The bis(η^3 -2-methallyl)ruthenium(II) complexes [Ru(η^3 -2-MeC₃H₄)₂(κ^2 -Ph₂PCH₂CH₂PR₂)] [R = *i*Pr (**2**), Cy (**3**)] were prepared from the cycloocta-1,5-diene derivative [Ru(η^3 -2-MeC₃H₄)₂(η^4 -C₈H₁₂)] (**1**) and the unsymmetrical 1,2-bis(phosphanyl)ethanes Ph₂PCH₂CH₂PR₂. The As,P analogue [Ru(η^3 -2-MeC₃H₄)₂(κ^2 -Ph₂PCH₂CH₂As*t*Bu₂)] (**4**) was obtained by the same route. The reaction of **2** with hexafluoroacetylacetonate afforded the chelate compound [Ru(κ^2 -[F₆-

acac)₂(κ^2 -*i*Pr₂PCH₂CH₂PPh₂)], whereas treatment of **2** and **3** with pentachlorophenol gave the related, more labile complexes [Ru(κ^2 -O,*Cl*-OC₆Cl₅)₂(κ^2 -R₂PCH₂CH₂PPh₂)] [R = *i*Pr (**6**), Cy (**7**)]. Preparation of the parent bis(acac) compound [Ru(κ^2 -acac)₂(κ^2 -*i*Pr₂PCH₂CH₂PPh₂)] (**8**), which could not be obtained from **2** and acacH, was achieved by ligand exchange of **6** and acetylacetone. The molecular structures of **2** and **6** were determined by X-ray crystallography.

Introduction

By attempting to modify the donor/acceptor properties of bidentate ligands with P, As, and Sb as donor atoms, we recently described two new synthetic methodologies for unsymmetrical bis(phosphanyl)methanes and 1,2-bis(phosphanyl)ethanes as well as for their As,P analogues.^[1,2] While the methane derivatives R₂PCH₂ER'₂ were prepared from the stannylated phosphanes R₂PCH₂SnR''₃ by metalation with MeLi or PhLi in the presence of tetramethylethylenediamine followed by treatment with R'₂PCl or R'₂AsCl,^[1] the corresponding disubstituted ethanes R₂PCH₂CH₂ER'₂ were obtained in a one-pot reaction from the cyclic sulfate C₂H₄O₂SO₂ by stepwise addition of R'₂ELi and R₂PLi, respectively. The latter method is also suitable for the preparation of *chiral* bidentate P,P donors of the general composition R₂PCH₂CH(Me)PPh₂ and R₂PCH₂CH₂CH(Me)-PPh₂ where the substituent R is a bulky alkyl or cycloalkyl group such as *i*Pr, *t*Bu, or C₆H₁₁.^[2,3]

In the initial phase of these studies, we tested the coordination properties of the new ligands toward rhodium(I) and isolated a series of square-planar and half-sandwich-type complexes including [Rh(η^4 -C₈H₁₂)(κ^2 -R-Ph₂PCH(Me)CH₂PCy₂)]PF₆^[3] and [(η^6 -C₆H₅R)Rh(κ^2 -Cy₂PCH₂P*i*Pr₂)]PF₆ (R = H, Me).^[1] In this paper we report the synthesis of a series of ruthenium(II) compounds with both Ph₂PCH₂CH₂PR₂ and Ph₂PCH₂CH₂As*t*Bu₂ as chelating ligands and η^3 -2-methallyl, pentachlorophenolate, and acetylacetonates as ancillary bidentate units. Some preliminary results of this work have already been communicated.^[2]

Results and Discussion

The preparation of the chelate complexes **2** and **3** (Scheme 1) followed the route which was used by Holle, Jolly, and Kuhnigk to obtain the related bis(η^3 -allyl)ruthenium(II) compounds with *i*Pr₂P(CH₂)_{*n*}P*i*Pr₂ (*n* = 1, 2, and 3) as ligands.^[4] The reaction proceeds in hexane under reflux conditions and affords the products as yellow solids in about 70% isolated yield. Compounds **2** and **3** are only slightly air-sensitive and, apart from pentane and ether, readily soluble in most common organic solvents. The ³¹P NMR spectra of both **2** and **3** display two sharp doublets for the nonequivalent phosphorus nuclei with ³¹P-³¹P coupling constants of 8.5 and 7.6 Hz, respectively. Due to the presence of the unsymmetrical 1,2-bis(phosphanyl)ethane ligand, the ¹H NMR spectra of **2** and **3** are rather complex, thus making an exact assignment of the signals for the CH₂ allyl protons difficult.

Scheme 1

The molecular structure of compound **2**, of which single crystals were obtained from a saturated solution in hexane, was determined by X-ray crystallography. The molecular

diagram (Figure 1) reveals that the coordination geometry around the metal center can be described as a distorted tetrahedron with the two phosphorus atoms P1 and P2 and the two central carbon atoms C40 and C50 of the allylic moieties at the corners of the tetrahedron. The bond lengths Ru–C40 and Ru–C50 are somewhat shorter than those from the ruthenium center to the terminal carbon atoms of the 2-methallyl ligands. This results in dihedral angles of $37.7(1)^\circ$ and $34.9(1)^\circ$ between the planes [C40,C41,C42] and [C50,C51,C52] of the π -allyl units and the plane of the five-membered chelate ring [Ru,P1,C2,C1,P2]. The distances Ru–P1 and Ru–P2 differ only slightly to those in similar phosphaneruthenium(II) complexes^[5–7] while the bite angle P1–Ru–P2 of $85.32(3)^\circ$ is nearly identical to that in [Ru(η^3 -2-MeC₃H₄)₂(κ^2 -Cy₂PCH₂CH₂PCy₂)] [$85.03(4)^\circ$].^[5]

In contrast to *i*Pr₂PCH₂As*t*Bu₂, which does not react with the starting material **1** by substitution of the cyclooctadiene ligand,^[3] the reaction of the ethane derivative Ph₂PCH₂CH₂As*t*Bu₂ with **1** affords the chelate complex **4** (see Scheme 1) as a yellow solid in 51% isolated yield. While the ³¹P NMR spectrum of **4** displays, in agreement with the proposed structure, a single resonance at $\delta = 79.4$, the ¹H NMR spectrum is very complex and shows several overlapping signals between $\delta = 2.95$ and 0.51 , which originate from the allyl, the *tert*-butyl and the CH₂ protons of the coordinated As₂P donor unit. In the ¹³C NMR spectrum of **4**, the CH₂ carbon atoms of the 2-methallyl units give rise to four doublets at $\delta = 39.6, 36.9, 36.3$, and 33.4 , thus confirming the presence of an additional unsymmetrical bidentate ligand.

Similarly to the starting material **1**, the substituted compounds **2** and **3** are also quite reactive towards Brønsted acids. However, in contrast to **1** which reacts cleanly with CF₃CO₂H to give [Ru(η^4 -C₈H₁₂)(μ -O₂CCF₃)₂],^[8] treatment of **2** or **3** with trifluoroacetic acid leads to a mixture of products which could not be separated by conventional techniques.

The reaction of **2** with two equivalents of hexafluoroacetylacetone affords, by protonation of both 2-methallyl ligands (and elimination of isobutene), the chelate complex **5** (Scheme 2) as a red air-stable solid in almost quantitative yield. Due to the coordination of the unsymmetrical 1,2-bis(phosphanyl)ethane, the two [F₆]acac units are non-equivalent and therefore the ¹³C NMR as well as the ¹⁹F NMR spectrum of **5** display four resonances for the carbon and fluorine nuclei of the CF₃ groups. The appearance of four quadruplets for the CF₃CO and of two singlets for the COCHCO carbon atoms equally illustrates the stereochemical nonequivalence of the [F₆]acac ligands.

Scheme 2

In contrast to the hexafluoro derivative [F₆]acacH, the parent compound acacH does not react, even in refluxing toluene, with the starting material **2**. The lower acidity of acetylacetone ($pK_a = 9.0$) compared to the hexafluoro analogue ($pK_a = 5.3$)^[9] presumably causes the difference in the reactivity of the two diketones toward the η^3 -2-methallylruthenium(II) complex **2**.

However, the bis(acac) compound **8** is accessible in a stepwise route via the intermediate bis(pentachlorophenolato) complex **6**. Both **6** and **7** are obtained in excellent yield as orange, moderately air-sensitive solids upon treatment of **2** and **3** with two equivalents of C₆Cl₅OH in toluene at room temperature. With regard to the spectroscopic data of **6** and **7**, the interesting feature is that the ¹³C NMR spectra (in [D₈]toluene) display at both 295 K and 188 K only one signal for the *ortho*- and one signal for the *meta*-carbon atoms of the OC₆Cl₅ units. This observation indicates that a fluxional process takes place in solution, which involves (on the NMR time scale) rapid coordination/decoordination of the chlorine atoms in *ortho* position of the six-membered rings to the metal center. There is good reason to believe that the stability of the chelating bonding mode (via

oxygen and chlorine) of the pentachlorophenolato ligands to the ruthenium center depends significantly on the coordination sphere since the tris(chelate) complexes $[\text{Ru}(\kappa^2\text{-OC}_6\text{Cl}_5)_2(\kappa^2\text{-Ph}_2\text{PCH}_2\text{PR}_2)]$ ($\text{R} = i\text{Pr}, \text{Cy}$) are fluxional at 295 K but rigid at 188 K,^[10] while the hydrido compound $[\text{RuH}(\kappa^2\text{-OC}_6\text{Cl}_5)(\text{CO})(\text{P}i\text{Pr}_3)_2]$ is nonfluxional on the NMR timescale even at room temperature.^[11]

The X-ray crystal structure analysis of **6** (Figure 2) confirms the existence of weak Ru–Cl interactions comparable to those between transition metals and other C–Cl bonds.^[12] The Ru–Cl distances of 2.498(1) Å and 2.524(1) Å are significantly longer than in *trans*- $[\text{RuCl}_2(\kappa^2\text{-Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2)_2]$ [2.4325(12) Å]^[13] and *trans*- $[\text{RuCl}_2(\kappa^2\text{-Ph}_2\text{PCH}_2\text{PPh}_2)_2]$ [2.426(1) Å],^[14] where “normal” covalent Ru–Cl bonds are present. The coordination geometry around the metal center in **6** is a distorted octahedron with a bite angle P1–Ru–P2 of 84.32(5)° that is almost identical to that in compound **2**. The bond angles Ru–O1–C1 [120.6(3)°] and Ru–O2–C7 [119.3(3)°] are considerably smaller than in the hydrido complex *trans*- $[\text{RuH}(\text{OC}_6\text{H}_4\text{-4-Me})(\kappa^2\text{-Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2)_2]$ [137.58(16)°]^[15] where no additional interaction between the C–H units of the phenolato ligand and the metal exists.

Molecular structure of compound **6**; the THF molecule is omitted for clarity; selected bond lengths [Å] and angles [°]: Ru–P1 2.2341(13), Ru–P2 2.2578(13), Ru–O1 2.088(3), Ru–O2 2.078(3), Ru–Cl2 2.5240(13), Ru–Cl8 2.4978(13); P1–Ru–P2 84.32(5), P1–Ru–O1 99.45(9), P1–Ru–O2 89.24(9), P1–Ru–Cl2 176.70(4), P1–Ru–Cl8 94.03(5), P2–Ru–O1 94.51(9), P2–Ru–O2 93.00(8), P2–Ru–Cl2 98.90(5), P2–Ru–Cl8 174.32(4), O1–Ru–O2 169.03(11), O1–Ru–Cl2 79.60(9), O1–Ru–Cl8 91.12(9), O2–Ru–Cl2 91.34(9), O2–Ru–Cl8 81.53(8), Cl2–Ru–Cl8 82.85(4).

In contrast to **2**, compound **6** reacts with acetylacetone in the presence of Na_2CO_3 to afford the bis(acac) complex **8** as a yellow air-stable solid in 89% isolated yield. Moreover, the bis(pentachlorophenolato) derivative **6** affords the bis($[\text{F}_6\text{Jacac}]$) complex **5** almost instantaneously upon treatment with $[\text{F}_6\text{JacacH}]$ in toluene. This pattern of reactivity indicates that **6** (and equally **7**) could be considered as a masked 14-electron species in which the additional interaction between the chlorine atoms in *ortho* position of the OC_6Cl_5 units and the metal center prevents a subsequent

oligomerization or decomposition process. We note that quite recently Baratta et al. reported another example of a ruthenium(II) complex with a formal 14-electron configuration; in this case two strong agostic RuHC interactions relieve part of the electronic unsaturation at the metal center.^[16]

Experimental Section

All operations were carried out under argon using Schlenk techniques. The starting material **1**^[17] as well as the ligands $\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PR}_2$ ($\text{R} = i\text{Pr}, \text{Cy}$) and $\text{Ph}_2\text{PCH}_2\text{CH}_2\text{AsrBu}_2$ ^[2,3] were prepared as described in the literature. – IR: Perkin–Elmer 1320. – NMR: Bruker AC 200 and AMX 400. – Melting points determined by DTA.

4. Preparation of [Ru(κ^2 -[F₆]acac)₂(κ^2 -Ph₂PCH₂CH₂PiPr₂)] (5): a) A solution of **2** (104 mg, 0.2 mmol) in toluene (5 mL) was treated at –78 °C with hexafluoroacetylacetone (88 μ L, 0.4 mmol), which led to a rapid change of color from yellow to dark red. After warming to room temperature and stirring the solution for 20 min, the solvent was evaporated in vacuo and the residue was dissolved in pentane (2 mL). The solution was chromatographed on Al₂O₃ (basic, activity grade I, height of column 10 cm). With pentane a red fraction was eluted, from which a dark red microcrystalline solid was obtained upon removal of the solvent; yield 147 mg (92%). – b) A solution of **6** (164 mg, 0.2 mmol) in toluene (5 mL) was treated with hexafluoroacetylacetone (71 μ L, 0.4 mmol), which led to a rapid change of color from orange to dark red. The solvent was evaporated in vacuo, the residue was washed with pentane (5 mL, –20 °C) and dried. X-ray Structure Determination of Compounds 2 and 6:^[18] Single crystals of **2** were grown from hexane at 25 °C and those of **6** from THF at 25 °C. Crystal data collection parameters for these structures are presented in Table 1. The data were collected with an Enraf–Nonius CAD4 diffractometer using monochromated Mo- K_α radiation (λ = 0.71073 Å). Intensity data were corrected for Lorentz and polarization effects. An empirical absorption correction was applied for both structures [Ψ scans; $T_{\min}$ = 0.90, $T_{\max}$ = 1.00 (**2**); $T_{\min}$ = 0.59, $T_{\max}$ = 0.80 (**6**)]. The structures were

solved by Patterson methods with SHELXS-97.^[19] All structures were refined by full-matrix least-squares procedures on F^2 , using SHELXL-97.^[20] The positions of all hydrogen atoms were calculated according to ideal geometry and refined by employing the riding method, except for H41a, H41b, H42a, H42b, H51a, H51b, H52a, and H52b of **2**, which were found in a differential Fourier synthesis and refined without restraints.

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft (SFB 347) and the Fonds der Chemischen Industrie. We are grateful to the latter in particular for a Ph.D. scholarship (to K. I.). We also thank Dr. W. Buchner and Mrs. M.-L. Schäfer for NMR measurements, Mrs. R. Schedl and Mr. C. P. Kneis for elemental analysis and DTA measurements. Generous support by the BASF AG and the Degussa-Hüls AG is also gratefully acknowledged.
