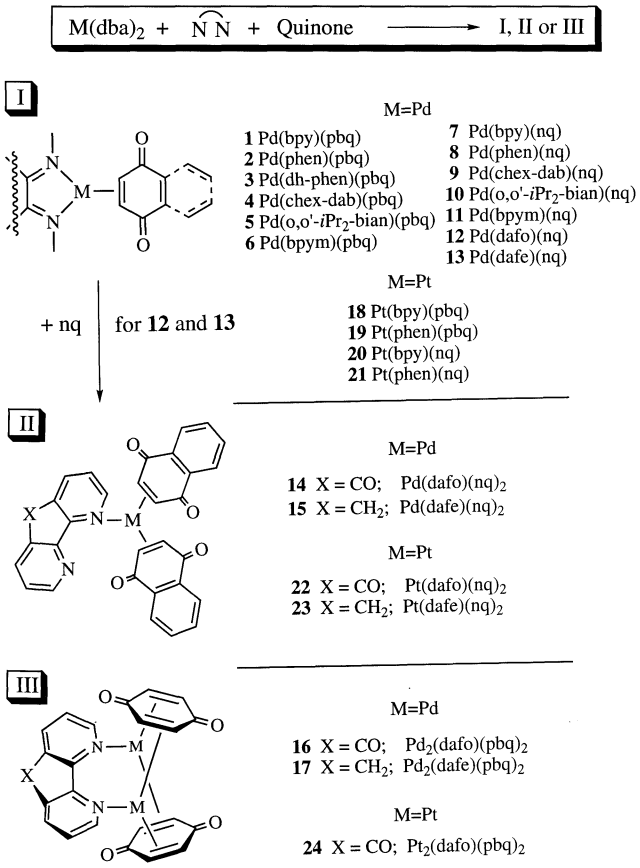
Results and Discussion

Synthesis of Zerovalent Palladium and Platinum Complexes (1−24)

At first, attempts were made to synthesize zerovalent Pd(N∩N)(alkene) complexes with electron poor alkenes such as dimethylfumarate, fumaronitrile or maleic anhydride. Unfortunately, for the bisnitrogen ligands, dafo, dafe or dh-phen (Figure 2), no isolable zerovalent palladium complexes could be obtained with any of these alkenes. However, employing the more electron-accepting *p*-quinones, relatively stable zerovalent palladium and platinum complexes have been obtained (Scheme 1).

Independent of the relative amount of starting materials, i.e. $Pd(dba)_2$, alkene and bidentate nitrogen ligand (Figure 2), zerovalent palladium complexes **1**−**11** with the general formula Pd(N∩N)(alkene) were formed [Scheme 1, type I; N∩N= bpy, phen, dh-phen, chex-DAB, *o,o′*-iPr_2-bian or bpym, and alkene = 1,4-benzoquinone (pbq) or 1,4-naphthoquinone (nq)]. Compounds **1**, **2**, **7**, and **8** have been reported previously[27]. The analytical data together with the crystal structure of Pd(bpy)(η^2-pbq) (**1**)[39] confirmed the 1:1:1 ratio of the metal, bisnitrogen ligand and *p*-quinone. These complexes are well soluble and stable in polar solvents such as chloroform, dichloromethane and tetrahydrofuran. Complexes containing bpym, *o,o′*-iPr_2-bian, cyclohexyl-DAB are even slightly soluble in ether and therefore they had to be synthesized in a slightly different way.

Scheme 1. Synthesis of zerovalent palladium and platinum complexes. bpy = 2,2′-bipyridine, phen = 1,10-phenanthroline, chex-dab = N,N′-dicyclohexyl-1,4-diaza- 1,3-butadiene, *o,o′*-*i*Pr2-bian = bis{*N*-(*o,o′*-diisopropyl)-phenylimino}acenaphthene, bpym = 2,2′-bipyrimidine, dafo = 4,5-diazafluoren-9-one), dafe = 4,5-diazafluorene, dh-phen = 5,6-dihydro-1,10-phenanthroline; pbq = 1,4-benzoquinone, nq = 1,4-naphthoquinone.



The Pd(N∩N-κ^2*N*)(*p*-quinone) complexes (**12**, **13**) were obtained using dafe or dafo and nq in a ratio 1:1:1 with respect to the starting material Pd(dba)$_2$. When using two equivalents of nq with respect to the starting material Pd(dba)$_2$ in the presence of dafo or dafe, the reaction resulted in complexes with the formula Pd(N∩N-κ*N*)(η^2-nq)$_2$ (**14**, **15**), as appeared from the ^{1}H NMR, analytical data, and an X-ray crystal structure for **14** (Scheme 1, type II). In these complexes a feature *uniquely* observed for these ligands occurs: dafo and dafe coordinate in a *monodentate* fashion and both nq ligands are η^2-coordinated. These complexes could also be prepared by adding one equivalent of nq to the complexes Pd(N∩N-κ^2*N*)(η^2-nq) (**12**, **13**) by substitution of one nitrogen atom. The compounds are soluble in polar solvents, but not very stable, decomposition takes place even at low temperatures.

When dafo or dafe was employed in combination with pbq, instead of nq, in attempts to synthesize zerovalent palladium complexes of the types mentioned above, yet another type of complex was obtained. Analytical and ^{1}H-NMR data revealed that, independent of the applied stoichiometry, always a complex of type Pd$_2$(μ^2-N∩N)(μ^2,η^2:η^2-pbq)$_2$ (**16**, **17**) was formed (Scheme 1, type III). Their molecular structure was confirmed by a single-crystal X-ray structure determination for **16** (vide infra). When using substoichiometric amounts of dafo or dafe and pbq with respect to the palladium metal, again complexes **16** and **17** were formed and part of the Pd(dba)$_2$ was recovered. The structure of a related dinuclear zerovalent palladium compound containing a bridging DAB moiety, [Pd(dmfu)$_2$]$_2$-μ-DAB, (DAB = *t*BuN=CH−CH=N*t*Bu), has been postulated but not isolated[40]. The complexes **16** and **17** are poorly soluble in polar solvents, in which slow decomposition takes place.

Several platinum analogues (**18**−**24**) could be synthesized in a similar way starting from Pt(dba)$_2$ (Scheme 1), albeit that, due to the slower substitution at platinum compared to palladium, distinctly longer reaction times were required.

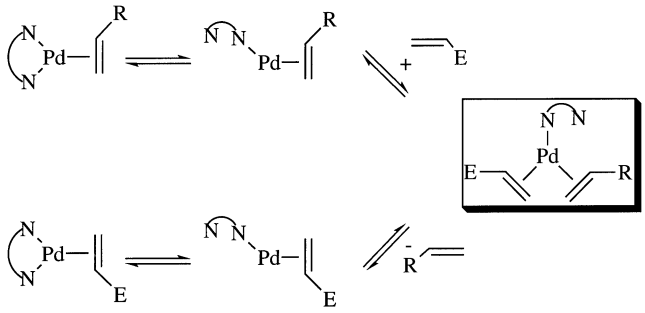
p-Quinone Substitution Reactions

In order to determine (i) the relative thermodynamic stability of the various complexes and (ii) the coordination behaviour of the respective N∩N-ligands in these cases, several *p*-quinone exchange reactions were carried out. The 1,4-naphthoquinone (nq) in the complex of type Pd(N∩N-κ^{2}N)(nq) (**7**−**11**) can be readily substituted for *p*-benzoquinone (pbq), adding one equivalent of the latter to these complexes yielded the Pd(N∩N−κ^2*N*)(pbq) analogues (**1**, **2**, **4**−**6**). Interestingly, when adding one equivalent of pbq to Pd(N∩N-κ^2*N*)(η^2-nq) (**12**, **13**), the novel bridged compounds Pd$_2$(μ^2-N∩N)(μ^2,η^2:η^2-pbq)$_2$ (**16**, **17**) were formed with the concomitant release of one molecule of bidentate nitrogen ligand and nq, instead of Pd(N∩N-κ*N*)(η^2-nq)(η^2-pbq). Adding an excess of nq to the Pd(N∩N-κ^2*N*)(η^2-nq) complexes (**7**−**11**) did not result in substitution of a nitrogen donor in these complexes, which would have resulted in the formation of complexes similar to Pd(N∩N−κ*N*)(η^2-nq)$_2$ (**14**, **15**). The formation of the latter type of complex is thus an exclusive property of the dafo and dafe within this series of bidentate nitrogen ligands. Adding one equivalent of pbq to the complex Pd(N∩N-κN)(η^2-nq)$_2$ (**14**, **15**) did not yield the mixed *p*-quinone complexes either; complete conversion to Pd$_2$(μ^2-N∩N)(μ^2,η^2:η^2-pbq)$_2$ (**16**, **17**) took place. Adding substoichiometric quantities of pbq to Pd(N∩N−κN)(η^2-nq)$_2$ (**14**, **15**) yielded only a mixture of Pd$_2$(μ^2-N∩N)(μ^2-pbq)$_2$ (**16**, **17**) and Pd(N∩N-κN)(η^2-nq)$_2$ (**14**, **15**), no mixed *p*-quinone complexes were observed. Adding nq to any of the complexes containing pbq did not result in substitution, the starting compounds were recovered. Hence, the complexes containing pbq are thermodynamically more stable than the complexes containing nq, which order is consistent with the relative electron-accepting properties of the *p*-quinones[35][35][37].

Alkene Substitution Reaction

The mechanism of alkene substitution in zerovalent palladium and platinum complexes has been described either by dissociative [via 14e Pd(N∩N-κ^2*N*)] or associative [via Pd(N∩N-κ^2*N*)(alkene)$_2$] pathways[6][41][42][43][44]. Clearly,

Scheme 2. Possible mechanism of alkene substitution in which the complexes **14**, **15**, **22**, and **23** are representative for the Pd(N∩N-κ*N*)(alkene)$_2$ intermediate



one of the donor atoms of the N∩N-ligand dafo or dafe can be non-coordinating, as has been unequivocally demonstrated by the isolation of the complexes **14**, **15**, **22**, and **23** and the X-ray crystal structure of **14**. These are 16-electron, Pd(N∩N-κ*N*)(η^2-alkene)$_2$ species. Hence, in addition to the mechanisms for alkene exchange mentioned above, the pathway as outlined in Scheme 2, in which dissociation of one of the N donor atoms of plays a key role, should be taken into account[45].

X-ray Crystal Structures of 1, 14, and 16

The molecular structures of **1, 14**, and **16** and the adopted numbering schemes are given in Figures 4−6. Selected bond distances and angles have been compiled in Tables 1 and 2. In all three complexes the palladium atom adopts a trigonal coordination geometry (taking the mid-point of the η^2-bond of the quinone as the point of attachment). In complex **1**, the palladium atom is bonded to two nitrogen atoms of the bpy ligand and one alkenic moiety of the *p*-quinone molecule. In complexes **14** and **16**, palladium is bonded to one nitrogen atom and to two alkenic moieties. In the latter complex, dafo bridges between two Pd^0 centers. In complexes **1** and **14** the *p*-quinone acts as a mono-, and in complex **16** as a bis-alkenic ligand.

The average Pd−N distances in **14** and **16** are comparable to those in several other Pd−α-diimine complexes, e.g. in PdCl(Me)(9,10-Me_2Phen)(ma)[46], PdCl(Me)(*o,o'*-*i*Pr_2-bian)[7], Pd(*o,o'*-*i*Pr_2-bian)(ma)[6] and in Pd(bpy)(dba)[47], but in **1** it is significantly shorter and similar to Pd(*p*-Tolbian)(ma)[48]. The average Pd−C distances are shorter than those in most other Pd(N∩N)(η^2-alkene) complexes, i.e. in PdCl(Me)(9,10-Me_2Phen)(ma)[46], Pd(bpy)(dba)[47], $Pd(dba)_3$[49], $Pd_2(dba)_3\cdot CH_2Cl_2$[50], $Pd_2(dba)_3\cdot CHCl_3$[27], and $Pd(Cy_2PCH_2CH_2PCy_2)(\eta^2\text{-}CH_2{=}CH{-}CH{=}CH_2)$[51]. Complexes **1** and **14** display a slight distortion from the trigonal planar situation, as reflected by the twist around the metal-alken bond of 9.49(0.46)° for complex **1** and 9.84(0.13) and 5.99(0.13)° for complex **14**. Such a "tetrahedral" distortion is a known phenomenon in d^{10} metal-alkene complexes[1c]. The plane of best fit through the *p*-quinone residues and the coordination plane intersect at 78.57(0.49)° for **1** and at 94.29(0.23) and 99.91(0.21)° for **14**, indicating that the metal-alkene bond is approximately perpendicular to the plane of the *p*-quinone. The perpendicular coordination of the pbq moiety is depicted in Figure 4b by a side-on view of the coordination plane of **1**.

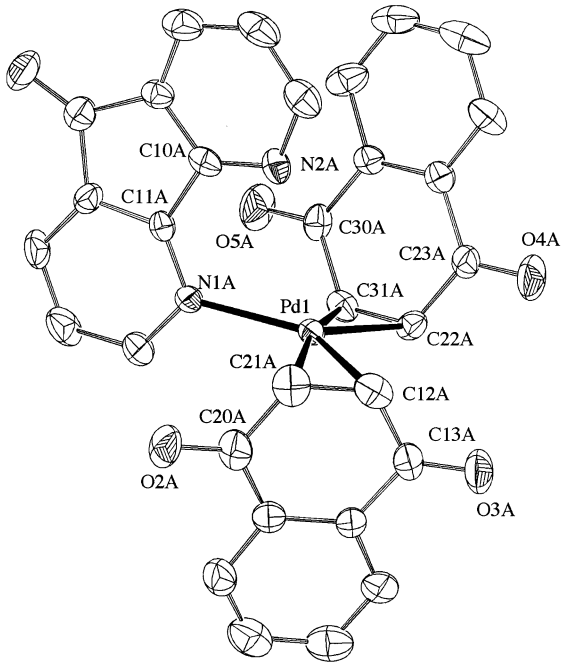
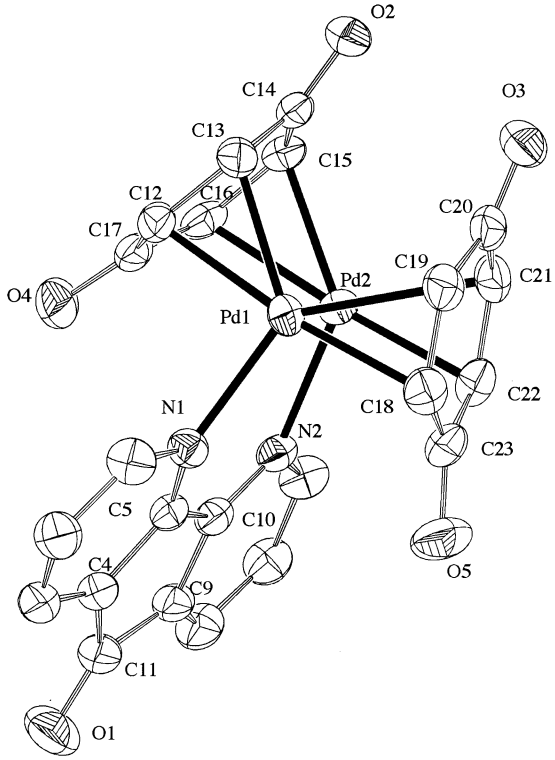
The alkenic and the carbonyl bonds in the *p*-quinone molecules in each of the three complexes are longer than in the free *p*-quinones[52], but the elongation of the coordinated C=C bond in **14** and **16** is less than in complex **1**, in which there are two nitrogen donor atoms instead of one. The carbonyl groups are bent away from the plane through the alkenic carbon atoms by 5.17(1.59) and 6.93(1.47)° for **1**, by 1.89(0.71), 0.43(0.42), 9.43(0.86), and 5.04 (0.83)° for **14**, and by 5.82(0.41), 0.74(0.41), 10.68(0.41), and 12.88(0.40)° for **16**.

Figure 5. Ortep drawing (30% probability level) of **14**



These angular distortions as well as elongations of the C=O double bonds in the *p*-quinone residue are comparable to those in $Pt(PPh_3)_2$(pbq)[30] and is also present in each of the previously reported structures with nickel−[53] and cobalt−*p*-quinone complexes[54]. In the case of **16**, the relatively large angular distortion of the carbonyl carbon atoms (vide supra) is mainly due to a steric interaction between the carbonyl groups of the two coordinated pbq moieties as is revealed by the view along the palladium palladium axis (Figure 6b). The distortion in the nitrogen ligands depends on the type of complex. Since dafo is monodentate coordinated in **14**, it shows no significant changes in bond angles and distances upon coordination compared with the free ligand[55]. However, in **16** the nitrogen ligand is distorted due to bridging coordination to two metal centers. The palladium atoms are not in the plane of the ligand; one palladium is positioned above and the other below the plane defined by N(1)C(5)C(10)N(2). The Pd(1)−Pd(2) vector intersects this plane by 7.72(0.35)°. This feature is nicely demonstrated in Figure 6c. The N(1)C(5)C(10) angle is 130.0° (free ligand 127.5°)[55] and the torsion angle N(1)C(5)C(10)N(2) is 11.3° (free ligand 0.0°). In complex **1**, due to the tetrahedral distortion, a torsion angle in the contiguous atoms N(1)C(5)C(10)N(2) of 7.43° is observed. The imine bonds in **1** and **16** are slightly elongated upon coordination in comparison with the free ligands.

Figure 6a. Ortep drawing (30% probability level) of **16**



The structure of the Pd(dafo)$(nq)_2$ complex (**14**) is unique, no similar complexes are known. An interesting feature of **14** is the non-bonding Pd(1A)−N(2A) distance of

Figure 6b. Plot of **16** viewed along the Pd(1)−Pd(2) axis

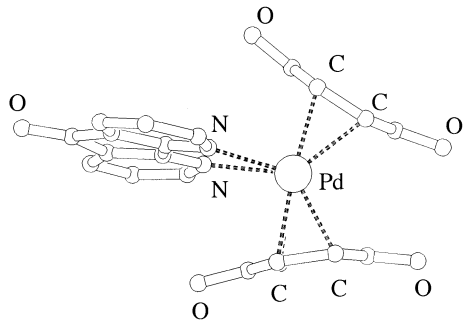


Figure 6c. Plot of **16** viewed through the Pd(1)−N(1)−N(2)−Pd(2) plane

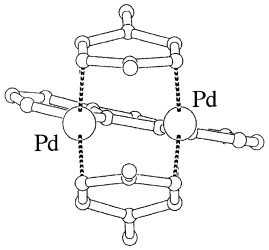


3.070(5) Å, which is too long for any significant bonding interaction between these two atoms. This non-bonding Pd−N distance is longer than the similar Pt−N distance in $PtCl_2(Me_2\text{-phen})(PPh_3)_2$ [2.673(6) Å][56]. The N(2A) atom is approaching an apical position at palladium and does not intermolecularly coordinate towards another palladium. There is no tendency for **14** to form a dimeric palladium complex such as **16**, which is probably due to the steric bulk of the *p*-naphthoquinone compared to *p*-benzoquinone.

The solid-state structure of complex **16** is unprecedented but resembles that of $Pd_2(dba)_3$[50], however, in the latter the two palladium centers are bridged by three dienes instead of two as in **16**. The Pd(1)−Pd(2) distance in complex **16** [2.7747(4) Å] is significantly shorter than in $Pd_2(dba)_3\cdot CHCl_3$ [3.245(2) Å][27] and $Pd_2(dba)_3\cdot CH_2Cl_2$ [3.237(5) Å][50]. The short Pd-Pd distance in **16** is due to the smaller span and conformational restriction of the dafo ligand as compared to dba and is close to a Pd^I-Pd^I bond, which usually range from 2.53 to 2.75 Å[57][58][59][60][61][62].

IR Spectroscopy

The infrared spectra of the complexes all show a bathochromic shift of the stretching frequency ν(C=O) of the *p*-quinones as compared to the free *p*-quinone[63], the magnitude of which depends on the type of complex. In the M(N∩N-κ*N*)(η^2-nq)$_2$ complexes, ν(C=O) is only slightly shifted ($\Delta\nu$ = 5 cm^{-1}), wheras in the type $M_2(\mu^2$-N∩N)(μ^2,η^2:η^2-pbq)$_2$ this shift is approximately 30 cm^{-1} and in the type M(N∩N-κ^2*N*)(η^2-Q) it amounts to $\Delta\nu$ = 60 cm^{-1}. The latter shift is larger than for comparable structures reported, $\Delta\nu$(CO) = 44, 25, and 18 cm^{-1} in $PdL_2(\eta^2$-pbq) for L = *n*Bu_3P, Ph_3P, and PhO_3P, respectively[24] and 43 and 47 cm^{-1} in Pd(COD)(η^2-Q) for Q = pbq and nq, respectively[30]. In structures of the type $Pt(PPh_3)_2(\eta^2$-Q) in which the *p*-quinone represents a series of substituted derivatives[30], this shift is usually 30−60 cm^{-1}. These low-frequency shifts underscore the importance of the back donation from palladium to the *p*-quinone and is an indicative tool to determine the type of complex obtained, as ν(C=O) decreases with an increasing number of nitrogen donor atoms coordinated to the palladium relative to thenumber of *p*-quinone double bonds. The relative small shifts reported for complexes **1**−**24** indicate only a relatively minor perturbation of the C=O stretching mode, hence coordination is apparently only through the double bonds of the *p*-quinone moiety, as has been confirmed by the X-ray crystal structures determined for **1**, **14**, and **16**. For compounds in which the C=O function participates in the bonding, ν(C=O) decreases much more (150−200 cm^{-1})[22].

NMR Spectroscopy

The ^{1}H- and ^{13}C-NMR data for the complexes **1**−**24** show the expected high-frequency shift for the protons of the nitrogen ligands upon coordination. Compared to the free *p*-quinones[64], the alkenic protons of the coordinated *p*-quinone show a shift of 0.96−1.75 ppm to lower frequency, which is comparable to the shift for complexes Pd(COD)(η^2-pbq) ($\Delta\delta$ = 1.03 ppm) and Pd(COD)(η^2-nq) ($\Delta\delta$ = 1.94 ppm)[30]. However, these shifts are considerably smaller than the shifts reported for the complexes of the type M(L)$_2$(η^2-alkene) (M = Pd, Pt, alkene = dmfu, ma, fn) where they amount to 3−3.5 ppm[6]. The alkenic carbon atoms show for the complexes of the type Pd(N∩N-κ^2*N*)(η^2-Q) a shift of ca. 30 ppm to lower frequency in their ^{13}C-NMR spectra, and of ca. 60 ppm for the complexes of the type M(N∩N-κ*N*)(η^2-nq)$_2$ and $Pd_2(\mu^2$-N∩N)(μ^2,η^2:η^2-pbq)$_2$, in keeping with the considerable amount of back-donation from palladium to the *p*-quinone caused by the combination of an electron rich d^{10} metal center with a σ-donating α-diimine ligand. The low frequency shifts of the alkenic protons in the analogous platinum complexes are more pronounced than in the palladium complexes, which is due to the higher Lewis basicity of platinum.

The ^{1}H-NMR spectra of the complexes Pt(N∩N-κ^2*N*)(η^2-pbq), **18** and **19** show fluxional behaviour; at ambient temperature and 300.13 MHz the protons assigned to the pbq appear as a slightly broadened singlet (the platinum satellites are not observed) which broadens upon lowering the temperature. At 213 K two broadened singlets belonging to the pbq ligand are present. We ascribe this feature to a degenerate rearrangement in which the Pt(N∩N-κ^2*N*) moiety is alternatingly η^2-bonded to either of the two equivalent alkenic sites of *p*-benzoquinone. The free energy of activation ($\Delta G^{\neq}$) for this process was calculated[65] to be 50.3±1.0 kJmol^{-1} (241 K) for **18** and 52.1±1.0 kJmol^{-1} (238 K) for **19**. The slow exchange regime could be reached, in contrast to the observation for Pt(COD)(η^2-pbq) in which it could not be reached even at 183 K[25]. For **1**−**6**, the palladium analogues of **18** and **19**, slow exchange could not be reached at 180 K (300.13 MHz), only a slight broad-

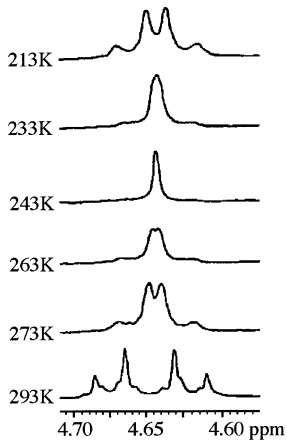
ening of the pbq-signal is observed. The ^{1}H-NMR data of the Pd(N∩N-κ^2*N*)(pbq) complexes (**1**−**6**) imply for the complexes in solution, either a rigid structure with the pbq η^4-bonded to the metal, or a low-energy degenerate rearrangement of a ground state η^2-bonded ligand. In view of the other results in solution and solid state, we prefer to assume the latter. For the platinum complexes it has been proven that in solution the latter assumption is true while clearly the rearrangement is in slow exchange at 213 K. Evidently, the rearrangement proceeds on the NMR time scale via an *intra*molecular process, since variation of the concentration had no effect on the free energy of activation of this rearrangement.

The complexes containing bpym, **6** and **11**, show dynamic behaviour resembling a previously described internal rotation of the two rings in bpym relative to each other in Pd(bpym)(η^3-allyl) compounds[66]. The exchange requires a cleavage of a Pd−N bond, i.e. a mechanism is involved in which two-coordinate intermediate complexes[67] exist in which the bidentate nitrogen ligand is coordinated in a monodentate way. The observed free energies of activation for this internal rotation are similar to those reported[66], $\Delta G^{\neq}$ = 53.7±1.0 kJmol^{-1} (243 K) for **6** and $\Delta G^{\neq}$ = 52.1±1.0 kJmol^{-1} (251 K) for **11**.

In complexes Pd(N∩N-κ*N*)(η^2-nq)$_2$ (**14**, **15**), both halves of the nitrogen ligand, which coordinates in a monodentate way, show identical chemical shifts in the ^{1}H- as well as in the ^{13}C-NMR spectra down to 160 K. We assign this behaviour to fast exchange between alternatingly coordinating N atoms of the ligand towards the palladium atom, representing a ligand flipping process analogous to that described by Natile[56]. These authors observed that, for Pt(2,9-dimethyl-1,10-phen)(PPh_3)Cl_2, in which the phenanthroline ligand coordinates in a monodentate way, the ligand flipping could be stopped at 150 K and splitting of the ligand signals is observed. The alternative, which is in agreement with the ^{1}H-NMR spectra, is the existence of the complexes **14** and **15** as tetrahedral 18e complexes in which the nitrogen ligand coordinates in a bidentate mode. However, in view of the solid state structure of **14** and the exchange experiments with *p*-quinones, which showed that complexes of type Pd(N∩Nκ^2*N*)(η^2-nq)$_2$ could be obtained for dafo and dafe ligands, but *not* in the cases utilizing bpy, phen etc., we reject this possibility. Adopting the view that the structure in solution is the same as the one in the solid state, i.e. a 16e complex with monodentate coordinating nitrogen ligand, the observations are easily explained on the basis of the different geometrical constraints of dafo and dafe (i.e. the larger bite angle) as compared to bpy and phen (see the introduction). In the case of **14**, and **15**, concomitantly with the ligand flipping another dynamic process takes place, as witnessed by a broadened singlet for the nq signals, indicating that the *p*-quinones are rotating. For this process, the slow exchange limit could not be reached (170 K at 300 MHz).

A peculiar dependence of the ^{1}H-NMR spectra of the complexes $Pt_2(\mu^2$-dafo)$(\mu^2,\eta^2{:}\eta^2$-pbq)$_2$ (**24**), $Pd_2(\mu^2$-dafo)$(\mu^2,\eta^2{:}\eta^2$-pbq)$_2$ (**16**) and $Pd_2(\mu^2$-dafe)$(\mu^2,\eta^2{:}\eta^2$-pbq)$_2$ (**17**) on the temperature has been observed. In the ^{1}H-NMR spectrum of the Pt compound **24**, the protons of pbq appear at 300.13 MHz as an A_2B_2 pattern with Δν(A−B) = 177 Hz, *J*(Pt,H) = 87.7 and 29.7 Hz. Cooling down the sample in $CDCl_3$ to 218 K showed a temperature dependence of the shifts for A and B as Δν(A−B) decreased by 30 Hz. The protons of pbq in the $Pd_2(\mu^2$-N∩N$)(\mu^2$-pbq$)_2$ complexes appear, in agreement with the solid state structure, at 293 K as an AA′BB′ pattern as is shown by the bottom spectrum in Figure 7. Simulation of the spectra (300.13 MHz) showed that for **16** Δν(A−B) = 9 Hz and the coupling constants are 8.3, 2.2, and 0.2 Hz. For **17** these values are Δν = 27 Hz and *J* = 8.2, 2.1, and 0.2 Hz. When cooling the sample to 253 K, the signal reverts into a singlet, upon further cooling to 213 K the pbq signal appears again as an AA′BB′ pattern albeit rather broadened (top spectrum, Figure 7; the latter broadening is probably due to the viscosity of the solvent at this temperature). We ascribe this process, on the basis of the observations made for the analogous platinum complex **24**, vide supra, to a temperature dependence of the chemical shift of the protons involved.

Figure 7. Variable-temperature ^{1}H-NMR of CH protons of pbq in **16**



Conclusion

A remarkable difference in coordination behaviour is observed between bidentate nitrogen ligands dafo and dafe and the other nitrogen ligands used in this study. In the case of dafo and dafe, exceptional Pd(N∩N-κ*N*)(η^2-nq)$_2$ and $Pd_2(\mu^2$-N∩N$)(\mu^2,\eta^2{:}\eta^2$-pbq$)_2$ complexes are formed. The monodenate or bridging coordination of the N∩N ligand in these instances is mainly a consequence of the annelation on the 3,3′-position of 2,2′-bipyridine by one carbon atom, by virtue of which the bite-angle of the ligands dafo and dafe is slightly but significantly larger compared to those of 2,2′-bipyridyl, phenanthroline, Ar-bian, and open-chain diazabutadienes. The stoichiometry in the Pd_x(N∩N)$(Q)_2$ complexes where N∩N = dafo or dafe depends on the nature of the *p*-quinone.

We thank the *Organization for the Advancement of Pure Research* (SON/NWO) and the *Stichting John van Geuns Fonds* for financial support for obtaining NMR instruments.

Experimental Section

General: All experiments were carried out using standard Schlenk techniques, under an atmosphere of dry nitrogen. The solvents were dried according to standard procedures and distilled before use. − ^{1}H- and ^{13}C-NMR spectra were recorded on a Bruker AMX 300 NMR spectrometer at 300.13 and 75.48 MHz, respectively. Chemical shift values are in ppm relative to TMS as external standard with high frequency shifts signed positive (protons are numbered according to Figure 2). Abbreviations used are s = singlet, d = doublet, t = triplet, pst = pseudo triplet, q = quartet, sep = septet, m = multiplet, br = broad; multiplicity, coupling constants (Hz) and number of protons in parenthesis. − IR spectra (KBr) were recorded on a Biorad FTS-7 IR spectrometer; abbreviations used: s = strong, m = medium, w = weak, br = broad, sh = shoulder. − Elemental analysis were carried out by Dornis and Kolbe, Mikroanalytisches Laboratorium, Mülheim a.d. Ruhr, Germany. − Mass spectra (FAB) were recorded by the Institute of Mass spectroscopy of the University of Amsterdam. − Dibenzylideneacetone (dba)[68], $Pd(dba)_2$[69], $Pt(dba)_2$[70], 4,5-diazafluoren-9-one (dafo)[19], 4,5-diazafluorene (dafe)[20], 5,6-dihydro-1,10-phenanthroline (dh-phen)[20], *N,N′*-dicyclohexyl-1,4-diaza-1,3-butadiene (chex-dab)[71][72] and bis[*N*-(*o,o′*-diisopropyl)phenylimino]-acenaphthene (*o,o′*-*i*Pr2-bian)[7] were synthesized according to published procedures. The *p*-quinones (Q) 1,4-benzoquinone (pbq) and 1,4-naphthoquinone (nq) and the *N*-ligands 2,2′-bipyridine (bpy), 2,2′-bipyrimidine (bpym), and 1,10-phenanthroline (phen) are commercially available and were used as received. Compounds **1**[39], **2**, **7** and **8** are known[27].

Synthesis of Palladium Complexes Pd(N∩N)(Q) (**1**−**3**, **7**, **8**, **12**, **13**): A typical procedure for the synthesis of [*(2,3-η)-1,4-benzoquinone](2,2′-bipyridine-k²N,N′)palladium(0)* (**1**), is given. $Pd(dba)_2$ (124.3 mg = 0.22 mmol), bpy (35.8 mg = 0.23 mmol), and pbq (26.8 mg = 0.25 mmol) were dissolved in toluene (60 ml) and stirred for thirty minutes at 20°C. The colour of the solution changed from dark purple to yellow and a dark compound precipitated. A solid was separated, which was dissolved in dichloromethane (50 ml) and this solution was filtered through Celite to remove metallic palladium. The solution was concentrated to ca. 5 ml and the product was precipitated with hexane (30 ml). The precipitate was filtered off and washed twice with toluene (30 ml), twice with ether (30 ml), and with hexane (30 ml) and dried under vacuum which gave a red brown solid (85%). The analogous complexes were synthesized in a similar way. The yields ranged from 84 to 93%. Dark red crystals of suitable for an X-ray crystal structure determination were obtained by slow diffusion of hexane in a solution of **1** in dichloromethane at 4°C.

(2,2′-Bipyridine-k²N,N′)[(2,3-η)-1,4-Benzoquinone]-palladium(0) (**1**): ^{1}H NMR ($CDCl_3$, 293 K): 8.55 (d, 4.7, H1), 8.09 [d, 7.9, H(X)], 8.01 (dd, 7.9, 7.9, H2), 7.53 (dd, 7.9, 4.7, H3), 5.71 [s, H(pbq)]. − ^{13}C NMR ($CDCl_3$, 213 K): 178.3 (s, *C*=O), 153.8 (s), 150.7 (d), 140.1 (d), 127.7 (s), 122.5 (d), 103.5 (d). − IR: 1602 (s, br). − Mass found *m/z* = 371 (calcd. = 370.7).

(1,10-Phenanthroline-k²N,N′)[(2,3-η)-1,4-naphthoquinone]-palladium(0) (**8**): ^{1}H NMR ($CDCl_3$, 293 K): 8.94 [d, 4.7, H1(NN)], 8.37 [d, 8.2, H2(nq)], 8.07 [m, H3(nq)], 7.82 [s, H(X)], 7.79 [dd, 8.2, 4.7, H2(NN)], 7.42 [m, H3(NN)], 5.01 [s, H1(nq)]. − ^{13}C NMR not recorded due to low solubility and instability. − IR: 1617 (s, br). − Mass found *m/z* = 447 (calcd. 446.9).

(4,5-Diazafluoren-9-one-k²N,N′)[(2,3-η)-1,4-naphthoquinone]-palladium(0) (**12**): ^{1}H NMR ($CDCl_3$, 293 K): 8.02 [d, 7.6, H1(NN)], 7.93 [m, H3(NN) + H2(nq)], 7.58 [m, H3(nq)], 7.38 [dd, 7.6, 5.4, H2(NN)], 5.66 [s, br, H1(nq)]. − ^{13}C NMR not recorded due to low solubility and instability. − IR: 1629 (s), 1727 (s, dafo). − Mass found *m/z* = 447 (calcd. 446.7).

(4,5-Diazafluorene-k²N,N′)[(2,3-η)-1,4-naphthoquinone]-palladium(0) (**13**): ^{1}H NMR ($CDCl_3$, 293 K): 8.33 [m, br, H1(NN)], 7.94 [m, H3(NN) + H2(nq)], 7.48 [m, H3(nq)], 7.40 [m, H2(NN)], 5.12 [s, H1(nq)], 4.03 [s, H(X)]. − ^{13}C NMR not recorded due to low solubility and instability. − IR: 1626 (s). − Mass found *m/z* = 433 (calcd. 432.8).

Synthesis of Palladium Complexes Pd(N∩N)(Q) (**4**−**6** and **9**−**11**): A typical procedure for the synthesis of *[(2,3-η)-1,4-benzoquinone](o,o′-iPr₂-bian-k²N,N′)palladium(0)* (**5**) is given. $Pd(dba)_2$ (124.3 mg = 0.22 mmol), *o,o′*-*i*Pr_2-bian (115.1 mg = 0.23 mmol), and pbq (26.8 mg = 0.25 mmol) were dissolved in acetone (50 ml) and stirred for thirty minutes at 20°C. It was difficult to see a clear colour change although the colour of the solution slightly changed from dark purple to dark red. The solution was filtered to remove the metallic palladium and the solution was concentrated to a fraction of its original amount. The product was precipitated with hexane (30 ml) and washed twice with ether (30 ml) and with hexane (30 ml) and dried under vacuum which gave a red brown solid (87%). The other complexes were synthesized in a similar way. The yields ranged from 87 to 95%.

(N,N′-Dichexyl-1,4-diaza-1,3-butadiene-k²N,N′)[(2,3-η)-1,4-benzoquinone]palladium(0) (**4**): ^{1}H NMR ($CDCl_3$, 293 K): 8.06 (s, NN), 5.47 [s, H(pbq)], 3.45 [m, NC*H*(*c*hex)], 1.90−1.28 [m, (*c*hex)]. − ^{13}C NMR ($CDCl_3$, 293 K): 186.6 (s, *C*=O), 156.6 (d), 98.9 (d), 71.0 (d), 32.8 (t), 24.3 (t), 24.2 (t). − IR: 1615, 1634. − Mass found *m/z* = 435 (calcd. 435.4).

Bis(o,o′-diisopropylphenylimino)-acenaphtene-k²N,N′)[(2,3-η)-1,4-benzoquinone]palladium(0) (**5**): ^{1}H NMR ($CDCl_3$, 293 K): 8.03 (d, 8.3, H3), 7.16 (pst, H2), 7.36 [m, H(Ph)], 6.73 (d, 11.7, H1), 5.28 [s, H(pbq)], 3.29 [sept, 6.8, (C*H*, *i*Pr)], 1.43 [d, 6.8, (CH_3, *i*Pr)], 0.96 [d, 6.9, (CH_3, *i*Pr)]. − ^{13}C NMR ($CDCl_3$, 293 K): 185.2 (s, *C*=O), 167.1 (s), 143.4 (s), 142.9 (s), 137.2 (s), 131.1 (s), 130.6 (d), 128.6 (d), 127.0 (s), 126.9 (s), 124.14 (d), 123.7 (d), 99.0 (d), 28.7 (d), 23.3 (q), 22.9 (q). − IR: 1623. − Mass found *m/z* = 715 (calcd. = 715.8).

(1,10-Phenanthroline-k²N,N')[(2,3-η)-1,4-naphthoquinone]platinum(0) (**21**): ^{1}H NMR ($CDCl_3$, 293 K): 9.33 [d, 4.9, J_{Pt-H}: 31.1, H1(NN)], 8.50 [d, 8.2, H3(NN)], 8.11 [m, H2(nq)], 7.87 [s, H(X)], 7.84 [dd, 8.2, 4.9, H2(NN)], 7.44 [m, H3(nq)], 4.74 [s, J_{Pt-H}: 76.1, H1(nq)]. − ^{13}C NMR not recorded due to low solubility and instability. − IR: 1625 (s). − Mass found *m/z* = 534.078 (calcd. 533.4).

Synthesis of Palladium Complexes Pd(N∩N)(Q)₂ (**14**, **15**): These compounds can be synthesized in two ways, either in one or in two steps, and both methods will be described here.

Method A: (4,5-Diazafluoren-9-one-κN)bis[(2,3-η²)-1,4-naphthoquinone]palladium(0) (**14**): To a brown/red solution of Pd(dafo)(nq) **12** (44.8 mg = 0.1 mmol) in dichloromethane (50 ml) was added naphtoquinone (nq) (15.9 mg = 0.1 mmol), and the solution turned green/yellow after several minutes at 20°C. The same work-up procedure as for the Pd(N∩N)(Q) complexes was followed and this gave a green/yellow solid (83%).

Method B: Pd(dafo)(nq)₂ (**14**) *and Pd(dafe)(nq)₂* (**15**): $Pd(dba)_2$ (140.5 mg = 0.24 mmol), dafo (0.25 mmol), and nq (79.1 mg = 0.50 mmol) were dissolved in 40 ml of toluene and stirred for two hours at 20°C. The colour of the solution changed from dark purple to yellow and a dark compound precipitated. The same work-up procedure as for the Pd(N∩N)(Q) complexes was followed and this gave a green/yellow solid (yield: 93% for **14** and 87% for **15**). Orange crystals suitable for X-ray diffraction were obtained by slow diffusion of hexane in a solution of **14** in dichloromethane/methanol (1:1, v/v) at 4°C.

(4,5-Diazafluoren-9-one-κN)bis[(2,3-η²)-1,4-naphthoquinone]palladium(0) (**14**): ^{1}H NMR ($CDCl_3$, 293 K): 8.01 [d, 7.4, H1(NN)], 7.78 [m, H3(NN) + H2(nq)], 7.49 [m, H3(nq)], 7.28 [dd, 7.4, 5.4, H2(NN)], 5.19 [s, H1(nq)]. − ^{13}C NMR ($CDCl_3$, 223 K): 188.5 (s, *C*=O), 185.4 (s, *C*=O), 161.4 (s), 154.7 (d), 133.8 (d), 133.7 (s), 133.5 (d), 130.6 (s), 127.1 (d), 126.5 (d), 80.9 (d). − IR: 1653 (s, br), 1730 (s, dafo). − Mass found *m/z* = 628 ([M+Na]$^{+\cdot}$) (calcd. 627.9). − $C_{31}H_{18}N_2O_5Pd$: found (calcd.): C, 58.74 (58.15), H, 2.76 (2.83), N, 4.28 (4.37).

(4,5-Diazafluorene-κN)bis[(2,3-η²)-1,4-naphthoquinone]palladium(0) (**15**): ^{1}H NMR ($CDCl_3$, 293 K): 8.02 [d, 7.7, H1(NN)], 7.89 [m, H3(NN) + H2(nq)], 7.52 [m, H3(nq)], 7.32 [dd, 7.7, 5.1, H2(NN)], 5.47 [s, H1(nq)], 3.98 [s, H(X)]. − ^{13}C NMR ($CDCl_3$, 223 K): 185.4 (s, *C*=O), 157.1 (s), 149.3 (d), 134.7 (d), 133.8 (s), 133.5 (d), 139.3 (s), 126.3 (d), 125.0 (d), 33.3 (t), =*C*H (nq) not observed. − IR: 1657 (s, br). − Mass found *m/z* = 433 (calcd. 591.0), the found mass corresponds to [Pd(dafe)(nq)]$^+$.

Synthesis of Platinum Complexes Pt(N∩N)(Q)₂ (**22**, **23**): The analogous platinum complexes **22**, **23** were synthesized in a similar way according to method B as described above but again longer reaction times were needed (14 hrs at 20°C). The yields were 75 and 78% respectively.

(4,5-Diazafluoren-9-one-κN)bis[(2,3-η²)-1,4-naphthoquinone]platinum(0) (**22**): ^{1}H NMR ($CDCl_3$, 293 K): 8.05 [d, 7.6, H1(NN)], 7.78 [m, H3(NN) + H2(nq)], 7.47 [m, H3(nq)], 7.30 [dd, 7.6, 5.4, H2(NN)], 4.77 [s, br, H1(nq)]. − ^{13}C NMR ($CDCl_3$, 223 K): 188.7 (s, *C*=O), 187.9 (s, *C*=O), 134.3 (d), 134.0 (s), 133.8 (d), 133.4 (d), 130.6 (s), 125.9 (d), 67.9 (d), *C*=N (s) and *C*=N (d) not observed. − IR: 1654 (s), 1731 (s, dafo). − Mass found *m/z* = 716 ([M+Na]$^+$) (calcd. 716.6). − $C_{31}H_{18}N_2O_5Pt$: found (calcd.): C, 49.65 (49.09), H, 2.79 (2.39), N, 3.91 (3.69).

(4,5-Diazafluorene-κN)bis[(2,3-η²)-1,4-naphthoquinone]platinum(0) (**23**): ^{1}H NMR ($CDCl_3$, 293 K): 7.92 [d, 7.9, H1(NN)], 7.73 [m, H3(NN) + H2(nq)], 7.43 [m, H3(nq)], 7.23 [m, H2(NN)], 4.75 [s, br, H1(nq)], 3.98 [s, H(X)]. − ^{13}C NMR ($CDCl_3$, 223 K): 189.1 (s, *C*=O), 134.5 (s), 134.1 (s), 133.6 (d), 133.3 (d), 127.2 (d), 125.8 (d), 67.8 (d), 33.3 (t), *C*=N (s) and *C*=N (d) not observed. − IR: 1666 (s, br). − Mass found *m/z* = 702 ([M+Na]$^+$) (calcd. 702.6).

Synthesis of Palladium Complexes Pd₂(N∩N)(Q)₂ (**16**, **17**): A typical procedure for the synthesis of *bis{[μ-(2,3-η²:5,6-η²)]-1,4-benzoquinone}-μ-(4,5-diazafluoren-9-one-k²N,N')bis-[palladium(0)]* (**16**) is given. $Pd(dba)_2$ (140.5 mg = 0.24 mmol), dafo (0.12 mmol) and pbq (25.9 mg = 0.24 mmol) were dissolved

in toluene (50 ml) and stirred for fifteen minutes at 20°C. The colour of the solvent changed from dark purple to yellow and a dark green compound precipitated. This solid was washed with toluene (2 × 20 ml) and with diethylether (2 × 20 ml). In order to remove the metallic palladium the compound was dissolved in dichloromethane and filtered through Celite. The solution was evaporated to a fraction of its original amount and the product was precipitated with hexane. The remaining yellow green solid was dried in vacuum (yield: 90% for **16** and 88% for **17**). Dark green crystals suitable for X-ray diffraction were obtained by slow diffusion of hexane in a solution of **16** in dichloromethane/methanol (1:1, v/v) at 4°C.

Bis{[μ-(2,3-η²:5,6-η²)]-1,4-benzoquinone}-μ-(4,5-diazafluoren-9-one-k²N,N′)bis[palladium(0)] (**16**): ^{1}H NMR ($CDCl_3$, 293 K): 8.79 (d, 5.5, H1), 8.31 (d, 7.6, H3), 7.48 (dd, 7.6, 5.5, H2), 4.45 [ddd, 8.3, 2.2, 0.2, H(pbq)], 4.48 [ddd, 4.0, 1.0, 0.1, H(pbq)]. − ^{13}C NMR not recorded due to low solubility. − IR: 1629 (s, br), 1726 (s, dafo). − Mass found *m/z* = 634 ([M+Na]$^+$) (calcd. = 634.2). − $C_{23}H_{14}N_2O_5Pd_2$: found (calcd.): C, 44.57 (45.20), H, 2.65 (2.31), N, 4.38 (4.58).

Bis{[μ-(2,3-η²:5,6-η²)]-1,4-benzoquinone}-μ-(4,5-diazafluorene-k²N,N′)bis[palladium(0)] (**17**): ^{1}H NMR ($CDCl_3$, 293 K): 8.75 (d, 4.5, H1), 8.16 (d, 7.6, H3), 7.40 (dd, 7.6, 4.5, H2), 4.65 [ddd, 8.2, 2.1, 0.2, H(pbq)], 4.56 [ddd, 8.2, 2.1, 0.2, H(pbq)], 4.07 (s). − ^{13}C NMR (CD_2Cl_2, 293 K): 189.1 (s, *C*=O), 154.2 (d), 146.7 (s), 138.0 (d), 125.6 (d), 83.0 (d), 79.6 (d), 34.3 (t), *C*=CH (s, dafe) not observed. − IR: 1634 (s, br). − Mass found *m/z* = 597 (calcd. 597.2).

Synthesis of Platinum Complexe $Pt_2(N\cap N)(Q)_2$ (**24**): The analogous platinum complex **24** was synthesized similarly, but a reaction time of 14 hrs was required; the yield was 71%.

Bis{[μ-(2,3-η²:5,6-η²)]-1,4-benzoquinone}-μ-(4,5-diazafluoren-9-one-k²N,N′)bis[platinum(0)] (**24**): ^{1}H NMR ($CDCl_3$, 293 K): 8.83 (d, 5.5, J_{Pt-H}: 29.7, H1), 8.39 (d, 7.6, H3), 7.49 (dd, 7.6, 5.7, H2), 4.45 [d, 7.5, J_{Pt-H}: 87.7, H(pbq)], 3.86 [d, 7.5, J_{Pt-H}: 44.6, H(pbq)]. − ^{13}C NMR not recorded due to low solubility. − IR: 1640 (s, br), 1733 (s, dafo).

p-Quinone Substitution Reactions: *p*-Quinone substitution reactions were carried out for several combinations of complexes and *p*-quinones in varying stoichiometries. A typical experiment has been described below and the other substitution reactions proceeded in a similar way. *p*-Benzoquinone (11.2 mg = 0.1 mmol) was added to a solution of **7** (37.1 mg = 0.1 mmol) in dichloromethane (30 ml), which solution was then stirred for one hour at 20°C. After evaporation of the solvent the remaining solid was washed with diethylether (3 × 10 ml) and dried in vacuum. The residue as well as the organic products were analyzed with ^{1}H NMR spectroscopy.

X-ray Crystal Structure Determination: The crystal, collection, and refinement data of complexes **1**, **14**, and **16** have been compiled

Table 3. Crystallographic data for Pd(bpy)(pbq) **1**, Pd(dafo)(nq)$_2$ **14**, and Pd_2(dafo)(pbq)$_2$ **16**

in Table 3. Data collection for these crystals was performed on an Enraf-Nonius CAD-4 diffractometer with graphite-monochromated Cu-*Kα* radiation for **1** and **14** and Mo-*Kα* radiation for **16** and ω-2θ scan. Two reference reflections were measured hourly and showed no decrease during the course of the data collection for the complexes **1** and **16** and 6% decrease for complex **14**, which was corrected for. Unit-cell parameters were refined by a least-squares fitting procedure using 23 reflections with 80<2θ<84° for **1**, 80.1<2θ<84.9° for **14**, and 40<2θ<42° for complex **16**. Corrections for Lorentz and polarization effects were applied. The structure of the complexes **1** and **16** was solved by Direct Methods while the structure of **14** was solved by the PATTY option of the DIRDIF91 program system[73]. After isotropic refinements on **1** and **16**, peaks were found in a ΔF synthesis which were interpreted as water and methanol respectively which were used as solvents during crystallization. The hydrogen atoms were calculated. Full-matrix least-squares refinement on *F*, anisotropic for the non-hydrogen atoms and isotropic for the hydrogen atoms, restraining the latter in such a way that the distance to their carrier remained constant at approximately 1.09 Å, converged to the R -values mentioned in Table 3. An empirical absorption correction, DIFABS[74] was applied. Scattering factors were taken from the literature[75][76][77]. Since the space group of complex **14** is polar, it was necessary to use the Flack absolute structure parameter[78], which refined to $x = 0.032(11)$. In case of the crystals of complex **14**, the matching of the two independent molecules for all non-hydrogen atoms resulted in a rms-value of 0.13 Å and a non-crystallographic center of symmetry is present (located at $x = 0.50$, $y = 0.37$, $z = 0.38$). The anomalous scattering of Pd was taken into account. For **1** and **16** calculations were performed with XTAL[79] and for **14** with SHELXL[80]. Thermal ellipsoid and molecular plots were made using the PLUTON and PLATON programs[81]. Atomic coordinates, thermal parameters and bond lengths and angles have been deposited ar the Cambridge Crystallographic Data Centre, see instructions to authors. Any request to the CCDC for this material should quote the full literature citation and the reference number 100791.

[45] Recently, an X-ray crystal structure of a divalent palladium complex [PdCl(η^3-allyl)(Ar-bian-κ*N*) authenticated the possibility of monodentate coordination of sterically demanding *rigid* α-diimine ligands[17]. This finding indicates that dissociation of one N atom is retarded for RBN ligands such as Ar-bian, but that also in these cases it may be a vital process in insertion reactions of CO and unsaturated organic compounds into Pd−C bonds.

Received October 16, 1997

Keywords: Bis(pentamethylcyclopentadienyl)phosphanes / Aminobis(pentamethylcyclopentadienyl)phosphanes

The bis(1,2,3,4,5-pentamethyl-1,3-cyclopentadien-1-yl)phosphanes **3**−**7** are formed in good yields by the reaction of the halogenophosphanes **2a** or **2b** with the appropriate nucleophile. Following another route, the dialkylaminobis(pentamethylcyclopentadienyl)phosphanes **11a**−**c** have been synthesized by the treatment of dichloro(dialkylamino)phosphanes with two equivalents of (pentamethylcyclopentadienyl)lithium. The compounds **3**−**11** have been characterized by multinuclear NMR spectroscopy and **3**, **5**, **6**, and **11a** have also been characterized by single-crystal X-ray diffraction studies. The molecular structure of **11a** is governed by steric congestion, which typically would lead to a parallel arrangement of the two pentamethylcyclopentadienyl ligands at the phosphorus atom. However, surprisingly, the crystal structure of the (dimethylamino)phosphane **11a**, exhibits a tilted, rather than a parallel, conformation of the pentamethylcyclopentadienyl groups [tilt angle: 130.6(1)°].

Previous comprehensive investigations of the main-group cyclopentadienyl (Cp) compounds[1][2][3] have revealed a variety of unusual structures and bonding modes analogous to those observed for the cyclopentadienyl transition-metal compounds[4]. Depending on the availability of the valence orbitals and the geometric parameters of the central atom, mono-, di-, tri-, and pentahapto complexation has been achieved[5][6][7][8]. Moreover, by replacing Cp with the permethylated Cp* substituent, a significantly increased kinetic stability of the resulting complexes could be achieved, which made the isolation of several new types of compounds possible[3][4].

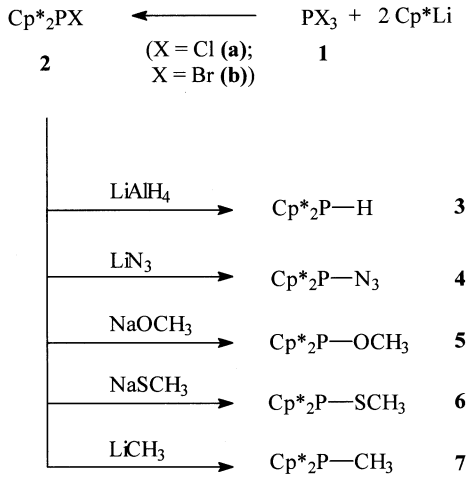
In the course of studies dealing with the dynamic behaviour of such systems (1,5-sigmatropic rearrangements) several pentamethylcyclopentadienyl-(Cp*-)substituted phosphanes have been synthesized[9][10]. On heating these Cp*-substituted phosphanes were shown to be thermally stable, which is not the case for the corresponding Cp compounds[11][12]. Recently, in the case of Cp*-substituted phosphenium cations and iminophosphanes, the haptotropic rearrangement has been proven to occur[13].

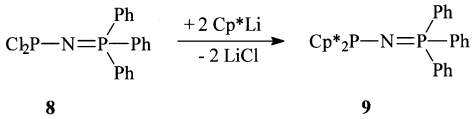
Results

Halogeno-Substituted Bis(Cp*)phosphanes

The synthesis of the chloro- and bromobis(Cp*)phosphanes[10] has been optimized, to enable characterisation by X-ray crystallography[23]. Treatment of PCl_3/PBr_3 with 2.5 equivalents of Cp*Li[10][14] at 0°C in pentane and after stirring for 10 h affords the desired halogenobis(Cp*)phosphanes **2a** and **2b**. Both compounds are obtained as yellow, thermally stable solids, that can be distilled in vacuo.

Scheme 1. Synthesis of new bis(Cp*)phosphanes by nucleophilic displacement





Starting from these halogenophosphanes **2a** and **2b** a variety of previously unknown bis(Cp*)phosphanes could be obtained by a nucleophilic displacement reaction. There-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0331 $ 17.50+.50/0

fore, the reduction to the phosphane **3**, on reaction of **2a**, **b** with lithium tetrahydridoaluminate in ether, proceeds in the usual manner. Due to the coupling with the directly bonded proton ($^1J_{PH} = {}_1$90.0 Hz) and the six methyl protons ($^3J_{PH} = {}_1$6.5 Hz) the ^{31}P-NMR spectrum of compound **3** exhibits a characteristic pattern of a doublet of septuplets.

The reaction of the halogenophosphanes with lithium azide in pyridine produces the azidophosphane **4** in good yield. The reaction time depends strongly on the nature of the halogen atom. While the reaction takes several days for **2a**, in the case of **2b** the exchange is completed after 1−2 h, which may be due to the weaker P−Br bond compared to the P−Cl bond.

In general, owing to the high steric congestion of the two Cp* substituents, a prolonged reaction time is necessary. However, in the case of the thermally stable compounds the reaction rate can be increased by heating the reaction mixture. Since the displacement of the Cp* moiety is a common side reaction of the nucleophilic attack at **2a**, **b**, a detailed balance of the reaction parameters is necessary. Reaction of **2a**, **b** with sodium methoxide at 40−50°C in methanol readily furnishes **5** as a crystalline compound. However, the corresponding (methylthio)phosphane **6** could be obtained at lower temperatures (0°), if a highly polar solvent such as DMF is used. With respect to this conversion the bromo derivative **2b** is seen to be more reactive than the chloro congener **2a**. Since sodium thiomethoxide is unsoluble in pure toluene or other unpolar solvents, a mixture of toluene/DMF is used as solvent in order to achieve a good solubility of the nucleophile. Methyllithium also reacts with **2a** and **2b** by displacement of the halide group at low temperature, despite the transition state of this reaction being more strained than in the previous cases. The conversion of **2a**,**b** into compound **7** is optimized in ether.

The identity of the compounds **3**−**7** was confirmed by NMR spectroscopy and elemental analysis. In addition, crystals suitable for an X-ray structure determination have been obtained for **3**, **5** and **6**.

NMR Spectra: In contrast to the compounds Cp*PR_2, which exhibit a mirror plane perpendicular to the ring, molecules of the type Cp*$_2$PR show diastereotopic methyl groups, which is similar to the situation in the phosphanes Cp*PRR′. All methyl groups are anisochronous, which corresponds to the observation of five sets of signals in the proton-NMR spectra.[10] However, these signals sometimes do not appear resolved, as, for instance, in the case of the compounds **3** and **4**, where the chemical shift of the methyl groups in positions 3 and 4 are almost the same.[15]

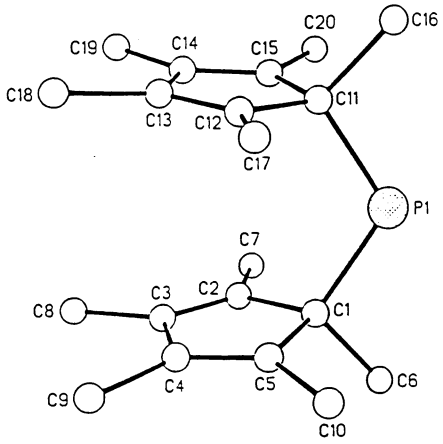
An incidental isochrony of the methyl groups 3 and 4, not only in the ^{1}H- but also in ^{13}C{^{1}H}-NMR spectra, can be observed in compound **2**. A borderline case of this situation may be ascribed to compounds **5** and **7**, in which the ^{13}C-NMR signals of the carbon atoms appear very close to each other but are still distinguishable. Owing to the greater dispersion of ^{13}C-NMR shifts, the influence of the substituents attached to the phosphorus atom on the shielding of the methyl groups 3 and 4 is more significant in ^{13}C-NMR than ^{1}H-NMR spectroscopy.

X-ray Structures of 3, 5, and 6: The molecular structures of **3**, **5**, and **6** in the crystal show significant similarities. The X-ray structures agree well with the results from multinuclear NMR spectroscopy and confirm the presence of

two η^1-bounded Cp* rings in all three cases. These rings are planar (deviation < 1 pm) and exhibit an almost parallel relative arrangement. However, these rings adopt no ecliptic conformation but are slightly twisted, probably in order to minimize repulsive interactions of the methyl groups. The planarity of these rings causes a deviation from ideal tetrahedral angles at the saturated, sp^3-hybridised carbon atoms (angles: C5−C1−C2 and. C12−C11−C15). These findings correspond well with the results for other bis(η^1-Cp*)-substituted congeners, for which X-ray structures are available, e.g. Cp^*_2S[16] or $Cp^*_2SiCl_2$[17]. The proton in the secondary phosphane **3** can not be localized in the differential Fourier-analysis, due to the proximity of the phosphorus atom. The P−C bond lengths in all the three molecules are in the range of 187.7−190.6 pm, as expected for such compounds, but are slightly elongated with respect to the standard bond length of 185 pm.[18]

The largest P−C value in this series has been found for compound **6**. However, the P−S distance (211.7 pm) in this compound, as well as the P−O distance (164.1 pm) in **5** are completely normal and in the range for regular P−chalkogene single bonds.[18]

Figure 2. Molecular structure of Cp^*_2PH **3**[a]



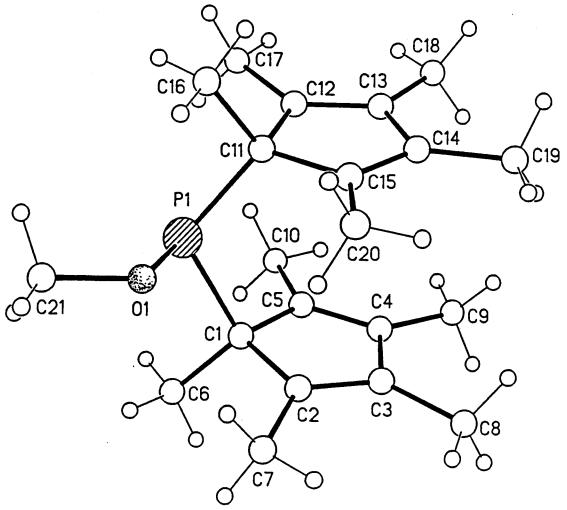
[a] Selected bond lengths [pm] and angles [°]: P1−C1 187.7 (4), P1−C11 188.9 (5); C1−P1−C11 112.6 (2), P1−C1−C6 104.1 (3), P1−C11−C16 103.4 (3); interplanar angle between Cp* planes: 9.6(3)°.

Amino-Substituted Bis(Cp*)phosphanes

The formation of amino-functionalized bis(Cp*)phosphanes can be accomplished by an inverse strategy, connecting the P−N bond prior to the P−C bonds. Therefore the corresponding aminodichlorophosphane was treated with 2.2 equivalents of Cp*Li in pentane as solvent.

For convenience an exess of Cp*Li was used, which reduces the reaction time significantly. The presence of two Cp* moieties at the same phosphorus atom limits, due to steric hindrance, the variety of possible substituents at the nitrogen atom. An imino group should be a suitable nitrogen-containing substituent because it has a small steric bulk. Following this concept the phosphoraneimino-substituted bis(Cp*)phosphane **9**, was readily obtained as pale

Figure 3. Molecular structure of Cp^*_2POMe **5**[a]



[a] Selected bond lengths [pm] and angles [°]: P1−O1 164.1 (3), P1−C1 188.0 (4), P1−C11 187.8 (4); C1−P1−C11 110.5 (2), P1−C1−C6 104.0 (2), P1−C11−C16 105.0 (2), O1−P1−C1 100.2 (2), O1−P1−C11 100.2 (2), P1−O1−C21 118.7 (3); interplanar angle between Cp* planes: 7.0(2)°.

10d **12** **13**

yellow solid starting from the corresponding dichlorophosphane **8** and two equivalents of Cp*Li[15].

Moreover, the syntheses of the dimethylamino (**11a**) and diethylamino (**11b**) derivatives were also sucessful by this method, while in contrast the introduction of an diisopropylamino group failed. In the latter case the reaction of dichloro(diisopropylamino)phosphane (**10d**)[19] with excess Cp*Li produces the monosubstituted phosphane **12**[20].

NMR Spectra: Similar to the ^{1}H-NMR spectra of the compounds **3**−**7**, the anisochrony of all methyl groups in the bis(Cp*)aminophosphanes **11a**−**c** can be observed as well. However, the signals for the latter compounds appear clearly separated and do not overlap as in the previously described case.

Figure 5. The NMR data were assigned according to the depicted numbering

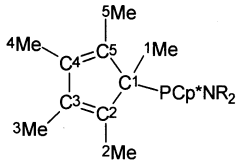

Table 3. ^{1}H-NMR data of **11a**−**c** (C_6D_6)

	11a	**11b**	**11c**

X-ray Structure of **11a**: The dimethylamino-substituted bis(Cp*)phosphane **11a** crystallizes as colourless prisms and in the space group $P\bar{1}$. Similarly to the previously described structures both rings are bonded in an η^1 manner and are perfectly planar. However, a significantly different feature of this molecule is the surprisingly nonparallel orientation of the Cp* rings, which are tilted by 130.6(1)°. This compound represents the first example of a bis(Cp*)-phosphane with a nonparallel arrangement of the Cp* rings.

It is unlikely that this unusual geometry is due to a direct interaction of the nitrogen atom and its lone pair with the twisted Cp* ring, since the almost planar environment at this center [$\measuredangle$ N: 358.8(1)°] is a common feature of aminophosphanes[21][22]. Any influence of the phosphorus atom, which is pyramidalized to the same extent [$\Sigma\measuredangle$ P: 325.3(1)°]

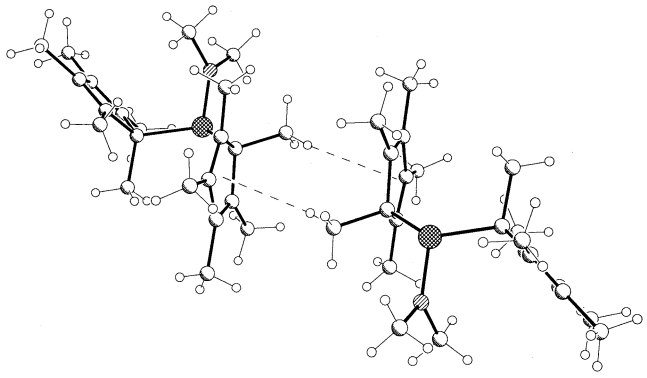
as in other bis(Cp*)phosphanes, on the arrangement of the rings can also be discounted.

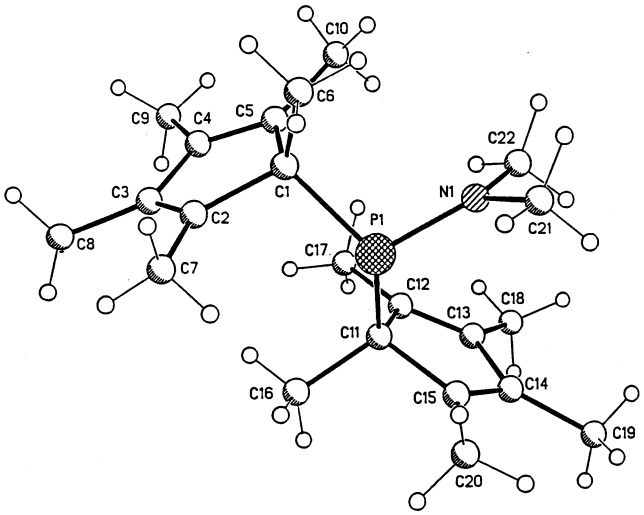
The most probable reason for this unusual geometric feature arises from the packing of the molecules within the crystal. There is an orientation of one proton of the methyl group in the 4-position towards the twisted Cp* ring of another molecule, generated by symmetry transformation $-x$, $2 - y$, $2 - z$, and vice versa.

Figure 6. Intermolecular interactions of the aminophosphane **11a** in the crystal



The P−C bond lengths in **11a** [191.1(3) pm] are even longer than in the previously mentioned compounds. Additionally, the P−N bond appears slightly shortened [168.0(3) pm]. These findings may be ascribed to tendency towards partial ionic character in **11a**.

Figure 7. Molecular structure of Cp_2PNMe_2 **11a**[a]



[a] Selected bond lengths [pm] and angles [°]: P1−N1 168.0 (3), P1−C1 191.1 (3), P1−C11 191.0 (3), N1−C21 145.7 (5), N1−C22 144.6 (5); C1−P1−C11 112.7 (1), N1−P1−C1 106.8 (1), N1−P1−C11 105.8 (1), P1−N1−C21 116.5 (3), P1−N1−C22 128.8 (3), C21−N1−C22 113.5 (3); interplanar angle between Cp* planes: 130.6(1)°.

We thank the *Deutsche Forschungs-Gemeinschaft* and the *Fonds der Chemischen Industrie* for continued financial support. S. K. thanks the *Finnish Academy of Science* for a grant.

Experimental Section

All reaction steps were carried out under dried argon in order to exclude air and moisture; glassware, reagents and solvents were similarly prepared. − ^{31}P NMR: Bruker AMX 300 (121.5 MHz); external standard 85% H_3PO_4. − ^{13}C NMR: Bruker AMX 300 (75.5 MHz); external standard tetramethylsilane. − ^{1}H NMR: Bruker AMX 300 (300 MHz); external standard tetramethylsilane. ^{31}P- and ^{13}C-NMR spectra were recorded with ^{1}H decoupling. A positive sign means low field with respect to the standard. − MS: Kratos MS 50 and VG Instruments VG 12-250 (EI, direct inlet). The given *m/z* values refer to the isotope of highest abundance for each element. − M.p.: Measured without correction in sealed capillaries in a melting point apparatus supplied by Firma Büchi, Flawil/Switzerland. − Elemental analyses: Heraeus CHN-O-Rapid. − The literature procedure for the syntheses of the bis(Cp*)halogenophosphanes **2a** and **2b** has been slighly modified[10].

Chlorobis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**2a**) *and Bromobis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane* (**2b**): 1.8 ml (20 mmol) of PCl_3 or 19 ml (20 mmol) of PBr_3 was added slowly at 0°C to a suspension of 3.4 g (24 mmol) of Cp*Li in 50 ml of pentane. The mixture was cooled to room temp. and stirred vigorously for a further 10 h. The insoluble precipitate was removed by filtration and washed several times with pentane. The volume of the combined filtrate was reduced to approximately 10 ml, the product crystallised on cooling to −35°C. − **2a**: Yield: 5.5 g (87%, rel. PCl_3). − ^{31}P{^{1}H} NMR (C_6D_6): δ = 165.5 (s). − **2b**: Yield: 6.4 g (82%, rel. PBr_3). − ^{31}P{^{1}H} NMR (C_6D_6): δ = 167.8 (s).

Bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**3**): A solution of 1.5 g (4.5 mmol) of **2a** in 3 ml of diethyl ether was added, at 0°C, to a suspension of 70 mg of $LiAlH_4$ in 5 ml of diethyl ether. After warming to room temp. and further stirring, the solvent was removed. The residue was extracted with pentane and, after separation from the unsoluble precipitate, the filtrate was concentrated. On cooling to −35°C, the product was obtained as colorless crystals. Yield: 0.8g (59%), m.p. 108°C. − ^{31}P{^{1}H} NMR (C_6D_6): δ = −42.2 (s). − MS (180°C/70 eV); *m/z* (%): 302 (8) [M^+], 167 (100) [M^+ − Cp*], 135 (13) [Cp*$^+$] and further fragments. − $C_{20}H_{31}P$ (302.2): calcd. C 79.43, H 10.33; found C 77.71, H 10.33.

Azidobis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**4**): 3.5 g (9.2 mmol) of **1b** was dissolved in 5 ml of pyridine. While cooling with ice, 0.47 g (9.5 mmol) of LiN_3 was added as pure solid. Under continuous stirring, the mixture was warmed to room temp. within 0.5 h and the pyridine was removed in vacuo. The residue was extracted with pentane and, after separation from the unsoluble precipitate, the filtrate was concentrated. On cooling to −35°C the product was obtained as colorless solid, which was then recrystallised several times to remove impurities. Yield: 2.3 g (73%), m.p.. 70°C (dec.). − ^{31}P{^{1}H} NMR (C_6D_6): δ = 138.2 (s) − MS (100°C/70 eV), *m/z* (%): 343 (8) [M^+], 315 (6) [$M^+ - N_2$], 301 (4) [$M^+ - N_3$], 270 (29) [Cp*$_2^+$], 208 (39) [M^+ − Cp*], 135 (13) [Cp*$^+$] and further fragments. − UV/Vis (pentane): λ_{max} (lgε) = 215 nm, 230, 265. − $C_{20}H_{30}N_3P$ (343.5): calcd. C 69.94, H 8.80, N 12.23; found C 68.69, H 8.67, N 12.02.

Methoxybis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**5**): 0.64 g (1.9 mmol) of **1a** was dissolved in 10 ml of pentane and added, under continuous stirring, to 0.05 g (2.1 mmol) of sodium in 20 ml of methanol at room temp. After the addition was completed, the mixture was stirred for a further 3 h at 40°C. The volatile components were removed in vacuo, and the residue extracted with pentane. After filtration and on cooling to −70°C, the product was obtained as white needles. Yield: 0.46 g (73%), m.p. 84−88°C. − ^{31}P{^{1}H} NMR (C_6D_6): δ = 184.8 (s) − MS (100°C/40 eV); *m/z* (%): 332 (3) [M^+], 301 (0.5) [$M^+ - OCH_3$], 197 (100) [M^+ − Cp*], 135 (70) [Cp*$^+$] and further fragments. − An analysis was not performed.

Methylthiobis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**6**): 0.54 g (1.5 mmol) of **1b**, dissolved in 3 ml of toluene/DMF (2:1), was added to an equivalent amount of $NaSCH_3$ (0.1 g) in 2 ml of DMF at 0°C. The solution was stirred for 1 h at ambient temp. The solvents were evaporated under reduced pressure and the residue extracted with pentane. After separation of the solid precipitate, the filtrate was concentrated and the product crystallised at −35°C. Recrystalisation at the same temp. yielded the product as pale yellow crystals. Yield 0.46 g (88%), m.p. 95−100°C. − ^{31}P{^{1}H} NMR (C_6D_6): δ = 85.1 (s) − MS (100°C/35 eV); *m/z* (%): 348 (15) [M^+], 301 (15) [$M^+ - SCH_3$], 270 (3) [Cp*$_2^+$], 213 (100) [M^+ − Cp*], 166 (30) [Cp*P$^+$], 135 (50) [Cp*$^+$] and further fragments. − $C_{21}H_{33}PS$ (348.5): calcd. 348.2041; found 348.2046 (MS).

Methylbis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)phosphane (**7**): 3.5 ml (2.2 mmol) of CH_3Li (1.6 M in diethyl ether) was added slowly to 0.67 g (2 mmol) of **1a** in 5 ml of diethyl ether at −78°C. After warming to room temp., the volatile parts of the mixture were removed in vacuo. The residue was extracted with pentane and, after separation from the unsoluble precipitate, the filtrate was concentrated. On cooling to −35°C, the product was obtained as a solid which was recrystallised several times, finally at 0°C to yield 0.5 g (79%) of white crystals. m.p. 138−140°C. − ^{31}P{^{1}H} NMR (C_6D_6): δ = 72.9 (s) − MS (100°C/35 eV); *m/z* (%): 316 (15) [M^+], 301 (5) [$M^+ - CH_3$], 270 (1) [Cp*$_2^+$], 181 (100)

[M^+ − Cp*], 166 (20) [Cp*P^+], 135 (60) [Cp*$^+$] and further fragments. − $C_{21}H_{33}P$ (316.5): calcd. 316.2322; found 316.2327 (MS).

Bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)-(triphenylphosphoranylimino)phosphane (**9**): A suspension of 0.6 g (4.0 mmol) of Cp*Li in pentane (10 ml) was treated dropwise with 0.8 g (2 mmol) of dichloro(triphenylphosphoranylimino)phosphane[15] at −40°C. The solution was stirred for a further 12 h and warmed to room temp. After filtration, the solution was concentrated and the product isolated after crystallisation from ether/THF at 5°C. The product **8** was obtained as yellow crystals. Yield 0.8 g (70%), m.p. 170°C (dec.). − $^{31}P\{^1H\}$ NMR (ether/C_6D_6): δ = 93.0 (d, $^2J_{PP}$ = 109 Hz), 17.8 (d, J_{PP} = 109 Hz). − ^1H NMR ([D_8]THF): δ = 7.9−7.6 (m, 2 H), 7.5−7.4 (m, 3 H) H arom., 2.0 (s, 3 H), 1.7 (s, 6 H), 0.7 (d, 3 H, $^3J_{PH}$ = 14.1 Hz) C_5Me_5. − $^{13}C\{^1H\}$ NMR ([D_8]THF): δ = 141.7 (d, 2.1 Hz), 138.7 (s), 138.0 (s), 136.6 (d, 1.5 Hz), 63.0 (dd, $^1J_{PC}$ = 39.5 Hz, $^3J_{PC}$ = 9.6 Hz) C_5 ring; 133.7 (d, 2.6 Hz), 133.1 (dd, $^1J_{PC}$ = 45.2 Hz, $^3J_{PC}$ = 2.7 Hz), 129.1 (s), 128.5 (s) C_{arom}; 22.1 (d, $^2J_{PC}$ = 11.6 Hz), 13.7 (d, 2.7 Hz), 12.5 (s), 11.5 (s), 11.4 (s) C_5Me_5. − MS (300°C/40 eV); *m/z* (%): 577 (6) [M^+], 576 (13) [M^+ − H], 443 (60 [M^+ − Cp*], 308 (100) [M^+ − 2Cp*], 262 (65) [PPh_3^+], 135 (44) [Cp*$^+$] and further fragments. − $C_{38}H_{45}NP_2$ (577): calcd. C 79.00, H 7.85, N 2.42; found C 78.91, H 8.05, N 2.39.

(Dialkylamino)bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)-phosphanes (**11a**−**c**): A suspension of 0.68 g (4.8 mmol) of Cp*Li in pentane was treated dropwise with 2 mmol of **10a**−**c** at room temp. The solution was stirred for a further 12 h and filtered afterwards. The solution was concentrated and the product isolated after crystallisation at −35°C. In all three cases yellow crystals were obtained.

(Dimethylamino)bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)-phosphane (**11a**): Yield: 0.59 g (86%), m.p. 103−105°C. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 117.3 (s). − MS (25°C/70 eV); *m/z* (%): 345 (0.2) [M^+], 301 (0.4) [M^+ − $N(CH_3)_2$], 270 (0.7) [Cp*$_2^+$], 213 (100) [M^+ − Cp*], 166 (20) [Cp*P^+], 135 (20) [Cp*$^+$] and further fragments. − An analysis was not performed.

(Diethylamino)bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)-phosphane (**11b**): Yield: 0.61 g (81%), m.p. 53−55°C. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 116.5 (s). − MS (200°C/25 eV); *m/z* (%): 373 (2) [M^+], 301 (1) [M^+ − $N(C_2H_5)_2$], 270 (15) [Cp*$_2^+$], 238 (90) [M^+ − Cp*], 166 (20) [Cp*P^+], 135 (100) [Cp*$^+$] and further fragments. − $C_{24}H_{40}NP$ (373.6): calcd. C 77.17, H 10.79, N 3.75; found C 76.91, H 10.85, N 3.53.

Bis(1,2,3,4,5-pentamethyl-2,4-cyclopentadien-1-yl)piperidinophosphane (**11c**): Yield: 0.58 g (75%), m.p. 83−85°C. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 116.8 (s). − MS (200°C/25 eV); *m/z* (%): 385 (4) [M^+], 301 (1) [M^+ − $N(CH_2)_5$], 250 (90) [M^+ − Cp*], 166 (35) [Cp*P^+], 135 (100) [Cp*$^+$] and further fragments. − $C_{25}H_{40}NP$ (385.6): calcd. C 77.88, H 10.46, N 3.63; found C 77.41, H 10.02, N 3.48.

X-ray Structure Determination of **3**, **5**, **6**, *and* **11a**: The structures were solved by direct methods (SHELXTL-Plus[24]). The non-hydrogen atoms were refined anisotropically, H atoms were refined using a riding model [full-matrix least-squares refinement on F (**3**, **5**: SHELXTL-plus[24]) and F^2 (**6**, **11a**: SHELXL-93[25]), respec-

Received October 20, 1997

Keywords: Carbene complexes / Carbyne complexes / Asymmetric synthesis / Carbohydrates / Chiral auxiliaries

Chiral carbene complexes [Cp(CO)$_2$Mn=C(OR*)Ph] (**4a**−**e**) were prepared by reaction of [Cp(CO)$_2$Mn=C(OAc)Ph] (**2**) with HOR* [HOR* = 1,2:3,4-di-*O*-isopropylidene-D-galactopyranose (**3a**), 2,3,4,6-tetra-*O*-acetyl-D-galactopyranose (**3b**), 2,3,4,6-tetra-*O*-acetyl-D-glucopyranose (**3c**), (*S*)- (**3d**) and (*R*)-1,2-*O*-isopropylideneglycerol (**3e**)]. The replacement of a CO ligand with $PTol_3$ in **4a**−**e** proceeded diastereoselectively to give [Cp(CO)($PTol_3$)Mn=C(OR*)Ph] (**5a**−**e**). The diastereoselectivity increased in the order **a**, **b**, **c**, **d**: de = 8% (**5a**), 33% (**5b**), 70% (**5c**), > 96% (**5d**). For (*R*)-**5d** the isomer with the (*S*) configuration at manganese (S_{Mn}) was formed predominantly. For (*S*)-**5d**, only (R_{Mn},*S*)-**5d** was detected (de > 96%). Photolysis of (*R*)-**4d** in the presence of phosphites or phosphanes afforded (S_{Mn})-[Cp(CO)(PR_3)Mn=C(OR*)Ph] [PR_3 = $P(OPh)_3$ (**8**), $P(OMe)_3$ (**9**), $P(OMe)_2Ph$ (**10**), $P(OMe)Ph_2$ (**11**), PPh_3 (**12**), $P(C_6H_4Cl\text{-}p)_3$ (**13**)] with a de > 96%. Photolysis of (*S*)-**4d** in the presence of $P(OMe)_3$ gave (R_{Mn},*S*)-**9**. Complex (*R*)-**14** [related to (*R*)-**4d**] was obtained from [Cp(CO)$_2$Mn=C(OAc)Tol-*p*] and **3d**. Replacement of CO by PR_3 in (*R*)-**14** gave (S_{Mn},*R*)-[Cp(CO)(PR_3)Mn=C(OR*)Tol-*p*] [R = Tol-*p* (**15**), OMe (**16**), C_6H_4Cl-*p* (**17**)] with a de > 96%. In solution, the $PTol_3$-substituted complex **5d** is configurationally stable whereas the $P(OMe)_3$ complex **9** epimerizes slowly at room temperature in CH_2Cl_2, Et_2O, and THF within about one week.

Introduction

Chiral transition-metal complexes play a prominent role in enantioselective synthesis and catalysis. In these complexes either the metal[1] or one or more ligands carry the chiral information. Although a wide variety of carbohydrates are available from the chiral pool, the number of reports on their use as chiral auxiliaries in transition-metal chemistry is rather restricted.[2] The preparation of new carbohydrates via organometallic compounds was recently described by Dötz et al.[3]

Recently, we reported the synthesis of chiral complexes of manganese and rhenium. These complexes, of the type [Cp(CO)$_2$M=C(OR*)R′] (M = Mn, Re, OR* = mannofuranosyl, glucofuranosyl, fructopyranosyl, R′ = Ph, Tol), were obtained by addition of the monoanion of the corresponding protected carbohydrate to the cationic carbyne complexes [Cp(CO)$_2$M≡CR′]$^+$.[4]

Another route to chiral carbene complexes involves nucleophilic substitution by chiral alcoholates, such as (−)-mentholate and borneolate, of the acetoxy substituent in acetoxycarbene complexes of manganese [Cp(CO)$_2$Mn=C(OAc)R′].[5][6]

Photolysis of the chiral carbohydratocarbene complexes in the presence of phosphanes or phosphites (L) afforded chiral-at-metal carbene complexes of the type [Cp(CO)(L)M=C(OR*)R′]. The diastereomeric excess (de) ranged from 0 to 80% and depended on the nature of the carbohydrate and the entering phosphorus ligand. The diastereoselectivity increased with increasing nucleophilicity of L. The highest diastereoselectivity was obtained with OR* = 2,3:5,6-di-*O*-isopropylidene-β-D-mannofuranosyl and L = tritolylphosphane.

In this paper we report (a) on the synthesis of chiral dicarbonyl(carbohydratocarbene) complexes by alcoholysis of [acetoxy(aryl)carbene]dicarbonyl(cyclopentadienyl)manganese with protected carbohydrates and chiral alcohols, (b) on the synthesis of diastereomerically pure carbene(carbonyl)phosphane complexes, and (c) on the ready access to pure compounds of both configurations at the chiral metal center.

Results and Discussion

Successive reaction of the lithium benzoylmanganate **1** with TMEDA and acetyl bromide gave the thermolabile acetoxy carbene complex **2** as described previously.[5] The reaction of **2** with partially protected carbohydrates that are unprotected either in the 6-position [1,2:3,4-di-*O*-isopropylidene-D-galactopyranose (**3a**)] or in the 1-position [2,3,4,6-tetra-*O*-acetyl-D-galactopyranose (**3b**) and 2,3,4,6-tetra-*O*-acetyl-D-glucopyranose (**3c**)] afforded the chiral-at-ligand dicarbonyl(cyclopentadienyl)[alkoxy(phenyl)carbene] complexes **4a**−**c** in 40−66% yield (Scheme 1). The complexes (*R*)- and (*S*)-**4d** were obtained from the reaction of **2** with the enantiomerically pure alcohols (*S*)- and (*R*)-1,2-*O*-isopropylideneglycerol, (*S*)- and (*R*)-**3d**.[7]

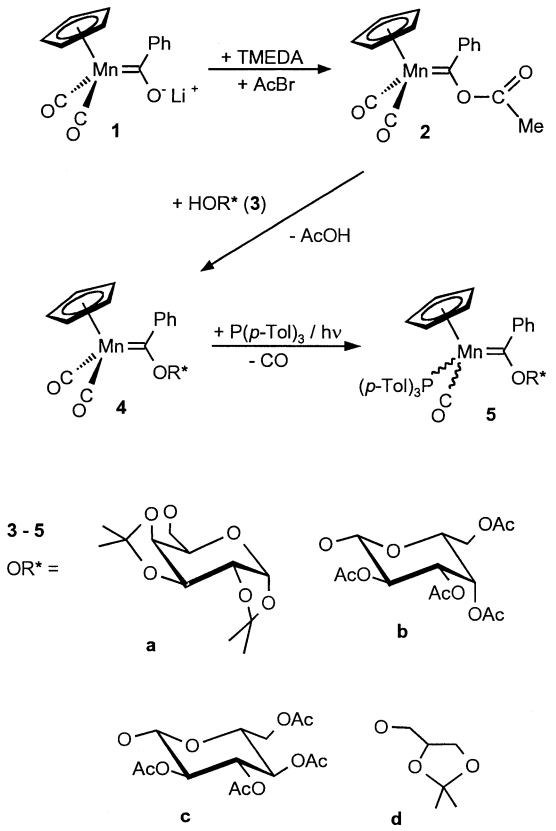
Scheme 1

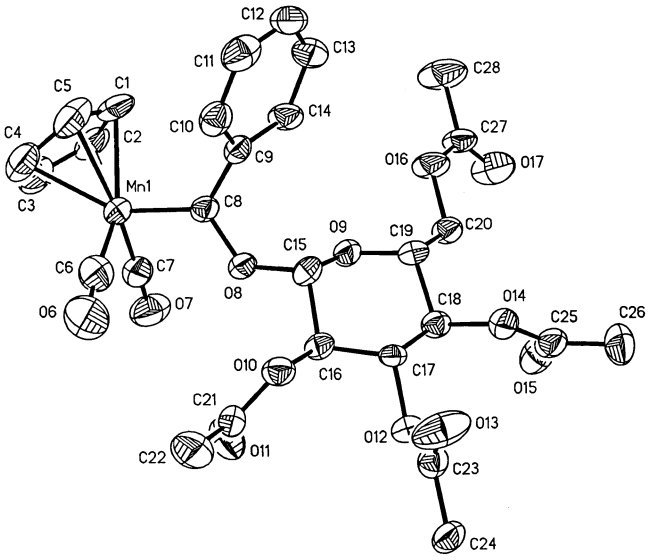


The NMR spectra of **4a**−**c** unambiguously show that the carbohydrato residue is bonded to the carbene carbon atom by the oxygen atom at C-6 (**4a**) or at C-1 (**4b**, **c**). The absence of a low-field resonance for the 1-H atom at the anomeric center in **4b** and **4c** indicates an β-configuration of the glucosyl and the galactosyl groups. This configuration was confirmed by the X-ray structural analysis of **4c** (Figure 1).

Complex **4c** exhibits a pseudo-octahedral geometry (Figure 1). The Mn−C(carbene) distance [1.857(7) Å] is comparable to that usually observed in CpL_2Mn(carbene) complexes.[4][8] The carbene ligand adopts the sterically least congested conformation. The carbene plane [C(8), Mn(1), C(9), O(8)] is slightly twisted with respect to the plane formed by the atoms C(7), Mn(1), and C(8) [torsion angle C(7)−Mn(1)−C(8)−O(8) −27.9(8)°] and strongly twisted with respect to the phenyl plane [torsion angle Mn(1)−C(8)−C(9)−C(10) 64.0(9)°].

In our earlier studies on the selectivity of the CO/PR_3 exchange in carbohydratocarbene complexes, the highest diastereoselectivity was observed for PR_3 = tri(*p*-tolyl)phosphane. Therefore, tri(*p*-tolyl)phosphane was also used in the initial studies with **4a**−**d**. Photolysis of the complexes **4a**−**d** in toluene at −30°C for several minutes in the presence of tritolylphosphane afforded the carbene complexes **5a**−**d** in moderate to high yield (Scheme 1). The compounds **5b** and **5c** are slightly photolabile. Partial decomposition had already occurred during irradiation, thus reducing the yield. Total transformation of the dicarbonyl complexes led to a low yield. Since the starting materials, complexes **4b** and **4c**, can be easily separated from the product complexes **5b** and **5c**, irradiation was terminated before **4b** and **4c** were completely consumed.

Figure 1. Structure of complex **4c** in the crystal (without H atoms)[a]



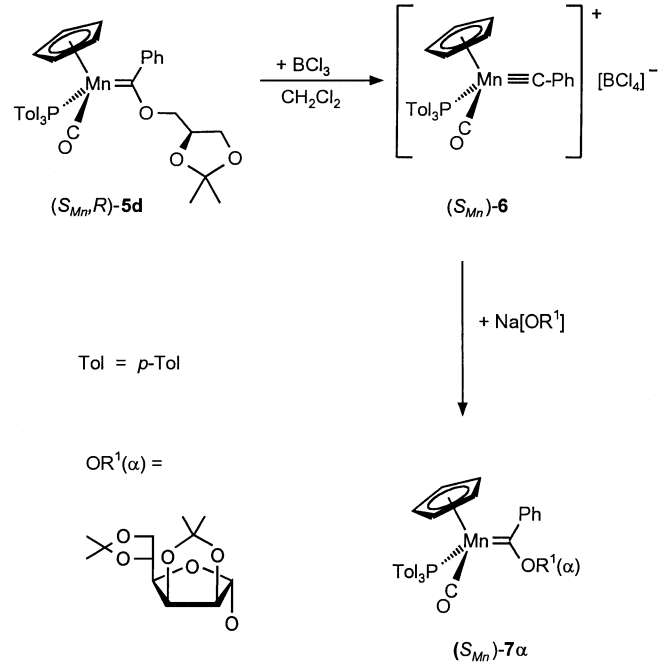
[a] Selected distances [Å] and angles [°] (standard deviations in parentheses): Mn(1)−C(6) 1.773(10), Mn(1)−C(7) 1.747(9), Mn(1)−C(8) 1.857(7), C(6)−O(6) 1.156(12), C(7)−O(7) 1.168(11), C(8)−O(8) 1.375(8); C(6)−Mn(1)−C(7) 89.4(4), C(6)−Mn(1)−C(8) 88.4(4), Mn(1)−C(8)−C(9) 124.8(5), Mn(1)−C(8)−O(8) 119.2(5), C(9)−C(8)−O(8) 116.0(6).

The ^{1}H-NMR signals of the cyclopentadienyl protons were easily detected and appeared as doublets due to coupling with the phosphorus atom. For **5a**−**c** two doublets were observed in each case: δ = 4.49, 4.53 ($^3J_{PH}$ = 1.82 Hz, 1.80 Hz; **5a**), 4.60, 4.63 ($^3J_{PH}$ = 1.79 Hz, 1.55 Hz; **5b**), and 4.64, 4.71 ($^3J_{PH}$ = 1.71 Hz, 1.45 Hz; **5c**). Therefore, the complexes **5a**−**c** were obtained as mixtures of diastereomers. The diastereomeric excess varied considerably. The diastereomeric excess, as determined by integration of the Cp resonances in the reaction mixtures, was 8% (**5a**), 33% (**5b**), and 70% (**5c**). In contrast to **5a**−**c**, each of the two glycerol derivatives (*R*)-**5d** and (*S*)-**5d** exhibit only one doublet for the cyclopentadienyl ring (δ = 4.45, $^3J_{PH}$ = 1.6 Hz). Similarly, only one ^{13}C-resonance signal for the Cp carbon atoms, and one ^{31}P signal for the tritolylphosphane ligand were detected for (*R*)-**5d** and (*S*)-**5d**. From these results a de of > 96% was deduced.

Complex (*R*)-**5d** was assigned the (S_{Mn}) configuration [(S_{Mn},*R*)-**5d**].[9] In order to corroborate the assignment, the complex was transformed into the known β-mannofuranosylcarbene complex (S_{Mn})-**7β**.[5] The structure of (S_{Mn})-**7β** has already been established by X-ray analysis.[5] Treatment of (S_{Mn},*R*)-**5d** with BCl_3 gave the chiral cationic carbyne complex (S_{Mn})-**6** by abstraction of [OR*]$^-$. Subsequent reaction with the sodium salt of an α,β mixture of 2,3:5,6-di-*O*-isopropylidene-D-mannofuranose Na[OR^1] afforded the α-mannofuranosylcarbene complex (S_{Mn})-**7α** (Scheme 2).

The identity of (S_{Mn})-**7α** was confirmed by comparison of its ^{1}H-NMR spectrum with that of an authentic sample.

Scheme 2



When the same reaction sequence was applied to (*S*)-**5d** the diastereomer (R_{Mn})-**7α** was obtained. Therefore, (*S*)-**5d** was assigned the (R_{Mn}) configuration.

The carbohydrate substituent clearly exerts considerable influence on the diastereoselectivity of the CO exchange reaction. From earlier experiments it followed that the photo-induced Mn−CO dissociation is the initiating and rate-limiting step of the substitution reaction. The range of diastereoselectivities observed can be rationalized by the different abilities of the OR* groups to intramolecularly stabilize the diastereomeric intermediates. It is very likely that an oxygen atom of the OR* substituent coordinates to the vacant coordination site of the intermediate resulting from loss of a CO ligand.

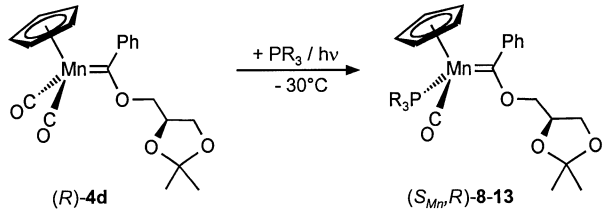
In the synthesis of complex **5a** the coordinating oxygen atom in the intermediate is presumably the pyranosyl oxygen atom, giving rise to the formation of a six-membered metallaheterocycle. However, due to the anomeric effect the pyranosyl oxygen atom is relatively electron-poor. Therefore, the coordination is weak and, consequently, the diastereomeric excess is only 8%.

The intermediate in the synthesis of **5b** and **5c** can be stabilized by interaction with either the carbonyl oxygen atom of the acetate group at C-2 (formation of an eight-membered metallacycle) or with the pyranosyl oxygen atom (formation of a five-membered metallacycle). The reactions of tri(*p*-tolyl)phosphane with tetramethyl- and tetrabenzyl-protected gluco- and galactopyranosylcarbene complexes instead of **4b** and **4c** gave diastereoselectivities similar to those of **4b** and **4c**.[10] Therefore, the formation of an eight-membered metallacycle by interaction of manganese with the carbonyl oxygen atom of the acetate group at C-2 in the intermediate is unlikely. The difference in the de values is probably caused by steric interaction of the acetoxy substituent at C-4 with the cyclopentadienyl ring.

The significantly higher diastereoselectivity in the reaction of (*R*)-**4d** and (*S*)-**4d** with $PTol_3$, as compared to that of **4a**−**c**, is probably due to the higher flexibility of the isopropylideneglycerol substituent in forming the most stable metallacyclic intermediate.

In contrast to furanosyl- and pyranosylcarbene complexes, the high diastereoselectivity of the PR_3/CO exchange is not confined to tritolylphosphane as the entering nucleophile. Within the limits of error, the replacement of CO by $P(OPh)_3$, $P(OMe)_3$, $P(OMe)_2Ph$, $P(OMe)Ph_2$, PPh_3, and $P(C_6H_4Cl\text{-}p)_3$ in (*R*)-**4d** also proceeded diastereospecifically (de > 96%) to afford (S_{Mn},*R*)-**8**−**13** (Scheme 3).

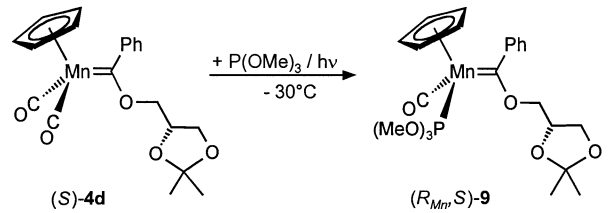
Scheme 3



PR_3	$P(OPh)_3$	$P(OMe)_3$	$P(OMe)_2Ph$	$P(OMe)Ph_2$	PPh_3	$P(C_6H_4Cl\text{-}p)_3$
	8	**9**	**10**	**11**	**12**	**13**

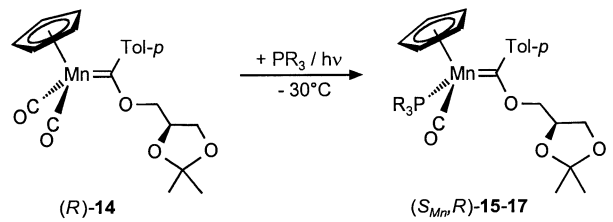
Analogously, the photolysis of (*S*)-**4d** in the presence of $P(OMe)_3$ gave (R_{Mn},*S*)-**9** (Scheme 4).

Scheme 4



The reaction of (*R*)-**14** with PR_3 afforded the complexes (S_{Mn},*R*)-**15**−**17** (Scheme 5) with a de > 96%. Complex (*R*)-**14** was prepared from [$Cp(CO)_2Mn$=C(OAc)Tol-*p*] and (*S*)-**3d**[7] in an analogous way to (*R*)-**4d**.

Scheme 5



R = Tol-*p* (**15**), OMe (**16**), C_6H_4Cl-*p* (**17**)

In contrast, photolysis of [Cp(CO)$_2$Mn=C(β-*O*-mannofuranosyl)Tol-*p*] in the presence of phosphites or phosphanes gave much lower de values [PR_3 = $P(OPh)_3$ (0%), $P(OMe)_3$ (12%), $P(C_6H_4Cl\text{-}p)_3$ (56%)].

All NMR spectra of the complexes **8**−**17** showed the expected resonances to confirm the formation of only one diastereomer in each case. However, the 600-MHz NMR spectra of these complexes indicated the presence of two isomers in solution. Most of the complexes exhibited two sets of ^{1}H- and ^{13}C-resonance signals for the diastereotopic methyl groups of the isopropylidene function [$\Delta\delta(^1H)$ = 0.01−0.03 ppm, $\Delta\delta(^{13}C)$ = 0.1 ppm; see Experimental Section]. For complex **8** two doublets for the carbonyl and the carbene carbon atom [$\Delta\delta(^{13}C)$ = 0.2 ppm] were observed, and for the complexes **8** and **10**−**12** two ^{31}P signals [$\Delta\delta(^{31}P)$ = 0.2 ppm] were detected.

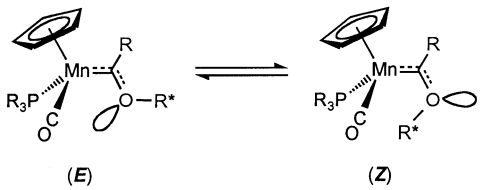
Both isomers are in equilibrium, as shown by variable-temperature NMR spectroscopy. Complex (S_{Mn},*R*)-**5d** exhibits two sets of resonance signals for the diastereotopic methyl groups. The ratio of the two sets at room temperature was 1:1. When the solution was cooled the ratio was 5:1 (at −23°C) and > 20:1 (at −43°C). Warming the solution to ambient temperature restored the original 1:1 ratio.

In order to determine whether or not the splitting of the signals indicated the presence of a mixture of diastereomers, a diastereomeric mixture of (S_{Mn},*R*)-**5d** and (S_{Mn},*S*)-**5d** was prepared from (S_{Mn})-**6** and a mixture of the sodium salts of 1,2-(*S*)- and 1,2-(*R*)-*O*-isoproylidene gycerol [(*S*)- and (*R*)-**3d**]. For (S_{Mn},*R*)-/(S_{Mn},*S*)-**5d** the shift difference between the ^{31}P signals was $\Delta\delta(^{31}P)$ = 1.9 ppm, and this value is approximately 10 times larger than that observed with **8** and **10**−**12**. Therefore, the splitting of the signals cannot be due to a mixture of diastereomers.

Hindered rotation around (a) the C(carbene)−aryl bond, (b) the Mn=C(carbene) bond, and (c) the C(carbene)−O bond may account for the splitting of signals. Complex (S_{Mn},*R*)-**15** exhibits a simple A_2B_2 pattern for the C(carbene)−C_6H_4Me hydrogen atoms. Therefore, option (a) can be ruled out. Barriers to rotation around the C(carbene)−C(aryl) bonds in neutral aryl-substituted, heteroatom-stabilized carbene complexes are usually very low.[11] However, substantial barriers were observed in cationic benzylidene complexes of iron and ruthenium, [Cp(CO)$_2$M=C(C_6H_4R)H]$^+$ and [Cp(CO)(PPh_3)M=C(C_6H_4R)H]$^+$ (M = Fe, Ru; R = H, F, Me, OMe: $\Delta G^{\neq}$ = 9.0−14.5 kcal/mol).[12]

The two remaining possibilities, (b) and (c), have been observed in various carbene complexes.[13][14] The bonding situation in [Cp(CO)$_2$Mn=C(OMe)Ph] and [Cp(CO)$_2$Mn=CMe_2] has also been analyzed theoretically.[15] The splitting of the Cp resonance signal in [Cp(CO)(PPh_3)Mn=C(OMe)-Ph] at low temperature (below −90°C) was attributed by Geoffroy et al. to a hindered rotation around the Mn=C(carbene) bond. An activation barrier of $\Delta G^{\neq}$ = 9.8 kcal/mol was calculated.[8a] However, for the complexes (S_{Mn},*R*)-/(R_{Mn},*S*)-**5d** and (S_{Mn},*R*)-**8**−**17** we consider hindered rotation around the C(carbene)−O bond [(*E*)/(*Z*) isomerization with respect to the C−O partial double bond, see Scheme 6] to be a preferable explanation for the NMR-spectroscopic observations since a splitting of signals was not observed with either the corresponding mannofuranosylcarbene or the gluco- and galactopyranosylcarbene complexes. The bulkiness of the OR* substituents in these complexes presumably disfavors the (*Z*) conformation. The strong temperature dependence of the equilibrium constant also agrees well with (*E*)/(*Z*) isomerism.

Scheme 6



Similarly, two sets of ^{13}C- and ^{31}P-NMR signals were reported for the alkoxy(amino)carbene complexes of platinum *cis*-[$Cl_2(PPh_3)$Pt=C(NHR′)OR″] (R′ = Me, Et; R″ = 1,2,3,4-tetra-*O*-deoxy-β-D-glucosyl) and these were explained in terms of hindered rotation around the carbene carbon−heteroatom bond.[2c]

Epimerization studies were carried out with the $PTol_3$- and the $P(OMe)_3$-substituted complexes (S_{Mn},*R*)-**5d** and (S_{Mn},*R*)-**9**. In pentane and CH_2Cl_2, (S_{Mn},*R*)-**5d** was configurationally stable for at least 96 hours at room temperature. However, in neat $P(OMe)_3$ substitution of the coordinated $PTol_3$ by $P(OMe)_3$ was observed. The substitution presumably proceeds by an associative mechanism. An associative mechanism has also been suggested for the substitution of PPh_3 by $PTol_3$ in the related complex [Cp(CO)(PPh_3)Mn=C(OMe)Et]. The reaction rate was observed to increase with increasing $PTol_3$ concentration.[8a]

The $P(OMe)_3$-substituted complex (S_{Mn},*R*)-**9** was stable in pentane or acetone, but slowly epimerized in dichloromethane, diethyl ether, and tetrahydrofuran. The (S_{Mn},*R*)-/(R_{Mn},*R*)-**9** ratio after 96 hours at room temperature was 4.4 (CH_2Cl_2), 2.76 (Et_2O), and 4.8 (THF). The epimerization rate was enhanced by exposure to daylight. After 96 hours at room temperature in the dark, the (S_{Mn},*R*)-/(R_{Mn},*R*)-**9** ratio was only 6.5 as opposed to 2.76 when exposed to light. The epimerization is very likely to proceed by dissociation and readdition of $P(OMe)_3$. Consequently, when $P(OCD_3)_3$ was added to a solution of (S_{Mn},*R*)-**9** in Et_2O the (S_{Mn},*R*)-/(R_{Mn},*R*)-**9** ratio after 96 hours was within the limits of error, and was the same as that in the absence of uncoordinated phosphite. In addition, $P(OCD_3)_3$ was incorporated into the complex.

In contrast to our results with carbene complexes, the phosphite-substituted benzoyl complex [Cp(NO){$P(OEt)_3$}-Mn−C(O)Ph] is configurationally stable[16] whereas the PPh_3-substituted acyl complexes [Cp(NO)(PPh_3)-Mn−C(O)C_6H_4R] racemize in toluene (half-life for R = H: 21 minutes at 25°C). A dissociative mechanism was deduced from kinetic studies.[17][18] A linear relationship between the Hammett σ constants of the *para* substituents and the rates of racemization was observed. However, the

steric effect seemed to be the most important factor in determining the configurational stability of the complexes.[1b] The higher configurational stability of (S_{Mn},*R*)-**5d** as compared to phosphite-substituted complex (S_{Mn},*R*)-**9** is probably due to the stronger Mn−P bond in the phosphane complex.

Our results demonstrate that diastereomerically pure carbene(phosphane) and -(phosphite) complexes of manganese are readily available through PR_3/CO exchange in chiral [Cp(CO)$_2$Mn=C(OR*)R′] complexes. Both configurations at manganese [(R_{Mn}) and (S_{Mn})] are accessible by choosing either an (*S*)- or an (*R*)-glycerol derivative as the chiral auxiliary. The carbene(phosphane) complexes are configurationally stable. Reaction of these complexes with Lewis acids gives a convenient method for the preparation of enantiomerically pure chiral-at-metal [Cp(CO)LMn(carbyne)]$^+$ complexes (see Scheme 2). The configuration at the manganese atom does not change on addition of nucleophiles to the carbyne carbon atom in these complexes [e. g. (S_{Mn})-**6**], meaning that a large number of enantiomerically pure carbene complexes is readily accessible. Finally, oxidative decomplexation of the carbene ligand and addition of other nucleophiles (L′) should now offer a simple route to other chiral complexes of manganese [Cp(CO)(PR_3)MnL′].

Support of this work by the *Fonds der Chemischen Industrie* is gratefully ackowledged.

Experimental Section

All operations were carried out under either nitrogen or argon by using conventional Schlenk techniques. Solvents were dried by refluxing over sodium/benzophenone ketyl or CaH_2 and were freshly distilled prior to use. The silica gel used for chromatography (J. T. Baker, silica gel for flash chromatography) was saturated with argon. The yields refer to analytically pure compounds and were not optimized. The complexes **1**[19] and **2**,[5] the carbohydrates 2,3,4,6-tetra-*O*-acetyl-D-glucopyranose and 2,3,4,6-tetra-*O*-acetyl-D-galactopyranose,[20][21] 1,2:3,4-di-*O*-isopropylidene-D-galactopyranose[22] as well as $PTol_3$ and tris(*p*-chlorophenyl)phosphane[23] were prepared according to literature procedures. $PPh(OMe)_2$ and $PPh_2(OMe)$ were purchased from Strem Chemicals, Inc. $P(OPh)_3$ was obtained from Janssen, TMEDA from Merck. $P(OMe)_3$ and acetyl bromide were purchased from Fluka. − IR: FT-IR spectrophotometer, Bio.-Rad. − ^{1}H NMR, ^{31}P NMR, and ^{13}C NMR: Bruker WM 250, Bruker AC 250, Bruker DRX 600, Jeol JNX 400. Unless specifically mentioned, ^{1}H-NMR spectra were recorded at 250 MHz and ^{13}C- and ^{31}P-NMR spectra at 400 MHz. All spectra were recorded in [D$_6$]acetone at room temp. Chemical shifts are reported relative to the residual solvent peaks [^{1}H: δ(H) = 2.05 and ^{13}C: δ(*C*H$_3$) = 29.8] or to external H_3PO_4 (^{31}P). − MS: Finnigan MAT 312 (EI) or Finnigan MAT 312/AMD5000 (FAB).

General Procedure for the Synthesis of the Complexes **4a**−**c**, (*R*)-**4d**, (*S*)-**4d** *and* (*R*)-**14**: 4.5 mmol of the corresponding carbohydrate or glycerol derivative was added at −50°C to a solution of **2** or its tolylcarbene analogue, prepared from 3.0 mmol of acetyl bromide and 3.0 mmol of **1** or Li[Cp(CO)$_2$Mn−C(=O)Tol-*p*], respectively, in 50 ml of CH_2Cl_2. The resulting solution was stirred for 0.5 h at −50°C, warmed to 0°C and stirred for a further 4.5 h at 0°C. The solvent was removed in vacuo at room temp. The dark brown residue was dissolved in CH_2Cl_2/pentane {6:1 (**4a**), 2:1 (**4b**), 8:3 (**4c**), 2:1 [(*R*)- and (*S*)-**4d**, (*R*)-**14**]} and chromatographed at −20°C on silica gel with mixtures of CH_2Cl_2, pentane and ether (see below for ratios).

General Procedure for the Synthesis of the Complexes **5a**−**d**, **8**−**13**, *and* **15**−**17**: A solution of 0.6 mmol of **4a**−**d** or **14**, and 0.9 mmol of the corresponding PR_3 in 30 ml of toluene was irradiated (see below for duration) at −30°C while passing a slow stream of argon through the solution. The solvent was removed in vacuo at room temp. The residue was dissolved in CH_2Cl_2/pentane (see below for ratio) and chromatographed at −20°C on silia gel.

Dicarbonyl(cyclopentadienyl)[(1:2,3:4-di-O-isopropylidene-D-galactopyranos-6-yloxy)phenylcarbene]manganese (**4a**): Chromatography with CH_2Cl_2/pentane (6:1) afforded a yellow band (30 mg) and then elution with CH_2Cl_2/pentane/Et_2O (6:1:0.5) gave a dark red band. Removal of the solvent from the dark red fraction afforded complex **4a** as a sticky brown oil. Yield: 1.47 g (66%, based on **2**). − IR (CH_2Cl_2): ν(CO) = 1959 cm^{-1} vs, 1888 s. − ^{1}H NMR: δ = 1.30, 1.32, 1.34, 1.52 (4 × s, 3 H each, Me), 4.10−4.69 (m, 6 H, 2-H, 3-H, 4-H, 5-H, CH_2), 4.78 (s, 5 H, Cp), 5.46−5.53 (m, 1 H, 1-H), 7.02−7.06 (m, 2 H, Ph), 7.27−7.39 (m, 3 H, Ph). − ^{13}C NMR: δ = 24.7, 25.1, 26.3, 26.4 (Me), 67.8 (C-6), 71.3 (C-4), 71.6 (C-2), 71.8 (C-5), 75.5 (C-3), 87.9 (Cp), 97.1 (C-1), 109.2, 109.9 (*C*Me$_2$), 123.7, 128.2, 154.9 (Ph), 232.7, 232.9 (2 × CO), 334.3 (Mn=C). − MS (EI, 70 eV): *m*/*z* (%) = 524 (8) [M$^+$], 509 (5) [M$^+$ − Me], 468 (100) [M$^+$ − 2 CO], 120 (26) [CpMn$^+$]. − $C_{26}H_{29}MnO_8$·1/5 pentane (538.6): calcd. C 60.18, H 5.87; found C 60.21, H 5.77.

Dicarbonyl(cyclopentadienyl)[(2,3,4,6-tetra-O-acetyl-β-D-galactopyranosyloxy)phenylcarbene]manganese (**4b**): Chromatography with CH_2Cl_2/pentane (7:3) gave a yellow band (60 mg). Subsequent elution with CH_2Cl_2/pentane/Et_2O (7:3:1) first gave a dark red and then an orange band. Removal of the solvent of the orange fraction afforded complex **4b** as an orange oil. Crystallization from 75 ml of CH_2Cl_2/pentane (2:1) gave an orange powder. Yield: 730 mg (40%, based on **2**), m.p. 68°C (dec.). − IR (CH_2Cl_2): ν(CO) = 1971 cm^{-1} vs, 1903 s. − ^{1}H NMR: δ = 1.92, 2.03, 2.08, 2.16 (4 × s, 3 H each, Me), 4.05−4.18 (m, 3 H, H-5, CH_2), 4.83 (s, 5 H, Cp), 5.19−5.24 (m, 1 H, 3-H), 5.37−5.38 (m, 1 H, H-4), 5.43−5.46 (m, 1 H, 1-H), 5.52−5.63 (m, 1 H, 2-H), 7.04−7.07 (m, 2 H, Ph), 7.30−7.39 (m, 3 H, Ph). − ^{13}C NMR: δ = 20.4, 20.5, 20.6 (Me), 62.3 (C-6), 68.0 (C-4), 69.4 (C-2), 71.3 (C-5), 72.3 (C-3), 88.5 (Cp), 99.1 (C-1), 124.2, 128.2, 129.6, 153.9 (Ph), 169.7, 170.0, 170.4, 170.6 (*C*OMe), 231.3, 232.5 (2 CO), 334.2 (Mn=C). − MS (EI, 70 eV): *m*/*z* (%) = 612 (0.5) [M$^+$], 556 (0.4) [M$^+$ − 2 CO], 331 (40) [OR*$^+$ − OH], 225 (9) [CpMnC(Ph)O$^+$], 55 (58) [Mn$^+$]. − $C_{28}H_{29}MnO_{12}$ (612.1): calcd. C 54.91, H 4.77; found C 55.02, H 4.99.

Dicarbonyl(cyclopentadienyl)[(2,3,4,6-tetra-O-acetyl-β-D-glucopyranosyloxy)phenylcarbene]manganese (**4c**): Chromatography with CH_2Cl_2/pentane (8:3) gave a yellow band (200 mg), and then elution with CH_2Cl_2/pentane/Et_2O (8:3:1) gave first a brown and then an orange band. The orange band afforded **4c** as an orange powder. Recrystallization from 7 ml of CH_2Cl_2 gave **4c** as light orange plates. Yield: 910 mg (46%, based on **2**), m.p. 130°C (dec.). − IR (CH_2Cl_2): ν(CO) = 1972 cm^{-1} vs, 1905 s. − ^{1}H NMR: δ = 1.95, 1.97, 2.03, 2.07 (4 × s, 3 H each, Me), 3.71−3.78 (m, 1 H, 5-H), 4.05−4.24 (m, 2 H, CH_2), 4.83 (s, 5 H, Cp), 5.08−5.39 (m, 4 H, 1-H, 2-H, 3-H, 4-H), 7.32−7.35 (m, 2 H, Ph), 7.38−7.44 (m, 3 H, Ph). − ^{13}C NMR: δ = 20.4 (4 Me), 62.5 (C-6), 68.9 (C-4), 71.8 (C-2), 72.9 (C-5), 73.1 (C-3), 88.6 (Cp), 98.8 (C-1), 124.2, 128.1, 128.5, 153.5 (Ph), 169.6, 169.9, 170.2, 170.6 (4 *C*OMe), 231.4, 232.3 (2 CO), 333.8 (Mn=C). − MS (70 eV): *m*/*z* (%) = 612 (2) [M$^+$], 556 (0.4) [M$^+$ − 2 CO], 331 (66) [OR*$^+$ − OH], 271 (6) [OR*$^+$ − OH

X-ray Structural Analysis of **4c**: $C_{28}H_{31}MnO_{12}·CH_2Cl_2·CH_4O$, molecular mass 731.4, crystal size 0.3 × 0.3 × 0.3 mm (obtained by slow diffusion of pentane into a solution of **4c** in CH_2Cl_2/methanol); monoclinic crystal system, space group C_2, *a* = 16.793(4), *b* = 12.929(3), *c* = 16.992(4) Å, β = 109.63(1)°; *V* = 3476.6(14) Å^3, *Z* = 4, $d_{calcd.}$ = 1.397 g cm^{-3}; μ (Mo-K_α) = 0.577 mm^{-1}, *F*(000) = 1520. Wyckoff scan, 2θ range 4−54°, scan speed variable 2.0−30.0° min^{-1} in ω. 4117 independent reflections with 3978 [$F > 3\sigma(F)$]. Data were collected at −31°C with the crystal mounted in a glass capillary on a Siemens P4 diffractometer (graphite monochromator, Mo-K_α radiation, λ = 0.71073 Å). The structure was solved (Patterson methods) and refined by using the SHELXTL

PLUS (VMS) program package. 397 parameters refined, $R = 0.068$, $Rw = 0.065$. Largest difference peak (hole) +0.60 eÅ^{-3} (−0.50 eÅ^{-3}). The positions of the hydrogen atoms were calculated by assuming ideal geometry ($d_{C-H} = 0.96$ Å) and their coordinates were refined together with the attached C atoms as a "riding model". The dichloromethane was disordered and was isotropically refined in two different positions assuming equal occupation. Methanol was also isotropically refined. The positions of all other atoms were refined anisotropically by full-matrix least-squares methods. Complete lists of atomic coordinates and thermal parameters were deposited.[24]

[7] Although the stereogenic center is not involved in the substitution of the alcoholates in **3d** and **3e** for the acetoxy group in **2** its designation changes. That is because the reaction of the (*S*)-glycerol **3d** gives the (2*R*)-2,3-dihydroxypropyloxycarbene complex **4d**. This is due to a change in the priority of the different groups at the stereogenic center.

Keywords: Rhodium / Phosphanes / Ligand redistribution / Dichloromethane activation / Oxidative addition

Dichloromethane reacts with dinuclear rhodium complexes [{(PR$_3$)$_2$Rh}$_2$(μ-Cl)$_2$] to give the bridging-methylene complexes [{(PR$_3$)$_2$RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] (PR$_3$ = PEt$_3$, PPh$_2$Me). The structure of the PEt$_3$ complex has been established by X-ray diffraction study. The early stages of the reaction of [{(C$_8$H$_{14}$)$_2$Rh}$_2$(μ-Cl)$_2$] with monophosphanes have been monitored by ^{31}P NMR, evidencing chloride bridges cleavage and phosphane redistribution processes.

Activation of dihalomethanes by low oxidation state transition metal complexes has attracted a great deal of interest as a means of generating haloalkyl transition metal derivatives which are versatile precursors for a wide range of useful compounds[1]. Oxidative addition of diiodo and dibromomethane is well documented, and, although less common, the case of dichloromethane is now well recognized.

Several examples of simple oxidative addition of dichloromethane (CH_2Cl_2) to electron-rich Rh^I complexes of mono or polydentate phosphorus[2][3], nitrogen[4][5][6], sulfur[7], and phosphorus/nitrogen[8][9] ligands have been reported. They usually afford chloromethylrhodium(III) complexes.

However, we found only two examples of double oxidative addition of CH_2Cl_2 on binuclear Rh^I complexes[10][11]. The chloride-bridged rhodium(I) dimer [{(dppe)Rh}$_2$(μ-Cl)$_2$] [dppe = 1,2-bis(diphenylphosphanyl)ethane] has been reported to react with CH_2Cl_2 to generate a bridging-methylene rhodium(III) complex (eq. 1)[10].

$$[\{(dppe)Rh\}_2(\mu\text{-}Cl)_2] + CH_2Cl_2 \xrightarrow{25°C,\ 36h} [\{(dppe)RhCl\}_2(\mu\text{-}Cl)_2(\mu\text{-}CH_2)] \quad (1)$$

The other example concerns the oxidative addition of *gem*-dichlorocarbons on the binuclear basic complex [{Rh(μ-pz)(CN*t*Bu)$_2$}$_2$] (pz = pyrazolate) to give [{Rh(μ-pz)Cl(CN*t*Bu)$_2$}$_2$(μ-CHR)][11].

In this paper, we report that activation of CH_2Cl_2 to generate methylene-bridged dimers is not limited to dinuclear Rh^I complexes and to Rh^I complexes bearing chelating diphosphanes, and can be obtained from both mononuclear and dinuclear monophosphane rhodium(I) complexes. Furthermore, some insight is given on the intermediates involved in the reaction of monophosphanes with the chloro-bridged dimer [{(C$_8$H$_{14}$)$_2$Rh}$_2$(μ-Cl)$_2$], **1** (C$_8$H$_{14}$ = cyclooctene).

As part of our work on the synthesis of amidorhodium complexes, we have been led to prepare the dimer [{(PEt$_3$)$_2$Rh}$_2$(μ-Cl)$_2$], **2**[12][13]. Compound **2** is prepared in pure form [^{31}P{^{1}H} NMR, δ (THF) = 44.3, $J_{P\text{-}Rh}$ = 194 Hz] by treating 4 equivalents of PEt$_3$ with **1** in THF. It can also be prepared in CH_2Cl_2 by reacting the starting materials for 10 min, followed by immediate evaporation of the solvent. Incidentally, we observed that if the reaction time in CH_2Cl_2 is longer than 10 min, a second complex is formed [^{31}P{^{1}H} NMR, δ (CH_2Cl_2) = 31.1, $J_{P\text{-}Rh}$ = 147 Hz] which becomes the only reaction product after 2 h. This new complex was isolated by precipitation with THF. Apart from the expected signals for the triethylphosphane ligands, the ^{1}H-NMR spectrum exhibits a broad signal at δ = 3.7, which becomes sharper on phosphorus decoupling, and the ^{13}C{^{1}H,^{31}P} NMR spectrum shows a triplet at δ = 38.9 ($J_{C\text{-}Rh}$ = 22 Hz, see Experimental Section). These signals could correspond to the methylene bridge of a dinuclear Rh^{III} complex, as suggested by the relatively small $J_{P\text{-}Rh}$ coupling constant. This complex was definitely identified as the methylene-bridged dinuclear complex [{(PEt$_3$)$_2$RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] **3** by single crystal X-ray diffraction analysis.

The molecular structure, which has a 2-fold symmetry, is shown in Figure 1. The binuclear structure is built up by two rhodium centers joined by two chloride ligands and a bridging methylene unit the carbon of which is located on the 2-fold axis. This structure is very similar to that of the recently reported [{(dppe)RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] complex[10]. As in the dppe compound, each rhodium center has a symmetrical, quasi-octahedral environment and formally can be considered as Rh^{III}. A comparison of important bond distances and bond angles within the

P(1)−Rh(1)−P(2)	95.51(2)	84.72(3)
Cl(1)−Rh(1)−C(1)	81.95(4)	80.70(7)
Cl(1′)−Rh(1)−C(1)	81.55(4)	80.29(7)
Cl(2)−Rh(1)−C(1)	166.99(5)	172.0(1)
P(1)−Rh(1)−C(1)	98.04(4)	96.62(8)
P(2)−Rh(1)−C(1)	92.42(3)	100.02(7)
Rh(1)−Cl(1)−Rh(1′)	75.58(1)	76.20(2)
Rh(1)−C(1) −Rh(1′)	93.7(1)	95.2(2)

The main differences are observed for the angles around the metal atom. They are certainly related to the larger strain resulting from the chelating coordination of the dppe ligand, as is clearly shown by the P(1)−Rh(1)−P(2) angle which varies from 95.51° in the triethylphosphane complex to 84.72° in the dppe one.

This results (eq. 2) shows that the activation of CH_2Cl_2 by a chloride-bridged rhodium(I) dimer discovered by Fryzuk et al. (eq. 1) is not limited to the case of rhodium(I) complexes with chelating diphosphanes[10].

$$[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2] \;\xrightarrow[\text{RT, 2h}]{CH_2Cl_2}\; [\{(PEt_3)_2RhCl\}_2(\mu\text{-}Cl)_2(\mu\text{-}CH_2)] \quad (2)$$

2 → **3**

More surprisingly, the same methylene-bridged dinuclear rhodium complex **3** is formed as the major product by reaction of the mononuclear complex $[(Et_3P)_3RhCl]$ with CH_2Cl_2 for 24 h at room temperature. On the basis of ^{31}P-NMR analysis, some others unidentified (phosphane)rhodium complexes are also formed in small amounts.

$$[(PEt_3)_3RhCl] \;\xrightarrow[\text{RT, 24 h}]{CH_2Cl_2}\; [\{(PEt_3)_2RhCl\}_2(\mu\text{-}Cl)_2(\mu\text{-}CH_2)] + \ldots \quad (3)$$

3

This result (eq. 3) is somewhat surprising in view of the reaction described by Milstein et al. in the case of PMe_3 (eq. 4)[2].

$$[(PMe_3)_3RhCl] + CH_2Cl_2 \xrightarrow{C_6H_6} \begin{matrix}[(PMe_3)_3RhCl_2(CH_2Cl)] \\ + \\ [(PMe_3)_2RhCl_3(CH_2PMe_3)]\end{matrix} \xrightarrow{\Delta} X \quad (4)$$

Indeed PEt_3 and PMe_3 have similar electronic properties (pK_a 8.69 vs 8.65) and differ by their cone angles, only (132° vs 118°)[14]. Nevertheless, this reaction may occur via displacement of an equilibrium between $[(PEt_3)_3RhCl]$ and $[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2]$, a well-known process in the case of $[(PPh_3)_3RhCl]$[15]. The different behaviour of $[(PMe_3)_3RhCl]$ may be merely ascribed to the unfavorable dissociation of the smaller phosphane.

In the course of our study of the reaction of PEt_3 (4 equiv.) with $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ **1**, we made another interesting observation. Indeed, according to literature data[16][17][18], e.g. in the case of Ph_2PMe[18], this reaction was believed to occur by stepwise replacement of the cyclooctene ligands, without cleavage of the chloride bridges, to ultimately yield $[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2]$ (**2**). We surprisingly observed that, after a few min at room temp. in dichloromethane, the very major phosphane complex is $[(PEt_3)_3RhCl]$. The reaction rapidly evolves to generate the chloride-bridged dimer **2**, together with the bridging-methylene one **3** which is the only product after 1 h. The observation of $[(PEt_3)_3RhCl]$ as the only phosphane complex (no free PEt_3) at the early stage of the reaction implies the presence of unreacted **1** and suggests a subsequent redistribution of the phosphane ligands. This was demonstrated independently by reacting $[(PEt_3)_3RhCl]$ (4 equiv.) with **1** (1 equiv.) in THF, affording quantitatively $[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2]$ (^{31}P NMR) (eq. 5).

$$4[(PEt_3)_3RhCl] + \underset{\mathbf{1}}{[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]} \xrightarrow[10\ min]{THF} 3\underset{\mathbf{2}}{[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2]} \quad (5)$$

The above results led us to reinvestigate the previously reported reaction of PPh_2Me (4 equiv.) with **1**[18] by ^{31}P-NMR monitoring at the early stage of the reaction at room temperature. In THF, the reaction is very fast. Within 5 min the main reaction product is $[\{(PPh_2Me)_2Rh\}_2(\mu\text{-}Cl)_2]$ and only traces of other complexes {among which $[(PPh_2Me)_3RhCl]$} are observable. In CH_2Cl_2, however, a mixture of 5 complexes is observed after 5−10 min. The major product is $[(PPh_2Me)_3RhCl]$ (^{31}P NMR: δ = 31.8, dt, $J_{P\text{-}Rh}$ = 187 Hz, $J_{P\text{-}P}$ = 42 Hz and δ = 16.5, dd, $J_{P\text{-}Rh}$ = 139 Hz, $J_{P\text{-}P}$ = 42 Hz). Among the four others complexes, only two could be identified. On the basis of literature data[18], one is $[\{(PPh_2Me)(C_8H_{14})Rh\}_2(\mu\text{-}Cl)_2]$ (^{31}P NMR δ = 40.4, $J_{P\text{-}Rh}$ = 187 Hz) while the other is the expected $[\{(PPh_2Me)_2Rh\}_2(\mu\text{-}Cl)_2]$ (^{31}P NMR: δ = 34.0, $J_{P\text{-}Rh}$ = 196 Hz). Among the two other minor complexes, one gives a broad doublet (^{31}P NMR: δ = 32.8, $J_{P\text{-}Rh}$ = 194.5 Hz) and the second a spin figure which resembles that of a tris(phosphane)rhodium(I) complex (^{31}P NMR: δ = 22.8, dt, $J_{P\text{-}Rh}$ = 150 Hz, $J_{P\text{-}P}$ = 24 Hz anf δ = 10.6, dd, $J_{P\text{-}Rh}$ = 96 Hz, $J_{P\text{-}P}$ = 24 Hz). After 20 min, all the above signals have evolved to leave those of the dinuclear complex $[\{(PPh_2Me)_2Rh\}_2(\mu\text{-}Cl)_2]$, exclusively. Then this signal progressively vanishes to cleanly leave a doublet (^{31}P NMR: δ = 17.7, $J_{P\text{-}Rh}$ = 148 Hz) attributed to the methylene-bridged $[\{(PPh_2Me)_2RhCl\}_2(\mu\text{-}Cl)_2(\mu\text{-}CH_2)]$ (**4**) which can be readily isolated. This CH_2Cl_2 activation appears to be slower than in the case of $[\{(PEt_3)_2Rh\}_2(\mu\text{-}Cl)_2]$, probably as a consequence of the lower electron-donating ability of PPh_2Me (pK_a = 4.57) as compared to that of PEt_3[14].

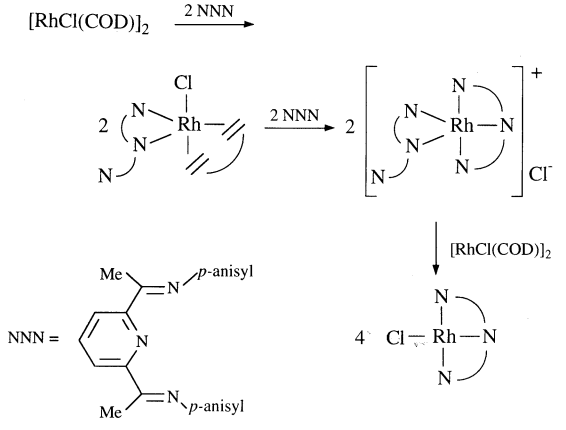
It is thus clear that when $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ **1** is treated with 4 equivalents of PR_3 (either PEt_3 or PPh_2Me), cleavage of chloride bridges occurs, followed by phosphane redistribution, affording the dinuclear complexes $[\{(PR_3)_2Rh\}_2(\mu\text{-}Cl)_2]$. In both cases, these complexes activate CH_2Cl_2 to give the methylene-bridged complexes $[\{(PR_3)_2RhCl\}_2(\mu\text{-}Cl)_2(\mu\text{-}CH_2)]$.

As a complement, we also studied the reaction of **1** with only 2 equivalents of either PEt_3 or PPh_2Me, again by ^{31}P-NMR monitoring at the early stage of the reaction at room temperature. Indeed, the authors who previously reported on the reaction with PPh_2Me indicated that the NMR spectra were recorded several hours after mixing the reactants[18].

In both cases, after 5−10 min mixing the reactants in THF at room temperature, the tetrasubstituted $[\{(PR_3)_2Rh\}_2(\mu\text{-}Cl)_2]$ and the disubstituted $[\{(C_8H_{14})(PR_3)Rh\}_2(\mu\text{-}Cl)_2]$ complexes are present as the two major products. In the case of PPh_2Me, three others complexes are also observable, two of them giving rise to doublets (^{31}P NMR: δ = 40.0, $J_{P\text{-}Rh}$ = 187 Hz and δ = 33.2, $J_{P\text{-}Rh}$ = 195 Hz) and the third one (minor) giving a spin figure corresponding to a tris(phosphane)rhodium complex, as previouly observed with 4 equivalents of PPh_2Me (vide supra). After 2 h, only the doublet corresponding to the expected $[\{(C_8H_{14})(PR_3)Rh\}_2(\mu\text{-}Cl)_2]$ is present.

Thus, although the cleavage of the chloride bridges could not be clearly evidenced in the case of two equivalents of phosphane, these results indicate that reaction of monophosphanes with $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ always involves substitution of the four cyclooctene ligands, followed by redistribution of the phosphane with unreacted starting complex.

It must be noted that a *related* ligand redistribution process has been recently evidenced by NMR in the special case of terdentate nitrogen ligands[5].



The resulting complex has also been shown to react with CD_2Cl_2 at 298 K to yield the corresponding chloro-

methyl complex $[RhCl_2(CD_2Cl)(\{2,6\text{-}C(Me)=N\text{-}p\text{-}anisyl\}_2C_5H_3N)]$[5].

This research was supported by the *Centre National de la Recherche Scientifique* and by the *Région Midi-Pyrénées* (France) which are gratefully acknowledged. The authors also wish to thank *B. Donnadieu* for collection of the X-ray data and *F. Lacassin* for NMR experiments.

Experimental Section

General: All reactions were performed under argon using standard Schlenk techniques. $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ **1** was prepared according to the literature procedure[19]. − C, H analyses: Perkin-Elmer 2400 apparatus. − NMR: Bruker AC 200 (monitoring of reactions), AMX 400 (isolated complexes) (400.1, 162.0, 100.6, and 12.6 MHz, for ^1H, ^{31}P, ^{13}C, and ^{103}Rh, respectively). For ^1H NMR, CD_2Cl_2 as solvent, $\delta_H = 5.33$; for ^{31}P NMR, H_3PO_4 as external standard; for ^{13}C NMR, CD_2Cl_2 as solvent, $\delta_C = 52.9$; for ^{103}Rh NMR, CD_2Cl_2 as solvent, rhodium metal as external standard.

[{(PEt$_3$)$_2$RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] (**3**): Triethylphosphane (0.37 ml, 2.51 mmol) was added to a solution of $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ (0.450 g, 0.63 mmol) in CH_2Cl_2 (20 ml). After 2 h stirring at room temp., the solvent was evaporated under reduced pressure. The resulting powder was washed with THF (20 ml) and dried in vacuo (0.401 g, 77%). − ^1H NMR: δ = 1.25 (m, 36 H, C*H*$_3$CH$_2$P), 2.00 (m, 12 H, CH$_3$C*H*$_2$P), 2.15 (m, 12 H, CH$_3$C*H*$_2$P), 3.69 (bs, 2 H, CH$_2$).−$^{31}P\{^1H\}$ NMR: δ = 34.4, d, $J_{P\text{-}Rh}$ = 147 Hz. − $^{13}C\{^1H,^{31}P\}$ NMR: δ = 8.12 (s, *C*H$_3$CH$_2$), 18.20 (s, CH$_3$*C*H$_2$), 38.88 (t, $J_{C\text{-}Rh}$ = 22 Hz, *C*H$_2$). − $^{103}Rh\{^1H\}$ NMR: δ = 1696 (t). − $C_{25}H_{62}Cl_4P_4Rh_2$ (834.3): calcd. C 35.99, H 7.49; found C 35.32, H 7.43.

[{(PPh$_2$Me)$_2$RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] (**4**): The same procedure as above was followed using PPh_2Me (41 µl; 0.217 mmol) and $[\{(C_8H_{14})_2Rh\}_2(\mu\text{-}Cl)_2]$ (0.039 g; 0.054 mmol) in CH_2Cl_2 (0.7 ml) and 6 h stirring at room temp. (0.045 g; 71%). − ^1H NMR: δ = 1.53 ($A_3XMX'A'_3$ spin system with a broad line symmetrically flanked by two sharp lines separated by 10.8 Hz, 12 H, C*H*$_3$P), 4.25 (bs, 2 H, C*H*$_2$), 6.9−7.6 (m, 40 H, aromatic H). − $^{31}P\{^1H\}$ NMR: δ = 20.31, d, $J_{P\text{-}Rh}$ = 148.7 Hz. − $^{13}C\{^{31}P\}$ NMR: δ = 14.90 (q, $J_{C\text{-}H}$ = 133 Hz, *C*H$_3$P), 56.78 (tt, $J_{C\text{-}H}$ = 143 Hz, $J_{C\text{-}Rh}$ = 18 Hz, *C*H$_2$), 127−133 (aromatic C). − $^{103}Rh\{^1H\}$ NMR: δ = 1847 (t). − $C_{53}H_{54}Cl_4P_4Rh_2$ (1162.5): calcd. C 54.76, H 4.68; found C 54.25, H 4.49.

X-ray Crystallographic Analysis of [{(PEt$_3$)$_2$RhCl}$_2$(μ-Cl)$_2$(μ-CH$_2$)] (**3**): X-ray quality crystals were obtained by slow diffusion of THF vapors into a concentrated CH_2Cl_2 solution of the complex. The data were collected on a Stoe Imaging Plate Diffraction System (IPDS) equipped with an Oxford Cryosystems cooler device. The crystal-to-detector distance was 80 mm. 115 exposures (2 min per exposure) were obtained with $0 < \varphi < 149.5°$ and with the crystals rotated through 2° in φ. Coverage of the unique set was over 99% complete to at least 24°. Crystal decay was monitored by measuring 200 reflexions per image. The Final unit cell parameters were obtained by the least-squares refinement of 5000 reflections. Only statistical fluctuations were observed in the intensity monitors over the course of the data collection.

The structure was solved by direct methods (SIR92)[20] and refined by least-squares procedures on F_o. One of the methyl of an ethyl group attached to P(1) is distributed statistically over two positions. The coordinates for these disordered carbon atoms were refined applying geometrical restraints to maintain reasonable C−C distances and C−C−C bond angles. H atoms were located on difference Fouriers maps, but they were introduced in calculation in idealized positions [d(CH) = 0.96 Å] and their atomic coordinates were recalculated after each cycle. They were given isotropic thermal parameters 20% higher than those of the carbon to which they are attached. Only the H atoms attached to the C methylene carbon were refined with an isotropic thermal parameter. Least-squares refinements were carried out by minimizing the function $\Sigma w(|F_o| - |F_c|)^2$, where F_o and F_c are the observed and calculated structure factors. The weighting scheme used in the last refinement cycles was $w = w'\{1 - [\Delta F/6\sigma(F_o)]^2\}^2$ where $w' = 1/\Sigma_1{}^nA_rT_r(x)$ with 3 coefficients Ar for the Chebyshev polynomial $A_rT_r(x)$ where x was $F_c/F_c(max)$[21]. Models reached convergence with $R = \Sigma(||F_o| - |F_c||)/\Sigma(|F_o|)$ and $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w(F_o)^2]^{1/2}$, having values listed in Table 1. Criteria for a satisfactory complete analysis were the ratios of rms shift to standard deviation less than 0.1 and no significant features in final difference maps. Details of data collection and refinement are given in Table 2.

Keywords: Gallium / Indium / Low-valent compounds

Tetrakis[bis(trimethylsilyl)methyl]digallane(4) (**1**) with a Ga−Ga single bond and the corresponding diindane(4) **2** with an In−In single bond were treated with different protic reagents: *tert*-Butyl alcohol did not react with **1** at all, while phenol gave a mixture of unknown products, which could not be separated. The more acidic pentafluorophenol did not react as an acid, but C−F bonds were cleaved to form almost quantitatively the dimer $(R_2GaF)_2$ **5**, which was characterized by a crystal-structure determination. Water and **1** yielded the dimeric dialkylgallium hydroxide **6**. The Ga−Ga bond was also cleaved by the reaction of **1** with durylthiophenol (duryl = 2,3,5,6-tetramethylphenyl), which gave two main products: $R_2Ga(SDuryl)$ **7** and $RGa(SDuryl)_2$ **8**. In contrast, the chelating acid dibenzoylmethane reacted by means of a substituent exchange, with the release of two equiv. of bis(trimethylsilyl)methane for each formula unit of **1**, to form **9**, in which the Ga−Ga bond is retained and each chelating 1,3-diphenyl-1,3-propanedionato ligand is in a terminal position bonded to only one Ga atom, in more than 80% yield. The Ga−Ga bond is shortened [244.1(1) pm] compared to that in the starting compound tetraalkyldigallane(4) **1**. The In−In bond of diindane(4) **2** is, however, cleaved in a similar reaction with dibenzoylmethane, and only the fragmentation product dialkyl(1,3-diphenyl-1,3-propanedionato)indium **10** could be isolated.

Tetrakis[bis(trimethylsilyl)methyl]dielement(4) compounds with the elements aluminium[1], gallium (**1**)[2], and indium (**2**)[3] in an unusually low oxidation state of +II and an element−element single bond, showed a remarkable reactivity towards carboxylic acids: Dialane(4) reacted on treatment with benzoic acid by the insertion of the Al atoms into the O−H bond, the cleavage of the Al−Al bond and the reduction of the proton by two electrons to give a hydride anion[4]. Both dialkylaluminium fragments of the product are unsymmetrically bridged by an O,O′-benzoato group and an hydride ion to form the six-membered heterocycle **3**. A similar product could not be obtained with diindane(4) **2**, which may be due to the inherently low thermal stability of In−H bonds. Instead, two monoindium compounds, monomeric R_2InO_2CR and dimeric $RIn(O_2CR)_2$, were formed[4], probably by fragmentation, the precipitation of indium metal and the release of elemental hydrogen. The most interesting products, **4**, were isolated from the reactions of digallane(4) **1** with aromatic and aliphatic carboxylic acids[5]. Two bis(trimethylsilyl)methyl groups are replaced by carboxylato groups, which occupy a bridging position above the considerably shortened Ga−Ga bond. Remarkably, the C−Ga−Ga−C group is almost linear and the angle between the normals of the planes of the carboxylato ligands approaches 90°. The reaction of **1** with less acidic diphenyltriazene led to a partial fragmentation and oxidation of digallane(4) **1**. Two main products are formed: by cleavage of the Ga−Ga bond the monogallane $R_2Ga(N_3Ph_2)$ and by substituent exchange, the digallane $R_2Ga_2(N_3Ph_2)_2$, in which, in contrast to **4**, the chelating substituents are terminally bonded[6]. The substituent exchange thus opened up an easy route for the synthesis of novel organodigallium compounds, and we systematically employed further protic reagents like alcohol or acetylacetone derivatives.

Reactions of Digallane(4) 1 with Alcohols and Water

tert-Butyl alcohol did not react with **1** at all, even when a large molar excess of 4 equiv. of the alcohol for each formula unit of **1** was used, and the mixture was refluxed in hexane for several days. The reaction of the more acidic phenol in a molar ratio of 2 to 1 in boiling hexane resulted in the complete consumption of **1** after a period of four days, but a mixture of unknown products was formed, which could not be separated by recrystallization; only trace amounts of a colorless solid, which was not further characterized, crystallized out of solution in pentane. Pentafluorophenol reacted with **1** not as an acid, but by the cleavage of

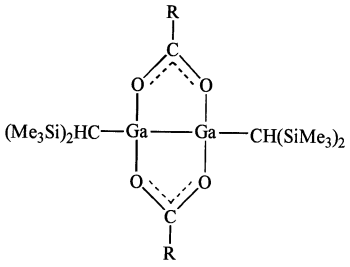
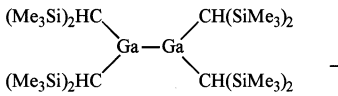
3



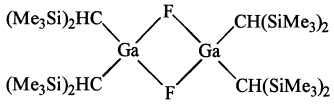
4

C−F bonds. The reaction required more than 48 h in boiling hexane, and only one product could be isolated after recrystallization from pentane in a yield of more than 80%. A dialkylgallium fluoride **5**, which is a dimer in the solid state (see below) and in solution, as cryoscopically determined in benzene, was formed by the cleavage of the Ga−Ga bond (eq. 1). **5** thus differs from the recently published analogous compound $Br-Ga[CH(SiMe_3)_2]_2$[7] and the corresponding chloroaluminium derivative $Cl-AlR_2$[1], which are both monomeric in solution, with coordinatively unsaturated central atoms, probably due to strong steric interactions between the bulky bis(trimethylsilyl)methyl substituents. A dimer was, however, also observed in the corresponding hydroxide[8], so that, interestingly, the smallest donor atoms are able to form the most stable dimers. Because OH and F are the most electronegative of the employed substituents, this observation may be explained as resulting from a more effective ionic interaction and a high electrostatic contribution to the bonding in these molecules. The monomeric bromide $BrGaR_2$ and the dimeric fluoride **5** differ significantly in their ^{13}C-NMR spectra. The C atoms bonded to gallium show a chemical shift of $\delta = 25.6$ in the bromo derivative, which is within the range usually observed with bis(trimethylsilyl)methyl compounds of tricoordinated Ga atoms[2][7]. In **5**, however, the corresponding resonance is shifted to higher field ($\delta = 16.6$), characteristic for compounds with tetracoordinated Ga atoms. Absorptions in the IR spectra at 525 and 490 cm^{-1} could be assigned to the stretching vibrations of the Ga_2F_2 unit[9]. Dimesityl- and diisopropylgallium fluoride, as recently published by Neumüller et al.[10], are also dimeric in solution, and the IR absorptions at 473 and 450 cm^{-1} (R = mesityl) and 496 cm^{-1} (R = benzyl) were assigned to the Ga_2F_2 molecular center. In comparison to these gallium fluorides ($\delta = -152.7$ and -169.7) the ^{19}F-NMR resonance of **5** is shifted downfield to $\delta = -109.5$. The similar cleavage of a C−F bond of a fluorinated aromatic compound accompanied by the formation of an Al−F bond has recently been reported[11].

Water also does not react with **1** by the release of bis(trimethylsilyl)methane, but by the oxidation of the gallium



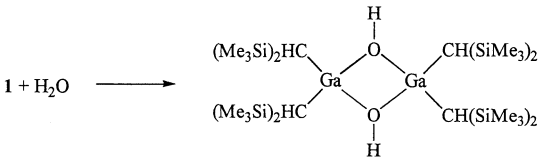
1



5

(1)

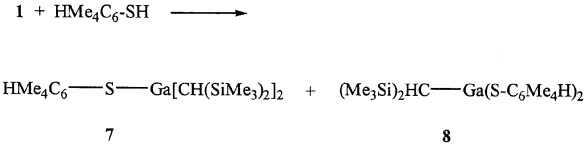
atoms and cleavage of the Ga−Ga bond. Dimeric dialkylgallium hydroxide **6** is formed (eq. 2), which is isolated after recrystallization from *n*-pentane in a yield of about 50%. Elemental hydrogen is probably formed as a byproduct, which could, however, not be detected due to its small amount. **6** has been obtained in our group before by another route and was characterized by a crystal-structure determination[8].



6

(2)

The behavior of thioalcohols was investigated in a reaction of **1** with the sterically shielded durylthiol (duryl = 2,3,5,6-tetramethylphenyl). After 72 h in boiling hexane, 70% of **1** was consumed. Two new products were formed, which could be separated with difficulty by repeated recrystallization to yield a small amount of an enriched sample of **8**, while the second component **7**, could only be detected in mixtures with **8**. Both products were identified spectroscopically as $R_2GaSDuryl$ **7** and $RGa(SDuryl)_2$ **8**. The pure compounds **7** and **8** could not be obtained by the reaction of $Ga[CH(SiMe_3)_2]_3$[2] with one or two equiv. of durylthiol in solution or in a melt at 120°C; in all reactions, **7** was only formed as a minor component, while reactions in the molar ratio of 1:2 gave impure samples of **8**, which could not be purified by recrystallization. The spectroscopic information obtained for the impure monothiolato product is not sufficient enough to discuss the degree of oligomerization, but the dithiolato product seems to be at least a dimer with a tetracoordinated Ga atom, as can be seen from the chemical shift of the carbon atom bonded to Ga ($\delta = 15.5$).



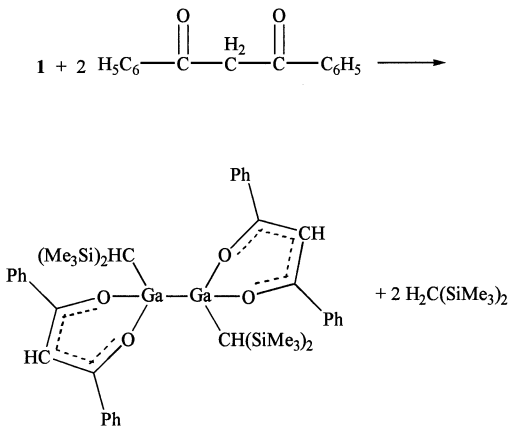
7 8

(3)

Reaction of Digallane(4) 1 and Diindane(4) 2 with Dibenzoylmethane

As shown before, non-chelating acidic compounds such as alcohols or thioalcohols reacted exclusively by the cleavage of the Ga−Ga bond. We hoped to realize the substituent exchange by retaining the Ga−Ga bond, when we treated **1** with a chelating protic acetylacetone derivative. This reaction was of particular interest because, up to now, we had observed either a bridging or a terminal coordination by the chelating ligand in the products of both successful substituent exchange reactions. The reason for this different behavior is not well understood, but it possibly depends on the distance between the coordinating atoms (bite) with the N−N distance in the triazenido ligand too short to facilitate the bridging of the Ga−Ga bond.

When we treated a yellow solution of the digallane(4) **1** in pentane with two equiv. of dibenzoylmethane at −50°C (eq. 4), the color changed at about −10°C to give an orange solution, from which orange-red crystals of **9** were obtained at −50°C in a yield of 79%. In contrast to the reactions described above, two equiv. of $CH_2(SiMe_3)_2$ are formed for each formula unit of **1**, as shown by NMR spectroscopy. Elemental analysis, mass spectrometry, the cryoscopic molar-mass determination in benzene and the integration of the ^{1}H-NMR spectrum confirm the structure of a digallium compound with two bis(trimethylsilyl)methyl and two 1,3-diphenyl-1,3-propanedionato substituents. In the NMR spectra, the resonances of the methine protons and the α-carbon atoms of the $CH(SiMe_3)_2$ groups are strongly shifted upfield (^{1}H: δ = −0.09; ^{13}C: δ = 10.4) compared to those of the starting compound **1** (δ = 1.09 and 25.9, respectively)[2], clearly indicating a coordination number of four at the Ga atoms. The atoms of the electronically delocalized π system of the 1,3-diphenyl-1,3-propanedionato group show the usual chemical shifts: δ = 185.7 [*C*(O)], 93.9 [*C*(H)] and δ = 6.52 (*H*). In contrast to the colorless triazenido or carboxylato digallium compounds mentioned above, **9** is deeply orange with absorptions at 420 and 340 nm in the UV/Vis spectrum; the color, however, is mainly a function of the chelating group and is often observed in its reaction products.



9 (4)

Until now, all reactions of protic reagents with diindane(4) **2** resulted in the cleavage of the In−In bond and precipitation of elemental indium. Because of the formation of the digallium compound **9** in a high yield with only minor byproducts, we treated **2** with dibenzoylmethane under similar conditions to those described above for **1** in a molar ratio of 1:2. As originally intended, the formation of bis(trimethylsilyl)methane could be detected by NMR spectroscopy, but only as a minor component, and a black precipitate of elemental indium indicated a disproportionation reaction and the fragmentation of the starting compound **2**. A crystalline product was isolated from *n*-pentane at −30°C, which was identified by its NMR spectra and its molar mass as the dialkylindium compound **10** (eq. 5). The yield of **10** based on dibenzoylmethane amounted to only 43%, and an excess of the diketone crystallized as a second fraction. Reactions in an equimolar ratio gave **10** in a yield of 86% based on dibenzoylmethane, but a small part of the starting compound **2** was recovered. The course of these reactions may give some insight into the reaction mechanism: Similar to the reactions with carboxylic acids[4] described in the introduction, the In atoms are probably oxidized by the OH proton of the enol form of the diketone, accompanied by insertion into the O−H bond. The intermediate with an In−H bond similar to the Al compound **3** is unstable, and decomposes by the release of elemental hydrogen, which may lead to the formation of the isolated product dialkyl(1,3-diphenyl-1,3-propanedionato)indium **10** and an InR_2 radical, which could disproportionate via an alkylindium(I) derivative, stable only with bulkier $C(SiMe_3)_3$ substituents[12], to form elemental indium and the corresponding trialkylindane. The highly soluble indane[3] could indeed be identified as the main component of the mother liquor after isolation of **10** and the unreacted diindane(4) **2**. Product **10** was synthesized by the treatment of the corresponding trialkylindane with one equiv. of dibenzoylmethane in a yield of almost 90%. Due to its molar mass in benzene, **10** is monomeric in solution. The resonances of the methine groups bonded to indium are shifted upfield [^{1}H: δ = −0.18 (*H*CIn); ^{13}C: δ = 11.9 (*C*In)], which is characteristic of a coordination number of four at the indium atom and verifies the chelating coordination by the 1,3-diphenyl-1,3-propanedionato ligand.

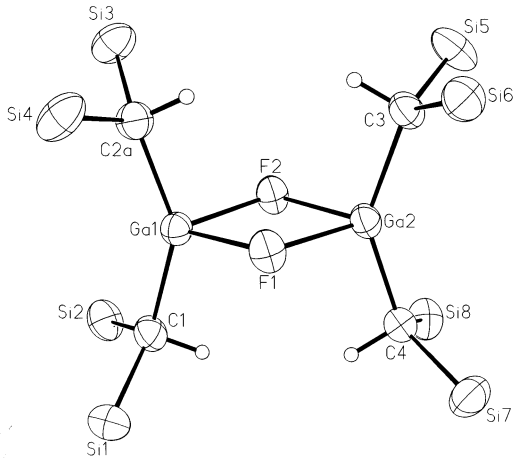
Crystal Structures of Compounds 5 and 9

Figure 1 shows the molecular structure of the dimeric compound $(R_2GaF)_2$ **5** [R = $CH(SiMe_3)_2$], which crystallizes in the centrosymmetric triclinic space group $P\bar{1}$ with two dimers in each unit cell. The four $CH(SiMe_3)_2$ substituents are arranged in a terminal position and the dialkylgallium fragments are bridged by both fluorine atoms. A four-membered Ga_2F_2 heterocycle results; this is almost ideally planar with a maximum deviation of an atom of 2.9 pm. The GaC_2 planes with the methine carbon atoms of the bis(trimethylsilyl)methyl groups are almost exactly perpendicular to this plane, and the normals of the planes include angles of 90.6° (Ga1C1C2) and 89.6° (Ga2C3C4). The bond angles in the heterocycle are most acute at the Ga atoms (76.9°) and much enlarged at the F atoms (103.0°); almost identical angles were observed in the recently published corresponding di(μ-hydroxo)digallium derivative[8]. Dialkylgallium fluorides have been known for a long time. They usually form trimers (R = Me, Et[13], *i*Pr[10]), and it was only recently that a dimer, which was sterically highly shielded by four bulky mesityl substituents, was characterized by a crystal-structure determination[10]. A tetrameric modification was observed by Schmidbaur et al. with R = Me[13]. The Ga−F bonds in **5** and $(Mes_2GaF)_2$ [194.7(2) pm] are quite similar; for **5** they deviate only slightly from the average value of 196.6 pm. The $CH(SiMe_3)_2$ substituents of comparable dialuminium or digallium compounds usually show a conformation in which the methine hydrogen atom of one substituent points between both $SiMe_3$ groups of the second $CH(SiMe_3)_2$ substituent[1][2][3]. This conformation is only observed at the atom Ga1 in **5**, while at Ga2 the four trimethylsilyl groups are neighbored and can be transferred onto each other by non-crystallographic mirror planes. Thus, the molecule is not centrosymmetric in the solid state, although only one singlet of the $SiMe_3$ groups was observed in the NMR spectra in solution. The molecule shows a disorder (54−46%), and the bis(trimethylsilyl)methyl group of C2 occupies a second position, which gives the same conformation as observed at Ga2. The point group of the second molecule is thus approximately D_{2h}.

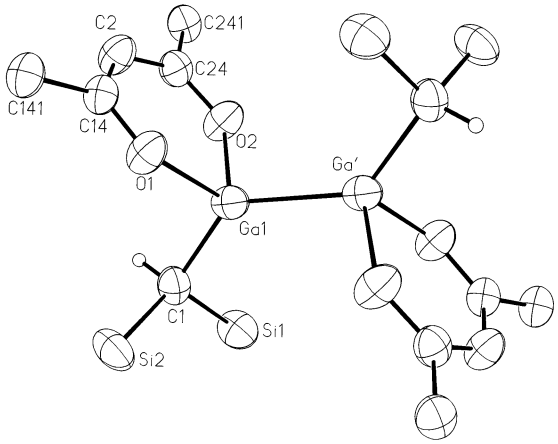
The molecular structure of **9** is depicted in Figure 2. The molecule is located on a crystallographic center of symmetry, which intersects the Ga−Ga bond. Two bis(trimethylsilyl)methyl groups are replaced by chelating 1,3-diphenyl-1,3-propanedionato ligands, which in contrast to the corresponding carboxylato derivative **4**[5], but similarly to the product obtained with diphenyltriazene[6], occupy terminal positions and are bonded to only one Ga atom. Due to its crystallographic symmetry, the molecule has an ideal *trans* conformation. The Ga−Ga bond length is 244.0 pm, which is slightly shorter than in the triazenide compound [245.79(6) pm] with a synclinal molecular conformation[6], but longer than in **4** [238.5(2) pm][5]. Compared to the starting compound **1** [254.1(1) pm][2] a significant shortening is observed; all Ga−Ga distances lie in the range characteristic of Ga−Ga bonds in organoelement or inorganic derivatives[14]. The Ga−C bond length is lengthened [199.5(5) pm] compared to the carboxylato-bridged compound **4** [195.7(8) pm], but the Ga−O distances are significantly reduced [**9**: 195.9(3) pm; **4**: 201.1(6) pm], which might be caused by the bridging of the Ga−Ga bond and the resulting larger steric stress in **4**. The distance between the coordinating atoms in the chelate ring of **9** (278.9 pm) is much larger than in the carboxylato-bridged derivative **4** (224.0 pm)[5]. A shorter bite is observed with the triazenido ligand (209.2 pm)[6], which occupies a terminal position.

Figure 1. Molecular structure of **5**; the ellipsoids are drawn at the 40% probability level; methyl groups are omitted for clarity; only one position of the disordered $CH(SiMe_3)_2$ group at C2 is drawn[a]



[a] Selected bond lengths [pm] and angles [°]: Ga1−F1 196.3(3), Ga1−F2 195.4(3), Ga2−F1 197.4(3), Ga2−F2 197.3(3), Ga1···Ga2 307.7, Ga1−C1 197.1(5), Ga1−C2 199.7(9), Ga1−C2A 194(1), Ga2−C3 196.5(5), Ga2−C4 196.4(5); F1−Ga1−F2 77.2(1), F1−Ga2−F2 76.5(1), Ga1−F1−Ga2 102.8(1), Ga1−F2−Ga2 103.2(1), C1−Ga1−C2 126.8(3), C1−Ga1−C2A 147.1(4), C3−Ga2−C4 143.8(2).

Figure 2. Molecular structure of **9**; the ellipsoids are drawn at the 40% probability level; methyl and phenyl groups are omitted for clarity; only one position of the disordered $CH(SiMe_3)_2$ group at C1 is drawn[a]



[a] Selected bond lengths [pm] and angles [°]: Ga1−Ga1′ 244.0(1), Ga1−C1 199.5(5), Ga1−O1 195.9(3), Ga1−O2 194.8(3); O1−Ga1−O2 91.1(1), O1−Ga1−C1 102.8(2), O2−Ga1−C1 103.6(2), Ga1′−Ga1−C1 133.9, Ga1′−Ga1−O1 110.0(1), Ga1′−Ga1−O2 107.2(1) (symmetry operation to generate Ga1′: $-x$, $-y$, $1-z$).

The kind of the coordination, terminal or bridging, seems therefore not to be determined by the magnitude of the distance between the coordinating atoms, and remains an open question, in which case a particular coordination is adopted. The (1,3-diphenyl-1,3-propanedionato)gallium heterocycle is almost planar, with the maximum deviation from the plane of 8.1 pm by the oxygen atom O1; its bond lengths and angles resemble that of comparable derivatives of gallium in an oxidation state of +III[15].

We are grateful to the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* for generous financial support.

Experimental Section

General: All procedures were carried out under purified argon in dried solvents (*n*-pentane, cyclopentane, and *n*-hexane with $LiAlH_4$, benzene with Na/benzophenone). Compounds **1** and **2** were synthesized as described in ref.[2][3], durylthiol was obtained by the reduction of $ClSO_2-C_6Me_4H$ with $LiAlH_4$[16], dibenzoylmethane and pentafluorophenol (Aldrich) were sublimed in vacuo, *tert*-butyl alcohol was treated with Na and distilled, phenol (99+%, Aldrich) was used without further purification.

Synthesis of $(R_2GaF)_2$ **5**: 0.91 g (1.17 mmol) of digallane(4) **1** was dissolved in 50 ml of *n*-hexane and treated with 0.43 g (2.34 mmol) of solid pentafluorophenol. The mixture was heated under reflux for 48 h, and the color changed from yellow to colorless. The solvent was evaporated and the residue recrystallized from *n*-pentane (20/−30°C). Yield: 0.83 g (87%); colorless, slightly air-sensitive crystals; m.p. (argon; closed capillary) 157°C. − ^{1}H NMR (C_6D_6, 300 MHz): δ = 0.17 (1 H, GaCH), 0.16 (18 H, $SiMe_3$). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 16.6 (GaC), 3.5 ($SiMe_3$). − ^{19}F NMR (C_6D_6, 282 MHz): δ = −109.5. − IR (CsBr, paraffin): $\tilde{\nu}$ = 1314 cm^{-1} (w), 1262 (sh), 1252 (vs, δCH_3), 1171 (w), 1018 (vs), 995 (sh, δCH), 843 (vs), 777 (s), 762 (s), 723 [s, ρCH_3(Si)], 673 (m, ν_{as}SiC), 646 (w), 613 (w, ν_sSiC), 573 (vw), 527 (w, νGa_2F_2), 509 (w, νGaC_2), 490 (w, νGa_2F_2), 463 (vw, νGaC_2), 421 (vw), 376 (vw, δSiC). − $C_{28}H_{76}F_2Ga_2Si_8$ (815.0): calcd. F 4.7, Ga 17.1; found F 4.5, Ga 16.9. − Mol. mass: 745 (cryoscopically in benzene).

Reaction of Digallane(4) **1** *with Water:* Digallane(4) **1** (0.19 g, 0.25 mmol) was dissolved in 20 ml of *n*-hexane and treated with 8.8 µl of water. The mixture was stirred vigorously for 6 h until the water phase was completely consumed. The solvent was evaporated, and the residue recrystallized from *n*-hexane (20/−50°C). Yield: 0.103 mg (51%) colorless crystals of compound **6**; characterization see ref.[8].

Reaction of Digallane(4) **1** *with Durylthiol:* Digallane(4) **1** (0.695 g, 0.896 mmol) was dissolved in 40 ml of *n*-hexane and cooled to −30°C. 23.3 ml of a 0.077 M solution of durylthiol (1.79 mmol) in *n*-hexane was added. The mixture was warmed to room temperature and stirred for 72 h. The pale yellow solution was concentrated and the residue recrystallized from *n*-pentane. A mixture of both products **7** and **8** was obtained with the dithiol derivative **8** enriched as the less soluble component. − ^{1}H NMR of $R_2GaSCMe_4H$ **7** (C_6D_6, 300 MHz): δ = 6.76 (1 H, phenyl), 2.55 and 2.10 (each 6 H, methyl of duryl), 0.22 (36 H, $SiMe_3$); methine proton signal not detected. − Characterization of **8**: colorless, slightly air-sensitive crystals; m.p. (argon; closed capillary) 146°C. − ^{1}H NMR (C_6D_6, 300 MHz): δ = 6.71 (2 H, phenyl), 2.48 and 2.05 (each 12 H, methyl of duryl), 0.18 (18 H, $SiMe_3$); methine proton signal not detected. − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 137.3, 134.0, 132.3, 130.9 (all phenyl), 21.0 and 20.2 (methyl of duryl), 15.5 (GaC), 3.2 ($SiMe_3$). − IR (CsBr, paraffin): $\tilde{\nu}$ = 1553 cm^{-1} (w, phenyl); 1462 (vs), 1377 (vs, paraffin); 1302 (w), 1260 (m), 1250 (s, δCH_3), 1155 (vw), 1020 (m), 1003 (m, δCH), 964 (m), 862 (s), 839 (vs), 775 (s), 762 (s), 721 [s, ρCH_3(Si)], 675 (m, ν_{as}SiC), 629 (w), 613 (vw, ν_sSiC), 546 (w), 517 (w, νGaC), 461 (m), 430 (w), 397 (w), 378 (w, νGaS, δSiC). − $C_{27}H_{45}GaS_2Si_2$ (559.7): calcd. Ga 12.5; found Ga 12.2.

Synthesis of Dialkylbis(µ-1,3-diphenyl-1,3-propanedionato-O,O′)digallium **9**: A solution of 0.314 g (1.40 mmol) of dibenzoylmethane in 50 ml of *n*-pentane was added dropwise to a cooled solution (−50°C) of digallane(4) **1** (0.518 g, 0.67 mmol) in 75 ml of *n*-pentane. The mixture was slowly warmed to room temperature, and the color changed at about −10°C from yellow to orange. The solvent was evaporated, the residue thoroughly dried in vacuo to completely remove bis(trimethylsilyl)methane and recrystallized from 60 ml of *n*-pentane (20/−50°C). Yield: 0.478 g (79%); orange-red, slightly air-sensitive crystals; m.p. (argon; closed capillary) 168−169°C. − ^{1}H NMR (C_6D_6, 300 MHz): δ = 7.81 (4 H, pseudo-d, *o*-H of phenyl), 7.09 (2 H, pseudo-t, *p*-H of phenyl), 7.01 (4 H, pseudo-t, *m*-H of phenyl), 6.52 [1 H, s, $HC(CO)_2$], 0.40 (18 H, s, $SiMe_3$), −0.09 (1 H, s, GaCH). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 185.7 (CO), 138.3, 132.2, 128.4 (all phenyl), 93.9 [$C(CO)_2$], 10.4 (GaC), 3.8 ($SiMe_3$). − IR (CsBr, paraffin): $\tilde{\nu}$ = 1973 cm^{-1} (vw), 1954 (vw), 1912 (vw), 1892 (vw), 1852 (vw), 1804 (vw), 1765 (vw, phenyl), 1591 (m), 1535 (s), 1524 (s, chelate), 1466 (vs), 1362 (vs, paraffin), 1316 (s), 1304 (s), 1252 (sh), 1244 (s), 1229 (sh, δCH_3), 1182 (m), 1157 (m), 1127 (m), 1092 (m), 1063 (s, νCC, νCO), 1022 (vs), 999 (w, δCH), 970 (vw), 953 (vw), 939 (s), 914 (s), 862 (sh), 841 (vs), 787 (m), 756 (vs), 716 νr, ρCH_3(Si)], 694 (sh), 681 (s), 669 (sh, ν_{as}SiC), 629 (s), 617 (s, ν_sSiC), 556 (s), 527 (s), 509 (vs), 494 (m), 455 (w, νGaC, νGaO), 436 (w), 395 (w), 338 (vw, δSiC). − UV (*n*-hexane): λ_{max} (lg ε) = 200 nm (5.0), 260 (4.6), 340 (4.7), 421 (3.8). − FD MS; *m/z*: 903.3, 904.7, 906.7 [all M^+, in agreement with a calculated isotope pattern]. − $C_{44}H_{60}Ga_2O_4Si_4$ (904.7): calcd. Ga 15.4; found Ga 15.4. − Mol. mass: 855 (cryoscopically in benzene).

Reaction of Diindane(4) **2** *with Dibenzoylmethane:* A solution of 0.086 g (0.38 mmol) of dibenzoylmethane in 20 ml of *n*-pentane was added to a cooled (−90°C) solution of 0.323 g (0.37 mmol) of diindane(4) **2** in 20 ml of *n*-pentane. The mixture was slowly warmed to room temperature, the color changed from orange to brown and elemental indium precipitated. After filtration and concentration, compound **10** crystallized as a yellow solid on cooling to −50°C. A quarter of the starting compound **2** was isolated as a second fraction. The mother liquor contained the readily soluble $In[CH(SiMe_3)_2]_3$ as a main component. Yield of **10**: 0.210 g (86% based on dibenzoylmethane); characterization of **10**: see below.

Synthesis of Dialkyl(1,3-diphenyl-1,3-propanedionato-O,O′)indium **10**: A solution of 0.348 g (1.55 mmol) of dibenzoylmethane in 30 ml of *n*-pentane was added to a cooled (−80°C) solution of 0.943 (1.59 mmol) of $In[CH(SiMe_3)_2]_3$ in 20 ml of *n*-pentane. The mixture was slowly warmed to room temperature, filtered and concentrated in vacuo. **10** crystallized on cooling to −30°C. Yield: 0.931 g (89%); yellow, slightly air-sensitive crystals; m.p. (argon; closed capillary) 121°C. − ^{1}H NMR (C_6D_6, 300 MHz): δ = 7.98 (4 H, pseudo-d, *o*-H of phenyl), 7.13 (6 H, m, phenyl), 6.83 [1 H, s, $HC(CO)_2$], 0.29 (36 H, s, $SiMe_3$), −0.18 (2 H, s, GaCH). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 186.6 (CO), 139.8, 132.0, 128.7, 127.8 (all phenyl), 95.2 [$C(CO)_2$]; 11.9 (GaC), 3.9 ($SiMe_3$). − IR (CsBr, paraffin): $\tilde{\nu}$ = 1971 cm^{-1} vw, 1954 (vw), 1912 (vw), 1892 (vw), 1802 (vw), 1718 (vw, phenyl), 1591 (s, phenyl), 1541 (s), 1516 (vs, νCO, νCC of the chelate), 1476 (vs), 1364 (vs, paraffin), 1312 (m), 1259 (m), 1258 (s), 1246 (s), 1227 (m, δCH_3), 1184 (w), 1157 (w), 1125 (w), 1092 (w), 1057 (w, νCC,νCO), 1020 (s), 1011 (s,

δCH), 968 (vw), 936 (m), 926 (m), 914 (m), 843 (vs), 785 (m), 772 (m), 754 (m), 743 (s), 708 [s, ρCH_3(Si)], 677 (s), 665 (s, ν_{as}SiC), 625 (m), 610 (w, ν_sSiC), 542 (w), 521 (w), 484 (m, νInC, νInO), 394 (vw, δSiC). − $C_{29}H_{49}InO_2Si_4$ (656.9): calcd. In 17.5; found In 17.2. − Mol. mass: 605 (cryoscopically in benzene).

Crystal-Structure Determinations: Single crystals of compounds **5** and **9** were obtained by recrystallization from hexane and cyclopentane, respectively. Crystal data and structure refinement parameters are given in Table 1[19]. Both compounds show a disorder of one bis(trimethylsilyl)methyl group, which is best described as a different orientation of the methine hydrogen atoms. Although the carbon atoms occupy different positions in each disordered group, the Si atoms coincide in compound **5**; in **9** all atoms of the $CH(SiMe_3)_2$ group are disordered. The disordered atoms were isotropically refined under restrictions of bond lengths and angles (exception: the higher occupied position in **9**); the occupancy factors are 0.54 and 0.46 in **5** and 0.87 and 0.13 in **9**.

Keywords: Phosphorus / Phosphonic anhydrides / Oligophosphonic acids / Peptide synthesis / Solid-state structures

By reaction of $RP(O)Cl_2$ with $RP(O)(OSiMe_3)_2$, phosphonic anhydrides $(RPO_2)_3$ (R = *t*Bu, 2-methylphenyl, 2,4,6-trimethylphenyl) **1a−c** are conveniently obtained. In contrast to **1b** and **1c**, compound **1a** is remarkably stable against protolysis. Intermediates of hydrolysis of **1a**, namely tris(*tert*-butyl)triphosphonic acid (**2**) and bis(*tert*-butyl)diphosphonic acid (**3**), can also be isolated in good yield. The structures of **1−3** were determined mainly by NMR spectroscopy (^1H, ^{13}C, ^{31}P). Assuming an energetic preference for the chair conformations in solution, and considering the steric requirements of the bulky substituents R, configurations Ia (point group C_s, two R in equatorial positions) for **1a** and **b**, and IIa (point group C_{3v}, all R equatorial) for **1c** are suggested. − Reaction of **1a** with *N*-benzyloxycarbonylglycine (**4**) in methanol affords strong evidence that in the first step of peptide synthesis with $(RPO_2)_3$, a mixed anhydride of triphosphonic acid and the *N*-protected amino acid is formed. − The crystal structure of **1a** (monoclinic, space group $P2_1/n$) widely corresponds to the suggested configuration Ia, but reveals an envelope conformation for the six-membered ring with a P_3O_2 plane in the crystal. In the crystal structure of the octahydrate of the disodium salt of **2** (monoclinic, space group $P2_1/c$), it can be seen that the polar end groups of the anions $[tBu_3P_3O_7]^{2-}$ together with the water molecules and the Na^+ cations form hydrogen-bonded double-layers, strictly separated from each other by the non-polar *tert*-butyl groups of the anions.

Introduction

A variety of methods have been reported in the literature for the preparation of phosphonic anhydrides $(RPO_2)_n$. These methods usually result in mixtures of oligomers which are difficult to separate[1][2][3].

Compounds of this composition were also obtained when the corresponding cyclophosphanes were oxidized with dry oxygen (R = CF_3, average number $\bar{n}$ = 3−4[4], R = Ph, $\bar{n}$ = 5[5]).

Thermolysis and flash vacuum pyrolysis of tBuP(O)(OSiMe_3)X (X = Cl, Br) afforded the trimer $(t\text{BuPO}_2)_3$[6].

Among other alkylphosphonic anhydrides, compound $(\text{PrPO}_2)_3$, which is commercially available, is recommended as a condensation reagent in the synthesis of peptides[7].

As phosphinic anhydrides $R_2P(O)-O-P(O)R_2$ are readily accessible by treating $R_2P(O)Cl$ and silyl esters $R_2P(O)(OSiMe_3)$ with elimination of Me_3SiCl[8], we now used the analogous reaction between phosphonoyl chlorides $RP(O)Cl_2$ and silyl phosphonates $RP(O)(OSiMe_3)_2$ for the synthesis of the title compounds. By this method we obtained, in excellent yield and purity, alkyl compounds $(RPO_2)_n$ as highly viscous, colorless oils that are readily hydrolyzable. They can be distilled under vacuum, and some of them gradually crystallize after standing at room temperature. According to cryoscopic measurements in benzene, $\bar{n}$ varied from 11 (R = Pr) to 6 (R = Bu, Pentyl) within a wide range of concentrations[9].

In case of bulky substituents R, we isolated well-defined trimers **1a−1c**. Their configurations and some of their reactions are discussed in the following sections[10].

Trimeric Phosphonic Anhydrides 1a−1c

On heating equimolar quantities of $RP(O)Cl_2$ and $RP(O)(OSiMe_3)_2$, **1a−1c** are obtained as colorless crystals with sharp melting points. While **1a** and **1b** are readily soluble in toluene, benzene, $CHCl_3$, or CH_2Cl_2, **1c** is fairly soluble only in the latter two solvents. **1b** and **1c** are rapidly dissolved by methanol or H_2O, with the formation of phosphonic acid esters RP(O)(OMe)OH or phosphonic acids $RP(O)(OH)_2$.

$(RPO_2)_3$

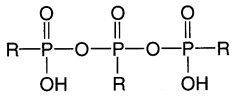
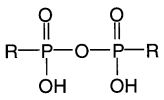
a: R = *t* Bu
b: R = 2-methylphenyl
c: R = 2,4,6-trimethylphenyl



2

R = *t* Bu
2a: Disodium salt · 2 H_2O
2b: Disodium salt · 8 H_2O



3

R = *t* Bu
3a: Disodium salt · 3 H_2O

1a, however, is remarkably stable in this respect. As shown by NMR spectroscopy, solutions of **1a** in methanol

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0361 $ 17.50+.50/0

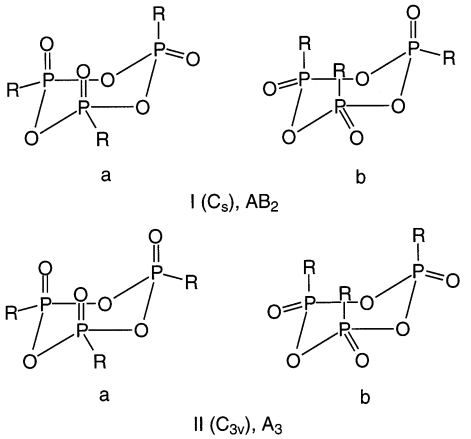
or ethanol remain unchanged even after boiling for several hours. Hydrolysis is so slow that it is possible (as is shown later) to isolate intermediates of this reaction.

While in the mass spectra of **1b** and **1c**, abundant peaks for the molecular ions are observed, the signal for $M^{+\cdot}$ in the spectrum of **1a** is of low intensity. The spectrum of the latter compound is characterized by a successive loss of C_4H_8 from the molecular ion. A peak m/z = 192 (19%) corresponding to $[HPO_2]_3^{+\cdot}$ indicates that this process can occur without fragmentation of the six-membered ring.

NMR Spectra

Assuming a six-membered ring structure for **1**, and an energetic preference for the chair conformations, structures I and II, both with conformations a and b, have to be considered (Figure 1).

Figure 1. Possible structures of cyclic trimers **1** (chair conformations), point groups, and $^{31}P\{^1H\}$ spin systems



These should give rise to AB_2 or A_3 spin systems in their $^{31}P\{^1H\}$-NMR spectra, and we did in fact observe AB_2 systems for **1a** and **1b** and an A_3 system for **1c**. The correspondence of the observed spectra given in the Experimental Section with spectra simulated with parameters ν_A = 1912.3 Hz, ν_B = 1824.1 Hz, J_{AB} = 50.9 Hz (**1a**) and ν_A = 163.5 Hz, ν_B = −33.1 Hz, J_{AB} = 42.6 Hz (**1b**) is excellent. Considering the steric requirements of the bulky substituents R, structure Ia is therefore suggested for **1a** and **1b**, while structure IIa appears to be the most probable one for **1c**. In the crystal, **1a** adopts an envelope conformation with point group C_s and a P_3O_2 plane.

The ^{1}H-NMR spectra are in accordance with the suggested structures for **1a** and **1b**. The spectrum of the *tert*-butyl compound shows two doublets of relative intensity 1:2, a ratio that has also been found for the methyl protons in the spectrum of the 2-methylphenyl compound **1b**. The spectrum of **1c**, however, is more complex as several broad resonance signals for methyl groups and aromatic protons are observed.

Tris(*tert*-butyl)triphosphonic Acid (2), Bis(*tert*-butyl)diphosphonic Acid (3), and Their Disodium Salts 2a, 2b, and 3a

By reaction of equimolar quantities of **1a** and H_2O in ethanol at 50−60°C for 3.5 h, **2** is obtained as colorless crystals that are soluble in $CHCl_3$, methanol, or ethanol, and melt at 152°C. **2** is a strong dibasic acid (in water at room temperature: pK_{a1} not determinable, pK_{a2} = 2.29). Aqueous solutions of **2** were found to be stable for at least 10 h at room temperature. The $^{31}P\{^1H\}$-NMR spectrum corresponds to an AB_2 spin system (with close approximation to AX_2), and the $^1H\{^{31}P\}$-NMR spectrum shows two resonance signals (intensity ratio 2:1) for the *tert*-butyl groups, as well as one signal in the range of acidic protons. Neutralisation of **2** by NaOH affords **2a**, the dihydrate of its disodium salt. The octahydrate **2b** is obtained by diffusion-controlled precipitation from aqueous solutions of **2a** with acetone. **2b** forms large transparent leaflets, the crystal structure of which is reported.

Bis(*tert*-butyl)diphosphonic acid (**3**) is formed together with *tert*-butylphosphonic acid when the triphosphonic acid (**2**) is heated with concentrated hydrochloric acid for 1 h. After 4 h, tBuP(O)$(OH)_2$ is the sole reaction product. Reaction of **1a** with EtONa (molar ratio 1:4) in refluxing ethanol for 1 h affords the disodium salt of acid **3**. Both compounds were isolated as hydrates of composition **3**·1.5 H_2O and **3a**. They form colorless needles, which loose their water of crystallization on heating at 80−100°C. Compound **3**, m.p. 198−200°C, is soluble in water or acetone, **3a** readily dissolves only in water.

Reaction of (tBuP$O_2)_3$ (1a) with an *N*-Protected Amino Acid

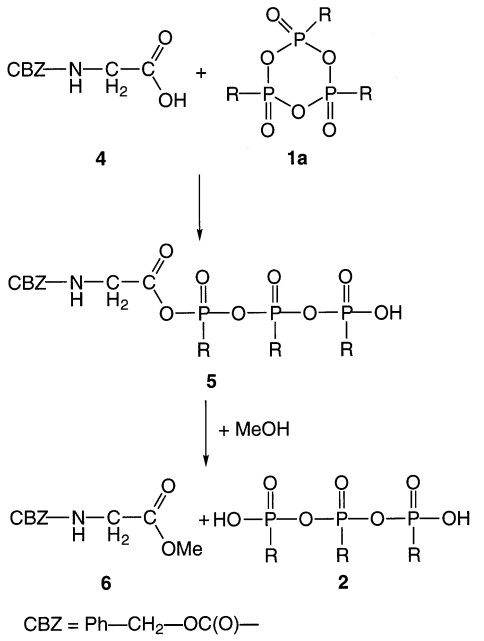
Considering the general methods for peptide synthesis with other phosphorus compounds[11] it can be assumed that with $(PrPO_2)_3$ for example, the first step of the reaction is ring opening and formation of a mixed anhydride of the corresponding triphosphonic acid, and an *N*-protected amino acid. In a subsequent step, the mixed anhydride is thought to react with a carboxyl-protected amino acid, affording triphosphonic acid and the peptide.

Since **1a**, as well as the triphosphonic acid **2**, have been found to be stable against methanolysis, we tried to substantiate the opening step of this peptide synthesis by treating equimolar amounts of **1a** and the *N*-protected amino acid *N*-benzyloxycarbonylglycine (**4**) in methanol. After 3 h at 65°C, the reaction was complete. The reaction product, a colorless, highly viscous oil, was investigated by NMR spectroscopy and GC-MS. The conclusions drawn from the results are shown in Scheme 1, and may be summarized as follows:

The $^{31}P\{^1H\}$-NMR spectrum ($CDCl_3$) of the reaction mixture reveals the presence of one AX_2 system and several strongly overlapping multiplets at δ = 21−23, 30−31, and 32−34. The parameters of the AX_2 system (δ_A = 21.30 (t); δ_X = 31.30 (d); J_{AX} = 49.3 Hz) correspond well with those of the triphosphonic acid **2**. Moreover, a precipitate obtained by adding hexane to the methanolic solution of the reaction product was clearly identified as **2**.

P,P-COSY reveals the presence of 2 AMX spin systems with the following parameters: δ_A = 22.10 (t); δ_M = 30.40 (d); δ_X = 33.70 (d); J_{AM} = 48.3 Hz; J_{AX} = 46.9 Hz and δ_A = 21.80 (t); δ_M = 30.60 (d); δ_X = 33.10 (d); J_{AM} = 47.7 Hz; J_{AX} = 47.2 Hz. The AMX systems possibly result from

Scheme 1. Suggested reaction of **1a** with *N*-benzyloxycarbonylglycine (**4**) (methanol, 65°C, 3 h), R = *t*Bu



the two pairs of diastereomers expected for the mixed anhydride **5** in Scheme 1. According to this scheme, acid **2** and the methyl ester **6**, detected by GC-MS, are formed by methanolysis of **5**. Alternatively, reaction of **4** with **5**, with formation of the anhydride of **4** followed by methanolysis, may be regarded as the source of **6** and **2**.

The ^{1}H-NMR spectrum ($CDCl_3$) of the reaction product shows groups of resonance signals that correspond to protons of the compounds in Scheme 1. They can be assigned as follows:

$\delta(PCCH_3)$ = 1.06−1.56; $\delta(CH_2COOH)$ = 3.51−3.80; $\delta(COCH_3)$ = 4.00−4.06; $\delta(C_6H_5CH_2)$ = 5.17; $\delta(C_6H_5CH_2)$ = 7.24−7.53; $\delta(OH)$ = 9.50−9.70 (s, br.).

Thus, there is strong evidence that mixed anhydrides of phosphonic acids and *N*-protected amino acids (in Scheme 1 represented by **5**) are intermediates in peptide synthesis with $(RPO_2)_n$.

Crystal Structures

In the molecular structure of **1a** in the crystal, trimeric units of tBuPO$_2$ form six-membered rings of P_3O_3, with two *tert*-butyl groups directed to one side of the ring and one group to the other (Figure 2). In slight contrast to the assumed chair conformation used for the interpretation of the NMR data in solution, the P_3O_3 ring takes on an envelope conformation in the crystal, with the oxygen atom O23 as an apex with a deviation of 0.43 Å from the least-squares plane defined by the other five ring atoms. Although the observed deviations from the furthermore assumed symmetry (C_S) of the molecule are small (C_S asymmetry parameters for atoms P1 and O23 are only 2°), their significance is supported by the molecule lying in general position 4e of space group $P2_1/n$.

All bond lengths and angles are in good agreement with common values, and no intermolecular contacts less than the sum of the corresponding van der Waals radii occur. Remarkable geometrical parameters are the angles P1−O12−P2 and P1−O13−P3 with 136.2 and 136.0° respectively, in contrast to the more common value of 130.3° for P2−O23−P3. Also, a distortion of the tetrahedral coordination of the phosphorus atoms is observed, insofar as all bond angles involving the P=O bonds are widened [On−Pn−Cn 116.0−116.5°, On−Pn−O(ring) 111.6−114.6°], and the remaining angles reduced [O(ring)−Pn−O(ring) 101.0−102.8°, O(ring)−Pn−Cn 105.1−106.3° with n = 1, 2, or 3, respectively].

The molecular structure of **2b** consists of one anion $[t\mathrm{Bu_3P_3O_7}]^{2-}$, two Na^+ cations, and eight water molecules, with all atoms in general positions 4e of space group $P2_1/c$. While most geometrical parameters of the anion (Figure 3) agree well with usual values, the oxygen atoms of the two configurations P1−O21−P2 and P2−O23−P3 are significantly shifted towards the central phosphorus atom P2 [mean bond lengths 1.574(3) Å for P2(central)−O and 1.641(2) Å for P1/P3(terminal)−O]. These discrepancies in the four formally equivalent single P−O bonds may be in correlation with the fact that the double bonded O22 at the central P atom is the only atom of the anion coordinating

Figure 2. Molecular structure of **1a** in the crystal[14], thermal ellipsoids represented on a 25% probability scale, hydrogen atoms with fixed radii of 0.15 Å

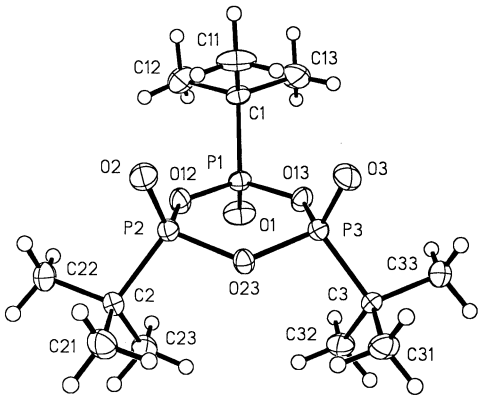


Figure 3. Anion $[t\mathrm{Bu_3P_3O_7}]^{2-}$ of **2b** in the crystal[14], thermal ellipsoids represented on a 40% probability scale, hydrogen atoms with fixed radii of 0.17 Å

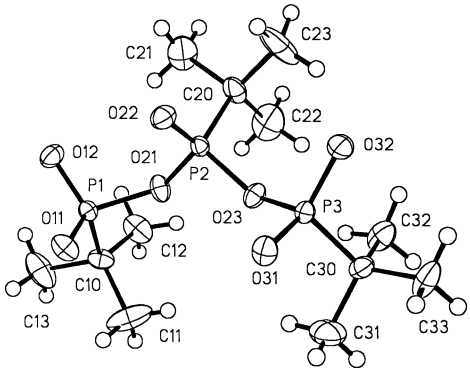

one of the sodium atoms. The other oxygen atoms O11, O12, O31, and O32 accept two or three hydrogen bonds donated by seven of the eight water molecules.

Atom Na1 is hexacoordinated by five water molecules and atom O22 in the form of a distorted octahedron. The coordination of Na2 is made up by five water molecules only, best described as a highly distorted square-based pyramid, sharing one edge with the octahedron of Na1. These two concatenated polyhedra are expanded to a unit of four edge-connected polyhedra by a crystallographic inversion center lying on another edge of the Na1 octahedron.

The complete connectivity of cations, anions, and water molecules making up the crystal structure is very complex (if only because of 16 different hydrogen bonds). In summary it can be said that the anions and seven of the eight water molecules form a hydrogen-bonded layer parallel to the *ac* plane. Two of these layers are concatenated by the eighth water molecule and the two Na^+ cations to form a double layer with all polar parts of the crystal structure (water, Na^+, end groups PO_2^-) on the inside and the non-polar *tert*-butyl groups on the outside of such a double layer. By this arrangement of the anions, any further connectivity between those layers to form a three-dimensional framework is prevented, and only van der Waals contacts between methyl groups of neighbouring layers are observed.

Experimental Section

The silyl esters, and compounds **1** were prepared and handled under inert conditions. − Melting points (uncorrected) were determined in sealed tubes with a melting-point apparatus 510 H (Büchi, Switzerland). − ^{1}H-, ^{13}C-, and ^{31}P-NMR spectroscopy: Bruker AM 200, TMS (^{1}H), sodium salt of 3(trimethylsilyl)propionic acid (^{1}H, ^{13}C) as internal and 85% H_3PO_4 (^{31}P) as external reference. Downfield shifts are positive and given in parts per million, and coupling constants are expressed in Hz. − EI-MS: Varian Mat 311 A (IE 70 eV). − GC-MS: GC 5890−MSD 5970 (Hewlett Packard). Only the main peaks are listed. − Cryoscopy: Cryoscopic unit A 0284 (Knaur, Berlin). − Osmometry: Osmometric unit 11.00, T = 37°C (Knaur, Berlin). − Thermogravimetry: Mettler TA 1. − pK_a values: Potentiometric titration with NaOH using hardware of Schott, Hofheim and the program system MINI T401 and ITERAX[12]. − Elemental analysis: C,H,N: Analyzer 2400 (Perkin−Elmer). P: Photometrically[13] after decomposition with conc. HNO_3 in a stainless steel bomb, type DAB II (Berghof, D-72800 Emingen).

X-ray Crystallographic Study of **1a**: $C_{12}H_{27}O_6P_3$; formula mass 360.25 g mol^{-1}; monoclinic space group $P2_1/n$ (no. 14); a = 7.590(3), b = 27.06(1), c = 8.926(3) Å; β = 95.16(3)°; V = 1826(1) Å^3; Z = 4; $d_{calcd.}$ = 1.310 Mg m^{-3}; μ(Mo-K_α) = 0.346 mm^{-1}; F(000) = 768. Siemens P3 (upgraded Syntex P2$_1$) diffractometer, Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator. Data collection at room temperature in ω/2Θ mode (4° ≤ 2Θ ≤ 55°) on a colorless crystal of about 0.5 × 0.6 × 0.9 mm yielded 4460 reflections, which after merging the symmetry equivalents, gave 4169 independant reflections with 3150 observations with $I > 2\sigma(I)$[14]. After solving the structure by direct methods[15] a final full-matrix least-squares refinement against F^2 [16] of all 4169 reflections resulted in $wR2$ = 0.1773 and $R1$ (obs. refl. only) = 0.0526 for 199 variables, using a "riding" model for the hydrogen atoms with U(H) = 1.3U_{eq}(C). A final difference Fourier map gave min./max. residual electron densities of −0.72/0.50 e Å^{-3}[17].

X-ray Crystallographic Study of **2b**: $C_{12}H_{43}Na_2O_{15}P_3$; formula mass 566.35 g mol^{-1}; monoclinic space group $P2_1/c$ (no. 14); a = 10.869(1), b = 31.139(4), c = 9.123(1) Å; β = 114.59(1)°; V = 2807.7(5) Å^3; Z = 4; $d_{calcd.}$ = 1.340 Mg m^{-3}; μ(Mo-K_α) = 0.301 mm^{-1}; F(000) = 1208. Siemens P3 (upgraded Syntex P2$_1$) diffractometer, Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator. Data collection at room temperature in ω/2Θ mode (4° ≤ 2Θ ≤ 55°) on a colorless crystal of about 0.2 × 0.5 × 0.6 mm yielded 6791 reflections which after merging the symmetry equivalents gave 6405 independant reflections with 4930 observations with $I > 2\sigma(I)$[14]. After solving the structure by direct methods[15] a final full-matrix least-squares refinement against F^2 [18] of all 6405 reflections resulted in $wR2$ = 0.1190 and $R1$ (obs. refl. only) = 0.0404 for 362 variables. For the H atoms of the methyl groups, a riding model with U(H) = 1.3U_{eq}(C) was used, while the H atoms of the water molecules, all being involved in hydrogen bonds, were refined independently with isotropic temperature factors. A final difference Fourier map gave min./max. residual electron densities of −0.67/1.50 e Å^{-3}[17].

Starting materials were mostly prepared according to methods reported in the literature: $(Me_3SiO)_3P$[19], *t*BuP(O)Cl$_2$[20][21], 2-MeC$_6$H$_4$P(O)Cl$_2$[22][23][24], 2,4,6-Me$_3$C$_6$H$_2$P(O)Cl$_2$[24][25], *t*BuP(O)(OSiMe$_3$)$_2$[26], *N*-benzyloxycarbonylglycine[27].

Bis(trimethylsilyl) 2-Methylphenylphosphonate: Following the procedure of Issleib et al.[28] 16 mmol of $(Me_3SiO)_3P$ was added dropwise with stirring to a mixture of 16 mmol of 2-bromotoluene and 0.8 mmol of anhydrous $NiCl_2$ at 160°C. The Me_3SiBr formed in the reaction was continuously distilled off and the residue distilled in vacuo. Colorless, hydrolyzable liquid, b.p. 94°C/0.2 Torr; yield 57%. − $C_{13}H_{25}O_3PSi_2$ (316.5): calcd. C 49.34, H 7.96; found: C 48.95, H 7.86. − EI-MS; *m/z* (%): 316 (30). − ^{31}P{^{1}H} NMR (neat): δ = 0.52 (s). − ^{1}H NMR (C_6D_6): δ = −0.63 (d, $^4J_{PH}$ = 1.16, OSi*Me*$_3$), 1.79 (s, C$_6$H$_4$*Me*), 6.24 (m, C$_6$*H*$_4$Me), 7.37 (m).

Bis(trimethylsilyl) 2,4,6-Trimethylphenylphosphonate: Preparation as before from 21 mmol of $(Me_3SiO)_3P$, 21 mmol of 2,4,6-Me$_3$C$_6$H$_2$Br, and 1 mmol of $NiCl_2$; yield 41%. Colorless, hydrolyzable liquid, b.p. 91°C/0.15 Torr, m.p. 39°C. − $C_{15}H_{29}O_3PSi_2$ (344.5): calcd. C 52.29, H 8.48; found C 52.08, H 7.51. − EI-MS; *m/z* (%): 344 (34). − ^{31}P{^{1}H} NMR (toluene): δ = 4.5 (s). − ^{1}H NMR (C_6D_6): δ = 0.45 (s, OSi*Me*$_3$), 2.24 (s, C$_6$H$_2$*Me*$_3$), 3.06 (s) (intensity ratio 1:2), 6.98 (d, C$_6$H$_2$).

tert-Butylphosphonic Anhydride **1a**: A mixture of 50 mmol of *t*BuP(O)Cl$_2$ and 50 mmol of *t*BuP(O)(OSiMe$_3$)$_2$ was heated for 8 h at 170−180°C and the Me_3SiCl formed was continually distilled off. Subsequently, the reaction product was heated for another 3 h at 110°C in vacuo in order to remove unreacted starting materials, and crystallized from toluene/pentane; yield 46%. Colorless crystals, m.p. 166°C, 150−152°C[6]; 194−195°C[3]. − $C_{12}H_{27}O_6P_3$ (360.3): calcd. C 40.01, H 7.55, P 25.79; found C 39.89, H 7.56, P 25.71. − Mol. mass (cryoscopic in benzene): 358 (0.031 molal), 375 (0.089 molal). − EI-MS; *m/z* (%): 360 (3), 304 (80), 248 (67), 192 (19), 57 (100). − ^{31}P{^{1}H} NMR ($CDCl_3$): AB$_2$ spin system, δ$_A$ = 24.23, δ$_B$ = 23.83, J_{AB} = $^2J_{PP}$ = 50.6, δ = 24.12 (s, $CDCl_3$)[6], 31.16 (s, C_6D_6)[3]. − ^{1}H{^{31}P} NMR (C_6D_6): δ = 1.43 (s), 1.32 (s), intensity ratio 1:2.

2-Methylphenylphosphonic Anhydride (**1b**): 13 mmol of 2-MeC$_6$H$_4$P(O)(OSiMe$_3$)$_2$ and 13 mmol of 2-MeC$_6$H$_4$P(O)Cl$_2$ in 40 ml of toluene were heated so that the Me_3SiCl which formed and small amounts of toluene were continually distilled off. At the end of the reaction the distillate consisted solely of toluene. After concentrating the solution, **1b** was precipitated by slow addition of ligroin (100−140°C); yield 97%. Colorless, very hydrolyzable crystals, m.p.

123−125°C. − $C_{21}H_{21}O_6P_3$ (462.3): calcd. C 54.65, H 4.58, P 20.10; found C 54.34, H 4.38, P 19.90. − Mol. mass (cryoscopic in benzene): 458 (0.085 molal), 462 (0.112 molal). − EI-MS; *m/z* (%): 462 (100), 309 (19), 155 (28). − $^{31}P\{^1H\}$ NMR (C_6D_6): AB_2 spin system, $\delta_A = 1.99$, $\delta_B = -0.46$; $J_{AB} = {}^2J_{PP} = 42.6$. − ^1H NMR (C_6D_6): δ = 2.72 (s, CH_3), 3.01 (s), intensity ratio 2:1; 7.04 (m, C_6H_4), 8.25 (m), 8.65 (m).

2,4,6-Trimethylphenylphosphonic Anhydride (**1c**): Preparation as mentioned before from 20 mmol of 2,4,6-$Me_3C_6H_2P(O)(OSiMe_3)_2$ and 20 mmol of 2,4,6-$Me_3C_6H_2P(O)Cl_2$ in 70 ml of toluene. The anhydride formed is only sparingly soluble in toluene, and was thus precipitated in the course of the reaction as colorless hydrolyzable crystals that could be used without further purification; yield 58%, m.p. 250°C. − $C_{27}H_{33}O_6P_3$ (546.5): calcd. C 59.34, H 6.09, P 17.00; found C 59.02, H 5.83, P 17.00. − EI-MS; *m/z* (%): 546 (100), 364 (38), 183 (40). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 1.48 (s). − ^1H NMR ($CDCl_3$): δ = 2.34, 2.59, 2.81 (intensity ratio 2:4:3, CH_3); 6.97, 7.04 (C_6H_2), (in all cases broad signals).

Tris(tert-butyl)triphosphonic Acid (**2**): A solution of 40 mmol of **1a** in 150 ml of ethanol, containing 40 mmol of H_2O, was heated at 60°C for 3 h. After evaporation of the solvent, the residue is washed with ligroin (100−140°C) and dried in vacuo; yield 54%. Colorless, crystalline powder, soluble in $CHCl_3$, MeOH, EtOH, or water, m.p. 152°C. − $C_{12}H_{29}O_7P_3$ (378.3): calcd. C 38.01, H 7.73, P 24.56; found C 38.02, H 7.87, P 24.30. − The acid is associated via hydrogen bonds. − IR (KBr): $\tilde{\nu}$ = 2663 cm^{-1}, 2298 cm^{-1}, 1654 cm^{-1}. − Mol. mass (osmometric in $CHCl_3$, 37°C): 609 (0.063 molal, 672 (0.123 molal). − $^{31}P\{^1H\}$ NMR (C_6D_6): AB_2 spin system, $\delta_A = 20.31$, $\delta_B = 31.05$; $J_{AB} = {}^2J_{PP} = 49.3$. − ^1H NMR ($CDCl_3$): δ = 1.30 (d, $^3J_{PH}$ = 18.2, PCMe), 1.36 (d, $^3J_{PH}$ = 19.6), intensity ratio 2:1, 11.84 (s, OH).

Disodium Salts of Tris(tert-butyl)triphosphonic Acid, Dihydrate (**2a**) *and Octahydrate* (**2b**): After neutralization of 5 mmol of **2** in 10 ml of H_2O with 1 M NaOH, the resulting sodium salt was precipitated by adding acetone. Crystallization from acetone/water and drying at 20°C in vacuo afforded **2a** as shiny small leaflets that are readily soluble in water; yield practically quantitative. **2b** was obtained as transparent plates, m.p. > 300°C, from a concentrated solution of the disodium salt in H_2O by diffusion-controlled precipitation with acetone, and drying in vacuo at 20°C. − $C_{12}H_{27}Na_2O_7P_3 \cdot 2\ H_2O$ (458.3): calcd. C, 31.45; H, 6.82; P, 20.28; found C, 31.17; H, 6.63; P, 20.05. − $C_{12}H_{27}Na_2O_7P_3 \cdot 8\ H_2O$ (566.4): calcd. C, 25.45; H, 7.65; found C, 25.60; H, 7.58. − According to the results of thermogravimetric measurements, both hydrates loose their water of crystallization completely between 80−100°C. − $^{31}P\{^1H\}$ NMR (D_2O): AB_2 spin system, $\delta_A = 19.80$, $\delta_B = 29.50$; $J_{AB} = {}^2J_{PP} = 49.7$. − ^1H NMR (D_2O): δ = 1.16 (d, $^3J_{PH}$ = 16.9, PC*Me*), 1.27 (d, $^3J_{PH}$ = 18.91), intensity ratio 2:1.

Bis(tert-butyl)diphosphonic Acid (**3**): After heating 2.6 mmol of **2** with 10 ml of conc. hydrochloric acid for 1 h, the clear solution was cooled to room temperature. The resulting precipitate was filtered off and dried in vacuo at 20°C. Crystallization from toluene afforded colorless needles, m.p. 198−200°C that are soluble in acetone and sparingly soluble in H_2O; yield 23%. − $C_8H_{20}O_5P_2 \cdot 1.5\ H_2O$ (285.2): calcd. C 33.68, H 8.07, P 21.73; found C 33.28, H 8.16, P 21.45. − EI-MS; *m/z* (%): 459 (11), 259 (22), 202 (100), 146 (33), 138 (51), 123 (12), 83 (20), 57 (83). − $^{31}P\{^1H\}$ NMR ([D_6]acetone): δ = 32 (s). − ^1H NMR ([D_6]acetone): δ = 1.40 (m, PCMe); 4.55 (s, br., POH).

tert-Butylphosphonic Acid can be isolated from the filtrate by concentration and crystallization of the residue from toluene; yield 72%; colorless needles, m.p. 188−190°C (see ref.[30] 191°C), soluble in H_2O or acetone. − $^{31}P\{^1H\}$ NMR ([D_6]acetone): δ = 39.50 (see ref.[30] 37.00, [D_6]acetone).

Disodium Salt **3a**: A solution of EtONa from 28.4 mmol of Na in 20 ml of EtOH was added dropwise to 7.1 mmol of **1a** in 20 ml of EtOH. After heating for 1 h, the sodium salt formed was filtered off and dried in vacuo at 20°C; yield 57%. Colorless needles from water/acetone, m.p. > 320°C. Loss of weight between 80−110°C: 15.5% (TG), calcd.: 15.16%. − $C_8H_{18}Na_2O_5P_2 \cdot 3\ H_2O$ (356.2): calcd. C 26.98, H 6.79, P 17.39; found C 26.78, H 6.82, P 17.39. − $^{31}P\{^1H\}$ NMR (D_2O): 26.30 (s). − ^1H NMR (D_2O): $[AX_9]_2$ spin system centered at δ = 1.13. − ^{13}C NMR (D_2O): X-part of an AA′X spin system centered at δ = 33.91, coupling constants obtained according to ref.[29]: $^2J_{PP}$ = 48.6; $^1J_{PC}$ = 144.5; $^3J_{PC'}$ = 2.0.

Reaction of **1a** *with N-Benzyloxycarbonylglycine* (**4**): 10 mmol of **4** in 20 ml of methanol was added to a heated solution of 10 mmol of **1a** in 10 ml of methanol. After boiling the mixture for 3 h, the solvent was removed in vacuo at room temperature. The residue was a highly viscous, colorless liquid. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): AX_2 spin system $\delta_A = 21.30$ (t); $\delta_X = 31.30$ (d); $J_{AX} = 49.3$; two AMX spin systems $\delta_A = 22.10$ (t); $\delta_M = 30.40$ (d); $\delta_X = 33.70$ (d); $J_{AM} = 48.3$; $J_{AX} = 46.9$ and $\delta_A = 21.80$ (t); $\delta_M = 30.60$ (d); δ_X = 33.10 (d); $J_{AM} = 47.7$; $J_{AX} = 47.2$ Hz. − ^1H NMR ($CDCl_3$): δ = 1.06−1.56 ($PCCH_3$); 3.51−3.80 (CH_2COOH); 4.00−4.06 ($COCH_3$); 5.17 ($C_6H_5CH_2$); 7.24−7.53 ($C_6H_5CH_2$); 9.50−9.70 (s, br., OH). − GC-MS of **6**; *m/z* (%): 223(9), 108(80), 91(100).

Received September 19, 1997

Keywords: Phthalocyanines / Indium / Indium−carbon bond

The synthesis of highly soluble chloro(phthalocyaninato)indium(III) complexes R_xPcInCl (**3a**: R^1 = *tert*-butyl, R^2 = H, x = 4 and **4a**: $R^1 = R^2$ = *n*-pentyl, x = 8), and their reactions with R′MgBr [R′ = *p*-trifluoromethylphenyl- (**b**), *m*-trifluoromethylphenyl- (**c**), *p*-fluorophenyl- (**d**), perfluorophenyl- (**e**)] leading to the stable σ-bonded aryl(phthalocyaninato)indium(III) complexes **3b−e**, **4b−e** are described. All compounds were characterized by IR, UV/Vis, MS, ^{1}H, ^{13}C and ^{19}F NMR as well as elemental analyses. Phenyl(phthalocyaninato)indium(III) (**4f**) was prepared by the reaction of $(n\text{-}C_5H_{11})_8$PcInCl (**4a**) with PhLi. The high solubility of the complexes **3a−e** and **4a−f** is, aside from the influence of the peripheral substituents, considered to be derived from the large dipole moments present which are due to the strongly electron withdrawing axial ligands, and from the lower tendency of axially substituted phthalocyaninato metal complexes to form aggregates.

Phthalocyanines and phthalocyaninato metal complexes have been investigated in detail for many years[1], particularly with regard to their properties as dyes[2]. More recently their widespread potential in material sciences[3] has been discovered. Besides numerous other applications these "functional dyes" have also attracted considerable interest in the field of non-linear optics[4]. It is the extensively delocalized π-system in phthalocyanines which gives rise to large optical non-linearities. Furthermore, due to the diversity of the structural features[5] of phthalocyanines, tuning of the optical properties can be achieved by synthetic variations. For example, about 70 different elements have been incorporated into the phthalocyanine core, some of them with different oxidation states, and in addition there are one or two sites which coordinate a variety of axial ligands. The introduction of a diversity of peripheral substituents, with many possibilities to alter the substitution pattern with respect to the number and position of the substituents, has a strong influence[6] on the electronic absorption spectra and optical non-linearities. Other factors[4] which affect optical non-linearities are the length of π-electron conjugation, the crystal structure, and the thin film fabrication techniques employed. The aim of our current research is a systematic study of the effect of axial substitution on non-linear optical (NLO) properties, and specifically on the optical limiting properties of phthalocyanines. Axial substitution will have several effects: it can alter the electronic structure of the phthalocyanine, it can introduce a dipole moment perpendicular to the macrocycle, and, via steric effects, it can also alter the spatial relationships between neighbouring molecules and thus the magnitude of the intermolecular interactions. Large axial substituents can alter the packing of the molecules in the solid state and the tendency to aggregate in solution. Each of these effects can influence the NLO properties. In fact a correlation between the magnitude of the third-order non-linear optical susceptibility tensor $\chi^{(3)}$ for third harmonic generation (THG) experiments[4] and axial substitution has been noted. The reason for this effect may be associated with the fact that there is a permanent dipole moment in these materials.

Several axially substituted phthalocyanines have been reported[4][7] to be good non-linear absorbers for optical limiting, but there has been no study of the effect of different axial substitution patterns on the relevant optical properties of these materials.

Our approach here is to investigate the influence of different axial substituents on the reverse saturable absorption, and optical limiting properties, of soluble peripherally alkylsubstituted phthalocyaninatoindium(III) complexes. Among the axially substituted phthalocyanines, $(t\text{Bu})_4$PcInCl[7] has one of the largest positive non-linear absorption coefficients. It has been used to manufacture optical limiting devices.

A comparative study of the optical properties of $(t\text{Bu})_4$PcInCl with several aryl substituted phthalocyaninatoindium(III) complexes (see Scheme 1) is in progress. The aryl ligands are chosen so as to alter both the spatial and electronic properties of the materials. Compared with the chloro ligand, aryl substituents will introduce steric crowding and should reduce the tendency, which is common in phthalocyanines, to form aggregates . Due to the increasing electron withdrawing properties of the aryl ligands, these

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0367 $ 17.50+.50/0

materials should possess an increasing ground state dipole moment.

Scheme 1. Synthesis of the chloro- and aryl(phthalocyaninato)indium(III) complexes

We have therefore synthesized a series of monoaxially chloro and aryl substituted phthalocyaninatoindium(III) complexes R_xPcIn(R′) [**3**: R^1 = *tert*-butyl, R^2 = H, x = 4 and **4**: R^1 = R^2 = *n*-pentyl, x = 8; R′ = chloro- (**a**), *p*-trifluoromethylphenyl- (**b**), *m*-trifluoromethylphenyl- (**c**), *p*-fluorophenyl- (**d**), perfluorophenyl- (**e**), phenyl- (**f**); see Scheme 1], which we expect to have similar steric, but different electronic, properties.

Although there are some reports on the preparation of phthalocyaninato[8] as well as porphyrinato[9] metal complexes with metal−alkyl or metal−aryl σ-bonds, to our knowledge nothing is known about complexes of the type PcIn(R′). From studies of alkyl- and aryl(porphyrinato)indium(III) complexes[10] it is known that their stability depends largely on the electron withdrawing properties of the axial ligands. Organometallic complexes containing strongly electron withdrawing perfluoroaryl groups generally show quite different properties than derivatives of the same containing a simple phenyl group[11]. In many cases it was shown that the carbon−metal bond in perfluorophenyl metal complexes is extraordinarily robust for a σ-bond[12].

Coincidentally, the electron withdrawing properties of the ligands which were attached to the indium atom in order to obtain complexes with substantial axial dipole moments are, at the same time, responsible for the stability of these compounds.

Results and Discussion

The complexes (*t*Bu)$_4$PcInCl (**3a**)[7] and (C_5H_{11})$_8$PcInCl (**4a**) were prepared starting from stoichiometric amounts of 4-*tert*-butylphthalonitrile (**1**)[13] or 4,5-bis(*n*-pentyl)-phthalonitrile (**2**)[14] and $InCl_3$ in quinoline in the presence of catalytic amounts of DBU. The aryl(phthalocyaninato)-indium(III) complexes **3b−e** and **4b−e** were synthesized by the reaction of freshly prepared aryl Grignard compounds with the respective R_xPcInCl complexes **3a** or **4a** (see Scheme 1). The complexes **3a−e** and **4a−e** were characterized by IR, UV/Vis, MS, ^{1}H, ^{13}C, and ^{19}F NMR as well as elemental analyses.

In an attempt to synthesize the parent phenyl(phthalocyaninato)indium(III) complexes **3f** and **4f** starting from PhLi and **3a** or **4a,** it became clear that these compounds are less stable than the fluorinated derivatives. Only a few milligrams of **4f** could be isolated by extraction with *n*-hexane from the crude product. The decomposition product R_8PcH_2 showed poor solubility in this solvent. The small amount obtained limited the characterization of **4f** to MS, IR and UV/Vis. However, a satisfactory elemental analysis could be obtained for this complex. Phenyl(phthalocyaninato)indium(III) **3f** could not be separated from (*t*Bu)$_4$PcH$_2$ in the same way due to the high solubility of the latter in *n*-hexane.

The complexes are highly soluble in various organic solvents such as toluene, dichloromethane, and chloroform. The tetrasubstituted compounds **3a−e** exhibit a much higher solubility in acetone than the corresponding octa-substituted compounds, **4a−f**. (*t*Bu)$_4$PcIn(PFP) (**3e**) is even slightly soluble in methanol. In general, the aryl substituted complexes **3b−e** and **4b−f** are more soluble in solvents of medium polarity, such as dichloromethane, than the corresponding chloroindium(III) complexes **3a** and **4a**. The peripherally tetrasubstituted phthalocyanines **3a−e** consist of a mixture of four structural isomers[15], as regards the fact, that the *tert*-butyl groups can occupy either two positions R^1 or R^2 in each of the isoindoline units of the macrocycles. They are more soluble[3a][16] than their structural counterparts that have eight substituents, assuming the same substitution pattern (herein: 2,3). The high solubility of the aryl substituted phthalocyanines **3b−e** and **4b−f** indicates that they possess quite large axial dipole moments. The enhanced solubility of the complexes **3b−e** and **4b−f**, com-

pared to the chloro analogues **3a** and **4a**, shows that the usual tendency of phthalocyanines to form aggregates[17] can be effectively suppressed by axial substitution. The more sterically demanding the axial ligands are, the lower will be the degree of aggregation.

Elemental analyses and mass spectral data of all the investigated phthalocyaninatoindium(III) complexes suggest the molecular formulas $R_xPcInCl$ and $R_xPcIn(R')$ for the compounds **3a**, **4a** and **3b−e**, **4b−f**, respectively. For each complex a cluster of peaks, almost identical in intensity to that calculated for its respective isotopic composition, was observed in the field desorption mode. Fragmentation was not observed under these conditions.

In Table 1 the IR data of the aryl(phthalocyaninato)indium(III) complexes are reported. Only the additional absorptions, which do not appear in the spectra of the respective chloro substituted phthalocyanines **3a** or **4a**, are listed in Table 1. Characteristic vibrations for aryl groups bound to a metal atom[18] are found in the range 190−1650 cm^{-1}. In the 670−830 cm^{-1} range vibrational frequencies associated with the C−H out of plane deformation modes of the axial aryl groups appear. The intense absorption bands of the C−F stretching mode are found between 900−1460 cm^{-1}. The vibrational frequencies between 1500−1640 cm^{-1} are associated with the ring vibrations of the axial ligands. The weak absorption band of the In−Cl stretching mode at 336 and 327 cm^{-1} appears in the spectra of the chloro derivatives **3a** and **4a**, respectively. The In−C stretching mode can not be unambiguously assigned due to coupling with C−C modes and vibrations of the phthalocyaninic macrocycle.

Table 1. IR data of the investigated $R_xPcIn(R')$ complexes (KBr pellets)

Ph	**4f**					1359								

The electronic absorption data of the complexes investigated are summarized in Table 2. The spectra of **3a−e** and **4a−f** show the typical pattern[17a] of phthalocyaninato metal complexes, with an intense Q band absorption and its vibrational satellites Q(1,0) and Q(2,0), as well as lower intensity π-π* transitions within the heteroaromatic π-system [B(0,0), B(1,0)]. Introduction of electron-donating alkyl groups in the periphery of the macrocycle leads to a bathochromic shift of the Q band maximum[6b][6c]. The octasubstituted complexes **4a−e** have their Q band shifted to the red by $\Delta\lambda$ = 16.0−17.3 nm, and the tetrasubstituted complexes **3a−e** by $\Delta\lambda$ = 7.1−7.8 nm (see Table 2), with respect to the unsubstituted PcInCl[19]. In contrast, the axial ligands introduced have little influence on the wavelength of the Q band maximum. The observed red shifts are only of the order of 1 nm.

Table 2. UV/Vis data of the investigated $R_xPcInCl$ and $R_xPcIn(R')$ complexes in chloroform

Phthalocyanine Pc	Axial ligand R′	λ_{max} [nm]

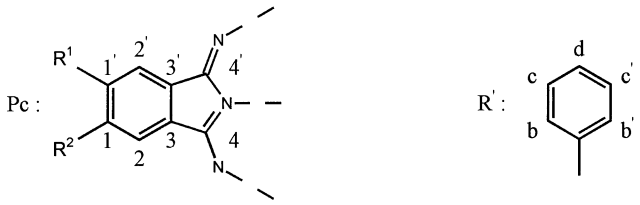
[a] All of these bands appear as shoulders.

The ^{1}H-NMR spectrum of $(t\text{Bu})_4$PcInCl (**3a**) shows three multiplets in the aromatic region centred at δ = 8.30, 9.30 and 9.45 for the 1-H, 2-H and the 2′-H protons, respectively (see Figure 1). The values for the corresponding protons of all of the aryl substituted complexes **3b−e** are close to those of **3a**, despite the different axial ligands. ^{1}H-NMR data of protons of the macrocycle and peripheral substituents are listed in the experimental section for each compound. The downfield shifts of $\Delta\delta \approx$ 0.4, 0.18 and 0.13 for the 1-H, 2-H and 2′-H protons in these compounds point to the fact that the σ-bonded aryl groups lead to stronger deshielding of the aromatic protons, especially of those closer to the heteroaromatic ring system (2-H, 2′-H), than does the chloro ligand. The same can be seen by comparison of $(C_5H_{11})_8$PcInCl (**4a**) and $(C_5H_{11})_8PcIn(R')$ (**4b−e**). In the ^{1}H-NMR spectrum of **4a** the aromatic protons give rise to a singlet at δ = 9.10. The signals of the corresponding protons 2,2′-H of **4b−e** are shifted downfield by $\Delta\delta$ = 0.16−0.18.

In contrast, the signals of the axial ligands are considerably shielded by the influence of the large diamagnetic ring-current[20] of the heteroaromatic π-electron system of the phthalocyanine. The shorter the distance between these protons and the centre of the macrocycle, the larger the upfield shift (see Table 3). This is in agreement with the

Figure 1. Notation of the atoms of the macrocycles and axial ligands



proposed structures for the aryl(phthalocyaninato)indium(III) complexes **3b–e** and **4b–e**. The absolute upfield shifts were explicitly calculated by comparing the shifts of corresponding protons for the $R_xPcIn(R')$ complexes and for R′Br, where no influence of a macrocyclic diamagnetic ring-current exists.

Table 3. ^{1}H-NMR data[a] of the protons for the axial ligands in the $R_xPcIn(R')$ complexes and for R′Br[a]

Axial ligand R′	Phthalocyanine Pc		Protons of R′ δ	multi/ intens	Protons of R′Br δ	Upfield shift Δδ

		H-c,c′	5.64−5.71	m/2	6.90-6.97	−1.25
	4d	H-b,b′	4.00−4.06	m/2	7.40−7.45	−3.39
		H-c,c′	5.62−5.70	m/2	6.90−6.97	

[a] Spectra were recorded in $CDCl_3$ at 300K (250.131MHz).

In the ^{13}C-NMR spectra of the compounds synthesized a slight deshielding effect is observed for the carbon atoms close to the indium atom. Again the signals for those carbon atoms in the aryl(phthalocyaninato)indium complexes **3b–e** and **4b–e**, being closer to the phthalocyanine core (C-4 and C-4′), are shifted further downfield than those for C-3 and C-3′ (see Figure 1). Only some of the carbon atom resonances of the axial ligands could be detected. This is due to the C–F coupling leading to split signals of low intensity, the low number of atoms in each set of magnetically equivalent carbon atoms in the ligand compared to the macrocycle, and to the fact that the solubility of the complexes is still too low with regard to the factors limiting the signal intensity which were mentioned previously.

The ^{19}F-NMR data of eight $R_xPcIn(R')$ complexes are given in Table 4. $CDCl_3$ was used as internal standard with $CFCl_3$ as a reference. One narrow singlet was observed for the complexes PcIn(*p*-TMP) (**3b**, **4b**) and PcIn(*m*-TMP) (**3c**, **4c**), all with similar chemical shifts and close to the fluorine signal in α,α,α-trifluorotoluene at −63.9[21]. Due to H–F coupling, multiplets centred at −113.4 and −113.8 are observed for the complexes PcIn(*p*-FP) (**3d**) and (**4d**), respectively. These values are close to that of fluorine in fluorobenzene: −113.1[21]. Three signals are found in the spectra of the perfluorophenyl complexes **3e** (**4e**) at −122.1 (−122.0), −160.9 (−161.2) and −153.3 (−153.7) for the *o*-, *m*-, and *p*-fluorine atoms, respectively. In relation to pentafluorobenzene, whose signals for the same nucleus are at −139.2, −162.7 and −154.5[22a], the *o*-fluorine atoms close to the indium(III) metal are remarkably deshielded. The deshielding of aromatic fluorine atoms in complexes where they are in the *ortho* position of a metal–carbon bond has already been observed and discussed[22]. The spin systems of fluorine in the PcIn(PFP) complexes **3e** and **4e** have typical AA′MM′X patterns[23], which is in agreement with their proposed structures.

Table 4. ^{19}F-NMR data[a] for the $R_xPcIn(R')$ complexes in chloroform

[a] Spectra were recorded in $CDCl_3$ at 300K (235.334 MHz). Chemical shifts (δ) upfield from the reference $CFCl_3$ are defined as negative. – [b] With broad-band proton decoupling.

In conclusion stable aryl(phthalocyaninato)indium(III) complexes have been prepared starting from chloro(phthalocyaninato)indium(III) and aryl Grignard reagents or aryl lithium compounds, respectively. Electron withdrawing substituents at the aryl ligands are essential to increase the stability of the complexes obtained. All aryl(phthalocyaninato)indium(III) compounds prepared are highly soluble in common organic solvents. Studies on the non-linear optical properties of these new phthalocyaninato complexes, particularly with regard to their optical limiting properties, are in progress.

We would like to thank Dr. *J. S. Shirk* of the *Naval Research Laboratory* in Washington, DC for many helpful discussions and Mrs. *Heike Dorn* for recording the ^{19}F-NMR spectra. We thank the *Fonds der Chemischen Industrie* for the financial support of this work.

Experimental Section

All reactions were carried out under a dry nitrogen atmosphere. THF was distilled from sodium benzophenone ketyl prior to use, quinoline from calcium hydride. *p*-Trifluoromethylbromobenzene, *m*-trifluoromethylbromobenzene, *p*-fluorobromobenzene, perfluorobromobenzene were obtained from commercial sources. 4-*tert*-Butylphthalonitrile (**1**)[13] and 4,5-bis(*n*-pentyl)phthalonitrile (**2**)[14] were prepared according to literature procedures. – FT-IR:

Perkin Elmer Spectrum 1000. − UV/Vis: Shimadzu UV-365. − MS: Varian Mat 711 (FD, temperature of the ion source: 30°C). − ^{1}H, ^{13}C NMR: Bruker AC 250 (^{1}H: 250.131 MHz, ^{13}C: 62.902 MHz). − ^{19}F NMR: Bruker Avance DRX 250 (235.334 MHz). − Elemental Analyses: Carlo-Erba Elemental Analyser 1104, 1106.

General Procedures: The Grignard compounds R′MgBr [R′ = *p*-trifluoromethylphenyl- (**b**), *m*-trifluoromethylphenyl- (**c**), *p*-fluorophenyl- (**d**), perfluorophenyl- (**e**)] were prepared by stirring a mixture of the corresponding substituted bromobenzenes [338 mg (**b**, **c**), 263 mg (**d**), 371 mg (**e**); 1.5 mmol] and Mg turnings (38.9 mg, 1.6 mmol), previously activated by means of an ultrasonic bath, in freshly dried THF (3 ml) at room temp. After most of the magnesium had been consumed, the solution was diluted to a volume of 10 ml by addition of THF. The solution was transferred into a pressure equalizing addition funnel containing a small quantity of glass wool to hold back excess solid magnesium.

Chloro-(tetra-(tert-butyl)phthalocyaninato)indium(III) and Chloro-(octa-(n-pentyl)phthalocyaninato)indium(III) (**3a**, **4a**): A mixture of $InCl_3$ (1.52 g, 6.88 mmol), 4-*tert*-butylphthalonitrile [(**1**), 5.07 g, 27.52 mmol] or 4,5-bis(*n*-pentyl)phthalonitrile [(**2**), 7.38 g, 27.52 mmol], dry quinoline (12 ml), and DBU (1 ml) were stirred at 180°C for 5 h. The solvent was removed by distillation under reduced pressure, leaving a dark green residue, which was chromatographed on silica gel using chloroform as the eluent in order to remove large amounts of the impurities. Then the crude compounds **3a** and **4a** were recrystallized from mixtures of CH_2Cl_2/MeOH (v/v 4:3) or $CHCl_3$/EtOH (v/v 15:7), respectively, by slowly evaporating the more volatile chloromethanes in a rotary evaporator at 40−60°C under slightly reduced pressure. To complete crystallization, the mixtures were kept in a refrigerator overnight. The complexes were collected by filtration, washed twice with methanol and dried at 80°C in vacuo. − (tBu)$_4$PcInCl (**3a**): Yield 2.98 g (49%), blue-green microcrystals. − IR (KBr): $\tilde{\nu}$ = 3075 cm^{-1} vw, 2957 vs, 2903 m, 2866 m, 1613 vw, 1485 s, 1393 m, 1364 m, 1330 vs, 1280 m, 1256 s, 1199 w, 1147 w, 1087 vs, 1047 m, 922 s, 896 w, 831 m, 761 w, 746 m, 693 w, 671 w, 602 vw, 568 vw, 524 vw, 444 vw, 336 w. − UV/Vis ($CHCl_3$): λ_{max} = 697.3 nm, 667.1 (sh), 628.2, 359.5, 339.7 (sh). − ^{1}H NMR ($CDCl_3$): δ = 1.82−1.84 (m, 36 H, tBu), 8.27−8.33 (m, 4 H, 1-H), 9.27−9.33 (m, 4 H, 2-H), 9.42−9.47 (m, 4 H, 2′-H). − ^{13}C NMR ($CDCl_3$): δ = 32.01−32.04 (CH_3), 36.16 (CMe_3), 119.71−119.80 (C-2′), 123.09−123.21 (C-2), 128.48−128.56 (C-1), 135.07−135.23 (C-3), 137.49−137.72 (C-3′), 152.74−153.50 (C-4,4′), 154.55−154.72 (C-1′). − MS (FD); *m*/*z*: 886.2 [M$^+$]. − $C_{48}H_{48}ClInN_8$ (887.2): calcd. Aryl(tetra-(tert-butyl)phthalocyaninato)indium(III) and Aryl-(octa-(n-pentyl)-phthalocyaninato)indium(III) (**3b−e**, **4b−e**): In a typical reaction, a freshly prepared solution of R′MgBr [R′ = *p*-trifluoromethylphenyl- (**b**), *m*-trifluoromethylphenyl- (**c**), *p*-fluorophenyl- (**d**), perfluorophenyl- (**e**)] in THF (10 ml; 0.15 M R′MgBr), was added dropwise to a stirred solution of **3a** or **4a** (0.3 mmol) in dry THF (25 ml). The reaction was monitored by TLC (silica gel/toluene) and stopped when all of the R_xPcInCl (**3a**, **4a**) had been consumed. The deep green mixture was poured on ice and was extracted several times with diethyl ether. The combined organic layers were washed with water and dried with $MgSO_4$. After evaporation of the solvent, the residue was subjected to column chromatography (silica gel/toluene). Light was strictly excluded during this step. Further purification of the complex was achieved by recrystallization from mixtures of CH_2Cl_2 and methanol, as described above. The pure phthalocyanine was dried in vacuo at 70°C for 3 h. − (tBu)$_4$PcIn(*p*-TMP) (**3b**): Yield 134.4 mg (45%), bluish green powder. − IR (KBr): $\tilde{\nu}$ = 3076 cm^{-1} vw, 2959 s, 2903 m, 2867 w, 1614 w, 1599 vw, 1487 s, 1388 m, 1365 m, 1327 vs, 1280 m, 1257 s, 1200 w, 1164 m, 1152 m, 1128 s, 1086 vs, 1047 s, 1016 w, 954, 922 m, 897 vw, 831 m, 819 w, 760 w, 747 m, 694 w, 678 w, 671 w, 603 vw, 566 vw, 525 vw, 446 vw. − UV/Vis ($CHCl_3$): λ_{max} = 698.0 nm, 667.3 (sh), 628.6, 369.3, 340.9 (sh). − ^{1}H NMR ($CDCl_3$): δ = 1.80 (m, 36 H, tBu), 4.17 (d, J = 7.6 Hz, 2 H, H-b,b′), 6.17 (d, J = 7.6 Hz, 2 H, H-c,c′), 8.32−8.36 (m, 4 H, 1-H), 9.44−9.52 (m, 4 H, 2-H), 9.57−9.59 (m, 4 H, 2′-H). − ^{13}C NMR ($CDCl_3$): δ = 32.00−32.04 (CH_3), 36.12−36.15 (CMe_3), 119.68 (C-2′), 122.54 (q, J = 3.7 Hz, C-c,c′) 123.04 (C-2), 128.29−128.36 (C-1), 134.26 (C-a), 135.40−135.48 (C-3), 137.84−137.92 (C-3′), 153.69−154.24 (C-4,4′), 154.38−154.48 (C-1′). − ^{19}F NMR ($CDCl_3$): δ = −64.1. − MS (FD); *m*/*z*: 995.9 [M$^+$]. − $C_{55}H_{52}F_3InN_8$ (996.9): calcd. First Results in the Preparation of Phenyl(octa-(n-pentyl)phthalocyaninato)indium(III) (**4f**): Phenyllithium in cyclohexane/diethyl ether (0.5 M) at room temp. was added dropwise to a solution of **4a** (122.4 mg, 0.1 mmol) in dry THF (25 ml). The reaction was monitored by TLC (silica gel/toluene) and stopped when all of the R_8PcInCl (**4a**) had been consumed. The deep green mixture obtained was worked up as described above. The complex **4f** was separated from the crude mixture by stirring it in *n*-hexane. Due to the insolubility of the metal free phthalocyanine (formed during the reaction) in this solvent, pure phenyl(phthalocyaninato)indium(III) was obtained after filtration and evaporation of the solvent. – $(C_5H_{11})_8$PcIn(Ph) (**4f**): Green powder. – IR (KBr): $\tilde{\nu}$ = 2955 cm^{-1} vs, 2926 vs, 2858 s, 1618 vw, 1483 m, 1466 m, 1400 w, 1378 w, 1359 m, 1333 s, 1098 vs, 1079 m, 1011 w, 893 w, 868 vw, 745 m, 732 w, 724 m. – UV/Vis ($CHCl_3$): λ_{max} = 706.6 nm, 676.2 (sh), 635.8, 375.9, 353.6 (sh). – MS (FD); *m/z*: 1263.7 [M^+]. – $C_{78}H_{101}InN_8$ (1265.5): calcd. C 74.03; H 8.04; N 8.85; found C 73.97; H 7.91; N 8.96.

Keywords: α-Metallated amino acids / Palladium / Platinum / Oxidative addition / α-Bromoglycinate

Oxidative addition of methyl *N*-benzoyl-2-bromoglycinate to bis(dibenzylideneacetone)palladium, in the presence of 2,2′-bipyridyl, and to $(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)$ gives the α-metallated glycine esters **1a** and **2a**. Abstraction of bromide from **1a**, **2a**, using $AgSbF_6$ or $AgBF_4$, affords the cationic C,O-chelate complexes $[(bpy)Pd{-}CH(CO_2Me)NHC(Ph)O]^+$ (**1b**,**c**) and $[(Ph_3P)_2Pt{-}CH(CO_2Me)NHC(Ph)O]^+$ (**2b**), respectively, featuring coordination of the amide O atom. The complexes **1b** and **2b** have been characterized by X-ray diffraction.

α-Haloglycine esters are valuable synthons for the synthesis of modified α-amino acids[3]. Recently, we used these compounds for the introduction of α-amino acid residues into organometallic systems[4], giving products that may find application in the labelling of amino acids and peptides, a growing field in bioinorganic chemistry[5]. α-Metallated amino acids are intermediates in the asymmetric hydrogenation of dehydroamino acids and have been detected as such by Halpern et al.[6] and Brown et al.[7] by means of NMR spectroscopy.

Structures of α-metallated amino acids have been reported by Vahrenkamp et al.[8] and by ourselves[4b]. Recently, Bergens et al.[9] characterized a C,O-bound intermediate in the hydrogenation of methyl α-acetamidocinnamate, derived from a $(BINAP)(H)Ru^{II}$ catalyst.

The easy access to α-metallated amino acids by oxidative addition of methyl *N*-benzoyl-2-bromoglycinate to $Me_2Pt(bpy)$ (bpy = 2,2′-bipyridyl)[4b] prompted us to search for square-planar complexes with the halide and the *C*-bound α-amino acid in a *cis* configuration. Abstraction of halide from these should yield simple models for intermediates in the hydrogenation of dehydroamino acids, with coordination of the amide O atom.

The oxidative addition of organic halides to zerovalent palladium and platinum complexes[10], e.g. to $(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)$[11] or to $(dba)_2Pd$ (dba = dibenzylideneacetone)[12] is a general method for the synthesis of σ-bonded organometallic complexes.

Results and Discussion

The reactions of methyl *N*-benzoyl-2-bromoglycinate with $(dba)_2Pd$ in the presence of bpy, and with $(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)$ yielded the α-metallated complexes **1a** and **2a**, respectively, in good yields. The compounds were found to be light-sensitive and relatively unstable in air and towards organic solvents. Abstraction of bromide from **1a**, **2a**, using $AgSbF_6$ or $AgBF_4$, led to coordination of the amide group, thereby affording the stable C,O-chelate complexes **1b**,**c** and **2b**.

The IR spectra of **1a** and **2a** show typical ester and amide absorptions at 1715 and 1640 cm^{-1}. The shift of the carbonyl ester band to lower wavenumbers ($\tilde{\nu} \approx 30\ cm^{-1}$) compared with the corresponding band in α-amino acid esters has been observed previously[4b]. The lower wavenumber of the amide absorption in **1b**,**c** and **2b** (1600 cm^{-1}) is characteristic of a coordinated amide group. The ^{1}H-NMR spectrum of **1a** exhibits a doublet due to the CH proton, as expected, while that of complex **1c** features a broad singlet.

The signal of the Pt−CH proton in **2a** appears as a pseudo-quadruplet with satellites due to ^{195}Pt−C−H coupling. In the ^{1}H-NMR spectrum of **2b**, a doublet of triplets is observed for the α-CH proton due to *cis* and *trans* ^{31}P−Pt−C−H coupling.

The ^{13}C-NMR spectra of **1c** and **2b** show the expected resonances. Two ^{31}P-NMR signals for the two non-equivalent P atoms are observed for **2b**. Their ^1J(Pt−P) values differ significantly because of the different *trans* influence of the strong C and weak O donors, similar to the situation in $(Ph_3P)_2Pt{-}C(H)(CO_2R)C(O)O$[13].

Cationic alkyl- or acyl$(bpy)Pd^{II}$ complexes readily react with CO, isonitriles, alkenes or allenes[14]. Surprisingly, **1a** does not undergo insertion of CO, ethylene or allene at atmospheric pressure. Treatment with *tert*-butylisonitrile leads only to coordination of the isonitrile {$\tilde{\nu} = 2222\ cm^{-1}$ [ν(CN)]} and no insertion product could be detected.

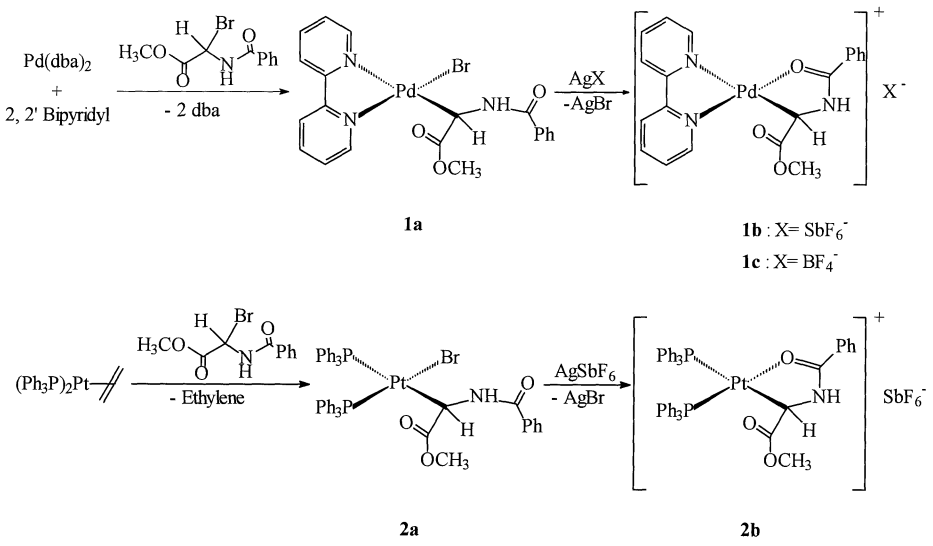

Figure 1. Molecular structure of **1b**[a]

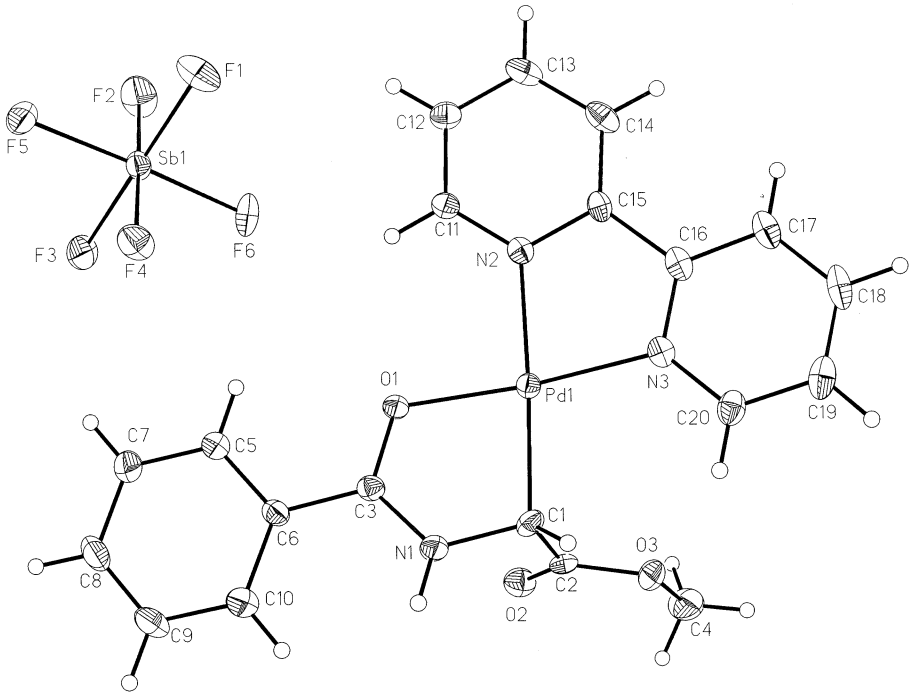


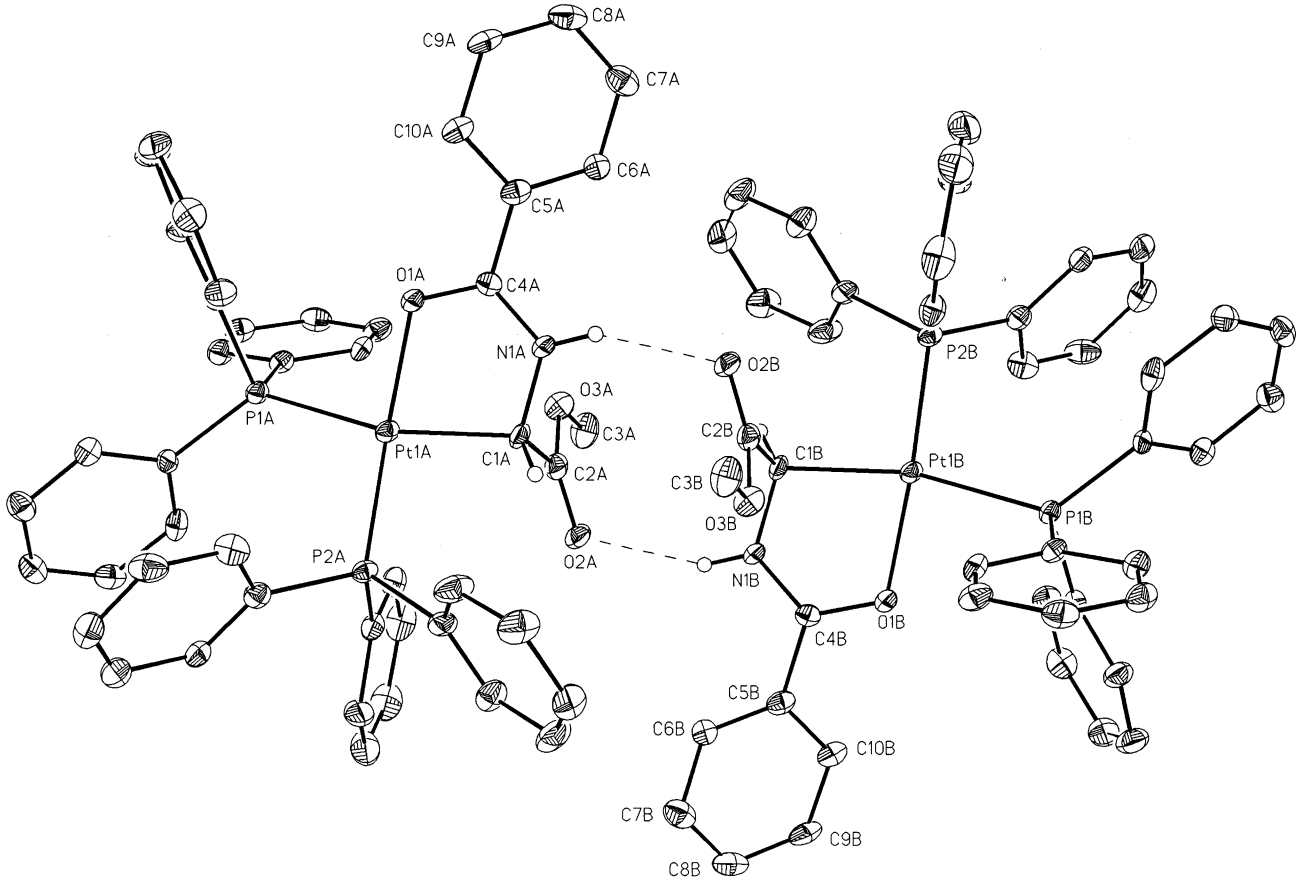
[a] Selected bond lengths [pm] and angles [°]: Pd1−N2 205.2(5), Pd1−N3 201.9(5), Pd1−O1 201.3(4), Pd1−C1 203.3(6), O1−C3 127.5(7), C3−N1 132.2(8), N1−C1 146.0(8); N2−Pd−N3 80.0(2), O1−Pd1−C1 82.4(2), Pd1−C1−N1 104.2(4), Pd1−O1−C3 113.4(4).

Crystal Structure Determinations of 1b and 2b

Crystals suitable for structure determination by X-ray diffraction were obtained by liquid-liquid diffusion of diethyl ether into an acetone solution of **1b** at room temperature and from a dichloromethane solution of **2b** layered with *n*-pentane. The unit cell of **1b** was found to contain the α*S* and α*R* enantiomers (at C1), with a parallel arrangement of the molecules and pairs of enantiomers (with a center of symmetry, Pd···Pd 427 pm) in the lattice. As expected on the basis of the spectroscopic data, the amino acid is coordinated to the Pd atom through the α-carbon atom and the amide group (Figure 1).

The palladium center in **1b** has a square-planar environment with Pd−N distances (203−205 pm) similar to those reported for related complexes[12][15]. The Pd−C distance [203.3(6) pm] compares well with values found for other sp^3 carbon atoms *trans* to an sp^2 nitrogen atom[15]. The acyl CO bond length [127.5(7) pm] is typical for a carbonyl group, although the CO absorption in the IR spectrum (1602 cm^{-1}) is suggestive of more single-bond character. The α-carbon atom is approximately tetrahedrally coordinated, with the largest deviation from ideal geometry being manifested in the N−C−Pd angle (104°). The chelate ring is almost planar and has a (small) O−C−N−C torsion angle of 11.7°.

Figure 2. Structure of **2b**[a]



[a] Selected bond lengths [pm] and angles [°]: Pt1−P1 232.8(2), Pt1−P2 223.3(2), Pt1−O1 208.9(4), Pt1−C1 210.0(6), O1−C4 128.1(7), C4−N1 130.9(8), N1−C1 146.0(8); P1−Pt1−P2 99.91(6), C1−Pt1−O1 80.8(2), Pt1−C1−N1 104.4(4), Pt1−O1−C4 112.1(4).

A similar structure is found for **2b**. The two P atoms in **2b** are seen to deviate from the coordination plane by 18° and 3.4°, respectively. The Pt−α-C bond length [210.0(6) pm] is comparable to that found in other platinum(II) complexes with Pt−α-alkyl bonds[16].

Interestingly, pairs of enantiomers α*S* and α*R* are found in the crystal (Figure 2), which are linked through two hydrogen bonds between the amino and the carbonyl groups of the methyl ester (N−H···O 286 pm).

Support by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged. We thank Professor Dr. *W. Steglich*, München, for valuable discussions.

Experimental Section

General: All reactions were carried out in dry solvents under argon. − NMR: Jeol GSX 270 (^{1}H 270.0; ^{13}C 100.4; ^{31}P 109.3 MHz) with tetramethylsilane as internal standard; H_3PO_4 (85%) as external standard. − IR: 5ZDX FT-IR. − $(dba)_2Pd$[18], (η^2-ethylene)$(Ph_3P)_2Pt$[19] and methyl *N*-benzoyl-2-bromoglycinate[3b] were prepared according to literature procedures. $AgBF_4$ and $AgSbF_6$ were purchased from Aldrich and stored in the dark under argon.

(bpy)[CH(NHCOPh)(CO$_2$Me)]PdBr (**1a**): To a solution of 173 mg (0.3 mmol) of $(dba)_2Pd$ in 10 ml of benzene, 47 mg (0.3 mmol) of 2,2′-bipyridyl and 82 mg (0.3 mmol) of methyl *N*-benzoyl-2-bromoglycinate were added. The mixture was stirred for 1 h

at room temp., during the course of which a yellow-green powder precipitated. The precipitate was separated by centrifugation, washed with diethyl ether (2 × 10 ml), and dried in vacuo. Yield 128 mg (80%), yellow-green powder, m.p. 164°C. – IR (KBr): $\tilde{\nu}$ = 3407 cm^{-1} m (NH), 1716 s (CO_2), 1633 s (NCO). – ^1H NMR ($CDCl_3$): δ = 3.74 (s, 3 H, CH_3), 5.32 (d, ^3J = 9.2 Hz, 1 H, CH), 7.36–7.49 (m, 4 H, NH, C_6H_5), 7.57–7.74 (m, 2 H, bpy), 7.86–8.21 (m, 6 H, bpy, C_6H_5), 9.25 (d, ^3J = 3.94 Hz, 1 H, *o*-bpy), 9.35 (d, ^3J = 5.4 Hz, 1 H, *o*-bpy). – $C_{20}H_{18}N_3O_3BrPd \cdot 0.5C_6H_6$ (573.8): calcd. C 48.15, H 3.69, N 7.32; found C 47.97, H 3.71, N 7.26.

[CH(NHCOPh)(CO$_2$Me)](PPh$_3$)$_2$PtBr (**2a**): To a solution of 224 mg (0.3 mmol) of (η^2-ethylene)($Ph_3P)_2Pt$ in 10 ml of benzene, 82 mg (0.3 mmol) of methyl *N*-benzoyl-2-bromoglycinate was added. Gas evolution was observed and the yellow solution was stirred for 1 h. A white residue was separated by centrifugation, the volatiles were evaporated from the supernatant solution, and the residue was washed with pentane (3 × 15 ml). Yield 268 mg (90%), white powder, m.p. 104°C (decomp.). – IR (KBr): $\tilde{\nu}$ = 3413 cm^{-1} m (NH), 1713 s (CO_2), 1647 s (NCO), 280 m (PtBr). – ^1H NMR (C_6D_6): δ = 3.78 (s, 3 H, CH_3), 5.44 (pseudo-q, $^3J_{PH}$ = 9.7 Hz, $^2J_{PtH}$ = 93.6 Hz, 1 H, CH), 6.94–8.74 (m, 36 H, NH, C_6H_5, PPh_3). – ^{31}P NMR (C_6D_6): δ = 17.90 (d, $^2J_{PP}$ = 16.5 Hz, $^1J_{PtP}$ = 1902.9 Hz), 20.45 (d, $^2J_{PP}$ = 16.5 Hz, $^1J_{PtP}$ = 4481.5 Hz). – $C_{46}H_{40}NO_3BrP_2Pt$ (991.8): calcd. C 55.71, H 4.07, N 1.41; found C 55.51, H 4.76, N 1.75.

General Procedure for the Abstraction of Bromide from **1a** and **2a**: To a solution of 160 mg (0.3 mmol) of **1a** [or 297 mg (0.3 mmol) of **2a**] in 10 ml of acetone, a solution of 58 mg (0.3 mmol) of $AgBF_4$ or 103 mg (0.3 mmol) of $AgSbF_6$ in 5 ml of acetone was added. Reaction was indicated by the rapid precipitation of AgBr; the suspension was stirred for 1 h in the dark at room temp. and then the precipitate was separated by centrifugation. The colorless/yellow solution was concentrated in vacuo and the residue was washed with diethyl ether (**1b**,**c**) or pentane (**2b**) (2 × 15 ml) and dried in vacuo.

[(bpy)Pd–CH(CO$_2$Me)NHC(Ph)O]$^+$ BF$_4^-$ (**1c**): Yield 154 mg (95%), colorless powder, m.p. 193°C (decomp.). – IR (KBr): $\tilde{\nu}$ = 3410 cm^{-1} m (NH), 1707 s (CO_2), 1602 s (NCO), 1083 (BF_4^-). – ^1H NMR ($CDCl_3$ + DMSO): δ = 3.33 (s, 3 H, CH_3), 4.57 (s, 1 H, CH), 7.14–7.43 (m, 5 H, Ph, bpy), 7.71 (d, ^3J = 7.6 Hz, 2 H, Ph), 7.92 (pseudo-q, ^3J = 7.7 Hz, 2 H, bpy), 8.01–8.11 (m, 2 H, bpy), 8.43 (d, ^3J = 5.5 Hz, 1 H, bpy), 8.71 (d, ^3J = 5.2 Hz, 1 H, bpy), 9.77 (s, 1 H, NH). – ^{13}C NMR ($CDCl_3$ + DMSO): δ = 50.86, 51.25 (CH, CH_3), 122.30, 122.98, 126.64, 126.71, 126.73, 127.77, 128.07, 132.89, 140.07, 140.44, 147.62, 152.66, 152.71, 155.72 (bpy, Ph), 173.90, 178.63 (CO_2, NCO). – $C_{20}H_{18}BF_4N_3O_3Pd$ (541.6): calcd. C 44.35, H 3.35, N 7.76; found C 43.89, H 3.17, N 7.61.

[(Ph$_3$P)$_2$Pt–CH(CO$_2$Me)NHC(Ph)O]$^+$ SbF$_6^-$ (**2b**): Yield 309 mg (90%), colorless powder, m.p. 158°C (decomp.). – IR (KBr): $\tilde{\nu}$ = 3437 cm^{-1} m (NH), 1709 m (CO_2), 1607 m (NCO), 1098 (SbF_6^-). – ^1H NMR ($CDCl_3$): δ = 3.27 (s, 3 H, CH_3), 5.44 (dt, $^3J_{(PH)trans}$ = 9.9 Hz, $^3J_{(PH)cis}$ = 2.1 Hz, $^3J_{HH}$ = 2.1 Hz, $^2J_{PtH}$ = 46.8 Hz, 1 H, CH), 7.00–7.71 (m, 35 H, PPh_3, Ph), 8.24 (pd, $^4J_{PH}$ = 6.5 Hz, $^3J_{HH}$ = 2.1 Hz, 1 H, NH). – ^{13}C NMR ($CDCl_3$): δ = 50.62 (CH_3), 62.82 (dd, $^2J_{(PC)trans}$ = 81.8 Hz, $^2J_{(PC)cis}$ = 3.6 Hz, CH), 127.57–134.87 (m, 42 C, PPh_3, Ph), 173.64 (d, $^3J_{(PC)trans}$ = 4.7 Hz, CO_2), 180.78 (dd, $^3J_{(PC)trans}$ = 10.6 Hz, $^3J_{(PC)cis}$ = 3.4 Hz, NCO). – ^{31}P NMR ($CDCl_3$): δ = 8.33 (d, $^2J_{PP}$ = 19.8 Hz, $^1J_{PtP}$ = 4223.1 Hz), 22.87 (d, $^2J_{PP}$ = 19.8 Hz, $^1J_{PtP}$ = 2243.5 Hz). – $C_{46}H_{40}F_6NO_3P_2PtSb$ (1147.6): calcd. C 48.14, H 3.51, N 1.22; found C 48.53, H 3.89, N 1.24.

Crystal Structure Determinations: A suitable single crystal of **1b** or **2b** was mounted on a glass fibre with perfluoroether oil. After cooling to –80°C, the crystal was optically centered on a Siemens P4 four-circle diffractometer equipped with a CCD area detector. The dimensions of the unit cell were determined from the observed reflections (> 10 σ) in 4 × 15 frames with different ψ and χ orientations. Data collection was performed with 10-s exposures at two different χ settings with Δψ intervals of 0.3° (altogether 1296 frames). Data reduction was performed with the program SAINT of Siemens Analytical Instruments, and a semiempirical absorption correction was applied. The structures were solved by the heavy-atom method and successive Fourier synthesis using the SHELX-93 program (G.W. Sheldrick, University of Göttingen). All non-hydrogen atoms were refined anisotropically. H atoms bound to carbon atoms were placed in calculated positions and refined with a riding model. *N*-bonded H atoms were located in the difference Fourier synthesis and were freely refined with a fixed isotropic N. Selected crystallographic data and data relating to the structure solutions and refinement are summarized in Table 1.

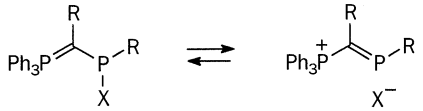
Keywords: Phosphanes / Phosphorus ylides / Nucleophilic addition / Structure elucidation / NMR spectroscopy

Chlorophosphanyl and dichlorophosphanyl alkylidene- and benzylidenephosphoranes **6** and **8** are converted by reaction with $LiAlH_4$ to the respective phosphanes **7** and **9**. The former can be isolated, but decompose on heating or on protonation to give the ylidyl diphosphane **11** and the phosphonium ylide or phosphonium salt, respectively. The final products are the cyclooligophosphanes **15**–**17**. Only the *C-tert*-butyl derivative **7c** is stable in both regards. The conformation of the RPH group in **7** as compared to that of the RPCl group in **6** clearly reflects their different interaction with the ylide moiety.

The most notable feature of ylide-substituted halophosphanes **1** (X = Cl, Br) is the elongated P–X bond and the ease of dissociation of this bond[1][2][3].



1

In these compounds, the electron-accepting halophosphane moiety matches the electron-donating ylide moiety. As a consequence, the system is stabilized and in particular the $C-P^{III}$ bond is strengthened. The exchange of the halogen for hydrogen will, in contrast result in a mismatch of the two moieties and consequently in labile P–C bonds. With the exception of **7e**[4] (see below), no primary or secondary phosphanes with an ylide substituent are known. Special examples of secondary ylidylphosphanes **4** with Ar = 2,4,6-$tBu_3C_6H_2$ are proposed as intermediates from the 2:1 reaction of triphenylphosphonium ylide **2** and the monochlorophosphane **3**. The final products of this reaction are triphenylphosphane and the phosphaalkenes **5** [mixtures of (*E*/*Z*) isomers][5].

We report here the synthesis of ylidylphosphanes by a Cl/H-substitution and on their thermal decomposition, which is different to the one described for **4**.

Synthesis of Ylidylphosphanes

By reaction with $LiAlH_4$ at −40°C in THF solution, the chlorophosphanyl benzylidenephosphoranes **6** are converted to the phosphanyl derivatives **7**, which are stable at room temperature and can be isolated as orange (R = alkyl) or yellow (R = Ph) crystals. The compounds are readily

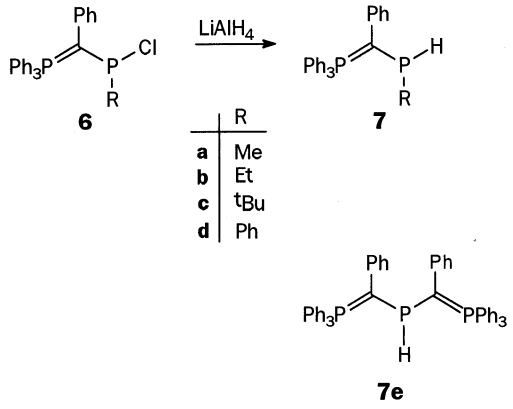
	R
a	H
b	Me
c	Et
d	Pr
e	Ph

soluble in THF and benzene but hardly soluble in pentane, and, except for **7c**, they are unstable in dichloromethane. This synthesis could not be extended, however, to examples with Me in place of Ph as the substituent at the ylidic carbon atom. In this case, from the analogous reaction, no ylidylphosphanes could be identified. A further example of type **7**, with two ylide substituents (**7e**, R = Ph_3PCPh) is formed as stable red crystals from the reaction of the bis(ylidyl)phosphenium chloride $(Ph_3PCPh)_2P^+Cl^-$ with $LiAlH_4$[4].

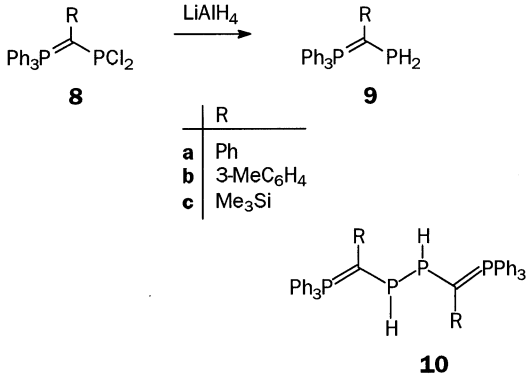
Under the same conditions, dichlorophosphanyl benzylidenephosphoranes **8a**, **b** and dichlorophosphanyl trimethylsilylmethylenephosphorane **8c** are converted by $LiAlH_4$ to the respective ylidylphosphanes **9**. They can be identified in solution at −40°C by their NMR spectra and can be observed for a short time at room temperature, but due to their thermal instability they cannot be isolated. In the reaction of **8c**, the bis(ylidyl)diphosphane **10c** is observed as a second, slightly more thermally-stable product.

Of particular interest among the ^{31}P-NMR data (Table 1) are the coupling constants $^2J_{PP}$ of the ylidylphosphanes

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/0303–0381 $ 17.50+.50/0



9 and **7**. They are considerably smaller than those of the dichlorophosphanes **8** (around 227 Hz) and the chlorophosphanes **6** (around 179 Hz). A value around 159 Hz as found for most compounds **9** and **7** still corresponds, however, to a synperiplanar orientation of the electron lone pair at P^{III} and the phosphonio group (as it is also observed in the crystal, see below). The much smaller constants of **9c** and **7e**, however, indicate that the antiperiplanar conformer has a large predominance in these cases.



The ^{13}C-NMR spectra of compounds **7** as compared to those of compounds **6** reflect the Cl/H exchange by a high-field chemical shift of the ylidic carbon signal as well as by a slight increase in $^1J_{P(V)C}$ and a sharp decrease in $^1J_{P(III)C}$. These changes correspond well to a reduced electron transfer from the ylide to the P^{III} moiety.

Like other secondary phosphanes, the ylidylphosphane **7d** can be converted to the corresponding lithium phosphide by reaction with butyllithium in tetrahydrofuran.

Molecular Structures of Ylidylphosphanes

Crystals of **7a**·THF and **7d**·0.5 THF, suitable for X-ray structure analyses were obtained from THF solutions saturated at ambient temperature, to which pentane was added. The results of the structure determinations are shown in Figure 1 and Table 2. In both cases, the ylidic carbon atom C1 has a planar coordination sphere and the electron lone pair at P2 shows a roughly synperiplanar orientation with respect to the phosphonio center P1. This conformation has been found, in general, for ylidylphosphanes[1]. The bond lengths and angles of the two structures do not differ significantly and are in agreement with standard values.

For comparison, Table 2 also shows the structural data of the chlorophosphane **6a**. While the pyramidal P^{III}-coordination (sum of angles 302±1°) and the average of the two dihedral angles (130±2°) is essentially the same in all three cases, the conformation and the individual dihedral angles P1−C1−P2−C2 and P1−C1−P2−H/Cl in the hydrogen derivatives **7** are quite different from those in the chloro compound **6**. The angle P−C−P−Cl in **6** is, in fact, much smaller than the average, resulting in a near-ecliptic alignment of the P−Cl bond and the ylidic electron pair and allowing an effective charge transfer into the P−Cl bond. The corresponding dihedral angles P−C−P−H in **7** are, in contrast, larger than the average value and the P−H bond seems to avoid the described alignment. The dihedral angles are thus inversely ordered to the substituent's electronegativity Cl > C and C > H. The different charge transfer connected to the different conformation can also be monitored from the bond P2−C1 which is much shorter in the chloro derivative **6** than in the hydrogen derivatives **7**. Finally the

Thermolysis of Ylidylphosphanes

If the ylidylphosphanes **7a**, **b**, **d** are heated in solution to 60 °C for several hours, they completely decompose to the ylide **2e** and a mixture of the cyclotri-, cyclotetra-, and cyclopentaphosphanes **15**, **16**, and **17**. The formation of this mixture seems to be kinetically determined and requires a pathway consistent with the formation of small cyclophosphanes off the thermodynamic equilibrium. Such a pathway is proposed in Scheme 1. If the heating is interrupted after a few minutes, besides unreacted ylidylphosphanes **7**, the ylidyldiphosphanes **11** can in fact be clearly identified by their ^{31}P-NMR spectra and, somewhat less clearly, also the ylidyltriphosphanes **12**.

Scheme 1
