Aluminium Atoms at High Connectivity Sites in Polyhedral Polyborane Analogous Clusters: From Aluminaboranes to Carbaalanes

Werner Uhl*[a] and Frank Breher[a]

Keywords: Carbaalanes / Cluster compounds / Electron deficiency / Aluminium / Boron

Cluster chemistry in the third main group has long been restricted to compounds of the lightest element boron. However, about 30 years ago the first compounds were synthesized and characterized in which single aluminium atoms adopted positions of high connectivity in polyhedral borane or carbaborane clusters. The next successful step in these efforts to establish a chemistry analogous to that of the polyboranes with the heavier elements of the third main-group was the synthesis of *closo*-dodecaaluminate $[Al_{12}iBu_{12}]^{2-}$ at the beginning of the nineties, which was the first homonuclear aluminium analogue of a polyborate anion and had a core exclusively formed by aluminium atoms. Another class of interesting new aluminium compounds was formed by the carbaalanes, which were synthesized and characterized for the first time only recently. They have clusters of aluminium and carbon atoms, and are similar to the carbaborane analogues in that their structures seem to be determined by the number of electron pairs in their molecular centers in accordance with the Wade rules.

Introduction

Polyhedral compounds containing clusters of boron atoms have been well-known since the pioneering work of Alfred Stock at the beginning of this century.[1] Usually, the boron atoms in these clusters have a high connectivity[2] and are attached to up to six other boron atoms, as observed for a boron atom located above a boat-shaped six-membered ring in $[B_{11}H_{11}]^{2-}$.[3] Essentially, the configuration of these clusters is determined by the number of electron pairs delocalized in their molecular cores;[2][4] the addition of more electrons gives more open clusters. They can all be derived from the corresponding *closo* polyborate anions, in which the number of electron pairs exceeds the number of vertices by one. Two and three extra electron pairs are required for the electron count in *nido* or *arachno* compounds, respectively. The syntheses[5] of those polyborate anions or polyborane molecules often starts with diborane(6) (B_2H_6) or the borate anion $[BH_4]^-$, but in many cases the very sophisticated procedures yield the products in only poor yields. Nevertheless, these polyboron compounds form a class of well-characterized and highly interesting species with fascinating structures and bonding situations

Werner Uhl studied chemistry at the Technical University, Karlsruhe (Germany) where he obtained his PhD, after two years at the University of Marburg (Germany) under the supervision of Professor Gerd Becker, in 1980. Thereafter he undertook two years of industrial experience in the research and development department at the NUKEM company in Hanau (Germany), before he followed G. Becker to the University of Stuttgart (Germany) in 1983. He completed his "habilitation" in inorganic chemistry in 1989 and became a Professor of Inorganic Chemistry at the University of Oldenburg in 1992. In October 1999, he moved to the Philipps University of Marburg.

Frank Breher studied chemistry at the University of Oldenburg (Germany) where he graduated in 1998. After one year in the research group of Professor Uhl he moved with his group to the Philipps University of Marburg in September 1999. His research activities are focused on the synthesis of carbaalane cluster compounds.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

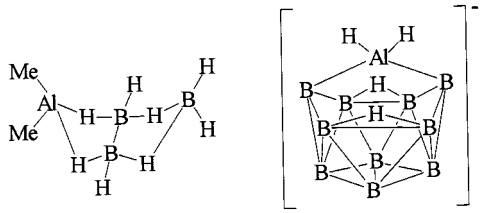
in their clusters, and were thoroughly investigated by conventional physical methods of structure determinations and quantum chemical calculations.[2]

Many years after the first synthesis of polyhedral polyboranes the carbaboranes were obtained as a new class of compounds; they have one or more boron atoms of the clusters replaced by carbon atoms. Often, they were synthesized by the reaction of polyboranes or some activated derivatives with alkynes,[2,5,6] but once again the yields are very low in most cases. The hydroboration of borylalkynes as a facile method for the synthesis of carbaboranes will be discussed in more detail later on. The structures and the bonding situation of these carbaboranes are quite similar to those of the pure boranes and this became clearer after the isolobality between the fragments BH^- and CH was recognized in the Sixties.[2] Carbaboranes are now known in huge numbers with a large variety of different structures and of carbon to boron ratios. They have been used to synthesize many fascinating derivatives with elements of the main group or transition metals enclosed in their clusters,[5] of which, as an example, only the dicarbollide ligand[7] will be mentioned, which gives coordination compounds similar to cyclopentadienyl complexes.

In contrast to these well-established classes of polyhedral cluster compounds, no comparable chemistry has been developed with aluminium which is the next heavier homologue of boron in the third main group. Only a few compounds have been described in the literature, in which one aluminium atom occupies a vertex in a borane or carbaborane cluster or which has a skeleton of aluminium atoms similar to the *closo* borate anions. Both these classes of compounds will be described in the next sections in more detail. Carbaalanes, which have clusters exclusively formed by aluminium and carbon atoms, analogous to the carbaboranes, have been obtained and completely characterized for the first time only recently by our group, they will be discussed in the last section of this Microreview.

Tetrahedral and neutral cluster compounds such as the rare examples containing boron, B_4Cl_4[8] (Scheme 1) or $B_4(CMe_3)_4$,[9] will not be considered here as they do not fit in the classic scheme of ordering in borane or carbaborane chemistry. This type of clusters has found considerable interest in current organoaluminium chemistry and several remarkable compounds with tetrahedra of aluminium atoms such as $Al_4Cp^*_4$[10] (Cp^* = pentamethylcyclopentadienyl), $Al_4[Si(CMe_3)_3]_4$[11] (Scheme 1), $Al_4[C(SiMe_3)_3]_4$,[12] or $Al_4[Si(SiMe_3)_3]_4$[13] have been reported in the literature. The cluster compound $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ was synthesized starting with aluminium(I) chloride and has three polyhedral shells of Al atoms and will also not be considered here.[14] The rapidly growing and fascinating chemistry of monovalent aluminium as well as the similar chemistry of the heavier homologues gallium, indium and thallium has been reviewed several times before.[15–17] Furthermore, we will not discuss compounds derived from these Al^I derivatives, which formally obey the Wade rules[4] for *closo* clusters like $Al_3Cp^*_3As_2$ with a trigonal bipyramidal Al_3As_2 cluster[18] and which, from quantum chemical calculations, have a delocalized electronic system in their molecular cores.



Scheme 1

Aluminaboranes and Aluminacarbaboranes

Few compounds are known in which single aluminium atoms occupy the positions of boron atoms in polyboranes. The simplest one (**1**) is derived from tetraborane(10), in which one bridging BH_2 group is replaced by an $AlMe_2$ group (Scheme 2). This compound was synthesized in high yield by the reaction of $[B_3H_8]^-$ with dimethylaluminium chloride,[19][20] and its structure was confirmed by an electron diffraction experiment in the gas phase.[20][21] Its conformation is quite similar to that of tetraborane(10),[22] although the inner B–B bond is lengthened. The Al–B distance of the Al–H–B three center bonds was found to be 231.6 pm which, as expected, is much longer than the Al–B distances observed in the other cage compounds discussed here. Decaborane(14) gave the aluminapolyborate anion $[AlH_2B_{10}H_{12}]^-$ (**2**) upon treatment with trimethylamine alane or monochloroalane adducts $AlXH_2{\cdot}NMe_3$ (X = H, Cl).[23][24] The structure is derived from that of $B_{10}H_{14}$ with the aluminium atom bridging the boron atoms in the 2,6 position of the boron polyhedron (Scheme 2). Compound **2** was claimed in 1965 to be the first compound containing a direct Al–B bond. Aluminium boranate $Al(BH_4)_3$ was reported to react with diborane(6), pentaborane(9) or tetraborane(10) with the formation of three different polyhedral aluminaboranes, for which the compositions AlB_4H_{11}, AlB_5H_{12}, and, after a decomposition reaction, AlB_6H_{13} were given.[25] The structures of these compounds are uncertain, although a polymeric structure with Al–H bridges was suggested from some physical and chemical properties. A *closo* aluminaboranate anion (**3**) analogous to $[B_{12}H_{12}]^{2-}$ was obtained according to Equation 1.[26] It possesses an icosahedron of eleven boron atoms and one aluminium atom (Figure 1). The B–B distances (176.0 to 185.6 pm) are within the normal range reported for polyboranes, the longer ones were observed for the pentagon bridged by the Al atom. As expected, the five B–Al distances are almost equidistant (213.1 to 214.0 pm) and the Al–C vector is only slightly tilted (by 2°) from the normal of that plane, which is formed by the five nearest boron atoms.

Much more information is available concerning carbaborane derivatives containing one aluminium atom, and much of the work has been done by the group of Hawthorne. A 3-alumina-1,2-dicarba-*closo*-dodecaborane **(4)**, obtained by the treatment of 1,2-dicarbaundecaborane with triethylaluminium (Equation 2),[27] has an icosahedral

structure with the Al atom coordinated to both carbon atoms and three boron atoms as well as the terminal ethyl group (Figure 2). The Al−B and Al−C bond lengths in the cluster are 217.3 and 213.7 pm, respectively. As expected, the terminal Al−C bond is much shorter and has a length of 193.0 pm. The terminal Al−C bond is tilted from the normal of the B_3C_2 plane by 19.5°, so that the methylene group of the disordered ethyl substituent approaches both carbon atoms of the cluster. Compound **4** may be described as a dicarbollyl complex with a carbaboranate ligand coordinated to an Al atom; indeed, such compounds were later used as dicarbollyl transfer reagents.[28] The Al atom of **4** is electrophilic and, upon treatment with THF[29] or phosphanes,[30] adducts are formed in which the connectivity of the Al atoms is reduced to a normal value of four as shown by a crystal structure determination of a phosphane derivative (Figure 3). The cluster is attached to the Al atom by only one boron atom, and the Al−B distance is 212.8 pm, which is shorter than the three Al−B separations observed in the *closo* cluster **4**. The contacts of the Al atom to both remaining boron atoms are much longer (248.0 pm on average) and indicate no further significant bonding interaction. A similar reduction of the connectivity of the Al atoms was observed in some other cluster compounds, which had AlR_2 or AlRL (L = Et_2O) groups in bridging positions[29,30−33] and which are not discussed here in detail.

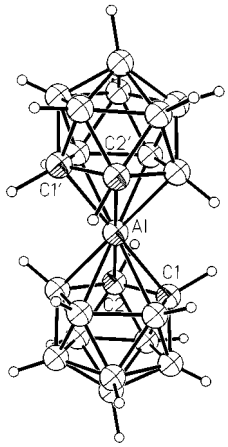
Two remarkable bis(dicarbollide)aluminium sandwich compounds were described by the group of Hawthorne,[30,34–36] and may be named as *commo*-3,3′-bis(3-alumina-1,2-dicarba-*closo*-dodecaboranate) (Figure 4). One compound was obtained by the treatment of the aluminacarbaborane **4** with carbon monoxide.[30][34] It has an *exo* diethylaluminium group coordinated by two hydrogen atoms to one of the carbaborane clusters. The second compound (**5**) was synthesized by the reaction of diethylaluminium chloride with a thallium salt of the corresponding carbaborane (Equation 3).[30][35] An anionic symmetric sandwich compound (**5**, Figure 4) was isolated, in which



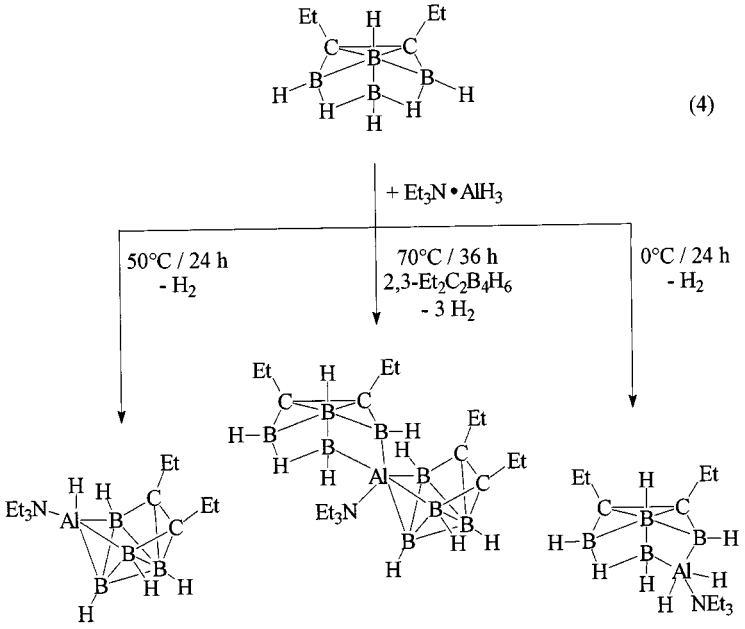


Figure 4. Molecular structure of $[Al(B_9C_2H_{11})_2]^-$ **5**;[34] boron atoms (not shaded) are not labelled

$$2\ Tl_2[7,8\text{-}C_2B_9H_{11}] + 4\ Et_2AlCl \longrightarrow Tl[Al(C_2B_9H_{11})_2] + 2\ Tl[AlEt_3Cl] + Tl[AlEt_2Cl_2] \quad (3)$$

5

two *closo* aluminacarbaboranes have a common Al atom. As expected, the Al–C and Al–B distances (224 to 230 pm and 214 to 229 pm, respectively) are longer than the distances observed in the monodicarbollyl compound **4**, which is probably caused by the greater connectivity of the Al atom (ten in **5**, six in **4**). Further *commo* derivatives with smaller carbaborane moieties are also known from the literature.[30,37,38] The aluminium atoms in these compounds have, however, normal coordination numbers of four. In one compound, the Al atom bridges two *nido*-6,9-dicarbadecaboranate ligands via their carbon atoms.[37] The metal atom resides above the six-membered B_4C_2 heterocycles with a boat conformation and is tetrahedrally coordinated by all four carbon atoms. The Al–C distances are 206 pm, which is longer than expected for tetracoordinated Al atoms. The Al–B distances are much longer (253 pm) indicating a very weak bonding interaction. In the second compound two *nido*-2,7-dicarba-octaboranate units are bridged by a common Al atom.[38] Once again the metal atom is tetrahedrally coordinated by the four carbon atoms of the ligands. The distance between both carbon atoms of one ligand is smaller than that in the carbaborate cage discussed before and, probably due to the lower steric strain, the Al–C distances are shorter (201.8 pm). Two of the Al–B distances are quite short (228 pm on average) and may indicate a further bonding interaction.

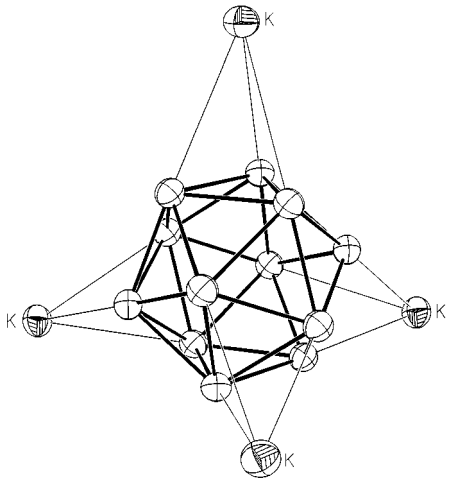
Small aluminacarbaborane clusters not stabilized by donor atoms, beside the *commo* compounds just cited, are rare. One article reported the reaction of the anionic cababorane $[2,3\text{-}C_2B_4H_7]^-$ with dimethylaluminium chloride,[39] which should yield μ-dimethylaluminium-2,3-*nido*-dicarbahexaborane(8). It was described as a very unstable compound in the liquid form or in solution and was thermolyzed in the gas phase to yield the unstable *closo* compound $MeAlC_2B_4H_6$. Remarkably, the gallium analogues of both compounds are much more stable and were isolated and

(4)

characterized.[39][40] Another reaction has been published, in which *nido*-$Et_2C_2B_4H_6$ was treated with the triethylamine alane adduct and from which, depending on the reaction conditions, three different products were obtained (Equation 4).[41] In accordance with the NMR and IR spectroscopic data, as well as elemental analyses, the authors suggested the structures given in Equation 4, which all have Al atoms with a higher connectivity than four.

The Icosahedral Compound $[Al_{12}iBu_{12}]^{2-}$ (6)

Compound **6** is the only known polyhedral organoelement compound containing only aluminium atoms which obeys the Wade rules for a *closo* cluster. It was obtained and characterized by a crystal structure determination in our group in 1991.[42] In 1976 the reduction of di(isobutyl)-aluminium chloride with elemental potassium was reported to yield tetra(isobutyl)dialane(4) with an Al−Al bond.[43] The compound was isolated as a brown oil and characterized by a hydrolysis experiment. However, in our experience, very large substituents are required to stabilize such dialuminium compounds, which contain bivalent aluminium atoms, against disproportionation reactions; we succeeded in isolating the first stable and completely characterized dialane(4), when we employed bulky bis(trimethylsilyl)methyl groups.[44] Therefore, we reinvestigated the synthesis of the isobutyl derivative and found a completely different result (Equation 5).[15] The main product is not the dialumium derivative originally proposed, but a potassium chloride adduct of tri(isobutyl)aluminium, which may be formed by a disproportionation reaction. A solid precipitated out of the reaction mixture, from which two products were extracted by treatment with toluene. One of these was identified as $K[Cl_2AliBu_2]$. The other one (**6**) was isolated as dark red crystals in a very low, but reproducible, yield of about 2%, and was identified as $K_2[Al_{12}iBu_{12}]$ by a crystal structure determination (Figure 5).[42] Compound **6** possesses an almost undistorted icosahedron of twelve aluminium atoms and is isoelectronic with the *closo*-borate anion $[B_{12}H_{12}]^{2-}$. The Al−Al distances are in a narrow range of 267.9 to 269.6 pm and are only slightly lengthened relative to the Al−Al single bonds in tetraalkyldialane(4) compounds (264 to 266 pm).[44][45] As shown in Figure 5, four triangles of each Al_{12} cluster are bridged by potassium ions to give a three-dimensional network in the solid state with tetrahedrally coordinated cluster anions and linearly coordinated potassium cations. Thus, the arrangement of anions and cations is quite different to that in solid $K_2[B_{12}H_{12}]$.[46]



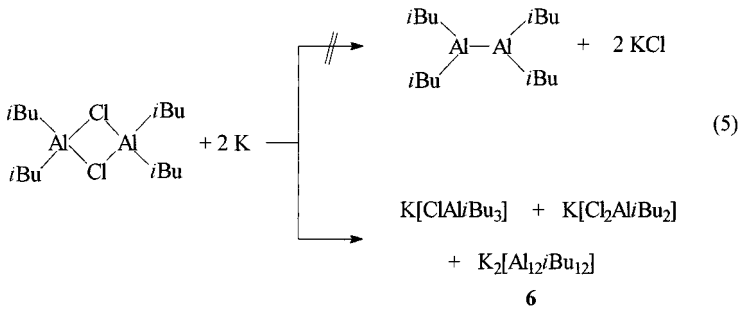


Figure 5. Crystal structure of $K_2[Al_{12}iBu_{12}]$ **6**;[42] isobutyl groups are omitted; each icosahedron is surrounded by four potassium ions to give a three-dimensional network

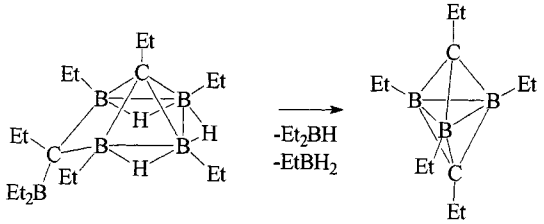
Compound **6** is only moderately stable in solution and decomposes slowly with the precipitation of elemental aluminium. In the crystalline form, it is much more stable with a decomposition point of 150 °C. The crystals can be stored in air for about two hours with no obvious signs of decomposition, but then slowly a colorless substance, probably aluminium hydroxide, is formed on their surfaces. Cyclovoltammetry revealed a reversible one-electron oxidation process, followed by a second irreversible oxidation.[47] In this respect the dodecaaluminate is similar to the corresponding boron compounds.[48]

A further anionic polyhedral cluster compound formed exclusively from aluminium atoms has been postulated by the group of Schnöckel, but until now it has not been isolated in a pure form or structurally characterized.[49] The reaction of aluminium(I) chloride with *tert*-butyllithium yielded a dark red, quite stable product of, presumably, a neutral oligomeric *tert*-butylaluminium(I) compound. Treatment of this intermediate with sodium/potassium alloy gave a radical anion (Equation 6) which, from an ESR spectroscopic characterization and quantum chemical calculations, was identified as the octahedral hexaaluminium compound $[Al_6(CMe_3)_6]^-$.[49] Furthermore, theory showed that the hypothetical neutral hexamer is much more stable

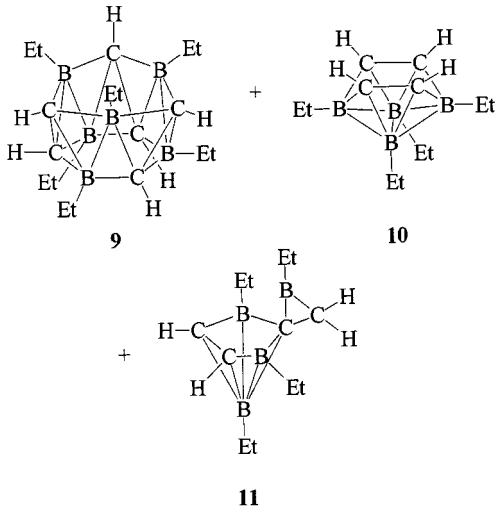


than the monomeric fragments (540 kJ/mol), and that the molecule is further stabilized by the addition of an electron and the formation of the radical anion by 140 kJ/mol.[16][49]

$$n\,AlCl + n\,LiCMe_3 \longrightarrow Al_n(CMe_3)_n \xrightarrow{Na/K} [Al_6(CMe_3)_6]^{\bullet -} \quad (6)$$

Hydroboration for the Synthesis of Carbaboranes; Some Remarks on Hydroalumination

The reaction of polyboranes with alkynes is the standard method for the synthesis of polyhedral carbaboranes.[5] However, mixtures are often formed and the isolation of pure products, even in a poor yield, is extremely difficult. The hydroboration of dialkylborylalkynes or bis(dialkylboryl)ethynes, followed by condensation reactions, offers an alternative route for the synthesis of carbaboranes, and several recent reports described such reactions, which yielded the products in some cases in a moderate to high yield.[50–57] For instance, treatment of diethylborylethyne with a large excess of diethylboron hydride afforded 1-carba-*arachno*-pentaborane(10) **(7)** (Equation 7), which by loss of diethylboron hydride and ethylboron dihydride gave *closo* dicarba-pentaborane(5) **(8)**.[51] Other products were identified, when the selectivity of the reaction was reduced.[55]



$$Et_2B{-}C{\equiv}C{-}Me + Et_2BH\ (excess) \xrightarrow[-Et_3B]{} \quad (7)$$

7 **8**

A mixture of carbaboranes was formed by the reaction of a diborylethyne with an excess of dialkylboron hydride (Equation 8), from which three products were isolated and characterized by NMR spectroscopy, one crystal structure determination and comparison of the observed data with those obtained by quantum chemical calculations.[54,56,57] Compound **9** was identified as a hexacarba-*arachno*-dodecaborane(12), which has a hexagonal antiprism of carbon and boron atoms.[56] The tetracarba-*nido*-octaborane(8) derivative **(10)** was isolated in a yield of 9% and contains a hexagonal face in a boat form, which has two pairs of carbon atoms bridged by two boron atoms.[54] The third compound **11** was isolated and characterized as a mixture with **10**. It was identified as a spiro compound, in which a 2,3,5-tricarba-*nido*-hexaborane cluster was connected to a three-membered C_2B heterocycle by a common carbon atom.[57] Some further examples, which are not discussed here in detail, show that the hydroboration reaction is a powerful method for the synthesis of such carbaborane clusters.

$$Et_2B{-}C{\equiv}C{-}BEt_2 + Et_2BH\ (excess) \xrightarrow[-Et_3B]{} \quad (8)$$

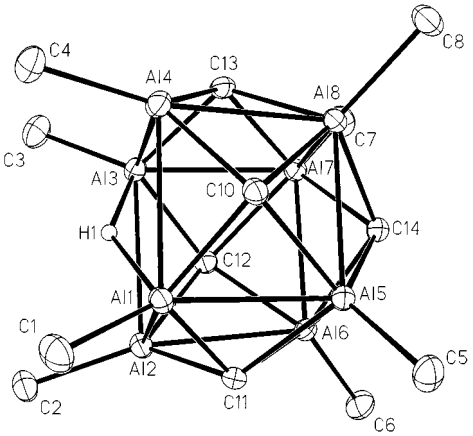
9 **10**

11

Similar to hydroboration is hydroalumination, which has been used in the synthesis of alkylaluminium derivatives and in preparative organic chemistry.[58][59] In many cases, the products obtained by the addition of Al–H bonds to alkynes were, however, not isolated and characterized, but hydrolyzed to liberate the corresponding hydrocarbons.[59] Thus, only poor information concerning the structure of most of the organoaluminium intermediates is available in the literature. To the best of our knowledge, the hydroalumination of aluminium alkynides, which is similar to the reactions of the boron compounds cited above, and may open the route to the formation of cluster compounds, has been described in only two papers. In a conference report, Wilke and Schneider described the reaction of diethylaluminium hydride with diethylaluminium butynide,[60] which in a first step yielded the product of a twofold hydroalumination $(Et_2Al)_3C{-}CH_2{-}C_2H_5$. This compound was characterized by deuterolysis and oxidation and decomposes upon heating to 50 or 60 °C with the formation of triethylalane and an unknown residue. A similar reaction with dimethylaluminium hydride and dimethylaluminium propynide afforded a solid which, in addition to hydrolysis, was characterized by elemental analysis and molar mass determination. These results were interpreted in terms of the formation of an adamantane-like cage compound ("pseudo-aluminoadamantane"), which has seven Al atoms and four C atoms. Two of the Al atoms should be bridged by hydride ions. Remarkably, this compound showed no tendency to form adducts with diethyl ether.[60] The hydroalumination of dimethylaluminium ethynide, generated in situ, with dimethylaluminium hydride was reported to afford $(AlMe)_6(CCH_3)_4$ with a true adamantane structure in which the tricoordinated Al atoms occupy the bridging po-

sitions.[60] In view of the results discussed below, it seems probable that the Wilke group had synthesized the first carbaalanes in 1963 without recognizing, however, their true structure and the importance of their particular and fascinating bonding situation.

Similar reactions were carried out by a Russian group in 1988.[61] They treated some diethylaluminium alkynides with isobutylaluminium hydride and obtained oily residues, which by hydrolysis experiments were identified as the products of the twofold hydroalumination, similar to the intermediate discussed in the preceding paragraph. In our opinion, however, it is not clear from these experiments whether they indeed had these trialuminium compounds or whether their reactions already gave cluster derivatives. In our experience, the reactions of differently substituted aluminium starting compounds, as described in ref.,[61] afford complicated mixtures of products by dismutation reactions. Thus, we suppose that they never had a pure component in their oily residues.



Carbaalanes

We began to investigate hydroalumination reactions because we were interested in an effective method for the synthesis of polyaluminium compounds, which are useful as chelating Lewis-acids in phase transfer processes or in anion recognition.[62] We succeeded in synthesizing these compounds by the reaction of polyalkynes with dialkylaluminium hydrides. The trialuminium derivatives, which were obtained by a twofold hydroalumination of aluminium alkynides as cited above, are of particular interest for such investigations, although we never observed a reaction at room temperature or in solution when we employed aluminium phenylethynides as starting compounds.

A hydroalumination reaction was observed when we dissolved dimethylaluminium phenylethynide in a slight excess of dimethylaluminium hydride (Equation 9) and heated the mixture to 80 °C for two days.[63] As shown by NMR spectroscopy, a large quantity of trimethylaluminium was formed, which was distilled off at room temperature in vacuo. Recrystallization of the residue afforded the colorless product $(AlMe)_8(CCH_2Ph)_5H$ (**12**). Compound **12** possesses a unique molecular structure (Figure 6), which comprises a cluster of eight aluminium and five carbon atoms. The aluminium atoms occupy the vertices of a slightly distorted cube, of which five faces are bridged by carbon atoms. The sixth face is bridged by a hydrogen atom. Each aluminium atom is further coordinated to one methyl group, and each carbon atom of the cluster is further attached to a benzyl group. Long Al−Al distances are observed for the hydrogen bonded face (279.7 pm), while the remaining eight edges of the cube are shorter (260.5 pm). The short distances are similar to those found in dimeric trimethylaluminium $(AlMe_3)_2$ (261 pm)[64] containing a 3c-2e Al−C−Al bond, and they are shorter than the Al−Al single bond in tetraalkyl compounds $R_2Al-AlR_2$.[44][45] Thus, they are consistent with a multicenter bonding interaction in the cluster. The Al−C separations within the cluster range between 201.8 pm and 214.1 pm and depend on the coordination sphere of the aluminium atoms. The shortest ones are observed to the Al atoms of the hydrogen bonded face and the longest to the carbon atom C14 at the opposite site of the cube. All are longer than the terminal Al−Me distances (195.0 pm). The formation of **12** may be described by the repeated hydroalumination of the starting aluminium ethynide and by condensation reactions with the release of trimethylalane. Furthermore, methylaluminium dihydride may be formed by the dismutation equilibrium of dimethylaluminium hydride and may be important at least for the introduction of the bridging hydride ion.

$$11\ Me_2AlH + 5\ Me_2Al{-}C{\equiv}C{-}Ph \longrightarrow (AlMe)_8(CCH_2Ph)_5H + 8\ AlMe_3 \quad (9)$$

12

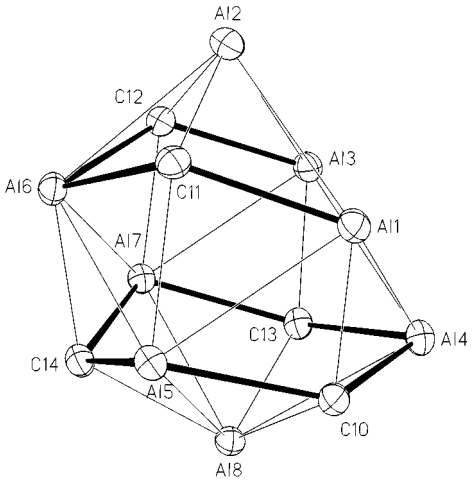


Figure 6. (a) Molecular structure of $(AlMe)_8(CCH_2C_6H_5)_5H$ **12**;[63] hydrogen atoms with the exception of H1 and benzyl groups are omitted. (b) The carbon and aluminium atoms of the rotated cluster with Al8 at the bottom, the bold lines characterize the planes discussed in the text

Each aluminium atom contributes two electrons and each carbon atom three electrons to the bonding in the cluster. Including the electron of the bridging hydrogen atom, a to-

tal electron count of 16 electron pairs results, which, in accordance with Wade's rules, gives an *arachno* configuration for the 13 vertex cluster of **12**. The corresponding *closo* polyborate $[B_{15}H_{15}]^{2-}$ is known only from quantum chemical calculations.[65] It has a hexagonal antiprism in its molecular center, of which the hexagonal faces are bridged by one and two boron atoms, respectively. The cluster of **12** can be derived from this structure, which is best recognized when it is placed on the aluminium atom Al8 (Figure 6). This atom bridges a six-membered heterocycle (Al4, Al5, Al7, C10, C13 and C14) in a chair form. The next plane comprises only five atoms (Al1, Al3, Al6, C11 and C12), and one vertex remains unoccupied, which is the approximate position of the bridging hydrogen atom H1. The atom Al2 resides above this plane. Thus, two vertices are unoccupied in comparison with *closo* $[B_{15}H_{15}]^{2-}$, which is in accordance with an *arachno* structure. However, **12** does not adopt an antiprismatic molecular center − owing to the large differences between the Al−Al and Al−C distances the planes are in an almost eclipsed conformation. Compound **12** was the first well-characterized cluster compound containing exclusively aluminium and carbon atoms to be reported in the literature. Owing to the obvious similarity between this compound and polyboranes or carbaboranes with respect to its structure and electronic configuration, we suggested the name carbaalanes[66] for this new class of organoaluminium derivatives.

When we reduced the excess of dimethylaluminium hydride, **12** was formed only as a minor by-product,[67] and a dark red compound $(AlMe)_8(CCH_2Ph)_5(C{\equiv}CPh)$ **(13)** was isolated in a yield of 40%; this compound has no hydrogen atoms attached to aluminium (Equation 10). The molecular structure of **13** (Figure 7) is quite similar to that of the colorless hydrido-bridged cluster **12**, except that the sixth face of the Al_8 cube is bridged by a phenylethynido ligand. Despite the different bridging atoms, the bond lengths in the cluster are almost indistinguishable from those of **12**, and the Al−Al separations of the ethynido-bridged face are longer (282.9 pm) than the remaining Al−Al distances (258.2 to 262.2 pm). The hydrido- or ethynido-bridged face of each cube is distorted to a rhombus with different distances between aluminium and the bridging atoms (Al−H: 191 and 221 pm in **12**; Al−C: 217.4 and 241.1 pm in **13**). Thus, these bridges may be interpreted as 3c-2e bonds with weak secondary interactions. The C−C bond length of the ethynide group (124.1 pm) is slightly longer than the standard bond length of a C≡C triple bond (120 pm[68]), and accordingly the absorption of the C≡C triple bond in the IR spectrum is shifted to 1956 cm^{-1}, which is more than 100 cm^{-1} lower than usually observed (e.g. in compound **15** discussed below with an exo ethynide group). These observations verify a particular bonding and electronic situation at the open face of the cluster, which may be compared with that of carbaboranes. Thus, we expect that, similar to the carbaboranes, the carbaalanes may show an interesting and unprecedented chemical reactivity.

Other products were formed when diethylaluminium derivatives were employed for the hydroalumination reaction.

$$10\ Me_2AlH + 6\ Me_2Al{-}C{\equiv}C{-}Ph \longrightarrow (AlMe)_8(CCH_2Ph)_5(C{\equiv}CPh) + 8\ AlMe_3 \quad (10)$$

13

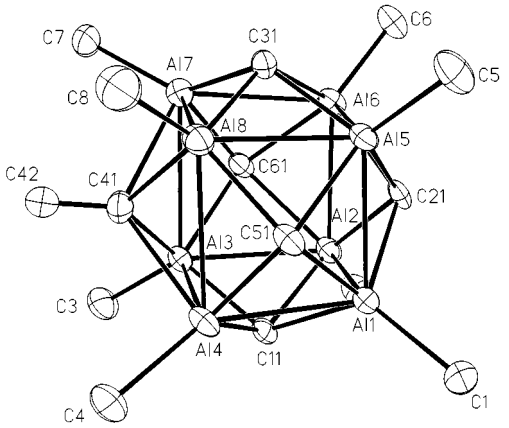

Figure 7. Molecular structure of $(AlMe)_8(CCH_2C_6H_5)_5(C{\equiv}C{-}C_6H_5)$ **13**;[67] hydrogen atoms, the phenyl group attached to C42 and benzyl groups are omitted

An orange-red product (**14**) was isolated after heating a mixture of the corresponding ethynide and hydride to 50°C for 18 hours (Equation 11).[69] Once again, trialkylaluminium ($AlEt_3$) was detected as a main product, which was distilled off in vacuo. Although the crude product contained **14** in a high concentration, the crystalline compound was obtained in only a 36% yield. A crystal structure determination confirmed the compound to be $(AlEt)_7(C{=}CHPh)_2(CCH_2Ph)_3H$ (Figure 8), which has seven Al and five carbon atoms in its cluster and may be derived from compound **12** with one vertex of the Al_8 cube unoccupied. The five carbon atoms are in two different positions: three of them bridge four Al atoms, while two reside above a triangle of Al atoms. The first ones belong to $C{-}CH_2{-}C_6H_5$ groups, similar to the bridging groups in compound **12**, while the second ones (C3,C3′) are alkenylidene carbon atoms of C=C double bonds. One further Al_3 triangle is bridged by a hydrogen atom. Thus, only one hydroalumination step with $EtAlH_2$ is missing to obtain a compound analogous to **12**. The Al−Al distances of the carbon- or hydrogen-bonded faces (268.2 and 270.7 pm, respectively) are shorter than those observed for the hydrogen-bonded face in **12**, while the remaining Al−Al separations are quite similar (256.9 and 260.0 pm). The C=C double bonds (136.0 pm on average) are only slightly lengthened relative to the standard bond length.[68] The alkenylidene groups adopt an orientation, in which a part of the π-orbitals overlaps the open face of the cluster. If the π-electrons are added to the number of cluster electrons, 16 electron pairs are obtained, which are in accordance with a *hypho* structure. Indeed, the cluster of **14** can be derived from that of the *closo*-borate $[B_{15}H_{15}]^{2-}$[65] with three vertices unoccupied. The molecular structure has five different ethyl groups, two different benzyl groups and the ethenylidene groups, and some

of the CH_2 groups are diastereotopic. Thus, very complicated NMR spectra resulted, some of their more important aspects are discussed later on.

$$9\ Et_2AlH + 5\ Et_2Al{-}C{\equiv}C{-}Ph \longrightarrow (AlEt)_7(C{=}CHPh)_2(CCH_2Ph)_3H + 7\ AlEt_3 + \mathbf{(15)} \quad (11)$$

14

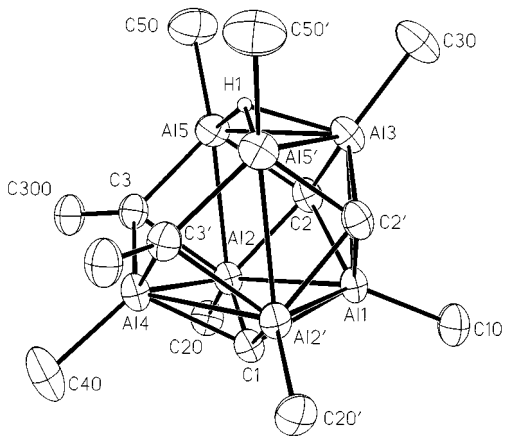

Figure 8. Molecular structure of $(AlEt)_7(CCH_2C_6H_5)_3(C{=}CHC_6H_5)_2H$ **14**;[69] hydrogen atoms with the exception of H1, phenyl and benzyl groups and the methyl groups of the ethyl substituents are omitted; the molecule is located on a crystallographic mirror plane

A second product (**15**) was isolated from the mother liquor after the separation of **14**.[69] Compound **14** was completely converted into **15** by heating a benzene solution to 60°C for several days. Monitoring of the rearrangement by NMR spectroscopy gave a first order reaction, which has an estimated rate constant of $k \approx 4 \times 10^{-5}$ sec^{-1} and a free enthalpy of activation of $\Delta G^{\neq} \approx 110$ kJ/mol. A much faster reaction was observed when the crude product from the reaction was heated to 110°C for one hour (Equation 12). Compound **15** is isomeric with **14**, but has a different structure with a cluster of seven Al and four C atoms [$(AlEt)_7(CCH_2Ph)_4(C{\equiv}CPh)H$, Figure 9]. One edge of the cluster (Al3−Al6) is bridged by a hydrogen atom and a second one (Al2−Al5) by an ethynide group. The Al_7C_4 molecular core has twelve electron pairs, which is in accordance with a *closo* configuration. Indeed, the structure of the cluster is analogous to that of *closo*-$[B_{11}H_{11}]^{2-}$[3] and has a six-membered heterocycle in a boat conformation bridged by an Al atom as a very characteristic structural motif. With the exception of the distances to the unique Al atom Al7, short Al−Al separations were observed, which are between 258.1 and 259.4 pm for the unsupported Al−Al edges, while they are little lengthened for the bridged ones (261.2 and 267.5 pm). Much longer distances of 281.8 to 292.1 pm were observed to the atom Al7 above the boat shaped Al_4C_2 heterocycle. A similar lengthening of the B−B distances to that unique position was observed in the undecaborate dianion (B−B = 200.9 pm).

$$(AlEt)_7(C{=}CHPh)_2(CCH_2Ph)_3H \xrightarrow{\Delta} (AlEt)_7(CCH_2Ph)_4(C{\equiv}CPh)H \quad (12)$$

14 **15**

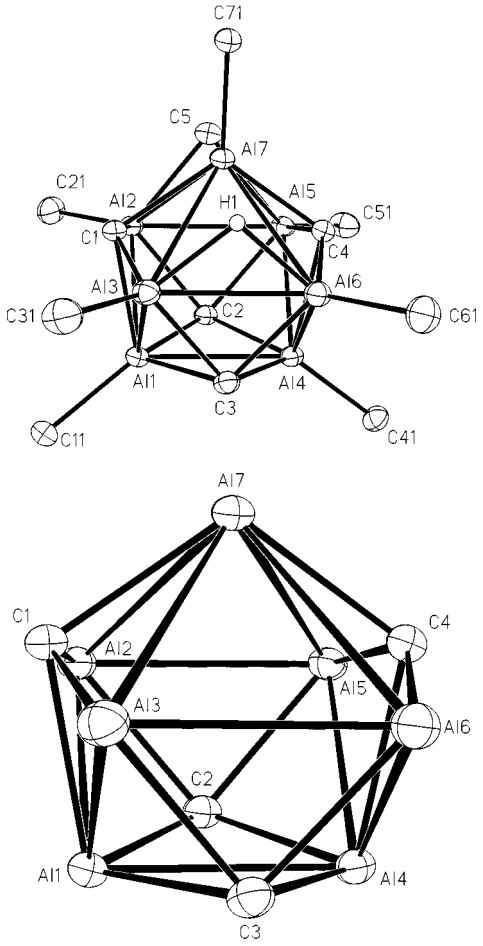

Figure 9. Molecular structure of $(AlEt)_7(CCH_2C_6H_5)_4(C{\equiv}C{-}C_6H_5)H$ **15**;[69] (a) shows the cluster with the exo hydrogen and ethyne (C5) ligands and the α carbon atoms of the ethyl substituents; (b) gives the naked cluster and shows the remarkable analogy to $[B_{11}H_{11}]^{2-}$

As described above, compound **14** containing seven Al atoms and two C=C double bonds may be converted into an *arachno* derivative analogous to **12** by a single hydroalumination step with $EtAlH_2$. However, only alkyl or aryl aluminium dihydrides with very bulky substituents are available.[70] Dihydrides bearing smaller substituents may be formed in trace amounts by the dismutation equilibrium of dialkylaluminium hydrides, and we suppose that they are intermediates in the hydroalumination reactions described here. Therefore, we treated compound **14** with an excess of diethylaluminium hydride in order to hydroaluminate **14** and to synthesize the corresponding *arachno* compound. The mixture of the starting materials was heated to 60°C

for 18 hours without additional solvent, and triethylaluminium was formed as detected by NMR spectroscopy. All volatile components were removed in vacuo, and recrystallization of the residue from *n*-pentane afforded colorless crystals of product **16** in a yield of 69% (Equation 13). The molecular structure is analogous to that of **12** containing a cube of eight Al atoms, of which five faces are bridged by carbon atoms and one face is occupied by a hydrogen atom. The reaction according to Equation (13) gives an important insight into the mechanism of the formation of these carbaalane clusters.

$$\underset{\mathbf{14}}{(AlEt)_7(C{=}CHPh)_2(CCH_2Ph)_3H} + Et_2AlH \text{ (excess)} \xrightarrow[-\ Et_3Al]{} \underset{\mathbf{16}}{(AlEt)_8(CCH_2Ph)_5H} \quad (13)$$

The complete characterization by NMR spectroscopy and assignment of resonances to all atoms of these compounds was extremely difficult, and despite the application of advanced NMR spectroscopic techniques (H,H COSY, HMQC and HMBC NMR spectra) not all resonances could clearly be assigned to particular atoms. However, those resonances which are important for the discussion of these clusters, were clearly resolved and assigned. ^{27}Al NMR spectroscopic data have not yet been recorded. The ^{13}C NMR resonances of the cluster carbon atoms show a strong shift to low field (δ = 21 to 35). Similar shifts were calculated for a carbaborane cluster which has an alternating arrangement of boron and carbon atoms (see above).[56] A chemical shift of 0 ppm is usually observed for compounds which have carbon atoms attached to aluminium with a higher coordination number than three. Those shifts were detected here for the α-carbon atoms of the terminally coordinated methyl or ethyl substituents. Similarly, the bridging hydrogen atoms show a low-field shift in the ^1H NMR spectra and resonate at about 4.7 to 5.3 ppm, while in the starting dimethyl or diethyl aluminium hydrides the hydrido bridges have resonances of δ = 2.92 and 2.79, respectively. The resonances of the CH_2 protons of the benzyl groups are also shifted to a lower field (δ = 3.0 to 3.7). We have not yet succeeded in the unambiguous assignment of absorptions in the IR spectra to cluster vibrations. All IR spectra show some weak absorptions in the typical range for Al−C bonds (≈ 450 to 550 cm^{-1}) and intense, broad absorptions at 660 to 710 cm^{-1}, which, however, is the range of deformation vibrations of the phenyl groups. Thus, their more intuitive assignment to cluster vibrations can only be discussed with reservation. Polyhedral carbaalanes without phenyl groups may help to clarify this point.

Concluding Remarks

A deficiency of electrons causes the singular property of boron to form clusters which require a delocalized bonding description. As described here, similar compounds are now available with its heavier homologue aluminium, in which Al atoms occupy positions of high connectivity in delocalized electronic systems; these compounds obey the same rules concerning structure and electron count. Nevertheless differences between both kinds of compounds should not be ignored. The aluminium derivatives are often more reactive and less stable than the boron clusters. This may be due to the low electronegativity of aluminium, which leads to a significant charge separation in all heteronuclear bonds. Steric shielding, which has been used for the preparation of so many compounds with unusual structures in main group chemistry, seems to have only a minor influence here, instead the stabilization of these clusters may be caused mainly by the delocalization of electron density. The investigation of the chemical reactivity of the carbaalanes as a new class of compounds is just beginning, but a broad application in research such as in catalytic processes seems to be possible, in particular due to their facile synthesis. Future work will show whether this type of aluminium chemistry will reach a similar importance and diversity as that of boron

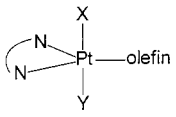
Electrophilic Attack of $[I(py)_2]^+(NO_3^-)$ on Three-Coordinate Pt^0 Precursors: Synthesis and In Vitro Antitumor Activity of Water-Soluble, Five-Coordinate Pt^{II} Complexes

Mario Bigioni,*[a] Paolo Ganis,[b] Achille Panunzi,*[c] Francesco Ruffo,[b] Carmela Salvatore,[a] and Antonio Vito[d]



Keywords: Platinum / N ligands / Water soluble complexes / Antitumor agents / Electrophilic additions

$[I(py)_2]^+(NO_3^-)$ oxidatively adds to the three-coordinate platinum(0) precursors [Pt(*N*,*N*-chelate)(olefin)] affording the cationic five-coordinate products [Pt(*N*,*N*-chelate)I(py)(olefin)]$^+(NO_3^-)$ (**1**) {*N*,*N*-chelate = 2,9-Me_2-1,10-phenanthroline (dmphen), 2-methyl-6-[(phenylimino)methyl]pyridine (pimpy) and 2-methyl-6-[(4-methoxyphenylimino)methyl]pyridine (mpimpy)}. The crystal structure of [Pt(pimpy)I(py)(dimethyl fumarate)]$^+(NO_3^-)$ is reported. The crystals are triclinic, space group *P*1(bar), with *a* = 13.511(2), *b* = 13.754(2), *c* = 8.678(1) Å, α = 95.2(1)°, β = 92.5(2)°, γ = 64.7(1)°, *Z* = 2. Type **I** complexes, which are soluble both in chlorinated solvents and in water, were tested for cytotoxicity against a panel of tumour cell lines of various histotypes including NSCLC H460, leukaemic HL-60, ovarian A 2780, IGROV-1, SKOV-3, and an ovarian carcinoma A 2780/CP selected for resistance to *cis*-platin [DDP = *cis*-diamminedichloroplatinum(II)]. [Pt(dmphen)I(py)(methyl acrylate)]$^+(NO_3^-)$ was the most active in all cell lines tested, its antitumoural activity in vitro being comparable to that of DDP.

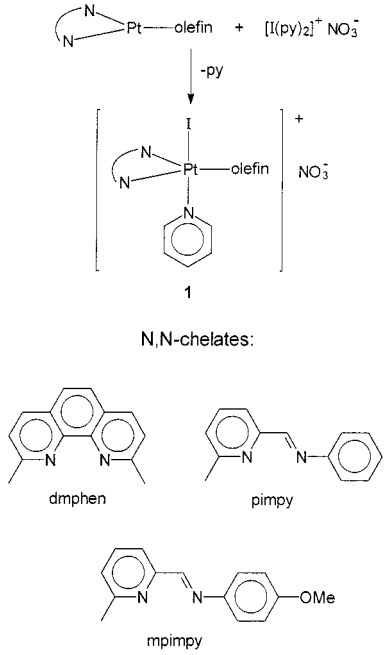
Introduction

Cisplatin [DDP = *cis*-diamminedichloroplatinum(II)] is an extensively investigated anticancer drug used in the treatment of some solid tumours such as ovarian, testicular and bladder cancers.[1] Its therapeutic efficacy is often limited by its dose-related nephrotoxicity and by the development of drug resistance, depending on the increase of intracellular glutathione,[2] increased tolerance to DNA damage or increased DNA repair.

Many analogues have been synthesised in an attempt to either decrease the toxic side effects of the parent drug or to overcome the intrinsic and induced resistant phenotype and so broaden the clinical spectrum of antitumour activity.

I

Figure 1. General formula for type **I** complexes



In the last few decades interest in five-coordinate platinum(II) complexes (**I**) (Figure 1) has increased.[3]

The stability of these species is prompted by the presence of sterically hindered nitrogen chelates, e.g. 2,9-Me_2-1,10-phenanthroline (dmphen). Such ligands inhibit olefin loss because the resulting square-planar product would suffer severe constraints in the coordination plane.[3] Some type **I** complexes of formula [PtCl(Me)(dmphen)(olefin)]BF_4[4] and [PtCl($SnMe_nCl_{4-n}$)(dmphen)(dimethyl fumarate)][5] have been tested in vitro against some tumour cell lines with promising results. As far as we know, this was the first investigation on coordinatively saturated platinum(II) derivatives, since a literature search shows that other studies have been concerned with square-planar platinum(II)[6] or octahedral platinum(IV) species.[7] The insolubility in water of the above-mentioned species of type **I** limits a further development of these studies. Thus, we were prompted to investigate the feasibility of related compounds with properties more suitable to pharmacological uses. Keeping in mind that a charged complex may display a good solubility in water without loss of pharmacological activity,[8] we aimed to prepare cationic water-soluble complexes of type **I**. A straightforward procedure was found to be the oxidative addition of the readily available iodonium salt $[I(py)_2]^+(NO_3^-)$[9] to three-coordinate platinum(0) precursors[10] (Scheme 1).

Herein we describe the synthesis of novel type **I** species, their NMR characterisation and the crystal structure of a

representative complex. This paper reports the pharmacological advantages of new modifications introduced in the type **I** species on the inhibitory effect of the growth of selected tumoural DDP resistant and sensitive cell lines.

Results and Discussion

Synthesis, NMR Characterisation and Reactivity of Type I Complexes

Cationic five-coordinate Pt^{II} complexes are known.[11,12] They were obtained by chloride abstraction starting from a suitable precursor in the presence of a silver salt [Equation (1) and Equation (2)]:

$$[PtCl(R)(N,N\text{-chelate})(olefin)] + AgBF_4 + MeCN \rightarrow [Pt(R)(MeCN)(N,N\text{-chelate})(olefin)](BF_4) + AgCl \quad (1)$$

$$cis\text{-}[PtCl_2(MeCN)(olefin)] + AgBF_4 + N,N\text{-chelate} \rightarrow [PtCl(MeCN)(N,N\text{-chelate})(olefin)](BF_4) + AgCl \quad (2)$$

Route 1 allowed the synthesis of type **I** derivatives containing a hydrocarbyl group R and a neutral ligand (e.g. MeCN) in the axial positions. The second procedure afforded the related chloro derivatives. In the latter case, only products with electron-rich olefins could be obtained, since the required precursors *cis*-$[PtCl_2(L)(olefin)]$ are not available when the olefin bears electron-withdrawing substituents. The synthetic procedure herein described bypasses this obstacle and allows the attainment of several cationic halo complexes containing electron-acceptor olefins.

The method is based on the well-known ability of three-coordinate platinum(0) complexes of general formula [Pt(*N,N*-chelate)(olefin)] to undergo electrophilic attack.[10] Thus, the iodonium(I) salt $[I(py)_2]^+(NO_3^-)$[9] oxidatively adds to the suitable Pt^0 complexes with formation of pyridine and of the corresponding five-coordinate complexes, which contain a pyridine and an iodide in the axial positions (Scheme 1).

The N,N ligands used in this work are shown in Scheme 1. The products **1** are listed in Table 1 with their labels. The reactions were performed in chloroform, which is a good solvent for both reagents and products. The only exception was the addition to [Pt(dmphen)(maleic anhydride)], which required the use of tetrachloroethane due to the poor solubility of the Pt^0 precursor.

Type **I** complexes could be crystallised by slow addition of diethyl ether to the reaction mixture. They are soluble both in water and chlorinated solvents, except for the dibenzoylethylene derivative, which is only soluble in chlorinated solvents. The products are fairly stable in solution, and no appreciable decomposition could be seen even after several hours.

The possibility that water may substitute iodide in one of the apical positions has been ruled out by conductivity measurements. Actually, if hydrolysis occurred, the dipositive cation $[Pt(N,N\text{-chelate})(H_2O)(py)(olefin)]^{2+}(I^-)(NO_3^-)$ should form. However, the molar conductivities of type **I** complexes in water are in the range $1.0-1.3 \times 10^2$ $ohm^{-1}\cdot cm^2\cdot mol^{-1}$. These values are close to that measured (1.4×10^2 $ohm^{-1}\cdot cm^2\cdot mol^{-1}$) for an authentic 1:1 salt, i.e. $K[PtCl_3(C_2H_4)]$. On the other hand, the conductivity of a 2:1 salt such as K_2PtCl_4 in water is significantly higher (2.3×10^2 $ohm^{-1}\cdot cm^2\cdot mol^{-1}$).

The NMR spectra were recorded in D_2O in most cases (Table 1). It is possible to assign unequivocally a trigonal bipyramidal geometry to the products on the basis of arguments already thoroughly discussed for related species.[3] As for the dmphen derivatives **1a-e**, the number of isomers theoretically predicted depends on the symmetry of the alkene. Dimethyl maleate and maleic anhydride can afford two rotamers, while methyl acrylate could afford two enantiomeric pairs. In all cases, only one spectral pattern was observed, indicating that the olefins coordinate with a high degree of stereoselectivity. Dimethyl fumarate gives rise to a pair of enantiomers, obviously not distinguishable by NMR spectroscopy in the absence of chiral interference.

In the case of pimpy (**1h**), we observed the expected two diastereomers (each one a pair of enantiomers) for the complex with dimethyl fumarate. Slow recrystallization of the complex affords only one pair whose X-ray crystal structure is described below. Finally, complex **1i** with mpimpy and dimethyl maleate should also exist as two diastereomers (pairs of enantiomers). The high degree of stereoselectivity in olefin coordination allows us to detect only one pair in solution.

Description of the Molecular Structure of 1h

A view of the structure of the cation giving the atom numbering scheme is shown in Figure 2. Selected bond lengths and angles and torsion angles are listed in Table 2.

The bipyramidal trigonal coordination about the metal is as expected and does not differ substantially from that found for similar five-coordinate Pt^{II} complexes.[3] The li-

gands iodide and pyridine occupy the axial positions, the pimpy ligand and the fumarate double bond are in the equatorial coordination sites. All the atoms of pimpy, except those of the phenyl group bonded to N2, lie in a plane almost coincidental with the equatorial coordination plane of Pt (the corresponding dihedral angle is ca. 3°). Also C14 and C17 of the olefin bond of dimethyl fumarate are contained in this plane with deviations of less than 0.01–0.02 Å. The phenyl group bonded to N2 is rotated about the

bond C8−N2 in order to relieve short contact interactions between HC9 and HC1 (here at 2.1 Å). The rotation is imposed by the pyridine group in the apical position on Pt such as to produce the most favourable contact distances between these two groups. The atoms C17 and C14, at distances of 1.44 Å, reveal, as found in several similar complexes,[13,14] a sharp dehybridization $sp^2 \rightarrow sp^3$ due to a consistent platinum-to-olefin back-donation. As a consequence, a rotation about the bond C14−C17 is allowed (here it is ca. 132°, i.e. 48° from a *trans* conformation). This rotation is imposed by stereochemical requirements in order to relieve intramolecular interactions, with I on one side (I···O1 = 3.4 Å; I···C15 = 3.3 Å) and the pyridine group on the other side (N3···C18 = 2.88 Å; N3···O3 = 2.95 Å). Repulsions between pimpy and dimethyl fumarate also cooperate to this effect, in particular C7 with O4, and C18 and C13 with O2. These interactions cannot be avoided through a rotation about the coordination axis of the olefin owing to demands imposed by the coordination geometry about the metal.[14] Dimethyl fumarate in its observed configuration seems to have no influence on the conformation or on the choice of coordination isomerism by the Schiff base at Pt (or vice versa, the Schiff base does not appear to induce any preference for the coordination of dimethyl fumarate in either of its prochiral configurations). Thus, we believe that the diastereoisomer examined here is the one favoured in the crystal only because of crystal field forces. All the other geometrical parameters are normal and have been exhaustively discussed in our previous structural reports.[12−14]

Cytotoxic Activity

The cytotoxic activity of six cisplatin (DDP) analogues were studied on a panel of three human carcinoma cell lines in comparison with the parent compound. The drugs were dissolved in DMSO and diluted with 0.9% NaCl solution. After further dilution in culture, DMSO is present at a concentration ranging from 0.01 to 1%. The pattern of cellular response is shown in Table 3.

Table 3. Cytotoxicity (IC_{50} μM) of type **I** compounds in comparison to DDP

Compound	A-2780	GLC-4	H-460
DDP	0.33 ± 0.06	0.53 ± 0.10	0.67 ± 0.10
1a	0.49 ± 0.18	1.59 ± 0.12	1.28 ± 0.49
1b	4.41 ± 0.02	1.96 ± 0.25	2.69 ± 0.60
1d	0.40 ± 0.07	0.40 ± 0.13	0.092 ± 0.003
1f	0.25 ± 0.16	0.58 ± 0.21	3.08 ± 0.95
1g	1.30 ± 0.12	1.85 ± 0.27	2.96 ± 0.59
1i	4.2 ± 0.6	2.39 ± 0.48	4.43 ± 1.44

Compound **1d** showed an activity similar to DDP on A2780 and GLC-4 cell lines, while on the H460 cell line the IC_{50} value was at least three orders of magnitude greater than that of the parent compound. The other analogues exhibited a cytotoxic potency lower or, at best, similar to that of DDP. The cytotoxic activity of **1d** was further evaluated on two additional ovarian cell lines (IGROV and SKOV-3) and on two leukaemia cell lines (human HL-60 and murine L1210). It exhibited a cytotoxic activity similar to (SKOV-3 cells) or three times higher (IGROV cells) than DDP, whereas on HL-60 and L1210 leukaemia its potency was lower (Table 4).

Table 4. Cytotoxicity (IC_{50} μM) of **1d** in comparison to DDP

Cell lines	DDP	**1d**
A 2780	0.33 ± 0.07	0.40 ± 0.07
A 2780/CP	3.3 ± 0.1	1.32 ± 0.03
H460	0.67 ± 0.10	0.09 ± 0.003
SKOV-3	4.2 ± 2.5	1.45 ± 0.33
IGROV	1.0 ± 0.7	0.13 ± 0.03

L1210	1.0 ± 0.13	1.65 ± 0.07
GLC-4	0.53 ± 0.10	0.40 ± 0.13

In the A2780 sub-line selected for resistance to DDP (A2780/CP), characterised by an increased ability to repair drug-induced DNA damage, compound **1d** was cross-resistant to DDP with a Resistance Index (RI) value of 3 (vs. 10).

Conclusion

New cationic, water-soluble, trigonal bipyramidal complexes of platinum(II) were prepared by oxidative addition of $[I(py)_2]^+(NO_3^-)$ to suitable platinum(0) precursors. The products were tested for cytotoxicity against a panel of tumour cell lines of various histotypes. The data show that the new class of Pt^{II} five-coordinate complexes is endowed with promising antitumor properties. The next step will therefore be the characterisation of the antitumour efficacy of the compounds in vivo. In the meantime, studies evaluating the potential nephrotoxic effects of the molecule will be performed.

Experimental Section

General: NMR spectra were recorded at 250 or 200 MHz on a Bruker AC-250 or a Varian XL-200 spectrometer. The three-coordinate precursors [Pt(*N*,*N*-chelate)(olefin)][10] and $[I(py)_2]^+(NO_3^-)$[9] were prepared according to literature procedures. Solvents and reagents were of analytical grade and were used without further purification.

Type-1 Complexes: To a solution of the appropriate [Pt(*N*,*N*-chelate)(olefin)] precursor (0.20 mmol) in chloroform (1 mL) was added $[I(py)_2]^+(NO_3^-)$ (0.20 mmol) previously dissolved in the minimum amount of chloroform. Careful addition of diethyl ether prompted the crystallisation of the product, which was washed with diethyl ether and dried under vacuum (yield: 80−90%). In the case of the precursor [Pt(dmphen)(maleic anhydride)] the reaction was performed in tetrachloroethane.

X-ray Data Collection and Refinement of the Structure of 1h: A crystal of **1h** suitable for X-ray analysis was obtained from dichloro-

methane/diethyl ether. Crystal data, intensity data and processing details for **1h** are shown in Table 5.

The data were obtained with a Philips PW-100 four-circle automated diffractometer with graphite monochromator. Intensity data were collected at 25 °C using the θ−2θ scan method. Two reference reflections, monitored periodically, showed no significant variations in intensity. Data were corrected for Lorentz and polarization effects and an empirical absorption correction was applied (Ψ scan). The position of Pt was determined from a three-dimensional Patterson function. All the remaining atoms, except for the hydrogens, were located from successive Fourier maps using SHELX-76. The hydrogen atoms were located at calculated positions and refined with a fixed geometry with respect to their carrier atoms (C−H = 1.08 Å). Anisotropic thermal parameters were used for all the atoms except for the anion NO_3^- and the hydrogens. Blocked-cascade least-square refinements converged to $R = 0.060$.

Actually, the structure shows an appreciable degree of disorder due to the high libration of the anionic NO_3^- group which seems also to be solvated with one (or more likely less) water molecule through hydrogen bonds. This question could not be resolved through density measurements. The corresponding disorder could not be established with certainty from structure refinements and difference Fourier syntheses. These facts explain the relatively high value of the *R* index and the highest map residuals (see Table 5). Nonetheless, they do not invalidate the most relevant structural features here described.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no CCDC-143825. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-003; E-mail: deposit@ccdc.cam.ac.uk].

Evaluation of Cytotoxic Activity: The cytotoxicity of all compounds was studied on a variety of human tumour cell lines of different types, using the SRB assay.[15] Briefly, the A 2780 (1.0×10^4 cells/mL), A 2780/CP (7.0×10^3 cells/mL), SKOV-3 (4.0×10^4 cells/mL), IGROV-1 (2.5×10^4 cells/mL), L1210 (5.0×10^3 cells/mL), HL-60 (5×10^3 cells/mL), H460 (7×10^3 cells/mL) or GLC-4 (7×10^3 cells/mL) cell line was seeded in 96-well microtiter plates and incubated for 24 h at 37 °C in a 5% CO_2 incubator. Drugs were then added to the wells to achieve final drug concentrations ranging from 0.1 to 100 μM. After 24 h of drug exposure, the cells were washed twice with PBS and incubated in a drug-free medium for about three doubling times (72 h). The cells were then fixed with 16% TCA, incubated at 4 °C for 1 h and finally rinsed five times with tap water and dried thoroughly. The cells were stained with 100μL/well of SRB (0.4% in 1% acetic acid) for 15 min, rinsed five times in 1% glacial acetic acid and suspended in 10 mM TRIS-HCl (pH = 10.5) buffer solution. The absorbance was measured with Microplate Reader (BioRad MR 3550) at 570 nm. The results were expressed as IC_{50}, calculated from dose-response curves, and defined as the drug concentration required for a 50% reduction of absorbance compared to control cells. Each experiment was repeated at least three times.

Acknowledgments

We thank the Consiglio Nazionale delle Ricerche and the Ministero dell'Università e della Ricerca Scientifica (Programmi di Ricerca Scientifica di Rilevante Interesse Nazionale, Cofinanziamento 1998−1999) for financial support and the Centro Interdipartimentale di Metodologie Chimico-Fisiche, Università di Napoli "Federico II", for NMR facilities. Simple Preparations of the Anhydrous and Solvent-Free Uranyl and Cerium(IV) Triflates $UO_2(OTf)_2$ and $Ce(OTf)_4$ − Crystal Structures of $UO_2(OTf)_2(py)_3$ and $[\{UO_2(py)_4\}_2(\mu\text{-}O)][OTf]_2$

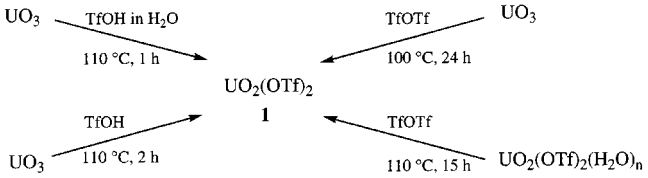
Keywords: Uranium / Cerium / Triflate complexes / Oxo complexes / Structure elucidation



Treatment of UO_3 with pure triflic acid TfOH at 110 °C or with boiling triflic anhydride TfOTf afforded $[UO_2(OTf)_2]$ (**1**) in high yields. The latter was also prepared by the reaction of UO_3 with TfOH in water, or by dehydration of $[UO_2(OTf)_2(H_2O)_n]$ in boiling TfOTf. Anhydrous $[Ce(OTf)_4]$ (**2**) was similarly obtained from the commercially hydrated compound. X-ray analysis revealed that in $[UO_2(OTf)_2(py)_3]$ (**3**), the triflate ligands are monodentate whereas they are dissociated in $[\{UO_2(py)_4\}_2(\mu\text{-}O)][OTf]_2$ (**4**).

Introduction

Complexes of the uranyl moiety UO_2^{2+} are very familiar in actinide chemistry since considerable attention has been paid to their structure, physico-chemical properties and catalytic behaviour in a number of organic transformations.[1] It is interesting to note that most of these studies have been performed on compounds which were isolated from aqueous media. The development of anhydrous uranyl chemistry has long been impeded by the lack of easily available starting materials[2] and hence it is only very recently that a convenient preparation of $[UO_2Cl_2(THF)_3]$ has been reported.[3] In view of the major interest of metallic triflates in both organic[4] and inorganic syntheses,[5] and following our recent work on uranium triflates,[6] we decided to prepare the anhydrous and solvent-free uranyl and cerium (IV) triflates $[UO_2(OTf)_2]$ (**1**) and $[Ce(OTf)_4]$ (**2**). This will also be useful for further studies on the high oxidation-state chemistry of the f-block elements. Here we present convenient and large scale preparations of **1** and **2**; we also describe the X-ray crystal structures of the pyridine adduct $[UO_2(OTf)_2(py)_3]$ (**3**) (py = pyridine) and the μ-oxo derivative $[\{UO_2(py)_4\}_2(\mu\text{-}O)][OTf]_2$ (**4**).

Results and Discussion

Synthesis of the hydrated uranyl triflate $[UO_2(OTf)_2(H_2O)_n]$ was first performed by treating UO_3 with two equivalents of triflic acid in water.[7] Difficulties were encountered in the dehydration of this complex by the Kumagawa method, forming the acetonitrile adduct $[UO_2(OTf)_2(NCMe)_n]$ which was then used for the synthesis of inclusion compounds with crown-ethers. The anhydrous and solvent-free uranyl triflate **1** can be prepared by a number of different routes, as described in Scheme 1.

Scheme 1. Syntheses of the uranyl triflate **1**

A pale yellow solution was rapidly obtained by treating a suspension of uranium trioxide in water with a 10-fold excess of freshly distilled triflic acid. After evaporation and drying under vacuum at 200 °C, compound **1** was isolated as a pale yellow powder; the yields varied from 65 to 90%. This synthesis of **1** is analogous to that of UO_2Cl_2 by reaction of UO_3 with HCl.[8] However, thermal dehydration of uranyl triflate is straightforward whereas that of $[UO_2Cl_2(H_2O)_n]$ requires further treatment with dry HCl at 300 °C.[8] This was previously exploited in the preparation of anhydrous lanthanide(III) triflates,[9] and is related to the final sublimation of the triflic acid monohydrate [TfO][H_3O]. The synthesis of **1** can be described by Equation (1) and (2).

$$UO_3 + (2+x)\,TfOH \xrightarrow{H_2O} UO_2(OTf)_2.xL \quad (1)$$

$$UO_2(OTf)_2.xL \xrightarrow[\text{vacuum}]{200\ ^\circ C} UO_2(OTf)_2 + xL \quad (2)$$

1 L = [TfO][H_3O]

While UO_3 was found to react with HCl only in the presence of moisture,[8] it also reacted in suspension in pure TfOH to give **1,** which was recovered in almost quantitative yield after evaporation and prolonged heating at 200 °C under vacuum. However, direct reaction of metal oxides with anhydrous triflic acid may sometimes lead to the

formation of complexes solvated with the excess acid,[9] which can easily induce polymerization of THF,[10] a common solvent in uranium chemistry. Thus, the reaction of UO_3 with TfOH in aqueous solution should be preferred for the synthesis of **1**.

Nevertheless, the most convenient and efficient synthesis to **1** proved to be the reaction of uranium trioxide with triflic anhydride. A suspension of UO_3 in pure TfOTf was quantitatively transformed, after 24 h at 100 °C, into **1** which was easily recovered after evaporation of excess anhydride. The superiority of this synthetic route, shown in Equation (3), is related to the facile elimination of excess TfOTf, which is a poor coordinating reagent and has a lower boiling point (81−83 °C, 745 Torr) than triflic acid (162 °C, 760 Torr). In addition, reaction (3) does not generate side products, whereas sublimation of triflic acid hydrate, formed from reaction (2), requires a higher temperature (200 °C) and is time consuming.

$$UO_3 + TfOTf \xrightarrow{100\ ^\circ C} \underset{\mathbf{1}}{UO_2(OTf)_2} \quad (3)$$

Uranyl triflate **1**, like the other uranyl salts, is very hygroscopic and a practical dehydration method would be highly desirable. Triflic anhydride can also be used as a dehydrating agent and **1** was conveniently obtained by heating a suspension of $[UO_2(OTf)_2(H_2O)_n]$ in pure TfOTf at 110 °C for 15 h, according to Equation (4). Triflic acid is the only side product released during the process and was evaporated off with the excess anhydride.

$$UO_2(OTf)_2(H_2O)_n + n\ TfOTf \xrightarrow{110\ ^\circ C} \underset{\mathbf{1}}{UO_2(OTf)_2} + 2n\ TfOH \quad (4)$$

Irrespective of its mode of preparation, compound **1** was obtained in a pure state, as shown by the elemental analyses and the IR spectra, which confirm the absence of hydrated species.

In a similar way, with TfOTf as a dehydrating agent, the anhydrous cerium(IV) triflate $Ce(OTf)_4$ (**2**) was isolated as a pale yellow powder from the commercially available bright yellow compound $[Ce(OTf)_4(H_2O)_n]$ (n = 2−5) [Equation (5)]. After drying for 15 h at 100 °C, no reduction to Ce^{III} species was observed; the purity of **2** was established by elemental analyses as well as from IR and NMR spectra. $[Ce(OTf)_4(H_2O)_{1.5}]$ was previously prepared by successive treatment of cerium(IV) ammonium nitrate with potassium carbonate and triflic acid in water but could not be further dehydrated because of its decomposition above 120 °C into a trivalent cerium(III) species.[11] In addition to its applications in organic synthesis as a strong Lewis acid and oxidizing agent, compound **2** would be considered as a valuable precursor for the preparation of new cerium(IV) derivatives, while $CeCl_4$ is not stable, and its chemistry could be compared to that of its 5f analogue $U(OTf)_4$.[6b]

$$Ce(OTf)_4(H_2O)_n + n\ TfOTf \xrightarrow{20\ ^\circ C} \underset{\mathbf{2}}{Ce(OTf)_4} + 2n\ TfOH \quad (5)$$

In the solid state, compounds **1** and **2** are likely to adopt a polymeric structure with OTf bridges; such a structure has previously been found in some uranyl alkylsulfonate compounds which form infinite chains with bidentate bridging RSO_3 groups.[12,13] Compounds **1** and **2** are soluble in coordinating solvents like pyridine, THF and diethyl ether, giving stable Lewis base adducts.

The X-ray crystal structure of the mononuclear complex $[UO_2(OTf)_2(py)_3]$ (**3**) is shown in Figure 1 together with selected bond lengths and angles. The uranium atom is found in the most common pentagonal bipyramidal configuration of uranyl complexes with the equatorial plane defined by three nitrogen atoms of the pyridine ligands and two oxygen atoms of the triflate groups that are monodentate and non-adjacent. The U−O(triflate) bond lengths of 2.370(2) and 2.394(2) Å are identical to those found in $[UO_2(OTf)_2(H_2O)_3{\cdot}2benzo\text{-}15\text{-}crown\text{-}5]$ [2.38(1) and 2.392(9) Å][14] and in the monomeric sulfonato complexes $[UO_2(O_3SR)_2(H_2O)_3]$ (R = *p*-tolyl or mesityl) which vary from 2.355(6) to 2.406(7) Å.[13] The structural parameters of the OTf ligand are unexceptional. The structure of $[UO_2(OTf)_2(THF)_3]$, which could not be solved with good accuracy because of the poor quality of the crystals, shows the same arrangement of the equatorial ligands as in the above pyridine adduct **3** or the bromide analogue $[UO_2Br_2(THF)_3]$.[15]

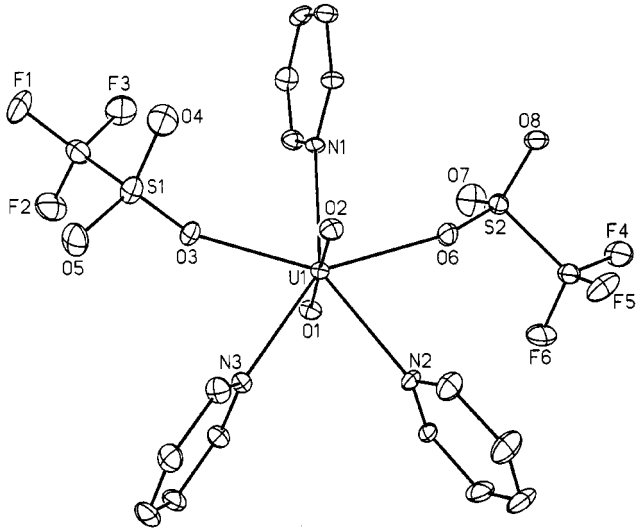

Figure 1. X-ray crystal structure of $UO_2(OTf)_2(py)_3$ (**3**) with thermal ellipsoids at the 40% probability level; selected bond lengths (Å) and angles (°): U−O(1) 1.744(2), U−O(2) 1.747(2), U−O(3) 2.370(2), U−O(6) 2.394(2), U−N(1) 2.529(2), U−N(2) 2.541(2), U−N(3) 2.518(2); O(1)−U−O(2) 178.49(9), N(1)−U−O(3) 72.82(7), N(1)−U−O(6) 73.00(8), N(3)−U−O(3) 73.47(7), N(2)−U−O(6) 71.06(8), N(2)−U−N(3) 69.71(8)

During one of the crystallizations of the bright yellow needles of **3**, a few round, yellow-green crystals were also deposited. X-ray analysis revealed that the μ-oxo complex $[\{UO_2(py)_4\}_2(\mu\text{-}O)][OTf]_2$ (**4**) had been formed, almost certainly after partial hydrolysis of **3** with adventitious traces

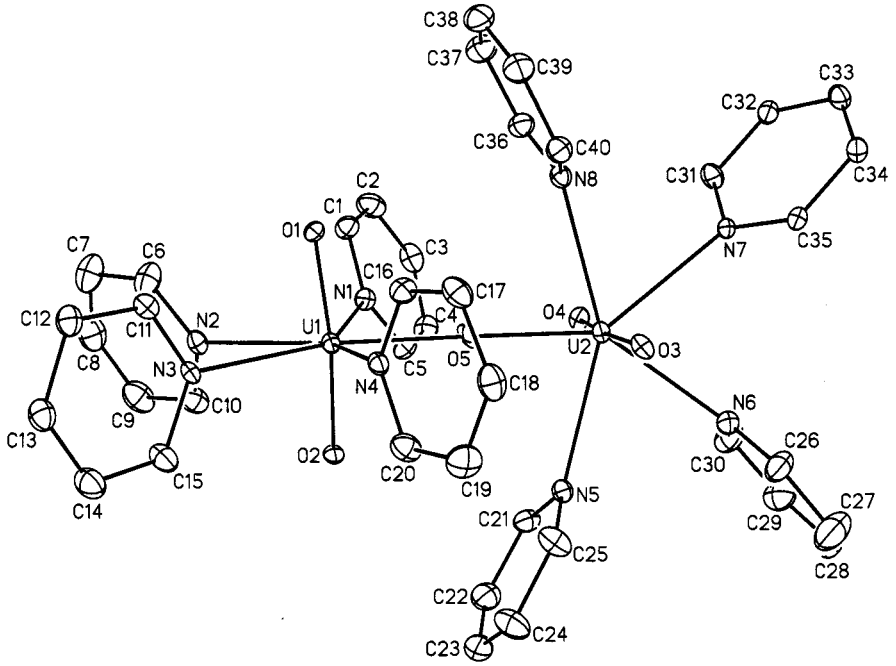

Figure 2. X-ray crystal structure of $[\{UO_2(py)_4\}_2(\mu\text{-}O)][OTf]_2$ (**4**) with thermal ellipsoids at the 15% probability level; selected bond lengths (Å) and angles (°): U(1)−O(1) 1.765(5), U(1)−O(2) 1.778(4), U(1)−N(1) 2.615(5), U(1)−N(2) 2.609(6), U(1)−N(3) 2.589(5), U(1)−N(4) 2.579(5), U(1)−O(5) 2.105(5), U(2)−O(3) 1.779(4), U(2)−O(4) 1.777(4), U(2)−N(5) 2.572(6), U(2)−N(6) 2.610(6), U(2)−N(7) 2.601(6), U(2)−N(8) 2.582(6), U(2)−O(5) 2.085(5); O(1)−U(1)−O(2) 173.1(2), N(1)−U(1)−N(2) 68.33(18), N(2)−U(1)−N(3) 71.88(17), N(3)−U(1)−N(4) 68.33(17), N(4)−U(1)−O(5) 74.81(17), N(1)−U(1)−O(5) 77.27(18), O(3)−U(2)−O(4) 171.5(2), N(5)−U(2)−N(6) 68.1(2), N(6)−U(2)−N(7) 73.35(19), N(7)−U(2)−N(8) 69.73(18), N(8)−U(2)−O(5) 74.3(2), N(5)−U(2)−O(5) 75.7(2), U(1)−O(5)−U(2) 173.7(2)

of water in the solvent. Compound **4** was obtained in larger quantities by crystallization of $[UO_2(OTf)_2(H_2O)_n]$ from pyridine/diethyl ether. The crystals of **4** are composed of discrete OTf anions, which display the expected geometry, and of $[\{UO_2(py)_4\}_2(\mu\text{-}O)]$ dications, the structure of which is shown in Figure 2 with selected bond lengths and angles. The pentagonal bases of each uranyl moiety, composed of the four nitrogen atoms of the pyridine ligands and the common oxygen atom of the μ-oxo group, are nearly orthogonal, intersecting at an angle of 88.3(1)°. The U(1)−O(5)−U(2) bridge is almost linear [173.7(2)°] with short metal−oxygen bond lengths which average 2.09(1) Å, reflecting a π interaction between the bridging oxygen and the metal.[16] This geometry of pseudo-D_{2d} symmetry is the best for the minimization of steric interactions between the two metallic fragments. It is interesting to note that, while linearly oxo-bridged binuclear compounds of early transition metals, lanthanides(III) and actinides(IV) are well documented,[17] compound **4** represents, to the best of our knowledge and from a search of the data of the Cambridge Crystallography Centre, the first example of such a uranyl complex. The other oxo bridged derivatives of uranyl exhibit a higher nuclearity ensured by μ_3-O bridges.[18]

In both **3** and **4**, the U−O bond lengths of the UO_2 moieties are unexceptional, ranging from 1.744(2) Å to 1.780(3) Å, as are the U−N(py) bond lengths which vary from 2.518(2) to 2.614(3) Å. These values compare well with those found in $[UO_2(NO_3)_2(py)_2]$ [<U−O> = 1.751(15) Å, U−N = 2.543(15) Å],[19a] $[UO_2(C_{15}H_{11}O_2)_2(py)]$ [<U−O> = 1.75(1) Å, U−N = 2.569(6) Å][19b] and $[UO_2(C_8H_{13}O_3)_2(py)]$ [<U−O> = 1.76(2) Å, U−N = 2.595(24) Å].[19b] It is noteworthy that, in contrast to **3**, the OTf groups of **4** are totally dissociated, having been replaced with pyridine ligands. This distinct behaviour is difficult to explain. More generally, the triflate ligands in $[UO_2(OTf)_2(H_2O)_3\cdot 2benzo\text{-}15\text{-}crown\text{-}5]$[14] and all the crystallographically characterized triflates of U^{III} and U^{IV} − $[U(OTf)_2(OPPh_3)_4][OTf]$,[6b] $[U(OTf)_4(OPPh_3)_3]$,[6c] $[U(C_5H_5)_3(OTf)(CNtBu)]$,[6a] $[U(C_5Me_5)_2(OTf)_2(H_2O)]$,[6a] and $[U(C_8H_8)(OTf)_2(OPPh_3)_2]$[6c] − were found not to have been displaced by strong oxygen and nitrogen Lewis bases. This clearly indicates that the uranium−triflate bond, whatever the metal oxidation state, is not as weak as could be expected.

Experimental Section

All preparations were carried out under argon (less than 2 ppm oxygen and water) using standard Schlenk- and vacuum-line techniques, or in a glove box. Solvents were thoroughly dried and deoxygenated by standard methods and distilled immediately before use. $[D_8]$THF was dried over Na-K alloy. IR spectra were obtained on a Perkin−Elmer 1725X spectrometer. Elemental analyses were performed by Analytische Laboratorien at Lindlar (Germany). The yellow powder of UO_3 was supplied by the Commissariat à l'Energie Atomique. $[Ce(OTf)_4(H_2O)_n]$ was supplied by Aldrich. Triflic acid (98 or 99%, Aldrich) and triflic anhydride (99%, Aldrich) were

distilled before use. $[UO_2(OTf)_2(H_2O)_n]$ was synthesized as previously reported.[7]

Uranyl Triflate $UO_2(OTf)_2$ (1). − From UO_3 and TfOH in Water: In the glove box, freshly distilled triflic acid (620 mL, 7 mmol) was added with a microsyringe into a 100 mL round-bottomed flask containing a suspension of UO_3 (210 mg, 0.7 mmol) in deoxygenated and demineralized water (15 mL). The trioxide was dissolved in a few minutes and the pale yellow solution was then refluxed for one hour to ensure complete reaction. Water was then evaporated off under vacuum and collected in a trap connected between the flask and the vacuum line and cooled in liquid nitrogen. The pale yellow residue was further heated at ca 200 °C under vacuum for 24 h and the white solid of $[TfO][H_3O]$ was eliminated by sublimation. During this step, the viscous drops that appeared on the upper walls of the flask were heated with a hot air stripper. Compound **1** was isolated as a pale yellow powder with yields varying from 65 to 90%; it turned bright yellow in air because of rapid hydration. − $C_2F_6O_8S_2U$ (568): calcd. C 4.22, F 20.06, S 11.28; found C 4.40, F 19.85, S 11.43. − IR (KBr in air): $\tilde{\nu}$ = 3593 (m), 3509 (m), 3217 (s) 1598 (s), 1262 (s), 1179 (s), 1034 (s), 950 (w), 905 (U=O, s), 769 (s), 643 (s), 581 (w), 519 (w), 478 (m); the IR spectrum of **1** in nujol between KBr plates shows no bands for water in the region 3600−3000 cm^{-1}.

From UO_3 and Pure TfOH: Triflic acid (ca 3 mL) was distilled into a 100 mL round-bottomed flask containing UO_3 (320 mg, 1.1 mmol) and the mixture was magnetically stirred for 2 h at 110 °C. The excess TfOH was distilled under vacuum into a trap cooled in liquid nitrogen and connected between the flask and the vacuum line. Compound **1** was obtained in 87% yield (550 mg) after drying for 24 h at 200 °C under vacuum. The IR spectra were identical to those described above.

From UO_3 and TfOTf: Freshly distilled triflic anhydride (ca 3 mL) was added in the glove box into a 100 mL round-bottomed flask containing UO_3 (205 mg, 0.7 mmol). The suspension was refluxed for 24 h whilst magnetically stirring. The excess TfOTf was distilled under vacuum into a trap connected between the flask and the vacuum line and cooled in liquid nitrogen. Further drying of the residue for 1 h at 100 °C under vacuum afforded **1** in 96% yield (340 mg). − $C_2F_6O_8S_2U$ (568): calcd. C 4.22, F 20.06, S 11.28; found C 4.37, F 19.81, S 11.37. The IR spectra were identical to those described above.

By Dehydration of $UO_2(OTf)_2(H_2O)_n$ with TfOTf: Triflic anhydride (ca 3 mL) was distilled under vacuum into a 100 mL round-bottomed flask containing the hydrated uranyl triflate $[UO_2(OTf)_2(H_2O)_n]$ (352 mg) and the bright yellow suspension was magnetically stirred at 110 °C for 15 h; the initial colour of the solid turned pale yellow. After cooling to room temperature, excess TfOTf was distilled off and **1** was obtained in almost quantitative yield (330 mg) after drying at 200 °C for 20 h under vacuum. − $C_2F_6O_8S_2U$ (568): calcd. C 4.22, F 20.06, S 11.28; found C 4.29, F 19.94, S 11.32. The IR spectra were identical to those described above.

Cerium(IV) Triflate $Ce(OTf)_4$ (2): Triflic anhydride (ca 3 mL) was distilled under vacuum into a 50 mL round-bottomed flask containing the hydrated cerium(IV) triflate $[Ce(OTf)_4(H_2O)_n]$ (500 mg). The yellow suspension was magnetically stirred for 1 h at 50 °C and then for 15 h at room temperature. The excess TfOTf was evaporated off and the pale yellow residue was dried under vacuum, first at room temperature for 10 h and then at 100 °C for 15 h. Compound **2** was obtained in almost quantitative yield (450 mg); its colour turned bright yellow upon exposure to air. − $C_4CeF_{12}O_{12}S_4$ (736): calcd. C 6.52, S 17.42; found C 6.39, S 17.25. Whereas the ^1H NMR spectrum of the commercially available $[Ce(OTf)_4(H_2O)_n]$ shows a broad signal at δ = 13.6 corresponding to H_2O, the spectrum of **2** in $[D_8]$THF confirms the absence of water and traces of triflic acid; polymerization of the solvent was not observed after 10 days. IR of $Ce(OTf)_4(H_2O)_n$ (KBr): $\tilde{\nu}$ = 3443 (s), 1660 (m), 1636 (m), 1244 (s), 1187 (m), 1031 (s), 771 (w), 640 (s), 582 (m), 524 (s). The IR spectrum of **2** in nujol between KBr plates shows no bands for H_2O; the IR spectrum of **2** in KBr pellet carried out in air is identical to that of $[Ce(OTf)_4(H_2O)_n]$.

X-ray Crystallography of 3: Single crystals were obtained by slow diffusion of diethyl ether into a solution of **3** in pyridine. A yellow crystal of approximate dimensions 0.30 × 0.20 × 0.15 mm was selected. Diffraction collection was carried out on a Nonius diffractometer equipped with a CCD detector. The lattice parameters were determined from ten images recorded with 1° Φ-scans and later refined on all data. The data were recorded at 173 K. A 180° Φ-range was scanned with 2° steps with a crystal-to-detector distance fixed at 35 mm. Data were corrected for Lorentz-polarization and absorption[20] effects. The structure was solved by the heavy-atom method and refined by full-matrix least-squares on F^2 with anisotropic thermal parameters for all non-H atoms. H atoms were introduced at calculated positions and constrained to ride on their parent C atom. $C_{17}H_{15}F_6N_3O_8S_2U$ (805.47), monoclinic, space group $P2_1/n$, a = 8.5920(17), b = 15.733(3), c = 18.687(4) Å, β = 94.73(3)°, V = 2517.5(9) $Å^3$, Z = 4, D_c = 2.125 g cm^{-1}, Mo-$K\alpha$ (λ = 0.71073 Å), μ_{Mo} = 6.705 mm^{-1}, $F(000)$ = 1520, total reflections = 12022, independent reflections = 3361 (R_{int} = 0.077), observed reflections [$I > 2\sigma(I)$] = 2864, R_1 = 0.0334, wR_2 = 0.0890. All calculations were performed on an O2 Silicon Graphics Station with the SHELXTL package.[21]

X-ray Crystallography of 4: During one of the crystallizations of **3**, a few single crystals of **4** were deposited. A yellow crystal of approximate dimensions 0.35 × 0.25 × 0.20 mm was selected. Diffraction collection was carried out on a Nonius diffractometer equipped with a CCD detector. The lattice parameters were determined from ten images recorded with 1° Φ-scans and later refined on all data. The data were recorded at 173 K. A 180° Φ-range was scanned with 2° steps with a crystal to detector distance fixed at 35 mm. Data were corrected for Lorentz-polarization and absorption [20] effects. The structure was solved by the heavy-atom method and refined by full-matrix least-squares on F^2 with anisotropic thermal parameters for all non-H atoms. H atoms were introduced at calculated positions and constrained to ride on their parent C atom. Due to imperfect absorption corrections and rather poor quality of data, the U−O−U angles of the uranyl fragments deviate from linearity. $C_{42}H_{40}F_6N_8O_{11}S_2U_2$ (1487.0), monoclinic, space group $P2_1/c$, a = 19.352(4), b = 13.248(3), c = 19.631(4) Å, β = 91.12(3)°, V = 5031.9(17) $Å^3$, Z = 4, D_c = 1.963 g cm^{-1}, Mo-K_α (λ = 0.71073 Å), μ_{Mo} = 6.597 mm^{-1}, $F(000)$ = 2824, total reflections = 12163, independent reflections = 6686 (R_{int} = 0.073), observed reflections [$I > 2\sigma(I)$] = 4744, R_1 = 0.047, wR_2 = 0.102. All calculations were performed on an O2 Silicon Graphics Station with the SHELXTL package.[21]

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-138645 **(3)** and -138646 **(4)**. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

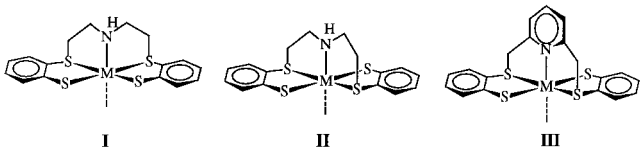
Transition Metal Complexes with Sulfur Ligands, 142[‡]

Inert and Labile [Ru(L)('pyS_4')] Complexes with Rigid [$RuNS_4$] Cores and *trans*-Thiolate Donors [L = PPh_3, PEt_3, DMSO, CO, NO^+, N_2H_4; 'pyS_4'$^{2-}$ = 2,6-Bis(2-mercaptophenylthio)dimethylpyridine(2–)]

Dieter Sellmann,*[a] Klaus Engl,[a] and Frank W. Heinemann[a]

Dedicated to Professor Wilhelm Preetz on the occasion of his 65th birthday



Keywords: Ruthenium / Sulfur ligands / Exchange reactions

In a quest for ruthenium complexes having [$RuNS_4$] cores, a non-fluxional configuration, *trans*-thiolate donors, and exchangeable coligands L, [Ru(L)('pyS_4')] complexes have been synthesized ['pyS_4'$^{2-}$ = 2,6-bis(2-mercaptophenylthio)dimethylpyridine(2–)]. Treatment of [$RuCl_2(PPh_3)_3$] with 'pyS_4'$^{2-}$ gave [Ru(PPh_3)('pyS_4')] (**1**). Alkylation of **1** with excess MeI yielded [Ru(PPh_3)('pyS_4'–Me_2)]I_2 (**2**). [Ru(DMSO)('pyS_4')] (**3**) was obtained from [$RuCl_2(DMSO)_4$] and 'pyS_4'$^{2-}$. The PPh_3 or DMSO coligands in **1**, **2**, and **3** proved to be very inert to substitution. Only the DMSO could be displaced by CO under drastic conditions yielding [Ru(CO)('pyS_4')] (**4**). Treatment of [$RuCl_2(CH_3CN)_4$] with 'pyS_4'$^{2-}$ yielded [Ru('pyS_4')]$_2$ (**5**); in the presence of PEt_3 or N_2H_4 mononuclear [Ru(PEt_3)('pyS_4')] (**6**) and [Ru(N_2H_4)('pyS_4')] (**7**) were formed. Template alkylation of NBu_4[Ru(NO)($S_2C_6H_4$)$_2$] with 2,6-bis(tosyloxymethyl)pyridine gave [Ru(NO)('pyS_4')]Tos (**8**). Complex **8** proved to be the best suited precursor for L exchange reactions. Under reducing conditions, **8** releases its NO ligand and the resulting [Ru('pyS_4')] fragments can combine either with each other to give **5**, or with PEt_3 and N_2H_4 to yield **6** and **7**, respectively. All complexes have been characterized by spectroscopic methods and elemental analysis; **1**, **2**, **3**, and **4** have also been submitted to X-ray structure analysis.

Introduction

Transition metals in sulfur-dominated coordination spheres form the active centers of numerous oxidoreductases, e.g. of nitrogenases, hydrogenases, and CO dehydrogenases.[1] Efforts to elucidate the molecular mechanisms of the enzyme reactions and to find competitive catalysts with enzyme-like activity are a major impetus in the search for low molecular weight complexes that combine structure and reactivity features of the enzyme metal–sulfur [MS] centers.[2] An important aspect of this search is the design of new ligands that meet specific requirements with regard to donor atom sets, configurations, stability, and reactivity of the resulting complexes.[3]

In this respect, the 'N_HS_4'$^{2-}$ [= 2,2'-bis(2-mercaptophenylthio)diethylamine(2–)] ligand has proved particularly versatile.[4] It has yielded a large number of [Fe(L)('N_HS_4')] complexes with L comprising the nitrogenase-relevant molecules CO, NO, N_2H_2, N_2H_4, and NH_3, although not N_2. This prompted us to investigate the coordination behaviour of 'N_HS_4'$^{2-}$ towards ruthenium as well; it was anticipated that with the kinetically more inert ruthenium, species that are labile with iron would become isolable. However, practically all our experiments in this area proved unsuccessful. Besides the problem of finding [Ru(L)('N_HS_4')] complexes with exchangeable coligands L, the diastereoisomerism of the [M('N_HS_4')] fragments led to the formation of inseparable mixtures of diastereomeric [Ru(L)('N_HS_4')] species. In [M(L)('N_HS_4')] complexes, the [M('N_HS_4')] fragments can exist in two diastereomeric forms, indicated by formulae I and II (Scheme 1).

Scheme 1. Configurations of [MNS_4] complexes

While in the case of iron these diastereomers isomerize via five-coordinate intermediates to yield, depending on the coligand L, either I or II,[4,5] the ruthenium analogues do not isomerize, due to the inert nature of the ruthenium donor bonds. In order to eliminate this problem, we replaced the flexible $N(C_2H_4)_2$ bridge of the 'N_HS_4'$^{2-}$ ligand by the rigid 2,6-bis(methylene)pyridine bridge and synthesized the ligand 'pyS_4'$^{2-}$ [= 2,6-bis(2-mercaptophenylthio)-dimethylpyridine(2–)].[6] This 'pyS_4'$^{2-}$ ligand indeed yielded iron complexes consistently containing the fragment III.[6,7] It is also noteworthy that the hydrazine complex [Fe(N_2H_4)('pyS_4')] contains a low-spin Fe^{II} center,[7] in con-

trast to the [Fe(N_2H_4)('N_HS_4')] complex, which has the core structure I and a high-spin Fe^{II} center.

In this paper we report our efforts to synthesize [Ru(L)('pyS_4')] complexes and to find species in which the L coligands may be displaced by nitrogenase-relevant small molecules. The exchange of L proved to be the major problem.

Results

The HCl adduct ('pyS_4'–H_2) · HCl served as the starting material for preparing the ligand. It was routinely deprotonated with three equivalents of LiOMe to give Li_2'pyS_4'. The subsequent reactions of Li_2'pyS_4' with suitable Ru precursor complexes are summarized in Scheme 2.

Scheme 2. Syntheses and reactions of [Ru('pyS_4')] complexes; (a) + [$RuCl_2(PPh_3)_3$]/MeOH/15 h/room temp.; (b) + exc. CH_3I/THF/2 d/room temp.; (c) + [$RuCl_2(DMSO)_4$]/MeOH/15 h/room temp.; (d) + CO, 120 bar/THF/110 °C/3 d; (e) + [$RuCl_2(CH_3CN)_4$]/MeOH/4 h reflux; (f) + [$RuCl_2(CH_3CN)_4$]/exc. L (L = PEt_3, N_2H_4)/MeOH/4 h reflux; (g) + 'pyTos'/THF/4 h reflux; (h) + 2.5 $LiBEt_3H$/THF/2.5 d room temp.; (i) + exc. L (L = PEt_3, N_2H_4)/THF/room temp.

The PPh_3 complex [Ru(PPh_3)('pyS_4')] (**1**) was found to be readily soluble in CH_2Cl_2 or THF. Although PPh_3 is a relatively bulky ligand, it proved practically inert to substitution. As yet, we have not been able to exchange it by N_2H_4 or even CO, neither under standard conditions nor at elevated temperatures. Attempts to labilize the Ru–PPh_3 bond of **1** by alkylation of the thiolate donors using excess CH_3I gave [Ru(PPh_3)('pyS_4'–Me_2)]I_2 (**2**), which contains the 'pyS_4'–Me_2 ligand. Complex **2** was formed in diastereomerically pure form. The PPh_3 ligand in **2** has proved to be as substitution inert as that in **1**. Our next target complex was [Ru(DMSO)('pyS_4')] (**3**) as we anticipated that the DMSO ligand would be as labile as that in the related [Ru(DMSO)(PR_3)('S_4')] complexes with R = Cy, *i*Pr; 'S_4'$^{2-}$ = 1,2-bis(2-mercaptophenylthio)ethane(2–).[8a] However, the DMSO ligand in **3** also proved very inert and could not be exchanged for CO at room temperature at pressures ranging from 1–100 bar. Only under very drastic conditions in an autoclave (120 bar CO, 110 °C, THF) did a slow reaction (3 d) take place to give [Ru(CO)('pyS_4')] (**4**). Another potentially labile target complex was [Ru(CH_3CN)('pyS_4')]. Its synthesis was attempted starting from [$RuCl_2(CH_3CN)_4$] and Li_2'pyS_4'. However, heating in MeOH proved necessary in order to observe a reaction, and the resulting product was found not to contain CH_3CN. A red-brown solid precipitated, which was found to be practically insoluble in all common solvents. Its IR spectrum, elemental analysis, and mass spectrum, which featured an ion peak at *m/z* = 973, were compatible with the dinuclear [Ru('pyS_4')]$_2$ (**5**). Complex **5** was found not to react with boiling DMSO, pyridine, or with CO in these solvents. The reaction of [$RuCl_2(CH_3CN)_4$] with Li_2'pyS_4' took a different course when potential ligands such as PEt_3 or N_2H_4 were present. In these cases, the mononuclear complexes [Ru(PEt_3)('pyS_4')] (**6**) and [Ru(N_2H_4)('pyS_4')] (**7**) were formed. This might be indicative of the formation of a labile [Ru(CH_3CN)('pyS_4')] intermediate, which loses CH_3CN in boiling MeOH and either dimerizes to give **5** or adds PEt_3 and N_2H_4 to yield **6** and **7**, respectively. Complex **6** proved as inert to substitution as the PPh_3 complex **1**. Complex **7** demonstrates that the [Ru('pyS_4')] fragment can bind "hard" σ coligands. The purification of complexes **6** and **7** synthesized by this method proved troublesome. They were more easily obtained from reactions of the nitrosyl complex [Ru(NO)('pyS_4')]Tos (**8**). Complex **8** was obtained by template alkylation of NBu_4[Ru(NO)($S_2C_6H_4$)$_2$] with 2,6-bis(tosyloxymethyl)pyridine ('pyTos') in boiling THF. Pure **8** was precipitated from the reaction solution in good yield. It was found to be soluble in MeOH, DMF, and DMSO, but insoluble in THF, CH_2Cl_2, Et_2O, and *n*-hexane. The relatively high frequency of the ν(NO) absorption of **8** (1892 cm^{-1}) suggested that nucleophiles could be added to the NO ligand.[9] Indeed, rapid reactions occurred upon treatment of **8** with equimolar amounts of NH_3 or LiOMe in MeOH. Green-brown solids were immediately precipitated, which exhibited strong bands in their IR spectra at around 1800 cm^{-1}, consistent with the formation of ligands derived from NO. However, these products were so insoluble in all common solvents that they could not be adequately characterized.

In order to probe the reducibility of **8**, a cyclic voltammogram was recorded (Figure 1). The quasi-reversible (–275 mV) and irreversible (–1200 mV) redox waves in the cathodic region could tentatively be assigned to the formation of neutral [Ru(NO)('pyS_4')]^0 and anionic [Ru(NO)('pyS_4')]$^-$ complexes, which formally represent 19 and 20 valence electron [VE] species.

In order to achieve chemical reductions, **8** was treated with $LiBEt_3H$ and N_2H_4. On addition of $LiBEt_3H$ to a red-brown suspension of **8** in THF, gas was evolved and a deep-red solution was produced, from which red [Ru('pyS_4')]$_2$ (**5**) precipitated. The IR spectrum of the deep-red solution did not feature any bands attributable to an NO ligand. When a red-brown THF suspension of **8** was treated with an excess of N_2H_4, gas was again evolved and a deep-red solu-

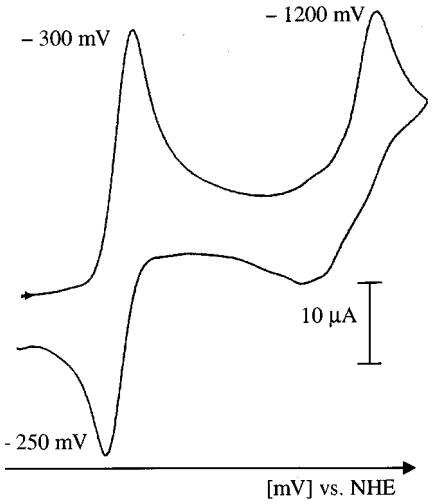

Figure 1. Cyclic voltammogram of [Ru(NO)('pyS$_4$')]Tos (**8**) in DMF (10^{-3} M **8**, 10^{-1} M NBu_4PF_6, $v = 0.02$ Vs^{-1})

tion was produced. Red microcrystals of the hydrazine complex **7** were precipitated upon addition of MeOH and Et_2O. In another experiment, a THF suspension of **8** was treated with excess PEt_3. A red-orange solid formed, which was characterized as the pure PEt_3 complex **6**. Phosphanes frequently act as reductants[10] and hence these results suggest that reduction of **8** gives a substitution labile species that releases NO to yield [Ru('pyS$_4$')] fragments. In the absence of suitable ligands, these fragments dimerize to give [Ru('pyS$_4$')]$_2$ (**5**), while in the presence of such ligands the corresponding [Ru(L)('pyS$_4$')] derivatives are formed.

Characterization and General Properties of the Complexes

As far as possible, all the complexes have been characterized by standard spectroscopic methods and by elemental analysis. The molecular structures of **1**, **2**, **3**, and **4** have been determined by X-ray diffraction analysis. All complexes are colored yellow-red to deep-red. The neutral complexes **1**, **3**, **4**, **6**, and **7** show moderate to good solubility in CH_2Cl_2 and THF, while the ionic complexes **2** and **8** are soluble in DMSO and DMF. The dinuclear species [Ru('pyS$_4$')]$_2$ (**5**) was found to be insoluble in all common solvents. Consequently, no NMR spectra of **5** could be recorded, and this complex could only be characterized by its IR and mass spectra and elemental analysis.

In the FD mass spectra, either the respective molecular ions or the [Ru('pyS$_4$')]$_2^+$ ion arising from dissociation of the coligand L and dimerization of the resulting [Ru('pyS$_4$')] fragments could be observed. The FD mass spectrum of [Ru(PPh$_3$)('pyS$_4$'–Me$_2$)]I$_2$ (**2**) exhibited only fragment ions resulting from demethylation, e.g. [Ru(PPh$_3$)('pyS$_4$'–Me)]$^+$ and [Ru(PPh$_3$)('pyS$_4$')]$^+$. The IR spectra in KBr featured the typical bands attributable to the [Ru('pyS$_4$')] fragment besides the characteristic bands of the coligands. For example, the ν(SO) band at 1015 cm^{-1} indicates *S*-coordination of the DMSO ligand in [Ru(DMSO)('pyS$_4$')] (**3**). Characteristic strong ν(CO) and ν(NO) bands are seen for **4** (1954 cm^{-1}) and **8** (1892 cm^{-1}), respectively, while ν(NH) bands at 3335, 3207, and 3042 cm^{-1} give evidence of the coordination of N_2H_4 in [Ru(N_2H_4)('pyS$_4$')] (**7**).

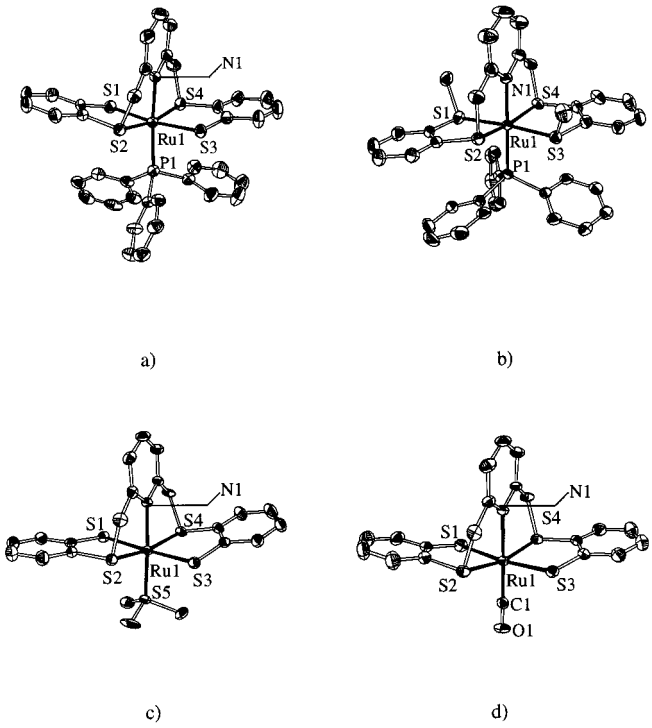

Figure 2. Molecular structures of [Ru(PPh$_3$)('pyS$_4$')] (**1**), [Ru(PPh$_3$)('pyS$_4$'-Me$_2$)]I$_2$ · 2 CH_2Cl_2 (**2** · 2 CH_2Cl_2), [Ru(DMSO)-('pyS$_4$')] · MeOH (**3** · MeOH), and [Ru(CO)('pyS$_4$')] · MeOH (**4** · MeOH) (50% probability ellipsoids; H atoms and solvent molecules omitted for clarity)

The $^{13}C\{^1H\}$-NMR spectra proved particularly helpful in establishing the diastereomeric purity of the complexes and the twofold symmetry of the [Ru('pyS$_4$')] fragments. The seventeen aromatic and two aliphatic C atoms of the [Ru('pyS$_4$')] fragments give rise to only ten ^{13}C signals. This is compatible with C_2 or C_S symmetry of the fragments. Steric considerations and the X-ray structure analyses show that in all cases the C_2-symmetric [Ru('pyS$_4$')] configuration with *trans*-thiolate donors is adopted. The singlet ^{13}C-NMR signal due to the two SCH_3 groups in [Ru(PPh$_3$)('pyS$_4$'–Me$_2$)]I$_2$ (**2**) proves that the thiolate alkylation of **1** yields only one diastereomer of **2**.

The AB splitting of the diastereotopic CH_2 protons, giving rise to two pseudo doublets is a characteristic feature of the [Ru('pyS$_4$')] pattern in the ^1H-NMR spectra. In some cases, a triplet due to the pyridine H_γ proton can also be observed. Usually, this triplet is superimposed by the signals of either the pyridine H_β, benzenedithiolate, or PPh_3 protons. Two DMSO methyl group singlets are seen for the DMSO complex **3**, while two N_2H_4 singlets are seen in the spectrum of the hydrazine complex **7**.

Table 1. Selected distances (pm) and angles (°) in [Ru(PPh_3)('pyS_4')] (**1**), [Ru(PPh_3)('pyS_4'–Me_2)]$I_2 \cdot 2\ CH_2Cl_2$ (**2** · 2 CH_2Cl_2), [Ru(DMSO)('pyS_4')] · MeOH (**3** · MeOH), and [Ru(CO)('pyS_4')] · MeOH (**4** · MeOH)

X-ray Structure Analysis

X-ray structure analyses of **1**, **2**, **3**, and **4** corroborated the spectroscopic conclusions with regard to the structures. Figure 2 depicts the molecular structures of [Ru(PPh_3)('pyS_4')] (**1**), [Ru(PPh_3)('pyS_4'–Me_2)]$I_2 \cdot 2\ CH_2Cl_2$ (**2** · 2 CH_2Cl_2), [Ru(DMSO)('pyS_4')] · MeOH (**3** · MeOH), and [Ru(CO)('pyS_4')] · MeOH (**4** · MeOH). Table 1 lists selected distances and angles.

In all the complexes, the ruthenium centers exhibit pseudo-octahedral coordination. The [Ru('pyS_4')] fragments are pseudo-C_2 symmetrical. The thiolate donors occupy positions *trans* to one another, and the coligands L occupy the positions *trans* to the pyridine N donor. Distances and angles show no anomalies.[8] The Ru–S(thiolate) distances are usually slightly longer than the Ru–S(thioether) distances. The Ru–N(pyridine) distances in all four complexes are almost identical. The molecular structure of **3** proves the *S*-coordination of the DMSO ligand, as had been concluded from the IR spectrum.

The results further indicate that the [Ru('pyS_4')] core is structurally very robust. This is also evidenced by a direct comparison of **1** and **2**. The Ru–N distances and the average Ru–S distances in **1** (235.3 pm) and the twofold methylated derivative **2** (234.9 pm) are practically identical. This demonstrates that the [$RuNS_4$] cores remain unaffected even when the electronic situation changes, as must occur upon alkylation of the thiolate donors. These results support the structure–function relationship of metal–sulfur complexes described in several previous papers.[2,11]

Discussion and Conclusion

The results reported herein demonstrate that the 'pyS_4'$^{2-}$ ligand forms ruthenium complexes possessing [Ru('pyS_4')] cores that (i) exhibit the desired configuration, having *trans*-thiolate donors, and (ii) are structurally robust. The new complexes were obtained either by direct reaction of 'pyS_4'$^{2-}$ with suitable Ru precursor complexes or by template alkylation of [Ru(NO)($S_2C_6H_4$)$_2$]$^-$ yielding [Ru(NO)('pyS_4')]Tos (**8**). In comparison with analogous [Fe(L)('pyS_4')] complexes, which are usually synthesized at room temperature, the synthesis of the corresponding [Ru(L)('pyS_4')] complexes has in many cases been found to require heating or very drastic conditions as, for example, in the case of the CO complex **4**. This reflects the more inert nature of Ru complexes as compared to their Fe counterparts. It also accounts for the fact that it is difficult to find complexes with labile L ligands that can serve as precursors for other [Ru(L)('pyS_4')] complexes. For example, the PPh_3 ligand in **1** is inert and could not be labilized by thiolate methylation, which can be expected to withdraw electron density from the Ru center and to weaken the Ru–PPh_3 bond.[11] Even the DMSO complex **3** proved virtually inert; only under very drastic conditions could a DMSO/CO exchange be achieved. Attempts to obtain labile [Ru(CH_3CN)('pyS_4')] complexes were unsuccessful, yielding only insoluble [Ru('pyS_4')]$_2$ (**5**) or, in the presence of PEt_3 or N_2H_4, the corresponding [Ru(L)('pyS_4')] complexes with L = PEt_3 (**6**) and N_2H_4 (**7**). Complexes **6** and **7** obtained by this method proved difficult to purify, probably due to the formation of side-products as a result of the drastic reaction conditions.

The best suited precursor complex for exchange reactions was ultimately found to be [Ru(NO)('pyS_4')]Tos (**8**). Cyclic voltammetry demonstrated the reducibility of **8**. The resulting 19 or even 20 valence electron species can be expected to be labile as antibonding orbitals must be populated.[4] Indeed, reduction of **8** with $LiBEt_3H$ leads to loss of the NO ligand with the formation of [Ru('pyS_4')]$_2$ (**5**). Reduction of **8** with excess N_2H_4 likewise releases NO, but the excess N_2H_4 adds as a ligand and the hydrazine complex **7** can be isolated in high yield in analytically pure form.

The potential of this method for the synthesis of [Ru(L)('pyS_4')] complexes with nitrogenase-relevant L ligands is currently being investigated.

Experimental Section

General Methods: Unless noted otherwise, all reactions and operations were carried out at room temperature under nitrogen using standard Schlenk techniques. Solvents were dried and distilled

prior to use. As far as possible, reactions were monitored by IR or NMR spectroscopy. Spectra were recorded with the following instruments: IR (KBr discs or CaF_2 cuvettes; solvent bands were compensated): Perkin–Elmer 983, 1620 FT-IR, and 16PC FT-IR. – NMR: Jeol FT-JNM-GX 270, EX 270, and Lambda LA 400; spectra were referenced to residual protio-solvent signals; chemical shifts are quoted on the δ scale (downfield shifts are positive) with respect to tetramethylsilane (^1H, $^{13}C\{^1H\}$ NMR) or 85% H_3PO_4 ($^{31}P\{^1H\}$ NMR); spectra were recorded at 25 °C. – Mass spectra: Jeol MSTATION 700 spectrometer. – Elemental analysis: Carlo Erba EA 1106 or 1108 analyzer. – Cyclic voltammetry was performed with a PAR 264A potentiostat using a three-electrode cell with a glassy carbon ROTEL A working electrode and Pt reference and counterelectrodes. Solutions were 10^{-3} M in the substance under investigation; TBA[PF_6] (10^{-1} M) was used as the supporting electrolyte. Potentials were referenced to the normal hydrogen electrode (NHE) using Fc/Fc^+ as an internal standard ($E_{Fc/Fc+} = +0.4$ V vs. NHE).[12]

$[RuCl_2(PPh_3)_3]$,[13] $[RuCl_2(DMSO)_4]$,[14] $[RuCl_2(CH_3CN)_4]$,[15] $NBu_4[Ru(NO)(S_2C_6H_4)_2]$,[16] 'pyTos' = 2,6-bis(tosyloxymethyl)pyridine),[17] and 'pyS_4'-H_2HCl[6] were prepared as described in the literature; LiOMe was purchased from Aldrich.

[Ru(PPh_3)('pyS_4')] (1): Solid $[RuCl_2(PPh_3)_3]$ (959 mg, 1.0 mmol) was added to a stirred MeOH solution (20 mL) of 'pyS_4'–$H_2 \cdot HCl$ (424 mg, 1.0 mmol) and LiOMe (3.0 mL of a 1 M solution in MeOH, 3.0 mmol). In the course of 15 h, a red-brown suspension was produced. The red-brown solid was separated, washed with MeOH (20 mL) and Et_2O (40 mL), dried, and dissolved in hot pyridine (40 mL). The resulting solution was cooled to room temperature and layered with MeOH (100 mL). Orange crystals precipitated, which were separated after 1 d, washed with MeOH (20 mL) and Et_2O (30 mL), and dried in vacuo. Yield: 615 mg of **1** (82%). – $C_{37}H_{30}NPRuS_4$ (748.94): calcd. C 59.34, H 4.04, N 1.87, S 17.12; found C 59.25, H 4.08, N 1.94, S 17.16. – MS (FD, CH_2Cl_2, ^{102}Ru); *m/z* = 749 [Ru(PPh_3)('pyS_4')]$^+$. – ^1H NMR (269.6 MHz, CD_2Cl_2): δ = 7.46–7.01 [m, 22 H, C_6H_4, P(C_6H_5) and pyridine], 6.87–6.76 (m, 4 H, C_6H_4), 4.94 (d, 2 H, CH_2), 4.46 (d, 2 H, CH_2). – $^{13}C\{^1H\}$ NMR (67.8 MHz, CD_2Cl_2): δ = 157.69, 157.45, 137.42, 136.81, 134.59 (arom. C), 133.85 [d, P(C_6H_5)], 132.40, 131.60, 130.87 (arom. C), 129.10 [d, P(C_6H_5)], 128.06 (arom. C), 127.71 [d, P(C_6H_5)], 121.31 [d, P(C_6H_5)], 58.68 (d, CH_2). – $^{31}P\{^1H\}$ NMR (109.38 MHz, CD_2Cl_2): δ = 49.0 (s).

[Ru(PPh_3)('pyS_4'–Me_2)]I_2 (2): 2 mL (32.13 mmol) of CH_3I was added to a stirred orange THF suspension (30 mL) of [Ru(PPh_3)('pyS_4')] (**1**) (350 mg, 0.47 mmol). A beige solid formed, which was separated after 2 d, washed with THF (80 mL) and Et_2O (40 mL), and dried in vacuo. Recrystallization from CH_2Cl_2/Et_2O yielded yellow crystals, which were separated, washed with Et_2O (20 mL), and dried in vacuo. Yield: 395 mg of **2** · 2 CH_2Cl_2 (70%). – $C_{41}H_{40}Cl_4I_2NPRuS_4$ (1202.68): calcd. C 40.95, H 3.35, N 1.16, S 10.66; found C 41.07, H 3.17, N 1.20, S 10.78. – MS (FD, CH_2Cl_2, ^{102}Ru); *m/z* = 749 [Ru(PPh_3)('pyS_4')]$^+$. – ^1H NMR (269.6 MHz, [D_6]DMSO): δ = 8.00 (d, 2 H, C_6H_4), 7.92 (t, 1 H, H_γ, pyridine), 7.83 (d, 2 H, C_6H_4), 7.64–7.52 [m, 6 H, C_6H_4, P(C_6H_5)], 7.30–7.17 [m, 15 H, C_6H_4, P(C_6H_5), H_β, pyridine], 5.80 (d, 2 H, CH_2), 5.23 (d, 2 H, CH_2), 2.12 (s, 6 H, CH_3). – $^{13}C\{^1H\}$ NMR (67.8 MHz, [D_6]DMSO): δ = 158.67, 138.06, 135.78, 133.78, 133.12 (arom. C), 132.76 [d, P(C_6H_5)], 131.99 [t, P(C_6H_5)], 130.96, 130.57, 130.27 (arom. C), 128.37 [d, P(C_6H_5)], 123.23, (arom. C), 55.54 (CH_2), 24.36 (CH_3). – $^{31}P\{^1H\}$ NMR (109.38 MHz, [D_6]DMSO): δ = 36.0 (s).

[Ru(DMSO)('pyS_4')] (3): Solid $[RuCl_2(DMSO)_4]$ (485 mg, 1.0 mmol) was added to a stirred MeOH solution (20 mL) of 'pyS_4'–$H_2 \cdot HCl$ (424 mg, 1.0 mmol) and LiOMe (3.0 mL of a 1 M solution in MeOH, 3.0 mmol). In the course of 15 h, a yellow suspension resulted. The yellow solid was separated, washed with MeOH (20 mL), dried, and dissolved in hot DMSO (20 mL). The resulting solution was cooled to room temperature and layered with MeOH (60 mL). Yellow crystals precipitated, which were separated after 2 d, washed with MeOH (20 mL) and Et_2O (30 mL), and dried in vacuo. Yield: 325 mg of **3** · MeOH (54%). – $C_{22}H_{25}NO_2RuS_5$ (596.82): calcd. C 44.28, H 4.22, N 2.35, S 26.86; found C 44.16, H 4.40, N 2.37, S 26.86. – IR (KBr): $\tilde{\nu}$ = 1015 cm^{-1} ν(SO). – MS (FD, CH_2Cl_2, ^{102}Ru); *m/z* = 565 [Ru(DMSO)('pyS_4')]$^+$. – ^1H NMR (269.6 MHz, [D_6]DMSO): δ = 7.70 (d, 2 H, C_6H_4), 7.45 (t, 1 H, H_γ, pyridine), 7.35 (d, 2 H, C_6H_4), 7.25 (d, 2 H, H_β, pyridine), 6.95–6.85 (m, 4 H, C_6H_4), 4.7 (s, 4 H, CH_2), 3.05 [s, 3 H, $CH_3S(O)CH_3$], 2.8 [s, 3 H, $CH_3S(O)CH_3$]. – $^{13}C\{^1H\}$ NMR (67.8 MHz, [D_6]DMSO): δ = 157.40, 155.60, 135.30, 132.60, 130.60, 130.10, 128.00, 121.50, 121.30, (arom. C), 55.70 (CH_2), 46.80, 46.30 (CH_3).

[Ru(CO)('pyS_4')] (4): In an autoclave, a yellow suspension of [Ru(DMSO)('pyS_4')] · MeOH (**3**) (330 mg, 0.55 mmol) in 30 mL of THF was exposed to CO gas (120 bar) for 3 d at 110 °C. The resulting yellow solution was then concentrated to dryness, the yellow residue was digested with MeOH (60 mL) and Et_2O (20 mL), and the product was dried in vacuo. Yield: 170 mg of **4** · MeOH (57%). – $C_{21}H_{19}NO_2RuS_4$ (546.70): calcd. C 46.14, H 3.50, N 2.56, S 23.46; found C 45.92, H 3.72, N 2.59, S 23.60. – IR (KBr): $\tilde{\nu}$ = 1954 cm^{-1} ν(CO). – MS (FD, CH_2Cl_2, ^{102}Ru); *m/z* = 515 [Ru(CO)('pyS_4')]$^+$. – ^1H NMR (269.6 MHz, CD_2Cl_2): δ = 7.63–7.60 (m, 2 H, C_6H_4), 7.46–7.43 (m, 3 H, C_6H_4, H_γ, pyridine), 7.19 (d, 2 H, H_β, pyridine), 7.02–6.91 (m, 4 H, C_6H_4), 5.07 (d, 2 H, CH_2), 4.59 (d, 2 H, CH_2). – $^{13}C\{^1H\}$ NMR (100.40 MHz, CD_2Cl_2): δ = 201.62 (CO), 156.23, 155.91, 136.76, 132.48, 131.02, 129.12, 122.60, 121.99 (arom. C), 58.11 (CH_2).

[Ru('pyS_4')]$_2$ (5): $LiBEt_3H$ (1.375 mL of a 1 M solution in THF, 1.375 mmol) was added to a red-brown suspension of [Ru(NO)('pyS_4')]Tos (**8**) (380 mg, 0.55 mmol) in 15 mL of THF. Gas was evolved and a deep-red solution was produced, from which a red-brown solid precipitated in the course of 2.5 d. This solid was separated, washed with MeOH (10 mL), THF (10 mL), and Et_2O (10 mL), and dried in vacuo. Yield: 120 mg of **5** · MeOH (43%). – $C_{39}H_{34}N_2ORu_2S_8$ (1005.33): calcd. C 46.59, H 3.41, N 2.79, S 25.51; found C 46.20, H 3.20, N 2.89, S 25.42. – MS (FD, DMSO, ^{102}Ru); *m/z* = 973 [Ru('pyS_4')]$_2^+$.

[Ru(PEt_3)('pyS_4')] (6): PEt_3 (0.5 mL, 3.40 mmol) was added to a red-brown suspension of [Ru(NO)('pyS_4')]Tos (**8**) (300 mg, 0.44 mmol) in 12 mL of THF. In the course of 20 h, an orange solid precipitated, which was separated, washed with MeOH (20 mL) and *n*-hexane (25 mL), and dried in vacuo. Yield: 100 mg of **6** (38%). – $C_{25}H_{30}NPRuS_4$ (604.80): calcd. C 49.65, H 5.00, N 2.32, S 21.20; found C 49.89, H 5.03, N 2.42, S 21.20. – MS (FD, CH_2Cl_2, ^{102}Ru); *m/z* = 605 [Ru(PEt_3)('pyS_4')]$^+$. – ^1H NMR (399.65 MHz, CD_2Cl_2): δ = 7.63–7.61 (m, 2 H, C_6H_4), 7.42–7.40 (m, 2 H, C_6H_4), 7.27 (t, 1 H, H_γ, pyridine), 7.10 (d, 2 H, H_β, pyridine), 6.90–6.82 (m, 4 H, C_6H_4), 4.78 (d, 2 H, CH_2), 4.42 (d, 2 H, CH_2), 1.90–1.79 (m, 3 H, P-CH_2CH_3), 1.57–1.46 (m, 3 H, P-CH_2CH_3), 0.97–0.89 (m, 9 H, P-CH_2CH_3). – $^{13}C\{^1H\}$ NMR (67.8 MHz, CD_2Cl_2): δ = 157.87, 156.39, 133.85, 132.34, 131.98, 130.69, 127.81, 120.90, 120.85 (arom. C), 59.26 (d, CH_2), 18.34 (d, P-CH_2CH_3), 7.70 (d, P-CH_2CH_3). – $^{31}P\{^1H\}$ NMR (161.70 MHz, CD_2Cl_2): δ = 34.7 (s).

[Ru(N_2H_4)('pyS_4')] (7): N_2H_4 (1.0 mL, 31.86 mmol) was added to a red-brown suspension of [Ru(NO)('pyS_4')]Tos (**8**) (200 mg, 0.29 mmol) in 20 mL of THF. Gas was evolved and a red solution was produced, from which a red oil separated. It was redissolved by the addition of MeOH (20 mL). Subsequent addition of Et_2O (40 mL) led to the precipitation of a microcrystalline red solid, which was separated, washed with MeOH (20 mL), THF (15 mL), and Et_2O (20 mL), and dried in vacuo. Yield: 50 mg of **7** (33%). – $C_{19}H_{19}N_3RuS_4$ (518.69): calcd. C 44.00, H 3.69, N 8.10, S 24.72; found C 43.97, H 3.70, N 7.56, S 24.53. – IR (KBr): $\tilde{\nu}$ = 3335, 3208, 3105 cm^{-1} ν(NH). – MS (FD, DMF, ^{102}Ru); *m/z* = 973 [Ru('pyS_4')]$_2^+$. – ^{1}H NMR (269.6 MHz, [D_7]DMF): δ = 7.75–7.72 (m, 2 H, C_6H_4), 7.46–7.42 (m, 2 H, C_6H_4), 7.12–7.07 (m, 3 H, pyridine), 6.92–6.81 (m, 4 H, C_6H_4), 4.86 (s, 2 H, –NH_2NH$_2$), 4.73 (d, 2 H, CH_2), 4.52 (d, 2 H, CH_2), 3.62 (s, 2 H, –NH$_2$NH_2). – ^{13}C{^{1}H} NMR (67.8 MHz, [D_7]DMF): δ = 159.60, 158.03, 133.09, 132.90, 131.85, 131.23, 127.86, 121.19, 120.77 (arom. C), 56.32 (CH_2).

[Ru(NO)('pyS_4')]Tos (8): A solution of 'pyTos' (2.27 g, 5.07 mmol) in 60 mL of THF was added dropwise to a stirred green solution of NBu_4[Ru(NO)($S_2C_6H_4)_2$] (3.32 g, 5.08 mmol) in 30 mL of THF and the resulting mixture was heated under reflux for 4 h. After cooling to room temperature, the precipitated red-brown solid was separated, washed with THF (60 mL) and Et_2O (30 mL), and dried in vacuo. Yield 1.96 g of **8** (56%). – $C_{26}H_{22}N_2O_4RuS_5$ (687.87): calcd. C 45.40, H 3.22, N 4.07, S 23.31; found C 45.45, H 3.38, N 4.04, S 22.98. – IR (KBr): $\tilde{\nu}$ = 1892 cm^{-1} ν(NO). – MS (FD, DMSO, ^{102}Ru); *m/z* = 517 [Ru(NO)('pyS_4')]$^+$. – ^{1}H NMR (269.6 MHz, [D_6]DMSO): δ = 8.01 (d, 2 H, C_6H_4), 7.79 (t, 1 H, H_γ, pyridine), 7.55 (d, 2 H, H_β, pyridine), 7.50–7.45 (m, 4 H, C_6H_4), 7.31–7.21 (m, 4 H, C_6H_4), 7.08 (d, 2 H, C_6H_4), 5.50 (d, 2 H CH_2), 5.29 (d, 2 H, CH_2), 2.25 (s, 3 H, CH_3). – ^{13}C{^{1}H} NMR (67.8 MHz, [D_6]DMSO): δ = 157.90, 149.12, 145.67, 140.22, 137.64, 132.95, 130.81, 129.58, 128.68, 128.07, 125.49, 125.24, 124.29 (arom. C), 55.22 (CH_2), 20.80 (CH_3).

X-ray Structure Analyses of [Ru(PPh_3)('pyS_4')] (1), [Ru(PPh_3)('pyS_4'-Me_2)]$I_2 \cdot 2\,CH_2Cl_2$ (2 · 2 CH_2Cl_2), [Ru(DMSO)('pyS_4')] · MeOH (3 · MeOH), and [Ru(CO)('pyS_4')] · MeOH (4 · MeOH): Orange platelets of [Ru(PPh_3)('pyS_4')] (**1**) were grown by layering a hot pyridine solution (8 mL) of **1** (110 mg, 0.15 mmol) with MeOH. Yellow rhombs of **2** · 2 CH_2Cl_2 formed upon layering a saturated CH_2Cl_2 solution of **2** with Et_2O. Yellow block-shaped crystals of **3** · MeOH were deposited from a saturated DMSO/MeOH solution at –30 °C. Yellow-orange needles of **4** · MeOH crystallized from a saturated CH_2Cl_2 solution of **4** upon layering with MeOH. Suitable single crystals were either sealed under N_2 in glass capillaries (**1**) or coated with inert perfluoropolyalkyl ether (**2** · CH_2Cl_2, **3** · MeOH, and **4** · MeOH). Data were corrected for Lorentz and polarization effects. An absorption correction was applied for **2** · CH_2Cl_2 using ΔF^2 methods (XABS2, T_{min} = 0.0644, T_{max} = 0.1740),[18] as well as for **3** · MeOH (T_{min} = 0.5690, T_{max} = 0.6561), and **4** · MeOH (T_{min} = 0.5707, T_{max} = 0.7288) on the basis of psi-scans.[19] The structures were solved by direct methods and refined using full-matrix least-squares procedures on F^2 (SHELXTL 5.03).[20] All non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms were taken from difference Fourier maps and their positional parameters were refined. Complex **1** was found to contain two crystallographically independent molecules in the asymmetric unit. Selected crystallographic data are summarized in Table .[21]

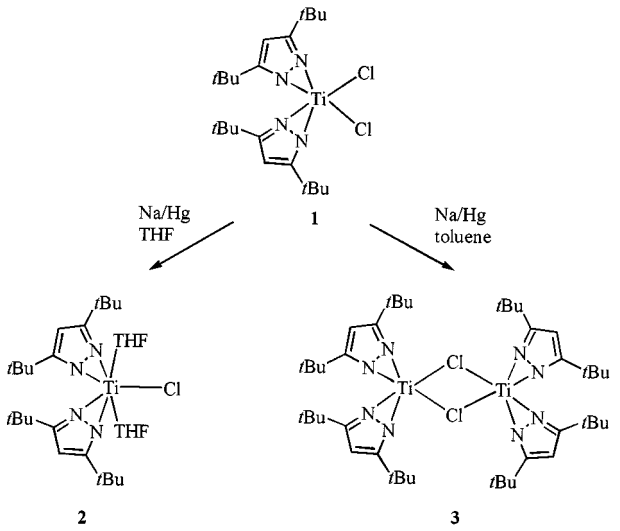
Titanium(III) Compounds with η^2-Pyrazolato Ligands

Nadia C. Mösch-Zanetti,*[a] Ralph Krätzner,[a] Christopher Lehmann,[a] Thomas R. Schneider,[a] and Isabel Usón[a]

Keywords: Pyrazole / Titanium / Redox reaction / Mercury / Amalgams

The reduction of $[L_2TiCl_2]$ (**1**) (L = 3,5-*tert*-butylpyrazolate) with 1% Na/Hg in tetrahydrofuran (THF) affords the complex $[L_2TiCl(THF)_2]$ (**2**), which crystallizes from hexane in moderate yield. The analogous reduction carried out in toluene gives dimeric $[(L_2TiCl)_2]$ (**3**) in high yield. If the reduction time is extended to 3 days, the complex $[L_3Ti]$ (**4**) is isolated as light blue crystals in low yield. An alternative procedure for preparing compound **4** requires mixing $[TiCl_3(THF)_3]$ with 3 equivalents of potassium 3,5-*tert*-butylpyrazolate in toluene. Crystallization from hexane affords **4** in high yield. Crystallographic data for **2**, **3** and **4** are presented.

Introduction



In the search for alternatives to the ubiquitous cyclopentadienyl ligand there has been considerable interest in other monoanionic species that may serve as ancillary ligands for early transition metals and that allow a better control of the electronic and steric properties. In particular, nitrogen-based systems have received considerable attention such as trispyrazolylborates,[1] amides,[2][3] amidinates,[4] aminoiminophosphoranates[5] and others.[6–8] A recent example that has caught our attention is the use of 3,5-disubstituted pyrazoles as ancillary ligands in early transition metal chemistry.[9–11] The coordination of pyrazole derivatives to mid- and late transition metals has been thoroughly investigated over many years. Of the four possible modes (bridging, η^1, η^2 and η^5), mainly bridging and η^1 have been observed.[12] The work of two research groups indicates that η^2-coordination towards early transition metals is favorable as they were able to isolate and structurally characterize several Ti^{IV}, Zr^{IV} and Ta^{V} complexes containing η^2-pyrazolato ligands.[10,13–15] According to a theoretical study[10] the presence of empty d-orbitals seems to be an important feature for η^2-coordination and, so far, all of the reported systems are d^0 metal complexes. Very recently, η^5-coordination has been reported for a late transition metal.[16] For a better understanding of the electronic features of these interesting systems we started to investigate the reduction chemistry of $[L_2TiCl_2]$. Our results can be compared to related Ti^{III} systems that contain other N-donor ligands such as amides,[3][17] N_4-macrocycles[18][19] or amidinates.[20][21]

Herein we report the synthesis and the molecular structure of three titanium(III) complexes that contain pyrazolato ligands. In all of these compounds the coordination mode of the pyrazolato ligand is exclusively η^2 and, to our knowledge, these represent the first d^1 metal complexes that contain η^2-pyrazolato ligands.

Results and Discussion

The starting material for our reduction chemistry is $[L_2TiCl_2]$ (L = 3,5-*tert*-butylpyrazolato = 3,5-tBu$_2$pz) **(1)**, first reported by Guzei and Winter.[22] We found that this compound can be conveniently synthesized by the addition of two equivalents of 3,5-tBu$_2$pzH to $TiCl_4(THF)_2$ in the presence of triethylamine in dichloromethane. Removal of the solvent, extraction and crystallization from hexane gave the product as yellow crystals in high yield. This synthetic route represents a slight modification to an improved procedure recently described.[13]

Scheme 1. Reduction of $[L_2TiCl_2]$

A 1% Na/Hg amalgam reduction of compound **1** at 0°C in THF gave paramagnetic $[L_2TiCl(THF)_2]$ **(2)** after 2 h, in moderate yield, which was isolated as blue crystals from hexane as shown in Scheme 1. The ^{1}H NMR spectrum shows broad signals in the range 1.55–2.16 ppm for $(CCH_3)_3$ and the β-protons of the coordinated THF molecules, and at 4.8 ppm for the α-protons of THF. Infrared spectroscopy also indicates the presence of THF, since in comparison to $[(L_2TiCl)_2]$ (vide infra) the IR spectrum

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 2000 1434–1948/00/0101–0013 $ 17.50+.50/0

shows two additional absorptions (1029 and 872 cm^{-1}). X-ray crystallography reveals a monomeric species with a pentacoordinated titanium atom in a trigonal bipyramidal environment, considering the pyrazolato ligands as occupying one coordination site each. The metal is further coordinated to two THF molecules and a Cl atom. Figure 1 shows an ORTEP view of the molecule, along with selected bond lengths and angles. The two THF molecules occupy the apical positions with an O1−Ti1−O2 angle of 176.2°. The four nitrogen atoms, the chloride and the titanium atom are in the equatorial plane to within a few degrees. The angles between each of these atoms and O1 or O2 vary within the range 86−93°. As expected, the length of the titanium chloride bond [2.4143(8) Å] is slightly longer than that in the titanium(IV) compound [L_2TiCl_2] [2.247(4) and 2.251(3) Å][22] due both to the larger covalent radius of Ti^{III} vs. Ti^{IV} and the higher coordination number. The structure is similar to the related compound [$(BTBA)_2TiCl(THF)$][20] [BTBA = *N*,*N*′-bis(trimethylsilyl)benzamidinate], where only one THF molecule is coordinated to Ti. In addition, it is noteworthy that the reduction of [Cp_2TiCl_2] in THF yields the base-free [$(Cp_2TiCl)_2$][23] suggesting that not only steric factors are responsible for the structure of compound **2**. The more electrophilic nature of the pyrazolato ligand relative to the cyclopentadienyl ligand leads to a rather electrophilic metal center which is stabilized by the coordination of additional base (two THF molecules).

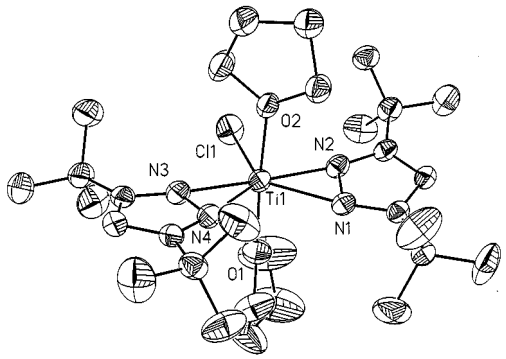

Figure 1. ORTEP view of [$L_2TiCl(THF)_2$] **(2)** drawn with 50% thermal ellipsoids; selected bond lengths (Å) and angles (°): Ti1−Cl1 2.4143(8); N1−Ti1−O1 86.67(8), N2−Ti1−O1 91.91(8), N3−Ti1−O1 89.91(8), N4−Ti1−O1 93.36(8), Cl1−Ti1−O1 91.26(6), N1−Ti1−O2 89.54(7), N2−Ti1−O2 85.50(7), N3−Ti1−O2 92.71(8), N4−Ti1−O2 86.96(8), Cl1−Ti1−O2 91.60(5).

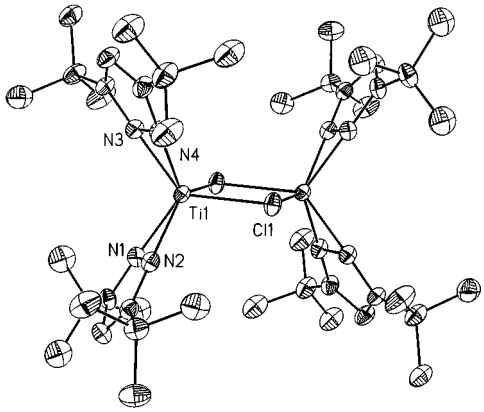
In an analogous reaction, 1% Na/Hg amalgam reduction of compound **1** at 0°C in toluene followed by workup in hexane gave blue-green crystals in high yield. X-ray crystallography reveals the species to be the base-free dimer [$(L_2TiCl)_2$] **(3)**. Figure 2 shows an ORTEP view of the molecule, along with selected bond lengths and angles. The structure is similar to the related titanocene derivative [$(Cp_2TiCl)_2$], which is also dimeric.[24] The Ti−Cl bonds [2.4265(8) Å and 2.4299(8) Å] are slightly shorter than in [$(Cp_2TiCl)_2$] (average 2.543 Å). However, the bond angles in the Ti_2Cl_2 core [Cl−Ti−Cl 89.59(2)° and Ti−Cl−Ti 90.41(2)°] contrast sharply with those in [$(Cp_2TiCl)_2$] (average Cl−Ti−Cl 77.98°, average Ti−Cl−Ti 101.96°). These trends (the shorter M−Cl bond length and the different angles in the Ti_2Cl_2 core) can be attributed to the smaller steric constraint in the molecule. The bite angle between the two ligands (considering the center of the N−N bond as the coordination site) is in the same range for compound **3** (116.6°) and [L_2TiCl_2] (113°).[22]



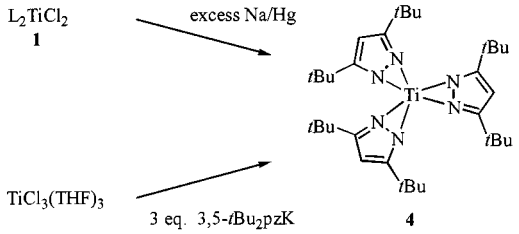


Figure 2. ORTEP view of [$(L_2TiCl)_2$] **(3)** drawn with 50% thermal ellipsoids; selected bond lengths (Å) and angles (°): Ti1−N1 2.027(2), Ti−N2 2.043(2), Ti−N3 2.040(2), Ti−N4 2.029(2), Ti1−Cl1 2.4265(8), Ti1−Cl1a 2.4299(8); Cl1−Ti−Cl1a 89.59(2), Ti1−Cl1−Ti1a 90.41(2); equivalent atoms "a" generated with: $-x + 1, -y, -z - 1$.

Reduction with an excess of Na/Hg over 3 days gave a black reaction mixture, from which, after extraction with hexane, light blue crystals could be isolated in low yield. X-ray crystallography revealed a titanium(III) species [L_3Ti] **(4)** containing three η^2-pyrazolato ligands. Alternatively, complex **4** has been synthesized conveniently and in high yield directly from $TiCl_3(THF)_3$ by the addition of 3 equivalents of *t*Bu_2PzK in toluene. Figure 3 shows an ORTEP view of the molecule, along with selected bond lengths and angles. The molecule has a crystallographic threefold axis running through Ti^{III}. The TiN_6 core is almost perfectly trigonal prismatic with a small deviation of 6° (angle between the projection of N1 and N2 onto a plane perpendicular to the C_3 axis). This is in contrast to the structure of [$(PhNC(H)NPh)_3Ti$], a related Ti^{III} compound with a TiN_6 core.[21] Its structure is best described as distorted trigonal antiprismatic. Due to the constraint imposed by the pyrazolato ring on the 1,2-*N*,*N*-bond length, a further tilting of the ligand cannot achieve an antiprismatic environment of the metal and leads to a higher steric repulsion between neighboring ligands.

Scheme 2. Formation of [L_3Ti]

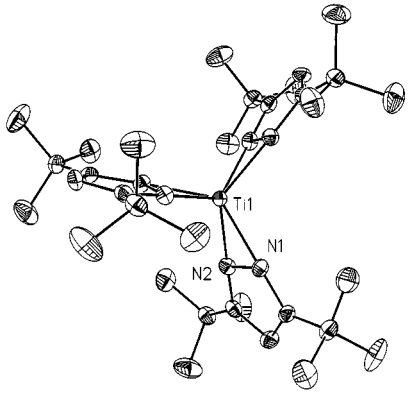

Figure 3. ORTEP view of [L_3Ti] **4** drawn with 50% thermal ellipsoids. Selected bond lengths (Å) and angles (°): Ti1−N1 2.034(3), Ti1−N2 2.038(3), N1−Ti1−N1b 109.37(1), N1−Ti−N1c 109.37(1), N1b−Ti−N1c 109.37(1); equivalent atoms "b" and "c" generated with: b = $-x + 1, -x + y, z$; c = $x - y + 1, -y + 1, z$).

In reactions with other reducing agents such as Mg, Zn or KC_8 the only isolable product was the homoleptic [L_3Ti] (**4**). The mechanism of formation of compound **4** in the reduction reaction is unclear. We assume that, initially, the system is reduced to Ti^{II}, but that bridging η^1-coordination then starts to compete with η^2-coordination at the large and electron-rich metal center. In addition, for steric reasons η^1-coordination is less favorable, although one example of a late transition metal has been reported.[25] Therefore such a bridging η^1 titanium(II) species is presumably not stable and disproportionates to [L_3Ti] and insoluble elemental titanium indicated by the black reaction mixtures. On these grounds it is less surprising that in several reduction reactions of [L_2TiCl_2] under 1 bar of N_2, C_2H_4 or CO the homoleptic titanium(III) species **4** has been isolated exclusively.

We have shown that η^2-coordination of pyrazolato ligands is favored for titanium centers with partially filled d-orbitals. However, very low oxidation states are not favored because, presumably, η^1-coordination starts to compete. So far, no reactivity at the ligands itself (such as C−H bond activation) has been observed. Therefore, as long as oxidation states are high to medium, η^2-pyrazolates may prove to serve as innocent ancillary ligands for a variety of metal centers.

Experimental Section

All reactions were carried out under dry nitrogen using standard Schlenk techniques. Solvents were dried by distillation from sodium/benzophenone or sodium/potassium alloy. [L_2TiCl_2] was prepared according to a literature procedure.[13] NMR spectra were recorded with a Bruker AC 250 spectrometer. IR samples were prepared as mineral oil mull, taken between KBr plates and obtained with a Bio-Rad FTS7 spectrometer. Mass spectra were obtained with a Finnigan MAT 8200 or MAT 95 spectrometer. Elemental analyses were performed in our institute.

[$L_2TiCl(THF)_2$] (2): A solution of **1** (0.71 g, 1.45 mmol) in THF (30 mL) was treated with one equivalent of 1% Na/Hg (0.037 g Na) at 0 °C for 2 h. The solvent was removed under reduced pressure, the resulting blue-green mixture extracted with hexane (30 mL) and filtered through Celite. Complex **2** was isolated at −25 °C as blue crystals (0.45 g, 53%). − ^{1}H NMR (C_6D_6): δ = 4.8 (br s, 8 H, α-H of THF), 2.16 (br s, 8 H, THF), 1.55 [br s, 36 H, C(CH_3)$_3$]. − IR (CsI): $\tilde{\nu}$ = 1508, 1361, 1252, 1233, 1029, 1020, 993, 872, 802, 720, 500, 478, 395, 322, 282 cm^{-1}. − MS: *m*/*z* = 441 [M^+ − 2THF]. − $C_{30}H_{54}ClN_4O_2Ti$ (586.10): calcd. C 61.48, H 9.29, N 9.56; found C 60.06, H 9.13, N 9.41.

[$L_2TiCl]_2$ (3): A solution of **1** (0.37 g, 0.78 mmol) in toluene (30 mL) was treated with 1% Na/Hg (0.023 g Na) at 0 °C for 2 h. The solvent was removed under reduced pressure, the resulting blue-green mixture extracted with hexane (30 mL) and filtered through Celite. Complex **3** was isolated at −25 °C as green crystals (0.29 g, 83%). − ^{1}H NMR (250 MHz, C_6D_6): δ = 6.04 (s, 2 H, C*H*), 1.30 [s, 36 H, C(CH_3)$_3$]. − IR (CsI): $\tilde{\nu}$ = 1506, 1364, 1253, 1233, 1018, 982, 820, 806, 719, 492, 399, 387, 323 cm^{-1}. − MS: *m*/*z* = 441 [M^+/2]. − $C_{44}H_{76}N_8Cl_2Ti_2$ (883.77): calcd. C 59.80, H 8.67, N 12.68; found C 59.40, H 8.85, N 12.59.

[L_3Ti] (4). Method 1: A solution of **1** (0.47 g, 0.98 mmol) in toluene (30 mL) was treated with an excess of 1% Na/Hg (0.113 g Na) for 3 days. The solvent was removed under reduced pressure, the resulting dark brown mixture extracted with hexane (30 mL) and filtered through Celite. Complex **4** was isolated at −25 °C as light blue crystals (0.15 g, 26%).

Method 2: $TiCl_3(THF)_3$ (0.62 g, 1.7 mmol) and *t*Bu$_2$pzK[26] (1.15 g, 5.3 mmol) were placed in a Schlenk flask and toluene was added. The mixture was stirred at room temperature for 5 h. The volatiles were removed under reduced pressure and the residue was extracted with 30 mL of hexane. Complex **4** was isolated at −25 °C as light blue crystals (0.80 g, 82%). − ^{1}H NMR (250 MHz, C_6D_6): δ = 2.05 [br s, C(CH_3)$_3$]. − IR (CsI): $\tilde{\nu}$ = 1529, 1364, 1252, 1232, 1020, 991, 808, 721, 501, 408 cm^{-1}. − MS: *m*/*z* = 585 [M^+]. − $C_{33}H_{57}N_6Ti$ (585.71): calcd. C 67.67, H 9.81, N 14.35; found C 67.53 H 10.39 N 14.29.

X-ray Crystal Structure Analysis

The crystals were mounted on a glass fiber in a rapidly cooled perfluoropolyether.[27] Diffraction data were collected on a Stoe-Siemens-Huber four-circle diffractometer coupled to a Siemens CCD area-detector at 153(2) K for **2** and 133(2) K for **3** and **4**, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), performing φ- and ω scans. The structures were solved by direct methods using SHELXS-97[28] and refined against F^2 on all data by full-matrix least-squares with SHELXL-97.[29] All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model.

Compound 2: The single-crystal X-ray structure shows **2** to crystallize in the tetragonal space group $P4_2/n$ with one molecule in the asymmetric unit. One of the coordinated THF molecules is heavily disordered and was refined on two positions. Three difference electron density peaks near the inversion center at 0.25, 0.25, 0.25 were refined as a THF molecule with an occupancy of 0.25, using similarity restraints for 1−2 and 1−3 interatomic distances (bond lengths and angles) and displacement parameters.

Compound 3: The asymmetric unit contains half a molecule of compound **3** and a partially occupied molecule of toluene, which is disordered over the inversion center. Two of the four *t*Bu groups are heavily disordered and were refined on three positions.

Compound 4: The data for compound **4** were modeled as merohedrally twinned using the twin matrix (-1,0,0; 0,-1,0; 0,0,1). The twinning parameter refined to a value of 0.457(3). The three highest

Microwave-Assisted Rapid Incorporation of Ruthenium into Lacunary Keggin-Type Polyoxotungstates: One-Step Synthesis, ^{99}Ru, ^{183}W NMR Characterization and Catalytic Activity of $[PW_{11}O_{39}Ru^{II}(DMSO)]^{5-}$

Alessandro Bagno,[a] Marcella Bonchio,*[a] Andrea Sartorel,[a] and Gianfranco Scorrano[a]

Keywords: Polyoxometalates / Ruthenium / Homogeneous catalysis / Oxidations / Microwaves

Microwave irradiation for 15 minutes allowed the highly selective hydrothermal synthesis of the diamagnetic, air-stable oxidation catalyst $[PW_{11}O_{39}Ru^{II}(DMSO)]^{5-}$, as confirmed by ^{1}H, ^{31}P, ^{99}Ru and ^{183}W NMR techniques.

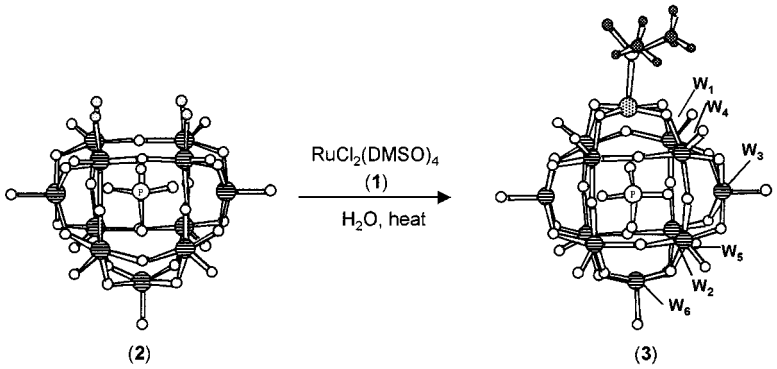
Introduction

The design of transition metal based catalysts is finding new resources within the field of polyoxometalate chemistry.[1] In this respect, Keggin-type polyoxotungstates with mono-lacunary structures of formula $[XW_{11}O_{39}]^{n-}$ (X = B, Si, Ge, P, As), represent a unique class of ligands.[1][2] Properly referred to as inorganic porphyrin analogs,[2] they provide a rigid, hydrolytically stable, thermally robust, nonoxidizable framework that behaves as a pentadentate environment to include a catalytically active transition metal center.[1][2] Derivatization of such species with ruthenium retains a major interest in the field of homogeneous catalysis, especially within the domain of metal-mediated oxidations.[3−7] In fact, ruthenium porphyrin-based systems have been proved to carry out dioxygen activation,[8] to react with N_2O[9] and, in general, to promote highly chemo- and stereoselective oxidative transformations in the presence of various oxygen donors.[3][10] Despite their appealing potential, the synthesis of ruthenium-substituted polyoxotungstates is not straightforward and presents a series of problems, as indicated by the few literature reports published to date.[4−7] In particular: (i) use of the commercially available ruthenium source "$RuCl_3{\cdot}nH_2O$" produces either a mixture of undefined species or a low yield of the target compound; (ii) high temperatures and prolonged reaction times are generally needed; (iii) the formation of paramagnetic Ru^{III} complexes hampers both the NMR monitoring of the reaction and the structural elucidation of the final product.

Herein we report that $[RuCl_2(DMSO)_4]$ (**1**)[11] reacts with the lacunary tungstate ligand $[PW_{11}O_{39}]^{7-}$ (**2**)[12] in water at 200°C under microwave irradiation,[13] leading, after 15 minutes, to the complete incorporation of a ruthenium atom into the polyoxometalate framework, and to the selective production of the diamagnetic, air-stable, complex $[PW_{11}O_{39}Ru^{II}(DMSO)]^{5-}$ (**3**). Scheme 1 illustrates the synthetic approach described above and presents the optimized geometries of both **2** and **3** obtained with PM3(tm) semiempirical calculations.

^{183}W NMR spectroscopy provides an elegant tool to monitor the progress of the reaction. In Figure 1, spectra (a) and (b) allow us to examine the outcome of the metalation performed in water under conventional heating (100°C, 1 atm, 48 hours), or under microwave irradiation (200°C, 15 atm, 15 min), respectively.

As expected,[5] the formation of a Ru^{II} complex leads to a marked deshielding of the signals relative to the two W atoms adjacent to the substituted center (W_1 and W_4 in Scheme 1). The new set of six resonances is consistent with the formation of a unique species **3**.[5] This can be easily seen in Figure 1a, where the resonances of both **3** and of the unreacted **2** are present in a ca. 50:50 ratio. Therefore, the spectroscopic analysis of both reaction mixtures highlights the remarkable acceleration of the process achieved by the microwave irradiation, as it results in the complete disappearance of the ligand signals after only 15 minutes (Figure 1b).



The assignment of the six resonances pertaining to the ruthenium complex **3** (W atom labels are shown in Scheme 1) is based on the analysis of W−W connectivities and $^{2}J_{WOW}$ scalar couplings determined from ^{183}W NMR COSY experiments with selective excitation (see Experimental Section). A sample spectrum is shown in Figure 2, while the complete set of results is collected in Table 1.

Homonuclear ^{183}W 2D COSY or INADEQUATE techniques have been employed for the structural elucidation of polyoxotungstates.[12] However, since the number of scalar couplings present in such systems is relatively small, the 1D COSY technique with selective excitation[14] provides an attractive alternative, since it allows for the collection of all connectivity information in separate experiments (whose number will not exceed the number of tungsten resonances) retaining the high resolution typical of 1D spectra.

As further evidence confirming the complete substitution and the selectivity of the process, analysis of the reaction mixture by ^{99}Ru NMR spectroscopy revealed a single signal, relative to **3**, at $\delta = 7737$ (Figure 3), whereas the signal for the precursor **1** is found at $\delta = 3976$. To the best of our

knowledge this is the first observation of a ^{99}Ru signal in a polyoxometalate inorganic matrix.

Complex **3** displays a remarkable catalytic activity in the presence of sodium periodate ($NaIO_4$) or potassium monopersulfate ($KHSO_5$) which were used as primary oxidants in the oxidation of cyclooctene and adamantane, respectively.[15] Particularly interesting is the ruthenium-promoted cleavage of the olefinic double bond which proceeds in water, with no need of organic solvent or phase transfer agent, leading to 90% conversion of the substrate in 4 hours

and ^{99}Ru NMR spectroscopic analysis, the reaction mixture was passed through a Li^+-form resin (Amberlite IR 120). Further purification of **3** can be achieved by chromatography on a Sephadex G-15 column with water as eluent. – IR (KBr): $\tilde{\nu}$ = 1067, 1049, 1018, 964, 885, 793, 691, 589, 513 cm^{-1}. – MS (FAB); *m/z*: 2893−2891 [$(M + H)^+$, $HLi_5PW_{11}O_{39}Ru(DMSO)^+$], calcd. 2893.

The reported procedure for the synthesis of **3** involves a two-step reaction requiring the reduction of $[PW_{11}O_{39}Ru^{III}(H_2O)]^{4-}$ by electrolysis or prolonged heating in DMSO.[5]

NMR Characterization: ^{183}W and ^{99}Ru spectra were obtained at 9.4 T (16.67 and 18.43 MHz, respectively) on a Bruker Avance DRX 400 instrument, equipped with a standard (^{31}P-^{109}Ag) 10-mm broadband probe which could be tuned below its specifications. The π/2 pulse duration was ca. 50 μs for both nuclei. ^{183}W and ^{99}Ru chemical shifts are externally referenced to 2 M aq. Na_2WO_4 or 0.3 M aq. $K_4Ru(CN)_6$, respectively. Typically, ca. 10^3 transients were collected in 32K or 1K data points, respectively. Selective COSY spectra were carried out with the standard sequence,[14] employing a 20-ms Gaussian-shaped selective pulse (π/2) at the desired offset and a 10-ms delay (the total evolution delay being ca. 20 ms). This value was found to be the optimum compromise between the need to emphasize the smallest couplings (4−5 Hz) and the relatively fast longitudinal relaxation (T_1 values being between 0.7−1.1 s). In order to gain insight into the molecular structure and the magnetic properties of the catalytically active ruthenium nucleus, ab initio calculations of the NMR properties of **3** are being performed.

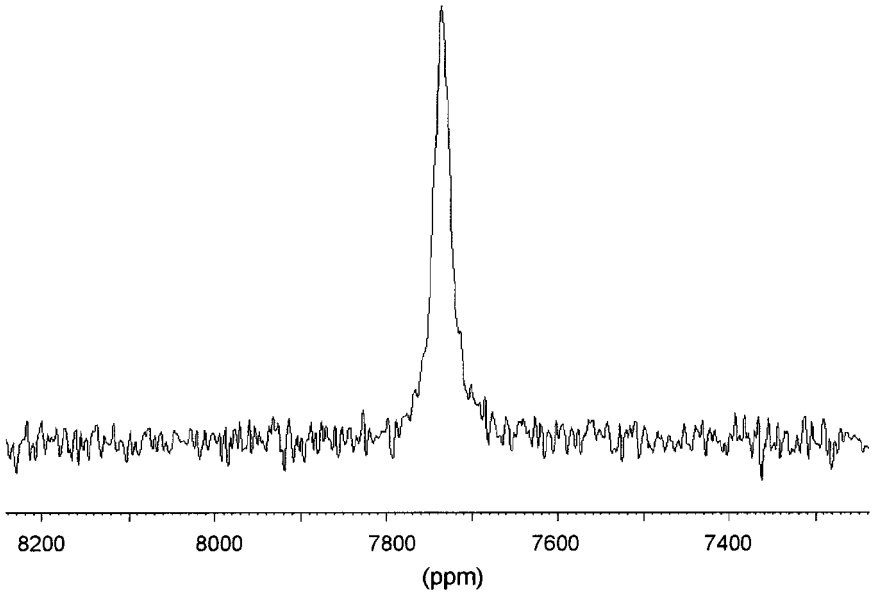

Figure 3. ^{99}Ru NMR spectrum of (**3**)

at 50 °C, 1,8-octanedioic acid (suberic acid) being formed in 83% yield. In the hydroxylation of adamantane, complex **3** exhibits the high selectivity typical of ruthenium-based catalysts.[3][10] The reaction occurs smoothly at 50 °C in a two-phase medium (1,2-dichloroethane/H_2O) and performs the preferential attack at the tertiary C−H site of the substrate (54% conversion after 20 hours) affording 1-adamantanol and 1-chloroadamantane as major products.[16] Further studies concerning the synthesis of tungstoruthenate catalysts together with the scope and mechanism of their promoted oxidations are currently in progress, especially with the aim to devise environmentally sustainable oxidation processes.[17]

Experimental Section

Preparation of $[PW_{11}O_{39}Ru^{II}(DMSO)]^{5-}$ (3): $K_7PW_{11}O_{39}$ (2.0 g) and $RuCl_2(DMSO)_4$ (0.3 g) in 50 mL of water were placed in a closed reactor (HPR-1000/10S, Milestone) equipped with temperature and pressure control units and irradiated inside the cavity of the MW Ethos-1600 labstation (Milestone) according to the following parameters: initial power, 350 W; initial time, 2 min; final power, 300 W; T_{max} = 200 °C; reaction time, 15 min. Before ^{183}W

Catalytic Oxidations: Cyclooctene (0.51 mmol) was suspended in 5 mL deionized water containing $NaIO_4$ (1.95 mmol) and **3** (5 μmol). After 4 hours, the unreacted olefin and the products were extracted with Et_2O (5 × 5 mL) from the acidified reaction mixture and analyzed by GC and ^1H and ^{13}C NMR spectroscopy.

Adamantane (0.195 mmol) and Bu_4NHSO_4 (0.096 mmol) were dissolved in 1,2-dichloroethane (2 mL) and reacted at 50 °C with an aqueous solution (2 mL) containing **3** (0.01 mol) and Oxone (0.4 mmol, added in 3 portions over 3 hours). The reaction was monitored by GC and products were identified by GC-MS analysis and by comparison with authentic samples. The observed product

distribution was as follows: 1-adamantanol (53%), 1-chloroadamantane (32%), adamantanone (10%), 2-chloroadamantane (5%); 2-adamantanol was detected only in traces.

Acknowledgments

Tripodal Oxygen Ligand Supported Palladium(II) Complexes: Alkylation, Carboxymethylation, and CO Insertion Reactions – X-ray Crystal Structure Determination of $[PdL_2]$, $L^- = [(C_5H_5)Co\{P(O)(OMe)_2\}_3]^-$, a Novel Homoleptic Oxygen Ligand Palladium Complex

Wolfgang Kläui,*[a] Marcus Glaum,[a] Ekkehardt Hahn,[b] and Thomas Lügger[b]

Dedicated to Prof. Dr. H. Werner on the occasion of his 65th birthday

Keywords: Palladium / Tripodal ligands / O ligands / Fluxionality

The reaction of $[PdCl_2(CH_3CN)_2]$ with the silver salt of the tripodal oxygen ligand $L^- = [(C_5H_5)Co\{P(O)(OMe)_2\}_3]^-$ yields the homoleptic oxygen ligand complex $[PdL_2]$ (**1**). The molecular structure of **1** was determined by single-crystal X-ray diffraction: monoclinic space group $P2_1/n$; a = 8.515(1), b = 13.627(2), c = 15.828(2) Å; β = 92.44(1)°; V = 1834.9(7) Å^3; Z = 2. The complexes $[Pd(PPh_3)XL]$ [X = Cl (**2a**), Br (**2b**), I (**2c**)] have been prepared starting from **1**. Complex **2a** reacts with PPh_3 to form $[Pd(PPh_3)_2L]Cl$ (**3a**) and $[Pd(PPh_3)_2L]L$ (**3b**). Treatment of **2a** with CO in MeOH yields the carboxymethyl complex $[\{(PPh_3)(COOMe)Pd(\mu\text{-}Cl)\}_2]$ (**4**) and the protonated ligand HL. The carboxymethyl complex **4** shows some catalytic activity for the copolymerization of CO and ethene. Complex **4** reacts with AgL to yield $[Pd(PPh_3)(COOMe)L]$ (**6**). Alkylation of **2a** with Me_4Sn leads to the methyl complexes $[Pd(PPh_3)MeL]$ (**7**) and $[Me_2ClSnL]$ (**8**). CO insertion in the palladium–carbon bond of **7** gives the stable acetyl complex $[Pd(PPh_3)\{C(O)Me\}L]$ (**10**). The palladium(II) complexes **1**, **2**, **3**, **6**, **7**, and **10** of the tripodal oxygen ligand L are all fluxional molecules that have been studied by temperature-dependent ^{1}H- and ^{31}P-NMR spectroscopy.

Introduction

Palladium coordination chemistry is dominated by phosphorus and nitrogen donor ligands. Due to their backbonding ability, phosphorus donor ligands stabilize not only palladium in the oxidation state II but also zero-valent palladium.[1] Stable palladium(IV) complexes of phosphorus donor ligands are rarely described in the literature.[2][3] Nitrogen donor ligands usually stabilize palladium in the oxidation state II. Organometallic palladium(IV) complexes with nitrogen ligands were reported by Byers et al. in 1986.[4] Until recently, the organometallic chemistry of palladium with oxygen donor ligands was limited to palladium(II). In 1993 we reported the first organopalladium(IV) complex with oxygen donor ligands.[5] The oxygen ligands used are the mono-anionic half-sandwich complexes $[(C_5H_5)Co\{P(O)R_2\}_3]^-$ (short: L_R^-),[6] which can coordinate by means of three P=O units (Figure 1). The steric and electronic properties of L_R^- are adjustable through different substituents R (R = −alkyl, −O−alkyl, −O−phenyl). The electronic properties of this class of ligands are similar to those of fluoride and oxide ions, which makes them a useful model for metal oxide surfaces.

We became interested in the question whether palladium complexes of L_R^- are catalytically active. Reactions which involve a change of the palladium oxidation state from II to IV have been discussed recently.[7,8,9] The previously-described palladium(II) chemistry of L_R^- is limited to a few allyl−[10][11] and aryl−palladium complexes that are catalytically inactive.[12] We now report the preparation of new organopalladium(II) complexes of the tripodal oxygen ligand L_{OMe}^-, stereochemically nonrigid, methyl, acetyl, and carboxymethyl complexes and their possible role in catalytic reactions.

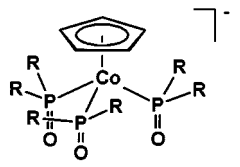

Figure 1. Schematic representation of the tripodal oxygen ligand L^-

Results and Discussion

$[PdL_2]$ (1), a Novel Homoleptic Palladium Complex

According to the HSAB concept, the palladium(II) ion is a soft metal ion.[13] Consequently, it prefers softer ligands to harder ones on complex formation. From this point of view, it makes sense that homoleptic palladium(II) complexes with hard oxygen donors are rarely observed. Known examples for homoleptic oxygen donor ligand Pd complexes are the palladium tetraaqua ion,[14] palladium carboxylate,[15] and palladium acetylacetonate.[16] All of these

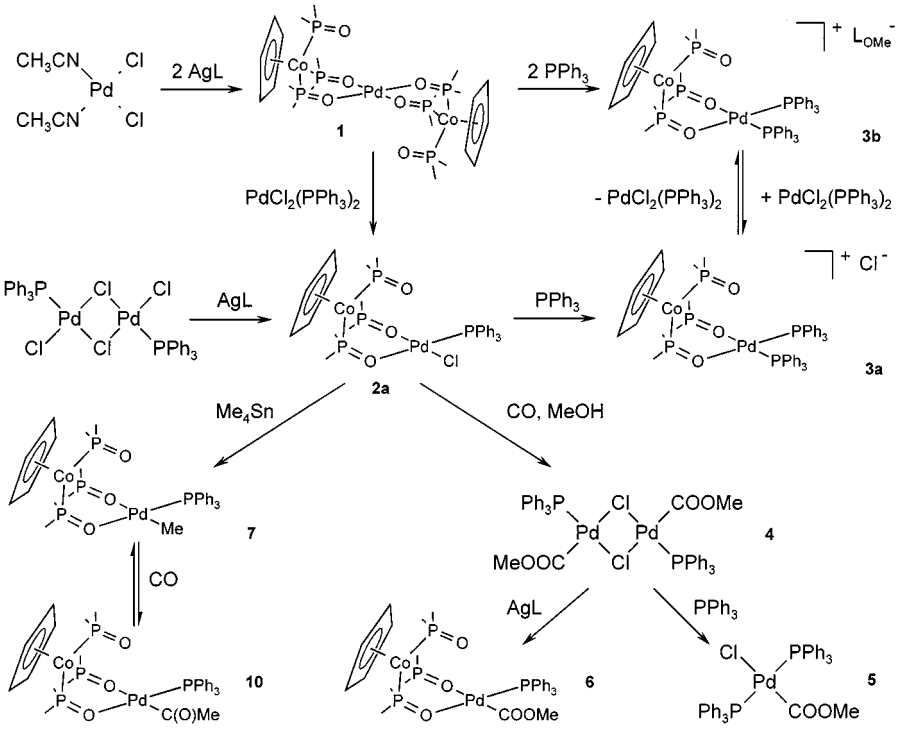
complexes feature labile oxygen palladium bonds and this explains the popularity of such complexes as starting material for new palladium complexes, as catalysts or catalyst precursors.



We have synthesized the new homoleptic Pd complex $[PdL_2]$ (**1**) (L = $[(C_5H_5)Co\{P(O)(OMe)_2\}_3]$) from $[PdCl_2(CH_3CN)_2]$ and AgL in dichloromethane (Scheme 1). Recrystallization from acetonitrile yielded dark red crystals of **1**. ^1H- and $^{31}P\{^1H\}$-NMR spectra of **1** in solution indicated that it was a fluxional molecule on the NMR time scale. The $^{31}P\{^1H\}$-NMR spectrum at room temperature (Figure 2) revealed a broad singlet for the three phosphorus atoms of each of the two ligands. Due to rapid site exchange reactions, all six phosphorus atoms appear equivalent. Upon cooling of the sample to 193 K a splitting of the signal into two AM_2 systems was observed, which gave evidence for the presence of two isomers. The observed spin system revealed that the tridentate ligands coordinate in these isomers only with two of the three donor groups. Based on the NMR data only, it is not possible to determine the exact underlying configuration. One can think of a "*cis*" and "*trans*" isomer in which the non-coordinating P=O units are positioned on either the same or on opposite sides of the palladium coordination plane (Figure 3).

Due to the rapid rearrangement process and hence equivalence of all methyl groups, the room-temperature ^1H-NMR spectrum (Figure 4) showed a poorly-resolved "virtual quadruplet" at δ = 3.8. On cooling to 193 K, the molecular symmetry changed from C_{3V} to C_S. The resulting $A[MX_3(Y_3)_2]_2$ spin system (A, M = ^{31}P; X, Y = ^1H) gave rise to one doublet and two "virtual triplets". The presence of two isomers that did not interconvert at low temperature was again shown by the doubling of signals. In the ^1H-NMR spectrum, two doublets ($^3J_{HP}$ = 11 Hz) could be clearly distinguished while the expected four "virtual triplets" superimposed in a way that left only two distinguishable multiplets. The two cyclopentadienyl signals at around δ = 5.1 indicated that the two isomers were formed in nearly equal amounts.

The stereochemical non-rigidity can be regarded as a fast nucleophilic substitution of a non-coordinating P=O unit for a coordinating one. Numerous investigations showed that the nucleophilic substitution at palladium(II) complexes[17] and other square planar d^8-complexes[18] follows an associative mechanism through a five coordinate transition state. It has been shown that this associative mechanism is also operative in the water exchange reaction at the palladium tetraaqua ion.[19][20] The rearrangement process of the ligands in **1** probably occurs via a five-coordinate transition state too. The alternative dissociative mechanism would feature a three-coordinated transition state with one mono-coordinated ligand. A coordination number of three is highly unlikely for a palladium(II) centre with hard ligands.

X-ray Crystal Structure of $[PdL_2]$ (1)

Complex $[PdL_2]$ (**1**) crystallized in the monoclinic space group $P2_1/n$ with a = 851.5(1), b = 1362.7(2), c = 1582.8(2) pm, β = 92.44(1)°. Data collection parameters, selected bond lengths and angles are listed in Tables 1−3. The palladium atom in **1** is coordinated by four oxygen atoms in a square planar fashion. The two tripodal ligands each use

Scheme 1. Synthesis and reactions of tripodal oxygen ligand supported palladium(II) complexes

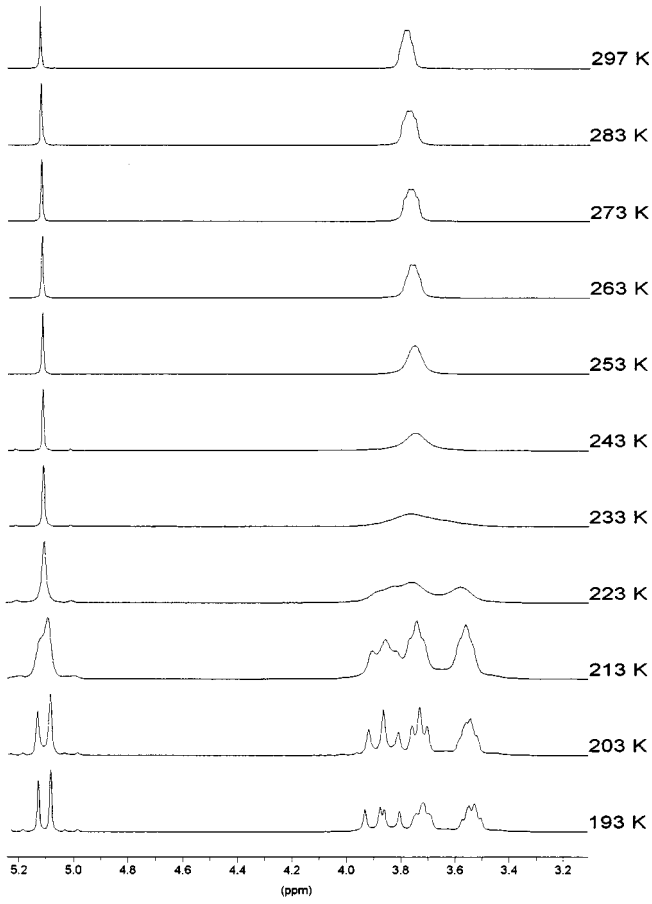

Figure 4. ^{1}H-NMR spectrum of **1** in CD_2Cl_2 at various temperatures

only two donor groups to coordinate the Pd^{II} ion (Figure 5). The measured O1−Pd−O4 chelate angle of 92.6(1)° deviates only slightly from the ideal value (90°) for a square planar geometry. The observed palladium−oxygen bond lengths are equal within experimental error [Pd−O 199.6(3), 199.4(3) pm] and fall in the expected range.[22] The distances are similar to the reported Pd−O contacts in palladium acetate (197.3−201.4 pm)[15] and are slightly longer than the corresponding bonds in $[Pd(acac)_2]$ (196(1) pm).[16]

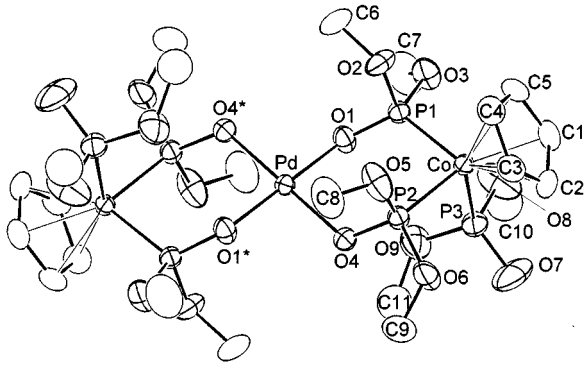

Figure 5. ORTEP plot of **1** showing 50% probability ellipsoids and the atomic numbering scheme; starred atoms represent transformed coordinates of the type $1 - x$, $1 - y$, $1 - z$

Due to the bidentate coordination mode of the tripodal ligand L^- the bond lengths and angles differ slightly in each of the $P(O)(OMe)_2$ groups. The coordinating P=O units show longer phosphorus−oxygen bond lengths [P−O 151.5(3), 151.7(3) pm] than the non-coordinating one [P=O 145.9(4) pm], which corresponds to a partial loss of double bond character of the phosphoryl units. In the solid state, the non-coordinating P=O units are twisted away

from the palladium centre. A similar orientation was observed in the analogous trispyrazolylborate complex $[Pd\{HB(pz)_3\}_2]$,[21] where the two tripodal ligands also bind with two donor groups only.

Reaction of PdL_2 with $[PdCl_2(PPh_3)_2]$

Complex **1** undergoes a metathesis reaction with $[PdCl_2(PPh_3)_2]$ to form the new chloro complex $[Pd(PPh_3)ClL]$ (**2a**) that was isolated as air-stable red crystals (Scheme 1). Reaction of $[\{(PPh_3)ClPd(\mu\text{-}Cl)\}_2]$ with the silver salt AgL (Scheme 1) was an alternative route to **2a**. The homologous, dark brown iodo complex $[Pd(PPh_3)IL]$ (**2c**) is similarly available from PdI_2 in acetonitrile with PPh_3 and subsequent addition of AgL. The deep red bromo complex $[Pd(PPh_3)BrL]$ (**2b**) was prepared by halide exchange from **2a** with silver triflate and $[NBu_4]Br$.

Room-temperature 500 MHz $^{31}P\{^1H\}$-NMR spectra of **2a**−**c** showed local C_{3v} symmetry for the tripodal oxygen ligands L which corroborated the fluxionality of these molecules. Below 223 K the singlet was split into a triplet and a singlet, a fact that can be explained by two different exchange rates of the two coordinated $P(O)(OMe)_2$ groups with the non-coordinated $P(O)(OMe)_2$ group. The triplet is assigned to the $P(O)(OMe)_2$ group in a *trans* position to the chloride ligand that exerts a much weaker *trans* effect than triphenylphosphane. At 173 K, the rearrangement process of **2a** became so slow on the NMR time scale that the $^{31}P\{^1H\}$-NMR spectrum revealed one broad signal for each of the three phosphorus atoms which was consistent with the expected C_1 symmetry.

Again we have no direct evidence for the mechanism of the ligand rearrangement process. We can exclude dissociation of the triphenylphosphane ligand since the triphenylphosphane phosphorus nucleus in **2a**−**c** showed coupling to the phosphorus nuclei of the ligand L. We assumed a transition state with coordination number five at the palladium centre to explain the dynamic NMR behaviour of complex **1.** The coalescence temperature for **2a** was significantly lower than for **1**. A possible explanation for this observation is the presence of a triphenylphosphane ligand in **2a**. Square planar d^8-metal complexes with soft ligands are more likely to form five-coordinate species than compounds with hard donors.[23] Consequently it would be easier for the palladium centre in **2a** to form a five-coordinate complex which in turn would decrease the energy barrier for the observed interconversion.

Reaction of $[Pd(PPh_3)ClL]$ (2a) with Triphenylphosphane

The reaction of **2a** with one equivalent of PPh_3 was complex. The first step was chloride ligand displacement and formation of the complex $[Pd(PPh_3)_2L]Cl$ (**3a**). Complex **3a** dismutated partly to form $[Pd(PPh_3)_2L]L$ (**3b**) and $[PdCl_2(PPh_3)_2]$ (Scheme 1). The same equilibrium mixture was obtained when we treat **3b** with one equivalent $[PdCl_2(PPh_3)_2]$. Compounds **3a**, **b** were identified by their ^{31}P-NMR spectrum. The formation of an ionic compound were followed by conductivity measurements during the reaction of **2a** with PPh_3. The molar conductivity of a dichloromethane solution of **2a** (c = 0.001 mol·l^{-1}) increased upon the addition of one equivalent PPh_3 from 0.2 to 49 $\mu\Omega^{-1}\cdot cm^{-2}\cdot mol^{-1}$.

The analogous reaction of the cyclopentadienyl complex $[Pd(PEt_3)BrCp]$ with triphenylphosphane has been reported to yield the ionic complex $[Pd(PEt_3)(PPh_3)Cp]Br$.[24] According to this observation, only the formation of **3a** would have been expected. The fact that we observed the formation of **3a** and **3b** demonstrates the much lower affinity of palladium(II) towards the oxygen ligand L than towards the carbon ligand Cp.

Reactivity of $[Pd(PPh_3)ClL]$ (2a) towards Carbon Monoxide and Ethene in Methanol

Alkoxycarbonyl palladium complexes are an interesting class of compounds. They are discussed as important intermediates during the synthesis of oxalic acid esters from carbon monoxide and alcohols.[25] Furthermore they are assumed to form as intermediates during the ester forming

hydrocarboxylation of olefins and the copolymerization of olefins with carbon monoxide to yield polyketones.[26–28]

We have therefore looked at the reactivity of the tripodal oxygen ligand palladium complex **2a** toward carbon monoxide, ethene, and methanol. Compound **2a** is stable in methanol. However, under carbon monoxide at 40 bar, the methoxycarbonyl complex $[\{(PPh_3)(COOMe)Pd(\mu\text{-}Cl)\}_2]$ (**4**) (Equation 1) was formed. The oxygen ligand took up the proton and was displaced as HL. According to our knowledge, **4** is the first halide-bridged methoxycarbonyl palladium complex. Its IR spectrum showed strong C=O and C–O–C valence vibrations that are characteristic of methoxycarbonyl complexes.[25] From the $^{31}P\{^1H\}$-NMR spectrum one must conclude that the dinuclear complex **4** exists as a *cis*/*trans* isomer mixture in solution.[29] The analogous reaction of $[Pd(PPh_3)Cl(acac)]$ with CO in methanol also led to the methoxycarbonyl palladium complex **4** (Equation 2). PPh_3 cleaved the chloride bridge in **4** and yielded the mononuclear complex $[PdCl(COOMe)(PPh_3)_2]$ (**5**), which was identified by comparison of its IR- and NMR data with the values reported in the literature.[25]

$$[Pd(PPh_3)ClL]\ (\mathbf{2a}) + CO + MeOH \rightarrow [\{(PPh_3)(COOMe)Pd(\mu\text{-}Cl)\}_2]\ (\mathbf{4}) + 2\ HL \quad (1)$$

$$[Pd(PPh_3)Cl(acac)] + CO + MeOH \rightarrow [\{(PPh_3)(COOMe)Pd(\mu\text{-}Cl)\}_2]\ (\mathbf{4}) + 2\ Hacac \quad (2)$$

Synthesis of $[Pd(PPh_3)(COOMe)L]$ (6)

We wondered whether the loss of the oxygen ligand–palladium bond during the formation of the methoxycarbonyl group meant that a complex with both the ligand L and a methoxycarbonyl group coordinated to palladium was unstable. We found that this type of compound was perfectly stable. It could be obtained in a clean reaction starting from the chloride bridged methoxycarbonyl complex **4** and AgL (Scheme 1). The product $[Pd(PPh_3)(COOMe)L]$ (**6**) is a yellow crystalline material, stable in moist air and soluble in polar solvents. It showed the same non-rigidity as the chloride complex **2a**, i.e. it exhibited the same type of dynamic NMR behaviour. Apart from the signal of the methoxycarbonyl group, the NMR spectra of the complexes **6** and **2** are identical. However, down to 203 K it was not possible to reach the slow exchange limit. Absorption bands at 1672 cm^{-1} [ν(C=O)] and 1078 cm^{-1} [ν(O–C–O)], characteristic of methoxycarbonyl complexes, were visible in the IR spectrum of **6**.[25]

The palladium complex **2a** is a catalyst precursor for the copolymerization of carbon monoxide with ethene. The reaction in methanol at 80°C under 25 bar each of ethene and CO produced a perfectly alternating polyketone. Under these reaction conditions, complex **2a** was transformed into the methoxycarbonyl complex **4**. We do not know whether **4** was the catalytically active compound or just another catalyst precursor. The system was not stable towards formation of metallic palladium and the polyketone yields were low.

Alkylation Reaction of 2a with Me_4Sn

The treatment of palladium halide complexes with organotin reagents is a standard procedure to form palladium–carbon bonds.[31] The attempted alkylation of the palladium chloride compound **2a** with Me_4Sn turned out to be a complex reaction. The reaction yielded the expected methyl palladium compound $[Pd(PPh_3)MeL]$ (**7**) together with the oxygen ligand tin complex $[Me_2ClSnL]$ (**8**) and the dinuclear palladium complex $[\{(PPh_3)MePd(\mu\text{-}Cl)\}_2]$ (**9**). Complex **9** is a known compound. It has been prepared form [PdMeCl(cod)] with one equivalent of PPh_3[30] and by alkylation of $[\{(PPh_3)ClPd(\mu\text{-}Cl)\}_2]$ with tetramethyltin.[32] The oxygen ligand tin complex **8** can be synthesized from Me_2SnCl_2 and the sodium salt of the ligand NaL (Equation 3).

$$Me_2SnCl_2 + NaL \rightarrow [Me_2ClSnL]\ (\mathbf{8}) \quad (3)$$

At room temperature, compound **8** exhibited fluxional behaviour in the ^1H-NMR spectrum: The tripodal ligand shows local C_{3v} symmetry. The tin methyl groups appeared as expected as a singlet with the typical $^2J_{HSn}$ satellites due to their coupling with the tin isotopes ^{117}Sn (72 Hz) and ^{119}Sn (75 Hz). These coupling constants were similar to reported values for analogous trispyrazolylborate complexes like $[SnMe_2ClTp]$ ($^2J_{119Sn\text{-}H}$ = 66 Hz)[33] and $[SnMe_2ClTp^{Me,Me}]$ ($^2J_{117Sn\text{-}H}$ = 67 Hz, $^2J_{119Sn\text{-}H}$ = 72 Hz).[34] It is possible to slow down the exchange process on cooling the sample to 203 K. The proton NMR signals of L revealed the expected lowering of symmetry from C_{3v} to C_s and the $^{31}P\{^1H\}$-NMR spectrum accordingly displayed an AM_2-spin system at the slow exchange limit. In the $^{119}Sn\{^1H\}$-NMR spectrum of **8** the slow exchange limit was already reached at 253 K. The quadruplet signal observed at room temperature ($^2J_{Sn\text{-}P}$ = 88±1 Hz) was split into a multiplet that could be interpreted as the A-part of an AXY_2-spin system.

Insertion of Carbon Monoxide in $[Pd(PPh_3)MeL]$ (7)

We were interested to see whether the methylpalladium complex **7** catalyzed the formation of polyketones. Our experiments show that **7** was able to reversibly insert carbon monoxide to yield the acetyl palladium complex $[Pd(PPh_3)\{C(O)Me\}L]$ (**10**). However, the acetyl palladium complex did not react further under an ethene atmosphere. The acetyl complex **10** possessed remarkable stability. Heating in high boiling solvents under vacuum led to deinsertion of carbon monoxide and to the formation of the methyl complex **7** in a clean reaction. A dichloromethane or acetonitrile solution of **10** could be stored for several weeks without decomposition. Analogous acetyl complexes of palladium with acetylacetonate as oxygen ligand decomposed easily in solution with the formation of metallic palladium. The ^1H-, ^{13}C-, and ^{31}P-NMR data of the $[Pd(PPh_3)L]$ part of **10** were similar to the ones of the complexes discussed above. The proton NMR signal of the acetyl group was

observed at δ = 2.18. A characteristic ^{13}C-signature was given by the carbonyl carbon atom, which appeared as a doublet at δ = 226 ($^2J_{C\text{-}P}$ = 2 Hz). The ν(C=O) IR-absorption occurred at 1703 cm^{-1}.

Concluding Remarks

The tripodal oxygen ligand L seemed to be more efficient than most other oxygen ligands in stabilizing organopalladium fragments. The reactions of the complexes that we have observed are probably reasonable models of reactions that occur or have been postulated to occur at palladium−metal oxide surface species. The pronounced non-rigid behaviour of the palladium complexes described here has its equivalent in the high mobility of Pd on silica and alumina surfaces.

Experimental Section

General: All reactions were carried out under nitrogen using standard Schlenk techniques. Filtration was done with 1-μm membrane filters (regenerated cellulose, Schleicher & Schuell). Acetonitrile was used as purchased (p.a. quality); all other solvents were dried by standard methods and distilled prior to use. − NMR spectra were recorded with a Bruker DRX 200 spectrometer, chemical shifts are given in ppm using the solvent signal as reference. Signal multiplicity is indicated by the following abbreviations: s = singlet, d = doublet, t = triplet, q = quadruplet, vq = "virtual quadruplet". − IR spectra were taken with a Bruker IFS 66 FT spectrometer. − Elemental analyses were performed in the Institut für Pharmazeutische Chemie, Universität Düsseldorf, using a Perkin−Elmer CHN-2400/II elemental analyzer.

[PdL$_2$] (1): To a suspension of [$PdCl_2(CH_3CN)_2$] (0.43 g, 1.7 mmol) in dichloromethane (30 mL) was added slowly at −30°C a solution of AgL[35] (2.2 g, 3.9 mmol) in CH_2Cl_2 (20 mL). The reaction mixture was warmed slowly to room temperature and heated at reflux for 1 h. Filtration of the black suspension through a membrane yielded a clear yellow solution. Removal of the solvent and recrystallization from a small amount of acetonitrile gave 1.20 g of yellow crystals (69%). − ^1H NMR ($CDCl_3$): δ = 3.80 (vq, $^3J_{HP}$ = 10 Hz, 18 H, OCH_3), 5.12 (s, 5 H, C_5H_5). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 126 (br. s, P_{ligand}). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 52.6 (s, OCH_3), 90.6 (s, C_5H_5). − IR (KBr): $\tilde{\nu}$ = 2992 cm^{-1} (w), 2944 (m), 2839 (w), 1423 (m), 1165 (s, P=O), 1117 (vs), 1067 (vs), 1007 (vs), 828 (m), 777 (s), 750 (s), 724 (s), 563 (m, P=O). − $C_{22}H_{46}Co_2O_{18}P_6Pd$ (1008.7): found C 26.42, H 4.42, Pd 10.73; calcd. C 26.20 H 4.60 Pd 10.52. − FAB-MS: positive ions: *m/z* (%) = 1031.7 (15) [M + Na]$^+$, 1009.7 (88) [M + 2]$^+$, 510.2 (100) [CoL$^+$]; negative ions: *m/z* = 1008.3 (11) [M$^-$], 451.1 (100) [L$^-$].

[Pd(PPh$_3$)ClL] (2a): $PdCl_2$ (1.41 g, 7.95 mmol) and PPh_3 (2.09 g, 7.95 mmol) were suspended in acetonitrile (100 mL) and heated at reflux for 2 h. The solvent was removed in vacuo and the orange precipitate of [$PdCl_2(PPh_3)]_2$ was dissolved in of dichloromethane (80 mL). A solution of AgL (4.45 g, 7.95 mmol) in dichloromethane (40 mL) was added slowly at −50°C. The reaction mixture was allowed to warm to −30°C when the mixture turned black. The suspension was stirred for an additional 2 h at room temperature and filtered through a membrane to give a red solution. The solvent was removed in vacuo and the residue was recrystallized from acetonitrile (ca. 200 mL) to yield 4.85 g of red crystals (72%). − ^1H NMR ($CDCl_3$): δ = 3.59 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.09 (s, 5 H, C_5H_5), 7.3−7.7 [m, 15 H, P(C_6H_5)$_3$]. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 115 (s, P_{ligand}), 26.7 [q, $^3J_{PP}$ = 5 Hz, $P(C_6H_5)_3$]. − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 52.4 (s, OCH_3), 90.3 (s, C_5H_5), 128.7 [d, J_{CP} = 12 Hz, P(C_6H_5)$_3$], 128.9 [d, J_{CP} = 58 Hz, P(C_6H_5)$_3$], 131.5 [s, P(C_6H_5)$_3$], 135.2 [d, J_{CP} = 11 Hz, P(C_6H_5)$_3$]. − IR (nujol): $\tilde{\nu}$ = 1462 cm^{-1} (vs), 1436 (m), 1175 (sh), 1154 (s, P=O), 1089 (s), 1041 (vs), 1008 (vs), 771 (m), 712 (s), 562 (m, P=O). − $C_{29}H_{38}ClCoO_9P_4Pd$ (855.3): found C 40.55, H 4.69; calcd. C 40.72, H 4.48. − MS (EI); *m/z* (%): 961 (10.8) [Co(L)$_2$]$^+$, 856 (3.7) [M$^+$ + 2], 262 (100) [PPh_3^+], 183 (60.3) [PPh_2^+ − 2], 108 (26.5) [PPh^+].

[Pd(PPh$_3$)BrL] (2b): Compound **2a** (0.31 g, 0.37 mmol) and AgOTf (0.11 g, 0.43 mmol) were dissolved in acetonitrile (10 mL) and stirred for 15 min. The AgCl precipitate was separated by membrane filtration and the clear solution was treated with [NBu_4]Br (0.12 g, 0.37 mmol). After about 60 minutes the red−brown precipitate was separated by filtration, dried, and recrystallized from a small amount of acetonitrile. Yield 0.10 g (30%). − ^1H NMR ($CDCl_3$): δ = 3.59 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.10 (s, 5 H, C_5H_5), 7.3−7.9 [m, 15 H, P(C_6H_5)$_3$]. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 114.4 (s, P_{ligand}), 28.5 [q, $^3J_{PP}$ = 5 Hz, $P(C_6H_5)_3$]. − IR (nujol): $\tilde{\nu}$ = 1463 cm^{-1} (s), 1377 (m), 1161 (s, P=O), 1089 (vs), 1043 (vs), 1006 (vs), 770 (s), 560 (m, P=O). − $C_{29}H_{38}BrCoO_9P_4Pd$ (899.8): found C 38.39, H 4.23; calcd. C 38.71, H 4.26.

[Pd(PPh$_3$)IL] (2c): Prepared analogously to **2a** using PdI_2 (0.52 g, 1.4 mmol), PPh_3 (0.38 g, 1.4 mmol) and AgL (0.80 g, 1.4 mmol). Yield 1.10 g (80%). − ^1H NMR ($CDCl_3$): δ = 3.59 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.10 (s, 5 H, C_5H_5), 7.4−7.9 (m, 15 H, P(C_6H_5)$_3$). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 112.6 (s, P_{ligand}), 28.9 [q, $^3J_{PP}$ = 5 Hz, $P(C_6H_5)_3$]. − IR (nujol): $\tilde{\nu}$ = 1463 (s), 1377 (m), 1160 (s, P=O), 1089 (vs), 1043 (vs), 1005 (vs), 768 (s), 706 (s), 538 (s). − $C_{29}H_{38}CoIO_9P_4Pd$ (946.8): found C 36.68, H 3.74; calcd. C 36.79, H 4.05.

[Pd(PPh$_3$)$_2$L]L (3b): Compound **1** (0.10 g, 0.10 mmol) and PPh_3 (53 mg, 0.20 mmol) were dissolved in dichloromethane (10 mL). After 30 min, the solvent was removed in vacuo leaving a brown−red wax that could not be crystallized. − ^1H NMR ($CDCl_3$): δ = 3.27 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3 of L$^-$), 3.67 {vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3 of [Pd(PPh_3)$_2$L]$^+$}, 4.95 (s, 5 H, C_5H_5 of L$^-$), 5.14 {s, 5 H, C_5H_5 of [Pd(PPh_3)$_2$L]$^+$}, 7.1−7.6 [m, 30 H, P(C_6H_5)$_3$], $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 117 {s, P_{ligand} of [Pd(PPh_3)$_2$L]$^+$}, 105 (s, P_{ligand} of L$^-$), 34.5 {q, $^3J_{PP}$ = 4 Hz, [Pd(*P*Ph_3)$_2$L]$^+$}. − IR (KBr): $\tilde{\nu}$ = 3052 cm^{-1} (w), 2939 (w), 1436 (m), 1147 (s, P=O), 1076 (s), 1040 (vs), 1007 (vs), 834 (w), 748 (m), 706 (m), 562 (m, P=O).

[{(PPh$_3$)(COOMe)Pd(μ-Cl)}$_2$] (4): A solution of **2a** (0.35 g, 0.41 mmol) in methanol (5 mL) was placed in an autoclave and kept for 1 h under a CO pressure of 40 bar. The formation of a yellow solution and a white precipitate was observed. The white solid was separated by membrane filtration, washed with a small amount of methanol and dried in vacuo. Yield 0.11 g (58%). − ^1H NMR (CD_2Cl_2): δ = 3.14 (s, 3 H, COOCH_3), 7.5−7.8 [m, 15 H, P(C_6H_5)$_3$]. − $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = 27.6 [s, $P(C_6H_5)_3$], 26.8 [s, $P(C_6H_5)_3$]. − IR (KBr): $\tilde{\nu}$ = 2943 cm^{-1} (w), 1672 (vs, C=O), 1479 (m), 1433 (s), 1417 (m), 1083 (vs, C−O−C), 750 (s), 697 (s), 533 (s).

[PdCl(COOMe)(PPh$_3$)$_2$] (5): Compound **4** (70 mg, 0.075 mmol) and PPh_3 (40 mg, 0.15 mmol) were dissolved in dichloromethane (10 mL). The mixture was stirred for 30 min and the solvent was removed in vacuo. The residue was treated with a little acetonitrile to give a white solid, which was filtered off and dried under vacuum. Yield 68 mg (60%). − ^1H NMR (CD_2Cl_2): δ = 2.50 (s, 3 H,

COOCH_3), 7.3−7.9 [m, 30 H, P(C_6H_5)$_3$]. − ^{31}P{^{1}H} NMR (CD_2Cl_2): δ = 20.4 [s, P(C_6H_5)$_3$]. − IR (KBr): ṽ = 3051 cm^{-1} (w), 1672 (vs, C=O), 1656 (s, C=O), 1433 (s), 1095 (m, C−O−C), 1064 (s), 693 (s), 519 (s). $C_{38}H_{33}ClO_2P_2Pd$ (725.5): found C 61.11, H 6.50; calcd. C 62.91, H 4.58.

[Pd(PPh$_3$)Cl(acac)]: [{(PPh$_3$)ClPd(μ-Cl)}$_2$] (1.0 g, 1.1 mmol) and [Ag(acac)] (0.47 g, 2.3 mmol) were stirred in acetonitrile (20 mL) for 1.5 h at room temperature. The reaction mixture was filtered through a membrane. The residue was extracted with dichloromethane. Both solutions were combined and the solvent was removed in vacuo. The yellow residue was recrystallized from acetone. Yield 0.72 g (63%). − ^{1}H NMR ($CDCl_3$): δ = 1.60 (s, 3 H, CH_3), 2.14 (s, 3 H, CH_3), 5.35 (s, 1 H, CH), 7.4−7.9 [m, 15 H, P(C_6H_5)$_3$]. − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 30.2 [s, P(C_6H_5)$_3$]. − IR (KBr): ṽ = 1575 cm^{-1} (s, C=O), 1565 (s, C=O), 1513 (s), 1434 (m), 1378 (m), 1097 (m), 691 (m), 536 (m), 515 (m), 497 (m). − $C_{23}H_{22}ClO_2PPd$ (503.7): found C 54.93, H 4.46; calcd. C 54.89, H 4.41.

[{(PPh$_3$)(COOMe)Pd(μ-Cl)}$_2$] (4) from [Pd(PPh$_3$)Cl(acac)]: [Pd(PPh$_3$)Cl(acac)] (0.30 g, 0.60 mmol) in methanol (5 mL) were treated for 60 min at room temperature with a CO pressure of 10 bar. Yield: 0.23 g (84%) grey-white precipitate, spectroscopic data as reported above.

Copolymerization of CO/Ethene with [Pd(PPh$_3$)ClL$_{OMe}$] (2a) and [{(PPh$_3$)(COOMe)PdCl}$_2$] (4): Compound **2a** (50 mg, 0.06 mmol) in methanol (20 mL) was pressurized in a 50-mL autoclave with 25 bar of CO and 25 bar of ethene at 80°C. Yield: 90 mg of polyketone as a grey precipitate. − TON = 16 g polyketone·(g Pd·h)$^{-1}$; IR (KBr): ṽ = 1692 cm^{-1} [ṽ(C=O)]. An analogous experiment with **4** (27 mg, 0.03 mmol) yielded polyketone (0.11 g). − TON = 18 g polyketone·(g Pd·h)$^{-1}$.

[Pd(PPh$_3$)(COOMe)L] (6): Compound **4** (0.10 g, 0.11 mmol) and AgL (0.12 g, 0.22 mmol) were dissolved in dichloromethane (10 mL) and stirred for 2 h. The precipitated AgCl was filtered off and the solvent was removed in vacuo. The yellow residue was recrystallized with a little acetonitrile. Yield 0.13 g (66%). − ^{1}H NMR ($CDCl_3$): δ = 3.15 (s, 3 H, COOCH_3), 3.59 (vq, 18 H, $^3J_{PH}$ = 11 Hz, OCH_3), 5.10 (s, 5 H, C_5H_5), 7.3−7.8 [m, 15 H, P(C_6H_5)$_3$]. − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 112.7 (s, P_{ligand}), 27.3 [q, $^3J_{PP}$ = 4 Hz, P(C_6H_5)$_3$]. − ^{13}C{^{1}H} NMR (CD_2Cl_2): δ = 51.9 (vq, OCH$_3$), 53.2 (s, COOCH$_3$), 90.1 (s, C_5H_5), 128.8 [d, J_{CP} = 11 Hz, P(C_6H_5)$_3$, 131.1 [d, J_{CP} = 3 Hz, P(C_6H_5)$_3$], 132.2 [d, J_{CP} = 52 Hz, P(C_6H_5)$_3$], 134.9 [d, J_{CP} = 12 Hz, P(C_6H_5)$_3$]. − IR (KBr): ṽ = 2935 cm^{-1} (m), 2827 (w), 1672 (vs, C=O), 1437 (s), 1175 (vs, P=O), 1078 (vs, C−O−C), 1047 (vs), 1002 (vs), 833 (m), 695 (s), 575 (s, P=O). $C_{31}H_{41}CoO_{11}P_4Pd$ (878.9): found C 42.65, H 4.63; calcd. C 42.36, H 4.70.

[Pd(PPh$_3$)MeL] (7): Compound **2a** (1.0 g, 1.2 mmol) and Me_4Sn (0.23 g, 1.3 mmol) were dissolved in dichloromethane (10 mL) and stirred for 4 h at room temperature. The reaction mixture became opaque and turned yellow almost instantly. The white precipitate formed [{(PPh$_3$)MePd(μ-Cl)}$_2$] (**9**) was isolated by centrifugation, washed with dichloromethane and dried. The yellow supernatant was reduced in volume and the residue was recrystallized twice from a small amount of acetonitrile. Yellow crystals of **7** were isolated and dried. The mother liquor was reduced in volume and stored at −20°C, which resulted in the formation of yellow crystals of [Me_2ClSnL] (**8**). Yields: 0.24 g of **9** (49%), 0.32 g of **7** (33%), and 0.14 g of **8** (22%). − Selected spectroscopic data for **7**: ^{1}H NMR ($CDCl_3$): δ = 0.48 (d, $^3J_{HP}$ = 2 Hz, 3 H, PdCH_3), 3.61 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.12 (s, 5 H, C_5H_5), 7.3−7.7 [m, 15 H, P(C_6H_5)$_3$]. − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 112.2 (s, P_{Ligand}), 39.6 [q, $^3J_{PP}$ = 4 Hz, P(C_6H_5)$_3$]. − For **8**: ^{1}H NMR ($CDCl_3$): δ = 0.54 [s, $^2J_{HSn}$ = 74 Hz, 6 H, Sn(CH_3)$_2$], 3.72 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.14 (s, 5 H, C_5H_5). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 115.3 (s, P_{ligand}). − For **9**: ^{1}H NMR ($CDCl_3$): δ = 0.67 (broad s, 3H, PdCH_3), 7.2−7.8 [m, 15H, P(C_6H_5)$_3$]. − $C_{38}H_{36}Cl_2P_2Pd_2$ (838.4): found C 54.47, H 4.41; calcd. C 54.44, H 4.33. − IR (KBr): ṽ = 3072 cm^{-1} (w, C−H), 3049 (w, C−H), 2977 (w, C−H), 2893 (w, C−H), 1479 (m, C−C), 1435 (s, C−C), 1097 (s), 743 (m, C−H), 705 (s, C−H), 538 (s), 525 (m), 511 (s), 493 (m).

[Me_2ClSnL] (8): Me_2SnCl_2 (0.31 g, 1.4 mmol) and NaL (0.67 g, 1.4 mmol) were stirred in dichloromethane (10 mL). The yellow crystals of NaL dissolved slowly and a white precipitate was formed (NaCl). After 16 h, the mixture was filtered and the yellow filtrate was concentrated in vacuo to give a yellow powder (0.72 g, 81%) which was recrystallized from acetonitrile. Yield 0.49 g of yellow crystals (54%). − ^{1}H NMR ($CDCl_3$): δ = 0.55 [s, $^2J_{H\text{-}119Sn}$ = 75 Hz, $^2J_{H117Sn}$ = 72 Hz, 6 H, Sn(CH_3)$_2$], 3.73 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.14 (s, 5 H, C_5H_5). − ^{1}H NMR (CD_2Cl_2, 203 K): δ = 0.38 [s, $^2J_{H\text{-}119Sn}$ = 74 Hz, $^2J_{H\text{-}117Sn}$ = 72 Hz, 6 H, Sn(CH_3)$_2$], 3.63 (d and vt superimposed, OCH_3), 3.70 (vt, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.15 (s, 5 H, C_5H_5). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 115.3 (s, P_{ligand}). − ^{31}P{^{1}H} NMR (CD_2Cl_2, 203 K): AB_2-spin system, ν_A = 119.5, ν_B = 116.5, J_{AB} = 146 Hz. − ^{119}Sn{^{1}H} NMR (CD_2Cl_2): δ = −344.3 (q, $^2J_{P\text{-}119Sn}$ = 86±1 Hz). − ^{119}Sn{^{1}H} NMR (CD_2Cl_2, 253 K): δ = −346.7 [dt (AXY_2-spin system), $^2J_{119SnP}$ (J_{AX}) = 107±1 Hz, $^2J_{119SnP}$ (J_{AY}) = 73±1 Hz]. − $C_{13}H_{29}ClCoO_9P_3Sn$ (635.4): found C 24.69, H 4.64; calcd. C 24.57, H 4.60. − IR (KBr): ṽ = 2988 cm^{-1} (w), 2948 (m), 2912 (w), 2841 (w), 1459 (m), 1424 (m), 1175 (s), 1120 (vs) (P=O), 1029 (vs), 833 (m), 785 (s), 735 (m), 591 (vs, P=O). − MS (EI); *m/z* (%): 621 (100) [SnMeClL]$^+$, 601 (28) [SnMe$_2$L]$^+$, 571 (8) [SnL]$^+$, 497 (7), 480 (13), 418 (12).

[Pd(PPh$_3$){C(O)Me}L] (10): Carbon monoxide was bubbled for 30 min through a solution of **7** (0.19 g, 0.23 mmol) in dichloromethane (10 mL). The solvent was removed at room temperature in vacuo and the residue was recrystallized from acetonitrile. Yield: 0.12 g (61%). − ^{1}H NMR ($CDCl_3$): δ = 2.18 [d, $^4J_{HP}$ = 1 Hz, 3 H, C(O)CH_3], 3.61 (vq, $^3J_{HP}$ = 11 Hz, 18 H, OCH_3), 5.10 (s, 5 H, C_5H_5). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 111.5 (s, P_{ligand}), 27.4 [q, $^3J_{PP}$ = 3 Hz, P(C_6H_5)$_3$]. − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 34.9 [s, C(O)CH$_3$], 51.9 (vq, $^2J_{CP}$ = 9 Hz, OCH$_3$), 90.2 (s, C_5H_5), 128.8 [d, J_{CP} = 11 Hz, P(C_6H_5)$_3$], 130.9 [d, J_{CP} not resolved, P(C_6H_5)$_3$], 132.4 [d, J_{CP} = 47 Hz, P(C_6H_5)$_3$], 135.0 [d, J_{CP} = 13 Hz, P(C_6H_5)$_3$], 225.9 [d, $^2J_{CP}$ = 2 Hz, C(O)CH$_3$]. − IR (KBr): ṽ = 3048 cm^{-1} (w), 2974 (w), 2936 (m), 2829 (w), 1703 (vs, C=O), 1439 (m), 1162 (vs, P=O), 1115 (s), 1034 (vs), 1006 (vs), 833 (w), 706 (s), 582 (m, P=O). − $C_{31}H_{41}CoO_{10}P_4Pd$ (862.9): found C 43.42, H 4.89; calcd. C 43.15, H 4.79.

X-ray Crystal Structure Determination of [PdL$_2$] (1): A suitable crystal of **1** was selected and mounted on an Enraf−Nonius CAD-4 diffractometer. Important crystal and data collection details are listed in Table 3. Data for **1** were collected at room temperature using ω-2Θ scans. Raw data were reduced to structure factors[36] (and their esd′s) by correcting for scan speed, Lorentz and polarization effects. No crystal decay was detected and no absorption corrections were applied at this stage. The systematically absent reflections showed the space group to be $P2_1/n$. The positional parameters for Pd and Co were obtained from a three-dimensional Patterson map. Positional parameters for all other non-hydrogen atoms were found in subsequent difference Fourier maps. The positional parameters for all non-hydrogen atoms were refined by using first isotropic, and later anisotropic thermal parameters. An em-

pirical absorption correction (DIFABS[37]) was applied after refinement of the positional parameters of all non-hydrogen atoms with isotropic thermal parameters. A difference Fourier map calculated after refinement of the positional parameters with anisotropic thermal parameters showed the positional parameters of almost all hydrogen atoms. However, hydrogen atoms were added to the structure model at calculated positions [d(C−H) = 95 pm][38] and are unrefined. The isotropic temperature factors for hydrogen atoms were fixed to be 1.3 times the B_{eq} of the parent atom. All calculations were carried out with the MolEN[39] package. ORTEP[40] was used for molecular drawings. The Pd atoms reside on a crystallographic inversion centre. The asymmetric unit contains 1/2 molecule of **1**. Crystallographic data for the structure of **1** have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-118725. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]. Figure 5 shows one molecule of **1** (the contents of two asymmetric units) with the employed crystallographic numbering scheme.

Table 3. Crystal and data collection details for **1**

Crystal size	0.50 × 0.41 × 0.32 mm
Empirical formula	$C_{22}H_{46}Co_2O_{18}P_6Pd$
Molecular mass	1008.71 amu
a	8.515(1) Å
b	13.627(2) Å
c	15.828(2) Å
β	92.44(1)°
V	1834.9(7) Å^3
Space group	$P2_1/n$
Z	2
$d_{calcd.}$	1.826 g/cm^3
$d_{obsd.}$	1.83 g/cm^3
μ	1.70 mm^{-1}
Data-coll. temp.	298(2) K
2Θ range	2° to 45°
Measured intensities	2694
Unique data	2386
Observed data	2188
Observation criterion	$Fo^2 \geq 3\sigma(F_o^2)$
Absorption correction	DIFABS
R	4.32%
R_w	6.00%
GOF	1.431
No. of variables	224
Resid. electr. dens.	0.79/−0.97 e/Å^3 (near Pd)

Acknowledgments

We thank Dr. W. Peters for his help with the dynamic NMR spectra, Prof. Dr. K. Jurkschat for measuring Sn-NMR spectra, the Fonds der Chemischen Industrie for financial support, and Degussa AG, Hanau, for a loan of palladium chloride.

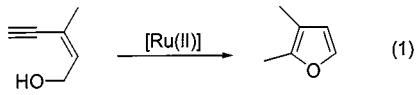
Benzimidazole, Benzothiazole and Benzoxazole Ruthenium(II) Complexes; Catalytic Synthesis of 2,3-Dimethylfuran

Bekir Çetinkaya,[a] Ismail Özdemir,*[a] Christian Bruneau,[b] and Pierre H. Dixneuf*[b]

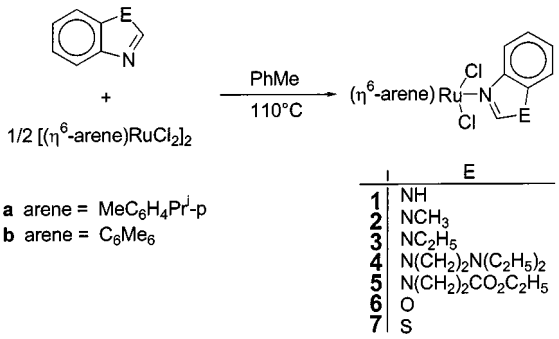


Dedicated to Professor W. P. Fehlhammer for his scientific contribution and on the occasion of his 60th birthday

Keywords: Arene complexes / Ruthenium / Benzimidazole / Benzothiazole / Benzoxazole / Cycloisomerisation

Fourteen ruthenium(II) complexes of the type $[RuCl_2(\eta^6\text{-arene})L]$, (arene = 1,4-$MeC_6H_4Pr^i$ or C_6Me_6; L = benzimidazole derivative in which the NH group is substituted by *N*-alkyl or isoelectronic O or S atoms) have been prepared by cleavage of $[RuCl_2(\eta^6\text{-arene})]_2$ with the *N*-heterocycle L. Their spectroscopic and electrochemical properties are described. The effect of the nature of the benzazole (L) on the catalytic activity of these complexes for the intramolecular cyclization of (Z)-3-methylpent-2-en-4-yn-1-ol into 2,3-dimethylfuran has also been studied; the benzimidazole complexes were found to be the most active.

Introduction



Transition metal complexes with ligands containing nitrogen-donor atoms have recently shown their potential to successfully promote the catalytic transformation of organic compounds.[1] These discoveries motivate the search for new metal complexes with *N*-coordinated ligands and the evaluation of their catalytic properties. In this context, Rh^I complexes of 1-alkyl-2-imidazoline in which the imidazoline coordinates through the N(3) atom of the ring have already been shown to catalyse the cyclopropanation of styrene with ethyl diazoacetate in good yield.[2] Our contribution to this field has recently started with the syntheses of the 2-imidazoline and 1,4,5,6-tetrahydropyrimidine complexes of Ru^{II} which are capable of catalyzing the intramolecular cyclization of (*Z*)-3-methylpent-2-en-4-yn-1-ol into 2,3-dimethylfuran (Equation 1) and the observation of the higher efficiency of the tetrahydropyrimidine complexes.[3]

(1)

In this paper we report the straightforward preparation of a series of (η^6-arene)ruthenium complexes of *N*-coordinated benzimidazole derivatives in which the NH group is substituted by *N*-alkyl or isoelectronic O or S atoms (Scheme 1). Their spectroscopic and electrochemical properties are described and the influence of the nature of the benzazole ligand L on the catalytic activity of these complexes in the formation of 2,3-dimethylfuran has also been studied.

Scheme 1. Synthetic route to benzazole complexes of Ru^{II}

Results and Discussion

The complexes **1**−**7** were prepared in 74−89% yield by simply heating the appropriate benzazole (L) with $[RuCl_2(\eta^6\text{-arene})]_2$ in toluene (Scheme 1). The compounds **1**−**7** were precipitated as red-brown crystalline solids upon cooling the reaction mixture, isolated by filtration and washed with *n*-hexane (see Table 1). The complexes **1**−**7** are perfectly stable in the solid state and show spectroscopic properties indicating that they all are N(3)-bonded. However, the reaction of benzimidazole with $[Ru(H_2O)(NH_3)_5)]^{2+}$, followed by HCl-catalyzed hydrolysis, has been reported to form C(2)-bonded benzimidazole ligand.[4] On the other hand, X-ray crystallographic studies revealed that 2,5-dimethylbenzoxazole, potentially an ambidentate ligand, coordinates to the Pt^{II} centre through the *N*-donor atom.[5] An X-ray structure of cyclopalladated complexes of *N*-acetyl-2-phenyl-benzimidazole has also been described.[6]

The nature of the bonding in the benzazole complexes **1**−**7** was readily shown by NMR spectroscopy (Tables 2 and 3). ^{13}C NMR spectroscopy was the most useful tool for structure elucidation. Thus, from our previous experience,[6][7] we expected that *C*-coordination would result in a shift of the carbene carbon nucleus to high frequency i.e. 190−210 ppm, while *N*-coordination would result in a low

frequency shift towards 160 ppm. The signal pattern for the nitrogen donor ligands and ^{13}C NMR chemical shifts were consistent with the proposed structure; the imino carbon appeared as a typical singlet in the ^{1}H-decoupled mode in the 142.6−160.6 ppm range. The ^{1}H NMR spectra of the complexes further supported the assigned structures; the resonances for C(2)−H were observed as sharp singlets in the 7.3−9.7 ppm range. An electrochemical study by cyclic voltammetry showed that these new complexes present one reversible redox wave for the system Ru^{II}/Ru^{III} located in the range 1−1.3V/ECS (Table 4). For the electron releasing C_6Me_6 ligand the redox process takes place at lower potential.

Catalytic Studies

Although various ruthenium catalysts have been reported[3,8,9] for the intramolecular cyclization of (*Z*)-enynols (Equation 1), the search for more efficient catalysts is necessary. Therefore, we evaluated the new ruthenium complexes **1−7** for this reaction. With 1 mol-% of Ru catalyst at 80°C (*Z*)-3-methylpent-2-en-4-yn-1-ol gave moderate to good yields of the cyclization product. These results are summarized in Table 5. They show that the most efficient complexes are **3a** and **5a** (Table 5, entries 7, 12, 13). The best yields were obtained at 80°C for 2−4 h. Comparison of the catalysts containing *p*-cymene (**a** type) and hexa-

methylbenzene (**b** type) indicates that the presence of the *p*-cymene ligand gives a much better catalyst precursor. This may be due to the higher lability of the *p*-cymene ligand. The nature of the nitrogen ligand also has a strong influence on the catalytic activity as the ruthenium benzimidazole complexes **3** and **5** are the best catalysts and are much more efficient than the benzoxazole or benzothiazole complexes.

In conclusion, the preparation of ruthenium(II)-benzazole (L) complexes (**1**−**7**) is straightforward from the benzazole ligand and commercially available $[RuCl_2(arene)]_2$. The benzazoles behave as *N*-centered nucleophiles and all the complexes showed moderate to good catalytic activity for the cyclization of (*Z*)-3-methylpent-2-en-4-yn-1-ol into 2,3-dimethyfuran at 80°C, but (*p*-cymene)$RuCl_2$(benzimidole) appeared to give the best catalyst precursors.

Experimental Section

General: Unless otherwise stated, manipulations were performed under an oxygen-free nitrogen atmosphere with previously dried solvents and standard Schlenk techniques. The complexes $[RuCl_2(p-MeC_6H_4CHMe_2)]_2$ and $[RuCl_2(C_6Me_6)]_2$ were prepared according to literature methods.[10] 1-Substituted benzimidazoles, used for the synthesis of **2**−**5**, were prepared from the potassium salt of benzimidazole by following the literature procedure.[11] Infrared spectra were recorded as KBr pellets in the range 4000−400 cm^{-1} on a ATI UNICAM systems 2000 Fourier Transform spectrometer. ^{1}H NMR spectra (300.131 MHz) and ^{13}C NMR spectra (75.5 MHz) were recorded on a Bruker AM 300

WB FT spectrometer with δ referenced to residual solvent $CDCl_3$. Microanalyses were performed by the TÜBITAK (Ankara−Turkey) or Service Central D′analyses du Centre National de la Recherche Scientifique (Vernaison-France).

General Procedure for the Preparation of Ruthenium(II) Benzazole Complexes 1−7: A solution of the azole (2.1 mmol) in toluene (20 mL) and $[RuCl_2(p-MeC_6H_4CHMe_2)]_2$ or $[RuCl_2(C_6Me_6)]_2$ (1.0 mmol) were heated for 2 h under reflux. Upon cooling to room temperature, orange crystals of **1−7** were obtained. The crystals were filtered, washed with *n*-hexane (2 × 15 mL) and dried under vacuum. The reported yields are based on $[RuCl_2(\eta^6\text{-arene})]_2$ and relevant physical data are compiled in Tables 1−4.

Catalytic Reaction Conditions: Ruthenium catalyst (0.1 mmol) was added to 10 mmol of neat (*Z*)-3-methylpent-2-en-4-yn-1-ol without a solvent. The mixture was stirred in an oil bath at 80°C for 1−32 hours. The conversion of the starting enynol was determined by gas chromatography and the pure furan was isolated by distillation under reduced pressure.

Acknowledgments

The authors are grateful to TÜBITAK and CNRS for financial support (cooperative program 2504).

Dedicated to Prof. Helmut Werner on the occasion of his 65th birthday

Keywords: Tripod ligands / Hindered rotation of vinylidene ligands / $CpML_2$ chelate ligands / Ruthenium / Carbenes / Carbene-type ligands / Cyclic voltammetry

The tripodal ligand $[CH_3C(CH_2C_5H_4)(CH_2PPh_2)_2]^-$ reacts with $RuCl_2(PPh_3)_3$ to produce $CH_3C(CH_2\text{-}\eta^5\text{-}C_5H_4)(CH_2\text{-}\eta^1\text{-}PPh_2)_2RuCl$, [*tripod*$CpL_2RuCl$], **1**. Complex **1** undergoes substitution of the chlorine function with various nucleophiles L′ to produce [*tripod*CpL_2RuL']$^+$. The carbonyl derivative (L′ = CO) **2**, isonitrile (L′ = RNC) **3**, nitrile compounds (L′ = RCN) **4**, and a tolane adduct (L′ = η^2-PhC≡CPh) **5** are obtained when **1** is treated with the appropriate ligands in polar solvents. Halide acceptors (e.g. $TlPF_6$) are generally needed to promote these reactions. The cyanide derivative *tripod*CpL_2RuCN (**3a**) is alkylated by $F_3CSO_3CH_3$ to give the isonitrile derivative [*tripod*$CpL_2RuCNMe$]$^+$ **3b**. Terminal alkynes HC≡CR produce vinylidene compounds [*tripod*CpL_2RuL']$^+$, where L′ = C=CHR (R = *t*Bu, **7b**; R = Ph, **7c**), or allenylidene derivatives, L′ = C=C=CPh_2 (**6**), depending on the nature of R (R = CPh_2OH for synthesis of **6**). Trimethylsilylacetylene gives the parent vinylidene species, L′ = C=CH_2 (**7a**), which is transformed to the Fischer-type carbene compound, L′ = C(OMe)Me (**8**), upon treatment with methanol. The vinylidene species **7** are deprotonated by NaOMe to produce the alkynyl compounds *tripod*$CpL_2RuC{\equiv}CR$ (**9**). Methylation of **9** with $F_3CSO_3CH_3$ results in the vinylidene derivatives L′ = C=C(Me)R (R = *t*Bu, **7d**; R = Ph, **7e**), having two organic substituents at the terminal carbon centre. For all vinylidene compounds with two different substituents at their terminal carbon atom, hindered rotation of the single-faced vinylidene π-ligand about its Ru–C bond is observed. Analysis by ^{31}P-NMR spectroscopic coalescence measurements as well as line-shape analyses reveals activation enthalpies of around 40 kJmol^{-1} for this rotation, with small activation entropies of around ±10 Jmol^{-1}K^{-1}. Solid-state structures of nine compounds of the type [*tripod*CpL_2RuL']$^{+n}$ (n = 0, 1) demonstrate the remarkable conformational rigidity of the *tripod*CpL_2Ru template. They also show that the possible strain imposed by linking the Cp ligand and the two donor groups L in one and the same chelate scaffolding does not appear to impose a serious steric strain on these templates.

Introduction

$CpML_2$ compounds have played an important role in the development of organometallic chemistry as a tool for organic synthesis.[1] The $CpFe(CO)_2$ template and the $CpFeL_2$ species have been extensively studied[2] with regard to their interactions with organic substrates and many organic transformations mediated by this type of template have been reported.[2][3] Many of the organometallic derivatives that are rather unstable with $CpFeL_2$ as the organometallic group, making them non-isolable, are comparatively stable with the $CpRuL_2$ fragment as the organometallic moiety. Accordingly, there is a considerable volume of literature concerning the structure and properties of organic derivatives of the $CpRuL_2$ template.[3][4]

An inherent problem in the stereochemical interpretation of the reactions of such templates is the potential non-rigidity of $CpML_2$ fragments.[3−6] Quite early on in their seminal contributions, Brunner et al.[3][6] demonstrated that in the course of a reaction, CpMLL′ templates (M = Mn, Fe) may undergo inversion of configuration in a process geometrically similar to the inversion of ammonia. This type of behaviour tends to reduce the applicability of such CpMLL′ templates in diastereoselective organic transformations.

It thus appears that $CpML_2$ templates in which this type of configurational instability is prevented through appropriate design of the ligands might be of some use for the further development of this branch of chemistry. An appropriate design would impose a geometrical constraint upon the mutual positions of the Cp and L donors. Such a constraint is inherent in tripodal ligands, where the three donor groups, the Cp residue, and the L donors are bridged by a covalent framework. If the covalent linkers are sufficiently short, inversion of such a $CpML_2$ entity, once formed, becomes geometrically impossible.

As part of a strategy centred on the synthesis of a wide variety of neopentane-based tripod ligands $CH_3C(CH_2X)(CH_2Y)(CH_2Z)$ (X, Y, Z = donor groups), ligands of the

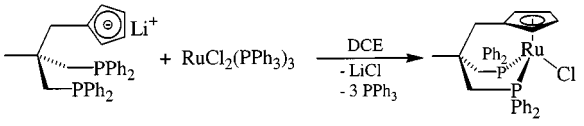
type $[CH_3C(CH_2C_5H_4)(CH_2PR_2)(CH_2PR'_2)]^-$ have been prepared.[7] It was shown that this type of ligand is capable of producing $CpML_2$ entities (M = Mn, Mo, Fe, Co) with the Cp residue and the phosphorus donor entities linked via the neopentane framework.[7][8]



In this paper, we report on the synthesis of a variety of compounds containing the $CH_3C(CH_2C_5H_4)$-$(CH_2PPh_2)_2Ru$ template. Derivatives of this template incorporating nitrile, isonitrile, carbene, vinylidene, and allenylidene moieties, amongst others, are described. Their mutual transformations as well as their structures and redox properties are discussed. The dynamic behaviour of the corresponding vinylidene species is analysed.

Results and Discussion

1. Synthesis of $CH_3C(CH_2$-η^5-$C_5H_4)$-$(CH_2$-η^1-$PPh_2)_2RuCl$ (1)

The ligand $CH_3C(CH_2C_5H_4)(CH_2PPh_2)_2Li$ is accessible from $CH_3C(CH_2OH)_3$ in a few steps.[7] It had previously been observed that its tripodal coordination to metals may necessitate some specialized reaction procedures in order to avoid the formation of coordination polymers as well as of Cp_2M compounds.[7][8] Thus, it was not surprising that reaction of $RuCl_3 \cdot n\,H_2O$ with the ligand in ethanol, which represents a standard protocol for the preparation of $Cp(PPh_3)_2RuCl$,[9] did not work with the tripodal ligand. Either no reaction or decomposition of the ligand was observed under these conditions.

Using $RuCl_2(dmso)_4$ as the starting material[10] was found to lead to the desired *tripod*CpL_2RuCl compound **1**, albeit only in small yields [$CH_3C(CH_2C_5H_4)(CH_2PPh_2)_2Ru$ will henceforth be abbreviated as *tripod*CpL_2Ru]. It was eventually found that $RuCl_2(PPh_3)_3$, prepared from $RuCl_3 \cdot n\,H_2O$ and PPh_3 in methanol,[11] reacts with [*tripod*$CpL_2]^-$ in 1,2-dichloroethane (DCE) at 90°C to produce a fair yield of **1**.

1

Chromatographic separation of **1** from PPh_3 on Al_2O_3, using diethyl ether/CH_2Cl_2 as the mobile phase, gives the desired product in yields of up to 60%. The identity of **1**, already apparent from its analytical and spectroscopic data (Table 8), was further corroborated by its X-ray analysis (Figure 1; Tables 4, 5, and 7).

The primary reason for analyzing the structure of **1** was, however, to gain insight into the steric encumbrance imposed on the $CpML_2$ entity by the fixed tripodal arrangement of its ligand constituents.

Figure 2b shows a spacefilling model of **1**, which indicates that the chlorine function is well protected by the constituents of the ligand. For comparison, the spacefilling model of $Cp[PPh_2CH(CH_3)CH_2PPh_2]RuCl$[12] is shown in Figure 2a. It is evident that in this compound, where there is no covalent link between the Cp group and the diphosphane ligand, the PPh_2 groups adopt a different orientation that makes the chlorine function more accessible. It therefore seems likely that associatively initiated reactions should be problematic with **1**, while dissociative initiation, i.e. removal of the chlorine in a first step, might well be favorable. In this respect, it is interesting to compare **1** with $Cp(PPh_3)_2RuCl$[13] (Figure 2c). The potentially reactive chlorine position appears to be even less accessible in the latter PPh_3 derivative as compared to **1** (Figure 2b). Nevertheless, $Cp(PPh_3)_2RuCl$ has in fact been found to be quite reactive with respect to chlorine substitution. A reaction of $Cp(PPh_3)_2RuCl$ initiated by an associative process is difficult to imagine (Figure 2c). Dissociative activation of this compound might, however, follow from PPh_3 as well as from Cl^- dissociation, which may account for its reactivity.[13] Dissociative activation of **1** by cleavage of one of the M−P bonds should be largely disfavoured by the chelate nature of the ligand. It thus appears that the only low energy pathway leading to chlorine substitution in **1** should

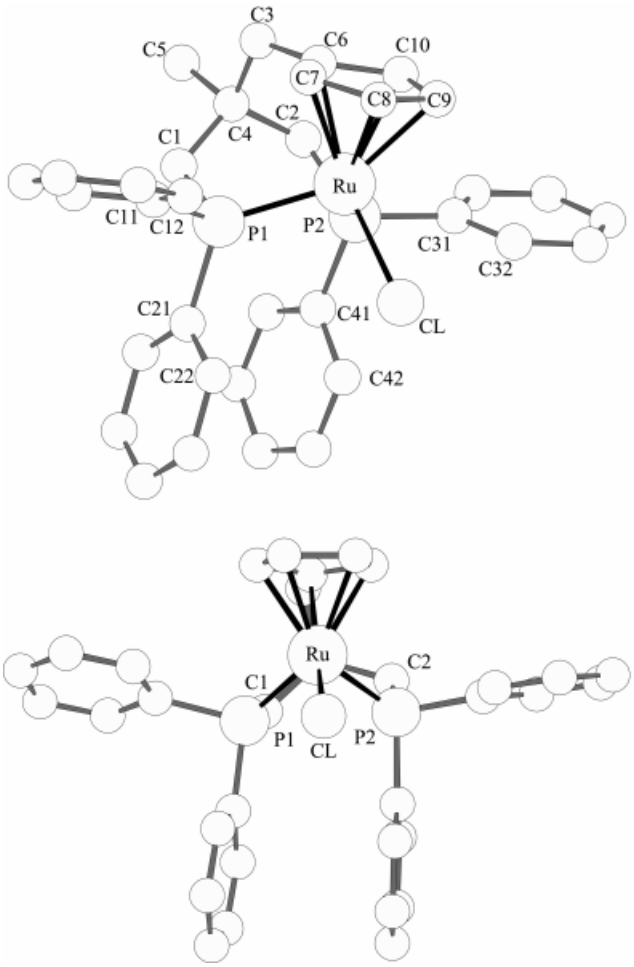


Figure 1. The structure of **1** in two different projections: top − general view; bottom − view along the Ru−C4 axis (the labelling scheme adopted for atoms of the tripodal ligand, as shown here for **1**, is consistently used for all structures reported in this paper)

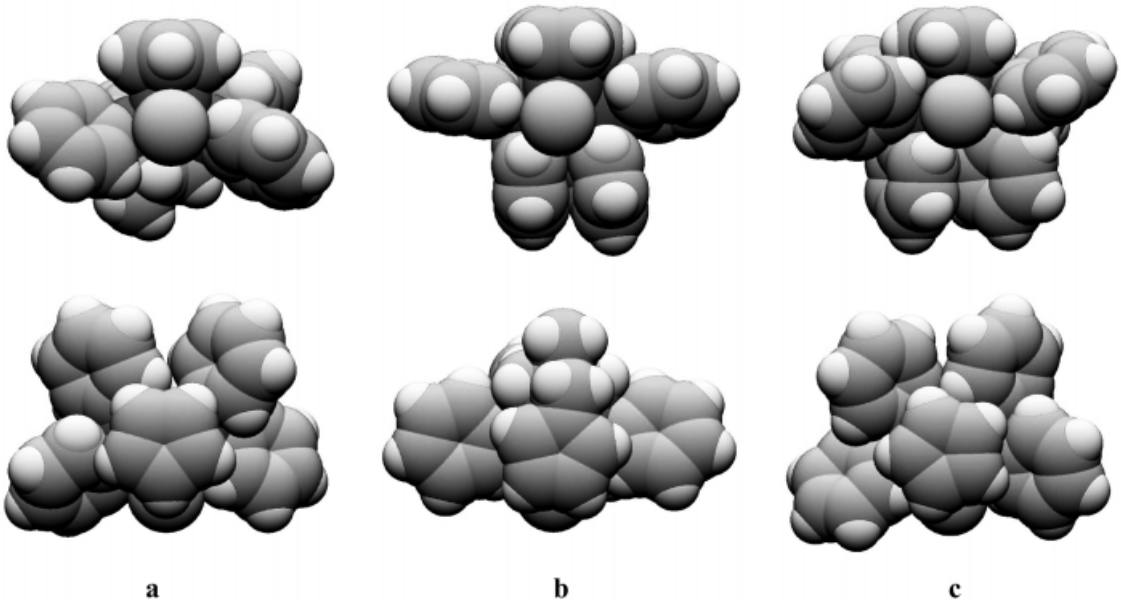

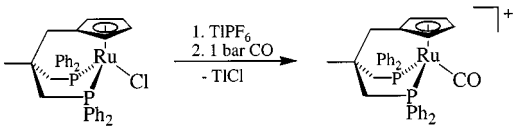

Figure 2. Spacefilling models of CpL_2Ru compounds as seen along the Cl−Ru axis (top) and in a projection onto the Cp planes (bottom); a: $Cp[PPh_2CH(CH_3)CH_2PPh_2]RuCl$; b: **1**; c: $Cp(PPh_3)_2RuCl$

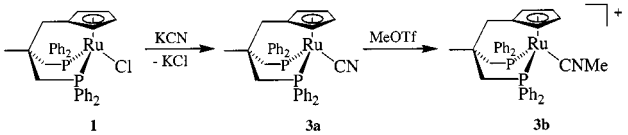
be that involving heterolytic cleavage of the Ru−Cl bond. Bearing this in mind, the optimum conditions for substituting the chlorine function in **1** should be realized by using polar solvents and by carrying out the reactions in the presence of halide acceptors. In this way, a series of transformations of **1** has been achieved.

2. Substitution Reactions of 1

The cationic carbon monoxide derivative **2** is obtained when a solution of **1** in CH_2Cl_2 is treated with $TlPF_6$ under CO at 1 bar.



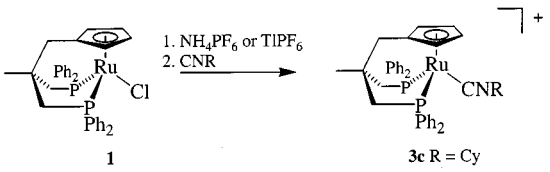
1 **2**

Analytically pure $\mathbf{2} \cdot PF_6$ can subsequently be isolated as a yellow microcrystalline powder (Table 8). Its $\tilde{\nu}_{CO}$ absorption is observed at 1966 cm^{-1}, in the region characteristic for $[CpL_2RuCO]^+$ compounds.[14] The pattern of NMR signals observed for the coordinated *tripod*CpL_2 ligand (Table 8) unequivocally proves its identity. The ^{31}P-NMR resonance is observed at $\delta = 45.3$. ^{13}C-NMR resonances are observed for all the individual carbon atoms of the ligand as well as for the coordinated CO group (Table 8).

Due to the rigid chelate framework, there are two distinct types of phenyl groups. Figure 2b (top) clearly shows these two classes: with respect to an idealized C_s symmetry (vertical mirror plane in Figure 2b), two phenyl groups, one at each of the two phosphorus nuclei, lie closely parallel to this plane. The remaining two phenyl groups are closely parallel to one another and lie in a "horizontal" plane at right angles to the idealized mirror plane. The *ipso* carbons of these two classes of phenyl residues give rise to two distinct NMR signals, which appear as pseudo triplets due to ^{31}P coupling. The carbon atoms in the *para* position show no apparent ^{31}P coupling. The pattern due to the carbon atoms of the coordinated cyclopentadienyl system is clearly resolved (Table 8).

In the ^1H-NMR spectrum, the Cp protons show the expected AA′XX′ pattern. The methylene protons of the CH_2 groups bonded to phosphorus give rise to two distinct doublets in the $^1H\{^{31}P\}$-NMR spectrum, while the CH_2 group linked to the Cp entity is seen as a broad singlet (Table 8). These NMR spectroscopic observations are in agreement with analogous findings reported for other compounds containing the same type of *tripod*CpL_2 ligand.[7][8] The same general features of the NMR spectra of **2**, as discussed above, also hold true for the other ruthenium derivatives of the same ligand described in this paper. The relevant data are collected in Tables 8−13 (Experimental Section); in the following paragraphs the discussion will be limited to references to these tables, except for compounds **7a−e**, where dynamic processes are observed.

1 reacts with KCN in methanol to produce **3a**, which is obtained as a yellow microcrystalline powder in analytically pure form after chromatographic workup.

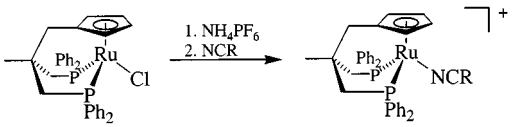


1 **3a** **3b**

The identity of **3a** was confirmed by its spectroscopic data (Table 8) as well as by an X-ray analysis (Figure 3; there are two crystallographically independent species **3a** in

the crystal, only one of which is depicted in Figure 3; Tables 4, 5, and 7).

As a derivative of **3a**, the isonitrile compound **3b** was obtained by treating **3a** in CH_2Cl_2 with $F_3CSO_3CH_3$. The triflate salt of **3b**, obtained as a pale-yellow powder, has been fully characterized (Table 9) by its spectroscopic and analytical data.

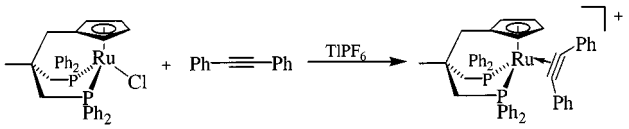


When methanolic solutions of **1** are treated with isonitriles, substitution does not take place spontaneously. Only when $TlPF_6$ is added to these solutions is complete substitution observed.

1 **3c** R = Cy

Instead of $TlPF_6$, NH_4PF_6 may also be used as an activator. The PF_6 salt of **3c** is obtained as a pale-yellow powder in analytically pure form, with all the spectroscopic data being consistent with the given constitution (Table 9). As is often found for isonitrile derivatives, the ^{13}C-NMR signal of the isonitrile carbon cannot be detected[15] while the signals of all the other carbon atoms are clearly evident (Table 9).

The chlorine function in **1** may also be replaced by nitriles.



1 **4a** R = Me **4b** R = Ph

A methanolic solution of **1** reacts smoothly with acetonitrile in the presence of NH_4PF_6 to produce the PF_6 salt of **4a**. The benzonitrile derivative **4b** is accessible by the same type of procedure. Compounds **4** are obtained as yellow microcrystalline salts and have been fully characterized by their spectroscopic and analytical data (Tables 9 and 10). X-ray analysis of **4b** · PF_6 leaves no doubt as to its constitution (Figure 3; Tables 4, 5, and 7).

The substitution reactions of **1** leading to **2**–**4** are analogous to corresponding reactions in the chemistry of conventional CpL_2Ru compounds, i.e. compounds where the Cp ligand is not covalently linked to the donor groups L.[14–16] It appears that chlorine substitution in **1** is not drastically impeded by the reduced flexibility of the cage-type *tripod*CpL_2Ru template. This is an important observation with regard to the analysis of the reactivity of **1** towards alkynes, since all of the many transformations known for the system CpL_2Ru/alkyne necessarily start with a substitution reaction.

3. Transformation of Alkynes by the *tripod*CpL_2Ru Template

Solutions of **1** in CH_2Cl_2 react with 1,2-diphenylacetylene when the reaction mixture is activated with $TlPF_6$. Substitution of the chlorine function of **1** by the alkyne function is a slow process requiring many hours at 25°C to reach completion.

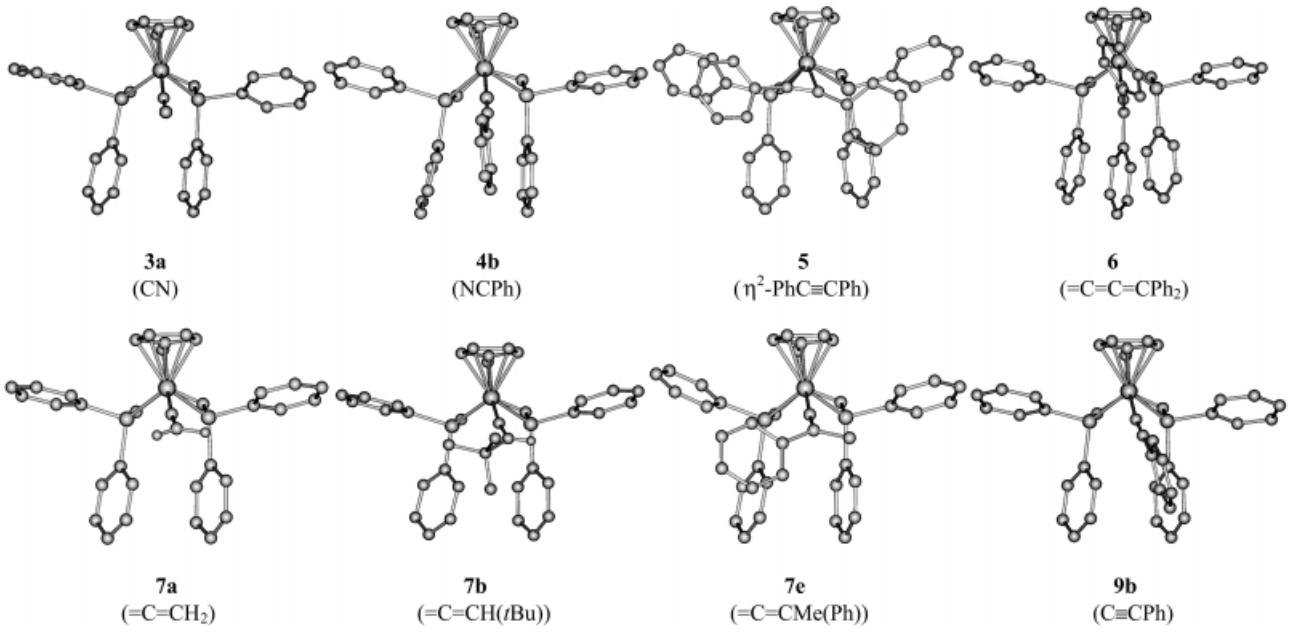
1 **5**

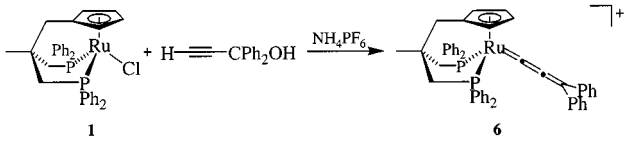
The PF_6 salt of **5** is obtained as an orange-yellow powder. Crystals may be obtained by slow diffusion of diethyl ether into DCE solutions of **5** · PF_6. The constitution of the compound has been verified by HR-FAB analysis (see Experimental Section, Table 14) and NMR spectroscopy (Table 10), and furthermore by an X-ray structure determination (Figure 3, Tables 4, 5, and 7). Despite the fact that the determined structure is not very accurate, due to the rather poor quality of the crystals obtained, the constitution of **5**·PF_6 is clear beyond doubt (Figure 3). The rotational orientation of the alkyne entity relative to the *tripod*CpL_2Ru template is close to orthogonal to the idealized mirror plane (Figure 3) and thus corresponds to the geometry anticipated by MO reasoning.[17] The length of the coordinated C–C triple bond (127.2 pm) as well as the bond angles C(alkyne)–C(alkyne)–C_i(phenyl) (148.1°, 147.8°) fall within the ranges normally observed for η^2-bonded alkynes.[18] It appears that the phenyl substituents at the alkyne ligand and the horizontal pair of phenyl substituents at the phosphorus centres are subject to some interference, which is manifested in a torsional position of the latter phenyl groups significantly different from the average (Figure 3; Tables 4 and 5).

Whenever terminal alkynes are reacted with a CpL_2Ru precursor, rearrangements tend to occur.[19] Although it has always been thought highly probable that the first step in such reactions is again η^2-coordination of the alkyne,[20] this has only recently been proved to be the case.[19–21] Mechanistic alternatives based on oxidative addition with C–H bond cleavage as the first step have also been proposed[20,22,23] and have in fact been verified with templates other than $CpRuL_2$.[23][24] For $CpRuL_2$, theoretical reasoning[20] tends to disfavour this latter hypothesis[20–24] and the observation that η^2-coordination does in fact occur gives additional credit to the suggestion that the transformation undergone by alkynes HC≡CR at $CpRuL_2$ templates involves η^2-coordination of the alkyne as the first step.

Since the characterization of **5** shows that the *tripod*CpL_2Ru template is capable of η^2-bonding of alkynes, alkynes HC≡CR can be expected to undergo transformations similar to those that have been observed with traditional $CpRuL_2$ entities.[19]

One of the standard transformations mediated by $CpRuL_2$ templates is the generation of allenylidene ligands





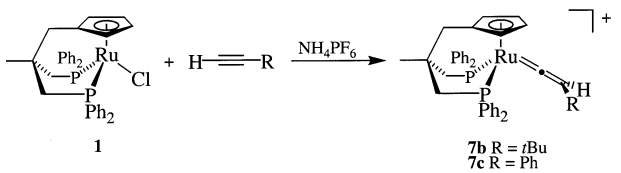


Figure 3. X-ray structures of compounds **3−9**; view along the Ru−C4 axis; coligands are shown in brackets

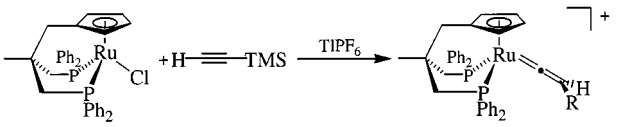
from $HC{\equiv}C{-}CR_2OH$.[25] This type of transformation is found to proceed equally well with *tripod*CpL_2Ru as the template. An orange suspension of **1** in methanol containing NH_4PF_6 reacts with $HC{\equiv}C{-}CPh_2OH$ to produce a purple solution of **6**, the PF_6 salt of which can be isolated as a microcrystalline purple solid.

A correct elemental analysis and the spectroscopic signature of **6** (Table 10) leave no doubt as to its identity. An X-ray analysis of the PF_6 salt of **6** (Figure 3, Tables 4, 5, and 7) reveals an almost linear arrangement of the $Ru{-}C_3$ chain of the allenylidene fragment (Table 5). The coordination plane of the terminal sp^2 carbons of the ligand is almost coincident with the idealized mirror plane of the coordination polyhedron (Figure 3). The rotational position of the phenyl groups at the terminal carbon of the allenylidene ligand also tends to be close to this orientation (Figure 3).

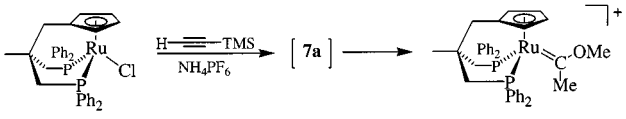
Terminal alkynes lacking the reactive group at the γ-carbon that leads to the allenylidene ligand in **6**, produce vinylidene species **7b/c** when reacted with **1** under appropriate activation.



Products **7b/c** can be isolated as their PF_6 salts. Orange-brown **7b** · PF_6 and red-brown **7c** · PF_6 have been fully characterized by their analytical and spectroscopic data (Table 11). X-ray analysis of **7b**·PF_6 [Tables 4, 6, and 7; Figure 3 (there are two crystallographically independent species **7b** in the crystal, only one of which is shown in Figure 3)] shows that the orientation of the vinylidene ligand with respect to the $CpML_2$ template is such that the coordination plane about the β-carbon of the vinylidene group is "horizontal". This type of orientation is in line with expectation, considering the different π-bonding capabilities of the d-type orbitals of the $CpML_2$ unit.[17][26] The differentiation between these two π-bonding metal orbitals − that in the idealized mirror plane leading to a weaker π-interaction and the other, vertical to it, having better π-bonding capabilities − is generally not sufficient to lead to just one rigid conformation. Nevertheless, the preferred orientation, as predicted by theory,[17,19,26] is generally found to be adopted in solid-state structures. This also holds true for all the structurally characterized vinylidene compounds described in this paper. It is also the case for the allenylidene species **6** where, due to one additional carbon atom in the unsaturated chain, the sp^2 plane of the terminal carbon atom should lie within the idealized mirror plane of the template, as is indeed found (Figure 3, **6**).[17][26]

The barrier to ligand rotation imposed by this type of π-bonding has been estimated to be around 10−20 $kJmol^{-1}$ by theory,[17][26] while experimentally determined values have amounted to 29−42 $kJmol^{-1}$ for CpL_2Fe compounds[27] and to around 40 $kJmol^{-1}$ for $CpRuL_2$ compounds.[19][28] It would appear that the conformational rigidity of the *tripod*CpL_2Ru framework and the use of ^{31}P-NMR spectroscopy as the means of monitoring may allow

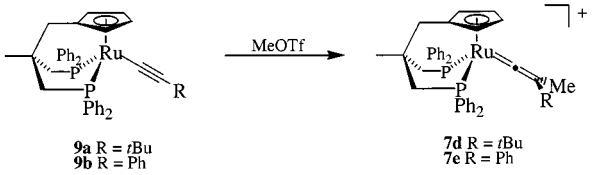
experimental estimation of this barrier for compounds **7**. On cooling, CD_2Cl_2 solutions of **7c** are found to show a broadening of the ^{31}P-NMR signal at $\delta = 51.4$ (178 K), such that at 170 K a splitting of this single resonance into two components ($\delta = 51.5, 51.6$) is observed (Table 1). Solubility problems prohibit analysis at lower temperatures in this case.



One sharp ^{31}P-NMR signal ($\delta \approx 51.5$) is observed for **7b** at temperatures above 178 K. Some broadening of the signal is apparent around 178 K ($\delta = 51.5$). At 159 K, two doublets are observed ($\delta = 51.4$ and 52.3; $^2J_{AB} = 45$ Hz). Coalescence occurs at 170 K ($\delta = 51.8$).

The above observations indicate that a dynamic process is operative, rendering the two phosphorus nuclei non-equivalent at low temperature while, in a dynamic sense, they are equivalent at higher temperatures. In order to further elucidate the nature of this dynamic process, the parent vinylidene compound **7a** was synthesized by reacting a suspension of **1** in CH_2Cl_2 containing $TlPF_6$ with $HC{\equiv}CSiMe_3$ to give **7a** · PF_6.

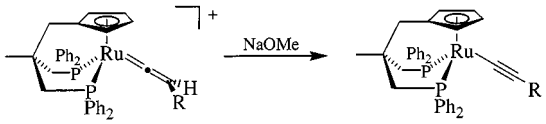
1 **7a** R = H



7a · PF_6 was isolated as a yellow microcrystalline solid and has been characterized by all the standard analytical tools (Table 11), including by an X-ray structural analysis (Figure 3; Tables 4, 6, and 7). An analogous reaction of **1** in methanol in the presence of NH_4PF_6, although initially producing **7a** (NMR control), ultimately led to the formation of the carbene compound **8**.

1 **8**

The transformation of vinylidene ligands into carbene ligands is not without precedence,[29] although it has been reported that in some cases the transformation is sufficiently slow to allow the isolation of the intermediate vinylidene species, even in the presence of methanol.[29b] The yellow-brown salt **8** · PF_6 has been fully characterized by a complete set of standard analytical data (Table 12).



In relation to the dynamic behaviour observed for **7b/c**, the ^{31}P-NMR spectroscopic behaviour of **7a** is of interest. If the appearance of two ^{31}P-NMR signals for **7b/c** at low temperatures were to stem from a differentiation of the surroundings of the two phosphorus nuclei by a helical twist of the chelate scaffolding − which would be dynamic at high temperatures and frozen out at low temperatures − this splitting should also be observed for **7a** (assuming that the activation barrier for the twist of the cage is largely independent of the nature of the substituents at the terminal carbon of the vinylidene ligand). It is found, however, that down to 170 K, which represents the lowest accessible temperature, the ^{31}P-NMR resonance of **7a** remains as a sharp singlet. Freezing out of the twist of the cage can therefore be ruled out as the basis of the dynamic phenomena observed for **7b/c**. Due to the symmetry of the ligand, analysis of **7a** cannot of course provide data that might allow to answer the question as to whether it is the rotation of the vinylidene ligand about its ligand−metal bond that forms the basis of the phenomena observed for **7b/c**. This question might be addressed if it were possible to slow down this rotation to such an extent that the phenomena might be observed at higher temperatures, thereby circumventing the aforementioned solubility problems. Substitution of the terminal carbon of the vinylidene unit by two different organic groups can be expected to effectively serve this purpose. With this in mind, procedures allowing the synthesis of **7d/e** were developed, which were ultimately obtained from the alkynyl species as shown.

9a R = *t*Bu
9b R = Ph

7d R = *t*Bu
7e R = Ph

The alkynyl species **9a/b** are themselves available by deprotonation of the corresponding vinylidene compounds **7b/c**.

7b R = *t*Bu
7c R = Ph

9a R = *t*Bu
9b R = Ph

Compounds **9** are obtained as lemon-yellow materials of a somewhat waxy consistency. Their analytical data correspond to the depicted formulae and their spectroscopic data are in full agreement with the assigned constitutions (Table 13). X-ray analysis of **9b** gave independent confirmation of its identity (Figure 3; Tables 4, 6, and 7).

4. Model Compounds for the Analysis of Vinylidene Rotation

The alkynyl derivatives **9** are found to react smoothly with $F_3CSO_3CH_3$ as an alkylating agent in a type of reaction well-established in CpL_2Ru chemistry.[30] The triflate salts of **7d/e** are obtained as microcrystalline solids (**7d** orange-red, **7e** brick-red). Their analytical and spectroscopic data (Table 12), as well as an X-ray analysis of **7e** (Figure 3; Tables 4, 6, and 7) leave no doubt as to their constitutions. The orientation of the coordination plane of the terminal carbon of the vinylidene group is again as in **7b** (and **7a**, see above), such that this plane is vertical to the idealized mirror plane of the *tripod*CpL_2Ru template (Figure 3).

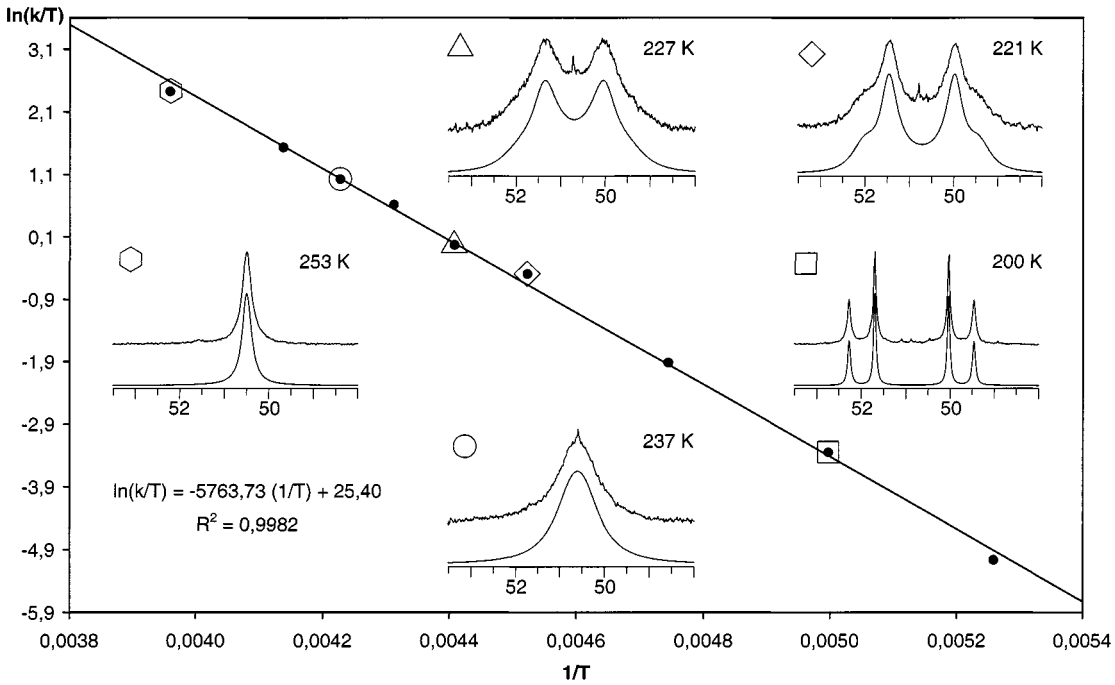


Figure 4. Eyring plot and examples of experimental (top) and simulated spectra (bottom) for compound **7e**

The ^{31}P-NMR spectrum of the triflate salt of **7e** shows one sharp signal at $\delta = 50.5$ at temperatures down to 253 K. At 242 K, significant broadening is observed, with two individual signals evolving at 227 K and a sharp pair of doublets being evident at 211 K. From the coalescence temperature of 232 K, $\Delta G^{\ddagger}_{232}$ may be estimated to be 44.5 kJmol^{-1}, corresponding to a rate constant of $k_{232} = 452$ s^{-1} (Table 1). Line shape analysis[31] of the complete set of spectra obtained at the specific temperatures given in Table 2 neatly reproduces the observed patterns (Figure 4).

The corresponding Eyring plot shows no significant deviation from linearity over the whole range of temperatures from 253 K to 190 K (Table 2; Figure 4). From this, the activation enthalpy $\Delta H^{\ddagger}$ can be estimated to be 47.9 kJmol^{-1}; $\Delta S^{\ddagger}$ is found to be 13.6 Jmol^{-1}K^{-1} (Table 2; Figure 4).

Table 1. Rotational barriers estimated from coalescence temperatures

	T [K]	P_A [ppm]	P_B [ppm]	J_{AB}[Hz]	Tc [K][a]	ΔG_{Tc} [kJ mol^{-1}]
7b	178	51.5			170	32.7[b]
	159	51.4	52.3	45		
7c	178	51.4			175	34.0[b]
	170	51.5	51.6	n.d.		
7d	253	50.3			227	43.1[b]
	200	49.8	52.0	48.6		
7e	253	50.5			232	44.5[b]
	211	49.8	52.0	48.6		

[a] Tc = coalescence temperature. – [b] $k_{Tc} = 303$ s^{-1} for **7b**; 254 s^{-1} for **7c**; 566 s^{-1} for **7d**; 452 s^{-1} for **7e**.

The same type of experiments were performed with **7d** (see data in Table 2). The fit obtained by line shape analysis[31] was equally good and the corresponding Eyring plot was again linear over the whole temperature range [$\ln(k/T) = -4849.09(1/T) + 22.3$; $R^2 = 0.9935$]. The thermodynamic data estimated from line shape analysis are given in Table 2, along with the estimates from the coalescence temperature (227 K) of k_{227} (566 s^{-1}) and $\Delta G^{\ddagger}_{227}$ (43.1 kJmol^{-1}) (see Table 1). For **7d** and **7e**, the respective $\Delta H^{\ddagger}$ values are found to be 40.3 kJmol^{-1} and 47.9 kJmol^{-1} (Table 2).

Table 2. Calculated rotational barriers and thermodynamic parameters from line shape analyses

T [K]	**7d** k [s^{-1}]	**7e** K [s^{-1}]
253	5300	2850
242	2650	1120
237	–	660
232	1025	430
227	–	220
221	340	135
211	95	31
200	24	7
190	5.5	1.2
178	2	–
Thermodynamic data	$\Delta H^{\ddagger} = 40.3$ kJ mol^{-1}	$\Delta H^{\ddagger} = 47.9$ kJ mol^{-1}
	$\Delta S^{\ddagger} = -12.12$ J mol^{-1}K^{-1}	$\Delta S^{\ddagger} = 13.60$ J mol^{-1}K^{-1}
	$\Delta G_{298}{}^{\ddagger} = 43.9$ kJ mol^{-1}	$\Delta G_{298}{}^{\ddagger} = 43.9$ kJ mol^{-1}

The activation entropies are small for both compounds (Table 2). Since a conservative estimate of the standard deviation of $\Delta S^{\ddagger}$ is around 7 Jmol^{-1}K^{-1}, the $\Delta S^{\ddagger}$ values (**7d**: $\Delta S^{\ddagger} = -12$ Jmol^{-1}K^{-1}; **7e**; $\Delta S^{\ddagger} = +14$ Jmol^{-1}K^{-1}) do not warrant a detailed discussion. However, the small magnitude of these values indicates that the steric crowding and

strain within the molecule are not subject to any great changes along the reaction coordinate.

7b/c can be thought of as analogues of **7d/e** having a hydrogen substituent at the terminal position where **7d/e** bear a methyl group. As mentioned above, the low temperature limit of the rotational exchange process cannot be reached experimentally with **7b/c**. Line shape analysis is therefore not possible for these compounds due to the fact that the shifts and coupling constants of the $P_{A/B}$ system are not experimentally accessible. From the coalescence temperatures, the parameters given in Table 1 can be deduced; the $\Delta G^{\neq}$ values at these temperatures are about 10 kJmol^{-1} smaller than the values estimated for **7d/e** at their coalescence temperatures (Table 1). Of course, this cannot be solely attributed to the steric relief caused by substituting a methyl group for a hydrogen since electronic factors are also likely to come into play.

Barriers to rotation of around 10−20 kJmol^{-1} for processes of the type analysed have been predicted by theoretical methods.[17][26] The experimental data for $CpL_2Fe{=}C{=}CRR'$ indicate barriers of 29−42 kJmol^{-1} and corresponding experiments on $CpL_2Ru{=}C{=}CRR'$ lead to activation barriers of around 40 kJmol^{-1}.[27][28] The activation barriers for the *tripod*CpL_2Ru−vinylidene compounds **7** (Tables 1 and 2) are thus in favorable agreement with the theoretical predictions as well as with data obtained for similar compounds.

5. Cyclic Voltammetry

The broad variation of the coligands in compounds **1**−**9** allows for some kind of systematic comparison of their electrochemical behaviour (Table 3).

The first four entries in Table 3 correspond to neutral species. Oxidation is reversible for the first three compounds (**1**, **9a**, **9b**) and occurs in the range 20−200 mV (SCE). The oxidation process can be attributed to the Ru^{II}/Ru^{III} redox couple, since, at least for **1** with the simple chlorine ligand, there is no other plausible explanation. Since the reversible oxidation of the two alkynyl compounds (**9a/b**) occurs in the same range as found for the chloro derivative **1**, the electrochemical process responsible for this oxidation wave should still be the reversible Ru^{II}/Ru^{III} oxidation. The organic substituents are only of secondary influence and are clearly not oxidized themselves in the potential range below 200 mV. At higher potentials, around 1100 mV, a second irreversible oxidation of compounds **9** is observed (Table 3), the probable nature of which will be discussed alongside the discussion of the redox behaviour of compounds **7** and **8** (see below).

With CN as the ligand, as in **3a**, the first oxidation is irreversible. Although comparison of this irreversible process at $E_P^A = 660$ mV with the reversible processes at $E_{1/2} \leq 220$ mV observed for **1**, **9a/b** is not strictly valid in a thermodynamic sense, the CN group would be expected to shift the oxidation potential to higher values, as is observed. The first irreversible oxidation of **3a** leads to a product that is − again irreversibly − reduced at $E_P^C = -190$ mV. The nature of this product is not known. At $E_{1/2} = 1164$ mV, a second oxidation of **3a** is observed, which is reversible. The nature of the product responsible for this signal is again unknown. It is highly improbable that this feature corresponds to the formal +IV oxidation state of ruthenium. On the other hand, the observed $E_{1/2}$ is close to that observed for the oxidation of the cationic isonitrile species **3b/c**, and hence some similar structure − possibly a coordinated CNH ligand − cannot be ruled out.

The next group of compounds comprises the cationic species **2**, **3b/c**, **4**, **5**, which, in contrast to the members of the final group, do not have carbene, vinylidene, or allenylidene ligands. The carbon monoxide derivative **2** is difficult

Table 3. Electrochemical data for compounds **1** to **9**[a]

compound	ligand	potential	$E_{1/2\ (Fc)}$	ΔE_{Fc}

8	COMe(Me)	$E_{1/2} = 1066$; $\Delta E = 103$	442	127

[a] All potentials are given in mV vs. SCE. The data refer to a scan rate of 200 mV/s. To check the reversibility, scan rates of 50, 100, 200, 400, 600, and 800 mV/s were also applied. The square-root relationship between peak height and scan rate expected for reversible processes was observed in each case. For ease of comparison, the compounds are sorted into blocks, the order of which does not necessarily correspond to the sequence of numbers used for designating the compounds. With the exception of compound **2**, which was analyzed in CH_3CN solution, all measurements were performed in CH_2Cl_2 solution. In each case, the first line of data refers to an oxidative process. The second line, where relating to irreversible processes, refers to the anodic potential of a second oxidation wave at higher potentials. If the potential is less positive (**3a**, **2**, **7a**−**7c**) than that required for the oxidation (first line), the second line refers to the cathodic potentials of the reduction waves corresponding to the products generated by the oxidation (ECE). Only for compound **6** are both oxidation and reduction found to be reversible. For reversible processes, the separation $\Delta E = E_P^A - E_P^C$ is given, together with the ΔE_{Fc} observed in the same experiment for the electrochemically reversible ferrocene redox couple at around 430 mV. − [b] Quasi-reversible oxidation.

to oxidize and reduce. Both processes are irreversible. The isonitrile analogues **3b/c** are reversibly or quasi-reversibly oxidized at around 1250 mV. With nitriles as coligands, as in **4a/b**, reversible oxidation at somewhat lower potentials is observed.

The 1,2-diphenylacetylene derivative **5** shows a reversible oxidation at 986 mV, in the same region as observed for the oxidation of the nitrile derivatives (**4a/b**). It can be seen that oxidation of these cationic compounds occurs at markedly higher potentials than found for the neutral species of the first group. This is well in accord with expectation, since abstracting an electron from a cation clearly requires more energy than ionizing a neutral species. The relatively narrow range of oxidation potentials observed for the compounds of this group (Table 3) again points to an Ru^{II}/Ru^{III} redox process similar in nature to that inferred for compounds of the first group.

The cationic compounds **6**–**8**, containing carbene ligands, form a class of their own. Of the vinylidene species **7**, compounds **7a**–**c** show irreversible oxidations around 1200–1400 mV, while the oxidations of **7d/e** are reversible and occur at $E_{1/2}$ = 1187 mV and $E_{1/2}$ = 1133 mV, respectively. Since **7a**–**c** have at least one hydrogen atom bonded to the terminal sp^2 carbon, while in **7d/e** these positions are both blocked by organic groups, it is reasonable to assume that the presence of a hydrogen in the β-position of the coligands is responsible for the irreversibility of the oxidation process observed for **7a**–**c**. In other words, deprotonation of the oxidized species may be at the basis of the observation that first oxidations of **7d/e** are reversible while those of **7a**–**c** are not. As an indication of the plausibility of this argument, the narrow range of potentials over which the oxidations of **7a**–**e** are observed (ca. 1100 to 1400 mV) may be invoked. If the primary oxidation products of the compounds **7b/c**, $[tripodCpL_2RuC{\equiv}C(H)tBu]^{2+}$ ($\mathbf{7b}^+$) and $[tripodCpL_2RuC{\equiv}C(H)Ph]^{2+}$ ($\mathbf{7c}^+$), were to undergo deprotonation, they would be transformed into $\mathbf{9a}^+$ and $\mathbf{9b}^+$, respectively. However, these compounds are known to be irreversibly oxidized at potentials around 1100 mV (Table 3), which are lower than those needed for the oxidation of **7b** and **7c**. If a process as described for **7b/c** occurs, the signals of the redox process **9a**/$\mathbf{9a}^+$ would not be expected to be observed in the voltammogram of **7b**/$\mathbf{7b}^+$ (nor analogously signals due to **9b**/$\mathbf{9b}^+$ in the voltammogram **7c**/$\mathbf{7c}^+$) and indeed no such signals are found.

Irreversible reduction at rather negative potentials is observed for **7a/b/c/e** (−1900 to −1700 mV, Table 3) and a second irreversible oxidation is seen for **7d**. The potentials at which compounds **7d/e** are reversibly oxidized are in approximately the same region as those at which reversible or quasi-reversible oxidation of compounds **3**, **4**, **5** takes place. They are also close to the potential measured for the reversible oxidation of the carbene compound **8** (1066 mV). Thus, it is obvious that the first oxidation potentials of cationic compounds in the second group (**3**–**5**) and the third group (**7**–**8**) fall in a rather narrow range, irrespective of the broad variation in the nature of the coligands. This implies that for all these cationic species the oxidation process is adequately described by the Ru^{II}/Ru^{III} redox couple. The allenylidene compound **6** also fits into this scheme, since it shows a reversible oxidation at $E_{1/2}$ = 1203 mV (Table 3). As expected for an allenylidene species, it may also be reversibly reduced (Table 3), with the extra electron being delocalized over the cumulenic system.

[a] Standard deviations in units of the least significant digit given in each case. Z represents the centre of the Cp ring; X, Y, W refer to the organic residues at Ru in the sequence Ru-X-Y-W; Hc represents an auxiliary point, fixed at the phosphorus atoms such that it points towards the observer (Figure 1, bottom) and is parallel to the C4–Ru axis (Figure 1). – [b] As footnote [c] with respect to the second independent molecule. – [c] For the sake of comparison, the configuration has been inverted with respect to the deposited data. – [d] Some additional angles: **5**: C(sp)–C(sp)–C(*i*-Ph) 148.1(9), 147.8(9). **6**: C(β)–C(γ)–C(*i*-Ph) 117.1(5), 121.1(5).

6. Structural Characteristics of the *tripod*CpL_2Ru Template

The structures of nine compounds derived from the *tripod*CpL_2Ru template are shown in Figures 1 and 3, with the geometrical data being collected in Tables 4–6. The data in Table 4 shows that the distances within the *tripod*CpL_2Ru template are not significantly influenced by the coligands bound to this template. The Ru–P distances are found to range only from 224 to 232 pm (Table 4). The Ru–C_{Cp} distances fall within a range from 215 to 230 pm, while the C–C distances within the Cp residue lie between 139 and 145 pm.

The P–Ru–P angles (Tables 5 and 6) are found in the narrow range from 84° to 88°. The angles subtended at the ruthenium centre by the centre of the Cp residue and the phosphorus atoms show a similarly small degree of scatter (112 to 120°, Tables 5 and 6). The position at which the coligand is bound to the template is likewise defined by a narrow range of P–Ru–X (X = coligand; 87 to 104°) and Z–Ru–X angles (Z = centre of the Cp molecule; 126 to 132°).

The coordination polyhedron around the ruthenium centre is thus fairly constant in shape (Figure 3) and is not significantly influenced by the various types of coligands

[a] The crystals tend to contain solvate molecules. The number and type of solvate molecules found per formula unit is given in the column header.

(Figure 3). The secondary interaction within the *tripod*CpL_2Ru templates, which governs their conformation, will be closely similar in all of its *tripod*CpL_2RuL' compounds (L′ = coligand) due to the fact that the distances and valence angles within the templates are also closely similar. It can be seen from Figures 1 and 3 that the conformations adopted by the *tripod*CpL_2Ru templates are in fact rather similar for the whole group of compounds. This is shown in a quantitative way by the torsion angles C_o−C_i−P−Hc (where Hc denotes an auxiliary point fixed to

[a] Diastereotopic hydrogen atoms at CH_2P groups. − [b] CH_3, CH_2, CH, and C carbons were assigned by means of a 135° DEPT experiment. − [c] Individual assignment of the resonances to the different classes of phenyl rings was not possible.

the phosphorus atom with the resulting vector pointing in the direction C4−Ru towards the observer), which indicate that − with the exception of **5** − the phenyl rings tend to be aligned parallel to this auxiliary vector within a maximum deviation of 39° and with an average deviation of only 18° (Tables 5 and 6).

It is apparent from Figure 3 (**5**) that the η^2-coordinated 1,2-diphenylacetylene coligand interferes with the orientation of the phenyl groups of the template. The data in Table 5 reveals correspondingly large torsion angles up to a maximum value of 45°. Whereas constitutionally the templates *tripod*CpL_2Ru have mirror symmetry, conformationally this cannot be so due to the skew within the chelate scaffolding. The entries in Figures 1 and 3 and Tables 4−6 have been arranged such that the torsion of the scaffolding has the same sense in all the structures. It can be seen from Figure 3 as well as from Tables 5 and 6 that the most prominent torsion occurs with respect to the C4−C2−P2−Ru part of the scaffolding (−18 to −34°). The least prominent skew is consistently observed for the C4−C1−P1−Ru part (+1 to −9°), with the skew of the part bearing the cyclopentadienyl molecule, C4−C3−C6−Ru, being intermediate −5 to −16° (Figures 1 and 3; Tables 5 and 6). It appears that the difference in the torsion angles C4−C1−P1−Ru (small) and C4−C2−P2−Ru (large) is mirrored in the Ru−P distances, which, although similar, are systematically larger for Ru−P1 (mean 228.5 pm) than for Ru−P2 (mean 227.0 pm) in all the compounds studied (Table 4). This may be taken as an indication of some strain within the chelate cage, which is also evident from the $Ru-C_{Cp}$ distances. The sequence of these distances is such that the bond to the carbon atom C6 (mean 220.3 pm), which is linked to the chelate cage, tends to be the shortest, while the bonds to C8/C9 are systematically longer (mean values 227.4 and 225.7 pm, respectively); the Ru−C7/C10 bonds have intermediate lengths (mean values 223.1 and 222 pm). This pattern of bond distances corresponds to a shift of the ruthenium atom parallel to the plane of the Cp ligand in the direction of C6, away from its ideal position below the centre of this ring (*d* in Table 4). The distances within the Cp ligand respond to this asymmetry in a systematic way. The C6−C7/C6−C10 bonds are longer (mean 143.3 pm) than the C7−C8/C9−C10 bonds (mean 140.7 pm), with the remaining C8−C9 bond also being rather long (mean 142.7 pm). This pattern is seen in all the individual compounds investigated and thus represents a general trend. In a few cases where at first glance this pattern appears to be contradicted by the numerical values, the standard deviations of these values make the apparent contradiction insignificant.

Taken together, the indications of strain within the chelate scaffolding are only minor since the variance in the geometrical parameters, which would be expected to have equal values in an unstrained system, is not significantly larger than that observed in compounds where there is no steric strain imposed by a chelate cage.[4,12,19] The chemical behaviour of the *tripod*CpL_2Ru template can thus be expected to be similar to that exhibited by the non-chelate templates of the type CpL_2Ru, as has indeed been observed.

[a] Diastereotopic hydrogen atoms at CH_2P groups. − [b] CH_3, CH_2, CH, and C carbons were assigned by means of a 135° DEPT experiment. − [c] Individual assignment of the resonances to the different classes of phenyl rings was not possible.

Conclusion

The chelate ligand $CH_3C(CH_2C_5H_4)(CH_2PPh_2)_2Li$ forms templates $CH_3C(CH_2\text{-}\eta^5\text{-}C_5H_4)(CH_2\text{-}\eta^1\text{-}PPh_2)_2Ru$, *tripod*$CpL_2Ru$, which bind to coligands L′ in a similar manner as known for the non-chelate analogues $CpRuL_2$. With anionic ligands (L′ = Cl^-, CN^-, acetylides), neutral compounds *tripod*CpL_2RuL' are obtained. With neutral ligands (L′ = nitriles, isonitriles, vinylidenes, allenylidenes) cationic species [*tripod*$CpL_2RuL']^+$ are formed. The reactivity of the template and its coordination compounds is similar to that reported for the non-chelate analogues $CpRuL_2$.[4][19]

Structural analyses of nine coordination compounds containing the *tripod*CpL_2Ru entity show that the conformation of the template is little affected by the nature of coligand bonded to it. The results also demonstrate that there is no great strain within the chelate cage. Nevertheless, the cage is rather rigid, such that inversion − which may be a problem in the reaction of non-chelate compounds of this type − cannot occur. Reactions of chiral versions of this template can thus be expected to allow for undisturbed diastereochemical control.

The barriers to rotation of the vinylidene fragments about their bonds to the *tripod*CpL_2Ru template amount to $\Delta H^{\neq}$ = 40.3 kJmol^{-1} in C=CMe(*t*Bu) and $\Delta H^{\neq}$ = 47.9 kJmol^{-1} in C=CMe(Ph), as estimated by means of ^{31}P-NMR spectroscopy. These values lie in a range typical for the rotation of such single-faced π-acceptors about their Ru−C bond in unstrained CpL_2Ru vinylidene compounds.

Experimental Section

General Remarks: Unless noted otherwise, all manipulations were carried out under argon by means of standard Schlenk techniques. All solvents were dried by standard methods[32] and distilled under argon. The solvents $CDCl_3$ and CD_2Cl_2 used for NMR spectroscopic measurements were degassed by three successive "freeze-pump-thaw" cycles and dried over 4 Å molecular sieves. − NMR: Bruker Avance DPX 200 at 200.12 MHz (^1H), 50.323 MHz ($^{13}C\{^1H\}$), 81.015 MHz ($^{31}P\{^1H\}$) or Bruker Avance DRX 500 at 500.13 MHz (^1H), 125.76 MHz ($^{13}C\{^1H\}$), 202.46 MHz ($^{31}P\{^1H\}$); at 303 K unless stated otherwise; chemical shifts (δ) in ppm with respect to residual solvent peaks as internal standards: $CDCl_3$ (^1H: δ = 7.27; ^{13}C: δ = 77.0); CD_2Cl_2 (^1H: δ = 5.32; ^{13}C: δ = 53.8). ^{31}P chemical shifts (δ) in ppm with respect to 85% H_3PO_4 (^{31}P: δ = 0) as external standard. − IR: Bruker IFS-66 spectrophotometer; KBr discs. − MS (EI): Finnigan MAT 8230: Fast-atom bombardment (FAB) with xenon; matrix: 4-nitrobenzyl alcohol. − HR-MS (EI): VG ZAB 2F and HR-MS (FAB) JEOL JMS 700; matrix: 4-nitrobenzyl alcohol. − Elemental analyses: Microanalytical Laboratory of the Organisch-Chemisches Institut, Universität Heidelberg. − Melting points: Gallenkamp MFB-595 010; values are not corrected. − Cyclic voltammetry: Metrohm "Universal Meß- und Titriergefäß", Metrohm GC electrode RDE 628, platinum electrode, SCE electrode, Princeton Applied Research potentiostat Model 273; substrate concentration 10^{-3} M in 0.1 M nBu$_4$NPF_6/CH_2Cl_2.

Crystallographic Structure Determinations: The measurements were carried out on a Siemens P4 four-circle diffractometer (for **3a**) or on an Enraf−Nonius Kappa CCD diffractometer, using graphite-monochromated Mo-K_α radiation throughout. In the case of the Siemens P4 four-circle diffractometer measurements, the intensities

[a] dec. = decomposition. – [b] HR-FAB. – [c] HR-EI. – [d] I: vapour diffusion of diethyl ether into a CH_2Cl_2 solution of the complex, 25°C. Ia: slow diffusion of diethyl ether into a DCE solution of the complex, 25°C. II: slow evaporation of the solvent from a $CDCl_3$ solution of the complex. III: a saturated CH_2Cl_2 solution of the complex (at 25°C) was crystallized at −20°C. – [e] As found in 4 different experiments.

of three check reflections (measured every 100 reflections) remained constant throughout the data collection, thus indicating crystal and electronic stability. The data collected on the Siemens P4 diffractometer were corrected as usual, including an experimental absorption correction. The data from the Enraf−Nonius Kappa CCD device were processed using the standard Nonius software.[33] All calculations were performed using the SHELXT PLUS software package. Structures were solved by direct methods with the SHELXS-97 program and refined with the SHELXL-97 program.[34] Graphical handling of the structural data during solution and refinement was performed with XPMA.[35] Atomic coordinates and anisotropic thermal parameters of the non-hydrogen atoms were refined by full-matrix least-squares calculations. Data relating to the structure determinations are collected in Table 7. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-127499 to CCDC-127507. Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) +44 (0)1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

Preparation of *tripod*CpL_2RuCl (1): $CH_3C(CH_2C_5H_4)(CH_2PPh_2)_2Li$ (613 mg, 1.2 mmol) was added to a solution of $RuCl_2(PPh_3)_3$[11] (959 mg, 1.0 mmol) in 1,2-dichloroethane[36] (20 mL). After heating for 3 h at 90°C, the solvent was evaporated in vacuo and the orange-brown residue was purified by chromatography on Al_2O_3 (Brockmann activity grade III). Elution with 500 mL of diethyl ether removed the PPh_3. Using a 1:1 mixture of CH_2Cl_2/diethyl ether, the product was then eluted in an orange fraction. Chromatography on SiO_2 using diethyl ether/CH_2Cl_2, 10:1, as eluent also afforded **1**, but it was not possible to remove traces of non-reacted $RuCl_2(PPh_3)_3$ and PPh_3 (produced during the reaction) by this method. The purity of the $RuCl_2(PPh_3)_3$ was seen to play an important role in determining the yields; 40−60% of **1** could be obtained as an orange powder, which was found to decompose at 228°C. For all other analytical data, see Table 8. From a CH_2Cl_2 solution of **1** saturated at 30°C, orange crystals could be collected after 8 weeks at 25°C.

Preparation of *tripod*CpL_2RuCO^+ (2): $TlPF_6$ (89 mg, 0.26 mmol) was added to a solution of **1** (144 mg, 0.23 mmol) in 10 mL of CH_2Cl_2. The solution was completely degassed by performing several freeze-pump-thaw cycles and was then saturated with CO. After 18 h, the mixture had become yellow, TlCl was filtered off, and the solvent was removed in vacuo. The residual yellow solid was washed with diethyl ether (3 × 20 mL) and dried in vacuo to give **2** (96%) as a yellow powder (decomposing at 248°C). For analytical data, see Table 8. – HR-FAB: calcd. 633.1050; found 633.1072.

Preparation of *tripod*CpL_2RuCN (3a): KCN (20 mg, 0.31 mmol) was added to a solution of **1** (150 mg, 0.23 mmol) in 10 mL of CH_3OH. After refluxing for 15 min, the solution became lemon-yellow. The solvent was then removed and the residue was filtered through a plug of SiO_2 (∅: 2 cm, *l*: 5 cm) using < 300 mL of ethanol. Removal of the solvent from the filtrate afforded **3a** (81%) as a lemon-yellow powder, which was found to decompose above 242°C. Crystals suitable for X-ray analysis were obtained by solvent diffusion from a saturated $CDCl_3$ solution of **3a** at 25°C. For analytical data, see Table 8. – HR-EI: calcd. 631.1132; found 631.1170.

A: General Procedure for the Synthesis of [*tripod*$CpL_2RuL']^+$ Complexes (L′ = nitrile, isonitrile, allenylidene, vinylidene, and carbene;

3c, 4a, 4b, 6, 7b, 7c, and 8): To methanol (20 mL) were added *tripod*CpL_2RuCl **1** (190 mg, 0.3 mmol) and NH_4PF_6 (100 mg, 0.61 mmol) to give an orange suspension. An excess of the appropriate nitrile, isonitrile, or alkyne (Table 14) was then added to the solution, which was subsequently stirred for up to 18 h at 25°C or for up to 1 h under reflux. When the reaction was complete, the reaction mixture had changed colour − yellow in the case of nitriles and isonitriles, red-brown or purple with alkynes. The solvent was then evaporated in vacuo and the residue was redissolved in CH_2Cl_2. The resulting solution was filtered to remove NH_4Cl and the excess NH_4PF_6. The solvent was then evaporated once more and the residual solid was washed with diethyl ether (3 × 10 mL) to give the PF_6 salt of [*tripod*CpL_2RuL']$^+$ in analytically pure form. For analytical data, see Tables 9 to 12.

B: General Procedure for the Synthesis of [*tripod*CpL_2RuL']$^+$ Complexes (L′ = vinylidene, η²-alkynyl; 7a, 5): To a suspension of *tripod*CpL_2RuCl **1** (190 mg, 0.3 mmol) and $TlPF_6$ (115 mg, 0.31 mmol) in CH_2Cl_2 (15 mL) was added a fivefold excess of the appropriate alkyne (Table 14). Upon stirring at 25 °C for 18 h, the initially orange solution became yellow. The reaction mixture was then filtered, the filtrate was concentrated in vacuo, and the residue was washed with diethyl ether (3 × 10 mL) to give the PF_6 salts of the corresponding [*tripod*CpL_2RuL']$^+$ complexes in analytically pure form. For analytical data, see Tables 10, 11, and 14.

C: General Procedure for Transformation of Vinylidene Compounds (7) into Alkynyl Compounds (9): To a solution of 0.25 mmol of the appropriate vinylidene compound in 10 mL of methanol, sodium methoxide solution (prepared by treating 5 mg of Na with 10 mL of methanol) was added dropwise over a period of 1 min. The solution immediately turned yellow. After stirring for 1 h at 25°C, the solvent was removed in vacuo. The residue was redissolved in CH_2Cl_2, the resulting solution was filtered, and the solvent was removed once more. The product was extracted with diethyl ether (3 × 10 mL) and was in each case obtained as a lemon-yellow waxy powder (Table 14). For analytical data, see Tables 13 and 14.

D: General Procedure for Alkylations: To a solution of 0.3 mmol of **3a** or **9** in 10 mL of CH_2Cl_2 was added 0.05 mL of $F_3CSO_3CH_3$. After stirring for 15−30 min at 25 °C, the resulting mixture became almost colourless in the case of **3a** and red in the case of **9**. After filtration, the filtrate was concentrated in vacuo and the residue was washed with diethyl ether (3 × 10 mL). For analytical data, see Tables 9, 12, and 14.

Acknowledgments

This work was supported by the German Science Foundation (SFB 247) and the Fonds der Chemischen Industrie. A generous loan of ruthenium(III) chloride from Degussa AG, Frankfurt, is gratefully acknowledged. We are indebted to Dr. J. Groß and Mr. T. Jannack for performing mass spectrometric measurements, to Mr. D. Günauer for carrying out cyclovoltammetric experiments, and to the staff of the microanalytical laboratory of the Organisch-Chemisches Institut der Universität Heidelberg for providing elemental analyses.

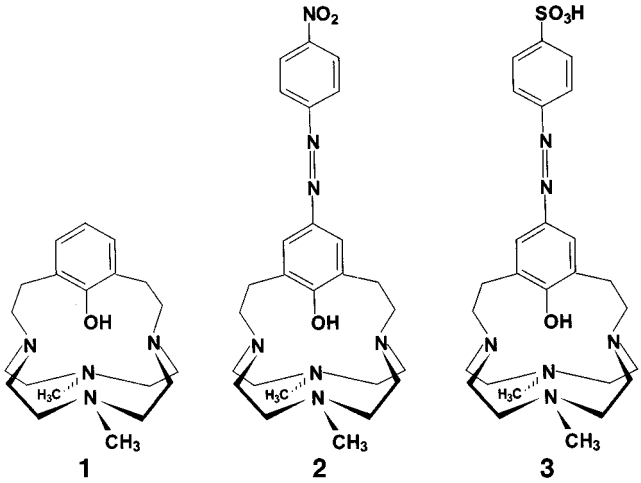
Synthesis, Crystal Structures and Lithium Encapsulation by Some Phenolic Aza Cages



Mauro Micheloni,*[a] Mauro Formica,[a] Vieri Fusi,*[a] Paolo Romani,[a] Roberto Pontellini,[a] Paolo Dapporto,[b] Paola Paoli,[b] Patrizia Rossi,[b] and Barbara Valtancoli[c]

Keywords: Cages / Synthesis / Lithium / Crystal structures / Chromophores

Three new macrocyclic cages **1**, **2** and **3**, able to selectively encapsulate the lithium ion, were studied. The synthesis and characterization of **2** and **3** are reported. The basicity behaviour of the three cages was investigated by spectrophotometry and by ^{1}H and ^{13}C NMR spectroscopy. The protonation constants were determined by potentiometric methods in aqueous solution (I = 0.15 mol dm^{-3} NMe_4Cl, T = 298 ± 0.1 K) and were found to be logK_1 = 11.67(5), 10.77(7), 11.17(7); logK_2 = 7.76(5), 5.7(1), 5.6(1); logK_3 = 1.3(1), 2.4(1), 1.9(1) for **1**, **2**, and **3**, respectively. The lithium equilibrium complex formation $Li^+ + L = LiL_{H-1} + H^+$ was monitored by ^{13}C and ^{7}Li NMR spectroscopy, as well as by spectrophotometric and potentiometric techniques; log values of –9.1(1) and –8.0(1) were found for **1** and **3**, respectively. For **2**, precipitation of the lithium complex occurs. UV/Vis studies in aqueous solution show a significant shift towards high energy of the λ_{max} in the lithium complex, indicating the potential for application of these ligands in colourimetric analysis. The crystal structure of **1** was examined by single crystal X-ray diffraction. Data collection was performed on two samples, namely **1a** and **1b**, obtained from two different crystallization procedures. Crystals of **1a** are monoclinic, space group $P2_1/n$, while **1b** crystallized in an orthorhombic space group $Pc2_1b$. The cell parameters are a = 12.423(3), b = 14.378(9), c = 28.436(7) Å, β = 93.74(2)° for **1a**, and a = 10.674(4), b = 14.408(2), c = 17.034(2) Å for **1b**. Molecular simulations were carried out on both conformational isomers **1a** and **1b**, with results indicating that the two isomers have essentially the same flexibility.

Introduction

Lithium is a very important element and is certainly one of the most studied alkaline earth metals.[1] Lithium derivatives are important in many fields, ranging from high-performance batteries to the treatment of patients affected by manic depression.[2–5] Lithium ions have also been shown to exert antiviral activity against DNA-type viruses,[6] although the mechanisms by which Li^+ is involved in biological systems are unknown. Neither the natural nor the synthetic molecules available to date are selective enough to preferentially bind lithium ions under physiological conditions. Furthermore, the similarity of their chemical behaviour to that of other alkaline metal ions[7] makes the design of ligands able to selectively bind the lithium ion in the presence of sodium in aqueous solution very challenging. In this paper, we report a study of three new compounds **1**, **2** and **3** (see Scheme 1) able to encapsulate the lithium ion in aqueous solution. These novel chromoionophores exhibit high selectivity for Li^+ over the other alkaline ions in water and in alcohol solutions, leading to changes in the optical properties of the chromophore. Compound **1** can be considered as the precursor of compounds **2** and **3** in which azo chromophores external to the molecular cavity have been added. The aim of this work was to investigate whether or not the chromophores were sensitive to the Li^+ binding.

Scheme 1. Ligand drawing

Results and Discussion

Equilibrium Studies

All macrocycles behave as triprotic bases (see Table 1), although they possess five protonation sites. One proton cannot be removed even at very high pH values. The ^{1}H NMR spectra of the neutral species carried out in $CDCl_3$

show a peak at δ = 10.1, 9.8 and 9.6 for the species **1**, **2**, and **3**, respectively, each integrating for one proton. These resonances were assigned to the deshielded acidic proton.[8−10] Upon addition of H_2O or CH_3OH to the chloroform solution, the signals did not disappear, indicating a slow exchange on the NMR time scale with the mobile protons of the solvent. Instead, the resonance disappeared when D_2O or CD_3OD was added. The value of the resonances, together with the experimental evidence, suggest that the proton is stabilized inside the macrocyclic cavity by a network of hydrogen bonds involving the phenolic and amine functional groups. The values of the stepwise basicity constants (see Table 1) indicate that all compounds are rather strong bases in the first, measurable step of protonation. Cage **1** is only slightly more basic than **2** and **3**; this is also true in the second basicity step: $\log K_2 = 7.76$ for **1** (see Table 1) versus $\log K_2 = 5.7$ and $\log K_2 = 5.6$ for **2** and **3**, respectively. The presence of bulky electron-withdrawing substituents on the aromatic ring in **2** and **3** but not in **1** may explain this moderate difference in basicity. In all three compounds, there is a marked decrease in the basic strength as the degree of protonation increases. This behaviour is expected for all aza cages,[11] in which positive charges are forced close to each other as a result of the molecular topology, thus making further addition of protons less energetically favoured.

The ^{13}C NMR spectrum recorded in D_2O at pH = 4, where the $[H_2\mathbf{1}]^{2+}$ species is prevalent in solution, showed twelve peaks, due to a reduced C_s symmetry in solution on the NMR time scale, instead of the expected C_{2v}.[12] Analysis of the spectrum revealed that the symmetry element lost is the plane passing through the bridgehead nitrogen atoms, while the other plane containing the nitrogen atoms, the methyl group and the phenolic oxygen atom is preserved. The ^{13}C NMR spectra of the triprotonated species of the other two ligands showed a similar pattern. This feature was attributed to the stiffened conformation of the protonated ligand that hinders the free interconversion of the phenolic fragment inside the macrocyclic cavity.

The involvement of the phenolic group in the protonation steps is well demonstrated by the UV/Vis absorption spectra of the ligands recorded at different pH values in water, as shown in Table 2. This spectral feature suggests that in the neutral species (L), the acidic proton is located on the tetraaza base, while the chromophore is in its anionic form. In fact, for all the ligands it was possible to observe a bathochromatic shift of the main wavelength from the acidic to the basic field. This different behaviour of the chromophore in the opposite pH fields for all the ligands can be attributed to the deprotonation of the phenolic group. The change in λ_{max} is due to the presence of the phenol hydroxy form at low pH values and to the phenolate form for **1**, or to the tautomeric hydrazone form for **2** and **3**.

Cage **1** shows a different behaviour in methanolic solution: The absorption spectra for the phenolic group do not change when the pH is varied from acidic to alkaline values, and the same wavelength and molar absorptivity (λ = 272 nm, ε = 1400 M^{-1} cm^{-1}) are conserved. In other words, the phenolic group always appears in its hydroxy form. This behaviour could be explained by the different solvation power of the two media, allowing the charge separation in water that is less favourable in methanol.

Table 1. Protonation and lithium equilibrium constants of **1**, **2** and **3** ($\log K$) in aqueous solution (298 ± 0.1 K, I = 0.15 mol dm^{-3} NMe_4Cl)

Reaction	**1**	**2**	**3**
$L + H^+ = HL^+$	11.67(5)[a]	10.77(7)	11.17(7)
$HL^+ + H^+ = H_2L^{2+}$	7.76(5)	5.7(1)	5.6(1)
$H_2L^{2+} + H^+ = H_3L^{3+}$	1.3(1)	2.4(1)	1.9(1)
$Li^+ + L = LiL_{H-1} + H^+$	−9.1(1)		−8.0(1)

[a] Values in parentheses are the standard deviation in the last significant figure.

Lithium Complexation

Direct potentiometric measurements indicate that compounds **1** and **3** bind lithium selectively (see Table 1). In the case of **2**, precipitation of the lithium complex prevents any equilibrium constant determination. The equilibrium constants reported in Table 1 for **1** and **3** refer to an overall process in which the Li^+ is bound and, at the same time, the last proton present in the cage is removed, yielding a neutral LiL_{H-1} species ($Li^+ + L = LiL_{H-1} + H^+$). Because the protonation constant involved is too high to be measurable in the absence of Li^+, as stated in the previous section, the stability constants relative to the neat complexation process $Li^+ + L_{H-1}{}^- = LiL_{H-1}$ can only be estimated. The $\log K$ for the process $H^+ + L_{H-1}{}^- = L$ should be significantly greater than 11.67 and 11.17 for **1** and **3**, respectively, and, because values of 9.1 and 8.1 (see Table 1) should be subtracted, a $\log K > 3$ is expected for the neat complexation process ($Li^+ + L_{H-1}{}^- = LiL$) for both cages.

The coordination of the alkaline metal ions by ligands **1**, **2** and **3** was also investigated by ^1H, ^{13}C and ^7Li NMR techniques. Using ^1H and ^{13}C NMR spectroscopy as a diagnostic technique, no evidence was found for complex formation with sodium and potassium ions in both aqueous and alcoholic solution. Instead, all the ligands readily bind the smallest Li^+ and the solid complexes were isolated as reported in the Experimental Section.

These solid compounds are soluble in organic solvents such as $CDCl_3$ and their ^7Li NMR spectra present a sharp peak, shifted by 1.0, 0.9, and 0.9 ppm downfield for **1**, **2**, and **3**, respectively, relative to that of the free ion. The ^7Li NMR spectrum of the $Li[Li\mathbf{3}_{H-2}]$ species in $CDCl_3$ presents another resonance at δ = 0, attributed to the lithium ion, which is not complexed due to the stoichiometry of the species; these chemical shift values were preserved in other solvents such as CD_3OD or CD_3CN. When an excess of Li^+ was added to an alkaline alcohol solution of **1** or **2**, the ^7Li NMR spectra also contained two peaks, one for the complexed and one for the free solvated ion. The presence of two types of lithium ion resonances indicates that the

ions do not exchange their positions on the NMR time scale.

The UV/Vis electronic experiments in aqueous solution revealed a shift toward higher energy of the maximum wavelength (λ_{max}) in the lithium complexes relative to those of the free amine (Table 2). The difference between the λ_{max} of the two spectra is 25 nm (see Table 2) for **2**, allowing a visible colour change. For **3**, the difference is smaller (18 nm), but still significant.

The UV/Vis absorption spectra demonstrated that for **1**, the last acidic proton is not removed even in strongly alkaline media. If we compare the ^{13}C NMR spectrum of the [Li**1**$_{H-1}$] species with that recorded in alkaline alcoholic solution for ligand **1** (see Figure 1), it is possible to observe the large downfield shift of a signal that can be assigned to the carbon atoms C-9 in the α position to the phenolic oxygen atom. An upfield shift of the aromatic signals of C-6 and C-8, β and γ, respectively, to the phenolic function in the complex was also evident. This behaviour confirms that in order to interact with the lithium ion, the macrocycles must lose the last acidic proton that in other conditions remains on the cage. This is also shown by the UV/Vis spectrum of the [Li**1**$_{H-1}$] compared with that of the free amine recorded in methanol solution. In fact, the free amine shows a λ_{max} at 272 nm while the [Li**1**$_{H-1}$] complex exhibits its λ_{max} at 302 nm. These data can be explained again by the deprotonation of the hydroxy group. It should be stressed once again that when other alkali metal ions were added to an alkaline alcoholic solution no changes in the spectral feature of the ligands were detected. In other words, the complexation does not occur in the presence of alkali ions different from Li^+, even at high concentrations, indicating that ligands **1**−**3** are able to completely discriminate Li^+ from the other alkali ions. This selectivity could be related to the small dimensions of the macrobicyclic cavity, in which larger ions cannot be encapsulated.

Table 2. UV/Vis spectra characteristics (λ_{max} and $\varepsilon[\lambda_{max}]$) of compounds **1**, **2** and **3** in aqueous solution at pH = 2, 12, > 12 and their lithium complexes

Compound	λ_{max} [nm] pH = 2	pH = 12	pH > 12	$\varepsilon[\lambda_{max}]$ M^{-1} cm^{-1} pH = 2	pH = 12	pH > 12

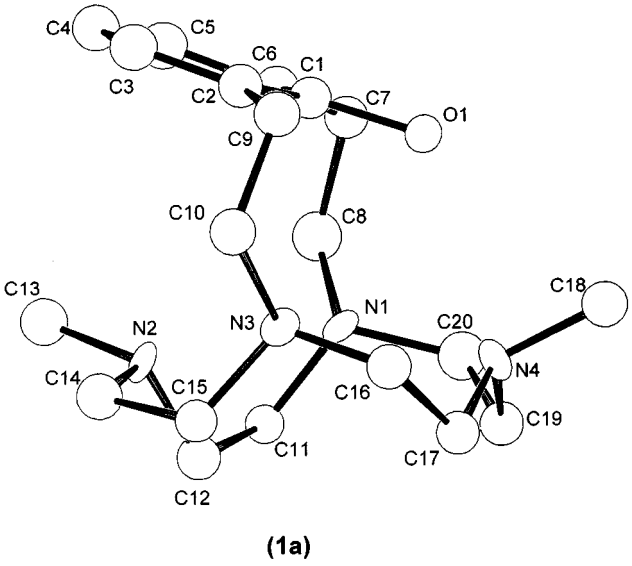
X-ray Structures

$C_{20}H_{38}N_4O{\cdot}2HClO_4$ (1a)

The crystal lattice is made up of $C_{20}H_{34}N_4O^{2+}$ cations $[H_2\mathbf{1}]^{2+}$ and perchlorate counterions; two independent $[H_2\mathbf{1}]^{2+}$ protonated ligands are present in the asymmetric unit. Several geometrical parameters characterising the 3D-arrangement of the two macrobicycles are reported in Table 3. The overall shapes of the two independent cations appear to be identical. As a consequence Figure 2 shows only one independent $[H_2\mathbf{1}]^{2+}$ cation. Interestingly, both cations show the same unusual sequence of torsion angles defining the conformation of the [12]aneN_4 ring, which was found to be of the [2334] type.[13] Analysis of the solid-state structures[14] collected in the Cambridge Structural Database[15] revealed that the [12]aneN_4 diprotonated ring always adopts a square C-corner[3333] conformation with only one exception ([2424] type[14b]), and as expected all the retrieved species are *trans*-diprotonated. In our case, the acidic hydrogen atoms were not localized; however, considering a *trans* disposition, the methylated nitrogen atoms appear to be the sites most likely to undergo protonation. In fact, taking into account the geometry of the fourth position at the nitrogen atoms, i.e. the distance between the two protons, this is the arrangement that best minimizes the electrostatic repulsion of the two positive charges. Given this disposition of the two protons, there would be, besides two pairs of N−H···N hydrogen bonds, an N4···O1 (N6···O2) hydrogen bond and a favourable interaction between the hydrogen atom on N2 (N8) and the aromatic ring. The line connecting the N2 (N8) with the C_6 centre of mass is almost perpendicular to the phenyl ring [80.2(5)°, 81.6(4)°] for the two independent cations.

Each oxygen atom of both the phenol moieties interacts with two oxygen atoms provided by two perchlorate counterions (O1···O16 3.23(2), O1···O18 2.87(2), O2···O12 3.11(2), O2···O11 2.93(2) Å).



$C_{20}H_{34}N_4O{\cdot}2HClO_4{\cdot}H_2O$ (1b)

The asymmetric unit is composed of one $C_{20}H_{34}N_4O^{2+}$ cation ($H_2\mathbf{1}^{2+}$), two ClO_4^- counterions and one water molecule. Figure 2 shows the structure of **1b** as determined by X-ray diffraction. The four nitrogen atoms N1, N2, N3 and

Table 3. Geometrical parameters characterizing compounds **1a** and **1b**[a]

N2−phenyl[b]	80.2(5)	81.6(4)	87.96(2)

[a] For the **1a′** cation we have: N5, N8, N7 and N6 instead of N1, N2, N3 and N4, respectively. − [b] Angle between the vector N2−centre of the phenol ring and the C_6H_5 plane.

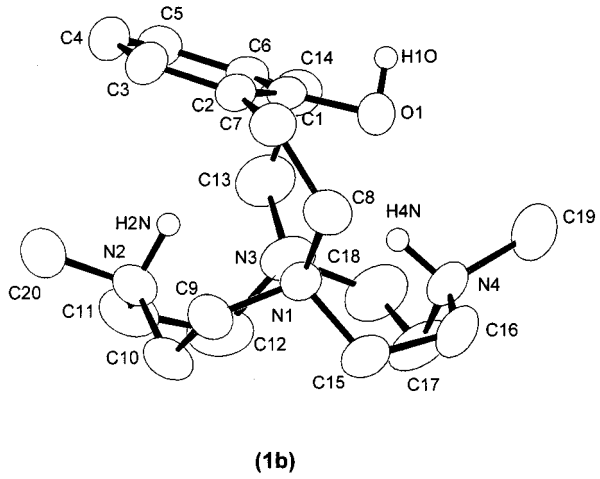

Figure 2. ORTEP view of the cations **1a** and **1b**; for sake of clarity, only one independent cation of the **1a** species is reported

N4 lie in a plane, with a maximum deviation of 0.121(6) Å (for N4) from the mean plane. The angle between the N_4 mean plane and that described by the phenyl ring is 15.5(1), with the hydrogen atom H1O directed out of the macrocyclic cavity.

Some short hydrogen bonds, involving the hydrogen atoms bonded to the N2 and N4 atoms, ranging from 1.92(7) to 2.8(1) Å (see Table 3) are present. In particular, the distance between the hydrogen atom H2N and the phenyl plane is rather short [2.3(1) Å] and the N2−H2N bond direction is almost perpendicular to the phenyl ring [87.96(2)°].[16] These interactions could confer a certain rigidity to the cation (see Figure 2). The macrocycle assumes a [3333] conformation, the most common for this type of ligand. The hydrogen atom H1O is outside the cavity and interacts with the oxygen atom of a water molecule [H1O···O10 2.46(8) Å] and with an oxygen atom of a perchlorate ion [H1O···O4 2.79(8) Å].

The shapes of the two conformational isomers (**1a** and **1b**) are similar, despite the different conformation of the [12]aneN_4 ring, as proved by the very similar values for the angles between the phenyl plane and the N_4 mean plane (see Table 3). The distance from N2 (N8 in **1a′**) to the phenyl plane is almost similar in all the structures, and the vector (N2−centre of the ring) is quite perpendicular to this plane for every isomer. Given this 3D similarity between **1a** and **1b**, the hypothesis about the localization of the protons in isomer **1a** appears to be likely.

Molecular Modelling Results

The first goal of the molecular modeling study was to gain some idea of the relative stability of the two conformational isomers of $[H_2\mathbf{1}]^{2+}$ found from the X-ray analyses. Geometric optimizations of **1a** and **1b**, starting from their solid-state structures and performed with both the force fields (CVFF and CFF91), maintained the original arrangement for the tetraaza ring as well as the orientation of the phenol arm. The two isomers were found to be almost isoenergetic once optimized by using CVFF, while the CFF91 potential shows a slight preference for the [3333] sequences of dihedrals which appears to be more stable by ca. 3 kcal.

Concerning the dynamics study, Table 4 reports the temperature of several MD runs performed on **1a** and **1b** using both the above-mentioned potential types. The aim was to test the conformational freedom of this cage, which could appear rather rigid, both due to the steric hindrance of the

phenol group and the network of hydrogen bonds. The analysis of the trajectories extracted during the MD runs underlined the fact that, in both the conformers, the phenol moiety can oscillate above the tetraaza ring, thus taking the hydroxy group into the other part of the cage in an equivalent position. It is worth noting that these results are in agreement with that found in the NMR solution experiments: the neutral species is more flexible than the triprotonated species.

Vacuum results show that using the CVFF force field, both **1a** and **1b** interconvert at 800 K. With the CFF91 force field, on the other hand, we noted that while **1a** already interconverts at 1300 K, 1400 K is needed to rearrange **1b**. Interestingly, the transition state reached during the rearranging of the [3333] cage (**1b**) was detected (T = 900 K, force field CVFF) (Figure 3). It is characterized by a [2334] sequence of torsions in the N_4-cyclododecane moiety, the phenol moiety being almost perpendicular to the N_4 mean plane (89°), with the hydrogen atom of the hydroxy group lying 0.3 Å out of the plane described by the bonded oxygen atom and the two bridgehead nitrogen atoms. Finally, the hydrogen atom of the hydroxy group is involved in a hydrogen bond interaction with one of the bridgehead nitrogen atoms (1.73 Å), while the oxygen atom comes into close contact with both the hydrogen atoms of the *N*-methylated groups (1.73 and 1.86 Å).

MD calculations performed in water show that both the conformational isomers interconvert at 1100 K with the CVFF force field and at 1300 K with the CFF91 one. It is noteworthy that the "umbrella" inversion affects a methylated nitrogen atom of both cations already at 800 K with the force field CVFF, 900 K with CFF91. To obtain some information about the relative flexibility of the two isomers, the mean square displacement (MSD) of two pseudoatoms defined as the geometric centre of the $N_4(CH_3)_2$ moiety and of the C_6H_5O group was monitored during each MD run: No significant trend was detected either in vacuo or in solvent, i.e., the flexibility of the two conformational isomers is nearly identical.

Table 4. Temperatures of the MD simulations performed with the CVFF and CFF91 force fields; the temperature at which the "interconversion" of the phenol group (see text) takes place is reported in bold

Conclusions

The molecular topology of compounds **1**−**3** is characterized by the presence of a three-dimensional macrocyclic cavity and of a chromophoric group sensitive to the lithium complexation and to the protonation step. It was possible to show that **1**−**3** do not lose the last acidic proton in aqueous solution under the experimental conditions used. Compound **1** shows different proton location in the neutral species in water or in alcoholic solution. All three ligands are able to selectively bind the lithium ion in either aqueous or alcoholic solution, exhibiting selectivity over the other alkaline metal ions. This remarkable selectivity is attributed to the small dimensions of the macrocyclic cavity, in which alkali metals larger than lithium cannot be encapsulated. The coordination of Li^+ perturbs the optical properties of the chromophore in solution, leading to a modification in the electronic absorption spectra. The colour change in aqueous solution for compounds **2** and **3** is in the range of the visible frequencies, while **1** undergoes a better variation in methanol solution. This behaviour provides an opportunity to use compounds **1**−**3** in reagents for colourimetric analysis. In instances where the extraction mode is applicable, all the chromoionophores can be used. In fact, all the solid lithium complexes isolated and characterized show high solubility in organic solvents such as $CHCl_3$.

Experimental Section

General Remarks: ^1H, ^{13}C and ^7Li NMR spectra were recorded with a Bruker AC-200 instrument, operating at 200.13, 50.33 and 77.78 MHz, respectively. In ^1H NMR experiments peak positions are reported relative to HOD (δ = 4.75) and dioxane was used as reference in ^{13}C NMR spectra (δ = 67.4). ^7Li peaks are reported relative to free $LiClO_4$. ^1H-^1H and ^1H-^{13}C correlation experiments were performed to assign the signals. Solvents and starting products were used as purchased. − Spectrophotometric measurements: Absorption spectra were recorded at 298 K with a Varian Cary-100 equipped with a temperature control unit. − Potentiometric measurements: All potentiometric measurements were carried out in 0.15 mol dm^{-3} Me_4NCl at 298.0 ± 0.1 K, in the pH range 2−11,

using the fully automatic equipment that has been already described.[17] The emf data were acquired with the PASAT computer program.[17] The electrode was calibrated as a hydrogen concentration probe by titrating known amounts of HCl with CO_2-free Me_4NOH solutions and determining the equivalence point by Gran's method,[18] which gives the standard potential $E°$ and the ionic product of water K_w. At least two or three measurements were performed. The HYPERQUAD[19] computer program was used to process the potentiometric data and to calculate the protonation constants. − Ligand synthesis: The synthesis of **1** has been already reported in ref.[12] For compounds **2** and **3**, the diazonium salts for the coupling reactions were freshly prepared and utilized following standard methods, starting from 4-nitroaniline or sulfanilic acid.

Synthesis of 2: A solution of **1** (346 mg, 1 mmol) in HCl (5 M, 20 mL) was cooled to 0° C and slowly added to a suspension at 0° C of diazonitrobenzene salt, freshly prepared from *p*-nitroaniline (138 mg, 1 mmol) in 30 mL of acidic water. The reaction was kept at room temperature and stirred for 2 h. The solution was made alkaline with an NaOH solution, and extracted with $CHCl_3$ (6 × 50 mL). The organic layers were collected, dried with anhydrous Na_2SO_4 and vacuum-concentrated to give an orange solid which was dissolved in ethanol and treated with 65% perchloric acid to give the diperchlorate salt of **2** as an orange solid. It was recrystallized from hot ethanol. Yield: 543 mg (78%). − ^{1}H NMR (D_2O, pH = 3): δ = 2.23 (s, 3 H), 2.71 (s, 3 H), 2.90 (m, 4 H), 3.25 (br., 8 H), 3.36 (br., 8 H), 3.45 (m, 4 H), 7.92 (s, 2 H), 7.93 (d, 2 H), 7.40 (d, 2 H). − ^{13}C NMR (D_2O, pH = 3): δ = 28.4, 43.8, 44.2, 49.4, 51.0, 55.0, 56.8, 58.0, 122.6, 126.5, 127.1, 135.3, 146.7, 148.4, 154.7, 157.4. − $C_{26}H_{39}Cl_2N_7O_{11}$ (695.21): calcd. C 44.83, H 5.64, N 14.08; found C 44.7, H 5.7, N 14.0.

Synthesis of 3: A solution of **1** (346 mg, 1 mmol) in HCl (5 M, 20 mL) was cooled to 0° C and slowly added to a suspension at 0° C of diazobenzensulfonate, freshly prepared from sulfanilic acid (173 mg, 1 mmol) in 30 mL of acidic water. The reaction was kept at room temperature for 2 h under constant stirring. The pH was adjusted to 9 and an orange solid was separated from the solution. The solid was dissolved in the minimum amount of ethanol and the solution treated with 65% perchloric acid to give the diperchlorate salt of **3** as an orange solid. It was recrystallized from hot ethanol. Yield: 534 mg (73%). − ^{1}H NMR (D_2O, pH = 3): δ = 2.04 (s, 3 H), 2.49 (br., 4 H), 2.79 (br., 8 H), 3.08 (br., 11 H), 3.38 (br., 4 H), 7.59 (s, 2 H), 7.69 (d, 2 H), 7.81 (d, 2 H). − ^{13}C NMR (D_2O, pH = 3): δ = 28.3, 42.3, 42.9, 49.6, 51.2, 55.4, 57.1, 58.8, 123.8, 125.2, 128.1, 134.5, 145.6, 148.7, 154.2, 159.1. − $C_{26}H_{40}Cl_2N_6O_{12}S$ (730.18): calcd. C 42.69, H 5.51, N 11.49; found C 42.6, H 5.6, N 11.3.

Preparation of the Complexes

[Li1] (4): A solution of LiOH (10 mg, 0.44 mmol) in methanol (15 mL) was added to a solution of **1**·2$HClO_4$ (55 mg, 0.1 mmol) in methanol (15 mL). The reaction mixture was stirred for 15 min and then concentrated to dryness. The yellow solid was suspended in $CHCl_3$ (20 mL) and the mixture was filtered to separate the inorganic excess. The organic solution was dried with Na_2SO_4. On addition of cyclohexane (25 mL), a white precipitate formed, yield 28 mg (79%). − ^{13}C NMR ($CDCl_3$): δ = 28.3, 42.7, 51.6, 56.3, 60.3, 122.7, 128.0, 134.2, 159.9. − $C_{20}H_{33}LiN_4O$ (352.28): calcd. C 68.16, H 9.44, N 15.90; found C 68.0, H 9.5, N 15.7.

[Li2] (5): This compound was synthesized from **2**·2$HClO_4$ (35 mg, 0.05 mmol) following the same procedure reported for **4** giving **5** as an orange solid, yield 21 mg (83%). − ^{13}C NMR ($CDCl_3$): δ = 28.5, 42.3, 43.4, 52.2, 55.7, 59.3, 61.4, 61.7, 123.5, 127.1, 127.6, 135.1, 145.3, 150.5 155.0, 161.2. − $C_{26}H_{36}LiN_7O_3$ (501.30): calcd. C 62.26, H 7.23, N 19.55; found C 62.1, H 7.1, N 19.3.

[$Li_2$3] (6): This compound was synthesized from **3**·2$HClO_4$ (37 mg, 0.05 mmol) following the same procedure reported for **4**, giving **6** as a violet solid, yield 19 mg (70%). − ^{13}C NMR ($CDCl_3$): δ = 30.8, 45.1, 52.0, 56.6, 59.3, 124.0, 126.9, 129.2, 134.2, 146.6, 148.2, 156.5, 160.4. − $C_{26}H_{36}Li_2N_6O_4S$ (542.28): calcd. C 57.56, H 6.69, N 15.49; found C 57.4, H 6.5, N 15.3.

Caution! Perchlorate salts of organic compounds are potentially explosive; these compounds must be handled with great care.

X-ray Crystallographic Studies: Crystallization procedure: Several attempts to obtain single crystals of $[H_2\mathbf{1}]^{2+}$ suitable for X-ray diffraction analysis were made. Finally, by slow concentration of an acidic H_2O/CH_3OH solution of $C_{20}H_{34}N_4O$(**1**)/$NaClO_4$, $[H_2\mathbf{1}]^{2+}$ single crystals were obtained. Unfortunately, the quality of the data was rather poor and a second crystallization attempt was needed. $C_{20}H_{34}N_4O$(**1**)/$NaClO_4$ was dissolved in an acidic water solution ($HClO_4$) and the solution was concentrated, affording single crystals suitable for X-ray analysis. − Crystal data and refinement details of structures **1a** and **1b** are reported in Table 5. Unit cell parameters and intensity data for compound **1a** were obtained with a Nonius CAD4 diffractometer, while for the second compound a Siemens P4 was used. Cell parameters were determined by least-squares fitting of 25 centered reflections for both structures. Intensity data were corrected for Lorentz and polarization effects. The structures were solved using the SIR-97 program[20] and subsequently refined by the full-matrix least-squares program SHELXL-93.[21] After this, absorption corrections were made using the Walker and Stuart's method.[22] The hydrogen atoms bonded to the carbon atoms were introduced in calculated positions in both cases, and their coordinates were refined in agreement with those of the linked atoms. For both structures, these hydrogen atoms were refined with an overall isotropic temperature factor [U = 0.089(7) Å^2 for **1a** and 0.074(4) Å^2 for **1b**]; the hydrogen atoms bonded to the oxygen atom and the two hydrogen atoms of the cation were not determined in structure **1a**, while in compound **1b** they were detected in difference syntheses and their positions were refined, as was the isotropic displacement parameter which converged to 0.09(3), 0.03(1) and 0.07(2) Å^2, for H2N, H4N and H1O, respectively. The hydrogen atoms of the water molecule in compound **1b** were not introduced. Atomic scattering factors and anomalous dispersion corrections for all the atoms were taken from ref.[23] Geometrical calculations were performed by PARST93.[24] The molecular plots were produced by the ORTEP program.[25] Crystallographic data (excluding structural factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-128541, -128542 for **1a** and **1b**. Copies may be obtained without charge from CCDC, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Molecular Simulations: Geometric optimizations (MM) and molecular dynamics (MD) simulations were performed on both the conformational isomers **1a** and **1b** found in the two X-ray diffraction measurements. In all cases, calculations were made by using two different force fields, CVFF and CFF91, both provided by Discover®,[26] with the aim of verifying that the behaviour of **1a** and **1b** does not depend on the force field used. Before starting the MD simulation, the geometry of each compound was optimized using the following routines: steepest descent, conjugate gradient and fi-

nally Newton-Raphson. The same sequence of algorithms was used for the molecular mechanics calculations. In the molecular dynamics, the equilibration procedure lasted 15 ps in all runs, after which the trajectories were monitored for 1500 ps, and snapshot conformations were saved every ps. MD simulations were carried out, under vacuum and in water, at different temperatures to gain some insight into the conformational freedom, i.e. the flexibility, of the two isomers (see Table 4); water calculations were performed mimicking the solvent by using a distance-dependent dielectric constant of 80.0. − Calculations were performed using the InsightII-Discover package supplied by MSI.[26] Molecular dynamics trajectories were analyzed and visualized by means of the Analysis module also provided by MSI. The computer program was implemented on a 3AT IBM computer.

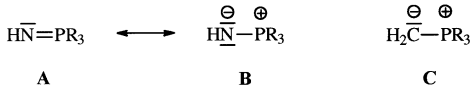
Transition Metal Complexes with Sulfur Ligands, 140[+]

Mononuclear Ni, Pd and Pt Complexes with $'S_3'^{2-}$ Thioether Thiolate and $HNPnPr_3$ Phosphorane Imine Ligands [$'S_3'^{2-}$ = Bis(2-mercaptophenyl)sulfide (2–)]

Dieter Sellmann,*[a] Franz Geipel,[a] and Frank W. Heinemann[a]



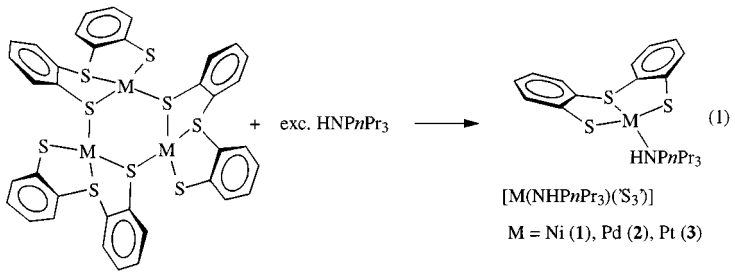
Dedicated to Professor Dirk Walther on the occasion of his 60th birthday

Keywords: Phosphorane imine / Sulfur ligands / Nickel / Palladium / Platinum

Reaction of the trinuclear $[M('S_3')]_3$ complexes {M = Ni (**4**), Pd (**5**), Pt (**6**); $'S_3'^{2-}$ = bis(2-mercaptophenyl)sulfide (2–)} with $HNPnPr_3$ yielded the new phosphorane imine complexes $[M(NHPnPr_3)('S_3')]$ {M = Ni (**1**), Pd (**2**), Pt (**3**)}. The complexes **1**–**3** have been completely characterized and are rare examples of mononuclear phosphorane imine complexes with late transition metals. Spectroscopic and structural results indicate that the $HNPnPr_3$ ligands favor the ylidic structure when binding to $[M('S_3')]$ fragments. X-ray structure determinations showed that $[M(NHPnPr_3)('S_3')]$ complexes associate through N–H···S(thiolate) bridges to give centrosymmetric dimers.

Introduction

Phosphorane imines $HNPR_3$ (R = alkyl, aryl), their *N*-organosubstituted $RNPR_3$ analogues and deprotonated phosphorane imide derivatives $[NPR_3]^-$ have proved to be versatile ligands. For example, $HNPR_3$ ligands can bind to metal centers in high, medium or low oxidation states, e.g. $[TiF_3(NPPh_3)(NHPPh_3)]_2$,[1] $[Zr_2Cl_4(NPMe_3)_4(NHPMe_3)]$,[2] $[Cp^*TaF_4(NHPPh_3)]$,[3] $[CoCl_2(NHPMe_3)_2]$,[4] $[PdCl(\eta^3\text{-}C_3H_5)(NHPPh_3)]$, $[Rh(CO)_2Cl(NHPPh_3)]$[5] and $[Mo_2(CO)_6(\mu\text{-}NHPPh_3)_3]$.[6] Phosphorane imides $[NPR_3]^-$, which are unstable in the free state and which can act as building blocks in numerous metal clusters, form as PR_3 adducts of nitrido or intermediary nitrene ligands, or can result from deoxygenation of nitrosylligands by phosphanes as demonstrated by complexes of the type $[MX(NPR_3)]_4$ (M = Mn, Co, Ni, Zn; X = Cl, Br, I),[7] $[NiCl(\mu^3\text{-}NH)(\mu^3\text{-}NPMe_3)(PMe_3)]$[8] and $[Mo(NPR_3)(NO)('S_4')]$[9] {R = alkyl, aryl, $'S_4'^{2-}$ = 1,2-bis(2-mercaptophenylthio)ethane (2−)}. The coordination chemistry of phosphorane imides has recently been reviewed.[10] Phosphorane imido metal complexes with terminal $[M-NPR_3]$ groups exhibit an interesting peculiarity which is still poorly understood. The M−N−P angle of such complexes can vary over a wide range from nearly 180° to almost 120°[10] as demonstrated by $[MoCl_4(NPPh_3)(pyridine)]$ {176.6(6)°}[11] and $[Mo(NPMePh_2)(NO)('S_4')]$ {129.7(4)°}.[12] As yet, it has not been possible to correlate unambiguously these angles with properties such as coordination number or oxidation state of the metal centers. Nevertheless, the structural variability of M−N−PR_3 groups suggests that NPR_3^- ligands are electronically flexible in the sense that they can act as two- or four-electron donors.[10] Electronic flexibility or ambiguity is also suggested for free $HNPR_3$ compounds by the valence bond formulae **A** and **B**.



A **B** **C**

While formula **A** indicates a double bond character for the PN bond, the dipolar formula **B** exhibits a PN single bond and emphasizes the isoelectronic nature of phosphorane imines and the phosphorane ylides **C**. A high-precision low-temperature neutron and X-ray diffraction study of $HNPPh_3$[13] did not yield structural evidence for the preference of either formula **A** or formula **B**. Our interest in phosphorane imine or imido complexes originates from reactions that transform small nitrogen-containing molecules into other compounds in the coordination sphere of sulfur rich molecules.[14] In this context, we noted that phosphorane imine complexes of the late transition metals are rare. The few examples known usually contain *N*-substituted $RNPR_3$ ligands such as in $[CuCl_2(Me_3SiNPMe_3)]_2$,[15] where removal of the nitrogen substituent leads to phosphorane imido clusters, for example, $[Cu_6Cl_6(NPMe_3)_4]^+$.[16] $[NiCl(PMe_3)(Ph_2P(o\text{-}C_6H_4)-N=PMe_3)]^+$ appears to be the first mononuclear nickel phosphorane imine complex described in the literature.[17] It was obtained only recently and contains an $N=PMe_3$ entity as part of a chelate ligand. $[NiBr_2\{HNP(NMe_2)_3\}_2]$ is the second example of mononuclear nickel phosphorane imine complexes

and was mentioned in the review article cited above.[10] Other mononuclear complexes of nickel, palladium and platinum with parent $HNPR_3$ imine ligands are unknown. We have now obtained such complexes from reactions of the trinuclear $[M('S_3')]_3$ complexes[18] {M = Ni, Pd, Pt, $'S_3'^{2-}$ = bis(2-mercaptophenyl)sulfide(2−)} with $HNPnPr_3$. The resulting $[M(NHPnPr_3)('S_3')]$ complexes were fully characterized and are described here.

Results and Discussion

Treatment of the trinuclear $[M('S_3')]_3$ (M = Ni, Pd, Pt) complexes with a slight excess of $HNPnPr_3$ yielded the mononuclear $[M(NHPnPr_3)('S_3')]$ complexes {M = Ni (**1**), Pd (**2**), Pt (**3**)} according to Equation 1.

In the course of the reactions, the black $[Ni('S_3')]_3$ or dark-red $[Pt('S_3')]_3$ complexes slowly dissolved and red-purple (Ni) or yellow (Pt) solutions formed, from which the corresponding $[M(NHPnPr_3)('S_3')]$ complexes were isolated in an analytically pure form. The complexes **1**−**3** readily dissolve in THF, acetone or CH_2Cl_2, but are only sparingly soluble in Et_2O, *n*-hexane, or CH_3CN. The IR spectra of **1**−**3** (KBr discs) exhibit the typical absorption patterns for the $[M('S_3')]$ fragments and, in addition, sharp ν(NH) bands of the $HNPnPr_3$ ligands in the region of 3273−3292 cm^{-1}. In comparison to the ν(NH) of free $HNPnPr_3$ (3367 cm^{-1}), the ν(NH) bands are slightly red-shifted. The complexes **1**−**3** are diamagnetic and yielded high-resolution NMR spectra. Figure 1 shows the ^1H NMR spectrum of **1**. The splitting pattern in the aromatic region is characteristic for $[M('S_3')]$ fragments and can be used as a diagnostic probe for monitoring these reactions.

The chemical shifts of the NH protons depend on the metal center binding the $HNPnPr_3$ ligand. In comparison to uncoordinated $HNPnPr_3$ with an NH signal at δ = −0.59 (CD_2Cl_2), the NH signals of the complexes (CD_2Cl_2) are either high-field shifted (**1**: δ = −1.85) or low-field shifted (**2**: δ = −0.03; **3**: δ = +0.54). Thus, within the series of complexes **1**−**3**, the NH protons are increasingly deshielded, possibly indicating an increasing NH acidity of the $HNPnPr_3$ ligands. The NH signals are slightly broadened and not split by $^2J_{H-P}$ coupling (down to temperatures of −60°C), although the NH signal of complex **3** exhibits a $^2J_{H-Pt}$ coupling constant of 41.5 Hz. The $^{13}C\{^1H\}$ NMR spectra exhibit only six signals for the twelve aromatic C atoms of the $'S_3'$ ligand, indicating a twofold symmetry of the $[M('S_3')]$ fragments. The NH chemical shifts are of interest with regard to the ylene structure **A** or ylide structure **B**. Protons at sp^2 hybridized N atoms in HN=X compounds (X = NH, CH_2, CR_2) such as diazenes, methylene imines or ketimines, are usually strongly low-field shifted (δ = 10−15), regardless of whether the HN=X species are in the free state or are coordinated to metal centers.[19] The NH signals of **1**−**3**, and of other diamagnetic $HNPR_3$ com-

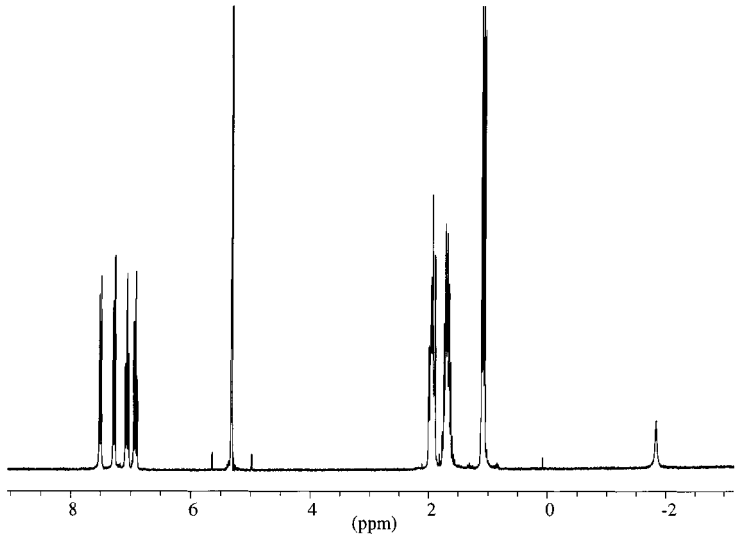

Figure 1. ^1H NMR spectrum of $[Ni(NHPnPr_3)('S_3')]$ (**1**) in CD_2Cl_2

plexes,[3,5,6] however, appear in the shift range typical of ammonia, amines, hydrazines etc. Thus the NH shifts of **1**−**3** seem to suggest the single bond formula **B** rather than the double bond structure **A** for complexed HNP*n*Pr$_3$.

X-ray Structure Determinations of 1−3

The molecular structures of all three complexes were determined by X-ray structure analyses. The crystals contain discrete molecules which, however, form dimers through N−H···S(thiolate) contacts. Figure 2 depicts their molecular structures and Table 1 lists selected distances and angles.

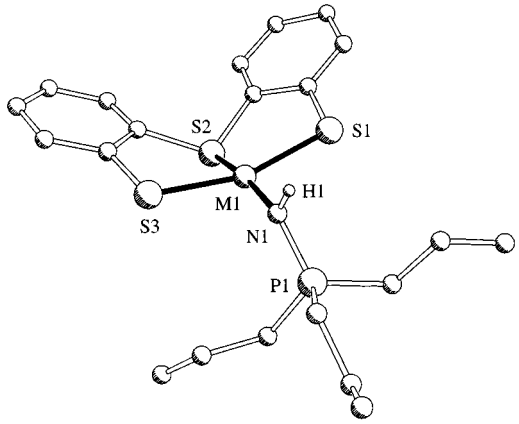

Figure 2. Molecular structure of [M(NHP*n*Pr$_3$)('S$_3$')] {M = Ni (**1**), Pd (**2**), Pt (**3**)}, (C bonded H atoms omitted)

N1−H1···S3a[a]	169(5)	165(5)	141

[a] Symmetry code: −x + 1, −y + 2, −z + 1

Complexes **1**−**3** are isostructural. The HNP*n*Pr$_3$ ligands coordinate through their N donors to the [M('S$_3$')] fragments. The resulting [MNS$_3$] core geometries are considerably tetrahedrally distorted and not strictly planar as would be expected for four-coordinate low-spin d^8 M^{II} centers. A comparison of the [N1−M1−S2] and [S1−M1−S3] angles in complexes **1**−**3** demonstrates that this distortion is most pronounced in the nickel complex **1**, which exhibits angles of 170.9(2)° and 161.77(6)°, respectively. This distortion is to a major extent caused by the topology of the 'S$_3$' ligand. The sp^3 hybridization of the central thioether S donor (S2) forces the [M('S$_3$')] fragments to adopt a butterfly-like conformation, in which the two 'S$_3$' benzene ring planes exhibit an average dihedral angle of 109°.

The M−S distances in the [M('S$_3$')] fragments lie in the ranges observed also for other Ni^{II}, Pd^{II} and Pt^{II} thioether thiolate complexes.[20] However, it should be noted that the M−S2(thioether) distances of **1** {211.6(2) pm}, **2** {221.75(9) pm} and **3** {220.8(4) pm} are relatively short and are smaller than the corresponding M−S(thiolate) distances. This is a significant feature of [M('S$_3$')] fragments and is probably caused by the steric constraints of the 'S$_3$' ligand.[18] The M−N distances of **1** {191.7(5) pm}, **2** {206.3(3) pm} and **3** {205.0(14) pm} indicate M−N single bonds, but are also relatively short. This is shown by comparing, for example, the Ni−N distances in **1** {191.7(5) pm}, the phosphorane imine complex [NiCl(PMe$_3$)(Ph$_2$P(*o*-C$_6$H$_4$)−N=PMe$_3$)]$^+$ {201.1(7) pm}[17] and the oligonuclear phosphorane imido complex [NiBr(NPMe$_3$)]$_4$ (av. 202.1 pm).[7c] The P−N distances of **1** {159.5(5) pm}, **2** {159.6(3) pm} and **3** {163(2) pm} are identical within the 3 σ criterion. Calculations on HNPMe$_3$[21] and the above mentioned diffraction study of HNPPh$_3$[13] indicate that such distances are compatible with formulae **A** and **B**. The M−N−P and the (less accurate) M−N−H angles of **1** {127.1(3)°, 118(5)°}, **2** {123.5(2)°, 116(4)°} and **3** {122.0(9)°} suggest, at first glance, sp^2 hybridization of the N donors. However, the angle sums around the N atoms of **1** (355.1°) and **2** (354.5°) show that the coordination geometry of the three-coordinate N donors is not strictly planar but slightly distorted to trigonal pyramidal.

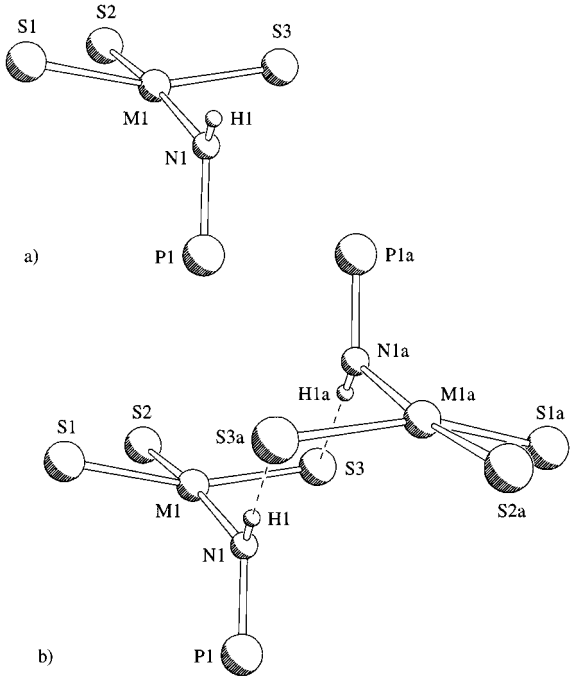

Figure 3. Views of (a) the core atoms of [M(NHP*n*Pr$_3$)('S$_3$')] (**1**−**3**), and (b) their dimerization through N−H···S(thiolate) bridges

Figure 3 illustrates the dimerization of [M(NHP*n*Pr$_3$)-($'S_3'$)] complexes through N−H···S(thiolate) bridges. The resulting dimers possess crystallographically imposed centers of inversion. The HNP*n*Pr$_3$ ligands coordinate to the [M($'S_3'$)] fragments in such a way that the NH bonds are approximately orthogonal to the [MNS$_3$] cores giving rise to N···S(thiolate) distances between two adjacent molecules of 366.0(5) pm in **1**, 368.7(3) pm in **2** and 367(2) pm in **3**. The corresponding H···S(thiolate) distances, which are shorter than the sum of the van der Waals radii (N = 155 pm, H = 120 pm, S = 180 pm),[22] and the N−H···S directionality (see Table 1), indicate hydrogen bonding. Inter- and intramolecular hydrogen bonds between HNPR$_3$ and chloride or iodide co-ligands have previously been suggested in [CdI$_2$(NHPPh$_3$)$_2$]$_2$[23] and [Cp*$_2$UCl$_2$-(NHPPh$_3$)].[24]

Conclusions

Three new phosphorane imine complexes have been synthesized and characterized. The complexes **1**−**3** are rare examples of mononuclear phosphorane imine complexes containing late transition metals. In addition, **1**−**3** contrast with previously reported complexes as their metal coordination spheres contain only sulfur donors, apart from the HNPR$_3$ ligand. Coordination of HNP*n*Pr$_3$ to the [M($'S_3'$)] fragments causes a considerable stabilization of HNP*n*Pr$_3$ towards hydrolysis. ^{1}H NMR spectroscopic data and the X-ray crystal structures indicate that HNP*n*Pr$_3$ favors the ylidic structure **B** when binding to [M($'S_3'$)] fragments. Studies are underway to evaluate the synthetic potential of the NH group and the influence of the electron-rich sulfur donors upon the reactivity of the HNP*n*Pr$_3$ ligands

Experimental Section

General: Unless stated otherwise, all reactions and manipulations were carried out under nitrogen using standard Schlenk techniques. Solvents were dried and distilled before use. As far as possible, reactions were monitored by IR or NMR spectroscopy. Spectra were recorded on the following instruments: IR (KBr discs or CaF_2 cuvettes, solvent bands were compensated) Perkin−Elmer 983, 1620 FT IR or 16PC FT-IR. NMR: Jeol-JNM-GX 270, EX 270 or Lambda LA 400 with the protio-solvent signal used as an internal reference. Chemical shifts are quoted on the δ scale (downfield shifts are positive) relative to tetramethylsilane (^{1}H, ^{13}C{^{1}H} NMR) or 85% H_3PO_4 (^{31}P{^{1}H} NMR). Spectra were recorded at 25°C. Mass spectra: Jeol MSTATION 700 spectrometer. Elemental analyses: Carlo Erba EA 1106 or 1108 analyzer. The starting [M($'S_3'$)]$_3$ complexes {M = Ni (**4**), Pd (**5**), Pt (**6**)}[18] and HNP*n*Pr$_3$ (**7**)[25] were prepared by literature methods.

[M(NHP*n*Pr$_3$)($'S_3'$)] (M = Ni, Pd, Pt). − General Procedure: HNP*n*Pr$_3$ (**7**) was added to suspensions of **4**−**6** in 10 mL of THF. The reaction mixtures were stirred for 12 h at room temperature yielding red-purple, red-brown, or yellow solutions. Undissolved traces of white material were removed by centrifugation. The solutions were reduced in volume to about 2 mL, layered with 10 mL of acetonitrile and cooled to −30°C. Precipitated microcrystals were separated after one week, washed with 10 mL of acetonitrile and dried in vacuo.

[Ni(NHP*n*Pr$_3$)($'S_3'$)] (1): Synthesised from **4** (510 mg, 0.55 mmol) and **7** (0.48 mL, 2.20 mmol) to give **1** as red-purple microcrystals. Yield: 424 mg (53%). − $C_{21}H_{30}NNiPS_3$ (482.32): calcd. C 52.30, H 6.27, N 2.90, S 19.94; found C 52.69, H 6.36, N 3.08, S 18.34. −

Table 2. Selected crystallographic data of [Ni(NHP*n*Pr$_3$)($'S_3'$)] (**1**), [Pd(NHP*n*Pr$_3$)($'S_3'$)] (**2**) and [Pt(NHP*n*Pr$_3$)($'S_3'$)] (**3**)

X-ray Structure Analyses of [Ni(NHP*n*Pr$_3$)(′S$_3$′)] (1), [Pd(NHP*n*Pr$_3$)(′S$_3$′)] (2) and [Pt(NHP*n*Pr$_3$)(′S$_3$′)] (3): Dark red rhombohedra were obtained by slowly evaporating a concentrated acetone solution of **1**. Red single crystals were formed by layering a CD_2Cl_2 solution of **2** with *n*-hexane. Yellow single crystals were grown by slowly evaporating a concentrated THF solution of **3**. Suitable single crystals were sealed under N_2 in glass capillaries. Data were corrected for Lorentz and polarization effects. For **2** and **3** absorption effects have been corrected using Psi-scans (see Table 2), while for **1** absorption effects have been neglected. The structures were solved by direct methods (SHELXTL 5.03[26]). Full-matrix least-squares refinement was carried out on F^2 (SHELXTL 5.03). All non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms of **1** and **2** were taken from the difference Fourier map and were either refined isotropically **1** or kept fixed with a common isotropic displacement parameter **2**. In the case of **3** the hydrogen atoms were geometrically positioned with isotropic displacement parameters fixed at 1.5 times *U*(eq) of the preceding carbon atom. Selected crystallographic data are summarized in Table 2.[27]

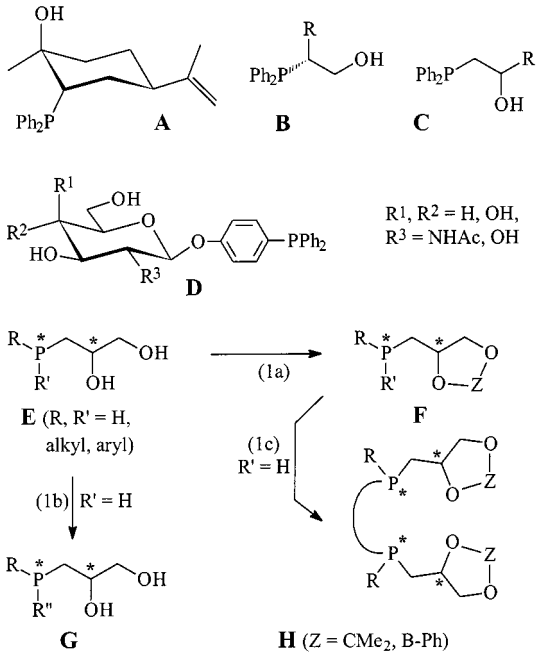
Water-Soluble Phosphanes, 11[+]

Syntheses and Coordination Chemistry of Chiral Phosphanyl Glycerols and Their Derivatives – X-ray Structure of (*R*)-$Ph_2P–CH_2–C^aH–O–B(Ph)–O–C^bH_2$($C^a$–$C^b$)

David J. Brauer,[a] Peter Machnitzki,[a] Thomas Nickel,[a] and Othmar Stelzer*[a]



Dedicated to Professor Dr. R. Schmutzler on the occasion of his 65th birthday

Keywords: (*R*)-(+)-2,3-Epoxy-1-propanol / 2,3-Dihydroxyalkyl phosphanes / 1,3,2-Dioxaborolane / 1,3-Dioxolane ring / Enantiopure phosphanes / Complexes

Reaction of (*R*)-(+)-2,3-epoxy-1-propanol with Ph_2PH, Ph(Me)PH, or $PhPH_2$ in the superbasic medium KOH/DMSO affords the novel chiral phosphanes **1a**–**1c**. While **1a** is obtained enantiomerically pure, **1b** and the secondary phosphane **1c** are formed as mixtures of diastereoisomers (R_PR_C, S_PR_C) with homochiral β carbon atoms. Derivatization of **1a** with phenylboronic acid or 2,2-dimethoxypropane yields **2a** and **3a** with 1,3,2-dioxaborolane and 1,3-dioxolane ring systems, respectively. The X-ray structure of **2a** (space group $P2_1$) reveals the presence of four molecules of *R* configuration in the unit cell. Nucleophilic phosphanylation of (*R*)-(–)-2,3-*O*-isopropylideneglycerol tosylate with Ph_2PH, Ph(Me)PH, or $PhPH_2$ yields chiral **3a**–**3d**. Compound **3b** was obtained enantiomerically pure. The secondary phosphane **3c** has been employed in syntheses of the hydrophilic tertiary phosphanes **3e**, **3f** and of the novel bidentate phosphane ligands **3g**, **3h**, all of which have homochiral β carbon atoms. Pd^{II} complexes PdL_2Cl_2 of **1a**, **2a**, **3a** (L) are formed as mixtures of *cis*/*trans* isomers. Rh^I complexes of **1a**, **3a**, and bidentate **3h** have also been synthesized.

Functionalized hydrophilic phosphanes have attracted considerable interest in recent years, mainly because of their application as ligands in catalytically active coordination compounds and organometallic complexes.[2] The hydrophilic character was introduced by modification of the neutral phosphane ligands with polar groups.[3–5] The concept of attaining hydrophilicity by incorporation of hydroxyl groups at the periphery of the ligands has attracted much less attention.[6a] Chiral and achiral ligands containing monohydroxylated alkyl groups, e.g. **A**, have been obtained by addition of phosphides to oxiranes.[6b,6c] These reactions proceed with high regioselectivity,[7a,7b] i.e. the phosphorus nucleophile attacks preferentially at the least substituted carbon atom of the epoxide ring system. Using enantiopure epoxides obtained by Sharpless epoxidation[6d] of allyl alcohols, optically active hydroxylated phosphanes have been obtained by this method.[6e] The experimentally observed preference for inversion of configuration at the carbon atom attacked in the nucleophilic ring-opening of epoxides has been supported by theoretical studies.[7b]

Enders and Berg[8] developed a multi-step synthesis of optically active 2-hydroxyalkyl diphenylphosphanes (*R*)-$Ph_2P–CH(R)–CH_2–OH$ (**B**) starting from simple aldehydes. Kinetic resolution of the racemate of $Ph_2P–CH_2–CH(OH)R$ (**C**) (R = Me, Et, *n*Pr) through acylation with isopropenyl acetate under rabbit gastric lipase catalysis yielded the corresponding ligands in enantiomerically enriched form. Hydrophilic hydroxyalkylphosphanes containing carbohydrate moieties (**D**) have also been reported.[10]

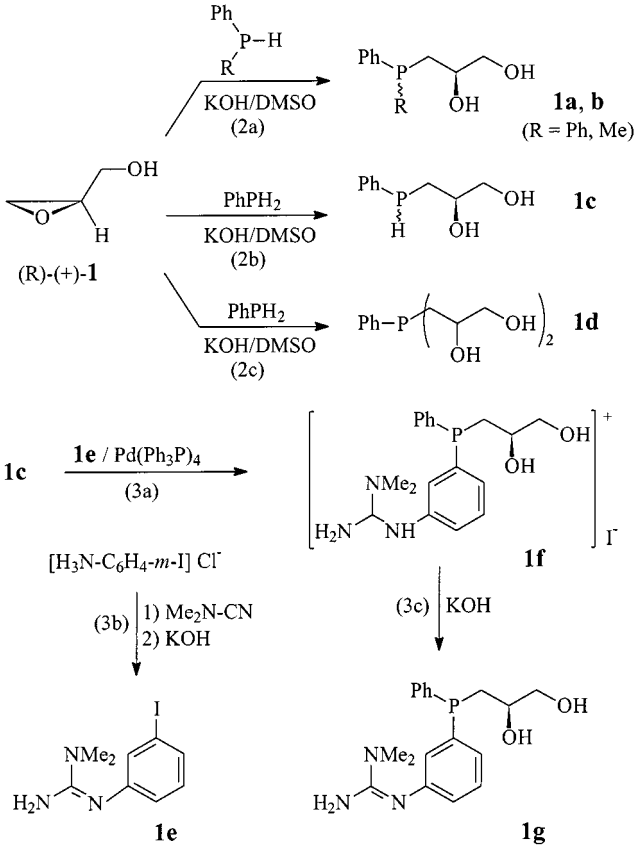
Their dual functionality renders hydroxyalkylphosphanes hemilabile (P,O) ligands,[11] which are of great potential in homogeneous catalysis. Their physical properties may be tuned by derivatization of the OH groups.[12] The introduction of additional OH groups in vicinal positions and functionalization of the phosphorus atoms (**E**, R′ = H) add further interesting possibilities in the context of a systematic ligand tailoring, allowing the formation of 1,3-dioxolane and 1,3-dioxaborolane ring systems at the 1,2-diol moieties (**F**) (Equation 1a) and P−C coupling reactions to yield chiral mono- or bidentate tertiary phosphane ligands (**G**, **H**) (Equations 1b, 1c).

We report herein on the synthesis of ligands of type **E** and their derivatives **F**−**H**, which may formally be derived from glycerol by replacement of a terminal OH group by a phosphanyl substituent ("phosphanyl glycerols").

Results



Chiral Phosphane Ligands with 2,3-Dihydroxypropyl Substituents

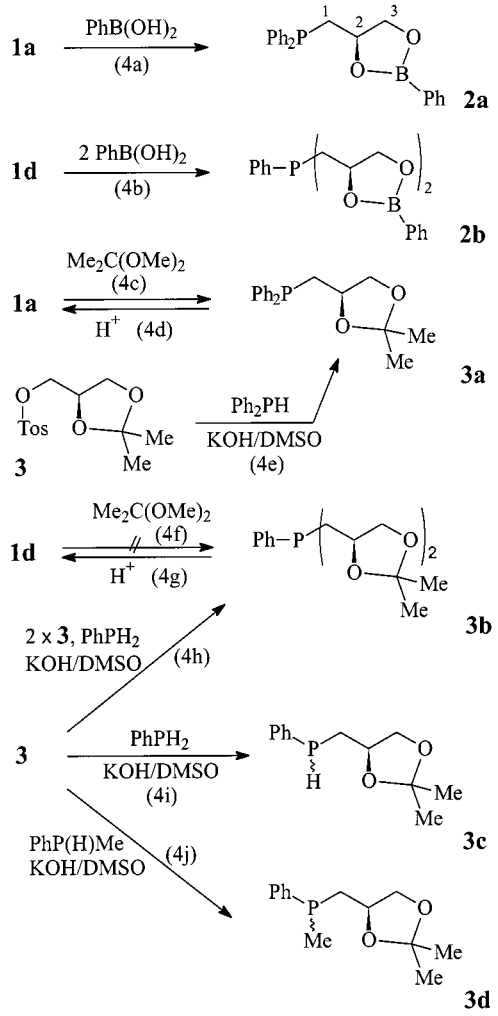
The synthesis of type **E** ligands containing 2,3-dihydroxypropyl substituents was achieved by nucleophilic opening of the epoxide ring system in glycidol (2,3-epoxy-1-propanol, **1**) using primary or secondary phosphanes in the superbasic medium DMSO/KOH.[13] Thus, **1a** and **1b** were formed in high yields by reaction of Ph_2PH[14a] or Ph(Me)PH[14b] with racemic **1** under these conditions (Equation 2a).

While **1a** shows only one signal at δP = −21.2 in its $^{31}P\{^1H\}$-NMR spectrum, **1b** with two centers of chirality (P, β-C) exhibits two resonances (δP = −39.1, −41.0, intensity ratio 1:1), which may be assigned to the *erythro* and *threo* isomers (R_PR_C/S_PS_C and R_PS_C/S_PR_C). Optically active **1a** {$[\alpha]_D^{20}$ = −19.4° (*c* = 1.3, CH_2Cl_2), δP = −21.2} is formed if commercially available (*R*)-(+)-**1** ($[\alpha]_D^{23}$ = +12°, neat, enantiomeric purity ≈98% *ee*) is employed in this reaction. This has been established from analysis of the $^{31}P\{^1H\}$-NMR spectrum of the disubstituted Pd complex **4** of **1a** (see below). Due to the chiral carbon atom in the β-position, the phenyl groups of the Ph_2P substituent in **1a** are non-equivalent, as indicated by the observation of two sets of resonances for the *ipso*, *ortho*, and *meta* carbon atoms in the $^{13}C\{^1H\}$-NMR spectrum.

The technique developed for the syntheses of **1a** and **1b** can also be used to prepare secondary phosphanes containing 2,3-dihydroxypropyl substituents with chiral β carbon atoms. Thus, reaction of $PhPH_2$[14c] with one equivalent (*R*)-(+)-glycidol gave **1c** in high yields (Equation 2b). The $^{31}P\{^1H\}$-NMR spectrum of **1c** features two resonances of about equal intensity at δP = −63.05 and −63.39, which may be assigned to the *erythro* and *threo* isomers. Under proton coupling, these signals are split into doublets [$^1J(^{31}P\text{-}^1H)$ = 212 Hz] showing additional fine structure [^nJ(PH), *n* = 2, 3].

Treatment of $PhPH_2$ with two equivalents of racemic **1** gave the tertiary phosphane **1d** as a mixture of three diastereoisomers (two *meso* forms and an enantiomeric pair; $^{31}P\{^1H\}$-NMR spectrum: δP = −32.8, −33.8, −34.4, intensity ratio 1:2:1) (Equation 2c). An analogous effect of two asymmetric carbon centers in the α- or β-positions on the $^{31}P\{^1H\}$-NMR spectra of chiral secondary phosphanes with $H-P(-C^*-C-)_2$ or $H-P(-C-C^*-)_2$ skeletons has been reported.[15] If (*R*)-(+)-**1** is employed instead of racemic **1**, one diastereoisomer of **1d** with homochiral β carbon atoms is formed {$[\alpha]_D^{20}$ = −25.7° (neat); −11.0° (*c* = 10, MeOH)}, which shows a single resonance at δP = −33.8 in its $^{31}P\{^1H\}$-NMR spectrum. Signals of low intensity (ca. 3% of the main signal) at δ = −32.8 and −34.4 may be assigned to the *meso* forms obtained, since the enantiomeric purity of (*R*)-(+)-**1** was only 97% *ee*. The formation of **1d** evidently proceeds with high stereoselectivity. However, in order to achieve a complete transformation of $PhPH_2$ and the intermediate secondary phosphane **1c** to **1d**, an excess of **1** or (*R*)-(+)-**1** (ca. 10−15%) had to be applied. The excess **1** and side-products formed during the reaction could not be completely separated by distillation due to the thermal instability of **1d**.

Scheme 1



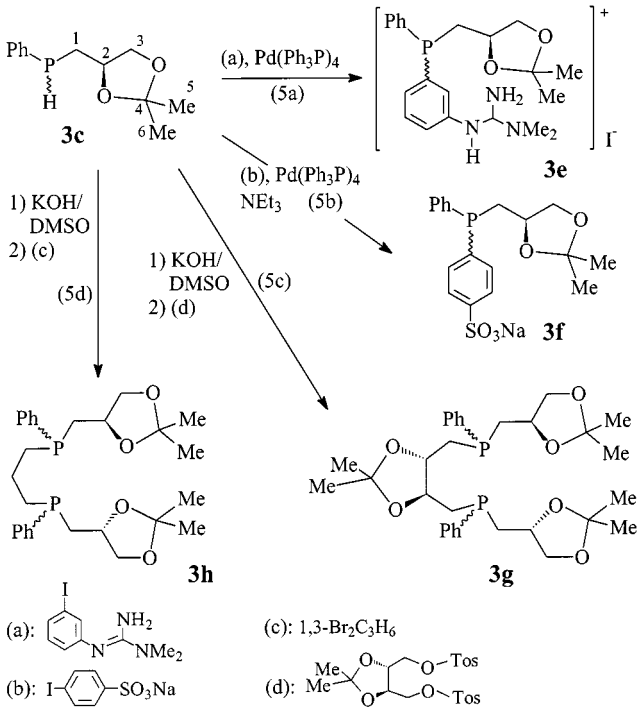
The secondary phosphane **1c** can be used as a building block for the synthesis of tertiary phosphanes containing dihydroxylated propyl substituents with chiral carbon and phosphorus atoms. In the context of a research program aimed at the development of chiral, water-soluble phosphanes for two-phase catalysis, the introduction of substituents bearing polar cationic or anionic groups was of pri-

mary interest.[5b] Nucleophilic phosphanylation[16a] or Pd-catalyzed P−C coupling,[16b,17] as developed earlier by us, could be used as the fundamental synthetic principles. Thus, reaction of **1c** with the iodophenyl guanidine **1e**[18] in the presence of a catalytic amount of $Pd(Ph_3P)_4$[19] gave the guanidinium phosphane **1f** (Equation 3a). In order to isolate it from the reaction mixture and to allow its further purification, **1f** was deprotonated with KOH to give the neutral guanidinophosphane ligand **1g** (Equation 3c). **1e** was obtained from 3-iodoanilinium chloride by reaction with Me_2NCN and subsequent deprotonation of the intermediate guanidinium salt with KOH.[18]

Direct and Indirect Derivatization of 1a, 1c, and 1d

The 2,3-dihydroxypropyl substituents and the PH functionality in **1a**−**1d** offer numerous possibilities for fine tuning of their ligand properties.

Chiral ligands **2a**, **2b** bearing Lewis acidic sites are accessible by reaction of enantiomerically pure **1a** or **1d**, respectively, with phenylboronic acid (Equation 4a, 4b). This access to aromatic boronate esters has been exploited in the synthesis of boron analogues of DIOP by Fields and Jacobsen.[20]



Scheme 2

The formation of **2a** from enantiopure (*R*)-(−)-**1a** proceeds with retention of configuration at the β carbon atom (see X-ray structural analysis of **2a**). The $^{31}P\{^1H\}$-NMR spectrum of **2b** features an intense signal at δP = −37.39 corresponding to the main (*RR*)-isomer. Additional resonances of low intensity at δP = −36.41 and −39.57 may be assigned to the two *meso* forms of **2b**, derived from the *meso* isomers present in the starting material **1d** (see above). If racemic **1d** is employed in this reaction (Equation 4b), a 1:2:1 mixture of three diastereoisomers of **2b** is obtained, which gives rise to resonances at δP = −36.46, −37.42, and −39.60 in the $^{31}P\{^1H\}$-NMR spectrum.

Ketalization of optically active **1a** with 2,2-dimethoxypropane using *p*-toluenesulfonic acid as catalyst yields (*R*)-(+)-2,3-*O*-isopropylideneglycerol-1-diphenylphosphane **3a** (Equation 4c). However, attempts to synthesize oligofunctional **3b** by ketalization of **1d** were not successful, a multi-component mixture being formed (Equation 4f). The phosphane ligand (*R*)-(+)-Glyphos (**3a**) was first prepared by Brunner and Leyerer[21a] in moderate yield by reaction of Ph_2PK in dioxane with (*R*)-(−)-2,3-*O*-isopropylidene-1-glycerol tosylate **3**. Very recently, Kerr et al.[21b] published an analogous synthetic procedure for (*R*)-(+)-Glyphos starting from D-mannitol. We have now found that this ligand may be obtained much more easily and in substantially higher yields by nucleophilic phosphanylation of enantiomerically pure (*R*)-(−)-**3** with Ph_2PH in the superbasic medium DMSO/KOH (Equation 4e). Using this methodology, the tertiary and secondary phosphanes **3b**−**3d** have also been prepared by employing $PhPH_2$ or Ph(Me)PH and (*R*)-(−)-**3** as the starting materials (Equations 4h−4j). **3b** shows only one signal (δP = −35.57) in its $^{31}P\{^1H\}$-NMR spectrum, indicating that it is formed stereoselectively [(*R,R*)-isomer] according to Equation 4h. In **3b**, with homochiral β carbon atoms, the two CH_2−P, CH−O, and CH_2O groups are non-equivalent. Compared with the spectra of **3a**, a doubling of the line patterns in the ^1H- and $^{13}C\{^1H\}$-NMR spectra is therefore observed.

The phosphanes **3c** and **3d** with two centers of chirality give rise to two $^{31}P\{^1H\}$-NMR signals [δP = −62.94, −63.44 (**3c**): δP = −38.96, −41.22 (**3d**)], which, in the case of **3c**, are split into doublets under proton coupling [^1J(PH) = 211.1 or 208.6 Hz]. The isopropylidene protecting group in **3a** may be cleaved by reaction with small amounts of *p*-toluenesulfonic acid, leading to the formation of **1a** without loss of optical activity (Equation 4d). Very recently, this method has been used by Brunner and Rückert[22] for the synthesis of **1a** using **3a** as starting material.

The PH functionality renders **3c** a valuable synthon for the preparation of further functionalized mono- or bidentate phosphanes. The bidentate ligand **3h** was thus obtained by alkylation of **3c** using 1,3-dibromopropane in the superbasic medium DMSO/KOH (Equation 5d). As evidenced by the $^{31}P\{^1H\}$-NMR spectrum, **3h**, with homochiral β carbon atoms, is formed as a mixture of three diastereoisomers ($R_CR_PR_PR_C$, $R_CS_PS_PR_C$, and $R_CR_PS_PR_C$), two of them ($R_CR_PR_PR_C$, $R_CS_PS_PR_C$) with equivalent (δP =

Scheme 3

−29.81, −31.46, respectively) and one ($R_CR_PS_PR_C$) with chemically non-equivalent phosphorus atoms [δP = −29.68, −31.32, ^4J(PP) = 1.0 Hz]. The value observed for ^4J(PP) is typical for long-range coupling constants (0−5 Hz) in trimethylene-bridged diphosphorus compounds.[23] If (*R,R*)-(+)-1,4-di-*O*-*p*-toluenesulfonyl-2,3-*O*-isopropylidene-D-threitol is used instead of 1,3-dibromopropane for coupling to **3c**, the bidentate ligand **3g** is obtained as a mixture of three diastereoisomers [$R_CR_P(S_C)_2R_PR_C$, $R_CS_P(S_C)_2S_PR_C$, $R_CR_P(S_C)_2S_PR_C$], in one of which [$R_CR_P(S_C)_2S_PR_C$] the P atoms are non-equivalent, as reflected in the $^{31}P\{^1H\}$-NMR spectrum (Equation 5c).

Derivatization of **3c** is also possible by means of Pd-catalyzed P−C coupling reactions with iodoaromatic compounds.[16b,17] Thus, on reaction of **3c** with iodophenyl guanidine **1e**, the cationic phosphane ligand **3e** is obtained in high yield (Equation 5a). Using sodium *p*-iodobenzenesulfonate[24] in the presence of NEt_3, the anionic phosphane **3f** is formed (Equation 5b). **3e** and **3f** are obtained as mixtures of diastereoisomers.

X-ray Structure of (*R*)-$Ph_2P-CH_2-C^aH-O-B(Ph)-O-C^bH_2$ [*C*^{a}−*C*^{b}]

Crystals suitable for X-ray structural analysis were obtained by recrystallization of (*R*)-(+)-**2a** from ethanol. The unit cell of the crystal of **2a** (space group $P2_1$) used for the X-ray analysis contains two crystallographically independent molecules forming pairs of antiparallel oriented molecules A and B both showing (*R*) configuration at the β carbon atom. The numbering scheme for **2a** and selected bond lengths and angles are collected in Figure 1.

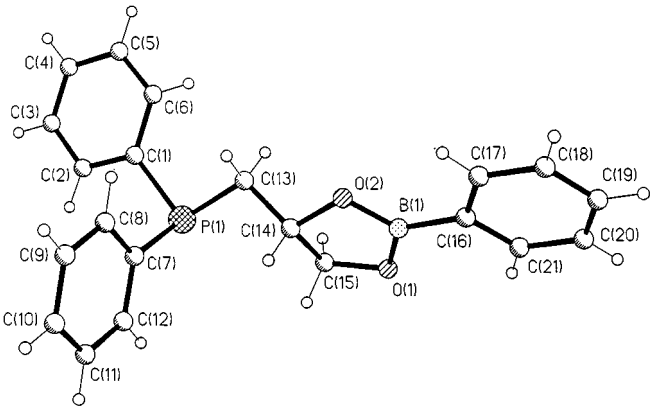


Figure 1. Molecular structure of **2a**; selected interatomic distances [Å] and angles [°]: P(1)−C(1) 1.836(6), P(1)−C(7) 1.822 (7), P(1)−C(13) 1.851(6), C(14)−O(2) 1.463(7), C(15)−O(1) 1.443(7), C(14)−C(15) 1.525, B(1)−O(1) 1.384(8), B(1)−O(2) 1.369(8), B(1)−C(16) 1.509(9); C(1)−P(1)−C(7) 101.76(29), C(1)−P(1)−C(13) 101.83(30), C(7)−P(1)−C(13) 101.46(28), O(1)−B(1)−O(2) 111.9(5)

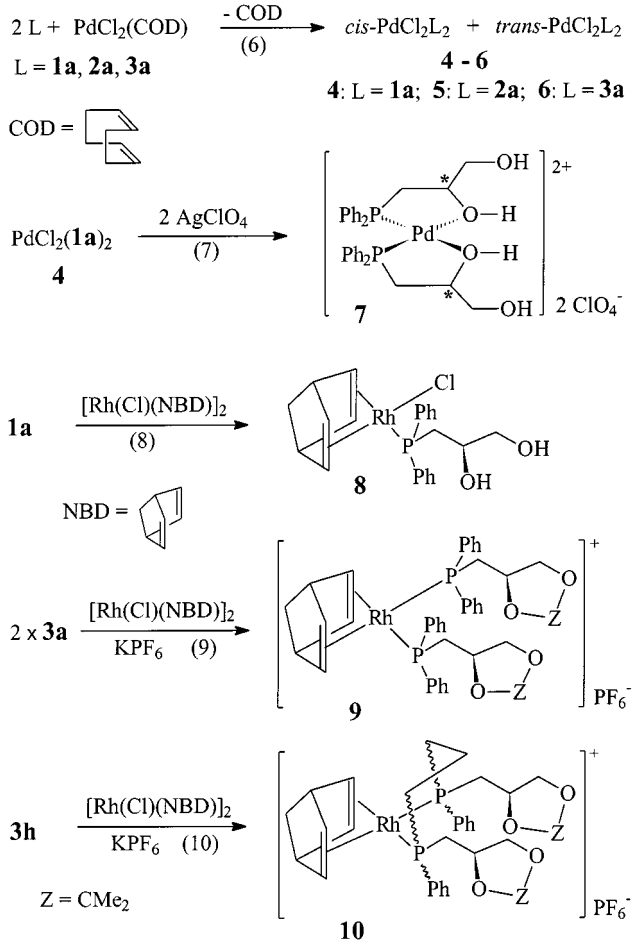

In the two independent molecules (A, B), the geometrical parameters of the PC_3 skeleton are slightly different, the P−C distances [P(1)−C(1) 1.836(6), P(1)−C(7) 1.822(7), P(1a)−C(1a) 1.805(7), P(1a)−C(7a) 1.836(6) Å] and C−P−C bond angles [C(1)−P(1)−C(7) 101.8(3), C(1a)−P(1a)−C(7a) 101.2(3)°] within the Ph_2P groups being comparable to those in Ph_3P.[25,26] The torsional arrangements of the aromatic ring planes within the Ph_2P units of the two independent molecules A and B are also different.

The atoms within the cyclic boronic diester moieties O(1)−C(14)−C(15)−O(2)−B(1)[*O(1)−B(1)*] are coplanar to within 0.084 Å, the coordination at B(1) or B(1a) being distorted trigonal planar [O(1)−B(1)−O(2) 111.9(5), O(2)−B(1)−C(16) 123.0(6), O(1)−B(1)−C(16) 125.1(6)°]. The aromatic substituent at B(1) or B(1a) and the BO_2C_2 cyclic boronic diester unit are arranged in an almost coplanar fashion, the interplanar angle between the plane of the aromatic ring system and the plane defined by B(1), O(1), O(2), and C(16) being just 4.42°. Similar coplanarity of the BO_2 group with the aromatic ring has been found in other aromatic boronic acids and their esters.[27]

Palladium(II) and Rhodium(I) Complexes of 1a, 2a, 3a, 3h

On reaction of enantiomerically pure **1a**, **2a**, or **3a** with $PdCl_2$(COD) in a 2:1 molar ratio, complexes of the composition $PdCl_2L_2$ are formed (Equation 6), which show two signals in their $^{31}P\{^1H\}$-NMR spectra in the ranges δ = 40−28 and δ = 15−13. By analogy with literature data for *cis*- and *trans*-Cl_2PdL_2 complexes,[28,29] the low field signals are assigned to the *cis* isomers and the high field resonances to the *trans* isomers of **4**−**6**. The relative intensities of the $^{31}P\{^1H\}$-NMR signals of both isomers (*cis*/*trans*) vary from 10:1 (**4**), through 1:1 (**6**), to 1:7 (**5**). The assignment of the $^{31}P\{^1H\}$-NMR resonances to *cis*/*trans* isomers is corroborated by analysis of the $^{13}C\{^1H\}$-NMR spectra, which fea-

ture signals (e.g. for C1, C3, C_{ipso}, C_{ortho}, C_{meta}) of corresponding intensity with doublet or triplet fine structures (for the numbering of the aliphatic C atoms, see Scheme 3). Thus, **4**, which exists predominantly as the *cis* isomer, shows signals with doublet fine structure for C1 and C3, while a singlet is observed for C2. In the case of **6**, two $^{13}C\{^1H\}$-NMR resonances are observed for the carbon atoms C1 and C_o, C_m of the phenyl substituents with doublet or triplet fine structures (X parts of ABX spin systems,[30] A, B = ^{31}P, X = ^{13}C) for the *cis* and *trans* isomers, respectively. Each of the two isomers show singlets for C2, C3, and C4. The Me groups of the CMe_2 units (C5, C6) in the two isomers of **6** (*cis*, *trans*) are diastereotopic due to the center of asymmetry at the β carbon. The same applies to the two Ph substituents of the Ph_2P groups in **5** (existing mainly as the *trans* isomer) and **6**; two sets of $^{13}C\{^1H\}$-NMR resonances with triplet fine structure are observed for the aromatic carbon atoms C_{ipso}, C_{ortho}, and C_{meta} of the *trans* isomer.

Scheme 4

Treatment of a toluene solution of **4** with $AgClO_4$ gave the dicationic complex **7** (Equation 7). Similar types of reactions have been reported by Pringle et al.[31–33] for palladium(II) and platinum(II) complexes of phosphanyl alcohols $Ph_2P-CH_2-CRR'-OH$ (R, R′ = H, Me). Complex **7** shows one signal at δP = 52.46 in its $^{31}P\{^1H\}$-NMR spectrum, in a range consistent with a *cis* geometry. A resonance of low intensity at δP = 47.63 may possibly be due to the *trans* isomer of **7**. The assignment of the main signal to the *cis* isomer is in accord with the filled-in doublet appearance of the $^{13}C\{^1H\}$-NMR resonances of the aromatic carbon atoms (C_o, C_m) at δC = 136.48, 134.59, 131.28, 130.83 (X parts of ABX-type spin systems,[30] A, B = ^{31}P, X = ^{13}C) in the $^{13}C\{^1H\}$-NMR spectrum.

On reaction of $[RhCl(NBD)Cl]_2$ with **1a**, complex **8** is formed (Equation 8). A signal at δP = 23.54 observed in the $^{31}P\{^1H\}$-NMR spectrum of **8** is split into a doublet by ^{103}Rh-^{31}P coupling [$J(^{103}Rh$-$^{31}P)$ = 168.7 Hz]. If **3a** is treated with $[RhCl(NBD)Cl]_2$ in a 2:1 molar ratio in the presence of KPF_6 using acetone as solvent, the cationic complex **9** is obtained (Equation 9). A similar procedure has been used by Schrock and Osborn[34] for the preparation of the corresponding Ph_3P complex. The $^{31}P\{^1H\}$-NMR spectrum features a doublet at δP = 24.41 [$J(^{103}Rh$-$^{31}P)$ = 155.7 Hz] and a septet at δP = 142.97 [$J(^{31}P$-$^{19}F)$ = 707.8 Hz] for the PF_6^- ion. An analogous reaction with the bidentate ligand **3h** affords complex **10** as a mixture of three diastereoisomers (Equation 10), two of them giving rise to a simple doublet in the $^{31}P\{^1H\}$-NMR spectrum {symmetrical isomers, δP = 7.73 [$J(^{103}Rh$-$^{31}P)$ = 143.9 Hz], 7.48 [$J(^{103}Rh$-$^{31}P)$ = 146.1 Hz]}. The unsymmetrical diastereoisomer with non-equivalent phosphorus atoms (AB part of an ABX spin system, A, B = ^{31}P, X = ^{103}Rh) gives rise to eight lines (δP(A) = 5.62 {$J[^{103}Rh$-$^{31}P(A)]$ = 145.9 Hz}; δP(B) = 7.37 {$J[^{103}Rh$-$^{31}P(B)]$ = 145.9 Hz, $J[^{31}P(A)$-$^{31}P(B)]$ = 52.32 Hz})

Experimental Section

General: For experimental details, see Part 10 of this series.[1] – NMR spectra were recorded on a Bruker AMX 400 or a Bruker AC 250 instrument. – Mass spectra were obtained on a Varian MAT 311 A. – Racemic and (*R*)-(+)-glycidol (2,3-epoxy-1-propanol), 3-iodoaniline, phenylboronic acid, (*S*)-(+)-2,2-dimethyl-4-hydroxymethyl-1,3-dioxolane were purchased from Aldrich GmbH and used without further purification. 1,5-Cyclooctadiene dichloro palladium(II),[35] norbornadienechlororhodium(I) dimer,[36] (*R*)-(−)-2,3-*O*-isopropylideneglycerol tosylate **3**,[37] and $Pd(Ph_3P)_4$[19] were prepared according to literature methods. 3-Iodophenyl guanidine (**1e**)[5b,18] and sodium *p*-iodobenzenesulfonate[24] were prepared according to methods that we have described previously.

Preparation of *rac*- and (*R*)-(−)-2,3-Dihydroxypropyl-1-diphenylphosphane [*rac*-1a and (*R*)-(−)-1a]: 2.0 g (11.0 mmol) or 12.6 g (67.5 mmol) of diphenylphosphane was added to a suspension of 0.83 g (13.0 mmol) or 4.90 g (77.0 mmol) of KOH powder (88%) in 10 or 50 mL of dimethyl sulfoxide (DMSO). The reaction mixture was stirred for 1 h at ambient temperature. On addition of 0.90 g (12.0 mmol) of *rac*-glycidol or 5.0 g (68.0 mmol) of (*R*)-(+)-glycidol, the orange color of the solution disappeared. 10 mL of water was then added and thereafter the solvents were removed in vacuo (70°C, 0.01 mbar). The remaining residue was redissolved in 10 or 50 mL of ethanol and the solution was neutralized with conc. HCl. The precipitate of KCl formed was filtered off and the solvent was stripped off in vacuo (80°C, 0.01 mbar) leaving the phosphanes *rac*-**1a** (2.4 g, 84%) and (*R*)-(−)-**1a** (14.8 g, 84%) as colorless oily liquids. They were purified by distillation in vacuo (oil bath temperature 180°C, 0.01 mbar). – (*R*)-(−)-**1a**: $C_{15}H_{17}O_2P$ (260.3):

calcd. C 69.22, H 6.63; found C 69.14, H 6.63. – MS: *m/z* (%): 260 (32) [M^+], 243 (18) [$M^+ - OH$], 229 (4) [$M^+ - CH_2OH$], 199 (100) [$M^+ - C_2H_3(OH)_2$], 183 (65) [$M^+ - C_6H_5$]. – ^{1}H NMR (C_6D_6): δ = 2.21–2.43 (2 H), 3.55–3.72 (2 H), 3.92 (1 H), 4.1 (2 H, OH), 7.04–7.19, 7.46–7.55 (10 H). – $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 33.49 (14.2), 67.51 (9.2), 70.60 (16.3), 128.63 (9.2), 128.75, 128.83 (6.1), 133.03 (18.3), 133.45 (19.3), 139.18 (13.2), 139.49 (12.2). – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −21.22. – $[\alpha]_D^{20}$ = −19.4° (*c* = 1.3, CH_2Cl_2).

Preparation of [(*R*,*S*)$_P$,*R*$_C$]-2,3-Dihydroxypropyl-1-phenylmethylphosphane (1b): 1.05 g (16.5 mmol) of KOH, 1.8 g (14.5 mmol) of Ph(Me)PH, and 1.07 g (14.5 mmol) of (*R*)-(+)-glycidol were reacted according to the same procedure as described for **1a**. Yield: 2.33 g (81%). – *rac*-**1b**: $C_{10}H_{15}O_2P$ (198.2): calcd. C 60.60, H 7.63; found C 59.98, H 7.67. – MS: *m/z* (%): 198 (29) [M^+], 181 (17.6) [$M^+ - OH$], 138 (100) [$M^+ - C_2H_2(OH)_2$]. – ^{1}H NMR (CD_3OD): δ = 1.33 (3.4, 3 H), 1.35 (3.1, 3 H), 1.74–1.97 (2 H), 3.32–3.71 (1 H), 4.15 (OH), 7.36, 7.54 (5 H). – $^{13}C\{^1H\}$ NMR (CD_3OD): δ = 12.56 (13.4), 13.24 (13.0), 36.68 (13.5), 37.08 (12.6), 67.81 (8.5), 68.19 (9.2), 71.26 (13.0), 71.89 (14.8), 129.44 (6.1), 132.54 (18.3), 132.64 (19.3), 141.84 (13.2), 129.55, 129.64. – $^{31}P\{^1H\}$ NMR (CD_3OD): δ = −39.13, −40.95.

Preparation of *rac*- or [(*R*,*S*)$_P$,*R*$_C$]-2,3-Dihydroxypropyl-1-phenylphosphane (1c): 2.0 g (18.2 mmol) or 1.5 g (13.5 mmol) of phenylphosphane was reacted with 1.4 g (22.0 mmol) or 1.0 g (15.7 mmol) of KOH and 1.48 g (20.0 mmol) or 1.1 g (14.8 mmol) of *rac*- or (*R*)-(+)-glycidol according to the same procedure as described for **1a**. 2.78 g (83%) of *rac*-**1c** and 1.98 g (80%) of [(*R*,*S*)$_P$,*R*$_C$]-**1c** were obtained as oily liquids. – *rac*-**1c**: $C_9H_{13}O_2P$ (184.2): calcd. Preparation of [(*R*,*S*)$_P$,*R*$_C$]-2,3-*O*-Isopropylideneglycerol-1-phenylphosphane (3c) and [(*R*,*S*)$_P$,*R*$_C$]-2,3-*O*-Isopropylideneglycerol-1-phenylmethylphosphane (3d): These ligands were prepared in an analogous manner as (*R,R*)-(+)-**3b**, employing 5.04 g (45.8 mmol) of $PhPH_2$ or 1.08 g (8.7 mmol) of Ph(Me)PH, 3.20 g (50.3 mmol) or 0.63 g (9.6 mmol) of KOH, and 13.1 g (45.8 mmol) or 2.49 g (8.7 mmol) of (*R*)-(−)-2,3-*O*-isopropylideneglycerol tosylate. Yields: 6.7 g (65%) of **3c**, 1.48 g (71%) of **3d**. Purification of **3c** and **3d** was achieved by vacuum distillation (**3c**: 74–76°C, 0.01 mbar, **3d**: 104°C, 0.01 mbar). – **3c**: $C_{12}H_{17}O_2P$ (224.2): C 64.27, H 7.64; found C 63.83, H 7.67. – MS: *m/z* (%): 224 (7.4) [M^+], 209 (11.2) [$M^+ - CH_3$], 166 (83.9) [$M^+ - C_3H_6O$], 125 (100) [$M^+ - C_5H_8O_2$], 110 (46.4) [$PhPH_2$]. – ^1H NMR (C_6D_6): δ = 1.24, 1.25, 1.35, 1.37 (6 H), 1.62–1.70, 1.75–1.91, 2.08–2.15 (2 H), 3.28–3.38, 3.63–3.84, 3.91–4.05, 4.32–4.47 (4 H), 7.03–7.38 (5 H). – $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 25.84, 25.98, 27.23, 27.27, 28.27 (15.3), 28.30 (14.3), 70.00 (5.2), 70.02 (5.1), 74.83 (10.2), 74.92 (8.1), 108.86, 109.13, 128.24, 128.65 (5.1), 128.70 (4.1), 133.84 (16.3), 134.08 (16.3), 135.29 (11.2), 135.33 (11.2). – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −62.94 (211.1), −63.44 (208.6). – **3d**: $C_{13}H_{19}O_2P$ (238.3): C 65.53, H 8.04; found C 65.25, H 7.91. – MS: *m/z* (%): 238 (20.7) [M^+], 223 (80) [$M^+ - CH_3$], 138 (45.8) [$M^+ - C_5H_8O_2$], 124 (100) [PhMePH]. – ^1H NMR (C_6D_6): δ = 1.15 (4.1), 1.20 (3.6, 3 H), 1.28, 1.32, 1.41, 1.42 (6 H), 1.64–1.74, 1.81–2.04 (2 H), 3.33–4.16 (3 H), 7.07–7.71 (5 H). – $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 12.49 (14.3), 12.82 (15.3), 26.05, 27.26 (4.1), 35.57 (16.3), 36.56 (15.3), 70.29 (9.2), 70.67 (9.2), 74.23 (15.3), 74.94 (18.3), 108.85, 128.60 (7.1), 128.61 (7.1), 128.73, 128.76, 131.89 (19.3), 140.56 (14.2), 140.95 (14.2). – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −38.96, −41.22.

Preparation of 2,3-*O*-Isopropylideneglycerol-1-[3-(*N*,*N*-dimethylguanidinium)phenyl]phosphane Iodide (3e): 0.55 g (2.45 mmol) of [(*R*,*S*)$_P$,*R*$_C$]-**3c** and 0.71 g (2.45 mmol) of 3-iodophenylguanidine were dissolved in 10 mL of acetonitrile and 2.8 mg (1.0 mol-%) of the catalyst $Pd(Ph_3P)_4$ was added. After stirring the reaction mixture at 60°C for 5 h, all volatiles were removed in vacuo. [(*R*,*S*)$_P$,*R*$_C$]-**3e** was obtained as an off-white powder, which was recrystallized from acetone. Yield: 1.13 g (90%). – [(*R*,*S*)$_P$,*R*$_C$]-**3e**: $C_{21}H_{29}IN_3O_2P$ (513.3): calcd. C 49.13, H 5.69, N 8.19; found C 49.81, H 5.57, N 7.77. – ^1H NMR ([D$_6$]acetone): δ = 1.23, 1.24, 1.31, 1.33 (6 H), 3.30 (6 H), 2.47–2.55, 3.58–3.66, 3.92–4.10, 4.15–4.22 (5 H). – $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 26.72, 27.86, 34.27 (11.2), 41.26, 71.21 (10.2), 71.31 (10.2), 75.18 (19.3), 109.88, 109.86, 126.19, 126.27, 129.59 (3.8), 129.76 (5.7), 130.01 (6.7), 130.03 (7.6), 130.99, 131.07, 131.94 (20.3), 132.28 (22.4), 134.38 (19.1), 134.64 (20.4), 134.88 (20.3), 137.86 (7.1), 137.92 (6.1), 139.22 (13.2), 139.35 (13.2), 142.17 (15.3), 142.45 (16.3), 157.34, 157.36. – $^{31}P\{^1H\}$ NMR ([D$_6$]acetone): δ = −20.68, −20.87.

Preparation of (2,3-*O*-Isopropylideneglycerol)[4-(sodiumsulfonato)-phenyl]phenylphosphane (3f): 0.73 g (3.25 mmol) of the secondary phosphane [(*R*,*S*)$_P$,*R*$_C$]-**3c** and sodium *p*-iodobenzenesulfonate were dissolved in 15 mL of methanol and 0.36 g (3.58 mmol) of NEt_3 was added. After the addition of 38.0 mg (1.0 mol-%) of the catalyst $Pd(Ph_3P)_4$, the reaction mixture was heated to 60°C and stirred for 24 h. The solvent was then removed in vacuo and the remaining residue was extracted with 25 mL of dichloromethane. On concentration of the combined extracts to dryness, **3f** was obtained as a pale-yellow powder. Yield: 1.3 g (99%). The sample was found to contain a small amount of $HNEt_3I$, which could not be completely removed by extraction. – **3f**: $C_{18}H_{20}NaO_5PS$: (402.4): calcd C 53.73, H 5.01; found C 53.09, H 5.51. – ^1H NMR (D_2O): δ = 1.14, 1.24 (6 H), 2.14–2.36 (2 H), 3.36–3.49, 3.77–4.02 (3 H), 7.02–7.94 (9 H). – $^{13}C\{^1H\}$ NMR (D_2O): δ = 27.41, 28.59, 34.50 (14.2), 34.55 (13.2), 71.76 (9.2), 75.92 (18.3), 111.48, 127.93, 131.07 (6.1), 131.52, 131.71, 134.75 (19.3), 135.04 (20.3), 135.24 (19.4), 135.58 (20.4), 139.05 (11.2), 143.99 (13.2), 144.11 (13.2), 145.66, 145.83. – $^{31}P\{^1H\}$ NMR (D_2O): δ = −22.1, −22.5.

Preparation of (*S*,*S*)-2,3-*O*-Isopropylidene-2,3-dihydroxy-1,4-bis[(*R*,*R*)-2′,3′-*O*-isopropylideneglycerol-1-phenylphosphano]butane (3g), Diastereomeric Mixture: To a solution of 0.36 g (11.0 mmol) of KOH in 10 mL of DMSO, 1.11 g (4.95 mmol) of **3c** was added and the solution was stirred for 1 h. A solution of 1.16 g (2.47 mmol) of (*R*,*R*)-(+)-1,4-di-*O*-*p*-toluolsulfonyl-2,3-isopropylidene-D-threitol in 20 mL of DMSO was then added and the mixture was stirred for 10 h. After the addition of 15 mL of water, the mixture was extracted with 50 mL of CH_2Cl_2. Evaporation of all volatiles in vacuo (20°C, 0.01 mbar) left **3g** as an off-white solid, which was dried in vacuo at 80°C. Yield: 1.32 g (93%). – **3g**: $C_{31}H_{44}O_6P_2$ (574.6): calcd. C 64.79, H 7.72; found C 65.20, H 7.63. – MS: *m/z* (%): 574 (<1) [M^+], 559 (2) [$M^+ - CH_3$], 558 (4) [$M^+ - CH_3 - H$], 459 (100) [$M^+ - C_6H_{11}O_2$], 351 (29) [$M^+ - C_6H_{11}O_2 - C_6H_5P$]. – ^1H NMR (C_6D_6): δ = 1.17–1.41 (18 H), 1.78–2.30 (8 H), 3.31–4.24 (8 H), 7.11–7.53 (10 H) – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −33.50 (isomer A), −37.50 (isomer B), −33.81, −37.24 (1.5) (isomer C).

Preparation of 1,3-Bis[(*R*,*R*)-2,3-*O*-isopropylideneglycerol-1-phenylphosphano]propane (3h), Diastereomeric Mixture: 1.84 g (8.2 mmol) of [(*R*,*S*)$_P$,*R*$_C$]-**3c** was added to a suspension of KOH powder (88%) in 20 mL of DMSO. 0.83 g (4.1 mmol) of 1,3-dibromopropane was added and the reaction mixture was stirred at ambient temperature for 8 h. The product was then extracted with dichloromethane (3 × 20 mL). The extracts were pooled and dried with $MgSO_4$. After removing the solvent in vacuo, **3h** was obtained as a colorless oily liquid. Yield: 1.56 g (78%). – **3h**: $C_{27}H_{38}O_4P_2$ (488.5): calcd. C 66.38, H 7.84; found C 66.28, H 7.86. – MS: *m/z* (%): 488 (2)

[M^+], 473 (15) [$M^+ - CH_3$], 374 (100) [$M^+ - C_6H_{10}O_2$], 373 (92) [$M^+ - C_6H_{11}O_2$], 259 (18) [$M^+ - 2\ C_6H_{11}O_2 + H$], 258 (18) [$M^+ - 2\ C_6H_{11}O_2$]. – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −29.81 (isomer A), −31.46 (isomer B), −29.68, −31.32 (1.0) (isomer C).

Syntheses of the Complexes L_2PdCl_2 (L = 1a, 2a, 3a) (4−6): The ligands **1a** (1.46 g, 5.6 mmol), **2a** (0.42 g, 1.2 mmol), and **3a** (0.5 g, 1.66 mmol) were dissolved in 10 mL aliquots of dichloromethane and stirred with 0.80 g (2.8 mmol) or 0.17 g (0.6 mmol) or 0.24 g (0.83 mmol) of 1,5-cyclooctadiene dichloropalladium(II) for 3 h. After evaporation of the solvent in vacuo, the complexes were obtained as yellow or cream-colored solids. Yields: 1.92 g (98%) of **4**, 0.43 g (83%) of **5**, 0.62 g (96%) of **6**. – Bis[(*R*)-(−)-2,3-dihydroxypropyl-1-diphenylphosphane]dichloropalladium(II) (**4**): $C_{30}H_{34}Cl_2O_4P_2Pd$ (697.9): calcd. C 51.63, H 4.91; found C 50.99, H 5.24. – $^{13}C\{^1H\}$ NMR (CD_3OD): δ = 38.31 (*N* = 35.5 Hz), 66.37 (*N* = 14.9 Hz), 72.84, 127.75 (*N* = 58.0 Hz), 129.87 (*N* = 11.2 Hz), 130.19 (*N* = 11.2 Hz), 132.65, 132.67, 133.72 (*N* = 11.2 Hz), 135.85 (*N* = 11.2 Hz). – $^{31}P\{^1H\}$ NMR (CD_3OD): δ = 26.38 (*trans*), 43.02 (*cis*). – Bis[(*R*)-(+)-1,3,2-dioxaborolano-4-methyl-2-phenyldiphenylphosphane]dichloropalladium(II) (**5**): $C_{42}H_{40}B_2Cl_2O_4P_2Pd$ (869.7): calcd. C 58.00, H 4.64; found C 57.82, H 4.58. – $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 32.91 (*N* = 27.8 Hz), 72.37, 74.01, 127.68, 128.21 (*N* = 10.7 Hz), 128.31, 128.44 (*N* = 10.2 Hz), 129.1 (*N* = 47.8), 129.9 (*N* = 47.3 Hz), 130.69, 130.75, 131.42, 133.55 (*N* = 12.2 Hz), 134.39 (*N* = 13.2 Hz), 134.88. – $^{31}P\{^1H\}$ NMR: ($CDCl_3$): δ = 13.63 (*trans*), 30.95 (*cis*). – Bis[(*R*)-(+)-2,3-*O*-isopropylideneglycerol-1-diphenylphosphane]dichloropalladium(II) (**6**): $C_{36}H_{42}Cl_2O_4P_2Pd$ (778.0): calcd. C 55.58, H 5.44; found C 55.31, H 5.28. – $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 25.56, 25.81, 26.82, 26.95, 30.77 (*N* = 28.5 Hz), 32.76 (*N* = 33.6 Hz), 70.22, 70.35, 72.25, 73.01, 108.90, 109.31, 128.18 (*N* = 10.5 Hz), 128.34 (*N* = 11.5 Hz), 128.49 (*N* = 9.5 Hz), 128.64 (*N* = 11.5 Hz), 130.40, 130.49, 131.55, 133.75 (*N* = 10.5 Hz), 134.14 (*N* = 12.4 Hz), 134.19 (*N* = 9.5 Hz), 134.49 (*N* = 12.4 Hz). – $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 13.63 (*trans*), 28.13 (*cis*).

Preparation of Bis[(*R*)-(−)-2,3-dihydroxypropyl-1-diphenylphosphane]palladium(II) Diperchlorate (7): 0.22 g (1.06 mmol) of silver(I) perchlorate (in 5 mL of toluene) was added to a solution of 0.17 g (0.24 mmol) of **4** in 15 mL of toluene and the reaction mixture was stirred for 2 h. The solvent was then removed in vacuo and the remaining residue was extracted with 20 mL of CH_2Cl_2. The combined extracts were concentrated in vacuo to a volume of 10 mL. The precipitate formed on addition of 10 mL of diethyl ether was filtered off and the filtrate was concentrated to dryness in vacuo. Yield: 0.18 g (92%). – **7**: $C_{30}H_{34}Cl_2O_{12}P_2Pd$ (825.9): calcd. C 43.63, H 4.15; found C 43.65, H 3.87. – $^{13}C\{^1H\}$ NMR ([D_6]acetone): δ = 37.04 (*N* = 32.4 Hz), 65.27 (*N* = 15.0 Hz), 75.72, 123.10 (*N* = 60.0 Hz), 125.28 (*N* = 62.1 Hz), 130.86 (*N* = 11.2 Hz), 131.30 (*N* = 13.2 Hz), 134.61 (*N* = 11.2 Hz), 135.0, 135.34, 136.49 (*N* = 13.2 Hz). – $^{31}P\{^1H\}$ NMR ([D_6]acetone): δ = 51.50 (*cis*).

Preparation of (Bicyclo[2.2.1]hepta-2,5-diene)chloro[(*R*)-(−)-2,3-dihydroxypropyl-1-diphenylphosphane]rhodium(I) (8): To a suspension of 0.49 g (1.06 mmol) of bicyclo[2.2.1]hepta-2,5-dienechlororhodium(I) dimer in 8 mL of methanol, a solution of 0.55 g (2.12 mmol) of **1a** was added and the reaction mixture was stirred for 2 h. After removal of the solvent, **8** was obtained as an orange powder. Yield: 0.98 g (94%). – **8**: $C_{22}H_{25}ClO_2PRh$ (490.8): calcd. C 53.84, H 5.13; found C 53.32, H 5.11. – ^1H NMR ($CDCl_3$): δ = 1.39 (2 H), 3.63, 3.65, 3.77 (6 H), 2.39−2.47 (2 H), 2.61−2.69 (2 H), 4.16−4.25 (1 H), 7.30−7.69 (10 H). – $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 33.29 (23.4), 63.81 (3.1), 67.18 (12.2), 67.77, 128.30 (9.2), 128.46 (9.2), 129.89 (2.0), 130.43 (2.0), 131.19 (41.7), 132.19 (42.7), 132.50 (10.2), 133.66 (11.2 Hz). – $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 23.54 [^1J(Ph−P) = 168.7 Hz].

Preparation of (Bicyclo[2.2.1]hepta-2,5-diene)bis[(*R*)-(+)-2,3-*O*-isopropylideneglycerol-1-diphenylphosphane]rhodium(I) Hexafluorophosphate (9): 1.0 g (3.33 mmol) of **3a** and 0.38 g (0.83 mmol) of bicyclo[2.2.1]hepta-2,5-dienechlororhodium(I) dimer were dissolved in 15 mL of acetone. After addition of 0.31 g (1.67 mmol) of KPF_6, the reaction mixture was stirred for 12 h at ambient temperature and then concentrated in vacuo to a volume of 5 mL. The precipitate deposited on addition of 20 mL of diethyl ether was filtered off and dried in vacuo. Yield: 1.5 g (96%). – **9**: $C_{43}H_{50}F_6O_4P_3Rh$ (940.7): calcd. C 54.90, H 5.36; found C 54.06, H 5.33. – $^{13}C\{^1H\}$ NMR ([D_6]acetone): δ = 26.64, 26.74, 31.60 (*N* = 23.4 Hz), 54.49, 69.14, 71.81 (*N* = 10.9 Hz), 74.71, 93.1 (*N* = 92.4 Hz), 110.92, 130.20, 130.26, 132.10, 132.19 (*N* = 42.7 Hz), 132.62 (*N* = 44.8 Hz), 132.68, 134.38 (*N* = 10.2 Hz), 135.22 (*N* = 11.2 Hz). – $^{31}P\{^1H\}$ NMR ([D_6]acetone): δ = 24.4 (155.7); PF_6^-: δ = −142.97 [^1J(P−F) = 707.8 Hz]. – $[\alpha]_D^{20}$ = −78° (*c* = 5, CH_3CN).

Preparation of (Bicyclo[2.2.1]hepta-2,5-diene)-[1,3-bis{(*R*,*R*)-2,3-*O*-isopropylideneglycerol-1-phenylphosphano}propane]rhodium(I) Hexafluorophosphate (10): 0.79 g (1.62 mmol) of **3e**, 0.39 g (0.84 mmol) of bicyclo[2.2.1]hepta-2,5-dienechlororhodium(I) dimer, and 0.31 g (1.68 mmol) of KPF_6 were reacted according to the same procedure as described for **9**. The complex **10** was obtained as an orange powder. Yield: 1.32 g (98%). – **10**: $C_{34}H_{46}F_6O_4P_3Rh$ (828.6): calcd. C 49.29, H 5.60; found C 49.10, H 5.58. – $^{31}P\{^1H\}$ NMR ([D_6]acetone): δ = 7.48 [J(^{103}Rh−^{31}P) = 146.1 Hz] (isomer A), 7.72 [J(^{103}Rh−^{31}P) = 143.9 Hz] (isomer B), 5.62 [P(A)], 7.37 [P(B)] {J[^{31}P(A)−^{31}P(B)] = 52.3 Hz, J[^{103}Rh−^{31}P(A)] = 145.9 Hz, J[^{103}Rh−^{31}P(B)] = 145.9 Hz}.

Crystal Structure Analysis of (*R*)-$Ph_2P-CH_2-C^aH-O-B(Ph)-O-C^bH_2$ [*C^a-C^b*]: A crystal of (*R*)-(+)-**2a** was mounted in a glass capillary. X-ray data were collected using a Siemens P3 diffractometer equipped with a graphite monochromator and employing Cu-K_α radiation. The structure was solved by direct methods and refined on F^2 by full-matrix least-squares techniques using all unique data with all non-hydrogen atoms anisotropic and hydrogen atoms positioned geometrically. The value of the absolute

Table 1. Experimental data relating to the X-ray structure of **2a**

formula weight	346.2
temperature	293(2) K
crystal system	monoclinic
space group	$P2_1$
unit cell dimensions	*a* = 11.6050(11) Å
	b = 12.3033(13) Å
	c = 13.177(2) Å
	β = 98.769(8)°
V	1859.6(3) Å^3
Z	4
$D_{calcd.}$	1.236 Mg/m^3

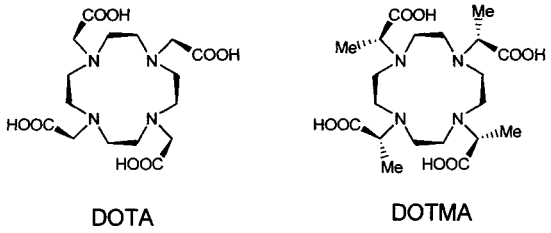
Solution Equilibria in YbDOTMA, a Chiral Analogue of One of the Most Successful Contrast Agents for MRI, GdDOTA



Lorenzo Di Bari,[a] Guido Pintacuda,[b] and Piero Salvadori*[a]

Keywords: Macrocyclic ligands / Conformational equilibria / EXSY spectroscopy / Lanthanide-induced shifts / Solution structure

The structure and the conformational equilibria in aqueous and methanolic solutions of YbDOTMA (DOTMA = (1*R*,4*R*,7*R*,10*R*)-α,α′,α′′,α′′′′-tetramethyl-1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid) are investigated and the dynamics studied by means of NMR methods. The presence of two isomeric forms in slow exchange is confirmed and quantitatively characterized by EXSY. The exchange peaks are assigned to the inversion of the conformation of the macrocycle ring. No evidence is obtained of a reorientation of the methyl acetate substituents. The protons switch between positions with the same geometrical factors, i.e. positions that would have the same pseudocontact shifts were it not for the different magnetic susceptibility anisotropies of the two species; steady-state NOE spectra on the major form allow unequivocal assignment of the conformations of the two isomers.

Introduction

Macrocyclic octadentate ligands derived from a tetraazacyclododecane (cyclen) ring have received attention from several research groups as a result of their ability to form stable and nonlabile complexes with metal, mainly lanthanide, cations. In particular, one of the most successful ligands, DOTA[1] (Scheme 1), whose Gd^{III} complex is widely used as a contrast agent in MRI and in biomedical applications, has been thoroughly investigated through the whole *f* transition.[2−9]

Scheme 1

More recently, chiral nonracemic derivatives and homologues of DOTA have also been synthesized and studied.[10−14] Among them, DOTMA (Scheme 1) is one of the most promising ligands because of the high relaxivity of its Gd complex.[15] Its crystal structure has been solved and some data reported, but the full set of coordinates is not yet available.[15] To our knowledge, no comprehensive study of the dynamics in solution of DOTMA complexes has so far appeared in the literature although a preliminary report on YbDOTMA can be found in a MRI/MRS context.[14][16]

Chiral Ln^{3+} complexes are expected to show optical activity of the lanthanide *f*−*f* transitions owing to the dissymmetrical crystal field the cation experiences. Indeed, preliminary results from a near-infrared (980 nm) circular-dichroism study of Yb complexes has been reported.[17] To understand the electronic spectroscopy of the lanthanide transitions, it is essential to have a clear picture of the structure in solution, particularly regarding the coordination polyhedron. Also, all the conformational rearrangements occurring at ordinary temperatures must be fully characterized. We undertook a thorough conformational and dynamical investigation of this molecule, making profit of a preliminary study due to Brittain and Desreux[10] and of the huge amount of work on DOTA-like molecules.[2−9]

The solid-state X-ray characterization of Ln^{3+} complexes with DOTA analogues reveals that the eight coordination sites, four nitrogens and four oxygens, provided by these ligands, are arranged in two parallel squares, tilted by an angle φ (Figure 1). According to the value of this angle the coordination polyhedron can range from a perfect antiprism (φ = 45°) to a prism (φ = 0°). Neither limiting case has been observed so far in the crystal structures and most known geometries cluster around two values: φ = 15° and 30°. For example, LnDOTA (Ln = Eu,[3] Gd,[5] Lu[7]) and the Eu-phenylethyl amide synthesized by Parker[11] belong to the latter group; to the former can be assigned La-DOTA,[9] LaDOTAM,[18] EuTHP,[19] $YDOTPBz_4$[20] and Parker's Eu-naphthylethyl amide.[12]

These two structures actually correspond to two main internal degrees of freedom. One, concerning the conformation of the ring (Figure 1a), can assume two forms referred to as (δδδδ) and (λλλλ),[21] which are in enantiomeric relation. The other involves the rotation about the $N-C^{\alpha}$ bond (Figure 1b), switching the substituent residue between

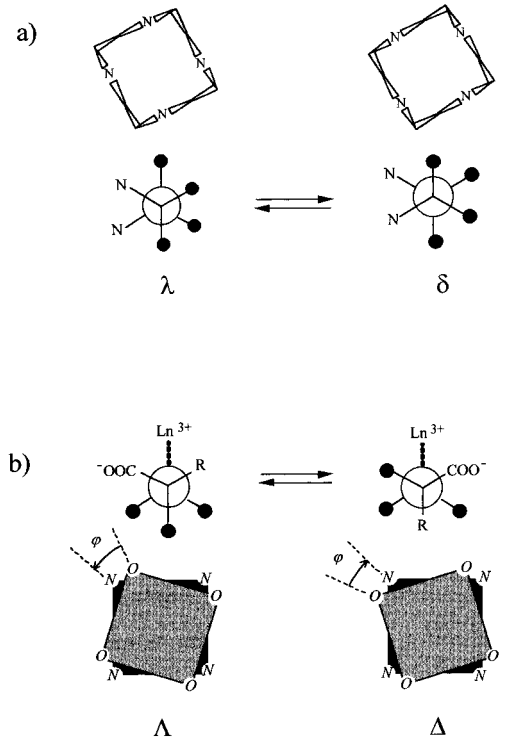
two *gauche* conformations. This induces a sign change in the distortion of the coordination polyhedron, named as Δ or Λ.



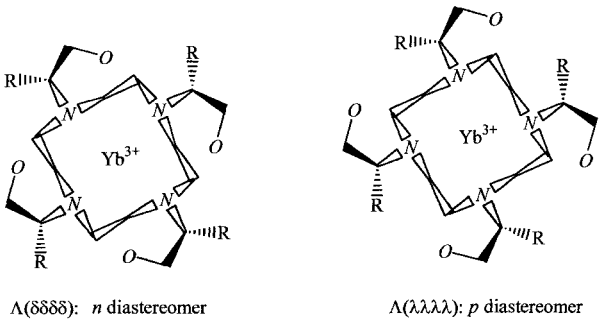


Figure 1. a) Equilibria between the δ and γ forms of the cyclen ring. The Newmann projection is referred to the bond connecting two ethilenic carbons of the macrocycle; the black circles represent the hydrogen atoms; b) equilibria between the Δ and Λ conformation of the cyclen side-arms in the DOTA-type complexes with $Ln^{(III)}$. The Newmann projection refers to the bond between the acetate C^{α} and the nitrogen; the black circles represents the hydrogen atoms and R = H, Me (DOTA and DOTMA, respectively). On the bottom, a schematic representation of the coordination polyhedron is depicted: at the corners of the light gray squares are the oxygens and at the corners of the dark ones the nitrogen atoms (the water molecule possibly axially coordinated is not indicated).

The two descriptors can be alike or different, e.g. Λ(λλλλ) or Λ(δδδδ), giving rise to a diastereomeric pair *p* or *n,* respectively (Scheme 2, *R* = H, Me).[22] A further relevant parameter to take into account is the orientation of the carboxylate bond, which is less accessible to experimental determination via NMR spectroscopy.

Scheme 2

The two diastereoisomeric forms *n* and *p* show a different arrangement of the oxygen atoms, in order to preserve the Ln−O distances at a value of about 2.4 Å. Accordingly, a less distorted (φ = 15°) coordination polyhedron corresponds to the *p* diastereomer, while the *n* diastereomer has a much more distorted (φ = 30°) structure.[4][8]

Most complexes have also been structurally characterized in solution, often using the paramagnetic character of the metal centre.[2−4,6,8,10] While in most cases there is no evidence of structural equilibria and X-ray geometries possibly reflect the most likely conformation in solution, the complexes of DOTA reveal an intriguing network of solution equilibria, which have been studied by various NMR techniques, with reference to limiting crystal geometries. In particular, Aime and co-workers pointed out that the ratio of populations of *n* and *p* types varies along the lanthanide series[4] and that superimposed on the conformational change, there is a hydration−dehydration equilibrium,[8] whose position depends on the size of the central ion.[4]

The pseudocontact shifts of YbDOTA[10] reveal that the two sets of signals for the two forms are proportional. This means that the sets of geometrical factors of the protons in the two forms are equal. This does not necessarily mean that *each* proton occupies a position characterized by the *same* geometrical factor in the two forms, since there can be a pairwise proton-swap between equivalent sites. In 1992, Aime and co-workers[4] assigned the two spectra to two *different* structures, corresponding to the diastereomeric pair *p* and *n*. Indeed, they demonstrated the occurrence of such a rearrangement through EXSY measurements, as discussed in ref.[4] and ref.[6] and below. However, no positive evidence of the assignment of the *n* structure to the major component of YbDOTA in solution can be found in the pseudocontact shifts. In the present work, to our knowledge for the first time, we use such a simple experiment as a monodimensional NOE measurement to assign unequivocally the structure of the major isomer.

The presence of a stereogenic centre on the side arm in DOTMA complicates the equilibrium network, since, for instance, the two forms Λ(λλλλ) and Δ(δδδδ) are no longer equivalent. The intrinsic chirality of the ligand is shown to induce a preference in the distortion of the coordination polyhedron, which in the present work is demonstrated to be Λ. This finding is essential in understanding the chiroptical properties of YbDOTMA.

Results

The spectrum of YbDOTMA in water, as discussed by Brittain and Desreux,[10] shows that the complex is present in solution in two forms ′D′ and ′d′ in slow exchange, characterized by different anisotropy factors D_D and D_d and different signal intensities, by analogy with YbDOTA.[4] However, unlike in DOTA, here the less populated form has the larger value of the *D* factor. We can observe that the spectra of the two forms are exactly proportional (isomorphic), as demonstrated in Figure 2, and

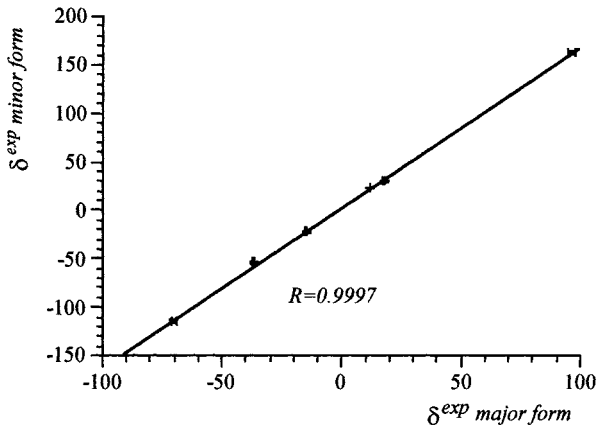

Figure 2. Correlation plot between the experimental δ^{exp} values of the major (D) and minor (d) forms of YbDOTMA in D_2O.

only the large difference between the anisotropy factors, D_D and D_d, justifies the appearance of two distinct sets of signals for the two isomers. It follows that, at least in principle, the two spectra can be associated with the same molecular structure. Alternatively, two conformations must be found bearing the protons in positions characterized by very similar geometrical factors.

Following Brittain and Desreux,[10] a set of suitable parameters for the spectral assignment can be produced from the coordinates of GdDOTA[5] [we chose to start from the Λ(δδδδ) form]. Since the spectrum is compatible with a C_4 symmetry, the analysis of the pseudocontact shifts involves only a linear fitting of one parameter (of the anisotropy D). The geometry factors for sets of equivalent protons were averaged in order to compensate for the lower symmetry of the crystal structure.[23] The pro-*R* hydrogen on each acetate arm was replaced by a methyl group with standard bond lengths and angles. The methyl acetate arm was then systematically rotated around the N−C^{α} bond to obtain the best agreement[24] between the geometrical factors and the observed pseudocontact shifts, finding an optimal value of the torsion angle YbNC^{a}M of about 167° (which corresponds to a coordination geometry of Λ-type). The carboxylate was then rotated to restore the distance Yb−O of 2.4 Å, but this had no effect on the proton geometrical factors.

In such a way, a full set of satisfactory geometrical parameters and the relative structure were obtained. It should be observed that the solution of this optimization is unique, which excludes a rotation of the methyl acetate as the origin of the two forms, in agreement also with other findings on similar structures.[13]

An equivalent set was provided by the following stereochemical operations on these structures: (i) mirror image (inversion) of the whole complex; (ii) epimerization of the four C^{α} stereocentres (these operations must be followed again by the carboxylate rotation). The result was once more a (*RRRR*)-YbDOTMA, but the arrangement of the macrocyclic ring is opposite. In other words, the tetraazacyclododecane shifts from a (λλλλ) to a (δδδδ) conformation. Obviously, starting from the Δ(λλλλ) form of GdDOTA, one would obtain first the Λ(λλλλ) isomer and, after the formal inversion and epimerization, the other. The two sets of geometrical factors for the cyclen ring are obviously equal. For the methyl group and for the CH such equality does not follow by necessity; however, the difference between the geometrical factors calculated for the two forms is less than 10%. Any attempt to use this small difference for structural assignment is nullified by the proportionality of the spectra of the two species. Furthermore, smaller geo-

Table 1. Experimental and calculated lanthanide-induced NMR shifts (δ, in ppm) of the major and minor YbDOTMA species in D_2O and MeOD (T = 25°C). The factors in the second column are calculated on a structure derived, as described in the text, from GdDOTA[5] (see also Table 4); induced chemical shifts are relative to diamagnetic LuDOTA (as far as it concerns the ring protons and the acetate one) and to a value of δ = 0.9 for the case of the methyl resonance.

metrical adjustments[4] may account for minor improvements of the agreement factors.

In such a way, a full set of satisfactory geometrical parameters and two relative structures were obtained (see Table 1 and Figure 3).[25] The coordination geometry is of Λ type in both cases, with the same torsion angles around the N−C$^{\alpha}$ bond; only the arrangement of the macrocycle is opposite.

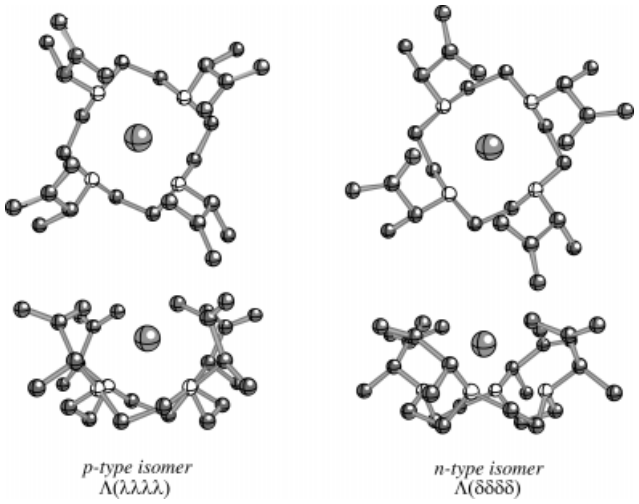

Figure 3. Two isomeric structures of YbDOTMA compatible with the observed proton paramagnetic shifts. On the left a Λ(λλλλ) conformation is displayed, on the ringt a Λ(δδδδ) one. They have been assigned to the major and minor form, respectively.

In order to determine the thermodynamic parameters for the isomerization equilibrium, a variable-temperature study was undertaken. On increasing the temperature, the signals of the minor form become comparatively smaller, which indicates a negative enthalpy for this process. We recorded the spectra in methanol as well, in order to cover a broader temperature range. Indeed, the spectrum in this solvent is very similar to that in water reported in Table 1; once more two forms are present, whose resonances can be predicted with the same geometrical factors used above. The two anisotropy factors are of the same order of magnitude as those found in water and their ratio seems solvent independent. Furthermore, in methanol the minor form is slightly more populated at room temperature than in water (D/d = 14.2 and 20, respectively). The main difference between the two solvents is that in MeOD the resonances of the counterion, *N*-methylglucammonium, which are strongly concentration and temperature dependent, are clearly visible, downfield shifted. Therefore, we can conclude that the cation is at least partly bound in methanol, while it is not in D_2O. The downfield shift shows that it lies axially above or below the metal centre, similar to recently reported for phosphonate systems.[26]

On recording variable temperature spectra in MeOD between −80 and 60°C one observes a migration of all the signals according to the variation of *D*, predicted by Bleaney.[27] Unfortunately, the values collected in Table 2 do not allow $1/T$ and $1/T^2$ dependences to be unambiguously distinguished. Furthermore, at low temperature, all the lines become broader, owing to faster transverse relaxation.

Table 2. Temperature variation of the anisotropy susceptivity parameter *D* of the major form of YbDOTMA and of the equilibrium constant *K* between the two isomers.

temperature (°C)	$\mathcal{D}$ (±100)	$\frac{[d]}{[D]}$ %
60	3180	6.55
25	3490	7.0
0	3770	8.1
-25	4025	9.6
-50	4450	12.0
-80	5070	14.2

The persistence of signals of the minor form up to 60°C could be observed, although at this temperature they appear very broadened. In fact, they start to coalesce with those of the major form, because of the faster equilibrium and of the smaller spectral width, which implies more stringent requirements for the slow exchange limit.

Integration of the signals of the methyl in the two forms afforded an estimation of the temperature dependence of the equilibrium constant, *K*, shown in Table 2. This gave the thermodynamic parameters in methanol: $\Delta H_s^0(M) = -4.0 \pm 0.9$ kJ mol^{-1} and $\Delta S_s^0(M) = -35.4 \pm 0.5$ J K^{-1} mol^{-1}. In D_2O, the temperature range that can be covered goes from 0 to 50°C, because above this limit the signals of the minor form become exceedingly broad. In water, the following values were found: $\Delta H_s^0(W) = -8 \pm 2$ kJ mol^{-1} and $\Delta S_s^0(W) = -50 \pm 10$ J K^{-1}mol^{-1}.

The dynamics of the interconversion between the two forms has been investigated through two-dimensional exchange spectra (EXSY) at variable mixing time in water and in methanol at 25°C.

From inspection of Figure 4, we observe the following equilibria, with reference to the notation of Table 1:

$$M \rightleftharpoons m$$
$$E \rightleftharpoons a$$
$$A \rightleftharpoons e$$

while there is no evidence of exchange within the major or the minor form [e.g., E ⇌ A], either between equatorial or axial protons of the two forms [e.g., E ⇌e]. Therefore, we can conclude that the isomerization process involves a ring inversion, exchanging the macrocycle hydrogens between positions characterized by pairwise equal geometrical factors. Such an observation is in perfect agreement with the structure pair determined above and depicted in Figure 3. Unfortunately, following their construction, it is impossible to assign either of the two to the major or minor component.

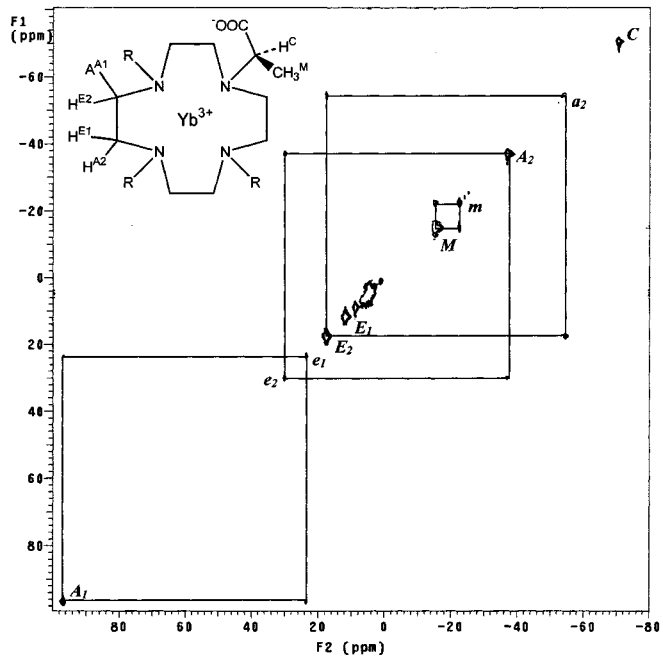

Figure 4. Proton labelling and EXSY spectrum of YbDOTMA at 25°C in D_2O (within −80 and 100 ppm). Upper and lower case letters refer to the major and minor forms resonances, respectively.

To this end, steady-state NOE[28] spectra were recorded between selected protons of the molecule (see Supporting Material). When the resonance at δ = −70.4, due to the methyl acetate methyn proton C, is irradiated, an intense enhancement of E_2 is observed, while no effect is detected on E_1; at the same time, on saturating A_2, C is enhanced. The interpretation of these data is discussed in the next section.

A quantitative evaluation of EXSY spectra at variable mixing time, τ_m, allowed us to assess the dynamic constant for the observed kinetic process. Direct analysis, as described by Perrin and Gipe,[29] of the integrated intensity matrix, $\mathbf{A}(\tau_m)$ for a given τ_m gives the dynamic matrix, **L**,

$$\mathbf{L} = \frac{1}{\tau_m}\ln(\mathbf{P}^{-1}\mathbf{A}) = \frac{1}{\tau_m}\mathbf{U}^{-1}\ln(\mathbf{\Lambda})\,\mathbf{U} \quad (1)$$

where **U** is the matrix of eigenvectors and the diagonal matrix **Λ** contains the eigenvalues, $\{\mathbf{\Lambda}\}_{ii}$, of $\mathbf{P}^{-1}\mathbf{A}$. The diagonal matrix **P** contains the relative populations of the exchanging species,[30] so that the elements of $\mathbf{P}^{-1}\mathbf{A}$ are the normalized amplitudes of the peaks.

We repeated the experiment with different mixing times, ranging from 5 to 30 ms, and we measured the integral of the methyl signals in the two forms and of the cross peaks between them, as reported in Table 3.

Cross relaxation gives only a negligible contribution to the cross-peak amplitudes at the very short τ_m used in our experiments, hence the off-diagonal elements of **L** are $L_{ij} = -k_{ij}$, where k_{ij} is the first-order rate constant for the exchange from site *i* to site *j*. Equation (1) then gives the rates, also shown in Table 3, whose average value is 6.3 ± 0.8 s^{-1} for the D → d process and 136 ± 16 s^{-1} for the reverse in water, whereas, for the same processes in methanol one finds 6.9 ± 0.6 s^{-1} and 93 ± 4 s^{-1}, respectively.[31] These values seem to be quite reliable, since the ratio between the two constants in water [k_{dD}/k_{Dd} = 21.6] is in agreement with the relative concentrations of the two isomers (major/minor = 20 under our experimental conditions) and the same holds true in methanol, as well. We can observe that the dynamics in the two solvents are very similar, which justifies our extrapolation of the thermodynamic data obtained in methanol to water.

Discussion

The possible solution equilibria in YbDOTMA can be represented, by analogy with YbDOTA,[8] as in Figure 5.

Table 3. Integrated intensity matrix for the exchange of the signals of the methyl group in water and in methanol. The index 1 represents the resonance frequency of M and 2 the one of m, so that I_{11} and I_{22} are the intensities of the diagonal peaks of the forms D and d, while I_{12} and I_{21} are the intensities of the cross-peaks, all normalized to I_{11} = 100.

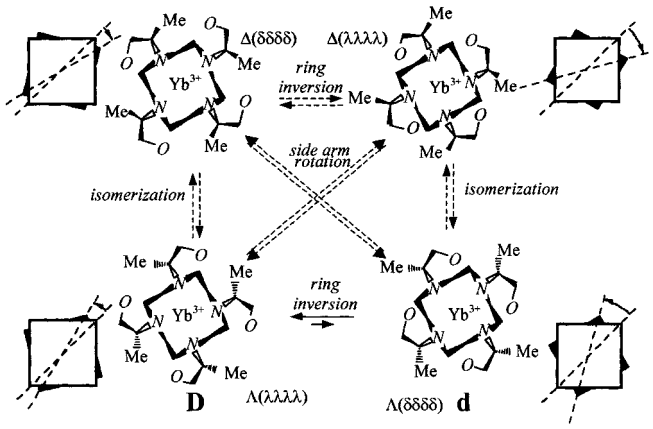

Figure 5. Schematic representation of the structure and dynamics of the diastereomers of YbDOTMA complexes. The conformation of the chelate systems and the coordination polyhedron are depicted. Following the interconversion between the major and minor forms, a different distortion of the coordination polyhedron is forced in the two forms, as discussed in the text.

The exchange processes in the rows are due to an inversion of the macrocyclic ring, while those on diagonals rely upon a rotation of the methyl acetate arms. In the columns, the two motions occur simultaneously (and possibly concertedly). On the left the *p* diastereomers are presented, on the right the *n*. In the case of DOTA, the two forms along each column are optical antipodes, whereas for DOTMA, the presence of the stereogenic centres at the C^{α} makes them diastereomers. Although this is only a crude representation, it shows that in the two rows the coordination polyhedra are distorted antiprisms with opposite tilt angles. Clearly, since DOTA is achiral, the sign of such a distortion is irrelevant (it cannot be defined on a macroscopic level).

The populations of all the four DOTMA structures must be expected to be different. Indeed, only two species could be identified in the one-dimensional ^{1}H-NMR spectrum, in largely different amounts; both have Λ conformation of the side arm, bearing the methyl group *anti* with respect to $N-Yb^{III}$. The excellent agreement of the chemical shifts with geometrical factors derived from a crystal structure rules out any fast motion and confirms the substantial rigidity of the chelate systems already reported in the literature.[4] We have observed that there is no evidence of a rotation of the methyl acetate arm, which amounts to saying that only one of two rows of Scheme 1 is populated and therefore that only one equilibrium is present in solution for YbDOTMA, between the Λ(λλλλ) and Λ(δδδδ) forms.

On the basis of the paramagnetic shifts (as well as the Yb-proton distances and therefore of Curie relaxation rates) it is not possible to assign either of the two conformations to the minor or major isomer; in contrast, the NOE spectra allow one to assign unequivocally the structure of the major isomer to one of the two conformations. In effect, the neat NOE between the C and E_2 protons cannot be justified for an *n*-type structure, since the two protons are far apart (3.35 Å). On the contrary, in the *p*-type the interproton distance is only 2.55 Å.[32] We can conclude that the Λ(δδδδ) conformation must be assigned to the minor isomer and the Λ(λλλλ) to the major one, as depicted in Figure 3; the relevant parameters of such geometries are shown in Table 4. It must be stressed that, in reverse analogy with YbDOTA, the metal ion is more buried in the major form in the case of YbDOTMA.

Table 4. Conformation and relevant atomic distances [Å] and angles in the two isomers of YbDOTMA. The geometries were obtained from the X-ray data of GdDOTA (ref.[5]), according to the procedure descibed in the text.

	major form	minor form
	Λ(λλλλ)	Λ(δδδδ)
O-O	3.07	3.19
N-N	2.97	2.97
Yb-O	2.48	2.48
Yb-plane(O_4)	1.01	0.72
Yb-N	2.66	2.66
Yb-plane(N_4)	1.63	1.63
twist angle (φ)	17°	40°
YbNC$^{\alpha}$Me	167°	167°
NC$^{\alpha}$CO	324°	324°

The kinetic rates are of the same order of magnitude of those reported for YbDOTA by Jacques and Desreux.[6] In the present case, however, only one process is observed, linked to the inversion of the macrocyclic ring. Apparently, the rotation of the methyl acetate arm is strongly hindered, by analogy with what observed in some LnDOTA analogues.[13][33] The detailed comparison with the kinetic rates of DOTA is not straightforward, owing to the different molar ratios of the forms in the two complexes. The averages of the direct to reverse rates of ring inversion at 25°, weighted for the two populations, gives 44.8 s^{-1} for YbDOTA[8][21] and 12.5 s^{-1} for YbDOTMA. The dynamics of the latter is probably slowed down by the crowding due to the presence of the methyl on the side branches.

The thermodynamic data for the interconversion process show both negative enthalpy and entropy. Apparently, the minor form is slightly more stable and only entropically unfavoured. The loss of entropy in the process D → d indicates that in this conversion the order of the system increases, which is compatible with a different coordination number of the central cation, that should be larger for the minor form. Aime et al.[8] reported that on going from the major to the minor form of YbDOTA, $\Delta H^{\circ} = +17.5$ kJ mol^{-1} and $\Delta S^{\circ} = +45$ J K^{-1} mol^{-1} and they attributed the large and *positive* entropy change to the release of a water molecule, axially coordinated in the former. This hypothesis is also strongly supported by variable-pressure NMR. Since the reaction entropy is rather similar to that found for the conversion m′→ M in DOTA,[8] it seems quite reasonable to extrapolate this result to DOTMA, where the major form should be eight coordinate and the minor form should be hydrated and nine coordinate; this further con-

sideration is in agreement with the assignment of an M-type structure (*n* diastereomer) to the minor isomer, where the metal ion is less hindered.

Conclusions

Pseudocontact shifted ^{1}H-NMR spectra of YbDOTMA have demonstrated that in solution two forms are present which exchange slowly and are, in principle, both compatible with the same set of geometrical factors for the protons. Two-dimensional EXSY spectra, on the other side, show that the two forms correspond to different conformations of the macrocyclic ring, in diastereomeric relation, as *p* or *n* forms. This is in close analogy with DOTA derivatives.[8][33] Only steady-state NOE spectra, however, indicate the geometry of the major isomer, thus finally solving the problem of the structural assignment of this molecule in solution in a fully consistent way and without reference to crystal structures. While three different equilibria could be observed for YbDOTA, in the temperature range examined in this work only one has been detected between the two YbDOTMA species, since the presence of the methyl group in the acetate side arms enhances the conformational homogeneity of the chelate system, constraining the arrangement of the pendant groups and favouring one conformation of the cycle ethylene groups.

The steric hindering affects the kinetic parameters, too, and quantitative EXSY measurements show that the ring inversion is slowed down with respect to the corresponding process in YbDOTA. The thermodynamic parameters of the equilibrium indicate that the structural rearrangement may be accompanied by a hydration process. The relative populations of the two forms and the hydration−dehydration dynamics are in reverse analogy with YbDOTA.[33]

It is noteworthy that the two species in equilibrium are Λ(λλλλ) and Λ(δδδδ), thus characterized by the same helicity about the metal cation. One can therefore conclude that, by analogy with other chiral ligands,[11−13] YbDOTMA shows a transfer of chirality from a local stereogenic element to the overall structure. This is a key point in understanding the stereochemistry and consequently the chiroptical properties of these complexes

Experimental Section

General: The anionic homochiral and enantiopure YbDOTMA complex as a methylglucammonium salt was a gift from Bracco Italy S.p.A. and was dissolved in D_2O (21.8 mg in 0.5 mL, 52.80 mM) and MeOD (6.95 mg in 0.5 mL, 16.83 mM). The NMR spectra were recorded on a Varian VXR 300 Spectrometer operating at 7.1 T, equipped with a VT unit stable within 0.1°C. Where not otherwise specified, the temperature was 25°C. The 90° pulse length was 14.5 μs. The recycle delay in all experiments was above 0.5 s, largely exceeding 5 T_1 of all YbDOTMA proton resonances and ensuring instrumental recovery. − Steady-state NOE spectra were recorded with 4096 transients after 0.5 s with cw presaturation of the relevant signals. − EXSY spectra were recorded with the standard NOESY sequence, using the hypercomplex method to obtain phase sensitivity in both dimensions. Since zero quantum coherences have an antiphase character, they cannot contribute neither in integrated nor in point amplitude in systems with a linewidth largely exceeding the scalar couplings; thus no attempt was made to suppress them. 2048 points were collected for each of the 512 t_1 increments, covering a spectral window of 50000 Hz in two dimensions. The matrices were zero-filled to 2 K × 2 K and weighted by Lorentz-to-Gauss functions in both dimensions. Since all quantitative analyses were performed only on the methyl resonances (within 12000 Hz from the transmitter), no correction for finite pulse length was used. No baseline correction was applied and the 1- and 2-dimensional integrals were evaluated with the VNMR software with reference to the area immediately adjacent to each peak. The pseudocontact shifts were calculated with reference to the data reported for LuDOTA.[4] The geometric factors for the protons were calculated with the aid of standard molecular modelling software.[23] In the first place, only the four cyclen-proton resonances were considered: a tentative value for *D* was obtained, through which starting values for the geometric factors of the acetate and the methyl protons were assessed. The dihedral angle about the N−C$^\alpha$ bond was systematically varied in order to approach those values. This procedure revealed that only one minimum could be found. Thereupon, for values of the dihedral YbNC^{a}M between 165° and 170°, all the geometric factors and pseudocontact shifts were included in the linear fitting, seeking for the best agreement factor.[24] − ^{1}H-NMR spectrum at 300 MHz of YbDOTMA in D_2O and in MeOD (Figure S1), correlation plot between the experimental δ^{exp} values and the geometrical factors calculated for YbDOTMA in D_2O (Figure S2), variable temperature behavior (from 25 to −80°C) of the methyl resonances of YbDOTMA (Figure S3), NOE difference spectra of YbDOTMA obtained upon saturation of the acetate C resonance of the major form (Figure S4) are available as supporting Information.

Acknowledgments

We thank Bracco Italy S.p.A. for a generous gift of YbDOTMA.

[22] We prefer to borrow the stereochimical descriptors *n* and *p*, which clarify the diastereomeric nature of the rearranged forms, and avoid reference to the major form of YbDOTA. Indeed, the structures of the predominant form in solution depend on the nature of the ligand and on the size of the central ion.
[23] All the operations on the structures described can be performed with a standard molecular modelling package, such as *Hyperchem* (Hypercube Inc.) or *CS ChemDraw Pro* (CambridgeSoft Corporation).
[24] The agreement factor *R* between calculated, δ_s(calcd., *i*), and experimental, δ_s(exp., *i*), pseudocontact shifts, defined as:

$$R^2 = \frac{\sum_i (\delta_i^{calc} - \delta_i^{exp})^2}{\sum_i (\delta_i^{exp})}$$

is reported in Table 1, as well. We can observe that, even if the *R* value for the major isomer is slightly lower, the agreement is very good for both structures. Variation of the torsion around the $N-C^{\alpha}$ bond by 5° about the optimal value does not imply a relevant increase of the factor, *R* (about 10% higher when the angle is 170°).
[25] The geometrical factors calculated on the basis of the published of GdDOTA (ref.[5]) lead to the assignment shown in ref.[6], featuring the two protons on each macrocycle carbon bearing different numbers. This is in agreement with that reported by several authors (ref.[6][21]), but in contrast with Aime and coworkers (ref.[4][15]).

[31] The errors on these values were estimated through their dispersion for the various experiments.
[32] The NOE between A_2 and C is not diagnostic, since in both structures Λ(δδδδ) and Λ(λλλλ) the two protons are nearby. Furthermore, it is very difficult to detect, owing to the large relaxation rates of the two nuclei, which sit close to the paramagnetic centre.

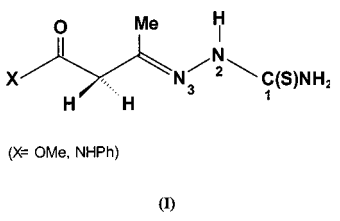
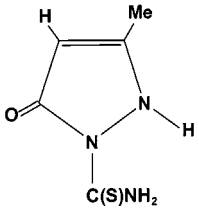
Reactions of Cadmium(II) Acetate with Acetoacetanilide and Methylacetoacetate Thiosemicarbazones: A Cyclization Process Leading to a Pyrazolone − The Molecular and Crystal Structures of the Free Ligands and the Complex [CdL_2Py] (HL = 2-[Amino(thioxo)methyl]-5-methyl-2,3-dihydro-1*H*-3-pyrazolone, Py = Pyridine)

José S. Casas,[a] María V. Castaño,*[a] Eduardo E. Castellano,[b] María S. García-Tasende,[a] Agustín Sánchez,[a] María L. Sanjuán,[a] and José Sordo[a]



Keywords: Cadmium(II) pyrazolonates / Thiosemicarbazones / Cyclizations / 2-[Amino(thioxo)methyl]-3-pyrazolone / ^{1}H-, ^{13}C-, ^{113}Cd-NMR spectra

Acetoacetanilide- and methylacetoacetate thiosemicarbazones (HTSC^1 and HTSC^2, respectively) react with cadmium(II) acetate in methanol, giving complexes containing the ligand 2-[amino(thioxo)methyl]-5-methyl-2,3-dihydro-1*H*-3-pyrazolonate (L^-). An X-ray diffraction study of the structures of HTSC^1, HTSC^2, HL, and [CdL_2Py], identified the main structural changes in the cyclization process. Additionally, the coordination of the metal in the complexes [CdL(AcO)] · 2 MeOH and [CdL_2] · 3 H_2O was analyzed using IR spectroscopy in the solid state and ^{1}H-, ^{13}C-, and ^{113}Cd-NMR spectroscopy in solution. On reaction with aqueous trifluoroacetic acid, both complexes releases the free pyrazolone, which can be easily isolated.



Cadmium is an environmental pollutant of worldwide concern. In most studies of its interaction with natural or man-made chelating agents, the products, complexes with a wide range of coordination spheres[1] and stabilities,[2] have shown no regiochemical modification of the ligand. We report here two cases of complexation involving cyclization of the ligand.

In spite of the frequent use of thiosemicarbazones (HTSCs) as ligands, mainly with transition metals,[3] only six complexes of HTSCs with cadmium have been fully identified by X-ray diffraction: namely, five adducts of cadmium with neutral HTSC and halide ligands[4] and the complex [$Cd(TSC)_2$] (TSC^- = pyridine-2-carbaldehyde thiosemicarbazonate).[4a] These six compounds exhibit a surprising range of coordination numbers (4, 5, 6, and 7) and coordination polyhedra (tetrahedral, bipyramidal trigonal, highly distorted octahedral and distorted bipyramidal pentagonal).[4]

As part of our work in this field, we recently prepared some HTSCs derived from β-keto esters and β-keto amides (**I**) and reacted them with cadmium(II) acetate in methanol solution. In view of the previous work of Jayasree and Aravindakshan,[5] we expected to obtain cadmium(II) complexes of the mono- or bi-deprotonated ligands, with or without an accompanying acetate ligand. Instead, we obtained new Cd^{II} compounds containing, in deprotonated form, the ligand 2-[amino(thioxo)methyl]-5-methyl-2,3-dihydro-1*H*-3-pyrazolone (HL, **II**).

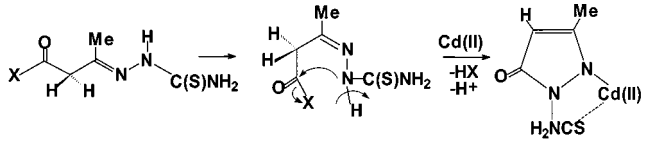
(I)

(II)

The new pyrazolonate complexes [CdL(OAc)] · 2 MeOH and [CdL_2] · 3 H_2O are interesting for at least two reasons. Firstly, under acidic conditions they release the free pyrazolone; thus, reaction of this type of HTSC with Cd^{II} acetate and subsequent acidification, constitutes a means of obtaining good yields of compounds that are of great interest in organic, biological, pharmaceutical, analytical and agricultural chemistry.[6] Secondly, these cadmium(II) pyrazolonates appear to be the first to have been characterized by X-ray diffraction. In this paper we suggest a plausible reaction pathway and describe the structural characterization of the complexes in the solid state and in solution.

Results

Synthesis of the Complexes



The analytical, spectroscopic, and structural data (vide infra) suggest that the HTSC molecules may be transformed into the final pyrazolonate ligand (L^-) via the reaction

pathway shown in Scheme 1. This pathway is similar to that described by Katrizky et al.[7] for the condensation of a β-ketoester with hydrazine (Knorr′s synthesis of 2,4-dihydro-3*H*-pyrazol-3-ones).

The cyclization, with concomitant elimination of HX (= aniline in HTSC[1] and methanol in HTSC[2]) seems to be favoured by the Cd^{II} cation, possibly because the cadmium(II) thiosemicarbazonate is formed first, deprotonating N(2) and so favouring nucleophilic attack by N(2) on the −C(O)X group.

Scheme 1. Proposed cyclization mechanism

This reaction is related to those investigated by S.A. Samath et al.,[8] who found that β-ketoester complexes of Cu^{II} incorporated phenylhydrazine into the coordination sphere of the metal after a condensation/elimination reaction with the β-ketoester, and that cyclization to pyrazolones occurred upon subsequent demetallation with H_2S. In the reaction of HTSC[1] and HTSC[2] with Cd^{II}, the elimination/cyclization processes is so favoured that no thiosemicarbazonate intermediates were isolated at room temperature. The cadmium(II)-induced process is also related to previously described cyclizations of aldehyde thiosemicarbazones,[9] but differs from these latter examples in that it seems to involve no change in the oxidation state of the metal.

Structures of the Ligands

The numbering scheme used for the ligands are shown in Figure 1, and selected bond lengths and angles are listed in Table 1.

The bond lengths in the thiosemicarbazone ligands indicate the double bond character of C(5)−O [C(5)−O(2) in HTSC[2]], C(2)−N(3), and C(1)−S. In accordance with the canonical forms associated with the TSC chain[10] this also suggests some multiplicity in C(1)−N(2) and C(1)−N(1). In HTSC[1] the SC(1)N(1)N(2)N(3)C(2)C(3)C(4) and C(6)C(7)C(8)C(9)C(10)C(11)N(4) moieties are both planar (Rms. = 0.028 and 0.010, respectively) and form a dihedral angle of 67.9°; C(5) and O lie outside these planes. In HTSC[2] too, most atoms lie in one of two, almost orthogonal planes (dihedral angle 85.8°), one containing the TSC backbone [SN(1)C(1)N(2)N(3)C(2), Rms. = 0.019] and the other containing the non-thiosemicarbazone moiety C(4)C(5)O(1)O(2)C(6) (Rms. = 0.007); in this case C(3) lies outside these planes. In both HTSC[1] and HTSC[2], the configuration of the thiosemicarbazone chain is, as usual in this type of compound, (*E*) with respect to the C(2)−N(3) (aldimine) bond, and the thioamide S and N(3) atoms are mutually *trans* with respect to the C(1)−N(2) bond. This latter arrangement allows the formation of a strong intra-

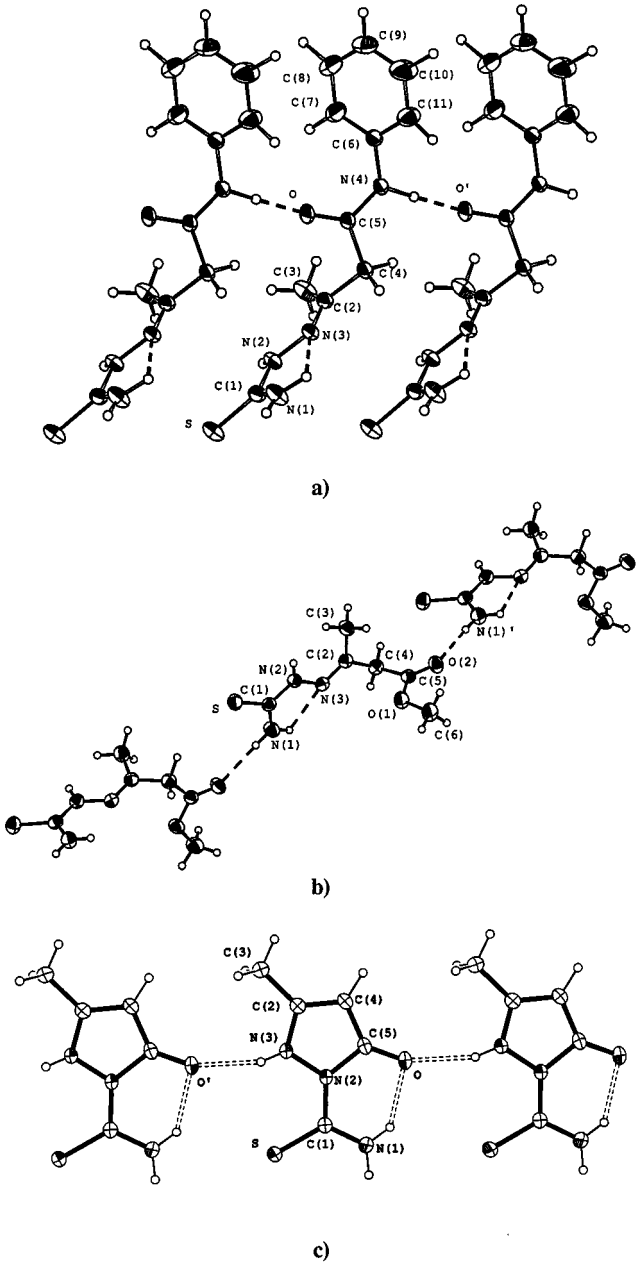

Figure 1. Crystal structures (with 30% probability ellipsoids) of a) HTSC[1], b) HTSC[2] and c) HL, showing intra- and intermolecular hydrogen bonds

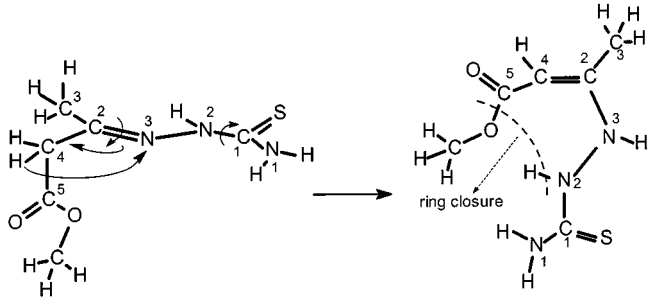
molecular hydrogen bond between N(1)−H and N(3) (Figure 1, Table 1), which must aid the partial multiplicity of C(1)−N(1) bond in restricting rotation of the $-NH_2$ group in solution (vide infra NMR data). As Figure 1 and Table 1 show, there is also an intermolecular hydrogen bond between the carbonyl oxygen and N(4) (in HTSC[1]) or N(1) (in HTSC[2]), and this links the molecules in the lattice.



The formation of HL from these HTSC ligands implies that significant structural rearrangement occurs. The steps hypothesized are (Scheme 2): i) a 180° rotation about the C(1)−N(2) bond (as usually occurs when thiosemicarbazonates coordinate to a metal ion);[11] ii) a rotation about the C(2)−N(3) bond (by 67.9 and 85.8° in HTSC[1] and

[a] Values for the two L^- ligands. – [b] Carbonyl group distance. – [c] Symmetry operation: i) $x-1, y, z$; ii) $x+1, 1.5-y, z-0.5$; iii) $x-1, y, z$; iv) $-x, 0.5+y, 0.5-z$; v) $0.5+x, 1.5-y, -z$.

$HTSC^2$, respectively) so as to make the TSC and non-TSC moieties almost coplanar; iii) displacement of the double bond from C(2)−N(3) to C(2)−C(4) with simultaneous proton transfer from C(4) to N(3); and iv) deprotonation of N(2)−H, elimination of HX, and ring formation. This sequence of changes is in keeping with the following observed changes in bond lengths and bond angles: a) shortening of the C(2)−C(4) bond (which formally becomes a double bond), shortening of the C(4)−C(5) bond [which probably becomes involved in charge delocalization between O and C(5)] and lengthening of the C(2)−N(3) bond (which formally changes from double to single); b) narrowing of the [N(2)−N(3)−C(2)] and [N(3)−C(2)−C(4)] angles and widening of the [C(1)−N(2)−N(3)] angle, which are all affected by ring closure; and c) narrowing of the N(1)−C(1)−N(2) angle, possibly due to the strong intramolecular hydrogen bond −NH···O=C that is present in the cyclic compound (see Table 1). An intermolecular hydrogen bond between the carbonyl oxygen and the N(3)−H group of a neighbouring molecule is also shown in Figure 1 and Table 1.

Scheme 2. Hypothesized rearrangement of $HTSC^2$ under cyclization

Structure of the Complex $[CdL_2Py]$

Recrystallization of $[CdL(OAc)] \cdot 2\,MeOH$ from pyridine afforded monocrystals of $[CdL_2Py]$ (see Figure 2 for the numbering scheme used). In this complex, the deprotonated ligand coordinates to Cd^{II} via N(3) and the exocyclic S atom, as is usual in thiosemicarbazonates. According to Addison et al's τ-criterion,[12] the value $\tau = 0.63$ means that the coordination polyhedron is closer to a trigonal bipyramid (theoretical $\tau = 1$), with N(3) and N(6) in the apical positions [N(3)−Cd−N(6) = 170.3°], than to a square pyramid ($\tau = 0$). The bond lengths in the $[CdN_3S_2]$ kernel ($Cd-N_{Py}$ = 2.312 Å, average Cd−S = 2.554 Å, average $Cd-N_{TSC}$ = 2.293 Å) are shorter than in all the other cadmium(II) thiosemicarbazone derivatives studied so far,[4] including those in which the pyridine ring is part of the coordinated ligand [Cd^{II}-pyridine-2-carbaldehyde thiosemicarbazones[4a] and Cd^{II}-2,6-diacetylpyridine monothiosemicarbazone[4b]]. The bond lengths in this kernel are also clearly shorter than those reported for bis(benzothiazole-2-thiolato-*N,S*)bis(pyridine)cadmium(II) $[Cd(C_7H_4NS_2)_2(Py)_2]$,[13] which like $[CdL_2Py]$ contains two N,S-bound rings and coordinated pyridine (although it must be borne in mind that $[Cd(C_7H_4NS_2)_2(Py)_2]$ contains two mol of Py and its cadmium has a coordination number of six). In fact, the $Cd-N_{Py}$ distance is close to the minimum value found in the CSD[14] for Cd-pyridine compounds (2.300 Å), and is well below the mean, 2.355 Å. These data suggest strong metal-ligand interaction.

As in the free ligand, the pyrazolone rings are planar [Rms. = 0.009 and 0.010 for N(2)N(3)C(2)C(3)C(4)-C(5)O(1) and N(5)N(6)C(7)C(8)C(9)C(10)O(2), respectively] but upon coordination undergo certain structural changes that are worth mentioning. The C−S bond lengthens, though the fact that the lengthening is less than in the Cd^{II} complex of deprotonated pyridine-2-carbaldehyde

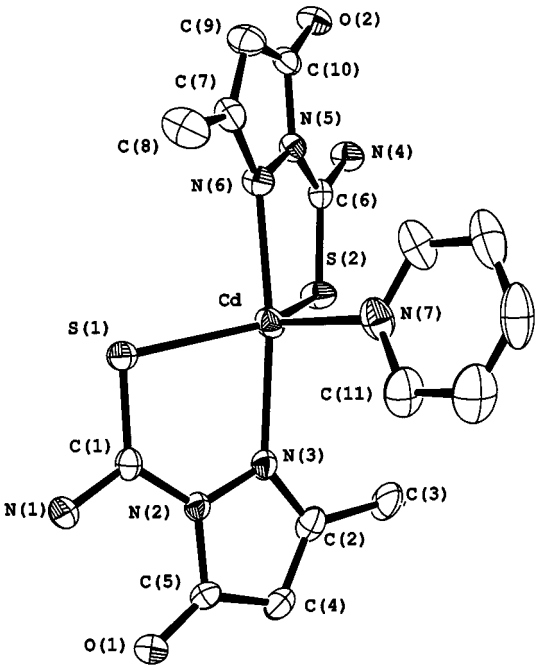

Figure 2. Molecular structure of $[CdL_2Py]$ (with 30% probability ellipsoids); selected bond lengths [Å] and angles [°]: Cd−S(1) 2.5546(11), Cd−S(2) 2.5540(11), Cd−N(3) 2.294(3), Cd−N(6) 2.292(3), Cd−N(7) 2.312(4), S(1)−Cd−S(2) 132.43(5), S(1)−Cd−N(3) 77.50(9), S(1)−Cd−N(6) 98.59(9), S(1)−Cd−N(7) 113.74(10), S(2)−Cd−N(3) 98.48(9), S(2)−Cd−N(6) 77.53(9), S(2)−Cd−N(7) 113.83(11), N(3)−Cd−N(6) 170.35(13), N(3)−Cd−N(7) 95.0(2), N(6)−Cd−N(7) 94.7(2)

thiosemicarbazone[4a] shows that there is less thione-to-thiol evolution in the pyrazolone compound. The associated shortening of the C(1)−N(2) bond is correspondingly slight, suggesting that the multiplicity of this bond increases only slightly upon coordination of the ligand to cadmium. The evolution of the bond lengths in the O(1)−C(5)−C(4)−C(2) and O(2)−C(10)−C(9)−C(7) pyrazolonato moieties [shortening of the C(4)−C(5)/C(9)−C(10) bonds and lengthening of the O(1)−C(5)/O(2)−C(10) and C(2)−C(4)/C(7)−C(9) bonds] is indicative of π-charge delocalization in this part of the ring upon metallation of nitrogen.

In $[CdL_2Py]$ the intramolecular $-NH_2\cdots O$ hydrogen bond is somewhat shorter than in the free ligand (2.625 Å). Four intermolecular hydrogen bonds involving the $-NH_2$ groups and the carbonyl O atoms connect the molecules of the complex in a three-dimensional network.

IR Spectroscopy

The significant IR bands of $HTSC^1$ and $HTSC^2$ (Experimental Section) were identified on the basis of previous data.[4a,5,15,16] Bands due to the $-N(H)C_6H_5$ and $-OCH_3$ groups were lost upon cyclization (this is more evident for $HTSC^1$ than $HTSC^2$, the $-OCH_3$ bands of which overlap those of the thiosemicarbazone fragment).

The N,S-coordination of the ligand L^- in $[CdL_2Py]$, shown by X-ray diffraction (vide supra), does not significantly shift the ring bands from their positions in the spectrum of free HL, but does shift the low-energy ν(C=S) band to lower wavenumbers and suppresses the high-energy band. The C=O group is non-coordinated, but is strongly involved in hydrogen bonds, which, together with the electronic reordering consequent on deprotonation and *N*-metallation, shift ν(C=O) to lower wavenumbers than in the spectrum of HL.

The positions of the main ring bands and ν(C=S) suggest that L^- is also N(3),S-coordinated in $[CdL(OAc)]\cdot 2\,MeOH$ and $[CdL_2]\cdot 3\,H_2O$. However, the larger shift in ν(C=O) suggests that this group is also Cd-coordinated in these two compounds. This would reduce the involvement of the −C=O group in strong hydrogen bonds with the NH_2 group, and might therefore explain why ν(N−H) lies at higher wavenumbers than for $[CdL_2Py]$. It thus seems reasonable to hypothesize that both $[CdL_2]\cdot 3\,H_2O$ and $[CdL(OAc)]\cdot 2\,MeOH$ have polymeric structures, with Cd hexacoordinated in an $N_2S_2O_2$ kernel in $[CdL_2]\cdot 3\,H_2O$, and pentacoordinated in an NSO_3 kernel in $[CdL(OAc)]\cdot 2\,MeOH$. The acetate anion in the latter complex is likely to be bidentate (it is difficult to draw this conclusion with certainty from the difference between ν_{as}(COO) and ν_s(COO) because of the breadth of the bands at 1602 and 1399 cm^{-1}, to which ν_{as}(COO) and ν_s(COO) must contribute[17]).

NMR Spectroscopy

The ^1H NMR spectra of $HTSC^1$ and $HTSC^2$ show two groups of signals for each of the groups $-N(1)H_2$, $-N(2)H$, $-C(2)H_3$, and $-C(4)H$, indicating that there is probably more than one conformer in solution (only signals for the major conformer are indicated in the Experimental Section). Signals for $-OCH_3$ and $-HNC_6H_5$ are also observed. The ^1H-NMR spectrum of HL differs markedly from those of its precursors: the signals of $-N(H)C_6H_5$ and $-OCH_3$ are missing, the −NH and $-CH_3$ protons are more deshielded, and there is a new signal at δ = 5.16 corresponding to the $-C(4)H$ group left upon loss of a proton by $-C(4)H_2$ in the cyclization process.

The ^1H-NMR spectra of the Cd^{II} complexes obtained by reaction of $HTSC^1$ and $HTSC^2$ with Cd^{II} acetate provided the first evidence of the cyclization of these ligands. They show no $-N(H)C_6H_5$ or $-OCH_3$ signals, and instead show a new signal at about δ = 4.7 which corresponds to the −CH signal latter observed at δ = 5.16 in the spectrum of HL. In view of this, the reaction was followed spectroscopically at room temperature by running spectra of a 2:1 $HTSC^1/Cd(OAc)_2$ mixture in DMSO. The spectrum of the freshly prepared mixture shows signals suggesting the initial formation of the complex $[Cd(TSC^1)_2]$, since only the signal of the −N(2)H proton is missing. The spectrum recorded 12 h later contains signals corresponding to $[Cd(TSC^1)_2]$ and $[CdL_2]$, and also signals for free aniline [at δ = 7.01(t), 6.57(t), 6.49(d), and 4.99(s)].

Comparison of the ^{1}H-NMR spectra of HL and its Cd^{II} complexes shows that coordination led to deprotonation of the ligand, as indicated by loss of the N(3)H signal.

In the ^{13}C-NMR spectrum, the main effects of coordination are a shielding of C(4) by about 5.5 ppm and a deshielding of C(2) and C(5) by about 4 ppm (Table 2). C(3) is deshielded by about 2 ppm, while the C(1) signal is hardly shifted. These data show that coordination causes only small modifications in the electronic charge distribution of the N(3)−N(2)−C(1)SNH_2 fragment, but major modifications in the fragment C(3)−C(2)−C(4)−C(5)−O, in accordance with the X-ray data for [CdL_2Py] in the solid state. This suggests that the solid−state coordination mode persists in [D_6]DMSO. The virtually constant position of the C(1) signal is attributable to slight shielding [due to some evolution from an N(2)−C(1)=S towards an N(2)=C(1)−S configuration] being offset by the deshielding inductive effect of the metal−sulfur bond.

The ^{113}Cd-NMR spectrum of [CdL_2] · 3 H_2O shows a single signal at δ = 281 (Table 2), which indicates greater shielding than is expected in an [S_2N_2] kernel.[18] In fact, even though the shielding of the ^{113}Cd nucleus generally increases with its coordination number,[19] the signal is even further upfield than in the complex [Cd(TSC)$_2$] (HTSC = pyridine 2-carboxyaldehyde thiosemicarbazone)[4a] which has an [S_2N_4] kernel. This probably indicates an increase in coordination number due to coordination to DMSO oxygen atoms. The fact that the ^{113}Cd chemical shift of [CdL_2Py] is exactly the same as that of [CdL_2] · 3 H_2O, showing Cd to have the same chemical environment in both, therefore suggests that in the former the Py ligand is replaced by molecules of solvent.

Table 2. ^{13}C- and ^{113}Cd-NMR chemical shifts (in ppm)

Compound	δC(1)	δC(2)	δC(3)	δC(4)	δC(5)	δ(^{113}Cd)
HTSC^1	178.8	148.8	16.8	46.5	167.3	
HTSC^2	178.9	147.2	16.8	43.7	170.1	
HL	175.8	152.7	12.1	91.4	163.3	
[CdL(AcO)] · 2 MeOH	176.3	157.3	14.7	85.7	167.0	156 286
[CdL_2] · 3 H_2O	176.2	156.8	14.7	86.0	166.7	281
[CdL_2Py]	176.1	156.8	14.4	85.9	166.7	281

[a] CH_3COO^-: 22.1 (Me), 178.0 (COO^-).

The ^{113}Cd-NMR spectrum of [CdL(OAc)] · 2 MeOH shows signals at both δ = 156 and 286 (area ratio 5:1). This suggests the existence of an equilibrium involving at least two species, in which the cadmium atom has different environments. Assuming that the replacement of S and N atoms by O atoms increases shielding,[20] the signal at δ = 156 can probably be assigned to the primary complex [CdL(OAc)], in which the Cd coordination sphere comprises pyrazolone N and S atoms (one each) together with O atoms from the OAc ligand and, probably, from the solvent. The signal at δ = 286, which lies very close to that of [CdL_2], may be due to a small amount of the later species being formed upon dissolution of [CdL(OAc)] · 2 MeOH in DMSO. The evolution of [CdL(OAc)] · 2 MeOH to [CdL_2] is also supported by the FAB mass spectrum of the former complex, in which the [CdL_2] peak is clearly observed, and by [CdL_2Py] having been isolated from a pyridine solution of [CdL(OAc)] · 2 MeOH (vide supra). The fact that the ^{113}Cd spectrum of [CdL(OAc)] · 2 MeOH shows no separate signal for the $Cd(OAc)_2$ that must be formed if the bispyrazolonate species is the result of symmetrization of [CdL(OAc)], may be due to the $Cd(AcO)_2$ signal being very broad.

Concluding Discussion

When acetoacetanilide and methylacetoacetate thiosemicarbazones (HTSC^1 and HTSC^2, respectively) react with cadmium(II) acetate in methanol, an elimination/cyclization process leads to the complexes [CdL(OAc)] · 2 MeOH and [CdL_2] · 3 H_2O (HL = 2-[amino(thioxo)methyl]-5-methyl-2,3-dihydro-1*H*-3-pyrazolone). In the case of HTSC^1, ^{1}H-NMR monitoring in [D_6]DMSO at room temperature suggests that the probable course of the reaction is initial formation of [Cd(TSC^1)$_2$] followed by gradual release of aniline and concomitant cyclization. Determination of the structures of the ligands HTSC^1, HTSC^2, and HL by X-ray diffraction showed the structural changes involved in this process.

Recrystallization of the complex [CdL(OAc)] · 2 MeOH from pyridine gave the new compound [CdL_2Py] which was also studied by X-ray diffraction. The structural parameters of the trigonal bipyramidal coordination sphere suggest that the N,S-bound L^- ligand and the pyridine ligand both form very strong bonds with the cadmium(II) ion. The coordination modes present in [CdL_2] · 3 H_2O and [CdL(OAc)] · 2 MeOH were diagnosed on the basis of their solid state IR spectra and ^{1}H-, ^{13}C-, and ^{113}Cd-NMR spectra in [D_6]DMSO: in solid state, both appear to have polymeric structures, with Cd hexacoordinate in [CdL_2] · 3 H_2O and pentacoordinate in [CdL(OAc)] · 2 MeOH. In [D_6]DMSO, solvent molecules appear to be included in the coordination sphere of the metal.

On reaction with aqueous trifluoroacetic acid both [CdL_2] · 3 H_2O and [CdL(OAc)] · 2 MeOH release the free pyrazolone, which can be easily isolated

Experimental Section

Thiosemicarbazide (Merck), acetoacetanilide (Merck), acetylacetoacetate (Aldrich), and cadmium acetate (Probus) were used as received. The HTSCs were obtained by the method of Jayasree and Aravindakshan.[5]

HTSC^1: M.p. 161°C. − $C_{11}H_{13}N_4OS$,: calcd. C 52.78, H 5.43, N 22.39, S 12.82; found C 52.75, H 5.60, N 22.54, S 12.74. − IR (KBr): $\tilde{\nu}$ = 3428 (s), 3268 (vs, b) 3155 (s), [ν(N−H)], 1655 (s), [ν(C=O)], 1595 (vs), [ν(C=N)], 1545 (s), 1248 (m), [ν[−N(H)C_6H_5], 1090 (s), 872 (m), [ν(C=S)]. − ^{1}H NMR (DMSO): δ = 10.17 [s, 1 H, N(4)*H*], 10.05 [s, 1 H, N(2)*H*], 8.16 [s, 1 H, N(1)H_2), 7.62 [s, 1 H, N(1)H_2], 7.03 [t, 1 H, C_6H_5(*Hp*)], 7.28 [t, 2 H, C_6H_5(*Hm*)], 7.57 [d, 2 H, C_6H_5(*Ho*)], 3.32 [s, 2 H, C(4)H_2], 1.98 [s, 3 H, C(3)H_3].

HTSC^2: M.p. 120°C. − $C_6H_{11}N_3O_2S$,: calcd. C 38.08, H 5.86, N 22.20, S 16.95; found C 38.25, H 6.05, N 22.10, S 17.60. − IR (KBr): $\tilde{\nu}$ = 3402 (vs), 3277 (vs), 3169 (s), [ν(N−H)], 1719 (vs), [ν(C=O)], 1599 (vs), [ν(C=N)], 1440 (m), [δ(−OCH_3)], 1246 (s), [ν(C−O)], 1090 (s), 853 (m), [ν(C=S)]. − ^{1}H NMR (DMSO): δ = 10.15 [s, 1 H, N(2)*H*], 8.54 [s, 1 H, N(1)H_2], 7.60 [s, 1 H, N(1)H_2], 3.33 [s, 2 H, C(4)H_2], 1.94 [s, 3 H, C(3)H_3].

The cyclic ligand **2-[amino(thioxo)methyl]-5-methyl-2,3-dihydro-1*H*-3-pyrazolone (HL)** was originally obtained serendipitously as a by-product of the synthesis of acetoacetanilide thiosemicarbazone; the solid formed when the reaction mixture was refluxed for 7 h recrystallizing from methanol as a mixture of HTSC^1 and HL. Diffraction and spectroscopic studies were performed using HL crystals separated by hand under a stereoscopic microscope. Later (vide infra) HL was also obtained by acidification of cadmium(II) complexes. − M.p. 185°C. − $C_5H_7N_3OS$: calcd. C 38.21, H 4.49, N 26.73, S 20.40, found C 38.5, H 4.5, N 26.5, S 21.6. − IR (KBr): $\tilde{\nu}$ = 3269 (vs), 3164 (vs), [ν(N−H)], 1654 (vs), [ν(C=O)], 1592 (vs), 1550 (vs), 1507 (m), [ν(ring)], 1093 (s), 875 (m), [ν(C=S)]. − ^{1}H NMR (DMSO): δ = 11.98 [s, 1 H, N(3)*H*], 10.36 [s, 1 H, N(1)H_2], 9.66 [s, 1 H, N(1)H_2], 5.16 [s, 1 H, C(4)*H*], 2.17 [s, 3 H, C(3)H_3].

Analytical data were obtained with a Fisons Instruments EA1108CHNS-O microanalyzer. − ^{1}H- and ^{13}C-NMR spectra were recorded on a Bruker WM-250 or a Bruker AMX-300, and ^{113}Cd-NMR spectra on a Bruker AMX-500. Chemical shifts are quoted on the δ scale (downfield shifts positive) relative to tetramethylsilane (^{1}H and ^{13}C NMR) or 0.1 M $Cd(ClO_4)_2$ (^{113}Cd NMR). The ^{13}C-NMR spectra of the thiosemicarbazone ligands HTSC^1 and HTSC^2 were interpreted on the basis of the chemical shifts, the multiplicity of the signals in the non-proton-decoupled spectra and DEPT-135 experiments, and that of HL on the basis of previous assignments for similar rings.[6] − Infrared spectra were recorded using KBr discs in Mattson Cygnus 100 and Bruker IFS66V spectrometers. − Mass spectra were recorded on a Kratos MS50TC spectrometer. − Melting points were determined in a Büchi apparatus.

Synthesis of [CdL(OAc)]·2 MeOH: A solution of HTSC^1 (0.50 g, 2 mmol) in methanol (15 mL) was added to a hot solution of $Cd(OAc)_2 \cdot 2\,H_2O$ (0.53 g, 2 mmol) in the same solvent (5 mL). After 4 days stirring, the pale yellow solid formed was filtered out and dried under reduced pressure. − M.p. 198°C. − $C_9H_{17}N_3O_5SCd$: calcd. C 27.6, H 4.3, N 10.7; found C 27.5, H 4.5, N 10.5. − MS (FAB, nitrobenzyl alcohol); *m*/*z* (%): 424 (76) [CdL_2], 328 (35) [M − 2 MeOH], 270 (60) [$C_5H_7N_3OSCd$], 140 (97) [$C_5H_7N_3S$], 99 (100) [$C_2H_2N_3S$]. − IR (KBr): $\tilde{\nu}$ = 3410 (m, br), [ν(OH)], 3236 (s, br), [ν(N−H)], 1602 (vs, br), [ν(C=O)], 1602 (vs, br) 1497 (m), [ν(ring)], 757 (m, br), [ν(C=S)]. − ^{1}H NMR (DMSO): δ = 11.72 [s, 1 H, N(1)H_2], 9.72 [s, 1 H, N(1)H_2], 4.67 [s, 1 H, C(4)*H*], 4.10 (c, 2 H, CH_3OH), 3.11 (d, 6 H, CH_3OH), 2.10 [s, 3 H, C(3)H_3], 1.83 (s, 3 H, CH_3COO).

Synthesis of [CdL_2]·3 H_2O: A solution of methylacetoacetate thiosemicarbazone (HTSC^2, 0.50 g, 2.64 mmol) in methanol (30 mL) was added to a methanolic solution (15 mL) of $Cd(OAc)_2 \cdot 2\,H_2O$ (0.70 g, 2.64 mmol). The mixture was refluxed for 2 h and stirred for a further 12 h. The white solid formed was filtered out and dried under reduced pressure; it decomposed before melting. − $C_{10}H_{18}N_6S_2O_5Cd$: calcd. C 25.1, H 3.8, N 17.6; found C 25.3, H 3.3, N, 17.4. − MS (FAB, nitrobenzyl alcohol); *m*/*z* (%): 425 (32) [M − 3 H_2O], 309 (31) [$C_6H_6N_4S_2Cd$], 270 (55) [$C_5H_8N_3OSCd$], 99 (91) [$C_2H_2N_3S$]. − IR (KBr): $\tilde{\nu}$ = 3550 (m), [ν(OH)], 3390 (m), 3223 (m, brs), [ν(N−H)], 1600 (vs, br), [ν(C=O)], 1600 (vs, br) 1498 (m), [ν(ring)], 752 (m, br), [ν(C=S)]. − ^{1}H NMR (DMSO): δ = 11.73 [s, 1 H, N(1)H_2], 9.70 [s, 1 H, N(1)H_2], 4.67 [s, 1 H, C(4)*H*], 1.97 [s, 3 H, C(3)H_3]. A small part of the product was recrystallized from pyridine and X-ray measurements and spectral studies were performed on the crystalline product so obtained, [CdL_2Py]: IR (KBr): $\tilde{\nu}$ = 3097 (s, br), 2959 [s, br, ν(N−H)], 1629 (vs, br), [ν(C=O)], 1600 (s), 1490 (m), [ν(ring)], 752

X-ray Crystal Structure Determinations: Data were collected on an Enraf–Nonius CAD-4 diffractometer. The structures were solved using the Patterson method for HTSC[1] and [CdL_2Py] and direct methods for HTSC[2]and HL, followed by normal difference Fourier techniques. The H atoms were introduced in calculated positions with fixed C–H distances and isotropic thermal parameters (C–H 0.95 Å; B_{iso} = 4 Å^2). The structures were refined by the full-matrix least-squares method (anisotropically for the non-H atoms). Atomic scattering factors were those included in SHELX93.[21] Other programs used were SHELX76[22]and, ORTEP.[23] Crystal and refinement data are listed in Table 3.[24]

Reactivity of Complexes in Acidic Media: Preliminary experiments exploring the behaviour of [CdL(AcO)] · 2 MeOH and [CdL_2] in acidic aqueous suspensions were performed using F_3CCOOH(aq) as proton source. The complexes released free HL, which precipitated and was easily isolated.

Photocatalyzed Oxidation of Cyclohexene and Cyclooctene with $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ and $(n\mathrm{Bu_4N})_4W_{10}O_{32}$/$Fe^{III}$[*meso*-Tetrakis(2,6-dichlorophenyl)-porphyrin] in Homogeneous and Heterogeneous Systems

Keywords: Photocatalysis / Polyoxotungstates / Catalytic oxidations / Iron porphyrins

Photoexcitation of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ is a suitable mean of oxidizing cyclohexene and cyclooctene with O_2 at room temperature and pressure. This process can be carried out in homogeneous solution as well as using the decatungstate in a dispersed form after its heterogenisation on silica. Cyclohexene and cyclooctene are mainly oxidized to the corresponding hydroperoxides as a consequence of primary photoprocesses which lead to the formation of allylic radicals. The presence of the Fe^{III}[*meso*-tetrakis(2,6-dichlorophenyl)porphyrin] chloride as cocatalyst strongly affects the photocatalytic properties of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$, playing a key role in the allylic-hydroperoxide dependent oxidation of the cycloalkenes. In the photooxidation of cyclohexene, the porphyrin increases the photocatalytic efficiency of the decatungstate in terms of total turnover number and catalyses the decomposition of cyclohexenyl hydroperoxide with the selective formation of cyclohex-2-en-1-ol. On the other hand, its presence during the photoinduced oxidation of cyclooctene favours the formation of cyclooctene epoxide by addition of ROO· and RO· radicals to the double bond. In the case of cyclooctene, the heterogenisation of the decatungstate on the solid support also affects the chemoselectivity of the photocatalytic process in the absence of the iron porphyrin complex.

Introduction

The catalytic oxidation of hydrocarbons at room temperature and atmospheric pressure using environmentally friendly reagents, such as O_2, is an important goal both in fine and industrial chemistry.[1] In this challenging field, a number of groups are investigating polyoxometallates as catalysts with a noticeable activity in the oxidation of numerous organic compounds.[2] Their heterogenisation with solid matrices is attracting more and more interest[3] because the support makes them more easily handled and recycled than in homogeneous solution and, moreover, it can play a fundamental role in controlling both the efficiency and the selectivity of the catalytic process. In this framework, we have recently reported that photoexcitation of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ supported on silica induces the oxidation of cyclohexane by O_2.[4] In particular we pointed out that the $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$ system is a very promising photocatalyst for synthetic purposes, because its efficiency is comparable to that of the semiconductor TiO_2, with the advantage that it does not cause any oxidative mineralisation of the substrate.

We examine here the photocatalytic properties of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ **1** and $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$ **2** in the oxidation of cyclohexene and cyclooctene. We have chosen these two substrates as representative unsaturated hydrocarbons which are expected to present different oxidation mechanisms under aerobic conditions.[5] As part of our continuing interest in composite systems based on the use of polyoxotungstates and iron porphyrins,[6] we have also investigated the photocatalytic properties of **1** and **2** in the presence of Fe^{III}[*meso*-tetrakis(2,6-dichlorophenyl)porphyrin] chloride [Fe(TDCPP)Cl] as cocatalyst. In this case, we are interested in verifying the possible role of the porphyrin complex in governing the oxidation product distribution through its well-known mechanisms.[7] The bulky substituents in the *ortho* positions of the porphyrin *meso*-aryl groups provide a steric protection of the aromatic ring against a rapid oxidative degradation of the complex during both thermal[8] and photochemical catalytic processes.[9]

Results and Discussion

EPR Spin Trapping Investigation

In this section we report the results obtained during photoexcitation of **1** and **2** in the presence of phenyl *tert*-butyl nitrone, which is known to trap radicals to give more stable nitroxides.[10] Although the trapping process is not quantitative, in many instances the captured radical can be identified by the parameters obtained from the EPR spectrum. Using this technique, we revealed the radical species formed during the oxidation of cyclohexane[6a] and cyclohexylamine[11] photocatalysed by complex **1**.

Both **1** and **2** were irradiated in a CH_3CN/cyclohexene (6:1) mixture containing phenyl *tert*-butyl nitrone (1×10^{-3} mol·dm^{-3}) inside the cavity of an EPR spectrometer. The spectrum obtained is shown in Figure 1. It consists of a triplet of doublets with hyperfine coupling constants (a_N =

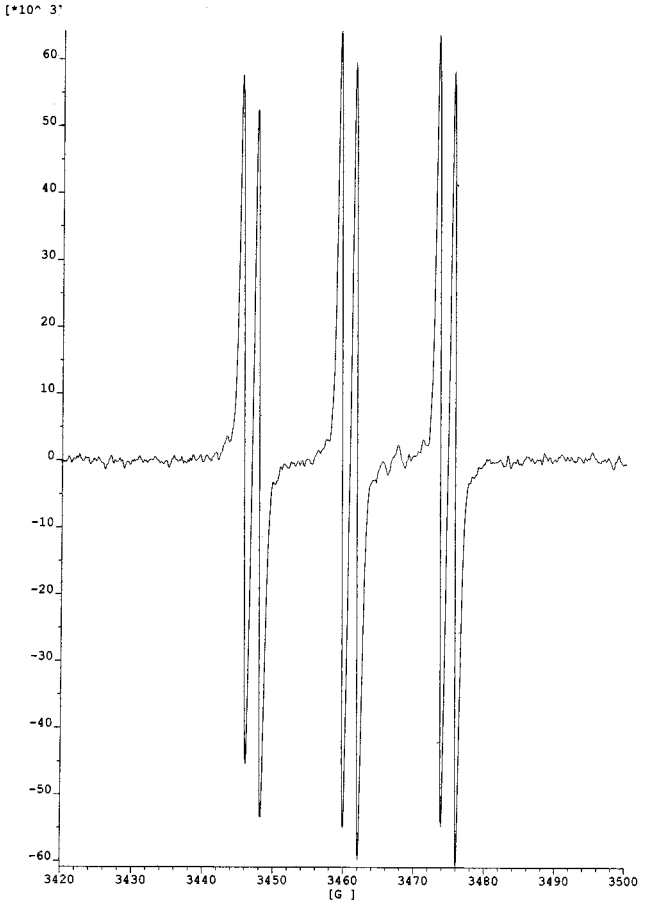
13.7 G and a_H = 2.1 G) which can be assigned to the adducts between the spin trap and cyclohexenyl radicals.[10] This spectrum remained the same even when an analogous irradiation was performed under anaerobic conditions. We can therefore conclude that it is not due to the trapping of cyclohexenylperoxo radicals, which are known to form a paramagnetic adduct with very similar hyperfine coupling constants.[12] The trapping of cyclohexenyl radicals is in agreement with the results of other authors who proposed that the dimeric species obtained in analogous experiments under anaerobic conditions originated from the coupling of these allylic radicals.[13]



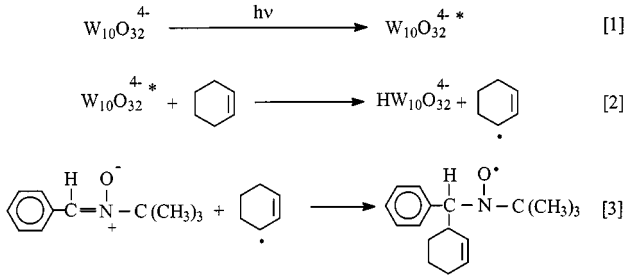


Figure 1. EPR spectrum obtained during irradiation ($\lambda > 320$ nm) of an aerated cyclohexene/CH_3CN (1:6 v/v) solution of $W_{10}O_{32}^{4-}$ (1×10^{-3} mol·dm^{-3}) in the presence of phenyl *tert*-butyl nitrone (1×10^{-3} mol·dm^{-3})

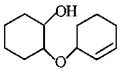
The detection of allylic radicals indicates that the photoinduced oxidation of cyclohexene occurs according to the mechanisms already proposed for the oxidation of other hydrocarbons and alcohols.[14] In particular, compound **1** in the photogenerated excited state is able to abstract a hydrogen from the cycloalkene to produce allylic radicals according to Equations 1 and 2. These radical species can be trapped by phenyl *tert*-butyl nitrone giving a paramagnetic nitroxide stable enough to be detected by EPR spectroscopy (Equation 3).

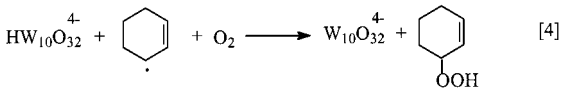
We failed to detect any EPR signals on irradiating **1** or **2** in CH_3CN/cyclooctene (6:1), indicating that the photoinduced oxidation of cyclooctene (Equation 2), although possible, does not give a steady state concentration of allylic radicals that is sufficiently high to obtain an observable paramagnetic adduct with phenyl *tert*-butyl nitrone. The different behaviour of the two investigated cycloalkenes can be explained by taking into account that cyclooctene is much less reactive than cyclohexene in hydrogen-abstraction processes. In particular, the relative rate constants differ by a factor of 17, depending mainly on the degree of reorganization required to give a planar allylic radical.[5]

Photocatalyzed Oxygenations with $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ and $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$



The EPR experiments show that under photolytic conditions, the decatungstate is able to initiate the oxidation of cyclohexene through allylic hydrogen abstraction (Equations 1 and 2). It is clear that for efficient catalytic cycles to be observed, the polyoxotungstate in its original form should be easily restored after the primary photoreduction. It has already been reported that **1** and **2** in their oxidised states can be regenerated by O_2, which, in turn, undergoes a reductive activation process[14c,15] with a pseudo first-order rate constant of about 150 s^{-1}.[6b] On this basis, we have investigated the possibility of inducing the photocatalytic oxidation of cyclohexene to stable products in the presence of O_2.

In typical experiments, **1** (2×10^{-4} mol·dm^{-3}) was irradiated in a CH_3CN/cyclohexene (6:1) mixture saturated with O_2, and **2** (20 g·dm^{-3}) as a powder suspension in the same dispersing medium. The selected excitation wavelength range ($300 < \lambda < 370$ nm) and the amounts of photocatalysts were chosen so that the maximum absorption of the incident light was the same in the two systems. Table 1 reports the distribution of the oxidation products and the overall turnover values after two hours irradiation.



Photoexcitation of **1** in the homogeneous phase leads to the oxidation of cyclohexene to the corresponding allylic hydroperoxide as the main product (about 90% of the overall oxidized cycloalkene). In agreement with literature data on the photocatalysed oxidation of alkanes in the presence of decatungstates and O_2, we propose that the hydroperoxide is formed according to Equation 4.[14c]

In agreement with previous evidence,[16] we also observed the formation of cyclohex-2-en-1-ol and cyclohex-2-en-1-one during irradiation. On the basis of literature data regarding alkane photooxidation with **1**,[6,14c] we propose that

Table 1. Photocatalytic properties[a] of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ **1** and $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$ **2** in CH_3CN/cyclohexene (6/1), in the presence of 760 Torr of O_2, with and without Fe(TDCPP)Cl

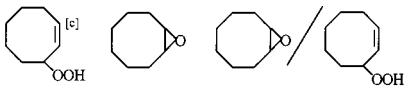
[a] 3 ml of CH_3CN/cyclohexene 6:1 containing **1** ($2x10^{-4}$ mol· × dm^{-3}, 0.6 μmol of irradiated polyoxotungstate) or **2** (20 g·dm^{-3}, 1.93 μmol of irradiated polyoxotungstate) were irradiated for 120 minutes at 22 ± 1°C. Excitation wavelengths: 300<λ<370 nm. Light intensity: 15 mW × cm^{-2}. The error calculated on the basis of the obtained concentration data is ±5%. – [b] μmol of oxidised cyclohexene/μmol of decatungstate. – [c] Total peroxides are determined with the iodometric method; however, considering that cyclohexene exhibits a higher reactivity than acetonitrile and on the basis of literature data,[14c] we can approximate that the allylic hydroperoxide is the main component. – [d] Initial concentration of Fe(TDCPP)Cl: 2 × 10^{-5} mol × dm^{-3}. – [e] 180 minutes after light interruption. – [f] The reported values are corrected for the thermal decomposition of hydroperoxide inside the chromatographic column (see Experimental section). – [g] The photocatalyst has been used for four consecutive cycles, leading to similar values within the experimental error.

[4]

the formation of these products occurs mainly according to Equations 5–9 which involve the decatungstate both in its excited state and in its photoreduced form.

The possibility that the allylic hydroperoxide undergoes a secondary disproportionation or reactions with the cycloalkene without the involvement of the photoexcited decatungstate can be excluded since the total turnover number and the product distribution did not show any appreciable change when irradiation is interrupted. This statement is in agreement with the conclusion of a previous paper concerning the oxidation of cyclohexene by hydroperoxides in the presence of polyoxoanions.[17] Another possible reaction leading to the formation of allylic oxidation products is the well-known direct photochemistry of hydroperoxides.[18] However this possibility can be ruled out by taking into account the fact that the chosen amount of decatungstate avoids any possible light absorption by the hydroperoxide. Finally, we have to consider that some possible autooxidation reactions may give the observed traces of cyclohexene epoxide. Thus, the hydroxy ether reported in the last column of Table 1 can originate from the opening of the epoxide ring as a consequence of a nucleophilic attack by cyclohex-2-en-1-ol, favoured by the presence of protons. Despite a significant reduction in the turnover values, the use of the heterogeneous photocatalyst **2** does not cause any significant change in the nature and distribution of the oxidation products of cyclohexene.



The absence of any EPR signals during irradiation of **1** or **2** in the presence of cyclooctene is in agreement with the low tendency of this cycloalkene to release allylic hydrogen atoms and, therefore, to form hydroperoxides according to Equation 4. On the other hand, even small amount of hydroperoxides are sufficient to initiate radical chain processes under aerobic conditions leading to the autooxidation of cyclooctene. This process is well-known to occur via addition of ROO· or RO· radicals to the double bond and is largely responsible for cyclooctene epoxide formation.[5]

In line with the above accepted mechanism, Table 2 shows that irradiation of **1** or **2** in a CH_3CN/cyclooctene mixture (6:1) saturated with O_2 leads to the formation of allylic hydroperoxide and cyclooctene epoxide, although with turnover values significantly lower than those obtained during the photooxidation of cyclohexene. It is worth not-

ing that, contrary to what was observed with cyclohexene, heterogenisation of the decatungstate on the solid support affects the chemoselectivity of the photocatalytic process by increasing the epoxide/hydroperoxide concentration ratio.

tive moiety of both the integrated systems **1/**Fe(TDCPP)Cl and **2/**Fe(TDCPP)Cl. The presence of Fe(TDCPP)Cl induces the following main effects on the photocatalytic properties of **1** in the oxidation of cyclohexene (Table 1): (i)

Table 2. Photocatalytic properties[a] of $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ **1** and $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$ **2** in CH_3CN/cyclooctene (6:1), in the presence of 760 Torr of O_2, with and without Fe(TDCPP)Cl

[a] 3 ml of CH_3CN/cyclooctene (6:1) containing **1** (2×10^{-4} mol·dm^{-3}, 0.6 μmol of irradiated polyoxotungstate) or (**2**) (20 g·dm^{-3}, 1.93 μmol of irradiated polyoxotungstate) were irradiated for 120 minutes at 22 ± 1°C. Excitation wavelengths: 300<λ<370 nm. Light intensity: 15 mW × cm^{-2}. Reported values are ±5%. – [b] μmoles of formed product/μmoles of irradiated decatungstate. – [c] Because of the lower reactivity of cyclooctene, we were forced to verify the amount of peroxide, deriving from CH_3CN, formed during irradiation. We observed that it was negligible with respect to that obtained from cyclooctene. – [d] Initial concentration of Fe(TDCPP)Cl: 2×10^{-5} mol × dm^{-3}. – [e] 180 minutes after light interruption. – [f] The photocatalyst has been used for four consecutive cycles, leading to similar values within the experimental error.

A confirmation that the overall oxidation process is initiated by a hydrogen abstraction process from the cycloalkene comes from some additional experiments in which the decatungstate was irradiated in the presence of styrene which, under our photocatalytic conditions, is not oxidised at all.

Since we observe that the oxidation of both cyclohexene and cyclooctene does not continue when irradiation is interrupted, we can conclude that the photoreduced decatungstate plays a key role in the oxidation mechanism. In particular, it could participate in the formation of RO· and ROO· according to Equations 5–7.

As a final note on the use of the heterogeneous photocatalyst **2**, we should point out that it presents the important characteristic of not suffering irreversible modification, except a negligible release of the polyoxotungstate into solution (less than 2%). Moreover, it could be reused several times without any significant loss of photocatalytic activity. These features make **2** a very promising system in heterogeneous catalysis, where the advantages deriving from a higher ease of employment and recycling of the photocatalyst are often priority objectives.

Photocatalyzed Oxygenations with $(n\mathrm{Bu_4N})_4W_{10}O_{32}$ and $(n\mathrm{Bu_4N})_4W_{10}O_{32}/SiO_2$ in the Presence of Fe(TDCPP)Cl

Irradiation of **1** and **2** was also carried out in the presence of Fe(TDCPP)Cl (2×10^{-5} mol·dm^{-3}) as cocatalyst. Since the decatungstate absorbs more than 95% of the selected incident light, it can be considered the photochemically active moiety of both the integrated systems **1/**Fe(TDCPP)Cl and **2/**Fe(TDCPP)Cl. The presence of Fe(TDCPP)Cl induces the following main effects on the photocatalytic properties of **1** in the oxidation of cyclohexene (Table 1): (i) the efficiency in terms of total turnover increases; (ii) a lower amount of allylic hydroperoxide is obtained; (iii) the sum of the alcohol and the ketone represents 40% of the overall oxidised cycloalkene; (iv) the ketone to alcohol concentration ratio decreases (from 4.1 to 1.6). Table 1 also shows that the presence of the iron porphyrin has the additional effect of inducing a residual catalytic activity after irradiation is interrupted. This activity changes the product distribution by converting the allylic hydroperoxide mainly to cyclohex-2-en-1-ol, whose concentration increases to almost 100%.

Fe(TDCPP)Cl also affects the catalytic properties of **2** during irradiation as well as in the dark. In these cases, the effects are similar to those observed in the homogeneous phase, but appear less evident. This could be due to the fact that the iron porphyrin complex preferably remains in solution, thereby reducing its interactions with the supported photocatalyst and the reactive species photogenerated in the neighbours.

As far as the stability of the porphyrin complex is concerned, we do not observe any appreciable bleaching of its UV/Vis spectrum in the wavelength range from 350 to 700 nm thus indicating that it does not undergo any significant degradation during the irradiation. This fact represents an important improvement with respect to both the photocatalytic activity of the iron porphyrins alone[19] and the same composite system used in the photooxidation of cyclohexane.[6b]

The possibility that the photoreduced decatungstate can transfer one electron to the iron(III) porphyrin,[20] so creating a ferrous complex able to induce the reductive acti-

vation of O_2, can be ruled out, since the reoxidation of $W_{10}O_{32}^{5-}$ by O_2 is known to be the kinetically favoured process under aerobic conditions.[6b,6c] Therefore, we consider that the iron porphyrin in its oxidised form plays a dominant role in the overall oxidation mechanism. In particular, an iron-porphyrin-mediated decomposition of allylic hydroperoxides to give the corresponding alcohols according to Equations 10−13 can be proposed on the basis of intensive studies on halogenated iron porphyrins.[21] The great significance of this reaction pathway in the overall oxidation mechanism is demonstrated by the residual reactivity observed after irradiation. In fact, under these conditions, cyclohex-2-en-1-ol cannot undergo photoinduced oxidation by the decatungstate (Equation 8) and so has the possibility to reach concentrations higher than those of cyclohex-2-en-1-one.

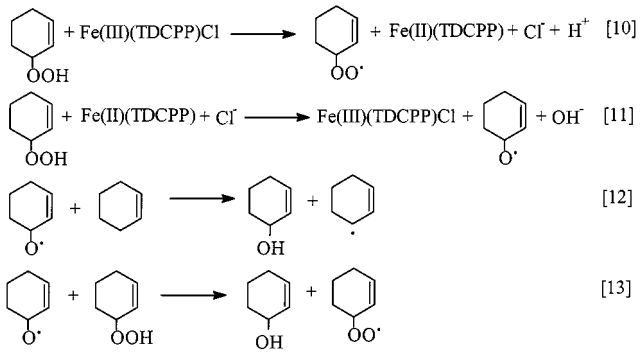

Table 2 shows that the iron porphyrin also affects the chemoselectivity of the oxidation of cyclooctene, significantly increasing the epoxide/hydroperoxide concentration ratio. Its main effect is likely to be that it favours the decomposition of the allylic hydroperoxide to give ROO· and RO· radicals following reactions similar to those shown in Equations 10 and 11 for cyclohexene. In agreement with previous evidence, these species are able to epoxidize cyclooctene by addition to the double bond.[5]

On the basis of the bleaching of the iron porphyrin during the photoinduced cyclooctene oxidation we conclude that about 300 equivalents of allylic hydroperoxide and cyclooctene epoxide were formed per equivalent of consumed iron porphyrin.

Conclusion

Photoexcitation of $(n\text{Bu}_4\text{N})_4\text{W}_{10}\text{O}_{32}$ is a suitable means of performing the catalytic oxidation of cycloalkenes by O_2 at room temperature and pressure. This process can be carried out in homogeneous solution as well as by using the decatungstate in a dispersed form after its heterogenisation on silica. Cyclohexene and cyclooctene are mainly oxidized to allylic hydroperoxides as a consequence of allylic hydrogen abstraction both in homogeneous solution and in the heterogeneous system. In the case of cyclooctene, the heterogenization of the decatungstate on the solid support affects the epoxide/hydroperoxide concentration ratio. The EPR spin trapping investigation has revealed for the first time the formation of cyclohexenyl radicals during the photocatalytic process.

The Fe(TDCPP)Cl complex can increase the efficiency of the photocatalytic process and affects its chemoselectivity. In particular, the iron porphyrin can catalyse the decomposition of allylic hydroperoxides giving, exclusively, the allylic alcohol from cyclohexene. On the contrary, this process induces the formation of epoxide from cyclooctene.

The possibility of obtaining allylic hydroperoxides in the presence of metalloporphyrins with molecular oxygen and light as reagents can open new perspectives for the development of new, clean processes of interest in oxidative syntheses.

Experimental Section

General: IR: Nicolet 510P FTIR instrument in KBr, fitted with a Spectra-Tech collector diffuse reflectance accessory (range from 4000 to 200 cm^{-1}). − EPR: X-band Bruker 220 SE, calibrated with α-α′-diphenylpicrylhydrazyl. − UV/Vis: Kontron Uvikon 940. − GC: Dani 8521, equipped with a FID detector and a packed column (Carbowax, 20 M, 5% on Chromosorb W-AW). − Irradiation: medium-pressure Hanau Q-400 mercury lamp.

Compound **1** and Fe(TDCPP)Cl were synthesised following literature procedures.[22] CH_3CN was a commercial spectroscopic grade solvent (Carlo Erba), used as received. Cycloalkenes were purchased from Fluka and employed after distillation. Phenyl *tert*-butyl nitrone was purchased from Aldrich and employed without any further purification.

Procedures: Heterogenisation of **1** on silica, leading to **2**,[4] was performed by dissolving 0.1 g of the decatungstate in CH_3CN and adding 1 g of colloidal silica (0.012 μm, Strem Chemicals). Subsequently, the suspension was continuously shaken at room temperature for two hours. The excess CH_3CN was evaporated at 80°C, and the sample was then dried at 100°C for 24 hours. UV/Vis spectra indicated that after this treatment the powder photocatalysts were stable and did not release the decatungstate in CH_3CN. IR spectra of the solid sample **2** have shown the characteristic bands for tetraalkylammonium cations [$\tilde{\nu}$ = 2963 and 2875 cm^{-1} (-CH_3 and -CH_2), 1481 (C−H of CH_3, C−H of CH_2), 1383 (C−H of CH_3)] and for $W_{10}O_{32}^{4-}$ [$\tilde{\nu}$ = 958, 890, 802 cm^{-1}].[23]

EPR spin-trapping experiments were carried out by irradiating (λ > 320 nm), directly in the EPR cavity, an aerated solution of **1** (1×10^{-3} mol·dm^{-3}) in CH_3CN and cycloalkene (6:1) containing phenyl *tert*-butyl nitrone (5×10^{-3} mol·dm^{-3}). A flat quartz cell was used as the reaction vessel. Signals of significant intensity were not observed in the absence of the polyoxoanion, or cycloalkene or light. Analogous experiments were carried out with **2** (20 g·dm^{-3}) dispersed in the same mixed solvent.

Continuous irradiations were performed with a Hg medium pressure lamp, selecting a wavelength range from 300 to 370 nm with a chemical-optical filter made from a Corning glass filter and a cuvette with a path length of 1 cm containing a $NiSO_4$ solution (0.8 g·cm^{-3}). The amounts of irradiated photocatalysts have been chosen in order to have the maximum absorption of incident light in any case. A 3 mL solution of **1** (2×10^{-4} mol·dm^{-3}, 0.6 μmol of decatungstate) in CH_3CN and cycloalkene (6:1) mixed solvent was irradiated for 120 minutes under an O_2 pressure of 760 Torr at 22 ± 1°C. The same procedure has been followed for **2** (20 g·dm^{-3}, 1.93 μmol of decatungstate). Catalyst **2** was kept in suspension by

magnetic stirring. The UV/Vis spectrum of the CH_3CN/cycloalkene mixture after the photocatalytic experiment with **2** indicated that between 1% or 2% of decatungstate had been lost from the silica-supported catalyst. When needed, Fe(TDCPP)Cl (2×10^{-5} mol·dm^{-3}) was added before irradiation.

The reaction products were determined by GC analysis comparing their retention times with those of authentic samples, and with iodobenzene as internal standard. No oxidation products were observed when blank experiments were run in the dark.

The determination of hydroperoxides was performed by a spectrophotometric standard method reported in the literature.[24] The concentrations of the allylic oxidation products obtained from cyclohexene could not be determined by GC analysis of the irradiated sample because the allylic hydroperoxide is thermally unstable and is expected to decompose inside the chromatographic column to give a mixture of cyclohex-2en-1ol and cyclohex-2-en-1-one.[14c] On the other hand, it was possible to perform the GC analysis of the ketone in the irradiated sample, after a complete reduction of the allylic hydroperoxide to the corresponding alcohol by an excess of iodide; control experiments showed that the ketone is not reduced to the corresponding alcohol by iodide. The difference between the alcohol concentration obtained in this last experiment and that of the allylic hydroperoxide obtained by the spectrophotometric method represents the amount of alcohol formed during the photocatalytic experiment. On this basis, we could also calculate the amounts of alcohol and ketone formed inside the chromatographic column: the allylic hydroperoxide was decomposed by 45% to give a mixture of the corresponding alcohol and ketone in the concentration ratio 1:2.

Acknowledgments

We thank Dr. Battioni and Dr. Mansuy of the Laboratoire de Chimie et Biochimie Pharmacologique and Toxicologique, URA 400 CNRS, Université Paris V, for their work in the synthesis of the iron porphyrin complex used in this study. Financial support from the MURST (Ministero della Università e della Ricerca Scientifica e Tecnologica) and the CNR (Consiglio Nazionale delle Ricerche, project 95/95−5%) is gratefully acknowledged.

Structural Studies of MCM-48 Derivatized with (1,1′-Ferrocenediyl)dimethylsilane

Paula Ferreira,[a] Isabel S. Gonçalves,[a] Fred Mosselmans,[b] Martyn Pillinger,[a] João Rocha,*[a] and Alan Thursfield[a]

Keywords: Mesoporous materials / MCM-48 / Immobilization / (1,1′-Ferrocenediyl)dimethylsilane / ^{13}C and ^{29}Si solid-state NMR / Sandwich-complexes

The walls of the cubic mesoporous silicate MCM-48 have been grafted with ferrocenyl end groups by a ring-opening reaction of the *ansa*-bridged ferrocene [Fe{(η-C_5H_4)$_2$SiMe_2}], carried out in a pentane solution at room temperature. The orange product has been characterized by elemental analysis, powder X-ray diffraction, ^{13}C and ^{29}Si solid-state NMR, N_2 adsorption measurements, and Fe K-edge EXAFS. A high loading has been obtained (8.18 mass % Fe) and, as a result of the inclusion of the organometallic moiety, the N_2 adsorption isotherm exhibits a lower uptake. Direct structural evidence for the surface attachment of both single ferrocenyl and short chain oligo(ferrocenyl) fragments has been obtained.

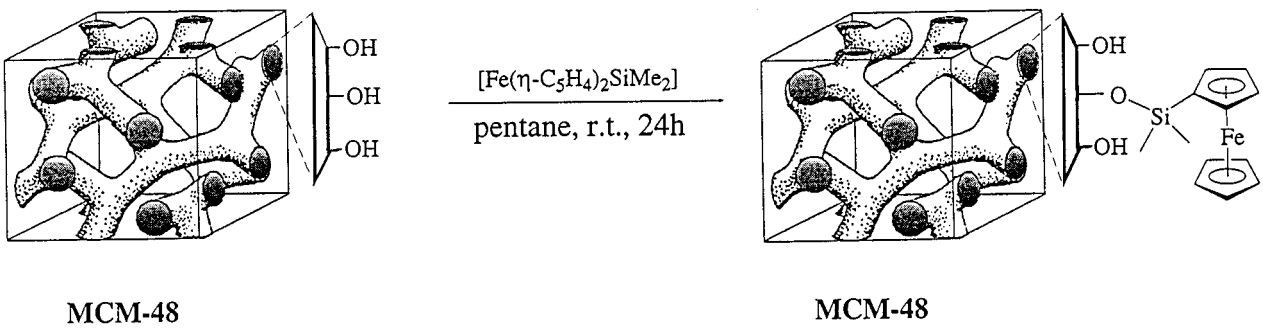
Introduction

Interest in the inclusion chemistry of mesoporous oxides has accelerated since the report in 1992 by researchers at the Mobil Corporation of the discovery of a new generation of liquid crystal surfactant templated aluminosilicates,[1] distinguished by having highly ordered structures with high surface areas (1000 $m^2\ g^{-1}$), high pore volumes (1 $cm^3\ g^{-1}$), and very narrow pore-size distributions, tuneable in the range 20−100 Å. The so-called M41S family includes the thermally stable hexagonal MCM-41 and cubic MCM-48 phases. Their unique properties have stimulated research in areas that include sorption and phase transitions in confined spaces, ion exchange, the formation of intrachannel metal, metal oxide, and semiconductor clusters, and inclusion of metal complexes and other guests.[2] Like the commonly used silica and alumina supports, the inner surfaces of these mesoporous hosts contain pendant Si−OH groups (silanols) that enable covalent anchoring of functional groups to the channel walls. Potential applications include heterogeneous catalysis and photocatalysis involving bulky grafted catalysts and/or the conversion of large substrates, separation, removal of heavy metals, and chromatography. Our objective is the immobilization of relevant complexes on the surfaces of these mesoporous supports.

Much of the published work to date has been centred on MCM-41 as the mesoporous host. In contrast, little has been reported regarding MCM-48 which has a very different lattice. The pore system in MCM-41 is simple and consists of a hexagonal arrangement of parallel one-dimensional channels. MCM-48 possesses a complex pore architecture consisting of two mutually intertwined but unconnected three-dimensional nets. It is assumed that the silica interface resembles a minimal surface of the gyroid type.[3] Recently, O′Brien et al. showed that the walls of MCM-41 may be functionalized with ferrocenyl end groups by a ring-opening reaction with the strained metallocenophane [Fe{(η-C_5H_4)$_2$SiMe_2}].[4] We have followed up this work and now wish to report structural studies on MCM-48 functionalized with (1,1′-ferrocenediyl)dimethylsilane. The results are compared with MCM-41. All materials have been fully characterized by elemental analysis, powder X-ray diffraction, N_2 adsorption, magic-angle spinning (MAS) NMR (^{13}C, ^{29}Si) and Fe K-edge EXAFS spectroscopies.

Results and Discussion

Synthesis and Spectroscopic Characterization



The synthesis and some reaction chemistry of (1,1′-ferrocenediyl)dimethylsilane and other derivatives have been reported, and it was found that [1]ferrocenophanes are susceptible to nucleophilic attack by ROH.[5] This ring-opening reaction is responsible for the persistent attachment of the [Fe{(η-C_5H_4)$_2$SiMe_2}] unit to surfaces. Like silica and alumina supports, MCM-48 should be capable of surface reactions via terminal silanol groups.

Mixing of a suspension of MCM-48 with excess of the organometallic (1,1-ferrocenediyl)dimethylsilane in pentane at room temperature for 24 hours gives an orange solid MCM-48/[Fe{(η-C_5H_4)$_2$SiMe_2}] (**1**, Scheme 1). The air-stable powder was washed with pentane to remove a small portion of converted ferrocene and some unchanged [Fe{(η-C_5H_4)$_2$SiMe_2}].

Elemental analysis indicated that a high loading of [Fe{(η-C_5H_4)$_2$SiMe_2}] in the material had been achieved (8.18% mass Fe). The powder X-ray diffraction pattern of

parent MCM-48 (Figure 1) can be indexed on a cubic unit cell (using the strongest reflection, d_{211}, a = 88.616 Å). The pattern of functionalized MCM-48 is consistent with retention of the cubic mesoporous structure. The strongest peak shifts slightly (a = 86.559 Å). In addition, the observed slight decrease in peak intensities does not necessarily reflect a decrease in the order of the structure but could instead be due to a decrease in the scattering contrast between the silica framework and the pores as a result of inclusion of the ferrocenyl groups.[6]

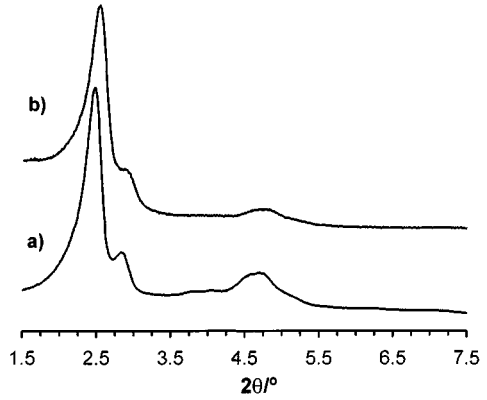

Figure 1. Powder X-ray diffraction patterns of a) as-synthesized and b) functionalized MCM-48

Solid-State NMR Studies

The ^{29}Si-CP MAS NMR spectrum of functionalized MCM-48 (Figure 2) exhibits two broad overlapping peaks $\delta = -108.8$ and -101.5, assigned to the Q_4 and Q_3 units of the silica framework, respectively. A small amount of Q_2 environments (faint peak at $\delta = -91.2$) is also present [$Q_n = Si(OSi)_n(OH)_{4-n}$]. Both the ^{29}Si CP MAS and MAS NMR spectra clearly show that upon functionalization the intensity of the Q_3 (and Q_2) peak decreases considerably. This result is consistent with the observed large decrease in the intensity of the IR absorption-band associated with OH groups on the silica surface [ν(OH) = 3742 cm^{-1}].[7] Functionalized MCM-48 also displays two strong resonances at high-frequency. The peak at δ = 6.5 may be assigned to Si−O−**Si**Me_2Fc environments (Fc = ferrocenyl group),[4] and the signal at $\delta = -6.4$ has been previously assigned to the bridging silicon atoms in small oligomeric units of poly(ferrocenylsilane), the first unit of which is bound to the channel wall.[8] A third faint peak is seen at $\delta = -2.3$. At present, we are unable to assign this resonance.

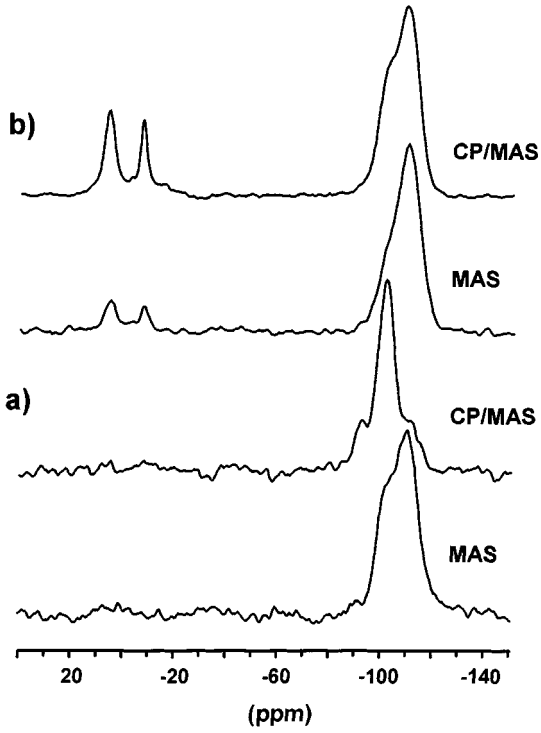

Figure 2. ^{29}Si-CP MAS and MAS NMR spectra of a) as-synthesized and b) functionalized MCM-48

The solid-state ^{13}C-CP MAS NMR spectrum of MCM-48/[Fe{(η-$C_5H_4)_2SiMe_2$}] (**1**) is shown in Figure 3. The spectrum exhibits three resonances at δ = 72.3, 68.6 and 0.1, attributed to C_5H_4Si, C_5H_5, and $SiMe_2$, respectively. The unusually high-field resonance at δ = 33.5, for the cyclopentadienyl carbon attached to silicon in the [Fe{(η-$C_5H_4)_2SiMe_2$}], shifted to a more conventional value δ = 72.3 in the spectrum of the material **1**.

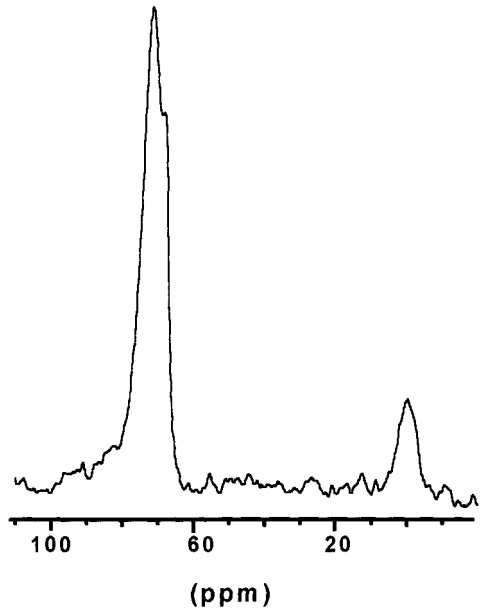

Figure 3. ^{13}C CP MAS spectrum of functionalized MCM-48

N_2 Adsorption Studies

The calcined MCM-48 sample gave a type IV N_2 adsorption isotherm (Figure 4) as designated in the IUPAC classification,[9] which is typical of a mesoporous solid and is comparable to that reported by other workers for cubic mesoporous MCM-48.[10] A well-defined step, and sharp inflection between relative pressure $P/P_o = 0.3$ and 0.4 corresponds to capillary condensation and suggests a rather narrow pore size distribution. The calcined MCM-41 sample also gave a type IV N_2 adsorption isotherm.

BET surface areas were calculated with the average area occupied by a N_2 molecule in the monolayer taken as 16.2 Å^2. Values of 770 m^2 g^{-1} and 970 m^2 g^{-1} were obtained for MCM-48 and MCM-41, respectively. The N_2 adsorption isotherms of the functionalized MCMs are quite different from those of the parent materials, demonstrating a lower uptake. Diffusion of N_2 through the pore system of the functionalized MCM-41 material was found to be extremely slow, hence the isotherm presented is produced from nonequilibrium points, but it serves to indicate the greatly reduced uptake. These results indicate that the free pore volume of the materials has been reduced as a result of immobilization of ferrocenyl fragments on the internal surface of the mesoporous hosts. In support of this conclusion, the BET surface areas decreased to 500 m^2 g^{-1} for MCM-48 and 270 m^2 g^{-1} for MCM-41, although of course the latter value is based on nonequilibrium data but again serves as a general indicator.

EXAFS Studies

The Fe K-edge EXAFS of MCM-41 and MCM-48 derivatized with [Fe{(η-C_5H_4)$_2$SiMe_2}] were analysed by beginning with a model of ferrocene for the Fe centre, and therefore selecting a single shell of ten carbon atoms (fit A). Refinement gave very similar theoretical fits to both EXAFS spectra and very similar structural parameters with an average Fe−C bond length of 2.06−2.07 Å and a Debye-Waller factor of 0.011−0.012 Å^2 (Table 1).

[a] T = Atom type. − [b] N = Coordination number. Note that the errors in EXAFS-derived coordination numbers for well-defined shells are generally accepted to be of the order 20%. − [c] r = interatomic distance (standard deviations in parentheses). The systematic errors in bond lengths arising from data collection and analysis procedures are ± 0.02−0.03 Å for well-defined coordination shells. − [d] Debye−Waller factor; σ = root-mean-square deviation of interatomic distance about r. − [e] R factor = $(\Sigma|\chi^{calc} - \chi^{exp}| k^3 dk / \Sigma|\chi^{exp}| k^3 dk) \times 100\%$.

These results are comparable to those reported by O'Brien et al. for MCM-41 modified with the same complex (10 carbons at 2.045 Å, $2\sigma^2$ = 0.007 Å^2).[4] The coordination number for this shell was subsequently refined, and in both cases the best fits were obtained with a value of about 8.5 (fit B, Figure 5). It may be concluded therefore that the structural integrity of the ferrocenyl units has remained intact in the functionalid MCMs, given that errors in EXAFS-derived coordination numbers for well defined shells are generally accepted to be of the order of 20%. Additional shells in the model for nonbonded silicon or carbon atoms were not reliable as either the resulting structural parameters were poorly defined (high statistical errors) or the decrease in the fit index was not statistically significant.

In the fit to the Fe K-edge EXAFS of (1,1-ferrocenediyl)-dimethylsilane (fit A, 10 carbon atoms), the refined Fe−C bond length was slightly shorter (2.02 Å) and the Debye−Waller factor was significantly higher (0.024 Å^2) than the corresponding values obtained for the derivatized MCMs (Table 1). Overall the fit was much poorer (R-factor 52.7%). The high Debye−Waller factor is indicative of high thermal and/or static disorder in the Fe−C bond. In this *ansa*-bridged ferrocene, the cyclopentadienyl rings are tilted with respect to one another by an angle of 20.8°, the compound is appreciably strained and there is significant departure from planarity at the *ipso* carbon atom.[12] These factors are responsible for the compounds reactivity to ring-opening polymerizations. The iron lies closer to the *ipso* carbon and the two carbons adjacent to it than the two opposite it. The resulting wide and nonsymmetric distribution in Fe−C bond lengths (1.99−2.07 Å) explains the high EXAFS-derived Debye−Waller factor and the inadequate fit to the EXAFS. Attempts to fit more than one shell for bonded carbon atoms were unsuccessful. In contrast the shell of ten carbon atoms in fit A for the MCM-supported materials was well-defined and this is good evidence that the ring strain in the organometallic guest molecule has been released, i.e., that a ring-opening reaction has occurred and the cyclopentadienyl ligands are parallel, resulting in a narrower and more symmetric distribution in Fe−C bond lengths.

An attempt was made to improve the model for [Fe{(η-$C_5H_4)_2SiMe_2$}] by including a shell for nonbonded silicon, expected at 2.69 Å. This resulted in a modest improvement in the fit and a reasonable value for the distance but the statistical errors for the structural parameters of this shell

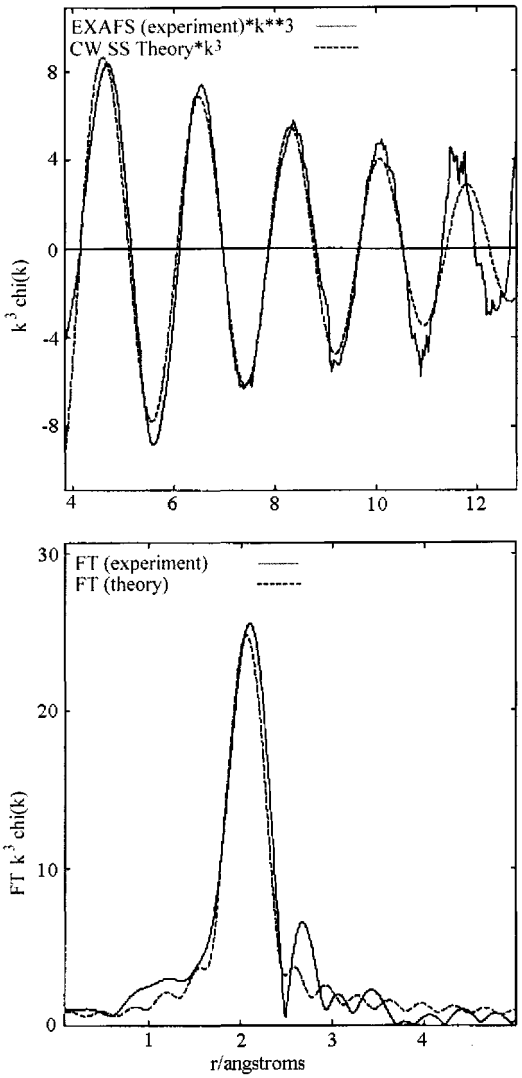

Figure 5. Fe K-edge k^3-weighted EXAFS spectrum and Fourier transform, phase-shift corrected for carbon (—— experimental; ------- curved wave theory, fit B in Table 1) of functionalized MCM-48 at 298 K.

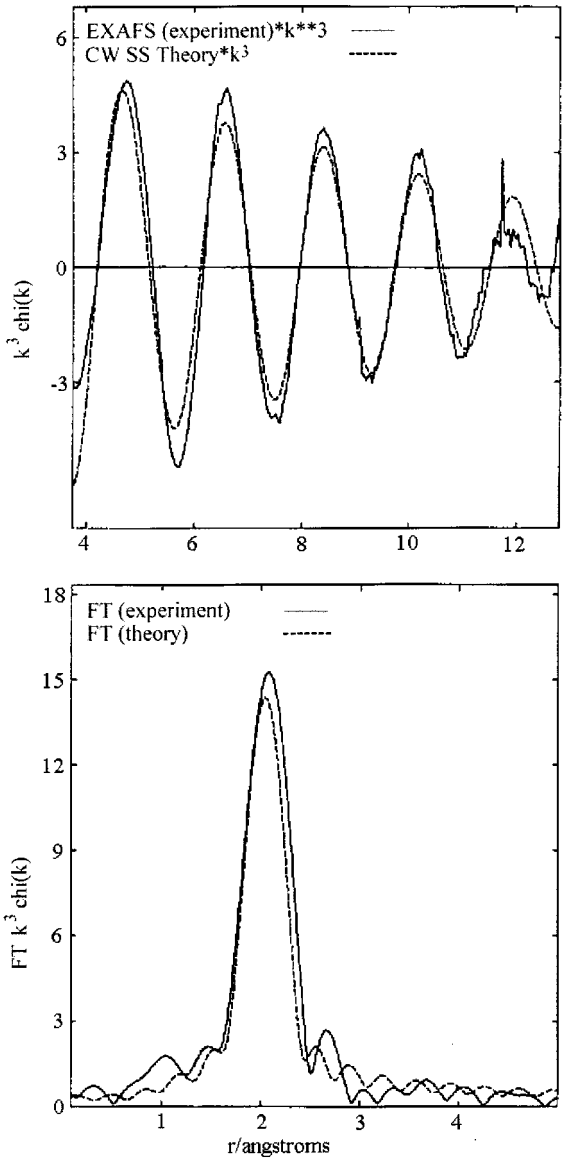

Figure 6. Fe K-edge k^3-weighted EXAFS spectrum and Fourier transform, phase-shift corrected for carbon (—— experimental; ------- curved wave theory, fit B in Table 1), of [Fe{(η-$C_5H_4)_2SiMe_2$}] at 298 K

were very large: R factor 45.5%, $E°$ −1.8 eV, r(Fe−C) 2.023(5) Å, 2 σ^2 0.0236(17) Å^2, r(Fe···Si) 2.736(33) Å, 2 σ^2 0.0176(83) Å^2. A better fit to the experimental data was obtained by starting from fit A and refining the coordination number (fit B, Table 1, Figure 6). The final value was 4.3 but the error in this value must be much higher than 20% for the reasons outlined above.

Conclusion

The pore walls of mesoporous siliceous MCM-48 have been successfully derivatized with (1,1′-ferrocenediyl) dimethylsilane. The organometallic complexes react with the MCM-48 surface silanols (particularly of the Q^3 type) to give a $C_5H_4SiMe_2$−O linkage to the silica surface. Despite the fact that MCM-48 and MCM-41 possess very different mesoporous surfaces, this process strongly resembles the process previously reported for the functionalization of the latter by strained ferrocenophanes.

Experimental Section

General: All preparations and manipulations were performed using standard Schlenk techniques under an oxygen-free and water-free argon atmosphere. Pentane was dried by reflux over Na/benzophenone ketyl, distilled under argon, and kept over 4-Å molecular sieves. − Powder X-ray diffraction (XRD) data were collected on a Philips Xpert diffractometer using Cu-K_α radiation filtered by Ni. − Microanalyses were performed at the TU Munich. − Infrared spectra were recorded on a Unican Mattson Mod 7000 FTIR spectrophotometer using KBr pellets and/or solutions. − ^{29}Si- and ^{13}C-NMR spectra were recorded at 79.49 and 100.62 MHz, respectively, on a (9.4 T) Bruker MSL 400P spectrometer. ^{29}Si-MAS NMR spectra were recorded with 40° pulses, spinning rates of 5.0−5.5 kHz, and 60 s recycle delays. ^{29}Si-CP MAS NMR spectra were recorded with 5.5 μs pulses, a spinning rate of 5.0 kHz and 5 s recycle delays. Chemical shifts are quoted in parts per million relative to TMS. ^{13}C-CP MAS NMR spectra were recorded with 4.5 μs pulses, a spinning rate of 8 kHz, and a 4 s recycle delay. Chemical shifts are quoted in ppm relative to TMS. − Nitrogen adsorption isotherms were recorded using a CI electronics MK2-M5 microbalance connected to a vacuum manifold line. The as-made MCM samples (typically around 0.02 g) were dehydrated overnight at 723 K to an ultimate pressure of 10^{-4} mbar, and then cooled to room temperature prior to adsorption. Extra care with the functionalized materials was necessary and so the samples were dehydrated at 423 K to prevent the destruction of the functionalities. Nitrogen isotherms were then recorded at 77 K. Equilibration of each data point was monitored using CI electronics Labweigh software, and the pressure monitored using an Edwards Barocel pressure sensor. Specific surface areas, A_{BET}, were determined from the linear part of the BET equation (P/P_o = 0.05−0.3). − Fe K-edge X-ray absorption spectra were collected at room temperature in transmission mode on station 9.2 [double crystal Si(220) order-sorting monochromator, 50% harmonic rejection] of the Synchrotron Radiation Source at the Daresbury Laboratory, operating at 2 GeV in single bunch mode, with typical currents of 13−19 mA. Solid samples, diluted if necessary with boron nitride, were held between layers of mylar film in 0.5 mm thick aluminium plates. Two spectra were recorded for each sample and summed using the program EXCALIB, available on the Daresbury computer XRSSERV1. The program EXBACK was used to extract the raw EXAFS, $\chi^E(k)$, and curve-fitting analyses, by least-squares refinement of the non-Fourier filtered k^3-weighted EXAFS data, were carried out within EXCURVE (version EXCURV98[13]) using spherical wave methods.[14] Phase shifts were calculated using Von Bart ground state and H. Lundqvis exchange potentials.

[Fe{(η-$C_5H_4)_2SiMe_2$}] was prepared by the method reported by Wrighton[15] and purified by sublimation under vacuum.

MCM-41 was synthesized according to the literature employing [($C_{14}H_{29}$)NMe_3]Br as a templating agent.[16] After calcination (540 °C/6 h) and dehydration (200 °C under a vacuum 10^{-4} Torr for 8 h) the material was characterized by XRD, N_2 adsorption and IR spectroscopy.

MCM-41/[Fe{(η-$C_5H_4)_2SiMe_2$}] was prepared as described in the literature.[4] Elemental analysis indicated 8.33 mass-% Fe. − IR

(KBr, $\tilde{\nu}$, cm^{-1}): 3574 vs, 3096 m, 2963 m, 1645 s, 1365 m, 1234 vs, 1169 vs, 901m, 816 s, 798 s, 667 m. – (^1H, ^{13}C, ^{29}Si) NMR data are in agreement with ref.[4]

MCM-48 was synthesized according to the literature employing $[(C_{16}H_{33})NMe_3]Cl$ as a templating agent.[17,10b] After calcination (540°C/6 h) and dehydration (220°C under a vacuum 10^{-4} Torr for 6 h) the material was characterized by XRD, N_2 adsorption and IR spectroscopy.

Preparation of MCM-48/[Fe{(η-$C_5H_4)_2SiMe_2$}]: A suspension of MCM-48 (0.5 g) in pentane (15 mL) was treated with a solution of [Fe{$C_5H_4)_2SiMe_2$}] (0.35 g) in pentane. After 24 h at room temperature, the resulting suspension was filtered off and the remaining orange solid was washed several times with pentane, and dried under an oil-pump vacuum. The pentane washings contained trace amounts of the starting material [Fe{(η-$C_5H_4)_2SiMe_2$}] and ferrocene, identified by solution ^1H-NMR spectroscopy. – Elemental analysis indicated 8.18 mass-% Fe. – IR (KBr, $\tilde{\nu}$ cm^{-1}): 3454 vs, 3103 m, 2960 m, 1637 s, 1423 m, 1234 vs, 1169 vs, 1081 vs, 968 m, 900m, 822 s, 798 s, 667 m, 453 s.

Acknowledgments

We thank PRAXIS XXI and FEDER for partial funding. P. Ferreira (BD) thanks PRAXIS XXI for a grant. I.S.G. wants to thank the CRUP (Acções Integradas Programme) for generous support.

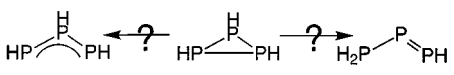
Calculated Properties and Ring-Chain Rearrangements of Triphosphirane (P_3H_3)



Minh Tho Nguyen,*[a] Alk Dransfeld,[a] Luc Landuyt,[a] Luc G. Vanquickenborne,[a] and Paul v. R. Schleyer[b]

Keywords: Ab initio calculations / Ionization potentials / Phosphorus / Heterocycles / Small ring systems

Ab initio quantum chemical calculations have been used to explore the P_3H_3 potential energy surface focussing on the ring-chain rearrangements of the three-membered ring in $(PH)_3$ (**1**), the parent triphosphirane. Relative energies between stationary points were estimated using the QCISD(T)/6–311G(d,p) method based on MP2/6–31G(d,p) geometries and corrected for zero-point contributions. Ring strain, proton affinities, ionization and excitation energies and heats of formation have been evaluated using larger basis sets, e.g. 6–311++G(3df,2p). The cyclic *trans*-triphosphirane (**1a**) is the most stable P_3H_3 isomer and lies about 40 kJ/mol below the open-chain phosphanyldiphosphene (H_2P–P=PH). The decrease of ring strain in three-membered rings when CH_2 is replaced by PH is confirmed. Triphosphirane **1a** is a virtually strain-free ring and even gains some stabilization relative to three separate P–P single bonds. The reduced ring strain also helps diminish the phosphorus inversion barrier to 224 kJ/mol compared to the monocyclic isomers of $(CH_2)(PH)_2$ and $(CH_2)_2(PH)$. Compound **1a** follows a pure ring-opening or a 1,2-hydrogen shift rather than a combined motion pathway, in fundamental contrast with corresponding processes of diphosphirane and phosphirane. This is due to the existence of an open-chain P_3H_3 phosphorane intermediate stabilized by allylic conjugation. The pericyclic ring-opening of **1a** is the most favored process but the energy barrier in the gas phase is about 180 kJ/mol high. Electron density is largely delocalized within the three-membered P_3 ring not only in the C_{3v}-symmetric **1b** (all-*cis*) but also in **1a** (C_s). The proton affinity of **1a** is similar to that of PH_3. The proton affinities decrease with n in *cyclo*-$(CH_3)_{3-n}(PH)_n$ and their values were obtained: PA(**1a**) = 777 ±10, PA(diphosphirane) = 799 ±10 and PA(phosphirane) = 802 ±10 kJ/mol. Heats of formation are evaluated as follows ($\Delta H°_{f0}$ at 0 K in kJ/mol): **1a**, 70 ±10; *cyclo*-$(PH)_2(PH_2)^+$ (protonated **1a**), 821 ±10; diphosphirane, 85 ±10; *cyclo*-$(CH_2)(PH)(PH_2)^+$ (protonated diphosphirane), 814 ±10; phosphirane, 86 ±10; and protonated phosphirane, 812 ±10 kJ/mol. All P rings remain cyclic following ionization to the radical cations. Adiabatic ionization energies (IE_a) are estimated as: **1a** and diphosphirane, 9.3 ±0.3 eV and phosphirane 9.5 ±0.3 eV. The first UV absorption band shifts toward the longer wavelength region on going from phosphirane to **1a**. The GIAO/B3LYP computed magnetic shieldings for **1a** and related molecules reveal a clear relationship between the narrow bond angles in the rings and their unusually strong magnetic shielding. The similarity of the predicted ^{31}P-NMR signals in **1a** and its heteroanalog diphosphirane, $(CH_2)(PH)_2$, can be rationalized in terms of a compensation of the carbon-substituent effect (downfield shift) and the bond-bending effect imposed by the ring (upfield shift).

Introduction

Phosphorus, in a similar way to carbon, is able to form stable open-chain and cyclic compounds with homonuclear bonds.[1] While the five-membered nitrogen ring (pentazole) could only be postulated as an intermediate at −50 °C,[2][3] the corresponding phosphorus ring in pentaphosphaphosphol was identified[4] at room temperature. An impressive number of polyphosphorus compounds have thus been prepared by different groups.[5−11] A simple example illustrates the close similarity between the chemistries of phosphorus and carbon: The experimentally known monocyclic P_5^- ion[4] is analogous to the cyclopentadienyl anion.[12] In general, the existence of polyphosphorus compounds as rings or chains depends on the number of P atoms involved. The simplest polyphosphane, which may have a ring and a chain isomer, was detected in 1972.[13] While many substituent-stabilized three-membered phosphorus homocycles (called triphosphiranes or cyclotriphosphanes) have been synthesized since,[11,13,14] the corresponding open-chain isomers are rare. The triphosphorus hydride, P_3H_3, has been positively identified by mass-spectrometric techniques,[13] but no information on its molecular structure is available. The ^{31}P-NMR-chemical shifts of three-membered rings comprising tricoordinate phosphorus cannot be described with substituent increments.[15][16] The question arises as to whether there are relationships between the NMR-chemical

shifts and geometric or electronic parameters in the parent three-membered compounds with 1−3 endocyclic phosphorus atoms and the related acyclic molecules. The tendency of phosphorus to accommodate cyclic structures easily is well established;[17] the competition between ring and chain often turns in favor of the former. However, the rare observation of open-chain P_3R_3 compounds raises the question about their thermodynamic and kinetic stabilities.

Previous theoretical studies[18−23] on the P_3H_3 model system were mainly confined to the electronic structure, ring strain and inversion barriers of the cyclic triphosphirane. The ring-chain conversion of the simplest parent triphosphirane, *cyclo*-$(PH)_3$, has not been investigated before. As part of our theoretical study on the structure and reactivity of P-containing three-membered rings,[24−27] we examine here the P_3H_3 potential energy surface by means of ab initio molecular orbital methods. In particular, the molecules with open-chain structures and their thermodynamic stability were investigated. The computed molecular properties of triphosphirane are discussed in the context of its organic heteroanalogs (diphosphirane and phosphirane).

Computational Details

Ab initio molecular orbital calculations were performed with the Gaussian 94 series of programs.[28] To facilitate comparison with our previous studies on phosphirane and diphosphirane,[24][26] we provide data derived with the same theoretical method. Higher-level computational results are included in the discussion. Each stationary point was characterized by harmonic vibrational analysis. Furthermore, the identity of each transition structure was determined by intrinsic reaction coordinate (IRC) calculations. Transition structures are designated by the **X/Y** notation where **X** and **Y** are the equilibrium structures connected by the TS. Geometrical parameters of the relevant equilibrium and TS were optimized using second-order Møller-Plesset perturbation theory, MP2/6-31G(d,p), which partly incorporates electron correlation. Based on these MP2/6-31G(d,p) geometries, the relative energies of the points on the (P_3H_3) energy surface have been estimated by single-point electronic energy computations using the quadratic configuration interaction method, QCISD(T), and the 6-311G(d,p) basis set. Improved estimates for thermochemical quantities were obtained by calculations with the larger 6-311++G(d,p) and 6-311++G(3df,2p) basis sets. The GIAO approach[29] was used to calculate magnetic shieldings at B3LYP/6-311G(d) //MP2/6-31G(d,p) level. Electron distributions (Mulliken) and the Wiberg bond indices, WBI,[30] were evaluated at the same level. For the open-shell systems, correlated wavefunctions were constructed using unrestricted Hartree-Fock (UHF) references. Throughout this paper, bond lengths are given in Ångstrøms, bond angles in degrees, magnetic shieldings in ppm, total energies in hartrees, zero-point vibrational and relative energies, unless otherwise noted, in kJ/mol.

Results and Discussion

Before examining the various chemical properties of triphosphirane and the related three-membered rings, the P_3H_3 potential energy surface will be first presented in order to establish the thermochemical and kinetic stabilities of the possible isomers.

The P_3H_3 Potential Energy Surface

Selected optimized structural parameters of the relevant stationary points considered at the MP2/6−31G(d,p) level of accuracy are given in Figures 1 and 2. The calculated total and zero-point vibrational energies are recorded in Table 1 while the relative energies are summarized in Table 2. The potential energy profiles are illustrated schematically in Figures 3 and 4. In general, the same energy ordering between the P_3H_3 structures considered was found at all levels employed. The discussion in this section is based on QCISD(T)/6−311G(d,p) //MP2/6−31G(d,p) + scaled ZPE/HF/6−31G(d,p) //HF/6−31G(d,p) energies. Triphosphirane can exist in the *trans* (**1a**) and the *cis* (**1b**) form. The endocyclic P−P distances (2.210 to 2.225 Å, Figure 1) are slightly longer than in diphosphane (2.209 Å, H_2P-PH_2). As expected, **1a** is more stable than **1b** [E_{rel}(*cis*) = 17 kJ/mol]. In **1b** the P atom environments remain strongly pyramidal; the phosphorus inversion barrier of **1a** is 217 kJ/mol via the TS **1a/1a**. This is far larger than the inversion barrier in PH_3, which is only 148 kJ/mol at the same level of theory (a more accurate estimate is discussed below). As seen in Table 2, **1a** is the P_3H_3 global minimum lying well below the open-chain isomers **2**, **3** and **4**. The cyclic form **5**, with a formal P=P double bond and a tetracoordinate P atom, is a high energy isomer that lies 137 kJ/mol above **1a**. Of the three different types of open-chain species, phosphanyldiphosphenes **2** are the more stable, followed by phosphoranes **4** and then phosphanylphosphinidenes **3**. Each of these species exhibits several conformations and configurations; here we present only the most stable and representative structures. The symmetrical conformer **2b** (C_s) of phosphanyldiphosphene is marginally more stable, by 1 kJ/mol, than **2a** (C_1), which is 42 kJ/mol less stable than **1a**. The preference of the phosphanyl group for a symmetrical configuration is similar to that in analogous phosphapropenes[31] where an interaction between the P lone pair and π electrons is weak.[32] Among the phosphoranes with allyl conjugation of the π system on the phosphorus backbone structure, **4a** is most stable [E_{rel} (**4b**) = 9 kJ/mol relative to **4a**]. Nevertheless, **4a** is 115 and 73 kJ/mol less stable than **1a** and **2a**, respectively. Stabilization by allylic conjugation is more pronounced (P−P = 2.06 Å) in **4a** than in the corresponding acyclic $P(PH)_2^-$ anion[11] (P−P = 2.09 Å). In contrast to the formal Lewis description of the central phosphorus atom in these molecules as pentavalent, the sum of Wiberg bond indexes, ΣWBI, is only four (one single P−H and two allylic, 1.5 fold, bonds; ΣWBI is 3.8 for **4a**; in "CH_2=PH=PH" ΣWBI is 3.9). Therefore, σ^3,λ^4-P is the

best characterization[8] of the allyl-type phosphorus valence.

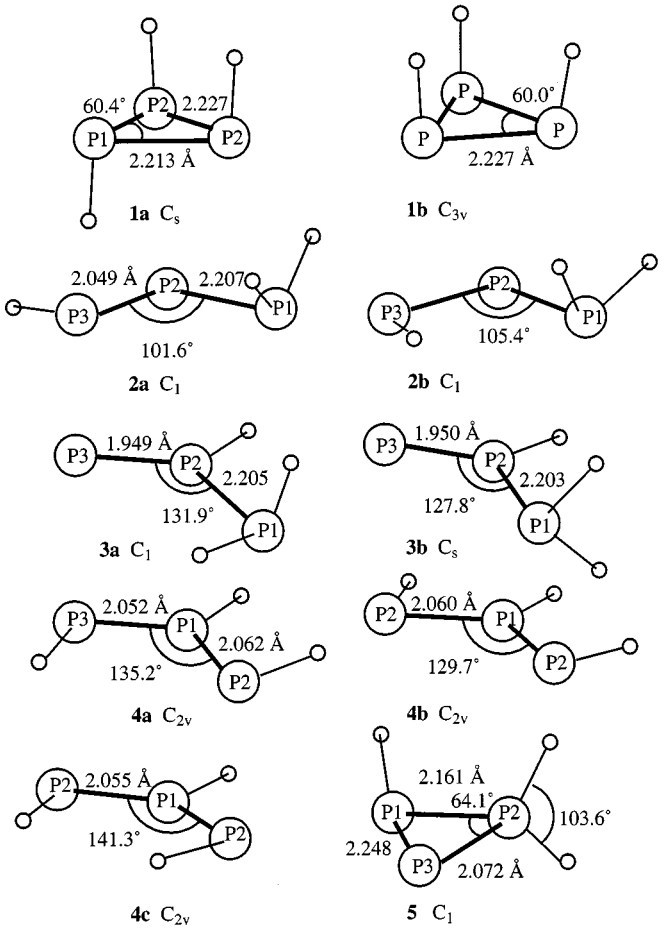

Figure 1. Minimum structures of P_3H_3 optimized at RMP2(fc) /6−31G(d,p)

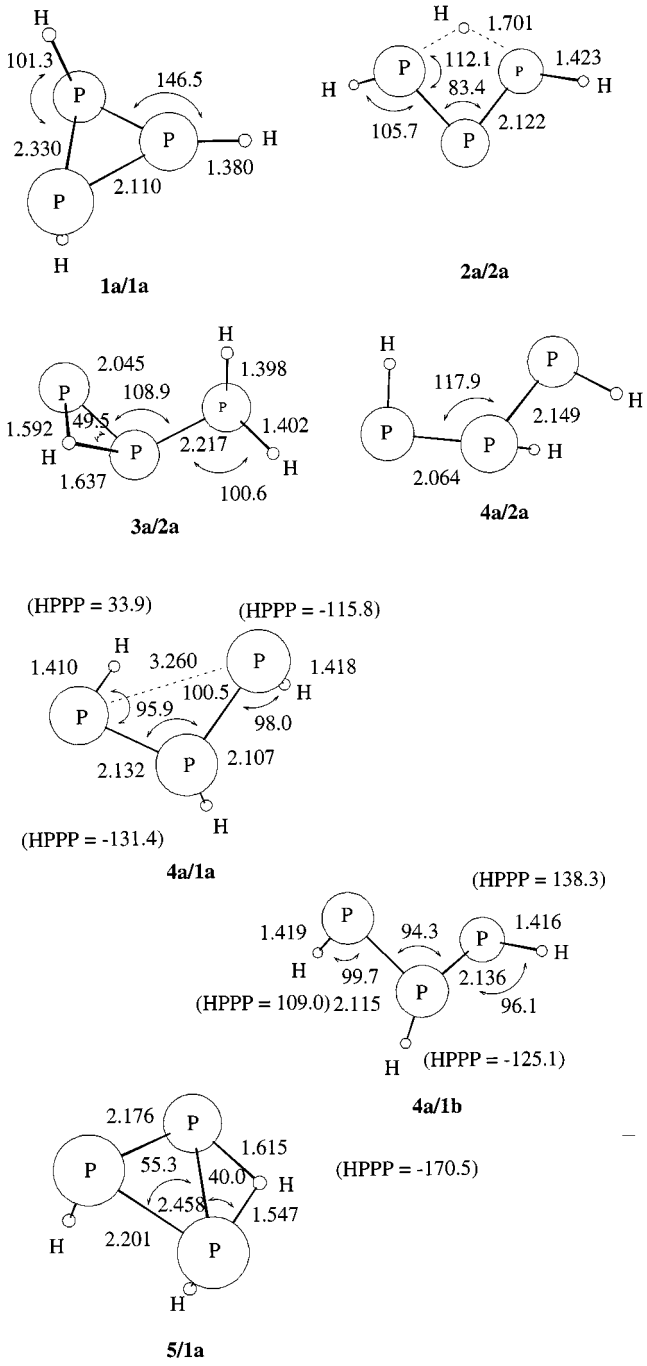

Figure 2. Transition structures of P_3H_3 optimized at RMP2(fc) /6−31G(d,p)

The singlet phosphanylphosphinidenes **3** represent the least stable open-chain isomers. As in $P-PH_2$, i.e. the unsubstituted case,[33−35] the central P atom has a planar configuration (**3b**; approximately planar in **3a**). The staggered conformer **3a** is slightly more stable than the C_s-symmetrical conformer **3b** with the phosphorus lone pair in the plane of the phosphinidine π bond. Conformer **3a** is 141 kJ/mol above **1a** and 99 kJ/mol above **2a**. Compared with the parent tautomers,[35] RHP=P/RP=PH with R=H, the phosphanyl group in **3a** ($R = PH_2$) has little effect on the relative energy of the tautomers. Accordingly, the P−P distances in **2**, as well as in **3**, remain almost unaffected upon replacing H in the parent by PH_2. It is well known that phosphinidenes usually have a triplet electronic ground state.[36][37] For the simplest phosphanylphosphinidene (H_2P-P), the triplet state with C_s symmetry was shown to lie about 28 kJ/mol below the corresponding closed-shell singlet state (see our previous study at the same level of accuracy).[35] In contrast, for **3a** calculations indicate that the triplet state is not clearly preferred (lowest-lying singlet is only 6.6 kJ/mol higher in energy than the triplet). While the π-donor effect of the PH_2 group is negligable for the P2−P3 bond in **2** and triplet **3**, it shifts electron density into the phosphinidine bond (P2−P3 is polarized towards δ^1-P in singlet **3**). As a result the energy of the singlet **3a** relative to the triplet is distinctly reduced.

Overall, successive replacement of the CH_2 in cyclopropane by PH tends to reinforce the thermodynamic stability of the cyclic isomer. In the all-phosphorus case considered here, the ring is by and large the most stable form. Whether it is also the kinetically most stable isomer will be examined in the following section.

Interconversions Between the P_3H_3 Isomers

As shown in Figures 3 and 4, **1a** can undergo a ring-opening simply by breaking an endocyclic P−P bond to give phosphorane **4**. This opening, via **4a/1a**, is not accompanied at all by a hydrogen shift from one P center to another. Despite extensive searches, a single-step pathway connecting **1a** either to diphosphene **2a** or to phosphinidene **3a** could not be located. The behavior of **1a** thus differs basically from that of its homologous phosphirane and diphosphirane.[24] The pure ring openings in the latter molecules require activation energies that are much larger than those for pathways where hydrogen transfer is involved. This is presumably due to the fact that the TS **4a/1a** profits from the allyl delocalization, which stabilizes triphosphorane **4a**. The ring opening of the *cis*-triphosphirane (**1b**) through **4b/1b** is an even more facile process. This implies that a *cis*-triphosphirane might be formed kinetically upon ring-closure of a triphosphorane like **4b**. A 1,2-shift of the hydrogen between two ring atoms via **5/1a** is also possible, without ring opening, to yield the cyclic compound **5**. The energy barrier for transformation of **1a** to **5** is somewhat larger than that for ring-opening but slightly smaller than that for inversion. The energy diagram in Figure 3 demonstrates the peculiar feature of **1a**, which prefers either a pure ring opening or a 1,2-shift but does not undergo combined motions.

Chain-chain rearrangements are summarized in Figure 4. The isomers **2**, **3** and **4** are related to each other by a single 1,2- or 1,3-hydrogen shift. Structure **2a/2a** is the TS for an antarafacial 1,3-hydrogen shift between the two terminal P atoms of the diphosphene **2a**. The energy barrier of 141 kJ/mol relative to **2a** is rather low for this type of process.[31] The corresponding barrier for 1,3-H shift in diphosphapropene ($H_2P-CH=PH \rightarrow HP=CH-PH_2$) has been calculated to be 163 kJ/mol at the same level of accuracy. Again the reduced ring strain in **2a/2a** facilitates this isomerization. Two observations are worth noting: (i) a TS for a suprafacial migration could not be located, in contrast to the situation in phosphapropenes,[31] and the high stability of **4** renders this migrating mode inoperative; (ii) experimental results have shown that 1,3-shifts in P compounds are thermally accessible unimolecular processes.[38] The rearrangement via **2a/2a** is therefore quite a realistic connection. Both 1,2-H shift TSs **4a/2a** and **3a/2a** have similar energies but lie above the TS **2a/2a** for 1,3-H shift and **4a/1a** for ring opening. Ring-closure of phosphorane **4a** is favored over isomerization to another acyclic isomer. The connection between **1a** and the most stable open-chain phosphanyldiphosphene, **2a**, takes place in two steps through the intermediate **4a**. The most energy-demanding step is the 1,2-H shift (**4a/2a**). While the reaction barriers in the triphosphorus system differ fundamentally from those con-

taining only one P atom, physical properties differ only gradually.

Comparison of Triphosphirane Properties with Those of $(CH_2)_{3-n}(PH)_n$ with $n < 3$

Having established that the triphosphirane **1a** is the most stable form among P_3H_3 isomers, we now discuss some of its molecular properties and compare them with those of other three-membered rings built from PH and/or CH_2 groups (diphosphirane, phosphirane and cyclopropane).

Barrier of Inversion at Phosphorus

The inversion process at phosphorus in acyclic and cyclic molecules has been examined previously.[24,39,40] The semi-empirical finding that "the barrier in $(PH)_3$ is smaller than that in PH_3"[9][20] is a misleading artifact of the MNDO method. Our ab initio calculated inversion barriers, $\Delta_{inv}E$, are compiled in Table 3. The listed $\Delta_{inv}E$ values confirm that the phosphorus inversion barrier is about 100 kJ/mol larger in three-membered rings than in the corresponding acyclic molecules.[40] In the $(CH_2)_{3-n}(PH)_n$ series the barrier decreases with n (when σ^4-C is replaced by σ^3-P). How can this be explained? While "normal" (not T-shaped) TSs of σ^3-P have bond angles at phosphorus of around 120°, the three-membered ring only allows a Y-shaped TS with an endocyclic angle of around 60°. This bond-angle constraint rationalizes the pronounced destabilization of the $TS_{inv,P}$ in the rings relative to the related acyclic molecule [e.g. $(PH)_3$ vs. $HP(PH_2)_2$, cf. Table 3]. As the endocyclic bond angle at the inversion center increases (53° for phosphirane, 60° for diphosphirane, and 68° in the $TS_{inv,P}$ of **1a**) the phosphorus inversion barrier decreases.

Table 3. Inversion barriers at phosphorus in kJ/mol of σ^3-phosphorus in $(CH_2)_{3-n}(PH)_n$ rings (triphosphirane, $n = 3$; diphosphirane, $n = 2$; phosphirane, $n = 1$) and PH_3 calculated at different levels of theory[a]

Method[a]	$n = 1$	$n = 2$	$n = 3$	PH_3

Experiment[b]				132

[a] Based on MP2(fc)/6−31G(d,p) geometries and corrected for zero-point energies. − [b] Estimated[51] experimental phosphorus inversion barrier. − [c] A. Göller and T. Clark (*Chem Commun.* **1997**, 1033) reported a value of 278 kJ/mol at CCSD(CT)/6-31+G(d)//MP2 /6-31+G(d) with C_s symmetry.

Ring Strain

The strain in a cyclic species arises from the enforced deformation of bond angles from their normal values in acyclic systems. To estimate the ring strain, different isodesmic reactions using reference molecules that are as strain-free as possible can be employed.[41][42] Here, simple bond separation reactions (Table 4) provide reasonable measures for ring strains. These values are somewhat sensitive to the computational methods. For cyclopropane, where experimental heats of formation are available, the calculated value using MP4SDTQ/6−311++G(3df,2p) + ZPE calculations compares quite well with the experimental data. From the results in Table 4, two important points can be concluded: (i) the ring strain decreases consistently on going from cyclopropane to triphosphirane; for each replacement of a CH_2 by a PH the ring strain is reduced by about 25 kJ/mol; (ii) for **1a**, variation of the calculated value with respect to the methods employed suggests that the isodesmic reaction considered might be slightly endothermic. The endothermicity obtained at MP4 is particularly interesting as lower level calculations[19,43,44] consistently predicted a small but significant exothermicity for reaction (1) (Table 4). In contrast to the conventional wisdom, corrections for zero-point vibration energies are found to be important: They change the energies of reactions (1) to (4) by up to 20 kJ/mol. The smaller ring strain in cyclophosphanes, relative to cyclopropane, is often interpreted as arising from two main factors; namely (i) the inherent ability of σ^3 phosphorus to form small rings owing to its sp^3 hybridization[9] and (ii) a larger concentration of its s electrons in the lone pair coupled with a greater use of its p electrons to form ring bonds.[19] In other words, formation of stronger ring-P bonds results in a partial compensation of the inherent destabilization due to bond angle deformation. Another question regards whether the endocyclic bond angle also has an effect on the ability of the lone pair of phosphorus to bind a proton.

Proton Affinities of Phosphorus

Table 5 lists the calculated proton affinities (PA) of related cyclic and acyclic phosphorus-containing molecules. A number of observations are worth mentioning: (i) Accurate calculations of PA with an absolute error of ±5 kJ/mol could only be achieved by using fairly large basis sets; for PH_3, the experimental value can be reproduced by calculations with the 6−311++G(3df,2p) basis set with either the MP4 or the QCISD(T) method. (ii) The relative trend in PAs can, however, be well established using lower level calculations; the difference in PAs between PH_3 and $PH(CH_3)_2$ is computed to be 112 ± 5 kJ/mol at the QCISD(T)/6−311G(d,p) + ZPE level whereas the experimental[45] difference is 113 kJ/mol. (iii) Comparison of calculated as well as experimental[45] PAs of PH_3, CH_3PHCH_3 and H_2PPHPH_2 shows that methyl substituents tend to increase the PA; the phosphanyl group also exerts a similar effect but to a lesser extent; while the PA is increased by 112 kJ/mol by two CH_3 groups (R = CH_3 in HPR_2), two PH_2 groups make it only 75 kJ/mol larger than in PH_3. (iv) In contrast, PAs in polyphosphaphosphiranes are quite close to each other; their PAs are around 800 kJ/mol, irres-

pective of the number of P atoms within the ring. (v) Comparing PA($H_3C-PH-CH_3$) with PA(phosphirane) on the one hand and PA($H_2P-PH-PH_2$) with PA(triphosphirane, **1a**)[46] on the other hand, clearly emphasizes that the strong effect of methyl and the weaker effect of the phosphanyl groups on PA is virtually offset in the cyclic structures. It is remarkable that the PA value of **1a** is very near to that of PH_3. The behavior of phosphirane toward protonation thus differs from that of aziridine, its nitrogen analog, which has a much larger PA (about 70 kJ/mol) than NH_3.[47][48] It is also worth noting that a stable phosphiranium cation has been isolated and characterized recently.[46][49]

Heats of Formation

At the present time, accurate thermochemical data on phosphorus compounds are rather scarce. Heats of formation of small low-coordinated P species have been determined mainly by quantum-chemical calculations.[47] Therefore, it would be useful to evaluate this quantity for the three-membered rings and their protonated forms. Table 6 records our estimates for heats of formation at 0 K of neutral species, using heats of isodesmic reactions (1), (2) and (3) listed in Table 4 in conjunction with experimental[50] and theoretical values evaluated for the reference molecules. Heats of formation of the protonated species were determined from the data for neutral counterparts and proton affinities given in Table 5. At the level of theory considered, namely MP4SDTQ /6−311++G(3df,2p) + ZPE, absolute errors of about ±10 kJ/mol in heats of formation can be expected. We note that our estimate for phosphirane, $\Delta H°_{f0}$(phosphirane) = 86 ±10 kJ/mol, differs somewhat from the experimental value at 298 K (69 ± 2 kJ/mol; in the compilation of Lias et al.[50]).

Table 6. Heats of formation of polyphosphaphosphiranes, *cyclo*-$(CH_2)_n(PH)_{3-n}$ (with n = 1, 2, and 3), and their protonated forms ($\Delta H°_{f0}$ at 0 K in kJ/mol)

Ionization and Excitation Energies

The vertical excitation energies as well as the geometries of the ionized structures give additional insight into the electronic structure of these rings. In contrast to cyclopropane, where the ring opens after ionization, the radical cation minimum of **1a** is cyclic **1a**$^{+\cdot}$ (Figure 5). The lengths of the P−P bonds that are *trans*-substituted are only slightly longer in **1a**$^{+\cdot}$ than in **1a**. In contrast, the *cis*-substituted P−P distance is clearly (0.103 Å) shorter in the radical cation. This can be rationalized by the reduced repulsion of the less populated *cis*-oriented phosphorus lone pairs, which form a 3-electron/2-center π bond in **1a**$^{+\cdot}$. The en-

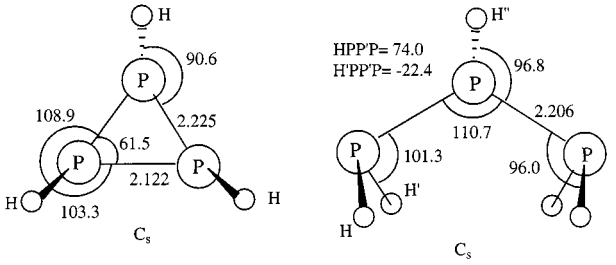

Figure 5. Minimum structure of the *cyclo*-$(PH)_3$ radical cation optimized at UMP2(fc) /6−31G(d,p) and and of the best triphosphane, $PH_2-PH-PH_2$, minimum structures at RMP2(fc) /6−31G(d,p)

ergy decrease due to geometrical relaxation, measured by the difference between vertical and adiabatic ionization energies, is only 0.25 eV in **1a**$^{+\cdot}$.

Separate calculations on some simple phosphanes indicate that IE_as calculated at QCISD(T)/6−311++G(d,p) + ZPE level are consistently underestimated by about 0.3 eV. Taking this correction into account, we estimate the values: IE_a = 9.3 ±0.3 eV for both **1a** and diphosphirane and IE_a = 9.5 ±0.3 eV for phosphirane (Table 7). The latter value agrees well with the available experimental estimate of 9.4 ±0.1 eV.[50] Thus, adiabatic ionization energies of three-membered P rings are rather independent of the number of P atoms. Note that the IE_a = 9.87 eV of PH_3[50] is somewhat larger than for the polyphosphaphosphiranes. The first vertical electronic excitation energies of P rings are listed in Table 7. CIS/6−311++G(d,p) calculations, which include only singly excited configurations, provide only upper bounds for this property; usually, an overestimation of 0.5 eV relative to the experimental value is expected.[26] More realistic estimates assume a systematic correction of 0.5 eV to CIS values. With the basis set employed, no Rydberg states could be identified. It is apparent that the first transition energy decreases with increasing number of P atoms. A shift of the absorption bands toward longer wavelength region is noticeable.

Table 7. Calculated adiabatic ionization energies and vertical excitation energies of polyphosphaphosphiranes (eV)

Molecule	First ionization energies[a]	First vertical excitation energies[b]

NMR Properties of Triphosphirane and Related Molecules

Table 8 shows, for the $PH(PH_2)_{2-n}(CH_3)_n$ molecules with n = 0, 1, and 2, that the magnetic shielding, $\sigma(^{31}P)$, decreases with decreasing electron density around the ^{31}P nucleus. This is in agreement with a more general study.[16] Since the range of the phosphorus valence in this set of molecules, characterized by the sum of Wiberg bond indices, ΣWBI(P), is small (2.8−3.1), no significant correlation with $\sigma(^{31}P)$ can be established. The bond-angle sum at phosphorus, Σα, ranges from 236.5° in phosphirane, $(PH)(CH_2)_2$, to 303.5° in $(PH)_3$. In contrast to the atomic charges, which do not correlate with the chemical shifts in these cyclic molecules, the bond angles are roughly related to $\sigma(^{31}P)$. The square of the correlation coefficient is 0.82 for the σ − Σα and 0.74 for the σ − α(P) relationship. Despite the fact that these relationships are rough, they indicate that the unusually large ^{31}P shieldings in the small rings are due to the small bond angles at σ^3-P. The similarity of $\sigma(^{31}P)$ of the two symmetry equivalent atoms in **1a** and the phosphorus atoms in diphosphirane can therefore be rationalized by compensation of two effects: (i) the more electronegative endocyclic substituents reduce $\sigma(^{31}P)$ (charge changes from −0.06 to +0.11) and (ii) the contracted endocyclic bond angle, which increases magnetic shielding [angle α(P) changes from 59.8° to 53.3°].

Summary and Conclusions

We explored the P_3H_3 potential energy surface by ab initio methods, MP2/6−31G(d,p), with particular focus on ring-chain rearrangements of triphosphirane **1**. Further-

more, molecular properties of **1** are compared with those of other polyphosphaphosphiranes and cyclopropane. A number of conclusions emerge from this theoretical study: (i) The cyclic *trans*-triphosphirane (**1a**) is by far the most stable P_3H_3 isomer; the most stable open-chain isomer is phosphanyldiphosphene, which lies about 42 kJ/mol above **1a**. The cyclic form is increasingly favored upon successive replacement of C by P in polyphosphaphosphiranes, $(CH_2)_{3-n}(PH)_n$ (n = 1−3). (ii) The energy ordering of P_3H_3 isomers is (in kJ/mol): **1a** (0) > phosphanylphosphene (42) > phosphorane (115) > cyclic PH−P=PH_2 (137) > phosphanylphosphinidene (141). (iii) Isomer **1a** is almost a strain-free ring; it even exhibits a small stabilization relative to three separated P−P single bonds. In contrast to cyclopropane, ring strain in phosphirane has essentially vanished. (iv) As the ring strain decreases from phosphirane to triphosphaphosphirane, the phosphorus inversion barrier, $\Delta_{inv}E$, also decreases. $\Delta_{inv}E$ of *cyclo*-$(PH)_3$ is only 224 kJ/mol. (v) Isomer **1a** has a proton affinity, PA, that is almost identical to that of PH_3, PA(**1a**) = 777 ±10 kJ/mol. The values for diphosphirane (799 ±10 kJ/mol) and phosphirane (802 ±10 kJ/mol) are somewhat larger, but they are far smaller than the corresponding values of their open-chain counterparts. This reduced PA appears to be due to the bonding characteristics of the three-membered rings. (vi) Another special feature of the carbon−phosphorus triangles is that the calculated adiabatic ionization energies, IE_a, are rather similar for all polyphosphaphosphiranes (IE_a = 9.5 ±0.3 eV for phosphirane; 9.3 ±0.3 eV for diphosphirane and **1a**). The first UV absorption band shifts toward shorter wavelength on going from phosphirane to triphosphirane. (vii) The heats of formation are computed to be ($\Delta H°_{f0}$ at 0 K in kJ/mol): 70 ± 10 *trans*-triphosphirane, 821 ± 10 protonated triphosphirane, 85 ± 10 *trans*-diphosphirane, 814 ± 10 protonated diphosphirane, 86 ± 10 phosphirane, and 812 ±10 protonated phosphirane. (viii) The ^{31}P-NMR-chemical shifts of the C_s-symmetric *trans*-triphosphirane are predicted to be at δ = −249 for one phosphorus and δ = −278 for the two *cis*-substituted nuclei. (ix) In contrast to phosphirane, triphosphirane undergoes preferentially either a ring-opening by P−P bond breaking or a 1,2-hydrogen shift, but not a combined motion. Ring-opening is, in the gas phase, the more favored reaction path but the energy barrier for this process is still rather large [213; at QCISD(T)/6−311G(d,p) //RMP2(fc)/6−31G(d,p) 190 kJ/mol]. The TS of ring-opening profits from stabilization by a three-center π bond completely formed in triphosphaallyl, PH=PH=PH. For the parent triphosphirane the conversion into the open-chain phosphanyldiphosphene is a two-step process in which the 1,2-H shift is the most energy-demanding step.

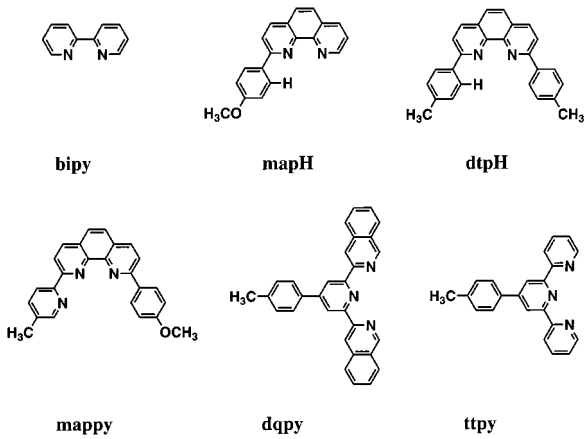
Electrochemical and Spectroscopic Properties of Cyclometallated and Non-Cyclometallated Ruthenium(II) Complexes Containing Sterically Hindering Ligands of the Phenanthroline and Terpyridine Families



Francesco Barigelletti,*[a] Barbara Ventura,[a] Jean-Paul Collin,*[a] Robert Kayhanian,[a] Pablo Gaviña,[a][+] and Jean-Pierre Sauvage[a]

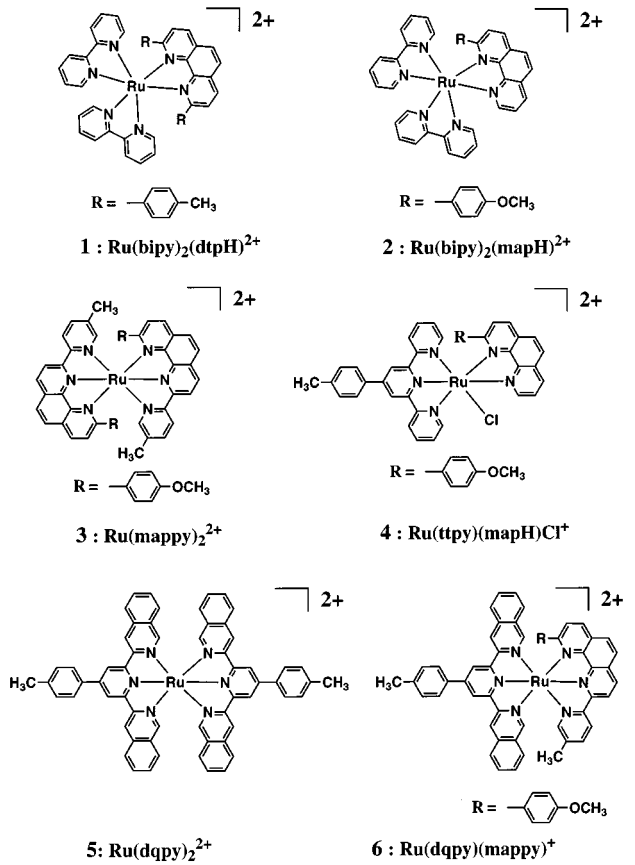
Keywords: Ruthenium / Phenanthroline / Luminescence / Sterically hindered ligands / Terpyridine / Cyclometallation

Two series of cyclometallated and noncyclometallated ruthenium(II) complexes incorporating mono- or disubstituted 1,10-phenanthroline- and 2,2′:6′,2″-terpyridine-type ligands have been synthesized and characterized. An X-ray crystal structure for one of the complexes, Ru(ttpy)(mapH)(Cl)(PF_6), has been obtained (mapH = 2-*p*-anisyl-1,10-phenanthroline; ttpy = 4′-tolyl-2,2′:6′,2″-terpyridine). Distinct electrochemical and photophysical properties have been observed for the two series: a remarkable feature is the observation of relatively long-lived MLCT excited states (from 70 to 106 ns at room temperature in CH_3CN) for three of the cyclometallated complexes. A discussion is given on the role of factors like sigma donation by the cyclometallating ligands, interligand steric hindrance and interligand π-π interactions that affect the electrochemical and spectroscopic properties.

Introduction

The photophysical behavior of transition metal polypyridine complexes is of prime importance in molecular devices based on photoinduced electron and energy transfer reactions.[1] Numerous studies on complexes exhibiting luminescence from metal-to-ligand charge-transfer (MLCT) excited states have shown the determining effects of different factors on the excited state properties.[2] Among others, the energy level of the low-lying states (energy gap law),[3] the electron delocalization on the acceptor ligand,[4] as related to its structure and rigidity[5] have been correlated with parameters like absorption and luminescence wavelengths, lifetime and quantum yield. With the aim of developing new approaches to the tuning of excited-states properties, we have prepared a series of ruthenium(II) complexes incorporating cyclometallated and noncyclometallated sterically hindering ligands. In these complexes, the electron density distribution associated with the presence of cyclometallating positions may result in improved luminescence properties, as illustrated below for some of the compounds investigated. We also show that the interligand interactions between hindering ligands can play a non-negligible role in determining the luminescence properties[6] provided that the steric constraint does not distort excessively the octahedral coordination. The schematic structures of the relevant ligands are illustrated in Scheme 1. A preliminary report of some properties of compounds **4**, **7**, and **9** has been published previously.[7]

Scheme 1



Results and Discussion

The ruthenium complexes synthesized and studied are represented in Scheme 2 (**1**−**6**: noncyclometallated compounds) and Scheme 3 (**7**−**10**: cyclometallated compounds). Cyclometallated ruthenium(II) complexes involving ligands that contain a phenyl group adjacent to a nitrogen donor atom are relatively easy to obtain.[8] Depending on the potential donor atoms implied and the experimental conditions, the complexation reaction leads to the normal N_6 coordination sphere or to the N_5C set.[9] The reaction of paramagnetic ruthenium(III) species ($RuLCl_3$; L = ttpy, dqpy or mappy) with one equivalent of hindering phenanthroline (mapH, dtpH or mappy) in refluxing glacial acetic acid in the presence of a mild reducing agent (*N*-ethylmorpholine) gave the complexes **3** to **10**. In the case of

complexes **1** and **2**, the ruthenium precursor was Ru(bipy)$_2$Cl$_2$. All the compounds were characterized by ^{1}H-NMR and FAB-MS spectra and these data are in full agreement with their postulated structures.

Scheme 2

Scheme 3

The X-ray structures of **7** and **9** have already been reported.[7] Single crystals of **4** were obtained by crystallization from a mixture acetonitrile and benzene. The ORTEP diagram of **4** is shown in Figure 1. Selected bond lengths and bonds angles are presented in Table 1. For comparison purposes some data concerning **7** and **9** are also given.

The ruthenium ligand environment exhibits a distorted octahedral geometry with the terpyridine ligand coordinated in meridional configuration. The phenanthroline plane is orthogonal to the terpyridine mean plane whereas the anisyl substituent is in a stacking position with the central pyridine of the terpyridine (the angle between these rings is 4.2° and the distance between planes is around 3.4 Å). The chloride ion is directed from the N2 nitrogen atom of the phenanthroline. The Ru−Cl bond length of 2.391 Å is very similar to that reported for other ruthenium terpyridine chloro complexes, such as 2.405 Å for Ru(terpy)(bpz)Cl$^+$[10] (bpz = 2,2′-bipyrazine) and 2.400 Å for [Ru(terpy)(CO)$_2$Cl]Cl.[11] The terpyridine ligand affords two almost identical Ru−N bond lengths of ca. 2.05 Å (Ru−N3 and Ru−N5) whereas the distance Ru−N4 is shorter for the central pyridine (1.950 Å). The two side pyridines bind to ruthenium at angles of 79.3° (N3−Ru−N4) and 79.8° (N4−Ru−N5) and these angles also show that terpyridine is constrained such that it cannot fit with an ideal (90°) geometry.

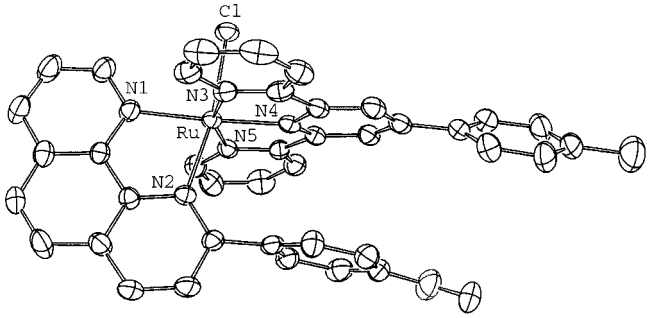

Figure 1. ORTEP representation of the X-ray structure of **4**. The hydrogen atoms and PF_6 anion have been omitted for clarity. Thermal ellipsoids are scaled to enclose 30% of the electronic density

Contrary to what was observed in compound **7** and **9**[7] the Ru−N1 and Ru−N2 bond lengths are in agreement with the usual coordination of the substituted phenanthroline to the ruthenium. In fact, for **7** and **9**, the unusually long Ru−N1 (for **7**) and Ru−N2 (for **9**) bond lengths (2.198 Å and 2.256 Å, respectively) could be the consequence of a *trans* effect (due to the carbon atom in the *trans* position) as well as the constrained geometry inherent in terpyridine-type chelate.

The electrochemical data for the noncyclometallated (**1** to **6**) and cyclometallated (**7** to **10**) ruthenium complexes are presented in Table 2. Oxidations are metal-centered and reductions are ligand-centered processes respectively. Reversible monoelectronic waves are observed for almost all

redox couples. As expected, compounds **1**, **2** and **3** display redox processes typical of the well-known bipyridine, phenanthroline, and terpyridine complexes.[1] In compound **4**, due to the coordinated chloride ion, the ruthenium is easier to oxidize (by 500 mV as compared to **3**) and one ligand is more difficult to reduce. In compounds **5** and **6**, the presence of electron-withdrawing quinoline ligands provides a slightly higher acceptor character to these complexes than the classical bis(terpyridine) compound.

Table 2. Redox potentials (vs SCE) measured by cyclic voltammetry. Conditions: CH_3CN (nBu$_4$NBF$_4$ = 0.1 M), v = 100 mVs^{-1}, room temperature.

[a] Large cathodic current occurs without distinctive peak. − [b] Irreversible.

For complexes **7** to **10**, the effect of the cyclometallation on the stability of the Ru^{III} state is illustrated by a cathodic shift of 750 mV. This behavior demonstrates the strong σ-donating character of the anionic (map^- or dtp^-) ligands. The ligand-centered reduction is also strongly affected by the presence of the cyclometallating ligand. In fact, the first reduction in these compounds occurs at around −1.6 V while it occurs around −1.3 V for **1** and **2**.

The absorption maxima, the molar absorption coefficients and the luminescence properties in acetonitrile and in butyronitrile are collected in Table 3 and representative absorption spectra in the series are shown in Figure 2.

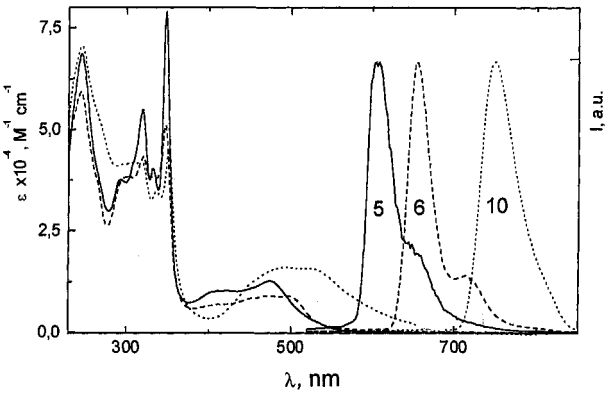

Figure 2. Absorption spectra (acetonitrile, room temperature) and normalized luminescence spectra (butyronitrile, 77 K) of complexes **5**, **6**, and **10**

The absorption bands in the UV region are ascribed to ligand-centered transitions (^{1}LC) and those occurring in the visible part, with ε around 10^4 M^{-1} cm^{-1}, correspond to ^{1}MLCT transitions.[1a] In the case of the cyclometallated complexes (**7**−**10**) the absorption bands occurring at low energy (495 to 527 nm) could be attributed to MLCT transitions involving the LUMO of the noncyclometallating ligand, i.e. ttpy (case of **7**, **9**, **10**) or mappy (case of **8**). Actually, as has already been established,[12] the level of the LUMO for the cyclometallated (anionic) ligand is expected to be higher in energy than that of an isoelectronic but neutral polypyridine ligand.

All the ruthenium complexes exhibit an intense luminescence at 77 K in butyronitrile (Table 3). The luminescence band maxima for the cyclometallated complexes are bathochromically shifted with respect to the noncyclometallated compounds. At room temperature, in CH_3CN, a more distinct behavior appears between the two series. Whereas compounds **1** and **3**−**6** are nonluminescent, as found for many tpy-containing derivatives,[1c] the cyclometallated complexes **8**, **9** and **10** luminesce and display relatively long-lived excited states (from 70 to 106 ns). This behavior can be understood in terms of the interplay of MLCT and metal-centered (MC) excited states, as discussed below.

In the case of ruthenium terpyridine-type complexes the distorted octahedral geometry induces a relatively weak ligand field at the metal center.[1c] As a consequence, effective pathways for deactivation of the ^{3}MLCT state are established by population of thermally accessible upper-lying ^{3}MC states. This effect is likely to be enhanced by the presence of bulky substituents in the α-position with respect to the N atom (case of **3** and **6**). This type of argument also could be used to explain the behavior of **1**, in which 2,9-bis-*p*-tolyl-1,10-phenanthroline is associated with a Ru(bipy)$_2$ core. In contrast, if the coordination sphere of the metal is less constrained as in **2**, a sizable luminescence can be observed.

Table 3. Spectroscopic properties[a]

[a] Acetonitrile solvent at room temperature, butyronitrile at 77 K.

In the case of cyclometallated ruthenium complexes it has already been recognized[13] that the strong ligand field provided by σ-donation at the carbon coordination increases the energy gap between the lowest-lying ^{3}MLCT levels (which involve the noncyclometallating ligand) and the upper-lying ^{3}MC states. This increase is basically due to a loading of electron density at the metal center, which results both in destabilization of the ^{3}MC level and stabilization of the ^{3}MLCT level (as indicated by the values of the luminescence band maxima at 77 K, Table 3). It is noteworthy that, according to the ″energy-gap law″, the latter effect is expected to enhance the nonradiative processes from the emitting state.[3] In the case of **8**, **9** and **10**, the balance of these effects results in sizable luminescence at room temperature, which is not the case for most of the terpyridine-containing ruthenium complexes.[1c] We noticed that, for **8**, **9**, and **10**, large ligand fragments undergoing interligand π-π interactions are present,[7] which can assist an extended electron delocalization for the MLCT states and result in the known beneficial effects noted in the case of large rigid ligands.[4] By contrast, the Ru(ttpy)(map)$^+$ (**7**) complex, which is necessarily devoid of such interligand interactions, does not luminesce at room temperature (Table 3).

Experimental Section

Physical Measurements: ^{1}H NMR: Bruker WP200 SY (200 MHz). – UV/Vis: Kontron Uvikon 860. – MS: VG ZAB-HF, Thomson THN 208. – Cyclic voltammetry data: PAR model 273A potentiostat, Pt disk as working electrode, CH_3CN solution, 0.1 M Bu_4NBF_4 as supporting electrolyte, Pt wire as auxiliary electrode, SCE as reference electrode.

Photophysical Measurements: Absorption spectra were determined with a Perkin–Elmer Lambda 5 spectrometer. – Uncorrected luminescence spectra were obtained from a Spex Fluorolog II fluorimeter equipped with a Hamamatsu R928 phototube. Uncorrected band maxima are used throughout the text. The luminescence quantum yields, Φ, were obtained from dilute solutions (the absorbance at the selected excitation wavelength was < 0.1)[20a] by analysing spectra that were corrected for the photomultiplier response and by comparison with the spectrum of Ru(bpy)$_3^{2+}$ (Φ = 0.028 in aerated water).[20b] Luminescence lifetimes were obtained with an IBH single photon apparatus employing a lamp filled with N_2; the decays were found to follow a single exponential behavior in each case. Further details were given elsewhere.[21] The experimental uncertainties were estimated to be 2 nm for the absorption and luminescence spectra, 20% for the luminescence intensities and 10% for the luminescence lifetimes.

Materials and General Procedures: The following chemicals were prepared according to literature procedures: 2-*p*-anisyl-1,10-phenanthroline (**mapH**);[14] 2,9-bis(*p*-tolyl)-1,10-phenanthroline (**dtpH**);[15] 4′-tolyl-2,2′,6′,2″-terpyridine (**ttpy**);[16] Ru(bp)$_2$Cl$_2$·2H$_2$O;[17] Ru(ttpy)Cl$_3$.[18]

2-*p*-Anisyl-9-(4-methyl-2-pyridyl)-1,10-phenanthroline (mappy): To a degassed solution of 2-bromo-5-methylpyridine (0.757 g, 4.4 mmol) in dry ether (15 mL) at −78°C was added dropwise *n*BuLi (soln. in hexane approx. 1.3 m, 3.7 mL, 4.84 mmol). The resulting red solution was warmed to −40°C and stirred at this temperature, under Ar, for 30 min. The organolithic solution was then transferred, by cannula, to a degassed solution of 2-*p*-anisyl-1,10-phenanthroline (1.145 g, 4.0 mmol) in dry ether (35 mL) at 0°C. The mixture was stirred under argon for 3 h at 0°C and then for a further 3 h at 10°C. After hydrolysis at 0°C with water (15 mL), the organic layer was decanted and the aqueous layer extracted with dichloromethane. The combined organic layers were rearomatized by succesive additions of MnO_2 (3 × 3 g, 3 g each 20 min), dried over $MgSO_4$ and filtered. After evaporation of the solvent the crude product was purified by column chromatography on alumina, with dichloromethane as eluent. The product, **mappy**, was obtained as a pale yellow solid (0.89 g, 59%). The solid crystallized from ethanol to give pale yellow crystals (m.p. 243.5–245.0°C). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 9.00 (d, *J* = 8.2 Hz, 1 H, H$^{3'}$), 8.82 (d, *J* = 8.4 Hz, 1 H, H^3), 8.58 (d, *J* = 2.2 Hz, 1 H, H$^{6'}$), 8.45 (d, *J* = 8.9 Hz, 2 H, 2 H^o), 8.36 (d, *J* = 8.4 Hz, 1 H, H^4), 8.29 (d, *J* = 8.5 Hz, 1 H, H^7), 8.11 (d, *J* = 8.5 Hz, 1 H, H^8), 7.81 (dd, *J* = 8.2 and 2.2 Hz, 1 H, H$^{4'}$), 7.79 (s, 2 H, H^{5,6}), 7.13 (d, *J* = 8.9 Hz, 2 H, 2 H^m), 3.94 (s, 3 H), 2.46 (s, 3 H). – Anal. calcd. for $C_{25}H_{19}N_3O$ (377.45): C 79.55, H 5.07, N 11.13; found: C 79.30, H 5.26, N 11.17.

3-Acetylisoquinoline: To sodium ethoxide (0.27 g, 0.012 mol) in dry benzene (40 mL) was added, with stirring, a mixture of methyl 3-isoquinoline carboxylate (1.8 g, 9.6 mmol) and anhydrous ethyl acetate (1.14 g, 15.8 mmol) in benzene (35 mL). The mixture was allowed to reflux with stirring for 24 h. The mixture was allowed to cool to room temperature and poured into a solution of sodium hydroxide (0.40 g, 0.01 mol) in water (7 mL). The light yellow solid that separated on the addition of the base was filtered off and water

(20 mL) was added to the filtrate. After decantation of the phases, the benzene layer was washed with water and the combined aqueous layer was extracted with ether (3 × 30 mL). The combined organic layers were evaporated and combined with the light yellow solid. To this was added concentrated hydrochloric acid and the mixture was heated to reflux for 2 h. On cooling, the mixture was made basic with sodium carbonate, the organic layer was extracted with ether (2 × 40 mL) and dried over sodium sulfate. Removal of the ether and purification on silica (dichloromethane/hexane 80:20) gave 1.23 g (75%) of 3-acetyl-isoquinoline. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 9.26 (s, 1 H), 8.45 (s, 1 H), 8.05−7.94 (m, 2 H), 7.79−7.67 (m, 2 H), 2.80 (s, 3 H). − MS (EI); *m*/*z*: 171.

2,6-Diisoquinolyl-(4-tolyl)pyridine (dqpy): To a dried sample of 3-acetyl-isoquinoline (1.23 g, 7.19 mmol), ammonium acetate (3.6 g, 46.7 mmol) and acetamide (5.54 g, 93.8 mmol) was added *p*-tolualdehyde (0.37 g, 3.11 mmol). The mixture was heated with stirring to 170°C under solvent-free conditions under an atmosphere of argon for 3 h. After this time the temperature of the reaction mixture was lowered to 120°C and the mixture was added to a solution of sodium hydroxide (2.8 g, 0.07 mol) in water (10 mL), a process that resulted in a brownish oil. The mixture was left at this temperature for a further 2 h. The dark brown oil and the yellow hot solution was poured into a beaker and, after cooling, the brown oil solidified. The solid was dissolved in acetic acid (10 mL) and refluxed for 2 h. 47% hydrobromic acid (10 mL) was then added and the mixture was left to stir at room temperture for a further 2 h. After this time, addition of a 5 N solution of potassium hydroxide (20 mL) resulted in the formation of a precipitate. The organic layer was extracted with dichloromethane (3 × 60 mL) and the combined organic layers were washed with sodium hydrogen carbonate and dried over magnesium sulfate. After column chromatography on alumina (hexane/ether; 8:2), dqpy was obtained as a white material (1.3 g, 43%). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.36 (s, 2 H), 9.08 (s, 2 H), 8.83 (s, 2 H), 8.08 (d, 2 H, *J* = 7.29 Hz), 8.03 (d, 2 H, *J* = 8.04 Hz), 7.87 (d, 2 H, *J* = 8.22 Hz), 7.74 (td, 2 H, *J* = 1.28 Hz), 7.63 (td, 2 H, *J* = 1.10 Hz), 7.33 (d, 2 H, *J* = 7.86 Hz), 2.43 (s, 3 H). − MS (EI); *m*/*z*: 423.2.

Ru(mappy)Cl$_3$: To absolute ethanol (30 mL) in a 100 mL round-bottomed flask was added $RuCl_3 \cdot 3H_2O$ (0.042 g, 0.132 mmol) and mappy (0.050 g, 0.132 mmol). The mixture was heated at reflux for 3 h with vigorous stirring. After this time, the reaction mixture was cooled to room temperature and the fine brown powder was collected by vacuum filtration, washed with cold absolute ethanol (3 × 30 mL) followed by Et_2O (3 × 30 mL) and dried under vacuum to give 0.065 g (84%) of Ru(mappy)Cl_3.

Ru(dqpy)Cl$_3$: This compound was prepared in the same manner as for the analogous compound, Ru(mappy)Cl_3, in almost quantitative yield. The insoluble brown-red product obtained was used without further purification.

General Workup Procedure for the Complexes 1 to 10: After reaction, the solvent was removed under reduced pressure and the colored solid was redissolved in methanol. The colored solution was filtered to remove any trace of unchanged starting complex and the filtrate obtained was added to an aqueous solution of KPF_6 (0.5 g in 50 mL of water) to give a solid. This solid was purified by silica gel chromatography, eluting with a mixture of CH_2Cl_2/CH_3OH (95:5) for all the complexes excepted for **5**, where the elution was performed with a CH_3CN/H_2O/saturated KNO_3 mixture (100:10:1).

Ru(bipy)$_2$(dtpH)(PF$_6$)$_2$ (1): A suspension of $Ru(bipy)_2Cl_2 \cdot 2H_2O$[17] (0.065 g, 0.13 mmol) and dtpH (0.046 g, 0.13 mmol) in acetic acid (10 mL) with 2−3 drops of *N*-ethylmorpholine was refluxed under argon for 3 h. Yield 0.033 g (24%). − ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 8.56 (d, 2 H, *J* = 8.22 Hz), 8.28 (s, 2 H), 8.25 (d, 2 H, *J* = 8.22 Hz), 8.09 (td, 2 H, *J* = 6.21 Hz, *J* = 1.47 Hz), 7.82 (d, 2 H, *J* = 8.21 Hz), 7.78 (d, 2 H, *J* = 5.49 Hz), 7.70 (d, 2 H, *J* = 8.24 Hz), 7.52−7.39 (m, 4 H), 7.02 (br, 2 H), 6.65−6.61 (m, 7 H), 5.96 (br, 3 H), 2.16 (s, 6 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 919 (20) [M − PF_6^-], 774 (10) [M − 2PF_6^- + e^-], 617 (12) [M − 2PF_6^- − bipy + e^-].

Ru(bipy)$_2$(mapH)(PF$_6$)$_2$ (2): A suspension of $Ru(bp)_2Cl_2 \cdot 2H_2O$ (0.050 g, 0.096 mmol) and mapH (0.026 g, 0.09 mmol) in acetic acid (7 mL) with 2−3 drops of *N*-ethylmorpholine was refluxed under argon for 4 h. Yield 0.065 g (68%). − ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 8.62 (d, 1 H, *J* = 8.4 Hz), 8.56 (dd, 1 H, *J* = 8.4 Hz, *J* = 1.29 Hz), 8.40 (d, 1 H, *J* = 7.86 Hz), 8.34 (d, 1 H, *J* = 7.50 Hz), 8.31−8.22 (m, 4 H), 8.07 (td, 1 H, *J* = 7.86 Hz, *J* = 8.01 Hz), 7.99−7.94 (m, 4 H), 7.91 (d, 1 H, *J* = 5.49 Hz), 7.74−7.62 (m, 4 H), 7.49−7.31 (m, 6 H), 7.29 (br, 1 H), 7.07 (d, 1 H, *J* = 5.67 Hz), 6.93 (t, 1 H, *J* = 7.11 Hz), 3.70 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 845 (50) [M − PF_6^-], 700 (35) [M − 2PF_6^- + e^-].

Ru(mappy)$_2$(PF$_6$)$_2$ (3): A suspension of Ru(mappy)Cl_3 (0.060 g, 0.10 mmol) and mappy (0.039 g, 0.10 mmol) was heated to reflux for 3 h in glacial acetic acid (6 mL) with 2−3 drops of *N*-ethylmorpholine. Yield 0.10 g (87%). − ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 8.77 (d, 2 H, *J* = 8.6 Hz), 8.63 (d, 2 H, *J* = 8.6 Hz), 8.44 (t, 4 H, *J* = 8.06 Hz), 8.24 (s, 4 H), 7.69 (dd, 2 H, *J* = 8.20 Hz, *J* = 1.2 Hz), 7.36 (d, 2 H, *J* = 8.34 Hz), 6.23−6.19 (br, 2 H), 6.15 (s, 2 H), 5.93−5.63 (m, 6 H), 3.76 (s, 6 H), 1.89 (s, 6 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 1001 (15) [M − PF_6^-], 856 (24) [M − 2PF_6^- + e^-].

Ru(ttpy)(mapH)(Cl)(PF$_6$) (4) and Ru(ttpy)(map)(PF$_6$) (7): Ru(ttpy)Cl_3 (0.10 g, 0.19 mmol) and mapH (0.054 g, 0.19 mmol) were heated to reflux for 3 h in glacial acetic acid (6 mL) with 2−3 drops of *N*-ethylmorpholine. Yield: 0.042 g (35%) of the cyclometallated product [Ru(ttpy)(map)PF_6] (**7**) and 0.060 g (31%) of the noncyclometallated product [Ru(ttpy)(mapH)(Cl)PF_6] (**4**). **Noncyclometallated complex (4):** ^{1}H NMR (200 MHz, CD_3CN): δ = 8.88 (s, 2 H), 8.54 (d, 2 H, *J* = 7.78 Hz), 8.49 (d, 1 H, *J* = 8.86 Hz), 8.32 (dd, 1 H, *J* = 8.19 Hz), 8.22 (d, 1 H, *J* = 8.23 Hz), 8.08 (d, 2 H, *J* = 8.34 Hz), 7.85 (d, 1 H, *J* = 8.88 Hz), 7.93−7.86 (m, 2 H), 7.77 (d, 1 H, *J* = 1.62 Hz), 7.74 (d, 1 H, *J* = 1.62 Hz), 7.69 (d, 1 H, *J* = 1.65 Hz), 7.52 (d, 2 H, *J* = 8.06 Hz), 7.34−7.25 (m, 3 H), 6.92 (td, 2 H, *J* = 7.24 and 1.34 Hz), 6.36 (dd, 1 H, *J* = 5.92 Hz), 5.34 (d, 1 H, *J* = 2.42 Hz), 3.39 (s, 3 H), 2.50 (s, 3 H). − MS; *m*/*z* (%): 891 (35) [M − PF_6^-], 746 (100) [M − 2PF_6^- + e^-].

Compound 7: ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 8.75 (dd, 1 H, *J* = 6.72 Hz, *J* = 1.56 Hz), 8.32 (d, 1 H, *J* = 8.86 Hz), 8.34−8.17 (m, 5 H), 8.10 (s, 2 H), 7.87 (dd, 2 H, *J* = 7.8 Hz, *J* = 1.45 Hz), 7.79 (d, 2 H, *J* = 8.32 Hz), 7.47 (d, 2 H, *J* = 8.06 Hz), 7.37 (dd, 2 H, *J* = 5.38 Hz, *J* = 1.36 Hz), 7.17 (d, 2 H, *J* = 8.34 Hz), 7.11−7.09 (m, 2 H), 6.45 (d, 2 H, *J* = 8.88 Hz), 6.07 (d, 2 H, *J* = 8.60 Hz), 3.52 (s, 3 H), 2.52 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 855 (40) [M^+], 710 (100) [M − PF_6^-].

Ru(dqpy)$_2$(PF$_6$)$_2$ (5): A suspension of Ru(dqpy)Cl_3 (0.070 g, 0.11 mmol) and dqpy (0.049 g, 0.12 mmol) was heated to reflux for 6 h in glacial acetic acid (8 mL) with 2−3 drops of *N*-ethylmorpholine. Yield 0.040 g (30%). − ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 9.09 (d, 8 H, *J* = 7.88 Hz), 8.24 (d, 8 H, *J* = 10.08 Hz), 8.07 (4 H, *J* = 8.12 Hz), 7.79 (d, 1 H, *J* = 1.48 Hz), 7.75 (t, 2 H, *J* = 1.72 Hz), 7.71 (d, 1 H, *J* = 1.72 Hz), 7.68−7.54 (m, 8 H), 2.56 (s, 6 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 1093 (15) [M − PF_6^-], 948 (35) [M − 2PF_6^- + e^-].

Ru(dqpy)(mappy)(PF_6)$_2$ (6): A suspension of Ru(dqpy)Cl_3 (0.08 g, 0.13 mmol) and mappy (0.048 g, 0.13 mmol) was heated to reflux for 5 h in glacial acetic acid (12 mL) with 2−3 drops of *N*-ethylmorpholine. Yield 0.076 g (49%) of **6** as a dark violet solid. − ^{1}H NMR (300 MHz, CD_2Cl_2): δ = 9.06−8.90 (m, 3 H), 8.70 (s, 2 H), 8.54 (d, 1 H, *J* = 8.76 Hz), 8.39 (d, 2 H, *J* = 8.22 Hz), 8.32 (d, 1 H, *J* = 8.97 Hz), 8.24−8.18 (m, 5 H), 7.83 (td, 3 H, *J* = 1.11 Hz, *J* = 1.26 Hz, *J* = 1.08 Hz), 7.76 (s, 2 H), 7.67−7.52 (m, 7 H), 7.36 (d, 1 H, *J* = 8.22 Hz), 6.60 (d, 2 H, *J* = 8.79 Hz), 6.11 (d, 2 H, *J* = 8.58 Hz), 3.51 (s, 3 H), 2.60 (s, 3 H), 1.96 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 1047 (80) [M − PF_6^-], 902 (100) [M − 2PF_6^- + e^-], 451 (55) [(M − 2PF_6^-)/ 2].

Ru(mappy)(dtp)(PF_6) (8): A suspension of Ru(mappy)Cl_3 (0.060 g, 0.10 mmol) and dtpH (0.039 g, 0.10 mmol) was heated to reflux for 3 h in glacial acetic acid (6 mL) with 2−3 drops of *N*-ethylmorpholine. Yield 0.040 g (41%).. − ^{1}H NMR (200 MHz, CD_3CN): δ = 8.57 (d, 1 H, *J* = 2.68 Hz), 8.39−8.27 (m, 4 H), 8.20 (d, 1 H, *J* = 8.86 Hz), 8.09 (d, 1 H, *J* = 8.84 Hz), 7.99 (d, 2 H, *J* = 6.71 Hz), 7.92 (d, 1 H, *J* = 6.2 Hz), 7.82 (d, 2 H, *J* = 7.8 Hz), 7.50 (d, 1 H, *J* = 9.68 Hz), 7.34−7.18 (m, 2 H), 6.59−6.52 (m, 2 H), 6.32 (d, 1 H, *J* = 8.32 Hz), 6.12 (d, 2 H, *J* = 8.31 Hz), 5.87−5.76 (br, 3 H), 5.70 (d, 2 H, *J* = 8.32 Hz), 5.04 (s, 1 H), 3.66 (s, 3 H), 2.08 (s, 3 H), 1.82 (s, 3 H), 1.64 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 838 (100) [M − PF_6^-]

Ru(ttpy)(dtp)(PF_6) (9): A mixture of Ru(ttpy)Cl_3 (0.070 g, 0.13 mmol) and dtpH (0.047 g, 0.13 mmol) was heated to reflux for 3 h in glacial acetic acid (6 mL) with 2−3 drops of *N*-ethylmorpholine. Yield 0.042 g (35%). − ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 8.39 (s, 2 H), 8.31 (d, 1 H, *J* = 8.32 Hz), 8.24 (d, 2 H, *J* = 7.80 Hz), 8.48−8.20 (m, 4 H), 8.05 (d, 1 H, *J* = 8.86 Hz), 7.96 (d, 2 H, *J* = 8.06 Hz), 7.74 (d, 1 H, *J* = 7.78 Hz), 7.73 (td, 2 H, *J* = 1.48 Hz, *J* = 6.72 Hz), 7.53 (d, 2 H, *J* = 7.8 Hz), 7.30 (d, 2 H, *J* = 8.32 Hz), 7.24 (d, 1 H, *J* = 1.22 Hz), 6.94 (dd, 1 H, *J* = 11.56 Hz, *J* = 1.34 Hz), 6.93 (t, 1 H, *J* = 1.62 Hz), 6.68 (d, 2 H, *J* = 7.8 Hz), 6.57 (dd, 1 H, *J* = 6.72 Hz, *J* = 1.30 Hz), 5.97 (d, 2 H, *J* = 7.8 Hz), 2.53 (s, 3 H), 2.02 (s, 3 H), 1.78 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 784 (100) [M − PF_6^-].

Ru(dqpy)(dtp)(PF_6) (10): A suspension of Ru(dqpy)Cl_3 (0.070 g, 0.11 mmol) and dtpH (0.041 g, 0.11 mmol) was heated to reflux for 3 h in glacial acetic acid (10 mL) with 2−3 drops of *N*-ethylmorpholine. Yield: 0.072 g (64%) of **10** as a dark purple solid. − ^{1}H NMR (300 MHz, CD_2Cl_2): δ = 8.59 (s, 3 H), 8.52 (d, 1 H, *J* = 8.76 Hz), 8.44 (s, 3 H), 8.38 (d, 1 H, *J* = 8.76 Hz), 8.29 (d, 1 H, *J* = 6.96 Hz), 8.26 (d, 1 H, *J* = 6.39 Hz), 8.02 (t, 7 H, *J* = 8.76 Hz, *J* = 7.14 Hz), 7.79 (d, 2 H, *J* = 8.04 Hz), 7.68 (t, 2 H, *J* = 6.93 Hz, *J* = 8.22 Hz), 7.58 (d, 2 H, *J* = 7.86 Hz), 7.50 (td, 2 H, *J* = 1.11 Hz, *J* = 1.11 Hz, *J* = 1.08 Hz), 7.37 (d, 2 H, *J* = 8.4 Hz), 6.75 (d, 2 H, *J* = 7.68 Hz), 6.54 (d, 1 H, *J* = 6.57 Hz), 6.09 (d, 2 H, *J* = 7.86 Hz), 2.61 (s, 3 H), 2.29 (s, 3 H), 2.08 (s, 3 H). − MS (FAB-MS) (nitrobenzyl alcohol matrix); *m*/*z* (%): 1029 (5) [M^+], 884(100) [M − PF_6^-].

X-ray Data Collection: Details concerning the crystal structure are given in Table 4. For all computations the MolEN package was used.[19] Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystollographic Data Centre as supplementary publication no. CCDC-119759. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: (internat.) +44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 4. X-ray experimental data of Ru(ttpy)(mapH)(Cl)(PF_6) (**4**)

Formula	$C_{41}H_{31}N_5OClRu{\cdot}PF_6$
Molecular mass	891
Color	red
Crystal system	monoclinic
a [Å]	15.378(4)
b [Å]	13.263(3)
c [Å]	20.306(6)
β [deg]	90.54(2)
Volume [Å^3]	4141.4
Z	4
$D_{calcd.}$ [g cm^{-3}]	1.553
Wavelength [Å]	1.5418
m [cm^{-1}]	47.206
Space group	$P2_1/c$
Diffractometer	Philips PW1100/16
Crystal dimensions [mm]	0.30 × 0.20 × 0.10
Temperature [°C]	−100
Radiation (monochromated)	Cu-K_α graphite
Mode	q/2q flying step-scan
Scan speed [deg^{-1}]	0.020
Step width [deg]	0.05
Scan width [deg]	1.10 + 0.14*tg(q)
Octants	±*h*+*k*+*l*
$q_{min/max}$ [deg]	3/54
Number of data collected	5459
Number of data with *I* > 3s(*I*)	4247
Number of variables	559
$Abs_{min/max}$	0.89/1.11
R(*F*)	0.037
$R_w(F)$	0.062
P	0.08
Largest peak in final diff. [e·Å^{-3}]	0.07
GOF	1.434

Acknowledgments

This work was performed with financial support from the CNRS (France), CNR (Italy), and the HCM Research Network (Contract no. ERBCH RXCT930145). We thank André De Cian, Nathalie Kyritsakas and Jean Fischer for the X-ray structure and Patrice Staub for his technical assistance.

Two Examples of Novel and Unusual Double-Layered, Two-Dimensional Cu^{II} Compounds with Bridging 1,3-Bis(1,2,4-triazol-1-yl)propane

Gerard A. van Albada,*[a] Reinier C. Guijt,[a] Jaap G. Haasnoot,[a] Martin Lutz,[b] Anthony L. Spek,[b] and Jan Reedijk*[a]

Keywords: Polymeric copper complexes / Group–subgroup relationships / 2D-sheets

The synthesis and characterisation of two new polymeric Cu^{II} complexes is described, i.e. $\{[Cu(btp)_2(CH_3CN)(H_2O)](CF_3SO_3)_2\}_n$ (**1**) and $\{[Cu(btp)_2(CH_3CN)_2](ClO_4)_2\}_n$ (**2**), in which btp = [1,3-bis(1,2,4-triazol-1-yl)propane]. Compound **1** crystallizes in space group $P2_1/c$ with a = 11.9337(15) Å, b = 20.108(6) Å, c = 12.748(6) Å, β = 92.247(14)°, and Z = 4. Compound **2** crystallizes in space group $Pna2_1$ with a = 18.770(8) Å, b = 12.648(8) Å, and c = 12.019(8) Å. The structures refined to $R1$ values of 0.0683 for **1** and 0.0846 for **2**. In both structures the Cu^{II} ions are linked by the bridging ligands, resulting in two-dimensional networks. Two such curved layers are arranged on top of each other with center-to-center of layer distances of 2.12 Å in **1** and 1.98 Å in **2**. Such double layers are separated from each other by 10.05 Å in **1** and 9.385 Å in **2**. The space between the double layers is occupied with interstitial anions. No significant interaction between Cu^{II} ions is observed by EPR and magnetic susceptibility measurements. The compounds form a new class of a lattice engineered system held together by the Cu^{II} ions. – The coordination geometry of the copper ions is distorted octahedral, with the equatorial plane formed by the N4 nitrogens of the four triazole groups and the axial sites occupied by solvent molecules; acetonitrile and water in structure **1** and two acetonitrile molecules in structure **2**. The two structures are related by a group–subgroup relationship, which appears to be the first such case in supramolecular chemistry. – The Cu–N vibrations in the FIR region are found at 274 cm^{-1} for **1**, and at 276 cm^{-1} for **2**. The ligand-field maxima are observed at about $16{\cdot}10^3$ cm^{-1}, with a shoulder at about $12{\cdot}10^3$ cm^{-1}. The ν_{CN} stretching vibrations of the acetonitrile molecules are found at 2303 and 2261 cm^{-1} for **1**, and at 2313, 2294, 2278, and 2260 cm^{-1} for **2**.

Introduction

Metal complexes with supramolecular features in their structure have recently aroused much interest as materials with potentially new electronic, optical, magnetic, or catalytic properties.[1] Given the strong preference of Cu^{II} for square-planar based geometries, bridging ligands would be almost ideally suited for building a square 2-dimensional lattice. Well-known classical cases are structures like $(cation)_2CuCl_4$[2] (cation = organic substituted ammonium). Such 2D systems also allow the coordination of weak axial ligands, like in some clathrate compounds.[3]

When bridging ligands are large, cavities result which need to be filled to form a stable lattice. and This can be accomplished by, for instance, the counter anions and/or guest molecules, or by the formation of interpenetrating lattices.[1a] With proper vertical stacking of such 2D systems, supramolecular systems with channels might result, in which the anions and/or guest molecules could move or migrate. A totally different way of packing would be a case where layers occur in pairs, and be organized in such a way that a corner of a lattice grid in one 2D lattice cell, lies above the cavity of the other cell, filling it up with its axial ligand. In such a case double-layers of 2D lattices result, which as such can be separated by counter anions and solvent/guest molecules. Such systems, when properly stabilized with strongly bridging ligands, would have the axial ligand sites of the copper ions accessible for ligand exchange and/or − more importantly − catalytic reactions, with the reagents transported through the spaces [slabs] between the double-layers.

For Cu^{II} a number of 2D and 3D frameworks are already known with *N,N′*-bidentate spacers.[4] In most cases the spacer molecules are rigid heterocyclic ligands;[4a,5] however, only a few structures are known in which the 2D or 3D frameworks consist of two heterocyclic donors linked by spacers of variable length, like in the compound Cu^{I}[(1,4-bis(4-pyridyl)butadiyne],[4b] and Cu^{II} and Mn^{II} compounds with [(1,2-bis(imidazol-1′-yl)alkane] ligands.[6]

Recently, a new class of ligands, [bis(1,2,4-triazol-1-yl)-alkanes], was developed in our laboratories and characterised by X-ray diffraction. A variety of new types of polymeric 2D and 3D frameworks with Fe^{II} and Mn^{II} were found.[7]

We now wish to report the first case of two examples of such lattice-engineered systems using Cu^{II}, and generating double layers of a 2D system. By the using the ligand [1,3-bis(1,2,4-triazol-1-yl)propane] (abbreviated btp), we synthe-

sized two compounds, i.e. $Cu(btp)_2(CH_3CN)(H_2O)](CF_3SO_3)_2$ (**1**) and $[Cu(btp)_2(CH_3CN)_2](ClO_4)_2$ (**2**), from which crystal structures were obtained.

Results and Discussion

Description of the Crystal Structures

The structures of both compounds are depicted in Figures 1 and 2, respectively, together with the numbering scheme and relevant bond length and bond angle information. In both structures, the coordination polyhedra of the Cu^{II} ions are distorted octahedra, in which the equatorial plane is formed by the N4 nitrogens of the triazole groups, with Cu−N distances of 2.009(4)−2.020(3) Å in **1** and 1.974(12)−2.039(12) Å in **2**. The axial positions in the octahedra are occupied by weaker ligands, i.e. solvent molecules, acetonitrile and water in **1**, and two acetonitrile molecules in **2**. The axial distances in **1** are 2.399(4) Å for Cu−N and 2.462(4) Å for Cu−O. In **2** the axial Cu−N distances are 2.260(15) and 2.665(15) Å, the latter at a semi-coordination distance.

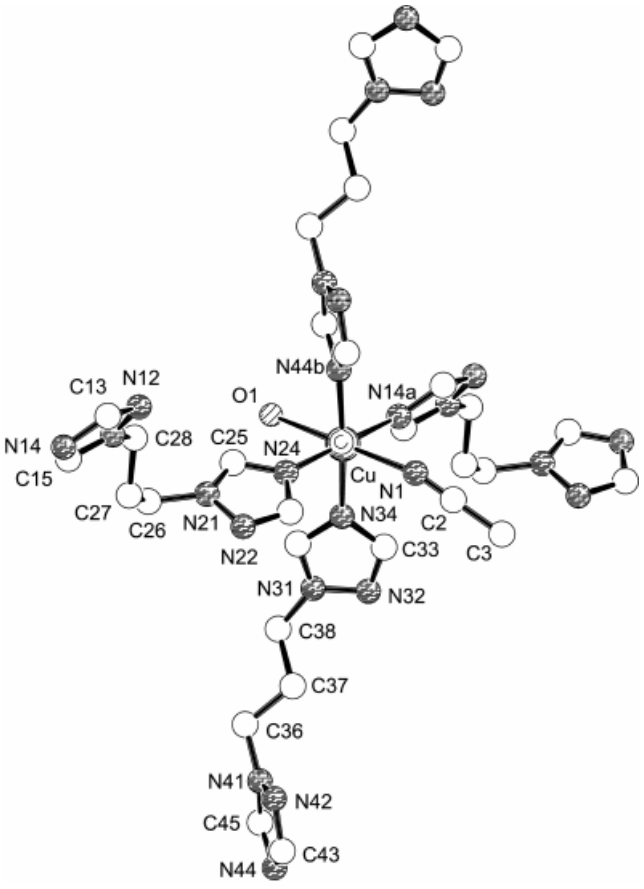

Figure 1. Coordination environment of the Cu atom in $\{[Cu(btp)_2(CH_3CN)(H_2O)](CF_3SO_3)_2\}_n$ (Structure **1**) with atom-labelling scheme. Hydrogen atoms and triflate anions are omitted for clarity. Symmetry operations: $a = x - 1, y, z$; $b = x, y, z - 1$. Bond length [Å] and angles [°]: Cu−O1 2.462(4); Cu−N1 2.399(4); Cu−N14a 2.013(3); Cu−N34 2.020(3); Cu−N44b 2.011(3); Cu−N24 2.010(3); N24−Cu−N44b 91.05(13); N24−Cu−N14a 178.51(14); N44b−Cu−N14a 90.04(13); N24−Cu−N34 89.11(13); N44b−Cu−N34 175.17(15); N14a−Cu−N34 89.72(13); N24−Cu-N1 91.93(14); N44b−Cu−N1 93.12(14); N14a−Cu−N1 89.02(14); N34−Cu−N1 91.70(14); N24−Cu−O1 90.43(14); N44b−Cu−O1 88.44(13); N14a−Cu−O1 88.59(13); N34−Cu−O1 86.73(13); N1−Cu−O1 177.14(13).

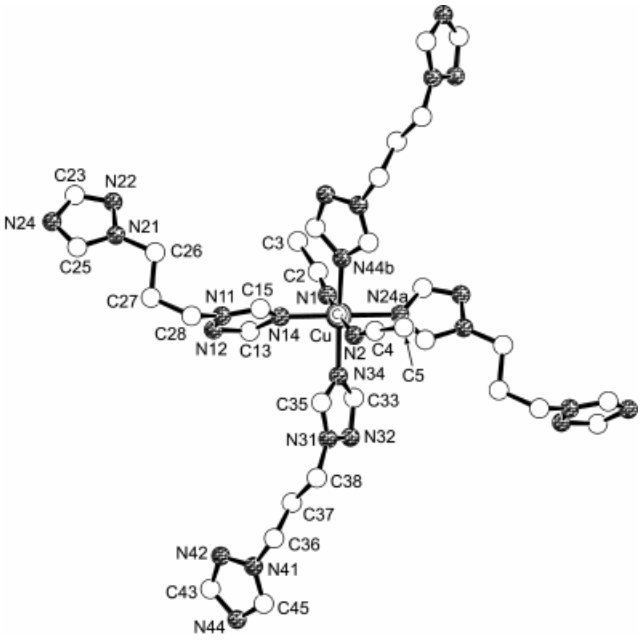

Figure 2. Coordination environment of the Cu atom in $\{[Cu(btp)_2(CH_3CN)_2](ClO_4)_2\}_n$ (structure **2**) with atom-labelling scheme. Hydrogen atoms and perchlorate anions are omitted for clarity. Only one configuration of the disordered acetonitrile (N1−C3) is shown. Symmetry operations: $a = x, y, z + 1$; $b = x, y + 1, z$. Bond length [Å] and angles [°]: Cu−N1 2.261(15); Cu−N14 1.974(13); Cu−N34 2.029(14); Cu−N24a 2.040(13); Cu−N44b 2.009(14); Cu−N2 2.665(15); N14−Cu−N44b 90.6(5); N14−Cu−N34 89.9(5); N44b−Cu−N34 169.0(5); N14−Cu−N24a 178.0(5); N44b−Cu−N24a 89.1(5); N34−Cu−N24a 90.1(5); N14−Cu−N1 90.1(5); N44b−Cu−N1 92.7(6); N34−Cu−N1 98.3(6); N24a−Cu−N1 91.9(5); N14−Cu−N2 91.0(5); N44b−Cu−N2 84.5(5); N34−Cu−N2 84.5(5); N24a−Cu−N2 87.0(5); N1−Cu−N2 177.0(5).

In both structures, the Cu^{II} ions are linked by the btp ligands, building up polymers to a two-dimensional network. In **1**, this 2D sheet is situated parallel to the crystallographic *a,c* plane. A second layer with no bonding interaction to the first one, is situated 2.12 Å above it. So in fact these two layers, shown in Figure 3, should be considered as a double layer. The double layers are stacked in the crystallographic *b* direction with a distance of $b/2 = 10.054$ Å. The space between the sets of double layers is filled up with the triflate anions as shown in Figure 4. The crystal structure of **1** is further stabilized by H-bonding between the water molecule and oxygens of the triflate anion [O1···O2 2.780(6) Å and O1···O5 2.855(5) Å].

The situation in **2** is quite similar. Here the 2D sheets are located parallel to the crystallographic *b,c* plane, and stacked in the *a* direction. The distance within the double layer is even smaller (1.98 Å). Because perchlorate anions are smaller than triflate anions the distance between the double layers is shortened to 9.385 Å ($= a/2$).

The cell parameters of both structures differ slightly, which must be caused by the different anions. The reason

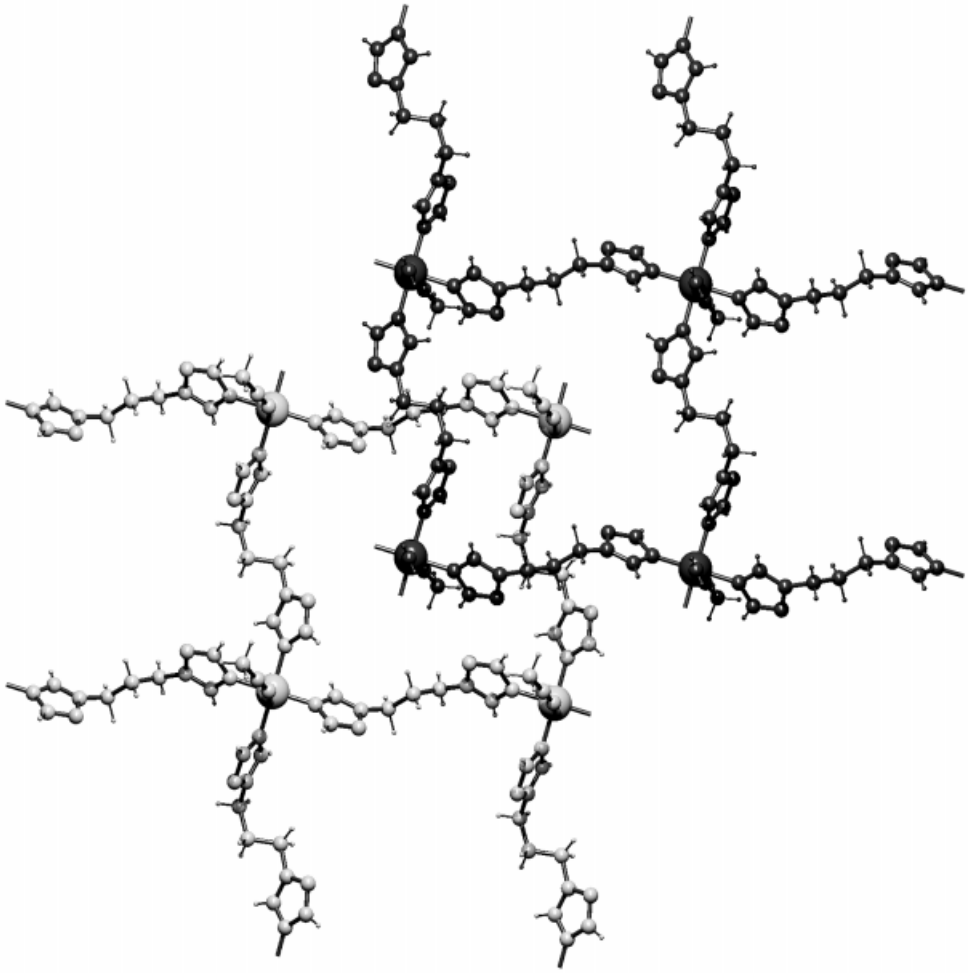

Figure 3. View along the crystallographic b-axis on one double layer in structure **1**

for changing the orientations of the unit cell in **1** and **2** was to achieve the standard setting of the space groups. The space groups $P2_1/c$ for **1** and $Pna2_1$ for **2** are both subgroups of the same super-group; *Pnma.* While such "family tree" relations are well-known in other areas of inorganic chemistry, such as in perovskite-like structures,[8] to our knowledge, this is the first case of such a group−subgroup relationship in supramolecular coordination chemistry.

The shortest Cu−Cu distances are 8.753(3) Å in **1** and 8.946(4) Å in **2**. These distances are shorter than observed in $[(Cu(bim)_{2,5})(ClO_4)_2 \cdot 2\ MeOH]$ [bim = 1,2-bis(imidazol-1′-yl)ethane],[6a] one of the few compounds that also have an alkane chain as a spacer, in which the Cu−Cu distance is 12.55 Å. In fact, this confirms the importance of this family of ligands in adjusting the metal-metal distance. With other metals like Fe^{II} and Mn^{II}, this type of ligand [bis(1,2,4-triazol-1-yl)alkanes] leads to a variety of 2D and 3D structures.[7]

Ligand Field Spectra

The d-d transitions in the UV-Vis-NIR absorption spectra for both Cu compounds are found at about $16{\cdot}10^3$ cm^{-1}, with a shoulder at about $12{\cdot}10^3$ cm^{-1} (See Table 1). These values agree with ligand field transitions for copper square-planar or square-planar based CuN_4 or a CuN_4X_2 chromophore.[9]

EPR and Magnetic Properties

The EPR measurements on **1** and **2** reveal the normal parameters (see Table 1) for a Cu^{II} isolated spin $S = {}^1/_2$,[9a] as almost no Cu−Cu interaction is present due to the large distances between the Cu centres. The $A_{//}$ value of ca. 17 mT (measured as a frozen solution at 77 K) is consistent with a $CuN_4(X)_{1-2}$ (X = N,O) geometry around the copper ion.[9] Magnetic susceptibility data recorded down to 40 K indicate a magnetic moment of 1.8 B.M., below which a slight decrease is observed down to 5 K, which is at best in agreement with a very weak exchange coupling.

Infrared Spectra

In the infrared spectrum the vibrations of the acetonitrile molecules are found at 2261 and 2303 cm^{-1} for compound

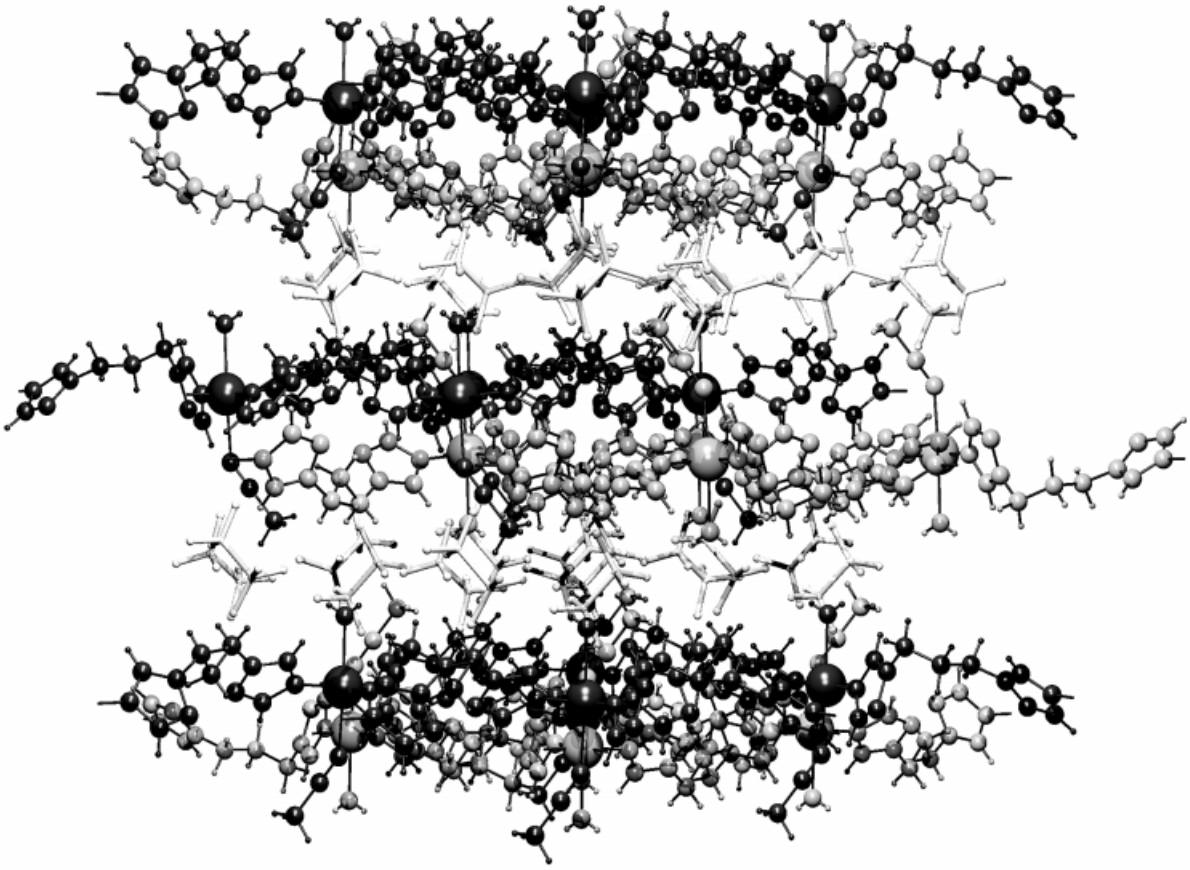

Figure 4. Stacking of the double layers in structure **1** in the direction of the crystallographic *b* axis. The double layers are separated by the triflate anions. (View along [1.0.1])

Table 1. UV-VIS-NIR, EPR, and FIR spectral data[a] for Cu^{II} compounds with btp

Compound	UV-VIS-NIR [10^3 cm^{-1}]	EPR values, (powder, room temp.) $g_\perp$, $g_{//}$	EPR values, 77 K[b] $g_\perp$, $g_{//}$, $A_{//}$ [mT]	MIR [cm^{-1}] ν_{CN}	FIR [cm^{-1}] ν_{Cu-N}
1, $\{[Cu(btp)_2(CH_3CN)(H_2O)](CF_3SO_3)_2\}_n$	ca.12.0 (sh) 16.1	2.07, ca.2.4 (vw)	2.06, 2.27, 17.3	2303 (w), 2261 (m)	274
2, $\{[Cu(btp)_2(CH_3CN)_2](ClO_4)_2\}_n$	ca.12.0 (sh) 16.8	2.07, ca.2.4 (vw)	2.06, 2.30, 16.4	2313 (w), 2278 (m) 2294 (vw), 2260 (m,sh)	276

[a] Abbreviations: vbr = very broad, vw = very weak, sh = shoulder. – [b] Frozen solution in DMSO/MeOH (1:1)

1, which contains only one coordinated acetonitrile molecule. In compound **2**, which has two acetonitrile molecules, with one short distance of 2.260(15) Å and one long Cu–N distance of 2.665(15) Å, the vibrations are found at 2313 and 2278 cm^{-1} for the first and at 2294 and 2260 cm^{-1} for the second acetonitrile molecule. In each case, the bands at lower frequencies are assigned to the C≡N stretching vibration and those at higher frequencies to the $\nu_3+\nu_4$ combination band mixed with C≡N stretch.[10] In the far-infrared region, the Cu–N vibrations are clearly visible as strong broad peaks at 274 cm^{-1} for **1** and at 276 cm^{-1} for **2**, which is comparable with Cu–N vibrations given in the literature.[11]

In summary, the compounds presented herein are a first step in a new series of supramolecular compounds, and we are currently working on the use of metal ions other than Cu^{II}, as well as changing the anions and axial ligands to synthesizing materials that can be used as host/guest molecules and can be active in catalytic processes.

Experimental Section

General: C, H, N, and Cu determinations were performed by the Microanalytical Laboratory of University College, Dublin, Ireland. – Ligand field spectra were obtained on a Perkin–Elmer Lambda 900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference. – X-band EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer using DPPH (g = 2.0036) as a standard. – FTIR spectra were obtained on a Bruker 113v infrared spectrophotometer as KBr disks (4000–400 cm^{-1},

mirror velocity 0.166 cm/s, resolution 2 cm^{-1}), or as polyethylene mulls (600−100 cm^{-1}, mirror velocity 0.099 cm/sec, resolution 2 cm^{-1}, Mylar 3.5 μ beam splitter). − Magnetic susceptibilities were measured in the temperature range 5−300 K with a Manics DSM-8 susceptometer. Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

Synthesis of the Ligand. − 1,3-Bis(1,2,4-triazol-1-yl)propane: A modified literature procedure[12] was followed. To a solution of 0.5 mol 1*H*-1,2,4-triazole in 200 mL of absolute ethanol, an equimolar amount of metallic sodium was added in small portions, while cooling in ice and stirring vigorously. When the formation of sodium triazolate was completed, 0.22 mol of 1,3-dichloropropane was added, while still cooling and stirring. The solution was then heated under reflux for 7 days. After cooling to room temperature the precipitate of sodium chloride was filtered off. The ethanol filtrate was evaporated to a small volume, while the desired product separated. The compound was recrystallized from absolute ethanol (yield 64%). − ^{1}H NMR data ([D$_6$]DMSO, TMS as a standard): δ = 2.29 (q, 2 H), 4.18 (t, 4 H), 7.97 (s, 2 H), 8.52(s, 2 H).

Compounds 1 and 2: 1.2 mmol of hydrated Cu^{II} salt and 1.2 mmol of the ligand were each dissolved in 10 mL of water/acetonitrile (1:1). The Cu^{II} salt solution was then added slowly to the ligand solution and filtered to remove any undissolved material. After a few days the blue-green products separated and were isolated by filtration and dried in air (yield 70%). − Elemental analysis: for $Cu(btp)_2(CH_3CN)(H_2O)](CF_3SO_3)_2$: found (calc) (%) 27.82 (28.73) C, 3.24 (3.24) H, 22.43 (21.81) N, 14.67 (14.66) F, 8.18 (8.34) Cu. For $[Cu(btp)_2(CH_3CN)_2](ClO_4)_2$: found (calc) (%) 29.25 (30.84) C, 3.59 (3.74) H, 27.21 (27.98) N, 10.22 (10.12) Cl, 9.24 (9.07) Cu.

X-ray Data Collection and Structure Determination: The single crystal X-ray diffraction work was done at 150 K on an Enraf−Nonius CAD4T diffractometer with rotating anode and Mo-*Kα* radiation (graphite monochromator, λ = 0.71073 Å). Unit cell parameters were determined from a least-squares treatment of the SET4 setting angles of 25 reflections and were checked for the presence of higher lattice symmetry. No absorption correction was considered necessary. The structures were solved with automated Patterson methods and subsequent phase refinement techniques (DIRDIF[13a]). Refinement was done with SHELXL97.[13b] In **1** the non-hydrogen atoms of the acetonitrile molecule were refined as a rigid group; the hydrogens of the water molecule were refined freely with isotropic displacement parameters. All other hydrogens were located in the difference map and were not refined. In **2** the copper and chlorine were refined with anisotropic displacement parameters. All other non-hydrogen atoms were refined freely with isotropic displacement parameters; one of the acetonitrile molecules is disordered. The hydrogen atoms were in calculated positions and not refined. All other calculations were performed with the PLATON package.[13c] Crystallographic data and information about the structure determination are given in Table 2.

Colour pictures of Figures 3 and 4 are available as supplementary material (also on http://www.cryst.chem.uu.nl/structures/s1725a/s1725a.html)

Tables with atomic coordinates of all atoms, anisotropic thermal parameters, bond lengths and angles, and tables of observed and calculated structure factors are available from one of the authors (A.L.S.)

Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-115865 for structure **1** and CCDC-115866 for structure **2**. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44(1223)336−033, E-mail: deposit@ccdc.cam.ac.uk].

[14] The angles around the Cu^{II} ions are only slightly deviating from a perfect octahedron [N14−Cu−N24b = 178.51(12) and N34−Cu−N44b = 175.17(14)° for **1**; N14−Cu−N24c −178.0(6) and N34−Cu−N44d = 169.0(5)° for **2**]. The octahedron can therefore be considered as extended along the C_4 axis or as tetragonally distorted.

Synthesis and Structural Characterization of Tin(IV) *N*-nitroso-*N*-phenylhydroxylaminato Complexes: Crystal Structures of $Sn(O_2N_2Ph)_4$, $Ph_2Sn(O_2N_2Ph)_2$ and $[Me_2Sn(O_2N_2Ph)_2]_2$

Keywords: Coordination chemistry / Inorganic rings / O ligands / Structure elucidation / Tin

Reaction of cupferron [NH_4L, L = PhN(O)NO$^-$] with tin(IV), diphenyltin(IV) and dimethyltin(IV) halides yields the cupferronato complexes SnL_4 (**1**), Ph_2SnL_2 (**2**) and $[Me_2SnL_2]_2$ (**3**). All were characterized by FT-IR, FT-Raman, NMR (^{1}H, ^{13}C and ^{119}Sn) spectroscopic methods and X-ray structural analysis. An almost ideal, very rare dodecahedral geometry is found in the structure of **1**. The hexacoordinated tin center exhibits a bicapped tetrahedral geometry in complex **2**. The tin centers are heptacoordinated in a pentagonal bipyramidal geometry in the dimeric complex **3**. These complexes incorporate five-membered SnO_2N_2 and four-membered Sn_2O_2 inorganic rings. Vibrational spectral data are consistent with the structures determined. The ^{119}Sn NMR spectra indicate that in solution **1** retains its octacoordinated nature; in compound **2** the tin atom is hexacoordinated, while in **3** the tin atom is pentacoordinated.

Introduction

We became interested in tin and organotin(IV) *N*-nitroso-*N*-phenylhydroxylaminato (cupferronato) complexes since many organotin compounds are known to display antitumor activity.[1] In addition, the biological activity of cupferron [NH_4L, L = PhN(O)NO$^-$] has also been investigated, carcinogenic, genotoxic, mutagenic and DNA-damaging effects being observed.[2] The knowledge of the coordination chemistry of cupferron could provide more information about the interaction modes of nitric oxide with metal centers of biologically important species (e.g. hemes or heme models) and could help to elucidate the mechanism of activation of the NO-receptor enzyme guanylate cyclase.[2] Moreover, a large structural diversity of cupferronato complexes is expectable due to the ability of tin to exhibit various coordination geometries[3] and to the diverse coordination patterns of cupferronato anion.[4] In order to accumulate precise structural data concerning the binding modes of *N*-nitroso derivative with tin we prepared tin and diorganotin(IV) cupferronato complexes: $Sn(O_2N_2Ph)_4$ (**1**), $Ph_2Sn(O_2N_2Ph)_2$ (**2**) and $[Me_2Sn(O_2N_2Ph)_2]_2$ (**3**) which were investigated by FT-IR, FT-Raman, multinuclear (^{1}H, ^{13}C and ^{119}Sn) NMR as well as X-ray diffraction analysis.

Results and Discussion

Reaction of cupferron [NH_4L, L = PhN(O)NO$^-$] with SnI_4 in chloroform (Equation 1) results in the formation of **1**.

$$SnI_4 + 4\,NH_4L \xrightarrow{CHCl_3} \underset{\mathbf{1}}{SnL_4} + 4\,NH_4I \quad (1)$$

In similar manner, cupferron reacts with diorganotin dichlorides R_2SnCl_2 (R = Ph and Me) in acetone or dried MeOH (Equation 2) to give **2** and **3**.

$$n\,R_2SnCl_2 + 2\,n\,NH_4L \xrightarrow[\text{or MeOH}]{\text{acetone}} \underset{\begin{array}{c}\mathbf{2}\text{: n = 1, R = Ph}\\ \mathbf{3}\text{: n = 2, R = Me}\end{array}}{[R_2SnL_2]_n} + 2\,n\,NH_4Cl \quad (2)$$

All the complexes **1**−**3** are stable and are soluble in $CHCl_3$ and *n*-heptane.

Structures in the Solid State

Vibrational Behavior

The FT-IR and Raman spectra were recorded for the complexes **1**−**3** in the 3500−100 cm^{-1} spectral range. As was expected all these new compounds display ν(N−N), ν(N=O) and δ(ONNO) absorption bands typical for the $PhN_2O_2^-$ ligand.[4] Taking into account the coordination of the anionic cupferronato ligand to the metal centers through the oxygen atoms, the Sn−O stretching vibration

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 2000 1434−1948/00/0101−0127 $ 17.50+.50/0

was also characteristic.[4] Selected bands and assignments are listed in Table 1.

X-ray Crystallographic Studies

The molecular structures of compounds **1**, **2** and **3** are shown in Figures 1–3, respectively. Selected bond lengths and angles are listed in Table 2 and Table 4.

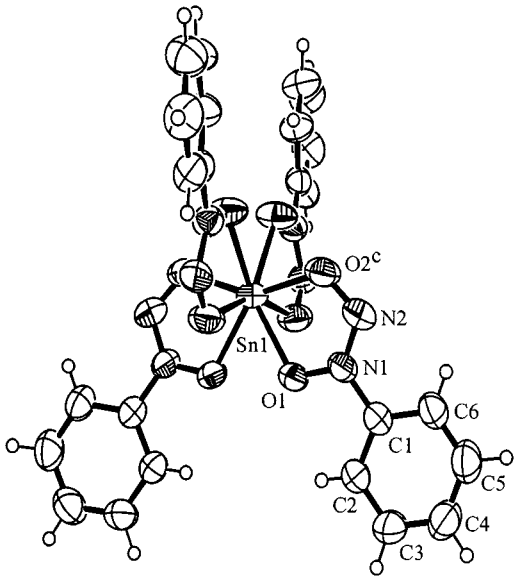

Figure 1. Molecular structure of **1**

The molecular structure of **1** provides a new example of an octacoordinated Sn^{IV} species in an almost perfect dodecahedral geometry of the metal center coordination environment defined by eight oxygen atoms from the four cupferronato ligands. Hitherto, only four Sn^{IV} complexes with octacoordinated tin centers have been characterized by X-ray crystallography: tin tetranitrate,[5] stannic phthalocyanine,[6] tin tetraacetate,[7] and tetrakis(tropolonato)tin.[8] The distortion of the idealized dodecahedron towards the bicapped trigonal prism and/or square antiprism can be described by δ and φ parameters.[9] As shown in Table 3, the four δ (29.5°) and two φ (0°) values are identical in an ideal dodecahedron, while this equality becomes more or less changed for the bicapped trigonal prism and square antiprism. The δ and φ values observed for **1** reveal an almost perfect dodecahedral geometry around the tin atom.

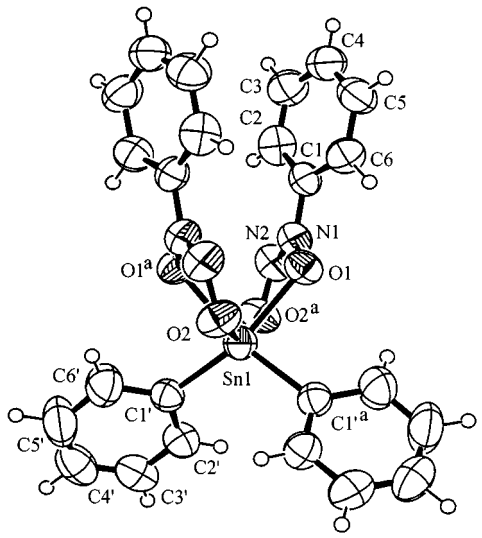

Figure 2. Molecular structure of **2**

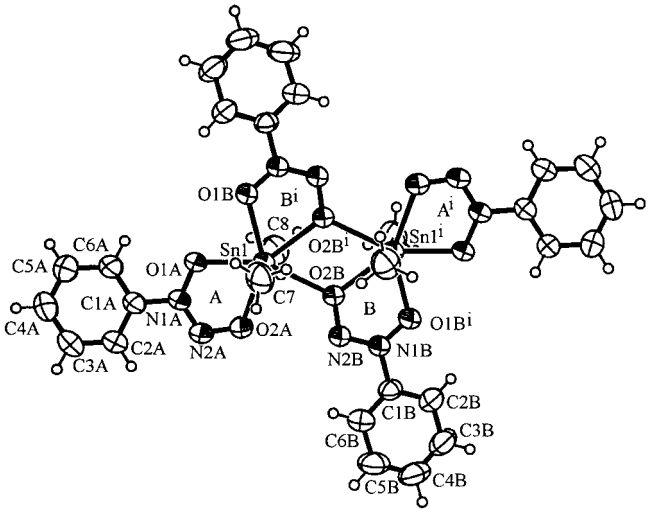

Figure 3. Molecular structure of **3**

The cupferronato anions are bound to the Sn^{IV} center in a bidentate chelating fashion leading to five-membered carbon-free chelate rings SnO_2N_2 with an O(1)–Sn(1)–O(2)^c bite angle of 70.1(1)°. The Sn–O(2) bond length is slightly shorter (by 0.041 Å) than that of Sn–O(1), and somewhat longer than the ideal value of 2.14 Å.[3] The average Sn–O bond length of 2.164 Å is, however, consistent with tin-oxygen distances observed in other octacoordinated tin(IV) species, such as $Sn(NO_3)_4$ (average Sn–O = 2.161 Å)[5] and the recently reported Sn(tropolonato)$_4$ (average Sn–O = 2.168 Å).[8]

The crystal lattice is built up from infinite one-dimensional C–H···O interactions, C(3)–H(3)···O(2) [C–H = 0.94 Å; H···O = 2.45 Å; C···O = 3.37 Å; C–H···O = 165.8°] that extends through (x, 0.5 − y, −0.5 − z). This hydrogen-bonding interaction has no significant impact on the adoption of the almost ideal dodecahedral geometry.

Table 2. Selected interatomic bond lengths (Å), bond angles (°) and torsion angles (°) for **1** and **2**

	1	**2**

Equivalent atoms (i) generated for **1** by c = (x, −y + 0.5,−z + 0.5), and for **2** by a = (−x, y, −z + 0.5).

Table 3. Ideal and observed δ (°) and φ (°) for octacoordinated complexes

Complex	δ				φ	
dodecahedron[9]	29.5	29.5	29.5	29.5	0	0
bicapped trigonal prism[9]	0	21.7	48.2	48.2	16.1	16.1
square antiprism[9]	0	0	52.5	52.5	10.8	10.8
1	28.4	28.4	25.7	25.7	−1.9	1.1

In the class of hexacoordinated tin(IV) compounds the octahedral geometry is predominant.[3] Distorsions in the solid state can be attributed to a compromise between the close packing and the ideal shape of the molecules.[9] In complex **2** the hexacoordinated metal center surrounded by two carbon atoms of two phenyl groups and four oxygen atoms of the chelating cupferronato anions exhibits a slightly distorted bicapped tetrahedral arrangement.[10] In this arrangement the capping ligand atoms O(1) and O(1)^{a} are located in the middle of two faces of the nearly regular tetrahedron C(1′)^{a}···C(1′)···O(2)···O(2)^{a}. The basic tetrahedral geometry around the tin center is retained with angles C(1′)^{a}−Sn(1)−C(1)′ of 107.74(2)°, C(1)′−Sn(1)−O(2) and symmetry equivalent C(1′)^{a}−Sn(1)−O(2)^{a} of 108.2(1)°, and these values are close to the ideal tetrahedral value. The Sn(1)−C(1)′, Sn1−C(1′)^{a} and Sn(1)−O(2), Sn(1)−O(2)^{a} distances belonging to the tetrahedral core are almost equal. Otherwise, the Sn(1)−O(2) distances are close to the ideal value for a normal covalent bond 2.14 Å, while the Sn(1)−O(1) distances are somewhat longer. The O(1)−Sn(1)−O(2)^{a} bite angle of 69.7(1)° is comparable to the bite angle measured in **1** and depends partially on the strain in the five-membered inorganic SnO_2N_2 ring.

The ligand hydrogens in the *para* position interact with the π system of the phenyl rings (1 − x, y, 1.5 − z) bound directly to the tin atom via weak C−H···π interactions [C(4)···π = 3.84 Å, H(4)···π = 3.09 Å, C(4)−H(4)···π = 139.4°].

Equivalent atoms (i) generated for L = B by (−x, −y, −z).

According to the X-ray data compound **3** is represented by the centrosymmetric dimeric structure $[Me_2Sn(O_2N_2Ph)_2]_2$. Both tin(IV) centers are heptacoordinated. The nearly pentagonal bipyramidal coordination is achieved by one bidentate chelating (A and its symmetry equivalent, A^{i}) and two triconnective bridging cupferronato ligands (B and its symmetry equivalent B^{i}) lying in the equatorial plane, and two methyl groups occupying the axial positions. This arrangement with five equatorial oxygen atoms is similar to those reported for the bridged binuclear and polynuclear pentagonal bipyramidal dimethyltin(IV) complexes of aminocarboxylate and aminopolycarboxylate ligands.[11−14] In the majority of these structures,[11−13] while the methyl groups are invariably in the axial position, one oxygen is replaced by a nitrogen atom. There is an additional case where two oxygen atoms are replaced by two nitrogen atoms.[14]

A notable feature in the structure of **3** is the occurrence of a central planar [torsion angle: O2(B)^{i}−Sn(1)^{i}−O(2B)−Sn(1) = 0.(0)°] four-membered Sn_2O_2 ring. In this ring, the two pairs of Sn−O distances [Sn(1)−O(2B)^{i} and Sn(1)−O(2B)] are unequal, and the bridging oxygen atoms [O(2B) and O(2B)^{i}] participate in two additional, planar, five-membered SnO_2N_2 rings resulting in a Sn···Sn separation of 4.108 Å. Distannoxanes generally form dimeric ladder-type structures that also contain a planar four-membered Sn_2O_2 ring,[3][15] a feature which can be found in the bridged binuclear and polynuclear pentagonal bipyramidal dimethyltin(IV) complexes discussed.[11−14] The Sn(1)−O(2B)^{i} bond length in the triconnective bridging ligand seems to be significantly longer by 0.121 Å than the corresponding distance of 2.274(2) Å for the chelating ligand. The O(1B)−Sn(1)−O(2B)^{i} bite angle in ligand B deviates by ca 4° from the bite angle of the chelating ligands.

There are weak intramolecular hydrogen bonds such as C−H···O [C(6A)···O(1A) 2.69 Å, H(6A)···O(1A) 2.35 Å, C(6A)−H(6A)···O(1A) 100.8°] between the phenyl hydrogens and the ONNO group.

In the crystal lattice the symmetry-related dimeric molecules interact along the *a* axis *via* weak C−H···π interactions [C(6B)···π 3.56, H(6B)···π 3.30 Å, C(6B)−H(6B)···π 98.8°].

Structures in Solution

^{1}H, ^{13}C and ^{119}Sn NMR spectra were recorded (in $CDCl_3$) to gain some insight into the solution structure of the complexes. For proton-containing groups directly attached to the Sn atom (Me, Ph), proton spectra exhibited ^{119}Sn (and ^{117}Sn) satellite signals due to $^{2}J(^{119}Sn-^{1}H)$ or $^{3}J(^{119}Sn-^{1}H)$ couplings. In a similar fashion, resonances due to the carbon atoms in groups attached to tin exhibited ^{119}Sn (and ^{117}Sn) satellites arising from one-bond and multiple bond $^{n}J(^{119}Sn-^{13}C)$ spin−spin couplings. The relationship[16,17] $|^{1}J(^{119}Sn-^{13}C)| > |^{3}J(^{119}Sn-^{13}C)| > |^{2}J(^{119}Sn-^{13}C)| > |^{4}J(^{119}Sn-^{13}C)|$ was used to assign the ^{13}C resonances of the phenyl moiety. All the ^{1}H and ^{13}C chemical shifts have the values normally expected and can be found in the Experimental Section.

The chemical shift values of the ^{119}Sn resonance signals of similar tin(IV) complexes are known to reflect the coordination of the Sn atoms in the solution state.[17] Thus in **1**, the observed −747.9 ppm, falls within the range observed in chloroform solutions of other octacoordinated tin(IV) compounds such tetrakis(tropolonato)tin(IV) [$\delta(^{119}Sn)$ = −793.10 ppm][8] and tetrakis(1-pyrrolecarbodithioato)-tin(IV) [$\delta(^{119}Sn)$ = −729.2 ppm].[18]

The magnitude of the vicinal Sn−H coupling, $|^{3}J(^{119}Sn-^{1}H)|$ = 77 Hz exhibited by the resonance due to the *ortho* protons of the Sn−Ph rings in **2** reflects the (equilibrium) rotational angle of the aromatic ring in liquid state.[17] The angle C−Sn−C calculated from the available relationships with the $|^{1}J(^{119}Sn-^{13}C)|$ coupling[19] indicates an increase in C−Sn−C angle from 107.7° in the solid to 176.4° in solution, which is consistent with octahedral Sn^{IV} units with two phenyl groups in *trans* positions.[19]

Lockhart and Manders noticed that the $|^{2}J(^{119}Sn-^{1}H)|$ coupling constant is a function of coordination number of dimethyltin(IV) compounds, ranging between 64 and 79 Hz for pentacoordinated compounds.[20] For **3** the $|^{2}J(^{119}Sn-^{1}H)|$ coupling constant of 76.8 Hz indicates pentacoordination in chloroform solution. A single resonance at −159.2 ppm observed in the ^{119}Sn NMR spectra is compatible with the pentacoordinated geometry proposed for the structure in solution. Comparison with ^{119}Sn chemical shifts (−126, −129, −121, and −133 ppm, respectively) of pentacoordinated dimethyltin(IV) alkoxides $Me_2Sn(OR)_2$ (R = Et, ^{n}Pr, ^{i}Bu and ^{n}Bu) serves to confirm this interpretation.[21] These data, combined with the $|^{1}J(^{119}Sn-^{13}C)|$ coupling constants, tend to confirm that this compound has a pentacoordinated geometry in solution.[19]

Conclusion

A noteworthy trend has been observed in the bonding pattern of the O-donor cupferronato anion in the $[R_nSnL_{4-n}]_m$ series of tin(IV) cupferronate complexes. The nature of the organic moieties attached to tin produces significant changes in coordinational behavior of the ligand: bridging coordination,[4][22] bridging-chelating and chelating coordination patterns are observed. The bonding mode of the ligand to tin is reflected in the length of the Sn−O bonds and in the O(1)−Sn(1)−O(2) bite angles (Table 2 and 4). The Sn(1)−O(1) bond lengths in complexes **1**−**2** are significantly longer than Sn(1)−O(2), while the opposite was observed for **3** and for the tetrameric trimethyltin(IV) cupferronate $[Me_3SnL]_4$, which contains an unprecedented inorganic metallamacrocycle $Sn_4O_8N_8$.[22] For the chelating ligands the O(1)−Sn(1)−O(2) bite angles lie in the narrow range 69−70° while for the triconnective bridging and bridging ligands[22] this angle tends to close up by approximately 4−5°. In spite of the varied coordination behavior of the nitrosohydroxylaminato [N(O)NO] group in the cupferronato tin complexes, a comparison of the corresponding structural data does not reveal major differences. The N(O)NO moiety is essentially planar. The N(1)−N(2) bond length is shorter than an N−N single bond (1.45 Å) and is closer to an N=N double bond (1.21 Å).[23] The N(1)−O(1) and N(2)−O(2) bond length is between single (1.40 Å) and double bonds (1.21 Å).[23] These data reveal the same electron delocalization along the nitrosohydroxylaminato group in all tin compounds investigated here.

Experimental Section

General Methods: The preparation and purification of the complexes were carried out in the open air, or in dry atmosphere, with anhydrous organic solvents. Organic solvents for reactions and recrystallization were distilled from appropriate drying agents prior to use. The SnI_4 reagent was prepared by a published method.[24] All other starting materials were obtained from commercial sources as pure compounds.

Microanalyses (C, H and N) of the complexes were performed by the Microanalytical Service of the Department of Chemistry, University of Santiago de Compostela (Spain). FT-IR spectra were recorded with a Perkin−Elmer 2000 spectrometer. FT-Raman spectra were recorded with a Bruker FT Raman spectrometer (IFS model 66). Solution NMR data were recorded on a Varian Unity Inova 400 spectrometer in $CDCl_3$, using TMS as internal standard for ^{1}H and ^{13}C, and $SnMe_4$ for ^{119}Sn as external reference.

Preparation of Tetrakis(*N*-nitroso-*N*-phenyl-hydroxylaminato)tin-(IV), Sn[PhN(O)NO]$_4$, (1): The ammonium salt NH_4[PhN(O)NO] (0.50 g, 3.25 mmol) was added to a solution of SnI_4 (0.51 g, 0.81 mmol) in 15 mL chloroform. The NH_4I promptly precipitated and the mother liquor became colorless. After stirring for 20 minutes at room temperature, the precipitate was filtered off and the liquid was evaporated. Recrystallization from *n*-heptane gave the product as colorless crystals. Yield 0.22 g, 40%, melting point 168−172°C (decomp.). − FT-IR (KBr): $\tilde{\nu}$ = 1486 cm^{-1}(Ph) (m), 1465 (Ph) (m), 1356 (N−N) (s), 1300 (vs), 1205 (N=O) (ms), 1168 (N=O) (ms), 949 (ONNO) (s), 758 (Ph) (s), 696 (Ph) (s), 684

(OSnO) (m, sh), 410 (s), 401 (Sn−O) (s), 237 (C−H) (vs). − FT-Raman: $\tilde{\nu}$ = 1590 cm^{-1}(C−H) (m), 1487 (C−H) (w), 1361 (N−N) (w), 1314 (vs), 1167 (N=O) (w), 1004 (Ph) (m), 940 (ONNO) (m), 112 (m). − ^{1}H NMR ($CDCl_3$, 399.92 MHz, 30°C): δ = 7.97 (m, 2 H, Ph-H2, -H6), 7.43 (m, 3 H, Ph-H3, -H4, -H5). − ^{13}C NMR ($CDCl_3$, 100.6 MHz, 30°C): δ = 140.0 (s, Ph-C1), 130.3 (s, Ph-C4) ppm; 129.1 (s, Ph-C3, -C5), 119.6 (s, Ph-C2, -C6). − ^{119}Sn NMR ($CDCl_3$, 149.106 MHz, 30°C): δ = −747.9 (s). − $C_{24}H_{20}N_8O_8Sn$ (667.17): calcd. C 43.2, H 3.0, N 16.8; found C 43.1, H 3.3, N 16.8.

Preparation of Diphenylbis(*N*-nitroso-*N*-phenyl-hydroxylaminato)-tin(IV), $Ph_2Sn[PhN(O)NO]_2$ (2): The salt NH_4[PhN(O)NO] (0.20 g, 1.29 mmol) was added to a solution of Ph_2SnCl_2 (0.22 g, 0.64 mmol) in 15 mL acetone. The NH_4Cl promptly precipitated. After stirring for one hour at room temperature, the precipitate was filtered off and the mother liquor was concentrated to low volume, and 5−10 mL *n*-heptane was added. This solution was placed in the refrigerator overnight to yield **2** as a pale yellow solid. Recrystallization from *n*-heptane gave the product as colorless crystals. Yield 0.21 g, 60%, melting point 87−88°C. − FT-IR (KBr): $\tilde{\nu}$ = 1483 cm^{-1} (Ph) (m), 1463 (Ph) (m), 1429 (m), 1344 (N−N) (ms), 1294 (vs), 1214 (N=O) (w), 1181 (N=O) (s), 1156 (s), 926 (ONNO) (s), 762 (Ph) (s), 733 (s), 696 (Ph) (s), 686 (OSnO) (m, sh), 400 (Sn−O) (s), 267 (vs), 122(w). − FT-Raman: $\tilde{\nu}$ = 1591 cm^{-1} (C−H) (s), 1486 (C−H) (w), 1465 (C−H) (vw), 1345 (N−N) (m), 1307 (vs), 1158 (C−H) (mw), 1070 (C−H) (vw), 1025 (C−H) (w), 1005 (Ph) (s), 998 (s), 930 (ONNO) (m), 168 (m), 110 (ms). − ^{1}H NMR ($CDCl_3$, 399.92 MHz, 30°C): δ = 7.97 (m, 2 H, Ph-H2, -H6), 7.72 [m, ^3J (^{119}Sn−^{1}H) = 77 Hz, 2 H, Ph_A-H2, -H6], 7.46−7.36 (m, 6 H). − ^{13}C NMR ($CDCl_3$, 100.6 MHz, 30°C): δ = 145.6 [m, ^1J(^{119}Sn, ^{13}C) = 908.3 Hz, Ph_A-C1], 140.0 (s, 1, Ph-C1), 135.6 [m, ^2J (^{119}Sn−^{13}C) = 58.8 Hz, Ph_A-C2, -C6], 130.6 (s, Ph-C4), 129.5 [m, Ph_A-C4, ^4J(^{119}Sn−^{13}C) = 17.2 Hz], 129.2 (s, Ph-C3, -C5), 128.6 [m, ^3J(^{119}Sn−^{13}C) = 85.0 Hz, Ph_A-C3, -C5], 119.7 (s, Ph-C2, C6). − ^{119}Sn NMR ($CDCl_3$, 149.106 MHz, 30°C): δ = −327.2 (b, s). − $C_{24}H_{20}N_4O_4Sn$ (547.13): calcd. C 52.7, H 3.7, N 10.2; found C 52.5, H 3.4, N 10.2.

Preparation of Dimethylbis(*N*-nitroso-*N*-phenyl-hydroxylaminato)-tin(IV), $[Me_2Sn(PhN(O)NO)_2]_2$ (3): The salt NH_4[PhN(O)NO] (0.40 g, 2.58 mmol) dissolved in 15 mL MeOH was added to a solution of Me_2SnCl_2 (0.28 g, 1.27 mmol) in 15 mL MeOH. The NH_4Cl promptly precipitated. After stirring for one hour at room temperature, the solution was concentrated to low volume and cooled in a refrigerator for 24 hours. The microcrystalline product deposited was filtered, dried in an anhydrous atmosphere and recrystallized from *n*-heptane as colorless crystals. Yield 0.31 g, 57%, melting point 112−114°C. − FT-IR (KBr): $\tilde{\nu}$ = 1488 cm^{-1} (Ph) (m), 1465 (Ph) (ms), 1351 (N−N) (ms), 1336 (N−N) (ms), 1294 (vs), 1216 (N=O) (s), 1180 (N=O) (ms), 1156 (s), 923 (ONNO) (s), 756 (Ph) (s), 693 (Ph) (s), 683 (OSnO) (ms sh), 545 (Sn−C) (m), 401(Sn−O) (vs), 217 (C−H) (s), 189 (C−H) (s). − FT-Raman: $\tilde{\nu}$ = 1592 cm^{-1} (C−H) (s), 1489 (C−H) (w), 1353 (N−N) (mw), 1298 (vs), 1218 (N=O) (w), 1199 (N=O) (w), 1005 (Ph) (m), 929 (ONNO) (mw), 546 (Sn−C) (w), 517 (SnC_2) (m), 112 (m). − ^{1}H NMR ($CDCl_3$, 399.92 MHz, 30°C): δ = 7.93 (m, 2 H, Ph-H2, -H6), 7.45 (m, 3 H, Ph-H3, -H4, -H5), 0.77 [s, ^2J(^{119}Sn−^{1}H) = 76.8 Hz, ^2J(^{117}Sn−^{1}H) = 73.4 Hz, ^1J(^{13}C−^{1}H) = 132.6 Hz, 3 H, Sn−CH_3]. − ^{13}C NMR ($CDCl_3$, 100.6 MHz, 30°C): δ = 140.0 (s, Ph-C1), 130.3 (s, Ph-C4), 129.1 (s, Ph-C3, -C5), 119.6 (s, Ph-C2, -C6), 7.8 [m, ^1J(^{119}Sn, ^{13}C) = 647.7 Hz, Sn−CH_3]. − ^{119}Sn NMR ($CDCl_3$, 149.106 MHz, 30°C): δ = −159.2 (b, s). − $C_{28}H_{32}N_8O_8Sn_2$ (846.04): calcd. C 39.8, H 3.8, N 13.2; found C 39.8, H 4.0, N 13.2.

X-ray Structure Determination for 1−3

Crystal data and refinement parameters are summarized in Table 5. Intensity data were collected on an Enraf−Nonius CAD-4 diffractometer with graphite monochromated Mo-K_α radiation (λ = 0.71073 Å) using the ω-2θ scan technique. Three standard reflections were monitored every hour; these remained constant within

Ionic Silver Amino Complexes Displaying Liquid Crystalline Behavior Close to Room Temperature

Ana C. Albéniz,[a] Joaquín Barberá,[b] Pablo Espinet*,[a] M. Carmen Lequerica,[a] Anne M. Levelut,[c] F. Javier López-Marcos,[b] and José L. Serrano*[a]

Keywords: Metallomesogens / Liquid crystals / Silver / N ligands / Amines

The liquid crystalline properties of a series of ionic silver complexes $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]X$ (X = NO_3, n = 6, 8, 10, 12, 14; X = BF_4, n = 8, 10, 12, 14), derived from silver nitrate or tetrafluoroborate and aliphatic amines, have been investigated by optical microscopy, DSC, and X-ray diffraction. The materials exhibit a birefringent fluid phase identified as a smectic A mesophase by optical microscopy and X-ray diffraction. Some of the complexes are liquid crystalline at temperatures close to room temperature. The X-ray results are consistent with the existence in the mesophase of a bilayer organization. The silver cations adopt a U-shape, which allows for the adoption of this bilayer arrangement, with alternating ionic and apolar regions and a short-range square-planar array inside the cationic sublayers. The thermodynamic parameters suggest that the melting transition clearly involves only disorder (melting) of the chains, whereas the clearing transition implies breaking the anion-cation arrangement.

Introduction

Metallomesogens (metal complexes that are formed with organic ligands and exhibit liquid crystalline behavior) have considerably enhanced the field of liquid crystals.[1] The vast majority of metallomesogens reported so far have a rod- or disk-shaped rigid core (usually with aryl rings) bearing long hydrocarbon tails. Ionic amphiphilic metal complexes have been reported less frequently.[2]

In this paper we report the synthesis and liquid crystalline properties of two series of ionic silver complexes, both of which are based on apparently simple coordination compounds $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]X$ (X = NO_3, n = 6, 8, 10, 12, 14; X = BF_4, n = 8, 10, 12, 14). These compounds appear to be deceptively simple as they are similar in stoichiometry and metal coordination to other compounds based on 4-substituted pyridines {$[AgL_2]X$; L = 4-substituted pyridine; X = alkyl sulfate, BF_4, CF_3SO_3, NO_3, PF_6}.[3] In fact they turn out to be structurally very different: the cation, which lacks rigid rings, has a flexible aliphatic structure that is able to adopt any shape, whereas in the pyridine derivatives previously reported, the cation has, by necessity, an extended central rigid rod-like geometry. In this respect the complexes reported here are more similar to the U-shaped structures found for *trans*-$[PdCl_2\{PEt_2(O\text{-}chl)\}_2]$ (chl = cholesteryl)[4] and for the silver complexes [AgL]X with the macrocyclic ligand 1,10-bis[4-(dodecyloxy)-benzoyl]-1,10-diaza-4,7,13,16-tetrathiacyclooctadecane.[5]

Thus the complexes reported in this paper combine a number of unusual features: (i) their mesogenic behavior appears at rather low temperatures; (ii) the metal is included in the promesogenic cation; (iii) X-ray characterization of their mesophases supports a bilayer structure reminiscent of that observed in classical lyotropic bilayer mesophases, with the cation adopting a U-shaped geometry comparable to that observed in phospholipid-based lyotropic derivatives.

Results and Discussion

Synthesis

The complexes were prepared by the stoichiometric reaction of the appropriate silver salt, AgX, and the corresponding alkylamine in acetonitrile (Equation 1), and were isolated as crystalline solids. They are light-sensitive and their preparation and handling must be carried out in the dark. However, they can survive moderately long exposure to light, such as the periods required for the microscopy studies.

$$AgX + 2\ NH_2n\text{-}C_nH_{2n+1} \rightarrow [Ag(NH_2n\text{-}C_nH_{2n+1})_2] \quad (1)$$

Microscopy Studies

Optical microscopy with polarized light revealed that the solids melt, upon heating, to a fluid phase exhibiting a dark homeotropic texture with some elongated bright birefringent regions. At a higher temperature the texture disappears, with the fluid phase becoming isotropic. Upon cooling the resultant isotropic liquid, some *bâtonnets* are formed at the transition point to the mesophase, but they immediately disappear to leave a homeotropic texture consisting of dark areas scattered, in some cases, with small

focal-conic domains and Maltese crosses. This behavior is typical of a fluid lamellar (S_A) mesophase.[6] All the compounds studied underwent some decomposition when exposed to air and visible light in the isotropic state. Therefore extended heating and repeated heating-cooling cycles are to be avoided.

DSC Studies

The DSC data are collected in Table 1. The thermograms show two endothermic peaks on heating (exothermic on cooling) corresponding to the solid-to-mesophase and the mesophase-to-liquid transitions. Occasionally, small endothermic peaks were observed in the first heating scan at temperatures below the melting point (crystal-crystal transitions or pre-melting phenomena) but these were not usually observed in subsequent cooling or reheating scans. The existence of the liquid crystal phase at very low temperatures (compared to common metallomesogens) for the short chain derivatives is noteworthy. The mesophases of some complexes can be supercooled to below room temperature.

In the two series of complexes (nitrates and tetrafluoroborates) the melting temperatures increase steadily with the number of carbon atoms in the hydrocarbon chains (Table 1). The clearing temperatures increase with the number of carbon atoms for short chains, reach a maximum, and decrease for the longer chains. In each series the melting molar enthalpy $(\Delta H_M)_{melt}$ and entropy $(\Delta S_M)_{melt}$ values increase steadily with the number of carbon atoms in the aliphatic amine (Table 1), and are very different from one series (NO_3^-) to the other (BF_4^-). In contrast, the clearing molar enthalpy and entropy values, $(\Delta H_M)_{clear}$ and $(\Delta S_M)_{clear}$, decrease steadily upon increasing the number of carbon atoms in the aliphatic chain. A closer examination can be made by means of a crude but informative linear plot of these values against number of carbon atoms in the chain.

Table 1. Optical, thermal and thermodynamic data of $[Ag(NH_2\text{-}C_nH_{2n+1})_2]X$ complexes (C: crystal; S_A: smectic A mesophase; I: isotropic liquid).

The fitting of the lines for $(\Delta H_M)_{melt}$ is remarkably good for both series (Figure 1). The slope affords the contribution to the melting enthalpy per carbon atom in the cation and the values are $(\Delta H_C)_{melt} = 1.395$ kJ·mol^{-1} for the NO_3^- series and 2.568 kJ·mol^{-1} for the BF_4^- series. The fit for $(\Delta S_M)_{melt}$ is also quite good and affords values of $(\Delta S_C)_{melt} = 3.583$ J·K^{-1}·mol^{-1} for the NO_3^- series and 6.753 J·K^{-1}·mol^{-1} for the BF_4^- series. The $(\Delta H_M)_{melt}$ and $(\Delta S_M)_{melt}$ values extrapolated for $n = 0$ (even though they lack a rigorous physical meaning are in all cases very small compared to the value $2n(\Delta H_C)_{melt}$ or $2n(\Delta S_C)_{melt}$, even for the shortest chains. This indicates that the melting enthalpy and melting entropy values almost exclusively arise due to the chains and, hence, the melting transition mainly involves melting of the chains, whereas the anion-cation interactions seem to be hardly affected. The nature of the anion, however, clearly affects the ΔH_C and ΔS_C values, which are almost twice as high for the BF_4^- series than for the NO_3^- series. In a purely ionic anion-cation interaction no difference should be expected, thus this effect is a reflection of some covalent donor interaction from the anion to the silver center. Such an interaction would be expected to be higher from the O atoms of the NO_3^- than from the F atoms of the BF_4^-.[7] Consequently, the silver atom becomes less of an acceptor towards the amine when the anion is NO_3^-, the chain is less polarized, and the chain interactions diminish, as is observed.

The fitting of the lines for $(\Delta H_M)_{clear}$ and $(\Delta S_M)_{clear}$ is also acceptable for both series (Figure 2). The slopes in this case are small and negative. The intercepts at $n = 0$ are comparatively high and are similar for both anions: about 5.9 kJ·mol^{-1} for $(\Delta H_M)_{clear}$ and 15.0 J·K^{-1}mol^{-1} for $(\Delta S_M)_{clear}$. This suggests that the clearing transition is mainly due to the melting of the anion-cation arrangement. The actual values are tuned by the size of the cation, with the transition becoming easier for the bulkier the cation.

X-ray Studies

X-ray diffraction experiments were carried out on magnetically oriented mesophases of three nitrate complexes (hexylamine, octylamine, and decylamine derivatives) and one tetrafluoroborate complex (octylamine derivative).

Two regions can be distinguished in the X-ray patterns {Figure 3 shows the pattern of $[Ag(octylamine)_2]BF_4$ at 50 °C}. In the low angle region a set of sharp arcs (labelled A), which extend over ±20° around the magnetic field direction, correspond to lattice spacing ratios 1, 1/2, 1/3, etc., and are characteristic of a lamellar system. The layer periodicity *d* is 18.8 Å, 22.5 Å, and 27.0 Å for the hexylamine, octylamine, and decylamine nitrate complexes, respectively, and 21.9 Å for the octylamine tetrafluoroborate complex (Table 2). In the wide-angle region the long-exposure time patterns exhibit two diffuse rings, both showing a large azimuthal spreading. The intensity maxima correspond to mean distances $l/(2\sin\theta) = 2\pi \cdot q^{-1}$ that are equivalent to 6.3−6.4 Å (labelled B) and 4.5 Å (labelled C).

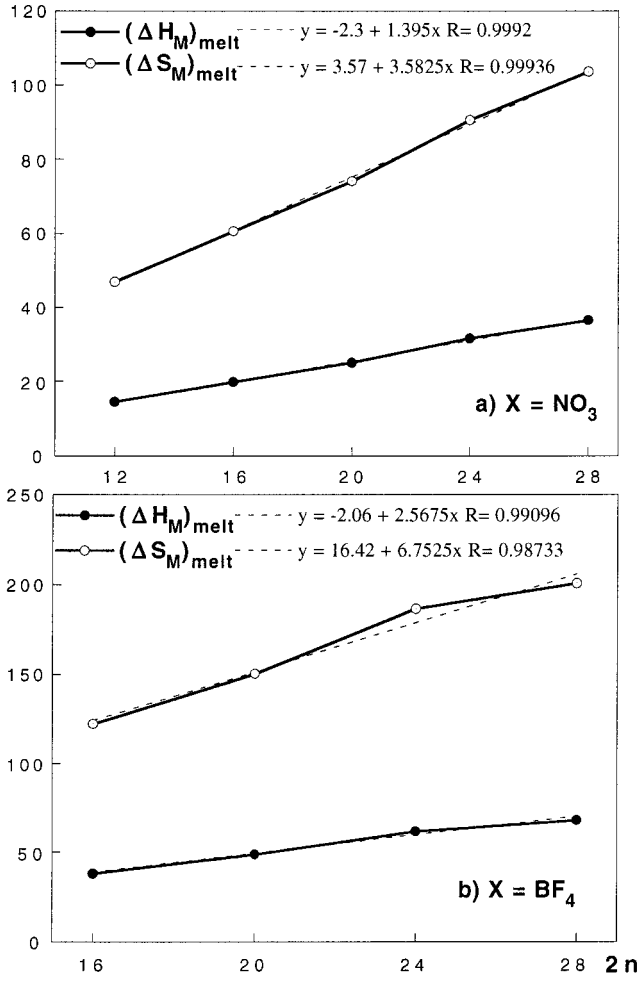

Figure 1. Plot of melting molar enthalpy $(\Delta H_M)_{melt}$ and entropy $(\Delta S_M)_{melt}$ values versus the total number of carbon atoms in the complex, $2n$, for: (a) $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]NO_3$; (b) $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]BF_4$.

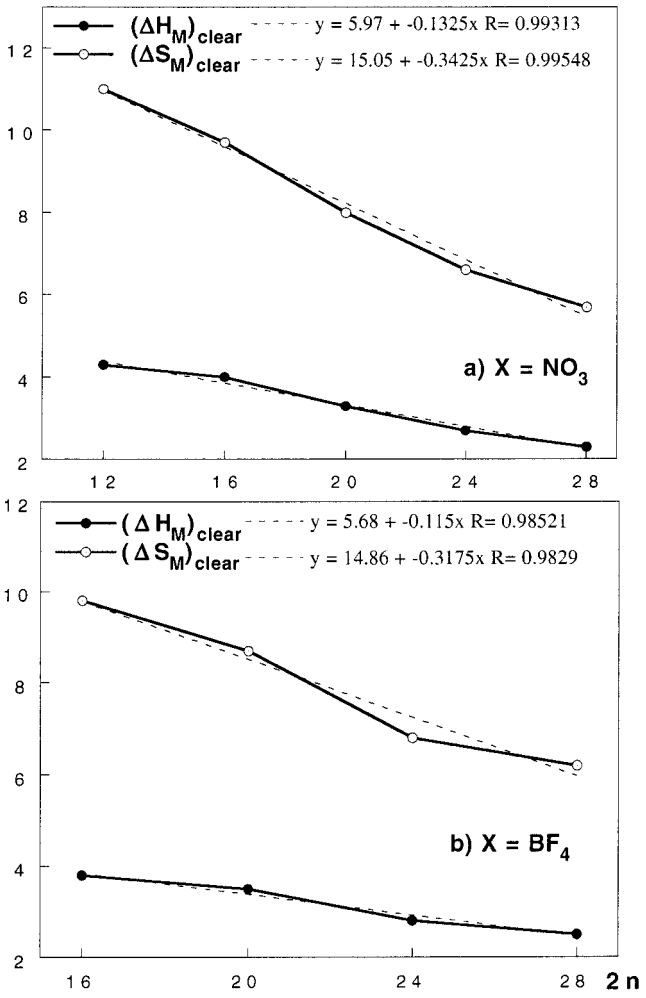

Figure 2. Plot of clearing molar enthalpy $(\Delta H_M)_{clear}$ and entropy $(\Delta S_M)_{clear}$ values versus the total number of carbon atoms in the complex, $2n$, for: (a) $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]NO_3$; (b) $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]BF_4$.

The only set of sharp reflections observed corresponds to the lamellar structure and therefore there is no periodic intra-lamellar order. Moreover, this set of arcs is aligned along the magnetic field and confirms the existence of a smectic A mesophase. The number of observed reflections on the layer planes is higher than usual for thermotropic smectic phases, although the intensities of these reflections decrease monotonically as the scattering vector is increased. Therefore the heavy components of the complex, namely the silver atom and the anion, are located in a thin slab of the smectic layer. Moreover, it is possible to give an estimation of the positional fluctuations of the heavy components of the layer from the Debye−Waller factor, $\exp(-2q\langle u^2\rangle)$. If this factor is equal to 10^{-6} for the fourth order ($q = 4 \times 2\pi/d$), the average extension of the heavy sublayer will be equal to a tenth of the total layer thickness d.

The diffuse ring at 4.5 Å is characteristic of a molten paraffinic medium. The mosaic spread of the smectic planes is large and consequently it is not possible to determine the degree of orientational order of the chains. However, since

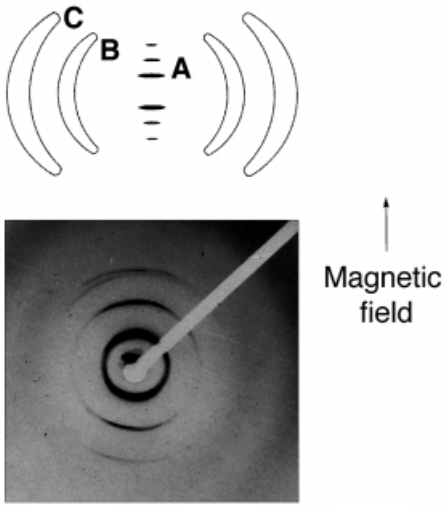

Figure 3. X-ray diffraction pattern of the magnetically aligned mesophase of $[Ag(NH_2n\text{-}C_8H_{17})_2]BF_4$ (at 50°C) along with a schematic interpretation of the pattern.

Table 2. Distances [Å] in $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]X$ complexes measured in the mesophase by X-ray diffraction

X	n	d_A	d_B	d_C
NO_3	6	18.8	6.3	4.5
NO_3	8	22.5	–	–
NO_3	10	27.0	–	–
BF_4	8	21.9	6.4	4.5

the ring is nearly isotropic, the chains are likely to be poorly oriented. The second diffuse ring at 6.4 Å reveals that the intralayer ordering is more complex than for usual rod-like smectogenic molecules. The fact that 6.4 Å $\sqrt{4.5} \approx 2$ Å is consistent with a short range square array. However, it is important to note that, given the intensity of the diffuse ring at 4.5 Å, it cannot be simply considered as a second order maximum arising from a local square primitive cell with a lattice constant of 6.4 Å. It rather suggests that the equatorial scattering pattern results from the superposition of two different lattices, the area of one (approximately 6.4 Å × 6.4 Å = 41 Å^2) being twice as much as the area of the other (approximately 4.5 Å × 4.5 Å = 20 Å^2). It is important to note that an area of 41 Å^2 corresponds to twice the cross-sectional area of a hydrocarbon chain in an quasiextended conformation.[8]

The results described above, as well as density criteria, are consistent with the presence of two $[AgL_2]X$ units in the tetragonal cell that are arranged in such a way that the chain-to-chain distance is about 4.5 Å and the mean distance of 6.4 Å describes the ordering of the polar head groups. All these requirements can only be fulfilled if the silverdiamine cations adopt a U-shape and arrange themselves in a bilayer structure (Figure 4). The silver atoms form a square-planar local array of 6.4 Å size, and the aliphatic chains extend on each side of a central slab containing the polar groups in such a way that the two hydrocarbon chains belonging to the same cation point in the same direction. This arrangement is adequate to fill space efficiently and accommodate the anions between these layers, where a good anion-cation electrostatic interaction (with some covalent component for the nitrate series, as discussed above) can be obtained. Figure 5 and Figure 6 show a space-filling model of this kind of arrangement. Clearly the intralayer order in the mesophase must be lower and also just local. This structure is comparable to the L_δ phase observed in phospholipid-based lyotropic systems.[6] A bilayer organization of U-shaped cations has also been found in some thermotropic ionic metallomesogens based on macrocyclic N,S-containing ligands.[5] However, in that case the in-plane order does not correspond to a local square lattice but to a periodic undulation of the ionic sublayer.

It is important to note that the scattering factors of a silver atom (47) and the anions (31 for NO_3^-, or 40 for BF_4^-) are quite similar. Consequently, these two components must be close to each other, both in the plane perpendicular to the director and in the direction parallel to the director, in order to make a contribution to the intensity scattered in the Bragg reflections and in the 6.4 Å and 4.5 Å rings. Assuming that the silver atoms in the proposed arrangement lie at the corners of the two-dimensional square lattice and the anions lie at the center of the square, the 4.5 Å ring would arise from chain-chain and cation-anion interferences, and the 6.4 Å ring from cation-cation and anion-anion interferences.

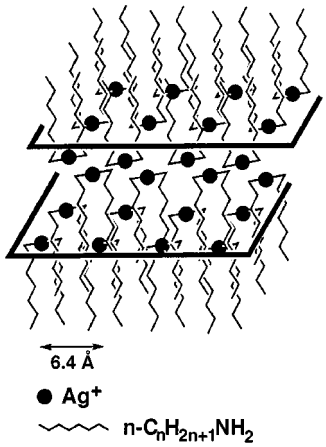

Figure 4. Model of a bilayer in the liquid crystal phase of $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]X$ complexes (anions omitted).

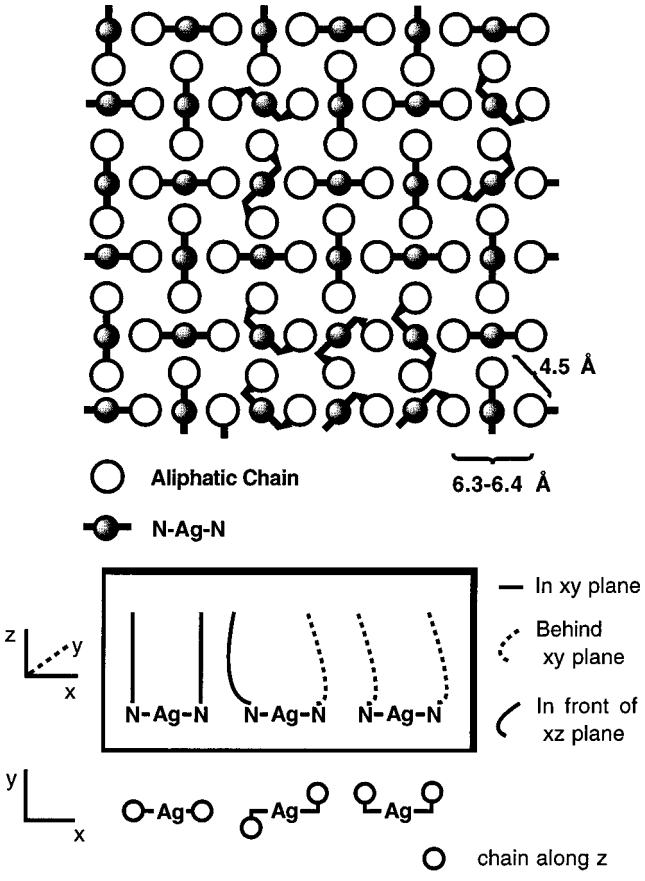

Figure 5. Sketch of the arrangement of the cations in the mesophase viewed along the director (perpendicular to the layer plane). The flexibility of the aliphatic chains allows different arrangements with respect to the N–Ag–N bond, which are a source of disorder and are illustrated in the lower part of the figure.

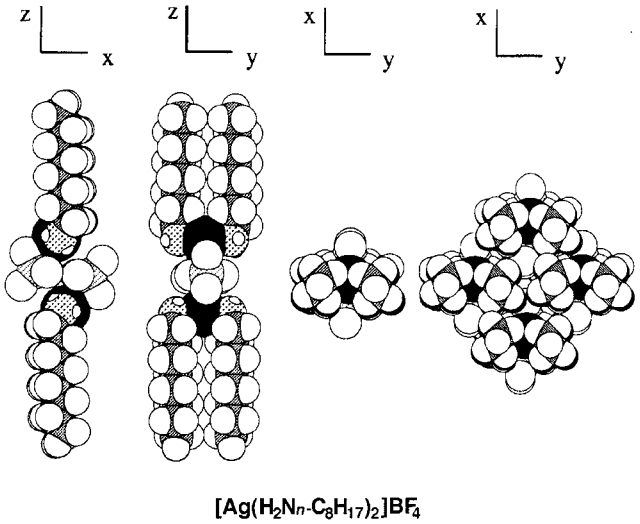

Figure 6. Space-filling model proposed for the complexes (X = BF_4). Left: possible arrangement of two anions and two cations (as the building block of the bilayers) viewed along the three axis. Right: packing of eight anions and eight cations (four up and four down) viewed along the z axis. Note that the overall packing results in a cylindrical cluster that should be able to rotate quite freely, thus introducing additional disorder. (Ag = black solid; N = large dots; B = small dots; C = shadow, H and F = white).

An alternative structural model could be proposed in which the local tetragonal unit cell contains one $[AgL_2]X$ unit per local cell. In this model the silverdiamine cation would sit at the four corners of the cell in an extended (rod-like) conformation parallel to the four-fold axis and the anions would be at the center of the cell. In this model the 4.5 Å ring would arise from anion-cation interferences and the 6.4 Å ring from anion-anion and cation-cation interferences. However, a tetragonal cell of width 6.4 Å and length *d* (Table 2) containing only one $[AgL_2]X$ unit would lead to very inefficient packing. Indeed, the density associated with this model would be too low (approximately 0.8 g cm^{-3}), and the average area per chain would be too large (S = 6.4 Å × 6.4 Å = 41 $Å^2$). Moreover, the intensity ratio of the two diffuse rings should be the reverse of that actually observed. Therefore this array, based on extended (rod-like) silverdiamine cations, is not consistent with the X-ray data and must be discounted. A similar structure with interdigitated layers would be consistent with the observed local order, but should lead to a layer thickness twice as small as that experimentally measured.

The bilayer model contains two molecules per unit cell, leading to a reasonable estimated density (approximately 1.6 g cm^{-3}), and fits all the X-ray data. The surface available for each paraffinic chain is about 20.0−20.5 $Å^2$ (S = 6.4 Å × 6.4 Å/2). Unfortunately we have not been able to grow single crystals of the complexes, but further support for the bilayer model comes from powder X-ray experiments carried out at room temperature on the decylamine nitrate complex. The powder pattern corresponds to a three-dimensional triclinic phase with parameters a = 5.03 Å, b = 8.84 Å, c = 27.2 Å, α = 93.0°, β = 93.3°, γ = 92.3°, with two molecules per unit cell. Parameter c is almost identical to the interlayer spacing (27.0 Å) found for the mesophase of the same compound (see Table 2). The fact that in the crystalline structure there are two molecules in a pseudo-rectangular section of approximately 5.0 Å × 8.8 Å = 44 $Å^2$ proves that is it possible for two molecules to be located in the two-dimensional square lattice of 41 $Å^2$ proposed for the mesophase. The calculated density of the crystal packing is 1.33 g cm^{-3}, whereas the density estimated for the mesophase is about 1.6 g cm^{-3}. This high value can be explained because it has been calculated on the basis of the diffraction data from the locally ordered areas in the mesophase. In fact, the square array has a short correlation range, and the presence of some rod-shaped molecules in with the U-shaped molecules cannot be ruled out. In addition, the orientational order of the chains is weak and the angle between the two chains of a molecule is widely fluctuating.

Finally, it is interesting to note that there are indications that the silverdiamine cations with long aliphatic primary amines may also adopt a U-shape in aqueous solution. In fact it has been reported that the values of ΔH^0 and ΔS^0 for the coordination of *n*-butyl- and *n*-pentylamine to Ag^+ are anomalous when compared with the values for the corresponding protonation reactions. It has been suggested that "a possible explanation for these anomalies is that there may be some hydrophobic interaction between the two ends of the hydrophobic chains". Clearly, although not explicitly stated, this implies the adoption of a U-shape.[9]

Conclusions

In summary, these simple silver coordination compounds reveal that metal cations can induce thermotropic behavior in non-mesogenic ligands, even if these ligands lack rigid cores and have only short aliphatic chains. Moreover, very low transition temperatures are obtained. The diffraction data support a bilayer model based on the packing of U-shaped silverdiamine cations. The thermodynamic parameters suggest that the melting transition involves only disorder (melting) of the chains, whereas the clearing transition involves breaking the anion-cation arrangement

Experimental Section

General: All compounds were satisfactorily characterized by IR spectroscopy and elemental microanalysis. − IR spectra were recorded on a Perkin−Elmer 1600 (series FTIR) spectrometer. − Microanalyses were performed with a Perkin−Elmer 240 B microanalyzer. − The optical textures of the mesophases were studied with a Meiji polarizing microscope equipped with a Mettler FP8 hot stage and an FP80 central processor. − The transition temperatures and enthalpies were measured by differential scanning calorimetry with a Perkin−Elmer DSC-7 instrument operated at a scanning rate of 10°C/min on heating. The apparatus was calibrated with indium (156.6°C; 28.4 $J \cdot g^{-1}$) as a standard. − X-ray diffraction experiments were carried out on magnetically aligned samples held in Lindemann glass capillary tubes of 1 mm diameter. The capillary tube, containing the sample, was set in an oven placed

between the poles of a magnet (magnetic field 0.3 T). The sample was irradiated with a point-focused X-ray beam (Cu-K_α radiation, $\lambda = 1.541$ Å) perpendicular to the magnetic field. The camera was evacuated in order to suppress air scattering. The diffraction patterns were collected on a flat film perpendicular to the X-ray beam. Powder experiments were carried out in a Guinier diffractometer (Huber 644) operating with a Cu-$K(\alpha_1)$ beam ($\lambda = 1.5405$ Å) issued from a germanium monochromator. The samples were held in rotating Lindemann glass capillaries (0.5 mm diameter) and the diffraction patterns were registered with a scintillation counter.

Preparation of $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]NO_3$ ($n = 6$ and 8): A solution of $AgNO_3$ (0.255 g, 1.5 mmol) and amine (3.0 mmol) in acetonitrile (ca. 10 mL) was stirred at room temperature for 2 h. The resulting solution was concentrated under vacuum until crystallization began. Diethyl ether was added and the suspension was cooled in the freezer overnight. The white needles obtained were collected by filtration, washed with ether and dried under vacuum. Yield: 65% ($n = 6$) and 75% ($n = 8$). − Analytical data: ***n* = 6**: calcd. C 38.72, H 8.12, N 11.29); found C 38.31, H 8.25, N 11.30. −***n* = 8**: calcd. C 44.86, H 8.94, N 9.81; found C 44.74, H 9.31, N 9.79.

Preparation of $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]NO_3$ ($n = 10$, 12 and 14): A suspension of $AgNO_3$ (0.221 g, 1.3 mmol) and amine (2.6 mmol) in acetonitrile (ca. 15 mL) was stirred at room temperature for 6 h. The resulting white suspension was concentrated under vacuum. Diethyl ether was added and the suspension was cooled in the freezer overnight. The crystallized product was collected by filtration, washed with ether and dried under vacuum. Yield: 70−90%. If necessary, the products can be further purified by recrystallization from acetonitrile/diethyl ether. − Analytical data ***n* = 10:** calcd. C 49.58, H 9.57, N 8.67; found C 49.79, H 10.04, N 8.63. − ***n* = 12:** calcd. C 53.32, H 10.07, N 7.77; found C 53.23, H 10.36, N 7.80. − ***n* = 14**: calcd. C 56.36, H 10.47, N 7.04; found C 56.51, H 10.50, N 6.93.

Preparation of $[Ag(NH_2n\text{-}C_nH_{2n+1})_2]BF_4$: A suspension of $AgBF_4$ (0.234 g, 1.2 mmol) and amine (2.4 mmol) in acetonitrile (ca. 10 mL) was stirred at room temperature under nitrogen for 6 h. The resulting solution ($n = 8$) or white suspension ($n = 10$, 12, 14) was concentrated under vacuum and cooled in the freezer overnight. The crystallized white product was collected by filtration, washed with ether and dried under vacuum. Yield: 60−75%. If necessary, the products can be further purified by recrystallization from acetonitrile/diethyl ether. − Analytical data ***n* = 8:** calcd. C 42.41, H 8.45, N 6.18; found C 42.61, H 8.83, N 6.30. − ***n* = 10:** calcd. C 47.17, H 9.10, N 5.50; found C 47.27, H 9.30, N 5.54. − ***n* = 12**: calcd. C 50.99, H 9.63, N 4.95; found C 51.40, H 10.01, N 4.91. − ***n* = 14**: calcd. C 54.11, H 10.06, N 4.51; found C 54.35, H 10.20, N 4.37.

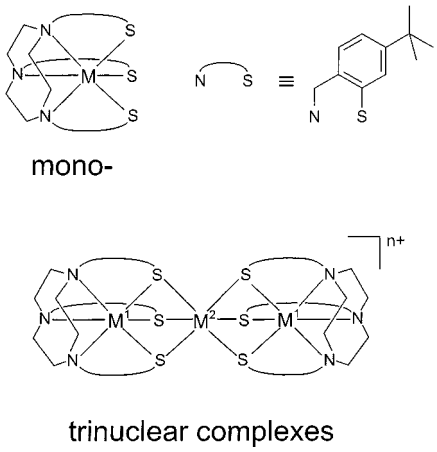
Molecular and Electronic Structure of Two Linear Thiophenolate-Bridged Heterotrinuclear Complexes $[LFeRuFeL]^{2+/3+}$ (L = 1,4,7-Tris(4-*tert*-butyl-2-mercaptobenzyl)-1,4,7-triazacyclononane)

Belen Albela,[a] Eckhard Bill,[a] Oliver Brosch,[a] Thomas Weyhermüller,[a] and Karl Wieghardt*[a]

Keywords: Thiolato-bridged complexes / Iron / Ruthenium / Mixed-valent compounds / Mössbauer spectroscopy



The reaction of $[Fe^{III}L]$ with $[Ru^{II}Cl_2(dmso)_4]$ in methanol under argon, affords, upon addition of $NaPF_6$, brown crystals of $[LFeRuFeL](PF_6)_2 \cdot 3\ CH_3OH$ (**1**). Its one-electron oxidation product $[LFeRuFeL](PF_6)_3$ (**2**) [L = 1,4,7-(4-*tert*-butyl-2-mercaptobenzyl)-1,4,7-triazacyclononane] was generated by using one equivalent of $[NO]BF_4$. The crystal structure determination of $[LFeRuFeL](BPh_4)_2 \cdot CH_3CN \cdot 3\ (CH_3)_2CO$ shows that **1** contains a trinuclear, face-sharing thiolato-bridged dication. Mössbauer spectroscopy established that the oxidation state distribution of **1** can best be described by $Fe^{2.5}Ru^{III}Fe^{2.5}$ and **2** by $Fe^{III}Ru^{III}Fe^{III}$. Complex **1** possesses a diamagnetic (S_t = 0) and **2** an S_t = 1/2 ground state. The electronic structures of **1** and **2** are rationalized by an MO picture involving Fe–Ru metal-metal bonds of bond order 0.5 in both species. Complex **1** is formally a mixed valence compound with complete delocalization of the "excess electron" (class III).

Introduction

In a series of papers[1−6] we have recently shown that mononuclear complexes of the type $[M^{III}L]$ (where L represents the trianionic ligand 1,4,7-tris(4-*tert*-butyl-2-mercaptobenzyl)-1,4,7-triazacyclononane and M = Fe, Ru) readily form homo- or heterotrinuclear complexes $[LM^1M^2M^1L]^{n+}$ with metal ions. These cations are isostructural, containing three face-sharing octahedra, namely two terminal $[M^1L]$ units comprising a *cis*-N_3S_3 donor set and a central MS_6 moiety. The three thiolato pendant arms of L form μ_2-thiolato bridges (Scheme 1). Complexes of this type have been shown to possess a rich redox chemistry where the isostructural tetra-, tri-, di- and monocationic species of a given transition metal ion combination are accessible via simple one-electron transfer steps. Thus it is possible to study magnetic exchange phenomena in paramagnetic species in a well-defined ligand matrix as a function of the local d^n electron configuration of the respective metal ion.

We have recently studied the complexes $[LFeFeFeL]^{2+/3+}$ [3] and their homologs $[LRuRuRuL]^{2+/3+}$.[5] It was shown that the two isoelectronic dications display an S_t = 1 ground state in the case of the tri-iron species but an S_t = 0 ground state for the triruthenium species. In contrast, both trications have an S_t = 1/2 ground state. In order to obtain a better understanding of their electronic structure, we decided that it would be of value to investigate the isoelectronic *hetero*trinuclear analogs $[LFeRuFeL]^{2+/3+}$. Here we report the synthesis, the molecular and electronic structures, and spectroscopic characterizations of these cations.

Results

Preparation of Complexes

Reaction of the mononuclear species $[Fe^{III}L]$[1][2] with $[Ru^{II}Cl_2(dmso)_4]$ (dmso = dimethyl sulfoxide) in the ratio 1:1 in methanol, under argon, at elevated temperatures, produced a clear, dark brown solution from which, upon addition of $NaPF_6$, brown microcrystals of $[LFeRuFeL](PF_6)_2 \cdot 3\ CH_3OH$ (**1**) were obtained. Recrystallization of this material from acetone/acetonitrile (1:1) and addition of $Na[BPh_4]$ afforded single crystals of $[\{LFe\}_2Ru](BPh_4)_2 \cdot CH_3CN \cdot 3\ (CH_3)_2CO$.

When the above reaction mixture was cooled, treated with one equivalent of $[NO]BF_4$, and stored at 4°C, brown microcrystals of $[LFeRuFeL](PF_6)_3$ (**2**) were obtained after addition of $NaPF_6$. Complex **2** is the one-electron oxidized form of **1**.

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 2000 1434−1948/00/0101−0139 $ 17.50+.50/0

Electronic spectra of solutions **1** and **2** in CH_3CN are displayed in Figure 1. The spectrum of **1** shows absorption maxima λ_{max} (ε, $L \cdot mol^{-1} \cdot cm^{-1}$) at 365 sh (ca. $9.5 \cdot 10^3$), 475 ($4.1 \cdot 10^3$), 670 sh ($2.0 \cdot 10^3$), 830 ($1.9 \cdot 10^3$), 1320 nm ($3.6 \cdot 10^3$); for **2** these values are at ca. 420 sh ($1.2 \cdot 10^4$), ca. 550 sh ($4.7 \cdot 10^3$), ca. 620 sh ($3.2 \cdot 10^3$), 750 sh ($2.0 \cdot 10^3$). Clearly, the intense band at 1320 nm in the spectrum of **1** is an intervalence charge transfer band (see below) since it is absent in the spectrum of **2**.

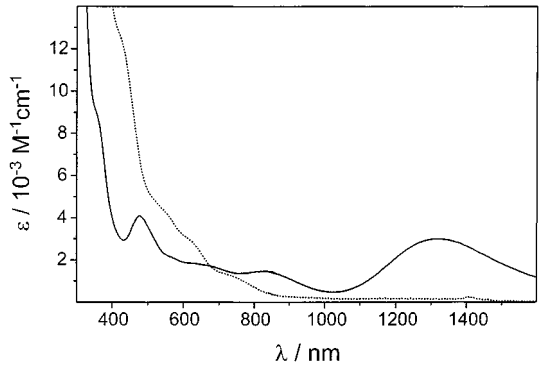

Figure 1. Electronic spectra of **1** (−) and **2** (---) in CH_3CN

The cyclic and square-wave voltammograms of **1** and **2** measured in CH_3CN (0.10 M $[N(nBu)_4]PF_6$) at 293 K are identical and are shown in Figure 2. Three reversible one-electron transfer processes are observed at $E^1_{1/2} = 1.09$ V vs ferrocenium/ferrocene (Fc^+/Fc), $E^2_{1/2} = -0.07$ V vs Fc^+/Fc, and $E^3_{1/2} = -1.07$ V vs Fc^+/Fc which are assigned as depicted in Equation 1.

$$[LFeRuFeL]^{4+} \underset{+e}{\overset{-e}{\rightleftharpoons}} [LFeRuFeL]^{3+} \underset{+e}{\overset{-e}{\rightleftharpoons}} [LFeRuFeL]^{2+} \underset{+e}{\overset{-e}{\rightleftharpoons}} [LFeRuFeL]^{1+} \quad (1)$$

Reduction of the dication to the monocation is only reversible on the time-scale of a CV experiment; it decomposes to $[Fe^{II}L]^-$ and (probably) $[Ru^{II}(NCCH_3)_6]^{2+}$ at slower scan rates. The small peaks at −0.75 V and +0.60 V vs Fc^+/Fc correspond to the [FeL]/$[FeL]^-$ and $[Ru^{III}(NCCH_3)_6]^{3+/2+}$ couple, respectively.

Magnetic Susceptibility and EPR Spectroscopy

Temperature-dependent magnetic-susceptibility measurements in the range 2−298 K were performed on a SQUID magnetometer in a field of 1 T. The raw data were corrected for underlying diamagnetism by using Pascal's tabulated constants. Temperature-independent paramagnetism (TIP), χ_{TIP}, is a fit parameter.

Figure 3 shows the calculated effective magnetic moments as a function of the temperature for **1** (top) and **2** (bottom). For complex **1**, μ_{eff} varies from 0.59 μ_B at 2 K to 1.97 μ_B at 290 K, which is predominantly due to TIP ($\chi_{TIP} \approx 2.0 \cdot 10^{-3}$ cm^3 mol^{-1}). Thus **1** has a diamagnetic $S_t = 0$ electronic ground state. A small amount of a paramagnetic impurity (< 2%) is also present in the sample of **1**.

The temperature-dependence of the effective magnetic moment of **2** was satisfactorily modeled for an $S_t = 1/2$ ground state with the following parameters: $g = 2.11$; $\chi_{TIP} = 1380 \cdot 10^{-6}$ cm^3 mol^{-1}. Note that large TIP values have been found for all trinuclear complexes of the type $[LFeMFeL]^{n+}$ (M = Cr, Co, Fe, Ni).[3−6]

The $S_t = 1/2$ ground state of **2** has been confirmed by its X-band EPR spectrum in CH_3CN solution at 10 K, which is shown in Figure 4. An axial signal with $g_\perp = 2.31$ and $g_\parallel = 1.86$ has been observed. The average $g^{av} = 2.16$ is

Crystal Structure Determination

Crystals of $[LFeRuFeL](BPh_4)_2 \cdot CH_3CN \cdot 3\,(CH_3)_2CO$ consist of well-separated dications $[LFeRuFeL]^{2+}$ and tetraphenylborate anions together with acetonitrile and acetone molecules of crystallization. Figure 5 shows different views of the dication and Table 1 summarizes bond lengths and angles of the trinuclear core. The dication consists of three face-sharing thiolato-bridged octahedra with two terminal iron ions and a central ruthenium ion. The stereochemistry of these trinuclear cations, $[\{LM^1\}_2M^2]^{n+}$, has been discussed previously.[3,5,6] The staggered configuration of the six tertiary butyl groups (looking down the Fe···Ru···Fe axis) in the achiral stereoisomer $\Delta(\lambda\lambda\lambda)\cdots\Lambda(\delta\delta\delta)$ yields a stable structure which has been observed in all cases where the M1···M2 distance is >2.9 Å. Only in $[LRuRuRuL](PF_6)_2 \cdot H_2O$ has the $\Delta(\lambda\lambda\lambda)\cdots\Delta(\lambda\lambda\lambda)$ [and its enantiomer $\Lambda(\delta\delta\delta)\cdots\Lambda(\delta\delta\delta)$] diastereomer been observed.[5] In this case, the six tertiary butyl groups are eclipsed and the Ru−Ru distance is at 2.775 Å. The dication in **1** adopts the achiral $\Delta(\lambda\lambda\lambda)\cdots\Lambda(\delta\delta\delta)$ configuration. The ruthenium ion is located on a crystallographic inversion center. The average Fe−N and Fe−S bond lengths at 2.061(4) and 2.251(4) Å are indentical to those observed in all other structure containing an $[LFeMFeL]^{n+}$ cation.[1−6] Interestingly, the three crystallographically independent Ru−S distances of the central RuS_6 moiety are not quite equivalent. There are two longer Ru−S distances at 2.368(1) Å and a shorter one at 2.350(1) Å (tetragonally compressed octahedron). The Fe···Ru distance at 2.804(1) Å is short and may indicate the onset of direct metal−metal bonding. In $[LRuRuRuL]^{2+}$ the Ru−Ru distance is found at 2.775(1) Å[5] and in $[LFeFeFeL]^{2+}$ the Fe···Fe distance is 2.848(1) Å.[3]

Mössbauer Spectroscopy

Complexes **1** and **2** have been studied by ^{57}Fe-Mössbauer spectroscopy in zero and applied fields. For both compounds, the zero-field spectra recorded on solid material at 80 K are single quadrupole doublets that could be fitted with Lorentzian lines as shown in Figure 6. The two local iron sites in **1** and **2** are indistinguishable; the parameters are summarized in Table 2. Since the same behavior is

found for the measurements at liquid helium temperatures, we can exclude the possibility of dynamic processes like valence detrapping playing a role. The ^{57}Fe-Mössbauer parameters of **1** and **2** clearly show that the redox states of the complexes are related to the iron oxidation states. The higher isomer shift and the lower quadrupole splitting of **1** indicates the more ferrous character of iron in **1** than in **2**. The iron ions in both **1** and **2** are low-spin.

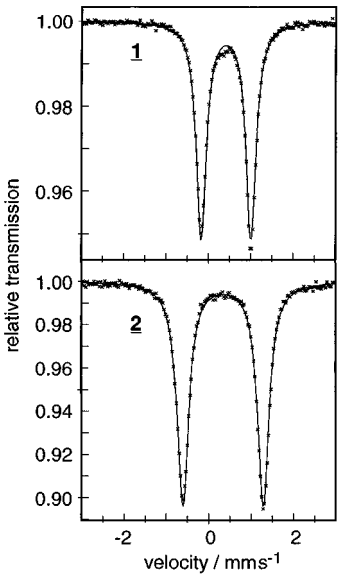

Figure 6. Zero-field Mössbauer spectra of crystalline samples of **1** and **2** measured at 80 K. The solid lines are a fit with Lorentzian lines with isomer shift, quadrupole splitting and line width (fwhm) of (**1**: $\delta = 0.41$ mm s^{-1}, $\Delta E_Q = 1.18$ mm s^{-1}, $\Gamma = 0.33$ mm s^{-1}) and (**2**: $\delta = 0.34$ mm s^{-1}, $\Delta E_Q = 1.83$ mm s^{-1}, $\Gamma = 0.33$ mm s^{-1}). The small difference in isomer shift relative to the 4.2 K values given in Table 2 originates from the second-order Doppler shift

The Mössbauer parameters of **1** and **2** fit perfectly in a $\delta/\Delta E_Q$ correlation diagram (Figure 7A) that we have previously established for a series of isostructural complexes with the same $[FeMFe]^{n+}$ core where M is Cr, Fe, or Co. The terminal iron sites thus have variable formal oxidation states, which depend on the cluster oxidation state and on

the degree of valence delocalization mediated via the central MS_6 unit.[3] If we take these compounds as a reference series (Table 3) we can determine the iron valences of **1** and **2**. In particular, the Mössbauer isomer shift is a sensitive parameter for this purpose because it is a measure of the charge density at the iron nucleus. The apparently linear correlation of oxidation state and isomer shift shown in Figure 7B reveals an iron oxidation state of 2.9 for **2** (≈ +III) and an intermediate value of 2.5 for the reduced analogue **1**. Therefore the central ruthenium ion in this system must be persistently close to the trivalent state (+III) and

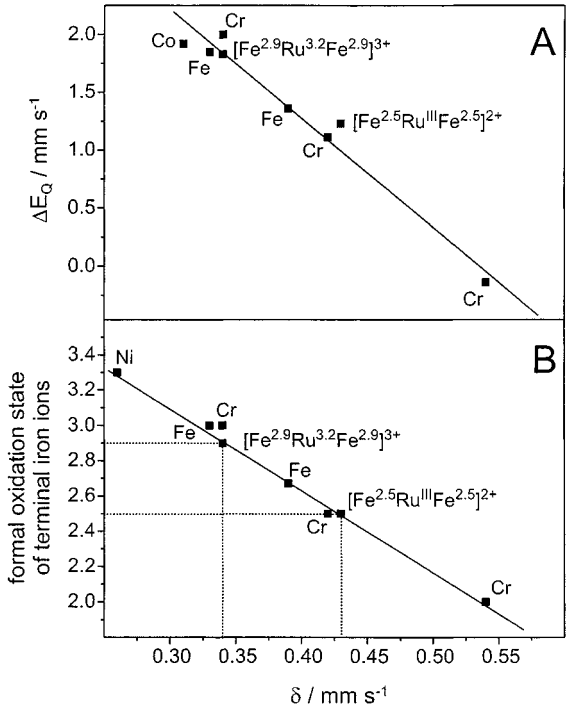

Figure 7. (A) Plot of the quadrupole splitting and ^{57}Fe-Mössbauer isomer shift for **1** and **2** together with the values of related complexes with the $[FeMFe]^{n+}$ core, M = Cr, Fe, Co, Ni taken from ref.[3][6] − (B) Correlation of the formal oxidation state and isomer shift for the same set of compounds. with an applied field of 7 T at 4.2 K (Figure 8). The spectrum could be readily simulated with the usual nuclear Hamiltonian[7][8] for the external field and a vanishing internal field. The sign of V_{zz} is found to be positive with η = 0.3. The parameters are summarized in Table 2.

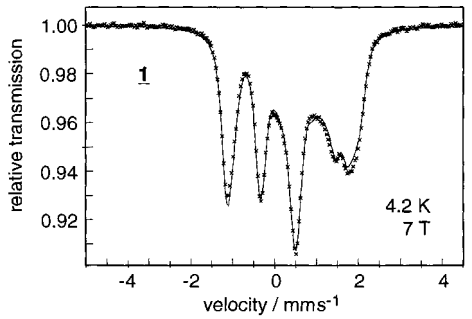

Figure 8. Magnetically perturbed Mössbauer spectrum of **1** measured at 4.2 K with a field B = 7 T applied perpendicular to the γ-rays. The solid line is a simulation for a diamagnetic system (zero internal field); the parameters are given in Table 2

Figure 9 shows the magnetic Mössbauer spectra of solid complex **2** recorded with applied fields of 4 T and 7 T at 4.2 K and 120 K. The spin ground state S_t = 1/2 of complex **2** is well separated from the excited states and the limit of strong coupling ($J >> \mu_B B$, kT) is valid even at 120 K according to the static magnetic susceptibility measurement. We have therefore used an effective spin Hamiltonian for the description of the magnetic Mössbauer spectra.[3] At liquid helium temperatures the spectra were simulated in the slow relaxation limit whereas at 120 K fast relaxation prevails. To limit the number of free parameters the g factors were fixed to the values determined from EPR. The sign of V_{zz} is unambiguously positive, as is clearly shown by the 120 K measurement, and the asymmetry parameter is 0.2(1). This result discloses the order of the 1e and a_1 iron 3d orbitals in the trigonal symmetry (t_{2g} in O_h symmetry).[3][9] The positive V_{zz} is consistent with a large positive valence electron contribution to the efg which is expected for an $(1e)^4(a_1)^1$ electron configuration if the 1e orbital set is lower in energy than the a_1 orbital.

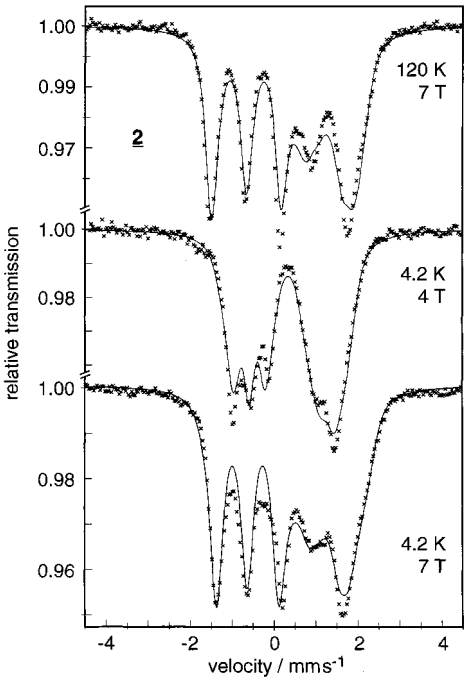

Figure 9. Magnetically perturbed Mössbauer spectrum of **2** measured at 4.2 K and 120 K with the indicated fields applied perpendicular to the γ-rays. The solid lines are a simulation for a system spin S_t = 1/2; the parameters are given in Table 2

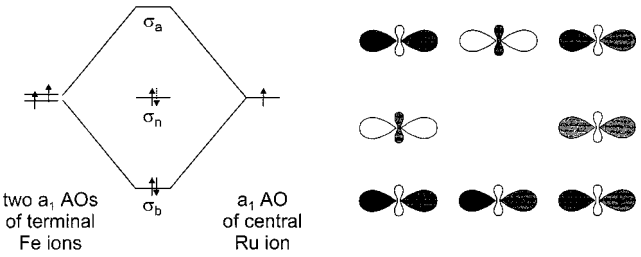
Surprisingly, the fits required a finite value of the asymmetry parameter η = 0.2(1), and an Euler angle β = 22° which orients the principal z'-axis of the efg off from the principal z'-axis of the g and A tensors. The deviation is in contrast to the anticipated C_{3v} symmetry of the complex. A close inspection of the molecular structure shows a small distortion of the local iron sites in the crystal. There are two slightly longer Fe−S bonds [Fe(1)−S(3) and Fe(1)−S(3)′] and the RuS_6 octahedron shows a tetragonal compression with two shorter Ru−S bonds [Ru(1)−S(1) and Ru(1)−S(1)′].

The internal magnetic field induced by the total spin (S_t = 1/2) of the complex has a relatively small isotropic contribution and large anisotropy as shown by the trace and the components of the hyperfine coupling tensor given in Table 2 ($1/3\mathrm{Tr}(A)/g_N\beta_N$ = −1.46 T). This closely resembles the magnetic properties of iron in the corresponding $[FeFeFe]^{3+}$ complex.[3] The asymmetry owes its origin to significant spin-dipolar contributions to the A tensor, due to spin-orbit interaction in the $3d^5$ configuration of the low-spin Fe^{III}. The sign of the isotropic contribution to A is negative as it is for usual mononuclear iron compounds. This demonstrates that the local spins of the iron ions are parallel to the cluster spin, whereas the Ru^{III} spin is antiparallel, giving rise to the $|S_t = 1/2, S^* = 1>$ ground state. The A-tensor components given with respect to the total spin can be converted into local values related to the iron spin by using the spin projection factor derived from an application of the Wigner-Eckart theorem: $A_{(S_t=1/2)} = 2/3\ a_{S=1/2}$.



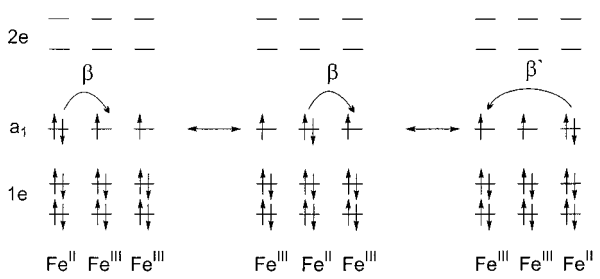
The obtained local values are $a_{S = 1/2}/g_N\mu_N$ = (−4.61, −4.61, +2.65) T.

In summary, Mössbauer spectroscopy allows one to experimentally determine the formal oxidation state of the iron ions in $[LFeMFeL]^{n+}$ complexes. As shown in Figure 7A, the isomer shift and the quadrupole splitting parameters of all complexes of this type reported to date are linearly correlated, and the corresponding data of **1** and **2** are in excellent agreement with this correlation. We have conclusively shown[3] that the iron ions in $[LFeCr^{III}FeL]^{3+}$ are purely low-spin ferric ions (oxidation state +III), whereas in $[LFeCr^{III}FeL]^{1+}$ they are low-spin ferrous (+II) and in $[LFeCr^{III}FeL]^{2+}$ are a mixed valent species with delocalized electronic structure (two $Fe^{2.5}$ ions). A plot of the corresponding ^{57}Fe-isomer shift vs the formal oxidation state is again linear, as displayed in Figure 7B. Using this correlation, an oxidation state of 2.9 (≈ +III) for **2** and of 2.5 for **1** is determined for the respective iron ions. Thus, **1** may be described as a $[LFe^{2.5}Ru^{III}Fe^{2.5}L]^{2+}$ and **2** as a $[LFe^{III}Ru^{III}Fe^{III}L]^{3+}$ species. In this manner we have established that the reduction of **2** by one-electron, yielding **1**, affects only the iron ions, and that both **1** and **2** contain a central Ru^{III} ion. Furthermore, the observation in the ^{57}Fe-Mössbauer spectrum of **1** of only a single iron site − even at 4.2 K − renders the dication a mixed valent species with a completely delocalized "excess" electron (class III according to Robin and Day[10]); the alternative formulation of **1** as a $[LFe^{III}Ru^{II}Fe^{III}L]^{2+}$ species is clearly ruled out by its Mössbauer spectra.

Discussion

In the preceding section it has been experimentally established that the cation $[LFeRuFeL]^{3+}$ in complex **2** contains two low-spin ferric ions with an $(1e)^4(a_1)^1$ local electron configuration and a central low-spin Ru^{III} ion, probably also with an $(1e)^4(a_1)^1$ configuration. The S_t = 1/2 ground state can then be rationalized by a MO description invoking two weak Fe−Ru bonds. The formation of three-center MOs by overlap of metal t_{2g} orbitals (specifically the a_1 orbitals) having lobes along the threefold symmetry axis, yields a bonding σ_b, a nonbonding σ_n, and an antibonding σ_a molecular orbital.[11][12] There are three electrons to occupy these MOs, σ_b^2 and σ_n^1, yielding an S_t = 1/2 ground state (Scheme 2). In the structurally characterized species $[Ru_3Cl_8(PEt_3)_4][SbF_6]$[13] a Ru−Ru distance at 2.91 Å has been found and a formal Ru−Ru bond order of 0.5 has been proposed. Analogously, an Fe−Ru bond of bond order 0.5 can be envisaged in $[LFeRuFeL]^{3+}$ (as in its previously described isoelectronic homotrinuclear species $[LRu^{III}Ru^{III}Ru^{III}L]^{3+}$).[5]

It is interesting that the isoelectronic species $[LFe^{III}Fe^{III}Fe^{III}L]^{3+}$ containing a low-spin central and two low-spin terminal ferric ions also possesses an S_t = 1/2 ground state.[3] The Fe···Fe distance has been determined at 2.86(2) Å by EXAFS spectroscopy or 2.79(2) Å from a low-quality X-ray crystal structure. The observed very strong antiferromagnetic coupling (J_a < −400 cm^{-1}) has been rationalized as originating from direct exchange between local a_1-orbitals and the onset of metal−metal bonding.



Scheme 2. Schematic MO representation for $[\{LFe\}_2Ru]^{2+/3+}$

Mössbauer spectroscopy unequivocally demonstrates that one-electron reduction of **2** to **1** affects only the two terminal iron ions which are on the time scale of this spectroscopy equivalent: $[LFe^{2.5}Ru^{III}Fe^{2.5}L]^{2+}$. The Ru−Fe distance at 2.804(1) Å is in the range where direct metal−metal bonding is certainly a possibility. The MO scheme (Scheme 2) immediately implies that the "excess" electron occupies the σ_n MO, giving rise to an electron configuration $\sigma_b^2\sigma_n^2$ where the Fe−Ru bonds also have a BO of 0.5 and the dication adopts a diamagnetic ground state. Similarly, $[LRuRuRuL]^{2+}$ has been shown to possess an S_t = 0 ground state and a relatively short Ru−Ru distance at 2.775(1) Å.[5]

On the other hand, isoelectronic $[LFeFeFeL]^{2+}$ possesses an S_t = 1 ground state[3] with no thermally accessible excited spin states. The Fe···Fe distance has been determined to be 2.848(2) Å which is slightly, but significantly, longer than in **1** or $[LRuRuRuL]^{2+}$. From Mössbauer spectroscopy, a fractional oxidation state of +2.67 for each of the three iron ions has been determined. The positive sign of the quadrupole splittings indicated that the local a_1-orbitals are the magnetic orbitals. The origin of the S_t = 1 ground state has been rationalized by a double exchange mechanism over three metal centers (Scheme 3). Only parallel alignment of the three respective local spins allows the excess electron to be transferred over all *three* metal centers. The negative sign of the effective Mössbauer hyperfine coupling constants A_i^{iso} indicates positive spin density at the central *and* terminal centers, thereby corroborating the above picture.[3] In this instance Fe···Fe metal bonding does not play a significant role, but delocalization of the excess electron via a double exchange mechanism enforces the above triplet ground state.

Finally, for the isoelectronic species $[LFe^{III}Co^{III}Fe^{III}L]^{3+}$, the observed S_t = 1 ground state[3] is thought to be attained via strong intramolecular ferromagnetic exchange coupling between two localized low-spin ferric ions which is mediated by a low-spin Co^{III} ion. For a detailed discussion of this rather surprising result see ref.[3][4] Interestingly, $[LRu^{III}Co^{III}Ru^{III}L]^{3+}$ also possesses an S_t = 1 ground state.[14] In both low-spin cobalt(III) containing species no metal-metal bonding is anticipated to play a role due to the

Scheme 3. Electron delocalization in $[\{LFe\}_2Fe]^{2+}$

small size of a cobalt(III) ion (the overlap of a_1 orbitals is very poor).

In the isoelectronic series $[LRuRuRuL]^{2+}$, **1**, $[LFeFeFeL]^{2+}$, $[LRu^{III}Co^{III}Ru^{III}L]^{3+}$, and $[LFe^{III}Co^{III}Fe^{III}L]^{3+}$, each containing 16 valence electrons, the actual ground state correlates with the extent of direct metal−metal bonding, which is significant only in the first two cases, where it yields an $S_t = 0$ ground state. In $[LFeFeFeL]^{2+}$ delocalization of an excess electron over all three iron sites enforces a triplet ground state via double exchange, whereas in $[LRu^{III}Co^{III}Ru^{III}L]^{3+}$ and $[LFe^{III}Co^{III}Fe^{III}L]^{3+}$ there is no metal-metal bonding and the $d^5d^6d^5$ electron configuration is *localized*. Intramolecular spin exchange (ferromagnetic in nature) yields the observed triplet ground state

Experimental Section

Syntheses: The ligand $H_3L \cdot 3\,HPF_6$ was prepared by following the published procedure for $H_3L \cdot 3\,HCl$ by using an HPF_6 solution (ether) instead of HCl in the last step. The synthesis of the mononuclear species $[Fe^{III}L]$ has been described previously.[1]

$[LFeRuFeL](PF_6)_2 \cdot 3\,CH_3OH$ (1): A degassed solution of [FeL] (0.30 g; 0.42 mmol) and $[Ru^{II}Cl_2(dmso)_4]$ (0.20 g; 0.42 mmol) in CH_3OH (50 mL) were heated to reflux under argon for 3 h. To the cooled (20°C) dark brown solution an excess of $NaPF_6$ (1.0 g) dissolved in degassed CH_3OH (25 mL) was added. Within a few hours at 4°C a brown microcrystalline precipitate formed which was collected by filtration (Yield: 0.19 g; 50%). Recrystallization of this material from an acetone-acetonitrile mixture (1:1) produced, after addition of $Na[BPh_4]$, single crystals of $[LFeRuFeL](BPh_4)_2 \cdot CH_3CN \cdot 3\,(CH_3)_2CO$ suitable for X-ray crystallography. − $C_{78}H_{108}N_6S_6RuFe_2(PF_6)_2 \cdot 3\,CH_3OH$: calcd. C 50.95, H 6.30, N 4.37, S 10.01; found C 51.5, H 6.1, N 4.2, S 10.3. − LSIMS *m/z* $[\{LFe\}_2Ru]^+$ 1535; $\{[\{LFe\}_2Ru](PF_6)\}^+$ 1679.6; $[\{LFe\}_2Ru]^{2+}$ 768.3.

$[LFeRuFeL](PF_6)_3$ (2): A degassed solution of [FeL] (0.30 g; 0.42 mmol) and $[RuCl_2(dmso)_4]$ (0.20 g; 0.42 mmol) in CH_3OH (50 mL) was heated to reflux under argon for 3 h. To the cooled (20°C) solution $[NO]BF_4$ (0.05 g; 0.42 mmol) was added and then stirred at 45°C for 3 h. Upon addition of $NaPF_6$ (0.3 g; 1.8 mmol) dissolved in CH_3OH (25 mL) and storage at 4°C for a few hours, a brown precipitate formed (0.15 g). Recrystallization of this material from CH_3CN afforded brown microcrystals of **2**. − $C_{78}H_{108}N_6S_6RuFe_2 \cdot (PF_6)_3$: calcd. C 47.56, H 5.53, N 4.27, S 9.77; found: C 47.2, H 5.5, N 4.1, S 9.5. − ESI (pos. ion) mass spectrometry: $[\{(LFe)_2Ru\}(PF_6)_2]^+$ 1824.2; $[\{(LFe)_2Ru\}(PF_6)]^+$ 1679; $[\{(LFe)_2Ru](PF_6)]^{2+}$ 839.3; $[(LFe)_2Ru]^{2+}$ 766.8.

X-ray Structure Determination: A brown single crystal of $[LFeRuFeL](BPh_4)_2 \cdot CH_3CN \cdot 3\,(CH_3)_2CO$ was mounted on an Enraf−Nonius CAD4 diffractometer in a glass capillary sealed under argon. Graphite-monochromated Mo *Kα* radiation (λ = 0.71073 Å) was used. Cell constants were obtained from a least-squares fit of the setting angles of 25 carefully centered reflections. Intensity data were collected at 100(2) K by using the ω-2θ scan technique, corrected for Lorentz and polarization effects, but no absorption correction was carried out due to the small absorption coefficient.

The Siemens ShelXTL software package[15] was used for solution, refinement, and artwork of the structure which was readily solved and refined by direct methods and difference Fourier techniques. All non-hydrogen atoms were refined anisotropically except the methyl carbon atoms of one disordered acetonitrile and acetone molecule which were isotropically refined on two sites (with occupancy factors 0.5 for each atom). All hydrogen atoms were placed at calculated positions and refined as riding atoms with isotropic displacement parameters. $C_{137}H_{169}B_2Fe_2N_7O_3RuS_6$, M = 2388.54 g mol^{-1}, crystal dimensions 0.49 × 0.35 × 0.21 mm, monoclinic, $Z = 2$, space group $P2_1/c$, a = 12.926(4), b = 15.613(4), c = 31.467(9) Å, β = 90.24(3)°, V = 6350(3) Å^3, $\rho_{calcd.}$ = 1.249 g cm^{-3}, T = 100(2) K, 2θ range = 5.6 to 50.0°, 11387 measured reflections, 11167 unique reflections, 6958 observed reflections [$I > 2\sigma(I)$], 710 parameters, $R_1 = 0.056$, $wR_2 = 0.135$. Further details of the crystal structure determination have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC−125733. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ [Fax: +44 (0)1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Physical Measurements: UV/Vis/near-IR spectra of CH_3CN solutions of **1** and **2** were measured on a Perkin−Elmer Lambda 19 spectrophotometer in the range 210−3200 nm at ambient temperature. − Cyclic and square-wave voltammetric and coulometric measurements were performed on EG & G equipment (potentiostat/galvanostat model 273A) on Ar-flushed acetonitrile solutions of samples containing 0.10 M $[N(nBu)_4]PF_6$ as supporting electrolyte at a glassy carbon working electrode and a $Ag/AgNO_3$ reference electrode. Ferrocene (Fc) was added as internal standard; all potentials are referenced vs the Fc^+/Fc couple. − Temperature-dependent magnetic susceptibilities of powdered samples were measured by using a SQUID magnetometer (Quantum Design) at 1.0 T (2.0−300 K). For calculations of the molar magnetic susceptibility, χ_M, the experimental susceptibilities were corrected for the underlying diamagnetism of the sample by using tabulated Pascal's constants. The temperature-independent paramagnetism (χ_{TIP}) was obtained by a fitting procedure. − The X-band EPR spectrum of a frozen solution of **2** was recorded on a Bruker ESP 300E spectrometer equipped with a helium flow cryostat (Oxford Instruments ESR 910). The X-band resonator was a dual-mode cavity (Bruker ER 4116 DM/95). − The Mössbauer spectra were recorded on an alternating constant-acceleration spectrometer. The minimal linewidth was 0.24 mm s^{-1} (full width at half-height). The sample temperature was maintained constant in either an Oxford Variox or an Oxford Mössbauer-Spectromag cryostat. The latter is a split-pair superconducting magnet system for applied fields up to 8 T where the temperature of the sample can be varied in the range 1.5−250 K. The field at the samples is oriented perpendicular to the γ-beam. The $^{57}Co/Rh$ source (1.8 GBq) was positioned at room temperature inside the gap of the magnet system at a zero-field position. Isomer shifts are referenced relative to α-iron metal at 295 K. Details of the analysis within the usual spin Hamiltonian

formalism are given in ref.[3] The depicted fits are the results of an optimization applied simultaneously to the whole series of experimental spectra.

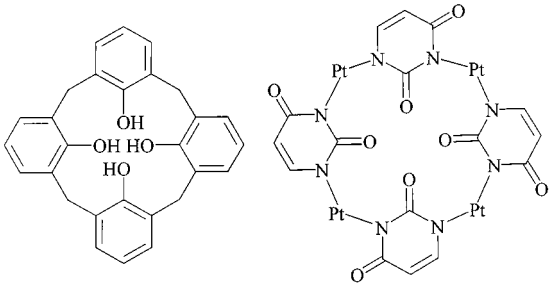
[(Ethylenediamine)Pt(uracilate)]$_4$ – A Metal Analogue of Calix[4]arene: Coordination Chemistry of Its 1,3-Alternate Conformer towards First-Row Transition-Metal Ions

Jorge A. R. Navarro,[a] Eva Freisinger,[a] and Bernhard Lippert*[a]



Keywords: Platinum / Uracil / Nucleobase / Host-guest chemistry

The open "molecular box" [(en)Pt(U-N^1,N^3)]$_4$ (**1**) (where en = ethylenediamine, U = uracil dianion) is able to act as an efficient ligand for additional metal ions. Reactions of the 1,3-alternate conformer of **1** with divalent metal ions result in the formation of octanuclear compounds of the general formula [(en)Pt(U-N^1,N^3,O^2,O^4)M]$_4$X$_8$ [M = Cu^{2+}, X = Cl (**2a**), X = $(SO_4)_{0.5}$ (**2b**), and M = Co^{2+} (**3**), Ni^{2+} (**4**), Zn^{2+} (**5**) with X = $(SO_4)_{0.5}$], in which the heterometals are bound at the exocyclic oxygen atoms of the uracil nucleobases. The structurally characterized heteronuclear compounds show a 1,3-alternate arrangement of the uracil nucleobases. Pt–M contacts are in the range 2.743(2)–2.804(2) Å; the Pt atoms act as weak σ donors to the heterometals. In spite of the high degree of positive charge associated with compounds **2a**–**5**, they do not behave as hosts for anions. This is a consequence of the orientation of the four nucleobases which, in contrast to a cone arrangement, does not produce a sufficiently large cavity for the incorporation of anions.

Introduction

Calixarenes and related cyclic compounds are presently the subject of considerable attention owing to their versatility as hosts for inclusion complexation.[1] In addition to their host-guest chemistry, calixarenes can also act as efficient ligands for metal ions, either through their basic oxo surfaces[2][3] or through the arene π electrons.[4] Analogous macrocyclic coordination compounds are likewise also the focus of considerable research efforts as they may also exhibit host-guest chemistry, which might ultimately be combined with the intrinsic magnetic, optical, catalytic, and structural properties of metal ions.[5]

[(en)Pt(U-N^1,N^3)]$_4$ (**1**) (where en = 1,2-diaminoethane, U = uracil dianion) shows structural similarities to calix[4]-arenes (Scheme 1) and is an interesting example of a macrocyclic coordination compound that combines receptor properties analogous to those of classical calixarenes[6] with versatility as a ligand for metal ions.[7]

In a previous report, we showed **1** to be a very efficient ligand towards metal ions, leading to various stoichiometries depending on the nature of the metal ion and the original conformation of the metallocalixarene.[6] A frequently encountered problem in the structural characterization of such heteronuclear compounds stems from the large number of anions present. Due to anion disorder problems, it proved impossible, in spite of a well-characterized octanuclear cation, to report complete X-ray crystallographic characterizations. Only in one case, namely that of [(en)Pt(U-N^1,N^3,O^2,O^4)Pt$(NH_3)_2]_4(NO_3)_8$, was a complete structure determination achieved.[7c] In this communication, we report on the coordination chemistry of **1** towards first row divalent transition metal ions, which has led to the generation of a series of octanuclear compounds having sulfate or chloride anions. In three cases, it has been possible to obtain X-ray quality crystals. In addition, the potential of these compounds to act as anion receptors has been studied.

Results

Reaction of a solution of freshly prepared **1** with 4 equiv. of a divalent transition metal salt at pH = 5−6 results in an immediate color change of the solution (other than in the case of Zn^{2+}), which is accompanied by a drop in the pH by 2−3 units. In the case of Zn^{2+}, addition of the metal salt leads to a significant downfield shift (+0.33 ppm) of the H^5 resonance of uracil in the ^{1}H-NMR spectrum, as well as an upfield shift (−0.10 ppm) of the H^6 resonance, indicating the formation of a thermodynamically stable species. In all other cases (compounds **2a**−**4**), the aforementioned immediate color change of the solution, to green (Cu^{2+}), purple (Co^{2+}), and yellow-green (Ni^{2+}), indicates rapid complexation of the heterometal by **1**. In each case,

four metal ions are incorporated in the resulting compound, giving [(en)Pt(U-N^1,N^3,O^2,O^4)CuCl$(H_2O)_2]_4Cl_4$ (**2a**) and [(en)Pt(U-N^1,N^3,O^2,O^4)M$(H_2O)_3]_4(SO_4)_4$ (M = Cu, **2b**; Co, **3**; Ni, **4**; Zn, **5**). The structures of **2a**, **2b**, and **5** have been fully resolved by X-ray crystallography. The compounds consist of octanuclear cations of approximate S_4 molecular symmetry (see Figures 1 and 2), four chloride (**2a**) or sulfate (**2b**, **5**) counterions, and water molecules of hydration.

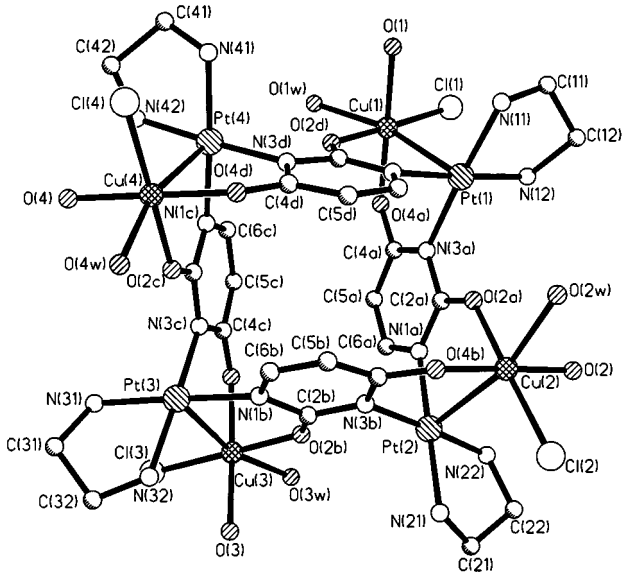

Figure 1. View of the cation [(en)Pt(U-N^1,N^3,O^2,O^4)CuCl$(H_2O)_2]_4^{4+}$ in **2a**

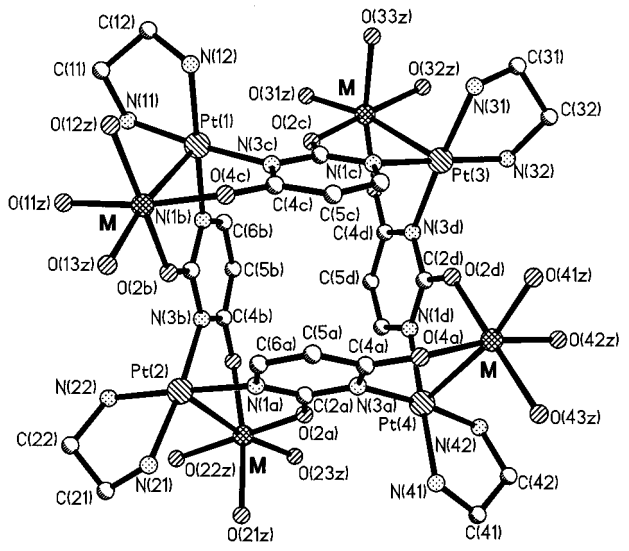

Figure 2. Perspective view of the isomorphous cations of type [(en)Pt(U-N^1,N^3,O^2,O^4)M$(H_2O)_3]_4^{8+}$ in **2b** (M = Cu^{2+}) and **5** (M = Zn^{2+})

The structures of the cations are similar to that of the original cyclic [(en)PtHU(N^1,N^3)$]_4^{4+}$ framework of **1**, with the uracil N^1 and N^3 sites platinated and a 1,3-alternate arrangement of the uracil nucleobases. There is little variation in the dimensions of the box between the complexes, the starting **1**, and the octanuclear compound [(en)Pt(U-N^1,N^3,O^2,O^4)Pt$(NH_3)_2]_4(NO_3)_8$.[7c] The mean separation between the platinum centers, which define the sides of the box, is ca. 5.8 Å, while the diagonal measures ca. 8.2 Å. In addition to the four platinum centers, four $[CuCl(H_2O)_2]^+$, $[Cu(H_2O)_3]^{2+}$, or $[Zn(H_2O)_3]^{2+}$ entities are strongly bound to pairs of exocyclic O^2 and O^4 donor atoms of uracil in **2a**, **2b**, and **5**, respectively. The spatial disposition of the four heterometals in the molecular box is 1,3-alternate, with a displacement of ca. 1.9 Å from the plane defined by the four platinum centers (mean deviation ca. 0.05 Å). The four copper ions in both compounds **2a** and **2b** reside in tetragonally distorted octahedral [4+1+1] environments (see Table 1). In the case of **5**, the zinc centers have distorted octahedral [5+1] environments.

Table 1. Metal−metal separations and average Pt^{2+} and M^{2+} environments (Å) in **2a**, **2b**, and **5**

	2a	**2b**	**5**
Pt−M	2.764(2)	2.804(3)	2.743(1)
	2.760(2)	2.790(3)	2.788(1)
	2.778(2)	2.767(3)	2.777(1)
	2.770(2)	2.789(3)	2.778(1)

Pt−N3	2.04(1)	2.02(2)	2.027(6)

[a] Water molecules placed in *cis* position to the Pt center. − [b] Water molecule placed in *trans* position to the Pt center.

In **2a**, the equatorial positions of the copper coordination spheres are occupied by uracil O^2 and O^4 donor atoms, a water molecule, and a chloride ion, while the axial positions are occupied by water molecules and Pt^{2+} centers. In **2b** and **5**, the heterometals have coordination environments analogous to those in **2a**, differing only in that the equatorial chloride anion is replaced by a water molecule. The Pt−M separations [2.743(2)−2.804(3) Å, see Table 1] are very similar to those found in related di-[8] or trinuclear[9] complexes containing bridging 1-methyluracilato ligands and *cis*-Pt$(NH_3)_2$ entities, where distances of 2.684(1) Å and 2.765(3) Å have been observed. These distances are significantly longer than those found in heteronuclear complexes derived from *trans*-Pt$(NH_3)_2$,[10] where Pt−M distances as short as 2.49 Å have been found as a consequence of a particularly favourable interaction between the occupied d_{z^2} orbital of Pt^{2+} and the $d_{x^2-d y^2}$ orbitals of Cu^{2+} or Pd^{2+} centers.[11] Nevertheless, the Pt^{2+} centers in **2a**−**5** probably also act as weak σ-donors, as is the situation with other first row transition metals.[12] The weakness of the Pt−M interaction is highlighted by the fact that in compound **5** the axial water ligand is more closely bound to the Zn^{2+} center than the equatorial water ligand, whereas in the case of the copper compounds the tetragonal distortion is always found along the Pt−Cu axis with longer Cu^{2+}−axial water ligand separations. Taking into account the fact that the d^{10}

Zn^{2+} is not subject to a Jahn−Teller effect, in contrast to the d^9 Cu^{2+} ion, it is tentatively concluded that the Pt−Cu interaction is as weak as the Pt−Zn interaction. The tendency of Zn^{2+} to form octanuclear complexes and the weakness of the Pt−Zn donation may be offset by a stronger Zn^{2+}−axial water ligand interaction. The close structural similarities of related di- and trinuclear PtM and Pt_2M complexes (M = Pt^{2+}, Pd^{2+}, Cu^{2+}, Zn^{2+}, etc.) containing bridging uracil nucleobases suggest that the octanuclear frameworks in compounds **3** and **4** may be analogous.[13]

No unusual packing features are observed in **2a**, **2b**, and **5**. Octanuclear cations do not interact directly but are rather separated by counterions and water molecules. Multiple H-bonding interactions are seen between the Cl^- or SO_4^{2-} anions and the amino and water ligands coordinated to the metal centers of the cations, although none of these are unusual.

It has previously been reported that compound **1** displays interesting behaviour in solution, with two main species being present, namely the 1,3-alternate and cone conformers. Depending on the experimental conditions, either of the two main species can be stabilized.[7] It is interesting to note that compound **1** in its cone conformation has been shown to be able to incorporate either four[7c] or only one additional metal ion,[6] instead of always four in the case of the 1,3-alternate conformer. Therefore, it may be concluded that the 1,3-alternate form is a much more efficient ligand for divalent metal ions as a result of a more favorable orientation of the exocyclic donor groups of the uracil nucleobases.

The ability of **5** to include anions in its cavity has been studied by means of ^{1}H-NMR spectroscopy using a series of sulfonate anions (see Experimental Section). However, in contrast to the anion host-guest chemistry exhibited by some of the metallated species of the cone conformer of **1**,[6] we found that **5** is unable to include anions in spite of its high positive charge. In fact, the ^{1}H-NMR spectrum of **5** remains unaltered following the addition of anions. Moreover, X-ray analysis results prove beyond doubt that neither chloride (**2a**) nor sulfate anions (**2b**, **5**) are included in the cavity of the compounds. Space-filling representations of the compounds with the 1,3-alternate conformation clearly reveal that the cavity is too small to permit the inclusion of an anion (Figure 3).

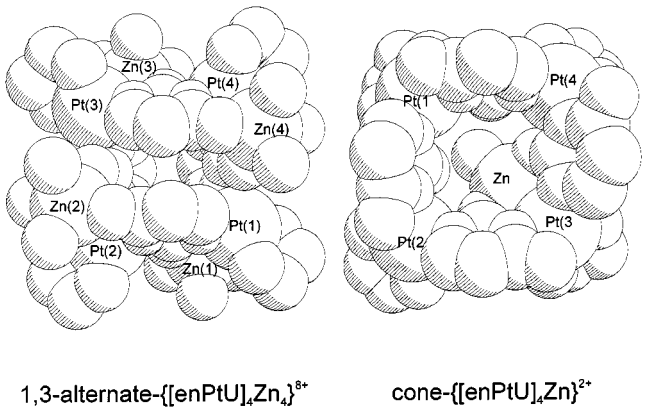

Figure 3. Space-filling representation of the 1,3-alternate-{(en)PtU]$_4$Zn$_4$}$^{8+}$ cation in **5** from the present work and the cone-{(en)PtU]$_4$Zn}$^{2+}$ cation in compound **2b** from ref.[6]

The opening of the cavity, as estimated from the separation between two opposite C^5 atoms of the uracil nucleobases, measures just ca. 3.5 Å in **5** compared to ca. 8.2 Å in cone-{(en)PtU]$_4$Zn(H$_2$O)}$^{2+}$.[6] Since the metal ions bound to the exocyclic oxygen atoms prevent a 1,3-alternate → cone conversion, this situation does not change with time.

Experimental Section

Materials: enPtCl$_2$,[14] (en)PtCl(UH-N^1)]Cl,[15] and [(en)Pt(UH-N^1,N^3)]$_4$(NO$_3$)$_4$ (**1**)[7b] were prepared from K$_2$PtCl$_4$, ethylenediamine, and uracil (Sigma) as appropriate. Sodium *p*-toluenesulfonate (TS) was purchased from Merck; sodium 3-[tris(methylsilyl)]-1-propanesulfonate (TSP), sodium 1-propanesulfonate (PS), sodium ethylsulfonate (ES), and sodium methylsulfonate (MS) from Aldrich.

Synthesis of [(en)Pt(U-N^1,N^3,O^2,O^4)CuCl(H$_2$O)$_2$]$_4$Cl$_4$ · *n* H$_2$O (2a): A freshly prepared solution of **1** (150 mg) in 10 mL of H$_2$O was passed through an anion-exchange column in its Cl^- form. The eluate was concentrated to a volume of 1 mL in a stream of dry N$_2$ and then CuCl$_2$ (30 mg) in 1 mL of H$_2$O was added. An immediate color change from pale-green to brown-green was observed. After storage of the solution for a week, brown-green crystals of **2** could be collected. Yield 46 mg (20%). − C$_{24}$H$_{80}$Cl$_8$Cu$_4$N$_{16}$O$_{28}$Pt$_4$ (2359.13): calcd. C 12.22, H 3.42, Cl 12.02, N 9.50; found C 11.8, H 3.3, Cl 11.6, N 9.2.

Synthesis of [(en)Pt(U-N^1,N^3,O^2,O^4)M(H$_2$O)$_3$]$_4$(SO$_4$)$_4$ · *n* H$_2$O (2b, 3, 4, 5): The general procedure used for the synthesis of the complexes was as follows: a freshly prepared solution of **1** (0.059 mmol) in 3 mL of H$_2$O (pH = 4.9) was mixed with a solution of the metal salt (0.24 mmol) in 1 mL of H$_2$O. Following the addition of the metal salt, the pH value of the respective solutions dropped to 2.5−3 and some turbidity appeared, which was removed by centrifugation. Storage of the resulting solutions (**2a**, green; **3**, purple; **4**, green; **5**, colorless) led to the deposition of crystalline precipitates of the resulting complexes within one day. − **2a:** green, yield 50 mg (34%). − C$_{24}$H$_{80}$Cu$_4$N$_{16}$O$_{44}$Pt$_4$S$_4$ (2459.75): calcd. C 11.72, H 3.28, N 9.11; found C 11.9, H 3.3, N 9.3. − **3:** purple, yield 37 mg (25%). − C$_{24}$H$_{80}$Co$_4$N$_{16}$O$_{44}$Pt$_4$S$_4$ (2441.19): calcd. C 11.81, H 3.30, N 9.18; found C 11.9, H 3.0, N 9.7. − **4:** yellow-green, yield 50 mg (34%). − C$_{24}$H$_{80}$N$_{16}$Ni$_4$O$_{44}$Pt$_4$S$_4$ (2440.38): C 11.81, H 3.30, N 9.18; found C 11.8, H 3.1, N 9.3. − **5:** colorless, yield 50 mg (34%). − C$_{24}$H$_{80}$N$_{16}$O$_{44}$Pt$_4$S$_4$Zn$_4$ (2467.11): calcd. C 11.68, H 3.27, N 9.08; found C 11.9, H 3.1, N 9.6. − ^{1}H NMR (200 MHz, D$_2$O, pH* = 6.5): δ = 2.75 (s, 4 H, CH$_2$), 5.67 (d, *J* = 7.0 Hz, 1 H, 5-H), 7.69 (d, *J* = 7.0 Hz, 1 H, 6-H).

Instrumentation: IR spectra (in KBr pellets) were recorded with a Bruker IFs 113v FT-IR spectrometer. − ^{1}H-NMR spectra were recorded with a Bruker AC 200 FT NMR spectrometer in D$_2$O solution using NMe_4^+ (δ = 3.18 relative to TMS) as an internal standard.

NMR Titrations: Stock solutions ($1\cdot10^{-2}$ M) of the 1,3-alternate conformer of **1** were prepared in D$_2$O. To a 0.40-mL sample of this solution in a 5-mm NMR tube at pH* = 6.5 was added 4 equiv. of 0.2 M ZnSO$_4$ solution, followed by increasing aliquots of (0.4 M

or 4 M) solutions of NaX (X = TSP, TS, PS, ES, MS) (pH* indicates uncorrected pH meter reading). ^{1}H-NMR spectra were recorded for ten different mixtures and the shifts of the H^5 and H^6 resonances of uracil were analyzed as described previously[6] in order to evaluate the association constants.

X-ray Crystallography: Intensity data for **2a**, **2b**, and **5** were collected with an Enraf−Nonius KappaCCD diffractometer[16] (Mo-K_α, λ = 0.71069 Å, graphite monochromator) with sample-to-detector distances of 30.7, 32.7, and 25.7 mm, respectively. The whole sphere of reciprocal space was covered by measurement of 360 frames rotating about ω in steps of 1° with scan times of 13, 230, and 40 s per frame. Preliminary orientation matrices and unit cell parameters were obtained from the peaks of the first ten frames and were then refined using the whole data set. Frames were integrated and corrected for Lorentz and polarization effects using DENZO.[17] The scaling and the global refinement of crystal parameters were performed by SCALEPACK.[17] Reflections that were partly measured on previous and following frames were used to mutually scale these frames. Merging of redundant reflections partly eliminates absorption effects and, if present, also takes crystal decay into account.

The structures were solved by standard Patterson methods[18] and refined by full-matrix least squares based on F^2 using the SHELXTL-PLUS[19] and SHELXL-93 programs.[20] The atom scattering factors were taken as those given in the SHELXTL-PLUS program. Transmission factors were calculated using SHELXL-97.[21] Hydrogen atoms were placed in calculated positions and refined with a common isotropic temperature factor. In the case of **2a**, only two of the positions of the chloride counterions were found to be fully occupied. For the remaining two anions, seven positions were assumed, as represented by the seven strongest peaks showing a reasonable H-bonding pattern. The residual peaks were assigned to positions fully or partly occupied by water molecules. All non-hydrogen atoms were refined anisotropically, with the exception of a few disordered chloride anions and water molecules. In **2b**, only the heavy atoms, the oxygens of one sulfate, and seven of the eleven water molecules could be anisotropically refined because of the poor reflections-to-parameters ratio. In compound **5**, part of the water molecules and the disorder shown by the oxygens of two sulfate counterions could only be calculated isotropically. Crystal data and data collection parameters are summarized in Table 2.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-101632, -127613, and -127614. Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses of Chiral, Intramolecularly Coordinated Aluminum Bromides

Jens Müller,*[a] Ralf Schröder,[b] and Ruimin Wang[b]

Keywords: Aluminum / Ab initio calculations / Isomers / Intramolecular donor–acceptor systems

Three aluminum compounds Ar*$AlBr_2$ (**1**), Ar*AlBr*t*Bu (**2**), and Ar*$_2$AlBr (**3**), incorporating the chiral ligand Ar* = 2-[1-(*S*)-$Me_2NCH(Me)]C_6H_4$, have been synthesized by salt metathesis reactions and have been characterized by multinuclear NMR (^{1}H, ^{13}C, and ^{27}Al), mass spectrometry, and elemental analysis. The molecular structure of compound **3** has been determined by a single-crystal X-ray analysis (space group $P2_12_12_1$). Alane **2** exists as a temperature-independent equilibrium mixture of two diastereomers in solution (ratio 45:55); results of NOE experiments on **2** are discussed. Only one isomer was found for compound **3** in solution and its dynamic behavior has been investigated by variable-temperature NMR methods; a ΔH of 56.6(4) kJ mol^{-1} and a ΔS of –0.79(1) J K^{-1}mol^{-1} were deduced from band-shape analysis of the ^{1}H-NMR signals of the *N*-bound methyl groups.

Introduction

The first organometallic compound with an intramolecular donor group was described by Bähr and Müller in 1955.[1] The authors synthesized the two intramolecularly coordinated alanes $[EtO(CH_2)_4]AlEt_2$ and $[Et_2N(CH_2)_3]AlEt_2$, which contain five- and six-membered rings, respectively. According to cryoscopic measurements, these air- and moisture-sensitive substances are monomeric in benzene solution.[1] Since this investigation, many more intramolecularly coordinated organometallic compounds of the Group 13 elements have been synthesized.[2] One of the driving forces behind these investigations is the need for volatile, non-pyrophoric precursors for chemical vapor deposition (CVD). Recently, it has been shown that Group 13 nitrides, which are promising materials for new microelectronic and optoelectronic devices,[3] can be grown by CVD of intramolecularly coordinated Group 13 azides.[4]

When we started our investigations of aluminum compounds, intramolecularly coordinated with the commonly used 2-[(dimethylamino)methyl]phenyl ligand, the diethyl derivative $[2\text{-}(Me_2NCH_2)C_6H_4]AlEt_2$[5] was the only known example. We investigated the tetracoordinated alanes $[2\text{-}(Me_2NCH_2)C_6H_4]AlRR'$ [R/R′ = Me/Me, Cl/Cl, Cl/Me, Cl/*t*Bu, and Cl/$C(SiMe_3)_3$] and the pentacoordinated alanes $[2\text{-}(Me_2NCH_2)C_6H_4]_2AlCl$, $[2\text{-}(Me_2NCH_2)C_6H_4]_2AlMe$, and $[2\text{-}(Me_2NCH_2)C_6H_4]AlCl_2(L)$ (L = H_2N*i*Pr, thf).[6] In the same year, Cowley et al. published the structures of the bromide $[2\text{-}(Me_2NCH_2)C_6H_4]AlBr_2$ and the hydride $[2\text{-}(Me_2NCH_2)C_6H_4]AlH_2$, which is a dimer in the solid state.[7]

A trigonal-bipyramidal complex with two bidentate ligands and one monodentate ligand with an idealized C_2-symmetry exists as Λ and Δ enantiomers (Figure 1). In the case of the alanes $[2\text{-}(Me_2NCH_2)C_6H_4]_2AlCl$ and $[2\text{-}(Me_2NCH_2)C_6H_4]_2AlMe$, we found a rapid equilibration between the Δ and Λ isomers with respect to the ^{1}H-NMR time scale.[6] In order to ascertain whether a cleavage of the Al−N donor bonds is involved in this process, we synthesized some novel aluminum compounds intramolecularly coordinated through a chiral, one-armed phenyl ligand, namely 2-[1-(*S*)-(dimethylamino)ethyl]phenyl. The main advantage of this chiral ligand is illustrated by Figure 2. If we assume a fast envelope inversion of the five-membered ring in compound **A**, this species exhibits C_s point-group symmetry, i.e. the two *N*-bound methyl groups are equivalent and thus give rise to one resonance in the ^{1}H- and ^{13}C-NMR spectra. Similar spectra are obtained for compound **A** when the N donor atom is not coordinated to the acceptor M. Compound **B**, which incorporates the chiral phenyl ligand, shows no symmetry (C_1 point group) and therefore two resonances for the NMe_2 group are to be expected. However, if the N donor atom is not coordinated to the acceptor M, pyramidal inversion at the N atom renders the attached methyl groups equivalent on the NMR time scale, thus resulting in only one resonance. Consequently, the chiral, one-armed phenyl ligand is an ideal substituent for probing whether the amino group is coordinated to the acceptor M. This chiral ligand has previously been used in main group chemistry for similar purposes.[8]

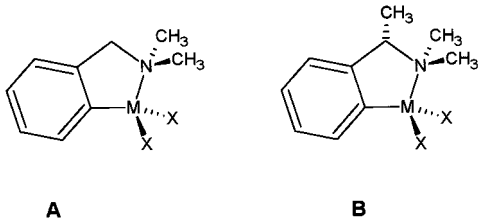

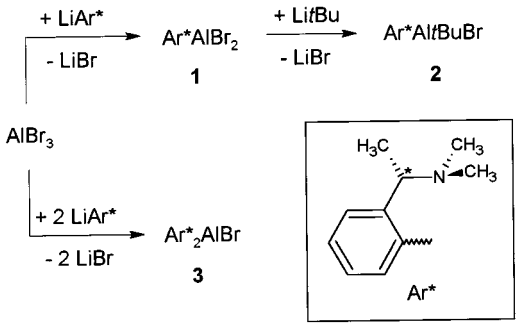

Figure 2. Complexes incorporating the achiral (**A**) and the chiral (**B**), one-armed phenyl ligand

In this paper, we report on the syntheses and properties of three chiral, intramolecularly coordinated alanes.

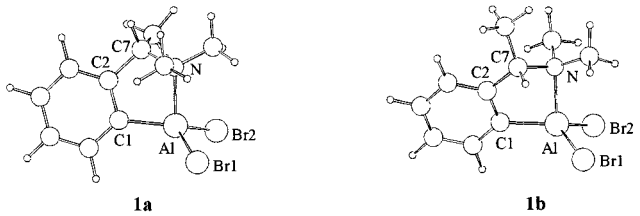
Results and Discussion

The intramolecularly coordinated alanes **1**, **2**, and **3**, which are accessible in high yields by salt metathesis reactions (Scheme 1), have been characterized by multinuclear NMR, mass spectrometry, and elemental analyses.

Scheme 1. Syntheses of compounds **1**, **2**, and **3**

It is known that the chemical shifts of ^{27}Al nuclei are very sensitive to the number of coordinated ligands.[9] Thus, the tetracoordination of the Al atom in compound **1** can be deduced from the ^{27}Al-NMR shift of $\delta = 129$; a similar value of $\delta = 127$ has been found for the dichloride [2-(Me_2NCH_2)C_6H_4]$AlCl_2$ incorporating the achiral, one-armed phenyl ligand.[6][10] The ^{1}H- and ^{13}C-NMR spectra of **1** each show one set of signals, in accordance with a C_1-symmetrical species having an intramolecularly coordinated dimethylamino group.

Five-membered rings, such as that in **1**, usually exist in an envelope conformation with the nitrogen atom displaced out of the AlC_3 plane. In the case of **1**, this could result in two diastereomers depending on the bending direction of the nitrogen atom. We were interested in assessing whether an envelope conformation could be "frozen" and therefore we examined compound **1** by variable-temperature ^{1}H-NMR spectroscopy. Between +80 and −80°C, the NMR spectra show only one set of signals for the chiral chelating ligand; coalescence was not observed. This means that either the inversion of the five-membered ring is fast at −80°C with respect to the NMR time scale, or that this inversion is slow but one isomer is very much favored over the other. In order to distinguish between these two alternatives, we investigated the structure of **1** by ab initio methods. Figure 3 shows the optimized geometries of the two diastereomers at the HF/6-31G(d) level of theory.[11]



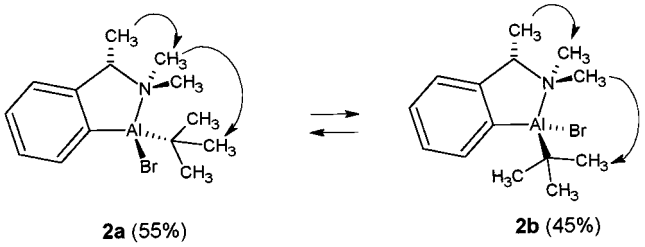


Figure 3. Calculated structures of compound **1** [HF/6-31G(d) level]; selected bond lengths [pm], angles and torsion angles [°] for **1a** (**1b**): Al−N 205.9 (205.2), Al−Br1 228.6 (229.2), Al−Br2 229.2 (228.3), Al−C1 195.6 (195.4); N−Al−C1 86.7 (86.8), N−Al−Br1 107.7 (106.2), N−Al−Br2 108.1 (107.8), C1−Al−Br1 119.6 (116.2), C1−Al−Br2 118.4 (121.6), Br1−Al−Br2 111.9 (113.0); Al−C1−C2−C7 5.8 (−3.3), C1−C2−C7−N −30.2 (−32.8)

In isomer **1a**, the H atom bound to the chiral carbon center is staggered with respect to the Me_2N group, whereas in **1b** the methyl group of the chiral carbon atom occupies this position. The difference between the calculated Gibbs free energies of **1a** and **1b** at −80°C is only 1.1 kJ/mol, which corresponds to an equilibrium mixture of **1a**/**1b** in the ratio 2:1.[12][13] Of course, too much importance should not be attached to the absolute magnitude of the ΔG value; the calculation merely shows that the two isomers **1a** and **1b** are very similar in energy. This means that the envelope inversion in **1** is not frozen at −80°C in solution, otherwise two sets of signals would be seen in the ^{1}H-NMR spectrum.

One bromide ligand in compound **1** can readily be substituted by a *tert*-butyl group to form the alane **2** in 84% isolated yield (Scheme 1). The tetracoordination of the Al atom in **2** is evident from the ^{27}Al-NMR shift of $\delta = 149$; a similar value has been found for [2-(Me_2NCH_2)C_6H_4]-Al*t*Bu ($\delta = 145$).[6] Compound **2** consists of the two isomers **2a** and **2b** (Scheme 2), as revealed by two complete sets of signals in the ^{1}H- and ^{13}C-NMR spectra.

Scheme 2. Equilibrium between the two isomers **2a** and **2b**; arrows correspond to intense signals in the NOE experiment (see text for details)

Within experimental error, the ratio of 55:45 found for **2a**/**2b** at ambient temperature does not change over the temperature range from −80 to +80°C, which means that the transformation between **2a** and **2b** is thermally neutral ($\Delta H \approx 0$ kJ/mol). That the two species do indeed exist in equilibrium was proven by NMR methods. We did not observe coalescence of any of the signals in the ^{1}H-NMR spectra of compounds **2a**/**2b** over the temperature range from +80 to −80°C, but an NOE experiment clearly showed that

an exchange between the two isomers occurs. If one nitrogen-bound methyl group of a particular isomer, e.g. **2a**, is irradiated, there is a magnetization transfer to the two nitrogen-bound methyl groups of **2b**. This can be rationalized by assuming a cleavage of the Al−N bond, followed by a 180° rotation about the Al−C bond and re-formation of the Al−N bond. Furthermore, when the N atom is not coordinated to the Al center, a rotation about the N−C* bond, N inversion, and re-formation of the Al−N bond result in an exchange of the two *N*-bound methyl groups of one particular isomer. Because of the dynamic behavior, the signals detected in the NOE experiment are caused by magnetization transfer and NOE. However, an unambiguous assignment of the two sets of signals to the respective isomer is possible; e.g. for both isomers there is an intense NOE from the methyl group bound to the chiral carbon to one nitrogen-bound methyl group, but the *tert*-butyl ligand shows an intense NOE to this NMe group in isomer **2a** and to the other NMe group in isomer **2b** (see arrows in Scheme 2).

In order to study the dynamic behavior of compound **2** in detail, we conducted 2D EXSY experiments, which we envisaged as possibly being an appropriate NMR technique.[14] Unfortunately, however, the intensities of the cross-peaks were too low for the desired evaluation (see Experimental Section).

The alane **3** was obtained in 72% yield as a pure substance (Scheme 2), which was found to crystallize in the space group $P2_12_12_1$ (Figure 4).

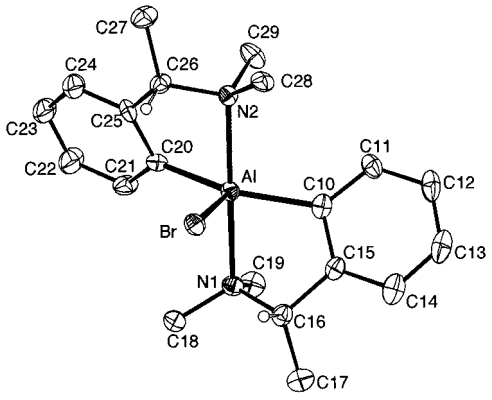

Figure 4. Molecular structure of **3** (PLATON,[20] thermal ellipsoids drawn at a 30% probability level); selected bond lengths [pm], angles and torsion angles [°]: Al−N1 217.9(7), Al−N2 216.8(7), Al−Br 239.6(2), Al−C10 202.6(8), C10−C15 140(1), C15−C16 154(1), C16−N1 150(1), C16−C17 154(1), Al−C20 199.2(8), C20−C25 142(1), C25−C26 152(1), C26−N2 150.0(9), C26−C27 1.52(1); N1−Al−N2 177.0(3), N1−Al−Br 91.7(2), N1−Al−C10 79.7(3), Al−N1−C16 103.8(5), N2−Al−Br 91.2(2), N2−Al−C20 80.0(3), Al−N2−C26 102.7(4), Br−Al−C10 105.3(2), Br−Al−C20 107.5(2), C10−Al−C20 147.2(3), C18−N1−C19 108.5(6), C28−N2−C29 108.5(6); Br−Al−N1−C18 55.5(5), Br−Al−N1−C19 177.7(4), Br−Al−N2−C28 52.9(5), Br−Al−N2−C29 175.6(5), Al−C10−C15−C16 10.8(8), Al−C20−C25−C26 5.5(8)

The aluminum atom in **3** is distorted trigonal-bipyramidally coordinated, with N1 and N2 in axial positions and C10, C20, and Br in the equatorial plane. The N1−Al−N2 axis is almost linear [N1−Al−N2 = 177.0(3)°] and the sum of the three angles in the equatorial plane is 360°. The deviation from ideal trigonal-bipyramidal geometry is manifested in an angle of 100.3(2)° between the least-squares plane comprising N1, Al, N2, and Br and the equatorial plane. Similar angles have been found in [2-(Me_2NCH_2)-C_6H_4]$_2$AlMe (101°)[6] and [2-(Me_2NCH_2)C_6H_4]$_2$Al(N_3) (101°)[4a] incorporating the achiral one-armed phenyl ligand. Clearly, these deviations from ideal trigonal-bypyramidal geometry can be attributed to the steric requirements of the two chelating ligands. Al−N donor bond lengths are known to vary over a wide range. The Al−N bond lengths of 217.9(7) pm for Al−N1 and 216.8(7) pm for Al−N2 in compound **3** are comparable with those found in five-fold coordinated alanes having similar chelating ligands and one electronegative substituent, e.g. 216.8(5) and 220.9(4) pm in [2-(Me_2NCH_2)C_6H_4]$_2$Al(N_3), 218.9(2) and 221.0(2) pm in [$Me_2N(CH_2)_3$]$_2$AlCl, and 216.7(2) and 219.9(2) pm in [$Me_2N(CH_2)_3$]$_2$Al(N_3).[4a]

As mentioned in the introduction, a trigonal-bipyramidal complex with two bidentate ligands and one monodentate ligand with an idealized C_2 symmetry exists as Λ and Δ enantiomers (Scheme 1). In the case of compound **3**, each of the chelating ligands incorporates an (*S*)-configured carbon atom, hence the Λ and Δ forms constitute a pair of diastereomers. Furthermore, five-membered rings such as those in **3** exist in envelope conformations with the nitrogen atoms being the "flap" atoms; e.g. N1 and N2 in **3** are displaced out of the respective AlC_3 planes by 79 and 81 pm. Because compound **3** contains two fused five-membered rings, three isomers for each of the Λ and Δ diastereomers are possible, depending on the "bending directions" of the nitrogen "tips". In the case of compound **3**, we found the Δ isomer with both N atoms bent in the same direction, giving an idealized C_2-symmetrical molecule.

The alane **3** shows a resonance at δ = 95 in its ^{27}Al-NMR spectrum, which is in the typical range for five-fold coordinated aluminum;[9] a similar chemical shift has been found for [2-(Me_2NCH_2)C_6H_4]$_2$AlCl (δ = 96).[6] The ^{27}Al resonance is unchanged over the temperature range from −40 to +80°C, which means that, time-averaged, the aluminum remains pentacoordinated. However, at high temperatures, the ^{1}H-NMR spectra show only one set of signals for the two chelating ligands with only *one* singlet for the four *N*-bound methyl groups. With decreasing temperature, the resonance of the NMe_2 groups get broader and finally resolves into *two* sharp singlets at −80°C. These findings are in accord with a C_2-symmetrical compound and we assume that the geometry of the molecule in solution corresponds to that found in the crystalline state. The coalescence of the NMe_2 signals indicates that the two methyl groups of each amino group undergo rapid positional interchange with respect to the NMR time scale. This can be rationalized if one assumes that the NMe_2 group is detached from the Al atom, undergoes a subsequent 180° rotation about the C* −N bond, then N inversion, and finally a re-formation of the N−Al donor bond. From band-shape analyses of the ^{1}H-NMR signals of the NMe_2 groups, we deduced a ΔH of

56.6(4) kJ mol^{-1} and a ΔS of $-0.79(1)$ J K^{-1} mol^{-1} for this dynamic process.[15]

As mentioned in the introduction, the chiral one-armed phenyl ligand has previously been used in main group chemistry, in particular for the Group 13 elements indium[8d] and thallium[8c] by van Koten et al. They investigated Ar*InMe$_2$, Ar*$_2$InCl, Ar*TlCl$_2$, and Ar*$_2$TlCl {Ar* = 2-[1-(*S*)-Me$_2$NCH(Me)]C$_6$H$_4$} and found that in all cases the N atom is coordinated to the In or Tl atom at low temperatures in solution; for all species, a process involving cleavage and re-formation of the nitrogen−element donor bond was found by NMR methods. As in the case of the alane **3**, for the pentacoordinated species Ar*$_2$InCl and Ar*$_2$TlCl only one diastereomer was detected by NMR spectroscopy at low temperatures.

Experimental Section

General Remarks: All procedures were carried out under a dry nitrogen atmosphere using standard Schlenk techniques. Solvents were dried by standard procedures, distilled, and stored under nitrogen over molecular sieves (4 Å). $AlBr_3$ (> 98%, Aldrich) was sublimed prior to use; 2-[(*S*)-1-(dimethylamino)ethyl]phenyllithium was synthesized as described in the literature.[16] *t*BuLi (1.7 M in pentane) was purchased from Aldrich. − NMR: Varian Unity 500 (ambient temp.; 499.843, 130.195, and 125.639 MHz for ^{1}H, ^{27}Al, and ^{13}C, respectively); spectra were calibrated against residual protons of the deuterated solvents. ^{1}H- and ^{13}C-NMR chemical shifts are reported relative to TMS and ^{27}Al-NMR shifts relative to the external standard [Al(acac)$_3$] in C$_6$D$_6$. As a result of the electric quadrupole moment of the ^{27}Al nucleus, the carbon atoms bound to aluminum could not be detected in the ^{13}C-NMR measurements. The assignments of the ^{1}H- and ^{13}C-NMR signals were made either with the aid of ^{1}H/^{13}C-HMQC and NOE experiments or according to the literature.[6] The 2D EXSY ^{1}H-NMR experiments on compound **2** were performed with a Bruker DRX 500 instrument (5 mm ^{1}H probe head) over the temperature range 20−45°C. The NOESYTP pulse program, with mixing times between 0.4 and 1.2 s, was used. − Elemental analyses (C, H, N): Carlo Erba elemental analyzer, Model 1106. − MS: Finnigan MAT 95.

Band-shape analyses of nine ^{1}H-NMR spectra (−20 to +80°C) of compound **3** were performed with the program *DNMR − Sim (Version 1.0)*.[15a] The ΔH and ΔS values were calculated using the equation $\ln(k/T) = -\Delta H/RT + \Delta S/R + \ln(k_B/h)$.[15b] The standard error limits quoted for ΔH and ΔS are based on the linear regression.

Dibromo{2-[(*S*)-1-(dimethylamino)ethyl]phenyl}aluminum (1): 3.65 g (23.5 mmol) of 2-[(*S*)-1-(dimethylamino)ethyl]phenyllithium was added to a solution of 6.28 g (23.5 mmol) of $AlBr_3$ in 150 mL of toluene at −78°C. After 30 min, the cooling bath was removed and the reaction mixture was stirred at ambient temperature for 16 h. The mixture was then filtered and the solvent was removed under high vacuum. Sublimation (100°C; ca. 10^{-3} mbar) yielded 6.30 g (80%) of compound **1**. − ^{1}H NMR: δ = 0.94 (d, *J* = 6.9 Hz, 3 H, CHC*H*$_3$), 1.84 (s, 3 H, NCH$_3$), 2.05 (s, 3 H, NCH$_3$), 3.48 (q, *J* = 6.9 Hz, 1 H, C*H*CH$_3$), 6.76 (m, 1 H, 3-H), 7.08/7.14 (2 m, 2 H, 4-,5-H), 7.60 (m, 1 H, 6-H). − ^{13}C NMR: δ = 14.48 (s, CH*C*H$_3$), 39.19 (s, NCH$_3$), 45.33 (s, NCH$_3$), 67.71 (s, *C*HCH$_3$), 124.17/127.80/129.72 (3 s, 3 C, C-3/4/5), 136.32 (s, C-6), 148.31 (s, C-2). − ^{27}Al NMR: δ = 129 ($h_{1/2}$ = 1800 Hz). − HRMS: *m*/*z*: calcd. for [M$^+$] 334.9288; found 334.9289. − MS: *m*/*z* (%) = 335 (13) [M$^+$], 320 (21) [M$^+$ − CH$_3$], 230 (100) [M$^+$ − C$_8$H$_9$], 134 (48) [C$_9$H$_{12}$N$^+$], 105 (20) [C$_8$H$_9^+$], 72 (58) [C$_4$H$_{10}$N$^+$]. − C$_{10}$H$_{14}$AlBr$_2$N (335.02): calcd. C 35.85, H 4.21, N 4.18; found C 35.13, H 4.20, N 4.04.

Bromo(*tert*-butyl){2-[(*S*)-1-(dimethylamino)ethyl]phenyl}aluminum (2): A 1.7 M solution of *t*BuLi in pentane (8.1 mL, 13.8 mmol) was slowly added to a solution of 4.61 g (13.8 mmol) of **1** in 100 mL of toluene at −78°C. After 15 min, the cooling bath was removed and the reaction mixture was stirred at ambient temperature for 16 h. The mixture was then filtered and the solvent was removed under high vacuum. Sublimation (115°C, ca. 10^{-3} mbar) yielded 3.61 g (84%) of a 55:45 mixture of two isomers (**2a** and **2b**). − ^{1}H NMR: Isomer **2a** (55%): δ = 0.77 (d, *J* = 6.8 Hz, 3 H, CHC*H*$_3$), 1.22 (s, 9 H, C$_4$H$_9$), 1.53 [s, 3 H, N(CH$_3$)$_2$], 2.19 [s, 3 H, N(CH$_3$)$_2$], 3.96 (q, *J* = 6.8 Hz, 1 H, C*H*CH$_3$), 6.76 (m, 1 H, 3-H), 7.10 (m, 2 H, 4-,5-H), 7.65 (m, 1 H, 6-H); isomer **2b** (45%): δ = 1.04 (d, *J* = 6.8 Hz, 3 H, CHC*H*$_3$), 1.16 (s, 9 H, C$_4$H$_9$), 1.88 [s, 3 H, N(CH$_3$)$_2$], 1.96 [s, 3 H, N(CH$_3$)$_2$], 3.31 (q, *J* = 6.8 Hz, 1 H, C*H*CH$_3$), 6.74 (m, 1 H, 3-H), 7.10 (m, 2 H, 4-,5-H), 7.68 (m, 1 H, 6-H). − ^{13}C NMR: Isomer **2a** (55%): δ = 8.62 (s, 1 C, CH*C*H$_3$), 29.97 (s, 3 C, C$_4$H$_9$), 36.33 [s, 1 C, N(CH$_3$)$_2$], 43.92 [s, 1 C, N(CH$_3$)$_2$], 65.50 (s, 1 C, *C*HCH$_3$), 123.69 (s, 1 C, C-3), 127.18/128.71 (2 s, 2 C, C-4/5), 136.59 (s, 1 C, C-6), 147.94 (s, 1 C, C-2); isomer **2b** (45%): δ = 16.26 (s, 1 C, CH*C*H$_3$), 29.58 (s, 3 C, C$_4$H$_9$), 41.12 [s, 1 C, N(CH$_3$)$_2$], 44.90 [s, 1 C, N(CH$_3$)$_2$], 70.20 (s, 1 C, *C*HCH$_3$), 123.69 (s, 1 C, C-3), 127.32/128.71 (2 s, 2 C, C-4/5), 137.26 (s, 1 C, C-6), 149.53 (s, 1 C, C-2). − ^{27}Al NMR: δ = 149 ($h_{1/2}$ = 4400 Hz). − MS: *m*/*z* (%) = 311 (0.3) [M$^+$], 254 (100) [M$^+$ − C$_4$H$_9$], 211 (29) [C$_8$H$_9$AlBr$^+$], 134 (81) [C$_9$H$_{12}$N$^+$], 105 (15) [C$_8$H$_9^+$], 72 (19) [C$_4$H$_{10}$N$^+$]. − C$_{14}$H$_{23}$AlBrN (312.23): calcd. C 53.86, H 7.43, N 4.49; found C 52.72, H 7.48, N 4.37.

Bromobis{2-[(*S*)-1-(dimethylamino)ethyl]phenyl}aluminum (3): 2.18 g (14.0 mmol) of 2-[(*S*)-1-(dimethylamino)ethyl]phenyllithium was added to 1.87 g (7.0 mmol) of $AlBr_3$ in 40 mL of toluene at −78°C. After 10 min, the cooling bath was removed and the mixture was stirred for 64 h. All volatile components were then removed under high vacuum and the residue was extracted with 120 mL of hexane in a soxhlet apparatus. Removal of the hexane under high vacuum afforded 2.05 g (72%) of compound **3**. Single crystals of compound **3** were obtained from the hexane solution in the soxhlet apparatus. − ^{1}H NMR (60°C): δ = 1.12 (d, *J* = 6.4 Hz, 6 H, CHC*H*$_3$), 2.35 [br. s, 12 H, N(CH$_3$)$_2$], 4.70 (br. s, 2 H, C*H*CH$_3$), 7.02 (m, 2 H, 3-H), 7.20 (m, 4 H, 4-,5-H), 7.80 (m, 2 H, 6−H); (−60°C): δ = 0.82 (d, *J* = 6.7 Hz, 6 H, CHC*H*$_3$), 1.91 [s, 6 H, N(CH$_3$)(C*H*$_3$)], 2.45 [s, 6 H, N(C*H*$_3$)(CH$_3$)], 4.81 (q, 2 H, C*H*CH$_3$), 7.02 (m, 2 H, 3-H), 7.26 (m, 4 H, 4-,5-H), 7.79 (m, 2 H, 6-H); $T_{coal.}$: 22°C [Δν = 270 Hz, N(CH$_3$)$_2$]. − ^{13}C NMR: δ = 9.19 (br. s, 2 C, CH*C*H$_3$), 37.12 [br. s, 2 C, N(CH$_3$)$_2$], 43.43 [br. s, 2 C, N(CH$_3$)$_2$], 63.27 (s, 1 C, *C*HCH$_3$), 124.77/125.73/127.76 (3 s, 6 C, C-3/4/5), 147.34 (br. s, 2 C, C-6), 151.81 (s, 2 C, C-2). − ^{27}Al NMR: δ = 95 ($h_{1/2}$ = 5500 Hz). − MS: *m*/*z* (%) = 387 (19) [M$^+$ − CH$_3$], 323 (15) [M$^+$ − Br], 254 (30) [M$^+$ − C$_{10}$H$_{14}$N], 134 (100) [C$_9$H$_{12}$N$^+$], 105 (27) [C$_8$H$_9^+$], 72 (64) [C$_4$H$_{10}$N$^+$]. − C$_{20}$H$_{28}$AlBrN$_2$ (403.34): calcd. C 59.56, H 7.00, N 6.95; found C 59.20, H 7.09, N 7.00.

Ab initio Calculations: The GAUSSIAN-94 package,[11] run on a cluster of workstations (Rechenzentrum der RWTH Aachen), was employed for all ab initio calculations. The vibrational analyses of compounds **1a** and **1b** were performed at the HF/6-31G(d) level. The total energies E_h [HF/6-31G(d) in Hartrees] and the ZPVE (in kJ mol^{-1}; in parentheses) are as follows: **1a**: −5823.185119 (634.14); **1b**: −5823.184664 (634.27).

Single Crystal X-ray Structure Determination of 3: C$_{20}$H$_{28}$AlBrN$_2$, Enraf−Nonius CAD4 diffractometer; Mo-K_α radiation, λ =

0.71073 Å, graphite monochromator; data collection by ω scans at 243 K; colorless crystal, 0.20 × 0.28 × 0.36 mm, orthorhombic space group $P2_12_12_1$ (No. 19); a = 9.452(2), b = 10.937(3), c = 19.225(4) Å, U = 1987(2) Å^3, Z = 4, ρ_{calcd} = 1.35 g/cm^3, μ(Mo-K_α) = 20.95 cm^{-1}; 3924 reflections were collected in the scan range $2 < \theta < 25°$. After Lorentz and polarization corrections, an empirical absorption correction on the basis of azimuthal scans[17] (min. trans. 0.765, max. trans. 1.000) was applied prior to averaging symmetry related intensity data. 2752 independent observations with $I > \sigma(I)$ were used in the structure solution by direct methods;[18] refinement with the SDP program system[19] for 217 variables; all non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included as a riding model [C−H = 98 pm, U_{iso}(H) = 1.3 U_{iso}(C)]. R = 0.069, R_w = 0.057, $w^{-1} = \sigma^2(F_o)$, GoF = 1.134. Max. residual electron density: 0.786 eÅ^{-3}.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-127942. Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) +44 (0)1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We are grateful to the Deutsche Forschungsgemeinschaft and to the Fonds der Chemischen Industrie for generous financial support. We would also like to thank Prof. B. Wrackmeyer (Bayreuth) for performing the 2D EXSY experiments on compound **2**, and B. Rußbüldt for growing suitable crystals of **3**.

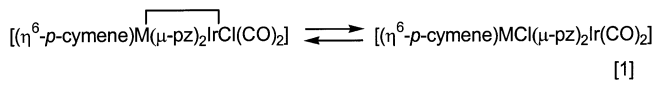
Different Reactivity Patterns in Dinuclear Pyrazolate-Bridged Complexes: Stereoselective Formation of Ketonic Carbonyls

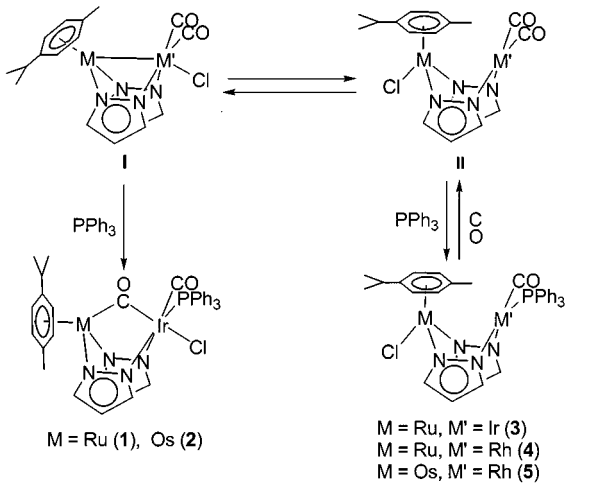


Daniel Carmona,*[a] Joaquina Ferrer,[a] José Miguel Arilla,[a] Josefa Reyes,[b] Fernando J. Lahoz,[a] Sergio Elipe,[a] Javier Modrego,[a] and Luis A. Oro*[a]

Keywords: Pyrazolato complexes / Dinuclear complexes / Ketonic carbonyls / Ruthenium / Osmium / Rhodium / Iridium

The metal–metal bonded dicarbonyl compounds [(η^6-*p*-cymene)M(μ-pz)$_2$IrCl(CO)$_2$](*M–Ir*) react stereospecifically with PPh_3 to yield an enantiomeric pair of ketonic carbonyl compounds [(η^6-*p*-cymene)M(μ-CO)(μ-pz)$_2$IrCl(CO)(PPh_3)] [M = Ru (**1**), Os (**2**)] in which the chloride ligand is *trans* to the bridging ketone group. However, the non metal–metal bonded isomers [(η^6-*p*-cymene)MCl(μ-pz)$_2$M′(CO)$_2$], under similar conditions, eliminate CO forming the monosubstitution products [(η^6-*p*-cymene)MCl(μ-pz)$_2$M′(CO)(PPh_3)] [M = Ru; M′ = Ir (**3**), Rh (**4**). M = Os; M′ = Rh (**5**)]. Removal of the chloride ligand in **1** affords [RuIr(η^6-*p*-cymene)(CO)$_2$(PPh_3)(pz)$_2$]BPh_4 as two isomers, **6a**,**b**. The related OsIr compound [(η^6-*p*-cymene)Os(μ-CO)(μ-pz)$_2$Ir(CO)(PPh_3)]BPh_4 (**9**) has been prepared from [(η^6-*p*-cymene)Os(CO)(μ-pz)$_2$Ir(CO)$_2$]BPh_4 (**7**) and PPh_3. Again, the OsRh tricarbonyl related to **7** [(η^6-*p*-cymene)Os(CO)(μ-pz)$_2$Rh(CO)$_2$]BPh_4 (**8**) reacts differently with PPh_3 affording [(η^6-*p*-cymene)Os(CO)(μ-pz)$_2$Rh(CO)(PPh_3)]BPh_4 (**10**).

Introduction



Heterodinuclear complexes are promising candidates for new stoichiometric and catalytic reactions.[1] Synergism between the metal centres is believed to be responsible for the improved activity of these heterodimetallic catalysts.[2][3] We have previously described an unusual isomerization equilibrium between heteronuclear pyrazolato complexes implying a chlorotropic shift and the reversible cleavage and formation of M−Ir bonds (M = Ru, Os)[4] according to Equation 1.

[1]

We now report on the reaction of the above-mentioned complexes towards triphenylphosphane. This reaction is remarkable because it allows the synthesis of new heterodimetallic complexes that contain bridging ketonic carbonyls supported by unusual *cis* frameworks.[5] Furthermore, according to the structural parameters (see below), the reaction implies the oxidation of the iridium from +1 to +3; from theoretical calculations,[6] the ketonic carbonyl group could be envisaged as a CO^{2-} ligand.

Scheme 1. Reaction of isomers **I** and **II** with PPh_3

Results and Discussion

Complexes **1** and **2** were prepared in good yield by treating the metal−metal bonded compounds **I** with triphenylphosphane in dichloromethane (Scheme 1). The IR spectra of **1** and **2** showed two strong absorptions in the 2000 and 1650 cm^{-1} regions attributable to ν(CO) stretching modes. The first one is assignable to a terminal metal carbonyl whereas the lower frequency band, in the range expected for organic carbonyls, is typical for ketonic carbonyl ligands.[5] The addition of phosphane caused the molecule to become chiral and, consequently, the ^1H NMR spectra of the complexes showed six resonances, each integrating for one proton, attributable to six inequivalent C−H pyrazolate protons, and two AB systems and two doublets assignable to the aromatic and isopropyl methyl

protons of the *p*−cymene ligand, respectively.[7] The molecular structure of complex **1** was determined by an X-ray crystallographic study (Figure 1). Complex **1** has the ruthenium and iridium atoms triply bridged by two *exo*-bidentate nitrogen-bonded pyrazolates and one CO ligand. The ruthenium atom completes its coordination sphere with an η^6-bonded *p*-cymene ring. The iridium displays a distorted octahedral geometry typical for Ir^{III} complexes and is also linked to a chloride, *trans* to the carbon atom of the bridging carbonyl [Cl−Ir−C(17) = 167.95(18)°], to a terminal carbonyl and to the triphenylphosphane ligand. The six-membered ring formed by the metals and the pyrazolate nitrogen atoms adopts the usual boat conformation.[8] The Ru···Ir distance observed, 3.4089(5) Å, excludes any significant metal−metal interaction. The structural parameters of the bridging CO ligand [C(17)−O(1) = 1.177(8) Å, Ru−C(17)−Ir = 109.8(3), Ru−C(17)−O(1) = 128.1(6), and Ir−C(17)−O(1) = 121.3(5)°] compare well with those found for ketonic carbonyls[5] suggesting an sp^2 hybridization for the carbon atom. The Ir−N distances, 2.095(6) and 2.069(6) Å, are in the range described for other Ir^{III} complexes with bridging pyrazolate ligands.[8] It is interesting to point out the high stereoselectivity of this reaction; only the enantiomeric pair in which the ketonic carbonyl is *trans* to the chlorine atom has been detected among the three possible geometrical isomers (in the other two the ketonic group would be *trans* to the terminal CO or to the PPh_3 ligand).

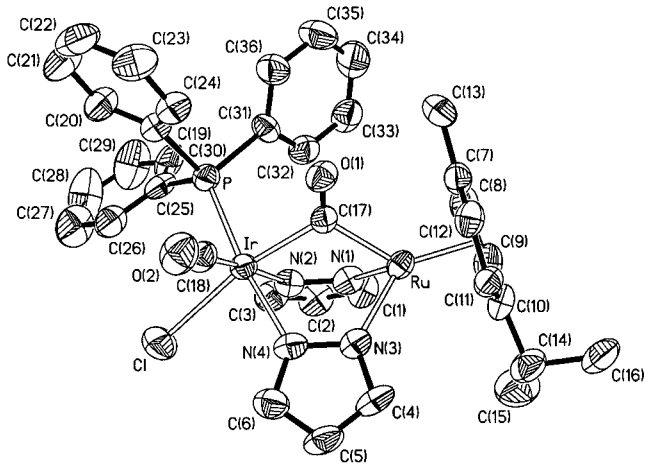

Figure 1. Molecular structure of **1** together with the atom numbering scheme used

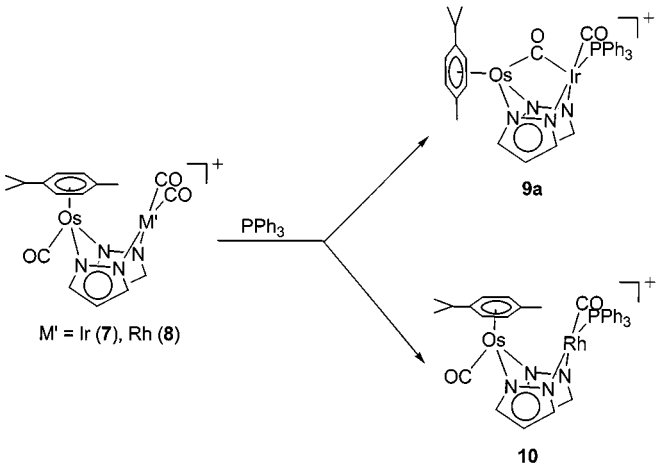

On the other hand, the non metal−metal bonded isomers **II** (Scheme 1) reacted with PPh_3 with apparent elimination of CO affording the monocarbonyls **3−5**. Their IR spectra showed a unique strong band at ca. 2000 cm^{-1} corresponding to the ν(CO) stretching mode. The substitution of one of the CO groups by the phosphane also caused the molecules to become chiral as revealed by their ^1H NMR spectra (see Experimental Section). As expected, the ^{31}P NMR spectra of the M−Rh complexes **4** and **5** consist of a doublet due to the coupling to ^{103}Rh, whereas a singlet at 1.8 ppm was observed for the Ru−Ir species **3**. The proposed structure for complexes **3−5** is that depicted in Scheme 1 (only one enantiomer has been drawn). The above reaction is reversible: treatment of compounds **3** and **5** with CO afforded the corresponding dicarbonyl species **II**. However, for the RuIr complex, the final isolated product was **1**, because of the chlorotropic equilibrium which operates between **I** and **II**. In fact, complex **3** has only been detected by IR and ^{31}P NMR spectroscopy in the reaction of the appropriate compound **II** with PPh_3.

The chloride ligand in **1** can easily be removed by treatment with $NaBPh_4$ in methanol, giving a 45:55 mixture of

Scheme 2. Reaction of compounds **7** and **8** with PPh_3

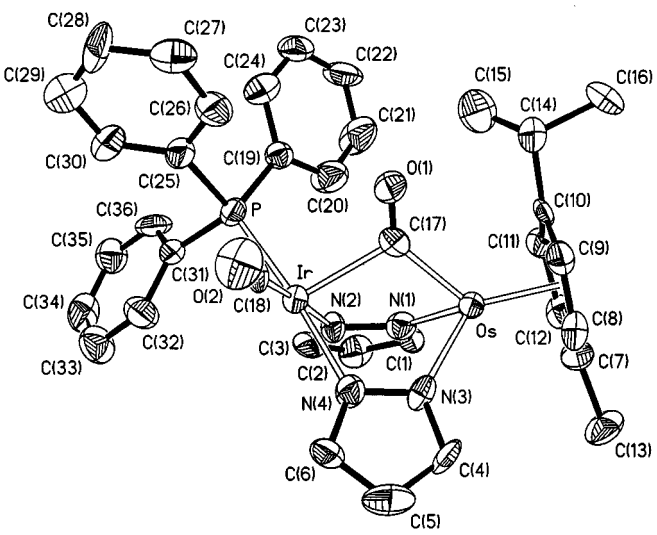

Figure 2. Molecular representation of the dinuclear cation of compound **9** with the atom labelling scheme

two isomers of stoichiometry $[RuIr(\eta^6\text{-}p\text{-cymene})(CO)_2(PPh_3)(pz)_2]BPh_4$ (**6a,b**). According to ^1H NMR spectroscopic data the minor isomer is chiral while the major is achiral. The IR spectrum of the mixture revealed the presence of both terminal (2035 cm^{-1}) and ketonic (1780 cm^{-1}) CO groups. In this context, it is interesting to mention that the related tricarbonyl compound $[(\eta^6\text{-}p\text{-cymene})Os(CO)(\mu\text{-}pz)_2Ir(CO)_2]BPh_4$ (**7**)[9] reacts with PPh_3 to yield, by CO elimination, the ketonic OsIr complex $[(\eta^6\text{-}p\text{-cymene})Os(\mu\text{-}CO)(\mu\text{-}pz)_2Ir(CO)(PPh_3)]BPh_4$ (**9**) whilst the homologous OsRh compound $[(\eta^6\text{-}p\text{-cymene})Os(CO)(\mu\text{-}pz)_2Rh(CO)_2]BPh_4$ (**8**)[9] yields, under similar conditions, the non-ketonic dicarbonyl compound $[(\eta^6\text{-}p\text{-cymene})Os(CO)(\mu\text{-}pz)_2Rh(CO)(PPh_3)]BPh_4$ (**10**) (Scheme 2).

The structures of complexes **9** and **10** have been determined by X-ray diffraction methods. For compound **9**, the molecular structure of the dinuclear cation closely resembles that of **1**, after the loss of the terminal chloride ligand (Figure 2). Thus, complex **9** contains the two metal atoms, osmium and iridium, triply bridged by one CO and two pyrazolate ligands. As in **1**, the osmium atom completes its coordination sphere with an η^6-bonded *p*-cymene ring. In this case, however, the iridium centre displays a distorted square-based pyramidal geometry with the carbon atom of the bridging carbonyl ligand occupying the apical position, and with the terminal carbonyl, the triphenylphosphane ligand and the pyrazolate nitrogen atoms forming the polyhedron base. The osmium−iridium separation is very similar to that reported in **1**, 3.3941(12) Å, and excludes any intermetallic interaction. The structural parameters of the bridging carbonyl group serve again to confirm the ketonic nature of this ligand (see Table 1). Unfortunately, in the case of **10**, only very small and weakly diffracting crystals were obtained. Although the data collected for these crystals were of reduced quality, they allowed us to verify the dinuclear framework and, in particular, the absence of any bridging CO group between the two metals.

In conclusion, it is worthwhile to point out the remarkable stereoselectivity encountered in the preparation of **1** and **2** from **I** and in the isolation of **9** from **7**. Furthermore, the different reactivity towards PPh_3 that has been found for species **I** and **II**, and for **7** and **8**, is also noteworthy. Most probably, the greater tendency of iridium(I) compared to that of rhodium(I) to pentacoordination and to be oxidised to M^{3+} would explain the obtained results.

Experimental Section

General: All solvents were dried and distilled before use. All reactions were performed under nitrogen. − IR: Perkin−Elmer 783. CH_2Cl_2 as solvent. − NMR: Varian XL (300.0 MHz and 121.4 MHz, for ^1H and ^{31}P, respectively). For ^1H NMR, TMS as internal standard; for ^{31}P NMR, $CDCl_3/CHCl_3$, (1:1, v/v) as solvent.

$[(\eta^6\text{-}p\text{-cymene})Ru(\mu\text{-}CO)(\mu\text{-}pz)_2IrCl(CO)(PPh_3)]$ (1): Triphenylphosphane (60 mg, 0.23 mmol) was added to a solution of $[(\eta^6\text{-}p\text{-cymene})Ru(\mu\text{-}pz)_2IrCl(CO)_2]$ (150 mg, 0.23 mmol) in dichloromethane (25 mL). After stirring for 12 h the solution was reduced in volume to 0.5 mL under vacuum. Slow addition of diethyl ether led to the precipitation of orange **1** (149 mg, 71%), which was filtered off, washed with diethyl ether and dried under vacuum. Complex **2** was similarly prepared from the corresponding OsIr dicarbonyl. Complexes **4−5** were similarly prepared starting from the corresponding species **II**. The reaction time was 2 h.

5: $C_{35}H_{35}ClN_4OOsPRh$ (887.27): calcd. C 47.39, H 3.94, N 6.31; found C 46.63, H 3.64, N 6.06. − IR: ν̃ = 1980 cm^{-1} (CO). − ^{1}H NMR ($CDCl_3$): δ = 7.65 (br. s, 1 H, $H_{3/5}$ pz), 7.57 (br. s, 1 H, $H_{3/5}$ pz), 6.54 (br. s, 1 H, $H_{5/3}$ pz), 6.09 (br. s, 1 H, H_4 pz), 5.74 (br. s, 1 H, H_4 pz), 6.57, 5.45 (AB system, J_{AB} = 5.1 Hz, C_6H_4 *p*-cymene), 6.10, 5.22 (AB system, J_{AB} = 5.1 Hz, C_6H_4 *p*-cymene), 2.45 (sp, 1 H, C*H*Me$_2$ *p*-cymene), 1.77 (s, 3 H, Me *p*-cymene); 1.20 (d, $^3J_{HH}$ = 6.9 Hz, 3 H, CH*Me* *p*-cymene), 1.02 (d, $^3J_{HH}$ = 6.9 Hz, 3 H, CH*Me* *p*-cymene). − ^{31}P NMR: δ = 42.3 (d, $^1J_{RhP}$ = 154 Hz).

[RuIr(η^6-*p*-cymene)(CO)$_2$(PPh$_3$)(pz)$_2$]BPh$_4$ (6a,b): To a solution of [(η^6-*p*-cymene)Ru(μ-CO)(μ-pz)$_2$IrCl(CO)(PPh$_3$)] (**1**) (100 mg, 0.11 mmol) in methanol (40 mL) was added $NaBPh_4$ (79 mg, 0.23 mmol). An orange solid precipitated which, after stirring for 15 h, was filtered off and washed with cold methanol (79 mg, 60%). − $C_{60}H_{55}BIrN_4O_2PRu$ (1199.21): calcd. C 60.11, H 4.62, N 4.69; found C 60.19, H 4.92, N 4.76. − ^{1}H NMR ($CDCl_3$): δ = 6.48 (br. s, pz), 6.20 (br. s, pz), 6.01 (pt, pz), 5.98 (pt, pz), 5.94 (pt, pz), 5.29 (s, C_6H_4 *p*-cymene), 5.13 (br. s, C_6H_4 *p*-cymene), 4.89 (br. s, C_6H_4 *p*-cymene), 2.40 (m, C*H*Me$_2$ *p*-cymene), 1.81 (s, Me *p*-cymene), 1.79 (s, Me *p*-cymene), 1.13 (d, ^3JHH = 6.7 Hz, CH*Me* *p*-cymene), 0.94 (d, $^3J_{HH}$ = 6.3 Hz, CH*Me* *p*-cymene), 0.94 (d, $^3J_{HH}$ = 6.3 Hz, CH*Me* *p*-cymene). − ^{31}P{^{1}H} NMR: δ = −12.3 (s), 1.2 (s).

[(η^6-*p*-cymene)Os(μ-CO)(μ-pz)$_2$Ir(CO)(PPh$_3$)]BPh$_4$ (9): To a solution of [(η^6-*p*-cymene)Os(CO)(μ-pz)$_2$Ir(CO)$_2$]BPh_4 (100 mg, 0.09 mmol) in dichloromethane (20 mL) was added PPh_3 (25 mg, 0.09 mmol). After stirring for 1 h the solution was evaporated to *ca.* 0.5 mL under vacuum. Slow addition of diethyl ether led to a yellow precipitate (107 mg, 88%), which was filtered off, washed with diethyl ether and dried under vacuum. Complex **10** was similarly prepared from the corresponding OsRh tricarbonyl parent compound.

9: $C_{60}H_{55}BIrN_4O_2OsP$ (1288.37) calcd. C 55.95, H 4.27, N 4.35; found C 55.40, H 4.01, N 4.13. − IR: ν̃ = 2045, 1745 cm^{-1} (CO). − ^{1}H NMR [$(CD_3)_2CO$]: δ = 8.07 (m, 1 H, $H_{3/5}$ pz), 6.17 (br. s, 1 H, $H_{3/5}$ pz), 6.05 (br. s, 1 H, H_4 pz), 5.96 (br. s, 1 H, H_4 pz), 6.64, 6.29 (AB system, J_{AB} = 6.3 Hz, C_6H_4 *p*-cymene), 5.95, 5.76 (AB system, J_{AB} = 5.7 Hz, C_6H_4 *p*-cymene), 2.89 (sp, 1 H, C*H*Me$_2$ *p*-cymene), 2.40 (s, 3 H, Me *p*-cymene), 1.30 (d, $^3J_{HH}$ = 6.6 Hz, 3 H, CH*Me* *p*-cymene), 1.06 (d, $^3J_{HH}$ = 6.6 Hz, 3 H, CH*Me* *p*-cymene). − ^{31}P NMR (δ): 1.5 (s).

10: $C_{60}H_{55}BN_4O_2OsPRh$ (1199.05): calcd. C 60.12, H 4.59, N 4.67; found C 59.98, H 4.62, N 4.58. − IR: ν̃ = 2019, 1998 cm^{-1} (CO). − ^{1}H NMR [$(CD_3)_2CO$]: δ = 6.60 (br. s, 1 H, $H_{3/5}$ pz), 6.25 (br. s, 1 H, H_4 pz), 5.91 (br. s, 1 H, H_4 pz), 6.12 (AB system, J_{AB} = 6.0 Hz, C_6H_4 *p*-cymene), 5.99 (AB system, J_{AB} = 6.6 Hz, C_6H_4 *p*-cymene), 2.60 (sp, 1 H, C*H*Me$_2$ *p*-cymene), 1.93 (s, 3 H, Me *p*-cymene), 1.17 (d, $^3J_{HH}$ = 6.6 Hz, 3 H, CH*Me* *p*-cymene), 1.10 (d, $^3J_{HH}$ = 6.9 Hz, 3 H, CH*Me* *p*-cymene). − ^{31}P NMR: δ = 41.3 (d, $^1J_{RhP}$ = 154 Hz).

X-ray Crystal Structure Analysis: Crystal data for **1**: $C_{36}H_{35}ClIrN_4O_2PRu{\cdot}CHCl_3$, M = 1034.79, orange irregular block (0.35 × 0.29 × 0.19 mm), monoclinic, space group $P2_1/n$, Z = 4, a = 10.8933(7), b = 17.8179(15), c = 20.0620(14) Å, β = 94.908(7)°, V = 3879.7(7) Å^3, D_c = 1.772 g cm^{-3}, μ = 4.171 mm^{-1}, *F(000)* = 2024. Intensity data were collected at 293 K on a Siemens-Stoe AED2 diffractometer with graphite-monochromated Mo-*K*α radiation (λ = 0.71073 Å) using a ω/2θ scan. The structure was solved by Patterson method (SHELXS-97)[11] and refined on F^2 by full-matrix least-squares (532 parameters, 106 restraints; SHELXL-97[11]). Static disorder was observed for the isopropyl group of the *p*-cymene and for a phenyl ring of the phosphane ligand; a chloroform solvent molecule was also found disordered. Anisotropic adps were used for nondisordered non-hydrogen atoms. A total of 6871 unique reflections were obtained from 7257 measured reflections [R_{int} = 0.0236; 4534 with $I > 2\sigma(I)$]. Final agreement factors *R1* = 0.0420, *wR2* = 0.0965 and S = 0.904. The final Fourier difference map showed residual peaks in the range 1.57 to −1.86 e/Å^3; the most intense were close to the iridium atom. Crystal data for **9**: $C_{60}H_{55}BIrN_4O_2OsP{\cdot}(CH_3)_2CO$, M = 1346.34, yellow irregular block (0.32 × 0.17 × 0.08 mm), triclinic, space group $P\bar{1}$, Z = 2, a = 9.623(2), b = 16.991(3), c = 18.605(4) Å, α = 71.390(10), β = 85.13(2), γ = 76.01(2)°, V = 2797.3(10) Å^3, D_c = 1.598 g cm^{-3}, μ = 4.723 mm^{-1}, *F(000)* = 1328. Intensity data were collected at 200 K on a Siemens P4 diffractometer with graphite-monochromated Mo-*K*α radiation (λ = 0.71073 Å) using a θ/2θ scan. The structure was solved by direct methods (SIR92)[12] and refined as described for **1** (SHELXL-97)[11] from 696 parameters and 65 restraints. Disorder was observed for the isopropyl group and for the acetone solvent molecule. 9619 unique reflections from a total of 12234 collected reflections [R_{int} = 0.0825; 6184 with $I > 2\sigma(I)$]. Final refinement with *R1* = *0*.0690, *wR2* = *0*.1821 and S = 1.037. The final Fourier difference map showed residual extrema in the range 1.84 to −0.98 e/Å^3; those positive over 1 e/Å^3 where localised close to the metal atoms. Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-131460 (**1**) and CCDC-131461 (**9**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (E-mail: deposit@ccdc.cam.ac.uk).

The assignment of the signals within each heterocyclic ring was made by double resonance decoupling experiments. Furthermore, the resonance of the H_4 proton of the pyrazolate *trans* to the phosphorus ligand could be identified because of its multiplicity: a long range $^5J_{HP}$ coupling constant,[10] of similar value to $^3J_{H4H3}$ and $^3J_{H4H5}$, was observed. Finally, the H_3 and H_5 protons could also be unambiguously assigned from its $^4J_{H3P}$ coupling constant.

A New Route to Iminoarsanes

Christian Kruppa,[a] Martin Nieger,[a] Bernd Ross,*[a] and Inka Väth[a]

Keywords: Arsenic / Imino compound / Hydrazinoiminoarsane / Aminoiminoarsane

Dehydrohalogenation of (2,4,6-tri-*tert*-butylphenylamino)chloro[tris(trimethylsilyl)hydrazino]arsane **(3)** or [*tert*-butyl(trimethylsilyl)amino]chloro(2,4,6-tri-*tert*-butylphenylamino)arsane **(4)** with DBU yields novel stable compounds containing an As–N double bond, (2,4,6-tri-*tert*-butylphenylimino)[tris(trimethylsilylhydrazino]arsane) **(5)** and [*tert*-butyl(trimethylsilyl)amino]-(2,4,6-tri-*tert*-butylphenylimino)arsane **(6)**. The structure of **5** was confirmed by an X-ray structure determination.

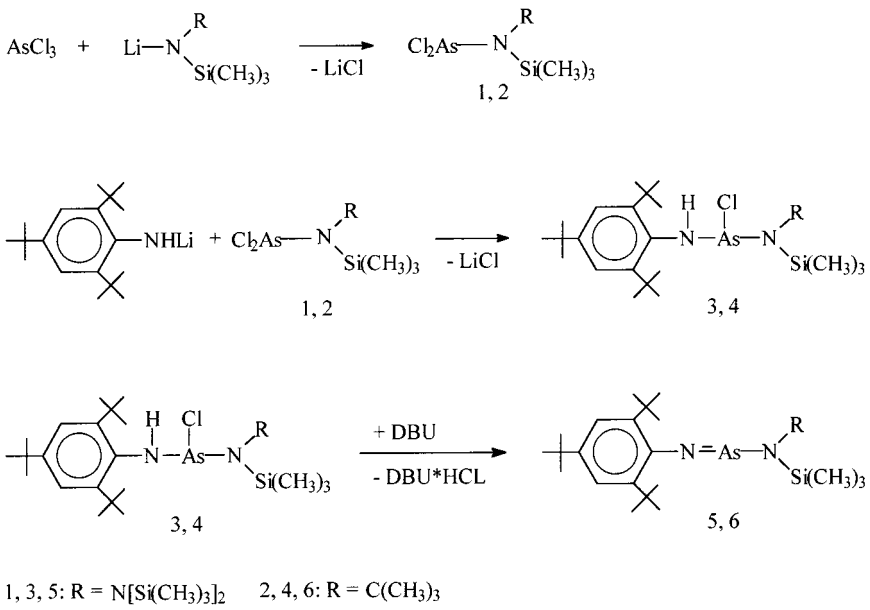
Introduction

In contrast to the well-known iminophosphanes[1] little is known about the corresponding compounds containing an As−N double bond.[2−4] The first compound in which an As−N double bond was clearly proven by X-ray structural analysis was (2,4,6-tri-*tert*-butylphenylamino)(2,4,6-tri-*tert*-butylphenylimino)arsane prepared by Lappert et al. in 1986.[5] It is an example for an aminoiminoarsane, in which the As−N (p-p)π-bond is stabilized by both steric and electronic effects. Ten years later Roesky et al. described the synthesis and X-ray structural characterization of *As,N*-bis[2,4,6-tris(trifluoromethyl)phenyl]iminoarsane,[6] an iminoarsane which is only kinetically stabilized by its bulky organyl groups. Herein we report the preparation of hydrazino- and aminoiminoarsanes using a new method to generate the As−N (p-p)π-bond.

Results and Discussion

Synthesis

The Lappert and Roesky methods for the synthesis of iminoarsanes are based on generation of the As−N (p-p)π-bond by alkali metal chloride elimination from *N*-metalated aminochloroarsanes, produced by substituting an H-atom of the amino group with lithium or potassium amide. Our method of synthesis is distinct from these syntheses as it uses the principle of direct base-induced dehydrohalogenation of aminochloroarsanes to iminoarsanes. Bisaminochloroarsanes suitable for the dehydrohalogenation to aminoiminoarsanes were obtained by successively substituting two chlorine atoms of $AsCl_3$ by treatment with lithium organyl amides. The introduction of two amino groups in a stepwise sequence with isolation of the primary formed aminodichloroarsane allows the synthesis of bisaminochloroarsanes and corresponding aminoiminoarsanes with differently substituted N atoms (Scheme 1).



Treatment of $AsCl_3$ with lithium tris(trimethylsilyl)hydrazide or lithium trimethylsilyl(*tert*-butyl)amide, yielded the hydrazinodichloroarsane **1** or the aminodichloroarsane **2**, respectively. These compounds react with lithium (2,4,6-tri-*tert*-butylphenyl)amide to give the hydrazinoaminochloroarsane **3** and the bisaminochloroarsane **4**. All precursors were isolated in good yield and have not yet been described, except for compound **1**.[4b] Compounds **3** and **4** were dehydrohalogenated by reaction with 1,8-diazabicyclo(5.4.0)undec-7-ene (DBU) to give the hydrazinoiminoarsane **5** and the aminoiminoarsane **6** in good yields. Compound **6** is a red-orange amorphous solid and compound **5** is a red crystalline solid from which crystals suitable for X-ray structural analysis could be isolated. Under dry, oxygen-free argon both these novel compounds are stable indefinitely.

X-ray Crystal Structure of 5

A suitable crystal for data collection was obtained from toluene at room temperature. The molecular structure is shown in Figure 1 and selected bond lengths and angles are given in the legend. The As−N double bond of compound **5** has an (*E*)-configuration and a bond length of 170.8(3) pm. This bond length is comparable to those found for the aminoiminoarsane [171.4(7) pm] synthesized by Lappert et al.[5] and the iminoarsane [170.7(2) pm] prepared by Roesky et al.[6] The As1−N2 distance [182.2(2) pm] is shorter than the calculated value (187 pm) for an As−N single bond.[7] Therefore it is likely that there is some conjugation of the hydrazino nitrogen (N2) lone pair with the As−N (p-p)π-bond system, which one would expect because of the sp^2-hybridization of the planar coordinated N2 atom (sum of angles at N2 = 360°). The N2−N3 distance of 148.0(3) pm lies within the range expected for N−N single bonds (147 pm).[8] The nitrogen (N3) lone pair is not available for conjugation effects because of the perpendicular arrangement of the nitrogen lone pairs at N2 and N3. The plane formed by the phenyl ring occupies a vertical position to the central π-system. For that reason there is no conjugation between the two π-systems.

Experimental Section

General Remarks: All investigations were carried out in the absence of air and moisture under dry, oxygen-free argon. − ^{1}H NMR: Varian EM 360 (60 MHz) or Bruker WH 90 (90 MHz), standards used: residual solvent or TMS. − ^{13}C NMR: Bruker WH 90 (22 MHz), standard used: solvent. − ^{29}Si NMR: Bruker AMX 300 (59.63 MHz), external standard TMS. − Mass spectra: Kratos MS 50. − IR spectra: Bruker FT IR IFS 113 V. − Microanalyses were performed by the microanalytical laboratory E. Pascher, Remagen-Bandorf. − Trimethylsilyl(*tert*-butyl)amine[9] and tris(trimethylsilyl)hydrazine[10] were prepared as reported in the literature.

Dichloro[tris(trimethylsilyl)hydrazino]arsane (1): Tris(trimethylsilyl)hydrazine (13 g, 52.4 mmol), dissolved in diethyl ether (120 mL), was treated with *n*BuLi (34 mL of a 1.6 M solution in *n*-hexane, 52.4 mmol) at room temperature and stirred for 1 h. This solution was then added dropwise at −78°C to $AsCl_3$ (9.5 g, 52.4 mmol), dissolved in diethyl ether (40 mL). Stirring was continued for another hour whilst allowing the mixture to warm to room tempera-

ture. Thereafter the solvent was removed under reduced pressure, and the residue was extracted with *n*-hexane (40 mL). Lithium chloride was filtered off and cooling at −24°C over two days yielded **1**. Yield: 14.4 g (70%), colourless solid, M.p. 130°C (slow decomposition). − ^{1}H NMR (C_6D_6): δ = 0.13 [s, 18 H, N(Tms)$_2$], 0.41 [s, 9 H, NTms]. − ^{13}C NMR (C_6D_6): δ = 2.51 [s, N(Tms)$_2$], 2.70 [s, NTms]. − MS (EI): *m*/*z* (%) = 392 (0.1) [M$^+$], 377 (3) [M$^+$ − CH_3], 357 (10) [M$^+$ − Cl], 247 (100) [M$^+$ − $AsCl_2$], 73 (95) [Tms$^+$] and other fragments.

[*tert*-Butyl(trimethylsilyl)amino]dichloroarsane (2): Trimethylsilyl(*tert*-butyl)amine (7.25 g, 50 mmol), dissolved in diethyl ether (20 mL), was mixed with *n*BuLi (31.5 mL of a 1.6 M solution in *n*-hexane, 50 mmol) at 0°C. Following 1 h stirring at room temperature the solution of the lithium salt was added dropwise to $AsCl_3$ (9.1 g, 50 mmol), dissolved in diethyl ether (20 mL), at −78°C during 30 mins. The mixture was then warmed slowly to room temperature, lithium chloride was filtered off and the solvent was removed under reduced pressure. Distillation of the remaining yellow-brown oil yielded **2**. Yield: 11.79 g (81%), Bp. 78°C/1 mbar. − ^{1}H NMR ($CDCl_3$): δ = 0.43 [s, 9 H, Tms], 1.53 [s, 9 H, *t*Bu]. − ^{13}C NMR ($CDCl_3$): δ = 6.05 [s, Si(*C*H$_3$)$_3$], 33.86 [s, C(*C*H$_3$)$_3$], 61.92 [s, *C*(CH$_3$)$_3$]. − MS (EI): *m*/*z* (%) = 289 (1) [M$^+$], 274 (33) [M$^+$ − CH_3], 254 (5) [M$^+$ − Cl], 218 (15) [M$^+$ − CH_3 − isobutene], 198 (21) [M$^+$ − Cl − isobutene], 166 (100) [M$^+$ − TmsCl − CH_3], 73 (80) [Tms$^+$], 57 (92) [*t*Bu$^+$] and other fragments.

(2,4,6-Tri-*tert*-butylphenylamino)chloro[tris(trimethylsilyl)hydrazino]arsane (3): 2,4,6-Tri-*tert*-butylphenylamine (1.25 g, 4.8 mmol), dissolved in diethyl ether (10 mL), was treated with *n*BuLi (3 mL of a 1.6 M solution in *n*-hexane) at room temperature. After stirring for 30 mins. the solution of the lithium salt was added dropwise to dichloro[tris(trimethylsilyl)hydrazino]arsane **(1)** (1.88 g, 4.8 mmol), dissolved in diethyl ether (50 mL). Stirring was continued for 30 mins. and the solvent was removed under reduced pressure. The residue was extracted with *n*-hexane (10 mL) and lithium chloride was filtered off. Crystallization from the filtrate at −78°C yielded **3**. Yield: 1.5 g (50%), light rose solid, M.p. 81−83°C. − ^{1}H NMR (C_6D_6): δ = 0.26 [s, 9 H, N(Tms)$_2$], 0.34 [s, 9 H, N(Tms)$_2$], 0.42 [s, 9 H, AsNTms], 1.28 [s, 9 H, *p*-*t*Bu], 1.56 [s, 18 H, *o*-*t*Bu], 5.82 [s, 1 H, NH], 7.49 [s, 2 H, Aryl]. − ^{13}C NMR (C_6D_6): δ = 3.80 [s, N{Si(*C*H$_3$)$_3$}$_2$], 3.86 [s, N{Si(*C*H$_3$)$_3$}$_2$], 3.98 [s, AsNSi(*C*H$_3$)$_3$], 30.48 [s, *p*-*C*(CH$_3$)$_3$], 31.71 [s, *p*-C(*C*H$_3$)$_3$], 34.55 [s, *o*-C(*C*H$_3$)$_3$], 36.71 [s, *o*-*C*(CH$_3$)$_3$], 124.08 [s, C3, C5], 138.13 [s, C4], 141.02 [s, C2, C6], 143.19 [s, C1]. − ^{29}Si NMR (C_6D_6): δ = 11.37 [N(Tms)$_2$], 12.37 [N(Tms)$_2$], 16.06 [NTms]. − MS (EI): *m*/*z* (%) = 617 (2) [M$^+$], 602 (0.4) [M$^+$ − CH_3], 581 (5) [M$^+$ − HCl], 509 (0.4) [M$^+$ − TmsCl], 357 (100) [M$^+$ − Mes*NH], 334 (54) [M$^+$ − HCl − N_2Tms_3], 247 (75) [$Tms_3N_2^+$], 73 (82) [Tms$^+$], 57 (20) [*t*Bu$^+$] and other fragments.

[*tert*-Butyl(trimethylsilyl)amino]chloro(2,4,6-tri-*tert*-butylphenylamino)arsane (4): 2,4,6-Tri-*tert*-butylphenylamine (3 g, 11.5 mmol), dissolved in diethyl ether (130 mL), was treated with *n*BuLi (9.3 mL of a 1.6 M solution in *n*-hexane) at room temperature. After stirring for 30 mins. the solution of the lithium salt was added dropwise at −78°C to [*tert*-butyl(trimethylsilyl)amino]dichloroarsane **(2)** (3.32 g, 11.5 mmol), dissolved in diethyl ether (20 mL). The mixture was warmed slowly to room temperature and stirring was continued for 1 h. The solvent was removed under reduced pressure and the residue was extracted with *n*-hexane (15 mL). Lithium chloride was filtered off and cooling of the filtrate at −78°C for three weeks yielded **4**. Yield: 3.6 g (60%), colourless solid, M.p. 90−92°C. − ^{1}H NMR (C_6D_6): δ = 0.47 [s, 9 H, Tms], 1.33 [s, 9 H, *p*-*t*Bu], 1.40 [s, 9 H, N−*t*Bu], 1.66 [s, 18 H, *o*-*t*Bu], 6.03 [s, 1 H, NH], 7.55 [s, 2 H, Aryl]. − ^{13}C NMR (C_6D_6): δ = 6.26 [s, Si(*C*H$_3$)$_3$], 30.41 [s, *p*-*C*(CH$_3$)$_3$], 31.58 [s, *p*-C(*C*H$_3$)$_3$], 33.78 [s, NC(*C*H$_3$)$_3$], 34.10 [s, *o*-C(*C*H$_3$)$_3$], 36.82 [s, *o*-*C*(CH$_3$)$_3$], 59.54 [s, N*C*(CH$_3$)$_3$], 124.05 [s, C3, C5], 138.20 [s, C4], 144.67 [s, C1], 145.03 [s, C2, C6]. − MS (EI): *m*/*z* (%) = 514 (6) [M$^+$], 479 (2) [M$^+$ − Cl], 260 (90) [Mes*NH$^+$], 254 (20) [M$^+$ − Mes*NH], 246 (100) [Mes*H$^+$], 198 (84) [TmsNHAsCl$^+$] and other fragments.

(2,4,6-Tri-*tert*-butylphenylimino)[tris(trimethylsilyl)hydrazino]-arsane (5): DBU (0.39 g, 2.55 mmol), dissolved in *n*-hexane (5 mL), was added dropwise to (2,4,6-tri-*tert*-butylphenylamino)chloro[tris-(trimethylsilyl)hydrazino]arsane **(3)** (1.5 g, 2.43 mmol), dissolved in *n*-hexane (10 mL), at room temperature. The solution immediately turned red. Stirring was continued for 1 h, DBU·HCl was filtered off and crystallization from the filtrate at −26°C yielded **5**. Yield: 1.08 g (77%), red crystalline solid, M.p. 164−170°C. − ^{1}H NMR (CCl_4/TMS): δ = 0.2 [s, 18 H, N(Tms)$_2$], 0.5 [s, 9 H, NTms], 1.34 [s, 9 H, *p*-*t*Bu], 1.44 [s, 18 H, *o*-*t*Bu], 7.27 [s, 2 H, Aryl]. − ^{13}C NMR (C_6D_6): δ = 2.67 [s, Si(*C*H$_3$)$_3$], 30.41 [s, *p*-*C*(CH$_3$)$_3$], 32.06 [s, *p*-C(*C*H$_3$)$_3$], 33.82 [s, *o*-C(*C*H$_3$)$_3$], 36.73 [s, *o*-*C*(CH$_3$)$_3$], 121.77 [s. Controlled Thiolate Coordination and Redox Chemistry: Synthesis, Structure, Axial-Binding, and Electrochemistry of Dinickel(II) Dithiolate Macrocyclic Complexes

Sally Brooker,*[a] Paul D. Croucher,[a] Tony C. Davidson,[a] Geoffrey S. Dunbar,[a] Corina U. Beck,[b] and S. Subramanian[c]

Keywords: Macrocycles / Nickel / Redox chemistry / Schiff bases / S ligands

A single crystal X-ray analysis of $[Ni_2L1](ClO_4)_2 \cdot MeCN \cdot 1/4\ H_2O$, **1a** [formed directly from a mixture of nickel(II) template ions, 2,6-diformyl-4-methyl-thiophenolate, and 1,4-diaminobutane] reveals that the nickel(II) ions are in square-planar N_2S_2 environments and that the four "bowed" dinickel macrocycles in the asymmetric unit pack around a single central perchlorate template ion encapsulating it to form "star" clusters of stoichiometry $\{[Ni_2L1]_4(ClO_4)\}^{7+}$. These "stars" stack together, via π–π-stacking interactions, to form two-dimensional sheets, which are separated from one another by layers of the remaining perchlorate anions and solvent molecules. Reduction, by $NaBH_4$, of the four imine bonds in $[Ni_2L2](ClO_4)_2$ **2a** (analogous to **1a** but formed from 1,3-diaminopropane not 1,4-diaminobutane) or $[Ni_2L2](CF_3SO_3)_2$ **2b** to amine bonds produces the corresponding tetra-amine complex, $[Ni_2L3](ClO_4)_2$ **3**. These complexes are shown to contain diamagnetic nickel(II) ions by a combination of magnetic, NMR and UV/Vis spectroscopic results. The ^1H NMR spectra of **1–3** run in $[D_3]MeNO_2$ and in $[D_3]MeCN$ are consistent with increasing axial binding ability in the order: **3** < **2** < **1**. Thiocyanate ion binding studies reveal that **1** and **2** are able to coordinate two thiocyanate ions, forming $[Ni_2L1(NCS)_2]$ **4** and $[Ni_2L2(NCS)_2]$ **5** respectively, whereas **3** does not. Single crystal X-ray analyses of complexes **4** · 2 MeCN and **5** · MeCN show that adjacent square-planar and octahedral nickel(II) ions result. Two one-electron oxidations *and* two one-electron reductions are a feature of the electrochemistry of **1–3** in MeCN: curiously, the potentials for the oxidation processes are almost invariant whereas those for the reduction processes vary as anticipated. EPR spectroscopy shows that the first one-electron reduction process and the first one-electron oxidation process are metal centred. Spectroelectrochemical studies and redox titrations indicate that a purplish-coloured complex is produced by one-electron oxidation of **2** (λ = 870 nm, ε = 1320 L mol cm^{-1}). The synthesis of a phenolate analogue, $[Ni_2L'(MeCN)_4](ClO_4)_2$ (**6**), of the thiophenolate complex **2a** is also detailed. Complex **6** undergoes two one-electron oxidations in MeCN, but, in contrast to the thiophenolate complexes **1–3**, these occur at much higher potentials. Only a single one-electron reduction process is observed and this occurs at a more negative potential than for any of **1–3**.

Introduction

There is intense interest in modelling nickel thiolate metalloprotein active sites including the [Ni,Fe] hydrogenases mixed metal active site which is responsible for catalysing the reversible oxidation of dihydrogen, $H_2 = 2\,H^+ + 2\,e^-$.[1–4] Many dinickel thiolate-bridged complexes have been reported although the number which have been fully characterised (ie. structure and physical properties including redox chemistry) is still relatively small.[5] As a result of these biologically-inspired studies much is being learnt about fundamental thiolate coordination chemistry. Gaining an understanding of the nature of the redox products of polynuclear thiolate complexes is a considerable and fascinating challenge.[6–9]

Robson and co-workers investigated the coordination chemistry of some acyclic ligands prepared from the thiolate-precursor (*S*)-(2,6-diformyl-4-methylphenyl)dimethyl thiocarbamate.[10–13] We,[14–19] and others[20–24] have subsequently prepared a range of Schiff-base macrocycles from this thiolate-precursor: most of these macrocycles can be templated by nickel(II) ions thus giving direct access to the complexes of interest. By using *macrocyclic* ligands the many problems typically encountered when working with transition metal thiolates are minimised and the resulting thiolate coordination chemistry can be explored in a relatively controlled way.[25] The investigation of the dinickel(II) thiolate macrocyclic complexes $[Ni_2Lj]X_2$ **1–3** (j = 1–3 and X = ClO_4^- for complexes **1a**, **2a**, and **3** respectively, j = 1–2 and X = $CF_3SO_3^-$ for complexes **1b** and **2b** respectively) and $[Ni_2Lj(NCS)_2]$ **4** and **5** (j = 1 for complex **4** and j = 2 for complex **5**), shown in Figure 1, is presented.

Results and Discussion

Synthesis

The red complexes $[Ni_2L1](ClO_4)_2 \cdot MeCN \cdot 1/4\ H_2O$, **1a**, $[Ni_2L1](CF_3SO_3)_2 \cdot H_2O$, **1b**, and $[Ni_2L2](CF_3SO_3)_2$, **2b**, were prepared in acceptable yields. The sodium borohydride reduction of the tetra-imine analogue **2b**, to produce the red tetra-amine complex $[Ni_2L3](ClO_4)_2$ **3**, in excellent yield (80%), was carried out according to the method described by Curtis.[26] The ability of this complex to resist protonation during the acidic workup is remarkable and indicates that there is no remaining nucleophilicity associated with the bridging thiolate suphur atoms. The red-black complexes $[Ni_2L1(NCS)_2]$ **4** and $[Ni_2L2(NCS)_2]$ **5** were prepared by the addition of a solution of 2.2 equivalents of NaSCN to acetonitrile solutions of **1** and **2**, respectively. Complex **4** is obtained in excellent yield (83%) in marked contrast to **5** (19%). No change occurred on addition of 2.2 equivalents of NaSCN to a red acetonitrile solution of **3** whereas an excess of NaSCN caused the solution to turn green and deposit, over time, a green oily solid. The IR spectrum of this impure complex indicated that the nickel ions had been removed from the ligand and formed a simple salt. This was not pursued further. We found the direct preparation of the previously reported[21] phenolate complex, $[Ni_2L'(MeCN)_4](ClO_4)_2$ **6**, non-trivial. Therefore the dichloride analogue[27] was prepared and reacted with silver perchlorate[28] to give a green powder which was then recrystallised from MeCN by vapour diffusion of diethyl ether to give **6**.

In the case of the tetra-imine macrocyclic complexes **1a**, **1b**, **2b**, and **6** IR spectroscopy showed imine formation (1615, 1614, 1623, 1639 cm^{-1}, respectively) and that no unchanged carbonyl or primary amine functional groups were present. The IR spectrum of the perchlorate complex **1a** did not show bands consistent with the very small amount of lattice water present (1/4 H_2O per macrocyclic complex) whereas for the triflate complex **1b** the IR spectrum was consistent with the presence of lattice water[29] (bands were observed at 3526, 3462, and 1623 cm^{-1}) and this was subsequently confirmed by microanalysis (one H_2O per macrocyclic complex). In contrast, the triflate complex **2b** did not have these IR bands and microanalysis gave no evidence for the presence of any waters of crystallisation. The IR spectra of **4** and **5** are consistent with retention of the imine macrocycle (1628 and 1621 cm^{-1} respectively), loss of the perchlorate anions and gain of thiocyanate anions (2081 and 2075 cm^{-1}, respectively). The brown powder formed as the major by-product in the low yielding reaction to form **5** has a shoulder at ca. 1652 cm^{-1} in the IR spectrum indicating that it is a ring-opened complex. This presumably results from imine hydrolysis relieving the strain of encircling a, larger, high spin nickel(II) ion.

Satisfactory elemental analyses were obtained for all of the new complexes, $[Ni_2L1](ClO_4)_2 \cdot MeCN \cdot 1/4\ H_2O$ **1a**, $[Ni_2L1](CF_3SO_3)_2 \cdot H_2O$ **1b**, $[Ni_2L2](CF_3SO_3)_2$ **2b**, $[Ni_2L1(NCS)_2]$ **4**, $[Ni_2L2(NCS)_2]$ **5**, and $[Ni_2L'(MeCN)_4](ClO_4)_2$ **6**. The red complexes **1**−**3** were found to be diamagnetic ($\mu = 0.0$ BM in all cases) which is consistent with a square planar nickel(II) formulation. The red-black complex **4** has a magnetic moment of 2.8 BM per complex which is consistent with the presence of a single high-spin nickel(II) ion per complex.

Crystal Structures

The structures of **2a** and **3** have been reported previously.[16][19] Red crystals of **1a** suitable for X-ray crystal structure analysis were grown from acetonitrile solutions by vapour diffusion of diethyl ether. The structure determination reveals that the asymmetric unit contains *four* dinickel(II) dithiolate macrocycles which, despite lacking crystallographic symmetry, are reasonably similar to each other and form a "star" which is templated on a perchlorate ion (Figure 2, Tables 1 and 2). Each nickel atom is square

planar, as predicted, and is located within 0.05 Å of the mean plane through the N_2S_2 donors provided by the respective macrocycle. Bonds between these donors and the nickel atoms are typical for square planar nickel(II).[16][30] In each macrocycle one of the two nickel atoms interacts very weakly with the central perchlorate ion (Figure 2, Ni···O 3.34−3.36 Å). The mean planes of the two N_2S_2 donor sets within each macrocycle intersect at angles of 137.6° [for Ni(7), Ni(8)] to 140.0° [for Ni(5), Ni(6)]. In addition, each of the macrocycles is bent such that the two aromatic rings are inclined almost at right angles (84.2−97.0°) to each other. The tetrahedrally-distorted bridging-thiolate sulfur donors (Ni−S−Ni 92.3−93.6, Ni−S−C 97.4−108.4°) facilitate this folding of the macrocycles and in doing so reveal their geometrical flexibility.[31−33]

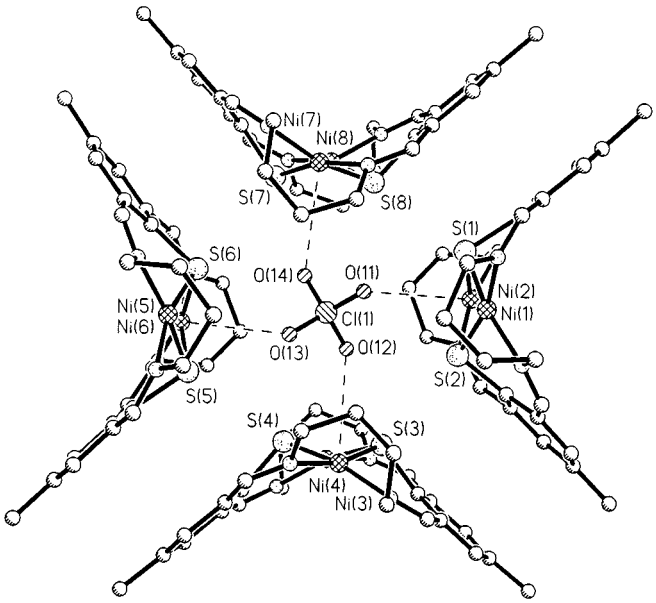

Figure 2. Perspective view of the four $[Ni_2L1]^{2+}$ cations and one of the perchlorate ions, Cl(1), in the asymmetric unit of **1a** (hydrogen atoms, solvent molecules, and remaining perchlorate ions omitted for clarity)

The folding is optimal for the formation of a large number of favourable π−π interactions both between phenyl rings within the asymmetric unit [Figure 2, pairs of π-stacked aromatic rings intersect at 7.8(7)−10.2(7)° and are 3.17(3)−3.65(1) Å apart] and between symmetry generated units [Figure 3, pairs of parallel, π-stacked aromatic rings are 3.43−3.53 Å apart]. Both edge-on ("T") and offset face-to-face π−π interactions[34] are observed and these result in the formation of sheets of dinickel macrocyclic cations, between which lie layers of counter ions and solvent molecules [with the exception of perchlorate Cl(1) which is at the centre of the four macrocycles in the asymmetric unit (Figure 2)].

Differences in the coordination environment of the square planar nickel(II) ions in $L1^{2-}$ compared to those in $L2^{2-}$ are revealed by an examination of the dihedral angles between the respective NiN_2 and NiS_2 planes: the longer alkyl chain in **1a** has caused some buckling and tetrahedral

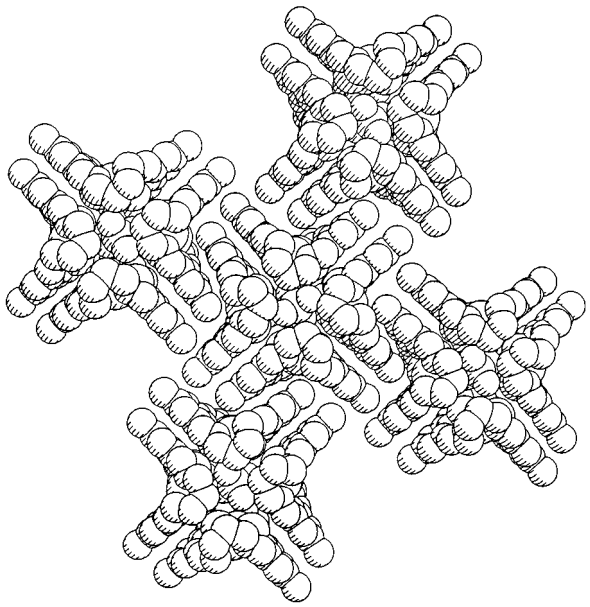

Figure 3. Space-filling diagram of part of a sheet of π−π-stacked $[Ni_2L1]^{2+}$ cations of **1a** [hydrogen atoms, anions, and solvent molecules omitted for clarity, with the exception of the central perchlorate ion, Cl(1)]

distortion away from square planar (15.4−18.9°), whereas an almost planar (slightly folded) arrangement is found in **2a** (2.3−6.1°).[16] A series of related mononickel acyclic complexes has been studied and a wide variation in properties was found depending on the degree of distortion.[30] To probe the significance of this distortion binding studies were undertaken and led to the formation and characterisation of **4**.

Red-black crystals of **4** · 2 MeCN suitable for X-ray crystal structure analysis were grown from the acetonitrile reaction solutions on standing. The structure determination (Figure 4, Tables 1 and 2) reveals that the thiocyanate anions are indeed coordinated to nickel(II). Interestingly both thiocyanate ions bind to one nickel atom, Ni(2), giving it a distorted octahedral geometry overall [Ni(2) is 0.010(2) Å out of the $N(macro)_2S_2$ plane] whilst the remaining nickel atom, Ni(1), remains square planar [Ni(1) is 0.036(2) Å out of the N_2S_2 plane]. Bond lengths to Ni(1) are in the usual range observed for square planar nickel(II) complexes and the corresponding bond lengths involving Ni(2) are ca. 0.2 Å longer as is typical of octahedral (high spin) nickel(II) complexes.[16,35,36]

Complex **4** is folded in the same way as complex **1a**: the two $N(macro)_2S_2$ planes intersect at 140.2(1)° and the two phenyl ring planes at 86.7(1)° in **4** compared to averages of 138.8(2)° and 85.3(4)°, respectively, for **1a**. Slightly larger S···S [2.79−2.83 in **1a** vs. 2.979(2) Å in **4**] and Ni···Ni separations [3.12−3.14 in **1a** vs. 3.2935(8) Å in **4**] are observed in **4**. The three-dimensional packing arrangements of **1a** and **4** are different as a result of the differences in anion template effects. Rather than the anion templating the packing together of the macrocyclic complexes, as is the case with the perchlorate ion in **1a**, the thiocyanate ions block the formation of all but one set of π−π interactions.

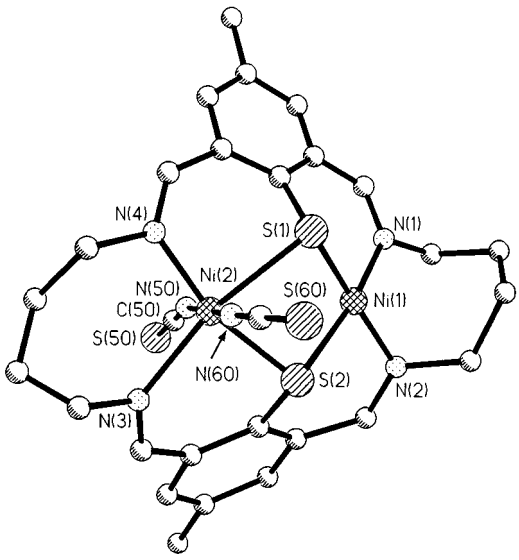

Figure 4. Perspective view of $[Ni_2L1(NCS)_2]$ **4** (hydrogen atoms and solvent molecules omitted for clarity)

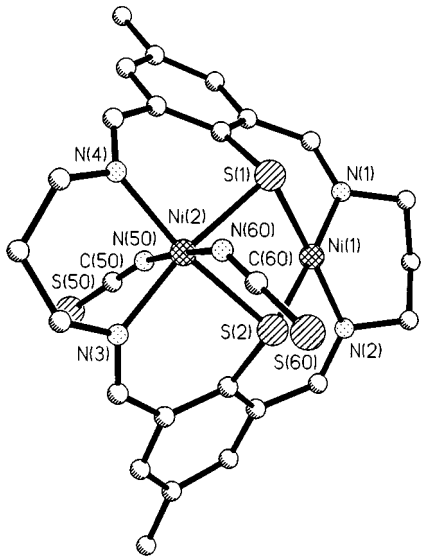

Figure 5. Perspective view of $[Ni_2L2(NCS)_2]$ **5** (hydrogen atoms and solvent molecule omitted for clarity)

The successful formation of **4** prompted us to test whether or not the analogous reaction could be carried out with the less tetrahedrally distorted, macrocyclic complex of the smaller ring $L2^{2-}$, $[Ni_2L2](ClO_4)_2$ **2b**. Red-black crystals of **5** · MeCN suitable for X-ray analysis were obtained, in low yield, from the reaction of **2b** with 2.2 equivalents of NaSCN in MeCN. A similar overall structure to that of **4** is revealed by the structure determination: one nickel atom remains square planar [Ni(1) is 0.003(1) Å out of the N_2S_2 plane] whilst the other is distorted octahedral [Ni(2) is 0.026(1) Å out of the $N(macro)_2S_2$ plane] and coordinated to both thiocyanate ions (Figure 5, Tables 1 and 2). The bond lengths to Ni(1) and Ni(2) are similar to those found in **4** and reflect the respective low spin and high spin configurations of these atoms. The smaller ring size of $L2^{2-}$ is still sufficient to accommodate the high-spin nickel(II) ion. However, there is sufficient ring strain induced by the change in spin state to promote Schiff-base hydrolysis (by traces of moisture) and ring opening, as the major product of the reaction with NaSCN is shown by IR spectroscopy to be a ring opened product (see above).

Comparison of the structure of the perchlorate derivative **2a** with the thiocyanate derivative **5** leads to similar trends to those obtained from the comparison of the corresponding $L1^{2-}$ analogues **1a** and **4**. Complex **5** is folded with the $N(macro)_2S_2$ planes intersecting at 142.21(6)° and the two phenyl ring planes, almost at right angles to one another, intersecting at 91.17(9)° [av. 146.4(2) and 102.4(4)° respectively in **2a**]. Slightly larger S···S [av. 2.839(5) in **2a** vs. 3.011(1) Å in **5**] and Ni···Ni separations [av. 3.146(2) in **2a** vs. 3.244(1) Å in **5**] are observed in **5**. Again the coordinated thiocyanate ions block all but one set of π-π interactions.

Complexes with adjacent square planar and octahedral nickel(II) ions have been reported previously.[14,18,35,37–39] Of these one of the most closely related examples is **A1**, a dinickel(II) complex derived from a "three-quarter" amine thiolate ligand (Figure 6).[39] In this complex both of the thiocyanate ions coordinated to the nickel ion which was bound to the secondary, as opposed to the primary, amine groups due to the slightly weaker field strength exerted by them. However, in complexes **4** and **5** the differing nickel(II) geometries have resulted despite the provision of potentially identical metal ion binding sites and this situation is much less common. We have observed this situation before for the macrocyclic thiolate complex **A2** (Figure 6), where the macrocycle provided potentially identical N(imine)N(amine)SO donor sites,[14][18] but the isolation of complexes **4** and **5** is an important extension of the series of dinickel thiolate complexes produced to date[11,14,16,18–21,25,39–43] as, until recently, it was thought that the $N(imine)_2S_2$ systems exclusively formed square planar complexes.

Table 1. Selected bond lengths (Å) in $[Ni_2L1](ClO_4)_2(MeCN)\cdot 1/4\,H_2O$ **1a**, $[Ni_2L1(NCS)_2]$ **4**, and $[Ni_2L2(NCS)_2]$ **5**

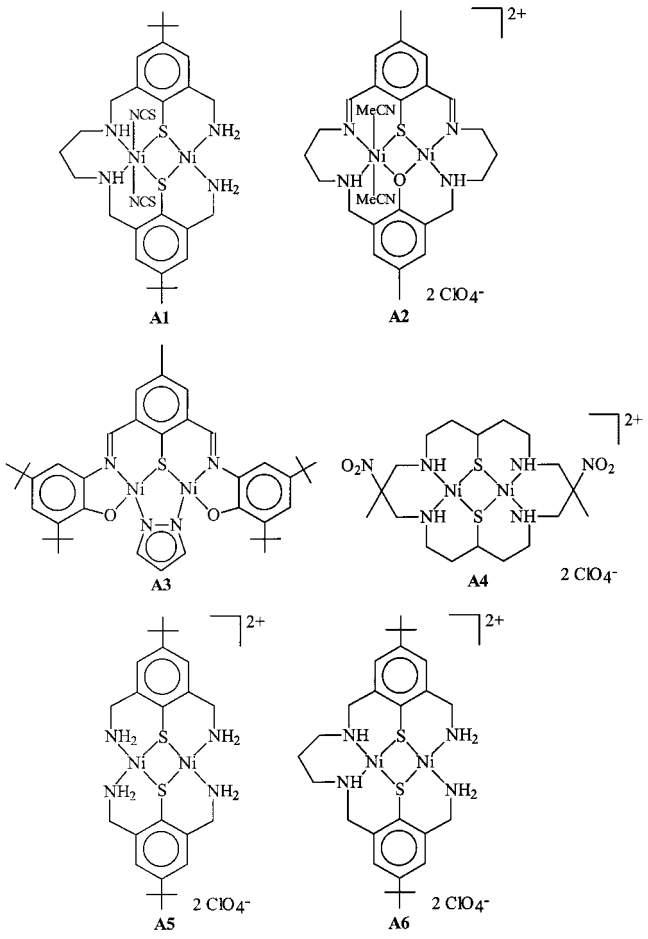

Figure 6. Dinickel(II) thiolate complexes **A1**−**A6**

NMR Studies

In the non-coordinating solvent $[D_3]MeNO_2$ **1**−**3** all gave easily assigned diamagnetic ^1H- and ^{13}C-NMR spectra. In coordinating solvents such as $[D_3]MeCN$ and $[D_7]DMF$ complexes **1**−**3** have some tendency to coordinate solvent molecules in the otherwise vacant axial sites leading to traces of paramagnetic species in solution. The ^1H-NMR spectrum obtained at elevated temperatures for **2** in $[D_3]MeCN$ could be assigned but that obtained for **1** was too broad over the temperature range studied (253 to 333 K). In contrast, **3**, the amine analogue of **2**, gave a reasonably sharp ^1H-NMR spectrum at ambient temperature showing that this complex remains close to diamagnetic even in acetonitrile solution. The amine proton signal for complex **3** has now been correctly identified[19] via a NH/ND exchange experiment: a few drops of a $[D_3]MeOD/D_2O$ (95:5) mixture was added to a solution of **3** in $[D_3]MeNO_2$ which caused the signal at 3.58 ppm to disappear over a period of days. In $[D_7]DMF$ no ^1H-NMR spectrum was obtained for complexes **1** and **2** whilst complex **3** gave a very broad spectrum. Consistent with this, an axial interaction with a DMF molecule was observed in the crystal structure of the hexafluorophosphate salt of **2**.[20]

The NMR data, in both $[D_3]MeNO_2$ (**1**−**3**) and $[D_3]MeCN$ (**2**, **3**), indicate that the macrocycles remain intact in these solvents.

Cyclic Voltammetry Studies

Of particular interest in this series of compounds are the effects of (a) increasing the size of the macrocyclic cavity, $L1^{2-}$ vs. $L2^{2-}$, (b) changing the nature of the nitrogen donors, from imine groups in **2** to amine groups in **3**,[19] and (c) changing from thiophenolate donors in **2** to phenolate donors in **6**. Representative cyclic voltammograms for compounds **1**−**3** and **6** in MeCN are presented in Figure 7 and the potentials of the four well-separated (> 0.2 V) one-electron redox processes for **1**−**3** are provided in Table 3. The three well-separated (> 0.2 V) one-electron redox processes for **6** occur at -1.40^{I}, $+1.05^{QR}$, and $+1.26^{I}$ V (referenced to 0.01 M $AgNO_3/Ag$ and recorded at 200 mV s^{-1}). The redox processes are considered to be predominantly metal centred (vide infra) and the following discussion is made in light of this assignment.

Intriguingly the $[Ni_2Lj]^{2+/3+}$ and $[Ni_2Lj]^{3+/4+}$ potentials ($j = 1-3$) show relatively small shifts upon quite large changes in the ligation of the nickel centres. The peak separation, ΔE, for the first process in all three systems was comparable to that of ferrocene indicating that this is a reversible process in each case, a conclusion that is further supported by analysis of the ratio of peak currents and scan rate dependence.[44]Like the $[Ni_2Lj]^{2+/3+}$ process the position of the $[Ni_2Lj]^{3+/4+}$ process shifts very little from $j = 1$ to $j = 3$. However in each case the peak separation for this second process is larger than that observed for the first process, and the ratio of the peak currents differs significantly from unity, indicating that the $[Ni_2Lj]^{3+/4+}$ couple is a

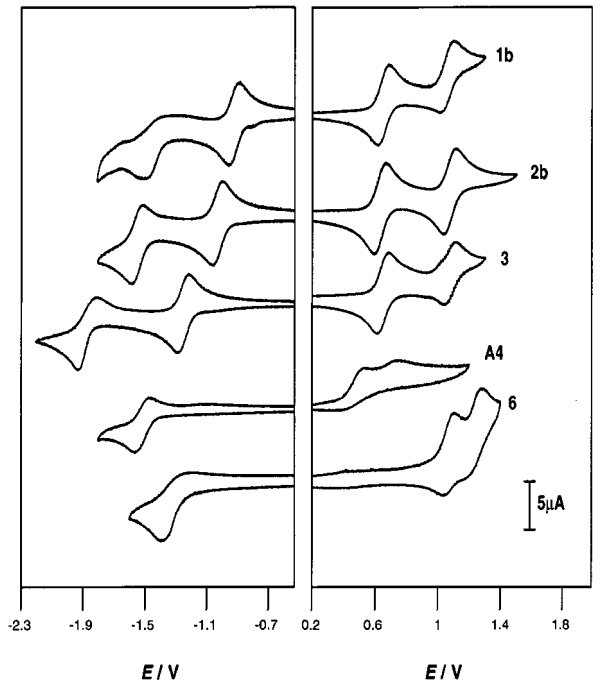

Figure 7. Cyclic voltammograms of complexes (listed from top to bottom) **1b**, **2b**, **3**, **A4**, and **6** in MeCN (200 mV s^{-1}, 0.1 M NEt_4ClO_4, platinum electrode, vs. 0.01M $AgNO_3$/Ag)

Table 3. Potentials ($E_{1/2}$, V) and E (V) for the dinickel complexes $[Ni_2Lj]^{2+}$, (j = 1−3,′). All data were referenced to 0.01 M $AgNO_3$/Ag and recorded at 200 mV s^{-1}. In all cases the Fc/Fc^+ couple, added as an internal reference, occurred at +0.13 V with ΔE = 0.07 V

Complex	$[Ni_2Lj]^{0/+}$	$[Ni_2Lj]^{+/2+}$	$[Ni_2Lj]^{2+/3+}$	$[Ni_2Lj]^{3+/4+}$
1b[a]	−1.45 (0.16)^{I}	−0.92 (0.07)^{R}	+0.64 (0.06)^{R}	+1.05 (0.08)^{QR}
2b[a]	−1.46 (0.07)^{R}	−1.01 (0.06)^{R}	+0.63 (0.08)^{R}	+1.07 (0.08)^{QR}
3[a]	−1.86 (0.10)^{QR}	−1.18 (0.08)^{R}	+0.69 (0.08)^{R}	+1.10 (0.08)^{QR}
1b[b]	−1.49 (0.09)^{QR}	−0.95 (0.09)^{R}	+0.50^{I}	–

[a] Solvent = MeCN, [b] solvent = DMF, [c] solvent = $MeNO_2$. ^{R} reversible, ^{QR} quasireversible, ^{I} irreversible (hence in this case E_{pc} or E_{pa} is quoted not $E_{1/2}$); these assignments were made on the basis of peak separation ΔE (cf. ferrocene), analysis of the ratio of peak currents and scan rate dependence of $E_{1/2}$.[44] Electron counts (in MeCN): **1b** $[Ni_2L1]^{2+} \rightarrow [Ni_2L1]^{+}$ 0.87 e-equivalent; **2b** $[Ni_2L2]^{2+} \rightarrow [Ni_2L2]^{3+}$ 0.95 e-equivalent and $[Ni_2L2]^{3+} \rightarrow [Ni_2L2]^{4+}$ 0.88 e-equivalent; **3** $[Ni_2L3]^{2+} \rightarrow [Ni_2L3]^{3+}$ 0.98 e-equivalent.

quasi-reversible process in all three cases.[44] Thiolate donors are known to stabilise high metal ion oxidation states[45] so the fact that the two one-electron oxidation processes observed for the phenolate analogue, complex **6**, occur at much more positive potentials is consistent with expectations.[46−48] Changes to the ligand, either by increasing the macrocyclic cavity size or by changing from imines to amines, usually has a much larger effect on the potentials than is the case here.[49][50]

In contrast, the peak positions for the $[Ni_2Lj]^{2+/+}$ and $[Ni_2Lj]^{+/0}$ processes (j = 1−3) are very sensitive to the changes in the macrocyclic ligand. The $[Ni_2Lj]^{2+/+}$ processes are reversible for all three complexes **1**−**3**. The $[Ni_2Lj]^{2+/+}$ process occurs at −1.01 V for $[Ni_2L2]^{2+}$ while the complex with the larger macrocyclic cavity, $[Ni_2L1]^{2+}$, is easier to reduce, by 90 mV, and the complex of the tetra-amine macrocycle, $[Ni_2L3]^{2+}$, is harder to reduce, by 170 mV. Only a single one-electron irreversible reduction process is observed for the phenolate analogue, complex **6**, and it occurs at a significantly more negative potential, as is expected[45] (although not *always* observed)[11] due to the presence of the harder phenolate donors. In only one of the three systems was the $[Ni_2Lj]^{+/0}$ process truly reversible, namely the $[Ni_2L2]^{+/0}$ couple. The $[Ni_2L1]^{+/0}$ process is irreversible whilst the $[Ni_2L3]^{+/0}$ process is quasi-reversible. These $[Ni_2Lj]^{+/0}$ processes shift in the same direction as the shifts observed for the $[Ni_2Lj]^{2+/+}$ processes. The $[Ni_2L2]^{+/0}$ and $[Ni_2L1]^{+/0}$ processes occur at a similar potentials (−1.46 and −1.45 V, respectively) whereas the $[Ni_2L3]^{+/0}$ process is 370 mV more negative {ie. $[Ni_2L3]^{+}$ is harder to reduce}. No second reduction process was observed for **6**.

Overall the $[Ni_2Lj]^{2+/+}$ and $[Ni_2Lj]^{+/0}$ potentials for the complexes of the tetra-imine-containing ligands $L1^{2-}$ and $L2^{2-}$, **1** and **2**, are significantly less negative than those for the complex of the tetra-amine-containing ligand $L3^{2-}$, **3**. The imine-containing ligands stabilise the reduced metal centre(s) more effectively than the amine-containing ligand (which has no imine π* orbital).[49][50] It had been hoped that conversion of the hydrolytically unstable imine bonds to relatively stable amine bonds would make the reductive electrochemistry more reversible as decomposition via, for instance, water attack of the adjacent imine bond would no longer be possible. However these redox processes are actually less reversible than those of the tetra-imine analogue **2**.

A study of a large number of mono nickel(II) tetra-aza macrocycles has shown that there is a correlation between the size of the macrocycle cavity and the potentials, with the larger cavities stabilising the nickel(I) oxidation state.[49] This has been interpreted as indicating that the d^9 nickel(I) ion is larger than the d^8 nickel(II) ion and is therefore better accommodated by a larger ring, resulting in a less negative potential for the $Ni^{2+/+}$ process.[49][51] Our results are consistent with this correlation.

As the NMR studies (above) indicated that some solvent coordination is occurring in MeCN and DMF solutions but not in $MeNO_2$, cyclic voltammograms were also run in DMF and $MeNO_2$. The results for **2** are shown in Figure 8 and Table 3. In DMF and MeCN, the $[Ni_2L2]^{2+/+}$ and $[Ni_2L2]^{+/0}$ processes are relatively insensitive to the change in solvent indicating that the formally $Ni^{II}Ni^{I}$ and Ni^{I}_2 species coordinate solvent molecules only weakly, if at all. However, in DMF, the $[Ni_2L2]^{3+/4+}$ process is a substantial 230 mV less positive {$[Ni_2L2]^{3+}$ is easier to oxidise in DMF than in MeCN}. This shift is to be expected as the Ni^{III} ion will be stabilised by axial coordination of solvent molecules,[11][51] and DMF has a greater tendency to bind axially than MeCN.[48] The results obtained in the non-coordi-

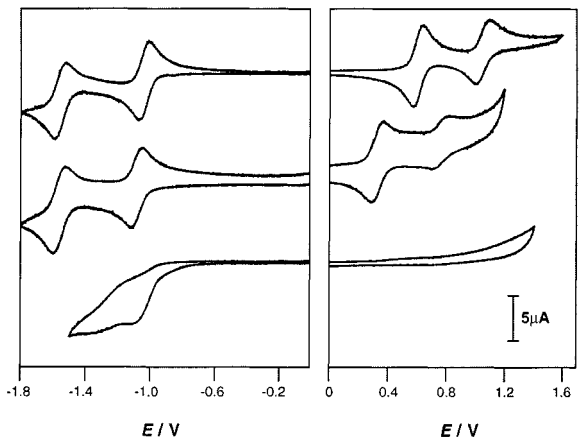

Figure 8. Solvent dependence of cyclic voltammograms of **2b**: comparison of cyclic voltammograms obtained in MeCN (top), DMF (middle), and $MeNO_2$ (bottom) (200 mV s^{-1}, 0.1 M NEt_4ClO_4, platinum electrode, vs. 0.01M $AgNO_3$/Ag)

nating solvent, $MeNO_2$ (Figure 8, Table 3), are consistent with this explanation. No oxidation processes are observed for **2** within the $MeNO_2$ solvent window: two reduction processes are observed but they are irreversible so a meaningful comparison of the potentials is not possible. These observations are consistent with the processes being largely metal centred.

The results of this solvent dependence study are also consistent with those obtained for an acyclic dinickel thiophenolate complex **A3** (Figure 6):[11] the reduction processes varied only slightly with solvent (CH_2Cl_2, acetone, THF, PrCN, and DMF) indicating that there was little or no solvent coordination to the nickel(I) centres whereas the first oxidation process was less positive in DMF than in the other solvents investigated [ie. CH_2Cl_2 (where the processes became reversible), acetone, and THF], which was attributed to solvent coordination to the nickel(III) centres.

As expected, the cyclic voltammetry results for complex **2b** in MeCN are consistent within experimental error with those reported for the perchlorate salt **2a**[16,52] and for the hexafluorophosphate salt of **2**.[22] To date no electrochemical properties have been reported for the other Schiff base macrocyclic di- and tetra-nickel(II) complexes derived from the 2,6-diformylthiophenolate head unit.[23][24] The cyclic voltammogram we obtained in MeCN for the dark orange dinickel(II) aliphatic-thiolate macrocyclic complex **A4** (Figure 6) is shown for comparison in Figure 7.[25] The relatively electron-rich aliphatic-thiolate donors stabilise Ni^{III} and destabilise Ni^{I} relative to the aromatic-thiolate donors in Lj^{2-}, $j = 1-3$. Changing the ligation around the nickel(II) ions from two separate tridentate ligands, complex **A5**, to one "three-quarter" hexadentate ligand, complex **A6** (Figure 6), results in improved reversibility of the two one-electron, metal centred, reductions in DMF.[39] As expected, on completely encircling the nickel ions with a hexadentate *macrocyclic* ligand, as in complexes **1**–**3**, the reversibility improves still further.

In summary, in these three macrocyclic dinickel(II) thiolate systems, $[Ni_2Lj]^{2+}$ where $j = 1-3$, the two one-electron oxidation processes are relatively insensitive to the changes made to the ligand but are sensitive to changes in solvent (MeCN vs. DMF vs. $MeNO_2$). As we believe the oxidation processes, $[Ni_2Lj]^{2+/3+}$ and $[Ni_2Lj]^{3+/4+}$, are primarily metal centered (vide infra) it seems likely that the relatively invariant value of the potentials for $j = 1-3$ for a particular solvent is largely due to the consistent supply of an axial donor (either N of MeCN or O of DMF). In contrast the $[Ni_2Lj]^{2+/+}$ and $[Ni_2Lj]^{+/0}$ processes, which are also believed to be primarily metal centred, are significantly influenced by changes to the ligand but are relatively insensitive to changes in solvent (MeCN vs. DMF). As expected, a change in the nitrogen donors from imines to amines made the potentials more negative, while increasing the size of the macrocyclic cavity made the potentials slightly less negative. The formally nickel(I) centres are expected to be square planar hence the lack of solvent dependence.

EPR Spectra

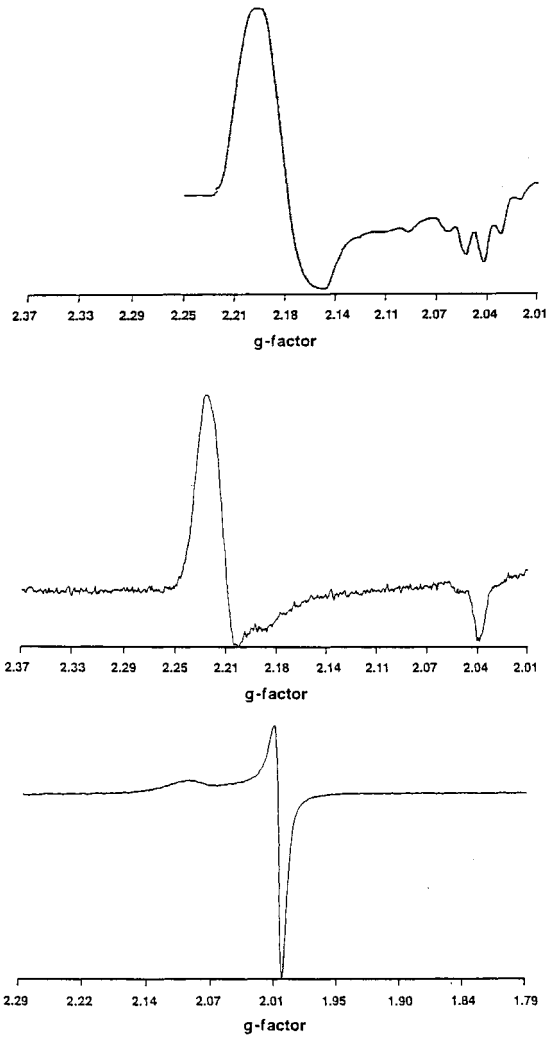

Figure 9. EPR spectra of 10^{-4} mol L^{-1} chemically generated $[Ni_2L2]^{3+}$ (top, 10 mW, 9.142 GHz), electrochemically generated $[Ni_2L2]^{3+}$ (middle, 0.816 mW, 9.284 GHz), and $[Ni_2L3]^{+}$ (bottom, 0.766 mW, 9.284 GHz), in MeCN at 77 K

Due to the instability of the majority of the redox products on a time scale of minutes (cf. the cyclic voltammetry time scale) EPR spectroscopic studies were limited to the oxidation products (both electrochemically and chemically generated) of complexes **2** and **3**, and the reduction products (electrochemically generated) of complexes **1** and **3**.

The EPR spectrum of the purple solution obtained by one electron electrochemical oxidation of **2b** at 1.0 V vs Ag wire is shown in Figure 9. The spectrum is characteristic of the presence of an axial Ni^{III} centre, with $g_{||} = 2.04$ and $g_{\perp} = 2.22$, indicating the presence of a mixed valent Ni^{II}-Ni^{III} centre.[51] Similar EPR behaviour was observed for the purple, electrochemically generated $[Ni_2L3]^{3+}$ species.

Chemical oxidation of an MeCN solution of **2a** with aqueous Co^{III} in 1 M $HClO_4$ yielded a purple solution which again gave an EPR spectrum typical of an axial Ni^{III} centre, with $g_{||} = 2.04$ and $g_{\perp} = 2.17$. The $g_{||}$ feature shows hyperfine splitting associated with two axially coordinated MeCN solvent molecules.

The reduction products of complex **2** were not stable enough to be studied by EPR, however, those of complexes **1** and **3** were investigated (Figure 9). The orange-brown one-electron reduction products of **1** and **3** showed very similar EPR behaviour consistent with a metal-centred reduction to a d^9 Ni^{I} centre ($g_{||} = 2.11$, $g_{\perp} = 2.00$).[51]

These results are consistent with both the first one-electron oxidations and reductions being largely metal based with little delocalisation onto the ligand. Importantly there is no evidence for the presence of organic radicals. The nature of the formally Ni^{I}_2 and Ni^{III}_2 species could not be established due to the low stability of these products.

Electronic Spectra

In $MeNO_2$, MeCN, and DMF the red dinickel(II) complexes **1**−**3** all have an absorption band in the range 490−520 nm (ε = 900−1800 L mol^{-1} cm^{-1}) which is assigned as a ligand-to-metal charge transfer (LMCT) transition, S$\pi \rightarrow$ Ni.[5][39] This band occurs at slightly higher energy in the case of the amine complex **3** (490 nm) than in the imine analogue **2** (510 nm) leading to the former being somewhat more red in colour than the latter. In DMF, in addition to the 490−520 nm band, some further low intensity bands/shoulders are observed at longer wavelengths which are presumably due to axial solvent coordination to least one of the two nickel atoms.[39] Only in the case of complexes **1** and **3** can distinct bands be clearly identified: the lowest energy band, $^3A_{2g} \rightarrow {}^3T_{2g}$, occurs at 990 nm (80 L mol^{-1} cm^{-1}) for **3** and at 860 nm (25 L mol^{-1} cm^{-1}) for **1**. This corresponds to a smaller Δ_O for **3** (10,101 cm^{-1}) than for **1** (11,630 cm^{-1}), consistent with the NMR finding that **3** is less able to bind solvent molecules axially than **1**. In all cases further bands are observed at higher energy, below 380 nm, due to intraligand transitions. Over a period of weeks both the $MeNO_2$ and DMF solutions of **1**−**3** slowly decolorise whereas the acetonitrile solutions remain red.

The instability of the majority of the redox products on a time scale of minutes limited the UV/Vis studies to the oxidation products (both electrochemically and chemically generated) of complex **2** and the one-electron reduction product (electrochemically generated) of complex **1**.

Complex **1b** was electrochemically reduced in MeCN at −1.10 V vs. 0.01 M $AgNO_3$/Ag (87% of one-electron equivalent) resulting in an orange solution: the 510 nm band diminishes in absorbance and an isobestic point is observed at 495 nm (Figure 10). This mixed valent complex, $[Ni_2L1]^+$, is reasonably stable at ambient temperature under argon but attempts to further reduce it by one electron were unsuccessful.

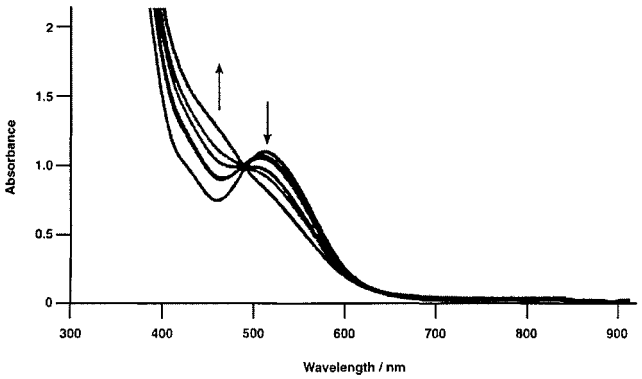

Figure 10. Electrochemical one electron reduction of **1b** in MeCN followed by UV/Vis spectroscopy

Controlled potential electrolysis of **2b** in MeCN at +0.90 V vs. 0.01 M $AgNO_3$/Ag removes one-electron (97%) giving a purplish-coloured solution: a new band develops at approximately 870 nm (isobestic point at ca. 390 nm). This mixed valent complex, $[Ni_2L2]^{3+}$, is reasonably stable at ambient temperature under argon. When a second electron is removed from this sample, by holding the potential at +1.40 V vs. 0.01 M $AgNO_3$/Ag, a dark green solution results, and the 870 nm band bleaches out. Nickel(III) complexes are typically green in colour.[53] Removal of the second electron to form $[Ni_2L2]^{4+}$ is nontrivial due to the low stability of this fully oxidised species.

Complex **2a** was also chemically oxidised by titrating with CAN [ammonium cerium(IV) nitrate]. The titration with the first equivalent of CAN (Figure 11) resulted in a new absorption band at 870 nm. When the titration was continued with the second equivalent of CAN (Figure 11) a dark green solution resulted. During this second stage of the titration the feature at 870 nm decreased in absorbance, as did all of the other bands. Due to the instability of this fully oxidised species it is not possible to determine whether the 870 nm band (11,494 cm^{-1}, ε = 1,320 L mol cm^{-1}) observed for the mixed valent $[Ni_2L1]^{3+}$ complex is due to a ligand to nickel(III) charge transfer transition or to a Class II intervalence charge transfer transition (the bandwidth at half height is approximately 5400 cm^{-1} which is greater than the calculated value of 5153 cm^{-1}).[54]

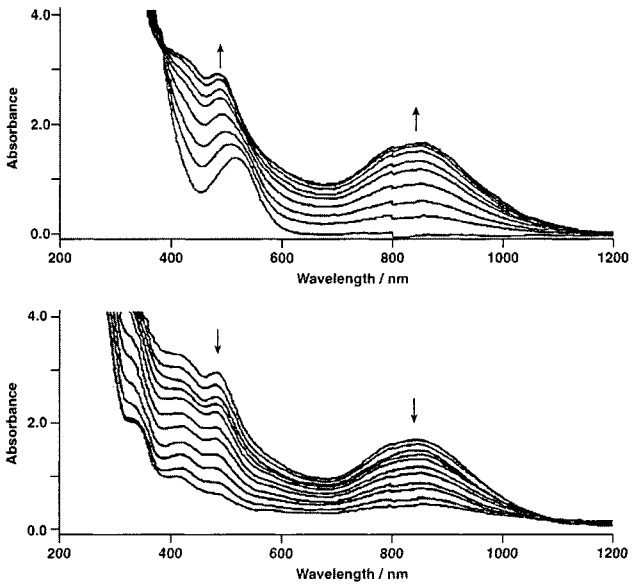

Figure 11. Titration of a 2.7 mL aliquot of a 6.34×10^{-4} mol L^{-1} MeCN solution of **2a**, firstly with one (top) and then with a second (bottom) equivalent of CAN (0.0785 mol L^{-1}, aliquots of 2 μL per scan)

Conclusion

The nickel coordination chemistry of $L1^{2-}$ and $L2^{2-}$ has produced a range of attractive and interesting products, including rare examples of adjacent N_2S_2 and N_4S_2 nickel(II) ions despite the provision of potentially equivalent binding sites. The aim of increasing the degree of tetrahedral distortion over that found in the macrocycle $L2^{2-}$ by increasing the macrocycle cavity size, despite the strong preference of the nickel ions to be square planar in this donor environment, has been achieved with $L1^{2-}$. This increased tetrahedral distortion confers a greater tendency for dinickel(II) complexes of $L1^{2-}$ to bind molecules axially. The ability to manipulate and control the environments of the nickel(II) ions in this way is important with respect to developing model complexes suitable for binding/reactivity studies, and is facilitated by the wide range of geometries which the bridging thiolate donors can adopt.

Experimental Section

Measurements were carried out as previously described,[16] with the exception of most of the NMR spectra which, where noted, were obtained on a Varian 500 MHz spectrometer. Magnetic moments were obtained on a Johnson Matthey Alfa Products Mk1 magnetic susceptibility balance. Electrochemical experiments were performed using a PAR 273A potentiostat/galvinostat in a 3-electrode cell (design by Dr. E. Bothe and Prof. K. Wieghardt, MPI für Strahlenchemie) using Pt working and counter electrodes and a $Ag/AgNO_3$ reference electrode. *tert*-Butyl ammonium perchlorate (recrystallised twice from H_2O and dried in vacuo at room temperature) was used as the supporting electrolyte. All solutions were degassed thoroughly with argon and an argon atmosphere was maintained during the experiments. (*S*)-(2,6-Diformyl-4-methylphenyl)dimethylthiocarbamate[16] and $[Ni_2L'Cl_2]$[27] were prepared according to the literature procedures. Isopropanol (IPA) was stored over CaO, then decanted and distilled. HPLC grade MeCN and DMF were distilled from CaH_2 (DMF in vacuo) immediately before use. Reactions were carried out using Schlenk techniques.

CAUTION: *Perchlorate salts are potentially explosive and should therefore be handled with appropriate care.*

$[Ni_2L1](ClO_4)_2 \cdot MeCN \cdot 1/4\ H_2O$ (1a): (*S*)-(2,6-Diformyl-4-methylphenyl)dimethylthiocarbamate (0.251 g, 1.00 mmol) in IPA (80 cm^3) was brought to reflux. NaOH (0.040 g, 1.00 mmol) was added, the resulting orange solution refluxed for 5 hours, then $Ni(ClO_4)_2 \cdot 6\ H_2O$ (0.365 g, 1.00 mmol) in IPA (20 cm^3) and 1,4-diaminobutane (0.088 g, 1.00 mmol) in IPA (20 cm^3) were added. After 4 hours the mixture was filtered hot to obtain **1a** as an impure red-brown solid. Repeated fractional recrystallisation from MeCN by vapour diffusion of diethyl ether gave $[Ni_2L1](ClO_4)_2(MeCN) \cdot 1/4\ H_2O$ **1a** as large red crystals suitable for X-ray structural analysis. The sample was washed with H_2O to give analytically pure **1a** (0.170 g, 42%). (Found: C 40.6, H 4.2, N 9.0, S 8.0, Cl 8.6. $C_{28}H_{33.5}Cl_2N_5Ni_2O_{8.25}S_2$ requires C 40.8, H 4.1, N 8.5, S 7.8, Cl 8.6%); λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 510 (1 800); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 1624, 1090, 623; Λ_m(MeCN) = 268 mol^{-1} cm^2 Ω^{-1} (c.f. 220−300 mol^{-1} cm^2 Ω^{-1} for a 2:1 electrolyte in MeCN);[55] FAB mass spectrum *m*/*z* 578 $[Ni_2L1]^+$.

$[Ni_2L1](CF_3SO_3)_2 \cdot H_2O$ (1b): The reaction was performed as for $[Ni_2L1](ClO_4)_2$ but nickel(II) trifluoromethansulfonate hexahydrate (0.465 g, 1.00 mmol) was used instead of nickel(II) perchlorate hexahydrate. In contrast to $[Ni_2L1](ClO_4)_2$ the reaction solution became clear red-brown on addition of the amine and after two hours at reflux the solution was reduced in volume in vacuo to ca. 30 cm^3. From this solution red single crystals of $[Ni_2L1](CF_3SO_3)_2 \cdot H_2O$ were grown by vapour diffusion of diethyl ether (0.171 g, 38%). (Found C 37.7, H 4.0, N 6.1, S 13.9. $C_{28}H_{32}F_6N_4Ni_2O_7S_4$ requires C 37.5, H 3.6, N 6.3, S 14.3%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 3526, 3462, 1623, 1614, 1257, 1026, 636; δ_H (500 MHz, CD_3NO_2, 298 K): 8.03 (4 H, s), 7.60 (4 H, s), 3.97, 3.65 (4 H, t; 4 H, d), 2.39 (6 H, s), 3.45, 2.25 (4 H, d; 4 H,q) δ_C (125 MHz, CD_3NO_2, 298 K): 169.4, 141.8, 140.5, 136.2, 121.7, 61.7, 27.5, 20.9; λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 510 (1800), ($MeNO_2$) 515 (1410), (DMF) 520 (900), 860 (25); Λ_m(MeCN) = 280 mol^{-1} cm^2 Ω^{-1} (c.f. 220−300 mol^{-1} cm^2 Ω^{-1} for a 2:1 electrolyte in MeCN);[55] FAB mass spectrum *m*/*z* 578 $[Ni_2L1]^+$; μ = 0.0 BM.

$[Ni_2L2](ClO_4)_2$ (2a): A slight modification of the synthesis reported previously:[16] (*S*)-(2,6-Diformyl-4-methylphenyl)dimethylthiocarbamate (0.251 g, 1.00 mmol) in IPA (80 cm^3) was brought to reflux. NaOH (0.040 g, 1.00 mmol) was added, the resulting orange solution refluxed for 5 hours. Nickel(II) perchlorate hexahydrate (0.365 g, 1.00 mmol) in IPA (20 cm^3) was then added. To the dark red-brown mixture was added 1,3-diaminopropane (0.074 g, 1.00 mmol) in IPA (20 cm^3). The mixture was refluxed for five hours and then filtered whilst hot. The resulting red-brown solid was repeatedly recrystallised from MeCN by vapour diffusion of diethyl ether to remove the brown impurity yielding $[Ni_2L2](ClO_4)_2$ as large red single crystals (0.161 g, 43%). (Found: C 38.4, H 3.7, N 7.4, S 8.0, Cl 9.8. $C_{24}H_{26}Cl_2N_4Ni_2O_8S_2$ requires C 38.4, H 3.5, N 7.5, S 8.5, Cl 9.4%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 1615, 1084, 622; δ_H (300 MHz, CD_3CN, 343 K) reference external TMS: 9.48 (4 H, s), 7.54 (4 H, s), (ca. 4.50, ca 4.31) (4 H, t, br; 4 H, t, br), 2.46 (6 H, s), (2.24, 1.64) (2 H, d; 2 H, s). λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 510 (1600), Λ_m(MeCN) = 265 mol^{-1} cm^2 Ω^{-1} (c.f. 220−300 mol^{-1} cm^2 Ω^{-1} for a 2:1 electrolyte in MeCN);[55] FAB mass spectrum *m*/*z* 550 $[Ni_2L2]^+$.

$[Ni_2L2](CF_3SO_3)_2$ (2b): The reaction was performed as for $[Ni_2L2](ClO_4)_2$ but nickel(II) trifluoromethansulfonate hexahydrate (0.465 g, 1.00 mmol) was used instead of nickel(II) perchlorate hexahydrate. In contrast to $[Ni_2L2](ClO_4)_2$ the reaction solution became clear red-brown on addition of the amine. After two hours at reflux the solution was reduced in volume in vacuo to ca. 5 cm^3, 10 cm^3 of MeCN added and red crystals of $[Ni_2L2](CF_3SO_3)_2$ obtained by vapour diffusion of diethyl ether (0.14 g, 33%). (Found: C 36.4, H 3.5, N 6.3, S 14.8. $C_{26}H_{26}F_6N_4Ni_2O_6S_4$ requires C 36.7, H 3.1, N 6.6, S 15.1%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 1615, 1259, 1026, 637; δ_H (500 MHz, CD_3NO_2, 298 K): 7.93 (4 H, s), 7.56 (4 H, s), 4.38, 3.80 (4 H, t,; 4 H, d), 2.37 (6 H, s), 2.30, 1.60 (2 H, d; 2 H,q) δ_C (125 MHz, CD_3NO_2, 298 K): 167.9, 141.6, 140.1, 135.9, 123.0, 63.1, 29.3, 20.8. λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 510 (1500), ($MeNO_2$) 510 (1480), (DMF) 510 (1040); Λ_m(MeCN) = 265 mol^{-1} cm^2 Ω^{-1} (c.f. 220−300 mol^{-1} cm^2 Ω^{-1} for a 2:1 electrolyte in MeCN);[55] FAB mass spectrum *m*/*z* 550 $[Ni_2L2]^+$; μ = 0.0 BM.

$[Ni_2L3](ClO_4)_2$ (3): To an ice-cold, fine particulate suspension of $[Ni_2L2](CF_3SO_3)_2$ **2b** (0.13 g, 0.18 mmol) in methanol (40 cm^3), was added $NaBH_4$ (0.030 g, 0.77 mmol) in water (2 cm^3). The reaction mixture was allowed to warm to room temperature, stirred for one hour and then refluxed for a further two hours. Then 5% $HClO_{4(aq)}$ (20 cm^3) was added and the mixture refluxed for one hour before being filtered whilst hot to remove $[Ni_2L3](ClO_4)_2$ as a red powder. Further crops were obtained by slow evaporation of the reaction filtrate (0.106 g, 80%). (Found C 37.5, H 4.8, N 7.2, S 8.7, Cl 9.3. $C_{24}H_{34}Cl_2N_4Ni_2O_8S_2$ (**3**) requires C 38.0, H 4.5, N 7.4, S 8.5, Cl 9.3%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 3220, 1603, 1096, 622; δ_H (500 MHz, CD_3NO_2, 298 K) 7.20 (4 H, s), 3.68 (4 H, d), 3.59 (4 H, d), 3.58 (4 H, s), 2.92 (4 H, td), 2.51 (4 H, dt), 2.25 (6 H, s), 2.02 (2 H, m), 1.85 (2 H, m); δ_C (125 MHz, CD_3NO_2, 298 K) 140.3, 135.6, 134.2, 121.7, 56.2, 50.4, 27.1, 21.1; λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 490 (1500), ($MeNO_2$) 490 (1430), (DMF) 490 (900), 990 (80); Λ_m(MeCN) = 280 mol^{-1} cm^2 Ω^{-1} (c.f. 220−300 mol^{-1} cm^2 Ω^{-1} for a 2:1 electrolyte in MeCN);[55] FAB mass spectrum *m*/*z* 558 $[Ni_2L3]^+$; μ = 0.0 BM.

$[Ni_2L1(NCS)_2]$ (4): Complex **1b** (0.040 g, 0.046 mmol) was dissolved in MeCN (2 cm^3) to give a deep red solution. To this was added, in a dropwise fashion, a colorless solution of sodium thiocyanate (0.0085 g, 0.103 mmol) in MeCN (3 cm^3). Over time the solution became colorless and red-black crystals of **4** developed. These were filtered off and dried under vacuum (0.027 g, 83%). (Found: C 48.2, H 4.5, N 12.4, S 18.1. $C_{28}H_{30}N_6Ni_2S_4$ (**4**) requires C 48.3, H 4.3, N 12.1, S 18.4%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 2081, 1628; λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 340 (2960); Λ_m(freshly prepared solution in DMF) = 50 mol^{-1} cm^2 Ω^{-1} (c.f. 65−90 Ω^{-1} mol^{-1} cm^{-1} for a 1:1 electrolyte in DMF);[55] FAB mass spectrum *m*/*z* 636 $[Ni_2(L1)(SCN)]^+$; 578 $[Ni_2(L1)]^+$; μ = 2.8 BM.

$[Ni_2L2(NCS)_2]$ (5): A colourless MeCN solution (4 cm^3) of sodium thiocyanate (0.0128 g, 0.154 mmol) was layered on top of a deep red MeCN solution (1 cm^3) of **2b** (0.060 g, 0.071 mmol). On standing, red-black crystals of **5** formed, along with a brown precipitate, leaving a light yellow solution. The crystals were physically separated from the powder, washed with MeCN and dried in vacuo (0.009 g, 19%). (Found: C 47.2, H 3.6, N 13.0, S 19.7. $C_{26}H_{26}N_6Ni_2S_4$ (**5**) requires C 46.8, H 3.9, N 12.6, S 19.2%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 2075, 1621; λ_{max}/nm (MeCN) (ε/L mol^{-1} cm^{-1}) 335 (2820); Λ_m(DMF) = 70 Ω^{-1} mol^{-1} cm^{-1} (c.f. 65−90 Ω^{-1} mol^{-1} cm^{-1} for a 1:1 electrolyte in DMF);[55] FAB mass spectrum *m*/*z* 550 $[Ni_2L2]^+$.

$[Ni_2L'(MeCN)_4](ClO_4)_2$ (6): $[Ni_2L'Cl_2]$ (0.120 g, 0.17 mmol) was dissolved in a 1:1 mixture of MeCN:water (10 cm^3). To this green solution was added $AgClO_4$ (0.072 g, 0.35 mmol) and the resulting off-white precipitate filtered off.[28] Overnight a dark green crystalline solid formed in the filtrate. This was collected and recrystallised from MeCN by vapour diffusion of diethyl ether to give **6** as large dark green blocks (0.115 g, 76%). (Found: C 43.3, H 4.6, N 12.5, $C_{32}H_{38}Cl_2N_8Ni_2O_{10}$ requires C 43.5, H 4.3, N 12.7%); $\tilde{\nu}/cm^{-1}$ (KBr disk, inter alia) 1639, 1083, 625; λ_{max}/nm (MeCN) (ε/L^{-1} mol^{-1} cm^{-1}) 375 (12800); Λ_m(DMF) = 180 mol^{-1} cm^2 Ω^{-1} (c.f. 130−170 Ω^{-1} mol^{-1} cm^{-1} for a 2:1 electrolyte in DMF);[55] FAB mass spectrum *m*/*z* 617 $[Ni_2(L')(ClO_4)]^+$; 518 $[Ni_2L']^+$.

X-ray Crystallography: Data were collected, on **1a** at 153 K with a Siemens P4 four circle diffractometer and on **5** and **6** at 158 K with a Bruker SMART diffractometer, using graphite-monochromated Mo-*K*α radiation (λ = 0.71013 Å). The data were corrected for Lorentz and polarisation effects and empirical absorption corrections were applied. Hydrogen atoms were inserted at calculated positions and rode on the atoms to which they are attached (including isotropic thermal parameters which were equal to 1.2 times the equivalent isotropic displacement parameter for the attached non-hydrogen atom).

Crystal data for **1a** ($C_{28}H_{33.5}Cl_2N_5Ni_2O_{8.25}S_2$): M_r = 412.3, red block, 0.50 × 0.50 × 0.40 mm, triclinic, space group *P*-1, *a* = 18.174(4), *b* = 18.997(9), *c* = 23.121(8) Å, α = 70.56(3), β = 69.58(3), γ = 77.78(2)°, *V* = 7013(4) $Å^3$, *Z* = 8, μ = 1.40 mm^{-1}, ρ_{calc} = 1.562 g cm^{-3}. A total of 18709 reflections were collected in the range 4 < 2θ < 45°, and the 18013 independent reflections were used in the structural analysis after a semi-empirical absorption correction had been applied (T_{min} = 0.41, T_{max} = 0.50). The structure, four independent macrocyclic complexes in the asymmetric unit, was solved by direct methods (SHELXS-86)[56][57] and refined against all F^2 data (SHELXL-93)[58] to *R1* = 0.083 [for 10954 $F > 4\sigma(F)$; *wR2* = 0.239 and GOF = 1.04 for all 18013 F^2; 1370 parameters; all Ni, S/N/alkyl-C atoms of the macrocycles, O/N/Cl of the full occupancy solvents and perchlorates, Cl(8) and Cl(9) of the partial occupancy perchlorates, anisotropic; 2 (of 8) perchlorates and 2 (of 4) acetonitriles disordered; +1.77/−1.11 e$Å^{-3}$].

Crystal data for **4** · 2 MeCN ($C_{32}H_{36}N_8Ni_2S_4$): M_r = 778.4, red-black rectangular plate, 0.80 × 0.20 × 0.03 mm, triclinic, space group *P*-1, *a* = 10.134(2), *b* = 11.273(2), *c* = 16.112(4) Å, α = 83.957(3), β = 82.082(3), γ = 73.049(3)°, *V* = 1739.7(6) $Å^3$, *Z* = 2, μ = 1.36 mm^{-1}, ρ_{calc} = 1.486 g cm^{-3}. A total of 11118 reflections were collected in the range 5 < 2θ < 53°, and the 6468 independent reflections were used in the structural analysis after a semi-empirical absorption correction had been applied (T_{min} = 0.43, T_{max} = 1.00). The structure was solved by direct methods (SHELXS-97)[56][57] and refined against all F^2 data (SHELXL-97)[58] to *R1* = 0.0446 [for 4250 $F > 4\sigma(F)$; *wR2* = 0.1220 and GOF = 0.92 for all 6468 F^2; 419 parameters; all non-hydrogen atoms anisotropic; +0.79/−0.61 e$Å^{-3}$].

Crystal data for **5** · MeCN ($C_{28}H_{29}N_7Ni_2S_4$): M_r = 709.2, red-black rectangular plate, 0.60 × 0.30 × 0.03 mm, monoclinic, space group $P2_1/c$, *a* = 12.466(5), *b* = 14.267(5), *c* = 17.226(6) Å, β = 93.792(5)°, *V* = 3056.9(19) $Å^3$, *Z* = 4, μ = 1.54 mm^{-1}, ρ_{calc} = 1.541 g cm^{-3}. A total of 32103 reflections were collected in the range 5 < 2θ < 53°, and the 6244 independent reflections were used in the structural analysis after a semi-empirical absorption correction had been applied (T_{min} = 0.76, T_{max} = 1.00). The structure was solved by direct methods (SHELXS-97)[56][57] and refined against all F^2 data (SHELXL-97)[58] to *R1* = 0.0328 [for 3601 $F > 4\sigma(F)$; *wR2* = 0.0612 and GOF = 0.79 for all 6244 F^2; 373 parameters; all non-hydrogen atoms anisotropic; +0.51/−0.49 e$Å^{-3}$].

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-125078, CCDC-125079 and CCDC-125080. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (+44) 1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

This work was supported by grants from the University of Otago. We are grateful to Professor W. T. Robinson and Dr. J. Wikaira (University of Canterbury) for the X-ray data collections, B. M. Clark (University of Canterbury) for the FAB mass spectra, Dr. M. Thomas (University of Otago) for obtaining the NMR spectra, and to V. Camplin and R. Cooke (University of Otago) for their help. The help and advice given to us by Professor A. McAuley (University of Victoria), particularly regarding the interpretation of the EPR spectra run by CB and SS, is greatly appreciated. We thank Dr. E. Bothe and Professor K. Wieghardt (MPI für Strahlenchemie) for providing us with details of their spectroelectrochemical cell design and gratefully acknowledge the glass blowing skills of J. Wells (University of Otago) which allowed construction of this cell.

Pyrazolato Metal Complexes: Synthesis, Characterization and X-ray Crystal Structures of Polynuclear Organometallic Re–Mn Derivatives

G. Attilio Ardizzoia,*[a][+] Girolamo LaMonica,[a][+] Angelo Maspero,[a] Massimo Moret,[b] and Norberto Masciocchi*[b][+]

Keywords: Pyrazolato ligands / Rhenium / Manganese / Crystal structure / Heterometallic complexes

By reacting $[Re(CO)_3(Hpz)_2(pz)]$ (Hpz = pyrazole) with $[Mn(CO)_5Br]$ in toluene in the presence of Et_3N, the dinuclear complex $[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH)$ (**1**) was obtained. The reaction of **1** with molecular oxygen affords the tetranuclear compound $[(CO)_3Re(pz)_3Mn(O)_3Mn(pz)_3Re(CO)_3](Et_3NH)_2$ (**3**) or the trinuclear compound $[(CO)_3Re(pz)_3Mn(pz)_3Re(CO)_3](Et_3NH)_2$ (**5**) depending on the experimental conditions. Complexes **1**, **3** and **5** were characterized in the solid state by single crystal X-ray diffraction analysis and were showed to contain Re···Mn interactions linked by and tris-μ_2-pyrazolato bridges. In **5**, a short [2.397(4) Å] tris(μ_2-oxo)bridged Mn^{IV}–Mn^{IV} contact is found, leading to strong antiferromagnetic coupling of the d^3 ions. The homometallic species $[(CO)_3Mn(pz)_3Mn(CO)_3](Et_3NH)$ (**2**) was also prepared and found to be isostructural with **1**.

Introduction

The formation of polynuclear complexes whose atoms are kept at nearly fixed distances by ancillary ligands is a strict requirement for multicentred catalysis; in particular, when specific synthetic routes to heteropolymetallic species can be devised, complexes where the synergic effects of metals of different nature, geometry or oxidation state are present can be prepared.[1]

In a recent paper we have demonstrated that the organometallic complex $[(CO)_3Re(Hpz)_2(pz)]$,[2] once deprotonated, can act as a multidentate ligand toward the metals of group 11 in the +I oxidation state.[3] The proposed analogy of this ligand with the trispyrazolylborate anion was, however, partially obscured by the observation that "tripod-like" coordination of group 11 metal atoms did not occur, probably because of their peculiar electronic and steric requirements which favour low-coordination numbers. Therefore, in order to substantiate our hypothesis, we decided to react $[(CO)_3Re(Hpz)_2(pz)]$ with molecular fragments prone to hexacoordination. For this we have chosen $[Mn(CO)_5Br]$ which, upon removal (and substitution) of three ligands, can easily afford stable 18-electron Mn^I species. Accordingly, in this paper we report the synthesis and chemical reactivity of polynuclear Re−Mn species which contain metal-metal interactions linked by rare tris(μ_2-pyrazolato) bridges, along with their spectroscopic, magnetic and structural characterization.

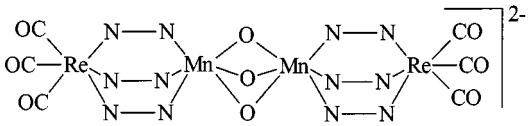
Results and Discussion

The pyrazole/pyrazolate derivative compound $[(CO)_3Re(Hpz)_2(pz)]$ reacts with $[Mn(CO)_5Br]$ in the presence of Et_3N leading to the dinuclear ionic derivative $[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH)$ **(1)** according to Equation 1.

$$[(CO)_3Re(Hpz)_2(pz)] + [Mn(CO)_5Br] \longrightarrow [(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH) \quad (1)$$

The IR spectrum of **1** in toluene shows four strong carbonyl stretching absorptions at 2023, 2008, 1915 and 1901 cm^{-1}, respectively. The latter two (broad) bands are due to the superimposition of the E vibration modes expected for a facial coordination of the carbonyl ligands bonded to the metal centres,[4] later confirmed by the X-ray diffraction study reported below, while the first two absorptions are assigned to the A_1 mode of carbonyls coordinated to the manganese(I) and rhenium(I) centres, respectively.

In order to draw useful structural and spectroscopic comparisons, we tried to synthesize the homometallic dirhenium derivative $[(CO)_3Re(pz)_3Re(CO)_3](Et_3NH)$, by reacting $[(CO)_3Re(Hpz)_2(pz)]$ with a stoichiometric amount of $[Re(CO)_5Br]$ in the presence of Et_3N. Unfortunately, all attempts to reach this goal failed, unreacted $[(CO)_3Re(Hpz)_2(pz)]$ being always recovered. In contrast to this, when $[Mn(CO)_5Br]$ was reacted with pyrazole in the presence of triethylamine, the homobimetallic manganese(I) derivative $[(CO)_3Mn(pz)_3Mn(CO)_3](Et_3NH)$ **(2)** could be easily prepared in high yields. The proposed structure of complex **2**, originally prepared and spectroscopically characterized by Trofimenko[5] as its tetraethylammonium salt, is here confirmed by means of a X-ray powder diffraction study (see Experimental Section).



The ^1H NMR spectrum of **1**, measured in $[D_6]$acetone at −80°C, shows only one set of signals for each pyrazolate proton, revealing the equivalence of the three pyrazolate

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 2000 1434−1948/00/0101−0181 $ 17.50+.50/0

groups; on the other hand, bridging of two different metal centres causes the splitting of the H(3)/H(5) proton signals [two doublets at δ = 7.81 (J = 2.19 Hz) and δ = 7.79(J = 1.75 Hz) and a *pseudo*-triplet centred at δ = 6.15]. Moreover, the signals attributable to the triethylammonium cation are also clearly detected [δ = 1.41 (t, J = 6.29 Hz, CH_3), δ = 3.40 (q, J = 6.29 Hz, CH_2), δ = 4.00 (br, N*H*)]. For the sake of comparison, in the related homometallic species $[(CO)_3Mn(pz)_3Mn(CO)_3](Et_3NH)$ **(2)** due to the equivalence of the H(3) and H(5) protons, only one doublet (δ = 7.79, J = 2.19 Hz), a triplet at δ = 6.15 and the signals attributable to the Et_3NH^+ cation are found. On the basis of the observed values of the $J_{4,(3,5)}$ coupling constants, we tentatively attribute the downfield doublet in the ^{1}H NMR spectrum of **1** to the H protons leaning out over the manganese(I) centre.

Reactivity of 1 With O_2

Complex **1** reacts with molecular oxygen leading, depending on the experimental conditions, to different species. When CH_2Cl_2 solutions of **1** are exposed to an O_2 atmosphere, a pronounced colour change of the solution from pale yellow to dark red occurs, and the formation of a brick-red precipitate takes place. An X-ray structure analysis (see later) revealed this species to be the tetranuclear rhenium(I)/manganese(IV) $[Re_2Mn_2(CO)_6(O)_3(pz)_6](Et_3NH)_2$ complex, **(3)**, where two $[(CO)_3Re(\mu\text{-}pz)_3Mn]$ sub-units are connected together through three μ_2-oxo bridges.

Therefore, the complete reaction leading to **3** can be written as:

$$2\,[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH) + 3/2\,O_2 \rightarrow [Re_2Mn_2(CO)_6(O)_3(pz)_6](Et_3NH)_2 + 6\,CO \quad (2)$$

The IR spectrum of solid **3** shows the typical pattern of carbonyl absorptions for a *fac* geometry around the rhenium(I) centre [2053(s) and 1903(br) cm^{-1}]; moreover, two strong, broad bands in the 1800−1600 cm^{-1} region are present and can be attributed to H-bonds between the triethylammonium protons and the oxo bridges, as found by the crystallographic study.

Depicting the organometallic residue $\{(CO)_3Re(pz)_3\}^{2-}$ as {L} and, hence, **3** as $[\{L\}Mn(O)_3Mn\{L\}]^{2-}$, it is easy to show that **3** belongs to the relatively large class of dinuclear face-sharing octahedral complexes of the $[L_nM(X)_3ML_n]^{m-}$ type, containing d^3-d^3 metals.[6] For this class of derivatives, it has been shown[6a] that the spin-exchange interaction is independent of the type of bridging ligand (X = O^{2-}, OH^-, RO^-, Cl^-, Br^-, I^-) and also of the nature of the metal centre [M = Mn^{IV}, Cr^{III}, V^{II}], the only relevant parameter being the metal−metal distance. A plot of ln(J) versus the M−M distance D_{M-M} (J being the spin-exchange coupling constant) is linear, leading to a phenomenological equation of the type $J = B\cdot\exp(-\varepsilon D_{M-M})$.[6a] The species which allowed the determination of this law contain d^3 ions with intermetallic distances in the 2.3−4.0 Å range depending on the type of the bridging ligands; consequently, many different values of spin interactions could be found, with 2J estimates ranging from 0 to −780 cm^{-1}, equivalent to μ_{RT} values in the 3.9−0.5 BM (per metal centre) range.[6a] For complex **3** we measured a μ_{RT} value of 0.99 BM, revealing a strong antiferromagnetic interaction between the two manganese(IV) centres, in agreement with the short Mn−Mn separation [2.394(3) Å, vide infra] and with that predicted on adopting the aforementioned equation.[7]

According to the strong antiferromagnetic coupling between the Mn^{IV} centres, the ^{1}H NMR spectrum of complex **3** shows well resolved signals, without substantial band broadening or paramagnetic shifts. Its spectral features are quite similar to those of the parent compound $[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH)$ **(1)**. In the pyrazolate proton region two doublets, centred at δ = 7.81 and 7.76 (J = 2.01 and 1.83 Hz) and assigned to the H(3) and H(5) protons leaning out over the rhenium and manganese centres are present. The pyrazolate protons in the 4-position give rise to a pseudo-triplet centred at δ = 6.10. The spectral features do not change significantly upon changing the temperature, revealing the high rigidity of the $M(\mu\text{-}pz)_3M'$ core.

Complex **3** can be easily protonated to the neutral oxo/dihydroxo species $[(CO)_3Re(pz)_3Mn(OH)_2(O)Mn(pz)_3Re(CO)_3]$ **(4)** by employing stoichiometric amounts of aqueous HBF_4. In complex **4**, the ν(CO) absorptions are found at 2037 and 1926 cm^{-1}, slightly shifted with respect to the parent compound **3**; moreover, a broad band attributable to ν(OH) is found at about 3500 cm^{-1}. Such a reaction can be quantitatively reversed by treating **4** with Et_3N. Interestingly, excess HBF_4 does not lead to the formation of the cationic $[(CO)_3Re(pz)_3Mn(OH)_3Mn(pz)_3Re(CO)_3]^+$ species.

When $[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH)$ **(1)** was reacted with O_2 in the presence of free pyrazole [or when the mother liquors of reaction (1) were exposed to air], the trinuclear species $[(CO)_3Re(pz)_3Mn(pz)_3Re(CO)_3](Et_3NH)_2\cdot H_2O$ **(5)** was isolated in low yields (see Experimental Section) and crystallographically characterized. The IR spectrum of **5** shows two bands attributable to ν(CO) at 2018 (sharp) and 1901 (broad) cm^{-1}, in agreement with the facial geometry about the rhenium(I) centres. This latter reaction is accompanied by the formation of noncarbonylic manganese species. IR evidence suggests that, most probably, hydroxo/pyrazole derivatives of Mn^{II} are formed, but their real nature still remains unclear. Work is in progress in order to identify these species, which could not be easily isolated by standard chemical or chromatographic techniques.

Crystal Structures of 1, 3 and 5

All these compounds are ionic species, containing $[Et_3NH]^+$ cations and organometallic polynuclear anions; in addition, crystals of **5** contain clathrated water molecules. ORTEP drawings of the complex anions are shown in Fig-

ures 1, 2 and 3, respectively; a summary of chemically relevant bond lengths is presented in Table 1.

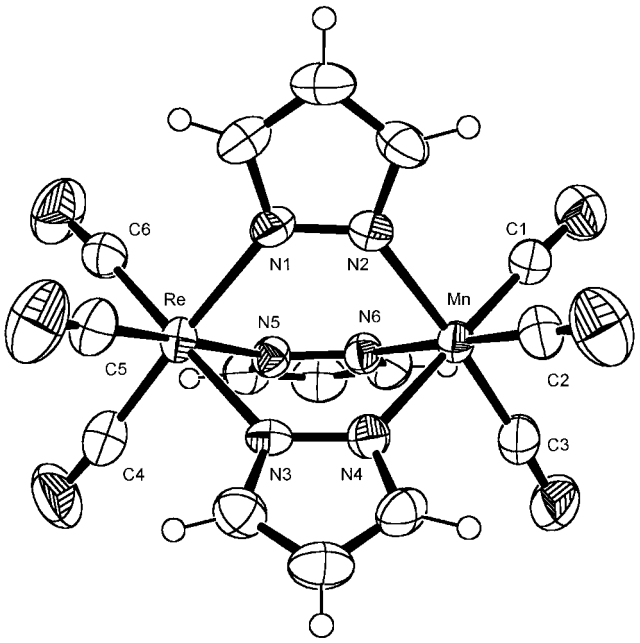


Figure 1. ORTEP drawing of the $[(CO)_3Re(pz)_3Mn(CO)_3]^-$ anion in **1**, with partial labelling scheme; thermal ellipsoids are drawn at the 30% probability level; hydrogen atoms are given arbitrary radii

Table 1. Synoptic collection of relevant bond lengths (e.s.d.'s in parentheses)

[a] These values may be slighly affected by the Re/Mn disorder discussed in the text. − [b] The anion in **3** possesses crystallographically imposed *mm2* symmetry, while that of **5** lies on an inversion centre.

All three species contain "terminal" *fac*-$M(CO)_3$ (M = Re or Mn) fragments, connected by a tris-pyrazolato bridge (tpb) or longer (linear) spacers, i.e. [(tpb)Mn(μ−O)$_3$Mn(tpb)] in **3** and [(tpb)Mn(tpb)] in **5**. Therefore, the nature of the metal atoms in **1**, **3** and **5** can be easily depicted by the Re^I-Mn^I, $Re^I-Mn^{IV}-Mn^{IV}-Re^I$ and $Re^I-Mn^{II}-Re^I$ sequences, respectively.

Only a few polynuclear complexes bearing tris-pyrazolato bridges are known, the only structurally characterized species being $[(ON)Ni(tpb)Ni(NO)]^-$ (containing a tris-3,5-dimethylpyrazolato bridge),[8] $[Cu_3(fpz)_5]$ [Hfpz = 3,5-bis(trifluoromethyl)pyrazole],[9] $[(C_5Me_5)Ir(tpb)Rh(OOH)(dppe)]^+$,[10] $[(C_5Me_5)Ir(tpb)Ni(R_3BH)]$ and [(*p*-cymene)-Ru(tpb)Ni(R_3BH)] (HR = 4-bromo-3-isopropylpyrazole).[11] In such species, as well as in compounds **1**, **3**, and **5**, the rare M(tpb)M fragment mimics structural features which are usual for tris(pyrazolyl)borato metal complexes. Indeed, the trispyrazolylborato derivatives of **1** and **3**, as well as a bis(μ$_2$-oxo) analogue of **5**, obtained by formally replacing the organometallic $(CO)_3Re(pz)_3$ fragment with the $HB(pz)_3$ tripod, have been known for a long time.[12] Differently, heterobridged metals possessing a $(\mu\text{-}pz)_a(\mu\text{-}X)_b$ (a + b = 2, 3) core are quite common.[13] In addition, several triazolato and tetrazolato complexes of this kind are present in the Cambridge Crystallographic Database but, since the vast majority are not organometallic species, they will not be discussed any further; however, these observations show that the M(tpb)M fragments should not be rare at all and, as confirmed by the present study, that they can easily be prepared if the proper synthons are used.[14]

As expected, in complexes **1**, **3** and **5**, the M−C distances of the *fac*-$M(CO)_3$ [average values (Å): Re−C 1.89 (in **1**), 1.90 (**3** and **5**); Mn−C 1.81 (**1**)] reflect the larger atomic radius of Re vs. Mn; analogously, Re^I-N bond lengths are about 0.1 Å larger than the Mn^I-N ones.[15] However, if compared to those found in the mononuclear precursors (for which, typically, Re^I-N ca. 2.19 Å),[2] a relevant shortening of the M−N bonds is evident; this effect can possibly be related to the Mn−N−N angles of the (tpb)$Mn(CO)_3$, (tpb)Mn(μ-O)$_3$Mn(tpb) and (tpb)Mn(tpb) fragments which are wider (>126°) than those found in the known species $[Re(CO)_3(Hpz)_2(pz)]$, $[Re(CO)_3(Hpz)(pz)(py)]$ and $[(CO)_3Re\{(pz)_2Br\}Re(CO)_3]^-$ (ca. 124°)[2]; indeed, overlap between the metal d orbital(s) and the nitrogen lone-pairs is most effective for Re−N vectors bisecting the $N_{ipso}-N-C_{ipso}$ angles (ca. 108°), i.e. for Re−N−N angles close to (360 − 108)/2 = 126°. The slightly divergent nature of the pyrazolato ligands in **1**, **3** and **5** is also confirmed by comparing the theoretical Re−Mn distances [$(Re-N_{avg.} + Mn-N_{avg})\cdot\sin(36°) + N-N_{avg.} = 3.85$, 3.83 and 3.83 Å] to the observed values [3.905(1), 3.897(2) and 3.854(2) Å, respectively]. For the sake of comparison, a dimanganese(I) species, structurally similar to **1** but bearing 5-fluoromethyltetrazolates (Hftz), $[(CO)_3Mn(ftz)_3Mn(CO)_3]^-$, shows an Mn−Mn interaction of 3.79 Å.[16]

Since each tpb fragment binds through six donor nitrogen atoms, all metals in **1**, **3** and **5** are octahedrally coordinated: the manganese atoms of **3** are bound to three pyrazolates and three oxo-bridges, while Mn^{II} in **5** is bound to six different pyrazolates. Rather surprisingly, and in disagreement with Shannon's radii for octahedrally coordi-

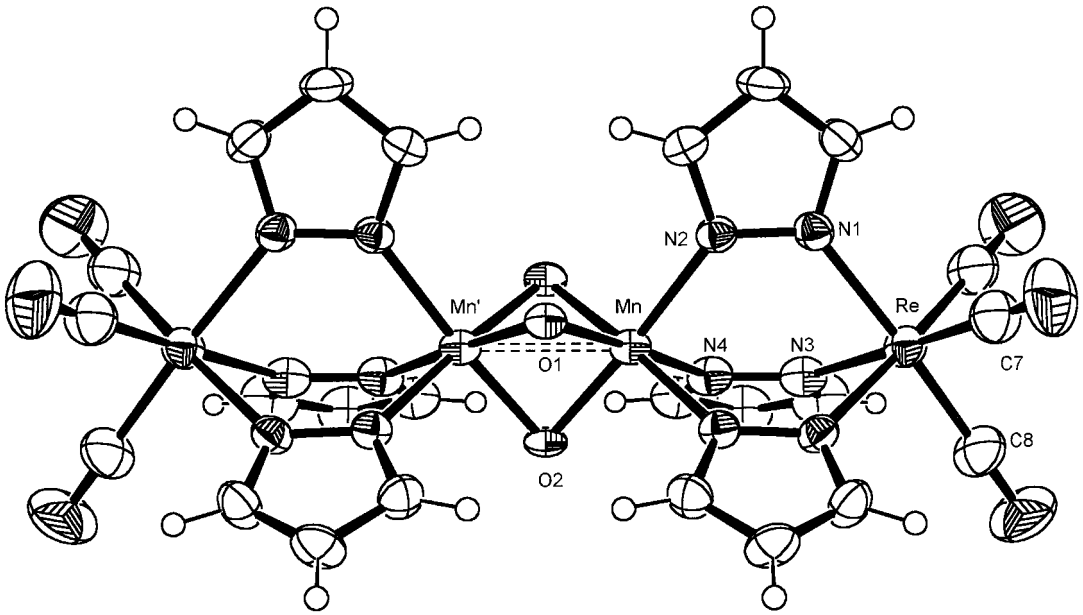

Figure 2. ORTEP drawing of the $[(CO)_3Re(pz)_3Mn(O)_3Mn(pz)_3Re(CO)_3]^{2-}$ anion in **3**, with partial labelling scheme; the dashed bond links Mn^{IV} ions which are 2.394(3) Å apart; thermal ellipsoids are drawn at the 50% probability level, hydrogen atoms are given arbitrary radii

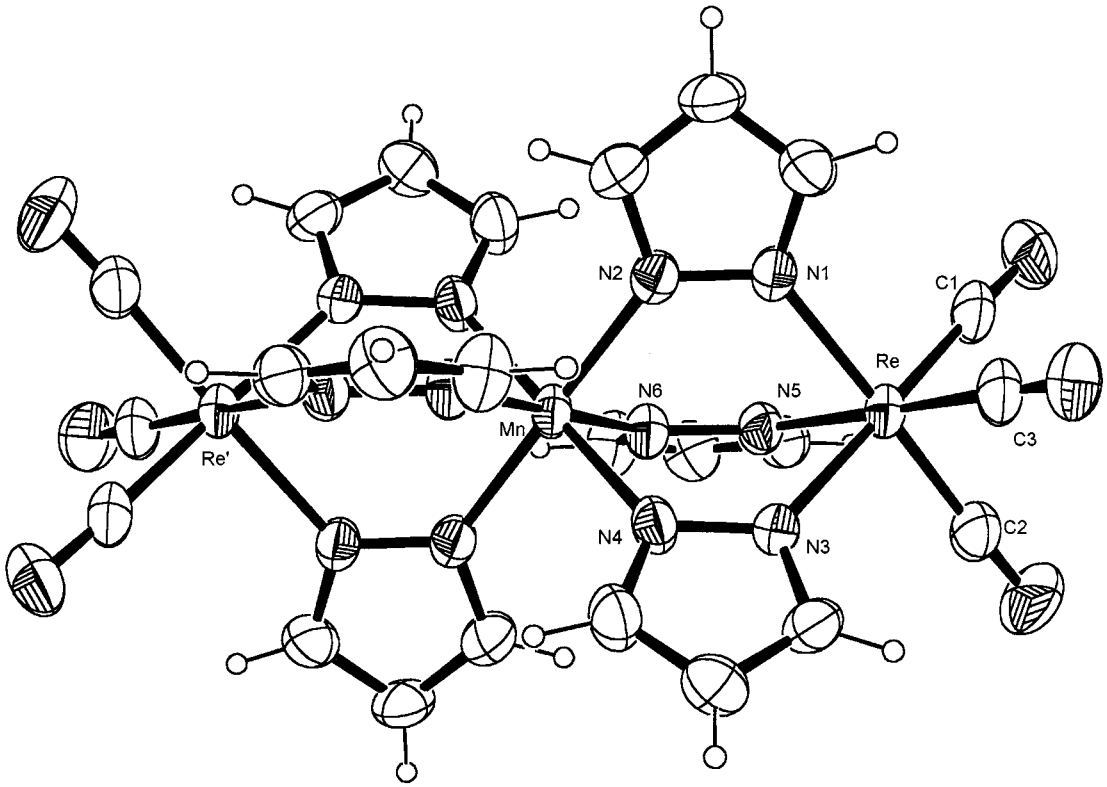

Figure 3. ORTEP drawing of the $[(CO)_3Re(pz)_3Mn(pz)_3Re(CO)_3]^{2-}$ anion in **5**, with partial labelling scheme; thermal ellipsoids are drawn at the 50% probability level; primed atoms are symmetry-equivalents; hydrogen atoms are given arbitrary radii

nated atoms,[17] Mn^{II} (probably a high-spin d^5 ion) in **5** shows bond lengths comparable with those found in tetravalent (d^3) Mn in **3** (see Table 1). This effect needs further comments: owing to the very short Mn···Mn interaction [2.394(3) Å],[18] and in agreement with the observed magnetic response of powders of **3**, a rather profound interaction occurs between the two d^3 ions, making each Mn atom formally seven- rather than six-coordinate; in addition, the very narrow Mn−O−Mn angles (ca. 81°) are also a consequence of this "incipient" bond.

Interestingly, a similar trioxo bridge with a very short M···M distance [M = Tc, a Mn congener, Tc···Tc = 1.867(4) Å] was extensively discussed in experimental[19] and theoretical[20] reports, but was eventually found to be a pure artifact stemming from poor structural analysis of a misinterpreted rhenium species, i.e. solid $(C_5Me_5)ReO_3$, which affords rare two-dimensional polytypes.[21] With these aspects in mind, and suspecting a similar behaviour, we also formulated a crystal disorder of the hypothetical $Re^{I}-Mn^{VII}$ $[(CO)_3Re(tpb)MnO_3]^-$ species, which was easily discarded on the basis of packing considerations, chemical and spectroscopic analyses and much poorer agreement factors. However, since it has been shown here that species such as tris-pyrazolylborates and their organometallic analogue $[(CO)_3Re(tpb)]^{2-}$ have similar coordinating capabilities, and thanks to the well-recognized similarity of the cyclopentadienyl and $[HB(pz)_3]^-$ fragments,[22] it is likely that the still elusive $[(CO)_3Re(tpb)MnO_3]^-$ may exist.

Conclusions

The present work has demonstrated that organometallic analogues of the tris-pyrazolylborato ligands can be successfully employed in building heterometallic species. In addition, selective oxidation of one of the metals was easily attained, opening the way to the synthesis of polynuclear species containing metals in different, and tunable, oxidation states, which may be of interest in multimetal-centred homogeneous catalysis. Accordingly, tris-pyrazolato-bridged $Re^{I}-Mn^{I}$, $Re^{I}-Mn^{II}$ and $Re^{I}-Mn^{IV}$ species were prepared. Also, preliminary results on analogous oxidation reactions of **2** revealed the formation of $Mn^{I}-Mn^{IMnII}-Mn^{I}$ and $Mn^{I}-Mn^{III}-Mn^{I}$ links, but their complete characterization will be reported in a forthcoming paper.

In addition, in the light of our continuous interest in the chemistry of coordination polymers containing metal−diazolato links,[23] the formation of {M(tpb)M} and {M(tpb)M(μ-O)$_3$M} fragments opens the way, at least in principle, to the preparation of robust species containing linear chains of metals and displaying a variety of physical properties such as interesting electrical, magnetic and optical effects.[24]

Experimental Section

Solvents were dried and purified by standard methods. Pyrazole and $[Mn(CO)_5Br]$ (Aldrich Chemical Co.) were used as supplied, $[Re(CO)_5Br]$[25] and $[Re(CO)_3(Hpz)_2(pz)]$[2] were prepared according to literature procedures. Infrared spectra were measured on a BIO RAD FTIR 7 instrument, ^1H NMR spectra were acquired on a Bruker AC-300 FT spectrometer operating at 300.13 MHz. Magnetic data were achieved employing a Sherwood Scientific magnetic susceptibility balance. Elemental analyses were performed at the Microanalytical Laboratory of this University (C, H, N). All reactions were carried out using standard Schlenk techniques.

$[(CO)_3Re(pz)_3Mn(CO)_3](Et_3NH)$ (1): $[(CO)_3Re(Hpz)_2(pz)]$ (360 mg, 0.761 mmol) was dissolved in 8 mL of toluene and solid $[Mn(CO)_5Br]$ (216 mg, 0.785 mmol) was added with stirring. Deoxygenated Et_3N (0.5 mL) was then added and the solution kept at 45°C for 4 h. During this time, evolution of CO from the reaction medium was accompanied by the formation of a pale yellow precipitate. The solid was then filtered, washed with water and dried under vacuum (481 mg, 89% yield) − $C_{21}H_{25}MnN_7O_6Re$ (712): calcd. C 35.39, H 3.51, N 13.76; found C 35.25, H 3.55, N 13.87. Crystals suitable for X-ray structure analysis were obtained by slow diffusion of *n*-hexane into a dichloromethane solution of **1**.

$[(CO)_3Mn(pz)_3Mn(CO)_3](Et_3NH)$ (2): $[Mn(CO)_5Br]$ (300 mg, 1.09 mmol) was added to a solution of pyrazole (134 mg, 1.97 mmol) in toluene (10 mL) kept at 60°C. Et_3N (0.5 mL) was then added and the formation of a yellow precipitate observed. After 6 h, the suspension was cooled to room temperature, and 10 mL of *n*-hexane were added to the reaction medium in order to reduce the solubility of **2**. The solid was then filtered, washed with water and dried under vacuum (550 mg, 86% yield). − $C_{21}H_{25}Mn_2N_7O_6$ (581): calcd. C 43.37, H 4.30, N 16.87; found C 43.01, H 4.21, N 16.41.

$[(CO)_3Re(pz)_3Mn(O)_3Mn(pz)_3Re(CO)_3](Et_3NH)_2$ (3): A solution of **1** (160 mg, 0.225 mmol) in CH_2Cl_2 (5 mL) was stirred under a dioxygen atmosphere for 6 h. During this time a brick-red solid formed. The solid was then filtered off, washed with diethyl ether and dried under vacuum (232 mg, 79% yield). − $C_{36}H_{50}Mn_2N_{14}O_9Re_2$ (1304): calcd. C 33.13, H 3.83, N 15.03; found C 33.22, H 3.45, N 14.67. Crystals suitable for X-ray structure analysis were obtained by slow diffusion of *n*-hexane into an acetone solution of **3**.

$[(CO)_3Re(pz)_3Mn(OH)_2(O)Mn(pz)_3Re(CO)_3]$ (4): Complex **3** (200 mg, 0.153 mmol) was dissolved in acetone (5 mL) and aqueous HBF_4 (48% wt, solution in water, 60 μL) was added. The colour of the solution turned from red to violet. After 15 min. stirring, the solution was evaporated to dryness and the solid was extracted with CH_2Cl_2 (in order to remove the formed $Et_3NH{\cdot}BF_4$). The violet solution was then evaporated to dryness and the residue was triturated with diethyl ether, filtered off and dried under vacuum. (115 mg, 68% yield). − $C_{24}H_{20}Mn_2N_{12}O_9Re_2$ (1102): calcd. C 26.13, H 1.82, N 15.25; found C 26.22, H 2.15, N 15.37.

$[(CO)_3Re(pz)_3Mn(pz)_3Re(CO)_3](Et_3NH)_2{\cdot}H_2O$ (5): To a solution of pyrazole (160 mg, 1.17 mmol) in CH_2Cl_2 (10 mL) was added complex **1** (200 mg, 0.281 mmol) with stirring. The solution was maintained overnight under a dioxygen atmosphere. During this time, the colour of the solution turned from yellow to deep red. The solution was evaporated to dryness and the solid treated with water, filtered and dried under vacuum. The crude product was then dissolved in acetone (3 mL) and *n*-hexane (15 mL) was allowed to diffuse into the solution. Complex **5** was isolated as well-shaped red crystals. (92 mg, 27% yield). − $C_{36}H_{52}MnN_{14}O_7Re_2$ (1219): calcd. C 35.44, H 4.27, N 16.08; found C 35.28, H 4.31, N 15.97.

Crystallography. − Single Crystal Data Collection and Reduction: Crystals of **1**, **3**, **5** were mounted, in air and at room temperature, on the tip of a glass fiber and optically centred in the X-ray beam with the aid of goniometer heads. For **1** and **5**, a CAD4 Enraf−Nonius diffractometer, equipped with graphite monochromated Mo-*Kα* radiation (λ = 0.71073 Å) was used, and the HV generator set at 50 kV and 30 mA. Cell parameters were determined by least-squares on the basis of the setting angles of 25 reflections having $10 < \theta < 14°$. The data collections were performed by the ω-technique with constant scan speed but variable scan range. The crystal stabilities under diffraction conditions were checked by monitoring three standard reflections every 180 minutes: relative decay values of about 6.5 and 20.4% were observed. Analytical absorption cor-

rections were applied, using ψ-scans of three suitable reflections having χ near 90°. The measured intensities were corrected for decay, Lorentz, polarization and background effects and reduced to F_o^2. The crystal of **3** was measured on a SMART Bruker diffractometer, equipped with a CCD area detector and graphite monochromatized Mo-*Kα* radiation (generator setting: 40 kV, 45 mA). Initial cell parameters were determined on the basis of the angular settings of 34 unique reflections. A full hemisphere of data (1350 frames, ω scan, Δω = 0.3°, *t* = 50s) was collected; integration by SAINT[26] and absorption correction by SADABS[27] lead to a total of 18908 F_o^2 values.

Single Crystal Structure Solution and Refinement: All three structures have been solved by direct methods (SIR97[28]) and difference Fourier methods, and subsequently refined by full-matrix least-squares against F_o^2 using all reflections and the program SHELX[29] on an IBM compatible PC. Scattering factors for neutral atoms (including dispersion corrections) were taken from the internal library of SHELX. Owing to the very similar packing environment of the $Mn(CO)_3$ and $Re(CO)_3$ fragments in **1**, a partial disorder [refined values 0.773(1):0.227(1)] is observed for Re/Mn substitution, which has been modeled using the EXYZ and EADP options of SHELX97; this disorder is also reflected by the presence of a few weak reflections which violate the systematic absences conditions. The very small size of the acicular crystal of **3** (10 × 10 × 200 μm) and the larger sphere of data collected are reflected by rather poor estimates of the integrated intensities of the weak reflections (see *R*1 and R_{int} in Table 2); a parallel refinement, performed only with intense data [$I > 10\sigma(I)$], resulted in much better agreement factors (*R*1 = 0.027 and *wR*2 = 0.048 for the same structural model). Apart from the cation and water oxygen atoms in **5** (which experience very large thermal motion or unrationalized static disorder, leading to poor(er) agreement factors), all remaining non-H atoms have been treated anisotropically. Hydrogen atoms were ultimately included in calculated positions and refined isotropically riding on the atoms to which they are attached. A list of crystal data, refinement parameters and final agreement factors can be found in Table 2.[30]

X-ray Powder Diffraction: The light yellow powders of **2** were gently ground in an agate mortar and then deposited on the clean surface of a Si(511) monocrystal with the aid of a thin layer of silicone grease. XRPD data were collected in the step-scan θ:2θ mode on a Rigaku D-III/Max horizontal-scan diffractometer equipped with parallel (Soller) slits and a graphite monochromator (Cu-*Kα* λ = 1.5418 Å) in the diffracted beam. Generator set at 40 kV and 40 mA; Slits used: DS = 1.0°; AS = 1.0°; RS = 0.3 mm. Δ2θ = 0.02°, t = 5 s; the sample was rotated at about 60 rpm about the scattering axis in order to minimize preferred orientation effects. A whole pattern profile fitting performed by the Le Bail method[31]

using GSAS[32] afforded the following lattice parameters (a = 9.774; b = 16.286, c = 16.002 Å, β = 92.09°), indicating the strict isomorphous character of the powders of **2** with compound **1**. Since these two unit cells are very similar, they probably share atoms with similar fractional coordinates: indeed a Rietveld refinement for fixed, isotropic atoms, whose coordinates are taken from **1** (with the obvious replacement of Re by Mn), rapidly converged to R_p = 0.083 and R_F = 0.085, demonstrating the validity of such a structural model (see Figure 4); however, since powder diffraction is known to afford only approximate bonding parameters, no further refinements were performed in the search for better powder data fitting by the customary (for single-crystal data) independent atom model.

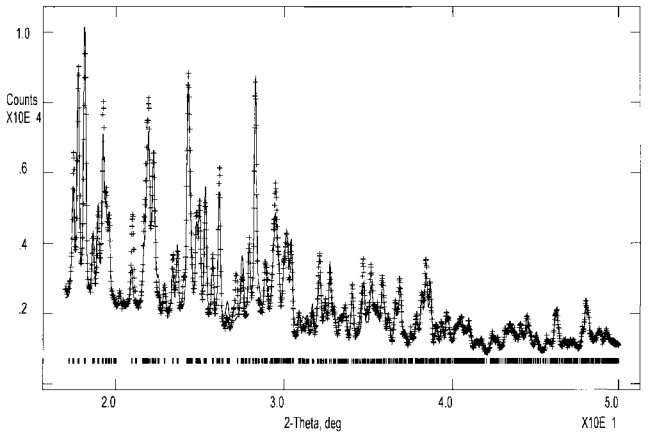

Figure 4. Rietveld refinement plot for $[(CO)_3Mn(pz)_3Mn(CO)_3](Et_3NH)$ (**2**) in the 17 < 2θ < 50° range, with peak markers at the bottom

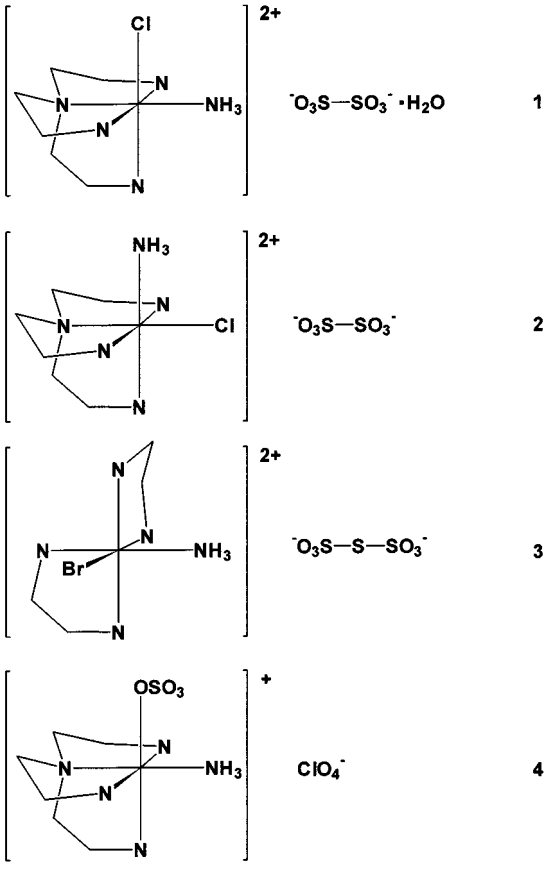
The Interaction between Amminehalocobalt(III) Cations and Polythionate Anions: Hydrogen-Bonding Patterns and S–S Bond Cleavage Reactions



Hyungphil Chun,[a] W. Gregory Jackson,[b] Josephine A. McKeon,[b] Fernando B. Somoza, Jr.,[a] and Ivan Bernal*[a]

Keywords: Cobalt(III) / Dithionate / Trithionate / Sulfato ligand

Crystal structures of amminehalocobalt(III) compounds with di- or trithionate anions have been determined in order to know whether they interact to adopt specific molecular packing patterns and whether di- and trithionate anions undergo the S–S bond cleavage reactions as has been found for the $S_4O_6^{2-}$ ion. In the structures of *p*-[Co(tren)(NH_3)Cl]-S_2O_6•H_2O (**1**) and *t*-[Co(tren)(NH_3)Cl]S_2O_6 (**2**), the configurational differences in the cations dictate the hydrogen-bonding pattern with the dithionate anion to lead to racemic structures. *cis*-[Co(en)$_2$(NH_3)Br]S_3O_6 (**3**) also crystallizes in a racemic space group $P2_1/c$ in which the ions form a macrocyclic hydrogen-bonded network. Aqueous solutions of $S_3O_6^{2-}$ and *p*-[Co(tren)(NH_3)Cl]$^{2+}$ produce *p*-[Co(tren)(NH_3)(OSO_3)]ClO_4 (**4**) which is believed to be derived from the hydrolytic cleavage of S–S bond in the trithionate anion. These results reinforce our previous observation of the S–S cleavage reactions for the tetrathionate anion.

In the course of investigating crystallization behavior of Werner-type cobalt(III) compounds, Bernal et al. reported that the *cis*-[Co(en)$_2$(NH_3)Br]$^{2+}$ cation spontaneously resolves into its optical antipodes when crystallized with the $S_4O_6^{2-}$ ion.[1] And, in a recent study, we reported that when the $S_4O_6^{2-}$ ion was used to crystallize the *cis*-α-[Co(trien)(NH_3)Cl]$^{2+}$ ion, an unexpected cleavage at a S−S bond, followed by a disproportionation, occurs to give *cis*-α-[Co(trien)(NH_3)Cl]S_5O_6.[2] Also reported in that paper was the crystal structure of K[Co(tren)(NH_3)(OSO_3)]-S_4O_6·2H_2O produced by the same cleavage reaction of $S_4O_6^{2-}$ ion. These observations led us to further investigate the hydrogen-bonding modes of amminehalocobalt(III) cations with polythionate anions and the specificity of S−S bond cleavage reactions.

In this study, we discuss the crystal structures of *p*-[Co(tren)(NH_3)Cl]S_2O_6·H_2O (**1**), *t*-[Co(tren)(NH_3)Cl]S_2O_6 (**2**), *cis*-[Co(en)$_2$(NH_3)Br]S_3O_6 (**3**) and *p*-[Co(tren)(NH_3)-(OSO_3)]ClO_4 (**4**). Although the cations of **1** and **2** differ only in the position of the NH_3 ligand with respect to the tertiary nitrogen atom of the tren ligand, their molecular packing structures show totally different hydrogen-bonding patterns leading to the racemic structures. The crystal structure of **3** is interesting in that the cation crystallizes as a conglomerate with a tetrathionate anion[1] but as a racemate with two bromide ions and two water molecules of crystallization.[3] Compound **3** also is interesting when viewed against the fact that the $S_3O_6^{2-}$ ion underwent a hydrolytic cleavage reaction while the chloro ligand of the *p*-[Co(tren)(NH_3)Cl]$^{2+}$ ion was replaced to produce compound **4**.

Although both *p* and *t* isomers of the [Co(tren)(NH_3)Cl]$^{2+}$ ion and their related compounds have been studied extensively by Buckingham and co-workers,[4−6] their crystal

structures have not been reported in the CSD[7] except for a few compounds with an *N*-methylated tren ligand.[8] Also it is noted that Asakura et al. reported a chiral autocatalysis reaction leading to the preparation of an optically pure form of the cation of **3** as a bromide salt without water molecules of crystallization.[9]

Results and Discussion

As described by Buckingham and co-workers,[4] the red compound *p*-[Co(tren)(NH_3)Cl]Cl·ClO_4 was prepared by ligand substitutions of four ammine groups with the tren ligand followed by acidic cleavage (HCl) of the peroxo bridge of [Co(NH_3)$_5$(O_2)(NH_3)$_5$Co](NO_3)4·2H2O and then converted into a dithionate salt to give compound **1**. Its molecular structure is shown in Figure 1.

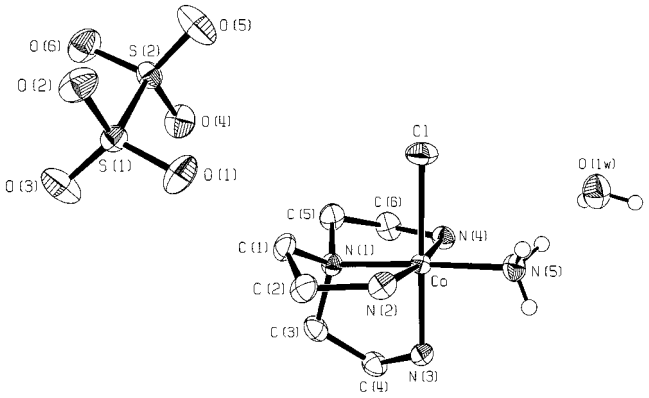

Figure 1. ORTEP diagram of **1** drawn at 50% probability level; hydrogen atoms of the tren ligand have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.964(2), Co−N(2) 1.967(2), Co−N(3) 1.930(2), Co−N(4) 1.963(2), Co−N(5) 1.959(2), Co−Cl 2.2783(9), S(1)−S(2) 2.1357(9) Å; N(1)−Co−N(5) 177.33(10), N(2)−Co−N(4) 171.32(9), N(3)−Co−Cl 178.70(7)°

In the geometry of the cobalt cation, the largest deviation from a regular octahedron is the angle N(2)−Co−N(4) [171.32(9)°]and N(5)−Co−Cl [87.21(8)°]. The former is a consequence of the geometrical features of the tren ligand and the latter is attributed to the weak the internal hydrogen bonds between Cl and hydrogen of the ammine ligand. For the anion, two S−O bond lengths, S(1)−O(1), 1.435(2) Å and S(2)−O(5), 1.436(2) Å, are significantly shorter than the other four [average 1.452(2) Å] and the two oxygen atoms do not participate in any hydrogen bond shorter than 2.5 Å.

When [Co(tren)Cl_2]Cl is stirred in a warm methanolic ammonia solution, the other isomer *t*-[Co(tren)(NH_3)Cl]Cl_2 is isolated as a reddish purple microcrystalline precipitate with a reasonable yield (> 50%) and then converted into a dithionate salt to give compound **2**. In the structure shown in Figure 2, the crystallographic asymmetric unit contains the cobalt cation and two $-SO_3$ fragments of a dithionate anion in different positions.

The fragment generates the other half when an inversion symmetry operation is performed. The structural parameters for the cation and anion show the same trends as those

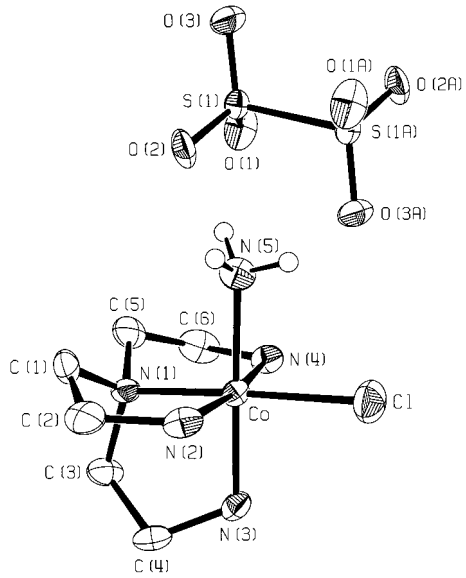

Figure 2. Molecular structure of **2**; hydrogen atoms of the tren ligand have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.949(4), Co−N(2) 1.959(5), Co−N(3) 1.939(5), Co−N(4) 1.946(5), Co−N(5) 1.976(5), Co−Cl 2.247(2), S(1)−S(1A) 2.114(3) Å; N(2)−Co−N(4) 171.5(2), N(3)−Co−N(5) 178.3(2), N(1)−Co−Cl 176.56(13)°

of **1** described above. **3** was prepared by adding an aqueous solution of $K_2S_3O_6$ to a saturated solution of *cis*-[Co($en)_2$(NH_3)Br]Br_2 and its molecular structure is shown in Figure 3.

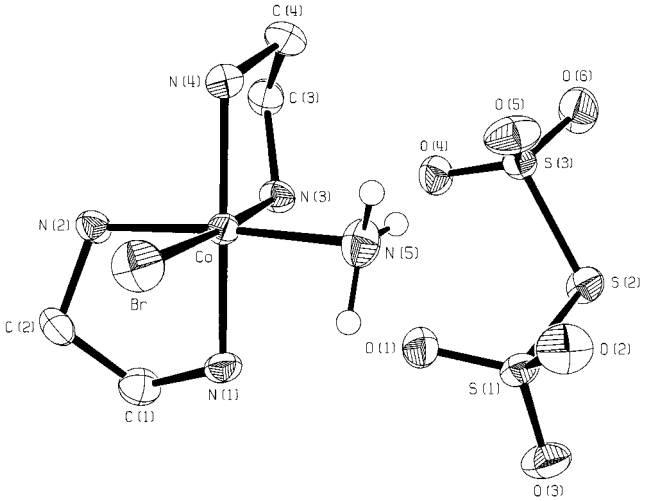

Figure 3. Molecular structure of **3**; hydrogen atoms of the en ligands have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.945(3), Co−N(2) 1.958(3), Co−N(3) 1.961(3), Co−N(4) 1.962(3), Co−N(5) 1.960(4), Co−Br 2.3915(10), S(1)−S(2) 2.1120(13), S(2)−S(3) 2.092(2) Å; N(1)−Co−N(4) 176.81(14), N(2)−Co−N(5) 174.7(2), N(3)−Co−Br 176.42(11), S(1)−S(2)−S(3) 102.71(7)°

In the structure, the two S−S bonds of the trithionate anion are not equal in distances [2.1120(13) and 2.092(2) Å] and the six S−O lengths fall within their 3σ ranges with the average of 1.443(3) Å.

For compound **4**, a solution mixture of *p*-[Co(tren)(NH_3)Cl]Cl·ClO_4 and $K_2S_3O_6$ did not yield any

crystalline product, unlike the compounds **1** and **2**, which began to crystallize almost immediately after mixing the two reactants. Instead, a white powdery precipitate was slowly deposited on the bottom of the beaker as the solvent evaporated. When the solution was concentrated, it was divided into four portions. Three of them were used for liquid diffusion with acetone, ethanol and acetonitrile and from the fourth the solvent was allowed to evaporate slowly. Only the one with ethanol produced a small amount of red crystals after standing for several weeks. A suspicion for the integrity of the trithionate thus entered our mind and was later proved to be true when we solved the structure. The structure and geometrical parameters of the cation shown in Figure 4 are very similar to the one produced by hydrolytic cleavage of the $S_4O_6^{2-}$ anion.[2]

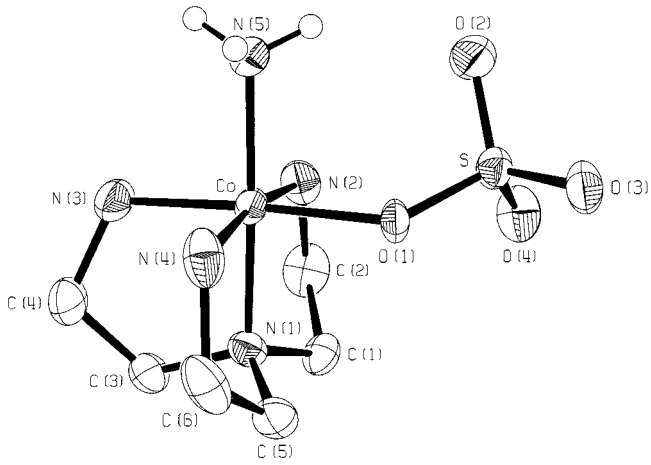

Figure 4. View of the cation of **4**; hydrogen atoms of the tren ligand have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.962(4), Co−N(2) 1.935(5), Co−N(3) 1.926(5), Co−N(4) 1.974(5), Co−N(5) 1.955(5), Co−O(1) 1.958(3), S−O(1) 1.510(4), S−O(2) 1.460(4), S−O(3) 1.464(4), S−O(4) 1.476(4) Å; N(1)−Co−N(5) 178.1(2), N(2)−Co−N(4) 170.8(2), N(3)−Co−O(1) 175.1(2), Co−O(1)−S 131.3(2)°

In the packing structure of **1**, shown in Figure 5, a dithionate anion displays hydrogen bonds with a cation in a side-on fashion.

Such one-to-one side-on contacts are possible because the ammine ligand is *cis* to all three hydrogen-bearing nitrogen atoms of the tren ligand. That is, the so-called *p* configuration of the cation allows the hydrogen atoms of N-donor atoms to be arranged around two trigonal faces of an octahedron. The closest hydrogen bond found was between the oxygen atom of a water molecule and a hydrogen atom of the ammine ligand [2.005(42) Å].

The apparently complicated packing structure of **2**, shown in Figure 6, can be best understood by realizing that the three hydrogen-bearing nitrogen atoms of the tren and the NH_3 ligands are lying on the same plane.

As a consequence, four dithionate anions are arranged around a tetragonal basal plane of an octahedron to form hydrogen bonds with hydrogen atoms of tren and of the NH_3 ligand. Since the anions are positioned on crystallographic inversion centers, as mentioned above, the two cobalt cations connected to $-SO_3$ ends of a dithionate anion by hydrogen bonds are a racemic pair.

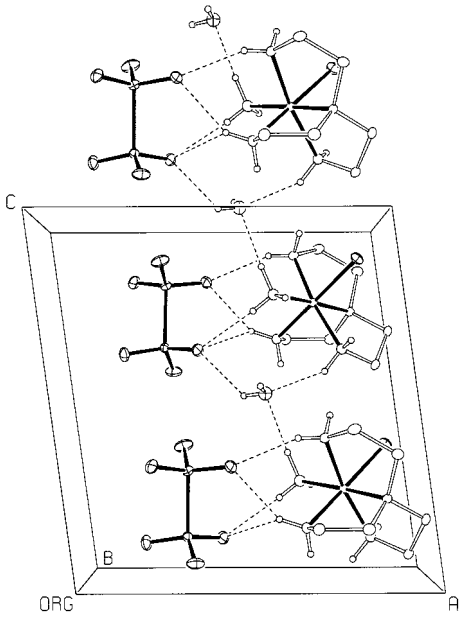

Figure 5. Packing of ions and water molecules of crystallization of **1**; the molecules shown are related by *c*-glide plane symmetry; hydrogen bonds shorter than 2.5 Å are shown as dotted lines

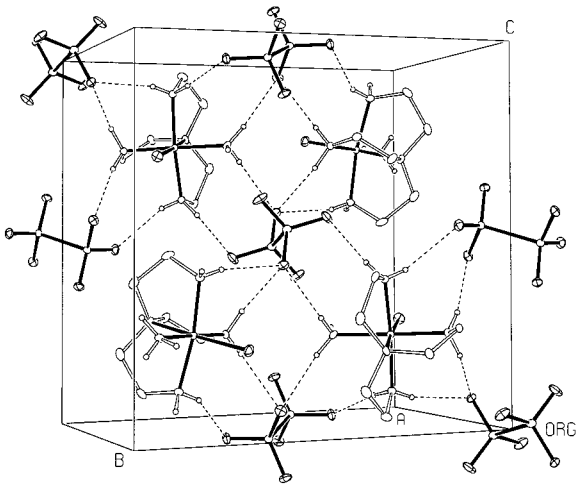

Figure 6. Packing diagram of **2** showing hydrogen-bonded interactions; note that dithionate anions are positioned on crystallographic inversion centers.

Figure 7 depicts the packing of *cis*-$[Co(en)_2(NH_3)Br]^{2+}$ ions with trithionate anions in **3**.

In the structure, an $-SO_3$ end of a trithionate ion bridges two neighboring cations to form a macrocyclic hydrogen-bonded network made of four molecules. Meanwhile, the $-SO_3$ moieties, which are not involved in forming the network, have contacts with other cations located along the *a* axis of the unit cell, and those cations form the macrocyclic networks again.

Trithionate ($S_3O_6^{2-}$) has been known to thermally decompose to produce SO_4^{2-}, SO_2 and S in aqueous solution.[10] And as the preparation and structure of **3** implies, the divalent anion is perfectly stable in aqueous solutions

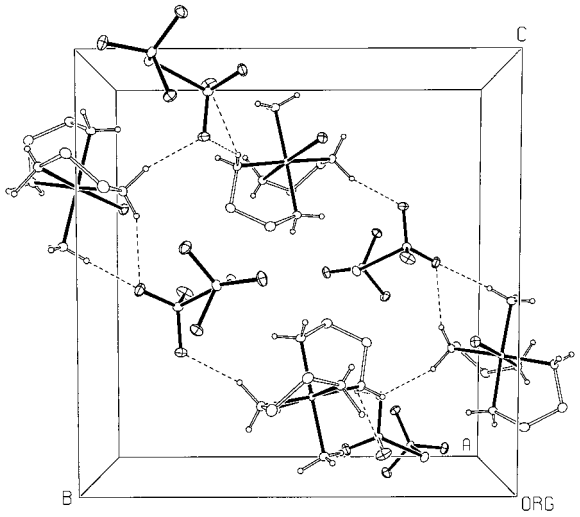

Figure 7. Macrocyclic hydrogen-bonded network structure of **3**; dotted lines represent hydrogen bonds shorter than 2.5 Å

at room temperature for the relatively short period of time required for crystallization. However, the production of compound **4**, in conjunction with our previous report,[2] might suggest the ability of $[CoN_4(NH_3)X]^{n+}$ ions [where N_4 is tren or trien, but not $(en)_2$] to apparently promote the cleavage reactions of S−S bonds in a series of polythionates. Dithionate, which has no reduced form of sulfur atoms, however, does not readily cleave its single S−S bond (although it does in strong acid, albeit slowly).

The trien and especially the tren complexes are slow to hydrolyze by the spontaneous pathway, but are very base-sensitive, and base-catalyzed hydrolysis of bound Cl^- or Br^- is the major contribution to the hydrolysis rate even at pH = 7−8. Certainly, color changes consistent with formation of $[CoN_4(NH_3)(OH_2)]^{3+}$ are observed for solutions of these ions in water, in the presence or absence of polythionates, over periods of hours. Thus, for tren and trien complexes where the time scale for the crystallization are long (days to weeks), sulfato complexes are formed, and sulfur, free sulfate and polythionates of different stoichiometry are also formed by hydrolysis and disproportionation of the original polythionate (be it $S_4O_6^{2-}$ or $S_3O_6^{2-}$). Slow anation of the aquametal complex by sulfate logically accounts for the formation of the sulfato complex, and it preferentially crystallizes from solution simply because it is less soluble than the other components. We also note that the crystalline potassium polythionate salts have a finite shelf life, $K_2S_4O_6$, $K_2S_5O_6$ and $K_2S_6O_6$ in particular, such that fresh solutions of aged salts (months to years) can lead to the immediate crystallization of unexpected polythionates. Moreover, we note that the published syntheses[11] of the penta- and hexathionates are not particularly reproducible.

Activation to hydrolysis through metal ion coordination of amino acid esters and peptides have long been known and well documented,[12,13] and a similar mechanism for $S_nO_6^{2-}$ merits consideration. For example, polythionate complexes $[Co(N)_4(NH_3)O_3S(S)_nSO_3]^+$ might be formed

from the aqua complex by anation, and cleaved at the S−S bond nearest the polarizing Co^{III} center by activated hydrolysis, thereby providing the sulfato complex. We have as yet not performed the appropriate control experiments to either support or discount this mechanism, but note that the synthesis of even the simplest polythionate complex, $[Co(NH_3)_5O_3SSO_3]^+$, has so far eluded us. Chelated polythionates are likely to be more viable, and we are presently investigating potential 5- and 6-membered ring systems derived from $S_2O_6^{2-}$ and $S_3O_6^{2-}$, respectively, in the *cis*-$[Co(en)_2X_2]^+$ system.

In summary, di- and trithionate anions do not show a specific hydrogen-bonding pattern with amminehalocobalt(III) cations; according to the geometrical arrangement of hydrogen atoms around the coordination sphere, they show a one-to-one side-on pattern or play end-on bridging roles. Sulfur−sulfur bonds in polythionates other than $S_2O_6^{2-}$ seem to be prone to slow hydrolytic cleavage reactions at room temperature.

Experimental Section

General: *p*-$[Co(tren)(NH_3)Cl]Cl{\cdot}ClO_4$ and *t*-$[Co(tren)(NH_3)Cl]Cl_2$ were prepared by known methods[4] except for chromatographic procedures. *cis*-$[Co(en)_2(NH_3)Br]Br_2$ was prepared by the method reported earlier.[3] $Na_2S_2O_6{\cdot}2H_2O$ (Fisher Scientific Company) was used as received. Elemental analyses were carried out by the Galbraith laboratories.[14]

$K_2S_3O_6$: Each of the two methods described in Brauer's book[11] was used. A set of X-ray data was collected for a single crystal to confirm its structure. The structure is known[15]: orthorhombic, *Pmnb*, $a = 5.751(6)$, $b = 9.810(1)$, $c = 13.700(3)$, $Z = 4$ and $R = 0.0381$ for 672 observed reflections [$> 2\sigma(I)$]. − $K_2S_3O_6$ (270.37): calcd. S 35.57; found S 35.73.

***p*-$[Co(tren)(NH_3)Cl]S_2O_6{\cdot}H_2O$ (1):** A solution of partly dissolved *p*-$[Co(tren)(NH_3)Cl]Cl{\cdot}ClO_4$ (1.97 g, 5 mmol) in 40 mL of water was filtered directly into a 50-mL aqueous solution containing $Na_2S_2O_6{\cdot}2H_2O$ (7.27 g, 30 mmol) so that the two solutions formed layers. Dark red crystals began to grow within 30 min. − $C_6H_{23}ClCoN_5O_7S_2$ (435.79): calcd. C 16.54, H 5.33, Cl 8.13, Co 13.52, N 16.08, S 14.71; found C 16.24, H 5.52, Cl 8.20, Co 14.03, N 15.79, S 15.10.

***trans*-$[Co(tren)(NH_3)Cl]S_2O_6$ (2):** 0.40 g(1.2 mmol) of *t*-$[Co(tren)(NH_3)Cl]Cl_2$ was dissolved in 5 mL of water and added to a 10-mL aqueous solution of 0.50 g (2.1 mmol) of $Na_2S_2O_6{\cdot}2H_2O$. Purple crystals were formed immediately and collected the next day (0.21 g, 41%). − $C_6H_{21}ClCoN_5O_6S_2$ (417.77): calcd. C 17.25, H 5.07, N 16.76; found C 17.31, H 5.08, N 16.35.

***cis*-$[Co(en)_2(NH_3)Br]S_3O_6$ (3):** To a saturated solution of *cis*-$[Co(en)_2(NH_3)Br]Br_2$ in water was added an aqueous solution of $K_2S_3O_6$. Crystals suitable for X-ray work were grown from water by the same method but using more dilute solutions. − $C_4H_{19}BrCoN_5O_6S_3$ (468.24): calcd. C 10.29, H 4.09, N 14.96; found C 10.28, H 4.16, N 14.85.

***p*-$[Co(tren)(NH_3)(OSO_3)]ClO_4$ (4):** This compound was prepared by the same method used for **1** except for using $K_2S_3O_6$ instead of $Na_2S_2O_6{\cdot}2H_2O$. The solution was frequently filtered off in order to remove a white powdery precipitate, most likely S and $KClO_4$. A small amount of single crystals were obtained by liquid diffusion with ethanol after 2 months.

Crystallography: For all four compounds, the intensity data were collected with an Enraf−Nonius CAD-4 diffractometer at room temperature and SHELXS-86[16] and SHELXL-93[17] were used to solve and refine the structures. All the hydrogen atoms of **1**, **2** and **3** were located from difference maps and refined isotropically; those of **4** were placed in their geometrically ideal positions with isotropic temperature factors 1.2 times those of the attached non-hydrogen atoms. In the refinement of **3**, relatively large residual electron densities found in the final difference map were ignored since they are too close to cobalt and bromide (< 1 Å). The structures of **2** and **4**, for which many weak reflections were collected, yielded *R* factors a little higher than the other two. Parameters for data collection and structure refinements are summarized in Table 1. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre[7] as supplementary publication no. CCDC-118583 to -118586. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank the Robert A. Welch Foundation for support of this research (Grant E-592 to I. B.) and for a fellowship granted to H. C. Financial support from the Australian Research Council (to W. G. J.) is gratefully acknowledged, and also, I. B. thanks the National Science Foundation for the funds used in purchasing the diffractometer.

Synthesis, Crystal Structures, and Solution Properties of *N*-Methylene(phenyl)phosphinic Acid Derivatives of Cyclen and Cyclam

Jan Rohovec,[a] Mojmír Kývala,[a] Pavel Vojtíšek,[a] Petr Hermann,[a] and Ivan Lukeš*[a]

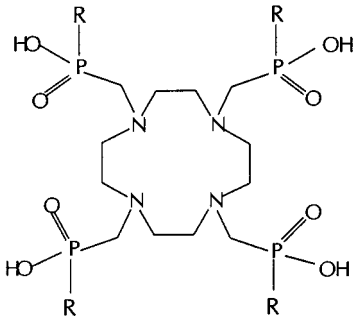
Keywords: Acid derivatives / Cyclen and cyclam derivatives / Phosphinic acid / Potentiometry / Protonation and stability constants / ^{31}P-NMR titration / Hydrogen bonding

Two phenylphosphinic acid derivatives of tetraaza macrocycles, (1,4,7,10-tetraazacyclododecanetetrayl)tetrakis(methylene)tetrakis(phenylphosphinic acid)] (H_4L^1) and (1,4,8,11-tetraazacyclotetradecanetetrayl)tetrakis(methylene)tetrakis(phenylphosphinic acid)] (H_4L^2), were synthesised and the crystal structures of H_4L^2 and its bis(1-adamantylammonium) salt were determined. In both the structures, the ring conformation is virtually the same and is stabilised by hydrogen bonds. Protonation constants of the acids and stability constants of their Zn^{2+} and Cd^{2+} complexes were determined pH-metrically at 25 °C and at an ionic strength of 0.1 mol dm^{-3} (KNO_3). The pK_A values found for both the compounds are lower than those for their carboxylic analogues and correspond to the expected electron-withdrawing ability of the –P(Ph)O_2H moiety. The value pK_1 of the last dissociation constant of H_4L^1 is surprisingly high. The complexes of Zn^{2+} and Cd^{2+} with $(L^1)^{4-}$ and $(L^2)^{4-}$ are less stable than those with other similar ligands, which is in accordance with lower overall basicity of H_4L^1 and H_4L^2. A pronounced drop in the stability of the complexes of H_4L^2 can be explained by partial coordination of the ligand to the metal ions. The solution properties of the ligands were also investigated by ^{31}P-NMR spectroscopy. The spectra observed suggest stable (on the NMR time scale) conformations of the protonated ligands in solution. A comparison of NMR spectra in solution and CP/MAS-NMR spectra indicates that the structures of the conformers roughly correspond to the structures observed in the solid state. The conformations are stabilised by intramolecular hydrogen bonds and by hydrophobic interactions of phenylphosphinic moieties. The conformers are stable even at 90 °C, but not in the presence of complexing metal ions.

A large number of derivatives of 12- and 14-membered tetraazamacrocycles, "cyclen" and "cyclam", have been described. The macrocycles are usually substituted on the nitrogen atoms by four identical pendant groups. The selectivity of complexation (i.e. the stability of the complexes) of such ligands towards various metal ions can be tuned by adjusting the ring size, the number or kind of coordinating atoms in the ring and the type of side chain.[1] Tetraazacycles with acetate side chains and their complexes are the most thoroughly studied substances of this kind.[2] They form thermodynamically very stable complexes, the most stable being generally those formed with di- and trivalent metals.[1][2] Some of the complexes formed are kinetically inert; e.g. with lanthanides.[3] These complexes have been widely tested because of their use, e.g. as contrast substances in MRI,[4] for labelling antigenic antibodies using metal radioisotopes[4c,5] for both diagnostic and therapeutic purposes, and also as catalysts for the splitting of nucleic acids.[6]

Some years ago, a study of aza cycles with side chains containing a methylenephosphonic[7–9] ($-CH_2-PO_3H_2$) or methylenephosphinic[7a,10–16] [$-CH_2-P(R)O_2H$] groups was begun, in a search for ligands with properties different from those containing acetic acid groups. Variation of the R group should also contribute to a change in the ion selectivity and properties of the macrocyclic compounds. Therefore, we studied the influence in a series of simple aminomethylphosphinic acids $H_2NCH_2P(R')O_2$ H, where R′ = H, methyl, phenyl, or *tert*-butyl.[17] Changes in complexing properties of the simple acids were surprisingly large, the formation constants increasing from phenyl to methyl, *tert*-butyl and hydrogen substituents. Except for R′ = H, the order follows that of the increasing basicity of the acids. Thus, we focused on the study of the influence of the methylene(phenyphosphinic acid) substituent on complexing properties of the 12- and 14-membered tetraazacycles. We have reported on the synthesis of 1,4,7-triazacyclononane and 1,4,7,10-tetraazacyclododecane functionalised with methylenephosphinic pendant groups [R = $-CH_2-P(H)O_2H$].[18] In the present paper, we report the synthesis, structure and solution properties of two polyazamacrocycle ligands; the previously described[19] (1,4,7,10-tetraazacyclododecanetetrayl)tetrakis(methylene)tetrakis(phenylphosphinic acid)] (H_4L^1), and the new ligand (1,4,8,11-tetraazacyclotetradecanetetrayl)tetrakis(methylene)tetrakis(phenylphosphinic acid)] (H_4L^2). The formulae of both the ligands studied, together with those of analogous ligands known from the literature and mentioned in the discussion, are shown in the following scheme.

Results and Discussion



Synthesis

Compounds H_4L^1 and H_4L^2 were synthesised by the Mannich reaction of 1,4,7,10-tetraazacyclododecane tetra-

hydrochloride and 1,4,8,11-tetraazacyclotetradecane tetrahydrochloride, respectively, with paraformaldehyde and phenylphosphinic acid in aqueous HCl. The reaction conditions, i.e. concentration of HCl, rate of the addition of paraformaldehyde and temperature in the range 50−110 °C, were optimised for both the syntheses and the best conditions are described in the Experimental Section. The ligand H_4L^2 precipitated from the reaction mixture as $H_4L^2 \cdot n\,HCl$ ($n = 3-4$) and was purified by recrystallisation from methanol containing propylene oxide to give the free acid. The ligand H_4L^1 was isolated as an oily ammonium salt after ion-exchange chromatography of the reaction mixture and was subsequently converted into the free acid by acidification. In some cases, the acid contained traces of HCl, which were usually removed in high vacuum over KOH. Samples of the ligands for potentiometric measurements were recrystallised from MeOH solution containing propylene oxide to remove any traces of HCl. Elemental analysis, thin layer chromatography, ^{31}P-CP/MAS-NMR spectra of the bulk materials, and X-ray analysis of H_4L^2 indicate that both the compounds were obtained in the pure form.

Synthesis of phosphinic acid derivatives of azamacrocycles by the Mannich reaction in acid aqueous solution seems to be a convenient reaction; however, the reaction conditions for each phosphinic acid and azamacrocycle have to be optimised to reduce *N*-methylation of the cycle.[20] In accordance with the literature,[20][21] we can confirm that the side reactions are suppressed by a lower temperature, higher acidity, higher concentration of reagents than is usually recommended and by the use of paraformaldehyde, instead of an aqueous solution of formaldehyde, and its slow addition.

Structure

In solving the structure of $H_4L^2 \cdot 4\,H_2O$ we wanted to confirm the protonation and conformation of the $(H_2L^2)^{2-}$ anion. Only bis(1-adamantylammonium) salt $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ was found to form crystals suitable for X-ray analysis. Structures of both the compounds are shown with the numbering scheme in Figures 1 and 2. Tables 1 and 2 list selected bond lengths and angles. Superposition of the molecular structures of H_4L^2 and $(H_2L^2)^{2-}$ is projected in Figure S1 (see Supplementary Material).

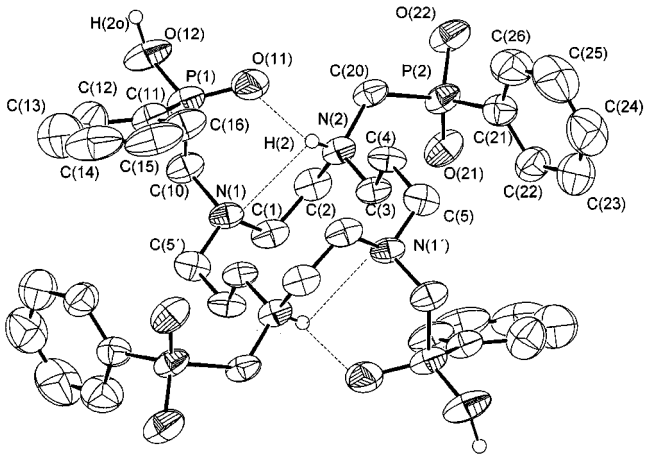

Figure 1. View of $H_4L^2 \cdot 4\,H_2O$ with the atom numbering scheme. The hydrogen bonds are denoted with primed lines

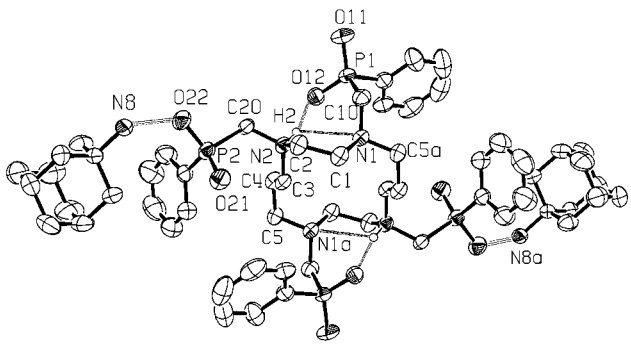

Figure 2. View of $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ with the atom numbering scheme. The hydrogen bonds in the structure of the $(H_2L^2)^{2-}$ anion are denoted with primed lines

In the crystalline state, both the compounds exist as zwitterions with two protonated nitrogen atoms in the rings and their structures contain the centres of symmetry. A comparison of bond lengths and angles in the rings shows that the ring conformation is virtually the same for both structures. This is also evident from the superposition of the two molecules, as shown in Figure S1 in the Supplementary Material available (see footnote on the first page). The ring conformations are stabilised by hydrogen bonds N2−H2···O11 (2.67 Å) in $H_4L^2 \cdot 4\ H_2O$ and N2−H2···O12 (2.70 Å) in $(AdNH_3)_2(H_2L^2) \cdot 6\ H_2O$. The bond lengths of N2−N1 are 2.88 Å and 2.89 Å respectively, which would point to additional hydrogen bonds, although the angles N2−H2.N1 are about 110° and, hence, we assume only a weak interaction.

The coordination around the P atoms significantly departs from the regular tetrahedron. In both the structures, the P−O distances are strongly influenced by hydrogen bonds and in $H_4L^2 \cdot 4\ H_2O$ also by protonation. In the structure of $H_4L^2 \cdot 4\ H_2O$, the molecules are linked through a very short hydrogen bond (2.4 Å) between P(1)−O(12)−H(20)···O(22)−P(2) to give a polymeric struc-

ture with the P−O distances virtually the same due to the strong hydrogen bond. The P(1)−O(11) and P(2)−O(21) distances are also very similar and are linked by hydrogen bonds with an H_2O molecule [P(2)−O(21)] or with the N(2)−H(2) bond [P(1)−O(11)]. In the structure of $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ the P−O distances are shorter than in $H_4L^2 \cdot 4\,H_2O$. All oxygen atoms are linked through hydrogen bonds of 2.8−2.9 Å with the nitrogen of adamantylammonium or with molecules of water (Table 2). The changes in the geometry on C10 and C20 atoms also correspond to the protonation of phosphinic acid groups. The longest C−P and the shortest C−N distance was found for N1−C10−P1 (the phosphinic acid group is protonated) in H_4L^2.

Comparing the structure of $H_4L^2 \cdot 4\,H_2O$ with structures of $H_4teta \cdot 6\,H_2O$[22] (H_4teta = 1,4,8,11-tetraazacyclotetradecane-1,4,8,11-tetraacetic acid) and $H_4dotp \cdot 7\,H_2O$[23] (H_4dotp = 1,4,8,11-tetraazacyclotetradecane-1,4,8,11-tetrapropionic acid), it is clear that orientation of the acetic groups in H_4teta is completely different from that of phosphinic acid groups in H_4L^2 and the conformations of both the rings also show small differences. On the other hand, the molecular structure of H_4dotp is very similar to that of H_4L^2, and that of $Na_2H_2dotp \cdot 16\,H_2O$[24] is similar to $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$. In the structures, the orientation of two pendant arms towards protonated nitrogen atoms of the ring and formation of the same motif of hydrogen bonds and conformation were found. The similarity of H_4dotp to H_4L^2 probably results from better flexibility of the propionic acid arms in contrast to the short acetic acid moiety.

Differences in protonation of both phosphinate groups and amine of the ring were also observed in ^{31}P-CP/MAS-NMR spectra. In the spectrum of $H_4L^2 \cdot 4\,H_2O$, two signals at δ = 33.2 and 20.4 were observed and in the spectrum of $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$, signals at δ = 23.5 and 15.6 were observed. From the solution NMR titration curves of (aminoalkyl)phosphinic[25−27] and (aminoalkyl)phosphonic[28] acids, it is known that the minimum of the curve corresponds to a system with protonated amine and deprotonated phosphorus acid groups. Therefore, in the ^{31}P-CP/MAS-NMR spectrum of $H_4L^2 \cdot 4\,H_2O$ the signal at δ = 33.2 should correspond to $N-CH_2-P(Ph)O_2H$ and that at δ = 20.4 to $NH^+-CH_2-P(Ph)O_2^-$ moieties, while in the spectrum of $(AdNH_3)_2(H_2L^2) \cdot 6H_2O$ the signal at δ = 23.5 corresponds to $N-CH_2-P(Ph)O_2^-$ and that at δ = 15.6 to $NH^+-CH_2-P(Ph)O_2^-$ moieties. The value of the chemical shift of the $NH^+-CH_2-P(Ph)O_2^-$ system is higher for H_4L^2 than for $(H_2L^2)^{2-}$ and this is probably due to the strong intermolecular hydrogen bond mentioned previously. The assignment of phosphorus signals confirms the values found in the ^{31}P-CP/MAS-NMR spectra of a simple (aminomethyl)(phenyl)phosphinic acid $H_3N^+CH_2P(Ph)O_2^-$ (δ = 20.8) and its sodium salt (δ = 27.8). In the spectrum of the solid H_4L^1, two phosphorus signals at δ = 24.0 and 26.7 were also observed, and thus a similar way of protonation is assumed.

Potentiometry

The calculated values of the protonation and stability constants are given in Table 3. The computed standard deviations seem to be inadequately small. This fact mainly points to a high precision and good reproducibility of the measurements, the use of a suitable calibration function with many degrees of freedom and also to a large number of experimental points. However, the real accuracy is substantially lower (and the real standard deviations are substantially larger). According to the conclusions of several inter-laboratory tests the real standard deviations of the determined protonation and stability constants are at least 0.05−0.1 units on the logarithmic scale,[29] which is discussed in the Supplementary Materials.

A comparison of pK_A values determined for H_4L^1 and H_4L^2 with the values for cyclen, cyclam and their acetic acid, methylenephosphinic acid, and methylenephosphonic acid derivatives is shown in Table 4. From the comparison, it is clear that the protonation scheme of both the acids H_4L^1 and H_4L^2 corresponds to the protonation of the other ligands. The first two protonations occur in the alkaline region and reflect protonations of two opposite nitrogen atoms of the ring. On the basis of protonation of $H_4L^2 \cdot 4\,H_2O$ and $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ in the solid state and on comparison of the constants in Table 4, we assume that the next protonations occur on phosphinic moieties.

Table 3. Protonation constants of H_4L^1 and H_4L^2 and stability constants of their Zn^{2+} and Cd^{2+} complexes at 25°C and I = 0.1 mol dm^{-3} (KNO_3); the values in parentheses are standard deviations given by the programme

Ion	Species	$\log \beta_{pqr}$ H_4L^1	H_4L^2
H^+	HL^{3-}	11.436(7)	9.85(1)
	H_2L^{2-}	18.71(1)	19.793(5)
	H_3L^-	21.46(2)	21.639(9)
	H_4L	22.91(2)	
Zn^{2+}	ZnH_2L	21.06(5)	21.92(5)
	$ZnHL^-$	18.61(4)	
	ZnL^{2-}	15.92(1)	9.79(1)
	Zn_2L	18.32(5)	
	$Zn(H_{-1}L)^{3-}$	4.16(2)	
	$Zn_2(H_{-2}L)^{2-}$	3.45(2)	−3.24(3)
	$Zn_2(H_{-4}L)^{4-}$		−26.11(4)
Cd^{2+}	CdH_2L		22.05(5)
	$CdHL^-$	20.96(2)	
	CdL^{2-}	18.24(2)	9.91(2)
	Cd_2L	21.32(3)	12.99(4)

The last dissociation constant (pK_1) of H_4L^1 is unexpectedly higher than the values for H_4L^3 and H_4L^4, probably due to steric hindrance and hydrophobic interactions, which are discussed in the NMR section, and is not as strongly influenced by the electron-withdrawing $-P(R)O_2^-$ group[17] as the next protonation steps. The values for the other steps (pK_2, pK_3) indicate that the $-P(Ph)O_2^-$ group is more electron-withdrawing than $-CO_2^-$ and $-PO_3^{2-}$, as was expected from the well-known order observed for simple aminophosphinic, phosphonic, and carboxylic acids.[17]

In comparison with the phosphinic acid derivatives of cyclen, we can also observe an influence of the substituent on the phosphorus atom. The values increase in the order $H_4L^3 < H_4L^1 < H_4L^4$, i.e. from H to phenyl and ethyl substituents. The same order was observed for phosphinic analogues of glycine.[17] The pK_A values of H_4L^1 and other phosphinic acids were also reported in a short communication[26] and were discussed for similar azacyclic phosphinic acid ligands in ref.[27] We agree with Sherry's[27] opinion; therefore, the pK_A values found for H_4L^1 from potentiometry and NMR titration published previously[26] are incorrect. A reverse order of pK_1 and pK_2 found for H_4L^2 is discussed in the Supplementary Material.

Systems with the diamagnetic metal ions Zn^{2+} and Cd^{2+} were also studied in order to obtain information on whether solution conformations influence of the coordination ability of the ligands (see NMR section). Results are presented in Table 3 and are compared with the constants of the related ligands in Table 4. In the system with Zn^{2+}, H_4L^1 forms species $[ZnH_2L^1]$, $[ZnHL^1]^-$, $[ZnL^1]^{2-}$, $[Zn_2L^1]$, $[ZnH_{-1}L^1]^{3-}$ and $[Zn_2H_{-2}L^1]^{2-}$. The protonated species were found at a pH of around 3 with a low abundance. The anion $[ZnL^1]^{2-}$ is the predominant species in the neutral region (molar ratio M/L = 1:1). In the alkaline region, hydroxo complexes $[ZnH_{-1}L^1]^{3-}$ (molar ratio M/L = 1:1) and $[Zn_2H_{-2}L^1]^{2-}$ (molar ratio M/L = 2:1) were observed. In the system with Cd^{2+}, H_4L^1 forms species $[CdHL^1]^-$, $[CdL_1]^{2-}$ and $[Cd_2L^1]$. Hydroxo complexes were not found.

In contrast to H_4L^1, H_4L^2 forms species $[ZnH_2L^2]$, $[ZnL^2]^{2-}$, $[Zn_2H_{-2}L^2]^{2-}$, and $[Zn_2H_{-4}L^2]^{4-}$ in the system with Zn^{2+} and $[CdH_2L^2]$, $[CdL^2]^{2-}$, and $[Cd_2L^2]$ in the system with Cd^{2+}. The species $[MH_2L^2]$ have the same number of protons as $(H_2L^2)^{2-}$ and, thus, evidence for their existence can be provided by potentiometry only indirectly; however, its inclusion into the chemical model significantly improved the goodness of fit. For the protonated complexes, we suggest protonation of two nitrogen atoms of the ring. The almost simultaneous deprotonation of both the nitrogen atoms is similar to the process observed for the free H_4L^2. Interactions of the metal ions with the ligands in the acid region were confirmed by NMR measurements (see below).

As expected, the stability constant values of H_4L^1 with Zn^{2+} and Cd^{2+} (15.92 and 18.24) are lower than those of H_4dota (21.10 and 21.31) due to the lower overall basicity of the ligand caused by the electron-withdrawing effect of the phosphinic acid group. On the other hand, the stability constant of H_4L^1 with Cd^{2+} is higher than that for Zn^{2+}, probably due to the larger size of the cadmium ion, which may enable coordination of more pendant arms than for Zn^{2+}, in an analogous way to that observed for 1,4,8,10-tetraazacyclododecane-1,4,8,10-tetrakis(acetamide).[31] Azacycles with methylenephosphinic acid pendant arms seem to be selective to larger ions.[18] For $[ML^1]^{2-}$, we can assume coordination of all nitrogen atoms of the ring as is the case in other cyclene derivatives (e.g. H_4dota). The pK_A values of the $[MHL^1]^-$ for both the metal ions (2.69 for Zn^{2+} and 2.72 for Cd^{2+}) are close and could be attributed to protonation of phosphinic acid pendant arms.

In contrast to H_4L^1 systems, the stability constant values of H_4L^2 for complexes with both of the cations (9.79 for Zn^{2+} and 9.91 for Cd^{2+}) are much lower (Table 4) than the values for H_4teta (16.40 and 18.02, respectively). These lower values could result from differences in the size of the ring for H_4L^1 and H_4L^2, from the lower overall basicity of H_4L^2 in comparison with other ligands and, mainly, from a different bonding mode of the ligand. If we compare the stability constant values for H_4L^2 and H_4teta, we can see that the values for H_4L^2 are about half (on the logarithmic scale) that for H_4teta. This points to the fact that only a part of H_4L^2 is coordinated in $[ML^2]^{2-}$ complexes. The suggestion could be supported by formation of complexes with the ratio M/L = 2:1.

NMR Spectroscopy

Contrary to our expectation, extremely broad signals in the ^{1}H-NMR spectra of both the compounds and the presence of several signals in the ^{31}P-NMR spectra were found, and these roughly correspond to the spectra of the compounds in the solid state. Some ^{31}P-NMR spectra of both the compounds in dependence on pD are shown in Figure 3. From Figure 3, it is evident that coalescence of the signals occurs only in the strong alkaline region after full deprotonation of the compounds. The coalescence of the signals in the neutral region does not occur, even at a temperature of 90°C. In our opinion, the hydrophobic phenyl

groups surround protonated amines in H_4L^1 or H_4L^2 molecules and thus protect them against attack by bulk water. Consequently, the hydrogen bonds N(2)−H(2)···O(11) in H_4L^2 and in $(H_2L^2)^{2-}$ and analogous hydrogen bonds in $(H_2L^1)^{2-}$ are stable in solution and, therefore, can stabilise some ligand conformations. After complete deprotonation, the structures are not stabilised by hydrogen bonds, fast conformation changes occur and only one sharp signal is observed in ^{31}P-NMR spectra. The conformations can also be stabilised by hydrophobic interactions between phenyl groups and/or phenyl-propylene/ethylene chains. Analogous changes in the ^{31}P-NMR spectra were observed for 1,2-diaminoethane-*N*,*N*,*N*′,*N*′-tetrayl-tetramethylene-tetrakis-(phenylphosphinic acid).[25a] Two peaks in the ^{31}P-NMR spectrum at low temperature were also observed in a solution of H_8L^5, which is in accordance with the molecular structure of the compound in the solid state.[32]

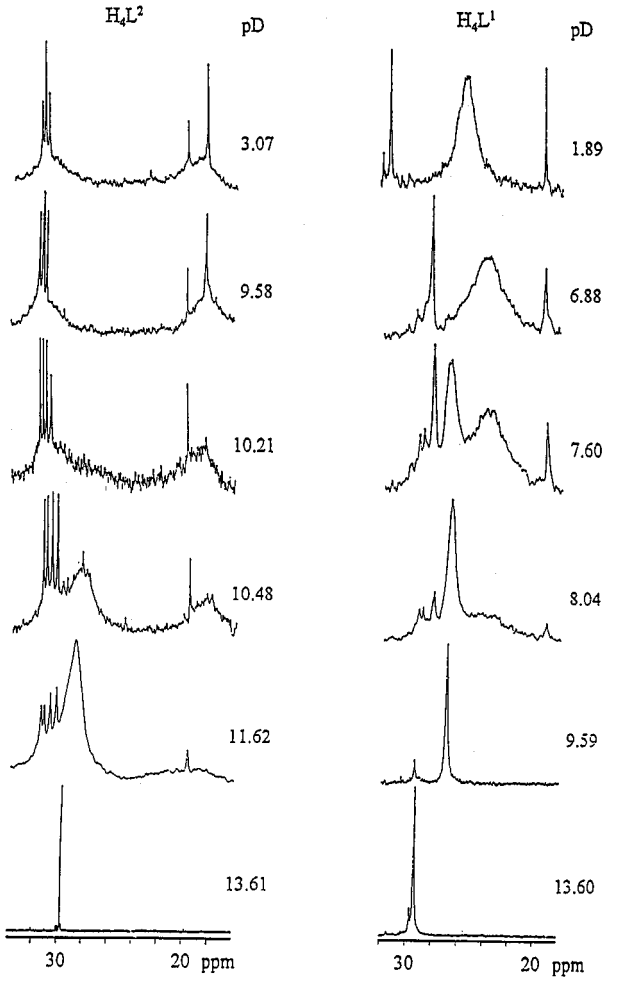

Figure 3. The ^{31}P-NMR spectra of H_4L^1 (right) and H_4L^2 (left) in dependence on pD

The ^{31}P-NMR spectra of H_4L^1 show the same features as the spectra of H_4L^2; however, the conformation of $(H_2L^1)^{2-}$ does not seem to be as rigid as that of $(H_2L^2)^{2-}$. In the spectra in the region of pD = 1.89−6.88 (pH ≈ 2.6−6.5), two sharp signals at δ = 19 corresponding to the pendant arm with the protonated amine and at δ = 30 corresponding to the pendant arm with the deprotonated amine were observed. In addition to the signals at δ = 19 and 30, the spectrum contains a broad signal at about δ = 25. Fast protonation of a phosphinic acid pendant arm occurs, as can be illustrated by the changes in the chemical shifts of the peaks in the acid region. The broad signal probably reflects a number of conformers in which all phosphorus atoms are equivalent with respect to the site of protonation. On the other hand, the sharp signals belong to a conformer with nonequivalent phosphorus atoms. The sharp peak at δ = 30 changes its position with pD significantly whereas the other one changes only negligibly. Thus, it is evident that the former peak corresponds to a phosphinic group where the third protonation takes place. Near the pD value corresponding to the pK_2 = 7.27 (pD = 7.6, pH ≈ 7.2), a strong sharp signal at about δ = 27 appears and reflects the $(HL^1)^{3-}$ species. The spectrum looks like a superposition of the spectra at lower and higher pD values. This is a consequence of a slow exchange (dissociation) of protons in $(H_2L^1)^{2-}$ and differences in the structure of conformers belonging to $(H_2L^1)^{2-}$ and $(HL^1)^{3-}$species. The signal at δ = 27 is dominant in the spectra over the range of pD 7.5−10.5. With the last deprotonation (pD = 10.9−13.6), the signal becomes increasingly sharp and continuously moves to δ = 29, which confirms the fast proton exchange in the $(HL^1)^{3-}$ anion.

The acid pK's determined from the ^{31}P-NMR titration in the range of −log[H^+] 1.0−2.5 under the conditions of the potentiometric titrations correspond to the values found from potentiometry. The changes in the ^{31}P-NMR spectra indicate the unsymmetrical protonations of phosphinic acid groups as the peaks at about δ = 19 and 30 are shifted to different pH values.

H_4L^2 exhibits virtually the same spectrum in the range of pD 3.07−9.58. This range of pD corresponds to conformers of a species $(H_2L^2)^{2-}$ in which two nitrogen atoms are protonated [see the crystal structure of $(AdNH_3)_2(H_2L^2)\cdot 6\,H_2O$]. As mentioned above, the ^{31}P-NMR titration curves of (aminoalkyl)phosphinic and (aminoalkyl)-phosphonic acids point to the fact that the minimum of the curve corresponds to a system with protonated amine and deprotonated phosphorus groups.[25−27] Therefore, signals in the region δ = 18−20 reflect $NH^+-CH_2-PPhO_2^-$ pendant arms and signals in the region δ = 30−32 reflect $N-CH_2-PPhO_2^-$ pendant arms bound by hydrogen bonds to the other nitrogen atoms of the ethylenediamine chains (see the crystal structure of the adamantylammonium salt). The broad peak observed in the spectrum of H_4L^1 at about δ = 25 was not found in the spectrum of H_4L^2, probably due to the presence of propylene chains in H_4L^2 dividing the molecule into two almost independent parts each stabilised by the hydrogen bond. The spectra in the region above pD 10.21, i.e. pH 9.8, (Figure 3) reflect the first and second deprotonations of the ring. A new signal at δ = 28 is seen and this belongs to $(HL^2)^{3-}$ and $(L^2)^{4-}$ species in almost fast conformation changes with the fast deprotonation of the last proton as indicated by a continuous change of the chemical shift from δ = 28 to 30 and by a sharpening of

the signal. At pD = 13.61, the deprotonation is complete and only one sharp signal is observed in the spectrum. Unfortunately, full interpretation of all observed changes in the ^{31}P-NMR spectra of the ligand is more complicated than for H_4L^1.

We wanted to know whether the ligand conformations are influenced by the presence of complexing ions and thus ^{31}P-NMR spectra of both the ligands in the presence of Zn^{2+} or Cd^{2+} were measured. The NMR spectra are very sensitive to complexation. Only one sharp signal at about δ = 27 is observed in the spectra of the solutions containing H_4L^1 with Zn^{2+} or Cd^{2+} in the L:M molar ratio 1:1 in the wide region of pH from 1.8 to 12. The signal is observed even in the acid region where formation of protonated complexes starts. Similarly, H_4L^2 in the M/L ratio 1:1 gives a sharp peak (δ = 26) in the neutral region and a very broad unresolved peak (δ = 18−32) in acidic solution (pH 2.0). This behaviour confirms the presence of metal ion/ligand interactions and, therefore, complexes $[MH_2L^2]$ should be present in acidic solutions. We assume that nitrogen atoms are protonated in the species and metal ion/ligand interactions occur through phosphinic acid groups. These results indicate a fast exchange of a metal ion between ligand molecules. On the other hand, H_4L^1 or H_4L^2 in the presence of noncoordinating ions such as Li^+ or K^+ (concentration of LiCl or KCl solutions was about 3 mol·dm^{-3}) in the neutral region give virtually the same spectra as the solutions with a low ionic strength. These results suggest that complexation of metal ions with ligands through phosphinic acid group(s) and/or nitrogen atom(s) breaks the system of hydrogen bonds that stabilise conformations of free ligands.

Experimental Section

Chemicals: Cyclen hydrochloride[33] and cyclam hydrochloride[34] were synthesised using known procedures. Other chemicals used were from commercial sources and were of the best quality available.

Crystallography: Crystals of $H_4L^2 \cdot 4\,H_2O$ and $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ suitable for X-ray diffraction were obtained from methanol/water solutions. For unit-cell and space-group determinations and for data collections, crystals of both the compounds were mounted at random orientations on glass fibres using an epoxy glue and were coated with a thin paraffin film. An Enraf−Nonius CAD4 diffractometer was used for measurements at 293(2) K with Mo-K_α radiation (λ = 0.71073 Å). Unit-cell dimensions were determined from angular settings of every twenty-five high-order (θ from 14 to 15° and from 13.5 to 14.5°, respectively) reflections using the CAD4 centring routines. Selected crystallographic and other relevant data for both compounds are listed in Table 6.

Intensities were collected using variable scan speeds to assure constant statistical precision. Three standard reflections measured every hour were used to confirm the stability of the crystal and of the experimental conditions. The orientation of the crystal was checked by measuring five standards every 100 reflections. The data were corrected for Lorenz polarisation, but not for absorption. The extinction correction was applied only in the case of $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$ using the procedure included in SHELXL97.[35] The structure was solved by a combination of Patterson and Fourier methods (SHELXS86,[36] SHELXL97) and refined by full-matrix least-squares techniques (SHELXL97). Scattering factors for neutral atoms used were included in the program SHELXL97. The hydrogen atoms were found (with the exception of two hydrogen atoms of the water molecules in the structure of H4L2···4 H_2O) on the difference maps and refined isotropically. The partially disordered water molecules in the crystal lattice of H4L2···4 H_2O were described as two oxygen atoms [O(8) and O(8A)] in two close positions [distance O(8)···O(8A) 0.81(1) Å]. The refined total occupancy of this water molecule converged to unity within experimental error and the final relative ratio of the individual position was 0.69:0.31.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-118658 $[(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O]$ and -118659 $(H_4L^2 \cdot 4\,H_2O)$. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: (internat.) +44(1223)336-033; E-mail:deposit@ccdc.cam.ac.uk].

Chemicals and Stock Solutions for Potentiometric Titrations: Stock solutions of the individual metal cations were prepared by dissolving appropriate nitrates recrystallised from aqueous solutions. The

metal contents in the solutions were determined by titration with Na_2H_2edta solution. Nitric acid was prepared by passing aqueous potassium nitrate solution through a Dowex 50 W-8 column in the H^+ form because of traces of NO and NO_2 present in the concentrated acid. KOH solution was standardised against potassium hydrogen phthalate and HNO_3 solution against the KOH solution. Stock solutions of the ligands were prepared by dissolving solids in a standard KOH solution (≈ 1.8 equivalents) followed by addition of water. Analytical concentrations of the ligands were determined by pH-metric end-point titrations. Four protons of H_4L^1 in the presence of an equivalent amount of $Cu(NO_3)_2$ and two protons of H_4L^2 were titrated using a potassium hydroxide solution of known analytical concentration.

Potentiometric Titrations: Titrations were carried out in a vessel thermostatted at 25±0.1°C, at an ionic strength of I (KNO_3) = 0.1 mol·dm^{-3} and in the presence of an excess of HNO_3 in the region $-\log[H^+] = 1.8-12$ [except for the titrations where precipitation of $Zn(OH)_2$ and $Cd(OH)_2$ was detected] using a PHM 240 pH-meter, a 2 cm^3 capacity Radiometer ABU 900 automatic piston burette and a GK 2401B combined electrode (Radiometer). The initial volume was 5 cm^3 and concentration of both the ligands was 0.002 mol.dm^{-3} due to their low solubility in the acid region. The metal:ligand ratios were 2:1, 1:1 and 1:2. Titration for each ratio was carried out at least three times. Each titration consisted of about 40 points. An inert atmosphere was ensured by constant passage of argon saturated with the solvent vapor during measurements. The stability constants for $M^{2+} - OH^-$ systems included in the calculations and $pK_w = 13.78$ were taken from the literature.[37] The protonation and stability constants β_{pqr} are concentration constants and are defined by $\beta_{pqr} = [M_pH_qL_r]/[M]^p\cdot[H]^q\cdot[L]^r$. The constants and the analytical concentrations were calculated using the program OPIUM.[38] The program minimises the criterion of the generalised least squares method using the calibration function where the additive term E_0 contains standard potentials of the electrodes used and contributions of inert ions to the liquid-junction potential, S corresponds to the Nernstian slope, the value of which should be close to the theoretical value and $j_1[H^+]$ and $j_2[OH^-]$ terms are contributions of the H^+ and OH^- ions to the liquid-junction potential. It is clear that j_1 and j_2 cause deviation from a linear dependence between E and $-\log[H^+]$ only in strongly acidic and strongly alkaline solutions.

$$E = E_0 + S\cdot\log[H^+] + j_1[H^+] + j_2(K_W/[H^+])$$

NMR Spectra: NMR spectra were obtained with a Varian Inova Plus instrument, ^{1}H (400 MHz) at 25°C with sodium 4,4-dimethyl-4-silapentane-1-sulfonate as an internal standard, $^{31}P\{^1H\}$ (161,.9 MHz) with 85% H_3PO_4 as an external standard. The ^{31}P-NMR titration experiments were performed in D_2O at concentrations of the ligands of 0.01 mol·dm^{-3} and at room temperature. The pD values (pD = pH + 0.40; electrode calibration in pH scale using standard buffers) were adjusted by addition of KOD or DCl solutions. Solutions for ^{31}P-NMR titrations in the acidic region ($-\log[H^+] = 1.0-2.5$) and the measurements in the presence of metals were run under the same conditions as the potentiometric measurements in H_2O with D_2O in the coaxial capillary for the lock. ^{31}P-CP/MAS-NMR spectra were measured at 161.9 MHz, spinning 4 kHz, contact time 0.5 ms and repetition time 8 s with $CaHPO_4$ as external standard.

Synthesis of $H_4L^1 \cdot 4\,H_2O$: To a stirred suspension of cyclen hydrochloride (1.0 g, 3.14 mmol) and phenylphosphinic acid (2.75 g, 19.3 mmol) in 20 mL of aqueous HCl (1:1, v/v) was added paraformaldehyde (0.85 g, 28.3 mmol) in portions at 100°C over 7 h. A clear solution was formed after addition of the first portion of paraformaldehyde [***Caution:*** Formation of carcinogenic $(ClCH_2)_2O$ cannot be excluded, work in an efficient fumehood]. The reaction mixture was held at the same temperature for 2.5 h. The volatiles were removed using a rotary evaporator and the resulting yellow oily residue was co-distilled three times with water. The residue was dissolved in an H_2O/EtOH mixture (1:1, v/v) and loaded onto Dowex 50 W8 cation exchange resin in the H^+ form. The resin was washed with H_2O and the product was subsequently eluted with 10% aqueous NH_3. Fractions containing H_4L^1 as its ammonium salt were evaporated. The oily product obtained was dissolved in 7 mL of an H_2O/EtOH mixture (1:1, v/v) and acidified with 1 mol dm^{-3} HCl to pH ≈ 1. H_4L^1 started to crystallise after scratching of the flask wall and standing overnight. The product was filtered off, washed with water, and dried at 100°C over solid KOH under vacuum (1.33 kPa). The solution was filtered (S4), evaporated, and the product precipitated by addition of water. Yield 1.7 g (65%). M.p. 200−203°C (dec.). Elemental analysis: found (calcd.) C 50.2 (50.2); H 6.1 (6.5); N 6.6 (6.5). − ^{1}H NMR (0.1 M KOD/D_2O): δ = 2.51 (s, 16 H, NCH_2), 2.91 (d, 8 H, $^2J_{PH}$ = 6.4 Hz, NCH_2P), 7.5−7.9 (m, 20 H, aryl H). − $^{31}P\{^1H\}$ NMR (0.1 M KOD/D_2O): δ = 29.38. A sample used for potentiometric measurements was recrystallised from refluxing MeOH containing propylene oxide.

Synthesis of $H_4L^2 \cdot 4\,H_2O$: To a stirred suspension of cyclam hydrochloride (0.8 g, 1.9 mmol) and phenylphosphinic acid (2.0 g, 14 mmol) in 7.5 mL of aqueous HCl (1:1, v/v) was added paraformaldehyde (0.9 g, 30 mmol) in portions at 65°C over 2 h [***Caution:*** Formation of carcinogenic $(ClCH_2)_2O$ cannot be excluded, work in an efficient fumehood]. A clear solution formed during addition of paraformaldehyde and a white precipitate of the product began to separate after addition of approximately half of the amount. The mixture was stirred for 3 h at 65°C to complete the reaction. A white precipitate of $H_4L^2 \cdot n$ HCl (n = 3−4) was filtered off, washed with 5% aqueous HCl, acetone, and dried over KOH. The hydrochloride was converted into H_4L^2 by dissolution in a large volume of boiling methanol and addition of an excess of propylene oxide (2 mL) to trap HCl. The solution was concentrated to about 1/4 volume and crystallisation started after addition of water. The isolated product was dried to constant weight under vacuum (1.33 kPa) over KOH at 100°C in an Abderhalden apparatus. Yield 1.3 g (75%). M.p. 221−224°C (dec.). − Elemental analysis: found (calcd.) C 51.6 (51.4); H 6.6 (6.8); N 6.5 (6.3). − ^{1}H NMR (0.1 M KOD/D_2O): δ = 0.82 (bp, 4 H, $CH_2CH_2CH_2$), 1.87 (s, 8 H, NCH_2CH_2N), 2.07 (bt, 8 H, $NCH_2CH_2CH_2N$), 2.32 (d, 8 H, NCH_2P, $^2J_{PH}$ = 9.4 Hz), 7.3−7.5 (m, 20 H, aryl H). − $^{31}P\{^1H\}$ NMR (0.1 M KOD/ D_2O): δ = 29.8, s.

Synthesis of $(AdNH_3)_2(H_2L^2) \cdot 6\,H_2O$: To a stirred MeOH/$H_2O$ (1:1, v/v, 10 mL) solution of $H_4L^2.4H_2O$ (0.89 g, 1 mmol) was added a methanolic solution (10 mL) of 1-adamantylamine (0.30 g, 2 mmol). The product crystallised from the solution during a few days. Yield 0.65 g (53%). M.p. 207−209°C (dec.). Elemental analysis: found (calcd.) C 56.9 (56.7), H 7.8 (8.0), N 6.9 (6.8).

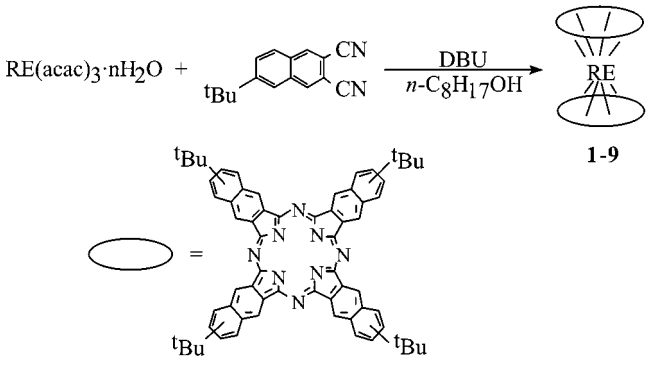
Keywords: Rare earth complexes / Naphthalocyaninato ligand / Double-decker complexes

A series of rare earth(III) double-deckers RE[Nc(*t*Bu)$_4$]$_2$ [RE = La, Ce, Pr, Nd, Eu, Gd, Tb, Y, Er; Nc(*t*Bu)$_4$ = dianion of tetra(*tert*-butyl)-2,3-naphthalocyanine] (**1**–**9**) have been prepared by treating RE(acac)$_3$ · *n* H$_2$O (acac = acetylacetonate) with 6-*tert*-butylnaphthalonitrile in refluxing *n*-octanol in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU). These novel sandwich-type complexes have been spectroscopically characterized. The electrochemical studies show that the first oxidation and the first reduction potentials increase with the size of the central metal ions with a relatively small separation (0.28–0.33 V), reflecting the narrow HOMO–LUMO gap.

Introduction



Sandwich-type phthalocyaninato metal complexes, in which the large conjugated π systems are held in close proximity by metal ions, have found widespread applications in materials science.[1] The lutetium complex Lu(Pc)$_2$ (Pc = dianion of phthalocyanine), for example, is the first intrinsic molecular semiconductor with a conductivity of $5\cdot10^{-5}$ $\Omega^{-1}cm^{-1}$ in thin films,[2] and shows promising electrochromic[3] and gas-sensing properties.[4] As the bulk characteristics of a molecular material are largely related to the properties of individual molecules, various modifications have been made on these sandwich compounds with the goal of improving their performance as advanced materials.

Long alkyl side chains[5] and crown-ether units[6] are two common functionalities added to the macrocycles to facilitate the formation of various mesophases and supramolecular structures. Another rational modification involves the replacement of the Pc ring with a naphthalocyaninato (Nc) ligand. Having more delocalized π systems, the resulting sandwich complexes should have distinct electronic and electrical properties. This has been demonstrated by L′Her et al. who show that the energy gap between the highest and lowest molecular orbitals (HOMO and LUMO) is much narrower for these Nc complexes than for the Pc counterparts.[7] Although these Nc-containing sandwich compounds appear to be promising, only a few lutetium Nc complexes have been known so far.[2,7,8] We have recently extended this series of compounds by reporting the first heteroleptic europium complexes having mixed Nc and porphyrinato ligands.[9] In this paper, we describe a new series of homoleptic Nc double-decker complexes of various rare earth metals. By changing the size of the metal center, the ring-to-ring separation can be altered, thereby providing another method of fine tuning the electronic properties of this novel class of complexes.

Results and Discussion

All the double-deckers **1**–**9** were prepared by base-promoted cyclization of 6-*tert*-butylnaphthalonitrile in refluxing *n*-octanol in the presence of 0.25 equiv. of RE(acac)$_3\cdot n$ H$_2$O (RE = La, Ce, Pr, Nd, Eu, Gd, Tb, Y, Er) and DBU (Scheme 1). The use of additional naphthalonitrile also gave a significant amount of metal-free 2,3-naphthalocyanine H$_2$[Nc(*t*Bu)$_4$]$_2$ as a side product, as in the case of phthalocyanines,[10] which complicated the purification process. Changing the solvent to *n*-pentanol, *n*-hexanol, 1,2,4-trichlorobenzene, or 1-chloronaphthalene did not give the desired products, indicating that solvent is a critical factor for these reactions.

Scheme 1. Synthesis of rare earth double-deckers

The lutetium analog Lu[Nc(*t*Bu)$_4$](Pc) was reported previously, but only very few characterizing data were given.[11]

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 2000 1434–1948/00/0101–0205 $ 17.50+.50/0

As is the case in the Pc complexes,[10] these reactions afforded the protonated species $REH[Nc(tBu)_4]_2$ or the monoanions $\{RE[Nc(tBu)_4]_2\}^-$ as the initial products, which underwent oxidation in air to give the corresponding one-electron ring-oxidized complexes $RE[Nc(tBu)_4]_2$. The UV/Vis spectra of the dark-brown sandwich intermediates and the dark-blue/violet oxidized products were very different (see below), so the course of the reactions could be monitored by electronic absorption spectroscopy. The rate of conversion depended on the size of the metal center. Intermediates with a smaller metal center (heavy lanthanide) were more susceptible to oxidation than those with a larger metal ion (light lanthanide) which is consistent with the electrochemical data as described below. The oxidation was also found to be accelerated by the acidity of silica gel; only the ring-oxidized species **1**−**9** were isolated after chromatographic purification. It is worth noting that the yield of these double-deckers increases gradually with the size of the central metal ion (Table 1). This is in line with the $RE(Por)_2$ series (Por = dianion of *meso*-tetraphenylporphyrin or octaethylporphyrin),[12] but in contrast with the trend observed for $RE(Pc)_2$[13] and $RE[Pc(OC_8H_{17})_8]_2$,[14] showing that bis(phthalocyaninato) complexes are easier to obtain and more stable with the smaller rare earth cations.

All these double-deckers, after being purified by column chromatography and recrystallization, were essentially pure, as shown by thin-layer chromatography. However, satisfactory analytical data could not be obtained which might be due to the presence of traces of impurities, which could not be completely removed by conventional purification methods.[15] The compounds, however, were unambiguously characterized with a range of spectroscopic methods. The matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectra of all these double-deckers [except RE = Gd (**6**)] showed prominent signals attributed to the molecular ions, whose isotopic patterns were in good agreement with the respective simulated spectra (Table 1).

The electronic absorption spectra of **1**−**9** were recorded in $CHCl_3$/EtOH (1:1) and the data are summarized in Table 1. The spectral features resembled those of bis(phthalocyaninato) rare earth complexes (except RE = Ce),[10,16] except that all absorption bands were significantly red-shifted in the Nc series due to the extended conjugation. The spectra could thus be interpreted in a similar manner.

Figure 1 gives the UV/Vis spectra of the La, Eu, and Er double-deckers. It can be seen from this figure and Table 1, that while the B band (328−334 nm) remains relatively unshifted, both the Q band (767−799 nm) and the π-radical anion band (593−648 nm) are shifted to the red as the ionic radius of the tervalent metal cation increases from Er to La. A similar trend was also observed for the broad near-IR band (1818−2346 nm) which is characteristic of sandwich compounds having an unpaired electron in one of the rings. Similar to the Pc[17] and Por analogs,[12b,18] a linear correlation could be established between the wavenumbers of these absorptions and the RE^{III} ionic radii (Figure 2).[19] All the observation shows that as the ring-to-ring separation increases with the size of the metal ion, the π-π interactions between the Nc rings become weaker. Another interesting feature for these spectra is the intensities of the two visible bands in ca. 600−700 nm which are generally higher for sandwich compounds with a larger metal center.

Among these complexes, the Ce double-decker **2** is particularly interesting. To our knowledge, the metal center in all known Ce double-deckers including $Ce(Por)_2$,[20] $Ce(Pc)_2$,[21] and Ce(Pc)(Por)[22] is tetravalent. The presence of π-radical anion bands and the near-IR absorptions in the spectra of **2**, however, strongly suggests that the cerium center, like all the other rare earth ions, is tervalent and one of the Nc rings exists as a π-radical anion, i.e. $Ce^{III}\{[Nc(tBu)_4]^{2-}\}\{[Nc(tBu)_4]^{\bullet-}\}$. The electronic environment imposed by the Nc ligands seems to be unique to stabilize the Ce^{III} state and allow a facile one-electron ring-oxidation.

Upon addition of $NaBH_4$ to solutions of **1**−**9** in $CHCl_3$/EtOH (1:1), the absorption spectra were remarkably changed and the resulting spectra could be attributed to the monoanions $\{RE[Nc(tBu)_4]_2\}^-$ in which both macrocycles are dianionic. The spectral data for these anions are summarized in Table 2, and the spectra for the La, Eu, and Er double-deckers, after being treated with $NaBH_4$, are displayed in Figure 3.

It is interesting to note that while the B band (328−333 nm) is virtually unshifted upon reduction, the Q

{Tb[Nc(*t*Bu)$_4$]$_2$}$^-$	332	405 (sh)	654 (sh)	718	808
{Y[Nc(*t*Bu)$_4$]$_2$}$^-$	332	401 (sh)	657 (sh)	719	821
{Er[Nc(*t*Bu)$_4$]$_2$}$^-$	333	400 (sh)	647 (sh)	715	821

agrees with that which is observed for the analogous Pc anions.[23]

As expected, the characteristic near-IR band was not seen for these anions, showing that the single-hole species **1**−**9** underwent a one-electron ring-reduction. It is also worth noting that the time for complete spectral changes again depends on the size of the metal center ranging from a few minutes (for RE = La, Ce) to more than one hour (for RE = Y, Er). This is in accord with our previous observation that the intermediates REH[Nc(*t*Bu)$_4$]$_2$ or {RE[Nc(*t*Bu)$_4$]$_2$}$^-$ with a smaller metal center are easier to undergo oxidation than those with a larger metal ion.

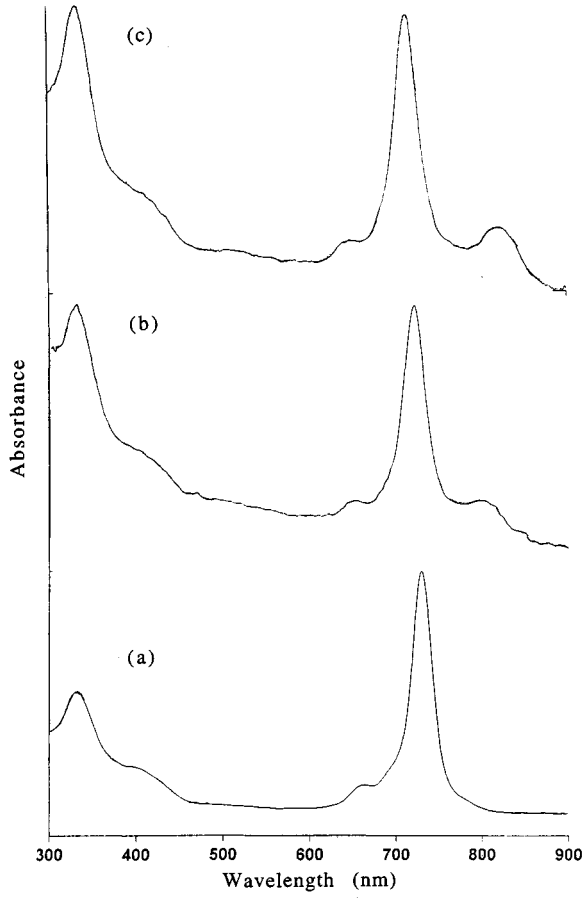

Figure 3. UV/Vis spectra of (a) La[Nc(*t*Bu)$_4$]$_2$ (**1**), (b) Eu[Nc(*t*Bu)$_4$]$_2$ (**5**), and (c) Er[Nc(*t*Bu)$_4$]$_2$ (**9**) in $CHCl_3$/EtOH (1:1) after the addition of $NaBH_4$

It is well-documented that all $RE^{III}(Pc)_2$ complexes show a strong IR band at ca. 1310 cm^{-1} which is a diagnostic band for the Pc π radical anion ($Pc^{\bullet -}$).[24] This band was also seen in this Nc series with the exact position (1313−1329 cm^{-1}) depending on the metal center (Table 1). It suggests that, due to the similar structure, the Nc π radical anion ($Nc^{\bullet -}$) also gives a marker IR band at roughly the same position as for $Pc^{\bullet -}$.

The electrochemical properties of the Nc double-deckers **1**−**9** in CH_2Cl_2 were studied by cyclic voltammetry (CV) and differential pulse voltammetry (DPV). The voltammograms generally displayed three quasi-reversible couples at 0.1−0.24, −(0.07−0.23), and −(1.18−1.24) V, all vs. the saturated calomel electrode (SCE), which could be assigned to the first one-electron oxidation and the first two one-electron reductions of the sandwich compounds, respectively. Additional couples could be revealed for some complexes, usually by DPV. Figure 4 gives the voltammograms of $Y[Nc(tBu)_4]_2$ (**8**) for exemplification and the results are tabulated in Table 3.

Similar to what is observed with the Pc analogs [cation][$RE(Pc)_2$] (cation = NBu_4,[25] Li[23]), the first oxidation and the first reduction potentials are linearly dependent on the ionic radius of the metal center (Figure 5), while the other redox processes are rather insensitive to the metal ions. The separation between these two potentials (0.28−0.34 V), which reflects the HOMO−LUMO gap of the complexes, is comparable with that reported for Lu(2,3-Nc)$_2$ (0.29 V) and Lu(1,2-Nc)$_2$ (0.33 V),[7] but significantly smaller than that for the Pc counterparts (ca. 0.40 V).[10]

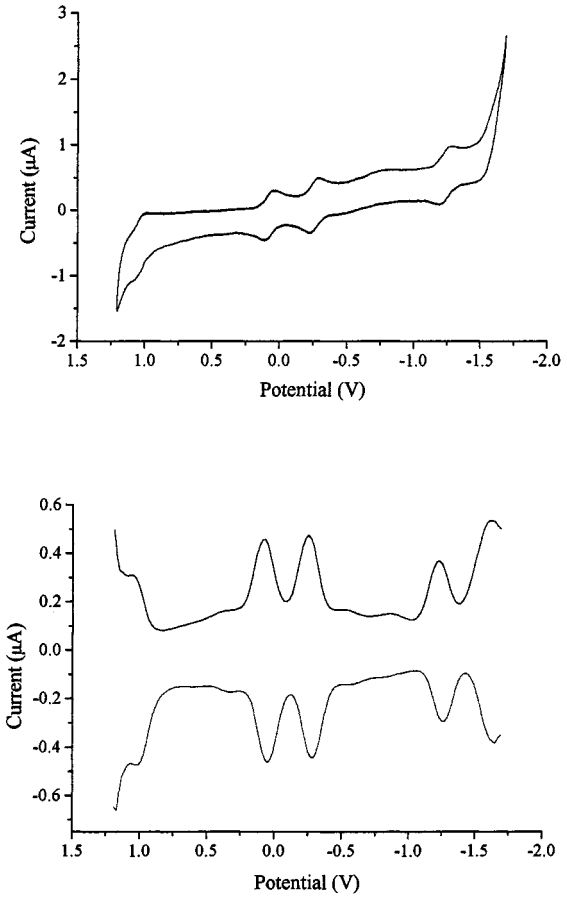

Figure 4. Cyclic voltammogram (upper) and differential pulse voltammogram (lower) of $Y[Nc(tBu)_4]_2$ (**8**) in CH_2Cl_2 containing 0.1 M $[Bu_4N][ClO_4]$ at a scan rate of 100 mV s^{-1}

[a] Recorded with $[Bu_4N][ClO_4]$ as electrolyte in CH_2Cl_2 (0.1 M) at ambient temperature. Potentials were obtained by cyclic voltammetry with a scan rate of 100 mV s^{-1}, and are expressed as half-wave potentials ($E_{1/2}$) in volts relative to SCE, unless otherwise stated. − [b] By differential pulse voltammetry. − [c] May also contain the Ce^{III}/Ce^{IV} couple.

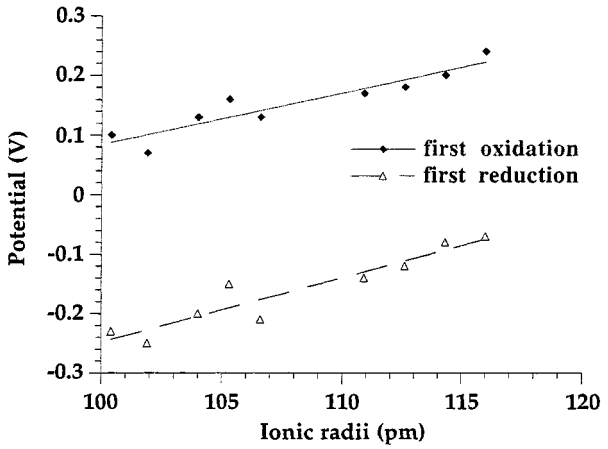

Figure 5. Redox potentials of $RE[Nc(tBu)_4]_2$ (**1**−**9**) as a function of the ionic radius of the RE^{III} ions[19]

The electrochemical behavior of $Ce[Nc(tBu)_4]_2$ (**2**) is of particular interest, as the Ce^{III} metal center may also undergoes an oxidation to Ce^{IV}. However, apart from the ring-based redox couples, no additional couple could be observed. As the peak to peak separation (ΔE) for the second oxidation of **2** was large (270 mV), as shown in its cyclic voltammogram, and the differential pulse voltammogram showed that the peak was broad and slightly split, it is likely that the Ce^{III}/Ce^{IV} couple is also embedded at this position. It has been found that the reversibility of the Ce^{III}/Ce^{IV} couple for sandwich-type compounds is usually poor, probably because the electron exchange between the electrode and the Ce center is retarded by the bulky ligands, which also participate in the electron transfer.[26] Our assignment thus seems to be in line with the previous findings.

Experimental Section

n-Octanol was distilled from sodium. The electrolyte $[Bu_4N][ClO_4]$ was recrystallized from dry acetone three times prior to use. All other reagents and solvents were of reagent grade and used as received. 6-*tert*-Butylnaphthalonitrile[27] and $RE(acac)_3 \cdot n\ H_2O$[28] were prepared by previously described methods. – UV/Vis: Hitachi U-3300. – Near-IR: Hitachi U-3100. – IR: Perkin–Elmer 1600. – MALDI-TOF-MS: Bruker BIFLEX III, α-cyano-4-hydroxycinnamic acid as matrix. – Electrochemical measurements were carried out with a BAS CV-50 W voltammetric analyzer. The cell comprised inlets for a platinum-sphere working electrode, a silver-wire counter electrode and an $Ag/AgNO_3$ (0.1 M in MeCN) reference electrode which was connected to the solution by a Luggin capillary whose tip was placed close to the working electrode.[29] Typically, a 0.1 M solution of $[Bu_4N][ClO_4]$ in CH_2Cl_2 containing the sample was purged with nitrogen for 20 min, then the voltammograms were recorded at ambient temp. Potentials were referenced to the Ag/Ag^+ couple in MeCN, which was taken as +0.31 V vs. SCE as determined for this system previously using ferrocene as an internal standard.[30]

General Procedure for the Preparation of $RE[Nc(tBu)_4]_2$ (1–9): A mixture of $RE(acac)_3 \cdot n\ H_2O$ (0.10 mmol), 6-*tert*-butylnaphthalonitrile (93 mg, 0.40 mmol), and DBU (40 mg, 0.26 mmol) in *n*-octanol (2 mL) was refluxed overnight (> 18 h) under a slow stream of nitrogen. The dark brown mixture was cooled to room temperature and the volatiles were removed under reduced pressure. The residue was purified by column chromatography on a silica gel, with $CHCl_3$ as eluent to develop a blue band containing the desired double-decker. The product obtained by this method was further purified by the same chromatographic procedure, followed by recrystallization from a mixture of $CHCl_3$ and MeOH to give a dark blue/violet powder.

Keywords: Manganese / Radicals / Cyclic dimer complexes / Exchange coupling parameters / Spin states

Temperature-dependent paramagnetic susceptibility data for two cyclic dimer complexes of bis(hexafluoroacetylacetonato)manganese(II) with 5-*tert*-butyl-1,3-phenylenebis(*N*-*tert*-butylaminoxyl) and 4-(*N*-*tert*-butyl-*N*-oxyamino)pyridine have been analyzed to obtain two sets of two intramolecular exchange coupling parameters J_1 and J_2. A previous model, based on one of these interactions being much weaker than the other, could not be explicitly correlated to these actual exchange-coupling parameters. However, the energy levels of the low-lying spin states were found to be reproduced reasonably well by the approximate method.

Introduction

Coordination polymers $(R-\pi-R-M)_n$ and $(R-\pi-L-M)_n$, consisting of magnetic metal ions M and basic free radicals R−π−R and R−π−L with two ligating sites, constitute recent highlights in molecular-based magnets since they afford samples exhibiting high Curie temperatures in the range 3.4−46 K.[1] It is very often the case that there are two or more kinds of exchange pathways in such systems (Scheme 1) and, therefore, the temperature dependence of the paramagnetic susceptibility data is not simple to analyze rigorously.[2] As a first approximation, such spin systems may be analyzed by assuming a model in which one of the interactions is much stronger than the other. Then high-temperature susceptibility data would be regarded as governed by the stronger interaction, and lower temperature data would be approximated by the development of the weaker interactions between the pseudo-spins already established at the high temperature.[3−6] The physical meaning of the effective exchange coupling thus obtained is not understood straightforwardly. We have attempted to make the physical meaning of such effective exchange coupling clearer by taking advantage of the cyclic units in which the numbers of the spins are finite and rigorous solutions of the spin Hamiltonian are feasible.

Scheme 1. Schematic presentation of the spin systems

Results and Discussion

Cyclic Coordination Complex of Bis(hexafluoroacetylacetonato)manganese(II) with {5-*tert*-Butyl-1,3-phenylenebis(*N*-*tert*-butylaminoxyl)} (1)

The 1:1 complex $[Mn(hfac)_2\mathbf{1}]_2$ was obtained by reaction of bis(hexafluoroacetylacetonato)manganese(II) [Mn(hfac)$_2$]

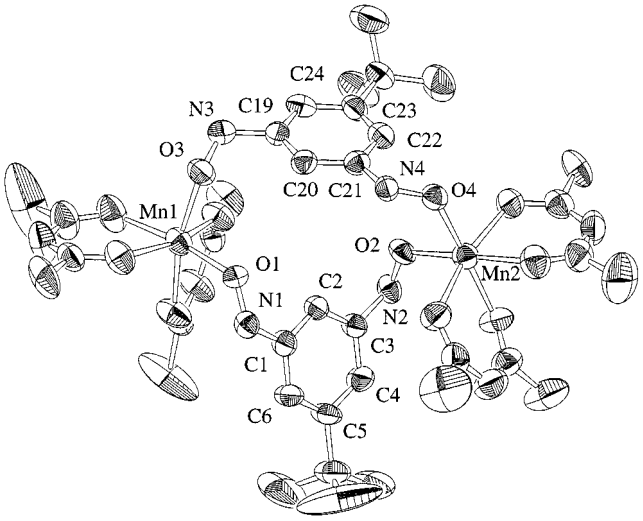
with the diradical 5-*tert*-butyl-1,3-phenylenebis(*N*-*tert*-butylaminoxyl) **(1)**.[3] Its crystal structure (Figure 1) shows that it is a cyclic analog of previously described 1-D complex polymers made up of similar components without ring *tert*-butyl groups or with halogen substituents in their place.[1b,1e] The molecule consists of two Mn^{II} ions ($S = 5/2$) and four aminoxyl radicals ($S = 1/2$) arranged in a ring as shown in Scheme 2.



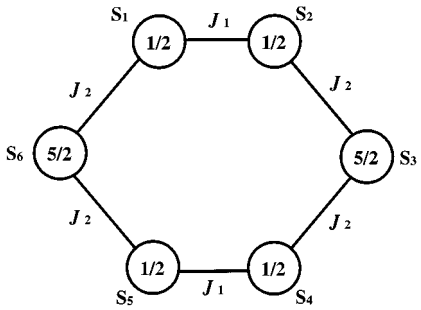


Figure 1. Structure of the cyclic complex $[Mn(hfac)_2\mathbf{1}]_2$; fluorine atoms, *N*-*tert*-butyl groups and hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 50% probability level

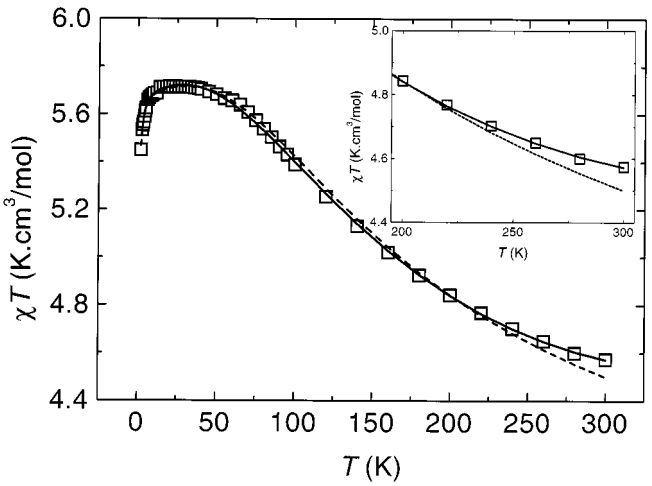
Scheme 2. A cyclic arrangement of the spins in $[Mn(hfac)_2{\cdot}\mathbf{1}]_2$

$S = 3/2$ pseudo-spins [5/2 − (2 × 1/2)], obtained by assuming a predominant antiferromagnetic (AF) coupling (J_2) between the manganese(II) ions and the two coordinated radicals. This high-spin ground state is stabilized with respect to the upper energy levels by a few hundred wavenumbers, as deduced from the decrease of χT upon increasing temperature. A decrease of χT at the lowest temperatures may be analyzed in terms of intermolecular AF coupling.



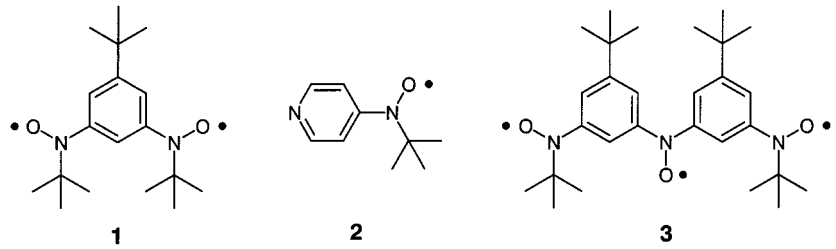


Figure 2. Dependence of the χT product on temperature T for the $[Mn(hfac)_2\mathbf{1}]_2$ complex; full and broken curves correspond to the best-fit theoretical curves based on the exact and approximate solutions, respectively (see text); the high-temperature region is expanded and shown in Inset

On this basis, the experimental data were fitted in a previous paper[7] by using a model of dimers of $S = 3/2$ pseudo-spins, with the exchange constant J and a molecular field contribution to account for the weak inter-dimer interactions. Note that the high temperature value of 4.57 Kcm^3mol^{-1} is significantly higher than that expected for two isolated $S = 3/2$ spins, suggesting a strong ferromagnetic coupling. The best agreement between theory and experiment was found for $J = +68.6$ K (±0.6 K), a Weiss constant of $\theta = -0.10$ K, and a Lande factor g = 2.002,

The molar paramagnetic susceptibility χ of the complex was investigated in the temperature range 2−300 K. The χT values exhibit a continuous increase from room temperature down to ca 50 K, reaching a plateau at 5.71 Kcm^3mol^{-1} (Figure 2). This value agrees well with the theoretical spin-only value for a $S = 3$ spin ground state, which can be explained from a ferromagnetic (F) interaction between two taking into account a scaling factor of 0.954 related to sample quality, errors in sample weighing, etc.[3] However, above 220 K, the calculated data are somewhat lower than the experimental data points (see broken curve in Figure 2). Similar analysis of a chain polymer consisting of bis(hexafluoroacetylacetonato)manganese(II) and *m*-phenylenebis(*N*-*tert*-butylaminoxyl) in a 1:1 ratio gives a ferro-

magnetic exchange constant $J = +23$ K (± 5 K) for repeating $S = 3/2$ units.[4] In these analyses, J is an "effective" interaction between pseudo-spins, and it is assumed that the Mn−aminoxyl AF interaction J_2 is much more efficient than the F intraligand aminoxyl−aminoxyl one (J_1).

Clearly, such a description may be improved by considering the rigorous spin Hamiltonian of the magnetic system:

$$\mathbf{H} = -J_1(S_1S_2 + S_4S_5) - J_2(S_2S_3 + S_3S_4 + S_5S_6 + S_6S_1) - g\mu_B H\sum S_i \quad (1)$$

corresponding to the sum of the exchange (H_{ex}) and field dependent contributions. In this expression, J_1 and J_2 are the exchange constants defined above, $S_i = 5/2$ for $i = 3$, (6 manganese(II) ions) and $S_i = 1/2$ for the others (aminoxyl radicals). The g factor is assumed to be 2.0 for both spin carriers (isotropic spins).

The energy levels of H_{ex} were determined by using as basis functions $|F_i>$ the direct products of the individual spin states $|m_{si}>$ quantified through their z component. Owing to the values of the m_{si} components, the total number of basis functions is $6^2 \times 2^4 = 576$. Taking into account the spin space symmetry, the size of the largest block to be diagonalized is reduced to 84×84.

The energy levels of the magnetic system are given by the eigenvalues of the exchange matrix whose coefficients are given by the products $<F_i|H_{ex}|F_j>$. They are obtained numerically by diagonalization of the matrix $[H_{ij}]$ (see Experimental Section); the temperature dependence of the magnetic susceptibility χ is then deduced from the usual expression:[8]

$$\chi = \frac{Ng^2\mu_B^2\sum M_{S_i}^2 \exp(-E_i/kT)}{kT\sum(2S_i+1)\exp(-E_i/kT)} \quad (2)$$

For comparison with the experimental data, this expression has been modified by taking the molecular field contribution into account with the Curie-Weiss law. The best result, illustrated in Figure 2 for the parameters $J_1 = +1005$ K (± 11 K), $J_2 = -539$ K (± 19 K), and Weiss constant $\theta = -0.10$ K (± 0.01 K), with a scaling factor 0.954,[9] gives a very good description of the experimental data over the whole temperature range. Simulation of the high-temperature values was very much improved: from 4.50 to 4.57 Kcm^3mol^{-1} for the observed value of 4.58 Kcm^3mol^{-1} at 300 K (see solid curve in Figure 2). It thus appears that the pseudo-spin approximation is not valid to determine the actual interactions. Indeed, unlike the assumption made previously, the radical-radical interaction (J_1) is found to be stronger than the manganese(II)−radical one (J_2). Furthermore, the value of J_1 is about 30 times greater than that refined in the pseudo-spin approximation. Let us recall that the "efficiency" of the exchange interaction depends also on the spin values; the energy is actually governed by $\approx JS^2$. As a result, the aminoxyl−aminoxyl and Mn−aminoxyl interaction energies are shown to be $1005 \times (1/2)(1/2) = 251$ K and $-539 \times (5/2)(1/2) = -674$ K, respectively. The latter remains stronger but does not justify the neglect of J_1 with respect to J_2. This result is in agreement with the fact that the room temperature value of χT is significantly higher than that expected for two independent $S = 3/2$ pseudo-spins.

Using the refined values of J_1 and J_2, the energy levels obtained for the above system are plotted in Figure 3 for the different spin S. It appears that the low lying levels correspond to S ranging from 3 to 0, according to the energy scheme expected for a ferromagnetic dimeric unit of $S = 3/2$ spins. These energy levels are contrasted in Figure 4 with those of the $S = 3/2$ dimer exhibiting an exchange constant $J = +68.6$ K, as reported above. A clear similarity between the two diagrams explains why the dimer approximation gives quite a satisfactory fit to the experimental data. Indeed, the energy gap between the $S = 3$ and $S = 2$ levels in the dimer model is shown to be $3J = +205.8$ K which is similar to that obtained for the real system, $\Delta E = f(J_1, J_2) \approx 190$ K.

Within the present model, all the energy levels of the hexamer system are taken into account for the calculation of $\chi T = f(T)$, while only 4 levels are involved in the dimer approximation. Thus, as the higher energy levels are neglected, the experimental susceptibility is not well reproduced at high temperature (dashed curve in Figure 2).

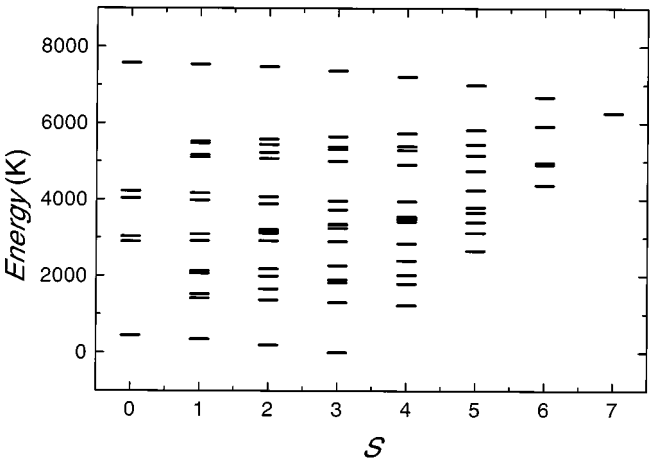

Figure 3. An energy level diagram calculated for the magnetic hexamer with the refined values of J_1 and J_2

Cyclic Coordination Complex of Bis(hexafluoroacetylacetonato)manganese(II) with 4-(*N*-*tert*-Butyl-*N*-oxyamino)pyridine (2)

The complex $[Mn(hfac)_2\mathbf{2}]_2$ was obtained by reaction of bis(hexafluoroacetylacetonato)manganese(II) with the radical 4-(*N*-*tert*-butyl-*N*-oxyamino)pyridine **(2)** in a 1:1 ratio.[5] The crystal structure (Figure 5) shows that it consists of two Mn^{II} ions ($S = 5/2$) and two aminoxyl radicals ($S =$

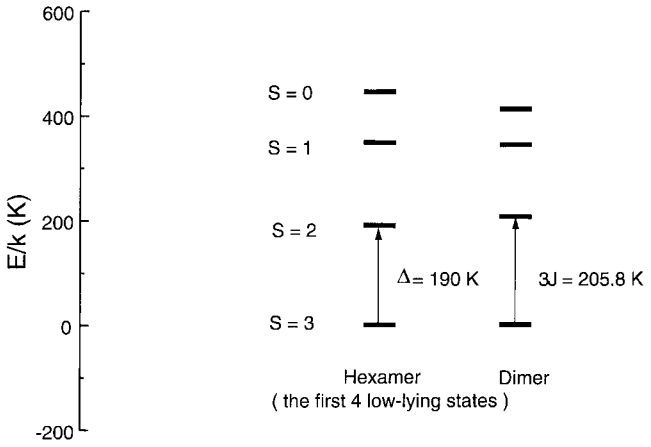

Figure 4. Comparison between the low-lying energy levels as obtained from the hexamer model and the dimer approximation for $[Mn(hfac)_2\mathbf{1}]_2$

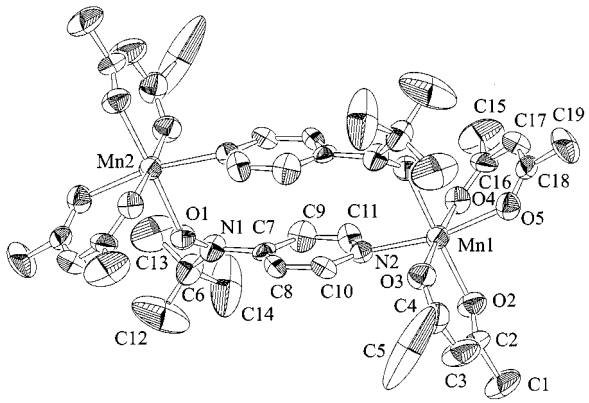
1/2) forming a four-spin ring as illustrated in Scheme 3. The manganese atoms are coordinated to the pyridyl nitrogen atom on one side and the aminoxyl radical ligand, through the oxygen, on the other. Thus, two different exchange constants J_1 and J_2 have to be considered.



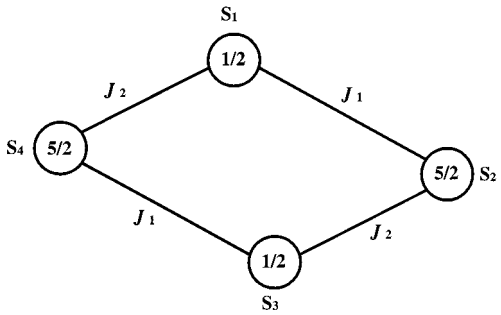


Figure 5. ORTEP view of the cyclic complex $[Mn(hfac)_2\mathbf{2}]_2$ at 30% probability; hydrogen atoms are omitted for clarity

Scheme 3. A cyclic arrangement of the spins in $[Mn(hfac)_2\cdot\mathbf{2}]_2$

The magnetic susceptibility has been investigated in the range 2.5−300 K (Figure 6). The χT versus T plot shows a continuous increase from 6.4 Kcm^3mol^{-1} at 300 K to 9.97 Kcm^3mol^{-1} at 2.5 K. The high temperature value is close to that expected for two noninteracting $S = 2$ spins, whereas the low temperature behavior agrees with that of an $S = 4$ ground state ($g = 2$). In reference to the previous Mn^{II}−radical complex, the magnetic behavior of this system may be described as ferromagnetic dimers of $S = 2$ pseudo-spins, arising from strong AF interactions between the directly bonded manganese(II) and aminoxyl centers. The experimental data, tentatively fitted to the dimer model by assuming two $S = 2$ pseudo-spins, are well reproduced for the effective interaction $J = +8.70$ K and $g = 1.97$ (see broken curve in Figure 6).

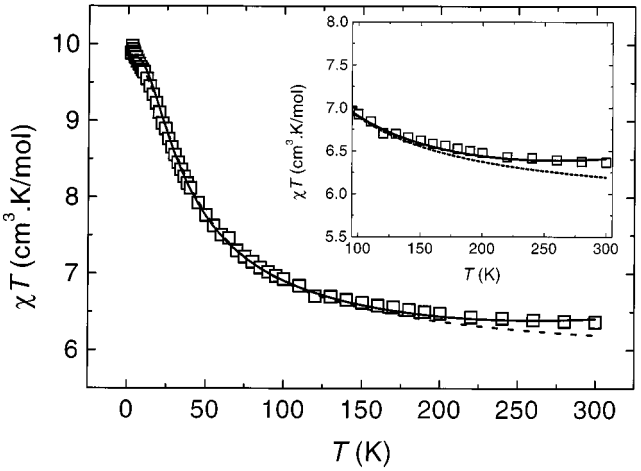

Figure 6. Variation of the χT vs T for the $[Mn(hfac)_2\mathbf{2}]_2$ complex; full and broken curves correspond to the best-fit theoretical curves based on the exact and approximate solutions, respectively (see text); the high-temperature region is expanded and shown in Inset

In the same way as above, and in order to compare the Mn−NO interactions in both systems, the actual spin Hamiltonian for the cyclic array of four spins, expressed as:

$$\mathbf{H} = -J_1(S_1S_2 + S_3S_4) - J_2(S_2S_3 + S_4S_1) - g\mu_B H\Sigma S_i \quad (3)$$

has been solved exactly. In this expression, J_1 and J_2 now stand for the exchange pathways between the Mn^{II} and NO through the pyridine ring and the direct coordination bond, respectively (Scheme 3). This model gives a very good agreement between theoretical and experimental susceptibility data, especially in the high temperature region (Figure 6), for the refined parameters $J_1 = -22.6$ K (±0.1 K), $J_2 = -372$ K (±9 K) and a scaling factor of 0.980. All the exchange couplings are antiferromagnetic, and a ferrimagnetic ground-state is stabilized. Note that the former value is in good agreement with the exchange constant of −24.8 K[9] between Mn^{II} and aminoxyl radical through the 4-pyridyl unit in the mononuclear 1:2 complex [Mn(hfac)2**2**2].[5] In this complex, the Mn^{II} ion is only coordinated to the pyridyl nitrogen atoms.

The energy scheme, corresponding to the refined values of J_1 and J_2, is contrasted to that for the $S = 2$ dimer in Figure 7. The energy gap between the ground state and the first excited state is shown to be $4J = +34.8$ K in the dimer limit, in very good agreement with that obtained for the exact model based on Equation 3 (34.8 K).

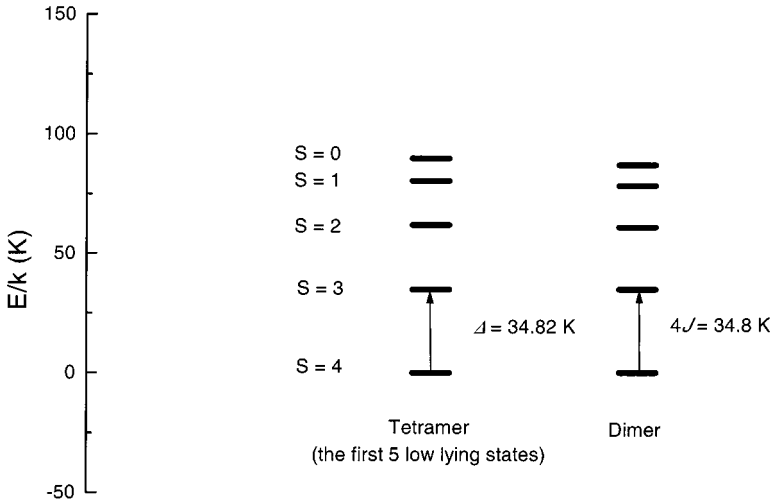

Figure 7. Comparison between the low-lying energy levels as obtained by using the tetramer model and the dimer approximation for $[Mn(hfac)_2\mathbf{2}]_2$

The Exchange Coupling Parameters J_1 and J_2 Obtained by Exact Solution

These are summarized in Table 1. The intraligand NO−NO interaction (J_1) obtained for $[Mn(hfac)_2\mathbf{1}]_2$ is as large as 10^3 K. From a classical-classical and quantum-classical chain model, Markosyan and co-workers obtained $J_1 \geq 350$ K for a 3-D complex of $[Mn(hfac)_2]$ with the tris(-aminoxyl) triradical **3** which has a *m*-phenylene connectivity.[4] The χT values for the free ligand **1** stay constant at 1 Kcm^3mol^{-1} between 4 K and room temperature, confirming that the corresponding J_1 value should be much larger than 300 K.[10] The intraligand NO−NO coupling in the neat triradical **3** is 480 K.[10][11] The value obtained in this study serves as the first example in which the magnitude of the ferromagnetic coupling parameter in *m*-phenylenebis(aminoxyl) compounds has been determined rigorously. The ferromagnetic J_1 values in these compounds originate from the in-phase spin polarization of the π-electrons on the *m*-phenylene rings due to their topology. The limited data available seem to suggest that the magnitude of such F coupling increases upon complexation with magnetic metal ions. Accumulation of more data is necessary before such a conclusion is confirmed.

It should be noted that all the direct Mn^{II}−NO exchange interactions through coordination bonds represented by J_2 are of the same order: −539, −372, and −520 K for $[Mn(hfac)_2\mathbf{1}]_2$, $[Mn(hfac)_2\mathbf{2}]_2$, and $[\{Mn(hfac)_2\}_3\mathbf{3}_2]_2$, respectively. Gatteschi et al. obtained similar AF coupling values ranging from −210 to −430 K for the coupling of Mn^{II} with 2-substituted 4,4,5,5-tetramethyl-4,5-dihydro-3-oxylimidazol-1-oxides, so called Ullman′s nitronyl nitroxides. The AF interactions derive from the pairing of the unpaired electrons in the dπ metal and pπ ligand orbitals.

Finally, we note that the indirect Mn^{II}−NO exchange coupling through the 4-pyridyl unit is AF: −22.6 and −24.8 K for cyclic $[Mn(hfac)_2\mathbf{2}]_2$ and mononuclear 1:2 complex $[Mn(hfac)_2\mathbf{2}_2]$, respectively.[5][10] The π-electrons on the pyridine ring should be polarized in such a way that the 3- and 5-carbons and the ring nitrogen atom carry positive spin which in turn overlap with the π-type d-orbital of the magnetic Mn^{II} ion attached to the pyridyl nitrogen atom. The reduced AF interaction is reasonable considering the Mn^{II} complex of bis(4-pyridyl)carbene.[13]

Table 1. Comparison of the related exchange coupling parameters

Radical or metal-radical complex	J_1/K intraligand NO - NO	J_1/K Mn(II) - NO via the 4-pyridyl unit	J_2/K directly coordinated Mn(II) - NO
$[Mn(hfac)_2\bullet\mathbf{1}]_2$	1005 ± 11		-539 ± 19
1	>300		
$[\{Mn(hfac)_2\}_3\bullet\mathbf{3}_2]$	>350		-520
3	480 ± 40		
$[Mn(hfac)_2\bullet\mathbf{2}]_2$		-22.6 ± 0.1	-372 ± 9
$[Mn(hfac)_2\bullet\mathbf{2}_2]$		-24.8 ± 0.2	
$[Mn(acac)_2\bullet\mathbf{2}_2]$		-20.4 ± 0.1	

Conclusion

Is there a merit in the pseudo-spin model for analyzing the temperature-dependence of the magnetic susceptibility of complex magnetic systems? Note that, whereas the energy values of the spin states are directly proportional to J in the dimer units, they are nonlinear combinations of J_1 and J_2 in the polymeric complexes investigated. As a result, J is an "effective" interaction with no physical meaning, and cannot be related to the actual interactions (even the sign may differ) in the latter, except when one interaction is negligible. Finally, let us point out that the use of such pseudo-spin models has an important merit of giving an insight into the splitting of the low lying spin-states. The information obtained here should be useful,[14][15] for the comparison of the exchange interactions in extended heterospin systems and for the design of such new systems.

Experimental Section

Preparation of the Complexes: The cyclic dimer complexes $[Mn(hfac)_2\mathbf{1}]_2$[3] and $[Mn(hfac)_2\mathbf{2}]_2$[5] were prepared by mixing bis(hexafluoroacetylacetonato)manganese(II) with radical ligands **1** and **2** in a 1:1 ratio as described previously.

X-ray Structures: The structures and magnetic data for cyclic complexes $[Mn(hfac)_2\mathbf{1}]_2$[3] and $[Mn(hfac)_2\mathbf{2}]_2$[5] have already been reported. Crystallographic data (excluding structure factors) for the structures $[Mo(hfac)_2\mathbf{1}]_2$ and $[Mo(hfac)_2\mathbf{2}]_2$ reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publications no. CCDC-114418 and -135189, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12, Union Road, GB-Cambridge CB2 1EZ, UK [Fax: int. code + 44/1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]..

Magnetic Measurements: Fine crystalline samples were mounted in a capsule (Japan Pharmacopoeia No. 5, o. d. 4.5 × 11 mm) and measured on a Quantum Design MPMS-5S SQUID susceptometer at 500 G. Corrections for the diamagnetic contribution of the samples were made by using Pascal′s constants. The diamagnetic contribution of sample capsules and holding straws used was in the range -3.7×10^{-5} – -6.7×10^{-5} emu.G.

Theoretical/Computational Analysis of the Magnetic Susceptibility Data: *SPIN*, a computer program for calculation and analysis of the magnetic properties of low dimensional systems, was employed.[16] An optimized diagonalization vectorial subroutine was used, from the library of the French institute for development and means in computer science, IDRIS (Orsay, France); the MINUIT function minimization program of the CERN library (CERN, Geneva, Switzerland) was used as a minimization subroutine.

Acknowledgments

This work is a part of the research project No. 980626 supported by the French institute for development and means in computer science, IDRIS, Orsay, France. The work was also supported by Grant-in-Aid for COE Research "Design and Control of Advanced Molecular Assembly Systems" (No. 08CE2005) from the Ministry of Education, Science, Sports, and Culture, Japan. P. R. and T. I. are thankful to the Japanese Society for the Promotion of Science for a Visiting Grant and a Postdoctoral Fellowship, respectively.

Mechanisms of Cyclopalladation Reactions in Acetic Acid: Not So Simple One-Pot Processes

Montserrat Gómez,[a] Jaume Granell,[a] and Manuel Martinez*[a]

Keywords: Reaction mechanisms / Cyclopalladation / Acetic acid / Pd–C bond stability / Polynuclear species / Palladium

The processes operating during the synthetic cyclopalladation reactions of imines in acetic acid have been studied from a kinetico-mechanistic point of view. These reactions include a fast initial coordination to the palladium through the N-donor atom of the imine, followed by the proper C–H bond activation to produce the acetato bridged dimeric species. At this point, the lability of the bridging acetato groups, the hydrolysis of the C–Pd bonds, and/or the hydrolysis of C=N *exo* bonds contribute to the generation of dark red polynuclear compounds. The processes occurring after the C–H activation have been followed kinetically, both from palladium acetate plus imine, and the synthetically pure isolated acetato dimers as starting materials. The kinetic and activation parameters have been found identical within experimental error whatever the starting material was ($k^{323} = 1.5 \times 10^{-4}$ s^{-1}; $\Delta H^{+} = 51$ kJ mol^{-1}; $\Delta S^{+} = -163$ JK^{-1} mol^{-1} $\Delta V^{+} = +19$ cm^3 mol^{-1} for the 4-ClC_6H_4–CH=N–CH_2–C_6H_5 imine derivative **1a**). Acidolysis of C–Pd bonds has been found to occur in these polynuclear species. When alternative monomeric $C_{benzylic}$–Pd bond-containing complexes are possible follow ups of the reactions produce them as final dead-end complexes ($k^{323} = 2.2 \times 10^{-5}$ s^{-1}; $\Delta H^{+} = 61$ kJ mol^{-1}; $\Delta S^{+} =$ JK^{-1} mol^{-1} $\Delta V^{+} \approx 0$ cm^3 cm^{-1} for the [2,4,6-$(CH_3)_3$]C_6H_2–CH=N–CH_2-[2-$(CH_3)C_6H_4$] imine derivative **3d**). The same study has been carried out with primary amines in order to check the validity of the data if C=N bond hydrolysis is taking place in the imine derivatives with *exo* C=N bonds. For complexes with similar type of metallacycles, the results agree reasonably well with the proposed mechanism [$k^{323} = 1.2 \cdot 10^{-4}$ s^{-1}, $\Delta H^{+} = 46$ kJ·mol^{-1}, $\Delta S^{+} = -180$ J·K^{-1}mol^{-1}, $\Delta V^{+} = -16$ cm^3·mol^{-1} for the polynuclear formation of the C_6H_5–CH_2–NH_2 derivative **4e**; $k^{323} = 3.0 \cdot 10^{-4}$ s^{-1}, $\Delta H^{+} = 55$ kJ·mol^{-1}, $\Delta S^{\ddagger} = -147$ J·K^{-1}mol^{-1}, $\Delta V^{+} = -24$ cm^3·mol^{-1} for the polynuclear formation of the C_6H_5–CH_2–N=CH–2,3,6-$(CH_3)_3C_6H_2$ derivative **2c**].

Introduction

Cyclometallation reactions were one of the first known examples of C–H bond activation and cyclometallated compounds of a wide variety of ligands (containing N, P, As, O, or S as heteroatoms) have been described.[1] The cyclopalladation of N-donor ligands has been extensively studied by a number of research groups, and this reaction has acquired great interest because of the applications of metallacycles in many areas including organic synthesis,[2] homogeneous catalysis,[3] the design of new metallomesogenes,[4] and antitumor drugs.[5] The factors that influence the ease and mode of cyclopalladation of N-donor ligands are not entirely understood, but in general the following trends are accepted: intramolecular electrophilic attack of "Pd^{2+}" at the carbon atom, strong tendency to form five-membered metallacycles, and preferential activation of aromatic versus benzylic C–H bonds.[1]

There are few studies on these reactions dealing with kinetico-mechanistic information for the cyclopalladation of N-donor ligands like tertiary amines,[6] imines,[7] 2-phenylpyridines,[8] or triamines.[9] For these reactions, a highly ordered transition state has been proposed, in which the leaving proton is accepted by a base. Recently, the formal relationship that may be established between the cyclometallation reaction and the protonation of σ M–C bonds of d^8 organometallic species has been pointed out, as well as the possible role of arenonium ions in both processes.[10]

Very little information is available about the nature of the species existing in these reaction solutions. It is generally assumed that cyclopalladated compounds maintain their dimeric structure in solution, but recently it has been shown by ^{1}H-NMR spectroscopy that compounds like [Pd(μ-Br){$C_6H_4CH(CH_3)NH_2$}]$_2$ and [Pd{1-CH_2-2-(CH=$NCH_2C_6H_4$)-3,5-$(CH_3)_2C_6H_2$}(CH_3COO)]$_2$ adopt mononuclear structures in acetone[11] and acetic acid respectively.[7a]

Following our research on the cyclopalladation of N-donor ligands[12] and the mechanisms operating on organometallic reactions involving the activation of C–H and C–X bonds,[13] we present, in this paper, the study of the process that occurs between imines and palladium acetate in an acetic acid solution, both from a kinetic and a synthetic point of view. The imines have been selected to allow comparison of the behaviour of *endo*- and *exo*-metallacycles containing $C_{arom.}$–Pd or $C_{benz.}$–Pd bonds. As an extension of this work, the action of palladium acetate on primary amines has also been investigated.

Results and Discussion

The processes taking place when imines ***a***, ***b***, ***c***, and ***d*** (Scheme 1) are treated stoichiometrically with palladium acetate in acetic acid have been studied both from a synthetic and from a kinetic point of view. Although the for-

mation of cyclopalladated compounds is a well-established reaction, and even kinetico-mechanistic studies have been carried out by us[7] and other groups,[6] when the compounds are prepared in an acetic acid solution, important quantities of undefined material appear, and reduced yields are evident, compared with the reactions carried out in toluene (20% yield in acetic acid versus 60% in toluene for compounds **2c** and **2d**).[7a,12a] The available kinetic studies carried out in acetic acid also show the presence of further processes, once the main C−H electrophilic bond activation has taken place.[7a] Previous studies have indicated that the isolated acetato-bridged cyclopalladated complexes have significant differences when considered in acetic acid or in toluene. Furthermore, even though the nature of the complexes in solution is also dependent on the nature of the activated C−H bond (benzylic in **3c** and **3d**, versus aromatic in **2c** and **2d**), differences in behaviour for *endo*, **1a** and **1b**, versus *exo*, **2c** and **2d**, compounds are not so certain. In any case, it is clear that the lability of protonated bridging or terminal acetato groups plays a key role in the overall process.

Scheme 1 shows a simplified view of the reactivity involved in these cyclopalladation reactions. Discussion of Scheme 1 has to be carried out very cautiously. Any of the processes depicted (i.e. **I**, **II**, and **III**) does not necessarily have to be a single reaction; in fact, most of them have to be considered as rather complex reactions. Consequently, any rate constants and activation parameters discussed are ***apparent*** values that can only be considered as such, despite the fact that can be very informative about the equivalence of processes between different systems.

Examination of Scheme 1 gives a very good viewpoint of the cyclopalladation process. Reaction **I** takes place by the initial fast formation of a 1:1 coordination compound in stoichiometric conditions, followed by the proper C−H bond activation.[19] Kinetic measurements both in toluene and acetic acid are available at variable temperature and pressure, and the results have already been published.[7a]

The crude yellow acetato-bridged complexes isolated from the reaction **I**, **1a** and **1b**, are stable for days in the solid state, but when dissolved in acetic acid a deep red solution is formed; the process (**II**) is complete after 3 h at 70°C. Kinetic studies at variable temperature and pressure have been carried out. Table 1 collects the available data together with those for all the other processes depicted in Scheme 1. Despite the similar reactivity, the values determined for the volume of activation indicate a dramatic difference between the mechanism for the *endo*, **1a** and **1b**, and *exo*, **2c** and **2d**, complexes. Although in both cases an induction period exists, for the *exo* complexes this period is much better defined.

Where possible, spectroscopic and kinetic measurements for the initiation have been made (Table 1). If the reaction is carried out in the presence of palladium acetate (**II′**) the intensity of the red colour increases with its concentration, and the induction period decreases. The kinetic results agree with those of the experiments carried out in the absence of $Pd(CH_3COO)_2$, that is, the palladium acetate concentration does not affect the rate constant, only its extent. The deep red reaction mixture formed when the reaction was carried out with *exo* complexes, **2c** and **2d**, contains free aldehyde, as detected by ^{1}H-NMR spectroscopy. For the *endo* com-

plexes, **1a** and **1b**, the amount of aldehyde is less important, and appears after longer periods. Furthermore, practically no free or metallated amine is found by NMR spectroscopy, indicating that most of it remains coordinated to the palladium through the N atom. The presence of polynuclear species in the red reaction mixture has been detected by FAB and ion-spray (IS) mass-spectrometry. While mass spectra for the isolated yellow material (**1a**, **1b**, **2c**, and **2d**) indicate molecular peaks corresponding to the formulated dimer complexes, the isolated red material following process **II** has peaks at masses that correspond to species containing further acetato and palladium groups.

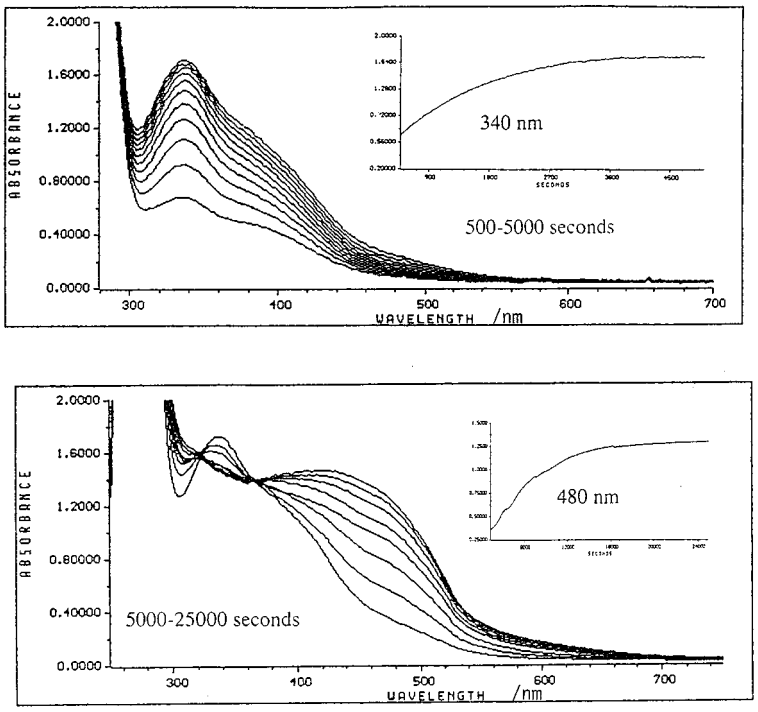
The IS mass spectrum of the red solid obtained from the reaction between palladium acetate and imine ***a*** shows peaks up to 1121, while the molecular weight of the dinuclear compound **1a** is 786. Furthermore, proton NMR spectroscopy of this red material shows an extremely complicated pattern in the 2.0 ppm zone, indicating that many different types of acetato ligands are present in the material, as should correspond to an undefined polynuclear compound. Further confirmation of our assumptions comes from the fact that in spite of pure dinuclear acetato bridged compounds usually being obtained in solid state after a purification process (recrystallization or column chromatography), the action of palladium acetate on 2-dimethylaminotoluene in acetic acid affords a trinuclear species, of general formula $[Pd_3(C-N)_2(\mu_2\text{-}O_2CCH_3)_4]$ (C−N≡metallated amine), as a mixture of *cis* and *trans* isomers [in relation to the $Pd_3(CH_3COO)_4$ moiety].[14] In addition, the formation of trinuclear species containing acetato bridges, isostructural to palladium acetate, has recently also been described for ligands containing C,S donor atoms.[15]

Process **I** + **II** corresponds, *de facto*, to the standard synthetic procedure in acetic acid. Under these conditions, besides cyclometallated complexes, the red coloured solution is always observed to some extent. Purification of the obtained product by column chromatography produces the final acetato-bridged dimer plus some quantities of an unidentified red material. The existence, in the acetic acid reaction medium, of palladium acetate and the final cyclometallated complex should enable the formation of polynuclear species according to reaction sequence **I** and **II′**. Kinetic measurements at variable temperature and pressure are available for this reaction sequence starting from imine and palladium acetate. Table 1 collects the data corresponding to the process that follows the C−H bond activation already described in previous studies.[7] The results agree with those obtained from the reactions carried out with the crude isolated yellow acetato dimers, **1a**, **1b**, **2c**, and **2d** (processes **II** and **II′**).

Figure 1 collects all the spectroscopic changes observed in the UV/Vis spectrum for the sequence **I** + **II**. For the reactions carried out with *exo* compounds, **2c** and **2d**, keeping these intense red solutions for 24 h at 80°C produces the light yellow *endo* monomeric complexes, **3c** and **3d**, as indicated by NMR experiments in deuterated acetic acid (process **III**).[7a] Kinetic measurements at variable temperature and pressure are available for this process starting from the isolated *exo* dimers, and these are also collected in Table 1. These *endo*, $C_{benz.}-Pd$ bond containing, complexes seem to be the dead-end of the whole process given their stability over very long periods in acetic acid.

The results, although difficult to interpret unequivocally, can be rationalized by taking into account the different stabilities in acid medium of the $C_{benz.}-Pd$ and $C_{arom.}-Pd$ bonds, as well as the reactivity of the labile acetato bridging groups. From the results presented, it is evident that, while the $C_{arom.}-Pd$ bond-containing complexes can be hydrolyzed in acetic acid, the stability of the metallacycles containing $C_{benz.}-Pd$ bond is much higher. This stability can be related both to the nature of the C−Pd bond, and to the final form of the complex in acetic acid (dimeric or polynuclear in the case of $C_{arom.}-Pd$ bond-containing complexes and monomeric for the $C_{benz.}-Pd$ bond-containing complexes). The presence of monomeric cyclometallated complexes containing $C_{benz.}-Pd$ bonds in acetic acid that do not evolve during long periods indicate that these are the most thermodynamically favourable compounds under these conditions. These results can be related with the ligand exchange reaction of N-donor ligands on cyclopalladated compounds. It has been shown that Pd^{II} effectively migrates to the ligand, forming the palladacycle less susceptible to acidolysis.[16]

As for the details of the reactivity, from the kinetic and activation parameters data, *endo* and *exo* cyclometallated $C_{arom.}-Pd$ bond-containing complexes present dramatic differences in their reaction mechanism. This can be attributed to the greater ease of Pd−C acidolysis of *exo*-metallacycles[16c] and the hydrolysis of the C=N imine bond, as seen by NMR spectroscopy. Given the fact that the reaction mixture contains "all the necessary ingredients", and that the cyclopalladated amine derivatives react with benzaldehydes to form imine *endo*-metallacycles (see below), long



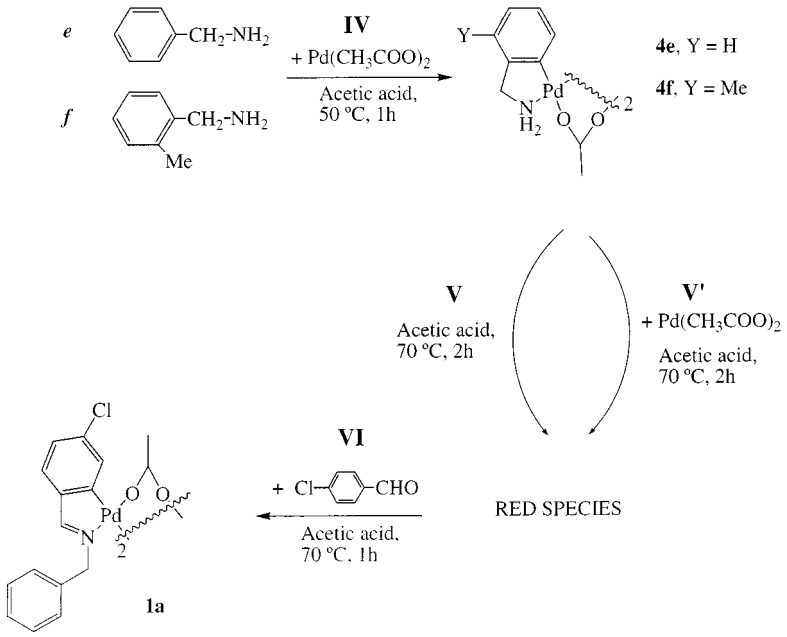


Figure 1. UV/Vis spectroscopic changes for the synthetic process, **I** + **II**, at 50°C between palladium acetate ($1\cdot10^{-3}$ M) and imine ***a*** ($1\cdot10^{-3}$ M) depicted in Scheme 1; above, metallation process (**I**); below, polynuclear formation process (**II**)

standing periods at high temperature of these red solutions produce the final dead-end monomeric *endo* $C_{benz.}-Pd$ bond-containing complex. On the other hand, the induction period for the *endo* metallacycle for the same process has to be the formation of palladium acetate via the initial $C_{arom.}-Pd$ *endo* bond hydrolysis, given the fact that the presence of palladium acetate seems to somehow reduce this induction period. From then on, the complex reaction to produce polynuclear red material (and a certain degree of decomposition) takes place with kinetic and activation parameters independent of the presence of palladium acetate in the reaction medium. The pressure activation parameters derived for the processes agree with this differentiation. While the activation volume for the polynuclear formation process for the ***a*** and ***b*** imines *endo* $C_{arom.}-Pd$ bond-containing complexes is positive, in spite of the extremely negative activation entropy, the value measured for the process that takes place for the *exo* $C_{arom.}-Pd$ bond-containing complexes is very negative. Kinetic factors seem to be dominant in the differentiation of these two processes as seen for the inverse cyclometallation reaction already studied.

In view of the interest of the processes labeled as **II** and **III** for **2c** and **2d**, the action of palladium acetate on primary amines has also been studied. It is generally accepted that primary amines are inert towards cyclometallation reactions, but they can undergo cyclopalladation if experimental conditions are appropriate. The action of $AgClO_4$ on coordination compounds $[PdCl_2L_2]$ (L=primary amine), or the action of palladium acetate on the amines in a 1:1 ratio leads to the cyclopalladation of primary amines with good yields. These results have been explained by the generation of coordinatively unsaturated species that experience the metallation.[11][17] The cyclopalladated derivative of benzylamine was prepared by refluxing a 1:1 mixture of palladium acetate and the amine in acetonitrile, as has been reported,[17e] and the cyclopalladation of the 2-methylbenzylamine was accomplished under the same reaction conditions. The dimeric compound obtained in this latter case $[Pd(CH_3COO)(3\text{-}CH_3C_6H_3CH_2NH_2)]_2$ (**4f**) was characterized by elemental analyses and NMR spectra. The monomeric triphenylphosphane complex $[PdBr(3\text{-}CH_3C_6H_3CH_2NH_2)(PPh_3)]$ (**5f**) was prepared by reaction of the acetate bridged derivative with LiBr and PPh_3 in acetone.

The action of palladium acetate on these primary amines in acetic acid was also studied; in this case the addition of deuterated pyridine to a deuterated chloroform solution of the compounds obtained, shows the formation of the $[Pd(CH_3COO)(C-N)([D_5]py)]$ (C−N ≡ ***e*** or ***f*** metallated amine, see Scheme 2) derivatives, indicating that the metallation of these ligands can take place even in acetic acid. The proton NMR spectra of the compounds obtained in absence of deuterated pyridine show, in addition to the signals of the dimeric derivatives, new signals at $\delta = 2.2-1.7$ suggesting that, under these reaction conditions, polynuclear acetato bridged complexes are also formed. This fact has been confirmed by mass spectra. The overall process depicted in Scheme 2 and its study from a kinetic point of view has also been carried out. Again, reaction **IV** takes place by the initial fast formation of the 1:1 coordination

Scheme 2. Reactivity involved in the cyclopalladation reactions of amines in acetic acid

compound in stoichiometric conditions, followed by the $C_{arom.}-H$ bond activation.

The metallation process has been studied kinetically in toluene solution at variable temperature and pressure. Table 2 collects the kinetic and thermal and pressure activation parameters for this process together with relevant comparative data; the results in solution agree with those obtained for the already published[7] metallation reactions. For the reactions studied in acetic acid solution, the activation parameters show important differences with respect to the systems already published. These observations can be explained by the fact that the metallation product obtained in acetic acid, although containing the palladacycle depicted in Scheme 2, does not correspond to that isolated according to literature procedures. As in the processes depicted in Scheme 1, the isolated solid dimer prepared according to the literature procedure is stable indefinitely, but when dissolved in acetic acid evolves to produce intense red coloured solutions. This reaction has been studied, both in neat acetic acid and in an acetic acid solution of palladium acetate, on the crude isolated acetato dimer (processes **V** and **V′** respectively). After an induction period, the formation of an intense red coloured solution takes place; the kinetic and activation parameters determined for this process are the same, within experimental error, in both cases and are characterized by extremely negative activation entropies and a negative volume of activation. Table 3 collects these data together with those for all the processes depicted in Scheme 2.

The induction period can be detected spectrophotometrically, although it implies very small absorbance changes; the kinetic and thermal activation parameters associated indicate dramatic changes with respect to the other processes involved in the overall reaction scheme. As seen in Table 3, the activation enthalpy is extremely large and the

Table 2. Kinetic and activation parameters for the cyclometallation reaction of palladium acetate with the amines ***e*** and ***f*** indicated in Scheme 2 in toluene and acetic acid solutions (process **IV**); literature data from the related imines ***c*** and ***d*** from Scheme 1 are also included.[7]

value found for the activation entropy is very positive. As for the activation volume, an extremely large positive value is estimated from the experiments. Its determination has not been possible due to the fact that there is an important pressure retardation of the initiation process with small spectroscopic changes implied, and that the above mentioned process has a large pressure acceleration with important differences in the spectra. The presence of polynuclear species in the red reaction mixture is clearly indicated in solid state by mass spectrometry, as well as in solution (^{1}H-NMR spectroscopy). Peaks up to 757 are observed in the FAB mass spectrum of the red solid obtained from the reaction of palladium acetate and amine ***e***. The molecular weight of the dinuclear compound **4e** is 543. From gas chromatography analysis of the crude red solution small quantities of free amine are also detected. Under synthetic conditions in acetic acid solution (process **IV** + **V**) the final red coloured solution is always observed. Kinetic measurements have been carried out at variable temperature and pressure for the reaction following the C−H bond activation process; the results obtained for both thermal and pressure activation parameters and collected in Table 3. When *para*-chlorobenzaldehyde is added to the crude deep red solution in acetic acid, condensation with the amine takes place, producing the *endo* cyclometallated compound, **1a**, derived from the corresponding imine as detected by NMR spectroscopy.

The results from the data in Scheme 2 have to be interpreted together with those for the imine derivatives. It is noteworthy to indicate that the behaviour of the cyclometallated amine has to be directly related to the reactivity of the *exo* cyclometallated complexes, **2c** and **2d**, containing $C_{arom.}$−Pd bonds, once the initial C=N bond hydrolysis has taken place (see above). The fact that formation of an intense red coloured solution is observed, both in synthetic conditions in acetic acid and by further treatment of the isolated acetato dimers in neat acetic acid or acetic acid solutions of palladium acetate, is a clear indication that the reactivity is related to the acidolysis of the $C_{arom.}$−Pd bond in the complexes. Again mass spectra indicate that important amounts of polynuclear species are present in the isolated red material. Nevertheless, even in these intense red polynuclear containing solutions, the presence of cyclometallated complexes is always detected, no full decomposition of the cyclopalladated compound is taking place.

Reaction of these red solutions with the corresponding aldehyde produces solutions where the *endo* cyclometallated complex **1a**, already described, is detected. We assume that the presence of the free amine in the polynuclear material solutions allows for the amine-aldehyde condensation;[20] thereafter the cyclometallation process, already described for the imine derivatives, takes place. As for the kinetic and activation parameters measured, an interesting fact is that those related to reaction **V** are in perfect agreement with those measured for the appearance of the polynuclear-containing red solutions for the reactions of the *exo* imine derivative complexes, **II**. In both cases, an initiation reaction is detected, while for the *exo* imine complexes it has been proven to be partly due to the hydrolysis reaction of the C=N bond, for compounds **4e** and **4f** this reaction has to be related solely to the hydrolysis of the main $C_{arom.}$−Pd bond. It is also interesting to note that, although in the presence of palladium acetate in the acetic acid solution medium this initiation also exists, it involves smaller spectral changes. It seems evident that the initiation process in this reaction needs the presence of $Pd(CH_3COO)_2$ in order to start the formation of the red polynuclear material. In this respect, the values measured for the activation parameters (specially the activation volume) for the synthetic process **IV** + **V**, have to be looked into more carefully. Given the fact that the $C_{arom.}$−H bond activation of the amines (process **IV**) is much slower (see Table 2) than the fast initiation process of reaction **V**, detected when the isolated acetato dimer **4e** is dissolved in acetic acid (see Table 3), the values determined for the polynuclear formation process starting from amine and palladium acetate mixtures, probably also contain a contribution from the C−H bond activation reaction, **IV**.

Conclusions

In summary, our mechanistic studies have shown that the reaction between imines and palladium acetate, in acetic acid solution, is a rather complex process in which several different reactions, such as acidolysis of Pd−C and C=N bonds, and substitution on the acetato bridging positions take place. It has also been found that cyclopalladated amine compounds react with benzaldehydes to afford the corresponding metallated imines in the *endo* form. Even the structures generally assumed for all these complexes are not so simple and they strongly depend on the reaction conditions. Under smooth conditions (25°C, 1 h), dimeric species containing five-membered metallacycles in *endo* (**1a** and **1b**) and *exo* (**2c** and **2d**) conformations, are formed and can be isolated as yellow solids in good yields. Longer reaction periods or higher temperatures induce the formation of polynuclear red materials due to the reactivity of the acetato bridging groups, as well as the reactivity of the C−Pd and C=N bonds. Obviously these more drastic reaction conditions favour the formation of the more thermodynamically stable metallacyclic species (*endo* six-membered monomeric cycles versus *exo* five-membered dimeric cycles, for ligands ***c*** and ***d***). In any case, the reaction mixture contains polynuclear species that can be detected, both in solution by NMR spectroscopy and in solid state by mass spectrometry. The cyclometallation of amines ***e*** and ***f*** in acetic acid has also been accomplished for the first time; in an analogous way, dimeric cyclopalladated compounds are initially formed, but the existence of dynamic processes affords some final polynuclear species.

Deeper interpretation of the kinetic and activation data available would be speculative at this point, given the multitude of steps taking place in any of the processes depicted in the reaction schemes. Further detailed studies for some of these systems are currently under way in order to establish a better kinetic understanding.

Experimental Section

General: ^{1}H- and ^{31}P{^{1}H}-NMR spectra were recorded on a Varian XL-200 (200 MHz) or Bruker 250 DRX (101.25 MHz) spectrometer. Chemical shifts (in ppm) are relative to $SiMe_4$ for ^{1}H and to 85% H_3PO_4 for ^{31}P spectra. The solvents used were $CDCl_3$ for ^{1}H spectra and $CHCl_3$ for ^{31}P spectra. − IR spectra were recorded as KBr disks on a Nicolet 520 FT-IR spectrometer. − GC analyses were performed on a Hewlett-Packard 5890 Series II gas chromatograph (50-m Ultra 2 capillary column 5% phenylmethylsilicone and 95% dimethylsilicone) with a FID detector. − Microanalyses were performed by the Institut de Química Bio-Orgànica de Barcelona (CSIC) and by the Serveis Científico-Tècnics de la Universitat de Barcelona. − Mass spectra (FAB and IS) were recorded on a Micromass VG-Quattro spectrometer; the samples were introduced in a matrix of 2-nitrobenzyl alcohol for FAB spectra and a mixture of water/acetonitrile was used as eluent for ion-spray spectra. − Imines **a**−**d** and cyclopalladated compounds **1a**, **1b**, **2c**, **2d**, and **4e** were prepared according to literature procedures.[12a,17e,18]

[Pd(CH$_3$COO)$_2$(4-ClC$_6$H$_4$CH=NCH$_2$C$_6$H$_5$)$_2$]: 0.100 g ($0.45\cdot10^{-3}$ mol) of palladium acetate and 0.21 g of **a** ($0.90\cdot10^{-3}$ mol) were dissolved in 10 cm^3 of toluene and stirred at room temperature for 2 hours, affording a pale yellow precipitate. The solid was filtered off and washed successively with toluene and diethyl ether, and dried under reduced pressure. Yield: 0.24 g (80%). − $C_{32}H_{30}Cl_2N_2O_4Pd$ (683.91): calcd. C 56.22, H 4.42, N 4.10; found C 56.26, H 4.48, N 4.38. − ^{1}H NMR: δ = 9.06 (br. s, 1 H, C*H*=N), 7.70−7.10 (m, 9 H, aromatic), 5.39 (s, 2 H, CH_2N), 1.60 (s, 3 H, CH_3).

Synthesis of 1a: 0.080 g of **4e** ($0.15\cdot10^{-3}$ mol) and 0.082 g of 4-chlorobenzaldehyde ($0.60\cdot10^{-3}$ mol) were treated with 5 cm^3 of acetic acid at 75°C overnight. The solution was filtered over celite, and the solution was concentrated under reduced pressure. After addition of diethyl ether, a yellow solid was precipitated. The solid **1a** was filtered off and washed successively with hexane and diethyl ether, and dried in vacuo.

[Pd(CH$_3$COO)(3-CH$_3$C$_6$H$_3$CH$_2$NH$_2$)]$_2$ (4f): 0.3 g ($0.25\cdot10^{-3}$ mol) of 2-methylbenzylamine, ***f***, were treated with palladium acetate ($0.25\cdot10^{-3}$ mol, 0.55 g) in acetonitrile at reflux for 4 h and then filtered. The solution was concentrated in vacuo, and the solid, obtained after addition of diethyl ether was recrystallised from chloroform/diethyl ether to obtain **4f** in 60% yield (0.4 g). Anal. [found (calcd. for $C_{20}H_{26}N_2O_4Pd_2$ (571.24): C 42.3 (42.05), H 4.7 (4.59), N 5.0 (4.90)%. − ^{1}H NMR: δ = 7.25 (m, 1 H, aromatic), 6.80 (br m, 2 H, aromatic), 4.00 (br m, 2 H), 3.05 (br. s, 2 H), 2.05 (br. s, 6 H, CH_3−C$_6$H$_3$, CH_3COO). ^{1}H NMR (**4f**+[D$_5$]py): δ = 7.15 (m, 1 H, aromatic), 7.05 (br m, 1 H, aromatic), 6.0 (br d, 1 H, aromatic), 4.62 (br. s, 2 H, NH_2), 4.42 (s, 2 H, CH_2N), 2.26 (s, 3 H, CH_3), 1.98 (s, 3 H, CH_3COO).

[PdBr(3-MeC$_6$H$_3$CH$_2$NH$_2$)(PPh$_3$)] (5f): 0.15 g ($0.25\cdot10^{-3}$ mol) of **4f** were treated with PPh_3 ($0.50\cdot10^{-3}$ mol, 0.14 g) and LiBr ($0.5\cdot10^{-3}$ mol, 0.046 g) in acetone at room temperature for 45 min and then filtered. The solution was concentrated in vacuo, and the solid, obtained after addition of diethyl ether was recrystallized from chloroform to obtain **5f** in 80% yield (0.23 g). − $C_{26}H_{25}BrNPPd$ (568.77): calcd. C 54.91, H 4.43, N 2.46; found C 54.5, H 4.5, N 2.60. − ^{1}H NMR: δ = 7.90−7.70 (m, 6 H, aromatic),7.60 7.40 (m, 9 H, aromatic), 6.75 (d, 7.2 Hz, 1 H, aromatic), 6.46 (t, 7.2 Hz, 1 H, aromatic), 6.36 (br t, 1 H, aromatic), 4.46 (s, 2 H, CH_2N), 4.05 (br. s, 2 H, NH_2), 2.35 (s, 3 H, CH_3). − ^{31}P{^{1}H} NMR: δ = 41.5 (s).

Kinetics: The reactions at atmospheric pressure were followed by UV/Vis spectroscopy in the full 750−300 nm range on a HP8542A instrument equipped with a multicell transport, thermostated (±0.1°C) with a circulation bath. Observed rate constants were derived from the absorbance versus time traces at the wavelengths where a maximum increase or decrease of absorbance was observed. The general kinetic technique is that previously described.[13] The concentration range for the different compounds used in this work is the same as that in previous papers;[7] no dependence on the different concentrations has been found for any of the rate constants in the $0.7-1.3\cdot10^{-3}$ M range. For runs at high pressure, a previously described pressurizing system and high pressure cell were used.[7][13] In these cases, the absorbance versus time traces were recorded on a J&M TIDAS instrument. Rate constants were derived from exponential least-square fitting by the standard routines. Least-square errors for the rate constants were always in the range of 10−15% of the calculated value. All post-run fittings to rate laws were done by standard, commercially available fitting programmes.

Novel Organometallic Derivatives of Thioesters of the Trivalent Phosphorus Acids: Synthesis and Structure

Vasily A Milyukov,[a] Alexander V. Zverev,[a] Sergey M. Podlesnov,[a] Dmitry B. Krivolapov,[a] Igor A. Litvinov,[a] Aidar T. Gubaidullin,[a] Olga N. Kataeva,*[a] Allan G. Ginzburg,[b] and Oleg G. Sinyashin[a]

Keywords: Thiophosphites / X-ray diffraction, / Manganese / Iron / Phosphorus

Thioesters of the phosphorous acid containing cymantrenyl and ferrocenyl substituents at sulfur were obtained for the first time from the reaction of organometallic disulfides with white phosphorus. According to an X-ray diffraction study tricymantrenyl trithiophosphite adopts an unusual asymmetric *cis*, *gauche*, *trans* conformation along the P–S bonds with respect to the phosphorus lone electron pair. Tri-ferrocenyl trithiophosphate possesses a classical propeller-like structure in the solid state which is different from its oxygen analogue.

Introduction

The chemistry of the thioesters of the trivalent phosphorus acids is a topic of great current interest and has experienced significant advances in recent years.[1] Surprisingly, the synthesis and structure of organometallic thioesters of the trivalent phosphorus acids has not been previously reported. The synthesis of such compounds provides a promising approach to obtain novel bi- and polynuclear complexes of transition metals, the coordination ability of trithiophosphites being promoted by their conformational flexibility due to internal rotation around the P−S bonds.[2−6]

In this paper we report the method of synthesis and the structure of novel thioesters of the trivalent phosphorus acids containing cymantrenyl and ferrocenyl fragments at the sulfur atoms.

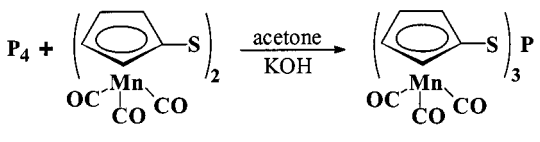
Results and Discussion

Syntheses

Three general methods for the preparation of the thioesters of the trivalent phosphorus acids are known. The first one[7] involves the phosphorylation of mercaptans by chlorides of the trivalent phosphorus acids. This reaction can proceed both in the presence or absence of the hydrogen chloride acceptors (R, R′ = alkyl or aryl):

$$RSH + R'_{3-n}PCl_n \longrightarrow R'_{3-n}P(SR)_n + HCl \quad (1)$$

Following this method we have synthesised *S*-cymantrenyldiphenylthiophosphinite, the first compound belonging to the class of organometallic thioesters of the trivalent phosphorus acids.[8] This compound was obtained from the reaction of cymantrenylmercaptan with diphenylchlorophosphane in boiling dichloromethane. However, it appears that this method has significant limitations and does not allow us to obtain organometallic thioesters of phosphorous or phosphoric acid, though oxygen analogues − triferrocenyl phosphite and the corresponding phosphate − were prepared by Max Herberhold and co-workers[9] by the interaction of ferrocenol with PCl_3.



The second method[10] involves the phosphorylation of mercaptides of alkali metals by chlorides of the trivalent phosphorus acids:

$$RSNa + R'_{3-n}PCl_n \longrightarrow R'_{3-n}P(SR)_n + NaCl \quad (2)$$

The most simple and convenient way to obtain trithiophosphites[11] is by the treatment of dialkyl (diaryl) disulfides with white phosphorus, this reaction also being used[12] to synthesise triseleno- and tritellurophosphites:

$$6(RS)_2 + P_4 \longrightarrow 4(RS)_3P \quad (3)$$

This reaction proceeds under mild conditions in aprotic solvents in the presence of a small amount of 15N KOH. In order to introduce a metal-containing thio-group at the phosphorus atom, for example cymantrenyl or ferrocenyl, the corresponding organometallic disulfides can be used as precursors to give tricymantrenyl and triferrocenyl trithiophosphites. Tricymantrenyl trithiophosphite was obtained in one step at room temperature in high yield by the reaction of white phosphorus with dicymantrenyl disulfide (**1**) in acetone solution.

Scheme 2. Synthesis of triferrocenyl trithiophosphite and trithiophosphate

The identity of trithiophosphite **2** was unequivocally determined by ^{1}H, ^{31}P NMR and IR spectroscopy as well as by X-ray single crystal diffraction.

A similar method was used to obtain triferrocenyl trithiophosphite (**3**) from diferrocenyl disulfide and white phosphorus. Its structure was proved by ^{1}H and ^{31}P NMR spectroscopy.

Compound **3** did not form single crystals suitable for X-ray analysis, but was easily oxidized to give triferrocenyltrithiophosphate (**4**) which was studied by X-ray single crystal diffraction.

Structures

Tricymantrenyl trithiophosphite has nine axes of internal rotation: three P−S bonds, three C−S bonds and three Mn−cyclopentadienyl axes. Rotation around the P−S bonds results in a totally asymmetric structure with three cymantrenylthio-groups exhibiting different orientations towards the phosphorus lone electron pair: *cis* around the P−S3 bond (torsion angle −7.2°), *gauche* around the P−S2 bond (−31.0°) and *trans* (178.1°) around the P−S1 bond (Figure 1). The torsion angles around the S−C bonds vary within smaller limits with an almost orthogonal orientation of the P−S bonds with respect to the cyclopentadienyl planes and the largest deviation from the perpendicular arrangement of 16° for the *cis* cymantrenylthiogroup (S3−C31). As for the third set of axes, the rotational flexibility of the cymantrenyl substituents leads to large thermal displacement parameters of the carbonyl groups and their variable orientation respective to the cyclopentadienyl rings in the three cymantrenyl moieties.

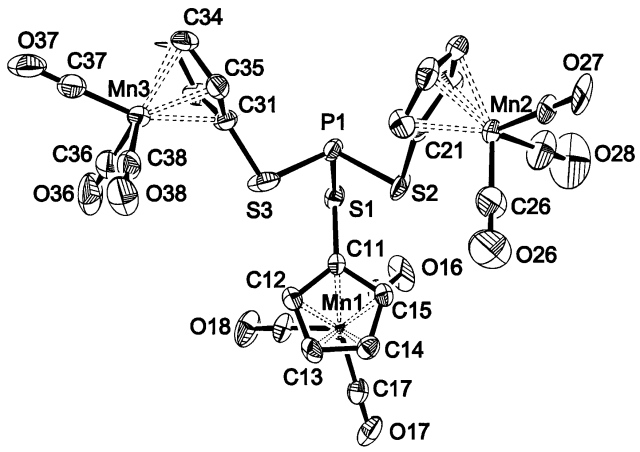

Figure 1. Molecular structure of compound **2** and atomic numbering

The carbonyl groups in the cymantrenyl substituents are staggered with respect to the C−S bonds and nearly eclipsed with respect to the C−H bonds, with torsion angles O=C···C−H of between 7 and 23°. The asymmetry of the structure accounts for an appreciable difference between the corresponding geometrical parameters in this molecule (Table 1). The P1−S1−C11 valence angle, 104.6(1)°, is 7° bigger than the angles at the two other sulfur atoms due to steric repulsion between the cyclopentadienyl ring (C11−C15) and the S2 and S3 atoms. Two short C−H···O intermolecular contacts, which meet the crystallographic criteria for weak hydrogen bonds are observed in the crystals of **2** with participation of the hydrogen atoms of the "trans"-cyclopentadienyl ring: C12−H12···O27′ (1 + *x*, 1/2 − *y*, −1/2 + *z*), C12−H12 0.88(3) Å, H12···O27′ 2.58 Å, ∠C12−H12−O27′ 158(2)°; C15−H15···O38′′ (*x*, 1/2 − *y*, 1/2 + *z*), C15−H15 0.96(3) Å, H15···O38′′ 2.59 Å, ∠C15−H15−O38′′ 153(2)°.

In comparison with thiophosphites which do not contain a metal atom, tricymantrenyl trithiophosphite **2** has a rather unusual structure, although the geometry of its central inorganic part is very close to that of non metal containing derivatives, in particular triphenyl trithiophosphite.[13] In the crystal, a propeller-like conformation (C_3-symmetry) was observed for most of the phosphorus compounds containing three identical SR groups studied regardless of the phosphorus coordination number.[13−15] A *cis*-orientation of the SR group relative to the phosphorus lone electron pair is also unusual even in the liquid and gaseous phases, with a mixture of several conformers with *gauche* and *trans* orientations of the alkylthio or phenylthio groups relative to the phosphorus lone electron pair or phosphoryl (thiophosphoryl) bonds being found normally.[2−6] Thus, several factors might be responsible for the unusual structure of **2** in the crystalline phase: the bulkiness of the cymantrenyl groups, their irregularity caused by the respective rotation of the carbonyl moieties and cyclopentadienyl rings, the ability of the carbonyl groups to participate in intermolecular interactions with the C−H bonds. In a series of reviews[16−19] it was shown that such weak interactions can significantly influence the observed conformations of molecules and are responsible for their crystal packing.

In order to compare the structure of the cymantrenylthio fragment in trithiophosphite **2** and in disulfides, we have carried out an X-ray study of the dicymantrenyldisulfide **1**. Its molecular structure is shown in Figure 2. The orientation of the five-membered rings with respect to the carbonyl groups is identical for both cymantrenyl fragments in

the molecule. Two cymantrenylthio groups are twisted around the central S−S bond by 103.3(1)° with the S−S bond being perpendicular to both cyclopentadienyl rings. The same perpendicular arrangement around the central S−S bond is observed in the chloro-substituted derivative of dicymantrenyl disulfide[20] and in bis[2-(1-dimethylaminoethyl)ferrocenyl]disulfide.[21] In general the structures of **1** and its chloro derivative are very similar and the values of the S−S and S−C bonds and valence angles at the sulfur atoms are the same within experimental error (Table 1). The substitution of one of the sulfur atoms in dicymantrenyl disulfide by phosphorus does not significantly effect the geometry of the cymantrenylthio moieties in **2**. The orientation of the S−P bonds relative to the cyclopentadienyl rings is perpendicular in trithiophosphite, as is the orientation of the S−S bond in **1**.

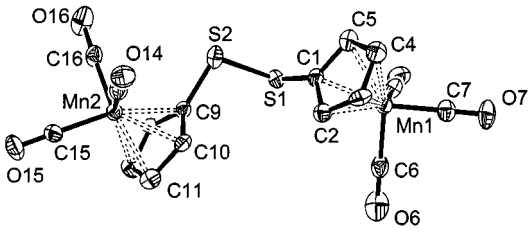

Figure 2. Molecular structure of compound **1** and atomic numbering

Table 1. Selected geometrical parameters[a]

Parameter	**2**	**4**
Bond lengths, Å		
P=O	–	1.453(6)
P1−S1	2.107(1)	2.077(3)
P1−S2	2.120(1)	2.080(4)
P1−S3	2.121(2)	2.090(4)
S1−C11	1.760(4)	1.76(1)
S2−C21	1.766(4)	1.781(9)
S3−C31	1.759(4)	1.75(1)
Bond angles, deg.		
S1−P1−S2	98.88(6)	100.6(1)
S1−P1−S3	103.38(7)	101.8(2)
S2−P1−S3	102.57(7)	102.3(2)
S1−P1−O1	–	117.1(3)

P1−S1−C11	104.6(1)	100.9(3)
P1−S2−C21	98.5(1)	103.0(3)
P1−S3−C31	98.3(1)	99.9(4)

[a] Selected parameters for compound **1**: Bond lengths S1−S2 2.066(1), S1−C1 1.764(3), S2−C9 1.757(3) Å; bond angles S2−S1−C1 102.1(1), S1−S2−C9 102.8(1)°.

An X-ray study of triferrocenyl trithiophosphate (Figure 3) showed that this molecule, in contrast to tricymantrenyl trithiophosphite, adopts a classical propeller-like conformation with *gauche* orientations of all three ferrocenylthio groups relative to the P=O bond. Three C−S−P=O torsion angles in this molecule are equal to −54.2, −45.9, and −46.5°. The respective orientation of the ferrocenyl moieties and the P−S bonds is slightly different. It is perpendicular around the C1−S1 and C11−S2 bonds and slightly skewed around the C21−S3 bond with ∠ P−S3−C21−C22 = 75.6°. An almost symmetrical conformation results in equal (within experimental error) P−S, O=PS and PSC bond angles in the molecule (Table 1). The ferrocenyl substituents have the symmetrical structure of ferrocene with planar and nearly parallel cyclopentadienyl rings. The dihedral angles between the rings in the ferrocene moieties are 0.9 (Fc^1), 0.7 (Fc^2) and 2.5° (Fc^3). The angles δ at iron between the two cyclopentadienyl ring centers are 178.9 (Fc^1), 178.0 (Fc^2) and 178.7° (Fc^3). The geometry of the ferrocenyl substituents in **4** is the same as in its oxygen analogue triferrocenyl phosphate,[9] although the conformations of the two molecules are totally different. Unlike the thio derivative, triferrocenyl phosphate adopts an asymmetrical conformation in the crystal with *cis*, *gauche* and *trans* (∠O=P−O−C = −27.8, −73.4, 178.7°) orientations of the ferrocenyloxo groups with respect to the P=O bond. The dihedral angles between the P−O bonds and the cyclopentadienyl rings are also different, being equal to 40.2, −77.3 and −2.7° for the three ferrocenyl substituents. Thus, the organometallic thioester and ester of phosphoric acid have completely different structures. One of the reasons for this difference is the presence of several intermolecular C−H···O short contacts observed in the crystal of the oxygen derivative

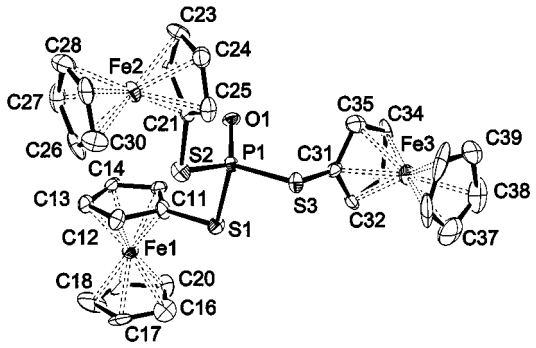

Figure 3. Molecular structure of compound **4** and atomic numbering

Experimental Section

All syntheses were performed using standard Schlenk techniques under an argon atmosphere using pre-dried solvents saturated with argon. The initial organometallic disulfides were obtained following refs.[22][23] IR spectra were measured on an UR-20 spectrometer. ^{1}H and ^{31}P NMR spectra were recorded on the NMR-FT spectrometers MSL-400 and WM-250 (Bruker) with deuteriated solvents (C_6D_6, $CDCl_3$).

Tricymantrenyl Trithiophosphite (2): To a solution of dicymantrenyl disulfide (0.75 g, 1.6 mmol) in acetone (30 mL) were added white phosphorus (0.037 g, 0.28 mmol) and KOH (0.02 mL 15N KOH). The reaction mixture was stirred at ambient temperature for one hour. The solvent was then evaporated and the residue was recrystallized twice from a mixture of benzene/hexane (1:1) to give yellow-green crystals of **2** (0.7 g, 90%), m.p. 125°C. – ^{1}H NMR(C_6D_6): δ = 4.21 (m, 2 H_α), 4.56 (m, 2 H_β). – ^{31}P ($CDCl_3$): δ = 128. – IR (hexane): $\nu_{C=O}$ = 1945, 2025 cm^{-1}. – $C_{24}H_{12}Mn_3O_9PS_3$ (736.34): calcd. C 39.15, H 1.64, P 4.21, S 13.06; found C 38.94, H 1.62, P 4.00, S 13.25.

Triferrocenyl Trithiophosphite (3): To a solution of diferrocenyldisulfide (1.1 g, 2.5 mmol) in acetone (30 mL) were added white phosphorus (0.052 g, 0.4 mmol) and 0.2 mL 15N KOH. The reaction mixture was stirred at room temperature for one hour. The solvent was then evaporated and the residue was recrystallized twice from a mixture of benzene/hexane (1:1) to give dark-orange crystals of **3** (0.93 g, 81%), m.p. 200−203°C. − ^{1}H NMR(C_6D_6): δ = 4.35 (m, 2 H_α), 4.52 (m, 2 H_β), 4.50 (s, 5 H). − ^{31}P ($CDCl_3$): δ = 131. − $C_{30}H_{27}Fe_3PS_3$ (760.37): C 52.82, H 3.99, P 4.54, S 14.09; found C 52.74, H 3.95, P 4.25, S 14.15.

Triferrocenyl Trithiophosphate (4): A solution of triferrocenyltrithiophosphite (2.1 g, 3 mmol) in benzene (20 mL) was boiled with the constant bubbling of air through it during one hour. The solvent was evaporated and the residue was recrystallized from a mixture of benzene/hexane (2:1) to give dark-orange crystals of **4** (1.77 g, 85%), m.p. 230°C. − ^{1}H NMR(C_6D_6): δ = 4.3 (m, 2 H_α), 4.45 (m, 2 H_β), 4.52 (s, 5 H). − ^{31}P ($CDCl_3$): δ = 47.7. − $C_{30}H_{27}Fe_3OPS_3$ (776.37): C 51.60, H 3.89, P 4.44, S 13.77; found C 51.67, H 3.87, P 4.31, S 14.25.

X-ray Structure Determination: The X-ray diffraction data were collected on a CAD4 Enraf−Nonius automatic diffractometer with the graphite monochromated Mo K_α radiation (λ = 0.71073 Å) in the ω-scan mode.

Crystal Data for 1: $C_{16}H_8Mn_2O_6S_2$, formula weight 470.24, (yellow prism, crystal dimensions 0.1 × 0.2 × 0.3 mm), space group $P2_1/n$, a = 6.495(1), b = 12.141(2), c = 22.509(2) Å, β = 93.27(2)°, V = 1772.1(4) Å^3 at 20°C, Z = 4, ρ = 1.76 (g·cm^{-3}), μ = 16.24 cm^{-1}, total number of reflections measured 6041, number of observed reflections with $I > 3\sigma(I)$ 2714, number of variables 267, final R/R_w = 0.032/0.030.

Crystal Data for 2: $C_{24}H_{12}Mn_3O_9PS_3$, formula weight 736.34, (crystal dimensions 0.4 × 0.25 × 0.2 mm), space group $P2_1/c$, a = 10.519(3), b = 21.598(6), c = 12.788(2) Å, β = 98.32(1)°, V = 2875(1) Å^3 at 20°C, Z = 4, ρ = 1.70 (g·cm^{-3}), μ = 15.58 cm^{-1}, total number of reflections measured 9262, number of observed reflections with $I > 3\sigma(I)$ 3520, number of variables 409, final R/R_w = 0.038/0.044.

Crystal Data for 4: $C_{30}H_{27}Fe_3OPS_3 \cdot C_6H_6$, formula weight 776.37, (crystal dimensions 0.4 × 0.1 × 0.04 mm), space group $C2/c$, a = 25.353(3), b = 10.873(3), c = 23.147(4) Å, β = 103.04(1)°, V = 6212(2) Å^3 at 20°C, Z = 8, ρ = 1.66 (g·cm^{-3}), μ = 16.58 cm^{-1}, total number of reflections measured 14329, number of observed reflections with $I > 3\sigma(I)$ 3669, number of variables 363, final R/R_w = 0.058/0.057. The stability of the crystals and the experimental conditions was checked every two hours by measuring three control reflections, while the orientation was monitored every 200 reflections by centering two standards. No significant decay was observed. Corrections for Lorentz and polarization effects were applied. An empirical absorption correction based on ψ-scans was applied for all crystals. The structures were solved by direct methods and difference Fourier syntheses using the MolEN package.[24] All non-hydrogen atoms were refined anisotropically, H-atoms, located in ΔF maps, were refined isotropically for **1** and **2**; for **4** H-atoms were placed into calculated positions and included into structure factor calculations with fixed positional and thermal parameters. It should be noted that crystals of **4** are stabilized by solvate benzene molecules, in which four carbon atoms are disordered.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 130650−130652 (**1, 2, 4**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

Dipolar and Non-Dipolar Pyridine and Bipyridine Metal Complexes for Nonlinear Optics

Hubert Le Bozec*[a] and Thierry Renouard[a]

Keywords: Pyridine derivatives / Bipyridine derivatives / Metal complexes / Chromophores / Nonlinear optics

Metal complexes of pyridine and bipyridine-type ligands represent an important class of nonlinear optical (NLO) materials: (i) They can incorporate a variety of functionalised ligands with a wide range of metals which can give rise to tuneable NLO properties; (ii) they are generally associated with intense low-lying charge-transfer excitations such as metal to ligand charge-transfer (MLCT) or intraligand charge-transfer (ILCT); (iii) bipyridyl ligands are also good building blocks that allow the construction of octupolar complexes with a defined geometry and symmetry. This review describes the recent developments in the design of such dipolar and octupolar chromophores for second-order nonlinear optics.

1. Introduction

The search for new molecular materials with large second-order nonlinear optical properties (NLO) is currently the subject of considerable investigations due to their potential applications in photonic devices such as frequency doublers and electrooptic modulators.[1] Organic and met-

Hubert Le Bozec was born in Brittany, France. He entered the CNRS in 1978 and received his "Doctorat d'Etat" in 1981 from the University of Rennes 1, working under the supervision of Prof. Pierre Dixneuf. After a postdoctoral period in 1982 at the University of North Carolina (Chapel Hill, USA) with Prof. Thomas Meyer, he returned to Rennes and was promoted "Directeur de Recherche" in 1994. His research interests concern the coordination chemistry of bipyridyl metal complexes and their application in nonlinear optics as well as the chemistry of group-6 and group-8 carbene metal complexes.

Thierry Renouard was born in 1971 in Saint Brieuc, France. He studied Chemistry at the University of Rennes 1 and obtained his Ph. D. in 1998, under the supervision of Dr. Hubert Le Bozec. In the same year, he joined the group of Prof. Michael Grätzel at the Swiss Federal Institute of Technology in Lausanne as a Post-Doctoral fellow. His current research interest concerns the synthesis of novel sensitizers for photovoltaic cells.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

allo-organic materials are of particular interest because of their large NLO susceptibilities and fast response times; they also provide good architectural flexibility to tailor their molecular structures and maximize the optical nonlinearity.[2−4] Thus, extensive efforts are now directed towards the design and synthesis of efficient chromophores which can be incorporated into macroscopic assemblies such as polymers, to form materials exhibiting large NLO responses.[5−7]

Traditionally, chromophores possessing large molecular hyperpolarisability β responses contain donor and acceptor substituents linked through a π-backbone. A great deal of work has been carried out over the past 20 years toward the synthesis of noncentrosymmetric dipolar (or "push-pull") molecules such as functionalised benzene, stilbene, polyene or azobenzene derivatives.[8−12] Moreover, a comprehensive understanding of the design of dipolar organic molecules with optimised molecular hyperpolarisability β has been established − recent computational and experimental studies have introduced several concepts such as bond-length alternation (BLA),[13−16] reduced aromaticity in the ground state,[17] as well as the criterion of electron deficiency or excessivity[18] to establish structure-property relationships for nonlinear optical molecules.

Beyond this classical dipolar approach, a new concept of octupolar nonlinearities has been recently proposed on the basis of group theoretical and quantum mechanical studies.[19][20] The molecular hyperpolaribility β can be reduced into two irreducible components $\beta_{J=1}$ (dipolar part) and $\beta_{J=3}$ (octupolar part). For molecules belonging to purely octupolar space groups such as D_3, D_{3h}, T_d, and D_2, the vector part of β is canceled out and only the octupolar contribution of β remains. The advantages of using nondipolar chromophores include easier noncentrosymmetric arrangements and an improved nonlinearity/transparency trade-off. An increasing number of two- and three-dimensional (2D and 3D) octupolar molecules has appeared in the literature[21] with the development of the Hyper Raleigh Scattering technique (see Background). For example, research on octupolar structures has recently focused on organic molecules with threefold symmetry such as triamino-trinitrobenzenes derivatives,[22] crystal violet cation,[23] trisubstituted amines[24] and cyanine salts.[25]

In the late 1980s, the field of molecular materials for nonlinear optics was extended to organometallic and coordination compounds.[11][26] One reason is that they offer a wide range of metals with different oxidation states and ligands which can give rise to tuneable electronic properties. In addition many complexes are known to possess low-lying charge-transfer states which can be associated with large nonlinearities. Non-centrosymmetric structures can also be achieved by coordination of different ligands to a metal centre. For example, there has been considerable interest in using metallocenes, especially ferrocene derivatives, as donor groups since the pioneering work of Green and co-workers in 1987 who reported a second-harmonic generation (SHG) efficiency 62 times that of the urea standard for the compound (*Z*)-1-ferrocenyl-2-(4-nitrophenyl)ethene.[27][28] Metal complexes of nitrogen-heterocyclic ligands, such as pyridines and oligopyridines, represent another important class of NLO chromophores which have received increasing attention over the last ten years. These ligands, which can be easily functionalized, are among the most widely studied in coordination chemistry resulting in a wide choice of stable complexes.[29] They are generally associated with intense low-energy metal to ligand charge-transfer (MLCT) or intraligand charge-transfer (ILCT) [also known as ligand-centred (LC)] excitations. In addition, bipyridyl ligands are excellent building blocks for the construction of octupolar metal complexes like $[M(bpy)_3]^{n+}$ of D_3 symmetry and $[M(bpy)_2]^{n+}$ of D_{2d} symmetry. This microreview highlights the recent developments in the design of pyridyl- and bipyridyl-metal complexes for nonlinear optics. The first part is concerned with dipolar chromophores whereas the second part will deal with the more recent and promising field of octupolar metal complexes. In each section we have gathered the chromophores into two categories: (i) complexes in which the NLO response is dictated by a MLCT transition, and (ii) complexes with ligands bearing π-donor substituents in which the main charge-transfer governing the NLO response is an ILCT transition.

2. Background

The second-order nonlinear effect is correlated with quadratic (or first molecular) hyperpolarisability β. The dipole moment μ induced in a molecule by an intense external electric field E can be expressed by the relationship of Equation 1, where α is the linear polarisability, and β and γ the first and second molecular hyperpolarisability, respectively.

$$\mu = \alpha \cdot E + \beta \cdot E^2 + \gamma \cdot E^3 + \cdots \quad (1)$$

The coefficient β governs the magnitude of the second-order response, and vanishes in a centrosymmetric medium.

The experimental determination of β can be carried out by using the Electric-Field-Induced Second Harmonic generation (EFISH) method.[30−32] A high-voltage electric pulse breaks the centrosymmetry of the liquid by a dipolar orientation of the molecules. This technique allows determination of $\gamma + \mu \cdot \beta/5kT$, where γ is the cubic hyperpolarisability of the molecule, μ its dipole moment, and β the vectorial projection of the first hyperpolarisability tensor along the dipole direction. By neglecting the third order contribution, β can be evaluated. The ground state dipole moment can be measured independently by a classical method based on the Guggenheim law.[33] Modelling the dispersion of β for a two-level system according to Equation 2 enables us to extract a frequency-independent nonresonant $\beta(0)$ value.[31][34]

$$\beta = \frac{3e^2\hbar^2}{2mW^3} F(W,\omega) f \Delta\mu \quad (2)$$

With respect to Equation 2, W is the energy of the CT transition, ω the fundamental frequency, f the oscillator strength of the charge-transfer band, $\Delta\mu = \mu_{exc} - \mu_g$ the

difference between excited- and ground-state moments, and F the dispersion factor, which is defined by Equation 3; β is related to the static hyperpolarisability coefficient $\beta(0)$ by $\beta = \beta(0) \cdot F(W,\omega)$.

$$F(W,\omega) = \frac{W^4}{\left[W^2 - (\hbar\omega)^2\right]\left[W^2 - (2\hbar\omega)^2\right]} \quad (3)$$

The experimental determination of β can also be carried out with the Hyper-Raleigh Scattering (HRS), also termed Harmonic Light Scattering (HLS), method.[35][36] This is a unique technique for β measurement of nondipolar and/or ionic molecules. For such molecules the EFISH experiment is not possible as it requires uncharged species and a non-zero ground state dipole moment. The HRS method is based on an incoherent scattering of the second harmonic originating from the fluctuation of optically induced microscopic dipoles. The HRS harmonic response can be expressed as in Equation 4, where $I^{2\omega}$ is the scattered SHG intensity, I^{ω} is the intensity of the fundamental wave, G is a geometrical factor, N_1 (N_2) is the molecular density of the solute (solvent) and $<\beta_1^2>$ ($<\beta_2^2>$) is the orientational average of the square of the first hyperpolarisability of the solute (solvent).

$$I^{2\omega} = G(N_1<\beta_1^2> + N_2<\beta_2^2>)\,(I^{\omega})^2 \quad (4)$$

The HLS technique also allows us to determine the individual components of the β tensor.[37] In the case of nondipolar molecules, the static hyperpolarisability $\beta(0)$ at zero-frequency may be calculated using a three-level model.[38] The dispersion factor is similar to that of a two-level system (Equation 3).

3. Dipolar Complexes

3.1 Dipolar Complexes with Metal-to-Ligand Charge-Transfer Transitions

In 1986, Frazier and co-workers[39] investigated for the first time the second-harmonic powder efficiencies of the 4-substituted group-6 metal carbonyl pyridyl complexes **1** (Figure 1). However, only very weak SHG efficiencies, from 0 to 1 relative to ammonium dihydrogen phosphate (ADP), were obtained. Presumably most of these complexes crystallise in centrosymmetric space groups. The first examples of metal-bipyridine complexes possessing second-order polarisabilities were reported by Calabrese and Tam in 1987.[40] They studied the macroscopic SHG powder efficiencies by the Kurtz technique at 1.06 μm. The rhenium(I) complexes (bpy)Re(CO)$_3$X (**2**) [X = Cl, CF_3SO_3] were found to crystallise in a noncentrosymmetric space group and gave SHG efficiencies from 1.6 to 3 times that of urea. Other complexes such as (4-Y-pyridine)$_2$Re(CO)$_3$Br (**3**) [Y = H, styryl], (bpy)MCl_4 (**4**) [M = Pd, Pt] and (bpy)M(CO)$_4$ (**5**) [M = Cr, Mo, W] showed rather small SHG efficiencies ranging from 0.1 to 1.2 times that of urea (Figure 1). The first EFISH studies on metal pyridine and bipyridine (or phenanthroline) complexes were described by Cheng et al.[41][42] They measured the molecular hyperpolarisability β of (4-Y-pyridine)W(CO)$_5$ (**1a**), (4-Y-stilbazole)W(CO)$_5$ (**1b**) and (5-Y-1,10-phenanthroline)W(CO)$_5$ (**6**) (Figure 1). Their optical nonlinearities, ranging from -2 to -20×10^{-30} esu, were significantly enhanced relative to that of the free ligands. The negative values of β are consistent with the negative solvatochromism observed for such complexes by Wrighton and co-workers.[43] The use of 4-substituted pyridines with electron-acceptor groups led to a bathochromic shift of the MLCT transition energy and to larger β values. These trends can be explained by the lowering of the π*-acceptor orbital of the pyridine (phenanthroline) ligands and a decrease in the energy gap of the MLCT transition. Respectable nonlinearities were observed for complexes containing nitro-substituted ligands such as (4-NO_2-stilbazole)W(CO)$_4$ [$\beta = -20 \times 10^{-30}$ esu] and (5-Y-1,10-phenanthroline)W(CO)$_5$ [$\beta = -18 \times 10^{-30}$ esu].[41]

A ZINDO-SOS computational study of the related (4-Y-pyridine)Cr(CO)$_5$ (**1a**) and (4-Y-stilbazole)Cr(CO)$_5$ (**1b**) has more recently been described by Ratner, Marks and co-workers.[44] The computed molecular hyperpolarisabilities were in good agreement with the experimental values. These calculations also showed that the NLO response is dictated by the MLCT transition, that the pyridine ring is the primary charge acceptor and that the calculations also predicted the negative sign of β and an increase of the NLO response when electron-accepting groups are attached to the pyridine ring.

Thompson et al.[45] investigated the second-order NLO properties of iron(III) compounds Fe(SALEN)(4-Y-pyridyl)X (**7**), where X is a halide or an azide (Figure 2). The Kurtz powder test gave a sizeable SHG efficiency twice that of urea when X = N_3, whereas weak SHG intensities were found for the other complexes (0−0.2 × urea). The nonlinearity finds its origin in charge-transfer transitions in both the SALEN ligand and pyridyl-iron system. Attempts to measure the molecular hyperpolarisability β by EFISH in chloroform failed due to low solubility and dissociation of the pyridyl ligand. Thompson and co-workers also described the preparation of an interesting polymer chain **8** from the reaction of Mn(SALEN)Br and 4-pyridyl glycinate ligands or 4-(pyridylthio)acetic acid (Figure 2).[46] The polymers consisted of metal centres bridged by 4-pyridyl ligands. The crystal structures showed a head-to-tail alignment of adjacent dipoles along the polymer backbone. Unfortunately, adjacent polymer chains were antiparallel, so no NLO effects were observed.

Large molecular hyperpolarisabilities have recently been observed by Coe et al.[47] in donor-acceptor ruthenium(II) complexes. They reported the synthesis of a series of *trans*-$[Ru(NH_3)_4(L^A)(L^B)]^{n+}$ complexes **9**, where L^A and L^D are acceptor/donor-substituted pyridyl ligands (Figure 2). All these complexes show highly solvatochromic low energy $d\pi(Ru) \rightarrow \pi^*(L^A)$ metal-to-ligand charge-transfer bands in the visible region. Using the HRS technique at 1.064 μm, large β values in the range $230-790 \times 10^{-30}$ esu were found, especially for complexes **9b−9d** containing *N*-meth-

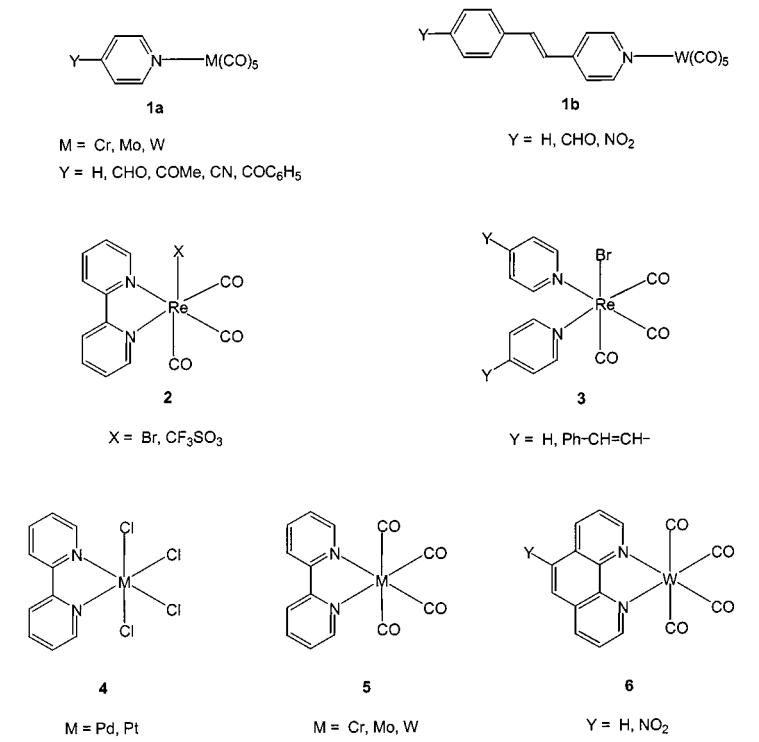

Figure 1. Dipolar complexes with MLCT transitions

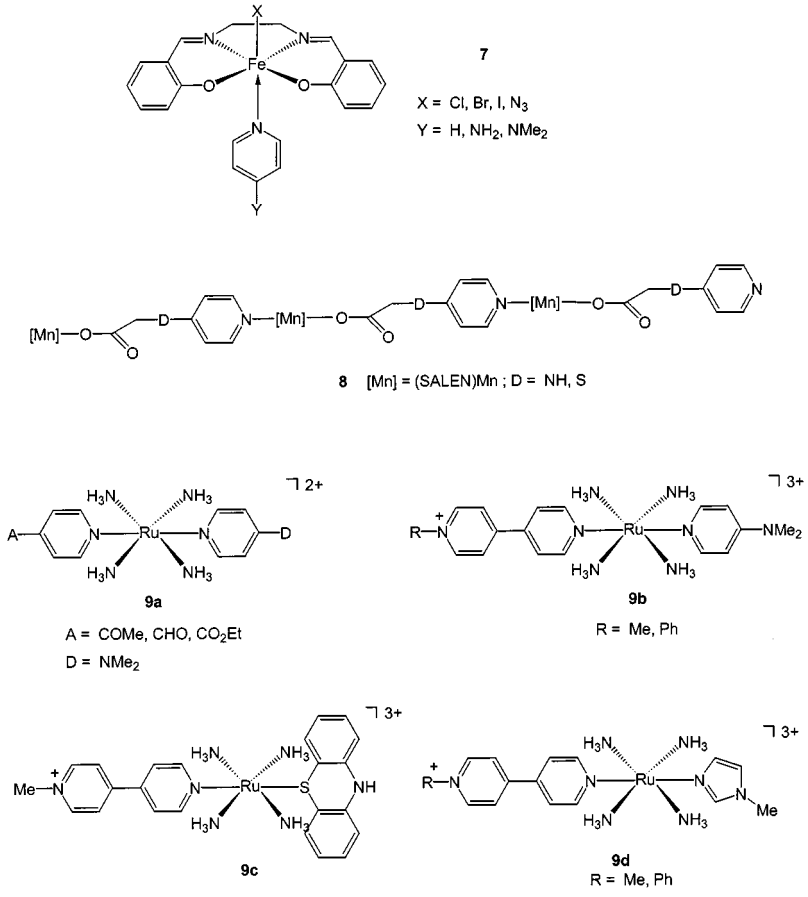

Figure 2. Dipolar complexes with MLCT transitions

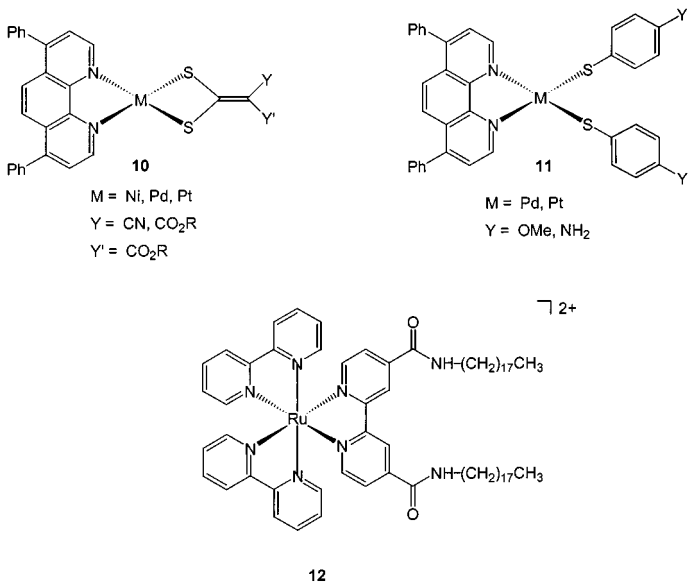

Figure 3. Dipolar diimine metal complexes with MLCT transitions

yl- and *N*-phenyl-4,4′-bipyridinium (MQ^+) as electron-acceptor ligands. As these complexes absorb in the region of the second harmonic (0.532 μm), the large β values were attributed in part to resonance enhancement. Static hyperpolarisabilities $\beta(0)$ were also calculated and ranged from 10 to 266×10^{-30} esu.

Eisenberg and co-workers[48] prepared a series of mixed-ligand transition-metal diimine dithiolate complexes **10−11** (diimine = phenanthrolines, bipyridines; metal = Ni, Pd, Pt) and studied their NLO properties by EFISH at 1.91 μm. Some examples of complexes are displayed in Figure 3. Their lowest-energy excited states involve a HOMO which is a mixture of M(d)- and dithiolate-orbital character and a LUMO which is a π* orbital of the diimine ligands. This transition has been termed by the authors as "charge-transfer-to-diimine."[49][50] The role of the metal ion, dithiolate and diimine ligands in the tuning of the optical and nonlinear optical properties was investigated. Negative β values in the range 0 to -40×10^{-30} esu were found. Larger values of β were observed with Pt^{II} metal ions and dithiolate ligands containing electron-donating substituents such as in **11**. In contrast, complexes **10** with dithiolate ligands containing electron-withdrawing groups exhibited reduced β values: a decrease of the electron-donating strength of the dithiolate and the presence of another charge-transfer-to-dithiolate, which is vectorially opposed to the charge-transfer-to-diimine, were proposed to explain the lowering of the molecular hyperpolarisability.

Matsuo and co-workers[51] studied the second-harmonic generation of the amphiphilic tris(2,2′-bipyridyl)ruthenium(II) complex **12** in a Langmuir-Blodgett film (Figure 3). Amide groups were introduced at the 4,4′-position of one bipyridine ligand in order to increase the vectorial properties of the MLCT. The absorption spectrum of the LB film showed a typical MLCT band at 450 nm and another at 480 nm which was assigned to the MLCT transition to the 4,4′-diamide-2,2′-bipyridine ligand. The β value was estimated to be 70×10^{-30} esu. Second harmonic generation was also observed from ultrathin polyvinyl chloride films impregnated with the same tris(bipyridyl)ruthenium(II) complex.[52]

3.2 Dipolar Complexes with Intraligand Charge-Transfer Transitions

In the first phase of our work on bipyridyl metal complexes for nonlinear optics, we developed the synthesis of the 4-alkenyl-2,2′-bipyridines **13−14** bearing π-donor substituents (Figure 4).[53][54] These ligands are easily available from 4,4′-dimethyl-2,2′-bipyridine.[55] The optical UV/Vis absorption spectra of **13** showed a characteristically intense solvatochromic intramolecular charge-transfer transition, whereas that of the metallocenylvinyl bipyridines **14** exhibited two less intense bands assigned to MLCT and π−π* transitions, respectively.[28b,56] The EFISH measurements of **13** and **14** at 1.34 μm[57] indicated moderate β values ranging from 4 to 14×10^{-30} esu; the most efficient donor group was, as expected, dibutylaminophenyl [4-$Bu_2N-C_6H_4$- >> 4-RO−C_6H_4- ≈ $(C_5H_5)Fe(C_5H_4$-) > $(C_5H_5)Ru(C_5H_4$-)]. These ligands were coordinated to acceptor organometallic fragments, and two types of complexes were prepared: octahedral rhenium(I) carbonyl complexes of general formula *fac*-(bpy)$Re(CO)_3X$ (**15**) and tetrahedral zinc and mercury complexes of general formula $(bpy)MX_2$ (**16**) (Figure 4).[53][57] A selection of optical and nonlinear optical data are displayed in Table 1. We observed a red shift of the ILCT transition ($\Delta\lambda \approx 40-70$ nm) which was sensitive to the nature of both the organometallic moiety and the conjugated donor group. For a given donor group (for example Bu_2N), the relative ordering of the acceptor strength was: $Re(CO)_3Br$ > $ZnCl_2$ > $Zn(OAc)_2$ >

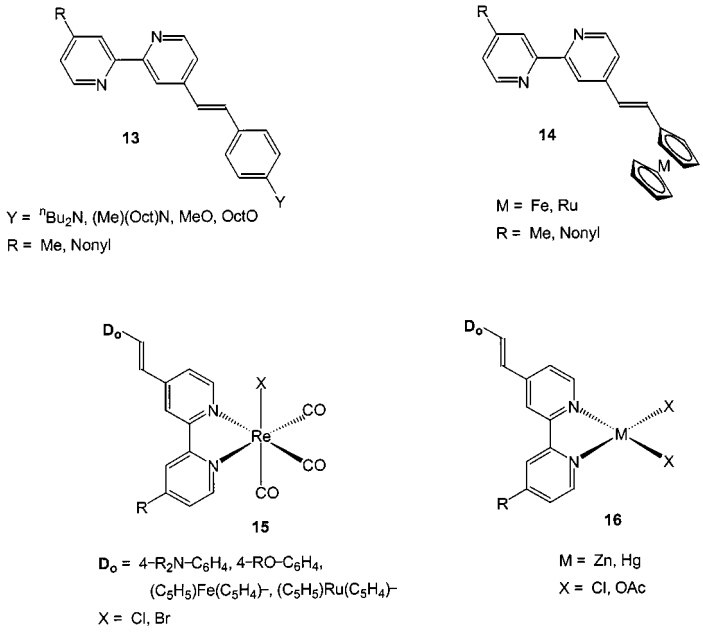

Figure 4. Dipolar bipyridine metal complexes with ILCT transitions

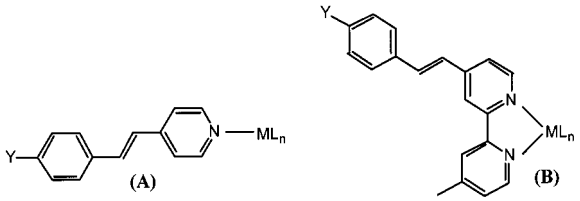
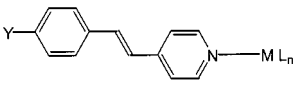


$HgCl_2 > Hg(OAc)_2$. In addition to the ILCT band, each of the rhenium complexes also exhibited a less intense absorption near 380 nm, which was assigned to a $d\pi(Re) \rightarrow \pi^*$ (bpy) transition. Upon coordination, the β values were found to increase by a factor ranging from 2 to 11 (Table 1). The inductive acceptor strength of the ML_n fragment contributes mainly to the enhancement of the NLO response. A conformational change of the bipyridine ligand upon chelation [trans $\rightarrow$ cis] could also play a non negligible role. The ordering of the β values followed that found for the relative energies of the ILCT bands, with the exception of the rhenium complexes **15** which were less efficient than the corresponding zinc complexes **16**: The presence of two vectorially opposed charge-transfer axes (MLCT and ILCT) in **15** could contribute to the decrease in β. The largest static response was found for compound **16** with dibutylaminophenyl as the electron donor and zinc dichloride as the electron acceptor [$\beta(0) = 71 \times 10^{-30}$ esu]; its molecular nonlinearity $\mu\cdot\beta(0)$ [$\mu\cdot\beta(0) = 831 \times 10^{-48}$ esu], which is the relevant parameter for poled polymer applications, compared well with that of the prototypical chromophore disperse red 1 [$\mu\cdot\beta(0) = 450 \times 10^{-48}$ esu].[58]

Molecular quadratic hyperpolarisabilities of donor-substituted stilbazole complexes have also been recently studied by several groups. Bruce and Thornton[59] prepared mesogenic 4-alkoxystilbazole complexes of Rh^I and Ir^I **17** (Figure 5). A chiral alkoxy chain such as (*S*)-(+)-2-methylbutoxy was used in order to promote noncentrosymmetric packing in the solid state. A bathochromic shift ($\Delta\lambda \approx 20-30$ nm) was observed upon complexation of the ligand to the $[MCl(CO)_2]$ fragment. The complexation also resulted in enhanced values of μ by a factor of ca. 2, and $\beta(0)$ by a factor of ca. 1.5 (Table 1). Ratner, Marks and co-workers[44] studied the experimental and computed NLO properties of [4-(dimethylamino)stilbazole]$M(CO)_5$ complexes **18** (M = Cr, W). The EFISH studies at 1.064 μm indicated an increase in β of two times the organic stilbazole ligand. The calculated β [65×10^{-30} esu] was in excellent agreement with the observed experimental molecular hyperpolarisability [61×10^{-30} esu]. It is noteworthy that this response is larger and of an opposite sign to the (4-acceptorstilbazole)$M(CO)_5$ derivatives **1b**. As for the donor substituted bipyridine metal complexes **15**, the NLO response is here dictated by an ILCT transition and the role of the metal fragment is that of an inductive acceptor. ZINDO calculations were used to study the difference in electronic populations between ground state and excited state: The study showed that the MLCT excitation is of secondary importance since only 0.14 electrons are transferred from $M(CO)_5$.[44]

Marder et al.[60] have recently examined the NLO properties of the same 4-donorstilbazoles and their Lewis acidic borane adducts **19** (Figure 5). The β values of the free stilbazole ligands were found to be larger than those of the related 4-alkoxy- or 4-aminostyryl-2,2′-bipyridine (**13**) (Table 1).[57] This difference could be explained by the transoid conformation of the bipyridine ligands and thus to the presence of opposed charge-transfer excited states which are expected to reduce the magnitude of β. The red shift ($\Delta\lambda \approx 40-90$ nm) of the intramolecular charge-transfer transition upon coordination of the Lewis acidic boranes was more pronounced than when the same ligands were complexed to $W(CO)_5$[44] or $[M(CO)_2Cl]$.[59] Enhanced molecular hyperpolarisabilities β by a factor > 2 were found in all cases. The largest value was found for the dimethylaminostilbazole adduct with $B(C_6F_5)_3$. Its molecular nonlinearity $\mu\cdot\beta(0)$ [724×10^{-48} esu] was found to be similar to that of our bipyridine zinc complexes **16** (Table 1).



The NLO properties of several donor-vinylpyridine metal complexes, containing an organometallic fragment as the donor group, have recently been reported in the literature.

Figure 5. 4-Donor stilbazole complexes

The heterobimetallic ferrocenyl(vinylpyridine)ML$_n$ compounds **20** were simultaneously prepared by Mata et al.[61] and by Lee et al.,[62] and their NLO responses measured by the HRS technique at 1.064 μm (Figure 6). Quite different β values were found for identical complexes by the two groups [for example, ML$_n$ = $W(CO)_5$: $\beta = 101 \times 10^{-30}$ esu[61] and 282×10^{-30} esu[62]]. Surprisingly, large β values were obtained, especially for cationic complexes [ML$_n$ = $Re(CO)_5^+$, $\beta_{1.06}$ (HRS) = 712×10^{-30} esu[62]], in comparison with that for our heterobimetallic ferrocenyl-bipyridine rhenium complexes **15** [$\beta_{1.34}$ (EFISH) = 17×10^{-30} esu]. However, since they absorbed relatively close to the frequency doubled scattered light ($\lambda/2$ = 532 mm), these values were substantially resonance enhanced. Gimeno, Persoons and co-workers[63] described the synthesis and HRS measurements of the novel enynylruthenium(II)–chromium(0) or –tungsten(0) bimetallic complexes **21** (Figure 6). The efficiencies of the half sandwich indenylbis(triphenylphosphane)ruthenium–alkynyl donor moiety was demonstrated by large hyperpolarisabilities, particularly when the pyridine ligand was coordinated to $W(CO)_5$ [λ_{max} = 462 nm; $\beta_{1.06} = 535 \times 10^{-30}$ esu; $\beta(0) = 71 \times 10^{-30}$ esu].

4. Non-Dipolar Complexes

4.1 Octupolar Complexes with Metal-to-Ligand Charge-Transfer Transitions

The quadratic nonlinear susceptibility of octupolar metal complexes was first demonstrated by Zyss et al[64] for the tris(bipyridine)- and tris(phenanthroline)ruthenium(II) cations **22** and **23** (Figure 7). These complexes have attracted intense interest over the past twenty years due to their luminescence properties and capacity for electron- and energy-transfer processes.[65] They possess D_3 symmetry and exhibit intense absorption transitions near 450 nm assigned to $d\pi(Ru) \rightarrow \pi^*$(bpy or phen) MLCT transitions. Large β_{HRS} values of 210×10^{-30} and 170×10^{-30} esu were found at 1.064 mm for **22** and **23**, respectively. However, the first hyperpolarisability of $Ru(bpy)_3^{2+}$ **22** was recently reexamined by Morrison et al,[66] and estimated to be 25×10^{-30} esu. The large β value appeared to be mainly due to a two-photon excited luminescence, and a typical red emission with a luminescence lifetime of 210 ns was observed by exciting with the harmonic frequency at 532 nm.

To achieve enhanced optical nonlinearities by extension of the π-electron system and introduction of strong ac-

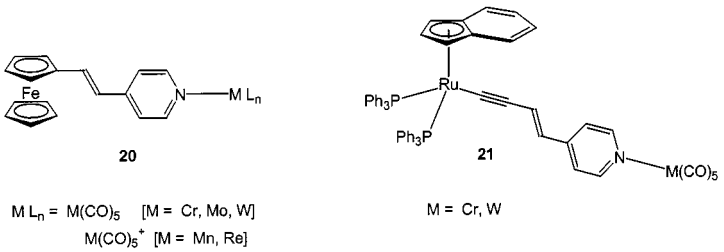

Figure 6. Dipolar heterobimetallic complexes

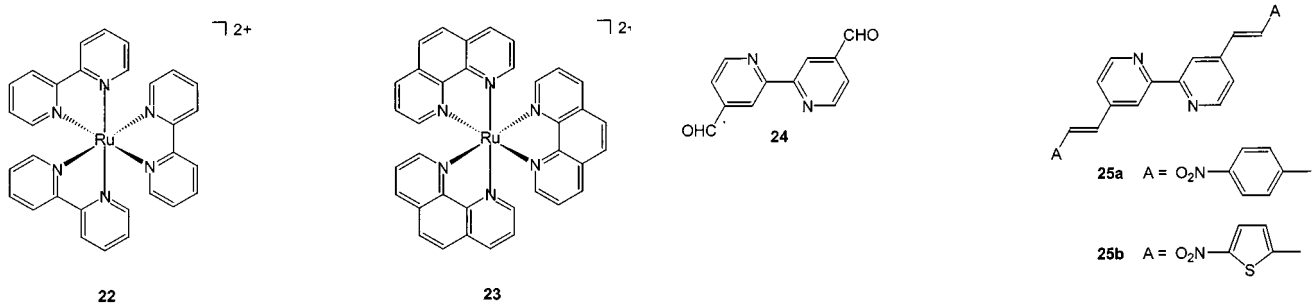

Figure 7. Octupolar diimine complexes with MLCT transitions

ceptor groups, we prepared the 4,4′-dialkenyl-2,2′-bipyridines **25a**,**b** containing nitrophenyl and nitrothienyl substituents.[67] To this end we have developed a convenient method for the preparation of the precursor 4,4′-diformyl-2,2′-bipyridine (**24**), based on the enamination of 4,4′-dimethyl-2,2′-bipyridine. Ligands **25a**,**b** were readily obtained from **24** by a classical Wittig-Horner reaction (Figure 8). The synthesis of tris(bipyridyl)ruthenium(II) (**26b**) was achieved by treating **25b** with ruthenium trichloride (Figure 8).[68] As expected from the presence of strong acceptors, the MLCT transition [λ_{max} (acetone) = 508 nm] was significantly red-shifted with respect to Ru(bpy)$_3^{2+}$. Unfortunately, very poor solubility precluded its β measurement by the HRS technique.

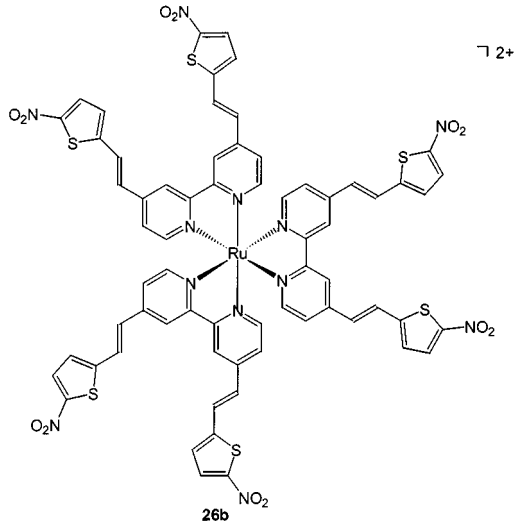

Figure 8. 4,4′-Dialkenyl-2,2′-bipyridines containing acceptor substituents, and corresponding octupolar ruthenium complexes

4.2 Octupolar Complexes with Intraligand Charge-Transfer Transitions

4.2.1. Octahedral Complexes

To design octupolar tris(bipyridyl)ruthenium(II) with a multidirectional intraligand charge-transfer as the main transition responsible for the NLO response, we developed the synthesis of a series of 4,4′-dialkenyl-2,2′-bipyridine ligands **27** bearing π-donor substituents (dialkylaminophenyl and alkoxyphenyl) by the same route employed for the preparation of bipyridines **19** (Figure 9).[54] The corresponding complex [Ru(**27**)$_3$](PF$_6$)$_2$ (**28**) showed characteristically intense charge-transitions ($\varepsilon \approx 120000-150000$) which were sensitive to the nature of the donor group.[68][69] For complexes **28a**,**b** [D = NBu$_2$, N(Me)(Oct)], a very broad ILCT band was observed at ca. 500−510 nm; the MLCT transition, expected at ca. 450−480 nm, was hidden by the more intense ILCT band. For **28c** (D = OOct) two maxima could be easily identified, the main ILCT transition at 380 nm and the less intense MLCT transition at 482 nm. The first HRS measurement of **28a** at 1.34 μm in chloroform gave an exceptionally high β value of 2200×10^{-30} esu.[69] This value was recently found to be overestimated due to some two-photon excited luminescence, and new measurements gave reduced, but still high, hyperpolarisabilities [**28a**: $\beta_{HRS} = 1130 \times 10^{-30}$ esu; **28b**: $\beta_{HRS} = 1000 \times 10^{-30}$ esu[70]]. The alkoxy derivative **28c** gave a smaller β value [$\beta_{HRS} = 490 \times 10^{-30}$ esu] but displayed a better nonlinearity-transparency trade-off. The ordering of the β values was the same as that found from the relative energies of the ILCT bands i.e. **28a** > **28b** >> **28c**.

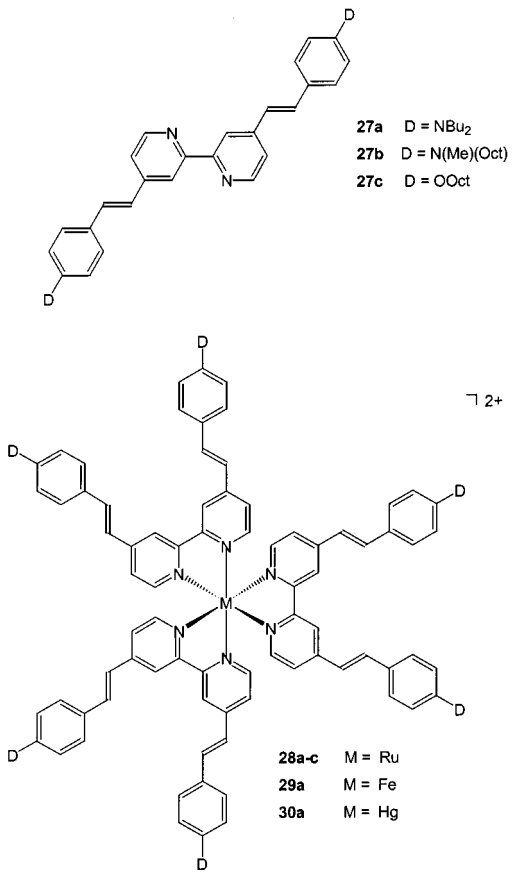

Figure 9. 4,4′-Dialkenyl-2,2′-bipyridines bearing π-donor substituents and corresponding octahedral complexes

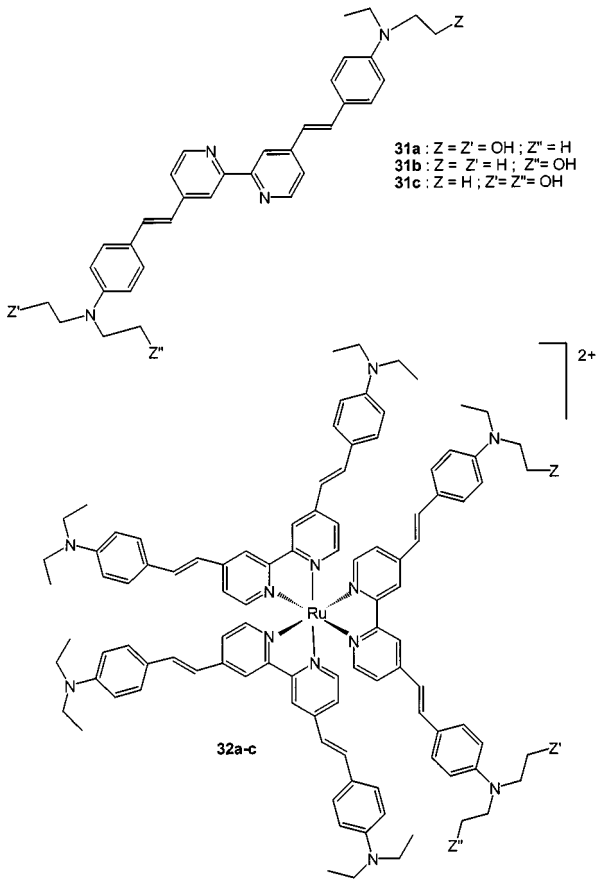

Figure 10. Hydroxy-functionalised bipyridines and corresponding octahedral complexes

The influence of the metal on the linear and nonlinear optical properties was also investigated.[68] For example, the iron derivative **29a** exhibited two absorption bands, the more intense ILCT transition blue-shifted with respect to the ruthenium derivative **28a** [λ_{max} = 467 nm] and the less intense blue-shifted MLCT transition [λ_{max} = 593 nm]. The mercury(II) derivative **30a** showed only the absorption band at λ_{max} = 438 nm, attributable to the ILCT transition, and the antagonist MLCT transition was nonexistent as expected from the high third ionisation potential of mercury. Smaller β values were obtained for such complexes [**29a**: $\beta_{HRS} = 260 \times 10^{-30}$ esu; **30a**: $\beta_{HRS} = 515 \times 10^{-30}$ esu], showing that the nonlinearity-transparency compromise can be fine-tuned by changing the metallic centre.

A current approach for the design of NLO materials is the covalent attachment of NLO-phores to a polymer backbone. As this approach usually requires the introduction of appropriate reactive functionalities at the electron-donating site of the chromophore, we have performed the synthesis of the mono- and dihydroxy-substituted 4,4′-bis(dialkylaminostyryl)-2,2′-bipyridines (**31**) (Figure 10).[71] The synthetic methodology for the preparation of the corresponding ruthenium complexes **32** was based on the sequential coordination of the "parent" 4,4′-bis(*p*-diethylaminostyryl)-2,2′-bipyridine and of the appropriate hydroxy-functionalised bipyridine **31**. Thus, macroscopic organisation of such octupoles in noncentrosymmetric assemblies can be envisaged from the new optical poling method.[72]

4.2.2. Tetrahedral Complexes

In comparison to D_{3h} and D_3 compounds, only a few examples of nondipolar tetrahedral chromophores have been investigated for nonlinear optics.[72−75] Bipyridine- or phenanthrolinecopper(I) complexes with substituents α to the nitrogen atoms are known to give stable tetrahedral molecules of D_{2d} symmetry.[76] Thus, we designed the new 4,4′-diaminostyryl-6,6′-dimethyl-2,2′-bipyridines (**33**); the corresponding copper(I) complexes **34** were simply obtained by treatment of the ligand with $Cu(CH_3CN)_4^+$ (Figure 11).[77] The UV/Vis spectra displayed the characteristic ILCT transition at $\lambda_{max} \approx 420$ nm, which was considerably blue-shifted relative to the corresponding ruthenium(II) complexes **28**. The MLCT transition was typically observed at ca. 480 nm as a shoulder of the more intense ILCT band.

Their molecular hyperpolarisabilities, measured by means of the HRS technique at 1.34 μm, revealed large β values, especially with the most effective electron-donating dialkylamino group [NRR′ = N*n*Bu$_2$ $\beta_{HRS} = 144 \times 10^{-30}$ esu]. Compared to the octahedral tris(bipyridyl)ruthenium(II) complex **28a**, the copper(I) derivatives **32** showed reduced values, as expected from the higher energy of the ILCT ex-

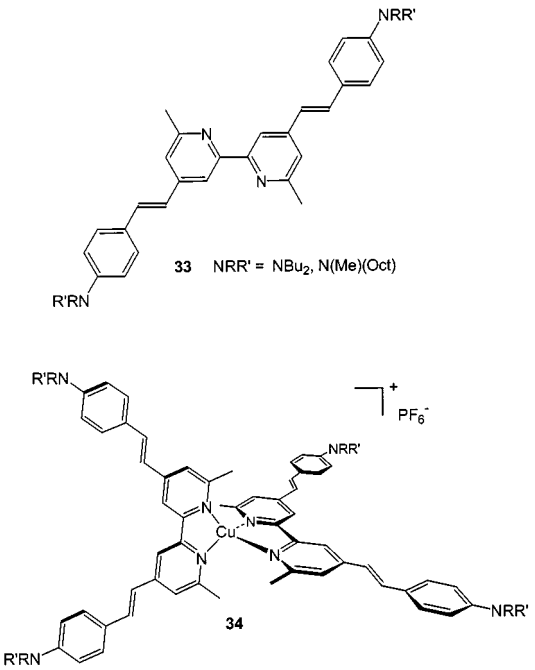

Figure 11. Tetrahedral octupolar copper(I) complexes

cited state. However, these complexes represent a new class of nondipolar NLO organometallic chromophores combining good transparencies and large nonlinearities.

5. Concluding Remarks

Studies on pyridyl- and bipyridylmetal complexes for nonlinear optics have been extensively developed since the first report of Frazier in 1986.[39] In such complexes, the NLO response can be dictated by either a MLCT or ILCT transition and the pyridine ring plays the role of the primary acceptor. Many strategies have emerged that allow access to new NLO chromophores. The most widely studied systems are still dipolar compounds, and versatile synthetic methodologies allow the design and synthesis of efficient second-order nonlinear materials. Octupolar bipyridyl metal complexes remain an emerging field of research. However, as the geometry can be imposed by the nature of the metallic centre and its oxidation state, many other polypyridyl metal derivatives can be potentially used in the construction of NLO compounds with the required 3D octupolar symmetry. Finally, the ability to substitute the pyridine rings with various functional groups offers the possibility of easily incorporating such types of chromophores into polymers. Development of these polymetallic materials will be an interesting challenge in the forthcoming years.

The experimental work reported from our group was performed by Manuel Bourgault, Thierry Renouard, Thomas Le Bouder, Barbara Lognoné, Philippe Dupau and Philippe Massiot. The EFISH and HRS studies were performed by Dr. Zyss′s group (ENS Cachan). We are grateful to all of them.

Reactivity of Silyl-Substituted Heterobimetallic Iron–Platinum Hydride Complexes towards Unsaturated Molecules, I Alkyne Insertions into the Platinum-Hydride Bond, Phosphane-Induced σ-Alkenyl–μ-Vinylidene Rearrangements and Formation of μ-Isonitrile Complexes

Michael Knorr*[a][+] and Carsten Strohmann[b]

Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Heterobimetallics / Hydride complexes / Alkenyl complexes / μ-Isonitrile complexes / Silicon / Iron / Platinum

The heterobimetallic hydride complexes [(OC)$_3$Fe{Si(OMe)$_3$}(μ-Ph$_2$PXPPh$_2$)Pt(H)(PR$_3$)] (**1a**: X = CH$_2$, PR$_3$ = PPh$_3$; **1b**: X = NH, PR$_3$ = PPh$_3$; **1c**: X = CH$_2$, PR$_3$ = PMePh$_2$) have been prepared by the oxidative addition of [(OC)$_3$Fe(H){Si(OMe)$_3$}(η^1-Ph$_2$PXPPh$_2$)] to [Pt(H$_2$C=CH$_2$)(PPh$_3$)$_2$] or by reaction of K[(OC)$_3$Fe{Si(OMe)$_3$}(η^1-dppm)] with *trans*-[Pt(Cl)(H)(PPh$_3$)$_2$]. The solid-state structure of compound **1b** has been determined by single-crystal X-ray diffraction. 1-Alkynes such as methylpropiolate or phenylacetylene insert in a regiospecific manner into the Pt–H bond of **1** to yield the σ-alkenyl complexes [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-Ph$_2$PXPPh$_2$)Pt{C(R)=CH$_2$}] (**2a**: X = CH$_2$, R = CO$_2$Me; **2b**: X = NH, R = CO$_2$Me; **3a**: X = CH$_2$, R = Ph). Addition of the Pt–H bond of **3a** across the triple bond of [D$_1$]phenylacetylene affords [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-dppm)Pt{C(Ph)=C(D)H}] (**3a***) having the deuteron *trans* to platinum (*cis* addition). This insertion reaction is accompanied by dissociation of the platinum-bonded PR$_3$ ligand and saturation of the vacant coordination site by a dative μ-η^2-Si–O→Pt interaction. When **3** is treated with PR$_3$ again, a subsequent phosphane-induced rearrangement leading to vinylidene-bridged complexes [(OC)$_3$Fe{μ-C=C(H)R′}(μ-Ph$_2$PXPPh$_2$)Pt(PR$_3$)] (**4a**: X = CH$_2$, R′ = Ph, PR$_3$ = PPh$_3$; **4b**: X = NH, R′ = Ph, PR$_3$ = PPh$_3$; **4c**: X = CH$_2$, R′ = Ph, PR$_3$ = PMePh$_2$; **4d**: X = CH$_2$, R′ = *p*-tolyl, PR$_3$ = PPh$_3$) occurs. Upon purging a solution of **3a** with carbon monoxide, the labile CO adduct [(OC)$_3$Fe{Si(OMe)$_3$}(μ-dppm)-Pt(CO){C(Ph)=CH$_2$}] **5a** is formed, addition of 2,6-xylyl isocyanide to **2a** and **3a** affords the isonitrile adducts [(OC)$_3$Fe{Si(OMe)$_3$}(μ-dppm)Pt(CNxylyl){C(R)=CH$_2$}] (**5b**: R = CO$_2$Me; **5c**: R = Ph), respectively. When hydride complex **1a** is allowed to react with stoichiometric amounts of aromatic isonitriles, formal elimination of HSi(OMe)$_3$ occurs, yielding the heterodinuclear isonitrile-bridged complexes [(OC)$_3$Fe(μ-C=N-R)(μ-dppm)Pt(PPh$_3$)] (**6a**: R = 2,6-xylyl; **6b**: R = *o*-anisyl; **6c**: R = *p*-anisyl; **6d**: R = *p*-C$_6$H$_4$NH$_2$) and the bis(isonitrile) complexes [(OC)$_2$(RN≡C)Fe(μ-C=N–R)(μ-dppm)Pt(PPh$_3$)] (**7a**: R = 2,6-xylyl; **7b**: R = *p*-anisyl). Single-crystal X-ray diffraction studies perfomed on **6a** and **6b** reveal that the molecular structures of these μ-isonitrile complexes closely resemble the μ-vinylidene complexes **4**. The two metal centers are bridged in a symmetric manner by strongly bent CNR ligands, the aromatic groups R being oriented towards the Fe(CO)$_3$ moiety. Electrophilic addition of HBF$_4$ to the basic nitrogen atom of the μ-CNR ligand transforms **6** to the cationic μ-aminocarbyne complexes [(OC)$_3$Fe{μ-CN(H)R}(μ-dppm)Pt(PPh$_3$)][BF$_4$] (**8a**: R = 2,6-xylyl; **8b**: R = *p*-anisyl; **8c**: R = *p*-C$_6$H$_4$NH$_2$).

Introduction

The insertion of small molecules such as CO, CO$_2$, CNR, olefins, and alkynes into the metal−hydride bond of mononuclear transition metal complexes represents a fundamental reaction in organometallic chemistry, which is also of great relevance for homogenous catalysis.[1] The olefin insertion leading to transition metal alkyl complexes (as well as the reverse reaction, the β-elimination), has especially been the subject of numerous experimental and theoretical studies.[2] The insertion of alkynes into the metal−hydride bond, affording vinyl or alkenyl complexes, is very much related to the olefin insertion. In general, it is assumed that alkene and alkyne insertions proceed in most cases via a cyclic four-membered transition state. The insertion of acetylenes and isonitriles R−N≡C (which also possess a reactive triple bond) across the Pt−H bond of mononuclear platinum complexes has been examined in detail by Clark and co-workers.[3][4]

In the course of our investigations into the insertion and activation of small molecules by heterobimetallic complexes, we were interested in studying the insertion of such molecules into the Pt−H bond of heterodinuclear systems of the type L$_n$M−Pt(H)L$_2$, containing two *different* metal centers linked by a metal−metal bond. The influence of

the second adjacent metal center close to a square planar platinum(II) moiety on the regio- and site selectivity of this important reaction was of special interest. Here we report on the reactivity of 1-alkynes and aromatic isonitriles towards heterobimetallic iron−platinum hydride complexes and their transformation into σ-alkenyl, μ-vinylidene, and μ-isonitrile complexes, respectively.

Results and Discussion

For our studies on the reactivity of heterometallic hydride complexes towards unsaturated molecules, the alkoxysilyl-substituted dinuclear complex $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(H)(PPh_3)]$ **1a** appeared to be a promising system. Compound **1a** has been previously prepared by oxidative addition of the hydrido-silyl complex $[(OC)_3Fe(H)\{Si(OMe)_3\}(\eta^1\text{-dppm})]$ to the Pt^0 complex $[Pt(H_2C{=}CH_2)(PPh_3)_2]$.[5] Alternatively, this starting material can also be synthesized by the reaction of the metallate $K[(CO)_3Fe\{Si(OMe)_3\}(\eta^1\text{-dppm})]$[6a] with *trans*-$[Pt(Cl)(H)(PPh_3)_2]$ in 86% isolated yield (Scheme 1). In order to fine-tune the steric and electronic environment around the square-planar platinum center, we also prepared the bis(diphenylphosphanylamine)-bridged derivatives $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppa})Pt(H)(PPh_3)]$ **1b** and $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(H)(PMePh_2)]$ **1c** as precursors for reactivity studies (Scheme 1). All derivatives of **1** can be handled in the solid state in air without significant decomposition. They show only moderate solubility in aromatic solvents, but are fairly soluble in $CHCl_3$ and CH_2Cl_2.

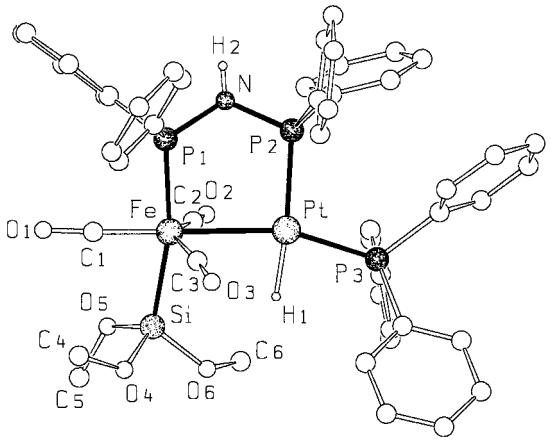
Scheme 1

Comparative IR studies indicate that the dppa-backbone of **1b** slightly reduces the electron density of the bimetallic system, whereas due to the better σ-donor capacity of PPh_2Me relative to PPh_3, a slight shift of the ν(CO) frequencies to lower wavenumbers is noticeable for **1c**. A weak absorption band observed at 2119 cm^{-1} is assigned to the ν(PtH) stretch. The pattern of the hydride resonances in the ^{1}H-NMR spectra are virtually identical for all derivatives of **1** and consistent with a terminal platinum-bonded hydride ligand. For example, in the spectrum of **1b**, a doublet of triplets is observed at δ = −4.09 due to a strong P_{trans}-H coupling of ^2J = 209 Hz and an accidentally identical P_{cis}-H and P-H coupling of ^2J and ^{3+4}J = 16 Hz. In addition, the hydride signal is flanked by platinum satellites with a Pt-H coupling of ^1J = 662 Hz. For all new dppa-spanned compounds presented in this paper, a pronounced downfield shift is observed for the dppa phosphorus nuclei in the $^{31}P\{^1H\}$-NMR spectra compared to those of the dppm-spanned analogues. Thus, the AMX-type spectrum of **1b** consists of three mutually coupled phosphorus resonances. The doublet of doublets due to the dppa-phosphorus on iron at δ = 119.7 is strongly coupled [$^{2+3}J(P^1\text{-}P^2)$ = 138 Hz] to the dppa-phosphorus on platinum, whose resonance is found at δ = 81.7. Further splitting results from the platinum-bonded PPh_3 ligand at δ = 29.9 with couplings of 12 and 63 Hz, respectively. All resonances are flanked by ^{195}Pt satellites, the Pt-P couplings of which (J = 87, 2884, and 3503 Hz) are also evident in the ^{195}Pt-NMR spectrum giving rise to a doublet of doublets of doublets centered at δ = −2999.

Crystal Structure of $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppa})Pt(H)(PPh_3)]$

The molecular structure of the dinuclear hydride complex **1b** including the atom numbering scheme is shown in Figure 1. Suitable crystals were obtained by slow diffusion of hexane into a saturated dichloromethane solution of **1b**. The iron and platinum centers are linked by a dppa bridge and a metal−metal bond. The Fe−Pt separation of 2.670(2) Å is almost identical to that observed in the trifluorosilyl-substituted complex $[(OC)_3Fe(SiF_3)(\mu\text{-dppm})Pt(H)(PPh_3)]$ [2.661(1) Å].[7] The coordination geometry around the Fe atom may be viewed as a distorted octahedral, consistent with a formal $Fe(d^7)$−$Pt(d^9)$ situation. The silyl ligand, which is situated *trans* to P(1) [Si−Fe−P(1) 167.71(4)°] has a Fe−Si bond length of 2.298(2) Å, which is in the typical range found for other heterometallic systems having a terminal $Si(OMe)_3$ unit. For example, a Fe−Si bond length of 2.271(4) Å has been found in $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Cu(PPh_3)]$.[6] Three meridianal arranged carbonyl ligands complete the environment of the iron center. The square-planar coordination geometry around the platinum center involves the Fe atom, two phosphorus atoms (one from the dppa-bridge [Pt−P(2) 2.304(2) Å], the second one from the PPh_3 ligand [Pt−P(3) 2.228(2) Å] and a hydride ligand [Pt−H(1) 1.544(4) Å]. The root mean square deviation from the plane passing through Fe, P(2), P(3), and H(1) amounts to 0.102 Å. Due to the good data set collected for **1b**, some electron density could successfully be refined as a *terminal* hydride position. This is consistent with the other spectroscopic results obtained (see above). The hydride ligand is quite close to one of the oxygen atoms of the $Si(OMe)_3$ group [d(O(6)···H(1)) 2.45(4) Å]. Similiar

close contacts were already observed for $[(OC)_3Fe(SiF_3\}(\mu\text{-}dppm)Pt(H)(PPh_3)]$,[7] where a weak intramolecular interaction between the hydride ligand and two F atoms of the SiF_3 ligand (bifurcated hydrogen bond with H···F 2.39(7) and 2.50(6) Å] was even retained in solution. As noticed for the latter hydride complex, the Pt−P(2) bond length of **1b** [2.304(2) Å] is significantly longer than that of Pt−P(3) [2.228(2) Å], which might reflect the high *trans* influence of the hydride ligand.



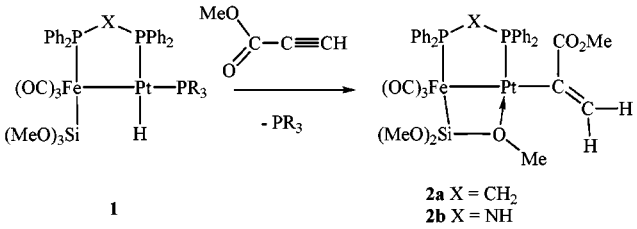


Figure 1. View of the crystal structure of **1b** showing the atom numbering scheme; selected bond lengths [Å] and angles [°]: Fe−Pt 2.670(2), Fe−Si 2.298(2), Fe−P(1) 2.203(2), Pt−P(2) 2.304(2), Pt−P(3) 2.228(2), Fe−C(1) 1.746(1), Fe−C(2) 1.756(4), Fe−C(3) 1.757(4), C(1)−O(1) 1.44(4), C(2)−O(2) 1.47(4), C(3)−O(3) 1.153(4), P(1)−N 1.684(3), P(2)−N 1.681(3), N−H(2) 0.81(4); Si−Fe−P(1) 167.71(4), H(1)−Pt−Fe 80.5(13), H(1)−Pt−P(3) 79.8(13), Fe−Pt−Si 100.61(6), C(1)−Fe−Si 80.11(13), C(2)−Fe−Si 85.85(12), C(3)−Fe−Si 86.01(13), O(1)−C(1)−Fe 177.6(3), O(2)−C(2)−Fe 177.3(3), O(3)−C(3)−Fe 175.2(4), C(1)−Fe−P(1) 87.67(13), C(2)−Fe−P(1) 96.68(12), C(3)−Fe−P(1) 99.79(13), C(1)−Fe−Pt 179.28(12), C(2)−Fe−Pt 72.47(13), C(3)−Fe−Pt 68.85(13), P(1)−Fe−Pt 91.61(6), P(2)−Pt−P(3) 105.60(6), Fe−Pt−P(2) 93.86(6), Fe−Pt−P(3) 157.68(3), P(1)−N−P(2) 119.8(2)

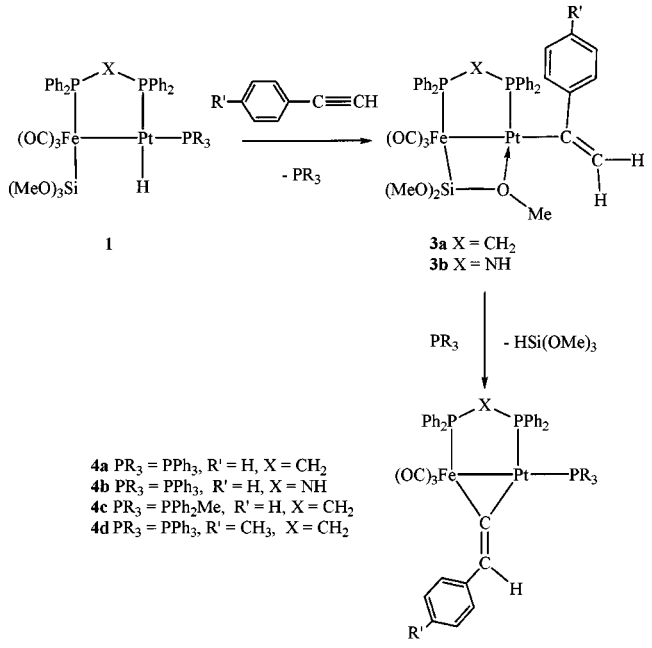
Reactivity towards 1-Alkynes

Upon addition of a threefold excess of methyl propiolate to a CH_2Cl_2 solution of **1a**, quantitative insertion into the platinum−hydride bond occurred within 4 h at ambient temperature leading to the heterobimetallic σ-alkenyl complex $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-}dppm)Pt\{C(CO_2Me)=CH_2\}]$ **2a** (Scheme 2). Elemental analyses and spectroscopic data showed that the alkyne insertion is accompanied by dissociation of the platinum-bonded PR_3 ligand. The vacant coordination site on the platinum center is electronically saturated by a dative interaction of a methoxy group of the trimethoxysilyl ligand, forming a four-membered Fe−Si−O→Pt cycle. This feature has been studied in detail, both in solution and in the solid state.[5,8,9] The σ-alkenyl complex **2a** is also formed using the Ph_2MeP-substituted derivative **1c** as starting material. In an analogous manner, the dppa-bridged insertion product $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-}dppa)Pt\{C(CO_2Me)=CH_2\}]$ **2b** is formed after addition of methyl propiolate to **1b**. Elemental analyses and spectroscopic data indicated that a triphenylphosphane oxide ligand, which stems from partial oxidation of the liberated PPh_3, is probably bonded by a hydrogen bond to the N−H group of the dppa ligand of **2b**. In all the cases, insertion occurs in a regioselective manner, affording the isomer with the ester group attached on the α-carbon. The new yellow compounds, which were moderately soluble in diethyl ether, were stable in solution for longer periods and thus permitted extensive multinuclear NMR measurements to be made (see Experimental Section).

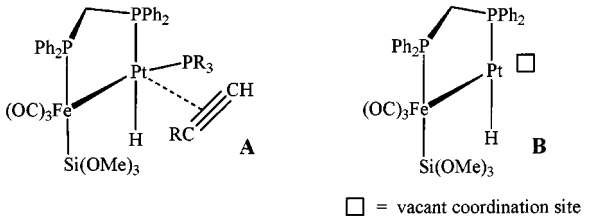


Scheme 2

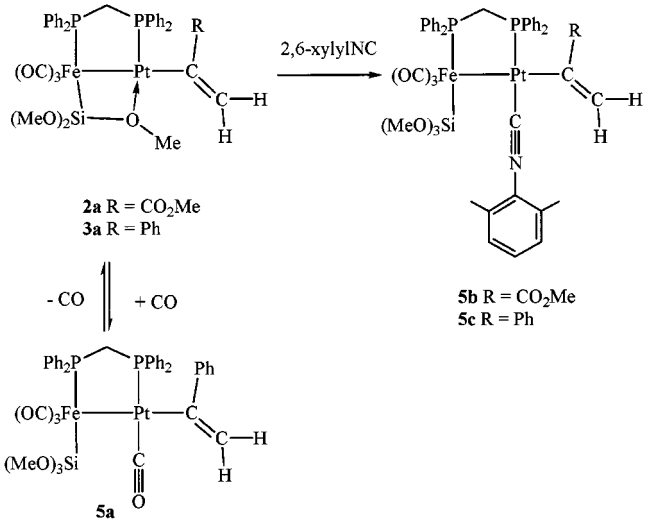
A more complicated reaction occurred, when **1a** was treated with the less reactive phenylacetylene. ^{31}P-NMR monitoring of the course of the reaction revealed that 40 min after addition of 10 equivalents of phenylacetylene to **1a**, a ca. 60:40 mixture of unchanged **1a** and insertion product $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-}dppm)Pt\{C(Ph)=CH_2\}]$ **3a** was formed. The latter gave rise to an AX-type spectrum consisting of a doublet at $\delta = 61.2$ due to the phosphorus on iron, which is coupled to the platinum-bonded phosphorus at $\delta = 6.9$ with $^{2+3}J(P^1\text{-}P^2) = 41$ Hz. The latter resonance shows a very large ^1J coupling of 5010 Hz to the ^{195}Pt nucleus, whereas the former displays a small ^{2+3}J(Pt-P) coupling of 61 Hz. In addition, a broad signal centered at $\delta = -4.2$ due to the liberated PPh_3 is observed. After several hours, the intensity of the signals due to **3a** grows, whereas that of the hydride complex **1a** diminishes. In addition, a third set of signals emerges consisting of three mutually coupled resonances centered at $\delta = 63.0$, 43.6, and 22.2, whose chemical shifts and couplings are identical to those of the vinylidene-bridged complex $[(OC)_3Fe\{\mu\text{-}C=C(H)Ph\}(\mu\text{-}dppm)Pt(PPh_3)]$ **4a**. Compound **4a** has been prepared recently by the reaction of the vinylidene-bridged complex $[(OC)_3Fe\{\mu\text{-}C=C(H)Ph\}(\mu\text{-}dppm)Pt(CO)]$ with triphenylphosphane and was structurally characterized by an X-ray diffraction study.[10] Within 24 h, compound **1a** had been completely consumed and only the ^{31}P resonances of **3a** and **4a** were detected in a ca. 10:90 ratio. The quantitative transformation of the intermediate **3a** to **4a** may have been prevented by partial oxidation of the liberated PPh_3, since a singlet at $\delta = 29.5$ due to minor amounts of $O=PPh_3$ was also detected in the ^{31}P-NMR spectrum.

In a similar manner, phenylacetylene inserted into the Pt−H bond of **1b** to yield first the dppa-bridged σ-alkenyl complex $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-}dppa)Pt\{C(Ph)=CH_2\}]$ **3b** as an intermediate, which was characterized only

in solution [^{31}P δ = 111.2 P(Fe), 45.5 P(Pt), ^{2+3}J(P^1-P^2) = 45 Hz; ^{195}Pt δ = −2345, dd, ^1J(Pt-P) = 5524 Hz, ^{2+3}J(Pt-P) = 55 Hz]. The latter was finally transformed in situ to the new stable μ-vinylidene complex [(OC)$_3$Fe{μ-C=C(H)Ph}(μ-dppa)Pt(PPh$_3$)] **4b** after reaction with PPh$_3$. The derivatives [(OC)$_3$Fe{μ-C=C(H)Ph}(μ-dppm)Pt(PMePh$_2$)] **4c** and [(OC)$_3$Fe{μ-C=C(H)*p*-tolyl}(μ-dppm)Pt(PPh$_3$)] **4d** were prepared according to Scheme 3 by reaction of **1c** and **1a** with phenylacetylene and *p*-tolylacetylene, respectively.



Scheme 3

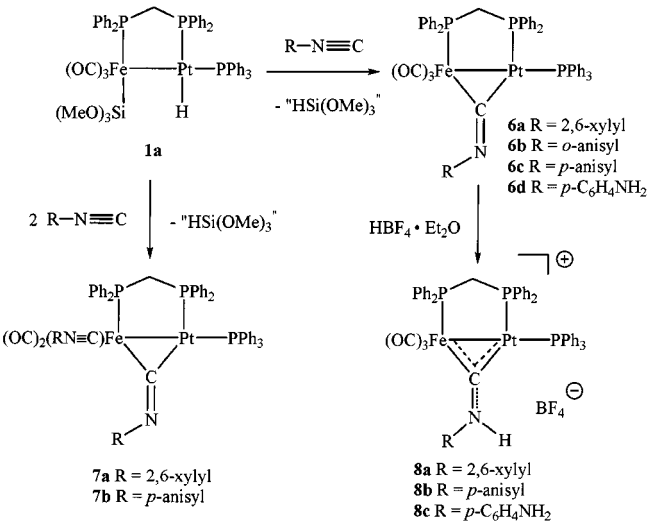


In order to assign the stereochemistry of the alkenyl group of **3a** unambiguously, we isolated this complex by stopping the reaction before all of **3a** had been converted into **4a**. Due to its solubility in an ether/hexane mixture, the alkenyl complex could be separated from unchanged **1a** and the final product **4a** by extraction. The geminal position of the alkenyl hydrogen atoms can be deduced from the ^{1}H-NMR spectrum, which shows no resolved coupling between these two protons. The broadened singlet at δ = 5.96 is assigned to the (*E*)-proton in a *trans* position to the platinum center, since it displays a strong Pt-H coupling of ^3J = 108 Hz, whereas the (*Z*)-proton signal at δ = 5.09 shows a coupling constant of *J* = 58 Hz only. Similar magnitudes and coupling patterns have been reported for mononuclear complexes of the type [L$_n$Pt(C(R)=CH$_2$}].[11] For regioisomer [L$_n$Pt{(*E*)-C(H)=CH(Ph)}], a *trans* coupling ^3J(H-H) of ca. 17 Hz should be expected, while regioisomer [L$_n$Pt{(*Z*)-C(H)=CH(Ph)}] should exhibit a *cis* coupling ^3J(H-H) of ca. 10 Hz.[11] Consistent with a rigid Fe−Si−O→Pt unit, two distinct signals in a 2:1 ratio at δ = 3.76 and 3.65 due to different methoxy groups are also observed. Employing [D$_1$]phenylacetylene (98%) as substrate, only the resonance of the (*Z*)-vinyl proton is observed in the ^{1}H-NMR spectrum of the deuterated complex **3a***. The resonance of the (*E*)-vinyl deuteron is found in the ^{2}H-NMR spectrum at δ = 6.07. This isotopic labeling experiment proves that insertion of [D$_1$]phenylacetylene occurred in a *cis* manner. The ^{13}C{^{1}H} NMR recorded at 268 K (see Experimental Section) further corroborates our structural proposal for **3a** possessing the same stereochemistry at the alkenyl group as [(OC)$_3$Fe{μ-Si(OMe)$_2$-(OMe)}(μ-Ph$_2$PXPPh$_2$)Pt{C(CO$_2$Me)=CH$_2$}] **2**.

The subsequent σ-alkenyl−μ-vinylidene rearrangement in the presence of PR$_3$, observed for the alkenyl complexes [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-Ph$_2$PXPPh$_2$)Pt{C(R)=CH$_2$}], seemed to depend in a sensitive manner on the electronic behaviour of the organic group R at the α-carbon atom of the alkenyl ligand. When [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-dppm)Pt{C(CO$_2$Me)=CH$_2$}], possessing a strong electron-withdrawing CO$_2$Me group, was treated with two equivalents of PPh$_3$ or PMePh$_2$, no σ-alkenyl−μ-vinylidene rearrangement was observed even after several hours. However, this transformation could be induced by addition of PPh$_3$ to **3**a. In an NMR experiment, performed in CDCl$_3$ solution, **3a** was gradually converted into the μ-vinylidene complex **4a** within 5 h after addition of three equivalents of PPh$_3$. A somewhat related phosphane-induced transformation has recently been studied on heterodinuclear acyl complexes of the type [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-dppm)Pt{C(=O)R}] (R = Me, Et). The latter acyl complexes were converted into μ-silyloxycarbene complexes [(OC)$_3$Fe{μ-C(R)OSi(OMe)$_3$}(μ-dppm)-Pt(PR′$_3$)] after addition of phosphanes or phosphites; the rate of the rearrangement depended on the basicity of PR′$_3$.[12] In the case of **3a**, the phosphane-promoted rearrangement occurs with concomitant reductive elimination of HSi(OMe)$_3$, as proved by NMR monitoring. Trimethoxysilane elimination has previously been observed upon treatment of the hydrido complex [(OC)$_3$Fe{μ-Si(OMe)$_2$(OMe)}(μ-dppm)Rh(H)(Cl)] with carbon monoxide and during the reaction of [(OC)$_3$Fe(H){Si(OMe)$_3$}(η^1-dppm)] with *fac*-[Re(CO)$_3$((THF)(μ-Br)]$_2$ affording the bromide-bridged complex [(OC)$_3$Fe(μ-Br)(μ-dppm)Re-(CO)$_3$].[13] Mechanistically, this alkenyl−vinylidene rearrangement probably involves intramolecular migration of a hydrogen atom from the β-carbon to the α-carbon of the alkenyl ligand, which forms the β-carbon of the vinylidene bridge after rearrangement. Related hydridovinylidene−alkenyl rearrangement involving α-hydrogen shifts have been investigated experimentally and theoretically in mononuclear tantalum and ruthenium complexes.[14] It should be noted that in the latter example, phenylacetylene has been inserted into the Ru−H bond of [RuHX(H$_2$)(PR$_3$)$_2$], leading to an alkenyl intermediate [L$_n$Ru−C(H)=C(H)Ph)] bearing the phenyl group on the β-carbon atom.[14b] An open question remains as to whether alkyne coordination on platinum prior to insertion into the Pt−H bond is associative or dissociative (Scheme 4). Both the initial formation of a penta-coordinated intermediate **A** or the initial dissociation of a ligand like PPh$_3$ (creating a vacant coordination site as in **B**) are well established pathways for migratory insertion reactions occurring in platinum com-

plexes.[15] We performed the reaction of **1a** with phenylacetylene in the presence of three equivalents of PPh_3 to investigate the role of the phosphane concentration on the acetylene insertion rate. Unfortunately, progressive fragmentation of the Fe−Pt bond occurred, leading to several mononuclear species, among them *trans*-$[Fe(CO)_3(PPh_3)_2]$.

Scheme 4



Scheme 5

We have recently shown that CO instantaneously reacts with dinuclear alkyl complexes of the type $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-dppm})PtR]$ (R = Me, Et, norbornyl) to give, by opening of the $\mu\text{-}\eta^2\text{-Si}-O$ bridge, the CO adducts $[(CO)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(CO)R]$. These intermediates rearrange due to a CO migratory insertion reaction into the Pt−C bond to the stable acyl complexes $[(OC)_3Fe\{\mu\text{-}Si(OMe)_2(OMe)\}(\mu\text{-dppm})Pt\{C(=O)R\}]$.[8] However, no spectroscopic change was noticed upon purging a solution of **2a** with a gentle stream of CO for 2 h. In contrast, **3b** afforded the CO adduct $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(CO)\{C(Ph)=CH_2\}]$ **5a**, as evidenced by the appearance of a new ν(CO) vibration due to the Pt-bonded carbonyl ligand at 2088 cm^{-1} in the IR spectrum, and the emergence of a new AX pattern in the ^{31}P-NMR spectrum centered at δ = 60.8 and 15.0 with a P-P coupling constant of ^{2+3}J = 78 Hz and a P-Pt coupling constant of ^{1}J = 3414 Hz. Since **5a** readily lost the carbonyl ligand under reduced pressure regenerating **3a**, this complex could not be isolated. In the presence of stoichiometric amounts of 2,6-xylyl isocyanide, the dative Pt−OMe bond was instantaneously broken and the isonitrile adducts $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(CNxyly)\{C(R)=CH_2\}]$ (**5b**: R = CO_2Me; **5c**: R = Ph) were isolated as stable yellow solids. In addition to the three ν(CO) stretches of the $Fe(CO)_3$ unit, the IR spectra of **5b/5c** displayed a strong vibration at 2181/2176 cm^{-1}, consistent with a terminal bonding mode of the isonitrile ligand at the platinum center.

Reactivity of 1 towards Isonitriles

The insertion of isonitriles into the Pt−H bond of platinum hydrido complexes leading to formimidoyl complexes $[L_nPt\{C(H)=NR\}]$ is a well established reaction.[3a,16] With the anticipation of inserting isonitriles C≡N−R into the Pt−H bond of **1**, we reacted **1a** with a stoichiometric amount of aromatic isonitriles in CH_2Cl_2 to yield heterodinuclear formimidoyl complexes.[17a] Surprisingly, no formyimidoyl complexes were isolated. Instead, the isonitrile-bridged bimetallic complexes $[(CO)_3Fe(\mu\text{-}C=NR)(\mu\text{-dppm})Pt(PPh_3)]$ (**6a**: R = 2,6-xylyl, **6b**: R = *o*-anisyl, **6c**: R = *p*-anisyl, **6d**: R = *p*-aminophenyl) were obtained as stable orange-yellow solids (Scheme 6). The NMR spectra of **6** resemble those of the structurally related dppm-bridged μ-vinylidene complexes **4a** and **4c**. Indicative of a bridging bent isonitrile ligand are the IR spectra of **6**, which displayed a broadened ν(C=N) vibration of medium intensity in the range between 1667−1669 cm^{-1}.

Scheme 6

Crystal Structures of $[(OC)_3Fe(\mu\text{-}C=N-R)(\mu\text{-dppm})Pt(PPh_3)]$

In heterobimetallic μ-isonitrile complexes $M(\mu\text{-}C=N-R)M'$ possessing a bent C=N−R arrangement, two isomeric forms are a priori conceivable, which differ in the relative orientation of R towards M or M′. In order to elucidate unambiguously the orientation of R and the degree of inclination, the molecular structure of

6a · 1.5 CH_2Cl_2 shown in Figure 2 has been determined by a single-crystal X-ray diffraction study. Suitable crystals were obtained by layering a saturated dichloromethane solution with Et_2O. The iron and platinum centers are linked by a dppm bridge and a metal−metal bond, whose Fe−Pt separation of 2.552(4) Å is almost identical to that of the vinylidene complex [$(OC)_3$Fe{μ-C=C(H)Ph}(μ-dppm)Pt(PPh_3)] [2.5503(8) Å].[10] Also, the other structural features are very reminiscent of the molecular structure of the latter compound. The bridging isonitrile ligand is symmetrically situated between the metals, with Fe−C(1) and Pt−C(1) distances of 1.988(8) and 1.994(8) Å, respectively. The length of the C(1)−N double bond of 1.20(1) Å is comparable to that of the W−Pt complex [$(OC)_4$W(μ-C=NCH_2SO_2−*p*-tolyl)(μ-dppa)Pt(PPh_3)] [1.229(12) Å][17b,17d] and to those reported for some homobimetallic isonitrile-bridged systems.[19] The C(1)−N−C(2) angle is extremely bent [122.1(8)°], the xylyl group being oriented towards the Fe$(CO)_3$ moiety. A comparable inclination with an average C−N−C angle of 123.1°, was found for the μ-C=N−Et ligands of [$(EtNC)_3$Fe−μ-CNEt)$_3$Fe(C-NEt)$_3$],[18d] whereas for most structurally characterized bent μ-CNR systems, C−N−C angles in the range between 130−133° have been documented.[18] For example, a C−N−C angle of 131.7(3)° has been determined for the bridging xylyl isocyanide ligands of the dinuclear compound *trans*-[η^5-CpFe(CN−2,6-xylyl)(μ-CN−2,6-xylyl)]$_2$.[18g] An unusual, widened C−N−C angle of 149.4(23) Å has been observed recently in a Pd(μ-CN*t*Bu)(μ-SiR_2)Pd complex.[18l,18m] We believe that this strong bending observed in **6a** may be caused by electronic factors, since the π-acceptor capacity of bridging isonitrile ligands is correlated to the degree of inclination.[19] Because the isonitrile complexes **6** represent electron-rich systems due to the presence of two metal centers in low oxidation states with three phosphorus donors as ligands, a strongly bent isonitrile bridge behaving as a good π-acceptor can at least partially compensate for the high electron density by back-bonding into π*-orbitals. Note that a bridging vinylidene unit, as encountered in **4**, also behaves as an efficient π-acceptor ligand.[20][21] As already discussed for the molecular structures of the μ-vinylidene complex **4a**[10] and the cationic μ-aminocarbyne complex [$(OC)_3$Fe(μ-CN(H)*o*-anisyl)(μ-dppa)Pt(PPh_3)],[17c,17d] the orientation towards the carbonyl fragment is imposed by the *steric bulk* of the triphenylphosphane ligand on platinum, which would otherwise interfere unfavorably with the 2,6-xylyl group.

As can be seen from Figure 3, which shows the core structure of **6b** along the Fe−Pt axis, the structural features of the *o*-anisyl isocyanide bridged derivative **6b** are similar to those of **6a**. As found in **6a**, the aromatic group of the isonitrile bridge is bent and aligned parallel to the Pt−Fe axis [C(2)−N−C(1)−Fe 4.14°]. Compared to **6a**, the C(1)−N−C(2) angle is somewhat widened and amounts to 127.2(9)°. At present we cannot state, whether this widening is due to a substituent effect on the phenyl group or caused by packing effects. The two mean planes defined by Fe−P(1)−P(2)−Pt and Fe−C(1)−Pt are nearly coplanar,

the angle between them being 6.20°. The rms deviation from the mean plane passing through Pt, C(1), P(2), P(3), and Fe is quite small and has been determined to be 0.025 Å (0.051 Å for **6a**). As in **6a**, a distorted square planar description seems to be appropriate for the coordination geometry around the platinum center.

In order to obtain compounds **6a–c** in satisfactory yields (ca 65–75%), slow stoichiometric addition of the corresponding isonitrile is important. When **1a** was directly mixed with a stoichiometric quantity of CNR, the isolation of pure **6** was hampered by competing formation of the bis(isonitrile) complexes $[(OC)_2(RN{\equiv}C)Fe(\mu\text{-}C{=}N{-}R)(\mu\text{-}dppm)Pt(PPh_3)]$ (**7a**: R = 2,6-xylyl; **7b**: R = *p*-anisyl) and separation from unchanged starting material **1a**. Compounds **7**, possessing both a bridging and a terminal iron-bonded CNR ligand, were formed as the sole species, when **1a** was allowed to react with 2 equivalents of the corresponding isonitrile for 8 h at ambient temperature. The coordination of the terminal CNR ligand in an orthogonal position relative to the metal–metal bond can be deduced from the IR spectra, which showed two ν(CO) stretches of approximate equal intensities. This pattern is only consistent with a *cis* arrangement of the two carbonyl ligands of the $Fe(CO)_2$ unit.[22] In addition, two ν(CN) vibrations due to the terminal and bridging isonitrile ligands were found in the IR spectra of **7a** and **7b** at 2089/2092 and 1655/1653 cm^{-1}, respectively. Compared to complexes **6**, the position of the latter absorption is shifted by ca. 16 wavenumbers to lower frequencies. This is probably due to the additional electron-donating effect of the second terminal CNR ligand, which is partially compensated by back-bonding in π* orbitals of the μ-CNR ligand, thus weakening the C=N bond.

At first glance, the formation of **6** and **7** seems to involve a simple reductive elimination of $HSi(OMe)_3$ as encountered in the σ-alkenyl–μ-vinylidene conversion of **2** into **4**. However, no evidence for the formation of trimethoxy silane was obtained. IR and ^{31}P-NMR monitoring revealed that one hour after the addition of two equivalents of CNR, breaking of the metal–metal bond occurred. A doublet of doublets found in the ^{31}P-NMR spectrum and an intense ν(CO) stretch at 1828 cm^{-1} indicated the formation of the metallate $[(OC)_3Fe\{Si(OMe)_3\}(\eta^1\text{-}dppm)]^-$.[6] The nature of the cationic fragment remains speculative. The observation of a very broad resonance in the ^{31}P-NMR spectrum at δ = 13.1 and a terminal ν(CN) stretch at 2185 cm^{-1} could be consistent with the existence of cationic species of the type $[Pt(H)(CNR)_2(PPh_3)]^+$, similar to the known complexes *trans*-$[Pt(H)(CN\textit{p}\text{-}tol)(PEt_3)_2]^+$, $[Pt(H)(CN\textit{p}\text{-}anisyl)(PEt_3)_2]^+$, and $[Pt(H)(PPh_3)_3]^+$.[3a,23] This assumption is further corroborated by the observation of a new broad and unresolved hydride resonance in the ^1H-NMR spectrum at δ = −6.27 exhibiting a Pt-H coupling constant of ^1J = 804 Hz. The mechanism of this reaction affording the μ-isonitrile complexes **6** and **7** has not been investigated further, since in the meantime more rational syntheses for complexes $[(OC)_3Fe(\mu\text{-}C{=}N{-}R)(\mu\text{-}Ph_2PXPPh_2)Pt(PPh_3)]$ have been developed by us.[17b–17d]

N-Protonation of $[(OC)_3Fe(\mu\text{-}CNR)(\mu\text{-}dppm)Pt(PPh_3)]$

As already described for $[(OC)_3Fe(\mu\text{-}CNR)(\mu\text{-}dppa)Pt(PPh_3)]$,[17c,17d] electrophilic addition of H^+ to the basic nitrogen atom of the μ-(CNR) ligand of **6** led instantaneously in a quantitative manner to stable cationic μ-aminocarbyne complexes $[(OC)_3Fe(\mu\text{-}CN(H)R)(\mu\text{-}dppm)Pt(PPh_3)][BF_4]$ (**8a**: R = 2,6-xylyl; **8b**: R = *p*-anisyl; **8c**: R = *p*-$C_6H_4NH_2$) (Scheme 5). According to the FAB^+ mass spectrum of the *p*-$C_6H_4NH_2$-substituted derivative **8c**, which displayed an intense peak at *m*/*z* 1100 (55%) for the cation, only monoprotonation occurred, despite the use of excess $HBF_4 \cdot Et_2O$. Characteristic NMR features of these *N*-protonated species are given for **8a** as an example. In the $^{13}C\{^1H\}$-NMR spectrum, the resonance of the μ-carbyne carbon is found downfield (doublet of doublets at δ = 313.7 with P–C couplings of ^2J = 77 and 11 Hz; in the ^1H-NMR spectrum, the N–H signal gave rise to a broad unresolved multiplet at δ = 9.18. Compared to the neutral precursors **6a**, the P^1-P^2 coupling in the $^{31}P\{^1H\}$-NMR spectrum was substantially reduced to ^{2+3}J = 89 Hz. Furthermore, a upfield shift of the dppm resonances of ca. 14 ppm results from the *N*-protonation, whereas the position of the PPh_3 ligand remains nearly unchanged. The doublet of doublets of doublets pattern at δ = − 2456 observed in the ^{195}Pt-NMR spectrum of **8a** is shifted downfield relative to the signal of **6a** (−2586), the Pt-P^3 coupling constant being reduced from ^1J = 4264 Hz (**6a**) to ^1J = 3739 Hz. The similar $^{31}P\{^1H\}$-NMR spectrum of derivative **8b**, showing the three mutually coupled phosphorus nuclei together with the coupling to the ^{195}Pt nucleus (33% natural abundance), is depicted in Figure 4.

A consequence of the positive charge, combined with the strong π-acceptor capacity of the μ-aminoarbyne ligand, is the IR shift of the ν(CO) vibrations to higher frequencies. Due to the decrease of the bond order of the C–N bond, the ν(CN) absorption is now detected at 1527 cm^{-1}. These spectroscopic data indicate that the aminocarbyne complexes **8** are also structurally closely related to the μ-vinylidene complexes **4** presented above.

Conclusion

These investigations have shown that the alkoxysilyl-substituted dinuclear hydride complexes **1** possess an interesting reactivity towards unsaturated molecules, which in most cases is difficult to predict. Whereas 1-alkynes insert in a regioselective manner into the Pt–H bond of **1** to yield σ-alkenyl complexes, reaction with aromatic isonitriles affords the RNC-bridged Fe–Pt complexes **6** and **7**. The phosphane-induced σ-alkenyl–μ-vinylidene rearrangement leading to $[(OC)_3Fe(\mu\text{-}C{=}C(H)R)(\mu\text{-}Ph_2PXPPh_2)Pt(PR_3)]$ and the formation of the μ-isonitrile complexes $[(OC)_3Fe(\mu\text{-}C{=}N\text{-}R)(\mu\text{-}dppm)Pt(PPh_3)]$ complement our previous studies on phosphane- and CO-induced silyl migrations resulting in μ-silyloxycarbene complexes $[(OC)_3Fe\{\mu\text{-}C(R)OSi(OMe)_3\}(\mu\text{-}dppm)Pt(PR_3)]$ and $[(OC)_3Fe\{\mu\text{-}C(Me)OSi\text{-}$

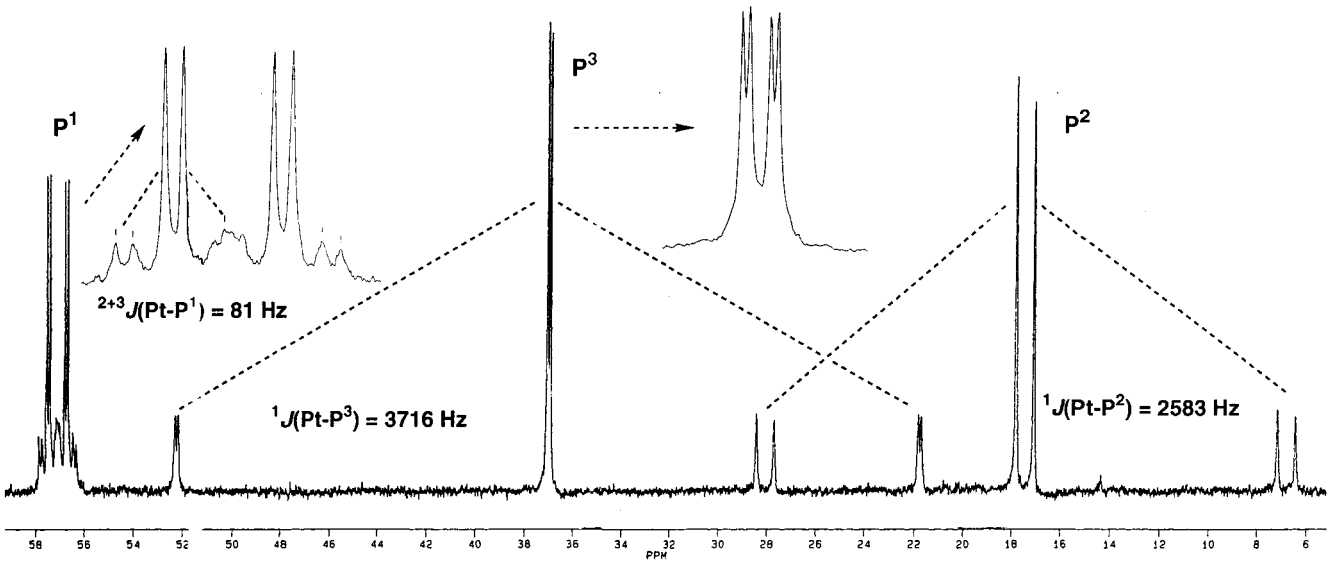

Figure 4. $^{31}P\{^1H\}$-NMR spectrum of $[(OC)_3Fe(\mu\text{-}CN(H)p\text{-anisyl})(\mu\text{-dppm})Pt(PPh_3)][BF_4]$ **8b** showing the three mutually coupled phosphorus nuclei together with the ^{195}Pt couplings

$(OSiMe)_3\}(\mu\text{-dppm})Pd(CO)]$.[12] The formation of these structurally closely related heterobimetallics underlines the tendency of these electron-rich systems to adopt a Fe(μ-C)M (M = Pd, Pt) core structure, bridged by μ-vinylidene, μ-isonitrile, μ-aminocarbyne, and μ-silyloxycarbene units behaving as efficient π-acceptor ligands. Our findings concerning the migratory insertion of activated alkynes such as DMAD or hexafluorobutyne into the Pt−H bond of **1**, as well as the molecular structures of the insertion products and their chemistry will be the subject of a forthcoming paper.[17e]

Experimental Section

All reactions were performed in Schlenk-tube flasks under purified nitrogen. Solvents were dried and distilled under nitrogen before use, toluene and hexane from sodium, dichloromethane from P_4O_{10}. Nitrogen was passed through BASF R3−11 catalyst and molecular sieve columns to remove residual oxygen and water. − Elemental C, H, and N analyses were performed on a Leco Elemental Analyzer CHN 900. − The ^1H-, $^{31}P\{^1H\}$-, ^{29}Si-INEPT and $^{13}C\{^1H\}$ NMR spectra were recorded at 200.13, 81.01 39.76, and 50.32 MHz, respectively, on a Bruker ACP 200 instrument. Phosphorus chemical shifts were referenced to 85% H_3PO_4 in H_2O with downfield shifts reported as positive. ^{195}Pt chemical shifts were measured with a Bruker ACP 200 instrument (42.95 MHz) and externally referenced to K_2PtCl_4 in water with downfield chemical shifts reported as positive. NMR spectra were recorded in pure $CDCl_3$, unless otherwise stated. The presence and amount of CH_2Cl_2 and Et_2O retained in **3a**, **3c**, **6a**, **8a**, and **8b** was determined from the ^1H-NMR spectra. − The reactions were generally monitored by IR spectroscopy in the ν(CO) region. − The acetylenes and 2,6-xylyl isocyanide were obtained from Aldrich and Fluka and were used as received. $[Pt(Cl)(H)(PPh_3)_2]$, $[Pt(H_2C{=}CH_2)(PPh_3)_2]$, dppa, dppm, and anisyl isocyanide were prepared as described in the literature.[24−28] $[(OC)_3Fe(H)\{Si(OMe)_3\}(\eta^1\text{-dppa})]$ was prepared as described for $[(OC)_3Fe(H)\{Si(OMe)_3\}(\eta^1\text{-dppm})]$.[6]

Preparation of $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-dppm})Pt(H)(PPh_3)]$ (1a): To a solution of $[Pt(H)(Cl)(PPh_3)_2]$ (756 mg, 1.0 mmol) in CH_2Cl_2 (10 mL), 1 equiv. of $K[(OC)_3Fe\{Si(OMe)_3\}(\eta^1\text{-dppm})]$ (685 mg, 1.0 mmol) was added. After stirring for 4 h at ambient temperature, the yellowish solution was filtered and concentrated. Compound **1a** was precipitated by slow addition of hexane and washed with Et_2O. The resulting crude off-white product, which was sufficiently pure for further reactions, was then dried in vacuo. Yield: 949 mg (86%). For ^1H- and ^{31}P-NMR data see ref.[5] − IR (KBr): $\tilde{\nu}$ = 2149 cm^{-1} (w) ν(PtH); 1952 (s), 1885 (vs), 1865 (vs) ν(CO). − $^{195}Pt\{^1H\}$ NMR: δ = −2916 [ddd, $^{2+3}J(Pt\text{-}P^1)$ = 87, $^1J(Pt\text{-}P^2)$ = 2074, $^1J(Pt\text{-}P^3)$ = 3544 Hz]. − ^{29}Si-INEPT NMR: δ = 10.6 [dt, $^3J(P^2\text{-}Si)$ = 7, $^3J(P^3{-}Si)$ = 7, $^2J(P^1\text{-}Si)$ = 38 Hz]. − $C_{49}H_{48}FeO_6P_3PtSi$ (1104.84): calcd. Collection of the X-ray Data and Structure Determination: For **1b**, **6a**, and **6b** data were collected with a Siemens Stoe AED2 four-circle diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The final unit cell parameters were obtained by least squares on the setting angles for 20 reflections with 2Θ = 20−23°. Data were corrected semiempirically for absorption correction using Ψ scans. SHELXS-97 and SHELXL-97 computer programs were used.[29] Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-114806−114808. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Crystal Structure Determination of 1b: Collection of crystallographic data: intensity data were collected using the Ω/2Θ scan mode at 293 K. $C_{48}H_{46}FeNO_6P_3PtSi$ (1104.80): colorless crystals with approximate dimensions 0.3 × 0.2 × 0.2 mm, monoclinic, space group $P2_1/n$; a = 10.069(9), b = 18.475(10), c = 24.71(2) Å, β = 101.12(6)°, V = 4.510(6) Å^3, Z = 4, $\rho_{calcd.}$ = 1.627 g cm^{-3}, F(000) = 2208; 9351 independent reflections in the scan range 1.68° < 2θ < 53.0°, of which 9351 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 734 parameters; $R1 = \Sigma|F_{o-Fc}|/\Sigma|F_o| = 0.0247$ [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2} = 0.0603$ (all data), GoF = 1.034; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries, except for H(1) and H(2), which were refined isotropically. Highest residual electron density 1.105 eÅ^{-3}.

Crystal Structure Determination of 6a: Collection of crystallographic data: intensity data were collected using the Ω/2Θ scan mode at 293 K. $C_{56.5}H_{49}Cl_3FeNO_3P_3Pt$ (1240.17): orange crystals with approximate dimensions 0.2 × 0.3 × 0.4 mm, triclinic, space group $P-1$; a = 12.08(2), b = 13.54(3), c = 18.60(3) Å, α = 101.86(14)°, β = 100.72(13)°, γ = 111.81(12)°, V = 2646(8) Å^3, Z = 2, $\rho_{calcd.}$ = 1.557 g cm^{-3}, F(000) = 1238; 9172 independent reflections in the scan range 1.90° < 2θ < 50.0°, of which 8179 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 604 parameters; $R1 = \Sigma|F_{o-Fc}|/\Sigma|F_o| = 0.0673$ [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2} = 0.1871$ (all data), GoF = 1.075; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 2.653 eÅ^{-3}.

Crystal Structure Determination of 6b: Collection of crystallographic data: intensity data were collected using the Ω/2Θ scan mode at 293 K. $C_{54}H_{44}FeNO_3P_3Pt$ (1114.75): orange crystals with approximate dimensions 0.4 × 0.4 × 0.3 mm, monoclinic, space group $P2_1/n$; a = 18.727(4), b = 12.668(3), c = 20.706(4) Å, β = 109.19(3)°, V = 4639(2) Å^3, Z = 4, $\rho_{calcd.}$ = 1.596 g cm^{-3}, F(000) = 2224; 6968 independent reflections in the scan range 1.79° < 2θ < 48.0°, of which 6866 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 578 parameters; $R1 = \Sigma|F_{o-Fc}|/\Sigma|F_o| = 0.0488$ [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2} = 0.1466$ (all data), GoF = 1.200; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 2.621 eÅ^{-3}.

Acknowledgments

The Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie is gratefully thanked for habilitation grants and financial support to M. K. and C. S. We are also indebted to Prof. M. Veith and Dr. P. Braunstein for their support and for providing the institute's facilities.

"Crowned" Fe_4S_4 Clusters as Electrochemical Metal Ion Sensors

Robertus J. M. Klein Gebbink,[a] Stephen I. Klink,[a] Martinus C. Feiters,*[a] and Roeland J. M. Nolte*[a]

Keywords: Iron-sulfur clusters / Crown ethers / Electrochemical devices / Host-guest chemistry

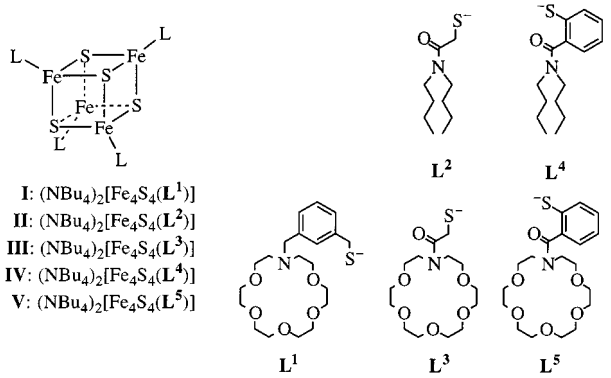
A series of Fe_4S_4 cluster compounds, **I**, **III**, and **V**, in which the cuboidal cluster core is appended with four crown ether thiolate ligands, and **II** and **IV**, bearing thiolate ligands without crown ether parts, has been synthesized and characterized. The spectroscopic and electrochemical properties of these compounds are determined by the electronic nature of the thiolate ligands. Only in the case of **III**, where a very short α-thioacetyl linker was used to connect the crown ether ligands to the cluster core, was a restricted conformational freedom of the ligand observed. A detailed electrochemical study of the influence of alkali and earth alkali metal ions (Li^+, Na^+, K^+, Mg^{2+}, and Ba^{2+}) on the reversible $2^-/3^-$ reduction of the cluster compounds was performed. In the case of the crown ether appended clusters **I**, **III**, and **V**, the addition of these metal ions resulted in an anodic shift, i.e. in positive direction, of the reduction potential (modulation effect) and to larger current responses (promotion effect). The magnitude of the modulation effects is determined by the binding affinity of the metal ions in the crown ether ligands, and by the distance between bound metal ions and the redox active cluster core. Variation of the linker between the cluster core and the metal ion binding site resulted in cluster compounds with almost inverse selectivities for e.g. K^+ and Ba^{2+} in the case of **I** and **III**. For the large effects found for compound **I** a lariat binding mode is proposed.

Introduction

Iron sulfur clusters play various roles as prosthetic groups in proteins. Their main function is to catalyze electron transfer reactions, e.g. to another redox active prosthetic group within a protein, or from one protein to another.[1] In a biological environment, tetranuclear Fe_4S_4 clusters generally exist in oxidation states that are designated as $3^-/2^-/1^-$ when the charges on the cysteinyl ligands are considered together with the core charge.[2] Synthetic thiolate clusters of this type show a somewhat richer redox chemistry; they can exist in four distinct oxidation states, $4^-/3^-/2^-$ and 1^-.[3] Early studies on biological and synthetic systems have shown that the potentials at which these states interconvert are strongly influenced by the environment of the cluster. Factors such as hydrogen bonding to the cluster, electron-donating or -accepting properties of the thiolate ligands, hydrophobicity of the ligands, and solvent polarity are all important in determining the actual values of the redox potentials.[4] In general, it can be said that the (partial) electron delocalization in the clusters is the reason why these systems are easily influenced by polarizing forces.

One of the challenges in the field of electrochemical sensory devices is to develop molecular systems that selectively recognize metal ions in general, and alkali and alkaline earth metal ions in particular.[5] Many of these systems are based on transition metal complexes, because they have a rich and well-understood electrochemistry. In these systems a binding site for the above-mentioned metal ions is located closely to a transition metal ion. Upon binding of a metal ion the redox potential of the transition metal complex is changed. This can be caused either by through-space electrostatic interactions or communication via various bond linkages between the binding site and the redox-active center. In the latter case the connector between the binding site and the redox-active site should be conducting in order to achieve the desired effect, whereas in the former case this is not required. In either case, the transition metal ion should be easily polarized to undergo a change in its redox potential. Two examples of such polarizable systems are ferrocene and $[Ru(bipy)_3]^{2+}$, which have both been frequently used in electrochemical devices.[5]

Fe_4S_4 thiolate clusters can also be considered as suitable building blocks for this purpose, as (i) they have a rich and well-defined electrochemistry, (ii) their redox potentials are highly sensitive to polarizing effects, (iii) they can be relatively easily functionalized, and (iv) four ligands can be used to influence one redox center. For these reasons, we decided to study thiolate clusters as the redox-active site for the recognition of alkali and alkaline earth metal ions. As mentioned earlier, these clusters bear a 2− or 3− overall negative charge in their most stable forms, whereas most other systems used for this purpose are neutral or positively charged. These clusters are therefore expected to lack repulsive Coulomb forces that disturb the interaction with metal ions; instead, one can take advantage of attractive Coulomb forces to favour it.



In this paper, the synthesis, characterization, and properties as electrochemical devices of a small series of crown ether substituted clusters will be presented. A simple aza crown ether compound, 1-aza-4,7,10,13,16-pentaoxacyclooctadecane (monoaza-18-crown-6), was used as the metal ion binding unit because of its ease of functionalization,

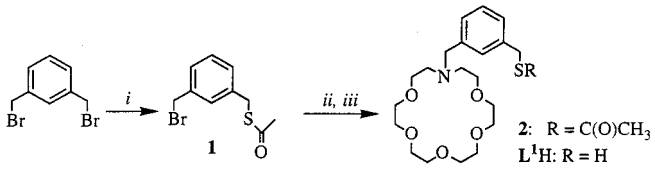
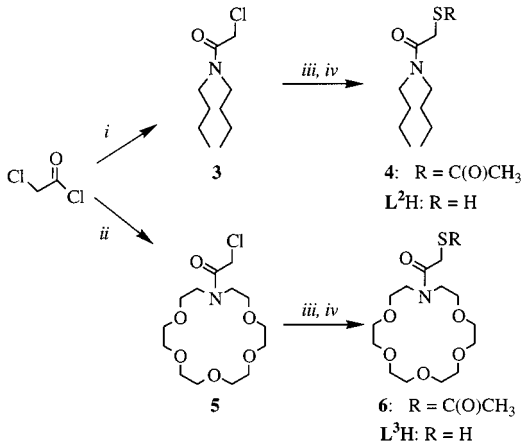
and its well-documented binding properties towards metal ions.[6] The binding selectivity of this crown ether is mainly determined by its size compatibility with a metal ion guest, and increases in the order $Li^+ \approx Mg^{2+} < Na^+ < K^+ \approx Ba^{2+}$.



First of all, three cluster compounds **I**, **III**, and **V** were synthesized with different crown ether thiol ligands. The actual binding unit is not changed in this small series, but the spacer units and the nature of the thiol groups are. In addition, two cluster compounds **II** and **IV** were synthesized and to some extent studied, as these cluster compounds lack the crown ether moieties and can therefore be considered as model compounds.

Results and Discussion

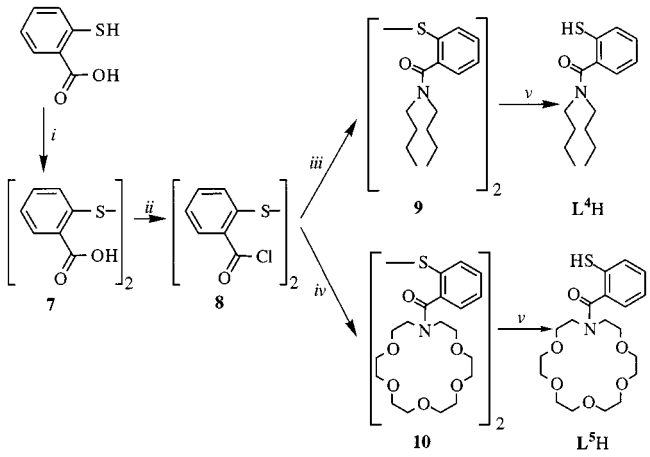


Ligand Synthesis

The synthesis of ligand $\mathbf{L^1}$H is depicted in Scheme 1. Starting from α,α′-dibromo-*m*-xylene, one of the bromide substituents was replaced by a thioacetyl group using a procedure described by Kellogg and co-workers[7] in which freshly distilled thioacetic acid was treated with K_2CO_3 to obtain the thioacetate nucleophile. After purification, the desired monobromide **1** was coupled to monoaza-18-crown-6 in DMF in the presence of base. The final step involved the hydrolysis of the thioacetyl function to the desired thiol. This reaction proceeded smoothly under acidic conditions in methanol (3% HCl) and under an inert gas.[8] Due to the presence of an internal base, i.e. the tertiary amine group, $\mathbf{L^1}$H is prone to dimerize under aerobic conditions. This compound was, therefore, kept strictly under N_2 during workup and storage. The overall yield of $\mathbf{L^1}$H was 41%.

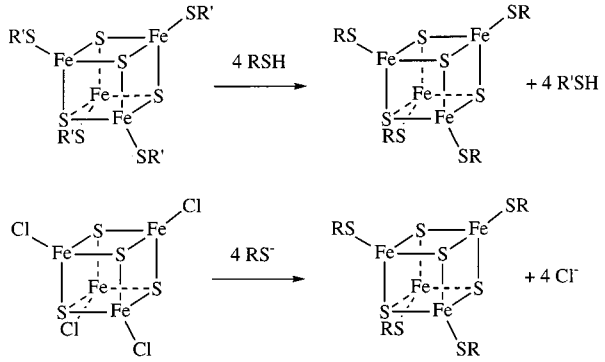
Scheme 1. Synthesis of ligand $\mathbf{L^1}$H: (*i*) K_2CO_3, $CH_3C(O)SH$, DMF; (*ii*) monoaza-18-crown-6, K_2CO_3, DMF; (*iii*) 3% HCl/MeOH

In the synthesis of ligand $\mathbf{L^2}$H and $\mathbf{L^3}$H, the spacer unit was added to the respective secondary amines, di-*n*-butylamine and monoaza-18-crown-6, prior to introduction of the protected thiol functionality, as is shown in Scheme 2. The respective secondary amines were acylated at the nitrogen position by treatment with freshly distilled α-chloroacetyl chloride, followed by substitution of the halide by a thioacetyl group as discussed above. The desired thiols were then isolated after hydrolytic deprotection of the thioacetate by treatment with 3% HCl in methanol. Overall yields were 16 and 52% for $\mathbf{L^2}$H and $\mathbf{L^3}$H, respectively. Because these compounds lack an internal base, they are less sensitive to oxidative dimerization than $\mathbf{L^1}$H.



Scheme 2. Synthesis of ligands $\mathbf{L^2}$H and $\mathbf{L^3}$H: (*i*) di-*n*-butylamine, K_2CO_3, DMF; (*ii*) monoaza-18-crown-6, K_2CO_3, toluene; (*iii*) K_2CO_3, $CH_3C(O)SH$, DMF; (*iv*) 3% HCl/MeOH

A different strategy was used for the synthesis of $\mathbf{L^4}$H and $\mathbf{L^5}$H (Scheme 3). In the first step, 2-thiosalicylic acid was protected as its disulfide, which was then converted into the corresponding diacid chloride by treatment with thionyl chloride. Acylation of secondary amines with this diacid chloride proceeded smoothly in the presence of triethylamine as a base. The final step, cleavage of the disulfide bond to yield two identical thiols, was performed in a water/dioxane mixture with triphenylphosphane as the nucleophile, under acidic conditions.[9] Pure samples of $\mathbf{L^4}$H and $\mathbf{L^5}$H could be obtained by column chromatography. The overall yields were 48 and 52% for $\mathbf{L^4}$H and $\mathbf{L^5}$H, respectively.



Synthesis and Characterization of Substituted Fe_4S_4 Clusters

Cluster compounds **I**−**V** were synthesized by ligand exchange reactions (Scheme 4),[10] and were isolated as dianionic species with either tetraalkylammonium or tetraphenylphosphonium counter ions. In one approach, these exchange reactions are based on an acid-base equilibrium, in which a more acidic thiol replaces a more basic thiolate ligand from an $Fe_4S_4(SR)_4$ cluster.[11] By making use of volatile thiols as the leaving group, e.g. tertiary butyl thiol, the equilibrium is easily driven to one desired product by

Scheme 3. Synthesis of ligands $\mathbf{L^4}$H and $\mathbf{L^5}$H: (*i*) H_2O_2, KOH, water; (*ii*) $SOCl_2$; (*iii*) di-*n*-butylamine, TEA, CH_2Cl_2; (*iv*) monoaza-18-crown-6, TEA, CH_2Cl_2; (*v*) PPh_3, dioxane/water/HCl

applying a "dynamic" vacuum. The other approach makes use of an Fe_4S_4 cluster that bears good leaving groups such as Cl^- ligands. The thiol used in these reactions is first deprotonated in order to make it a better nucleophile and to prevent the formation of HCl. Both methods were applied in the syntheses of clusters **I**−**V** since each of them has its advantages. The first method proceeds under very mild conditions without the need of any additive, whereas the second method is much faster but suffers from the fact that a base has to be added which may lead to counter ion scrambling.

Scheme 4. Preparation of Fe_4S_4 cluster compounds by ligand exchange reactions

Prior to the synthesis of the cluster compounds, test reactions were performed in situ in an electrochemical cell, and followed by differential pulse voltammetry (DPV). With this procedure, the quality of the freshly prepared thiols was tested, and an indication of the electrochemical characteristics of the final cluster compounds was obtained. On a preparative scale, the desired cluster compounds **I**−**V** were isolated as black oils after filtration of the crude reaction mixtures, followed by repeated precipitations from solution, and in vacuo removal of residual solvent.

Initial spectroscopic characterization of the isolated cluster compounds was performed by means of UV/Vis spectroscopy. Their UV/Vis characteristics closely matched the properties of related cluster compounds[12][13] and confirmed the integrity of the cubane core in these newly synthesized compounds (see Experimental Section). Further characterization was performed by NMR spectroscopy and electrochemical techniques (vide infra). NMR showed that all isolated cluster compounds contained residual solvent. In spite of the above workup procedures, and after several crystallization attempts and washings of the isolated products with various nonsolvents, it was not possible to remove these solvent traces. Elemental analyses of the isolated cluster compounds were therefore not performed.

NMR spectra of Fe_4S_4 cluster compounds in general are characterized by large chemical shifts of nuclei close to the cluster core and by broadened signals, due to the thermal accessibility of paramagnetic excited states at ambient temperature.[14] These two features can be observed in Figure 1, which shows the ^{1}H-NMR spectrum of cluster **III** in [D_7]DMF solution. In Table 1, the isotropic shifts are listed for the protons closest to the cluster core in clusters **I**−**V**. These shifts are defined as the difference in chemical shift for a given nucleus in the free ligand and in the cluster compound. For clusters **I**−**III** the shifts all have a negative sign, whereas for clusters **IV** and **V** some have a positive sign. The latter observation is a characteristic feature of aryl thiolate-substituted clusters and is correlated to the sign of spin density at the respective carbon atom in the aromatic ring. For aliphatic ligands, the sign has been shown to be non-alternative; its magnitude depends strongly on the distance between the metal center and the hydrogen nucleus.[14]

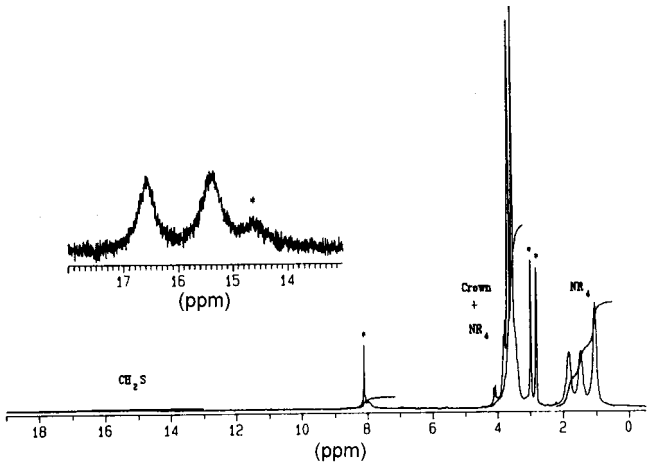


Figure 1. ^{1}H-NMR spectrum of cluster compound **III** in [D_7]DMF (the asterisks denote unassigned peaks and residual solvent peaks)

These general features were also found in temperature-dependent NMR studies on clusters **III** and **IV**, in the temperature range 298−350 K. The experiments showed that the isotropic shifts for these cluster compounds changed in magnitude upon increase of the temperature, due to a higher occupation of the first excited state, whereas their sign did not change. The temperature dependencies of the isotropic shifts are listed in Table 1, and were analyzed as linear relationships. Similar linear dependencies have been

Table 1. Isotropic shifts of ligand protons in cluster compounds **I**−**V**, together with their temperature dependence (temperature range: 300−340 K; solvent: [D_7]DMF or [D_6]DMSO, see Experimental Section)

observed for other cluster compounds in the same temperature range.[14][15]

An interesting feature from Figure 1 is the fact that the CH_2−S hydrogen signals in cluster **III** appeared as two singlets with approximately equal intensity. Apparently, the ligands in **III** have a restricted rotational freedom, which results in nonequivalent methylene hydrogen atoms due to the angular dependence of their isotropic shifts. Similar observations have been made for the cysteinyl methylene hydrogenatoms in iron-sulfur proteins and in oligopeptide model compounds.[16][17] For cluster **II**, only one signal was observed for the CH_2−S protons, suggesting that in **III** the crown ethers play a determining role in restricting the conformation of the ligands.

The electrochemical properties of **I**−**V** were studied by means of cyclic voltammetry (CV) and differential pulse voltammetry (DPV) in DMF. This solvent was chosen because both R_4N and Ph_4P salts of iron-sulfur clusters are soluble in it. Numerical data of the study are presented in Table 2.

Table 2. Electrochemical data for the 2−/3− reduction of cluster compounds **I**−**V** in DMF[a]

[a] For conditions see Experimental Section. Pt working electrode. − [b] Potentials are given relative to the Fc/Fc^+ redox couple in the same solvent.

The halfwave potentials ($E_{1/2}$) for the 2−/3− reduction of clusters **I**, **IV**, and **V** compare well with values for simple, related thiolate clusters. For $[Fe_4S_4(SCH_2Ph)_4]^{2-}$ and $[Fe_4S_4(SPh)_4]^{2-}$ the $E_{1/2}$ values have been reported to be −1.74 and −1.52 V, respectively.[18] The corresponding $E_{1/2}$ for cluster **II** has an intermediate value; this reflects the fact that the thiolate ligands in this compound have relatively strong electron-accepting properties. The halfwave potentials of these cluster compounds are therefore solely determined by the electronic properties of the thiolate ligands. In contrast, the $E_{1/2}$ value of cluster **III** was found to be 70 mV more positive than that of cluster **II**. This is probably caused by the crown ethers, which are in close proximity of the cluster core due to the short acetyl spacers. The exact nature of the influence of the crown ethers on the reduction potential is not yet understood. NMR experiments showed that the ligands in **III** have restricted conformations (vide supra).

For all cluster compounds, the peak separations (ΔE_p) in the cyclic voltammograms and the peak widths at half peak height ($W_{1/2}$) in the differential pulse voltammograms were larger than the theoretical values of 59 mV and 90.4 mV, respectively. These deviations indicate that the electron-transfer rate between the electrode and the cluster compound is slow on the experimental time scale. A reason for the electrochemically quasi-reversible redox processes, in the case of the crown ether-functionalized compounds, could be the shielding of the cluster core from the electrode. Direct contact between the electrode and the redox-active species is desirable, as diminished contact delays the velocity of electron-transfer between the redox active moiety and the electrode, resulting in large peak separations. In addition, the ratio of the peak currents for the backward and the forward processes (i_b/i_f) in CV did not approach the value of 1 in most cases.

To obtain insight into the factors that govern the electrochemical properties of the above-mentioned cluster compounds, a more elaborate study was undertaken for compounds **IV** and **V**. First of all, scan rate dependent CV experiments were performed. The $E_{1/2}$ values of both clusters were found to be independent of the scan rate, whereas ΔE_p increased considerably with increasing scan rate. A linear relationship was found between the cathodic peak current ($i_{p,c}$) and the square root of the scan rate ($\upsilon^{1/2}$), suggesting that the mass transport of redox-active species toward the Pt electrode was diffusion-controlled. In addition, it was found that at higher scan rates the 2−/3− reduction was chemically more reversible. The 2−/3− reductions can therefore be described as chemically quasi-reversible, which implies that the reduction of the cluster core is followed by a chemical reaction that is fast enough to influence the voltammetric analysis (EC mechanism). This can either be due to the coordinating properties of the solvent, which would lead to diminished stability of the generated 3− cluster, or to ligand reactivity.

For cluster compound **IV**, the solvent and the type of electrode in the electrochemical experiments were varied. In solvents with relatively high ε, the $E_{1/2}$ values of **IV** were similar to those of $[Fe_4S_4(SPh)_4]^{2-}$, i.e. −1.52 V and −1.40 V in DMF and acetonitrile, respectively. In dichloromethane, the $E_{1/2}$ for **IV** was found to be 100 mV more negative than for $[Fe_4S_4(SPh)_4]^{2-}$. This might be the result of ion pair formation or (diminished) interactions of the cluster with the solvent. The electrochemical reversibility was im-

proved in acetonitrile. The best results were obtained, however, when a pyrolytic graphite-edge (PGE) electrode was used. With this electrode, also in DMF, a rather fast electron transfer was observed, together with a somewhat higher chemical reversibility. Compared to Pt electrodes PGE electrodes are chemically less inert, i.e. due to surface oxidation, interactions between electrode and redox-active species are more plausible.

In conclusion, it appears that the relatively large organic ligands influence the electrochemical behaviour of cluster compounds **I**−**V** to some extent. Due to shielding of the negatively charged cluster core by the large organic ligands, which apparently slows down the electron transfer from electrode to cluster core, the observed electrochemical processes were not always ideal. By varying the circumstances under which the compounds were studied, however, it was shown that these clusters inherently undergo reversible redox transitions.

Electrochemical Recognition of Alkali and Alkaline Earth Metal Ions

The effects of alkali and alkaline earth metal ions on the $E_{1/2}$ for the 2−/3− transition of cluster compounds **I**, **III**, **IV**, and **V**, were investigated by performing DPV experiments in the presence of varying amounts of perchlorate salts of lithium, sodium, potassium, magnesium, and barium. The use of the DPV technique has the advantage that very small amounts of material can be used. This technique also has a higher resolution compared to CV. Figure 2 shows the changes in the differential pulse voltammograms of cluster compound **I** and of **V** upon the addition of Ba^{2+} ions. The peak potentials for the reduction of both compounds shift to more positive values, i.e. the clusters are more easily reduced to the 3− form. Compound **I** exhibited so-called multi-wave behaviour, whereas **V** showed a continuous shift of its E_p (vide infra). Similar titrations were performed with the cluster compounds **III** and **IV**.

In all cases, a change in E_p occurs in an anodic, i.e. in a positive direction (Table 3). The magnitude of this change depends on the cluster compounds as well as on the metal ions. For example, Ba^{2+} ions give a shift in E_p of 190 mV with **I**, but only 20 mV with **IV**. The crown ether parts in the ligands thus appear to be essential to give large changes in the electrochemical properties of the Fe_4S_4 core upon addition of metal ions. A more detailed investigation of the effect of the crown ether ligands on the electrochemical behaviour toward alkali and alkaline earth metal ions was performed with compounds **I**, **IV**, and **V**, and is described below.

Table 3. Changes in E_p for the reduction of compounds **I**, **III**, **IV**, and **V** upon addition of 10 equivalents of metal ion[a]

	I	III	IV	V
Li^+	90 (120)	(0)	0 (0)	0 (10)
Na^+	30 (n.d.)[b]	–	0 (10)	50 (60)
K^+	40[c] (n.d.)[b]	–	0 (10)	50 (60)
Mg^{2+}	190[d] (290)[e]	(130)	30 (90)	70 (110)
Ba^{2+}	190[d] (210)	(120)	20 (50)	30 (50)

[a] In parentheses the E_p change when a large excess (100 equivalents) of metal ion is added. − [b] n.d. = not determined. − [c] Reached after 2 equivalents had been added. − [d] Reached after 4 equivalents had been added. − [e] Small additional peak observed.

Promotion and Modulation Effects

First of all, it is worthwhile to explain the difference between promotion and modulation effects on the electrochemical properties of redox active species. In general, promotion effects involve an improvement of both current response and electrochemical reversibility of a redox process, and in addition often involve an increase of peak currents after repetitive CV scans. Modulation effects involve changes in the potential of a redox process. The electrochemistry of large biomolecules often suffers from very poor current responses due to slow electron transfer from the redox active entity, embedded in the protein core, to the electrode.[19] Addition of a promoter increases the electron-transfer rate either by improving the protein-electrode interaction or by mediating electron transfer. Generally, promoters are polar or charged compounds that bear coordinating groups. Sometimes the use of a promoter also results in an altered $E_{1/2}$. In that case this compound behaves as a

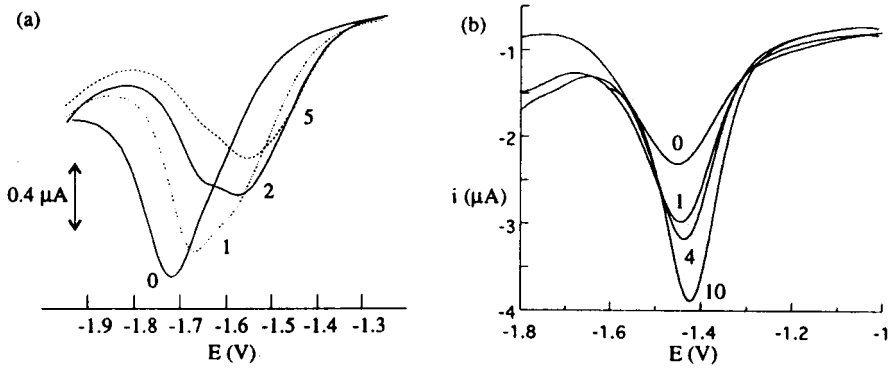

Figure 2. Changes in E_p upon addition of Ba^{2+} ions for the reduction of (a) compound **I** (prepared in situ) and (b) compound **V**, followed by DPV; numbers correspond to the amount of metal ion added (mol. equiv.)

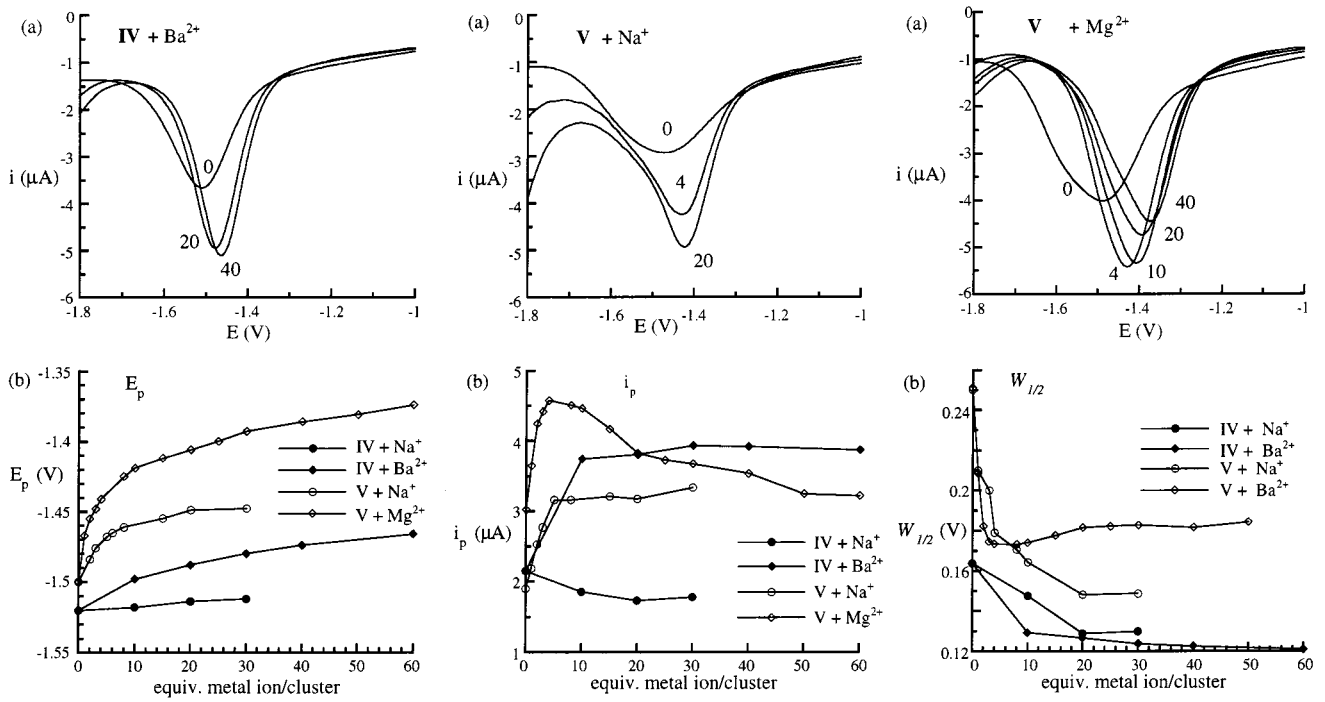

Figure 3. (a) DPV titrations of compound **IV** with Ba^{2+} ions, and compound **V** with Na^+ and Mg^{2+} ions, numbers correspond to the amount of metal ion added; (b) corresponding titration curves (including those for compound **IV** and Na^+) in which E_p, i_p, and $W_{1/2}$ are plotted as a function of the amount of metal ion added

modulator as well. Promoter/modulator effects similar to those observed for proteins have also been observed for semi-encapsulated, synthetic cluster compounds.[20][21]

Overlays of subsequent differential pulse voltammograms in the titration of cluster compounds **IV** with Ba^{2+} ions, and **V** with Na^+ and Mg^{2+} ions are shown in Figure 3a. Figure 3b shows the titration curves in which i_p, and $W_{1/2}$ (and also E_p, see below) are plotted as a function of the amount of metal ion added per cluster. The curves derived from the titration of **IV** with Na^+ ions are also shown. For compound **IV**, a small decrease in current response (i_p) was observed upon the addition of monovalent alkali metal ions. The addition of divalent metal ions clearly resulted in an increase in i_p as well as in the electrochemical reversibility of the redox process (decreased $W_{1/2}$ value). The i_p and $W_{1/2}$ values of **V** improved considerably upon the addition of monovalent as well as divalent metal ions, except in the case of Li^+ for which only minor improvements were observed (not shown).

The fact that divalent metal ions have an influence on the electrochemical properties of **IV** indicates that the overall negative charge of **IV** to some extent hampers a clean redox process. Divalent metal ions are assumed to form a layer of positive charges on a negatively charged electrode, thereby facilitating the reduction of negatively charged species, while monovalent metal ions do not give this effect.[22] This phenomenon can be explained by the larger polarizing strength of the divalent alkaline earth metal ions as compared to the monovalent alkali metal ions.

The addition of metal ions to cluster compound **V**, with the exception of Li^+, resulted in an improvement of the current response and in smaller $W_{1/2}$ values (vide supra). The titration curves in Figure 3b indicate that changes in these parameters are directly related to the amount of metal ion that is added to **V**. These promotion effects were already observed upon addition of less than four equivalents of metal ions per cluster. Binding of more than two monovalent metal ions by **V** converts this compound from an overall negatively to an overall positively charged species, resulting in a more favourable interaction with the negatively charged electrode. This observation is in sharp contrast to the large excess of $Ba(ClO_4)_2$ which is required to promote the electrochemistry of metalloproteins and the earlier mentioned semi-encapsulated cluster compounds.[19–21] This strongly suggests that specific binding of metal ions in the crown ether rings causes the observed effects. In addition, compound **IV**, having no specific metal ion binding sites, was only affected at metal ion concentrations approaching the millimolar range.

The promoter effects observed for cluster compound **I** were in line with those obtained for **V**, albeit less pronounced (not shown). Apparently, the larger flexibility of the crown ether ligands in **I** as compared to **V** results in a better electrochemical behaviour even without the addition of metal ions.

Changes in the peak potentials of compounds **IV** and **V** vary from 0 for Li^+ to 70 mV for Mg^{2+} after the addition of 10 equivalents of these ions per cluster compound (Table 3). In general, the changes of the E_p of **IV** are very small; a maximum modulation of 20–30 mV for divalent metal ions is observed. This small change may be the result of a weak coordination of the metal ions to the amide function

in the ligand, or may be caused by changes in the electrode surface as pointed out above. At very high metal ion concentration, larger effects were observed with Mg^{2+} and Ba^{2+}, suggesting that either of the two factors became more important in the modulation process.

For compound **V**, the modulation effects are more pronounced than for **IV**. The titration curves in Figure 3b show that the largest effect is achieved after the addition of several equivalents of Na^+. For Ba^{2+}, the major effect is achieved after the addition of approximately 20 equivalents (not shown). After the addition of an excess of modulator, minor additional changes in E_p were observed. These additional changes closely match the effects found for compound **IV** at low modulator concentrations.

In Figure 2a, an overlay of sequential voltammograms for the titration of compound **I** with Ba^{2+} is depicted (vide supra). Figure 4 presents the changes in E_p for this compound upon the addition of Ba^{2+}, Na^+, and K^+ ions. Due to the multi-wave behaviour observed in the Ba^{2+} titration and problems with the deconvolution, the Ba^{2+} curve in Figure 4 deviates from an ideal titration curve. Nevertheless it can be concluded that the effect of Ba^{2+} ions is much larger than the effects of K^+ and Na^+ ions. The addition of very small amounts of both Ba^{2+} and K^+ results in a steep rise in E_p, whereas for Na^+ this is not observed. In accordance with the observations for compound **V**, it is likely that the binding of ions in the crown ether ligands of the cluster contributes most to the observed changes in E_p. The fact that multi-wave behaviour is observed with Ba^{2+}, as well as with Li^+ and Mg^{2+} ions, points to a strong binding of these metal ions by compound **I**.

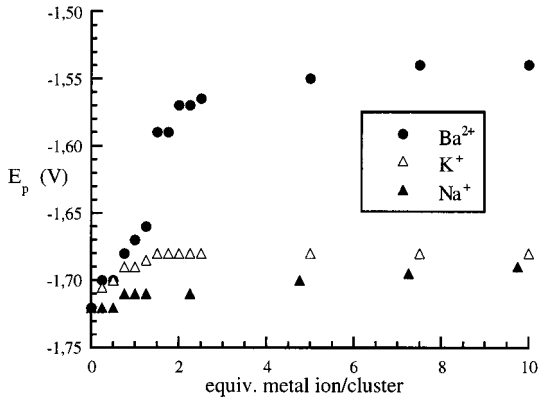

Figure 4. Changes in E_p upon titration of compound **I** with Na^+, K^+, and Ba^{2+} ions

Rationalization of the Modulator Effects

The different changes in E_p upon the addition of stoichiometric amounts of metal ions to cluster compounds **I** and **V** probably arise from the fact that the affinities of the crown ether ligands of the host compounds for the metal ions are different. As was mentioned in the introduction, the binding of metal ions in the monoaza-18-crown-6 ligands of **I** is expected to follow the trend $Li^+ \approx Mg^{2+} < Na^+ < K^+ \approx Ba^{2+}$, which is based on size complementarity. From the point of view of charge stabilization, the divalent metal ions are expected to bind more strongly than the monovalent metal ions.[6] The binding constants for the ligands of **V** were anticipated to be lower than those of the ligands of **I**. The acyl functions on the nitrogen centers in the aza crown ether rings of **V** lead to a host molecule which is a less efficient metal ion binder. This modification could explain the generally smaller changes in E_p found for **V**. However, these rules of thumb do not explain the trends in responses of compounds **I** and **V**.

Figure 5 shows the dependence of the modulation of the E_p of compound **I** on the charge density of the metal ion that causes the modulation. Metal ions bearing a high charge density give rise to a larger change in the reduction potential than metal ions bearing a low charge density. In other words, the higher the polarizing strength of the metal ion, the larger the modulation of the redox properties of the polarizable Fe_4S_4 core in **I**. It is likely therefore that this modulation is governed by electrostatic forces. In this way, metal ions with similar binding constants or ionic radii such as K^+ and Ba^{2+}, but different polarizing effects, bring about different modulations. Similar observations have been made by Hall et al. for their ferrocene based cryptates.[23]

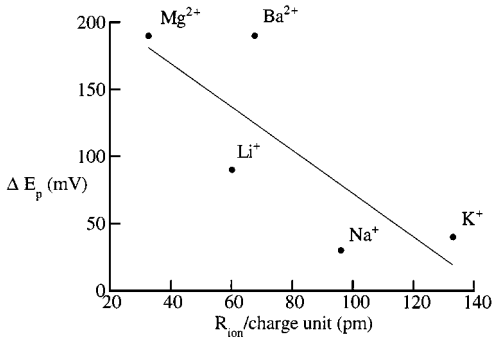

Figure 5. Dependence of the metal ion induced change in $E_{p,red}$ of compound **I** on the charge density of the metal ion

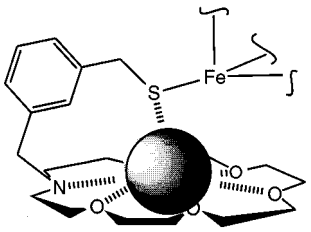
The multi-wave behaviour that is observed for **I** in combination with Ba^{2+}, Li^+, and Mg^{2+} ions, and the magnitude of the modulations, suggests that the binding of these metal ions by **I** is strong. Since the connection between the binding site and redox site in **I** is not conducting, the metal ions should be bound in very close proximity to the redox active center in order to be able to affect the redox potential to the observed extent. It is proposed therefore, that compound **I** binds metal ions in a lariat-ether fashion,[24] with the oxygen and nitrogen atoms of the crown ether ring and the negatively charged thiolate sulfur atom, which coordinates to the cluster, as donor atoms (see Figure 6). In this way the interaction between the binding site and the redox site would be through-bond instead of through-space and the overall negative charge of the cluster compounds would contribute to its interaction with metal ions. Similar lariat

interactions have been proposed before by Gokel et al. in nitrobenzene pivoted crown ethers.[25]



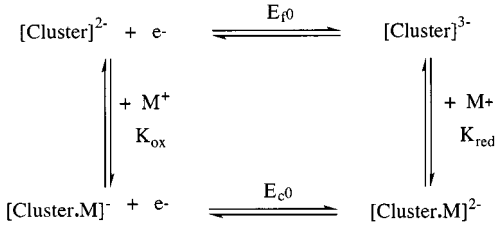


Figure 6. Proposed mode of metal ion binding by compound **I**

Due to conformational restrictions, the host-guest interaction in **V** is not expected to be similar to that of **I**. As in cluster compound **I**, there is no conducting connection between the redox center and the binding site in this compound. An effective impact on the redox potential of the cluster core should, therefore, arise via through-space interactions. The more rigid ligand connection in **V** compared to **I** is likely to result in a less favourable approach of the metal ion to the redox active center, which could explain that, in general, smaller modulation effects and no multiwave behaviour were observed for compound **V**. Combining the values from Table 3 with the curves in Figure 3b, and taking into account the metal ion charge densities, one can conclude that the binding constants in **V** roughly follow the trend $Li^+ < Ba^{2+} < Mg^{2+} < Na^+ < K^+$. In particular, acylation of the aza crown ether rings seems to influence the binding of metal ions with a high charge density in a negative sense. The modulation effects observed for **V** can then be explained by combining the known trend in binding constants with the polarizing strength of the metal ions.

Another way of dealing with the observed modulation effects is presented in Scheme 5, which is taken from earlier papers by Kaifer et al.[26] Starting from a redox-active host compound (an Fe_4S_4 cluster in this case) and an uncomplexed guest, there are two ways to come to a reduced host-guest complex. In one way, the guest is bound by the host compound in the first step, resulting in a facilitated reduction of the redox active center. In the second way, the redox-active center is first reduced, which in turn results in an enhanced binding of the guest.

Scheme 5. Pathways for metal ion complexation in an Fe_4S_4 cluster compound; E_c^0 and E_f^0 are the midpoint potentials for the complex and the free ligand, respectively

For the respective reduction potentials and binding constants Equation 1 can be derived.[26]

$$E_p^{complex} - E_p^{free} = - RT/n\mathrm{F}\ [\ln K_{red}/K_{ox}] \quad (1)$$

In words, the ratio of the binding constants of a guest in the reduced and oxidized host is given by the change in E_p brought about by the binding of the guest. In this model, the modulations that are observed for the cluster compounds reflect the enhanced binding of metal ions by these compounds upon reduction of the cluster core. Comparison of the modulations brought about by the different metal ions will then involve more than just the comparison of binding constants of the oxidized host. Equation 1 has been shown by Kaifer to be valid for systems with $K_{ox} > 10^4$. For systems with $1 < K_{ox} < 10^4$, which is expected to be the range for our compounds, the increase in binding constant is underestimated by this Equation.[26] The results of application of the above-mentioned analysis to the effects found for **I** and **V** are presented in Table 4.

Table 4. Ratio of K_{red} and K_{ox} for binding of different metal ions in compounds **I** and **V**[a]

	I	**V**
Li^+	33 (13)	–
Na^+	3 (1)	7 (3)
K^+	5 (2)	7 (3)
Mg^{2+}	1600 (650)	5 (2)
Ba^{2+}	1600 (650)	2 (1)

[a] Determined after the addition of 4 equivalents of metal ion. Estimated errors are given in parenthesis.

The titration curves presented in Figure 4 indicate that more than 2 and possibly 4 metal ions are bound to the crown ether cluster compounds. From our experiments it could not be determined whether the four binding sites behaved independently from each other, in terms of equal binding constants for every site, or that these sites influenced each other, e.g. by diminishing the binding of every next metal ion. It should be noted that applying Equation 1 might lead to overestimated values in the latter case. The numbers in Table 4 should therefore not be treated as absolute values but merely as representing trends in metal ion affinities of the cluster compounds.

Conclusion

A number of new thiolate-functionalized iron-sulfur cubane clusters **I**–**V** were prepared and characterized. In **I**, **III**, and **V**, the cluster cores are appended with binding sites for metal ions, viz. crown ether ligands. Electrochemical studies show that the large crown ether ligands hamper, to some extent, the electrochemical analysis of the cluster compounds. Only in the case of cluster compound **III** does the presence of the relatively large ligands have a pronounced effect on the $E_{1/2}$ value. Here, the ligands are believed to have a restricted conformational freedom, resulting in a more effective shielding of the cluster core.

Examination of the promotion and modulation effects of metal ions on cluster compounds **I**, **IV**, and **V** reveals that

the largest effects occur in the case of the crown ether functionalized cluster compounds **I** and **V**. Addition of stoichiometric amounts of metal ions leads to large changes in the electrochemical characteristics of the cluster reduction, implying that metal ions are bound in the crown ether ligands. Smaller changes arise from electrode modification, which facilitates the reduction of the negatively charged cluster compounds, as was shown for compound **IV**. Reduction of the cluster compounds enhances their affinity for alkali and alkaline earth metal ions. A lariat-binding mode is proposed for the complexation of metal ions to compound **I**, resulting in a more or less through-bond interaction between the redox site and the crown ether bound metal ion. In this way, binding of metal ions by this compound is favoured by the negative charge of its redox center. Such a favourable interaction was ruled out, however, for compound **V** due to restrictions in the conformation of its ligands; probably related to the lack of rotational freedom of the amide bonds. The modulations observed for compound **V** seem to take place via through-space interactions. Overall, the characteristic features of the modulations measured for the novel cluster compounds were shown to be governed by the interplay of crown ether selectivity, ligand flexibility, and electrostatic forces. As a result, the modulations observed for compounds **I** and **V** are in sharp contrast to each other. Whereas **I** shows a strong response towards Ba^{2+} ions and hardly any response towards K^+, compound **V** displays much smaller effects and an opposite selectivity.

The results presented here show that crown ether-functionalized iron-sulfur clusters can serve as electrochemically active host compounds, and can in principle be applied as building blocks for the construction of electrochemical sensory devices which are able to display selective responses towards charged species

Experimental Section

General Procedures: All chemicals were commercial products and were used as received. α-Chloroacetyl chloride was synthesized using a literature procedure.[27] Di-*n*-butylamine and thioacetic acid were distilled under reduced pressure. Diethyl ether was distilled from sodium metal/benzophenone, hexane was distilled from sodium metal, and dichloromethane and chloroform were distilled from $CaCl_2$. Pyridine and triethylamine were distilled from CaH_2. DMF used for electrochemical experiments was stored over BaO for at least one day, after which it was distilled under reduced pressure. Ethyl acetate used for flash chromatography was distilled from K_2CO_3/Na_2CO_3. Hexane used for the same purpose was distilled once using a rotary evaporator. All other solvents were used as received. Manipulations involving thiol compounds were performed under N_2 unless stated otherwise. Glassware used in thiol handling was left overnight in a hypochlorite solution to prevent stench. Manipulations involving iron-sulfur clusters were performed using standard Schlenk techniques. − Flash chromatography was performed on Silica Gel (60 H) purchased from Merck, or on neutral alumina purchased from Across. Prior to use, neutral alumina was activated to activity III, according to the Brockman scale.[28] − TLC analyses were performed on silica 60 F_{254} coated glass plates from Merck. Thiol compounds were detected by treatment of the TLC plates with a nitroprusside reagent.[29] − FT-IR spectra were recorded with a BioRad FTS 25 instrument. − UV/Vis spectra were recorded with a Perkin−Elmer Lambda 5 instrument. − ^{1}H-NMR spectra were recorded with Bruker WF-90, Bruker AC-100, Bruker WM-200, Bruker AC-300, or Bruker AM-400 instruments (internal standards: $CDCl_3$ as solvent TMS, δ_H = 0.00; [D_6]DMSO as solvent, δ_H = 2.50; [D_7]DMF as solvent, δ_H = 2.94). − Mass spectra were obtained from a VG 7070E instrument [FAB$^+$ (3-nitrobenzyl alcohol), EI$^+$]. − Elemental analyses were performed with a Carlo Erba EA 1180 instrument. − Melting points were measured with a Reichert−Jung Hotstage 600 instrument (uncorrected values). − Electrochemical analysis (CV, DPV) were performed with an EG & G Princeton Applied Research Model 273 Electrochemistry System equipped with Model 270 Electrochemical Analysis Software 200. Reference electrodes: Ag/AgCl (0.1 M LiCl) in DMF, Ag/AgI (0.02 M Bu_4NI/0.1 M Bu_4NPF_6) in CH_2Cl_2, and Ag/Ag$^+$ (0.1 M $AgNO_3$) in CH_3CN. Supporting electrolyte: 0.1 M tetrabutylammonium hexafluorophosphate (TBAH). All measurements were performed under an inert gas, using a conventional three-electrode electrochemical cell equipped with either platinum or PGE working and Pt auxiliary electrodes. PGE electrodes were polished with 0.3 μm alumina, rinsed with water, and sonicated in water for 10 min before use. Before every session, the experimental setup was tested using ferrocene and $[Fe_4S_4(S\mathit{t}Bu)_4](NBu_4)_2$. Halfwave and peak potentials are given against the reversible Fc/Fc$^+$ couple. Scan rates were 100 mV/s (CV) and 10 mV/s (DPV) unless stated otherwise. Concentrations of electroactive species were between 0.01 mM and 1 mM.

α-Bromo-α′-thioacetyl-*m*-xylene (1): To a solution of K_2CO_3 (1.05 g, 7.6 mmol) in 4 mL of DMF was slowly added a solution of freshly distilled thioacetic acid (1.14 g, 15 mmol) in 2 mL of DMF. After CO_2 formation had ceased, the resulting yellow solution was diluted with the same amount of DMF. This diluted solution was added dropwise to a solution of α,α′-dibromo-*m*-xylene (4.0 g, 15.2 mmol) in 20 mL of DMF, and the resulting mixture was stirred overnight under the exclusion of light. These manipulations were all performed under N_2. After filtration and removal of the solvent in vacuo, the resulting residue was dissolved in 100 mL of diethyl ether, washed with water (3×), dried with $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography (silica, ethyl acetate/hexane = 1:10, v/v) yielded 2.1 g (54%) of **1** as a yellow oil. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 2.36 [s, 3 H, C(O)CH_2], 4.11 (s, 2 H, ArCH_2S), 4.45 (s, 2 H, ArCH_2Br), 7.29 (m, 4 H, Ar*H*). − EI-MS; *m*/*z*: 260 [M]$^+$. − $C_{10}H_{11}BrOS$ (259.2): calcd. C 46.35, H 4.28, S 12.37; found C 46.50, H 4.39, S 11.85.

1-(α-Thioacetyl-*m*-xylyl)-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (2): A solution of **1** (390 mg, 1.51 mmol) in 5 mL of DMF was added dropwise to a solution of 4,7,10,13,16-pentaoxa-1-azacyclooctadecane (400 mg, 1.51 mmol) in 15 mL of DMF which contained some K_2CO_3 as a base. The reaction mixture was stirred overnight at 40°C under N_2, after which the solvent was removed under reduced pressure. The resulting oil was dissolved in 40 mL of dichloromethane, washed twice with a saturated aqueous $NaHCO_3$ solution, dried with $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography (silica, $CHCl_3$/MeOH/TEA = 97:2:1, v/v) yielded 530 mg (80%) of **2** as a viscous yellow oil. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 2.36 [s, 3 H, C(O)CH_3], 2.78 (t, *J* = 6.6 Hz, 4 H, NCH_2CH$_2$O), 3.62 (m, 22 H, OCH_2, ArCH_2N), 4.11 (s, 2 H, ArCH_2S), 7.24 (m, 4 H, Ar*H*). − FAB-MS; *m*/*z*: 442 [M + 1]$^+$. − $C_{22}H_{35}NO_6S$ (441.6): C 59.84, H 7.99, N 3.17, S 7.26; found C 59.63, H 8.05, N 3.22, S 7.36.

1-(α-Mercapto-*m*-xylyl)-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (L^{1}H): A solution of **2** (200 mg, 0.45 mmol) in 5 mL of 3%

HCl in methanol was stirred at ambient temperature for 3 d. At this point, TLC analysis showed one spot that was positive in a sodium nitroprusside test. To the reaction mixture were then added 20 mL of dichloromethane and 10 mL of water. The layers were neutralized using a saturated aqueous $NaHCO_3$ solution, after which the organic layer was washed once again with water. After drying with $MgSO_4$, filtration, and removal of the solvent under reduced pressure, 170 mg (95%) of **L^{1}H** was obtained as a yellowish oil. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 1.75 (t, *J* = 7.3 Hz, 1 H, *SH*), 2.78 (t, *J* = 6.0 Hz, 4 H, N*CH*$_2$CH$_2$O), 3.62 (m, 22 H, O*CH*$_2$, Ar*CH*$_2$N, Ar*CH*$_2$S), 7.24 (m, 4 H, Ar*H*). − $C_{20}H_{33}NO_5S$ (399.5): calcd. C 60.28, H 8.09, N 3.51, S 8.09; found C 60.44, H 8.24, N 3.67, S, 8.18.

(α-Chloroacetyl)di-*n*-butylamine (3): To a solution of di-*n*-butylamine (1.06 g, 7.8 mmol) in CH_2Cl_2 (75 mL) which contained 1.1 mL of triethylamine as a base, was added dropwise a solution of α-chloroacetyl chloride (875 mg, 7.75 mmol) in 25 mL of CH_2Cl_2. The reaction mixture was stirred overnight at ambient temperature and subsequently washed (3×) with a saturated aqueous $NaHCO_3$ solution, and dried with $MgSO_4$. Flash chromatography (silica, $CHCl_3$/MeOH = 98.5:1.5, v/v) gave **3** as a colourless oil in 26% yield. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 0.82−1.04 (m, 6 H, *CH*$_3$), 1.14−1.70 (m, 8 H, *CH*$_2$*CH*$_2$CH$_3$), 3.20−3.43 (m, 4 H, N*CH*$_2$), 4.07 (s, 2 H, *CH*$_2$Cl). − EI-MS; *m*/*z*: 205 $[M]^+$. − $C_{10}H_{20}ClNO$ (205.7): calcd. C 58.38, H 9.80, N 6.81; found C 57.95, H 10.17, N 6.87.

[α-(Thioacetyl)acetyl]di-*n*-butylamine (4): Under N_2, 299 mg (2.15 mmol) of K_2CO_3 was allowed to react with 155 μL of thioacetic acid in a minimum amount of DMF. The resulting solution was added dropwise to a solution of **3** (446 mg, 2.16 mmol) in DMF, and this mixture was stirred overnight under the exclusion of light. After removal of the solvent under reduced pressure, the residue was dissolved in CH_2Cl_2 and washed twice with brine and once with water. The organic layer was dried with $MgSO_4$. Flash chromatography (silica, $CHCl_3$/MeOH = 99:1, v/v) yielded **4** as a yellow oil in 65% yield (345 mg). − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 0.84−1.05 (m, 6 H, CH$_2$CH$_2$*CH*$_3$), 1.19−1.73 (m, 8 H, *CH*$_2$*CH*$_2$CH$_3$), 2.39 [s, 3 H, C(O)*CH*$_3$], 3.22−3.43 (m, 4 H, N*CH*$_2$), 4.37 (s, 2 H, *CH*$_2$S). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2959, 2932, 2874 (CH_2, CH_3), 1695 (C=OCH$_3$), 1647 (C=O), 1428, 1377 (CH_2, CH_3), 1355 (C=OCH$_3$), 733 (CH_2). − EI-MS; *m*/*z*: 245 $[M]^+$. − $C_{12}H_{23}NO_2S$·0.5MeOH (260.4): calcd. C 57.44, H 9.64, N 5.36, S 12.26; found C 57.46, H 9.49, N 5.68, S 12.07.

(α-Mercaptoacetyl)di-*n*-butylamine (L^{2}H): To a solution of **4** (130 mg, 0.53 mmol) in 3 mL of CH_2Cl_2 was added 3 mL of 6% HCl in MeOH. The resulting mixture was stirred overnight. At this point, TLC analysis revealed a single spot that turned red when treated with nitroprusside. The reaction mixture was diluted with CH_2Cl_2 and neutralized with saturated aqueous $NaHCO_3$, washed once with water and dried with $MgSO_4$. Removal of the solvent in vacuo yielded 108 mg (100%) of **L^{2}H** as a brownish-yellow oil. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 0.99−0.89 (m, 6 H, CH$_2$CH$_2$*CH*$_3$), 1.26−1.37 (m, 4 H, CH$_2$*CH*$_2$CH$_3$), 1.49−1.61 (m, 4 H, *CH*$_2$CH$_2$CH$_3$), 2.17 (t, *J* = 7.43 Hz, 1 H, *SH*), 3.20−3.36 (m, 6 H, N*CH*$_2$CH$_2$, CH$_2$S). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2958−2863 (CH_2, CH_3), 2554 (SH), 1642 (C=O), 1454, 1430, 1376 (CH_2, CH_2). − EI-MS; *m*/*z*: 203 $[M]^+$. − No reproducible analysis could be obtained for this compound.

1-(α−Chloroacetyl)-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (5): To a solution of 4,7,10,13,16-pentaoxa-1-azacyclooctadecane (300 mg, 1.14 mmol) in 15 mL of toluene, containing some solid K_2CO_3 as a base, a solution of α-chloroacetyl chloride (150 mg, 1.3 mmol) in 2 mL of toluene was added dropwise. The reaction mixture was stirred overnight at ambient temperature, after which the solvent was removed in vacuo. The resulting residue was dissolved in 50 mL of dichloromethane; this solution was washed twice with a saturated aqueous $NaHCO_3$ solution, dried with $MgSO_4$, and filtered. After removal of the solvent under reduced pressure, 350 mg (90%) of **5** was obtained. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 3.82 (m, 24 H, O*CH*$_2$, N*CH*$_2$), 4.24 (s, 2 H, *CH*$_2$Cl). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3003, 2872 (br, CH_2), 1648 (C=O), 1455, 1353 (CH_2), 1121 (COC), 712 (CH_2). − EI-MS; *m*/*z*: 340 $[M]^+$. − $C_{14}H_{26}ClNO_6$ (339.8): calcd. C 49.54, H 7.73, N 4.13; found C 49.45, H 7.84, N 4.09.

1-[α-(Thioacetyl)acetyl]-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (6): To prepare this compound, a similar procedure as described for the synthesis of **4** was used. A DMF solution of potassium thioacetate, prepared from K_2CO_3 (100 mg, 0.72 mmol) and thioacetic acid (100 mg, 1.3 mmol), was added to a DMF solution containing **5** (350 mg, 1.03 mmol). After workup using dichloromethane and flash chromatography (silica, $CHCl_3$/MeOH = 98:2, v/v) compound **6** (250 mg, 61%) was obtained as a viscous, yellow oil. − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.38 (s, 3H, *CH*$_3$), 3.50−3.81 (m, 24 H, O*CH*$_2$, N*CH*$_2$), 3.98 (s, 2 H, *CH*$_2$S). − ^{13}C NMR (75 MHz, $CDCl_3$): δ = 30.5 (CH_3), 32.5 (SCH_2), 48.0 (NCH_2), 70.0−71.5 (m, OCH_2), 168.5 (NC=O), 196.0 (SC=O). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2867 (br, CH_2, CH_3), 1691 (SC=O), 1656, 1648 (C=O), 1468, 1450 (CH_2, CH_3), 1353 ($COCH_3$), 1120 (COC), 732 (CH_2). − EI-MS; *m*/*z*: 379 $[M]^+$. − No reproducible analysis could be obtained for this compound.

1-(α-Mercaptoacetyl)-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (L^{3}H): This compound was prepared using the procedure described for compound **L^{2}H**. Starting from **6** (100 mg, 0.24 mmol), 77 mg (95%) of ligand **L^{3}H** was isolated. − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.17 (t, *J* = 7.52 Hz, 1 H, *SH*), 3.40−3.76 (m, 26 H, O*CH*$_2$, N*CH*$_2$, S*CH*$_2$). − ^{13}C NMR (75 MHz, $CDCl_3$): δ = 27.0 ($HSCH_2$), 47.83 (NCH_2), 70.03−71.78 (m, OCH_2), 171.1 (NC=O). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2867 (br, CH_2), 2546 (SH), 1654 (C=O), 1448, 1421 (CH_2), 1119 (br, COC). − EI-MS; *m*/*z*: 338 $[M]^+$. − No reproducible analysis could be obtained for this compound.

2,2′-Dithiobisbenzoic Acid (7):[30] To a solution of thiosalicylic acid (8 g, 51.9 mmol) and NaOH (6.4 g, 160 mmol) in 60 mL of water was added very slowly, by means of a dropping funnel, 25 mL of a solution of 15% H_2O_2 in water. During the addition the reaction mixture was cooled on ice. After the addition was completed the mixture was slowly allowed to come to ambient temperature. Finally, it was stirred overnight at 60°C. The mixture was again cooled on ice, and neutralized with aqueous 2N HCl, which resulted in the formation of a white precipitate. The product was filtered off, washed with cold ethanol and cold water, and dried in vacuo. This procedure yielded 6.3 g (80%) of **7** as a white powder, m.p. 298−299°C. − ^{1}H NMR (90 MHz, [D$_6$]DMSO): δ = 7.39 (m, 2 H, Ar*H*$^{4,4'}$), 7.62 (m, 4 H, Ar*H*$^{5,5'}$, Ar*H*$^{6,6'}$), 8.04 (m, 2H, Ar*H*$^{3,3'}$). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3500−2500 (OH), 1673 (C=O), 735 (ArH). − FAB-MS; *m*/*z*: 306 $[M]^+$. − $C_{14}H_{10}O_4S_2$·0.25EtOH (317.8): calcd. C 56.20, H 3.74, S 20.69; found C 56.20, H 3.36, S 20.81.

***N*,*N*,*N*′,*N*′-Tetra-*n*-butyl-2,2′-dithiobisbenzoylamine (9):** A suspension of **7** (410 mg, 1.33 mmol) in 10 mL of $SOCl_2$ was heated under reflux overnight, yielding a clear solution. After removal of the excess of $SOCl_2$ in vacuo, the resulting residue, **8**, was dissolved in 5 mL of dichloromethane. This solution was then added dropwise to a solution of di-*n*-butylamine (387 mg, 3.0 mmol) and of triethylamine (220 μL) in 50 mL of dichloromethane. The reaction mixture

was stirred overnight at ambient temperature, after which it was washed (3×) with a saturated aqueous $NaHCO_3$ solution. The organic layer was dried with $MgSO_4$, filtered, and concentrated. After purification by flash chromatography (alumina, CH_2Cl_2/EtOH = 99:1, v/v) compound **9** (650 mg, 82%) was obtained as a yellowish, viscous oil. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 0.90 (m, 12 H, $CH_2CH_2CH_3$), 1.50 (m, 16 H, $CH_2CH_2CH_3$), 3.10 (t, *J* = 8.2 Hz, 4 H, NCH_2CH_2), 3.52 (t, *J* = 7.4 Hz, 4 H, NCH_2CH_2), 7.24 (m, 6 H, Ar*H*$^{4,4'}$, Ar*H*$^{5,5'}$, Ar*H*$^{6,6'}$), 7.67 (m, 2 H, Ar*H*$^{3,3'}$). − FAB-MS; *m*/*z*: 529 $[M + H]^+$. − No reproducible analysis could be obtained for this compound.

***N*,*N*-Di-*n*-butyl-2-mercaptobenzoylamine (L^4H):** A solution of **9** (528 mg, 1.0 mmol) and triphenylphosphane (263 mg, 1.0 mmol) in a mixture of aqueous 37% HCl (2.5 mL), water (7.5 mL), and dioxane (40 mL) was stirred overnight at 40 °C. The organic solvent was removed under reduced pressure and 100 mL of dichloromethane was added to the residue. The organic layer was washed (3×) with a saturated aqueous $NaHCO_3$ solution, dried with $MgSO_4$, filtered, and concentrated. Purification by means of flash chromatography (alumina, CH_2Cl_2/EtOH = 99:1, v/v) yielded 420 mg (80%) of L^4H as a viscous oil. − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 0.90 (m, 6 H, $CH_2CH_2CH_3$), 1.50 (m, 8 H, $CH_2CH_2CH_3$), 3.10 (t, *J* = 8.0 Hz, 2 H, NCH_2CH_2), 3.52 (t, *J* = 8.0 Hz, 2 H, NCH_2CH_2), 4.74 (s, 1 H, *SH*), 7.25 (m, 4 H, Ar*H*). − FT-IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3055 (Ar), 2958, 2932, 2872 (CH_2, CH_3), 2519 (SH), 1628 (C=O), 1462, 1425, 1377 (CH_2, CH_3), 773, 747 (ArH). − EI-MS; *m*/*z*: 265 $[M]^+$. − $C_{15}H_{23}NOS{\cdot}0.5EtOH$ (288.4): calcd. C 66.62, H 9.09, N 4.86, S 11.11; found C 66.71, H 8.64, N 5.31, S 11.01.

***N*,*N*′-(2,2′-Dithiobenzoyl)bis(4,7,10,13,16-pentaoxa-1-azacyclooctadecane) (10):** To prepare this compound, a similar procedure as described for **9** was used. Starting from 4,7,10,13,16-pentaoxa-1-azacyclooctadecane (395 mg, 1.5 mmol), 478 mg (80%) of **10** was obtained as a yellowish, viscous oil after flash chromatography (alumina, CH_2Cl_2/EtOH = 95:5, v/v). − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 3.71 (m, 24 H, OCH_2, NCH_2), 7.39 (m, 2 H, Ar*H*$^{4,4'}$), 7.62 (m, 4 H, Ar*H*$^{5,5'}$, Ar*H*$^{6,6'}$), 8.04 (m, 2 H, Ar*H*$^{3,3'}$). − FAB-MS; *m*/*z*: 835 $[M + K]^+$, 819 $[M + Na]^+$, 797 $[M + H]^+$. − $C_{38}H_{56}N_2O_{12}S_2{\cdot}0.5EtOH$ (831.2): calcd. C 56.81, H 7.31, N 3.44, S 7.88; found C 57.14, H 7.04, N 3.71, S 7.55.

2-Mercaptobenzoyl-4,7,10,13,16-pentaoxa-1-azacyclooctadecane (L^5H): This compound was prepared in a similar way as ligand L^4H. Starting from **10** (200 mg, 0.25 mmol) and triphenylphosphane (66 mg, 0.25 mmol), compound L^5H was obtained in 75% yield (150 mg) after flash chromatography (alumina, CH_2Cl_2/EtOH = 95:5, v/v). − ^{1}H NMR (90 MHz, $CDCl_3$): δ = 3.50−3.63 (m, 24 H, OCH_2, NCH_2), 3.86 (s, 1 H, *SH*), 7.25 (m, 4 H, Ar*H*). − EI-MS; *m*/*z*: 399 $[M]^+$. − No reproducible analysis could be obtained for this compound.

Synthesis of Cluster Compounds: In situ synthesis of cluster compounds **I**−**V** for initial electrochemical characterization was performed by the stepwise addition of 4−6 equivalents of thiol ligand and 4−6 equivalents of base to the appropriate amount of $(PPh_4)_2[Fe_4S_4Cl_4]$ in DMF. A stock solution of 0.081 M of $[Bu_4N]OH$ in methanol was used as the base. Differential pulse voltammograms were recorded after the addition of each equivalent ligand and base, and after equilibration. Typically, 1.8 mg (1.54 μmol) of $(PPh_4)_4[Fe_4S_4Cl_4]$ was used in these experiments. Quantitative synthesis of the cluster compounds for detailed characterization was performed by using either the chloro cluster reaction starting from $(PPh_4)_2[Fe_4S_4Cl_4]$, or the ligand exchange reaction starting from $(Bu_4N)_2[Fe_4S_4(StBu)_4]$. The starting materials, $(PPh_4)_2[Fe_4S_4Cl_4]$[31] and $(Bu_4N)_2[Fe_4S_4(StBu)_4]$[32] were synthesized using published methods.

$(Bu_4N)_2[Fe_4S_4(L^1)_4]$ (I): To a stirred solution of $(PPh_4)_2[Fe_4S_4Cl_4]$ (38.2 mg, 0.033 mmol) in 15 mL of DMF was added a solution of L^1H (65 mg, 0.163 mmol, 5 equiv.) in 5 mL DMF. After this addition was completed, 2 mL of 0.081 M $[Bu_4N]OH$ in methanol was added dropwise to the reaction mixture. After stirring for several hours, the reaction mixture was filtered and then concentrated in vacuo, followed by the addition of Et_2O to induce precipitation of the desired product. Storage at −20 °C overnight resulted in the formation of the tetrabutylammonium salt **I**, which was isolated as a black oil after decanting the supernatant and drying in vacuo (yield not determined). − ^{1}H NMR (90 MHz, $[D_6]$DMSO): δ = 0.81−1.10 [m, br., 24 H, CH_3 (NBu_4)], 1.19−1.81 [m, br., 32 H, $CH_2CH_2CH_3$ (NBu_4)], 2.68 (NCH_2, the structure of this peak is obscured by the solvent peak), 3.02−3.36 [m, 16 H, NCH_2 (NBu_4)], 3.36−3.75 (m, 104 H, OCH_2, NCH_2, NCH_2Ar), 7.20 [m, br., 4 H, Ar*H*], 7.49−7.90 (m, 12 H, Ar*H*), 15.08 [ds, br, 8 H, SCH_2]. − UV/Vis (DMF): λ_{max} (nm) = 300 (sh), 420.

$(Bu_4N)_2[Fe_4S_4(L^2)_4]$ (II): To a solution of the thiol ligand L^2H (55 mg, 0.27 mmol) in 5 mL of DMF was added dropwise a solution/suspension of $(Bu_4N)_2[Fe_4S_4(StBu)_4]$ (54.6 mg, 0.056 mmol) in 10 mL of DMF. The resulting black solution was stirred for several hours under dynamic vacuum, and overnight under N_2. After filtration, the volume was reduced in vacuo to about 1 mL and a large amount of Et_2O was added. The Schlenk vessel was placed at −20 °C overnight, which resulted in the precipitation of a black powder. The product was finally isolated by decantation of the supernatant, washing with Et_2O, and drying under vacuum. This procedure gave **II** as a black oil in 91% yield (84 mg). − ^{1}H NMR (200 MHz, $[D_6]$DMSO): δ = 0.87−0.97 (m, 48 H, CH_3), 1.29−1.56 (m, 64 H, CH_2CH_3, NCH_2CH_2), 3.18−3.33 (m, 32 H, NCH_2), 13.83 [s, br, 8 H, SCH_2]. − UV/Vis (DMF): λ_{max} (nm) = 301, 415, 620 (sh).

$(Bu_4N)_2[Fe_4S_4(L^3)_4]$ (III): This compound was prepared using the procedure described for compound **II**. Starting from L^3H (98.4 mg, 0.29 mmol, 5 equiv.) and $(Bu_4N)_2[Fe_4S_4(StBu)_4]$ (69.6 mg, 0.058 mmol), a black oil was obtained. The yield was not determined. − ^{1}H NMR (200 MHz, $[D_7]$DMF): δ = 1.05 [s, br, 24 H, CH_3 (NBu_4)], 1.49 [s, br, 16 H, CH_2CH_3 (NBu_4)], 1.85 [s, br, 16 H, NCH_2CH_2 (NBu_4)], 3.40−4.13 [m, 112 H, OCH_2, NCH_2, NCH_2 (NBu_4)], 15.35, 16.58 [d, br, 8 H, SCH_2]. − UV/Vis (DMF): λ_{max} (nm) = 300, 410, 660 (sh).

$(Bu_4N)_2[Fe_4S_4(L^4)_4]$ (IV): This compound was prepared using the procedure described for compound **II**, using L^4H (18.5 mg, 0.7 mmol, 5.8 equiv.) and $(Bu_4N)_2[Fe_4S_4(StBu)_4]$ (14.3 mg, 0.12 mmol). THF was used as the nonsolvent in the isolation of the black oil, **IV** (yield was not determined). Inspection of the ^{1}H-NMR spectrum showed that this compound was contaminated with some free ligand L^4H. − ^{1}H NMR (200 MHz, $[D_6]$DMSO): δ = 0.64−1.57 (m, 112 H, $CH_2CH_2CH_3$), 2.95−3.45 [m, 32 H, NCH_2, NCH_2 (NBu_4)], 3.73 [s, br, 4 H, *p*Ar*H*], 5.32 [s, br., 4 H, *o*Ar*H*], 7.97 [s, br., 4 H, *m*Ar*H*], 8.28 [s, br, 4 H, *m*Ar*H*]. − UV/Vis (DMF): λ_{max} (nm) = 307 (sh), 458.

$(Bu_4N)_2[Fe_4S_4(L^5)_4]$ (V): This compound was prepared using the procedure described for compound **II**. Amounts used were: 32 mg (0.08 mmol, 6.3 equiv.) of L^5H and 15.18 mg (0.013 mmol) of $(Bu_4N)_2[Fe_4S_4(StBu)_4]$. The yield of the black oil, **V**, was not determined. − ^{1}H NMR (90 MHz, $[D_6]$DMSO): δ = 0.79−1.09 [m, 24 H, CH_3 (NBu_4)], 1.09−1.78 [m, 32 H, $CH_2CH_2CH_3$ (NBu_4)], 3.01−3.94 [m, 114 H, NCH_2, OCH_2, *p*Ar*H*, NCH_2 (NBu_4)], 5.29

[s, br, 4 H, *o*Ar*H*], 7.96 [s, br, 4 H, *m*Ar*H*], 8.39 [s, br, 4 H, *m*Ar*H*]. – UV/Vis (DMF): λ_{max} (nm) = 307 (sh), 452.

Acknowledgments

This work was supported by the Dutch Foundation for Chemical Research (SON) with financial aid from the Dutch Foundation for Scientific Research (NWO). The authors would like to thank Dr. J. G. M. van der Linden for fruitful discussions and Mrs. A. M. Roelofsen for help with electrochemical experiments. In addition, R. Fokkens of the Institute for Mass Spectrometry at the University of Amsterdam is acknowledged.

[11] Kinetic studies on this type of exchange reaction have been performed by Henderson et al. They showed that in the absence of acid a thiolate ligand first dissociates from the cluster, leaving one iron center with a vacant coordination site, followed by nucleophilic attack at this center of a second thiolate. In the presence of acid, the dissociation of the first thiolate is facilitated by protonation. See: R. A. Henderson, K. E. Oglieve, *J. Chem. Soc., Dalton Trans.* **1993**, 1467–1472.

$[Hg_7As_4I_3](SnI_3)$: Trapping the SnI_3^{1-} Anion in the Cavities of the Unprecedented Mercury-Arsenic-Iodine Network

Andrei V. Olenev,[a] Alexei I. Baranov,[b] Andrei V. Shevelkov,*[a] and Boris A. Popovkin[a]

Keywords: Host–guest compounds / Tin / Mercury / Pnictide halides

A novel host–guest compound $[Hg_7As_4I_3](SnI_3)$ has been prepared by a standard ampoule technique and its crystal structure was determined. It crystallizes in a cubic system [space group $P2_13$, a = 13.110(1) Å, Z = 4] with a unique structure type. The crystal structure comprises two parts: the three-dimensional $[Hg_7As_4I_3]^{1+}$ host network, and the SnI_3^{1-} guest anions encapsulated in the cavities of the network. The network is built from the As_2Hg_7 bitetrahedra and As_2Hg_6 octahedra, which share corners, and contains an additional iodine atom connected to one of the mercury vertices. The SnI_3^{1-} anion has the shape of a pyramid with the tin atom in a vertex. According to the quantum-chemistry calculations, the geometry of the anion deviates substantially from the equilibrium one, and is influenced by the distant mercury atoms of the host network.

Introduction

The rapidly developing field of inorganic supramolecular chemistry covers a large diversity of compounds, and classes of compounds, the important feature of which is a weak interaction between host and guest units.[1] In most cases, electrically neutral hosts and guests constitute supramolecular compounds, and their interaction is normally limited to van der Waals forces. However, in compounds where hosts and guests are electrically charged, weak electrostatic host−guest interaction is expected. The "weakness" of such an interaction is sometimes illustrated by the positional and/or rotational disorder of small guest anions encapsulated in host structures, but perfectly ordered structures are not rare cases.[2]

A number of inorganic supramolecular compounds containing linearly coordinated mercury in the host substructures has been reported in the literature.[3−10] Apart from $2HgS{\cdot}SnBr_2$,[3] a unique one-dimensional host−guest compound, all mercury-based supramolecular compounds comprise charged guests and hosts. Hg_2VO_4 is the exception and contains the Hg_2^{2+} cations in the host network.[4] In all other compounds, hosts are three-dimensional cationic networks, based on divalent mercury atoms linearly coordinated by Group-15 elements. Two principal types of networks can be distinguished in these compounds according to the dimension of the voids. Channels are the characteristic feature of the Millon′s base salts[5][6] and their phosphorus and arsenic analogs,[7][8] while closed cavities form in highly symmetric mercury pnictide halides, such as $[Hg_6As_4](HgCl_6)Hg_{0.4}$ and related cases.[9][10] Different types of positional disorder of guest anions are frequently observed in both types of compounds, indicating the weakness of the host−guest interaction.[5,8−10]

The structure of host networks and the size of the voids are primarily controlled by the nature and coordination demands of the elements composing the network. In all mercury/pnicogen networks, linearly coordinated mercury atoms alternate with tetrahedrally coordinated pnicogen atoms. Pnicogens, other than nitrogen, adopt a tetrahedral coordination in any oxidation state, and at least two of them, −2 and −3, are displayed in supramolecular mercury pnictide halides.[7−10] In the −2 oxidation state, pnicogens form Z_2^{4-} dumbbells, which substantially influence the size of the voids; the greater the number of dumbbells, the smaller the size.[8] Therefore, the size of the voids does not necessarily increase on going from nitrogen to antimony. The second factor that controls the size of the voids is the nature and the size of the guest. The latter can serve as a template, and the network forms around it in the course of the synthesis. In recent work[8] we have shown that decreasing the size of the tetrahedral anion ZnX_4^{2-} from X = I to X = Cl leads to the Hg/As networks with decreasing size of the voids; and the adjustment of the network dimensions to the size of the anions occurs through a formation of the As−As bonds.

In the course of our research, aimed at the preparation of new host−guest compounds based on a mercury−pnicogen framework, we attempted the synthesis of $[Hg_6As_4](SnI_6)Hg$. Taking into account the ease of suppressing the Sn^{II} lone electron pair in the iodine environment,[11] we expected to obtain an ordered analog of a supramolecular compound $[Hg_6As_4](HgCl_6)Hg_{0.4}$.[10] The latter possesses a 3D cationic network, $[Hg_6As_4]^{4+}$, with voids of different sizes. The larger cavities are filled with regular octahedral anions $(HgCl_6)^{4-}$, while the smaller cavities are partially (40%) filled by zero-valent mercury atoms. Surprisingly, another new compound, $[Hg_7As_4I_3](SnI_3)$, having a unique crystal structure, but the same overall composition as the target phase, was obtained. In this article we report

the synthesis and crystal structure of a novel supramolecular compound $[Hg_7As_4I_3](SnI_3)$. The influence of the charged host network on the geometry of the guest $(SnI_3)^{1-}$ anion is analyzed based on the quantum-chemistry ab initio calculations.

Results and Discussion

Synthesis and X-ray Study

$[Hg_7As_4I_3](SnI_3)$ was obtained from a stoichiometric mixture of mercury, arsenic, tin, and mercury diiodide by a standard two-step ampoule synthesis at 670 K over 10 d. The almost single-phase product appears as a black polycrystalline, air-stable bulk sample, dark-brown after fine grinding. After accounting for the weak admixture reflections, an X-ray pattern taken from the sample was indexed in a primitive cubic cell with a unit cell edge $a = 13.1117(6)$ Å (Guinier data). Single crystals suitable for the structure determination were prepared by annealing the starting materials mixed in a 2:2:1:2 ratio at 670 K for 1 week in a sealed silica ampoule. The crystal structure was refined based on single-crystal X-ray data (Table 1). The refinement confirms both crystal system and composition.

[a] $R1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$. – [b] $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{1/2}$, $w = [\sigma^2(F_o^2) + 0.0310\,(F_o^2 + 2F_c^2)/3]^{-1}$.

Description of the Crystal Structure

Atomic positions, equivalent isotropic displacement parameters, and selected bond lengths and valence angles are summarized in Tables 2 and 3. Two parts of the crystal structure of $[Hg_7As_4I_3](SnI_3)$ can be subtracted: a $[Hg_7As_4I_3]^{1+}$ positively charged framework and $(SnI_3)^{1-}$ anions, which are encapsulated in the cavities of the framework (Figure 1). The $(SnI_3)^{1-}$ anion comprised of the unique tin and I(2) atoms has a shape of a trigonal pyramid with the tin atom at the vertex, the Sn−I distances and I−Sn−I angles being 2.95 Å and 90.97°, respectively. Surprisingly, we have not found any data on such an anion in literature, although the analogous $(SnCl_3)^{1-}$ anion with the same shape has been observed in various compounds.[12]

[a] U_{eq} is defined as one third of the trace of the orthogonalized U_{ij} tensor.

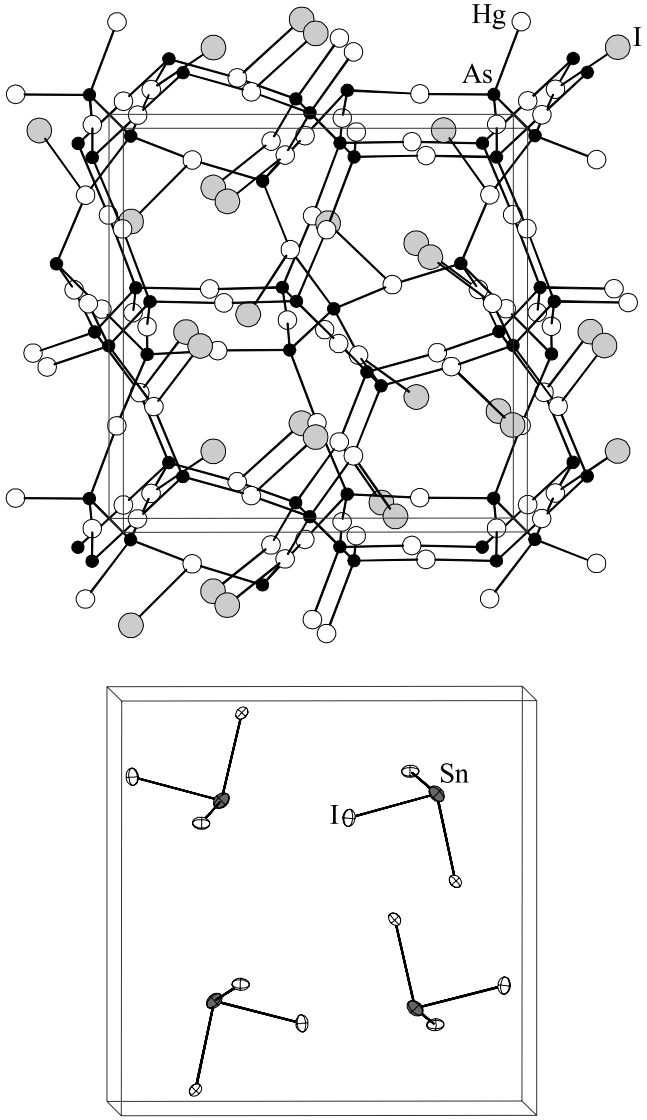

Figure 1. Building units of the crystal structure of $[Hg_7As_4I_3](SnI_3)$; a fragment of the $_\infty{}^3[Hg_7As_4I_3]^{1+}$ framework (top) and a distribution of the $(SnI_3)^{1-}$ within the unit cell (bottom)

The 3D cationic net is built of the arsenic, mercury, and one of two nonequivalent iodine atoms. Three independent mercury atoms have almost the same linear coordination of two arsenic atoms. While the coordination of the Hg(1) atom is regular, the As−Hg−As angle deviates from 180° for the Hg(2) and Hg(3) atoms. Clearly, a rather distant (3.16 Å) iodine neighbor, the I(1) atom, which we consider to belong to the cationic net, causes the departure from linearity in the case of the Hg(2) atom. The Hg−I separation of 3.16 Å is noticeably longer than the covalent interactions in all three forms of HgI_2 (2.62−2.78 Å),[13] but is only slightly longer than the Hg−I distances in various mercury pnictide iodides (3.03−3.14 Å).[14]

Four independent arsenic atoms have a tetrahedral coordination of two different types. The As(1) and As(2) atoms are surrounded by four mercury atoms. These two tetrahedra are connected through the common Hg(1) atom, forming a bitetrahedral As_2Hg_7 unit (Figure 2). The As(3) and As(4) atoms are joined in an As−As dumbbell, and each of them completes its tetrahedral coordination with three mercury atoms. Six mercury atoms thus surround the dumbbell, forming an As_2Hg_6 octahedron (Figure 2). The bitetrahedra and octahedra share vertices to compose the cationic net, the polyhedral presentation of which is drawn in Figure 3. It should be mentioned that the analogous building blocks, the P_2Hg_6 octahedra and P_2Hg_7 bitetrahedra, are found in $Hg_9P_5I_6$,[15] which, however, possesses another type of crystal structure.

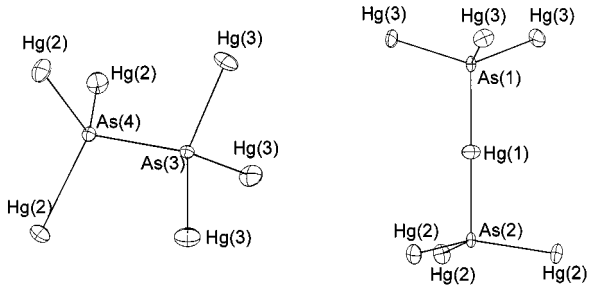

Figure 2. Coordination of the arsenic atoms in $[Hg_7As_4I_3](SnI_3)$ (50% probability ellipsoids)

The As−As separation of 2.40 Å is usual for numerous pnictide halides containing As_2^{4-} anions.[8,10,16,17] It falls in the range of 2.37−2.43 Å, where the shortest and longest distances refer to $Hg_4As_2Br_3$[10] and $Hg_{19}As_{10}Br_{18}$,[17] respectively. The As−Hg distances (2.46−2.53 Å) are also typical for the mercury arsenide halides,[8,10,17] and do not depend much on the formal oxidation state of the arsenic atoms, −3 for As(1) and As(2), and −2 for As(3) and As(4). The absence of the Hg−Hg bonds indicates that the oxidation state +2 can be assigned to the mercury atoms, and hence the crystallographic formula $[(Hg^{2+})_7(As^{3-})_2(As_2^{4-})(I^{1-})_3](SnI_3)^{1-}$ can be derived for the title compound. The formula reflects an unusual composition of the cationic network. To our knowledge, it is the second example of the mercury-based supramolecular compound, which has a halogen atom as a part of the cationic net. A host−guest compound $[Hg_9As_4Br_2](Bi_2Br_{10})$ has been reported[18] to contain two bromine atoms per network formula.

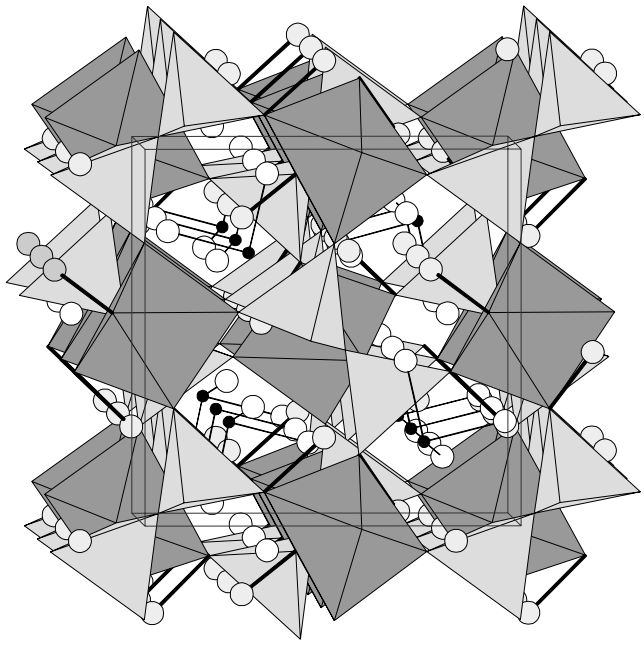

Figure 3. A polyhedral presentation of the crystal structure of $[Hg_7As_4I_3](SnI_3)$; polyhedra: As_2Hg_6 octahedra, dark gray; As_2Hg_7 bitetrahedra, light gray; atoms: tin, filled circles; I(1), shaded circles; I(2), open circles

Theoretical Study of SnI_3^{1-}

The SnI_3^{1-} anion encapsulated in the closed cavities of the three-dimensional network exhibits a geometry well predicted by the Gillespie-Nyholm rules.[19] Qualitatively, one can expect a pseudo-tetrahedral arrangement of three iodine atoms and one lone electron pair around the Sn^{2+} cation in an isolated $(SnI_3)^{1-}$ anion, with I−Sn−I angles being lower than regular tetrahedral ones. The Extended Hückel[20] calculations, performed on the anion having the geometry found from the structure refinement, show (Figure 4) that the $4a_1$ orbital, the HOMO, has the greatest contribution from the tin 5s and $5p_z$ atomic orbitals. These orbitals interact slightly with the iodine 5p orbitals (namely, $5p_z$ orbitals if each iodine atom resides on its local coordinate system with z axis pointing to the tin atom). The resulting orbital, the HOMO, can be considered as a lone electron pair, as visualized in Figure 5.

The anion trapped in the 3D cationic net, however, may feel the influence of the charged net. While the Sn−I(1) separation is rather distant (3.63 Å), the I(2) atom, which belongs to the anion, lies not very far from three mercury atoms, which belong to the cationic framework. The respective distances of 3.36−3.43 Å significantly exceed the sum of the respective covalent radii, but are even shorter than the longest Hg−I separation of 3.51 Å observed in the structure of the yellow modification of HgI_2.[13] Thus, a slight "host−guest" interaction is expected to affect the geometry of the anion under consideration. To obtain the

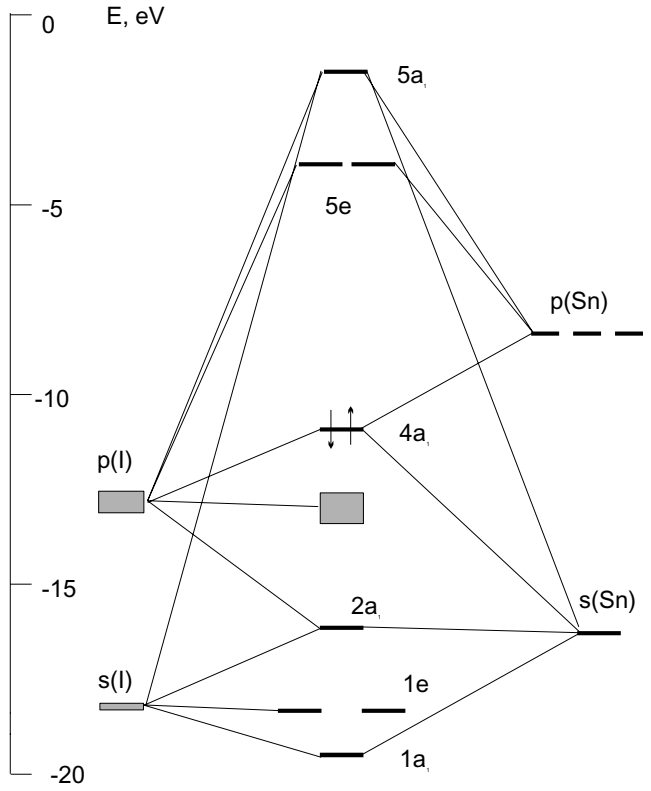

Figure 4. The Extended Hückel molecular orbital diagram for the $(SnI_3)^{1-}$ anion in $[Hg_7As_4I_3](SnI_3)$; mainly nonbonding orbitals in the energy range of −13.3 to −12.5 eV, localized on the iodine atoms, are shown as a dashed box

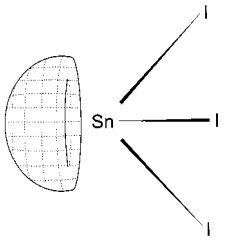

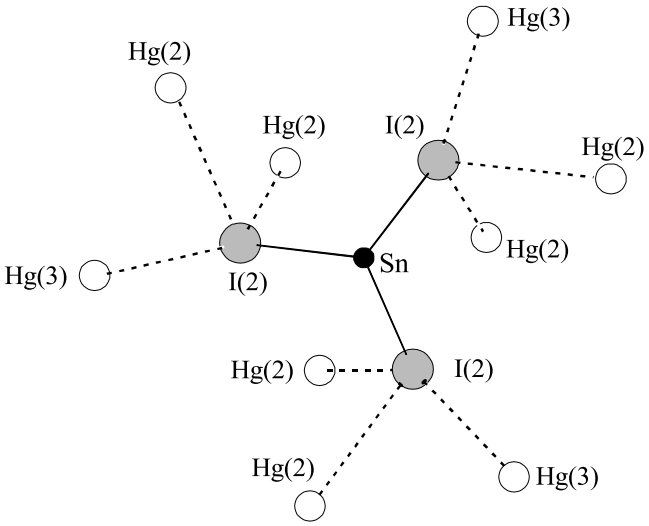

Figure 5. The shape of the $4a_1$ orbital (HOMO) of the isolated $(SnI_3)^{1-}$ anion from the Extended Hückel calculations

equilibrium geometry of $(SnI_3)^{1-}$, quantum-chemistry ab initio RHF calculations[21] were performed. The geometry of the $(SnI_3)^{1-}$ anion was optimized with both Sn−I bond lengths frozen at d(Sn−I) = 2.95 Å (C_{3v} symmetry) and without any constraints (C_{3v} and C_s symmetries). Constraint-free calculations converged at 2.900 Å Sn−I bond length and 99.18° I−Sn−I bond angle. These values deviate significantly from 2.952(3) Å and 90.9(1)° found from the structure refinement. Only marginal geometry differences were encountered between anions optimized in the C_s and C_{3v} point groups. Optimization with the frozen Sn−I bond length resulted in less than 0.2° I−Sn−I angle difference with the fully optimized ion. The results of the calculations can be explained with the help of Figure 6, which shows the arrangement of the distant mercury atoms of the network around the $(SnI_3)^{1-}$ anion. The observed $(SnI_3)^{1-}$ anion exhibits a Sn−I bond length 0.05 Å longer than the equilibrium bond length, and such an elongation indicates a slight bonding interaction of the iodine atoms with the mercury atoms. Evidently, the almost 9° difference in the I−Sn−I bond angle is also caused by the same I−Hg interaction, since the optimization with the Sn−I distance frozen at 2.95 Å gives the same I−Sn−I angle as the full optimization. Therefore, the observed I−Sn−I bond angle value of 90.9° is obviously a result of the "combined influence" (a vector sum) of nine mercury atoms on the anion under consideration.

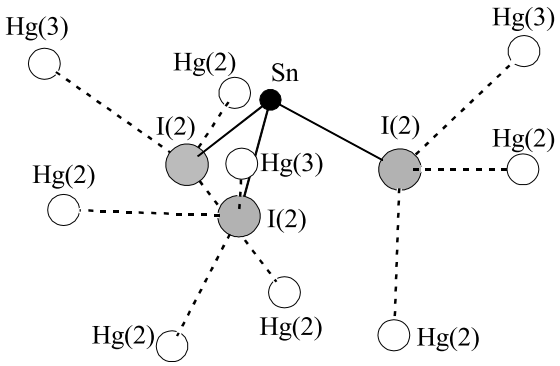

Figure 6. Arrangement of the distant mercury atoms around the $(SnI_3)^{1-}$ anion in the structure of $[Hg_7As_4I_3](SnI_3)$: a) a view along the 3-fold axis; b) a side-view almost along a (011) direction of the unit cell

Conclusions

$[Hg_7As_4I_3](SnI_3)$ is a novel host−guest compound possessing two interesting structural features. Firstly, the cationic network is composed not only of mercury and arsenic, but also iodine atoms. Secondly, the closed cavities are filled with the $(SnI_3)^{1-}$ anions, which have never been observed as guest units in supramolecular compounds. The positions

of the SnI_3^{1-} anions within the unit cell are accurately determined; no sign of positional and/or rotational disorder has been observed during the structure refinement. Together with deviation of the observed anion geometry from that at equilibrium, this indicates the existence of a weak host−guest interaction in the title compound, the nature of which was not investigated in this work. However, such an interaction seems to be very important in the formation of compounds. Evidently, being isolated from each other in the closed cavities of the 3D network, the anions cannot exhibit ion exchange, nor can they enter the well-formed net. The net itself carries a positive charge, and hence cannot exist without anionic guests. Consequently, the title compound can only form spontaneously during the synthesis through a self-assembly process.

Experimental Section

Synthesis: Liquid mercury, gray arsenic, tin powder and mercury diiodide (all > 99.9% purity) were mixed in a 4:4:1:3 molar ratio. The mixture (1 g) was vacuum-sealed in a silica tube and annealed for 10 d at 670 K with intermediate grinding. An X-ray analysis (Guinier FR-552, Nonius) of the product revealed traces of unchanged starting materials, while most reflections belonged to a new phase. The corresponding reflections were indexed in a cubic system with a unit cell parameter a = 13.1117(6) Å. For the single-crystal preparation, the starting materials were mixed in a molar ratio 2:2:1:2 and vacuum-sealed in a silica tube, 60 mm in length and 7 mm inner diameter. The ampoule was placed in a vertical furnace, heated slowly (30°/h) to 670 K and exposed to this temperature for 1 week. After cooling to room temperature at 30°/h, well-formed black crystals were found all over the ampoule. The crystals were separated mechanically, and an X-ray analysis confirmed them to be the desired phase.

Crystal Structure Determination: A suitable single crystal (0.25 × 0.1 × 0.05 mm) was selected from the sample and mounted on a CAD-4 (Nonius) goniometer head for structure investigation. A cubic unit cell parameter a = 13.110(1) Å was refined based on 24 well-centered reflections in the angular range 10.56° < θ < 13.47°. Data were collected at ambient temperature in the ω-2θ scan mode with data collection parameters listed in Table 1. A semi-empirical absorption correction was applied to data based on ψ-scans of 6 reflections having their χ angles close to 90°. Analysis of systematic reflection conditions showed that two space groups $P2_13$ (No. 198) and $P4_232$ (No. 208) were the possibilities. The refinement was successful in the lower symmetry space group $P2_13$. Positions of mercury, tin and iodine atoms were found by direct methods. Arsenic atoms were localized by a sequence of Δρ(xyz) syntheses and least square cycles. The final anisotropic refinement on F^2 led to R_1 = 0.0464 and wR_2 = 0.0939. All calculations were carried out using SHELX97 programs.[22] Further details of the crystal structure determination may be obtained from Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository number CSD-410814.

Computational Aspects: Extended Hückel calculations were carried out on the $(SnI_3)^{1-}$ anion, with the geometry found from the crystal structure refinement (Table 3) using CACAO program.[23] Atomic orbital parameters were taken from the literature.[24] Ab initio RHF calculations were performed using GAMESS-US program. SBKJC effective core potentials applied to all atoms and SBKJC basis set[25] implemented in GAMESS were used. Starting geometry of the $(SnI_3)^{1-}$ was taken from the crystal structure refinement. Geometry optimizations were performed by the quasi-Newton algorithm[26] implemented in GAMESS. The followed Hessian computation and normal vibration analysis showed all stationary points located to be minima.

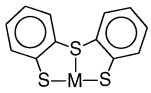
Transition Metal Complexes with Sulfur Ligands, 139[+]

Synthesis and Exchange Reactions of Sulfur-Rich Nickel and Palladium [M(L)('S_3')] Complexes ['S_3'$^{2-}$ = Bis(2-mercaptophenyl)sulfide(2–)]

Dieter Sellmann,*[a] Franz Geipel,[a] and Frank W. Heinemann[a]

Dedicated to Professor Egon Uhlig on the occasion of his 70th birthday



Keywords: Nickel complexes / Palladium complexes / S ligands / Exchange reactions / Azide / Sulfinylimide

In order to obtain suitable precursors for nickel and palladium complexes that model the reactivity of the active sites of hydrogenases and CO dehydrogenases, a series of [M(L)('S_3')] complexes has been synthesized [M = Ni^{II}, Pd^{II}; 'S_3'$^{2-}$ = bis(2-mercaptophenyl)sulfide(2–)]. X-ray structure determinations of [Ni('S_3')]$_3$ (**1**) and [Pd('S_3')]$_3$ (**2**) have revealed that the [M('S_3')] fragments trimerize to give six-membered [MS]$_3$ rings, which exhibit chair conformations with alternating M^{II} centers and thiolate bridging atoms. Reactions of the parent complex [Ni('S_3')]$_3$ (**1**) with nucleophiles L, such as thiolates SR^- (R = *t*Bu, Cy, Me, Ph), phosphanes PR_3 (R = Cy, Ph), chloride, or azide, have been found to yield the corresponding anionic or neutral [Ni(L)('S_3')] complexes, which were isolated as (NBu_4)[Ni(SR)('S_3')] [R = *t*Bu (**3**), Cy (**4**), Me (**5**), Ph (**6**)], [Ni(PR_3)('S_3')] [R = Cy (**7**), Ph (**8**)], (NBu_4)[Ni(Cl)('S_3')] (**9**), and (NBu_4)[Ni(N_3)('S_3')] (**10**). When treated with Me_3SiX, the S*t*Bu$^-$ ligand in (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**) was exchanged to give (NBu_4)[Ni(X)('S_3')] [X = Cl^- (**9**), N_3^- (**10**), NCS^- (**11**), NSO^- (**12**)]. The palladium complex [Pd('S_3')]$_3$ (**2**) could also be cleaved with S*t*Bu$^-$, but the resulting (NBu_4)[Pd(S*t*Bu)('S_3')] (**13**) proved inert towards exchange reactions with Me_3SiX. All the mononuclear complexes have been characterized by standard spectroscopic techniques and by elemental analysis. The molecular structures of **3**, **4**, **6**, **7**, **8**, **9**, and **13** have been determined by X-ray crystallography. The [MS_3L] core geometries of all the complexes are non-planar, exhibiting a considerable tetrahedral distortion.

Introduction

Much of the current interest in nickel thiolate−thioether complexes stems from the discovery that nickel in sulfur-rich coordination spheres forms the active centers of enzymes such as hydrogenases[1] and CO dehydrogenases.[2] In the quest for model compounds of these enzymes, a considerable number of new nickel complexes with different donor sets and geometries has been synthesized.[3,4,5] However, complexes exhibiting structural (Ni−S coordination) and functional (catalysis of enzyme reactions) features of the enzymes have remained extremely rare. Our search for such compounds has recently yielded complexes containing [M('S_3')] fragments (M = Ni, Pt) with the tridentate ligand 'S_3'$^{2-}$ = bis(2-mercaptophenyl)sulfide(2−).[6]

The [M('S_3')] fragments with d^8 electron metal(II) centers were anticipated to have an accessible site for the coordination and activation of substrates. With regard to hydrogenases, dihydrogen and hydride are, of course, the substrates of primary interest. Unfortunately, however, all attempts to coordinate these species to [Ni('S_3')] fragments have to date been unsuccessful,[6] despite the fact that NMR spectroscopic investigations have yielded conclusive evidence for the formation of [Pt(H)('S_3')]$^-$.[6] Further experiments showed that a favored reaction of [M('S_3')] fragments is oligomerization to give either dinuclear [Ni('S_3')]$_2$ or trinuclear [Pt('S_3')]$_3$. These complexes contain thiolate bridges, which block the fourth coordination site at the metal centers. As a consequence, they are extremely sparingly soluble in all common solvents such that homogeneous phase reactions are prevented. The thiolate bridges in [Ni('S_3')]$_2$ or [Pt('S_3')]$_3$ may be cleaved by nucleophiles such as PMe_3 or cyanide. The resulting mononuclear [M(L)('S_3')] derivatives are much more soluble than the parent complexes, but the coligands L proved to be inert.[6] Thus, the aim of the work described herein was to obtain [M(L)('S_3')] species with exchangeable coligands L and thus a readily accessible coordination site.

Results

Cleavage of [Ni('S_3')]$_3$ and Substitution Reactions of [Ni(L)('S_3')] Complexes (L = PR_3, SR^-)

The extremely insoluble [Ni('S_3')]$_2$ parent complex has previously been obtained from $Ni(ac)_2 \cdot 4\,H_2O$ and 'S_3'-H_2.[6] A solvothermal recrystallization from hot DMF (175°C) in a sealed ampoule yielded single crystals, X-ray structure analysis of which showed the product to contain dinuclear [Ni('S_3')]$_2$. On repeating the synthesis, we have now obtained single crystals from the mother liquor of the reaction solution at room temperature. An X-ray structure determination of these crystals revealed that they consisted of the trinuclear [Ni('S_3')]$_3$ (**1**). Complex **1** is structurally analogous to [Pt('S_3')]$_3$ and shows that the crystallization conditions can influence the trimerization vs. dimerization of [Ni('S_3')] fragments. These results prompted us to synthesize [Pd('S_3')]$_3$ (**2**) as well (for the sake of completeness). Complex **2** was obtained from 'S_3'-Li_2 and [$PdCl_2$(COD)] (Scheme 1).

Scheme 1. Synthesis and reactions of [Ni('S_3')] and [Pd('S_3')] complexes

In order to achieve an all-sulfur coordination of the nickel center, we first examined reactions of [Ni('S_3')]$_3$ with thiolates. Both small and sterically demanding thiolates, such as SMe^- and SCy^-, gave essentially the same results. When black-brown THF suspensions of [Ni('S_3')]$_3$ (**1**) were treated with MeOH solutions of the respective NaSR salts at room temperature, dark-brown solutions resulted. Addition of NBu_4OH and subsequent workup yielded the dark-brown to black salts (NBu_4)[Ni(SR)('S_3')] with R = *t*Bu (**3**), Cy (**4**), Me (**5**), and Ph (**6**). These salts were found to be readily soluble in THF, acetone, MeOH, and CH_2Cl_2, but insoluble in Et_2O and *n*-hexane. The molecular structures of (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**), (NBu_4)[Ni(SCy)('S_3')] (**4**), and (NBu_4)[Ni(SPh)('S_3')] (**6**) were determined by X-ray diffraction analysis.

Reactions with the bulky phosphanes PCy_3 and PPh_3 were then investigated in order to probe the lability of the phosphanes and the potential for formation of agostic C−H···Ni interactions in [Ni(PR_3)('S_3')] complexes. The [Ni(PR_3)('S_3')] complexes with R = Cy (**7**), Ph (**8**) were readily formed from THF suspensions of [Ni('S_3')]$_3$ and the respective phosphanes. They were fully characterized but proved as inert to substitution as [Ni(PMe_3)('S_3')]. No agostic C−H···Ni interactions could be detected, neither by X-ray structure determinations nor by ^{1}H-NMR spectra.

Halides and Pseudohalides as Nucleophiles

Initial attempts to cleave [Ni('S_3')]$_3$ with weak nucleophiles such as chloride from NMe_4Cl to give the [Ni(Cl)('S_3')]$^-$ anion invariably proved unsuccessful. However, this anion was readily formed when the S*t*Bu derivative (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**) was treated with Me_3SiCl. The resulting (NBu_4)[Ni(Cl)('S_3')] (**9**) has been fully characterized and its molecular structure has been determined by X-ray diffraction analysis.

Since these results proved the viability of [Ni(Cl)('S_3')]$^-$, we repeated the attempts to cleave [Ni('S_3')]$_3$ directly with chloride, but employed NBu_4Cl instead of NMe_4Cl. Indeed, when suspensions of [Ni('S_3')]$_3$ in THF were treated with equimolar amounts of NBu_4Cl at room temperature, (NBu_4)-[Ni(Cl)('S_3')] (**9**) was formed in yields in excess of 70%. Analogously, (NBu_4)[Ni(N_3)('S_3')] (**10**) was obtained first from (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**) and Me_3SiN_3 and subsequently from the direct reaction between [Ni('S_3')]$_3$ and NBu_4N_3. Syntheses of (NBu_4)[Ni(NCS)('S_3')] (**11**) and (NBu_4)[Ni(NSO)('S_3')] (**12**) required the "silylating" procedure. Thus, complexes **11** and **12** were obtained from (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**) using Me_3SiNCS and Me_3Si-NSO, respectively. The driving force behind these syntheses is presumably the formation of Me_3SiS*t*Bu. Attempts to obtain (NBu_4)[Ni(NCO)('S_3')] using either of the aforementioned two methods proved unsuccessful.

The palladium complex [Pd('S_3')]$_3$ (**2**) could also be cleaved with S*t*Bu$^-$ to yield (NBu_4)[Pd(S*t*Bu)('S_3')] (**13**). Exploratory experiments showed the S*t*Bu$^-$ ligand in **13** to be inert. For example, treatment of **13** with Me_3SiX (X = Cl, N_3, NCS, or NSO) did not yield the corresponding [Pd(X)('S_3')]$^-$ ions.

Characterization of Complexes and Monitoring of Reactions

All the complexes are diamagnetic and have been characterized by standard spectroscopic techniques and elemental

analysis. Several of the complexes have also been characterized by X-ray structure analysis. In contrast to the extremely insoluble starting complexes [M('S_3')]$_3$, all [M(L)('S_3')] derivatives with phosphane or anionic coligands L proved sufficiently soluble in THF, acetone, or CH_2Cl_2 to allow recording of their NMR spectra. The solutions are black-brown (**3**−**6**), orange (**12**), red (**7**, **8**, **11**, **13**), or violet (**9**, **10**).

The ^{1}H-NMR splitting pattern of the aromatic protons is a typical feature of the [M('S_3')] fragment and can be used as a "fingerprint" of the individual complexes since

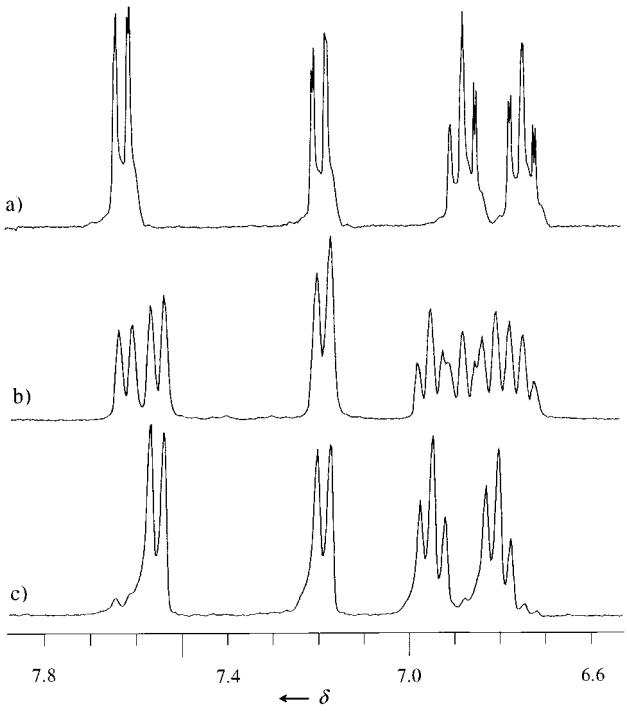

Figure 1. Aromatic region of the ^{1}H-NMR spectra of (a) (NBu_4)[Ni(S*t*Bu)('S_3')] in [D_8]THF, (b) 2 h after addition of Me_3SiN_3, and (c) after 12 h and almost complete formation of (NBu_4)[Ni(N_3)('S_3')]

the multiplet shifts specifically depend on the coligands L.

Figure 1 illustrates the ^{1}H-NMR spectroscopic monitoring of the reaction between (NBu_4)[Ni(S*t*Bu)('S_3')] (**3**) and Me_3SiN_3. The clean aromatic multiplets demonstrate that complex **3** is converted into the azido complex **10** without the formation of any other complexes as by-products. This is further corroborated by the IR spectrum and, in particular, the UV/Vis spectrum of the reaction solution, which shows two isosbestic points (Figure 2). In all cases, the ^{13}C{^{1}H}-NMR spectra of the mononuclear complexes exhibit six ^{13}C signals for the twelve aromatic C atoms of the 'S_3' ligand, in accordance with the twofold symmetry of the [M('S_3')] fragments. Strong and characteristic bands in the IR spectra are well suited for identifying the complexes **10** (2037 cm^{-1}), **11** (2105 cm^{-1}), and **12** (1230, 1030 cm^{-1}).

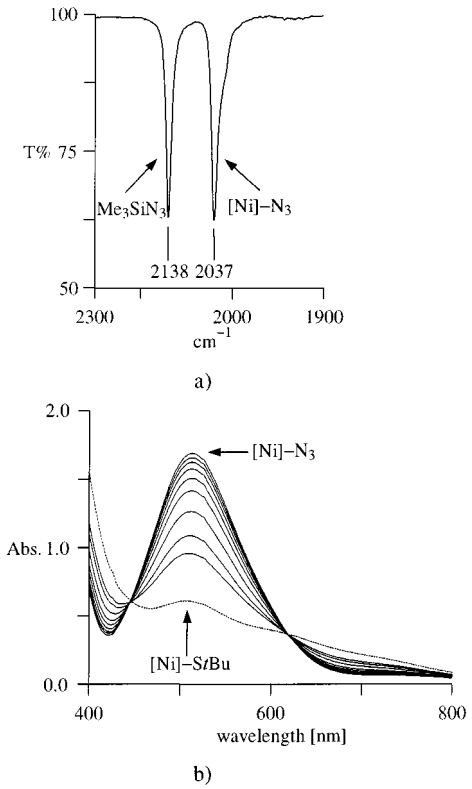

Figure 2. (a) IR spectrum of the reaction solution containing (NBu_4)[Ni(S*t*Bu)('S_3')], Me_3SiN_3, and the resulting (NBu_4)[Ni(N_3)('S_3')], (b) UV/Vis monitoring of the reaction between (NBu_4)[Ni(S*t*Bu)('S_3')] and Me_3SiN_3 in THF

X-ray Structure Determinations

Several of the complexes were obtained in the form of single crystals suitable for X-ray structure analysis. Figure 3 depicts the mononuclear structures, showing different views of the individual species. Table 1 lists selected distances and angles.

All the complexes were found to consist of discrete molecules or ions. The [M('S_3')] fragments invariably exhibit the characteristic butterfly-shape, which arises from the rigid 'S_3' topology and sp^3 hybridization of the central S(thicether) donor.[6] The 'S_3' topology is also responsible for the tetrahedral distortion of the [MS_3L] cores, which are not planar as might have been expected for low-spin four-coordinate d^8 electron metal(II) centers. Figure 4 illustrates this tetrahedral distortion in [Ni(Cl)('S_3')]$^-$.

Distances and angles show no anomalies. It has been pointed out previously that the M−S(thiother) distances are invariably shorter than the corresponding M−S(thiolate) distances and are practically unaffected by the *trans* ligands L. Because the ligands used here range from "hard" chloride, through "soft" σ-π donating thiolates, to σ-donor/π-acceptors such as phosphanes, the [M('S_3')] fragments evidently also exhibit the structural invariance that has previously been noted as a typical feature of [MS_x] centers.[7] The molecular structure of the PCy_3 complex [Ni(PCy_3)('S_3')] (**7**) differs from those of all the other complexes in that it has crystallographic C_S symmetry.

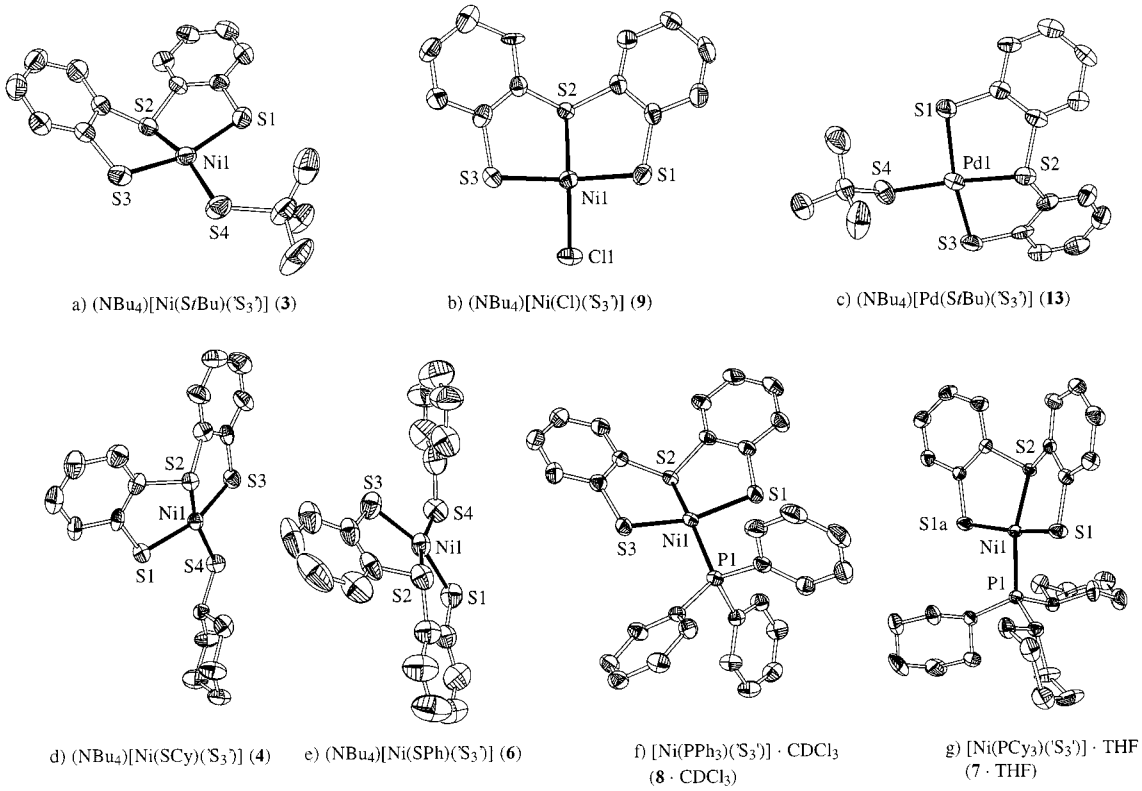

Figure 3. ORTEP plots of (a) $(NBu_4)[Ni(StBu)('S_3')]$ (**3**), (b) $(NBu_4)[Ni(Cl)('S_3')]$ (**9**), (c) $(NBu_4)[Pd(StBu)('S_3')]$ (**13**), (d) $(NBu_4)[Ni(SCy)('S_3')]$ (**4**), (e) $(NBu_4)[Ni(SPh)('S_3')]$ (**6**), (f) $[Ni(PPh_3)('S_3')] \cdot CDCl_3$ (**8** · $CDCl_3$), and (g) $[Ni(PCy_3)('S_3')] \cdot THF$ (**7** · THF); 50% probability ellipsoids; hydrogen atoms, solvent molecules and counterions omitted for the sake of clarity; different projections were chosen to illustrate the tetrahedral distortion of the $[M('S_3')]$ fragments

[a] S3 = S1a (symmetry code: x, $-y - {}^1/_2$, z).

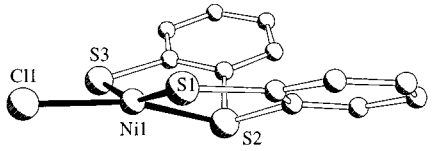

Figure 4. View showing the tetrahedral $[NiClS_3]$ core distortion in $[Ni(Cl)('S_3')]^-$

Figure 5 depicts views of the two trinuclear $[M('S_3')]_3$ complexes **1** and **2** from different angles, while Table 2 lists selected distances and angles. Like the previously described $[Pt('S_3')]_3$ complex,[6] the trinuclear $[Ni('S_3')]_3$ (**1**) and $[Pd('S_3')]_3$ (**2**) exhibit a cyclohexane-like $[M^{II}S]_3$ six-membered ring with a chair conformation that leads to a characteristic propeller-like twist of the three $[M('S_3')]$ units (Figure 5b). Related structures have been found for $[Ni('\mu\text{-}S_2C_3Me_2')]_3$,[5e] $[Ni('t BuS_4')]_3$,[8] and $[Pd(SC_2H_4SC_2H_4S)]_3$.[9]

Concluding Discussion

The trinuclear complex $[Ni('S_3')]_3$ (**1**) has been characterized. Complex **1** and the similarly new $[Pd('S_3')]_3$ (**2**) now complete the series of $[M('S_3')]_3$ complexes with Ni^{II}, Pd^{II}, and Pt^{II}. The extremely sparingly soluble $[Ni('S_3')]_3$ (**1**) gave

[a] L = S3a (symmetry code: $-y-1, x-y-1, z$). − [b] M2 = Ni1b (symmetry code: $-x+y, -x-1, z$). − [c] Three independent $[Pd('S_3')]$ units. − [d] Pd2−S4. − [e] Pd3−S7. − [f] L = S9. − [g] L = S3. − [h] L = S6. − [i] Pd2−Pd3. − [j] Pd3−Pd1. − [k] S6−S9. − [l] Pd2−S6−Pd3. − [m] Pd3−S9−Pd1.

mononuclear $[Ni(L)('S_3')]$ complexes with L = thiolates, phosphanes, halides, and pseudohalides, which proved to be much more soluble than **1**. The chloro ligand in $(NBu_4)[Ni(Cl)('S_3')]$ (**9**) and the S*t*Bu$^-$ ligand in $(NBu_4)[Ni(S\mathit{t}Bu)('S_3')]$ (**3**) were found to be labile, making **3** and **9** suitable starting materials for the synthesis of other $[Ni(L)('S_3')]$ complexes that had previously been found to be inaccessible by direct reaction of $[Ni('S_3')]_3$ and the respective L. It is noteworthy that $(NBu_4)[Ni(N_3)('S_3')]$ (**10**) represents one of the few azido complexes in which a hard azide ligand is bound to a sulfur-rich metal complex fragment.[10] Very few such NSO complexes have been reported[11] and, to the best of our knowledge, $(NBu_4)[Ni(NSO)('S_3')]$ (**12**) represents the first NSO complex with an $[MS_x]$ center.

Experimental Section

General Methods: Unless noted otherwise, all reactions and operations were carried out under nitrogen using standard Schlenk techniques. Solvents were dried and distilled prior to use. − As far as possible, reactions were monitored by IR or NMR spectroscopy. Spectra were recorded on the following instruments: IR (KBr discs or CaF_2 cuvettes, solvent bands were compensated): Perkin−Elmer 983, 1620 FT-IR, and 16PC FT-IR. − NMR: Jeol JNM-GX 270, EX 270, and Lambda LA 400 with the residual protio-solvent signal used as an internal reference. Chemical shifts are quoted on the δ scale (downfield shifts are positive) relative to tetramethylsilane (^1H, $^{13}C\{^1H\}$ NMR) or 85% H_3PO_4 ($^{31}P\{^1H\}$ NMR); spectra were recorded at 25°C. − UV/Vis: Shimadzu UV3101 PC spectrophotometer. − Mass spectra: Jeol MSTATION 700 spectrometer. − Elemental analyses: Carlo Erba EA 1106 or 1108 analyzer. − Me_3SiCl, Me_3SiN_3, Me_3SiNCS, NBu_4Cl, and PR_3 were purchased from either Aldrich or Fluka;

'S_3'-H_2,[6] [$PdCl_2$(COD)],[12] and Me_3SiNSO[13] were prepared according to literature methods.

[Ni('S_3')]$_3$ (1): A solution of 'S_3'$-H_2$ (4.327 g, 17.28 mmol) in THF (70 mL) was added dropwise to $Ni(ac)_2 \cdot 4\ H_2O$ (4.300 g, 17.28 mmol) in MeOH (10 mL) and the resulting brown suspension was refluxed for 4 h. The black-brown precipitate was then separated by filtration, washed with THF (50 mL), and dried in vacuo. A second batch of the product was obtained in the form of single crystals on slow evaporation of the solvent from the filtrate at room temperature. Yield: 5.093 g of **1**·THF (89%). − $C_{40}H_{32}Ni_3OS_9$ (993.41): calcd. C 48.36, H 3.25, S 29.05; found C 48.01, H 3.03, S 30.58.

[Pd('S_3')]$_3$ (2): A solution of 'S_3'$-H_2$ (1.327 g, 5.3 mmol) in THF (30 mL) was combined with *n*BuLi (4.24 mL, 10.6 mmol) at −50°C and the mixture was subsequently allowed to warm to room temperature. Addition of [$PdCl_2$(COD)] led to a dark-red reaction mixture, which was stirred at room temperature overnight and then stored at −30°C for 24 h. A brown solid precipitated, which was separated, washed with MeOH/THF, and dried in vacuo. Yield: 1.536 g of **2** · THF (77%). − $C_{40}H_{32}OPd_3S_9$ (1136.48): calcd. C 42.28, H 2.84, S 25.39; found C 42.29, H 2.71, S 24.79.

(NBu$_4$)[Ni(SR)('S_3')], where R = *t*Bu (3), Cy (4), Me (5), Ph (6) − General Procedure: The appropriate thiol was first deprotonated in MeOH by the addition of one equivalent of NaOMe or LiOMe. The resulting solution was then combined with a black-brown suspension of [Ni('S_3')]$_3$ (**1**) in THF and the mixture was stirred until all the solid material had dissolved (ca. 30 min). One equivalent of NBu_4OH in MeOH was then added and all volatile components were removed in vacuo. The residue obtained was taken up in THF (ca. 20 mL), undissolved material was removed by filtration, and the filtrate was concentrated to one-third of its original volume. On layering with Et_2O or *n*-hexane, black crystals precipitated, which were separated after 4 d, washed with Et_2O (60 mL), and dried in vacuo.

(NBu$_4$)[Ni(S*t*Bu)('S_3')] (3): 1.685 g (1.83 mmol) of **1**; 5.1 mL (5.61 mmol) of a 1.1 M solution of NaS*t*Bu in MeOH; 6.9 mL (5.52 mmol) of a 0.8 M solution of NBu_4OH in MeOH; 30 mL of THF. Yield: 1.858 mg (53%). − $C_{32}H_{53}NNiS_4$ (638.71): calcd. C 60.18, H 8.36, N 2.19, S 20.08; found C 60.14, H 8.81, N 2.29, S 19.47. − ^{1}H NMR (269.6 MHz, [D_6]acetone): δ = 7.67 (d, 2 H, C_6H_4), 7.22 (d, 2 H, C_6H_4), 6.94 (m, 2 H, C_6H_4), 6.82 (m, 2 H, C_6H_4), 3.48 (t, 8 H, NCH_2), 1.77 (m, 8 H, NCH_2CH_2), 1.50 (s, 9 H, $SCCH_3$), 1.37 [m, 8 H, $N(CH_2)_2CH_2$], 0.90 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (100.4 MHz, [D_6]acetone): δ = 158.0, 134.3, 129.8, 128.2, 128.0, 121.0 (C_6H_4), 59.4 (NCH_2), 40.1 ($SCCH_3$), 37.5 ($SCCH_3$), 24.6, 20.3 [$NCH_2(CH_2)_2$], 13.9 [$N(CH_2)_3CH_3$].

(NBu$_4$)[Ni(SCy)('S_3')] (4): 1.365 g (1.48 mmol) of **1**; 8.84 mL (4.42 mmol) of a 0.5 M solution of NaSCy in MeOH; 4.44 mL (4.44 mmol) of a 1.0 M solution of NBu_4OH in MeOH; 50 mL of THF. Yield: 2.508 g (85%). − $C_{34}H_{55}NNiS_4$ (664.78): calcd. C 61.43, H 8.34, N 2.11, S 19.29; found C 61.35, H 8.45, N 2.19, S 18.68. − ^{1}H NMR (269.6 MHz, [D_6]acetone): δ = 7.65 (d, 2 H, C_6H_4), 7.20 (d, 2 H, C_6H_4), 6.94 (m, 2 H, C_6H_4), 6.82 (m, 2 H, C_6H_4), 3.49 (t, 8 H, NCH_2), 2.43−1.10 [m, 27 H, $NCH_2(CH_2)_2$, SC_6H_{11}], 0.90 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.8 MHz, [D_6]acetone): δ = 157.2, 134.7, 129.8, 128.4, 128.1, 121.2 (C_6H_4), 69.3, 59.5, 39.9, 29.6, 29.4, 24.7, 20.4, 14.1 (SC_6H_{11}, $NC_{16}H_{36}$).

(NBu$_4$)[Ni(SMe)('S_3')] (5): 369 mg (0.41 mmol) of **1**; 12.32 mL (1.23 mmol) of a 0.1 M solution of LiSMe in MeOH; 1.50 mL (1.20 mmol) of a 0.8 M solution of NBu_4OH in MeOH; 20 mL of THF. Yield: 494 mg (69%). − $C_{29}H_{47}NNiS_4$ (596.63): calcd. C 58.38, H 7.94, N 2.35, S 21.49; found C 58.11, H 8.27, N 2.39, S 21.39. − ^{1}H NMR (269.6 MHz, [D_6]acetone): δ = 7.66 (d, 2 H, C_6H_4), 7.21 (d, 2 H, C_6H_4), 6.96 (m, 2 H, C_6H_4), 6.84 (m, 2 H, C_6H_4), 3.50 (t, 8 H, NCH_2), 1.78 (m, 8 H, NCH_2CH_2), 1.59 (s, 3 H, SCH_3), 1.38 [m, 8 H, $N(CH_2)_2CH_2$], 0.90 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.7 MHz, [D_6]acetone): δ = 156.9, 134.9, 129.8, 128.4, 128.2, 121.2 (C_6H_4), 59.5, 24.6, 20.4, 13.9, 11.1 (SCH_3, $NC_{16}H_{36}$).

(NBu$_4$)[Ni(SPh)('S_3')] (6): 845 mg (0.92 mmol) of **1**; 5.52 mL (2.76 mmol) of a 0.5 M solution of NaSPh in MeOH; 3.50 mL (2.80 mmol) of a 0.8 M solution of NBu_4OH in MeOH; 20 mL of THF. Yield: 1.400 g (77%). − $C_{34}H_{49}NNiS_4$ (658.70): calcd. C 61.99, H 7.50, N 2.13, S 19.47; found C 62.03, H 7.47, N 2.14, S 19.57. − ^{1}H NMR (269.6 MHz, CD_2Cl_2): δ = 7.70 (d, 2 H, C_6H_5), 7.55 (d, 2 H, C_6H_4), 7.21 (d, 2 H, C_6H_4), 7.02−6.84 (m, 7 H, C_6H_5, C_6H_4), 3.18 (t, 8 H, NCH_2), 1.50 (m, 8 H, NCH_2CH_2), 1.29 [m, 8 H, $N(CH_2)_2CH_2$], 0.87 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.7 MHz, CD_2Cl_2): δ = 155.0, 140.3, 133.8, 134.4, 129.4, 128.1, 127.7, 127.2, 122.6, 121.4 (C_6H_5, C_6H_4), 59.4, 24.6, 20.3, 13.9 ($NC_{16}H_{36}$).

[Ni(PR$_3$)('S_3')], where R = Cy (7), Ph (8) − General Procedure: The appropriate PR_3 was added as a solid to a stirred black-brown THF suspension of [Ni('S_3')]$_3$ (**1**). In the course of few seconds, a deep-red solution formed, which was filtered. Upon dropwise addition of MeOH (ca. 20 mL), a dark-red solid precipitated, which was separated, washed with MeOH (ca. 50 mL), and dried in vacuo.

[Ni(PCy$_3$)('S_3')] (7): 665 mg (0.72 mmol) of **1**; 841 mg (3.00 mmol) of PCy_3; 10 mL of THF. Yield: 1.16 g (91%). − $C_{30}H_{41}NiPS_3$ (587.50): calcd. C 61.33, H 7.03, S 16.37; found C 61.47, H 7.29, S 16.23. − IR (KBr): $\tilde{\nu}$ = 1099 cm^{-1}, δ(PCH). − ^{1}H NMR (270.6 MHz, $CDCl_3$): δ = 7.70 (d, 2 H, C_6H_4), 7.40 (d, 2 H, C_6H_4), 7.10 (m, 2 H, C_6H_4), 7.00 (m, 2 H, C_6H_4), 2.20−1.20 [m, 33 H, $P(C_6H_{11})_3$]. − ^{13}C{^{1}H} NMR (67.7 MHz, $CDCl_3$): δ = 152.4 (d, $^3J_{P,C}$ = 10.2 Hz), 132.2, 129.7, 128.2, 127.0, 122.2 (C_6H_4), 34.0 (d, $^1J_{P,C}$ = 20.2 Hz), 30.0, 27.6 (d, $J_{P,C}$ = 10.1 Hz), 26.4 [$P(C_6H_{11})_3$]. − ^{31}P{^{1}H} NMR (109.4 MHz, $CDCl_3$): δ = 28.3 [s, $P(C_6H_{11})_3$]. − MS (FD, THF); *m/z*: 587 [Ni(PCy_3)('S_3')]$^+$.

[Ni(PPh$_3$)('S_3')] (8): 500 mg (0.54 mmol) of **1**; 525 mg (2.00 mmol) of PPh_3; 5 mL of THF. Yield: 894 mg (97%). − $C_{30}H_{23}NiPS_3$ (569.36): calcd. C 63.29, H 4.07, S 16.89; found C 63.47, H 4.17, S 16.51. − IR (KBr): $\tilde{\nu}$ = 1094 cm^{-1}, δ(PCH). − ^{1}H NMR (269.6 MHz, $CDCl_3$): δ = 7.82 (m, C_6H_5), 7.72 (d, 2 H, C_6H_4), 7.46 (m, C_6H_5), 7.28 (d, 2 H, C_6H_4), 7.07 (m, 2 H, C_6H_4), 7.01 (m, 2 H, C_6H_4). − ^{13}C{^{1}H} NMR (67.7 MHz, CD_2Cl_2): δ = 152.8 (d, $^3J_{P,C}$ = 5.7 Hz), 134.9 (d, $J_{P,C}$ = 12.2 Hz), 132.6, 131.3, 130.0 (d, $^1J_{P,C}$ = 48.0 Hz), 129.7, 129.0, 128.6 (d, $J_{P,C}$ = 10.8 Hz), 127.8, 123.0 [C_6H_4, $P(C_6H_5)_3$]. − ^{31}P{^{1}H} NMR (109.4 MHz, $CDCl_3$): δ = 30.4 [s, $P(C_6H_5)_3$].

(NBu$_4$)[Ni(Cl)('S_3')] (9): [Ni('S_3')]$_3$ (**1**) (1.660 g, 1.80 mmol) and NBu_4Cl (1.550 g, 5.41 mmol) were combined in THF (20 mL) and the mixture was stirred at room temperature for 24 h to give a violet suspension. This suspension was then cooled to −30°C, and the precipitate was filtered off, washed with THF, and dried in vacuo. Yield: 2.311 g (73%). − $C_{28}H_{44}ClNNiS_3$ (584.99): calcd. C 57.49, H 7.58, N 2.39, S 16.44; found C 56.98, H 7.68, N 2.36, S 16.54. − ^{1}H NMR (269.7 MHz, [D_8]THF): δ = 7.63 (d, 2 H, C_6H_4), 7.18 (d, 2 H, C_6H_4), 6.94 (m, 2 H, C_6H_4), 6.77 (m, 2 H, C_6H_4), 3.53 (t, 8 H, NCH_2), 1.75 (m, 8 H, NCH_2CH_2), 1.38 [m, 8 H, $N(CH_2)_2CH_2$], 0.90 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR

(67.7 MHz, [D$_6$]acetone): δ = 153.9, 138.2, 131.7, 129.4, 129.0, 122.3 (C_6H_4), 59.4, 24.8, 20.7, 14.1 ($NC_{16}H_{36}$).

(NBu_4)[Ni(N_3)('S_3')] (10): A 1.0 M THF solution of NBu_4N_3 (3.0 mL, 3.00 mmol) was added to a black-brown suspension of [Ni('S_3')]$_3$ (**1**) (900 mg, 0.97 mmol) in THF (10 mL). The reaction mixture was stirred overnight at room temperature to give a violet solution, which was then filtered. Layering of the filtrate with (iPr)$_2$O (10 mL) led to the precipitation of black-violet microcrystals, which were separated, washed with (iPr)$_2$O, and dried in vacuo. Yield: 1.364 g (79%). − $C_{28}H_{44}N_4NiS_3$ (591.55): calcd. C 56.85, H 7.50, N 9.47, S 16.26; found C 56.87, H 8.47, N 9.17, S 16.36. − IR (KBr): $\tilde{\nu}$ = 2035 cm^{-1}, ν(N_3). − ^{1}H NMR (269.7 MHz, [D$_8$]THF): δ = 7.56 (d, 2 H, C_6H_4), 7.19 (d, 2 H, C_6H_4), 6.96 (m, 2 H, C_6H_4), 6.81 (m, 2 H, C_6H_4), 3.49 (t, 8 H, NCH_2), 1.75 (m, 8 H, NCH_2CH_2), 1.39 [m, 8 H, $N(CH_2)_2CH_2$], 0.89 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.8 MHz, [D$_8$]THF): δ = 154.9, 134.7, 129.7, 128.5, 128.3, 121.6 (C_6H_4), 59.6, 25.0, 20.7, 14.2 ($NC_{16}H_{36}$).

(NBu_4)[Ni(X)('S_3')] from 3 and Me_3SiX, where X = Cl^- (9), N_3^- (10), NCS^- (11), NSO^- (12) − General Procedure: The appropriate Me_3SiX was added to a black-brown THF solution of (NBu_4)[Ni(StBu)('S_3')] (**3**). A color change was observed within a period of time ranging from 5 min up to 48 h depending on the Me_3SiX compound. All volatile components were then removed in vacuo, and the residue obtained was extracted with Et_2O (ca. 10 mL), separated, washed with Et_2O, and dried in vacuo.

(NBu_4)[Ni(Cl)('S_3')] (9): 250 mg (0.39 mmol) of **3**; 0.10 mL (1.07 mmol) of Me_3SiCl; 3 mL of THF; volatile components were removed after 30 min.; violet powder.

(NBu_4)[Ni(N_3)('S_3')] (10): 275 mg (0.43 mmol) of **3**; 0.15 mL (1.47 mmol) of Me_3SiN_3; 15 mL of THF; volatile components were removed after 24 h; violet powder.

(NBu_4)[Ni(NCS)('S_3')] (11): 125 mg (0.20 mmol) of **3**; 0.07 mL (0.47 mmol) of Me_3SiNCS; 3 mL of THF; volatile components were removed after 5 min; dark-red powder. Yield: 114 mg (94%). − $C_{29}H_{44}N_2NiS_4$ (607.61): calcd. C 57.33, H 7.30, N 4.61, S 21.11; found C 56.82, H 7.33, N 4.78, S 20.12. − IR (KBr): $\tilde{\nu}$ = 2105 cm^{-1}, ν(NCS). − ^{1}H NMR (269.6 MHz, [D$_6$]acetone): δ = 7.66 (d, 2 H, C_6H_4), 7.21 (d, 2 H, C_6H_4), 7.06 (m, 2 H, C_6H_4), 6.92 (m, 2 H, C_6H_4), 3.47 (t, 8 H, NCH_2), 1.81 (m, 8 H, NCH_2CH_2), 1.45 [m, 8 H, $N(CH_2)_2CH_2$], 0.95 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.7 MHz, [D$_6$]acetone): δ = 153.3 (C_6H_4), 140.6 (NCS), 133.2, 129.3, 129.0, 128.0, 122.4 (C_6H_4), 59.2, 24.4, 20.2, 13.8 ($NC_{16}H_{36}$).

(NBu_4)[Ni(NSO)('S_3')] (12): 1.00 g (1.57 mmol) of **3**; 500 mg (3.70 mmol) of Me_3SiNSO; 20 mL of THF; volatile components were removed after 2 d; orange powder. Yield: 824 mg (86%). − $C_{28}H_{44}N_2NiOS_4$ (611.60): calcd. C 54.99, H 7.25, N 4.58, S 20.97; found C 54.75, H 7.22, N 4.21, S 20.28. − IR (KBr): $\tilde{\nu}$ = 1230 cm^{-1}, ν_{asym}(NSO), 1030 cm^{-1}, ν_{sym}(NSO). − ^{1}H NMR (269.6 MHz, [D$_8$]THF): δ = 7.59 (d, 2 H, C_6H_4), 7.19 (d, 2 H, C_6H_4), 6.95 (m, 2 H, C_6H_4), 6.81 (m, 2 H, C_6H_4), 3.41 (t, 8 H, NCH_2), 1.65 (m, 8 H, NCH_2CH_2), 1.35 [m, 8 H, $N(CH_2)_2CH_2$], 0.85 [t, 12 H, $N(CH_2)_3CH_3$]. − ^{13}C{^{1}H} NMR (67.8 MHz, [D$_8$]THF): δ = 155.8, 134.1, 129.9, 128.4, 128.2, 121.5 (C_6H_4), 59.6, 25.0, 20.7, 14.2 ($NC_{16}H_{36}$).

(NBu_4)[Pd(StBu)('S_3')] (13): A 1.1 M MeOH solution of NaStBu (0.74 mL, 0.81 mmol), NBu_4Cl (220 mg, 0.80 mmol), and [Pd('S_3')]$_3$ (**2**) (290 mg, 0.27 mmol) were combined in THF (10 mL). The resulting mixture was stirred at room temperature for 24 h to give a red solution. Undissolved material was removed by filtration, and the red filtrate was concentrated to one-third of its original volume. Layering with Et_2O led to the precipitation of red crystals, which were separated after 4 d, washed with Et_2O (10 mL), and dried in vacuo. Yield: 452 mg (81%). − $C_{32}H_{53}NPdS_4$ (686.44): calcd. X-ray Structure Analyses of [Ni('S$_3$')]$_3$ · 3 THF · 6 MeOH (1 · 3 THF · 6 MeOH), [Pd('S$_3$')]$_3$ · 2 CH$_2$Cl$_2$ (2 · 2 CH$_2$Cl$_2$), (NBu$_4$)[Ni(S*t*Bu)('S$_3$')] (3), (NBu$_4$)[Ni(SCy)('S$_3$')] (4), (NBu$_4$)[Ni(SPh)('S$_3$')] (6), [Ni(PCy$_3$)('S$_3$')] · THF (7 · THF), [Ni(PPh$_3$)('S$_3$')] · CDCl$_3$ (8 · CDCl$_3$), (NBu$_4$)[Ni(Cl)('S$_3$')] (9), and (NBu$_4$)[Pd(S*t*Bu)('S$_3$')] (13): Black hexagons of **1** · 3 THF · 6 MeOH were grown by slow evaporation of the solvent at room temperature from the THF/MeOH mother liquor resulting from the synthesis of [Ni('S$_3$')]$_2$.[6] Black single crystals of **2** · 2 CH$_2$Cl$_2$ were formed upon layering a CH$_2$Cl$_2$ solution of **2** with Et$_2$O. Black-red plates of **3**, **4**, **6**, and **13** were obtained directly from the respective reaction solutions. Orange plates of **7** · THF were grown by layering a THF solution of **7** with MeOH. Red-brown blocks of **8** · CDCl$_3$ were similarly grown by layering the CDCl$_3$ solution of **8** that had been used for NMR measurements with MeOH. Black plates of **9** were grown by layering a THF solution of **9** with Et$_2$O. In all cases, suitable single crystals were sealed in glass capillaries under N$_2$. Data were collected at 200 K (**1** · 3 THF · 6 MeOH, **3**, **4**, **6**, **7** · THF, **8** · CDCl$_3$, **9**, **13**) or 298 K (**2** · 2 CH$_2$Cl$_2$) on a Siemens P4 or a Nicolet R3 m/V (**2** · 2 CH$_2$Cl$_2$) diffractometer using graphite-monochromated Mo-K_α radiation (λ = 71.073 pm) by the ω-scan technique. In the case of **2** · 2 CH$_2$Cl$_2$ and **3**, an absorption correction was applied on the basis of ψ-scans. The structures were solved by direct methods (SHELXTL-PLUS[14a] or SHELXTL 5.03[14b]). Full-matrix least-squares refinement was carried out on F^2 (SHELXL-93[14c] or SHELXTL 5.03[14b]). All non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms in **3**, **4**, **6**, **7** · THF, **8** · CDCl$_3$, and **9** were taken from the difference Fourier map and were kept fixed with a common isotropic displacement parameter. In the case of **1** · 3 THF · 6 MeOH, **2** · 2 CH$_2$Cl$_2$, and **13**, the hydrogen atoms were geometrically positioned with isotropic displacement parameters fixed at 1.5 times the U(eq) of the adjacent carbon atom. One *n*-butyl group (C40−C43) in the cation of **3** is evidently disordered, but no well-separated sites could be refined. In the case of complex **9**, the crystal under study proved to be a pseudomerohedral twin. The twin component ratio was refined to give 0.694(1) and 0.306(1), respectively. Selected crystallographic data are listed in Tables 3 and 4.[15]

Aluminium Coordinations in Zeolite Mordenite By ^{27}Al Multiple Quantum MAS NMR Spectroscopy

Tie-Hong Chen,[a] Bart H. Wouters,[a] and Piet J. Grobet*[a]

Keywords: NMR spectroscopy / Zeolites / Al-coordination / Mordenite

^{27}Al 3Q MAS NMR spectroscopy has been applied to study the coordination state of the species giving the 30 ppm Al NMR signal in the ^{27}Al MAS NMR spectrum of activated mordenite materials. From the ^{27}Al 3Q MAS NMR measurements it is evident that the broad peak at 30 ppm in the ^{27}Al NMR spectrum of the mordenite calcined at temperatures up to 600 °C comes mainly from the distorted four-coordinated Al. By simulation a quadrupolar coupling constant of 5.8 MHz was estimated for the distorted tetrahedral Al. For samples calcined at 650 and 700 °C, a small amount of pentacoordinated Al emerges. The majority of the signal, however, arises from distorted tetrahedral Al. A two-step calcination results in a significant contribution of the pentacoordinated Al to the signal at 30 ppm. From the simulated line-shape, a quadrupole coupling constant of 6.2 MHz is obtained for the latter signal. These data show that during the calcination of the mordenite, the coordination environment at the Al centre gradually becomes distorted to give rise to the shoulder at 30 ppm. With the increase of the calcination temperature, pentacoordinated Al species form

Introduction

Since the discovery of the ultrastabilisation process of zeolites, the relationship between the structure and the properties of these materials has puzzled many scientists. ^{27}Al and ^{29}Si solid-state NMR spectroscopy has significantly contributed to unraveling the structural changes accompanying the ultrastabilisation.[1] Although ^{27}Al MAS NMR is nowadays routinely applied in this field of research,[2][3] some questions regarding the interpretation of the spectra still need to be answered due to the interaction of the quadrupolar aluminium nucleus with the surrounding electric field. This not only broadens the spectral lines but also results in a quadrupole-induced chemical shift of the NMR signals.[4]

In the ^{27}Al MAS NMR spectrum of hydrothermally activated zeolites, signals centred at 60, 30 and 0 ppm can easily be observed. The signal at 60 ppm is attributed to tetrahedrally coordinated Al species whereas that at 0 ppm is assigned to octahedrally coordinated species. The interpretation of the signal at 30 ppm, however, needs further discussion. In literature reports on the ultrastable Y zeolite (USY) several assignments are reported for the latter signal: four-coordinated Al species shifted upfield due to the quadrupolar induced chemical shift,[5][6] pentacoordinated Al[7][8] or an overlap of both four- and five-coordinated Al species.[9]

The activation conditions cannot be overlooked in any discussion about the coordination number of the different aluminium species in the activated zeolites. Several studies indicate key differences in the Al speciation due to the method of activation.[5,6,9] Owing to the ability to average out the second-order quadrupolar interaction of the Al nucleus, some improvement regarding the assignment of the signal at 30 ppm was obtained by the technique of Double Rotation (DOR) NMR spectroscopy.[10] In a sample of single thermally treated zeolite Y a signal was observed at 47.5 ppm due to tetrahedrally coordinated Al, while in the doubly hydrothermally treated sample, the signal at 30 ppm was assigned to the pentacoordinated Al species. However, because of the low spinning rates of the inner rotor, spinning side bands can overlap with actual resonance lines.[11] Some ambiguity therefore remains in the assignments.

With the development of two-dimensional multiple quantum MAS NMR spectroscopy a powerful tool for the study of quadrupolar nuclei is available.[12][13] This method can refocus the second-order anisotropic broadening of the half-integer quadrupolar nuclei by selecting the multiple-quantum transition (3Q or 5Q) and transferring it to the single-quantum signal over two time domains. Isotropic resolution can be obtained, while problems with overlapping spinning side bands are avoided because of the high spinning rate of the MAS rotor.

Here we report ^{27}Al 3Q MAS NMR spectroscopic experiments on the activated zeolite mordenite, for which a signal at 30 ppm in the ^{27}Al MAS NMR spectrum has been reported.[14] The focus of this paper will be on the coordination state of the Al species giving rise to this signal.

Results and Discussion

Figure 1 shows the ^{27}Al MAS NMR spectra of the parent and the 550 to 700°C calcined H-mordenite samples after hydration, as well as the two-step activated mordenite. The signal at 55 ppm in the spectrum of parent H-mordenite (Figure 1a) is assigned to the framework tetrahedrally coordinated Al atoms, while that at 0 ppm results from extra-framework Al atoms in an octahedral environment.[14]

Some framework-related octahedrally coordinated Al may appear at 0 ppm as was recently reported for the HY.[15] The small signal that can be seen at 30 ppm is probably due to activation at 400°C and the subsequent acid washing that was performed to prepare the acid form of the sample (Figure 1).

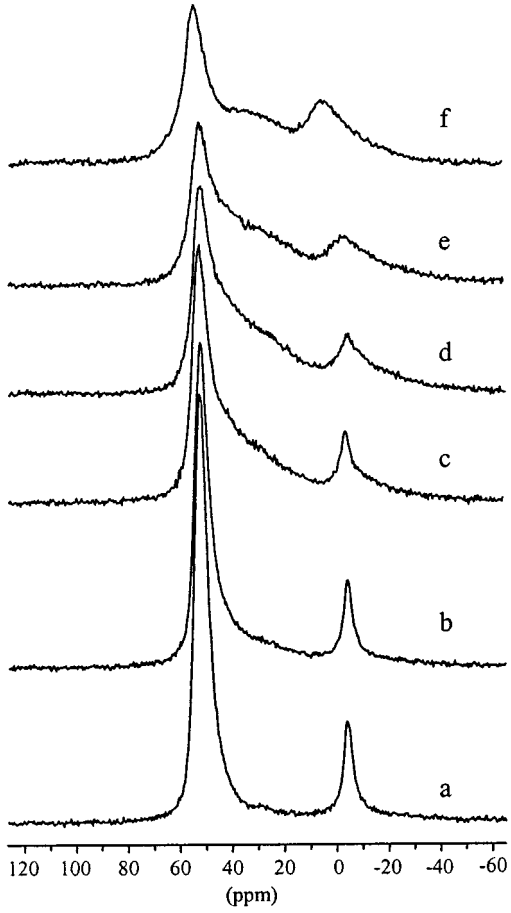

Figure 1. ^{27}Al MAS NMR spectra of zeolite mordenite; (a) parent mordenite, (b) 550°C calcined, (c) 600°C calcined, (d) 650°C calcined, (e) 700°C calcined and (f) the two-step calcination

In the spectra of the calcined samples (Figure 1, b−f), besides the peaks at 55 and 0 ppm, a broad line gradually emerges at around 30 ppm, with increasing calcination temperature, while the 0 ppm signal broadens. Furthermore, the total Al intensity within the spectra decreases. For the sample calcined at 700°C, an intensity loss of 15−20% was found relative to the parent sample. The formation of "NMR-invisible Al" at high calcination temperatures is in agreement with the measurements of Grobet et al. for the zeolite Y.[5] Because of this "NMR-invisible Al", quantification of the Al content from the ^{27}Al MAS NMR spectrum is not possible, in contrast to the statement of Barras et al.[14]

By application of the two-dimensional ^{27}Al 3Q MAS NMR technique the resolution of the ^{27}Al MAS NMR spectra of the calcined mordenite samples is enhanced, as shown in Figure 2. In these spectra the position of the lines in the MAS-dimension corresponds to the conventional ^{27}Al MAS NMR measurements, while isotropic resolution is obtained in the second dimension. In the spectrum of the parent H-mordenite (Figure 2a) a strong signal (A) originating from the framework Al and a signal (B) due to the octahedrally coordinated Al are seen. Furthermore a small signal (C) appears near the four-coordinated Al (signal A). From the projection on the MAS-axis signal C can be correlated with the small signal at 30 ppm in the 1D ^{27}Al MAS NMR spectrum (Figure 1a). Artificial peaks along the isotropic dimension near signal (A) can be observed due to the truncation of the NMR signal in the *t1* time domain (see Experimental Section).

After calcination at 550°C (Figure 2b), signals A and B are still present, while the intensity of signal C is increased. This process continues until 600°C (Figure 2c). From its position in the isotropic-dimension of the 3Q MAS NMR spectrum, signal C should also be regarded as arising from four-coordinated aluminium species. Pentacoordinated species are expected to be found between signals A and B. From both the centre of gravity and the tailing of the signal in the MAS-dimension a significantly higher quadrupolar coupling constant (QCC) than that of the tetrahedral signal A is expected.

A slice through signal C, parallel to the MAS-dimension, of the sample calcined at 600°C is shown in Figure 3a. From the fitting of a theoretically calculated powder pattern to this slice the quadrupole parameters can be obtained.[16] Due to the high dispersion which is typical of zeolite samples,[17] only average values can be obtained for both the chemical shift and the quadrupolar parameters. Several authors have published quadrupolar coupling constants for the signal at 30 ppm in the ^{27}Al MAS NMR spectrum of an activated zeolite Y. Ray and Samoson estimated a QCC of 6.2 MHz for a single thermally dealuminated Y sample.[10] Coster et al. indicate that nonframework Al debris in the USY are consists of two species contributing to the signal in 30 ppm region. The first has an isotropic chemical shift of about 58 ppm and a QCC of 6 MHz, the second an isotropic shift of 40 ppm and a slightly lower QCC.[17] For the simulated powder pattern of Figure 3b a quadrupolar constant of 5.8 MHz and an asymmetry parameter (η) of 0.4 were used. These values agree well with those reported in the literature. A Gaussian line broadening of 50 Hz was introduced to the theoretical line shape to account for the dispersion of the chemical shift. The dispersion of the quadrupolar parameters was not taken into account and this may explain the rudimentary nature of the fit. The isotropic chemical shift determined by the simulated pattern is at 59 ppm, giving further evidence that signal C originates from four-coordinated Al as expected from the position of this line in the isotropic dimension. From the high quadrupolar coupling constant, and the consequent dispersion in the 2D MQ spectrum, a highly distorted site is expected. The broad band at 30 ppm in the corresponding 1D spectra (Figure 1a−c) arises from this kind of distorted Al species.

If the temperature of calcination is further increased to 650°C, an additional signal (D) appears in the ^{27}Al 3Q

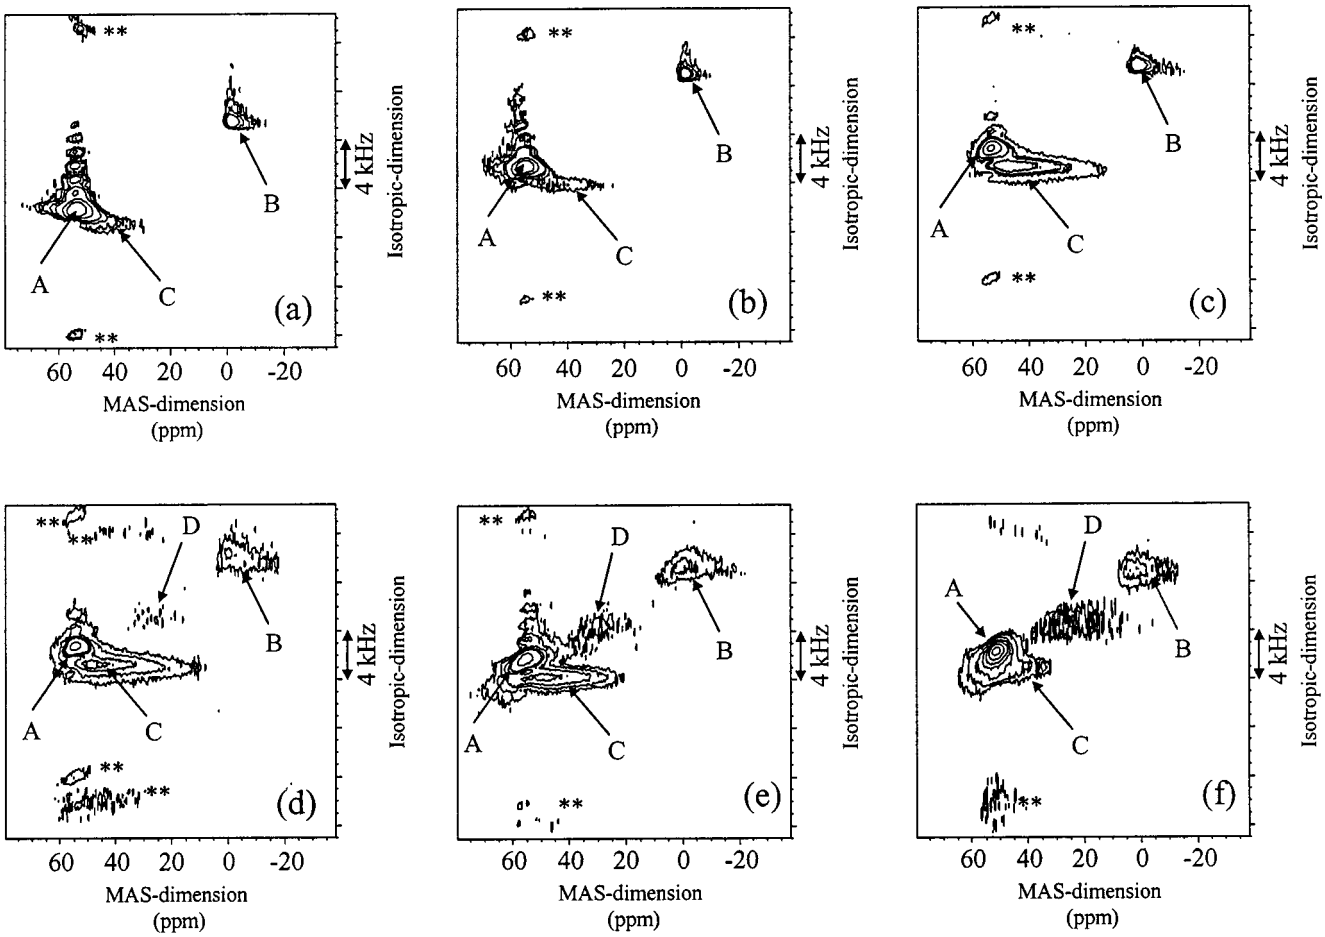

Figure 2. ^{27}Al 3Q MAS NMR spectra of zeolite mordenite; (a) parent sample, (b) 550°C calcined, (c) 600°C calcined, (d) 650°C calcined, (e) 700°C calcined and (f) the two-step calcination; ** denote spinning side bands

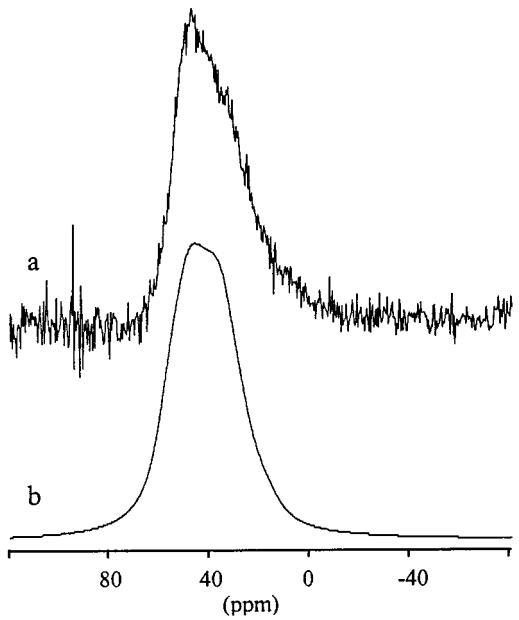

Figure 3. (a) Slice through signal (C) in Figure 2c, (b) simulation with a calculated quadrupolar powder pattern, QCC = 5.8 MHz, η = 0.4, and δ^{cs}_{iso} = 59

MAS NMR spectrum (Figure 2d). The intensity of signal D is weak but becomes more pronounced after calcination at 700°C (Figure 2e). The much lower intensity of signal D relative to signal C in Figures 2d and 2e can either be explained by the low quantity of the former species or by differences in the excitation efficiency of the multiple quantum transition under our experimental conditions. From the position of signal D in the ^{27}Al 3Q MAS NMR spectra, which is between those expected for tetrahedral and octahedral coordination, the Al species giving rise to signal D should be pentacoordinated.

From the 3Q MAS NMR spectra it can be observed that signal B gradually broadens in both the MAS and isotropic dimension, implying that its QCC and its isotropic chemical shift became more dispersed. The properties of signal C do not change as the calcination temperature increases from 600 to 700°C.

Spin-lattice relaxation measurements on the USY revealed that the signal at 30 ppm is not due to a single Al site but results from a mixture of different Al species, which are believed to be in a nonframework environment.[18] From the projection of signals C and D on the MAS-dimension, it is clear that both contribute to the broad hump at 30 ppm in the 1D spectrum.

After the two-step activation of the mordenite (Figure 2f), a significant contribution of the pentacoordinated Al species (signal D) to the signal at 30 ppm is encountered. By simulation of a slice through signal D, a quadrupolar coupling constant of 6.2 MHz is estimated (Figure 4), which is slightly higher than the value obtained for the distorted tetrahedral Al after a single activation. However, for the two-step calcination of zeolite Y, Ray et al. found a lower QCC for the pentacoordinated Al species than for the distorted Al sites seen after a single hydrothermal treatment.[10] On the other hand, Rocha et al. indicate an increase of the QCC in zeolite Y with increasing degree of dealumination of the sample.[9] These differences may result from the activation conditions applied by the authors.

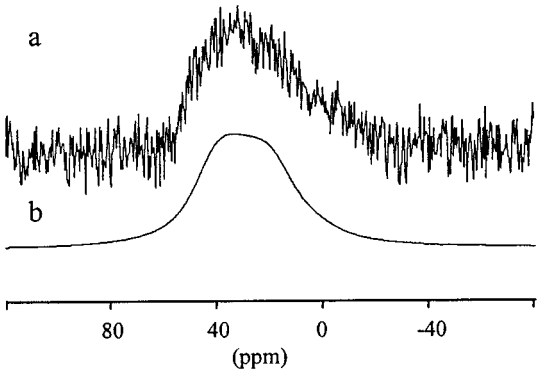

Figure 4. (a) Slice through signal (D) in Figure 2f, (b) simulation with a calculated quadrupolar powder pattern, QCC = 6.2 MHz, $\eta = 0.5$, and $\delta^{cs}_{iso} = 44$

For both the distorted tetrahedral Al sites and the pentacoordinated aluminium similar QCC′s are observed. Therefore the excitation efficiency, which is dependent on the QCC, is not responsible for the low intensity of the pentacoordinated Al species observed in the spectra of samples calcined above 600°C. This implies that only a small amount of the latter species is formed. The signal at 30 ppm in the ^{27}Al MAS NMR spectrum can thus mainly be assigned to distorted tetrahedral Al. Only after a second activation step does a significant part of this signal result from five-coordinate Al.

Conclusion

In the ^{27}Al MAS spectra of the parent, 550, 600, 650, 700°C calcined zeolite mordenite, three signals are observed at 55, 30 and 0 ppm, respectively. The 55 ppm signal is related to tetrahedrally coordinated Al species while the 0 ppm line is related to octahedrally coordinated Al. A broad 30 ppm signal gradually appears when the calcination temperature is increased. From the ^{27}Al 3Q MAS NMR experiments it can be concluded that during the calcination of mordenite, tetrahedral Al species gradually undergo distortion. Due to the second order quadrupolar broadening, these species give rise to the 30 ppm shoulder in the 1D spectrum. Further increase of the calcination temperature to 650°C and above results in the formation of pentacoordinated Al. These species contribute to the 30 ppm signal although the majority of this band remains related to distorted tetrahedral Al. After a second calcination the formation of pentacoordinated aluminium species is more pronounced.

Experimental Section

Samples: Commercially available H-mordenite with a Si/Al ratio of 6.2, referred to as the parent sample, was subjected to different calcination treatments. This parent sample was heated in a muffle furnace for 2 hours at temperatures of 550, 600, 650 and 700°C. All the calcined samples were placed in a desiccator to hydrate over a saturated NH_4Cl solution for at least one week. After hydration, the sample calcined at 650°C was calcined a second time at 500°C for two hours and was subsequently equilibrated in a desiccator. This latter sample will be referred to as the two-step activated mordenite.

NMR Measurements: ^{27}Al NMR spectra were measured on a Bruker MSL-400 spectrometer at 104.26 MHz. The MAS spin rate was 12.5 kHz. ^{27}Al MAS NMR spectra were recorded with a short 0.6 μs pulse (corresponding to π/18 flip angle). A "split-*t1*" 3Q pulse sequence was applied for the triple-quantum MAS NMR experiments to obtain a sheared spectrum without further treatment of the 2D data.[19] The three pulses of 100 kHz had a length of 3.5, 1.2 and 0.6 μs. 200 FID′s for each experiments were accumulated with a time increment of 5 μs. 1920 scans were accumulated for each FID. The TPPI method was used in the 2D data acquisition and processing. ^{27}Al chemical shifts were referenced to a 0.5 M $Al(NO_3)_3$ solution.

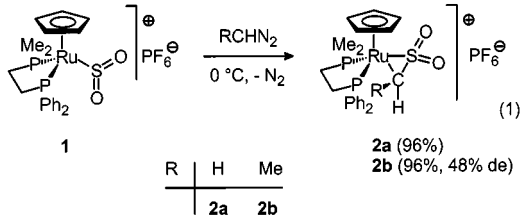
Enantioselective Organic Syntheses With Chiral Transition Metal Complexes, 11[+]

Chiral Ruthenium–Sulfene Complexes – Synthesis and C–C Coupling Reactions

Wolfdieter A. Schenk,*[a] Jürgen Bezler,[a] Nicolai Burzlaff,[a] Michael Hagel,[a] and Bernhard Steinmetz[a]

Keywords: Enolates / Nucleophilic additions / Ruthenium / S ligands / Sulfenes

Reaction of the chiral racemic complex [CpRu(mppe)-(SO_2)]PF_6 (**1**, mppe = $Me_2PC_2H_4PPh_2$) with diazomethane or -ethane gave the sulfene complexes [CpRu(mppe)(RHC=SO_2)]PF_6 (R = H, **2a**; R = Me, **2b**). Treatment of **2a** with prochiral enamines or deprotonated β-oxo esters yielded C–C coupling products with 32–60% de. An analog of **2a**, [NmcpRu(mppe)(H_2C=SO_2)]PF_6 (**8**, Nmcp = neomenthylcyclopentadienyl) was prepared in a four-step synthesis starting from LiNmcp and [$RuCl_2(PPh_3)_3$]. Repeated crystallization of the intermediate [NmcpRu(mppe)Cl] (**6**) provided diastereomerically pure **6′** which added methylene stereospecifically to give diastereomerically pure **8′**. Compound **8** turned out to be much less reactive towards nucleophiles than **2a**, but still added deprotonated ethyl 2-methyl-3-oxobutanoate with 44% de. The chiral, enantiomerically pure sulfur dioxide complex [CpRu(chir)(SO_2)]PF_6 [**10**, chir = (*S*,*S*)-$Ph_2PCHMeCHMePPh_2$] was synthesized from [CpRu(chir)Cl] and SO_2 and was characterized by X-ray crystallography. Reaction of **10** with diazomethane gave the enantiomerically pure sulfene complex [CpRu(chir)(H_2C=SO_2)]PF_6 (**11**). Addition reactions of **11** with *N*-(1-cyclopentenyl)morpholine, as well as with various enolates derived from β-oxo esters or 1,3-diesters proceeded with high yields and 20–90% de. The structure of a diastereomerically pure addition product, [CpRu(chir)(SO_2CH_2C(Me){C(O)Me}{C(O)O*t*Bu}] (**13d′**), was determined crystallographically and was shown to have (*R*) configuration at the quaternary carbon atom. After alkylation of one of the S=O functions, the sulfinate ligand was cleaved from the metal center by ligand substitution with acetonitrile, and the resulting acetonitrile complex **15** was converted back into **10** by treatment with SO_2.



In previous publications we described the synthesis of ionic sulfene complexes of the type [$Cp(R_3'P)_2Ru(RHC$=SO_2)]PF_6 (R = H, Me) by methylene addition to sulfur dioxide complexes.[1–3] Through the coordination to a transition metal atom, the sulfene molecule experiences considerable stabilization as well as umpolung. The latter was demonstrated by addition reactions with a number of heteroatom and carbon nucleophiles, which occurred exclusively at carbon.[2][3]

The use of chiral transition metal complexes as diastereodirecting auxiliaries in stoichiometric reactions is a topic of long-standing interest.[4][5] In the majority of the work, complexes of the types [$CpMo(CO)_2(L-L^*)$],[6] [$CpM(NO)(PPh_3)L$] (M = Mn,[4] Re[7]), [$CpFe(CO)(PPh_3)L$][8][9] and [$CpRu(L-L^*)L$][10] (L–L* = chiral bidentate ligand) were employed. If L is a coordinated alkene, such complexes may undergo nucleophilic additions with remarkable diastereoselectivity.[5,7,11] In this context it seemed promising to carry out C–C coupling reactions with chirally modified sulfene complexes.

Results

Complexes with Metal-Centered Chirality

Reaction of the chiral racemic sulfur dioxide complex **1**[12] with diazomethane or -ethane gave the sulfene complexes **2a** and **2b** as colorless, crystalline, and thermally quite sensitive materials (Equation 1).

(1)

1

2a (96%)
2b (96%, 48% de)

Compound **2a** was obtained as a single isomer with the CH_2 group *cis* to the PPh_2 group of the $Me_2PC_2H_4PPh_2$ (mppe) ligand. A strong NOE upon irradiation of the Cp resonance allowed the identification of the *exo*-H of the sulfene as well as the *exo*-CH_3 of the diphosphane ligand. Due to the small dihedral angle H–C–Ru–P,[2] the *endo*-H is strongly coupled to the *cis*-phosphorus atom,[13] which was shown by selective ^{31}P decoupling to be that of the PPh_2 group. Four different rotamers/diastereoisomers are possible for **2b**, of which only two were observed in a 74:26

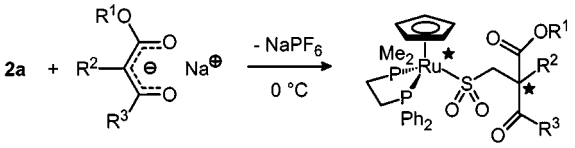
ratio. The major isomer **2b′** has the structure shown in Equation 1, as evidenced again by the large coupling of the *endo*-H with the PPh_2 group. The relative configurations of the two stereocenters are thus $R_{Ru},R_C/S_{Ru},S_C$. Unfortunately, the resonance of the sulfene-H of the minor isomer **2b″** could not be detected due to extensive signal overlap. In view of the fairly low diastereoselectivity of the addition reaction described below, it is reasonable to assume that **2b″** is the ($R_{Ru},S_C/S_{Ru},R_C$) diastereomer but we have no way of distinguishing between the two possible rotamers.

Cationic sulfene complexes readily undergo C−C coupling reactions with enamines.[3] Thus, treatment of **2a** with *N*-(1-cyclopentenyl)morpholine gave the immonium salt **3** in 76% yield and 60% de (Equation 2).

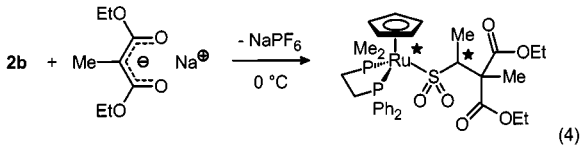


(2)

3 (76%, 60% de)

Immonium salt **3** is a colorless crystalline compound whose constitution was readily inferred from its spectroscopic data. Particularly characteristic is the AB system of the methylene group at sulfur and the downfield signal of the immonium carbon at $\delta = 203.4$. The shift differences in the NMR spectra of the two diastereoisomers are rather small due to the large spatial separation of the two stereocenters.

Reaction of **2a** with deprotonated β-oxo esters gave the neutral addition products **4a**−**c** in fair yields and diastereoselectivities (Equation 3).

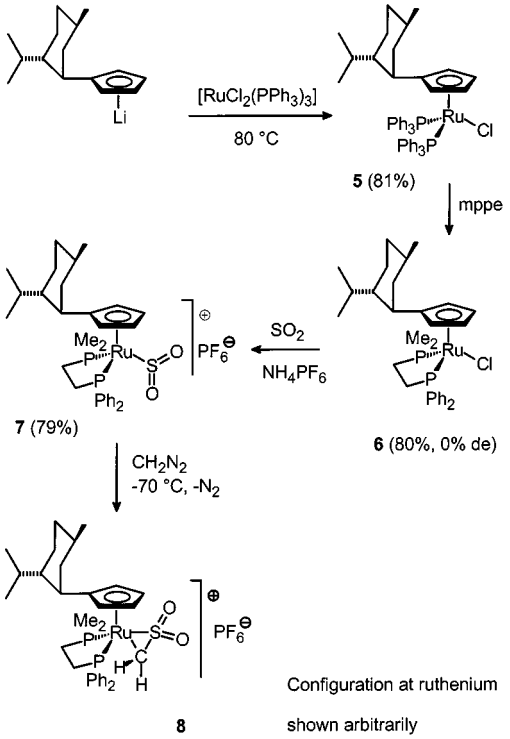


(3)

R^1	Et	*t*-Bu	Et
R^2, R^3	Me, Me	Me, Me	$-CH_2CH_2CH_2-$
	4a	**4b**	**4c**

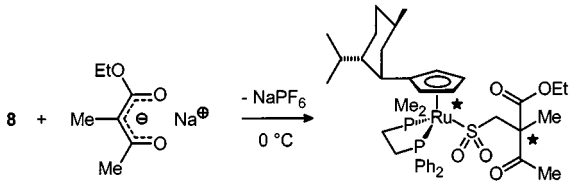
4a (54%, 42% de)
4b (60%, 48% de)
4c (63%, 32% de)

Through chromatography and crystallization the major diastereoisomers could be enriched. The stereochemical course of enolate reactions is strongly influenced by the nature of the counter cation.[14] Therefore, the reaction of **2a** with deprotonated ethyl 2-oxocyclopentanecarboxylate was carried out on a small scale in the presence of various salts. Upon addition of $LiClO_4$, $MgBr_2$, or $ZnCl_2$ to the reaction mixture, the diastereoselectivity disappeared almost completely. However, the coupling product **4c** was formed with 81% de when the sodium enolate was first converted into a titanium enolate and then added to **2a**. Unfortunately, we were unable in this case to separate **4c** without its decomposition from the titanium-containing side products. Nevertheless, it appears that, with the choice of suitable reagents, highly stereoselective addition reactions can be performed.



Nucleophilic additions on **2b** should be stereospecific with respect to the configuration at the sulfene carbon atom. Still, the addition of the sodium enolate of diethyl methylmalonate produced **4d** in somewhat lower de than expected (Equation 4). This is certainly due to competing decomposition which may affect both diastereoisomers of the thermolabile starting material **2b** at slightly different rates.

(4)

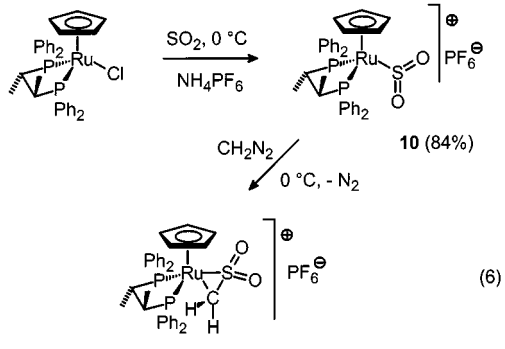


4d (71%, 26% de)

Although the results obtained so far were not overly promising we set out to synthesize enantiomerically pure analogs of **1** and **2a** (Scheme 1). Reaction of neomenthylcyclopentadienyllithium with $[RuCl_2(PPh_3)_3]$ gave **5** in high yield as a yellow crystalline compound which, unlike its C_5H_5 analog, is readily soluble even in aliphatic hydrocarbons. Notable spectroscopic features are four separated NMR signals of the protons on the cyclopentadienyl ring, and a narrow AB system in the ^{31}P NMR spectrum. Phosphane exchange with mppe gave **6** in high yield as a 50:50 mixture of diastereoisomers. Through repeated crystallizations a small amount of diastereomerically pure **6′** was obtained as orange-yellow crystals. Treatment of **6** with sulfur dioxide at room temperature gave the SO_2 complex **7** in high isolated yield as a yellow crystalline material. Similarly, **6′** gave **7′** as a single diastereoisomer, which to our knowledge is the first chiral, enantiomerically pure complex of sulfur dioxide.

Scheme 1. Synthesis of diastereoisomeric neomenthylcyclopentadienyl ruthenium complexes

The reaction of **7** or **7′** with diazomethane produced the expected sulfene complex either as the 50:50 mixture **8** or in its diastereomerically pure form **8′** (Scheme 1), both of which are brownish-white semisolid materials. Disappointingly, **8** and **8′** turned out to be even more labile than **2a**, to preclude the isolation of analytically pure samples and to hamper their use in further reactions considerably. In the next experiments, **8** was therefore generated in situ. The reaction with *N*-(1-cyclopentenyl)morpholine resulted only in complete decomposition of the sulfene complex. Enolate addition, however, gave the expected product **9**, after workup in 47% yield, as a 72:28 mixture of two diastereoisomers (Equation 5).



9 (47%, 44% de) (5)

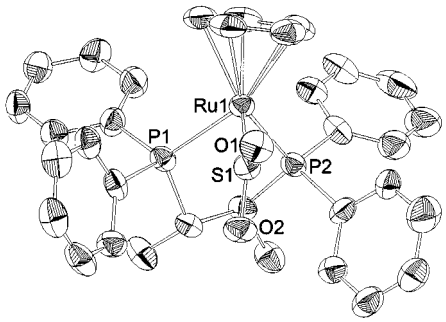
Since this reaction is not expected to proceed with significantly higher diastereoselectivity than that described in Equation 3, we have to assume that the two remaining stereoisomers were lost during workup. Although **9** is a stable compound, neomenthylcyclopentadienyl complexes do not tend to crystallize well, therefore making it impossible to obtain analytically pure samples or achieve any further diastereoisomer enrichment.

Complexes with Ligand-Centered Chirality

We recently found that ligand-centered reactions of [CpRu(chir)L] complexes [chir = (*S*,*S*)-2,3-bis(diphenylphosphanyl)butane] proceed with remarkably high diastereoselectivity.[15−19] For example, the oxidation of coordinated thioethers routinely gave de values greater than 80% and up to 98%.[16−18] Thus, besides avoiding the tedious diastereoisomer separation step, we also expected improved selectivities for the C−C coupling reactions of sulfene complexes containing this chiral diphosphane ligand. The enantiomerically pure sulfur dioxide complex **10** was obtained as a yellow solid in high yield from [CpRu(chir)Cl] and SO_2 (Equation 6).

(6)

Diffusion of hexane into a dichloromethane solution gave crystals of **10**·$2CH_2Cl_2$ suitable for X-ray structure determination. Figure 1 shows a view of the cation. The structure may be described as distorted octahedral, in which the C_5H_5 ligand occupies three sites. As expected,[20][21] the SO_2 ligand aligns itself in the pseudo mirror plane of the $CpRu(PR_3)_2$ complex fragment. The two P−Ru−S angles differ by 5.3° as a result of the asymmetric nature of the chiral diphosphane ligand. The geometry around sulfur is perfectly planar, with the sum of the bond angles being 359.9°.



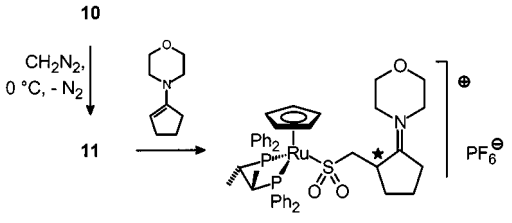


Figure 1. Molecular structure of [CpRu(chir)(SO_2)]PF_6·2 CH_2Cl_2 (**10**·$2CH_2Cl_2$) (hydrogen atoms, anion, and solvent molecules omitted); selected distances [pm] and angles [°] (standard deviations in parentheses): Ru(1)−P(1) 232.9(2), Ru(1)−P(2) 232.2(2), Ru(1)−S(1) 212.8(2), S(1)−O(1) 143.2(6), S(1)−O(2) 145.8(6), S(1)−Ru(1)−P(1) 88.48(8), S(1)−Ru(1)−P(2) 93.81(9), P(1)−Ru(1)−P(2) 83.41(8), Ru(1)−S(1)−O(1) 120.9(3), Ru(1)−S(1)−O(2) 125.1(3), O(1)−S(1)−O(2) 113.9(4)

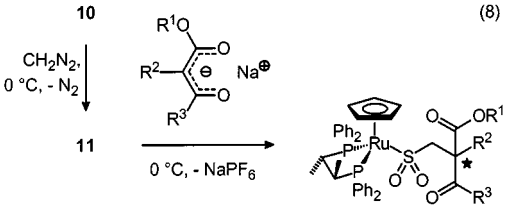

The reaction of **10** with diazomethane at −70°C gave the enantiomerically pure sulfene complex **11** in almost quantitative yield (Equation 6). Sulfene complex **11** is a colorless, crystalline compound which decomposes in solution at 20°C. NMR spectra taken at −60 °C revealed that **11** exists as a single rotamer. The two sulfene protons give signals at δ = 0.85 and 2.31, the latter of which was shown by NOE to arise from the proton *syn* to the Cp ligand.

In the following experiments the sulfene complex **11** was produced in situ and was treated with carbon nucleophiles. Thus, treatment of the solution with *N*-(1-cyclopentenyl)-morpholine gave **12** in 81% yield and 64% de (Equation 7). Apparently, the chir ligand does not introduce excessive steric hindrance that would inhibit the nucleophilic addition at the sulfene ligand. Furthermore, the diastereoselectivity achieved here represents some improvement over the analogous reaction of the racemic mppe complex **2a** (Equation 2).

12 (81%, 64% de) (7)

Reactions of **11** with deprotonated diethyl methylmalonate or deprotonated β-oxo esters gave the expected addition products **13a**−**e** in good yields (Equation 8). Complexes **13b** and **13d** were formed with considerably higher diastereoselectivity than their mppe analogs **4a** and **4b**.

(8)

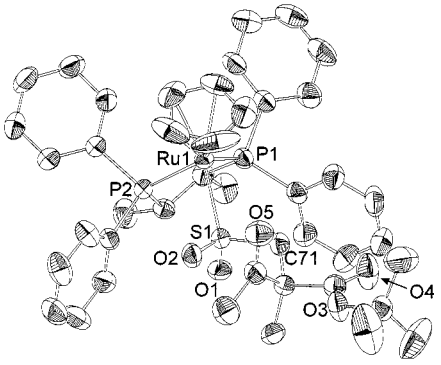
After recrystallization, the major diastereoisomer of **13d** was obtained pure and was subjected to an X-ray structure determination. A view of the molecule is shown in Figure 2.The geometry around ruthenium is very similar to that of **10**. The addition of an organic group to the SO_2 ligand results in a slight decrease of the Ru−P bond lengths and a sizeable increase of the Ru−S distance by 17.4 pm. The latter is due to the combined effects of raising the coordination number at sulfur from three to four and occupying the vacant b_2 orbital at sulfur, which is responsible for the carbene-type π-backbonding in η^1-planar SO_2 complexes.[20] Nevertheless, the Ru−S bond is still shorter than expected for a single bond, but this is commonly observed for electron-rich sulfinato complexes.[22] The difference of the P−Ru−S angles has increased to 8.8° as a result of the repulsions encountered between the organic groups of the sulfinate ligand and the chiral chelate phosphane. The configuration at the former enolate carbon atom C72 is (*R*).



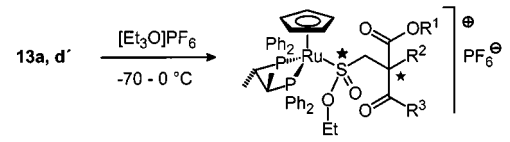


Figure 2. Molecular structure of [CpRu(chir){SO_2CH_2C(Me){C(O)Me}[C(O)O*t*Bu}}] (**13d′**) (hydrogen atoms omitted); selected distances [pm] and angles [°] (standard deviations in parentheses): Ru(1)−P(1) 228.0(2), Ru(1)−P(2) 228.3(2), Ru(1)−S(1) 230.2(2), S(1)−O(1) 146.7(3), S(1)−O(2) 146.8(4), S(1)−C(71) 182.7(5), S(1)−Ru(1)−P(1) 94.10(5), S(1)−Ru(1)−P(2) 85.28(5), P(1)−Ru(1)−P(2) 84.95(5), Ru(1)−S(1)−O(1) 115.3(2), Ru(1)−S(1)−O(2) 109.7(2), O(1)−S(1)−O(2) 113.4(2), Ru(1)−S(1)−C(71) 110.7(2)

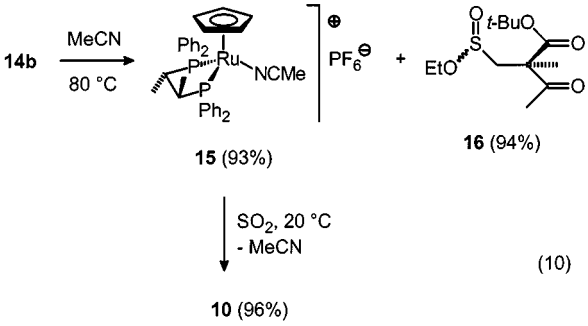
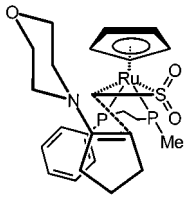


Electron-rich sulfinato complexes may be readily alkylated at one of the S=O functions.[3][23] Thus, reaction of **13a** or diastereomerically pure **13d′** with triethyloxonium hexafluorophosphate gave the sulfinic acid ester complexes **14a**, **b** in almost quantitative yields and, in the case of **14a**, good diastereoselectivity (Equation 9).

R^1	Et	*t*-Bu	
R^2, R^3	Me, OEt	Me, Me	
	14a	**14b**	
			14a (92%, 62% de)
			14b (94%, 6% de)

(9)

Sulfinic acid esters are weak donors which may readily be released from the metal.[3] Thus, heating **14b** in acetonitrile under reflux gave the acetonitrile complex **15** along with the diastereomeric ester **16**. Compound **15** may be converted back into the SO_2 complex **10** by treatment with sulfur dioxide (Equation 10).



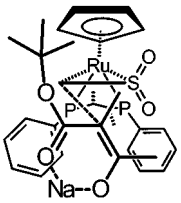
(10)

Discussion

In the symmetrical complex [CpRu(dppe)(CH_2=SO_2)]PF_6, the sulfene ligand rotates rapidly on the NMR timescale.[3] Therefore, we have to assume that in the similar sulfene complexes **2a**, **2b**, and **11**, the different rotamers are in thermodynamic equilibrium, dictated solely by steric requirements. Thus, for **2a** only one rotamer is found, in which the small CH_2 group is positioned *cis* to the large PPh_2 end of the chelate diphosphane. In **2b** the major (R_{Ru},R_C/S_{Ru},S_C) diastereoisomer has an analogous geometry with the methyl group in an *exo* position. The second isomer is most likely to be the opposite diastereomer. Both may even be in a slow equilibrium via an η^2-(S=O) bonded intermediate similar to the recently characterized sulfur trioxide complex [Cp*Ru(PMe_3)$_2$(η^2-O=SO_2)]-PF_6.[24]

Of the nucleophilic additions of **2a**, the reaction with the enamine (Equation 2) stands out for its fairly large diastereoselectivity. In this case, a prediction of the stereochemical course may be warranted. Simple molecular models suggest that the approach of (*R*)-**2a** on the *re* side of the enamine is favored, since this avoids any close contact

between the morpholino substituent and the *P*-phenyl group protruding into the space around the sulfene ligand (Scheme 2).



Scheme 2. Diastereoselective approach of *N*-(1-cyclopentenyl)morpholine to sulfene complex **2a**

The main product of the reaction (Equation 2) should thus be the (R_{Ru},R_C/S_{Ru},S_C) diastereoisomer. A remarkable gain in the diastereoselectivity of formation of **4c** was achieved when a titanium enolate was used. Such effects are often observed[14] but are difficult to interpret, since Ti^{IV} complexes of β-dicarbonyl compounds in solution invariably exist as mixtures of different monomers and dimers.[25] Precoordination of titanium to one of the sulfene oxygens may also have an influence.

Knowing that reactions at [NmcpRu(CO)$_2$X] proceed with rather low diastereoselectivity,[26][27] we had expected that the reactivity of the neomenthylcyclopentadienyl sulfene complex **8** would be quite similar to that of its C_5H_5 analog **2a**. Indeed, the de values of the formation of **4a** (Equation 3) and **9** (Equation 5) are almost the same. Nevertheless, the neomenthyl substituent does introduce considerable steric hindrance, as is seen in the lack of any reactions of **8** with enamines. An inspection of the molecular structures of [NmcpRu(CO)(PPh$_3$)I],[26] [NmcpRu(dppe)IEt]OTf,[27] and [NmcpRu(dppe)Cl][28] shows that the substituents at phosphorus force the Nmcp ligand into a rotational arrangement which places the neomenthyl group in close proximity to the site of the sulfene ligand and thus impedes nucleophilic additions. In view of the combined difficulties − low reactivity of the sulfene complex, unsatisfactory diastereoselectivity, and inefficient diastereoisomer separation − we finally abandoned the concept of chirality-at-the-metal.

The synthesis of the chiral, enantiomerically pure sulfene complex **11** posed no challenge at all. At low temperature, **11** is present as a single rotamer with the sulfene ligand oriented in such a way that the SO_2 group is placed into the largest void of the [CpRu(chir)] complex fragment.[17] The stereochemical course of the enamine addition (Equation 7) should therefore be again as outlined by Scheme 2, that is, the major diastereomer of **12** is expected to have (*R*) configuration at the newly created stereocenter. Unfortunately, we were unable to grow crystals of **12** suitable for an X-ray structure determination.

In the case of the enolate addition product **13d**, the (*R*) configuration at carbon was corroborated crystallographically. The outcome of the reaction would thus suggest a transition state as shown in Scheme 3, in which the large *tert*-butoxy group of the β-oxo ester is placed in the vicinity of the Cp ligand, which is less bulky than the PPh_2 groups of the chelate diphosphane. The solvated Na^+ cation is too far removed to interfere with the ruthenium complex.

Scheme 3. Diastereoselective approach of deprotonated β-oxo ester to sulfene complex **11**

Enantiomerically pure esters of sulfinic acids are important starting materials for the stereoselective synthesis of chiral sulfoxides.[29] It was, therefore, quite gratifying that the alkylation of **13a** (Equation 9) proceeded with good stereoselectivity. Inspection of the molecular structure of **13d′** or the closely related achiral sulfinate complex [CpRu(dppm)(SO_2Et)][22] shows that the SO_2R ligand in halfsandwich complexes is always oriented so that one of the two S=O groups is nested between the phenyl groups of the chelate diphosphane while the other one is accessible from the direction of the Cp ligand. For a chiral sulfinate complex with a fixed rotational arrangement of the SO_2R ligand such as **13a**, this means that the formation of the (R_S) ester complex will be favored. In the alkylation of **13d′**, the low de is then probably the result of a mismatch situation caused by the stereocenter at the quaternary carbon atom.

Conclusions

Chiral ruthenium halfsandwich complexes combine two interesting and potentially quite useful properties, the stabilization of otherwise short-lived unsaturated species, and the asymmetric induction in ligand-based reactions. The enantiomerically pure fragment $[CpRu(chir)]^+$ in particular stands out for its ready accessibility and excellent crystallization of almost all of its complexes. A promising potential in synthetic applications can thus be easily foreseen

Experimental Section

General Remarks: All experiments were carried out in Schlenk tubes under nitrogen in suitably purified solvents. The crystallization of oily products was often conveniently induced by immersing the Schlenk tube in a small ultrasonic cleaning bath. − IR: Perkin−Elmer 283, Bruker IFS 25. − ^{1}H NMR: Bruker AMX 400, δ values relative to TMS; diastereotopic methylene protons of ethoxy groups in most cases gave well-resolved ABX_3 spectra with ^2J(H,H) = 9−11 Hz and ^3J(H,H) = 7.2 Hz; for the sake of simplicity they are denoted in the following as "res. m" (resolved multiplet). − ^{13}C NMR: Bruker AMX 400, δ values relative to TMS; assignments were routinely checked by DEPT; in some cases the ^{13}C NMR signals of quaternary carbon atoms were too weak to be detected. ^{31}P NMR: Bruker AMX 400, δ values relative to 85% H_3PO_4. The ^{1}H and ^{13}C NMR signals of the phosphane ligands and the ^{31}P NMR signal of the PF_6^- ion are very similar for all compounds and have therefore been omitted from the lists of spectral data. − Elemental analyses: Analytical Laboratory of the Insti-

tut für Anorganische Chemie. − The following starting materials were obtained as described in the literature: [CpRu(mppe)(-SO_2)]PF_6 (**1**),[12] diazomethane, diazoethane,[30] neomenthylcyclopentadiene,[31] $[RuCl_2(PPh_3)_3]$,[32] [CpRu(chir)Cl].[33] Enolates were obtained from the corresponding 1,3-dicarbonyl compounds by deprotonation with sodium bis(trimethylsilyl)amide. All other reagents were used as purchased.

[CpRu(mppe)(CH_2=SO_2)]PF_6 (2a): To a solution of **1** (89 mg, 0.14 mmol) in dichloromethane (15 mL), a solution of diazomethane in diethyl ether (0.6 mL, 0.2 mmol) was added at −70 °C. Gas evolution and a rapid color change to pale yellow were observed. The mixture was allowed to warm to 0 °C, and was concentrated rapidly to 2 mL. Hexane (15 mL) was added to precipitate the tan-colored microcrystalline product. Yield 87 mg (96%), m.p. 98 °C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 0.20 [dd, ^2J(H,H) = 4.4 Hz, ^3J(P,H) = 16.1 Hz, 1 H, SO_2=CH_2], 2.41 [d, ^2J(H,H) = 4.4 Hz, SO_2=CH_2], 5.68 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = −19.1 [d, ^2J(P,C) = 6 Hz, SO_2=CH_2], 95.1 (s, C_5H_5). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 66.4 [d, J(P,P) = 18 Hz, PMe_2], 78.3 [d, J(P,P) = 18 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1236, 1104 cm^{-1} (S=O). − $C_{22}H_{27}F_6O_2P_3RuS$ (663.5): calcd. C 39.83, H 4.10; found C 39.97, H 4.00.

[CpRu(mppe)(CHMe=SO_2)]PF_6 (2b): This compound was prepared from **1** (146 mg, 0.22 mmol) and diazoethane (0.25 mmol) as described above except that the product was isolated at −30 °C by addition of precooled hexane. Yield 146 mg (96%), m.p. 129 °C (dec.). − Major diastereoisomer (74%): ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 0.68 [dq, ^3J(H,H) = 6.4 Hz, ^3J(P,H) = 16.4 Hz, 1 H, SO_2=CH], 1.50 [d, ^3J(H,H) = 6.4 Hz, 3 H, CH_3], 5.61 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 2.1 [d, ^2J(P,C) = 5 Hz, CH=SO_2], 18.6 (s, CH_3), 95.9 (s, C_5H_5). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 67.6 [d, J(P,P) = 19 Hz, PMe_2], 77.6 [d, J(P,P) = 19 Hz, PPh_2]. − Minor diastereoisomer (26%): ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 1.74 [d, ^3J(H,H) = 6.4 Hz, 3 H, CH_3], 5.46 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 91.4 (s, C_5H_5). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 64.6 [d, J(P,P) = 15 Hz, PMe_2], 85.8 [d, J(P,P) = 15 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1220, 1117 cm^{-1} (S=O). − $C_{23}H_{29}F_6O_2P_3RuS$ (677.5): calcd. C 40.77, H 4.31, S 4.73; found C 41.08, H 4.51, S 4.45.

[CpRu(mppe)$SO_2CH_2(C_9H_{15}NO)$]PF_6 (3): To a solution of **2a** (73 mg, 0.11 mmol) in dichloromethane (10 mL), a solution of *N*-(1-cyclopentenyl)morpholine in diethyl ether (0.5 mL, 0.12 mmol) was added at −70 °C. The solution was allowed to warm to 20 °C and stirred for an additional hour at this temperature. The mixture was then concentrated to 2 mL and the colorless product was precipitated by adding diethyl ether. Yield 68 mg (76%), m.p. 127 °C (dec.). − Major diastereoisomer (80%): ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 1.61−2.19 (m, 4 H, 2 × CH_2), 2.31 [dd, ^2J(H,H) = 13.6 Hz, ^3J(H,H) = 7.2 Hz, 1 H, SO_2CH], 2.44 [dd, ^2J(H,H) = 13.6 Hz, ^3J(H,H) = 7.2 Hz, 1 H, SO_2CH], 2.77−2.96 (m, 4 H, 2 × OCH_2), 3.72−3.99 (m, 4 H, 2 × NCH_2), 4.97 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 21.0 (s, C-4), 31.7 (s, C-3), 35.6 (s, C-5), 43.2 (s, C-2), 58.9 (s, NCH_2), 61.9 (s, NCH_2), 64.3 (s, OCH_2), 66.0 (s, OCH_2), 70.5 (s, SO_2CH_2), 84.0 (s, C_5H_5), 203.4 (s, C=N). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 51.7 [d, J(P,P) = 28 Hz, PMe_2], 85.2 [d, J(P,P) = 28 Hz, PPh_2]. − Minor diastereoisomer (20%): ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 1.61−2.19 (m, 4 H, 2 × CH_2), 2.77−2.96 (m, 4 H, 2 × OCH_2), 3.72−3.99 (m, 4 H, 2 × NCH_2), 4.92 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 22.3 (s, C-4), 32.4 (s, C-3), 35.1 (s, C-5), 39.7 (s, C-2), 65.6 (s, OCH_2), 67.0 (s, OCH_2), 74.1 (s, SO_2CH_2), 84.1 (s, C_5H_5). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 51.8 [d, J(P,P) = 26 Hz, PMe_2], 85.3 [d, J(P,P) = 26 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1678 cm^{-1} (C=N), 1132, 1017 cm^{-1} (S=O). − $C_{31}H_{42}F_6NO_3P_3RuS$ (816.7): calcd. C 45.59, H 5.18, N 1.72; found C 44.95, H 5.08, N 1.57.

Addition of Enolates to 2a: To a solution of Na[$N(SiMe_3)_2$] (40 mg, 0.22 mmol) in THF (5 mL), an equimolar amount of the respective C−H acidic compound was added at −70 °C. The resulting slurry was then added to a solution of **2a** (135 mg, 0.20 mmol) in THF (20 mL). The mixture was allowed to warm to 20 °C and stirred for 2 h. The solvent was removed under vacuum, the oily residue was taken up in dichloromethane and chromatographed (neutral alumina, activity grade I, acetone/dichloromethane, 5:1). A broad, pale-yellow band containing the product was collected. The solvent was evaporated and the colorless product was recrystallized from benzene/hexanes.

4a: Yield 72 mg (54%), m.p. 115 °C (dec.). − Major diastereoisomer (71%): ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 1.13 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.49 (s, 3 H, CH_3), 2.18 [d, ^2J(H,H) = 13.5 Hz, 1 H, SO_2CH_2], 2.26 (s, 3 H, CH_3), 3.46 [d, ^2J(H,H) = 13.5 Hz, 1 H, SO_2CH_2], 3.98 (res. m, OCH_2), 4.89 (s, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ = 13.9 (s, CH_3), 20.3 (s, CH_3), 27.8 (s, CH_3), 57.8 (s, C_{quat}), 60.9 (s, OCH_2), 74.7 (s, SO_2CH_2), 84.3 (s, C_5H_5), 171.9 (s, CO), 207.1 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20 °C): δ = 53.3 [d, J(P,P) = 28 Hz, PMe_2], 87.0 [d, J(P,P) = 28 Hz, PPh_2]. − Minor diastereoisomer (29%): ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 1.22 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.37 (s, 3 H, CH_3), 1.81 (s, 3 H, CH_3), 2.19 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 3.21 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 4.17 (res. m, OCH_2), 4.92 (s, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ = 14.0 (s, CH_3), 18.5 (s, CH_3), 24.8 (s, CH_3), 59.3 (s, C_{quat}), 61.1 (s, OCH_2), 71.6 (s, SO_2CH_2), 84.1 (s, C_5H_5), 172.0 (s, CO), 204.4 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20 °C): δ = 53.5 [d, J(P,P) = 27 Hz, PMe_2], 86.8 [d, J(P,P) = 27 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1738, 1706 cm^{-1} (CO), 1187, 1150, 1000 cm^{-1} (S=O). − $C_{29}H_{38}O_5P_2RuS$ (661.7): calcd. 4c: Yield 85 mg (63%), m.p. 177 °C (dec.). − Major diastereoisomer (66%): ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 1.14 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 2.34 [d, ^2J(H,H) = 13.8 Hz, 1 H, SO_2CH_2], 3.31 [d, ^2J(H,H) = 13.8 Hz, 1 H, SO_2CH_2], 3.96 (res. m, 2 H, OCH_2), 4.90 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ =

14.0 (s, CH_3), 19.8 (s, CH_2), 30.8 (s, CH_2), 37.5 (CH_2), 58.6 (s, C_{quat}), 60.9 (s, OCH_2), 72.5 (s, SO_2CH_2), 84.5 (s, C_5H_5), 170.8 (s, CO), 215.5 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 53.3 [d, J(P,P) = 28 Hz, PMe_2], 86.9 [d, J(P,P) = 28 Hz, PPh_2]. − Minor diastereoisomer (34%): ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.21 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.63 [d, ^2J(H,H) = 13.5 Hz, 1 H, SO_2CH_2], 3.15 [d, ^2J(H,H) = 13.5 Hz, 1 H, SO_2CH_2], 4.13 [q, ^3J(H,H) = 7.1 Hz, 2 H, OCH_2], 4.94 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 19.1 (s, CH_2), 19.5 (s, CH_3), 30.4 (s, CH_2), 37.0 (s, CH_2), 59.8 (s, C_{quat}), 61.2 (s, OCH_2), 69.0 (s, CH_2SO_2), 84.2 (s, C_5H_5), 169.2 (s, CO), 213.7 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 53.4 [d, J(P,P) = 28 Hz, PMe_2], 86.7 [d, J(P,P) = 28 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1742, 1721 cm^{-1} (CO), 1150, 1121, 1024, 1011 cm^{-1} (S=O). − $C_{30}H_{38}O_5P_2RuS$ (673.7): calcd. C 53.48, H 5.69; found C 52.62, H 5.44.

4c by Titanium Enolate Addition: Ethyl 2-oxocyclopentanecarboxylate (35 mg, 0.22 mmol) was deprotonated as described above and then treated at −30°C with $TiCl(OiPr)_3$. After addition of **2a** (135 mg, 0.20 mmol), the mixture was allowed to warm to 20°C and was stirred for 2 h. The solvent was removed under vacuum, and the oily residue was taken up in CD_2Cl_2 and analysed by ^{1}H and ^{31}P NMR, which indicated the formation of **4c** with 81% de. Attempted workup by hydrolysis and chromatography, however, resulted in an intractable mixture from which **4c** could not be separated in pure form.

[CpRu(mppe){$SO_2CH(Me)(C_8H_{13}O_4)$}] (4d): To a solution of $Na[N(SiMe_3)_2]$ (103 mg, 0.56 mmol) in THF (20 mL), diethyl methylmalonate (87 mg, 0.50 mmol) was added at −70°C. In a separate reaction, a solution of **1** (325 mg, 0.50 mmol) in dichloromethane (25 mL) was treated with a solution of diazoethane in diethyl ether (2.0 mL, 0.51 mmol) at −70°C and stirred at this temperature for 5 min. The two solutions were combined at −70 °C, and the resulting mixture was allowed to warm to 20 °C and was stirred for an additional hour. The solvent was then removed under vacuum and the oily residue was taken up in dichloromethane and chromatographed (neutral alumina, activity grade I, acetone/dichloromethane, 2:1). A broad, pale-yellow band containing the product was collected. The solvent was evaporated and the product was recrystallized from benzene/hexanes. Yield 251 mg (71%), m.p. 106°C (dec.). − Major diastereoisomer (63%): ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 0.19 [d, ^3J(H,H) = 7.2 Hz, 3 H, CH_3], 1.14 [t, ^3J(H,H) = 7.2 Hz, 3 H, CH_3], 1.17−1.26 (m, 3 H, CH_3), 1.46 (s, 3 H, CH_3), 3.45 [q, ^3J(H,H) = 7.2 Hz, 1 H, SO_2CH], 3.98−4.28 (m, 4 H, 2 × OCH_2], 4.84 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 9.7 (s, CH_3), 14.0 (s, CH_3), 14.1 (s, CH_3), 14.5 (s, CH_3), 58.0 (s, C_{quat}), 60.8 (s, OCH_2), 61.0 (s, OCH_2), 74.2 (s, SO_2CH), 83.5 (s, C_5H_5), 171.1 (s, CO), 171.2 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 61.0 [d, J(P,P) = 16 Hz, PMe_2], 85.9 [d, J(P,P) = 16 Hz, PPh_2]. − Minor diastereoisomer (37%): ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.16 [t, ^3J(H,H) = 7.2 Hz, 3 H, CH_3], 1.17−1.26 (m, 3 H, CH_3), 1.24 [d, ^3J(H,H) = 8.0 Hz, 3 H, CH_3], 1.45 (s, 3 H, CH_3), 3.70 [q, ^3J(H,H) = 8.0 Hz, 1 H, SO_2CH], 3.98−4.28 (m, 4 H, 2 × OCH_2], 5.00 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 12.5 (s, CH_3), 14.0 (s, CH_3), 15.1 (s, CH_3), 29.4 (s, CH_3), 56.9 (s, C_{quat}), 61.0 (s, OCH_2), 61.2 (s, OCH_2), 71.7 (s, SO_2CH), 83.3 (s, C_5H_5), 171.1 (s, CO), 171.2 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 51.6 [d, J(P,P) = 29 Hz, PMe_2], 81.5 [d, J(P,P) = 29 Hz, PPh_2]. − IR (Nujol): $\tilde{\nu}$ = 1731 cm^{-1} (CO), 1165, 1051 cm^{-1} (S=O). − $C_{31}H_{42}O_6P_2RuS$ (705.8): calcd. [NmCpRu(PPh_3)$_2$Cl] (5): To a solution of (+)-neomenthylcyclopentadiene (1.94 g, 9.49 mmol) in diethyl ether (50 mL) was added, at 0°C, a solution of methyllithium in diethyl ether (6.25 mL, 10.0 mmol). The mixture was allowed to warm to room temperature and was stirred overnight. A white precipitate was formed, which was washed thoroughly with diethyl ether; the resulting solution was dried under vacuum. The lithium neomenthylcyclopentadienide (84 mg, 0.40 mmol) was added to a solution of [$RuCl_2(PPh_3)_3$] (336 mg, 0.35 mmol) in benzene (30 mL). The mixture was heated under reflux for 1 h, causing a color change to orange. The solvent was removed under vacuum and the residue was chromatographed (silica gel, acetone/dichloromethane, 10:1). A broad orange band containing the product was collected and concentrated to dryness. The residue was taken up in hexane and treated with ultrasound whereupon the product separated out as an orange crystalline powder. Yield 212 mg (70%), m.p. 125°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 0.74 [d, ^3J(H,H) = 6.4 Hz, 3 H, CH_3], 0.89 [d, ^3J(H,H) = 6.4 Hz, 3 H, CH_3], 0.91 [d, ^3J(H,H) = 6.4 Hz, 3 H, CH_3], 1.01−1.77 (m, 7 H, Nm), 2.43−2.51 (m, 2 H, Nm), 2.88−2.96 (m, 1 H, Nm), 3.05, 3.62, 3.91, 4.02 (4 × s, 4 × 1 H, C_5H_4Nm). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 21.3 (s, CH_3), 22.4 (s, CH_3), 22.7 (s, CH_3), 24.9 (s, CH_2), 28.0 (s, CH), 28.6 (s, CH), 34.3 (s, CH), 35.4 (s, CH_2), 38.1 (s, CH_2), 50.2 (s, CH), 73.5, 76.1 (2 × s, 2 × C_5H_4), 78.7, 80.4 [2 × d, ^2J(P,C) = 9 Hz, 2 × C_5H_4], 115.9 [d, ^2J(P,C) = 5 Hz, C_5H_4]. − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 39.9 [d, ^2J(P,P) = 41 Hz], 40.8 [d, ^2J(P,P) = 41 Hz]. − $C_{51}H_{53}ClP_2Ru$ (864.5): calcd. Liberation of the Sulfinic Acid Ester 16: 14b (0.22 g, 0.22 mmol) was dissolved in acetonitrile (10 mL) and heated under reflux for 15 h. Thereafter, the mixture was concentrated to dryness, and the resulting residue was suspended in diethyl ether. Upon ultrasonic treatment, complex **15** separated as a yellow powder, which was filtered off, washed with diethyl ether, and dried. The filtrate was concentrated to dryness, leaving the ester **16** as a colorless, spectroscopically pure oil.

15: Yield 0.16 g (93%), m.p. 113°C (dec.). − ^{1}H NMR (400 MHz, [D$_6$]acetone, 20°C): δ = 1.78 (s, 3 H, CH_3), 4.70 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, [D$_6$]acetone, 20°C): δ = 3.2 (s, CH_3), 83.2 [t, ^2J(P,C) = 2 Hz, C_5H_5], 127.5 (s, CN). − ^{31}P NMR (162 MHz, [D$_6$]acetone, 20°C): δ = 75.7 [d, *J*(P,P) = 40 Hz], 85.4 [d, *J*(P,P) = 40 Hz]. − $C_{35}H_{36}F_6NP_3Ru$ (778.7): calcd. X-ray Structure Determination of [CpRu(chir)(SO$_2$)]PF$_6$·2CH$_2$Cl$_2$ (10·2CH$_2$Cl$_2$): $C_{33}H_{33}F_6O_2P_3RuS{\cdot}2CH_2Cl_2$: molecular mass 971.49, crystal size 0.6 × 0.4 × 0.35 mm, obtained by diffusion of pentane into a concentrated dichloromethane solution; orthorhombic crystal system, space group $P2_12_12_1$ (No. 19), a = 12.6062(13), b = 16.025(2), c = 19.614(3) Å; V = 3962.3(9) Å^3, Z = 4, $d_{calcd.}$ = 1.629 g cm^{-3}; μ(Mo-K_α) = 9.00 cm^{-1}. Data were collected at 193 K in the range 2° < Θ < 25° from slightly more than one-eighth of the reflection sphere (index range $0 \le h \le 14$, $-3 \le k \le 19$, $-3 \le l \le 23$, Enraf−Nonius CAD4 diffractometer, graphite monochromator, Mo-K_α radiation, λ = 0.71073 Å). Of the 5595 measured reflections, 5128 were symmetry-independent and 4117 were classified as observed [$I_0 > 2\sigma(I_0)$]. An empirical absorption correction based on Ψ-scans was applied (average transmission 89.3%). The structure was solved by Direct Methods using the program package SHELXS-93[34] with hydrogen atoms included in their calculated positions. Refinement with the program package SHELXL-96[35] gave R_1 = 0.0545, wR_2 = 0.1214. The five highest maxima of a final difference Fourier map were below 0.78 e/Å^3. Further details of the structure determination may be obtained from the Cambridge Crystallographic Data Centre on quoting the depository number CCDC-132910.

X-ray Structure Determination of [CpRu(chir){SO$_2$CH$_2$C(Me)-{C(O)Me}[C(O)O*t*Bu]}] (13d′): $C_{43}H_{50}O_5P_2RuS$: molecular mass 841.90, crystal size 0.4 × 0.3 × 0.25 mm, obtained by diffusion of heptane into a concentrated benzene solution; tetragonal crystal system, space group $P4_32_12$ (No. 96), a = 16.389(2), b = 16.389(2), c = 29.607(5) Å; V = 7952(2) Å^3, Z = 8, $d_{calcd.}$ = 1.406 g cm^{-3}; μ(Mo-K_α) = 2.07 cm^{-1}. Data were collected at 293 K in the range 2° < Θ < 27° from one-eighth of the reflection sphere (index range $0 \le h \le 20$, $0 \le k \le 20$, $0 \le l \le 37$, Enraf−Nonius CAD4 diffractometer, graphite monochromator, Mo-K_α radiation, λ = 0.70930 Å). Of the 9400 measured reflections, 8646 were symmetry-independent and 5906 were classified as observed [$I_0 > 2\sigma(I_0)$]. An empirical absorption correction based on the counts of nine reflections was applied. The structure was solved by the Patterson method, with the program package SHELXS-86,[36] with hydrogen atoms included in their calculated positions. Refinement with the program package SHELXL-93[37] gave R_1 = 0.0444, wR_2 = 0.07128. The five highest maxima of a final difference Fourier map were below 0.30 e/Å^3. Further details of the structure determination may be obtained from the Cambridge Crystallographic Data Centre on quoting the depository number CCDC-132859.

Nickel Chelate Complexes of 2-Alkylphenylphosphanylphenolates: Synthesis, Structural Investigation and Use in Ethylene Polymerization

Joachim Heinicke,*[a] Manuela Koesling,[a] Robert Brüll,[b] Wilhelm Keim,[b] and Hans Pritzkow[c]

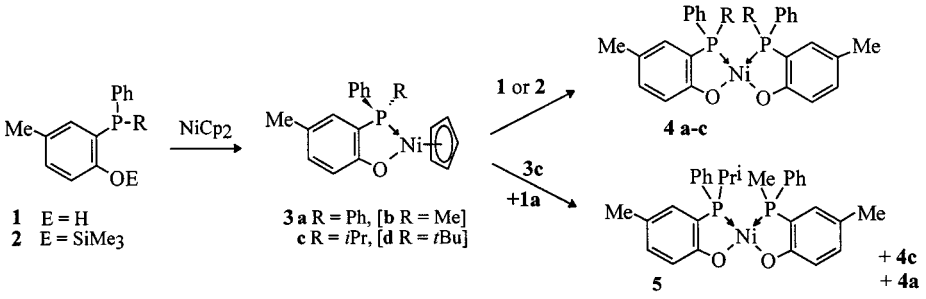
Keywords: Phosphanylphenolate / Cyclopentadienylnickel complexes / Chelates / Ethylene polymerization / Crystal structure / Polymerizations

2-Diphenylphosphanyl- and 2-alkylphenylphosphanyl-4-methylphenols **1** or their silyl ethers **2** and equimolar amounts of nickelocene react in benzene preferably to give orange-brown diamagnetic cyclopentadienylnickel chelate complexes [η-CpNi(P⌒O)] (**3**). Addition of a second equivalent of **1** or **2** affords (*RR*) and (*SS*) diastereoisomers of *cis*-bis(P⌒O-chelates) **4a–c** (R = Ph, Me, *i*Pr) or the unsymmetrical *cis*-bis(P⌒O-chelate) **5**, whereas with bulkier substituted derivatives **1d** or **2d** (R = *t*Bu) the second step is hindered or retarded. The reactivity of **1d** remains high towards nickel salts in polar solvents, but in contrast to **1a–c**, yielding **4**, a sparingly soluble green *trans*-bis(P–O-chelate) nickel complex **6d** is formed. Complexes formed in situ from **1** or **2** and $Ni(COD)_2$ in toluene catalyze the polymerization of ethylene. The cyclopentadienyl (P⌒O) complexes **3**, however, are too stable to be active in this process. The crystal and molecular structure of **3c** and **4c** are described.

Introduction

Functionalized phosphanes containing hard and soft donor centers allow various coordination modes with transition metals in high or low oxidation states and thus have attracted considerable interest in complex chemistry and homogenous catalysis. Tertiary 2-phosphanylphenolates[1−3] prefer bis(P⌒O-chelate) transition-metal complexes;[2,4] these are remarkably stabilized, are formed even by dealkylation of 2-phosphanylphenyl-alkyl ether complexes[5] and are able to undergo *O*,*O*′-coordination with a second hard metal ion.[6] Furthermore, monophosphanylphenolate chelate complexes bearing an additional phosphane molecule,[7] a solely *P*-coordinate 2-phosphanylphenol or a cyclopentadienyl ligand[2,8,9] are known. Very recently, phenylnickel diphenylphosphanylphenolate phosphane complexes were reported.[10] In view of the crucial role of mono(P⌒O-chelate) species in the industrially important homogenous nickel-catalyzed oligomerization of ethene (Shell Higher Olefin Process, SHOP),[11] we investigated complex chemical reactions of various *P*-substituted 2-phenylphosphanyl-4-methylphenols **1a−d** and their *O*-trimethylsilyl ethers **2a−d** with nickelocene in toluene, some nickel salts or complexes in more polar solvents and the polymerization with catalysts obtained from phosphanylphenols and $Ni(COD)_2$. The influence of substituents on the polymerization will be reported separately.

Results and Discussion



Reactions

2-Diphenylphosphanyl-4-methylphenol (**1a**) and an equimolar amount of nickelocene in benzene afford the cyclopentadienyl(P⌒O-chelate)nickel complex **3a** ($\delta^{31}P$ = 37.8; $\Delta\delta$ = 65 ppm) and a small amount of *cis*-$(P\text{-}O)_2Ni$ (**4a**) ($\delta^{31}P$ = 34.4; $\Delta\delta$ = 61.6 ppm) (Scheme 1). 2-Isopropylphenylphosphanyl-4-methylphenol (**1c**) exhibits a higher selectivity for monosubstitution and is isolated as pure orange-brown **3c** ($\delta^{31}P$ = 50.5; $\Delta\delta$ = 80.3 ppm) from a benzene solution at 20°C. Contamination by **4c** is observed if the complex is precipitated by ether or, markedly increased, on heating solutions of **1c** or **2c** with nickelocene. The silyl ethers **2** are less reactive than **1** and the higher temperatures required favor contamination by **4**. Reactions of the methyl- (**1b**, **2b**) or *tert*-butyl derivatives (**1d**, **2d**) with nickelocene (1:1) in benzene furnish brown diamagnetic substances, which are highly soluble in benzene, THF, CH_2Cl_2 or chloroform. NMR spectra of the products give evidence of monosubstitution of the *tert*-butyl derivatives, whereas disubstitution to **4b** is preferred for the sterically less demanding methyl species. This is seen in the ^{1}H-NMR spectra by pseudotriplets for the *P*-methyl protons. A side product with $\delta^{31}P$ = 26.4 (ca. 15%) in the reaction with **2b**, which could not be isolated, is tentatively assigned to **3b**. Like the other η^5-cyclopentadienyl(P⌒O-chelate)nickel complexes, it exhibits modest larger values of the typical downfield coordination shift of five-membered chelate complexes[12] than the *cis*-bis(phosphanylphenolato)nickel com-

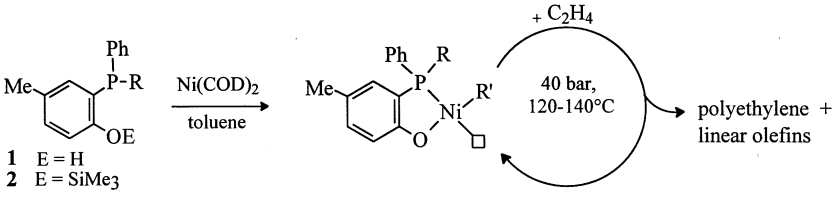
The reaction of nickelocene with two equivalents of **1a−c** or **2a−c** in benzene smoothly gives *cis*-bis(P−O-chelate)nickel complexes **4a−c,** indicating an easy replacement of the second cyclopentadienyl ligand in the 18-valence-electron complexes **3**. Similarly, addition of **1b** to **3c** yields the unsymmetrical *cis*-[Ni(P⌒O)(P′⌒O)] chelate complex **5**. Contamination by **4c** and to a smaller amount by **4b** (ratio roughly 60:30:10) provides evidence that ligand substitution is not limited to the cyclopentadienyl anion but involves also the (P⌒O-chelate) group. The reaction of nickelocene with two equivalents of the *tert*-butyl-substituted 2-phosphanylphenol derivatives **1d** or **2d** in benzene does not proceed completely. Neither **4d** nor **6d** can be detected. It is assumed that the conversion in benzene is hindered or slowed for steric reasons. In polar solvents, however, the ligand exchange is much faster, and bis(P⌒O)nickel complexes are formed with **1a−c** or **2a−c** as well as with **1d** or **2d**. The reason is the high driving force for the bis(phosphanylphenolato)nickel complexes which are also the usual products in reactions with nickel acetylacetonate, with aqueous nickel salts in methanol, or anhydrous nickel salts in THF if a sufficient amount of base or buffer is added. Similarly, attempts to prepare [(Ph*t*BuP⌒O)NiBr(PPh$_3$)$_n$] by reacting **1d(Li)** with $NiBr_2 \cdot 2PPh_3$ in ether in an equimolar ratio failed in favor of the bis(P⌒O)nickel complex (Scheme 2). The bulkier *tert*-butyl derivatives react differently to the others, forming brown solutions of **4a−c**, by precipitation of a diamagnetic green *trans*-bis(P⌒O-chelate)nickel complex **6d** which is insoluble or sparingly soluble in all common organic solvents.

Catalysis

The organonickel phosphanylphenolates **3** are structurally related to organonickel phosphanylenolates,[9,13-15] which form the catalytically active species in the Shell Higher Olefin Process.[10] Attempts to oligomerize ethylene by using the cyclopentadienylnickel complex **3c** at 40 bar and 140°C failed, however. The reason is, that despite the easy replacement of the cyclopentadienyl group by **1** or **2**, the semisandwich complexes **3** are thermally very stable and are unable to form catalytically active η^1-CpNi- or NiH-(PO-chelate) complexes. DTA of **3c** indicates loss of cyclopentadiene only at 190−210°C (endothermic). Complete decomposition of the Ni(P⌒O-chelate) structure occurs at 280−340°C. For comparison, the thermal degradation of **4c** proceeds in the same temperature range (280−340°C) after an exothermic process at 271°C, whereas **5d** starts to decompose at even higher temperature (310−340°C). The importance of the loss of the cyclopentadienyl group for catalytic activity was demonstrated for the less stable related

Scheme 2. Reactions of **1** or **2** with nickel salts



phosphanylenolate complex [Ni(η^5-Cp){Ph_2PCH=C(Ph)O}] (decomp. at 130°C) which like other nickel enolate complexes becomes active at the decomposition temperature and thus gives evidence that the remaining (phosphanylenolato)nickel hydride represents the starting catalyst.[11,13b] That less stable organonickel complexes obtained from phosphanylphenols and $Ni(COD)_2$ catalyze the polymerization or oligomerization of ethylene was first claimed by Singleton.[16] A catalyst prepared from *o*-diphenylphosphanylphenol and $Ni(COD)_2$ was found to convert ethylene in high yield (95%) to linear polyethylene and a lower amount of linear oligomers whereas a catalyst prepared with 2-diethylphosphanylphenol was found to be much less active (conversion 3.5%) and shows high preference for lower oligomers (C_4 68%, C_6 24%, C_8 4.3%). The recently reported phenylnickel phosphanylphenolate phosphane complexes[10] and an immobilized [$PhNi(PPh_3)$(2-Ph_2P-6-HO-$C_6H_3O^-$)] (P⌒O-chelate) complex[17] were found to oligomerize ethylene. We observed that complex solutions prepared from the alkylarylphosphanylphenol **1c** or its silyl ether **2c** and equimolar amounts of Ni(1,5-COD)$_2$ form catalysts for the formation of polymers and smaller amounts of oligomers of ethylene with high selectivity for linear structures (Scheme 3). Toluene was used as the solvent to avoid conversion into the catalytically inactive bis(phosphanylphenolato)nickel complex **4c,** which as seen above, is strongly favored in more polar solvents. Indeed, no catalytic activity was observed if the reaction was run in ethanol. In toluene, at 50 bar/160°C, the oligomer-to-polymer ratio was 15%:85%. The oligomer portion consisted of linear olefins, mainly from C_6 to C_{26} with a flat maximum at C_{16}/C_{18}. The polymer exhibits sharp absorptions for vinyl end groups at 909 and 991 cm^{-1} ($\tilde{\nu}_{C=C}$ 1641 cm^{-1}) and a small band for CH_3 at 1368 cm^{-1} but only weak bands for the *trans*-CH=CH or C=CH_2 groups and no indications of branching.[18] X-ray powder diffraction revealed high crystallinity. A molar mass distribution with M_w = 9310 $gmol^{-1}$ (corresponding to n = 330) and M_n = 6087 $gmol^{-1}$ was determined. The results with **1c** and **2c** are similar and can be attributed to the easy formation of (P⌒O-chelates) in both cases, as was also found in the reaction with nickelocene.

Structure Investigations

Compounds **3**–**5** are sparingly soluble in hexane or ether but easily soluble in benzene, CH_2Cl_2, chloroform or THF, allowing structure elucidation by multinuclear NMR spectra. **6d**, obtained as powder or microcrystals, was not sufficiently soluble for solution-NMR studies, and therefore was structurally characterized in comparison with **4c** by a solid-state ^{31}P-NMR investigation which is reported separately.[19] The solid-state structures of **3c** and **4c** were determined by single-crystal X-ray structure analysis.

^{13}C-NMR data of **3c** indicate unambiguously the semi-sandwich arrangement by a doublet for the cyclopentadienyl group and typical doublet or singlet signals for the phosphanylphenolate ligand with $J(^{31}P^{13}C)$, depending on the position towards the phosphorus atom. Proton, CH-COSY and phosphorus-NMR data of **3c** support the proposed structure. The assignment of the proton signals of **3a**, **3b** and **3d** was done by comparison with those of **3c**. In the solid state, **3c** crystallizes in the centrosymmetric space group $P\bar{1}$ with two independent molecules in the asymmetric unit, which show no significant deviations. The molecular structure of **3c** (Figure 1) shows a perpendicular arrangement of the Cp^- moiety and the planar (P⌒O) chelate ring (89.1 and 88.5°), with the Ni atom only slightly distorted from this plane. The distance from Ni to the cyclopentadienyl carbon atom (C21 and C39, respectively) placed in the *trans* position to the oxygen atom, are significantly shorter than are the Ni–C distances to the remaining cyclopentadienyl carbon atoms. This indicates a stabilization of the Ni–C bond by the phenolate *trans* coordination which for related catalytically active organonickel phosphanylphenolate species is important for the chain growth in the polymerization or oligomerization of ethylene. The C–P–C angles are typical for tetracoordination at the phosphorus atom, whereas the small P–Ni–O and C_{aroxy}–P–Ni angles result from geometric factors of the rigid five-membered ring and the bond lengths. The slight increase of the P–Ni–O angle (by 2–3°) in comparison to (diphenylphosphanylenolato)-[13–15] and (diphenylphosphanylalkoxido)nickel complexes[20,21] is consistent with a shorter P–Ni bond length (ca. 5 pm) within the ring.

In solution ^{1}H- and ^{13}C-NMR spectra of **4**, various nuclei show "triplets" or other multiplets representing the A_n or A_nA_n' part of A_nXX' or $A_nA'_nXX'$ spin systems by coupling with two ^{31}P nuclei (X, X′) and hence, reveal the bis(P⌒O-chelate) nature of **4**. The appearance depends on the relative magnitudes and signs of all coupling constants in the spin system.[22,23] Whereas the *cis* geometry of **5** is deduced from $^2J_{PP}$ = 80 Hz, which is much smaller than $^2J_{PP}$ in *trans*-methylnickel(phosphanylphenolato)PMe_3 complexes (ca. 316 Hz),[24] the geometry of **4** cannot easily be derived from the NMR data. In the proton spectrum

Scheme 3

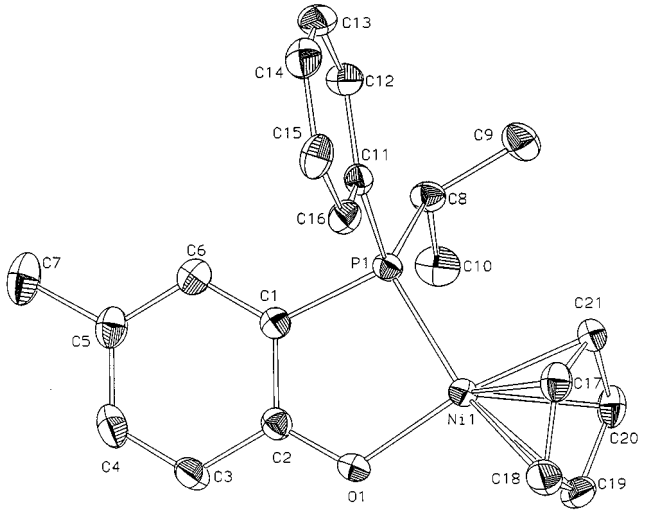


Figure 1. ORTEP plot of **3c**; selected bond lengths [Å] and angles [°], corresponding data for the second independent molecule are given in brackets: Ni1−P1 2.126(2) [2.132(2)], Ni1−O1 1.889 (3) [1.885(3)], Ni1−C21 2.048(4) [2.048(4)], Ni1−(C17−20) 2.144(4)−2.155(4) [2.146−2.162(4)], P1−C1 1.807(4) [1.807(4)], P1−C11 1.819(4) [1.823(4)], P1−C8 1.840(3) [1.850(3)]; O1−Ni1−P1 89.49(11) [89.56(12)], Ni1−P1−C1 98.90(13) [98.48(14)], C2−C1−P 111.9(2) [112.3(2)], C2−O1−Ni1 118.3(1) [118.1(2)], O1−C2−C1 121.5(3) [121.5(3)], C1−P1−C11 105.7 (2) [107.4(2)], C1−P1−C8 107.0(2) [106.2(2)]

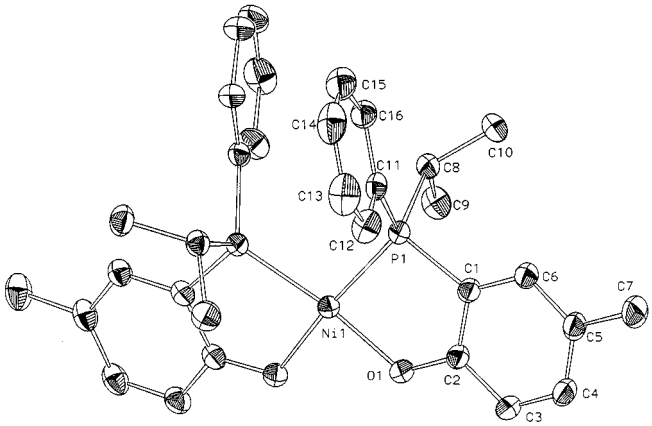

Figure 2. ORTEP plot of **4c**; selected bond lengths [Å] and angles [°]: Ni1−P1 2.1423 (13), Ni1−O1 1.885 (2), P1−C1 1.800 (2), P1−C11 1.814 (3), P1−C8 1.844 (3); P1−Ni1−P£1 97.93 (7), O1−Ni1−O£1 87.50 (11), O1−Ni1−P1 87.50 (8), Ni1−P1−C1 99.22 (10), C2−C1−P1 110.9 (2), C2−O1−Ni1 118.7 (2), O1−C2−C1 121.6 (2), C1−P1−C11 107.16 (12), C1−P1−C8 109.55 (12); symmetry transformation used to generate equivalent atoms: £1: $-x$, y, $-z + 1/2$)

of **4c** multiplets are observed for the diastereotopic methyl groups of $PCHMe_2$ resembling a "doublet of a doublet" and a "filled-in doublet" with doublet splitting of the external lines. Pseudotriplets by coupling with two ^{31}P nuclei ($|J_{XX'}| > |J_{AX} - J_{AX'}|$) are observed in the proton spectra of **4b** (PMe) or **6d** ($PCMe_3$) as well as in the ^{13}C-NMR spectra of **4b**,**c**. The two external lines in the five-line pattern in the A part (^{13}C) depend significantly on $^2J_{PP}$ and should allow an assignment of the geometry. However, the intensity of these lines is too low, even for the resonances of C2 or C_i(Ph), which exhibit the largest $^{31}P-^{13}C$ couplings and should display the most intensive external lines. As mentioned above, the geometry of **4c** was determined by solid-state investigations.[19] From the ^{31}P-CP/MAS NMR study, a two-bond coupling constant $^2J_{PP}$ of ca. 75 Hz was determined, thus indicating *cis* geometry. Detailed structural information is provided by the single-crystal X-ray structure analysis indicating a slightly distorted square-planar *cis* configuration of **4c** (Figure 2). The molecule has a crystallographic two-fold axis through the Ni atom yielding the (*RR*) or (*SS*) configuration. The P−Ni−O and P′−Ni−O′ planes are twisted by 7.1°. The distances and angles within the five-membered rings are similar to those in **3c** (P−Ni−O less by 2°). The O−Ni−O′ angle (87.5°) is somewhat smaller than 90° whereas the P−Ni−P′ angle is considerably widened in order to reduce steric repulsion of the P substituents. For the sterically less hindered methyl derivative **4a,** we observe characteristic ^{31}P- and ^1H-NMR signals of a second nickel atom bis(P⌒O-chelate) (B) (about 15%), which gives evidence of the existence of *rac* and *meso* isomers of **4a**.

The bulkier nickel bis(2-*tert*-butylphenylphosphanyl-4-methylphenolate) (**6d**), resembling *trans*-[Ni(tBu$_2$P−C$_6$H$_4$O)$_2$][2a] and *trans*-[Ni($Ph_2PCH_2R_2O)_2$] (R = CF_3)[20] in its unusual green color and low solubility, prefers an (*RS*)/(*SR*)-*trans* configuration with an inversion center at the nickel atom, as established by the high symmetry found in the solid-state ^{31}P-NMR investigation.[19] The low coordination shift of $\Delta\delta(^{31}P)$ = 43 ppm for **6d** as compared to $\Delta\delta(^{31}P)$ = 61−75 ppm for **4a−c** may be indicative for the different geometry but the lack of data for comparison needs further investigations to establish such a dependence.

Conclusion

(P⌒O-chelate)nickel(II) complexes **3−6** containing phosphanylphenolato ligands may be obtained by reaction of phosphanylphenols **1** or their silyl ethers **2** with nickelocene or nickel salts. Monochelates are formed with nickelocene in benzene. Small substituents, addition of polar solvents or increased temperature favor formation of bis(P⌒O-chelate)nickel complexes. Complexes formed in situ from **1c** or **2c** and equimolar amounts of $Ni(COD)_2$ in toluene were found to catalyze the formation of linear polymers and a smaller amount of oligomers of ethylene. From the slower formation of catalytically inactive **6d** from **1d** and nickelocene in benzene or toluene, it may be concluded that bulkier organonickel 2-phosphanylphenolate (P⌒O-chelate) complexes form interesting catalysts for olefin oligomerization or polymerization. The strengthening of the Ni−C bond in the *trans* position to the oxygen atom, as observed in **3c**, suggests a strong influence of donor properties at the O^- site on the chain length of polyethylene. A more detailed study on the influence of steric and electronic effects of substituents at the phosphorus atom and the aroxy group on polymerization or oligomerization of ethylene is in progress.

Experimental Section

General: All reactions were carried out under argon, using Schlenk techniques and freshly distilled dry solvents. Synthesis, properties and structures of the *P*-tertiary *o*-phosphanylphenols have been described elsewhere.[3b] Thermal analyses were carried out with a TGDTA92 (SETARAM) instrument. UV-Vis spectra were recorded with a Lambda19 spectrometer (Perkin−Elmer), mass spectra with a single-focussing mass spectrometer AMD40 (Intectra). NMR spectra were measured in $CDCl_3$ (unless indicated otherwise), using a multinuclear FT-NMR spectrometer ARX300 (Bruker) at 300.13 (^{1}H), 75.47 (^{13}C), and 121.49 (^{31}P) MHz. Shift references are tetramethylsilane for ^{1}H and ^{13}C, and H_3PO_4 (85%) for ^{31}P. For resonances which are part of a A_nX_2 spin system (X = ^{31}P) vc denotes "virtual coupling", τ the usual triplet appearance of the A resonance (n = 1) and $N = |J + J'|$.

Reactions of 1 and 2 with Nickelocene in Equimolar Ratio. − Cyclopentadienyl(2-diphenylphosphanyl-4-methylphenolato)nickel (3a): A solution of **1a** (900 mg, 3.08 mmol) in benzene (10 mL) was added to a solution of nickelocene (580 mg, 3.07 mmol) in benzene (10 mL) and stirred for 2 h. Most of the solvent (ca. 18 mL) was removed in vacuo and ether (5 mL) was added to give 1.15 g of an orange-brown precipitate, consisting of **3a** and **4a** (ca. 70%:30%, d^{31}P = 37.8, 34.5). Column chromatography on silica gel yielded 0.7 g (55%) of pure **3a** by elution with $CHCl_3$/acetone (10:1). − ^{1}H NMR: δ = 2.13 (s, 3 H, 4-Me), 5.31 (s, 5 H, Cp), 6.63 (d, $^3J_{HH}$ = 7−8, $^4J_{PH}$ = 5.5 Hz, 1 H, 6-H), 6.87 (d, $^3J_{HH}$ = 7−8 Hz, 1 H, 5-H), 6.87 (d, $^3J_{PH}$ = 10 Hz, 1 H, 3-H), 7.35−7.55 (m, 6 H, *m,p*-H), 7.65−7.8 (m, 4 H, *o*-H). − $C_{24}H_{21}NiOP$ (415.10): calcd. C 69.44, H 4.80; found C 69.62, H 4.95.

Cyclopentadienyl(2-isopropylphenylphosphanyl-4-methylphenolato)-nickel (3c): (a) A solution of **1c** (274 mg, 1.06 mmol) in benzene (10 mL) was added to nickelocene (200 mg, 1.06 mmol) in benzene (10 mL). After 1 d, about 80% of the solvent was removed. Within 3 d, 216 mg (53%) of orange-brown **3c** crystallized, m.p. 184°C. − UV/Vis [MeOH; λ_{max}/nm (ε/M^{-1}cm^{-1})]: 454 (880), 301 (1700), 267 (1500), 226 (sh, 2600). − ^{1}H NMR and CH COSY (C_6D_6): δ = 0.99 (dd, $^3J_{PH}$ = 18.5, $^3J_{HH}$ = 7.0 Hz, 3 H, Me_A), 1.17 (dd, $^3J_{PH}$ = 16.8, $^3J_{HH}$ = 6.9 Hz, 3 H, Me_B), 2.04 (m, 1 H, CH), 2.07 (s, 3 H, 4-Me), 5.18 (s, 5 H, Cp), 6.81 (d, $^3J_{HH}$ = 8.5, 1 H, 5-H), 6.97 (dd, $^3J_{HH}$ = 8.5, $^4J_{PH}$ = 5.5 Hz, 1 H, 6-H), 7.07 (s, 1 H, 3-H), 6.94 (m, 1 H, *p*-H), 7.06 (m, 2 H, *m*-H), 7.66 (m, *o*-H). − ^{13}C NMR (C_6D_6): δ (J_{PC}) = 18.2 (d, 1.9 Hz, Me_B), 18.8 (d, 5.6 Hz, Me_A), 20.4 (s, Me-4), 27.4 (d, 31.0 Hz, CH), 91.4 (d, 1.8 Hz, Cp), 117.9 (d, 51.1 Hz, C_q-2), 119.3 (d, 9.9 Hz, C-6), 121.9 (d, 7.0 Hz, C_q-4), 128.9 (d, 10.4 Hz, 2 C-*m*), 129.9 (d, 2.6 Hz, C-3), 130.5 (s, C-*p*), 131.9 (d, 10.3 Hz, 2 C-*o*), 134.1 (d, 1.7 Hz, C-5), 134.2 (d, 43.3 Hz, *i*-C), 176.1 (d, Hz, C_q-1). − ^{31}P {^{1}H} NMR: δ = 50.4. − $C_{21}H_{23}NiOP$ (381.1): calcd. C 66.19 H 6.08 P 8.13; found C 66.26 H 6.48 P 7.76. − (b) 965 mg of **2c** (2.9 mmol) in benzene (10 mL) was added to nickelocene (545 mg, 2.9 mmol) in benzene (10 mL). No visible reaction took place within 5 d at 20°C, but on reflux (24 h) a dark brown solution was formed. Work up as above afforded 750 mg (70%) of **3c**, m.p. 185°C. A trace of **4c** was formed besides **3c**. The proportion increased up to 1:3 in larger runs and on precipitation with ether from the benzene solution. Single crystals of **3c** and of **4c** were grown from benzene/nitromethane (ca. 1:1) solution.

Reactions of Nickelocene with Two Equivalents of 1 or 2. − *cis*-Bis(2-isopropylphenylphosphanyl-4-methylphenolato)nickel (4c): (a) Nickelocene (831 mg, 4.4 mmol) in benzene (10 mL) was added to **1c** (2.27 g, 8.8 mmol) in benzene (10 mL). The color turned from green to brown within 1 h, and an orange-brown precipitate was formed after refluxing for 30 min. After removing a part of the solvent, the suspension was filtered, **4c** was washed with a little benzene and dried at 10^{-2} Torr (8 h) affording 1.65 g (65%) of an orange powder, m.p. 278−280°C. − ^{1}H NMR and CH COSY: δ = 0.98 (dd, $^3J_{PH}$ = 12.7, $^3J_{HH}$ = 6.8 Hz, 6 H, Me_A), 1.24 (m, 2 H, C*H*Me_2), 1.41 (vc, $^3J_{HH} \approx$ 7 Hz, 6 H, Me_B) 2.08 (s, 6 H, 4-Me), 6.42 (vc, 2 H, 3-H), 6.88 (dτ, $^3J_{HH}$ = 8.6, N = 5.2 Hz, 2 H, 6-H), 7.02 (br. d, $^3J_{HH}$ = 8.6 Hz, 2 H, 5-H), 7.40 (m, 4 H, *o*-H), 7.51 (m, 4 H, *m*-H), 7.60 (m, 2 H, *p*-H). − ^{13}C NMR: δ (N_{PC}) = 16.6 (τ, N = 8.2 Hz, Me_B), 19.4 (τ, N = 6.8 Hz, Me_A), 20.0 (s, Me-4), 23.0 (τ, N = 28.1 Hz, CH), 112.9 (τ, N = 54 Hz, C_q-2), 118.2 (τ, N = 13.8 Hz, C-6), 123.5 (τ, N = 6.9 Hz, C_q-4), 128.8 (τ, N = 10.0 Hz, C-*m*), 129.2 (τ, N = 46.3 Hz, C-*i*), 131.0 (s, C-*p*), 131.4 (s, C-3), 132.1 (τ, N = 8.3 Hz, C-*o*), 135.2 (s, C-5), 175.1 (τ, N = 16.6 Hz, C_q-1). − ^{31}P {^{1}H} NMR: δ = 45.3. − $C_{32}H_{36}NiO_2P_2$ (573.27): calcd. C 67.05 H 6.33 Ni 10.24 P 10.81; found C 66.76 H 6.66 Ni 10.56 P 10.27. (b) A solution of nickelocene (493 mg, 2.6 mmol) and **2c** (1.73 g, 5.2 mmol) in benzene (30 mL) was refluxed for 3 d to afford a brown solution. Most of the benzene was removed by distillation. From the residual suspension (ca. 3 mL) the solid was separated by filtration and washed with cold benzene (1 mL) yielding 319 mg (21%) of **4c**, m.p. 285°C. − ^{31}P NMR: δ = 45.3.

Reaction of 1b with 3c: A solution of **3c** (0.95 g, 2.5 mmol) in benzene (10 mL) was added to **1b** (0.57 g, 8.8 mmol) in benzene. About 12 mL of benzene was distilled off. 1.1 g of a brown precipitate was separated from the resulting viscous solution and analyzed by ^{31}P NMR ($CDCl_3$). The precipitate was found to be a mixture of the unsymmetrical *cis*-bis(P⌒O-chelate) **5** and the symmetrical *cis*-bis-(P⌒O-chelates) **4c** and **4b** (intensity ratio roughly 60:30:10). − ^{31}P{^{1}H} NMR of **5**: δ = 46.4 (d), 21.7 (d), $^2J_{PP}$ = 80 Hz.

Reactions of 1 or 2 with Nickel Salts or Complexes. − *cis*-Bis(2-diphenylphosphanyl-4-methylphenolato)nickel (4a): $NiCl_2 \cdot 6H_2O$ (650 mg, 2.74 mmol) was dissolved in hot methanol (20 mL), and a solution of **1a** (1.6 g, 5.48 mmol) in methanol (5 mL) was added. A rapid color change to orange started on addition of Et_3N of which a total of 1.1 g (10.9 mmol, ca. 100% excess) was added. After removing the solvent, the solid residue was crystallized from MeOH/CH_2Cl_2 (1:1) and dried for 2 h at 10^{-2} Torr to yield 1.4 g (80%) of orange-brown **4a** containing a small amount of water. − ^{1}H NMR: δ = 2.04 (s, 6 H, 4-Me), 3.50 (s, 2 H, H_2O), 6.47 (vc to br. τ, 2 H, 3-H), 6.89 (dτ, $^3J_{HH}$ = 8.7, N = 5.5 Hz, 2 H, 6-H), 7.02 (br. d, $^3J_{HH}$ = 8.7 Hz, 2 H, 5-H), 7.42 (m, 4 H, *o*-H), 7.10 (τ, $^3J \approx$ 7.4−7.6 Hz, 4 H, *m*-H), 7.32 (τ, $J \approx$ 7.3−7.5 Hz, 2 H, *p*-H). − ^{31}P{^{1}H} NMR: δ = 34.4. − $C_{38}H_{32}NiO_2P_2 \cdot H_2O$ (659.32): calcd. Ni 8.90; found Ni 8.85.

***cis*-Bis(2-methylphenylphosphanyl-4-methylphenolato)nickel (4b):** (a) A solution of **1b** (103 mg, 0.45 mmol) in ethanol (5 mL) was added to a warm solution of nickel acetate · 4 H_2O (57 mg, 0.23 mmol) in ethanol (10 mL), affording a yellow solution which slowly turned brown. The solvent was removed in vacuo (after 3 d), the remainder was extracted with CH_2Cl_2 and dried with Na_2SO_4. Hexane was added and a part of the solvent (mainly CH_2Cl_2) was evaporated in vacuo to yield a brown precipitate which was dried for 2 h at 10^{-2} Torr. 70 mg (59%) of two isomers of **4b** were obtained, isomer ratio (A)/(B) ca. 85%:15% with δ(^{31}P) = 21.9, 20.0. − ^{1}H NMR: (A): δ = 1.09 (τ, N = 11.7 Hz, 6 H, PMe), 2.06 (s, 6 H, 4-Me), 6.43 (br. τ, N = 8−9 Hz, 2 H, 3-H), 6.87 (m, 2 H), 6.98 (m, 2 H), 7.4−7.6 (m, 10 H, Ph); (B): δ = 1.87 (τ, N = 11.1 Hz, PMe), other signals superimposed. − ^{13}C NMR: δ (N_{PC}) = 9.1 (τ, N = 32 Hz, PMe), 20.0 (Me-4), 118.3 (τ, C-6), 124.6 (τ, C-4), 128.9 (C-*p*), 129.1 (τ, N = 10.6 Hz, C-*m*), 131.4 (τ, N = 10.6 Hz, C-*o*), 135.3 (C-5); weak intensities of C-1, C-2, C-*i* signals. − $C_{28}H_{28}NiO_2P_2$ (517.17): calcd. Ni 11.35; found Ni 11.08. − (b) An equimolar mixture of

2b (647 mg, 2.14 mmol) and nickel acetylacetonate (550 mg, 2.14 mmol) was refluxed for 8 h in benzene (30 mL) to give, after removal of 2/3 of the solvent, 188 mg (34%) of the bis(phosphanylphenolate) **4b**, m.p. 216−218°C. − UV/Vis [MeOH, λ_{max}/nm (ε/$M^{-1}cm^{-1}$)]: 403(400), 347 (1.300), 293 (sh), 281 (14.000), 220 (sh, 17.000). − $^{31}P\{^1H\}$ NMR: δ = 21.8.

***cis*-Bis(2-isopropylphenylphosphanyl-4-methylphenolato)nickel (4c):** **2c** (193 mg, 0.59 mmol) and nickel acetylacetonate (54 mg, 0.21 mmol) were refluxed for 8 h in benzene (20 mL) to give, after removal of the bulk of the solvent, 88 mg (73%) of **4c**, NMR data as above.

***trans*-Bis(2-isopropylphenylphosphanyl-4-methylphenolato)nickel (6d):** (a) 160.8 mg (0.735 mmol) of $NiBr_2$ and 170 μL of HBr (48%, 1.51 mmol) were dissolved in warm methanol and two equivalents of **1d** (400 mg, 1.47 mmol) in methanol (7 mL) were added. A transient brown color was observed in the mixing area, indicating an equilibrium with dominance of octahedral Ni^{2+} complexes in solution [λ_{max}/nm: 398 (st), 730 (w), 660 (sh)]. On buffering with excess sodium acetate the solution turned brown and 265 mg (60%) of green **6d** precipitated. − (b) A solution of **1d** (588 mg, 2.16 mmol) in THF (15 mL) was added to a suspension of $NiBr_2$·1.1DME (337 mg, 1.09 mmol) in 15 mL of THF. On addition of LiO*i*Pr (2.3 mmol) the solution turned brown and a total of 415 mg (63%) of green **6d** precipitated. The reaction of $NiBr_2$·1.1DME with **2d** proceeded similarly. − (c) The best variant yielding microcristalline **6d** was the following: Butyllithium in hexane (9.6 mmol) was added at −5°C to 3.26 g (9.46 mmol) of **2d** in THF (20 mL). A solution of $NiBr_2$·$2Ph_3P$ (3.52 g, 4.73 mmol) in THF (40 mL) was added dropwise, forming a brown solution and, after 5−10 min, a green precipitate. The reaction was complete within 20−30 min and gave 2.06 g (73%) of microcrystalline, diamagnetic **6d**, m.p. 312−317°C (DTA 327.5°C with dec.). Above 120°C **6d** exhibited a reversible gradual color change via olive-green to yellow. The solubility in acetonitrile, nitromethane, methanol, acetone, benzene or hexane was very low and in THF, $CHCl_3$ or CH_2Cl_2 was just sufficient for UV/Vis spectra. − UV/Vis [THF; λ_{max}/nm, (relative intensities in satd. soln.)]: 611 (10), 434 (100), 391 (500), 320 st, 284 st, 275 st. − Solid-state NMR investigation see ref.[19] − $C_{34}H_{40}NiO_2P_2$ (601.3): calcd. C 67.92, H 6.70, Ni 9.76, P 10.30; found C 67.36, H 6.83, Ni 9.63, P 10.26. − X-ray powder diffraction data and density (in ethanol) = 0.89−0.95 gcm^{-3} fit best with a triclinic crystal system with unit cell dimensions of a_o = 10.126 Å, b_o = 17.630 Å, c_o = 12.184 Å, α = 89.44°, β = 90.55°, γ = 89.98°, Z = 2.

Thermal Analysis: DTA/TG analyses of **3c**, **4c** and **6d** were performed under nitrogen. **3c**: mass lost at 190−210°C, Δm_{210} = 17%, corresponding to cleavage of cyclopentadiene (endothermic); further continously increasing mass lost at 280−340°C, $\Delta m_{350} \approx$ 70%, endothermic peak at 309°C. **4c**: mass lost at 280−340°C, Δm_{350} = 66−72%, exothermic peak at 271°C, endothermic at 290°C. **6d**: mass lost at 310−340°C, Δm_{350} = 72%, endothermic peak at 328°C.

Catalysis Experiments: **1c** (56.8 mg, 0.22 mmol) or **2c** (72.6 mg, 0.22 mmol) in toluene (10 mL) were added at 0°C to a solution of $Ni(COD)_2$ (0.22 mmol) in toluene (10 mL). After stirring for 30 min, the solution was transferred into an autoclave, ethylene added until the pressure was 40 bar and heated for 12 h while stirring with a teflon-coated magnetic stirrer. **2c** was used first. At 60°C no conversion of ethylene occurred, at 120°C the pressure (8.7 g C_2H_4) decreased to 29 bar and polyethylene (3.65 g, 88% of converted ethylene) and a lower portion of linear olefins (C_4 to C_{26}) with a flat maximum at C_{16}/C_{18} was isolated. The TON was 666. X-ray powder diffraction and IR revealed high crystallinity and low branching of the PE. Use of a catalyst prepared from **1c** and $Ni(COD)_2$ and 8.7 g of C_2H_4 at 140°C led similarly to PE (TON = 698; 3.64 g of HDPE, 85% of converted ethylene), m.p. 121°C; DTA (5 K/min): 131.8°C (up), 117.2°C (down). M_w = 9310 $gmol^{-1}$, M_n = 6087 $gmol^{-1}$. Ethylene (40 bar) heated with a solution of **3c** (37.3 mg) in toluene (20 mL) for 12 h at 140°C was not converted. A more detailed study of ethylene polymerization and oligomerization with varied phosphanylphenols is in progress and will be described elsewhere.

Crystal Structure Analysis: Crystal data are presented in Table 2, selected bond angles and bond lengths are given in the captions of Figures 1 and 2. − Data collection: The crystals were mounted on a glass fiber in inert oil and transferred to the cold gas stream (−55°C) of the diffractometer (Siemens-Stoe AED2). Data were collected in the ω-scan mode using monochromated Mo-K_α radiation (0.71073 Å). − Solution and refinement: The structures were solved by direct methods (G.M. Sheldrick, *SHELXS-86*, Univ. Göttingen, **1986**) and were refined by the least-squares method based on F^2 with all measured reflections (G. M. Sheldrick, *SHELXL-93*, Univ. Göttingen, **1993**) using anisotropic temperature factors for all non-hydrogen atoms. Hydrogen atoms were included in calculated positions or as part of a rigid group (methyl). Only an isotropic temperature factor for each type of hydrogen atom was refined. − Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-114167 (**3c**) and -114168 (**4c**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

Financial support by the Deutsche Forschungsgemeinschaft and the Fond der Chemischen Industrie is gratefully acknowledged. We thank Dr. M. K. Kindermann and B. Witt for NMR experiments, P. Engler for thermal analyses, Prof. Dr. Fink (Mülheim) for determination of the molar mass distribution and Dr. H. Wulff for powder X-ray diffraction measurements.

Synthesis, Crystal Structure, Spectroscopic and Magnetic Properties of an Unprecedented Three-Dimensional Cu^{II} Coordination Compound of 1,2-Bis(1,2,4-triazol-4-yl)ethane

Yann Carcia,*[a] Petra J. van Koningsbruggen,*[a] Huub Kooijman,[b] Anthony L. Spek,[b] Jaap G. Haasnoot,[c] and Olivier Kahn†[a][+]

Keywords: Copper / Magnetic properties / Supramolecular chemistry / Three-dimensional architecture

A novel three-dimensional copper(II) compound of the formula $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6\cdot H_2O$ (btre = 1,2-bis(1,2,4-triazol-4-yl)ethane) has been synthesized. The structure has been solved at 150 K by single-crystal X-ray analysis. The compound $[C_{30}H_{44}Cu_3N_{30}O_2\cdot 6(ClO_4)\cdot H_2O]$ crystallizes in the triclinic space group $P\bar{1}$ with a = 12.488(1), b = 13.195(1), c = 19.756(2) Å, α = 78.959(8), β = 84.553(8), γ = 63.869(7)°, V = 2868.4(5) Å^3, Z = 2 (trinuclear Cu^{II} units), 6484 reflections [$I > 4\sigma(I)$], R_F = 0.0581, wR_2 = 0.1214. The structure of this coordination polymer consists of a three-dimensional network built up from linear trinuclear Cu^{II} cations of formula $[Cu_3(btre)_5(H_2O)_2]^{6+}$. This crystallographically independent unit comprises a linear array of three Cu^{II} ions linked by triple N1,N2-1,2,4-triazole bridges, yielding Cu1–Cu2 = 3.893(1) Å and Cu2−Cu3 = 3.889(1) Å. These linear trinuclear Cu^{II} units are linked by various pathways involving tridentate and tetradentate bridging btre ligands, which yields an unprecedented three-dimensional network. The Cu^{II} ions are weakly antiferromagnetically coupled with J = –1.01(2) cm^{-1} (based on the Hamiltonian: $\mathbf{H} = -J[S_{Cu1}\cdot S_{Cu2} + S_{Cu2}\cdot S_{Cu3}]$ using the expression for the molar magnetic susceptibility S = 1/2 of a linear trinuclear system). The nature and the magnitude of the antiferromagnetic exchange have been discussed on the basis of the structural features.

Introduction

Polynuclear coordination compounds containing derivatives of 1,2,4-triazole have been of increasing interest during the last decade. Several studies have dealt with the search for magneto-structural correlations for transition metal(II) compounds containing N1,N2-1,2,4-triazole bridges.[1−10] On the other hand, polynuclear (1,2,4-triazole)iron(II) compounds have been found to yield spin-crossover materials exhibiting cooperative behavior.[11−33]

The capability of the 1,2,4-triazole ligand to form a bridge between metal(II) ions by establishing the N1,N2 coordination mode makes them very useful for obtaining polynuclear coordination compounds in which the (paramagnetic) transition metal(II) ions are maintained at relatively short distances. Substituents have been attached to the N4 of the 1,2,4-triazole in order to prevent coordination at this position. Consequently, in coordination compounds, the ligand will be incorporated in its neutral form. Earlier studies dealt with 4-amino-1,2,4-triazole, of which mostly linear chain compounds have been obtained, where the metal(II) ions are linked by triple N1,N2-1,2,4-triazole bridges.[11b,12,13,16−20,23−29] This has been confirmed by an X-ray crystallographic study for $[Cu(4\text{-amino-}1,2,4\text{-triazole})_3](ClO_4)2\cdot 0.5H_2O$.[34] Using alkyl[21,30,31,35] or hydroxyalkyl substituents[8,22,32,33] of different sizes, this triply bidentate N1,N2 bridging of the 4-substituted 1,2,4-triazole ligand has again uniquely been found. In the absence of coordinating anions, this yields linear trinuclear compounds[21,30,31,35] or infinite linear chains.[8,21,22,32,33] On the other hand, taking 4-phenyl-substituted derivatives under the same experimental conditions only led to the formation of linear trinuclear species having triple N1,N2-1,2,4-triazole bridges.[36]

Surprisingly, with 4,4′-bis(1,2,4-triazole) (abbreviated as btr) this N1,N2 bridging coordination mode has not yet been observed. Instead, the ligand has been found to link transition metal(II) ions using N1 and N1′ − the nitrogen atoms originating from the two different 1,2,4-triazole rings − resulting in one-,[37] two-,[38−41] and three-dimensional[42] networks. The occurrence of solely this N1,N1′ bidentate coordination mode may be related to the observation that this coordination of btr is possible while keeping its geometric conformation close to that what has been found for the free ligand, i.e. with fairly perpendicular 1,2,4-triazole rings.[43] Furthermore, charge distribution efficiency considerations may favor a wide separation of the twofold positively charged transition metal(II) ions, which is indeed realized by this N1,N2′ bidentate coordination.

The purpose of this study is to investigate the way in which a more flexible linkage between the 1,2,4-triazole moieties, as compared to the direct N4−N4′ bond in btr, will influence the coordination mode of the ligand, and thus the type of compound to be formed. Therefore, we have

selected 1,2-bis(1,2,4-triazol-4-yl)ethane (abbreviated as btre). In this paper we describe the structure of a new type of polynuclear copper(II) compound together with its spectroscopic and magnetic properties.

Results and Discussion

Description of the Structure of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$

The structure of this coordination polymer consists of a three-dimensional network built up from linear trinuclear Cu^{II} cations of formula $[Cu_3(btre)_5(H_2O)_2]^{6+}$ (see Figure 1). This crystallographically independent unit comprises a linear array of three Cu^{II} ions linked by triple N1,N2-1,2,4-triazole bridges. Ligands labeled 3 and 4 have an inversion center at the middle of the ethylene linkage. One noncoordinating water molecule, as well as six free perchlorate anions complete the asymmetric unit. Selected bond lengths and bond angles are given in Tables 1 and 2. These linear trinuclear Cu^{II} units are linked via various pathways involving tridentate (ligands marked 1, 2, 5 and 6) and tetradentate (ligands marked 3 and 4) bridging btre ligands, yielding an unprecedented three-dimensional network (see Figure 2). The structure is additionally stabilized by hydrogen bonding involving coordinating as well as noncoordinating water molecules.

Marked atoms are generated by symmetry operations: [a] $-1 + x, y, z$. − [b] $1 - x, 1 - y, 2 - z$. − [c] $1 + x, y, z$. − [d] $2 - x, -y, 1 - z$.

Within the trinuclear Cu^{II} unit, three btre ligands link each pair of adjacent copper(II) ions via nitrogen atoms N1 and N2. The central ion, Cu2, is in a strongly distorted octahedral environment formed by six N-donating btre ligands. The coordination plane is formed by four nitrogen donor atoms at 1.988(5)−2.045(5) Å, whereas two btre li-

Marked atoms are generated by symmetry operations: [a] $-1 + x, y, z$. − [b] $1 - x, 1 - y, 2 - z$. − [c] $1 + x, y, z$. − [d] $2 - x, -y, 1 - z$.

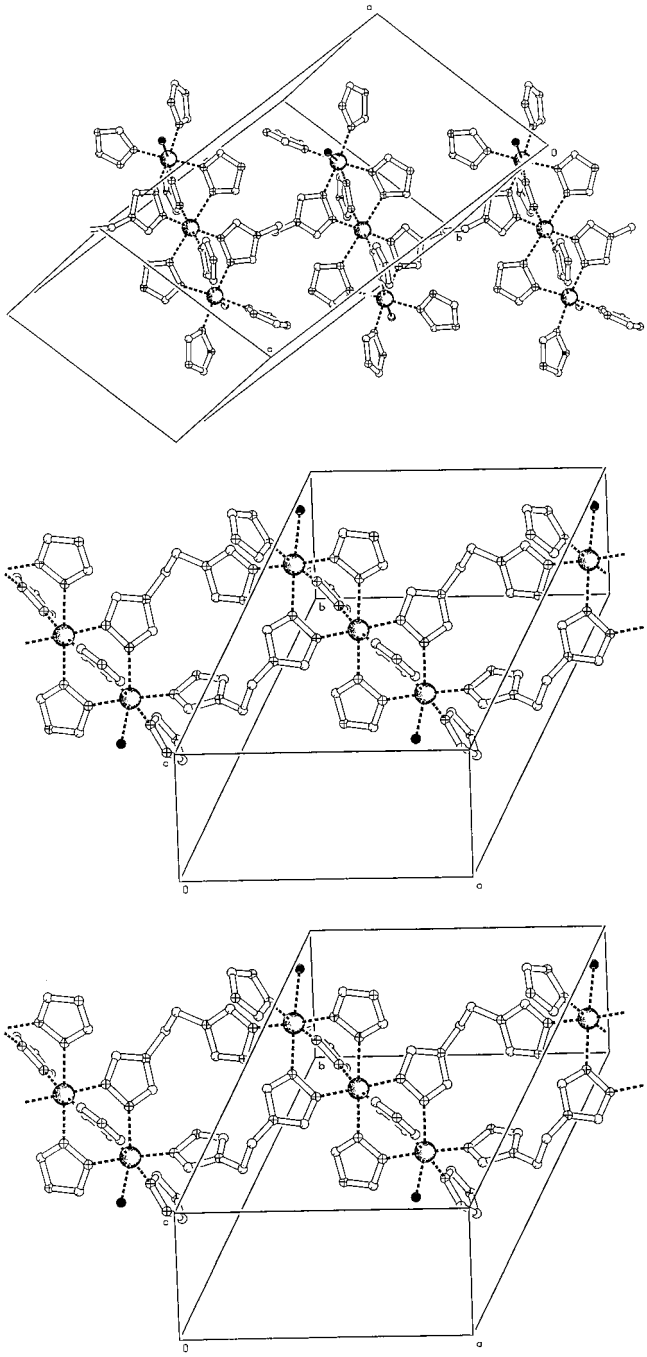

Figure 2. PLUTON[57] drawing showing the structure of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$: (a) (1 −1 1) chain of trinuclear Cu units linked by ligands 3 and 4; (b) (1 0 0) chain of trinuclear Cu units linked by ligands 2 and 5; (c) (1 −1 −1) chain of trinuclear Cu units linked by ligands 1 and 6

gands coordinate at significantly longer distances [2.359(5) and 2.454(5) Å to N102 and N601, respectively]. The coordination geometry about this Cu^{II} ion very closely resembles those of the Cu^{II} ions in the linear chain compounds $[Cu(4\text{-amino-}1,2,4\text{-triazole})_3](ClO_4)_2 \cdot 0.5H_2O$[34] and $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$ [hyetrz = 4-(2-hydroxyethyl)-1,2,4-triazole].[8] It is, however, in contrast to the geometry of the central Cu^{II} ion in the linear trinuclear compound $[Cu_3(metz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$ (metz = 3-methyl-4-ethyl-1,2,4-triazole),[42][44] where it appears that the dynamic Jahn−Teller distortion results in a completely regular octahedral coordination about the Cu^{II} ion octahedron, with six relatively short Cu−N distances of 2.14(5) Å.

The terminal copper(II) ions, Cu1 and Cu3, are linked to Cu2 via triple N1,N2-1,2,4-triazole bridges, resulting in a Cu1−Cu2 distance of 3.893(1) Å and a Cu2−Cu3 distance of 3.889(1) Å. This compares rather well to the Cu−Cu distances of 3.853(2) Å and 3.829(2) Å encountered in $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$.[8] However, it should be noted that the Cu−Cu distances observed in the present coordination polymer are significantly longer than the 3.719(7) Å for Cu^{II} ions linked by triple μ-N1,N2-1,2,4-triazole bridges in the linear trinuclear compound $[Cu_3(metz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$.[42][44] This may be related to the dynamic Jahn−Teller effect involving the central Cu^{II} ion in the metz compound.

As has also been observed in $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$,[8] that in order to establish the linkage of Cu^{II} ions in Jahn−

Teller-distorted octahedra by triple μ-N1,N2-1,2,4-triazole bridges, the geometric disposition of the ligands becomes such that important deviations from the ideal threefold axis running through the Cu^{II} ions are required. Also in the present compound, the N1,N2 bridging mode of all btre ligands involve unequal Cu−N distances, as well as Cu−N−N angles. The torsion angles Cu−N−N−Cu involving ligands 1, 2, 3, 4, 5, and 6 are 9.7(7)°, 20.7(7)°, 7.9(7)°, 4.9(8)°, −0.1(7)°, and 7.3(7)°, respectively.

The coordination octahedra around Cu1 and Cu3 are completed by two N-donating btre ligands and a coordinating water molecule, yielding an N_5O chromophore. For both terminal Cu^{II} ions, the axial coordination is formed by a water molecule and an N-donating btre ligand. The coordination plane of Cu2 [N201, N302, N401, N501] makes an angle of 68.3(2)° with the coordination plane of Cu1 [N101, N301, N511 ($-1 + x, y, z$), N111 ($1 - x, 1 - y, 2 - z$)], whereas the angle with the least-squares plane through the equatorial coordination sphere of Cu3 [N402, N602, N211 ($1 + x, y, z$), N611 ($2 - x, -y, 1 - z$)] is 61.4(2)°.

All 1,2,4-triazole rings are fairly planar: The maximum deviation of an atom from the least-squares plane through the ring atoms is 0.011(7) Å. The three-dimensional structure consists of three chains of trinuclear Cu units running in directions (1 −1 1), (1 0 0) and (1 1 −1). Each chain is formed by two ligands: 3 and 4, 2 and 5, and 1 and 6, respectively.

The btre ligands which are located on a crystallographic inversion center have N4−C1−C2−N4′ torsion angles of 180° and act as tetradentate ligands, linking two pairs of Cu^{II} ions originating from two different trinuclear units. Ligand 3 uses its N1 and N2 to link Cu1 and Cu2, and N1′ and N2′ to establish a bridge between Cu1 (symmetry operation: $1 - x, 1 - y, 1 - z$) and Cu2 ($1 - x, 1 - y, 1 - z$). Ligand 4 bridges Cu2 and Cu3 and links Cu2 ($2 - x, -y, 2 - z$) and Cu3 ($2 - x, -y, 2 - z$) by its symmetry-related counterpart. The resulting Cu−Cu distances are in the range 10.742(2)−11.460(2) Å. In this way, a chain of trinuclear units running along the $x, -y, z$ direction is formed (see Figure 2a). In fact, this doubly bridging coordination mode of btre involves an inversion lying on the middle of the ethylene bridge. Consequently, it may be more correct to describe this as a twisted chain of trinuclear entities.

The four other btre molecules are tridentate ligands, which have a bent conformation, as is illustrated by the values for the N4−C1−C2−N4′ torsion angles involving the N4,N4′ ethylene linkage. These angles are −79.5(7)°, −86.1(7)°, 75.5(7)° and 63.0(7)° for the ligands marked 1, 2, 5 and 6, respectively. The tridentate coordination is established by forming both a long and a rather short Cu−N bond length within the N1,N2 bridging triazole, together with a short Cu−N distance involving the second triazole ring. Ligand 2 and ligand 5 establish an N1,N2 bridge between two Cu^{II} ions within the asymmetric unit, and they coordinate with N1 of the second 1,2,4-triazole ring to a terminal Cu^{II} of a symmetry-related trinuclear entity. Ligand 2 establishes an N1,N2 bridge between Cu1 and Cu2, while coordinating with its triazole counterpart to Cu3 ($-1 + x, y, z$); while ligand 5 links Cu2 and Cu3 via its μ-N1,N2 coordination mode, and binds to Cu1 ($1 + x, y, z$). The resulting Cu−Cu distances are: Cu1−Cu3 ($-1 + x, y, z$) = 9.053(2) Å, Cu2−Cu3 ($-1 + x, y, z$) = 10.243(2) Å and Cu2−Cu1 ($1 + x, y, z$) = 10.136(2) Å. This yields a chain running along the x direction (Figure 2b).

A chain of trinuclear Cu^{II} entities along the $x, -y, -z$ direction is formed through the tridendate coordination of ligand 1 and ligand 6. Like ligands 2 and 5, these ligands also form a μ-N1,N2-1,2,4-triazole bridge between Cu^{II} ions within the asymmetric unit, together with the coordination of a nitrogen atom of the second 1,2,4-triazole ring to a symmetry-related Cu^{II} ion of another trinuclear unit. Ligand 1 links Cu1 and Cu2 via the N1,N2 bridging mode, and coordinates with N1′ to Cu1 ($1 - x, 1 - y, 2 - z$). Ligand 6, which establishes an N1,N2 bridge between Cu2 and Cu3, binds to Cu3 ($2 - x, -y, 1 - z$). The shortest Cu−Cu distances resulting from this coordination pathway are Cu1−Cu1 ($1 - x, 1 - y, 2 - z$) = 9.262(2) Å and Cu3−Cu3 ($2 - x, -y, 1 - z$) = 8.595(1) Å (Figure 2c).

The difference between the chains formed by ligands 2 and 5 and that formed by ligands 1 and 6 is that in the former chain, the link between each pair of adjacent tricopper units is formed by one ligand 2 and one ligand 5. In the latter chain, the links between adjacent tricopper units are formed by either two molecules of ligand 1 or two molecules of ligand 6.

In the present compound, the perchlorate anions are noncoordinating and some are involved in hydrogen bonding interactions with the btre ligands, as well as with the lattice water molecules. The noncoordinated nitrogen atoms of the tridentate ligands 1 and 2 are involved in hydrogen bonding. N112 ($2 - x, -y, 2 - z$) is hydrogen-bonded to water oxygen atom O2, which is in turn coordinated to Cu3. N212 accepts an (intermolecular) hydrogen bond from the noncoordinated water molecule O3. Details of the hydrogen bonds are listed in Table 3. The shortest "intermolecular" Cu−Cu distance is formed through hydrogen bond links. Cu1−O1−H···O2 ($-1 + x, 1 + y, z$) − Cu3 ($-1 + x, 1 + y, z$) gives a Cu−Cu distance of 6.784(1) Å.

Table 3. Selected interatomic distances [Å] and angles [°] for the hydrogen bonding interactions in $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$; estimated standard deviations in parentheses

D−H···A	D−H	H···A	D···A	D−H···A
O1−H1A···O2[a]	0.81(5)	1.99(6)	2.729(7)	151(7)
O1−H1B···O21[b]	0.81(7)	2.15(7)	2.900(9)	154(7)
O2−H2A···N112[c]	0.81(4)	2.23(7)	2.931(8)	146(7)
O2−H2B···O31[d]	0.80(9)	2.02(9)	2.828(9)	178(8)
O2−H2B···O33[d]	0.80(9)	2.59(8)	3.057(9)	119(7)
O3−H3A···O13[b]	0.82(6)	2.29(6)	3.060(8)	157(7)
O3−H3A···O14[b]	0.82(6)	2.36(7)	3.046(8)	142(6)
O3−H3B···N212	0.81(7)	2.11(7)	2.913(8)	168(7)

Marked atoms are generated by symmetry operations: [a] $-1 + x, 1 + y, z$. − [b] $1 - x, 1 - y, 1 - z$. − [c] $2 - x, -y, 2 - z$. − [d] $1 - x, -y, 1 - z$.

Spectroscopic Properties

The UV/Vis spectrum shows a broad asymmetric band with a maximum situated at 11.6×10^3 cm^{-1} and a shoulder at 9.3×10^3 cm^{-1}, which is in agreement with the presence of both CuN_6 and CuN_5O chromophores, as well as with the tetragonal distortion of the Cu^{II} octahedra.[45]

There is no evidence for a strong deviation from T_d symmetry for the noncoordinating perchlorate anions, as is indicated by the strong ν_3 absorption at 1102 cm^{-1} and the ν_4 at 623 cm^{-1} observed in the infrared spectrum.[46]

Magnetic Measurements

The magnetic behavior of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$ is shown in Figure 3 in the form of a $\chi_M T$ vs. T plot, χ_M being the molar magnetic susceptibility and T the temperature. At 296 K the $\chi_M T$ value is 1.278 cm^3 mol^{-1} K, which is about the value expected for three uncoupled copper(II) ions. The value of $\chi_M T$ decreases upon cooling, reaching a value of 0.732 cm^3 mol^{-1} K at 2 K. This behavior is characteristic for compounds with an overall antiferromagnetic interaction between the metal(II) ions. The structure indicates the presence of interconnected linear trinuclear Cu^{II} units, these trinuclear entities being magnetically isolated. Therefore, the magnetic data have been interpreted using the expression for the molar magnetic susceptibility of a linear trinuclear system with S = 1/2.[11a,47]

$$\chi_M T = (N\beta^2 g^2/4k)[(1 + e^x + 10e^{3x/2})/(1 + e^x + 2e^{3x/2})] \quad (1)$$

in which $x = J/kT$. J is the energy gap defined by the phenomenological spin Hamiltonian with quantum spin operators $\mathbf{S}_{Cu1}$, $\mathbf{S}_{Cu2}$, and $\mathbf{S}_{Cu3}$ where Cu1, Cu2 and Cu3 refer to nearest neighbor ions:

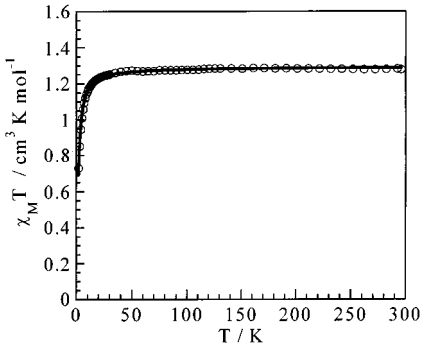

Figure 3. Observed (o) and calculated [—; $J = -1.01(2)$ cm^{-1}, $g = 2.14(1)$] $\chi_M T$ vs. T curves for $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$

$$\mathbf{H} = -J[S_{Cu1} \cdot S_{Cu2} + S_{Cu2} \cdot S_{Cu3}] \quad (2)$$

The assumption of negligible magnetic exchange between second neighbor copper(II) ions is justified in view of the study of the triply N1,N2-1,2,4-triazole bridged $Fe^{II}-Fe^{II}-Fe^{II}$[30] and $Co^{II}-Co^{II}-Co^{II}$[48] trinuclear clusters, where the central metal ion is diamagnetic, and no magnetic interactions could be detected between the paramagnetic terminal metal ions. In Equation 1, N, g, β, k, and T have their usual meanings. The g factor must be considered as an average value of the local Zeeman factors, and intercluster exchange interactions were supposed to be negligible. A good fit has been obtained for the parameters $g = 2.14(1)$ and $J = -1.01(2)$ cm^{-1} (see Figure 3).

The spectrum of the (S,S′) low-lying spin states, where S and S′ are the quantum numbers associated with the **S** and **S**′ operators:

$$\mathbf{S} = \mathbf{S}_{Cu1} + \mathbf{S}_{Cu2} + \mathbf{S}_{Cu3}$$

$$\mathbf{S}' = \mathbf{S}_{Cu1} + \mathbf{S}_{Cu3}$$

consists of a ground doublet (1/2, 1), an excited doublet (1/2, 0) at the energy $-J$, and an excited quartet at the energy $-3J/2$. This excited spin quartet state is further split into two Kramers doublets, which to a first approximation can be labeled as $M_S = \pm 1/2$ and $\pm 3/2$.

The X-band powder EPR spectra for $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$ have been recorded at 298 K and 4 K. The spectrum at 4 K is shown in Figure 4. It exhibits features around $g = 2$ that can be assigned to the envelop of the three resonances within the $M_S = \pm 1/2$ Kramers doublets, as well as a smaller feature around $g = 5.6$ that may be assigned to the resonance within the $M_S = \pm 3/2$ Kramers doublet. It should be noticed that, due to the low symmetry of the Cu^{II} triad, the $M_S = \pm 1/2$ and $M_S = \pm 3/2$ Kramers doublets states arising from the spin quartet are somewhat mixed.

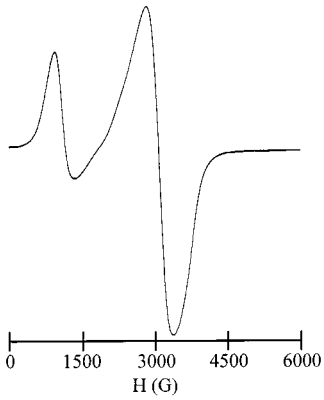

Figure 4. X-band powder EPR spectrum ($\nu = 9.46780$ GHz) of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$ recorded at 4 K

Concluding Remarks

The btre ligand has been shown to be a powerful tool in preparing supramolecular architectures. The structure of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$ represents an unprecedented architecture of a three-dimensional compound. Recently, a polynuclear Cu^{II} compound of a bis(imidazole) ligand has been reported. $[Cu(bim)_{2.5}](ClO_4)_2 \cdot 2CH_3OH$ [bim = 1,2-bis(imidazole-1-yl)ethane][49] contains Cu^{II} ions

in a distorted square-based pyramidal coordination environment. The neutral ligands in the $a-b$ plane bind to four Cu^{II} ions in a *trans* mode, leading to a two-dimensional sheet arrangement. The resulting Cu−Cu distances are 7.05 Å and 11.43 Å in this $a-b$ plane. Furthermore, the axially coordinating neutral bim ligand has a bent, *cis* conformation, and alternatively links the $a-b$ plane to sheets above and below. The closest inter-sheet Cu−Cu separation is 12.55 Å.

Upon using the btre ligand, a larger versatility in coordination is anticipated due to the presence of the additional nitrogen atom within the 1,2,4-triazole ring compared to the imidazole. In fact, in $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6 \cdot H_2O$ btre acts as a spacer between three and even four Cu^{II} ions. The tridentate ligands are bent, as is illustrated by the values for the N4−C1−C2−N4′ torsion angles involving the N4,N4′ ethylene linkage. These angles are −79.5(7)°, −86.1(7)°, 75.5(7)° and 63.0(7)° for the ligands marked 1, 2, 5 and 6, respectively. On the other hand, the N4−C1−C2−N4′ torsion angles of the tetradentate ligands 3 and 4 are restricted by crystallographic symmetry to a value of 180°.

Interestingly, the coordination mode of btre shows features already observed in coordination compounds of 3- or 4-substituted 1,2,4-triazoles where the well-known triply bidentate N1,N2 bridging of the 1,2,4-triazole ring has been found to result in linear trinuclear species.[21,30,31,35,50] In those cases, the chain growth is blocked by monodentately coordinated 1,2,4-triazole ligands and/or by water molecules. In fact, the trinuclear cation $[Cu_3(btre)_5(H_2O)_2]^{6+}$ can be regarded as a linear, trinuclear Cu^{II} compound of this type, in which the coordination environment about the terminal Cu^{II} ions is completed by two monodentate 1,2,4-triazole ligands and a water molecule. On the other hand, the btr ligand was originally designed in order to force a tetradentate coordination mode.[21] However, exclusively the N1,N1′ bidentate mode has been observed so far,[37−42] which may be due to charge distribution efficiency considerations, or more likely, may be ascribed to the fact that even in coordination compounds the btr ligand favors a conformation close to the one observed in the free ligand,[43] i.e. with fairly perpendicular 1,2,4-triazole nuclei. The more flexible nature of the ethylene linkage in the present btre ligand overcomes these problems, and indeed the tetradentate coordination has been achieved for some of the ligand molecules present. Furthermore, it could well be that this type of rigid tetradentate spacer allows a crystal packing of the trinuclear Cu^{II} units with distances close to those found in the compounds containing nonconnected trinuclear units of this type. Moreover, the bent, *cis*-btre ligands allows us to satisfactorily maintain these trinuclear entities, which are further stabilized by a network of hydrogen bonds.

In the present polynuclear Cu^{II} compound, a relatively small antiferromagnetic interaction [$J = -1.01(2)$ cm^{-1}] has been found between adjacent metal(II) ions. It may be proposed that the linear trinuclear Cu^{II} cations represent the magnetic entities responsible for this magnetic interaction. Indeed, the magnetic data could satisfactorily be interpreted using the theoretical expression for linear trinuclear S = 1/2 units. The low J value can be explained on the basis of the superexchange pathway and the geometry around Cu^{II}. The unpaired electron for the d^9 ion clearly resides in the $d(x^2 - y^2)$ orbital, with hardly any density in the direction of the axially coordinating 1,2,4-triazole ligands. The magnitude of the antiferromagnetic interaction between Cu^{II} ions can therefore be explained by the superexchange pathway involving the σ orbitals of the N1,N2 diazine moiety of the bridging triazole network.[1−10] It should be noted that the magnetic orbitals located on the Cu^{II} ion are only favorably oriented to yield a considerable overlap on the 1,2,4-triazole ligand, linking the metal(II) ions with rather short Cu−N distances. Consequently, the main pathway for the superexchange only proceeds through one triazole ligand, i.e. ligand 3 between Cu1 and Cu2, and ligand 4 between Cu2 and Cu3. However, the bridging geometry of these ligands is slightly asymmetric, involving unequal Cu−N−N angles. Furthermore, the 1,2,4-triazole tends to twist slightly out of the equatorial plane formed by the two Cu^{II} ions involved, which is illustrated by the torsion angles of 7.9(7)° and 4.9(8)° involving ligands 3 and 4, respectively. These features lead to a rather inefficient propagation of the superexchange via this bridging network, which explains the rather low isotropic interaction parameter. This compares very well to the $J = -1.18(2)$ cm^{-1} (based on the Hamiltonian: $\mathbf{H} = -J [\Sigma_i S_i \cdot S_{i+1}]$) observed for the linear chain compound $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$, having triple N1,N2-1,2,4-triazole bridges of comparable geometry.[8]

Only one linear trinuclear Cu^{II} compound containing triple N1,N2-1,2,4-triazole bridges has so far been structurally characterized. A detailed comparison with the magnetic data of $[Cu_3(metz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$ is not possible, since no accurate data are available as yet.[42][44]

We have shown that this first member of a new class of *N*,*N*′-bis(1,2,4-triazol-4-yl)alkane ligands leads to the creation of a unique new supramolecular Cu^{II} compound. Preliminary studies have already indicated that polynuclear Fe^{II} spin-crossover materials could be obtained using ligands of this family.

Experimental Section

Physical Measurements: Elemental analyses were performed by the Service Central d′Analyse (CNRS) in Vernaison, France. − Infrared spectra were carried out with a Perkin−Elmer Paragon 1000 FTIR spectrophotometer using KBr pellets. − UV/Vis spectra were recorded with a CARRY 5E spectrophotometer using the diffuse reflectance technique, with polytetrafluoroethylene as a reference. − X-band powder EPR spectra were obtained with a Bruker ESP 300 E electron spin resonance spectrometer. − Magnetic susceptibilities were carried out in the temperature range 300−2 K with a quantum design MPMS-5S SQUID magnetometer. − Magnetic data were corrected for diamagnetic contributions, which were estimated from the Pascal constants and were fitted to theoretical expressions by means of a Simplex routine. All parameters (J, g) were varied independently during the fitting procedure. This routine minimizes the function $R = |\Sigma|\chi_{obs} - \chi_{calc}|^2/|\Sigma|\chi_{obs}|^2|^{1.2}$.

Starting Materials: Commercially available solvents, monoformylhydrazine, triethyl orthoformate, ethylenediamine, and copper(II) perchlorate hexahydrate were used without further purification.

Synthesis of 1,2-Bis(1,2,4-triazol-4-yl)ethane (btre): The ligand btre was prepared from monoformylhydrazine, triethyl orthoformate, and ethylenediamine according to the general method described by Bayer et al.[51] Yield: 30%. M.p. > 260°C. – ^{1}H NMR (200 MHz, D_2O): δ = 2.67 (s, CH_2), 6.40 (s, trz–H), – IR: $\tilde{\nu}$ = 675 and 642 cm^{-1} (out-of-plane ring torsion vibrations of the 1,2,4-triazole), 887 cm^{-1} [C–H out of plane vibration (γ_{C-H})]. – $C_6H_8N_6$: calcd. C 43.90, H 4.91 N 51.19; found C 44.07, H 4.39, N 50.00.

Synthesis of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6\cdot H_2O$: $Cu(ClO_4)_2\cdot 6H_2O$ (0.48 mmol, 0.18 g), dissolved in 20 mL of water, was added to btre (1.52 mmol, 0.25 g), dissolved in 20 mL of water. The reaction mixture was diluted to 100 mL with water, and heated to give a clear solution. The compound precipitated upon cooling. The precipitate formed was left in the solution. Then, after a couple of days, well-shaped single crystals could be collected after slow evaporation of a part of the solvent at room temperature. Crystals were washed with water, and air-dried. Yield: 12.4%. – $C_{30}H_{46}Cl_6Cu_3N_{30}O_{27}$: calcd. C 21.68, H 2.79, Cl 12.80, Cu 11.47, N 25.28, O 25.99; found C 22.22, H 2.60, Cl 12.80, Cu 11.35, N 25.09, O 25.55.

Crystal Structure Determination of $[Cu_3(btre)_5(H_2O)_2](ClO_4)_6\cdot H_2O$: A blue, needle-shaped crystal of approximate dimensions 0.05 × 0.1 × 0.4 mm was mounted in a Lindemann glass capillary and transferred into the cold nitrogen stream on an Enraf–Nonius CAD4-T diffractometer on a rotating anode. Accurate unit-cell parameters and an orientation matrix were determined by least-squares fitting of the setting angles of 24 well-centered reflections (SET4[52]) in the range 10.0° < θ < 13.9°. The unit-cell parameters were checked for the presence of higher lattice symmetry.[53] Crystal data and details on data collection are presented in Table 4. Data were collected in ω scan mode with scan angle Δω = 0.73 + 0.35tanθ. Intensity data were collected up to θ = 26.5°. Intensity data of 11106 reflections were measured, 10579 of which were independent (R_{int} = 0.0665). Data were corrected for Lp effects and for 2% linear instability of the three periodically measured reference reflections during 50 h of X-ray exposure time, but not for absorption. The structure was solved by automated direct methods (SHELXS86[54]). Refinement on F^2 was carried out using full-matrix least-squares techniques (SHELXL-97[55]). Hydrogen atoms were included in the refinement on calculated positions riding on their carrier atoms, except for the water hydrogen atoms, which were located in a difference Fourier map. Their coordinates were included as parameters in the refinement. All nonhydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were included in the refinement with a fixed isotropic thermal parameter related to the value of the equivalent isotropic displacement parameter of their carrier atoms by a factor of 1.5 for the water hydrogen atoms and 1.2 for the other hydrogen atoms. Final refinement included 318 parameters and final weights were $w^{-1} = \sigma^2(F_o^2) + (0.0365P)^2 + 2.98P$, where $P = [(F_o^2, 0)_{max} + 2F_c^2]/3$. No residual density was found outside –0.66 and 0.95 e $Å^{-3}$. Neutral atom scattering factors and anomalous dispersion corrections were taken from the International Tables for Crystallography.[56] Geometrical calculations and illustrations were performed with PLATON.[57] Crystallographic data (excluding structure factors) for the structure reported in this paper has been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no CCDC-124884. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat) + 44-1223/336-033; E-mail: deposit@ccdc.cam.uk].

Mixed Linear (M,Sb) Chains in the New Antimonides $Hf_{10}M_{\delta}Sb_{6-\delta}$ (M = V, Cr, Mn, Fe, Co, Ni, Cu): Crystal and Electronic Structures, Phase Ranges, and Electrical and Magnetic Properties

Holger Kleinke,*[a,b] Christel Ruckert,[b] and Claudia Felser[c]

Keywords: Metal-rich antimonides / Magnetism / Structure and bonding / Conductivity / LMTO

The title compounds can be synthesized in quantitative yields by arc-melting of stoichiometric amounts of $HfSb_2$, Hf and one of the *3d* metals V, Cr, Mn, Fe, Co, Ni, and Cu. These antimonides crystallize in a substitution variant of the W_5Si_3 type, in which one position is statistically mixed, occupied by the *3d* metal atom M or the Sb2 atom in different ratios. Within the linear (M,Sb) chain, the M:Sb ratio may vary between 3:1 and 2:3. According to calculations of the electronic structures of $Hf_{10}M_{\delta}Sb_{6-\delta}$ with $\delta = 1$, these phases are metallic compounds stabilized by strong Hf–Hf, Hf–M, and Hf–Sb bonds, and to a smaller extent by bonding interactions within the linear (M,Sb) chain. The metallic character was confirmed by measurements of the electrical resistivity and the magnetism of selected samples. Whereas Pauli paramagnetism was observed experimentally for M = V, Co, and Ni, $Hf_{10}FeSb_5$ is apparently the only phase with localized magnetic moments and magnetic coupling. This is in agreement with the magnetic ground state obtained solely for the ordered structure model of $Hf_{10}FeSb_5$ with spin-polarized calculation within the local spin density approximation.

Introduction

The W_5Si_3 type is adopted by a variety of different phases, including mainly silicides, germanides and stannides of the valence electron-poor (so-called "early") transition metal atoms T.[1] In this structure type, linear chains of the T atoms run parallel to linear chains of main group elements E along [001] with the same interatomic distances in both chains. As a consequence a matrix effect, i.e. somewhat short T−T and long E−E distances or vice versa, may occur.

It is assumed that the W_5Si_3 structure type is basically limited to compounds of the third and fourth main group because the pnicogen and chalcogen atoms Q will most likely not form short Q−Q bonds in such metal-rich phases. Exceptions are the tellurides $M_xK_4Te_3$ (M = Ca, Sr)[2] which can be considered as electron-precise compounds $(M^{+2})_{0.5}(K^{+1})_4(Te^{-1})(Te^{-2})_2$, each Te^{-1} forming two one-electron-two-center bonds. However, one binary vanadium arsenide was described to crystallize in the W_5Si_3 structure type, the structure of which exhibits either a disordered As or a mixed (V,As) chain, thus reducing the As−As interactions.[3] Three examples based on antimony ($Zr_5M_{\delta}Sb_{3-\delta}$, M = Fe, Co, Ni, $\delta \approx 0.5$) are already known and show an incorporation of ca. 50% M atoms in the linear antimony chain.[4] Although alternating the M and Sb atoms within this chain would maximize the M−Sb bonds and prohibit the occurrence of Sb−Sb bonds, no long-range ordering was observed. This is probably a consequence of the gain in the configurational entropy. Note that each individual chain might be ordered, but in that case there could be no ordering between the chains, i.e. within the *a,b* plane.

In this paper, we present the results of our investigations of the Hf−M−Sb system with the *3d* metal atoms from titanium to copper. This includes different methods for the synthesis of the compounds $Hf_{10}M_{\delta}Sb_{6-\delta}$ (M = V, Cr, Mn, Fe, Co, Ni, and Cu), their crystal and electronic structures, phase ranges and magnetic properties. The phases $Hf_{10}M_{\delta}Sb_{6-\delta}$ are isostructural with the corresponding zirconium antimonides, which is not an obvious result, as investigations of ternary zirconium hafnium phosphides showed.[5−6]

Results and Discussion

Crystal Structure

The hitherto unknown antimonides $Hf_{10}M_{\delta}Sb_{6-\delta}$ (M = V, Cr, Fe, Mn, Co, Ni, Cu) occur in ternary variants of the W_5Si_3 structure type, the Hf atoms occupying the W sites and the M and Sb atoms replacing the Si atoms (Figure 1). Whereas the *8h* position is filled solely by antimony (Sb1), the *4a* site is occupied by mixtures of the M and Sb2 atoms without long-range ordering.

This comes along with a linear (M,Sb) chain with interatomic distances of approximately 280 pm which is surrounded by eight Hf2 atoms that form chains of face-condensed distorted square antiprisms (right part of Figure 2). The chains of Hf antiprisms, sheathed by the Sb2 atoms, are interconnected by Hf2−Hf2 bonds of ca. 320 pm to a

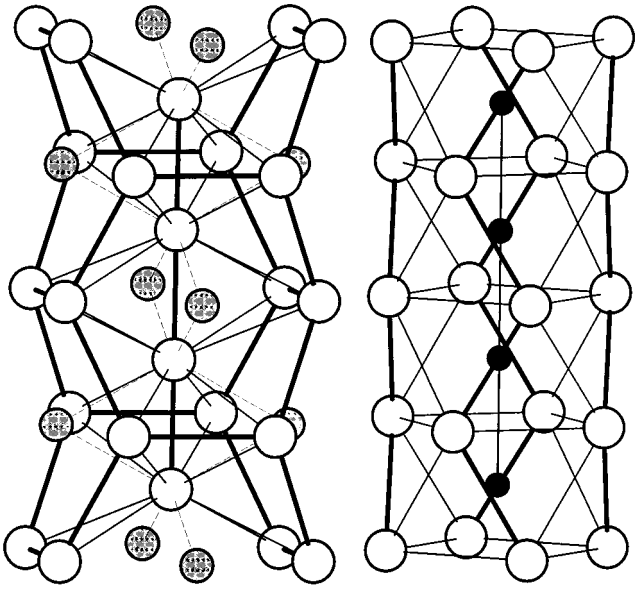

Figure 2. Columnar structure motifs of $Hf_{10}M_{\delta}Sb_{6-\delta}$; left: Chain of Hf1, surrounded by 8 Hf2 and 4 Sb1 atoms; the $Hf1Sb_4$ tetrahedra are indicated by dashed lines; right: chain of (M,Sb), situated in face-sharing $Hf2_8$ square antiprisms; Hf−Hf distances < 340 pm are indicated by bold lines

three-dimensional network surrounding linear chains of the Hf1 atoms ($d_{Hf1-Hf1} \approx 280$ pm). The Hf1 atoms are located in Sb_4 tetrahedra (left part of Figure 2), which are condensed via common vertices to form linear chains parallel to [001].

One can therefore divide the Hf−Hf distances into three classes. The first one includes the bonds within the linear Hf1 chain (ranging from $d = 277$ pm in $Hf_{10}Fe_{1.54}Sb_{4.46}$ to $d = 280$ pm in $Hf_{10}V_{0.80}Sb_{5.20}$ and $Hf_{10}V_{0.88}Sb_{5.12}$). The second one includes the distances of ca. 320−330 pm, and the third the longer ones of ca. 350 pm. These may be compared to elemental hafnium in its hexagonal modification with Hf−Hf distances of 313 and 320 pm, or to another Hf-rich antimonide, Hf_6NiSb_2, the structure of which exhibits Hf−Hf distances between 321 and 329 pm.[7] These comparisons reveal the extraordinary shortness of the bonds of class 1.

The Hf−Sb1 distances vary from 288 to 292 pm depending on the metal atom M and the δ parameter. The Hf−Sb2 bond lengths are somewhat shorter (between 278 and 289 pm); they are equal to the Hf−M distances by symmetry, which results in averaged values: since all M atoms are smaller than an Sb atom (e.g. the Pauling single bond radii: $r_V = 122$ pm, $r_{Ni} = 115$ pm, $r_{Cu} = 118$ pm, $r_{Sb} = 139$ pm[8]), the Hf−M distances are longer and the Hf−Sb2 distances shorter than in analogous compounds. This correlates well with the increase of the Hf2−(M,Sb2) distances with decreasing δ (Table 1), which range from 278 pm (δ = 1.54, M = Fe) to 289 pm (δ = 0.80 and 0.88, M = V). Correspondingly, the Hf−Sb distances of 296−297 pm in the structure of Hf_6NiSb_2 are much longer than the Hf−Ni bonds in the same structure (259 pm).[7]

The short Hf2−(M,Sb2) distance in the structure of $Hf_{10}Fe_{1.5}Sb_{4.5}$, i.e. in the case of the highest δ parameter (1.5), is reflected in a significant shift of the Hf2 atom towards the (M,Sb2) chain relative to all other examples with $0.80 \leq \delta \leq 1.18$ (see Table 2). This shift occurs with significantly smaller Hf2−Hf2 distances within the square antiprisms, but larger ones between the prisms (i.e. 334 pm vs. 320−321 pm) and between Hf1 and Hf2 (354 pm vs. 349−350 pm).

Electronic Structure

We successfully synthesized $Hf_{10}MSb_5$ with a variety of *3d* M atoms ranging from vanadium to copper. For a qualitative discussion of the influence of M on the electronic structure and thereby on the physical properties, the electronic structures were calculated for M = V and M = Ni, which are the most *d*-electron-poor and -rich examples, respectively (except for Cu). To model different possibilities of the ordering in the (M,Sb) chain, we calculated three hypothetical structures twice using the Extended Hückel approximation, i.e. in the Hf−V−Sb and in the Hf−Ni−Sb system. In model **I**, an ordering corresponding to the symmetry of space group *I*422 is assumed. In this case, M and Sb alternate in the two chains of the body-centered unit cell, with M of one chain being situated at the Sb position of the other chain, and thus exhibits the same *z* parameter. In model **II**, M and Sb also alternate within each chain, but the M atoms are located at the same positions in both chains of the body-centered unit cell. In model **III**, one chain consists only of M atoms and the other solely of Sb atoms. Models **II** and **III** can be described in the space groups *P*4/*nbm* and *P*4/*mcc*, respectively. In all cases, the stoichiometry remains the same, namely $Hf_{10}MSb_5$.

For general considerations, we will discuss model **I** of $Hf_{10}MSb_5$ with M = V and Ni. The densities of states calculated with the Extended Hückel approach (Figure 3) exhibit some significant differences as well as common features. In both cases, a peak occurs between ca. −12 and −15 eV, which consists mainly of the *5p* states of antimony. (The *5s* states are located below the energy window shown.) The contributions of each of Hf, V, and Ni to this peak point to covalent character of the metal−Sb bonds. The different chemistry of the M atoms vanadium and nickel is reflected in some differences in the densities of states: whereas the *3d* states of nickel are located in a sharp peak at −10 eV (well below the Fermi level of −8.56 eV), the vanadium states are extended broadly from ca. −10 eV up to well above the Fermi level of −8.09 eV). In the latter case, the M states occur in basically the same energy area as the Hf states. It is concluded that the *d* orbitals of Ni are more or less completely filled, whereas the V and Hf *d* states are partly occupied. This occurs with a significant number of states filled at the Fermi level for both $Hf_{10}MSb_5$ phases, which is larger in the case of M = V.

For an evaluation of the bonding situations, the semiempirical Hf−Hf, Hf−M, and Hf−Sb COOP curves, summed over all interactions in the unit cell, are shown in Figure 4. Averaged over the first Brillouin zone, almost no antibonding states are filled. Almost no Hf−Sb states occur at the

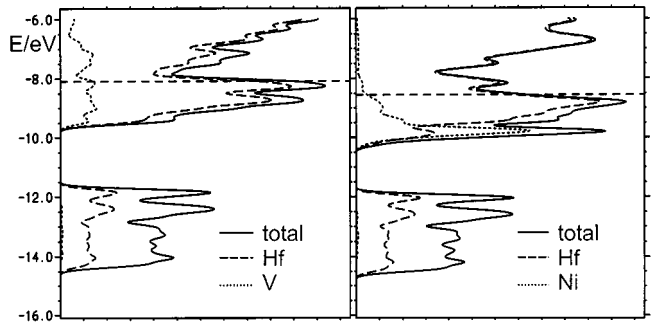

Figure 3. Calculated densities of states for $Hf_{10}MSb_5$ (EH approximation); left: M = V; right: M = Ni; horizontal lines: Fermi levels; solid line: total DOS; dashes: Hf contribution; dots: M contribution

Fermi level, which is dominated by bonding Hf−Hf interactions. Increasing the number of valence electrons would occur with more filled bonding Hf−Hf states, but with some filled antibonding Hf−M states in $Hf_{10}NiSb_5$. The Hf−V interactions are still bonding at the Fermi level (140 valence electrons), but become antibonding in character above −7.73 eV (ca. 151 valence electrons).

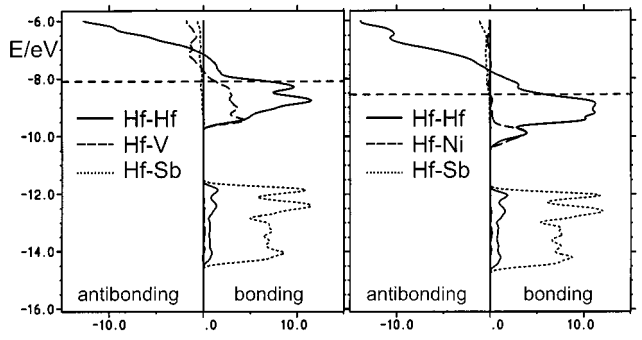

Figure 4. Selected summed COOP curves for $Hf_{10}MSb_5$; left: M = V; right: M = Ni; horizontal lines: Fermi levels; solid line: Hf−Hf interactions; dashed: Hf−M; dots: Hf−Sb; right parts of the diagrams: bonding interactions (+); left: antibonding (−)

After having considered some general features of the electronic structures, we focus now on the different structure models. In contrast to the model **III**, no homoatomic contacts occur in the (M,Sb) chains of models **I** and **II**. In model **I**, the M−Sb bonds of ca. 280 pm have net positive overlap populations although some antibonding states are filled in both cases (Figure 5). As a consequence of the filled *d* orbitals of nickel, antibonding Ni−Sb states occur above −10.5 eV, whereas fewer antibonding V−Sb states are filled. In addition to the differences in the antibonding states, the differences in the Mulliken overlap populations (*OP*) per bond (Ni−Sb: *OP* = 0.086; V−Sb: *OP* = 0.240) are also due to size effects (besides the dependence on the basis functions used): because of the smaller radius of nickel, a smaller overlap between the Ni and Sb orbitals is expected, which reflects itself in a smaller Pauling bond order *PBO* with $d(PBO) = d(1) - 60$ pm log *PBO*[8] [*PBO*(Ni−Sb): 0.38; *PBO*(V−Sb) = 0.48]. Since the differences in the (M,Sb) chains of models **I** and **II** arise solely from through-bond coupling between the chains, the interchain distance of 780 pm means that they are negligible. In model **III**, these bonds are replaced by homoatomic, namely M−M and Sb−Sb, interactions. They have definite bonding character in the case of $Hf_{10}VSb_5$ (V−V: *OP* = 0.24; Sb−Sb = 0.33), whereas the Ni−Ni interactions in $Hf_{10}NiSb_5$ are basically nonbonding (*OP* = 0.02), again because of the filled *d* orbitals. On the other hand, the Sb−Sb overlap populations in $Hf_{10}NiSb_5$ are of the same scale as in $Hf_{10}VSb_5$ (0.34 vs. 0.33). Comparable linear Sb−Sb chains were discussed recently:[9,10] in the structures of $(Zr,V)_{13}Sb_{10}$ and $(Zr,V)_{11}Sb_8$, the calculations revealed 1-electron 2-center *sigma* Sb−Sb bonds, which is in agreement with the values of the overlap populations of ca. 0.33 electrons per bond.

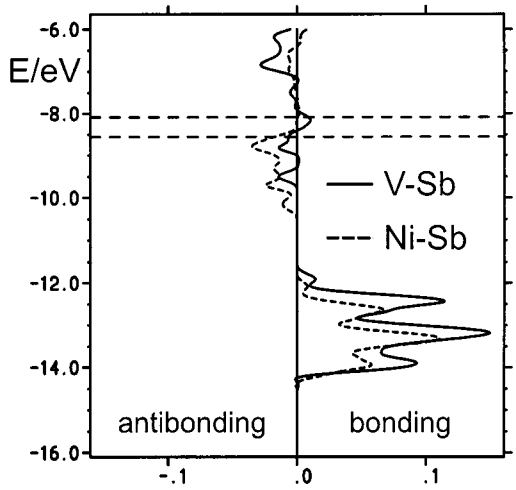

Figure 5. Averaged M−Sb COOP curves for $Hf_{10}MSb_5$; horizontal lines: Fermi levels; solid line: $Hf_{10}VSb_5$; dashed: $Hf_{10}NiSb_5$; right parts of the diagrams: bonding interactions (+); left: antibonding (−)

Based on the different Coulomb interactions one might expect that two M−Sb bonds are energetically favored relative to one M−M and one Sb−Sb bond. In the case of $Hf_{10}M_\delta Sb_{6-\delta}$, however, both M and Sb are somewhat negatively charged because of the more electropositive nature of hafnium, the major component of this phase. For example, the Pauling electronegativity values are 1.3 for hafnium, 1.6 for vanadium, 1.8 for nickel, and 1.9 for antimony. Correspondingly, the semiempirical Mulliken charges are −0.12 for vanadium and −0.49 for the Sb2 atom (Sb1: −0.67) in $Hf_{10}VSb_5$ (model **I**), and ≈0.00 for nickel and −0.43 for the Sb2 atom (Sb1: −0.49) in $Hf_{10}NiSb_5$ (model **I**). The metalloid antimony is obviously the most negatively charged atom, which renders reasonable the *antimonide* formulation for $Hf_{10}M_\delta Sb_{6-\delta}$. Furthermore, the Sb1 atom, being surrounded solely by Hf atoms, is more negatively charged than the Sb2 atom, which has two neighboring M atoms in model **I**. Both different kinds of Hf atoms show positive Mulliken charges, i.e. in the case of model **I** of $Hf_{10}VSb_5$ +0.17 for Hf1 and +0.38 for Hf2, and in the case of $Hf_{10}NiSb_5$ +0.06 for Hf1 and +0.29 for Hf2.

On the other hand, the charges of the M and Sb2 atoms obtained for model **III** differ significantly. The M atoms are

more and the Sb2 atoms less negatively charged in model **III** than in model **I** ($Hf_{10}VSb_5$: V −0.35 and Sb2 −0.07; $Hf_{10}NiSb_5$: Ni −0.22 and Sb +0.08). It is concluded that model **III** should exhibit a higher total energy because the Mulliken charges obtained are in direct contradiction to the trends expected based on electronegativity, especially for $Hf_{10}VSb_5$: the V atom exhibits a higher negative charge in model **III** than the Sb2 atom despite the lower electronegativity.

The entropy of an ordered structure generally differs from the disordered one by the configurational entropy. An estimation of the entropy of a completely disordered structure model $Hf_{10}MSb_5$, given by $\Delta S = -R\ \Sigma(X_i \ln X_i)$,[11] gives a value of 11.5 J/(molK). Since the free energy, ΔG, is determined by the equation $\Delta G = \Delta H - T\Delta S$, $T\Delta S$ is, besides the differences in the enthalpy, the factor which determines whether ordering occurs. According to our experiments, the minimum formation temperature of $Hf_{10}MSb_5$ is T = 1350°C, which corresponds to $T\Delta S = 0.2$ eV. Since this value is higher than the difference between the total energies of models **I** and **II** calculated with the LMTO method (0.02 eV in the case of $Hf_{10}NiSb_5$), one cannot expect complete (M,Sb) ordering from one chain to another.

The densities of states for the ordered structure model **I** of $Hf_{10}NiSb_5$, as obtained by the LMTO method, are shown in Figure 6. This shows that in contrast to the results of the Extended Hückel calculation, the peaks dominated by metal and antimony atoms do overlap. Furthermore, the overlap between the Hf and Ni states is more extensive than according to the EH calculations. The region around the Fermi level, however, is similar.

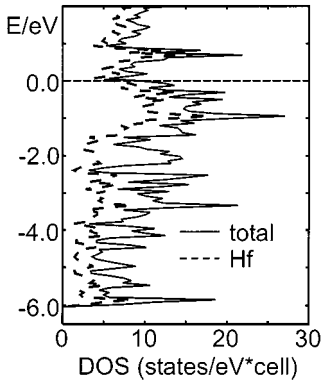

Figure 6. Calculated densities of states for $Hf_{10}NiSb_5$ (LMTO approach); DOS: Solid line: total DOS; dashes: Hf contribution

The significant densities of states at the Fermi level should occur with metallic properties, which is confirmed by several bands of $Hf_{10}NiSb_5$ crossing the Fermi level, as shown in Figure 7 which emphasizes the Ni centered bands with the fat band representation. The bands with a high Ni character occur about 2 eV below the Fermi level, which is reflected in a large Ni contribution to the densities of states in that energy area. Referring to the body-centered unit cell, two bands cross the Fermi level parallel to the c^* axis (symmetry lines ΓZ and XP), whereas no bands cross the Fermi level along the directions situated in the a^*,b^* plane, namely ΓX and PN. The latter is a consequence of the low dispersion of the Hf centered bands in the a,b plane, but does not imply one-dimensional metallic properties of all members of the $Hf_{10}M_{\delta}Sb_{6-\delta}$ series since the Fermi level depends on the number of valence electrons. The band structure of model **I** of $Hf_{10}VSb_5$ does not exhibit bands crossing the Fermi level along these symmetry lines, either, although that of $Hf_{10}FeSb_5$ does.

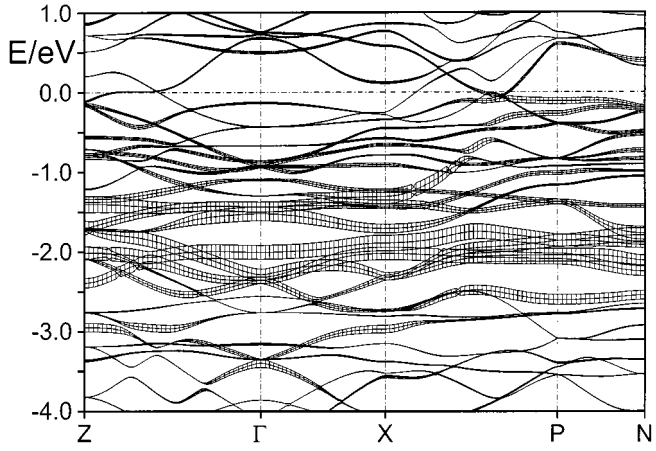

Figure 7. Band structure of $Hf_{10}NiSb_5$ (LMTO approach); fat bands projected on the Ni eigenvector contributions; symmetry points: Z = (−1/2, 1/2, 1/2); Γ = (0, 0, 0); X = (0, 0, 1/2); P = (1/4, 1/4, 1/4); N = (0, 1/2, 0) in units of the reciprocal primitive unit cell

Spin-polarized calculations within the local spin-density approximation were performed for the structure models containing the metal atoms Mn, Fe, Co, and Ni. Only in the case of $Hf_{10}FeSb_5$ was a magnetic ground state (0.6 μ_B) calculated. This occurred with a lowering of the total energy of just 4×10^{-5} eV relative to the non spin-polarized, and thus nonmagnetic, model calculation. The lower total energy is found to arise from a decrease in the number of states at the Fermi level, i.e. from 151 to 141 states/(eV × cell). The relatively small effects are a consequence of the small Fe content and the absence of any direct Fe−Fe interactions in $Hf_{10}FeSb_5$, while the difference between the energies of magnetic and (hypothetical) nonmagnetic α-Fe of 0.426 eV arises from a significant enhancement of Fe−Fe bonding.[12]

In order to check for a magnetic superstructure we carried out a spin-polarized self-consistent calculation of the tetragonal unit cell containing two (Fe,Sb) chains and thus two Fe atoms. The magnetic moments of the two Fe atoms were calculated to be +1.2 and −0.3 μ_B, respectively. Thus, the magnetic cell of $Hf_{10}FeSb_5$ in structure model **I** corresponds to the metric of the tetragonal unit cell in space group $P422$, with ferrimagnetic coupling between the Fe atoms of the two neighboring chains. However, different coupling of the magnetic moments of the Fe atoms resulted for the structure models **II** and **III**, namely ferromagnetic coupling with magnetic moments of 2.1 and 2.4 μ_B, respectively.

Physical Properties

The metal-rich composition, the presence of Hf−Hf contacts along all three directions, and the results of the electronic calculations discussed above strongly suggest metallic properties for all $Hf_{10}M_{\delta}Sb_{6-\delta}$ phases. The temperature dependence of the resistivity of a cold-pressed bar of the sample **II** (nominal composition $Hf_{10}CrSb_5$) is typical for a metallic sample (linearly increasing resistivity with increasing temperature), but the $\rho_{(10K)}/\rho_{(280K)}$ ratio of 0.94 is rather high. According to the Matthiesen rule $\rho(T) = \rho_i + \rho_L(T)$, the impurity contribution ρ_i to the measured resistivity $\rho(T)$ is basically independent of the temperature.[13] It is concluded that the contribution ρ_i is relatively large in this case, relative to the intrinsic lattice resistivity $\rho_L(T)$, thus leading to a small temperature dependence of the resistivity measured. This could be a consequence of either large grain boundaries or of an oxidation of the surface by oxygen, which we tried to minimize by working under an inert atmosphere in a glove-box as far as possible.

The metallic properties reflect themselves in the Pauli paramagnetism experimentally observed for the bulk samples of the initial compositions $Hf_{10}MSb_5$ with M = V, Co, and Ni (Figure 8). Aside from small Curie tails at low temperatures, the curves are basically temperature independent, indicating that no unpaired localized electrons are present in the samples investigated. On the other hand, the sample with the initial composition $Hf_{10}FeSb_5$ exhibits a slope typical of weak ferromagnetic or ferrimagnetic materials. This is in agreement with the results of the spin-polarized LMTO calculation, which yielded a magnetic moment only in the case of $Hf_{10}FeSb_5$.

Similar results were found experimentally for the antimonides Zr_5MSb_3 (Ti_5Ga_4 type): in the case of M = Fe ferromagnetic properties were observed, while Zr_5CoSb_3 and Zr_5NiSb_3 showed Pauli paramagnetism.[14]

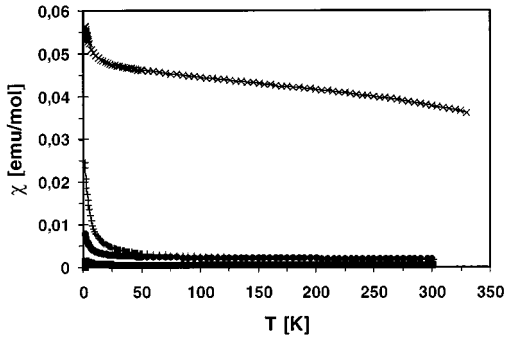

Figure 8. Temperature-dependence of the molar susceptibilities at 1 Tesla. ×: $Hf_{10}FeSb_5$; +: $Hf_{10}VSb_5$; filled circles: $Hf_{10}CoSb_5$; filled squares: $Hf_{10}NiSb_5$

To check for the ferromagnetic behavior, a field-dependent magnetization was measured at 5 Kelvin (Figure 9). Whilst the slope is familiar from ferromagnetic compounds, the hysteresis is almost zero, pointing to a very weak ferromagnetic material. The magnetic moment per Fe atom of 2 μ_B, as determined from an estimation of the saturation magnetization, suggests that the sample investigated consisted of different domains, i.e. a mixture of the different structure models, since the models **I**, **II** and **III** exhibit magnetic moments of 0.6, 2.1 and 2.4 μ_B, respectively (according to the LMTO calculations).

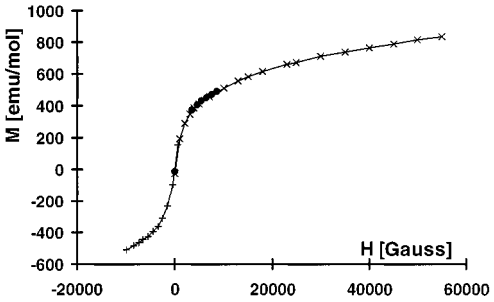

Figure 9. Field dependence of the magnetization *M* of $Hf_{10}FeSb_5$ at 5 Kelvin. +: 1. Series, *M* measured from 0 to 55000 Gauss; ×: 2. Series, field increased rapidly to 0, then *M* measured from 0 to 8500 Gauss

Conclusions

The new antimonides $Hf_{10}M_{\delta}Sb_{6-\delta}$ (M = V, Cr, Mn, Fe, Co, Ni, Cu) were synthesized and subsequently characterized by single crystal structure studies, calculations of the electronic structures, and measurements of the magnetic and electrical properties of selected samples. The compounds $Hf_{10}M_{\delta}Sb_{6-\delta}$, exhibiting a phase range of at least $0.80(4) \leq \delta \leq 1.54(6)$, crystallize in the W_5Si_3 structure type. The X-ray experiments revealed no long-range ordering of the M/Sb atoms on the Si site. The calculations suggest that an ordering within a given (M,Sb) chain is likely to occur, but the correlation between the chains are too small for systematic ordering between the chains. The disordering can be explained by an increase of the configurational entropy, compared to the ordered structure model. The phases $Hf_{10}M_{\delta}Sb_{6-\delta}$ are metallic without localized magnetic moments, except for M = Fe, where weak ferromagnetic properties are detected experimentally, in agreement with theoretical calculations based on the spin-polarized LMTO method.

Experimental Section

Syntheses: In order to minimize the loss of antimony during the process of arc-melting, we first prepared $HfSb_2$ as the antimony source in a fused silica tube at 650°C, starting from the elements in the stoichiometric 1:2 ratio (Hf: STREM, powder, 99.6% (including up to 2.2% zirconium), Sb: MERCK, powder, 99.8%). The compounds $Hf_{10}MSb_5$ were synthesized by arc-melting of stoichiometric ratios of Hf, $HfSb_2$ and M on a water-cooled copper hearth under a flow of argon (3 L/min). With weight losses of typically between 1 and 4 weight-%, the yields can be optimized by adding a small excess of antimony. Attempts to synthesize $Hf_{10}MSb_5$ with different *3d* metals M (from vanadium to copper, all powder; V: ABCR, −45 micron, 99.7%; Cr: VENTRON, −50 mesh, 99.8%; Mn: VENTRON, −325 mesh, 99.9%; Fe: STREM, 99.999%; Co: ALFA, −50 mesh, 99.8%; Ni: VENTRON, −150 mesh, 99.9%; Cu:

VENTRON, 99.9%) were successful in all cases, according to the powder diagrams of all reaction products and EDX investigations on selected samples ($Hf_{10}VSb_5$ and $Hf_{10}NiSb_5$, numbers **I** and **VI** in Table 3). An analogous reaction using titanium (Ti: ALFA, −100 mesh, 99.4%) instead of hafnium resulted in the formation of Ti_5NiSb_3[15] as the main product. A reaction using titanium as the *3d* metal did not yield the hypothetically isostructural "$Hf_{10}TiSb_5$", but resulted in the formation of the hitherto unknown compound $(Hf,Ti)_7Sb_4$[16] as the main product. Table 4 lists the lattice parameters obtained from the ground samples with the Guinier technique (Cu-K_{α}, using silicon as internal standard).

A single crystal of the sample **I** was investigated on an IPDS diffractometer (STOE). Parts of **I** and **VI** were annealed over a period of three weeks at 900 °C in tantalum tubes, placed in fused silica tubes sealed under vacuum. No differences were observed between the powder diagrams obtained before and after the annealing procedure. Nevertheless, the annealed samples of the initial compositions $Hf_{10}VSb_5$ (**VIII**) and $Hf_{10}NiSb_5$ (**IX**) were investigated also

by single crystal structure analyses. Reactions starting from $HfSb_2$, Hf, and different M atoms, carried out in sealed tantalum tubes without previous arc-melting, did not result in the formation of the $Hf_{10}M_{\delta}Sb_{6-\delta}$ phases after annealing for six days at temperatures of 1300°C. At a reaction temperature of 1350°C, $Hf_{10}Mn_{\delta}Sb_{6-\delta}$ formed, and a single crystal study was also performed using a small crystal of this sample (**X**).

A study of the phase range was carried out in the Hf−Fe−Sb system by arc-melting different mixtures, corresponding to the starting compositions of "$Hf_{10}Fe_{\delta}Sb_{6-\delta}$" with δ = 2, 1.75, 1.5, 1.25, 0.75, 0.5 and 0.25. At δ = 2 and 1.75, the phase $Hf_{10}Fe_{\delta}Sb_{6-\delta}$ formed together with other unidentified products, and at δ = 0.5 and 0.25, the hitherto unknown binary antimonide Hf_5Sb_3[17] was detected, as well as $Hf_{10}Fe_{\delta}Sb_{6-\delta}$. It is concluded that the phase range is within $0.5 < \delta < 1.75$. Correspondingly, a single crystal study of the sample with δ = 2 (**XI**) yielded the formula $Hf_{10}Fe_{1.54(6)}Sb_{4.46}$, and thus δ = 1.54(6).

Single-Crystal Studies: All five data sets were collected with an IPDS diffractometer. The data were corrected for Lorentz and polarization effects. No superstructure reflections were observed in any of these data sets. The structure solutions and refinements were performed using SHELXS86 and SHELXL97.[18] The systematic extinction of $l = 2n + 1$ for all *0kl* reflections (in addition to the integral extinctions, namely $h + k + l = 2n + 1$) restricted the possible space groups to $I4/mcm$ (W_5Si_3), $I4cm$ and $I\bar{4}c2$. The *4a* position of *I*4/*mcm*, which is occupied by a mixture of M and Sb atoms, has the multitude of four in all three space groups. To check for ordering on this site, all five structure models were refined in the space group *I*4*22*, which allows alternating M and Sb atoms within the (M,Sb) chains by splitting the *4a* site of *I*4/*mcm* into *2a* and *2b*. No ordering was observed. Final refinements in the space group *I*4/*mcm* yielded, in all cases, different ratios of the M and Sb atoms in this chain, which were refined under the restriction of $f_M + f_{Sb} = 1$, i.e. 100% occupancy in the sum of the occupancies of the M and Sb atoms. The results are summarized in the Tables 2, 5a and 5b.[19]

Calculations of Electronic Structures: Semiempirical band-structure calculations were performed using the Extended Hückel approximation.[20−22] The metal parameters were optimized by alternating charge iterations until convergence using constant Sb parameters (Table 6). The tetragonal cell (80 *k* points) was chosen for all calculations for consistency, because not all models considered exhibited the body-centered symmetry (see main text).

More sophisticated electronic calculations were carried out with the self-consistent TB-LMTO-ASA program within the local-density approximation.[23−25] The integration in *k* space was performed by the tetrahedron method[26] on a grid of 1331 irreducible *k* points. The *5f* orbitals of hafnium and the *4f* orbitals of antimony were included by using a downfolding technique. The symmetry points of the band structure were chosen according to Bradley and Cracknell.[27]

Table 6. Parameters used for EH calculations

[a] Values for the calculation on $Hf_{10}VSb_5$. − [b] Values for the calculation on $Hf_{10}NiSb_5$.

Transport Properties: Temperature dependent resistivity measurements were performed on a cold-pressed bar with the nominal composition $Hf_{10}CrSb_5$. The pellet was contacted at four points, which enables a measurement independent of the resistivities of the contacts.

Magnetic Properties: Magnetic data were obtained for the bulk samples of $Hf_{10}M_1Sb_5$ with M = Fe, V, Co, and Ni. Temperature-dependent measurements were made at 1 Tesla in the temperature range of 1.8−300 K on a Quantum Design MPMS SQUID magnetometer. The data were corrected for the diamagnetic atom cores.

Acknowledgments

The experimental work was carried out at the Department of Chemistry, University of Marburg. Financial support from the "Deutsche Forschungsgemeinschaft", the "Fonds der Chemischen Industrie" and the "Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie" is gratefully acknowledged. Insightful discussions with Professor Dr. B. Harbrecht are appreciated.

A Two-Step Palladium-Catalyzed Coupling Scheme for the Synthesis of Ferrocene-Labeled Amino Acids

Oliver Brosch,[a] Thomas Weyhermülle,r[a] and Nils Metzler-Nolte*[a]

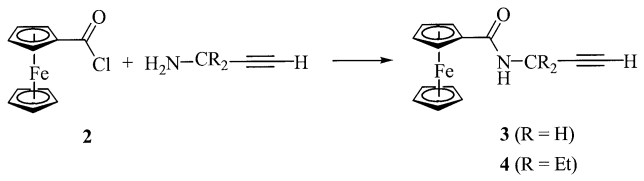
Keywords: Amino acids / Alkynes / Ferrocene / Palladium / Catalysis / Bioorganometallic chemistry / Biosensors

This work describes a Pd-catalyzed coupling of ferrocene alkyne derivatives to iodo amino acids. Ferrocene carboxylic acid propargyl amides were easily obtained in high yield. The crystal structures of the propargyl amine derivative **3** and the 1,1-diethylpropargylamine derivative **4** have been determined by X-ray diffraction. Pd-catalyzed coupling to ***p***-iodoanilide amino acids gave the corresponding ferrocene-labeled amino acid derivatives, which were easily purified by diethyl ether extraction in the case of the 1,1-diethyl derivatives **8**. The coupling reaction did not require anhydrous solvents and tolerated a variety of functional groups present in peptides such as alcohols (**8a**, Ser), thioethers (**8b**, Met), disulfide bonds (cystine, **12**) esters (as in the *N*-labeled Leu derivative **10**) and of course amides. A minor by-product of the coupling reaction, namely the homo-dimer bis(ferrocene carboxylic acid propargylamide) **9**, was identified in the crude reaction mixtures by mass spectrometry and independently synthesized by oxidative coupling (Glaser and Eglington) of **3**. All new compounds were completely characterized spectroscopically, including ^{15}N- and 2D NMR spectroscopy, Mössbauer spectroscopy and electrochemistry. This work introduces a versatile procedure for a selective functionalization of amino acids with organometallics at the *C-terminus* which is expected to be of general applicability to peptide chemistry.

Introduction

We are exploring new ways of covalently linking organometallic compounds to biomolecules.[1−5] In these conjugates, the organometallic moiety serves as a sensitive probe for the detection of the biomolecule, e. g. electrochemically[6−8] or by IR spectroscopy.[9−18] The key issue in any of these assays is *chemoselectivity*:[12,18] No doubt is to remain about the number of attached organometallics nor their site of attachment to the biomolecule − which may even be, for example, a large enzyme[10,11,13] or peptide hormone like secretin.[19] Also, the reaction should be mild enough to comply with the possibly sensitive organometallic compounds and the variety of functional groups present in a peptide. We[1] and others[20,21] have suggested the use of a Pd-catalyzed two-step coupling reaction for this purpose. In the first step, an anchoring group is incorporated into the peptide. Secondly, a suitably-functionalized organometallic compound is reacted with that anchoring group to form the covalent link to the peptide. The prerequisite of this concept is that the anchoring group is left untouched under standard peptide chemistry conditions and vice versa the reaction that links the organometallic to the peptide may not affect any functionality present in the peptide other than the anchoring group. In compliance with this prerequisite, our group has recently reported the synthesis of alkynyl amino acids for the coupling with organometallic halides and demonstrated the viability of our approach by selectively labeling the *N*- and *C*-protected tripeptide Boc-Phe-Glu-Met-OMe at the C_γ of Glu with a ferrocene derivative.[1] However, derivatizing a peptide with alkynyl groups is not feasable in solid-state synthesis of peptides as the alkyne may not withstand the concentrated HF frequently used to cleave the peptide from the support. In an effort to circumvent this problem, this work reports the synthesis of alkynyl ferrocene derivatives and their Pd-catalyzed coupling to iodobenzene amino acids with different functional groups. Iodinated aromatic compounds were previously used as radio-labels for amino acids[22] and monoclonal antibodies[23] and as such were successfully employed in solid support peptide synthesis.[24] In this study, alternatively-functionalized amino acids were chosen as model compounds for peptides and ferrocene was selected owing to its potential in electrochemical detection.[3,8,25−31]

Results and Discussion



Synthesis

Ferrocene carboxylic acid chloride **2**, which was prepared in situ by heating ferrocene carboxylic acid **1** at reflux with oxalic acid chloride, reacts with propargyl amine and 1,1-diethylpropargyl amine to give the ferrocene amido alkynes **3** and **4** in >90% yield (Scheme 1). Both derivatives are orange, crystalline solids and their solid-state structures were determined by X-ray diffraction (vide infra).

In these preparations, ferrocene carboxylic acid anhydride was frequently found as a by-product. To avoid the formation of this anhydride, we explored other means of activating the organometallic acid. Kraatz et al. prepared ferrocene amino acids by activation of **1** with hydroxybenzotriazole and dicyclohexylcarbodiimide in >70% yield.[32] In our hands, however, yields for this coupling were usually much lower. Isobutyl chloroformate/*N*-methyl-

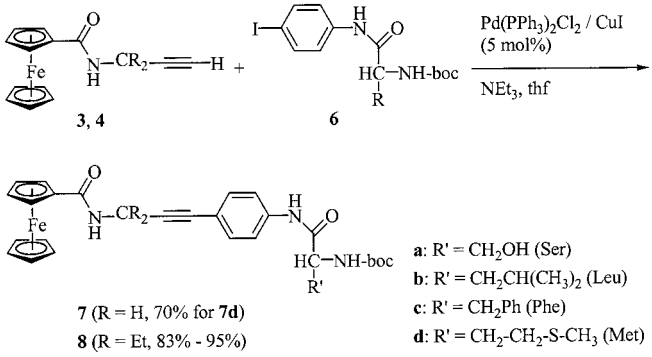
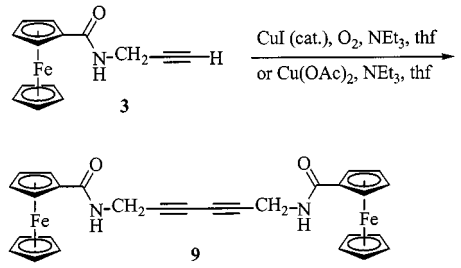


Scheme 1

morpholine in THF is an alternative well-established reagent for peptide coupling reactions in solution.[33] According to Scheme 2, ferrocene carboxylic acid isobutyl ester **5** could be prepared in 95% yield. However, 14 h of reflux were necessary to obtain **3** from **5** and propargyl amine. Unlike amino acids, which react with amines within minutes under comparable conditions,[34] ferrocene carboxylic acid is not easily activated by the most common reagents.



Scheme 2

Reaction of organometallic alkynes **3** and **4** with iodoarene amino acid derivatives **6** gave the desired ferrocene-labeled amino acids **7** and **8** in very good yield (Sonogashira coupling,[35–37] Scheme 3). By extracting the crude reaction products with diethyl ether, the diethyl derivatives **8** could be obtained as analytically pure solids. Owing to their reduced solubility, the simpler propargyl amine derivatives **7** were more difficult to separate from impurities. In fact, only the methionine derivative **7d** could be obtained analytically pure after extensive washing.

Scheme 3

The inability to obtain pure coupling products **7** prompted us to carry out a careful product analysis. Electron spray ionization mass spectrometry (ESI-MS) revealed the presence (< 5%) of an iron-containing by-product with m/z = 532. In addition, the ^{1}H-NMR spectrum of the crude reaction mixture contained a number of Cp signals, a signal for one amide proton and a further signal which was not assigned. Since we suspected that oxidative homo-coupling of **3** might have occurred, we set out to synthesize the dimer **9** by air oxidation of **3** with a catalytic amount of CuI (Glaser coupling,[38] 32% yield) or stoichiometric amounts of $Cu(OAc)_2$ under Ar (Eglington coupling,[38] 38% yield, Scheme 4). The bis-ferrocene-diyne **9** is an orange-coloured solid, which is stable both as a solid and in solution for prolonged periods of time.

Scheme 4

Characterization

Solid-State Structures of 3 and 4

Crystals of suitable quality for an X-ray structure analysis were obtained for the two alkynyl–ferrocene derivatives **3** and **4**. Both compounds crystallize in the orthorhombic space group *Pbca* with very similar unit cells and packing in the crystal lattice (see Table 1, Experimental Section). ORTEP plots of the molecular structures are shown in Figures 1 and 2, repectively. The amide groups are almost parallel to the plane of the neighbouring cyclopentadienyl ring (9° angle between amide and Cp least squares planes for **3** and 15.5° for **4**). The tilt of both cyclopentadienyl rings is 1.8° (**3**) and 2.5° (**4**) away from an eclipsed conformation (mean value of H/C–C–C–H dihedral angles) and the rings are almost parallel as shown by the centroid–Fe–centroid angle (179° and 177.8° for **3** and **4**, respectively). All these parameters compare well to related compounds.[32,39,40] Unlike ferrocene carboxylic acid, which forms dimers in the solid state,[40,41] both **3** and **4** form hydrogen bridges with their nearest neighbours through the amide bonds in the crystal lattice. By arranging in a "head-to-tail" fashion, the molecules form one-dimensional zigzag chains (Figure 3).

Spectroscopy and Discussion

The Sonogashira coupling has recently gained some attention for the synthesis of organometallic alkynes[42,43] and polymers.[44,45] Beck et al. have used *p*-ethynylphenylalanine, which is a potent inhibitor of tryptophan hydroxylase,[46] in Pd-catalyzed alkyne coupling reactions to obtain a variety of novel phenylalanine derivatives.[47–49] NMR spectroscopy provides an excellent handle to establish the constitution of all new compounds. The alkyne pro-

ton in **3** and **4** is readily detected at ca. δ = 2.3 as a singlet (**4**) or a triplet with $^4J_{HH}$ = 2.6 Hz due to coupling with the methylene protons (**3**). The success of the Pd-catalyzed coupling can be immediately established by ^{1}H-NMR spectroscopy, especially by the disappearance of this signal of the terminal alkyne. In an earlier report on ferrocene carboxylic acid amides of amino acids,[32] two signals were observed for the *ortho* protons of the substituted Cp ring owing to the presence of a chiral centre. Even at 500 MHz, we were unable to detect more than one signal for these *ortho* protons, probably because of the large distance between the Cp ring and the chiral centre. From molecular modelling (Sybyl force field[50]) of the alanine derivative **7e** (R = H, R′ = CH_3), it follows that the C≡C triple bond, an aromatic ring and two amide groups enforce a minimum distance of >10 Å between the iron centre and the chiral

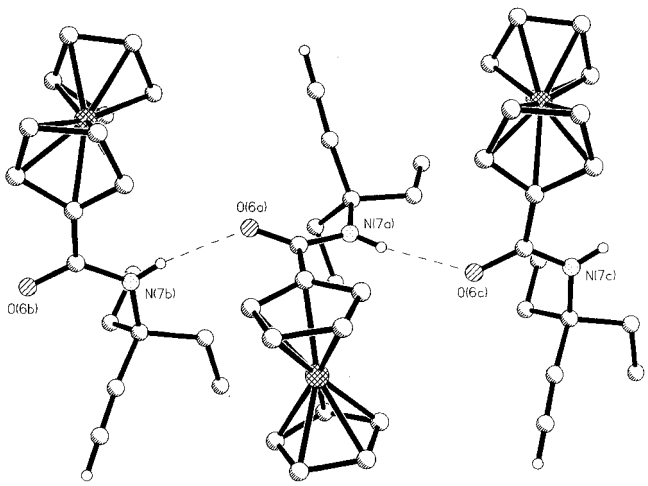

Figure 3. Part of the solid-state structure of **4**, showing the head-to-tail orientation of neighbouring molecules by means of hydrogen bridges. Distance N(7b)−O(6a) 2.998 Å

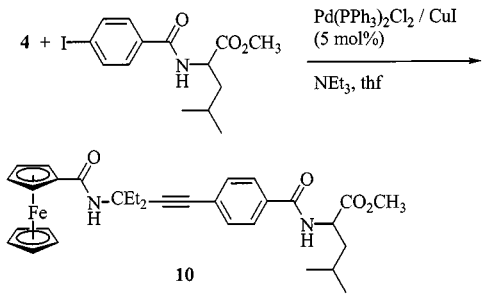
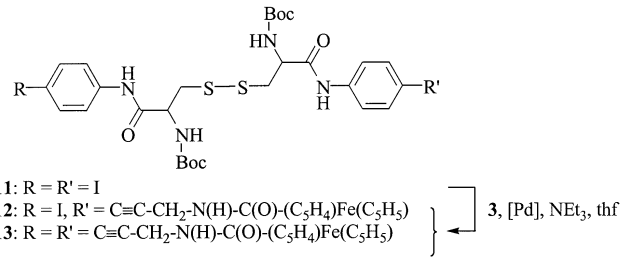


carbon atom C_α. There are also characteristic signals in the ^{13}C-NMR spectra of conjugates **7** and **8**, in particular for the two carbon atoms between which the new bond is formed. The alkyne carbon atom shifts downfield by about 13 ppm, whereas the signal of the aryl carbon atom, having been shielded by the iodine centre in **6** (ca. 87 ppm), is found at ca. 119 ppm in **7** and **8**. The alkyne ^{13}C-NMR signals for the diyne **9** are observed remarkably upfield (δ = 65.5 for the internal carbon atoms and δ = 76.7). These values are about 6 and 10 ppm higher than in a related phenylacetylene-chromium-tricarbonyl dimer[42] or in (ethynylcyclobutadiene)-cyclopentadienyl-cobalt dimer by Bunz and co-workers.[51] Since the NMR signals for all amide protons are readily detectable in aprotic solvents we used 2D indirect detection ^{1}H-^{15}N NMR spectroscopy to detect the ^{15}N-NMR signals of all nitrogen atoms in the new compounds. There are indeed characteristic ranges for ^{15}N-NMR shifts which will facilitate the identification of related coupling products in the future, namely δ_N = −275 for **7** and δ_N = −260 for **8**. The N_{Boc} signal is generally observed at δ_N = −290 and the anilide nitrogen atom at δ_N = −250.[52,53] All these chemical shifts are fairly insensitive to solvent changes, which indicates that intermolecular hydrogen bonds are broken up in solution for **7** and **8**. This notion is further substantiated by IR spectroscopy.

In the IR spectra of **3**, **4**, **7** and **8**, the C≡C stretching frequency is often too weak to be detected. It is, however, usually the strongest band in the RAMAN spectra. Upon substitution of the terminal proton, its frequency shifts by more than 100 cm^{-1} from 2121 cm^{-1} (**3**) and 2105 cm^{-1} (**4**) to about 2230 cm^{-1} (see Experimental Section). It is possible to distinguish between propargylamine compounds **7** and their 1,1-diethyl derivatives **8** on the basis of their RAMAN spectra alone since there is a difference of about 10 cm^{-1} in the respective stretching frequencies of the C≡C bond (ca. 2230 cm^{-1} in **8** and 2240 cm^{-1} in **7**), quite comparable to compounds **3** and **4**. Unfortunately, we were unable to obtain single crystals of the ferrocene amino acid

conjugates **7** or **8**. However, the IR spectrum of **7d** sheds some light on structural differences between the solid-state and solutions of **7** and **8**.[54,55] A broad band well below 3400 cm^{-1} for **7d** in a KBr pellet is indicative of hydrogen bonding involving the amide groups. These hydrogen bonds will govern the packing of molecules in the solid state[56] as described for **3** and **4**. In contrast, there is only one sharp amide band observed at 3428 cm^{-1} in CH_2Cl_2 solution, clearly showing that all hydrogen bonds are broken up even in aprotic solvents.[57]

Electrochemical detection − where applicable − is a useful tool in chromatography (HPLC-ECD) and the use of ferrocene derivatives in peptide chemistry has been explored by the group of Eckert.[6,7] Their approach of using activated acids of ferrocene derivatives was hampered by low yields in the coupling reactions or by precursors which were difficult to prepare. Using the methodology outlined in this work, we can easily prepare electrochemically active amino acid derivatives in high yield. To demonstrate the feasibility of ECD, compounds **7** and **8** were investigated electrochemically. Both groups of compounds show a reversible wave in the cyclic voltammogram (CV) at +173 mV (**7**) and between +187 and +197 mV (**8**) vs. ferrocene/ferrocenium. Similar values have previously been observed for ferrocene carboxylic acid amides.[32] A second, irreversible wave in the CV of **8d** is attributed to oxidation of the sulfur atom.



Compounds **7** and **8** demonstrate a general principle for the functionalization of the *C-terminus* of amino acids, which has not been achieved before. Naturally, this two-step procedure can also be applied to the labeling of the *N-terminus* of amino acids as shown in Scheme 5.

Scheme 5

An excess of *p*-iodobenzoic acid chloride is reacted with leucine methyl ester and subsequently coupled to **4** under Pd catalysis. The coupling product **10**, which is obtained analytically pure in 89% yield, is easily identified by its spectral features, namely the disappearance of the signal of the alkyne proton in the ^{1}H-NMR spectrum, characteristic changes in the ^{13}C-NMR spectrum as described above and a strong band at 2227 cm^{-1} in the RAMAN spectrum. Compounds **4** and **10** were also investigated by ^{57}Fe Mössbauer spectroscopy. The isomer shift (0.53 mm s^{-1} for **4** and 0.52 mm s^{-1} for **10**) and quadrupolar splitting [2.34 mm s^{-1} (**4**) and 2.32 mm s^{-1} (**10**)] are very similar to the values of ferrocene (0.53 mm s^{-1} and 2.37 mm s^{-1}).[58] This similarity indicates that attachment of an amino acid (**10**) or even functionalization of one Cp ring (**4**) has no significant influence on the field gradients of the iron nucleus. Significant deviations were observed only in compounds where the two Cp rings were no longer coplanar.[59]

Beck and co-workers have prepared a veritable number of stable Pd^{II} complexes of amino acids and peptides, in which the metal coordinates − usually in a chelating fashion − to the N, O, or S atoms of the amino acids.[5,60−65] Other authors reported the hydrolysis of amino acid esters by *ortho*-metallated Pd complexes.[66,67] In the light of their results, the success of the Pd-catalyzed coupling with amino acids is all the more surprising. A number of ubiquitous functional groups in peptide chemistry such as thio-ethers (**7d** and **8d**), alcohols (**8a**), esters (**10**), and of course amides is tolerated without notable loss of catalytic activity. Since disulfide bonds play a pivotal structural role in many enzymes,[68] and insertion reactions into disulfide bonds are well documented for Pt complexes,[69,70] the obvious question needs to be answered as to whether our coupling would work for cystine derivatives. The bis(*N*-Boc)-bis(*p*-iodo-anilined)-cystine **11** was prepared from activated *N*-protected cystine and two equivalents of *p*-iodo-aniline. Reaction with **3** under Pd-catalysis yielded the mono-ferrocene derivative **12** (Scheme 6).

Scheme 6

Using an excess of **3**, the bis-ferrocene derivative **13** could also be obtained but was impossible to purify. Regardless of the stoichiometry used, signals were detected for both **12** (*m*/*z* = 1004 for [**12** + Na]) and **13** (*m*/*z* = 1143 for [**13** + Na]) by ESI-MS in all preparations. We were able to obtain **12** in analytically pure form by liquid chromatography (HPLC). ^{1}H-NMR spectroscopy shows characteristic patterns for two AA′XX′ spin systems. In addition, the presence of eight ^{13}C NMR signals in the aromatic region is indicative of two different aromatic rings. A reversible oxidation occurs at a potential of +196 mV vs. Fc/Fc^+ for a solution of **12** in CH_2Cl_2. Controlled potential coulometry of this solution requires 89% of the charge calculated for *one* ferrocene unit. All these results taken together allow for the conclusion that the disulfide bridge in cystine derivatives does not interfere with the Pd-catalyzed alkyne coupling. Furthermore the two iodoarene rings are so far away from each other in **11** that it is impossible to control the

ratio of mono- to disubstitution during the Pd-catalyzed coupling to ferrocene derivative **3**.

Conclusion

We have demonstrated a general way of attaching amino acids to ferrocene derivatives by means of a Pd-catalyzed two-step procedure starting from the amino acid ester and ferrocene alkyne derivatives. Using this scheme, a selective labeling of the *C-terminus* of amino acids is possible.[13,21] A different approach for ferrocene functionalization of hemin was recently proposed by Ryabov et al. by means of activation of the propionic acid groups and reaction with ferrocene methylamine.[71] The disadvantage of their approach, i.e. unselective reaction of the activated acid with *any* primary amine, can only be resolved by employing different, "non-peptide" chemistry. The Pd-catalyzed Sonogashira coupling applied in this work tolerates a wide variety of functional groups often encountered in peptides and does not require dry solvents. In fact, Schmidtchen and coworkers have recently introduced water-soluble cationic phosphane ligands for Heck-type reactions in water.[72] It should be noted that the coupling reactions were usually carried out for 4 h at 80°C. Very similar yields and product purity were obtained by stirring for 24 h at room temperature, making this method suitable for the derivatization of more sensitive organometallic or biological compounds. Investigations along these lines are currently underway in our laboratory.

Experimental Section

General: All reactions were carried out in ordinary glassware and solvents without further precautions except where indicated. Chemicals were purchased from Aldrich-Sigma GmbH and Fluka AG and used as received, only enantiomerically pure L-amino acids were used. Ferrocene carboxylic acid chloride **1** was prepared by refluxing ferrocene carboxylic acid with oxalic chloride in CH_2Cl_2 for 1 h, followed by complete removal of all volatiles. The resulting red oil was handled under argon and used immediately. Iodoarene amino acids **6** were prepared from the pre-activated *N*-Boc-protected amino acids (isobutyl chloroformate and *N*-methylmorpholine) and *p*-iodoaniline in THF and recrystallized from hot heptane/THF (10:1).[73] − Melting points (uncorrected) were determined in a Tottoli apparatus (Büchi, Switzerland). − Elemental analysis were carried out by H. Kolbe, Analytisches Laboratorium, Mülheim. − IR spectra were recorded on a Perkin−Elmer System 2000 instrument as KBr disks, and additionally in CH_2Cl_2 solution where indicated. Frequencies $\tilde{\nu}$ are given in cm^{-1}. − RAMAN spectra were recorded on the same instrument as neat substances ($\tilde{\nu}$ in cm^{-1}). − UV/Vis spectra were recorded on a Perkin−Elmer Lambda 19 spectrometer, only the wavelengths of the highest-energy ferrocene transition is given in nm, ε ($dm^3mol^{-1}cm^{-1}$) in brackets. − Mass spectra were recorded by the mass spectrometry service group, Mülheim, on a MAT 8200 (Finnigan GmbH, Bremen) instrument (EI, 70 eV) or on a MAT95 (Finnigan GmbH, Bremen) instrument (ESI, CH_3OH solution, positive ion detection mode). Only characteristic fragments from EI spectra are given with relative intensities (%) in brackets. − HPLC separations were carried out on a Nucleosil-7-C_{18} column (Merck L6000 pump and Shimadzu SPD-2A UV detector operating at 260 nm), 4 mL min^{-1} flow rate with a methanol/water (5:1) mixture. − Cyclic voltammograms were obtained with a three-electrode cell and an EG&G Princeton Applied Research model 273A potentiostat. A $Ag/AgNO_3$ (0.01 mol L^{-1} in $AgNO_3$) reference electrode, a glass carbon disk working electrode of 2 mm diameter and a Pt wire counter electrode were used. CH_2Cl_2 solutions (ca. 10^{-4} mol L^{-1}) contained 0.1 mol L^{-1} Bu_4NPF_6 as supporting electrolyte. Potentials $E^{0\prime}$ were determined by square-wave voltammetry. As an internal standard, ferrocene was added in excess as a reference. − NMR spectra were recorded in $CDCl_3$ at room temp. on a Bruker ARX 250 (^1H at 250.13 MHz and ^{13}C), DRX 400 (^1H at 400.13 MHz, ^{13}C and 2D spectra) and DRX 500 (^1H at 500.13 MHz, ^{13}C, ^{15}N, 2D). ^1H and ^{13}C spectra were referenced to TMS, using the residual proton signals of the deuterated solvents (^1H) or solvent signals (^{13}C) as internal standards [$CDCl_3 \equiv 7.24$ (^1H) and 77.0 (^{13}C), DMSO ≡ 2.49 (^1H) and 39.5 (^{13}C), $CD_3OD \equiv 3.30$ (^1H) and 49.0 (^{13}C)]. Positive chemical shift values δ (in ppm) indicate a downfield shift from the standard, only the absolute values of coupling constants are given in Hz. ^{15}N spectra were referenced to the absolute frequency of 50.6969910 MHz, which was the resonance frequency of neat nitromethane under the same experimental conditions. All resonances were assigned by 2D NMR (H,H-COSY and ^1H,^{13}C-HMQC for ^1J and long-range couplings). ^{15}N chemical shifts were taken from the F1 projection of indirect detection ^1H,^{15}N-correlated 2D spectra with 1024/256 data points in F1/F2, processed after applying a matched cosine function and zero filling in both dimensions. − Mössbauer data were recorded on a spectrometer with alternating constant-accelaration and a ^{57}Co source in 6 μm Rh matrix. The minimum experimental line width was 0.24 mms^{-1} full width at half maximum. The sample temperature was maintained constant in an Oxford Instruments VARIOX cryostat. Isomer shifts are quoted relative to iron metal at 300 K.

X-ray Crystallographic Data Collection and Refinement: Transparent yellow-orange single crystals of 0.74 × 0.35 × 0.05 mm (**3**) and 0.47 × 0.20 × 0.03 mm (**4**) were sealed in glass capillaries and mounted on the diffractometer. Graphite monochromated Mo-*Kα* radiation (λ = 0.71073 Å) was used. For **3**, cell constants were obtained from a least square fit of the setting angles of 25 carefully centred reflections and intensities were collected by the usual ω/2θ scan technique and corrected for Lorentz and polarization effects. The Siemens ShelXTL software package (Siemens Analytical X-ray Instruments, Inc.) was used for solution and refinement of the structure. Neutral atom scattering factors were taken from the usual source.[74] All non-hydrogen atoms were refined anisotropically. H-atoms were placed at calculated positions and refined as riding atoms with isotropic displacement parameters. All crystallographic details are listed in Table 1. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre and allocated the deposition numbers CCDC 119109 (**3**) and CCDC 119110 (**4**). Copies of the data may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat). +44 1223/33 60 33; E-mail: deposit@ccdc.cam.ac.uk].

Preparations: Ferrocene propargylamine derivatives **3** and **4**: Ferrocene carboxylic acid chloride was dissolved in CH_2Cl_2 (40 mL). Propargylamine [(0.36 g, 6.5 mmol) for **3**, 1,1-diethylpropargylamine (0.72 g, 6.5 mmol) in the case of **4**] and triethylamine (0.66 g, 6.5 mmol) were added at room temp. and the solution was stirred for 4 h. After removal of the triethylamine−hydrochloride the solvent was removed in vacuo. The residue was dissolved in chloro-

form, the organic phase washed three times with water and dried with Na_2SO_4. After filtration and removal of the solvent, virtually pure products were obtained which could be recrystallized to yield single crystals. **3** (1.51. g, 87%), recrystallized from warm ethyl acetate/methanol, m.p. 167°C. − ^{1}H NMR ($CDCl_3$): δ = 5.85 (br, 1 H, N*H*), 4.66 (pseudo-t, 2 H, H_{Cp}), 4.34 (pseudo-t, 2 H, H_{Cp}) 4.21 (s, 5 H, H_{Cp}), 2.25 (t, *J* = 2.6 Hz, 1 H, C≡C*H*). − ^{13}C NMR ($CDCl_3$): δ = 170.2 (*C*=O), 80.3 (*C*≡CH), 71.5 (C≡*C*H), 75.0, 70.7, 69.8, 68.2 (C_{Cp}), 29.2 (*C*H$_2$). − ^{15}N NMR ($CDCl_3$): δ = −276. − IR: ṽ (cm^{-1}) = 3281 (m), 3264 (m), 2121 (w), 1634 (s). − Raman: 2121 cm^{-1} (C≡C). CV: +187 mV. MS (EI, 70 eV): 267 (100), 213 (4), 186 (14). − $C_{14}H_{13}FeNO$ (267.11): calcd. Upon addition of isobutyl chloroformate (0.3 g, 2.17 mmol) a white precipitate rapidly formed. After stirring for one hour, the solution was filtered and the solvent was removed in vacuo. The residue was dissolved in chloroform, the organic phase washed three times with water and dried with Na_2SO_4. After filtration the solvent was removed to yield 0.57 g (79%) of **5. 5** can be recrystallized from *n*-pentane, m.p. 46°C. − ^{1}H NMR ($CDCl_3$): δ = 4.84 (pseudo-t, 2 H, H_{Cp}), 4.51 (pseudo-t, 2 H, H_{Cp}) 4.28 (s, 5 H, H_{Cp}), 4.08 (d, *J* = 6.6 Hz, 2 H, C*H*$_2$), 2.05 (mult., 1 H, C*H*), 0.98 (d, *J* = 6.7 Hz, 6 H, C*H*$_3$). − ^{13}C NMR ($CDCl_3$): δ = 166.5 (Fc-*C*=O), 149.9 (*C*=O), 75.4 (*C*H$_2$), 72.8, 70.9, 70.2, 67.7 (C_{Cp}), 27.7 (*C*H), 18.8 (*C*H$_3$). − IR: ṽ (cm^{-1}) = 3450 (br), 1793 (s), 1731 (s). − MS (EI, 70 eV): 330 (35), 230 (100), 213 (38), 185 (8), 138 (31). − $C_{16}H_{18}FeO_4$ (330.16): calcd. C 58.2, H 5.5; found C 58.4, H 5.5.

General Procedure for Pd Coupling Reactions: The iodoamino acid (1 mmol), bis(triphenylphosphane)palladium(II) dichloride (35 mg, 0.05 mmol), and copper(I) iodide (9.5 mg, 0.05 mmol) were dissolved at room temp. in a deoxygenated mixture of THF (40 mL) and triethylamine (10 mL). The alkyne (1 mmol), dissolved in THF (3 mL) was added dropwise at room temp. After complete addition, the reaction mixture was immediately heated at reflux under argon for 4 hours. After cooling to room temp., the dark suspension was filtered and the solvents were removed on a rotary evaporator. The resulting residue was redissolved in chloroform, the organic phase was washed three times with water and dried with Na_2SO_4. After filtration *n*-pentane was added until a light orange precipitate was formed. The precipitate was collected and dried in vacuo for several hours to yield 70−95% of light orange product. If necessary the product can be purified by redissolving the precipitate in ether, filtration and evaporation of the solvent. − **7d**, m.p. 105−108°C. − ^{1}H NMR ($CDCl_3$): δ = 8.78 (s,br, 1 H, N*H*$_{Ar}$), 7.42 (pseudo-d, 2 H, H_{Ar}), 7.29 (pseudo-d, 2 H, H_{Ar}), 6.14 (s, 1 H, N*H*-CH$_2$), 5.41 (d, *J* = 8 Hz, 1 H, N*H*$_{Boc}$), 4.72 (s, 2 H, H_{Cp}), 4.37 (mult., 1 H, C$_\alpha$*H*), 4.36 (mult., 2 H, C*H*$_2$-C≡C), 4.33 (s, 2 H, H_{Cp}), 4.20 (s, 5 H, H_{Cp}), 2.59−2.55 (mult., 2 H, C$_\gamma$*H*), 2.15−2.12 (mult., 1 H, C$_\beta$*H*), 2.07 (s, 3 H, S-C*H*$_3$), 1.99−1.96 (mult., 1 H, C$_\beta$*H*), 1.41 (s, 9 H, C(C*H*$_3$)$_3$). − ^{13}C NMR ($CDCl_3$): δ = 170.3 (*C*=O), 170.2 (C_{Fc} = O), 156.1 (C_{Boc} = O), 137.8, 132.4, 119.5, 118.3 (C_{Ar}), 85.2 (*C*≡C-CH$_2$), 82.8 (C≡*C*-CH$_2$), 80.7 [*C*(CH$_3$)$_3$], 75.1, 70.7, 69.8, 68.3, (C_{Cp}), 54.3 (C$_\alpha$), 31.2 (C$_\beta$), 30.3 (C$_\gamma$), 30.0 (C≡C-*C*H$_2$), 28.3 [C(*C*H$_3$)$_3$], 15.3 (S-*C*H$_3$). − ^{15}N NMR ($CDCl_3$): d = −291 (*N*H$_{Boc}$), −274 (*N*H), −249 (*N*H$_{Ar}$). − IR: ṽ (cm^{-1}) = 3315 (br, m), 1678 (br, m), 1636 (br, m), 1601 (m). − IR (CH_2Cl_2): 3428 (m), 1701 (s), 1660 (s), 1606 (m). − Raman: 2240 cm^{-1}. − MS (ESI): 590 (M + H), 612 (M + Na), 628 (M + K). − $C_{30}H_{35}FeN_3O_4S$ (589.54): calcd. C 67.3, H 6.7, N 4.9; found C 67.5, H 6.8, N 4.8. − **9**: Compound **3** (267 mg, 1 mmol) was dissolved in methanol (30 mL). A solution of copper(II) acetate monohydrate (199.6 mg, 1 mmol) in a mixture of methanol (20 mL) and pyridine (10 mL) was added dropwise and the resulting solution was stirred at 60°C for one hour. After cooling to room temp., the solution was reduced to about one third of the initial volume and CH_2Cl_2 and water were added. The organic phase was separated, washed three times with water and dried with Na_2SO_4. After filtration, the solvent was removed on a rotary evaporator to yield 101 mg (38%) of light-orange product, m.p. 108°C. − ^{1}H NMR ($CDCl_3$): δ = 5.76 (br, 2 H, NH), 4.65 (pseudo-t, 4 H, H_{Cp}), 4.34 (pseudo-t, 4 H, H_{Cp}) 4.24−4.20 (mult., 14 H, H_{Cp} and CH_2). − ^{13}C NMR ([D$_6$]DMSO): δ = 169.0 (C=O), 76.7 (C≡C-C≡C), 75.3, 70.2, 69.3, 68.2 (C_{Cp}), 65.5 (C≡C-C≡C), 28.7 (CH_2). − IR: $\tilde{\nu}$ (cm^{-1}) = 3324 (br), 3306 (br), 1637 (s), 1533 (s). − MS (EI, 70 eV): 532 (100), 467 (19), 401 (14), 211 (15), 121 (19). − $C_{28}H_{24}Fe_2N_2O_2$ (532.20): calcd. C 63.2, H 4.6, N 5.3; found C 62.9, H 4.3, N 5.1. − **11**: Boc-protected cystine (10 mmol, 4.41 g) was dissolved in THF (100 mL) at room temp. and neutralized with *N*-methylmorpholine (2.02 g, 20 mmol). Isobutyl chloroformate (2.74 g, 20 mmol) was added and a white precipitate was rapidly formed. 4-iodoaniline (4.38 g, 20 mmol) was added and the solution was allowed to stir for one hour. The *N*-methylmorpholine hydrochloride was removed by filtration and the solvent was removed on a rotary evaporator. The resulting residue was redissolved in ether, the organic phase was washed three times with water and dried with Na_2SO_4. After filtration the solvent was removed to yield 7.1 g (84%) of **11**. **11** can be recrystallized from hot chloroform, m.p. 218°C. − ^{1}H NMR ([D$_6$]DMSO): δ = 10.14 (s, 2 H, NH), 7.61 and 7.42 (app. d, 4 H each, H_{Ar}), 7.20 (d, 2 H, $N_{Boc}H$, J = 7.6), 4.32 (mult., 2 H, $C_\alpha H$) 3.14 and 2.94 (mult., 2 H each, $C_\beta H_2$), 1.36 (s, 18 H, C(CH_3)$_3$). − ^{13}C NMR ([D$_6$]DMSO): δ = 169.3 (C=O), 155.2 (C_{Boc} = O), 138.5, 137.3, 121.7, 87.0 (C_{Phe}), 78.4 (C (CH_3)$_3$), 54.5 (C_α) 40.1 (C_β), 28.1 [C(CH_3)$_3$]. − ^{15}N NMR ([D$_6$]DMSO): δ = −290 (N_{Boc}), −249 (N_{Ar}). − IR: $\tilde{\nu}$ (cm^{-1}) = 3341 (m), 1685 (m), 1670 (s). − MS (EI, 70 eV): 842 (< 1%), 422 (9), 366 (32), 219 (46), 57 (88), 41 (100). − $C_{28}H_{36}I_2N_4O_6S_2$ (842.55): calcd. C 39.9, H 4.3, N 6.7; found C 40.0, H 4.4, N 6.6. − **12**, purified by HPLC: ^{1}H NMR ($CDCl_3$): δ = 9.32 (br, 2 H, NH_{Ar}), 7.61−7.54 (mult., 4 H, H_{Ar}), 7.38−7.36 (mult., 4 H, H_{Ar}), 5.84 (br, 1 H, NH-CH_2), 5.61 (br, 2 H, NH_{Boc}), 4.92 (mult., 2 H, $C_\alpha H$), 4.68 (pseudo-t, 2 H, H_{Cp}), 4.37−4.34 (mult., 4 H, H_{Cp} and CH_2), 4.21 (s, 5 H, H_{Cp}), 3.09−2.96 (mult., 4 H, $C_\beta H_2$), 1.45 [s, 18 H, C(CH_3)$_3$]. − ^{13}C NMR ($CDCl_3$): δ = 169.8 (C_{Fc} = O), 168.5 (C_{Cys}=O), 156.1 (C_{Boc} = O), 137.8, 137.2, 132.2, 122.6, 119.6, 120.4, 118.7, 85.3 (C_{Ar}), 88.2 (C≡C-CH_2), 82.8 (C≡C-CH_2), 80.5 [$C(CH_3)_3$], 75.1, 70.7, 69.8, 68.2 (C_{Cp}), 55.6 (C_α), 47.4 (C_β), 30.0 (CH_2), 28.4 [C(CH_3)$_3$]. − ^{15}N NMR ($CDCl_3$): δ = −292 (NH_{Boc}), −275 (NH), −250 (NH_{Ar}). − IR (CH_2Cl_2): 3420 (w), 3327 (w), 1683 (br, s), 1659 (sh). − MS (ESI, in CH_2Cl_2): 1004 [M + Na]. − $C_{42}H_{48}FeIN_5O_7S_2$ (981.76): calcd. C 51.4, H 4.9, N 7.1; found C 51.9, H 5.2, N 7.1. − **13**: Compound **13** could not be separated completely from **12**. Compounds **12** and **13** have virtually identical NMR spectra, except for the integration ratios. − MS (ESI, in CH_2Cl_2): 1043 [M + Na], 1160 [M + K].

Table 1. Crystallographic details

Compared Reductive Chemistry of Molybdenocene and Indenyl-Substituted Complexes

Maria J. Calhorda,[a,b] Carla A. Gamelas,[a,c] Carlos C. Romão,*[a] and Luís F. Veiros[d]

Keywords: Indenyl complexes / Cyclopentadienyl complexes / Molybdenocene / Ring slippage / Molybdenum / DFT calculations

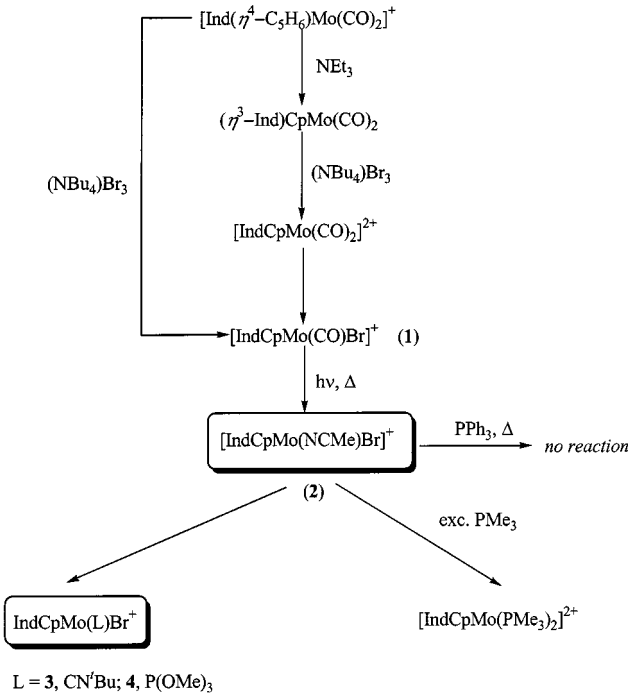
Reduction of [IndCpMo(L)Br]Br (L = **1a**, CO; **2**, NCMe) with Cp_2Co in the presence of two equivalents of the ligand L′ gives the ring-slipped neutral complexes [(η^3-Ind)CpMoL′$_2$] (L′ = **5**, CO; **6**, 1/2 dppe; **7**, PMe_3; **8**, $P(OMe)_3$; **9**, CN*t*Bu) in good yield. Products **7**, **8**, and **9**, but not [IndCpMoL′], are also formed in the presence of only 1 equivalent of L′ in modest yields. In the case of the reduction of [IndCpMo(L)Br]Br [L = **2**, NCMe; **3a**, CN*t*Bu; **4**, $P(OMe)_3$] mixtures of the complexes, [(η^3-Ind)CpMoL$_2$] (**8**, **9**) and [(η^5-Ind)CpMoL] [L = **11**, $P(OMe)_3$; **12**, CN*t*Bu] were obtained. The only product of formal type [(η^5-Ind)CpMoL] that could be prepared by these methods was the alkyne complex [(η^5-Ind)CpMo(η^2-PhC≡CPh)] (**10**). These results contrast with the well-known reductions of similar bis-cyclopentadienyl cations [Cp_2Mo(L)Br]$^+$, which produce [Cp_2MoL] complexes under the same conditions. The reduction of the dications [Cp_2MoL_2][BF_4]$_2$ [L = CO; $P(OMe)_3$] with Cp_2Co is now reported to afford the neutral complexes [CpMo(η^3-C_5H_5)(CO)$_2$] (**13**) and [Cp_2Mo($P(OMe)_3$)] (**14**), respectively, showing that the stability of the ring-slipped complexes is dependent on the other ligands. From DFT and EHMO calculations used to probe the bonding and the energetics of these ring slippage processes it is concluded that weak π acceptor ligands favour η^5-Ind → η^3-Ind slippage and disfavour η^5-Cp → η^3-Cp slippage at the $CpMoL_2$ fragment. Redox-induced ring slippages involve very similar energies for both indenyl and cyclopentadienyl complexes and should be able to produce more examples of the otherwise rare η^3-Cp coordination mode.

Introduction

We have recently reported the synthesis of a variety of indenyl analogues of molybdenocene and tungstenocene in the +4 oxidation state, [$IndCpMX_2$].[1] The chemistry of these complexes follows closely the chemistry of the corresponding metallocene derivatives, [Cp_2MX_2]. The most interesting reaction type observed so far is the facile, reversible, chemical and electrochemical reduction of several dications [$IndCpML_2$]$^{2+}$ to the ring-slipped neutral, 18e complexes [(η^3-Ind)CpML$_2$] (L = CO, dppe, PMe_3, bipy, CN*t*Bu).[2] Although the strictly parallel reductions of the corresponding metallocene dications [Cp_2ML_2]$^{2+}$ have never been reported, the general rule holding for the reductions of Cp_2M^{IV} complexes is the formation of Cp_2ML species, e.g. L = CO,[3] CNR,[4] (η^2-NCMe),[5] (η^2-C_2Ph_2),[3][6] (η^2-C_2H_4),[7] PR_3,[8] (η^2-CO_2).[9] Such species have played a central role in revealing the chemistry of the very reactive and electron-rich [Cp_2M^{II}] fragment (M = Mo, W). The only exception is the reduction of [Cp_2WCl(CO)]$^+$ under a CO atmosphere, to give [(η^3-Cp)CpW(CO)$_2$].[3b]

With the aim of continuing the comparative study of the chemistry of the [Cp_2Mo] and [IndCpMo] fragments, we set out to synthesize the Mo^{II} mixed-ring complexes [IndCpMoL] that might give access to the as yet unstudied [$IndCpMo^{II}$] fragment. As described in the present paper, in spite of the numerous different synthetic variations used, IndCpMo(η^2-C_2Ph_2) was the only such complex that we could isolate. Instead, the unexpectedly effective synthesis of ring-slipped complexes of type [(η^3-Ind)CpMoL$_2$] took place even at Mo/L = 1:1 ratios, suggesting that the electron-rich complexes [IndCpMoL] undergo facile ligand addition in contrast to their Cp_2MoL analogues. The comparison of the behaviour of the [IndCpMo] and [Cp_2Mo] fragments towards ring slippage was then studied by reduction of the corresponding cationic Mo^{IV} complexes under similar conditions. DFT and EHMO calculations were used to study these ring slippages and provide the energetic relationships between [(η^5-Cp′)CpMoL$_2$]$^{2+}$, [(η^3-Cp′)CpMoL$_2$], and [(η^5-Cp′)CpMoL] (Cp′ = Cp, Ind) complexes.

Results



Chemical Studies

In order to prepare the target [IndCpMoL] complexes we considered the methods that are well established for the synthesis of [Cp_2MoL] complexes. From all these methods, reductive dehalogenation from [IndCpMo(L)Br]$^+$ [L = **1**, CO; **2**, NCMe; **3**, CN*t*Bu; **4**, $P(OMe_3)_3$] was selected as the most practical method since we improved a convenient syn-

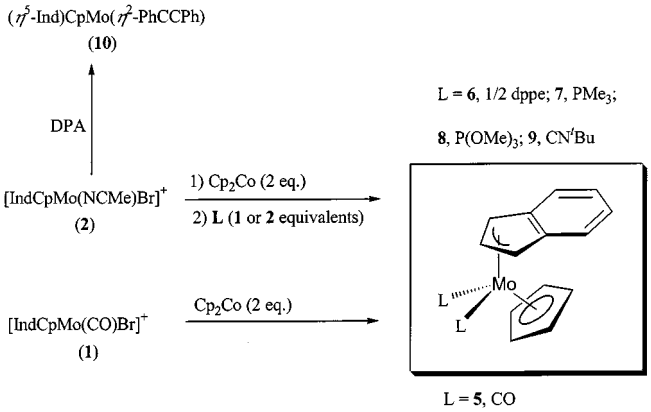
thesis of the appropriate starting halides **1** and **2**, whose congeners $[IndCpMo(L)X]^+$ (X = Cl, I) are known.[1] In fact, oxidation of $[(\eta^3\text{-Ind})CpMo(CO)_2]$ (**5**) with $(NBu_4)Br_3$ leads to the immediate precipitation of the white oxidation product $[IndCpMo(CO)_2]Br_2$, identified by comparison of its IR and ^{1}H-NMR spectra with those of an authentic sample;[1] further stirring of the suspension leads to substitution of one carbonyl ligand, affording [IndCpMo(CO)Br]Br (**1a**), as depicted in Scheme 1. The oxidation of $[IndMo(\eta^4\text{-}C_5H_6)(CO)_2]BF_4$ with $(NBu_4)Br_3$ is even better because it avoids the preparation of **5** and leads to $[IndCpMo(CO)Br]BF_4$ (**1b**) in 70% yield.

Scheme 1. Reaction sequence for the synthesis of the cationic $IndCpMo^{(IV)}$ derivatives

Refluxing **1a** in NCMe solution under visible light irradiation gave rise to complex **2** in 90% yield. Simple substitution of NCMe in **2** with CN*t*Bu and $P(OMe)_3$ afforded **3** and **4**. The characterization of these complexes was straightforward from their ^{1}H-NMR data and elemental analysis. The ^{1}H-NMR pattern of the indenyl ligand in **1**, **3**, and **4** is typical for η^5-coordination in asymmetric complexes, as resonances are doubled and occasionally superimposed, because the (normally equivalent) pairs of indenyl protons are now diastereotopic and, therefore, exhibit different chemical shifts. Complex **2**, on the other hand, shows only one resonance for protons $H^{1/3}$, probably due to a fast isomerization process in solution. This behaviour was also observed in the previously reported complex $[IndCpMo(NCMe)Cl]BF_4$.[1] Surprisingly, no reaction occurred between **2** and PPh_3, probably due to steric hindrance; the congener complex $[IndCpMo(PPh_3)Cl]BF_4$ has been prepared by the facile reaction of the dichloride $[IndCpMoCl_2]$ with PPh_3 in the presence of $TlBF_4$.[1] Reaction of **2** with PMe_3 under mild conditions readily gave the reported dication $[IndCpMo(PMe_3)_2]^{2+}$.[2]



Reduction of [IndCpMo(CO)Br]Br with Cp_2Co gave a dark solution. The hexane-soluble extract is $[(\eta^3\text{-Ind})CpMo(CO)_2]$ (**5**), identified by comparison of its IR and ^{1}H-NMR spectra with those of an authentic sample.[1] The IR spectrum displays two characteristic stretching vibrations of the *cis* carbonyl ligands, at $\tilde{\nu}$ 1959 and 1888 cm^{-1}. We could not observe the formation of the intermediate complex IndCpMo(CO) and the yield of the reaction is relatively low (40%).

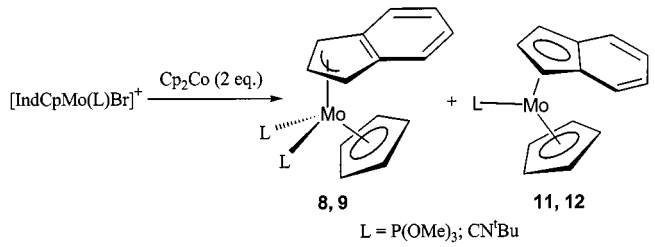
The metallocene fragments $[Cp_2M^{II}]$ (M = Mo, W) produce one of the most striking examples of side-on coordinated nitriles in complexes $[Cp_2M(\eta^2\text{-NCMe})]$.[5] These complexes are readily available by reduction of $[Cp_2MX_2]$ and provide one of the most useful starting materials for the preparation of other $[Cp_2ML]$ complexes, since the η^2-NCMe ligand is quite labile.[4][8]

We therefore attempted the reduction of $[IndCpMo(NCMe)Br]^+$ (**2**) with Cp_2Co in acetonitrile solvent. A brown-red solution was formed but, in spite of many attempts, we were unable to isolate any complex from the reaction mixture. Decomposition products were similarly obtained in the reduction of $[IndCpMoCl_2]$ with Na/Hg in NCMe, the method used for the synthesis of the $[Cp_2Mo(\eta^2\text{-NCMe})]$ analogues.

However, the chemical evidence described below points to the formation of some labile acetonitrile derivative of the fragment [IndCpMo], which can only be formulated as $[(\eta\text{-Ind})CpMo(NCMe)_x]$, that decomposes upon loss of NCMe solvent.

Treatment of the brown-red solutions of this compound with *one equivalent* of several ligands (L) affords the ring-slipped neutral complexes $[(\eta^3\text{-Ind})CpMoL_2]$ [**7**, L = PMe_3; **8**, L = $P(OMe)_3$; **9**, L = CN*t*Bu] instead of the intended congeners [IndCpMoL] (as depicted in Scheme 2). Compounds **7**–**9** are formed in < 50% yields (ca. 30%), as expected. In the case of PPh_3 no tractable product was obtained.

Scheme 2. Reductive reactions of the $IndCpMo^{(IV)}$ cations



On the other hand, reaction with 1 equivalent of diphenylacetylene (DPA) produces $[(\eta^5\text{-Ind})CpMo(\eta^2\text{-PhC}\equiv\text{CPh})]$ (**10**) in 80% yield. The analytical and ^{1}H-NMR

data agree with a structure with η^5-indenyl and only one DPA molecule, which is the same type of structure present in the analogous $[Cp_2Mo(\eta^2\text{-PhC}{\equiv}CPh)]$.[10] In fact, **10** presents the ^{1}H-NMR chemical shift pattern expected for η^5-coordination of the indenyl ligand in a neutral complex, with two multiplets for benzenoid protons H^{5-8} (δ = 6.93−6.90 and δ = 6.75−6.72), a triplet for H^2 (δ = 5.53), a doublet for $H^{1/3}$ (δ = 3.85), and a singlet for the Cp ring (δ = 4.21). Another reaction leading to **10** is discussed below.

Of course, the yields of complexes **7** to **9** increase to much higher values (ca. 50−90%) when *two equivalents* of the ligand L are used. Reaction with dppe affords [(η^3-Ind)CpMo(dppe)] (**6**). In the case of P(^{i}Pr)$_3$ (2 equiv.) no tractable product was obtained.

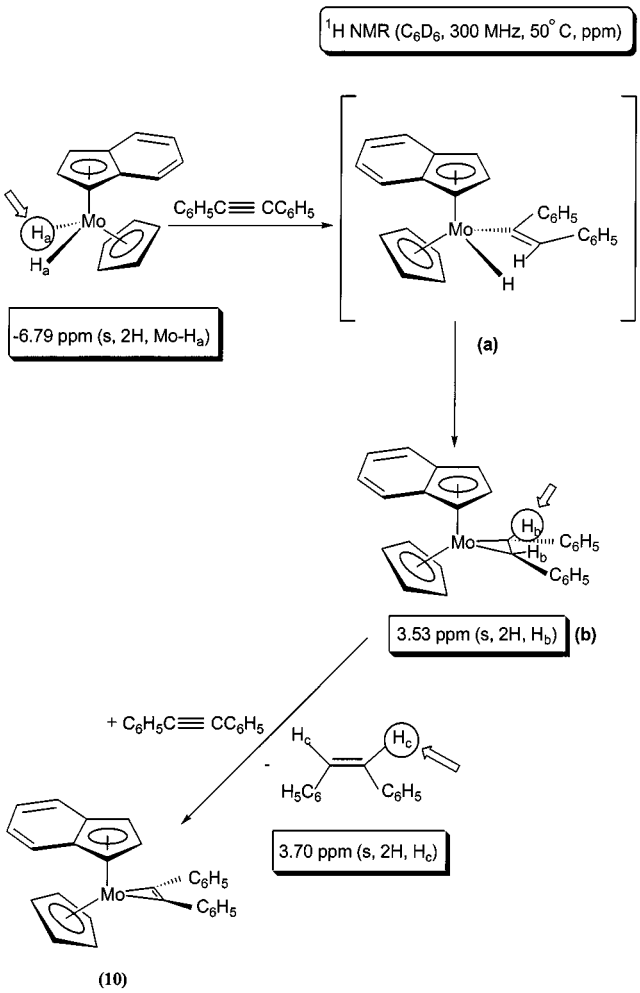
Complexes **6**−**9** have been previously prepared by reduction of the respective dications $[IndCpMoL_2]^{2+}$ with Cp_2Co;[2][11] reported preparations of **6** and **8** also include deprotonation of the cyclopentadiene cations $[IndMo(\eta^4\text{-}C_5H_6)(dppe)]BF_4$ and $[IndMo(\eta^4\text{-}C_5H_6)(P(OMe)_3)_2]BF_4$ with NEt_3.[2][11]

Reduction of [IndCpMo(L)Br]Br complexes [L = **3a**, CN*t*Bu; **4**, P(OMe)$_3$] produced mixtures of the respective [(η^5-Ind)CpMoL] [L = **11**, P(OMe)$_3$; **12**, CN*t*Bu] and [(η^3-Ind)CpMoL$_2$] (**8** and **9**), as depicted in Scheme 3. All attempts to separate the two products were unsuccessful due to their similar solubility properties. However, their presence in the mixtures is easily recognized by ^{1}H-NMR spectroscopy; *trihapto* and *pentahapto* complexes present distinctly different patterns of chemical shifts.[2]

Scheme 3. Reduction of the cations $[IndCpMo(L)Br]^+$

Complex [(η^5-Ind)CpMo(CN*t*Bu)] (**12**) presents the expected ^{1}H-NMR pattern for η^5-coordination mode of the indenyl ligand in a neutral complex. Signals in the ^{1}H-NMR spectrum of the mixture in C_6D_6 related to complex [(η^3-Ind)CpMo(CN*t*Bu)$_2$] are in agreement with those of an authentic sample (see Experimental Section).[2] A similar assignment was made for the resonances in the mixture of **11** and **8** (see Experimental Section).

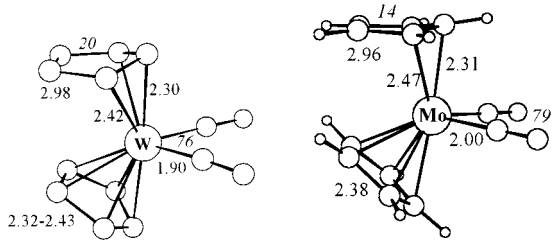
In order to be able to compare the properties of the Cp_2M and IndCpM complexes, the reduction of some dications $[Cp_2ML_2]^{2+}$ was carried out under the same conditions reported for the reduction of several mixed-ring dications $[IndCpML_2]^{2+}$.[2] Somewhat unexpectedly, the previously reported neutral complex [(η^3-Cp)CpMo(CO)$_2$][1] (**13**) was now obtained, in high yield (80%), upon reduction of $[Cp_2Mo(CO)_2]^{2+}$ with Cp_2Co. The reaction of $[Cp_2Mo(P(OMe)_3)_2]^{2+}$ under similar conditions affords [Cp_2Mo(P(OMe)$_3$)] (**14**), instead of [(η^3-Cp)CpMo(P(OMe)$_3$)$_2$]. This behaviour differs from that of the indenyl congener $[IndCpMo(P(OMe)_3)_2]^{2+}$, which is readily reduced to the neutral complex [(η^3-Ind)CpMo(P(OMe)$_3$)$_2$] (**8**).[11] The dication $[Cp_2Mo(CNtBu)_2]^{2+}$ (**15**) proved to be resistant to reduction by both Cp_2Co and Na/Hg.



The complex [(η^5-Ind)CpMo(η^2-PhC≡CPh)] (**10**), the only one in which the stoichiometry [IndCpMoL] is preferred over the ring-slipped complexes of stoichiometry [(η^3-Ind)CpMoL$_2$], is the final product of DPA insertion across the Mo−H bonds in $[IndCpMoH_2]$. Nakamura and Otsuka,[12] as well as Herberich and Okuda,[13] studied the analogous reaction between DPA and $[Cp_2MoH_2]$. Assuming the same mechanism, Scheme 4 summarizes our observations and relevant chemical shifts for this experiment. Reaction of the dihydride and DPA in a 1:2 ratio was monitored by ^{1}H-NMR spectroscopy in C_6D_6. After 1 h at room temperature no reaction had occurred. At 50°C, the resonances corresponding to the protons of stilbene, both coordinated (H_b at δ = 3.53 in intermediate **b**; Scheme 4) and free (H_c at δ = 3.70), immediately appeared. The vinyl-hydride intermediate **a** could not be observed because of the very fast second insertion step. Signals at δ = 5.26 and δ = 4.21 can be ascribed to the Cp rings of **b** and **10**, respectively. After 3 h at 50°C neither $[IndCpMoH_2]$ nor the stilbene complex **b** were present (the former was monitored by its characteristic hydride signal at δ = − 6.79 and the latter by its resonance at δ = 3.53), revealing the presence of **10** and some free DPA.

Theoretical Studies

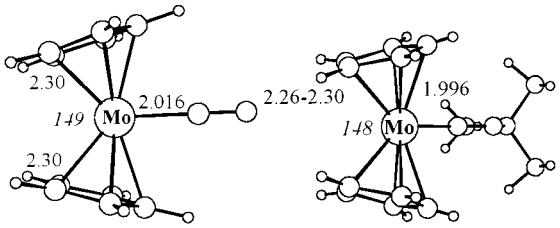
The previously described experiments indicate that the [IndCpMo] fragment produces only with difficulty the monoligand [IndCpMoL] derivatives, leading preferentially to the slipped [(η^3-Ind)CpMoL$_2$] species. On the other hand, for the [Cp_2MoL] complexes a different pattern is observed. [Cp_2MoL] complexes seem favoured over [(η^3-Cp)CpMoL$_2$], the only example of the latter being [(η^3-Cp)CpMo(CO)$_2$], which is easily accessible by reduction of its dicationic precursor.



We therefore performed DFT calculations[14] in order to find out the relative stabilities of these types of compounds, both for the biscyclopentadienyl and the indenylcyclopentadienyl systems. We started the calculations for models with L = CO but, in order to understand the different reactivities of the systems as a function of the ligand, the same study was repeated for L = P(OMe)$_3$.

The geometry of the following six compounds was optimized: [(η^5-Ring)CpMo(CO)$_2$]$^{2+}$ (**I**), [(η^3-Ring)CpMo(CO)$_2$] (**II**) and [(η^5-Ring)CpMo(CO)] (**III**) (Ring = **a**, Ind; **b**, Cp). The indenyl derivatives **Ia** and **IIa** are studied in detail using DFT calculations in another work,[11] and the reliability of the theoretical approach has been checked by comparing the optimized geometries with the available structures of the indenyl derivatives.[1] The remaining indenyl complex

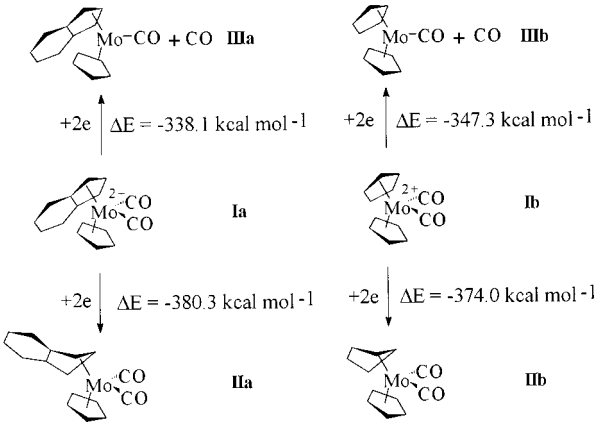
Scheme 4. Insertion of DPA across the Mo−H bonds



type (**IIIa**) has not been isolated and the optimized geometry cannot be compared with that of a known species. Concerning the biscyclopentadienyl complexes, there is a structure of the tungsten analogue of **IIb** [(η^3-Cp)CpW(CO)$_2$][15] and of the *tert*-Butylnitrile derivative of **IIIb** [$Cp_2Mo(CNtBu)$],[4] which can be used for comparison. The molybdenum and tungsten compounds are usually very similar as far as their geometric characteristics are concerned and therefore they can be compared. The main features of the geometry of [(η^3-Cp)CpW(CO)$_2$] and those of our optimized [(η^3-Cp)CpMo(CO)$_2$] are shown in Scheme 5 (left and right, respectively).

Scheme 5. Relevant distances and angles in [(η^3Cp)CpW(CO)$_2$] (left, exp.) and [(η^3Cp)CpMo(CO)$_2$] (right, calcd.)

The agreement is very good, both for distances and angles, except for the folding of the Cp ring, which is 6° less in the model than in the tunsgten compound. It should be remembered that, in the optimization procedure, the C−C and C−H distances of one Cp ring were kept fixed, with only the position of the ring being allowed to change. The second ring was totally optimized, in order to allow it to become η^3 if necessary (it always started as η^5).

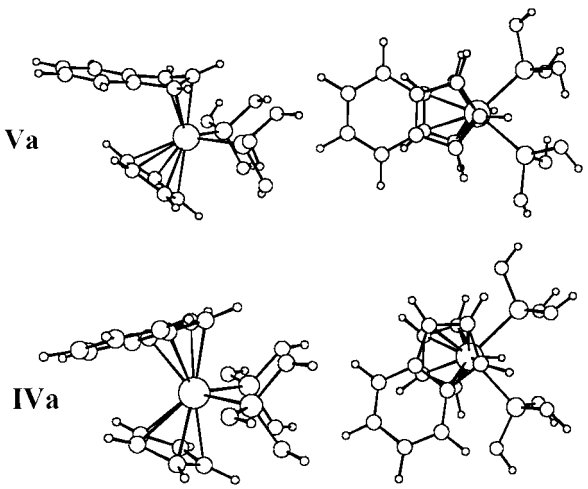


There is no carbonyl complex of type **III** structurally characterized, and the most similar to [$Cp_2Mo(CO)$] is [$Cp_2Mo(CNtBu)$],[4] the isonitrile ligand being also a π-acceptor. There are not so many parameters to compare in this situation, but the agreement between Mo−C distances and the Cp−Mo−Cp angle is acceptable, considering that it is not exactly the same species (Scheme 6).

Scheme 6. Relevant distances and angles in [$Cp_2Mo(CO)$] (left, calcd.) and [$Cp_2Mo(CNtBu)$] (right, exp.)

Finally, compound **I** $[Cp_2Mo(CO)_2]^{2+}$ has not been structurally characterized, but belongs to the large family of the [Cp_2MoL_2] complexes.[16] Both the Mo−C distances (ca. 2.35 Å), the C−Mo−C angle (139°) and the Cp−Mo−Cp angle (88°) fit in the general pattern.

The relative energies of the six compounds are given in Scheme 7, taking into account that to make the numbers directly comparable we added one molecule of free CO on going from **I** to **III**.



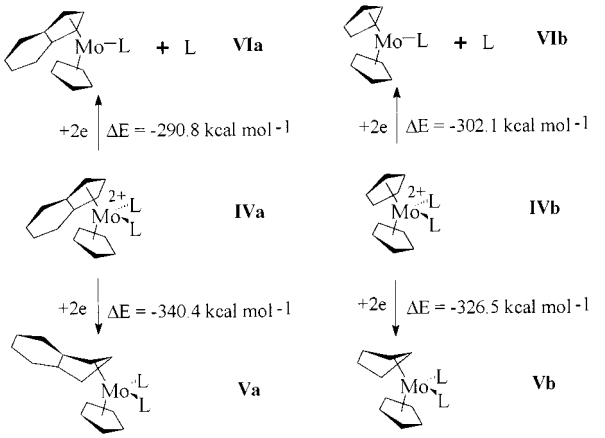
Scheme 7. Relative DFT energies of CO complexes

The energies of the final products are much lower for the η^3 species than for the monoligand derivative, both for Cp and Ind derivatives. Even taking into account the fact that

entropy should favour **IIIa** and **IIIb**, that difference is significant. Indeed, the experimental results show the formation of this species when the ligands are carbonyls, i.e. strong π-acceptors. When carbonyls are replaced by other ligands, such as phosphites, only the monoligand complex is formed for Ring = Cp and a mixture of both species is detected for the Ind system.

We therefore also performed DFT calculations for the corresponding phosphite complexes [L=P(OH)$_3$], [(η^5-Ring)CpMo(L)$_2$]$^{2+}$ (**IV**), [(η^3-Ring)CpMo(L)$_2$] (**V**), and [(η^5-Ring)CpMo(L)] (**VI**) (Ring = **a**, Ind; **b**, Cp), using P(OH)$_3$ instead of P(OMe)$_3$. The geometries of the six complexes were fully optimized.

The calculations on **IVa** and **Va** are also been discussed in another work, along with the description of the X-ray structures of the parent phosphite compounds.[11] It might be important to stress that the conformation of the indenyl ring in the η^3-coordination is different from that in the η^5-coordination. This is easily seen in Scheme 8, where the side and top views of [(η^5-Ind)CpMo(L)$_2$]$^{2+}$ (**IVa**) and [(η^3-Ind)CpMo(L)$_2$] (**Va**) are shown.



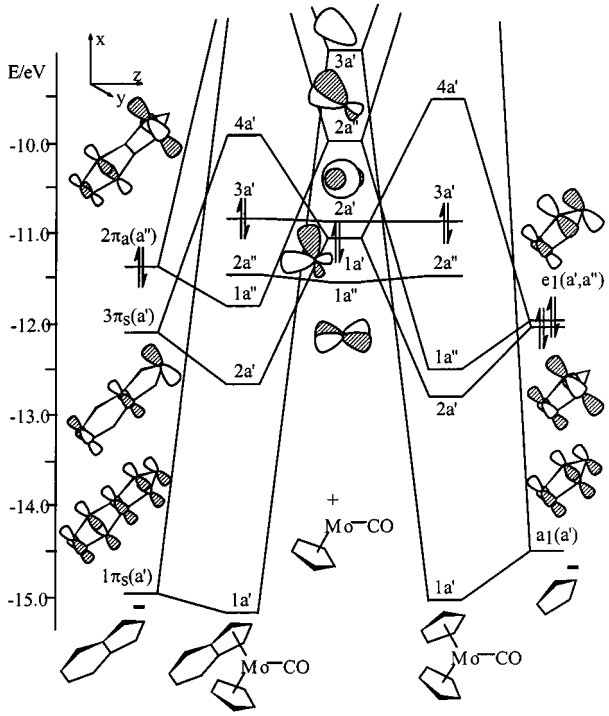
Scheme 8. Side (left) and top (right) views of the structures of complexes **Va** and **IVa**

For the η^3-Ind derivative, the ring is slipped away from the two L (phosphite) ligands and lies trans to them. The folding is plainly seen. The change of coordination to η^5 results in a planar ligand, so that the Ind ring approaches the Cp ring. Steric repulsion forces a rotation of the ring. This change in conformation of the ligand accompanying a change of hapticity has already been observed and analysed in another family of compounds.[17] The distances and angles in the geometries of the calculated complexes are within the range of expected values.

The relative energies of the six species are given in Scheme 9, the energy of **V** being adjusted with the energy of free P(OH)$_3$, as performed previously for the CO series of compounds.

The most striking feature is the similarity of Schemes 7 and 9, at first sight, and the very small difference of energy in the parallel redox processes that form [(η^3-Ind)CpMoL$_2$] and [(η^3-Cp)CpMoL$_2$] from their corresponding cations. A further comparison of these values is found in the Discussion. However, the understanding of the relative stability of the several species involved, namely, the reason why η^3-Ring derivatives are more stable for indenyl than Cp and why carbonyls stabilize η^3-Cp rings, can be traced qualitatively by extended Hückel calculations performed on the same models. The first important aspect when comparing Cp and Ind is that η^5-Cp binds more strongly than η^5-Ind. The calculated bonding energy (DFT calculation) between Cp$^-$ or Ind$^-$ and the CpMo(CO)$^+$ fragment is −237.5 and −221.4 kcal mol^{-1}, respectively. The reason is clearly seen on the molecular orbital diagram of Figure 1, where one compares the binding of each of the two rings to the CpMo(CO)$^+$ fragment.

Scheme 9. Relative DFT energies of P(OH)$_3$ complexes



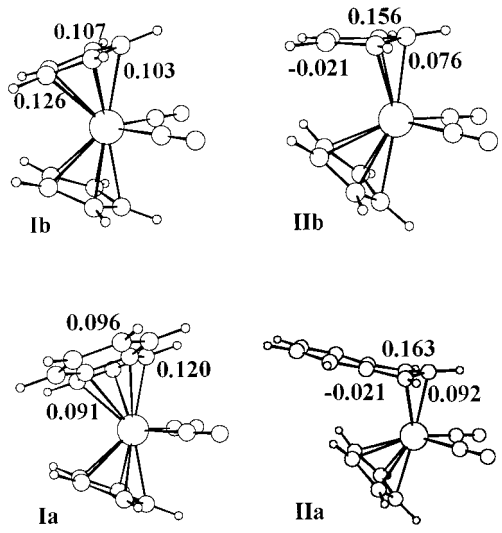


Figure 1. Molecular orbital diagram for the interaction between one η^5-Ind ring (left)/η^5-Cp (right) and the CpMo(CO)$^+$ fragment

Both rings formally donate three pairs of electrons into empty levels of the metal fragment. These electrons come from the lowest energy, totally symmetric a_1, and from the e_1 set in the Cp. The a_1 level is similar for the indenyl (lower energy, owing to the largest number of the carbon atoms and to bonding interactions), but those corresponding to the e_1 set are different, as not all the carbon atoms from the C_5 ring contribute to the orbital, and their contributions are smaller, as sketched on the left side of the drawing and discussed elsewhere.[18] As a result, the overlap between Ind−CpMo(CO) is smaller (0.45) than between Cp−CpMo(CO) (0.58) and the resulting bonding molecular orbitals have higher energies (1a″ is 18.5 kcal mol^{-1} higher and 2a′ is 2.3 kcal mol^{-1} higher for Ind, see diagram in Figure 1).

The same diagram can help us to understand why a η^3-coordination mode is more favorable for the indenyl ring. Upon bending, only three carbon atoms remain coordinated to the metal. For the Cp ring this is an effective loss of overlap, as the five carbon atoms were all strongly bound to the metal, while for the indenyl unit the two hinge atoms, which do not participate in all indenyl π orbitals, are much less affected by this distortion. This can be seen by the Mo−C overlap populations in Scheme 10, where we compare compounds **I** and **II**.

Scheme 10. Mo−C overlap populations (EHMO) in complexes **Ia,b** and **IIa,b**

The overlap populations between fragments lead us to the same conclusion, but in a different way. In fact, the Ring-[CpMo(CO)$_2$] overlap populations are 0.54 for Ring = η^5-Cp, 0.40 for Ring = η^5-Ind, 0.26 for Ring = η^3-Cp, and 0.30 for Ring = η^3-Ind. Another contribution to this behaviour is that the energy required to distort Cp is larger than that needed to distort Ind, as in the latter the orbitals of the resulting benzene ring are much stabilized relative to those of the ethylene formed from Cp. Brintzinger and co-workers attempted to understand these problems,[15c] but the lack of structural information at the time makes the results of their calculations difficult to compare.

When the carbonyl groups are replaced by other ligands, which are not (or are weaker) π-acceptors, the small stabilization provided to the bonding of the η^3-Cp ring by back-donation to the carbonyls is lost, and this explains the much higher energy of the comparable phosphite derivative. Other derivatives become more competitive.

Discussion

[Cp$_2$MoL] complexes are well known for being very electron-rich d^4 species. Their chemistry is, therefore, essentially characterized by oxidative addition reactions to the carbene-like metal fragment, as well as protonation and methylation with Mo−H and Mo−CH$_3$ formation, both of which reflect the nucleophilicity and basicity of the metal centre. Ligand substitution, L for L′, has also been reported for several complexes. Replacement of Cp by indenyl was expected to give 18e complexes with overall analogous reactivity since they would present the same type of high energy metal-based lone pairs. However, the results reported above point to the appearance of a new type of reactivity around [IndCpMoL] complexes. In fact, these complexes failed to be prepared by reductive methods analogous to those employed for [Cp$_2$MoL] and, even under stoichiometries favouring the formation of [IndCpMoL], ring-slipped [(η^3-Ind)CpMoL$_2$] complexes were always observed. The only exceptions were found for the diphenyl acetylene complex, [IndCpMo(η^2-C$_2$Ph$_2$)], *tert*-Butyl isocyanide and phosphite complexes [IndCpMo(CN*t*Bu)] and [IndCpMo(P(OMe)$_3$)], which are formed simultaneously with [(η^3-Ind)CpMo(CN*t*Bu)$_2$] and [(η^3-Ind)CpMo{P(OMe)$_3$}], respectively.

These results mean that the metal centre in [IndCpMoL] complexes readily accepts 2e donors according to the Equation (a).

$$[\text{IndCpMoL}] + \text{L} \rightleftharpoons [(\eta^3\text{-Ind})\text{CpMoL}_2] \quad \text{(a)}$$

In this equation the equilibrium seems to be shifted to the right hand side. For all that has been reported in the literature, the similar Equation (b) represents an equilibrium that is, in most cases, shifted to the left hand side.

$$[\text{Cp}_2\text{MoL}] + \text{L} \rightleftharpoons [(\eta^3\text{-Cp})\text{CpMoL}_2] \quad \text{(b)}$$

The only known exception is described in this work for L = CO. In general, these results are normal insofar as they fit in with the well established higher tendency of the indenyl ligand to undergo $\eta^5 \rightarrow \eta^3$ ring slippage when compared with the Cp ligand. However, the term tendency is qualitative and the very fact that there are unpredictable exceptions prompted us to attempt some quantification of the energetics involved in these ring slippages. The results of the

DFT calculations, which are summarized in schemes 7 and 9, can be written according to Equations (c)−(f).

$$[IndCpMo(CO)] + CO \rightleftharpoons [(\eta^3\text{-Ind})CpMo(CO)_2]\ \Delta E_1 = -42.2\ \text{kcal mol}^{-1} \quad (c)$$

$$[Cp_2Mo(CO)] + CO \rightleftharpoons [(\eta^3\text{-Cp})CpMo(CO)_2]\ \Delta E_2 = -26.7\ \text{kcal mol}^{-1} \quad (d)$$

$$[IndCpMo\{P(OH)_3\}] + P(OH)_3 \rightleftharpoons [(\eta^3\text{-Ind})CpMo\{P(OH)_3\}_2]\ \Delta E_3 = -49.6\ \text{kcal mol}^{-1} \quad (e)$$

$$[Cp_2Mo\{P(OH)_3\}] + P(OH)_3 \rightleftharpoons [(\eta^3\text{-Cp})CpMo\{P(OH)_3\}_2]\ \Delta E_4 = -24.4\ \text{kcal mol}^{-1} \quad (f)$$

From these energy differences, the following conclusions may be drawn:

(i) Both the indenyl and cyclopentadienyl ring slippages in Equations (a) and (b) are exothermic, but they are entropically disfavoured association processes (ΔE is negative in all equations).

(ii) The ring slippage of the indenyl complexes is more exothermic than that of the cyclopentadienyl congeners regardless of the nature of the ligand L ($|\Delta E_1| > |\Delta E_2|$; $|\Delta E_3| > |\Delta E_4|$).

(iii) Weaker π-acceptor ligands L favour the ring slippage of indenyl and disfavour the ring slippage of cyclopentadienyl, therefore widening the energy gap between the two similar transformations ($\Delta E_3 - \Delta E_4 = -25.1$ kcal mol^{-1}; $\Delta E_1 - \Delta E_2 = -15.4$ kcal mol^{-1}).

The last conclusion means that CO-containing fragments will level out the differences between indenyl and cyclopentadienyl slippage by facilitating the latter due to orbital stabilization of the η^3-Cp ligand, as shown in the EHMO studies. For the same reasons, indenyl slippages will be favoured in systems carrying weak π-acceptors and/or π-donors where the corresponding Cp slippages become strongly disfavoured. One might then set the value of ca. 15 kcal/mol as the lowest energy difference between a Cp and an indenyl ring slippage on the same fragment when it contains strong π-acceptor ligands. All other ligands will be less favourable for Cp ring slippage. This type of ligand dependence of the ring slippage has been experimentally observed and authenticated by DFT calculations for the reaction according to Equation (g) which takes place for L = NCMe but is thermodynamically forbidden for L = CNMe.[17]

$$[IndMo(CO)_2(L)_2]^+ + NCMe \rightleftharpoons [(\eta^3\text{-Ind})Mo(CO)_2(L)_2(NCMe)]^+ \quad (g)$$

Whereas the result of the second conclusion was largely expected due to the more facile ring slippages of indenyl relative to cylopentadienyl, the result of the first conclusion is not so obvious given the fact that the trihapto coordination of Cp has proven to be very difficult to achieve experimentally. We believe that one of the main difficulties is the need to overcome the entropy factor. The use of redox-induced ring slippage seems to be the most favourable method to achieve difficult ring slippages because it does not involve changes in the number of ligands in the coordination sphere. As a matter of fact, as depicted in Scheme 7, the reductions of the dications **Ia** and **Ib** to give the ring slipped products **IIa** and **IIb**, respectively, differ very little in energy (6.2 kcal mol^{-1}) and allow a simple synthesis of the thermally sensitive $[(\eta^3\text{-Cp})CpMo(CO)_2]$ complex. The mild conditions of the synthesis of $[(\eta^3\text{-Cp})CpW(CO)_2]$ by reduction of $[Cp_2W(CO)Cl]$ under a CO atmosphere (1 atm)[3b] are similar to our conditions and strongly contrast with the 100 atm of CO pressure necessary to prepare it from $[Cp_2W(CO)]$, according to Equation (b).[15b] Related observations were made for CO addition to $[Cp_2Cr(CO)]$.[15d] A classical example is the formation of the $[Ru(\eta^4\text{-}C_6R_6)(\eta^6\text{-}C_6R_6)]$ by reduction of its dicationic precursor $[Ru(\eta^6\text{-}C_6R_6)_2]$,[19a] but there are many other examples of these redox-induced slippages.[2][19] The formation of the ring slipped product **Vb** might appear likely from our calculations, as ΔE_4 is not too different from ΔE_2. The fact that such product has never been detected may be related to kinetic factors.

The examples reported in this work show the remarkable capacity of the $CpMo(CO)_2$ fragment to stabilize rather elusive trihapto-coordinated hydrocarbon ligands like η^3-Cp or the exocyclic-coordination of the fluorenyl ligand in $[(\eta^3\text{-}C_{13}H_9)(Ind)Mo(CO)_2]$.[20] The only examples of a different behaviour were the complexes $[IndCpMo(\eta^2\text{-}C_2Ph_2)]$ and the *tert*-Butyl isocyanide complex [IndCpMo(CN*t*Bu)]. We believe that the formation of the latter is favoured not only by the fact that CN*t*Bu is a good π-acceptor but also because $[(\eta^3\text{-Ind})CpMo(CNtBu)_2]$ is a rather bulky species. On the other hand, the coordination of the acetylene molecule may involve significant oxidative addition as in the analogous $[Cp_2Mo(\eta^2\text{-}C_2Ph_2)]$.[10] In this case the complex may be better considered as a Mo^{IV} species where no ring slippage is expected to occur.

Experimental Section

General: All experiments were carried out under dry nitrogen using Schlenk techniques. Solvents were dried by standard procedures (tetrahydrofuran, diethyl ether, toluene, and pentane over Na/benzophenone ketyl; dichloromethane, and acetonitrile with CaH_2), distilled under argon and kept over 4-Å molecular sieves (3 Å for NCMe). − Microanalyses were performed in our laboratories (ITQB). − ^{1}H NMR spectra were obtained with a Bruker AMX 300 spectrometer. − Infrared spectra were recorded with a Perkin−Elmer 457 and with a Unican Mattson Mod 7000 FTIR spectrophotometer using KBr pellets. − PMe_3,[21] $[(\eta^3\text{Ind})\text{-}CpMo(CO)_2]$, $[Ind(\eta^4C_5H_6)Mo(CO)_2]BF_4$, $[IndCpMo(NCMe)\text{-}Cl]BF_4$, $[IndCpMoH_2]$, $[Cp_2Mo(CO)_2][BF_4]_2$,[1] $[Cp_2Mo(P(OMe)_3)_2][BF_4]_2$[22] were prepared as described previously.

Preparation of [IndCpMo(CO)Br]Y (1). − Method (a): Treatment of a solution of $[(\eta^3\text{-Ind})CpMo(CO)_2]$ (0.45 g, 1.35 mmol) in CH_2Cl_2 with $(NBu_4)Br_3$ (0.65 g, 1.35 mmol) led to the immediate formation of a white precipitate of $[IndCpMo(CO)_2][Br]_2$. The mixture was stirred for 15 h and the purple precipitate of [IndCpMo(-CO)Br]Br (**1a**) was filtered off and washed with CH_2Cl_2. Yield: 60%. − **Method (b):** A solution of $[Ind(\eta^4\text{-}C_5H_6)Mo(CO)_2]BF_4$ (0.21 g, 0.50 mmol) in CH_2Cl_2 was treated with $(NBu_4)Br_3$ (0.24 g, 0.50 mmol) and stirred overnight. The violet precipitate of $[IndCpMo(CO)Br]BF_4$ (**1b**) was separated by filtration in 70% yield

and washed with CH_2Cl_2. – $C_{15}H_{12}Br_2MoO$ (464.01): calcd. C 38.82, H 2.61; found C 38.75, H 2.12. – Selected IR (KBr): $\tilde{\nu}$ = 3077, 2045 (*sv*, CO), 1539, 1413, 946, 856, 760 cm^{-1}. – ^1H NMR ([D_6]acetone, 300 MHz, room temp.): δ = 7.95 (m, 1 H, H^{5-8}), 7.74 (m, 2 H, H^{5-8}), 7.57 (m, 1 H, H^{5-8}), 7.12 (m, 1 H, H^{1-3}), 6.65 (t, 1 H, H^{1-3}), 6.45 (m, 1 H, H^{1-3}), 6.34 (s, 5 H, Cp).

Preparation of [IndCpMo(NCMe)Br]Br (2): A solution of [IndCpMo(CO)Br]Br (0.07 g, 0.15 mmol) in NCMe was refluxed and irradiated with a 60 Watt tungsten bulb for 5 h. The solution was evaporated to dryness and the residue efficiently extracted with CH_2Cl_2. The purple powder was obtained in 90% yield upon evaporation of the solvent. The product was purified by recrystallization from CH_2Cl_2/Et_2O. – $C_{16}H_{15}Br_2MoN$ (477.05): calcd. C 40.28, H 3.17, N 2.94; found C 40.48, H 3.49, N 3.32. – Selected IR (KBr): $\tilde{\nu}$ = 3100, 2317, 2278, 1427, 802, 758 cm^{-1}. – ^1H NMR (CD_3CN, 300 MHz, room temp.): δ = 7.35 [s (br), 4 H, H^{5-8}], 5.98 (t, 1 H, H^2), 5.83 (d, 2 H, $H^{1/3}$), 5.33 (s, 5 H, Cp), 2.12 (s, 3 H, CH_3).

Preparation of [IndCpMo($CNCMe_3$)X]Y (3). – Method (a): A solution of [IndCpMo(NCMe)Br]Br (0.11 g, 0.23 mmol) in CH_2Cl_2 was treated with excess CN*t*Bu (0.25 mL) and refluxed overnight. The solution was evaporated to dryness to afford the grey complex [IndCpMo($CNCMe_3$)Br]Br (**3a**) in 80% yield. This was recrystallized from CH_2Cl_2/Et_2O. – $C_{28}H_{39}Br_2MoN$ (645.38): calcd. C 52.11, H 6.09, N 2.17; found C 52.44, H 6.17, N 2.60. – Selected IR (KBr): $\tilde{\nu}$ = 3102, 2982, 2191, 1449, 1373, 1194, 1084, 845, 764 cm^{-1}. – ^1H NMR (CD_3CN, 300 MHz, room temp.): δ = 7.69–7.67 (m, 1 H, H^{5-8}), 7.56–7.54 (m, 2 H, H^{5-8}), 7.47–7.43 (m, 1 H, H^{5-8}), 6.02 (t, 1 H, H^{1-3}), 5.92 (t, 1 H, H^{1-3}), 5.75 [s (br), 1 H, H^{1-3}], 5.58 (s, 5 H, Cp), 1.60 (s, 9 H, CH_3). – **Method (b):** Treatment of a solution of [IndCpMo(NCMe)Cl]BF_4 (0.18 g, 0.40 mmol) in CH_2Cl_2 with excess CN*t*Bu (0.14 mL) at room temperature led to an immediate color change from green to dark violet. After stirring for 4 h the reaction mixture was concentrated to ca. 5 mL and Et_2O was added and caused the precipitation of the grey-violet complex [IndCpMo($CNCMe_3$)Cl]BF_4 (**3b**), which was recrystallized from CH_2Cl_2/Et_2O in 85% yield. – $C_{19}H_{21}BClF_4MoN$ (481.58): calcd. C 47.39, H 4.40, N 2.91; found C 47.48, H 4.25, N 3.41. – Selected IR (KBr): $\tilde{\nu}$ = 3095, 2982, 2193, 1449, 1373, 1194, 1084, 845, 764 cm^{-1}. – ^1H NMR ([D_6]acetone, 300 MHz, room temp.): δ = 7.89 (d, 1 H, H^{5-8}), 7.70–7.54 (m, 2 H, H^{5-8}), 7.40 (d, 1 H, H^{5-8}), 6.22 [s (br), 1 H, H^{1-3}], 5.97 (s, 1 H, H^{1-3}), 5.83 [s (br), 1 H, H^{1-3}], 5.79 (s, 5 H, Cp), 1.68 (s, 9 H, CH_3).

Preparation of [IndCpMo($P(OMe)_3$)Br]Br (4): A solution of [IndCpMo(NCMe)Br]Br (0.21 g, 0.43 mmol) in CH_2Cl_2 was treated with excess $P(OMe)_3$ (2.5 mL) and refluxed for 4 h. The solution was evaporated to dryness to afford the complex in 80% yield. The complex was recrystallized from CH_2Cl_2/Et_2O. – $C_{17}H_{21}Br_2MoO_3P$ (560.08): calcd. C 36.46, H 3.78; found C 36.65, H 3.49. – Selected IR (KBr): $\tilde{\nu}$ = 3082, 2942, 1425, 1541, 1134, 1042, 716 cm^{-1}. – ^1H NMR (CD_2Cl_2, 300 MHz, room temp.): δ = 7.45 (d, 1 H, H^{5-8}), 7.36–7.27 (m, 2 H, H^{5-8}), 7.21 (d, 1 H, H^{5-8}), 6.08 (m, 1 H, H^{1-3}), 5.72 (d, 1 H, H^{1-3}), 5.01 (t, 5 H, Cp), 4.50 [s (br), 1 H, H^{1-3}], 3.67 {d, 9 H, $P(OMe)_3$, [J_{PH} = 9.0 Hz]}.

Attempted Preparation of [IndCpMo(PMe_3)Br]Br: A solution of [IndCpMo(NCMe)Br]Br (0.20 g, 0.42 mmol) in CH_2Cl_2 was treated with excess PMe_3 (0.15 mL) and stirred for 3 h at room temperature. The pink precipitate of [IndCpMo(PMe_3)$_2$]Br_2 was filtered off and washed with CH_2Cl_2. Yield: 50%. – $C_{20}H_{30}Br_2MoP_2$ (588.16): calcd. C 39.91, H 5.02; found C 39.74, H 5.52. – Selected IR (KBr): $\tilde{\nu}$ = 3366, 3092, 2912, 1423, 1300, 965, 845, 779 cm^{-1}. – ^1H NMR (CD_3CN, 300 MHz, room temp.): δ = 7.72–7.68 (m, 4 H, H^{5-8}), 6.09 (m, 2 H, $H^{1/3}$), 5.48 (t, 1 H, H^2), 5.17 (t, 5 H, Cp, [$^3J_{PH}$ = 2.1 Hz]), 1.66–1.62 (t, 18 H, CH_3).

Preparation of Complexes [(η^3-Ind)CpMoL_2] (5–9): A suspension of [IndCpMo(L)Br]Br (L = **5**, CO; **6** to **9**, NCMe) in toluene (or NCMe) was treated with a solution of Cp_2Co (2 equiv.) in the same solvent at 0°C. Addition of the ligand (1 or 2 mol) caused an immediate change and after 2 h stirring at room temperature the solution was separated from [Cp_2Co]Br by filtration. The solvent was removed under vacuum and the residue extracted with Et_2O (3 × 30 mL). The product, which separated upon concentration and cooling of the extract, was identified by comparison of its IR and ^1H-NMR spectra with those of an authentic sample.[1,2,11]

Preparation of [(η^3-Ind)CpMo$(CO)_2$] (5): [IndCpMo(CO)Br]Br: 0.30 g, 0.65 mmol; Cp_2Co: 0.24 g, 1.29 mmol. Light protection. Purple microcrystalline complex (η^3-Ind)CpMo$(CO)_2$. Yield: 40%.

Preparation of [(η^3-Ind)CpMo(dppe)] (6): [IndCpMo(NCMe)Br]Br: 0.20 g, 0.42 mmol; Cp_2Co: 0.16 g, 0.84 mmol; dppe: 0.17 g, 0.42 mmol. Orange complex. Yield: 80%.

Preparation of [(η^3-Ind)CpMo$(PMe_3)_2$] (7). – (a) [IndCpMo(NCMe)Br]Br: 0.21 g, 0.44 mmol; Cp_2Co: 0.16 g, 0.87 mmol; PMe_3: 0.087 mL, 0.87 mmol. Orange complex. Yield, 90%. – **(b)** [IndCpMo(NCMe)Br]Br: 0.21 g, 0.44 mmol; Cp_2Co: 0.16 g, 0.87 mmol; PMe_3: 0.044 mL, 0.44 mmol. Orange complex. Yield: 45%.

Preparation of [(η^3-Ind)CpMo$(P(OMe)_3)_2$] (8). – (a) [IndCpMo(NCMe)Br]Br: 0.359 g, 0.752 mmol; Cp_2Co: 0.285 g, 1.504 mmol; $P(OMe)_3$: 2.5 mL, excess. Orange complex. Yield, 80%. – **(b)** [IndCpMo(NCMe)Br]Br: 0.179 g, 0.374 mmol; Cp_2Co: 0.142 g, 0.748 mmol; $P(OMe)_3$: 44 μL, 0.374 mmol. Orange complex. Yield: 40%.

Preparation of [(η^3-Ind)CpMo$(CNCMe_3)_2$] (9). – (a) [IndCpMo(NCMe)Br]Br: 0.27 g, 0.35 mmol; Cp_2Co: 0.13 g, 0.70 mmol; CN*t*Bu: 0.10 mL, excess. Reaction solvent: NCMe. Orange complex. Yield, 50%. – **(b)** [IndCpMo(NCMe)Br]Br: 0.27 g, 0.35 mmol; Cp_2Co: 0.13 g, 0.70 mmol; CN*t*Bu: 0.039 mL, 0.35 mmol. Reaction solvent: NCMe. Orange complex. Yield, 30%.

Preparation of [(η^5-Ind)CpMo(η^2-PhCCPh)] (10): A suspension of [IndCpMo(NCMe)Br]Br (0.20 g, 0.42 mmol) in toluene was treated with a solution of Cp_2Co (0.16 g, 0.84 mmol) in the same solvent at 0°C. Addition of DPA (0.075 mL, 0.42 mmol) caused an immediate change and after 2 h stirring at room temperature the solution was separated from [Cp_2Co]Br by filtration. The solvent was removed under vacuum and the residue extracted with Et_2O (3 × 30 mL). The garnet-like complex separated upon concentration and cooling of the extract to give 80% yield. – $C_{28}H_{22}Mo$ (454.43): calcd. C 74.01, H 4.88; found C 74.40, H 4.90. – Selected IR (KBr): $\tilde{\nu}$ = 3505, 3067, 1580, 1486, 1414, 1261, 824, 756 cm^{-1}. – ^1H NMR (C_6D_6, 300 MHz, room temp.): δ = 7.69 (d, Ph), 7.52–7.49 (m, Ph), 7.32 (t, Ph), 6.99–6.97 (m, Ph), 6.93–6.90 (m, 2 H, H^{5-8}), 6.75–6.72 (m, 2 H, H^{5-8}), 5.53 (t, 1 H, H^2), 4.21 (s, 5 H, Cp), 3.85 (d, 2 H, $H^{1/3}$).

Attempted Ppreparation of [(η^5-Ind)CpMoL] (11, 12) by Reduction of [IndCpMo(L)Br]Br: Treatment of a solution of [IndCpMo(L)Br]Br [L = $P(OMe)_3$, $CNCMe_3$] in NCMe with a solution of Cp_2Co (2 equiv.) in the same solvent, at 0°C, caused an immediate change. After 2 h stirring at room temperature the solvent was removed under vacuum and the residue extracted with toluene (3 × 30 mL). Upon evaporation of the solvent and washing of the residue with cold pentane, a mixture of two complexes, [(η^3-Ind)CpMoL_2] and [(η^5-Ind)CpMoL], was obtained. The previously

reported complexes [(η^3-Ind)CpMoL$_2$] were identified by comparison of the IR and ^{1}H-NMR spectra of the mixture with those of an authentic sample.[2][11]

Attempted Isolation of [(η^5-Ind)CpMo(P(OMe)$_3$)] (11): [IndCpMo{P(OMe)$_3$}Br]Br: 0.07 g, 0.125 mmol; Cp_2Co: 0.045 g, 0.25 mmol. Orange powder (mixture of two complexes). − Selected IR (KBr) $\tilde{\nu}$ = 3104, 2944, 1417, 1109, 1044, 1012, 808, 717 cm^{-1}. − ^{1}H NMR (C_6D_6, 300 MHz, room temp.); [(η^5-Ind)CpMo{P(OMe)$_3$}]: δ = 7.33−7.26 (m, 2 H, H$^{5-8}$), 7.06−7.00 (m, 2 H, H$^{5-8}$), 5.85 [t (br), 1 H, H^2], 5.71 (m, 2 H, H$^{1/3}$), 4.23 (d, 5 H, Cp, [J_{PH} = 1.8 Hz]), 3.76 {d, 9 H, P(OMe)$_3$, [J_{PH} = 10.8 Hz]}. − [(η^3-Ind)CpMo{P(OMe)$_3$}$_2$]: δ = 6.57−6.50 (m, 4 H, H$^{5-8}$), 4.58 (t, 5 H, Cp, [J_{PH} = 1.8 Hz]), 3.90−3.87 (m, 3 H, H$^{1-3}$), 3.24 {t, 18 H, P(OMe)$_3$, [J_{PH} = 10.8 Hz]}.

Attempted Isolation of [(η^5-Ind)CpMo(CNCMe$_3$)] (12): [IndCpMo(CNCMe$_3$)Br]Br: 0.09 g, 0.14 mmol; Cp_2Co: 0.052 g, 0.28 mmol; orange powder (mixture of two complexes). − Selected IR (KBr); [(η^5-Ind)CpMo(CNCMe$_3$)]: $\tilde{\nu}$ = 2934, 1934, 1728, 1456, 1198, 1036, 800, 737 cm^{-1}. − ^{1}H NMR (C_6D_6, 300 MHz, room temp.); [(η^5-Ind)CpMo(CNCMe$_3$)]: δ = 7.64−7.61 (m, 2 H, H$^{5-8}$), 6.93−6.90 (m, 2 H, H$^{5-8}$), 5.84 [s (br), 1 H, H^2], 5.65 [s (br), 2 H, H$^{1/3}$], 5.11 (s, 5 H, Cp), 1.22 (s, 9 H, CH_3). − [(η^3-Ind)CpMo(CNCMe$_3$)$_2$]: δ = 6.81 (t, 1 H, H^2), 6.64−6.61 (m, 2 H, H$^{5-8}$), 6.51−6.48 (m, 2 H, H$^{5-8}$), 4.80 (s, 5 H, Cp), 4.41 (d, 1 H, H$^{1/3}$), 1.04 (s, 18 H, CH_3).

Preparation of [(η^3-C_5H_5)CpMo(CO)$_2$] (13): A suspension of [Cp_2Mo(CO)$_2$][BF_4]$_2$ (0.27 g, 0.60 mmol) in toluene was treated with a solution of Cp_2Co (0.23 g, 1.21 mmol) in the same solvent at 0°C. After 3 h stirring at room temperature the solution was separated from [Cp_2Co]Br by filtration. The solvent was removed under vacuum and the residue extracted with hexane (3 × 30 mL). The green powder that separated upon concentration and cooling of the extract was identified by comparison of its IR and ^{1}H-NMR spectra with those of an authentic sample.[1] Yield, 80%.

Preparation of [Cp_2Mo(P(OMe)$_3$)] (14): A suspension of [Cp_2Mo{P(OMe)$_3$}$_2$][BF_4]$_2$ (0.34 g, 0.53 mmol) in NCMe was treated with a solution of Cp_2Co (0.23 g, 1.21 mmol) in the same solvent at 0°C. After 3 h stirring at room temperature the solvent was removed under vacuum and the residue extracted with Et_2O (3 × 30 mL). The brown powder was separated upon evaporation of the solvent. Yield: 30%. − $C_{13}H_{19}MoO_3P$ (350.21): calcd. C 44.59, H 5.47; found C 44.40, H 5.50. − Selected IR (KBr): $\tilde{\nu}$ = 3104, 2926, 1416, 1036, 866 cm^{-1}. − ^{1}H NMR (C_6D_6, 300 MHz, room temp.): δ = 4.14 (d, 10 H, Cp, [J_{PH} = 4.8 Hz]), 3.29 {t, 9 H, P(OMe)$_3$, [J_{PH} = 5.7 Hz]}.

Preparation of [Cp_2Mo(CNCMe$_3$)$_2$][BF_4]$_2$ (15): A solution of [Cp_2Mo(NCMe)$_2$][BF_4]$_2$ (0.34 g, 0.71 mmol) in CH_2Cl_2/NMF (2:1) was treated with excess CN*t*Bu (0.50 mL) and refluxed overnight. The solution was concentrated under vacuum (until the only remaining solvent was NMF) and Et_2O/EtOH (30:1) was added to precipitate the yellow complex. The compound was washed with CH_2Cl_2. Yield: 90%. − $C_{20}H_{28}B_2F_8MoN_2$ (566.01): calcd. C 42.44, H 4.99, N 4.95; found C 42.35, H 5.22, N 4.42. − Selected IR (KBr): $\tilde{\nu}$ = 3119, 3047, 2992, 2226, 2114, 1417, 1377, 1204, 1065, 872 cm^{-1}. − ^{1}H NMR (CD_3CN, 300 MHz, room temp.): δ = 5.92 (s, 10 H, Cp), 1.55 (s, 18 H, CH_3).

Molecular Orbital Calculations. − Extended Hückel Calculations: EH calculations were performed using the ICON8 program[23a,b] with modified H_{ij} values.[23c] The basis set for the metal atoms consisted of *n*s, *n*p and (*n* − 1)d orbitals. The s and p orbitals were described by single Slater-type wave functions, and the d orbitals were taken as contracted linear combinations of two Slater-type wave functions. The parameters used for Mo were [H_{ii} (eV), ζ]: 5s −8.77, 1.960; 5p −5.60, 1.900; 4d −11.06, 4.542, 1.901 (ζ_2), 0.5899 (C_1), 0.5899 (C_2). Standard parameters were used for other atoms. − The calculations were performed on model complexes with idealised geometries taken from the real structures quoted along the text. Thus, [(η^m-Ind)CpMo(CO)$_2$]$^{n+}$ (*m* = 3, *n* = 0 or *m* = 5, *n* = 2) and [(η^3-Cp)CpMo(CO)$_2$] complexes have a distorted tetrahedral geometry with C_s symmetry and Cp/Ind−Mo−Cp and CO−Mo−CO angles of 140° and 80°, respectively. The bis(η^5-Cp) model, [Cp_2Mo(CO)$_2$]$^{2+}$, has C_{2v} symmetry and the same L−Mo−L angles as mentioned above. The trihapto coordination mode of the indenyl and Cp ligands was accomplished by a 30° folding of those ligands. The mono-carbonyl models, [(Ind/Cp)CpMo(CO)], have a Cp/Ind−Mo−Cp angle of 140°, their symmetries being C_s for the Ind complex and C_{2v} for the Cp species. The bond lengths (Å) were as follows: M−(C_5 ring centroid) 2.00, M−C(CO) 2.00, C−O 1.15, C−C 1.40, C−H 1.08. − **DFT Calculations:** Density functional calculations[14] were carried out on model compounds based on the structures of the complexes described in the text, under C_s symmetry or no symmetry, using the Amsterdam Density Functional (ADF) program[24] developed by Baerends and co-workers.[25] The slipping, folding and position of the cyclopentadienyl and indenyl rings, the Mo−C(CO) distance and position of the carbonyl groups were optimized for the six carbonyl complexes. A full optimization was performed for the six phosphite complexes, using P(OH)$_3$ as a model for P(OMe)$_3$. Vosko, Wilk, and Nusair′s local exchange correlation potential was used,[26] with Becke′s nonlocal exchange[27] and Perdew′s correlation corrections.[28] The geometry optimization procedure was based on the method developed by Versluis and Ziegler,[29] using the nonlocal correction terms in the calculation of the gradients. The core orbitals were frozen for Mo ([1−4]s, [1−4]p, 3d) and C, N, O (1s), P (1s, 2s, 2p). Triple-ζ Slater-type orbitals (STO) were used for H 1s; C, N, O 2s and 2p; P 3s and 3p; Mo 5s, 5p, and 4d. One polarization function was added for H, C, N, O, and P.

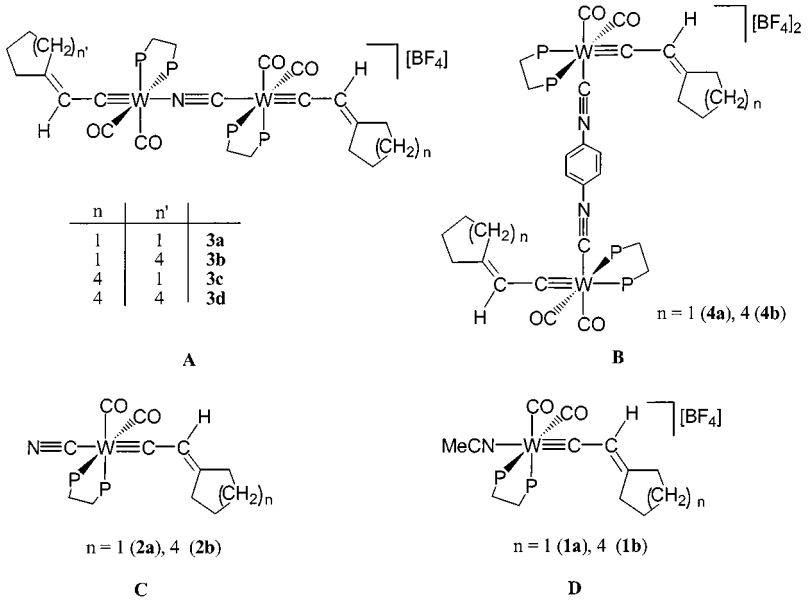
Mono and Dinuclear Tungsten Alkenyl-Carbyne Complexes Bridged by Cyanide and Diisocyanide Ligands: Synthesis, Electrochemical- and ^{183}W-NMR Studies

Lei Zhang,[a,b] M. Pilar Gamasa,[a] José Gimeno,*[a] Rodrigo J. Carbajo,[a] Fernando López-Ortiz,[a,c] M. Fátima C. Guedes da Silva,[b,d] and Armando J. L. Pombeiro*[b]

Keywords: Alkenylcarbynes / Dinuclear tungsten complexes / Electrochemistry / Tungsten NMR

Neutral *trans*-cyanide alkenylcarbyne complexes **2a** and **2b** have been prepared by reaction of the complex **1a** and **1b** with NaCN or $[Bu_4N]CN$. The reaction of complexes **2a** and **2b** with an equimolar amount of the acetonitrile complexes **1a** and **1b** in CH_2Cl_2 leads to the cationic cyanide-bridged bis(alkenylcarbyne) di-tungsten complexes **3a–d**. Diisocyanide-bridged bis(alkenylcarbyne) di-tungsten complexes **4a** and **4b** have been synthesized by the reaction of complexes **1a** and **1b** with 0.5 equivalents of the diisocyanide 1,4-$(CN)_2C_6H_4$. IR as well as ^{1}H-, ^{31}P{^{1}H}-, ^{13}C{^{1}H}-, and ^{183}W-NMR data are reported. The spectroscopic data show that in the dinuclear complexes **3a–d**, the bridging CN group and the alkenylcarbyne units are located in *trans* positions, while in the dinuclear complexes **4a** and **b**, the isocyanide groups of the bridging ligand 1,4-$(CN)_2C_6H_4$ and the two alkenylcarbyne moieties are *cis*. The ^{183}W chemical shifts of complexes **2a**, **2b**, **3a–d**, **4a**, and **4b** were obtained through two-dimensional indirect ^{31}P, ^{183}W NMR recording techniques. A downfield shifting of ^{183}W resonances of the cyanide-bridged dinuclear complexes **3a–d** with respect to the mononuclear ones, **2a** and **2b**, was observed. The δ^{183}W of isocyanide bridging dinuclear complexes **4a** and **4b** appear at higher field than those of the corresponding mononuclear cyanide **2a** and **2b** in accordance with the higher π-acceptor electron properties of the isocyanide ligand. The electrochemical behaviour of all the complexes has been investigated by cyclic voltammetry and controlled potential electrolysis in aprotic media and at a Pt (or vitreous C) electrode. Complexes **1**, **2**, or **3** undergo multi-electron irreversible oxidation processes involving anodically induced proton dissociation from the alkenylcarbyne ligands, and irreversible cathodic processes are also observed for all the complexes. The order of the redox potentials reflects that of the net electron π-acceptor/σ-donor character of the ligands and the ligating alkenylcarbynes are shown to behave as remarkably strong π-electron acceptors (even stronger than CO).



Introduction

Among the extensively studied chemistry of complexes with multiple metal−carbon bonds, that concerned with Fischer-type carbyne complexes of group 6 metals has remained a topic of interest during the last years.[1][2] However, it is now apparent that this chemistry is not as well developed as that of metal carbene derivatives. In particular, only a few carbyne complexes bearing α,β-unsaturated substituents have been described to date,[3] although the corresponding Fischer-type carbene derivatives have proven to be excellent substrates in modern organic synthesis. Even more rare derivatives are dinuclear complexes containing unsaturated carbyne groups.[4] Most of them are dimetallic species bearing a di-carbyne group acting as a bridging ligand: $[(\eta^5\text{-}C_5H_5)(CO)_2Cr{\equiv}C{-}CPh{=}CPh{-}C{\equiv}Cr(\eta^5\text{-}C_5H_5)(CO)_2]$,[5] {$[Br(CO)_4M{\equiv}C{-}(p\text{-}C_6H_4){-}C{\equiv}M(CO)_4Br]$ (M = Cr, W)},[6] {$[Tp'(CO)_2M{\equiv}C{-}CR{=}CR{-}C{\equiv}M(CO)_2Tp']$ (M = Mo; R = H. M = W; R = H, Me, CH_2Ph)}, {$[Tp'(CO)_2M{\equiv}C{-}C{\equiv}C{-}C{\equiv}M(CO)_2Tp']$ (M = Mo, W)}.[3c] Here we report the synthesis of ditungsten bis(alkenylcarbyne) complexes **A** and **B** along with the mononuclear complexes **C** (Scheme 1). Complexes of type **A** and **B** belong to a new type of α,β-unsaturated carbyne dimetallic derivatives in which the metal atoms are linked by a cyanide and diisocyanide bridging group.[7]

We have recently described[3b] the utility of the labile acetonitrile carbyne complexes **D** as excellent precursor of alkenylcarbyne and alkenylketenyl derivatives containing dithio ligands. In this work we report on an extension of this synthetic methodology which has led to the synthesis of dinuclear complexes of type **A** and **B**, obtained by the reaction of complexes **D** with the cyanide derivatives **C** and the diisocyanide ligand $C{\equiv}N{-}(1,4\text{-}C_6H_4){-}N{\equiv}C$, respec-

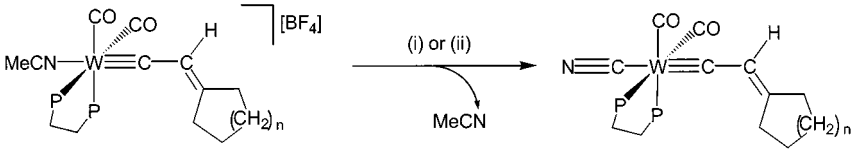
tively. Since the electrochemical investigation of complexes with multiple metal−carbon bonds is still a rather undeveloped field of research,[8−17] and has not been previously reported for alkenylcarbyne compounds, we have also studied the electrochemical behaviour of our novel alkenylcarbyne complexes. ^{183}W-NMR data of all the complexes are also reported.

Scheme 2. Two terminal unsaturated carbyne tungsten moieties linked by bridging ligands with π-electronic delocalized systems

Results and Discussion



Mononuclear Cyanide Alkenylcarbyne Complexes 2a and 2b

The addition of NaCN to an orange solution of complexes**1a** and **1b** in methanol at room temperature led to the substitution of the acetonitrile ligand by the cyanide anion to afford the neutral alkenylcarbyne complexes **2a** and **2b** (90−95% yield) isolated as air stable orange solids (Equation 1). Complexes **2a** and **2b** are also formed by the treatment of **1a** and **1b** with $[NBu_4]CN$ in CH_2Cl_2.

IR spectra (CH_2Cl_2) show the typical pattern of *cis*-dicarbonyl complexes, of two ν(CO) absorptions at 1999 and 1931 (**2a**), and 1998 and 1930 (**2b**) cm^{-1}. As expected for the transformation of cationic to neutral complexes, a lowering in absorption frequencies (ca. 12 cm^{-1}) is observed. The presence of the terminal linear CN ligand is confirmed by the IR spectra (CH_2Cl_2 solution or KBr pellet) which show a very weak ν(CN) absorption at 2112 cm^{-1}.[18][19] The phosphorus resonances appear in the ^{31}P-NMR spectra (Table 1) as singlet signals, indicating the chemical equivalence of the phosphorus atoms of dppe, and are therefore in accordance with the *trans* carbyne-cyanide arrangement. The *J*(W-P) values (ca. 225.5 Hz) are similar to those found in analogous complexes

$$[(dppe)(CO)_2(X)W{\equiv}CCH{=}\overline{CCH_2CH_2(CH_2)_n}CH_2]$$

(X = Cl, Br, I) which also show a similar *trans* arrangement of phosphorus nuclei to the carbonyl ligands.[3a] The ^{1}H-NMR shows a broad signal for the alkenyl proton (≡C−CH=) at δ = 4.98 (**2a**) and 4.66 (**2b**). The carbyne carbon resonances of these complexes appear in the ^{13}C-NMR spectra as triplet signals at δ = 283.4 [^2J(P-C) ca. 10 Hz] (Table 2). These signals appear at a lower field with respect to those shown by the corresponding halide carbyne complexes [δ = 266.9−269.8, ^2J(P-C) ca. 10 Hz][3a] and at

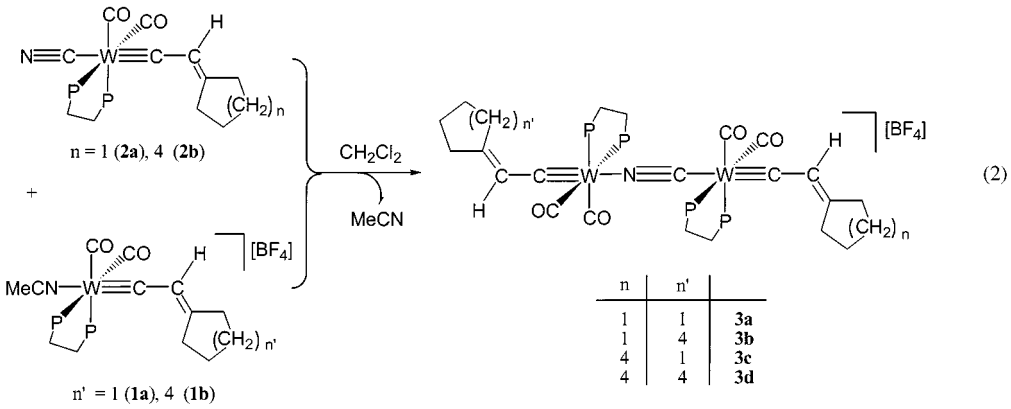
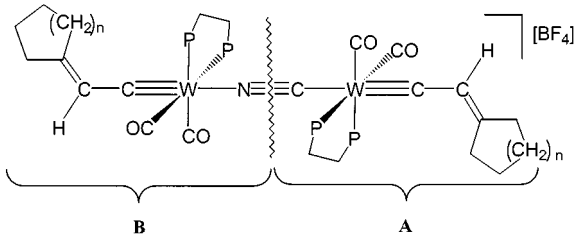
a higher field (ca. 8.5 ppm) than those of the cationic precursor complexes **1a** and **1b**. The resonances of the C_β atom of the alkenylcarbyne chain are assigned and distinguished by DEPT from the C_γ and the carbon atom of the cyanide group. The resonances of the *cis*-dicarbonyl ligands appear as doublet signals in the range of δ = 212.4−212.6 (Table 2) and are in accordance with the reported data for the similar alkenylcarbyne halide complexes.[3a]



Cyanide Bridged Bis(alkenylcarbyne) Dinuclear Complexes 3a−d

The reaction of complexes **2a** and **2b** with an equivalent of **1a** and **1b** in dichloromethane at room temperature for 1 hour led to the displacement of the acetonitrile ligand to give the cationic bis(alkenylcarbyne) di-tungsten complexes **3a−d** (82−85% yield) in which the metal atoms are bridged by the cyanide group (Equation 2).

Complexes **3a** and **3d** have been also prepared in similar yields from the treatment of **1a** and **1b** in methanol with NaCN in a 2:1 molar ratio. The reaction probably proceeds through the formation of complexes **2a** and **b** as intermediates.



IR and NMR spectroscopic data show the molecular asymmetry of these dinuclear complexes even for **3a** ($n = n' = 1$) and **3d** ($n = n' = 4$) containing two identical metal carbyne moieties. Thus, IR spectra (CH_2Cl_2) show (Table 1) two weak ν(C≡N) absorptions[18][19] at 2112−2113 and 2098−2100 cm^{-1} and two very strong ν(CO) absorptions at 2003−2004 and 1937−1938 cm^{-1} which apparently indicate an overlapping of the absorptions expected for the two unsymmetrical *cis*-dicarbonyl pairs of each tungsten moiety. Since the ν(C≡N) absorptions at higher frequency appear at a similar energy to those of complexes **2a** and **b**, they may be assigned to the ν(N≡C−W) stretching (side A in Figure 1) while those at lower energy are assigned to the corresponding ν(W−N≡C) (side B in Figure 1).

NMR data of **3a−d** are in accordance with the linear −C≡W−(μ-N≡C)−W≡C− arrangement. Thus, the ^{31}P-NMR spectra (Table 1) show two singlets at δ = 39.4−39.5 [*J*(W-P) = 227.8−230.5 Hz] and 40.9−41.0 [*J*(W-P) = 232.5−234.0 Hz], which are expected for each equivalent pair of phosphorus nuclei of dppe *trans* to carbonyl groups in sides **A** and **B** (Figure 1). As discussed before, since the higher-field signals are at the same chemical shifts as those of **2a** and **2b** (0.3 ppm higher), they are assigned to the two equivalent phosphorus atoms at side **A**, while those at

lower-field are assigned to the phosphorus atoms of side **B**. We were not able to assign the proton and carbon resonances (Tables 1 and 2) for each moiety **A** and **B** using the conventional methods due to the similar values of chemical shifts. However, the spectroscopic characterisations have been performed through 2D ^{1}H,^{183}W- and ^{31}P,^{183}W-HMQC experiments, as will be discussed below (^{183}W-NMR studies). The alkenyl proton resonances appear in the ^{1}H-NMR spectra (Table 1) as two different broad singlets.

^{13}C-NMR spectra (Table 2) show two carbyne carbon resonances at δ = 286.7−289.8 [J(P-C) = 9.4−9.6 Hz]. For complexes **3b** and **3c**, bearing two different carbyne groups at each side of the bridge, the signals appear as two triplets, while for **3a** and **3d** these resonances are not well defined and appear as two multiplets. The assignments of these resonances for each moiety have been done through 2D ^{1}H,^{13}C-HMBC correlation experiments, on the basis of the previously known proton assignments. The carbon resonances of the cyanide group are shifted to lower field (> 20 ppm) (Table 2) appearing very close to those of the C$_\gamma$ atom of the alkenylcarbyne chain, indicating that a significant electron donation has occurred in the formation of the dinuclear species through the coordination of the [W]−CN moiety of complexes **2a** and **2b**. ^{13}C-NMR spectra also show carbonyl resonances which appear as virtual doublet-of-doublet signals at δ = 211.4−213.2 [^2J(P-C) = 7.0−7.2, 29.9−37.3 Hz] (Table 2) as expected for each unequivalent *cis*-dicarbonyl pair.

Diisocyanide-Bridged Bis(alkenylcarbyne) Dinuclear Complexes 4a and 4b

The reaction of **1a** and **1b** in dichloromethane with 1,4-CNC_6H_4NC (1:0.5 molar ratio) at room temperature for 2 hours afforded the diisocyanide bridged di-cationic bis(alkenylcarbyne) di-tungsten complexes **4a** (n = 1) and **4b** (n = 4) (75−80% yield) (Equation 3).

The reaction for the formation of complex **4a** was monitored by ^{31}P-NMR in CH_2Cl_2 (D_2O as external lock reference). However only the resonances due to the starting complex, along with those of the final product, are observed. Although the formation of an intermediate mononuclear complex is plausible, apparently the subsequent coordination of the uncoordinated isocyanide group is more favoured than the formation of the intermediate. All attempts to prepare the mononuclear complexes by using a 1:1 molar ratio failed, giving instead mixtures of the dinuclear complexes **4a** and **4b** and the mononuclear ones. even if a large excess of the ligand was used.

Elemental analyses, conductivity, and spectroscopic data support the dinuclear nature of the complexes and the proposed symmetric structure. The IR spectra of **4a** and **4b** (CH_2Cl_2) show two very strong and broad ν(CO) absorptions at 2006−2008 and 1960−1961 cm^{-1}, typical of a *cis* dicarbonyl arrangement for each tungsten centre. The spectra also show one ν(C≡N) absorption at 2130 and 2132 cm^{-1}, for **4a** and **4b**, respectively (Table 3).

The NMR spectra indicate that the two isocyanide groups occupy the *cis* positions with respect to the carbyne ligand of the corresponding metal centre. Thus, ^{31}P-NMR spectra of **4a** and **4b** display (Table 3) two singlet resonances at δ = 21.6 and 40.0, and δ = 21.9 and 40.1, respectively, indicating the chemical unequivalence of the phosphorus atoms of dppe. The J(W-P) values allow the assignment of the coordination sites. Thus, the lower-field signals with relatively large values [J(W-P) = 229.6 and 231.6 Hz] are typical of a mutually *trans* P−CO arrangement, while those of the higher-field signals [J(W-P) = 83.9−85.4 Hz] are characteristic of a phosphorus atom *trans* to carbyne ligands.[3a] This reflects the high *trans*-influence of the carbyne ligand,[3a,20] and it is also in accord with previous reported data for similar derivatives. The carbyne carbon resonances in the ^{13}C{^{1}H} NMR spectra (Table 4) which ap-

pear as a doublet of doublets at ca. δ = 298 [^2J(P-C) ca. 22, 10 Hz] are also consistent with the *trans* position of the carbyne groups with respect to one of the phosphorus atom of dppe. The chemical unequivalence of the carbonyl groups is also shown by the corresponding carbon resonances. Thus, those of carbonyl groups *trans* to the phosphorus atom of dppe appear as a double doublet signal at δ = 209.3 [^2J(P-C) = 7.3–8.6, 24.0–24.5 Hz] while those of the *cis* carbonyl ligands appear as an apparent triplet signal at δ = 207.5–207.9 [^2J(P-C) = 7.4–7.5 Hz] (Table 4). Furthermore, $^{13}C\{^1H\}$-NMR spectra also show resonances of the equivalent isocyanide groups at δ = 161.6 (**4a**) and 161.9 (**4b**) as apparent triplets [^2J(P-C) = 7.5–8.4 Hz] along with that of the C_γ atom of the alkenylcarbyne chain observed as a singlet at δ = 175.0 (**4a**) or 174.5 (**4a**).

^{183}W-NMR Studies

^{183}W-NMR data of complexes **2a**, **2b**, **3a–d**, **4a**, and **4b** are collected in Table 5. ^{183}W data were acquired by indirect detection through ^1H and/or ^{31}P, using standard HMQC pulse sequence.[21][22] For transition metal nuclei the chemical shift is dominated by the paramagnetic contribution to the total shielding, which can be approximated by Equation 4, where *r* represents the distance to the valence d electrons from the metal nucleus, ΔE is the average electronic excitation energy, and ΔQ_N is the angular imbalance of charge. The angular imbalance of charge can be considered as constant for complexes having the same d-electron configuration and symmetry. In this way we can rationalise the chemical shifts variations of the complexes studied accord-

Table 4. Selected $^{13}C\{^1H\}$-NMR data for complexes **4a** and **4b**[a]

	C_α	C_γ	$(W-CN)_2$	2 CO *cis* to P	2 CO *trans* to P
4a	298.4 dd (22.0, 10.0)	175.0 s	161.6 *vr.* t (8.4)	207.5 *vr.* t (7.4)	209.3 dd (24.0, 8.6)
4b	298.3 dd (23.2, 9.0)	174.5 s	161.9 *vr.* t (8.4)	207.9 *vr.* t (7.5)	209.3 dd (24.5, 7.3)

ing to the fluctuations of the r and ΔE terms, showing an upfield shift of the metal nucleus when r or ΔE increase, and consequently a deshielding when one of the terms becomes smaller.

$$\sigma_p \approx -\langle r^{-3}\rangle(\Delta E)^{-1}\Sigma Q_N \qquad (4)$$

Table 5. ^{183}W-NMR data for complexes **2−4**

	δ^{183}W		δ^{183}W	
			A	B
2a	−2116	**3a**	−2094	−1819
2b	−2100	**3b**	−2096	−1804
4a	−2127	**3c**	−2078	−1821
4b	−2108	**3d**	−2078	−1805

The ^{183}W-NMR spectra of **2a** and **2b** (δ = −2116, −2100, respectively) show that the substitution of the acetonitrile ligand of the starting material **1a** and **1b** (δ = −1786, −1775, respectively)[21] by the cyanide ligand produces a shielding of the tungsten nuclei by 330−325 ppm. This upfield shift effect is in agreement with the higher π-acceptor ability of CN^- compared to CH_3CN, which implies an increase in the ΔE term of Equation 4. The 16 ppm deshielding of **2b** with respect to **2a** is of the same order of the ^{183}W chemical shift difference between found in the starting carbyne complexes (**1a** and **1b**). This fact can be, and is explained, by the electronic and steric effects induced by the change in of the carbocyclic moiety size.[21]

The assignment of δ^{183}W for each moiety **A** and **B** of dinuclear complexes **3a−d** (Figure 1) is in accordance with the corresponding chemical shifts of precursor complexes **1a** and **1b**, and **2a** and **2b**. Thus, the δ^{183}W signals at higher field, which can be compared to those of cyanide complexes **2a** and **2b**, are assigned to the **A** moiety, while those at lower field, which resemble appear at analogous chemical shifts of the acetonitrile complexes **1a** and **1b**, are assigned to moiety **B**. When moving from the mononuclear complexes **2a** and **2b** to the dinuclear ones **3a−d**, a downfield shift of 20−22 ppm in the δ^{183}W of the **A** substructure is observed. The bidentate coordination of the CN^- group, acting as a bridging ligand, produces a reduction in its π-acceptor ability and consequently a decrease of the ΔE term. As observed before, an increase in the size of the carbocyclic moiety in either the **A** or **B** part of complexes **3a−d** leads to a deshielding of the metal by 15−18 ppm. It is worth mentioning that in complexes **3b** and **3c** the larger carbocyclic ring produces the expected deshielding of the tungsten nucleus bonded to the corresponding carbyne, but also a 2 ppm upfield shift to the signal of the other metal. Although $^5J(^{183}W\text{-}^1H)$[23] are observed within each moiety **A** and **B**, there are no cross peaks between the tungsten atom of the **A** moiety with the proton and phosphorus nuclei of **B** (and vice versa). Hereby, this small shift can be assigned to field or solvent effects.

As expected, the δ^{183}W of complexes **4a** and **4b** appear at higher field than those of the corresponding **2a** and **2b** (8 and 11 ppm, respectively) in accordance with the higher π-acceptor ability of diisocyanide ligand 1,4-$(CN)_2C_6H_4$ with respect to the cyanide group. The ^{183}W chemical shift of complex **4b** bearing two eight-membered rings is deshielded by 19 ppm with respect to **4a**, as is also shown in the spectra of complexes **2a**, **2b**, and **3a−d** (see above).

In addition, the ^{183}W-NMR spectra allow the assignment of the ^{1}H and ^{13}C resonances in compounds **3a−d**. Thus, the assignment of the alkenyl proton resonance in each moiety (H_β and H_β') was done through their correlations with the metal nuclei in the ^{1}H, ^{183}W HMQC spectra. On the basis of these assignments the rest of the ^{1}H and ^{13}C resonances were identified through the conventional ^{1}H,^{13}C-HMQC and -HMBC experiments.

Electrochemical Studies

The electrochemical behaviour of the alkenylcarbyne complexes has been investigated by cyclic voltammetry (CV) and controlled potential electrolysis (CPE) in aprotic medium (see Experimental Section).

With the exception of the dicationic complexes **4** (for which no anodic wave was detected, their oxidation conceivably occurring only at a potential above that of the onset of the solvent/electrolyte discharge), all the compounds exhibit irreversible anodic and cathodic waves by CV (Table 6). The oxidation peak potential of the first (I) anodic wave ($^IE_p^{ox}$) for the cyanide complexes **2** (ca. 1.1 V vs. SCE) is lower than those shown by the other complexes (ca. 1.3−1.4 V, for **1** and **3**) in agreement with the known[24] stronger net electron σ-donor minus π-acceptor ability of cyanide compared with a nitrile or an isocyanide ligand.

Table 6. Cyclic voltammetric data for complexes **1−4**[a]

Compound	$^IE_p^{ox}$	$^{II}E_p^{ox}$	$^IE_p^{red}$	$^{II}E_p^{red}$
1a	1.34	1.58	−1.58	–
1b	1.28	1.59	−1.65	–
2a	1.07	1.34	−1.89	–
2b	1.09	1.42	−1.88	
3a	1.30	1.38	−1.58	−1.89
3b[b]	1.38	1.50	−1.65	−1.90
3c[b]	1.26	1.37	−1.70	−1.94
3d[b]	1.28	1.43	−1.73	−1.96
4a	–	–	−1.25	−1.48
4b[c]	–	–	−1.20	−1.43
$[W(CO)_4(dppe)]$ [d]	1.02[e]	–	–	–

[a] Potentials in Volt ± 0.02 vs. SCE measured in 0.2 mol dm^{-3} $[NBu_4][BF_4]$/MeCN {CH_2Cl_2 for compounds **3a**, **4a**, and $[W(CO)_4(dppe)]$} at a scan rate of 0.2 V s^{-1} and at a Pt disc (d = 0.5 mm) electrode, unless stated otherwise. – [b] In vitreous C; at a Pt electrode, only one broad wave is observed at ca. 1.4 V. – [c] In vitreous C. – [d] Included for comparative purposes. – [e] Reversible wave ($\Delta E_{1/2}^{ox}$ value given).

Moreover, the values of oxidation potential for all the complexes are higher than that for $[W(CO)_4(dppe)]$ ($E_{1/2}^{ox}$ = 1.02 V) which was also measured for comparative purposes, indicating that the alkenylcarbyne ligands are behaving as even stronger net electron π-acceptors than CO, thus compensating for the stronger net electron donor ability of the nitrile, isocyanide, or cyanide ligand compared

with CO, which should result in a lowering of the oxidation potential of our complexes relative to that of $[W(CO)_4(dppe)]$. This is consistent with the reported[9] behaviour of the carbyne ligands in *trans*-$[ReX(\equiv CCH_2R)(dppe)_2][BF_4]$ (X = F or Cl; R = alkyl, aryl, or ester).

For the cyanide-bridged dinuclear complexes **3**, two close and extensively overlapped anodic waves are observed. Since these complexes can be viewed as the assembling of the tungsten moieties **A** (attached to a formal isocyanide ligand) and **B** (attached to a formal nitrile ligand) (Figure 1) it is expected that the tungsten atom of moiety **A** undergoes an oxidation process at a more anodic potential with respect to that of moiety **B**. Moreover, $^{I}E_p^{ox}$ values for these complexes are close to those of the acetonitrile precursors **1**. This is in accord with the ^{183}W chemical shifts for parts **A** and **B** of complexes **3** (see above).

In the cyclic voltammograms of complexes **1**, **2**, and **3**, the first anodic wave (I) is followed, at a slightly higher potential, by a second one (II), also irreversible and broad, that partially overlaps with the former wave. Although this precluded an accurate discrimination of the respective numbers of electrons, the overall involvement, by CPE, of multi-electron anodic processes with electron-induced proton liberation from the alkenylcarbyne ligand is evident.

In fact, exhaustive anodic CPE of those complexes, usually in acetonitrile, corresponds to an overall consumption (waves I + II) of ca. 3 (complexes **1** or **2**) or ca. 4 (complexes **3**) faradays/mol. The evolution of H^+ is indicated by the detection, by CV (cathodic sweep) of the electrolysed solution, at a Pt electrode, of an irreversible and broad cathodic wave at ca. −0.5 V, assigned to H^+ reduction. This wave shifts to a much lower potential upon replacement of the Pt by a vitreous carbon electrode, in accord with the expected large overpotential required for H^+ reduction at the latter electrode. The proton emission was also measured by acid-base titration of the electrochemically oxidised complex solutions: ca. 1 H^+/molecule for complexes **2**, ca. 3 H^+/molecule for complexes **1**, or ca. 4 H^+/molecule for complexes **3**. The higher numbers of protons for **1** and **3** relative to **2** are in accord with the expected stronger acidity of the carbyne ligand in the former complexes, as a result of the charge and the absence of the stabilising strong electron-donor mono-hapto cyanide ligand. Moreover, the highest number of protons lost for compounds **3** may also reflect their biscarbyne (dinuclear) character.

Proton dissociation can also occur during the time scale of CV, at a sufficiently low scan rate, since its cathodic wave (with the above features) is detected as well upon scan reversal following the anodic scan of a solution of an alkenylcarbyne complex.

Consistent with an anodic multi-electron process, at a sufficiently high time scale, involving electron-induced proton loss followed by further oxidation of the product(s), the following observations by CV are possible: the anodic current-functions $i_p^{ox}\ C^{-1}\cdot v^{-1/2}$ (i_p^{ox} − anodic peak current, C − concentration, v − scan rate) increase (i) with a decrease of the scan rate (e.g. by a factor of ca. 2 from v = 10 V s^{-1}, when it corresponds roughly to a single-electron process, to 50 $mV\cdot s^{-1}$ for complexes **1**) and (ii) with addition of a base such as pyridine, which enhances the deprotonation step.

The proton liberation at the anodic process, now reported for the first time for alkenylcarbyne ligands, indicates a promotion of their acidic character as a result of oxidation of the complexes, and parallels the anodically induced deprotonation observed for the aminocarbyne (CNH_2) and isocyanide (CNH) ligands in *trans*-$[ReCl(CNH_n)(dppe)_2][BF_4]_{n-1}$ (n = 2 or 1)[10] and *trans*-$[FeH(CNH)(dppe)_2][BF_4]$,[25] as well as for some aminocarbene complexes[11a] of Pd^{II} or Pt^{II}. However, the behaviour of the alkenylcarbyne ligands of this study contrasts with the stability, toward anodically-induced deprotonation, of the carbyne ligands $\equiv CCH_2R$ in the complexes *trans*-$[ReX(\equiv CCH_2R)(dppe)_2][BF_4]$,[9] which undergo a reversible single-electron oxidation by CV. This difference conceivably results from the higher acidity of the alkenyl proton ($\equiv C-CH=$) of our complexes compared to the alkyl protons ($\equiv C-CH_2R$) in the Re compounds, and/or the occurrence of anodically induced *ortho*-deprotonation of the ring. Hence, the anodic conversion of a ligating alkenylcarbyne into e.g., an allenylidene or a vinylidene ligand is plausible, but unfortunately we did not succeed in the identification of the products of the CPE or of the attempted chemical oxidations by oxidising agents such as the triarylaminium (Magic Blue) salt $[N(4\text{-}BrC_6H_4)_3][SbCl_6]$.

The alkenylcarbyne complexes of this study display, by CV, a single-electron irreversible cathodic wave (as shown by CPE) (Table 6), which for the dinuclear compounds (**3** and **4**), is followed by a second one at a lower potential, which involves a two-electron process for **4** (as measured by CPE). The observation of the two distinct cathodic waves for complexes **4** with two identical metal centres could suggest an interaction through a delocalized LUMO along the bridged aromatic diisocyanide, but the complexity of the cathodic processes prevents such an interpretation.

Conclusions

In this work, novel types of dinuclear **A** and **B** and mononuclear **C** alkenylcarbyne Fischer-type tungsten complexes are reported (Scheme 1). Complexes of type **A** and **B** belong to a new type of α,β unsaturated carbyne dimetallic derivatives, in which the metal atoms are linked by a cyanide and diisocyanide bridging group. These novel dinuclear complexes display a π-conjugated system consisting of two terminal unsaturated carbyne tungsten moieties linked by bridging ligands with π-electronic delocalized systems (Scheme 2). There is currently much research on this type of derivatives because they disclose appropriate molecular arrangements, with potential utility as precursors of mixed valence complexes and materials with enhanced electrical conductivities and nonlinear optical (NLO) properties.[26] Our study also allowed the investigation, for the first time, of the electrochemical behaviour of alkenylcarbyne com-

plexes, revealing that (i) the alkenylcarbyne ligands are activated, by oxidation of their complexes, towards heterolytic C−H bond cleavage (a behaviour which is of potential synthetic interest for the generation of other unsaturated multiple metal-carbon bonded species) and that (ii) the alkenylcarbyne ligands behave as even stronger π-electron acceptors than CO.

Experimental Section

Synthesis and Characterization of Alkenylcarbyne Complexes: The reactions were carried out under dry nitrogen using Schlenk techniques. All solvents were dried by standard methods and distilled under nitrogen before use. The precursor complexes **1a**, and **b** were prepared by the literature methods.[3a] NaCN, $[Bu_4N]CN$, and 1,4-$(CN)_2C_6H_4$ (Aldrich Chemical Co.) were used as received. − Infrared spectra were recorded on a Perkin−Elmer 1720-XFT spectrometer. − Mass spectra (FAB) were recorded using a VG-Autospec spectrometer, operating in the positive mode; 3-nitrobenzyl alcohol (NBA) was used as the matrix. − The conductivities were measured at room temperature, in ca. 10^{-3} mol dm^{-3} acetone solutions, with a Jenway PCM3 conductivimeter. − The C, H, and N analyses were carried out with a Perkin−Elmer 240-B microanalyzer. − NMR spectra were run on Bruker AC300 and AMX400 spectrometers. The parameters used for the indirect detection experiments ^1H,^{183}W 2D HMQC and ^{31}P,$^{183}W\{^1H\}$ 2D HMQC have been previously described.[3a,21] The spectral reference used for ^{183}W was Na_2WO_4. − Selected IR and ^1H-, $^{13}C\{^1H\}$-, $^{31}P\{^1H\}$-, and ^{183}W-NMR spectroscopic data for the novel carbyne tungsten complexes are collected in Tables 1−5.

Preparation of Mononuclear Cyanide Alkenylcarbyne Complexes 2a and 2b. − General Procedure: A small excess of NaCN solid was added to an orange solution of **1a** or **1b** (0.2 mmol) in 20 mL of methanol. The mixture was stirred at room temperature for 2 h. The resulting solution was filtered off and the filtrate was evaporated to dryness. The residue was extracted with CH_2Cl_2 and the filtrate was dried under vacuum to give an orange solid. Yield: **2a**, 90%; **2b**, 95%.

The complexes **2a** and **2b** were also prepared following the procedure below: An orange solution of **1a** or **1b** (0.2 mmol) and 1 equiv. of $[NBu_4]CN$ in 10 mL of CH_2Cl_2 was stirred at room temperature for 2 h. After evaporation of the solvent to dryness the residue was extracted with toluene and filtered of on Alox. Removal of the solvent and washing the resulting solid with diethyl ether (2 × 10 mL) and hexane (2 × 10 mL) and drying in vacuo gave an orange solid. Yields ca. 70%.

Preparation of Diisocyanide-Bridged Bis(alkenylcarbyne) Ditungsten Complexes 4a and 4b: General Procedure: A mixture of complex **1a** or **1b** (0.2 mmol) and 0.5 equiv. of 1,4-phenylendiisocyanide (0.1 mmol) in 20 mL of dichloromethane was stirred at room temperature for 2 h. The resulting orange-red solution was evaporated to dryness and the residue was washed with diethyl ether (2 × 5 mL) and hexane (3 × 5 mL) to give an orange-red solid **4a** and **4b**. Yield: 75−80%. Conductivity (acetone, 20°C, $Ω^{-1}$ cm^2 mol^{-1}): **4a**, 200; **4b**, 195.

Spectral and Analytical Data for 4b: IR [KBr, ν(CN); ν(CO); ν(BF_4)] $\tilde{\nu}$ = 2128 (m); 1997 (vs), 1944 (s); 1055 (s, br). − ^{1}H NMR (δ, $CDCl_3$) 1.50 (m, 12 H, 6 CH_2), 1.76 (m, 4 H, 2 CH_2), 1.82 (m, 4 H, 2 CH_2), 2.20 (m, 4 H, 2 CH_2), 2.63 (m, 4 H, 2 CH_2), 2.8−3.2 [m, 8 H, 2 $P(CH_2)_2P$], 6.36−7.79 [m, 44 H, $(CN)_2C_6H_4$, 4 PPh_2]. − $^{13}C\{^1H\}$ NMR (δ, $CDCl_3$) 25.6 (m, 2 $PC_aH_2C_bH_2P$), 25.5 (s, 2 CH_2), 26.5 (s, 2 CH_2), 26.7 (s, 2 CH_2), 27.2 (s, 2 CH_2), 27.5 (m, 2 $PC_aH_2C_bH_2P$), 27.8 (s, 2 CH_2), 33.0 (s, 2 CH_2), 37.1 (s, 2 CH_2), 125.7−133.6 [m, $(CN)_2C_6H_2$, 4 PPh_2], 136.4 [d, ^3J(C−P) = 16.7 Hz, $C_β$, $C_β'$]. − MS (FAB, *m*/*z*) 0.5 [M^+ − 2 × (BF_4) − $(CN)_2C_6H_4$] = 773. $-C_{84}H_{82}B_2F_8N_2O_4P_4W_2$: calcd. C 54.6, H 4.5, N 1.5; found: C 53.8, H 4.3, N 1.8.

Electrochemical Measurements: The electrochemical experiments were performed on an EG & G PARC 273 potentiostat/galvanostat connected to a PC computer through a GPIB interface (National Instruments PC-2A) or on an EG & G PARC 173 potentiostat/galvanostat and an EG & G PARC 175 Universal programmer. Cyclic voltammetry was undertaken in a two-compartment three-electrode cell, at a platinum- or vitreous carbon-disc working electrode (d = 0.5 or 1 mm, respectively), probed by a Luggin capillary connected to a silver-wire pseudo-reference electrode; a platinum auxiliary electrode was employed. Controlled potential electrolyses were carried out in a two-compartment three electrode cell with platinum gauze working and counter electrodes in compartments separated by a glass frit; a Luggin capillary, probing the working electrode, was connected to a silver wire pseudo reference electrode. The electrochemical experiments were performed in an inert atmosphere (N_2) at room temperature. The potentials were measured in 0.2 mol dm^{-3} [NBu_4][BF_4]/MeCN or CH_2Cl_2, and are quoted relative to the saturated calomel electrode (SCE) by using as internal reference the $[Fe(\eta^5\text{-}C_5H_5)_2]^{0/+}$ couple (E_{-}^{ox} = 0.45 or 0.53 V vs. SCE).

The acid-base potentiometric titrations of the electrochemically oxidised solutions were carried out by using a solution of NaOH in MeOH that was standardised by titration against benzoic acid in MeCN or CH_2Cl_2. The results have been corrected for background effects by also performing, in each case, the titration of a blank electrolyte solution which has been electrolysed under identical conditions to those used for the corresponding complex solution.

Acknowledgments

This work was supported by the Dirección General de Investigación Científica y Técnica (Project PB96-0558) and the EU (Human Capital Mobility Programme, Project ERBCHRXCT 940501). L. Z. is grateful to the Spanish Ministerio de Asuntos Exteriores (Agencia Española de Cooperación Internacional) for a doctoral grant and the Fundaçao para a Ciencia e a Tecnologia, PRAXIS XXI Programme (Portugal) for a post-doctoral grant (for doing the detailed electrochemical studies). R. J. C. thanks the Spanish Ministerio de Educación y Cultura for a predoctoral fellowship.

Chiral 4-(Diphenylphosphanyl)-1-(dialkylamino)butane Ligands – Synthesis, Applications in Asymmetric Alkylation and Theoretical Study

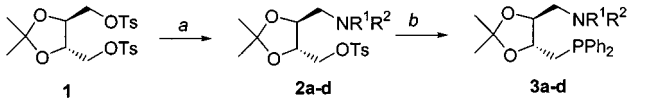
Fabien Robert,[a] Françoise Delbecq,[b] Christelle Nguefack,[a] and Denis Sinou*[a]

Keywords: Aminophosphanes / Palladium / Alkylations / Enantioselectivity / Theoretical study

Various 4-(diphenylphosphanyl)-1-(dialkylamino)butane ligands were prepared from commercial (2*S*,3*S*)-2,3-*O*-isopropylidene-D-threitol. These ligands, associated with $Pd_2(dba)_3$, gave enantioselectivities of up to 75% in the alkylation of racemic 1,3-diphenylprop-2-enyl acetate with dimethyl malonate anion. A theoretical study shows the important role played by two factors in the alkylation reaction: steric control, leading to the formation of a unique diastereoisomer of the π-allylpalladium complex, and orbital control, which orients the attack of the nucleophile *trans* to the phosphorus atom.

Introduction

Asymmetric metal catalysis is one of the most powerful methods for the preparation of enantiomerically pure compounds.[1] An impressive number of chiral ligands have been prepared and used, among them P,P-, P,N- and N,N-based ligands. The phosphanyloxazolines, P,N-based ligands, induce high enantioselectivities, particularly in the palladium-catalyzed allylic substitution.[2] In comparison, P,N ligands with an sp^3 nitrogen atom have been used less in asymmetric catalysis. Hayashi et al. prepared chiral β-(aminoalkyl)phosphanes[3] and [(aminoalkyl)ferrocenyl]-phosphanes.[4] Chiral aminophosphanes, in which the chirality is on the substituents of the nitrogen atom through a pyrrolidine[5−6] or a naphthyl unit,[7] have also been described more recently. These ligands were successfully used in asymmetric hydrogenation, cross-coupling reactions and mainly allylic substitution.



We recently reported, in a preliminary communication, the synthesis of chiral aminophosphanes derived from tartaric acid and their use in asymmetric alkylation.[8] We describe in this paper a full account of the synthesis of these new chiral ligands and their use as ligands in asymmetric alkylation, as well as a theoretical study concerning the nucleophilic attack on π-allyl(palladium) complexes associated with these ligands.

Results and Discussion

Synthesis of the P,N-Based Ligands

Ligands **3a**−**d**, bearing at least one aryl group at the nitrogen atom, were prepared from commercially readily available bis(tosylate) **1** (Scheme 1). Reaction of **1** at −17 °C in tetrahydrofuran with one equiv. of lithium diphenylamide, obtained by treating diphenylamine with *n*-butyllithium at −78 °C, gave diphenylamino tosylate **2a** in 26% yield. Subsequent treatment of compound **2a** with lithium diphenylphosphide in tetrahydrofuran led to the formation of the diphenylamino phosphane **3a** in 40% yield. Steric and electronic modifications of the substituents at the nitrogen atom were introduced with methyl(phenyl)-, *p*-methoxyphenyl(methyl)- and phenyl(α-naphthyl)amine instead of diphenylamine; the corresponding amino phosphanes **3b**, **3c**, and **3d** were obtained in 18%, 7%, and 21% yield, respectively, from compound **1**. All attempts to introduce the *p*-nitrophenyl(methyl)amino group failed, only the elimination product was observed.

d : $R^1 = C_6H_5$, R^2 = α-naphtyl

Scheme 1. a: $LiNR^1R^2$, THF, −17 °C; b: $LiPPh_2$, THF, 25 °C

Reaction of monotosylate **4**[9] with sodium azide in DMF gave the azido alcohol **5** in 95% yield (Scheme 2). Reduction of compound **5** with molecular hydrogen in the presence of 20% Pd/C led quantitatively to the amino alcohol **6**. Condensation of this amino alcohol **6** with two equiv. of benzyl bromide, 2,4,6-trimethylbenzyl bromide, 2-naphtylmethyl bromide or 2,2′-bis(bromomethyl)biphenyl in acetonitrile in the presence of potassium carbonate gave the bis(alkylamino) alcohols **7a**−**d** in 58−85% yield. Tosylation of these

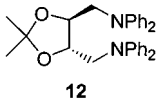
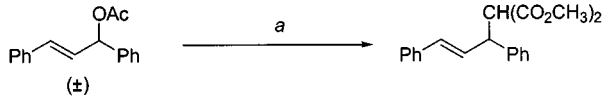


Scheme 2. a: NaN_3, DMF, 24 h, 95%; b: H_2, Pd/C, EtOH, 48 h, 100%; c: RCH_2Br (2 equiv.), K_2CO_3, CH_3CN, 30 min; d: $LiPPh_2$, THF, 25 °C

bis(alkylamino) alcohols **7** led to the bis(alkylamino) tosylates **8a**−**d**, whose treatment by lithium diphenylphosphide gave the desired bis(alkylamino) phosphanes **9a**−**d** in 40%, 45%, 20%, and 80% yield, respectively.

Reaction of amino alcohol **6** with two equiv. of tosyl chloride in pyridine gave the bis(tosylate) **10** in 65% yield (Scheme 3); tosylamino diphenylphosphane **11** was obtained in 73% yield by subsequent treatment of **10** with more than two equiv. of lithium diphenylphosphide. Finally, the bis(diphenyl)amino ligand **12** was obtained as a byproduct in the preparation of compound **2a**.



Scheme 3. a: TsCl, C_5H_5N, 25 °C, 65%; b: $LiPPh_2$, THF, 25 °C

Asymmetric Alkylation

The effectiveness of the above ligands in asymmetric allylic alkylation was tested in the reaction of racemic (*E*)-1,3-diphenylprop-2-enyl acetate with dimethyl malonate; an in situ catalyst prepared from $Pd_2(dba)_3$ and the chiral ligand in THF was used (Scheme 4).

Scheme 4. a: $CH_2(CO_2Me)_2$, base, cat. $Pd_2(dba)_3$, ligand

As a typical procedure, tris(dibenzylideneacetone)dipalladium and the amino phosphane were mixed in a solvent at room temperature under argon; *rac*-(*E*)-1,3-diphenylprop-2-enyl acetate was added, then the sodium salt of dimethyl malonate was added to the π-allylpalladium complex solution. The substituted product thus obtained was isolated by chromatography. The results are summarized in Table 1.

Table 1. Allylic alkylation of (±)-(*E*)-1,3-diphenylpropenyl acetate with dimethyl malonate, catalyzed by palladium complexes[a]

Entry	Ligand	Solvent	Conversion (%)[b]	ee (%)[b]

[a] [acetate]/[malonate]/[NaH]/[$Pd_2(dba)_3$]/[ixgand] = 50:150:150:1:2; solvent: THF; 25 °C; 24 h. − [b] Determined by HPLC analysis with chiral stationary column Daicel Chiralcel OD−H (hexane/2-propanol 98:2); the configuration of the alkylated product was (*S*).[10] − [c] *N*,*O*-Bis(trimethylsilyl)acetamide (or BSA) and KOAc were used instead of NaH. − [d] *N*,*O*-Bis(trimethylsilyl)acetamide only was used instead of NaH.

It should first be noted that the use of ligands with C_2 symmetry, such as DIOP or ligand **12**, led to the formation of the racemic alkylated product (Entries 1−2). Ligands **3a**−**d** gave enantioselectivities up to 69% in THF as the solvent (Entries 3−6). Dissymmetrization at the nitrogen atom increased the enantioselectivity, although an enantioselectivity of 50% was observed with **3a** as the ligand; values of 68% and 69% were obtained in the presence of **3b** or **3d**, respectively. The presence of a methoxy group on the phenyl ring lowered the enantioselectivity (63% for **3c**). To increase the enantioselectivity, the alkylation was performed under various conditions, with **3d** as the ligand. While the use of BSA as the base in the presence of KOAc gave both lower yield and enantioselectivity (Entry 7), performing the reaction in CH_2Cl_2 gave almost the same e.e. (68%) in the

presence or absence of KOAc (Entries 8−9). The use of toluene (Entry 10) or a mixture of toluene/CH_2Cl_2 (Entry 11) as solvent again gave low yield and enantioselectivity. The use of ligands **9** in this alkylation reaction led to high chemical yields, with enantioselectivities depending on the nature of the aromatic ring. The highest enantioselectivity (75%) was obtained with ligand **9b**, which has 2,4,6-trimethylbenzyl substituents on the nitrogen atom. Finally, ligand **11** gave low yield (only 49%) and quite modest enantioselectivity (39%). To obtain more insight into the reasons behind the high enantioselectivities when these ligands are used, we undertook a theoretical study.

Theoretical Study

Some theoretical studies on η^3-allyl complexes of palladium have already been reported. In the past, semi-empirical methods have been used to study the nucleophilic attack on such complexes: Extended Hückel type (EHT) calculations were carried out to probe the effect of ligand asymmetry,[11] to distinguish between the central and the terminal carbon atoms,[12] to calculate the effect of the substituents on the regioselectivity,[13] and CNDO type calculations were carried out to determine the ligand effects.[14] The conclusions of these studies were that the nucleophilic attack on η^3-allylpalladium complexes is orbital-controlled rather than charge-controlled. More recently, studies using ab initio methods, both at the Hartree−Fock level and with the density functional theory (DFT), have begun to appear.[15−20]

In the present work we have used both types of methods, EHT and DFT. To determine the site of the nucleophilic attack, we have used the same method as in our previous work.[13] Since the reaction is frontier orbital controlled, we have focused first on the shape of the complex LUMO (Lowest Unoccupied Molecular Orbital) which interacts with the nucleophile HOMO (Highest Occupied Molecular Orbital). The larger the coefficient on one carbon atom in this orbital, the easier is the attack of the nucleophile on that carbon atom. Then we have put some nucleophiles at the same distance to both terminal carbon atoms and compared the overlap populations. These calculations are based on the EHT method. However, it is known from experiments that the presence of ligands of different natures on the palladium center induces a dissymmetry in the complex.[21−23] The EHT method does not allow the optimization of geometries. This is why we used a DFT method for these optimizations, to have reliable geometries for the EHT calculations.

Computational Methods

The parameters used for the EHT calculations are the usual ones[24][25] and the program is ICON version 8.0 from the group of R. Hoffmann at Cornell University.[26] The ab initio calculations are performed with Gaussian 94[27] with the DFT formalism. The chosen function is that of Perdew and Wang (BPW91). For palladium and phosphorus, the pseudopotentials of Hay and Wadt are used with the corresponding double ζ basis set of Dunning/Huzinaga (D95). A d polarization function is added to the palladium, nitrogen and carbon atoms. The ligands on the phosphorus center are modelled by PH_3 and NH_3 to save computational time. Since the allyl moiety is symmetrical with one phenyl group on each terminal carbon atom, we chose to model it in the first instance by the unsubstituted allyl group C_3H_5. By doing this, we obtained the electronic effects without taking into account the steric effects.

Results

The optimized geometry is shown in Figure 1. The most important information is that the Pd−$C_{trans\text{-}P}$ bond (2.23 Å) is longer than the Pd−$C_{trans\text{-}N}$ one (2.16 Å). This result can be explained by the *trans* effect of the phosphorus atom, which is greater than that of the nitrogen atom.[28] Experimentally, the same difference was observed,[15] although the nitrogen ligand was not of the same nature (sp^2 instead of sp^3). The C^1-C^2 and C^2-C^3 bond lengths are not equal either (1.417 and 1.432 Å, respectively). This means that the C^2-C^3 bond has a weaker double bond character. The carbon atoms C^1 and C^3 are 0.14−0.15 Å above the P−Pd−N plane, and the allyl plane makes an angle of 111° with the Pd−C^1−C^3 plane. Similar geometries were found experimentally.[22,23,29] The charge on carbon atoms C^1 and C^3 (0.55 e^-) is the same. As found in our previous EHT study, the LUMO is mainly the antibonding combination of the d_{xy} orbital of the metal center and the n-allyl orbital and the next unoccupied orbital is composed almost exclusively of the π*-allyl orbital.

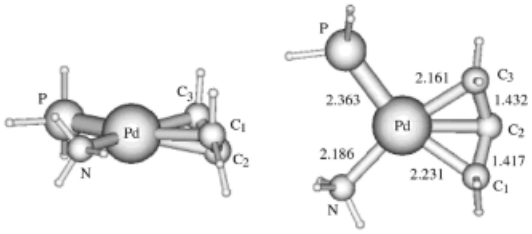

Figure 1. Optimized geometry for palladium complex Pd(NH_3)(PH_3)(η^3-allyl)

After this geometry optimization, we performed EHT calculations, following the method of our previous work.[13] We choose the same standard distances but we kept the difference between Pd−C^1 and Pd−C^3 bonds fixed (0.08 Å). The following geometry was used: Pd−P = 2.3 Å, Pd−N = 2.15 Å, Pd−C^1 = 2.20 Å, Pd−C^3 = 2.12 Å, $C^1-C^2 = C^2-C^3$ = 1.43 Å, P−Pd−N = 100°. For the sake of simplicity, the allyl plane was taken to be perpendicular to the P−Pd−N plane and to the bisector of the P−Pd−N angle. The hydrogen atoms on the carbon atoms C^1 and C^3 are bent away from the metal center by 15°. The projection on the *xy* plane is shown in Figure 2. The complex LUMO is also shown.

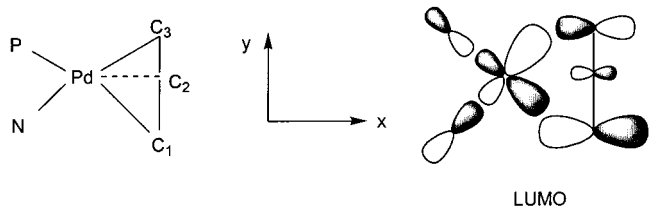

Figure 2. Projection of the model allyl−Pd complex on the *xy* plane and shape of its LUMO

We observe that the p_x coefficient is larger on the carbon atom C^1 than on C^3 (0.53 and 0.48, respectively). If the reaction is orbital-controlled, an incoming nucleophile will prefer to attack the carbon atom with the largest contribution in the LUMO. Hence it will preferentially attack C^1, *trans* to the phosphorus atom. Why is the LUMO dissymmetrical? The molecular orbital interaction diagram between the P−Pd−N and the allyl fragments shows that the LUMO, which is mainly antibonding between d_{xy} and the n-allyl orbital, also contains a small antibonding contribution of the π-allyl orbital and a small bonding contribution of the π*-allyl orbital, according to Equation 1.

$$\text{LUMO} = 0.80\ (\text{Pd}-\text{P}-\text{N LUMO}) - 0.69\ (\text{n}) - 0.04\ (\pi) + 0.08\ (\pi^*) \quad (1)$$

In fact, the LUMO of the P−Pd−N fragment is dissymmetric because the two ligands are different. This allows the mixing of the three allyl orbitals which are of different symmetry and they do not mix when the metal fragment is symmetrical (Figure 3).

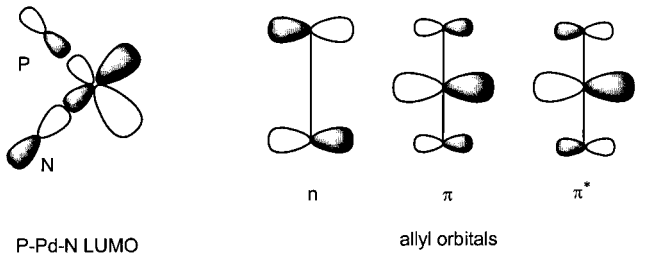

Figure 3. Shape of the LUMO of the P−Pd−N fragment and of the n, π and π* orbitals of the allyl fragment

However, we saw previously that other metal orbitals must be taken into account in the interaction with a nucleophile: for instance, the next LUMO and some occupied orbitals which have contributions to p_x of C^1 and p_x of C^3. Therefore, we tested the approach of some nucleophiles by putting them at the same distance to carbon atoms C^1 and C^3, and comparing the overlap population that represents the strength of the formed bond. To avoid too many steric repulsions, the allyl part is taken as being planar, this means that the hydrogen atoms are no longer bent away from the palladium center but are in the allyl plane (this looks like the transition state of an S_N2 reaction). We chose NH_3, $NHMe_2$ and the malonate anion $^-CH(CO_2Me)_2$ as nucleophiles, the latter of which is the nucleophile experimentally used in the present work. The amines and the malonate anion are put at 2 Å and 2.1 Å away from the carbon atoms, respectively. The best conformation of the nucleophile was searched for by rotating around the approach axis. The results are shown in Table 2. For all nucleophiles, the overlap population is larger with carbon atom C^1 than with C^3; this confirms that a nucleophile will preferentially attack at the carbon atom *trans* to the phosphorus atom, as long as only electronic interactions are taken into account. It is obvious that steric constraints, if for instance the carbon atoms are substituted, can reverse this trend.

Table 2. Overlap populations between a nucleophile and the terminal carbon atoms C^1 and C^3; energy in eV of the nucleophile HOMO

Nucleophile	HOMO	C^1	C^3
NH_3	−13.71	0.143	0.138
$NH(Me)_2$	−12.95	0.157	0.152
$^-HC(CO_2Me)_2$	−12.35	0.180	0.175

The interaction between the nucleophile and the allylic complex can be separated into terms of two-electron and four-electron interactions, by a simple perturbational treatment.[13][30] We consider the function f(x), which is the sum of the stabilizing interactions of the nucleophile HOMO with the vacant orbitals of the complex and the destabilizing interactions between the nucleophile HOMO and the occupied orbitals of the complex (Equation 2). The more positive f(x) is, the more the interaction is stabilizing.

$$f(x) = 0.75\Sigma(x + E_i)\ C_i^2 + \Sigma(0.875\ E_j - 0.125x)^2\ C_j^2/(E_j - x) \quad (2)$$

In Equation 2, x is the energy of the nucleophile HOMO, C_i and C_j are the coefficients of the p_x orbital of the attacked carbon atom in the occupied and vacant complex orbitals, respectively, and E_i and E_j are the energies of the corresponding complex orbitals; x was varied and f(x) was calculated for C_1 [$f_1(x)$] and C_3 [$f_3(x)$]. The difference $F(x) = f_1(x) - f_3(x)$ is drawn in Figure 4. If $F(x) < 0$, the nucleophile prefers carbon atom C^3, if $F(x) > 0$, the nucleophile prefers C^1. The attack preference depends on the HOMO of the nucleophile. For a high-lying HOMO (see Table 2), such as that of the malonate anion, carbon atom $C^{1\ trans}$ to the phosphorus atom is preferentially attacked; this agrees with the experimental results. The attractive two-electron interactions always favor the attack on $C_{trans\text{-}P}$ and, conversely, the repulsive four-electron interactions favor the attack on $C_{cis\text{-}P}$. Therefore, the site of attack depends on the balance between these two terms. The attractive term increases greatly with the HOMO energy. The repulsive term, being proportional to the sum of the interacting orbital energies (Equation 2), depends little on the HOMO position.

We therefore explained why the electronic interactions favor attack on carbon atom $C_{trans\text{-}P}$. We can predict that the use of a nucleophile with a higher HOMO than malonate, such as $^-C(CH_3)(CO_2Me)_2$, for example, would enhance the regioselectivity. How can the enantioselectivity be

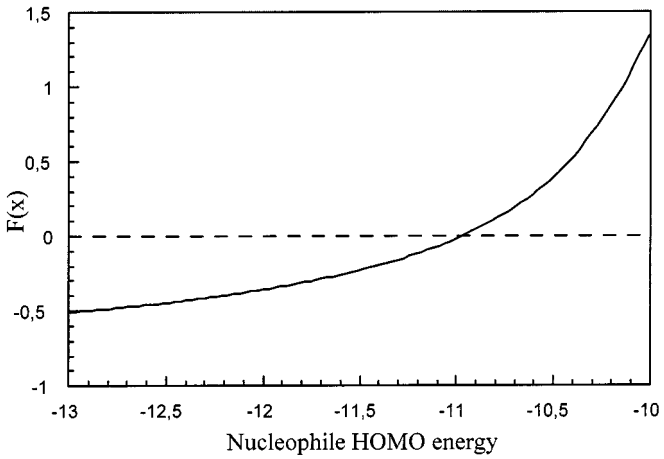

Figure 4. Plot of f(x) versus energy of the nucleophile HOMO

explained? For the π-allylpalladium complexes, two diastereoisomers are possible, *exo* and *endo* (Figure 5).

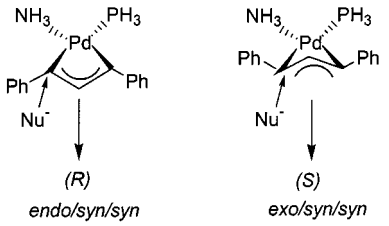

Figure 5. Most stable diastereoisomers of the model $(PH_3)(NH_3)$-(1,3-diphenylallyl)Pd complex

The phenyl rings may be positioned *syn* or *anti*, therefore eight diastereoisomers are possible. Using the EHT method, we calculated all of them and optimized the angle of the phenyl rings with the allyl plane. When the phenyl group is *syn*, it prefers to be in the allyl plane, when it is *anti*, it prefers to be perpendicular to this plane. This is in agreement with previous calculations.[5] The most stable isomers (by 13 kcal mol^{-1}) are those depicted in Figure 5 (*exo*/*syn*/*syn* and *endo*/*syn*/*syn*). With our model ligands PH_3 and NH_3, they are quasi isoenergetic, which cannot explain the enantioselectivity, since, by attack *trans* to the phosphorus atom, they each lead to one of the enantiomers (*S*) and (*R*). We therefore modeled the real catalyst by substituting the phosphorus and nitrogen atoms with phenyl and methyl groups, as shown in Figure 6. This corresponds to real catalysts [Pd/**3a**] and [Pd/**3b**], obtained by association of the palladium center with ligands **3a** and **3b**.

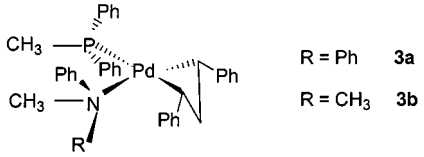

Figure 6. Modeling of the catalyst $Pd(CH_3PPh_2)(CH_3NPhR)(\eta^3$-1,3-diphenylallyl)

The substituents on the phosphorus and nitrogen atoms are disposed in a geometry that reproduced the X-ray structure of DIOP.[31] We calculated the *exo* and *endo* isomers for both [Pd/**3a**] and [Pd/**3b**]. For [Pd/**3b**] there are two *exo* and two *endo* isomers depending on the relative position (pseudo-axial or pseudo-equatorial) of the C_6H_5 and CH_3 substituents on the nitrogen atom. For [Pd/**3a**] the *exo* form is more stable by 30 kcal mol^{-1}. For [Pd/**3b**], the *exo* form is more stable by 18 kcal mol^{-1} when the methyl group is pseudo-axial and the *endo* form is more stable by 67 kcal mol^{-1} when the methyl group is pseudo-equatorial. However, the structure with the pseudo-equatorial methyl group is far less stable than that with the pseudo-axial one (47 kcal mol^{-1}). Therefore, of the four diastereoisomers of [Pd/**3b**], the most stable also has the *exo* geometry. The *exo* form of [Pd/**3a**] and [Pd/**3b**], attacked *trans* to the phosphorus atom, gives the (*S*) enantiomer, which is the one experimentally obtained. Despite the fact that the EHT method only gives qualitative results, the energy differences are large enough to be reliable. Hence, the enantioselectivity is explained by the existence of only one diastereoisomer of the complexes [Pd/**3a**] and [Pd/**3b**], regioselectively attacked *trans* to the phosphorus atom.

Conclusion

In conclusion, the new chiral amino phosphane ligands, easily obtained from tartaric acid, give enantioselectivities of up to 75% in the palladium-catalyzed alkylation of racemic 1,3-diphenylprop-2-enyl acetate with malonate anion. The calculations summarized in this paper allow the origin of the enantioselectivity in this asymmetric allylic alkylation to be understood. Two factors play an important role. The first one is steric control, which leads to the formation of a unique diastereoisomer (*exo*) of the η^3-allylpalladium complex. The second one is orbital control, which orients the nucleophile attack *trans* to the phosphorus atom; this is due to the dissymmetrical ligand. This is not the case for DIOP or ligand **12**. Our calculations also allow some predictions: To enhance the enantioselectivity, the HOMO of the nucleophile must be as high as possible. This means that the anion of $CH(CH_3)(CO_2Me)_2$ or of cyclopentanedione should be more efficient than the malonate anion $CH(CO_2Me)_2^-$

Experimental Section

General Remarks: ^{1}H NMR (200 or 300 MHz), ^{13}C NMR (50 or 75 MHz), and ^{31}P NMR (80 MHz) spectra were obtained with a Brüker AM 200 or AM 300 spectrometer. − Optical rotations were determined with a Perkin−Elmer 241 polarimeter. − GC analyses were recorded with a Shimadzu capillary gas chromatograph, equipped with a Chiraldex™ type B−PH (30 m × 0.32 mm) capillary column. − Reactions involving organometallic catalysis were carried out in Schlenk tubes under an inert gas. Tetrahydrofuran was distilled from sodium/benzophenone. (2*S*,3*S*)-2,3-*O*-Isopropylidene-1-*O*-*p*-toluenesulfonyl-D-threitol (**4**) was prepared according to a literature procedure.[9]

General Procedure for Preparation of Amino Tosylates 2: A solution of the lithium derivative of the secondary amine, obtained by mixing the amine (5 mmol) and butyllithium in hexane (5 mmol) in

THF (5 mL), was slowly added to a solution of ditosylate **1** (2.35 g, 5 mmol) in THF (5 mL) at −17°C. The solution was stirred for 1 h at −17°C, then 12 h at room temperature, and was finally treated with H_2O (50 mL). The organic compound was extracted with CH_2Cl_2 (3 × 50 mL). Evaporation of the solvent, followed by flash chromatography gave the amino tosylate **2**.

(2*S*,3*S*)-4-Diphenylamino-2,3-*O*-isopropylidene-1-*O*-tosylbutane-1,2,3-triol (2a): 26% yield; R_f = 0.5 (eluent: hexane/ethyl acetate, 4:1); $[\alpha]_D^{20}$ = +8.5 (*c* = 1.1, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.29 (s, 3 H, CH_3), 1.38 (s, 3 H, CH_3), 2.43 (s, 3 H, CH_3), 3.90−4.05 (m, 5 H, CH_2N, CH_2O, CHO), 4.05−4.20 (m, 1 H, CHO), 6.90−7.10 (m, 6 H, H_{arom}), 7.15−7.30 (m, 6 H, H_{arom}), 7.71 (d, *J* = 8.3 Hz, 2 H, H_{arom}). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 21.6 (CH_3), 26.8 (CH_3), 27.2 (CH_3), 55.0 (d, CH_2N), 69.2 (CH_2O), 76.0 (CHO), 76.9 (CHO), 110.2 (CMe_2), 121.2, 121.9, 128.0, 129.4, 129.8, 132.5, 145.0 and 148.0 (C_{arom}). − $C_{26}H_{29}NO_5S$ (467.58): calcd. C 66.79, H 6.86; found C 66.65, H 6.57.

(2*S*,3*S*)-2,3-*O*-Isopropylidene-4-methyl(phenyl)amino-1-*O*-tosylbutane-1,2,3-triol (2b): 32% yield; R_f = 0.4 (eluent: hexane/ethyl acetate, 4:1); $[\alpha]_D^{20}$ = +24.6 (*c* = 1.1, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.31 (s, 3 H, CH_3), 1.39 (s, 3 H, CH_3), 2.45 (s, 3 H, CH_3), 2.95 (s, 3 H, CH_3), 3.46 (dd, *J* = 15.0, 5.7 Hz, 1 H, CH_2N), 3.55 (dd, *J* = 15.0, 4.5 Hz, 1 H, CH_2N), 3.90−4.05 (m, 1 H, CHO), 4.05−4.20 (m, 3 H, CH_2O, CHO), 6.70 (m, 3 H, H_{arom}), 7.25 (m, 2 H, H_{arom}), 7.38 (d, *J* = 8.5 Hz, 2 H, H_{arom}), 7.76 (d, *J* = 8.5 Hz, 2 H, H_{arom}). − $C_{21}H_{27}NO_5S$ (405.51): calcd. C 62.20, H 6.71; found C 62.65, H 7.11.

(2*S*,3*S*)-2,3-*O*-Isopropylidene-4-*p*-methoxyphenyl(methyl)amino-1-*O*-tosylbutane-1,2,3-triol (2c): 25% yield; R_f = 0.55 (eluent: hexane/ethyl acetate, 3:1); $[\alpha]_D^{20}$ = +6.3 (*c* = 0.7, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.30 (s, 3 H, CH_3), 1.40 (s, 3 H, CH_3), 2.88 (s, 3 H, CH_3), 2.89 (s, 3 H, CH_3), 3.40 (d, *J* = 5.2 Hz, 2 H, CH_2N), 3.78 (s, 3 H, CH_3), 3.90−4.05 (m, 1 H, CHO), 4.05−4.20 (m, 3 H, CH_2O, CHO), 6.60−7.00 (m, 4 H, H_{arom}), 7.20−7.40 (m, 2 H, H_{arom}). − $C_{22}H_{29}NO_6S$ (435.54): calcd. C 60.67, H 6.71; found C 61.82, H 6.40.

(2*S*,3*S*)-2,3-*O*-Isopropylidene-4-α-naphthyl(phenyl)amino-1-*O*-tosylbutane-1,2,3-triol (2d): 25% yield; R_f = 0.42 (eluent: hexane/ethyl acetate, 5:1); $[\alpha]_D^{20}$ = +21.6 (*c* = 0.8, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.30 (s, 3 H, CH_3), 1.41 (s, 3 H, CH_3), 2.38 (s, 3 H, CH_3), 3.95−4.10 (m, 5 H, CH_2N, CH_2O, CHO), 4.15−4.25 (m, 1 H, CHO), 7.00−7.50 (m, 11 H, H_{arom}), 7.60−7.80 (m, 4 H, H_{arom}). − $C_{30}H_{31}NO_5S$ (517.64): calcd. C 69.61, H 6.04; found C 69.18, H 6.17.

(2*S*,3*S*)-4-Azido-2,3-*O*-isopropylidenebutane-1,2,3-triol (5): A mixture of (2*S*,3*S*)-2,3-*O*-isopropylidene-1-*O*-*p*-toluenesulfonyl-D-threitol (**4**)[9] (11.8 g, 37.5 mmol) and NaN_3 (3.5 g, 58 mmol) in DMF (95 mL) was heated at reflux for 24 h. After being cooled to room temperature, the solution was treated with H_2O (50 mL) and was then extracted with CH_2Cl_2 (3 × 50 mL). Evaporation of the solvent, followed by column chromatography (eluent: petroleum ether/ethyl acetate, 2:1) gave 6.6 g of compound **5** as an oil (95%); R_f = 0.3; $[\alpha]_D^{20}$ = −65.7 (*c* = 2.5, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.36 (s, 3 H, CH_3), 1.41 (s, 3 H, CH_3), 2.84 (s, 1 H, OH), 3.34 (dd, *J* = 13.1, 4.6 Hz, 1 H, CH_2N), 3.55 (dd, *J* = 13.1, 3.7 Hz, 1 H, CH_2N), 3.74 (dd, *J* = 13.8, 3.9 Hz, 1 H, CH_2O), 3.86 (dd, *J* = 13.8, 4.0 Hz, 1 H, CH_2O), 4.02 (ddd, *J* = 11.4, 4.6, 3.7 Hz, 1 H, CHO), 4.07 (ddd, *J* = 11.4, 4.0, 3.9 Hz, 1 H, CHO). − $C_7H_{13}N_3O_3$ (187.20): calcd. C 44.91, H 6.00; found C 44.96, H 7.28.

(2*S*,3*S*)-4-Amino-2,3-*O*-isopropylidenebutane-1,2,3-triol (6): A solution of azido alcohol **5** (3 g, 16 mmol) in ethanol (20 mL) was hydrogenated at room temperature and atmospheric pressure in the presence of 20% Pd/C (300 mg). After 48 h, the solution was filtered and the solvent was evaporated to give 2.57 g of amino alcohol **6** as an oil (100%); $[\alpha]_D^{20}$ = −47.3 (*c* = 1.0, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.32 (s, 3 H, CH_3), 1.38 (s, 3 H, CH_3), 2.20−2.50 (br. s, 3 H, NH_2, OH), 2.76 (dd, *J* = 12.6, 8.0 Hz, 1 H, CH_2N), 3.18 (dd, *J* = 12.6, 4.3 Hz, 1 H, CH_2N), 3.70−3.92 (m, 4 H, CH_2O, CHO). $C_7H_{15}NO_3$ (161.20): calcd. C 52.16, H 9.38; found C 51.76, H 9.16.

General Procedure for the Preparation of Amino Alcohols 7: The bromide (12.4 mmol) was slowly added to a mixture of amino alcohol **6** (1 g, 6.2 mmol) and K_2CO_3 (2,57 g, 18.6 mmol) in CH_3CN (6 mL), heated at reflux for 30 min. The reaction mixture was refluxed for 24 h, then cooled at room temperature, and treated with H_2O (10 mL). The solution was extracted with CH_2Cl_2 (3 × 30 mL). Evaporation of the solvent, followed by flash chromatography gave the corresponding dialkylated amino alcohol **7**.

(2*S*,3*S*)-4-Dibenzylamino-2,3-*O*-isopropylidenebutane-1,2,3-triol (7a): 85% yield; R_f = 0.3 (eluent: petroleum ether/ethyl acetate, 4:1); $[\alpha]_D^{20}$ = +32.1 (*c* = 0.8, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.35 (s, 3 H, CH_3), 1.40 (s, 3 H, CH_3), 2.63 (s, 1 H, OH), 2.72 (d, *J* = 5.5 Hz, 2 H, CH_2N), 3.60−3.90 (m, 8 H, CH_2O, CHO, CH_2N), 7.30−7.50 (m, 10 H, H_{arom}). − $C_{21}H_{27}NO_3$ (341.45): calcd. C 73.87, H 7.97, N 4.10; found C 73.73, H 8.12, N 4.04.

(2*S*,3*S*)-4-Bis(2,4,6-trimethylbenzyl)amino-2,3-*O*-isopropylidenebutane-1,2,3-triol (7b): 76% yield; R_f = 0.4 (eluent: petroleum ether/ethyl acetate, 4:1); $[\alpha]_D^{20}$ = +10.2 (*c* = 1, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ 1.35 (s, 3 H, CH_3), 1.41 (s, 3 H, CH_3), 1.65 (s, 1 H, OH), 2.23 (s, 6 H, CH_3), 2.26 (s, 12 H, CH_3), 2.58 (m, 2 H, CH_2N), 3.40−3.50 (m, 4 H, CH_2O), 3.49 (d, *J* = 12.5 Hz, 2 H, CH_2N), 3.69 (d, *J* = 12.5 Hz, 2 H, CH_2N), 3.80−4.00 (m, 2 H, CHO), 6.75 (s, 4 H, H_{arom}). − $C_{27}H_{39}NO_3$ (425.62): calcd. C 76.24, H 9.17; found C 76.21, H 9.34.

(2*S*,3*S*)-4-Bis(2-naphtylmethyl)amino-2,3-*O*-isopropylidenebutane-1,2,3-triol (7c): 82% yield; R_f = 0.34 (eluent: petroleum ether/ethyl acetate, 4:1); $[\alpha]_D^{20}$ = +14.0 (*c* = 0.65, $CHCl_3$). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.32 (s, 3 H, CH_3), 1.38 (s, 3 H, CH_3), 1.61 (s, 1 H, OH), 2.81 (d, *J* = 5.7 Hz, 2 H, CH_2N), 3.73 (d, *J* = 13.3 Hz, 2 H, CH_2N), 3.98 (d, *J* = 13.3 Hz, 2 H, CH_2N), 3.50−3.70 (m, 4 H, CH_2O), 4.00−4.20 (m, 2 H, CHO), 7.64 (m, 6 H, H_{arom}), 7.80−7.90 (m, 8 H, H_{arom}). − $C_{29}H_{31}NO_3$ (441.57): calcd. General Procedure for Preparation of Aminotosylates 8: p-Toluenesulfonyl chloride (1.13 g, 5.9 mmol, 1.1 equiv.) was added at 0°C to a solution of amino alcohol **7** (5.3 mmol) in pyridine (10 mL). After being stirred for 12 h, the solution was treated with cold H_2O (20 mL), and the organic product was extracted with CH_2Cl_2 (3 × 10 mL). Evaporation of the solvent gave a residue which was purified by flash chromatography to give the amino tosylate **8**.

Asymmetric Alkylation. − Typical Procedure: A solution of the sodium salt of dimethyl malonate, prepared from dimethyl malonate (118.9 mg, 0.900 mmol) and sodium hydride in THF (2 mL) at room temperature, was added to a mixture of $Pd_2(dba)_3$ (55 mg, 6.10^{-3} mmol), ligand (12.10^{-3} mmol) and *rac*-(*E*)-1,3-diphenylprop-2-enyl acetate (75.7 mg, 0.300 mmol) in THF (2 mL). The solution was stirred for 24 h and was then quenched with a small amount of water. Evaporation of the solvent, followed by column chromatography gave the alkylated product. The conversion and enantiomeric purity was determined by HPLC with a chiral stationary phase column Chiraldex OD−H (hexane/2-propanol = 98:2). The absolute configuration was determined by polarimetry.[10]

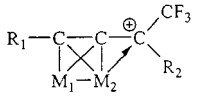
Reduction of Metal-Stabilized α-CF_3-Carbenium Ion Complexes under Mild Conditions: Synthesis, Structures, and Reactivity

Michel Gruselle,*[a] Bernard Malézieux,[a] Román Andrés,[a] Hani Amouri,[a] Jacqueline Vaissermann,[a] and Gagik G. Melikyan[b]

Keywords: Radicals / Carbenium ions / Clusters / Cobalt / Molybdenum



Complexed α-CF_3 propargyl alcohols of the general formula [(M_2L_6)\{μ-η^2,η^2-RC≡CCH(CF_3)(OH)\}] were prepared with M_2L_6 = $Co_2(CO)_6$, R = $CH_3(CH_2)_4$– (**1**), R = C_6H_5– (**2**); M_2L_6 = $Co_2(CO)_5P(C_6H_5)_3$, R = $CH_3(CH_2)_4$– (**3a**,**b**), R = C_6H_5– (**4a**,**b**); M_2L_6 = $Co_2(CO)_4$dppm, R = C_6H_5– (**5**); M_2L_6 = $Co(CO)_3$-MoCp$(CO)_2$, R = $CH_3(CH_2)_4$– (**6a**,**b**), R = C_6H_5– (**7a**,**b**). An X-ray molecular structure of the propargyl-alcohol complex [\{$Co_2(CO)_4$dppm\}\{μ-η^2,η^2-C_6H_5C≡CCH(CF_3)(OH)\}] (**5**) was also determined. The related carbenium ions [(M_2L_6)\{μ-η^2,η^3-RC≡CCH(CF_3)\}][BF_4] (**8–12**) were obtained from the parent propargyl alcohol complexes by direct protonation with HBF_4 · Et_2O in diethyl ether. These carbenium ions were reduced further by Zn in CH_2Cl_2 to give the alkyne adducts [(M_2L_6)\{μ-η^2,η^2-RC≡C$CH_2(CF_3)$\}] (**13–17**), as confirmed by the X-ray molecular structure of [$(Co_2(CO)_4$dppm)\{μ-η^2,η^2-C_6H_5-C≡C$CH_2(CF_3)$\}] (**17**). Treatment of the carbenium ion complex [\{$Co(CO)_3$MoCp$(CO)_2$\}\{μ-η^2,η^3-$CH_3(CH_2)_4$C≡CCH(CF_3)\}][BF_4] (**8**) with NaSMe unexpectedly afforded the reduced alkyne adduct [\{$Co(CO)_3$MoCp$(CO)_2$\}\{μ-η^2,η^2-$CH_3(CH_2)_4$C≡CCH_2-(CF_3)\}] (**13**), along with the alkyne-thioether diastereomers \{$Co(CO)_3$MoCp$(CO)_2$\}\{μ-η^2,η^2-$CH_3(CH_2)_4$C≡CCH(CF_3)(SMe)\}] (**18a**,**b**). Presumably, all the reduction reactions proceed primarily by the formation of the transient radical species, which are subsequently transformed into the reduced alkyne complexes by hydrogen abstraction from the solvent medium. Interestingly, in the case of the complexed alcohols [\{$Co_2(CO)_5P(C_6H_5)_3$\}\{μ-η^2,η^2-RC≡CCH(CF_3)(OH)\}] (**3a**,**b**) and (**4a**,**b**), the reduction process occurs in acidic medium in THF/CH_2Cl_2. An extensive study of the electronic and steric factors that influence the stability and reactivity of the carbenium ions were performed, which allowed us to explain the behavior of the related radical species in solution during the reduction process.

Introduction

Trifluoromethyl propargyl alcohols are easily available,[1] however their synthetic interest is still limited, due to the difficulty of preparing the related α-CF_3 carbenium ions prior to nucleophilic addition. Functionalization of the carbenium ion in the α-position relative to the CF_3 group is therefore a hard task.[2] Furthermore, the CF_3 function is a strong electron-withdrawing group and thus strengthens the C−O bond, which prevents the formation of a carbenium center (CF_3−C^+). In addition, the steric effects and electronic repulsion of the incoming nucleophiles with fluorine atoms of the α-CF_3 group decrease the reaction rate, and harsh conditions are often required.[3][4] To overcome such difficulties it is vital to stabilize the carbenium center (CF_3−C^+). This can be achieved by introducing a dinuclear cluster such as M_2L_6 = [−$Co_2(CO)_6$]; = [−$Cp_2Mo_2(CO)_4$] or a mixed dinuclear complex = [−$Co(CO)_3$MoCp$(CO)_2$] to the acetylenic unit of the trifluoromethyl propargyl alcohols. A direct metal···C^+ interaction with carbenium center therefore occurs, which stabilizes the whole complex and allows further functionalization to proceed under mild conditions.

Metal-stabilized carbon electron deficient systems of the type [(M_2L_6)(μ-η^2,η^3-RC≡CCR_2)]$^+$ have been the focus of several reviews.[5] The analogous carbon-radical complexes were also reported.[6] In the latter, coupling reactions were observed.[7] A synthetic application of this chemistry is the preparation of cyclic diacetylenic compounds promoted by recombination of [$Co_2(CO)_6$]$_2$ diacetylenic di-radicals.[8]

Pursuing our research investigations in this field we prepared a new class of α-CF_3-propargyl alcohol complexes, in which a dinuclear cluster of the type [$Co_2(CO)_6$], [Co_2-$(CO)_5P(C_6H_5)_3$], [$Co_2(CO)_4${$P(C_6H_5)_2$}$_2CH_2$], or heterobimetallic [$Co(CO)_3$MoCp$(CO)_2$] is coordinated to the acetylenic unit (−C≡C−) (Figure 1).

M_1 = M_2 = $Co_2(CO)_6$, R_1 = $(CH_2)_4CH_3$, R_2 = C_6H_5
M_1 = $Co(CO)_3$, M_2 = $MoCp(CO)_2$, R_1 = $(CH_2)_4CH_3$, R_2 = C_6H_5
M_1 = $Co(CO)_3$, M_2 = $MoCp(CO)_2$, R_1 = $(CH_2)_4CH_3$, R_2 = CH_3

Figure 1. General formula of metal-stabilized carbenium ion

In a preliminary communication,[9] we have shown that it is possible to obtain and isolate α-CF_3 methyl- or phenyl-substituted propargylium ions, when they are stabilized by

an adjacent bimetallic $[Co_2(CO)_6]$- or $[Co(CO)_3MoCp(CO)_2]$-acetylenic cluster. Through out the paper we will use the abbreviations $[Co_2]$ for $[Co_2(CO)_6]$, and [Co,Mo] for $[Co(CO)_3MoCp(CO)_2]$.

In this paper we describe the synthesis of bimetallic $[Co_2]$ and [Co,Mo] complexed acetylenic α-CF_3 alcohols and describe their ability to give carbenium ions in acidic medium. The capacity of these ions to be reduced, either directly from the complexed propargyl alcohols or starting from the related metal-stabilized carbenium ions, has also been investigated.

Results and Discussion

Synthesis, Structure, and Characterization of α-CF_3-Propargyl Alcohol Complexes $[(M_2L_6)\{\mu\text{-}\eta^2,\eta^2\text{-}RC{\equiv}CCH(CF_3)(OH)\}]$

The α-CF_3 propargyl alcohols were synthesized by treatment of the ethyltrifluoroacetate with the appropriate lithiated acetylenic compound: RC≡CLi [R = $CH_3(CH_2)_4-$; C_6H_5-]. The obtained ketones were then reduced by $NaBH_4$ in alcoholic medium, and the resulting alcohols are subsequently complexed by $Co_2(CO)_8$ leading to the alkyne complexes $[\{Co_2(CO)_6\}\{\mu\text{-}\eta^2,\eta^2\text{-}RC{\equiv}CC(OH)(CF_3)H\}]$ {R = $CH_3(CH_2)_4$-(**1**); R = C_6H_5-(**2**)} according to Scheme 1.

Scheme 1. Preparation of complexed $[Co_2(CO)_6]$propargyl alcohols

Substitution of a carbonyl ligand of complexes **1**−**2** by either a monophosphane $[P(C_6H_5)_3]$ or a chelating phosphane such as dppm = $[\{P(C_6H_5)_2\}_2CH_2]$ using standard methods[10] leads to the phosphane−$[Co_2]$-complexed alcohols **3a**, **3b**, **4a**, **4b**, and **5**. All compounds were completely characterized further, and the X-ray molecular structure of $[\{Co_2(CO)_4dppm\}\{\mu\text{-}\eta^2,\eta^2\text{-}C_6H_5C{\equiv}CCH(CF_3)(OH)\}]$ (**5**) was determined. This compound crystallizes in the monoclinic unit cell, space group *P*21/n. The bonding and molecular geometry of **5** are shown in a CAMERON[24] diagram in Figure 2. Crystallographic data and parameters for **5** are given in Table 4, selected bond lengths and angles are listed in Table 1. Complex **5** consists of a tetrahedral Co_2C_2 core with −C≡C− bond of the acetylene unit in a perpendicular orientation at a almost 90° angle relative to Co−Co bond. The metal-metal bond length of 2.473 Å conforms with previous literature values for a single Co−Co bond.[11] The coordination geometry of each Co center is a distorted octahedron occupied by the acetylene carbons, two carbonly ligands and a coordinated phosphane ligand of the bridged dppm unit.

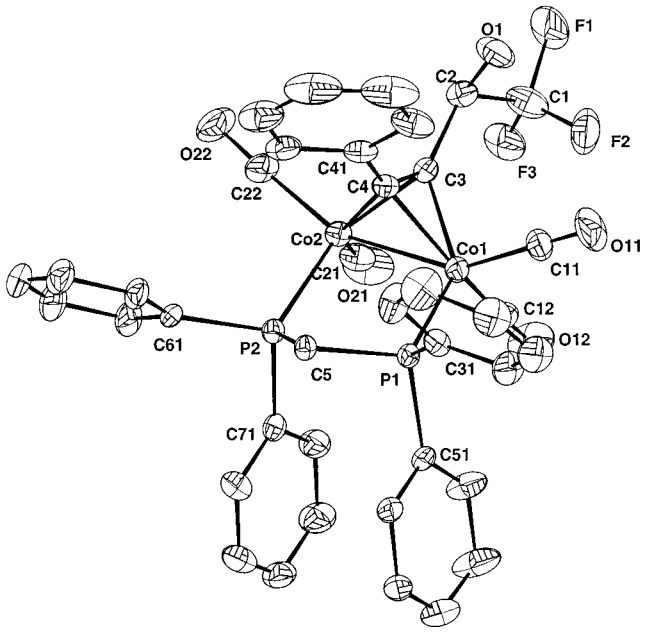

Figure 2. X-ray molecular structure of $[\{Co_2(CO)_4dppm\}\{\mu\text{-}\eta^2,\eta^2\text{-}C_6H_5C{\equiv}CCH(CF_3)(OH)\}]$ (**5**) with atom numbering system

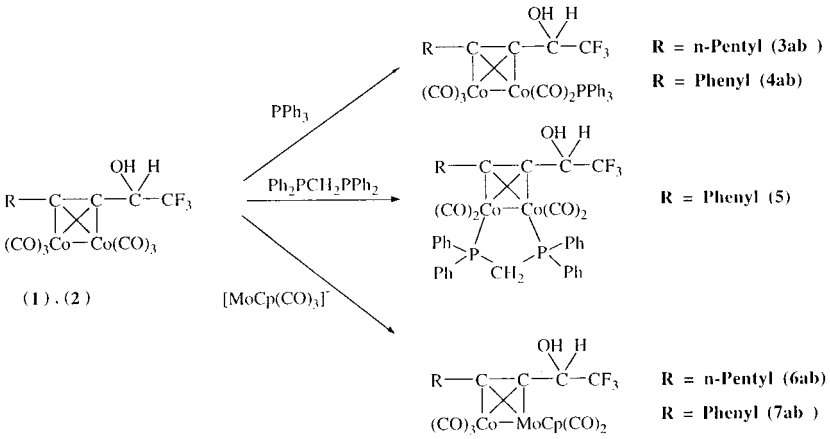

Table 1. Selected bond lengths [Å] and angles [°] for complex **5**

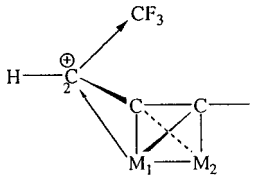
Co(1)−Co(2)	2.473(1)	Co(1)−P(1)	2.227(2)
Co(1)−C(3)	1.942(6)	Co(2)−P(2)	2.222(2)
Co(1)−C(4)	1.974(7)	Co(2)−C(3)	1.947(6)
Co(2)−C(4)	1.970(6)	C(3)−C(4)	1.357(9)
Co(1)−C(4)−Co(2)	77.7(2)	Co(1)−C(3)−Co(2)	79.0(2)
C(3)−C(4)−C(41)	141.5(6)	C(2)−C(3)−C(4)	126.6(7)

Furthermore, the α-CF_3-alcohol complexes **3a**, **b** and **4a**, **b** exist as a pair of diastereomers (Scheme 2). Starting from the $[Co_2]$-complexed alcohols **1**−**2**, the substitution of the metallic vertex $[Co(CO)_3]$ by the isolobal $[MoCp(CO)_2]$ leads to the hetero-bimetallic [Co,Mo]-complexed alcohols[12] obtained also as two diastereomers **6a**, **b** and **7a**, **b**, respectively. The complexed alcohols **1**−**7** thus obtained have the α-CF_3 substituent on the carbon atom bearing the hydroxyl function, while the C-4 acetylenic carbon is either substituted by an alkyl or an aryl substituent.



Mayr et al.[13] recently reported that alkyl or aryl substituents at C-4 do not affect the electronic density of the cluster unit, and consequently do not affect the electrophilicity of the corresponding $[Co_2]$−carbenium ions. The major differences among these complexed propargyl alcohols (**1**−**7**) therefore reside in the electronic nature of the bimetallic moieties coordinated to the acetylenic function.

It is well established that a cluster unit, or its electron donating ability, alleviates the positive charge of the adjacent α-carbenium center. It was previously shown by pK_R^+ measurements that the $[MoCp(CO)_2]$ vertex is much more

Scheme 2. Preparation of heterobimetallic [Co−Mo]- and [Co_2]-phosphane propargyl aclohols

efficient as an electron donating group than the [$Co_2(CO)_6$] unit[14][15] Consequently, the [Mo_2] or [Co,Mo] are much more stable and less reactive than the [Co_2]-complexed carbenium ions. Due to their low reactivity several X-ray structures of [Mo_2]- or [Co,Mo]-stabilized carbenium ions were reported in the literature.[1][5] However, very recently an X-ray structure of a [Co_2]−carbenium ion complex has been described. In this particular example, the carbenium center is flanked by two [Co_2] cluster units.[16] Spectroscopic results based on ^{1}H- and ^{13}C-NMR analysis and MO calculations on these metal-stabilized carbenium ions have shown that the electronic transfer occurs from the ligand to the carbon-deficient electronic center through the metal atom.[17] For instance, substituting a carbonyl ligand by a monophosphane or a diphosphane ligand has the dramatic effect of increasing the electronic density of the cluster core. This electronic density change is reflected on the ν_{CO} absorptions, which shift to low frequency.[18] Such behavior is illustrated by complex [{$Co_2(CO)_6$}{μ-η^2,η^2-$CH_3(CH_2)_4$-C≡CCH(CF_3)(OH)}] (**1**), which shows three ν_{CO} bands at 2097, 2057, and 2029 cm^{-1}. The related monophosphane complex [{$Co_2(CO)_5P(C_6H_5)_3$}{μ-η^2,η^2-$CH_3(CH_2)_2$-C≡CCH(CF_3)(OH)}] (**3**) exhibits ν_{CO} absorptions at 2063, 2015, 2005, 1987, and 1962 cm^{-1} (see Table 4). These results are in accord with those reported by Mayr et al,[13] which show that the carbenium ion complex [{$Co_2(CO)_5P(C_6H_5)_3$}{μ-η^2,η^3-HC≡CCH(C_6H_5)}]$^+$ is less electrophilic than the parent carbenium ion [$Co_2(CO)_6${μ-η^2,η^3-HC≡CCH(C_6H_5)}]$^+$. In summary, based on the literature data and our own experiments, we have classified the electron density on the cluster moieties of these α-CF_3-propargyl alcohols, in decreasing order as follows: [Co,Mo] > [Co_2P_2] > [Co_2P] > [Co_2]. As for carbenium ion complexes, it is noteworthy to remark that the carbenium center C-2 will be stabilized by the cluster unit, but to a different extent depending on the scale shown above. This should also overcome the withdrawing effect exerted by the α-CF_3 group. These two opposing effects (Figure 3) were examined by monitoring the reactivity of these carbenium ions in solution towards reduction. The results are presented in the next section.

[M_1-M_2] = [Co-Mo] = [$Co(CO)_3$-$MoCp(CO)_2$]
[Co_2] = [$Co_2(CO)_6$]
[Co_2P] = [$Co_2(CO)_5$ $P(Ph)_3$]
[Co_2P_2] = [$Co_2(CO)_4(P(Ph_2)_2CH_2$]

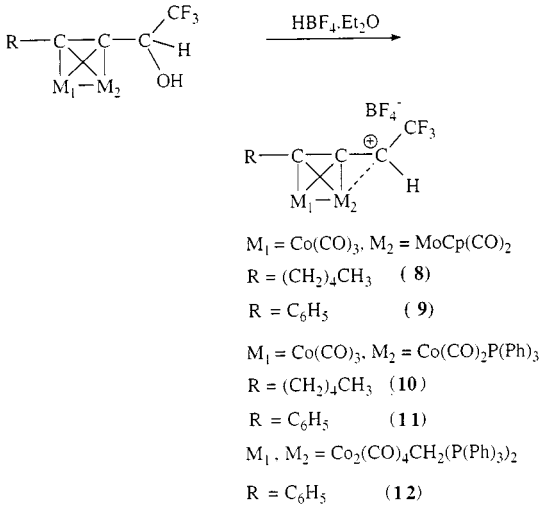


Figure 3. Schematic drawing showing two opposite interactions at the cabenium center: (a) metal-stabilized effect; (b) CF_3-distabilization attactive effect

Synthesis and Reduction of the Metal-Stabilized α-CF_3-Propargyl Carbenium Ion Complexes [(M_2L_6)-{μ-η^2,η^3-RC≡CCH(CF_3)}][BF_4]

Treatment of the propargyl alcohol complexes [{$Co_2(CO)_6$}{μ-η^2,η^2-RC≡CC(OH)(CF_3)H}] (**1−2**) by $HBF_4 \cdot Et_2O$ in ether did not afford any precipitate, as expected for the formation of the related carbenium ion salts. In contrast, the complexed alcohols **3−7** gave, under the same experimental conditions, the corresponding carbenium ions **8**, **9**, **10**, **11**, and **12**, respectively (Scheme 3). These results demonstrate that the electron donating effect of the [Co_2] cluster in Complexes (**1−2**) is not sufficient to overcome the α-CF_3 withdrawing effect. The ν_{CO} frequencies in the starting alcohols and their corresponding carbenium ions are listed in Table 3.

Furthermore, we noticed that protonation of the [Co_2P] complexed alcohols **3a**, **b** and **4a**, **b** by $HBF_4 \cdot Et_2O$ in a CH_2Cl_2/THF readily afforded the reduced complexes **15** and **16**, but not the related carbenium ion complexes

(Scheme 4). In the previous reaction the THF plays the role of the reducing agent, by acting as a mono-electron donor, as was previously reported.[19] Surprisingly, complexes **1**−**2**, were not reduced using CH_2Cl_2/THF as a solvent.

Scheme 3. Synthesis of the metal-stabilized carbenium ions (**8**−**12**).

It is also interesting to note that under the same experimental conditions the propargyl alcohols **5**−**7** afforded the carbenium ions **8**−**9** and **12**, therefore these compounds are very stable and cannot be reduced by the CH_2Cl_2/THF system. Carbenium ions **8**−**9** and **12** can readily be reduced, however, by using Zn/CH_2Cl_2 as reducing agent leading to compounds **13**−**14** and **17** (Scheme 5). The structures of these compounds were all identified by spectroscopic methods and elemental analysis (see Experimental Section), furthermore, the X-ray molecular structure of compound **17** was determined. The compound crystallizes with one molecule of acetone in the triclinic unit cell, space group *P*1. The bonding and molecular geometry of **17** are shown in a CAMERON[24] diagram in Figure 4. Crystallographic data and parameters for **17** are given in Table 4, selected bond lengths and angles are listed in Table 2. Complex **17** displays a tetrahedral Co_2C_2 core with -C≡C- bond of the acetylene unit in a perpendicular orientation at a almost 90° angle relative to Co−Co bond. The metal-metal bond length is 2.4876 Å, slightly longer than that of complex **5**.

The coordination geometry of each Co center is a distorted octahedron, occupied by the acetylene carbons, two carbonly ligands, and a coordinated phosphane ligand of the bridged dppm unit. Overall, the structure of **17** looks very similar to that of the parent molecule, **5**, and confirms its reduction since the hydroxyl group is now substituted by a hydrogen atom.

At this stage a few brief comments are required, since, according to our results, formation of a Co-complexed propargyl radical is only possible providing its related carbenium ion can be formed. This explains why the alcohol complexes **1**−**2** cannot be reduced by the THF/CH_2Cl_2 system. On the other hand, if the carbenium ion complex is strongly

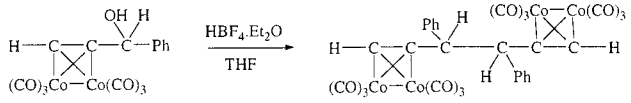
Scheme 4. Reduction of α-CF_3-propargyl alcohol complexes (**3**−**4**) using THF/CH_2Cl_2 in acidic medium

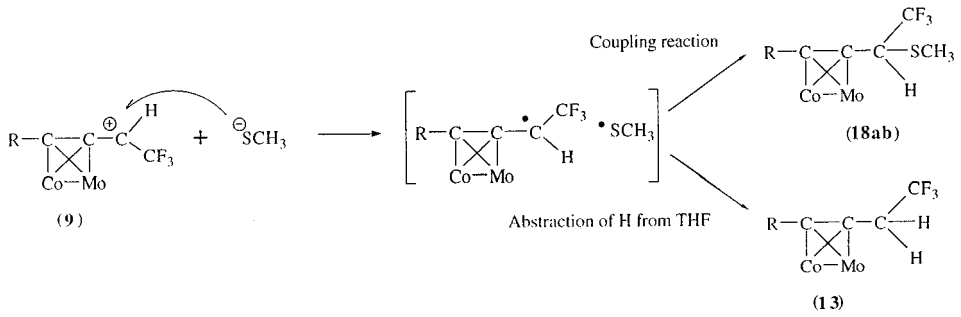


Scheme 5. Reduction of the metal-stabilized carbenium ions (**8**, **9**, and **12**) by Zn in CH_2Cl_2

Scheme 7. Possible reactions of carbon-centered radicals

stabilized by the bimetallic cluster, then the mono-electronic transfer from THF to the deficient electronic center is not possible, as shown by the alcohol complexes **5**−**7**, and the reaction stops at the carbenium ion stage. This hypothesis is also confirmed by the fact that the complex [{$Mo_2Cp_2(CO)_4$}{μ-η^2,η^2-HC≡CCH(C_6H_5)(OH)}], which is isolobal to the compound [{$Co_2(CO)_6$}{μ-η^2,η^2-HC≡CCH(C_6H_5)(OH)}], does not lead to coupling products. Finally, Co-stabilized carbenium ion exhibiting a stability between the two previous examples can be reduced by mono-electron transfer from THF to give the reduced compounds.

We would also like to outline that by either using the THF/CH_2Cl_2 system or by the action of Zn/CH_2Cl_2, our α-CF_3-propargyl alcohol complexes [{$Co_2(CO)_4L_2$}{μ-η^2,η^2-RC≡CC(OH)(CF_3)H}] (**3**−**7**) gave exclusively the reduction products, and never the coupling reaction products, which is the major product observed with [{$Co_2(CO)_6$}{HC≡CCH(C_6H_5)(OH)}] (Scheme 6).[19]



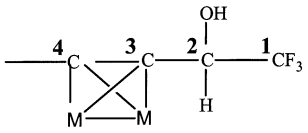
Scheme 6. Coupling reaction observed for a [CO_2]-complexed acetylenic alcohol in acidic medium

Generally, in carbon-centered radical reactions, the competition between coupling reactions, dismutation and abstraction of a hydrogen from the solvent, is a well documented area.[20](Scheme 7). For instance, primary carbon centered radical next to a hydrogen atom in the β position favors the dismutation reaction over the other reactions. Increasing the size of the substituents at the radical center favors the abstraction of a hydrogen from the solvent relative to recombination and dismutation. In our propargyl alcohol compounds, the presence of a CF_3 group in the alpha position to the carbon centered radical would impede the coupling reaction, due to electron repulsion, and hence abstraction of a proton from the solvent becomes the major reaction.

Another important feature of this chemistry was demonstrated when the carbenium ion complex [{$Co(CO)_3MoCp(CO)_2$}{μ-η^2,η^3-$CH_3(CH_2)_4$C≡CCH-(CF_3)}][BF_4] (**8**) was treated by NaSMe to give two compounds in 1:1 ratio. These compounds were identified, respectively, as the reduced compound [{$Co(CO)_3$-$MoCp(CO)_2$}{μ-η^2,η^2-$CH_3(CH_2)_4$C≡CCH(CF_3)H}] (**13**) and the substituted thio-ether complexes [{$Co(CO)_3$-$MoCp(CO)_2$}{μ-η^2,η^2-$CH_3(CH_2)_4$C≡CCH(CF_3)(SMe)}]-(**18a** and **b**) obtained as a pair of diastereomers. These results illustrate that the reaction between the isolated [Co,Mo] stabilized carbenium ion **9** and the methyl thiolato anion proceed through a radical pathway, whereby the transient radical pair species can either recombine in the solvent cage to give coupling reaction[21] as illustrated by formation of **18a**, **b** or, after diffusion from the solvent cage, would abstract a hydrogen atom from the solvent to afford the reduced alkyne adduct **13** (Scheme 8).

Conclusion

Co-complexed propargyl radicals may be formed during the reduction of α-CF_3 complexed acetylenic alcohols in acidic medium providing that their related carbenium ions are formed and are slightly stabilized. The stability of these carbenium ions depends on the electron donor ability of the bimetallic cluster. Our α-CF_3-complexed carbenium ions system seems to offer a new insight into, and the comprehension of the factors that allow certain cobalt-stabilized carbenium ions to undergo one electron reduction process rather than a substitution reaction. The present study shows that three classes of propargyl alcohol complexes can be distinguished. These classes could be defined as follows: class (a) − the parent alcohol complexes [{$Co_2(CO)_6$}{μ-η^2,η^2-RC≡CCH(CF_3)(OH)}] (**1**−**2**) cannot be reduced by THF/CH_2Cl_2 in acidic medium because the related [Co_2]-carbenium ions cannot be formed, class (b) − weakly stabilized carbenium ions such as [Co_2P] complexes **10** and **11** are easily reduced in acidic medium by THF/CH_2Cl_2, and class (c) − stable carbenium ions such as complexes **8**, **9**, and **12** can only be reduced when a strong reducing agent is used.



Scheme 8. Abstraction and coupling reactions occurring from a radical pair process

Experimental Section

General Methods: All reactions were carried out under an atmosphere of dry argon. Solvents were dried and distilled using standard techniques. Diethyl ether and THF were distilled from sodium benzophenone ketyl, dichloromethane and acetonitrile from sodium hydride, pentane was treated by sulfuric acid and distilled on sodium. Ethylrifluoroacetate, heptyne triphenylphosphane, Bis(diphenylphosphanyl)methane, $Mo_2Cp_2(CO)_6$, $Co_2(CO)_8$, HBF_4/Et_2O, aqueous 40% HBF_4, CD_2Cl_2, CD_3Cl, [D_6]acetone were used as purchased. − IR spectra were recorded on a Bio-rad FTS 165 spectrometer from KBr disks. All absorptions are expressed in wave numbers (cm^{-1}). − ^{1}H-, ^{13}C-, ^{19}F and ^{31}P-NMR spectra were recorded on a Bruker AM instrument, using standard programs for proton (299.MHz), carbon (75 MHz), fluoride (282 MHz) and phosphorus (124 MHz) spectra. NMR chemical shifts are reported in δ (ppm) relative to TMS (^{1}H, ^{13}C), $CFCl_3$ (^{19}F) or 85% H_3PO_4 (^{31}P); Data (^{13}C, ^{31}P) are proton decoupled. − Elemental analyses were performed by: "Centre régional de microanalyse-Université Pierre et Marie Curie".

Throughout the experimental section the carbon numbering system for the α-CF_3-propargyl alcohol complexes is shown on this diagram.

Synthesis of [{$Co_2(CO)_6$}-μ,η^2,η^2-(1,1,1-trifluoronon-3-yne-2-ol)] (1): To 1-heptyne (2.9 g, $3\cdot10^{-2}$ mol) in THF (40 mL) was added dropwise at 0°C, butyllithium (11.5 mL of a 2.5 M solution). After stirring 0.5 h, the mixture was cooled to −50°C and 2.48 g of ethyltrifluoroacetate ($2\cdot10^{-2}$ mol) were added dropwise. The mixture was stirred for 1 h and after attaining room temperature, 50 mL of NH_4Cl saturated aqueous solution were added. The organic phase was extracted by 3 × 25 mL of diethyl ether. The extracts were dried with $MgSO_4$ and the solvent removed under vacuum; The colorless oil was dissolved in 30 mL of ethanol and $NaBH_4$ (1.2 g) was added, progressively. The reaction was monitored by TLC on silica gel (eluent pentane/ether 5:1). The reaction was complete in one hour. After addition of water (50 mL) the organic phase was extracted by 3 × 25 mL of diethyl ether, dried ($MgSO_4$), and the solvent removed under vacuum to give a colorless oil (4.73 g). To the obtained oil in 50 mL of diethyl ether was added, at room temperature under argon, dicobalt octacarbonyl (1.2 g, 2.5 $.10^{-2}$ mol). The reaction was monitored by TLC on silica gel (eluent pentane/ether, 6:1). The reaction was complete in one hour. After adsorption of the crude product on silica gel, flash chromatography (pentane then pentane/ether, 10:1) leads to a dark red oil in 50% yield (5.1 g). − ^{1}H NMR ($CDCl_3$): δ = 5.12 (dq, J = 14.0 Hz, J = 7.2 Hz, 1 H, 2-H), 5.81 (t, J = 8.2 Hz, 2 H, 5-H), 2.53 (d, J = 7.2 Hz, 1 H, OH), 1.62 (m, 2 H, 6-H), 1.43 (m, 4 H, 7,8-H), 0.93 (t, J = 7.2 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 198.6 (CO), 123.2 (q, J = 282.0 Hz, C-1), 100.1 (C-3), 86.1 (C-4), 70.9 (q, J = 33.0 Hz, C-2), 32.9 (C-5), 31.3 (C-6), 31.0 (C-7), 22.0 (C-8), 13.5 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −75.9 (d, J = 6.1 Hz). − IR ν(CO): $\tilde{\nu}$ = 2095, 2057, 2029 cm^{-1}. − $C_{15}H_{13}Co_2F_3O_7$ calcd. C 37.52, H 2.73; found C 37.70, H 2.81.

[{$Co_2(CO)_6$}-{μ-η^2,η^2-(1,1,1-trifluoro-4-phenylbut-3-yne-2-ol)] (2): The same synthetic procedure was used for the preparation of compound (**2**) as was used for (**1**). − ^{1}H NMR ($CDCl_3$): δ = 7.36 (m, 3 H, C_6H_5), 5.57 (m, 2 H, C_6H_5), 5.37 (dq, J = 13.5 Hz, J = 6.1 Hz, 1 H, 2-H), 2.86 (d, J = 6.1 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 198.3 (CO), 137.2, 129.5, 128.9, and 128.2 (C_6H_5), 124.1 (q, J = 283.0 Hz, C-1), 92.8 (C-3), 85.6 (C-4), 71.3 (q, J = 31.9 Hz). − ^{19}F NMR ($CDCl_3$): δ = −76.58 (d, J = 6.1 Hz). − IR ν(CO): $\tilde{\nu}$ = 2089, 2050, 2020 cm^{-1}. − $C_{16}H_7Co_2F_3O_7$ calcd: C 39.54,H 1.45; found C 40.41, H 1.65.

[{$Co_2(CO)_5P(C_6H_5)_3$}-μ-η^2,η^2-(1,1,1-trifluoronon-3-yne-2-ol)] (3a, 3b): To 0.58 g of (**1**) (1.21 mmol) in THF (15 mL) was added $P(C_6H_5)_3$ (0.40 g, 1.52 mmol) in THF (35 mL) and 2.3 mL of a 1 M solution of sodium/benzophenone in THF. The reaction was monitored by TLC (silica gel, eluent pentane/ether 4:1). The reaction was left for one hour at room temperature, then the mixture was purified by flash chromatography, giving the two diastereomers, which were separated in the order of increasing polarity (**3a**) then (**3b**), as red oils, 0.35 g and 0.06 g (40% and 7% yield, respectively).

Compound 3a: ^{1}H NMR ($CDCl_3$): δ = 7.56−7.31 (m, 15 H, C_6H_5), 3.96 (dq, J = 14 Hz, J = 8.0 Hz, 1 H, 2-H), 2.22 (m, 1 H, 5-H), 1.99 (d, J = 8.0 Hz, 1 H, OH), 1.72 (m, 1 H, 5-H), 1.51 (m, 2 H, 6-H), 1.25 (m, 4 H, 7,8-H), 0.89 (t, J = 7.1 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 206.2, 204.8, and 200.9 (CO), 134.3 (d, J = 53.4 Hz, $C_{ipso,}$ C_6H_5), 133.0 (d, J = 10.1 Hz, $C_{ortho,}$ C_6H_5), 130.8 ($C_{para,}$ C_6H_5), 129.0 (d, J = 9.5 Hz, $C_{meta,}$ C_6H_5), 123.0 (q, J = 283.5 Hz, C-1), 96.1 (C-3), 92.7 (C-4), 68.9 (q, J = 32.5 Hz, C-2), 31.7, 31.5, and 31.2 (C-5-6-7), 22.7 (C-8), 14.2 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −76.5 (d, J = 6.1 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 52.9 (broad). − IR ν(CO): $\tilde{\nu}$ = 2063, 2015, 2005, 1987, and 1962 cm^{-1}.

Compound 3b: ^{1}H NMR ($CDCl_3$): δ = 7.62−7.55 (m, 15 H, C_6H_5), 4.13 (dq, J = 14 Hz, J = 7.8 Hz, 1 H, 2-H), 2.36 (m, 1 H, 5-H), 2.04 (m, 1 H, 5-H), 1.86 (d, J = 7.8 Hz, 1 H, OH), 1.51 (m, 2 H, 6-H), 1.29 (m, 4 H, 7,8-H), 0.90 (t, J = 7.1 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 206.1−201.1 (CO), 134.6 (d, J = 39.6 Hz,C_{ipso}), 133.0 (d, J = 10.4 Hz,C_{ortho}), 130.7 (C_{para}), 128.9 (d,

J = 8.4 Hz,C_{meta}), 123.5 (q, J = 234.7 Hz, C-1), 98.8 (C-3), 79.9 (C-4), 71.5 (q, J = 32.0 Hz, C-2), 32.7, 31.9, and 22.7 (C-6-7-8), 14.1 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −76.7.(d, J = 6.1 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 51.3.(broad). − IR ν(CO): $\tilde{\nu}$ = 2062, 2015, 1998, 1963 cm^{-1}. − $C_{32}H_{28}Co_2F_3O_6P$ calcd: C 53.81, H 3.94; found C 55.65, H 4.14.

[{$Co_2(CO)5P(C_6H_5)_3$}-μ-η²,η²-(1,1,1-trifluoro-4-phenylbut-3-yne-2-ol)] (4a,4b): Compounds (**4a**) and (**4b**) were prepared in the same way described for **3a** and **3b**, and were isolated in 35% and 25% yield, respectively.

Compound 4a: ^{1}H NMR ($CDCl_3$): δ = 7.41−7.19 (m, 20 H, C_6H_5), 3.97 (qui, J = 14.0 Hz, J = 7.8 Hz 1 H, 2-H), 2.03 (d, J = 7.8 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 200.5 (CO), 138.8 ($C_{ipso,}$ C_6H_5), 133.9 (d, J = 40.3 Hz, $C_{ipso,}$ PC_6H_5), 133.2 (d, J = 11.6 Hz, $C_{ortho,}$ PC_6H_5), 130.7 ($C_{meta,}$ PC_6H_5), 130.4 (C_6H_5), 128.8 (C_6H_5), 128.7 (d, J = 9.7 Hz, $C_{meta,}$ C_6H_5), 128.2 (C_6H_5), 124.0 (q, J = 284.0 Hz, C-1), 85.7 (C-3), 82.4 (C-4), 70.0 (q, J = 31.8 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −75.77(d, J = 6.0 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 48.27(broad). − IR ν(CO): $\tilde{\nu}$ = 2068, 2018 cm^{-1}.

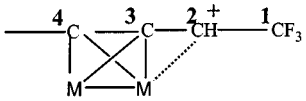
Compound 4b: ^{1}H NMR ($CDCl_3$): δ = 7.41−7.18 (m, 20 H, C_6H_5), 3.97 (dq, J = 14.0 Hz, J = 7.8 Hz, 1 H, 2-H), 1.88 (d, J = 7.8 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 205.9−203.9−200.5 (CO), 139.5 ($C_{ipso,}$ C_6H_5), 133.8 (d, J = 41.1 Hz, $C_{ipso,}$ PC_6H_5), 133.3 (C_6H_5), 133.2 (d, J = 10.7 Hz, $C_{ortho,}$ PC_6H_5), 130.6 (C_6H_5), 130.5 (d, J = 10.4 Hz, $C_{meta,}$ PC_6H_5), 128.8 (C_6H_5), 128.7 (d, J = 8.2 Hz, $C_{para,}$ PC_6H_5), 128.2 (C_6H_5), 124.6 (q, J = 283 Hz, C-1), 88.1 (C-3), 79.6 (C-4), 70.3 (q, J = 30.5 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −76.34 (broad). − ^{31}P NMR ($CDCl_3$): δ = 48.29 (broad). − IR ν(CO): $\tilde{\nu}$ = 2068, 2018 cm^{-1}. − $C_{33}H_{22}Co_2F_3O_6P$ calcd: C 55.02, H 3.08; found C 56.22, H 3.06.

[{$Co_2(CO)_4$dppm}-μ-η²,η²-(1,1,1-trifluoro-4-phenylbut-3-yne-2-ol)] (5): To a solution of **2** (0.5 g, 1.27 mmol) in 50 mL of hexane was added dppm (0.5 g, 1.30 mmol). After 0.5 h of reflux, the reaction was completed. The mixture was purified by flash chromatography on silica gel, using pentane as eluent then using pentane/ether (1:4). Complex **5** was obtained in 58% yield (0.66 g). − ^{1}H NMR ($CDCl_3$): δ = 7.25−6.91 (m, 25 H, C_6H_5), 5.20 (dq, J = 14.0 Hz, J = 7.5 Hz, 1 H, 2-H), 3.22 (m, 2 H, PCH_2P), 2.34 (d, J = 7.5 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 205.8, 202.4, and 202.0 (CO), 141.7 ($C_{ipso,}$ C_6H_5), 130.7, 128.8, and 126.4 ($C_{o,m,p,}$ C_6H_5), 138.1, 134.1, 132.8, 130.2, 129.7, and 128.3 (m, PC_6H_5), 124.6 (q, J = 281.4 Hz, C-1), 93.9 (C-4), 91.7 (C-3), 72.4 (q, J = 31.6 Hz, C-2), 34.4 (t,.J = 21.7 Hz, PCH_2P). − ^{19}F NMR ($CDCl_3$): δ = −76.7 (d, J = 6.0 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 37.7 (broad). − IR ν(CO): $\tilde{\nu}$ = 2066, 2029, 2001, 1974 cm^{-1}. − $C_{39}H_{29}F_3O_5P_2Co_2$ calcd: C 57.51, H 3.59; found C 54.37, H 3.54.

[{$Co(CO)_3MoCp(CO)_2$}-μ-η²,η²-(1,1,1-trifluoronon-3-yne-2-ol)] (6a, 6b): To 0.15 g (0.3 mmol) of **1** in 15 mL THF was added a solution of $NaMoCp(CO)_2$ in 15 mL THF, prepared from 0.15 g (0.3 mmol) of $Mo_2Cp_2(CO)_6$ and 0.014 g (0.6 mmol) of Na/1.4 g Hg [for the detailed preparation of $NaMoCp(CO)_3$ see reference[12]]. This mixture was stirred for 7 h at room temperature and monitored by TLC-silica gel using pentane/ether (2:1) as eluent. After chromatography on silica gel, two products were recovered, **2a** and **2b**, in the order of increasing polarity. Complexes **2a** and **2b** were obtained in 58.8% (0.10 g) and 35.3% (0.06 g) yield, respectively.

Compound 6a: ^{1}H NMR ($CDCl_3$): δ = 5.47 (s, 5 H, Cp), 5.07 (dq, J = 13 Hz, J = 5.8 Hz, 1 H, 2-H), 2.91 (t, J = 8.0 Hz, 2 H, 5-H), 2;39 (d, J = 5.8 Hz, OH), 1.75 (m, 1 H, 6-H), 1.60 (m, 1 H, 6-H), 1.40 (m, 4 H, 7,8-H), 0.92 (t, J = 6.8 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 203.0 (CO), 123.5 (q, J = 276.0 Hz, C-1), 105.2 (C-3), 90.3 (Cp), 79.8 (C-4), 73.4 (q, J = 32.0 Hz, C-2), 34.9 (C-5), 31.8 (C-6), 30.9 (C-7), 22.2 (C-8), 13.7 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −75.9 (d, J = 6.1 Hz). − IR ν(CO): $\tilde{\nu}$ = 2051, 2001, 1984, 1942 cm^{-1}. − $C_{19}H_{18}CoF_3MoO_6$ calcd: C 41.17, H 3.27; found C 42.99, H 3.12.

Compound 6b: ^{1}H NMR ($CDCl_3$): δ = 5.42 (s, 5 H, Cp), 4.94 (dq, J = 13.0 Hz, J = 7.4 Hz, 1 H, 2-H), 2.96 (m, 2 H, 5-H), 2;19 (d, J = 7.4 Hz, 1 H, OH), 1.63 (m, 2 H, 6-H), 1.40 (m, 4 H, 7,8-H), 0.91 (t, J = 6.8 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 202.9 (CO), 124.0 (q, J = 281.0 Hz, C-1), 104.1 (C-3), 90.4 (Cp), 78.6 (C-4), 73.5 (q, J = 31.0 Hz, C-2), 35.1 (C-5), 31.9 (C-6), 30.9 (C-7), 22.2 (C-8), 13.8 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −75.15(d, J = 6.5 Hz). − IR ν(CO): $\tilde{\nu}$ = 2052, 2003, 1987, and 1940 cm^{-1}. − $C_{19}H_{18}CoF_3MoO_6$ calcd: C 41.17, H 3.27; found C 43.11, H 3.16.



[{$Co(CO)_3MoCp(CO)_2$}-μ-η²,η²-(1,1,1-trifluoro-4-phenylbut-3-yne-2-ol)] (7a, 7b): A slightly modified procedure was used relative to that of (**6a**, and **6b**). A THF solution of **2** was heated under reflux for two hours with $NaMoCp(CO)_3$. The diastereomers **7a** and **7b** were separated by flash chromatography in the order of increasing polarity, and were obtained in 35% and 53% yield respectively (0.2 g) and (0.3 g).

Compound 7a: ^{1}H NMR ($CDCl_3$): δ = 7.43−7.33 (m, 5 H, C_6H_5), 5.46 (s, 5 H, Cp), 5.28 (dq, J = 13.0 Hz, J = 5.7 Hz, 1 H, 2-H), 2.27 (d, J = 5.7 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 225.6 (CO), 222.3 (CO), 202.7−202.3 (CO), 140.4 (C_{ipso}), 129.3 (C_{meta}), 128;6 (C_{ortho}), 127.6 (C_{para}), 124.7 (q, J = 282.2 Hz,C-1), 98.2 (C-3), 90.4 (Cp), 88.4 (C-4), 73.4 (q, J = 30.7 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −75.87 (d, J = 5.7 Hz). − IR ν(CO): $\tilde{\nu}$ = 2057, 2002, 1949 cm^{-1}.

Compound 7b: ^{1}H NMR ($CDCl_3$): δ = 7.43−7.32 (m, 5 H, C_6H_5), 5.46 (s, 5 H, Cp), 5.16 (dq, J = 13.0 Hz, J = 5.7 Hz, 1 H, 2-H), 2.34 (d, J = 5.7 Hz, 1 H, OH). − ^{13}C NMR ($CDCl_3$): δ = 225.4 (CO), 222.8 (CO), 203.0−201.8 (CO), 140.1 (C_{ipso}), 129.8 (C_{meta}), 128.5 (C_{ortho}), 127.9 (C_{para}), 124.9 (q, J = 283.0 Hz, C-1), 104.9 (C-3), 98.8 (C-4), 90.9 (Cp), 73.2 (q, J = 30.3 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −75.89 (d, J = 6.4 Hz). − IR ν(CO): $\tilde{\nu}$ = 2058, 1994, 1948 cm^{-1}. − $C_{20}H_{12}CoF_3MoO_6$ calcd: C 42.88, H 2.16; found C 43.90, H 2.54.

[{$Co(CO)_3MoCp(CO)_2$}-μ-η²,η³-(1,1,1-trifluoronon-3-yn-2-onium)] Tetrafluoroborate (8): To a solution of a mixture of (**6a**) and (**6b**) (0.277 g, 0.5 mmol) in 5 mL of ether was added HBF_4/Et_2O (0.25 mL). The red solution turns dark with the formation of an insoluble oil. The reaction was left for 1 h at room temperature, then the supernatant was removed and the oily material washed five times with diethyl-ether and finally dried under vacuum for several hours.

The carbon numbering system for the α-CF_3-carbenium complexes is illustrated by the following diagram:

^{1}H NMR (CD_2Cl_2): δ = 5.99 (s, 5 H, C_p), 5.94 (q, J = 7.2 Hz, 1 H, 2-H), 2.98 (m, 2 H, 5-H), 1.73 (m, 2 H, 6-H),1.38 (m, 4 H, 7,8-H), 0.93 (t, J = 6.6 Hz, 3 H, 9-H). − ^{13}C NMR (CD_3COCD_3): δ = 215.5, 209.2, and 198.2 (CO), 123.5 (q, J = 275.9 Hz, C-1), 107.3−84.7 (C-3,4), 94.0 (q, J = 36.9 Hz, C-2), 93.4 (s, Cp) (C-5), 35.7 (C-5), 32.6 (C-6), 31.4 (C-7), 22.4 (C-8), 13.9 (C-9). − ^{19}F

NMR (CD_2Cl_2): δ = −59.2 (broad). − IR ν(CO): $\tilde{\nu}$ = 2104, 2065, 2055, 2006, 1989, and 1947 cm^{-1}. − $C_{19}H_{17}BCoF_7MoO_5$ calcd: C 36.57, H 2.74; found C 34.88, H 3.00.

[{Co(CO)$_3$MoCp(CO)$_2$}-μ-η^2,η^3-(1,1,1-trifluoro-4-phenylbut-3-yn-2-onium)] Tetrafluoroborate (9): The same procedure was used as for compound **8**. − ^{1}H NMR (CD_2Cl_2): δ = 7.77 (m, 2 H, C_6H_5), 7.59 (m, 3 H, C_6H_5), 6.06 (q, *J* = 6.5 Hz, 1 H, C_6H_5), 7.43 (m, 2 H, C_6H_5), 7.35 (m, 3 H, C_6H_5), 6.06 (q, *J* = 6.5 Hz, 1 Hz), 6.04 (s, 5 H, Cp−Mo). − IR ν(CO): $\tilde{\nu}$ = 2108, 2072, 2005 cm^{-1}.

[{Co$_2$(CO)$_5$P(C$_6$H$_5$)$_3$}-μ-η^2,η^3-(1,1,1-trifluoronon-3-yne-2-onium)] Tetrafluoroborate (10): This compound hydrolyses rapidly in solution, therefore the ^{1}H-NMR spectrum could not be recorded, however the IR data are reminiscent of a cobalt−carbenium ion complex. − IR ν(CO): $\tilde{\nu}$ = 2138, 2063, and 2005 cm^{-1}.

[{Co$_2$(CO)$_5$P(C$_6$H$_5$)$_3$}-μ-η^2,η^3-(1,1,1-trifluoro-4-phenylbut-3-yne-2-onium)] Tetrafluoroborate (11): This compound hydrolyses rapidly in solution, therefore the ^{1}H-NMR spectrum could not be recorded. The infrared data are characteristic of a cobalt−carbenium ion complex. − IR ν(CO): $\tilde{\nu}$ = 2123, 2071, 2022 cm^{-1}.

[{Co$_2$(CO)$_4$dppm}-μ-η^2,η^3-(1,1,1-trifluoro-4-phenylbut-3-yne-2-onium)] Tetrafluoroborate (12): This complex hydrolyses rapidly in solution, therefore the ^{1}H-NMR spectrum could not be recorded. − IR ν(CO): $\tilde{\nu}$ = 2090, 2065, 2004, 1978 cm^{-1}. − $C_{39}H_{28}BCo_2F_7O_4P_2$ calcd: C 52.97, H 3.19; found C 52.52, H 3.85.

[{Co(CO)$_3$MoCp(CO)$_2$}-μ-η^2,η^2-(1,1,1-trifluoronon-3-yne)] (13): The carbenium ion complex **8** (0.11 mmol) was dissolved in CH_2Cl_2 (20 mL) and an excess of Zn powder (a small spatula portion) was added, and the reaction stirred for 20 minutes at room temperature then filtered, and the solvent removed under vacuum. The residue was purified by chromatography on silica gel using an Et_2O/pentane (10:90) mixture. Complex **13** was isolated as red-orange oily material in 85% yield (65 mg). − ^{1}H NMR ($CDCl_3$): δ = 5.37 (s, 5 H, C_p), 3.48 (oct, *J* = 10.6−4.3 Hz, 2 H, 2-H), 2.88 (t, *J* = 8.6 Hz, 2 H, 5-H), 1.61 (m, 2 H, 6-H),1.40 (m, 4 H, 7,8-H), 0.92 (t, *J* = 7.2 Hz, 3 H, 9-H).

[{Co(CO)$_3$MoCp(CO)$_2$}-μ-η^2,η^2-(1,1,1-trifluoro-4-phenylbut-3-yne)] (14): The preparation of this complex is similar to that of compound **13**. Thus, starting with 0.11 mmol of the carbenium ion complex **9** in CH_2Cl_2, the target compound **14** was isolated as a red-orange oily material in 80% yield (48 mg). − ^{1}H NMR (CD_3COCD_3): δ = 7.01 (m, 5 H, C_6H_5), 5.10 (s, 5 H, C_p), 3.37 (q, *J* = 9.75 Hz, 2 H, CH_2). − ^{13}C NMR ($CDCl_3$): δ = 233.1, 225.7, and 213.0 (CO), 141.2 ($C_{ipso,}$ C_6H_5), 128.9, 128.5, and 127.1 ($C_{o,m,p,}$ C_6H_5), 126.5 (q, *J* = 272 Hz, C-1), 91.4 (Cp), 95.5−90.8 (C-3, C-4), 39.2 (q, *J* = 29.3 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −64.43 (t, *J* = 9.8 Hz, CF_3). − IR ν(CO): $\tilde{\nu}$ = 2056, 2004, 1993, 1944 cm^{-1}. − Anal. for $C_{20}H_{12}CoF_3MoO_5$ calcd: C 44.14, H 2.22; found C44.26, H2.28.

[{Co$_2$(CO)$_5$P(C$_6$H$_5$)$_3$}-μ-η^2,η^2-(1,1,1-trifluoronon-3-yne)] (15): This complex was prepared by two different procedures:

Method A: This synthetic procedure is the same as the one described for complexes **13** and **14**. Complex **15** was obtained in 60% yield as red oily material (46 mg).

Method B: The alcohol starting materials **3a**, and **b** (100 mg, 0.142 mmol) were dissolved in 2 mL of CH_2Cl_2 in the presence of 31 μL of THF. The red solution was treated with $HBF_4 \cdot Et_2O$ (58 mL) at −5°C, and the reaction was left to attain room temperature. The solvents were removed and the residue was purified by chromatography on silica gel using Et_2O/pentane (10:90) as eluent. Complex **15** was isolated in 30% yield (30 mg). − ^{1}H NMR ($CDCl_3$): δ = 7.59−7.47 (m, 15 H, C_6H_5), 2.63 (q, *J* = 10.4 Hz, 2 H, 2-H), 2.20 (m, 1 H, 5-H), 2.04 (m, 1 H, 5-H), 1.60 (m, 1 H, 6-H), 1.47 (m, 1 H, 6-H), 1.31 (m, 4 H, 7,8-H), 0.91 (t, *J* = 6.4 Hz, 3 H, 9-H). − ^{13}C NMR ($CDCl_3$): δ = 206.4, 204.8, and 201.5 (CO), 134.6 (d, *J* = 40.2 Hz, $C_{ipso,}$ C_6H_5), 133.1 (d, *J* = 9.5 Hz, $C_{ortho,}$ C_6H_5), 130.7 (s, $C_{para,}$ C_6H_5), 128.9 (d, *J* = 7.3 Hz, $C_{meta,}$ C_6H_5), 125.9 (q,*J* = 279 Hz, C-1), 99.5−78.1 (C-3−4), 36.0 (q, *J* = 29 Hz, C-2), 32.1, 32.0, 31.4 (C-5, C-6, C-7), 22.7 (C-8), 14.2 (C-9). − ^{19}F NMR ($CDCl_3$): δ = −64.80.(t, *J* = 10.3 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 52.84.(broad). − IR ν(CO): $\tilde{\nu}$ = 2059, 2010, 2005, 1997, 1987, and 1963 cm^{-1}. − $C_{32}H_{28}Co_2F_3O_5P$ calcd: C 55.02, H 4.04; found C 52.85 H 4.25.

[{Co$_2$(CO)$_5$P(C$_6$H$_5$)$_3$}-μ-η^2,η^2-(1,1,1-trifluoro-4-phenylbut-3-yne)] (16): This compound was also prepared by the two synthetic procedures outlined above: Method A: Complex **16** was obtained as red powder in 90% (70 mg). − Procedure B: Compound **16** was isolated in a lower yield of 27% (40 mg). − ^{1}H NMR ($CDCl_3$): δ = 7.36−7.19 (m, 20 H, C_6H_5), 2.87 (m, 1 H, 2-H), 2.28 (m, 1 H, 2-H). − ^{13}C NMR ($CDCl_3$): δ = 204.0 (CO), 200.7 (CO), 140.0 ($C_{ipso,}$ C_6H_5), 133.9 (d, $C_{ipso,\ J}$ = 41.1 Hz, PC_6H_5), 133.3 (d, $C_{ortho,\ J}$ = 10.5 Hz, PC_6H_5), 130.5, 129.8, 128.7 (s, $C_{ortho,\ meta,\ para}$), 128.6 (d, *J* = 9.8 Hz, $C_{meta,}$ PC_6H_5), 127.0 (s, $C_{para,}$ PC_6H_5), 126.1 (q, *J* = 281 Hz, C-1), 86.3 (C-3), 90.8 (C-4), 35.2 (q, *J* = 29.3 Hz, C-2). − ^{19}F NMR ($CDCl_3$): δ = −64.75.(t, *J* = 9.1 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 49.53 (broad). − IR ν(CO): $\tilde{\nu}$ = 2065, 2013, and 1983 cm^{-1}. −$C_{33}H_{22}Co_2F_3O_5P$ calcd: C 56.27, H 3.15; found C 56.34, H 3.21.

[{Co$_2$(CO)$_4$dppm}-μ-η^2,η^2-(1,1,1-trifluoro-4-phenylbut-3-yne)] (17): In a similar manner to that described for complexes **13** and **14**, the reduced compound **17** was obtained from 0.11 mmol of the carbenium ion complex **12**, as a red-orange powder in 90% yield (79 mg). − ^{1}H NMR ($CDCl_3$): δ = 7.33−6.99 (m, 25 H, C_6H_5), 3.63 (m, 2 H, PCH_2P), 3.13 (m, 2 H, 2-H). − ^{13}C NMR ($CDCl_3$): δ = 205.9−202.6 (CO), 142.4 (s, $C_{ipso,}$ C_6H_5), 138.7, 134.4. and 132.8 (m, C_6H_5P), 132.7 (s, $C_{para,}$ C_6H_5), 130.7 (m, C_6H_5P), 130.4 ($C_{ortho,}$ C_6H_5), 128.6−128.2 (m, C_6H_5P), 125.9 (s, $C_{meta,}$ C_6H_5), 126.6 (q, *J* = 274.5 Hz, C-1), 93.8 (C-4), 88.9 (C-3), 39.1 (q, *J* = 28.9 Hz, C-2), 34.5 (t, *J* = 21.8 Hz, PCH_2P). − ^{19}F NMR ($CDCl_3$): δ = −64.90.(t, *J* = 10.49 Hz, CF_3). − ^{31}P NMR ($CDCl_3$): δ = 38.36 (s). − IR ν(CO): $\tilde{\nu}$ = 2027, 1999, 1969, 1959 cm^{-1}. − $C_{39}H_{29}Co_2F_3O_4P_2$ calcd: C 58.66, H 3.66; found C 56.67, H 3.70.

[{Co(CO)$_3$MoCp(CO)$_2$}-μ-η^2,η^2-(1,1,1-trifluoro-2-(methylthio)non-3-yne)] (18a, 18b) and [{Mo$_2$Cp$_2$(CO)$_4$}-μ-η^2,η^3-(prop-2-yn-1-onium)] Tetrafluoroborate (19): A mixture of the two alcohol diastereomers **6a**, and **b** (220 mg, 0.40 mmol) were dissolved in 10 mL of Et_2O. The red solution was protonated by 0.2 mL of $HBF_4 \cdot Et_2O$ at room temperature, affording a dark red oily precipitate. This material was isolated and washed 5 times with Et_2O. CH_2Cl_2 was then added (10 mL) and NaSMe (30 mg, 0.43 mmol.) was introduced, and the reaction was left to stir for 10 minutes. The solvent was removed and the residue was purified by chromatography on silica-gel using Et_2O/pentane 10:90 to yield inseparable mixture of the two diastereoisomer-substituted complexes **18a**, and **b** (1:1) in 35% yield (82 mg). The reduced complex **19** was obtained in 35% yield (74 mg).

Spectroscopic Data for 18a, and b: ^{1}H NMR ($CDCl_3$): δ = 5.44−5.40 (s, 5 H, C_p), 4.25 (m, 1 H, 2-H), 2.93 (m, 2 H, 5-H), 2.36−2.35 (s, 3 H, SCH_3), 1.7 (m, 2 H, 5-H), 1.65 (m, 2 H, 6-H), 1.42 (m, 4 H, 7,8-H), 0.92−0.93 (t, *J* = 6.3 Hz, 3 H, 9-H). − IR ν(CO): $\tilde{\nu}$ = 2051, 2000, 1985, 1939 cm^{-1}.

Spectroscopic Data for 19: ^{1}H NMR (CD_2Cl_2): δ = 7.39 (m, 5 H, C_6H_5), 7.15 (s, 1 H, 3-H), 7.00 (s, 1 H, 1-H), 5.38 (s, 5 H, Cp). − IR ν(CO): $\tilde{\nu}$ = 2052, 2006, 1993, 1907 cm^{-1}.

X-ray Structure Determination: Suitable crystals of [(Co_2(-CO)$_4$dppm)(μ-η^2,η^2-RC≡CCH(CF_3)(OH)] (**5**) were obtained by slow evaporation of a saturated solution in pentane/Et_2O (1:4), while complex [{Co_2(CO)$_4$dppm}{μ-η^2,η^2-C_6H_5C≡CCH_2(CF_3)}] (**17**) was obtained by slow evaporation of an acetone saturated solution. The selected crystal of complex **5** or **17** was glued on the top of a glass rod. Accurate cell dimensions and orientation matrix were obtained by least-squares refinements of 25 accurately centered reflections on a Nonius CAD4 diffractometer equipped with graphite-monochromated Mo-*K*α radiation. No significant variations were observed in the intensities of two checked reflections during data collection. The ψ-scan curve of **5** or **17** was flat, hence no absorption correction was applied. Complete crystallographic data and collection parameters for **5** and **17** are listed in Table 4. The data were corrected for Lorentz and polarization effects. Computations were performed by using the PC version of CRYSTALS.[22] Scattering factors and corrections for anomalous dispersion were taken from ref.[23] Complex **5** exhibited a disordered behavior for the CF_3−C−OH unit. A best structural resolution was achieved by considering two locations where the CF_3−C−OH fragment displayed occupation factor of (43%) and (57%). The asymmetric unit of complex **17** contains one molecule of solvated acetone, thus crystals of **17** decomposed at room temperature by loss of solvent and thus the X-ray data were recorded at low temperature. The structures of compounds **5** and **17** were refined by full-matrix least-squares with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were introduced in calculated positions in the last refinements and were allocated an overall refinable isotropic thermal parameter. Fractional parameters, anisotropic thermal parameters, and all bond lengths and angles are given in the Supporting Information for complexes **5** and **17**.

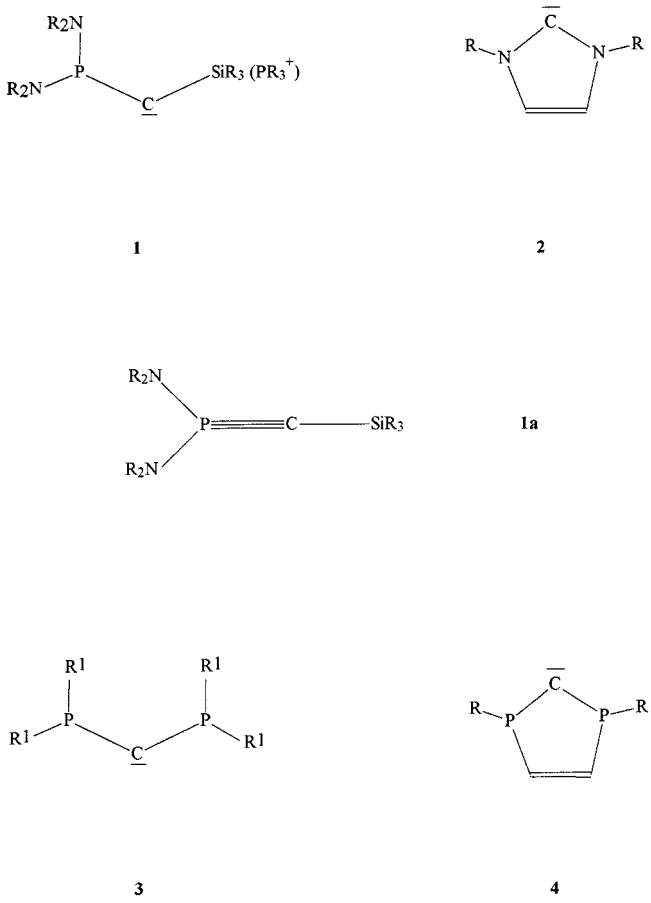
On the Electronic Properties of Substituted Phosphanylcarbenes

Wolfgang W. Schoeller[a]

Keywords: Phosphanylcarbenes / Substituent effects / Quantum chemical calculations



A phosphanyl group exerts much less π-conjugation properties than an amino group. On this basis, corresponding carbene structures exhibit much smaller singlet–triplet energy separations. Of the various structures investigated quantum-chemically the largest singlet–triplet energy separations are predicted for cyclic diphosphanylcarbenes, in which the two functional groups are incorporated into a ring system and the phosphorus atoms are substituted by phosphoraniminato groups. Then the singlet–triplet energy separations become essentially larger than for the Bertrand-type (push-pull) carbenes.

Introduction

Some time ago, Bertrand and co-workers reported in a series of pioneering investigations[1−9] the first syntheses of stable, isolable phosphanylcarbenes **1** (see Scheme 1). A prerequisite for the stability of the species is a substitution of the phosphanyl carbene with amino groups at phosphorus and an electron-withdrawing group (SiR_3, $PR_3^{(+)}$) at the carbon atom. The stabilizing effects of amino groups at the phosphorus and an electron-withdrawing group at the carbon atom have been rationalized by vinyl ylide structures, already suggested some time ago[1] for **1a** as a λ^5-phosphaalkyne structure. The assertion conforms with quantum-chemical calculations carried out later.[6] In other words, the positive charge at the phosphorus and the negative charge at the carbon atom are delocalized into the amino and the silyl (phosphonium) groups. It has been stated that the stabilities of the carbenes are often inversely proportional to the stability of the starting diazo compounds.[9]

Quantum-chemical calculations were first carried out on the singlet and triplet structural isomers of monophosphanylcarbene, H_2PCH.[10] An almost planar singlet state is predicted, with an inversion barrier of only 4 kcal mol^{-1}. It results in the electronic ground state, but only 3 kcal mol^{-1} lower in energy than the triplet state. The results are in agreement with more sophisticated calculations using the multiconfiguration-based unitary coupled electron pair approximation on parent phosphanyl carbenes.[11]

However, this study anticipates a somewhat larger energy difference (10 kcal mol^{-1}) between singlet and triplet states lowest in energy. While these two quantum chemical studies consider only a monophosphanyl-substituted carbene, a third study[12] examined the role of silicon substitution at the carbon (SiH_3) and of amino groups at the phosphorus atom. In essence, here the singlet−triplet energy separation is increased (13.9 kcal mol^{-1} in advantage to the singlet state, at PMP4 level) and the calculations indicate that this effect parallels an opening of the P−C−Si angle (135.7° predicted at MP2 level).

Scheme 1

Another representative of a stable carbene is the imidazol-2-ylidene **2** reported by Arduengo et al.[13][14] In this type of structure, the electron-deficient divalent carbon center is π-conjugated with two amino groups.[14][15] The carbenic nature and the question of their stabilities is presently under intensive debate, in particular the role of the heteroatom substituents.[16−22] To this end, a "mixed" car-

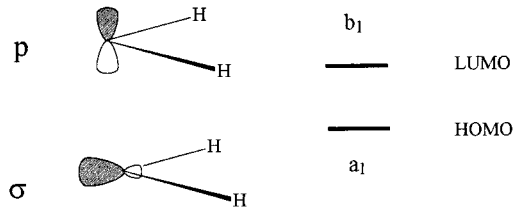
bene which contains a phosphanyl and an amino group has been observed in transient formation recently.[23]

One of the major questions is an analysis of the electronic properties of carbene structures which combine both features: that of the types **1** and **2**. This will be discussed in the present quantum-chemical study. We evaluate the following aspects in detail: (1) Symmetrical, phosphanyl-substituted carbenes **3** and unsymmetrical, Bertrand-type carbenes **1** with various donors (acceptors) at the phosphorus (carbon) atom; and finally (2) the effect of incorporation of phosphanyl groups into ring systems, such as in **4** and related ring systems. We will show that a phosphoraniminato ligand ($-NPH_3$) is more effective than an amino group, to enhance the singlet−triplet energy separation in a phosphanylcarbene.



Theoretical Section

All calculations were performed with the Gaussian set of programs.[24] For the optimization of structures, double-ζ basis sets [6-31g(d,p)][25−28] were used. These basis sets include a single set of polarization functions at all atoms. In order to account for a proper electron correlation treatment, the optimization of structures was at times performed at a density functional level, utilizing the hybrid density function of Becke, Lee and Parr.[29] All structures were characterized by corresponding vibrational analysis, to identify these as energy minima on the corresponding electronic hypersurfaces. For some cases, the optimized geometries were energetically refined by single-point calculations at 6-311+g(d,p) basis set level[30][31] within the coupled cluster approximation, including single and double excitations from the ground state wavefunction, and triple excitation by corrections [CCSD(t)].[32][33] For the studied cases, the more elaborate CCSD(t) calculations parallel the results of the density functional (DFT) calculations at B3LYP level. As a consequence, general trends on singlet stabilities of carbenes can be explored on a large series of structures at the DFT level. The analysis of electron densities were performed within the Weinhold-Reed partitioning scheme.[34][35] Further investigations were also undertaken with Bader's method of "atoms in molecules" (AIM),[36] in order to analyze in more detail the nature of bonding in the corresponding structures.

Results and Discussion

a. Symmetrically Substituted Diphosphanylcarbenes

The frontier orbitals of a carbene, e.g. of the simplest representative methylene, are given as in Scheme 2. In the lowest energy singlet state, two electrons reside in the σ-orbital ($^1\sigma^2\rangle$, $^1A_1$ configuration) while in the lowest energy triplet state, one electron is in the σ and the other electron in the p orbital ($^3\sigma^1p^1\rangle$, $^3B_1$ configuration). It is the well-known picture of carbenes.[37−39] As a consequence, triplet carbenes possess widened R−C−R angles as relative to their singlet counterparts. One expects that in a carbene CR_2, the valence angle R−C−R increases with decreasing electronegativity of R.[40][41] For the methylene, the density functional calculations yield an energy difference of 12.2 kcal mol^{-1} between both electronic configurations [at B3LYP/6-31g(d,p) level], in favour of the triplet ($^1A_1$, CH = 1.119 Å, H−C−H = 100.0°; $^3B_1$, CH = 1.082 Å, H−C−H = 133.5°). This value may be compared to 9.0 kcal mol^{-1} obtained from the detailed experimental investigations.[42]

Scheme 2

In order to gain insight into the bonding of the phosphanylcarbenes, a variety of substituted carbenes were studied. A summary of symmetrically substituted species, CR_2 (R = phosphanyl unit) were calculated and the most important facets (singlet−triplet energy separations, relevant bonding parameters) are collected in Table 1.

Table 1. Relevant bonding parameters (bond lengths in Å, bond angles in °) and energy separations between singlet and triplet states of symmetrically substituted R_2C carbenes

[a] In parentheses values with CCSD(t)/6-311+g(d,p)//B3LYP/6-31g(d,p) + zero-point vibrational energy correction. − [b] C_{2v} symmetry. − [c] Ref.[45] − [d] Ref.[44] − [e] S. Koda, *Chem. Phys.* **1982**, *66*, 383−390.

In most cases the species adopt a C_2 symmetry in their equilibrium structures (singlets and triplets). The matter may be illustrated for the parent diphosphanylcarbene, in

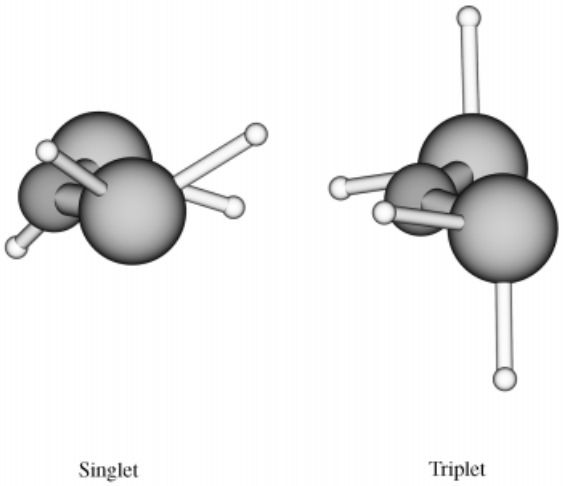

Figure 1. Molden plots of singlet and triplet diphosphanylcarbene

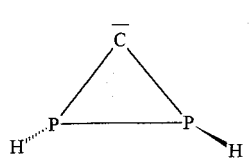
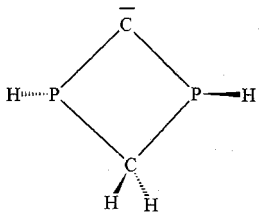
the Molden plots shown in Figure 1[43] of the singlet (left) and triplet (right) structures.

In the lowest energy singlet state (C_2 symmetry, P−C = 1.682 Å, P−C−P = 137.7°), the lone pairs at the phosphanyl groups tend to overlap with the empty p-orbital at the central carbon atom, so as to adopt π-conjugation, while in the lowest energy triplet state, the P−C bonds are elongated (1.765 Å, P−C−P = 137.7°) but the lone pairs at the phosphanyl substituents are almost perpendicularly oriented with respect to the central p-orbital. In both states the P−C−P angles are identical. Similar features were already predicted by previous quantum-chemical studies.[10]



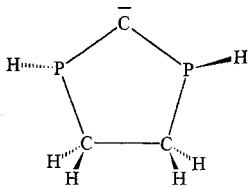
For comparison, we also included in our considerations the diaminocarbene. It adopts a planar (C_{2v} symmetry) structure in the singlet state, while the triplet state is confined to a twisted geometry (C_2 symmetry), in agreement with previous considerations.[44][45] For the diphosphanylcarbenes, the P−C distances are shorter in the singlet than in the triplet states. It indicates a stronger overlap in the former than in the latter. There is, however, an essential difference in the phosphanyl versus amino substitution. For R = NH_2 (diaminocarbene) in the singlet state the N−C−N valence angle is more acute than in the triplet state (112.2 vs. 122.5°). The trend is less unique for the various substituted diphosphanylcarbenes. The P−C−P angle is similar in both states [R = PH_2, $P(SiH_3)_2$, $P(CH_3)_2$, $P(NH_2)_2$], or even larger in the singlet relative to the triplet (R = PF_2) states.

Most of the singlet−triplet splitting is due to the height of the inversion barrier at the nitrogen or phosphorus atom. The large value for ΔE in the *N*-substituted carbenes is due to the low barrier at N (ca. 6 kcal mol^{-1} in NH_3)[46] which strongly stabilizes the singlet by allowing some back-donation into the vacant orbital. The much higher value for P (ca. 35 kcal mol^{-1} for PH_3)[46] leads to an inability of the P lone pair to stabilize the singlet and hence ΔE is much smaller. In addition, the more bent the phosphorus is compared to nitrogen (H−P−H in PH_3 is ca. 95° and H−N−H in NH_3 is ca. 109°), the more the triplet state will be stabilized as the lone pair at P is less repulsive than the lone pair on N when interacting with the single electron in the out-of-plane orbital on the carbene center. Since the C−N distance is much shorter than the C−P distance, the effects at the nitrogen are stronger than at the phosphorus atom. In accordance with Bent's rule,[47−49] within pyramidalization, the s-character of the lone pairs increases and the phosphorus atom utilizes more p-character in the formation of the σ-P−C bonds. It becomes a more electropositive substituent towards the central carbon atom. On this basis, it prefers a bonding situation in which the central carbon atom is expected to become more linear. At least this argument explains the essential difference in bonding between the singlet states of CR_2, R = PH_2 versus PF_2.



On the basis of these arguments, phosphanyl substituents with electronegative atoms [R = PF_2, $P(NH_2)_2$] possess small energy differences between singlet and triplet states lowest in energy. On the other hand, substituents which in general are known to decrease the inversion barrier in a phosphane [R = $P(CH_3)_2$, $P(SiH_3)_2$] increase the energy splitting. We have also studied the use of a phosphoraniminato group[50][51] [R = $P(PH(NPH_3)$] as a ligand at the phosphorus atom. The largest energy differences between singlet and triplet is obtained in this case. One may consider these substituents as extremely strong nucleophiles which increase the donor capability of a phosphanyl group. We have also probed the case of two phosphoraniminato ligands at the same phosphorus atom (see Table 1). It does not further increase the singlet−triplet energy gap. In the singlet state only one PR_2 (R = NPH_3) group is capable of interacting with the central carbon atom such as to maximize π-conjugation. The other PR_2 group is more strongly pyramidalized and avoids π-overlap with the central carbon atom. Overall, it causes reduction of the singlet equilibrium structure to C_1 symmetry. According to the population analysis in the investigated singlet structures (NBO and Laplacian of the electron densities), the carbon atom carries an excess negative charge (ca. −1.5 el), the phosphorus atoms are positively charged and the multiple bonding between the phosphorus and the carbon atom is weak (ca. 1.3 Wiberg bond indices).

Next we will discuss the bonding situation in diphosphanylcarbenes which are incorporated in a ring system. In these structures, a sharpened P−C−P angle is enforced which should be of more advantage to a singlet than to a triplet state. Various cases were studied and are collected in Table 2.



The singlet−triplet energy gap increases with increasing size of the ring system (Scheme 3). It is smallest for the 1.2-diphosphacyclopropenylidene (**5**, ΔE = 2.9 kcal mol^{-1}). The incorporation of a double bond in the five-membered ring system **4** (R = H) versus **7** slightly shortens the P−C bonds and concomitantly increases the singlet−triplet splitting. Compound **4** is the phosphorus analogue of the Arduengo carbene **2**.[15] We predict for the latter a sizeable energy splitting of 80.0 kcal mol^{-1} between lowest energy singlet and triplet states. Our findings are in agreement with previous calculations on this structure (ΔE = 79.3,[52]

	^{3}B	1.775	121.7	19.2

84.5[45] kcal mol^{-1}). Similar aspects have been found for the singlet−triplet energy separation in the Arduengo carbene **2** versus its hydrogenated analogue[53] and have been attributed to the effect of additional divalent state stabilization energy (DSSE).[54] In other words, in the singlet and to a lesser extent in the triplet states, additional cyclic π-delocalization is gained. The incorporation of the phosphanyl units into the five-membered ring system considerably stabilizes the singlet state of the carbene.[45] According to our calculations the singlet can be further stabilized by introduction of a phosphoraniminato ligand at the phosphorus atom (**4**, R = NPH_3). Thus one expects that the phosphorus analogue of the Arduengo carbene is a rather stable species. The population analysis indicates similar electron distributions to the alicyclic congeners for the ring structures. However, the P−C bonds are strengthened, as witnessed by their shortening. We have also tested the phosphorus analogue of the phosphoraniminato ligand (R = PPH_3). It appears to be less effective in the singlet stabilization than the former ligand (R = NPH_3).

b. Asymmetrical Phosphanylcarbenes

Next we will discuss the cases in which only one phosphanyl group is attached to the electron-deficient carbene center. The most prominent example is the push−pull substituted carbene **1**, already well investigated by quantum chemical investigations.[6][12] These calculations indicate that electron-withdrawing substituents at the carbon atom possess a particular role in the stabilization of a singlet carbene.[12] However, a detailed investigation of related substituents has hitherto not been given. In this section we want to demonstrate the influence of various substituted phosphanyl groups on the singlet stability of the various substituted species. We record here in more detail the results of the unsymmetrically substituted carbenes $R^1R^2PCR^3$, with R^1 and R^2 being different substituents and with R^3 as various electron-withdrawing groups. The results of the quantum-chemical investigations are collected in Table 3.

Table 3. Singlet−triplet energy separations and relevant bonding parameters of asymmetrically substituted carbenes, $R^1R^2PCR^3$

R^1	R^2	R^3	State	PC	∢PCR^3	ΔE (kcal mol^{-1})

			^{3}A	1.749	156.5	11.1
NH_2	NH_2	$PH_3^{(+)}$	^{1}A	1.545	176.4	0.0
			^{3}A	1.745	136.3	26.1
NH_2	NH_2	CF_3	^{1}A	1.584	126.4	0.0
			^{3}A	1.760	133.3	11.8
H_3PN	H	H	^{1}A	1.616	120.7	0.0
			^{3}A	1.765	130.7	17.1
H_3PN	H	SiH_3	^{1}A	1.588	140.7	0.0
			^{3}A	1.746	180.0	21.8
H_3PN	H	$PH_3^{(+)}$	^{1}A	1.589	141.7	0.0
			^{3}A	1.760	135.1	31.8

In agreement with the previous considerations,[10][12] the singlet−triplet separation for the monophosphanylcarbene is fairly small. Given a diaminophosphanyl ligand, R^3 is most effective in the order $SiH_3 \approx CF_3 < PH_3^{(+)}$. Most

noticeable is again the fact that the phosphoraniminato ligand reveals a particular role in the stabilization of the carbene. The most stable carbene is predicted to be the case with one phosphoraniminato ligand and one phosphonium group at the carbon centre. Alternatively, stable carbenes require diamino substitution at the phosphorus atom. The Wiberg bond indices indicate a bond with almost double-bond character between the phosphorus and the carbon atom for these structures, superimposed by a strong charge separation between them. It is in conformity with previous considerations.[12] We note that recently a quantum-chemical study on parent phosphanylcarbene H_2PCH and related structures has been reported.[55] Regarding these findings, the reported structural details of H_2PCH are similar, while for the push−pull carbene $(H_2N)_2PCSiH_3$ the reported singlet−triplet energy separation is essentially larger (26.9 kcal mol^{-1}) than our value (11.1 kcal mol^{-1}, see Table 3).[56]

It is of interest also to examine the effect of push−pull substitution in the case of aminocarbene, H_2NCH. We calculate for it a singlet−triplet energy separation of 29.8 kcal mol^{-1} [B3LYP/6-31g(d,p) with ZPE correction]. The energy gap decreases to 20.6 kcal mol^{-1} when the hydrogen atom is replaced by a silyl group. In other words, a push−pull mechanism which is operative in the phosphanylcarbenes, does not hold true for the aminocarbene, the singlet−triplet energy gap is even considerably decreased. It is known that silyl groups tend to bring the triplet character of a carbene to the fore.[57][58] Finally, these values are related to the experimental results of the aminophosphanylcarbene.[23] We predict an energy gap in ΔE = 27.8 kcal mol^{-1}, almost similar in magnitude to the monoaminocarbene. The diaminocarbene resulted to ΔE = 51.1 kcal mol^{-1}, in agreement with previous quantum-chemical investigations (see Table 1).

Conclusions

The effect of various types of substituents on the singlet−triplet energy separations have been studied by density functional theory. The results of our investigations can be summarized as follows:

(1) The singlet−triplet energy separation in the diphosphanylcarbenes can be increased by suitable substitution at the phosphorus atom. In the parent compound, the energy gap is fairly small, but it increases by alkyl substitution or most effectively by substitution with a phosphoraniminato ligand.

(2) A considerable stabilization of the singlet species is observed by incorporation of the diphosphanyl ligand into a five-membered ring system, resulting in the phosphorus analogue of the Arduengo carbene. Again the singlet−triplet energy separation is increased by introduction of the phosphoraniminato ligand.

(3) Asymmetric phosphanylcarbenes are most stable in the case of the phosphorus atom being substituted by amino groups or alternatively by the phosphoraniminato ligand and the carbon atom in addition being attached to an electron-withdrawing substituent, such as a silyl or a phosphonium group.

Our theoretical analysis predicts new types of substitutent patterns which are effective in stabilizing singlet ground states of phosphanylcarbenes. Its verification may be a challenge to the experimental chemist. Further investigations will be dedicated to an investigation of the nucleophilic versus electrophilic character[37] of phosphanylcarbenes, towards cycloaddition reactions as well as to their transition metal complexation properties.

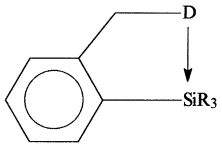
Pentacoordination at Fluoro-Substituted Silanes by Weak Lewis Donor Addition



Wolfgang W. Schoeller*[a] and Alexander Rozhenko[a]

Keywords: Fluorine / Silicon / Ab initio calculations / Donor-acceptor systems

Quantum chemical calculations at the ab initio level indicate that Lewis donors such as amine or water form weak donor–acceptor complexes with fluoro-substituted silanes. The strength of the donor–acceptor formation increases with increasing degree of fluorine substitution. Amine and water form strong adducts only for tetrafluorosilane. The higher element homologues of Lewis donors, such as phosphane and sulfur dihydride, do not in essence coordinate. A considerable role in donor–acceptor formation is exerted by chelation effects which impose intramolecular interactions on functionalized ligands. The corresponding structures are explored.

Introduction

Corriu and co-workers have presented pioneering contributions in a series of experimental studies on the understanding of pentacoordination at silicon.[1−3] The results of these investigations further increased the knowledge of nucleophilic substitution at silicon.[4,5] For the extension of the coordination sphere at the silicon center aromatic ligands with a dimethylamino-functionalized side chain were mainly used, as indicated in Scheme 1. In this structure the Lewis donor is forced into close proximity to the substituted silane unit resulting in a D−A complex (D = donor, A = acceptor). Only a few species with other donor elements in the side chain are known.[5−11] Recently a structural investigation of an alkoxy-substituted pentacoordinated silicon compound has been reported (**1**, D = OCH_3)[13] (Scheme 1).

D = OR, NR_2

R = alkyl, aryl, F, OR

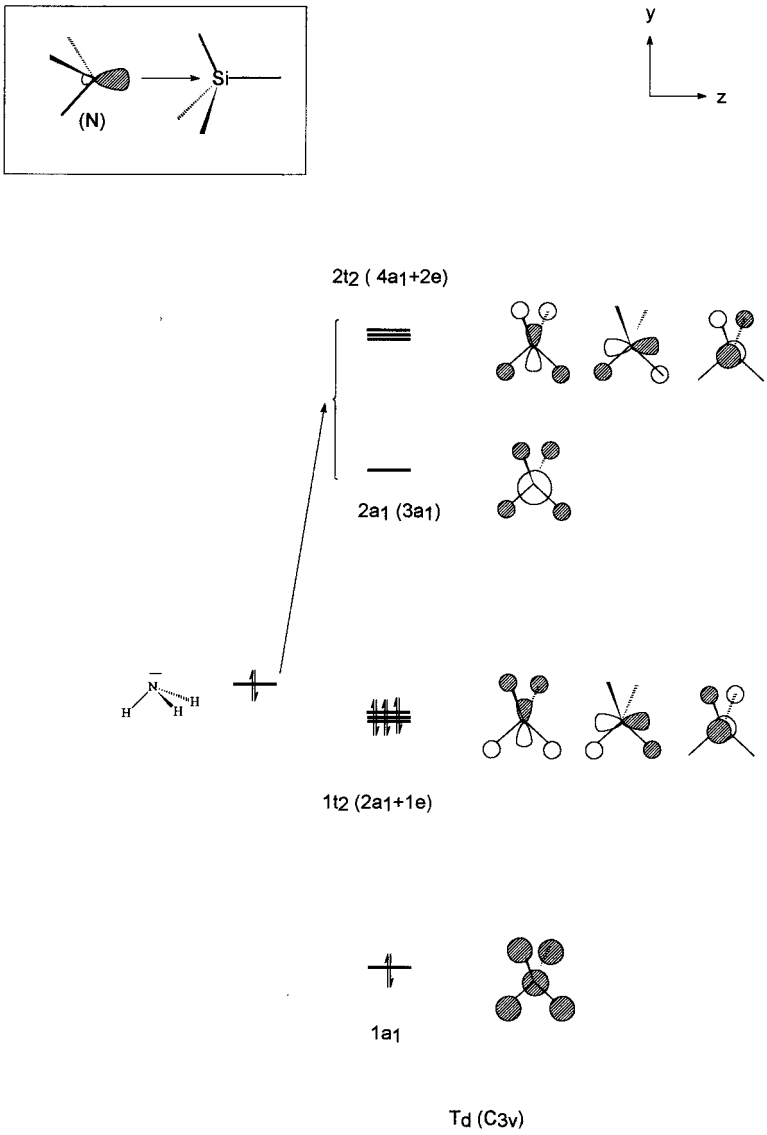
1

Scheme 1

Pentacoordination at silicon is usually monitored by ^{29}Si NMR spectroscopy[14] as the coupling to adjacent nuclei (^{19}F, ^{1}H) is influenced by pentacoordination.[15] This indicates that the stability of the pentacoordinated species is dictated by the electronegative fluorines at the silicon centre. Information about the varying strength of the donor-silicon interaction is also drawn from temperature-dependent NMR studies.[13] To this end an interesting 1,3-sigmatropic fluorine migration within a 2-phospha-1,3-disilaallyl derivative has been observed[16] thus indicating facile coordination at the silicon center with fluorine as a donor. One of the major questions is the magnitude of these bonding effects and how they are affected by the nature of the Lewis bases involved in the adduct formation.

Lewis bases can be classified into two categories, either as hard or soft donors, as discussed in detail in the pioneering work of Pearson et al.[17,18] In the present investigations we report quantum chemical calculations at an ab initio level which have a bearing on this problem. We will discuss the role of hard (NH_3, OH_2) and soft (PH_3, SH_2) donors for possible interaction with fluorosilanes. Fluorine atoms as substituents were chosen because they mimic best the effect of electronegative substituents attached to a silicon centre. In the experiment the coordination to a substituted silane is verified by intramolecular donor addition of an aromatic ligand functionalized with a donor side chain, e.g. compound **1**. Corresponding models will be explored in the last section of this publication. The details of the quantum chemical calculations are given in the Theoretical Section.

Results and Discussion



Qualitative Considerations

The donor−acceptor formation between an amine, phosphane, etc. and a silane is shown schematically in Scheme 2.

The parent silane possesses two sets of triply degenerate molecular orbitals (t_2 with T_d symmetry) constituted from the p-orbitals at the central silicon atom and the adjacent hydrogen atoms.[19] In addition, the s-orbital at the silicon atom forms a bonding and antibonding molecular orbital (a_1) with the neighbouring hydrogen atoms. Under the C_{3v} symmetry adopted in the donor−acceptor complex the t_2 orbitals reduce to (a_1 +e). A corresponding donor−acceptor interaction takes place by transfer of electron density from the n-orbital of the donor fragment (a_1) (lone pair

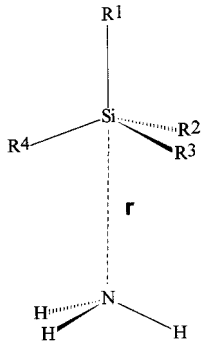
Scheme 2

orbital at NH_3, PH_3) into the antibonding orbitals (a_1) of the silane fragment. According to second-order perturbation theory[20–22] such a donor–acceptor interaction can be assumed to increase with the lowering of the ionization potential of the donor orbital, given the same acceptor. In other words PH_3 should be a better donor than NH_3 since the ionization potential of the former (9.9 eV) is smaller than that of the latter (10.9 eV); likewise OH_2 (12.6 eV) is a poorer donor than SH_2 (10.5 eV).[21] It is equivalent to the assignment that nitrogen is more electronegative than phosphorus. Thus within the concept of Pearson′s classification into hard and soft donors an amine is the harder donor than a phosphane.[23] Within the Klopman formulation of second-order perturbation theory[22] the interaction of the donor (nucleophile) and the acceptor (electrophile) is given according to Equation 1,



$$\Delta E = -\frac{Q_{nuc}Q_{elec}}{\varepsilon R} + \frac{2(c_{nuc}c_{elec}\beta)^2}{E_{HOMO(nuc)} - E_{LUMO(elec)}} \qquad (1)$$

with ε as the local dielectric constant (of the reaction medium), Q_{nuc} and Q_{elec} as the total charges at the overlapping atoms, E_{HOMO} and E_{LUMO} the molecular orbital energies of the donor (nucleophile) and the acceptor (electrophile) and ß as the overlap integral between the nucleophile and electrophile (for a detailed definition see ref.[22a]). The first term in this equation is simply the Coulombic repulsion or attraction. This term, which contains the total charge Q on each atom, is obviously important when ions or polar molecules are reacting together. The second term refers to the HOMO–LUMO interaction, as indicated schematically in the previous scheme. A priori one can differentiate between two extreme cases where either the coulombic term or the second term dominates. In the latter case one would expect that with decreasing ionization potential of the donor the adduct stability increases thus giving the opposite stability order, i.e. $OH_2 < NH_3$ for adduct formation. In general one assumes[20,21] that coulombic contributions are only important for interactions between charged species. This is not the case at hand as the Lewis donors and ac-

ceptors are neutral. From the qualitative discussion it is also clear that a possible HOMO−LUMO interaction, according to Equation (1), increases with the lowering of the LUMO energies of the silanes. This can be done by replacing the hydrogens with electronegative substituents. In this case at hand we have probed the effect on silanes successively substituted by fluorine. Such a situation is also observed experimentally,[15] where the shielding in the ^{29}Si NMR spectrum is changed by addition of amine to fluorine substituted silanes.

The Donor Adducts

In order to reveal the various factors which contribute to the overall donor-silicon stability we first determined the equilibrium structures for a selected variety of donor-adducts with NH_3, OH_2 and PH_3, SH_2 as donors, and with increasing fluorine substitution at the silicon center. In general the adducts tend to form a trigonal bipyramid, as shown in Scheme 3.

Scheme 3

The most relevant bonding parameter for the encounter complexes is given by r, the distance of the donor atom from the silicon center. Moreover, one has to differentiate between fluorine substitution at an equatorial (R^2, R^3, R^4) and/or an axial (R^1) position. The effect of substitution in both cases was investigated.

The binding energies (exothermic, in kcal/mol) of the various adducts together with the bonding parameter r (in Å) are collected in Table 1.

Overall the binding energies for the addition of an amine are fairly small. They increase with increasing fluorine substitution and are at a maximum for SiF_4. A fluorine in the axial position exerts a stronger acceptor effect towards the amine than in the corresponding equatorial position (e.g., structure 3 vs. 2 in Table 1) and the resulting adducts are slightly (ca. 2 kcal/mol) more stable. This reflects the well-known tendency that electronegative substituents in a trigonal bipyramid prefer the axial rather than the equatorial position, as already well rationalized on the basis of one-electron considerations.[19] We have also probed the results on the basis of more sophisticated calculations. By this we mean single point calculations on the equilibrium geometries with the CCSD(t)/6−311+g** method. The results

thus obtained (see Table 1) are similar, although the adduct energies are somewhat smaller.

Our analysis indicates fairly small adduct energies for amine and water coordination. For addition to SiF_4 the strengths of the stabilities is in the order OH_2 (4.0 kcal/mol) < NH_3 (8.5 kcal/mol) [at the TZP level, see Table 1]. The latter donor possesses a lower ionization potential than the former.[20] In order to gain a more detailed understanding we have also evaluated adduct formation for the donors PH_3 and SH_2. The results of these investigations are summarized in Table 2.

Table 2. Donor−acceptor binding energies (exothermic, in kcal/mol) of SiF_4 with PH_3 and SH_2

Donor	r [Å]	DZP[a]	TZP[b]

[a] MP2(fc)/6−31 g** plus zero-point vibrational energy correction. − [b] CCSD(t)/6−311+g**//MP2(fc)/6−31 g** plus zero-point vibrational energy correction, at level a).

Only the tetrafluorosilane, which exerts the strongest acceptor properties, was examined. As before the binding energies of the various donors are fairly small. The energy results indicate that the coordination ability of the tetrafluoro-substituted silane is much smaller for these two donors i.e. they are negligibly small.

On the basis of the Klopman concept[21,22] it is apparent that the electrostatic interactions [first term in Equation (1)] are not the dominant contribution to the overall stability of the resulting adducts otherwise the donor OH_2 would form a stronger adduct towards SiF_4 than NH_3, which is not the case. Since the energy contributions for the binding of the donors are rather weak a further bisection into various con-

tributions was not attempted. The fact that the donors PH_3 and SH_2 form only very weak adducts is also in agreement with the recently explored dual-parameters equation for the stability of silylene adducts.[24] Accordingly, the resulting stability of a donor−acceptor complex depends on: (a) the donor ability (as measured by the ionization potential) and (b) the stability of a hypothetically covalent D(onor)−Si bond.[24] For the present system it means that a covalent D−Si bond is almost comparable for the series OH_2 and NH_3, or alternatively for SH_2 and PH_3. For the former two donors it is stronger than for the latter two donors, although the stabilities for all the investigated cases are fairly small.

The Chelation Effect

In the experiment the donor centre is coordinated intramolecularly to the silane unit, in structures such as **1**. The aromatic ligand exerts conformational rigidity which forces the donor fragment towards the silicon centre. This should enhance a possible donor−acceptor interaction. In order to reveal this aspect in more detail we performed quantum chemical calculations (MP2/6−31 g**) on **1** with the donors D = −OH, $-NH_2$, −SH, $-PH_2$. Only the results for the former two donor structures will be summarized here (Scheme 4).

The silicon center was substituted by three fluorine atoms which take up one axial and two equatorial positions. The substitution pattern was chosen in order to maximize the donor−acceptor interaction. For D = −SH and $-PH_2$ no coordination was observed. In other words for these cases the donor function rotates away from the silicon center. In general the D−Si distances for the intramolecularly coordinated cases are shorter (N−Si 2.176, O−Si 2.441 Å) than in the corresponding adducts for bimolecular addition (N−Si 2.275, O−Si 2.685 Å) for the trifluoro-substituted cases, see Table 1). Thus on this basis the chelation effect by intramolecular coordination of the donor to the silicon center seems slightly more strongly pronounced for oxygen than for nitrogen coordination. The D−Si bond ratios for intra- versus intermolecular donor coordination are: N (2.275/2.176 = 1.046, O 2.685/2.441 = 1.100). It must be noted that the actual D−Si distances in the intramolecular coordinated complexes are dependent on the substituents (alkyl, silyl) at the donor. In addition the D−Si bond energies are rather weak and therefore also depend on the chosen computational level.[25]

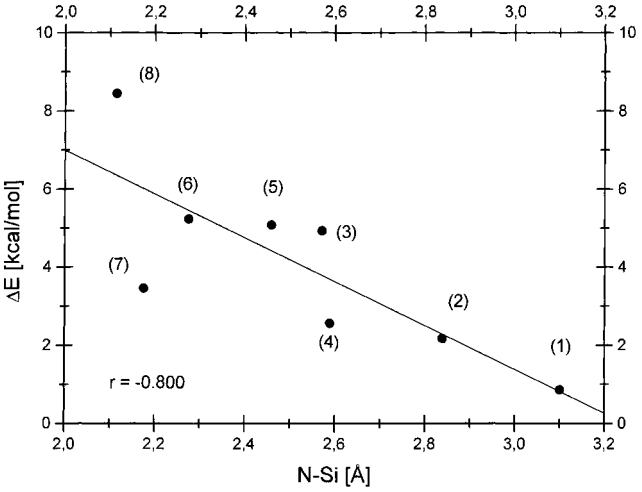

Figure 1. Linear correlation of N−Si distances (in Å) versus binding energies (negative, in kcal/mol) for amine coordination to substituted silanes

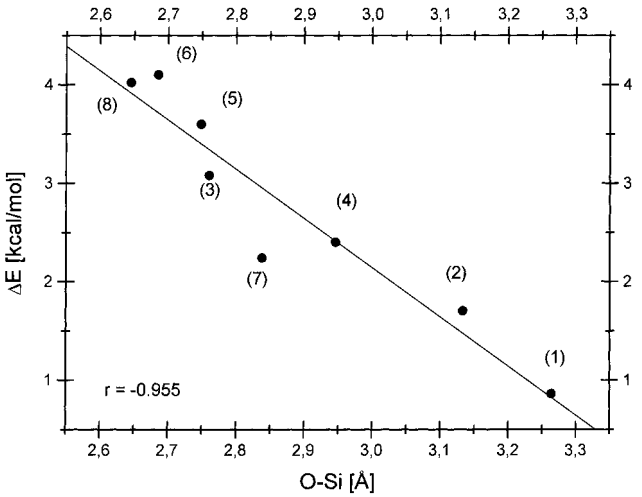

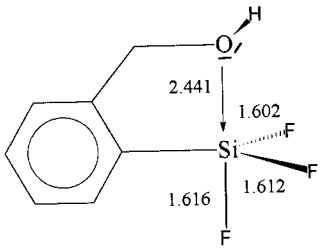

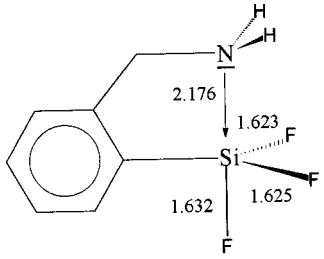

Figure 2. Linear correlation of O−Si distances (in Å) versus binding energies (negative, in kcal/mol) for water coordination to substituted silanes

To a first approximation the binding energies can be linearly related to the equilibrium bond lengths of the resulting donor−acceptor complexes. A rationale for this approach is given in the Experimental Section. A correspond-

Scheme 4

ing dependence of both quantities for amine and water addition is shown in Figure 1 (amine coordination) and Figure 2 (water coordination).

Accordingly, for both cases approximate linear relationships are apparent. It indicates that considerable changes in bond lengths (e.g. by 10%) cause only small changes in the resulting binding energies. On this basis it is evident that intramolecular coordination, such as in **1**, largely determines the actual equilibrium D−Si bond lengths, and, as we have seen, it is more pronounced for water than for amine coordination. Utilizing the linear relationship given in Figures 1 and 2 one can predict an extrapolation of the binding energies in the intramolecularly coordinated complexes **1**. They should be comparable and in the order of approx. 10 kcal/mol. Thus the binding energies are expected to be slightly larger than for the intermolecularly coordinated cases.

^{29}Si NMR Chemical Shifts

It is informative to analyze the effect of coordination on the chemical shifts of the silicon centers. We have calculated the corresponding ^{29}Si NMR chemical shifts for the cases of amine addition. A list of these values, obtained at the RHF and MP2 level of sophistication, are summarized in Table 3.

Table 3. d^{29}Si NMR shifts at RHF and MP2 level, with reference TMS

Compound	RHF[a,b]	MP2[a,b]	exp.[b]
TMS	0.0	0.0	0.0

[a] Basis set 6−311+g(2d,p). − [b] Chemical shifts relative to TMS: $\delta(^{29}Si) = \sigma(TMS) - \sigma(silane)$ [MP2 values]. σ(TMS) = 385.8 [367.2] ppm. − [c] C. Maerker, J. Kapp, P.v.R. Schleyer, in *Organosilicon Chemistry II*, Eds., N. Auner and J. Weis, VCH, 1996. − [d] Experimental values: H.C. Marsmann, *NMR Basic Principles and Progress, 17*, Springer, Berlin, **1981**.

For convenience we have also included here the values for tetramethylsilane (TMS) and the parent silyl cation. The results indicate a strong effect of electron correlation on the NMR chemical shifts only for the cases with low-lying empty orbitals, e.g., as the silyl cation, as seen by a comparison of the RHF versus MP2 values. For the other cases the computed chemical shifts at the RHF level are similar to those at the MP2 level. Is there a relationship between the changes in chemical shifts by coordination and adduct energies? In order to reveal a possible dependence between both quantities, we analyzed a linear relationship, as illustrated in Figure 3.

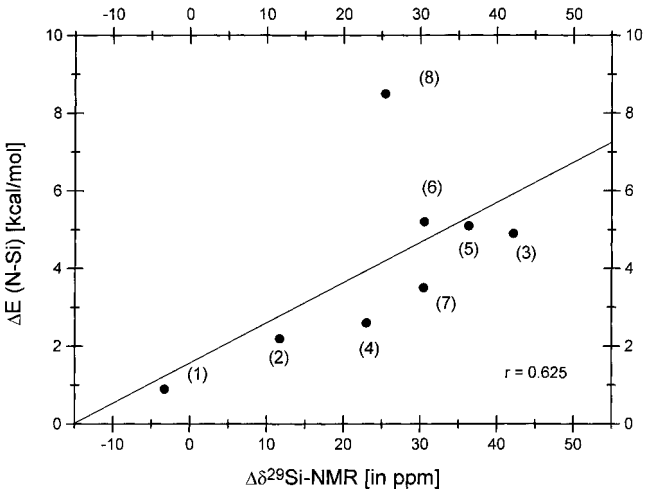

Figure 3. Linear correlation of amine adduct energies in (kcal/mol) versus differences in chemical shifts [$\Delta\delta^{29}Si = \delta^{29}Si$ (silane) − $d^{29}Si$ (silane−NH_3)]

We note that such a relationship is empirical, there is no theoretical justification for it. The difference in ^{29}Si NMR chemical shifts are given as the chemical shift of the amine-coordinated silane minus the chemical shift of the corresponding uncoordinated silane, at the MP2 level of sophistication (see Table 3). Our investigations indicate that a rough relationship between both quantities approximately exists, however the linear correlation is rather poor (r = 0.625).

Conclusions

The results of our investigations can be summarized as follows:

(1) Lewis donors, such as NH_3, PH_3, OH_2 and SH_2 form only weak donor−acceptor complexes with silanes. The effect of electronegative substituents was probed for fluorine. With increasing fluorine substitution the Lewis acidity is slightly increased.

(2) The donors NH_3 and OH_2 exert comparable donor properties, the former is slightly stronger than the latter whilst the higher element homologues PH_3 and SH_2 possess only negligible donor properties versus the substituted silane. The donor variety was studied for donation towards the best acceptor tetrafluorosilane. Within the Klopman concept one could describe the complexes by weak HOMO−LUMO interactions.

(3) For the intramolecular coordination shorter D−Si distances are observed than for intermolecular (bimolecular) coordination. Overall the resulting D−Si bonds are rather weak, in other words the chelating effects are dictating the equilibrium geometries

Experimental Section

Theoretical: The energy optimization of structures were performed using ab initio calculations with the valence double-ζ basis set, 6−31 g** of Pople et al.[26,27] Since donor−acceptor complexes are strongly determined by a superposition of covalent and ionic structures[28] all calculations were carried out at the MP2 level of optimization. Equilibrium geometries were identified by the corresponding vibrational analysis within the harmonic approximation. Further single-point calculations were done at the equilibrium geometries, utilizing the 6−311+g** basis set for first and second row elements.[29,30] This basis set has been considered of triple-zeta quality (TZP), since the 6−311 g basis set (triple split in the valence s- and p-shell) is augmented by one set of diffuse functions.[31] The basis sets utilized were augmented by a single set of polarization functions[32] at all atoms and the latter in addition by a set of diffuse functions.[33] Full details are given in the discussion. The NMR calculations were carried out with an enlarged basis set [6−311+g(2d,p)] at the optimized geometries. The isotropic shielding values were computed with the Gauge-Independent Atomic Orbital method (GIAO).[34,37] All calculations were performed with the Gaussian 98 set of programs.[38]

The Linear Bond Length-Bond Energy Relationship: Following the principal considerations of Pauling,[39] the energy of a bond as a function of the bond length is simply given by E(r) = A − B × ln (r), where A and B are constants and r the bond length. For small changes in the bond lengths this formula can be expanded in a Taylor series, resulting in an approximate linear relationship between the bond energy and the distance. Such an approximation holds true only for small changes in bond energies, as in the case at hand.

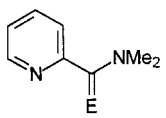
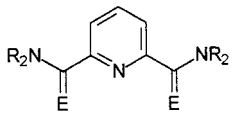
NMR Investigations of Restricted Rotations and Metallotropic Shifts in Rhenium(I) Tricarbonyl Halide Complexes of Pyridyl Carboxamide and Thioamide Ligands

Keith G. Orrell,*[a] Anthony G. Osborne,[a] Jade Ol Prince,[a] Vladimir Šik,[a] and Dionyssios K. Vellianitis[a]



Keywords: Pyridyl carboxamides / Carbonyl complexes / Rhenium / Metallotropic shifts / MMR spectroscopy

A series of rhenium(I) tricarbonyl halide complexes of pyridyl mono- and di-carboxamides and -thioamides has been studied by dynamic NMR techniques. Oxygen coordination to Re^{I} of the carboxamide ligand reduced the energy barrier to C−N rotation by 2−13 kJ mol^{-1} whereas sulfur−Re^{I} coordination of the thioamide ligands led to a reduction of 28−33 kJ mol^{-1}. In the pyridyl dicarboxamide and -dithioamide metal chelate complexes metallotropic shifts occur between the three donor atoms, O, N, O or S, N, S, energies [$\Delta G^{\ddagger}$ (298.15 K)] being in the range 78−89 kJ mol^{-1}; these high values arise from the strong electron donating properties of the -NR2 (R = Me, Et) groups.



Introduction

As part of a research programme into the coordination properties of terdentate ligands and the molecular dynamics in solution of the metal complexes that are formed when the ligand is acting as a bidentate chelate ligand to a metal, we have previously investigated some metal complexes formed by ligands such as 2,2′:6′,2′′-terpyridine(terpy)[1] and 2,6-bis(pyrazol-1-yl)pyridine (bppy)[2] that present a N_3 donor set to the metal moieties. From these studies we have obtained quantitative information on the mechanisms and energetics of molecular motions such as 1,4-metallotropic shifts,[3] and metal-hurdling[4] fluxions. In order to investigate potential electronic and steric effects on the structures and dynamic behaviour in solution of related ligands and the corresponding metal complexes we have initiated an investigation into some complexes formed by pyridine-based terdentate ligands that present an ONO or a SNS donor set to a metal. In this paper we report our findings for the synthesis and studies by the methods of dynamic NMR spectroscopy on the carboxamide and thioamide ligands, *N*,*N*-dimethyl-2-pyridinecarboxamide (dmpc), *N*,*N*-dimethyl-2-pyridinethioamide (dmpt), *N*,*N*,*N*′,*N*′-tetramethyl-2,6-pyridinedicarboxamide (tmpdc), *N*,*N*,*N*′,*N*′-tetramethyl-2,6-pyridinedithioamide (tmpdt), *N*,*N*,*N*′,*N*′-tetraethyl-2,6-pyridinedicarboxamide (tepdc), *N*,*N*,*N*′,*N*′-tetraethyl-2,6-pyridinedithioamide (tepdt) and the metal complexes [$ReX(CO)_3L$] (X = Cl or Br; L = dmpc, dmpt, tmpdc, tmpdt or tepdc).

The dicarboxamide compounds have previously been used as ligands for complex formation with the lanthanide elements[5][6] and with cobalt(II), copper(II) and nickel(II) of the d-block metals.[7,8,9] In all the metal complexes studied previously the ligands are acting in a terdentate chelate mode that uses the pyridyl nitrogen and the two oxygen atoms as the donor set. To the best of our knowledge the thioamides have not been employed as ligands.

E = S, R = Me tmpdt
E = S, R = Et tepdt

When the pyridyl dicarboxamide and dithioamide ligands act as bidentate chelates they may be described as hemilabile ligands.[10] Such ligands contain at least two different types of bonding group with different bonding strengths and these can lead to intramolecular ligand exchange processes ("fluxional shifts") and ligand displacement reactions. The coordination chemistry of such ligands has recently been reviewed.[11] This present work is a further contribution to this active area of chemistry.

Results

The carboxamide and thioamide ligands were prepared as described in the experimental section. The monofunctional ligands were air-stable oils and the difunctional ligands air-stable, crystalline solids. The rhenium(I) complexes of the ligands, namely *fac*-[$ReX(CO)_3L$] (X = Cl, L = tmpdc, tepdc, or tmpdt; X = Br, L = dmpc, tmpdc, tepdc, dmpt or tmpdt) were isolated in good yields as yellow or orange/red air-stable solids. The ligands and their Re^{I} complexes were characterised by melting point, IR and ^1H NMR spectroscopy, EI mass spectrometry, and, in the case of the metal complexes, by elemental analysis (Table 1).

In the metal carbonyl stretching region of the infrared spectra the complexes show three strong peaks (Table 1) consistent with a facial arrangement of the carbonyl groups.[1]

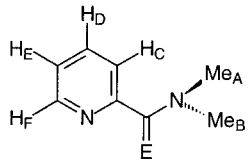
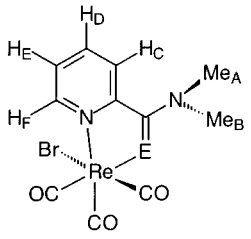
[a] Yield quoted relative to metal-containing reactant. – [b] Recorded as chloroform solution. – [c] Calculated values in parentheses.

This indicates that the pyridine-based ligands are acting as bidentate chelate ligands by substituting two equatorial carbonyl groups of the [ReX(CO)$_5$] compound. For the complexes derived from the dicarboxamide ligands two amide carbonyl stretching vibrations are observed in the infrared spectrum, one approximating to the free ligand value and the other 25–30 cm^{-1} lower. This observation indicates that the dicarboxamide ligands are bound to the metal in a bidentate chelate fashion via an ON donor set. This finding was confirmed by the ^{1}H NMR spectroscopic studies (see later).



(i) Monoamide ligands, (L), dmpc, dmpt and Complexes [ReBr(CO)$_3$L]

The ^{1}H NMR spectra of dmpc and dmpt consisted of six signals (Table 2), the pairs of *N*-methyl shifts indicating severe restriction to rotation about the C–N bond of the carboxamide and thioamide functions. This is fully in accordance with previous studies of such systems and, in particular, on dmpc.[12] Distinction between the *N*-methyl signals was based on the results of the NOE difference experiments (carried out on the corresponding dicarboxamides tmpdc and tepdc, see later).



The energy barrier to rotation in dmpc was measured by obtaining ^{1}H NMR spectra in the temperature range 303–373 K. On increasing the temperature the two *N*-methyl signals broadened, coalesced (at 363 K) and then changed to a single, sharp signal. A bandshape analysis of signals in the range 323–373 K yielded an activation energy (see later) in good agreement with a previous study.[12] In contrast, variable temperature ^{1}H NMR spectra of the thioamide dmpt showed no signal broadening up to ca. 393 K, indicating that the rate of C(S)–N bond rotation was slow on the NMR timescale even at 393 K. The 2D-EXSY NMR method,[13–15] which is sensitive to slower exchange rates that are not accompanied by any line broadening, was therefore applied in the temperature range 353–393 K with mixing times 0.8 s (353 K), 0.1 s (373 K) and 0.02 s (393 K). Clear cross-peaks between the *N*-methyl signals were observed at these temperatures, from which first-order rate constants for the bond rotation process were computed with the authors' D2DNMR program.[27]

Coordination of dmpc and dmpt to form ReBr(CO)$_3$ complexes led to strikingly different room temperature ^{1}H NMR spectra. These are shown in Figure 1, where it will be noted that [ReBr(CO)$_3$dmpc] shows a clear chemical shift

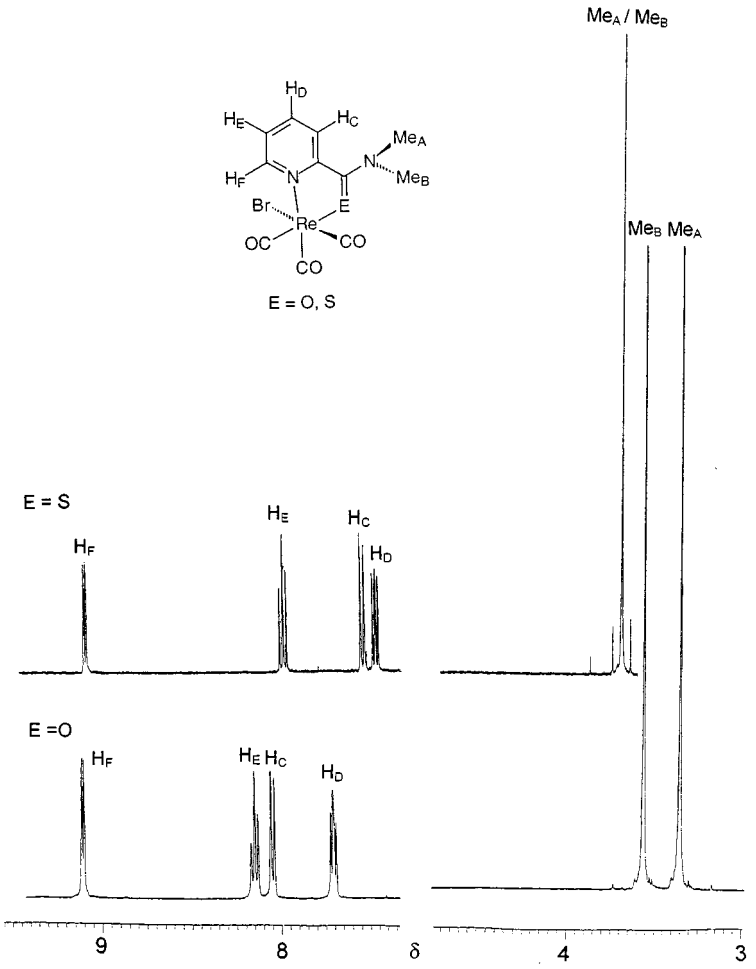

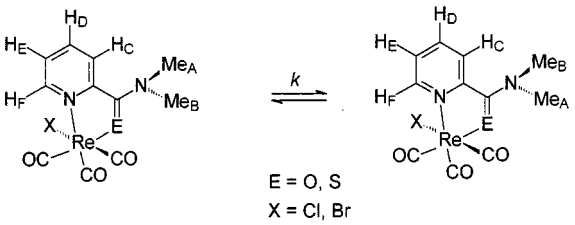

Figure 1. 400 MHz ^{1}H NMR spectra of [ReBr(CO)$_3$dmpc] and [ReBr(CO)$_3$dmpt] at 303 K in $(CDCl_2)_2$ and $CDCl_3$ respectively

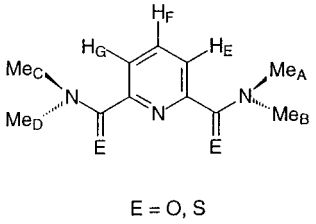
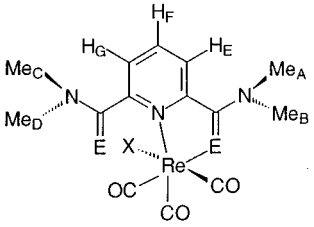
distinction between the *N*-methyl signals, whereas [ReBr(CO)$_3$dmpt] does not, implying that C−N rotation in the carboxamide complex is slow on the NMR timescale at ambient temperatures whereas in the thioamide it is fast.

The temperature dependencies of these exchange rates, *k*, described according to Scheme 1, were measured by recording the ^{1}H NMR spectra of [ReBr(CO)$_3$dmpc] in the range 303−413 K and of [ReBr(CO)$_3$dmpt] in the range 223−303 K. Coalescences of the pairs of *N*-methyl signals in these two complexes occurred at ca. 363 K and ca. 268 K, respectively. Bandshape analyses in these temperature ranges enabled energy barriers for the C−N rotations to be evaluated (see later).

Scheme 1. Restricted rotation of the NMe_2 group in the monoamide ligand complexes



(ii) Diamide ligands (L) tmpdc, tmpdt, and Complexes [ReX(CO)$_3$L] (X = Cl, Br)



The ligands tmpdc and tmpdt exhibited ^{1}H NMR spectral features (Table 3) very similar to their monofunctional counterparts dmpc and dmpt. Thus, at ambient temperatures both ligands displayed chemical shift distinction within each of the *N*/*N*′-dimethyl pairs. Unambiguous assignments were made with the aid of Nuclear Overhauser Enhancement (NOE) difference experiments on tmpdc.

Irradiation of the lower frequency methyl signal at δ = 3.07 caused a positive NOE of the pyridyl $H_{E/G}$ signal whereas no such effect was observed on irradiating the signal at δ = 3.15. The NOE was small indicating that the NMe_2 groups are not coplanar with the ring but rotated such that the methyls Me_A/Me_C are in shielding zones associated with the aromatic ring current.

On warming, exchange broadening of the *N*-methyl signals occurred in the case of tmpdc, with coalescence being achieved at ca. 353 K, whereas no significant broadening occurred for tmpdt until ca. 393 K, which was near the high-temperature limit of the solvent $(CDCl_2)_2$. The 2D-EXSY method was therefore used for tmpdt, and good quality, rate-sensitive spectra achieved at temperatures 353,

Table 3. ^{1}H NMR spectroscopic data for the ligands tmpdc, tmpdt and the complexes [ReX(CO)$_3$L] (L = tmpdc, tmpdt; X = Cl, Br)

Compound	δ_A	δ_B	δ_C	δ_D	δ_E (J_{EF}/Hz)	δ_F (J_{EF}, J_{FG}/Hz)	δ_G (J_{FG}/Hz)

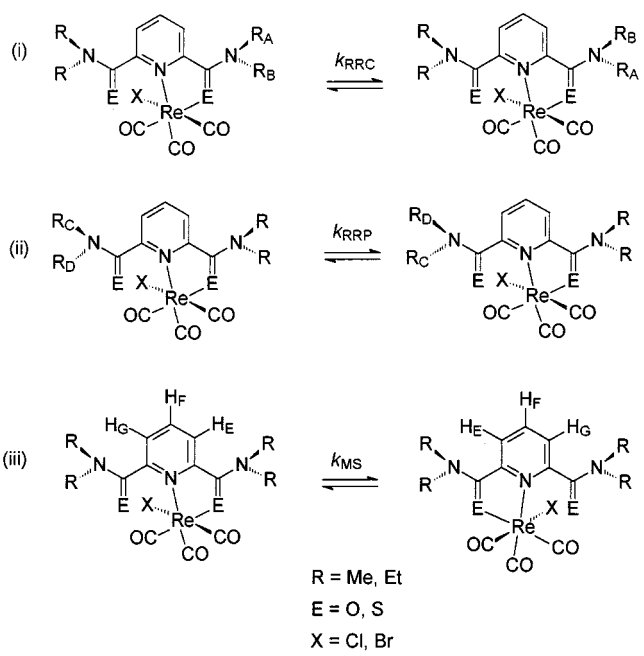
[ReBr(CO)$_3$tmpdt][b]	3.63 s	3.63 s	3.20 s	3.64 s	7.44 d (10.6)	7.95 t (10.6, 10.6)	7.31 d (10.5)



[a] Measured in $(CDCl_2)_2$ at 303 K. – [b] Measured in $CDCl_3$ at 303 K. s = singlet, d = doublet, t = triplet.

373 and 393 K, using mixing times of 0.5 s, 0.1 s and 0.01 s, respectively. The spectral characteristics of both these ligands indicate the very different degrees of restriction to C–N rotation in these species.

The ^{1}H NMR spectra of [ReX(CO)$_3$tmpdc] (X = Cl, Br) consisted of four separate *N*-methyl signals, the pair Me_A/Me_B associated with the coordinated carboxamide group being to high frequency of the other pair, Me_C/Me_D. On warming the $(CDCl_2)_2$ solution of the complex the signals of Me_A and Me_B began to broaden, coalescing at ca. 343 K and then sharpening to an averaged signal. The signals of Me_C and Me_D showed slight increases in bandwidth above ca. 323 K, indicating the onset of slow C–N rotation in the pendant – $C(O)NMe_2$ group as well as in the coordinated group. This broadening increased with increasing temperature until at ca. 403 K the Me_C/Me_D signals started to merge with the broad average Me_A/Me_B signal. By 413 K all signals had coalesced into a single broad signal. These changes are clearly indicative of the consecutive onset of (i) C–N rotation of the coordinated -$C(O)NMe_2$ group, (ii) C–N rotation of the pendant -$C(O)NMe_2$ group, and (iii) 1,4-metallotropic shifts which cause a loss of distinction between the coordinated and uncoordinated carboxamide functions. Further evidence for the 1,4-metallotropic shift was obtained from the signals of the pyridyl hydrogens at the 3- and 5-position (labelled H_E and H_G). These commenced broadening at 343 K and by 413 K had almost coalesced to a very broad band envelope with half-height width of ca. 100 Hz.
