**Keywords:** Ruthenium / S ligands / Hydrazine / Diazene

In the search for ruthenium complexes with sulfur-dominated coordination spheres that bind, activate, or stabilize nitrogenase relevant molecules, complexes containing the new and robust tetradentate ligand 'tpS<sub>4</sub>'-H<sub>2</sub> were synthesized. Treatment of [RuCl<sub>2</sub>(PPh<sub>3</sub>)<sub>3</sub>] with 'tpS<sub>4</sub>'<sup>2-</sup> gives [Ru(PPh<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')]<sup>+</sup> (**1**), which contains two labile PPh<sub>3</sub> ligands. The reaction of **1** with PET<sub>3</sub> or DMSO led to substitution of both PPh<sub>3</sub> ligands, yielding [Ru(PET<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')]<sup>+</sup> (**2**) and [Ru(DMSO)<sub>2</sub>('tpS<sub>4</sub>')]<sup>+</sup> (**3**), respectively. When treated with nitrogenous ligands, complex **1** lost only one PPh<sub>3</sub> ligand to yield [Ru(L)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> complexes where L = py (**7**), NH<sub>3</sub> (**8**), N<sub>2</sub>H<sub>4</sub> (**9**), NH<sub>2</sub>NHMe (**10**), and CH<sub>3</sub>CN (**12**), all of which are labile. The labile acetonitrile complex [Ru(CH<sub>3</sub>CN)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**12**) proved to be particularly suited as a precursor for the syntheses of other [Ru(L)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> complexes. The 18 and 19 valence electron NO complexes [Ru(NO)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup>BF<sub>4</sub><sup>-</sup> (**13**) and [Ru-

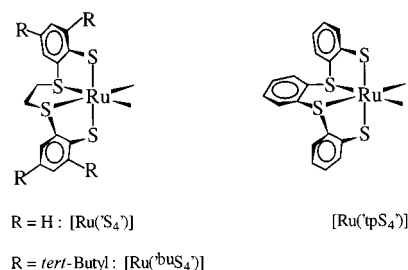

(NO)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**14**), (NEt<sub>4</sub>)[Ru(N<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**15**), [Ru(I)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**16**), and [Ru(N<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**17**) were obtained starting from complex **12**. The labile mononuclear hydrazine complex [Ru(N<sub>2</sub>H<sub>4</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**9**) gave the dinuclear complex [μ-N<sub>2</sub>H<sub>4</sub>{Ru(PPh<sub>3</sub>)('tpS<sub>4</sub>')}]<sup>2+</sup> (**18**) by dissociation of hydrazine. The dinuclear diazene complex [μ-N<sub>2</sub>H<sub>2</sub>{Ru(PPh<sub>3</sub>)('tpS<sub>4</sub>')}]<sup>2+</sup> (**19**) was obtained by oxidation of **9** and more readily from [Ru(CH<sub>3</sub>CN)(PPh<sub>3</sub>)('tpS<sub>4</sub>')]<sup>+</sup> (**12**) and N<sub>2</sub>H<sub>2</sub>, which was generated in situ from K<sub>2</sub>N<sub>2</sub>(CO<sub>2</sub>)<sub>2</sub> and acetic acid. The molecular structures of **7**, **13**, **16**, **18**, and **19** were determined by X-ray structure analyses. The complexes **18** and **19** represent the first complexes containing the hydrazine/diazene couple, which enables us to compare both the bonding features and the formation of N-H...S bridges when hydrazine and diazene bind to transition metal sulfur sites.

## Introduction

The stabilization, or coordination and activation of small molecules such as CO, N<sub>2</sub>, H<sub>2</sub>, NO, N<sub>3</sub><sup>-</sup>, N<sub>2</sub>H<sub>2</sub>, N<sub>2</sub>H<sub>4</sub>, and NH<sub>3</sub> by transition metal sulfur complexes is of pivotal interest for understanding the molecular mechanisms of nitrogenases.<sup>[1]</sup> It can be assumed that these molecules interact with the FeMo, FeV, or FeFe cofactors that are the active sites of nitrogenases. The FeMo cofactors of FeMo nitrogenase in the resting state have been shown by X-ray crystallography to contain [Fe<sub>7</sub>MoS<sub>9</sub>] clusters.<sup>[2]</sup> Similar structures are assumed for the FeV or FeFe cofactors of the alternative FeV and FeFe nitrogenases.<sup>[3]</sup> However, the functioning of these clusters has remained unexplained, not least because a compound that models basic structural and functional principles of the cofactors has yet to be found.

In particular, these principles are metal sulfur sites and the mild catalytic reduction of N<sub>2</sub> with biologically compatible redox potentials.<sup>[4]</sup>

In our search for such compounds we have found that both the [Ru('S<sub>4</sub>')]<sup>+</sup> fragments and their tertiary butyl derivatives [Ru('buS<sub>4</sub>')]<sup>+</sup> coordinate the complete series of above mentioned molecules, with the exception of N<sub>2</sub> (Scheme 1).<sup>[5]</sup>

Scheme 1. [Ru('R'S<sub>4</sub>')]<sup>+</sup> and [Ru('tpS<sub>4</sub>')]<sup>+</sup>

Another shortcoming of the [Ru('R'S<sub>4</sub>')]<sup>+</sup> complexes are ligand C-S cleavage reactions. In most cases, the [Ru('R'S<sub>4</sub>')]<sup>+</sup> fragments prove to be robust and the 'R'S<sub>4</sub>'<sup>2-</sup> ligands stay intact, behaving as spectator ligands. However, under strongly reducing or photolytic conditions, in reactions with

<sup>[b]</sup> Institut für Anorganische Chemie der Universität Leipzig, Linnéstraße 3, 04103 Leipzig, Germany

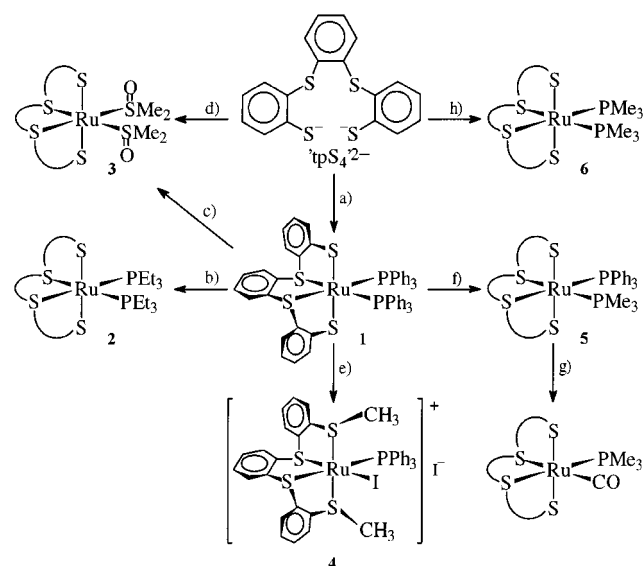

electron-rich metal complexes, and in reactions involving 19 valence electron complexes, C(alkyl)–S cleavage reactions take place yielding, among other products, 1,2-benzenedithiolate, or vinylthio(2-mercapto)benzene(1–) ligands and ethylene.<sup>[6]</sup> Since aromatic C–S bonds are more stable towards cleavage than C(alkyl)–S bonds, we synthesized the new dithioether–dithiolate ligand 'tpS<sub>4</sub>'<sup>2–</sup> = 1,2-bis(2-mercaptophenylthio)phenylene(2–), which contains exclusively aromatic C–S bonds. In a previous paper we described the syntheses of 'tpS<sub>4</sub>'<sup>2–</sup> and a few Ru, Os, and Ni complexes containing [M('tpS<sub>4</sub>')] fragments, demonstrating that the 'tpS<sub>4</sub>'<sup>2–</sup> ligand coordinates metals in the same helical manner as the 'RS<sub>4</sub>'<sup>2–</sup> ligands and is indeed stable toward C–S cleavage.<sup>[7]</sup> Preliminary tests also indicated that analogous [Ru('RS<sub>4</sub>')] and [Ru('tpS<sub>4</sub>')] complexes can have quite different substitution reactivity. This prompted us to systematically investigate the synthesis and reactivity of [Ru('tpS<sub>4</sub>')] complexes, focusing on hydrazine, nitrosyl, and azido derivatives as potential N<sub>2</sub> complex precursors,<sup>[8]</sup> because subtle differences in the [Ru('RS<sub>4</sub>')] and [Ru('tpS<sub>4</sub>')] fragments may

be decisive in the binding or nonbinding of N<sub>2</sub>.<sup>[9]</sup>

## Results

### Syntheses of [Ru('tpS<sub>4</sub>')] Complexes with DMSO, Phosphanes, and Nitrogenous Coligands

In the search for labile [Ru(L)(L')('tpS<sub>4</sub>')] complexes we probed the exchange of PPh<sub>3</sub> in the readily accessible [Ru(PPh<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')] (**1**) (Scheme 2).<sup>[7]</sup>

Scheme 2. Phosphane and DMSO exchange reactions of [Ru(PPh<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')] (**1**): a) + [RuCl<sub>2</sub>(PPh<sub>3</sub>)<sub>3</sub>], THF, 4 h, room temperature (room temp.); b) + exc. PEt<sub>3</sub>, THF, 3 min, reflux; c) DMSO, 5 min, reflux; d) + [RuCl<sub>2</sub>(DMSO)<sub>4</sub>], THF, 2.5 d, room temp.; e) + CH<sub>3</sub>I, 2 h, room temp.; f) + exc. PMe<sub>3</sub>, THF, 3 h, room temp.; g) + CO (1 bar), THF, 4 d, room temp.; h) + [RuCl<sub>2</sub>(PMe<sub>3</sub>)<sub>4</sub>], MeOH, 4 h, reflux

When **1** was treated with PEt<sub>3</sub>, [Ru(PEt<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')] (**2**) formed. Formation of the mixed phosphane complex [Ru-

(PEt<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] was not observed. Brief heating of **1** in DMSO yielded [Ru(DMSO)<sub>2</sub>('tpS<sub>4</sub>')] (**3**) which could be readily obtained directly from [RuCl<sub>2</sub>(DMSO)<sub>4</sub>] and 'tpS<sub>4</sub>'<sup>2–</sup>. With regard to the PEt<sub>3</sub> and DMSO reactions, the reactivity of **1** is in contrast to that of the parent complex [Ru(PPh<sub>3</sub>)<sub>2</sub>('S<sub>4</sub>')] which exchanges only one or none of its PPh<sub>3</sub> ligands under comparable conditions. An analogous behavior of **1** and the parent complex [Ru(PPh<sub>3</sub>)<sub>2</sub>('S<sub>4</sub>')] was found in the reactions with MeI and PMe<sub>3</sub>. Treatment of **1** in CH<sub>2</sub>Cl<sub>2</sub> with excess MeI afforded the doubly methylated derivative [Ru(I)(PPh<sub>3</sub>)('tpS<sub>4</sub>–Me<sub>2</sub>')] (**4**) in isomerically pure form. PMe<sub>3</sub> was able to substitute only one PPh<sub>3</sub> ligand in **1** to give [Ru(PMe<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**5**), even when an excess of PMe<sub>3</sub> was applied and the temperature was raised. The bis(PMe<sub>3</sub>) complex [Ru(PMe<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')] (**6**) formed from [RuCl<sub>2</sub>(PMe<sub>3</sub>)<sub>4</sub>] and Li<sup>+</sup>–'tpS<sub>4</sub>' in boiling MeOH.

In order to probe the lability of PMe<sub>3</sub> versus that of PPh<sub>3</sub> in [Ru(PMe<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**5**), complex **5** was treated with CO under standard conditions. Monitoring the reaction by IR and NMR spectroscopy as well as mass spectrometry showed the formation of [Ru(CO)(PMe<sub>3</sub>)('tpS<sub>4</sub>')] (**7**), indicating that in **5** the large PPh<sub>3</sub> is more labile than the small PMe<sub>3</sub> ligand.

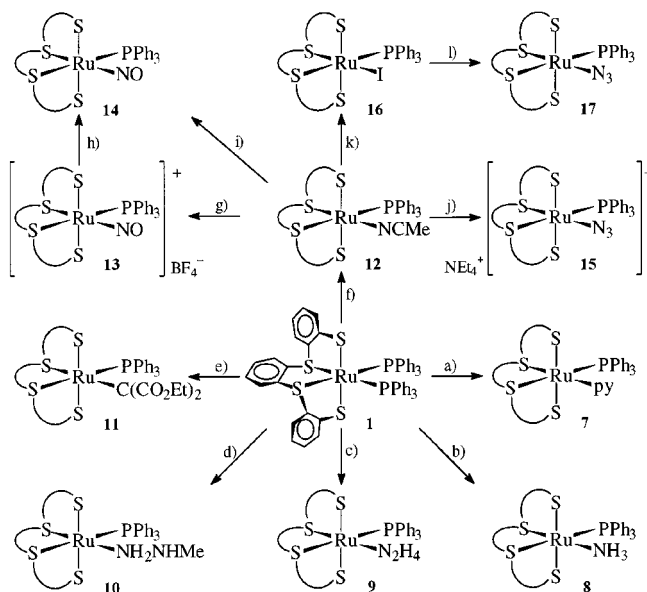

The complexes **2–6** proved to be less labile than the PPh<sub>3</sub> complex **1** and were not suited for exchange reactions with nitrogenous ligands. Attempts to exchange directly one PPh<sub>3</sub> in **1** for such ligands succeeded with pyridine, hydrazine(s), ammonia, and even diazomalonate ethyl ester, but failed for NO, NO<sup>+</sup>, or N<sub>3</sub><sup>–</sup>. In order to achieve their coordination it was necessary to proceed via the acetonitrile complex [Ru(MeCN)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**12**). Scheme 3 summarizes these reactions and complexes.

Brief heating of **1** in pyridine gave [Ru(py)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**7**). Treatment of **1** in THF with an excess of NH<sub>3</sub> gas, N<sub>2</sub>H<sub>4</sub>, or N<sub>2</sub>H<sub>3</sub>Me likewise afforded [Ru(NH<sub>3</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**8**), [Ru(N<sub>2</sub>H<sub>4</sub>)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**9**), and [Ru(N<sub>2</sub>H<sub>3</sub>Me)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**10**). In order to drive the reactions to completion, the solutions were usually heated to boiling for a short time. The conversion of **9** into a dinuclear hydrazine complex is described below.

A reaction was also observed between **1** and diethyl diazomalonate [N<sub>2</sub>C(CO<sub>2</sub>Et)<sub>2</sub>] in boiling THF. Monitoring the reaction by <sup>1</sup>H NMR spectroscopy showed that the primary product is presumably [Ru{N<sub>2</sub>C(CO<sub>2</sub>Et)<sub>2</sub>}(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**11**), which rapidly transforms into the carbene complex [Ru{C(CO<sub>2</sub>Et)<sub>2</sub>}(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**11**).

These results indicate that nitrogenous ligands are able to selectively substitute one PPh<sub>3</sub> in [Ru(PPh<sub>3</sub>)<sub>2</sub>('tpS<sub>4</sub>')] (**1**). In the quest for labile solvent complex derivatives of **1**, which had so far remained inaccessible, we now tried to obtain the acetonitrile complex [Ru(MeCN)(PPh<sub>3</sub>)('tpS<sub>4</sub>')] (**12**). The yellow complex **12** formed from boiling acetonitrile solutions of **1**, could be isolated in solid state, completely characterized, and proved an excellent starting material for further complexes.

The reaction of **12** with CO at ambient conditions established the lability of the MeCN ligand. The CO complex

Scheme 3. Coordination of nitrogenous ligands to the  $[\text{Ru}(\text{PPh}_3)(\text{tpS}_4)]$  fragment: a) pyridine, 10 min, reflux; b) +  $\text{NH}_3$  (gaseous), THF, 5 min, reflux; c) + exc.  $\text{N}_2\text{H}_4$ , THF, 10 min, reflux; d) + exc.  $\text{NH}_2\text{NHMe}$ , THF, 45 min, reflux; e) + exc.  $\text{N}_2\text{C}(\text{CO}_2\text{Et})_2$ , THF, 4 h, reflux; f) MeCN, 3 h, reflux; g) +  $\text{NOBF}_4$ ,  $\text{CH}_2\text{Cl}_2$ , 3 h, room temp.; h) +  $\text{LiBET}_3\text{H}$ , THF, 30 min, room temp.; i)  $\text{NO}$  (gaseous),  $\text{CH}_2\text{Cl}_2$ , 20 h, room temp.; j) +  $\text{NEt}_4\text{N}_3$ , acetone, 3 h, room temp.; k) +  $0.5 \text{ I}_2$ , THF 12 h, room temp.; l) + exc.  $\text{NEt}_4\text{N}_3$ , acetone, 3 d, room temp.

$[\text{Ru}(\text{CO})(\text{PPh}_3)(\text{tpS}_4)]$  [ $\nu(\text{CO}) = 1964 \text{ cm}^{-1}$ ] formed nearly instantly.  $[\text{Ru}(\text{CO})(\text{PPh}_3)(\text{tpS}_4)]$  also formed directly from **1** and CO. However, this reaction needed ca. 12 h to go to completion.<sup>[7]</sup>

Treatment of **12** with one equivalent of  $\text{NOBF}_4$  yielded  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]\text{BF}_4$  (**13**). Complex **13** is the first 18 valence electron nitrosyl complex with an  $[\text{RuPS}_4]$  core characterized by X-ray structure determination. It was of particular interest as a test complex for probing the stability of the  $\text{tpS}_4^{2-}$  ligand towards reduction.

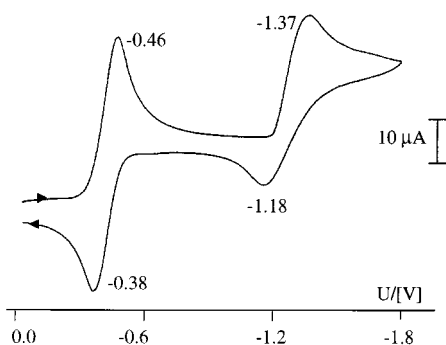

Figure 1. Cyclic voltammogram of  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]\text{BF}_4$  (**13**) in  $\text{CH}_2\text{Cl}_2$  ( $10^{-3} \text{ M}$ ,  $10^{-1} \text{ M}$   $\text{NBu}_4\text{PF}_6$ ,  $\nu = 0.05 \text{ V s}^{-1}$ )

The cyclic voltammogram (CV) of **13** in  $\text{CH}_2\text{Cl}_2$  (Figure 1) exhibited two redox waves in the cathodic region. The redox wave at  $E_{1/2} = -0.42 \text{ V}$  could be assigned to the reversible reduction  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]^+ / [\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]^0$  and indicated the viability of the neutral 19 valence electron nitrosyl complex  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]$  (**14**).

This result was corroborated by chemical reduction of **13** and the reaction of the acetonitrile complex **12** with NO gas. Monitoring the reaction of **13** with  $\text{LiBET}_3\text{H}$  in THF by IR spectroscopy showed that the  $\nu(\text{NO})$  band of **13** at  $1850 \text{ cm}^{-1}$  was replaced by a new band at  $1602 \text{ cm}^{-1}$ . No gas was evolved, and the intensity and frequency of the  $1602 \text{ cm}^{-1}$  band was found to be compatible with the formation of **14**.<sup>[10]</sup> Treating **12** with NO gas in  $\text{CH}_2\text{Cl}_2$  led to a strong  $\nu(\text{NO})$  band appearing in the same region at  $1605 \text{ cm}^{-1}$ . Complex **14** could be precipitated from this solution as red-brown solid by the addition of *n*-hexane. Complex **14** is highly reactive and almost instantly oxidized by traces of air to give the  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]^+$  cation, as indicated by the  $\nu(\text{NO})$  band at  $1842 \text{ cm}^{-1}$  (KBr). Complex **14** is paramagnetic and was only characterized by elemental analyses, IR spectroscopy, and mass spectrometry, which confirmed that the  $\text{tpS}_4^{2-}$  ligand remained intact.

Attempts to convert the nitrosyl ligands of either cationic **13** or neutral **14** into dinitrogen ligands by reactions with azide or ammonia have so far been unsuccessful. For the alternate route, in which the ligating azide is converted into  $\text{N}_2$  by attack with  $\text{NO}^+$ , azido complexes were needed. Treatment of **12** in acetone with one equivalent of  $\text{NEt}_4\text{N}_3$  yielded the azido complex  $(\text{NEt}_4)[\text{Ru}(\text{N}_3)(\text{PPh}_3)(\text{tpS}_4)]$  (**15**) whose formation could be established by IR and  $^1\text{H}$  NMR spectroscopy. However, **15** proved to be too labile to obtain  $^{13}\text{C}$  and  $^{31}\text{P}$  NMR spectra and rapidly decomposed, even in the solid state, to give a brown mixture of intractable products. Repeated attempts to purify **15** by recrystallization were unsuccessful. For these reasons, we tried to obtain a potentially more stable  $\text{Ru}^{\text{III}}$  azide complex via the  $\text{Ru}^{\text{III}}$  iodide complex  $[\text{Ru}(\text{I})(\text{PPh}_3)(\text{tpS}_4)]$  (**16**). Complex **16** formed from the reaction of the acetonitrile complex **12** with half an equivalent of iodine, and could be characterized by X-ray crystallography. The subsequent reaction of **16** with  $\text{NEt}_4\text{N}_3$  yielded  $[\text{Ru}(\text{N}_3)(\text{PPh}_3)(\text{tpS}_4)]$  (**17**) which was isolated in pure state and characterized by IR spectroscopy and mass spectrometry. As expected, and confirmed from the  $^1\text{H}$  NMR spectra showing broad and unresolved peaks, **16** and **17** are both paramagnetic. Complex **17** was further characterized by its cyclic voltammogram (Figure 2).

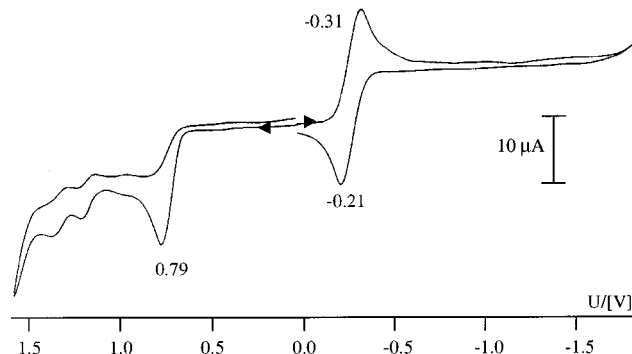

Figure 2. Cyclic voltammogram of  $[\text{Ru}(\text{N}_3)(\text{PPh}_3)(\text{tpS}_4)]\text{BF}_4$  (**17**) in  $\text{CH}_2\text{Cl}_2$  ( $10^{-3} \text{ M}$ ,  $10^{-1} \text{ M}$   $\text{NBu}_4\text{PF}_6$ ,  $\nu = 0.02 \text{ V s}^{-1}$ )

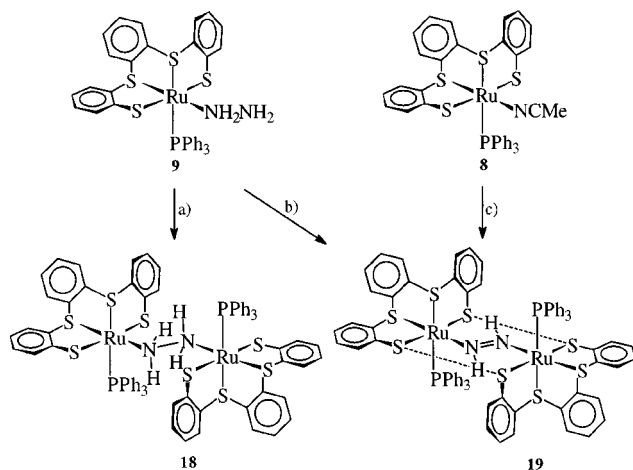

In the cathodic region, **17** showed a reversible redox wave at  $E_{1/2} = -0.26 \text{ V}$ . It is compatible with the reversible reduc-

tion of **17** to give the anion of the  $\text{Ru}^{\text{II}}$  complex **15**. Attempts to convert **17** photolytically, thermally, or by treatment with  $\text{HBF}_4$  in  $\text{CH}_2\text{Cl}_2$  into a dinitrogen complex remained unsuccessful.

### Dinuclear Hydrazine and Diazene Complexes with $[\text{Ru}(\text{PPh}_3)(\text{tpS}_4)]$ Fragments

The unsuccessful attempts to obtain a  $[\text{Ru}(\text{PPh}_3)(\text{tpS}_4)]$  dinitrogen complex via nitrosyl or azide precursors prompted us to return to the hydrazine complex  $[\text{Ru}(\text{N}_2\text{H}_4)(\text{PPh}_3)(\text{tpS}_4)]$  (**9**). As mentioned above, the  $\text{N}_2\text{H}_4$  ligand is labile. In this respect **9** resembles the other  $[\text{Ru}(\text{L})(\text{PPh}_3)(\text{tpS}_4)]$  complexes in which L is a  $\sigma$ -N donor ligand.

The complex  $[\text{Ru}(\text{N}_2\text{H}_4)(\text{PPh}_3)(\text{tpS}_4)]$  (**9**) did not yield a dinitrogen complex either. However, further investigation led to the characterization of  $[\mu\text{-N}_2\text{H}_4\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4)\}_2]$  (**18**) and  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4)\}_2]$  (**19**) which represent the first hydrazine and diazene couple characterized by X-ray structure determination (Scheme 4).

Scheme 4. Formation of dinuclear hydrazine and diazene complexes with  $[\text{Ru}(\text{PPh}_3)(\text{tpS}_4)]$  fragments: a)  $\text{CH}_2\text{Cl}_2$ , 7 d, room temp.; b)  $+\text{O}_2$ ,  $\text{CH}_2\text{Cl}_2$ , 36 h, room temp.; c)  $+\text{exc. K}_2\text{N}_2(\text{CO}_2)_2$ ,  $+\text{exc. CH}_3\text{CO}_2\text{H}$ , THF, 3 h, room temp.

Attempts to recrystallize **9** from  $\text{CH}_2\text{Cl}_2/\text{MeOH}$  mixtures afforded yellow microcrystals that proved so sparingly soluble that no NMR spectra could be recorded. The elemental analyses and IR spectra indicated that two molecules of mononuclear **9** had formed the dinuclear hydrazine complex **18** by dissociation of hydrazine. Carrying out the same experiment in THF/ $\text{Et}_2\text{O}$  mixtures afforded single crystals of **18**·THF, which could be structurally characterized. When the  $\text{CH}_2\text{Cl}_2$  solutions of the hydrazine complex **9** were treated with atmospheric oxygen, their color turned from yellow to dark green and green crystals precipitated. They were also sparingly soluble, but we were able to record a  $^1\text{H}$  NMR spectrum which exhibited a signal at  $\delta = 14.59$ , indicative of an  $\text{N}_2\text{H}_2$  ligand in a centrosymmetric dinuclear diazene complex of the type  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4)\}_2]$  (**19**). Intense absorptions at 307 and 463 nm in the UV/Vis spectrum also suggested the formation of **19**, which was finally and unambiguously character-

ized by an X-ray crystal structure determination of  $19 \cdot 4\text{CH}_2\text{Cl}_2$ .

The aerial oxidation of **9** afforded **19** in yields of 25%. A potential reason for the low yield is that the dinuclear hydrazine complex **18** must form before subsequent oxidation occurs to give **19**. Therefore we sought a better synthesis of **19** and found that much higher yields ( $> 80\%$ ) were obtained from the reaction of the labile acetonitrile complex **12** with  $\text{N}_2\text{H}_2$ , which was generated in situ by acidolysis of  $\text{K}_2\text{N}_2(\text{CO}_2)_2$  with dilute acetic acid in THF. This trapping of the unstable diazene in solution is possible with particular metal sulfur complex fragments and was first discovered with the synthesis of  $[\mu\text{-N}_2\text{H}_2\{\text{Fe}(\text{PPr}_3)(\text{S}_4')\}_2]$ .<sup>[11]</sup>

### General Properties and Spectroscopic Characterization of $[\text{Ru}(\text{L})(\text{L}')(\text{tpS}_4)]$ Complexes

As far as possible, all  $[\text{Ru}(\text{L})(\text{L}')(\text{tpS}_4)]$  complexes have been characterized by the common spectroscopic methods and elemental analyses. The molecular structures of **7**, **13**, **16**, **18**, and **19** have been determined by X-ray structure analysis. All  $\text{Ru}^{\text{II}}$  complexes are diamagnetic, while the two  $\text{Ru}^{\text{III}}$  complexes are paramagnetic as indicated by their  $^1\text{H}$  NMR spectra. The colors of the complexes range from yellow or orange (**1–12**), to green (**17**, **19**) and brown (**13**, **14**, **16**). All complexes, except the dinuclear species **18** and **19**, show moderate to good solubilities in  $\text{CH}_2\text{Cl}_2$ . The IR spectra of all complexes in KBr exhibit the typical absorptions of the  $[\text{Ru}(\text{tpS}_4)]$  fragment. A strong  $\nu(\text{CO})$  absorption at  $1968\text{ cm}^{-1}$  and a strong  $\delta(\text{PCH})$  at  $953\text{ cm}^{-1}$  characterize  $[\text{Ru}(\text{CO})(\text{PMe}_3)(\text{tpS}_4)]$  (**3**). A  $\nu(\text{SO})$  band at  $1015\text{ cm}^{-1}$  indicates sulfur coordination of DMSO in  $[\text{Ru}(\text{DMSO})_2(\text{tpS}_4)]$  (**3**). Weak  $\nu(\text{NH})$  ( $3334$ ,  $3292$ ,  $3245$ ,  $3164\text{ cm}^{-1}$ ) and  $\nu(\text{CN})$  ( $2271\text{ cm}^{-1}$ ) bands readily identify  $[\text{Ru}(\text{N}_2\text{H}_4)(\text{PPh}_3)(\text{tpS}_4)]$  (**9**) and  $[\text{Ru}(\text{MeCN})(\text{PPh}_3)(\text{tpS}_4)]$  (**12**) respectively. Strong  $\nu(\text{NO})$  bands at  $1852$  and  $1598\text{ cm}^{-1}$  characterize the nitrosyl complexes **13** and **14**. The azide complexes **15** and **17** show characteristic  $\nu(\text{N}_3)$  absorptions at  $2029$  and  $2036\text{ cm}^{-1}$ . The  $^1\text{H}$  NMR spectra of  $\text{C}_2$ -symmetric  $[\text{Ru}(\text{L})_2(\text{tpS}_4)]$  complexes exhibit a typical set of six multiplets for the aromatic 'tpS<sub>4</sub>' protons. This multiplet changes when the symmetry is lowered to  $\text{C}_1$  in  $[\text{Ru}(\text{L})(\text{L}')(\text{tpS}_4)]$  complexes. In all  $[\text{Ru}(\text{L})(\text{PPh}_3)(\text{tpS}_4)]$  complexes, the 'tpS<sub>4</sub>' multiplets are superimposed on the  $\text{PPh}_3$  multiplets. Thus, the  $[\text{Ru}(\text{L})(\text{PPh}_3)(\text{tpS}_4)]$  complexes usually are more readily identified by their  $^{13}\text{C}$  and  $^{31}\text{P}$  NMR spectra.

However, the  $^1\text{H}$  NMR spectrum of  $[\text{Ru}(\text{I})(\text{PPh}_3)(\text{tpS}_4\text{-Me}_2)]\text{I}$  (**4**) showed two singlets for the methyl groups, establishing that only one of several possible isomers had formed. The  $^1\text{H}$  NMR spectra of **8** and **12** exhibited characteristic singlets at  $\delta = 1.70$  and  $1.75$ , indicating the coordination of ammonia and acetonitrile. The hydrazine complex **9** gave rise to two multiplets at  $\delta = 4.2$  and  $4.1$  which are attributed to the Ru-bound  $\text{NH}_2$  group, and a broad singlet at  $\delta = 3.4$  which is assigned to the terminal  $\text{NH}_2$  group. The  $\text{N}_2\text{H}_2$  singlet at  $\delta = 14.59$  is characteristic of the diazene complex  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2]$  (**19**). Complex **19** was further characterized by its UV/Vis spectrum, showing a strong absorption at  $463\text{ nm}$  ( $\epsilon = 8162\text{ L}$

$\text{mol}^{-1} \text{ cm}^{-1}$ ) which is characteristic of the  $4c-6 e^- \pi$  bond system of  $[\text{M} \equiv \text{NH} \equiv \text{NH} \equiv \text{M}]$  fragments (Figure 3).<sup>[12]</sup>

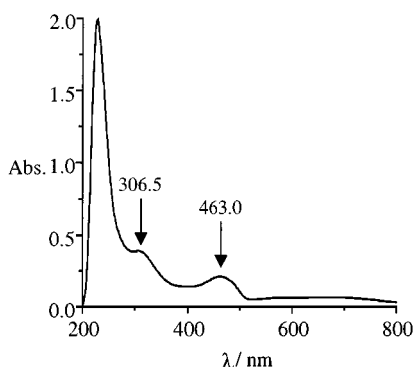

Figure 3. UV/Vis spectrum of  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2]$  in  $\text{CH}_2\text{Cl}_2$

### X-ray Structure Analysis

The molecular structures of  $[\text{Ru}(\text{py})(\text{PPh}_3)(\text{tpS}_4')]$  (**7**),  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4')]\text{BF}_4 \cdot \text{CH}_2\text{Cl}_2$  (**13**· $\text{CH}_2\text{Cl}_2$ ),  $[\text{Ru}(\text{I})(\text{PPh}_3)(\text{tpS}_4')]\text{CH}_2\text{Cl}_2$  (**16**· $\text{CH}_2\text{Cl}_2$ ),  $[\mu\text{-N}_2\text{H}_4\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2] \cdot 4\text{THF}$  (**18**· $4\text{THF}$ ), and  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2] \cdot 4\text{CH}_2\text{Cl}_2$  (**19**· $4\text{CH}_2\text{Cl}_2$ ) were determined by X-ray crystallography and are shown in Figure 4. Table 1 lists selected distances and angles.

In all cases the crystal lattices contain discrete molecules or ions. All compounds exhibit six-coordinate Ru centers, helical coordination of the  $\text{tpS}_4'^{2-}$  ligands with *trans*-thiolate and *cis*-thioether S donors, and *cis* coordination of the ligands  $\text{PPh}_3$  and  $\text{L} = \text{py}, \text{NO}, \text{I}, \text{N}_2\text{H}_4, \text{N}_2\text{H}_2$ .

Distances and angles lie in the range observed for related  $[\text{Ru}(\text{S}_4')]$  complexes. For example, in both the  $[\text{Ru}(\text{tpS}_4')]$  and  $[\text{Ru}(\text{S}_4')]$  complexes, the average Ru–S distances are found to be in the narrow range of 233–238 pm. This is worthy of note, in light of the different properties of the coligands which coordinate to the  $[\text{RuS}_4]$  cores, such as the  $\sigma$ - $\pi$  ligands  $\text{CO}$ ,  $\text{NO}^+$  or  $\text{N}_2\text{H}_2$ , or the  $\sigma$  ligands  $\text{N}_2\text{H}_4$  and pyridine. Even in the  $\text{Ru}^{\text{III}}$  complex  $[\text{Ru}(\text{I})(\text{PPh}_3)(\text{tpS}_4')]\text{CH}_2\text{Cl}_2$  (**16**· $\text{CH}_2\text{Cl}_2$ ), the average Ru–S distance (234 pm) does not significantly differ from that of  $\text{Ru}^{\text{II}}$  complexes. This invariance of averaged M–S distances in low-spin complexes having no electrons in anti-bonding orbitals has been previously discussed and can be traced back to the bonding properties of sulfur ligands, which can function as  $\sigma$ -donor,  $\sigma$ -donor- $\pi$ -acceptor, and  $\sigma$ -donor- $\pi$ -donor ligands.<sup>[13–15]</sup>

The diazene and hydrazine complexes **19**· $4\text{CH}_2\text{Cl}_2$  and **18**· $4\text{THF}$  deserve special consideration. They represent the first structurally characterized complexes containing the  $\text{N}_2\text{H}_2/\text{N}_2\text{H}_4$  couple, and enable comparison of both the differing bonding situations and the formation of N–H··S bridges when hydrazine or diazene bind to transition metal

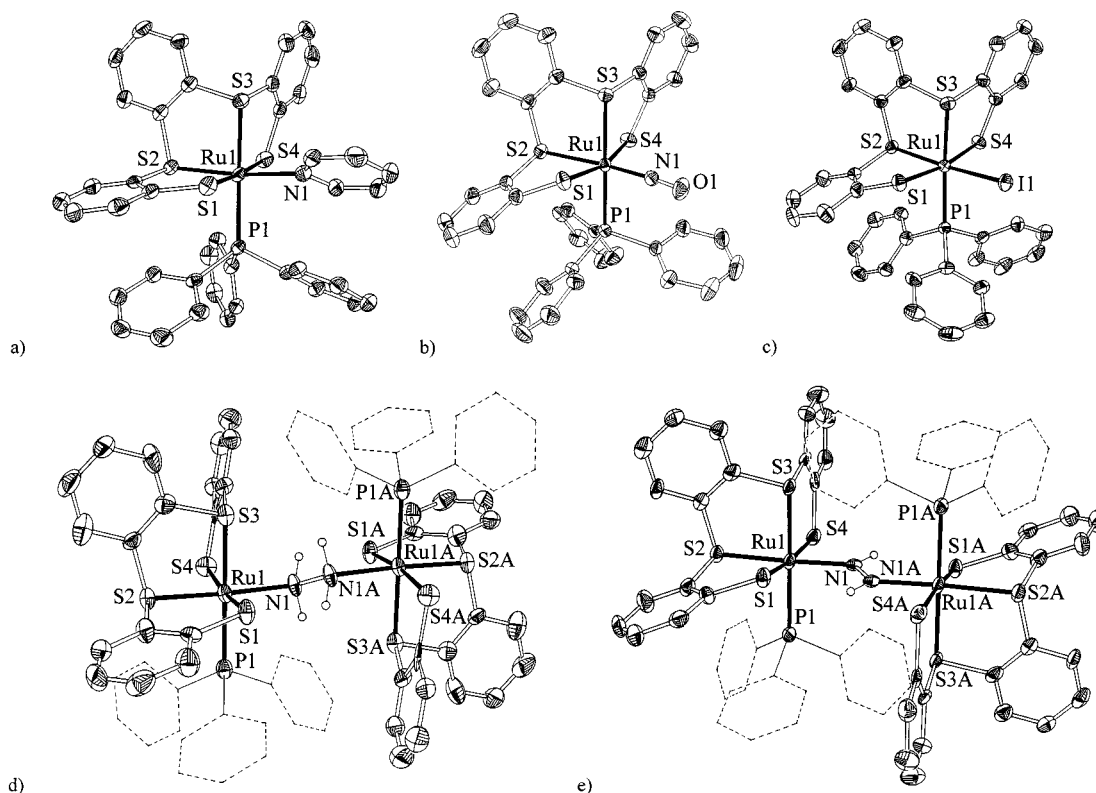

Figure 4. Molecular structures of a)  $[\text{Ru}(\text{py})(\text{PPh}_3)(\text{tpS}_4')]$  (**7**), b)  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4')]\text{BF}_4 \cdot \text{CH}_2\text{Cl}_2$  (**13**· $\text{CH}_2\text{Cl}_2$ ), c)  $[\text{Ru}(\text{I})(\text{PPh}_3)(\text{tpS}_4')]\text{CH}_2\text{Cl}_2$  (**16**· $\text{CH}_2\text{Cl}_2$ ), d)  $[\mu\text{-N}_2\text{H}_4\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2] \cdot 4\text{THF}$  (**18**· $4\text{THF}$ ), and e)  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4')\}_2] \cdot 4\text{CH}_2\text{Cl}_2$  (**19**· $4\text{CH}_2\text{Cl}_2$ ) (50% probability ellipsoids; C-bonded H atoms, solvent molecules, and  $\text{BF}_4^-$  anions omitted)

Table 1. sulfur sites. Both complexes possess a crystallographically imposed inversion symmetry. The N<sub>2</sub>H<sub>2</sub> and N<sub>2</sub>H<sub>4</sub> ligands bridge two enantiomeric [Ru(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)] fragments, and the centers of the N–N bonds represent the inversion centers. The average Ru–S distances in the hydrazine complex 18·4THF (235.1 pm) and the diazene complex 19·4CH<sub>2</sub>Cl<sub>2</sub> (236.6 pm) are also similar. The difference of 1.5 pm is a result of different Ru–S2 distances *trans* to the N<sub>2</sub>H<sub>4</sub> and N<sub>2</sub>H<sub>2</sub> ligands, which are 227.5(4) pm (18·4THF) vs. 232.9(2) pm (19·4CH<sub>2</sub>Cl<sub>2</sub>). All other Ru–S distances are identical within the 3σ criterion in both 18·4THF and 19·4CH<sub>2</sub>Cl<sub>2</sub>.

The Ru–S2 distance of 19·4CH<sub>2</sub>Cl<sub>2</sub> [232.9(2) pm] indicates the *trans* bond lengthening influence of the σ–π ligand N<sub>2</sub>H<sub>2</sub>, since the corresponding Ru–S2 distances of the σ ligand N<sub>2</sub>H<sub>4</sub> and pyridine complexes 18·4THF [227.5(4) pm] and 7 [227.7(1) pm] are shorter. The Ru–S distances *trans* to N<sub>2</sub>H<sub>2</sub> in the closely related complexes [μ-N<sub>2</sub>H<sub>2</sub>{Ru(PPh<sub>3</sub>)(‘S<sub>4</sub>’)}<sub>2</sub>] [228.2(2) pm] and [μ-N<sub>2</sub>H<sub>2</sub>{Ru(PPh<sub>3</sub>)(‘*bu*S<sub>4</sub>’)}<sub>2</sub>] [230.7(3) pm]<sup>[12]</sup> are slightly shorter than in 19·4CH<sub>2</sub>Cl<sub>2</sub>. Nonetheless, as in 19·4CH<sub>2</sub>Cl<sub>2</sub>, the Ru–S bonds *trans* to the N<sub>2</sub>H<sub>2</sub> ligand always represent the shortest Ru–S bonds in [μ-N<sub>2</sub>H<sub>2</sub>{RuS<sub>4</sub>}<sub>2</sub>] complexes so far characterized.

The different bonding properties of N<sub>2</sub>H<sub>2</sub> and N<sub>2</sub>H<sub>4</sub> are also illustrated by the Ru–N distances of 18·4THF [214.4(9) pm] and 19·4CH<sub>2</sub>Cl<sub>2</sub> [203.0(7) pm], indicating Ru–N single and partial Ru–N double bonds. The Ru–N distance in 18·4THF is comparable with that of the pyridine complex 7 [215.5(3) pm], while the Ru–N distance in 19·4CH<sub>2</sub>Cl<sub>2</sub> is rationalized by the [M≡NH≡NH≡M] 4c–6e<sup>−</sup> π bonding system, which is characteristic of this type of [μ-N<sub>2</sub>H<sub>2</sub>{M}]<sub>2</sub> complex.<sup>[12]</sup> The N–N distances in 18·4THF [149(2) pm] and in 19·4CH<sub>2</sub>Cl<sub>2</sub> [129(1) pm] correspond with N–N single and slightly elongated N–N double bonds.

In both 18·4THF and 19·4CH<sub>2</sub>Cl<sub>2</sub>, the Ru centers and the thiolate donors form approximated planes. When least-squares planes are calculated through the six atoms Ru1,

S1, S4, Ru1A, S1A, and S4A, the largest deviations from these planes are observed for the Ru centers, being 11.0(2) pm (18·4THF) and 10.8(1) pm (19·4CH<sub>2</sub>Cl<sub>2</sub>), respectively. In the diazene complex 19·4CH<sub>2</sub>Cl<sub>2</sub>, the diazene N atoms are also coplanar, deviating by only 5.5(6) pm. In the hydrazine complex 18·4THF, the hydrazine N atoms show a large deviation of 25.9(9) pm from the respective plane. This deviation gives rise to a step-like arrangement of the two enantiomeric [Ru(NH<sub>2</sub>)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)] halves of 18·4THF. The step height, calculated as distance between the two least-squares planes [Ru1, S1, S2, S4, N1] and [Ru1A, S1A, S2A, S4A, N1A], is 52.8 pm. The step-like arrangement of the two [RuNPS<sub>4</sub>] cores in 18·4THF is also reflected by the [S4–Ru1–N1–N1A] torsion angle of −151.9(1)°. [In the diazene complex, in which the Ru, the thiolate S and diazene N atoms form a nearly perfect plane, the corresponding angle is 173.9(9)°, close to the ideal of 180°.]

The arrangement of Ru, thiolate S, diazene N, or hydrazine N atoms enables the formation of stabilizing N–H⋯S hydrogen bonds in both 18·4THF and 19·4CH<sub>2</sub>Cl<sub>2</sub>. The N–H⋯S bonds are indicated by both the N–H⋯S vectors and the distances, which are shorter than the sum of the corresponding van der Waals radii (*r*<sub>H</sub> = 120 pm, *r*<sub>S</sub> = 185 pm) (Figure 5).

In the diazene complex 19·4CH<sub>2</sub>Cl<sub>2</sub>, two bifurcated and nearly planar N–H⋯S<sub>2</sub> (thiolate) bridges exist [*d*(H1⋯S1A) = 258 pm, *d*(H1⋯S4) = 289 pm]. In the hydrazine complex 18·4THF, two similar but nonplanar bifurcated hydrogen bonds are indicated by the H1⋯S1A (258 pm) and H1⋯S4 (298 pm) distances. It is significant that in the hydrazine complex the H2⋯S3A and the corresponding H2A⋯S3 distances of 288 pm indicate two additional hydrogen bonds between the thioether S atoms S3 and S3A and the NH<sub>2</sub> group atoms H2, and H2A. (Assuming sp<sup>3</sup> hybridization of the thioether S donors, the lone pairs at S3 and S3A indeed point directly at the positions of H2 and H2A respectively.)

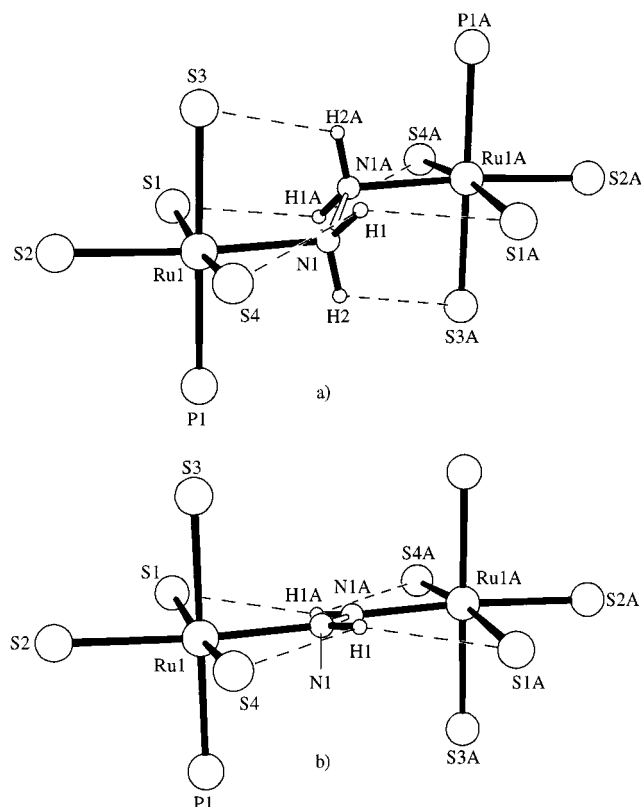

Figure 5. The  $[\mu\text{-N}_2\text{H}_x\{\text{RuPS}_4\}_2]$  cores of a) **18**·4THF ( $x = 4$ ) and b) **19**·4CH<sub>2</sub>Cl<sub>2</sub> ( $x = 2$ ) illustrating the  $[\mu\text{-N}_2\text{H}_x\{\text{RuS}_2(\text{thiolate})\}_2]$  planes and NH $\cdots$ S bridges

Due to the inversion center, the two NH<sub>2</sub> groups in **18**·4THF assume a staggered conformation, in contrast to the conformation in free hydrazine which exhibits a dihedral angle of about 95°. [16]

## Discussion and Conclusion

The  $[\text{Ru}(\text{tpS}_4)]$  fragment exhibits a similarly versatile coordination chemistry as the  $[\text{Ru}(\text{RS}_4)]$  fragments and binds a large number of coligands ranging from CO, NO, CR<sub>2</sub>, PR<sub>3</sub> to N<sub>3</sub>, N<sub>2</sub>H<sub>2</sub>, N<sub>2</sub>H<sub>4</sub>, and NH<sub>3</sub>. In addition,  $[\text{Ru}(\text{tpS}_4)]$  complexes undergo reactions and yield species not yet observed with  $[\text{Ru}(\text{RS}_4)]$  fragments. For example,  $[\text{Ru}(\text{PPh}_3)_2(\text{tpS}_4)]$  (**1**) exchanges both of its PPh<sub>3</sub> ligands with DMSO or PEt<sub>3</sub>. When the  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]^+$  (**13**) cation is reduced to give the neutral 19 valence electron species  $[\text{Ru}(\text{NO})(\text{PPh}_3)(\text{tpS}_4)]$  (**14**), the  $\text{tpS}_4^{2-}$  ligand stays intact, in contrast to the  $\text{RS}_4^{2-}$  ligands, which undergo C–S cleavage reactions. [6]

In the search for labile  $[\text{Ru}(\text{tpS}_4)]$  precursor complexes,  $[\text{Ru}(\text{PPh}_3)_2(\text{tpS}_4)]$  (**1**) was found to exclusively exchange one PPh<sub>3</sub> for nitrogenous ligands. This enabled the synthesis of N<sub>2</sub>H<sub>4</sub> and NH<sub>3</sub> complexes and, in particular, of the acetonitrile complex  $[\text{Ru}(\text{MeCN})(\text{PPh}_3)(\text{tpS}_4)]$  (**12**). Complex **12** made feasible the synthesis of the azido, iodo, and nitrosyl complexes. All attempts to obtain dinitrogen complexes have so far remained unsuccessful also with the

$[\text{Ru}(\text{tpS}_4)]$  fragment. However, structurally characterized transition metal sulfur complexes containing the hydrazine and diazene couple could be obtained for the first time. The complexes  $[\mu\text{-N}_2\text{H}_4\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4)\}_2]$  (**18**) and  $[\mu\text{-N}_2\text{H}_2\{\text{Ru}(\text{PPh}_3)(\text{tpS}_4)\}_2]$  (**19**) permitted a detailed analysis of the structural and bonding properties of hydrazine versus diazene complexes. The structural parameters indicate bifurcated N–H $\cdots$ S<sub>2</sub>(thiolate) hydrogen bonds in both **18** and **19** and additional N–H $\cdots$ S(thioether) bridges in the hydrazine complex **18**. The increased number of N–H $\cdots$ S hydrogen bonds formed when going from the diazene to hydrazine complexes is significant with regard to the “open-side” model of the FeMoco function in nitrogenases. [4a], [13a] According to this model, N<sub>2</sub> is activated through binding to two low-spin Fe<sup>II</sup> centers in [S, N, O] coordination spheres. Over the course of three subsequent [2 H<sup>+</sup>, 2 e<sup>−</sup>] reduction steps yielding NH<sub>3</sub> via N<sub>2</sub>H<sub>2</sub> and N<sub>2</sub>H<sub>4</sub> intermediates, an increased number of N–H $\cdots$ S(O) hydrogen bonds is instrumental in keeping the redox potential in the range −280 mV to ca. −500 mV, which are the both the thermodynamic limiting and biologically compatible values of enzymatic N<sub>2</sub> reduction.

## Experimental Section

**General Methods:** Unless otherwise noted, all reactions and operations were carried out at room temperature under nitrogen using standard Schlenk techniques. Solvents were dried and distilled before use. As far as possible, reactions were monitored by IR or NMR spectroscopy. – Spectra were recorded with the following instruments: IR (KBr disks or CaF<sub>2</sub> cuvettes, solvent bands were compensated): Perkin–Elmer 983, 1620 FT IR, and 16PC FT-IR. – NMR: Jeol FT-JNM-GX 270, EX 270, and Lambda LA 400 with the protio solvent signals used as a reference. Chemical shifts are quoted on the  $\delta$  scale (downfield shifts are positive) relative to tetramethylsilane (<sup>1</sup>H, <sup>13</sup>C{<sup>1</sup>H} NMR) or 85% H<sub>3</sub>PO<sub>4</sub> (<sup>31</sup>P{<sup>1</sup>H} NMR). Spectra were recorded at 25 °C. – Mass spectra: Jeol MSTATION 700 spectrometer. – UV/Vis: Shimadzu UV-3101 – Elemental analysis: Carlo Erba EA 1106 or 1108 analyzer. – Cyclic voltammetry was performed with a PAR 264A potentiostat using a three-electrode cell with glassy carbon ROTEL A working, Pt reference and Pt counter electrodes. Solutions were 10<sup>−3</sup> M in complex. TBA[PF<sub>6</sub>] (10<sup>−1</sup> M) was used as conducting electrolyte. Potentials were referenced to the normal hydrogen electrode via Fc/Fc<sup>+</sup> as internal standard ( $E_{\text{Fc}/\text{Fc}^+} = +0.4$  V versus normal hydrogen electrode). [17] – N<sub>2</sub>C(CO<sub>2</sub>Et)<sub>2</sub>, [18] K<sub>2</sub>C<sub>2</sub>N<sub>2</sub>O<sub>4</sub>, [19]  $[\text{RuCl}_2(\text{DMSO})_4]$ , [20]  $[\text{RuCl}_2(\text{PMe}_3)_4]$ , [21] NEt<sub>4</sub>N<sub>3</sub>, [22]  $[\text{Ru}(\text{PPh}_3)_2(\text{tpS}_4)]$  (**1**), [7] and  $\text{tpS}_4^{2-}\text{H}_2$ , [7] were prepared as described in the literature, LiOMe, MeI, NOBF<sub>4</sub>, LiEt<sub>3</sub>H, NH<sub>2</sub>NHMe, and N<sub>2</sub>H<sub>4</sub> were purchased from Aldrich.

**$[\text{Ru}(\text{PEt}_3)_2(\text{tpS}_4)]$  (**2**):** PEt<sub>3</sub> (0.5 mL, 3.4 mmol) was added to a yellow-orange suspension of  $[\text{Ru}(\text{PPh}_3)_2(\text{tpS}_4)]$  (**1**) (190 mg, 0.19 mmol) in THF (10 mL) and heated at reflux for 3 min. The resultant yellow solution was cooled to room temperature, and concentrated to dryness. The yellow residue was dissolved in THF (5 mL), the resulting solution was filtered, layered with *n*-hexane (50 mL) and cooled to −30 °C. Yellow microcrystals precipitated, which were separated after 1 d, washed with *n*-hexane (40 mL) and dried in vacuo. Yield: 70 mg of **2**·0.5THF (50%). – C<sub>32</sub>H<sub>46</sub>O<sub>0.5</sub>P<sub>2</sub>RuS<sub>4</sub> (**2**·0.5THF) (730.0): calcd. C 52.65, H 6.35, S

17.57; found C 52.90, H 6.56, S 17.21. – MS (FD, CH<sub>2</sub>Cl<sub>2</sub>, <sup>102</sup>Ru); *m/z*: 694 [Ru(P(Et<sub>3</sub>)<sub>2</sub>(‘tpS<sub>4</sub>’))]<sup>+</sup>. – <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>, 269.6 MHz): δ = 7.95–7.85 (m, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.75 (d, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.35 (d, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.25–7.18 (m, 2 H, C<sub>6</sub>H<sub>4</sub>), 6.90–6.75 (m, 4 H, C<sub>6</sub>H<sub>4</sub>), 1.95–1.75 (m, 12 H, P–CH<sub>2</sub>CH<sub>3</sub>), 1.10–0.97 (m, 15 H, P–CH<sub>2</sub>CH<sub>3</sub>). – <sup>13</sup>C{<sup>1</sup>H} NMR (100.40 MHz, CD<sub>2</sub>Cl<sub>2</sub>): δ = 158.9, 138.6, 136.8, 132.0, 131.5, 130.2, 129.7, 128.8, 121.1 [C(aryl)], 19.2 (t, P–CH<sub>2</sub>CH<sub>3</sub>), 8.5 (P–CH<sub>2</sub>CH<sub>3</sub>). – <sup>31</sup>P{<sup>1</sup>H} NMR (109.38 MHz, CD<sub>2</sub>Cl<sub>2</sub>): δ = 18.0 (s).

**[Ru(DMSO)<sub>2</sub>(‘tpS<sub>4</sub>’)] (3):** A yellow-orange suspension of [Ru(PPh<sub>3</sub>)<sub>2</sub>(‘tpS<sub>4</sub>’)] (1) (196 mg, 0.20 mmol) in DMSO (15 mL) was heated at reflux for 5 min, yielding a yellow-green solution. The solution was cooled to room temperature, combined with MeOH (75 mL), and stirred for 12 h. A yellow solid precipitated, which was separated, washed with MeOH (30 mL), Et<sub>2</sub>O (20 mL), and dried in vacuo. Despite several recrystallizations from CH<sub>2</sub>Cl<sub>2</sub>/MeOH, satisfactory elemental analyses could not be obtained. However, the NMR spectra of the yellow solid showed the absence of any PPh<sub>3</sub> resulting from the precursor complex 1. Yield: 50 mg of 3 (41%). – C<sub>22</sub>H<sub>24</sub>O<sub>2</sub>RuS<sub>4</sub> (3) (613.9): calcd. C 43.05, H 3.94; found C 44.42, H 4.13. – IR (KBr):  $\tilde{\nu}$  = 1015 cm<sup>−1</sup>, s, ν(SO). – MS (FD, CH<sub>2</sub>Cl<sub>2</sub>, <sup>102</sup>Ru); *m/z*: 614 [Ru(DMSO)<sub>2</sub>(‘tpS<sub>4</sub>’)]<sup>+</sup>. – <sup>1</sup>H NMR (269.6 MHz, CD<sub>2</sub>Cl<sub>2</sub>): δ = 7.85–7.80 (m, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.65 (d, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.50 (d, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.33–7.28 (m, 2 H, C<sub>6</sub>H<sub>4</sub>), 7.00 (t, 2 H, C<sub>6</sub>H<sub>4</sub>), 6.87 (t, 2 H, C<sub>6</sub>H<sub>4</sub>), 3.25 (s, 3 H, S–CH<sub>3</sub>), 3.05 (s, 3 H, S–CH<sub>3</sub>). – <sup>13</sup>C{<sup>1</sup>H} NMR (100.40 MHz, CD<sub>2</sub>Cl<sub>2</sub>): δ = 153.9, 137.1, 136.9, 132.5, 131.8, 130.7, 130.6, 130.0, 122.8, (C<sub>6</sub>H<sub>4</sub>), 46.3, 44.9 (S–CH<sub>3</sub>).

**[Ru(I)(PPh<sub>3</sub>)<sub>2</sub>(‘tpS<sub>4</sub>–Me<sub>2</sub>’)] (4):** MeI (0.5 mL, 8.0 mmol) was added while stirring to a yellow-orange solution of [Ru(PPh<sub>3</sub>)<sub>2</sub>(‘tpS<sub>4</sub>’)] (1) (140 mg, 0.14 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (30 mL) which changed its color to yellow over the course of 2 h. After addition of *n*-hexane (40 mL), a yellow solid precipitated, which was separated, washed with MeOH (10 mL), *n*-hexane (20 mL), and dried in vacuo. Recrystallization from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O (20 mL/40 mL) yielded yellow crystals, which were separated, washed with Et<sub>2</sub>O (20 mL), and dried in vacuo. Yield: 100 mg of 4 (71%). – C<sub>38</sub>H<sub>33</sub>I<sub>2</sub>PRuS<sub>4</sub> (4) (1004): calcd. C 45.47, H 3.31, S 12.78; found C 45.25, H 3.50, S 12.59. – <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>, 269.6 MHz): δ = 8.30 (t, 2 H, C<sub>6</sub>H<sub>4</sub>), 8.00 (d, 1 H, C<sub>6</sub>H<sub>4</sub>), 7.90–7.80 (m, 1 H, C<sub>6</sub>H<sub>4</sub>), 7.75–7.60 [m, 8 H, C<sub>6</sub>H<sub>4</sub> and P(C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>], 7.60–7.30 [m, 15 H, C<sub>6</sub>H<sub>4</sub> and P(C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>], 2.85 (s, 3 H, S–CH<sub>3</sub>), 2.05 (s, 3 H, S–CH<sub>3</sub>). – <sup>31</sup>P{<sup>1</sup>H} NMR (109.38 MHz, CD<sub>2</sub>Cl<sub>2</sub>): δ = 23.5 (s).

**[Ru(PMe<sub>3</sub>)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)] (5):** PMe<sub>3</sub> (0.8 mL, 7.70 mmol) was added to a yellow suspension of [Ru(PPh<sub>3</sub>)<sub>2</sub>(‘tpS<sub>4</sub>’)] (1) (400 mg, 0.41 mmol) in THF (15 mL). The suspension was stirred for 3 h, during the course of which a yellow solution resulted, which was filtered and concentrated to dryness to give a yellow residue. The residue was digested with *n*-hexane (40 mL) for 1 h, separated, washed with *n*-hexane (40 mL), and dried in vacuo. Yield 180 mg of 5 (55%). – C<sub>39</sub>H<sub>36</sub>P<sub>2</sub>RuS<sub>4</sub> (5) (796.0): calcd. **X-ray Structure Analyses of [Ru(py)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)] (7), [Ru(NO)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)]BF<sub>4</sub>·CH<sub>2</sub>Cl<sub>2</sub> (13·CH<sub>2</sub>Cl<sub>2</sub>), [Ru(I)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)]·CH<sub>2</sub>Cl<sub>2</sub> (16·CH<sub>2</sub>Cl<sub>2</sub>), [μ-N<sub>2</sub>H<sub>4</sub>{Ru(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)}<sub>2</sub>·4THF (18·4THF), and [μ-N<sub>2</sub>H<sub>2</sub>{Ru(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)}<sub>2</sub>·4CH<sub>2</sub>Cl<sub>2</sub> (19·4CH<sub>2</sub>Cl<sub>2</sub>):** Orange crystals of 7 were grown by layering a hot pyridine solution of 7 with MeOH. Dark-brown platelets of 13·CH<sub>2</sub>Cl<sub>2</sub> formed when a saturated CH<sub>2</sub>Cl<sub>2</sub> solution of 13 was layered with *n*-hexane. Black rhombohedra of [Ru(I)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)]·CH<sub>2</sub>Cl<sub>2</sub> (16·CH<sub>2</sub>Cl<sub>2</sub>) were obtained when a saturated CH<sub>2</sub>Cl<sub>2</sub> solution of 16 was layered with MeOH. Yellow platelets of [μ-N<sub>2</sub>H<sub>4</sub>{Ru(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)}<sub>2</sub>·4THF (18·4THF) crystallized from a THF solution of 18 layered with Et<sub>2</sub>O. Green platelets of 19·4CH<sub>2</sub>Cl<sub>2</sub> formed when air was injected into a yellow solution of [Ru(N<sub>2</sub>H<sub>4</sub>)(PPh<sub>3</sub>)(‘tpS<sub>4</sub>’)] (9) in CH<sub>2</sub>Cl<sub>2</sub>. – Suitable single crystals were mounted by using the oil-drop mounting technique.<sup>[23]</sup> For all data sets Lorentz and polarization corrections were applied. For 18·4THF absorption effects have been neglected. A ψ-scan absorption correction has been applied for 7 (*T*<sub>min</sub> = 0.4357, *T*<sub>max</sub> = 0.4699), 13·CH<sub>2</sub>Cl<sub>2</sub> (*T*<sub>min</sub> = 0.4254, *T*<sub>max</sub> = 0.4680), and 16·CH<sub>2</sub>Cl<sub>2</sub> (*T*<sub>min</sub> = 0.2677, *T*<sub>max</sub> = 0.3412). An empirical correction was used for 19·4CH<sub>2</sub>Cl<sub>2</sub> (SADABS, *T*<sub>min</sub> = 0.8294, *T*<sub>max</sub> = 0.9923).<sup>[24]</sup> All structures were solved by direct methods and were refined using full-matrix least-squares procedures on *F*<sup>2</sup> (SHELXTL 5.03).<sup>[25]</sup> – All non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms were taken from a difference Fourier map and were either refined isotropically (7), refined with a common isotropic displacement parameter (13·CH<sub>2</sub>Cl<sub>2</sub> and 16·CH<sub>2</sub>Cl<sub>2</sub>) or were kept fixed with a common isotropic displacement parameter

(18-4THF, 19-4CH<sub>2</sub>Cl<sub>2</sub>). The BF<sub>4</sub> anion in the structure of 13-CH<sub>2</sub>Cl<sub>2</sub> is disordered around the B1-F11 vector, where two possible sites have been refined such that they are both equally occupied (50%). Furthermore, the solvate CH<sub>2</sub>Cl<sub>2</sub> molecule is disordered with two different sites having occupancies of 74(4)% and 26(4)% respectively. In 16-CH<sub>2</sub>Cl<sub>2</sub>, one Cl atom of the solvate molecule is disordered. Two possible sites have been refined with occupancies of 61(5)% and 39(5)%. In 19-4CH<sub>2</sub>Cl<sub>2</sub> two of the solvate molecules are disordered with site occupancies of the two possible sites being refined to 77(1)% and 29(1)%. The hydrogen atoms of the solvate molecules in all structures are geometrically positioned. Selected crystallographic data are summarized in Table 2.<sup>[26]</sup>
