Green-black solutions of **5** in THF reacted with CH_3I with the formation of violet precipitates. These contain $[Cp'_4Nb_2Te(CH_3Te)]I$ ([**6**]**I**) or $[Cp'_4Nb_2(CH_3Te)_2]I_2$ ([**7**]$\mathbf{I_2}$) in quantitative yields depending on the employed stoichiometry (one or two equivalents of CH_3I). The composition of both compounds was confirmed by positive FAB mass spectra, which exhibit the peaks for the corresponding cations $[Cp'_4Nb_2Te(CH_3Te)]^+$ ([**6**]$^+$) and $[Cp'_4Nb_2(CH_3Te)_2]^{2+}$ ([**7**]$^{2+}$). The elemental analysis was close to the calculated value for [**6**]**I** and correct for [**7**]$\mathbf{I_2}$. The violet solution of [**7**]$\mathbf{I_2}$ in methanol was transformed into a dark blue precipitate in nearly quantitative yield upon addition of an aqueous solution containing two equivalents of NH_4PF_6. The composition $[Cp'_4Nb_2(CH_3Te)_2][PF_6]_2$ (**8**) roughly follows from the elemental analysis. The IR spectrum of **8** exhibits the typical absorption of the PF_6^- anion at 835 cm^{-1}. Complex **8** is poorly soluble in common solvents, thus preventing further spectroscopic investigations or recrystallization.

The ^1H NMR spectrum of [**6**]**I** (in CD_2Cl_2) shows one sharp singlet for the *t*Bu groups at δ = 1.53 and six multiplets between δ = 4.32 and 5.53 for the aromatic hydrogens. A singlet at δ = 2.45 was assigned to the μ-CH_3Te ligand. The ^1H NMR spectrum of [**7**]$\mathbf{I_2}$ (in CD_3OD) exhibits one slightly broadened singlet and two sharp singlets (intensity ratio 2:1:1) for the *t*Bu groups and eleven multiplets of different intensities between δ = 3.38 and 6.60 for the aromatic hydrogens. One sharp and one slightly broadened singlet at δ = 2.88 and 2.71, respectively, were tentatively assigned to the μ-CH_3Te ligands. From the solid state structure, which exhibits C_{2h} symmetry (see below), one might expect four equivalent Cp′ rings, i.e. one *t*Bu signal and four multiplets for the aromatic protons, provided the conformative flexibility of the Cp′ rings is blocked in solution.

The crystal structure of [**7**]$\mathbf{I_2}$ may be derived from its precursor $[Cp'_4Nb_2Te_2]$ (**5**). It contains a planar four-membered Nb_2Te_2 ring with four attached Cp′ ligands and two methyl groups, which are fixed at the Te bridges in a *trans* position (Figure 6). This arrangement, along with that of the *t*Bu groups in both niobocene units, gives rise to C_{2h} symmetry. The nonbonding Te(1)···Te(1′) distance (4.35 Å) and the angles at the Te bridges indicate that addition of electrophiles like CH_3^+ to **5** does not enhance attractive intraannular forces between the chalcogen atoms. Consequently, the positive charges may be localized at the Nb centers.

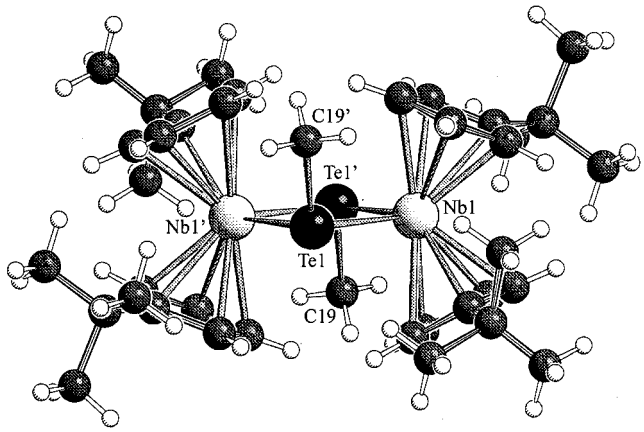

Figure 6. Molecular structure of $[Cp'_4Nb_2(CH_3Te)_2]^{2+}$ in [**7**]$\mathbf{I_2}$; selected distances [Å] and angles [°]: Nb(1)−Te(1) 2.838(3), Nb(1′)−Te(1) 2.876(4), Te(1)···Te(1′) 4.349(13), Nb(1)···Nb(1′) 3.707(9), Te(1)−C(19) 2.17(3); Nb(1)−Te(1)−Nb(1′) 80.9(1), Te(1)−Nb(1)−Te(1′) 99.1(1), Nb(1)−Te(1)−C(19′) 113.4(8), Nb(1′)−Te(1)−C(19′) 115.4(11), $C(1-5)_{center}$−Nb(1)−$C(10-14)_{center}$ 132.0(1)

The conformation found in the solid state may be caused by steric constraints, since the contacts between the $tBuC_5H_4$ hydrogens and the CH_3Te groups [*d*(H···H) ≥ 1.87 Å] are rather close. However, from the ^1H NMR spectra the presence of a further stereoisomer in solution with two nonequivalent Cp′ rings is evident. A further possibility would be an isomer with a *cis* arrangement of the CH_3Te ligands, the niobocene units being arranged as in the achiral *meso* form. Unfortunately, it was not possible to check this by dissolving separated crystals at low temperatures in order to carry out low temperature NMR investigations. However, there are some arguments supporting our hypotheses: a) Replacement of both CH_3 groups by the much bulkier $Cr(CO)_5$ groups leads to $[Cp'_4Nb_2Te_2{\cdot}2Cr(CO)_5]$ exclusively with C_{2h} symmetry. This follows from the room

temperature ^{1}H NMR spectrum, which exhibits only one singlet for the *t*Bu groups and four multiplets for the *t*BuC$_5$H$_4$ protons;[29] (b) electrochemical experiments carried out on **[7]I$_2$** (see below) confirm the homogeneity of the compound, so that a mixture of different compounds can be excluded.

Electrochemical Behavior of 5, [6]I, and [7]I$_2$

The electrochemical behavior of **5**, **[6]I**, and **[7]I$_2$** has been studied by cyclic voltammetry, rotating disk electrode (RDE) voltammetry, and electrolysis techniques. The voltammetric half-wave potentials are given in Table 2. For each compound, in the anodic area, reversible systems at +0.05 V (**5**) and +0.35 V (**[6]I**, **[7]I$_2$**) are observed, while the second oxidation steps at +0.59 V (**5**) and +0.80 V (**[6]I**, **[7]I$_2$**) are irreversible. The peaks at +0.35 and +0.80 V correspond to the oxidation of I^-.[30] The same oxidation peak potentials were obtained when Bu$_4$NI was used. In the cathodic part each complex exhibits two reversible one-electron systems in the potential range between −0.40 and −2.20 V (Figure 7). For these two reduction processes, the current ratio $i_{p,c}/i_{p,a}$ is equal to unity (or very close to it) for sweep rates v between 20 and 200 mV·s^{-1} and the peak current increases linearly with $v^{1/2}$. The half-wave potentials are independent of the potential scan rate and the peak shapes are characterized by $|E_{p,c} - E_{p,a}| \approx 60$ mV in agreement with a one-electron transfer controlled by diffusion.[31,32]

Table 2. $E_{1/2}$ values and HOMO and LUMO energies (eV) for complexes **5**, **[6]I** and **[7]I$_2$** (E values were determined with a carbon electrode vs. SCE; THF, 0.2 mol·L^{-1} Bu$_4$NPF$_6$)

	$E_{1/2\ ox2}$ [V]	$E_{1/2\ ox1}$ [V]	$E_{1/2\ red1}$ [V]	$E_{1/2\ red2}$ [V]	E_{HOMO}	E_{LUMO}
5	+0.59	+0.05	−1.83	−2.19	−4.427	−1.787
[6]I	+0.80	+0.35	−1.00	−1.34	−7.781	−5.615
[7]I$_2$	+0.80	+0.36	−0.39	−0.59	−11.414	−8.679

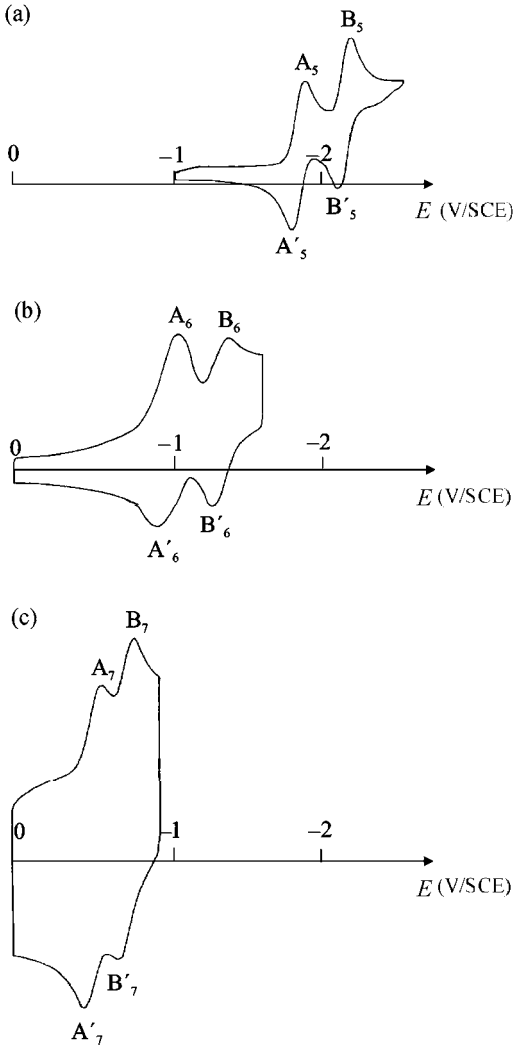

Figure 7. Cyclic voltammograms of complexes **5** (a), **[6]I** (b), and **[7]I$_2$** (c) in THF (0.2 mol·L^{-1} Bu$_4$NPF$_6$; initial potential 0 V, sweep rate 0.1 V·s^{-1})

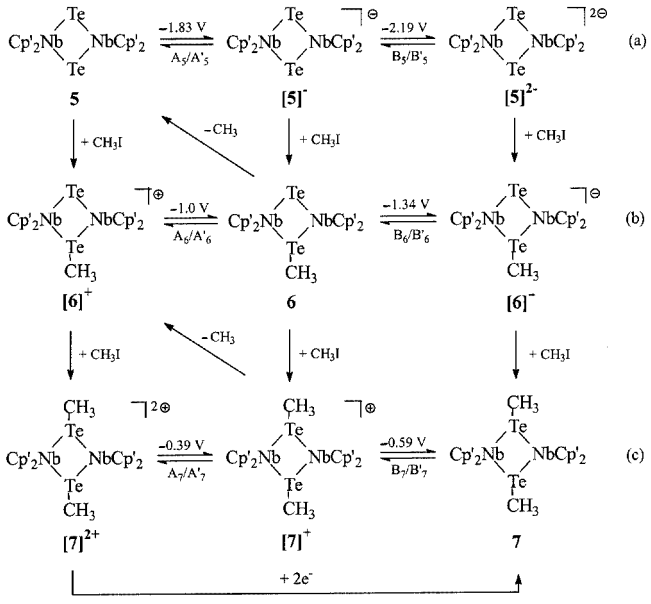
The processes that take place during reduction of complex **5** are represented in Scheme 2a. The anionic species **[5]**$^-$ and **[5]**$^{2-}$ are relatively unstable on the electrolysis time scale and it was not possible to characterize them. In complex **[6]I**, two reversible waves are observed at −1.0 and −1.34 V, respectively. The corresponding reduction processes concern the cation **[6]**$^+$ as shown in Scheme 2b. It is interesting to note that after quantitative reduction of **[6]**$^+$ at the first reduction potential the two systems A_5/A_5' and B_5/B_5' are observed. This means that complex **5** has been reformed via quantitative CH_3 elimination. The two-electron reduction of **[6]**$^+$ leads to the very unstable monoanion **[6]**$^-$.

For complex **[7]I$_2$**, each reduction step is found by means of coulometry to correspond to a one-electron process [see (a) in Figure 8]. After reduction at −0.80 V (plateau of wave B_7), 2 F·mol^{-1} have been consumed and the color of the solution turns from opaque purple to translucent brown. The resulting species **7** (Scheme 2c) is stable even on the electrolysis time scale since no evolution of the RDE voltammogram waves (B'_7/A'_7) occurs [see (b) in Figure 8]. In order to get an ^{1}H NMR spectrum the solvent was evaporated from the electrolyzed solution and the residue extracted with toluene. Unfortunately, upon concentration the solution changed to violet. The slow evolution of **7** may also be observed in the UV spectrum.

By oxidation of solutions of **7** at −0.5 V (plateau of wave B'_7) the cation **[7]**$^+$ is obtained, which exhibits the reduction wave B_7 and the oxidation wave A'_7 [see (c) in Figure 8] as well as a ten-line ESR signal characteristic of a complex containing a paramagnetic niobium(IV) center ($a_{iso(Nb)}$ = 65 G; g_{iso} = 2.0400). The electrogenerated species **[7]**$^+$ is relatively unstable with respect to **7**, probably due to a slow partial evolution with release of CH_3, which would result in the formation of **[6]**$^+$.

We have also studied the reduction behavior of **5** in the presence of CH_3I. We have verified that **5** spontaneously



Scheme 2

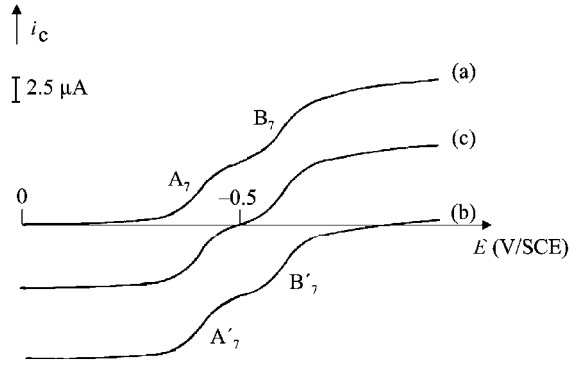


Figure 8. RDE voltammogram of [7]I_2 on carbon electrode in THF (0.2 mol·L^{-1} Bu_4NPF_6): (a) before electrolysis; (b) after 2 e^- reduction at −0.8 V; (c) after 1 e^- oxidation at −0.5 V

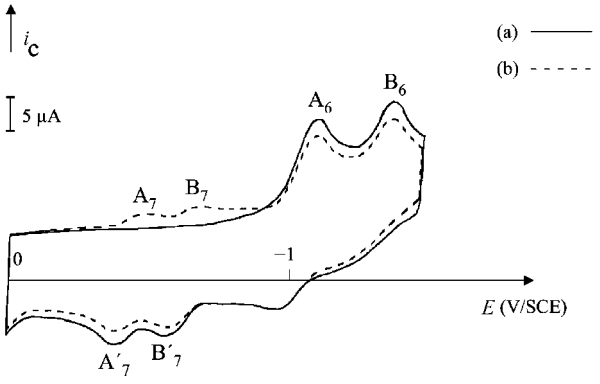

Figure 9. Cyclic voltammogram of **5** with CH_3I in THF (0.2 mol·L^{-1} Bu_4NPF_6): (a) first and (b) second sweeps. Initial potential 0 V, sweep rate 0.1 V·s^{-1}

gives $[6]^+$, for instead of the reduction peaks A_5/B_5 the peaks A_6/B_6 appear (Figure 9). When the potential sweep is reversed after B_6, two oxidation peaks A'_7 and B'_7 appear. This means that $[6]^-$ reacts quickly with CH_3I to give **7**. During the reverse sweep, peaks A_7 and B_7, characteristic of the dication $[7]^{2+}$, are observed.

The electrochemical results can be rationalized on the basis of a square scheme involving nine species. From one to the next species, one electron is exchanged horizontally (Scheme 2).

Theoretical Calculations

The bonding features of complexes **5**, $[6]^+$, and $[7]^{2+}$ have been investigated by DFT calculations. We have carried out geometry optimizations at the B3LYP/LANL2DZ level on models of these three complexes by introducing the unsubstituted C_5H_5 (Cp) ring instead of $tBuC_5H_4$ (Cp′). A full optimization yields a satisfactory agreement of calculated parameters with the experimental values for **5** and $[7]^{2+}$.[33] The most striking discrepancy has been found for the Nb−Nb distance in **5** [3.782 Å (Cp) vs. 3.647 Å (Cp′)]. The compositions and shapes of the HOMO and LUMO frontier orbitals are essentially the same for the three molecules studied. They are built of roughly a 35% contribution of 'd' atomic orbitals of each Nb atom and a 15% contribution of 'p' orbitals of each Te atom. The HOMO's exhibit a favorable Nb−Nb overlap and may be considered as metal−metal bonding orbitals while the LUMO's are the metal−metal antibonding ones. Their energies are included in Table 2. As an example, the shape of the LUMO for **5** is depicted in Figure 10.

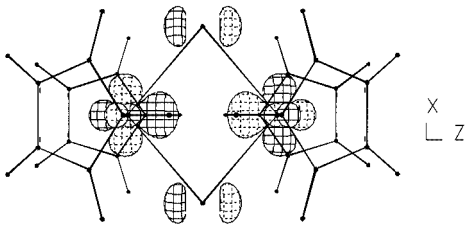

Figure 10. LUMO of **5**

The HOMO is concerned with the oxidation process, whereas the LUMO is used for reduction. As mentioned above, the oxidation waves for $[6]^+$ and $[7]^{2+}$ are probably covered by those of the I^-/I_2 system. However, the reduction potentials could be properly measured. There is a linear correlation between these reduction potentials for **5**, $[6]^+$, $[7]^{2+}$ and the calculated energies of the LUMO's of the corresponding model compounds (Table 2). Thus, the weak potential of −0.39 V is needed for reduction of $[7]^{2+}$, the LUMO of which is easily accessible for the incoming electron because of its low energy. Stronger potentials are necessary for reduction of $[6]^+$ and **5** because the energies of their LUMO's are higher. Assuming that a similar correlation (same slope) also holds for E_{HOMO} versus oxidation potential, the expected values for the first oxidation potentials should be close to 0.8 V for $[6]^+$ and 1.5 V for $[7]^{2+}$,with reference to 0.05 V, measured for **5**.

Conclusions

The reaction of $[Cp'_2NbH_3]$ with elemental tellurium gives $[Cp'_2Nb(Te_2)H]$ (**1**) in good yields. Complex **1** is a missing member of the class of group 5 dichalcogenido metallocene hydrides $[Cp_2M(X_2)H]$ (Cp = any cyclopentadienyl; M = Nb, Ta; X = S, Se, Te). In spite of some difficulties in obtaining complete analytical and spectroscopic data for **1** its structure may be deduced from the $Cr(CO)_5$ adduct **3**. Further support for the stabilization of the Nb(η^2-Te_2) moiety in the *t*Bu-niobocene part is also provided by the insertion of an $Fe_2(CO)_6$ unit into the Te−Te bond of **1**.[34] The fact that the bimetallic complex **3** gives the dinuclear, homometallic compound $[Cp'_4Nb_2Te_2]$ (**5**) under thermolytic conditions demonstrates the ability of **1** to eliminate Te. We have already shown that in the presence of suitable transition metal carbonyls **1** is a convenient Te transfer reagent for the synthesis of polymetallic metal telluride clusters.[25,35]

Experimental Section

General and Methods: All manipulations were performed with Schlenk techniques under N_2 or argon using dry solvents. Tellurium and SiO_2 (activity II-III, 63−200 μm) were degassed by several vacuum/N_2 cycles. Elemental analyses were performed at the Mikroanalytisches Laboratorium, Universität Regensburg. IR spectra were obtained with a Beckman 4240 instrument. ^{1}H NMR spectra were recorded with a Bruker ARX 400 instrument. FD and FAB mass spectra were obtained on a Finnigan MAT spectrometer. $[Cp'_2NbH_3]$ was prepared according to literature methods.[36] Electrochemistry: Cyclic voltammetry was carried out in a standard three-electrode cell with a Tacussel UAP4 unit cell. The reference electrode was a saturated calomel electrode (SCE) separated from the solution by a sintered glass disk. The auxiliary electrode was a platinum wire. For all voltammetric measurements, the working electrode was a vitreous carbon electrode. The controlled potential electrolysis was performed with an Amel 552 potentiostat coupled to an Amel 721 electronic integrator. Electrolyses were performed in a cell with three compartments separated with fritted glass of medium porosity. A carbon gauze was used as the cathode, a platinum plate as the anode and a saturated calomel electrode as the reference electrode. Computational details: All calculations on the closed shell complexes **5**, $[\mathbf{6}]^+$, and $[\mathbf{7}]^{2+}$ were performed using the GAUSSIAN 98 series of programs.[37] Density functional theory (DFT)[38] was applied with the B3LYP functional[39] and with the standard LANL2DZ basis set.[40] The input geometries for optimizations of **5** and $[\mathbf{7}]^{2+}$ were those from available X-ray data (C_5H_5 instead of $tBuC_5H_4$), while the averaged metric parameters from **5** and $[\mathbf{7}]^{2+}$ were used for the starting geometry of $[\mathbf{6}]^+$. The final wave functions and energy levels for **5**, $[\mathbf{6}]^+$, and $[\mathbf{7}]^{2+}$ were obtained from single point calculations carried out on optimized geometries at the same level of theory.

Synthesis of $[Cp'_2Nb(Te_2)H]$ (1): A mixture of $[Cp'_2NbH_3]$ (900 mg, 2.66 mmol), degassed tellurium powder (850 mg, 6.66 mmol), and freshly distilled THF (100 mL) was stirred for 48 h at 40 °C. During this time the color changed from bright brown to dark orange. After evaporation of the solvent the residue was suspended in toluene (12 mL) and transferred to the top of a chromatography column (SiO_2, column 15 × 3 cm). A dark orange band containing 1.27 g (2.15 mmol, 81%) of **1** was eluted with toluene. Red crystals were obtained from toluene/pentane (1:1). $C_{18}H_{27}NbTe_2$ (591.52): calcd. C 36.55, H 4.60; found C 35.36, H 4.25. Mol. mass 591.1 (FD-MS, toluene). ^{1}H NMR (400 MHz, CD_2Cl_2, 24 °C): δ = 6.56 (m, 2 H, C_5H_4R), 4.98 (m, 2 H, C_5H_4R), 4.74 (m, 2 H, C_5H_4R), 4.44 (m, 2 H, C_5H_4R), 1.39 (s, 18 H, CH_3), −3.50 (s, $^2J_{H,Te}$ = 86.7 Hz, 1 H, NbH). ^{125}Te{^{1}H} NMR (157 MHz, CD_2Cl_2): δ = −749.4.

Synthesis of $[Cp'_6Nb_4Te_4O]$ (2): A mixture of $[Cp'_2NbH_3]$ (900 mg, 2.66 mmol), untreated tellurium powder (850 mg, 6.66 mmol) and THF (100 mL) was stirred for 48 h at 40 °C, during which time the color changed to dark violet. After evaporation of the solvent the residue was suspended in toluene (12 mL) and chromatographed on SiO_2 (column 15 × 3 cm). A red-violet band containing $[Cp'_6Nb_4Te_4O]$ (**2**) in yields between 110 and 350 mg (0.07−0.22 mmol, 10−32%) was eluted with toluene. Then a dark orange band was eluted containing between 140 and 830 mg (0.24−1.40 mmol, 9−53%) of $[Cp'_2NbTe_2H]$ (**1**). Complex **2** was recrystallized from THF/Et_2O (4:1) $C_{54}H_{78}Nb_4OTe_4$ (1625.22): calcd. C 39.91, H 4.84; found C 40.13, H 5.01. Mol. mass 1625.7 (FD-MS, toluene). ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 5.75 (m, 4 H, C_5H_4R), 5.30 (m, 4 H, C_5H_4R), 5.11 (m, 4 H, C_5H_4R), 4.88 (m, 8 H, C_5H_4R), 4.18 (m, 4 H, C_5H_4R), 1.54 (s, 18 H, CH_3), 1.47 (s, 18 H, CH_3), 1.26 (s, 18 H, CH_3).

Synthesis of $[Cp'_2Nb(Te_2)H{\cdot}Cr(CO)_5]$ (3): A solution of **1** (520 mg, 0.88 mmol) in THF (50 mL) was added to a solution of $[Cr(CO)_5THF]$ (4.40 mmol) in THF (150 mL). The mixture was stirred for 15 h at room temperature in the dark. After evaporation of the solvent the brown residue was dried under high vacuum in order to remove reformed or excess $[Cr(CO)_6]$. Then the residue was dissolved in a mixture of toluene (12 mL) and acetone (2 mL). Chromatography on SiO_2 (column 20 × 5 cm) gave a golden brown band, containing $[Cp'_2Nb(Te_2)H{\cdot}Cr(CO)_5]$ (**3**) (620 mg, 0.79 mmol, 90%), which was recrystallized from toluene/pentane (1:1). $C_{23}H_{27}CrNbO_5Te_2$ (783.56): calcd. C 35.26, H 3.47; found C 35.12, H 3.61. Mol. mass 783.7 (FD-MS, toluene). IR (KBr): $\tilde{\nu}$ = 2050 s, 1945 vs, 1895 vs cm^{-1} [ν(CO)]. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 6.58 (m, 1 H, C_5H_4R), 6.27 (m, 1 H, C_5H_4R), 5.20 (m, 1 H, C_5H_4R), 5.14 (m, 1 H, C_5H_4R), 4.87 (m, 1 H, C_5H_4R), 4.73 (m, 1 H, C_5H_4R), 4.69 (m, 1 H, C_5H_4R), 4.64 (m, 1 H, C_5H_4R), 1.31 (s, 18 H, CH_3), −2.95 (s, $^2J_{H,Te}$ = 93.0 Hz, 1 H, NbH).

Synthesis of $[Cp'_6Nb_4Te_4O{\cdot}2Cr(CO)_5]$ (4): A solution of **2** (330 mg, 0.203 mmol) in THF (50 mL) was added to a solution of $[Cr(CO)_5THF]$ (0.908 mmol) in THF (150 mL). The mixture was stirred for 15 h at room temperature in the dark. After evaporation of the solvent the residue was dissolved in toluene (15 mL). Chromatography on SiO_2 (column 15 × 3 cm) gave a broad dark red band upon elution with toluene, containing $[Cp'_6Nb_4Te_4O{\cdot}2Cr(CO)_5]$ (**4**) (310 mg, 0.154 mmol, 76%). Crystals of **4** containing 1.5 molecules of toluene were obtained from toluene. $C_{64}H_{78}Cr_2Nb_4O_{11}Te_4$ (2009.32): calcd. for **4**·1.5C_7H_8 C 41.66, H 4.22; found C 41.61, H 4.23. Mol. mass 1625.3 ($[Cp'_6Nb_4Te_4O]$ (**2**); FD-MS, toluene). IR (KBr): $\tilde{\nu}$ = 2050 s, 1975 vs, 1920 vs cm^{-1} [ν(CO)]. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 6.50 (m, 1 H, C_5H_4R), 6.42 (m, 2 H, C_5H_4R), 6.22 (m, 1 H, C_5H_4R), 5.98 (m, 1 H, C_5H_4R), 5.91 (m, 2 H, C_5H_4R), 5.85 (m, 2 H, C_5H_4R), 5.76 (m, 2 H, C_5H_4R), 5.72 (m, 1 H, C_5H_4R), 4.85 (m, 1 H, C_5H_4R), 4.70 (m, 2 H, C_5H_4R), 4.35 (m, 1 H, C_5H_4R), 4.19 (m, 1 H, C_5H_4R), 4.05 (m, 1 H, C_5H_4R), 3.87 (m, 1 H, C_5H_4R), 3.83 (m, 1 H, C_5H_4R), 3.51 (m, 1 H, C_5H_4R), 3.20 (m, 1 H, C_5H_4R), 2.89 (m, 2 H,

C_5H_4R), 1.59 (s, 9 H, CH_3), 1.55 (s, 9 H, CH_3), 1.45 (s, 9 H, CH_3), 1.40 (s, 9 H, CH_3), 1.28 (s, 9 H, CH_3), 1.24 (s, 9 H, CH_3).

Thermolysis of $[Cp'_2NbTe_2H{\cdot}Cr(CO)_5]$ (3): A solution of **3** (350 mg, 0.447 mmol) in toluene (120 mL) was stirred for 15 h at 110 °C in the dark. Then the solvent was removed in vacuo and the residue was purified by chromatography on SiO_2 (column 15 × 3 cm). Elution with toluene first gave a red-violet band containing $[Cp'_6Nb_4Te_4O]$ (**2**) (25 mg, 0.015 mmol, 14%) and then a black-green band was eluted containing $[Cp'_4Nb_2Te_2]$ (**5**) (130 mg, 0.140 mmol, 63%). $C_{36}H_{52}Nb_2Te_2$ (925.81): calcd. C 46.70, H 5.66; found C 45.78, H 5.69. Mol. mass 925.6 (FD-MS, toluene). ^{1}H NMR (400 MHz, CD_2Cl_2, 24 °C): δ = 5.05 (m, 8 H, C_5H_4R), 4.46 (m, 8 H, C_5H_4R), 1.44 (s, 36 H, *t*Bu).

Synthesis of $[Cp'_4Nb_2Te(CH_3Te)]I$ ([6]I): A black-green solution of **5** (130 mg, 0.140 mmol) in THF (50 mL) was treated with CH_3I (19.9 mg, 0.140 mmol). While stirring the mixture at room temperature it turned slightly violet and a fine precipitate formed. After 30 min the solvent was evaporated in vacuo and the residue was washed twice with pentane. The resulting powder was dried under high vacuum to give **[6]I** in quantitative yield. **[6]I** was recrystallized from CH_2Cl_2/pentane (3:1). **[6]I:** $C_{37}H_{55}INb_2Te_2$ (1067.75): calcd. C 41.62, H 5.19; found C 41.58, H 4.67. Mol. mass 941.1 $\{[Cp'_4Nb_2Te(TeCH_3)]^+$ ($[\mathbf{6}]^+$); PI-LSIMS, NBA/MeOH$\}$. ^{1}H NMR (400 MHz, CD_2Cl_2, 24 °C): δ = 5.53 (m, 4 H, C_5H_4R), 5.21 (m, 2 H, C_5H_4R), 5.01 (m, 2 H, C_5H_4R), 4.67 (m, 2 H, C_5H_4R), 4.62 (m, 2 H, C_5H_4R), 4.32 (m, 4 H, C_5H_4R), 1.53 (s, 36 H, CH_3), 2.45 (s, 3 H, $TeCH_3$). UV/Vis **[6]I**: λ_{max} = 553 nm (ε = 3460 $L{\cdot}mol^{-1}{\cdot}cm^{-1}$ in CH_3OH).

Synthesis of $[Cp'_4Nb_2(CH_3Te)_2]I_2$ ([7]I_2): The procedure is analogous to that described for the synthesis of **[6]I** with the exception that two equivalents of CH_3I were employed. Recrystallization of $[Cp'_4Nb_2(CH_3Te)_2]I_2$ ([7]I_2) from CH_3OH gave violet needles. $C_{38}H_{58}I_2Nb_2Te_2$ (1209.65): calcd. C 37.72, H 5.03; found C 37.50, H 5.08. Mol. mass 956.3 $\{[Cp'_4Nb_2(CH_3Te)_2]^+$ ($[\mathbf{7}]^+$); PI-LSIMS, NBA/MeOH$\}$. ^{1}H NMR (400 MHz, CD_3OD, 24 °C): δ = 6.61 (m, 1 H, C_5H_4R), 6.55 (m, 2 H, C_5H_4R), 6.43 (m, 1 H, C_5H_4R), 5.89 (m, 1 H, C_5H_4R), 5.62 (m, 2 H, C_5H_4R), 5.53 (m, 1 H, C_5H_4R), 5.10 (m, 2 H, C_5H_4R), 4.60 (m, 2 H, C_5H_4R), 4.21 (m, 1 H, C_5H_4R), 4.11 (m, 2 H, C_5H_4R), 3.38 (m, 1 H, C_5H_4R), 2.88 (s, 3 H, $TeCH_3$), 2.71 (s, 3 H, $TeCH_3$), 1.53 (s, 18 H, CH_3), 1.51 (s, 9 H, CH_3), 1.50 (s, 9 H, CH_3). UV/Vis [7]I_2: λ_{max} = 550 nm (ε = 9120 $L{\cdot}mol^{-1}{\cdot}cm^{-1}$ in CH_3OH).

Synthesis of $[Cp'_4Nb_2(CH_3Te)_2][PF_6]_2$ (8): A solution of NH_4PF_6 (22 mg, 0.135 mmol) in H_2O (3 mL) was added to a solution of [7]I_2 (80 mg, 0.07 mmol) in MeOH (10 mL). While stirring the violet mixture for 30 min at room temperature a dark blue precipitate formed. This precipitate was separated by filtration and washed three times with small amounts of H_2O and Et_2O. The crude product was dissolved in hot acetonitrile (20 mL) and filtered. Evaporation of the solvent and drying under high vacuum gave $[Cp'_4Nb_2(CH_3Te)_2][PF_6]_2$ (**8**) (75 mg, 0.060 mmol, 91%). $C_{38}H_{58}F_{12}Nb_2P_2Te_2$ (1245.80): calcd. C 36.63, H 4.69; found C 37.72, H 4.80. IR (KBr): $\tilde{\nu}$ = 835 vs cm^{-1} [$\nu(PF_6)$].

X-ray Structure Determination: The structures of **2**, **3**, **4**, and [7]I_2 were solved by direct methods (Table 3). Subsequent difference Fourier syntheses revealed the position of the non-hydrogen atoms

and all these atoms were refined with anisotropic thermal parameters with the exception of **[7]I_2**. Hydrogen atoms were introduced on idealized positions and refined using a riding model. The H atom H(19) fixed at the Nb atom in the structure of **3** was formed in the difference Fourier synthesis as the third peak (0.7 electrons). After refinement the *R* values decreased significantly. The residual electron density of 2.868 e·Å^{-3} that was found after all refinement cycles is in the proximity (0.91 Å) of Te(1). The structure solution of **[7]I_2** was handicapped by a poor crystal quality. In this case refinement with anisotropic temperature factors was only possible for the heavy atoms. A void at *x*, *y*, *z* = 0, 0.5, 0.5 was localized with the program SQUEEZE.[41] It has a volume of 161 Å^3 and contains 11 electrons. This roughly corresponds to one molecule of methanol.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-172951 (**2**), CCDC-172952 (**3**), CCDC-172953 (**4**), and CCDC-172954 (**[7]I_2**). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank Prof. Dr. B. Wrackmeyer for recording the ^{125}Te NMR spectrum of **1**. We are grateful to the Deutsche Forschungsgemeinschaft for support of this work (Wa 485/6-2). Parts of this work were supported by the Deutscher Akademischer Auslandsdienst and the jyMinistère des Affaires Etrangères (program PROCOPE).

Synthesis and Reactivity of Ene-Diamido and Ene-Diolato [(Trimethylsilyl)-cyclopentadienyl]niobium(V) Complexes and a Comparative DFT Study of the Bonding Capabilities of Diazabutadiene and Butadiene Ligands

Agustín Galindo,[a] Manuel Gómez,*[b] Diego del Río,[a] and Fernando Sánchez[b]

Keywords: Niobium / Alkene ligands / N ligands / Cyclopentadienyl complexes / Density functional calculations

The reactions of [$NbCp'Cl_2(Me_3SiCCSiMe_3)$] ($Cp' = \eta^5$-$C_5H_4SiMe_3$) with 2,3-dimethyl-1,4-diphenyl-1,4-diaza-buta-1,3-diene (Me,Ph-DAD) and diketones R–CO–CO–R (R = Me, Ph) gave ene-diamido complexes [$NbCp'Cl_2$(Me,Ph-DAD)] (**1**) and ene-diolato complexes [$NbCp'Cl_2${O(R)CC(R)O}] (R = Me, **2**; Ph, **3**), respectively, with simultaneous elimination of bis(trimethylsilyl)acetylene. The NMR spectroscopic data of these compounds are in agreement with a *supine* conformation, with respect to the Cp′ ring, of the ene-diamido and ene-diolato ligands. In order to gain further information concerning the bonding capabilities of the ene-diamido ligand, a DFT study of the model complex [$NbCpCl_2$(HNCHCHNH)] (**I**) was performed. For comparison, a DFT analysis of the model compound [$NbCpCl_2(\eta^4$-$CH_2CHCHCH_2)$] (**II**) was also carried out. Differences in the bonding description of the diazabutadiene and butadiene ligands bonded to a common [$NbCpCl_2$] moiety are discussed. A detailed analysis of the fragment orbital interactions in **I** provides no evidence for any positive overlap between the Nb centre and the inner carbon atoms of the DAD ligand. Dialkylation of the dichloro complex **1** gave dialkyl derivatives [$NbCp'R_2$(Me,Ph-DAD)] (R = Me, **4**; CH_2SiMe_3, **5**; $CH_2C_6H_5$, **6**), for which the NMR spectroscopic data suggests a *prone* conformation of the DAD ligand. Treatment of the dimethyl derivative **4** with carbon monoxide and 2,6-dimethylphenyl isocyanide led to the formation of the oxa- and azaniobacyclopropane complexes [$NbCp'\{\eta^2$-$(E)CMe_2\}$(Me,Ph-DAD)] [E = O, **7**; $N(2,6\text{-}Me_2C_6H_3)$, **8**], respectively. Subsequent insertion of isocyanide into the Nb–C bond of **7** proceeds with formation of derivatives [$NbCp'\{\eta^2$-$(O)CMe_2$-$(CNAr)_x\}$(Me,Ph-DAD)], ($Ar = 2,6\text{-}Me_2C_6H_3$; x = 1, **9**; 2, **10**). All the complexes isolated were characterized by IR and NMR (^1H, $^{13}C\{^1H\}$) spectroscopy.

Introduction

Recent developments in the organometallic chemistry of early transition metals is due to the participation of metallocene systems as catalysts in important inorganic and organic reactions.[1] Modification of the cyclopentadienyl ligand by introduction of specific substituents, including an ansa-type bis(cyclopentadienyl) ligand, was the first strategy[2] in order to respond to each problem created in such processes. Another, more flexible approach, may be a half-metallocene system, in which one Cp ligand of the metallocene is replaced by different ancillary ligands. In any case, mono- and bis(cyclopentadienyl) complexes of early transition metals are now well established as important types of olefin polymerisation catalysts.[3] Although many systems are highly active and widely studied, precise reasons why certain ligands or ligand combinations produce effective catalysts remains obscure. In this context, nitrogen donor ligands have been incorporated into the cyclopentadienyl ring, such as the "constrained geometry" complexes,[4] and also mono- and polydentate amido complexes[5] without cyclopentadienyl ligands have been reported. In addition, dienes have been integrated as ligands, because [$M(\eta^5$-$C_5R_5)$(1,3-diene)] (M = Nb, Ta) fragments are isoelectronic and isolobal[6] to Group-4 metallocene fragments [$M(\eta^5$-$C_5R_5)_2$]. This relationship is extremely useful, since the metallocene species involved in synthetic and catalytic processes can potentially be replaced by monocyclopentadienyl(diene) complexes. In fact, these metallocene-like fragments stabilize reactive benzyne[7] species and their *cis*-dialkyl derivatives are catalyst precursors for the living polymerization of ethylene[8] and the stereoselective ROMP of norbornene.[9]

Several coordination modes have been reported[10] for transition metal complexes containing substituted 1,4-diaza-1,3-butadiene ligands (R,R′-DAD[11]). Scheme 1 shows a representation of the bonding modes found in mononuclear complexes in which the DAD ligand is bonded to the

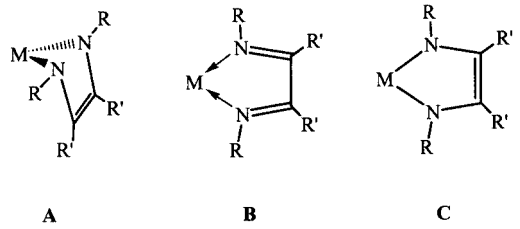


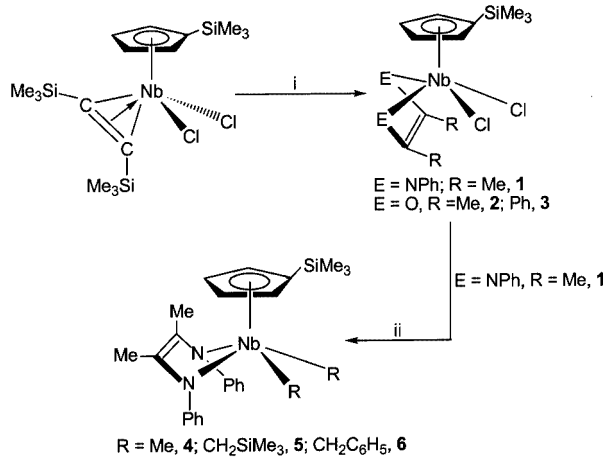
Scheme 1. Coordination bonding modes of 1,4-diaza-1,3-butadiene ligand (R,R′-DAD) found in mononuclear complexes in which the ligand is bonded to the metal centre through the two N atoms

metal centre through both N atoms. In the majority of early transition metals the diazabutadiene ligand acts as a dianionic ene-diamido chelate (mode **A**) and the metal-DAD moiety is characterized by a nonplanar disposition (folded envelope). The coordination mode **B**, α-diimine ligand, is well represented for many late transition metal complexes; meanwhile, bonding type **C**, a planar 2,5-diaza-1-metallacyclopent-3-ene, is less common in early transition metals.[12] In the last few years, the synthesis and characterization of a series of niobium and tantalum complexes containing 1,4-diaza-1,3-diene R,R′-DAD ligands[12a,13] (or closely related *o*-phenylenediamido ligands[14]) have been reported, in which the diazabutadiene behaves as a dianionic ene-diamido ligand (mode **A**) and shows a folded envelope geometry. When the compound has a cyclopentadienyl co-ligand, the DAD can adopt two conformations − *supine* and *prone* − relative to the Cp ring, depending on the coordination environment of the metal centre.[15]

In this paper, we report a synthetic study of half-sandwich niobium complexes containing ene-diamido and ene-diolato ligands and their chemical behaviour in alkylation and insertion reactions. Also, we present a comparative DFT study of the 1,4-diaza-1,3-butadiene and 1,3-butadiene ligands coordinated to the common $[NbCpCl_2]$ moiety, in order to look into the bonding capabilities of the diazabutadiene and butadiene ligands on high-valent complexes of early transition metals.

Results and Discussion

The treatment of $[NbCp'Cl_2(Me_3SiCCSiMe_3)]$[16] (Cp′ = η^5-$C_5H_4SiMe_3$) with 2,3-dimethyl-1,4-diphenyl-1,4-diazabuta-1,3-diene (Me,Ph-DAD) or diketones R−CO−CO−R (R = Me, Ph) in hexane leads to the precipitation of the corresponding half-sandwich complexes $[NbCp'Cl_2(Me,Ph\text{-}DAD)]$ (**1**) and $[NbCp'Cl_2\{O(R)CC(R)O\}]$ (R = Me, **2**; Ph, **3**), respectively, with elimination of bis(trimethylsilyl)acetylene (Scheme 2). The closely related half-sandwich 1,4-diaza-1,3-butadiene complexes with the general formula $[Nb(\eta^5\text{-}C_5R_5)Cl_2(DAD)]$[13d,13f,14a,14b] were previously known and they were essentially isolated by treatment of the tetrachloro compounds $[Nb(\eta^5\text{-}C_5R_5)Cl_4]$ (R = H, Me) with a dilithium salt of different DAD ligands. However, there is an example in which the experimental procedure is related to the synthesis of **1** and the DAD derivative was formed by a photochemical ligand-exchange reaction between $[NbCpCl_2(PMe_3)_3]$ and the *t*Bu,H-DAD ligand.[13a]



Scheme 2. Reagents and conditions: i: 1 equiv. E(R)C-C(R)E (E = NPh, R = Me, **1**; E = O, R = Me, **2**; Ph, **3**), hexane, 12 h, room temp.; ii: 2 equiv. MgClR (R = Me, **4**; CH_2SiMe_3, **5**; $CH_2C_6H_5$, **6**), diethyl ether, 12 h, room temp. (except for R = $CH_2C_6H_5$, −78 °C)

The IR spectra (Table 1) of **1**−**3** (and those of the other complexes of this work) show the characteristic absorptions for the (trimethylsilyl)cyclopentadienyl ring ($\nu_{C-H} \approx 841$ cm^{-1})[17] and the trimethylsilyl substituent [$\nu\delta_{as}(CH_3) \approx 1255$ cm^{-1}].[18] Absorptions due to the C=N, C=C, C−O, Nb−O, Nb−C and Nb−Cl stretching vibrations are observed at $\tilde{\nu} \approx$ 1630,[19] 1594,[20] 1173,[20e,21] 734,[22] 482[20e,21b] and 320[17,22,23] cm^{-1}, respectively. The ^1H and $^{13}C\{^1H\}$ NMR spectroscopic data (Table 2) are consistent with the stoichiometries and expected geometries of these complexes. The inner carbon atoms of the ene-diamido and ene-diolato ligands were observed as a singlet in the olefinic region between δ = 96 and 120. By contrast, the corresponding resonances of the uncoordinated DAD ligands are usually found in the region at δ ≈ 160 and those for 1,4-diazabuta-1,3-dienes coordinated in mode **B** the diene ^{13}C resonance occurs at an even lower field.[10a,24] This NMR spectroscopic data suggest an ene-diamido structure (mode **A**) for **1** and an ene-diolato one for the complexes **2** and **3**. Mashima et al. have recently highlighted[15] the geometric preferences of 1,4-diazadiene ligands on half-sandwich metallocene complexes of early transition metals. The ene-diamido ligand can adopt two conformations, *supine* and *prone*, relative to the η^5-C_5R_5 moiety. The adoption of a particular conformation depends on the coordination environment on the metal centre and the steric properties of the substituents of the DAD ligand. In most of the dichloro compounds this ligand adopts a *supine* conformation, except for a bulky substituted *t*Bu,H-DAD derivative $[TaCp^*Cl_2(t\text{Bu,H-DAD})]$[13e] and for the bis(trialkylsilyl)-*o*-phenylenediamido complexes, $[TaCp^*Cl_2\{(i\text{Pr}_3SiN)_2\text{-}o\text{-}C_6H_4\}]$[14a]

and $[M\{\eta^5\text{-}C_5H_3(SiMe_3)_2\}Cl_2\{(Me_3SiN)_2\text{-}o\text{-}C_6H_4\}]$[14b] (M = Nb, Ta). On the basis of the steric properties of the ligands and the NMR spectroscopic data of complexes **1**−**3** we conclude that both ene-diamido and ene-diolato ligands adopt the *supine* conformation (see Scheme 2).

Mealli, Ienco and Galindo have recently communicated a re-interpretation of the bonding scheme of the ene-diamido ligand in d^0-metal complexes.[25] Essentially, the folding of the DAD ligand (folded envelope geometry, mode **A**) in such complexes cannot be explained by using the standard description of σ^2,π adopted for the η^4 bonding of butadiene ligands to early transition metals. The experimentally observed folding cannot be attributed to the π donation from the central C=C linkage to the unsaturated metal centre, because this interaction is negligible, according to calculations.

In order to confirm this analysis we have performed DFT studies on the model complex $[NbCpCl_2(HNCHCHNH)]$ (**I**) analogous to derivative **1**. Also for comparison we have extended our calculations to the model complex $[NbCpCl_2(\eta^4\text{-}CH_2CHCHCH_2)]$ (**II**). Therefore, in this paper, we compare the ligands 1,4-diaza-1,3-butadiene (in its ene-diamido form) and 1,3-butadiene (in its 2-butene-1,4-diyl form) coordinated to the common moiety $[NbCpCl_2]$ (with a formal d^0 configuration). Full geometry optimisations were performed for the model compounds **I** and **II**. According to the remarks of Mashima et al.,[15] in dichloro-(cyclopentadienyl) Group-5 compounds the DAD ligand adopts a *supine* conformation, except for bulky substituted DAD derivatives. No steric crowding can be expected in model **I**, because it contains the simplest DAD ligand and, subsequently, only the *supine* orientation of the DAD ligand was calculated.[26] Analogously, for **II**, just the *supine* orientation of butadiene ligand was considered.[27] The use of BP86 or B3LYP functionals did not produce significant changes in the structural parameters and only data calculated at the B3LYP level of theory are discussed, while those at the BP86 level of theory are given as Supporting Information. The resulting final optimised geometries at the B3LYP level of theory are shown in Figure 1 and their coordinates are included as Supporting Information. Selected calculated parameters of complexes **I** and **II** and, for comparison, selected experimental data from X-ray crystallography have been collected in Tables 3 and 4, respectively.

In Table 3 we contrasted selected experimental data for several complexes containing the 1,4-diaza-1,3-butadiene fragment coordinated to the NbCp moiety with calculated parameters. Similarly, in Table 4 we made an analogous comparison for complexes containing the butadiene ligand coordinated to the same NbCp moiety. A general satisfactory agreement between the calculated and experimental values of geometrical parameters was found. In both cases (see Figure 1) the ligand was folded towards the metal centre and computed torsion angles of 120.7 (Nb−N1−N2−C2) and 92.8° (Nb−C1−C4−C3) for **I** and **II**, respectively, gave Nb−C contacts within the range of bonding distances (2.532 Å for **I** and 2.431 Å for **II**). The C1−C2 and C2−C3 bond lengths (1.407 Å in **I** and 1.395 Å in **II**, respectively) were shorter than that expected for a single C−C bond. In addition, the N1−C1 and N2−C2 bond lengths in **I** (1.366 Å) were longer than expected for a double N=C bond. The principal difference found in the common $[NbCpCl_2]$ fragment was the Cl−Nb−Cl bond angle, which opened up from 82.1° in **I** to 96.1° in **II**.

A qualitative FMO analysis helped to elucidate the major bonding components between 1,4-diaza-1,3-butadiene and 1,3-butadiene ligands and the common $[NbCpCl_2]$ fragment. When considering the substitution of 1,3-butadiene by the 1,4-diaza-1,3-butadiene ligand, we are replacing a ligand, capable of donating two pairs of electrons (two π pairs in the neutral form) by a ligand which is able to donate up to a maximum of four electron pairs (the equivalent two π pairs plus two in-plane σ pairs in the neutral form). A representation of the FMOs corresponding to the 1,4-diaza-1,3-butadiene ligand is shown in Scheme 3, in conjunction with the energy disposition of such orbitals and those well known for butadiene. Taking into account the

of *a′* (1*a′*, $d_{x^2-y^2}$, and 2*a′*, d_{z^2}) and one of *a″* (1*a″*, d_{xy}) symmetries, and a second subset, higher in energy, of two frontier orbitals (3*a′*, d_{xz} and 2*a″*, d_{yz}).

The interpretation of the bonding scheme of the η^4-butadiene ligand bound to early transition metals is well established.[29] In particular, a detailed early EHMO analysis was reported[30] for (cyclopentadienyl)tantalum complexes containing the bent 1-metallacyclopent-3-ene structure. The bonding description in **II** is similar and can be briefly summarized as follows: The strongest interactions are the donation of the π_2 orbital to 1*a″* and the donation of π_3* to 1*a′*, and also in minor proportion to the 2*a′* FMOs. Other minor details require no further discussion. The computed bond lengths in the butadiene fragment show the expected

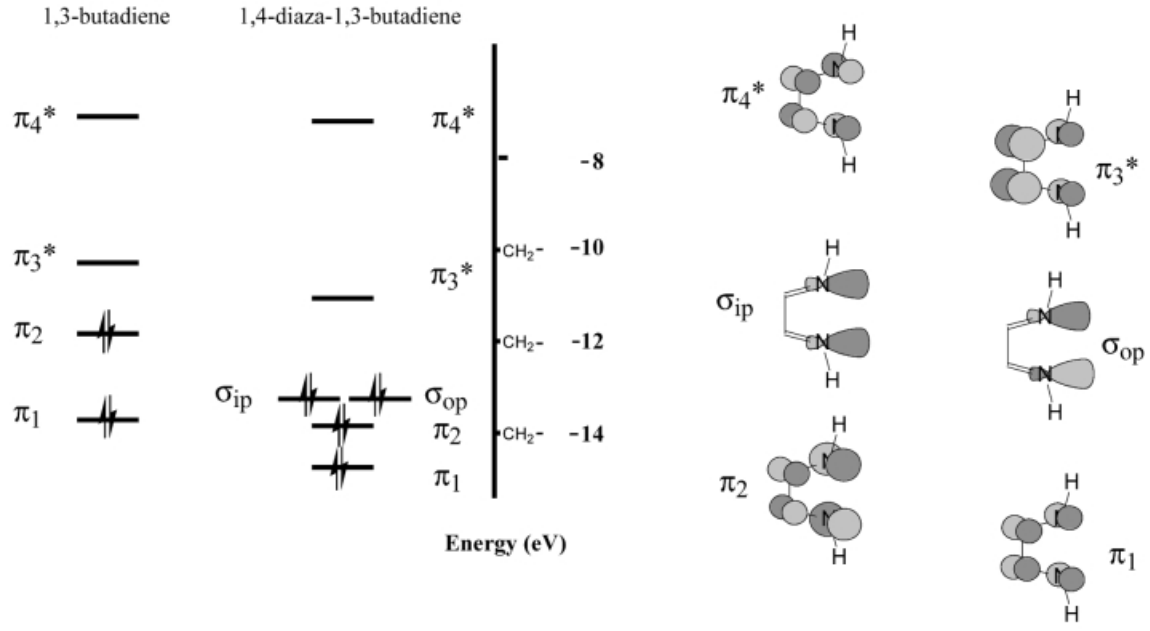
long-short-long bond alternation, indicating the involvement of the σ^2,π bonding contribution, and compare well with other bond lengths reported in recent related DFT studies.[31]

With reference to **I**, the FMO analysis shows that the strongest interaction is also the donation of the π_2 orbital (that is now substantially lower in energy in comparison with the similar π_2 orbital in the butadiene ligand, see Scheme 3) to 1*a″*. This donation is now completed by the participation of the *out-of-phase* σ_{op} contribution. The donation of the π_3* orbital is also active but is now directed preferentially to the 2*a′* FMO and only in a small percentage to 1*a′*. The latter metal orbital is substantially saturated by the donation of *in-phase* σ_{ip} FMO. These subtle dissimilarities in the bonding analysis in **I** with respect to **II** are responsible for the important differences found in the HOMO of the two model complexes (see Figure 2).

In the HOMO of **I** the nitrogen π lobes overlap significantly with the lobes of the 2*a′* ($d_{x^2-y^2}$) orbital while the carbon π orbitals (part of the ligand's HOMO π_3*) do not overlap with the metal lobes and are only involved in the C−C bonding interaction. Moreover, a detailed analysis of the fragment orbital interactions provides no evidence for carbon π electron donation toward the metal centre. Contrarily, the HOMO of **II** shows the overlap of all carbon π lobes of π_3* with both the 1*a′* and 2*a′* FMOs. In conclusion, the bonding of the ene-diamido (or diazabutadiene) ligand is different with respect to the conventional σ^2,π-description of the butadiene ligand. The donation through the π component is contributed by the nitrogen atoms, con-



Scheme 3. Representation of the FMOs corrresponding to the 1,4-diaza-1,3-butadiene ligand and energy distribution of such orbitals in comparison with those of 1,3-butadiene ligand

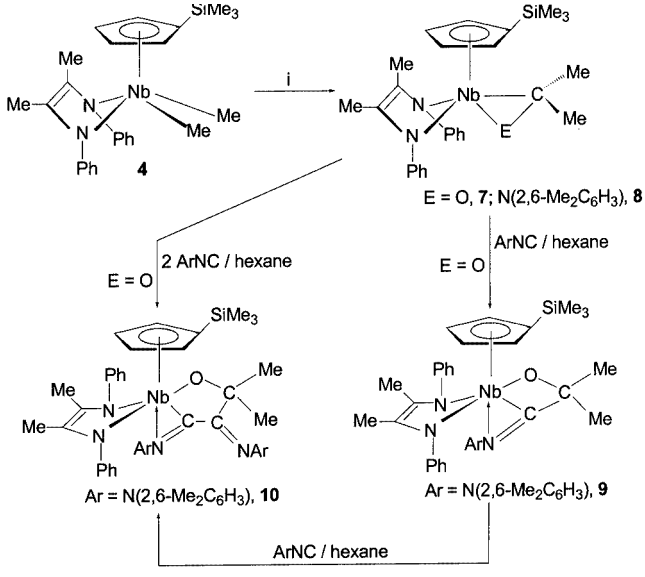
sequently, the interaction between the Nb and carbon atoms is not significant.

Alkylation of **1** with Grignard reagents, in a 1:2 molar ratio, yields the dialkyl complexes [$NbCp'R_2$(Me,Ph-DAD)] (R = Me, **4**; CH_2SiMe_3, **5**; $CH_2C_6H_5$, **6**) as red-brown microcrystalline solids (Scheme 2). The ^1H NMR spectrum of **4** displays a singlet at $\delta = 0.15$ due to Nb−Me and show an AB spin system for diastereotopic α-CH_2 protons of alkyl groups in the complexes **5** and **6**. A singlet due to the methyl substituents of the ene-diamido ligand emerges at $\delta \approx 1.75$, this being at higher field compared with that ($\delta = 1.84$) of the starting dichloro complex **1**. Additionally, the ^{13}C resonances of the inner carbon atoms show a high field displacement. The data, along with the preferential orientation discussed by Mashima et al.[15] in related complexes, suggest that the alkylation reactions of the dichloro complex involves an orientation change in the ene-diamido ligand from the *supine* conformation in **1** to the *prone* form in the dialkyl derivatives **4**−**6**.[32]

Dimethyl complex **4** reacts with carbon monoxide (1 atm) at room temperature in toluene to give the oxaniobacyclopropane complex [$NbCp'\{\eta^2$-$(O)CMe_2\}$(Me,Ph-DAD)] (**7**), in good yield (Scheme 4), as a result of a double migration of two methyl groups, first to the electrophilic carbon atom of the coordinated CO and then to the related η^2-acyl intermediate, which cannot be detected. The oxaniobacyclopropane moiety which is not further transformed, is analogous to that reported for (acetone)tantalum complexes [TaCp*



Scheme 4. Reagents and conditions: i: E = O, CO (1 atm), toluene, 5 d, room temp.; E = N(2,6-$Me_2C_6H_3$), 1 equiv. 2,6-$Me_2C_6H_3NC$, hexane, 12 h, room temp.

$X_2\{\eta^2\text{-}(O)CMe_2\}$] (X = Cl,[20e] Me[33]). When 1 equiv. of isocyanide 2,6-$Me_2C_6H_3NC$ is added to a hexane solution of **4** under rigorously anhydrous conditions, an orange solution is obtained, which after evaporation of the solvent produces the azaniobacyclopropane complex [NbCp′$\{\eta^2$-(ArN)$CMe_2\}$(Me,Ph-DAD)] (Ar = 2,6-$Me_2C_6H_3$, **8**). Formation of this compound can be explained as the result of two consecutive steps. The first step involves migration of one methyl group to the electrophilic isocyanide carbon atom, giving an η^2-iminoacyl intermediate,[19,34] which cannot be detected during monitoring of the entire reaction by ^{1}H NMR spectroscopy. Subsequent migration of the second methyl group to the iminoacyl carbon centre yields an azaniobacyclopropane system.[20a,20b,35] Dialkyl complexes **5**, **6** do not react with isocyanide at room temperature and when the solution is heated the reaction probably takes place simultaneously with the decomposition of the organometallic complex formed, leading to an unidentified product mixture.

On the other hand, azaniobacyclopropane complex **8** is obtained upon reaction of 2 equiv. of isocyanide with the dimethyl derivative **4**, in contrast to that observed in the case of the azatantalacyclopropane species [TaCp*$\{\eta^2$-(ArN)$CMe_2\}$][35b] (Ar = 2,6-$Me_2C_6H_3$; 2,4,6-$Me_3C_6H_2$), which in the presence of isocyanides gives the corresponding dichloro(imido) complexes [TaCp*Cl_2(NAr)] with elimination of the arylimine ketene Ar−N=C=CMe_2. However, the oxaniobacyclopropane complex **7** reacts with 1 or 2 equiv. of 2,6-$Me_2C_6H_3NC$ leading to the expected insertion products [NbCp′$\{\eta^2$-(O)CMe_2-$(CNAr)_x\}$(Me,Ph-DAD)] (Ar = 2,6-$Me_2C_6H_3$; x = 1, **9**; 2, **10**). Compound **9** can be transformed into **10** by a simple isocyanide insertion reaction.

The ^{1}H NMR spectra of complexes **7** and **8** show an AA′BB′ spin system for the proton atoms of the $C_5H_4SiMe_3$ ring, whereas the $^{13}C\{^1H\}$ NMR spectra show three carbon resonances for the same group, in agreement with the existence of a symmetry plane perpendicular to such a ring. At room temperature, the equivalence of both methyl groups of the oxa- and azaniobacyclopropane moiety (**7** and **8**), as evidenced by the ^{1}H and $^{13}C\{^1H\}$ NMR spectra, argue a metallacyclic structure whose plane defined by the niobium, oxygen (**7**) or nitrogen (**8**) and carbon atoms is perpendicular to the cyclopentadienyl ring plane. Unfortunately, we were not able to obtain crystals adequate for X-ray diffraction, but the structure must be reasonably similar to that presented for related azametallacyclopropane complexes [MCp*$X_2\{\eta^2$-(ArN)$CMe_2\}$] (Ar = 2,6-$Me_2C_6H_3$; X = Cl, Me; M = Nb,[35c] Ta[35b]). The chemical shifts of their DAD resonances are similar to that of **4**, indicating a *prone* conformation of the DAD ligand. Thus, the resonance at δ = 109.0 is assigned to the equivalent olefinic carbon atoms of the DAD ligand, while the signals corresponding to the C^α atom of the oxa- and azaniobacyclopropane systems appear at δ = 92.57 (**7**) and 75.7 (**8**); these signals shift to higher fields as compared with the acyl and iminoacyl carbon atom.[36]

In complexes **9** and **10**, the ^{1}H and $^{13}C\{^1H\}$ NMR spectra show four protons (ABCD spin system, although for **10** only two multiplets are observable as a result of the proton overlapped signals) and five carbon resonances for the $C_5H_4SiMe_3$ ring. The data are consistent with a metal centre chiral character and therefore there is not a symmetry plane perpendicular to the (trimethylsilyl)cyclopentadienyl ring. The ^{1}H NMR spectrum of both complexes **9** and **10** show six singlets corresponding to three protons each between δ = 2.54−1.03 and 2.58−0.76, respectively. The lower field resonances in both the interval δ = 2.54, 2.00 (**9**) and 2.58, 2.04 (**10**) can be assigned to the methyl substituents of the DAD ligand. These data suggest a 2,5-diazaniobacyclopent-3-ene mode for the DAD ligand. A similar behaviour has been found by Mashima et al.[13f] in the synthesis of mixed DAD-butadiene complexes of general formulation [M(η^5-C_5R_5)(η^2-Ar,H-DAD)(η^4-butadiene)] (M = Nb, R = Me, H Ar = 4-$MeOC_6H_4$; M = Ta, R = Me, H Ar = 4-$MeOC_6H_4$, 2-MeC_6H_4, Cy). The signals corresponding to the nonequivalent *o*-methylphenyl groups of the inserted isocyanide are observed as singlets at δ = 1.92 and 1.88 (**9**) and 2.02, 1.89, 1.88 and 1.74 (**10**), the two lower field resonances being assigned to the isocyanide directly bonded to the niobium atom. In addition, the rest of the signals, observed in its NMR spectra, are those expected for the proposed structures.

Conclusion

In this work, we synthesized several [(trimethylsilyl)cyclopentadienyl]niobium complexes with ene-diamido and ene-diolato ligands, through the reaction of [NbCp′Cl_2-($Me_3SiCCSiMe_3$)] with 2,3-dimethyl-1,4-diphenyl-1,4-diazabuta-1,3-diene (Me,Ph-DAD) and diketones. The spectroscopic data showed that the coordination mode of the chelating ligand depends, sensitively, on the ligand environment at the metal centre. Dichloro complexes **1**−**3** adopt a *supine* ene-diamido (**1**) or ene-diolato (**2**, **3**) structure. DFT studies have shown that the experimentally observed folding in DAD complexes (mode **A**) cannot be attributed to the π donation from the central C=C linkage because this interaction is negligible. The bonding of the ene-diamido ligand is different with respect to the conventional σ^2,π description of butadiene. The nitrogen atoms contribute to the donation through the π component and, consequently, the interaction between the niobium and carbon atoms is not significant. Reactions of dichloro complex **1** with alkylating reagents gave dialkyl complexes **4**−**6** and during the reaction course, the *supine* orientation of the ene-diamido ligand, bound to the metal centre, was flipped to the *prone* one. Dimethyl complex **4** reacts with carbon monoxide and isocyanide to give oxa- and azaniobacyclopropane derivatives **7** and **8** as a result of the migration of both methyl groups and via η^2-acyl and η^2-iminoacyl intermediates, respectively, which could not be observed. Successive isocyanide insertion reactions into the Nb−C bond take place in the

oxaniobacyclopropane complex **7** leading to the expected insertion products **9**, **10**.

Experimental Section

General: All reactions and manipulations were carried out under argon using standard Schlenk-tube and cannula techniques or in a conventional argon-filled glove-box. Solvents were refluxed in the presence of an appropriate drying agent and distilled and degassed prior to use: [D_6]benzene and hexane (Na/K alloy), diethyl ether (Na/benzophenone) and toluene (Na). Literature methods were employed for the synthesis of starting materials [Nb(η^5-$C_5H_4SiMe_3$)Cl_2($Me_3SiCCSiMe_3$)][16] and 2,3-dimethyl-1,4-diphenyl-1,4-diazabuta-1,3-diene (Me,Ph-DAD).[37] Reagent grades were purchased from commercial sources and used without further purification as follows: R−CO−CO−R (R = Me, Aldrich; R = Ph, Avocado), MgClR (Aldrich; R = Me 3 M in diethyl ether; R = CH_2SiMe_3, 1 M in diethyl ether; R = $CH_2C_6H_5$, 2 M in tetrahydrofuran), CO (Air Liquide) and 2,6-$Me_2C_6H_3NC$ (Fluka). Infrared spectra were recorded with Perkin−Elmer 883 and Spectrum 2000 spectrophotometers (4000−200 cm^{-1}) with samples as Nujol mulls between CsI plates or polyethylene pellets. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded with Varian Unity 300 and Varian Unity 500 Plus spectrometers; chemical shifts were referenced to the ^{13}C (δ = 128) and ^1H (δ = 7.15) residual resonances of the [D_6]benzene solvent. C, H and N analyses were carried out with a Perkin−Elmer 2400 microanalyser.

[NbCp′Cl_2(Me,Ph-DAD)] [Cp′ = η^5-$C_5H_4SiMe_3$; Me,Ph-DAD = PhNC(Me)C(Me)NPh] (1): A sample of [NbCp′Cl_2($Me_3SiCCSiMe_3$)] (0.70 g, 1.49 mmol) was dissolved in hexane (20 mL) in a Schlenk tube. After addition of a hexane (15 mL) solution of 2,3-dimethyl-1,4-diphenyl-1,4-diazabuta-1,3-diene (0.35 g, 1.49 mmol), the colour of the mixture changed to brown. The reaction mixture was stirred for 12 h at room temperature and then the resulting suspension was decanted and filtered. The residual solid was washed with cold hexane (2 × 5 mL), dried in vacuum and identified as complex **1**. Yield 0.71 g (89%). $C_{24}H_{29}Cl_2N_2NbSi$ (537.407): calcd. C 53.64, H 5.44, N 5.21; found C 53.52, H 5.53, N 5.11.

[NbCp′Cl_2{O(R)CC(R)O}] (R = Me, 2; Ph, 3): A solution of R−CO−CO−R (2.98 mmol; R = Me, 0.28 ml; Ph, 0.62 g) in hexane (20 mL) was added to a solution of [NbCp′Cl_2($Me_3SiCCSiMe_3$)] (1.40 g, 2.98 mmol) in hexane (25 mL) at room temperature. The mixture was stirred for 12 h. The resulting garnet suspension was filtered, the microcrystalline solid washed with cold hexane (2 × 5 mL), dried in vacuum and identified as **2** and **3**. **2:** Yield: 1.14 g (80%). $C_{12}H_{19}Cl_2NbO_2Si$ (387.179): calcd. C 37.23, H 4.95; found C 37.27, H 5.01. **3:** Yield: 1.26 g (85%). $C_{22}H_{23}Cl_2NbO_2Si$ (511.321): calcd. C 51.68, H 4.53; found C 51.58, H 4.66.

[NbCp′R_2(Me,Ph-DAD)] (R = Me, 4; CH_2SiMe_3, 5; $CH_2C_6H_5$, 6): A solution of MgClR (2.60 mmol; R = Me, 0.87 mL of a 3 M solution in diethyl ether; CH_2SiMe_3, 2.60 mL of a 1 M solution in diethyl ether; $CH_2C_6H_5$, 1.30 mL of a 2 M solution in THF) was added to a solution of **1** (0.70 g, 1.30 mmol) in diethyl ether (30 mL) at room temperature − except for R = $CH_2C_6H_5$ at −78 °C − and the mixture was stirred for 12 h. The $MgCl_2$ formed was removed by filtration and the resulting filtrate was concentrated to a volume of ca. 10 mL. On cooling to −40 °C, red-brown microcrystalline solids (**4**−**6**) were deposited. **4:** Yield: 0.41 g (64%). $C_{26}H_{35}N_2NbSi$ (496.571): calcd. C 62.89, H 7.10, N 5.74: found C 62.85, H 7.14, N 5.64. **5:** Yield: 0.50 g (60%). $C_{32}H_{51}N_2NbSi$ (584.765): calcd. C 65.73, H 8.79, N 4.79: found C 65.67, H 8.69, N 4.75. **6:** Yield: 0.51 g (60%). Repeated attempts to obtain a satisfactory microanalysis on this material were unsuccessful.

[NbCp′{η^2-(O)CMe_2}(Me,Ph-DAD)] (7): A toluene (20 mL) solution of **4** (0.70 g, 1.40 mmol) was placed into an ampoule under CO (1 atm) and then sealed. The reaction mixture was stirred at room temperature for 5 d. Then the ampoule was opened, the solution filtered, concentrated to ca. 5 mL and cooled to −40 °C to give **7** as red microcrystalline solid. Yield 0.55 g (75%). $C_{27}H_{35}N_2NbOSi$ (524.581): calcd. C 61.82, H 6.72, N 5.34; found C 61.72, H 6.68, N 5.27.

[NbCp′{η^2-(ArN)CMe_2}(Me,Ph-DAD)] (Ar = 2,6-$Me_2C_6H_3$) (8): A solution of isocyanide 2,6-$Me_2C_6H_3NC$ (0.18 g, 1.40 mmol) in hexane (10 mL) was added at room temperature to a reddish solution of **4** (0.70 g, 1.40 mmol) in hexane (30 mL) and stirred for 12 h. The resulting orange solution was filtered, concentrated to ca. 10 mL and cooled to −40 °C to give **8** as orange microcrystalline solid. Yield 0.62 g (70%). $C_{35}H_{44}N_3NbSi$ (627.749): calcd. C 66.97, H 7.06, N 6.69; found C 67.02, H 7.16, N 6.58.

[NbCp′{η^2-(O)CMe_2−$(CNAr)_x$}(Me,Ph-DAD)] [Ar = 2,6-$Me_2C_6H_3$; *x* = 1 (9); 2 (10)]. 9: A stirred solution of **7** (0.70 g, 1.33 mmol) in hexane (25 mL) was treated with 2,6-$Me_2C_6H_3NC$ (0.17 g, 1.33 mmol) in a 1:1 molar ratio and under rigorously anhydrous conditions for 48 h. The resulting solution was concentrated to ca. 10 mL and cooled to −40 °C to give **9** as dark brown microcrystalline solid. Yield 0.52 g (60%). $C_{36}H_{44}N_3NbOSi$ (655.759): calcd. C 65.94, H 6.76, N 6.41; found C 65.90, H 6.67, N 6.39. **10. Method A:** A dark-brown solution of **9** (0.70 g, 1.06 mmol) in hexane (30 mL) under rigorously anhydrous conditions in a Schlenk tube. After addition of a hexane (10 mL) solution of isocyanide 2,6-$Me_2C_6H_3NC$ (0.14 g, 1.06 mmol) the colour of the mixture changed to pale-brown. The reaction mixture was stirred for 48 h at room temperature and then the resulting suspension was decanted and filtered. The residual pale-brown solid was washed with cold hexane (2 × 5 mL), dried in vacuum and identified as **10**. **Method B:** The oxaniobacyclopropane complex **7** (0.70 g, 1.33 mmol) was dissolved in 30 mL of hexane and isocyanide 2,6-$Me_2C_6H_3NC$ (0.34 g, 2.66 mmol) in a 1:2 molar ratio. The solution was stirred and the brown solid formed after 4 d, it was collected by decanting the solvent, washed with 5 mL of cold hexane and identified as **10**. Yield 0.54 g (65%). Repeated attempts to obtain a satisfactory microanalysis on this material were unsuccessful.

Computational Details: The electronic structures and geometries of the model complexes were computed within the density functional theory at the BP86[38] and B3LYP[39] levels using the LANL2DZ[40] basis set. A set of *d* polarisation functions was added to Cl, C and N atoms. Only the results at the B3LYP level of theory have been discussed in the paper. BP86 results are completely equivalent and they have not been discussed but included as Supporting Information. All the optimised geometries were characterized as local energy minima by diagonalisation of the analytically computed Hessian (vibrational frequencies calculations). All the DFT calculations were performed using the Gaussian 98 suite of programs.[41] Molecular orbitals were visualised using the Chem3D Pro program.[42] The FMO analyses were performed with CACAO[43] using the coordinates, at the B3LYP level, of the optimised model complexes.

[26] The optimisation of **I** with a *prone* conformation was unsuccessful. The attempts of optimisation of this isomer show a tendency of the metal−DAD moiety to attain a 2,5-diaza-1-metallacyclopent-3-ene structure with a five-membered ring ap-

proximately planar. This state is characterized by one imaginary frequency: D. del Río, A. Galindo, unpublished results.
[27] The *prone* configuration of butadiene ligand in **II** is 13.6 kcal mol^{-1} less stable than the *supine* isomer: D. del Río, A. Galindo, unpublished results.

[32] Following the suggestion of one referee, we performed calculations on complex $NbCpMe_2(HNCHCHNH)$, as the simplest model of complexes **4**−**6**. The *prone* configuration of the DAD ligand in this model is a local minimum. However, the optimisation of the *supine* conformation was unsuccessful. Efforts to optimise this isomer yielded a planar five-membered ring where the metal−DAD moiety has a 2,5-diaza-1-metallacyclopent-3-ene structure, that is characterized by two imaginary frequencies. A complete report of this analysis will be published separately: D. del Río, A. Galindo, unpublished results.

Keywords: Tantalum / Cyclopentadienyl complexes / Hydride complexes / Alkylidene complexes

The reaction of [TaCp*Cp′Cl$_2$] with 1 equiv. of [Mg(CH$_2$C$_6$H$_5$)$_2$(THF)$_2$] or 2 equiv. of LiCH$_2$R (R = SiMe$_3$, CMe$_3$) leads to the formation of bis(μ-alkylidene) complexes [(TaCp*Cp′)$_2$(μ-CHR)$_2$], (R = C$_6$H$_5$, **1**; SiMe$_3$, **2**; CMe$_3$, **3**), whereas the alkylation of [TaCp*Cp′Cl$_2$] with 2 equiv. of LiCH$_2$CMe$_2$Ph gives the hydride tantalabenzocyclopentene complex [TaCp*Cp′(H)(η^2-CH$_2$–CMe$_2$-*o*-C$_6$H$_4$)] (**4**). All the complexes were characterized by IR and NMR spectroscopy. The molecular structure of complex **4** has been determined by X-ray diffraction methods. Complex **4** crystallizes in the monoclinic space group $P2_1/c$, with unit cell dimensions of a = 8.976(1) Å, b = 16.596(1) Å, c = 17.929(1) Å, β = 99.26(1)°, V = 2636(1) Å^3, Z = 4, $\rho_{calcd.}$ = 1.478 g·cm^{-3}, $R1$ = 0.0481 and $wR2$ = 0.133.

Introduction

Early transition metal alkylidene complexes are versatile organometallic compounds due to their participation as intermediates in a number of important stoichiometric and catalytic processes.[1] Likewise, the importance of such complexes is quite clear in the studies of olefin metathesis reactions[2] having shown to catalyze the polymerization of strained ring systems in ring opening metathesis polymerization (ROMP) and polymerization of acyclic dienes (ADMET).[1d,11,4] μ-Alkylidene complexes with the ligand bridging two metal centers have been investigated in more recent times and postulated as intermediates in Fischer−Tropsch, olefin metathesis and Ziegler−Natta catalysis processes.[1] Alkylidene compounds can be made, among other methods,[1] by an α-H abstraction from transition metal alkyls[5] in an intramolecular or intermolecular process, as has been demonstrated both for early[5] and late[6] transition metal complexes.

Transition metal metallacycles are the subject of considerable current interest[7,8] and sufficient evidence has been gained to demonstrate conclusively their participation in a number of catalytic reactions such as alkene metathesis[9] and oligomerizations,[10] C−H bond activation[11] and hydrocarbon isomerization.[12] Metallacyclic complexes have been obtained by intramolecular activation of a distal C−H bond of a coordinated ligand,[8e,8k,8o,13] although harder conditions are required for their activation by γ-[8a,8f,14] or δ-[4g,15]hydrogen abstraction. If the coordinated ligand is an alkyl group with distal aromatic C−H bonds, a metallacyclic compound containing both a M−C(alkyl) and a M−C(aryl) bond may be formed.[4g,8e,8k,13b,13c,16]

We report herein the results obtained in the study of the reactivity of the mixed-ring dicyclopentadienyltantalum complex [TaCp*Cp′Cl$_2$] (Cp* = η^5-C$_5$Me$_5$; Cp′ = η^5-C$_5$H$_4$SiMe$_3$) towards alkylating reagents and an NMR spectroscopy study and the X-ray molecular structure of the complex [TaCp*Cp′(H)(η^2-CH$_2$-CMe$_2$-*o*-C$_6$H$_4$)].

Results and Discussion

Toluene solutions of [TaCp*Cp′Cl$_2$] react with 1 equiv. of [Mg(CH$_2$C$_6$H$_5$)$_2$(THF)$_2$] or 2 equiv. of LiCH$_2$R (R = SiMe$_3$, CMe$_3$, CMe$_2$Ph) under ambient conditions to give the bis-μ-alkylidene complex [(TaCp*Cp′)$_2$(μ-CHR)$_2$], (R = C$_6$H$_5$, **1**; SiMe$_3$, **2**; CMe$_3$, **3**) and the hydride tantalabenzocyclopent-2-ene [TaCp*Cp′(H)(η^2-CH$_2$-CMe$_2$-*o*-C$_6$H$_4$)] (**4**), with simultaneous elimination of R−CH$_3$ (R = C$_6$H$_5$, SiMe$_3$, CMe$_3$) and PhMe$_2$C−CH$_2$−CH$_2$−CMe$_2$Ph, respectively (Scheme 1). All of the eliminated organic products were identified by ^{1}H NMR spectroscopy when the re-

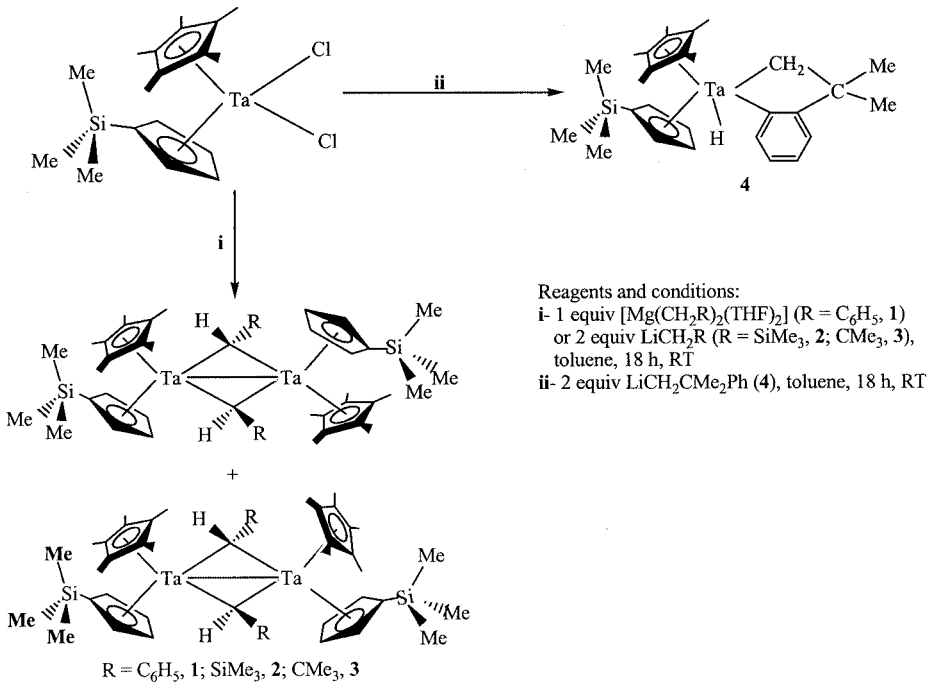


Scheme 1

actions were carried out in a sealed NMR tube with [D_6]benzene as solvent.

As a plausible reaction pathway we suggest the formation of the intermediate paramagnetic dialkyl complexes **I1**−**I4** in the first step (Scheme 2). These compounds can then evolve differently depending on the nature of the substituents: the intermediates **I1**−**I3**, undergo an α-H abstraction process[1d,1i,4g,5,7j,9d,17,18] to generate a transient tantalum(IV) alkylidene complex (step **i**), which then rearranges to form the bis-μ-alkylidene complexes **1**−**3**. It should be noted, however, that there are several examples where dialkyl [MCp_2R_2] complexes (M = Nb, Cp = η^5-C_5H_5, R = Me;[19a,19b] M = Ta, Cp = η^5-C_5H_4Me, R = Me;[19b] M = Nb, Ta, Cp = η^5-C_5H_5, R = CH_2SiMe_3;[19c] M = Ta, Cp = η^5-C_5H_5, R = Me[19d]) are thermally stable towards loss of alkane and undergo an α-elimination process.

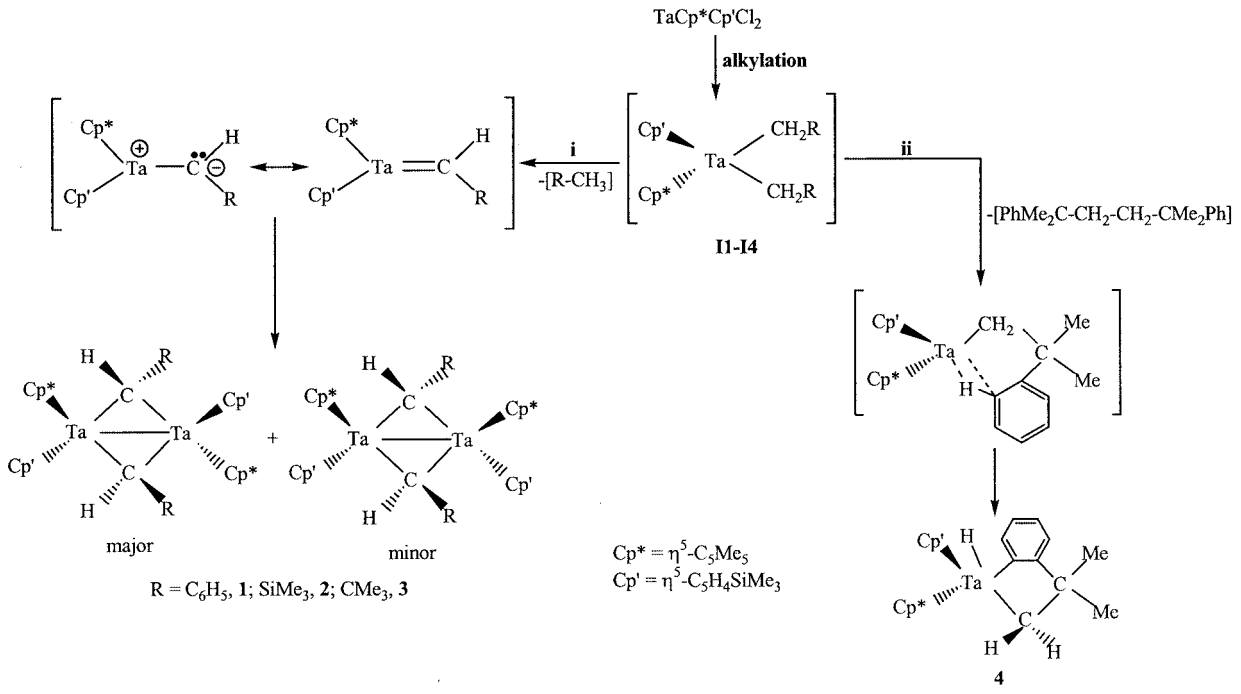
The presence of the neophyl group in the intermediate complex **I4** leads to a different reactivity with respect to that of the intermediates **I1**−**I3**. Thus, the reduction of two **I4** molecules produces the organic elimination product 2,5-dimethyl-2,5-diphenylhexane,[20] detected when the reaction is followed by ^{1}H NMR spectroscopy, and the corresponding neophyl tantalum(III) derivative (see Scheme 2, **ii**). Subsequent orthometalation of the phenyl ring produces the hydride tantalabenzocyclopent-2-ene complex **4** through the oxidative addition of a δ_{C-H} bond[8a,8e,8f,8k,8o,13−15] to the metal center.

All the complexes are soluble in aromatic and saturated hydrocarbons, diethyl ether and tetrahydrofuran. They are air- and moisture-sensitive, and rigorously dried solvents and handling under a dry inert atmosphere were found to be imperative for successful preparations. The compounds decompose rapidly upon exposure to air, both as solids and in solution.

The spectroscopic data (see Exp. Sect.) are in agreement with the proposed structures. The IR spectra show the characteristic absorptions for both cyclopentadienyl rings (Cp* = C_5Me_5:[21,22] ν_{C-C} =1030 cm^{-1}; $C_5H_4SiMe_3$:[23] ν_{C-H} = 839 cm^{-1}), as well as other internal vibrations of the different substituents [$\nu_{\delta s}(CH_3)$[24] = 1243 cm^{-1}]. The ν_{Ta-H} stretching vibration in the complex **4** appears as a broad band at 1804 cm^{-1}, in agreement with the data reported for other hydride complexes.[25]

The NMR spectroscopic data of **1**−**3** indicate the presence of two isomers for each complex in different ratios, depending on the steric bulk of the substituents [R = C_6H_5 (**1**) 9:1], (R = $SiMe_3$ (**2**) 2:1] and [R = CMe_3 (**3**) approx. 6:1] (see Exp. Sect). The trimethylsilylcyclopentadienyl ring appears as an ABCD spin system in the ^{1}H NMR spectra and five carbon resonances in the $^{13}C\{^1H\}$ NMR spectra. This pattern can be explained by the *anti*-disposition of the R (or H) group in the μ-CHR moiety with respect to the central core, which has two chiral tantalum atoms, as shown in Scheme 1, since a *syn*-disposition should show an AA′BB′ spin system in the ^{1}H NMR and three signals in the $^{13}C\{^1H\}$ NMR spectrum. We propose that the formation of two isomeric structures for **1**−**3** is related to the mutual disposition of the two different cyclopentadienyl rings: the more populated isomers are those with an *anti*-disposition of the bulkier η^5-C_5Me_5 groups.

Formulation of **4** as a hydride tantalabenzocyclopent-2-ene complex has been confirmed by a single-crystal X-ray diffraction study. The molecular structure of compound **4** is shown in Figure 1 and selected bond lengths and angles are given in Table 1. The molecule has the typical bent-



Scheme 2

metallocene structure with the tantalum atom bonded to two different cyclopentadienyl rings, and with a metallacycle system and a hydride atom located in the equatorial positions.

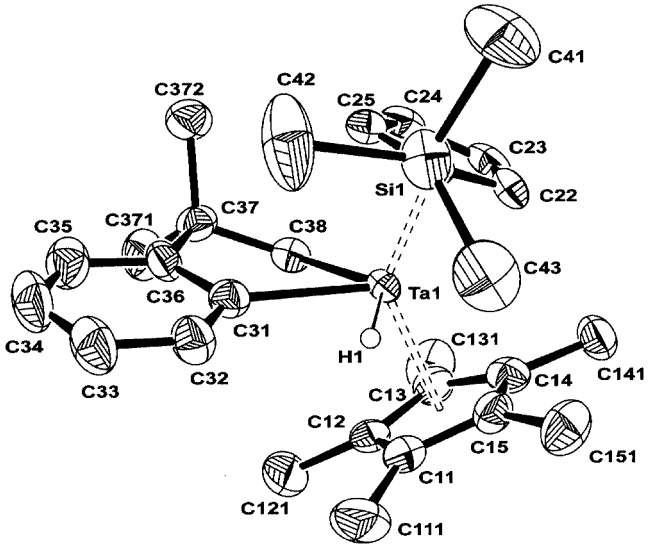


Figure 1. ORTEP view of the molecular structure of complex **4** with ellipsoids drawn at a 50% level

If Cp* and Cp′ are the centroids of the C_5Me_5 and the $C_5H_4SiMe_3$ rings, respectively, the angle Cp*−Ta−Cp′ is 133.96° and that between the planes of both cyclopentadienyl rings is 133.5°, implying that the η^5 coordination is maintained in both cases. These data are confirmed by the small range of C(Cp)−Ta distances [2.436(8) to

Table 1. Selected bond lengths (Å) and angles (°) for **4** [Cp* and Cp′ are the centroids of the C_5Me_5 and $C_5H_4(SiMe_3)$ rings, respectively]

2.466(8) Å for the Cp* ring and 2.406(8) to 2.449(8) Å for the Cp′ ring]. The Ta−Cp(centroid) distances are 2.143 Å for Cp* and 2.112 Å for Cp′. It is interesting to note that the value of the Cp*−Ta−Cp′ angle (133.96°) is smaller than that found in [TaCp*Cp′′H_3][21] (142.6°) or in [TaCp*$_2H_3$][23b] (148.3°), probably due to the bigger size of the equatorial ligand and the smaller size of the Cp′ ligand with respect to Cp′′, and it is even smaller than the angle found in *ansa*-bridged tantalum(III) hydride complexes such as [Ta{$Me_2Si(C_5Me_4)_2$}H(CO)][26] where the value is 139.7°.

The metallacycle moiety is located in the equatorial positions. If we define the equatorial plane with the Ta, C31 and C38 atoms, the distances to this plane of Cp*(1.96 Å) and Cp′(1.95 Å) are essentially the same, and the phenyl ring plane makes an angle of only 13.9(2)° with it. If we consider the Cp*−Ta−Cp′ plane, the metallacycle is located unsymmetrically with respect to it. The distances of C31, C36, C37 and C38 to this plane are 0.558, −0.418, −1.895 and −1.839 Å, respectively, with the more sterically demanding moiety of the ligand located in a lateral position leaving space for the hydride on the other side, near to the phenyl ring, as we can be seen in Figure 2. Compound **4** is the first hydrido tantalabenzocyclopent-2-ene complex reported until now, except for the telluro-formaldehyde complex [TaCp*$_2$(η^2-$TeCH_2$)H],[27] where a Ta−Te bond is described. The distances Ta−C31 [2.309(8) Å] and Ta−C38 [2.306(8) Å] are in the normal range for Ta−C single bonds. All the other parameters of the ligand are normal. No similar niobium(V) hydride metallacycle has been published either.

The ^{1}H NMR spectra of complex **4** in [D_6]benzene shows 13 signals with different multiplicities and one AB system (see Exp. Sect.), whereas in the carbon spectrum only 13 signals for the $C-H_n$ and five resonances for the quaternary carbon atoms are observed. Moreover, in the 2D ^{1}H-^{13}C heteronuclear correlation spectrum the cross peak for the ^{1}H doublet at δ = 2.60, which we assign to a classical Ta−*H* hydride resonance (T_1= 0.36 s at 233 K), was not observed. The observation of four protons and five resonances for the trimethylsilylcyclopentadienyl ring in the ^{1}H and the ^{13}C{^{1}H} NMR spectra, respectively, is due to the chiral nature of the tantalum atom.

The disposition of the hydride and the assignment of the H_α and H_β proton resonances of the Cp′ ring was realized with a differential NOE experiment by irradiating the $SiMe_3$ signal: NOE = 0.6% (δ = 3.52, H_α), 0.9% (δ = 4.55, H_β), 0.3% Ta−*H* and 0.6% *ortho*-H of phenyl ring. These data are in agreement with the location of the hydride atom close to the phenyl and trimethylsilyl groups as shown in Figure 2. The hydride is coupled (^3J = 4.4 Hz) with H38a (δ = 0.95) of the α-CH_2 group, which is in an *anti*-conformation (torsion angle ≈160°), and with H25 (δ = 4.34) of the η^5-$C_5H_4SiMe_3$ ring. Furthermore, in this spectrum we could also measure the spin-spin coupling constant (^4J = 0.85 Hz) between C_α-H38b (δ = 1.35) and the more deshielded H23 (δ = 6.14) of the Cp′ ring. This value must correspond to the "W" disposition of these protons, as shown in Figure 2c.

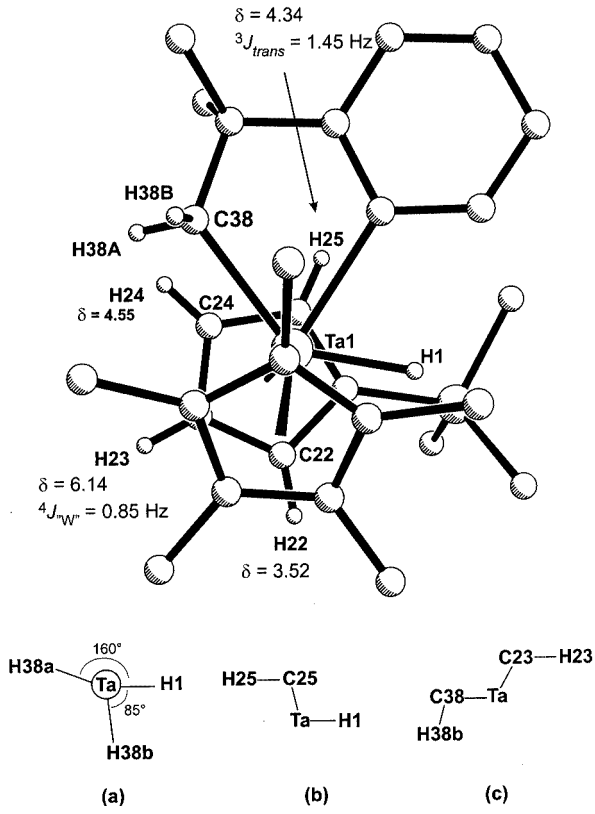

Figure 2. Top view of **4** with some relevant ^{1}H NMR spectroscopic data

Both the ^{1}H and ^{13}C spectra show a very large difference for the chemical shifts of the η^5-$C_5H_4SiMe_3$ ring (Δδ = 2.6 and 22.2 ppm, respectively) due to the cooperative electronic properties of the alkyl, phenyl and hydride groups bonded to the tantalum center.

Conclusions

The results discussed here demonstrate that μ-alkylidene tantalum and hydrido tantalabenzocyclopent-2-ene complexes can be obtained by treating the mixed dichlorodicyclopentadienyltantalum(IV) derivative [TaCp*Cp′Cl_2] with different alkylating reagents. In both cases the reaction takes place with the initial formation of dialkyl mixed tantalocene derivatives. When the alkylation is carried out with 1 equiv. of [$Mg(CH_2C_6H_5)_2(THF)_2$] or 2 equiv. of LiR (R = CH_2SiMe_3, CH_2CMe_3) the bis-μ-alkylidene complexes **1−3** are formed with simultaneous elimination of R−CH_3 (R = C_6H_5, $SiMe_3$, CMe_3). This transformation involves an α-H abstraction process to generate an intermediate tantalum(IV) alkylidene complex, which then rearranges to give a bis(μ-alkylidene) complex. However, if the starting dichloro derivative is treated with 2 equiv. of $LiCH_2CMe_2Ph$ the hydride tantalabenzocyclopent-2-ene complex **4** is isolated. Its formation can be explained by the reduction of the dialkyl derivative to give a neophyl radical, which dimerizes, and the corresponding mixed dicyclo-

pentadienyl neophyltantalum(III) derivative. A subsequent intramolecular activation of a distal aromatic C−H bond leads to **4**.

Experimental Section

General: All reactions and manipulations were carried out by using standard Schlenk techniques or in an argon-filled vacuum atmosphere glove box.[28] Solvents were refluxed over appropriate drying agents and distilled and degassed prior to use: [D_6]benzene and *n*-hexane (Na/K alloy), toluene (Na). Literature methods were employed for the syntheses of the starting materials [TaCp*Cp′Cl_2],[21] alkyllithium LiR (R = CH_2CMe_2Ph, CH_2SiMe_3, CH_2CMe_3)[29] and dibenzylmagnesium [$Mg(CH_2Ph)_2(THF)_2$].[30]

Infrared spectra were recorded with a Perkin−Elmer 583 spectrophotometer (4000−200 cm^{-1}) with samples as Nujol mulls between CsI plates or polyethylene pellets. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on Varian Unity-300 or Varian UnityPlus-500 spectrometers; chemical shifts are referenced to the ^{13}C (δ = 128) and residual ^1H (δ = 7.15) resonances of the [D_6]benzene solvent. C and H analyses were carried out on a Perkin−Elmer 240 C microanalyzer.

Synthesis of [(TaCp*Cp′)$_2$(μ-CHR)$_2$] (R = C_6H_5, 1; $SiMe_3$, 2; CMe_3, 3) and [TaCp*Cp′(H)(η^2-CH_2−CMe_2-*o*-C_6H_4)] (4): A mixture of [TaCp*Cp′Cl_2] (0.70 g, 1.33 mmol) and [$Mg(CH_2C_6H_5)_2(THF)_2$] (0.47 g, 1.33 mmol) or $LiCH_2R$ (2.66 mmol; R = $SiMe_3$: 0.25 g; CMe_3: 0.21 g; CMe_2Ph: 0.37 g) was stirred in toluene (30 mL) at room temperature for 18 h. $MgCl_2$ or LiCl were filtered off and the resulting solution evaporated to dryness. The residue was extracted with *n*-hexane (2 × 10 mL) and cooled to −40 °C overnight to give **1**−**3** as somewhat brown (**1**) or red-brown (**2**,**3**) sticky solids and **4** as pale brown crystals.

When these experiments were carried out in a sealed NMR tube with [D_6]benzene as solvent, the elimination organic products R−CH_3 (R = C_6H_5, **1**; $SiMe_3$, **2**; CMe_3, **3**) and $PhMe_2C$−CH_2−CH_2−CMe_2Ph (**4**) were detected in the ^1H NMR spectrum.

X-ray Structure Determination of 4: Crystals of compound **4** were obtained by crystallization from hexane. A suitably sized crystal sealed in a Lindemann tube was mounted on an Enraf−Nonius CAD 4 automatic four-circle diffractometer equipped with graphite monochromated Mo-K_α radiation (λ = 0.71073 Å). Crystallographic and experimental details of the structure are summarized in Table 2. Data were collected at room temperature. Intensities were corrected for Lorentz and polarization effects in the usual manner. No absorption or extinction corrections were made. The structure was solved, using the WINGX package,[31a] by direct methods (SHELXS-97)[31b] and refined by least-squares against F^2 (SHELXL-97).[31b] All non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were introduced from geometrical calculations and refined using a riding model with thermal parameters equivalent to those of the carbon atoms to which they are attached, except for the hydride atom, which was found with the XHYDEX[31c] program, included and refined isotropically in the last cycles of refinement.

Table 2. Crystal data and structure refinement for **4**

Empirical formula	$C_{28}H_{41}SiTa$
Formula mass	586.65
Crystal habit	prismatic
Colour	pale brown
Crystal size	0.22 × 0.28 × 0.30 mm
Space group	monoclinic, $P2_1/c$
a (Å)	8.976(1)
b (Å)	16.596(1)
c (Å)	17.929(1)
β (°)	99.26(1)
V (Å^3)	2636.0(4)
Z	4
$D_{calcd.}$ (g cm^{-3})	1.478
F(000)	1184
μ (cm^{-1})	42.27
Scan mode	ω/2θ $2.30 < \theta < 24.98$
Number of reflections	
Measured	4628
Observed	3326 ($I < 2\sigma(I)$)
Range of *hkl*	$-10 < h < 10$, $0 < k < 19$, $0 < l < 21$
Standard reflections	3 every 200 reflections
Refinement method	full-matrix least-squares on F^2
Final R indices all data[a]	$R1 = 0.0481$, $wR2 = 0.1330$
Final R indices [$I > 2\sigma(I)$]	$R1 = 0.0699$, $wR2 = 0.1510$
Largest diff.peak and hole (e/Å^3)	1.929 and −2.990
Goodness of fit on F^2	1.108

[a] $R1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$; $wR2 = \{\Sigma[\omega((F_o^2 - F_c^2)^2]/\Sigma[\omega(F_o^2)^2]\}^{1/2}$.

CCDC-174670 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We are grateful to the DGICYT (Project PB-97−0761) and to the Universidad de Alcalá (Project E009/98) for financial support of this research.

Regiospecific Reaction between Dimetallic Phosphido-Bridged W−W Complexes and Phosphane Imide − Electrophilic Site Switching by Metal−Metal Bond Formation

Shin-Guang Shyu,*[a] Ramsharan Singh,[a] Chi-Jung Su,[a] and Kuan-Jiuh Lin[a]

Keywords: Tungsten / P ligands / Bridging ligands / Electrophilic site switching

Reaction between $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_5$(*W–W*) (**2**) and $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) in THF at refluxing temperature is regiospecific with the CNR ligand coordinated to the $W(CO)_4$ unit to produce $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_4$-(CNR)(*W–W*) (**4**). Spectroscopic data indicate that the complex exists in two stereoisomeric forms in solution. The structure of the *cis* isomer was determined by a single-crystal X-ray diffraction study which indicates that the CNR ligand is coordinated to the W atom of the $W(CO)_4$ unit and *cis* to the phosphido bridge. Reaction between $CpW(CO)_3(\mu\text{-}PPh_2)W(CO)_5$ (**1**) and $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) in THF under similar condition is also regiospecific. However, the CNR ligand is coordinated to the CpW site to produce $CpW(CO)_2(CNR)(\mu\text{-}PPh_2)W(CO)_5$ (**3**). There are also two stereoisomers of the complex, which were separated by column chromatography. Structures of both isomers were determined by single-crystal X-ray diffraction studies.

Introduction

It is now evident that the formation of a metal−metal bond can influence the chemistry at adjacent metal centers in dinuclear complexes and clusters.[1] Recent studies of phosphido-bridged dimetallic complexes have revealed two interesting observations. First, one metal atom can promote substitution reactions at the adjacent metal carbonyl ligand upon the formation of the metal−metal bond.[2] Second, switching of the substitution site can occur when the metal−metal bond is formed.[2b] Apparently, the formation of the metal−metal bond can result in the donation of electron density from one metal atom to the other.[2a−2e] This electron density redistribution may alter the electrophilicity of the carbon atom of the carbonyl ligands attached to the metal atoms. Thus, the electrophilic site may switch from the carbonyl ligands on one metal atom to the carbonyl ligands on the other metal atom in heterodimetallic complexes upon the formation of the metal−metal bond.

Phosphane imides, deoxygenating reagents,[3] react with carbonylmetal compounds to produce (isocyanide)metal complexes.[4] Nucleophilic attack of a phosphane imide at the carbonyl carbon atom followed by the elimination of the triphenylphosphane oxides to generate the isocyanide ligand has been proposed as the reaction mechanism.[4a−4c] Here, we report a study of the regiospecific reactions between phosphane imides and phosphido-bridged dimetallic complexes $Cp(CO)_3W(\mu\text{-}PPh_2)W(CO)_5$ (**1**)[2d] and $Cp(CO)_2W(\mu\text{-}PPh_2)W(CO)_5$](*W−W*) (**2**)[2d] to produce $Cp(CO)_2(CNR)W(\mu\text{-}PPh_2)W(CO)_5$ (**3**) and $Cp(CO)_2W$-$(\mu\text{-}PPh_2)W(CO)_4(CNR)$(*W−W*) (**4**), respectively. Thus, there is electrophilic site switching in these phosphido-bridged dimetallic complexes upon metal−metal bond formation.

Results and Discussion

Regiospecific Reaction of 1 with Phosphane Imides and Molecular Structures of 3a and 3a′

Reaction of **1** with $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) produced two yellow solids **3** and **3′** in good yields (41% and 55%, Scheme 1). The ν(CN) stretching frequencies in their IR spectra indicate the terminal involvement of CNR in the coordination.[5] Signals corresponding to the protons of one isocyanide ligand were observed in their ^1H NMR spectra. Both complexes exhibited $^{31}P\{^1H\}$ NMR signals with two sets of J_{P-W} satellites at δ = −62.26 (**3a**) and −61.55 (**3a′**), respectively, indicative of a bridging phosphido group and the absence of a metal−metal bond.[6] The structures of **3a** and **3a′** were determined by single-crystal X-ray diffraction studies. Their structures are shown in Figures 1 and 2.

In complex **3a**, the diphenylphosphido ligand bridges two tungsten atoms with a W−W distance of 4.454(5) Å. This indicates that there is no metal−metal bond between the tungsten atoms. This is consistent with the observed upfield position of the phosphido signal in its $^{31}P\{^1H\}$ NMR spectrum. The isocyanide ligand CNPr is terminally coordin-

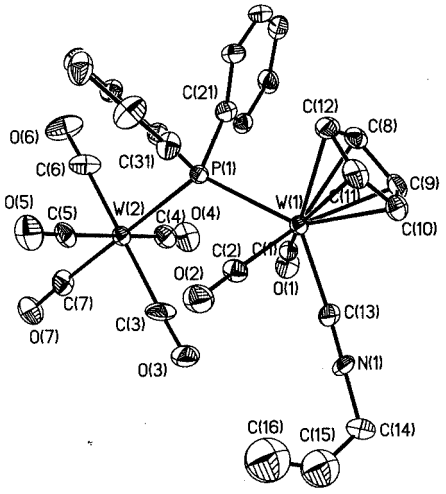

Figure 2. ORTEP drawing of **3a′**, hydrogen atoms are omitted

ated to W(1) of the CpW moiety. Thus, five CO ligands and $CpW(CO)_2(CNPr)PPh_2$ are coordinated to the W(2) atom to form a distorted octahedron around the W(2) atom. The doublet at δ = 200.44 (J_{P-C} =4.3 Hz, J_{C-W} = 123.8 Hz) in the $^{13}C\{^1H\}$ NMR spectrum is assigned to the four CO ligands on W(2) *cis* to the phosphido bridge. These four CO ligands are equivalent in the NMR spectrum because of the rotating of P−W(2) bond. Similar phenomena were observed in the $^{13}C\{^1H\}$ NMR spectra of complexes $CpFe(CO)_2(\mu\text{-}PPh_2)M(CO)_5$ (M = Cr, Mo, W).[10] The assignment is also based on the comparison of the resonance position of the *cis*-CO signal to the position of the *cis*-W(CO) signal [δ = 199.04 (d, J_{P-C} = 5.58 Hz, J_{W-C} = 121.29 Hz)] in $CpFe(CO)_2(\mu\text{-}PPh_2)W(CO)_5$.[7] The small doublet at δ = 201.62 (J_{P-C} = 18.12 Hz) is assigned to the *trans*-CO ligand based on a similar comparison with the resonance position [δ = 201.48 (d, J_{P-C} = 20.18 Hz)] of the *trans*-CO ligand of $CpFe(CO)_2(\mu\text{-}PPh_2)W(CO)_5$.[7] Also, the *trans*-CO ligand always has a lower field resonance than the resonance of the four *cis*-CO ligands as observed in $CpFe(CO)_2(\mu\text{-}PPh_2)M(CO)_5$ (M = Cr, Mo, W). The two carbonyl ligands on W(1) are non-equivalent and correspond to two broad humps (δ = 223 and 228) in the $^{13}C\{^1H\}$ NMR spectrum.

The structure of **3a′** is similar to the structure of complex **3a**. The isocyanide ligand is cordinated to the W(1) atom. The primary difference between them is that the two carbonyl ligands on W(1) are equivalent in **3a′** (cf. Figures 1 and 2). The doublet at δ = 223.40 (J_{P-C} = 15.10 Hz) in the ^{13}C NMR spectrum is assigned to the two equivalent carbonyl ligands based on the comparison of the resonance position of the CpW carbonyl ligands in $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_5(W\text{−}W)$ [δ = 226.56 (d, J_{P-C} = 17.19 Hz)][2d] and $CpW(CO)_2(\mu\text{-}PPh_2)Mo(CO)_5(W\text{−}W)$ [δ = 226.73 (d, J_{P-C} = 7.51 Hz)].[2e] Thus, the reaction between **1** and a

phosphane imide is regiospecific with the isocyanide ligand coordinated to the CpW moiety.

Regiospecific Reaction of $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_5$-(*W−W*) with $Ph_3P{=}NR$ (R= Pr, CH_2Ph, *i*Pr) and the Structure of *cis*-$CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_4(CN\text{-}Pr)$-(*W−W*)

Interestingly, the reaction between **2** and a phosphane imide is also regiospecific. However, the attack is on a carbonyl ligand of the $W(CO)_5$ moiety (Scheme 1). Complex **2** reacted with a phosphane imide to produce a maroon red solid. Spectroscopic data (IR, variable-temperature ^1H and $^{31}P\{^1H\}$ NMR) and elemental analyses indicate that the product is a mixture of *cis* and *trans* isomers of **4**. We have based this conclusion on the comparison of these spectroscopic data to those of $Cp(CO)_2M(\mu\text{-}PPh_2)Mo(CO)_4(CNR)$(*M−Mo*) (M = Mo, W).[8] In addition the structure of *cis*-$CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_4(CNPr)$(*W−W*) (**4a-*cis***) was determined by a single-crystal X-ray study (Figure 3).

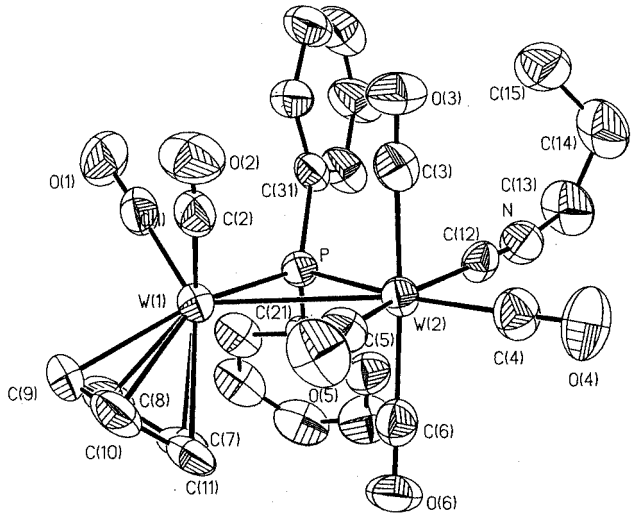

Figure 3. ORTEP drawing of **4a-*cis***, hydrogen atoms are omitted

The structure of **4a-*cis*** is similar to the structure of its W−Mo analogue $Cp(CO)_2W(\mu\text{-}PPh_2)Mo(CO)_4(CNPr)$-(*W−Mo*) where the isocyanide ligand coordinates to W in the *cis* position to the phosphido bridge.[8] A W−W distance of 3.1849(9) Å, which is similar to the W−Mo bond lengths of 3.1894(8) Å in $Cp(CO)_2W(\mu\text{-}PPh_2)Mo(CO)_4(CNPr)$(*W−Mo*) and 3.1942(12) Å in its parent compound **1**,[2d] indicates a metal−metal bond in the complex. This observation is consistent with the observed downfield resonance of the phosphorus signal in its $^{31}P\{^1H\}$ NMR spectrum.

Similar to $Cp(CO)_2Mo(\mu\text{-}PPh_2)M(CO)_4(CNR)$(*W−Mo*) (M = Mo, W), attempts to spectroscopically characterize the pure isomer failed.[8] When the crystals of the *cis* isomers were dissolved in solution, the ^1H and $^{31}P\{^1H\}$ NMR spectra of the solution were the same as that of the product mixture initially obtained. This indicates that isomerization occurs rapidly when the pure *cis* isomer is dissolved in the solvent.

Synthesis and Structure of $Cp(CO)_3W(\mu\text{-}PPh_2)W(CO)_4$-(CN*i*Pr) (5) − Possible Intramolecular Migration of the Isocyanide Ligand between W Atoms in Dimetallic Complex

In complex **1**, there are two sets of carbonyl ligands, one located on the $CpW(CO)_3$, and the other one on the $W(CO)_5$ unit. In principle, both sets of carbonyl ligands can be attacked by phosphane imides because there is no steric hindrance to protect the carbonyl ligands from the reaction. Intramolecular ligand exchanges have been observed in dimetallic complexes.[9] Thus, phosphane imides may attack the carbonyl ligand on the $W(CO)_5$ moiety followed by intramolecular ligand migration of the isocyanide ligand from W(2) to CpW(1). In order to evaluate the possibility of an intramolecular ligand exchange by an intermediate such as $Cp(CO)_3W(\mu\text{-}PPh_2)W(CO)_4(CNR)$, $Cp(CO)_3W(\mu\text{-}PPh_2)W(CO)_4(CN\textit{i}Pr)$ (**5**) was synthesized by the reaction between $CpW(CO)_3(PPh_2)$ and $W(CO)_4(CN\textit{i}Pr)(NCEt)$. In addition to spectroscopic characterizations, the structure of the complex was determined by a single-crystal X-ray study (Figure 4).

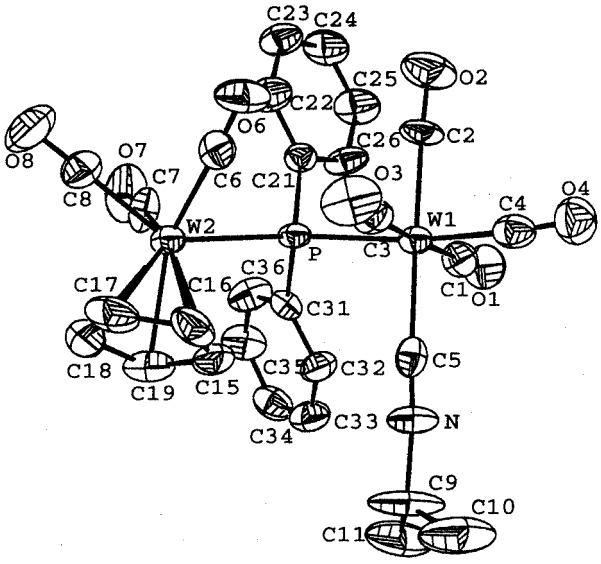

Figure 4. ORTEP drawing of **5**, hydrogen atoms are omitted

A W−W distance of 4.4548(7) Å indicates that there is no bonding between the two metal atoms in the complex. This observation is consistent with the observed upfield resonance of the phosphorus signal in its $^{31}P\{^1H\}$ NMR spectrum. The isocyanide ligand is coordinated to W(1) and is *cis* to the phosphido bridge ligand. The W−W distance of 4.4548(7) Å and the W(1)−P−W(2) angle of 116.71(9)° in **5** are similar to the W−W distance of 4.5096(11) Å and the W−P−W angle of 118.38(13)° in **1**.[2d] This indicates that the steric hindrance of the isocyanide ligand at the *cis* position in **5** is only slightly greater than the steric hindrance of the corresponding CO ligand in **1**.

Heating of **5** in THF to simulate the conditions of the reaction between **1** and phosphane imides does not produce **3** (Scheme 1). This observation excludes the possibility of an intramolecular exchange of the CNR ligand in an intermediate such as $Cp(CO)_3W(\mu\text{-}PPh_2)W(CO)_4(CNR)$ to form complex **3**. The regiospecific reaction between **1** and a phosphane imide is thus due to some electronic factor. The preferred attack on the carbonyl ligand of $CpW(CO)_3$ indicates that these carbonyl ligands must be more electrophilic than the carbonyl ligands of the $W(CO)_5$ unit.

Electrophilic Site Switching by Metal−Metal Bond Formation

The formation of a metal−metal bond may alter the regiospecificity of the reaction in two ways. First, it brings the two W atoms closer together, introducing steric crowding around the W(1) atom and rendering the attack of a phosphane imide at the CO ligands of the $CpW(CO)_2$ unit difficult. Second, the formation of the metal−metal bond can alter the electronic properties of the complex such that the CO ligands of the $W(CO)_5$ unit in **2** are more electrophilic than the CO ligands of the $CpW(CO)_2$ unit.

The CO ligands of the $CpW(CO)_2$ unit in **2** could still be attacked by a phosphane imide. Accordingly, one cannot exclude the steric hindrance argument completely. On the other hand, two considerations enable us to conclude that the electronic factor is dominant. First, in complex **1**, the carbonyl ligands of the $W(CO)_5$ unit are inert. Even under excess phosphane imide, no isocyanide ligand was observed to replace one of the CO ligands on the $W(CO)_5$ site. This observation indicates that the carbonyl ligand of the $W(CO)_5$ unit is not electrophilic enough to react with the nucleophilic phosphane imide under the reaction conditions. Second, one can consider the W−W bonding in **2** as a dative bond [donor−acceptor bond from W(2) to W(1)]. We may treat W(2) as a ligand of CpW(1) when one of the W(1) carbonyl ligands is removed from **1** by photolysis to form **2**.[2d,2e] Electron donation from the filled t_{2g} orbital of the W(2) atom to the W(1) atom upon formation of the metal−metal dative bond can reduce the electron density on W(2). The net result of this electron redistribution will be a decrease in $d_{xy}[W(2)] \rightarrow \pi^*(CO)$ bonding to the equatorial CO ligands.[2c−2e,2k] This will result in the reduction of the electron density on the carbon atoms of these equatorial CO ligands such that they become sufficiently electrophilic to react with the nucleophilic phosphane imides. In addition, when the electron-withdrawing CO ligand of the CpW(1) unit in **1** is replaced with the dative metal−metal bond to form **2**, electron back donation from W(1) to the two carbonyl ligands of W(1) becomes enhanced. The result is an increase in electron density of the carbon atoms of these CpW(1) carbonyl ligands. Thus, electronically, they are less reactive towards a nucleophile than the corresponding CpW(1) carbonyl ligands in **1**. We can consider that the formation of the metal−metal dative bond in **2** acts as a switch and triggers the nucleophilic attack on the $W(CO)_5$ carbonyl ligands by the activation of the equatorial CO ligands by W−W interactions. This switching of electrophilic site from the carbonyl ligands of the CpW unit in **1** to the carbonyl ligands of the $W(CO)_5$ unit in **2** in the heterodimetallic complexes by the formation of a metal−metal bond can be considered as a cooperative effect of the adjacent metal atom in dimetallic complexes.

Conclusions

Reaction between $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_5(W\text{−}W)$ and $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) in THF is regiospecific with the CNR ligand coordinated to the $W(CO)_4$ unit to produce $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_4(CNR)$ $(W\text{−}W)$. Reaction between $CpW(CO)_3(\mu\text{-}PPh_2)W(CO)_5$ and $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) under similar conditions is also regiospecific with the CNR ligand coordinated to the CpW site to produce $CpW(CO)_2(CNR)(\mu\text{-}PPh_2)W(CO)_5$. The switching of the electrophilic site from the carbonyl ligands of the CpW unit in **1** to the carbonyl ligands of the $W(CO)_5$ unit in **2** in the heterodimetallic complexes is considered as a cooperative effect of the adjacent metal atom in the dimetallic complexes. The redistribution of the electron density from W of the CpW moiety to the other W of the $W(CO)_5$ unit in **2** by the formation of a metal−metal bond is proposed as the reason for this switching.

Experimental Section

General Procedures: All reactions were carried out under purified nitrogen with standard Schlenk techniques. TLC and chromatographic work were performed in air. Infrared (IR) spectra were recorded with a Perkin−Elmer 882 infrared spectrophotometer. ^1H, ^{13}C and ^{31}P NMR spectra were recorded with Bruker AMX-500, AMX-400, AC-200 and AC-300 spectrometers. The ^{31}P NMR shifts are referenced to 85% H_3PO_4 with downfield chemical shifts as positive. Except as noted, NMR spectra were collected at room temperature. FAB mass spectra were recorded with a VG70-250S or a JEOL JMS-HX 110 mass spectrometer. Microanalyses were performed by the Microanalytical Laboratory at National Cheng Kung University, Tainan, Taiwan and Academia Sinica.

Materials: THF was distilled from potassium and benzophenone under purified nitrogen just before use. The complexes $CpW(CO)_3(\mu\text{-}PPh_2)W(CO)_5$ (**1**) and $CpW(CO)_2(\mu\text{-}PPh_2)W(CO)_5(W\text{−}W)$ (**2**) were prepared according to literature procedures.[2d] The compounds $Ph_3P{=}NR$ (R = Pr, CH_2Ph, *i*Pr) were prepared as described in the literature.[10]

$CpW(CO)_2(CNPr)(\mu\text{-}PPh_2)W(CO)_5$ (3a and 3a′): A mixture of **2** (0.120 g, 0.143 mmol) and $Ph_3P{=}NPr$ (0.094 g, 0.286 mmol) was dissolved in THF (20 mL) and the resulting solution was refluxed with stirring at 68 °C for about 70 h. The solvent was then removed under vacuum and the residue was chromatographed on grade III alumina and eluted with CH_2Cl_2/hexane to afford two fractions. The first yellow band was eluted with CH_2Cl_2/hexane (20:80) to obtain yellow solid compound **3a** after removing the solvent. Yield 0.052 g (41%). $C_{28}H_{22}NO_7PW_2$(883): calcd. C 38.08, H 2.51, N 1.59; found C 37.80, H 2.53, N 1.60. MS (FAB): m/z = 884 $[M + 1]^+$. The second band was eluted with CH_2Cl_2/hexane (25:75) to produce compound **3a′** as a yellow solid after removing the solvent. Yield 0.070 g (55%). $C_{28}H_{22}NO_7PW_2$(883): calcd. C 38.08, H 2.51,

N 1.59; found C 37.95, H 2.57, N 1.70. MS (FAB): *m*/*z* = 884 [M + 1]$^+$. Spectroscopic data of the complexes are presented in Table 1 of the Supporting Information (see also footnote on the first page of this article); for comparison, the spectroscopic data of the parent complexes **1** and **2** are also given there.

CpW(CO)$_2$(CNCH$_2$Ph)(μ-PPh$_2$)W(CO)$_5$ (3b and 3b′): Reaction and separation conditions similar to those for **3a** and **3a′** were applied to prepare **3b** and **3b′**. The reaction time was 70 h and 0.324 g (0.39 mmol) of **1** and 0.286 g (0.77 mmol) of Ph$_3$P=NCH$_2$Ph were used. **3b**: Yield: 0.168 g (46%). $C_{32}H_{22}NO_7PW_2$ (931): calcd. C 41.28, H 2.38, N 1.50; found C 41.13, H 2.45, N 1.43. MS (FAB): *m*/*z* = 932 [M + 1]$^+$. **3b′**: Yield: 0.166 g (46%). $C_{32}H_{22}NO_7PW_2$ (931): calcd. C 41.28, H 2.38, N 1.50; found C 41.34, H 2.47, N 1.47. MS (FAB): *m*/*z* = 932 [M + 1]$^+$. Spectroscopic data of the complexes are presented in Table 1 of the Supporting Information.

CpW(CO)$_2$(CN*i*Pr)(μ-PPh$_2$)W(CO)$_5$ (3c and 3c′): Reaction and separation conditions similar to those for **3a** and **3a′** were applied to prepare **3c** and **3c′**. The reaction time was 144 h and 0.380 g (0.45 mmol) of **1** and 0.288 g (0.90 mmol) of Ph$_3$P=N*i*Pr were used. 0.070 g of the parent complex **1** was recovered. **3c**: Yield: 0.036 g (11%). $C_{28}H_{22}NO_7PW_2$ (883): calcd. C 38.08, H 2.51, N 1.59; found C 37.87, H 2.55, N 1.56. MS (FAB): *m*/*z* = 884 [M + 1]$^+$. **3c′**: Yield: 0.070 g (22%). $C_{28}H_{22}NO_7PW_2$: (883) calcd. C 38.08, H 2.51, N 1.59; found C 37.70, H 2.55, N 1.61. MS (FAB): *m*/*z* = 856 [M − CO + 1]$^+$. Yields are based on the parent compound consumed in the reactions. Spectroscopic data of the complexes are presented in Table 1 in the Supporting Information.

CpW(CO)$_2$(μ-PPh$_2$)W(CO)$_4$(CNPr)(*W*−*W*) (4a-*cis* and 4a-*trans*): A mixture of **2** (0.306 g, 0.376 mmol) and Ph$_3$P=NPr (0.240 g, 0.752 mmol) was dissolved in THF (20 mL) and refluxed with stirring at 68 °C for about 12 h. The solvent was then removed under vacuum and the residue was chromatographed on grade III alumina and eluted with CH_2Cl_2/hexane to afford three fractions. A small amount of unchanged starting material was recovered from the first band on elution with 8% of dichloromethane in hexane. A small amount (0.011 g) of green compound was obtained from the second band on elution with 12% of dichloromethane in hexane and was not identified. A mixture of maroon red colored compounds CpW(CO)$_2$(μ-PPh$_2$)W(CO)$_4$(CNPr)(*W*−*W*) (**4a-*cis*** and **4a-*trans***) was obtained from the third band on elution with 16% of CH_2Cl_2/hexane. Combined yield of **4a-*cis*** and **4a-*trans***: 0.233 g (73%). $C_{27}H_{22}NO_6PW_2$ (855): calcd. C 37.92, H 2.59,N, 1.64; found C 38.02, H 2.74, N 1.65. Spectroscopic data indicate that the mixture consists of two isomers, which could not be separated by chromatography. Spectroscopic data are given in Table 1 of the Supporting Information.

CpW(CO)$_2$(μ-PPh$_2$)W(CO)$_4$(CNCH$_2$Ph)(*W*−*W*) (4b-*cis* and 4b-*trans*): Reaction and separation conditions similar to those for **4a-*cis*** and **4a-*trans*** were applied to prepare **4b-*cis*** and **4b-*trans***. The reaction time was 35 h and 0.354 g (0.440 mmol) of **2** and 0.324 g (0.870 mmol) of Ph$_3$P=NCH$_2$Ph were used. Combined yield of **4b-*cis*** and **4b-*trans***: 0.243 g (61%). $C_{31}H_{22}NO_6PW_2$ (903): calcd. C 41.23, H 2.46, N 1.55; found C 41.64, H 2.64, N 1.66. MS (FAB): *m*/*z* = 904 [M + 1]$^+$. Spectroscopic data indicate that the mixture consists of two isomers that could not be separated by chromatography. Spectroscopic data are given in Table 1 of the Supporting Information.

CpW(CO)$_2$(μ-PPh$_2$)W(CO)$_4$(CN*i*Pr)(*W*−*W*) (4c-*cis* and 4c-*trans*): Reaction and separation conditions similar to those for **4a-*cis*** and **4a-*trans*** were applied to prepare **4c-*cis*** and **4c-*trans***. The reaction time was 96 h and 0.407 g (0.500 mmol) of **2** and 0.319 g (1.000 mmol) of Ph$_3$P=N*i*Pr were used. Combined yield of **4c-*cis*** and **4c-*trans***: 0.180 g (42%). $C_{27}H_{22}NO_6PW_2$ (855): calcd. C 37.92, H 2.59,

Oxygen-Containing, Asymmetric "Dual-Side" Zirconocenes: Investigations on a Reversible Chain Transfer to Aluminum

Jürgen Kukral,[a] Petri Lehmus,[a] Martti Klinga,[b][‡] Markku Leskelä,[b][‡] and Bernhard Rieger*[a]

Keywords: Metallocenes / Propene polymerization / O ligands / Cyclopentadienyl ligands / Zirconium catalysts

A series of new oxygen-substituted, asymmetric zirconocene dichlorides (*rac*-{1-[5,6-(ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)ethane}zirconium dichloride (**3a**), *rac*-{1-[5,6-(ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)ethane}dimethylzirconium (**3b**) and *rac*-{[5,6-ethylenedioxy)-2-methyl-1-η^5-indenyl](9-η^5-fluorenyl)dimethylsilane}zirconium dichloride (**3c**)} have been prepared and their polymerization behavior was investigated in dependence of monomer concentration, temperature and catalyst activation. The presence of oxygen substituents on the indenyl ring results in a strong increase of polymerization activities and also of polymer molecular weights with decreasing Al/Zr ratio. Significantly higher molecular masses and activities were found for the dimethyl complex **3b** after activation with $[(C_6H_5)_3C^+][(C_6F_5)_4B^-]$ deriving from the absence of chain transfer to aluminum and higher concentration of active catalyst species. The mechanism of stereoerror formation of the oxygen-containing C_1-symmetric catalyst was investigated by deuterium labeling studies on propene monomers. The results are discussed on the basis of a reversible chain transfer to aluminum.

Introduction

We reported recently on a new family of asymmetric Zr^{IV} complexes that allows to achieve and adjust elastic polymer properties by a controlled placement of isolated stereoerrors along isotactic polypropene chains.[1] A widely disregarded issue in the development of metallocene chemistry was the incorporation of heteroatoms into the ligand framework, but it found growing interest in the last years.[2,3] First investigations were mainly restricted to methoxy groups as π-donors substituents. A negative influence on the catalyst activity and the polymer molecular weights was observed and explained by the interaction between the donor substituents and methylalumoxane (MAO) resulting in electron withdrawal instead of electron donation.[4] The introduction of amino groups in 2-position of indenyl ligands[5,6] was found by Brintzinger et al.[5] to give modest activities after an induction time of several hours. On the other hand, the investigation of sterically shielded 2-siloxy-substituted bis-(indenyl) complexes by Leino et al.[2] and Lehmus et al.[3] evidenced these complexes not to suffer from induction periods and to give a considerable increase in ethene polymerization activities compared to their unsubstituted analogues. Recently, Ewen et al.[7] reported on heteroatom-containing aromatic ligands with a polymerization performance rivaling that of the corresponding unsubstituted complexes.

In the present work a matter of particular interest was to combine both, the unique polymerization properties of our C_1-symmetric metallocene catalysts and the high potential for extending the concept of ligand design by introducing heteroatoms into the ligand framework. Therefore, the oxygen-substituted complexes **3a**–**c** (Scheme 1) were synthesized and tested in propene polymerization experiments using MAO and $[(C_6H_5)_3C^+][(C_6F_5)_4B^-]$ as cocatalysts. By imbedding the heteroatoms into a dioxane ring, we aimed at a protection of the heterocycle against C–O splitting reactions with MAO and thus to improve the catalyst stability.[8] Polymerization studies using deuterated propene were performed to elucidate the role of the aluminum cocatalyst in the mechanism of stereoerror formation of **3a**/MAO.[1b]

Results and Discussion

Ligand and Complex Synthesis

The ethylene-bridged ligand **2a**H_2 (Scheme 2, top) was synthesized via the 1-bromo-2-(9-fluorenyl)ethane intermediate. Analogously, the dimethylsilane-bridged ligand **2b** was prepared by addition of excess $(CH_3)_2SiCl_2$ to a vigor-

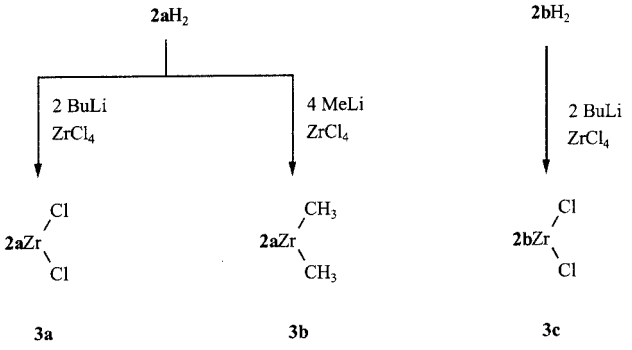

Scheme 2

ously stirred suspension of fluorenyllithium. Treatment of the ethylene- and silane-substituted fluorenyl intermediates with indenyllithium afforded the corresponding ligands **2a**,**b**H_2.[9] The zirconocene complexes **3a**−**c** (Scheme 2, bottom) were synthesized in moderate to high yields after reaction of the dilithium salt of the ligands **2a**,**b**H_2 with solid $ZrCl_4$ and purified by crystallization from toluene. Compounds **3a**,**b** are stable products and even the Si-bridged complex **3c** is, in contrast to related difluorenyl- or fluorenyl/indenylzirconium dichlorides,[1b,10] relatively stable in solution. The dimethyl derivative **3b** was obtained by a straightforward one-pot reaction of 4 equiv. of methyllithium with **2a**H_2, followed by the addition of $ZrCl_4$.[11] This simplified synthesis of the dimethylmetallocene evades separate preparation and isolation of the dichloro compounds and their subsequent reaction with methylmagnesium bromide or methyllithium.

Crystal and Molecular Structure

A single-crystal X-ray structure investigation was performed on complex **3a** (Figure 1, Table 4) which crystallizes in the monoclinic space group $P2_1/n$. The $Cp^{Flu}-Zr-Cp^{Ind}$ angle δ (Figure 2[12], Table 1, 128.1°) and φ (63.8°), the bite angle between the least-squares planes of the two Cp ligands, are in between those of the Zr complexes **EBI**[13] (δ = 126.9°[14], φ = 62.1°) and **EBF**[15] (δ = 129.0°[16], φ = 64.3°). In contrast, γ angles slightly larger than 180° (γ^{Flu} = 186.98°, γ^{Ind} = 182.82°) differ from results previously reported for other bridged indenyl and fluorenyl complexes for which typically values smaller than 180° were observed.[16] A genuine explanation of this effect cannot be given, yet. However, the resulting increased accessibility of the zirconium center is obviously one reason for the high activities of our asymmetric catalysts.[17]

The Zr−fluorenyl centroid bond of **3a** (2.59 Å) is distinctly longer than the distance between Zr^{IV} and the indenyl centroid (2.52 Å) leading to a nonsymmetric positioning of the Zr^{IV} center between the two Cp planes. A β^{Ind} value of 86.52° points toward a nearly ideal η^5-coordination of the indenyl ring to Zr^{IV}. This is different for the fluorenyl fragment. The value of β^{Flu} close to 80° (81.68°) and the corresponding Zr−C distances (ranging from 2.435 to 2.688 Å) clearly indicate a reduced hapticity of the fluorenyl fragment toward η^3-coordination.[18]

Propene Polymerization Experiments

Polymerization Activity

The experimental data (Table 2) indicate that all zirconocene compounds of the series **3a**−**c** are suitable catalysts for the polymerization of propene after MAO or $[(C_6H_5)_3C^+][(C_6F_5)_4B^-]$ activation.

The polymerization activities of the oxygen-containing complexes **3a**,**c**/MAO correlate tightly with the total amount of MAO. A distinct increase in catalyst activity could be observed with decreasing MAO concentration ($100 \leq Al/Zr \leq 2000$). The maximum activity is reached at Al/Zr ratios of around 300:1.[3] Seemingly, the polar oxygen substituents promote the approach of the Lewis acidic alu-

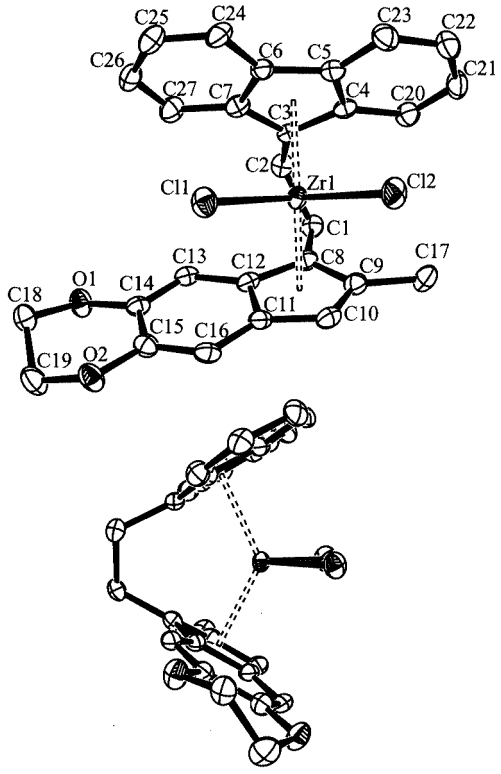

Figure 1. Two projections of the molecular structure and labeling scheme of complex **3a**

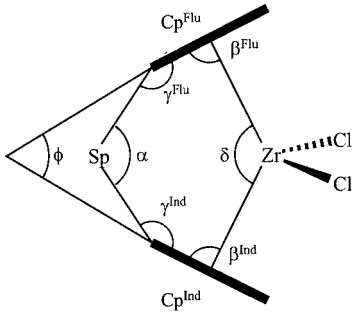

Figure 2. Schematic illustration of relevant band angles

minum cocatalyst to the zirconium center and accelerate the activation reaction in the apolar polymerization medium toluene. At higher cocatalyst concentrations excessive MAO operates as an polymerization-inhibiting agent. The incorporation of the heteroatoms into a ring system protects the oxygen groups sufficiently against MAO-induced C−O splitting and consequently inhibits catalyst decomposition.[19] A further significant activity increase up to a factor of 10 {at T_P = 30 °C up to 5100 kg PP (mol of Zr [C_3] h)$^{-1}$} could be observed for complex **3b/**[$(C_6H_5)_3C^+$][$(C_6F_5)_4B^-$] indicating that this cocatalyst provides a maximized concentration of active Zr^{IV} centers.[20]

The exchange of the ethylene bridge by a dimethylsilane unit results in slightly declined polymerization activities at T_P = 30 °C which, however, distinctly increases up to 3800 kg PP (mol of Zr [C_3] h)$^{-1}$ at 50 °C; **3c**/MAO is the first dimethylsilane-bridged system we investigated that shows not a rapid decomposition during the first minutes of the polymerization reaction,[1b] but rather leads to a constant propene consumption.

[a] Bond lengths are given in Å and angles in °. [b] av. Zr−centroid (Cp^{Flu},Cp^{Ind}) is the mean value of the 5 bonds of the carbon atom of the Cp plane to the Zr atom.

Molecular Weights

The molecular weights of the polypropenes obtained with **3a**−**c** decrease at higher Al/Zr ratios (Figure 3). The polydispersities of the polymer products are within the narrow range of 1.7 to 2.0 indicating homogeneous polymerization conditions. This decline shows again that chain transfer to aluminum plays a decisive role,[4,21] in line with the above discussion of catalyst activities. As a result of this facile chain termination reaction isopropyl end groups are observed after acidic workup (Figure 4)[5] instead of vinylic chain ends resulting from spontaneous β-H abstraction. After borate activation of **3b**, excluding the possibility of transfer to aluminum, the molecular weights improved from 3.0×10^4 up to 16.0×10^4 g mol^{-1} (Table 2, Entries 4, 8).

Stereoregularity

The [mmmm] pentad concentration of the polymers products resulting from **3a**−**c** varies over a broad range (34−65%, cf. Table 3) depending on temperature, monomer concentration and bridging unit. These results are in accordance with our recently published chain back-skip mechanism based on fluorenyl and indenyl units and with the slightly increased tacticity found for dimethylsilane-bridged zirconocenes.[1,22] Interestingly, the isotacticities of the polymers prepared with **3a**,**c**/MAO are independent of the Al/Zr

ratio. This is a surprising finding because reduced activities and molecular weights indicate a direct interaction of MAO and Zr^{IV} centers which we expected to affect also the stereoselectivity of the insertion reaction. Moreover, borate activation (**3b**/[$(C_6H_5)_3C^+$][$(C_6F_5)_4B^-$]) leads to increased isotacticities (Table 3, Entries 1–4, 6, 7) proving that MAO does contribute to the overall stereoselectivity of the polymerization reaction. One possible explanation of this striking role of MAO in the error formation process might be a reversible chain transfer reaction. The reduced molecular weights of the polymer products at higher Al/Zr ratios proved the unidirectional transfer of polymer chains from Zr^{IV} to aluminum. Relocation from aluminum to the other enantiomer of the C_1-symmetric catalyst species would lead to the formation of a single stereoerror and could – at enhanced frequencies – account for the observed reduction of isotacticities in case of MAO-activated complexes.[23]

Besides electronics effects,[4,24] for which we assume that they are not relevant for our type of asymmetric catalysts and different side selectivity (back-skip), chain end epimerization[25] could be responsible for stereoerror formation. In order to rule out this mechanism, we performed deuterium labeling experiments on stereoerror distributions of the asymmetric zirconocene **3a** and referenced the results to **EBI**/MAO as a representative, C_2-symmetric catalyst typically undergoing chain end epimerization at low monomer concentrations.

For **3a**/MAO we could not detect isomerization-induced stereoerrors at any of the applied monomer concentrations,[26] while for **EBI**/MAO a decrease in the monomer concentration raised the amount of [D]-[mrrm] stereoerror pentads, as expected (Figure 5, Table 3). These findings reflect a significant difference in the mechanism of stereoerror formation for these two catalyst systems. For **EBI**/MAO [mrrm] stereoerrors result to a large extent from kinetically competitive chain end isomerization reactions. The decisive factor causing stereoerrors in **3a**/MAO at high monomer concentrations is the kinetic competition between chain back-skip and monomer coordination to the aspecific side of the catalyst structure. At low C_3 pressure, a significant fraction of stereoerrors can be most likely ascribed to the above discussed reversible transfer to aluminum.

Table 3. Polypropene pentad distribution for C_2-symmetric **EBI**/MAO and C_1-symmetric **3a**/MAO (T_p = 50 °C)

Entry	Cat.[a]	Mon.[b]	[Mon.] [mol L^{-1}]	Al/Zr	[mmmm] [%]	[mmrr]	[mrrm]	[D]-[mrrm]

Conclusion

The asymmetric, dual-side catalysts presented in the current study combine both, the excellent capability of C_1-symmeteric metallocenes to produce tailor-made polypropenes and the potential to incorporate functionalities into highly active metallocene catalysts. The introduction of the heteroatoms into a benzodioxane ring enhances the catalyst stability during the polymerization process. The oxygen substitution obviously promotes MAO approach to the catalyst center resulting in high rates of catalyst activation at low cocatalyst concentrations (high cocatalyst efficiency). On the other side, facile chain transfer to aluminum is already observed at lower Al/Zr ratios again pointing toward the close proximity of Zr^{IV} and Al^{MAO} ions. The observed catalyst stereoselectivities are discussed by chain back-skip and by a mechanism for which MAO operates as a transporting agent of polymer chains between zirconium centers. Thereby, relocation of a chain from one enantiomer to the other leads to stereoerrors which afford the formation of lower isotactic polypropenes.

Experimental Section

General Remarks: All reactions were performed under dry argon using standard Schlenk techniques. Hydrocarbon and ether solvents were dried by distillation from $LiAlH_4$, dichloromethane was distilled from CaH_2. Fluorene, 1,2-(ethylenedioxy)benzene, 1,2-dibromoethane, methacryloyl chloride, *n*BuLi, MeLi, $ZrCl_4$, $AlCl_3$ and (*Z*)/(*E*)-1-bromo-1-propene (98%) and [D_1]methanol (99.5%) were used as received from Merck and Aldrich. The complex **EBI**[1b] and the trityl borate $[(C_6H_5)_3C^+][(C_6F_5)_4B^-]$[27] were prepared according to literature procedures. Methylaluminoxane and triisobutylaluminum were purchased from Witco and toluene for the polymerization reactions from Merck. All compounds were analyzed by ^1H NMR with a Bruker AC 200 or AMX 500 at ambient temperatures and referenced to TMS. Mass spectra were acquired with Finnigan (SSQ 7000) and Varian (MAT-711) instruments. Elemental analyses were determined in the Microanalytical Laboratory of the University of Ulm.

1-[D]-Propene: A mixture of (*Z*)/(*E*)-1-bromo-1-propene (72 g, 0.6 mol) was added to freshly cut lithium (12.5 g, 1.8 mol) in 300 mL of ether at 0 °C. After stirring overnight, the mixture was filtered and the filtrate concentrated to dryness. The resulting white solid lithium compounds were suspended in 200 mL of toluene. At 0 °C [D_1]methanol (24 g, 0.73 mol) was added and the evolving gas was condensed through a cold trap at −50 °C into a steel vessel at −196 °C. The gas was further purified by passing it through molecular sieves and bubbling it through triisobutylaluminum, resulting in a yield of 20.5 g of 1-[D]-propene (80%). The ^1H NMR spectrum [$CDCl_3$ (δ = 7.24), 500 MHz] showed that the product contained 41% of (*E*)-1-[D]-propene (*H*DC=CHCH$_3$) [δ = 4.91 (dq, ^3J = 10.0, ^4J = 1.5 Hz, 1 H)] and 59% of (*E*)-1-[D]-propene [δ = 5.00 (dq, ^3J = 17.0, ^4J = 1.8 Hz, 1 H)].

Polymerization Reactions with 1-[D]-Propene: Polymerizations with deuterated propene were performed in a 50-mL steel autoclave. The solvent toluene, cocatalyst MAO and the catalyst were fed under argon and allowed to reach the desired polymerization temperature.

After 10 min of contact time, monomer was added, and temperature (±1 °C) and pressure (±100 mbar) were kept constant. The polymerization was stopped by pouring the reaction mixture into acidified methanol. The polymer product was washed with a methanol/HCl solution and with methanol. The product was filtered and dried in vacuo at 60 °C overnight. The yields of deuterated polypropene were between 0.2 and 0.8 g.

Propene Polymerization Reactions: The polymerization reactions were performed in a 0.5-L or a 1-L Büchi steel reactor at constant pressure and temperature. The autoclave was charged with 200 or 300 mL of toluene, respectively, and with the desired amount of MAO. Subsequently, the polymerization temperature was adjusted, the reactor was charged with propene up to the desired partial pressure, and the preactivated catalyst solution (Al/Zr = 100:1) was injected into the autoclave via a pressure burette. The monomer consumption was measured by the use of a calibrated gas flow meter (Bronkhorst F-111C-HA-33P), and the pressure was kept constant during the entire polymerization period (Bronkhorst pressure controller P-602C-EA-33P). Pressure, temperature and consumption of propene were monitored and recorded online. The polymerization reactions were stopped and treated as described above.

Polymer Analysis: ^{13}C NMR spectra were recorded with a Varian GEMINI 2000 spectrometer ($C_2D_2Cl_4$, 100 °C, 75 MHz, 10 mm probe) or a Bruker AMX 500 spectrometer ($C_2D_2Cl_4$, 80 °C, 125 MHz, 5 mm probe) in the inverse gated decoupling mode with a 3-s pulse delay and a 45° pulse to attain conditions close to the maximum signal-to-noise ratio. The number of transients accumulated was between 5 and 15 K. The spectra were analyzed by known methods.[28] Molecular weights and molecular weight distributions were determined by gel permeation chromatography (GPC, Waters 2000, 140 °C in 1,2,4-trichlorobenzene) relative to polystyrene and polypropene standards.

5,6-(Ethylenedioxy)-2-methylindene (1): 42.7 mL (367.2 mmol) of 1,2-(ethylenedioxy)benzene was added slowly at −78 °C to a stirred solution of 51.4 g of $AlCl_3$ (385.6 mmol) and 35.7 mL (367.2 mmol) of methacryloyl chloride in 300 mL of dichloromethane and allowed to attain room temperature overnight. The solution was carefully hydrolyzed with ice, and the organic phases were separated, washed with an aqueous solution of K_2CO_3 and dried with Na_2SO_4. After removing the solvent and crystallization in pentane, 5,6-(ethylenedioxy)-2-methylindan-1-one was obtained as a solid (62.7 g, 306.9 mmol, 84%). 40.0 g (195.9 mmol) of 5,6-(ethylenedioxy)-2-methylindan-1-one was diluted in 100 mL of Et_2O and added at −78 °C to a suspension of 5.0 g of $LiAlH_4$ (131.7 mmol) in 100 mL of Et_2O. The reaction mixture was stirred overnight and carefully hydrolyzed with ice and aqueous HCl. After separating the organic phases, the solution was neutralized with an aqueous solution of K_2CO_3 and dried with Na_2SO_4. After evaporation of the solvent and crystallization from toluene/hexane (ca. 3:2) the diastereomeric alcohols were obtained as a crystalline solid (27.3 g, 132.3 mmol, 68%). The alcohol (15.0 g, 72.73 mmol) was dissolved in 100 mL of toluene and 1.0 g of *p*-toluenesulfonic acid was added. The solution was heated under reflux using a water separation funnel until no further water was produced. The reaction mixture was neutralized by washing with aqueous KOH and was subsequently dried with Na_2SO_4. The solvent was evaporated, and the indene **1** was obtained as a crystalline solid (7.8 g, 41.46 mmol, 57%). Data of the ketone: ^1H NMR (200 MHz, $CDCl_3$): δ = 1.27 (d, 3 H, CH_3), 2.63 (m, 2 H, CH_2, indanone ring), 3.27 (m, 1 H, CH, indanone system), 4.29 (m, 4 H, CH_2, dioxane ring), 6.68, 7.25 (2 s, 2 H, aromatic). MS (GC-MS): *m*/*z* (%) = 204 (100) [M^+]. $C_{12}H_{12}O_3$ (204.2): calcd. C 70.58, H 5.92; found C 70.96, H 5.92. Data of the Alcohol: ^1H NMR (200 MHz, $CDCl_3$): δ = 1.11 (d, 3 H, CH_3), 1.79 (broad, 1 H, OH group), 2.33 (d, 2 H, CH_2, indanol ring), 2.95 (m, 1 H, CH, indanol ring), 4.13 (m, 4 H, CH_2, dioxane ring), 4.55 (d, 1 H, CH, indanol ring), 6.61, 6.80 (2 s, 2 H, aromatic). MS (GC-MS): *m*/*z* (%) = 206 (100) [M^+]. $C_{12}H_{14}O_3$ (206.2): calcd. C 69.88, H 6.84; found C 69.66, H 6.79. Data of **1**: ^1H NMR (200 MHz, $CDCl_3$): δ = 2.15 (s, 3 H, CH_3), 3.20 (s, 2 H, CH_2, indene ring), 4.21 (m, 4 H, CH_2 dioxane ring), 6.31 (s, 1 H, CH olefinic), 6.80, 7.30 (2 s, 2 H, aromatic). MS (GC-MS): *m*/*z* (%) = 188 (100) [M^+]. $C_{12}H_{12}O_2$ (188.2): calcd. C 76.57, H 6.43; found C 76.16, H 6.59.

1-[5,6-(Ethylenedioxy)-2-methylindenyl]-2-(9-η^5-fluorenyl)ethane (2aH_2): 4.35 g (26.16 mmol) of fluorene was dissolved in 100 mL of Et_2O and cooled to −78 °C. Addition of a 1.6 M solution of *n*BuLi in hexane (16.4 mL, 26.16 mmol) and stirring for additional 2 h afforded the formation of fluorenyllithium. Subsequent cooling to −78 °C and further treatment with an excess of 1,2-dibromoethane (13.6 mL, 160 mmol) formed the substituted fluorenyl compound. The remaining mixture was allowed to attain room temperature and stirred for additional 4 h. Removal of the solvent and excess of 1,2-dibromoethane yielded the fluorenyl intermediate as a beige solid. This solid was added after dilution with 100 mL of Et_2O at ambient temperature to the separately prepared lithium salt of the 5,6-(ethylenedioxy)-2-methylindene (**1**) (4.92 g, 26.16 mmol). The reaction mixture was stirred overnight and refluxed for 2 h. The crude product was treated with a saturated aqueous solution of NH_4Cl and washed several times with water. The organic phase was separated and dried with Na_2SO_4. Evaporation of the solvent and crystallization from *n*-hexane yielded **2a**H_2 as a white solid (4.45 g, 11.7 mmol, 45%). Data of **2a**H_2: ^1H NMR (200 MHz, $CDCl_3$): δ = 1.25−1.69 (m, 4 H, CH_2 bridge), 1.78 (s, 3 H, CH_3), 2.97 (t, 1 H, CH, indene), 3.8 (t, 1 H, CH, 9*H*-fluorene), 4.17 (m, 4 H, CH_2, dioxane ring), 6.23 (s, 1 H, olefinic indene), 6.60, 6.63 (2 s, 2 H, aromatic indene), 7.16−7.70 (m, 8H, aromatic fluorene). MS (EI): *m*/*z* (%) = 380 (100) [M^+]. $C_{27}H_{24}O_2$ (380.5): calcd. C 85.23, H 6.36; found C 85.15, H 6.48.

(5,6-Ethylenedioxy-2-methylindenyl)(9-η^5-fluorenyl)dimethylsilane (2bH_2): 4.09 g (24.62 mmol) of fluorene was dissolved in 150 mL of Et_2O and cooled to −78 °C. Addition of a 1.6 M solution of *n*BuLi in hexane (15.4 mL, 24.62 mmol) and stirring for additional 4 h resulted in the formation of fluorenyllithium. Subsequent cooling to −78 °C and further treatment with an excess of dichlorodimethylsilane (13.6 mL, 98.5 mmol) afforded the substituted fluorenyl compound. The remaining mixture was allowed to attain room temperature and stirred for additional 2 h. Removal of the solvent and excess of dichlorodimethylsilane in vacuo gave the fluorenyl intermediate as a beige powder. This solid was added after dilution with 100 mL of Et_2O at ambient temperature to the separately prepared lithium salt of 5,6-(ethylenedioxy)-2-methylindene (**1**) (4.63 g, 24.62 mmol). The reaction mixture was stirred overnight and refluxed for 2 h. The crude product was treated with a saturated aqueous solution of NH_4Cl and washed several times with water. The organic phase was separated and dried with Na_2SO_4. Evaporation of the solvent and recrystallization from *n*-hexane yielded **2b**H_2 as a white solid (7.2 g, 17.8 mmol, 72%). Data of **2b**H_2: ^1H NMR (200 MHz, $CDCl_3$): δ = −1.64, −1.57 − (2 s, 6 H, CH_3 bridge), 0.94 (s, 3 H, CH_3), 3.03 (m, 4 H, CH_2, dioxane ring), 5.26 (s, 1 H, CH, olefinic), 5.63, 5.77 (2 s, 2 H, aromatic indene), 6.02−6.74 (m, 8 H, aromatic fluorene). MS (EI): *m*/*z* (%) = 410 (100) [M^+]. $C_{27}H_{26}O_2Si$ (410.6): calcd. C 78.98, H 6.38; found C 78.65, H 6.41.

***rac*-{1-[5,6-(Ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)-ethane}zirconium Dichloride (3a):** 1.7 g (4.47 mmol) of 1-[5,6-(ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)-ethane (**2a**H_2) was dilssolved in 150 mL of Et_2O and cooled to −78 °C. After treatment of the ligand precursor with 5.6 mL of *n*BuLi at −78 °C, the reaction mixture was warmed to room temperature and stirred for 4 h. Subsequently, the solvent was removed in vacuo and the resulting lithium salt was diluted with 60 mL of toluene. Cooling to −78 °C and addition of solid $ZrCl_4$ (1.04 g, 4.47 mmol) afforded the formation of an orange suspension which was warmed to room temperature and stirred overnight. The mixture was filtered, and the remaining solid fraction was extracted with toluene until the organic phase remained colorless. Removal of the solvent gave an orange powder from which pure **3a** (2.05 g, 3.79 mmol, 91%) could be obtained by crystallization from toluene solution. Data of **3a**: ^{1}H NMR (500 MHz, $CDCl_3$): δ = 2.14 (s, 3 H, CH_3), 3.72−4.58 (m, 4 H, CH_2, bridge), 6.01, 6.75 (s, 1 H, aromatic indene), 7.14−7.95 (m, 9 H, aromatic indene, aromatic fluorene). MS (EI): *m*/*z* = 538 (peak distribution of isotopes according to expected contents). $C_{27}H_{22}Cl_2O_2Zr$ (540.6): calcd. C 59.99, H 4.10; found C 59.56, H 4.17.

***rac*-{1-[5,6-(Ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)ethane}dimethylzirconium (3b):** 0.75 g (1.97 mmol) of 1-[5,6-(ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)ethane (**2a**H_2) was dissolved in 50 mL of Et_2O and cooled to −78 °C. After treatment of the ligand precursor with 4.94 mL (7.90 mmol) of MeLi at −78 °C, the reaction mixture was warmed to room temperature and stirred for 4 h. Solid $ZrCl_4$ (0.46 g, 1.97 mmol) was added to the stirred suspension of the lithium salt of **2a**H_2 at room temperature and the reaction mixture was stirred for 24 h with a final formation of a light-brown suspension. The solvent was removed in vacuo and replaced with toluene. The suspension was filtered and the residual solid fraction was extracted with toluene until the organic phase remained colorless. Removal of the solvent gave a yellow powder from which pure **3b** (0.66 g, 1.32 mmol, 67%) could be obtained by crystallization from toluene. Data of **3b**: ^{1}H NMR (200 MHz, $CDCl_3$): δ = −2.34, −1.36, (2 s, 6 H, CH_3), 1.94 (s, 3 H, CH_3), 3.37−4.21 (m, 4 H, CH_2 bridge), 5.97 (s, 1 H, indene), 6.65, 6.89 (2 s, 2 H, aromatic indene), 6.99−7.94 (m, 8 H, aromatic fluorene). $C_{29}H_{28}O_2Zr$ (499.8): calcd. C 69.70, H 5.65; found C 69.43, H 5.88.

***rac*-{[5,6-(Ethylenedioxy)-2-methyl-1-η^5-indenyl](9-η^5-fluorenyl)dimethylsilane}zirconium Dichloride (3c):** 1-[5,6-(Ethylenedioxy)-2-methyl-1-η^5-indenyl]-2-(9-η^5-fluorenyl)dimethylsilane (**2b**H_2) (1.80 g, 4.38 mmol) was dissolved in 50 mL of Et_2O and cooled to −78 °C. After treatment of the ligand precursor with 5.5 mL of *n*BuLi at −78 °C, the reaction mixture was warmed to ambient temperature and stirred for 2 h. Subsequently, the solvent was removed in vacuo and the resulting lithium salt was diluted with 50 mL of toluene. Cooling to −78 °C and addition of solid $ZrCl_4$ (1.02 g, 4.38 mmol) afforded the formation of an orange suspension which was warmed to room temperature and stirred overnight. The mixture was filtered, and the remaining solid fraction was extracted with toluene until the organic phase remained colorless. Removal of the solvent gave an orange powder. The zirconocene **3c** (1.37 g, 2.41 mmol, 55%) could be purified by washing with Et_2O and pentane. Data of **3c**: ^{1}H NMR (200 MHz, $CDCl_3$): δ = −0.44, −0.37 (2 s, 6 H, CH_3, bridge), 2.13 (s, 3 H, CH_3), 4.22 (m, 4 H, CH_2, dioxane ring), 6.46 (s, 1 H, indene), 6.82, 6.96 (2 s, 2 H, aromatic indene), 7.14−7.88 (m, 8 H, aromatic fluorene). MS (EI): *m*/*z* = 568 (peak distribution of isotopes according to expected contents). $C_{27}H_{24}Cl_2O_2SiZr$ (570.7): calcd. C 56.82, H 4.24; found C 56.58, H 4.54.

X-ray Crystallography: The unit cell parameters were determined and the crystal data of **3a** was collected with a Rigaku AFC7S single-crystal diffractometer at 193(2) K using Mo-K_α radiation (graphite monochromator, 0.71073 Å); 2-θ/ω scans. Intensities were corrected for Lorentz and polarization effects; TEXSAN (Molecular Structure Corporation, **1993**).[29] A ψ-scan absorption correction was made, 0.89 < T < 1.00 (North et al., **1968**).[30] Solution and refinement: SHELX97 (Sheldrick, **1997**),[31] direct methods. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined on calculated positions. The displacement factors of the H atoms were 1.2× or 1.5× to that of the host atom. One disordered toluene molecule is occupying the centre of symmetry. Graphics: SHELXTL/PC (Sheldrick, **1990**).[32] Deatils are listed in Table 4. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-164853. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Coordination of Ferrocenyl Ligands Bearing bipy Subunits: Electrochemical, Structural and Spectroscopic Studies

Ana Ion,[a] Mihai Buda,[a] Jean-Claude Moutet,*[b] Eric Saint-Aman,[b] Guy Royal,[b] Isabelle Gautier-Luneau,[c] Michel Bonin,[d] and Raymond Ziessel[e]

Keywords: N ligands / Sandwich complexes / Iron / Receptors / Cyclic voltammetry

The coordinative properties of mono(bipy) and bis(bipy) (bipy refers to 6- or 6,6′-substituted 2,2′-bipyridine) carbonyloxy- and carboxamido-bridged derivatives of ferrocene $\mathbf{L^{1-5}}$ towards a number of metal cations (Cu^{I}, Cu^{II}, Ni^{II}, Fe^{II}, Co^{II}, Hg^{II}, Pb^{II}, Ag^{I}) have been investigated by the interplay of voltammetry, mass spectrometry and X-ray diffraction studies. Particular attention was paid to the electrochemical recognition properties of these redox-active ligands, as monitored by modulation of the ferrocene/ferricinium redox couple upon complexation. It was found that the bis(bipy)-bridged ligands exhibit a *sandwich effect* that gives rise to a well-behaved voltammetric wave for the ferrocene fragment as an elegant signature of complexation. The ferrocenyl ester-bridged bis(bipy) ligand $\mathbf{L^2}$ forms a 2:2 complex in the solid state with Cu^{I}, while the crystal structure of the Cu^{II} complex reveals 1:1 stoichiometry. Upon dissolution, the 2:2 species dissociate rapidly into the $[Cu\mathbf{L^2}]^{+}$ complex. Finally, electrochemical and FAB-MS data have been used to conclude that these ferrocenyl ligands bind to iron(II) to generate unusual $[Fe(bipy)_2]^{2+}$-type complexes.

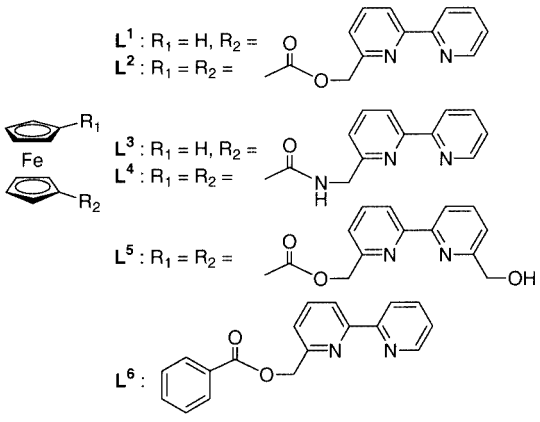
Introduction

Molecular structures comprising two or more coordinated cations are of considerable interest as reversible electron reservoirs able to effect the successive release of electrons. Such polynuclear metal complexes are also useful models for studying the effect of electronic coupling between metal centres in different oxidation states and for the coupling of a remote redox-active metal centre to a putative catalytic site. In earlier work, it was demonstrated that polypyridine ligands functionalized with ferrocene[1−4] could be used for the electrochemical recognition of certain metal cations in both homogeneous solution[1,2] and polymeric films,[3] and that the resultant dinuclear complexes displayed significant levels of electronic coupling between the metal sites. In extending this work, we now report on the complexation of selected metal cations (Cu^{I}, Cu^{II}, Ni^{II}, Fe^{II}, Co^{II}, Hg^{II}, Pb^{II}, Ag^{I}) with 1-bipy (bipy = 2,2′-bipyridine) and carbonyloxy- or carboxamide-bridged 1,1′-bis(bipy) derivatives of ferrocene (ligands $\mathbf{L^{1-5}}$, Scheme 1). Special attention has been given to studying the effect of cation binding on the electrochemical properties of the ferrocene units.



Scheme 1. Structures of ligands $\mathbf{L^{1-6}}$

In a preliminary study,[1] it was reported that the ester-bridged mono(bipy) and bis(bipy) derivatives of ferrocene ($\mathbf{L^1}$ and $\mathbf{L^2}$) are able to complex Cu^{I} and Cu^{II} by ensuring a bis(bipyridyl) environment around the bound cation. The crystal structure of the complex formed between $\mathbf{L^2}$ and Cu^{I} revealed the formation of a 2:2 (2 Cu^{I} + 2 $\mathbf{L^2}$) complex

having a *pseudo*-tetrahedral geometry around each cation. The molecular structure was best described as a double-stranded metallo-helicate, with each ligand wrapping around the two copper cations. X-ray structural determination of the $\mathbf{L^2}$ + Cu^{II} complex remains elusive at this time. However, the formation of a mononuclear Cu^{II} complex was evident from EPR experiments. It was further shown that redox ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ recognize copper cations by way of a large shift in the ferrocene/ferricinium (Fc/Fc^+) redox couple. Recently,[2] the formation of bis(bipy)Fe^{II} species upon coordination of Fe^{II} with the carboxamide-bridged mono- and bis(bipy) derivatives $\mathbf{L^{3,4}}$ was deduced from voltammetry, ^1H NMR spectroscopy, FT-IR spectroscopy and mass spectrometry studies. Furthermore, X-ray structural determination of the 1:1 $\mathbf{L^4}$ + Fe^{II} complex showed that the Fe^{II} coordination environment is provided by four nitrogen atoms belonging to the bipy subunits and by two oxygen atoms of the carbonyl groups lying in a "*cis*" environment and describing a distorted octahedral arrangement.

In this paper, we describe the coordination chemistry of copper cations with these ligands, paying particular attention to the complexation process between $\mathbf{L^2}$ and Cu^I. Furthermore, the possibility of obtaining a complex involving an Fe^{II} cation in a bis(bipy) environment from the ester-bridged derivatives $\mathbf{L^{1,2}}$ is also examined, as well as the electrochemical recognition properties of ligands $\mathbf{L^{1-5}}$ towards Ni^{II}, Co^{II}, Hg^{II}, Pb^{II} and Ag^I metal cations.

Results and Discussion

The electrochemical behaviour of the free ligands $\mathbf{L^{1-5}}$ in CH_3CN or CH_2Cl_2 solution is characterized by a one-electron, reversible wave that can be attributed to the ferrocene/ferricinium (Fc/Fc^+) redox couple (Table 1). The main purpose of the current investigation is to examine how complexation of $\mathbf{L^{1-5}}$ by various metal cations (Cu^I, Cu^{II}, Ni^{II}, Fe^{II}, Co^{II}, Hg^{II}, Pb^{II}, Ag^I) affects the electrochemical properties of the ferrocene unit.

Table 1. Electrochemical data for free ligands

[a]	$\mathbf{L^1}$	$\mathbf{L^2}$	$\mathbf{L^3}$	$\mathbf{L^4}$	$\mathbf{L^5}$
CH_3CN	0.33[b]	0.56[b]	0.26[c]	0.53[c]	0.59
CH_2Cl_2	0.45[b]	0.69[b]	[d]	0.51[c]	[d]

[a] $E_{1/2}$ [V] vs. $Ag/AgNO_3$ (0.01 M) + CH_3CN + TBAP (0.01 M), measured by CV at 0.1 V s^{-1}. [b] From ref.[1] [c] From ref.[3] [d] Not determined.

In general, addition of increasing amounts of a given metal cation to a solution of ferrocenyl ligand might be expected to cause one of two effects on the electrochemical activity of the Fc centre. First, cation complexation might induce a gradual positive shift in the Fc/Fc^+ redox potential (one-wave behaviour) due to electrostatic repulsion between the bound cation and the electrogenerated positive charge on the oxidized ferrocenyl subunit. This leads to a decrease of the association constant K_+ with the oxidized ligand and to a destabilisation of the resulting complex.[5] Consequently, $\Delta E_{1/2}$ reflects the balance of interactions between the neutral and charged ligand in its oxidized form with the adventitious metal cation.

Second, we might observe the growth of a new redox wave (two-wave behaviour) at the expense of the original wave for the free ligand. The two-wave behaviour can be linked to a high binding constant K with the neutral ligand in association with a large K/K_+ ratio.[6] It may also, in part, be due to a structural effect i.e. complexation of the binding centre can lead to noncoplanarity of the Cp rings in the complex which is known to result in a marked positive potential shift in complexed[5,7] or strained[8] ferrocenophanes. It should be emphasized that a two-wave feature allows the amperometric recognition and titration of the guest cation, while a one-wave behaviour allows a potentiometric titration.

In general, mono(bipy) ligands $\mathbf{L^1}$ and $\mathbf{L^3}$ form 1:2 (metal/ligand) complexes and give rise to weak complexation and one-wave behaviour, while bis(bipy) ligands $\mathbf{L^2}$ and $\mathbf{L^4}$ form 1:1 complexes and give rise to two-wave behaviour. The bis(bipy) ligand $\mathbf{L^5}$ forms 1:1 complexes, but shows reduced bonding and one-wave behaviour.

In addition to the change in the electroactivity of the Fc centre, the rise of new redox peak systems due to the formation of an electroactive metal complex can be observed in the CV profile. When the emergent complex is fairly stable, all the electrochemical perturbations reach full development at a metal cation/ligand mol ratio corresponding to the stoichiometry of the resultant complex.

Complexation of $\mathbf{L^{1-5}}$ with Cu^I and Cu^{II} Cations

The electrochemical data for complexes formed between $\mathbf{L^{1-5}}$ and Cu^I are summarized in Table 2. The relatively high Cu^I/Cu^{II} redox potential found for these complexes are in good agreement with those reported previously for various copper polypyridyl compounds.[9] In comparative experiments, we found that the reversible $Cu^{I/II}$ oxidation for the $[Cu(bipy)_2]^+$ complex occurs at $E_{1/2} = -0.19$ V, and at 0.26 V for the $[Cu(\mathbf{L^6})_2]^+$ complex where $\mathbf{L^6}$ is a bipy ligand simply mono-substituted with an electron-withdrawing carbonyloxy group.

Table 2. Electrochemical data for $\mathbf{L^1}$, $\mathbf{L^2}$, $\mathbf{L^3}$, $\mathbf{L^4}$, $\mathbf{L^5}$ + Cu^I

[a]	2 $\mathbf{L^1}$ + Cu^I [b]		$\mathbf{L^2}$ + Cu^I [b]		2 $\mathbf{L^3}$ + Cu^I	
	Fc/Fc^+	Cu^I/Cu^{II}	Fc/Fc^+	Cu^I/Cu^{II}	Fc/Fc^+	Cu^I/Cu^{II}
CH_3CN	0.38	0.19	0.71	0.10	0.37	−0.04
CH_2Cl_2	ads.	0.33	0.84	0.23	[c]	[c]
	$\mathbf{L^4}$ + Cu^I		$\mathbf{L^5}$ + Cu^I			
	Fc/Fc^+	Cu^I/Cu^{II}	Fc/Fc^+	Cu^I/Cu^{II}		
CH_3CN	0.60	−0.20	0.64	0.08		
CH_2Cl_2	0.67	−0.15	[c]	[c]		

[a] $E_{1/2}$ [V] vs. $Ag/AgNO_3$ (0.01 M) (see Table 1). [b] From ref.[1] [c] Not determined.

Complexation of $\mathbf{L^1}$ and $\mathbf{L^5}$ with Cu^I in CH_3CN solution results in a one-wave behaviour for the electrochemical response of the Fc centre, along with the rise of a redox peak system attributable to the complexed Cu^I/Cu^{II} redox couple (Table 2). The positive potential shift in the Fc/Fc^+ wave is equal to 50 mV for both ligands. Similar features in the CV behaviour of $\mathbf{L^1}$ and $\mathbf{L^5}$ are evident upon addition of Cu^I or Cu^{II}. Maximal potential shift of the Fc/Fc^+ wave and maximal intensity of the complexed Cu^I/Cu^{II} peak system are obtained at a $Cu^I/\mathbf{L^1}$ and $Cu^I/\mathbf{L^5}$ molar ratio equal to 0.5 and 1, respectively. This result is in keeping with the formation of $[Cu(\mathbf{L^1})_2]^+$ and $[Cu\mathbf{L^5}]^+$ complexes that provide for a bis(bipyridyl) environment around the bound cation. The 1:2 stoichiometry for isolated $[Cu(\mathbf{L^1})_2]^+$ was previously established.[1]

The complexation of $\mathbf{L^{2-4}}$ with Cu^I cations causes the emergence of a new redox peak system (two-wave behaviour) corresponding to the complexed Fc/Fc^+ redox couple

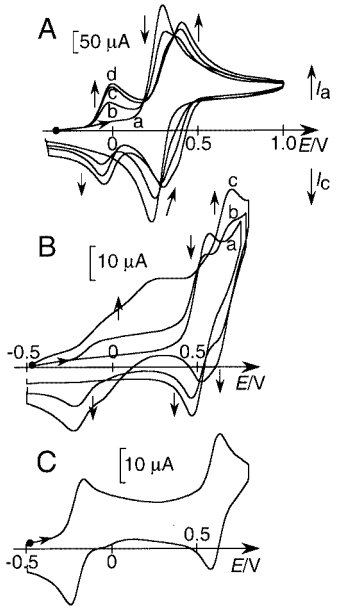

Figure 1. Cyclic voltammograms at a Pt disk (5 mm diameter) of (A) $\mathbf{L^3}$ (2.9 mM) in CH_3CN + TBAP 0.1 M: (a) free $\mathbf{L^3}$; (b) $\mathbf{L^3}$ + 0.2 Cu^+; (c) $\mathbf{L^3}$ + 0.4 Cu^+; (d) $\mathbf{L^3}$ + 0.5 Cu^+; (B) $\mathbf{L^4}$ (1.2 mM) in CH_2Cl_2 + TBAP 0.1 M: (a) free $\mathbf{L^4}$; (b) $\mathbf{L^4}$ + 0.5 Cu^+; (c) $\mathbf{L^4}$ + 1.0 Cu^+; (C) $[Cu\mathbf{L^4}](ClO_4)$ (0.5 mM) in CH_3CN + TBAP 0.1 M; scan rate 0.1 V s^{-1}

(see Figure 1, for example). Due to poor solubility of $\mathbf{L^4}$ in CH_3CN, complexation of this ligand with Cu^I was studied in CH_2Cl_2 (see B in Figure 1). The electrochemical data in CH_3CN solution were obtained, starting with the isolated $\mathbf{L^4}$ + Cu^I complex (see C in Figure 1).

A CV titration shows that the apparent stoichiometry of the complexes formed between $\mathbf{L^2}$, $\mathbf{L^3}$, or $\mathbf{L^4}$ and Cu^I or Cu^{II} is equal to 1:1, 1:2 and 1:1 (metal cation/ligand), respectively. The stoichiometry has been confirmed by MS data. The FAB-MS spectra of the isolated complexes exhibit peaks at m/z = 673 ($[Cu\mathbf{L^2}]^+$); 957 and 857 $\{[Cu(\mathbf{L^3})_2](ClO_4)^+$ and $[Cu(\mathbf{L^3})_2]^+$, respectively$\}$; 771 and 671 $\{[Cu\mathbf{L^4}](ClO_4)^+$ and $[Cu\mathbf{L^4}]^+$, respectively$\}$.

Complexation of Cu^I or Cu^{II} by $\mathbf{L^2}$ has been further studied. We reported previously that the crystal structure of the complex formed between $\mathbf{L^2}$ and Cu^I reveals the formation of a 2:2 (2 Cu^I + 2 $\mathbf{L^2}$) metallo-helicate complex, while the formation of a mononuclear Cu^{II} complex is evident from EPR experiments.[1] The latter result has been confirmed in this study where the X-ray structure of the isolated $[Cu\mathbf{L^2}](ClO_4)_2$ complex revealed the formation of a 1:1 complex (vide infra). The question of the conversion in solution between $[Cu_2(\mathbf{L^2})_2]^{2+}$ and $[Cu\mathbf{L^2}]^+$ thus remains to be addressed. In particular, identical electrochemical features, i.e. superimposable CV curves and same potentials for both complexed Cu^I/Cu^{II} and Fc/Fc^+ redox couples, were obtained following the addition of Cu^{II} instead of Cu^I. In addition, no change in the $E_{1/2}$ value and in the reversibility of the Cu^I/Cu^{II} and Fc/Fc^+ redox couples could be observed in the 5×10^{-2} M (saturated electrolytic solution, prepared from the isolated complex) to 10^{-5} M concentration range, demonstrating that no change occurs in the stoichiometry of the dissolved complex.[1]

Formation of 1:1 and 1:2 complexes from the dimer has been observed by high-resolution ES mass spectrometry upon dissolution of an authentic sample of $[Cu_2(\mathbf{L^2})_2](BF_4)_2$. ES mass spectra were recorded in the 5×10^{-5} to 5×10^{-3} M concentration range. Peaks at m/z (%) = 673.1 (100) and 1283.5 are observed from the ES mass spectra (Figure 2). The isotopic peaks are separated by 1.0 m/z unit, revealing a charge state of +1 for the corresponding ions. Therefore, the peaks at 673.3 and 1283.5 correspond to the $[Cu\mathbf{L^2}]^+$ and $[Cu(\mathbf{L^2})_2]^+$ species, respectively. In addition, the intensity of the peak at 1283.5 appears very weak and decreases with concentration from 1.1% at 5×10^{-3} M down to 0.5% at 5×10^{-5} M, while no peaks characteristic of the $[Cu_2(\mathbf{L^2})_2]^{2+}$ entity or additional peaks corresponding to other species could be detected in the ES-MS spectra. Interestingly, the formation of the 1:1 and 1:2 complexes from the genuine $[Cu_2(\mathbf{L^2})_2](BF_4)_2$ complex should be accompanied with the release of free Cu^I cations. Indeed, a weak peak at 186.7 (not shown in Figure 2) corresponding to $[Cu(CH_3CN)_3]^+$ is simultaneously observed during the ES-MS analyses.

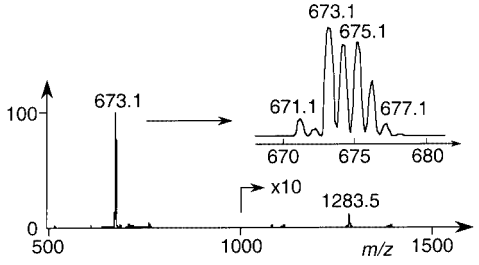

Figure 2. ES-MS spectrum of an acetonitrile solution of authentic $[Cu_2(\mathbf{L^2})_2](BF_4)_2$ (monocrystals) 5×10^{-3} M; Vc = 20 V; insert: isotopic pattern obtained for the peak at m/z = 673.1

On the basis of the electrochemical and electrospray mass spectrometry results, it can be clearly concluded that the 2:2 complex $[Cu_2(\mathbf{L^2})_2]^{2+}$ does not survive upon dissolution and dissociates rapidly to mainly form a 1:1 complex, along

with a minor 1:2 complex. The latter is not detected electrochemically and fully reversible CV behaviour is observed with Cu^{II} or Cu^{I} + $\mathbf{L^2}$ accounting for the reversible electroactivity of the 1:1 complex.

Comparing the electrochemical results obtained from $\mathbf{L^1}$−$\mathbf{L^5}$, we can highlight the benefit of a bis(bipyridyl)-bridged ferrocene ligand with respect to the electrochemical recognition of the metal cation. Complexation of $\mathbf{L^1}$ with copper leads to a one-wave feature for the Fc centre, while $\mathbf{L^2}$ allows amperometric titration of the copper through a two-wave behaviour for its Fc centre. However, complexation of the mono-substituted ligand $\mathbf{L^3}$ is responsible for an unexpected two-wave feature, although the wave corresponding to the complexed ferrocene centre partially overlaps that of the free ligand (see A in Figure 1). In contrast, the bis(bipyridyl)-bridged ligand $\mathbf{L^5}$ shows one-wave behaviour upon complexation of copper. As expected, the recognition properties of a given ligand are linked to its complexation ability. The presence of two additional electron-withdrawing groups in $\mathbf{L^5}$ and steric constraints imposed by the additional 6′-substitution in $\mathbf{L^5}$, as compared to $\mathbf{L^2}$, are responsible for weaker complexation and thus, for a decrease in its electrochemical recognition ability.

X-ray Molecular Structures of the Cu^{II} and Ni^{II} Complexes of Ligand L^2

The crystal structures of both complexes $\{Cu^{II}\mathbf{L^2}\}$ and $\{Ni^{II}\mathbf{L^2}\}$ reveal a 1:1 stoichiometry. The two compounds crystallize in the *C*2/*c* space group revealing 1.5 crystallographically independent dicationic molecular entities (Table 3). One entity is on the general position, and the second is lying on a twofold axis passing through the Fe and M^{II} (Cu2 or Ni2) atoms. The ORTEP view of the dicationic entities $[Cu\mathbf{L^2}]^{2+}$ is shown in Figure 3. The same atom labels are used in both complexes. Selected distances and bond angles of the two complexes are given in Table 4.

{$Cu^{II}L^2$}

The Cu^{II} environment is provided by four nitrogen atoms of the bipy subunits and two oxygen atoms of the carbonyl functions leading to a distorted octahedral coordination geometry. The square planes around Cu1 and Cu2 are defined by atoms O2, N1, N2, N3 and O6A, N5, N6, N5A, respectively (the mean-square deviations are 0.166 Å and 0.086 Å, respectively). The O4, N4 atoms and O6, N6 atoms occupy the axial positions, with the N4−Cu1−O4 and N6−Cu2−O6 angles equal to 168.7(1)° and 165.2(2)°, respectively. The Cu−N distances vary between 1.991(4) Å and 2.091(4) Å, and related Cu−O distances are significantly longer with Cu1−O2 = 2.226(4) Å and Cu1−O4 = 2.483(4) Å. The oxygen atoms adopt a *cis* position. The bipy units are slightly twisted (torsion angles between the cycles are equal to N1C5C6N2 = 4.7°; N3C25C26N4 = 12.1°; N5C45C46N6 = 10.1°). The cyclopentadienyl rings are almost parallel [the tilt angles are equal to 1.0(3)° for Fe1 and 0.35(20)° for Fe2] and the distances from the iron atom to the centroids of these planes are very similar [Fe1: 1.644(3) Å; Fe2: 1.639(3) Å]. An important observation is that the intermetallic distances [Fe1···Cu1 5.309(1) Å, Fe2···Cu2 5.153(2) Å] are far too long for any direct metal−metal interaction to be invoked.

{$Ni^{II}L^2$}

The Ni^{II} complex is isostructural with the Cu^{II} complex, the cation being surrounded by four nitrogen atoms provided by the bipyridine subunits and two oxygen atoms of

the linkers describing a slightly distorted octahedral coordination sphere.

In both structures, the ester groups are almost coplanar with the Cp rings and coordination of the Cu^{II} or Ni^{II} cations by the carbonyl moieties involves a conjugated frame between the ferrocenyl subunit and the metal centres.

Complexation of $\mathbf{L^{1-5}}$ with Ni^{II} Cations

The electrochemical data for complexation of $\mathbf{L^{1-5}}$ with Ni^{II} in the CH_3CN or CH_2Cl_2 electrolyte are summarized in Table 5. In terms of electrochemical response, the recognition properties of these redox-active receptors towards Ni^{II} are similar to that observed with Cu^{I} and Cu^{II}.

Complexation of Ni^{II} with $\mathbf{L^1}$ and $\mathbf{L^5}$ results in a one-wave feature for the Fc centre (e.g. Figure 4A for $\mathbf{L^1}$ + Ni^{II}). Addition of Ni^{II} to a solution of $\mathbf{L^1}$ or $\mathbf{L^5}$ induces a progressive weak positive shift of up to 60 mV in the potential of the Fc/Fc^+ couple. The maximal value is reached when 0.5 and 1 mol-equiv. of Ni^{II} have been added to $\mathbf{L^1}$ and $\mathbf{L^5}$, respectively. This suggests the formation of $[Ni(\mathbf{L^1})_2]^{2+}$ and $[Ni\mathbf{L^5}]^{2+}$ complexes where a bis(bipy) environment is provided for the cation. In the negative potentials range, the $\mathbf{L^1}$ + Ni^{II} system is characterized by two new reversible waves at $E_{1/2} = -0.98$ and -1.45 V (Figure 4A). Their intensity increases linearly with the amount of Ni^{II}, then remains constant after the addition of more than a 0.5 mol equiv. Above 0.5 mol-equiv., the CV curve displays the electrochemical response of free Ni^{II} salts as an irreversible cathodic peak around −1.5 V with the corresponding anodic peak being located around 0.2 V on the reverse scan. As judged by coulometric titration, the two reduction waves correspond to one-electron transfer leading to $[Ni(\mathbf{L^1})_2]^+$ and $[Ni(\mathbf{L^1})_2]^0$, respectively. Unfortunately, the poor stability of the electroreduced species excluded the assignment from EPR studies of the redox orbitals involved in these reductions. In contrast, addition of Ni^{II} to a solution containing $\mathbf{L^5}$ gives rise to an ill-behaved irreversible cathodic wave around −1.2 V and to electrochemical features typical of free Ni^{II}, whatever the nickel concentration used. This indicates the formation of an unlocked complex $[Ni\mathbf{L^5}]^{2+}$, which liberates Ni^{II} cations.

The $\mathbf{L^{2-4}}$ + Ni^{II} systems are best characterized by a two-wave behaviour for the Fc/Fc^+ redox couple in the presence of increasing amounts of Ni^{II} (see for example B in Figure 4; $\mathbf{L^2}$ + Ni^{II}). Upon progressive addition of Ni^{II} to $\mathbf{L^2}$, $\mathbf{L^3}$ or $\mathbf{L^4}$ in CH_3CN, a new redox wave corresponding to the complexed Fc/Fc^+ redox couple merges gradually at 0.80, 0.40 and 0.74 V, respectively. At the same time, the redox wave for the free Fc/Fc^+ couple vanishes. The cathodic electrochemical response of the complexes formed between Ni^{II} and $\mathbf{L^2}$ or $\mathbf{L^3}$ is revealed on the CV curves as two successive one-electron waves located at $E_{1/2} = -1.16$ and −1.47 V ($\mathbf{L^2}$; see B in Figure 4), and −1.33 and −1.48 V ($\mathbf{L^3}$). However, it must be noted that the electrochemical recognition properties of $\mathbf{L^3}$ are less marked than those of $\mathbf{L^2}$, for the following reasons: (*i*) the new signal corresponding to the complexed Fc/Fc^+ redox couple partially overlaps that of the free ligand, (*ii*) the two successive cathodic signals are ill-behaved and weakly separated, and (*iii*) a residual signal assigned to the free ligand remains observable in the presence of excess Ni^{II}.

Due to the poor solubility of $\mathbf{L^4}$ in CH_3CN solution, the cathodic features of the Ni^{II} + $\mathbf{L^4}$ system were determined in CH_2Cl_2 solution. In the accessible potential range only the first reduction of the $\mathbf{L^4}$ + Ni^{II} complex could be seen, at $E_{1/2} = -1.43$ V.

All perturbations due to the presence of Ni^{II} in solutions containing ligands $\mathbf{L^2}$, $\mathbf{L^3}$, or $\mathbf{L^4}$ reach their maximum intensity at a mol ratio Ni^{II}/ligand = 1, 0.5, and 1, respectively, suggesting the formation of complexes of the type $[Ni\mathbf{L^2}]^{2+}$, $[Ni(\mathbf{L^3})_2]^{2+}$, and $[Ni\mathbf{L^4}]^{2+}$. The stoichiometry of the $[Ni\mathbf{L^2}]^{2+}$ and $[Ni(\mathbf{L^3})_2]^{2+}$ species was confirmed by UV/Vis titration experiments. The titration curve (absorbance at λ_{max} = 460 nm of a CH_3CN solution of $\mathbf{L^2}$ as a function of increasing amounts of Ni^{II}) exhibits a sharp inflection point at an $Ni^{II}/\mathbf{L^2}$ mol ratio equal to 1 (ε_{max} = 140 M^{-1} cm^{-1}). The titration curve for the $\mathbf{L^3}$ + Ni^{II} complex (λ_{max} = 450 nm; ε_{max} = 500 M^{-1} cm^{-1}) displays an inflection point for $Ni^{II}/\mathbf{L^3} = 0.5$. In addition, FAB-MS spectra of the isolated $[Ni\mathbf{L^2}]^{2+}$ and $[Ni\mathbf{L^4}]^{2+}$ complexes display, exclusively, the *m/z* peaks corresponding to the 1:1 complex: *m/z* = 767 $\{[Ni\mathbf{L^2}](ClO_4)^+\}$ and 765 $\{[Ni\mathbf{L^4}](ClO_4)^+\}$.

The differences in the CV behaviour for these Ni^{II} complexes can be related to the nature of the $\mathbf{L^{1-5}}$ ligand. With $\mathbf{L^1}$ and $\mathbf{L^3}$ two ligands are involved in forming the complexes, while only one ligand is involved in the $\mathbf{L^2}$-, $\mathbf{L^4}$- and $\mathbf{L^5}$-based complexes, pointing to a bis(bipy) environment of the first coordination sphere of the metal centre. The *sand-*

wich effect provided by $\mathbf{L^2}$ or $\mathbf{L^4}$ causes a two-wave behaviour for the Fc/Fc^+ redox centre, while complexation of $\mathbf{L^1}$ or $\mathbf{L^3}$ leads to a simple anodic shift of the Fc oxidation ($\mathbf{L^1}$), or to a poorly resolved new signal ($\mathbf{L^3}$). As already discussed for its complexation with copper cations, the bis(bipy) ligand $\mathbf{L^5}$ shows reduced complexation ability and poor recognition properties.

The electrochemical reduction of nickel complexes proceeds by two successive one-electron transfers. This electrochemical behaviour is markedly different from that found for the complex formed between unsubstituted bipy and Ni^{II}. Under the same experimental conditions, the regular $[Ni(bipy)_2]^{2+}$ complex undergoes two successive, reversible electron transfers at $E_{1/2} = -1.55$ and -2.25 V in CH_3CN (see C in Figure 4). As reported previously,[10] reduction of $[Ni(bipy)_2]^{2+}$ is likely to occur following the $[Ni(bipy)_2]^{2+} \rightarrow [Ni(bipy)_2]^0 \rightarrow [Ni(bipy)_2]^-$ steps, the first step corresponding to a two-electron transfer. However, substitution of the bipy ligand with a simple electron-withdrawing group, as in $\mathbf{L^6}$, causes a dramatic change in this electrochemical mechanism. The CV curve recorded for Ni^{II} + 2 $\mathbf{L^6}$ in CH_3CN exhibits two reversible waves with comparable intensities at $E_{1/2} = -0.94$ and -1.43 V (see D in Figure 4). Further reduction is observed at a lower potential as an irreversible peak ($E_{1/2} = -2.02$ V, determined from RDE experiments). Coulometric titration has demonstrated that the three reductions are one-electron transfers, according to the following sequence: $[Ni(\mathbf{L^6})_2]^{2+} \rightarrow [Ni(\mathbf{L^6})_2]^{+} \rightarrow [Ni(\mathbf{L^6})_2]^0 \rightarrow [Ni(\mathbf{L^6})_2]^-$. Two additive effects could be responsible for such a change in the electrochemical behaviour of these complexes. It is obvious that substitution of the bipyridyl-binding site in $\mathbf{L^{1-6}}$ by electron-withdrawing groups leads to a stabilization of the reduced forms of the nickel complexes. Moreover, change in geometry between the unsubstituted bipy complex (likely to be square-planar) and the $\mathbf{L^{1-6}}$ complexes {likely to be octahedral as in $[Ni(\mathbf{L^2})]^{2+}$} might result in different redox properties.

Complexation of $\mathbf{L^{1-5}}$ with Fe^{II} Cations

Electrochemical data for complexation of $\mathbf{L^{1-5}}$ with Fe^{II} are summarized in Table 6. In a recent study,[2] we have shown that the complexation of $\mathbf{L^{3,4}}$ with Fe^{II} results in a two-wave behaviour for the Fc centre and in the formation of 1:2 $\{[Fe(\mathbf{L^3})_2]^{2+}\}$ and 1:1 $\{[Fe\mathbf{L^4}]^{2+}\}$ complexes. However, with $\mathbf{L^3}$ the intermediate formation at a low $Fe^{II}/\mathbf{L}$ ratio of the $[Fe(\mathbf{L^3})_3]^{2+}$ complex was evidenced from electrochemical experiments and UV/Vis titration.

Replacement of the amide linkage in $\mathbf{L^3}$ with the carbonyloxy linkage in $\mathbf{L^1}$ leads to strong modifications in the complexation pathway. Complexation of $\mathbf{L^1}$ with Fe^{II} in CH_3CN results in a one-wave behaviour of the electrochemical response for the Fc centre, which shifts from 0.33 V in free $\mathbf{L^1}$ to 0.37 V in the presence of excess Fe^{II}. The electrochemical response of the Fe^{II}/Fe^{III} redox couple in the $\mathbf{L^1}$-based complex is seen at $E_{1/2} = 0.95$ V, a value close to that found for $[Fe(\mathbf{L^3})_2]^{2+}$,[2] without any CV evidence for the intermediate formation of an "$Fe(bipy)_3$"-like species. The potentiometric titration curve displays a smooth inflection point around 0.5 mol-equiv. of Fe^{II}, which suggests the formation of an $[Fe(\mathbf{L^1})_2]^{2+}$ complex.

Table 6. Electrochemical data for $\mathbf{L^1}$, $\mathbf{L^2}$, $\mathbf{L^3}$, $\mathbf{L^4}$, $\mathbf{L^5}$ + Fe^{II}

[a]	$2\mathbf{L^1}$ + Fe^{II}		$\mathbf{L^2}$ + Fe^{II}		$2\mathbf{L^3}$ + Fe^{II}	
Fc/Fc^+	Fe^{II}/Fe^{III}		Fc/Fc^+	Fe^{II}/Fe^{III}	Fc/Fc^+	Fe^{II}/Fe^{III}
0.37	0.95		0.78[b]	0.98[b]	0.39[c]	0.97[c]
	$3\mathbf{L^3}$ + Fe^{II}		$\mathbf{L^4}$ + Fe^{II}		$\mathbf{L^5}$ + Fe^{II}	
Fc/Fc^+	Fe^{II}/Fe^{III}		Fc/Fc^+	Fe^{II}/Fe^{III}	Fc/Fc^+	Fe^{II}/Fe^{III}
0.39[c]	0.77[c]		0.64[c] [d]	0.99[c,d]	0.83[b]	0.98[b]

[a] $E_{1/2}$ [V] vs. $Ag/AgNO_3$ (0.01 M) (see Table 2), measured in CH_3CN electrolyte. [b] Irreversible oxidation. [c] From ref.[1] [d] $E_{1/2} = 0.73$ and 0.95 V in CH_2Cl_2.

In contrast, addition of Fe^{II} to a solution of $\mathbf{L^2}$ or $\mathbf{L^5}$ results in the appearance of a new Fc/Fc^+ oxidation wave at $E_{1/2} = 0.78$ and 0.83 V, respectively, at the expense of the free ligand (Figure 5). This wave reaches full development at an Fe^{II}/ligand mol ratio of 1 (Figure 5, curve b), suggesting the formation of 1:1 complexes in which the Fe^{II} centre is bound to two bipyridyl sites provided by the same metallo ligand, as established for bis(bipy)− and bis(phen)−ferrocene derivatives.[2] The stoichiometry of the complex $\mathbf{L^2}$ + Fe^{II} was confirmed from UV/Vis titration. Addition of Fe^{II} in a CH_3CN solution of $\mathbf{L^2}$ results in the appearance of an MLCT band ($\lambda_{max} = 450$ nm) of increasing intensity until 1 mol-equiv. of Fe^{II} has been added ($\varepsilon_{max} = 1.1 \times 10^3$ M^{-1} cm^{-1}). This result was further confirmed by the FAB mass spectrum of the isolated complex which displays peaks at $m/z = 765$ $\{[Fe\mathbf{L^2}](ClO_4)^+\}$ and 666 $\{[Fe\mathbf{L^2}]^{2+} - 1\}$.

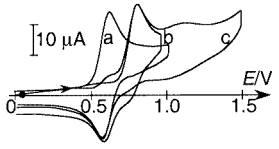

Figure 5. Cyclic voltammograms, in CH_3CN + TBAP (0.1 M), at a Pt disk (5 mm diameter) of 0.4 mM $\mathbf{L^2}$: (a) free $\mathbf{L^2}$; (b) $\mathbf{L^2}$ + 1.0 Fe^{2+} in the 0 to 0.95 V scan range; (c) $\mathbf{L^2}$ + 1.0 Fe^{2+} in the 0 to 1.45 V range; scan rate 0.1 V s^{-1}

However, oxidation of the complexed ligands $\mathbf{L^2}$ and $\mathbf{L^5}$ is irreversible in appearance. On the reverse scan, only the cathodic peak corresponding to the reduction of the ferrocene unit in the free ligand is observed (Figure 5, curve b). Thus, dissociation occurs upon oxidation of the $[Fe\mathbf{L^{2,5}}]^{2+}$ complexes, due to the establishment of repulsive electrostatic forces between the positively charged Fc^+ centre and the dicationic bound metal cation Fe^{II}. Moreover, in addition to the electrochemical signal due to the complexed Fc centre, the anodic response of the bound Fe^{II} cation is evident, on the CV curves, as a broad, ill-behaved irreversible wave at $E_{1/2} = 0.98$ V (determined from RDE experiments) for both complexes (Figure 5, curve c). It should be noted that a small wave corresponding to oxidation of free $\mathbf{L^2}$ re-

mains, even in the presence of a slight excess of Fe^{II}. As for the corresponding copper complexes, the $[FeL^5]^{2+}$ complex is less stable than its $[FeL^2]^{2+}$ analogue. Thus, the oxidation peak for free L^5 is apparent in the CV curves recorded even in the presence of a large excess of Fe^{II} (e.g. 2 mol-equiv.). These results are somewhat different from that found for the $[FeL^4]^{2+}$ complex, which shows reversible CV features. This is in keeping with a weaker binding of the Fe^{II} centre to the carbonyl oxygen atoms of the carbonyloxy group in L^1, compared to the amide donor group in L^3.

In addition, complexes formed from L^1, L^2, or L^5 with Fe^{II} display a broad, irreversible reduction wave at E_p = −1.38 V, −1.35 V, and −2.04 V, respectively. These features confirm that complexation affords species of the type $[Fe(bpy)_2]^{2+}$ rather than $[Fe(bpy)_3]^{2+}$-like complexes. The latter would be characterized by three reversible reduction waves in the negative potential region.

As has already been pointed out for the $[Fe(L^3)_2]^{2+}$ and $[FeL^4]^{2+}$ complexes,[2] ^1H NMR spectra of isolated $[Fe(L^1)_2](ClO_4)_2$ and $[FeL^2](ClO_4)_2$ complexes display resonances in a very large chemical shifts range (from δ = 83 to −10, and from δ = 81 to −9, respectively; see Exp. Sect.), attesting to a high spin configuration for these $\{Fe^{II}(bpy)_2\}$ species. This is confirmed by the rather low molar extinction coefficients of the visible transition in these complexes (600−1600 M^{-1} cm^{-1}; see Exp. Sect.), as compared to that found[11] with low-spin $[Fe(bipy)_2(CH_3CN)_2]^{2+}$ species (ε = 5600 M^{-1} cm^{-1} at 470 nm).

Complexation with Hg^{II}, Pb^{II}, Co^{II} and Ag^I Cations

Electrochemical data obtained in the course of complexation of L^2 with mercury(II), lead(II), cobalt(II) and silver(I) cations are summarized in Table 7. One-wave behaviour was found upon complexation of L^2 with Hg^{II}, with a maximum potential shift of 60 mV for the Fc/Fc^+ redox couple reached at an Hg^{II}/L^2 mol ratio of 1. The Hg^{II} + L^2 complex undergoes a reversible one-electron transfer at $E_{1/2}$ = 0.13 V. This indicates that Hg^I is stabilized upon complexation with L^2, since free Hg^{II} is reduced through a two-electron transfer to form Hg^0 at 0.22 V. Complexation of L^1 with Hg^{II} is also characterized by one-wave behaviour and leads to a lower positive potential shift (30 mV) in the Fc/Fc^+ redox potential, reached at an Hg^{II}/L^1 ratio close to 0.5. These results show the ability of L^1 and L^2 to provide a bipyridyl environment for the Hg^{II} metal cation. The stoichiometry has been further established by MS experiments. The FAB mass spectrum of the isolated L^2 + Hg^{II} complex, prepared as its triflate salt in the presence of an excess of ligand, displays only one peak at *m/z* = 961 $\{[HgL^2](CF_3SO_3)^+\}$ characteristic of a 1:1 complex. Analytical results are also in agreement with the formation of a 1:1 Hg^{II} + L^4 complex with the bis(carboxamide) ligand (see Exp. Sect.).

For Pb^{II}, the one-wave behaviour of the Fc/Fc^+ centre is characterized by a maximum potential shift of 80 mV that is reached at a Pb^{II}/L^2 mol ratio of 1. Reduction of the Pb^{II} + L^2 complex proceeds via several poorly defined steps. In contrast, two-wave behaviour is found upon addition of Co^{II} to L^2. The resultant Fc/Fc^+ redox couple appears at $E_{1/2}$ = 0.79 V, while the weakly reversible Co^{II} centred electron transfer is located at $E_{1/2}$ = 1.1 V. Maximum perturbation is reached at a Co^{II}/L^2 mol ratio of 1. However, the electrochemical signal for free L^2 remains visible on the CV curve even in the presence of excess Co^{II}. Finally, no complexation could be detected upon addition of Ag^I to L^2.

Conclusion

This study confirms the remarkable complexation and electrochemical recognition properties of bipyridyl−ferrocene metallo-synthons for adventitious metal cations. Complexation results in significant positive potential shifts of the ferrocene/ferricinium redox couple following a decrease in the electron density around the ferrocene centre. The bis(substitution) on the ferrocene centre improves the electrical connection between the bound metal cation and the ferrocenyl unit allowing effective electrochemical recognition of the metal cation through a two-wave behaviour for the ferrocene electrochemical response (*sandwich effect*). All the studied ligands afford a bis(bipyridyl) environment for the bound metal cations, which dictates the 1:1 stoichiometry with the bis(substituted) ligands and the 1:2 stoichiometry with the mono(substituted) ligands. In the solid state, Cu^I forms a 2:2 complex with L^2, which does not survive in solution, while Cu^{II} forms a 1:1 complex. The Cu^{II} and Ni^{II} complexes are isostructural with the cations being surrounded by four nitrogen atoms provided by the bipyridine subunits and two oxygen atoms of the linkers. Finally, formation of bis(bipy)-like complexes with Fe^{II} and other metal cations such as Hg^{II}, Pb^{II} and Co^{II} illustrates the wide versatility of the coordination features of these bipy−ferrocenyl ligands.

Experimental Section

Ligands: L^1, L^2, L^3, L^4 and L^5 were synthesized as reported previously.[1,3,4]

Table 7. Electrochemical data for L^2 + Hg^{II}, Pb^{II}, Ag^I and Co^{II}, and L^1 + Hg^{II}

[a] L^2 + Hg^{II}		L^2 + Ag^I	L^2 + Pb^{II}	L^2 + Co^{II}		$2L^1$ + Hg^{II}	
Fc/Fc^+	Hg^{II}/Hg^I	Fc/Fc^+	Fc/Fc^+	Fc/Fc^+	Co^{II}/Co^{III}	Fc/Fc^+	Hg^{II}/Hg^0
0.62	0.13	0.56[b]	0.64	0.79	1.10	0.59	−0.32

[a] $E_{1/2}$ [V] vs. $Ag/AgNO_3$ (0.01 M) (see Table 1), measured in CH_3CN electrolyte. [b] No electrochemical recognition.

L^6: L^6 was prepared according to a similar procedure based on the stoichiometric reaction of 6-(hydroxymethyl)-2,2′-bipyridine[12] with benzoyl chloride. Yield 85%. ^{1}H NMR (300 MHz, CD_3CN, 10 mM, 295 K): δ = 8.66 (1 H, *H*-6′-bipy), 8.41 (1 H, *H*-3-bipy), 8.32 (1 H, *H*-3′-bipy), 8.15 (2 H, *H*-*o*-bz), 7.77−7.87 (2 H, *H*-5-bipy and *H*-4-bipy), 7.44−7.59 (4 H, *H*-*m*-bz, *H*-*p*-bz, *H*-5′-bipy), 7.31 (1 H, *H*-4′-bipy), 5.60 (2 H, CH_2-bipy). FAB$^+$ MS: *m*/*z* = 291 [L^6 + 1]$^+$.

Complexes: All metal complexes were synthesized as their perchlorate or triflate salts, by reaction of stoichiometric amounts of the ligand (40 mg) and the salt of the selected metal cation [1 mol-equiv. in the case of the bis(bipy) derivatives and 0.5 mol-equiv. in the case of mono(bipy)] in a minimum volume of CH_3CN or CH_2Cl_2 at room temperature. The target complexes were precipitated on addition of diethyl oxide and isolated as orange solids by suction filtration (yields 80−90%). X-ray quality crystals were grown by vapour diffusion of diethyl oxide into an acetonitrile solution of the complexes {Cu^{II}L^2} or {Ni^{II}L^2}. [Cu(L^1)$_2$](ClO$_4$), [Cu$_2$(L^2)$_2$](ClO$_4$)$_2$, [Fe(L^3)$_2$](ClO$_4$)$_2$ and [FeL^4](ClO$_4$)$_2$ complexes have been previously described.[1,2] **Warning!** *Perchlorate salts are hazardous because of the possibility of explosion.*

[Cu(L^3)$_2$](ClO$_4$): UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 442 nm (1718). FAB$^+$ MS: *m*/*z* = 857 [Cu(L^3)$_2$]$^+$. FT-IR: ν(CO) = 1602 cm^{-1}; due to hygroscopic properties, no reproducible elementary analysis could be obtained with this compound.

[CuL^4](ClO$_4$): UV/Vis (MLCT band; CH_3CN) λ_{max}, (ε, M^{-1} cm^{-1}) = 444 nm (3250). FAB$^+$ MS: *m*/*z* = 671 [CuL^4]$^+$. FT IR: ν(CO) = 1634 cm^{-1}. $C_{34}H_{28}ClCuFeN_6O_6\cdot 2H_2O$ (807.516): calcd. C 50.57, H 3.99, N 10.41; found C 50.28, H 3.62, N 10.55.

[Ni(L^1)$_2$](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 458 nm (670). FAB$^+$ MS: *m*/*z* = 953 [Ni(L^1)$_2$](ClO$_4$)$^+$. FT IR: ν(CO) = 1603, 1645, 1714 cm^{-1}. $C_{44}H_{36}Cl_2Fe_2N_4NiO_{12}\cdot 2H_2O$ (1090.128): calcd. C 48.48, H 3.70, N 5.14; found C 47.93, H 3.63, N 5.17.

[NiL^2](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 460 nm (140). FAB$^+$ MS: *m*/*z* = 767 [NiL^2](ClO$_4$)$^+$. FT IR: ν(CO) = 1603, 1631, 1668 cm^{-1}. $C_{34}H_{26}Cl_2FeN_4NiO_{12}\cdot 3H_2O$ (922.105): calcd. C 44.29, H 3.50, N 6.08; found C 44.49, H 3.05, N 6.20.

[Ni(L^3)$_2$](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 445 nm (500). FAB$^+$ MS: *m*/*z* = 951 [Ni(L^3)$_2$](ClO$_4$)$^+$. FT IR: ν(CO) = 1601 cm^{-1}. $C_{44}H_{38}Cl_2Fe_2N_6NiO_{10}\cdot 2H_2O$ (1088.158): calcd. C 48.57, H 3.89, N 7.72; found C 48.97, H 3.82, N 7.74.

[NiL^4](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 448 nm (360). FAB$^+$ MS: *m*/*z* = 765 [NiL^4](ClO$_4$)$^+$. FT IR: ν(CO) = 1605 cm^{-1}. $C_{34}H_{28}Cl_2FeN_6NiO_{10}\cdot 3H_2O$ (920.135): calcd. C 44.38, H 3.72, N 9.13; found C 44.44, H 3.53, N 9.04.

[Fe(L^1)$_2$](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 448 nm (1610). FAB$^+$ MS: *m*/*z* = 951 [Fe(L^1)$_2$](ClO$_4$)$^+$. FT IR: ν(CO) = 1600, 1624, 1714 cm^{-1}. ^{1}H NMR (300 MHz, CD_3CN, 10 mM, 295 K): δ = 83.0 (2 H, *H*-*o*-bipy), 67.9, 56.4, 56.4 and 49.6 (2 H each, *H*-*m*-bipy), 13.8 (2 H, *H*-*p*-bipy), 7 to 0 (22 H, *H*-Cp, CH_2-bipy and *H*-*p*-bipy), −9.4 (4 H, CH_2-bipy). $C_{44}H_{36}Cl_2Fe_3N_4O_{12}\cdot 2H_2O$ (1087.275): calcd. C 48.61, H 3.71, N 5.15; found C 48.75, H 3.61, N 5.27.

[FeL^2](ClO$_4$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 450 nm (1100). FAB$^+$ MS: *m*/*z* = 765 [FeL^2](ClO$_4$)$^+$. FT IR: ν(CO) = 1661 cm^{-1}. ^{1}H NMR (300 MHz, CD_3CN, 10 mM, 295 K): δ = 80.5 (2 H, *H*-*o*-bipy), 62.0, 61.4, 56.6 and 17.8 (2 H each, *H*-*m*-bipy), 7.1 (2 H, *H*-*p*-bipy), 6.4 and 0.8 (4 H resp., *H*-Cp), −1.9 (2 H, *H*-*p*-bipy), −8.7 (4 H, CH_2-bipy). $C_{34}H_{26}Cl_2Fe_2N_4O_{12}\cdot H_2O$ (883.221): calcd. C 46.24, H 3.20, N 6.34; found C 45.97, H 3.10, N 6.37.

[HgL^2](CF$_3$SO$_3$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 432 nm (1720). FAB$^+$ MS: *m*/*z* = 961 [HgL^2](CF$_3$SO$_3$)$^+$. FT IR: ν(CO) = 1712 cm^{-1}. $C_{36}H_{26}F_6FeHgN_4O_{10}S_2$ (1109.177): calcd. C 38.98, H 2.36, N 5.05; found C 38.04, H 2.43, N 4.96.

[HgL^4](CF$_3$SO$_3$)$_2$: UV/Vis (MLCT band; CH_3CN): λ_{max} (ε, M^{-1} cm^{-1}) = 446 nm (450). FAB$^+$ MS: *m*/*z* = 959 [HgL^4](CF$_3$SO$_3$)$^+$. FT IR: ν(CO) = 1596, 1627 cm^{-1}. $C_{36}H_{28}F_6FeHgN_6O_8S_2\cdot 2H_2O$ (1143.238): calcd. C 37.82, H 2.82, N 7.35; found C 37.85, H 2.59, N 7.14.

Reagents, Instrumentation and Procedure: Acetonitrile (Rathburn, HPLC grade) was used as received. Dichloromethane was dried with neutral alumina (activity I) for at least 6 d before use. Tetra-*n*-butylammonium perchlorate (TBAP) was purchased from Fluka and dried under vacuum for 3 d at 80 °C. Electrochemical experiments were conducted in a conventional three-electrode cell under argon at 20 °C. The reference electrode was Ag/AgNO$_3$ (10 mM in CH_3CN containing 0.1 M TBAP). FAB (positive mode) mass spectra were recorded with an AEI Kratos MS 50 spectrometer fitted with an Ion Tech Ltd gun and using *m*-nitrobenzyl alcohol as matrix. ES-MS measurements were performed on a triple quadrupole mass spectrometer Quattro II (Micromass, Altrincham, UK). The ES source was heated to 80 °C. The sampling cone voltage (Vc) was 20 V to avoid any fragmentation processes. Sample solutions were introduced into the mass spectrometer source with a syringe pump (Harvard type 55 1111: Harvard Apparatus Inc., South Natick, MA, USA) with a flow rate of 4 μL min^{-1}. Calibration was performed using protonated horse myoglobin. Scanning was performed in the MCA (Multi Channel Analyser) mode, and several scans were summed to obtain the final spectrum. Elemental analyses were performed by the Service Central d'Analyses, CNRS, Lyon.

X-ray Structures: Crystals of the complexes between L^2 and M^{II} (where M^{II} is Cu^{II} or Ni^{II}) named {Cu^{II}L^2} and {Ni^{II}L^2}, respectively, were used for data collection with a STOE-IPDS diffractometer using Mo-K_α graphite-monochromated radiation (λ = 0.71073 Å). Intensity data were corrected for Lorentz and polarisation effects but not for absorption. Structure solution and refinement were performed with the SHELXTL package. A summary of the crystallographic data and structure refinement is given in Table 3. The two compounds {Cu^{II}L^2} and {Ni^{II}L^2} are isostructural. They crystallize in the *C*2/*c* space group with close cell parameters. Only the crystallization solvents are different. The crystallographically independent chemical formulae are [CuL^2]$_{1.5}$(ClO$_4$)$_3$ 0.5[(C_2H_5)$_2$O] 2.5(CH_3CN) and [NiL^2]$_{1.5}$(ClO$_4$)$_3$ [(C_2H_5)$_2$O] 1.5(CH_3CN) with a multiplicity of *Z* = 8; so there are 12 [ML^2]$^{2+}$ entities in the unit cell. All non-hydrogen atoms were refined with anisotropic thermal parameters, except for atoms of disordered solvents. Hydrogen atoms were generated in idealised positions (except for disordered solvents), riding on the carrier atoms with isotropic thermal parameters. CCDC-174044 {Cu^{II}L^2} and -174045 {Ni^{II}L^2} contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We warmly thank Drs. Hélène Nierengarten and Alain van Dorrselaer from the Laboratoire de Spectrométrie de Masse Bioorganique, at the ECPM in Strasbourg for their expertise in the ES-MS measurements.

Keywords: Aryl phosphites / N,P ligands / Palladium / Allylation / Rhodium / Hydrosilylation

New chiral *P,N*-hybrid aryl phosphites have been obtained by one-step phosphorylation of amino and imino alcohols. Complexation of the new ligands with $[Rh(CO)_2Cl]_2$, $[Pd(COD)Cl_2]$ and $[Pd(allyl)Cl]_2$ was found to give chelate complexes $[Rh(CO)Cl(\eta^2\text{-}P^{\frown}N)]$, $[PdCl_2(\eta^2\text{-}P^{\frown}N)]$ and $[Pd(allyl)(\eta^2\text{-}P^{\frown}N)]^+Cl^-$, respectively. With these new *P,N*-ligands, up to 82% *ee* enantioselectivity was achieved in the Pd-catalysed alkylation of ethyl 3-penten-2-yl carbonate with dimethyl malonate, up to 80% *ee* in the Pd-catalysed sulfonylation of methyl 3-penten-2-yl carbonate with sodium *p*-toluenesulfinate, and up to 50% *ee* in the Rh-catalysed hydrosilylation of acetophenone with diphenylsilane.

Introduction

Chiral *P,N*-bidentate compounds are one of the leading ligand groups in modern asymmetric catalysis.[1−3] Most such systems are phosphanes in nature, but phosphite-type *P,N*-hybrid ligands are acquiring progressively growing importance because of their synthetic availability, high π-acidity of the phosphorus atom and high resistance to oxidative destruction. In general, the presence of oxygen and/or nitrogen atoms in the first coordination sphere of the phosphorus atom offers the potential to tune the chemical stability of ligands, their donor/acceptor properties and steric demands. This has made it possible to achieve impressive results in catalytic enantioselective allylation, conjugate addition of organometallic compounds to enones, hydrosilylation and hydrogenation reactions.[1−9] Interestingly, each of the ligands mentioned has a phosphacyclic structure, normally constructed with the aid of effective chiral inductors such as BINOL, TADDOL, (1*R*,2*R*)-1,2-*N*,*N*′-bis(*p*-toluenesulfonylamino)-1,2-diphenylethane, (*S*)-2-(anilinomethyl)pyrrolidine etc.[1−9] Only one example[10] of the use of an achiral biphenol is known; the phosphitooxazoline derived from it is a phosphacyclic compound as well. We have recently reported syntheses of several chiral *P,N*-phosphites with acyclic phosphorus donor centres.[11,12]

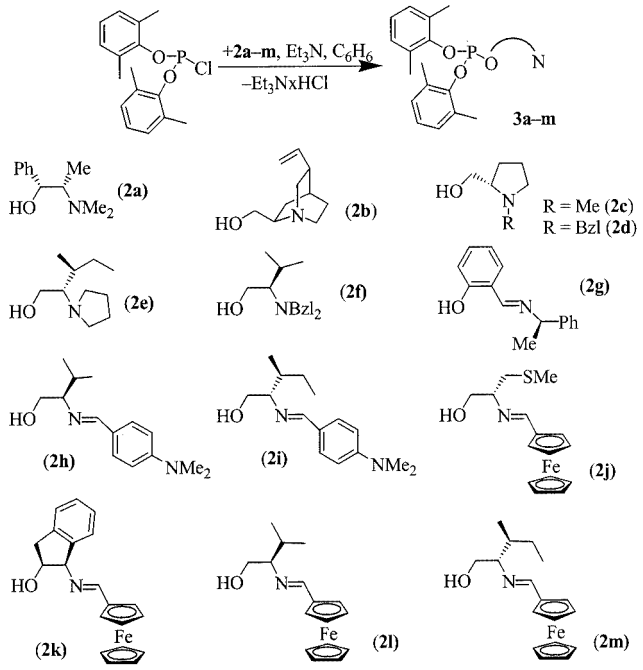
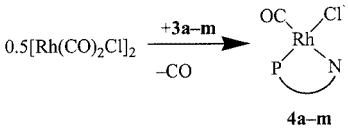
Results and Discussion

The new *P,N*-bidentate aryl phosphites were synthesized by one-step phosphorylation of the corresponding amino and imino alcohols with bis(2,6-dimethylphenyl) chlorophosphite.

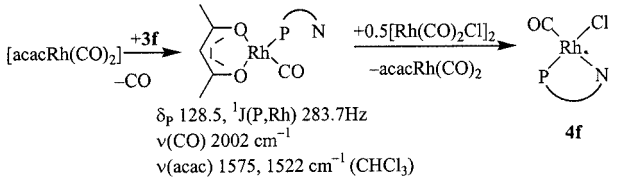


They divide into two groups: ligands **3a**−**3f**, possessing sp^3-hybridized nitrogen atoms, and ligands **3g**−**3m**, which have sp^2-hybridized nitrogen atoms. All the compounds **3a**−**m** are soluble in conventional organic solvents and stable under dry conditions for several months. On treatment with $[Rh(CO)_2Cl]_2$, their neutral carbonyl(chloro)Rh^I complexes were obtained.



The ν(CO) and $^1J_{P,Rh}$ parameters in their IR and ^{31}P NMR spectra act as sensitive indicators, which characterise the mode of complexation of the *P,N*-ligands and allow the π-acceptor ability of the phosphorus centre and the degree of electronic non-symmetry of the ligands to be estimated.[13−15]

In general, ligands **3a**−**3m** give chelate complexes. Thus, the $^1J_{P,Rh}$, $^1J_{C,Rh}$, $^2J_{C,P}$, ν(CO) and ν(Rh−Cl) data for complexes **4a**−**4m** (Tables 1 and 2) are in good agreement with the suggested structures.[13,15] Significant (9−11 ppm) coordination shifts $\Delta\delta_C$ [= δ_C(complex) − δ_C(ligand)] for the azomethine carbon atoms in complexes **4i** and **4l** (Table 2) also attest to the coordination of distant imino groups with the rhodium atom. However, complexation of some ligands displays special features. Thus, compounds **4e**−**4g**, **4j** and **4k** exist as two or more conformers (Table 1) similarly to known cationic rhodium, iridium[16] and palladium[17] *P,N*-chelates. In addition, the reactions between $[Rh(CO)_2Cl]_2$ and the compounds bearing cyclic (**3b**−**3e**) or sterically hindered acyclic (**3f**) sp^3-nitrogen donor centres produced some quantities of *trans*-$[Rh(CO)Cl(\eta^1\text{-}P^{\frown}N)_2]$ complexes, in which the compounds function as *P*-monodentate ligands. This was shown by their characteristic[13,18] IR and ^{31}P NMR spectroscopic data (the percentage of *trans* complexes determined by ^{31}P NMR is given in parentheses) for **3b**: δ_P = 122.8, $^1J_{P,Rh}$ = 204.9 Hz (8%); for **3c**: δ_P = 121.4, $^1J_{P,Rh}$ = 207.6 Hz, ν(CO) = 1995 cm^{-1} (20%); for **3d**: δ_P = 122.1, $^1J_{P,Rh}$ = 203.5 Hz, ν(CO) = 2000 cm^{-1} (45%); for **3e**: δ_P = 124.6, $^1J_{P,Rh}$ = 205.6 Hz, ν(CO) = 1994 cm^{-1} (30%); for **3f**: δ_P = 122.6, $^1J_{P,Rh}$ = 195.4 Hz, ν(CO) = 1993 cm^{-1} (54%). It was notable that, the higher the steric demands of the aza centre, the larger the amount of $[Rh(CO)Cl(\eta^1\text{-}P^{\frown}N)_2]$ complex. The reason for this seems to be an increase in steric hindrance for coordination of nitrogen atoms and, as a result, a fall in the proportion of chelate $[Rh(CO)Cl(\eta^2\text{-}P^{\frown}N)]$ products. To overcome this effect, the synthesis of complex **4f** was performed in a different way, by the exchange reaction previously developed for *P*-monodentate ligands.[19]



Imino phosphites **3g**−**3m**, independently of their steric demands, gave chelate products **4g**−**4m** only. They are therefore more typical chelate ligands than amino phosphites.

All the ligands **3a**−**3m** had highly π-acidic phosphorus centres. This was proved by the values of the ν(CO) and $^1J_{P,Rh}$ parameters for complexes **4a**−**4m**, which are significantly larger than those for the analogous amino phosphane based complexes (by 30−35 cm^{-1} and 80−100 Hz, respectively) and even their aminoalkyl phosphite counterparts (by 6−10 cm^{-1} and 10−15 Hz).[13−15] It is well known that increasing *P*-centre π-acidity in *P,N*-bidentate ligands favours high chemical and optical yields in such catalytic reactions as allylation, hydroboration/oxidation and hydrosilylation/oxidation of alkenes, and hydrosilylation of ketones.[1,2]

On the other hand, increasing σ-donor character in the *N*-centre results in higher optical yields in hydroboration/oxidation and hydrosilylation/oxidation of alkenes.[20,21] In this context, a concept of electronically non-symmetric ligands has been suggested (the higher the π-acceptor ability of the *P*-centre and the σ-donor ability of the *N*-centre, the more electronically non-symmetrical the compound).[14] This parameter can be estimated by the value of ν(CO) in the IR spectrum of the carbonyl(chloro) complex $[Rh(CO)Cl(P^{\frown}N)]$. In particular, for structurally similar complexes with identical phosphorus centres and different nitrogen centres, a compound with a lower value of ν(CO)

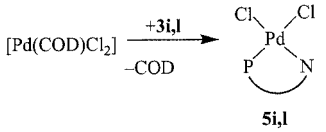
[a] The resonance of the carbonyl-type carbon atom: δ_C = 187.62 ($^1J_{C,Rh}$ = 71.1, $^2J_{C,P}$ = 17.3 Hz). [b] The resonance of the carbonyl-type carbon atom: δ_C = 187.42 ($^1J_{C,Rh}$ = 71.4, $^2J_{C,P}$ = 18.1 Hz).

possesses a more active σ-donor nitrogen-containing centre and hence is more electronically non-symmetric.[14,15] From this point of view, imino phosphites are the most electronically non-symmetric ligands among compounds **3a−3m** (Table 1). The exceptions are amino phosphite **4f**, bearing an dibenzylamino group, and the imino phosphites **3g** and **3j**. However, compound **3g** has a slightly different phosphorus centre and is actually a triaryl phosphite (unlike the other ligands), while ligand **3j** has an additional sulfur atom in its structure. Analogously to complexation with Rh^I, the new *P,N*-hybrid aryl phosphites form metal chelates with Pd^{II}.



5i,l

The IR and NMR spectroscopic data for the obtained complexes, shown in Tables 2 and 3, strongly supported the suggested mode of coordination. In particular, the δ_P values for complexes **5i** and **5l** (Table 3) are typical for six-membered palladacycles based on *P,N*-bidentate phosphites with acyclic phosphorus centres.[11,22] Large coordination shifts $\Delta\delta_C$, similar to those seen in the rhodium complexes **4i** and **4l**, were observed for the azomethine carbon atoms in complexes **5i** and **5l** (Table 2). Two equally intense ν(Pd−Cl) bands in the far IR regions of **5i** and **5l** (Table 3) resulted from the *cis* configuration of chloro ligands and different *trans* influences of phosphorus and nitrogen atoms.

Table 3. IR and ^{31}P NMR spectroscopic data for palladium complexes **5i**, **5l** and **6**

Compound	ν(Pd−Cl) (nujol, CsI) [cm^{-1}]	δ_P ($CDCl_3$)
5i	342, 288	77.2
5l	336, 292	74.1
6	−	132.7

In order to investigate details of the complex geometry, complexes **4i**, **5i** and **5l** were studied by single-crystal X-ray diffraction (see Figures 1, 2 and 3, Table 4). Comparison of the crystal packings of **4i** and **5i** revealed that the two compounds were isostructural. The principal geometry of the complexes is therefore only very slightly dependent on the nature of the metal centre and the terminal ligands. In all the complexes, the metal atoms are characterized by square-planar coordination with slightly different degrees of planarity. The maximum deviations from the mean plane are 0.15, 0.12 and 0.08 Å for **4i**, **5i** and **5l**, respectively.

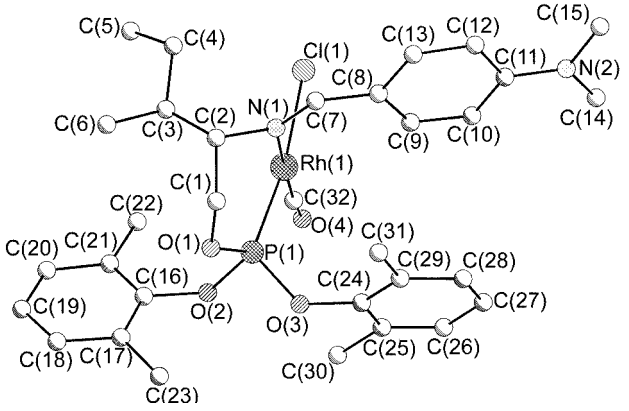


Figure 1. General view of complex **4i** and numbering scheme

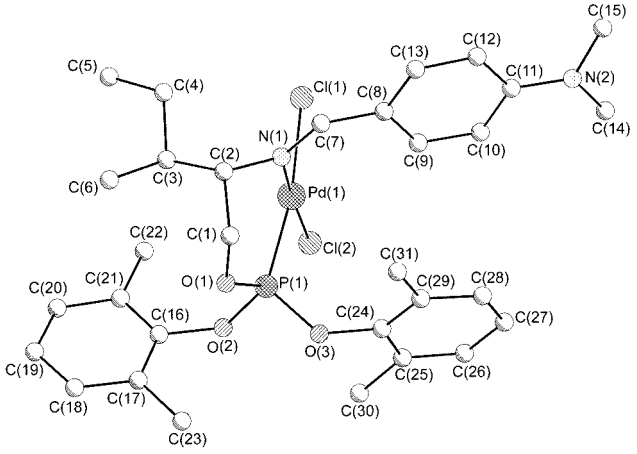

Figure 2. General view of complex **5i** and numbering scheme

The conformations of the six-membered metallacycles in the investigated compounds are far from regular, and can be described as distorted chairs in **4i** and **5i** and a distorted boat in **5l**. The difference in the conformation type seems to result from steric overcrowding due to introduction of the ferrocenyl moiety. In addition, the presence of the ferrocenyl substituent gives rise to significant changes in the mutual orientation of the 2,6-dimethylphenyl rings, with one of them approximately parallel to the Cp ring. Such an orientation of the C(8)−C(12) and C(26)−C(31) rings produces a decrease in the interplane separation to 3.32 Å, and could be regarded as an intramolecular stacking interaction. Despite this possible intramolecular stacking interaction, however, the geometry of the ferrocene moiety is actually unaffected. The ferrocene is characterized by the eclipsed conformation, with practically equal Fe(1)−centroid distances, 1.657 and 1.646 Å for the C(8)−C(12) and the C(13)−C(17) rings. In addition to the neutral dichloropalladium complexes, cationic complex **6** was obtained with ligand **3m**.

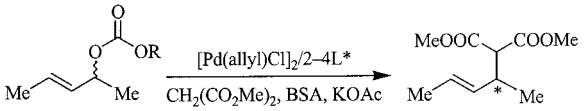
6

The ^{31}P and ^{13}C NMR spectra of complex **6** (see Exp. Sect. and Table 3) contained only one set of resonances, ex-

plicable either by the presence of only one of the possible *exo* and *endo* isomers or by their fast interconversion (see ref.[2], refs. cited therein and refs.[23,24]). It is noteworthy that the E_b(Cl2P) value of 198.4 eV in the XPS spectrum of compound **6** is close to the highest limit for chlorine anions.[25] Furthermore, the PD mass spectrum of complex **6** shows a rarely observable molecular ion peak (usually only the $[M - Cl]^+$ peak is observed). These facts allowed us to conclude that complex **6** exists as a contact ion pair.[26]

Some of the new *P,N*-(aryl phosphites) were tested in the palladium-catalysed allylic alkylation of ethyl 3-penten-2-yl carbonate with dimethyl malonate (Scheme 1, R = Et). The results are shown in Table 5. They allow the following conclusions to be made:



Scheme 1

[a] Yield of analytically pure product after column chromatography. [b] The *ee* values were determined by chiral GC (fused silica capillary column DP-TFA-γ-CD, 90 °C, He, 1.8 bar). [c] L*/Pd = 1.

1. Systems with sp^3-hybridized nitrogen atoms were not effective (*ee* < 11%, Entries 1−3).

2. Among the imino phosphites, ligands **3i**, **3k** and **3m** (Entries 5, 8, 22) were the most effective (up to 82% *ee*).

3. Optical yields greatly depended on the substituent at the chiral centre, as clearly demonstrated by the homologous ligands **3h** (24% *ee*) and **3i** (58% *ee*), as well as **3l** (38% *ee*) and **3m** (82% *ee*).

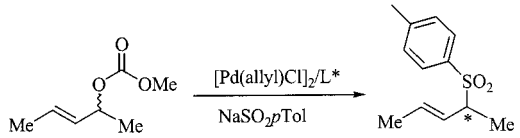
4. Optical yields depended significantly on the solvent used and the temperature. Notably, for ligand **3m** the latter correlation was nonlinear in character (Entries 11−14).

5. The L*/Pd ratio did not influence the effectiveness of a catalytic system much (compare Entries 19 and 22).

What should be discussed separately are significant increases in *ee* values on going from ligand **3h** to **3e** (by 14%, Entries 4 and 9) and, especially, from **3i** to **3m** (by 23%, Entries 6 and 19). Since the ν(CO) and $^1J_{P,Rh}$ values for their rhodium complexes [Rh(CO)Cl(η^2-P$^\frown$N)] are practically identical (Table 1), the electronic characteristics of the ligands (including the degree of electronic non-symmetry) are very much the same. Therefore, the effect is steric in nature, and the steric parameters of the ligands are indeed responsible for the difference in the optical yields in the catalytic reaction. Ligands **3i** and **3l** have similar structures and only the −N=CHR fragments are different. To estimate the bulkiness of the substituents, the cone angles θ_R for the *p*-$C_6H_4NMe_2$ and Cp_2Fe fragments were calculated by constructing appropriate computer models and from the X-ray data. The calculated cone angle for the Cp_2Fe fragment [θ_R = 159° (AM1), 157° (X-ray, complex **5l**)] is significantly larger than the angle for the *p*-$C_6H_4NMe_2$ fragment [θ_R = 133° (AM1), 129° (X-ray, complex **5i**)]. Hence, bulky substituents attached to the imine group of the *P,N*-(imino phosphite) ligands are likely to afford higher optical yields in the catalytic reaction.

The catalytic effectiveness shown by the catalytic system with ligand **3m** was comparatively high, since 1,3-dimethyl-substituted allylic substrates belong to a group termed "unmanageable".[27] There are only two known *P,N*-ligands that also give more than 80% enantioselectivity, one of the new generation phosphanyloxazolines (70−90% *ee*)[28] and a 2-(phosphanylaryl)pyridine-derived ligand (Scheme 1, R = Me, *i*Pr, Ph, 78−93% *ee*).[27] It should be noted that the mentioned high enantioselectivities were achieved by thorough optimization of the reaction conditions at a low temperature (−25 to −40 °C) and sometimes by addition of crown ethers.[27,28]

Some of the new *P,N*-bidentate aryl phosphites were tested in the Pd-catalysed allylic substitution of methyl 3-penten-2-yl carbonate with $NaSO_2p$Tol (Scheme 2). The obtained results are shown in Table 6. It is easy to see that main tendencies in this catalytic process were similar to those in the reaction with the malonate nucleophile discussed above. In particular, the highest enantioselectivities were demonstrated by the ligands with distant imino groups. It is important to note that the optical yield produced by imino phosphite **3m** (80% *ee*) was the best so far achieved in the reaction using *P,N*-ligands. Helmchen's phosphanyloxazolines, the most effective previously described *P,N*-ligands,



Scheme 2

gave up to 59% *ee*.[29] Moreover, unlike phosphanyloxazolines, our ligands did not give rise to the formation of a sulfinic acid ester as a side product. To the best of our knowledge, the only ligand giving higher results in this reaction [99% *ee*, with $Pd_2(dba)_3$ as a precatalyst] is one of Trost's *P*,*P*-bidentate ligands,[30] which form 13-membered chelate palladium complexes.[31]

Table 6. Enantioselective allylic sulfonylation of 3-penten-2-yl carbonate with $NaSO_2p$Tol according to Scheme 2

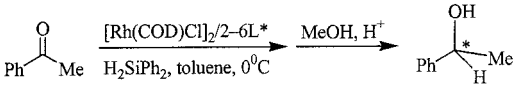
14	**3m**	1:1	DCM	room temp.	45	76 (*R*)
15	**3m**	1:1	DCM	0	21	80 (*R*)

[a] Yield of analytically pure product after column chromatography. [b] The *ee* values were determined by chiral GC (Lipodex-γ: 2,3-di-*O*-pentyl-6-*O*-methyl-γ-cyclodextrin (25m × 0.8 mm) column). [c] $Pd_2(dba)_3 \times CHCl_3$.

Ligands **3a**−**m** were also tested in the Rh-catalysed asymmetric hydrosilylation of acetophenone with diphenylsilane (Scheme 3). However, the achieved optical yields were rather low, with amino phosphites (up to 28% *ee*) once again being less effective than imino phosphites **3i** (45% *ee*) and **3m** (50% *ee*).



Scheme 3

Experimental Section

General Comments: All reactions were performed under argon in dehydrated solvents. IR spectra were recorded with a Specord M80 or Nicolet 750 instrument. ^{31}P, ^{13}C and ^{1}H NMR spectra were recorded with a Bruker AMX 400 instrument (162.0 MHz for ^{31}P, 100.6 MHz for ^{13}C and 400.13 MHz for ^{1}H). Complete assignment of all the resonances in ^{13}C NMR spectra was achieved by use of DEPT techniques. Chemical shifts (ppm) are given relative to Me_4Si (^{1}H and ^{13}C NMR) and 85% H_3PO_4 (^{31}P NMR). Mass spectra were recorded with a Kratos MS890 spectrometer (EI), an MSVKh TOF spectrometer with ionization by Cf-252 fission fragments (plasma desorption technique, PD), and a Micromass Platform 1 mass spectrometer through an "Openlynx" system (APCI technique). Electrospray (ES) ionisation mass spectra were measured with a Micromass BioQ II-ZS mass spectrometer. Organometallic compound solutions at 5−10 pmol/μL in THF or acetonitrile were infused by syringe pump (Harvard Apparatus Model 11) at 5 μL/min. Spectra were recorded over a mass range of 200−1200 Da and were calibrated relative to a mixed PEG standard. The X-ray photoelectron spectrum (XPS) was measured with a MAC-2 Riber spectrometer calibrated against Ag lines at 901.5 and 367.9 eV, correction for the sample charging was performed at C1s = 284.6 eV; the accuracy of the line maximum determination was ±0.1 eV. Cone angles θ_R of the substituents were determined from their conformations in the structures H-R obtained by computer calculations (AM1) and in the X-ray crystal structures of the corresponding complexes by the published approach.[32] Elemental analyses were performed at the Laboratory of Microanalysis (Institute of Organoelement Compounds, Moscow). Crystallographic data and refinement parameters for compounds **4i**, **5i** and **5l** are summarized in Table 7. The experimental data were collected at 110 K with a Bruker SMART 1000 CCD area detector by using graphite-monochromated Mo-K_α radiation (λ = 0.71072 Å, ω-scans with 0.3° steps in ω and 10 s per frame exposure). The absorption correction was applied semiempirically from equivalents. All the structures were solved by direct methods and refined by the full-matrix, least-squares technique against F^2 in the anisotropic (H atoms isotropic) approximation with the SHELXTL 5.1 package. Analysis of the Fourier density synthesis in **4i** showed that the isobutyl group [C(3)−C(6)] was disordered by two positions, which were included in the refinement with equal occupancies. The absolute configurations in **4i** and **5i** were determined by use of the Flack parameter. All hydrogen atoms with the exception of the disordered group were located from the Fourier synthesis and treated by a mixture of independent and constrained refinement. CCDC-173440 (**4i**), -173441 (**5i**) and -173442 (**5l**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]. $[Rh(CO)_2Cl]_2$,[33] $[Pd(COD)Cl_2]$,[34] $[Pd(allyl)Cl]_2$,[35] amino and imino alcohols **2d**,[36] **2f**,[37] **2g**,[38] **2h**,[11] **2l**[39] and bis(2,6-dimethylphenyl) chlorophosphite[12] were synthesized as published. The syntheses of compounds **2i**−**k** and **2m** were performed by techniques similar to that reported.[40] (*S*)-(+)-Isoleucinol, ferrocenecarboxaldehyde, 4-(dimethylamino)benzaldehyde and compounds **2a** and **2c** were purchased from Aldrich; (1*R*,2*S*)-(+)-*cis*-1-amino-2-indanol was purchased from Fluka. Amino and imino alcohols **2b** (quincoridine, Büchler GmbH), **2c**−**f**, **2h** and **2i** were azeotropically dried with benzene and distilled before use. Compounds **2a**, **2g** and **2j**−**2m** were dried under vacuum (2 Torr, 3 h) immediately before use.

Synthesis and Characterization

(2*S*,3*S*)-3-Methyl-2-(pyrrolidin-1-yl)pentan-1-ol (2e): A mixture of 1,4-dibromobutane (2.37 mL, 2×10^{-2} mol), (*S*)-(+)-isoleucinol (2.34 g, 2×10^{-2} mol) and K_2CO_3 (8.29 g, 6×10^{-2} mol) in acetonitrile (25 mL) was heated under reflux for 30 h. The mixture was then allowed to cool to room temp. and filtered, and the filter cake was washed with DCM (2×15 mL). The combined extracts were concentrated under vacuum (40 Torr) and the residue was distilled in high vacuum to give a yellow, paraffin-like product (2.297 g, 67% yield). B.p. 165−170 °C (0.8 Torr, kugelrohr distillation). ^{1}H NMR ($CDCl_3$): δ = 0.95 (t, ^{3}J = 7.4 Hz, 3 H, CH_2CH_3), 1.15 (d, ^{3}J = 6.8 Hz, 3 H, CH_3), 1.42 (m, 2 H, CH_2), 1.91 (m, 1 H, CH), 2.05 [m, 2 H, $(CH_2)_2$], 2.29[m, 2 H, $(CH_2)_2$], 3.00 (m, 1 H, CHN), 3.17 (m, 1 H, CH_2N), 3.22 (m, 1 H, CH_2N), 3.78 (m, 1 H, CH_2N), 3.94 (q, 1 H, CH_2N), 4.03 (m, 2 H, CH_2O), 4.27 (br. s, 1 H, OH). $C_{10}H_{21}NO$ (171.16): calcd. C 70.12, H 12.36, N 8.18; found C 69.86, H 12.12, N 7.98.

(2*S*,3*S*)-2-[4-(Dimethylamino)benzylideneamino]-3-methylpentan-1-ol (2i): (*S*)-(+)-Isoleucinol (1.17 g, 1×10^{-2} mol) was dissolved in 30 mL of dichloromethane. 4-(Dimethylamino)benzaldehyde (1.49 g, 1×10^{-2} mol), Na_2SO_4 (1 g) and 15 mL of dichloromethane were added to this solution with stirring, and the mixture was heated under reflux for 3 h. After the mixture had cooled to room temperature, the Na_2SO_4 was filtered off and washed with dichloromethane. The solvent was removed and the resulting residue was distilled under vacuum. Yellow viscous oil, 1.564 g (63% yield). n_D^{20} = 1.4411. B.p. 165−167 °C (0.8 Torr, kugelrohr distillation). ^{1}H NMR ($CDCl_3$): δ = 0.83 (t, ^3J = 7.6 Hz, 3 H, CH_2CH_3), 0.92 (d, ^3J = 6.8 Hz, 3 H, CH_3), 1.04 (m, 1 H, CH), 1.46 (m, 1 H, CH_2), 1.69 (m, 1 H, CH_2), 2.41 (br. s, 1 H, OH), 2.98 (m, 1 H, CHN), 3.00 [s, 6 H, $N(CH_3)_2$], 3.78 (m, 2 H, CH_2O), 6.67 (d, ^3J = 8.8 Hz, 2 H, H_{Ar}), 7.57 (d, ^3J = 8.8 Hz, 2 H, H_{Ar}), 8.08 (s, 1 H, CH=). ^{13}C NMR ($CDCl_3$): δ_C = 10.6 (s, CH_3), 15.2 (s, CH_3), 25.1 (s, CH_2), 36.2 (s, CH), 39.5 [s, $N(CH_3)_2$], 63.6 (s, CH_2O), 76.6 (s, CHN), 110.9−151.3 (s, C_{Ar}), 161.3 (s, CH=). $C_{15}H_{24}N_2O$ (248.19): calcd. C 72.54, H 9.74, N 11.28; found C 72.36, H 9.84, N 11.15.

(2*R*)-2-(Ferrocenylidineamino)-3-(methylthio)propan-1-ol (2j): This compound was synthesized analogously to **2i**, starting from (*R*)-2-amino-3-(methylthio)propan-1-ol (1.21 g, 1×10^{-2} mol) and ferrocenecarboxaldehyde (2.14 g, 1×10^{-2} mol). Orange-red solid, 2.636 g (83% yield). ^{1}H NMR(C_6D_6): δ = 1.87 (s, 3 H, CH_3), 2.62 (m, 2 H, CH_2S), 2.85 (s, 1 H, OH), 3.24 (m, 1 H, CHN), 3.69 (m, 2 H, CH_2O), 4.10 (m, 1 H, H_{Fc}), 4.12 (m, 1 H, H_{Fc}), 4.13 (s, 5 H, H_{Fc}), 4.46 (m, 1 H, H_{Fc}), 4.80 (m, 1 H, H_{Fc}), 8.02 (s, 1 H, CH=). $C_{15}H_{19}FeNOS$ (317.05): calcd. C 56.79, H 6.04, N 4.42; found C 56.50, H 3.87, N 4.13.

(1*R*,2*S*)-1-(Ferrocenylideneamino)indan-2-ol (2k): This compound was synthesized analogously to **2i**, starting from (1*R*,2*S*)-(+)-*cis*-1-amino-2-indanol (1.49 g, 1×10^{-2} mol) and ferrocenecarboxaldehyde (2.14 g, 1×10^{-2} mol). Dark yellow solid, 85% yield (2.933 g) after recrystallisation from toluene/heptane (1:1) mixture. ^{1}H NMR ($CDCl_3$): δ = 3.21 (m, 2 H, CH_2O), 3.99 (br. s, 1 H, OH), 4.21 (s, 5 H, H_{Fc}), 4.23 (t, ^1J = 1.9 Hz, 2 H, H_{Fc}), 4.42 (t, ^1J = 1.9 Hz, 2 H, H_{Fc}), 4.60 (m, 1 H, CHO), 4.67 (d, ^1J = 5.8 Hz, 1 H, CHN), 7.18 (m, 1 H, H_{Ar}), 7.28 (m, 1 H, H_{Ar}), 7.43 (m, 1 H, H_{Ar}), 7.49 (m, 1 H, H_{Ar}), 8.45 (s, 1 H, CH=). $C_{20}H_{19}FeNO$ (345.08): calcd. C 69.58, H 5.55, N 4.06; found C 69.31, H 5.29, N 4.00.

(2*S*,3*S*)-2-(Ferrocenylideneamino)-3-methylpentan-1-ol (2m): This compound was synthesized analogously to **2i**, starting from (*S*)-(+)-isoleucinol (1.17 g, 1×10^{-2} mol) and ferrocenecarboxaldehyde (2.14 g, 1×10^{-2} mol). Orange solid, 2.685 g (81% yield). ^{1}H NMR ($CDCl_3$): δ = 0.88 (t, ^3J = 7.2 Hz, 3 H, CH_2CH_3), 0.94 (d, ^3J = 6.8 Hz, 3 H, CH_3), 1.24 (m, 2 H, CH_2), 1.65 (m, 1 H, CH), 2.94 (m, 1 H, CHN), 3.82 (m, 2 H, CH_2O), 3.99 (1 H, *s, br*, OH), 4.10 (s, 5 H, H_{Cp}), 4.34 (m, 1 H, H_{Fc}), 4.37 (m, 1 H, H_{Fc}), 4.51 (m, 1 H, H_{Fc}), 4.72 (m, 1 H, H_{Fc}), 8.06 (s, 1 H, CH=). ^{13}C NMR ($CDCl_3$): δ = 10.8 (s, CH_3), 15.3 (s, CH_3), 25.7 (s, CH_2), 36.0 (s, CH), 63.8 (s, CH_2O), 66.9, 68.7, 69.9, 70.2, 70.3, 80.0 (all C_{Fc}), 77.9 (s, CHN), 161.9 (s, CH=). $C_{17}H_{23}FeNO$ (313.11): calcd. C 65.19, H 7.40, N 4.47; found C 65.47, H 7.23, N 4.09.

Preparation of Ligands; General Technique: A solution of bis(2,6-dimethylphenyl) chlorophosphite (0.832 g, 2.7×10^{-3} mol) in benzene (15 mL) was added dropwise to a stirred solution of the appropriate alcohol **2** (2.7×10^{-3} mol) and Et_3N (0.4 mL, 2.7×10^{-3} mol) in the same solvent (15 mL) at 0 °C. The reaction mixture was then heated to boiling point, allowed to cool down, stirred for 1 h at 50 °C, allowed to cool to room temp. and filtered. The solvent was removed under vacuum (40 Torr), and the residue was dissolved in hexane (20 mL), filtered, concentrated and dried under vacuum (1 Torr).

(1*R*,2*S*)-2-Dimethylamino-1-phenylpropyl Bis(2,6-dimethylphenyl) Phosphite (3a): Colourless oil, 0.913 g (75% yield). ^{31}P NMR ($CDCl_3$): δ = 146.7. ^{13}C NMR ($CDCl_3$): δ = 8.6 (s, CH_3), 17.53, 17.59, 17.72, 17.78 [CH_3(Ar)], 41.6 (s, NMe_2), 65.3 (d, ^3J = 3.8 Hz, CHN), 77.4 (d, ^2J = 13.3 Hz, CHO), 119.8−149.3 (C_{Ar}). MS (EI,

70 eV): *m/z* (%) = 451 (1) $[M]^+$, 380 (5), 273 (15), 162 (67), 122 (100). $C_{27}H_{34}NO_3P$ (415.22): calcd. C 71.82, H 7.59, N 3.10; found C 72.11, H 7.43, N 3.33.

Bis(2,6-dimethylphenyl) (2*R*,4*S*,5*R*)-(5-Vinylquinuclid-2-yl)methyl Phosphite (3b): Colourless oil, 0.841 g (71% yield). ^{31}P NMR (C_6D_6): δ = 138.4. ^{13}C NMR (C_6D_6): δ = 17.96, 18.00, 18.02, 18.05 [all *C*H_3(Ar)], 24.4 (s, CH*C*H_2CH), 26.9 (s, CH_2*C*H_2CH), 28.0 (s, CH_2*C*HCH_2), 40.2 (s, CH*C*HCH=), 48.0 (s, N*C*H_2CH), 49.2 (N*C*H_2CH_2), 56.2 (d, ^3J = 3.4 Hz, CHN), 64.1 (d, ^2J = 5.2 Hz, CH_2O), 114.3 (s, CH_2=), 140.8 (s, CH=), 119.9−149.5 (C_{Ar}). MS (EI, 70 eV): *m/z* (%) = 439 (4) $[M]^+$, 318 (95), 273 (9), 166 (42), 150 (100). $C_{26}H_{34}NO_3P$ (439.22): calcd. C 71.05, H 7.80, N 3.19; found C 69.85, H 7.52, N 3.40.

Bis(2,6-dimethylphenyl) [(2*S*)-1-Methylpyrrolidin-2-yl]methyl Phosphite (3c): Colourless oil, 0.724 g (69% yield). ^{31}P NMR (C_6D_6): δ = 137.3. ^{13}C NMR (C_6D_6): δ = 17.40 [s, *C*H_3(Ar)]. 17.44 [s, CH_3(Ar)], 22.6 [s, $(CH_2)_2$], 28.4 [s, $(CH_2)_2$], 41.2 (s, NCH_3), 57.2 (s, CH_2N), 64.0 (s, CHN), 65.1 (s, CH_2O), 119.4−149.2 (C_{Ar}). MS (EI, 70 eV): *m/z* (%): 387 (3) $[M]^+$, 289 (1), 273 (42), 122 (100). $C_{22}H_{30}NO_3P$ (387.19): calcd. C 68.20, H 7.80, N 3.62; found C 68.51, H 8.07, N 3.44.

[(2*S*)-1-Benzylpyrrolidin-2-yl]methyl Bis(2,6-dimethylphenyl) Phosphite (3d): Colourless oil, 0.962 g (77% yield). ^{31}P NMR (C_6D_6): δ = 136.6. ^{13}C NMR (C_6D_6): δ = 17.4 [s, *C*H_3(Ar)], 17.6 [s, *C*H_3(Ar)], 22.7 [s, $(CH_2)_2$], 28.4 [s, $(CH_2)_2$], 54.4 (s, CH_2Ph), 59.5 (s, CH_2N), 63.5 (d, ^3J = 4.2 Hz, CHN), 65.4 (d, ^2J = 3.4 Hz, CH_2O), 119.7− 149.3 (C_{Ar}). MS (EI, 70 eV): *m/z* (%) = 463 (1) $[M]^+$, 372 (3), 342 (47), 273 (3), 122 (85), 91 (100). $C_{28}H_{34}NO_3P$ (463.23): calcd. C 72.55, H 7.39, N 3.02; found C 72.81, H 7.01, N 3.36.

Bis(2,6-dimethylphenyl) (2*S*,3*S*)-3-Methyl-2-(pyrrolidin-1-yl)pentyl Phosphite (3e): Colourless oil, 0.813 g (68% yield). ^{31}P NMR ($CDCl_3$): δ = 136.1. ^{13}C NMR (C_6D_6): δ = 12.2 (s, CH_3). 14.6 (s, CH_3), 16.9, 17.3, 17.9, 18.1, [all *C*H_3(Ar)], 23.5 [s, $(CH_2)_2$], 27.4 (s, CH_2), 36.2 (s, CH), 51.5 (s, CH_2N), 65.3 (s, CH_2O), 76.1 (s, CHN), 119.6−149.5 (C_{Ar}). MS (EI, 70 eV): *m/z* (%) = 443 (1) $[M]^+$, 273 (38), 122 (100). $C_{26}H_{38}NO_3P$ (443.26): calcd. C 70.40, H 8.64, N 3.16; found C 72.66, H 8.94, N 3.38.

(2*R*)-2-(Dibenzylamino)-3-methylbutyl Bis(2,6-dimethylphenyl) Phosphite (3f): Colourless oil, 1.184 g (79% yield). ^{31}P NMR (C_6D_6): δ = 136.9. ^{13}C NMR (C_6D_6): δ = 18.0 [s, *C*H_3(Ar)], 18.1 [s, *C*H_3(Ar)], 20.5 (s, CH_3), 21.3 (s, CH_3), 27.9 (s, CH), 55.0 (s, CH_2Ph), 60.1 (s, CH_2O), 63.4 (d, ^3J = 4.0 Hz, CHN), 119.8−149.4 (C_{Ar}). MS (EI, 70 eV): *m/z* (%) = 555 (3) $[M]^+$, 464 (13), 273 (40), 122 (100). $C_{35}H_{42}NO_3P$ (555.29): calcd. C 75.65, H 7.62, N 2.52; found C 75.31, H 7.49, N 2.67.

Bis(2,6-dimethylphenyl) 2-({[(1*R*)-1-Phenylethyl]imino}methyl)-phenyl Phosphite (3g): Green oil, 1.099 g (82% yield). ^{31}P NMR (C_6D_6): δ = 139.9. ^{13}C NMR (C_6D_6): δ = 17.8 [s, CH_3(Ar)]. 17.9 [s, CH_3(Ar)], 25.4 (s, CH_3), 70.4 (s, CHN), 120.6−152.0 (s, C_{Ar}), 153.8 (s, CH=). MS (EI, 70 eV): *m/z* (%) = 498 (2) $[M + H]^+$, 376 (56), 408 (15), 273 (52), 105 (100). $C_{31}H_{32}NO_3P$ (497.21): calcd. C 74.83, H 6.48, N 2.82; found C 75.04, H 6.22, N 3.13.

(2*R*)-2-[4-(Dimethylamino)benzylideneamino]-3-methylbutyl Bis(2,6-dimethylphenyl) Phosphite (3h): Colourless oil, 1.093 g (80% yield). ^{31}P NMR (C_6D_6): δ = 136.8. ^{13}C NMR (C_6D_6): δ = 17.94 [s, *C*H_3(Ar)], 17.98 [s, *C*H_3(Ar)], 18.5 (s, CH_3), 20.1 (s, CH_3), 30.7 (s, CH), 40.0 [s, $N(CH_3)_2$], 65.1 (d, ^2J = 11.6 Hz, CH_2O), 77.1 (d, ^3J = 2.7 Hz, CHN), 111.8−152.1 (s, C_{Ar}), 161.2 (s, CH=). MS (EI, 70 eV): *m/z* (%) = 506 (2) $[M]^+$, 316 (52), 217 (66), 122 (100). $C_{30}H_{39}N_2O_3P$ (506.27): calcd. C 71.12, H 7.76, N 5.53; found C 71.41, H 8.05, N 5.77.

(2*S*,3*S*)-2-[4-(Dimethylamino)benzylideneamino]-3-methylpentyl Bis(2,6-dimethylphenyl) Phosphite (3i): Yellow oil, 1.165 g (83% yield). ^{31}P NMR ($CDCl_3$): δ = 136.4. MS (EI, 70 eV): *m/z* (%) = 520 (1) $[M]^+$, 400 (81), 316 (28), 122 (100). $C_{31}H_{41}N_2O_3P$ (520.29): calcd. C 71.51, H 7.94, N 5.38; found C 72.84, H 8.14, N 5.16.

Bis(2,6-dimethylphenyl) (2*R*)-2-(Ferrocenylideneamino)-3-(methylthio)propyl Phosphite (3j): Dark red oil, 1.193 g (75% yield). ^{31}P NMR (C_6D_6): δ = 135.9. ^{13}C NMR (C_6D_6): δ = 16.6 (s, SCH_3), 17.9 [s, *C*H_3(Ar)], 18.0 [s, *C*H_3(Ar)], 37.2 (s, CH_2S), 65.2 (s, CH_2O), 68.8, 69.3, 70.5, 70.6 (all C_{Fc}), 69.6 (s, C_{Cp}), 71.8 (d, ^3J = 3.4 Hz, CHN), 80.9 [s, C_{Fc}(*ipso*)], 124.4−149.5 (s, C_{Ar}), 162.3 (s, CH=). MS (EI, 70 eV): *m/z* (%) = 589 (3) $[M]^+$, 542 (36), 468 (98), 300 (34), 122 (100). $C_{31}H_{36}FeNO_3PS$ (589.15): calcd. C 63.16, H 6.16, N 2.38; found C 61.89, H 6.41, N 2.63.

Bis(2,6-dimethylphenyl) (1*R*,2*S*)-1-(Ferrocenylideneamino)indan-2-yl Phosphite (3k): Red oil, 1.197 g (72% yield). ^{31}P NMR (C_6D_6): δ = 138.2. ^{13}C NMR (C_6D_6): δ = 17.97, 18.02, 18.20, 18.26 [*C*H_3(Ar)], 38.9 (s, CH_2), 68.9, 69.6, 70.4, 70.5 (all C_{Fc}), 69.4 (s, C_{Cp}), 77.2 (d, ^2J = 3.4 Hz, CHO), 77.6 (s, CHN), 81.2 [s, C_{Fc}(*ipso*)], 120.2−153.3 (s, C_{Ar}), 160.9 (s, CH=). MS (EI, 70 eV): *m/z* (%) = 617 (2) $[M]^+$, 496 (2), 328 (24), 273 (7), 122 (100). $C_{36}H_{36}FeNO_3P$ (617.18): calcd. C 70.02, H 5.88, N 2.27; found C 69.79, H 6.14, N 2.55.

Bis(2,6-dimethylphenyl) (2*R*)-2-(Ferrocenylideneamino)-3-methylbutyl Phosphite (3l): Red oil, 1.233 g (80% yield). ^{31}P NMR ($CDCl_3$): δ = 135.1. MS (EI, 70 eV): *m/z* (%) = 571 (2) $[M]^+$, 450 (76), 282 (28), 122 (100). $C_{32}H_{38}FeNO_3P$ (571.19): calcd. C 67.26, H 6.70, N 2.45; found C 67.04, H 6.87, N 2.74.

Bis(2,6-dimethylphenyl) (2*S*,3*S*)-2-(Ferrocenylideneamino)-3-methylpentyl Phosphite (3m): Dark red oil, 1.343 g (85% yield). ^{31}P NMR (C_6D_6): δ = 135.9. ^{13}C NMR (C_6D_6): δ = 10.6 (s, CH_3). 15.3 (s, CH_3), 17.2 [s, *C*H_3(Ar)], 17.23 [s, *C*H_3(Ar)], 25.0 (s, CH_2), 36.3 (s, CH), 63.6 (s, CH_2O), 68.0, 68.2, 69.78, 69.80 (all C_{Fc}), 68.6 (s, C_{Cp}), 76.0 (s, CHN), 80.0 [s, C_{Fc}(*ipso*)], 123.5−148.7 (C_{Ar}), 160.6 (s, CH=). MS (APCI): *m/z* (%) = 586 (100) $[M + H]^+$, 464 (18), 314 (42), 122 (10). $C_{33}H_{40}FeNO_3P$ (585.21): C 67.70, H 6.89, N 2.39; found C 67.96, H 6.62, N 2.74.

Preparation of Complexes

Preparation of Rhodium Complexes 4b−4f and 4j: Rhodium complexes with ligands **3b−3h** and **3j** were synthesized for the NMR and IR experiments as follows. A solution of L* (3.6×10^{-4} mol) in $CHCl_3$ (1.5 mL) was added dropwise to a stirred solution of $[Rh(CO)_2Cl]_2$ (1.8×10^{-4} mol) in the same solvent (1.5 mL). A 1-mL sample of the resulting solution was then transferred to an NMR tube or IR cuvette and spectral experiments were carried out.

General Technique for Rhodium Complexes 4a, 4i and 4k−4m: A solution of the appropriate ligand (3.6×10^{-4} mol) in DCM (20 mL) was added dropwise to a stirred solution of $[Rh(CO)_2Cl]_2$ (0.070 g, 1.8×10^{-4} mol) in the same solvent (20 mL) at 20 °C. The reaction mixture was stirred at 20 °C for 30 min. The excess solvent was then removed under vacuum (40 Torr), and 10 mL of hexane was added to the residue. The obtained precipitate was separated by centrifugation, washed with hexane (2×10 mL) and dried under vacuum (2 Torr).

[Rh(CO)Cl(3a-P^N)] (4a): Yellow solid, 0.193 g (87% yield). IR (KBr): ν(CO) 2017 cm^{-1}. $C_{28}H_{34}ClNO_4PRh$ (617.10): calcd. C 54.43, H 5.55, N 2.27; found C 54.73, H 5.69, N 2.51.

[Rh(CO)Cl(3i-P^N)] (4i): Yellow solid, 0.221 g (89% yield). IR (KBr): ν(CO) 2008 cm^{-1}. $C_{32}H_{41}ClN_2O_4PRh$ (686.15): calcd. C 55.94, H 6.02, N 4.08; found C 56.28, H 5.74, N 4.39.

[Rh(CO)Cl(3k-P^N)] (4k): Yellow-brown solid, 0.260 g (92% yield). IR (KBr): ν(CO) 2010 cm^{-1}. $C_{37}H_{36}ClFeNO_4PRh$ (783.05): calcd. C 56.69, H 4.63, N 1.79; found C 56.93, H 4.31, N 2.10.

[Rh(CO)Cl(3l-P^N)] (4l): Yellow-brown solid, 0.239 g (90% yield). IR (KBr): ν(CO) 2008 cm^{-1}. MS (EI, 70 eV): *m/z* (%) = 702 (34) $[M - Cl]^+$, 674 (5) $[M - Cl - CO]^+$, 282 (52), 122 (100). MS (ES): *m/z* (%) = 702 (55) $[M - Cl]^+$, 300 (100). $C_{33}H_{38}ClFeNO_4PRh$ (737.06): calcd. C 53.72, H 5.19, N 1.90; found C 54.00, H 5.53, N 2.26.

[Rh(CO)Cl(3m-P^N)] (4m): Yellow-brown solid, 0.239 g (88% yield). IR (KBr): ν(CO) 2010 cm^{-1}. $C_{34}H_{40}ClFeNO_4PRh$ (751.08): calcd. C 54.31, H 5.36, N 1.86; found C 54.64, H 5.37, N 2.08.

[Rh(CO)Cl(3f-P^N)] (4f): A solution of ligand **3f** (0.200 g, 3.6×10^{-4} mol) in DCM (10 mL) was added dropwise to a stirred solution of [acacRh$(CO)_2$] (0.093 g, 1.8×10^{-4} mol) in the same solvent (10 mL) at 20 °C. The reaction solution was stirred for 30 min at room temp. to form [acacRh(CO)(η^1-P^N)] complex. A solution of [Rh$(CO)_2Cl]_2$ (0.070 g, 1.8×10^{-4} mol) in DCM (10 mL) was then added to this solution and, after the mixture had stirred for 1 h, all the volatiles were evaporated under vacuum (40 Torr). Regenerated [acacRh$(CO)_2$] was extracted from the residue with hexane (4×15 mL), and the final residue was dried under vacuum (2 Torr) to give the desired product. Yellow solid, 0.222 g (85% yield). IR (KBr): ν(CO) 2009 cm^{-1}. $C_{36}H_{42}ClNO_4PRh$ (721.16): calcd. C 59.88, H 5.86, N 1.94; found C 60.17, H 6.13, N 2.34.

General Technique for Palladium Complexes 5i and 5l: A solution of the appropriate ligand (**3i** or **3l**, 2×10^{-4} mol) in DCM (15 mL) was added dropwise to a stirred solution of [Pd(COD)Cl_2] (0.057 g, 2×10^{-4} mol) in the same solvent (15 mL) at room temp. After the mixture had been stirred for 1 h, the excess solvent was removed under vacuum (40 Torr) and 10 mL of ether was added to the residue. The obtained precipitate was separated by centrifugation, washed with ether (2×10 mL) and dried under vacuum (2 Torr).

***cis*-[PdCl$_2$(3i-P^N)] (5i):** Yellow solid, 0.126 g (91% yield). $C_{31}H_{41}Cl_2N_2O_3PPd$ (696.13): calcd. C 53.35, H 5.92, N 4.01; found C 53.62, H 6.22, N 3.87.

***cis*-[PdCl$_2$(3l-P^N)] (5l):** Yellow-brown solid, 0.135 g (90% yield). $C_{32}H_{38}FeCl_2NO_3PPd$ (747.04): calcd. C 51.33, H 5.12, N 1.87; found C 51.65, H 4.91, N 1.98.

[Pd(allyl)(3m-P^N)]$^+$Cl$^-$ (6): A solution of imino phosphite **3m** (0.234 g, 4×10^{-4} mol) in DCM (20 mL) was added dropwise to a stirred solution of [Pd(allyl)Cl]$_2$ (0.073 g, 2×10^{-4} mol) in the same solvent (20 mL) at room temp. After the mixture had been stirred for 1 h, the solvent was removed under vacuum, and the residue was washed with hexane (2×10 mL) and dried under vacuum (2 Torr). Yellow-brown solid, 0.288 g (94% yield). ^{13}C NMR (C_6D_6): δ = 11.6 (s, CH_3), 16.1 (s, CH_3), 18.7 [s, CH_3(Ar)], 18.8 [s, CH_3(Ar)], 25.1 (s, CH_2), 36.5 (s, CH), 55.0 (s, CH_2 [allyl, *trans*-N)], 67.0 (s, CH_2O), 68.2, 69.6, 70.2, 72.8 (all C_{Fc}), 69.4 (s, C_{Cp}), 75.3 (s, CHN), 80.2 [s, C_{Fc} (*ipso*)], 81.4 (d, ^2J = 42.8 Hz, CH_2 [allyl, *trans*-P)], 125.3 [d, ^2J = 8.2 Hz, CH(allyl)], 118.1−149.2 (s, C_{Ar}), 168.7 (s, CH=). MS (PD): *m/z* (%) = 767 (20) $[M]^+$, 732 (100) $[M - Cl]^+$, 690 (46), 585 (52), 121 (21). XPS: E_b [eV] = 338.2 (Pd $3d_{5/2}$), 134.0 (P 2p), 198.4 (Cl 2p), 399.6 (N 1s), 708.7 (Fe 2p). $C_{36}H_{45}FeClNO_3PPd$ (767.12): calcd. C 56.27, H 5.90, N 1.82; found C 56.58, H 6.11, N 2.02.

Catalytic Experiments

Palladium-Catalysed Alkylation of Ethyl 3-Penten-2-yl Carbonate with Dimethyl Malonate: [Pd(allyl)Cl]$_2$ (3.6 mg, 10^{-5} mol) and ligand **3** ($2-4 \times 10^{-5}$ mol) were dissolved in the appropriate solvent and the mixture was stirred at room temp. for 20 min. Ethyl 3-penten-2-yl carbonate (160 mg, 10^{-3} mol), dimethyl malonate (132 mg, 1.5×10^{-3} mol), BSA [*N,O*-bis(trimethylsilyl)acetamide] (305 mg, 1.5×10^{-3} mol) and KOAc (2.5 mg) were then added to the catalyst solution, and the mixture was stirred at room temp. for 24 h. The reaction mixture was then poured into saturated aqueous NH_4Cl solution and extracted with ether (2×50 mL). The combined organic extracts were washed with aqueous $NaHCO_3$ and water, dried (Na_2SO_4), filtered and concentrated under vacuum. Purification by flash chromatography (silica gel; petroleum ether/EtOAc, 8:1) gave the allylic alkylation product as a colourless oil. The (*S*) absolute configuration was ascribed to the product on the basis of the (−) sign of its optical rotation.[28]

Palladium-Catalysed Sulfonylation of Methyl 3-Penten-2-yl Carbonate with Sodium *p*-Toluenesulfinate: Ligand **3** ($1.1-2.2 \times 10^{-5}$ mol) was added to a solution of [Pd(allyl)Cl]$_2$ (2 mg, 5.5×10^{-6} mol) in the corresponding solvent at room temp. After the mixture had been stirred for 15 min, a solution of methyl 3-penten-2-yl carbonate (72.1 mg, 5×10^{-4} mol) in the appropriate solvent was added. Stirring was continued for 15 min and a suspension of $NaSO_2p$-Tol (178 mg, 10^{-3} mol) in the appropriate solvent was added. After the mixture had been stirred for 48 h, brine (10 mL) was added, and the mixture was extracted with THF. The organic phase was dried ($MgSO_4$) and concentrated under vacuum. Purification by flash chromatography (silica gel; hexane/EtOAc, 5:1) gave the product as a colourless oil. The (*R*) absolute configuration was ascribed to the product on the basis of the (−) sign of its optical rotation.[30]

A New Family of Organometallic Rhodium Complexes with [Rh(P*i*Pr$_2$Ph)$_2$] and [Rh(P*i*PrPh$_2$)$_2$] as Molecular Units

Helmut Werner,*[a] Frank Kukla,[a] and Paul Steinert[a]

Dedicated to Professor Walter Siebert on the occasion of his 65th birthday

Keywords: Allyl ligands / Alkyne ligands / Vinylidene complexes / Rhodium / Phosphanes

The π-allyl complexes [Rh(η^3-C_3H_5)(PR$_3$)$_2$] [PR$_3$ = P*i*Pr$_2$Ph (**4**), P*i*PrPh$_2$ (**5**)], prepared from [RhCl(C_8H_{14})$_2$]$_2$, PR$_3$ and the Grignard reagent C_3H_5MgBr, react with carboxylic acids and *p*-toluenesulfonic acid to give the chelate compounds [Rh(κ^2-O_2CR′)(PR$_3$)$_2$] (**8**–**10**) and [Rh{κ^2-O_2S(O)-*p*-Tol}(PR$_3$)$_2$] (**11**, **12**), respectively. While the reactions of **8**, **10** and **12** with CO afford the square-planar rhodium(I) complexes **13**–**15** with monodentate carboxylato and tosylato ligands, treatment of **8**–**10** and **11**, **12** with H_2 leads to the formation of the octahedral dihydridorhodium(III) derivatives [RhH$_2$(κ^2-O_2CR′)(PR$_3$)$_2$] (**16**–**18**) and [RhH$_2${κ^2-O_2S(O)-*p*-Tol}(PR$_3$)$_2$] (**19**, **20**). Similarly to CO, internal alkynes RC≡CCO_2Me (R = CO_2Me, Me) react with **8** and **9** by partial opening of the chelate bond to yield the π-alkyne complexes **21**–**23**, of which **23** with R = Me is quite labile and smoothly regenerates the starting material. In contrast, the reactions of **8** and **9** with terminal alkynes HC≡CR (R = Ph, CO_2Me) afford six-coordinate alkynyl(vinyl)rhodium(III) compounds **24**–**26** with a different stereochemistry at the C=C double bond depending on the substituent R. From **8** and HC≡CCH(Cl)Me the octahedral allenyl complex [RhCl(CH=C=CHMe)(κ^2-O_2CR′)(P*i*PrPh$_2$)$_2$] (**27**) is obtained, the molecular structure of which has been determined by X-ray crystallography. The reaction of [Rh(κ^1-O_2CR){η^2-C_2(CO_2Me)$_2$}(P*i*PrPh$_2$)$_2$] (**21**, **22**) with HC≡CPh also leads to the six-coordinate alkynyl(vinyl)rhodium(III) compounds **28**, **29**, which upon treatment with Me_3SiCl and thermolysis are stepwise converted into the four-coordinate π-enyne complex *trans*-[RhCl{η^2-Ph*C*≡*C*C(CO_2Me)=CHCO_2Me}(P*i*PrPh$_2$)$_2$] (**31**). The reaction of **31** with CO generates the uncoordinated substituted enyne. The rhodium(I) vinylidene complexes *trans*-[Rh(C≡CR′)(=C=CHR)(P*i*PrPh$_2$)$_2$] (**36**–**38**) were prepared in two steps from the tosylato complex **12** and terminal alkynes; they react with CO via migratory insertion to give the square-planar enynyl compounds *trans*-[Rh{η^1-C(C≡CR)=CHR′}(CO)(P*i*PrPh$_2$)$_2$] (**39**–**41**).

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

In the context of our investigations on low-valent organorhodium compounds,[1] we recently reported a high-yield synthesis of the π-allyl complexes [Rh(η^3-2-C_3H_4R)(P*i*Pr$_3$)$_2$] (R = H, Me, Ph) which readily react with Brønsted acids by cleavage of the allyl-metal bond.[2] If terminal alkynes HC≡CR were used as acidic substrates, the alkynyl(vinylidene)rhodium(I) compounds *trans*-[Rh(C≡CR)(=C=CHR)(P*i*Pr$_3$)$_2$] were obtained which, in the presence of CO or isocyanides, undergo an intramolecular C−C coupling process.[3] Since we observed that the course of the reactions of rhodium(I) compounds [Rh(X)(P*i*Pr$_3$)$_2$] (where X could be a carboxylate or tosylate) with HC≡CR depends on both the anionic ligand X$^-$ and the substituent R of the alkyne, we became interested to find out whether the nature of the phosphane would also have an influence on the composition of the products. In a recent paper, some evidence for this assumption was already presented.[4] The present article describes preparative routes to four-coordinate carboxylato- and tosylatorhodium(I) complexes with P*i*PrPh$_2$ and P*i*Pr$_2$Ph as ligands and reports in detail on their reactivity toward internal and terminal alkynes.

Results and Discussion

The method recently used by us for the synthesis of [Rh(η^3-C_3H_5)(P*i*Pr$_3$)$_2$][2] could also be applied for the preparation of the related complexes **4** and **5** (Scheme 1). Treatment of a suspension of **1** in toluene with P*i*Pr$_2$Ph or P*i*PrPh$_2$ in 1:4 molar ratio, followed by the addition of a solution of the Grignard reagent C_3H_5MgBr in ether, results in the formation of the π-allylrhodium(I) compounds **4** and **5**, which were isolated as yellow solids in about 80% yield. If the violet solution, formed upon the addition of P*i*Pr$_2$Ph or P*i*PrPh$_2$ to the starting material **1** in toluene, is dried in vacuo, the bis(phosphane)rhodium(I) derivatives **2** and **3** were obtained. These dimeric complexes are some-

what less air-sensitive than the triisopropylphosphane counterpart $[RhCl(PiPr_3)_2]_2$ [5] and can be stored under argon at room temperature without decomposition. The ^{31}P NMR spectra of **2** and **3** show the expected doublet with a large ^{31}P-^{103}Rh coupling constant of ca. 198 Hz that is typical for rhodium(I) compounds with $[Rh(PR_3)_2]$ as a building block and *cis*-disposed phosphane ligands.[2,4,6]

3, 5	$PiPrPh_2$
6	$PHiPr_2$
7	$PtBu_2Me$

Scheme 1

While the reactions of **2** and **3** with a twofold excess of the Grignard reagent C_3H_5MgBr also lead to the generation of **4** and **5**, the preparative route using **1** as the precursor is more convenient. It can also be applied for the synthesis of **6** and **7** with $PHiPr_2$ and $PtBu_2Me$ as the phosphane ligands. The ^1H NMR spectra of the π-allylrhodium(I) complexes **4** and **6** exhibit, besides the expected sets for the C_3H_5 protons, four resonances for the protons of the diastereotopic methyl groups of the $PiPr_2$ moieties, which are split into doublets of doublets due to ^{31}P-^1H and ^1H-^1H coupling. Moreover, the ^1H NMR spectrum of **6** shows a doublet of triplets at $\delta = 4.06$ with a large ^{31}P-^1H coupling constant of 256.5 Hz that is characteristic of a P-bonded hydrogen atom. The observation of two distinct signals for the nuclei of the *syn* and the *anti* protons of the terminal allylic CH_2 groups indicate that in solution at room temperature the $(\eta^3\text{-}C_3H_5)Rh$ unit is rigid and does not undergo an η^3-η^1-η^3 rearrangement.[7]

The π-allylic complexes **4** and **5** react smoothly with equimolar amounts of carboxylic acids or *p*-toluenesulfonic acid by cleavage of the allyl-metal bond (Scheme 2). The apparently more simple synthetic method, namely the reaction of **2** or **3** with RCO_2Na or RSO_3Na, led to mixtures of products which could not be separated by fractional crystallization or chromatographic techniques. Both the rhodium carboxylates **8**−**10** and the rhodium tosylates **11** and **12** are red air-sensitive solids which, with the exception of pentane, are readily soluble in common organic solvents. The IR spectra of the carboxylato compounds **8**−**10** display two bands in the region of 1425−1445 and 1480−1510 cm^{-1} assigned to the symmetric and asymmetric OCO stretching modes. According to various data from the literature,[8] there is no doubt that the RCO_2^- ligands of **8**−**10** are coordinated in a chelating and not in a bridging fashion as found for the bis(ethene)rhodium(I) and dicarbonylrhodium(I) derivatives $[\{Rh(\mu\text{-}O_2CR)(C_2H_4)_2\}_2]$ and $[\{Rh(\mu\text{-}O_2CR)(CO)_2\}_2]$, respectively.[9] We assume that a chelating bonding mode also results for the RSO_3^- unit in the complexes **11** and **12**, as has been confirmed for the bis(triisopropylphosphane) compound $[Rh\{\kappa^2\text{-}O_2S(O)R\}(PiPr_3)_2]$ (R = *p*-Tol; Tol = C_6H_4Me) by X-ray crystallography.[10]

Scheme 2

With regard to the mechanism of formation of **8**−**10** and **11**, **12** from the π-allyl metal precursors **4** and **5**, we assume that the primary step consists of an oxidative addition of the acid HX to the rhodium(I) center to give the six-coordinate rhodium(III) intermediates $[RhH(\kappa^1\text{-}X)(\eta^3\text{-}C_3H_5)(PR_3)_2]$ (X = O_2CR, O_3SR), which upon reductive elimination of propene afford the products. We note that upon treatment of $[Rh(\eta^3\text{-}C_3H_5)(PiPr_3)_2]$ with an equimolar amount of CF_3CO_2H in pentane at −20 °C a stable compound $[RhH(\kappa^1\text{-}O_2CCF_3)(\eta^3\text{-}C_3H_5)(PiPr_3)_2]$ has been isolated which reacts at 40 °C to give $[Rh(\kappa^2\text{-}O_2CCF_3)(PiPr_3)_2]$ and C_3H_6.[2]

In the presence of CO, the carboxylato complexes as well as the tosylato derivatives are quite labile and react by partial opening of the chelate bond. This behavior has been exemplified by the preparation of the mononuclear compounds **13**−**15** (Scheme 3 and 4), which were isolated as pale-yellow, almost air-stable solids in 93−98% yield. In contrast to **8** and **10**, the IR spectra of **13** and **14** confirm that the RCO_2^- units are coordinated in a monodentate fashion. The two phosphane ligands of **13**−**15** are *trans*-disposed, which is illustrated by the appearance of one doublet in the ^{31}P NMR spectra, the respective ^{31}P-^{103}Rh coupling constant being significantly smaller than for the starting materials **8**, **10** and **12** with a *cis*-disposed $Rh(PR_3)_2$ moiety.

The carboxylato compounds **8**−**10** also react at room temperature with dihydrogen to give the octahedral dihydridorhodium(III) complexes **16**−**18** by oxidative addition. The white solids are much less sensitive towards air than the rhodium(I) precursors and can be stored under argon for weeks. The ^{31}P NMR spectra of **16**−**18** show only one

Scheme 4

resonance, indicating that the two phosphanes remain in a *trans* disposition. In the ^{1}H NMR spectra, there is also only one set of signals at $\delta = -22.0$ to -22.7 for the hydride ligands, which is in agreement with the proposed structure shown in Scheme 3.

The tosylato derivatives **11** and **12** have the same reactivity towards H_2 as the carboxylato derivatives. However, the isolated dihydrido complexes **19** and **20** are less stable than **16**−**18** and in vacuo slowly lose dihydrogen to regenerate the starting materials **11** and **12**. Therefore, it is necessary that they are stored at low temperature under a H_2 atmosphere. Since the ^{1}H and ^{31}P NMR spectroscopic data of **19** and **20** are similar to those of **16**−**18**, we assume that at 25 °C the two possible stereoisomers rapidly interconvert on the NMR time scale. At −78 °C in [D$_8$]toluene, there is only a slight broadening of the single resonance in the ^{31}P NMR spectra, which indicates that even under these conditions the interconversion of the two isomers should be very fast.

The reactions of the carboxylato complexes **8** and **9** with $C_2(CO_2Me)_2$ proceed analogously to those with CO. Treatment of the starting materials in benzene with an equimolar amount of the alkyne at room temperature leads to an almost instantaneous change of color from dark red to yellow and finally affords the products **21** and **22** (see Scheme 5) in about 85% yield. The ^{1}H and ^{31}P NMR spectra of **21** and **22** are, with respect to the P*i*PrPh$_2$ ligands, quite similar to those of the carbonyl compound **13**, and thus there is no doubt that the coordination geometry around the metal center is square planar. The IR spectra of **21** and **22** show the ν(C≡C) stretching mode at 1810 cm^{-1} (for **21**) and 1785 cm^{-1} (for **22**), the decrease of about 450 cm^{-1} relative to free $C_2(CO_2Me)_2$ being in agreement with the strong π-acceptor character of the electron-poor alkyne.

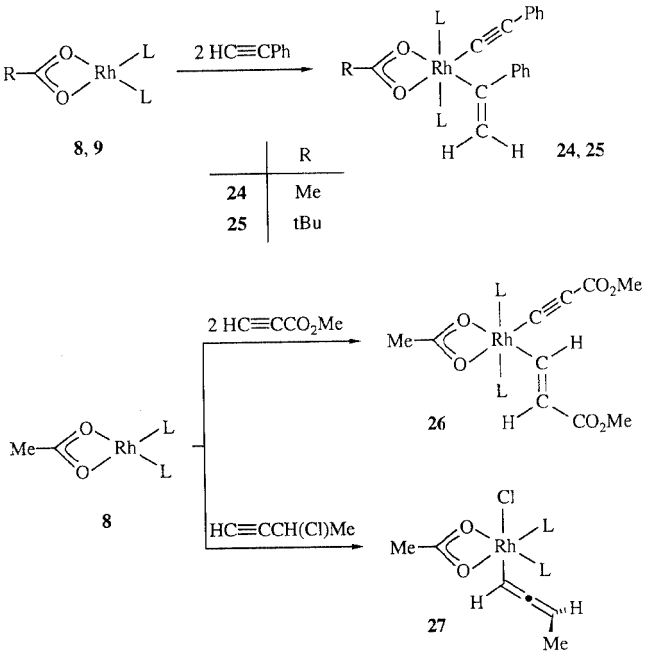
21	Me	P*i*PrPh$_2$
22, 23	*t*Bu	P*i*PrPh$_2$

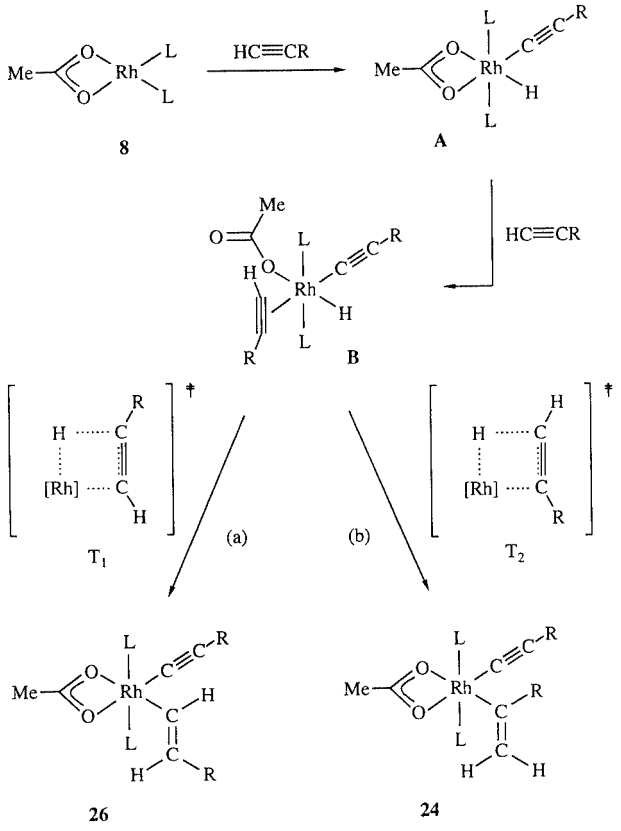
Scheme 5

While compound **8** does not react with MeC≡CCO$_2$Me in toluene at −20 °C, the corresponding reaction for **9** with MeC≡CCO$_2$Me under the same conditions takes place but is reversible. Only if the reaction mixture formed after stirring a solution of **9** and the alkyne in toluene at −20 °C for 2 h is worked-up rather quickly, and the crude product recrystallized from hexane at −78 °C, can a light yellow solid with the analytical composition corresponding to **23** be isolated. The ^{1}H and ^{31}P NMR spectra (measured in [D$_8$]toluene at −30 °C) differ only slightly from those of **22** and thus deserve no further comment.

The reactions of **8** and **9** with *terminal* alkynes take a different course to those of the same starting materials with $C_2(CO_2Me)_2$. Treatment of the carboxylato rhodium(I) complexes with two equiv. of phenylacetylene in toluene at −50 °C leads unexpectedly to the formation of the octahedral alkynyl(vinyl)rhodium(III) compounds **24** and **25** (Scheme 6), which were isolated as pale-yellow, only moderately air-sensitive solids in excellent yields. Although we attempted to detect the supposed intermediates [RhH(C≡CPh)(κ^2-O$_2$CR)(P*i*PrPh$_2$)$_2$] by monitoring the ^{1}H NMR spectra in [D$_8$]toluene at low temperature, we failed to observe the characteristic signals for such hydridometal species. Typical spectroscopic features of **24** and **25** are the two singlets for the stereochemically different protons of the C(Ph)=CH$_2$ ligand at about $\delta = 5.4$ to 6.0 in the ^{1}H NMR



Scheme 6. (L = P*i*PrPh$_2$)



Scheme 7. (L = P*i*PrPh$_2$)

spectrum and the doublet of triplets resonances for the alkynyl and vinyl carbon atoms in the region of δ = 100 to 150 in the ^{13}C NMR spectra. The ^{31}P NMR spectra of **24** and **25** display a sharp doublet at about δ = 30 with a ^{31}P-^{103}Rh coupling constant of 105−106 Hz that is in agreement with a *trans*-disposed Rh(PR$_3$)$_2$ unit.

The reaction of the acetato compound **8** with methyl propiolate also affords an octahedral alkynyl(vinyl)rhodium(III) complex **26** but with a different stereochemistry at the C=C double bond than **24**. While the ^{1}H NMR spectrum of **24** displays the signals for the vinylic protons at δ = 5.87 and 5.42, the ^{1}H NMR spectrum of **26** exhibits the two resonances at δ = 9.18 and 6.33. Both are split into doublets of doublets of triplets due to ^{1}H-^{1}H, ^{1}H-^{31}P and ^{1}H-^{103}Rh coupling. There is no doubt, in particular owing to the size of the ^{1}H-^{1}H coupling constant of 14.6 Hz, that in **26** the two protons at the C=C double bond are *trans* to each other. The same configuration has been found for the bis(triisopropylphosphane) complex [Rh(κ^2-O$_2$CCH$_3$)(C≡CCO$_2$Me){(*E*)-CH=CHCO$_2$Me}(P*i*Pr$_3$)$_2$], which was prepared in a stepwise manner from [RhH$_2$(κ^2-O$_2$CCH$_3$)(P*i*Pr$_3$)$_2$] and three equiv. of HC≡CCO$_2$Me under similar conditions.[11,12]

A proposal for the mechanism of the reactions of **8** with alkynes HC≡CR is outlined in Scheme 7. Although we have no evidence for the formation of intermediate **A**, we assume, in analogy to the reaction of [Rh(κ^2-O$_2$CCH$_3$)(P*i*Pr$_3$)$_2$] with phenylacetylene,[11] that in the first step such an alkynyl(hydrido)rhodium(III) species is generated. The addition of a second molecule of HC≡CR should give intermediate **B**. With regard to the next step, it probably depends on steric as well as electronic effects whether pathway (a) or (b) with the four-center transition states T$_1$ and T$_2$, respectively, is preferred. The above-mentioned dihydridorhodium compound [RhH$_2$(κ^2-O$_2$CCH$_3$)(P*i*Pr$_3$)$_2$], containing two phosphane ligands that are more bulky than P*i*PrPh$_2$, reacts with both HC≡CPh and HC≡CCO$_2$Me to give insertion products with a Rh−CH=CHR stereochemistry.[11,12] Moreover, the reaction of the six-coordinate hydridoiridium(III) compound [IrHCl(C≡CCO$_2$Me){κ^1-*P*-*i*Pr$_2$P(CH$_2$)$_2$OMe}{κ^2-*P*,*O*-*i*Pr$_2$P(CH$_2$)$_2$OMe}] with HC≡CCO$_2$Me also leads to an alkynyl(vinyl) complex with an Ir−CH=CHR linkage.[13]

In contrast to HC≡CPh and HC≡CCO$_2$Me, the chloro-substituted alkyne HC≡CCH(Cl)Me reacts with one equiv. of **8** to give the allenylrhodium(III) compound **27** in 88% yield instead of an alkynyl complex (see Scheme 6). In this process a migration of the chloride from the γ-carbon atom of the alkyne to rhodium takes place, followed by the formation of a σ bond between the metal and the remaining C$_3$ unit. Although a variety of allenyl-transition metal complexes have been prepared with allenyl halides as substrates, there is ample evidence that propargylic chlorides or propargylic alcohols can also be used to generate an M−CH=C=CRR′ bond.[14,15] Characteristic spectroscopic data for the allenyl ligand in **27** are the signals for the =CH and =CCH$_3$ protons at δ = 4.96 and 1.53, respectively, which not only couple to each other but also exhibit a ^{1}H-^{1}H coupling with the proton at the α-carbon atom. The ^{13}C NMR spectrum of **27** displays the resonances for the allenyl carbons at δ = 198.1, 87.4 and 83.0, of which only that of the metal-bound C atom at δ = 87.4 shows a ^{13}C-^{31}P and ^{13}C-^{103}Rh coupling.

The result of the X-ray crystal structure analysis of **27** is shown in Figure 1. The coordination geometry around rhodium is distorted octahedral with the two phosphanes *cis* and the chloride and the allenyl ligand *trans* to each other. Both the O1−Rh−O2 and P1−Rh−P2 bond angles deviate significantly from 90°, which is due on one hand to the bite angle of the chelating acetate and on the other to steric hindrance between the substituents at the two phosphorus atoms. The Cl−Rh−C1 axis is somewhat bent, the bond angle of 171.0(2)° being nearly identical to that of the octahedral allenylosmium complex [OsCl$_2$(η^1-CH=C=CPh$_2$)(NO)(P*i*Pr$_3$)$_2$] [170.5(1)°].[15] The Rh−C1 distance [2.052(5) Å] is slightly shorter than in *trans*-[Rh{η^1-(*Z*)-C(CH=CH$_2$)=CHPh}(CO)(P*i*Pr$_3$)$_2$] [2.088(5) Å][16] and *trans*-[Rh{η^1-C(CN)=CAn$_2$}(CO)(P*i*Pr$_3$)$_2$] [2.106(4) Å; An = *p*-C$_6$H$_4$OMe][17] but significantly longer than in the vinylrhodium cation [Rh{η^1-(*E*)-CH=CHCy}(κ^2-acac)(P*i*Pr$_3$)$_2$]$^+$ [1.98(1) Å].[18] The Rh−C1−C2 bond angle is almost exactly 120° and thus in agreement with the sp^2-hybridisation at the α-carbon atom of the C$_3$ chain. In close analogy to uncoordinated allenes,[19] the two planes [Rh,C1,C2,H1] and [C2,C3,C4,H3] are nearly perpendicular to each other, with a dihedral angle of 88(2)°.

Whereas attempts to reductively eliminate the enyne CH$_2$=C(Ph)−C≡CPh by warming or irradiating solutions of **24** or **25** failed, treatment of **25** with excess phenylacetylene in benzene at room temperature leads to the dimerization of the alkyne. The catalytic C−C coupling process can also be initiated by the carboxylatorhodium(I) compound **9** (the starting material for the preparation of **25**) and gives, under the conditions described in the Exp. Sect., the branched enyne CH$_2$=C(Ph)−C≡CPh almost exclusively. According to the ^{1}H NMR spectrum of the solution, taken after 80% of phenylacetylene has been consumed, the isomers (*E*)- and (*Z*)-PhCH=CH−C≡CPh are formed in less than 1% yield. In this context we note that Vinogradov et al. previously reported that [RhCl(PMe$_3$)$_3$] catalyses the dimerization of terminal alkynes HC≡CR (R = C$_3$H$_7$, C$_4$H$_9$, C$_6$H$_{13}$) to afford a mixture of the enynes CH$_2$=C(R)−C≡CR and (*E*)-RCH=CH−C≡CR with a selectivity of 95−98%.[20] In this case the formation of alkynyl(vinyl)rhodium(III) compounds as intermediates has been postulated.

An enyne of the composition RCH=C(R)−C≡CPh with R = CO$_2$Me has been generated from the alkyne complexes **21** and **22** in a stepwise manner. Treatment of a solution of **21** or **22** in dichloromethane at −20 °C with phenylacetylene leads instantaneously to a change of color from pale-yellow to red, followed quickly by a reverse change of color from red to pale-yellow. After removal of the solvent and extraction of the residue with acetone, the pale-yellow air-sensitive solids **28** and **29**, with an analytical composition corresponding to 1:1 adducts of the starting materials and HC≡CPh, could be isolated (Scheme 8). Both the IR and NMR spectra of **28** and **29** indicate that the two alkynes have been converted to an alkynyl and a vinyl ligand in the coordination sphere of the metal, the latter being generated from the coordinated disubstituted alkyne and the acidic hydrogen atom of phenylacetylene. The supposed *cis*-position of H and Rh at the C=C double bond is supported by

Figure 1. Scheme 8. (L = P*i*PrPh$_2$)

the chemical shift of the resonance of the vinylic proton in the ^{1}H NMR spectra, which is observed at δ = 6.00 (for **28**) and 6.04 (for **29**) and thus at higher field than in the case of a *trans*-position of H to rhodium.[3,16,21] The ^{13}C NMR spectroscopic data for the alkynyl and vinyl carbon atoms of **29** are quite similar to those of the structurally related compounds **24**−**26** and thus in agreement with the proposed structure. Regarding the course of the reaction of **21** and **22** with phenylacetylene, we assume that a similar mechanism is operative as suggested for the formation of **24** and **26**. Treatment of the square-planar starting materials **21** and **22** with HC≡CPh could lead via oxidative addition to a six-coordinate alkyne(alkynyl)hydridorhodium(III) species (see intermediate **B** in Scheme 7), which, after insertion of the alkyne RC≡CR into the Rh−H bond and concomitant closing of the chelate ring of the acetate, gives the products.

The alkynyl(vinyl) complexes **28** and **29** are thermally quite stable and even in the presence of CO do not react by intramolecular C−C coupling to yield *trans*-[Rh(κ^1-O$_2$CR)(CO)(P*i*PrPh$_2$)$_2$] and the enyne. Such a reductive elimination occurs if the related bis(triisopropylphosphane) compound [Rh(κ^2-O$_2$CCH$_3$)(C≡CCO$_2$Me){(*E*)-CH=CHCO$_2$Me}(P*i*Pr$_3$)$_2$] is stirred in benzene under a CO atmosphere at 80 °C.[12] However, if a solution of **28** or **29** in acetone is treated at −20 °C with an equimolar amount of Me$_3$SiCl, a fast reaction (illustrated by a quick change of color from pale-yellow to red) takes place and the five-coordinate chlororhodium(III) complex **30** is formed, along with the corresponding silyl ester RCO$_2$SiMe$_3$ (R = Me, *t*Bu; Scheme 8). While the signal for the vinylic proton in the ^{1}H NMR spectrum of **30** appears at practically the same position (δ = 6.04) as for the precursors **28** and **29**, the doublet resonance for the equivalent phosphorus atoms is observed in the ^{31}P NMR spectrum of **30** at δ = 18.9 and thus shifted upfield by 12−15 ppm from **28** and **29**. The change of the coordination number at rhodium could be responsible for this result. Although precise structural data for **30** (which is a red air-sensitive oil) are missing, we assume that the coordination geometry corresponds to a square pyramid with the vinyl group in the apical position, in analogy to [RhCl(C≡CPh){(*Z*)-CH=CHPh}(P*i*Pr$_3$)$_2$].[3]

The rearrangement of **30** to **31** by C−C coupling occurs smoothly and selectively in benzene at 60 °C and affords the enyne complex **31** as an orange, relatively air-stable solid in 75% isolated yield. The assumption that the enyne is coordinated through the triple bond is mainly supported by the IR spectrum, which shows the ν(C≡C) stretching mode at 1835 cm^{-1}, i.e. in a similar region as found for *trans*-[RhCl(η^2-PhC≡CPh)(P*i*Pr$_3$)$_2$].[22] Passing a slow stream of CO through a solution of **31** in CH$_2$Cl$_2$ at room temperature results in a displacement of the enyne by CO and leads to the carbonylrhodium(I) compound **32** and the free enyne **33**. The latter has been identified by comparison of its spectroscopic data with those from the literature.[23] As anticipated, **32** is also accessible from the dimer **3** and CO in virtually quantitative yield.

In contrast to the carboxylato derivatives **8** and **9**, the sulfonate **12** reacts with terminal alkynes HC≡CR (R = Ph, CMe$_2$OH) to give the four-coordinate rhodium(I) vinylidene complexes **34** and **35** instead of alkynyl(vinyl)- or allenylrhodium(III) complexes (Scheme 9). The reactions of **12** with HC≡CPh and HC≡CCMe$_2$OH in a molar ratio of 1:1 were carried out in toluene at room temperature and afford compounds **34** and **35** as violet air-sensitive solids almost quantitatively. Although it is safe to assume that in the initial step of the reaction an η^2-alkynerhodium(I) species is generated, which then rearranges, possibly via an alkynyl(hydrido)rhodium(III) intermediate, to the isolated product,[24] we failed to detect such a species by NMR spectroscopy. In analogy to the carboxylato complexes *trans*-

	R
34, 36	Ph
35, 37	CMe$_2$OH

Scheme 9. (L = P*i*Pr$_2$Ph)

[Rh(κ^1-O$_2$CR)(=C=CHPh)(P*i*Pr$_3$)$_2$] (R = CH$_3$, CF$_3$),[11] the ^{13}C NMR spectra of **34** and **35** display two low-field resonances at δ = 306.9 and 113.4 (for **34**) and δ = 308.2 and 115.7 (for **35**) assigned to the α- and β-carbon atoms of the vinylidene units.

The Rh−O bond in compounds **34** and **35** is quite labile and thus upon treatment of solutions of **34** or **35** in a 1:1 mixture of toluene and triethylamine with an equimolar amount of the corresponding alkyne HC≡CR at −50 °C a substitution of the tosylate by the alkynyl anion takes place. After warming to room temperature, removal of the solvent and extraction of the residue with ether the alkynyl(vinylidene) complexes **36** and **37** are isolated in 56−68% yield. These compounds, which are turquoise or dark-green solids, can also be obtained directly from **12** and a twofold excess of HC≡CR under similar conditions; in this case, however, the yield is only 34−45%. Compounds **36** and **37** are less stable in solution than the triisopropylphosphane derivatives *trans*-[Rh(C≡CR)(=C=CHR)(P*i*Pr$_3$)$_2$],[3] which could be due to a reduced shielding of the metal center by the smaller P*i*Pr$_2$Ph ligands. The alkynyl(vinylidene) compound **38**, with different substituents at the β-C atom of the carbon-bonded units, is accessible from **34** and the alkynol HC≡CCMe$_2$OH (see Scheme 10); it is significantly more air-sensitive than the counterparts **36** and **37**. Attempts to prepare the isomer of **38** with the composition *trans*-[Rh(C≡CPh)(=C=CHCMe$_2$OH)(P*i*Pr$_2$Ph)$_2$] failed. Treatment of a solution of **35** in toluene/NEt$_3$ with one equiv. of phenylacetylene affords a mixture of products which could not be separated by fractional crystallization or chromatographic techniques.

38, 41	CMe$_2$OH	Ph

Scheme 10. (L = P*i*Pr$_2$Ph)

The alkynyl(vinylidene) complexes **36**−**38** react quite rapidly with CO in dichloromethane at −20 °C to give exclusively the (*Z*) isomers of the enynylrhodium(I) compounds **39**−**41** in moderate to good yields (see Scheme 10). We assume that initially CO adds to the metal center, thus generating a five-coordinate 18-electron intermediate, which, after migration of the alkynyl ligand to the α-carbon atom of the vinylidene unit, transforms into the isolated product. The importance of steric factors probably explains why the attack of the alkynyl moiety occurs only at that side of the molecule that is opposite to the substituent R′. Compounds **39**−**41** are less air-sensitive than the precursors **36**−**38** both in the solid state and in solution. Typical spectroscopic data of **39**−**41** are the intense ν(CO) and ν(C≡C) stretching modes in the IR spectra at 1950−1955 cm^{-1} and 2070−2160 cm^{-1}, respectively, and the resonance for the vinylic =CH proton in the ^{1}H NMR spectra at δ = 8.07 (**39**), 7.18 (**40**) and 7.20 (**41**). The latter is split into a doublet of triplets due to ^{1}H-^{103}Rh and ^{1}H-^{31}P coupling. It should also be mentioned that the methyl groups of the P*i*Pr$_2$Ph ligands of **39**−**41** are diastereotopic and give rise to four doublets of virtual triplets in the ^{1}H NMR spectra. We interpret this observation by assuming a hindered rotation of the vinylic unit around the Rh−C σ-bond, probably caused by the steric requirements of the substituents at the phosphorus atoms and the C=C bond.

In conclusion, the work described in this paper illustrates that a series of rhodium(I) and rhodium(III) complexes with [Rh(P*i*Pr$_2$Ph)$_2$] and [Rh(P*i*PrPh$_2$)$_2$] as molecular building blocks is accessible starting from the π-allylrhodium(I) compounds **4** and **5**. Protolytic cleavage of the allyl-metal bond by carboxylic acids or *p*-toluenesulfonic acid leads to the formation of carboxylato- and tosylatorhodium(I) derivatives, which easily undergo both addition and oxidative addition reactions. With terminal alkynes as substrates, either alkynyl(vinyl)- or allenylrhodium(III) complexes were obtained. Provided that C≡CPh is the alkynyl and C(CO$_2$Me)=CH(CO$_2$Me) the vinyl ligand, the alkynyl(vinyl) complexes react with Me$_3$SiCl by intramolecular C−C coupling to give enynerhodium compounds from which the free enyne is generated upon treatment with CO. The alkynyl(vinylidene)rhodium(I) derivatives, which were prepared in a stepwise manner from rhodium tosylates and terminal alkynes, also react with CO by migratory insertion to afford stereoselectively four-coordinate enynylrhodium(I) complexes. Treatment of catalytic amounts of the pivalatorhodium compounds **9** or **25** with excess phenylacetylene leads to a dimerization of the alkyne and gives regioselectively the branched enyne CH$_2$=C(Ph)−C≡CPh.

Experimental Section

General: All operations were carried out under argon using Schlenk techniques. The starting materials **1**[25] and PH*i*Pr$_2$ [26] were prepared as described in the literature. NMR spectra were recorded at room temperature on Bruker AC 200, Bruker AMX 400 and JEOL FX 90 Q instruments, unless otherwise stated. Abbreviations used: s, singlet; d, doublet; t, triplet; m, multiplet; vt, virtual triplet; br, broadened signal; $N = {}^2J_{P,H} + {}^3J_{P,H}$ or ${}^2J_{P,C} + {}^4J_{P,C}$. The assignment of protons for the π-allyl ligand in compounds **4**−**7** is as follows: H$_m$ = proton at central carbon atom; H$_s$ = proton of terminal CH$_2$ groups in *syn* position to H$_m$; H$_a$ = proton of ter-

minal CH_2 groups in *anti* position to H_m. Melting and decomposition points were measured by differential thermal analysis (DTA).

Preparation of [RhCl(P*i*Pr$_2$Ph)$_2$]$_2$ (2): A suspension of **1** (250 mg, 0.35 mmol) in toluene (20 mL) was treated with P*i*Pr$_2$Ph (0.29 mL, 1.40 mmol) and stirred for 10 min at room temperature. The solvent was evaporated in vacuo, the remaining violet solid was washed three times with 5-mL portions of pentane and dried; yield 360 mg (98%); m.p. 105 °C (dec.). ^{1}H NMR (200 MHz, C_6D_6): δ = 7.37−6.79 (m, 20 H, C_6H_5), 2.28 (m, 8 H, PC*H*CH$_3$), 1.70, 1.11 (both m, 48 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 58.9 (d, $^1J_{Rh,P}$ = 197.7 Hz). $C_{48}H_{76}Cl_2P_4Rh_2$ (1053.8): calcd. C 54.71, H 7.27; found C 54.49, H 7.79.

Preparation of [RhCl(P*i*PrPh$_2$)$_2$]$_2$ (3): This compound was prepared as described for **2**, with **1** (250 mg, 0.35 mmol) and P*i*PrPh$_2$ (0.32 mL, 1.40 mmol) as starting materials. Violet solid; yield 394 mg (95%); m.p. 98 °C (dec.). ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 7.36−7.06 (m, 40 H, C_6H_5), 2.22 (m, 4 H, PC*H*CH$_3$), 0.92 (dd, $^3J_{P,H}$ = 14.4, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, CD_2Cl_2): δ = 55.2 (d, $^1J_{Rh,P}$ = 197.6 Hz). $C_{60}H_{68}Cl_2P_4Rh_2$ (1189.8): calcd. C 60.57, H 5.76; found C 60.08, H 5.81.

Preparation of [Rh(η^3-C$_3$H$_5$)(P*i*Pr$_2$Ph)$_2$] (4): A suspension of **1** (574 mg, 0.80 mmol) in toluene (5 mL) was treated with P*i*Pr$_2$Ph (0.66 mL, 3.20 mmol) and stirred for 10 min at room temperature. After cooling the solution to 0 °C, a 0.5 M solution of C_3H_5MgBr in ether (3.2 mL, 1.60 mmol) was added dropwise. A change of color from brown-violet to yellow occurred. The solvent was evaporated in vacuo, the residue was extracted with pentane (30 mL) and the extract was dried in vacuo. A yellow air-sensitive solid was obtained which was washed three times with 2-mL portions of acetone (0 °C) and dried; yield 700 mg (82%); m.p. 77 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6): δ = 7.41−6.83 (m, 10 H, C_6H_5), 5.02 (dtt, $^2J_{Rh,H}$ = 2.1, $^3J_{H,Ha}$ = 12.8, $^3J_{H,Hs}$ = 6.8 Hz, 1 H, H_m), 3.36 (d, $^3J_{H,Hm}$ = 6.8 Hz, 2 H, H_s), 2.49, 2.37 (both m, 4 H, PC*H*CH$_3$), 2.35 (dd, $^3J_{H,Hm}$ = 12.8, $^3J_{P,H}$ = 7.0 Hz, 2 H, H_a), 1.10 (dd, $^3J_{P,H}$ = 15.0, $^3J_{H,H}$ = 7.0 Hz, 6 H, PCHC*H*$_3$), 1.08 (dd, $^3J_{P,H}$ = 14.4, $^3J_{H,H}$ = 7.0 Hz, 6 H, PCHC*H*$_3$), 0.99 (dd, $^3J_{P,H}$ = 12.4, $^3J_{H,H}$ = 6.6 Hz, 6 H, PCHC*H*$_3$), 0.90 (dd, $^3J_{P,H}$ = 12.0, $^3J_{H,H}$ = 6.8 Hz, 6 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 53.2 (d, $^1J_{Rh,P}$ = 196.2 Hz). $C_{27}H_{43}P_2Rh$ (532.5): calcd. C 60.90, H 8.14; found C 60.23; H. 8.01.

Preparation of [Rh(η^3-C$_3$H$_5$)(P*i*PrPh$_2$)$_2$] (5): This compound was prepared as described for **4**, with **1** (287 mg, 0.40 mmol), P*i*PrPh$_2$ (0.37 mL, 1.60 mmol) and a 0.5 M solution of C_3H_5MgBr in ether (1.6 mL, 0.80 mmol) as starting materials. Yellow air-sensitive solid; yield 384 mg (80%); m.p. 76 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6): δ = 7.45−7.02 (m, 20 H, C_6H_5), 5.08 (dtt, $^2J_{Rh,H}$ = 2.1, $^3J_{H,Ha}$ = 12.2, $^3J_{H,Hs}$ = 6.8 Hz, 1 H, H_m), 3.31 (d, $^3J_{H,Hm}$ = 6.8 Hz, 2 H, H_s), 2.37 (dd, $^3J_{H,Hm}$ = 12.2, $^3J_{P,H}$ = 4.7 Hz, 2 H, H_a), 2.15 (m, 2 H, PC*H*CH$_3$), 0.99 (dd, $^3J_{P,H}$ = 14.7, $^3J_{H,H}$ = 6.9 Hz, 6 H, PCHC*H*$_3$), 0.91 (dd, $^3J_{P,H}$ = 14.4, $^3J_{H,H}$ = 7.0 Hz, 6 H, PCHC*H*$_3$). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 49.9 (d, $^1J_{Rh,P}$ = 197.3 Hz). $C_{33}H_{39}P_2Rh$ (600.5): calcd. C 66.00, H 6.55; found C 65.90, H 6.56.

Preparation of [Rh(η^3-C$_3$H$_5$)(PH*i*Pr$_2$)$_2$] (6): This compound was prepared as described for **4**, with **1** (287 mg, 0.40 mmol), PH*i*Pr$_2$ (0.24 mL, 1.60 mmol) and a 0.5 M solution of C_3H_5MgBr in ether (1.6 mL, 0.80 mmol) as starting materials. Yellow air-sensitive solid; yield 253 mg (83%); m.p. 65 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6): δ = 4.82 (dtt, $^2J_{Rh,H}$ = 1.9, $^3J_{H,Ha}$ = 12.7, $^3J_{H,Hs}$ = 7.2 Hz, 1 H, H_m), 4.06 (dt, $^1J_{P,H}$ = 256.5, $^3J_{H,H}$ = 4.8 Hz, 2 H, PH), 3.68 (d, $^3J_{H,Hm}$ = 7.2 Hz, 2 H, H_s), 2.22 (dd, $^3J_{H,Hm}$ = 12.7, $^3J_{P,H}$ = 5.9 Hz, 2 H, H_a), 2.01, 1.93 (both m, 4 H, PC*H*CH$_3$), 1.13 (dd, $^3J_{P,H}$ = 13.5, $^3J_{H,H}$ = 6.8 Hz, 6 H, PCHC*H*$_3$), 1.11 (dd, $^3J_{P,H}$ = 16.2, $^3J_{H,H}$ = 7.2 Hz, 6 H, PCHC*H*$_3$), 1.04 (dd, $^3J_{P,H}$ = 13.8, $^3J_{H,H}$ = 6.9 Hz, 6 H, PCHC*H*$_3$), 1.02 (dd, $^3J_{P,H}$ = 16.5, $^3J_{H,H}$ = 7.1 Hz, 6 H, PCHC*H*$_3$). ^{31}P NMR (36.2 MHz, C_6D_6): δ = 56.5 (d, $^1J_{Rh,P}$ = 187.6 Hz). $C_{15}H_{35}P_2Rh$ (380.3): calcd. C 47.38, H 9.28; found C 47.23; H 9.35.

Preparation of [Rh(η^3-C$_3$H$_5$)(P*t*Bu$_2$Me)$_2$] (7): This compound was prepared as described for **4**, with **1** (287 mg, 0.40 mmol), P*t*Bu$_2$Me (0.32 mL, 1.60 mmol) and a 0.5 M solution of C_3H_5MgBr in ether (1.6 mL, 0.80 mmol) as starting materials. Yellow air-sensitive solid; yield 320 mg (86%); m.p. 86 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6): δ = 4.63 (dtt, $^2J_{Rh,H}$ = 2.1, $^3J_{H,Ha}$ = 11.7, $^3J_{H,Hs}$ = 6.7 Hz, 1 H, H_m), 3.74 (d, $^3J_{H,Hm}$ = 6.7 Hz, 2 H, H_s), 1.92 (dd, $^3J_{H,Hm}$ = 11.7, $^3J_{P,H}$ = 6.1 Hz, 2 H, H_a), 1.22 (d, $^3J_{P,H}$ = 12.0 Hz, 18 H, PCCH$_3$), 1.14 (d, $^2J_{P,H}$ = 4.3 Hz, 6 H, PCH$_3$), 1.11 (d, $^3J_{P,H}$ = 11.6 Hz, 18 H, PCCH$_3$). ^{31}P NMR (36.2 MHz, C_6D_6): δ = 53.3 (d, $^1J_{Rh,P}$ = 196.4 Hz). $C_{21}H_{47}P_2Rh$ (464.5): calcd. C 54.31, H 10.20; found C 54.82, H 10.32.

Preparation of [Rh(κ^2-O$_2$CCH$_3$)(P*i*PrPh$_2$)$_2$] (8): A solution of **5** (180 mg, 0.30 mmol) in benzene (2 mL) was treated with acetic acid (17 μL, 0.30 mmol) and stirred for 1 h at room temperature. A change of color from yellow to dark red occurred. The solvent was evaporated in vacuo, the residue was extracted with acetone (20 mL) and the extract was concentrated to ca. 3 mL in vacuo. A dark-red microcrystalline solid was obtained, which was filtered, washed twice with 2-mL portions of acetone (0 °C) and dried; yield 165 mg (89%); m.p. 108 °C. IR (C_6H_6): ν(OCO$_{as}$) = 1510, ν(OCO$_{sym}$) = 1445 cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6): δ = 7.83−6.69 (m, 20 H, C_6H_5), 2.32 (m, 2 H, PC*H*CH$_3$), 1.95 (s, 3 H, O_2CCH_3), 1.10 (m, 12 H, PCHC*H*$_3$). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 61.9 (d, $^1J_{Rh,P}$ = 199.7 Hz). $C_{32}H_{37}O_2P_2Rh$ (618.5): calcd. C 62.14, H 6.03; found C 61.75, H 5.98.

Preparation of [Rh{κ^2-O$_2$CC(CH$_3$)$_3$}(P*i*PrPh$_2$)$_2$] (9): This compound was prepared as described for **8**, with **5** (150 mg, 0.25 mmol) and $(CH_3)_3CCO_2H$ (26 μL, 0.25 mmol) as starting materials; reaction time: 6 h. Dark-red solid; yield 129 mg (78%); m.p. 93 °C (dec.). IR (KBr): ν(OCO$_{as}$) = 1485, ν(OCO$_{sym}$) = 1430 cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6): δ = 7.52−6.81 (m, 20 H, C_6H_5), 2.37 (m, 2 H, PC*H*CH$_3$), 1.34 [s, 9 H, C(CH$_3$)$_3$], 1.02 (m, 12 H, PCHC*H*$_3$). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 62.2 (d, $^1J_{Rh,P}$ = 226.0 Hz). $C_{35}H_{43}O_2P_2Rh$ (660.9): calcd. C 63.64, H 6.56; found C 64.03, H 6.81.

Preparation of [Rh{κ^2-O$_2$CC(CH$_3$)$_3$}(P*i*Pr$_2$Ph)$_2$] (10): This compound was prepared as described for **8**, with **4** (149 mg, 0.28 mmol) and $(CH_3)_3CCO_2H$ (29 μL, 0.28 mmol) as starting materials; reaction time: 6 h. Dark-red solid; yield 123 mg (74%); m.p. 97 °C (dec.). IR (C_6H_6): ν(OCO$_{as}$) = 1480, ν(OCO$_{sym}$) = 1425 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.58−6.91 (m, 10 H, C_6H_5), 2.25 (m, 4 H, PC*H*CH$_3$), 1.53 (m, 12 H, PCHC*H*$_3$), 1.42 [s, 9 H, C(CH$_3$)$_3$], 1.15 (m, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 66.6 (d, $^1J_{Rh,P}$ = 202.1 Hz). $C_{29}H_{47}O_2P_2Rh$ (592.6): calcd. C 58.78, H 7.99; found C 58.51, H 8.02.

Preparation of [Rh{κ^2-O$_2$S(O)-*p*-Tol}(P*i*PrPh$_2$)$_2$] (11): A solution of **5** (180 mg, 0.30 mmol) in toluene (2 mL) was treated with 4-MeC$_6$H$_4$SO$_3$H (57 mg, 0.30 mmol) and stirred for 1 h at room temperature. A change of color from yellow to red occurred. The solvent was evaporated in vacuo, the residue was extracted with acetone (20 mL) and the extract was concentrated to ca. 2 mL in vacuo. Red crystals precipitated which were filtered, washed twice with 2-mL portions of acetone (0 °C) and dried; yield 185 mg (89%); m.p.

51 °C. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.58−6.91 (m, 24 H, C_6H_4 and C_6H_5), 2.31 (m, 2 H, PC*H*CH$_3$), 1.95 (s, 3 H, $C_6H_4CH_3$), 0.96 (m, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 63.3 (d, $^1J_{Rh,P}$ = 212.2 Hz). $C_{37}H_{41}O_3P_2RhS$ (730.7): calcd. C 60.82, H 5.66, S 4.39; found C 60.82, H 5.89, S 4.33.

Preparation of [Rh{κ^2-O$_2$S(O)-*p*-Tol}(P*i*Pr$_2$Ph)$_2$] (12): This compound was prepared as described for **11**, with **4** (128 mg, 0.24 mmol) and 4-Me$C_6H_4SO_3H$ (46 mg, 0.24 mmol) as starting materials. Red air-sensitive crystals; yield 138 mg (87%); m.p. 85 °C (dec.). ^{1}H NMR (200 MHz, C_6D_6): δ = 8.46−6.79 (m, 14 H, C_6H_4 and C_6H_5), 2.10 (m, 4 H, PC*H*CH$_3$), 1.97 (s, 3 H, $C_6H_4CH_3$), 1.35, 1.03 (both m, 12 H each, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 63.3 (d, $^1J_{Rh,P}$ = 212.2 Hz). $C_{31}H_{45}O_3P_2RhS$ (662.6): calcd. C 56.19, H 6.84, S 4.84; found C 55.82, H 6.53, S 4.71.

Preparation of *trans*-[Rh(κ^1-O$_2$CCH$_3$)(CO)(P*i*PrPh$_2$)$_2$] (13): A slow stream of CO was passed through a solution of **8** (62 mg, 0.10 mmol) in CH_2Cl_2 (10 mL) at room temperature for 10 s, leading to a rapid change of color from dark-red to light yellow. After removal of the solvent in vacuo, a light yellow solid was obtained, which was washed twice with 2-mL portions of acetone (0 °C) and dried; yield (98%); m.p. 135 °C. IR (KBr): ν(CO) = 1960, ν(OCO_{as}) = 1595, ν(OCO_{sym}) = 1370 cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6): δ = 7.83−7.41 (m, 20 H, C_6H_5), 2.93 (m, 2 H, PC*H*CH$_3$), 1.36 (s, 3 H, O_2CCH_3), 1.21 (dvt, *N* = 15.8, $^3J_{H,H}$ = 7.4 Hz, 12 H, PCHC*H*$_3$). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 40.7 (d, $^1J_{Rh,P}$ = 147.4 Hz). $C_{33}H_{37}O_3P_2Rh$ (646.5): calcd. C 61.31, H 5.77; found C 61.00, H 5.30.

Preparation of *trans*-[Rh{κ^1-O$_2$CC(CH$_3$)$_3$}(CO)(P*i*Pr$_2$Ph)$_2$] (14): This compound was prepared as described for **13**, with **10** (59 mg, 0.10 mmol) and CO as starting materials. Yellow solid; yield 59 mg (95%); m.p. 93 °C (dec.). IR (KBr): ν(CO) = 1955 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.77−7.07 (m, 10 H, C_6H_5), 2.42 (m, 4 H, PC*H*CH$_3$), 1.37 (dvt, *N* = 16.1, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHC*H*$_3$), 1.14 [s, 9 H, C(CH$_3$)$_3$], 1.03 (dvt, *N* = 14.2, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 46.4 (d, $^1J_{Rh,P}$ = 133.7 Hz). $C_{30}H_{47}O_3P_2Rh$ (620.6): calcd. C 58.07, H 7.63; found C 57.60, H 7.46.

Preparation of [Rh{κ^1-O$_2$S(O)-*p*-Tol}(CO)(P*i*Pr$_2$Ph)$_2$] (15): This compound was prepared as described for **13**, with **12** (66 mg, 0.10 mmol) and CO as starting materials. Yellow solid; yield 64 mg (93%); m.p. 153 °C (dec.). IR (KBr): ν(CO) = 1950 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.96−6.82 (m, 14 H, C_6H_5 and C_6H_4), 2.81 (m, 4 H, PC*H*CH$_3$), 1.95 (s, 3 H, $C_6H_4CH_3$) 1.44 (dvt, *N* = 16.9, $^3J_{H,H}$ = 7.5 Hz, 12 H, PCHC*H*$_3$), 0.96 (dvt, *N* = 14.5, $^3J_{H,H}$ = 7.0 Hz, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 47.7 (d, $^1J_{Rh,P}$ = 125.0 Hz). $C_{32}H_{45}O_4P_2RhS$ (690.6): calcd. C 55.65; H 6.57; found C 56.07, H 6.81.

Preparation of [RhH$_2$(κ^2-O$_2$CCH$_3$)(P*i*PrPh$_2$)$_2$] (16): A slow stream of H_2 was passed through a solution of **8** (62 mg, 0.10 mmol) in CH_2Cl_2 (5 mL) at room temperature for 5 min. After removal of the solvent in vacuo, a white solid was obtained which was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 56 mg (90%); m.p. 84 °C (dec.). IR (KBr): ν(RhH) = 2100, ν(OCO_{as}) = 1540, ν(OCO_{sym}) =1430 cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6): δ = 7.99−6.91 (m, 20 H, C_6H_5), 2.53 (m, 2 H, PC*H*CH$_3$), 1.52 (s, 3 H, O_2CCH_3), 1.21 (dvt, *N* = 15.9, $^3J_{H,H}$ = 8.0 Hz, 12 H, PCHC*H*$_3$), −22.01 (dt, $^1J_{Rh,H}$ = 22.4, $^2J_{P,H}$ = 18.0 Hz, 2 H, RhH). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 49.7 (d, $^1J_{Rh,P}$ = 119.4 Hz). $C_{32}H_{39}O_2P_2Rh$ (620.5): calcd. C 61.94, H 6.33; found C 62.20, H 6.48.

Preparation of [RhH$_2${κ^2-O$_2$CC(CH$_3$)$_3$}(P*i*PrPh$_2$)$_2$] (17): This compound was prepared as described for **16**, with **9** (66 mg, 0.10 mmol) and H_2 as starting materials. White solid; yield 58 mg (88%); m.p. 76 °C (dec.). IR (KBr): ν(RhH) = 2115, ν(OCO_{as}) = 1525, ν(OCO_{sym}) = 1430 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 6.99−6.71 (m, 20 H, C_6H_5), 2.33 (m, 2 H, PC*H*CH$_3$), 1.08 (dvt, *N* = 16.7, $^3J_{H,H}$ = 8.0 Hz, 12 H, PCHC*H*$_3$), 0.79 [s, 9 H, C(CH$_3$)$_3$], −21.13 (dt, $^1J_{Rh,H}$ = 21.8, $^2J_{P,H}$ = 17.4 Hz, 2 H, RhH). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 49.8 (d, $^1J_{Rh,P}$ = 119.2 Hz). $C_{35}H_{45}O_2P_2Rh$ (662.6): calcd. C 63.45, H 6.85; found C 63.90, H 7.12.

Preparation of [RhH$_2${κ^2-O$_2$CC(CH$_3$)$_3$}(P*i*Pr$_2$Ph)$_2$] (18): This compound was prepared as described for **16**, with **10** (65 mg, 0.11 mmol) and H_2 as starting materials. Colorless oil; yield 65 mg (99%). IR (KBr): ν(RhH) = 2120, ν(OCO_{as}) = 1520, ν(OCO_{sym}) = 1420 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.88−6.92 (m, 10 H, C_6H_5), 2.26 (m, 4 H, PC*H*CH$_3$), 1.28 (dvt, *N* = 14.5, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHC*H*$_3$), 1.14 [s, 9 H, C(CH$_3$)$_3$], 1.02 (dvt, *N* = 13.1, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHC*H*$_3$), −22.73 (dt, $^1J_{Rh,H}$ = 23.3, $^2J_{P,H}$ = 16.0 Hz, 2 H, RhH). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 55.3 (d, $^1J_{Rh,P}$ = 119.1 Hz). $C_{29}H_{49}O_2P_2Rh$ (594.6): calcd. C 58.58, H 8.31; found C 58.45, H 8.28.

Preparation of [RhH$_2${κ^2-O$_2$S(O)-*p*-Tol}(P*i*PrPh$_2$)$_2$] (19): This compound was prepared as described for **16**, with **11** (73 mg, 0.10 mmol) and H_2 as starting materials. White solid which has to be stored under dihydrogen; yield 62 mg (85%); m.p. 86 °C (dec.). IR (KBr): ν(RhH) = 2100 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.87−6.49 (m, 24 H, C_6H_5 and C_6H_4), 3.08 (m, 2 H, PC*H*CH$_3$), 1.80 (s, 3 H, $C_6H_4CH_3$), 1.12 (dvt, *N* = 15.8, $^3J_{H,H}$ = 7.9 Hz, 12 H, PCHC*H*$_3$), −21.51 (dt, $^1J_{Rh,H}$ = 27.6, $^2J_{P,H}$ = 15.8 Hz, 2 H, RhH). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 50.2 (d, $^1J_{Rh,P}$ = 117.8 Hz). $C_{37}H_{43}O_3P_2RhS$ (732.7): calcd. C 60.66, H 5.92; found C 61.21, H 6.21.

Preparation of [RhH$_2${κ^2-O$_2$S(O)-*p*-Tol}(P*i*Pr$_2$Ph)$_2$] (20): This compound was prepared as described for **16**, with **12** (60 mg, 0.09 mmol) and H_2 as starting materials. Colorless oil which has to be stored under dihydrogen; yield 59 mg (98%). IR (KBr): ν(RhH) = 2130 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.81−6.65 (m, 14 H, C_6H_5 and C_6H_4), 2.52 (m, 4 H, PC*H*CH$_3$), 1.87 (s, 3 H, $C_6H_4CH_3$), 1.28 (dvt, *N* = 14.5, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHC*H*$_3$), 0.98 (dvt, *N* = 14.5, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHC*H*$_3$), −24.04 (dt, $^1J_{Rh,H}$ = 27.6, $^2J_{P,H}$ = 16.0 Hz, 2 H, RhH). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 51.8 (d, $^1J_{Rh,P}$ = 117.7 Hz). $C_{31}H_{47}O_3P_2RhS$ (664.6): calcd. C 56.02, H 7.13, S 4.82; found C 55.31, H 7.01, S 4.75.

Preparation of *trans*-[Rh(κ^1-O$_2$CCH$_3$){η^2-C$_2$(CO$_2$Me)$_2$}(P*i*PrPh$_2$)$_2$] (21): A solution of **8** (74 mg, 0.12 mmol) in benzene (5 mL) at room temperature was treated dropwise with $C_2(CO_2Me)_2$ (14 μL, 0.12 mmol) with continuous stirring. A quick change of color from dark-red to yellow occurred. The solvent was evaporated in vacuo and the oily residue dissolved in hexane (2 mL). After the solution was stored at −78 °C for 12 h, a pale-yellow solid precipitated, which was separated from the mother liquor, washed twice with 2-mL portions of pentane and dried in vacuo; yield: 78 mg (85%); m.p. 94 °C (dec.). IR (KBr): ν(C≡C) = 1810, ν(C=O) = 1680, ν(OCO) = 1610 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.81−7.00 (m, 20 H, C_6H_5), 3.24 (s, 6 H, CO_2CH_3), 2.68 (m, 2 H, PC*H*CH$_3$), 1.55 (dvt, *N* = 14.0, $^3J_{H,H}$ = 7.0 Hz, 12 H, PCHC*H*$_3$), 1.34 (s, 3 H, O_2CCH_3). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 34.6 (d, $^1J_{Rh,P}$ = 118.3 Hz). $C_{38}H_{43}O_6P_2Rh$ (760.6): calcd. C 60.01, H 5.70; found C 60.48, H 5.95.

Preparation of *trans*-[Rh{κ^1-O$_2$CC(CH$_3$)$_3$}{η^2-C$_2$(CO$_2$Me)$_2$}(P*i*PrPh$_2$)$_2$] (22): This compound was prepared as described for **21**,

with **9** (79 mg, 0.12 mmol) and $C_2(CO_2Me)_2$ (14 μL, 0.12 mmol). Pale-yellow solid; yield 79 mg (86%); m.p. 84 °C (dec.). IR (KBr): ν(C≡C) = 1785, ν(C=O) = 1685, ν(OCO_{as}) = 1610 cm^{-1}. ^1H NMR (200 MHz, C_6D_6): δ = 7.85−6.98 (m, 20 H, C_6H_5), 3.32 (s, 6 H, CO_2CH_3), 2.64 (m, 2 H, PC*H*CH_3), 1.03 (dvt, *N* = 12.8, $^3J_{H,H}$ = 5.7 Hz, 12 H, PCHC*H*$_3$), 0.75 [s, 9 H, C(CH_3)$_3$]. ^{31}P NMR (81.0 MHz, C_6D_6): δ = 35.9 (d, $^1J_{Rh,P}$ = 120.0 Hz). $C_{41}H_{49}O_6P_2Rh$ (802.7): calcd. C 61.35, H 6.15; found C 60.97, H 5.98.

Preparation of *trans*-[Rh{κ^1-$O_2CC(CH_3)_3$}(η^2-MeC≡CCO_2Me)(P*i*PrPh$_2$)$_2$] (23): A solution of **9** (92 mg, 0.14 mmol) in toluene (2 mL) was treated dropwise at −20 °C with MeC_2CO_2Me (14 μL, 0.14 mmol). After stirring the solution at −20 °C for 2 h and then warming to room temperature, the solvent was evaporated in vacuo. The oily residue was dissolved in hexane (2 mL) and the solution worked up as described for **21**. Pale-yellow solid; yield 67 mg (63%); m.p. 64 °C (dec.). IR (KBr): ν(C≡C) = 1900, ν(C=O) = 1705, ν(OCO_{as}) = 1670 cm^{-1}. ^1H NMR (200 MHz, [D_8]toluene, 243 K): δ = 7.92−6.84 (m, 20 H, C_6H_5), 3.33 (s, 3 H, CO_2CH_3), 2.38 (m, 2 H, PC*H*CH_3), 1.32 [s, 9 H, C(CH_3)$_3$], 1.30 (dvt, *N* = 17.3, $^3J_{H,H}$ = 8.6 Hz, 12 H, PCHC*H*$_3$), 1.10 (s, 3 H, ≡CCH_3). ^{31}P NMR (81.0 MHz, [D_8]toluene, 243 K): δ = 36.4 (d, $^1J_{Rh,P}$ = 123.5 Hz). $C_{40}H_{49}O_4P_2Rh$ (758.7):calcd. C 63.33, H 6.51; found C 63.45, H 6.55.

Preparation of [Rh(κ^2-O_2CCH_3)(C≡CPh){C(Ph)=CH_2}(P*i*PrPh$_2$)$_2$] (24): A solution of **8** (93 mg, 0.15 mmol) in toluene (5 mL) at −50 °C was treated dropwise with phenylacetylene (32 μL, 0.30 mmol). After stirring the solution for 5 min at −50 °C and then warming to room temperature, the solvent was evaporated in vacuo. The oily residue was dissolved in hexane (20 mL) and the solution stirred at 0 °C for 2 h. A pale-yellow solid slowly precipitated, which was filtered, washed twice with 2-mL portions of hexane and dried in vacuo; yield 106 mg (86%); m.p. 81 °C (dec.). IR (KBr): ν(C≡C) = 2060, ν(C=C) = 1580, ν(OCO_{as}) = 1520 cm^{-1}. ^1H NMR (400 MHz, C_6D_6): δ = 8.04−6.46 (m, 30 H, C_6H_5), 5.87, 5.42 (both s, 1 H each, =CH_2), 3.35 (m, 2 H, PC*H*CH_3), 1.45 (dvt, *N* = 14.8, $^3J_{H,H}$ = 7.4 Hz, 6 H, PCHC*H*$_3$), 1.22 (dvt, *N* = 14.6, $^3J_{H,H}$ = 7.2 Hz, 6 H, PCHC*H*$_3$), 1.20 (s, 3 H, O_2CCH_3). ^{13}C NMR (100.6 MHz, C_6D_6): δ = 182.2 (s, O_2C), 148.4 [dt, $^1J_{Rh,C}$ = 30.4, $^2J_{P,C}$ = 8.9 Hz, Rh*C*(=CH_2)Ph], 134.2−124.0 (m, C_6H_5), 128.6 [dt, $^2J_{Rh,C}$ = 1.2, $^3J_{P,C}$ = 0.8 Hz, =CH_2], 108.7 (dt, $^2J_{Rh,C}$ = 10.2, $^3J_{P,C}$ = 2.3 Hz, ≡*C*Ph], 98.5 [dt, $^1J_{Rh,C}$ = 50.7, $^2J_{P,C}$ = 18.5 Hz, Rh*C*≡CPh], 25.6 (vt, *N* = 25.3 Hz, P*C*HCH$_3$), 22.9 (s, O_2CCH_3), 18.2, 17.4 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 31.0 (d, $^1J_{Rh,P}$ = 106.1 Hz). $C_{48}H_{49}O_2P_2Rh$ (822.8): calcd. C 70.07, H 6.00; found C 69.72, H 6.14.

Preparation of [Rh{κ^2-$O_2CC(CH_3)_3$}(C≡CPh){C(Ph)=CH_2}(P*i*PrPh$_2$)$_2$] (25): This compound was prepared as described for **24**, with **9** (99 mg, 0.15 mmol) and phenylacetylene (32 μL, 0.30 mmol) as starting materials. Pale-yellow solid; yield 109 mg (84%); m.p. 78 °C (dec.). IR (KBr): ν(C≡C) = 2050, ν(C=C) = 1580, ν(OCO_{as}) = 1485, ν(OCO_{sym}) = 1435 cm^{-1}. ^1H NMR (200 MHz, C_6D_6): δ = 8.02−6.83 (m, 30 H, C_6H_5), 5.96, 5.49 (both s, 1 H each, =CH_2), 3.54 (m, 2 H, PC*H*CH_3), 1.52 (dvt, *N* = 10.2, $^3J_{H,H}$ = 7.1 Hz, 6 H, PCHC*H*$_3$), 1.08 (dvt, *N* = 14.8, $^3J_{H,H}$ = 7.5 Hz, 6 H, PCHC*H*$_3$), 1.73 [s, 9 H, C(CH_3)$_3$]. ^{13}C NMR (100.6 MHz, C_6D_6): δ = 190.3 (s, O_2C), 150.5 [dt, $^1J_{Rh,C}$ = 28.7, $^2J_{P,C}$ = 18.5 Hz, Rh*C*(=CH_2)Ph], 135.5−125.4 (m, C_6H_5), 125.7 (dt, $^2J_{Rh,C}$ = 4.4, $^3J_{P,C}$ = 5.1 Hz, =CH_2), 109.3 (dt, $^2J_{Rh,C}$ = 8.7, $^3J_{P,C}$ = 4.7 Hz, ≡*C*Ph), 99.9 (dt, $^1J_{Rh,C}$ = 50.1, $^2J_{P,H}$ = 18.5 Hz, Rh*C*≡CPh), 39.4 [s, *C*(CH_3)$_3$], 27.1 [s, C(*C*H$_3$)$_3$], 26.4 (vt, *N* = 25.4 Hz, P*C*HCH$_3$), 19.3, 19.0 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 29.5 (d, $^1J_{Rh,P}$ = 104.6 Hz). MS (70 eV, e-spray): *m/z* = 864 [M^+]. $C_{51}H_{55}O_2P_2Rh$ (864.9): calcd. C 70.83, H 6.41; found C 70.79, H 6.40.

Catalytic Dimerization of Phenylacetylene: A solution of either **9** (165 mg, 0.25 mmol) or **25** (260 mg, 0.25 mmol) in benzene (25 mL) was treated with phenylacetylene (2.7 mL, 25 mmol) and hexane (1 mL, as a reference for GC) and stirred whilst irradiating with an Osram 500 W lamp (λ = 300 nm) at room temperature. After 6 h, the GC plot (measured with a Shimadzu GC-8A gas chromatograph and a FFAP column) revealed that 80% of phenylacetylene had been consumed. The volatiles were removed in vacuo and the remaining red-brown oil investigated by ^1H NMR spectroscopy. The ^1H NMR spectrum showed that the major product was the enyne PhC≡CC(Ph)=CH_2, whereas the isomeric butenynes (*E*)- and (*Z*)-PhC≡CCH=CHPh were present in less than 1%. The red-brown oil was dissolved in benzene (2 mL) and the solution chromatographed on Al_2O_3 (neutral, activity grade I, height of column 15 cm). A yellow fraction was eluted with hexane, which was then dried in vacuo. The yellow oil (which slowly polymerizes at temperatures above −40 °C) was identified as PhC≡CC(Ph)=CH_2 by comparison of its NMR spectroscopic data with those of the literature.[27]

Preparation of [Rh(κ^2-O_2CCH_3)(C≡CCO_2Me){(*E*)-CH=$CHCO_2Me$}(P*i*PrPh$_2$)$_2$] (26): This compound was prepared as described for **24**, with **8** (74 mg, 0.12 mmol) and methyl propiolate (22 μL, 0.24 mmol) as starting materials. Pale-yellow solid; yield 83 mg (88%); m.p. 132 °C (dec.). IR (KBr): ν(C≡C) = 2090, ν(C=O) = 1675, ν(OCO_{as}) = 1570 cm^{-1}. ^1H NMR (200 MHz, C_6D_6): δ = 9.18 (ddt, $^3J_{H,H}$ = 14.6, $^3J_{P,H}$ = 2.9, $^2J_{Rh,H}$ = 0.9 Hz, 1 H, RhCH), 7.77−6.95 (m, 20 H, C_6H_5), 6.33 (ddt, $^3J_{H,H}$ = 14.6, $^4J_{P,H}$ = 1.5, $^3J_{Rh,H}$ = 1.5 Hz, 1 H, =C*H*CO_2CH_3), 3.38, 3.36 (both s, 6 H, CO_2CH_3), 3.06 (m, 2 H, PC*H*CH_3), 1.30 (dvt, *N* = 15.7, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHC*H*$_3$), 1.06 (dvt, *N* = 15.0, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHC*H*$_3$), 1.05 (s, 3 H, O_2CCH_3). ^{13}C NMR (100.6 MHz, C_6D_6): δ = 184.7 (s, RhO_2CCH_3), 168.0 (dt, $^1J_{Rh,C}$ = 29.3, $^2J_{P,C}$ = 9.8 Hz, RhCH), 162.7 (dt, $^3J_{Rh,C}$ = 2.7, $^4J_{P,C}$ = 1.3 Hz, CCO_2CH_3), 153.7 (dt, $^3J_{Rh,C}$ = 1.6, $^4J_{P,C}$ = 1.3 Hz, *C*O_2CH_3), 135.2, 134.7 (both vt, *N* = 9.8 Hz, *ortho*-C of C_6H_5), 130.3, 130.2 (both s, *para*-C of C_6H_5), 129.2, 129.2 (both vt, *N* = 41.8 Hz, *ipso*-C of C_6H_5), 128.0, 127.9 (both vt, *N* = 9.4 Hz, *meta*-C of C_6H_5), 127.5 (dt, $^2J_{Rh,C}$ = 9.3, $^3J_{P,C}$ = 4.5 Hz, =*C*HCO_2CH_3), 109.1 (dt, $^1J_{Rh,C}$ = 50.5, $^2J_{P,C}$ = 17.1 Hz, Rh*C*≡C), 103.6 (dt, $^2J_{Rh,C}$ = 11.0, $^3J_{P,C}$ = 2.4 Hz, RhC≡*C*), 50.4, 50.1 (both s, CO_2CH_3), 26.9 (vt, *N* = 26.5 Hz, P*C*HCH$_3$), 23.9 (s, O_2CCH_3), 18.9, 18.8 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 33.6 (d, $^1J_{Rh,P}$ = 98.8 Hz). $C_{40}H_{45}O_6P_2Rh$ (786.7): calcd. C 61.07, H 5.77; found C 60.71, H 5.43.

Preparation of [RhCl(κ^2-O_2CCH_3)(CH=C=CHMe)(P*i*PrPh$_2$)$_2$] (27): A solution of **8** (93 mg, 0.15 mmol) in CH_2Cl_2 (5 mL) was treated at −20 °C with 3-chloro-1-butyne (13 μL, 0.15 mmol), leading to a rapid change of color from dark-red to yellow. After warming the solution to room temperature, the solvent was evaporated in vacuo. A yellow solid was obtained which was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 93 mg (88%); m.p. 124 °C (dec.). IR (KBr): ν(OCO_{as}) = 1460 cm^{-1}. ^1H NMR (400 MHz, C_6D_6): δ = 7.88−6.75 (m, 20 H, C_6H_5), 4.96 (dq, $^3J_{H,H}$ = 6.8, $^4J_{H,H}$ = 6.4 Hz, 1 H, =C*H*CH_3), 4.71 (m, 1 H, RhCH), 3.42, 3.23 (both m, 2 H, PC*H*CH_3), 2.15 (s, 3 H, CO_2CH_3), 1.53 (dd, $^3J_{H,H}$ = 6.8, $^5J_{H,H}$ = 2.7 Hz, 3 H, =CHC*H*$_3$), 1.15 (dd, $^3J_{H,H}$ = 16.1, $^3J_{P,H}$ = 7.0 Hz, 3 H, PCHC*H*$_3$), 1.03 (dd, $^3J_{H,H}$ = 14.3, $^3J_{P,H}$ = 7.0 Hz, 3 H, PCHC*H*$_3$), 1.02 (dd, $^3J_{H,H}$ = 16.0, $^3J_{P,H}$ = 6.8 Hz, 3 H, PCHC*H*$_3$), 0.89 (dd, $^3J_{H,H}$ = 15.1, $^3J_{P,H}$ = 6.8 Hz, 3 H, PCHC*H*$_3$). ^{13}C NMR (100.6 MHz, C_6D_6): δ = 198.1

(s, RhCH=*C*), 189.4 (s, O_2CCH_3), 134.6 (d, $^3J_{P,C}$ = 7.5 Hz, *meta*-C of Ph), 134.3 (d, $^3J_{P,C}$ = 6.6 Hz, *meta*-C of Ph), 133.9 (d, $^3J_{P,C}$ = 7.4 Hz, *meta*-C of Ph), 133.7 (d, $^3J_{P,C}$ = 6.3 Hz, *meta*-C of Ph), 129.3, 129.0, 128.8, 128.5 (all s, *para*-C of Ph), 126.1 (d, $^2J_{P,C}$ = 8.7 Hz, *ortho*-C of Ph), 125.9 (d, $^2J_{P,C}$ = 9.0 Hz, *ortho*-C of Ph), 125.5 (d, $^2J_{P,C}$ = 10.0 Hz, *ortho*-C of Ph), 125.4 (d, $^1J_{P,C}$ = 50.0 Hz, *ipso*-C of Ph), 125.4 (d, $^1J_{P,C}$ = 52.1 Hz, *ipso*-C of Ph), 125.3 (d, $^2J_{P,C}$ = 10.2 Hz, *ortho*-C of Ph), 124.5 (d, $^1J_{P,C}$ = 46.0 Hz, *ipso*-C of Ph), 124.4 (d, $^1J_{P,C}$ = 48.2 Hz, *ipso*-C of Ph), 87.4 (dt, $^1J_{Rh,C}$ = 17.7, $^2J_{P,C}$ = 10.7 Hz, RhCH), 83.0 (s, =*C*HCH$_3$), 25.9 (d, $^1J_{P,C}$ = 25.9 Hz, P*C*HCH$_3$), 25.7(s, O_2CCH_3), 25.4 (d, $^1J_{P,C}$ = 26.5 Hz, P*C*HCH$_3$), 17.9, 17.7, 16.9, 16.7 (all s, PCH*C*H$_3$), 13.3 (s, = CH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ(A) = 51.8, δ(B) = 51.3 (ABX spin system, $J_{A,B}$ = 32.0 Hz, $J_{A,X}$ = $J_{B,X}$ = 139.4 Hz). MS (70 eV, e-spray): *m*/*z* = 671 [M$^+$ − Cl]. $C_{36}H_{42}ClO_2P_2Rh$ (707.0): calcd. C 61.16, H 5.99, Rh 14.55; found C 61.14, H 6.19, Rh 14.21.

Preparation of [Rh(κ^2-O_2CCH_3)(C≡CPh){(*E*)-C(CO$_2$Me)=CHCO$_2$Me}(P*i*PrPh$_2$)$_2$] (28): A solution of **21** (106 mg, 0.14 mmol) in CH_2Cl_2 (5 mL) was treated at −20 °C with phenylacetylene (16 μL, 0.14 mmol) and stirred for 5 min at −20 °C. After a few seconds a change of color from yellow to red occurred, followed by a subsequent change of color in the opposite direction. After warming the solution to room temperature, the solvent was evaporated in vacuo and the residue extracted with acetone (20 mL). The extract was dried in vacuo to give a pale-yellow solid which was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 99 mg (82%); m.p. 140 °C (dec.). IR (KBr): ν(C≡C) = 2100, ν(C=O) = 1695, ν(OCO) = 1570 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 8.11−6.99 (m, 25 H, C_6H_5), 6.00 (s, 1 H, =C*H*CO$_2$CH$_3$), 3.80 (s, 3 H, CO$_2$CH$_3$), 3.52 (m, 2 H, PC*H*CH$_3$), 3.37 (s, 3 H, CO$_2$CH$_3$), 1.40 (dvt, *N* = 15.4, $^3J_{H,H}$ = 7.7 Hz, 6 H, PCHC*H*$_3$), 0.99 (dvt, *N* = 14.6, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHC*H*$_3$), 0.98 (s, 3 H, O_2CCH_3). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 34.3 (d, $^1J_{Rh,P}$ = 97.4 Hz). $C_{46}H_{49}O_6P_2Rh$ (862.7): calcd. C 64.04, H 5.72, Rh 11.93; found C 63.51, H 5.66, Rh 11.87.

Preparation of [Rh{κ^2-O$_2$CC(CH$_3$)$_3$}(C≡CPh){(*E*)-C(CO$_2$Me)=CHCO$_2$Me}(P*i*PrPh$_2$)$_2$] (29): This compound was prepared as described for **28**, with **22** (96 mg, 0.12 mmol) and phenylacetylene (14 μL, 0.12 mmol) as starting materials. Pale-yellow solid; yield 93 mg (86%); m.p. 116 °C (dec.). IR (KBr): ν(C≡C) = 2100, ν(C=O) = 1695, ν(OCO) = 1570 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.98−7.03 (m, 25 H, C_6H_5), 6.04 (s, 1 H, =C*H*CO$_2$CH$_3$), 3.89 (s, 3 H, CO$_2$CH$_3$), 3.54 (m, 2 H, PC*H*CH$_3$), 3.40 (s, 3 H, CO$_2$CH$_3$), 1.33 (dvt, *N* = 15.0, $^3J_{H,H}$ = 7.5 Hz, 6 H, PCHC*H*$_3$), 1.04 (dvt, *N* = 14.4, $^3J_{H,H}$ = 7.5 Hz, 6 H, PCHC*H*$_3$), 0.70 [s, 9 H, C(*C*H$_3$)$_3$]. ^{13}C NMR (100.6 MHz, C_6D_6): δ = 192.1 [s, $O_2CC(CH_3)_3$], 173.1, 162.2 (both s, *C*O$_2$CH$_3$), 162.2 [dt, $^1J_{Rh,C}$ = 33.9, $^2J_{P,C}$ = 9.5 Hz, Rh*C*(CO$_2$CH$_3$)], 136.5−125.4 (m, C_6H_5), 120.5 (dt, $^2J_{Rh,C}$ = 4.3, $^3J_{P,C}$ = 4.3 Hz, =*C*HCO$_2$CH$_3$), 106.6 (dt, $^2J_{Rh,C}$ = 8.6, $^3J_{P,C}$ = 1.9 Hz, ≡*C*C$_6$H$_5$), 100.2 (dt, $^1J_{RhC}$ = 48.6, $^2J_{P,C}$ = 20.5 Hz, Rh*C*≡C), 51.0, 50.3 (both s, CO$_2$*C*H$_3$), 39.6 [s, *C*(CH$_3$)$_3$], 27.0 (vt, *N* = 25.3 Hz, P*C*HCH$_3$) 26.7 [s, C(*C*H$_3$)$_3$], 20.1, 19.1 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 31.8 (d, $^1J_{Rh,P}$ = 97.2 Hz). $C_{49}H_{54}O_6P_2Rh$ (903.8): calcd. C 65.12, H 6.02; found C 65.44, H 6.18.

Preparation of [RhCl(C≡CPh){(*E*)-C(CO$_2$Me)=CHCO$_2$Me}(P*i*PrPh$_2$)$_2$] (30): A solution of either **28** (121 mg, 0.14 mmol) or **29** (127 mg, 0.14 mmol) in acetone (5 mL) was treated with freshly distilled Me$_3$SiCl (18 μL, 0.14 mmol) and stirred for 10 min at −20 °C. A rapid change of color from pale-yellow to red occurred. After warming the solution to room temperature and evaporating the solvent in vacuo, a red, thermally labile oil was obtained; yield 108 mg (92%) from **28** and 110 mg (94%) from **29**. IR (C_6H_6): ν(C≡C) = 2100, ν(C=O) = 1700 cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6): δ = 8.16−6.66 (m, 25 H, C_6H_5), 6.04 (s, 1 H, = C*H*CO$_2$CH$_3$), 3.98 (m, 2 H, PC*H*CH$_3$), 3.12, 2.99 (both s, 3 H each, CO$_2$CH$_3$), 1.44 (dvt, *N* = 15.2, $^3J_{H,H}$ = 7.8 Hz, 6 H, PCHC*H*$_3$), 1.15 (dvt, *N* = 14.6, $^3J_{H,H}$ = 7.2 Hz, 6 H, PCHC*H*$_3$). ^{31}P NMR (162.0 MHz, C_6D_6): δ = 18.9 (d, $^1J_{Rh,P}$ = 94.3 Hz); $C_{44}ClH_{46}O_4P_2Rh$ (839.2): calcd. C 62.98, H 5.53; found C 63.04, H 6.00.

Preparation of *trans*-[RhCl{η^2-PhC≡CC(CO$_2$Me)=CHCO$_2$Me}(P*i*PrPh$_2$)$_2$] (31): A solution of **30** (109 mg, 0.13 mmol) was stirred for 1 h at 60 °C. A change of color from red to orange occurred. After cooling the solution to room temperature, the solvent was removed in vacuo, and the residue was extracted with acetone (20 mL). The extract was dried in vacuo to give an orange solid which was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 82 mg (75%); m.p. 104 °C (dec.). IR (KBr): ν(C≡C) = 1835, ν(C=O) = 1704, ν(C=C) = 1565 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 8.19−6.91 (m, 25 H, C_6H_5), 6.70 (s, 1 H, = C*H*CO$_2$CH$_3$), 3.48, 3.32 (both s, 3 H each, CO$_2$CH$_3$), 3.10 (m, 2 H, PC*H*CH$_3$), 1.35 (dvt, *N* = 15.0, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHC*H*$_3$), 1.19 (dvt, *N* = 15.4, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHC*H*$_3$). ^{13}C NMR (100.6 MHz, C_6D_6): δ = 166.5, 165.7 (both s, CO$_2$), 130.9 (s, = *C*CO$_2$CH$_3$), 173.0−124.9 (m, C_6H_5), 120.2 (s, =*C*HCO$_2$CH$_3$), 108.5 (dt, $^1J_{RhC}$ = 15.3, $^2J_{P,C}$ = 2.9 Hz, Ph*C*≡C), 81.7 (dt, $^1J_{RhC}$ = 16.2, $^2J_{P,C}$ = 2.0 Hz, PhC≡*C*), 51.9, 51.5 (both s, CO$_2$*C*H$_3$), 25.4 (vt, *N* = 23.5 Hz, P*C*HCH$_3$), 19.9, 19.3 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 36.6 (d, $^1J_{RhP}$ = 117.7 Hz). MS (70 eV, e-spray): *m*/*z* = 803 [M$^+$ − Cl]. $C_{44}H_{46}ClO_4P_2Rh$ (839.2): calcd. C 62.98, H 5.53; found C 63.03, H 6.01.

Reaction of 31 with CO: A slow stream of CO was passed through a solution of **31** (84 mg, 0.10 mmol) in CH_2Cl_2 (10 mL) at room temperature for 10 s. An instantaneous change of color from orange to yellow occurred. The ^{1}H NMR spectrum of the solution indicated that the enyne **33** was formed along with **32**.[23] The solvent was evaporated in vacuo, the remaining yellow solid was washed twice with 1-mL portions of acetone (0 °C) and identified as **32**; yield 62 mg (98%).

Preparation of *trans*-[RhCl(CO)(P*i*PrPh$_2$)$_2$] (32): A slow stream of CO was passed through a suspension of **3** (48 mg, 0.04 mmol) in toluene (10 mL) at room temperature for 10 min. A change of color from violet to yellow occurred. After evaporation of the solvent in vacuo, the yellow solid was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 50 mg (99%); m.p. 140 °C. IR (KBr): ν(CO) = 1960 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.79−6.96 (m, 20 H, C_6H_5), 3.48 (m, 2 H, PC*H*CH$_3$), 1.10 (dvt, *N* = 15.5, $^3J_{H,H}$ = 7.5 Hz, 12 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 41.0 (d, $^1J_{Rh,P}$ = 123.5 Hz). $C_{31}H_{34}ClOP_2Rh$ (622.9): calcd. C 59.77, H 5.50, Rh 16.52; found C 60.21, H 5.99, Rh 16.74.

Preparation of [Rh{κ^1-O$_2$S(O)-*p*-Tol}(=C=CHPh)(P*i*Pr$_2$Ph)$_2$] (34): A solution of **12** (106 mg, 0.16 mmol) in toluene (2 mL) was treated with phenylacetylene (19 μL, 0.16 mmol) and stirred for 3 h at room temperature. A change of color from red to violet occurred. The solvent was evaporated in vacuo and the residue extracted with ether (25 mL). After drying the extract in vacuo, the remaining violet solid was washed twice with 10-mL portions of pentane (0 °C) and dried; yield 120 mg (98%); m.p. 67 °C (dec.). IR (CH_2Cl_2): ν(C=C) = 1650 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.75−6.56 (m, 19 H, C_6H_5 and C_6H_4), 2.82 (m, 4 H, PC*H*CH$_3$), 1.93 (s, 3 H, $C_6H_4CH_3$), 1.40 (dvt, *N* = 16.4, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHC*H*$_3$), 1.09 (dt, $^3J_{Rh,H}$ = 1.5, $^4J_{P,H}$ = 3.5 Hz, 1 H, =C*H*Ph), 0.93 (dvt,

N = 13.9, $^3J_{H,H}$ = 9.1 Hz, 12 H, PCHCH_3). ^{13}C NMR (100.6 MHz, C_6D_6): δ = 306.9 (dt, $^1J_{Rh,C}$ = 58.4, $^2J_{P,C}$ = 18.1 Hz, Rh=*C*=C), 143.7, 139.4, 134.9, 129.9, 128.6, 128.5, 127.9, 127.7, 126.8, 126.2, 125.3, 124.6 (all s, C_6H_5 and C_6H_4), 113.4 (dt, $^2J_{Rh,C}$ = 15.3, $^3J_{P,C}$ = 6.7 Hz, Rh=C=*C*), 30.4 (s, $C_6H_4CH_3$), 23.2 (vt, N = 22.3 Hz, P*C*HCH$_3$), 20.0, 18.5 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 43.3 (d, $^1J_{Rh,P}$ = 143.9 Hz). $C_{39}H_{51}O_3RhS$ (764.8): calcd. C 61.25, H 6.72; found C 60.87, H 6.68.

Preparation of [Rh{κ^1-O$_2$S(O)-*p*-Tol}(=C=CHCMe$_2$OH)(P*i*Pr$_2$Ph)$_2$] (35): This compound was prepared as described for **34**, with **12** (106 mg, 0.16 mmol) and HC≡CCMe$_2$(OH) (16 μL, 0.16 mmol) as starting materials; reaction time 1 h. Violet solid; yield 113 mg (95%); m.p. 58 °C (dec.). IR (CH_2Cl_2): ν(C=C) = 1635 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.59−6.81 (m, 14 H, C_6H_5 and C_6H_4), 2.87 (s, 3 H, $C_6H_4CH_3$), 2.57 (m, 4 H, PC*H*CH$_3$), 1.43 (dvt, N = 16.5, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHCH_3), 1.23 [s, 6 H, C(CH_3)$_2$OH], 1.05 (dvt, N = 13.9, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHCH_3), 1.00 (dt, $^3J_{Rh,H}$ = 0.6, $^4J_{P,H}$ = 3.1 Hz, 1 H, =C*H*R), signal of O*H* proton not found. ^{13}C NMR (100.6 MHz, C_6D_6): δ = 308.2 (dt, $^1J_{Rh,C}$ = 59.9, $^2J_{P,C}$ = 16.4 Hz, Rh=*C*=C), 143.9, 139.5, 135.2, 133.5, 130.1, 128.7, 128.1, 127.0 (all s, C_6H_5 and C_6H_4), 115.7 (dt, $^2J_{Rh,C}$ = 15.3, $^3J_{P,C}$ = 5.9 Hz, Rh=C=*C*), 43.0 [s, *C*(CH$_3$)$_2$OH], 31.8 (s, $C_6H_4CH_3$), 28.2 [s, C(*C*H$_3$)$_2$OH], 25.0 (vt, N = 25.9 Hz, P*C*HCH$_3$), 20.2, 18.7 (both s, PCH*C*H$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 42.4 (d, $^1J_{Rh,P}$ = 143.9 Hz). $C_{36}H_{53}O_4P_2RhS$ (746.7): calcd. 57.90, H 7.15; found C 58.06, H 6.97.

Preparation of [Rh(C≡CPh)(=C=CHPh)(P*i*Pr$_2$Ph)$_2$] (36): a) A solution of **12** (100 mg, 0.15 mmol) in a 1:1 mixture of toluene and freshly distilled triethylamine (5 mL) was treated with phenylacetylene (34 μL, 0.30 mmol) and stirred for 5 min at −20 °C. A smooth change of color from red to dark green occurred. After warming the solution to room temperature, the solvent was evaporated in vacuo and the residue was extracted with 25 mL of ether (0° C). The extract was dried in vacuo, the remaining residue was dissolved in 5 mL of pentane (0° C) and the solution stored at this temperature. Turquoise crystals precipitated after 1 min, which were filtered, washed twice with 1-mL portions of pentane (0 °C) and dried; yield 35 mg (34%).

b) A solution of **34** (107 mg, 0.14 mmol) in a 1:1 mixture of toluene and freshly distilled triethylamine (5 mL) was treated at −50 °C with phenylacetylene (15 μL, 0.14 mmol). A quick change of color from violet to dark green occurred. After warming the solution to room temperature, it was worked up as described for a). Turquoise crystals were obtained; yield 54 mg (56%); m.p. 78 °C (dec.). IR (KBr): ν(C≡C) = 2060, ν(C=C) = 1635 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.78−6.78 (m, 20 H, C_6H_5), 2.87 (m, 4 H, PC*H*CH$_3$), 1.42 (dvt, N = 17.9, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHCH_3), 1.28 (dt, $^3J_{Rh,H}$ = 0.7, $^4J_{P,H}$ = 3.7 Hz, 1 H, =C*H*Ph), 1.06 (dvt, N = 13.9, $^3J_{H,H}$ = 6.9 Hz, 12 H, PCHCH_3). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 46.8 (d, $^1J_{Rh,P}$ = 141.0 Hz). $C_{40}H_{49}P_2Rh$ (694.7): calcd. C 69.16, H 7.11, Rh 14.81; found C 68.62, H 7.08, Rh 14.40.

Preparation of [Rh(C≡CCMe$_2$OH)(=C=CHCMe$_2$OH)(P*i*Pr$_2$Ph)$_2$] (37): This compound was prepared as described for **36**, either according to method a) from **12** (106 mg, 0.16 mmol) and HC≡CCMe$_2$(OH) (32 μL, 0.32 mmol) or according to method b) from **35** (106 mg, 0.14 mmol) and HC≡CCMe$_2$(OH) (14 μL, 0.14 mmol). Dark green solid; yield 47 mg (45%) for a) and 63 mg (68%) for b); m.p. 78 °C (dec.). IR (KBr): ν(OH) = 3555, 3540, ν(C≡C) = 2060, ν(C=C) = 1625 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.44−7.04 (m, 10 H, C_6H_5), 2.88 (m, 4 H, PC*H*CH$_3$), 1.62 (s, 1 H, OH), 1.45 [s, 6 H, C(CH_3)$_2$OH], 1.36 (dvt, N = 16.1, $^3J_{H,H}$ = 7.3 Hz, 12 H, PCHCH_3), 1.06 (dvt, N = 13.5, $^3J_{H,H}$ = 6.2 Hz, 12 H, PCHCH_3), 0.92 [s, 6 H, C(CH_3)$_2$OH], 0.21 (dt, $^3J_{Rh,H}$ = 0.7, $^4J_{P,H}$ = 3.7 Hz, 1 H, =CHR), signal of the second OH proton not found. ^{31}P NMR (81.0 MHz, C_6D_6): δ = 45.7 (d, $^1J_{Rh,P}$ = 142.4 Hz). $C_{34}H_{53}O_2P_2Rh$ (658.7): calcd. C 62.00, H 8.11; found C 61.59, H 8.10.

Preparation of [Rh(C≡CCMe$_2$OH)(=C=CHPh)(P*i*Pr$_2$Ph)$_2$] (38): A solution of **34** (115 mg, 0.15 mmol) in a 1:1 mixture of toluene and freshly distilled triethylamine (5 mL) was treated at −50 °C with HC≡CCMe$_2$(OH) (15 μL, 0.15 mmol) and stirred for 5 min at this temperature. A change of color from violet to dark green occurred. After warming the solution to room temperature, the solvent was evaporated in vacuo. The residue was extracted with 25 mL of ether (0 °C) and the extract was dried in vacuo. The residue was dissolved in 3 mL of acetone (0 °C) and the solution stored for 3 min at this temperature. Dark green crystals precipitated, which were filtered, washed twice with 1-mL portions of acetone (0 °C) and dried; yield 40 mg (39%); m.p. 98 °C (dec.). IR (KBr): ν(OH) = 3350, ν(C≡C) = 2060, ν(C=C) = 1635 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.44−7.04 (m, 15 H, C_6H_5), 3.12 (m, 4 H, PC*H*CH$_3$), 1.60 (dvt, N = 15.7, $^3J_{H,H}$ = 8.0 Hz, 12 H, PCHCH_3), 1.20 (dvt, N = 13.3, $^3J_{H,H}$ = 6.6 Hz, 12 H, PCHCH_3), 1.07 [s, 6 H, C(CH_3)$_2$OH], 0.96 (dt, $^3J_{Rh,H}$ = 0.8, $^4J_{P,H}$ = 3.6 Hz, 1 H, =CHR), signal of OH proton not found. ^{31}P NMR (162.0 MHz, C_6D_6): δ = 45.9 (d, $^1J_{Rh,P}$ = 141.0 Hz). $C_{37}H_{51}OP_2Rh$ (676.7): calcd. C 65.68, H 7.60; found C 65.33, H 7.48.

Preparation of *trans*-[Rh{(*Z*)-C(=CHPh)C≡CPh}(CO)(P*i*Pr$_2$Ph)$_2$] (39): A slow stream of CO was passed through a solution of **36** (97 mg, 0.14 mmol) in CH_2Cl_2 (5 mL) at −20 °C for 10 s. A change of color from dark green to yellow occurred. After warming the solution to room temperature, the solvent was evaporated in vacuo. The residue was extracted with 25 mL of acetone (10 °C) and the extract was dried in vacuo. The remaining yellow solid was washed twice with 1-mL portions of acetone (0 °C) and dried; yield 87 mg (86%); m.p. 144 °C (dec.). IR (KBr): ν(C≡C) = 2120, ν(CO) = 1955 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 8.07 (dt, $^3J_{Rh,H}$ = 2.2, $^4J_{P,H}$ = 9.5 Hz, 1 H, =C*H*Ph), 7.81−6.94 (m, 20 H, C_6H_5), 2.78, 2.41 (both m, 2 H each, PC*H*CH$_3$), 2.26 (dvt, N = 15.9, $^3J_{H,H}$ = 7.0 Hz, 6 H, PCHCH_3), 1.13 (dvt, N = 15.0, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHCH_3), 0.87 (dvt, N = 15.2, $^3J_{H,H}$ = 6.6 Hz, 6 H, PCHCH_3), 0.65 (dvt, N = 16.1, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHCH_3). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 41.4 (d, $^1J_{Rh,P}$ = 145.3 Hz). $C_{41}H_{49}OP_2Rh$ (722.7): calcd. C 68.14, H 6.83; found C 67.80, H 7.28.

Preparation of *trans*-[Rh{(*Z*)-C(=CHCMe$_2$OH)C≡CCMe$_2$OH}(CO)(P*i*Pr$_2$Ph)$_2$] (40): This compound was prepared as described for **39**, with **37** (86 mg, 0.13 mmol) and CO as starting materials. Yellow solid; yield 75 mg (84%); m.p. 80 °C (dec.). IR (KBr): ν(C≡C) = 2160, ν(CO) = 1955 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 8.20−7.34 (m, 10 H, C_6H_5), 7.18 (dt, $^3J_{Rh,H}$ = 2.6, $^4J_{P,H}$ = 2.2 Hz, 1 H, =C*H*R), 4.64 (s, 1 H, OH), 3.00, 2.73 (both m, 2 H each, PC*H*CH$_3$), 2.00 (s, 1 H, OH), 1.97 [s, 6 H, C(CH_3)$_2$OH], 1.70 (dvt, N = 16.5, $^3J_{H,H}$ = 9.5 Hz, 6 H, PCHCH_3), 1.46 [s, 6 H, C(CH_3)$_2$OH], 1.42 (dvt, N = 13.9, $^3J_{H,H}$ = 8.4 Hz, 6 H, PCHCH_3), 1.35 (dvt, N = 12.1, $^3J_{H,H}$ = 6.6 Hz, 6 H, PCHCH_3), 1.25 (dvt, N = 13.9, $^3J_{H,H}$ = 7.3 Hz, 6 H, PCHCH_3). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 39.1 (d, $^1J_{Rh,P}$ = 142.4 Hz). $C_{35}H_{53}O_3P_2Rh$ (686.7): calcd. C 61.22, H 7.78; found C 61.53, H 7.72.

Preparation of *trans*-[Rh{(*Z*)-C(=CHPh)C≡CCMe$_2$OH}(CO)(P*i*Pr$_2$Ph)$_2$] (41): This compound was prepared as described for **39**,

with **38** (101 mg, 0.15 mmol) and CO as starting materials. Yellow oil; yield 40 mg (38%). IR (KBr): ν(C≡C) = 2070, ν(CO) 1950 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6): δ = 7.93−7.25 (m, 15 H, C_6H_5), 7.20 (dt, $^3J_{Rh,H}$ = 2.4, $^4J_{P,H}$ = 2.2 Hz, 1 H, =C*H*R), 4.53 (s, 1 H, OH), 2.77, 2.51 (both m, 2 H each, PC*H*CH$_3$), 1.46 (dvt, *N* = 16.5, $^3J_{H,H}$ = 6.9 Hz, 6 H, PCHC*H*$_3$), 1.25 (dvt, *N* = 15.7, $^3J_{H,H}$ = 6.9 Hz, 6 H, PCHC*H*$_3$), 1.23 [s, 6 H, C(C*H*$_3$)$_2$OH], 1.12 (dvt, *N* = 13.5, $^3J_{H,H}$ = 6.9 Hz, 6 H, PCHC*H*$_3$), 1.00 (dvt, *N* = 14.3, $^3J_{H,H}$ = 6.6 Hz, 6 H, PCHC*H*$_3$). ^{31}P NMR (81.0 MHz, C_6D_6): δ = 39.1 (d, $^1J_{Rh,P}$ = 140.9 Hz). $C_{38}H_{51}O_2P_2Rh$ (704.7): calcd. C 64.77 H 7.29, Rh 14.60; found C 64.68 H 7.34, Rh 14.22.

Determination of the X-ray Crystal Structure of 27: Single crystals were grown upon diffusion of ether into a saturated solution of **27** in CH_2Cl_2/methylcyclohexane. Crystal data (from 23 reflections, 10° < Θ < 14°): monoclinic; space group $P2_1/c$ (No. 14); *a* = 10.496(5), *b* = 17.455(5), *c* = 18.629(7) Å, β = 97.33(2)°; *V* = 3385(2) Å^3, *Z* = 4; $d_{calcd.}$ = 1.387 g cm^{-3}; μ(Mo-K_α) = 7.0 cm^{-1}; crystal size 0.23 × 0.38 × 0.48 mm; Enraf−Nonius CAD4, Mo-K_α radiation (0.71073 Å), graphite monochromator; *T* = 293(2) K; Θ-scan, max. 2Θ = 47.94°; 5011 reflections measured, 4691 independent, 3135 with $I > 2\sigma(I)$. Intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was applied. The structure was solved by direct method (SHELXS-86).[28] Atomic coordinates and anisotropic thermal parameters of the non-hydrogen atoms were refined by full-matrix least-squares method using the program package SDP from Enraf−Nonius. The hydrogen atoms H1 and H3 were found in a difference-Fourier synthesis and refined isotropically. The positions of all other hydrogen atoms were calculated according to ideal geometry and refined with the riding method. Conventional R = 0.0421 and weighted wR_2 = 0.0857 [for data with $I > 2\sigma(I)$]; R = 0.1019 and weighted wR_2 = 0.0991 (for all data); reflection/parameter ratio 12.1; residual electron density +0.939/−0.323 eÅ^{-3}.

CCDC-175652 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft (SFB 347) and the Fonds der Chemischen Industrie. We thank Mrs. R. Schedl and Mr. C. P. Kneis for elemental analysis and DTA measurements, Mrs. M.-L. Schäfer and Dr. W. Buchner for NMR spectra, Dr. G. Lange and Mr. F. Dadrich for mass spectra, and Mr. C. D. Brandt for drawing the molecular diagram.

Luminescent Star-Shaped Zinc(II) and Platinum(II) Complexes Based on Star-Shaped 2,2′-Dipyridylamino-Derived Ligands

Corey Seward,[a] Jun Pang,[a] and Suning Wang*[a]

Keywords: Starburst molecules / Zinc / Platinum / N ligands / Luminescence

New Zn^{II} and Pt^{II} complexes of the star-shaped ligands 2,4,6-tris(2,2′-dipyridylamino)-1,3,5-triazine (tdat), 1,3,5-tris(2,2′-dipyridylamino)benzene (tdab), 2,4,6-tris[*p*-(2,2′-dipyridylamino)phenyl]-1,3,5-triazine (tdapt) and 1,3,5-tris[*p*-(2,2′-dipyridylamino)phenyl]benzene (tdapb) have been synthesized and characterized. 1:1, 1:2 and 1:3 (ligand vs. the number of Zn atoms) Zn^{II} complexes of the tdat ligand have been identified. The 1:1 and 1:2 Zn^{II} complexes of tdat are dynamic in solution. For the tdab, tdapt and tdapb ligands, only 1:3 complexes of Pt^{II} and Zn^{II} have been isolated. Single-crystal X-ray diffraction analyses have been carried out for some of these new complexes, which revealed that there is a distinct difference in the arrangement of star-shaped ligands in the complexes of Zn^{II} and those of Pt^{II}. The Pt^{II} complexes of tdat and tdab adopt an unusual "bowl" shape and stack in a "head-to-tail" fashion in the crystal lattice. In contrast, the corresponding Zn^{II} complexes do not have a "bowl" shape. The difference between the Zn^{II} complexes and the Pt^{II} complexes can be attributed to the different coordination geometry preferred by the two metal ions. The Zn^{II} complex of tdapb displays several crystal motifs, two of which contain benzene molecules in the crystal lattices. All complexes are luminescent in the blue region, attributable to ligand-based $\pi \rightarrow \pi^*$ transitions.

Introduction

Luminescent metal complexes are a fascinating class of molecules that have found applications in many areas of chemistry and materials science. For example, it has been demonstrated recently that luminescent metal compounds can function as emitters in light emitting devices (LEDs).[1] Luminescent compounds have been used widely as sensors and probes for a variety of chemical and biological substances.[2] Luminescent transition metal compounds have also been demonstrated as models/centers for photochemical devices/reactions.[3] There is an increasing demand for new luminescent metal compounds that can perform one or two desired functions, such as emitting light in organic LEDs or detecting certain molecules of environmental concern. Toward that goal, recently we developed a class of blue luminescent star-shaped organic molecules of 2,2′-dipyridylamino derivatives based on 2,4,6-trisubstituted triazine and 1,3,5-trisubstituted benzene (Scheme 1) that have been found to be promising blue emitters in organic LEDs.[4] Star-shaped luminescent organic molecules have been explored extensively as either emitters or host materials in organic LEDs due to their good film-forming properties.[5] The corresponding luminescent star-shaped metal complexes may offer new properties that are not present in the organic molecules. For example, in a recent preliminary communication we reported that the star-shaped ligand tdapb {tdapb = 1,3,5-tris[*p*-(2,2′-dipyridylamino)phenyl]-benzene} forms a 1:3 complex with $ZnCl_2$ that is blue luminescent and has a highly selective fluorescent response toward benzene.[6] The highly selective fluorescent response of the zinc star-shaped complex was attributed to the extended molecular architecture in the crystal lattice. We have now extended our investigation to metal complexes of other members of our star-shaped ligands and Pt^{II} complexes. Unlike the Zn^{II} ion, which prefers a tetrahedral geometry, the Pt^{II} ion adopts a square-planar geometry. Consequently, it is anticipated that the molecular shape of Pt^{II} complexes will be quite different from those of the corresponding Zn^{II} complexes. Furthermore, Pt^{II} centers tend to enhance phosphorescence but quench fluorescence from the ligand, due to their d^8 electronic configuration. The replacement of Zn^{II} ions by Pt^{II} ions in the complex could therefore lead to a significant change of luminescent properties. Some interesting molecular and extended structural variations and dynamic behaviors in solution have been observed in the new complexes. In the present paper, we give a full account on the results of our comparative study on syntheses, structures and luminescent properties of Zn^{II} and Pt^{II} complexes with the four star-shaped ligands listed in Scheme 1.

Results and Discussion

Syntheses and Structures

Zn^{II} Complexes of 2,4,6-Tris(2,2′-dipyridylamino)-1,3,5-triazine (tdat) and 1,3,5-Tris(2,2′-dipyridylamino)benzene (tdab)

The Zn^{II} complexes of tdat and tdab were obtained from the reactions of $ZnCl_2$ with the corresponding ligand in either CH_2Cl_2/THF solution or CH_2Cl_2/methanol solution. For the tdat ligand, by controlling the stoichiometry of the reaction, three Zn^{II} complexes, $(ZnCl_2)$(tdat) (**1a**), $(ZnCl_2)_2$(tdat) (**1b**), and $(ZnCl_2)_3$(tdat) (**1c**) with a tdat ligand/Zn^{II} ratio of 1:1, 1:2 and 1:3, respectively, were obtained and characterized. However, for the tdab ligand, only the 1:3 complex $(ZnCl_2)$(tdab) (**2**) was isolated, regardless of the ratio of the tdab ligand to $ZnCl_2$ employed in the reaction. The tdat and tdab Zn^{II} complexes are all stable under air in solution and in the solid state. Except for **1a**, these complexes are scarcely soluble in common organic solvents. Compounds **1a**−**1c** and **2** were characterized by ^{1}H NMR spectroscopy and elemental analyses. Single crystals of **1b** and **2**, suitable for X-ray diffraction analyses were obtained and their structures were determined by X-ray diffraction experiments. The crystal structures of **1b** and **2** are shown in Figures 1 and 2, respectively. Selected bond lengths and angles are given in Table 1.

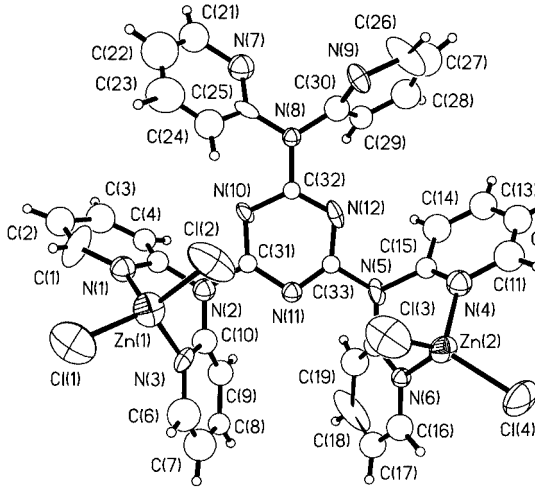

Figure 1. Molecular structure of **1b** with 50% thermal ellipsoids and labeling schemes

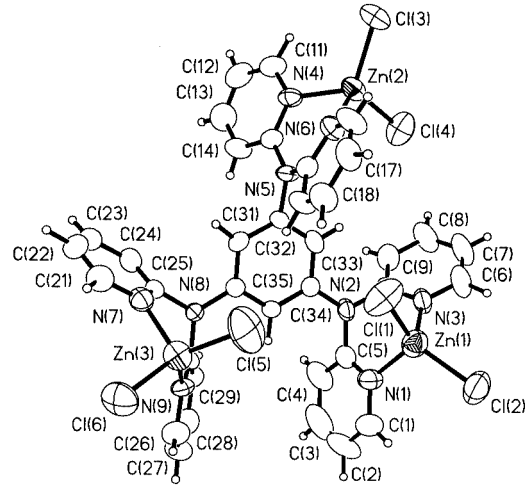

Figure 2. Molecular structure of **2** with 50% thermal ellipsoids and labeling schemes

As shown by Figure 1, the two $ZnCl_2$ units are chelated by two of the dipyridylamino groups in the tdat ligand in **1b** with a typical tetrahedral geometry and normal bond lengths.[7] The third dipyridylamino group does not coordinate. The two $ZnCl_2$ units are on the same side with respect to the triazine ring. The Zn(1)−Zn(2) distance is 7.302(2) Å. Based on the structure of **1b**, we can assume that in the 1:1 complex **1a** the $ZnCl_2$ unit is chelated by the dipyridylamino group in the same manner as observed in **1b**. Because of the existence of both coordinated and noncoordinated dipyridylamino groups in **1b**, one would expect that three sets of chemical shifts for the pyridyl groups (the two pyridyl groups bound to the Zn^{II} ion are not equivalent) should be observed in the ^{1}H NMR spectrum of **1b**. Similarly, three sets of chemical shifts for the pyridyl groups a, b and c (see Scheme 2) are expected for compound **1a**. However, at ambient temperature only one set of pyridyl chemical shifts was observed for both compounds **1a** and **1b**, which leads us to believe that there is a dynamic exchange for compounds **1a** and **1b** in solution. Compound **1b** does not have appreciable solubility in common organic solvents such as CH_2Cl_2, $CHCl_3$ or THF, precluding any low-temperature

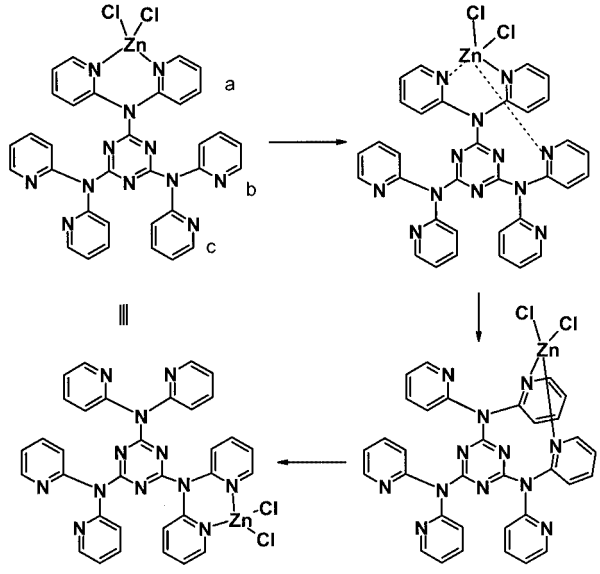
NMR experiments. Compound **1a** has a sufficient solubility in CH_2Cl_2 and allows us to carry out variable-temperature ^{1}H NMR experiments. The ^{1}H NMR spectra of **1a** over the temperature range of 180−298 K recorded in CD_2Cl_2 are shown in Figure 3, which confirms the existence of dynamic exchange of **1a** in solution. If compound **1a** retains its structure as shown in Scheme 2, twelve chemical shifts corresponding to three sets of pyridyl groups should be observed in the ^{1}H NMR spectrum of **1a**. The 180 K spectrum of **1a** displays eleven reasonably resolved peaks with some overlaps, indicating that **1a** indeed retains the expected structure in solution at low temperature. However, at ambient temperature, it undergoes a rapid exchange process, which might be attributed to an intramolecular "merry-go-round" by the $ZnCl_2$ unit as shown by Scheme 2. Alternatively, an intermolecular process that involves the dissociation of $ZnCl_2$ from the ligand and the reattachment to the ligand is also possible. Given the fact that no intermolecular exchange was observed in our previously reported Zn^{II} complexes involving dipyridyl chelate ligands,[8] we believe that the intramolecular process is most likely responsible for the dynamic exchange of **1a**. A similar exchange process is also believed to be responsible for the observed dynamic behavior of **1b**.

As shown in Figure 2, the three $ZnCl_2$ units in compound **2** are all chelated by dipyridylamino groups in the same manner as observed for compound **1b**. Two of the $ZnCl_2$ units are on the same side with respect to the central phenyl ring. However, the third $ZnCl_2$ unit is nearly parallel to the central phenyl ring with the two attached pyridyl rings above and below, respectively. The Zn(1)−Zn(3) separation distance of 7.148(2) Å − the shortest Zn−Zn distance in **2** [Zn(1)−Zn(2) = 7.602(2) Å, Zn(2)−Zn(3) = 9.376(1) Å] − is considerably shorter than that of **1b**. The tdat 1:3 complex **1c** is believed to have a structure similar to **2**.



Scheme 2

Pt^{II} Complexes of tdat and tdab

The light yellow 1:3 Pt^{II} complexes of tdat and tdab, **3** and **4**, were obtained from the reactions of the corresponding ligands with K_2PtCl_4 in a 1:3 ratio by using a solvent-layering/slow diffusion method. This procedure is necessary to obtain sufficiently large single crystals of **3** and **4** for X-

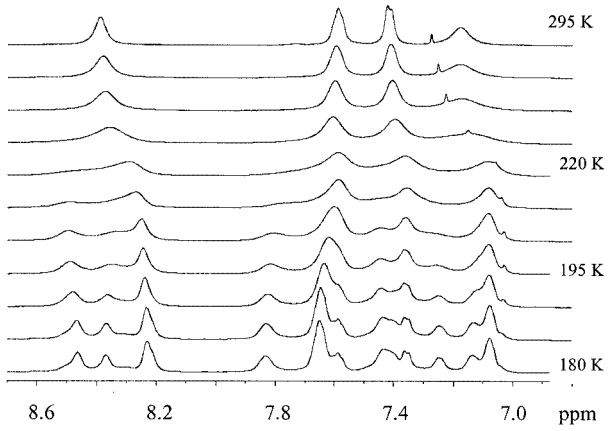


Figure 3. Variable-temperature ^{1}H NMR spectra of **1a** in CD_2Cl_2

ray diffraction analyses, due to the insolubility of the resulting complexes in organic solvents. Compounds **3** and **4** are stable in air. Because of the insolubility of **3** and **4** in organic solvents such as CH_2Cl_2 and DMSO, we were unable to obtain their ^{1}H NMR spectra. These two compounds were characterized by elemental analyses and single-crystal X-ray diffraction analyses. The structures of **3** and **4** are shown in Figures 4 and 6, respectively. Selected bond lengths and angles are listed in Table 1.

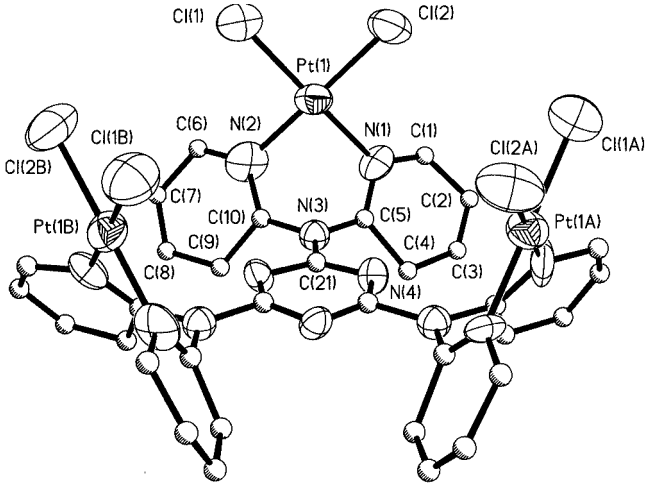

Figure 4. Molecular structure of one of the independent molecules of **3** with 50% thermal ellipsoids and labeling schemes; hydrogen atoms were omitted for clarity and carbon atoms are shown as ideal spheres

Compound **3** crystallizes in two different crystal lattices, hexagonal $R3c$ and monoclinic $P2_1/m$. The monoclinic form of **3** is isomorphous with that of **4**. Therefore, the discussion here focuses on the hexagonal form. There are two independent molecules of **3** in the asymmetric unit cells with similar structures. One of the independent molecules is shown in Figure 4. The three $PtCl_2$ groups in **3** are chelated by dipyridylamino units, resulting in a square-planar geometry for each of the Pt^{II} centers. The Pt−Cl and Pt−N bond lengths in **3** are normal.[3,9] Each molecule of **3** has a crystallographically imposed C_3 rotation symmetry. The intramolecular Pt−Pt separation distances of **3** are 7.710(2) Å and 7.570(2) Å, respectively, for the two independent molecules. The most remarkable feature of **3** is that all three $PtCl_2$ units are oriented on the same side of the triazine ring, thus forming a "bowl-shaped" structure. The absence of the "bowl" structure for compound **2** can be explained by the fact that this would bring the chloride ligands into close contact with each other because of the tetrahedral geometry of the Zn^{II} ion. The second remarkable feature of **3** is that the molecules of **3** stack in the crystal lattice along the C_3 axis, like a stack of bowls (Figure 5). The two neighboring molecules within the stack are rotated by about 40° with respect to each other, resulting in the formation of a polar column. Furthermore, these stacks of **3** are oriented to the same direction, thus resulting in the formation of the polar crystal lattice. The polar axial stacking of **3** could be attributed to intermolecular electrostatic interactions between the electronegative chloride ligands and the electropositive protons of the tdat ligand. The shortest intermolecular separation distance between the chlorine atom and the carbon atoms of the tdat ligand is 3.66 Å. The polar molecular stacking in the crystal lattice as displayed by compound **3** is quite uncommon and very interesting since it may lead to some unusual physical properties (i.e. nonlinear optical properties). We have not been able to

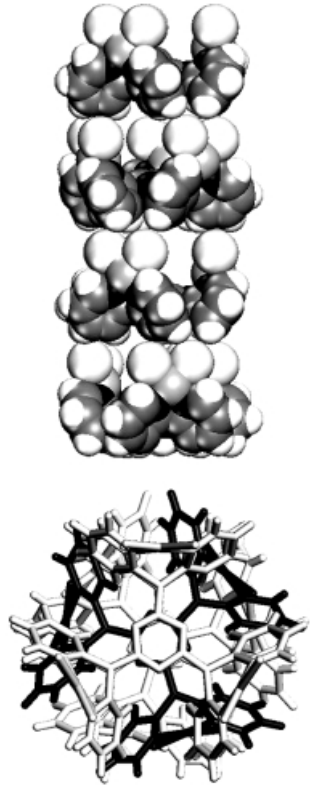

Figure 5. View of the stacking column of **3** projected along the C_3 axis (space-filling), and a view of the stacking column of **3** projected down the C_3 axis (stick)

study the optical/physical properties of the needle-like single-crystals of **3** because of their small sizes (< 0.1 mm in diameter).

The monoclinic form of compound **4** was identified and belongs to the centric monoclinic space group $P2_1/m$ with a crystallographically imposed mirror plane, upon which Pt(1), N(2), C(16) and C(19) lie. The structure of **4** is similar to that of **3**, except that the intramolecular Pt−Pt separation distances [8.271(2) Å, 8.279(2) Å] are much longer than those of **3** [the Pt−Pt separation distances of **3** in the $P2_1/m$ lattice are 7.829(2) Å and 8.069(2) Å], which could be attributed to the protons on the central phenyl ring in **4** that cause greater nonbonding interactions between the central phenyl ring and the pyridyl groups, compared to **3**. The major difference between the hexagonal form of **3** and the monoclinic form of **3** or **4** is the crystal lattice packing. In the crystal lattice of **4**, instead of stacking directly upon each other, the molecules are stacked in a "stair" fashion with a head-to-tail arrangement. In addition, the stacks of the molecules of **4** are oriented in two opposite directions as shown in Figure 6, thus resulting in a nonpolar crystal lattice. In the crystal lattices of **3** and **4** solvent molecules such as CH_2Cl_2 and H_2O were found, some of which were found to be trapped within the stacked column or inside the "bowl" of the Pt^{II} complex.

Zn^{II} Complexes of 2,4,6-Tris[p-(2,2′-dipyridylamino)-phenyl]-1,3,5-triazine (tdapt) and 1,3,5-Tris[p-(2,2′-dipyridylamino)phenyl]benzene (tdapb)

The colorless 1:3 zinc(II) complexes of tdapt and tdapb, namely $(ZnCl_2)_3$(tdapt) (**5**) and $(ZnCl_2)_3$(tdapb) (**6**) were obtained from the reactions of $ZnCl_2$ with the corresponding ligands in a 3:1 ratio in CH_2Cl_2/methanol solution. Both compounds are air-stable and have moderate solubility in organic solvents and have been characterized by elemental analyses and ^1H NMR spectroscopy. Attempts to obtain single crystals of **5** for X-ray diffraction analysis were unsuccessful. Compound **6** displays three different crystal motifs, depending on the solvent and the amount of each solvent used during crystallization. The first motif belongs to hexagonal space group $R\bar{3}$ with the formula $(ZnCl_2)_3$(tdapb)·$0.25C_6H_6$·$3CH_2Cl_2$ (**6a**), obtained from the solution of CH_2Cl_2 with a small amount of benzene. The second and third motifs belong to the triclinic space group $P\bar{1}$ with the formula $(ZnCl_2)_3$(tdapb)·$3C_6H_6$ (**6b**) and $(ZnCl_2)_3$(tdapb)·H_2O (**6c**), obtained from a solution of 1:1 CH_2Cl_2/benzene, and a methanol solution, respectively. Each of the crystal motifs was investigated by X-ray diffraction. The details of crystal structures of **6a** and **6b** are presented here. The molecular structure of the $(ZnCl_2)_3$(tdapb) molecule in all three motifs is similar, with an approximate C_3 symmetry. The C_3 symmetry for **6a** as shown in Figure 7 is rigorously imposed by the crystal symmetry. The molecular structure of compound **5** is believed to be similar to that of **6**. In the same manner as observed for compounds **1b** and **2**, the three $ZnCl_2$ units in compound **6** are chelated by the dipyridylamino groups with a typical tetrahedral geometry. The three $ZnCl_2$ units in **6a** are all on the same side with respect to the central phenyl ring. In the crystal lattice of **6a**, the two nearest molecules of **6** are paired and staggered in a *face-to-face* fashion with an intermolecular separation between the central phenyl rings of 3.85(1) Å. These pairs stack along the *c* axis to form a hexagonal column. As shown in Figure 8, a benzene molecule is situated directly above the central phenyl ring and sandwiched by two pairs of the Zn^{II} complex. The separation distance between the benzene molecule and the two central phenyl rings of **6** is 3.60(1) Å, indicative of the presence of π−π stacking interactions.

Figure 6. Stick diagram showing the stacking of **4** in the crystal lattice

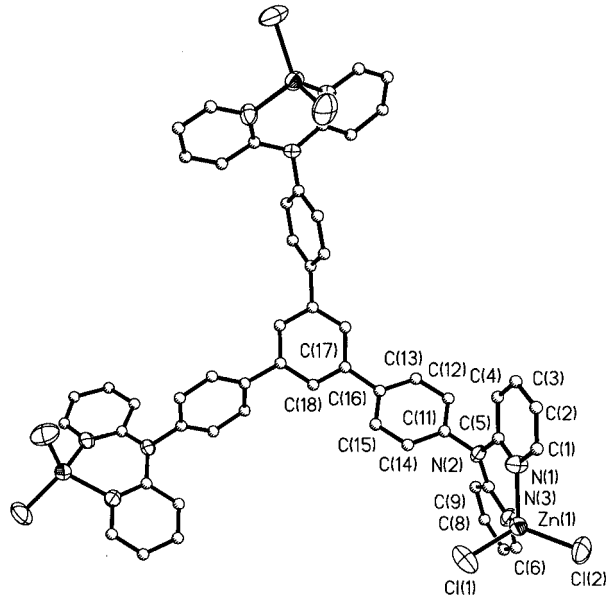

Figure 7. Molecular structure of one of the independent molecules of **6a** with 50% thermal ellipsoids and labeling schemes; hydrogen atoms are omitted for clarity; carbon atoms are shown as ideal spheres

There are three benzene solvent molecules per molecule of **6** in the crystal lattice of **6b**, which do not stack with the Zn^{II} complex in the *face-to-face* manner as observed in **6a**. Two of the benzene molecules are nearly perpendicular to the tdapb ligand while the remaining one is somewhat parallel to the tdapb ligand, but is perpendicular to a neighbor-

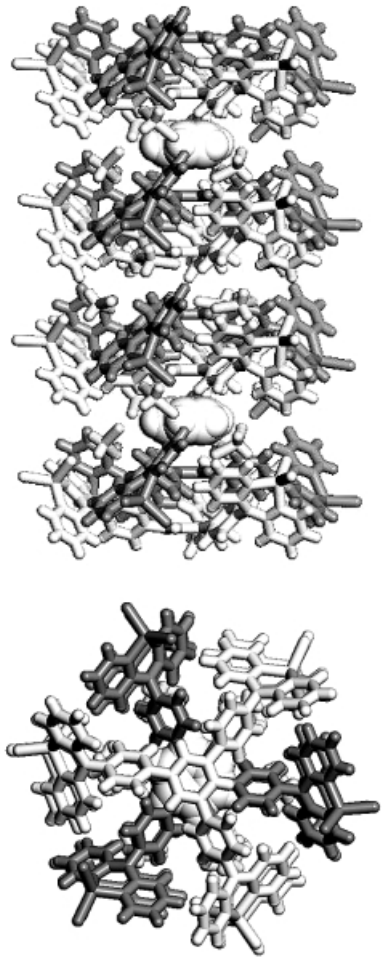

Figure 8. Diagram showing the pairing of **6a** (light gray and dark gray) and its stacking with benzene (space-filling) projected along the C_3 axis (left) and down the C_3 axis (right)

ing tdapb ligand of an adjacent molecule in the lattice. The π-π interactions in **6b** are therefore both *edge-to-face* and *face-to-face*.[10] The benzene solvent molecules are all located in the channels of the crystal lattice as shown by the unit cell packing diagram in Figure 9. The crystals of **6a** and **6b** indicate that compound **6** has a high affinity toward benzene in the solid state. In a recent report, we demonstrated that compound **6** is a highly selective fluorescent sensor for benzene vapor,[6] attributable to the high affinity of compound **6** in the solid state toward benzene. The free ligand tdapb is not effective as a fluorescent sensor for benzene, despite its bright blue luminescence. We believe that the coordination of the Zn^{II} ions to the tdapb ligand makes possible the formation of extended architectures in the solid state that attract benzene molecules and allow them to interact with the luminescent center effectively.

Pt^{II} Complexes of tdapt and tdapb

The 1:3 Pt^{II} complexes of tdapt and tdapb, namely $(PtCl_2)_3$(tdapt) (**7**) and $(PtCl_2)_3$(tdapb) (**8**) were obtained by using the same procedure as employed for **3** and **4**. Compounds **7** and **8** are insoluble in organic solvents, which precluded their study by solution NMR spectroscopy. Both

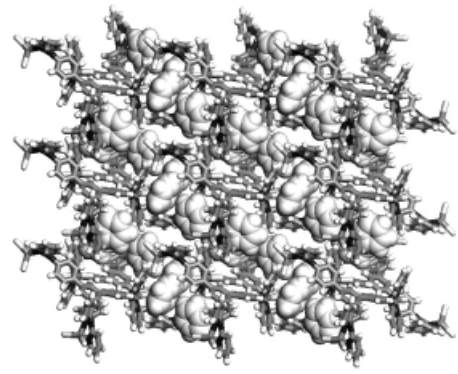

Figure 9. Unit cell packing diagram projected down the *b* axis; the benzene solvent molecules are highlighted as space-filling models

compounds form very thin, hair-like light yellow needles, too small for X-ray diffraction studies. Their compositions were confirmed by elemental analyses. We believe that the three $PtCl_2$ units in **7** and **8** are chelated by the dipyridylamino groups of the tdapt or tdapb ligand in the same manner as observed for compounds **3** and **4**.

Luminescent Properties

The free ligands tdat, tdab, tdapt and tdapb are blue-luminescent with a high quantum efficiency.[4] The nature of the emission of the free ligands is fluorescent, attributable to π→π* transitions. The Zn^{II} and Pt^{II} complexes of these ligands have also been found to be luminescent with broad emission bands that cover most of the blue region and resemble those of the free ligands. Therefore, we believe that the observed luminescence of the Zn^{II} and Pt^{II} complexes are ligand-based π→π* transitions localized mostly on the dipyridylamino chromophore. The luminescent intensity of the complexes is in general much weaker than that of the corresponding free ligand. For the Zn^{II} complexes, the decrease of luminescent intensity can be attributed to the chloride ligand, which is known to quench fluorescence through "heavy atom effects". The decrease of luminescent intensity of the Pt^{II} complexes can be attributed to the Pt^{II} center, which is an effective quencher of ligand fluorescence. No significant phosphorescence was observed for the Pt^{II} complexes. The luminescent data were obtained in solution and in the solid state for most of the Zn^{II} complexes. Because of their insolubility in organic solvents, only luminescent data in the solid state were obtained for the Pt^{II} complexes. For comparison purposes, the emission data of the free ligands (the details of luminescent data for the free ligands can be found in ref.[4]) are listed in Table 2, along with the luminescent data of the complexes. As a representative example, the emission spectra of tdapb and its Zn^{II} and Pt^{II} complexes **6** and **8** in the solid state are shown in Figure 10. The emission spectra of tdat and tdapt complexes are in general much broader than those of tdab and tdapb complexes. The contribution of the central triazine ring to the emission is likely to be responsible for the broad emission band. As shown in Table 2, the Zn^{II} complexes of tdab and tdapb show a significant red shift of

Table 2. Luminescence data

	Solution (CH_2Cl_2)			Solid	
	Excitation (λ_{max})	Emission (λ_{max})	Φ	Excitation (λ_{max})	Emission (λ_{max})
tdat	371	433	0.43	397	469
$(ZnCl_2)$(tdat) (**1a**)	295	418	0.011		
$(ZnCl_2)_2$(tdat) (**1b**)	292	399	0.08		
$(ZnCl_2)_3$(tdat) (**1c**)	292	318, 378	0.038	318	380
$(PtCl_2)_3$(tdat) (**3**)				346	414
tdab	385	412	0.53	387	412
$(ZnCl_2)_3$(tdab) (**2**)	316	426	0.097	385	447
$(PtCl_2)_3$(tdab) (**4**)				347	411
tdapt	420	440	0.78	423	461
$(ZnCl_2)_3$(tdapt) (**5**)	358	445	0.15	446	505
$(PtCl_2)_3$(tdapt) (**7**)				323	390
tdapb	367	384	0.16	380	409
$(ZnCl_2)_3$(tdapb) (**6**)	331	464	0.089	381	432
$(PtCl_2)_3$(tdapb) (**8**)				324	376

emission energy in solution, in comparison to the free ligands, which is consistent with our previously reported Zn^{II} complexes of tripyridylamines where two of the pyridyl groups are chelated to the Zn^{II} center and a similar red shift was observed.[7] The most dramatic red shift was displayed by the tdapt complex **5** which has an emission maximum at 505 nm in the solid state, even though it does not display a significant red shift in solution. This red shift is believed to be associated with intermolecular interactions of **5** in the solid state, but the details are not understood due to the lack of crystal data for **5**.

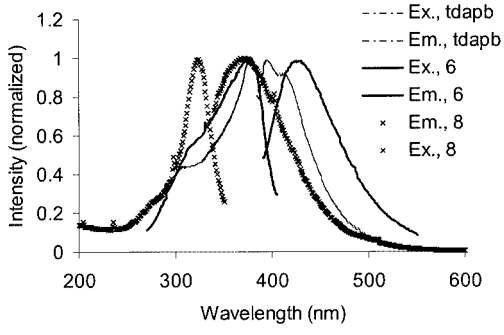

Figure 10. Excitation and emission spectra of tdapb, **6** and **8** in the solid state

For the Zn^{II} complex **6**, we examined the luminescent spectra of the three different crystal forms in the solid state, which revealed that there is no significant difference between their excitation or emission spectra. The exposure of complex **6** in the solid state or in a [poly(dimethylsiloxane)] (PDMS) matrix to a benzene vapor causes a decrease in emission intensity, attributable to fluorescent quenching via π−π interactions between benzene molecules and the complex (the details of the use of **6** as a fluorescent sensor for benzene can be found in ref.[4]). Blue-luminescent compounds are ideal for the detection of aromatic organic molecules because most aromatic organic molecules absorb strongly in the UV or near UV region. Therefore, in addition to the studies of **6**, systematic studies on the potential of the Zn^{II} complexes **1**, **2** and **5** as fluorescent sensors for aromatic organic solvent molecules are being carried out by our group and the results will be reported in due course.

The Pt^{II} complexes **3**, **4**, **7** and **8** have a broad emission band that is either similar to that of the free ligand or blue-shifted. The luminescent intensity of the Pt^{II} complexes in the solid state is clearly much weaker than those of the corresponding Zn^{II} compounds, attributable to fluorescent quenching by the Pt^{II} centers. Compounds **3** and **4** appear to have the tendency to attract small halogenated solvent molecules such as CH_2Cl_2 into their crystal lattices, as demonstrated by their crystal structural analyses. The effect of halogenated solvent molecules on the luminescence of compounds **3** and **4** in the solid state and the potential use of **3** and **4** as fluorescent sensors for halogenated molecules are being investigated.

In summary, we have demonstrated that the star-shaped ligands of tdat, tdab, tdapt and tdapb are capable of chelating to Zn^{II} and Pt^{II} centers to form a new class of luminescent star-shaped complexes. These complexes display interesting and unusual structural features and molecular arrangements in the solid state. Due to their low emission efficiency and poor volatility and solubility, these complexes are not suitable for electroluminescent applications. However, some of these complexes appear to have a high affinity toward certain organic solvent molecules and may find use as fluorescent sensors for these molecules.

Experimental Section

General: $ZnCl_2$ and K_2PtCl_4 were purchased from Strem Chemicals Co. Solvents were freshly distilled from appropriate drying reagents prior to use. ^1H NMR spectra were recorded by using Bruker Avance 300 MHz spectrometers. Elemental analyses were performed by Canadian Microanalytical Service, Ltd., Delta, British Columbia. Excitation and emission spectra were recorded with a Photon Technologies International QuantaMaster Model C-60 spectrometer. Melting points were determined with a Fisher−Johns melting point apparatus. The tdat, tdab, tdapt and tdapb ligands were synthesized based on the procedure reported recently.[4] All Pt^{II}

complexes reported herein are insoluble in common organic solvents. ^{1}H NMR spectra for these compounds are therefore not provided.

Synthesis of $(ZnCl_2)$(tdat) (1a): Zinc chloride (12 mg, 0.085 mmol) was dissolved in THF (10 mL); tdat (50 mg, 0.085 mmol) in 10 mL of CH_2Cl_2 was added to the zinc chloride solution at ambient temperature. The solution was stirred for 0.5 h. After the solution was allowed to stand for a few days, a colorless crystalline solid of $(ZnCl_2)$(tdat) was obtained (45 mg, yield 73%). ^{1}H NMR (CD_3OD, 298 K): δ = 8.28 (d, ^3J = 3.9 Hz, 6 H, py), 7.75 (dd, $^3J_1$ = 8.1, $^3J_2$ = 6.6 Hz, 6 H, py), 7.51 (d, ^3J = 8.4 Hz, 6 H, py), 7.21 (dd, $^3J_1$ = 7.2, $^3J_2$ = 4.8 Hz, 6 H, py). $C_{33}H_{24}Cl_2N_{12}Zn$ (724.29): calcd. C 54.67, H 3.34, N 23.19; found C 54.18, H 3.46, N 22.71.

Synthesis of $(ZnCl_2)_2$(tdat) (1b): Zinc chloride (23 mg, 0.17 mmol) was dissolved in THF (10 mL); tdat (50.0 mg, 0.085 mmol) in 10 mL of CH_2Cl_2 was added to the zinc chloride solution at ambient temperature. The solution was stirred for 0.5 h. After the solution was allowed to stand for a few days, a colorless crystalline solid of $(ZnCl_2)_2$(tdat) was obtained (37 mg, yield 50%). ^{1}H NMR ([D$_6$]DMSO, 298 K): δ = 8.24 (d, ^3J = 4.8 Hz, 6 H, py), 7.68 (dd, $^3J_1$ = 8.1, $^3J_2$ = 5.7 Hz, 6 H, py), 7.46 (d, ^3J = 8.1 Hz, 6 H, py), 7.12 (dd, $^3J_1$ = 5.7, $^3J_2$ = 4.8 Hz, 6 H, py). $C_{33}H_{24}Cl_4N_{12}Zn_2$ (860.58): calcd. C 46.02, H 2.81, N 19.52; found C 45.38, H 2.98, N 19.21.

Synthesis of $(ZnCl_2)_3$(tdat) (1c): Zinc chloride (35 mg, 0.255 mmol) was dissolved in THF (10 mL); tdat (50 mg, 0.085 mmol) in 10 mL of CH_2Cl_2 was added to the zinc chloride solution at ambient temperature. The solution was stirred for 0.5 h. After the solution was allowed to stand for a few days, a colorless crystalline solid of $(ZnCl_2)_3$(tdat) was obtained (62 mg, yield 74%). ^{1}H NMR ([D$_6$]DMSO, 298 K): δ = 8.24 (d, ^3J = 4.8 Hz, 6 H, py), 7.68 (dd, $^3J_1$ = 7.8, $^3J_2$ = 5.7 Hz, 6 H, py), 7.46 (d, ^3J = 8.1 Hz, 6 H, py), 7.12 (dd, $^3J_1$ = 5.7, $^3J_2$ = 4.8 Hz, 6 H, py). $C_{33}H_{24}Cl_6N_{12}Zn_3\cdot 1CH_2Cl_2\cdot 0.5THF$ (1117.77): calcd. C 38.64, H 2.68, N 15.02; found C 39.24, H 2.94, N 14.64.

Synthesis of $(ZnCl_2)_3$(tdab) (2): Zinc chloride (38 mg, 0.28 mmol) was dissolved in CH_3OH (10 mL); tdab (50 mg, 0.085 mmol) in 5 mL of CH_2Cl_2 was added to the zinc chloride solution at ambient temperature. The solution was stirred for 2 h. After the solution was allowed to stand for a few days at ambient temperature, a colorless crystalline solid of $(ZnCl_2)_3$(tdab) was obtained (64 mg, yield 75%). ^{1}H NMR ([D$_6$]acetone, 298 K): δ = 8.51 (d, ^3J = 5.4 Hz, 6 H, py), 8.08 (dd, $^3J_1$ = 9.0, $^3J_2$ = 6.9 Hz, 3 H, py), 7.63 (d, ^3J = 8.4 Hz, 6 H, py), 7.51 (dd, $^3J_1$ = 6.9, $^3J_2$ = 5.7 Hz, 6 H, py). 7.45 (s, 6 H, ph). $C_{36}H_{27}Cl_6N_9Zn_3\cdot 2CH_2Cl_2\cdot 3H_2O$ (1217.67): calcd. C 37.44, H 3.03, N 10.34; found C 37.20, H 2.46, N 10.66.

Synthesis of $[(PtCl_2)_3$(tdat)] (3): Benzene (4 mL) and a solution of K_2PtCl_4 (106 mg, 0.255 mmol) in a mixture of 3 mL of H_2O and 5 mL of DMSO were successively layered upon a solution of tdat (50 mg, 0.085 mmol) in 6 mL of CH_2Cl_2. The yellow K_2PtCl_4/H_2O/DMSO solution sank through the layer of benzene and settled upon the tdat/CH_2Cl_2 layer. The solvents were allowed to diffuse over several days at ambient temperature, yielding a yellow crystalline solid of $[(PtCl_2)_3$(tdat)] (52% yield). $C_{33}H_{24}Cl_6N_{12}Pt_3\cdot 1$DMSO (1466.68): calcd. C 28.65, H 2.04, N 11.46; found C 28.87, H 2.09, N 10.87.

Synthesis of $[(PtCl_2)_3$(tdab)] (4): Compound **4** was obtained in 38% yield by using the same procedure as for **3**. $C_{36}H_{27}Cl_6N_9Pt_3$ (1382.94): calcd. C 31.25, H 1.97, N 9.11; found C 31.25, H 2.25, N 8.95.

Synthesis of $(ZnCl_2)_3$(tdapt) (5): Zinc chloride (28 mg, 0.20 mmol) was dissolved in CH_3OH (10 mL); tdapt (50 mg, 0.061 mmol) in 5 mL of CH_2Cl_2 was added to the zinc chloride solution at ambient temperature. The solution was stirred for 2 h. After the solution was allowed to stand for a few days at ambient temperature, a colorless crystalline solid of $(ZnCl_2)_3$(tdapt) was obtained (39 mg, yield 42%). ^{1}H NMR ([D$_6$]DMSO, 298 k): δ = 8.67 (d, ^3J = 8.7 Hz, 6 H, py), 8.32 (d, ^3J = 8.7 Hz, 6 H, ph), 7.77 (dd, $^3J_1$ = 8.1, $^3J_2$ = 7.2 Hz, 6 H, py), 7.28 (d, ^3J = 8.7 Hz, 6 H, ph), 7.15 (dd, $^3J_1$ = 7.2, $^3J_2$ = 6.9 Hz, 6 H, py). 7.10 (d, ^3J = 8.1 Hz, 6 H, py). $C_{51}H_{36}Cl_6N_{12}Zn_3\cdot 0.5CH_2Cl_2$ (1267.32): calcd. C 48.76, H 2.91, N 13.25; found C 48.42, H 3.09, N 13.05.

Synthesis of $(ZnCl_2)_3$(tdapb) (6): A CH_2Cl_2 (5 mL) solution containing tdapb (50 mg, 0.061 mmol) was added to 10 mL of a CH_3OH solution containing $ZnCl_2$ (28 mg, 0.20 mmol) at ambient temperature; 10 mL of benzene was added to this solution. After stirring for 2 h, the mixture was allowed to stand for several days at ambient temperature. A colorless crystalline solid of $(ZnCl_2)_3$(tdapb) was obtained (58 mg, yield 76%). ^{1}H NMR ([D$_4$]methanol, 298 K): δ = 8.27 (d, ^3J = 5.1, 6 H, py), 7.90 (s, 3 H, Ph1), 7.86 (d, ^3J = 8.4 Hz, 6 H, Ph2), 7.77 (dd, $^3J_1$ = 6.3, $^3J_2$ = 2.1 Hz, 6 H, py), 7.31 (d, ^3J = 8.4 Hz, 6 H, Ph2), 7.14 (dd, $^3J_1$ = 5.1, $^3J_2$ = 2.1 Hz, 6 H, py), 7.11 (d, ^3J = 5.4 Hz, 6 H, py). $C_{54}H_{39}Cl_6N_9Zn_3\cdot 1/3C_6H_6$ (1247.87): calcd. C 53.85, H 3.20, N 10.10; found C 54.20, H 3.03, N 10.20. If the reaction was carried out in the absence of benzene and a small amount of benzene was added during the crystallization of **6**, the second crystal motif, $(ZnCl_2)_3$(tdapb)$\cdot 0.25C_6H_6\cdot 3CH_2Cl_2$, was obtained. $C_{54}H_{39}Cl_6N_9Zn_3\cdot 0.25C_6H_6\cdot 3CH_2Cl_2$ (1496.07): calcd. C 46.93, H 3.13, N 8.42; found C 46.61, H 2.94, N 8.80.)

Synthesis of $[(PtCl_2)_3$(tdapt)] (7) and $[(PtCl_2)_3$(tdapb)] (8): DMSO (2 mL), benzene (4 mL), and a solution of K_2PtCl_4 (76 mg, 0.184 mmol) in a mixture of 3 mL of H_2O and 5 mL of DMSO were successfully layered upon a solution of tdapt (50 mg, 0.061 mmol) or tdapb (50 mg, 0.061 mmol), respectively, in 6 mL of CH_2Cl_2. The Pt-containing solution sank through the benzene layer and into the DMSO layer and settled upon the tdapb or tdapt ligand layer in CH_2Cl_2. Solvents were allowed to diffuse over several days at ambient temperature, producing a yellow microcrystalline solid of $[(PtCl_2)_3$(tdapt)] (60% yield) and $[(PtCl_2)_3$(tdapb)] (95% yield), respectively. **7:** $C_{51}H_{36}Cl_6N_{12}Pt_3\cdot 1H_2O$ (1631.94): calcd. C 37.50, H 2.32, N 10.29; found C 37.19, H 2.39, N 10.09. **8:** $C_{54}H_{39}Cl_6N_9Pt_3\cdot 1CH_2Cl_2$ (1695.84): calcd. C 38.92, H 2.42, N 7.42; found C 38.52, H 2.61, N 7.48.

X-ray Crystallographic Analyses: Single crystals of **1b**, **2**−**4**, and **6** suitable for X-ray diffraction analyses were obtained. Attempts to obtain single crystals of the remaining compounds were unsuccessful. All crystals were mounted on glass fibers. Data were collected with a Bruker Smart CCD 1000 diffractometer with graphite-monochromated Mo-K_α radiation, operating at 50 kV and 35 mA at 23 °C, over a 2θ range of 3−57°. No significant decay was observed for any samples during the data collection. Data were processed with a Pentium III PC using the Bruker AXS SHELXTL NT software package. Neutral atomic scattering factors were taken from Cromer and Waber.[11] The crystals of **1b** were partially twinned and diffracted weakly. For compound **3**, two crystal motifs were observed, a hexagonal lattice and a monoclinic lattice. The monoclinic lattice of **3** is isostructural to that of **4** with unit cell dimensions of a = 9.9675(16), b = 21.356(4), c = 12.0891(19) Å, β = 98.532(4)°, V = 2544.9(7) Å^3. For compound **6**, three crystal motifs were observed, depending on the solvent used during crystallization. The unit cell parameters for two of the motifs **6a** and **6b** ob-

tained from benzene and CH_2Cl_2 solution are given in Table 3. The third motif **6c**, obtained from methanol solution, has the following unit cell parameters: triclinic, $P\bar{1}$, a = 13.134(9), b = 14.04(1), c = 16.67(1) Å, α = 73.01(1), β = 68.88(1), γ = 84.43(1)°, V = 2741(5) Å^3, Z = 2. The structure of **6c** is similar to that of **6b**, except that no benzene solvent molecules are present in the lattice. All structures were solved by direct methods. Almost all non-hydrogen atoms (except disordered solvent molecules) were refined anisotropically for all structures except compound **1b**. Due to the poor data quality of **1b**, only metal, chlorine and some nitrogen and carbon atoms could be refined anisotropically. Solvent molecules or H_2O were found in all crystals. Some of the solvent molecules are disordered. We invested considerable effort to model and refine the disordered solvent molecules. The positions for all hydrogen atoms except those of disordered solvent molecules or water molecules were either calculated or located directly from difference Fourier maps and their contributions to the structural factor calculation were included. The crystallographic data are given in Table 3. The ranges of selected bond lengths and angles are given in Table 1. CCDC-176676 (**1b**), -176678 (**2**), -176677 (**3**), -176675 (**4**), -163379 (**6a**), and -163380 (**6b**) contain the supplementary crystallographic data for this paper. Heterodinuclear Zinc(II)−Iron(III) Complexes and Dinuclear Zinc Complexes as Models for Zinc-Containing Phosphatases

Sabine Albedyhl,[a] David Schnieders,[a] Attila Jancsó,[b] Tamás Gajda,*[b] and Bernt Krebs*[a]

Keywords: Heterometallic complexes / Asymmetric ligands / Phosphates / Dinucleating ligands / Enzyme models

Five new dinuclear model complexes for zinc-containing phosphatases with dinucleating ligands have been prepared and characterized by single-crystal X-ray crystallography. The heterodinuclear, μ-alkoxo-bridged zinc(II)–iron(III) complexes **1**–**3** contain the symmetric ligands *N*,*N*,*N*′,*N*′-tetrakis[2-(5,6-dimethyl)benzimidazolylmethyl]-1,3-diamino-2-propanol (Htdmbpo) and *N*,*N*,*N*′,*N*′-tetrakis{2-[*N*′′-(2-hydroxyethyl)]benzimidazolylmethyl}-1,3-diamino-2-propanol (Hthebpo), and the asymmetric ligand *N*,*N*-bis[2-(4,5-dimethyl)benzimidazolylmethyl]-*N*′,*N*′-bis(2-pyridylmethyl)-1,3-diamino-2-propanol (Hbdmbbppo), respectively. X-ray crystallography revealed that the zinc center exhibits a trigonal-bipyramidal coordination, while the octahedral coordination sphere of the iron center is completed by a solvent molecule. In contrast, the zinc complexes **4** and **5**, which also have (alkoxo)(cacodylato)dimetal cores with the dinucleating ligands used in **1** and **3**, exhibit both metal centers in a trigonal-bipyramidal environment. Additionally, the solution speciation of the zinc(II) complexes formed with Htdmbpo and Hbdmbbppo were determined and the activity of the in situ prepared zinc complexes towards the transesterification of the RNA model substrate 2-(hydroxypropyl)-4-nitrophenyl phosphate (hpnp) was investigated. The dinuclear $[Zn_2LH_{-1}(OH)]^{2+}$ complex of both ligands efficiently promotes the transesterification. The kinetic data indicated a higher activity for the complex of the asymmetric ligand Hbdmbbppo, as a result of its stronger substrate binding ability.

Introduction

Model compounds simulate the characteristic properties of the active sites in enzymes. The synthesis and characterization of structural and functional model complexes contribute to the structure clarification and the comprehension of the catalytic mechanism of metalloenzymes. Investigation of inhibitor complexes and product complexes gives insight into the coordination mode of the substrate.

In this work we focused on the preparation of dinuclear model complexes for zinc-containing phosphatases. The purple acid phosphatase isolated from plants, and the serine/threonine protein phosphatase 1 and 2B (calcineurine) contain a zinc(II)−iron(III) center in their active sites.[1−3] Purple acid phosphatases hydrolyze activated phosphate monoesters within a pH range of 4−7. The octahedrally coordinated metal centers are 3.26 Å apart, and a terminal hydroxide ion at the iron center, a water molecule at the zinc center and a bridging hydroxide ion, in addition to the bridging carboxylate group of aspartate were included into the X-ray structure analysis from spectroscopic data.[1] The coordination sphere of the metal ions, which are separated by 3.3 Å and 3.0 Å, in the serine/threonine protein phosphatases 1 and 2B, respectively, is square-pyramidal at the iron atom and trigonal-bipyramidal at the zinc atom.[2] A water molecule is coordinated to the iron center, while another water molecule bridges the two metal ions. The coordination number is increased to six due to the bidentate binding of the phosphate group to the metal centers.[3]

Alkaline phosphatase, phospholipase C, nuclease P1 and phosphotriesterase contain at least two zinc centers.[4−7] Alkaline phosphatase is a widely distributed nonspecific phosphomonoesterase, which catalyzes through a covalent phosphoseryl intermediate.[8] The active site contains two zinc ions at a distance of 4.0 Å, and one magnesium ion. According to recent publications, all three metal centers contribute to the mechanism.[4] The zinc centers with a N_2O_3 donor set in the dinuclear unit of phospholipase C and nuclease P1 are bridged by a hydroxide ion or a water molecule and the carboxylate group of aspartate, and exhibit a trigonal pyramidal coordination.[5,6] Their distance apart was shown to be 3.3 Å and 3.2 Å, respectively. The bridging

hydroxide ion is proposed to be the attacking nucleophile in the serine/threonine protein phosphatases 1 and 2B, nuclease P1 and phosphotriesterase.

In these enzymes the first coordination sphere of the metal centers is comprised of nitrogen and oxygen donor atoms that are in common with the ligands in our systems. Furthermore, the metal−metal distances in both the enzymes and the prepared complexes are in the range of 3.0 to 4.0 Å, which is important for the co-operative interaction.

There are some examples of crystallized model compounds with interesting features reported in the literature. The model complex $[Zn_2(bbap)(Bz)(H_2O)](ClO_4)_2 \cdot 4MeOH$ {Hbbap = 2,6-bis[bis(2-benzimidazolylmethyl)aminomethyl]-4-methylphenol} for phospholipase C contains two zinc ions with different coordination spheres.[9] A new structural and perhaps functional feature in the chemistry of oligozinc enzymes was detected in the X-ray structure of $[Zn_2L(H_2O)(OH)](BPh_4)_2 \cdot 2.5C_3H_6O$ {HL = 2,5-bis[*N*,*N*-(diethylaminoethyl)aminomethyl]pyrazol}, which includes an intramolecular $H_3O_2^-$ bridge.[10] The hydrolytic activity of the complex $[Zn_2(bpan)(\mu\text{-}OH)(\mu\text{-}O_2PPh_2](ClO_4)_2$ {bpan = 2,7-bis[2-(2-pyridylethyl)aminomethyl]-1,8-naphthyridin}, in which the naphthyridin simulates the *syn*,-*syn* coordination of a bridging carboxylate group, was investigated using different model substrates.[11,12]

Currently, there is interest in the development of new ligands, especially asymmetric ligands and their metal complexes, which may be used as enzymatic models.[13−20] In addition to complexes with dissimilar metal centers due to asymmetric coordination as found in enzymes, heterodinuclear complexes are important with respect to enzymes containing two different metal ions.[21] So far, only a few heterodinuclear zinc(II)−iron(III) complexes with symmetric dinucleating ligands are known. They include four pyridine groups and contain a μ-phenoxo bridge and two further bridging ligands like acetate, diphenyl phosphate or molybdate.[22−26] Suzuki and co-workers characterized mixed-valent (μ-alkoxo)diiron(II,III) complexes with the ligand *N*,*N*,*N*′,*N*′-tetrakis(2-pyridylmethyl)-1,4-diamino-2-butanol by X-ray crystallography.[27] The asymmetric bridging unit leads to five- and six-membered chelate rings.

Here, we report on the synthesis and characterization of three heterodinuclear zinc(II)−iron(III) complexes with distinct coordination spheres, μ-alkoxo-bridging symmetric and asymmetric dinucleating ligands, as well as two corresponding zinc complexes. Their structures were determined by X-ray crystallography and characterized by additional spectroscopic measurements.

In the complexes $[Zn^{II}Fe^{III}(tdmbpo)(O_2AsMe_2)(HOMe)](ClO_4)_3 \cdot 4MeOH \cdot 2H_2O$ (**1**), $[Zn^{II}Fe^{III}(thebpo)(O_2AsMe_2)(H_2O)](ClO_4)(NO_3)_2 \cdot 3H_2O$ (**2**) and $[Zn^{II}Fe^{III}(bdmbbppo)(O_2AsMe_2)(HOMe)](ClO_4)_3 \cdot 1.5MeOH$ (**3**) the zinc ion exhibits a trigonal-bipyramidal environment, and the octahedrally ligated iron center has a coordination site occupied by a solvent molecule. This terminal solvent molecule at the iron center may act as the attacking nucleophile. In contrast to the μ-phenoxo-bridged complexes,[22−26] which are doubly bridged by two further ligands, the complexes described here contain only one further μ-cacodylato bridge. These complexes are model compounds for the kidney bean purple acid phosphatase product complex with inorganic phosphate, and for the inhibitor complex with tungstate.[1]

The zinc ions in the complexes **4** and **5** formulated as $[Zn^{II}_2(tdmbpo)(O_2AsMe_2)](ClO_4)_2 \cdot 5MeOH$ and $[Zn^{II}_2(bdmbbppo)(O_2AsMe_2)](ClO_4)_2 \cdot H_2O$, respectively, have an N_3O_2 donor set. Both zinc centers in **4** and one zinc center in **5** is symmetrically coordinated by two 4,5-dimethylbenzimidazole groups, while the second zinc center in **5** is coordinated by two pyridine groups, resulting in an asymmetric complex.

The activity of the in situ prepared complexes of these ligands and zinc perchlorate was studied with respect to the transesterification of hpnp, in order to determine the influence of the different coordinating groups. Similar systems were used by Komiyama and co-workers who investigated the cleavage of ribonucleotide dimers and compared the activity between mono-, di- and trinuclear complexes. The latter is a model for trinuclear zinc-containing phosphodiesterases like phospholipase C and nuclease P1.[28,29] Very efficient di- and trinuclear zinc catalysts, which were also prepared in situ, were described by Engbersen, Reinhoudt and co-workers and are based on calix[4]arene.[30−33] Recently, zinc-containing complexes with dinucleating imidazole ligands have been studied.[34,35] As various types of mechanisms are discussed, particularly with regards to the reacting nucleophile and the coordination mode of the substrate, further information will be drawn from the study of model complexes. Important aspects are the determination of the crystal structure, the identification of the active species in solution and the mechanism of the reaction of model compounds with substrates.

Results and Discussion

X-ray Crystal Structures of 1, 2 and 3

In order to mimic the active site of kidney bean purple acid phosphatase we used the symmetric and asymmetric dinucleating ligands Htdmbpo, Hthebpo and Hbdmbbppo to form heterodinuclear μ-alkoxo-bridged zinc(II)−iron(III) complexes with two differently coordinated metal centers. The zinc ion has a trigonal-bipyramidal geometry with an N_3O_2 donor set, whereas the iron center resides in an octahedral environment that is completed by a solvent ligand. Structures of the cations in **1**, **2** and **3** are depicted in Figures 1, 2 and 3.

The zinc ions are facially coordinated by two benzimidazole nitrogen atoms (N3 and N5) and one tertiary aliphatic nitrogen atom (N1) of the ligand. The iron centers in **1** and **2** are also coordinated by two benzimidazole nitrogen atoms (N7 and N9) and one tertiary aliphatic nitrogen atom (N2) of the ligand. The iron center in **3** is facially ligated by two pyridine nitrogen atoms (N7 and N8) and one tertiary aliphatic nitrogen atom (N2) of the ligand bdmbbppo. The metal centers are connected by the deprotonated μ-alkoxo

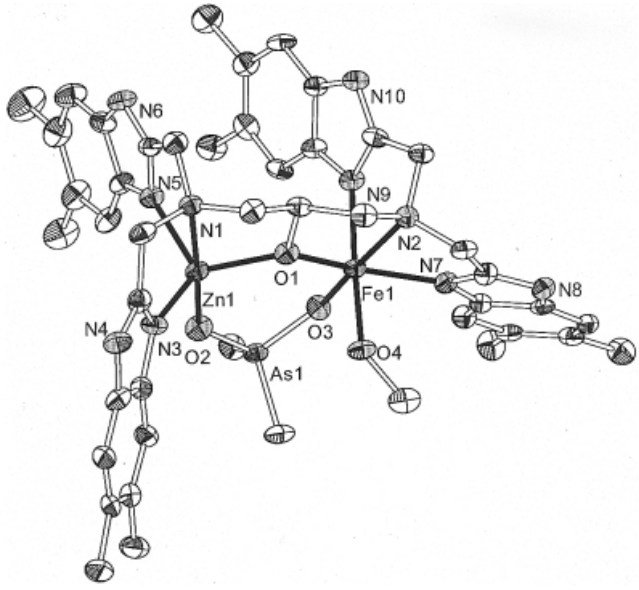

Figure 1. Structure of the cation in **1** showing 50% probability displacement ellipsoids; hydrogen atoms have been omitted for clarity

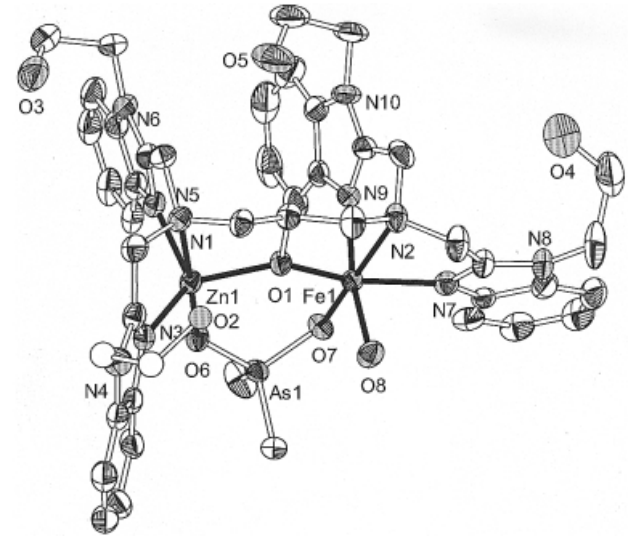

Figure 2. Structure of the cation in **2** showing 50% probability displacement ellipsoids; one hydroxyethyl group was refined isotropically; hydrogen atoms have been omitted for clarity

oxygen atom O1 of the ligand and the cacodylate bridge. An N_3O_3 donor set of the iron(III) center is formed by the additional coordination of a methanol molecule (O4−C46 and O4−C38) in **1** and **3**, respectively, and by a water molecule (O8) in **2**. The coordination polyhedra share one edge (O1). The cacodylate bridge in the inhibitor complexes shows the same bridging mode as in the enzyme. The inter-metal distances in **1**, **2** and **3** are 3.5635(12), 3.6053(13) and 3.5354(12) Å, respectively, and are slightly larger than in the enzyme. The Zn1−O1−Fe1 angles are 125.9(2)° in **1**, 127.7(2)° in **2** and 125.3(3)° in **3** and follow the same trend observed for the inter-metal distances (Table 1).

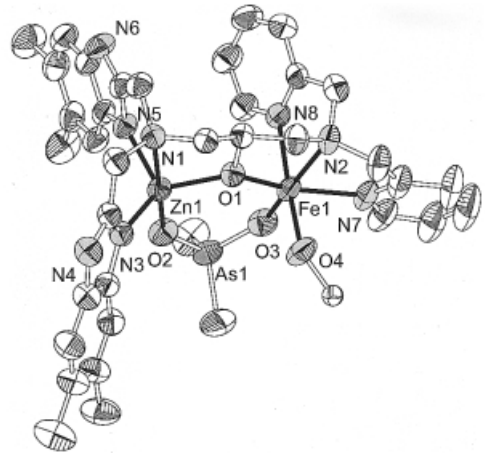

Figure 3. Structure of the cation in **3** showing 50% probability displacement ellipsoids

The axial positions of the trigonal-bipyramidal coordination polyhedra of the zinc ions are occupied by the tertiary nitrogen atom N1 and the oxygen atom of the cacodylate group, O2 in **1** and **3** and O6 in **2**. The distortion of the ideal coordination polyhedra towards the tertiary nitrogen atom results in angles smaller than 90° between N1 and the equatorially bound donor atoms. The geometrical distortion around the iron centers is demonstrated by the deviation of the three angles of the axial donor atoms by about 16° from the ideal 180° angle. The coordination polyhedra of the iron centers are distorted towards the tertiary nitrogen atom N2 in a similar manner as in the zinc centers. The angles between N2 and the atoms in *cis* position O1, N7 and N9 (N8 in **3**) are smaller than 90°, while the angles between N2 and the oxygen atoms O4 of the bound methanol molecules and the oxygen atom O8 of the water molecule are close to 90°.

The bond lengths between the tertiary nitrogen atoms (N1, N2) and the metal ions are much larger than the bond lengths between the aromatic nitrogen atoms of the ligands and the metal ions (Table 2). The bonds between Fe1 and the oxygen atoms O4 of the coordinating methanol molecules in **1** and **3** have lengths of 2.172(4) and 2.054(4) Å, respectively, as a result of the different properties of the benzimidazole and pyridine groups coordinated to the iron centers. The bond lengths between the oxygen atom O8 of the coordinating water molecule and Fe1 in **2** is 2.068(4) Å. The hydroxide ion coordinated to the iron(III) center has a much smaller distance of about 1.90 Å.[36]

To date, only the μ-cacodylato-bridged dinuclear complexes $[Fe^{III}_2(tbpo)(O_2AsMe_2)(OMe)(HOMe)](ClO_4)_3 \cdot 5MeOH \cdot 2H_2O$[37] [Htbpo = *N*,*N*,*N*′,*N*′-tetrakis(2-benzimidazolylmethyl)-1,3-diamino-2-propanol], $[Fe^{III}_2(tbpo)(O_2AsMe_2)(Cl)(H_2O)](ClO_4)_3 \cdot 5MeOH \cdot H_2O$[38] and $[Fe^{III}_2(mtbpo)(O_2AsMe_2)(Cl)_2(HOMe)](ClO_4)_2 \cdot 4MeOH$[39] [Hmtbpo = *N*,*N*,*N*′-tris(2-benzimidazolylmethyl)-*N*′-methyl-1,3-diamino-2-propanol] are known in which both iron centers have an octahedral coordination sphere. The distance between the oxygen atom of the water molecule and the iron(III) center in the second complex is 2.088(6)

Å, and therefore is similar to the corresponding distance in **2**. The presence of only one iron(III) center in both complexes was confirmed by magnetic measurements, where a linear increase of $1/\chi$ with temperature and no coupling effects were observed. The experimental μ_{eff} values are in accordance with the theoretical value of 5.92 μ_B for a high-spin iron(III) ion.

X-ray Crystal Structures of 4 and 5

The structures of the cations in **4** and **5** are provided in the Supporting Information (Figures S1 and S2).

The metal centers in complexes **4** and **5** have a trigonal-bipyramidal coordination sphere, with an N_3O_2 donor set. Their inter-metal distances are 3.562(2) Å and 3.5147(16) Å, respectively. Each zinc ion is facially coordinated by two benzimidazole nitrogen atoms (N3, N5 and N7, N9) or two pyridine nitrogen atoms (N7 and N8) and one tertiary aliphatic nitrogen atom (N1 or N2) of the ligand. They are connected by the deprotonated μ-alkoxo oxygen atom O1 of the ligand and one cacodylate bridge. The coordination polyhedra share one edge (O1). The Zn1−O1−Zn2 angles are 128.0(4)° and 125.9(3)°, respectively (Table 3). The axial positions of the trigonal-bipyramidal coordination polyhedra of the zinc ions are occupied by the tertiary nitrogen atoms N1 or N2, and one oxygen atom O2 or O3 of the cacodylate bridge. The average deviation from 180° is 2.3° at one metal center and 8.7° at the other metal center. The coordination polyhedra are distorted towards the tertiary nitrogen atoms as observed at the zinc centers in the complexes **1**, **2** and **3**. The differences in the average values for

the angles between the tertiary nitrogen atoms and the equatorially bound donor atoms of 76.8 and 77.2° in **4** and 76.6 and 79.0° in **5**, result from different coordinating groups at each metal center.

In addition, the bond lengths between the tertiary nitrogen atoms and the metal ions are longer than the bond lengths between the aromatic nitrogen atoms of the ligands and the metal ions (Table 4). The distances between the tertiary nitrogen atoms and the zinc ions are 2.375(9) Å and 2.387 (8) Å in **4**, and 2.467(7) Å and 2.255(8) Å in **5**. The greater difference (0.212 Å) between the distances observed in **5** is due to the asymmetry in complex **5**.

Solution Speciation

The solubility of the ligands and complexes in an ethanol/water mixed solvent allowed the solution study of the zinc(II) complexes of Htdmbpo (in 80 % ethanol/water, w/w) and Hbdmbbppo (in 35 % ethanol/water, w/w). These studies involved a series of pH-dependent measurements.

Table 5. Logarithmic formation constants for the proton and zinc(II) complexes of Htdmbpo (in 80 % ethanol/water, w/w, T = 298 K, I = 0.05 M $NaNO_3$) and of Hbdmbbppo (in 35 % ethanol/water, w/w , T = 298 K, I = 0.1 M $NaNO_3$); $\beta_{pqr} = [M_pL_qH_K]/[M]^p[L]^q[H]^r$, with estimated errors in parentheses (last digit)

pK_{21-3}^{21-2}	7.80	9.33
NP[a] (FP[b])	283 (0.012 cm^{-3})	300 (0.010 cm^{-3})

[a] NP: number of experimental points. [b] FP: fitting parameter.

The determined protonation and complex formation constants are listed in Table 5, together with some derived data (see pH-metric measurements in the Exp. Sect.). Four strongly overlapping deprotonation processes were observed at pH > 2 for both ligands. The fifth and sixth pK values are therefore much lower than 2, presumably due to the formation of a hydrogen bond between the two substituents of a given tertiary amino group.

In the presence of zinc(II) the same species were formed with both ligands. In an equimolar solution, the complex $[ZnL]^{2+}$ is dominant in the neutral pH range. Dinuclear $[Zn_2LH_{-x}]^{(4-x)+}$ complexes (x = 1−3) are also formed at pH > 7. The latter species already becomes dominant at pH = 4, in the presence of a twofold metal excess (Figure 4). The deprotonation during the formation of the first dinuclear complex ($[ZnL]^{2+} + Zn^{2+} = [Zn_2LH_{-1}]^{3+} + H^+$) takes place at surprisingly low pH (at pH ≈ 4), which suggests a concerted action of the two zinc(II) ions. The participation of the hydroxy group in this process should be particularly favorable, due to the preorganization of the metal ions by the ligand. In this way, the complex $[Zn_2LH_{-1}]^{3+}$ most likely has the same single μ-alkoxo-bridged structure as crystallographically determined for the complexes **4** and **5**. The succeeding two deprotonations, leading to the complexes $[Zn_2LH_{-2}]^{2+}$ and $[Zn_2LH_{-3}]^{+}$, involve the deprotonation of coordinated water molecules (the metal-induced deprotonation of the pyrrolic nitrogen atom of the benzimidazole moieties at pH ≈ 7−8, is very unlikely in the case of zinc(II)), thus they are better described as $[Zn_2LH_{-1}(OH)]^{2+}$ and $[Zn_2LH_{-1}(OH)_2]^{+}$. These two successive processes are rather well separated for the Hbdmbbppo complex ($pK_2 - pK_1 = \Delta pK$ = 2.2, see Table 5), which allows the formation of the species M_2LH_{-2} in relatively high concentrations, while ΔpK is only 0.73 for the Htdmbpo complex. The solution speciation of these systems is clearly different from that observed for a *N*,*N*′-dis-

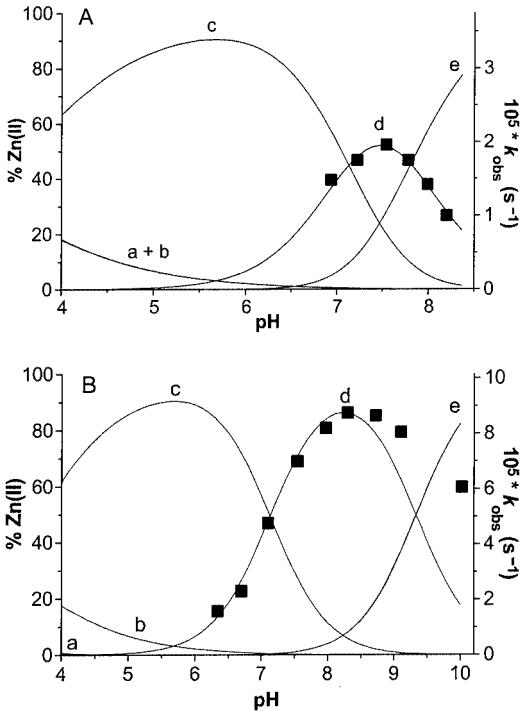

Figure 4. Species distribution curves (solid lines) and the effect of pH on the transesterification of hpnp (filled square) for the zinc(II)−Htdmbpo (A) and −Hbdmbbppo (B) systems (T = 298 K, [Htdmbpo] = 0.4 mM, [Hbdmbbppo] = 0.8 mM, $[Zn^{II}]/[L]$ = 2:1, [hpnp] = 1 mM); a: Zn^{II}, b: $[ZnL]^{2+}$, c: $[Zn_2LH_{-1}]^{3+}$, d: $[Zn_2LH_{-1}(OH)]^{2+}$, e: $[ZnLH_{-1}(OH)_2]^{+}$

ubstituted imidazole derivative of 1,3-diamino-2-propanol (in 65 % ethanol/water, w/w mixture)[34], where the process $[ZnL]^{2+} + Zn^{2+} = [Zn_2LH_{-1}(OH)]^{2+} + 2\ H^{+}$ takes place in a single step. This difference is probably the result of the higher stabilization of the 3*N*-coordinated zinc(II) ions in the present case. This can be demonstrated by the log K values of the above process, which are −7.06 for Htdmbpo, −7.37 for Hbdmbbppo and −11.34 for the *N*,*N*′-disubstituted imidazole derivative.[34]

Hydrolytic Studies

To screen the hydrolytic activity of the two systems described above, their ability to promote the transesterification of 2-(hydroxypropyl)-4-nitrophenyl phosphate (hpnp) was investigated. For these purposes pH-dependent measurements were carried out (see Exp. Sect.). In both the zinc(II)−Htdmbpo and −Hbdmbbppo ($[Zn^{II}]/[L]$ = 2:1) systems, notable transesterification activity was observed at pH > 6, parallel with the formation of the dinuclear species $Zn_2LH_{-1}(OH)$ (Figure 4). Based on the pH/rate constant profile, the successively formed $Zn_2LH_{-1}(OH)_2$ complex of Hbdmbbppo is also able to promote the transesterification, and its activity is almost half of the former $Zn_2LH_{-1}(OH)$ species. Such behavior was not observed with Htdmbpo. This difference may in part be due to the presence of the four bulky benzimidazole residues in Htdmbpo, which lower the binding ability of hpnp to the metal centers.

The rate of the transesterification shows first-order dependence on the concentration of the dinuclear complex

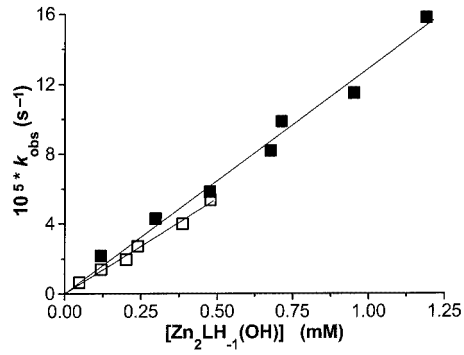

Figure 5. Dependence of k_{obs} on the concentration of $[Zn_2LH_{-1}(OH)]^{2+}$ complex of Htdmbpo (open square, pH = 7.50) and Hbdmbbppo (filled square, pH = 8.00); T = 298 K, $[Zn^{II}]/[L]$ = 2:1, [hpnp] = 1 mM

$[Zn_2LH_{-1}(OH)]^{2+}$ (Figure 5). The second-order rate constants determined from these plots are 0.109(3) $M^{-1}s^{-1}$ for Htdmbpo, and 0.129(4) $M^{-1}s^{-1}$ for Hbdmbbppo. These constants are somewhat higher than the second-order rate constant for the hydroxide ion catalyzed reaction (k_{OH} = 0.0745 $M^{-1}s^{-1}$).[34]

The initial rate of transesterification has also been determined as a function of the substrate concentration. The data depicted in Figure 6 show substrate saturation above 40−80-fold excess of hpnp. This indicates the validity of the Michaelis−Menten kinetics in our systems, i.e. the formation of a ternary $[Zn_2LH_{-1}(OH)(hpnp)]^{+}$ complex prior to the intramolecular transformation. The nonlinear least-squares fit of the data points, solid lines in Figure 6, gave the Michaelis constants (K_M) 12.9 mM and 5.2 mM, and catalytic rate constants (k_{cat}) 1.10×10^{-3} s^{-1} and 8.33×10^{-4} s^{-1} for the $[Zn_2LH_{-1}(OH)]^{2+}$ complexes of Htdmbpo and Hbdmbbppo, respectively. These k_{cat} values indicate ca. four orders of magnitude maximal rate acceleration for the hpnp transesterification by these complexes.[34] The dinuclear Htdmbpo zinc(II) complex possesses a somewhat higher catalytic rate constant, but its substrate binding ($1/K_M$) is two and a half times less effective than that of the corresponding Hbdmbbppo complex, which results in a higher overall activity of the latter complex.

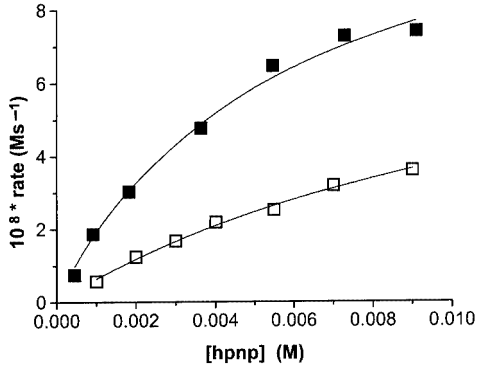

Figure 6. Saturation kinetic experiments for the transesterification of hpnp by the zinc(II)−Htdmpbo (open square, pH = 7.50, [L] = 1.6×10^{-4} M) and the zinc(II)−Hbdmbbppo (filled square, pH = 7.90, [L] = 1.8×10^{-4} M) systems; T = 298 K, $[Zn^{II}]/[L]$ = 2:1

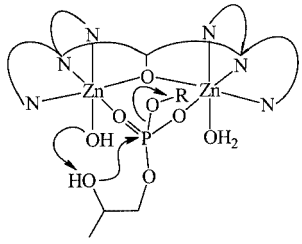
By analogy with the crystal structure of complexes **4** and **5** (which contain the cacodylate bridging unit analogous to the phosphate), $\mu_{1,3}$-bridged coordination of the substrate hpnp can be envisaged for the dinuclear center. This would create a double Lewis acid activation for the transesterification reaction. However, the inactivity of the species $[Zn_2LH_{-1}]^{3+}$ (Figure 4), clearly demonstrates that this effect alone does not provide sufficient rate acceleration. This would need the concerted action of the double Lewis acid activation and the intramolecular general base catalysis by a metal-bound hydroxide ion, which becomes possible only in the successively formed $[Zn_2LH_{-1}(OH)]^{2+}$ complex (Scheme 1).



Scheme 1. The proposed mechanism for the transesterification of hpnp by the dinuclear zinc(II) complexes

Conclusion

With the syntheses of the complexes **1**, **2** and **3**, the first characterization of three structurally similar, heterodinuclear zinc(II)−iron(III) complexes with bridging μ-alkoxo units has been accomplished. According to their structural and spectroscopic properties they are excellent structural models of the active site of kidney bean purple acid phosphatase, serine/threonine protein phosphatase 1 and calcineurin. The use of an asymmetric ligand offers the possibility to prepare tailor-made heterodinuclear complexes. The trigonal-bipyramidally coordinated zinc ion and the octahedrally coordinated iron center are bridged by only one additional cacodylate ligand. The coordination of a water or a methanol molecule to the iron(III) center is very interesting with respect to the discussion of the nucleophilic species in the catalytic mechanism of kidney bean purple acid phosphatase.

The dinuclear zinc complexes **4** and **5** serve as models for alkaline phosphatase, phospholipase C, nuclease P1 and phosphotriesterase. The in situ prepared dinuclear $[Zn_2LH_{-1}(OH)]^{2+}$ complexes of Htdmbpo and Hbdmbbppo possess notable transesterification activity towards the RNA model hpnp, around the neutral pH range. The dinuclear complex formed with the asymmetric ligand Hbdmbbppo showed higher activity as compared with that of the symmetric ligand Htdmbpo, due to its higher substrate binding ability. The results suggest a bifunctional mechanism in the case of both ligands, i.e. the concerted action of the double Lewis acid activation provided by the dimetallic core and the intramolecular general base catalysis provided by a zinc(II)-bound hydroxide ion.

Experimental Section

General Remarks: All chemicals were obtained from commercial sources and used as received. ***CAUTION:*** Although no problems were encountered, suitable care and precautions should be taken when handling the perchlorate salts.

Physical Measurements: ^{1}H NMR spectra were recorded with a Bruker AC 200 instrument. The chemical shifts are reported relative to an internal standard of tetramethylsilane. Elemental analyses were performed with an elemental Vario El III instrument. IR spectra were recorded with a Bruker IFS 48 FT spectrometer. UV/Vis spectra were obtained using a UVIKON 933 spectrometer of Kontron Instruments equipped with 1.0-cm matched quartz cells and operating in the range 190−900 nm. Cyclic voltammetric measurements were carried out using a BAS CV-50 W potentiostat. All experiments were run at room temperature under argon. A standard three-electrode cell was used equipped with a platinum electrode, an Ag/AgCl/3 M NaCl reference electrode and a glassy carbon electrode. Tetra-*n*-butylammonium perchlorate (0.1 M) was used as the supporting electrolyte. Magnetic susceptibility measurements were carried out with a Quantum Design SQUID magnetometer at 3 T in a temperature range of 2−300 K. The mass spectra were recorded with an electrospray mass spectrometer Quattro LCZ with a nanospray inlet.

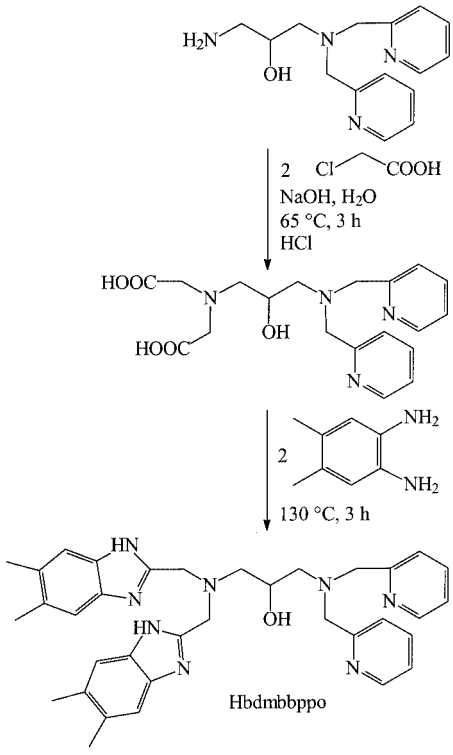
Synthesis: The barium salt of 2-(hydroxypropyl)-4-nitrophenyl phosphate (hpnp) was prepared according to a literature procedure.[40]

***N*,*N*,*N*′,*N*′-Tetrakis[2-(5,6-dimethyl)benzimidazolylmethyl]-1,3-diamino-2-propanol (Htdmbpo) and *N*,*N*,*N*′,*N*′-Tetrakis[2-(*N*′′-(2-hydroxyethyl)]benzimidazolylmethyl]-1,3-diamino-2-propanol (Hthebpo):** The symmetric ligands Htdmbpo and Hthebpo were synthesized as described previously.[41]

***N*,*N*-Bis[2-(4,5-dimethyl)benzimidazolylmethyl]-*N*′,*N*′-bis(2-pyridylmethyl)-1,3-diamino-2-propanol (Hbdmbbppo):** The asymmetric ligand Hbdmbbppo was prepared in a multi-step synthesis using *N*,*N*-bis(2-pyridylmethyl)-1,3-diamino-2-propanol. The preparation of the latter was carried out according to the procedure reported by Suzuki et al. with some modifications.[13] A mixture of phthalimidomethyloxirane and bis(2-pyridylmethyl)amine was heated for 3 d at 100−110 °C. The product was purified by silica gel column chromatography with a chloroform/methanol ratio of 9:1. The synthetic route of the final steps is depicted in Scheme 2.

Chloroacetic acid (2.58 g, 27 mmol) was dissolved in water (6 mL). An aqueous solution (8 mL) of sodium hydroxide (1.08 g, 35 mmol) was added under cooling in an ice bath. *N*,*N*-Bis(2-pyridylmethyl)-1,3-diamino-2-propanol (3.72 g, 14 mmol) was then added, and the mixture was heated to 65 °C. Once more an aqueous solution (8 mL) of sodium hydroxide (1.08 g, 35 mmol) was added over 1 h. After the solution had been stirred at 65 °C for 3 h, 6 M hydrochloric acid (13.6 mL, 90.9 mmol) was added. The solvent was removed in a rotary evaporator and the remaining solid was dissolved in ethanol. The precipitate was filtered off and the solvent was removed in a rotary evaporator to give *N*,*N*-bis(carboxyethyl)-*N*′,*N*′-bis(2-pyridylmethyl)-1,3-diamino-2-propanol. The product was used without further purification.

N,*N*-Bis(carboxyethyl)-*N*′,*N*′-bis(2-pyridylmethyl)-1,3-diamino-2-propanol (6.13 g, 16 mmol) and 4,5-dimethyl-1,2-phenylenediamine (4.49 g, 33 mmol) were dissolved in ethanol (5 mL) and thoroughly mixed, the solvent was subsequently removed. The mixture was heated for 3 h at 130 °C until no further water steam de-



Scheme 2. Final synthetic steps in the preparation of Hbdmbbppo

veloped. The residue was dissolved in a minimum of ethanol in a sonic bath. This solution was added to a mixture of water (150 mL) and concentrated ammonia (7 mL). A brown oily product precipitated, which was purified by silica gel column chromatography with tetrahydrofuran/methanol, 3:1. Yield: 5.09 g (8 mmol, 50%). M.p. 168 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.08 (m, 4 H, CH−CH_2−N), 2.35 (s, 12 H, CH_3), 3.86 (m, 9 H, CH, N−CH_2), 7.26 (m, 10 H, Ar−H), 8.39 (d, 2 H, Ar−H). IR (KBr, 4000−400 cm^{-1}): $\tilde{\nu}$ [cm^{-1}] = 3391 (s), 3054 (w), 2922 (s), 1722 (w), 1634(w), 1593 (s), 1571 (w), 1538 (w), 1447 (s), 1364 (m), 1308 (m), 1262 (w), 1149 (w), 1121 (w), 1096 (w), 1048 (w), 1021 (w), 1001 (w), 980 (w), 858 (m), 799 (w), 764 (s), 666 (w), 630 (w), 461 (w), 436 (w). MS: *m*/*z* = 589 $[M + H]^+$.

[$Zn^{II}Fe^{III}$(tdmbpo)(O_2AsMe_2)(HOMe)](ClO_4)$_3$·4MeOH·2H_2O (1): A methanol solution (5 mL) containing $Zn(ClO_4)_2$·6H_2O (64 mg, 0.17 mmol) and $Fe(ClO_4)_3$·9H_2O (89 mg, 0.17 mmol) was added to a suspension of Htdmbpo (141 mg, 0.17 mmol) in methanol (5 mL). The sodium salt of cacodylic acid (37 mg, 0.17 mmol), dissolved in methanol (5 mL), was then added to the solution. After slow evaporation of the solvent, red orange crystals (132 mg, 0.09 mmol, 52%) were obtained after 2 d. UV/Vis (acetonitrile): λ_{max} = 402 nm (ε = 2458 $M^{-1}cm^{-1}$). $C_{50}H_{79}AsCl_3FeN_{10}O_{22}Zn$ (1474.7): calcd. C 40.72, H 5.40, N 9.50; found C 40.07, H 5.24, N 9.78. Cyclic voltammetry (250 mV/s) in acetonitrile (1 mM): $E_{1/2}$ = 99 mV (Zn^{II}−Fe^{II}/Zn^{II}−Fe^{III}). The cathodic peak at −760 mV is arsenic-centered, μ_{eff} = 5.92 μ_B.

[$Zn^{II}Fe^{III}$(thebpo) (O_2AsMe_2)(H_2O)](ClO_4)(NO_3)$_2$·3H_2O (2): An aqueous solution (2.3 mL) of $Zn(NO_3)_2$·6H_2O (45 mg, 0.15 mmol) was added to a solution of Hthebpo (137 mg, 0.15 mmol) in acetonitrile (7.5 mL). After a few minutes, an aqueous solution (2.5 mL) of $Fe(NO_3)_3$·9H_2O (61 mg, 0.15 mmol) was added dropwise. A solution of the sodium salt of cacodylic acid, dissolved in acetonitrile (2.5 mL), was added after a few minutes. The pH of the solution was determined to be 3. After a few days, orange crystals (45 mg, 0.04 mmol, 23%) suitable for X-ray crystallography were obtained by diffusion of diethyl ether into the solution. The perchlorate anion in the complex is taken from the perchlorate adduct of the ligand. $C_{45}H_{63}AsClFeN_{12}O_{21.5}Zn$ (1347.7): calcd. C 40.11, H 4.71, N 12.47; found C 40.27, H 4.67, N 12.38. Cyclic voltammetry (250 mV/s) in DMSO (1 mM): $E_{1/2}$ = −74 mV (Zn^{II}−Fe^{II}/Zn^{II}−Fe^{III}). The cathodic peak at −720 mV is assigned to arsenic, μ_{eff} = 6.06 μ_B.

[$Zn^{II}Fe^{III}$(bdmbbppo)(O_2AsMe_2)](ClO_4)$_2$·5MeOH (3): After the reaction of Hbdmbbppo (103 mg, 0.17 mmol) in methanol (3 mL) with a methanol solution (2.5 mL) of $Zn(ClO_4)_2$·6H_2O (64 mg, 0.17 mmol), a methanol solution (2.5 mL) of $Fe(ClO_4)_3$·H_2O (62 mg, 0.17 mmol) was added dropwise after a few minutes. Finally, the sodium salt of cacodylic acid (38 mg, 0.18 mmol) in methanol (2 mL) was added. Slow evaporation of the solvent yielded brown crystals (41 mg, 0.04 mmol, 24%) suitable for X-ray crystallography. UV/Vis (methanol): λ_{max} = 335 nm (sh) (ε = 2570 $M^{-1}cm^{-1}$). $C_{39.5}H_{55}AsCl_3FeN_8O_{27.5}Zn$ (1224.4): calcd. C 38.75, H 4.53, N 9.15; found C 37.60, H 4.67, N 9.12. Cyclic voltammetry (250 mV/s) in acetonitrile (1 mM): $E_{1/2}$ = 157 mV (Zn^{II}−Fe^{II}/Zn^{II}−Fe^{III}). The cathodic peak at −740 mV is arsenic-centered, μ_{eff} = 6.00 μ_B.

[Zn^{II}_2(tdmbpo)(O_2AsMe_2)(HOMe)](ClO_4)$_3$·4MeOH·2H_2O (4): A methanol solution (5 mL) of $Zn(ClO_4)_2$·6H_2O (128 mg, 0.34 mmol) was added to a suspension of Htdmbpo (141 mg, 0.17 mmol) in methanol (10 mL). Then the sodium salt of cacodylic acid (37 mg, 0.17 mmol), dissolved in methanol (5 mL), was added to the solution. Colorless crystals (74 mg, 0.06 mmol, 35%) were obtained after 2 d by slow evaporation of the solvent. $C_{50}H_{75}AsCl_2N_{10}O_{16}Zn_2$ (1348.8): calcd. C 44.52, H 5.61, N 10.39; found C 43.20, H 5.47, N 10.70.

[Zn^{II}_2(bdmbbppo)(O_2AsMe_2)](ClO_4)$_2$·H_2O (5): An aqueous solution (3 mL) of $Zn(ClO_4)_2$·6H_2O (128 mg, 0.34 mmol) and an aqueous solution (2 mL) of the sodium salt of cacodylic acid were added to a solution of Hbdmbbppo (101 mg, 0.17 mmol) in acetonitrile (5 mL). Diffusion of diethyl ether into the solution afforded colorless crystals (101 mg, 0.09 mmol, 55%) after 4 d. $C_{37}H_{47}AsCl_2N_8O_{12}Zn_2$ (1072.4): calcd. C 41.44, H 4.42, N 10.45; found C 40.27, H 4.55, N 10.14.

pH-Metric Measurements: The protonation and coordination equilibria were investigated by potentiometric titration in an ethanol/water solvent mixture (35 or 80 % ethanol, w/w) [*T* = 298 ± 0.1 K, *I* = 0.1 M and 0.05 M ($NaNO_3$) for 35 and 80 % ethanol/water, w/w mixture, respectively], using an automatic titration set including a Dosimat 665 (Metrohm) autoburette, an Orion 710A precision digital pH-meter and an IBM-compatible PC. 20-mL sample solutions were titrated with 0.1 M NaOH, prepared from solid NaOH (Fluka) in an ethanol/water mixture. The accurate concentration of the NaOH solution was determined by KH−phthalate. The sample solutions were prepared from stock solutions of $Zn(ClO_4)_2$ and the corresponding ligands. The Orion 8103BN semimicro pH glass electrode was calibrated using standard aqueous buffer solutions (pH = 4.0, 7.0 and 10, Sigma) and the actual pH in the mixed solvent was then determined by subtracting 0.10 or 0.11 units (for 35 and 80% ethanol/water, w/w mixture, respectively) from the pH-meter reading according to the method of Bates.[42] The ionization constants of water determined by us under the conditions used [pK_w = 14.53(2) and 15.31(2) for 35 and 80 % ethanol/water, w/w

mixture, respectively] are in good agreement with the literature data.[43] The species formed in the systems were characterized by the general equilibrium process of Equation (1), where M denotes the metal ion and L the nonprotonated (neutral) ligand molecule.

$$pM + qL + rH \xleftrightarrow{\beta_{M_pL_qH_r}} M_pL_qH_r \quad (1)$$

The corresponding formation constants ($\beta_{M_pL_qH_r} \equiv \beta_{pqr} = [M_pL_qH_r]/[M]^p[L]^q[H]^r$) were calculated using the computer program PSEQUAD,[44] as concentration constants. The protonation and complex formation constants were determined from 3 and 6 independent titrations (60−80 data points per titration), respectively. The metal/ligand ratios varied between 1:2 and 3:1, with the metal ion concentration between 1.0×10^{-3} and 2.5×10^{-3} mol·dm^{-3}.

Kinetic Measurements: The transesterification of 2-(hydroxypropyl)-4-nitrophenyl phosphate[40] (hpnp) was monitored in a buffered ethanol/water mixed solvent [I = 0.1 or 0.05 M ($NaNO_3$), T = 298 K] by detecting the increase in the absorbance maximum at 400 nm of the 4-nitrophenolate anion (ε = 18900) (Figure 6). In all cases 0.04 M buffer (HEPES and CHES) was used. The pK of 4-nitrophenol was determined independently for our conditions (pK = 7.50 ± 0.02 and 8.47 ± 0.02 for 35 and 80% ethanol/water mixture, respectively). The initial concentration of hpnp varied from 0.4 mM to 9 mM. The initial slope method (≤ 4% conversion) was used to determine the pseudo-first-order rate constants. The reported data are the average of triplicate measurements with a reproducibility better than 10%. In a typical experiment, the pH of the solution containing 0.4−0.8 mM ligand, 0.8−1.6 mM zinc(II), buffer and background electrolyte was adjusted to the desired value. 2 mL of this solution was equilibrated at 298 K in the spectrophotometer, 100 μL of 0.02 M hpnp was then injected into the solution with efficient mixing. The increase in the absorbance at 400 nm was immediately monitored. Second-order rate constants were obtained from plots of first-order rate constants against the concentration for the complex $Zn_2LH_{-1}(OH)$, calculated from the formation constants determined by pH-metry.

X-ray Data Collection and Crystal Structure Determinations: The unit cell parameters and basic information about data collection and structure refinement are given in Table 6. Structures were solved by heavy-atom methods (SHELXS-97) and refined by full-matrix least-squares methods based on F^2 (SHELXL-97).[45] The location of a half occupied nitrate anion in **2** was not possible due

Synthesis and Characterization of Fe- or Cu-Substituted Molybdenum-Enriched Tungstodiphosphates

Robila Belghiche,[a,c] Roland Contant,[a] Yu Wei Lu,[a] Bineta Keita,[a] Mostefa Abbessi,[a,c] Louis Nadjo,*[a] and Jacqueline Mahuteau[b]

Keywords: Heteropolyanions / Dawson-type structures / Molybdenum / Transition metal cations / Electrocatalysis

Stereospecific routes were followed to synthesize five new Fe^{3+} and Cu^{2+}-substituted Mo-enriched Dawson-type heteropolyanions as aqueous soluble potassium salts: α_2-$K_7[Fe(OH_2)P_2W_{12}Mo_5O_{61}]$ and α_2-$K_7[Fe(OH_2)P_2W_{13}Mo_4O_{61}]$, α_1- and α_2-$K_8[Cu(OH_2)P_2W_{12}Mo_5O_{61}]$ and α_2-$K_8[Cu(OH_2)P_2W_{13}Mo_4O_{61}]$. The substituted species as well as their immediate lacunary precursors were characterized by IR, UV/Visible and ^{31}P NMR spectroscopy. In particular ^{31}P NMR spectroscopy indicates that isomerically pure compounds were obtained. The activity of these chemicals in electrocatalysis is illustrated by the reduction of nitrite for Fe^{3+} derivatives and the reduction of nitrate for Cu^{2+} compounds.

Introduction

Dawson-type tungstodiphosphates are interesting in their own right. More particularly, their ability to generate lacunary species and then metal cation substituted derivatives has aroused great attention.[1−10] The impetus was triggered by the pioneering remark of Baker[11] that monosubstituted heteropolyanions can be considered as the analogues of metalated porphyrins and used in catalytic processes with the advantage, relative to their organic counterparts, of thermal stability, robustness and inertness toward oxidizing environments. With regard to their electrochemistry and, correspondingly, their use in electrocatalysis, we are currently studying the parameters which eventually in conjunction with pH effects could induce the overlapping of the first waves of heteropolyanions (HPAs). The basic idea underlying this search is to trigger by reduced HPAs those energetically favourable cathodic processes that require several electrons to become effective.[6,8−10,12] Among several possibilities, the approach making use of substitution effects is considered in detail: in particular the location of the metal in the framework; the nature and number of substituents are expected to more or less influence the interactions between the electroactive centres within the HPA molecule. The two following examples can be cited in support of these anticipated results: i) A remarkably beneficial effect observed for the presence of molybdenum in the framework of Dawson-type HPAs used as electrocatalysts in the reduction of nitrite or nitric oxide aroused our interest.[5] For instance, the presence of a single Mo atom in the framework of $[P_2W_{17}MoO_{62}]^{6-}$ results in an improvement of 0.270 V in the potential at which the catalytic process is observed compared to the same process with $[P_2W_{18}O_{62}]^{6-}$. Such an improvement reaches 0.390 V with $[P_2Mo_{18}O_{62}]^{6-}$ instead of $[P_2W_{18}O_{62}]^{6-}$. At least two questions might result from this observation: they concern the influence of the number of Mo atoms in the molecule and the possible specificity of molybdenum in this particular process; ii) the presence of the Fe^{3+} cation in α_2-$[Fe(OH_2)P_2W_{15}Mo_2O_{61}]^{7-}$, abbreviated as α_2-$FeP_2W_{15}Mo_2$, substantially modifies the electrochemistry of this heteropolyanion compared with the behaviour of α_2-$[P_2Mo_3W_{15}O_{62}]^{6-}$ (α_2-$P_2Mo_3W_{15}$). In a pH 2 medium, the cyclic voltammogram of the latter compound begins with three diffusion-controlled one-electron waves. In contrast, the iron(III)-substituted complex displays a three-electron first wave at pH 2, as a result of the merging of the molybdenum and iron waves.[6,12] A study of this pattern as a function of pH allows the Fe^{3+} wave to be separated from the molybdenum reduction, thus confirming the mechanism leading to overlapping. Provisionally, it is also worth noting the use of Fe-substituted heteropolyanions in electrocatalytic processes.[4,13,14] The copper cation Cu^{2+} is another substituent known to be reducible in the close vicinity of the HPAs framework and therefore likely to result in a first wave in-

volving several electrons.[9,10,15] Furthermore, copper and iron complexes exhibit useful behaviours in several catalytic processes.[16,17]

The purpose of the present paper is to give a detailed account of the synthesis and characterization of pure samples of several Mo-rich Dawson-type tungstodiphosphates monosubstituted by Fe^{3+} or Cu^{2+}. The electrocatalytic behaviours of these chemicals are also illustrated briefly.

Results and Discussion

Numbering of Atoms and Main Abbreviations

The new heteropolyanions (HPAs) are: α_2-K_7-$[Fe(OH_2)P_2W_{12}Mo_5O_{61}]$ (α_2-$P_2W_{12}Mo_5Fe$) and α_2-K_7-$[Fe(OH_2)P_2W_{13}Mo_4O_{61}]$ (α_2-$P_2W_{13}Mo_4Fe$); α_1 and α_2-$K_8[Cu(OH_2)P_2W_{12}Mo_5O_{61}]$ (α_1- and α_2-$P_2W_{12}Mo_5Cu$) and α_2-$K_8[Cu(OH_2)P_2W_{13}Mo_4O_{61}]$ (α_2-$P_2W_{13}Mo_4Cu$). Scheme 1 gives the numbering of atoms in the framework of $[P_2W_{18}O_{62}]^{6-}$ from which all the present compounds are derived. In conjunction with Table 1, it permits a precise localization of all the substituent atoms in the W skeleton.

Syntheses

Table 1 summarises the formulas of the main intermediate compounds and those of the final substituted products described in the following. Stereospecific routes to obtain the precursor lacunary species were established by one of the present authors.[18] The substituted compounds of interest here were then synthesized along the same lines as those followed for α_2-$P_2W_{15}Mo_2Cu$ and α_2-$P_2W_{15}Mo_2Fe$.[6,8] Specific details are given in the Exp. Sect. Table 1 also emphasizes the remarkably high yields obtained for all the syntheses in the present work. ^{31}P NMR spectra indicated that isomerically pure compounds were obtained. This observation is remarkable because several isomeric species could have been expected owing to possible migration of molybdenum atoms in all the compounds. The lack of heating might be one of the reasons for obtaining such pure samples.

UV/Vis and IR Characterization

As expected, no characteristic absorption band was observed in the UV/Vis spectra of the new HPAs except for some shift in the yellow direction due to the presence of Mo atoms in the molecules. However, in anticipation of subsequent work, the stability of these complexes in pH 3 and 5 media was checked by monitoring their UV/Vis spectra over a period of at least 24 hours. The species were found to be stable in these media. Figure 1 allows a comparison of the IR characteristics of the main new HPAs synthesized in this work. In tungstophosphates, the most characteristic IR band shifts correspond to P−O vibrations between 1200 and 1000 cm^{-1}, and these shifts characterize lacunary species. With an iron or a copper atom added in the vacancy, despite the presence of Mo atoms a greater symmetry is restored in the substituted molecule, at least as far as IR spectra are concerned. It is worth noting an important broadening of the bands, which become somewhat featureless roughly in the 850−700 cm^{-1} region. On the whole, in a first approximation, the IR spectra are close to those of the corresponding saturated compounds, even though a few new bands or slight differences could be detected on comparative scrutiny of the spectra. This situation prevents any sharp identification by IR spectra of a given anion.

^{31}P NMR Spectroscopy

The NMR study of paramagnetic element-containing HPAs was performed by Jorris et al.[19] on $[P_2W_{17}O_{61}]^{10-}$ derivatives. In agreement with their observations, work of this group[6,8] has confirmed that the chemical shift of the P atom furthest from the paramagnetic centre and noted P(2) is practically unaffected by the presence of this centre, while P(1) resonances are shifted radically and broadened. This shift and broadening might be important enough to make the corresponding signal hardly or not at all observable. Table 2 gives the chemical shifts measured for all the Fe^{3+} and Cu^{2+}-substituted compounds synthesized in this work. Values for the same metal complexes derived from $[(1),2,3\text{-}P_2Mo_2W_{15}O_{61}]^{10-}$ are included for comparison. The expected features were obtained throughout and do not call for further comments. Figure 2 illustrates specifically the ^{31}P NMR spectrum of α_1-$CuP_2Mo_5W_{12}$. For this compound, a single resonance peak was observed, corresponding to P(2). As shown in Table 2 and Figure 2, the two spectra for the α_1 and α_2 isomers are sufficiently different to

allow for the characterization of each isomer and the determination of their respective proportion in a mixture.

Electrocatalytic Behaviours of the (Fe or Cu)-Substituted Mo-Containing HPAs

The assessment of the behaviours of HPAs towards the reduction of NO_x constitutes one of our favourite electrocatalytic tests. Table 3 and 4 summarize several results selected to illustrate the combined influences of Mo and Fe or Cu in the HPA molecules. Our work establishes the beneficial effect of the presence of Mo atoms within the framework of HPAs on the electrocatalytic reduction of nitrites[5,17] and nitrates.[16] Cyclic voltammetry at a scan rate of 2 $mV\cdot s^{-1}$ was used throughout for these tables. Quantitatively, the activities of the HPAs were expressed through the catalytic efficiency, defined as $CAT = 100 \times [I_{(HPA + NO_x)} - I^d_{(HPA)}]/I^d_{(HPA)}$, where $I_{(HPA + NO_x)}$ is the peak current for the reduction of the heteropolyanion (HPA) in the presence of NO_x and $I^d_{(HPA)}$ is the corresponding diffusion peak current for the HPA alone. The quantity of NO_x is defined in terms of the excess parameter γ ($\gamma = C^\circ_{NO_x}/C^\circ_{HPA}$).

For the electrocatalytic reduction of nitrites, Table 3 illustrates the example of Fe-HPA derivatives: a pH 5 medium was selected to avoid competition between several NO_x species for the catalytic process; the increase of the catalytic efficiency with the number of Mo atoms is obvious. Typically, the catalytic efficiency showed a threefold increase when the number of Mo atoms increased from 2 to 5.

The catalytic efficiencies for the catalytic reduction of nitrate by reduced Cu-monosubstituted Mo-containing HPAs are given in Table 4. It is gratifying that the electrocatalytic reduction of nitrate by substituted HPAs could be observed for the first time. The process is efficient with all the compounds in Table 4 and also with compounds of the $P_2W_{17}Cu$ series (not shown). The comparison clearly indicates[16] the beneficial effect of the presence of Mo atoms for enhancing the catalytic current. In Table 4, the correlation between the number of Mo atoms and the catalytic efficiency is not straightforward, probably because the electrocatalysis is triggered at least partly by the electrodeposited

Table 2. ^{31}P NMR chemical shifts for $[M^x(H_2O)(P_2Mo_yW_{17-y}O_{61})]^{(10-x)-}$ with $M^x = Fe^{3+}$, Cu^{2+} or □, (□ designates a vacancy), y = 3, 4 or 5

copper. Finally, a small isomeric effect between α_1- and α_2-$P_2W_{12}Mo_5Cu$ must be noted.

Conclusions

One of the basic ideas underlying this work originates in the observation that the presence of Mo atoms within the skeleton of tungsten-containing heteropolyanions results in a substantial improvement in the electrocatalytic behaviours of these compounds toward the reduction of nitrite or nitric oxide. Therefore, it was desirable to study the possibility of a correlation between the number and/or the location of these atoms in the framework with the catalytic efficiency. However, it soon appeared that an additional monosubstitution of the already Mo-substituted skeleton by Fe^{3+} or Cu^{2+} is also necessary in these catalysts. It was found that stereospecific synthesis routes available for obtaining several Mo-rich tungstodiphosphates allow direct access to the useful lacunary precursor species. It is gratifying that our procedures for the synthesis of the subsequent Fe^{3+} and Cu^{2+}-substituted derivatives result in pure compounds, as proved by several analytical techniques including IR spectroscopy and ^{31}P NMR spectroscopy. The usefulness of these new species in the electrocatalysis of nitrite and nitric oxide reduction was assessed. It is worth emphasizing particularly the activity of the present Cu-substituted derivatives toward the electrocatalytic reduction of nitrates. To the best of our knowledge, this process was observed for the first time with substituted heteropolyanions.

Experimental Section

NMR, IR and UV/Visible Spectroscopy and Elemental Analysis: ^{31}P NMR spectra were recorded in 5 mm outer diameter tubes on a Bruker Avance 400 apparatus operating at 161.97 MHz, in the Fourier transform mode. The ^{31}P chemical shifts were measured

for 0.01 M solutions of the polyanions in 1 M LiCl/D_2O solutions and were referenced to H_3PO_4. IR spectra were recorded in 1% weight of HPA in a KBr pellet on a Bruker IFS 66 FT-IR spectrophotometer. UV/Visible spectra were recorded on a Perkin−Elmer Lambda 19 spectrophotometer. Elemental analyses were performed by CNRS Service Central d′Analyse at Vernaison (France). The crystal water content was determined by the following procedure: Two silica crucibles were thoroughly cleaned, dried at 250° C in an oven and finally left to cool to room temperature in a drying vessel containing P_2O_5 as a desiccant. Each crucible was loaded with 150 to 300 mg of the complex of interest and then heated at 250° C in the oven for one hour. After cooling in the drying vessel, the mass loss was measured and converted into mol of water per mol of complex.

Electrochemical Experiments: Pure water was used throughout. It was obtained by passing through a Milli-RO_4 unit and subsequently through a Millipore Q water purification set. All chemicals were of high-purity grade and were used as received. CH_3COONa and CH_3COOH were commercial products (Prolabo). The pH 5 solution was made up with 0.5 M CH_3COONa + CH_3COOH. The solutions were de-aerated thoroughly for at least 30 min with pure argon and kept under a positive pressure of this gas during the experiments. The source, mounting and polishing of the glassy carbon (GC, Tokai, Japan) electrodes has been described previously.[17] The glassy carbon samples had a diameter of 3 mm. The electrochemical setup was an EG & G 273 A driven by a PC with 270 software. Potentials are quoted relative to a saturated calomel electrode (SCE). The counter electrode was a platinum gauze of large surface area. All experiments were performed at room temperature.

Preparations: The potassium salts of α_2-$[P_2W_{12}Mo_5]^{10-}\cdot 20H_2O$, $[P_2W_{12}Mo_6]^{6-}\cdot 14H_2O$, $[P_2W_{13}Mo_5]^{6-}\cdot 14H_2O$, $[P_2W_{14}Mo_4]^{6-}\cdot 14H_2O$, α_2-$[P_2W_{13}Mo_4]^{10-}\cdot 19H_2O$ and the mixed potassium/lithium salt of α_1-$[P_2W_{12}Mo_5]^{10-}\cdot 20H_2O$ were prepared by the published stereospecific routes.[18]

α_2-$K_7[Fe(OH_2)P_2W_{12}Mo_5O_{61}]\cdot 14H_2O$: A sample of α_2-$K_{10}[P_2W_{12}Mo_5O_{61}]\cdot 20H_2O$ (9.40 g, 2.10 mmol) was dissolved in 20 mL of 0.12 M $Fe(NO_3)_3$ (2.4 mmol) and 60 mL of Millipore water and the mixture stirred for 30 min. After treatment with solid KCl (15 g) followed by a saturated KCl solution (60 mL), a dark yellow solid (6.57 g) was filtered off and dried in air. $K_7[Fe(OH_2)P_2W_{12}Mo_5O_{61}]\cdot 14H_2O$: calcd. H_2O 6.27, Fe 1.30, K 6.36, Mo 11.14, P 1.44, W 51.24; found H_2O, 5.85, Fe 1.27, K 7.50, Mo 10.70, P 1.67, W 48.90.

α_2-$K_8[Cu(OH_2)P_2W_{12}Mo_5O_{61}]\cdot 16.5H_2O$: A sample of α_2-$K_{10}[P_2W_{12}Mo_5O_{61}]\cdot 20H_2O$ (9.40 g, 2.10 mmol) was dissolved in 20 mL of 0.12 M $Cu(NO_3)_2$ (2.4 mmol) and 60 mL of Millipore water and the mixture stirred for 20 min. After treatment with a saturated KCl solution (60 mL), a yellow-green solid (6.84 g) was filtered off and dried in air. $K_8[Cu(OH_2)P_2W_{12}Mo_5O_{61}]\cdot 16.5H_2O$: calcd. H_2O 7.16, Cu 1.44, K 7.11, Mo 10.91, P 1.41, W 50.17; found H_2O 6.75, Cu 1.31, K 7.69, Mo 10.32, P 1.65, W 47.18.

Cyclopentadienylmolybdenum(VI) and Molybdenum(V) Oxo Chemistry: New Synthetic and Structural Features

Dirk Saurenz,[a] Funda Demirhan,[a,b] Philippe Richard,[a] Rinaldo Poli,*[a] and Helmut Sitzmann[c]

Keywords: Cyclopentadienyl ligands / Molybdenum / Oxo ligands / X-ray crystallography

Convenient syntheses for Cp, Cp*, and related cyclopentadienyl derivatives (^{4}Cp = C_5H_iPr$_4$; Cp''' = C_5H_2tBu$_3$-1,2,4) of formula [(Ring)$_2$Mo$_2$O$_5$] are described. Compound [Cp$_2$Mo$_2$O$_5$] was produced in good yields by the rapid oxidation of red [CpMoO$_2$]$_4$ with PhIO in CH_2Cl_2. [Cp*$_2$Mo$_2$O$_5$] was obtained by CH_3COOH acidification of aqueous solutions of [Cp*MoO$_3$]$^-$Na$^+$, the latter being generated in a single step from [Cp*MoCl$_4$] and more than 5 equiv. of aqueous NaOH in air. Minor quantities of [Cp*MoO$_2$]$_2$ were also isolated from this reaction, although the formation of this by-product may be reduced by using a two-step basic hydrolysis procedure. Extension of the latter strategy also allowed the preparation of [^{4}Cp$_2$Mo$_2$O$_5$], [Cp'''$_2$Mo$_2$O$_5$], and [^{4}CpMoO$_2$Cl] in good yields, in addition to the by-product [Cp'''MoO$_2$]$_2$. X-ray structures are reported for compounds [^{4}Cp$_2$Mo$_2$O$_5$], [Cp'''$_2$Mo$_2$O$_5$], [Cp*MoO$_2$]$_2$, [Cp'''MoO$_2$]$_2$, and [^{4}CpMoO$_2$Cl].

Introduction

High oxidation state organometallic chemistry has experienced rapid development in the last 20 years, mostly justified by the search for efficient oxidation catalysts. Half-sandwich oxo derivatives of rhenium,[1–3] displaying a very rich chemical reactivity and catalytic activity, are an example of a well investigated class of compounds. Some of the earliest high oxidation state organometallics however, are the cyclopentadienyl oxo derivatives of molybdenum, first developed in the laboratory of M. L. H. Green.[4,5]

The stability of high oxidation state complexes requires the presence of electronegative and π-donating ligands such as halides or negatively charged oxygen- (oxo, alkoxo) or nitrogen-based (nitrido, imido, amido) ligands. The organic fragments most compatible with this ligand environment are odd-electron ones, such as alkyls (1-electron), allyls (3-electron), dienyls (5-electron), etc., while neutral organic fragments (olefins, arenes, etc.) need more electron-rich, low-valent metal centers to optimize bonding. These conditions confer a high degree of covalency on the resulting metal–carbon bonds, which consequently become quite resistant to hydrolytic conditions. It is therefore somewhat surprising that the physical behavior and chemical reactivity of high oxidation state organometallics has not been investigated systematically in water, although aqueous reagents are sometimes used for their syntheses. This contrasts with the well-developed aqueous chemistry of high oxidation state oxomolybdenum complexes.[6,7] On the other hand, the rich electrochemical behavior displayed by the metals involved, notably molybdenum, makes these molecules quite interesting for potential electrocatalytic applications. For these reasons, we initiated a research effort aimed at increasing our basic knowledge of the physical properties and chemical reactivity of organomolybdenum compounds in a variety of high oxidation states in water.

Although several investigations of cyclopentadienyl oxo complexes of molybdenum in high oxidation states have been reported,[8,9] routes to these materials cannot be considered to be completely satisfactory. In this first contribution, we focus on improvements in the synthetic procedures to produce compounds [Cp$_2$Mo$_2$O$_5$] and [Cp*$_2$Mo$_2$O$_5$], which we plan to use as starting materials for our studies. We also report an extension of the synthesis of analogues containing differently substituted cyclopentadienyl rings. We are interested in cyclopentadienyl rings with a high degree of substitution, as these are known to afford more inert metal-cyclopentadienyl bonds by restricting access to the

metal center, while at the same time rendering the other ligands more labile. Interesting reactivity may thus be expected. Some basic aqueous chemistry related to the optimization of the syntheses reported in this paper is also discussed. Detailed studies of the behavior of these compounds in water as functions of pH[10] and of electrode potential[11] have also been completed, and are being reported separately.

Results

The Cyclopentadienyl Oxo Molybdenum(VI) System

Discussion of Previously Reported Routes

As mentioned in the introduction, $[Cp_2Mo_2O_5]$ has been known since 1964, but no reliably high-yielding and practical synthesis seems to be available yet. It was first obtained in 20% yield, together with several other products, from the photolytic degradation of $[CpMo(CO)_3]_2$ in chloroform.[4] It has also been formed in low yields by adventitious oxygenation of solutions of various CpMo derivatives.[4,5] A synthesis in higher yield (79%) by oxidation of the dinuclear Mo^V compound $[CpMoO_2]_2$ has been reported. This, however, required use of Ag_2O as the oxygen-transfer agent and warming in CH_2Cl_2 at 55 °C for 1.5 days.[12] The precursor complex could in turn be obtained by hydrolysis of $[CpMoX_4]$ (X = Cl, Br) with excess water. A red isomer, formulated as a tetranuclear compound, was obtained immediately, while longer exposure to water or dissolution of the red isomer in acetone or chloroform slowly afforded a dinuclear orange isomer.[5,12] A similar behavior has been described for analogous compounds with monosubstituted cyclopentadienyl ligands.[12] Since the reported behavior of the red tetrameric form suggested that it was a chemically more labile form, we wondered whether the oxidation of this red isomer by sufficiently rapid oxygen-transfer agents might provide an easier route to the desired Mo^{VI} product in high yield before its conversion into the less reactive orange isomer.

New Synthetic Strategy

Several effective reagents are commonly used for oxygen-transfer chemistry, the most easily accessible one being H_2O_2. We were hesitant to use this reagent, because the formation of peroxo compounds of Mo^{VI} or W^{VI}, such as $[Cp^*W(O_2)(O)R]$[13−15] or $[Cp^*M(O_2)(O)Cl]$ (M = Mo, W),[16,17] by treatment of suitable precursors with either H_2O_2 or hydroperoxides has been described previously. Indeed, oxidation tests with H_2O_2 gave unsatisfactory results. The use of PhIO,[18] on the other hand, provided a rapid and convenient synthesis in two steps (>50% overall yield) from $[CpMoCl_4]$, itself easily available from commercially available $[Mo(CO)_6]$ [Equations (1) and (2)].[19] The second step was complete within 15 min at room temperature, and the best results were obtained when the solution was worked up immediately. If the product was allowed to stand in the dichloromethane solution, darker, insoluble by-products began to form. The intermediate red Mo^V oxo complex had to be isolated and removed from water; an attempt to carry out the synthetic procedure without this isolation step gave unsatisfactory results. This procedure, however, constitutes a significant improvement over those previously available, especially in terms of time efficiency, as both steps can be carried out at room temperature and the overall procedure may be accomplished in half a day.

$$4\,[CpMoCl_4] + 8\,H_2O \rightarrow [CpMoO_2]_4 + 16\,HCl \quad (1)$$

$$[CpMoO_2]_4 + 2\,PhIO \rightarrow 2\,[Cp_2Mo_2O_5] + 2\,PhI \quad (2)$$

The procedure described below for the Cp* and related analogues, via the hitherto unknown $[CpMoO_3]^-$ anion,[20] does not give satisfactory results for the Cp system.

The Pentamethylcyclopentadienyl Oxo Molybdenum(VI) System

Discussion of Previously Reported Routes

The Cp* compound was first reported in 1985 by Herberhold et al. as the product of the aerial oxidation of $[Cp^*Mo(CO)_2(NO)]$,[21] and was subsequently shown to form in low yield as a by-product in a variety of other reactions.[22−25] A high-yielding synthesis by aerial oxidation of $[Cp^*Mo(CO)_2]_2$ in chloroform was reported by Faller and Ma, although the product was said to be contaminated by ca. 15% of the chloride complex $[Cp^*MoO_2Cl]$ and needed further exposure to acetone/water for purification,[26] while the synthesis of the starting compound from commercially available $[Mo(CO)_6]$ is itself not free from pitfalls.[27,28] This reaction was re-examined later by Bottomley and shown to yield a host of other incompletely oxidized products under a variety of conditions.[29,30] The preparation from $[Cp^*MoCl_4]$ in 70−75% yield reported by Umakoshi and Isobe[31] is related to the synthetic procedure reported by us here, but was not optimized for large-scale syntheses and uses the exotic sodium oxometallate salts Na_2MoO_4, Na_2WO_4, or $NaVO_3$ as oxidants. Another reported high-yielding synthesis was by protonolysis of the unusual starting compound $[Cp^*Mo(N\mathit{t}Bu)_2Cl]$ with aqueous HCl.[32]

Finally, work carried out in Geoffroy's laboratory showed that the hydrolysis of $[Cp^*MCl_4]$ (M = Mo, W) in the presence of an amine ($\mathit{t}BuNH_2$) yields $\mathit{t}BuNH_3^+[Cp^*MO_3]^-$ in good yields,[33] while Sundermeyer showed that the same anions also form on treatment of the oxo-bridged dimers $[Cp^*_2M_2O_5]$ with tetrabutylammonium hydroxide.[32] Acidification of the anion solution, examined in the Geoffroy study for the tungsten compound, gave back the dinuclear complex through the presumed condensation of initially formed $[Cp^*WO_2(OH)]$.[33]

A detailed discussion of this reversible anion/dimer transformation and the aqueous chemistry of the tetrachloride

compounds is essential, as it forms the basis of our improved synthetic strategy. Geoffroy et al. reported that treatment of [Cp*$MoCl_4$] with 2 equiv. of NaOH in acetone/water in an open flask for more than 30 min gave [Cp*MoO_2Cl], while use of an unspecified excess of NaOH afforded the dinuclear [Cp*$_2Mo_2O_5$].[34] The reaction between [Cp*MoO_2Cl] and excess (3 equivalents) NaOH was also reported to yield the dinuclear compound. These observations seemed odd to us in view of Sundermeyer's result mentioned above, which we have confirmed (see next section).[35] In contrast with the apparent lack of reactivity between [Cp*$_2Mo_2O_5$] and excess aqueous NaOH, excess aqueous *t*$BuNH_2$ (a weaker base than NaOH) under analogous conditions yielded *t*$BuNH_3^+$[Cp*MoO_3]$^-$ in good yields.[34] Furthermore, it was shown that acidification of dichloromethane solutions of the *t*$BuNH_3^+$[Cp*MoO_3]$^-$ salt with acetic acid afforded [Cp*$_2Mo_2O_5$], which was recovered in 58% yield. From these observations, it would seem logical to imagine a pH-dependent equilibrium between the anionic mononuclear and the neutral dinuclear forms [Equation (3)] in water.[36] The anion should therefore be the ultimate product when excess strong base (e.g. NaOH) is present, in contrast to Geoffroy's report. On the basis of this hypothesis, we have developed the new synthetic procedure reported in the following section. Preliminary investigations indeed showed that yellow [Cp*$_2Mo_2O_5$] solutions in MeOH/H_2O became nearly colorless upon treatment with NaOH, and the resulting basic solutions turned yellow once more when the pH was lowered by addition of strong acids.

$$[Cp^*_2Mo_2O_5] + 2\ OH^- \rightleftarrows 2\ [Cp^*MoO_3]^- + H_2O \quad (3)$$

New Synthetic Strategy

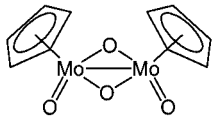
[Cp*$MoCl_4$] is conveniently prepared in high yields and purity[37] from commercially available [$Mo(CO)_6$] and was therefore the starting compound of choice for our synthetic work. As mentioned in the previous section, it seemed to us that excess NaOH under aerobic conditions should afford the cyclopentadienyltrioxomolybdate anion directly, according to the stoichiometry of Equation (4).

$$2\ [Cp^*MoCl_4] + 10\ OH^- + 1/2\ O_2 \rightarrow 2\ [Cp^*MoO_3]^- + 8\ Cl^- + 5\ H_2O \quad (4)$$

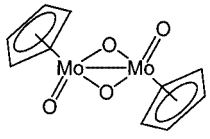
Treatment of acetone solutions of [Cp*$MoCl_4$] with a slight excess (ca. 6 equivalents) of aqueous NaOH in air for over a day at room temperature yielded a suspension of the pale yellow precipitate [Cp*MoO_3]$^-$$Na^+$, but also minor quantities of a soluble, colored by-product (identified as [Cp*MoO_2]$_2$, vide infra). Separation of this by-product was accomplished by complete evaporation of the solvent mixture and redissolution in pure water, which dissolved the sodium salt but not the by-product. Since the sodium organomolybdate salt might have been difficult to separate from NaCl and excess NaOH by fractional crystallization, we proceeded directly to its conversion into the neutral dimer, which is insoluble in pure water. Dropwise addition of acetic acid from a burette resulted, after neutralization of the excess base, in the instantaneous precipitation of the yellow product. Addition of acid was stopped when administration of one further drop of the acid solution did not cause any further precipitation. The synthetic procedure could therefore be handled as a simple titration reaction, allowing the use of close to the stoichiometric amount of acid. This was important because excess acetic acid is also partially extracted into the ether layer and large quantities of this compound may interfere with the crystallization procedure or even contaminate the organomolybdenum product. This procedure consistently gave a pure product with yields in excess of 60% on a 2 g scale. The synthesis could also be accomplished stepwise, by treatment of [Cp*$MoCl_4$] with three equivalents of NaOH for one day, followed by addition of three more equivalents of NaOH. In this fashion, the formation of the Mo^V by-product was avoided (see discussion). The isolated yield of the desired product, however, was not increased by this modified procedure.

Isolation and Structure of the [CpMoO_2]$_2$ By-Product*

The water-insoluble crop generated during the synthetic procedure described above contained orange-red crystalline [Cp*MoO_2]$_2$, which could be recovered in yields of up to 20% depending on the operating conditions. It seemed that not only the time of exposure to air but also the relative amount of water and acetone was important in determining the ratio between the Mo^V and Mo^{VI} products (see Discussion), smaller amounts of water seeming to favor a greater degree of oxidation. [Cp*MoO_2]$_2$ has been reported previously and shown to adopt two possible structures differing in the relative arrangement of the Cp* and terminal oxo ligands across the central Mo(μ-O)$_2$Mo plane: *syn* as in **I**[38] (like the analogous Cp system)[39] or *anti* as in **II**.[40] We have redetermined the structure of the *syn* form at lower temperature with a better precision. The results have been deposited with the CCDC but, since they do not differ significantly from those of the higher temperature structure, they are not explicitly reported here. The metal-metal distance in the *syn* polymorph [2.587(1) Å] is significantly shorter than that in the *anti* polymorph [2.647(3) Å],[40] undoubtedly because of the butterfly arrangement that allows the metals to approach each other, in contrast to the planar arrangement in the *anti* isomer. The same situation has been found for [(L)$_2Mo_2O_4$]$^{2+}$ (L = 1,5,9-triazacyclononane).[41,42]



I



II

Oxo Molybdenum(VI) and Molybdenum(V) Systems with Sterically more Encumbering Cyclopentadienyl Rings

Syntheses

The procedure described above for the Cp* system was applied in a straightforward manner to the hydrolysis of [^{4}CpMoCl$_4$] and [Cp′′′MoCl$_4$]. Again, aerial hydrolysis in both cases afforded solutions containing the water-soluble $Na^+[(Ring)MoO_3]^-$ salt. This was not isolated, but its presence was indicated by its behavior upon acidification, identical to that seen in the corresponding Cp* system described above. [^{4}Cp$_2$Mo$_2$O$_5$] and [Cp′′′$_2$Mo$_2$O$_5$] were obtained as yellow or yellow-orange crystalline solids that were insoluble in water but soluble in ether. Both were crystallized, and their structures were confirmed by X-ray diffraction methods (see next section). Like their Cp and Cp* analogues,[4,22] they displayed two IR vibrations typical of the Mo=O functionalities (symmetric and asymmetric at ca. 885 and 920 cm^{-1}, respectively) and one due to the asymmetric Mo−O−Mo stretch (at ca. 760 cm^{-1}).

While the ^{4}Cp system afforded the expected dinuclear Mo^{VI} product with no indication of incomplete oxidation, the Cp′′′ system behaved like the Cp* system described above and also gave a water-insoluble fraction, from which the dinuclear Mo^V complex [Cp′′′MoO$_2$]$_2$ was recovered. This compound was also characterized by X-ray diffraction methods (see below).

X-ray Structures of the [(Ring)$_2$Mo$_2$O$_5$] Compounds

Several X-ray structural determinations of various polymorphs of [Cp*$_2$Mo$_2$O$_5$][23−26] have been reported over the years and a discussion of the similarities between them is already available.[25] It is interesting to see whether the steric bulk of the cyclopentadienyl ligand plays any role on the other structural parameters. The geometries of compounds [^{4}Cp$_2$Mo$_2$O$_5$] and [Cp′′′$_2$Mo$_2$O$_5$] are shown in Figures 1 and 2, respectively, and the relevant metric data are compared in Table 1. The ^{4}Cp compound has a symmetry-imposed inversion center on the bridging oxygen atom, and two independent half molecules are contained in the asymmetric unit. The Cp′′′ compound, on the other hand, has a single entire molecule in the asymmetric unit. While the Mo−O−Mo angle is forced to be linear in the first case, it deviates quite substantially from linearity in the second one. This deviation is larger than the largest one previously observed for the related Cp* polymorphs [172.7(3)°]. The Mo=O and Mo-(μ-O) distances for the Cp* structures were found to be in the 1.67−1.72 Å and 1.85−1.90 Å ranges, respectively. The same parameters are within these ranges for both ^{4}Cp and Cp′′′ structures, the Mo-(μ-O) distances being towards the long end of this range in both cases.

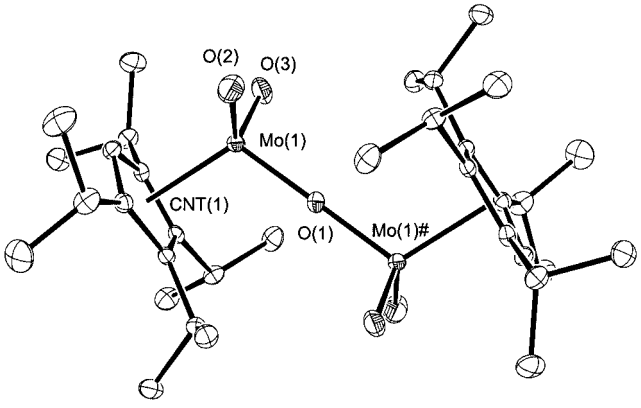


Figure 1. An ORTEP view of one of the two independent molecules of compound [^{4}Cp$_2$Mo$_2$O$_5$]; ellipsoids are drawn at the 50% probability level; the atom numbering scheme for the other molecule is as follows: Mo(2) for Mo(1), O(4) for O(1), O(5) for O(2), O(6) for O(3), and CNT(2) for CNT(1)

X-ray Structure of [Cp′′′MoO$_2$]$_2$

The geometry of [Cp′′′MoO$_2$]$_2$ is shown in Figure 3 and selected bonding parameters are reported in Table 2. The

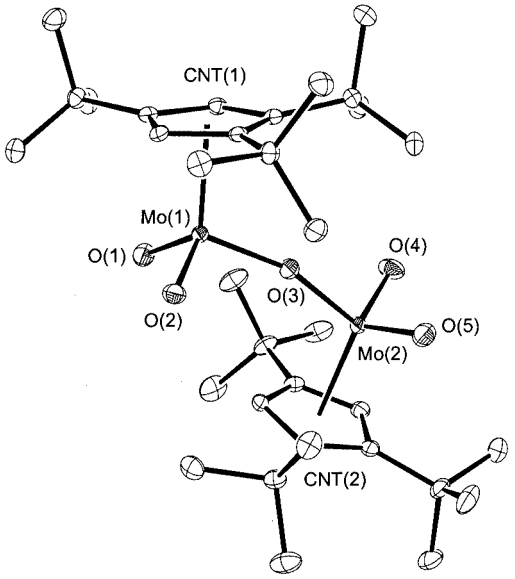

Figure 2. An ORTEP view of compound [Cp′′′$_2$Mo$_2$O$_5$]; ellipsoids are drawn at the 50% probability level

immediate striking feature is the relative *anti* arrangement of the two Cp′′′ groups: these are *syn* in the Cp analogue, while both arrangements are possible for the Cp* molecule. Although no unambiguous conclusion can be drawn, it seems reasonable to imagine that the steric bulk of the Cp′′′ ligand enforces the *anti* arrangement, while the compound might prefer the *syn* arrangement for electronic reasons. Therefore, the *syn* arrangement should be observed in the less crowded cases (such as Cp). It is easy to imagine how the placement of two Cp′′′ ligands into the *syn* structure (see drawing **I**) would introduce a severe strain in the molecule.

The Mo−Mo distance in [Cp′′′MoO$_2$]$_2$ compares quite well with that in the *anti* form of [Cp*MoO$_2$]$_2$ [2.647(3) Å].[40] This parameter is therefore much more sensitive to the geometry of the central Mo_2O_2 moiety (bent for the *syn* and planar for the *anti*) than to the type of cyclopentadienyl ring. The Mo=O and Mo-(μ-O) distances do not seem

sensitive to either effect, and are essentially identical to those of all other previously described molecules with this stoichiometry, whether *syn* or *anti*.

The $[^4CpMoO_2Cl]$ System

According to previous Cp* literature,[34] the aerobic hydrolysis of the tetrachloro compound with two equivalents of aqueous NaOH directly afforded the corresponding dioxochloro derivative. For the less electron-rich Cp system, on the other hand, excess water quite rapidly yielded the dioxo system, as seen above, even in the absence of base.[5] The ^{4}Cp system behaved similarly to the Cp*, to which it is sterically and electronically more similar. Identical yields of $[^4CpMoO_2Cl]$ were obtained when $[^4CpMoCl_4]$ was hydrolyzed in the presence of either three or two equivalents of NaOH. In the IR spectrum, the compound showed, as expected, Mo=O stretching vibrations essentially identical to those in the related oxo-bridged dinuclear complex and no band in the Mo−O−Mo stretching region. The structure of this product has also been confirmed by X-ray crystallography (see Figure 4); the relevant bond lengths and angles are reported in Table 3. While no structure for a $[(Ring)MoO_2X]$ (X = Cl or other halogen) seems to have been reported previously, related structures are those of $[\{C_5Ph_4[C_6H_3(OMe)_2\text{-}2,5]\}MoO_2(OMe)]$[43] and $[Cp^*MoO_2\{(2,6\text{-}i\text{Pr}_2C_6H_3)N(SiMe_3)\}_2Si_2O_2(OH)_3]$.[44] The Mo=O distances are quite similar in all these compounds. The Mo−Cl distance compares with related Mo^V−Cl distances and appears to be affected mostly by the steric pressure of the cyclopentadienyl ring, as suggested by the following examples: $[Cp^*MoOCl]_2O$: 2.368(2) Å,[31] $[CpMoOCl_2]$: 2.301(4) Å (average),[45] $[Cp^*MoOCl_2]$: 2.245(9) and 2.330(5) Å (averages) in two independent reports.[30,46]

Discussion

From the previous literature reports and from our results, the following simplified picture emerges for the aerobic hydrolysis of $[(Ring)MoCl_4]$ compounds (see Scheme 1). Hydrolysis of the first two Mo−Cl bonds affords $[(Ring)MoOCl_2]$, which can either undergo further hydrolysis to

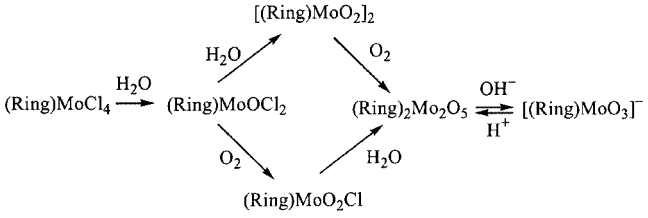
give $[(Ring)MoO_2]_2$ or may be oxidized to give $[(Ring)MoO_2Cl]$. Finally, the dioxo Mo^V dimer can be oxidized and the chlorodioxo Mo^{VI} complex can be hydrolyzed, to



Scheme 1

yield $[(Ring)_2Mo_2O_5]$ in both cases. Under basic conditions, however, the final product converts to the $[(Ring)MoO_3]^-$ anion. Of course, other intermediates must also be formed during these transformations, notably hydroxo complexes, the relative stability of which is supported by some evidence.[12,31,34]

If hydrolysis prevails over oxidation at the level of the first dichlorooxo intermediate, resulting in the dinuclear, metal-metal bonded dioxo compound $[(Ring)MoO_2]_2$, further oxidization by dioxygen to the Mo^{VI} dimer is rather difficult. This is what happens for the simple Cp system. In fact, even oxygen-delivering agents such as Ag_2O react with it slowly.[12] However, the kinetic red form is more reactive, and a successful strategy for the formation of $[Cp_2Mo_2O_5]$ with PhIO by this route is presented in this paper.

The rate of hydrolysis seems to decrease as the steric bulk of the cyclopentadienyl ring increases. The greater donating power of the bulkier rings may also retard the complete hydrolysis for electronic reasons. Oxidation of the dichlorooxo Mo^V species, on the other hand, should be made more favorable by more electron-rich ligands. At any rate, the oxidation step may then prevail over hydrolysis, resulting in the chlorodioxo Mo^{VI} species provided there is dioxygen available. This is the situation encountered for the Cp* system, for which aerobic hydrolysis in the presence of two equivalents of NaOH was reported to give a good yield of $[Cp^*MoO_2Cl]$.[34] The same also occurs for the ^4Cp system reported here with either two or three equivalents of NaOH. The use of neutral aqueous conditions should produce three acid equivalents, as shown in Equation (5). Evidently, the last chloride ligand is not hydrolyzed under neutral conditions, whereas at high pH (excess NaOH) the only recovered product (after acidification) is $[^4Cp_2Mo_2O_5]$.

$$2\,[^4CpMoCl_4] + 3\,H_2O + 1/2\,O_2 \rightarrow 2\,[^4CpMoO_2Cl] + 6\,Cl^- + 6\,H^+ \quad (5)$$

The relative rates of hydrolysis and oxidation for $[(Ring)MoOCl_2]$ should also depend on other factors such as the concentration of water, the nature of the organic solvent, and the pH. Although we have not carried out a comprehensive study of these effects, we do have qualitative indications that more Mo^V dimer complex is obtained when a

larger amount of water is used for the Cp* and Cp′′′ systems. If Scheme 1 is valid, one would expect that a greater concentration of OH^- (larger NaOH excess) should favor the hydrolysis pathway, resulting in the $[(Ring)MoO_2]_2$ system. Indeed, we did obtain a significant amount of this compound as a by-product when the hydrolysis was carried out in the presence of more than five equivalents of NaOH, whereas a good yield of $[Cp^*MoO_2Cl]$ was obtained by Geoffroy et al. with only two equivalents, with no mention of formation of the Mo^V product.[34] Indeed, repetition of the synthesis of $[Cp^*_2Mo_2O_5]$ by stepwise addition of three equivalents of NaOH, followed by three more equivalents a day later (without isolation of the intermediate $[Cp^*MoO_2Cl]$ complex) completely avoided the formation of the $[Cp^*MoO_2]_2$ by-product.

Some subtleties, however, are not yet completely understood. For instance, the Mo^V dimer was obtained for the Cp′′′ system, as for the Cp* system, but no analogous product was obtained for the ^{4}Cp system, even when five equivalents of NaOH were used. The use of excess NaOH, however, allows access (provided that the oxidation route is followed) to the water-soluble sodium salts of $[(Ring)MoO_3]^-$. Although we have not isolated and characterized the new anions of this type for the ^{4}Cp and Cp′′′ systems, their formation is indicated by the protonation reactivity, which is identical to that of the Cp* system: acidification of the water solutions yields the yellow, water-insoluble $[(Ring)_2Mo_2O_5]$ products.[36]

Conclusion

High oxidation state monocyclopentadienyl oxo derivatives of molybdenum are often the end products of oxidative decompositions of lower valent derivatives and were previously available only in low yields or through the use of impractical starting materials and/or reagents. The hydrolytic route from the easily accessible cyclopentadienylmolybdenum(V) tetrachlorides has been optimized and extended to the preparation of new compounds with sterically more encumbered rings. The stability of these compounds in air and aqueous media makes the exploration of their aqueous chemistry and electrochemistry possible. Investigations in those directions are ongoing in our laboratory.

Experimental Section

General Remarks: All reactions were carried out in a Jacomex glove box or by use of standard Schlenk techniques under an argon atmosphere. The solvents were dried by conventional methods (THF, Et_2O, heptane, and pentane from sodium benzophenone ketyl and CH_2Cl_2 from P_4O_{10}) and distilled under argon prior to use. EPR measurements were carried out at the X-band microwave frequency on a Bruker ESP300 spectrometer. The spectrometer frequency was calibrated with DPPH (g = 2.0037). ^{1}H NMR spectra were recorded on a Bruker AC 200 and referenced to the residual solvent protons of the deuterated solvent. The elemental analyses were carried out by the analytical service of the Laboratoire de Synthèse et d′Electrosynthèse Organométallique with a Fisons EA 1108 apparatus. The compounds $[(Ring)MoCl_4]$ (Ring = Cp, Cp* and ^{4}Cp) were prepared as described in the literature.[19,37,47] The compound $[Cp'''MoCl_4]$ was prepared by a straightforward adaptation of those procedures as described below.

Tetrachloro(1,2,4-tri-*tert*-butylcyclopentadienyl)molybdenum(V), $[Cp'''MoCl_4]$: $Mo(CO)_6$ (2.64 g, 10.0 mmol) and $NaCp'''$ (2.66 g, 10.3 mmol) were mixed as solids and suspended in 40 mL THF. The suspension turned into an orange solution during a 10 min period. It was then heated under reflux for 18 h. IR monitoring indicated the formation of $[Cp'''Mo(CO)_3]^-Na^+$ (strong peaks at 1885, 1784 and 1736 cm^{-1}, similar to literature values for the Cp* analogue). After the mixture had cooled to room temperature, MeI (700 μL, 11.25 mmol) was added to the deep orange-red solution, causing darkening to brown. After additional heating under reflux for 3 h, the solvent was removed in vacuo to leave a yellow brown residue, which was extracted into 60 mL CH_2Cl_2. After filtration, the deep-orange solution was evaporated to dryness to yield 4.13 g (9.64 mmol; 96.4%) of yellow-brown $[Cp'''Mo(CO)_3Me]$.

A portion of this product, (3.11 g, 7.26 mmol) was dissolved in 40 mL CH_2Cl_2. A suspension of $PhICl_2$ (4.99 g, 18.2 mmol) in 50 mL CH_2Cl_2 was added in small portions, causing a darkening of the orange brown solution to brown and then to deep violet with vigorous CO evolution. After having been heated under reflux for 90 min, the mixture was allowed to cool to room temperature and the solvents were evaporated to dryness. The violet black residue was washed with 2 × 20 mL pentane to remove the iodobenzene by-product. The deep violet solid $[Cp'''MoCl_4]$ was dried in vacuo. Yield 3.21 g, (93.7%). $C_{17}H_{29}Cl_4Mo$ (471.2): calcd. C 43.34, H 6.20; found C 43.57, H 6.44. EPR (CH_2Cl_2): g = 1.99, a_{Mo} = 38.2 G.

Tetraoxo-μ-oxodicyclopentadienyldimolybdenum(VI), $[Cp_2Mo_2O_5]$: $[CpMoCl_4]$ (0.555 g, 1.83 mmol) was placed in a flask containing distilled water (10 mL). Shaking of the resulting suspension for a few minutes gave rise to the formation of fine, deep red microcrystals. The product $([CpMoO_2]_4)$[12] was separated by decantation of the mother liquor, washed with water (3 × 10 mL) and quickly with acetone (5 mL), and dried in vacuo for 2 h (yield 0.28 g, 79.5%). This material (1.45 mmol of Mo) was then dissolved in dichloromethane (ca. 100 mL), and solid PhIO (0.22 g, 1.0 mmol) was added to the resulting solution. The mixture was stirred at room temperature for 15 min, resulting in a color change from red to yellow. A longer reaction time should be avoided as it affords larger amounts of insoluble by-products. The solution was filtered and the filtrate was evaporated to give yellow microcrystals. The product was purified by recrystallization from CH_2Cl_2/pentane, and dried in vacuo. Yield 0.207 g, 71.1% (56.5% from $[CpMoCl_4]$). The analytical (IR, NMR) properties of the compound corresponded to those reported in the literature[4] and confirmed its purity.

Tetraoxo-μ-oxobis(pentamethylcyclopentadienyl)dimolybdenum(VI), $[Cp^*_2Mo_2O_5]$ and Dioxodi-μ-oxobis(pentamethylcyclopentadienyl)dimolybdenum(V), $[Cp^*MoO_2]_2$: Deep violet $[Cp^*MoCl_4]$ (3.48 g; 9.33 mmol) was added to a stirred solution of aqueous NaOH (19 mL; 3 M; 57 mmol) in acetone (200 mL) in an open beaker. The resulting dark brown suspension was stirred for 18 h, resulting in a lightening of the color to orange and the precipitation of a pale yellow solid. After evaporation to dryness the brownish residue was extracted into 75 mL of distilled water and filtered. The pale yellow filtrate was acidified with diluted glacial acetic acid, causing precipitation of a yellow solid at pH 3.8−4.0. The acetic acid addition was stopped when the addition of one further drop did not cause

any additional precipitation. The precipitate was extracted with 4 × 100 mL portions of ether, the last extract being colorless. The combined organic layers were washed with distilled water and dried over $MgSO_4$ overnight. Evaporation of the solvent yielded 1.55 g (2.86 mmol; 61.3%) of $[(Cp^*MoO_2)_2O]$ as a yellow solid. The ^1H NMR spectrum of this compound (singlet at δ = 2.01 in $CDCl_3$) corresponded to that described in the literature.[26]

In another experiment, starting from 2.03 g of $[Cp^*MoCl_4]$, the water-insoluble orange-red solid remaining from the water extraction was also worked up. It was washed with 20 mL ether and then with 20 mL pentane, and was dried in vacuo to afford the dinuclear Mo^V compound $[(Cp^*MoO_2)_2]$ as an orange, crystalline solid (192 mg, 0.37 mmol; 13.6%). $C_{10}H_{15}MoO_2$ (263.2): calcd. C 45.64, H 5.74; found C 45.36, H 5.71. The ^1H NMR spectrum (δ = 1.98 in $CDCl_3$) corresponded to that reported in the literature.[38] Suitable single crystals for X-ray diffraction could be grown by layering a saturated THF solution with heptane at room temperature. Normally up to ca. 20% of this by-product was recovered, depending on the reaction conditions.

Tetraoxo-μ-oxobis(tetraisopropylcyclopentadienyl)dimolybdenum(VI), $[^4Cp_2Mo_2O_5]$: Deep purple $[^4CpMoCl_4]$ (609 mg, 1.29 mmol) was quickly added, as a solid, to a stirred mixture of acetone (75 mL), THF (75 mL) and aqueous NaOH (2.6 mL, 3 M, 7.8 mmol) in an open beaker. A brown suspension formed immediately, which lightened to orange yellow over a period of 2 h. After the mixture had been stirred overnight, the solvents were evaporated and the resulting yellow residue was extracted with 100 mL of warm water (50 °C). After filtration, the aqueous phase was acidified with diluted glacial acetic acid as described in the previous section, causing the precipitation of a yellow solid at pH 4. Extraction of this solid with 3 × 100 mL portions of ether, followed by separation of the organic layer, washing with water, and drying over $MgSO_4$, yielded a yellow ether solution, which was allowed to stand overnight and then was evaporated to dryness to yield 222 mg (0.3 mmol; 46.6%) of yellow $[(^4CpMoO_2)_2O]$. $C_{34}H_{58}Mo_2O_5$ (738.7): calcd. C 55.28, H 7.91; found C 54.69, H 8.25. IR (Nujol mull): $\tilde{\nu}$ = 919 s, 889 s, 760 s cm^{-1}. ^1H NMR ($CDCl_3$): δ = 6.01 (s, 1 H, ring-H), 3.10 (m, 4 H, C*H*Me_2), 1.39 [d, $J_{H,H}$ = 7.3 Hz, 6 H, CH(CH_3)$_2$], 1.30 [d, $J_{H,H}$ = 7.3 Hz, 12 H, CH(CH_3)$_2$], 1.19 [d, $J_{H,H}$ = 6.7 Hz, 6 H, CH(CH_3)$_2$]. ^1H NMR (C_6D_6): δ = 6.14 (s, 1 H, ring-H), 3.14 (m, 4 H, C*H*Me_2), 1.47 [d, $J_{H,H}$ = 6.7 Hz, 6 H, CH(CH_3)$_2$], 1.44 [d, $J_{H,H}$ = 7.0 Hz, 6 H, CH(CH_3)$_2$], 1.23 [d, $J_{H,H}$ = 7.0 Hz, 6 H, CH(CH_3)$_2$], 1.02 [d, $J_{H,H}$ = 7.0 Hz, 6 H, CH(CH_3)$_2$]. The ^1H NMR spectrum did not show any detectable Mo^V by-product. Yellow-orange single crystals suitable for X-ray diffraction were grown by slowly cooling a hot saturated heptane solution to room temperature.

Attempted Synthesis of Dioxodi-μ-oxobis(tetraisopropylcyclopentadienyl)dimolybdenum(V), $[^4CpMoO_2]_2$: $[^4CpMoCl_4]$ (670 mg, 1.42 mmol) was added to 150 mL of a stirred 1:1 mixture of acetone and distilled water, immediately yielding a brown suspension. The mixture was stirred for 40 hours, during which aliquots were withdrawn and the solid was separated, washed with water, and investigated by ^1H NMR spectrosopcy, showing the spectrum of $[^4Cp_2Mo_2O_5]$ as the only NMR-active species. The final mixture was filtered and the solid was washed with water and redissolved in pentane. After evaporation of the solvent, the residue was dried in vacuo to leave 240 mg (0.33 mmol; 46.8%) of $[^4Cp_2Mo_2O_5]$ as a orange powder (confirmed by ^1H NMR spectroscopy). Orange-red crystals could be grown by slowly cooling a hot saturated heptane solution to room temperature or by cooling a pentane solution to −25 °C. A single crystal from this batch showed the same unit cell as that of the yellow-orange crystals obtained from the procedure in the previous section.

Tetraoxo-μ-oxobis(1,2,4-tri-*tert*-butylcyclopentadienyl)dimolybdenum(VI), $[Cp'''_2Mo_2O_5]$ and Dioxodi-μ-oxobis(pentamethylcyclopentadienyl)dimolybdenum(V), $[Cp'''MoO_2]_2$: Purple $[Cp'''MoCl_4]$ (1.36 g, 2.89 mmol) was added to a stirred mixture of THF (75 mL), acetone (75 mL), water (10 mL) and aqueous NaOH (5.7 mL, 3 M, 17.1 mmol) in an open beaker. Some foaming occurred, and a Bordeaux-red solution formed immediately. No precipitate was detected during the following 24 hours of stirring at room temperature. Subsequent gentle heating (40−50 °C) of the mixture for two hours caused the precipitation of a red-violet product, which was collected on a filter, washed with water, and redissolved in THF. The solvents were evaporated to dryness to leave the Mo^V dimer $[(Cp'''MoO_2)_2]$ as the main product. Yield: 380 mg (0.53 mmol, 36.7%). $C_{17}H_{29}MoO_2$ (361.4): calcd. C 56.51, H 8.09; found C 56.72, H 8.12. IR (Nujol mull): $\tilde{\nu}$ = 922 s, 885 s, 764 vs cm^{-1}. ^1H NMR (C_6D_6): δ = 6.43 (s, 2 H, ring-H), 1.46 (s, 18 H, CMe_3 1,2-positions), 1.37 (s, 9 H, CMe_3 4-position). Suitable single crystals were grown by slowly cooling a hot saturated heptane solution to room temperature.

The orange-yellow filtrate was collected and the solvents were evaporated to dryness. The resulting yellow residue was extracted with 70 mL of distilled water and the extract was acidified with diluted glacial acetic acid to pH 4, as described above for the Cp* analogue. The yellow solid that precipitated was extracted with several portions of ether, and the combined organic layers (300 mL) were washed with 200 mL of distilled water and dried over $MgSO_4$. The lustrous yellow ether phase was allowed to stand overnight and was then evaporated to dryness, yielding 120 mg (0.16 mmol. 11.2%) of yellow $[(Cp'''MoO_2)_2O]$. $C_{34}H_{58}Mo_2O_5$ (738.7): calcd. C 55.28, H 7.91; found C 55.04, H 7.94. ^1H NMR (C_6D_6): δ = 5.63 (s, 2 H, ring-H), 1.58 (s, 18 H, CMe_3 1,2-position), 1.48 (s, 9 H, CMe_3 4-position). Suitable single crystals were grown by slowly cooling a hot saturated heptane solution to room temperature.

Alternative Route to Pure $[Cp'''_2Mo_2O_5]$: Acetone (120 mL) was mixed with an aqueous NaOH solution (6.6 mL, 3 M, 19.8 mmol). Purple $[Cp'''MoCl_4]$ (1.55 g, 3.29 mmol) was added, producing a deep red solution, followed by the supernatant slowly turning orange with formation of a white yellow precipitate within a 3 h period. After the mixture had been stirred overnight, all solvents were evaporated under reduced pressure and the yellowish residue was extracted with 100 mL of water and layered with 100 mL of ether. The ether layer remained colorless until the aqueous one was acidified with diluted acetic acid, causing the formation of a lustrous yellow precipitate, which was extracted by the ether. After addition of the last traces of acid to give rise to further precipitation, the aqueous phase was clear and colorless. The ether phases was washed three times with distilled water and dried over $MgSO_4$ overnight. Evaporation to dryness gave 890 mg (1.20 mmol, 73.2%) of orange-yellow $[Cp'''_2Mo_2O_5]$ without any detectable Mo^V by-product.

Chlorodioxo(tetraisopropylcyclopentadienyl)molybdenum(VI), $[^4CpMoO_2Cl]$: Aqueous NaOH (2.89 mL, 3 M, 8.67 mmol) was added to 250 mL of acetone. After addition of solid $[^4CpMoCl_4]$ (1.362 g, 2.89 mmol) the solution turned red and a white precipitate was formed. Stirring overnight changed the color of the supernatant to a bright yellow-orange. All solvents were removed in vacuo, leaving a yellow residue that was extracted with 200 mL of pentane. This pentane solution was dried over Na_2SO_4 and filtered, and the solvents were evaporated to dryness to leave 1.0 g of a yellow-or-

ange solid (2.52 mmol, 87%), which was then recrystallized from a saturated heptane solution at −30 °C. $C_{17}H_{29}ClMoO_2$ (396.8): calcd. C 51.45, H 7.36; found C 51.04, H 7.87. IR (Nujol mull): $\tilde{\nu}$ = 920 s, 890 s cm^{-1}. ^1H NMR ($CDCl_3$): δ = 6.06 (s, 1 H, ring-H), 3.14 (m, 4 H, C*H*Me_2), 1.40 [d, $J_{H,H}$ = 7.4 Hz, 6 H, CH(CH_3)$_2$], 1.35 [d, $J_{H,H}$ = 7.3 Hz, 6 H, CH(CH_3)$_2$], 1.31 [d, $J_{H,H}$ = 6.7 Hz, 6 H, CH(CH_3)$_2$], 1.25 [d, $J_{H,H}$ = 7.0 Hz, 6 H, CH(CH_3)$_2$]. A single crystal suitable for X-ray analysis was grown by slowly cooling a hot saturated heptane solution to room temperature. The same reaction was found to take place with just two equivalents of NaOH used, yielding the same product in an identical overall yield.

X-ray Crystallographic Study: The crystal and refinement parameters for all structures are listed in Table 4. All sets of data were collected on an Enraf−Nonius KappaCCD diffractometer at 110 K, using Mo-K_α radiation. The structures were solved by means of a Patterson search program[48] and refined with full-matrix, least-squares methods[49] based on $|F^2|$ with the aid of the WINGX program.[50] All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were located on final Fourier difference maps and freely refined with isotropic temperature factors fixed to 1.2 or 1.5 (for CH_3) times those of the corresponding parent atoms. Selected bond lengths and angles are listed in Table 1 for both independent molecules of [$^4Cp_2Mo_2O_5$] and for [Cp′′′$_2$$Mo_2O_5$], in Table 2 for [Cp′′′$MoO_2$]$_2$, and in Table 3 for [^{4}CpMoO_2Cl]. CCDC-173139−173143 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We are grateful to the Ministère de la Recherche and the CNRS for support through UMR 5632 and the French and German Ministries of Foreign Affairs for a bilateral Procope grant. DS thanks the Conseil Régional de Bourgogne for a postdoctoral fellowship and FD thanks the Scientific and Technical Research Council of Turkey (TUBITAK) for a NATO Science Fellowship Programme scholarship, and Celal Bayar University for a leave of absence.

[35] On the other hand, it is interesting to note that the use of excess aqueous NaOH in the hydrolysis reaction of [Cp*WCl_4] does not induce displacement of the residual chloride ligand in [Cp*WO_2Cl].[34]
[36] In reality, the aqueous behavior is even more complex and interesting. A detailed study of the aqueous speciation of the Cp*Mo^{VI} system over the entire pH range will be the topic of a separate report.[10]

Solvent-Free Lanthanoid Complexes Derived From Chelation-Supported Organoamide Ligands[‡]

Glen B. Deacon,*[a] Craig M. Forsyth,[a] and Natalie M. Scott[a]

Keywords: N,O ligands / Lanthanides / Halides / Metathesis / Structure elucidation

Treatment of $LnCl_3$ with three molar equivalents of LiL [(L = *N*-(2-methoxyphenyl)-*N*-(trimethylsilyl)amide (L^1) or *N*-(2-phenoxyphenyl)-*N*-(trimethylsilyl)amide (L^2)], generated in situ from LH and *n*BuLi, or with the isolated lithium complex $[Li(L^1)(OEt_2)]_2$ (for Ln = Yb) in THF afforded the solvent-free homoleptic complexes $[Ln(L)_3]$ [Ln = Yb (**1a**), Er (**1b**), Sm (**1c**), Pr (**1d**), Nd (**1e**), L = L^1; Ln = Yb (**2a**), Y (**2b**), Sm (**2c**), Nd (**2d**), La (**2e**), L = L^2). With a 2:1 LiL (generated in situ) to $LnCl_3$ molar ratio, the solvent-free heteroleptic complexes $[Ln(L)_2(\mu\text{-}Cl)]_2$ were obtained for L = *N*,*N*-dimethyl-*N*′-trimethylsilylethane-1,2-diaminate (en′) [Ln = Yb (**3a**), Er (**3b**), Sm (**3c**), Nd (**3d**), La (**3e**)], but not for L^1 or L^2, which gave $[Ln(L)_3]$ [Ln = Yb (**1a**), Nd (**1e**), L = L^1; Ln = Yb (**2a**), Nd (**2d**), La (**2e**), L = L^2]. However, treatment of $LnCl_3$ with two molar equivalents of the isolated crystalline lithium salt $[Li(L^1)(OEt_2)]_2$ in THF gave, for the heavier lanthanoids, the solvent-free heteroleptic complexes $[Ln(L^1)_2(\mu\text{-}Cl)]_2$ [Ln = Yb (**4a**), Er (**4b**), Tb (**4c**)], although the homoleptic complex $[Nd(L^1)_3]$ (**1e**) was obtained for Nd. In contrast, similar reactions of isolated $[Li(L^2)(DME)]$ with $LnCl_3$ yielded the heteroleptic species $[Ln(L^2)_2(\mu\text{-}Cl)]_2$ only for Ln = Nd [**5a**·$(PhMe)_2$]. At either end of the Ln series, the homoleptic $[Ln(L^2)_3]$ complexes [Ln = Yb(**2a**), La (**2e**)] were obtained. Single crystal X-ray analyses of **1e** or **2a**–**2e** (as their PhMe or C_5H_9Me solvates) showed these complexes to be monomeric and six-coordinate (*mer* isomer), whereas the heteroleptic complexes **4a**–**4c**, **5a** were found to be dimeric with bridging chloride atoms. Two chelating $[L^1]^-$ or $[L^2]^-$ units [*trans* O(Me/Ph) and *cis* amido groups] are bound to each lanthanoid centre completing a six-coordinate very distorted octahedral environment. The X-ray structure of $[Li(L^1)(OEt_2)]_2$ revealed a dimeric structure with each lithium four-coordinate and surrounded by one diethyl ether, two bridging amide nitrogens and a methoxy oxygen in a distorted tetrahedral array.

Introduction

The $6e^-$ donor cyclopentadienyl ligand (Cp) has been extensively used as a coligand with early transition metals for various types of catalytic transformations. Important applications include highly active group 4 and 5 metal and lanthanoid organometallic compounds in homogeneous Ziegler−Natta alkene polymerisation.[2−7] In the last decade an increasing number of investigators have turned their attention away from cyclopentadienyl ligands to find alternative systems to stabilise the metal-carbon bond for catalytic work.[7−9] Alternative systems using alkoxide and amide ligands in place of Cp have shown similar reaction chemistry with the stabilisation of early electron-deficient transition metals in medium to high oxidation states.[6,7,9−14] Of these two alternatives, greater opportunities for substituent variation exist for the amide ligand. There are numerous N-containing ligands that can stabilise heteroleptic lanthanoid complexes, such as bis(trimethylsilyl)amide,[15−18] benzamidinates,[19−21] aminotropiminates[22,23] and diazabutadienes.[24] These bulky ligands can block coordination sites around the metal centre leading to monomeric, hydrocarbon soluble, electron-poor species that display unique chemical properties. However, in comparison to the stability offered by the cyclopentadienyl ligand in $[Ln(Cp)_2(X)]$ (X = anion), the labile nature of organoamide ligands in such systems has often caused ligand redistribution, resulting in the isolation of homoleptic derivatives.[7,15,22,25,26] The incorporation of a supporting donor atom to give a bidentate amide ligand may improve the stability of the heteroleptic complexes. Encouragement for this idea came from the observation that *N*,*N*-dimethyl-*N*′-trimethylsilylethane-1,2-diaminate (en′) gave not only the homoleptic complexes $[Ln(en')_3]$ (Ln = Lu, Er, Eu, Sm, Nd, La) but also a single example of a heteroleptic derivative $[Er(en')_2Cl]$.[27] We now report a study of the use of the two new mixed N,O-donor bidentate amide ligands *N*-(2-methoxyphenyl)-*N*-(trimethylsilyl)amide (L^1)[28] and *N*-(2-phenoxyphenyl)-*N*-(trimethylsilyl)amide (L^2)[28,29] for preparing $[Ln(L)_3]$ and $[Ln(L)_2Cl]$ complexes, and extend the en′ heteroleptic series to lanthanoids other than Er. Previous studies on lanthanoid complexes containing the L^1 and L^2 ligands have shown them to be capable of supporting

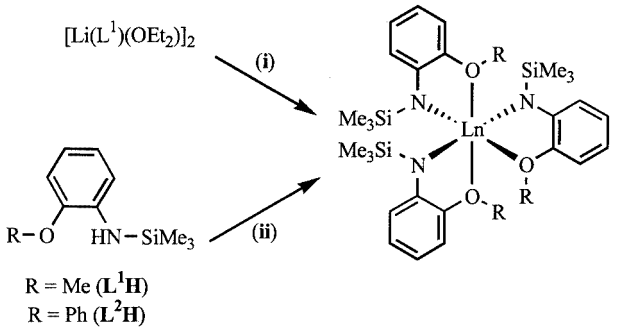
organo-oxo heteroleptic complexes viz. $[Yb(L^1)_2(\mu\text{-}OMe)]_2$ and $[Yb(L^2)_2(OPh)(THF)]$ (THF = tetrahydrofuran).[28]

Results and Discussion

A range of $[Ln(L)_3]$ complexes [L = L^1, Ln = Yb (**1a**), Er (**1b**), Sm (**1c**), Pr (**1d**), Nd (**1e**); L = L^2, Ln = Yb (**2a**), Y (**2b**), Sm (**2c**), Nd (**2d**), La (**2e**)] were prepared by treatment of $LnCl_3$ with three molar equivalents of LiL as the isolated $[Li(L^1)(OEt_2)]_2$ [Scheme 1 (i)] or generated in situ from the reaction of LH with *n*BuLi in THF [Scheme 1 (ii)]. The crystalline complexes $[Ln(L^1)_3]$ [Ln = Yb (**1a**), Er (**1b**), Sm (**1c**), Pr (**1d**), Nd (**1e**)] were isolated from hexane in good yield after removal of the precipitated LiCl. The $[Ln(L^2)_3]$ complexes [Ln = **2a**·(PhMe), **2a**·(C_5H_9Me) (from a 1:2 mol ratio synthesis − see below), **2b**·(C_5H_9Me), **2c**·(PhMe), **2d**·$(PhMe)_2$, **2e**·(PhMe)] were obtained by crystallisation of the bulk products from toluene. Whilst toluene solvates are not unusual, the isolation of methylcyclopentane solvates (as identified from X-ray crystallography) was unexpected. The latter are presumed to be derived from a trace impurity in one of the solvents (PhMe or hexane) used. Crystallisation of **2e**·(PhMe) from diethyl ether gave $[La(L^2)_3]$ (**2e**), which was used for an X-ray determination, whilst single crystals of solvent-free $[Nd(L^2)_3]$ (**2d**) were obtained by crystallisation of **2d**·$(PhMe)_2$ from hexane.



Scheme 1. Reagents and conditions: (i) THF, 0.33 equivalents of $YbCl_3$ followed by crystallisation from hexane (**1a**); (ii) *n*BuLi, THF, 0 °C, 0.33 equivalents of $LnCl_3$ followed by crystallisation from hexane (**1b**−**1e**) or toluene (**2a**·(PhMe), **2a**·(C_5H_9Me) (0.50 equivalents of $YbCl_3$), **2b**·(C_5H_9Me), **2c**·(PhMe), **2d**·$(PhMe)_2$, **2e**·(PhMe)]

Satisfactory elemental analyses (C, H N) were obtained for all of the homoleptic complexes although crystallographically characterised unsolvated **2e** was not examined as the corresponding toluene solvate was obtained analytically pure. In the case of **2a**·(C_5H_9Me) the analysis fitted for solvent-free $[Yb(L^2)_3]$ hence the methylcyclopentane was evidently removed from the lattice on drying the sample under vacuum. The corresponding undried yttrium complex analysed as the solvate. The infrared spectra of the complexes were virtually identical within each series and indicated the presence of coordinated L^1 or L^2 in accordance with the proposed compositions. For **2a**·(PhMe), **2c**·(PhMe), **2d**·$(PhMe)_2$ and **2e**·(PhMe) the presence of toluene could not be detected by infrared spectroscopy due to the large number of ligand bands. Asymmetric C−O−C stretching for $[Ln(L^1)_3]$ [Ln = Yb (**1a**), Er (**1b**), Sm (**1c**), Pr (**1d**), Nd (**1e**)] gives two sets of two bands while for L^1H only one set is observed.[28] For $[Ln(L^2)_3]$ [Ln = Yb {**2a**·(PhMe), **2a**·(C_5H_9Me)}, Y {**2b**·(C_5H_9Me)}, Sm {**2c**·(PhMe)}, Nd {**2d**·$(PhMe)_2$}, La {**2e**·(PhMe)}] this region displays three sets of two absorptions. This feature is different from the behaviour of L^2H, which displays only two sets of two absorptions in this region.[28] Generally, the ^1H NMR spectroscopic data for **1e**, **2b**·(C_5H_9Me), **2c**·(PhMe), **2d**·$(PhMe)_2$, **2e**·(PhMe) and **2e** indicate that one L environment is present in solution, in contrast to the two L environments observed in the solid state (see below). Presumably the ligands are rapidly exchanging under these conditions. Characteristic toluene resonances were observed for the **2c**−**2e**·$(PhMe)_n$ complexes and confirmed the number of toluene molecules of crystallisation per $[LnL_3]$ indicated by microanalysis. For **2b**·(C_5H_9Me) the ^1H NMR spectrum is consistent with the presence of methylcyclopentane,[30] although the integration indicated only half a methylcyclopentane molecule per $[Y(L^2)_3]$. However, the X-ray structure determination and elemental analyses indicated one C_5H_9Me per yttrium. Whilst the ^1H NMR spectrum of **1e** is similar to that of **2d**·$(PhMe)_2$ for structurally common protons, the paramagnetic behaviour of Nd^{3+} causes most backbone aromatic resonances on L^1 or L^2 to shift considerably from those of diamagnetic **2e** (see Exp. Sect.). In the mass spectra of **1c** and **1e**, the highest metal-containing fragment was attributable to the parent ion $[Ln(L^1)_3]^+$; loss of the groups $SiMe_3$ and OMe or OPh from the molecular ion was observed for **1b**, **2a**·(PhMe) or **2a**·(C_5H_9Me). The mass fragment $[Ln(L^1)_2]^+$ was observed in the spectra of all three complexes, as well as the metal-free fragment $[L^1H]^+$. The mass spectra of **2b**·(C_5H_9Me) and **2c**·(PhMe) showed a weak molecular ion $[Ln(L^2)_3]^+$ and associated fragment ions (notably $[Ln(L^2)_2]^+$ and $[Ln(L^2)]^+$) as well as an intense $[L^2H]^+$ ion. However for **2e**·(PhMe) the highest mass ion observed was $[La(L^2)_2]^+$. The UV/Vis/NIR spectrum of a solution of **1a** in DME exhibited absorptions characteristic of *f*←*f* transitions of the Yb^{3+} cation[31] near 1000 nm.

Single crystal X-ray diffraction data were collected for **1e** (Figure 1), **2a**·(PhMe) (Figure 2), **2d** and **2e**. Data were also obtained for **2a**·(C_5H_9Me) and **2b**·(C_5H_9Me) and have been deposited with the Cambridge Crystallographic Data Centre (CCDC-174206/7). Selected bond lengths and angles for **1e**, **2a**·(PhMe), **2b**·(C_5H_9Me), **2d** and **2e** are given in Table 1. Each of the molecules is monomeric with a six-coordinate metal centre surrounded by three bidentate L ligands (L = L^1 or L^2) with the bulky amido groups arranged in a *meridional* configuration. The geometry is best described as a distorted octahedron (best-fit polyhedron[32]) with the oxygen atoms [O(1) and O(3)], nitrogen atoms [N(1) and N(2)], and the other donor pair [O(2) and N(3)] occupying *transoid* sites. The *mer* arrangement of the L^1 or L^2 ligands differs from that of the closely related complex $[Ln(en')_3]$ (en′ = *N,N*-dimethyl-*N*′-trimethylsilylethane-1,2-diaminate)[27] which has a *fac* orientation of the bidentate

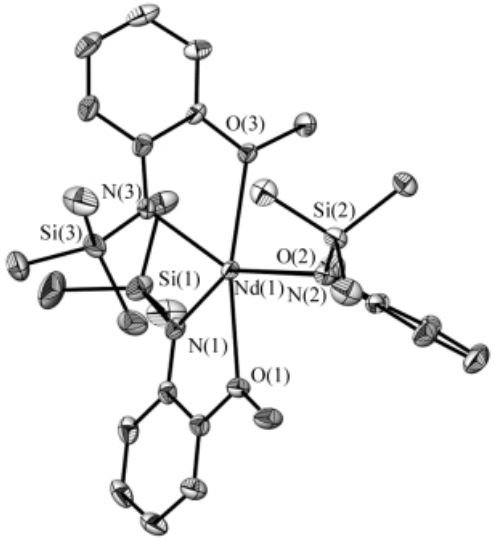


Figure 1. ORTEP view of $[Nd(L^1)_3]$ (**1e**) drawn with 50% ellipsoids; hydrogen atoms have been omitted for clarity

en′ amide ligands. The latter was unexpected since the very bulky $NSiMe_3$ groups are all in a *cis* disposition. Thus the N−Ln−N angles lie in the range [104.8(5)−109.0(1)°] for $[Ln(en')_3]$ (Ln = Lu, Er, Eu)[27] whereas **1e**, **2a**·(PhMe), **2d** and **2e** have two similar angles but one larger *transoid* angle (Table 1). Even with the *mer* configuration, two of the $NSiMe_3$ groups are pushed above and below the equatorial plane presumably to reduce steric repulsion from the otherwise closely proximate bulky amides. The less sterically dominating O(Me/Ph) groups occupy the *trans* sites with O(1)−Ln(1)−O(3) angles verging on linear, although the angles between the remaining *transoid* donors N(1)−Ln−N(2) and N(3)−Ln−O(2) are significantly less than 180°. This is presumably due to a combination of the small bite angle of the chelated L^1 or L^2 ligands and the proximity of the *cis* amide groups.

The geometry of $[Nd(L^2)_3]$ is almost identical to that of $[Nd(L^1)_3]$ with the angles defining the coordinated atoms differing by less than 10° (Table 1). Whilst the general appearance of the $[Ln(L^2)_3]$ complexes is the same, significant differences are apparent between the solvated and solvent-free structures. The *trans* N−Ln−N angles for unsolvated **2d** and **2e** are approximately 12° smaller than those for **2a**·(PhMe) and **2b**·(C_5H_9Me), and a similar, but less marked, trend is also observed for the *cis* N−Ln−N angles (Table 1). Thus the solvates are closer to a regular octahedral structure. These differences are clearly not due to the gradual change in ionic radii from La (1.03 Å) to Yb (0.87 Å).[33] For example, the smaller elements would be expected to be more sterically crowded causing a widening of the *cis* N−Ln−N angles through greater repulsion between the bulky $SiMe_3$ groups. In fact the opposite is observed. However, the *cis* N−Ln−N angles are not unreasonably narrow and still compare well with those of *fac*-$[Ln(en')_3]$.[27] Therefore the variation in angles is possibly associated with differences in the crystal packing required to accommodate solvent molecules.

A comparison of the metal-nitrogen distances with those of other lanthanoid organoamides can be made by subtraction of the appropriate metal ionic radius (Table 2).[33] Selected examples from the literature are listed in Table 2 and the values derived for the current $[Ln(L)_3]$ complexes (L^1: 1.37−1.40 Å, L^2: 1.36−1.43 Å) lie near the middle of the observed range (1.34−1.49 Å) and are therefore not unusual. For **1e**, **2a**·(PhMe) and **2b**·(C_5H_9Me) there is some variation in the Ln−N distances with one shorter [Ln(1)−N(3)] and two longer bonds, whereas the three Ln(1)−N(amide) bond lengths of **2d** and **2e** are very similar (Table 1). Whilst bond lengthening of the mutually *trans* amides might be expected, this is not observed for any of the complexes. Perhaps the inconsistently shorter Ln−N(3) distance reflects extraneous factors, for example packing forces. Subtraction values derived from the Ln−O distances (1.48−1.60 Å) are significantly longer than those derived from organolanthanoid or halolanthanoid ether complexes [$LnR_3(ether)_n$: 1.34 ± 0.05 Å);[34] $LnX_3(THF)_n$: 1.39−1.44 Å][35] but the Nd−O distances are shorter than those [2.614(4)−2.740(4) Å] in the related neodymium bidentate amide complex $[Nd\{Me_2Si(OtBu)(NtBu)\}_3]$.[36] The ether fragments of $[Nd\{Me_2Si(OtBu)(NtBu)\}_3]$ and $[Ln(L)_3]$ are bulkier than a simple ether ligand such as THF, and this may account for the long Ln−O distances, although the bond lengthening may also be an indication of general steric crowding in these complexes. The contraction of the subtraction values for the Ln−OPh bonds from La to Yb in the $[Ln(L^2)_3]$/$[Ln(L^2)_3]\cdot S_n$ complexes (Table 2) is contrary to the expected trend since the increase in steric crowding associated with the smaller size of the metal centre may result in metal-oxygen bond lengthening. Since there are two distinct groups of data corresponding to the presence or absence of a solvent of crystallisation, these variations in

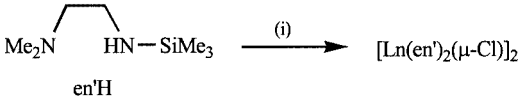
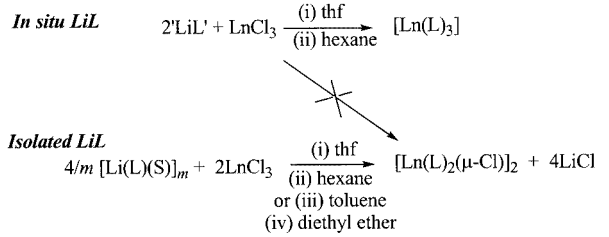
bond lengths and angles may be a result of a packing effect resulting from the presence or absence of the solvent.

With successful coordination of bidentate organoamide ligands [not only in the current examples, but also the previously reported [Ln(en′)$_3$] complexes (Ln = Lu, Er, Eu, Sm, Nd, La)],[27] the next challenge was to prepare heteroleptic chloride species of the type [Ln(L)$_2$Cl]. Such complexes are pivotal intermediates for the generation of catalytically active materials.[4,5,7] A one-pot reaction was initially reported[27] to be successful for the en′ ligand, yielding one example of the target molecules, [Er(en′)$_2$Cl]. This has now been shown to be general across the lanthanoid series with the preparation of the heteroleptic diorganoamidolanthanoid complexes [Ln(en′)$_2$(μ-Cl)]$_2$ [Ln = Yb (**3a**), Er(**3b**), Sm (**3c**), Nd (**3d**) and La (**3e**)] (Scheme 2). The lanthanoid products were very soluble in hydrocarbon solvents and were crystallised with difficulty from concentrated solutions at −20 °C. Furthermore, the removal of LiCl from the reaction mixture was tedious with numerous low temperature extractions required in order to obtain pure [Ln(en′)$_2$(μ-Cl)]$_2$ derivatives, which were subsequently isolated in only low to moderate yields.



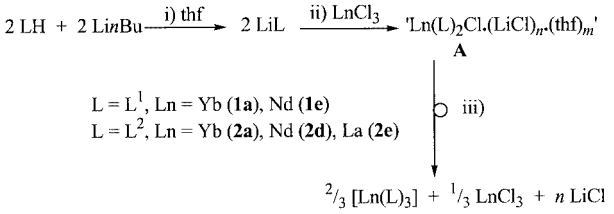
Scheme 2. Reagents and Conditions; (i) *n*BuLi, THF, 0 °C, then 0.5 equivalents of $LnCl_3$ (Ln = Yb, Er, Sm, Nd, La) followed by crystallisation from hexane

The addition of $LnCl_3$ to two molar equivalents of LiL (L = L^1, Ln = Yb, Nd; L = L^2, Ln = Yb, Nd, La), which was generated in situ in THF, resulted in complete dissolution of the starting materials. Extraction of the evaporated reaction mixtures with hexane gave the homoleptic complexes [Ln(L)$_3$] [L = L^1, Ln = Yb (**1a**), Nd (**1e**); L = L^2, Ln = Yb (**2a**·(C$_5$H$_9$Me) (from toluene/hexane), Nd (**2d**), La (**2e**)] instead of the target heteroleptic complexes [Ln(L)$_2$Cl] (Scheme 3). Subsequently, reactions using isolated crystalline lithium salts of L^1 and L^2, such as dimeric [Li(L^1)(-OEt$_2$)]$_2$ (below) or monomeric [Li(L^2)(DME)],[29] with a variety of $LnCl_3$ compounds in a 2:1 Li to $LnCl_3$ mol ratio, were found to give LnL_2Cl complexes [L = L^1, Ln = Yb (**4a**), Er (**4b**), Tb (**4c**); L = L^2, Ln = Nd {**5a**·(PhMe)$_2$}] (Scheme 3). Typically, hexane extraction was employed for the isolation of [Ln(L^1)$_2$(μ-Cl)]$_2$ (**4a**−**4c**) species whilst toluene was used for **5a**·(PhMe)$_2$ (Scheme 3). However, the isolation of the homoleptic products **2a** and **2e** from reactions of $LnCl_3$ with *two* equivalents of [Li(L^2)(DME)][29] was also observed. Thus these results show that for L^1 and L^2 there is only a narrow window of opportunity to prepare the heteroleptic chlorides. Access to complexes of the smaller lanthanoid elements Tb, Er and Yb is available with L^1, but the larger neodymium gives [Nd(L^1)$_3$] (**1e**) whilst L^2 yields the heteroleptic derivative for the larger Nd but not with the lighter (La) and heavier (Yb) extremes of the lanthanoid series. These results support the view of Lappert et al. that fully characterised isolated lithium complexes are more rewarding synthetically than reagents generated in situ.[48,49] The synthetic value of *pre-isolated* alkali metal alkyls has been demonstrated in routes to ytterbium(II) alkyls.[50]



Scheme 3. Reagents and Conditions; In situ ′LiL′; (ii) L = L^1, Ln = Yb (**1a**), Nd (**1e**); L = L^2, Ln = Yb (**2a**) (crystallised from toluene/hexane), Nd (**2d**), La (**2e**). *Isolated* LiL; (ii) L = L^1, Ln = Yb, Er, Tb, target **4a**−**4c** obtained; Ln = Nd gives **1e**; (iii) L = L^2, Ln = Nd, **5a**·(PhMe)$_2$ obtained; Ln = Yb, La afforded **2a**, **2e**; iv) L = L^2, Ln = La, **2e** obtained

The direct formation of [Ln(L)$_3$] from a 2:1 (Li:Ln) reaction in THF would leave 0.33 equivalents of $LnCl_3$ unchanged, and lanthanoid halides have low solubility in this solvent. Since all the $LnCl_3$ dissolved, it suggests that the heteroleptic species is formed initially, possibly stabilised as an "ate" complex such as **A** in Scheme 4. The formation of "ate" complexes has previously been observed for other bulky organoamidolanthanoids, for example [Yb{Me$_2$Si(O*t*Bu)(N*t*Bu)}$_2$(μ-Cl)$_2$Li(THF)$_2$][36] and [Nd{(CF$_3$)$_3$C$_6$H$_2$C(NSiMe$_3$)$_2$}(μ-Cl)$_2$Li(THF)$_2$].[42] Therefore the rearrangement presumably occurs on addition of hexane [or for L^2, Ln = Yb, toluene (even with isolated LiL^2); for Ln = La, also diethyl ether; Scheme 4 (iii)] with precipitation of LiCl and $LnCl_3$ or even $LiLnCl_4$. This is contrary to the in situ [Ln(en′)$_2$(μ-Cl)]$_2$ preparations where the heteroleptic derivatives were obtained from hexane. Crystallisation of the "ate" complexes (**A** in Scheme 4) was unsuccessful due to the very high solubility of the reaction products. The reasons for the difference in outcome between the use of isolated and in situ formed LiL in two cases (L = L^1, Ln = Yb; L = L^2, Ln = Nd) are not clear but plausibly the in situ reagents are less pure.



Scheme 4. Postulated rearrangement pathway

Elemental analyses (C, H, N and/or Ln) for the [Ln(L)$_2$(μ-Cl)]$_2$ complexes (except unanalysed **3b**, **3c**) were consistent with the proposed formulations and the absence of coordinated THF. For each ligand type the infrared spectra of the [Ln(L)$_2$(μ-Cl)]$_2$ complexes were almost identical, showing peaks attributable to the appropriate ligand and no evidence of THF. The spectra of **3a**−**3e** were very similar to those of the corresponding homoleptic species. In contrast

intense infrared absorptions of **4a**−**4c** attributable to C−O−C stretching of the MeOAr substituent were observed as two single bands at 1100−1000 cm^{-1}, whereas for *mer*-[Ln(L^1)$_3$] two bands were observed in each region. This may reflect the solely *trans* ether groups in **4a**−**4c** (below), whereas [Ln(L^1)$_3$] complexes have both *cis* and *trans* (Me)O−Ln−O(Me) arrays. Bands at 1266 and 859 cm^{-1} were observed for **5a**·(PhMe)$_2$ but not for **2d**·(PhMe)$_2$, and a band of the latter at 802 cm^{-1} was absent in the former, thereby distinguishing the spectra of the two complexes. Despite the paramagnetism of **5a**·(PhMe)$_2$, ^{1}H NMR resonances attributable to the L^2 ligand could be assigned (see Exp. Sect.), whilst those of toluene were in the usual diamagnetic region; integrations confirmed the proposed composition. Only a single L^2 environment was detected — consistent with the single type of L^2 coordination in the solid-state structure (below) — and the general spectral features were similar to those of **2d**·(PhMe)$_2$. The visible/near infrared spectrum of **5a**·(PhMe)$_2$ showed absorptions characteristic of Nd^{3+}.[31] Mass spectra identified a bimolecular species to be present for **3a**−**3e** with the highest-mass fragment, except for ytterbium, being the ion [Ln$_2$(en′)$_3$Cl$_2$]$^+$. (For the heavier ytterbium metal only the fragment [Yb$_2$(en′)$_2$Cl$_2$]$^+$ was detected due to limitations in the accessible mass spectrum range.) These data imply that the complexes have a dimeric structure of the type [Ln(en′)$_2$(μ-Cl)]$_2$ and contradict an earlier proposal of a monomeric structure for the Er complex also based on MS data.[27] Verification by X-ray diffraction studies has been unsuccessful owing to the difficulty in obtaining suitable crystals of the highly soluble complexes and an unsatisfactory data solution for the one set of apparently suitable crystals (**3d**).

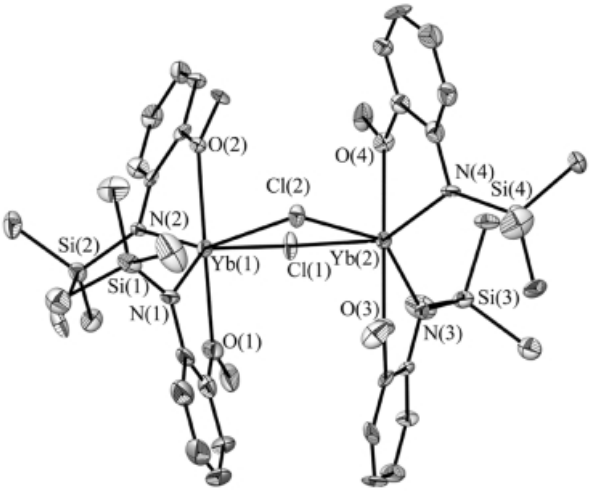


Figure 3. ORTEP view of one molecule of [Yb(L^1)$_2$(μ-Cl)]$_2$ (**4a**) drawn with 50% ellipsoids; hydrogen atoms have been omitted for clarity

The molecular structures of **4a** (Figure 3), **4b**, **4c** and **5a**·(PhMe)$_2$ (Figure 4) are dimeric with two lanthanoid atoms bridged by two chlorine atoms. The complexes **4a**−**4c** are isostructural and have the monoclinic centrosymmetric space group $P2_1/n$ with one dimer comprising the asymmetric unit. For **5a**·(PhMe)$_2$ a toluene of crystallisation is present in each asymmetric unit that comprises half the dimer with a crystallographic inversion centre located in the middle of the Nd_2Cl_2 plane. Selected bond lengths and angles for **4a**−**4c** and **5a**·(PhMe)$_2$ are given in Table 3. Two chelating [L]$^-$ (L = L^1 or L^2) units are bound to each lanthanoid centre in a similar fashion completing a six-coordination environment with a very distorted octahedral geometry. Clearly, the steric demand of two L ligands and one chloride is not sufficient to saturate all coordination sites on the lanthanoid metal since dimerisation takes place. Coordination of a molecule of THF generating monomeric [Ln(L)$_2$Cl(THF)] may occur in THF solution prior to workup in nonpolar solvents. The chloride-bridged dimer is presumably less crowded than [Ln(L)$_2$Cl(THF)] with the steric coordination number[51] for THF (1.2) larger than that for chloride (1.0). In addition, longer Ln−μ-Cl than Ln−Cl$_{ter}$ distances also reduce crowding. These factors favour elimination of any coordinated THF on isolation.

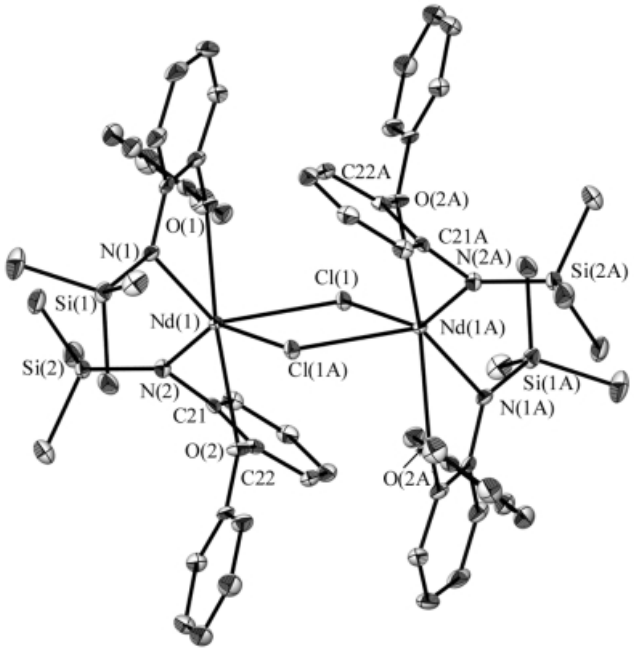

Figure 4. ORTEP view of [Nd(L^2)$_2$(μ-Cl)]$_2$.(PhMe)$_2$ (**5a**·(PhMe)$_2$] drawn with 50% ellipsoids; hydrogen atoms and toluene of crystallisation have been omitted for clarity

The coordination geometry in [Ln(L)$_2$(μ-Cl)]$_2$ is similar to that of the homoleptic derivatives [Ln(L)$_3$] (L = L^1, L^2). Two bridging chloride atoms in the former replace one equatorial L ligand of [Ln(L)$_3$]. The axial positions are occupied by the O(Me/Ph) group on L^1 or L^2 with O(1)−Ln(1)−O(2) angles close to the expected 180°. The remaining $NSiMe_3$ units and chloride atoms are located in mutually *cisoid* equatorial sites with the former lying above and below the equatorial plane. This arrangement presumably minimises steric repulsion between the *cis* $NSiMe_3$ groups as is also observed for the homoleptic complexes [Ln(L)$_3$] (see above). Generally the binding of the L^1 and L^2 ligands is similar to that in the corresponding homoleptic complexes, although there is a marginal shortening of the

[a] Symmetry transformations used to generate equivalent atoms: $-x + 2, -y + 2, -z + 1$.

Ln−N and Ln−O bond lengths consistent with the lower steric demand of two chlorides. The near planar (**4a**−**4c**) or planar [**5a**·$(PhMe)_2$] Ln_2Cl_2 cores exhibit symmetrical bridging of the chlorides in the L^1 complexes, although there is a difference of 0.07 Å between the two Nd−Cl distances of **5a**·$(PhMe)_2$. The distance between the lanthanoid centres is nonbonding (Table 3) and varies in line with the ionic radii of the respective metals (Table 2).

A notable feature of the coordination of the two L^2 ligands to neodymium in **5a**·$(PhMe)_2$ is the noticeable tilt in one of the aromatic backbones [C(21)−C(26)]. Thus the interplanar angle to the Nd−N−O plane is 61.41(7)° which is almost double that of the other L^2 ligand [31.49(6)°] and of the maximum observed for the homoleptic $[Ln(L^2)_3]$ derivatives. Associated with this tilt, two of the carbon atoms [C(21) and C(22)] approach the metal centre with distances of 2.911(2) and 3.035(2) Å, respectively, which are approximately 0.25 Å shorter than the corresponding distances for the other L^2 ligand. The former Nd−C distances are only marginally longer than π-arene lanthanoid interactions in, for example, $[Nd(\eta^6\text{-}PhH)(AlCl_4)_3]$[52] [Nd−C distances of 2.93(2) to 2.94(2) Å], and are similar to or shorter than intramolecular π-arene contacts [2.964(7)−3.158(9) Å] in neodymium aryloxide complexes such as $[Nd(Odpp)_3]$ ($Odpp^- = 2,6$-diphenylphenolate).[53] Thus, it appears that C(21) and C(22) form an intramolecular $\pi\text{-}\eta^2$ interaction with Nd and this bonding accounts for the tilt of the arene backbone.

For **3a**−**3e**, a similar dimeric structural type would be expected with *cis*-amide groups, *trans*-amine substituents and bridging chloride ions per six-coordinate lanthanoid centre (Figure 5), although other arrangements may also be possible.

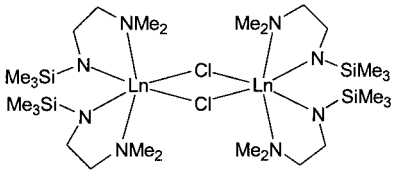

Figure 5. Postulated dimeric representation of $[Ln(en')_2(\mu\text{-}Cl)]_2$

Subtraction of the appropriate ionic radii from the Ln−Cl distances gives similar values to those of structurally characterised lanthanoid μ-chloride fragments supported by either amide or halide co-ligands (Table 2). For $[Nd(L^2)_2(\mu\text{-}Cl)]_2$ one value is slightly larger than in **4a**−**4c** complexes consistent with the greater steric crowding in the L^2 complex. Subtraction values for **4a**−**4c** and **5a**·$(PhMe)_2$ are similar to $[Yb(Cl)_2(\mu\text{-}Cl)(THF)_2]_2$ {which has an analogous donor array to $[Yb(L^1)_2(\mu\text{-}Cl)]_2$}[47] but are longer than those from the Yb−Cl distances of $[Yb(C_5H_5)_2(\mu\text{-}Cl)]_2$,[44] consistent with the greater steric coordination number[51] summation for $[Yb(Cl)_2(\mu\text{-}Cl)(THF)_2]_2$ (6.42) than $[Yb(C_5H_5)_2(\mu\text{-}Cl)]_2$ (6.08). The subtraction values for the Ln−Cl bonds in $[Ln(L^1)_2(\mu\text{-}Cl)]_2$ are similar to those of $[Sm(C_5Me_5)_2(\mu\text{-}Cl)]_3$ [46] (Table 2) suggesting a steric similarity between L^1 and C_5Me_5, even though the current structures are more like those of the unsubstituted cyclopentadienyl complex $[Yb(C_5H_5)_2(\mu\text{-}Cl)]_2$, as the $Sm(C_5Me_5)_2$ groups are rotated by 90°.[46] This may reflect both the more adaptable coordination environment of the

"edge-on" bound bidentate organoamide ligands compared with the "face-on" cyclopentadienyl ligand.

Synthesis and Crystal Structure of $[Li(L^1)(OEt_2)]_2$

The lithiation of L^1H with one equivalent of *n*BuLi in Et_2O afforded a white precipitate of $[Li(L^1)(OEt_2)]_2$. Satisfactory elemental analyses, despite numerous attempts, could not be obtained. The values are closer to those for LiL^1 and could suggest that loss of coordinated ether occurs during the lengthy journey to the analysis laboratories. However the ^1H NMR spectrum of $[Li(L^1)(OEt_2)]_2$ established the L^1 to Et_2O ratio, and showed a single methoxy ether peak and characteristic arene backbone signals (H-3−H-6). The room temperature ^7Li NMR spectrum of $[Li(L^1)(OEt_2)]_2$ shows a single lithium environment with a narrow ($\Delta\nu_{1/2}$ = 14 Hz) signal. The IR spectrum contained absorptions typical of a coordinated Et_2O molecule and of the L^1 ligand.

Crystals of $[Li(L^1)(OEt_2)]_2$ suitable for X-ray crystallography were obtained by recrystallisation of the crude material from diethyl ether. The structure of the complex $[Li(L^1)(OEt_2)]_2$ is dimeric (Figure 6). Selected geometric data are compiled in Table 4. Each four-coordinate lithium atom is surrounded by one diethyl ether, two bridging amide nitrogens [N(1) and N(1A)] and a methoxy oxygen atom in a distorted tetrahedral array. This distortion presumably arises from the restriction of the N−Li−O(Me) bite angle [83.6(2)°] as well as the ligation of the bridging amide nitrogens, N(1) and N(1A), to Li(1,1A). The N(1)−Li(1)−N(1A)−Li(1A) ring is essentially planar having the bidentate L^1 ligands parallel to each other, with the arene backbone approximately perpendicular to the central $(NLi)_2$ plane [74.9(1)°]. In comparison with L^1H,[28] binding of L^1 to lithium has little effect on the methoxy position in relation to the arene backbone plane [torsion angle: C(13)−C(12)−O(1)−C(10) 11.7(3)°]. The structure of $[Li(L^1)(OEt_2)]_2$ can be compared with those of other sterically-crowded $[\{Li(\mu\text{-}L)(OEt_2)\}_2]$ complexes [L = 8-quinolinyl(trimethylsilyl)amide (qsta)[54] or *N,N′*-di-*p*-tolylformamidinate (dtf)[55]]. However, the steric requirements for L^1 must be less than that of en′ which coordinates to lithium in an unsymmetrical dinuclear configuration in $[Li(en')_2Li(OEt_2)]$[27] with one four-coordinate and one three-coordinate Li. The Li−O(1) and Li−O(2) ether distances [2.000(4) Å, 1.991(4) Å respectively] in $[Li(L^1)(OEt_2)]_2$ are similar to those in related etherates (e.g. 1.94(3) Å in four-coordinate $[\{Li(qsta)(OEt_2)\}_2]$ and 1.943(6) Å in three-coordinate $[\{Li[N(SiMe_3)_2(OEt_2)\}_2]$[49]). The lithium bridging is not symmetrical as shown by the significant difference in the Li(1)−N(1) and Li(1)−N(1A) bond lengths of 0.129 Å. This unsymmetrical behaviour has been observed in the related $[\{Li(qsta)(OEt_2)\}_2]$ complex with bridging Li−N(amide) distances of 2.07(2) and 2.21(2) Å and is presumably due to the steric crowding by the chelating L^1 ligand. The sharp ^7Li and ^1H NMR spectra of $[Li(L^1)(OEt_2)]_2$ are consistent with observation of only one LiL^1 environment in the solid state.

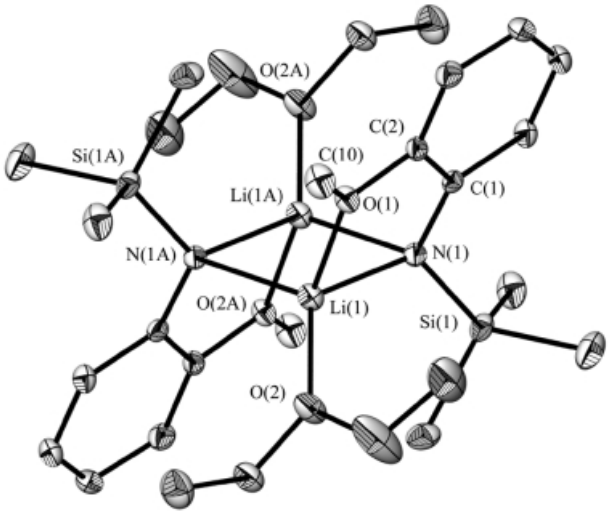

Figure 6. ORTEP view of $[Li(L^1)(OEt_2)]_2$ drawn with 50% ellipsoids; hydrogen atoms have been omitted for clarity

Conclusions

The preparation of solvent-free lanthanoid organoamide complexes of the type $[LnL_3]$ or $[Ln(L)_2(\mu\text{-}Cl)]_2$ (L = L^1, L^2, en′) can be achieved through incorporation of a pendant donor on the amide ligand. For the ether-substituted L^1 and L^2 derivatives, isolation of $[Ln(L)_2(\mu\text{-}Cl)]_2$ is critically dependent upon the correct choice of, and size of, the ligand and the lanthanoid metal, since otherwise rearrangement to the homoleptic complex is observed. The $[Ln(L)_2(\mu\text{-}Cl)]_2$ (L = L^1, L^2, en′) complexes represent a new class of solvent-free heteroleptic lanthanoid(III) amides which should be capable of further functionalisation by replacement of the halide.

Experimental Section

All reactions were carried out under dry nitrogen using dry box and standard Schlenk techniques. Solvents were dried by distillation from sodium wire/benzophenone. IR data (4000−650 cm^{-1}) were recorded for Nujol mulls sandwiched between NaCl plates with a Perkin−Elmer 1600 Fourier transform infrared spectrometer. NMR spectra were obtained either on a Bruker AC200 MHz (^1H) or a Bruker AC 400 MHz spectrometer (^7Li and ^1H) as indicated. Deuterated solvents were degassed and distilled from Na/K

alloy prior to use. ^{1}H NMR spectra were referenced to the solvent (C_6D_6 and C_7D_8) signals; the chemical shift for the ^{7}Li spectrum is given relative to external 0.1 M LiCl in D_2O at room temperature. Mass spectra were recorded with a VG Trio-1 GC mass spectrometer. Each listed *m*/*z* value for metal-containing ions is the most intense peak of a cluster pattern in good agreement with the calculated pattern. Elemental analyses (C, H N) were determined by the Campbell Microanalytical Service, University of Otago, New Zealand. Lanthanoid analyses were by complexometric titration with $[Na_2EDTA]$.[53,56] $[LnCl_3(THF)_n]$,[35] $LnCl_3$,[57] L^1H,[28] L^2H,[28,29] en′H,[27] $[Li(L^2)(DME)]$[29] were each prepared according to a reported procedure. *n*BuLi (1.6 M) (Aldrich) was used unstandardised but transferred to and stored in a Schlenk flask under nitrogen immediately on opening a new batch.

$[Yb(L^1)_3]$ (1a). Method 1: $[Li(L^1)(OEt_2)]_2$ (0.62 g, 1.12 mmol) was added to a stirred suspension of $[YbCl_3(THF)_3]$ (0.37 g, 0.75 mmol) in THF (40 mL) and the resulting mixture was stirred for 12 h. The solvent was removed under vacuum and hexane added (30 mL) giving a white precipitate. The red solution was filtered and the filtrate concentrated to 15 mL. A red crystalline product was obtained on standing for 2 h (0.41 g, 72%). IR (Nujol): $\tilde{\nu}$ = 1593 vs, 1561 vs, 1485 s, 1465 m, 1321 vs, 1294 vs, 1283 s, 1245 vs, 1209 s, 1159 w, 1059 w, 1051 s, 1012 s, 1000 vs, 913 br. s, 843 br vs, 822 s, 787 m, 770 s, 743 s, 681 s, 629 s, 598 s cm^{-1}. Vis/near IR (DME): λ_{max} (ε) = 431 (185), 874 (9), 911 (14), 945 (6), 978 (35) nm (dm^3 mol^{-1}). $C_{30}H_{48}N_3O_3Si_3Yb$ (756.23): calcd. C 47.66, H 6.40, N 5.56; found C 47.88, H 6.44, N 5.63.

Method 2 [2:1 Li to Ln mol ratio (in situ)]: *n*BuLi was slowly added (2.31 mL, 3.70 mmol) to a stirred solution of L^1H (0.71 g, 3.60 mmol) in THF (40 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. $[YbCl_3(THF)_2]$ (0.76 g, 1.80 mmol) was added to the resulting solution and the reaction mixture rapidly stirred for 12 h. The solvent was removed in vacuo, and hexane (30 mL) was added affording a white precipitate. The red solution was filtered and the filtrate volume reduced to ca. 2 mL under vacuum . Red crystals of $[Yb(L^1)_3]$ (**1a**) were deposited on standing overnight. The infrared spectrum was identical to that of **1a** obtained from **Method 1**.

$[Er(L^1)_3]$ (1b): *n*BuLi (2.30 mL, 3.70 mmol) was added to a stirred solution of compound L^1H (0.72 g, 3.70 mmol) in THF (40 mL) at 0 °C, and the resulting solution was warmed to room temperature over ca. 1 h. $[ErCl_3(THF)_{3.5}]$ (0.63 g, 1.20 mmol) was then added and the reaction mixture stirred for 15 h. The solvent was then removed under vacuum and hexane (30 mL) was added giving a white precipitate. The light pink solution was filtered and the filtrate volume reduced to 10 mL under vacuum. The light pink crystals deposited on standing for 12 h (0.43 g, 48%). IR (Nujol): $\tilde{\nu}$ = 1593 vs, 1561 vs, 1485 s, 1464 m, 1321 vs, 1284 vs, 1240 s, 1209 s, 1156 vs, 1117 vs, 1058 w, 1051 s, 1011 s, 1000 vs, 911 br. s, 841 br vs, 784 s, 768 s, 735 s, 681 s, 627 s, 597 s cm^{-1}. MS: *m*/*z* (%) = 646 (<1) $[Er(L^1)_2NC_6H_4]^+$, 556 (<1) $[Er(L^1)_2]^+$, 480 (<1) $[Er(L^1)(C_6H_4NSi)]^+$, 195 (35) $[(L^1H)]^+$, 180 (20) $[(L^1H) - Me]^+$, 165 (100) $[(L^1H) - 2Me]^+$, 150 (35) $[(L^1H) - 3Me]^+$, 135 (20) $[C_6H_5ONSi]^+$, 73 (20) $[SiMe_3]^+$, 58 (10) $[SiMe_2]^+$. $C_{30}H_{48}ErN_3O_3Si_3$ (748.22): calcd. C 48.03, H 6.45, N 5.60; found C 48.16, H 6.70, N 5.73.

$[Sm(L^1)_3]$ (1c): A similar preparation method to that used for compound **1b** gave yellow crystals of **1c** (0.36 g, 41%). IR (Nujol): $\tilde{\nu}$ = 1585 vs, 1559 vs, 1481 s, 1307 vs, 1279 vs, 1237 s, 1211 s, 1173 vs, 1117 vs, 1076 vs, 1058 w, 1050 vs, 1030 vs, 937 s, 919 s, 842 s, 825 s, 772 vs, 741 vs, 735 s, 662 vs, 616 s, 597 s cm^{-1}. MS: *m*/*z* (%) = 734 (<1) $[Sm(L^1)_3]^+$, 630 (<1) $[Sm(L^1)_2NC_6H_4]^+$, 540 (<1) $[Sm(L^1)_2]^+$, 464 (<1) $[Sm(L^1)(C_6H_4NSi)]^+$, 195 (35) $[(L^1H)]^+$, 180 (20) $[(L^1H) - Me]^+$, 165 (100) $[(L^1H) - 2Me]^+$, 150 (35) $[(L^1H) - 3Me]^+$, 135 (20) $[C_6H_5ONSi]^+$, 73 (20) $[SiMe_3]^+$, 58 (10) $[SiMe_2]^+$. $C_{30}H_{48}N_3O_3Si_3Sm$ (734.21): calcd. C 49.13, H 6.60, N 5.73; found C 48.55, H 6.67, N 5.67.

$[Pr(L^1)_3]$ (1d): A similar preparation method to that used for compound **1b** gave green crystals of **1d** (0.49 g, 57%). IR (Nujol): $\tilde{\nu}$ = 1590 vs, 1561 vs, 1484 s, 1449 s, 1320 vs, 1285 vs, 1246 br. s, 1210 s, 1164 vs, 1117 vs, 1058 w, 1050 s, 1011 s, 1002 vs, 915 br. s, 841 br. s, 768 s, 743 s, 674 s, 625 s, 597 s cm^{-1}. $C_{30}H_{48}N_3O_3PrSi_3$ (723.21): calcd. C 49.78, H 6.68, N 5.80; found C 49.56, H 6.71, N 5.97.

$[Nd(L^1)_3]$ (1e). Method 1: A similar preparation method to that used for compound **1b** gave blue crystals of **1e** (0.57 g, 65%). IR (Nujol): $\tilde{\nu}$ = 1590 vs, 1560 m, 1484 s, 1319 vs, 1285 vs, 1246 m, 1209 s, 1163 s, 1117 vs, 1058 w, 1050 s, 1011 s, 1002 vs, 914 br. s, 841 br vs, 767 s, 743 vs, 675 m, 625 s, 597 s cm^{-1}. MS: *m*/*z* (%) = 726 (10) $[^{144}Nd(L^1)_3]^+$, 622 (5) $[^{144}Nd(L^1)_2C_6H_4N]^+$, 532 (30) $[^{144}Nd(L^1)_2]^+$, 305 (5) $[^{142}Nd(L^1) - OMe]^+$, 195 (40) $[(L^1H)]^+$, 180 (15) $[(L^1H) - Me]^+$, 165 (70) $[(L^1H) - 2Me]^+$, 150 (30) $[(L^1H) - 3Me]$, 135 (25) $[C_6H_5ONSi]^+$, 73 (100) $[SiMe_3]^+$, 58 (35) $[SiMe_2]^+$. ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ = −16.98 (br. s, 9 H, OMe), −4.20 (br. s, 27 H, $SiMe_3$), 1.14 (s, 3 H, H-4 or H-5), 7.88 (s, 3 H, H-4 or H-5), 14.18 (s, 3 H, H-3 or H-6), 23.60 (s, 3 H, H-3 or H-6). $C_{30}H_{48}N_3NdO_3Si_3$ (724.21): calcd. C 49.55, H 6.65, N 5.78; found C 49.85, H 6.81, N 5.73.

Method 2 [using 1:2 Ln to L^1 mol ratio (in situ)]: *n*BuLi (2.31 mL, 3.70 mmol) was slowly added to a stirred solution of compound L^1H (0.71 g, 3.60 mmol) in THF (40 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. $[NdCl_3(THF)_2]$ (0.71 g, 1.80 mmol) was added to the resulting solution, and the reaction mixture was stirred rapidly for 12 h. The solvent was removed in vacuo, and hexane (30 mL) was added affording a white precipitate. The blue solution was filtered and the filtrate volume was reduced to ca. 2 mL under vacuum. Blue crystals deposited on standing overnight. The infrared spectrum was similar to that of **1e** (**Method 1**). Unit Cell data [$C_{30}H_{48}N_3NdO_3Si_3$, M = 724.2, monoclinic, a = 10.121(1), b = 18.876(1), c = 18.814(1) Å; α = 90°, β = 104.37(1)°, γ = 90°; V = 3500.2 Å^3, $T \approx$ 123 K] were in agreement with those of $[Nd(L^1)_3]$ from **Method 1** (Table 5).

Method 3 [using 1:2 Ln to Li (isolated) ratio)]: $[NdCl_3(THF)_2]$ (0.30 g, 0.75 mmol) and $[Li(L^1)(OEt_2)]_2$ (0.42 g, 0.75 mmol) were stirred together in THF (40 mL). After 12 h, the pale yellow solution was evaporated to dryness under reduced pressure and hexane added. The resulting white solid was filtered and the filtrate evaporated to dryness under vacuum affording a blue crystalline material (0.20 g, 55%). Infrared and ^{1}H NMR spectra were identical to those of **1e** (**Method 1**).

$[Yb(L^2)_3]$·(PhMe) [2a·(PhMe)]: *n*BuLi (1.88 mL, 3.00 mmol) was added to a stirred solution of L^2H (0.77 g, 3.00 mmol) in THF (40 mL) at 0 °C, and the resulting solution was warmed to room temperature over ca. 1 h. $[YbCl_3(THF)_2]$ (0.42 g, 1.0 mmol) was then added and the reaction mixture was stirred for 12 h. The solvent was then removed under vacuum and toluene (30 mL) was added giving a white precipitate. The red solution was filtered at −78 °C and the filtrate volume reduced to 25 mL under vacuum. Red crystals of good X-ray quality were deposited on standing overnight (0.70 g, 68%). IR (Nujol): $\tilde{\nu}$ = 1593 vs, 1558 m, 1480 s, 1278 vs, 1241 vs, 1186 vs, 1152 vs, 1097 s, 1072 w, 1051 s, 1020 m, 1005 w, 906 s, 858 sh w, 840 s, 824 s, 802 s, 778 m, 728 s, 692 vs, 626 w,

$[Yb(L^2)_3]\cdot(C_5H_9Me)$ [2a·(C_5H_9Me)]. Method 1 (using a 1:2 Ln:Li ratio): THF (40 mL) was added to the solids $[Li(L^2)(DME)]$ (0.53 g, 1.50 mmol) and $[YbCl_3(THF)_2]$ (0.32 g, 0.75 mmol) and the resulting mixture was stirring for 12 h. The solvent was then removed under vacuum and toluene (25 mL) added giving a white precipitate. The red solution was filtered at −78 °C and the filtrate volume reduced to 20 mL under vacuum. Red crystals of $[Yb(L^2)_3]\cdot(C_5H_9Me)$ (suitable for X-ray analysis) deposited on standing overnight (0.15 g, 24% [based on L^2]). IR (Nujol): $\tilde{\nu}$ = 1593 vs, 1560 m, 1480 sh w, 1307 w, 1280 s, 1242 s, 1152 s, 1185 s, 1098 s, 1072 m, 1052 s, 1020 m, 1004 w, 908 s, 858 sh w, 840 s, 824 s, 802 s, 780 m, 726 s, 691 s, 618 s cm^{-1}. MS: *m/z* (%) = 776 (<1) $[Yb(L^2)_2(C_6H_4N)]^+$, 686 (4) $[Yb(L^2)_2]^+$, 507 (4) $[Yb(L^2)(OC_6H_5)]^+$, 430 (10) $[Yb(L^2)]^+$, 415 (10) $[Yb(L^2) - Me]^+$, 353 (10) $[Yb(OC_6H_4NSiMe_3)]^+$, 337 (10) $[Yb(C_6H_4NSiMe_3)]^+$, 257 (45) $[(L^2H)]^+$, 242 (40) $[(L^2) - Me]^+$, 226 (5) $[(L^2) - 2Me]^+$, 165 (100) $[OC_6H_4NSiMe_2]^+$, 150 (35) $[C_6H_4ONSiMe]^+$, 73 (50) $[SiMe_3]^+$. $C_{51}H_{66}N_3O_3Si_3Yb$ (solvate) (1026.37): calcd. C 59.68, H 6.48, N 4.09. $C_{45}H_{54}N_3O_3Si_3Yb$ ($[Yb(L^2)_3]$) (942.27): calcd. C 57.36, H 5.78, N 4.46; found C 57.47, H 6.01, N 4.22.

Method 2 [2:1 Li to Ln mol ratio (in situ)]: *n*BuLi (1.65 mL, 2.60 mmol) was slowly added to a stirred solution of compound L^2H (0.64 g, 2.50 mmol) in THF (40 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. $[YbCl_3(THF)_{3.5}]$ (0.66 g, 1.25 mmol) was added to the resulting solution, and the reaction mixture stirred rapidly for 12 h. The solvent was removed in vacuo, and toluene (20 mL) added affording a white precipitate. The red solution was filtered and the filtrate volume reduced to ca. 2 mL under vacuum. Hexane (15 mL) was added to the oily residue resulting in an immediate precipitation of LiCl and a red solution. Red crystals deposited on standing and were dried at room temperature under vacuum. The infrared spectrum was similar to that of **2a**·(C_5H_9Me) above.

$[Y(L^2)_3]\cdot(C_5H_9Me)$ [2b·(C_5H_9Me)]: A similar procedure to that used for compound **2a**·(PhMe) gave colourless crystals of the title complex (0.61 g, 71%). IR (Nujol): $\tilde{\nu}$ = 1592 vs, 1582 s, 1557 m, 1489 s, 1278 vs, 1239 vs, 1210 s, 1170 s, 1152 vs, 1099 vs, 1071 m, 1049 s, 1020 m, 1004 w, 911 br. s, 860 w, 824 s, 776 s, 735 vs, 692 vs, 675 w, 625 w, 592 s, 560 w cm^{-1}. [Nd(L^2)$_3$]·(PhMe)$_2$ [2d·(PhMe)$_2$]. Method 1: A similar preparation method to that used for compound **2a**·(PhMe) gave blue crystals of the title complex (0.68 g, 62%). IR (Nujol): $\tilde{\nu}$ = 1591 vs, 1557 w, 1481 s, 1337 vs, 1285 vs, 1249 vs, 1187 vs, 1155 vs, 1103 vs, 1070 w, 1052 s, 1020 w, 1005 w, 916 vs, 826 s, 802 s, 773 s, 728 vs, 694 vs, 676 w cm^{-1}. ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ = −8.05 (br. s, 6 H, H-2′,H-6′), −1.22 (br. s, 27 H, $SiMe_3$), 0.48 (br. s, 6 H, H-3′,H-5′), 0.90 (s, 3 H, H-4 or H-5), 1.20 (br. s, 3 H, H-4′), 2.11 (s, 6 H, Ph*Me*), 6.97−7.14 (m, 13 H, H-4 or H-5 and *Ph*Me), 13.90 (br. s, 3 H, H-3 or H-6), 23.28 (br. s, 3 H, H-3 or H-6). $C_{59}H_{70}N_3NdO_3Si_3$ (1094.38): calcd. C 64.56, H 6.43, N 3.83; found C 64.48, H 6.54, N 4.13. Recrystallisation of [Nd(L^2)$_3$]·(PhMe)$_2$ from hexane afforded crystals of solvent free [Nd(L^2)$_3$] (**2d**) used for X-ray crystallography.

Method 2 [2:1 Li to Ln mol ratio (in situ)]: *n*BuLi (1.65 mL, 2.60 mmol) was slowly added to a stirred solution of compound L^{2}H (0.64 g, 2.50 mmol) in THF (40 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. [$NdCl_3(THF)_2$] (0.49 g, 1.25 mmol) was added to the resulting solution, and the reaction mixture was rapidly stirred for 12 h. The solvent was removed in vacuo, and hexane (30 mL) added affording a white precipitate. The blue solution was filtered and the filtrate volume reduced to ca. 15 mL under vacuum. Blue crystals of [Nd(L^2)$_3$] (**2d**) deposited on standing. (Infrared identification) Unit Cell data [$C_{45}H_{54}N_3NdO_3Si_3$, M = 910.3, monoclinic, a = 16.154(1), b = 15.459(1), c = 17.992(1) Å; α = 90°, β = 103.0(1°), γ = 90°; V = 4378.1 Å^3, $T \approx$ 123 K] were in agreement with those obtained for crystals from **Method 1** (Table 5).

[La(L^2)$_3$]·(PhMe) (2e·(PhMe)]. Method 1: A similar preparation method to that used for compound **2a**·(PhMe) gave yellow crystals of the title complex (0.35 g, 35%). IR (Nujol): $\tilde{\nu}$ = 1589 vs, 1557 m, 1480 s, 1287vs, 1249 vs, 1188 vs, 1155 vs, 1103 vs, 1070 w, 1050 s, 1020 m, 1004 w, 919 s, 858 w, 824 m, 803 vs, 770 vs, 694 vs, 675 w, 618 s, 592 s, 562 w cm^{-1}. MS: *m*/*z* (%) = 651 (3) [La(L^2)$_2$]$^+$, 395 (<1) [La(L^2)]$^+$, 257 (70) [(L^{2}H)]$^+$, 242 (65) [(L^{2}H) − Me]$^+$, 226 (15) [(L^2) − 2Me]$^+$, 165 (100) [$OC_6H_4NHSiMe_2$]$^+$, 150 (40) [$C_6H_4ONHSiMe$]$^+$, 135 (30) [C_6H_4OSiNH]$^+$, 73 (50) [$SiMe_3$]$^+$. ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ = 0.36 (s, 27 H, $SiMe_3$), 2.10 (s, 3 H, Ph*Me*), 6.11 (dd, ^3J = 8.1, ^4J = 1.4 Hz, 3 H, H-6), 6.28 (td, ^3J = 7.2, ^4J = 1.3 Hz, 3 H, H-5), 6.74−6.90 (m, 21 H, H-3, H-4, H-2′−6′), 6.97−7.13 (m, 5 H, *Ph*Me). $C_{52}H_{62}LaN_3O_3Si_3$ (999.32): calcd. C 62.44, H 6.25, N 4.20; found C 62.27, H 6.35, N 4.32. **Method 2 [La(L^2)$_3$] (2e) (using a 1:2 Ln to Li ratio):** $LaCl_3$ (0.18 g, 0.75 mmol) and [Li(L^2)(DME)] (0.53 g, 1.50 mmol) were stirred together in THF (40 mL). After 12 h, the pale yellow solution was evaporated to dryness under reduced pressure and toluene was added. The resulting white solid was filtered, the filtrate was evaporated to dryness and Et_2O was added (20 mL). The solution was concentrated to ca. 10 mL and on standing for two days colourless crystals of **2e** (suitable for an X-ray crystallographic study) were deposited (0.35 g, 77%). IR (Nujol): $\tilde{\nu}$ = 1590 vs, 1557 m, 1480 s, 1444 s, 1288 vs, 1251 vs, 1189 vs, 1155 vs, 1102 vs, 1072 w, 1052 s, 1020 m, 1004 w, 964 w, 917 s, 858 w, 826 m, 801 s, 771 s, 735 s, 722 s, 695 s, 674 w, 632 w, 622 s, 594 s, 559 w cm^{-1}. ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ = 0.35 (s, 27 H, $SiMe_3$), 6.10 (dd, ^3J = 7.6, ^4J = 1.2 Hz, 3 H, H-6), 6.26 (td, ^3J = 7.5, ^4J = 1.6 Hz, 3 H, H-5), 6.72−6.90 (m, 21 H, H-3,H-4, H-2′-6′).

Method 3 [2:1 Li to Ln ratio (in situ)]: *n*BuLi (1.65 mL, 2.60 mmol) was slowly added to a stirred solution of compound L^{3}H (0.64 g, 2.50 mmol) in THF (40 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. [$LaCl_3(THF)_2$] (0.49 g, 1.25 mmol) was added to the resulting solution, and the reaction mixture stirred rapidly for 12 h. The solvent was removed in vacuo, and hexane (30 mL) added affording a white precipitate. The pale yellow solution was filtered and the filtrate volume reduced to ca. 15 mL under vacuum. Light yellow crystals were deposited on standing. The infrared spectrum was identical with that of [La(L^2)$_3$] [**2e** (**Method 2**)].

[Yb(en′)$_2$(μ-Cl)]$_2$ (3a): *n*BuLi (3.75 mL, 6.00 mmol) was slowly added to a stirred solution of en′H (0.88 g, 1.00 mL, 5.50 mmol) in THF (50 mL) at 0 °C and the resulting solution was warmed to room temperature over ca. 1 h. [$YbCl_3(THF)_3$] (1.36 g, 2.75 mmol) was added to this solution, and the reaction mixture was rapidly stirred for 12 h. The solvent was removed in vacuo, and hexane added affording a white precipitate. The orange solution was filtered and the filtrate volume reduced to ca. 2 mL under vacuum. Orange crystals deposited on standing overnight (0.79 g, 55%). IR (Nujol): $\tilde{\nu}$ = 1401 w, 1351 m, 1270 w, 1258 m, 1238 m, 1176 w, 1160 w, 1105 m, 1091 m, 1078 m, 1031 w, 1010 s, 952 s, 925 s, 858 s, 832 m, 778 w, 740 m, 679 w, 665 w cm^{-1}. MS: *m*/*z* (%) = 736 (<1) [M(dimer) − (2 L)]$^+$, 701 (<1) [$Yb_2(L)_2Cl]^+$, 527 (2) [$Yb(L)_2Cl]^+$, 333 (50) [Yb(L)]$^+$, 73 (45) [$SiMe_3]^+$, 58 (100) [$SiMe_2]^+$. $C_{28}H_{76}Cl_2N_8Si_4Yb_2$ (1054.32): calcd. C 31.90, H 7.27, N 10.66, Yb 32.83; found C 31.35, H 7.28, N 9.60, Yb 33.18.

[Er(en′)$_2$(μ-Cl)]$_2$ (3b): A similar preparation method to that used for compound **3a** gave pink crystals of **3b** (0.76 g, 53%). IR in satisfactory agreement with that reported for an analytically pure sample.[27] MS: *m*/*z* (%) = 883 (<1) [M(dimer) − (L)]$^+$, 724 (1) [M(dimer) − (2 L)]$^+$, 521 (1) [$Er(L)_2Cl]^+$, 325 (25) [Er(L)]$^+$, 73 (35) [$SiMe_3]^+$, 58 (100) [$SiMe_2]^+$.

[Sm(en′)$_2$(μ-Cl)]$_2$ (3c): A similar procedure to that used for compound **3a** gave yellow crystals of **3c** (0.58 g, 42%). IR (Nujol): $\tilde{\nu}$ = 1401 w, 1349 m, 1310 w, 1258 m, 1246 s, 1195 w, 1169 w, 1156 sh w, 1103m, 1087 m, 1079 m, 1035 w, 1020 s, 953 m, 924 s, 859 s, 828 br. s, 779 sh m, 735 m, 676 w, 662 m, 619 w, 554 w cm^{-1}. MS: *m*/*z* (%) = 689 (<1) [M(dimer) − (2 L)]$^+$, 507 (1) [$Sm(L)_2Cl]^+$, 348 (20) [Sm(L)Cl]$^+$, 311 (15) [Sm(L)]$^+$, 281 (25) [Sm(L) − 2Me]$^+$, 73 (50) [$SiMe_3]^+$, 58 (100) [$SiMe_2]^+$.

[Nd(en′)$_2$(μ-Cl)]$_2$ (3d): A similar procedure to that used for compound **3a** gave blue crystals of **3d** (0.70 g, 51%). IR (Nujol): $\tilde{\nu}$ = 1348 m, 1259 m, 1246 s, 1168 w, 1104 m, 1079 m, 1154 m, 1036 w, 1020 s, 952 w, 938 s, 924 s, 851 s, 827 br. s, 780 sh m, 734 m, 676 w, 662 m, 554 w cm^{-1}. MS: *m*/*z* (%) = 835 (<1) [{^{144}Nd(L)$_2$(μ-Cl)}$_2$ − (L)]$^+$, 676 (<1) [{^{144}Nd(L$_2$(μ-Cl)}$_2$ − (2 L)]$^+$, 482 (1) [$^{144}Nd_2(L)Cl]^+$, 338 (50) [^{144}Nd(L)Cl]$^+$, 73 (45) [$SiMe_3]^+$, 58 (100) [$SiMe_2]^+$. $C_{28}H_{76}Cl_2N_8Nd_2Si_4$ (990.28): calcd. Nd 28.94; found Nd 29.15.

[La(en′)$_2$(μ-Cl)]$_2$ (3e): A similar preparation to that for compound **3a** gave colourless crystals of **3e** (0.63 g, 46%). IR (Nujol): $\tilde{\nu}$ = 1439 w, 1348 w, 1314 w, 1239 br. s, 1160 s, 1121 s, 1092 s, 1077 w, 1037 w, 1021 w, 998 m, 962 m, 923 m, 848 s, 830 br. s, 748 w, 725 m, 694 m, 664 w, 541 w cm^{-1}. MS: *m*/*z* (%) = 825 (5) [M(dimer) − (L)]$^+$, 457 (30) [$La(L)_2]^+$, 333 (80) [La(L)Cl]$^+$, 73 (20) [$SiMe_3]^+$, 58 (100) [$SiMe_2]^+$. $C_{28}H_{76}Cl_2La_2N_8Si_4$ (984.28): calcd. La 28.17; found La 28.02.

[Yb(L^1)$_2$(μ-Cl)]$_2$ (4a): [Li(L^1)(OEt$_2$)]$_2$ (0.76 g, 1.37 mmol) was added to a stirred suspension of [YbCl$_3$(THF)$_3$] (0.68 g, 1.37 mmol) in THF (40 mL). The solution was stirred for 15 h, the solvent was removed under vacuum and hexane (30 mL) was added. After heating the stirred solution for 2 h, the warm mixture was filtered and on cooling to room temperature the filtrate afforded red crystals (suitable for X-ray analysis) of the title complex (0.51 g, 63%). IR (Nujol): $\tilde{\nu}$ = 1594 s, 1563 w, 1318 w, 1290 s, 1277 s, 1242 vs, 1210 m, 1158 s, 1117 vs, 1051 m, 1002 s, 917 s, 844 vs, 826 s, 792 w, 768 m, 730 vs, 679 m, 627 w, 597 w cm^{-1}. Vis/near IR (DME): λ_{max} (ε) = 457 (156), 935 (4), 982 (18), 985 (17) nm (dm^3 mol^{-1}). $C_{40}H_{64}Cl_2N_4O_4Si_4Yb_2$ (1194.30): calcd. C 40.23, H 5.40, N 4.69; found C 39.15, H 5.57, N 4.72.

[Er(L^1)$_2$(μ-Cl)]$_2$ (4b): Addition of [Li(L^1)(OEt$_2$)]$_2$ (0.55 g, 1.00 mmol) to a suspension of [ErCl$_3$(THF)$_2$] (0.42 g, 1.00 mmol) in THF (40 mL) resulted in precipitation of a white solid and formation of a pink solution. The solvent was removed under vacuum and hexane added (30 mL). The mixture was then warmed and filtered. The filtrate was concentrated to ca. 25 mL affording X-ray quality pink crystals of **4b** (0.36 g, 61%). IR (Nujol): $\tilde{\nu}$ = 1593 s, 1563 w, 1318 w, 1291 s, 1277 m, 1242 s, 1210 w, 1158 s, 1116 vs, 1051 m, 1001 s, 916 vs, 843 vs, 822 s, 788 m, 768 m, 729 vs, 679 m, 626 s, 597 s cm^{-1}. $C_{40}H_{64}Cl_2Er_2N_4O_4Si_4$ (1182.73): calcd. C 40.62, H 5.45, N 4.74; found C 39.79, H 5.54, N 4.96.

[Tb(L^1)$_2$(μ-Cl)]$_2$ (4c): A similar preparation method to that used for compound **4a** gave large pale yellow crystals of **4c** (0.40 g, 68%). IR (Nujol): $\tilde{\nu}$ = 1593 s, 1563 w, 1504 s, 1320 w, 1293 s, 1265 s, 1240 s, 1210 w, 1158 s, 1115 vs, 1051 m, 1001 s, 914 vs, 842 vs, 826 sh w, 783 m, 766 m, 727 vs, 669 m, 625 s, 596 s cm^{-1}. $C_{40}H_{64}Cl_2N_4O_4Si_4Tb_2$ (1166.06): calcd. C 41.20, H 5.53, N 4.80; found C 41.42, H 5.39, N 4.76.

[Nd(L^2)$_2$(μ-Cl)]$_2$·(PhMe)$_2$ [5a·(PhMe)$_2$]: [Li(L^2)(DME)] (0.72 g, 2.00 mmol) was added to a stirred solution of [NdCl$_3$(THF)$_2$] (0.40 g, 1.00 mmol) in THF (40 mL). The resulting blue solution was evaporated to dryness and toluene was added (30 mL). The reaction mixture was filtered and the filtrate volume was reduced under vacuum (ca.15 mL). Upon standing overnight single blue crystals suitable for X-ray crystallography formed (0.35 g, 72%). IR (Nujol): $\tilde{\nu}$ = 1585 s 1294 s, 1266 m, 1243 s, 1185 s, 1160 s, 1100 s, 1074 w, 1036 m, 1022 w, 936 vs, 859 m, 828 br. s, 774 m, 746 s, 727 s, 690 s, 679 w, 623 w cm^{-1}. Vis/near IR (DME): λ_{max} (ε) = 527 (55), 586 (75), 755 (25), 811 (28), 885 (22) nm (dm^3 mol^{-1}). ^{1}H NMR (300 MHz, C_6D_6, 298 K): δ = −8.73 (br. s, 8 H, H-2′,H-6′), −5.04 (br. s, 36 H, SiMe$_3$), 0.08 (s, 8 H, H-3′,H-5′), 1.18 (s, 4 H, H-4′), 1.49 (br. s, 8 H, H-4, H-5), 2.10 (s, 6 H, Ph*Me*), 7.02−7.20 (m, 10 H, *Ph*Me), 15.4 (br. s, 4 H, H-3 or H-6), 30.95 (br. s, 4 H, H-3 or H-6). $C_{74}H_{88}Cl_2N_4Nd_2O_4Si_4$ (1569.22): calcd. C 54.64, H 5.65, N 3.57; found C 54.47, H 5.53, N 3.63.

[Li(L^1)(OEt$_2$)]$_2$: *n*BuLi (32 mL, 0.05 mol) was added dropwise to a stirred solution of L^{1}H (0.05 mol, 10 g) in Et$_2$O (80 mL) at 0 °C, and the resulting solution was warmed to room temperature over ca. 1 h. The resulting white precipitate was cooled to −78 °C, washed with hexane (40 mL) and dried under vacuum (11.9 g, 86%). A small amount of [Li(L^1)(OEt$_2$)]$_2$ was redissolved in Et$_2$O whereupon light-sensitive colourless crystals of good X-ray quality formed. IR (Nujol): $\tilde{\nu}$ = 1585vs, 1558s, 1280s, 1239s, 1212s, 1171s, 1117vs, 1052s, 1029vs, 934s, 840s, 821s, 734vs, 660s, 594s cm^{-1}. MS: *m*/*z* (%) = 201 (100) [LiL^1]$^+$, 195 (25) [L^{1}H]$^+$, 165 (60) [L^{1}H − 2Me]$^+$, 150 (25) [L^{1}H − 3Me]$^+$, 135 (20) [C$_6$H$_5$ONSi]$^+$, 73 (40) [SiMe$_3$]$^+$, 58 (20) [SiMe$_2$]$^+$. ^{1}H NMR (300 MHz, C_7D_8, 298 K): δ = 0.11 (s, 18 H, SiMe$_3$), 1.04 [t, ^3J = 7.0 Hz, 12 H, Me (OEt$_2$)], 3.26 [q, ^3J = 7.0 Hz, 8 H, CH$_2$ (OEt$_2$)], 3.35 (s, 6 H, OMe), 6.50−6.57 (dd, ^3J = 7.2, ^4J = 1.6 Hz, 2 H, H-6), 6.62−6.68 (td, ^3J = 7.0, ^4J = 1.5 Hz, 2 H, H-5), 6.85−6.95 (td, ^3J = 7.0, ^4J = 1.6 Hz, 2 H, H-4), 6.96−7.04 (dd, ^3J = 7.2, ^4J = 1.7 Hz, 2 H, H-3). ^{7}Li NMR (155.51 MHz, C_7D_8, 298 K): δ = 1.85. $C_{28}H_{52}Li_2N_2O_4Si_2$ (550.79) (solvate): calcd. C 61.06, H 9.52, N 5.09. $C_{10}H_{16}LiNOSi$ (201.27) (LiL^2): calcd. C 59.68, H 8.01, N 6.96; found C 58.92, 59.08, H 8.84, 8.67, N 5.82, 6.01.

Structure Determinations: Data for the crystallographic structure determinations of compounds **1e**, **2a**·(PhMe), **2d** and **2e** are given in Table 5 while similar data for **4a**−**4c**, **5a**·(PhMe)$_2$ and [Li(L^1)-

$(OEt_2)]_2$ are listed in Table 6. Data for **2a**·(C_5H_9Me) and **2b**·(C_5H_9Me) are provided in CCDC-174206/174207. Crystals were mounted in an inert atmosphere under viscous oil onto a glass fibre. Low-temperature (≈123 K) data were collected on an Enraf−Nonius CCD area-detector diffractometer (Mo-K_α radiation, λ 0.7107_3 Å, frames comprised 1.0° increments in φ and ω yielding a sphere of data) with proprietary software (Nonius B.V., 1998). Each data set was merged (R_{int} as quoted) to N unique reflections; the structures were solved by conventional methods and refined with anisotropic thermal parameter forms for the non-hydrogen atoms by full-matrix least-squares on all F^2 data using SHELX 97 software package.[58] Hydrogen atoms were included in their calculated positions and allowed to ride on the parent carbon atom with isotropic thermal parameters. For **2a**·(C_5H_9Me) and **2b**·(C_5H_9Me), the lattice solvent was also modelled as PhMe, disordered PhMe, or THF, and in each case the refinement was unstable by contrast with C_5H_9Me, the presence of which was also indicated by the NMR spectrum of **2b**. CCDC-174197 to CCDC-174207 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Selective Complexation of Uranium(III) over Cerium(III) and Neodymium(III) by 2,2′:6′,2′′-Terpyridine − X-ray Crystallographic Evidence for Uranium-to-Ligand π Back-Bonding

Jean-Claude Berthet,*[a] Christelle Rivière,[a] Yannick Miquel,[a] Martine Nierlich,[a] Charles Madic,[b] and Michel Ephritikhine*[a]

Keywords: Actinides / Uranium / Cerium / Neodymium / Lanthanides / N ligands / Cations

The addition of 2,2′:6′,2′′-terpyridine (terpy) to MI_3 (M = Ce, Nd, U) in anhydrous pyridine led to the quantitative formation of the bis-terpy complexes $[MI_2(terpy)_2]I$ [M = Ce (**1**) and Nd (**2**)] and $[MI_2(terpy)_2L]I$ [M = U and L = pyridine (**3**); M = Ce and L = H_2O (**4**)]. Conductometry measurements indicated that these complexes are 1:1 electrolytes in pyridine solution. ^1H NMR competition experiments showed that the terdentate ligand has a better affinity for U^{III} than for Ce^{III} or Nd^{III}. The X-ray crystal structures of solvates of **1**–**4** have been determined. The average U–N(terpy) bond lengths in **3** are 0.05 Å shorter than the mean Ce–N bond length in **4**; the U–N(central pyridine) distances are shorter than the U–N(distal pyridines) distances in **3**, while the reverse order is found in the early lanthanide compounds. These differences could reflect the presence of a π back-bonding interaction between the uranium atom and the terpy ligand.

Introduction

The separation of trivalent actinides (americium and curium) from trivalent lanthanides represents a challenging goal in the management of spent nuclear fuels. Such a separation process would permit the subsequent destruction of the long-lived americium and curium radionuclides by neutron bombardment, leading to their transmutation into short-lived isotopes; this scenario is called the partitioning and transmutation scenario (P & T).[1] Much attention has been paid to ligands that would favour the selective complexation of trivalent actinides (An^{III}) over trivalent lanthanides (Ln^{III}) in liquid/liquid solvent extraction processes. A generally accepted idea is that such a selectivity could be attainable by using soft nitrogen or sulfur ligands, since these would bind preferentially to the 5f ions as they are slightly less hard than the 4f ions.[2] These ligands should preferably be multidentate in order to compete with the water molecules in their coordination to the 4f and 5f ions. In fact, a number of nitrogen aromatic bases have been shown to selectively extract actinides rather than lanthanides from acidic aqueous effluents into an organic phase. In particular, it has been recently found that the terdentate ligand 2,2′:6′,2′′-terpyridine (terpy), in synergistic combination with 2-bromodecanoic acid, gave an Am^{III}/Eu^{III} separation factor $SF_{Am/Eu}$ of 7 at 0.01 M HNO_3, $SF_{Am/Eu}$ being defined as the ratio of the distribution ratios of Am^{III} and Eu^{III} in the organic and aqueous phases.[3] However, no actinide complex with terpy has been isolated and characterized so far, even though this ligand has been widely used in the coordination chemistry of the d transition metals[4] and 4f elements,[5−14] especially for the synthesis of complexes exhibiting unique luminescence and redox properties.

Following our comparative studies on the coordination of aromatic nitrogen bases to Ln^{III} and An^{III} ions, with the aim of investigating the factors that play a determining role in selectivity, the nature of the metal-ligand bond and the respective involvement of 4f and 5f electrons, we have examined the complexation of CeI_3, NdI_3 and UI_3 with terpy in anhydrous pyridine. As in our previous work on the complexation of these metal triiodides with 2,2′-bipyridine (bipy)[15] and 2,6-bis(5,6-dialkyl-1,2,4-triazin-3-yl)pyridines (btp),[16] U^{III} was used as an actinide analogue of the highly radiotoxic Am^{III} and Cm^{III}, and the similarly sized Ce^{III} and Nd^{III} were chosen as representatives of the lanthanides. The low complexing ability of the iodide counterion and the weaker solvation properties of pyridine relative to water are expected to favour the differentiation of the trivalent 4f and 5f ions. Here we report on the synthesis and characterization of the bis-terpy complexes $[MI_2(terpy)_2]I$ [M = Ce (**1**) and Nd (**2**)] and $[MI_2(terpy)_2L]I$ [M = U and L = pyridine (**3**); M = Ce and L = H_2O (**4**)]. The better affinity of the terdentate ligand for U^{III} vs. Ce^{III} and Nd^{III} was meas-

ured by ^{1}H NMR competition experiments and the distinct coordination of terpy to the 5f ion was revealed by X-ray crystallography with a comparison of the metal-nitrogen bond lengths in solvates of compounds **1**−**4**.

Results and Discussion

Formation of the bis-Terpy Complexes

Addition of two equivalents of terpy to a pyridine solution of $[MI_3(py)_4]$ (M = Ce, Nd, U; py = pyridine) led to the formation of the bis-terpy complex $[MI_3(terpy)_2]$ [M = Ce (**1**) or Nd (**2**)] or $[UI_3(terpy)_2(py)]$ (**3**). After evaporation of the solvent, the compound was washed with tetrahydrofuran and isolated as an orange (Ce), yellow (Nd) or dark red powder (U) in good yield. Complexes **1**−**3** gave satisfactory elemental analyses (C, H, N).

The conductivity of a 10^{-2} M solution of **1** or **3** in anhydrous pyridine at 20 °C has a value of 120 μS cm^{-1} which corresponds to a 1:1 electrolyte. Complexes **1**−**3** are thus totally dissociated in solution into a cation/anion pair of $[MI_2(terpy)_2(py)_x]^+$ and I^-. This dissociation is also observed in the crystal structures (vide infra). It has previously been found that at the same concentration and temperature, the dissociation of $[MI_3(py)_4]$ (M = Ce, U) and $[CeI_3(bipy)_2(py)]$ is equal to 40 and 60%, respectively, corresponding to a conductivity of 45 and 75 μS cm^{-1}, whereas $[UI_3(bipy)_2(py)]$ is almost completely dissociated into $[UI_2(bipy)_2(py)_x]^+$ and I^-.[15]

The ^{1}H NMR spectra of **1**−**3** in [D$_5$]pyridine at 20 °C exhibit a set of resonances corresponding to equivalent and symmetrical terpy ligands, thus indicating that the complexes are fluxional in solution, as usually observed with f elements compounds that undergo facile intramolecular exchange of the ligands. Coalescence of the signals occurs at lower temperature, although the slow-limit spectra could not be obtained.

In order to observe a 1:1 complex as a possible intermediate in the formation of **1**−**3**, a 10^{-2} M solution of $[MI_3(py)_4]$ (M = Ce, Nd, U) in [D$_5$]pyridine was titrated at 20 °C with terpy in the presence of cyclohexane as internal standard. The ^{1}H NMR spectra showed that, whatever the number n of ligand equivalents ($0 \leq n \leq 2$), only the 1:2 complex **1**, **2** or **3** was formed in an immediate and quantitative manner. For $n > 2$, free terpy was observed in solution, with no exchange with coordinated ligands, and no 1:3 complex was detected. In agreement with the ^{1}H NMR titration, the conductivity of the solution at 20 °C was found to grow in a linear fashion, from 45 to 120 μS cm^{-1}, with increasing quantities of terpy ($0 \leq n \leq 2$) and was then constant for $n > 2$. Such a preference for the formation of the 1:2 or 1:3 complexes with respect to the 1:1 complex remains very rare in coordination chemistry; for lanthanides, it has been observed with bipy[15] and terdentate nitrogen ligands.[16,17]

The quantitative formation of **1**−**3** in pyridine contrasts with that of the 1:1 complexes $[LnCl(terpy)(H_2O)_x]Cl_2$ (Ln = Ce − Lu),[5] $[Ln(terpy)(H_2O)_x]Br_3$ (Ln = La, Er, Tm, Yb, Lu),[6] $[Ln(O_2CCCl_3)_3(terpy)(L)]$ (Ln = Yb and L = MeOH; Ln = Lu and L = H_2O),[7] $[Ln(NO_3)_3(terpy)(H_2O)_x]$ (Ln = Nd, Ho, Er, Tm, Yb),[8] $[Er(NO_3)_3(terpy)(EtOH)]$[9] and $[Ln(NO_3)_2(terpy)(H_2O)_x][NO_3]$ (Ln = La, Gd, Tb, Lu)[10] which were synthesized from the corresponding lanthanide salts and one equivalent of terpy in a mixture of water and alcohol or in acetonitrile. Addition of two equivalents of terpy to the halides LnX_3 (X = Cl, Br) in ethanol gave the 1:2 complexes $[LnCl_3(terpy)_2(H_2O)_x]$ in the case of the heavier lanthanides (Eu, Gd, Dy and Er), whereas attempts to prepare the analogues of the early lanthanides Nd and Sm failed.[11] The 1:1.5 complexes $[Ln(NO_3)_2(terpy)_2][Ln(NO_3)_4(terpy)]$ (Ln = La, Nd, Sm, Tb, Dy, Ho) were formed by addition of four equivalents of terpy to a solution of the hydrated lanthanide nitrate in acetonitrile.[8a,10] These results show the difficulty in forming the bis-terpy compounds of the lighter lanthanides by using counterions and/or solvents with strongly coordinating properties. It is only with the weakly coordinating perchlorate anion that the 1:3 species $[Ln(terpy)_3][ClO_4]_3$ (Ln = Ce, Eu, Lu) crystallized from acetonitrile or ethanol solutions.[13] In this context, the formation of the bis-terpy complexes **1**−**3** as the sole products of the reactions of $[MI_3(py)_4]$ (M = Ce, Nd, U) with terpy in anhydrous pyridine is remarkable.

Not surprisingly, terpy was found to have a better affinity for the trivalent f ions than bipy, since under the same conditions it was necessary to add more than 10 (M = Ce, U) or 20 (M = Nd) equivalents of the bidentate ligand to $[MI_3(py)_4]$ to observe the complete formation of the corresponding 1:2 complexes $[MI_3(bipy)_2(py)]$ or $[MI_2(bipy)_2(py)]I$.[15] By considering only the contribution of the chelate effect,[18] the apparent formation constants $\log\beta_2$ of complexes **1**−**3** would range between 3.1 and 3.7. However, terpy is a much weaker complexant than the btp molecules which readily give the 1:3 complexes $[M(btp)_3]I_3$ (M = Ce, U) in a quantitative manner.[16]

Selective Complexation of U^{III} over Ce^{III} or Nd^{III}

The competition reactions of Ce^{III} or Nd^{III} and U^{III} with terpy were monitored by ^{1}H NMR spectroscopy. Addition of two mol equivalents of terpy to one mol equivalent of both $[CeI_3(py)_4]$ and $[UI_3(py)_4]$ in [D$_5$]pyridine led to the formation of complexes **1** and **3** with a U^{III}/Ce^{III} separation factor of 3.0. Similar experiments with $[NdI_3(py)_4]$ gave compounds **2** and **3** with a U^{III}/Nd^{III} separation factor of 2.5 (here, the separation factor is expressed as the ratio of the concentrations of **3** and **1**, or **3** and **2**). These results demonstrate that the terdentate ligand has a much better affinity for the 5f ion than for its 4f analogues. The U^{III}/Ce^{III} separation factor of 3.0 observed with terpy is greater than that of 1.3 determined from competition reactions of $[CeI_3(py)_4]$ and $[UI_3(py)_4]$ with bipy in the molar ratio of 1:1:2.

Previous studies on the MI_3/bipy system revealed that the bidentate ligand bipy has a slightly better affinity for $[CeI_2(py)_x]^+$ than for $[CeI_3(py)_4]$ while it coordinates almost exclusively to the cationic species $[UI_2(py)_x]^+$.[15] It was then

difficult to determine if the weakly selective complexation of U^{III} over Ce^{III} or Nd^{III} in pyridine solution would result from the stronger complexation of the σ-donor ligand bipy to the hard cation $[UI_2(py)_x]^+$ and/or from the π back-donation of the 5f orbitals into the π* orbitals of the aromatic ring. A more clear-cut situation is encountered with terpy in the competition reactions between Ce^{III} or Nd^{III} and U^{III} since all the 1:2 complexes **1**−**3** are totally dissociated in solution. The preferred formation of the U^{III} derivative **3** should be related to a more important covalent contribution to the metal-nitrogen bonding.

Moreover, it is remarkable that even though complexes **1**−**3** have all been prepared and crystallized from pyridine, only the uranium compound **3** retains a solvent molecule in its coordination sphere; this ligand is not labile and could not be eliminated by heating under vacuum. This better affinity of U^{III} vs. Ce^{III} or Nd^{III} for the pyridyl moiety would be an additional indication of the relatively greater softness of the trivalent 5f ion. However, crystallization of the cerium derivative **1** in pyridine in the presence of traces of water gave the addition product $[CeI_2(terpy)_2(H_2O)]I$ (**4**) (vide infra), showing the capacity of the lanthanide ion to coordinate the hard oxygen ligand in preference to the softer aromatic nitrogen base. The synthesis of the uranium compound $[UI_2(terpy)_2(H_2O)]I$ was attempted in order to compare its crystal structure with that of **4**. However, in the presence of traces of water, **3** was oxidized into an U^{IV} oxo complex; this latter will be reported in a forthcoming paper.

The selectivity of terpy for trivalent actinides over trivalent lanthanides, although significant, is much less important than that observed with btp molecules, which is ca. ten times greater.[16,19] The high actinide(III)/lanthanide(III) separation factors obtained with these ligands have been attributed to their weaker basicity and the much softer nature of their nitrogen atoms, which result in the formation of stronger actinide-nitrogen bonds with increased covalent character.

The distinct affinities of bipy, terpy and btp ligands for 5f vs. 4f trivalent ions could also be assessed through the crystal structures of their analogous complexes.

X-ray Crystal Structures of $[MI_2(terpy)_2]I\cdot 2py$ (M = Ce, Nd), $[UI_2(terpy)_2(py)]I\cdot 2py$ and $[CeI_2(terpy)_2(H_2O)]I\cdot 1.5py\cdot 0.5Et_2O$

Pyridine solvates of **1**, **2** and **3** crystallized upon slow diffusion of diethyl ether into pyridine solutions of the complexes; crystallization of **1** from solvents containing traces of water gave yellow crystals of $[CeI_2(terpy)_2(H_2O)]I\cdot 1.5py\cdot 0.5Et_2O$. The crystals are composed of cation/anion pairs and solvent molecules; selected bond lengths and angles for the cations are listed in Table 1.

Compounds **1·2py** and **2·2py** are isostructural; the structure of the cation $[CeI_2(terpy)_2]^+$ is shown in Figure 1. The metal is eight-coordinate in a very distorted square antiprismatic configuration. The two iodide ligands and two distal nitrogen atoms (N_d) of the two terpy ligands [N(3) and N(4)] occupy the opposite corners of the first square base, respectively, whereas the second basis is defined by the two central nitrogen atoms (N_c) [N(2) and N(5)] and the other two distal nitrogen atoms of the terdentate molecule [N(1) and N(6)], which are mutually *trans*. The average Ln−I bond lengths of 3.182(3) Å (Ln = Ce) and 3.153(4) Å (Ln = Nd) are similar to those in $[CeI_3(i\text{PrOH})_3]$ [3.157(1) Å],[20] $[CeI_3(bipy)_2(py)]$ [3.23(3) Å][15] and $[NdI_2(C_5Me_5)(py)_3]$ [3.1603(5) Å].[21] The Ln−N bond lengths are also not exceptional, with mean values of 2.63(2) Å (Ln = Ce) and 2.60(2) Å (Ln = Nd), and are similar to those found in $[LnCl_2(terpy)(H_2O)_5]Cl_2\cdot 3H_2O$ [2.64(2) and

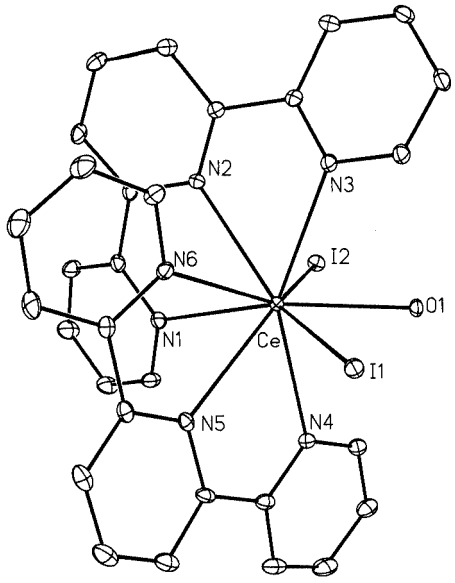

Figure 2. Crystal structure of the cation $[CeI_2(terpy)_2(H_2O)]^+$ in **4·1.5py·0.5Et$_2$O** with displacement ellipsoids at the 30% probability level

2.61(1) Å for Ln = Ce and Nd, respectively].[5] The Ce−I and Ce−N distances are systematically slightly longer than the Nd−I and Nd−N distances, in agreement with the 0.03 Å difference between the ionic radii of Ce^{III} and Nd^{III}.[22]

A comparison of the X-ray crystal structures of terpy complexes showed that the disparity that is usually observed between the $M-N_c$ and $M-N_d$ bond lengths (i.e. $M-N_c < M-N_d$) diminishes and is eventually reversed as the metal-ligand distance increases.[23] In the series of the lanthanide mono-terpy compounds, the experimental value of 2.58 Å has been found to be the limit for the $Ln-N_c$ distance at which this inversion would occur. Thus, the $Ln-N_c$ distances are generally longer than the $Ln-N_d$ distances for the early lanthanides, as observed in the cation $[Nd(NO_3)_2(terpy)_2]^+$.[8] However, the $Ln-N_c$ distances in **1** and **2** are intermediate between the $Ln-N_d$ distances in both terpy ligands. Such deviations from the general trend, which have also been observed in the other cations $[Ln(NO_3)_2(terpy)_2]^+$ (Ln = La, Sm, Tb),[8,12] have been explained by steric constraints in the coordination sphere.

The structures of the cations $[CeI_2(terpy)_2(H_2O)]^+$ and $[UI_2(terpy)_2(py)]^+$ are shown in Figure 2 and 3, respectively. The configuration of these nine-coordinate complexes can be described as a distorted square antiprism similar to that defined in compounds **1** and **2** which is capped on its I(1)N(3)I(2)N(4) base by a water or pyridine molecule. As a consequence of the coordination of this additional ligand, the I(1)−M−I(2) angles of 147.22(3)° (M = U) and 144.04(2)° (M = Ce) are larger than those found in **1** [119.12(2)°] and **2** [119.07(1)°], and the distortion from planarity of one of the two terdentate ligands [N(1)N(2)N(3)] is more pronounced, the standard deviations of the skeletal atoms from the median planes being ±0.21 Å in **3** and ±0.27 Å in **4**, almost 0.1 Å greater than those found in the other terpy ligands. A similar greater distortion of one of the terpy ligands has been observed in the cations $[Ln(NO_3)_2(terpy)_2]^+$ (Ln = Sm, Dy, Ho).[8] The average Ce−N bond length in **4** is 0.05 Å longer than that found in **1**, a difference which corresponds perfectly to that expected from the increase of the coordination number by one unit.[22] The $Ce-N_c$ distances of 2.691(4) and 2.692(4) Å are then longer than all the $Ce-N_d$ distances, which range between 2.652(4) and 2.686(4) Å. The Ce−I(1) bond length in **4** is 0.07 Å longer than the average Ce−I distance in **1**, although the Ce−I(2) bond length of 3.345(1) Å seems abnormally longer, perhaps reflecting the tendency for the iodide ion to dissociate. The $Ce-O(H_2O)$ bond length of 2.468(3) Å can be compared with the mean distance of 2.53(3) Å in the ten-coordinate complex $[CeCl_2(terpy)(H_2O)_5]Cl_2·3H_2O$.[5]

Because of the coordination of the extra pyridine molecule, the crystal structure of **3** cannot be compared directly with that of its cerium analogue, as was possible with the bipy and btp complexes $[UI_3(bipy)_2(py)]$[15] and $[U(btp)_3]I_3$.[16] However, careful examination of the terpy coordination in compounds **1**, **3** and **4** reveals quite distinct and interesting features. Firstly, the mean value of the U−N(terpy) bond lengths of 2.63(3) Å is exactly the same as the average Ce−N bond length in **1**, even though it would be expected to increase by about 0.05 Å in view of the coordination number of **3**, which is higher by one unit, and the ionic radius of U^{III}, which is about 0.01 Å longer than that of Ce^{III}.[22] It is noteworthy that the mean U−I bond length of 3.25(2) Å is 0.07 Å longer than the average Ce−I distance in **1** and corresponds effectively to the variation of the coordination number. On the other hand, the average U−N(terpy) bond length in **3** is 0.05 Å shorter than the mean Ce−N bond length in **4**, even though the two complexes have the same coordination number and exhibit quite similar geometrical parameters. These observations

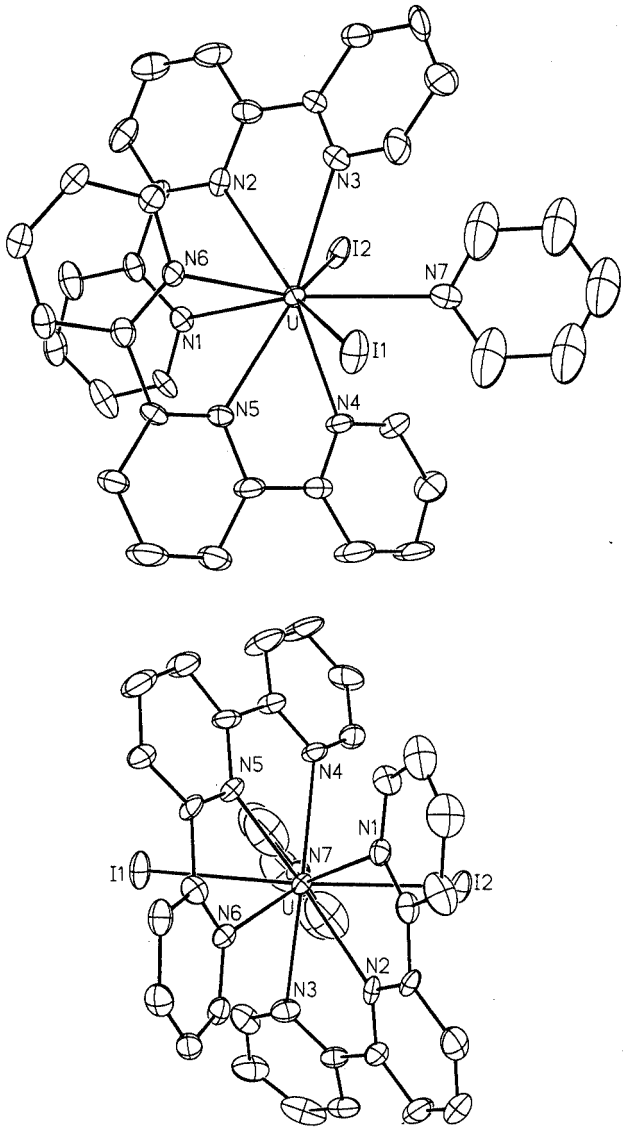

Figure 3. Crystal structure of the cation $[UI_2(terpy)_2(py)]^+$ in **3·2py** with displacement ellipsoids at the 30% probability level; views parallel (top) and perpendicular (bottom) to the bases of the distorted square antiprism

strongly suggest that the terpy ligand is more tightly bond to U^{III} in **3** than to Ce^{III} in **1** and **4**. If the U−N(terpy) bond lengths in **3** are considered to be ca. 0.05 Å shorter than those expected from a purely ionic bonding model, this variation is in the middle of the differences of 0.02 and 0.08 Å that have been measured between the U−N and Ce−N bond lengths in the analogous compounds $[MI_3(bipy)_2(py)]$[15] and $[M(btp)_3]I_3$ [16] (M = Ce, U), respectively. The shortening of the U−N bonds with respect to the Ce−N bonds follows the order bipy < terpy < btp which actually corresponds to the increasing preference of these molecules to bond $[UI_3(py)_4]$ vs. $[CeI_3(py)_4]$ in pyridine solutions. This trend in the interatomic distances indicates that the U−N bonds are stronger than the Ce−N bonds, probably due to a π back-bonding interaction between the uranium atom and the aromatic ligand that is much less likely in the lanthanide complex.[24]

The second striking feature in the structure of **3** concerns the U−N(2) and U−N(5) distances of 2.618(9) and 2.602(10) Å, which are shorter than all the other U−N(terpy) distances which vary from 2.624(9) to 2.657(10) Å. Complex **3** is a unique terpy compound in which the $M-N_c$ bond lengths, while being greater than 2.58 Å, are shorter than the $M-N_d$ bond lengths. As previously noted, the reverse order is generally observed in the terpy complexes of the early lanthanides, especially in **4**, and also in the bismuth compound $[Bi(S_2CNEt_2)I_2(terpy)]$ [$Bi-N_c$ = 2.63(2) Å; $Bi-N_d$ = 2.61(2) Å].[23] It is noteworthy that in these lanthanide and bismuth compounds, metal-to-ligand π back-bonding is unlikely. In the terpy complexes of the d transition metals, the $M-N_c$ distance is always shorter than the average $M-N_d$ bond length, a feature which has been attributed to a more efficient overlap of the metal t_{2g} orbitals with the π* orbitals of the central pyridyl moiety than with the distal pyridine rings.[25] Spectroscopic studies on terpy complexes of Cu^{II} have also shown that the central pyridine of the terpy ligand is a good π-acceptor.[26] That the $M-N_c$ bond length is the most sensitive to changes in the spin state of the metal ion was demonstrated by the structural studies of the cobalt complexes $[Co(terpy)_2]X_2$ (X = Cl, Br, I, SCN, ClO_4) in which the $Co-N_c$ distances contract by 0.21 Å on passing from a high-spin to low-spin electronic ground state, whereas the $Co-N_d$ distances contract by only 0.07 Å; this variation has been explained by a greater back-bonding from the cobalt to the central pyridine in the low-spin compound.[27] From these considerations, the fact that the $U-N_c$ distances are shorter than the $U-N_d$ distances in **3**, while the reverse situation is found in the aforementioned lanthanide and bismuth compounds, would be a further indication of the presence of a π back-bonding interaction between the metal centre and the terpy ligand in the uranium complex.

Conclusion

Addition of terpy to $[MI_3(py)_4]$ (M = Ce, Nd, U) in anhydrous pyridine gave the complexes $[MI_2(terpy)_2]I$ [M = Ce (**1**) and Nd (**2**)] and $[UI_2(terpy)_2(py)]I$ (**3**) which are unique examples of bis-terpy compounds of the early lanthanides and uranium. Competition experiments showed that terpy has a better affinity for UI_3 than for CeI_3 in pyridine solution, the separation factors being intermediate between those observed with the bipy and btp molecules. This order of selectivities, bipy < terpy < btp, corresponds to the order of the differences between the U−N and Ce−N bond lengths in the crystal structures of analogous U^{III} and Ce^{III} complexes. In the crystal structure of **3**, the first terpy complex of uranium, a further indication of the presence of a π back-bonding interaction between the trivalent 5f ion and the aromatic nitrogen ligand is given by the U−N(central pyridine) distances, which are shorter than

the U−N(distal pyridine) distances, while the reverse situation is observed in the early lanthanide terpy complexes.

Experimental Section

General: All experiments were carried out under argon (less than 2 ppm oxygen and water) using standard Schlenk and vacuum-line techniques or in a glove box. Solvents were thoroughly dried and deoxygenated by standard methods and distilled immediately before use. [D_5]pyridine was distilled over NaH and stored over 3 Å molecular sieves. The ^{1}H NMR spectra were recorded on a Bruker DPX 200 instrument and were referenced internally using the residual protio solvent resonances relative to tetramethylsilane ($\delta = 0$). Conductivity measurements were performed at 20 °C with a Consort C-832 conductometer; the cell constant was equal to 0.1 cm^{-1}. Elemental analyses were performed by Analytische Laboratorien at Lindlar (Germany). Terpyridine, CeI_3 and NdI_3 (Aldrich) were dried under vacuum, and [$UI_3(py)_4$] was synthesized as previously reported.[28]

Synthesis of [$CeI_2(terpy)_2$]I (1): A 25 mL round-bottomed flask was charged with CeI_3 (50 mg, 0.096 mmol) and terpy (45 mg, 0.19 mmol), and pyridine (20 mL) was condensed into it under vacuum at −78 °C. The suspension was heated at 100 °C until a clear solution was obtained. The solvent was evaporated off and the orange powder of **1** was washed with THF (15 mL) and dried under vacuum (90 mg, 94%). ^{1}H NMR (200 MHz, [D_5]pyridine): δ = 10.97 (d, J = 7.0 Hz, 2 H), 10.43 (s, 2 H), 10.36 (t, J = 7.0 Hz, 1 H), 8.47 (t, J = 7.0 Hz, 2 H), 6.51 (d, J = 7.0 Hz, 2 H), 3.88 (s, $w_{1/2}$ = 25 Hz, 2 H). $C_{30}H_{22}CeI_3N_6$ (987.4): calcd. C 36.49, H 2.24, N 8.51; found C 36.33, H 2.34, N 8.64.

Synthesis of [$NdI_2(terpy)_2$]I (2): An NMR tube was charged with NdI_3 (10.0 mg, 0.019 mmol), terpy (9.5 mg, 0.04 mmol) and freshly distilled pyridine (1.0 mL). The reaction mixture was heated at 110 °C for 30 min. After evaporation of the solvent, the yellow powder of **2** was washed with tetrahydrofuran (3 mL) and dried under vacuum (15 mg, 80%). ^{1}H NMR (200 MHz, [D_5]pyridine): δ = 11.85 (s,$w_{1/2}$ = 30 Hz, 4 H), 10.36 (s, $w_{1/2}$ = 20 Hz, 1 H), 9.18 (s, $w_{1/2}$ = 20 Hz, 2 H), 8.41 (s, $w_{1/2}$ = 25 Hz, 2 H), 7.7 (masked by the py resonance). $C_{30}H_{22}I_3N_6Nd$ (991.5): calcd. C 36.34, H 2.23, N 8.47; found C 36.57, H 2.34, N 8.53.

Synthesis of [$UI_2(terpy)_2(py)$]I (3): A 25 mL round-bottomed flask was charged with [$UI_3(py)_4$] (50 mg, 0.053 mmol) and terpy (25 mg, 0.20 mmol), and pyridine (20 mL) was condensed into it under vacuum at −78 °C. The dark solution was stirred for 30 min at 20 °C. The solvent was evaporated off and the dark red powder of **1** was washed with tetrahydrofuran (15 mL) and dried under vacuum (46 mg, 75%). ^{1}H NMR (200 MHz, [D_5]pyridine): δ = 24.61 (t, J = 7.0 Hz, 1 H), 18.20 (t, J = 7.0 Hz, 2 H), 10.49 (s, $w_{1/2}$ = 30 Hz, 4 H), 8.35 (s, $w_{1/2}$ = 20 Hz, 2 H), 7.02 (d, J = 6.0 Hz, 2 H). $C_{35}H_{27}I_3N_7U$ (1164.4): calcd. C 36.10, H 2.33, N 8.42; found C 36.39, H 2.93, N 8.17.

Conductometry Studies: A 10^{-2} M solution of Ce^{III} or U^{III} in anhydrous pyridine was prepared by dissolving CeI_3 (52.1 mg) or

$[UI_3(py)_4]$ (93.5 mg) in pyridine (10 mL). After 5 min at 20 °C, the electrode was immersed into the solution and the conductivity was equal to 45 μS cm^{-1}. The conductivity was found to grow linearly upon addition of n equivalents of terpy ($0 \leq n < 2$) to reach the maximum value of 120 μS cm^{-1} for $n \geq 2$. The conductivity of 10^{-2} M solutions of NaI or NR_4I (R = *n*-butyl or *n*-pentyl) in pyridine was also equal to 120 μS cm^{-1}.

Competition Experiments: An NMR tube was charged with CeI_3 (2.2 mg, 4.3 10^{-3} mmol) and $[UI_3(py)_4]$ (4.0 mg, 4.3 10^{-3} mmol) in $[D_5]$pyridine (1.0 mL), and cyclohexane (1.0 μL) was added with a microsyringe. Terpy (2.0 mg, 8.6 10^{-3} mmol) was added to the dark violet solution. After 10 min at 20 °C, the spectrum showed the complete complexation of terpy and the formation of **1** and **3** with a U^{III}/Ce^{III} molar ratio of 3.0. A similar experiment with NdI_3 in place of CeI_3 gave a mixture of **2** and **3** with a U^{III}/Ce^{III} molar ratio of 2.5.

An NMR tube was charged with CeI_3 (2.8 mg, 5.4 10^{-3} mmol) and $[UI_3(py)_4]$ (5.1 mg, 5.4 10^{-3} mmol) in $[D_5]$pyridine (1.0 mL), and cyclohexane (1.0 μL) was added with a microsyringe. Bipy (1.7 mg, 10.9 10^{-3} mmol) was added to the dark violet solution. After 10 min at 20 °C, the spectrum showed that 25% of the bipy was complexed, giving a mixture of the 1:1 and 1:2 complexes $[MI_3(bipy)(py)_x]$ and $[MI_3(bipy)_2(py)_x]$ (M = Ce, U)[12] with a U^{III}/Ce^{III} separation factor of 1.3.

X-ray Crystallography Studies: Crystal data and a summary of data collection and refinement parameters are given in Table 2. Diffraction collections were carried out on a Nonius diffractometer equipped with a CCD detector. The lattice parameters were determined from ten images recorded with 2° Φ scans and later refined on all data. A 180° Φ range was scanned with 2° steps with a crystal-to-detector distance fixed at 28 mm (**1**) or 30 mm (**2**, **3** and **4**). Data were corrected for Lorentz-polarization and absorption[29] effects. The structures were solved by the direct atom method and refined by full-matrix least-squares on F^2 with anisotropic thermal parameters for all non-hydrogen atoms. H atoms were introduced at calculated positions and constrained to ride on their parent C atom with an isotropic displacement parameter equal to 1.2 (CH, CH_2) or 1.5 (CH_3) times that of the parent atom. In compound **3**, all pyridine molecules were constrained to fit a regular hexagon with an equal anisotropic displacement parameter. In compound **4**, one pyridine and one diethyl ether solvent molecule were found on the same position and refined as disordered over two positions with an occupation factor of 0.5 each. All calculations were performed on an O2 Silicon Graphics Station with the SHELXTL package.[30]

CCDC-174669 (**1·2py**), -174667 (**2·2py**), -174668 (**3·2py**) and -174666 (**4·1.5py·0.5Et$_2$O**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

A Novel Configuration of a Benzoylacetonato-Diorganotin Species is Modified by an Electron-Withdrawing Substituent on Tin − Synthesis, IR and NMR Spectroscopy, Structure, and ab initio Studies

Claudio Pettinari,*[a] Fabio Marchetti,[a] Riccardo Pettinari,[a] Asta Gindulyte,[a] Lou Massa,[a] Miriam Rossi,[d] and Francesco Caruso*[e]

Keywords: Tin / O ligands / NMR spectroscopy / Crystal structure / Ab initio calculations

Diorganotin(IV) complexes of the β-diketonato benzoylacetonato ligand were synthesized and characterized with IR and multinuclear (H, C, Sn) NMR spectroscopy. The X-ray diffraction study of bis(benzoylacetonato)di-*tert*-butyltin(IV) shows two independent molecules in the crystallographic unit cell. The metal polyhedron is a distorted octahedral (Skewed Trapezoidal Bipyramidal) with the *trans* angle C–Sn–C of 151.5(5)°. Each ligand chelates the metal with different donor abilities [Sn–O bond lengths of 2.423(8) Å and 2.135(8) Å in one ligand, and 2.107(9) Å and 2.357(8) Å in the other]; results for the 2nd molecule are similar. The coordination arrangement differs from those of related bis(β-diketonato)diorganotin derivatives containing asymmetric ligands, which are characterized by an approximate C_s symmetry, in that both benzoylacetonato ligands point their methyl (and phenyl) substituents across (*anti*) the metal atom. Chelate planarity and some phenyl-chelate coplanarity was observed. Hartree–Fock (HF) and Density Functional Theory (DFT) calculated structures are in good agreement with those obtained using X ray analysis. DFT and HF calculated structures of bis(benzoylacetonato)diphenyltin(IV), having a similar connectivity as bis(benzoylacetonato)di-*tert*-butyltin(IV), differ markedly: the phenyls subtend a C–Sn–C bond angle of 180°, all Sn–O bond lengths are equal and the tin coordination sphere is a regular octahedron with the ligand bzac being isobidentate. This arrangement is caused by the phenyl electronic withdrawal effect. However, IR data for this compound show several Sn–O bands inconsistent with this configuration and suggest a different connectivity. Additional DFT structural calculations for $(bzac)_2SnPh_2$, performed on the connectivity resembling the "normal" *syn* geometry, show a conformational energy slightly lower than that of the centrosymmetric arrangement. Low temperature NMR spectra illustrate the possible rearrangements in solution.

Introduction

The acetylacetonato-like donors represent one of the most important classes of chelating ligands in the field of coordination chemistry, not only because of their technological applications,[1−4] but also for theoretical structural studies performed on their metal complexes.[5,6] Several studies have appeared in the literature regarding structural and spectroscopic features of tin(II)[7−11] and tin(IV) acetylacetonates,[12−23] including their catalytic properties in the formation of polyurethane in foams,[24] their promising antineoplastic activity,[25−27] and more recently, their use as molecular precursors in LAD (laser ablation and subsequent deposition) technology.[28]

Diorganotin(IV) acetylacetonates adopt a *trans* regular octahedral geometry[12] (Figure 1), whereas dihalotin(IV) acetylacetonates prefer the *cis*-dihalo octahedral configuration.[18]

Subsequent studies on monothioacetylacetonatotin[29] derivatives revealed the possibility of large deviations from ideal geometries in accordance with the Zahrobsky[30] and Kepert models.[31] Other studies on asymmetric β-diketonates have appeared recently, including our own systematic

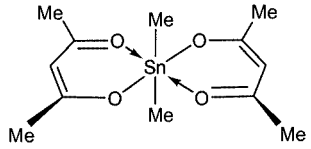

Figure 1. $(acac)_2Sn(CH_3)_2$

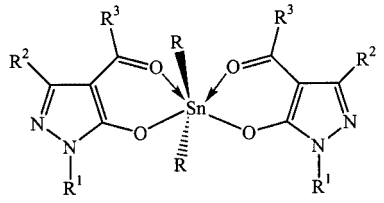
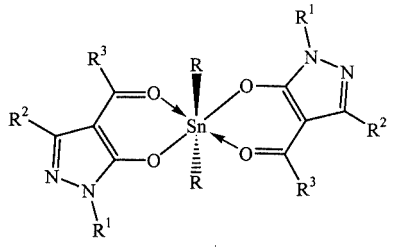
investigations on the structural aspects of tin(II)[32] and tin(IV)[33] derivatives containing 4-acyl-5-pyrazolonato ligands, which are β-diketonates fused to a pyrazole ring[34] containing three substituent groups. In these asymmetric ligands, the carbonyl nearest the heterocyclic ring is a better donor than the 4-acyl carbonyl group, and the diorganotin derivatives posses strongly deformed octahedral structures (Figure 2a) with both ligands pointing their equivalent arms in a *syn* configuration.



(a) *syn* configuration



(b) *anti* configuration

Figure 2. (a) *syn* configuration (b) *anti* configuration

Our studies have revealed the following geometrical features of these tin complexes: i) the *trans* C−Sn−C bond angle can be as small as 150°, and ii) the R groups are folded towards the O(acyl) atoms. The O(pyrazolonato) atom (that is, the oxygen closest to the pyrazole ring) forms a short, covalent, Sn−O bond (range 2.09−2.14 Å), whereas the O(acyl) atom forms a long, coordinative, Sn−O bond (range 2.22−2.46 Å).[33b] The asymmetric binding of these ligands reflects the different electronic donating ability of the oxygen atoms and is responsible for the octahedral deformation described earlier. In contrast, the dimethyltin derivative of the symmetrical β-diketonato acac has maximum electronic delocalization in the chelate moiety and is a perfect octahedron[12] (Figure 1). We have also found, however, that an appropriate choice of peripheral substituents on N1 allows the synthesis of isomers with a centrosymmetrical (*anti*) configuration (see **b** in Figure 2).[35]

It seems that the features determining the *syn* and *anti* configurations are subtle and more factors than those first hypothesized are responsible. For example, in octahedral diphenyltin compounds, *cis*-diphenyl species are also known. Specifically, in the case of bis(4-acyl-5-pyrazolonato)diphenyltin compounds, the *cis* arrangement has been observed with Mössbauer spectroscopy.[33c] Subtle molecular changes can also induce the *trans* form in related compounds such as Ph_2SnCl_2(2,2′-bipyridine), which is a *trans*-diphenyl *cis*-dichloro species, whereas (*p*-tolyl)$_2SnCl_2$(2,2′-bipyridine) is a *cis*-ditolyl *trans*-dichloro isomer.[36] Therefore, we decided to reinvestigate the field of diorganotin(IV) classical β-diketonates giving special attention to the asymmetric donor 1-phenylbutane-1,3-dionato, also known as benzoylacetonato (bzac), to derive some fundamental principles from the stereochemistry of these compounds.

Results and Discussion

Synthesis of the Diorganotin(IV) Derivatives 1−6

Derivatives $(bzac)_2SnR_2$ **1−6** were synthesized by interaction of two mmoles of bzacH and one mmole of the appropriate diorganotin(IV) acceptor in methanol in the presence two mmoles of $NaOCH_3$ (Scheme 1).

$$2bzacH + 2NaOCH_3 + R_2SnX_2 \rightarrow (bzac)_2SnR_2 + 2NaX + 2CH_3OH$$

	R	X		R	X
1	Me	Cl	**4**	*t*Bu	Br
2	Et	Cl	**5**	Cy	Cl
3	*i*Bu	Cl	**6**	Ph	Cl

Scheme 1

The reactions were performed according to methods previously employed with 4-acyl-5-pyrazolonato donors,[33] since they avoid hydrolysis. The yields of the reactions were higher when a large excess of bzacH was employed.

Spectroscopic Characterization

The infrared spectra of derivatives **1−6** show the carbonyl ν(C=O) shifted to lower frequencies upon complex formation, as expected for coordination of the β-diketonato ligand through both the oxygen atoms.[37] In the far-IR region several strong Sn−O bands[37] can be seen in the range 390−460 cm^{-1}. In the spectra of derivatives **1−5**, some medium to weak absorptions between 450 and 600 cm^{-1} were assigned to the ν(Sn−C) on the basis of literature reports.[38] In the spectrum of **6**, three strong bands in the range 250−310 cm^{-1} are due to ν(Sn−C).[39] In the spectra of **1−6**, the presence of several ν(Sn−O) and ν(Sn−C) modes indicates either distortion from ideal *trans*-octahedral geometry in the solid state (confirmed for **4** by the diffraction study, see below) or the presence of *cis* isomers.

The ^1H NMR spectra of derivatives **1** and **2** show one set of resonances for each magnetically equivalent group of protons. On cooling the samples, each signal splits into sev-

eral signals, two of which are very intense with respect to the others. We have measured the $^2J_{Sn,H}$ coupling constants and related them to the C−Sn−C angle.[40] From the empirical relation derived by Lockhart[40a] a C−Sn−C angle for compound **1** of ca. 160°, typical of skewed *trans*-octahedral species,[40] was found. For this reason, the two main resonances observed at low temperature for the CH_{bzac} and Me_{bzac} protons can be attributed to *syn* and *anti* isomers. The less intense signals are likely due to either *cis* isomers or four- to five-coordinate species involved in the interconversion mechanism between *syn* and *anti* isomers.

The ^{119}Sn NMR spectra of **1** and **2** further support our hypothesis: at room temperature only one resonance was detected, which split into two at 218 K.

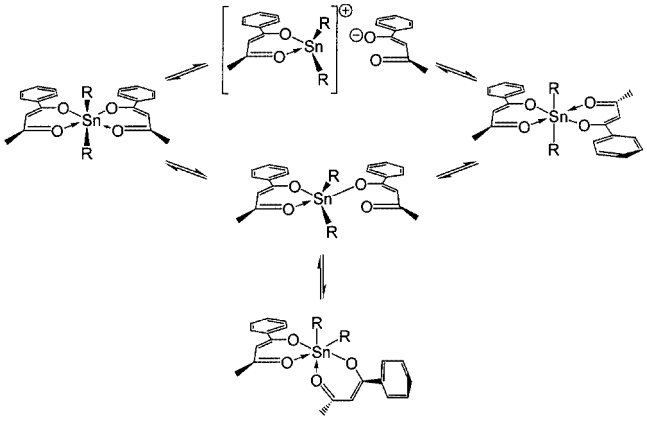
A similar situation was found for the derivatives **3**−**6** containing bulky or electron-withdrawing organic groups bonded to tin. In these compounds, the fluxionality is lost at higher temperature with respect to **1** and **2**. They show more than one set of resonances at room temperature, thus indicating that the energy required for the interconversion mechanism is a function of steric hindrance and electronegativity of the R groups coordinated to tin. At low temperatures, the ^{119}Sn NMR spectra of **5** and **6** show three resonances, two of which are dominant and are likely to be due to *syn* and *anti* isomers; the third is assigned to one *cis* $(bzac)_2SnR_2$ complex.[41]

Reports in the literature on possible mechanisms for configurational rearrangements of $(\beta\text{-diketonato})_2SnX_2$ complexes[39b,42] include: complete dissociation of one β-diketonato donor, to give a four coordinate intermediate; breaking of one M−O bond to give a five coordinate intermediate with a monodentate β-diketonato donor; and twisting mechanisms with subsequent rearrangement without any metal−ligand bond breaking.

To better understand the mechanism operating in solution for derivatives **1**−**6**, we carried out a ^{1}H NMR variable-temperature study of a mixture containing derivative **1** and the equivalent amount of free neutral bzacH proligand in $CDCl_3$. At room temperature, only one set of signals was observed, in accordance with ligand exchange in the complex, whereas at 218 K all resonances due to **1** and to the neutral bzacH in both enolic and ketonic forms were found. It seems that the twisting mechanism is excluded and the *syn-anti* conversion proceeds with breaking and re-formation of $Sn-O_{bzac}$ bonds through four- or five-coordinate intermediate species (Scheme 2). In the case of four coordinate intermediates the absence of conductivity in chlorohydrocarbon solvents could be attributed to ion pairing effects.

The variable-temperature ^{1}H NMR spectra indicate the following coalescence temperatures: 273 K (compounds **1** and **2**), 303 K (**3**), 323 K (**4** and **6**). These results further confirm the role of R groups on the configurational rearrangements.

The ^{119}Sn chemical shift is typical of six-coordinate SnC_2O_4 species, and is a function of steric and electronic features of R groups on tin. This is in agreement with previous studies on related $(4\text{-acyl-5-pyrazolonato})_2SnR_2$ derivatives.[33] The donating ability of $bzac^-$ is higher than that of 4-acyl-5-pyrazolonates, as the signals are generally high-field shifted with respect to that of 4-acyl-5-pyrazolonato complexes.



Scheme 2

The ^{13}C NMR spectra of **1**, **3**, and **4** show one broad set of resonances at room temperature. The magnitude of the $^1J(^{119}Sn-^{13}C)$ coupling constant of **1** (934 Hz) further supports the presence of *trans* isomers in solution.[40] The ^{13}C NMR spectrum of **6**, on the other hand, exhibits more than one set of resonances for each magnetically equivalent carbon atom, in accordance with the ^{1}H and ^{119}Sn NMR spectra.

X-ray Structural Discussion of Derivative $(bzac)_2Sn(tBu)_2$ (4)

The crystals of $(bzac)_2Sn(tBu)_2$ are formed by well separated molecules with no imposed crystallographic symmetry. Each asymmetric unit contains 2 molecules related by a local (non-crystallographic) inversion center at approximately [0.625, 0.0, 0.75] [see also Exp. Sect. and related Figure S1 (Supporting Information)]. Besides the inverted configuration only minor geometrical differences between these 2 molecules are observed, probably due to packing forces; one of these molecules is shown in Figure 3. The metal is six coordinate and surrounded by 4 O atoms from 2 bzac ligands, and 2 C atoms from the *tert*-butyl groups, which are almost eclipsed, as shown in Figure 4. Table 1 shows a selection of the structural data. The C−Sn−C bond angles [151.5(5)° for C11−Sn1−C15 in one molecule and 152.1(5)° for C51−Sn2−C55 in the other] are of the order found in bis(4-acyl-5-pyrazolonato)dialkyltin[33b] *syn* structures, as are the marked differences in Sn−O bonds in each ligand. The carbonyl closest to the methyl substituent in one ligand has the short Sn−O bond [Sn1−O2 = 2.135(8) Å], whereas in the other ligand the short bond is close to the phenyl substituent [Sn1−O21 = 2.107(9) Å]. This feature is uncommon for bzac compounds {but it does exist[43] in the anion $[(bzac)_4Eu]^-$} and contrasts with bis(4-acyl-5-pyrazolonato)diorganotin derivatives, where the short bond only appears in the carbonyl fused to the pyrazole ring, The ligand asymmetry differs from that of $(bzac)_2Sn^{II}$, which shows a short Sn−O bond for the

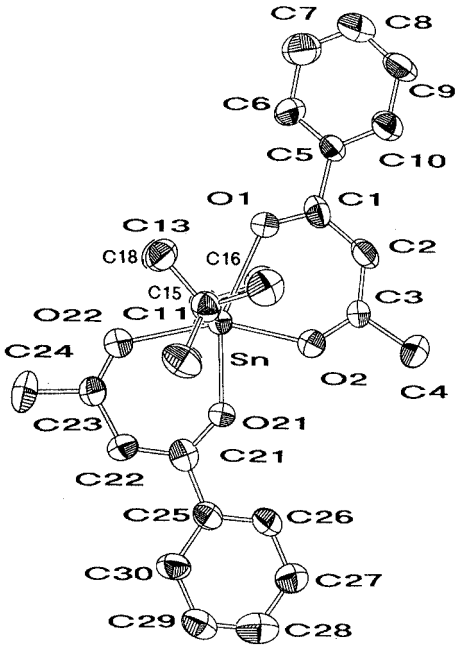


Figure 3. X-ray structure of $(bzac)_2Sn(tBu)_2$ (**4**). In this view, *tert*-butyl group C15−C18 (C15, C16, and C18 have small labels) is below the other *tert*-butyl C11−C14 (only C11 and C13 are labeled); H atoms are omitted.

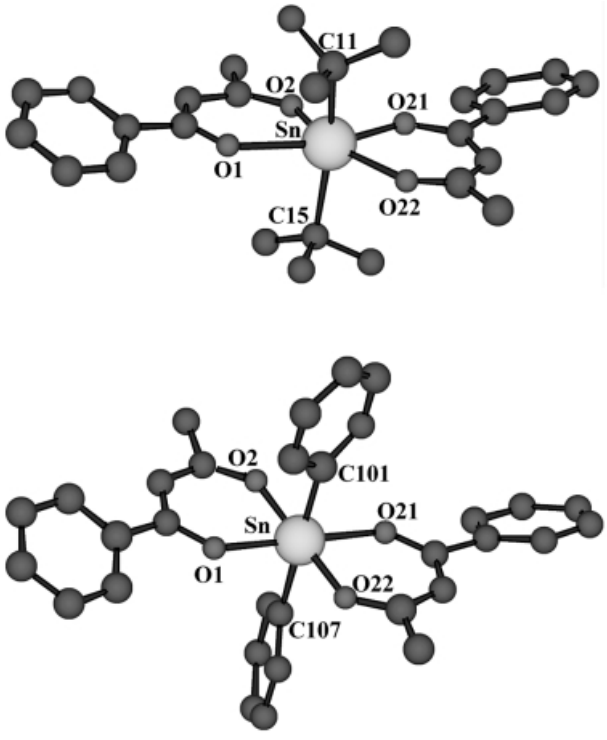

Figure 4. DFT structures of $(bzac)_2Sn(tBu)_2$ (**4**) and *anti* $(bzac)_2SnPh_2$ (**6**).

phenyl-carbonyl (2.13 Å) and a long Sn−O bond (2.29 Å) for the methyl-carbonyl, in both ligands.[10]

In analyzing the molecular arrangement, we see that the title compound has its bzac equivalent substituents (for instance both Ph groups) opposite each other. This is in contrast with *syn* bis(4-acyl-5-pyrazolonato)diorganotin derivatives that have the equivalent ligand substituents facing each other (see **a** in Figure 2). This opposite arrangement is reminiscent of the *anti* bis(4-acyl-5-pyrazolonato)diorganotin geometry[35] (see **b** Figure 2), although the latter also differs from the title compound and has a regular octahedral configuration with the C−Sn−C bond angle of 180°. Therefore, the structural form of the title compound is different from those so far observed.

X-ray data show planar chelate moieties. Thus, the least-square C1−C2−C3−O1−O2 plane has all atoms within 0.01 Å, and the C21−C22−C23−O21−O22 plane has all atoms within 0.04 Å; in the 2nd molecule these parameters are both 0.03 Å. The metals are contained in these chelate planes within 0.05 and −0.02 Å (for the 1st molecule) and −0.02 and 0.00 Å (for the 2nd molecule); therefore the molecule has a skewed trapezoidal bipyramidal (STB) configuration.[31] In addition, the dihedral angles between the two chelate planes are 2.4(2)°, in one molecule and 3.1(3)° in the other. Further, each phenyl substituent shows some co-planarity with its chelate moiety as seen by torsion angles O1−C1−C5−C6 [−19(2)°] and O21−C21−C25−C26 [−16(1)°].

There are two X-ray structures of di-*tert*-butyltin compounds containing four additional O atoms in the coordination sphere in the CSD database. These are di-*tert*-butyl-bis{[(*E*)-2-(2-hydroxy-5-methylphenyl)diazenyl]-benzoato-*O*,*O*′}tin(IV)[44] and di-*tert*-butyl-bis(1-phenyl-3-methylbenzoyl-pyrazolon-5-ato-*O*,*O*′)tin(IV).[45] In both complexes the oxygen ligands chelate the metal, as occurs in compound **4**. Comparison with compound **4** shows the former having a smaller C−Sn−C bond angle (141.0°) and a more deformed octahedron; the latter (containing a β-diketonato ligand) shows more similar features because its C−Sn−C bond angle is 150° and both *t*Bu groups are eclipsed as in compound **4** (see Figure 3).

Theoretical Study

The molecular structure of $(bzac)_2Sn(tBu)_2$ was also studied using theoretical methods. The starting coordinates were those obtained from the X-ray structure determination and were optimized by energy-minimization with the Hartree−Fock (HF) and Density-Functional Theory (DFT) methods. Structural data are included in Table 1. There is excellent agreement for the data obtained experimentally from the X-ray diffraction study for the deformed metal polyhedron including the sum of the *cis* O−Sn−O bond angles of 360°. The co-planarity in the chelate moieties resembles that observed with X-rays as shown by torsion angles in Table 1. The DFT structure is shown in Figure 4.

In previous studies on (4-acyl-5-pyrazolonato)organotin derivatives, we showed that an electron-withdrawing group on tin, such as Ph, behaves differently from alkyl groups.[33c] Due to the electron-withdrawing effect, phenyl groups pull electron density away from the metal and consequently induce more electron donation from the chelating ligands. Therefore, the normally weakly coordinated acyl carbonyl provides more electronic donation and this results in de-

[a] Methods, X-ray diffraction (XR); Hartree−Fock (HF); Density Functional Theory (DFT).

creased octahedral deformation.[33c] For this reason, we wanted to see if replacing the *tert*-butyl groups with phenyl groups resulted in some structural change, and so we also studied $(bzac)_2SnPh_2$ (**6**) theoretically. Therefore, the *tert*-butyl groups from $(bzac)_2Sn(tBu)_2$ were replaced by phenyls and the energy minimized as above (Figure 4 also depicts this calculated DFT molecule and Table 2 includes selected geometric data). This resulted in a dramatic variation on the molecular structure: the C−Sn−C bond angle became 180° and a regular octahedron was found. In addition, increased involvement in binding to tin by O1 and O22 was observed and all Sn−O bonds were equal (about 2.14 Å for HF or 2.19 Å for DFT).

Therefore, replacing the *tert*-butyl groups on tin with phenyls while keeping the $(bzac)_2Sn(tBu)_2$ connectivity, modified the skewed trapezoidal bipyramidal arrangement to regular octahedral. Moreover, the phenyl groups on tin caused the asymmetric binding of the ligand bzac to disappear, e.g. the ligand bzac became isobidentate. Co-planarity between phenyl substituents and chelate moieties was less marked than in the *tert*-butyl derivative, as seen from the corresponding torsion angles in Table 1 and 2.

However, IR data for $(bzac)_2SnPh_2$ show several Sn−O bands that are inconsistent with the symmetrical tin environment found using ab initio methods. IR results could imply either a *cis*-diphenyl structure or a *syn* STB structure with equivalent ligand arms (methyls or phenyls) facing each other. In other words, the theoretical study shows that the $(bzac)_2Sn(tBu)_2$ connectivity is not possible for $(bzac)_2SnPh_2$.

We then performed an additional DFT structural calculation for $(bzac)_2SnPh_2$, with a connectivity resembling the common *syn* geometry (see Figure 5). From the coordinates of *anti* $(bzac)_2SnPh_2$, obtained above, the methyl and the Ph groups belonging to the O1···O2 chelate were exchanged

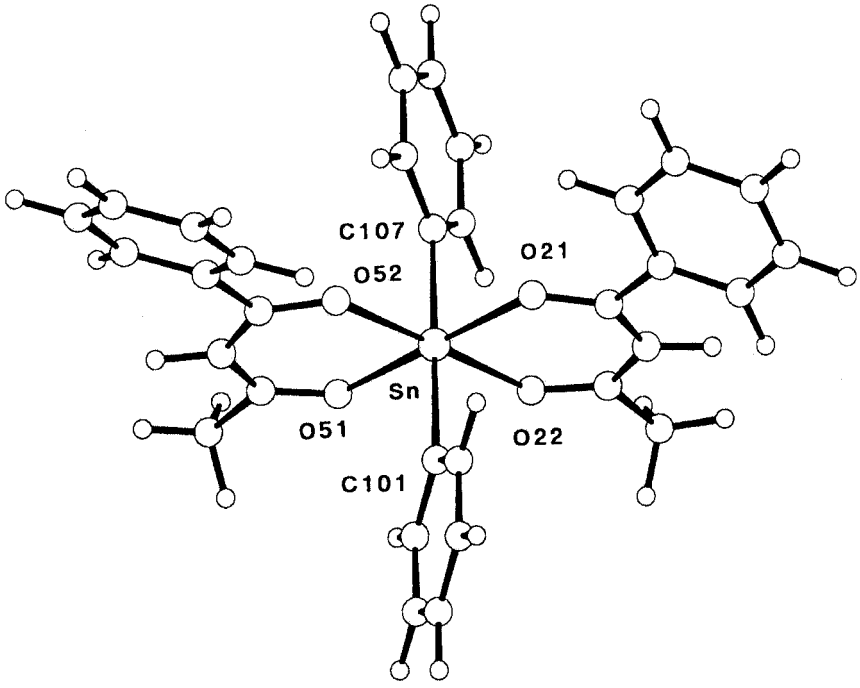

Figure 5. DFT structure of *syn* $(bzac)_2SnPh_2$ (**6**)

(this chelate is labeled O51···O52 in Figure 5), and a minimization process was performed as above. The resulting molecule posses a slight octahedral deformation characterized by a C−Sn−C bond angle of 178.3° and Sn−O bond lengths differ less in each ligand than in other *syn* (β-diketonato)SnR_2 compounds[33] (Sn−O21 = 2.198 Å and Sn−O22 = 2.176 Å in one ligand; Sn−O52 = 2.193 Å and Sn−O51 = 2.178 Å in the other ligand). From these results, the methyl carbonyl seems to be a slightly stronger donor that the phenyl carbonyl, which agrees with the phenyl electron-withdrawing and the methyl electron releasing effects. The Sn atom is included in the equatorial plane defined by the 4 oxygen atoms as expected for a STB geometry. Each chelate plane forms a similar dihedral angle with the corresponding attached phenyl ring (23.8 and 23.9°). The conformational energy of this *syn* structure is slightly lower than the one calculated with the *anti* geometry (0.03 kcal/mol). The experimental IR data seem consistent with the former option.

Conclusions

The already versatile stereochemistry of bis(β-diketonato)-diorganotin derivatives has been further enriched with the use of the ligand 1-phenylbutane-1,3-dionato (bzac). Derivative $(bzac)_2Sn(tBu)_2$ has a skewed trapezoidal bipyramidal (STB) configuration with methyl (and phenyl) ligand arms pointing opposite each other whereas in previously studied bis(β-diketonato)diorganotin derivatives,[33] the ligand arms were facing each other. The new structural form is ascribed to ligand asymmetry that induces different metal−O bond lengths.

The diffraction study shows that structural features of $(bzac)_2Sn(tBu)_2$ agree with HF and DFT calculated structures, including overall ligand planarity.

The molecular structure of $(bzac)_2Sn(tBu)_2$ contrasts with that of $(bzac)_2SnPh_2$ (calculated theoretically and *bearing the same connectivity*). The latter shows a regular octahedral configuration otherwise seen with the symmetric ligand acac. The phenyl groups on tin thus negate bzac ligand asymmetry, but since IR data for $(bzac)_2SnPh_2$ show several Sn−O bands indicating an asymmetrical Sn environment, the ab initio *anti* structure cannot be realistic. The *syn* structure, also calculated theoretically, agrees with IR results, though the energy difference between the *syn* and *anti* structures is small (0.03 kcal/mol) and comparison may be rather speculative. However, a *cis*-diphenyl structure is also an isomer that could explain the observed IR data. Further studies are planned to try to determine which is the actual isomer experimentally obtained.

It is concluded that a delicate balance of factors governs bis(β-diketonato)diorganotin stereochemistry. Several configurations are allowed dependent on a) tin's capacity for octahedral deformation; b) the interplay of electronic effects of the tin substituents; c) the intrinsic ligand asymmetry; and d) peripheral ligand modifications.

In closing, the NMR study shows that in the case of diorganotin(IV) complexes containing asymmetric β-diketonato ligands, a mixture of isomers is present in solution. Generally, the *trans* isomers are the most abundant and the conversions *cis-trans, syn-anti*, are strongly dependent on the temperature, and the bulkiness and electronegativity of the R groups. An asymmetric ligand demonstrates a completely different behavior in R_2Sn^{IV} species compared to symmetric

donors such as acac,[35] at least when electron-withdrawing substituents such as Ph are present.

Experimental Section

General Remarks: The organotin(IV) halides and benzoylacetone were purchased from Alfa (Karlsruhe) and Aldrich (Milwaukee) and used as received. The samples for microanalyses were dried under vacuum to constant weight (20 °C, about 0.1 Torr). Elemental analyses (C, H) were performed in house with Fisons Instruments 1108 CHNS-O Elemental Analyzer. IR spectra were recorded from 4000 to 100 cm^{-1} with a Perkin−Elmer System 2000 FT-IR instrument. ^1H, ^{13}C, and ^{119}Sn NMR spectra were recorded on a VXR-300 Varian spectrometer operating at 300 MHz for ^1H, 75 MHz for ^{13}C, and 111.9 MHz for ^{119}Sn, referred to TMS (^1H and ^{13}C) and $(CH_3)_4Sn$ (^{119}Sn). Relative intensities of signals are given in square brackets. The ^{119}Sn NMR experiments were carried with a spectral width of 900 ppm. Melting points were taken on an IA 8100 Electrothermal Instrument. The electrical conductances (reported as Ω^{-1} cm^2 mol^{-1}) of dichloromethane (M = mol/L) were measured with a Crison CDTM 522 conductimeter at room temperature.

Synthesis of the Complexes

Bis[1-phenylbutane-1,3-dionato]dimethyltin(IV) [(bzac)$_2$SnMe$_2$] (1): To a methanol solution (30 mL) of bzacH (2 mmol) was added $NaOCH_3$ (2 mmol) and $(t\text{Bu})_2SnCl_2$ (1 mmol). A precipitate slowly formed after stirring the mixture for 36 h. The precipitate was then filtered, washed with methanol (ca 10 mL), and dried under reduced pressure at room temperature. This was re-crystallized from chloroform/*n*-hexane. Yield 74%. m.p. 138−139 °C. $C_{22}H_{24}O_4Sn$: calcd. C 56.09, H 5.13; found C 56.34, H 5.04. IR (nujol, cm^{-1}): $\tilde{\nu}$ = 1587 s, 1555 vs, 1540 sh, 1507 vs, ν(C=O) + ν(C=C), 573 s, 521 s, 436 s, 408 s, 323 m, 280 m, ν(Sn−C) + ν(Sn−O) + δ(bzac). ^1H NMR ($CDCl_3$, 295 K): δ = 0.74 [s, $^2J(^{119}Sn\text{-}^1H)$ = 98.7, $^2J(^{117}Sn\text{-}^1H)$ = 94.8 Hz, 6 H, Sn−Me], 2.13 (s, 6 H, Me_{bzac}), 6.01 (s br, 2 H, CH_{bzac}), 7.4 (m), 7.88 (d, 10 H, Ph_{bzac}). ^1H NMR ($CDCl_3$, 273 K): δ = 0.75 [s, $^2J(Sn\text{-}^1H)$ = 97.5 Hz, 6 H, Sn−Me,), 2.14 (s, 6 H, Me_{bzac})], 6.01 [5], 6.2 [1] (s br, 2 H, CH_{bzac}), 7.4 (m), 7.9 (d, 10 H, Ph_{bzac}). ^1H NMR ($CDCl_3$, 248 K): δ = 0.76 [s, $^2J(Sn\text{-}^1H)$ = 97.8 Hz, 6 H, Sn−Me)], 2.15 [5], 2.21 [1] (s, 6 H, Me_{bzac}), 6.02 [5], 6.21 [1] (s, 2 H, CH_{bzac}), 7.4 (m), 7.88 (d, 10 H, Ph_{bzac}). ^1H NMR ($CDCl_3$, 218 K): δ = 0.76 [4], 0.77 [5] [s, 6 H, Sn−Me, $^2J(Sn\text{-}^1H)$ = 98 Hz], 2.17 [5], 2.22 [1] (s, 6 H, Me_{bzac}), 6.01 [5], 6.03 [4], 6.22 [2] (s, 2 H, CH_{bzac}), 7.4 (m), 7.88 (d, 10 H, Ph_{bzac}). ^1H NMR ($CDCl_3$, 326 K): δ = 0.75 [s, $^2J(Sn\text{-}^1H)$ = 97.5 Hz, 6 H, Sn−Me], 2.14 (s, 6 H, Me_{bzac}), 6.01 (s br, 2 H, CH_{bzac}), 7.4 (m), 7.88 (d, 10 H, Ph_{bzac}). ^1H NMR ($CDCl_3$+ equimolar quantity of bzac, 295 K): δ = 0.74 [s, $^2J(Sn\text{-}^1H)$ = 97.8 Hz, 6 H, Sn−Me], 2.15 [2], 2.19 [10], 2.23 [2] (s, 12 H, Me_{bzac}), 4.08 (s, 1 H, CH_{2bzac}), 6.00 [2], 6.20 [1], 6.20 [5], 6.24 [2] (s, 4 H, CH_{bzac}), 7.4 (m), 7.88 (d, 20 H, Ph_{bzac}), 16.4 (br, 3 H, OH_{bzac}). ^1H NMR ($CDCl_3$+ equimolar quantity of bzac, 223 K): δ = 0.75 [9], 0.79 [1] [s, $^2J(Sn\text{-}^1H)$ = 122 Hz, 6 H, Sn−Me], 2.16 (s, 12 H, Me_{bzac}), 6.11 (s br, 4 H, CH_{bzac}), 7.4 (m), 7.88 (d, 20 H, Ph_{bzac}). ^{13}C NMR ($CDCl_3$, 295 K): δ = 7.7 [s, $^1J(^{119}Sn\text{-}^{13}C)$ = 934, $^1J(^{117}Sn\text{-}^{13}C)$ = 886 Hz, Sn−Me] 28.9 (s, Me_{bzac}), 97.1 (s br, CH_{bzac}), 127.4, 128.3, 131.4, 138.8 (4s, Ph_{bzac}), 183.4 (s, CO_{bzac}), 193.0 (s, CO_{bzac}). ^{119}Sn ($CDCl_3$, 295 K): δ = −355. ^{119}Sn ($CDCl_3$, 273 K): δ = −356. ^{119}Sn ($CDCl_3$, 248 K): δ = −355 [4], 359 [5]. ^{119}Sn ($CDCl_3$, 218 K): δ = −356 [4], 361 [5]. Λм (10^{-3} м) = 0.05.

Derivatives **2**−**6** were synthesized in a similar way, **2** formed after stirring the solution for 36 h, **3** and **4** formed after 24 h, and **5** and **6** precipitated immediately upon mixing the reactants at 273 K.

Bis[1-phenylbutane-1,3-dionato]diethyltin(IV) [(bzac)$_2$SnEt$_2$] (2): Yield 80%. m.p. 157 °C dec. $C_{24}H_{28}O_4Sn$: calcd. C 57.75, H 5.65; found C 57.32, H 5.71. Λм (10^{-3} м) = 0.4.

X-ray Crystallographic Studies

The structure was solved using direct methods with SIR.[46] Psi-scan showed no absorption anisotropy.

Crystals were obtained directly from the reaction mixture. Crystal data were collected with a Syntex P21 diffractometer. A diffraction quality crystal was selected and mounted on the diffractometer. The search subroutine showed orthorhombic axes and symmetry was the orthorhombic confirmed by taking rotation photograph about the 3 axes. Psi-scan showed no absorption anisotropy. Cell volume implies 8 molecules/cell and systematic extinctions indicated 2 possible space groups, *Pnma* and $Pna2_1$ (Table 3). Attempts to solve the structure in the centrosymmetric *Pnma* space group (which implies one molecule/asymmetric unit) failed, whereas using $Pna2_1$ space group (corresponding to 2 molecules in the asymmetric unit) allowed structure resolution with SIR.[46] The two independent molecules in the asymmetric unit show the [*x*,*y*,*z*] coordinates of corresponding atoms (for instance atoms named Sn and Sn2) add to [1.24, 0.02, 1.49]. Therefore an approximate local inversion point [0.625, 0.0, 0.75] relating the two independent molecules exists. Figure S1 depicts the cell packing approximately along axis *b*.

Table 3. Summary of crystal data

Empirical formula	$C_{28}H_{36}O_4Sn$
Formula mass	555.28
Cryst habit	hexagonal plate
Cryst size (mm)	0.40 × 0.25 × 0.10
Cryst system	orthorhombic
Space group	$Pna2_1$ (no. 33)
Crystal color	colorless
a (Å)	18.156(4)
b (Å)	10.012(2)
c (Å)	29.739(7)
V (Å^3)	5406(3)
Z	8
T (K)	298
$D_{calcd.}$ (Mg m^{-3})	1.365
$2\theta_{max}$ (°)	56
μ (mm^{-1})	0.983
Wavelength (Å) (graph monchr)	Mo-K_α
Scan speed (°min^{-1})	2
Transmission factors	0.99−1.00
Scan range (°)	1.2
Measured reflections	8713
Unique reflections	8039
Refined reflections $F>1.5\sigma(F)$	5773
Refined parameters	595
R,[a] R_w	0.043, 0.056
S[b]	0.82

[a] $R(F) = \Sigma|(Fo - Fc)|/\Sigma Fo$. [b] $S = [\Sigma\{w(F_0^2 - F_c^2)^2\}/(n - p)]^{0.5}$, *n* = no. of data and *p* = no. of refined parameters.

Each of the 4 pairs of molecules forming the cell is located approximately in each quarter of the picture and darker atoms are closest to the viewer. The four local inversion centers are evident. A further attempt to refine the structure in the *Pnma* space by shifting tin atom coordinates such that the inversion center found in $Pna2_1$ became the origin in *Pnma* was unsuccessful. This could be expected because there is no mirror plane evident (required for *Pnma*) in Figure S1; also the existence of only 4 inversion centers is coherent with 4 positions in $Pna2_1$ whereas a truly *Pnma* space group would require 8 inversion centers. The existence of local (non-crystallographic) centers of symmetry has been discussed by Marsh et al. who found that this feature accounts for at least 70% of all $Pna2_2$ structures explored in the CSD database.[47] Reflections collected: *h* [0−25], *k* [0−14], *l* [0−41]. H atoms riding on attached C atoms at 0.96 Å and hydrogen *B(iso)* fixed. Atomic scattering factors were taken from the literature.[48]

CCDC-171306 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Theoretical Studies

All computations were carried out with the MULLIKEN program[49] package on an IBM/SP2 supercomputer. Hartree−Fock and MB3LYPDFT (Density-Functional Theory)[50] methods were used. The basis set used with both methods was 6−31G*. For the tin atom an ECP approximation[51−59] was applied, as implemented within MULLIKEN, using a double zeta basis. The MULLIKEN default convergence criteria were used in computations of energies and geometries.

Supporting Information (see also footnote on the first page of this article): HF and DFT Cartesian coordinates for $(bzac)_2Sn(tBu)_2$ and *anti* $(bzac)_2SnPh_2$, DFT Cartesian coordinates of *syn* $(bzac)_2SnPh_2$.

Copper Complexes of Chiral Tetradentate Binaphthyl Schiff-Base Ligands: Syntheses, X-ray Crystal Structures and Activity in Catalytic Asymmetric Cyclopropanation of Alkenes

Chi-Ming Che,*[a] Hoi-Lun Kwong,*[b] Wai-Cheung Chu,[a] Kin-Fai Cheng,[a] Wing-Sze Lee,[b] Hing-Sun Yu,[b] Chi-Tung Yeung,[b] and Keung-Kai Cheung[a]

Keywords: Asymmetric catalysis / Copper / Cyclopropanation / Schiff bases / Structure elucidation

A number of new chiral monomeric binaphthyl Schiff-base ligands H_2L [where H_2L = 2,2′-bis(3-R^1-5-R^2-2-hydroxybenzylideneamino)-1,1′-binaphthyl] and a series of chiral copper(II) complexes [CuL] were prepared in good or nearly quantitative yields. Some of the free ligands and the [CuL] complexes were structurally characterized by X-ray crystallography. Almost all the [CuL] complexes were found to be active catalysts for the asymmetric cyclopropanation of alkenes with ethyl or *tert*-butyl diazoacetate. Enantioselectivities of up to 77% *ee* were observed.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Optically active cyclopropanes play an important role as intermediates in the syntheses of insecticides and drugs.[1] In this context, the search for effective catalysts for asymmetric cyclopropanation has continued to attract considerable interest.[2−3] Chiral ligands such as semicorrine,[4−7] bisoxazolines,[8−12] bipyridines[13−19] and Schiff bases[20−23] are the most efficient ligands for copper-catalyzed alkene cyclopropanation with diazoacetate.

Schiff-base ligands bearing a C_2-chiral auxiliary have been employed for a number of metal-catalyzed asymmetric reactions, such as Cu-catalyzed aziridination,[24−25] Mn-catalyzed epoxidation,[26] Co-catalyzed cyclopropanation,[27−29] Cr-catalyzed ring opening[30] and the hetero-Diels−Alder reaction.[31] In view of the excellent enantiofacial discriminating power exhibited by binaphthylic ligands in asymmetric metal catalysis,[32] we have previously studied the binaphthylic Schiff-base ligands 2,2′-bis(3-R^1-5-R^2-2-hydroxybenzylideneamino)-1,1′-binaphthyl (H_2L) and reported the use of their manganese and chromium complexes in the asymmetric oxidation of alkenes[33−35] and their titanium complexes in the asymmetric trimethylsilylcyanation of aldehydes.[36] Recently, great interest in the copper complexes of these binaphthylic Schiff-base ligands has arisen from a study of their derivatives as models for catalytic galactose oxidase.[37]

In the present work we describe the synthesis of a series of chiral copper(II)-binaphthyl Schiff-base complexes [CuL] together with several new chiral H_2L ligands. Some of the H_2L and [CuL] compounds were characterized by X-ray crystallography. The use of [CuL] complexes as catalysts for the asymmetric cyclopropanation of alkenes with an alkyl diazoacetate was explored, and this represents the first asymmetric alkene cyclopropanation catalyzed by metal complexes bearing a tetradentate binaphthyl Schiff-base ligand.

Results and Discussion

Synthesis of Chiral Schiff-base Ligands H_2L and Their Copper(II) Complexes [CuL]

Treatment of chiral 2,2′-diamino-1,1′-binaphthyl with various substituted salicylaldehydes afforded a series of chiral binaphthyl Schiff-base ligands H_2L^{1-13} in good yields. The preparation and characterization of $H_2L^{1,2,4-9}$ have been reported previously by us.[33,35] The new ligands $H_2L^{3,10-13}$ described in this work were obtained as orange crystalline solids and were characterized by IR, ^{1}H NMR and ^{13}C NMR spectroscopy (see Exp. Sect.). The key NMR spectral features of $H_2L^{3,10-13}$ include the imine proton resonances at δ = 8.53−8.73 (singlets), the aromatic proton resonances at δ = 6.62−8.15 (multiplets), the phenolic proton resonances at δ = 12.06−13.46 (broad singlets), and the

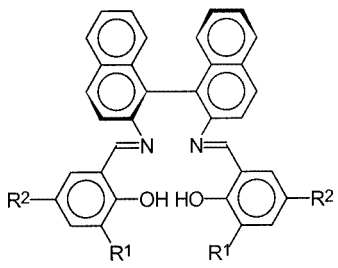
^{13}C resonances of the CH=N groups at $\delta = 160.3-163.3$ (singlets), all of which are similar to those reported for $H_2L^{1,2,4-9}$.[33,35] The IR spectra of $H_2L^{3,10-13}$ each show a strong band in the 3075−3800 cm^{-1} region attributable to ν(OH) and a band at about 1613 cm^{-1} attributable to ν(C=N).



Ligand	R^1	R^2
H_2L^1	Cl	Cl
H_2L^2	Br	Br
H_2L^3	I	I
H_2L^4	*t*Bu	*t*Bu
H_2L^5	Cl	*t*Bu
H_2L^6	*t*Bu	Cl
H_2L^7	*t*Bu	NO_2
H_2L^8	Et	NO_2
H_2L^9	H	NO_2
H_2L^{10}	H	Cl
H_2L^{11}	Cl	H
H_2L^{12}	EtO	H
H_2L^{13}	H	Ph

The chiral copper complexes of H_2L^{1-13} were prepared from the reaction of optically active H_2L^{1-13} with $Cu(OAc)_2$ in dichloromethane/methanol at room temperature. These complexes are air stable both as solids and in solution, as revealed by visible or IR spectroscopy. Elemental analysis indicated that they have a Cu:L molar ratio of 1:1. A principal feature of the IR spectra of these complexes is the intense absorption band ranging from 1584 to 1619 cm^{-1} which is assigned to ν(C=N). These ν(C=N) bands are shifted by about 10−27 cm^{-1} from those of the corresponding H_2L^{1-13} ligands.

X-ray Structure Analyses

The structures of H_2L^{12} and $[CuL^2]$ were determined by X-ray crystallography (see Figure 1−2). The crystallographic data are summarized in Table 1. Selected bond lengths and bond angles are given in Table 2−3.

Previously we reported the X-ray crystal structure of the racemic form of complex $[CuL^1]$.[33] Like $[CuL^1]$, the complex $[CuL^2]$ features a distorted tetrahedral CuN_2O_2 core. The bond angles in the CuN_2O_2 core lie in the range 88.7°−154.0° ($[CuL^2]$). The Cu−N and Cu−O bond lengths are ≈1.97 and ≈1.90 Å, respectively. CuL^2 also possesses a twisted seven-membered CuN_2C_4 ring. The dihedral angle between the two naphthyl rings is 72.49°, which is similar to that in $[CuL^1]$ (≈75°) but is considerably smaller than that of the free H_2L^{12} ligand (85.54°). Comparison of the structures of $[CuL^{1,2}]$ with the reported X-ray structure of a copper complex of the chiral Schiff base with a cyclohexyl rather than a binaphthyl moiety clearly shows that the binaphthyl moieties of $[CuL^{1,2}]$ enforce a non-square planar coordination geometry, while the cyclohexyl moiety prefers a square planar environment.

Enantioselective Cyclopropanation of Alkenes Catalyzed by CuL

Having prepared the copper complexes $[CuL^{1-13}]$, we studied their catalytic activities towards the asymmetric cyclopropanation of styrene with alkyl diazoacetates N_2CHCO_2R (R = Et, *t*Bu). The results are compiled in Table 4. Note that all the reactions were carried out in styrene. To reduce the formation of side products such as fumarate and maleate, the alkyl diazoacetate was added slowly in each case.

The results in Table 4 reveal that complexes $[CuL^{1-3,5,8-13}]$ are active catalysts for the above styrene cyclopropanations. The yields of the isolated cyclopropyl esters were moderate to excellent (32−99%) and the enantioselectivities obtained range from 3 to 73% *ee*. GLC analysis of the reaction mixtures showed that the *trans*/*cis* ratios of the cyclopropyl esters fall in the range of 65:35 to 80:20. The absolute configurations of the cyclopropyl esters were determined to be (*1S,2S*) and (*1S,2R*) for the *trans*- and *cis*-isomers, respectively. Variation of the structure of the

[a] Styrene was used as solvent. [b] For R = Et, enantiomeric excesses were determined by HPLC with Daicel Chiralcel OJ column. For R = *t*Bu, enantiomeric excesses were determined by GC with a chiraldex β-PH column. Absolute configurations were determined by comparing the order of elution of samples with known configuration (ref.[4]). [c] Isolated yield after chromatography.

diazoacetates had a large effect on both *trans*/*cis* diastereoselectivity and enantioselectivity. As shown in Table 4, when the R group changes from ethyl to a bulkier *tert*-butyl group the reactions gave higher *trans*/*cis* ratios and *ee*'s. This is consistent with the trend previously observed for other copper catalysts.[4] To the best of our knowledge, complexes $[CuL^{1-3,5,8-13}]$ are the first examples of a well-defined tetrahedral copper complex that is active for alkene cyclopropanation.

We found that ligands with different substituents on the phenolic rings of the Schiff-base ligands gave different results in both reactivity and selectivity, similar to the observation reported by Jacobsen and co-workers in the Mn-catalyzed epoxidation of alkenes.[38] For example, $[CuL^2]$, with $R^1 = R^2 = Br$ (entries 3 and 4), gave a higher enantioselectivity than $[CuL^{1,3}]$, with $R^1 = R^2 = Cl$ (entries 1 and 2), or I (entries 5−6). The effect of R^1 groups on the catalyst activity can be evaluated by comparing the results obtained for $[CuL^{1,6,10}]$ ($R^2 = Cl$; $R^1 = Cl$, *t*Bu and H respectively; see entries 1, 2, 11, 12, 19, and 20), and for $[CuL^{7-9}]$ ($R^2 =$

NO_2; R^1 = *t*Bu, Et and H, respectively, see entries 13−18), which shows that ligands with either electron-withdrawing or electron-donating R^1 groups (such as Cl or Et) *increased* the enantioselectivity. However, the ligands with R^1 = *t*Bu form the complexes [$CuL^{4,6,7}$] that are inactive in cyclopropanation (entries 7, 8, 11−14). This might be due to the bulkiness of the *t*Bu groups, which prevents the copper centers from interacting effectively with the incoming diazoacetates or styrene. The effect of R^2 groups on the catalyst activity is different from that of the R^1 groups. Comparison of the results obtained for [$CuL^{1,5,11}$] (R^1 = Cl; R^2 = Cl, *t*Bu and H, respectively; see entries 1, 2, 9, 10, 21, and 22), and for [$CuL^{9,10,13}$] (R^1 = H; R^2 = NO_2, Cl and Ph, respectively; see entries 17−20, 25 and 26) reveals that ligands with either electron-withdrawing or electron-donating R^2 groups almost all *reduced* the enantioselectivity. Also, the catalyst with R^2 = *t*Bu groups is active in cyclopropanation (entries 9 and 10). These results demonstrate that the reactivity and selectivity of the [CuL^{1-13}]-catalyzed styrene cyclopropanations are greatly affected by both the steric and electronic properties of the R^1 groups and by the electronic properties of the R^2 groups in the catalysts.

Evidently, of the thirteen copper complexes [CuL^{1-13}], complexes [$CuL^{2,11}$] are the best catalysts for the styrene cyclopropanation in terms of the product yields and enantioselectivity (see Table 4). Therefore, we studied the cyclopropanation of other alkenes with these two catalysts. The reactions were carried out in dichloromethane instead of styrene in order to get a better comparison of the substrate effects. Table 5 shows the results obtained for the cyclopropanation of various alkenes with *tert*-butyl diazoacetate. The isolated yields of cyclopropyl esters were good to excellent (57−96%) and the *trans*/*cis* ratios ranged from 74:26 to 90:10. Comparison of entries 1 and 2 in Table 5 with entries 4 and 22 in Table 4 indicates that the *trans*/*cis* ratios obtained in dichloromethane are higher than in styrene, although lower enantioselectivities were attained in the former solvent. For the cyclopropanation of most of the al-

[a] Dichloromethane was used as solvent. [b] For entries 1−7 and 12−15, enantiomeric excesses were determined by GC with a chiraldex β-PH column. For entries 8−11, enantiomeric excesses were determined by literature procedure (ref.[4]). Absolute configurations were determined by comparing the order of elution of samples with known configuration (ref.[4]). [c] Isolated yield after chromatography.

kenes in Table 5, [CuL[11]] was a better catalyst than [CuL[2]]. The former catalyst gave 77 and 66% *ee* (*trans*- and *cis*-isomers, respectively) for the cyclopropanation of chlorostyrene (entry 4) and a 90:10 *trans*/*cis* ratio for the cyclopropanation of *trans*-β-methylstyrene (entry 9), which are the highest *ee* value or *trans*/*cis* ratio in Table 5.

To probe the nature of the active intermediates in the cyclopropanation reactions, we measured the relative rates of the [CuL[2]]-catalyzed cyclopropanation of substituted styrenes with EDA through competition experiments. The Hammett plot of $\log(K_X/K_H)$ versus σ^+ is shown in Figure 3, which indicates that substituted styrenes with electron-donating groups (such as 4-methoxy- and 4-methylstyrenes) gave larger cyclopropanation rates, whereas those with electron-withdrawing groups (such as 4-chloro- and 4-trifluoromethylstyrenes) gave smaller cyclopropanation rates. A good σ^+ correlation is obtained with $\rho = -0.72$. This value is similar to those of other copper catalysts such as copper-terpyridine ($\rho = -0.79$) and copper-di-pyridyl ketone ($\rho = -0.74$) recently reported by our group.[39,40] The small negative value of ρ obtained supports the formation of electrophilic metal−carbene intermediates and only a moderate positive charge build-up at the benzylic carbon in the transition state in both systems.

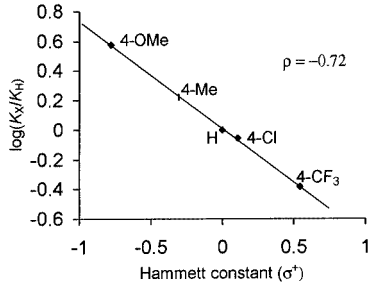

Figure 3. Hammett plot for the [CuL[2]]-catalyzed cyclopropanation of styrene with EDA

Conclusion

We have synthesizeds a series of tetrahedral copper(II) Schiff-base complexes [CuL] in nearly quantitative yield from the reaction of $Cu(OAc)_2$ with the chiral tetradentate binaphthyl Schiff-base ligands 2,2′-bis(3-R^1-5-R^2-2-hydroxybenzylideneamino)-1,1′-binaphthyl (H_2L). The structures of [CuL] feature distorted tetrahedral CuN_2O_2 cores, as revealed by X-ray crystallography. Almost all the chiral [CuL] complexes are good catalysts for the enantioselective cyclopropanation of alkenes with alkyl diazoacetate, affording the cyclopropyl esters in up to 77% *ee*. Both the steric and electronic properties of R^1 but only the electronic properties of R^2 have a large effect on the reactivity and enantioselectivity of the [CuL]-catalyzed cyclopropanation reactions. The highest enantioselectivity results from the catalyst bearing the new Schiff-base ligand L^{11} (R^1 = Cl, R^2 = H) prepared in this work.

Experimental Section

General: The chiral Schiff-base ligands $H_2L^{1,2}$ and H_2L^{4-9} were prepared as reported previously.[33,36] The substituted salicylaldehydes used in the syntheses were prepared by literature procedures.[41] Solvents for catalytic cyclopropanation were purified according to standard procedures.[42] *cis*-β-Methylstyrene was prepared by hydrogenation of 1-phenyl-1-propyne (Aldrich) using Lindlar catalysts.[43] All other alkene substrates used for catalytic cyclopropanation were purchased from Aldrich or Fluka and were purified either by vacuum distillation or by passing through activated alumina. IR spectra were recorded on a Shimadzu IR-470 or Nicolet 20sxc FTIR spectrometer, and NMR spectra were recorded on a Jeol GSX-270, Bruker 300 DPX or Bruker 500 DRX spectrometer in $CDCl_3$ unless otherwise stated, with TMS as internal standard at ambient temperature. Mass spectra were measured on a Finnigan MAT 95 high-resolution mass spectrometer and UV/Vis/NIR spectra on a Lambda 19 spectrometer. Analytical HPLC was performed on a Beckmann model 331 HPLC system with a model 163 variable UV/Vis detector or Hewlett Packard Model 1050 HPLC system. Chiral HPLC measurements were performed on a commercial column (Daicel Chemical Industries, Ltd., Chirlcel OJ). Analytical GC was performed on a Hewlett−Packard 5890 series II system equipped with an HP 5890A flame ionization detector and an HP 3395 integrator.

Preparation of the 1,1′-Binaphthyl Schiff-Base Ligands H_2L^3 and H_2L^{10-13}: A mixture of (*S*)-2,2′-diamino-l,l′-binaphthyl (0.5 mmol for H_2L^3, 1.0 mmol for the others) and the corresponding salicylaldehyde derivative (2.1 equiv.) in ethanol (10 mL for H_2L^3, 30 mL for the others) was stirred at room temperature for 3 h, resulting in precipitation of an orange solid. The precipitate was collected by filtration and washed with ethanol. Recrystallization from dichloromethane/ethanol afforded the desired product as an orange crystalline solid.

General Procedure for the Synthesis of [CuL]: A solution of $Cu(OAc)_2$ (1.5 equiv.) in methanol was added to a solution of binaphthyl ligand H_2L in dichloromethane. The mixture was stirred at room temperature for 3 h, resulting in precipitation of crude [CuL] as a dark green solid. The crude product was collected by filtration, washed with methanol and recrystallized with dichloromethane/ethanol or dichloromethane/pentane. Yield: close to 100%.

X-ray Crystallography: Suitable crystals of ligand H_2L^{12} and complex [CuL^2] were obtained by recrystallization of the compounds from dichloromethane/ethanol. Diffraction data were collected on a Rigaku AFC7R diffractometer at ambient temperature. Intensity data were corrected for Lorentz and polarization effects. Absorption corrections based on the χ scan technique were also applied. The structure was solved by direct methods (SIR 92) and refined on F by least-squares analysis. The absolute structure of the molecule was determined by analysis of both configurations including the anomalous scattering effect. Hydrogen atoms were placed in their ideal positions (C−H: 0.95 Å) and included in the structure factor calculations but were not refined. All calculations were performed on a silicon Graphic workstation with the teXsan package.[44]

CCDC-171639 and -171640 contain the supplementary crystallographic data for this paper (excluding structure factors). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

General Procedure for [CuL]-Catalyzed Diazoester Cyclopropanation of Styrene: A mixture of styrene (10 mmol) and [CuL] (0.5 mmol) was heated with stirring under nitrogen at 40 °C. To this mixture was added dropwise a solution of styrene (10 mmol) and ethyl or *tert*-butyl diazoacetate (5 mmol) over a period of 4 h. During this period, gas bubbles were evolved. The reaction was complete when no more bubbles were given off. The reaction products were isolated by column chromatography. The enantiomeric excess was measured by HPLC (Daicel Chemical Industries, Ltd., Chiral OJ column).

Relative Reactivity of Styrenes in the [CuL]-Catalyzed Cyclopropanation: In a typical competition reaction, equimolar amounts of styrene and substituted styrene (10 mmol each) and the copper

complex (0.5 mmol) were mixed in dichloromethane (5 mL) at 40 °C. To this mixture was added dropwise a solution of ethyl diazoacetate (1 mmol) over a period of 4 h. During this period, gas bubbles were evolved. The reaction was complete when no more bubbles were given off. The amounts of cyclopropyl esters formed were analyzed by GC and NMR spectroscopy.

Interactions between Copper(II) Complexes of Mono-, Bis-, and Tris(macrocyclic) Ligands and Inorganic or Organic Guests

Peter Comba,*[a] Yaroslaw D. Lampeka,*[b] Alexander Y. Nazarenko,[c] Alexander I. Prikhod'ko,[b] and Hans Pritzkow[a]

Keywords: Copper / Host-guest complexes / Macrocycles / Molecular recognition Template synthesis

The copper(II)-assisted condensation of $[Cu(2,3,2\text{-tet})]^{2+}$ [2,3,2-tet = bis-*N*,*N*′-(2-aminoethyl)propane-1,3-diamine] with formaldehyde and melamine (melamine = 2,4,6-triamino-1,3,5-triazine) afforded melamine-based mono-, bis-, and tris(macrocyclic) ligand/copper(II) complexes in approx. 30% overall yield. Three different monocopper(II), one dicopper(II), and one tricopper(II) complex structures are reported, as well as two structures of host-guest assemblies of the tricopper(II) complex with benzene-1,3,5-tricarboxylate and one resulting from a reaction with hexacyanoferrate(II) to afford an octanuclear Cu_6Fe_2 complex. These structures are discussed together with those of five previously reported similar compounds, and it is concluded that the two conformations of the tricopper(II) complex are similar in energy and that they are easily interconverted. The range of the structural flexibility of the tricopper(II) host is analyzed on the basis of the experimental structural data. The formation of the Cu_6Fe_2 assembly is assumed to be a stepwise procedure, the formation of the structurally previously unknown $[Fe_2(CN)_{11}]^{7-}$ anion is assisted by the Cu_3 host cation, and the host-guest assembly is stable in solution.

Introduction

Since the seminal work on the hexaamine cage ligands sepulchrate (sep)[1] and sarcophagine (sar) derivatives,[2,3] metal ion assisted Mannich-type condensations of primary amines with formaldehyde and amines or activated (acidic) alkanes have frequently been used to prepare open-chain, macrocyclic, and oligomacrocyclic ligands coordinated to various metal ions, primarily copper(II) and nickel(II).[4−14] Thanks to their rigidity, aromatic amines − and in particular the triamine melamine (melamine = 2,4,6-triamino-1,3,5-triazine) − are interesting candidates for "capping" groups in copper(II)-based template condensations. The poor acidity of the aniline-type amines in melamine is partially compensated by the presence of three azines, and we have established that the template reactions around copper(II) and nickel(II)[15] result in the desired products (see Scheme 1; similar results have also been published independently[16−18]).

Mono- and oligomacrocyclic ligands and their metal complexes have been used as hosts for organic and inorganic guest molecules.[19−24] Host-guest interactions range from π-stacking and van der Waals forces to hydrogen bonds and weak coordinative bonds. The last of these are interesting, specifically when labile sites such as the axial donors in Jahn−Teller active copper(II) complexes are involved, since the length and directionality of coordinative bonds allow the shape selectivity to be carefully tuned.[25] Examples of metal complex hosts include assemblies of tris[zinc(II)] compounds[26] and the stabilization of a reactive organic cation by a tetrahedral tetrakis[gallium(III)] complex host.[27] Here we present the syntheses of $[Cu(L^1)]^{2+}$, $[Cu_2(L^2)]^{4+}$, and $[Cu_3(L^3)]^{6+}$, together with structural studies of these complexes, as well as the structures of two host-guest complexes of $[Cu_3(L^3)]^{6+}$ with undecacyanodiferrate(II) and benzene-1,3,5-tricarboxylate.

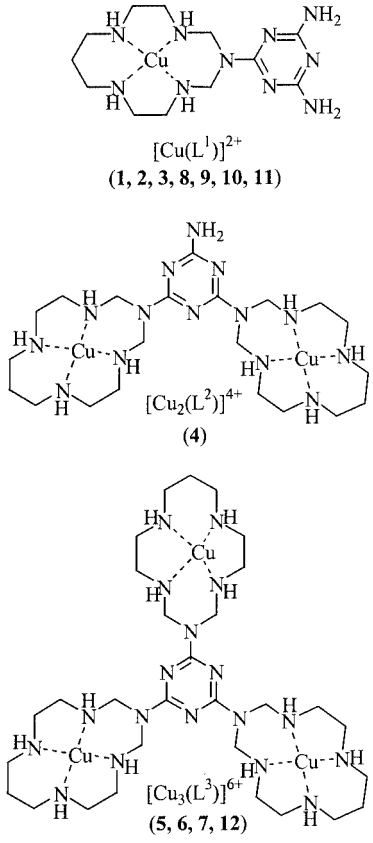
Results and Discussion

Syntheses and Solution Properties of the Copper(II) Complexes

The reaction between $[Cu(2,3,2\text{-tet})]^{2+}$, formaldehyde, and melamine in the presence of base (triethylamine) resulted in the formation of a mixture of mono-, di-, and



Scheme 1

trinuclear copper(II) compounds. Chromatographic separation yielded the pure copper(II) complexes of the mono-, bis- and tris(macrocyclic) melamine-based ligands: $[Cu(L^1)]^{2+}$, $[Cu_2(L^2)]^{4+}$ and $[Cu_3(L^3)]^{6+}$.

The infrared spectra of the three complexes were similar, and had features characteristic both of the melamine fragment and of the pentaazamacrocyclic ligand/copper(II) complexes. The number of bands corresponding to out-of-plane vibrations of the aromatic amino groups [$\delta(NH_2)$; 1660 cm^{-1} in crystalline melamine] were indicative of the nuclearity and the degree of protonation of the complexes: three bands (1690, 1640 and 1600 cm^{-1}) were observed in the protonated mono(macrocyclic) ligand complexes $[Cu(HL^1)](ClO_4)_3 \cdot H_2O$ and $[Cu(HL^1)](Cl)(ClO_4)_2 \cdot 0.5\ H_2O$, while two bands (1670 and 1600 cm^{-1}) were characteristic of the protonated bis(macrocyclic) ligand complex $[Cu_2(HL^2)](ClO_4)_5 \cdot 3H_2O$. Only one band was present in the spectra of the nonprotonated complexes $[Cu(L^1)](ClO_4)_2 \cdot H_2O$ (1600 cm^{-1}) and $[Cu_2(L^2)](ClO_4)_4 \cdot 2.5H_2O$ (1610 cm^{-1}). As expected, tris(macrocyclic) ligand complexes showed no strong band in this spectral region.

The electronic absorption spectra of the three complexes were also similar, and consisted of three transitions. The band in the visible region at 515 nm was typical of the four unresolved d-d transitions of the tetragonal copper(II) chromophore in complexes with 14-membered tetraazamacrocyclic ligands with weakly coordinated axial donors.[25,28] This transition did not depend on the nuclearity of the complex, and the molar absorptivity was proportional to the number of macrocyclic subunits in the molecule (see Exp. Sect.). This also applied for the LMCT transition at 253 nm. These two observations indicated that there was no significant direct electronic interaction between the copper chromophores in the oligomacrocyclic species. However, the high-energy electronic transition at approx. 210 nm, assigned to an intramolecular transition of the triazine residue [λ_{max} = 204 nm (ε = 52000 L mol^{-1} cm^{-1}) in melamine] showed a moderate bathochromic shift and a hyperchromic effect in the series $[Cu(L^1)]^{2+}$, $[Cu_2(L^2)]^{4+}$, $[Cu_3(L^3)]^{6+}$. This indicates increasing perturbation of the electronic structure of the aromatic ring by the attached macrocyclic ligand copper(II) complexes. The EPR spectrum of the mononuclear complex $[Cu(L^1)]^{2+}$ was typical for a tetragonal copper(II) tetraamine, with $g_{\|}$ = 2.190, $g_{\perp}$ = 2.041, and A_{II} = 205 10^{-4} cm^{-1}. Dipole-dipole interactions between the isolated chromophores were observed in EPR spectra of the oligonuclear complexes.[29]

Electrochemical oxidation of $[Cu(L^1)]^{2+}$, $[Cu_2(L^2)]^{4+}$, and $[Cu_3(L^3)]^{6+}$, measured by cyclic voltammetry with a glassy carbon electrode in neutral aqueous solution, was an irreversible process in each case. In highly acidic media (9.0 mol L^{-1} $HClO_4$) the copper(III) oxidation state can be stabilized,[30] and it is possible to obtain single, ill-resolved redox transformations with E_f at approx. 1.15 V vs. Ag/AgCl for all species {under similar conditions we have obtained the value E_f = 0.910 V for the $[Cu(cyclam)]^{3+/2+}$ couple (cyclam = 1,4,8,11-tetraazacyclotetradecane)}. The difference of approx. 200 mV reflected the electron-withdrawing effect of the melamine fragment, destabilizing the copper(III) state. Apparently, the destabilizing electrostatic effect due to the protonation of the triazine nucleus in highly acidic media is less important; this was also observed for the analogous nickel complexes.[15] Similarly to the behavior in the anodic region, all three copper compounds showed poorly resolved quasi-reversible $Cu^{II/I}$ cathodic waves at approx. −0.9 V vs. a saturated calomel electrode {acetonitrile solution, 0.1 mol L^{-1} [(nBu)$_4$N]ClO_4}.

Molecular and Crystal Structures of the Copper(II) Compounds

General Comments

Experimental solid-state structures of copper(II) complexes of mono-, di-, and trinucleating melamine-based ligands have been determined. They include the mono(macrocyclic) ligand complexes $[Cu(L^1)(OClO_3)_2] \cdot H_2O$ (**1**), $[Cu(HL^1)(OClO_3)_2](ClO_4) \cdot H_2O$ (**2**), and $\{[Cu(HL^1)(OH_2)(Cl)][Cu(HL^1)(OClO_3)(Cl)]\}(ClO_4)_3$ (**3**), the bis(macrocyclic) ligand complex $[Cu_2(L^2)(OClO_3)_4] \cdot H_2O \cdot CH_3OH$ (**4**), and the tris(macrocyclic) ligand complex $[Cu_3(L^3)(OH_2)_3](NO_3)_3(ClO_4)_3$ (**5**). The structures of two host-guest complexes with $[Cu_3(L^3)]^{6+}$ – $\{[Cu_3(L^3)]_2[Fe_2(CN)_{11}]\}(CN)(NO_3)_4 \cdot 34H_2O$ (**6**) and $[Cu_3(L^3)(OH_2)_6](C_9H_3O_6)_2 \cdot 40H_2O$ (**7**) ($C_9H_3O_6^{3-}$ = benzene-1,3,5-tri-

carboxylate) − have also been determined. These structures are discussed together with those recently reported for $[Cu(L^1)(OClO_3)_2]\cdot H_2O$ (**8**),[17] $[Cu(L^1)(CA\text{-}H)(OClO_3)]\cdot H_2O$ (**9**) (CA-H = cyanurate),[17] $[Cu(HL^1)(OClO_3)](ClO_4)_2\cdot 2H_2O$ (**10**),[16] $[Cu(HL^1)(OClO_3)_2](BA\text{-}H)\cdot 3H_2O$ (**11**) (BA-H = barbiturate),[17] and $[Cu_3(L^3)(OH_2)_2(OClO_3)_4](ClO_4)_2\cdot 3H_2O$ (**12**).[18]

The copper(II) ions in all structures reported here are coordinated to four nitrogen donors in the macrocycles, resulting in nearly planar CuN_4 chromophores (rms = 0.01−0.04 Å), with the copper(II) centers deviating from these planes only slightly (0.01−0.07 Å). The pentaaza macrocycles all have the expected *trans*-III (*RRSS*) configuration.[31] The metal−nitrogen distances (Table 1 and Supporting Information) fall in the range typical for copper(II) complexes with 14-membered tetraazamacrocyclic ligands.[32] Various coordination geometries are observed, including square-planar (4-coordinate, as in **10**), square-pyramidal (4 + 1, as in **6** and **9**), and square-bipyramidal [4 + 2, as in **4** and **7**; all interactions shorter than 3.0 Å are viewed as coordinative bonds, see Table 1].

The melamine rings in all complexes are nearly planar (rms = 0.00−0.02 Å). In view of the conjugation of the lone pairs of the melamine amino nitrogen atoms with the aromatic rings, the melamine residues were expected to be coplanar with the planes defined by the CNC fragments at the apexes of the substituted six-membered chelate rings (angle α: see Figure 1 and Table 1). However, this was only observed for one macrocyclic unit in the tris(macrocyclic) ligand complex **5** (α = 0.3°); in all other cases there were various degrees of deviation from coplanarity (2° ≤ α ≤ 27°). Also, the melamine-substituted CNC fragment is generally slightly tilted and this results in nonorthogonality of the mean plane of the triazine rings and the planes bisecting the macrocycles along the long axes (angle β, see Figure 1 and Table 1). Because of the *chair* conformation of the substituted six-membered chelate rings and the close to sp^2 hybridization of the bridgehead nitrogen atoms, the melamine rings are bent relative to the mean CuN_4 planes (angle γ in Figure 1 and Table 1). Therefore, the oligomacrocyclic ligand complexes each exist in two major conformations, depending on the orientation of the macrocyclic rings relative to the aromatic spacer group: *syn* (two macrocyclic units on the same side) or *anti* (two macrocyclic units on opposite sides) isomers for the bis(macrocyclic) compounds, and *syn*,*syn* or *syn*,*anti* isomers for the tris(macrocyclic) ligand complexes.

The conformational freedom (*syn* and *anti*) and the variability of the structural parameters α, β, and γ result in a variety of shapes of the oligonuclear copper(II) complexes. The largest variation is due to the tilt angle γ, which ranges from 11 to 62° (see Table 1). This gives rise to appreciable variation in the intramolecular copper−copper distances

Table 1. Structural parameters of the copper(II) complexes of the melamine-based oligomacrocyclic ligands L^1, L^2, and L^3

Complex	Intramolecular distances [Å]		Angles between the mean planes [°][a]				Orientation of the melamine rings

and, for the trinuclear compounds, considerable plasticity of the cavities for anion binding.

Mono(macrocyclic) Ligand Complexes

Three new structures of copper(II) complexes of L^1 are reported here (for ORTEP plots[33] see Figure 2), while four have been published before;[16,17] structural parameters for these are also included in Table 1. In three of the structures (**1**, **8**, and **9**), copper(II) is coordinated to the parent ligand L^1, while in the other four (**2**, **3**, **10**, and **11**) the melamine fragment is protonated at the central nitrogen atom ([N(8) and N(18) in Figure 2b,c), and so copper(II) is coordinated to HL^1. In the published structures (**9** and **11**), specific supramolecular interactions of the melamine fragments with substrates (carboxylates) were discussed.[16,17]

The structural parameters of all complexes are very similar; the main variations are in the axial coordination and the angles α, β, and γ. The structures reported here are six-coordinate, with ClO_4^- (**1** and **2**) and H_2O, Cl^-, and ClO_4^- (**3**) as axial donors. The most pronounced variation of the angles describing the relative orientation of the macrocyclic and melamine planes is that of the angle γ (37−62°). There is no apparent correlation of these parameters with other features (e.g., the protonation of the ligand), as was also observed for the corresponding nickel(II) complexes.[15]

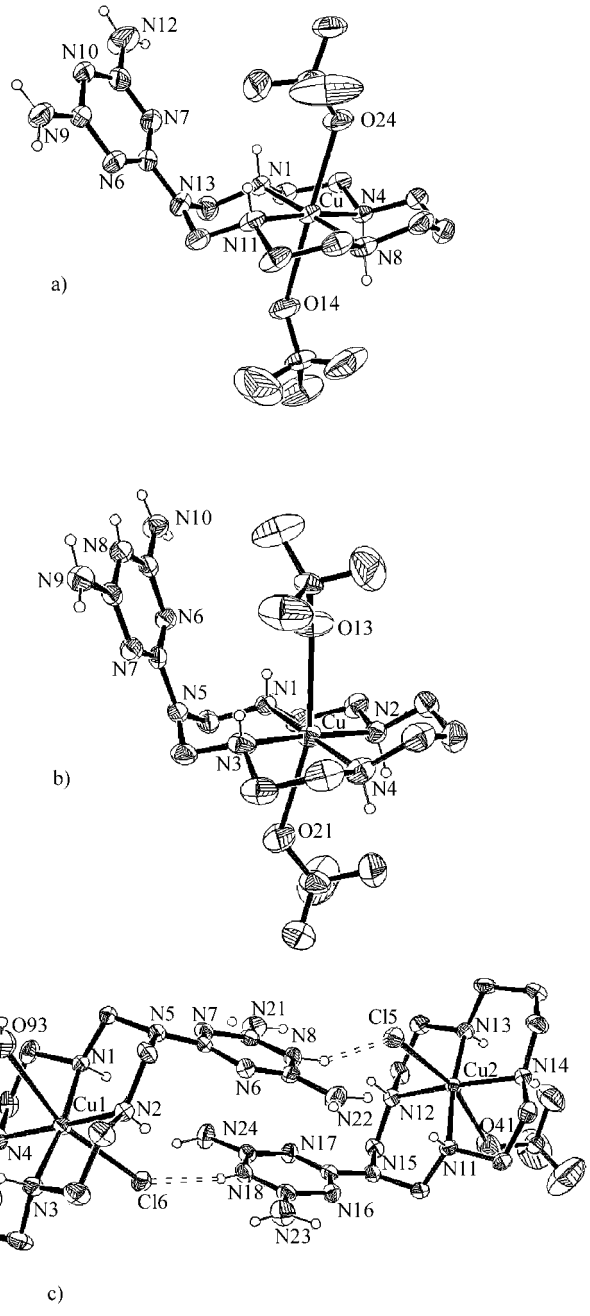

Figure 2. ORTEP[33] view (30% probability ellipsoids) of **1** (a), **2** (b), and **3** (c); C−H hydrogen atoms, lattice water molecules, and noncoordinated anions are omitted for clarity; selected distances and angles are shown in Table S1 (Supporting Information; see also footnote on the first page of this article)

Crystal Packing of the Mono(macrocyclic) Ligand Complexes

A major structural motif observed in the crystal lattices of the mononuclear melamine-based macrocyclic ligand/copper(II) complexes is the presence of infinite ribbons of copper(II) macrocycles, connected by hydrogen bonds, involving water molecules (**1**, **2**, **8**, **10**) or perchlorate anions (**3**). With the nonprotonated melamine groups (**1**, **8**) double-stranded tapes are formed between the self-complementary melamine rings [acceptor-donor-acceptor (ADA) pattern]. Protonation of the aromatic nitrogen atom of the triazine fragment breaks the self-complementarity (AAA pattern) and no double-stranded tapes are observed (**2**, **3**, **10**). Another common feature in the structures of the mono(macrocyclic) ligand complexes is an arrangement of the melamine rings that allows for π-stacking interactions; that is, the aromatic rings are nearly coplanar, with a distance of approx. 3.5.Å (Figure 3 and Table 1). An interesting variation in the structural motif of the π-stacked pairs within the hydrogen-bonded tapes is seen in **3** (see Figure 3, A- vs. B-type stacking for **1**, **2**, **8**, **10**, and **3**, respectively).

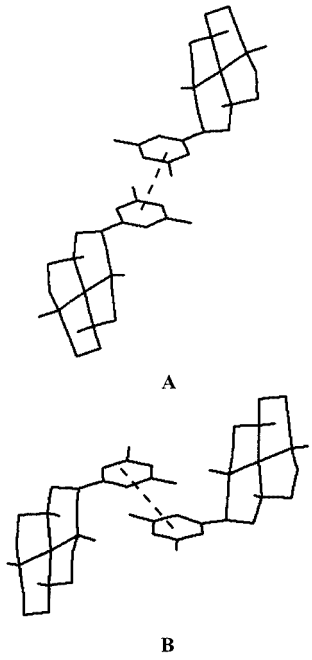

Figure 3. A- and B-type stacking in the lattices of the mono(macrocyclic) ligand complexes

Oligomacrocyclic Ligand Complexes

The bis(macrocyclic) ligand complex **4** crystallized as the *anti* isomer. Both copper(II) centers are six-coordinate (4 + 2, ClO_4^- donors, see Figure 4, Table 1 and Supporting Information) and the angle between the mean planes of the CuN_4 chromophores is 42.2°. Because of steric crowding there is no π-stacking of the melamine rings in the crystal lattice, but the aromatic rings of adjacent ligands are nearly coplanar.

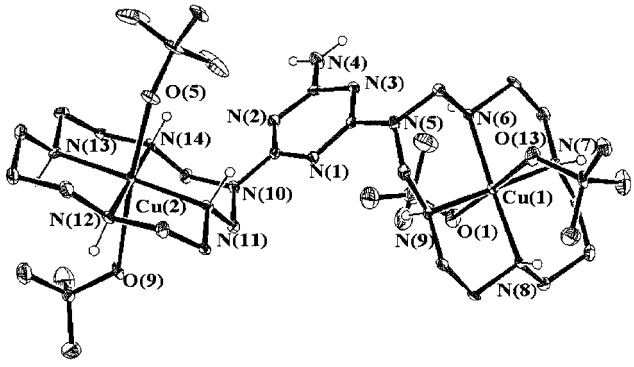

Figure 4. ORTEP[33] view (30% probability ellipsoids) of **4**; C−H hydrogen atoms and lattice solvent molecules are omitted for clarity; selected hydrogen bonds [Å]: Cl(5)···N(8) 3.072, Cl(6)···N(18) 3.099; selected distances and angles are shown in Table S2 (Supporting Information)

The three 14-membered rings of the tris(macrocyclic) ligand/copper(II) complex **5** are located on the same side of the melamine plane (*syn*,*syn* conformation), and the molecular cation looks like a flower with three petals (Figure 5a). This is a significant difference from the *syn*,*anti* conformation of the previously reported $[Cu_3(L^3)]^{6+}$ structure **12**.[18] There is a symmetry plane in **5**, bisecting the molecular cation through C(2)Cu(1)N(3)C(11)N(4). The angles between CuN_4 mean planes in **5** are 58.8° for the Cu(1)−Cu(2) and 74.6° for the Cu(2)−Cu(2a) chromophores, respectively, significantly larger than in **4**, and this is primarily due to differences in γ (see Table 1).

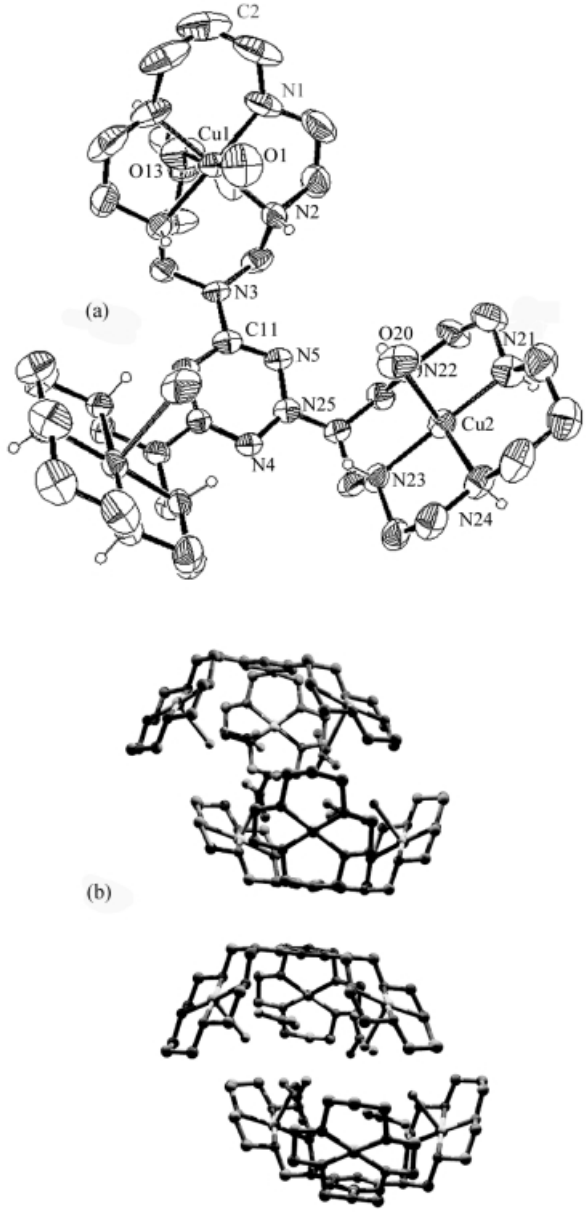

Figure 5. ORTEP[33] view (30% probability ellipsoids) of **5** (a) and its packing in the crystal lattice with the formation of the capsules (b); C−H hydrogen atoms, lattice water molecules, and anions are omitted for clarity; selected distances and angles are shown in Table S3 (Supporting Information)

In the crystal lattice, two concave "flowers" form an ellipsoidal "capsule", with the longest axis of approx. 15 Å (Figure 5b). The distance between parallel triazine rings in the capsule is 10.7 Å, and their centers are horizontally shifted by approx. 2.8 Å. Four disordered nitrate anions occupy the cavity of the capsule. Each of these forms hydro-

gen bonds to coordinated water molecules and to secondary nitrogen atoms of the macrocyclic ligands. Apparently, this bonding of NO_3^- is to some extent responsible for the stabilization of the *syn*,*syn* conformation of $[Cu_3(L^3)]^{6+}$ in **5**. The remaining anions and water molecules are located outside the capsules and form a network of hydrogen bonds. Interestingly, there are no obvious attractive interactions between the two symmetrically related halves of the capsule. In the crystal lattice the capsules are packed in order to allow for π-stacking interactions between coplanar and coaxial melamine rings (Figure 5b and Table 1).

Host-Guest Complexes Based on the $[Cu_3(L^3)]^{6+}$ Cation

The tricopper(II) compound **5**, based on the tris(macrocyclic) ligand, is a rare example of a rigid, hemispherical, positively charged transition metal complex host molecule (see Introduction and corresponding refs.). The interactions with the NO_3^- guest anions are nonspecific, but the charge, size, and shape of **5**, and in particular the fact that six axial sites of copper(II) centers are available for interactions in the hexanuclear capsules (see Introduction) indicated that − in terms of size, shape, and charge − carefully chosen guest molecules should give rise to interesting host-guest interactions. Evaluation of the geometry of the cavity indicated that corner-shared bis(octahedral) complexes have an ideal size and structure for selective interactions with the host **5**. Also, the structural plasticity of **5** (see above and Table 1) allows for some variation of the size of the guest molecules. To evaluate these ideas, the host complex **5** was treated with hexacyanoferrate(II).

Treatment of **5** with $K_4Fe(CN)_6$ in warm water resulted in the formation, in high yield, of a precipitate with the composition $[Cu_3(L^3)][Fe(CN)_6](NO_3)_2{\cdot}17H_2O$. Structural analysis revealed the unique and unprecedented structure $\{[Cu_3(L^3)]_2[Fe_2(CN)_{11}]\}(CN)(NO_3)_4{\cdot}34H_2O$ (**6**). Figure 6a is a structural plot of the molecular cation, and Figure 6b shows the arrangement of the $[Cu_3(L^3)]_2^{12+}$ capsules with the coordinated decacyano(μ-cyano)diiron(II)(7−) anion in the crystal lattice. The cationic halves of the capsule in **6** are, as to be expected, kept together by six Fe−CN−Cu bridges. Each $[Cu_3(L^3)]^{6+}$ cation is bound by two CN bridges to one iron center and by one CN bridge to the other iron center. This results in a rather symmetrical octanuclear Cu_6Fe_2 cluster with Cu−Fe distances of 5.16 ± 0.04 Å (crystallographically all six macrocyclic fragments of the capsule are nonequivalent).

The copper centers in **6** are five-coordinate, with one apical cyanide each (Cu−NC distances of 2.20−2.26 Å; see Table 1 and Supporting Information). These axial copper(II)−donor distances are in the expected range,[34] although both shorter[35−38] and longer[39,40] bonds have been found in complexes with $Fe^{II}-CN-Cu^{II}$ bridges. The relatively strong bonding of copper(II) to the axial ligands results in larger deviations of the atoms from the CuN_4 mean planes, as observed in the other copper(II) structures of L^1, L^2, and L^3 (rms = 0.08−0.09 Å), and in a significant shift of the copper centers towards the apical cyanide donors (0.15−0.21 Å). All CN bridges in **6** are bent (Cu−N−C in the range of 149−164°; see Supporting Information).

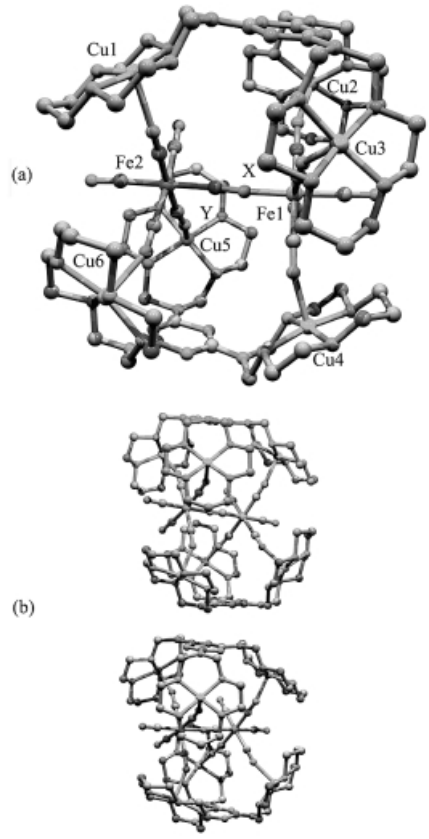

Figure 6. Structural plot of **6** (a) (X and Y = C or N) and its packing in the crystal lattice (b); hydrogen atoms, lattice water molecules, and anions are omitted for clarity; selected distances and angles are given as Supporting Information (Table S4)

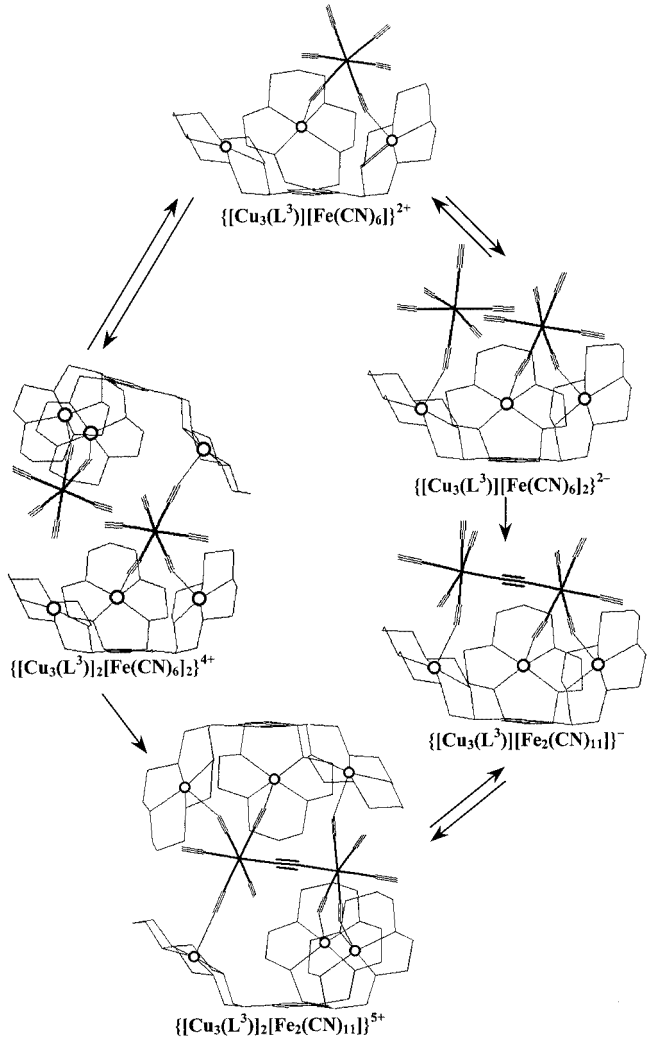
The coordination of the dinuclear anion inside the cavity does not give rise to large distortions of the host complex, and no changes in the conformation of the trinuclear cations are observed (see angles and intermetallic distances for **5** and **6** in Table 1). However, the distance of approx. 12.8 Å between the melamine rings in a capsule and a tilt of approx. 5.0° in **6** are significant changes in the shape of the cavity with respect to that in **5** (10.7 Å and 0°, respectively). Also, the relative orientation of the cationic halves is slightly different (rotation around the melamine−melamine axis). Therefore, as would be expected, there is considerable plasticity of the capsules, and this involves the angles α, β, and γ, as well as the relative orientation of the $[Cu_3(L^3)]^{6+}$ subunits and subtle changes in the copper(II) chromophores.

In the structural analysis, the decacyano(μ-cyano)diiron(II) core in **6** is unprecedented. The only other discrete polycyanodiiron anion that has been structurally characterized is pentacyanoiron(III)(μ-cyano)amminetetracyanoiron(III).[41,42] The main difference between the two structures is the degree of rotation of the iron chromophores around the NC−Fe−CN−Fe−CN axis. While the chromophores in the published diiron(III) structure are

practically eclipsed, there is a torsion of approx. 25° in the diiron(II) structure reported here. This is probably due more to the stereochemical demand of the cationic host than to the preferences of the decacyano(μ-cyano)diiron(II) anion. The coordination geometries of the iron(II) centers in undecacyanodiferrate(II) are nearly octahedral, with *cis*-C−Fe−C (or N) angles varying between 86 and 94° (see Supporting Information). The Fe−C distances (1.88−1.93 Å) are slightly shorter than those in other complexes (average of approx. 1.94 Å[34]). The relatively poor quality of the structure prevents a more detailed analysis. The remaining nitrate and cyanide anions in **6**, as well as the water molecules, are located outside the capsules and form an extended network of hydrogen bonds. As in **5** and the mononuclear complexes discussed above, there is a π-stacking interaction between the melamine rings of different capsules (Figure 6b and Table 1).

The inertness of hexacyanoferrate(II) suggests that $[Fe_2(CN)_{11}]^{7-}$ is assembled with assistance by the $[Cu_3(L^3)]^{6+}$ host, and the relatively strong (Fe−CN)−Cu bonds, together with the size and shape of the cavity of $[Cu_3(L^3)]_2^{12+}$, are assumed to be the driving force for the formation of the μ-cyano-bridged diiron(II) species. The previous observation of the *syn*,*anti* isomer of $[Cu_3(L^3)]^{6+}$ [18] and the species resulting from the reaction between **5** and benzene-1,3,5-tricarboxylate (see below) indicate that the *syn*,*syn* and *syn*,*anti* conformations of $[Cu_3(L^3)]^{6+}$ have similar energies and a low activation barrier for interconversion. Therefore, we do not assume that $[Fe_2(CN)_{11}]^{7-}$ is assembled inside the cavity of the host; the formation of **6**, rather, is assumed to be a stepwise process. Scheme 2 shows possible intermediates and reaction pathways for the formation of the Cu_6Fe_2 cluster (the plots are based on the observed structural parameters). The formation of oligonuclear cyanoferrate(II) species usually involves the reduction of the corresponding iron(III) compounds,[43,44] the reaction of aqua- or aminopentacyanoferrate(II) with hexacyanoferrate(II), or the photochemical labilization of cyanide ligands in $[Fe(CN)_6]^{4-}$.[45] Therefore, the host-guest complex **6** was assumed to be stable in solution.

The solution electronic and MS spectra supported this assumption. The electronic spectrum of **6** had the expected d-d transition at 547 nm (ε = 565 L $mol^{-1}cm^{-1}$, 94 L $mol^{-1}cm^{-1}$ per Cu^{II}), and the bathochromic shift of the absorption band relative to that in **5** is assumed to be due to the interactions with the axial CN donors. The absorption of $[Fe_2(CN)_{11}]^{7-}$ (λ = 385 nm[45]) was too weak to be observed, and was covered by the low-energy tail of intense charge-transfer transitions of the hexakis[copper(II)] capsule. Although the signal corresponding to the octanuclear unit was not detected in the ESI+ MS spectrum, there were several other sets of peaks that corresponded, on the basis of their isotopic pattern, to different polynuclear particles (see Figure 7 for examples). They can be assigned as follows: peaks of monocations with *m*/*z* = 1264.5 to $\{[Cu_3L^3\ Fe_2(CN)_{11}]^{1-} - 2\ H\}^+$ (calcd. 1265.5), 1179.4 to $\{[Cu_3L^3\ Fe_2(CN)_7(H_2O)]^{3+} - 2\ H^+\}^+$ (calcd. 1179.4), 1152.0 to $\{[Cu_3L\ Fe_2(CN)_6(H_2O)]^{4+} - 3\ H^+\}^+$ (calcd. 1152.4), 1116.0 to $\{[Cu_3L\ Fe_2(CN)_4(H_2O)_2]^{6+} - 5\ H^+\}^+$ (calcd. 1116.4); peak of a dication with *m*/*z* = 527.3 to $\{[Cu_3L^3\ Fe(CN)_5]^{3+} - H^+\}^{2+}$ (calcd. 1054.6). These data unequivocally confirmed the persistence in solution of the capsules observed in the solid state and indicated that the main pathway of fragmentation was the rupture of metal−cyanide bonds in **6**.



Scheme 2

Benzene-1,3,5-tricarboxylate was chosen as an example for an organic host molecular anion. Molecular models indicated that the tricarboxylate $C_9H_3O_6^{3-}$ might be included in the capsule. However, the crystallographic data of $[Cu_3(L^3)(OH_2)_6](C_9H_3O_6)_2{\cdot}40H_2O$ (**7**) (see Figure 8) reveal that $[Cu_3(L^3)]^{6+}$ now exists in the *syn*,*anti* conformation, with two tricarboxylate substrates bound by hydrogen bonds to the axial water donors and π-stacked to the melamine ring (see Table 1). We assume that this assembly is just one of the various local minimum structures, and this example shows how difficult it is to predict structures of supramolecular assemblies. Preliminary selectivity studies with tricarboxylates and with *m*- and *p*-phthalate indicated that **5** is a highly regioselective host,[46] and thorough select-

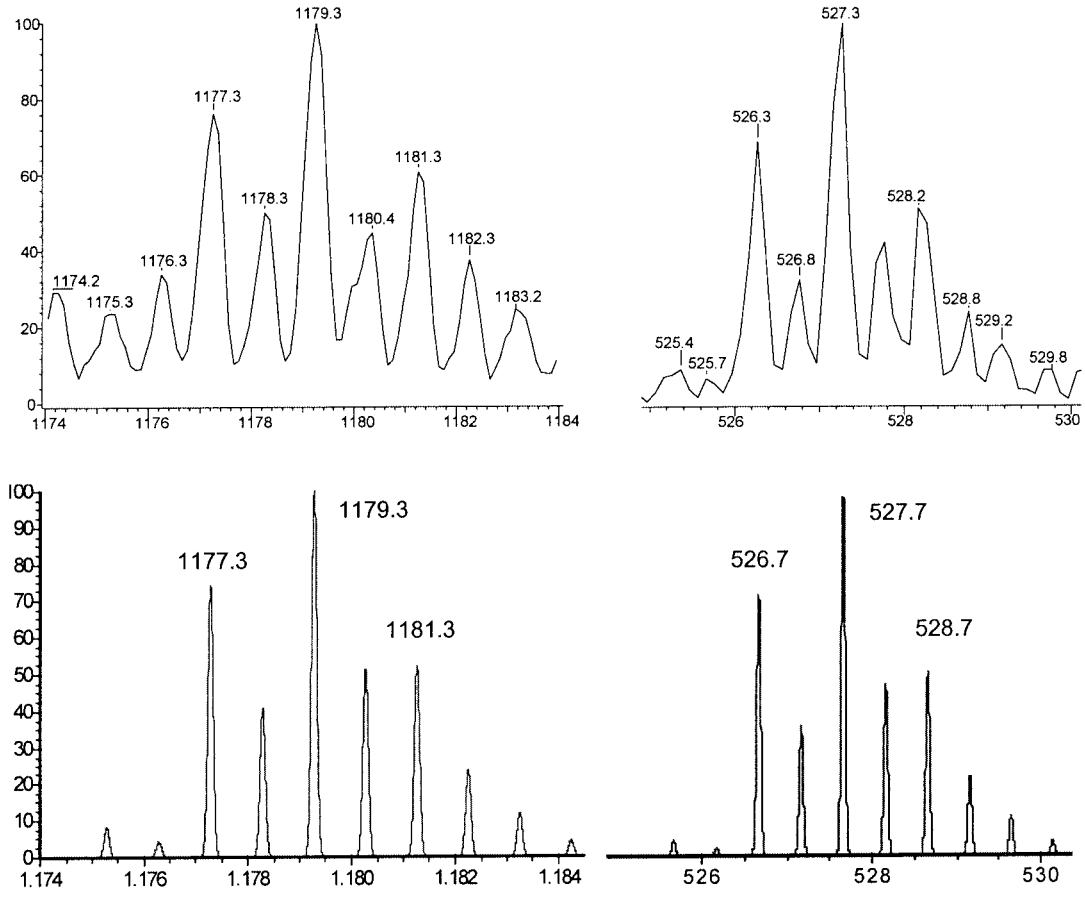


Figure 7. Fragments in the ESI MS of **6**: $\{[Cu_3L^3\ Fe_2(CN)_7(H_2O)]^{3+} - 2\ H^+\}^+$ (top left), $\{[Cu_3L^3\ Fe(CN)_5]^{3+} - H^+\}^{2+}$ (top right); bottom: calculated spectra

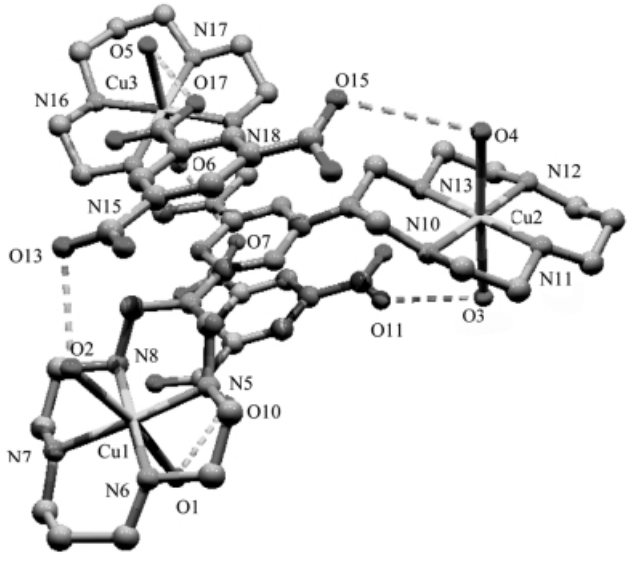

Figure 8. Structural plot of **7**; hydrogen atoms and lattice water molecules are omitted for clarity; selected H bonds [A]: O(6)···O(7) 2.858(3), O(1)···O(10) 2.703(3), O(3)···O(11) 2.736(3), O(2)···O(13) 2.805(3), O(4)···O(15) 2.714(3), O(5)···O(17) 2.804(3); selected distances and angles are shown in Table S5 (Supporting Information)

ivity studies and their interpretation might help in understanding of the structural preferences.

The structure of **7** is also of importance to illustrate the conformational flexibility and plasticity of **5**, and it supports the assumption that **5** acts as a flexible host that allows guest molecules to assemble in multi-step procedures with the assistance of the host, which in favorable circumstances might finally encapsulate (i.e., protect and shield) the guest molecules, as in the case of **6**. An interesting structural feature in this context is a significant flattening of the tricopper(II) host in **7**, especially in comparison with the structure of **12** (see Table 1). This is particularly apparent from the Cu−Cu distances and the angles γ, which are much smaller in **7** than in any other structure (see Table 1). This indicates a rather tight binding of benzene-1,3,5-tricarboxylates to the $[Cu_3(L^3)]^{6+}$ cation and is further evidence for the plasticity of the host molecule.

Conclusion

The copper(II)-assisted synthesis of melamine-based macrocyclic ligands coordinated to copper(II) produced the expected three products in moderate yield (approx. 30%).

The tris(macrocyclic) ligand complex (yield approx. 7%) exists in two major conformations, *syn*,*syn* and *syn*,*anti*, which are similar in stability. Structural studies indicated that the conformational equilibria may be influenced by host-guest interactions which may also influence the shape of each conformation of the tricopper(II) host through subtle structural changes. Preliminarily observed selectivities in host-guest complexation interactions, however, indicated that, although there is a certain structural plasticity of the melamine-based tricopper(II) host, deviation from the preferred geometry may result in a loss of steric energy. This also follows from the structural data of the entire set of copper(II) complexes.

The assembly of $[Fe_2(CN)_{11}]^{7-}$, assisted by the tricopper(II) host complex, and its full encapsulation is based on a combination of conformational flexibility of the host during the assembly procedure and a high degree of complementarity between the hexanuclear host and the dinuclear guest. The relatively strong and highly directional bonding of the guest to the axial copper(II) sites results an assembly that is stable in solution.

Experimental Section

Physical Methods: Infrared spectra (KBr pellets) were recorded with a Specord 75 IR (Carl Zeiss) spectrometer. Electronic absorption spectra were measured with a Specord M40 (Carl Zeiss) spectrophotometer. EPR spectra were recorded with a Bruker ESP300E spectrometer (9.4635 GHz) as approx. 1 10^{-3} mol dm^{-3} frozen (liquid nitrogen temperature) solutions in DMF/water (2:1). Triple-stage quadrupole mass spectra (ESI positive ion mode) were obtained with a Finnigan TSQ-700 mass spectrometer at 5.5 kV, 40 psi sheath gas and flow of liquid of 1.5 μL min^{-1}. Cyclic voltammograms were generated with a PI-50-1.1 potentiostat, equipped with a PR-8 function generator (Izmeritel, Gomel) and an N-307 X-Y recorder (ZIP, Krasnodar). A standard three-electrode scheme was used, consisting of a glassy carbon working electrode, a saturated calomel or Ag/AgCl reference electrode, and a Pt wire auxiliary electrode. All solutions for electrochemistry were purged with nitrogen before measurement. Analytical data were obtained from the microanalytical laboratory of the chemical institutes of the University of Heidelberg.

Structure Determinations: Reflections of representative crystals were measured with Siemens P4 (**1**, **2**, **3** and **5**) or Bruker AXS SMART 1000 (**4**, **6** and **7**) diffractometers with Mo-K_α radiation (λ = 0.71073 Å) and operating in the ω-scan mode. The absorption correction was applied in all cases. The structures were solved by direct methods (SHELXS86) and refined by full-matrix, least-squares methods based on F^2 (SHELXL97),[47] with use of anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms in **1**−**3** were placed in calculated positions; some disorder was observed for a water molecule and one of the perchlorate ions in **1**. Hydrogen atoms in **4** were also placed in calculated positions; only the hydrogen atoms at nitrogen atoms were located in a difference Fourier map and refined isotropically. Perchlorate anions are disordered. For **6**, one half of the capsule is disordered over two positions. Hydrogen atoms of the capsule were inserted in calculated positions. The anions and water molecules outside the capsule could not be located unambiguously and their hydrogen atoms were omitted. In **7**, only the hydrogen atoms of the molecular cation, the anions, and the coordinated water molecules were located and refined. The hydrogen atoms of the water clusters were located only partially, but not refined. Also, some water molecules in this part of the structure are probably disordered. The crystallographic data are given in Table 2. CCDC-171733 (**1**), -171702 (**2**), -171701 (**3**), -170075 (**4**), -134986 (**5**), -157762 (**6**), and -170076(**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Materials: AR grade chemicals and solvents were used as supplied for all reactions. $[Cu(2,3,2\text{-tet})](ClO_4)_2$ [2,3,2-tet = bis-*N*,*N*′-(2-aminoethyl)propane-1,3-diamine] and $[Cu(cyclam)](ClO_4)_2$ (cyclam = 1,4,8,11-tetraazacyclotetradecane) were prepared as described in the literature.[48]

Syntheses: ***Caution!*** Perchlorate salts of metal complexes are potentially explosive. Although we did not experience any problem, such complexes should be handled very carefully.

Template Synthesis: $[Cu(2,3,2\text{-tet})](ClO_4)_2$ (2.0 g, 4.7 mmol), melamine (1.0 g, 7.9 mmol), and triethylamine (5 mL) were dissolved under reflux in 120 mL of a water/ethanol (1:5) mixture. Aqueous formaldehyde (37%, 8.0 mL) was added dropwise over 1 h, and the mixture was refluxed for an additional 24 h and then cooled, filtered, and sorbed onto an SP-Sephadex C-25 cation exchange column (Na^+ form). The column was washed with water (1 L), and the macrocyclic products were eluted with aqueous solutions containing different concentrations of $NaClO_4$ or $NaNO_3$. The mono(-macrocyclic) ligand complex $[Cu(L^1)]^{2+}$ was eluted with 0.2 mol L^{-1} $NaClO_4$ as the second band, after unchanged $[Cu(2,3,2\text{-tet})]^{2+}$. For $[Cu(L^1)(OClO_3)_2]\cdot H_2O$ (**1**), the eluate was concentrated to 25 mL and cooled to room temperature. The purple precipitate of **1** was filtered off, washed with ethanol, and dried in air (yield 0.25 g, 9%). $C_{12}H_{28}Cl_2CuN_{10}O_9$ (590.87): calcd. C 24.39, H 4.78, N 23.71; found C 24.15, H 4.63, N 23.66. Electronic absorption spectrum (H_2O, 0.1 mol L^{-1} $NaNO_3$): λ_{max} (ε [L mol^{-1} cm^{-1}]) = 515 (87), 253 (8500), 209 nm (51000). Crystals of **1** suitable for X-ray analysis were grown by slow cooling of its basic (pH ≈ 10) aqueous solution, in the presence of $NaClO_4$. $[Cu(HL^1)(OClO_3)_2](ClO_4)\cdot H_2O$ **(2)** and $\{[Cu(HL^1)(OH_2)(Cl)]$-$[Cu(HL^1)(OClO_3)(Cl)]\}(ClO_4)_3$ **(3)** were obtained by recrystallization of **1** from 0.1 mol L^{-1} $HClO_4$ or HCl, respectively. The yields were nearly quantitative. **2:** $C_{12}H_{29}Cl_3CuN_{10}O_{13}$ (691.33): calcd. C 20.85, H 4.23, N 20.26; found C 20.86, H 4.42, N 20.00. **3:** $C_{12}H_{29}N_{10}Cl_3CuO_{8.5}$ (619.33): calcd. C 23.31, H 4.56, N 22.65; found C 23.35, H 4.94, N 22.75. The electronic spectra of both complexes in aqueous solution were identical to that of **1**. Crystals suitable for X-ray analysis were selected from precipitates formed after reaction. The bis(macrocyclic) ligand copper(II) complex $[Cu_2(L^2)]^{4+}$ was eluted with 0.4 mol L^{-1} $NaClO_4$. Cooling of concentrated (approx. 25 mL) eluate resulted in a purple precipitate with the stoichiometry $[Cu_2(L^2)](ClO_4)_4\cdot 2.5H_2O$. This was collected on a filter, washed with aqueous $NaClO_4$ (0.6 mol L^{-1}) and then ethanol, and dried in air (yield 0.34 g, 13%). $C_{21}H_{51}Cl_4Cu_2N_{14}O_{18.5}$ (1064.63): calcd. C 23.69, H 4.83, N 18.42; found C 23.91, H 4.74, N 18.24. An additional crop of $[Cu_2(L^2)]^{4+}$ in the form of the protonated ligand complex $[Cu_2(HL^2)](ClO_4)_5\cdot 3H_2O$ (up to 0.02 g) was obtained upon acidification of the filtrate with $HClO_4$ to pH ≈ 1. $C_{21}H_{53}Cl_5Cu_2N_{14}O_{23}$ (1174.09): calcd. C 21.48, H 4.55, N 16.70; found C 21.42, H 4.42, N 16.51. The electronic absorption spectra of the two complexes were identical (H_2O, 0.1 mol L^{-1} $NaNO_3$): λ_{max} (ε [L mol^{-1} cm^{-1}]) = 515 (176), 253 (16500), 213 nm (57600).

X-ray quality crystals of $[Cu_2(L^2)(OClO_3)_4]\cdot H_2O\cdot CH_3OH$ (**4**) were grown by vapor diffusion of diethyl ether in a methanol/water (2:1) solution of $[Cu_2(L^2)](ClO_4)_4\cdot 2.5H_2O$. The tris(macrocyclic) ligand complex $[Cu_3(L^3)]^{6+}$ was eluted with 0.8 mol L^{-1} $NaNO_3$. $[Cu_3(L^3)(OH_2)_3](NO_3)_3(ClO_4)_3$ (**5**) precipitated on concentration of the eluate to 25 mL, followed by the addition of 0.5 g of $NaClO_4$ (yield 0.15 g, 7%). **5:** $C_{30}H_{72}Cl_3Cu_3N_{21}O_{24}$ (1217.39): calcd. C 25.59, H 5.15, N 20.89; found C 25.82, H 5.20, N 21.11. Electronic absorption spectrum (H_2O, 0.1 mol L^{-1} $NaNO_3$): λ_{max} (ε [L mol^{-1} cm^{-1}]) = 515 (260), 253 (24400), 214 nm (87000). Purple crystals of **5** suitable for X-ray analysis were grown by slow cooling of an $NaNO_3$-saturated aqueous solution containing 10% of $NaClO_4$. Other salts of the tris(macrocyclic) ligand complex were also obtained. $[Cu_3(L^3)](ClO_4)_6\cdot 4H_2O$ was precipitated from an aqueous solution of **5** by addition of $NaClO_4$. The yield was nearly quantitative. $C_{30}H_{74}Cl_6Cu_3N_{18}O_{28}$ (1538.11): calcd. C 23.42, H 4.85, N 16.39; found C 23.28, H 4.98, N 16.68. Concentration of the initial eluate until the beginning of the precipitation of $NaNO_3$ yielded a purple compound, which was filtered, washed with small quantities of ice-cold water and ethanol, and dried in air (yield 0.03 g, 0.1%). According to its microanalytical data, the stoichiometry of the complex is $[Cu_3(L^3)](NO_3)_6\cdot 6H_2O$. $C_{30}H_{78}Cu_3N_{24}O_{24}$ (1349.47): calcd. C 26.70, H 5.82, N 24.91; found C 26.87, H 5.70, N 24.83. The absorption spectra of the two derivatives in aqueous solution were identical to that of **5**. The host-guest complex $\{[Cu_3(L^3)]_2[Fe_2(CN)_{11}]\}(CN)(NO_3)_4\cdot 34H_2O$ (**6**) was obtained by addition of an aqueous solution (5 mL) of $K_4[Fe(CN)_6]\cdot 3H_2O$ (0.0055 g, 0.013 mmol) to a hot aqueous solution (10 mL, 1 mol L^{-1} $NaNO_3$) of **5** (0.018 g, 0.013 mmol). The mixture was cooled very slowly. After several days, dark violet crystals were collected, washed with a small amount of ice-cold water and ethanol, and dried in air (yield 0.014 g, 72%). $C_{72}H_{200}Cu_6Fe_2N_{52}O_{46}$ (3023.13): calcd. C 28.60, H 6.67, N 24.09; found C 28.56, H 6.44, N 23.99. The CN stretching vibrations were observed as a single broad and intensive band, centered at 2032 cm^{-1}. Violet single crystals of **6** suitable for X-ray analysis were selected from the precipitate. The complex $[Cu_3(L^3)(OH_2)_6](C_9H_3O_6)_2\cdot 40H_2O$ (**7**) was prepared by addition of $C_6H_3(COONa)_3$ (0.01 g, 0.04 mmol) to a solution of $[Cu_3(L^3)](NO_3)_6\cdot 6H_2O$ (0.05 g, 0.04 mmol) in hot water (3 mL). The mixture was placed in a Dewar vessel filled with hot water and allowed to cool very slowly. Purple needles formed over a few days and were collected on a filter; single crystals suitable for X-ray analysis were then selected. The remaining crystals were washed with a small amount of ice-cold water, and dried in air, producing a purple powder (yield 0.026 g, 92% based on the carboxylate salt). According to its microanalytical data, the composition of the complex is $[Cu_3(L^3)](C_9H_3O_6)_2\cdot 15H_2O$: $C_{48}H_{99}Cu_3N_{18}O_{27}$ (1550.65): calcd. C 37.17, H 6.43, N 16.25; found C 37.10, 6.61, N 16.09.

DFT Calculations of ^{99}Ru Chemical Shifts with All-Electron and Effective Core Potential Basis Sets

Alessandro Bagno*[a] and Marcella Bonchio[a]

Keywords: Density functional calculations / Effective core potentials / NMR spectroscopy / Ruthenium

The nuclear shielding of ^{99}Ru in several complexes has been investigated computationally by DFT methods with effective core potential and all-electron basis sets. Shieldings calculated with ECP bases correlate very satisfactorily with available experimental data, although they are ca. one order of magnitude lower than the experimental values. The influence of molecular geometry (semiempirical vs. DFT) on the nuclear shielding is also examined and discussed, particularly in the case of species containing Ru–S bonds {[$RuCl_2(DMSO)_4$] and α-[$PW_{11}RuO_{39}(DMSO)$]$^{5-}$}. It is shown that such calculations may help the assignment of signals in ^{99}Ru NMR spectra of mono- and polynuclear complexes.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

NMR spectroscopy of transition metal nuclei is a very attractive tool for the elucidation of the structures of complexes of transition metals, and also for the determination of structure-activity relationships, since it directly probes the atomic centre most often responsible for reactivity, e.g. in catalysis.[1] However, general application of this experimental tool is often plagued by difficulties. Most transition metal nuclei span a very wide chemical shift range (10^3-10^4 ppm), and the dependence of this on the multiple coordination and binding modes of these metals is not easily predictable.[2,3] Furthermore, the majority of such nuclei have $I > 1/2$ and, as a result, NMR spectral lines tend to be broad, except where the local symmetry around the metal atom is relatively high. The practical difficulties associated with the detection of broad lines, together with the wide chemical shift range, sometimes renders signal assignment or even detection problematic. Therefore, it is highly desirable to be able to predict the major features of these NMR spectra.

Quantum chemical methods have proved very effective in predicting the nuclear shielding of many nuclei,[4] including transition metals.[5−7] Density-functional theory has proved to be especially effective in this regard.[5−8] However, such calculations with conventional all-electron basis sets on 2nd-row (and especially 3rd-row) transition metals are hampered by the rapid increase in the computational cost when many such heavy atoms are present (which is an important area of application; see below), and also by the onset of relativistic effects.[9] The obvious solution to this problem would be to employ a basis set with effective core potentials (ECPs), where the core electrons up to a given shell are treated in a simplified way by means of pseudopotentials (which also incorporate some relativistic corrections). The difficulty with regard to the calculation of NMR properties is that the functional form of ECPs leads, by construction, to incorrect behaviour (tending asymptotically to zero) at the nucleus. As a result, nuclear shieldings will be substantially underestimated.[10]

In relation to this issue, Moore and Healy[11] analysed the dependence of titanium shielding in titanium tetrahalides on all-electron and ECP basis sets. They found that the shielding contribution from inner shells is large but not very dependent on the basis set and the nature of the ligand, and that the contribution from the outermost core electrons (3s and 3p) is much smaller in magnitude, is paramagnetic and varies considerably. Therefore, these results suggest that the core contribution is essentially "transferable" among several species; however, the scope of such results is rather small, also considering the structural similarity of the species investigated.

Our own previous work on ^{183}W chemical shifts is consistent with the above results, which showed that the shieldings associated with a series of mono- and polynuclear tungsten complexes, calculated with ECP basis sets, are underestimated by ca. one order of magnitude. However, they correlate very well with experimental chemical shifts over a range of 8000 ppm.[12] We were then encouraged to expand the scope of these calculations to other transition metals of current interest.

Among the transition metals, ruthenium exhibits the widest range of oxidation states (eleven, from −II to +VIII) and several coordination geometries in each electronic configuration, as revealed by the large number of complexes

known that are of considerable interest in catalysis.[13] Ruthenium catalysts have indeed proved to be effective in a wide variety of organic transformations, generally featuring high efficiency and selectivity. These reactions include some fundamental processes, i.e. hydrogenation, carbon−carbon bond formation, and oxygenation by dioxygen activation.[13] In the latter field, two fairly diverse ruthenium-based catalysts, one carrying the tetramesitylporphyrinato ligand[14] and the more recent one using a totally inorganic polyoxotungstate framework,[15] have been claimed to be the most promising dioxygenase mimicking systems.

Ruthenium possesses two magnetically active isotopes (^{99}Ru and ^{101}Ru), both having $I > 1/2$, and hence are quadrupolar.[2,3] However, NMR spectroscopic investigations are usually restricted to ^{99}Ru ($I = 5/2$, $Q = 7.9$ fm^2),[16] since the other nuclide has a larger Q value. Even so, the NMR sensitivity of ^{99}Ru is rather low, which is often further complicated by the broad lines that are observed in species of low symmetry. It should also be mentioned that ruthenium NMR spectroscopy is practically feasible only on diamagnetic complexes, Ru^{II} (d^6) and Ru^{VIII} (d^0) species.

A relatively small data base of experimental NMR chemical shifts is available,[17−21] since the experimental difficulties mentioned above have prevented the detection of such signals in several low-symmetry environments.[2,3] However, the scope of ^{99}Ru NMR spectroscopy can indeed be broadened with modern spectrometers, as recently shown by Elsevier and co-workers;[22] further improvements regarding low-symmetry complexes are obtained by using supercritical fluids as solvents, where rotational correlation times can be decreased to a useful extent.[23] However, the available data extends over a few major types of compounds, notably various substituted bipyridyl, pyrazinyl, and mixed derivatives. ^{99}Ru shielding is extremely sensitive to its environment, spanning a known range of over 10^4 ppm from $\delta = -1363$ for $Ru(cp)_2$ to $\delta = 16050$ for $Ru(H_2O)_6^{2+}$.

Only one major computational study of ^{99}Ru NMR spectroscopic properties is available.[24] This work focussed on the quantitative prediction of such chemical shifts in a series of Ru complexes (mostly sharing a similar ligand pattern), which strictly mandates the use of all-electron basis sets. Thus, a comprehensive investigation of the performance of various basis sets and density functional methods was undertaken, which showed the high degree of accuracy that can be attained in such calculations. In particular, the better performance of hybrid functionals such as B3LYP was noted, both in terms of geometry and NMR spectroscopic properties.

However, as mentioned above, calculations with all-electron basis sets are intractable for large systems. Hence, in connection with the general interest in the catalytic properties of ruthenium-substituted polyoxometalates,[15,25,26] and based on our previous results[12] for ^{183}W, we have compared the performance of all-electron and ECP basis sets. We have carried out a computational investigation of the NMR spectroscopic properties of some ruthenium complexes for which experimental spectra, spanning most of the known shift range, are available. Our analysis includes a ruthenium-substituted polyoxotungstate anion, whose structural features and nuclear magnetic properties will be discussed in terms of the correlation with the ^{99}Ru NMR results.[26]

Computational Details

Few all-electron Gaussian basis sets are available for Ru;[27−30] in this study we employed the double-zeta polarised DZVP basis set.[29,31] No relativistic corrections were made, since very good results have also been obtained with non-relativistic calculations.[24] Since our earlier work on ^{183}W showed a similar performance of several ECPs,[12] notably those by Hay and Wadt (LANL2DZ),[32] Stevens−Basch−Krauss (CEP-121G)[33] and Dolg et al. (SDD),[34] this study will be limited to the first two.

In some cases (see Results) the LANL2DZ basis was augmented with one or two d functions from the 6-311G(d,p) or 6-311G(2d,2p) basis sets,[31] as follows. S: $\zeta = 0.650$ or $\zeta = 1.300$, 0.325; Cl: $\zeta = 1.500$, 0.375; C: $\zeta = 0.313$ or $\zeta = 1.252$, 0.313. Basis-set augmentation is denoted as LANL(*n*d,*n*d), where the first item refers to *n* d functions on S atoms, and the second (if present) to *n* d functions on Cl atoms. Thus, the basis augmented with 2 d functions both at S and at Cl will be denoted as LANL(2d,2d). The use of such augmented basis sets for the calculation of chemical shifts requires a corresponding augmentation of the basis set of the commonly accepted reference compound $Ru(CN)_6^{4-}$,[2,3] for which LANL(2d) and LANL(2d,2d) are identical since the augmentation always refers to carbon atoms. Hence, the LANL(2d) basis for $Ru(CN)_6^{4-}$ is equivalent to LANL(2d,2d) for S and Cl, since the basis of all ligands is augmented.[35] However, the augmentation of LANL(d) for $Ru(CN)_6^{4-}$ cannot be made in a consistent way, because this would actually imply one extra d function on just two equatorial carbon atoms, i.e. an inconsistent modelling of the cyano ligands. Hence, in this case only the shieldings calculated with this basis (but not the chemical shifts) will be compared.

^{99}Ru shieldings were calculated with the GIAO method by means of density functional theory (Becke's hybrid 3-parameter functional with Lee−Yang−Parr correlation, B3LYP[36])[24] and a (99,302) integration grid. Only the isotropic part of the shielding tensor [$\sigma = (\sigma_{11} + \sigma_{22} + \sigma_{33})/3$] is given. Calculated chemical shifts ($\delta = \sigma_{ref} - \sigma$) are referred to $Ru(CN)_6^{4-}$. All calculations were carried out with GAUSSIAN 98.[37]

Results and Discussion

For our analysis we chose a number of species of moderate size, evenly spanning the entire known chemical shift range (Table 1). In addition to these complexes, we also investigated a polyoxotungstoruthenate, α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$, which can be obtained by metallation of the

lacunary α-Keggin polyoxotungstate α-$[PW_{11}O_{39}]^{7-}$ with $[RuCl_2(DMSO)_4]$ under microwave irradiation.[26] The ^{99}Ru signal of α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$ (observed at $\delta = 7737$), is quite removed from that of the ruthenium precursor ($\delta = 3976$), and provides the first NMR spectrum of ruthenium embedded in a polyoxotungstate cage.[26] Therefore, it is of interest to extend the scope of our study to Ru complexes in this new environment.

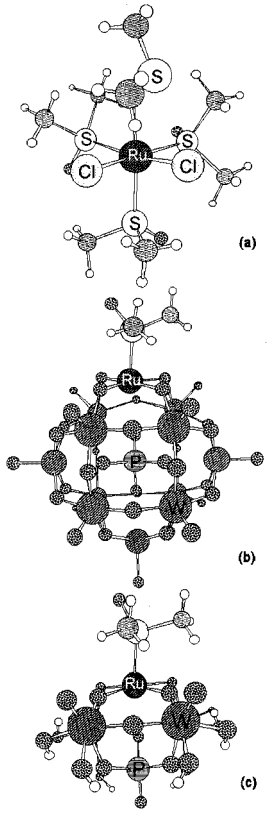
Geometrical features are discussed only in relevant cases (Scheme 1);[38−41] all calculated structures are given as Supporting Information as PDB files.

Shielding Calculations with ECP Basis Sets

The size of most complexes investigated in this work lies within the scope of current ab initio or DFT geometry optimisations. However, a comparison with shieldings obtained at geometries optimized with the PM3(tm) semiempirical level[43] was deemed necessary in order to establish whether shieldings calculated with the latter simpler method have some predictive value for ruthenium-containing polyoxometalates, whose size would be extremely demanding for higher-level methods.

Thus, ^{99}Ru shieldings were obtained for a series of Ru complexes, whose structures were optimised as reported in Table 1. The results calculated with ECP basis sets are presented in Table 1 and Figure 1.

Inspection of Table 1 firstly shows that with ECP basis sets the values of σ are smaller than the experimental values by one order of magnitude. However, calculated δ values correlate very well with the experimental data, as can be seen from the graphs in Figure 1. A linear fit is seen for δ_{calcd} vs. δ_{exptl} ($\delta_{calcd} = a\delta_{exptl} + b$). PM3(tm) geometry: $a = 0.10\pm0.04$, $b = 69\pm85$, $r^2 = 0.96$; LANL2DZ geometry: $a = 0.139\pm0.006$, $b = -59\pm42$, $r^2 = 0.995$; CEP-121G geometry: $a = 0.156\pm0.006$, $b = -90\pm45$, $r^2 = 0.997$. These correlation parameters can be used to estimate "experimental" chemical shifts from $\delta_{exptl} = (\delta_{calcd} - b)/a$. Based on the above standard deviations of *a* and *b*, error propagation formulas yield standard deviations on the estimated δ_{exptl} of about 300 ppm. This is of the same order as the typical spread of experimental values, which often differ by 200−300 ppm [up to 3000 ppm for $Ru(H_2O)_6^{2+}$].



Scheme 1. Calculated structures of ruthenium complexes. (a) $[RuCl_2(DMSO)_4]$ (B3LYP/DZVP); (b) α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$ [PM3(tm)]; (c) the model fragment $[PW_4RuO_{10}(OH)_8(DMSO)]^{5-}$ [B3LYP/LANL(d); see text]; O dotted, C solid grey, H white

Despite the low slope values observed (see below), the good correlations show that the calculation with ECP basis sets only introduces a systematic error, which is remarkably

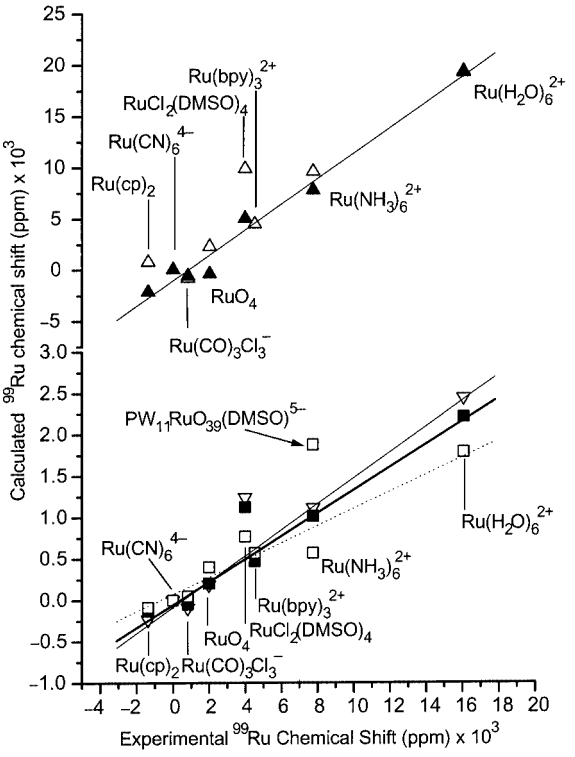


Figure 1. Correlation between experimental and calculated ^{99}Ru shieldings with ECP or all-electron basis sets; results of linear fittings are reported as $\delta_{calcd} = a\delta_{exptl} + b$; bottom panel: (a) empty squares, dotted line: B3LYP/LANL2DZ//PM3(tm); $a = 0.10\pm0.04$, $b = 69\pm85$, $r^2 = 0.96$; fit does not include the data for [RuCl$_2$(DMSO)$_4$] and α-[PW$_{11}$RuO$_{39}$(DMSO)]$^{5-}$; (b) solid squares, solid thick line: B3LYP/LANL2DZ//B3LYP/LANL2DZ; $a = 0.139\pm0.006$, $b = -59\pm42$, $r^2 = 0.995$; (c) down triangles, solid thin line: B3LYP/CEP-121G//B3LYP/CEP-121G; $a = 0.156\pm0.006$, $b = -90\pm45$, $r^2 = 0.997$); fits do not include the data points for [RuCl$_2$(DMSO)$_4$]; top panel: (d) empty triangles, no fit line: B3LYP/DZVP//B3LYP/LANL2DZ; (e) solid triangles, solid line: B3LYP/DZVP//B3LYP/DZVP; $a = 1.24\pm0.08$, $b = -1060\pm570$, $r^2 = 0.989$

constant for a wide array of species. The above correlations hold through the known chemical shift range of ca. 20000 ppm, thereby broadening the scope of such calculations beyond the range examined, e.g., in ref.[24]

Test calculations with pure functionals (BLYP, PW91PW91; data not reported) yielded very similar results in terms of absolute shieldings and more so in terms of the slope of the correlation lines.

We would like to point out that anionic, neutral and cationic species are equally well modelled, which implies a relatively minor solvent effect in determining the ^{99}Ru chemical shift. This may simply be a consequence of the very large range of chemical shifts investigated (i.e., solvent effects are smaller than our estimated accuracy of ±300 ppm), and should call for caution whenever smaller ranges are investigated, or when complexes with a labile coordination sphere are considered.

We also note that the performance of LANL2DZ and CEP-121G (at the respective geometries) is quite similar (Figure 1), but differ with the results of ref.[11] for Ti. The comparison of shifts calculated with a DFT geometry, rather than a semiempirical geometry shows that the fit quality is generally better even though the slope of the correlation line is not very different.

Hence, despite this large systematic error, ECP shielding calculations effectively model ^{99}Ru shifts to an accuracy that will enable the experimental NMR spectroscopist to close in on the spectral region where the signals may be expected, with obvious practical advantages. However, there are three major discrepancies emerging from the correlation in Figure 1.

(a) The calculated shielding of [Ru(NH$_3$)$_6^{2+}$], using the PM3(tm) geometry, fits rather badly in the correlation line, whereas if the geometry is optimized by an ECP method, the data fits very well; (b) the shielding of [RuCl$_2$(DMSO)$_4$] is only fairly well modelled with the PM3(tm) geometry, whereas both ECP geometries lead to an unacceptably deshielded chemical shift; (c) the shielding of α-[PW$_{11}$RuO$_{39}$(DMSO)]$^{5-}$ is grossly overestimated at the PM3(tm) geometry (the only practical approach for a molecule of this size), which yielded a Ru−S distance of 2.276 Å (Scheme 1). In the latter two cases, we are dealing with species possessing Ru−S bonds. The nature of the bonding of DMSO to ruthenium is a matter of current interest, justified by the recent discovery that haloruthenium (sulfoxide) complexes exhibit a remarkable anti-tumour activity, in addition to being versatile oxidation catalysts.[44] The effect of the Ru−S bond length on the ^{99}Ru shielding in [RuCl$_2$(DMSO)$_4$] and α-[PW$_{11}$RuO$_{39}$(DMSO)]$^{5-}$ has been studied in detail (see below).

Shielding Calculations with the All-Electron DZVP Basis Set

Although in practical terms ECP basis sets seem to perform remarkably well (except for the large systematic error), it is worthwhile to compare such results with the performance of an all-electron basis set, where the contribution of core electrons is explicitly taken into account. Thus, ^{99}Ru shieldings have been calculated for the same data set seen before, using both the previous LANL2DZ and newly optimized DZVP geometries (Table 2 and Figure 1).

The first major difference with respect to the previous results is, of course, that the order of magnitude of calculated shifts is now correct, as shown by the correlation parameters ($a = 1.24\pm0.08$, $b = -1060\pm570$, $r^2 = 0.989$), with a slope now close to unity. Shieldings calculated at this level of theory are, in fact, overestimated by 20%, which shows the need for a better basis set in order to arrive at the desired unit slope.[24] However, this is sufficient for the purposes of this work, since a well-behaved general trend is apparent.

The much better performance of the DZVP than the LANL2DZ geometries is also apparent. Since *valence* electrons are treated on a similar footing by both basis sets (e.g., no relativistic corrections are made, while scalar relativistic corrections are present only in the pseudopotentials pertaining to core electrons in LANL2DZ), the worse performance of the latter basis seems due to a deficiency in the valence region. In fact, the species giving the worst fitting (Figure 1d) is [RuCl$_2$(DMSO)$_4$], for which the LANL2DZ

[i] Not calculated, because the chemical shift lies well within the range encompassed by the other species and this compound is well behaved at the other theoretical levels, so that this large calculation is not expected to reveal new trends.

basis shown below is seen to be inadequate to model the Ru−S and Ru−Cl bonds.

Hence, in general terms the DZVP basis set has a performance similar to that of the ECP bases seen before. However, there is a considerable time penalty involved, DZVP calculations taking ca. 4 times longer than the corresponding LANL2DZ ones. The time issue may become crucial when planning to investigate systems containing a large number of heavy atoms, like polyoxometalates (see below).

Comparison of Shieldings Calculated with All-Electron and ECP Basis Sets

The large underestimation of the shieldings calculated with an ECP basis set is a known effect, previously observed by Ridard et al.[10] for ^{31}P, and by ourselves[12] for ^{183}W. This underestimation arises because molecular orbitals built from ECPs fall asymptotically to zero at distances smaller than the core radius, thereby losing all nodal features of orbitals replaced by the ECP. Since the shielding constant is calculated from integrals containing an r_N^{-3} term (r_N being an electron−nucleus distance), these integrals become too small in the vicinity of the nucleus.[10,12] The relationship between the data obtained by all-electron (AE, with DZVP) or ECP (with LANL2DZ) calculations is further investigated by dissecting the σ values into its diamagnetic (σ_d) and paramagnetic (σ_p) components, for a few representative complexes (Table 3).

Table 3. Diamagnetic and paramagnetic contributions to ^{99}Ru shielding with the DZVP and LANL2DZ basis sets

	DZVP[a]		LANL2DZ[a]	
	σ_d	σ_p	σ_d	σ_p
$Ru(cp)_2$	4281	−4652	252.4	−648.3
$Ru(CN)_6^{4-}$	4265	−6787	243.1	−772.2
$Ru(NH_3)_6^{2+}$	4263	−14520	234.6	−1776
$Ru(H_2O)_6^{2+}$	4261	−26050	234.2	−2975
RuO_4	4260	−6370	233.1	−964.4
av.	4266±10		239±10	

[a] At the respective geometries; see Tables 1−2.

Table 3 shows that σ_d is remarkably constant for all species investigated, with an average value of 4260±10 ppm (AE) or 240±10 ppm (ECP). The definition of core electrons in the LANL2DZ basis set includes all electrons up to the 3d shell. The hypothetical Ru^{16+} ion has only core electrons; accordingly, no shielding is calculated with the ECP basis, whereas σ_d = 3993 ppm is calculated with DZVP, which is in reasonably good agreement with the average value given above. On the other hand, the Ru^{8+} ion (with a [core] $4s^24p^6$ configuration) yields quite similar σ_d values with both AE and ECP methods (176 and 144 ppm, respectively). The further contribution to σ_d from 4d electrons is highlighted by the values for Ru^{2+} ([core] $4s^24p^64d^6$), which is again quite similar in both cases (80 ppm). Hence, although the valence region of the LANL2DZ basis is of somewhat lower quality than that of DZVP, the contribution of valence electrons to σ_d is calculated to be very similar; the small sensitivity of σ_d to the basis set is further confirmed. Indeed, the large difference of ca. 4000 ppm arising from the core electrons (being just an additive term) is irrelevant in the calculation of chemical shifts.

With regard to σ_p, we note that only a contribution from the 4d electrons can be expected, since all lower shells are closed. Thus, for Ru^{2+} we calculate σ_p = 362000 and 74000 ppm in the AE and ECP bases, respectively, with a ratio of 4.9. Table 3 shows that for Ru complexes a similar relationship also holds, $\sigma_p^{AE}/\sigma_p^{ECP}$ = 7−9. A linear fitting of σ_p^{AE} vs. σ_p^{ECP} yields a slope of 9.1, which corresponds to the relative slope (8.9) of the correlation lines in Figure 1b and e, and confirms that the large difference between experimental and ECP-calculated chemical shifts arises entirely from the paramagnetic term, in turn arising essentially from 4d electrons.

Ruthenium Shielding in $RuCl_2(DMSO)_4$

As noted above (see Figure 1), the calculated shifts for $RuCl_2(DMSO)_4$ fit reasonably well with the correlation line from the data obtained using the DZVP geometry, whereas all those with ECP or PM3(tm) geometries are too deshielded. We have investigated the origin of this discrepancy in

detail by analysing the effect of augmenting the ECP basis on (a) the geometry (especially the Ru−S bonds) and, (b) the ^{99}Ru shielding. The experimental and calculated Ru−S distances are reported in Table 4, whereas basis set and geometry effects on the calculated shielding are collected in Table 5.

In the X-ray structure,[41] Ru−S distances of the three *S*-coordinated DMSO molecules are 2.274, 2.284 Å (equatorial) and 2.245 Å (axial). In the PM3(tm) structure, relative Ru−S distances (Table 4) agree with the experimental ones, but the PM3(tm) method overestimates the Ru−S distances by 0.07 Å on average. Geometry optimization with both the LANL2DZ and CEP-121G basis sets yield very similar Ru−S distances (Table 4). However, although the relative distances are once again correct, these basis sets overestimate experimental Ru−S distances by 0.21−0.22 Å, with a poor fit with either correlation already mentioned.

A possible cause for this poor performance may lie in an inadequate treatment of the valence region of the S or Cl atoms. To address this issue, the LANL2DZ basis was augmented at the sulfur and/or chlorine atoms [LANL(d), LANL(2d), and LANL(2d,2d); see Computational Details].

Table 4 shows that geometry optimisation with the LANL(d) and LANL(2d) basis sets leads to a marked shortening of the Ru−S distances. However, they remain longer than the experimental distances (by 0.10 and 0.06 Å, respectively), while the Ru−Cl bond lengths are substantially overestimated (by ca. 0.1 Å). Augmentation of the chlorine basis [LANL(2d,2d)] also results in a slight lengthening of the Ru−S bonds and a shortening of the Ru−Cl bonds, which deviate by 0.05−0.06 Å from the experimental values. The latter basis is the best, as indicated by the average deviation of 0.063 Å over the Ru−S and Ru−Cl bonds (Table 4).

Shielding calculations were performed with all variants of the LANL2DZ basis, in combination with geometries obtained at the various levels available, as detailed in Table 5. We would like to mention at this point that no calculation was carried out at the experimental geometry, to ensure consistency of treatment with the other species.

The effect of the geometry and basis set on the calculated shielding can be summarized as follows. Augmenting the LANL2DZ basis set with polarisation functions on the ligands, i.e. improving their valence region, has remarkable effects on the geometry, as seen before. Thus, σ values calculated with the augmented basis sets (between −1296 and −1059) are substantially more shielded than the reference value of −1650 (Table 1), which goes in the right direction. However, this effect is primarily a result of the mentioned geometry changes, rather than of the basis set per se. For example, shieldings of −1650, −1296, or −1211 are calculated with the same basis set (LANL2DZ) at the LANL2DZ, LANL(d), or LANL(2d) geometry, respectively. Conversely, the shielding calculated with the LANL(2d) basis at the LANL2DZ geometry (−1521) is only slightly better than the reference value.

Further improvement is achieved by adopting the augmented basis for the shielding calculation also, which brings the value down to −1089 with LANL(2d). Augmentation of the Cl basis, once again, has a noticeable effect on the shielding (−1059), only when the calculation is run on the optimized structure. The results of these calculations are

Table 5. Calculated and experimental NMR chemical shifts [ppm] of ^{99}Ru in $Ru(CN)_6^{4-}$ and $RuCl_2(DMSO)_4$ with the LANL2DZ ECP basis set, augmented variously

Level[a]	$Ru(CN)_6^{4-}$ σ_{ref}	$[RuCl_2(DMSO)_4]$ σ	calcd. δ[b]
LANL//LANL	−529.1	−1650	1121
LANL//LANL(d)	−565.3	−1296	[c]
LANL(d)//LANL(d)	−533.2	−1171	[c]
LANL//LANL(2d)[d]	−479.8	−1211	731.2
LANL(2d)//LANL	−509.7	−1521	1011
LANL(2d)//LANL(2d)	−479.8	−1089	609.2
LANL(2d,2d)//LANL(2d)	−479.8	−1087	607.2
LANL(2d,2d)//LANL(2d,2d)	−479.8	−1059	579.2
LANL(2d,2d)//PM3(tm)	−258.2	−930.7	672.5

[a] All calculation with the B3LYP functional; see Table 1 for general remarks and experimental values. The LANL2DZ basis is abbreviated as LANL. Basis-set augmentation is denoted as LANL(nd,nd), where the first item refers to *n* d-functions on sulfur atoms, and the second (if present) to *n* d-functions on chlorine atoms (see Computational Details). For $Ru(CN)_6^{4-}$, LANL(2d) and LANL(2d,2d) are identical since the augmentation always refers to carbon atoms. [b] $\delta = \sigma_{ref} - \sigma$; the calculation for $Ru(CN)_6^{4-}$ is carried out at the corresponding level. [c] σ_{ref} cannot be consistently calculated (see Computational Details). [d] Ru−C = 2.096 Å.

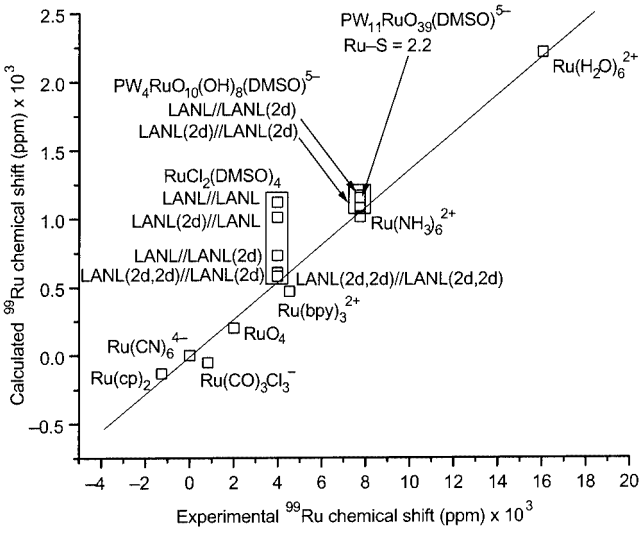

Figure 2. Basis-set and geometry effects on ^{99}Ru shieldings of $[RuCl_2(DMSO)_4]$, $[PW_4RuO_{10}(OH)_8(DMSO)]^{5-}$, and α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$ (not included in the fit; see text for these data); the geometry is at the B3LYP/LANL2DZ level (cf. Figure 1), except where noted; the LANL2DZ basis is abbreviated as LANL

summarized in Figure 2, which highlights the progressive trend of the calculated values towards a good fit with the correlation line. The value δ = 4590 is obtained after the calculated δ value of 579 is corrected by the appropriate fitting parameters, and compares with the experimental value (δ = 3976).

At the PM3(tm) geometry, shieldings of −1039 (Table 1) and −931 (Table 5) are calculated with LANL2DZ and LANL(2d,2d), respectively. This point further illustrates the dependence of the shielding on geometry, and highlights the better performance of augmented LANL2DZ.

A similar effect was found in the case of $[Ru(CO)_3Cl_3]^-$. Again, a geometry optimisation with the LANL(2d,2d) basis leads to a better modelling of the experimental structure, with an average deviation of the Ru−C and Ru−Cl bond lengths from those of the experimental structure[24] of 0.04 Å (0.06 Å with LANL2DZ). Accordingly, a slight improvement is noted in the calculated chemical shift (δ = −17, rather than δ = −51 with the non-augmented basis) which has a better fit in the correlation line, with an experimental value of δ = 816.

These results allow us to draw the following conclusions. (a) Although augmenting the ECP basis set with polarisation functions on the ligands has remarkable effects on the molecular geometry, any effect on the ruthenium shielding is mostly due to such geometry changes, since calculations with augmented basis sets but with non-optimised geometries only lead to minor improvements. (b) Calculated chemical shifts correlate with experimental values over the whole chemical shift range, even though some deviations from experimental geometries may be present, at least in the case of $[RuCl_2(DMSO)_4]$. (c) Chemical shifts calculated with various augmented valence regions converge to a value falling within the correlation line previously found; this confirms that the large scaling factors do not depend much on the chemical nature of the complex. However, the adequacy of such scaling factors in obtaining very accurate estimates is, perhaps, yet to be assessed.

Ruthenium Shielding in α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$

Although an experimental X-ray structure is not available, the general structural features are known from ^{183}W, ^{31}P, and ^{1}H NMR spectroscopic data.[26] The data point out that the complex (a) retains the basic α-Keggin structure, with one Ru atom replacing one W atom, and (b) one DMSO molecule is coordinated to the Ru atom, presumably through the S atom rather than the O atom. This indication is further strengthened by the fact that the PM3(tm) geometry optimisation of a structure with an *O*-coordinated DMSO molecule leads to the *S*-coordinated molecule.

The large size of this species renders a PM3(tm) geometry optimisation as the only feasible approach, which yields an Ru−S distance of 2.276 Å (structure b in Scheme 1). We note that this distance is shorter than the shortest distance in $RuCl_2(DMSO)_4$ (2.323 Å) computed at the same level. The calculated shielding at the B3LYP/LANL2DZ level is σ = −2146, corresponding to a calculated value of δ = 1875; after conversion into an estimated δ value through the pertinent correlation parameters, this corresponds to a very large overestimation (δ = 19000 vs. the experimental value of δ = 7737). The strategy adopted for improving the predictive power of such calculations is described as follows (see Table 6).

Table 6. Geometry effects on the ruthenium shielding in polyoxotungstoruthenates[a]

Geometry	*r*(Ru−S) [Å]	*E* [au]	σ
α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$			
PM3(tm)	2.276[b]	−3947.416803	−2146[c]
PM3(tm)	2.245[d]	−3947.412974	−1916[c]
PM3(tm)	2.200[d]	−3947.410692	−1681[e]
$[PW_4RuO_{10}(OH)_8(DMSO)]^{5-}$			
LANL2DZ	2.849[b][f]	−2196.998676	−3187
LANL2DZ	1.990[d][g]	−2196.852029	−1651
LANL(2d)	2.196[b]	−2197.144188	−1620[h]
LANL(2d)	2.196[b]	−2197.015405	−1697[i]

[a] B3LYP/LANL2DZ, except where noted. [b] Optimised Ru−S distance. [c] SCF convergence criteria reduced to 10^{-7}. [d] Ru−S distance constrained as stated. [e] SCF convergence criteria reduced to 10^{-6}. [f] Partially optimised structure (expulsion of DMSO). [g] Rest of molecule as in the preceding item. [h] Shielding calculated with the LANL(2d) basis set. [i] Shielding calculated with the LANL2DZ basis set.

The Ru−S distance was firstly constrained to 2.245 Å, as in the experimental structure of $[RuCl_2(DMSO)_4]$ (Table 4) and reoptimised by PM3(tm) under this constraint. A smaller value of σ (−1916) was obtained (Table 6), which corresponds to δ = 15900; however, this is still too high. Nevertheless, this result provides a first indication that a relatively short Ru−S distance should be expected.

In view of the huge computational cost of calculations on the whole complex, test calculations were run on the model fragment $[PW_4RuO_{10}(OH)_8(DMSO)]^{5-}$, featuring only the upper lacunary sites and with some protonated WO_6 units, so as to have the same charge as the target compound (Scheme 1, structure c). A B3LYP/LANL2DZ geometry optimisation led to the expulsion of the DMSO molecule (Ru−S distance > 4 Å), and (quite predictably) to an even larger deshielding ($\sigma = -3187$).[45]

The better performance observed with the LANL(2d) basis in the case of $[RuCl_2(DMSO)_4]$ indeed suggests its use as a possible remedy. On the other hand, by constraining the Ru−S bond length to 1.990 Å, the resulting more shielded $\sigma = -1651$ value further indicates a short Ru−S bond in the species under examination.

A B3LYP/LANL(2d) geometry optimisation led to a Ru−S distance of 2.196 Å. The shielding calculated with the same basis (−1620) gives an excellent fit in the pertinent correlation line (Figure 2). The same calculation run with the non-augmented basis [i.e., LANL2DZ//LANL(2d)] yields a similar but slightly worse shielding ($\sigma = -1697$). Hence, all data point to a substantially shorter Ru−S distance in the polyoxometalate than in $RuCl_2(DMSO)_4$.

Based on these arguments, we ran a further calculation on α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$ with the Ru−S distance fixed at 2.200 Å (close to the optimised value for the model, see above). The resulting shielding was $\sigma = -1681$ (Table 6). Thus, remarkably, shortening the Ru−S distance by 0.045 Å shields the ^{99}Ru nucleus by 235 ppm which, when converted into experimental data through the slope factor of 7.2, results in a value no less than 1700 ppm. This point illustrates the extreme sensitivity of ^{99}Ru chemical shifts to its coordination geometry.

Interpretation of these results should be based on the consideration that the geometry employed is derived partly (essentially all the polyoxometalate cage) from PM3(tm) and partly (the Ru−S distance) from DFT methods. However, since the Ru−S distance is apparently the most important parameter in determining the Ru shift, it is admissible to regard this data as belonging to the DFT correlation line (Figure 2), which shows an excellent fit. The calculated chemical shift would be (once corrected by the factor of 7.2) $\delta = 8700$, compared with the experimental value of $\delta = 7737$. We also note that, since the LANL(2d) basis overestimates the Ru−S distance by ca. 0.1 Å, we estimate that the distance in the polyoxometalate is 2.1 Å.

The general conclusion that can be drawn is that the valence region of the LANL2DZ basis set for sulfur is inadequate to model the Ru−S bond, leading to unacceptably long distances. However, this basis is acceptable for the calculation of the shielding, provided that the geometry is appropriate. We would also like to point out that despite the seemingly large error in this calculation (ca. 1000 ppm), this estimate would in fact be helpful in narrowing the spectral region to an extent which allows the reduction of the experimental problems associated with large spectral windows at low frequencies.[2]

Conclusion

ECP basis sets perform remarkably well in the calculation of ^{99}Ru chemical shifts, although such calculated shieldings are much smaller than those calculated by all-electron basis sets or experimental values. We should warn the reader that this approach is "semiempirical" in nature, since it assumes full transferability of the core contribution to the total shielding, and hence its cancellation when chemical shifts are calculated. We have provided a preliminary rationale for this assumption by analysing the relative contribution of the diamagnetic and paramagnetic terms; however, its scope must be independently tested, like in any other approach of this type. At this point, we have provided a set of data that should enable the NMR spectroscopist to obtain at least a rough estimate of the chemical shift of unknown complexes, even relatively large ones (after correction by an appropriate scaling factor). The all-electron DZVP basis set also performs well (albeit at an increased computational cost), particularly in the case of species containing Ru−S bonds. Such species are also successfully modelled by the LANL2DZ ECP basis set, provided that the valence region of the sulfur and chlorine atoms is augmented with d-type polarisation functions. The consistency of these data with those for ^{183}W[12] and ^{95}Mo[47] allows one to envision that the scope of such calculations can be expanded to other nuclei.

[45] An alternative modelling might employ the concept of locally dense basis sets,[46] i. e. featuring a high-quality basis set only on the atom whose properties are being calculated (Ru in this case). However, in the case of polyoxometalates like α-$[PW_{11}RuO_{39}(DMSO)]^{5-}$, this approach would not bring any substantial improvement in terms of computing time for such systems (containing a large number of heavy atoms), where a limiting factor is the size of the environment of the atom under study.

The First Well-Defined Tellurastannoxanes: the X-ray Structure of *trans*-[$(Bu_3SnO)_2\{CH_2(Ph_2SnO)_2\}_2Te$]

Jens Beckmann,[a] Dainis Dakternieks,*[a] Jenny O'Connell,[a] Klaus Jurkschat,[b] and Markus Schürmann[b]

Keywords: Tin / Tellurium / Cluster compounds / NMR spectroscopy / X-ray diffraction

The syntheses of well-defined tellurastannoxanes, *mer*-$(Bu_3SnO)_3Te(OH)_3$ (**1**), and *trans*-$(Bu_3SnO)_2[CH_2(Ph_2SnO)_2]_2Te$ (**2**), are reported. The compounds were characterized by ^{119}Sn and ^{125}Te NMR spectroscopy and compound **2** also by single crystal X-ray diffraction.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Currently there is great interest in molecular mixed-element oxides incorporating main group elemental oxide fragments such as $M(O^-)_3$ (M = B, Al, Ga), $MO(O^-)_3$ (M = P), or $M(O^-)_4$ (M = Si, Ge, Sn), mainly as a result of potential applications in material science and catalysis.[1,2] In most cases, the preferred valence numbers within these fragments preclude a degree of branching higher than four.

Although the synthesis of the first alkyl ester of orthotelluric acid, $Te(OH)_6$, was described early last century there have been only a few subsequent reports utilizing the acidic protons in $Te(OH)_6$ to build new organometallic complexes.[3] In one case molecular tellurasiloxanes, namely $[(Me_2SiO)_2]_3Te$ (**I**), and $(Me_3SiO)_8Te_2O_2$ (**II**)[4] were described and in another case a unique mixed-valence Te^{IV}-Te^{VI} species $\{OTe(C_8H_8)[(EtO)_2PS_2]\}_6Te$ (**III**) was reported.[5]

Here we present the syntheses of the first tellurastannoxanes *mer*-$[(Bu_3SnO)_3Te(OH)_3]$ and *trans*-$[(Bu_3SnO)_2\{CH_2(Ph_2SnO)_2\}_2Te]$. The former compound containing unsubstituted hydroxyl groups has potential as a building block for the preparation of ternary mixed-metal oxides, a class of compounds for which few examples are known.[6–8]

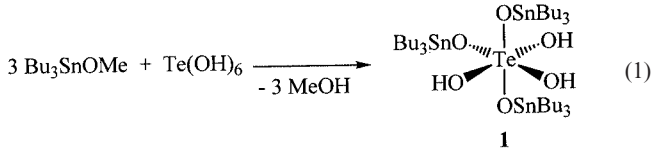
Results and Discussion

The reaction between $Te(OH)_6$ and three equivalents of Bu_3SnOMe quantitatively produced *mer*-$[(Bu_3SnO)_3Te(OH)_3]$ (**1**) [Equation (1)]:



(1)

1

Compound **1** was obtained as a colorless, odorless low-melting waxy material that slowly crystallized over several weeks. The ^{119}Sn NMR spectrum ($CDCl_3$) of **1** reveals two signals at $\delta = 81.9$ [$^2J(^{119}Sn-O-^{125}Te) = 434$ Hz] and 93.6 [$^2J(^{119}Sn-O-^{125}Te) = 504$ Hz] with an integral ratio of 1:2. The number of signals confirms the exclusive formation of

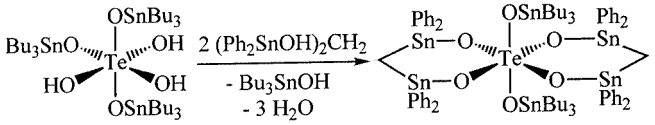
the *mer*-isomer. The ^{125}Te NMR spectrum ($CDCl_3$) of **1** shows a signal at δ = 721.5 with two $^2J(^{125}Te-O-^{119}Sn)$ couplings of 501 and 432 Hz. Bearing in mind the natural abundance of the isotopes ^{117}Sn, ^{119}Sn, and ^{125}Te the integration of the satellites with respect to the main signal allows determination of the connectivity of the tin and tellurium atoms. This method has already been applied for the identification of other compounds showing heteronuclear couplings, such as ^{117}Sn/^{119}Sn,[9−11] ^{29}Si/^{119}Sn,[12] and ^{29}Si/^{125}Te.[4] The molecular weight determination of **1** ($CHCl_3$) unambiguously indicates that no condensation to higher aggregates had occurred and suggests that all three remaining hydroxyl groups are still present. The IR spectrum of **1** (KBr) further supports the presence of hydroxyl groups by revealing a very broad ν(OH) stretching vibration at 3372 cm^{-1}. The reason for selective formation of the *mer*-isomer under these reaction conditions is still not understood. Reactions of $Te(OH)_6$ with Bu_3SnOMe in stoichiometric ratios other than 1:3 provided mixtures of products with a varying degree of substitution, $[(Bu_3SnO)_nTe(OH)_{n-6}]$ $(n \geq 3)$.[13] The identity of these species was unambiguously proven by ^{119}Sn and ^{125}Te NMR spectroscopy, although all attempts to isolate pure compounds from the mixtures failed. Moreover, reactions between $Te(OH)_6$ and other triorganotin methoxides, R_3SnOMe (R = Me, *c*Hex, Ph), also provided mixtures of products that could not be purified.[14]

The reaction of *mer*-$[(Bu_3SnO)_3Te(OH)_3]$ (**1**) with two equivalents of $(Ph_2SnOH)_2CH_2$ [15] gave, with elimination of water and one equivalent of tributyltin hydroxide (Bu_3SnOH), the spirocyclic tellurastannoxane derivative *trans*-$[(Bu_3SnO)_2\{CH_2(Ph_2SnO)_2\}_2Te]$ (**2**) in good yields [Equation (2)].



1 **2** (2)

Compound **2** is a colorless crystalline material. The ^{119}Sn NMR spectrum ($CDCl_3$) of **2** reveals two signals with an integral ratio of 2:1 belonging to the $(Ph_2SnO)_2CH_2$ moiety and the Bu_3SnO moiety, respectively, at δ = −40.2 $[^2J(^{119}Sn-O-^{117}Sn)$ = 632 Hz; $^2J(^{119}Sn-O-^{125}Te)$ = 353 Hz] and δ = 89.6 $[^2J(^{119}Sn-O-^{125}Te)$ = 393 Hz]. It is interesting to note that the chemical shift for the $(Ph_2SnO)_2CH_2$ moiety at δ = −40.2 is very close to that found for the *cyclo*-stannasiloxane $tBu_2Si(OSnPh_2)_2CH_2$ [$\delta(^{119}Sn)$ = −42.8], which also contains a $(Ph_2SnO)_2CH_2$ fragment incorporated into a six-membered ring.[16] The ^{125}Te NMR spectrum ($CDCl_3$) of compound **2** shows a signal at δ = 726.1 with two $^2J(^{125}Te-O-^{119}Sn)$ couplings of 397 and 355 Hz in the expected integral ratio. The number of signals in the ^{119}Sn NMR spectrum and the observed coupling patterns in both ^{119}Sn and ^{125}Te NMR spectroscopy confirms the coordination geometry of the tin atoms around the tellurium center.

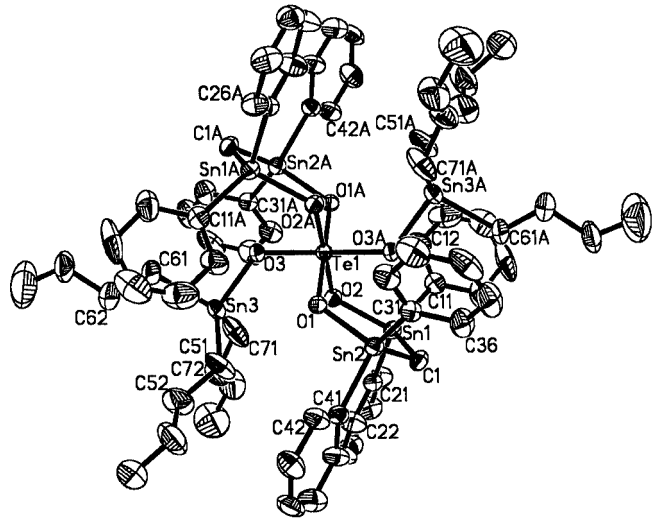


Figure 1. General view (SHELXTL-PLUS) of **2** showing 30% probability displacement ellipsoids and the atom numbering for **2** (symmetry transformations used to generate equivalent atoms: $a = -x + 0.5, -y - 0.5, -z + 1$)

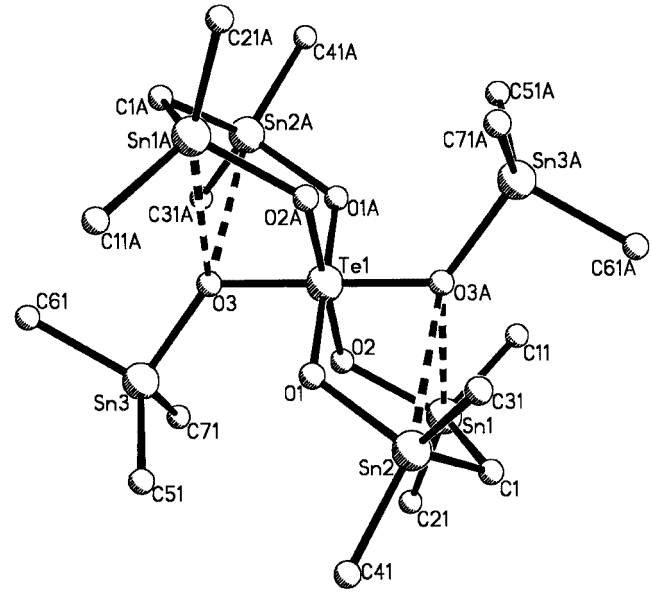

Figure 2. General view (SHELXTL-PLUS) of **2** demonstrating the [4+1] coordination of tin atoms Sn(1) and Sn(2); only primary carbon atoms are shown for clarity (symmetry transformations used to generate equivalent atoms: $a = -x + 0.5, -y - 0.5, -z + 1$)

The molecular structure of **2** is shown in Figure 1 and 2, and selected bond lengths, bond angles and torsion angles are listed in Table 1. The structure contains a crystallographic center of inversion across the tellurium atom Te(1), which coordinated in an octahedral fashion to six oxygen atoms. The mean Te−O bond length amounts to 1.912(3) Å, which is close to the bond length found in $[(Me_2SiO)_2]_3Te$.[4] The central mononuclear TeO_6 core is stannylated at O(3)/O(3a) by two tributylstannyl units and at O(1), O(2)/O(1a), O(2a) by two chelating bis(diphenylstannyl)methyl moieties, giving rise to the formation of a spiroundecane skeleton. The six-membered Te(1)−O(1)−Sn(2)−

C(1)−Sn(1)−O(2) ring exhibits an envelope conformation with Te(1) lying 1.133(3) Å above the plane of fitted atoms O(1), O(2), Sn(1), C(1), Sn(2). The maximal deviation of fitted atoms from the plane amounts to 0.027 Å. The Sn(1)−C(1)−Sn(2) angle of 112.9(2)° is close to the corresponding angle in the six-membered stannasiloxane ring *cyclo*-*t*$Bu_2Si(OSnPh_2)_2CH_2$ [113.9(4)°],[16] and related open-chain derivatives $H_2C(SnPh_2Cl)_2$ [113.4(10)°,[17] and $H_2C(SnPh_2Cl)_2$·HMPA (114.0°)].[18] A remarkable feature in the structure of compound **2** is the intramolecular Sn(1)−O(3a)/Sn(2)−O(3a) distances of 2.944(3)/3.003(3) Å, which are shorter than the sum of the van der Waals radii[19] of tin (2.20 Å) and oxygen (1.50 Å). As a consequence, the coordination geometry at Sn(1) and Sn(2) can best be described as a monocapped tetrahedron {[4+1]-coordination, geometrical goodness[20−22] Δ(Σ): 14.93° for Sn(1) and 14.62° for Sn(2)} with Sn(1) deviating 0.610(3) Å in the direction of C(21) from the plane defined by C(1), C(11), O(2), and Sn(2) deviating 0.609(3) Å in the direction of C(41) from the plane defined by C(1), C(31), O(1). Most interestingly, and caused by the ring constraint, the oxygen atom O(3a) approaches the Sn(1) and Sn(2) atoms through the faces defined by C(1), C(11), O(2) and C(1), C(31), O(1), and forces the phenyl rings containing C(21) and C(41), respectively, into the axial positions of the trigonal bipyramid, whereas O(2), C(1), C(11) and O(1), C(1), C(31) become equatorial. This is a rather unusual situation for pentacoordinated triorganotin compounds as the axial positions are usually occupied by the more electronegative substituents and the equatorial positions by the three organic substituents. Another consequence of the intramolecular Sn(1)−O(3a)/Sn(2)−O(3a) distances mentioned above is the increase of the O(3a)−Sn(3a) bond length [2.015(3) Å] with respect to the Sn(1)−O(2)/Sn(2)−O(1) bond lengths of 1.986(3)/1.982(3) Å, and the decrease of the Te(1)−O(3a)−Sn(3a) angle [127.55(15)°] in comparison with related Te−O−Si angles in $[(Me_3SiO)_8Te_2O_2]$ (**II**) (135.1−141.9°).[4] The intramolecular Sn(3)−O(1)/Sn(3)−O(2) distances of 3.518(3)/3.398(3) Å are also shorter than the sum of the van der Waals radii of the corresponding atoms but apparently they are not short enough to significantly disturb the tetrahedral geometry of Sn(3) (mean angle 109.3°).

Experimental Section

General Remarks: All manipulations were performed under an inert atmosphere of argon using standard Schlenk and vacuum line tech-

niques. Solvents were distilled from the appropriate desiccants prior to use. Literature procedures were used to prepare Bu_3SnOMe[23] and $(Ph_2SnOH)_2CH_2$.[15] The $Te(OH)_6$ was purchased from Fluka. NMR spectra were recorded in $CDCl_3$ using a Jeol GX 270 and a Varian 300 Unity Plus spectrometer at 85.39 (^{125}Te), 111.86 (^{119}Sn), 75.44 (^{13}C) and 299.98 (^{1}H) MHz. Chemical shifts (δ) are given in ppm and are referenced to Me_2Te (^{125}Te), Me_4Sn (^{119}Sn) and Me_4Si (^{13}C, ^{1}H). The elemental analyses were performed on an instrument from Carlo Erba Strumentazione (Modell 1106). The IR spectra were recorded on a Bruker FTIR IFS 113v spectrometer. The molecular weight measurement was carried out using a Knaur osmometer.

Synthesis of *mer*-[$(Bu_3SnO)_3Te(OH)_3$] (1): A mixture of Bu_3SnOMe (7.71 g, 24.0 mmol) and $Te(OH)_6$ (1.84 g, 8.0 mmol) was heated in toluene (10 mL) at 85 °C until the $Te(OH)_6$ was completely dissolved (approx. 4 h) and then for 2 h at 110 °C. Volatile components were removed in vacuum affording a colorless waxy residue of **1** (8.78 g, 8.0 mmol, 100%, m.p. 42 °C). ^{1}H NMR: δ = 0.92 (9 H), 1.24 (6 H), 1.34 (6 H), 1.61 (6 H). ^{13}C NMR δ = 13.8, 13.7 (β-*C*), 17.5 [$^1J(^1C-^{119}Sn)$ = 369 Hz; α-*C*], 17.8 [$^1J(^1C-^{119}Sn)$ = 366 Hz; α-*C*], 27.4, 27.5 (γ-*C*), 28.3 (δ-*C*). ^{119}Sn NMR: δ = 81.9 [1Sn, $^2J(^{119}Sn-O-^{125}Te)$ = 434 Hz], 93.6 [2 Sn, $^2J(^{119}Sn-O-^{125}Te)$ = 504 Hz]. ^{125}Te NMR: δ = 721.5 [$^2J(^{125}Te-O-^{119}Sn)$ = 501, $^2J(^{125}Te-O-^{119}Sn)$ = 432 Hz]. IR (KBr): $\tilde{\nu}$ = 3372 br. (ν_{OH}), 2956 vs, 2924 vs, 2871 vs, 2853.7 vs, 1463 s, 1377 m, 1074 m, 876 m, 734 s, 668 m, 621 s, 474 m cm^{-1}. $C_{36}H_{84}O_6Sn_3Te$ (1096.89): calcd. C 39.42, H 7.72; found C 40.25, H 8.20. MW ($CHCl_3$, 20 mg mL^{-1}): 1071.

Synthesis of *trans*-{$(Bu_3SnO)_2[CH_2(Ph_2SnO)_2]_2Te$]} (2): A mixture of **1** (1.10 g, 1 mmol) and $(Ph_2SnOH)_2CH_2$ (1.19 g, 2 mmol) in toluene (10 mL) was heated for 4 h at 80 °C. The precipitate formed (Bu_3SnOH) was separated by filtration and the volatile components were removed under vacuum. The solid residue was recrystallised from hexane/dichloromethane (3:1) affording **2** (1.57 g, 0.82 mmol, 82%, m.p. 173 °C). ^{1}H NMR: δ = 0.90 (6 H), 1.22 [4 H, $^2J(^1H-^{119}Sn)$ = 120 Hz; SnCH_2Sn], 1.23 (4 H), 1.34 (4 H), 1.62 (4 H), 7.0−8.1 (40 H, *Ph*). ^{13}C NMR: δ = −2.1 [$^1J(^{13}C-^{119}Sn)$ = 378 Hz; SnCH_2Sn], 13.6 (β-*C*), 17.4 [$^1J(^{13}C-^{119}Sn)$ = 360 Hz; α-*C*], 27.1 (γ-*C*), 28.0 (δ-*C*), 128.1 (*p*-*C*), 145.3 [$^1J(^{13}C-^{119}Sn)$ = 526 Hz; *i*-*C*], 128.3 (*p*-*C*), 128.8 (*m*-*C*), 129.0 (*m*-*C*), 136.0 (*o*-*C*) 136.1 (*o*-*C*), 143.5 [$^1J(^{13}C-^{119}Sn)$ = 684 Hz; *i*-*C*]. ^{119}Sn NMR: δ = −40.2 [4 Sn, $^2J(^{119}Sn-O-^{117}Sn)$ = 632, $^2J(^{119}Sn-O-^{125}Te)$ = 353 Hz; *Sn*CH_2Sn], 89.6 [2 Sn, $^3J(^{119}Sn-O-^{125}Te)$ = 393 Hz; *Sn*Bu_3]. ^{125}Te NMR: δ = 726.1 [$^2J(^{125}Te-O-^{119}Sn)$ = 397, $^2J(^{125}Te-O-^{119}Sn)$ = 355 Hz]. IR (KBr): $\tilde{\nu}$ = 3062 s, 3009 s, 2953 vs, 2918 vs, 2868 s, 1480 s, 1462 s, 1428 vs, 1374 m, 1345 m, 1297 m, 1188 m, 1076 vs, 1022 m, 997 m, 958 m, 867 m, 711 vs, 608 vs, 527 vs, 466 vs, 447 s, 343 s, 319s cm^{-1}. $C_{74}H_{98}O_6Sn_6Te$ (1923.6): calcd. C 46.21, H 5.14; found C 45.99, H 5.20.

X-ray Crystallographic Study. Crystal Data and Structure Solution of 2: $C_{74}H_{98}O_6Sn_6Te$, M_r = 1923.26, *monoclinic*, *C*2/*c*, *a* = 20.571(1), *b* = 14.150(1), *c* = 27.974(1) Å, β = 101.239(1)°, *V* = 7986.5(7) Å^3, *Z* = 4, $D_{calcd.}$ = 1.600 g·cm^{-3}, λ(Mo-K_α) = 0.71069 Å, *F*(000) = 3768, μ = 2.250 mm^{-1}, *T* = 291(1) K. The data collection covered almost the whole sphere of reciprocal space with 360 frames via ω-rotation (Δ/ω = 1°) at 2 × 10 s per frame on a Nonius KappaCCD diffractometer with a completeness of 93.2% in the θ range of 4.07 to 24.99°. The structure was solved by direct methods SHELXS-97[24] and refined by full-matrix least-squares calculations using SHELXL-97.[25] All non-H atoms were refined anisotropically. The H-atoms were placed in geometrically calculated positions using a riding model (including free rotation around C−C). The aromatic H atoms were refined with a common isotropic temperature factor [C−H_{aryl} 0.93 Å, U_{iso} 0.143(6) Å^2], while for the aliphatic H atoms the atomic displacement parameters were fixed to 1.5 times those of the C atoms. R_1 = 0.0317 for 3961 reflections with $I > 2\sigma(I)$ and wR_2 = 0.0698 for 6551 independent reflections with 395 refined parameters. The max./min. residual electron densities were 0.362 and −0.369 e Å^{-3}.

CCDC-173037 contains the supplementary crystallographic data for this paper (excluding structure factors). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The Recovery of a Rhodium-Containing Catalyst by Various New Silica-Based Amine Ion Exchangers

Jurjen Kramer,[a] Arjen Scholten,[a] Willem L. Driessen,*[a] and Jan Reedijk[a]

Keywords: Amine ligands / Complex stability / Ion exchange / Rhodium / Homogeneous catalysis

Various mono-, di-, and triamine ligands have been successfully attached to an inert silica backbone. Their efficiency in the recovery of the model catalyst $RhCl_3$ has been thoroughly investigated. Correlation of the distribution coefficients for Rh^{3+} as a function of the pH with recovery experiments, shows a subtle balance between the stability of the ligand-to-metal complexes and the elution efficiency. Rhodium ion exchanger complexes with log *D* values above 2.5 appear to be too stable to ensure a high (> 70%) desorption. A very high desorption (> 90%) has been effected with 2 M HNO_3 with ion exchangers containing monoamine ligands or sterically hindered diamine ligands. The adsorption medium appeared to be of major influence, both on the extractability and on the elution possibility.

Introduction

Homogeneous catalysts, being very powerful agents for the improvement of many organic reactions, are widely used in industrial processes. The high selectivity and turnover numbers that can be attained for a specific reaction are major advantages. However, since all reagents (substrate, catalyst, products) are present in the same solvent phase, the separation of the catalyst after use can be troublesome. Catalyst recovery is of major importance, though, as contamination of the product should be reduced to a minimum, and also because very expensive transition metals often form part of the catalyst.[1]

Ion exchange has proven to be a very suitable technique for the recovery of low concentrations of metal ions, due to the ease of separation of the adsorbed metal ions from the product stream. Moreover, a high selectivity for certain metal ions can be obtained by immobilizing (chelating) ligands on an inert, chemically and thermodynamically stable backbone. Earlier findings on the selective recovery of Cu showed fast exchange kinetics when silica was used as a backbone.[2]

We have chosen to focus on the recovery of Rh-containing homogenous catalysts, since the scarcity of rhodium, linked to its wide application in industrial processes such as hydroformylation and hydrogenation reactions,[1,3,4] has resulted in very high prices for this metal.

Previous investigations already pointed out the need to achieve optimal binding for efficient recovery.[5] This means that the affinity of the ligands for the Rh metal-ions should be sufficient for adsorption, but the affinity should not be too high, as this might prevent subsequent desorption. The elution process appears to be especially difficult, as shown by reports on incomplete desorption, unless very harsh, even damaging, conditions are applied.

Amine ligands are known to coordinate well to platinum group metals. Their special properties enable them to coordinate to transition metal ions,[7] as well as to interact with anionic complexes. In a previous report, our preliminary findings have been communicated on the recovery of Rh^{3+} with silica-based (poly)amine ion exchangers.[9] In the present paper a substantial extension of this study is given:

The ion exchangers **1b**−**9b** were prepared by immobilizing the corresponding ligands **1a**−**9a** onto silica, as depicted in Scheme 1. In order to gain insight into the factors that determine efficient recovery, the approach was manifold. Firstly, the effect of monodentate (ion exchangers **1b** and **2b**) versus bidentate (**3b**−**7b**) and possible tridentate (**8b** and **9b**) binding on the stability and recovery of rhodium metal ions was investigated. Secondly, the influence of *N*-alkylation was examined (**2b** and **5b**−**7b**), as protonation and deprotonation of amines are thought to play a prominent role in metal ion recovery. Thirdly, other features, such as the macrocyclic effect (**8b** vs. **9b**) and the size of the chelate ring (**3b** and **4b**) on the complex stability and Rh recovery, were considered. For this purpose, the stability of the various ligand-to-metal complexes was established by measuring the stability constants (log *D*) in dilute systems. Finally, the recovery was determined after initial adsorption in various media, with the additional aim to gain insight into the influence of the solvent on the recovery process.

Results and Discussion

Synthesis of the Ion Exchangers

The free trimethoxysilane ligands (**1a**−**8a**) were immobilized using a methanolysis reaction with the surface silanol groups of silica (see Scheme 1). To ensure monofunctionalization, the triazacyclononane (tacn, **9a**) ligand was coupled to a silica-anchored spacer (glymo, see Exp. Sect.). It is clear from the ligand concentration, based on the nitrogen and carbon contents, that the ligands are grafted, on average, through two OMe groups. Some of the remaining methoxy groups remain visible in the solid-state ^{13}C NMR spectrum (see Figure 1). The ligand concentrations of the functionalized silica were calculated from the weight percentage of nitrogen, as is generally done,[10] while the calculated C and H percentages, which are based on this ligand concentration, are given in parentheses (see Table 1). The ligand concentrations were found to increase with decreasing ligand size. This phenomenon is clearly demonstrated for the different diamine ligands (**3b**−**7b**), where the increasing bulkiness apparently hampers the grafting of the ligands. The relatively low ligand concentration of **9b** is the result of a different immobilization pathway (see Experimental Section). This sequence of grafting is less efficient, for steric reasons, and not all *tacn* ligands reacted with *glymo*-Si, clearly giving rise to a large difference in the observed and calculated values for carbon.

The solid-state CP MAS ^{13}C NMR spectra of the ion exchangers **1b**−**9b** are depicted in Figure 1−3. The characteristic ligand signals (see Table 1) of the solid-state spectrum correspond well to the ^{13}C NMR signals obtained in solution (see Experimental Section) for all the ion exchangers. However, as the resolution of solid-state NMR spectra is lower than that of solution NMR spectra, in some cases the close-lying peaks overlap, most notably for the alkylated diamine ion exchangers.

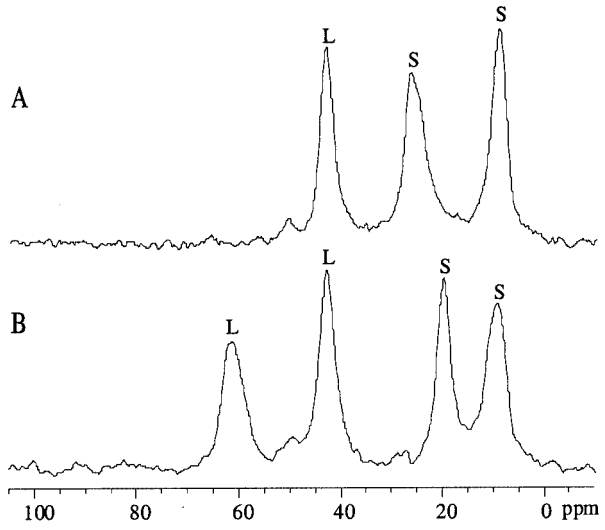

Figure 1. ^{13}C CP MAS NMR spectra of monoamine ion exchangers **1b** (A) and **2b** (B); peaks originating from $(R)_3SiCH_2CH_2$ are denoted **S**; all ligand signals, and signals originating from $(R)_3SiCH_2CH_2CH_2$, are marked **L**

pH-Dependent Complex Stability

The measurement of the distribution coefficient is a generally applied method for gaining insight into the stability of the metal-to-ligand binding,[11] and log *D* values of the different amine containing ligands with the rhodium metal-ions. These coefficients have been determined at different pH values. The stability results of the monoamine ion exchangers with Rh^{3+} are depicted in Figure 4, showing a similar pattern, although the log *D* values of the Rh-**2b** (NMe_2) complexes proved to be somewhat more pH dependent than those of the Rh-**1b** (NH_2) complexes. At pH < 2 the amines are predominantly protonated,[12,13] and binding is believed to occur via ion pairing, with positively charged amine groups binding to a negatively charged Rh complex of the type $[RhCl_{6-n}(H_2O)_n]^{(3-n)-}$ (with *n* generally 0−2).[14] Above pH 2, binding increasingly takes place through the lone pairs of the amine groups.

The lower stability, observed for both ion exchangers at pH 1−2, can be explained by the presence of high concentrations of chloride counterions, which compete for Rh binding with the ion exchangers. At higher pH, HOAc/NaOAc buffers were used, and the acetate ion clearly coordinated less strongly to the Rh metal-ions. The Rh binding of **2b** appears to be somewhat weaker than that of **1b**, as demonstrated by the lower log *D* values when large amounts of competing Cl^- ions are present.

The pH-dependent log *D* values of a series of different diamine ion exchangers are depicted in Figure 5. The highest stability was observed with the ethylenediamine (*en*) ion exchanger **3b**. The stability of the Rh complexes with **3b** proved to be some 3−10 times higher over the entire tested

Table 1. Characteristics of the ion exchangers **1b**−**9b**

Ion exchanger	^{13}C CP-MAS NMR (δ values)	% C (calcd.)	% H (calcd.)	% N[a]	Ligand conc.[a] (mmol/g)

9b	8, 23, 51, 73	9.34 (4.12)	1.75 (0.78)	1.20	0.29

[a] Ligand concentrations were calculated based on the nitrogen content.

pH range than the monoamine ion exchangers **1b** and **2b** (see Figure 4). Methylation of the amine groups [ion exchangers **5b** (*Me$_2$en*) and **6b** (*Me$_3$en*)] resulted in some lowering of the stability, especially at higher pH. However, the largest drop in the distribution coefficient was effected when the methyl groups were replaced by ethyl groups (**7b**, *Et$_3$en*). The complex stability is, on the average, 10 times lower than the non-alkylated **3b**. Finally, the complex stability of the propylenediamine-containing ion exchanger **4b** (*pren*) is significantly lower than **3b**.

The difference in Rh complex stability observed between the monoamine ion exchangers (see Figure 4) and *en* ion exchanger **3b** might be explained in terms of the capability of the latter to form highly stable five-membered chelate rings with the Rh metal ions, whereas the former can only bind in a monodentate fashion. The importance of the ring size appears to be demonstrated by comparison of **3b** and **4b**. The distribution coefficients of the *pren* ion exchanger are similar to **1b**, hence the advantage of bidentate binding seems to be nullified when the chelate ring size is not correct. This is in agreement with the findings of Comba[15] and Hancock[16] on metal ion selectivity, indicating the preference of chelating ligands that coordinate via five-membered chelate rings for relatively large metal ions such as those of the platinum group.

Alkylation of the amine functionalities affects the properties of the metal ion complexes in different, opposing ways. As alkyl substituents are electron donating groups, the nitrogen becomes a better σ donor upon replacement of the N−H group by a methyl or an ethyl moiety. On the other hand, the increased steric hindrance of the substituents negatively influences the complex stability. Furthermore, *N*-alkylation inhibits the formation of hydrogen bonds of the type M−N−H···O with the solvent, thus decreasing the outer-sphere solvation energy due to its greater hydrophobic nature. Consequently, the electron density on the nitrogen atom is decreased, resulting in weaker σ donating properties.[17,18] Which of these opposing factors contributes most is dependent on the metal ion.

A big drop in stability was observed when the methyl groups were replaced by ethyl moieties (**7b** vs. **6b**), presumably due to increased hydrophobicity and, to a lesser extent, steric hindrance. In the case of ion exchangers **5b** and **6b**, the loss of hydrogen bond formation seems to be compensated, to some extent, by the increased electron density on the nitrogen atoms; the steric influences of the smaller methyl groups appear to be less important.

The stability of the Rh-triamine complexes at varying pH is depicted in Figure 6. The stability at pH values where binding takes place via coordination, i.e. pH > 2, is similar for both **8b** (*dien*) and **9b** (*tacn*) and of the same order as the *en* ion exchanger **3b**. At low pH, the log *D* values of the *tacn*-Rh complexes dropped dramatically, a feature that was not observed for the linear equivalent.

A possible explanation may originate from the difference in protonation constants (log *K* values) of the two triamine ligands. The log K_2 and, even more pronounced, log K_3 values of *tacn* are much lower than those of *dien*, implying that protonation of the second and third amine atoms of tacn occurs at much lower pH than for dien.[7b,19] As the third amine in *tacn* is probably only starting to become protonated at pH 1, it is very likely that *tacn* has a 2^+ overall charge and hence this will not bind as strongly to the negatively charged Rh complexes as the *dien* ligands bearing a 3^+ charge. The retardation of the second and third protonation is predominantly caused by electrostatic repulsions in the small ring between the incoming protons and those already bound.[19] At high pH, this difference is absent, and both ion exchangers exhibit similar high log *D* values.

Recovery Experiments

Both the adsorption of Rh^{3+} in different solvents on the various different amine ion exchangers, and subsequent desorption were tested. Since the ligand concentrations of the ion exchangers vary significantly (see Table 1), it is more correct, in addition to the ligand capacity (*c*, in mmol/g), to look at the ligand occupation (*L*, in %) as well, which is defined as follows:

L = [uptake capacity for M^{n+} (in mmol/g ion exchanger)]/[ligand concentration (in mmol/g ion exchanger)].

As the solvent might influence the recovery of Rh metal ions, the adsorption was performed in three different media:

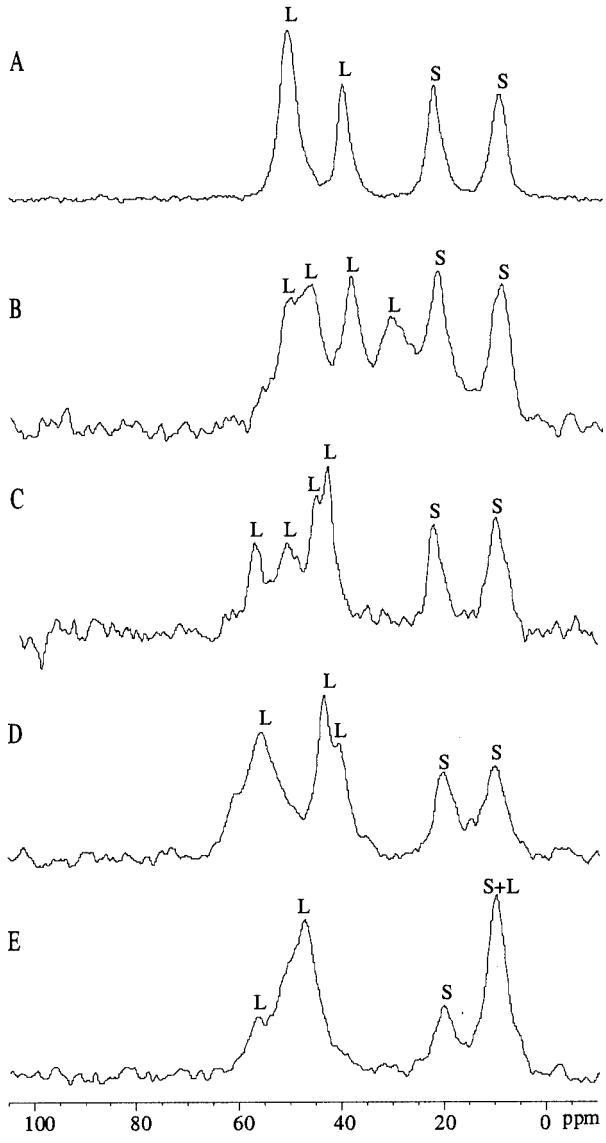

Figure 2. ^{13}C CP MAS NMR spectra of diamine ion exchangers **3B** (A), **4B** (B), **5B** (C), **6B** (D), and **7B** (E); peaks originating from $(R)_3SiCH_2CH_2$ are denoted **S**; all ligand signals, and signals originating from $(R)_3SiCH_2CH_2CH_2$, are marked **L**

distilled water, 1 M HCl, and absolute ethanol. Subsequent desorption was performed in 2 M HNO_3, as this eluent proved to be most efficient. The recovery results of amine ion exchangers are listed in Table 2. The most important recovery observations, for adsorption in water, are discussed below:

(1) Maximum ligand capacities of up to 0.5 mmol/g ($\approx$ 50 mg Rh/ g ion exchanger) were obtained, with ligand occupations not above 65%. For most ion exchangers, the ligand occupations lie around 50%, suggesting that the Rh metal-ions coordinate predominantly by an ML_2 fashion, in agreement with the observations of Zmievskaya[10b] and Tikhomirova.[7a]

(2) The desorption processes show the following trend: monoamines > diamines > triamines. Very high degrees of

desorption, after adsorption in H_2O, were obtained for ion exchangers **1b**, **4b**, and **7b**, with an *almost quantitative desorption* for ion exchanger **2b**. This recovery trend clearly indicates that coordination via five-membered chelate rings has a positive effect on the complex stability (see previous section), but an inverse effect on the elution, as the desorption drops from 93% (**1b**) through 71% (**3b**) to only 46% (**8b**).

(3) The correlation of the recovery with the complex stability is even more striking, as the desorption pattern for the diamine ion exchangers is: *Et_3en* (**7b**) ≥ *pren* (**4b**) >> *Me_3en* (**6b**) ≥ *en* (**3b**) > *Me_2en* (**5b**). Methylation of the amine groups does not influence the adsorption or the desorption to a large extent, but replacement of the methyl groups with ethyl groups results in high elution percentages. Adversely, the ligand occupation is decreased, although not dramatically. Chelation via six-membered chelate rings (**4b**) appears to be strong enough for sufficient binding (64%) and weak enough to ensure a high desorption percentage (91%).

(4) The recovery pattern of the triamines is quite similar, as expected from the log *D* experiments (Figure 6).

For all the ion exchangers, the adsorption was found to increase with the different solvents in the following order: HCl << H_2O ≤ EtOH. The ligand occupations lie mainly between 40% and 75% for adsorption in water or ethanol, whereas the adsorption in HCl never exceeds 25%. The relatively low ligand occupation, when the adsorption is done in 1 M HCl, can be attributed to the different binding mode, as already mentioned above. At low pH, the amines are protonated and, as the complex stability is lower, the extraction is seriously hampered by the presence of large amounts of competing Cl^- ions. On the other hand, a reasonably good desorption was obtained with all the ion exchangers (> 80%), demonstrating the absence of binding in a chelate fashion under these conditions.

Finally, although the adsorption in EtOH was most successful in many cases, the desorption often proved to be problematic (Table 2, most right column). This problem has to do with partial reduction of the Rh metal ions in this solvent, as reported by Hernan[20] and Kriek.[21] This explanation has been confirmed by comparison of the potential for elution after adsorption in various alcohols and a non-reducing solvent, acetonitrile. The desorption, after adsorption in methanol or 1-propanol, proved equally problematic, and appeared to be greatly improved after adsorption in acetonitrile.

The possibility of re-using our ion exchangers was also investigated, and a constant recovery percentage over five cycles of adsorption and desorption was established. Hence, no leaching of amine ligands was taking place. The details of the results will be published in a separate manuscript.[22]

Conclusions

In summary, highly efficient recovery of Rh metal ions was effected with some of the presented amine-containing silica-based ion exchangers. Although the recovery of Rh is known to be troublesome, almost quantitative desorption was attained with a few of the tested materials under relatively mild conditions, using 2 M HNO_3. The desorption efficiency proved to be highly dependent on the ligand-to-metal stability of the complexes and the following conclusion can be drawn: To ensure optimal Rh recovery, the log *D* values of the ligand-to-metal complexes should lie between 2.0 and 2.5. Above log $D = 2.5$, the complex stability is too strong to ensure good desorption. Below log $D =$

2.0, the low complex stability prevents a high adsorption, even though the ligand occupation in water was never below 30%. Alkylation of the amine group(s) induced a reasonable complex destabilization.

The extractability and the subsequent elution were dependent on the chosen medium, which influenced the character of the Rh species.

In order to apply these materials in a continuous system, industrially important factors, such as ligand exchange kinetics and selectivity of extraction, are currently being investigated.

Experimental Section

Reagents and Analytical Methods: All reactions were performed under an argon atmosphere using standard Schlenk techniques. All reagents and solvents were purchased from commercial sources and were used without further purification unless stated otherwise. Toluene was distilled from Na under argon and stored over molecular sieves (3Å). Methanol was distilled from Mg under an argon atmosphere and stored over molecular sieves. Silica (Aldrich Silica gel Davisil™, particle size 4−20 μm, surface area 480 m^2/g, pore volume 0.75 cm^3/g) was activated before use by heating in vacuo (200 mbar) at 50 °C for at least 48 hours.

^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker DPX 300 spectrometer operating at 300.1 MHz and at 75.5 MHz for ^{1}H and ^{13}C NMR, respectively, and chemical shifts are quoted with respect to TMS and internal solvents, as internal reference for ^{1}H and ^{13}C NMR, respectively. Solid-state ^{13}C NMR CP-MAS NMR spectra were recorded on a Bruker MSL 400 spectrometer operating at 100.6 MHz with a rotational spin speed of 10.5 kHz. Metal analyses were performed on a Perkin−Elmer 3100 atomic absorption (AAS) and flame emission spectrometer using a linear calibration method. Elemental analyses (C, H, N) were carried out by the Microanalytical Laboratory of the University College in Dublin. Mass spectra were recorded on a Finnigan MAT 900 equipped with a custom-made electrospray interface (ESI).

$RhCl_3 \cdot 3H_2O$, 3-(trimethoxysilyl)propylamine (*NH*$_2$, **1a**), *N*-[3-(trimethoxysilyl)propyl] ethylenediamine (*en*, **3a**), and *N*-[3-(trimethoxysilyl)propyl] diethylenetriamine (*dien*, **8a**) were purchased from Acros. [3-(dimethylamino)propyl]trimethoxysilane (*Me*$_2$*N*, **2a**) was synthesized according to a literature procedure,[23] and *N*-[3-(trimethoxysilyl)propyl]propylenediamine (*pren*, **4a**) was synthesized as described previously.[9]

***N,N*-Dimethyl[3-(trimethoxysilyl)propyl]ethylenediamine (*Me*$_2$*en*, 5a):** A mixture of 3-chloropropyltrimethoxysilane (16.8 mL, 18.1 g, 91.1 mmol) and *N,N*-dimethylethylenediamine (20.0 mL, 16.1 g, 182.1 mmol) was heated at 150 °C for 6 h and then overnight at room temperature. The light-yellow, biphasic solution was purified by vacuum distillation (b.p. 105−107 °C/1 Torr). Yield **5a** (colourless liquid) 6.4 g (28%). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.56 (t, 2 H, SiCH_2), 1.23 (br. s, 1 H, N*H*), 1.51 (dt, 2 H, $SiCH_2CH_2$), 2.14 (s, 6 H, N-CH_3), 2.30 (t, 2 H, $RNHCH_2CH_2NR_2$), 2.52 (t, 2 H, $SiCH_2CH_2CH_2$), 2.58 (t, 2 H, $RNHCH_2CH_2NR_2$), 3.45 (s, 9 H, OCH_3). ^{13}C NMR: δ = 6.5 (Si*C*H$_2$), 22.9 ($SiCH_2CH_2$), 45.4 [N(CH_3)$_2$], 47.1 ($SiCH_2CH_2CH_2$), 50.3 (O*C*H$_3$), 52.7 ($RNHCH_2CH_2NR_2$), 59.1 ($RNHCH_2CH_2NR_2$). ESI-MS *m*/*z* ($C_{10}H_{26}N_2O_3Si$, 250): 251 $[M + H]^+$.

***N,N,N′*-Trimethyl[3-(trimethoxysilyl)propyl]ethylenediamine (*Me*$_3$*en*, 6a):** A mixture of 3-chloropropyltrimethoxysilane (4.5 mL, 4.9 g, 24.5 mmol) and *N,N,N′*-trimethylethylenediamine (6.2 mL, 5.0 g, 48.9 mmol) was heated at 150 °C for 5 h. The clear, red, biphasic solution was purified by vacuum distillation (b.p. 140−143 °C/1 Torr). Yield **6a** (light yellow liquid) 2.15 g (33%). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.51 (t, 2 H, SiCH_2), 1.47 (dt, 2 H, $SiCH_2CH_2$), 2.14 (s, 9 H, N-CH_3), 2.23−2.40 (m, 6 H, N-CH_2), 3.45 (s, 9 H, OCH_3). ^{13}C NMR: δ = 6.5 (Si*C*H$_2$), 19.9 ($SiCH_2CH_2$), 42.2 (N-*C*H$_3$), 45.6 [N(*C*H$_3$)$_2$], 50.3 (O*C*H$_3$), 55.3 ($SiCH_2CH_2CH_2$), 57.2 [$RN(CH_3)CH_2CH_2N(CH_3)_2$], 60.9 [$RN(CH_3)CH_2$-$CH_2N(CH_3)_2$]. ESI-MS *m*/*z* ($C_{11}H_{28}N_2O_3Si$, 264): 265 $[M + H]^+$.

***N,N,N′*-Triethyl[3-(trimethoxysilyl)propyl]ethylenediamine (*Et*$_3$*en*, 7a):** A mixture of 3-chloropropyltrimethoxysilane (5.1 mL, 5.5 g, 27.9 mmol) and *N,N,N′*-triethylethylenediamine (10.0 mL, 8.0 g, 55.8 mmol) was heated at 150 °C for 6 h. The product was purified by vacuum distillation, yielding 2.6 g (30%) of a turbid white liquid (b.p. 130−134 °C/1 Torr). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.47 (t, 2 H, SiCH_2), 0.85−0.92 (m, 9 H, N-CH_2CH_3), 1.40 (dt, 2 H, $SiCH_2CH_2$), 2.14 (s, 9 H, N-CH_3), 2.30 (t, 2 H, $SiCH_2CH_2CH_2$), 2.36−2.43 (m, 10 H, N-CH_2), 3.42 (s, 9 H, OCH_3). ^{13}C NMR: δ = 6.5 (Si*C*H$_2$), 12.4, 12.5 (N-CH_2CH_3), 20.8 ($SiCH_2CH_2$), 48.2 [N(CH_2CH_3)$_2$], 48.8 ($SiCH_2CH_2CH_2NR_2$), 51.0 (O*C*H$_3$), 51.9 (N-*C*H$_2$CH$_3$), 52.5 ($R_2NCH_2CH_2NR_2$), 57.7 ($R_2NCH_2CH_2NR_2$). ESI-MS *m*/*z* ($C_{14}H_{34}N_2O_3Si$, 307): 308 $[M + H]^+$.

1,4,7-Triazacyclononane (*tacn*, 9a): *N,N′,N″*-Tris(*p*-toluenesulfonyl)-1,4,7-triazacyclononane (20.0 g, 33.8 mmol) was suspended in conc. H_2SO_4 (60 mL) in the presence of water (12 mL) and heated for 20 h at 140 °C. After cooling to room temp., the mixture was poured into EtOH (96%, 150 mL), cooled with a water bath. The suspension was filtered and dried with Et_2O, yielding the grey deprotected tacn-sulfuric acid salt (20.7 g). This salt was added to a mixture of NaOH (10 g, 0.25 mmol), water (15 mL), and toluene (70 mL) and heated under reflux for 2 h. The water was subsequently removed by a Dean−Stark separation in toluene for 3 h. Hot filtration of the suspension, followed by washing with hot toluene and chloroform (two times) and evaporation of the solvent, yielded 3.8 g (86%, 29.2 mmol) of **9a** as a light-yellow oil which slowly crystallized.

Synthesis of the Ion Exchangers: The free ligand (1.7 mmol **1a**−**8a**/g silica) was added to a suspension of silica in toluene (5−10 mL/g silica), and the mixture was stirred at room temperature for 48 h. After filtration, the residual reagents were removed by washing with toluene (3 ×). The ion exchangers **1b**−**8b** were further purified by heating under reflux in toluene in a Soxhlet apparatus for 24 hours, followed by drying at 50 °C in vacuo (200 mbar) until constant weight.

In the case of the *tacn* ligand **9a**, the following grafting procedure was followed: 3-glycidoxypropyltrimethoxysilane (glymo, 9.3 g, 41.9 mmol) was added to a suspension of silica (10.0 g) in toluene (75 mL) and the mixture heated for 24 h at 80 °C. The *glymo*-Si was washed, purified, and dried as indicated above. Ligand **9a** (3.1 g, 24.0 mmol) was added to a suspension of *glymo*-Si (9.5 g, ligand concentration: 0.88 mmol/g) in MeOH/toluene (both 50 mL) and the mixture was heated at 90 °C for 48 h. Purification was performed as discussed above.

log *D* Experiments: Distribution coefficients, with *D* = [mmol M^{n+}/g of dry ion exchanger]/[mmol M^{n+}/mL of solution], were determined as a function of the pH, employing 0.6 M NaCl/HCl buffer solutions (pH 1−2) and 0.6 M NaOAc/HOAc buffer solutions (pH 3−6). 25 mL of the appropriate buffer solution was added to a freshly[24] prepared solution of $RhCl_3 \cdot 3H_2O$, where the ligand-to-metal ratio was kept constant at 5 to 1, in 25 mL of demineralised

H_2O. Subsequently, 100 mg of ion exchanger was added and the suspension was agitated in polyethylene bottles mounted on a shaker for 48 hours at room temperature. After shaking, the samples were filtered and 25 mL of the filtrate was transferred into a 50 mL volumetric flask and the metal content subsequently analysed by AAS. The residue was washed with H_2O, EtOH, and Et_2O (3 ×), respectively, and dried in vacuo at 50 °C for 24 h. Samples for metal analysis were prepared by heating ca. 100 mg of loaded samples overnight in 5 mL of concentrated H_2SO_4. Subsequently, concentrated HNO_3 was added dropwise until the solutions became clear. After dilution in volumetric flasks the solution was filtered through a glass filter (P4) to remove residual, undigested silica. The filtrate was collected and analysed by AAS.

Blank uptake experiments with $RhCl_3$ using pure silica and *glymo*-Si were performed under various acidic conditions (up to 5 M HCl), neutral conditions, and using the above-mentioned buffer system. No significant uptake was detected. Hence, all uptake capacity can be attributed to the supported ligand system.

Recovery Experiments: For the adsorption experiments, 200 mg of ion exchanger was added to a fresh solution of $RhCl_3 \cdot 3H_2O$, where the ligand-to-metal molar ratio was kept constant at 1 to 1, in 50 mL of water, 1 M HCl, or EtOH (absolute). After agitation for 48 h, the suspension was filtered and the residue was washed with H_2O, EtOH, and Et_2O (3 ×), respectively. About 100 mg of the loaded ion exchanger was added to a 50 mL 2 M HNO_3 solution and the procedure was repeated. Both the loaded and eluted samples were subsequently dried and prepared for metal analysis as described above.

Acknowledgments

This research has been sponsored by IOP (Innovation Oriented research Programme, The Netherlands) Environmental Technology/Heavy Metals cluster Separation, project number IZW97411. Ing. F. ten Hoonte, Mrs. J. Erkelens, and Mr. J. J. M. van Brussel (Leiden Institute of Chemistry) are thanked for technical assistance. Mr. F. Lefeber, Mr. K. Erkelens, and Mr. J. G. Hollander are acknowledged for the collection of the solid-state ^{13}C CP MAS NMR spectra of the ion exchangers presented in this paper. *N,N′,N′′*-Tris(*p*-toluenesulfonyl)-1,4,7-triazacyclononane was kindly supplied to us by Dr. R. Hage (Unilever). Dr. W. Buijs (DSM Research) and Dr. R. Luckay (Stellenbosch University, South Africa) are acknowledged for stimulating discussions.

A New Type of Anionic Rearrangement in Metalated Benzylhydrazines

Hermann Sachdev*[a] and Cordula Preis[a]

Keywords: Lithium / Magnesium / Hydrazides / Rearrangements / Structural characterisation

Metalation of *N*,*N*-dibenzyl-*N*′-(trimethylsilyl)hydrazine with organyllithium and -magnesium compounds led to the migration of the benzyl group, and the deprotonation of Si–Me groups was observed. The syntheses and crystal structures of $Bzl_2N–NH_2$, $[Bzl(Li)N–N(SiMe_3)Bzl]_2$, and $[Mg[BzlN–N(SiMe_2CH_2)Bzl]_2$ are presented.

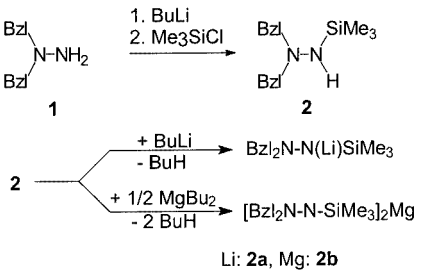
Introduction

Precursors of lithium−, magnesium−, and aluminium−nitrogen compounds with low aggregation degrees are highly desired for their use in the synthesis of nitridic ceramic composite materials[1] by CVD techniques. Different ligand systems have been investigated in order to obtain low-coordinated, volatile precursors.[2] The structural chemistry of amides of group-1, -2, and -13 metals has already been widely explored and indicates the formation of oligomeric or polymeric ring and cage structures.[3−5]

Hydrazines are interesting ligands, and metalated hydrazines exhibit a different coordination chemistry due to an additional donor atom in the α-position. Some recent aspects of the coordination chemistry of alkali metal hydrazides have been reported in the past,[6−8] and the syntheses of aluminium and gallium hydrazides were also studied as possible precursors for AlN[9] and GaN.[10,11] The structural chemistry of group-2 metal hydrazides is rather unexplored, and therefore we studied the synthesis and reactivity of alkaline earth metal hydrazides in order to compare them with the corresponding hydrazides of group-1 and -13 elements.[6−8]

Results and Discussion

In this report, the properties of *N*,*N*-dibenzyl-*N*′-(trimethylsilyl)hydrazine (**2**), prepared by silylation of *N*,*N*-dibenzylhydrazine (**1**), were characterized with respect to the coordination to lithium and magnesium atoms. The aim was to achieve the corresponding lithium and magnesium hydrazides **2a** and **2b**, respectively, in a straightforward reaction involving hydrazine **2** and organolithium or -magnesium compounds according to Scheme 1. The reactions were carried out in hexane to avoid additional coordination of donor solvent molecules at the metal atoms.



Scheme 1

Molecular Structures in the Solid State

In the course of this study, the solid-state structure of the starting material *N*,*N*-dibenzylhydrazine (**1**) was characterized. Single crystals suitable for X-ray structure determination could be obtained from freshly distilled *N*,*N*-dibenzylhydrazine by cooling at 4 °C.

The molecular structure is depicted in Figure 1. The crystals belong to the monoclinic system and the space group $P2_1/c$. The N−N bond length is 1.450(2) Å, the N−C distances are 1.467(2) Å [N(1)−C(7)] and 1.476(2) Å [N(1)−C(27)]. The nitrogen atom N(1) is threefold coordinated and shows sp^3-type bonding, as indicated by the sum of the bonding angles (330°).

The individual molecule is chiral in the solid state, but is linked to the corresponding enantiomer by hydrogen bonds via the $-NH_2$ groups. The N···H distance of the hydrogen bonds is 2.433 Å. This leads to a fourfold coordination of the nitrogen atom N(2), with N−N−H angles ranging from 103.4° to 108.9°, and a chain-like arrangement of the individual isomers in the crystal. It is interesting that the nitrogen atom N(2) of the hydrazide unit does not participate in the bonding via hydrogen bonds.

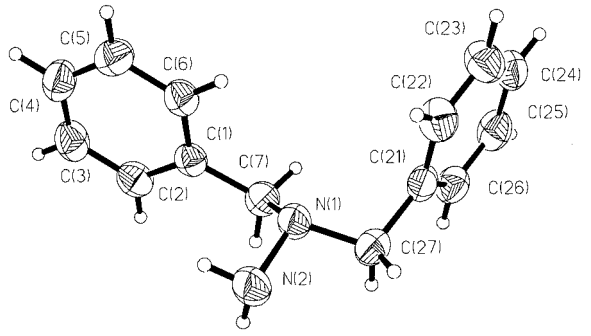

Figure 1. Molecular structure of *N*,*N*-dibenzylhydrazine (**1**); thermal ellipsoids are shown at a 50% probability level; selected bond lengths [Å] and bond angles [°]: N(1)−N(2) 1.4498(15), N(1)−C(7) 1.4672(18), N(1)−C(27) 1.4761(18), C(1)−C(7) 1.5184(19), C(21)−C(27) 1.5099(19); N(2)−N(1)−C(7) 111.37(10), N(2)−N(1)−C(27) 107.00(10), C(7)−N(1)−C(27) 111.42(11)

Light yellow crystals suitable for X-ray single-crystal structure determination could be obtained from the lithiation reaction in hexane (Scheme 1).[12] The molecular structure of the obtained product is depicted in Figure 2. It is a dimeric isomer of the anticipated product **2a**, *N*,*N*′-dibenzyl-*N*′-(trimethylsilyl)hydrazide (**3**), indicating the migration of a benzyl group.

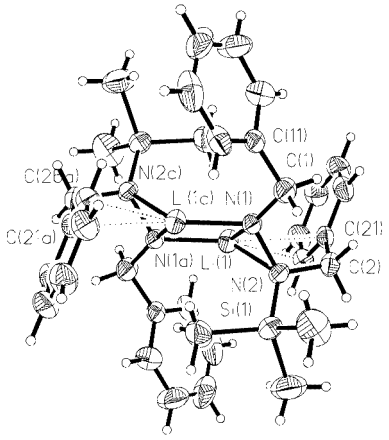

Figure 2. Molecular structure of dimeric lithium *N*,*N*′-dibenzyl-*N*′-(trimethylsilyl)hydrazide (**3**); thermal ellipsoids are shown at a 25% probability level and hydrogen atoms are omitted for clarity; selected atom distances [Å] and bond angles [°]: N(1)−N(2) 1.482(4), N(1)−C(1) 1.460(5), N(1)−Li(1) 1.924(8), N(1)−Li(1a) 1.954(7), C(1)−C(11) 1.483(6), Si(1)−N(2) 1.729(3), N(2)−C(2) 1.482(5), N(2)−Li(1) 2.091(8), C(2)−C(21) 1.489(6), C(21)−Li(1) 2.647(8),C(26)−Li(1) 2.678(8), Li(1)−Li(1a) 2.288(13); C(1)−N(1)−N(2) 111.4(3), C(1)−N(1)−Li(1) 150.6(4), N(2)−N(1)−Li(1) 74.5(3), C(1)−N(1)−Li(1a) 122.0(3), N(2)−N(1)−Li(1a) 120.0(3), Li(1)−N(1)−Li(1a) 72.3(3), N(1)−C(1)−C(11) 110.5(3), N(1)−N(2)−C(2) 113.9(3), N(1)−N(2)−Si(1) 115.5(2), C(2)−N(2)−Si(1) 119.2(3), N(1)−N(2)−Li(1) 62.4(2), C(2)−N(2)−Li(1) 103.9(3), Si(1)−N(2)−Li(1) 129.2(3), N(1)−Li(1)−N(1a) 107.7(3), N(1)−Li(1)−N(2) 43.08(19), N(1)a−Li(1)−N(2) 129.3(4)

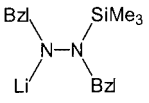
The crystal belongs to the triclinic system and space group $P\bar{1}$ and contains two independent dimers of **3** per unit cell. The bonding parameters of the individual molecules are very similar.



3

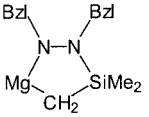
Figure 2 represents one centrosymmetric dimer with an Li_2N_4 core structure of two three-membered LiN_2 rings and a central four-membered Li_2N_2 ring. The observed Li_2N_4 core structure results from aggregation of two side-on-coordinated hydrazide units, a structural feature which has been observed for other dimeric lithiated silylhydrazides.[7,8]

In $(\mathbf{3})_2$, the nitrogen atoms of the hydrazide ligand show fourfold coordination, whereas the lithium atoms are threefold coordinated by two amide-type nitrogen atoms and one amine-type nitrogen atom.

The N−N bond length of the hydrazide unit is 1.482(4) Å. The Li−N distances of the four-membered Li_2N_2 ring [N(1)−Li(1) 1.924(8) Å, N(1)−Li(1a) 1.954(7) Å] are shorter than the distance between the coordinating α-nitrogen atom N(2) and the hydrazide ligand [N(2)−Li(1) 2.091(8) Å]. The distance between the lithium atoms Li(1)−Li(1a) is 2.288(13) Å; similar distances have been observed in other dimeric lithium silylhydrazides.[6−9]

Additional steric shielding of the lithium atoms results from interaction between the lithium atoms and the *ortho*-C−H position of the aromatic ring system of the benzyl groups of the hydrazide ligand [C(21)−Li(1) 2.647(8) Å, C(26)−Li(1) 2.678(8) Å]. Comparable Li−C distances were reported for lithiated hydrazides with aryl substituents.[7,8]

In a similar reaction of 2 equiv. of **2** with dibutylmagnesium according to Scheme 1, colourless single crystals suitable for X-ray structure determination were obtained from a hexane solution. The X-ray structure determination reveals the formation of a twofold deprotonated derivative **4** (1,2-dibenzyl-3,3-dimethyl-1,2-diaza-3-sila-5-magnesacyclopentane), instead of the anticipated hydrazide **2b**.



4

The crystal belongs to the triclinic system and space group $P\bar{1}$. The crystal structure of the hydrazide **4** is depicted in Figure 3.

The isolated product **4** is dimeric in the solid state. The magnesium atoms are coordinated by four nitrogen atoms and one carbon atom of the deprotonated trimethylsilyl group. This leads to an Mg_2N_4 core derived from side-on-coordinated MgN_2 rings. The Si−C bond length of the methylene group [Si(1)−C(15), 1.827 Å] is significantly shorter than the Si−C distances of the methyl groups (1.884 and 1.856 Å), due to the carbanionic nature of C(15).

Furthermore, there is a weak interaction between the magnesium atom and the π-electrons of the phenyl ring

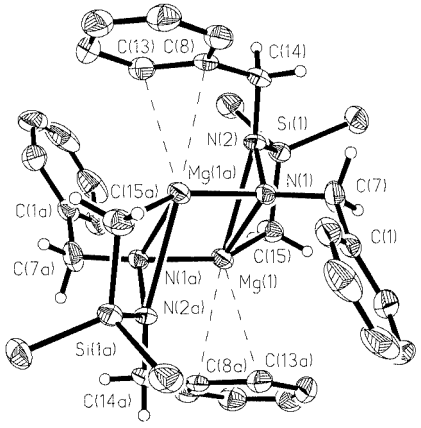


Figure 3. Molecular structure of **4**; thermal ellipsoids are shown at a 25% probability level and hydrogen atoms of aryl and methyl groups are omitted for clarity; selected bond lengths [Å] and bond angles [°]: N(1)−N(2) 1.491(4), Mg(1)−N(1) 2.121(3), Mg(1)−N(2) 2.596(3), Mg(1)−Mg(1a) 2.883(3), N(1)−Mg(1a) 2.044(3), N(2)−Mg(1a) 2.763(3), C(13)−Mg(1a) 2.789(4), C(8)−Mg(1a) 2.721(3), N(2)−C(14) 1.475(4), N(1)−C(7) 1.466(5), Si(1)−C(15) 1.827(4), Si(1)−C(16) 1.884(4), Si(1)−C(17) 1.856(4), Mg(1)−C(15) 2.129(4), Mg(1)−Mg(1a) 2.883(4); N(1a)−Mg(1)−N(1) 92.43(12), N(2)−Mg(1)−N(2a) 114.98(7), N(1)−Mg(1)−N(2) 35.05(10), N(2)−N(1)−Mg(1a) 101.65(19), N(2)−N(1)−Mg(1) 90.13(18), C(7)−N(1)−Mg(1a) 134.3(3), C(7)−N(1)−N(2) 110.1(2)

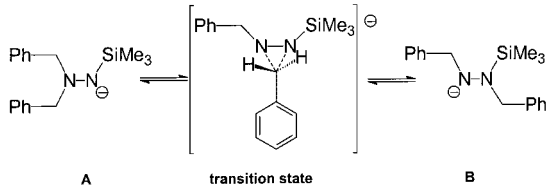
system. The C−Mg distances C(8)−Mg(1a) and C(13)−Mg(1a) range between 2.721 Å and 2.789 Å, and are shorter than the distance Mg(1a)−N(2) [2.763 Å]. When this interaction is considered as part of the coordination sphere, the magnesium atoms exhibit a sixfold coordination.

Both nitrogen atoms of the hydrazine ligand are involved in the coordination and the sum of the bond angles at the deprotonated nitrogen atom N(1) involving the surrounding atoms C(7), N(2), Mg(1) and Mg(1a) is 334.5° and 346.1°, respectively. Thus, the coordination geometry at the nitrogen centre N(1) is not planar, but resembles a distorted tetrahedral coordination. The C−N bond lengths (1.475 Å and 1.466 Å) are in the range of C−N single bonds (1.470 Å). The N−N bond length (1.491 Å) is slightly larger than that in *N*,*N*-dibenzylhydrazine (**1**) (1.450 Å).

The N−N bond lengths in the metalated species **3** and **4** are longer than that in **1**, due to the additional negative charge at the nitrogen atom. The C−N bond lengths of the benzylic groups are not significantly affected by the metalation. A comparable increase in the N−N bond length is reported for the structures of alkali metal organyl- and silylhydrazides.[6−9]

Discussion

The crystal structures of **3** and **4** both indicate the formation of an *N*,*N*′-dibenzylhydrazide isomer. Although *N*,*N*-dibenzyl-*N*′-(trimethylsilyl)hydrazine (**2**) was used as the starting material, migration of the benzyl group occurred during metalation with butyllithium and dibutylmagnesium according to Scheme 2, finally leading to compounds **3** and **4**. Thus, the rearrangement must have taken place during the reaction from the structural unit **A** to **B**, by migration of a benzyl group.



Scheme 2

The starting material consists of the pure isomer *N*,*N*-dibenzyl-*N*′-(trimethylsilyl)hydrazine (**2**), as indicated by the NMR spectroscopic data. The ^{29}Si NMR spectrum of **2** reveals a single resonance at δ = 2.23 and the ^{13}C NMR spectrum exhibits only one set of signals for the benzyl ligands (δ = 65.01, 126.96, 127.93, 129.85, and 138.01). The *N*,*N*′ isomer would have given rise to 10 resonances for the benzyl groups in the ^{13}C NMR spectrum, assuming free rotation of the ligands.

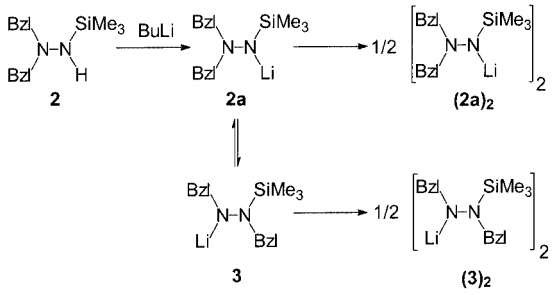
In the chemistry of silylated hydrazines, the migration of silyl groups is a common feature and has already been reported.[13,14] However, this is the first time that a similar rearrangement of benzyl groups is observed. Steric overcrowding cannot be considered to be responsible for this type of rearrangement, as indicated by the crystal structure of the unsubstituted hydrazine **1** (Figure 1), nor for the free rotation of the benzyl groups in solution of the hydrazines **1** and **2**, as indicated by the ^{13}C NMR spectroscopic data of these compounds. A stabilising effect of the negative charge by an aromatic system[7] is also not possible in this case. The migration of the benzyl group can be explained by an intramolecular S_N-type reaction caused by the increased nucleophilic character of the deprotonated hydrazide nitrogen atom in **A**, although stabilisation of the negative charge by the silyl group is possible (Scheme 2).

NMR Spectra

The ^{1}H and ^{13}C NMR spectra of the isolated crystals were recorded in C_6D_6 and indicate three different −CH_2− groups of the benzyl ligands and two different silyl groups. This is in accordance with the ^{29}Si and ^{7}Li NMR spectrum of the isolated crystal fraction. Two weak peaks (δ = 4.49 and 4.98) and two strong peaks (δ = −10.36 and 4.00) are present in the ^{29}Si NMR spectrum. Similar ^{29}Si NMR spectroscopic data were reported for other dimeric lithium silylhydrazides.[7,8] The ^{7}Li NMR spectrum exhibits two resonances at δ = −1.83 (major signal) and δ = −2.27. There is no change in the ^{29}Si and ^{1}H NMR spectra up to 60 °C. This indicates the presence of stable species in solution. According to the crystal symmetry of compound $(\mathbf{3})_2$, there are two different benzyl groups in the hydrazide unit, whereas the spectrum of compound $(\mathbf{2a})_2$ should exhibit only one set of signals for the benzylic groups in the case of free rotation of the substituents. The ^{1}H NMR spectroscopic data can be interpreted as a mixture of the dimer

isomers $(\mathbf{2a})_2$ and $(\mathbf{3})_2$ in solution, since there are three signals for the $N-CH_2-Ph$ groups, a resonance at $\delta = 3.74$ (25%, isomer **2a**) and two peaks at $\delta = 3.78$ and 4.07 (75%, isomer **3**).

The formation of the isomers **2a** and **3** can be explained by Scheme 3, which shows that during the lithiation of **2** the reaction proceeds in two different ways. In the first step, the monomer hydrazide **2a** is formed. In this monomer species, a rearrangement according to Scheme 2 is possible, leading to **3**.

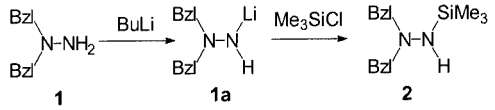


Scheme 3

The dimeric species $(\mathbf{2a})_2$ and $(\mathbf{3})_2$, once formed, are stable in solution and do not show any monomer−dimer equilibria or rearrangement equilibria, as indicated by measurement of high-temperature ^{29}Si NMR spectra in benzene up to 60 °C. The stability of the dimeric clusters is in agreement with rearrangement reactions observed in lithium silylhydrazides, which also show a high stability of the Li−N cluster once it is formed.[7,8]

Since the ^{7}Li and ^{29}Si NMR spectra of the solution and the crystals are similar, this indicates that the obtained crystal fraction is a mixture of the isomers $(\mathbf{2a})_2$ and $(\mathbf{3})_2$. It was not possible to isolate a suitable crystal of **2a** for a structure determination.[12] The rearrangement was not observed in hydrazines **1** and **2**, due to a weaker nucleophilic character of the deprotonated nitrogen atom.

An interesting feature of the synthesis of compound **2** from lithiated *N*,*N*-dibenzylhydrazine (**1a**) and chlorotrimethylsilane, is that the rearrangement was not observed during this reaction, although a hydrazide anion is formed as an intermediate according to Scheme 4.



Scheme 4

The different reactivity of the hydrazides **2a** and **1a** can be attributed to their coordination chemistry. The retention of the *N*,*N*-dibenzyl isomer in the reaction involving **1a**, may be due to the different degree of aggregation of the lithiated intermediate **1a**, which is insoluble in donor-free solvents, in contrast to the silylated species **2a** and **3**. The aggregation might involve only the deprotonated nitrogen atom of the hydrazide ligand leading to highly aggregated oligomers of the type $(\mathbf{1a})_n$, which prevent the rearrangement under normal reaction conditions. Such a kind of aggregation was observed in other magnesium and zinc hydrazides.[15] If the deprotonated nitrogen atom is shielded by intermolecular coordination, the S_N2-type benzylic rearrangement becomes less likely.

Reaction of *N*,*N*-Dibenzyl-*N*′-(trimethylsilyl)hydrazine with Dibutylmagnesium

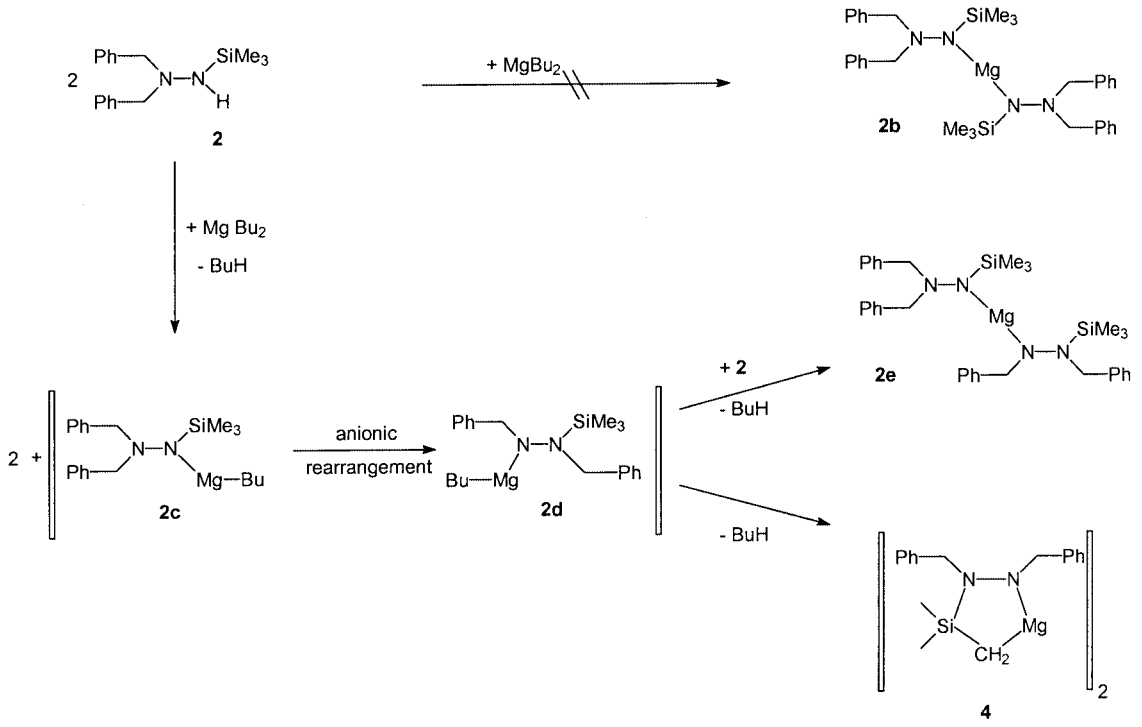
It was expected that the reaction of 2 equiv. of **2** with dibutylmagnesium would lead to the formation of a magnesium bis(hydrazide) **2b** according to Scheme 1. However, crystals of compound **4** were recovered in a 40% yield with respect to the magnesium content.

The solid-state structure of the isolated crystals of compound **4** reveals a magnesium hydrazide, where an additional deprotonation of a methyl group has taken place, leading to an $-N^{-}(Bzl)-SiMe_2-CH_2^{-}$ dianionic fragment. A mechanism explaining the formation of **4** is depicted in Scheme 5.

The first step of the reaction is the formation of organylmagnesium hydrazide **2c**. From this intermediate, migration of a benzyl group similar to that in lithium hydrazide **3** takes place, leading to the *N*,*N*′-dibenzyl isomer **2d**. From this intermediate **2d**, the reaction can proceed in two different directions. The butyl group acts as a base towards the proton of an Me_3Si- group in an intramolecular deprotonation reaction, leading to compound **4**, which was isolated and characterised by NMR spectroscopy and single-crystal diffractometry. The second reaction pathway leads to the formation of a magnesium bis(hydrazide) with unsymmetrically substituted ligands **2e**, by reaction of **2d** with the starting material **2**. Other types of deprotonation reactions involving $N-SiMe_3-$ groups were reported for solutions of heterobimetallic lithium and magnesium amides by elimination of an amine,[16] and by deprotonation of transition metal compounds with strong bases like butyllithium or lithium and sodium silylamides.[17] The formation of the five-membered $N-SiMe_2-CH_2-Mg$ ring structure in **4** may be attributed to the Lewis acidity of magnesium and the coordinating effects of the $Mg-N-N-$ unit, although a kinetic effect caused by the presence of *n*- and *sec*-butyl groups in commercially available dibutylmagnesium might be possible. However, the latter influence was not observed in the synthesis of other magnesium amides[16,18] and hydrazides[15] with sterically demanding silyl substituents, nor in the synthesis of organylmagnesium amides and hydrazides.[15]

The ^{29}Si NMR spectrum of the solution shows the starting material **2** ($\delta = 1.73$, highest intensity) to be present, as well as an additional signal at $\delta = 4.97$, of equal intensity, which is attributed to compound **4**. The resonance for the isolated compound **4** in C_6D_6 is at $\delta = 3.82$

Furthermore, weak resonances are present in the low-field region ($\delta = 3.65, 4.27, 4.92, 5.62, 11.24, 14.38$) and in the high-field region ($\delta = -8.76, -8.06, -7.33, -6.67$). The two resonances at lower field can be assigned to the



Scheme 5. Mechanism for the formation of the magnesium hydrazide **4**

rearranged dimeric organylmagnesium hydrazide **2d** (δ = 11.24, 14.38). The two sets of signals with four peaks each at δ = 3.65, 4.27, 4.92, 5.62 and δ = −8.76, −8.06, −7.33, −6.67 can be assigned to the dimeric magnesium hydrazide **2e**. At higher temperatures, no change in the intensity or peak shift was observed in the spectrum up to 60 °C.

An interesting feature to note is that there is no reaction when **4** is heated with the remaining starting material **2** up to 60 °C, although the basicity of the carbanion **4** should enable deprotonation of the hydrazide. This can be attributed to the high stability of the ionic core fragment and the steric shielding of **4**.

Conclusion

A new type of anionic rearrangement was observed in metalated benzylhydrazines, leading to the formation of *N*,*N*′-dibenzylhydrazides by migration of a benzyl group. With respect to the reaction of dibutylmagnesium with **2**, the rearrangement is the dominant reaction, instead of the formation of the corresponding magnesium hydrazide. The migration of the benzyl group is less dominant in the lithiation of the hydrazide **2**, which can be attributed to the different coordination and ionic nature of the metal−nitrogen bond. Furthermore, the influence of donor solvents on the coordination of the metal centres and the migration of the benzyl group has to be studied in more detail.

Experimental Section

General: All experiments were performed by using modified Schlenk techniques and anhydrous conditions under argon. Solvents were freshly distilled from Na/K alloy. Butyllithium (1.6 M in hexane), dibutylmagnesium (1 M in heptane, 1:1 isomer mixture of *n*- and *sec*-butyl groups), and *N*,*N*-dibenzylhydrazine were obtained commercially (Aldrich) and used as received. NMR spectra were recorded in C_6D_6 or $CDCl_3$ with a Bruker ACP 200 spectrometer (TMS as external standard; ^{1}H: 200 MHz, ^{13}C: 55.0 MHz, ^{29}Si: 39.7, ^{7}Li: 77.7 MHz). Attempts to prepare compound **3** and **4** in donor solvents like THF or ether failed and led to ether cleavage reactions, and deprotonation reactions of toluene were observed with compound **4** at higher temperatures. Compounds **3** and **4** may ignite if exposed to air. For the X-ray structure determination of the single crystals, a STOE IPDS diffractometer was used (Mo-K_α, λ= 0.71073 Å, graphite monochromator). The structures of the compounds **1** and **4** were solved by direct methods and for **2** the Patterson method was applied and refined by full-matrix least-squares methods (data are listed in Table 1). Anisotropic thermal parameters for all non-hydrogen atoms in the final cycles, isotropic refinement for hydrogen atoms positioned by geometry. SHELXS 97 and SHELXL 97 computer programs were used.[19] CCDC-168709 to -168711 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The Reaction of Poly(chlorophosphazene)s with *p*-Aminophenol − Specific Formation of Aminophosphazenes with Terminal OH Groups and Aryloxyphosphazenes with Terminal NH_2 Groups

Gabino A. Carriedo,*[a] José. I. Fidalgo Martínez,[a] F. J. García Alonso,[a] E. Rodicio González,[a] and A. Presa Soto[a]

Keywords: Polymers / Inorganic polymers / Polyphosphazenes / *p*-Aminophenol

The outcome of the reaction of the bifunctional reagent *p*-aminophenol (HO-C_6H_4-NH_2) with the cyclic triphosphazene [$N_3P_3Cl_6$] is very dependent on the solvent, the temperature, and the proton abstractor. In THF at room temperature with K_2CO_3 the reaction is very slow and takes place only through the NH_2 group to give a mixture of aminophosphazenes, but in refluxing acetone with Cs_2CO_3 the reaction is fast and occurs through both the NH_2 and the OH groups leading to crosslinked products. The analogous reaction with the bis-spirocyclodichlorotriphosphazene [$N_3P_3Cl_2(O_2C_{12}H_8)_2$] ($O_2C_{12}H_8$ = 2,2′-dioxybiphenyl) is also dependent on the conditions, but is more selective. At room temperature in THF with K_2CO_3 the reaction gives mostly aminophosphazene derivatives, while in refluxing acetone with Cs_2CO_3 the known aryloxyphosphazene [$N_3P_3(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2$] (**1**) is obtained exclusively. Accordingly, the reactions of *p*-aminophenol with high molecular weight poly(dichlorophosphazene) $[NPCl_2]_n$ in THF at room temperature in the presence of K_2CO_3, occur exclusively through the NH_2 groups without crosslinking, forming solutions of the aminophosphazene random copolymers $\{[NPCl_2]_{1-x}[NPCl(NHC_6H_4OH)]_x\}_n$ (**2a**) ($x < 1$) and $\{[NP(NHC_6H_4OH)_2]_{x-1}[NPCl(NHC_6H_4OH)]_{2-x}\}_n$ (**2b**) ($x > 1$) that carry terminal OH groups. The reaction of **2a** with NH_2Bu (Bu = *n*-butyl) gave the stable and soluble polymers $\{[NP(NHBu)_2]_{1-x}[NP(NHBu)(NHC_6H_4OH)]_x\}_n$ (**3**). Also, in agreement with the cyclic models, the reaction of *p*-aminophenol with the partially substituted copolymer $\{[NP(O_2C_{12}H_8)]_{0.8}[NPCl_2]_{0.2}\}_n$ occurs only at refluxing temperatures and in the presence of Cs_2CO_3, producing the poly(aryloxyphosphazene) derivative $\{[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_4NH_2)_2]_{0.2}\}_n$ (**4**) possessing terminal NH_2 groups, or, if the chlorine substitution is completed with phenol, the analogous polymer $\{[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_5)(OC_6H_4NH_2)]_{0.2}\}_n$ (**5**).

Introduction

Poly(phosphazene)s,[1] which consist of chains of -N=PX_2- units, are usually prepared by chlorine substitution in the parent poly(dichlorophosphazene) $[NPCl_2]_n$. Many aryloxyphosphazenes of the type $[NP(OC_6H_4R)_2]_n$ can therefore be synthesized by reacting $[NPCl_2]_n$ with phenoxides of the type $NaOC_6H_4R$. However, this method may not be effective in some special cases, for example with bifunctional reagents,[2] or with phenoxides carrying R groups that can also react with the P−Cl bonds, as these reactions could result in crosslinking.[3] The introduction of R groups that could incorporate interesting chemical reactivity to the phosphazenes polymers therefore presents several challenges frequently requiring protection and deprotection synthetic steps.[3]

One of the reactive groups with potential interest is R = NH_2. Although there are reports describing the incorporation of -$OC_6H_4NH_2$ functions to cyclic triphosphazenes directly from $NaOC_6H_4NH_2$,[4] the method most widely used is based on the formation of an -NO_2 derivative, followed by its catalytic reduction to the amine.[3,5−9] Other methods include the hydrolysis of an acetamido precursor.[10]

Previously, we have shown[11] that chlorine substitution reactions in phosphazenes may be carried out using one equivalent of phenol HOC_6H_4R in the presence of M_2CO_3 (M = K or Cs), and that the poly(dichlorophosphazene) $[NPCl_2]_n$ reacts with the bifunctional reagent 2,2′-(HO)C_6H_4-C_6H_4(OH) and K_2CO_3 without crosslinking, affording the phosphazene polymer $[NP(O_2C_{12}H_8)]_n$.[12a] We used the same type of direct reaction with binaphthol and produced the chiral poly(binaphthoxyphosphazene)s.[12b]

The above observations led us to investigate the direct reaction of the bifunctional *p*-aminophenol ($HOC_6H_4NH_2$) with chlorophosphazenes and Cs_2CO_3, and try to activate the OH group selectively with the aim of obtaining uncrosslinked poly(phosphazene)s with terminal -NH_2 groups

in one step. However, we found that the aminophenol reacts either through the OH or the NH_2 depending on the nature of the chlorophosphazenes and on the reaction conditions.

Results and Discussion

In order to obtain information about the reactivity of *p*-aminophenol ($HOC_6H_4NH_2$) towards chlorophosphazenes under various conditions, we first studied its reactions with two cyclic models: the unsubstituted hexachlorocyclotriphosphazene [$N_3P_3Cl_6$] and the partially substituted spirocyclic derivative bis(2,2′-dioxybiphenyl)dichlorocyclotriphosphazene [$N_3P_3Cl_2(O_2C_{12}H_8)_2$].[12a]

The reaction of $HOC_6H_4NH_2$ (6.1 equiv.) with [$N_3P_3Cl_6$] at room temperature in THF and using K_2CO_3 as a proton abstractor proceeded very slowly and exclusively through the NH_2 group. After 11 days the ^{31}P NMR spectrum of the THF solution showed the presence of two main products (Table 1), which, by comparison with known substituted cyclic aminophosphazenes,[13] could be identified as the geminally tetrasubstituted [$N_3P_3Cl_2(HNC_6H_4OH)_4$] and the hexasubstituted [$N_3P_3(HNC_6H_4OH)_6$] derivatives (for the related species [$N_3P_3(NHC_6H_4OMe)_6$] the value is δ = 6.4). No signals attributable to aryloxyphosphazenes were detected (the well-known [$N_3P_3(OC_6H_4NH_2)_6$] derivative[1d] has a singlet near δ = 11 in THF[5]).

Table 1. ^{31}P NMR spectroscopic data (δ) for the cyclic phosphazenes in THF solution; the data given are the center of the multiplets of the A_2 (pseudo doublet) and M (pseudo triplet) part of the A_2M spin systems, or the singlet of the A_3 spin systems

Derivative	A_2	M	A_3
[$N_3P_3Cl_2(HNC_6H_4OH)_4$]	2.1	23.6	
[$N_3P_3(HNC_6H_4OH)_6$]			5.5
[$N_3P_3Cl_2(O_2C_{12}H_8)_2$]	20.0	28.9	
[$N_3P_3Cl(NHC_6H_4OH)(O_2C_{12}H_8)_2$]	26.5	8.0	
[$N_3P_3(NHC_6H_4OH)_2(O_2C_{12}H_8)_2$]	28.3	2.4	
[$N_3P_3Cl(OC_6H_4NH_2)(O_2C_{12}H_8)_2$]	23.9[a]		
[$N_3P_3(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2$]	26.9	11.8[b]	

[a] This A_2B system shows a complex signal centered at δ = 23.9. In acetone it appears at δ = 24.8. [b] In acetone at δ = 27.5 and 12.6, and in [D_6]DMSO at δ = 26.7 and 12.0.

This conclusion was corroborated by the ^{13}C NMR spectrum (**a** in Figure 1) that showed the presence of free *p*-aminophenol and sharp peaks for the C_6H_4 group at δ = 152.5 (one carbon atom), 133.2 (one carbon atom), 121.1 (two carbon atoms), and 115.0 (two carbon atoms). As will be further discussed below, comparison of these data with those corresponding to various phenols and phosphazene derivatives (Table 2), unambiguously demonstrates that they correspond to aminophosphazenes and not to aryloxyphosphazenes.

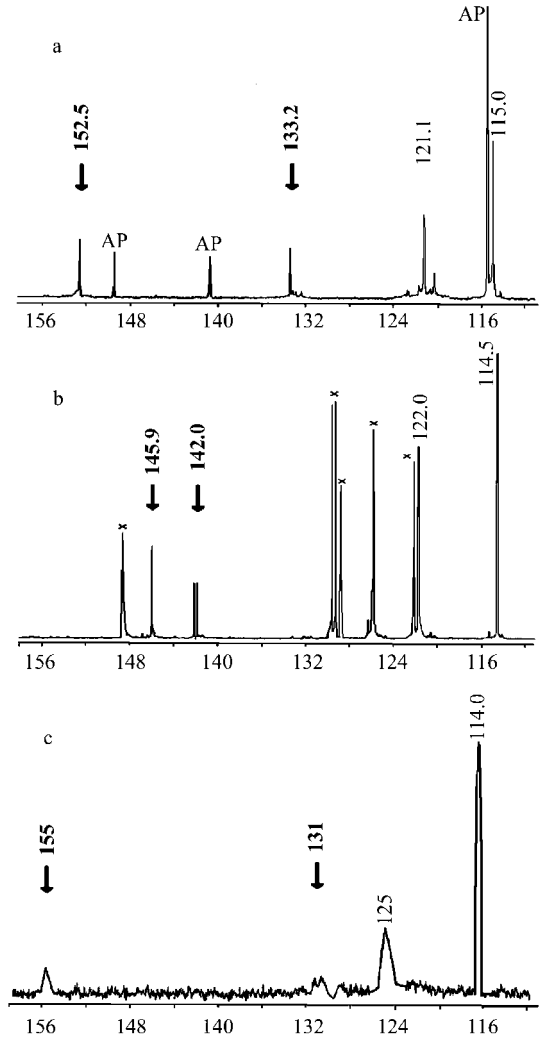

Figure 1. ^{13}C NMR spectra of: 1a) aminophosphazenes formed in the reaction between [$N_3P_3Cl_6$] and *p*-aminophenol in THF at room temperature with K_2CO_3 (AP = signals of the free *p*-aminophenol); 1b) [$NP(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2$] (**1**) in THF (*x* = peaks corresponding to the carbon atoms of the $O_2C_{12}H_8$ group); 1c) THF solution of polymer **2a** (*x* = 0.4)

The data in Table 2 show that when a *para*-disubstituted benzene derivative of the type H-B-C_6H_4-R reacts with a phosphazene P−Cl bond to form -NP-B-C_6H_4-R units, the chemical shift of the carbon bonded to B decreases by ca. 5 ppm, while that of the carbon bonded to R increases by ca. 3 ppm (tendencies consistent with the data for the molecules H-B-C_6H_4-R and those of their E-B-C_6H_4-R derivatives, where E is an electron-withdrawing group[17]). Therefore, starting from *p*-aminophenol $H_2NC_6H_4OH$, for which the weak carbon atom peaks appear (in THF) at δ = 149.2 (C bonded to the OH) and 140.5 (C bonded to the NH_2), the formation of $NP(NHC_6H_4$-OH) units should give two well-separated peaks close to δ = 153 and 135, in complete agreement with the two secondary carbon signals of the products mentioned above, while for the formation of $NP(OC_6H_4$-$NH_2)$ units two very close peaks near δ = 143 would have been expected.

Table 2. ^{13}C NMR chemical shifts of the ring carbon atoms corresponding to the HB-C_6H_4-R molecules and to the A-C_6H_4-B groups bonded to poly(phosphazene); all the spectra were recorded in $CDCl_3$ unless otherwise stated

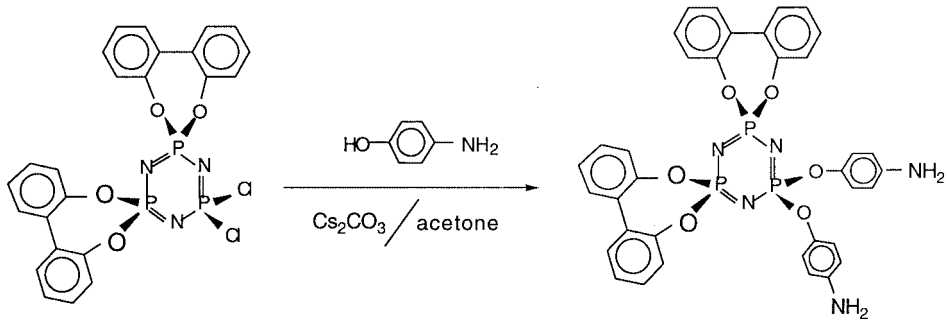
[a] Solvent not available. [b] [D_6]DMSO. as solvent. [c] J_{C-F} = 250 Hz. [d] 1-Methyl-2-pyrrolidinone (NMP) as solvent.

When carried out in refluxing acetone with Cs_2CO_3 as proton abstractor, the reaction of *p*-aminophenol with $[N_3P_3Cl_6]$ was much faster, although in this case both the NH_2 and the OH groups were activated. After one hour the ^{31}P NMR spectrum of the resulting solution showed very broad and complex signals, suggesting polymerized and crosslinked products, among which it was possible to detect some of the sharp peaks corresponding to the aminophosphazenes mentioned above, together with others closer to those expected for aryloxyphosphazenes.

The reaction of *p*-aminophenol (2.1 equivalents) with the dichlorophosphazene cyclic model $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ was also very dependent on the conditions but was much more selective. In THF at room temperature with K_2CO_3, therefore, the process was very slow and occurred selectively, but not exclusively, through the NH_2 group. After 20 days the ^{31}P NMR spectrum showed, in addition to the starting dichlorophosphazene (ca. 14 mol %), the presence of a mixture of $[N_3P_3Cl(NHC_6H_4OH)(O_2C_{12}H_8)_2]$ (65%), $[N_3P_3(NHC_6H_4OH)_2(O_2C_{12}H_8)_2]$ (12%), $[N_3P_3Cl(OC_6H_4NH_2)(O_2C_{12}H_8)_2]$ (5%), and another very weak A_2M spin system with the pseudo-triplet at δ = 13.1 and the pseudo-doublet at δ = 26.4, which could be attributed to the mixed species $[N_3P_3(NHC_6H_4OH)(OC_6H_4NH_2)(O_2C_{12}H_8)_2]$ (1%). The known compound[9] $[N_3P_3(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2]$ (**1**) was not present (see below).

Again, this result was supported by the ^{13}C NMR spectrum of the THF solution, which, in addition to the signals of free aminophenol and those for the $O_2C_{12}H_8$ groups, showed the two expected sharp peaks at δ = 152.4 and 133.3 indicative of the $NP(NHC_6H_4OH)$ units, and two other much weaker signals at δ = 145.5 and 142.3 (doublet) corresponding to the aryloxyphosphazene derivatives.

In contrast, the reaction of *p*-aminophenol with $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ in refluxing acetone and using Cs_2CO_3 as proton abstractor gave first the aryloxyphosphazene intermediate $[N_3P_3Cl(OC_6H_4NH_2)(O_2C_{12}H_8)_2]$ (see Table 1), and finally the known bis(*p*-aminophenoxy)-containing compound $[N_3P_3(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2]$ (**1**) (Scheme 1), which was isolated in good yield. This compound had been obtained previously by hydrogenation of the $-OC_6H_4NO_2$ derivative.[9] No products from the reac-



1

Scheme 1

tion between the P−Cl bonds and the NH_2 groups were observed.

As expected, the ^{13}C NMR spectrum of the *p*-hydroxyaminophosphazene[9](**1**) in THF (see **b** in Figure 1), showed signals for the weak carbon atoms of the C_6H_4 groups at $\delta = 145.9$ and 142.0 (doublet with $J_{P,C} = 7.3$ Hz) (see the Exp. Sect. for NMR spectroscopic data in [D$_6$]DMSO). These data confirmed all the conclusions outlined above and also showed that ^{13}C NMR spectroscopic data are very useful in distinguishing between NP-NHC_6H_4-OH and NP-OC_6H_4-NH_2 units.

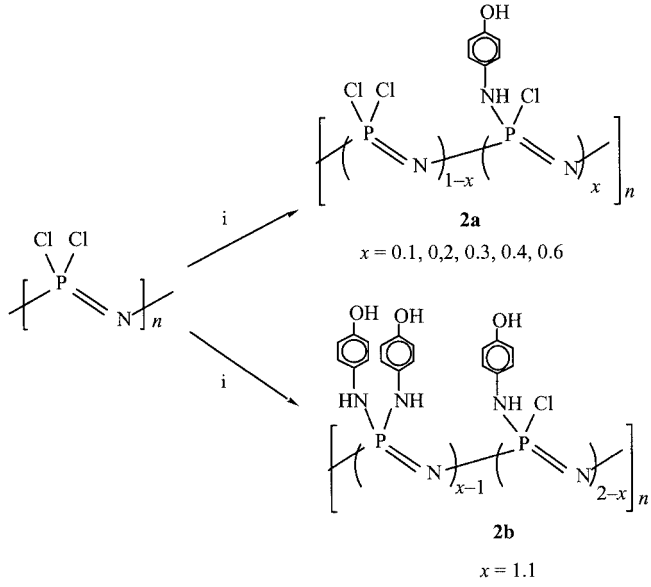
The selectivity of the reactions of *p*-aminophenol with $[N_3P_3Cl_6]$ and $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ under the different conditions used in this work is totally consistent with the experimental knowledge accumulated from the substitution of chlorine atoms in chlorophosphazenes by phenols and amines.

We have established[11] that in refluxing acetone and in the presence of cesium carbonate the reactions of the phenols RC_6H_4OH with chlorocyclophosphazenes are very fast. With K_2CO_3 as proton abstractor they are slower, and in THF as solvent are much slower. Logically, at room temperature they are much slower than at reflux. Also, the phenols where R is an electron-donating group react more slowly. Therefore, in the case of *p*-aminophenol the reactions through the phenolic OH group should be extremely slow in THF at room temperature with K_2CO_3, but much faster in refluxing acetone and with Cs_2CO_3.

The reactions through the NH_2 group are also dependent on the temperature, although they are more affected by steric factors, less sensitive to the solvent and, as expected, they are almost independent of the alkaline carbonate used as proton abstractor. Consistently, the reaction with $[N_3P_3Cl_6]$ in THF at room temperature with K_2CO_3 occurs only through the NH_2 group, i.e., the aminophosphazenes are the expected kinetic products. In refluxing acetone with Cs_2CO_3 the OH becomes sufficiently activated and the *p*-aminophenol reacts through both groups leading to cyclomatrix products. The same effects operate in the case of the $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ derivative, although this compound is less reactive towards substitution than the $[N_3P_3Cl_6]$. Therefore, in THF at room temperature with K_2CO_3 a very slow reaction through the NH_2 group is the main process observed, whereas in refluxing acetone with Cs_2CO_3 the reaction through the OH group becomes sufficiently fast to give the aryloxyphosphazene derivatives exclusively (again under kinetic control).

The overall results from the reactivity of *p*-aminophenol with the cyclic models suggested to us the possibility of synthesizing high molecular weight poly(phosphazene)s with terminal *p*-hydroxyphenylamino or *p*-aminophenoxy groups in one step from *p*-aminophenol and poly(chlorophosphazene)s.

We observed that the reaction of $[NPCl_2]_n$ with x equivalents of $HOC_6H_4NH_2$ per $NPCl_2$ unit ($x < 1$), in THF at room temperature with $1.5x$ equivalents of K_2CO_3 (i in Scheme 2) occurred exclusively through the NH_2 groups, producing solutions of the random copolymers with composition $\{[NPCl_2]_{1-x}[NPCl(NHC_6H_4OH)]_x\}_n$ (**2a**) [$x = 0.1$, 0.2, 0.3, 0.4, 0.6]. Above $x = 1$ the copolymers had the formula $\{[NP(NHC_6H_4OH)_2]_{x-1}[NPCl(NHC_6H_4OH)]_{2-x}\}_n$ (**2b**) ($x > 1$), although, even when using a large excess of the *p*-aminophenol, it was not possible to reach substitution degrees higher than $x = 1.2$, as beyond that point the substitution process became very slow.



Scheme 2. i. nx $HOC_6H_4NH_2$ + K_2CO_3/THF, room temperature

The reaction was faster at reflux, but in this case gave insoluble materials, indicating the activation of the OH groups of the aminophenol and their concomitant crosslinking by reaction with the P−Cl bonds. Consistently, we observed that crosslinking could be favored by working with more concentrated solutions of the reactants, by using a large excess of the alkaline carbonate, or by using Cs_2CO_3 instead (as mentioned previously,[11] this reagent makes the reactions of phenols with chlorophosphazenes much faster). Moreover, solutions of the polymers **2a** are only moderately stable at room temperature, especially in the presence of carbonates, giving rise to gelatinous precipitates on standing for several days. We also checked that on carrying out the reaction in the absence of the K_2CO_3 only half the amount of *p*-aminophenol was incorporated into the polymers **2**, the other half reacting as a proton abstractor to give the ammonium salt.

The ^{31}P NMR spectra of THF solutions of the polymers **2** were consistent with their formulation. Thus, for example, for **2a** ($x = 0.4$) the spectrum (Figure 2) shows three signals: a sharp peak at $\delta = -17.4$, corresponding to the fraction of the $NPCl_2$ groups surrounded by two other $NPCl_2$ units and far from the $NPCl(NHC_6H_4OH)$ units, a very broad signal with a maximum at ca. $\delta = -25$, corresponding to the $NPCl_2$ groups surrounded by two $NPCl(NHC_6H_4OH)$ units; and a broad signal centered at ca. $\delta = -15$, due to the $NPCl(NHC_6H_4OH)$ units. For the other copolymers **2a** the spectra changed depending on the value of x. Thus, the

signal attributable to $NPCl(NHC_6H_4OH)$ varied from $\delta = -15$, when placed between two $NPCl_2$ groups, to $\delta = -7$ for those placed inside two other $[NPCl(NHC_6H_4OH)]$ units. Taking into account that the expected mechanism for the reaction of chlorophosphazenes with aromatic primary amines is non-geminal,[14,15] the fraction of $[NP(NHC_6H_4OH)_2]$ units can be considered negligibly small in **2a**. For **2b** ($x = 1.1$) the corresponding broad signal appeared at $\delta = -13$, in agreement with the reported value for similar bis-aminophosphazenes.[16]

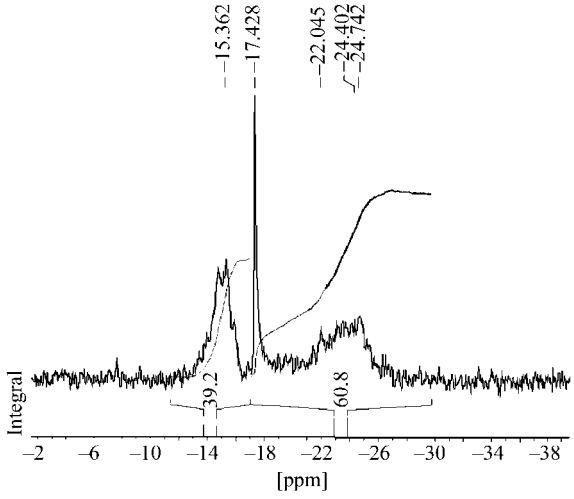


Figure 2. ^{31}P NMR spectrum of **2a** ($x = 0.4$) in THF (see text)

A very valuable proof of the nature of the polymers **2** came from the ^{13}C NMR spectra of the THF solutions (Figure 1c), which showed peaks at $\delta = 155$ (one carbon atom), 131 (one carbon atom), 125 (two carbon atoms) and 116 (two carbon atoms) for the C_6H_4 group, well in agreement with the expected values for NP-NHC_6H_4-OH units and not for NP-OC_6H_4-NH_2 units (see discussion above and Figure 1).

The formation of aminophosphazenes **2** instead of the aryloxyamino derivatives in the reactions of Scheme 2 was also supported by other chemical observations. We found that while the poly(dichlorophosphazene) reacts quickly at room temperature in THF with $NH_2C_6H_4OMe$ and K_2CO_3 to give very similar ^{31}P NMR spectra to those for **2** (the substitution was also incomplete), no reaction occurs with phenol HOC_6H_5 under the same conditions (only in the presence of cesium carbonate and refluxing for 40 hours is the totally substituted polymer obtained[11]). This demonstrates that under the conditions of Scheme 2, the *p*-aminophenol cannot react with $[NPCl_2]_n$ by the OH groups and, therefore, the products observed must be aminophosphazenes.

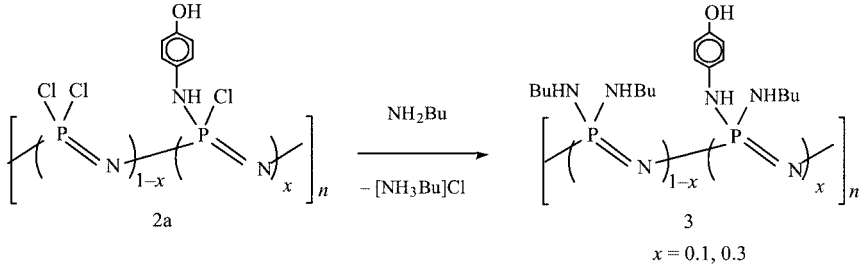
Attempts to use the polymers **2** as precursors for the synthesis of phosphazene copolymers possessing terminal OH groups by reacting them with *p*-substituted phenols (HOC_6H_4R) and cesium carbonate at room temperature were unsuccessful as the replacement of the chlorines by the corresponding phenoxy groups was far too slow to go to completion; heating at reflux led to insoluble products with residual chlorine contents close to 5% by weight.

As described in other cases,[18] however, the polymers **2a** could be stabilized by completing the chlorine substitution with *n*-butylamine (NH_2Bu) (see Scheme 3) to obtain the copolymers $\{[NP(NHBu)_2]_{1-x}[NP(NHBu)(NHC_6H_4OH)]_x\}_n$ (**3**) as stable solids. The chlorine content was very low (0.25%), confirming the complete substitution and ruling out the presence of quaternized ammoniun chlorides. The solubility decreased rapidly as x increased, and therefore polymers with $x > 0.3$ could not be prepared. Moreover, although soluble in THF when freshly prepared, their solubility decreases after some time in the solid state. Occasionally, the solid obtained after the first precipitation step in water (see Exp. Sect.) was sparingly soluble in THF. As the numbers of P−Cl bonds present in the substituted products is negligible, these effects may be attributed to the formation of a three-dimensional net of H-bonding interactions.

All the spectroscopic data for **3a** ($x = 0.3$; see Exp. Sect.) were in agreement with the proposed structure. Thus, the IR spectra showed, together with the expected phosphazene absorptions, a broad intense band centered at 3300 cm^{-1} due to all the -PNHR- units,[13,14,19] and two bands at 1515 and 827 cm^{-1} indicative of the *p*-disubstituted -C_6H_4- group. The latter are less intense in the polymers **3** with $x = 0.1$. The band of the terminal OH group was hidden under the broad absorption of the -PNH- group.

Significantly, as discussed above, the $^{13}CNMR$ spectrum showed, along with the peaks of the NPNHBu group,[18] signals at $\delta = 152.1$ and 136.5 as expected for the groups -$NPNHC_6H_4OH$, the intensity of which increased with x.

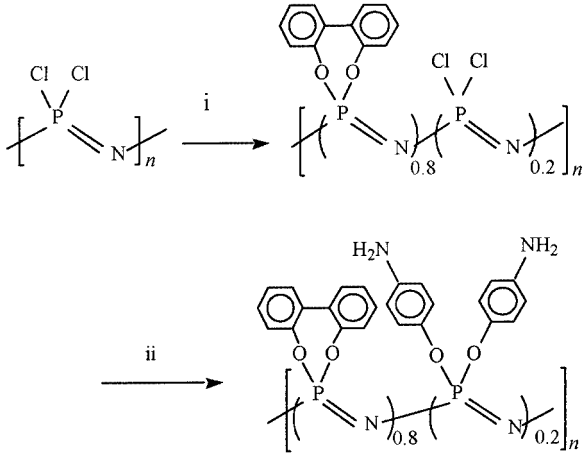
The molecular weight (M_w) of **3a** is of the order of 2×10^5, showing the expected degradation of the chains during reaction with the amine.[18] The thermogravimetric analysis



Scheme 3

(TGA) of **3** showed a decomposition beginning near 70 °C (see Exp. Sect.). This rather low thermal stability may be due, as in the case of other aminophosphazenes,[33] to the elimination of volatile amines. Surprisingly, no well-defined glass transition (T_g) was detected in the differential scanning calorimetry (DSC) curves from −100 °C to 150 °C.

In contrast to the case of $[NPCl_2]_n$, the partially substituted phosphazene copolymer $\{[NP(O_2C_{12}H_8)]_{0.8}[NPCl_2]_{0.2}\}_n$ [12] did not react with *p*-aminophenol at room temperature in the presence of K_2CO_3. Refluxing and the use of Cs_2CO_3 were necessary, although under those conditions, and in agreement with the cyclic models, the reaction occurred exclusively through the OH group to give the aryloxyphosphazene copolymer $\{[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_4NH_2)_2]_{0.2}\}_n$ (**4**) (Scheme 4). Long reflux times and various successive additions of aminophenol were, however, necessary to reach a product with chlorine contents below 0.1%. As a result, the M_w of **4** was only 2.5×10^5, and the yield was low (21%). Moreover, the polymers isolated from different experiments showed that the content of the $NP(OC_6H_4NH_2)_2$ units could be not be perfectly controlled, varying between 0.1 and 0.2, and that on reducing the reaction time with aminophenol the M_w of the products was higher, approaching 8×10^5.



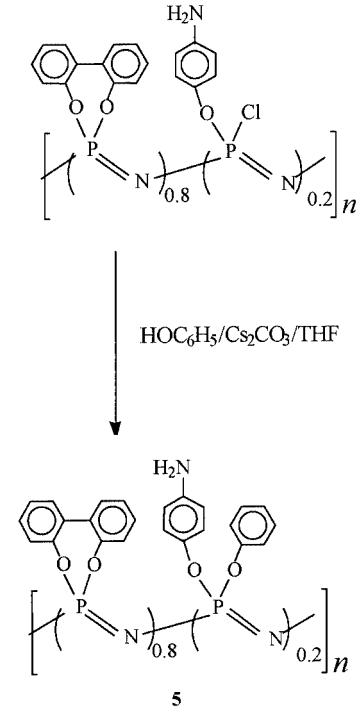
4

Scheme 4. i: HO-C_6H_4-C_6H_4-OH + K_2CO_3 in refluxing THF; ii: HO-C_6H_4-NH_2 + C_2CO_3 in refluxing THF

Clearly, prolonged refluxing in the presence of an excess of aminophenol caused extensive reduction of the chain length, which can be explained by taking into account that the aryloxides may be replaced by anilide ions in phosphazenes,[20] and that the poly(arylaminophosphazene)s are labile to nucleophilic cleavage.[21]

Our attempts to increase the $NP(OC_6H_4NH_2)_2$ units to 40% in the reaction of Scheme 4 resulted in the formation of brown insoluble materials with residual chlorine values of around 0.3% by weight. The known phosphazene polymers $\{[NP(OC_6H_5)_2]_{1-x}[NP(OC_6H_4NH_2)(OC_6H_5)]_x\}_n$ with $x = 0.3$ and 0.7, which have been prepared in high yields by reduction of a *p*-nitrophenoxy precursor,[5,6] are soluble.[5] Therefore, although the presence of the biphenoxy groups may reduce the solubility, it is likely that the insolubility of polymers of type **4** with more than 20% of $NP(OC_6H_4NH_2)_2$ units is due only to crosslinking side reactions during the second step of its synthesis.

These considerations led us to design the synthesis of the polymer $\{[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_5)(OC_6H_4NH_2)]_{0.2}\}_n$ (**5**), shown in Scheme 5, by first forming the intermediate $\{[NP(O_2C_{12}H_8)]_{0.8}[NPCl(OC_6H_4NH_2)]_{0.2}\}_n$ using the precise amount of aminophenol to avoid degradation, and then completing the substitution with HOC_6H_5. The product, isolated in 60% yield, contained only 0.14% residual chlorine and was a stable and soluble white polymer with an M_w of 9×10^5.



5

Scheme 5

All the analytical and spectroscopic properties of the polymers **4** and **5** were consistent with their proposed formulation (see Exp. Sect.). The IR spectra showed the two typical absorptions near 3450 and 3370 cm^{-1} (and another one at 1624 cm^{-1}) characteristic of the terminal NH_2 groups,[9] (also present in the cyclic model **1**) while no absorption for terminal OH was observed.

The ^{31}P NMR spectra showed a broad signal at around $\delta = -6$, characteristic of the skeletal phosphorus atoms of the $[NP(O_2C_{12}H_8)]$ units, which, as discussed elsewhere,[12] shows that the P atoms are part of a seven-membered ring, and a signal near $\delta = -19$ belonging to the $[NP(OC_6H_4NH_2)_2]$ or $[NP(OC_6H_5)(OC_6H_4NH_2)]$ units (for the known polymers $\{[NP(OC_6H_5)_2]_{1-x}[NP(OC_6H_4NH_2)_x]\}_n$, the chemical shift is $\delta = -19$[5,6]). The relative intensities of the two signals agreed well with the averaged formula of the copolymers, and no signals in the region of $\delta = -15$, corresponding to aminophosphazene units $[NP(NHC_6H_4OH)_2]$,[16] were observed.

The ^1H NMR spectra showed a broad signal near δ = 5, also present in the spectrum of **1**, that may be assigned to the NH_2 protons.[9] For the NH protons of the $[NP(NHC_6H_4R)_2]$ units the signal is expected at ca. δ = 3.[19]

The ^{13}C NMR spectrum showed broad peaks at δ = 145 and 142 (in $[D_6]$DMSO), which, as discussed above, correspond to aryloxyphosphazenes with pendant amino groups and not to aminophosphazenes with pendant OH groups. The weak broad signal at δ = 152 unambiguously corresponds to the phenoxy groups, and the intense one at δ = 148 to the abundant biphenoxy groups present in the chains.[12a]

The thermal stability of **4** and **5**, as measured by TGA, is only moderate. Thus, a slow decomposition begins at ca. 100 °C (**4**) or 50 °C (**5**); the residue left at 800 °C was of the order of 50% in both cases (see Exp. Sect.). As in the case of other aryloxyphosphazenes, the thermal decomposition occurs with elimination of volatile cyclic phosphazenes; other organic products also formed.

Because of the presence of dioxybiphenyl phosphazene units and polar NH_2 terminal groups it was expected that the polymers **4** and **5** should have high T_g values. In fact the DSC curves of both polymers showed very well-defined heat capacity steps with T_g = 155 °C for **4** and T_g = 140 °C for **5**.

Conclusion

Polymeric chlorophosphazenes may be selectively reacted in THF with substoichiometric amounts of *p*-aminophenol under kinetic control either at the OH or NH_2 groups, depending on the conditions. The reaction with poly(dichlorophosphazene) at room temperature and with K_2CO_3 occurs exclusively at the NH_2 group producing aminophosphazenes with terminal OH groups. However, if the available P−Cl bonds are not abundant, as is the case with partially substituted aryloxyphosphazene-chlorophosphazene copolymers, the process is very slow at room temperature, and on carrying out the reaction at reflux and in the presence of Cs_2CO_3 it occurs exclusively at the OH of the *p*-aminophenol, producing aryloxyphosphazenes with pendant NH_2 groups. These observations have led to the designed synthesis of phosphazene copolymers containing NHC_6H_4OH or $OC_6H_4NH_2$ groups directly from *p*-aminophenol.

Experimental Section

General Remarks: K_2CO_3 and Cs_2CO_3 were dried at 140 °C prior to use. Acetone was distilled from anhydrous $CaSO_4$. THF was treated with KOH and distilled twice from Na in the presence of benzophenone. Petroleum ether refers to that fraction with a boiling point in the range 60−65 °C. The diphenol $HOC_6H_4C_6H_4OH$ and *p*-aminophenol $NH_2C_6H_4OH$ were used as purchased (Aldrich). Butylamine was distilled from CaH_2. Hexachlorocyclotriphosphazene $[N_3P_3Cl_6]$ (Fluka) was purified from hot petroleum ether and dried under vacuum. The cyclic phosphazene $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ was prepared as described elsewhere.[12a] The starting polymer $[NPCl_2]_n$ was prepared as described by Magill et al.[22] All the reactions were carried out under dry nitrogen.

The IR spectra were recorded with a Perkin−Elmer Paragon 1000 spectrometer. NMR spectra were recorded on Bruker AC-200 and AC-300 instruments. ^1H and $^{13}C\{^1H\}$ NMR are given in δ relative to TMS. $^{31}P\{^1H\}$ NMR are given in δ relative to external 85% aqueous H_3PO_4. Coupling constants are in Hz. C, H and N analyses were performed with a Perkin−Elmer 240 microanalyzer. Cl analyses were performed by Galbraith laboratories. Unless stated otherwise, the analytical data given for the cyclic phosphazenes correspond to the isolated reaction products without purification. GPC were measured with a Perkin−Elmer apparatus equipped with a model LC 250 pump, a model LC 290 UV, and a model LC 30 refractive index detector. The samples were eluted with a 0.1wt.-% solution of tetra-*n*-butylammonium bromide in THF through Perkin−Elmer PLGel (Guard, 10^5, 10^4 and 10^3 Å) at 30 °C. Approximate molecular weight calibration was obtained using polystyrene standards having narrow molecular weight distributions. T_g values were measured with a Mettler DSC 300 equipped with a TA 1100 computer. TGA were performed on a Mettler TA 4000 instrument. The polymer samples were heated at a rate of 10 °C/min from ambient temperature to 800 °C under a constant flow of nitrogen.

$[N_3P_3(OC_6H_4NH_2)_2(O_2C_{12}H_8)_2]$ (1): $NH_2C_6H_4OH$ (0.33 g, 3.02 mmol) and Cs_2CO_3 (1.59 g, 4.88 mmol) were added to a solution of $[N_3P_3Cl_2(O_2C_{12}H_8)_2]$ (0.7 g, 1.22 mmol) in acetone (40 mL) and the mixture was refluxed with stirring for 19 hours to give a brown mixture. The volatile components were evaporated to dryness and the residue was washed successively with 0.5 M aqueous NaOH (3 × 50 mL) and water (2 × 50 mL). The residue was then dissolved in acetone, dried with solid anhydrous Na_2SO_4, filtered, and the solvents evaporated. The pale brown solid was washed with hexane (2 × 40 mL) and dried under vacuum. Yield: 0.78 g (88.9%). $C_{36}H_{28}N_5O_6P_3$ (719.56): calcd. C 60.1, H 3.92, N 9.73; found C 59.4, H 3.95, N 9.15. IR (KBr): $\tilde{\nu}$ = 3437 w, 3341 w (NH_2), 1625 (NH_2), 1230 s, 1173 vs (N=P), 1271 m, 1093 m (POC) cm^{-1}. $^{31}P\{^1H\}$ NMR ($[D_6]$DMSO): δ = 12.02 $[(POC_6H_4NH_2)_2]$, 26.7 [A_2M system, J_{AM} = 90 Hz, $P(O_2C_{12}H_8)$]. ^1H NMR ($[D_6]$DMSO): δ = 7.65 (d, *J* = 7.5, 4 H), 7.51 (dd, *J* = 7.4, 4 H), 7.42 (dd, *J* = 7.5, 4 H), 7.16 (d, *J* = 7.9, 4 H) ($O_2C_{12}H_8$), 6.96 (d, 4 H), 6.63 (d, *J* = 8, 4 H, OC_6H_4-N), 5.10 (br. s, NH_2). $^{13}C\{^1H\}$ NMR ($[D_6]$DMSO): δ = 147.2 (t), 130.1, 129.7, 127.9, 126.4, 121.6 ($O_2C_{12}H_8$), 146.4, 140.1 (d, $J_{P,C}$ = 7.3), 121.1 (d, $J_{P,C}$ = 4.1), 114.2 ($OC_6H_4NH_2$).

THF Solutions of $\{[NPCl_2]_{1-x}[NPCl(NHC_6H_4OH)]_x\}_n$ (2a) ($x < 1$), $\{[NP(NHC_6H_4OH)_2]_{x-1}[NPCl(NHC_6H_4OH)]_{2-x}\}_n$ (2b) ($x > 1$): $NH_2C_6H_4OH$ (0.94*x* g, 8.6*x* mmol) and K_2CO_3 (1.78*x* g, 12.9*x* mmol) were added to a solution of $[NPCl_2]_n$ (1 g, 8.6 mmol) in THF (200 mL) and the mixture was mechanically stirred for 10 hours ($x < 1$) or 40 hours ($x > 1$) at room temperature.

The ^{31}P NMR spectrum of the solutions of **2a** showed two groups of signals having maxima that depended on *x*, one in the region of δ = −25 to −17 ($NPCl_2$) and the other in the range δ = −15 to −7 [$NPCl(NHC_6H_4OH)$] with relative intensities (1 − *x*):*x*. For **2b** (x = 1.1) the ^{31}P NMR spectra showed a broad signal at δ = −13 attributable to $[NP(NHC_6H_4OH)_2]$ besides the [$NPCl(NHC_6H_4OH)$] signal at δ = −7.

The ^{13}C NMR of the solutions showed peaks at δ = 155, 131, 125 and 116.

The solutions were unstable on standing for several days, especially if heated, giving rise to a gelatinous precipitate.

$\{[NP(NHBu)_2]_{0.7}[NP(NHBu)(NHC_6H_4OH)]_{0.3}\}_n$ (3a): $NH_2C_6H_4OH$ (0.40 g, 3.66 mmol) and K_2CO_3 (0.60 g, 4.34 mmol) were added to a solution of $[NPCl_2]_n$ (1.40 g, 12.1 mmol) in THF (150 mL), and the mixture was stirred mechanically for 18 hours at room temperature. NH_2Bu (24.4 mL, 18.06 g, 246.9 mmol) was then added at 0 °C, the mixture stirred at this temperature for 30 minutes, and then for another 125 hours at room temperature. After adding 150 mL of THF, the mixture was filtered through celite, concentrated, and added to 1.5 L of water. The resulting fibrous, pink precipitate was washed with water (2 × 1.5 L) and the solid was dried overnight in a desiccator containing P_2O_5 at reduced pressure. The product was dissolved in THF (400 mL) and filtered through activated carbon to eliminate the pink color. The resulting solution was concentrated and added to hexane (1.5 L). The final solid was filtered and dried under vacuum at room temperature for two days. Yield: 1.42 g (59%). $C_{8.6}H_{18.8}N_3O_{0.3}P$ (200.03): calcd. C 51.6, H 9.47, N 21.0; found C 49.7, H 8.82, N 20.3. Chlorine content 0.25%. IR (KBr): $\tilde{\nu}$ = 3334 s, br., (NH), 1515 s, 827 s, (*p*-C6H4-), 1256 s, 1209 vs (N=P), 1118, 1093 m (PNC) cm^{-1}. $^{31}P\{^1H\}$ NMR ([D$_8$]THF): δ = 4.5 [NP(NHBu)$_2$], −3.7 [br. m, NP(NHC$_6$H$_4$OH)(NHBu)]. ^1H NMR ([D$_8$]THF): δ = 7.5 (OH), 7.16, 6.65 (br. m, C$_6$H$_4$), 3.01 (CH$_2$-NH), 2.67 (NH), 1.5 (br. m, -CH$_2$CH$_2$-), 1.05 (br. m, CH$_3$-). $^{13}C\{^1H\}$ NMR ([D$_8$]THF): δ = 152.1, 136.5, 120.0 (2 C), 116.1 (2 C), (C$_6$H$_4$), 41.5, 34.6, 20.8, 14.4 (NHBu). M_w (GPC): 230 000, M_w/M_n = 3.7. TGA: Continuous weight loss from 70 °C, with two fast stages at 220 °C (−32%) and 640 °C (−58%). Final residue at 800 °C: 2.2%.

Other polymers $\{[NP(NHBu)_2]_{1-x}[NP(NHBu)(NHC_6H_4OH)]_x\}_n$ with x between 0.1 and 0.3 were prepared similarly using $NH_2C_6H_4OH$ (1.32x g, 12.1x mmol), K_2CO_3 (2.0x g, 14.5x mmol) and NH_2Bu (273x mL, 202x g., x mmol). The yield was of the order of 50%. The compounds were sometimes slightly pink and lost their solubility on standing. On occasions the solid obtained from the first precipitation in water was only sparingly soluble. In all cases, the chlorine contents were of the order of 0.26% and the M_w (GPC) of ca. 500 000.

$[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_4NH_2)_2]_{0.2}\}_n$ (4): 2,2′-Biphenol (2.39 g, 12.84 mmol) and K_2CO_3 (7.1 g, 51.37 mmol) were added to a solution of $[NPCl_2]_n$ (1.86 g, 16.05 mmol) in THF (200 mL), and the mixture was refluxed with mechanical stirring for 24 hours. $NH_2C_6H_4OH$ (1.4 g, 12.83 mmol) and Cs_2CO_3 (4.18 g, 12.83 mmol) were then added and the refluxing was continued for 24 hours (t_1). More *p*-aminophenol (1.4 g, 12.83 mmol) was added to the resulting mixture and refluxing was further continued for 24 hours (t_2). Following the same procedure as above, the polymer **4** was isolated as a pale brown solid that was dried for three days under vacuum at 20 °C. Yield: 0.8 g (21%). $C_{12}H_{8.8}N_{1.4}O_2P$ (235.58): calcd. C 61.2, H 3.76, N 8.32; found C 61.1, H 3.45, N 7.71. Chlorine content 0.08%. IR (KBr): $\tilde{\nu}$ = 3440 w, 3372 w (NH_2), 1624 w (NH_2), 1247 s, 1194 vs (N=P), 1272 m, 1096 m (POC) cm^{-1}. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −5.9 [br. m, P(O$_2$C$_{12}$H$_8$)], −19.4 (br. m, P-OC$_6$H$_4$-). ^1H NMR ($CDCl_3$): δ = 7.4−6.6 (br. m, aromatic rings), 6.2 (NH_2). $^{13}C\{^1H\}$ NMR ([D$_6$]DMSO): δ = 148, 129, 128, 125, 122 (O$_2$C$_{12}$H$_8$), 145, 142, 121, 114 (OC$_6$H$_4$NH$_2$) (all broad). M_w (GPC): 250 000, M_w/M_n = 3.2. T_g (DSC) = 155 °C. ΔC_p = 0.30 J[gK]$^{-1}$. TGA: Decomposition begins at 100 °C (−3.5%). It is fast at 300 °C (−14%) and very fast at 400 °C. Final residue at 800 °C: 53%.

The same experimental procedure, but with t_1 = 48 h and t_2 = 30 h, gave a more soluble polymer in 43% yield as a pale brown solid having the formula $[NP(O_2C_{12}H_8)]_{0.9}[NP(OC_6H_4NH_2)_2]_{0.1}\}_n$. $C_{12}H_{8.4}N_{1.2}O_2P$ (232.37): calcd. C 62.0, H 3.64, N 7.2; found C 62.5, H 3.59, N 6.91. Chlorine content 0.05%. M_w (GPC): 800.000, M_w/M_n = 4.2. T_g (DSC) = 155 °C, ΔC_p = 0.26 J[gK]$^{-1}$.

$[NP(O_2C_{12}H_8)]_{0.8}[NP(OC_6H_5)(OC_6H_4NH_2)]_{0.2}\}_n$ (5): 2,2′-biphenol (1.95 g, 10.47 mmol) and K_2CO_3 (5.8 g, 42.0 mmol) were added to a solution of $[NPCl_2]_n$ (1.52 g, 13.1 mmol) in THF (200 mL), and the mixture was refluxed with mechanical stirring for 25 hours. $NH_2C_6H_4OH$ (0.81 g, 7.46 mmol) and Cs_2CO_3 (2.43 g, 7.46 mmol) were then added and the refluxing was continued for another 40 hours. HOC_6H_5 (0.5 g, 5.31 mmol) and more Cs_2CO_3 (1.73 g, 5.31 mmol) were added to the mixture, and refluxing was continued for a further 23 h. Following the same procedure as above, the polymer **5** was isolated as a white solid that was dried for three days under vacuum at 20 °C. Yield: 1.9 g (62%). $C_{12}H_{8.6}N_{1.2}O_2P$ (232.57): calcd. C 62.0, H 3.73, N 7.23; found C 61.8, H 3.92, N 7.43. Chlorine content 0.14%. IR (KBr): $\tilde{\nu}$ = 3451 w, 3374 w (NH_2), 1624 (NH_2), 1247 s, 1193 vs (N=P), 1272 m, 1096 m (POC) cm^{-1}. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −5.9 [br. m, P(O$_2$C$_{12}$H$_8$)], −20.0 (br. m, P-OC$_6$H$_4$-). ^1H NMR ($CDCl_3$): δ = 7.4−6.6 (br. m, aromatic rings), 6.2 (NH_2). $^{13}C\{^1H\}$ NMR ([D$_6$]DMSO): δ = 148, 129, 128, 125, 122 (O$_2$C$_{12}$H$_8$), 152, 120 (OC$_6$H$_5$), 145, 142, 121, 114 (OC$_6$H$_4$NH$_2$) (all broad). M_w (GPC): 900 000. M_w/M_n = 4.3. T_g (DSC) = 140 °C. ΔC_p = 0.28 J[gK]$^{-1}$. TGA: Decomposition begins at 40 °C and is continuous, gets faster at 125 °C and at 350 °C is very fast. Residue at 800 °C: 49%.

Synthesis, X-ray Structures, NMR Studies and Density Functional Calculations of (η^2-Fumarodinitrile)palladium(0) Complexes Containing Dihydro(phosphanylphenyl)oxazole Ligands

Margareta Zehnder,*[a] Markus Neuburger,[a] Silvia Schaffner,[a] Martin Jufer,[b] and Dietmar A. Plattner*[b]

Keywords: Palladium / N,P ligands / Oxazolines / Alkene ligands / Density functional calculations

The (fumarodinitrile)palladium(0) complexes **4a**–**4d** with various 4-substituted 2-[2′-(diphenylphosphanyl)phenyl]-4,5-dihydrooxazole ligands **1a**–**1d** have been prepared and characterized. NMR spectroscopic investigations give evidence that the complexes exist in two forms in solution. The diastereomeric ratio is highly dependent on the 4-substituent at the oxazoline moiety. Substituents reaching into the fumarodinitrile area (**4a** and **4d**) favor one diastereoisomer. Less intrusive substituents (**4b** and **4c**) lead to a diastereomeric ratio of about 1:1. X-ray structures reveal that only one isomer is found in the crystalline solid state. For **4a** and **4d** it is the same as the major diastereoisomer in solution. The orientation of the fumarodinitrile ligand of **4b** is opposite to that of **4a** and **4d**. In all complexes, the fumarodinitrile ligand is not planar. The C–CN and C–H bonds are bent away from the palladium atom. The NC–C=C–CN torsion angle is about 150°. DFT/B3LYP calculations confirm the structural features found in the solid-state structures. For an accurate description of the coordination sphere, extended basis sets for the palladium and phosphorus atoms must be employed. The energetic difference computed for the two diastereoisomers of **4a** reflect the ratios in solution as observed by NMR spectroscopy.

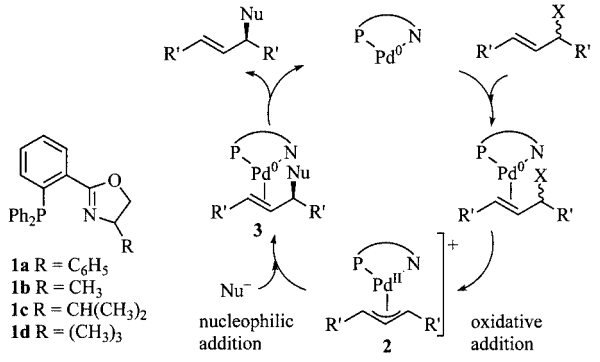
Introduction

Pd-catalyzed enantioselective C−C and C−N bond-forming substitutions at allylic positions are an important and ever growing area of research.[1] In particular palladium complexes with chiral, bidentate mixed donor ligands have proven to be highly effective catalysts for this kind of reaction.[2] By applying chiral ligands of the dihydro(phosphanylaryl)oxazole type (**1**; Scheme 1), selectivities in the bond-forming reaction of up to 99% *ee* can be induced using allylic systems with bulky terminal substituents (R′ = Ph, *i*Pr).[3] However, selectivities are lowered when (*n*-alkyl)allyl substrates are used,[4] thus demanding a re-evaluation of the actual catalytic reaction mechanism.



Scheme 1. Catalytic cycle of the allylic substitution reaction

The structural investigation of crucial reaction intermediates in the catalytic cycle is a prerequisite for mechanistic research. Cationic [Pd^{II}(η^3-allyl)(phosphanyloxazoline)] complexes **2** are generally assumed to be such reaction intermediates. Early studies were based on the assumption that the stereodetermining step in the allylic substitution would proceed by an early transition step, thus focusing mainly on the characterization of the cationic (η^3-allyl)palladium(II) species.[5−7] Later research, however, suggested a transition state occurring further along the reaction coordinate.[8] Therefore, the structure and reactivity of the Pd^0(olefin) complex formed by attack of the nucleophile at the allylic complex have to be addressed in order to establish a model that could account for the observed selectivities. Due to their instability, the actual (η^2-olefin)palladium(0) complexes **3** have not been accessible by X-ray analysis as yet.

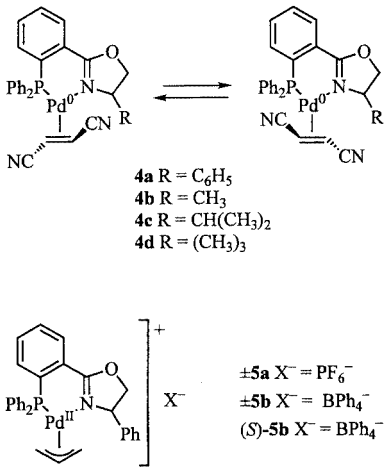
Recently, structural information has been derived from extended NMR spectroscopic experiments.[9] X-ray structures of zero-valent palladium complexes with bidentate ligands and (*E*)-alkenes are restricted to those bearing electron-deficient olefins as dibenzylideneacetone (dba),[10] fumarodinitrile (fdn), and dimethylfumarate (dmfu).[11]

It is known that Pd^0(olefin) complexes can be involved in dynamic processes.[12] Asymmetric N,P ligands give rise to 2 isomers with symmetric substituted olefins and 4 isomers with asymmetric substituted olefinic groups. Interchanging processes by olefin rotation and a dissociation/reassociation process are assumed.[10–12] In this contribution, we report a combined NMR spectroscopic, X-ray crystallographic, and theoretical study of the structures of [Pd^0(η^2-fdn)(**1**)] complexes **4a**–**4d**, as models of the crucial intermediates in the Pd-catalyzed allylic substitution reaction (Scheme 2). To obtain more information about the characteristics of the [metal(phosphanyloxazoline)] moiety the crystal structures of [Pd^{II}(η^3-allyl)(**1a**)] cations **5** and of [Zn(**1a**)Cl_2] (**6**) were included for comparison.[7]

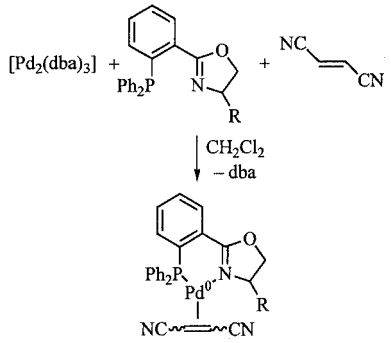


Scheme 2

Results and Discussion

Syntheses

The syntheses of the [Pd(fdn)(**1**)] complexes were performed by addition of the phosphanyloxazoline **1** to a $Pd_2(dba)_3$·$CHCl_3$ solution followed by addition of the fumarodinitrile (Scheme 3). Purification by column chromatography afforded **4** in moderate to good yield (60–90%). The compounds are of considerable stability. In solution they may be stored for several days without appreciable decomposition.



Scheme 3

NMR Spectroscopy

At room temperature, the complexes **4** exist in solution as a mixture of two diastereoisomers. The isomers differ in the orientation of the alkene with respect to the oxazoline substituent. The diastereomeric ratio is significantly dependent on the substituent at the 4-position of the oxazoline ring. In the phenyl (**4a**) and *tert*-butyl (**4d**) derivatives containing bulky oxazoline substituents reaching into the alkene area one isomer is favored. The diastereomeric ratio of the methyl and isopropyl derivatives **4b** and **4c** with less intrusive oxazoline substituents is about 1:1.

For an interconversion from isomer **M** to isomer **m**, a ligand dissociation/reassociation reaction is required. The equilibration process can be monitored by NMR spectroscopy: When the pure crystalline solid is dissolved in $CDCl_3$, only the signals of the solid-state isomer can be detected at first. Upon standing the second isomer arises until the equilibrium is reached within 2 h. As the crystal structures of **4a**, **4b**, and **4d** are known (see below), an unambiguous assignment of the signals to the two isomers was possible. In every case, the major diastereoisomer is found in the solid state.

The signals of the alkene protons demonstrate a high-field shift with respect to the free ligand (Table 1). They are assigned according to their $^3J_{H,P}$ coupling constants; $^3J_{H,P}$ is larger for a *trans* than for a *cis* coupling. The double doublet of the alkene proton *cis* to P ($J_{H,P} \approx 3$ Hz) appears at a lower field than the pseudotriplet of the alkene proton *trans* to P ($J_{H,H} \approx J_{H,P} \approx 10$ Hz) does.

Table 1. Selected NMR spectroscopic data: δ in ppm ($J_{H,H}$, $J_{H,P}$ in Hz)

		H–C_{cisP}	H–C_{transP}	P{H}
4a	80%	3.02 (9.4, 3.2)	1.89 (9.7)	18.93
	20%	3.00 ([a], 3.2)	2.43 (9.8)	19.36
4b	52%	3.22 (9.3, 3.0)	2.73 (9.7)	20.13
	48%	3.16 (9.3, 3.3)	2.81 (9.5)	19.56
4c	52%	3.15 (9.3, 3.3)	2.75 (9.5)	19.30
	48%	3.21 (9.6, 2.9)	2.71 (10.0)	19.48
4d	75%	3.20 (9.3, 3.3)	2.61 (9.3)	20.50
	25%	3.24 (9.8, 2.5)	2.72 (10.0)	19.73

[a] Signal overlap.

In **4a** the signal of the alkene proton *cis* to the oxazoline moiety of the major diastereoisomer is shifted to a higher field with respect to the corresponding signal of the minor isomer. The high-field shift is due to the aromatic shielding effect of the oxazoline substituent. This confirms the assignment of the major isomer to diastereoisomer **M**.

Crystal Structures

X-ray analyses of **4a**, ±**4b**, (*S*)-**4b**, and **4d** were carried out. Selected geometric parameters are reported in Table 2. Views are given in Figures 1, 2, 3, and 4. The methyl derivatives ±**4b** and (*S*)-**4b** differ solely in the chirality; in ±**4b** the racemic and in (*S*)-**4b** the enantiomerically pure phosphanyloxazoline was applied.

Table 2. Selected bond lengths [Å], bond angles [°] and torsion angles [°] for **4a**, ±**4b**, (*S*)-**4b**, and **4d**; comparison with the calculated structures **M4** and **m4**

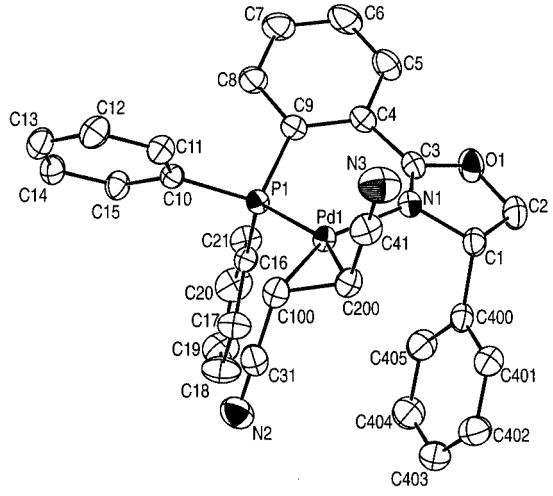

Figure 1. Molecular structure of **4a** with the atom numbering scheme

The alkene ligand of **4a** and **4d** adopts the orientation, which is considered to be sterically favored; the nitrile group *cis* to the dihydrooxazole moiety is on the opposite side of the coordination plane with respect to the oxazoline substituent. The alkene ligand in ±**4b** and (*S*)-**4b** is reversely orientated.

Except for the orientation of the fumarodinitrile the complexes demonstrate a close similarity. The coordination geometry is trigonal. The C=C bond of the fumarodinitrile

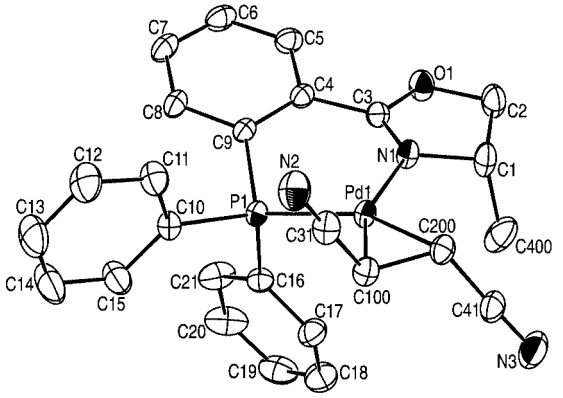

Figure 2. Molecular structure of ±**4b** with the atom numbering scheme

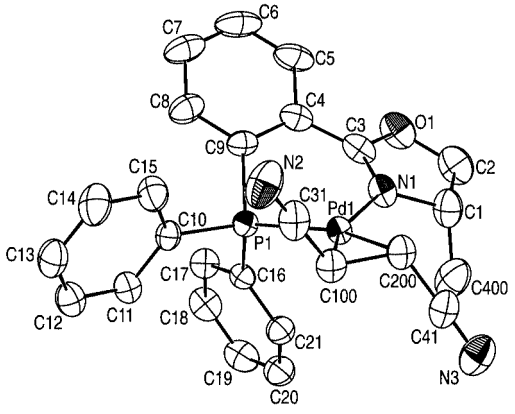

Figure 3. Molecular structure of (*S*)-**4b** with the atom numbering scheme

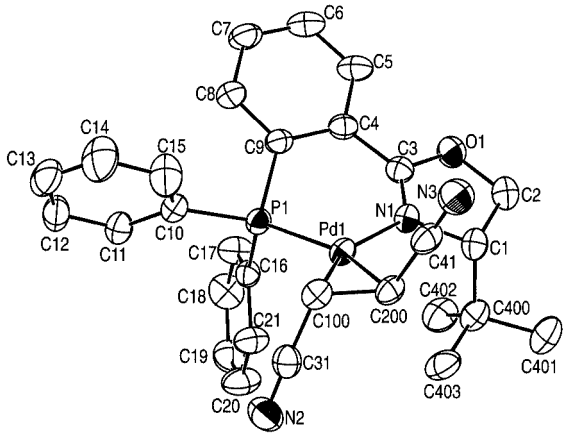

Figure 4. Molecular structure of **4d** with the atom numbering scheme

ligand is positioned approximately in the N/Pd/P coordination plane. Bond lengths and angles of the coordination sphere are in the same range for all compounds independent of the oxazoline substituent and the orientation of the alkene ligand. Due to the *trans* influence of the phosphorus atom the Pd−C distance *trans* to the phosphorus atom is longer than that *trans* to the nitrogen atom.

The fumarodinitrile ligand is not planar. The C−CN and C−H bonds are bent away from the palladium atom. The NC−C=C−CN torsion angle is about 150°. The average value of the C=C bond of 1.44 Å is significantly longer than that for the free olefin (1.36 Å). Both the deviation of the planarity and the elongation of the olefin bond provide evidence of a partial sp^3 hybridization of the olefinic carbon atoms.

The phosphanyloxazoline ligand adopts the characteristic conformation, which, so far, has been found in all coordinated phosphanyloxazolines of type **1**. Due to the nonplanarity of the chelate ring one *P*-phenyl group adopts a pseudoaxial and the other a pseudoequatorial position. The oxazoline substituent is axially positioned and lies on the same side of the coordination plane as the axial *P*-phenyl ring. Although the general features of the ligand conformation are similar, a superposition of the N/Pd/P coordination plane of the X-ray structures shows some variability of the puckering of the six-membered chelate ring (Figure 5). Independently of the conformation of the chelate ring the chiral center adopts a rather rigid position with respect to the N/Pd/P plane expressed in a nearly constant P−Pd−N−C(1) torsion angle of −150° for the ligand with (*S*) configuration.

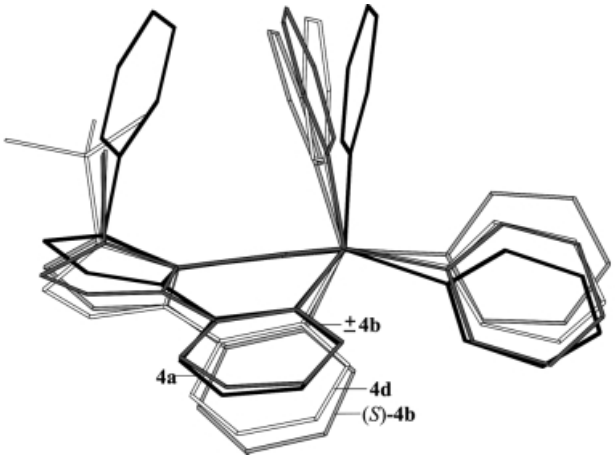

Figure 5. Superposition of the [Pd(**1**)] moiety of complexes **4a**, ±**4b**, (*S*)-**4b**, and **4d**; the N/Pd/P plane is perpendicular to the paper plane

DFT Calculations

Allylpalladium complexes have been the subject of numerous theoretical studies.[13] In contrast, much less computational effort has been directed at (olefin)palladium(0) complexes. Most (olefin)palladium(0) complexes computed so far are product complexes of nucleophilic attack at very simple allylpalladium model complexes and therefore lack any real-world counterpart.[14] Generally, systematic comparisons between computed geometries and experimental structural data of (olefin)palladium(0) complexes are missing, mainly due to the scarcity of available crystallographic data. For a meaningful description of the complete hypersurface of the reaction, starting from an allylpalladium complex and going to the olefin product complex via the transition state of a nucleophilic attack, a computational method should also be able to reproduce the geometrical features of the (olefin)palladium(0) species. With the X-ray crystallographic data at hand, we are now in a position to address this task.

In this work, the (fumarodinitrile)palladium(0) complex **4a** was computed as the complete chemical system (as **M4**) in order to account for all steric and electronic factors of the chiral ligand. The crystal structure of **4a** served as a starting point and reference for the geometry optimization. The electronic ground state of the complex was assumed to be a singlet, following theoretical work of Blomberg et al.[15] The LANL2DZ level was chosen as a starting point in our calculations in order to obtain a more or less accurate description of the geometry of the coordination sphere.[16] With regard to the overall conformation of the molecule, the LANL2DZ-optimized structure showed a qualitatively good agreement with the structure found in the solid state. The calculated distances between the olefinic carbon atoms and the metal center as well as the length of the olefinic carbon−carbon bond were in good agreement with the crystallographic data, as were all calculated bonds between C, H, N, and O atoms (differences < 3 pm). The LANL2DZ level failed mainly in the description of the Pd−P bond. The bond length exceeded the experimental one by more than 14 pm. This problem was addressed by augmenting the basis set with a different contraction scheme for palladium (3311/3111/211/1) and a fairly large full electron basis set (6-311G**) for phosphorus (basis set B). Using this augmented basis set, the calculated Pd−P bond length exceeded the experimental one by only 5 pm (see Tables 2 and 3).

Table 3. Selected bond lengths [Å], bond angles [°] and torsion angles [°] for **4a**, **5**, and **6**

	4a	**5a**	**±5b**	(*S*)-**5b**	**6**
M−N	2.118(1)	2.073(1)	2.071(6)	2.097(2)	2.066(3)
M−P	2.278(1)	2.257(1)	2.264(1)	2.262(1)	2.385(1)
N−M−P	89.2(1)	90.4(1)	88.0(2)	87.1(1)	87.2(1)
P−M−N−C(1)	−148.1	−152.1	−149.0	−149.1	−146.3

In a further step, the fumarodinitrile moiety was rotated 180° around the Pd−olefin bond, resulting in the diastereomeric complex **m4**. The geometry of **m4** was also optimized with basis set B. The difference in calculated energies between the diastereomeric complexes is very small, with the complex observed in solid state more stable by ca. 1 $kJ \cdot mol^{-1}$. This is in perfect agreement with our NMR spectroscopic studies which show that complex **4a** exists as a mixture of two diastereoisomers in solution, and the complex found to be energetically lower by the calculations, is favored.

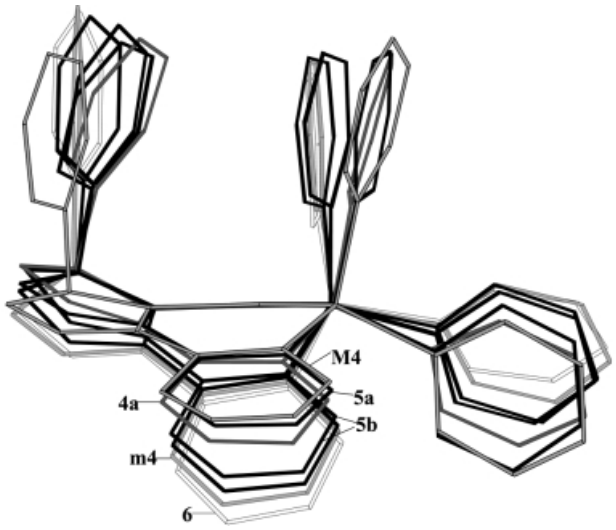

Figure 6. Superposition of the [M(**1a**)] moiety of complexes **4a**, **5**, **6**, and the calculated structures **M4** and **m4**; the N/Pd/P plane is perpendicular to the paper plane

A superposition (Figure 6) of the X-ray structures containing a [Pd(**1a**)] moiety and the calculated structures **M4** and **m4** (gray) demonstrates that the calculated structures almost represent the extremes of chelate ring puckering, **M4** with the flattest and **m4** with the most puckered chelate ring.

The conformation of **m4** is closer to zinc complex **6** (colorless) than to the palladium structures. However, the deviations are too small to be significant. **M4** demonstrates a flattening of the double ring system. The P−Pd−N−C(1) angle of −167° deviates from all other values lying in the range of 146−154°.

The good agreement between the calculated energy difference of the two diastereomeric complexes **M4** and **m4** with the NMR spectroscopic results, indicates that density functional methods in combination with selectively enlarged basis sets give a fairly accurate description of complexes such as **M4** or **m4**. Taking into account that employing the augmented basis set results in an almost negligible increase of computing time but drastically improves the quality of the calculation, we have now established a methodology which allows us to address further tasks such as computing the hypersurface for nucleophilic attack at an allylpalladium complex.

Conclusion

Due to their facile accessibility and their stability [(fumarodinnitrile)(phosphanyloxazoline)palladium(0)] complexes allow for the study of the interaction between the olefin and the chiral ligand. In solution the complexes demonstrate fluxional behavior. The diastereomeric ratio is dependent on the bulk of the oxazoline substituent. A comparison of the X-ray structures of Pd^0- and Pd^{II}(phosphanyloxazoline) complexes with various additional ligands shows that the phosphanyloxazoline backbone adopts a well-defined conformation independent of the oxidation state of the central atom and of additional ligands. DFT/B3LYP calculations with extended basis sets for the palladium and phosphorus atoms confirm the structural features found in the solid-state structures.

Experimental Section

General: $Pd_2(dba)_3{\cdot}CHCl_3$[17] and the phosphanyloxazoline ligands **1**[18] were prepared according to literature procedures. Commercially available material was recrystallized. Solvents for chromatography were distilled before use. The reactions were carried out under N_2 using dried glassware. Column chromatography (CC): SiO_2, C 560, 0.035−0.070 mm, F 254, Chemische Fabrik, Uetikon. NMR spectra were recorded at 25° C with a Varian-Gemini 300 spectrometer with $CDCl_3$ as solvent. ^{1}H NMR: 300 MHz, chemical shifts in ppm relative to $CHCl_3$ as internal reference (δ = 7.26), coupling constants J in Hz. ^{31}P{H} NMR: 121 MHz, triphenylphosphate as external reference (δ = −18.0).

(±)-{2-[2′-(Diphenylphosphanyl-κ*P*)phenyl]-4,5-dihydro-4-phenyloxazole-κ*N*]}(η^2-fumarodinitrile)palladium(0) (4a). General Procedure (GP): A solution of $Pd_2(dba)_3{\cdot}CHCl_3$ (206 mg, 0.20 mmol) and **1a** (163 mg, 0.40 mmol) in CH_2Cl_2 (7 mL) was stirred for 30 min at 20 °C until the dark purple solution turned dark brown. Subsequently, fumarodinitrile (31.2 mg, 0.4 mmol) was added. The solution was stirred for 2 h and turned yellow. The solution was concentrated and transferred onto a 10 × 2 cm SiO_2 column and eluted with hexane/EtOAc (2:1). Evaporation of the solvent yielded a yellow crystalline solid, stable to moisture and air (157 mg, 66.7%). Recrystallization in EtOH/CH_2Cl_2 (20:1) afforded yellow crystals suitable for X-ray analysis. Major isomer (80%): ^{1}H NMR: δ = 8.20−8.24 (m, 1 H, ArH), 6.93−7.62 (m, 18 H, ArH), 5.60 (dd, J = 10.4, 8.5 CH), 4.83 (dd, J = 10.4, 8.9, CH_2), 4.27 (dd, J = 8.9, 8.5, CH_2), 3.02 (dd, J = 9.4, $J_{H,P}$ = 3.2, H_{cisP}) 1.89 (t, J = 9.7, H_{transP}). ^{31}P{H} NMR: δ = 18.93. Minor isomer (20%): ^{1}H NMR: δ = 8.16−8.20 (m, 1 H, ArH), 6.93−7.62 (m, 18 H, ArH), 5.39 (dd, J = 10.4, 7.5 CH), 4.79 (dd, J = 10.4, 8.8, CH_2), 4.35 (dd, J = 8.8, 7.5, CH_2), 3.0 (dd, $J_{H,P}$ = 3.2, H_{cisP}) 2.43 (t, J = 9.8, H_{transP}). ^{31}P{H} NMR: δ = 19.36.

(±)-{2-[2′-(Diphenylphosphanyl-κ*P*)phenyl]-4,5-dihydro-4-methyloxazole-κ*N*]}(η^2-fumarodinitrile)palladium(0) (±4b): According to GP from $Pd(dba)_2$ (115 mg, 0.20 mmol) and ±**1b** (69 mg, 0.20 mmol) and fumarodinitrile (16.8 mg, 0.2 mmol). Yield 90 mg, 84.9%. Crystalline isomer (52%): ^{1}H NMR: δ = 8.01−8.05 (m, 1 H, ArH), 7.36−7.55 (m, 12 H, ArH), 6.94−7.00 (m, 1 H, ArH), 4.45−4.57 (m, 2 H), 3.99−4.03 (m, 1 H), 3.21 (dd, J = 9.5, $J_{H,P}$ = 3.1, H_{cisP}), 2.73 (t, J = 9.7, H_{transP}), 1.24 (d, J = 6.4, Me); ^{31}P{H}: δ = 20.13. Isomer II (48%): ^{1}H NMR: δ = 8.11−8.15 (m, 1 H, ArH), 7.34−7.56 (m, 12 H, ArH), 7.04−7.12 (m, 1 H, ArH), 4.45−4.55 (m, 2 H), 4.07−4.11 (m, 1 H), 3.16 (dd, J = 9.3, $J_{H,P}$ = 3.3, H_{cisP}), 2.81 (t, J = 9.4, H_{transP}), 1.34 (d, J = 6.2, Me); ^{31}P{H} NMR: δ = 19.57.

(*S*)-{2-[2′-(Diphenylphosphanyl-κ*P*)phenyl]-4,5-dihydro-4-methyloxazole-κ*N*]}(η^2-fumarodinitrile)palladium(0) [(*S*)-4b): According to GP from $Pd(dba)_2$ (115 mg, 0.20 mmol) and *S*-**1b** (69 mg, 0.20 mmol) and fumarodinitrile (16.8 mg, 0.2 mmol). Yield 87 mg, 82.1%.

(*S*)-{2-[2′-(Diphenylphosphanyl-κ*P*)phenyl]-4,5-dihydro-4-isopropyloxazole-κ*N*]}(η^2-fumarodinitrile)palladium(0) (4c): According to

GP from $Pd_2(dba)_3$·$CHCl_3$ (206 mg, 0.20 mmol) and **1c** (149 mg, 0.40 mmol) and fumarodinitrile (31.2 mg, 0.4 mmol). Yield 202 mg (90%). Crystalline isomer: ^{1}H NMR: δ = 8.08−8.12 (m, 1 H, ArH), 7.32−7.72 (m, 12 H, ArH), 7.06 (m, 1 H, ArH), 4.26−4.40 (m, 3 H), 3.15 (dd, J = 9.3, $J_{H,P}$ = 3.3, H_{cisP}) 2.75 (t, $J \approx 9.5$, H_{transP}), 2.26−2.38 (m, 1 H, $CH(Me)_2$], 0.88 (d, J = 7.0, Me) 0.42 (d, J = 7.1, Me); ^{31}P{H} NMR: δ = 19.30. Isomer II: ^{1}H NMR: δ = 8.08−8.12 (m, 1 H, ArH), 7.32−7.72 (m, 12 H, ArH), 6.97 (m, 1 H, ArH), 4.26−4.46 (m, 3 H), 3.21 (dd, J = 9.6, $J_{H,P}$ = 2.9, H_{cisP}), 2.71 (t, $J \approx 10$, H_{transP}), 2.25−2.37 [m, H−C$(Me)_2$], 0.91 (d, J = 7.1, Me), 0.15 (d, J = 6.8, Me); ^{31}P{H} NMR: δ = 19.48.

(*S*)-4-*tert*-Butyl-{2-[2′-(diphenylphosphanyl-κ*P*)phenyl]-4,5-dihydrooxazole-κ*N*]}(η^2-fumarodinitrile)palladium(0) (4d): According to GP from $Pd(dba)_2$ (115 mg, 0.20 mmol), **1d** (87.7 mg, 0.20 mmol) and fumarodinitrile (15.6 mg, 0.20 mmol). Yield 77 mg (67.3%). Major isomer (70%): ^{1}H NMR: δ = 8.15−8.19 (m, 1 H, ArH), 7.29−7.57 (m, 12 H, ArH), 7.00 (m, 1 H, ArH), 4.39−4.43 (m, 2 H), 4.14−4.18 (m, 1 H), 3.20 (dd, J = 9.3, $J_{H,P}$ = 3.3, H_{cisP}) 2.61 (t, J = 9.3, H_{transP}), 0.71 (s, 9 H, Me); ^{31}P{H} NMR: δ = 20.05. Minor isomer (30%): ^{1}H NMR: δ = 8.15−8.19 (m, 1 H, ArH), 7.29−7.57 (m, 12 H, ArH), 6.90 (m, 1 H, ArH), 4.38−4.43 (m, 2 H), 4.13−4.18 (m, 1 H), 3.24 (dd, J = 9.8, $J_{H,P}$ = 2.5, H_{cisP}) 2.72 (t, $J \approx 10$, H_{transP}), 0.67 (s, 9 H, Me); ^{31}P{H} NMR: δ = 19.73.

X-ray Crystallographic Studies: Crystal data and parameters of the data collections are compiled in Table 4. Data collection was performed at ambient temperature (293° K) with a KappaCCD diffractometer, Mo-K_α radiation (λ = 0.71069 Å, graphite monochromator). The data were indexed and scaled by using the programs DENZO and SCALEPACK.[20] The data were corrected for Lorenz and polarization effects. The structures were solved by direct methods.[21] Anisotropic least-squares refinement against F_o was carried out on all non-hydrogen atoms using the program CRYSTALS.[22] The hydrogen atoms of the alkene were located by Fourier difference synthesis and refined isotropically. All other hydrogen atoms were included in calculated positions. Scattering factors were taken from the International Tables of Crystallography, vol. IV. CCDC-165323 to -165326 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Methods: All calculations were performed with the Gaussian98 (Revision A9) suite of programs[23] using an HP PA8500 at the Swiss Center for Scientific Computing in Manno, Switzerland, with the hybrid Becke exchange functional[24] and the correlation functional of Lee, Yang, and Parr[25] (B3LYP). All structures were fully optimized without geometry constraints. The reported relative energies are not zero-point-corrected. Basis sets used for geometry optimizations and energy calculations were i) LANL2DZ (D95 on first row,[26] Los Alamos ECP plus DZ on Na-Bi[27]) which includes a 341/321/31 contraction scheme for palladium and ii) 3311/3111/211/1[14c] (3311/3111/211 contraction of the minimal basis set of Hay and Wadt,[27] augmented with one f-polarization function[28]) basis set with Los Alamos ECP for palladium and 6-311G**[29] for phosphorus and D95 for C, H N and O (referred to as basis set B).

Acknowledgments

Spectroscopic Properties, Electrochemistry, and Reactivity of Mo^0, Mo^I, and Mo^{II} Complexes with the [Mo(bpa)$(CO)_3$] Unit [bpa = bis(2-picolyl)amine] and Their Application for the Labelling of Peptides

Dave R. van Staveren,[a][‡] Eberhard Bothe,[a] Thomas Weyhermüller,[a] and Nils Metzler-Nolte*[b]

Dedicated to Professor Karl Wieghardt on the occasion of his 60th birthday

Keywords: Amino acids / Bioinorganic chemistry / Carbonyl ligands / Molybdenum / Spectro-electrochemistry

The synthesis of the complexes [Mo(bpa)$(CO)_3$] (**1**) and [Mo(Bz-bpa)$(CO)_3$] (**2**) [bpa = bis(2-picolyl)amine; Bz-bpa = *N*-benzylbis(2-picolyl)amine] is described. These compounds have been characterized by spectroscopic techniques including multinuclear NMR spectroscopy (^{1}H, ^{13}C, and ^{95}Mo), and also by X-ray crystallography. Complexes **1** and **2** underwent reversible one-electron oxidations in acetonitrile and dichloromethane with Bu_4NPF_6 as supporting electrolyte to yield the 17-electron organometallic compounds $\mathbf{1}^+$ and $\mathbf{2}^+$. With Bu_4NBr as supporting electrolyte in dichloromethane, on the other hand, **1** and **2** underwent electrochemically irreversible two-electron oxidations, resulting in the formation of [Mo(bpa)$(CO)_3$Br]$^+$ and [Mo(Bz-bpa)$(CO)_3$Br]$^+$. Infrared spectra and electronic spectra of these oxidized species were recorded in spectro-electrochemical studies. The electrochemical behaviour and the infrared spectroscopic data of **1**, **2**, and their oxidized derivatives are compared in detail with those of analogous tricarbonylmolybdenum complexes with the ligands 1,4,7-triazacyclononane and hydridotris(pyrazolyl)borate. The complex [Mo(bpa)(CO)Br]Br_3 (**3**) could be prepared by oxidation of **1** with elemental bromine. Under aerobic aqueous conditions, **3** reacted further to yield the dinuclear diamagnetic Mo^V complex [Mo_2(bpa)$_2$(O)$_2$(μ-O)$_2$](Br,PF_6) (**4**). The identity of **4** was confirmed by a single-crystal X-ray crystallographic study. Finally, the syntheses of two bioconjugates of [Mo(bpa)$(CO)_3$], in which bpa ligands are covalently linked to the *N*-termini of an amino acid (Phe-OMe, **8a**) and of a dipeptide (Ala-Phe-OMe, **8b**), are described. These bioconjugates were comprehensively characterized (including elemental analysis, ^{1}H, ^{13}C, and ^{95}Mo NMR, IR, MS, and electrochemistry). All analytical data supported the proposed constitution and underscore the potential of the Mo(bpa)$(CO)_3$ group as a robust marker group in bioorganometallic chemistry.

Introduction

There is considerable interest in the labelling of biomolecules with organometallic fragments that possess carbonyl ligands.[1−3] The corresponding bioconjugates can be detected in picomolar quantities by infrared spectroscopy, as shown by Jaouen, Salmain, and co-workers.[4] Together with IR spectroscopy, electrochemistry of metal complexes is a very attractive detection method, offering good sensitivity and a high signal-to-background ratio.[5,6] We have recently introduced the versatile and robust Mo(allyl)$(CO)_2$ moiety as a marker group in bioorganometallic chemistry.[7−9] However, perhaps the most obvious low-valent Mo fragment is *fac*-Mo$(CO)_3$, in the form of octahedral [L_3Mo$(CO)_3$] complexes. For biological applications, the ligand L_3 must fulfil several requirements. It must be readily accessible, easily substituted with a handle for biomolecules, and furnish very stable Mo$(CO)_3$ complexes. Well-known examples of [L_3Mo$(CO)_3$] complexes include L_3 = 1,4,7-triazacyclononane (tacn; [9]aneN_3) and hydridotris(pyrazolyl)borate [HB$(pz)_3$] as tridentate ligands. We propose the bis(2-picolyl)amine ligand [*bis*(*picolyl*)*amine*, bpa] as an interesting alternative, because its Mo$(CO)_3$ complexes are readily accessible and very stable, as shown here. Moreover, in contrast to tacn and hydridotrispyrazolylborate, the bpa ligand can easily be derivatized with a (protected) acid functionality,[10,11] which makes binding to biomolecules possible.[11,12]

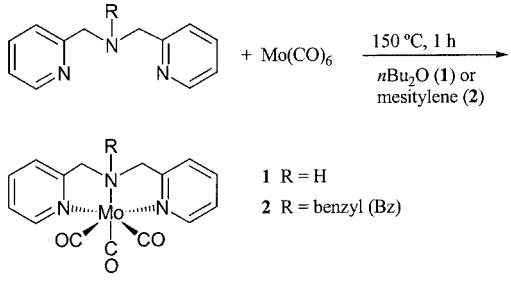
The ligand bpa, first reported by Romary et al.,[13] is one of the classical tridentate nitrogen donor ligands in coordination chemistry, but (bpa)metal complexes containing *organometallic* fragments are relatively scarce. Only four organometallic bpa complexes have so far been structurally characterized by X-ray crystallography: namely, [Rh(bpa)(cod)]BPh_4 [cod = (*Z*,*Z*)-1,5-cyclooctadiene],[14] [Pt(bpa)CH_3]Cl,[15] [Pt(bpa)(η^1-allyl)$(CH_3)_2$]Br,[15] and [W(bpa)(η^3-allyl)$(CO)_2$]PF_6.[16] A significant number of *fac*-[L_3Mo$(CO)_3$] complexes, with L_3 being a tridentate nitrogen donor ligand, have been structurally characterized.[17–34] However, no Mo(bpa)$(CO)_3$ derivatives have yet been reported. Krüger and Helm reported the synthesis and X-ray crystal structure of a related compound, in which the potentially tetradentate ligand *N*,*N*′-dimethyl-2,11-diaza-[3.3](2,6)pyridinophane acts as a tridentate ligand structurally analogous to bpa.[17]

In this paper, we report the synthesis, structural characterisation, spectroscopic properties, electrochemical behaviour and chemical reactivity of Mo^0, Mo^I, and Mo^{II} complexes containing the Mo(R-bpa)$(CO)_3$ unit (R = H or Bz). Furthermore, the suitability of Mo(R-bpa)$(CO)_3$ complexes for the labelling of biomolecules is demonstrated by the synthesis of two derivatives, an amino acid (Phe) and a dipeptide (Ala-Phe), in which the Mo(R-bpa)$(CO)_3$ derivative is covalently linked to the *N*-termini.

Results and Discussion

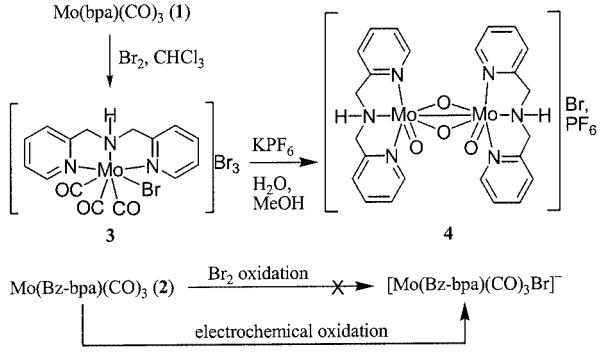
Synthesis and Reactivity

The complexes [Mo(bpa)$(CO)_3$] (**1**) and [Mo(Bz-bpa)$(CO)_3$] (**2**) were synthesized by heating the ligand with $Mo(CO)_6$ in deoxygenated di-*n*-butyl ether (for **1**) or deoxygenated mesitylene (for **2**) at 150 °C for 1 h under argon, as shown in Scheme 1. Complex **1** was isolated as a deep yellow powder, whereas **2** was obtained as an orange solid. All the characterisation data for **1** and **2** were consistent with their proposed constitutions. These compounds were stable in air for days in the solid state. In solution, complex **1** was much more sensitive than **2** towards air, with decomposition of **1** taking place within 1–2 h.



Scheme 1

When **1** was treated with elemental bromine in deoxygenated $CHCl_3$ under argon, the orange-brown complex [Mo(bpa)$(CO)_3$Br]Br_3 (**3**) was obtained (see Scheme 2), as concluded from the results of elemental analysis, infrared spectroscopy and ESI positive mass spectrometry. In the solid state, this compound was stable towards dioxygen for approximately 1 d, but in solution decarbonylation of complex **3** took place within 5–10 min when only traces of water were present. NMR spectroscopic data of compound **3** could not be obtained. When **3** was dissolved in MeOH under aerobic conditions and an aqueous solution of KPF_6 was added, the dinuclear complex [Mo_2(bpa)$_2(O)_2$(μ-$O)_2$](Br,PF_6) (**4**) invariably precipitated, and therefore appears to be the thermodynamic sink of the mixture (see Scheme 2). The reactivity of **3** differed from that of [Mo([9]aneN_3)$(CO)_3$Br]Br_3, as the latter compound can be crystallized from aerobic aqueous solutions.[35]



Scheme 2

When **2** was treated with Br_2 under conditions identical to those used for the synthesis of **3**, an oil formed initially, but an orange-brown solid was obtained upon removal of the solvent in vacuo. Although results from elemental analysis fitted well for [Mo(Bz-bpa)$(CO)_3$Br]Br_3, other characterisation data could not be obtained, due to the instability of this compound in solution. However, [Mo(Bz-bpa)$(CO)_3$Br]$^+$ could be generated by electrochemical methods (see Scheme 2), as concluded from spectro-electrochemical investigations (vide infra).

X-ray Crystal Structures of 1, 2, and 4

X-ray quality single crystals of complexes **1** and **2** were obtained by slow concentration of H_2O/CH_3CN solutions under streams of argon. The unit cell of each compound was found to consist of two crystallographically inequivalent molecules (named A and B), which display slightly different bond lengths and angles. ORTEP diagrams for one of the independent molecules of each of **1** and **2** are depicted in Figures 1 and 2, respectively. Geometrical information for both structures is summarized in Table 1. Molecules B of **1** and **2** are labelled consecutively: N(1) in A corresponds to N(4) in B, and C(35) in B corresponds to C(13) in A, etc. The two independent molecules in the two structures are fairly similar.

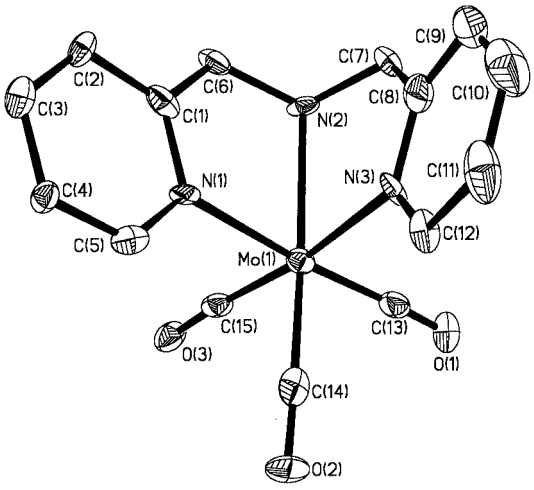


Figure 1. ORTEP projection for one of the two crystallographically independent molecules (A) of **1** with thermal ellipsoids at 50% probability level; hydrogen atoms have been omitted for clarity

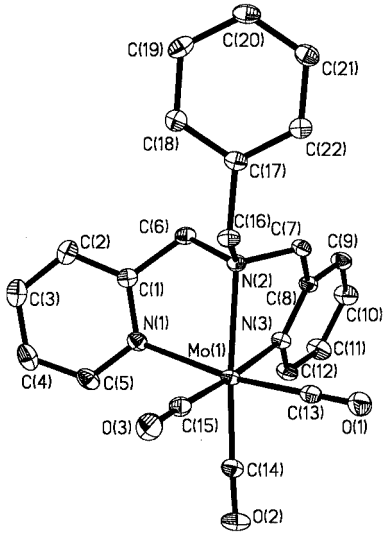

Figure 2. ORTEP plot for one of the two crystallographically independent molecules (A) of **2** with thermal ellipsoids at 50% probability level; hydrogen atoms have been omitted for clarity

The Mo atoms in both structures are in distorted octahedral $[N_3C_3]$ coordination environments, each with the three carbonyl groups and the (substituted) bis(2-picolyl)-amine ligand occupying a face of the octahedron. This facial arrangement of the carbonyl ligands has also been observed in analogous complexes with various tridentate N-donor ligands.[17−34] In both molecules of **1** and **2**, the Mo−N(amine) bond length is considerably longer than the Mo−N(pyridine) bond lengths. Unfortunately, the quality of the structure of **1** is not high enough to allow a detailed discussion of the other bond lengths in this structure. All of the differences between molecule A and molecule B of **2** are small and might be interpretable on the basis of packing effects. In both structures the deviation from idealized octahedral symmetry is evident from the C−Mo−C angles: values of less than 90° are observed for all of those. In fact,

Table 1. Selected bond lengths [Å] for $[Mo(bpa)(CO)_3]$ (**1**) and $[Mo(Bz\text{-}bpa)(CO)_3]$ (**2**)

	1	**2**
Molecule A:[a]		
Mo(1)−N(1)	2.229(10)	2.272(3)
Mo(1)−N(2)	2.301(10)	2.337(2)
Mo(1)−N(3)	2.234(11)	2.255(3)
Mo(1)−C(13)	1.92(2)	1.933(3)
Mo(1)−C(14)	1.91(2)	1.935(2)
Mo(1)−C(15)	1.91(2)	1.945(3)
Molecule B:[b]		
Mo(2)−N(4)	2.249(11)	2.250(3)
Mo(2)−N(5)	2.308(11)	2.331(2)
Mo(2)−N(6)	2.249(11)	2.252(3)
Mo(2)−C(35)	1.92(2)	1.938(3)
Mo(2)−C(36)	1.89(2)	1.932(3)
Mo(2)−C(37)	1.92(2)	1.953(3)

[a] The unit cells of both compounds contain two crystallographically independent molecules, named A and B. [b] Molecule B is labelled consecutively: i.e., N(4) in B corresponds to N(1) in A and C(35) in B corresponds to C(13) in A, etc.

all structures so far reported for *fac*-$Mo(CO)_3$ complexes with tridentate N-donor ligands display C−Mo−C angles smaller than 90°,[17−34] and this deviation thus appears to be a general feature for this type of compounds.

There is only one example in the literature of a structurally characterized *fac*-$Mo(CO)_3$ compound with the molybdenum atom coordinated by two pyridine nitrogen atoms and one amine nitrogen atom of the same ligand. The potentially tetradentate ligand *N*,*N*′-dimethyl-2,11-diaza[3.3]-(2,6)pyridinophane acts as a tridentate ligand in that compound.[17] The Mo−N(pyridine) bond lengths in the structure of that complex are approximately 0.04 Å longer than the Mo−N(amine) bond lengths. This is in sharp contrast with structures **1** and **2**, in which the Mo−N(pyridine) bond lengths are considerably shorter than the Mo−N(amine) bond lengths.

X-ray quality single crystals of $[Mo_2(bpa)_2(O)_2(\mu\text{-}O)_2](Br,PF_6)$ (**4**) were obtained by slow concentration of an $MeOH/H_2O$ solution. An ORTEP representation of the cationic part of **4** is shown in Figure 3, with selected bond length and bond angle information summarized in Table 2.

The cationic part of the structure consists of two Mo(bpa)(O) moieties bridged by two oxo ligands, with the terminal oxo ligands occupying *cis* positions relative to each other. The four-membered ring comprised of the two Mo atoms and the two bridging oxo ligands has the puckered conformation observed in all crystal structures containing a *syn*-$[Mo_2(O)_2(\mu\text{-}O)_2]$ core with additional multidentate ligands.[36−39] The short internuclear Mo−Mo distance of 2.5432(5) Å is indicative of an Mo−Mo single bond, consistent with the observed diamagnetism of the complex.

The bromide ion (not depicted in Figure 3) is involved in hydrogen bond interactions with the two NH groups, with Br···N contacts of 3.258(4) Å and 3.358(4) Å [Br···N(5) and Br···N(2), respectively]. Two very similar crystal structures

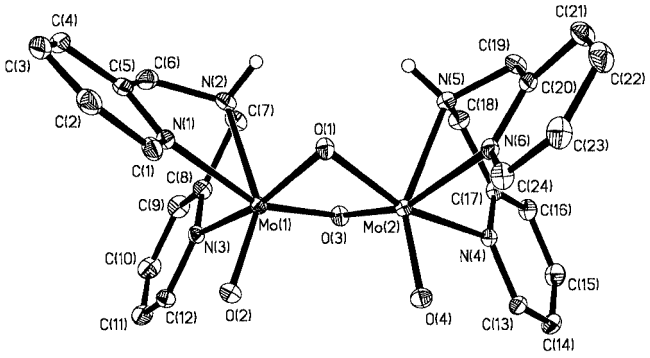

Figure 3. ORTEP representation for the cationic part in **4** with thermal ellipsoids at 50% probability level; hydrogen atoms, except amine hydrogen atoms, have been omitted for clarity

Table 2. Selected bond lengths [Å] and bond angles [°] for [Mo_2-$(bpa)_2(O)_2(\mu\text{-}O)_2$](Br,$PF_6$) (**4**)

Mo(1)−N(1)	2.219(2)	Mo(2)−N(6)	2.227(2)
Mo(1)−N(2)	2.313(2)	Mo(2)−N(5)	2.294(2)
Mo(1)−N(3)	2.263(2)	Mo(2)−N(4)	2.245(2)
Mo(1)−O(2)	1.687(2)	Mo(2)−O(4)	1.692(2)
Mo(1)−O(1)	1.934(2)	Mo(2)−O(1)	1.921(2)
Mo(1)−O(3)	1.935(2)	Mo(2)−O(3)	1.933(2)
Mo(1)−Mo(2)	2.5432(5)		
O(1)−Mo(1)−O(2)	110.10(7)	O(1)−Mo(2)−O(4)	110.70(7)
O(3)−Mo(1)−O(2)	111.83(7)	O(3)−Mo(2)−O(4)	112.29(7)
O(1)−Mo(1)−O(3)	91.43(6)	O(1)−Mo(2)−O(3)	91.88(6)
Mo(1)−O(1)−Mo(2)	82.55(6)	Mo(2)−O(3)−Mo(1)	82.22(6)

with ethyl or methylethyl linkers between the two bpa ligands have been reported,[37] and these display Mo-donor atom bond lengths nearly identical to those in **4**. Apparently, the hydrogen-bonded bromide ion forces the bpa ligands into the same conformation as the ethyl and methylethyl linkers do. It would be expected that this bromide ion would be bound very tightly because, apart from hydrogen bond interactions, it is also involved in an electrostatic interaction with the dinuclear molybdenum complex of charge 2+.

NMR Spectroscopy

In solution, the hydrogen atoms of the picolyl-CH_2 groups become magnetically inequivalent due to metal coordination of the three nitrogen atoms. Therefore, the ^1H NMR spectrum of **2** showed two doublets at $\delta = 4.67$ and $\delta = 3.72$ with intensity two and a ^2J coupling constant of 15.5 Hz (see Supporting Information, Figure S1). In the ^1H NMR spectrum of **1** on the other hand, the appearance of the picolyl-CH_2 hydrogen atom resonances was influenced by the amine NH group. This NH hydrogen atom resonated at $\delta = 6.14$, with a ^3J coupling constant of 6.6 Hz. One of the pairs of magnetically inequivalent picolyl-CH_2 hydrogen atoms resonated as a doublet at $\delta = 4.06$, with a ^2J coupling constant of 16.8 Hz, whereas the other pair appeared as a doublet of doublets at $\delta = 4.33$, with a ^2J coupling constant of 16.8 Hz and a ^3J coupling constant of 6.6 Hz. The size of these coupling constants in the ^1H NMR spectrum of **1** can be explained by the Karplus equation.[40] Analysis of the crystallographic data[41] shows that the absolute value of the HNCH torsion angles is close to 30° for one set of protons and close to 90° for the other (see Supporting Information, Figure S2 and Table S3). The calculated $^3J_{H,H}$ values of 5.9 Hz and 0.2 Hz, respectively, are in good agreement with the observed coupling constants in the ^1H NMR spectrum, indicating that the solid-state structure does not differ to any large extent from the structure of **1** in solution.

The ^{13}C NMR spectra of **1** and **2** each showed two signals corresponding to the CO ligands at $\delta \approx 230$ (see Exp. Sect.), with the signal at the higher chemical shift having approximately twice the intensity of the signal at lower frequency. The CO ligand *trans* to the amine nitrogen atom was more shielded due to increased π-backbonding, whereas the CO ligands in positions *trans* to the pyridine groups had to compete with the pyridine rings for π-backbonding.

Results from ^{95}Mo NMR measurements are summarized in Table 3, together with the chemical shifts for several other *fac*-$Mo(CO)_3$ compounds with N-donor ligands, for comparison. The chemical shifts of *fac*-[$Mo(N_3)(CO)_3$] complexes span a range of about 350 ppm, with compounds **1** and **2** showing resonances in the high frequency region of that range. The molybdenum nucleus in **2** was deshielded by 89 ppm compared to complex **1**. This downfield shift upon alkylation of the bis(picolyl)amine nitrogen atom is the reverse of the trend observed for the 1,4,7-triazacyclononane derivatives: [$Mo(Me_3[9]aneN_3)(CO)_3$] resonated 226 ppm upfield from [$Mo([9]aneN_3)(CO)_3$]. At first sight, an upfield shift should be expected, as the electron density at the Mo nucleus increases upon alkylation of the amine ligand. While this is true for the triazacyclononane series, the opposite trend holds for **1** and **2**. However, for heavier elements such as Mo, steric effects such as ligand bulkiness and chelate ring size, as well as local symmetry effects, have an important influence on the chemical shift of the element.[42,43] The downfield shift of **2** with respect to **1** may therefore be explained on the basis of steric effects. In fact, the Mo-donor atom bond lengths in the X-ray crystal struc-

ture of **1** show a trend towards being somewhat shorter than their counterparts in **2**.

Electrochemistry

Both **1** and **2** underwent reversible one-electron oxidations in CH_3CN and CH_2Cl_2 with Bu_4NPF_6 as supporting electrolyte at potentials slightly more negative than the Fc/Fc^+ couple. The redox potentials for these complexes are listed in Table 4, together with those for the related 1,4,7-triazacyclonane (tacn) and hydridotris(3,5-dimethylpyrazolyl)borate [$HB(Me_2pz)_3$] complexes. The redox potentials for **1** and **2** appear to be solvent-dependent, with the lower oxidation potential measured in CH_2Cl_2. Table 4 shows that the oxidation potentials of **1** and **2** are very similar to those of the tacn and Me_3-tacn complexes. The hydridotris(3,5-dimethylpyrazolyl)borate anionic analogue $[Mo\{HB(Me_2pz)_3\}(CO)_3]^-$ undergoes a one-electron oxidation at slightly higher potential than the tacn, bpa and Bz-bpa complexes.

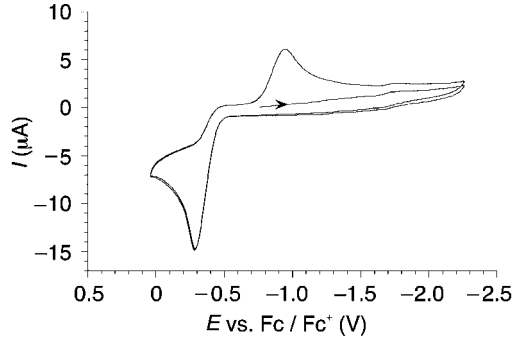

Figure 4. Cyclic voltammogram of **2** (10^{-3} M) in CH_2Cl_2 in the presence of Bu_4NBr (0.1 M); two consecutive cycles (scan rate 200 mV/s) starting from −0.8 V moving first to −2.3 V; note that the reduction peak at −0.95 V appears only in the second cycle

In CH_2Cl_2 and with Bu_4NBr as the supporting electrolyte, the electrochemical behaviour of **1** and **2** was completely different. Irreversible oxidations took place, with peak potentials of −0.37 V vs. Fc/Fc^+ (for **1**) and −0.28 V vs. Fc/Fc^+ (for **2**). Controlled potential coulometry on both compounds established these oxidations as two-electron processes, attributable to formation of the seven-coordinated complexes $[Mo(bpa)(CO)_3Br]^+$ and $[Mo(Bz\text{-}bpa)(CO)_3Br]^+$. Formation of seven-coordinated Mo^{II} species has also been reported for *fac*-$Mo(CO)_3$ complexes with two different tacn derivatives.[25,48] After generation of the seven-coordinated species $[Mo(bpa)(CO)_3Br]^+$ and $[Mo(Bz\text{-}bpa)(CO)_3Br]^+$, single reduction peaks were observed at more negative potentials, namely at −1.20 V vs. Fc/Fc^+ for $[Mo(bpa)(CO)_3Br]^+$ and −0.95 V vs. Fc/Fc^+ for $[Mo(Bz\text{-}bpa)(CO)_3]^+$, as shown in Figure 4 for complex **2**.

The reductive peaks only appeared during the second of two consecutive cyclic voltammograms. This demonstrates that the seven-coordinated complexes formed upon oxidation of the starting material in the first cycle are reduced at this potential. With the aid of controlled potential coulometry, the number of transferred electrons for this reduction process was shown to be two, again yielding the neutral compounds **1** and **2**. The bpa derivatives differ from the tacn analogues in this respect, because the corresponding reduction peak of the seven-coordinated species for the tacn complexes was not observed in the range from −2.0 V to +2.0 V.[25,48] Additional evidence for the chemical reversibility of the two-electron oxidation of **1** and **2** was also obtained from UV and IR spectroelectrochemical investigations (see below).

Electronic Spectroscopy

The electronic spectra of **1** and **2** in MeCN were very similar, each displaying two intense MLCT bands, with maxima at 327 nm ($\varepsilon = 6.1\cdot10^3$ $M^{-1}\cdot cm^{-1}$) and 416 nm ($\varepsilon = 6.9\cdot10^3$ $M^{-1}\cdot cm^{-1}$) for **1** and at 329 nm ($\varepsilon = 6.3\cdot10^3$ $M^{-1}\cdot cm^{-1}$) and 429 nm ($\varepsilon = 7.0\cdot10^3$ $M^{-1}\cdot cm^{-1}$) for **2**.

UV/Vis spectroelectrochemical investigations could only be performed on **2**, since $\mathbf{1}^+$ and $[Mo(bpa)(CO)_3Br]^+$ (the oxidation products of **1**) were both very reactive in solution and partially reacted further during the time required for coulometry (several minutes), probably to yield oxo species. The changes in the electronic spectrum during the electrochemical oxidation of complex **2** in CH_2Cl_2 were monitored with both Bu_4NPF_6 and Bu_4NBr as supporting electrolyte, as depicted in Figure 5. During oxidation, in the presence both of PF_6 and of bromide anions, the MLCT bands at 429 nm and 329 nm gradually disappeared, as a result of the decreased electron availability at the Mo ion in the Mo^I and Mo^{II} forms. With Bu_4NPF_6 as supporting electrolyte (formation of $\mathbf{2}^+$), a new shoulder appeared at around 350 nm, with a molar extinction coefficient of around $4.8\cdot10^3$ $M^{-1}\cdot cm^{-1}$, while an isosbestic point was present at 320 nm. In the presence of bromide anions [formation of $Mo(Bz\text{-}bpa)(CO)_3Br^+$], a new shoulder appeared at 370 nm, with a molar extinction coefficient of around $1.4\cdot10^3$ $M^{-1}\cdot cm^{-1}$, and an isosbestic point was present at 307 nm. After both oxidations, the formed complexes could be reduced at appropriate potentials, once again yielding the UV/Vis spectrum of **2**, without any significant loss in absorbance (i.e., within 99%). This finding is additional evidence for the chemical reversibility of the oxidations.

Infrared Spectroscopy

The infrared spectra of **1** and **2** in THF showed three ν_{CO} vibrations: at 1904, 1790, and 1779 cm^{-1} for **1**, and at 1906,

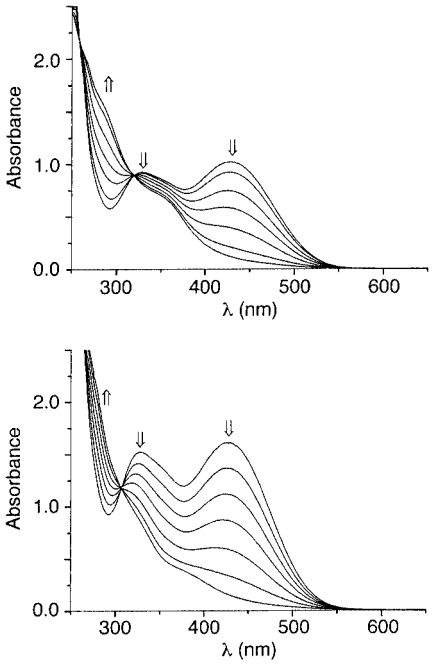

Figure 5. Changes in the electronic spectrum of **2** during coulometry in CH_2Cl_2 at 0° C; top: in the presence of 0.1 M Bu_4NPF_6, one-electron oxidation (formation of $\mathbf{2}^+$), $2.92\cdot10^{-4}$ M of **2**, path-length 0.5 cm; bottom: in the presence of 0.1 M Bu_4NBr, two-electron oxidation {formation of [Mo(Bz-bpa)$(CO)_3$Br]$^+$}, $4.61\cdot10^{-4}$ M of **2**, path length: 0.5 cm

1794, and 1782 cm^{-1} for **2**. This is consistent with C_s symmetry, for which three ν_{CO} vibrations are expected (A′ + 2 A′′). In the case of [Mo(Me_3[9]aneN_3)$(CO)_3$] the three nitrogen atoms are identical, resulting in a complex with C_{3v} symmetry, for which only two infrared-active vibrations should be expected (A_1 + E, at 1907 cm^{-1} and 1773 cm^{-1}, respectively).

The infrared spectrum of [Mo(bpa)(CO)Br]Br_3 (**3**) was measured conventionally between NaCl windows in THF solution, whereas infrared spectra of $\mathbf{1}^+$, $\mathbf{2}^+$, and [Mo(Bz-bpa)$(CO)_3$Br]$^+$ were recorded in situ during electrochemical oxidation of **1** and **2** in an OTTLE cell. As a representative example, the infrared spectral changes during the oxidation of **2** to $\mathbf{2}^+$ are depicted in Figure 6.

The carbonyl stretching vibrations in the infrared spectra of the compounds in this study are summarized in Table 5, together with values of analogous tacn and hydridotris(pyrazolyl)borate compounds. As can be observed, the ν_{CO} stretching vibrations of **1** and **2**, their 17-electron derivatives

[a] Complex has C_s symmetry. [b] Complex has C_{3v} symmetry. [c] Complex generated electrochemically in an OTTLE cell.

$\mathbf{1}^+$ and $\mathbf{2}^+$, and the seven-coordinated complexes **3** and $[Mo(Bz\text{-}bpa)(CO)_3Br]^+$ showed trends similar to those seen with their tacn and hydridotris(pyrazolyl)borate analogues. The electron availability of the molybdenum ion in these species decreases upon increase of the metal ion's oxidation state, resulting in a shift of the ν_{CO} vibrations to higher wavenumbers.

EPR Spectroscopy

Because the electrochemical and spectro-electrochemical investigations on **2** indicated good stability of the one-electron oxidized complex $\mathbf{2}^+$, this latter compound was subjected to EPR spectroscopic investigation. The X-Band EPR spectrum of $\mathbf{2}^+$ (generated by coulometry) as a frozen CH_2Cl_2 solution is depicted in Figure 7, together with the resulting spectrum from the simulation procedure.

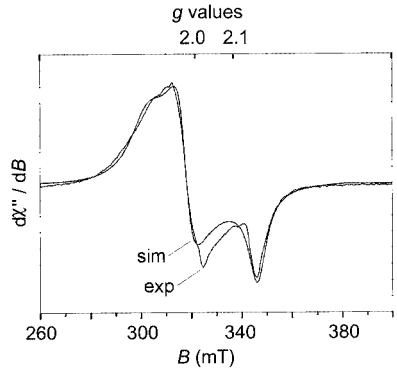

Figure 7. X-Band EPR spectrum of $\mathbf{2}^+$, generated by coulometry, in frozen CH_2Cl_2 solution (0.1 M Bu_4NPF_6) and its simulated spectrum; $T = 50$ K; power: 0.2 mW; frequency: 9.46494 GHz; modulation: 1.25 mT

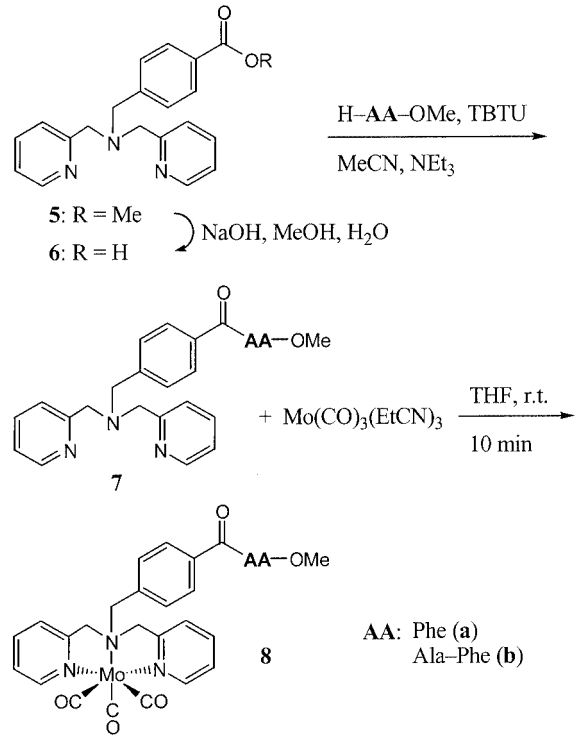
Although the fit is not perfect, it clearly shows the rhombic nature of the $S = 1/2$ spectrum, with simulated g values $g_x = 2.238$, $g_y = 2.131$, and $g_z = 1.954$. These g values are slightly higher than those reported for $[Mo(benzyl_3[9]aneN_3)(CO)_3]^+$ in a frozen DMF solution, which were $g_x = 2.188$, $g_y = 2.040$, and $g_z = 1.992$.[50] The discrepancy between the simulated and the experimental spectrum of $\mathbf{2}^+$ might be due to the presence of small amounts of paramagnetic decomposition products. Indeed, no satisfactory EPR spectra of the related compound $\mathbf{1}^+$ could be obtained, because the EPR spectra contained several additional resonances. As mentioned above, the spectro-electrochemical investigations on **1** showed that $\mathbf{1}^+$ had partially decomposed during the time required for the coulometry (several minutes).

Labelling of Biomolecules

Complex **2** showed particularly good stability towards dioxygen and water. We have therefore set out to use this type of $(bpa)Mo(CO)_3$ derivative for the labelling of biomolecules, in particular amino acids and peptides. The synthetic strategy is outlined in Scheme 3. The ligand *N*-(*p*-carboxybenzyl)bis(2-picolyl)amine (**6**) was prepared in good yield from methyl *p*-(bromomethyl)benzoate and bis(2-picolyl)amine, followed by base hydrolysis of the methyl ester. With TBTU [*O*-(1*H*-benzotriazol-1-yl)-*N*,*N*,*N*′,*N*′-tetramethyluronium tetrafluoroborate] as the activating reagent, **6** was coupled to the amino groups of phenylalanine methyl ester and the dipeptide alanyl-phenylalanine methyl ester to yield **7a** and **7b**, respectively. With a view to future applications in the labelling of more sensitive biomolecules, **7** was not treated directly with $Mo(CO)_6$, because of the vigorous conditions required for quantitative labelling. Instead, the *fac*-$Mo(CO)_3$ fragment was introduced under very mild conditions, by treatment with $[Mo(CO)_3(EtCN)_3]$. After 5−10 min of stirring at room temperature, an orange precipitate formed. After filtration and drying in vacuo, compounds **8a** and **8b** were obtained in pure form in 80% yield.



Scheme 3

The spectroscopic data of **8a** and **8b** confirmed the proposed constitution of the bioconjugates. First of all, the IR spectra showed three ν_{CO} vibrations at 1906, 1793, and 1782 cm^{-1} (Table 5). A ^{95}Mo NMR resonance was observed at $\delta = -849$ for both compounds, identical to the chemical shift of **2**. In addition, resonances for the metal carbonyl ligands at $\delta \approx 230$ were observed in the ^{13}C NMR spectra. Coordination of the *fac*-$Mo(CO)_3$ fragment to the nitrogen atoms of the substituted bpa ligand was also evident in the ^1H NMR spectra. The hydrogen atoms of the picolyl-CH_2 groups are magnetically inequivalent, forming an AB system with a coupling constant of about 15.5 Hz. Unlike in **2**, an additional small coupling of 1.5 Hz (**8a**) and 3.4 Hz (**8b**) was observed. All other NMR signals could be as-

signed unambiguously by analogy with **2** and with the help of 2D NMR spectroscopy. Finally, both compounds **8a** and **8b** were reversibly oxidized at −0.27 V vs. Fc/Fc^+ in CH_2Cl_2. All of these analytical properties demonstrated that neither the carbonyl group nor the attached biomolecule have a strong influence on the spectroscopic properties of the Mo(bpa)$(CO)_3$ group.

Discussion

The experimental and spectroscopic results described above show that the properties of **1** and **2** are similar to those of their 1,4,7-triazacyclonane and hydridotris(pyrazolyl)borate analogues. However, differences in reactivity and electrochemical behaviour between these three types of compounds were observed. Compounds **1** and **2** showed reversible one-electron oxidations with Bu_4NPF_6 as supporting electrolyte at potentials similar to those for the tacn derivatives, whereas the Mo^0/Mo^I transition for [Mo{HB$(Me_2pz)_3$}$(CO)_3]^-$ occurred at a slightly higher potential. With Bu_4NBr as supporting electrolyte, **1** and **2** each underwent electrochemically irreversible two-electron oxidation, to yield the seven-coordinated complexes [Mo(bpa)$(CO)_3Br]^+$ and [Mo(Bz-bpa)$(CO)_3Br]^+$, respectively. These Mo^{II} complexes could be reduced once more at a potential of around −1.0 V, again yielding complexes **1** and **2**. For the complexes [Mo(R_3-tacn)$(CO)_3$] (R = Me or benzyl), electrochemical formation of [Mo(R_3-tacn)$(CO)_3Br]^+$ was reported, but the corresponding re-reduction to yield the Mo^0 complexes was not observed between +2.0 V and −2.0 V.[25,48] One difference in reactivity between [Mo(bpa)$(CO)_3Br]^+$ and [Mo(tacn)$(CO)_3Br]^+$ is that the latter compound could be crystallized from aerobic aqueous solutions,[35] whereas the former reacted further to yield the dinuclear Mo^V complex [Mo_2(bpa)$_2(O)_2$(μ-$O)_2$](Br,PF_6).

Another difference from the analogous tacn and hydridotris(pyrazolyl)borate complexes was observed in the solution infrared spectra of **1** and **2**, since **1** and **2** have point-group symmetry C_s, whereas the tacn and hydridotris(pyrazolyl)borate complexes are of point-group symmetry C_{3v}. The degeneracy of the vibrations of *E* symmetry in the tacn and hydridotripyrazolylborate complexes is abolished in **1** and **2**.

A suitable organometallic labelling group for biomolecules must be readily introducible. For both the tacn and pyrazolylborate ligands, selective monosubstitution with a handle for labelling is difficult to achieve. The bpa ligand, on the other hand, is readily substituted with a carboxylic acid group. Reaction between (activated) organometallic acids and free amino groups in the biomolecule has long been known to be a successful strategy.[55−60] Secondly, the bioconjugate must be stable in water and air for quite some time. In addition, the property of the labelling group that is to be used for detection of the conjugate should not depend much on the attached biomolecule. Jaouen and coworkers have developed IR spectroscopy of bioorganometallic compounds into an immunoassay (*C*arbonyl *M*etallo *I*mmuno *A*ssay, CMIA) and thereby demonstrated the suitability of IR spectroscopy as a sensitive and reliable detection method.[2,4,61,62] We have recently reported amino acid and peptide derivatives of [CpMo(allyl)$(CO)_2$].[7] These compounds were readily isolated in the presence of water and showed promising spectroscopic properties. However, they could not be reversibly oxidized and did not show the required long-term stability in air. We were then able to show that isolobal replacement of the cyclopentadienyl ligand with histidinate resulted in complexes of the general type [Mo(His)(allyl)$(CO)_2$], with very favourable electrochemical properties and much increased stability towards air even in solution.[8,9]

In this work, we have demonstrated that *fac*-Mo$(CO)_3$ derivatives of the bpa ligand are well suited for the labelling of biomolecules. On comparing benzyl-substituted [Mo(Bz-bpa)$(CO)_3$] (**2**) to the bioconjugates **8** we note that there is very little influence of the attached biomolecule on the spectroscopic properties of the metal complex. Owing to this property, as well as its demonstrated stability in an aqueous, aerobic environment, this group is a well-suited marker for biomolecules. We are currently extending the chemistry described here to other biomolecules, as well as towards solid-phase synthesis of peptides.

Experimental Section

General: All syntheses and manipulations of the metal complexes were performed under argon by standard Schlenk techniques, unless otherwise noted. All solvents were deoxygenated before use unless otherwise noted. Elemental analyses were performed by H. Kolbe, Microanalytisches Laboratorium, Mülheim/Ruhr, Germany. Infrared spectra were recorded with a Perkin−Elmer FT-IR spectrophotometer 2000 as KBr disks and/or in THF solutions between NaCl windows (either a 0.5-mm or 1.0-mm spacer), with a spectral resolution of either 2.0 cm^{-1} or 4.0 cm^{-1}. For the IR spectroelectrochemical measurements, an OTTLE cell consisting of CaF_2 windows with a pathlength of 0.17 mm was used (2.0 cm^{-1} resolution). ^1H and ^{13}C NMR spectra were recorded with Bruker ARX 250 (^1H at 250.13 MHz), Bruker DRX 400 (^1H at 400.13 MHz) and Bruker DRX 500 (^1H at 500.35 MHz) spectrometers. The spectra were referenced to TMS, using the ^{13}C or residual protio signals of the deuterated solvents as internal standards. ^{95}Mo NMR spectra were recorded with a Bruker DRX 500 spectrometer (32.6 MHz for ^{95}Mo), with a 2 M Na_2MoO_4 solution in D_2O at an apparent pH = 11 as an external standard. Mass spectra in the electron impact mode (EI; 70 eV) were recorded with a Finnigan MAT 8200 mass spectrometer. Only characteristic fragments are given, with intensities in parentheses and possible composition between brackets. The spectra were normalized against the most intense peak, which therefore had intensity 100%. ElectroSpray Ionisation mass spectra (ESI-MS) in the positive ion mode were recorded with a Hewlett−Packard HP 5989 mass spectrometer. The solvent used is given in parentheses, and the possible composition of the peaks is between brackets. Electronic spectra were recorded with a Hewlett−Packard HP 8452A diode array spectrophotometer. Cyclic voltammograms and square-wave voltammograms in CH_2Cl_2 or MeCN solutions with Bu_4NPF_6 or Bu_4NBr as supporting electrolytes were recorded with an EG&G Potentiostat/Galvanostat 273A.

A three-electrode cell was employed, with a glassy-carbon working electrode, a platinum-wire auxiliary electrode and an $Ag/AgNO_3$ reference electrode (0.01 M $AgNO_3$ in MeCN). For determination of the redox potentials, ferrocene was added as an internal standard. Controlled potential coulometry measurements (both for preparative purposes and for UV/Vis spectroelectrochemical studies) were performed in CH_2Cl_2 solutions with the same supporting electrolytes by employing the potentiostat described above, but with a Pt-grid as working electrode, a Pt-brush auxiliary electrode separated from the working electrode compartment by a vycor frit and a $Ag/AgNO_3$ (0.01 M $AgNO_3$ in MeCN) reference electrode. Thin layer infrared spectro-electrochemical measurements were performed with an OTTLE cell of 0.17 mm optical pathlength consisting of a Pt-grid working electrode, a glassy-carbon counterelectrode and a Ag-wire as "quasi-reference electrode". The EPR spectrum was recorded as a frozen solution (generated by controlled potential coulometry) with a Bruker ESP 300E spectrometer, equipped with an ER 041 XK-D microwave bridge. The EPR spectrum was simulated with the program GFIT.[63] Bis(2-picolylamine) and $Mo(CO)_6$ were purchased from Aldrich. The compounds *N*-benzylbis(2-picolyl)amine,[64] $[Mo([9]aneN_3)(CO)_3]$,[35] $[Mo([9]aneN_3(CO)_3Br]Br_3$,[35] $[Mo(Me_3[9]aneN_3)(CO)_3]$,[48] and $[Mo(CO)_3(EtCN)_3]$[65] were synthesized according to literature procedures.

Compound 1: A suspension of bis(2-picolyl)amine (1.0 g, 5.0 mmol) and $Mo(CO)_6$ (1.3 g, 5.0 mmol) in degassed di-*n*-butyl ether (75 mL) was heated at 150 °C for 1 h, during which a deep yellow precipitate formed. After the mixture had been allowed to reach room temperature, the solid material was collected by filtration and dried in vacuo. Yield: 1.8 g (95%). Crystals suitable for X-ray analysis were grown by slow concentration of a CH_3CN/H_2O mixture (5:1, v/v) under a stream of argon. $C_{15}H_{13}MoN_3O_3$ (379.22): calcd. C 47.51, H 3.46, N 11.08; found C 47.15, H 3.40, N 11.03. IR (KBr): $\tilde{\nu}$ = 3323 (w) ν_{NH}, 1901 (s), 1891 (vs), 1784 (s), 1769 (s), 1742 (vs) ν_{CO}. IR (THF): $\tilde{\nu}$ = 1904 (vs), 1790 (s), 1779 (s) ν_{CO}. MS (EI): *m/z* (%) = 381 (14) $[M^+]$, 353 (2) $[M - CO]^+$, 325 (1) $[M - 2\,CO]^+$, 297 (31) $[M - 3\,CO]^+$, 93 (100). ^1H NMR ($[D_6]$DMSO, 400.13 MHz): δ = 8.73 (app. d, 2 H, H_{Pyr}), 7.65 (m, 2 H, H_{Pyr}), 7.27 (app. d, 2 H, H_{Pyr}), 7.14 (pseudo t, 2 H, H_{Pyr}), 6.14 (t, $^3J_{H,H}$ = 6.6 Hz, 1 H, NH), 4.33 (dd, $^2J_{H,H}$ = 16.8, $^3J_{H,H}$ = 6.6 Hz, 2 H, CH_2), 4.06 (d, $^2J_{H,H}$ = 16.8 Hz, 2 H, CH_2). ^{13}C NMR ($[D_6]$DMSO, 62.9 MHz): δ = 231.4, 229.3 (CO), 159.5, 150.1, 137.5, 123.0, 122.0 (C_{Pyr}), 59.6 (CH_2). ^{95}Mo NMR (CH_3CN, 32.6 MHz): δ = −938 ($\Delta_{1/2}$ = 36 Hz).

Compound 2: A suspension of *N*-benzylbis(2-picolyl)amine (0.96 g, 3.30 mmol) and $Mo(CO)_6$ (0.88 g, 3.30 mmol) in deoxygenated mesitylene (40 mL) was heated at 150° C for 1 h, during which an orange solid precipitated. After the mixture had been allowed to cool to ambient temperature, the precipitate was isolated by filtration, washed with *n*-hexane (10 mL) and dried in vacuo. Yield: 1.28 g (83%). Crystals suitable for X-ray structure determination were grown by slow concentration of a CH_3CN/H_2O (10:1, v/v) solution under a stream of argon. $C_{22}H_{19}MoN_3O_3$ (469.34): calcd. C 56.30, H 4.08, N 8.95; found C 56.18, H 4.02, N 9.05. IR (KBr): $\tilde{\nu}$ = 1898 (vs), 1776 (s), 1752 (vs) ν_{CO}. IR (THF): $\tilde{\nu}$ = 1906 (vs), 1794 (s), 1782 (s) ν_{CO}. MS (EI): *m/z* (%) = 471 (6) $[M^+]$, 443 (4) $[M - CO]^+$, 387 (13) $[M - 3\,CO]^+$, 197 (100). ^1H NMR ($[D_6]$DMSO, 400.13 MHz): δ = 8.68 (app. d, 2 H, H_{Pyr}), 7.68 (m, 2 H, H_{Ar}), 7.59 (m, 2 H, H_{Ar}), 7.46 (m, 3 H, H_{Ar}), 7.16 (pseudo d, 2 H, H_{Ar}), 7.08 (m, 2 H, H_{Ar}), 4.67 (d, $^2J_{H,H}$ = 15.5 Hz, 2 H, CH_2), 4.66 (s, 2 H, $CH_{2,Bz}$), 3.72 (d, $^2J_{H,H}$ = 15.5 Hz, 2 H, CH_2). ^{13}C NMR (CD_3CN, 125.8 MHz): δ = 232.3, 231.3 (CO), 159.9, 151.6, 138.4, 133.6, 132.5, 129.7, 129.4, 124.1, 123.3 (C_{Ar}), 71.0 ($CH_{2,Bz}$), 65.4 (CH_2). ^{95}Mo (CH_3CN, 32.6 MHz): δ = −849 ($\Delta_{1/2}$ = 47 Hz).

Compound 3: Br_2 (1.0 g, 0.3 mL, 6.3 mmol) was added dropwise to a suspension of **1** (0.5 g, 1.3 mmol) in degassed $CHCl_3$ (50 mL), resulting in a clear orange-red solution. The mixture was stirred for 45 min, during which an orange-brown powder precipitated. The solid was collected by filtration, washed with $CHCl_3$ (10 mL) and pentane (10 mL) and air-dried. Yield: 0.66 g (73%). $C_{15}H_{13}Br_4MoN_3O_3$ (698.84): calcd. C 25.78, H 1.88, N 6.01; found C 25.20, H 1.79, N 5.97. IR (KBr): $\tilde{\nu}$ = 3155 (w) ν_{NH}, 2037 (s), 1950 (br, vs) ν_{CO}. IR (THF): $\tilde{\nu}$ = 2055 (s), 1989 (s), 1935 (s) ν_{CO}. MS (ESI-pos., CH_2Cl_2): *m/z* = 460 $[Mo(bpa)(CO)_3Br]^+$, 432 $[Mo(bpa)(CO)_2Br]^+$, 404 $[Mo(bpa)(CO)Br]^+$, 376 $[Mo(bpa)Br]^+$.

Compound 4: $[Mo(bpa)(CO)_3Br]Br_3$ (**3**, 0.5 g, 0.7 mmol) was dissolved in MeOH (30 mL) under aerobic conditions, followed by addition of a KPF_6 (0.66 g, 3.60 mmol) solution in H_2O (10 mL). Upon standing overnight, an orange powder formed; this was isolated by filtration, washed with Et_2O (15 mL) and air-dried. Yield: 0.21 g (68%). Crystals suitable for X-ray diffraction were obtained by slow concentration of an MeOH solution. $C_{24}H_{26}BrF_6Mo_2N_6O_4P$ (879.25): calcd. C 32.78, H 2.98, N 9.56; found 32.67, H 2.91, N 9.47. IR (KBr): $\tilde{\nu}$ = 962 (m) $\nu_{Mo=O}$, 747 (m) $\nu_{as}[M - O]$. MS (ESI-pos., MeOH): *m/z* = 737 $[M - PF_6]^+$, 657 $[M - PF_6 - HBr]^+$, 327 $[M - PF_6 - Br]^{2+}$. ^{13}C NMR ($[D_6]$DMSO, 62.9 MHz): δ = 158.6, 151.7, 142.4, 125.7, 124.2 (C_{Pyr}), 55.3 (CH_2). ^1H NMR ($[D_6]$DMSO, 250.13 MHz) shows broadened signals at room temperature. This could be due to paramagnetic impurities or coalescence as found for a related compound.[37]

Compound 5: NEt_3 (0.69 mL, 5.00 mmol) was added to a solution of bis(2-picolyl)amine (1.0 g, 5.0 mmol) and methyl *p*-(bromomethyl)benzoate (1.15 g, 5.00 mmol) in THF (35 mL), and the mixture was refluxed for 1.5 h. The mixture was allowed to reach room temperature and subsequently filtered to remove a white precipitate. After removal of the solvent under reduced pressure, the oily residue was redissolved in Et_2O (40 mL) and filtered to remove a red solid. Evaporation of the solvent yielded 1.4 g (81%) of a light orange oil, which was used as such in the next step. $C_{21}H_{21}N_3O_2$ (347.4). MS (EI): *m/z* = 347 (2) $[M^+]$, 316 (2) $[M - OCH_3]^+$, 255 (100) $[M - C_6H_6N]^+$. ^1H NMR ($CDCl_3$, 250.1 MHz): δ = 8.49 (app. d, 2 H, H_{pyr}), 7.95 (d, $^3J_{H,H}$ = 8.3 Hz, 2 H, H_{Ar}), 7.62 (pseudo t, 2 H, H_{pyr}), 7.52 (pseudo d, 2 H, H_{pyr}), 7.46 (d, ^3J = 8.3 Hz, 2 H, H_{Ar}), 7.12 (pseudo t, 2 H, H_{pyr}), 3.87 (s, 3 H, OCH_3), 3.78 (s, 4 H, $CH_{2,picolyl}$), 3.71 (s, 2 H, CH_2). ^{13}C ($CDCl_3$, 100.6 MHz): δ = 166.9 (C=O), 159.3 (C_q, pyr), 148.9 (C_{Pyr}), 144.5 ($C_{Ar,q}$), 136.3 (C_{Pyr}), 129.5 (C_{Ar}), 128.9 ($C_{Ar,q}$), 128.6 (C_{Ar}), 122.7 (C_{Pyr}), 122.0 (C_{Pyr}), 60.0 (CH_2, picolyl), 58.1 (CH_2), 51.9 (OCH_3).

Compound 6: A solution of NaOH (0.8 g, 20 mmol) in 5 mL of H_2O was added to a solution of **5** (1.4 g, 4.0 mmol) in MeOH (20 mL), and the mixture was stirred for 2 h at ambient temperature. The pH was adjusted to 7 by dropwise addition of 2 M HCl, followed by removal of the solvent under reduced pressure. The sticky white residue was triturated with $CHCl_3$ (200 mL), followed by filtration to remove NaCl. The $CHCl_3$ solution was dried with $MgSO_4$. Removal of the solvent under reduced pressure afforded a yellow sticky oil, to which CH_3CN (30 mL) was added, followed by vigorous stirring. After approximately 15−30 min, a white precipitate formed. The solution was stored at 0 °C for 2 h, to effect further precipitation and the white solid was then isolated by filtration and dried in vacuo. Yield 0.7 g (53%). $C_{20}H_{19}N_3O_2$ (333.4). IR (KBr): $\tilde{\nu}$ = 1698 (m) $\nu_{C=O}$. MS (EI): *m/z* = 333 (1) $[M]^+$, 241 (100)

$[M - C_6H_6N]^+$. ^1H NMR ($CDCl_3$, 250.1 MHz): δ = 11.35 (br, 1 H, CO_2H), 8.59 (app. d, 2 H, H_{Pyr}), 8.01 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, H_{Ar}), 7.66 (pseudo t, 2 H, H_{Pyr}), 7.59 (app. d, 2 H, H_{Pyr}), 7.44 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, H_{Ar}), 7.80 (pseudo t, 2 H, H_{Pyr}), 3.85 (s, 4 H, CH_2), 3.73 (s, 2 H, $CH_{2,Bz}$). ^{13}C NMR ($CDCl_3$, 62.9 MHz): δ = 169.3 (C=O), 159.8, 148.4, 143.1, 137.2, 130.0, 128.8, 123.4, 122.4, 122.0 (all C_{Ar}), 59.3 (CH_2), 58.2 ($CH_{2,Bz}$).

Compound 7a: NEt_3 (1.0 mL, 0.7 g, 7.2 mmol), phenylalanine methyl ester hydrochloride (216 mg, 1.0 mmol), and TBTU (323 mg, 1.0 mmol) were added to a suspension of **6** (333 mg, 1.0 mmol) in CH_3CN (10 mL), and the mixture was stirred for 30 min at ambient temperature. After evaporation of the solvent in vacuo, CH_2Cl_2 (100 mL) was added to the sticky residue, followed by filtration to remove ammonium salts. The CH_2Cl_2 solution was washed with aqueous 2 M $NaHCO_3$ (75 mL) and the phases were separated. The aqueous phase was extracted with CH_2Cl_2 (2 × 75 mL) and the combined organic extracts were dried with $MgSO_4$. Most of the solvent was removed under reduced pressure, followed by further evaporation of the solvent in vacuo, affording a light yellow, glassy solid. Yield: 440 mg (89%). $C_{30}H_{30}N_4O_3$ (494.6). MS (EI): *m*/*z* = 494 (3) $[M]^+$, 463 (1) $[M - OCH_3]^+$, 435 (2) $[M - CO_2CH_3]^+$, 402 (100) $[M - C_6H_6N]^+$. ^1H NMR ($CDCl_3$, 250.13 MHz): δ = 8.49 (m, 2 H, H_{pyr}), 7.63 (m, 4 H, H_{Ar}), 7.50 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, H_{Ar}), 7.43 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, H_{Ar}), 7.24 (m, 3 H, H_{Ar}), 7.01 (m, 4 H, H_{Ar}), 6.57 (d, $^3J_{H,H}$ = 8.2 Hz, 1 H), 5.06 (m, 1 H, $C_\alpha H$), 3.76 (s, 4 H, CH_2), 3.72 (s, 3 H, OCH_3), 3.68 (s, 2 H, $CH_{2,Bz}$), 3.21 (m, 2 H, $C_\beta H_2$). ^{13}C NMR ($CDCl_3$, 62.9 MHz): δ = 172.1 ($C{=}O_{ester}$), 166.9 ($C{=}O_{amide}$), 159.0, 148.7, 142.9, 136.7, 136.0, 132.6, 129.1, 128.8, 128.5, 127.1, 127.0, 122.9, 122.2 (C_{Ar}), 59.7 (CH_2), 58.0 ($CH_{2,Bz}$), 53.6, 52.3 (C_α and OCH_3), 37.6 (C_β).

Compound 7b: The dipeptide Boc-Ala-Phe-OMe (350 mg, 1.0 mmol) was dissolved in CH_2Cl_2 (5 mL) and CF_3CO_2H (10 mL), and the mixture was stirred for 1 h at room temperature. After removal of the solvent in vacuo, Et_2O (15 mL) was added to the residue, followed by removal of the solvent in vacuo. This last step was performed three times in order to remove any traces of trifluoroacetic acid. The solid, white residue was suspended in CH_3CN (10 mL), followed by addition of NEt_3 (1.50 mL, 1.09 g, 10.8 mmol), compound **6** (333 mg, 1.0 mmol), and TBTU (323 mg, 1.0 mmol). After the mixture had been stirred at ambient temperature for 30 min, the solvent was removed in vacuo. To the sticky residue was added CH_2Cl_2 (100 mL), followed by filtration to remove ammonium salts. The CH_2Cl_2 solution was washed with aqueous $NaHCO_3$ (2 M, 75 mL), followed by separation of the phases. The aqueous phase was extracted with CH_2Cl_2 (2 × 75 mL), and the combined organic extracts were dried with $MgSO_4$. Most of the CH_2Cl_2 was removed under reduced pressure, followed by further evaporation of the solvent in vacuo, affording a white glassy solid. Yield: 520 mg (92%). $C_{33}H_{35}N_5O_4$ (565.7). MS (EI): *m*/*z* = 565 (6) $[M]^+$, 534 (3) $[M - OCH_3]^+$, 506 (1) $[M - CO_2CH_3]^+$, 473 (100) $[M - C_6H_6N]^+$. ^1H NMR ($CDCl_3$, 400.13 MHz): δ = 8.51 (app. d, 2 H, H_{Pyr}), 7.69 (m, 4 H, H_{Ar}), 7.53 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, H_{Ar}), 7.46 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, H_{Ar}), 7.18 (m, 2 H, H_{Ar}), 7.06 (m, 5 H, H_{Ar}), 6.92 (m, 2 H, both NH), 4.80 (m, 1 H, $C_\alpha H$), 4.66 (m, 1 H, $C_\alpha H$), 3.91 (s, 4 H, CH_2), 3.82 (s, 2 H, $CH_{2,Bz}$), 3.67 (s, 3 H, OCH_3), 3.09 (m, 1 H, $C_{\beta,Phe}H$), 3.00 (m, 1 H, $C_{\beta,Phe}H$), 1.40 (d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3). ^{13}C NMR ($CDCl_3$, 100.6 MHz): δ = 172.0, 171.7 ($C{=}O_{ester}$ and $C{=}O_{Ala\text{-}Phe}$), 166.7 (C=O), 157.7, 148.4, 137.3, 135.7, 132.9, 129.2, 129.1, 128.4, 127.3, 127.0, 123.5, 122.6 (C_{Ar}), 59.2 (CH_2), 58.1 ($CH_{2,Bz}$), 53.4, 52.3 (OCH_3 and $C_{\alpha,Phe}$), 49.0 ($C_{\alpha,Ala}$), 37.7 ($C_{\beta,Phe}$), 18.2 ($CH_{3,Ala}$).

Compound 8a: A solution of **7a** (0.40 g, 0.80 mmol) in THF (10 mL) was added dropwise to a stirred solution of $Mo(CO)_3(NCEt)_3$ (0.28 g, 0.80 mmol) in THF (15 mL). The mixture was stirred for 10 min at room temperature, during which an orange precipitate formed. The mixture was concentrated to about 15 mL in vacuo, and the orange solid was collected by filtration, washed with Et_2O (10 mL) and dried in vacuo. Yield: 0.44 g (82%). $C_{33}H_{30}MoN_4O_6$ (674.55): calcd. C 58.76, H 4.48, N 8.31; found C 53.13, H 4.67, N 8.92; (repeated attempts did not improve the C values). IR (KBr): $\tilde{\nu}$ = 1900 (vs) ν_{CO}, 1779 (s) ν_{CO}, 1759 (s) ν_{CO} + $\nu_{C=O}$. IR (THF): $\tilde{\nu}$ = 1906 (vs), 1793 (s), 1782 (s) ν_{CO}. MS (FAB-pos.; dimethoxybenzyl alcohol): *m*/*z* = 676 $[M]^+$, 648 $[M - CO]^+$. ^1H NMR (CD_3CN, 500.35 MHz): δ = 8.77 (m, 2 H, H_{Pyr}), 7.81 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, H_{Ar}), 7.62 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, H_{Ar}), 7.49 (m, 2 H, H_{Ar}), 7.31 (m, 5 H, NH and $H_{Ar,Phe}$), 7.24 (m, 1 H, $H_{Ar,Phe}$), 7.00 (m, 4 H, H_{Pyr}), 4.92 (m, 1 H, $C_\alpha H$), 4.76 (s, 2 H, $CH_{2,Bz}$), 4.51 (d, $^2J_{H,H}$ = 15.4 Hz, 2 H, CH_2), 3.73 (dd, $^2J_{H,H}$ = 15.4, $^4J_{H,H}$ = 1.6 Hz, 2 H, CH_2), 3.69 (s, 3 H, OCH_3), 3.32 (m, 1 H, $C_\beta H$), 3.17 (m, 1 H, $C_\beta H$). ^{13}C NMR (CD_3CN, 125.8 MHz): δ = 232.3, 231.3 (CO), 173.1 ($C{=}O_{ester}$), 167.4 ($C{=}O_{amide}$), 159.8, 151.7, 138.4, 138.3, 137.1, 135.0, 132.8, 130.2, 129.5, 128.2, 127.8, 124.1, 123.3 (C_{Ar}), 70.4 ($CH_{2,Bz}$), 65.5 (CH_2), 55.2, 52.9 (OCH_3 + C_α), 38.0 (C_β).

Compound 8b: A solution of **7b** (0.40 g, 0.80 mmol) in THF (10 mL) was added dropwise to a stirred solution of $Mo(CO)_3(NCEt)_3$ (0.28 g, 0.80 mmol) in THF (15 mL). Stirring was continued for 10 min at room temperature, during which an orange precipitate formed. The mixture was concentrated to about 15 mL in vacuo, and the orange solid was collected by filtration, washed with Et_2O (10 mL) and dried in vacuo. Yield: 0.47 g (79%). $C_{36}H_{35}MoN_5O_7$ (745.63): calcd. C 57.99, H 4.73, N 9.39; found C 58.09, H 4.82, N 9.26. IR (KBr): $\tilde{\nu}$ = 1900 (vs) ν_{CO}, 1778 (s) ν_{CO}, 1761 (s) ν_{CO} + $\nu_{C=O}$. IR (THF): $\tilde{\nu}$ = 1906 (vs), 1793 (s), 1782 (s) ν_{CO}. MS (FAB-pos.; dimethoxy benzyl alcohol): *m*/*z* = 747 $[M]^+$, 719 $[M - CO]^+$. ^1H NMR ([D$_6$]DMSO, 500.35 MHz): δ = 8.69 (app. d, 2 H, H_{Pyr}), 8.49 (d, $^3J_{H,H}$ = 7.6 Hz, 1 H, NH), 8.30 (d, $^3J_{H,H}$ = 7.6 Hz, 1 H, NH), 7.97 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, H_{Ar}), 7.80 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, H_{Ar}), 7.59 (pseudo t, 2 H, H_{Pyr}), 7.22 (m, 5 H, $H_{Ar,Phe}$), 7.15 (app. d, 2 H, H_{Pyr}), 7.09 (pseudo t, 2 H, H_{Ar}), 4.72 (s, 3 H, $CH_{2,Bz}$ and CH_2), 4.69 (d, $^4J_{H,H}$ = 3.4 Hz, 1 H, CH_2), 3.71 (dd, $^2J_{H,H}$ = 15.7, $^4J_{H,H}$ = 3.4 Hz, 2 H, CH_2), 4.56 (m, 1 H, $C_\alpha H$), 4.50 (m, 1 H, $C_\alpha H$), 3.59 (s, 3 H, OCH_3), 3.03 (m, 1 H, $C_\beta H_{Phe}$), 2.99 (m, 1 H, $C_\beta H_{Phe}$), 1.32 (d, $^3J_{H,H}$ = 7.2 Hz, 3 H, $CH_{3,Ala}$). ^{13}C NMR ([D$_6$]DMSO, 125.8 MHz): δ = 231.2, 230.3 (CO), 172.4, 171.8 ($C{=}O_{ester}$ + $C{=}O_{Ala}$), 165.6 (C=O), 158.8, 150.0, 137.5, 137.0, 135.4, 134.0, 131.4, 129.1, 128.2, 127.5, 126.5, 123.0, 122.3 (C_{Ar}), 68.9 ($CH_{2,Bz}$), 64.2 (CH_2), 53.6, 51.8 ($C_{\alpha,Phe}$ and OCH_3), 48.6 ($C_{\alpha,Ala}$), 36.6 ($C_{\beta,Phe}$), 17.7 ($CH_{3,Ala}$).

X-ray Crystallography: Transparent yellow single crystals of **1** and **2** were coated with perfluoropolyether, picked up with glass fibres and mounted on a Nonius Kappa-CCD diffractometer, equipped with a rotating Mo anode setup. An orange/yellow crystal of **4** was mounted on a Siemens SMART diffractometer with a sealed X-ray tube. Both diffractometers were equipped with graphite monochromators [λ(Mo-K_α) = 0.71073 Å] and a cryogenic nitrogen stream operating at 100(2) K. Crystallographic data of the compounds are listed in Table 6. Cell constants were obtained from a least-squares fit of the diffraction angles of several thousand strong reflections. Intensity data were corrected for Lorentz and polarisation effects. Crystal faces of **4** were determined and the face-indexed correction routine embedded in SHELXTL[41] was used to account for absorption, giving minimum and maximum transmission factors of 0.642 and 0.882. Intensity data of **2** were corrected by use of the

semiempirical correction program MULSCANABS, part of the PLATON99[66] program suite, giving transmission factors of 0.757 and 0.944. Intensity data of **1** were left uncorrected. The Siemens SHELXTL[41] software package was used for solution, refinement, and depiction of the structures, and neutral atom scattering factors of the program were used. Non-hydrogen atoms were refined anisotropically, and hydrogen atoms were placed at calculated positions and refined as riding atoms with isotropic displacement parameters. CCDC-168208 (**1**), -168209 (**2**) and -168210 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

The experimental work described in this article was carried out at the Max-Planck-Institut für Strahlenchemie. The authors are grateful to Professor K. Wieghardt for generous support of our work and to Professor P. Chaudhuri for many helpful discussions. Dr. E. Bill is thanked for his help with the EPR spectroscopic data acquisition and interpretation. Kerstin Sand and Jörg Bitter are kindly acknowledged for recording the NMR spectra. Heike Schucht and Petra Höfer are thanked for their technical assistance with the X-ray crystal structure determination and spectro-electrochemical measurements, respectively. This work was supported financially by the Fond der Chemischen Industrie and a Karl-Ziegler fellowship (N. M.-N.).

Synthesis, Characterization, and Interconversion of the Rhenium Polyhydrides $[ReH_3(\eta^4\text{-}NP_3)]$ and $[ReH_4(\eta^4\text{-}NP_3)]^+$ {NP_3 = tris[2-(diphenylphosphanyl)-ethyl]amine}

Alberto Albinati,[a] Vladimir I. Bakhmutov,*[b] Natalia V. Belkova,[c] Claudio Bianchini,*[d] Isaac de los Rios,[d] Lina Epstein,*[c] Evgenii I. Gutsul,[c] Lorenza Marvelli,[e] Maurizio Peruzzini,*[d] Roberto Rossi,*[e] Elena Shubina,[c] Evgeni V. Vorontsov,[c] and Fabrizio Zanobini[d]

Keywords: Rhenium / Tripodal ligands / Phosphanes / Hydride ligands

The rhenium(III) dichloride complex $[ReCl_2(\eta^4\text{-}NP_3)]Cl$ (**1**) was prepared from $[ReCl_3(CH_3CN)(PPh_3)_2]$ by treatment with the tripodal tetradentate ligand $N(CH_2CH_2PPh_2)_3$ (NP_3) in ethanol. The reaction of **1** with $LiAlH_4$ in THF gave the rhenium(III) trihydride $[ReH_3(\eta^4\text{-}NP_3)]$ (**2**), which was converted into the rhenium(V) tetrahydride $[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (**3**) by protonation in CH_2Cl_2 with $HBF_4{\cdot}OMe_2$, followed by a metathetical reaction with $NaBPh_4$. The classical polyhydride nature of **2** and **3**, as well as the overall molecular structures in solution, were determined by NMR spectroscopy, ^1H NMR relaxation, and IR spectroscopy. The polyhydride complexes **2** and **3** are stereochemically nonrigid in solution, and the thermodynamic parameters associated with the fluxional processes were determined by variable-temperature NMR studies. A single-crystal X-ray analysis of **3** has shown the complex cation $[ReH_4(\eta^4\text{-}NP_3)]^+$ to be eight-coordinated by the four donor atoms of NP_3 and by four terminal hydride ligands in a distorted dodecahedral geometry. An in situ IR study in CH_2Cl_2 has shown that the protonation of **3** occurs regioselectively at the metal center with no formation of a dihydrogen complex. Kinetic hydrogen bond products of the formula $[(\eta^4\text{-}NP_3)H_3Re{\cdots}HOR]$ (ROH = C_2H_5OH, CFH_2CH_2OH, CF_3CH_2OH) were intercepted by IR spectroscopy at low temperature. The thermodynamic parameters associated with the formation of the hydrogen bond adducts were determined by either IR spectroscopy applying the Iogansen equation or van't Hoff plots of the formation constant vs. temperature.

Introduction

In conjunction with phosphane ligands, rhenium can form stable polyhydride complexes in a variety of metal oxidation states, coordination numbers, and structures.[1] In particular, both classical ($Re-H_x$) and nonclassical $[Re-(H_2)_x]$ structures have been reported, which may contain as many as seven hydride ligands.[1] The ability to react with either dihydrogen or hydride ions from different sources makes phosphanerhenium systems effective hydrogen sponges. Unlike late transition metals, however, the coordinated hydrogen is not easily transferred to unsaturated substrates, which limits the application of rhenium-based catalysts in catalytic hydrogenations.[2] On the other hand, the capability to form homologous series of polyhydride complexes, often in equilibrium with each other by dihydrogen loss/uptake, confers to phosphanerhenium compounds a great potential both in hydrogen storage and transport, which will be a priority in chemistry in the next years,[3] and for model studies of hydride-containing enzymes such as nitrogenases and hydrogenases.[4] Moreover, the chemistry of rhenium is very similar to that of the germane element technetium-99, which is largely used in diagnostics and radio therapeutics.[5] Although we are not aware of any utilization of technetium-99 or rhenium-186/188 polyhydrides (polydeuterides), it cannon be excluded a priori that such compounds may have important applications in nuclear medicine.

Tripodal polyphosphane ligands are particularly amenable to forming stable polyhydride rhenium compounds due to the nucleophilicity of trivalent phosphorus as well as the ability to generate sterically congested pockets into which the metal atom is almost buried. These ligands may therefore react only with small molecules or ions.[6]

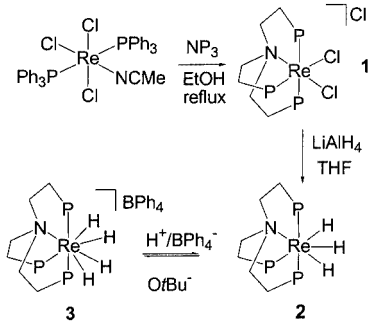
The "hydride" chemistry of rhenium with the tripodal tridentate ligand $MeC(CH_2PPh_2)_3$ (triphos) has been intensely investigated in the last few years, leading to interesting results with regard to the formation of classical and nonclassical polyhydrides with the metal center in the oxidation states from +1 to +7.[7−9] In contrast, no rhenium complex with the potentially tetradentate aminophosphane $N(CH_2CH_2PPh_2)_3$ (NP_3) has been described in the literature, which is surprising as (NP_3)metal complexes are known for almost all middle and late-transition metals[6,10] including technetium.[11] A rhenium(III) tetrahydride with the tripodal phosphane ligand $P(CH_2CH_2PPh_2)_3$ has been described, but no X-ray structure was reported.[12]

The presence of the amine nitrogen donor and of two CH_2 spacers separating the phosphorus donors from the bridgehead atom makes NP_3 more flexible than triphos and also increases the overall basicity at the coordinated metal center.[13,14] Ultimately, this may result in increased stability of Re−H_x moieties as well as a richer diversity of coordination geometries since NP_3 may act as an η^4, η^3-*P*$_3$, η^3-*N*,*P*,*P*, and η^2-*P*,*P* ligand.[14]

In this article we describe the synthesis, structure, and spectroscopic characterization of the first rhenium(III) and rhenium(V) polyhydride complexes stabilized by NP_3, using $[ReCl_2(\eta^4\text{-}NP_3)]Cl$ (**1**) as a precursor. Particular attention was paid to the study of the solution structure of the complexes $[ReH_3(\eta^4\text{-}NP_3)]$ (**2**) and $[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (**3**), as well as the proton transfer that converts **2** into **3** via hydrogen bond adducts $[(\eta^4\text{-}NP_3)H_3Re\cdots HOR]$.

Results and Discussion

The preparations and the principal reactions described in this paper are reported in Scheme 1. Selected IR spectroscopic data for the new complexes are given in the Exp. Sect. together with analytical and physicochemical properties.



Scheme 1

Synthesis and Characterization of $[ReCl_2(\eta^4\text{-}NP_3)]Cl$ (1)

By reaction of NP_3 with the rhenium(III) complex $[ReCl_3(CH_3CN)(PPh_3)_2]$ in refluxing ethanol, the complex $[ReCl_2(\eta^4\text{-}NP_3)]Cl$ (**1**) was obtained in good yield as air-stable lemon-yellow microcrystals. The combined analytical, conductivity and spectroscopic characterization of **1** is unequivocally consistent with an octahedral geometry of the complex cation $[ReCl_2(\eta^4\text{-}NP_3)]^+$ with all the four donor atoms of NP_3 coordinated to the metal center. Complex **1** is paramagnetic (μ_{eff} = 2.0 μ_B) and thus the $^{31}P\{^1H\}$ NMR spectrum did not provide any useful information due to the rapid relaxation of the coordinated phosphorus nuclei. The ^1H NMR spectrum exhibit the typical Knight-shifted appearance[7] with relatively sharp resonances, some of which feature unusually large shifts (up to $\delta = -40.83$).

Synthesis and Characterization of the Classical Rhenium(III) and Rhenium(V) Polyhydrides $[ReH_3(\eta^4\text{-}NP_3)]$ (2) and $[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (3)

The dichloride **1** was quantitatively converted into the ivory-colored trihydride complex $[ReH_3(\eta^4\text{-}NP_3)]$ (**3**) by treatment with a large excess (ca. 20 equiv.) of $LiAlH_4$ in refluxing THF for 6 h. The reaction was conveniently monitored by $^{31}P\{^1H\}$ NMR spectroscopy, which showed no intermediate species along the conversion of **1** to **2**.

Complex **2** is air-stable in both the solid state and solutions of both CH_2Cl_2 and $CHCl_3$, in which no H/Cl exchange was observed within 24 h at room temperature. The IR spectrum contains two strong ν(Re−H) absorptions at 1949 and 1905 cm^{-1} that shifted to lower frequencies in the spectrum of the perdeuterated derivative $[ReD_3(\eta^4\text{-}NP_3)]$ (**2-D$_3$**) [ν(Re−D) = 1399 and 1371 cm^{-1}, $k_{H/D}$ = 1.39]. The perdeuterated derivative was prepared by treating **1** with $LiAlD_4$ in refluxing THF.

The trihydride **2** is fluxional on the NMR time scale. In CD_2Cl_2, the slow-exchange $^{31}P\{^1H\}$ NMR spectrum was attained at −63 °C in the form of two broad lines at δ = 52.9 (1 P) and 36.6 (2 P). On increasing the temperature, the two NMR signals coalesced between −30 and −35 °C and then transformed into a single resonance at δ = 41.9 at room temperature. The exchange process of the three phosphorus atoms matches the fluxionality of the hydride resonances. Indeed, the ^1H NMR spectrum of **2** at −63 °C showed two hydride signals at δ = −4.05 (1 H) and −9.50 (2 H) that transformed into a quadruplet at δ = −7.6 with *J*(HP) = 13.4 Hz on increasing the temperature to 22 °C. The coalescence of the hydride resonances was observed at −23 °C from which a free activation energy ($\Delta G^{\neq}_{250K}$) of 44.8 kJ mol^{-1} could be calculated by using the Shanan Atidi-Bar Eli approach that takes into account the different populations of the exchanging sites.[15] The low-temperature limiting spectrum of **2** points to a pentagonal-bipyramidal structure in solution (seven-coordination geometry) that has been already observed for rhenium polyhydrides.[1e,7,12]

Treatment of the trihydride **2** in THF or dichloromethane with protic acids such as $HOSO_2CF_3$, $HBF_4{\cdot}OMe_2$, or CF_3COOH, followed by a metathetical reaction with $NaBPh_4$ in EtOH, gave off-white crystals of the classical tetrahydride complex $[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (**3**). The protonation is reversible: the reaction with strong bases, such as KO*t*Bu, in THF regenerated the neutral trihydride **2** quantitatively.

Compound **3** was air-stable in both the solid state and solution and behaved as a typical 1:1 electrolyte in dichloro-

methane. The solid-state IR spectrum shows a strong and sharp absorption at 1996 cm^{-1} due to the ν(Re−H) vibration that shifted to 1435 cm^{-1} ($k_{H/D}$ = 1.39) in the perdeuterated derivative $[ReD_4(\eta^4\text{-}NP_3)]BPh_4$ (**3-D$_4$**). It is worth noting that no H/D exchange was observed when a solution of **3** in THF or CH_2Cl_2 was treated with either MeOD or D_2O even after prolonged heating to temperatures close to the boiling point (in situ NMR experiment). This behavior, which is not common for metal polyhydride complexes, is identical to that of the iron trihydride $[Fe(H)(\eta^2\text{-}H_2)(\eta^4\text{-}PP_3)]BPh_4$ containing the tripodal tetradentate ligand $P(CH_2CH_2PPh_2)_3$.[16] The addition of 1 equiv. of CF_3SO_3D to a CD_2Cl_2 solution of **3** at ambient temperature did not result in the incorporation of deuterium. At high temperature, extensive decomposition took place to give paramagnetic material, which was not characterized further.

In keeping with the behavior of the large majority of transition metal polyhydrides,[1e] the complex cation $[ReH_4(\eta^4\text{-}NP_3)]^+$ was stereochemically nonrigid in solution on the NMR time scale. At room temperature, the $^{31}P\{^1H\}$ NMR spectrum in CD_2Cl_2 showed a sharp ($\omega_{1/2} \approx 4$ Hz) singlet resonance at δ = 38.73 associated with a fast-exchange motion of the three phosphorus atoms of NP_3 (A_3 spin system). An off-resonance experiment, conserving a residual coupling between the hydride ions and the phosphorus atoms, transformed the singlet into a quintuplet [$J(PH)_{residual} \approx 7$ Hz], and confirmed the presence of four hydride ions coordinated to the rhenium atom. On decreasing the temperature, the ^{31}P NMR resonance broadened and then coalesced at ca. −70 °C to give a broad hump with $\omega_{1/2} \approx 185$ Hz. Decoalescence of the resonance occurred at a lower temperature, with formation of two distinct signals integrating 2:1. However, the decoalescence process was not complete as the resolution of the expected AM_2 splitting pattern was not observed even at −90 °C (δ = 41.85, $\omega_{1/2}$ = 90 Hz; δ = 33.69, $\omega_{1/2}$ = 89 Hz). Assuming the occurrence of an $A_3 \rightleftarrows A_2M$ exchange and applying the Gutowski−Holm equation corrected for the different population of the exchanging sites, a $\Delta G^{\neq}_{203K}$ value of 36.8 kJ mol^{-1} was estimated at the coalescence temperature.[15,17]

For a further decrease in the temperature down to −115 °C using a 1:1 (v/v) mixture of CD_2Cl_2 and $CFCl_3$ as solvent, the lower field resonance (2 P) significantly broadened and then transformed into a broad hump that was almost merged with the baseline ($\omega_{1/2}$ = 432 Hz). In contrast, the signal at higher field (1 P) became sharper (δ = 33.46, $\omega_{1/2}$ = 24 Hz) without showing any fine structure, however. This NMR behavior suggests the existence of a second dynamic process responsible for the magnetically nonequivalence of the three phosphorus nuclei of NP_3 and also points to an AMX splitting pattern in the slow motion regime.

Figure 1 shows the variable-temperature ^1H NMR spectra in the hydride region of **3**, dissolved in a 1:1 (v/v) mixture of CD_2Cl_2 and $CFCl_3$. At 20 °C, the spectrum showed a narrow quadruplet [$J(HP)$ = 13.1 Hz] centered at δ = −6.62, which is consistent with a complete and fast scrambling of the four hydride ions. A careful NMR integration of this signal, with respect to the aliphatic triphos resonances, confirmed the presence of four hydride ligands. As the temperature was lowered, the hydride resonance lost its multiplicity (−20 °C), transformed into a broad hump (−40 °C, $\omega_{1/2}$ = 64 Hz) before finally coalescing into the baseline (ca. −60 °C). Complete decoalescence of the signal occurred slightly below −90 °C to give two well-separated signals (integrating 1:3), which at −100 °C fell at δ = −3.00 ($\omega_{1/2}$ = 115 Hz) and δ = −7.74 δ ($\omega_{1/2}$ = 85 Hz), respectively. Below this temperature, broadening of both resonances occurred, but freezing out of the solvent did not allow us to obtain any information on the limiting spectrum.

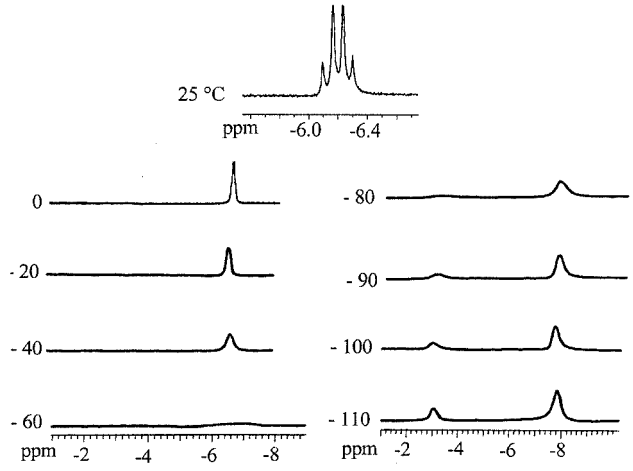


Figure 1. Variable-temperature ^1H NMR spectra in the hydride region of $[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (**3**) dissolved in a 1:1 (v/v) mixture of $CD_2Cl_2/CFCl_3$ (300 MHz, TMS reference)

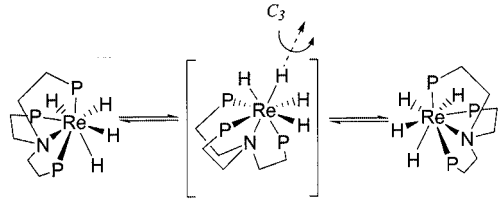
The proton NMR spectroscopic data allowed us to calculate the free energy of activation for the process of exchanging the hydride ligands in **3**. A possible mechanism for this exchanged is proposed in Scheme 2.[1e] Introducing a Δν value of 1420 Hz, a $\Delta G^{\neq}_{213K}$ value of 38.1 *k*J mol^{-1} was calculated at the coalescence temperature. Remarkably, this value is in good agreement with the free activation energy obtained from the NMR coalescence analysis of the ^{31}P NMR spectra (vide supra). A line-shape analysis of the ^1H NMR spectra (Figure 1) with the DNMR-5 program in the temperature range from 253 to 183 K gave the following τ values for the less populated low-field signal: 0.0000067 s at 253 K, 0.000013 s at 233 K, 0.00027 s at 213 K, 0.0011 s at 193 K, and 0.0027 s at 183 K. From these values we calculated $\Delta H^{\neq}$ = 33.5 *k*J mol^{-1} and $\Delta S^{\neq}$ = −12.1 *k*J mol^{-1} K^{-1} (note that the slightly negative entropy is consistent with an intramolecular exchange) and hence $\Delta G^{\neq}_{203K}$ = 36.0 *k*J mol^{-1}, which is similar to the value obtained from the coalescence temperature.



Scheme 2

Relaxation Study of the Rhenium Polyhydrides 2 and 3

The variable-temperature relaxation times T_1 for the hydride ligands in **2** and **3** were measured at different magnetic fields by using the standard inversion-recovery sequence (Table 1).

Table 1. Variable-temperature (T_1) NMR spectroscopic data for $[ReH_3(\eta^4\text{-}NP3)]$ (**2**) and $[ReH_4(\eta^4\text{-}NP_3)]^+$ (**3**)

Temp. [*K*]	T_1 [ms] A	B	C

[a] The T_1 measurements on **2** were carried out at 400 MHz in CD_2Cl_2. [b] The letter A denotes the T_1 values of the hydride ligands in the fast motion regime. The letters B and C indicate the relaxation times of the two kinds of hydride resonances appearing below the coalescence temperature; B, low-field resonance; C, high-field resonance. [c] The T_1 measurements on **3**, prepared in situ from **2** by adding 4 equiv. of CF_3COOH, were carried out at 400 MHz in CD_2Cl_2. [d] The T_1 measurements on an isolated sample of **3** were carried out at 300 MHz in a 1:1 $CD_2Cl_2/CFCl_3$ mixture. [e] Due to broadness of the signal close to the coalescence temperature, no T_1 value is given.

At low temperature, when the hydride−hydride exchange is slow on the NMR time scale, the relaxation times of the two types of hydride ligands in **2** were found to be practically identical. A relatively long T_{1min} value was observed between −50 and −40 °C (129−127 ms) for both hydride resonances supporting the classical nature of the trihydride **2**.

The tetrahydride **3** was prepared in situ as trifluoroacetate salt by adding a fourfold excess of CF_3COOH to a CD_2Cl_2 solution of **2**, and the relaxation times T_1 were initially measured at 400 MHz. A rather small T_{1min} value of 97 ms was determined for the four exchanging hydride ions at ca. −50 °C. Spin-saturation transfer experiments showed the absence of any exchange between the hydride ligands of **3** and protons of the acid, even at −23 °C, which strongly supports the hypothesis that the observed T_{1min} value is undistorted. A comparison of $1/T_{1min}$ measured for both **2** and **3** allowed us to estimate the relaxation contribution to the overall relaxation rate provided by the additional hydride ligand in **3**. Using a contribution of 2.5 s^{-1}, a minimum hydride−hydride distance of 1.84 Å was obtained from Equation (1), in which ν is the spectrometer frequency.[18] The H−H separation estimated in this way nicely supports the classical tetrahydride formulation of **3** and is also consistent with the results of an X-ray structural analysis (see below).

$$r(H-H) = 5.815\,(T_{1min}/\nu)1/6 \quad (1)$$

The interpretation of T_{1min} data in terms of bond lengths in metal polyhydride complexes is affected by a rather high degree of ambiguity, particularly when the different hydride sites cannot be completely frozen out.[19] Additional uncertainty may come also from the contribution of dipolar interactions with the neighboring nuclei in the ancillary ligands that cannot be neglected, and from the presence of a quadrupolar nucleus (i.e. rhenium) which may affect remarkably the observed relaxation rate by a significant metal hydride dipole−dipole interaction.[20,21] In the case at hand, according to the protocol of Halpern and co-workers, a T_{1min} value of ca. 97 ms can be calculated by subtracting the contributions of the rhenium atom and of as many as 12 *ortho* protons of the tripodal ligands to the relaxation rate of **3**, scaled up to 500 MHz.[20] The calculated value is in line with that reported by Crabtree and co-workers for the classical polyhydride $[ReH_6\{PhN(CH_2CH_2PPh_2)_2\}]BF_4$ (T_{1min} = 93 ms),[22] and also matches well the T_{1min} value of 94 ms determined by Morris and co-workers for the cognate complex $[ReH_4(\eta^4\text{-}PP_3)]BF_4$, for which the absence of an intact dihydrogen ligand was suggested on the basis of similar T_1 arguments.[12]

In a second series of NMR experiments, the spin-lattice relaxation times for the hydride ligands in **3** were determined at 300 MHz in the temperature range from +20 to −110 °C in $CD_2Cl_2/CFCl_3$. The results were in line with those obtained using a higher magnetic field. A plot of T_1 [ms] vs. temperature ($1000/T$ [K^{-1}]) is presented in Figure 2, while T_1 data are collected in Table 1. At room temperature, when the four hydride ligands are rapidly exchanging, a relatively short T_1 of 106 ms was measured. As the temperature was lowered to the coalescence point, T_1 also decreased steadily, and at −40 °C, just above the coalescence point, a value of 77 ms was observed. Below the coalescence temperature, the two hydride sites showed longer and comparable relaxation times that increased with decreasing temperature. At −100 °C, when the dynamic process was still far from being completely frozen out, T_1 values as long as 111 and 106 ms were determined for the two distinct hydride resonances. Interpolation of the whole set of data al-

lowed us to find an average T_{1min} value of ca. 71 ms at −50 °C that agrees well, after scaling up to 400 MHz (94 ms), with the relaxation data obtained at higher magnetic field carried out in CD_2Cl_2 solution (97 ms).

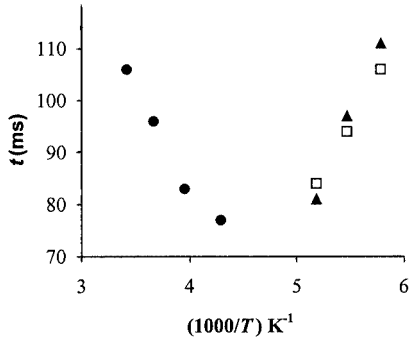

Figure 2. Plot of T_1 [ms; $CD_2Cl_2/CFCl_3$, 1:1 (v/v), 300 MHz] vs. temperature ($1000/T$ [K^{-1}]) for the polyhydride [$ReH_4(\eta^4$-$NP_3)]BPh_4$ (**3**); • T_1 values of the four hydride atoms in the fast-exchange motion ($\delta = -6.62$); □ T_1 values of the hydride signal ($\delta = -3.00$); T_1 values of the hydride signal ($\delta = -7.74$)

Further support for the classical nature of **3** was obtained from a comparison of its variable-temperature T_1 dependence with that exhibited by the authentic η^2-H_2 complex $[Ir(H)_2(H_2)(triphos)]^+$ [triphos = $CH_3C(CH_2PPh_2)_3$].[23] Below the coalescence point, the T_1 times for the two types of hydrides in **3** were found to lengthen considerably (Table 1), while the values for the two hydride ions in the iridium complex with triphos[23] showed a divergent behavior: the relaxation time of the classical hydrides increased, while that of the molecular hydrogen ligand continued to decrease with the temperature.

X-ray Crystal Structure of [$ReH_4(\eta^4$-$NP_3)]BPh_4$ (3)

An ORTEP view of the cation $[ReH_4(\eta^4$-$NP_3)]^+$ is given in Figure 3, while selected bond lengths and angles are listed in Table 2. The immediate coordination sphere of the rhenium atom consists of the nitrogen and phosphorus atoms of the NP_3 moiety and of four hydride ligands. As previously discussed (see Exp. Sect.), only three out of the four hydride ions (labeled as H1, H2, and H3 in Figure 3) were successfully refined. The fourth (H4) is also shown (in the position obtained from the Fourier difference map) to give a pictorial representation of the full coordination polyhedron.

As expected[24,25] for an eight-coordinated polyhydride, complex **3** adopts a distorted dodecahedral geometry in accordance with the ^1H NMR spectroscopic data. The Re−H distances [av. 1.67(7) Å] fall in the expected range, and are similar to those found by low-temperature neutron diffraction in $[ReH_5(PPh_3)_2(indole)]$[26] [av. 1.683(2) Å].

The expected low precision in the location of the hydride ions by X-ray diffraction, prevents a detailed discussion of their geometries. We note, however, that the H···H separations are consistent with both the NMR spectroscopic data and the classical nature of this complex.

Two types of Re−P distances have been found in the complex cation: two shorter [av. 2.376(7) Å] and one longer [2.402(2) Å] due to the influence of a pseudo-*trans*-hydride ion. All Re−P separations fall in the expected range and are comparable, for example, with those found in (triphos)-iridium complexes (2.30−2.40 Å)[27,28] All the other distances are unexceptional and do not deserve additional comment.

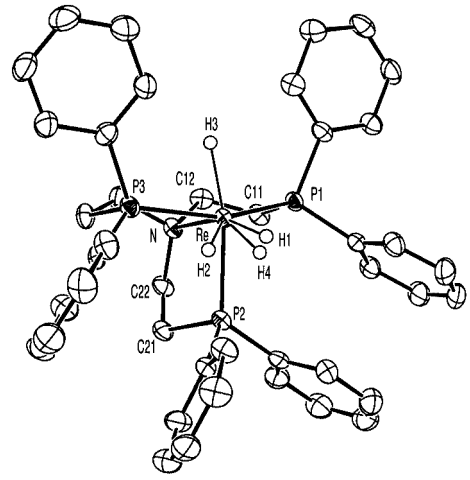

Figure 3. ORTEP view of the complex cation [$ReH_4(\eta^4$-$NP_3)]BPh_4$ (**2**) showing thermal ellipsoids at 30% probability; only H1, H2, and H3 have been refined (see text)

Table 2. Selected bond lengths [Å] and angles [°] for compound **3**, with e.s.d.s values in parentheses

Re−P(1)	2.381(2)	Re−Hy1	1.60(5)

P(3)−Re−N	80.8(1)		

In situ IR Study of the Interaction of 2 with Different Proton Donors

It has been recently demonstrated that proton-transfer reactions such as that occurring in the transformation of **2** into **3** may take place via intermediate species containing M−H···HOR hydrogen bonds.[29,30] A successful strategy to show the eventual formation of hydrogen bond adducts involves an in situ IR study of the interactions between the starting metal (poly)hydride and acids of different strength. We therefore decided to monitor the reactions of **2** with C_2H_5OH, CFH_2CH_2OH (MFE), CF_3CH_2OH (TFE), $CH_2ClCOOH$ (MClA), and CF_3COOH (TFA) by variable-temperature IR spectroscopy in CH_2Cl_2, taking into consideration the variation of the dielectric constant of the solvent with temperature.[30−32]

In the absence of added acid, the IR spectrum of **2** exhibits a complicated absorbance pattern in the ν(M−H) region, which is a common feature to many transition metal

polyhydrides.[33,34] After removing the contribution due to the overtones of the phenyl rings using the spectra of **1** and **2-D$_3$**, the spectrum showed the presence of three overlapped ν(Re−H) bands (1866, 1938, and 1977 cm^{-1}) whose intensities increased with decreasing temperature down to 200 K (see Figure 4a).

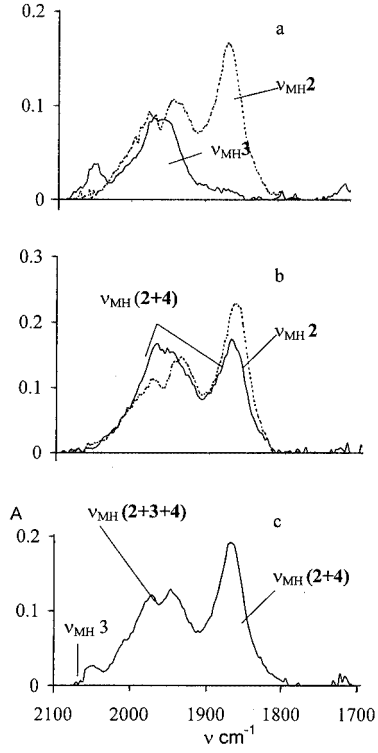

Figure 4. IR spectra in the ν(ReH) region (CH_2Cl_2 solution; −70 °C): a: spectra of **2** alone (0.0.1 M) (- - -) and in the presence of TFA (0.01 M) (———); b: spectra of **2** alone (0.015 M) (- - -) and in the presence of MFE (0.075 M) (———); c: spectrum of **2** (0.014 M) in the presence of TFE (0.014 M)

When a strong proton donor such as TFA or MClA was treated with **2** (metal hydride/acid, 1:1), a plain proton transfer occurred and the classical polyhydride **3** was generated with no detection of any intermediate species along the proton transfer process, i.e. the ν(ReH) stretching of **2** disappeared with concomitant formation of new bands due to **3** at higher energy [1960 (vs) cm^{-1} and 2050 (w) cm^{-1}] (see Figure 4a). The latter band was masked by the phenyl overtones of the tetraphenylborate anion in the solid-state spectrum. In addition, the typical ν(CO) bands of free MClA (1730−1720 cm^{-1}) and TFA (1810−1780 cm^{-1}) were replaced by new strong ν^{as}(OCO) bands due to the carboxylate anions at 1620 and 1685 cm^{-1}, respectively.

In an attempt to intercept a hydrogen bond adduct, weaker acids were used in the protonation of **2**. Indeed, irrespective of the hydrogen donor, the IR spectra in the ν(OH) region obtained at 290 K by addition of **2** (0.04 M) to CH_2Cl_2 solutions containing TFE, C_2H_5OH, or MFE (Table 3)[35] showed that the intensity of the band due to the stretching vibrations of the OH group in the free acid decreased, while a new broad and intense band, assigned to a hydrogen-bonded adduct, appeared at lower frequency. The frequency shifts [$\Delta\nu = \nu(OH)^{free} - \nu(OH)^{bonded}$] was found to increase with the proton-donor ability of the alcohol in the order C_2H_5OH < MFE < TFE.

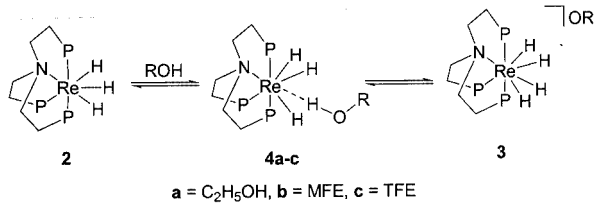
Table 3. Spectral characteristics of the hydrogen bond adducts [$(NP_3)H_3Re\cdots HOR$] (**4a**−**c**), enthalpy values ($-\Delta H^0$) in CH_2Cl_2 at 290 K and E_j factors

[$(NP_3)H_3Re\cdots HOR$]	$\nu(OH)^{bonded}$ [cm^{-1}]	$\Delta\nu_{OH}$ [cm^{-1}]	$-\Delta H^0$ [kJ mol^{-1}]	E_j
C_2H_5OH (**4a**)	3375	212	18.8	1.45
MFE (**4b**)	3336	244	20.5	1.47
TFE (**4c**)	3220	385	26.4 (24.7)[a]	1.53 (1.45)

[a] The $-\Delta H^0$ value given in parentheses was obtained from the van't Hoff plot (Figure 5).

Once it had been established that the proton-transfer reaction involved in converting **2** to **3** was traversed by a detectable H-bonded intermediate, it only remained to discriminate between the two potential H bond acceptor sites in **2**, i.e. the hydride ligand or the metal center.[36] In reality, although the intermediacy of hydrogen bond adducts of the type ReH···HX, preceding the formation of nonclassical η^2-H_2 species, have been reported to occur in several cases,[29,30,37−40] the rhenium center in **2** possesses a lone electron pair that may be straightforwardly protonated to give the classical hydride **3**. Accordingly, we could not disregard a priori the preliminary formation of a metal-centered Re···HX adduct upon interaction of **2** with the alcohol.

The occurrence of a low frequency shift of the ν(M−H) band has been unequivocally established as a general spectroscopic criterion to assess the formation of hydrogen bonding involving the hydride ligand.[29,30] In the present case, the addition of a weak proton donor such as EtOH, MFE, or TFE to a CH_2Cl_2 solution of **2** did not result in the appearance of any new band or shoulder at *low frequency*. In contrast, either of these alcohols at −70 °C caused a little, but evident, *high frequency* shift (ca. 10 cm^{-1}) of the ν(Re−H) band at 1866 cm^{-1} as well as the envelop of the two other absorptions between 1945 and 1980 cm^{-1} (see Figure 4b). These spectral changes are therefore inconsistent with an interaction between an Re−H moiety and the proton donor, whereas they support the formation of hydrogen-bonded adducts of the type [$(NP_3)H_3Re\cdots HOR$] (**4a**−**c**) as shown in Scheme 3. The occurrence of a metal-centered hydrogen bonding preceding the protonation of the metal atom has been demonstrated for a few organometallic compounds.[41−44]



Scheme 3

The enthalpy associated with the hydrogen bond formation in the Re···HOR adducts (**4a**−**c**) was calculated from the experimental IR frequency shifts listed in Table 3 through the Iogansen correlation[45] reported in Equation (2).

$$-\Delta H^{\circ} = 18\,\Delta\nu/(720 + \Delta\nu) \quad (2)$$

In the case of **4c**, it was difficult to accurately determine the position of $\nu(OH)^{bond}$, because this band fell close to the ν(CH) bands of both **2** and the CH_2Cl_2 solvent. The thermodynamic parameters for **4c** were therefore independently calculated from the temperature dependence of the formation constant (K_f) using the van't Hoff Equation (3).

$$\ln K_f = -\Delta H^{\circ}/RT + \Delta S/R \quad (3)$$

The formation constant K_f for the equilibrium illustrated in Equation (4) was determined in the temperature range from +20 to −30 °C following the decrease in the optical density of the band assigned to the free OH group.

$$[ReH_3(NP_3)] + CF_3CH_2OH \rightleftharpoons [(NP_3)H_3Re\cdots HOCH_2CF_3] \quad (4)$$

The corresponding van't Hoff plot, shown in Figure 5, allowed us to figure out both the enthalpy and entropy changes [$-\Delta H^0 = 24.7 \pm 1.3$ kJ mol^{-1}, $-\Delta S^0 = 56.5 \pm 2.1$ kJ mol^{-1} K^{-1}]. Notably, the value of $-\Delta H^0$ calculated from the van't Hoff plot is close to that independently obtained by using Equation (2) (Table 3).

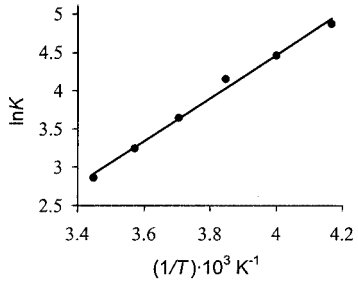


Figure 5. van't Hoff plot in the range +20 to −30 °C for the reaction of **2** with TFE

Table 3 also lists the basicity factors E_j relative to the different proton donors used in this study that were calculated by using the "rule of factors" [Equation (5)].[46]

$$E_j = \Delta H_{ij}/\Delta H_{11}\, P_i \quad (5)$$

The E_j values for **2** are practically constant (1.46 ± 0.01) for all the three proton donors listed in Table 3. Remarkably, the proton-accepting ability of the rhenium atom appeared to be higher than the E_j values previously determined for other metal-containing complexes.[29,30] Such a high E_j value for **2** might explain why the proton transfer was observed even in the presence of relatively weak proton donors such as TFE.

The study of the interaction of **2** with TFE at different temperatures and concentrations allowed us to observe the multiple equilibrium between the initial hydride **2**, the hydrogen bond adducts **4c**, and the final product **3** (Scheme 3). This equilibrium is significantly shifted to the right at either low temperature or high TFE concentrations. The solution IR spectrum of **2** in the presence of TFE at −70 °C is very complicated (see Figure 4c): the band at 1877 cm^{-1} was assigned to the ν(ReH) stretching of both the H-bonded complex **4c** and the starting hydride **2**, the band at 2050 cm^{-1} could be assigned to the ν(ReH) of **3**, while the broad absorbance between 1940 and 1970 cm^{-1} was attributed to the envelope of ν(ReH) bands due to the three rhenium species in equilibrium (Scheme 3). There is little doubt, however, that the spectral changes occurring in the ν(MH) region, following the addition of TFE to a solution of **2**, unequivocally point to the rhenium atom as the site where the hydrogen bond interaction with the proton donor primarily occurs.

A recently reported ab initio study of the protonation of [CpRe(PH$_3$)(NO)(H)] and [CpRe(CO)(NO)(H)] has shown that the substitution of CO by PH$_3$ increases the rhenium basicity and hence shifts the regioselectivity of proton attack from the terminal hydride ion to the metal center.[47] The remarkable nucleophilic character of the NP$_3$ ligand would analogously increase the basicity of the rhenium center in **2**, thus allowing for its regioselective protonation. As a matter of fact, the less electron-rich complex [ReH(CO)$_2$(triphos)] has been found to react with various proton donors forming selectively ReH···HOR adducts.[38,39]

Conclusions

We have described in this work the synthesis and characterization of the first rhenium polyhydride complexes stabilized by the tripodal polydentate ligand N(CH$_2$CH$_2$PPh$_2$)$_3$ (NP$_3$). In both [ReH$_3$(η^4-NP$_3$)] (**2**) and [ReH$_4$(η^4-NP$_3$)]BPh$_4$ (**3**) the polydentate ligand uses all its donor atoms for coordination. The classical polyhydride structure of **2** and **3** has been unambiguously determined by a variety of spectroscopic techniques in solution as well as a single-crystal X-ray analysis of the rhenium(V) derivative. Most importantly, an in situ IR study of the protonation of **2** by weak Brønsted acids has shown that the proton selectively attacks the metal atom to give kinetic hydrogen-bonded adducts of the formula [(η^4-NP$_3$)H$_4$Re···HOR] (ROH = C$_2$H$_5$OH, CFH$_2$CH$_2$OH, CF$_3$CH$_2$OH) that ultimately convert into the thermodynamically stable classical polyhydride **3** with no formation of transient η^2-H$_2$ species.

Experimental Section

General Procedures: Tetrahydrofuran (THF) and diethyl ether were purified by distillation from LiAlH$_4$ under nitrogen, dichlorome-

thane was heated under reflux overnight in the presence of P_2O_5 and distilled just prior of use. All other reagents and chemicals were reagent grade and, unless otherwise stated, were used as received from commercial suppliers. All reactions and manipulations were routinely performed under dry nitrogen by using standard Schlenk-tube techniques. The solid complexes were collected on sintered-glass frits and washed as indicated before being dried in a stream of nitrogen. The ligand $N(CH_2CH_2PPh_2)_3$ (NP_3)[48] and the complex $[ReCl_3(CH_3CN)(PPh_3)_2]$[49] were prepared as described in the literature. Deuterated solvents for NMR measurements (Merck and Aldrich) were dried with molecular sieves (4 Å). ^1H NMR spectra were recorded with Varian VXR 300 or Bruker AC200 spectrometers operating at 299.94 or 200.13 MHz (^1H), respectively. Peak positions are relative to tetramethylsilane and were calibrated against the residual solvent resonance. $^{31}P\{^1H\}$ NMR spectra were recorded with either the Varian VXR 300 or Bruker AC200 instruments operating at 121.42 and 81.01 MHz, respectively. Chemical shifts were measured relative to external 86% H_3PO_4 with downfield values taken as positive. The proton NMR spectra with broad-band phosphorus decoupling were recorded with the Bruker AC200 instrument equipped with a 5-mm inverse probe and a BFX-6 amplifier device using the wideband phosphorus decoupling sequence GARP. The variable-temperature spin-lattice relaxation times (T_1) in complexes **2** and **3** were measured in dichloromethane at 300 and 400 MHz by the inversion-recovery method using the standard $180°-\tau-90°$ pulse sequence. The calculations of the relaxation times were made using the fitting routines of the Varian VXR300 and Bruker AMX-400 spectrometers. The 90° pulse on the hydride samples was carefully measured at each temperature before running the T_1 measurements. The errors in T_1 determinations were less than 10%. Infrared spectra were recorded as Nujol mulls with a Perkin–Elmer 1600 series FT-IR spectrometer between KBr plates. The molar conductivity of **1** was measured with an AMEL model 134 conductance cell connected to a model 101 conductivity meter. The conductivity data were obtained at sample concentrations of 10^{-3} M in MeOH at room temperature (25 °C). Elemental analyses (C, H, N) were performed by using a Carlo Erba model 1106 elemental analyzer. IR measurements in CH_2Cl_2 were carried out with a Specord M82 spectrometer in CaF_2 cells. The cell width was 0.04–0.12 cm. The concentration range of the solutions for IR studies was between 10^{-1} and 10^{-3} M. For the low-temperature measurements a Carl Zeiss Jena cryostat was employed in the temperature range −80 to 30 °C using a stream of liquid nitrogen. The accuracy of temperature adjustment was ±0.5 °C. The position of ν(OH) bands corresponds to their barycenter. The formation constants at every temperature (−30 to +20 °C) were determined by the decrease of ν(OH) optical density of the absorption band assigned to the free OH group.

$[ReCl_2(\eta^4\text{-}NP_3)]Cl$ (1): A suspension of $[ReCl_3(CH_3CN)(PPh_3)_2]$ (0.30 g, 0.36 mmol) and NP_3 (0.30 g, 0.46 mmol) in ethanol (60 mL) was heated under reflux under nitrogen for ca. 4 h, during which time the orange solid dissolved to give a clear yellow solution. The solution was then reduced in volume to ca. 20 mL before adding diethyl ether (30 mL) whilst stirring to precipitate **1** as lemon-yellow microcrystals. Yield, based on Re 0.27 g, 0.29 mmol (80%). $C_{42}H_{42}Cl_3NP_3Re$ (875.38): calcd. C 53.3, H 4.5, N 1.5; found C 53.2, H 4.4, N 1.1. $\Lambda_{M(methanol)} = 146\ \Omega^{-1}\ cm^2\ mol^{-1}$.

$[ReH_3(\eta^4\text{-}NP_3)]$ (2): Solid $LiAlH_4$ (0.64 g, 16.86 mmol) was added portionwise to a stirred suspension of **1** (0.80 g, 0.85 mmol) in 100 mL of THF. The mixture was gently heated to reflux temperature and stirred for 6 h. After cooling to 0 °C, the excess $LiAlH_4$ was carefully hydrolyzed by addition of a mixture of THF/H_2O (30 mL, 10:1, v/v). The resulting slurry was filtered through a Hirsch funnel to remove the lithium and aluminum hydrolysis products. The volume of the filtrate was reduced to ca. 20 mL before adding 20 mL of a 1:2 (v/v) EtOH/*n*-hexane solution. Concentration of the solution under a stream of nitrogen gave ivory-colored microcrystals of **2**. Yield, 0.53 g, 0.63 mmol (74%). $C_{42}H_{45}NP_3Re$ (842.95): calcd. C 59.8, H 5.4, N 1.7; found C 60.1, H 5.5, N 1.6. IR (Nujol mull): $\tilde{\nu}$ = 1949 (ν_{ReH}), 1905 cm^{-1}. The perdeuterated derivative $[ReD_3(\eta^4\text{-}NP_3)]$ (**2-D_3**) was prepared with an isotopic purity higher than 90% (^1H NMR) by substituting $LiAlD_4$, D_2O, and C_2H_5OD for the protonated analogues in the above procedure.

$[ReH_4(\eta^4\text{-}NP_3)]BPh_4$ (3): A Schlenk tube was charged with 0.50 g of **2** (0.59 mmol) and 10 mL of degassed dichloromethane. To this solution, cooled to 195 K with a dry ice/acetone bath, was added via syringe an excess of $HBF_4{\cdot}OMe_2$ (0.2 mL, 1.6 mmol), and the temperature was raised to ca. 20 °C before adding a solution of $NaBPh_4$ (0.50 g, 1.46 mmol) in EtOH (5 mL) whilst stirring. Concentration under nitrogen gave off-white crystals of **3**. Colorless plates of **3** were obtained by slow crystallization from a diluted CH_2Cl_2/EtOH (2:1, v/v) solution. Yield 0.63 g, 0.54 mmol (92%). $C_{66}H_{66}BNP_3Re$ (1163.20): calcd. C 68.2, H 5.7, N 1.2; found C 68.6, H 5.9; N 1.2. IR (KBr): $\tilde{\nu}$ = 2030 w, br. (ν_{ReH}), 1996 m br.; ν_{BPh4} 1680, 610 cm^{-1}. The perdeuterated derivative $[ReD_4(\eta^4\text{-}NP_3)]BPh_4$ (**3-D_4**) was prepared with an isotopic purity higher than 95% (^1H NMR) from **2-D_3** by using CF_3OSO_2D and C_2H_5OD in place of HBF_4 and ethanol.

Reaction of 3 with KO*t*Bu: Addition of solid KO*t*Bu (0.20 g, 1.78 mmol) to a THF solution of **3** (0.20 g, 0.17 mmol) regenerated the neutral trihydride **2**. Yield 89%.

X-ray Crystallography: Single crystals of **3** suitable for an X-ray diffraction analysis were obtained as described above. A crystal was mounted on a glass fiber, on a CAD4 diffractometer, which was used for the space group determination and for the data collection, which was carried out at −80(2) °C. Unit cell dimensions were obtained by least-squares fit of the 2θ values of 25 high-order reflections. Crystallographic and other relevant data are listed in Table 4. Data were measured with variable scan speed to ensure constant statistical precision on the collected intensities. Three standard reflections were used to check the stability of the crystals and of the experimental conditions and measured every hour. The collected intensities were corrected for Lorentz and polarization factors and empirically (Ψ scans) for absorption.[50] The standard deviations on intensities were calculated in terms of statistics alone. The structure was solved by a combination of Patterson and Fourier methods and refined by full-matrix least squares[51] {the function minimized being $\Sigma[w(F_o - 1/kF_c)^2]$}. All non-hydrogen atoms were treated anisotropically. Towards the end of the refinement, four strong peaks were found, in a Fourier difference maps, at distances consistent with those expected for the hydrido ligands. Therefore these peaks were included in the refinement and treated isotropically. However, while three hydrogen atoms converged to give a reasonable geometry, maintaining also positive values for the displacement parameters, the fourth gave an Re–H separation that was considered too short, as well as a negative thermal factor, and thus was discarded. No other acceptable peak for the missing hydride ion was found in the Fourier difference maps. No extinction correction was deemed necessary. The scattering factors used, corrected for the real and imaginary parts of the anomalous dispersion, were taken from the literature.[52] The contribution of the hydrogen atoms in calculated positions [C–H = 0.95 Å, B(H) = 1.3

$\times$ B(C_{bonded}) Å^2] was taken into account but not refined. Upon convergence no significant features were found in the Fourier difference maps of both compounds. A selection of bond lengths and angles is given in Table 2 (vide infra). All calculations were performed using the MOLEN crystallographic package,[51] and the structures drawn using the program ORTEP.[53] The supplementary crystallographic data for this paper are contained in publication CCDC-179058. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 4. Experimental data for the X-ray diffraction study of compound **3**

Empirical formula	$C_{67}H_{64}BCl_2NP_3Re$
Formula mass	1244.10
T [C°]	−80(2)
Crystal system	triclinic
Space group	$P\bar{1}$
a [Å]	12.358(2)
b [Å]	14.871(2)
c [Å]	16.545(6)
α [°]	107.04(3)
β [°]	91.98(3)
γ [°]	91.44(2)
V [Å^3]	2903(1)
Z	2
$\rho_{calcd.}$ [g cm^{-3}]	1.42
μ [cm^{-1}]	23.35
Radiation	Mo-K_α (graphite-monochromated, λ = 0.71069 Å)
No. independent data collected	8793
No. observed reflections	7762 [$\|I_o\| > 3.5\sigma(I)$]
Transmission coeff.	1.00−0.94
R[a]	0.033
R_w	0.066
GOF	1.55

[a] $R = \Sigma(|F_o - (1/k)F_c|)/\Sigma|F_o|$; $R_w = [\Sigma_w(F_o - (1/k)F_c)^2/\Sigma_w|F_o|^2]^{1/2}$, where $w = [\sigma^2(F_o)]^{-1}$; $\sigma(F_o) = [\sigma^2(F_o^2) + f^4(F_o^2)]^{1/2}/2F_o$.

Acknowledgments

Thanks are due to INTAS (contract 00-00179), NATO (contract HTECH-CRG 972135), CNR/RAS bilateral agreement and RFBR (project No 99-03-33270) for financial support. Support from the EC (RTN network HYDROCHEM) is also gratefully acknowledged. I. d. l. R. thanks the Ministerio de Ciencia y Tecnologia (Spain) for a post-doctoral grant.

[45] The empirical rule of factors reported by Iogansen[46] demonstrates the invariability of the proton-donor (P_i) and proton-acceptor (E_j) properties of organic acids and bases in hydrogen bonding. In Equation (5), ΔH_{11} is the enthalpy of hydrogen bonding for a standard donor/acceptor couple (i.e. PhOH/Et_2O: $P_1 = E_1 = 1$). E_j depends on neither the nature of the proton donor nor the solvent and may therefore be assumed as an absolute measurement of the proton-accepting ability of each potential site of hydrogen bonding.[30]

COVER PICTURE

The cover picture shows the ability of a new unsymmetrical ligand to act as either monodentate or bidentate; controlling this behaviour is important in catalytic processes. Details are discussed in the article by J. D. Woollins et al. on p. 1635 ff.

The Important Role of Some Ancillary Ligands in the Chemistry of Carbonylmetal Cluster Complexes − Selected Reactivity of Triruthenium Clusters Containing Deprotonated 2-Aminopyridines

Javier A. Cabeza[a]

Dedicated to my former mentors, Professors Luis A. Oro, Peter M. Maitlis and Víctor Riera

Keywords: Ruthenium / Cluster compounds / N ligands / Aminopyridines / Hemilabile ligands

The presence of deprotonated 2-aminopyridines (apy ligands) as face-capping ancillary ligands in carbonyltriruthenium cluster complexes facilitates their reactivity (mild reaction conditions) and increases the regioselectivity of their reactions. This is probably due to the hemilabile character of the apy ligands that help maintain the cluster nuclearity and also provides reaction pathways of low activation energy. Thus, the presence of apy ligands in triruthenium cluster complexes of the type $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apy)(CO)_9]$ has allowed an extensive and regioselective derivative chemistry that is surveyed in this review. A comparative study of the reactivity of 2-amino-, 2-mercapto- and 2-hydroxypyridines with triruthenium clusters is followed by a survey of selective reactions of apy-bridged triruthenium cluster complexes that covers substitution processes, protonation reactions, oxidative addition of hydrogen, hydrosilanes and hydrostannanes, reactions with alkynes and diynes, reactions of coordinated alkenyl and ynenyl ligands, synthesis and reactivity of cationic non-hydridic clusters, preparation of higher-nuclearity clusters and some catalytic applications.

I. Introduction

Regioselectivity is a major concern in the derivative chemistry of carbonyl transition metal cluster complexes.[1] Mixtures containing mono- and/or dinuclear complexes are frequently formed as reaction products and, even when no cluster fragmentation occurs, single products are seldom observed.[2]

The above statement is particularly true for the derivative chemistry of the most common ruthenium and osmium cluster starting materials, such as $[Ru_3(CO)_{12}]$, $[Os_3(CO)_{12}]$ and many of their trinuclear derivatives. The low regioselectivity of many of their reactions is a consequence of some intrinsic characteristics of this type of compounds: (a) they are saturated species (48 valence electrons) with high kinetic stability, frequently requiring thermal or photochemical activation to undergo chemical transformations; (b) metal−metal bonds are rather weak and are easily cleaved under thermal or photochemical conditions; and (c) due to their polynuclear nature, cluster complexes may undergo transformations at more coordination sites than mononu-

Javier A. Cabeza was born in Soria (Spain) in 1958. He obtained his Ph.D. from the University of Zaragoza in 1983, working on heteropolynuclear complexes of the platinum-group metals, under the supervision of Luis A. Oro. After two years of postdoctoral studies at the University of Sheffield, investigating arene complexes of osmium, with Peter M. Maitlis, he returned to Zaragoza as a postdoctoral researcher in October 1985. There he started his work on carbonylruthenium cluster complexes, in collaboration with Luis A. Oro. In 1987 he was appointed "Profesor Titular" of Inorganic Chemistry at the University of Oviedo, where he currently leads a research group interested in fundamental aspects of organometallic cluster chemistry.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

clear species and, consequently, once the corresponding activation energy has been reached (particularly if this is high), their reactions often lead to mixtures of products.

Ligand (generally CO) dissociation is usually a requisite for reactions of saturated carbonyl transition metal cluster complexes, since a vacant site is often necessary for the incoming reagent to enter the coordination shell of the cluster complex.[3,4] It is implicit that the lower the activation energy of this step, the more selective the reaction will be, since the risks of cluster fragmentation and reactions at different cluster coordination sites are diminished. To ensure selectivity, a low activation energy should be associated with an appropriate energy minimum. Several methods have been devised to reduce the activation energy of reactions of such cluster complexes, the following being the most important ones:

(a) To carry out the reactions in the presence of trimethylamine oxide.[5] This reagent can react with coordinated CO to give CO_2, in the presence of the appropriate ligand, even at very low temperatures (−78 °C).

(b) To start from "activated" cluster complexes containing weakly coordinating ligands.[6] Acetonitrile is easily displaced by many reagents from complexes such as $[M_3(CO)_{12-x}(MeCN)_x]$ (M = Ru,[6a] Os;[6b] x = 1, 2 or 3). These complexes are normally prepared by treating the parent carbonylmetal complexes with acetonitrile in the presence of the appropriate amount of trimethylamine oxide. Alkenes[6c] and dienes[6d] have also been used as weakly coordinating ligands.

(c) Redox catalysis.[7] The substitution of CO by other ligands can be carried out under mild conditions (room temperature) by performing the reactions in the presence of catalytic amounts of strong reducing reagents, such as the benzophenone ketyl radical anion.

(d) Chemical catalysis. The presence of catalytic amounts of hard anions, such as halides, pseudohalides, carboxylates (as PPN^+ salts, in the absence of ion pairing),[8] or methoxide[9] or hydride[10] sources can promote the substitution of CO ligands by other ligands.

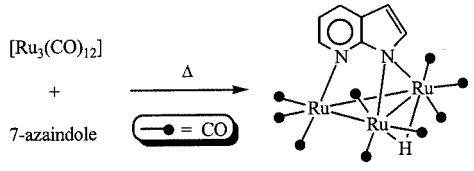
As far as reactivity is concerned, cluster complexes containing bridging ligands with hard-donor atoms[11] are a particular case among carbonyl transition metal cluster complexes because they exhibit an *enhanced substitutional lability*,[12] undergoing reactions under mild conditions. Such ancillary ligands have been termed as *hemilabile* ligands.[12] Although a few examples of bridging monodentate hemilabile ligands are known (chloride,[13] isocyanate[14]), most hemilabile ligands are bidentate and contain both soft- and hard-donor atoms.[15,16] As carbonyl transition metal cluster complexes have soft metal atoms, the softer donor atom of the ligand binds strongly to the metal atom(s), while coordination of the harder donor atom should be labile enough to provide reaction pathways of low activation energy. In addition to helping prevent cluster breakup, these ligands direct the cluster reactivity to reaction sites close (usually *cis*) to the hard-donor atom, thus inducing regioselective reactions.

As long as it is not inconvenient to a particular research project to have a hemilabile ligand attached to the metal cluster, and provided the right hemilabile ligand is chosen, cluster compounds containing a hemilabile ligand have been shown to be the starting materials of choice for studying cluster−ligand interactions,[15,17] for exploring the reactivity of cluster-coordinated ligands,[15,17] and for preparing cluster catalysts.[18]

During the last ten years, Lavigne's and Cabeza's groups have shown that deprotonated 2-aminopyridines (apy) are superb hemilabile ligands in carbonyltriruthenium cluster complexes. This microreview comments on the synthesis and selected reactivity of apy-bridged carbonyltriruthenium cluster complexes. A comparative study of the reactivity of 2-amino-, 2-mercapto- and 2-hydroxypyridines with triruthenium clusters is followed by a survey of selective reactions of apy-bridged cluster complexes that comprises not only substitution processes, but also oxidative additions, protonation reactions, reactions of coordinated ligands, preparation of higher-nuclearity clusters and some catalytic applications. The review is concluded by describing the properties of apy ligands, highlighting the great influence that such ancillary ligands have on the reactivity of the cluster compounds they are coordinated to.

II. Comparative Reactivity of 2-Amino-, 2-Mercapto- and 2-Hydroxypyridines with Triruthenium Clusters

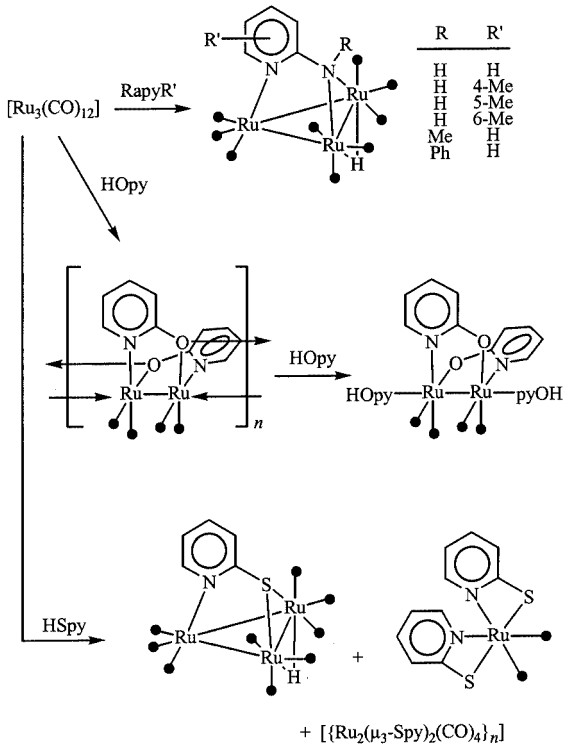
We reported the synthesis and X-ray structure of the first carbonyltriruthenium cluster containing an apy ligand in 1988.[19] It was prepared by treating $[Ru_3(CO)_{12}]$ with 7-azaindole in refluxing hexane (Scheme 1). This work was prompted by the finding that ethylene glycol and methanol could be prepared from synthesis gas using a combination of $[Ru_3(CO)_{12}]$ and 7-azaindole as catalyst precursors.[20]



Scheme 1

These results led us to examine the reactivity of $[Ru_3(CO)_{12}]$ with a series of 2-amino-, 2-mercapto- and 2-hydroxypyridines. These ligand precursors are structurally very similar, but differ in their acid-base properties. All reactions need thermal activation (60−110 °C). 2-Aminopyridines (Hapy) afford only trinuclear hydrido derivatives containing face-capping ligands, regardless of the presence of substituents on the pyridine ring or on the exocyclic nitrogen atom, and regardless of the ratio of the reactants (Scheme 2).[21] However, 2-mercapto- and 2-hydroxypyridine (HSpy and HOpy, respectively) lead to several products depending on the ratio of the reactants. No evidence was obtained for the presence of an intermediate trinuclear

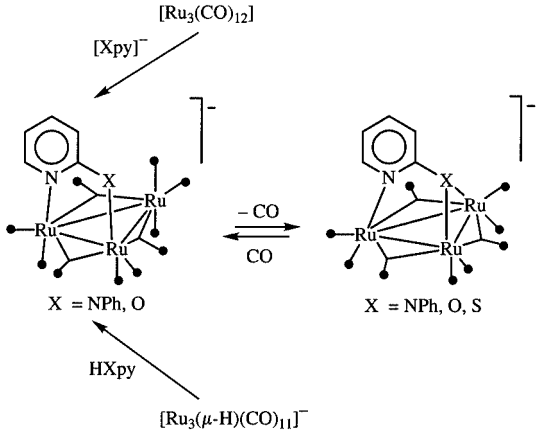
complex in the reactions of $[Ru_3(CO)_{12}]$ with 2-hydroxypyridine.[21] The complex $[Ru_3(\mu\text{-}H)(\mu_3\text{-}Spy)(CO)_9]$ was isolated in a low yield because it reacts readily with 2-mercaptopyridine to give polymeric $[\{Ru_2(\mu_3\text{-}Spy)(CO)_4\}_n]$ (analogous to the polymer derived from 2-hydroxypyridine) and/or monomeric $[Ru(Spy)_2(CO)_2]$ (Scheme 2).[22]



Scheme 2

In parallel to our work, Lavigne's group studied the reactions of $[Ru_3(CO)_{12}]$ with deprotonated 2-anilino-, 2-mercapto- and 2-hydroxypyridines (Phapy, Spy and Opy, respectively) and showed that the results were comparable with those of the reactions of $[Ru_3(\mu\text{-}H)(CO)_{11}]^-$ with the neutral ligands (Scheme 3).[23] While only a face-capping derivative was observed for the Spy ligand, both edge-bridging and face-capping derivatives were observed for the Phapy and Opy ligands. Interestingly, interconversion of the decacarbonyl and nonacarbonyl derivatives of the Phapy ligand is observed under milder conditions (25 °C, CO or inert gas purge), while interconversion of the corresponding Opy derivatives is not observed (the decacarbonyl Opy complex could only be partially decarbonylated after prolonged refluxing under a stream of inert gas).[23]

The very mild conditions under which the above-mentioned interconversion of the anionic Phapy derivatives takes place indicate that the reversible opening of the amido bridge in μ_3-apy ligands is a low activation energy process. Although such a bridge opening has been observed only in very few occasions in neutral cluster complexes containing μ_3-apy ligands (vide infra), it is believed that in their reactions such an opening may also be responsible for their high reactivity.[23] This, in addition to the higher stability of the trinuclear apy derivatives than that of the Opy and Spy



Scheme 3

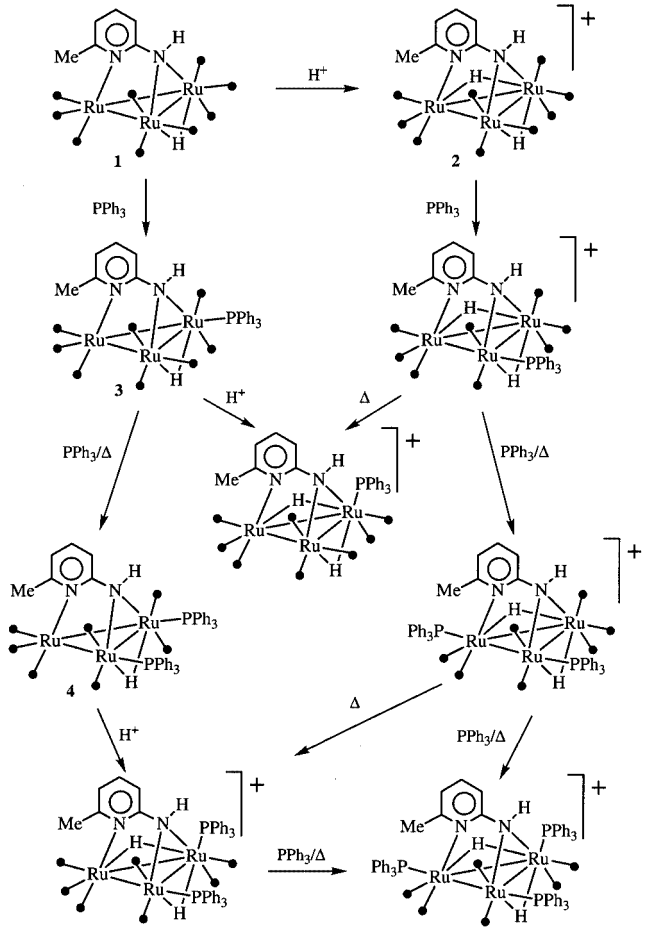
complexes, makes the apy ligands excellent ancillary ligands for triruthenium cluster complexes. This statement is demonstrated by the rich, easy and regioselective derivative chemistry commented in the following section of this review.

III. Selected Reactivity of Triruthenium Clusters Containing Deprotonated 2-Aminopyridines

As starting material, we chose the complex $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apyMe)(CO)_9]$ (**1**, HapyMe = 2-amino-6-methylpyridine, Scheme 4) because the presence of the methyl group on the pyridine ring facilitates the monitoring of the reactions by NMR spectroscopy, without sterically interacting with other ligands. In addition, the presence of the N−*H* hydrogen atom results in an appropriate solubility/insolubility of the complexes in polar/nonpolar solvents.

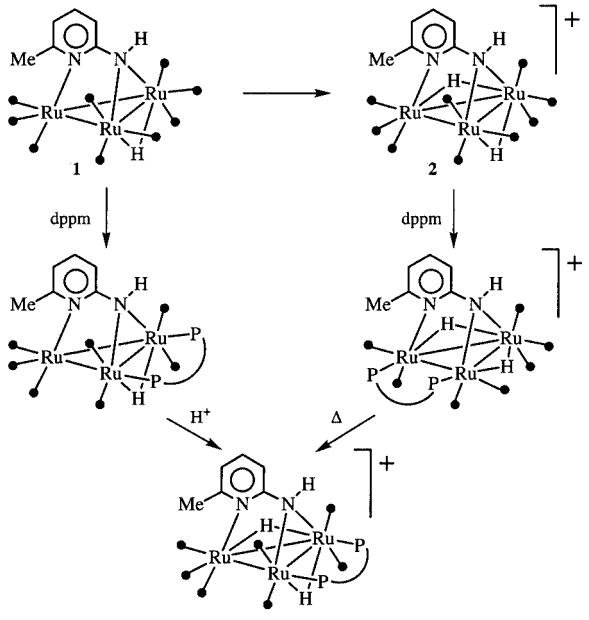
III.a. Reactions with Phosphanes

Simple carbonyl substitution reactions are frequently used to determine the position of reactive sites in cluster complexes. Schemes 4 and Scheme 5 show the reactivity of complex **1** and its protonated derivative $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}apyMe)(CO)_9]^+$ (**2**) with triphenylphosphane[24,25] and bis(diphenylphosphanyl)methane,[26] respectively. It is remarkable that all reactions are regioselective and that the successive substitutions take place stepwise. Moreover, the first substitutions occur instantaneously at room temperature, while further substitutions require gentle heating (60−70 °C). With triphenylphosphane, under kinetic conditions, the substitutions take place in positions *cis* to the bridging amido fragment and/or *cis* to the hydrido ligand, indicating a strong *cis*-labilizing effect of these ligands. The rigidity of the dppm ligand results in the coordination of the two P atoms at the equatorial sites on adjacent metal atoms. In the case of some cationic complexes, the kinetic products isomerize on heating resulting in the thermodynamic products by dissociative mechanisms (such isomerizations are inhibited by the presence of the free phosphanes in solution). Stable neutral methoxycarbonyl derivatives (not



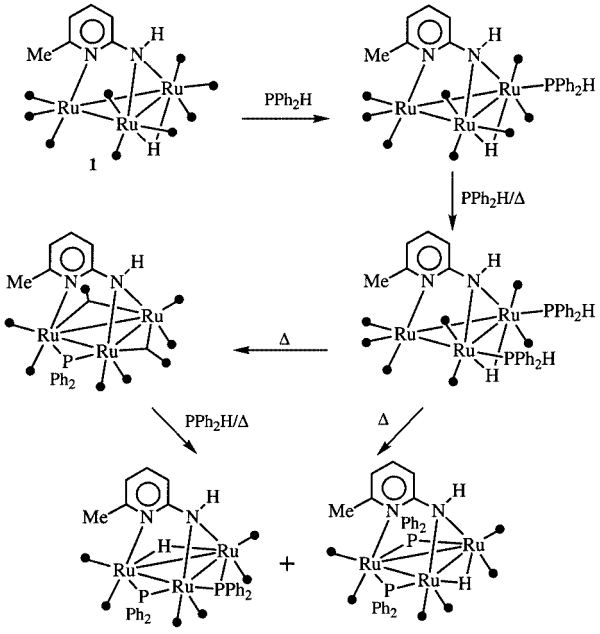
Scheme 4

represented in Schemes 4 and Scheme 5) are produced when the cationic complexes are treated with potassium methoxide.[24−26]



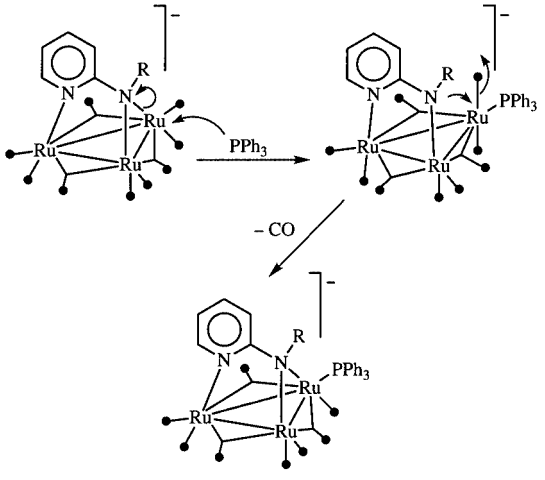
Scheme 5

Facile activation of the P−H bond of diphenylphosphane has been observed on heating diphenylphosphane derivatives of complex **1** (Scheme 6).[27]



Scheme 6

Basolo and Lavigne studied the mechanism of exchange of CO by phosphane ligands in a series of anionic complexes $[Ru_3(\mu_3\text{-Rapy})(CO)_9]^-$, having different R substituents on the exocyclic N atom (Scheme 7).[28] Second-order kinetics were found (associative-type mechanism), which is consistent with a two-step process in which the first step is the coordination of the phosphane with the concomitant opening of an Ru−N arm. This adduct evolves into the final substituted product. The energy barrier for the second step depends on the nucleophilicity of the amido group. In fact, the initial adduct can be isolated when R = Ph, but it is too short-lived when R = Me. These results clearly demonstrate the hemilabile character of the apy ligands in these complexes.



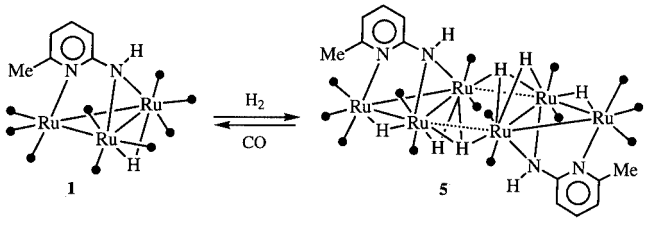
Scheme 7

III.b. Reactions with Hydrogen, Silanes and Stannanes

The reactions of these three reagents with unsaturated organic substrates are of great practical importance and need the intermediacy of metal catalysts. We wondered whether such reactions could be promoted by apy-bridged triruthenium clusters.

Prior to this study, the reactivity of carbonyltriruthenium cluster complexes with these three reagents had been relatively uninvestigated. This is probably because their reactions with $[Ru_3(CO)_{12}]$ frequently give products of different nuclearity, i.e. $[Ru_4(\mu\text{-}H)_4(CO)_{12}]$,[29] $[Ru_2(SiR_3)_2(CO)_8]$ and $[Ru(ER_3)_2(CO)_4]$ (E = Si, Sn).[30] Interestingly, a few trinuclear products containing ER_3 groups have been obtained using $[Ru_3(MeCN)(CO)_{11}]$,[31] $[Ru_3(\mu\text{-}H)(CO)_{11}]^-$,[32] or ligand-bridged clusters[33] as starting materials.

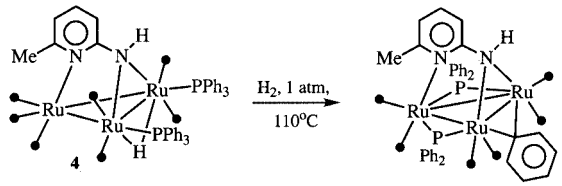
Complex **1** is an efficient catalyst precursor for the homogeneous hydrogenation of alkynes to alkenes and dienes to monoenes.[34] This catalytic activity prompted us to study the stoichiometric reactions that might be involved in the catalytic process. The reaction of complex **1** with hydrogen (1 atm, 110 °C) leads to the hexanuclear hexahydrido 92-electron derivative $[Ru_6(\mu_3\text{-}H)_2(\mu\text{-}H)_4(\mu_3\text{-}apyMe)_2(CO)_{14}]$ (**5**, Scheme 8),[35] erroneously formulated as $[Ru_3(\mu\text{-}H)_3(\mu_3\text{-}apyMe)(CO)_8]$ when it was first reported.[34] This remarkable complex consists of two unsaturated (46-electron) trinuclear units connected to each other through two bridging hydride ligands. The shortest Ru···Ru distance between the two trinuclear units is 3.292(3) Å, too long to be considered an Ru−Ru bond. It regenerates complex **1** when exposed to carbon monoxide (1 atm, 20 °C), but undergoes CO substitution instead of ligand addition when treated with P(*p*-tolyl)$_3$ at room temperature. Complex **5** is even more effective than **1** as a catalyst precursor for the homogeneous hydrogenation of diphenylacetylene under very mild conditions (1 atm, 50 °C).[36]



Scheme 8

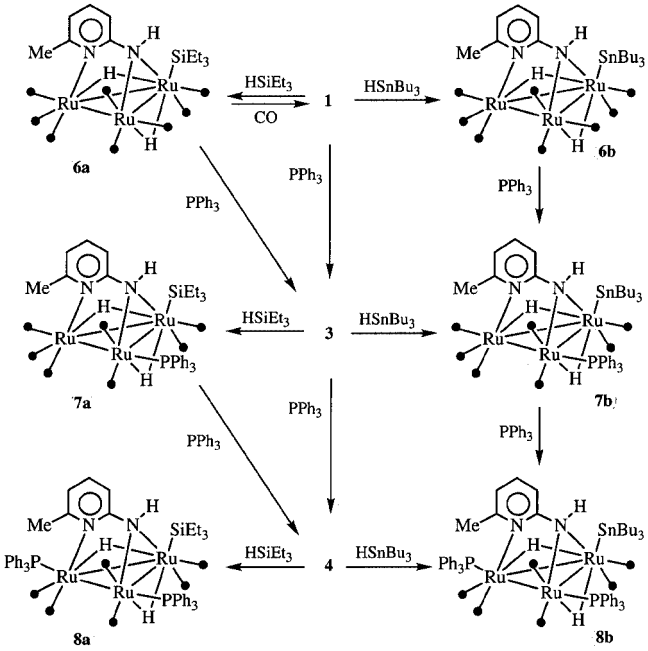
As occurs with $[Os_3(\mu\text{-}H)_2(CO)_{10}]$,[29] the hydrogenation of **1** implies the oxidative addition of hydrogen to a trinuclear cluster complex and the elimination of two CO ligands to give an unsaturated 46-electron species. While the osmium species is stable, the ruthenium species dimerizes to give **5**. Unsaturated 46-electron clusters of ruthenium are very rare. To date, only one trinuclear derivative has been reported, i.e. $[Ru_3(\mu\text{-}H)(\mu\text{-}PPh_2)(CO)_9]$.[37] A hexanuclear complex related to **5**, but containing thioureate instead of apyMe ligands, has also been reported.[38]

While the substituted complex $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apyMe)(PPh_3)(CO)_8]$ (**3**; Scheme 4) does not react with hydrogen, the disubstituted derivative $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apyMe)(PPh_3)_2(CO)_7]$ (**4**) undergoes two P−C bond activation processes on reaction with hydrogen (1 atm, 110 °C), leading to a complex containing a bridging phenyl group and two bridging diphenylphosphido ligands, i.e. $[Ru_3(\mu\text{-}Ph)(\mu_3\text{-}apyMe)(\mu\text{-}PPh_2)_2(CO)_6]$ (Scheme 9).[39] A few more triruthenium clusters containing bridging phenyl groups derived from PPh_3 ligands have been reported in the last few years.[17,40−42] It appears that cluster complexes of this type have an unusual ability of stabilizing bridging phenyl groups.



Scheme 9

The clusters $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apyMe)(PPh_3)_x(CO)_{9-x}]$ [x = 0 (**1**), 1 (**3**), 2 (**4**)] react with $HSiEt_3$ to give the oxidative substitution products $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}apyMe)(SiEt_3)(PPh_3)_x(CO)_{8-x}]$ [x = 0 (**6a**), 1 (**7a**), 2 (**8a**)]. Similar reactions with $HSnBu_3$ afford $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}apyMe)(SnBu_3)(PPh_3)_x(CO)_{8-x}]$ [x = 0 (**6b**), 1 (**7b**), 2 (**8b**)], which are isostructural with the corresponding silyl derivatives (Scheme 10).[43] The reactions of **6a** and **7a** with PPh_3 results in the elimination of $HSiEt_3$, rendering the complexes **3** and **4**. However, similar reactions with the tin-containing compounds **6b** and **7b** afford the substitution products **7b** and **8b**, respectively. Further, while **6b** is stable under carbon monoxide, the silyl derivative **6a** regenerates complex **1** under the same conditions. These reactions, which represent the first systematic study of the reactivity of triruthenium clusters with silanes and stannanes, demonstrate



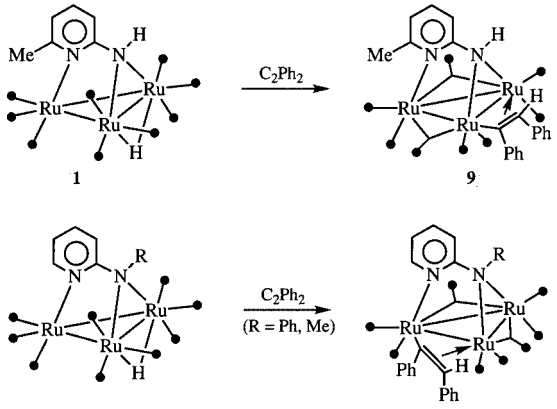
Scheme 10

that the hydrido(stannyl) complexes are much more stable than the hydrido(silyl) derivatives towards the elimination of the corresponding triorganostannanes or triorganosilanes.

III.c. Reactions with Alkynes

Alkynes have always attracted the attention of organometallic cluster chemists because of their versatile reactivity.[44] They are good ligands that bind strongly to the metal atoms, and are prone to undergo facile insertion processes and coupling reactions with other ligands.

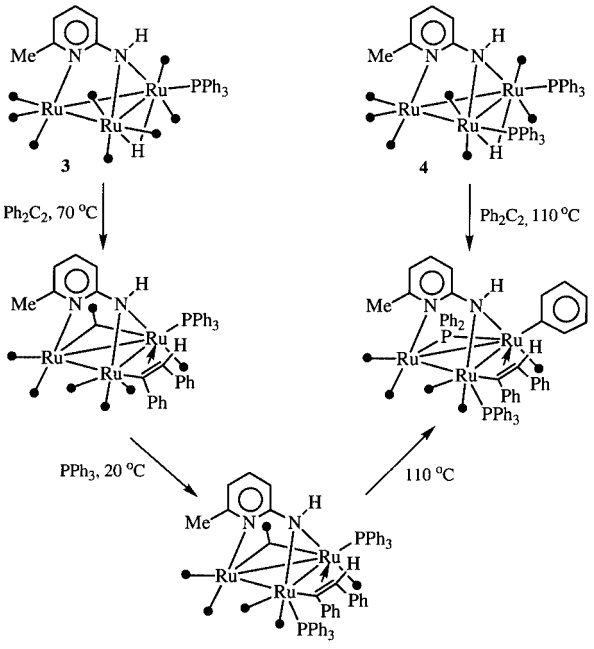
Cluster complexes of the type $[Ru_3(\mu\text{-}H)(\mu_3\text{-}apy)(CO)_9]$ react easily (10−20 min, 40−60 °C) with alkynes to give derivatives that contain edge-bridged alkenyl ligands. For steric reasons, the position of the alkenyl group within the clusters depends on the presence or absence of substituents on the amidic N atom (Scheme 11).[23,45]



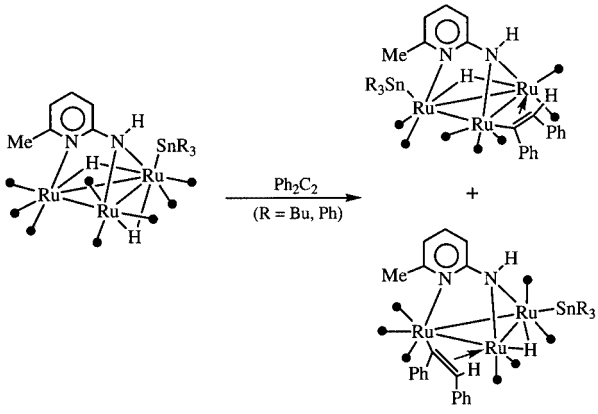
Scheme 11

The phosphane-substituted complexes **3** and **4** also react with diphenylacetylene to give alkenyl derivatives (Scheme 12).[46,47] The conditions needed for the reaction of the disubstituted complex **4** (110 °C, 75 min) induced the cleavage of a P−C bond giving a phenyl derivative that can be isolated.[47] The monosubstituted alkenyl derivative $[Ru_3(\mu_3\text{-}apyMe)(\mu\text{-}PhCH{=}CPh)(PPh_3)(CO)_7]$ promotes the catalytic hydrogenation of diphenylacetylene under mild conditions (1 atm, 80 °C). A kinetic analysis of this reaction indicated the presence of intermediate trinuclear clusters as catalytic species.[48]

The reaction of diphenylacetylene with the hydrido(silyl) compound $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}apyMe)(SiEt_3)(CO)_8]$ (**6a**) gives the alkenyl complex $[Ru_3(\mu_3\text{-}apyMe)(\mu\text{-}PhCH{=}CPh)(CO)_8]$ (**9**) and $HSiEt_3$.[46] Analogous reactions of hydrido(stannyl) compounds give a mixture of two isomeric hydrido(stannyl)-alkenyl derivatives (Scheme 13).[49] Interestingly, the reactions of the alkenyl complex **9** with tertiary silanes and stannanes give similar mixtures of compounds including (alkenyl)hydrido(silyl) and (alkenyl)hydrido(stannyl) derivatives.[46,49] It should be noted that in all the compounds having alkenyl and ER_3 ligands, these ligands are attached to different metal atoms. This may explain why no hydrosilylated or hydrostannated diphenylacetylene is observed when diphenylacetylene and triorganosilanes or triorganostannanes are allowed to react in the presence of complex **1**.



Scheme 12

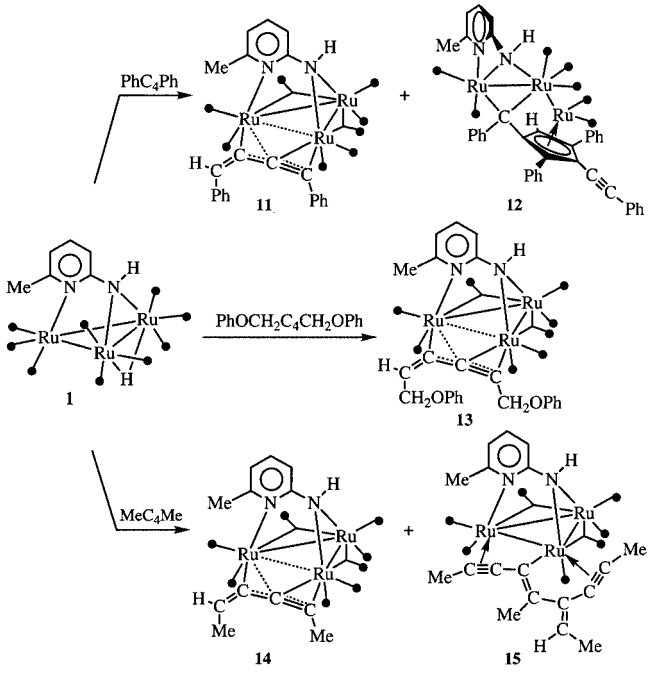


Scheme 13

It has been reported that $[Ru_3(\mu\text{-}H)(\mu_3\text{-}Phapy)(CO)_9]$ promotes the regioselective polymerization of phenylacetylene to *cis*-polyphenylacetylene, but only in the presence of a catalytic amount of $HSiEt_3$.[50] The role played by the silane remains unknown. In the absence of silane, 1,2,4-triphenylbenzene is obtained. When (triphenylsilyl)acetylene is used as the incoming substrate, a poor catalytic dimerization to (*E*)-1,4-bis(triphenylsilyl)but-1-yn-3-ene is observed.[50]

Compound **1** reacts with diphenylbutadiyne and 1,6-diphenoxyhexa-2,4-diyne in THF at refluxing temperature to give the ynenyl derivatives $[Ru_3(\mu_3\text{-}apyMe)(\mu\text{-}RC{\equiv}CC{=}CHR)(CO)_8]$ [R = Ph (**11**), CH_2OPh (**13**); Scheme 14]. These products contain a 1,4-disubstituted butynen-3-yl ligand η^3-coordinated to two ruthenium atoms. The remarkable compound $[Ru_3(\mu\text{-}apyMe)\{\mu_3\text{-}\eta^6\text{-}PhCC_5(C{\equiv}CPh)$-

$HPh_2\}(CO)_7$] (**12**), which contains an η^5-cyclopentadienyl ring and a bridging carbene fragment, has also been obtained from the reaction of **1** with diphenylbutadiyne.[51]



Scheme 14

As diynes contain asymmetric alkyne fragments, there are two possible products resulting from the insertion of one of their alkyne fragments into a metal−hydride bond.[51] While compounds **11** and **13** contain butynen-3-yl ligands that clearly result from one of the two possible insertion regioisomers, compound **12** arises from an unprecedented [3+2]-cycloaddition reaction of an unobserved 1,4-diphenylbutynen-4-yl ligand (of the other insertion regioisomer) with a triple bond of a second diphenylbutadiyne molecule. Both insertion regioisomers have been isolated from the reaction of [Ru_3(μ-H)(μ_3-Phapy)$(CO)_9$] with diphenylbutadiyne.[52]

The reaction of complex **1** with an excess of hexa-2,4-diyne in refluxing THF gives the trinuclear derivative [Ru_3-(μ_3-apyMe)$\{\mu$-η^5-MeC≡CC(=CHMe)CMe=CC≡CMe$\}$-$(CO)_7$] (**15**) as the final product (Scheme 14). This compound contains an unprecedented diynedienyl ligand that arises from the coupling of hexa-2,4-diyne with the hex-2-yn-4-en-4-yl ligand of the intermediate [Ru_3(μ_3-apyMe) μ-MeCH=CC≡CMe)$(CO)_8$] (**14**). This intermediate is the first compound observed in the reaction of **1** with hexa-2,4-diyne, but it could not be isolated free of **15**.[53]

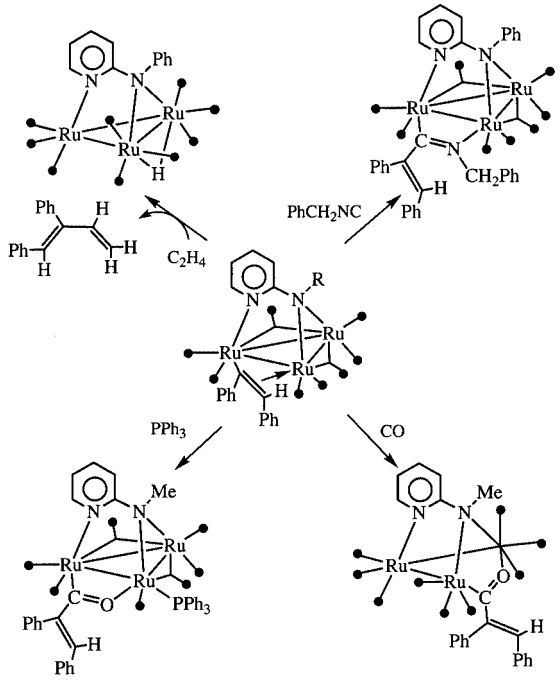
From the results described above, it can be inferred that alkynes can easily be activated in the form of alkenyl (vinyl) ligands by carbonyl(hydrido)triruthenium clusters containing bridging apy ligands. It is worth noting that the presence of the face-capping ligand in the clusters is essential in maintaining the cluster nuclearity, since it is well known that the reactions of alkynes and alkenes with hydridotriruthenium clusters containing edge-bridging ligands provoke the loss of one metal center, rendering bridged dinuclear products.[54]

III.d. Reactivity of Alkenyl Derivatives

Many of the alkenyl complexes commented on above were considered to be ideal candidates for reactivity studies, including the chemical modification of the alkenyl ligand itself.

Both the neutral alkenyl complex [Ru_3(μ_3-apyMe)(μ-PhCH=CPh)$(CO)_8$] (**10**) and its protonated derivative [Ru_3(μ-H)(μ_3-apyMe)(μ-PhCH=CPh)$(CO)_8$][BF_4] (**16**) promote the catalytic hydrogenation of diphenylacetylene under very mild conditions. The neutral complex is more efficient (TOF = 38.8 h^{-1})[55] than the cationic complex (TOF = 29.2 h^{-1})[56] under comparable reaction conditions [333 K, $p(H_2)$ = 0.573 atm]. (*Z*)-Stilbene is the kinetic product, but it is progressively isomerized to (*E*)-stilbene. Hydrogenation of stilbenes to 1,2-diphenylethane was not detected. Detailed chemical and kinetic studies on these reactions indicated the presence of intermediate trinuclear clusters as catalytic species in both cases.

Lavigne's group has studied a number of very interesting C−C bond-forming reactions starting from [Ru_3(μ_3-Rapy)(μ-PhCH=CPh)$(CO)_8$] (R = Ph or Me), that are outlined in Scheme 15.



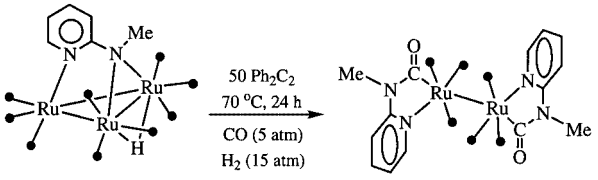
Scheme 15

Stoichiometric ethylene−diphenylacetylene codimerization has been observed on treating [Ru_3(μ_3-Phapy)(μ-PhCH=CPh)$(CO)_8$] with ethylene.[57] The mononuclear complex [Ru(PhCH=CPhCH=CH_2)$(CO)_3$] is a by-product of this reaction. It is proposed that the reaction proceeds by ethylene insertion into the metal−alkenyl group, followed by β-elimination. The elimination of free butadiene

competes with the elimination of the mononuclear butadiene complex.

The reaction of $[Ru_3(\mu_3\text{-Phapy})(\mu\text{-PhCH=CPh})(CO)_8]$ with benzyl isocyanide at room temperature leads to $[Ru_3(\mu_3\text{-Phapy})(\mu\text{-PhCH=CPhC=NCH}_2\text{Ph})(CO)_8]$, which contains an alkenylimino ligand (Scheme 15).[50] This insertion reaction is related to the rapid uptake of triphenylphosphane (room temperature), giving the acyl derivative $[Ru_3(\mu_3\text{-Meapy})(\mu\text{-PhCH=CPhC=O})(PPh_3)(CO)_7]$.[58] Second-order kinetics indicate that the initial step is an associative addition of the PPh_3 ligand to the metal cluster without CO loss.

In addition, a related 50-electron acyl derivative, i.e. $[Ru_3(\mu_3\text{-Meapy})(\mu\text{-PhCH=CPhC=O})(CO)_9]$, is formed when the alkenyl precursor is exposed to CO (Scheme 15).[58] Hydrogenation (25 °C, 5 atm) of this complex causes the elimination of α-phenylcinnamaldehyde and the recovery of the hydrido complex $[Ru_3(\mu\text{-H})(\mu_3\text{-Meapy})(CO)_9]$. The overall transformation constitutes a stepwise hydroformylation of diphenylacetylene. Attempts to achieve a catalytic process led to the isolation of the catalytically inactive dinuclear derivative $[Ru_2(MeCOapy)_2(CO)_6]$ as the major metal-containing product (Scheme 16).[58] This reaction represents the first (and so far unique) example of the degradation of an apy-bridged triruthenium cluster, probably due to the harsh reaction conditions.



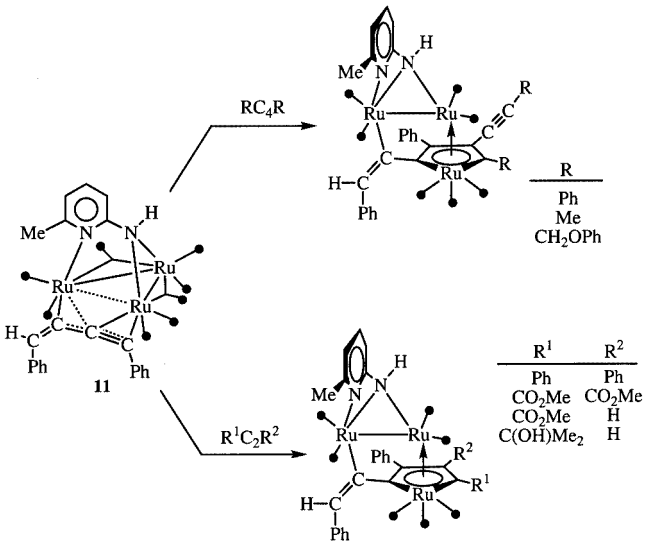
Scheme 16

The reactivity of the ynenyl derivatives $[Ru_3(\mu_3\text{-apyMe})(\mu\text{-RC}\equiv\text{CC=CHR})(CO)_8]$ [R = Ph (**11**), CH_2OPh (**13**)] with diynes and alkynes has been studied.[51] In all cases, the products contain a ruthenacyclopentadienyl fragment formed by the coupling of the coordinated ynenyl ligand of the starting material with a triple bond of the new reagent (Scheme 17). While all compounds derived from **11** have the alkenyl C=CHR (R = Ph) fragment with an (*E*) configuration (R *trans* to Ru, Scheme 17), most of the products derived from **13**, have the alkenyl C=CHR (R = CH_2OPh) fragment with an (*E*) configuration.

It is interesting to note that all these ruthenacyclopentadienyl derivatives, as well as complex **12** (Scheme 14), have a 5-electron donor apyMe ligand attached to only two metal atoms, a coordination mode previously unobserved for apy ligands in cluster chemistry that strongly supports the hemilabile character of these ligands.

III.e. Synthesis and Reactivity of Cationic Non-Hydridic Clusters

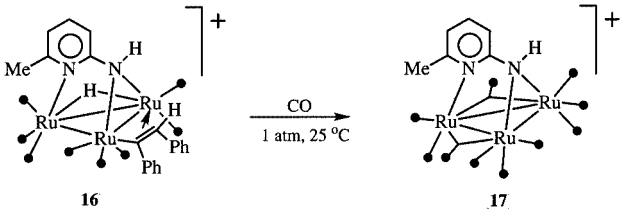
Simple protonation of neutral carbonyl cluster complexes frequently leads to cationic hydridic derivatives.[19,24,25]



Scheme 17

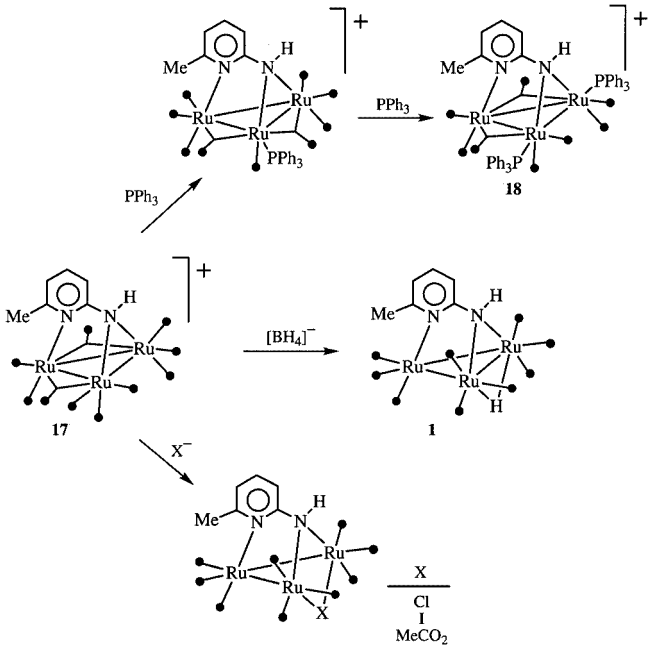
However, very few non-hydridic cationic carbonyl clusters have been described. For ruthenium, prior to the cluster complexes commented on below, only a few examples of trinuclear 50-,[59] 47-[60] or 46-electron[60] species were known.

The presence of the alkenyl and hydride ligands in the cationic complex $[Ru_3(\mu\text{-H})(\mu_3\text{-apyMe})(\mu\text{-PhCH=CPh})(CO)_8][BF_4]$ (**16**) prompted us to study reactions that might induce the reductive elimination of (*Z*)-stilbene, and that would give cationic cluster compounds containing non-hydridic ligands. Although reactions with phosphane ligands only lead to CO-substitution products,[61] complex **16** reacts gently (1 atm, 20 °C) with carbon monoxide giving the cationic complex $[Ru_3(\mu_3\text{-apyMe})(CO)_{10}][BF_4]$ (**17**) in quantitative yield (Scheme 18). (*Z*)-Stilbene is a by-product of this reaction.[62] No other non-hydridic 48-electron cationic triruthenium cluster complexes were known prior to the publication of complex **17**.

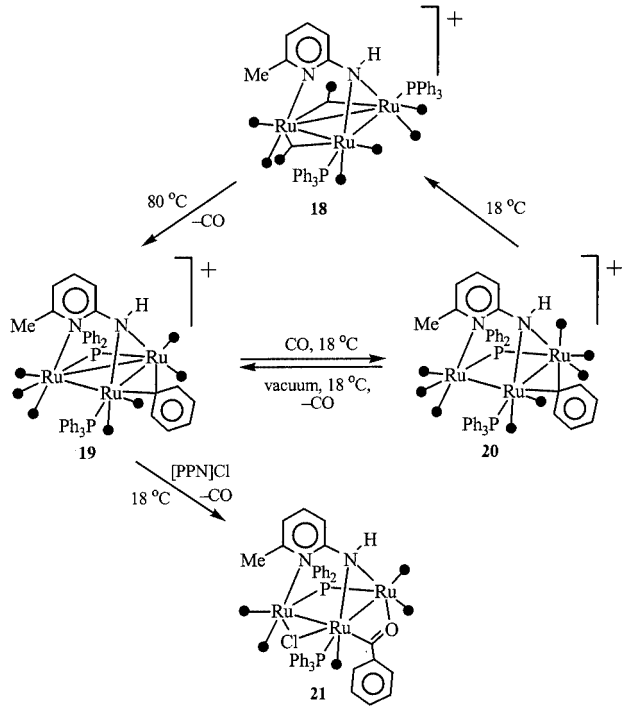


Scheme 18

The reactivity of complex **17** markedly reflects a very high electrophilicity. It easily undergoes CO-substitution reactions on treatment with a variety of nucleophiles, including phosphanes,[62] hydrides, halides and carboxylates (Scheme 19), and is unstable in donor solvents (acetone, THF).[63]



Scheme 19

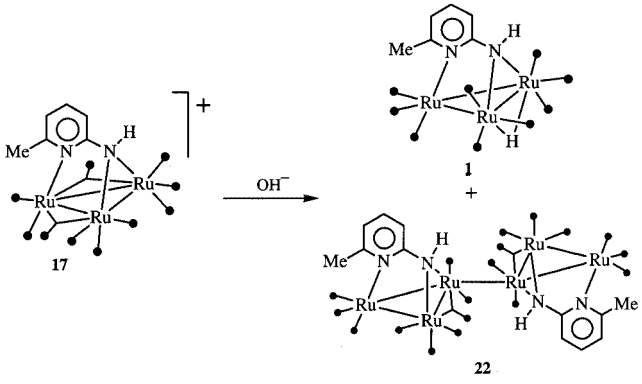


Scheme 20

It is worth noting that the thermal activation of a P−C bond of the disubstituted compound $[Ru_3(\mu_3\text{-apyMe})(PPh_3)(CO)_8][BF_4]$ (**18**) leads to the phenyl derivative $[Ru_3(\mu\text{-Ph})(\mu_3\text{-apyMe})(\mu\text{-}PPh_2)(PPh_3)(CO)_7][BF_4]$ (**19**). Treatment of **19** with carbon monoxide regenerates **18** via the 50-electron intermediate $[Ru_3(\mu\text{-Ph})(\mu_3\text{-apyMe})(\mu\text{-}PPh_2)(PPh_3)(CO)_8][BF_4]$ (**20**) (Scheme 20).[41] These reactions represent the only reversible triphenylphosphane P−C bond activation reaction reported in carbonyl cluster chemistry. The characterization of the neutral acyl derivative $[Ru_3(\mu\text{-PhCO})(\mu\text{-Cl})(\mu_3\text{-apyMe})(\mu\text{-}PPh_2)(PPh_3)(CO)_5]$ (**21**), which arises from the reaction of **19** with [PPN]Cl, supports the formulation assigned to **19**.[41]

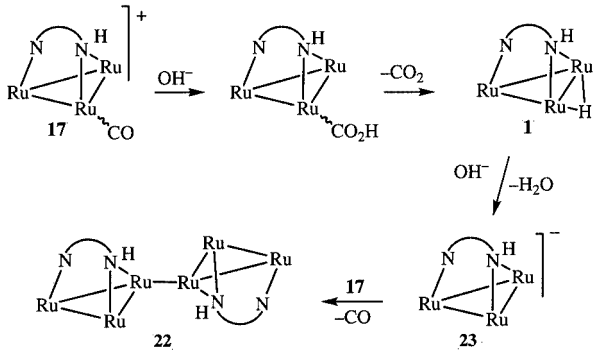
III.f. Reactions Leading to Higher-Nuclearity Clusters

As part of the study of the reactivity of the cationic complex **17**, we treated it with aqueous NaOH. Two complexes were obtained, i.e. **1** and the hexanuclear derivative $[Ru_6(\mu_3\text{-apyMe})_2(CO)_{18}]$ (**22**) (Scheme 21).[64] The latter is the only example of a hexanuclear cluster consisting of two vertex-linked metal triangles in the chemistry of ruthenium.



Scheme 21

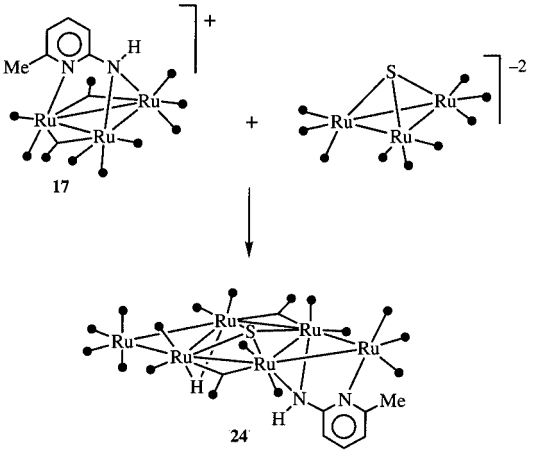
A possible reaction pathway for this transformation is sketched in Scheme 22.[64] It involves the nucleophilic attack of the coordinated CO ligand of complex **17** by the hydroxide anion, to give an unstable hydroxycarbonyl species that rapidly releases CO_2, rendering the neutral hydride **1**. Before all of complex **17** has been consumed, complex **1** deprotonates with more OH^- giving the anionic derivative $[Ru_3(\mu_3\text{-apyMe})(CO)_9]^-$ (**23**). Finally, **23** reacts with the remaining complex **17** to give CO and the hexanuclear cluster **22**. This reaction sequence is supported by the facts that **17** does react with **23** to give **2**, and that **1** can be deprotonated with NaOH to afford **23**. Alternatively, compound **22** can also be prepared by zinc reduction of complex **17**.[64]



Scheme 22

The hexanuclear compound $[Ru_6(\mu\text{-H})(\mu_4\text{-S})(\mu_3\text{-apyMe})(CO)_{17}]$ (**24**), which consists of two closed trimetal units connected by two metal−metal bonds, has been prepared

by reaction of the cationic complex **17** with the anionic cluster $[Ru_3(\mu_3\text{-}S)(CO)_9]^{-2}$ (Scheme 23).[63] Although other related carbonylhexaruthenium cluster compounds containing μ_4-S ligands are known,[38][65] they are electron-rich derivatives since their electron count (94-electrons) has two electrons more than those required by electron-precise clusters containing eight metal−metal bonds (92 electrons). In contrast, compound **24** is electron-precise.

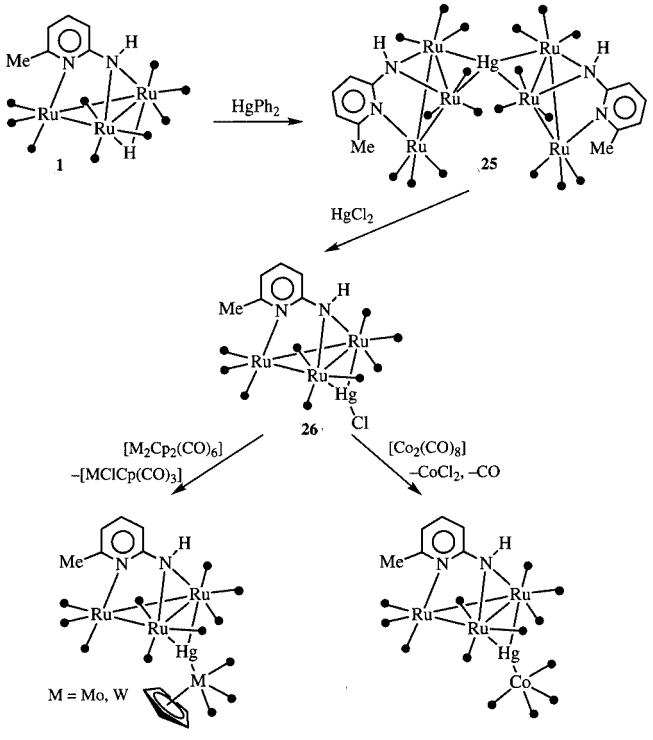


Scheme 23

The reactions of anionic carbonyl clusters with mononuclear cations have often been used to prepare higher-nuclearity cluster compounds.[66] However, no reactions of cationic carbonyl clusters with anionic complexes had been reported prior to the publication of compound **17**. This is probably because cationic non-hydridic clusters were not readily accessible and because a proton transfer from the cation to the anion occurs when cationic hydridic clusters are used. This results in a mixture of two neutral complexes rather than a cluster of higher nuclearity.

The mercury-containing hexaruthenium cluster $[Ru_6(\mu_4\text{-}Hg)(\mu_3\text{-}apyMe)_2(CO)_{18}]$ (**25**) has been prepared by treating complex **1** with diphenylmercury (Scheme 24).[67] This complex reacts with mercury(II) chloride to give $[Ru_3(\mu\text{-}HgCl)(\mu_3\text{-}apyMe)(CO)_9]$ (**26**). In both cases, the mercury atoms span the same Ru−Ru edge as the amido moiety.

Redistribution reactions of compound **26** with the metal−metal-bonded dimers $[M_2Cp_2(CO)_6]$ (M = Mo, W) and $[Co_2(CO)_8]$ give mixtures of the mixed-metal clusters $[\{Ru_3(\mu_3\text{-}apyMe)(CO)_9\}(\mu\text{-}Hg)ML_n]$ (ML_n = $MoCp(CO)_3$, $WCp(CO)_3$, $Co(CO)_4$] and the corresponding chloro complexes $[MClL_n]$ (Scheme 24).[68] These mixtures can be separated. Besides these reactions, the only additional example of a reaction of a metal cluster containing an HgX (X = halogen) moiety with a neutral complex containing metal−metal bonds is that of $[Ru_3(\mu\text{-}HgI)(\mu_3\text{-}C_2t\text{Bu})(CO)_9]$ with $[Ru_3(CO)_{12}]$, which gives $[\{Ru_3(\mu_3\text{-}C_2t\text{Bu})(CO)_9\}_2(\mu_3\text{-}Hg)_2Ru(CO)_4]$ as the major product.[69]



Scheme 24

IV. Concluding Remarks

The following are the principal features associated with apy ligands in carbonyltriruthenium clusters:

(a) The apy ligands remain unchanged under most reaction conditions, thus avoiding undesirable side reactions.

(b) The reactions take place under mild conditions (25−100 °C), probably induced by a hemilabile effect of the apy ligands.

(c) Reactivity (CO substitution) is directed to positions *cis* to the apy amido group, thus leading to regioselective reactions in most cases.

(d) The trinuclear cluster framework is preserved during the reactions because of the mild reaction conditions, and because of the anchor effect of the apy ligands, which maintains the metal atoms in adequate proximity.

(e) This type of cluster complexes show an unusual ability to stabilise bridging phenyl groups.

(f) The compounds have a convenient solubility in polar solvents (insoluble in nonpolar solvents), particularly if the exocyclic nitrogen atom is part of an N−H group.

(g) The basicity of the apy ligands can be tuned by introducing substituents on the exocyclic nitrogen atom.

(h) The reactions can easily be monitored by ^{1}H NMR spectroscopy, particularly if the pyridine ring contains a methyl substituent.

Up to date, over a hundred carbonyltriruthenium cluster complexes containing bridging apy ligands have been reported. This wide-ranging cluster chemistry includes quite a few outstanding reactions and products, which have been surveyed in this review. No doubt, this rich derivative chemistry has been facilitated by the presence of deprotonated 2-aminopyridines as ancillary ligands in the clusters.

Acknowledgments

The author wishes to thank the researchers cited in the references for their contribution to the chemistry surveyed in this review and, in particular, his colleagues and friends José M. Fernández-Colinas and Ignacio del Río. Continuous financial support from the Spanish Ministry of Education is also acknowledged (Projects PB92-1007, PB95-1042, and PB98-1555).

[1] Throughout this review, the term cluster complex refers to a complex containing at least three metal atoms supported by at least two metal−metal bonds.

The Polyhedral State of Molecular Matter

Arnout Ceulemans*[a] and Erwin Lijnen[a]

Keywords: Group theory / Topological chemistry / Polyhedra / Fullerenes / Cubanes / Boranes

The review introduces the mathematical concept of a complex, as an original way to describe the topology of a polyhedral molecule. It shows how this concept can be applied to electronic structures and magnetic and vibrational properties. Using symmetry it identifies topologically invariant orbitals and moments.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

1. Introduction

A molecule is a set of atomic nuclei held together by a cloud of electrons. In its simplest representation this form of matter can be conceived as a collection of beads held together by strings. The mathematical concept, which corresponds to this representation, is the concept of a *graph*.[1] In the graph-like state only the connections between atoms count, and there is no information on their spatial arrangement. Nonetheless this representation is extremely useful, not only to retrieve molecules in a data-base, but also to rationalise many important molecular properties.[2]

The topic of this review will be a higher form of molecular organisation, which we describe as the *polyhedral* state. Inorganic chemists already have an intuitive knowledge of polyhedra, as structural units of many inorganic compounds. In its polyhedral state, molecular matter is not just a set of points and lines, but it is furthermore specified that certain closed loops of lines will form faces. In turn faces themselves may enclose a finite region of space which is a cell or a chamber. The mathematical concept, which corresponds to this polyhedral representation, is the concept of a *polyhedral complex*.[3]

Unlike its graph relative, the complex concept is not known outside mathematics. In section 2 we will thus first have to explain its proper meaning. For this no special mathematical background will be required, except for a general knowledge of group theory for chemists, as may be found in Cotton's book.[4] In section 3 we will then represent a fundamental result about the symmetries of polyhedral complexes, which opens up this concept for applications on molecular matter. In the subsequent sections, several applications related to electronic structure and elastic and magnetic properties of network molecules are reviewed.

2. Polyhedral Complexes

In the chemical literature a polyhedron refers to a surface which is wrapped around a finite region of space, and consists of many polygons or faces; in turn the faces are bor-

Arnout Ceulemans (left) is full Professor of Chemistry at the University of Leuven. He received his Ph. D. in Leuven while working in the group of Luc Vanquickenborne on theoretical models for ligand field photochemistry. He habilitated in 1986 in Leuven with a thesis on the Jahn−Teller effect in complexes and clusters. He teaches Group Theory, Chemical Physics, and Inorganic Chemistry. His main research interests are the application of group-theoretical and topological methods at the border between chemistry and physics.

Erwin Lijnen (right) graduated in chemistry at the University of Leuven in 2001. He is currently Aspirant of the Fund for Scientific Research − Flanders (Belgium) and prepares a doctoral thesis in the laboratory of Quantum Chemistry at the K. U. Leuven on topological representations of tridimensional molecular structures.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

dered by edges; finally the edges connect vertices. Chemists are also familiar with Euler's celebrated theorem that states that the numbers of vertices, edges, and faces, denoted as v, e, and f, respectively, obey the rule as given in Equation (1).

$$v - e + f = 2 \tag{1}$$

This theorem holds for any polyhedron that can be mapped on the surface of a sphere.[5] It can, however, be generalised to polyhedral nets on surfaces with other topologies as shown in Equation (2).

$$v - e + f = \chi \tag{2}$$

Here χ is a fixed integer, the Euler characteristic, which marks the particular topology of the surface on which the polyhedron is embedded. As an example for a sphere with g handles or holes, the Euler characteristic reads as given in Equation (3) with $g = 0$ for a sphere, $g = 1$ for a torus or doughnut, $g = 2$ for a pretzel etc.; g is also called the genus of the surface.

$$\chi = 2 - 2g \tag{3}$$

Turning from chemistry to mathematics we must now become acquainted with the ingredients of the polyhedral complex in the mathematical sense. Of course the same structural elements, vertices, edges, and faces, will appear, but there are some nontrivial amendments, and, above all, we must find out what happens to the Euler characteristic.

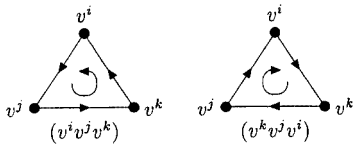
Vertices are zero-dimensional objects, and therefore are trivial. A given vertex will be denoted as v^i. At the next level, an edge is already not just a line connecting two vertices, but rather an arrow, pointing from one of these vertices to the other. Hence an edge between two vertices, say v^i and v^j will be denoted as the *ordered* pair $(v^i v^j)$, where we agree to identify the first vertex, v^i, as the tail of the arrow, and the second, v^j, as its head. The ordering itself is purely a matter of choice. We might as well denote the same edge by the inverted ordering, $(v^j v^i)$. Since the corresponding arrow points in the opposite direction, we can write Equation (4).

$$(v^i v^j) = -(v^j v^i) \tag{4}$$

The requirement that the edges be ordered is therefore not just a trivial feature: it transforms the edges to signed quantities, and therefore creates algebra on the surface of the polyhedron. At this point it is of course difficult to appreciate all its implications, but we hope this will gradually become clear in the forthcoming sections.

In a similar way a face is an ordered closed loop of vertices. Consider for instance three vertices, say v^i, v^j, and v^k, which form a triangular face, then we may denote this face as the ordered trio $(v^i v^j v^k)$. This notation defines the face as a closed loop, $v^i \rightarrow v^j \rightarrow v^k \rightarrow v^i$. For an external observer this circulation will have a definite sense, either clockwise or anticlockwise. Again if we invert the ordering, we invert this sense, and we can write Equation (5).

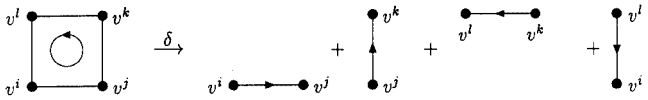
$$(v^i v^j v^k) = -(v^k v^j v^i) \tag{5}$$



Vertices, edges, and faces are layers of organisation, involving objects of dimension zero (point), one (line), and two (plane), respectively. We could also include the next layer of 3D objects or cells, but will not further consider this here.

As in all organised structures consecutive layers are in touch. The topdown descent from higher to lower dimensional objects is called *bordering* or *taking the boundary.*

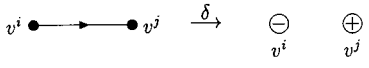
The boundary of a face is a sum of the arrows along the surrounding edges. We will avoid the rigorous mathematical definition of this operation and write it in a simple pictorial way as



or as

$$\delta(v^i\ v^j\ v^k\ v^l) = (v^i\ v^j) + (v^j\ v^k) + (v^k\ v^l) + (v^l\ v^i)$$

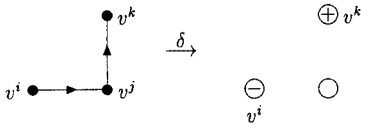
where the Greek letter δ represents the boundary operation. Likewise the boundary of an edge is the difference between its head vertex and its tail



or

$$\delta(v^i\ v^j) = v^j - v^i.$$

Interestingly, not all combinations of a given level have boundaries. As an example, when the number of incoming and outgoing arrows on a given vertex is the same, this vertex is not a boundary, e.g.



This part of the theory is the most interesting from our point of view: we must look for combinations that are not boundaries of some higher level, and have no boundaries on some lower level. Such combinations are *topological invariants* of the polyhedron, and are extremely important from the point of view of electronic structures. In mathematics they are called *homologies*.[6] These are the concepts behind the Euler characteristic. Our task will be to identify them properly, since they hold the key to the topology. To summarise, in Table 1 we list the ingredients of a tetrahedral complex. This complex can be embedded on a sphere and therefore has Euler characteristic $\chi = 2$. It indeed contains two homologies, which we will try to find in the next section with the help of group theory.

Table 1. Elements of a tetrahedral complex

Vertices or Atoms	Edges or Bonds	Faces
v^0	(v^0v^1)	$(v^0v^1v^2)$
v^1	(v^0v^2)	$(v^0v^1v^3)$
v^2	(v^0v^3)	$(v^0v^2v^3)$
v^3	(v^1v^2)	$(v^1v^2v^3)$
	(v^1v^3)	
	(v^2v^3)	

3. From Topology to Symmetry and Back

If the polyhedron exhibits a point-group symmetry, we can apply its symmetry elements to the set of vertices. The action of a symmetry element on a vertex is very simple: it just maps this vertex on some other vertex of the complex. It therefore can be described as a permutation of the elements in the set of vertices. Hence we can write Equation (6), where R_i is the image of i under this mapping.

$$Rv^i = v^{R_i} \tag{6}$$

This expression is all one needs to determine how the ordered objects, edges and faces, of the polyhedral complex behave under symmetry operations. Indeed one has for an ordered pair Equation (7).

$$R(v^iv^j) = (v^{R_i}v^{R_j}) \tag{7}$$

The resulting image $(v^{Ri}v^{Rj})$ is again an edge, which will also belong to the complex, although it might have been defined in opposite order as $(v^{Rj}v^{Ri})$ in which case we can always rewrite the equation as Equation (8).

$$R(v^iv^j) = -(v^{R_j}v^{R_i}) \tag{8}$$

Similarly, mapping of face circulations under symmetry elements may produce images that differ by a sign from the selected list of faces, but in any case a face will always be mapped by R on another face which will be symmetric to the former one.

In this way we can easily determine the transformation matrices describing the action of the symmetry elements on the components of the polyhedral complex. These matrices form representations of the symmetry group. In Table 2 we introduce appropriate symbols for the representations of vertices, edges and faces.

Table 2. Symmetry representation for the elements of a complex

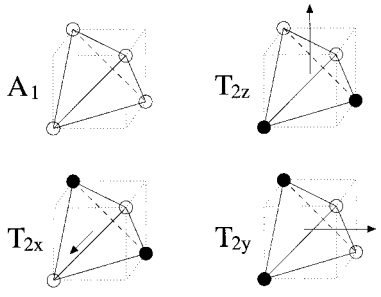
Element	Symbol	Type
vertex	$\Gamma_\sigma(v)$	scalar
edge	$\Gamma_\parallel(e)$	vector
face	$\Gamma_\odot(f)$	rotor

Here Γ is the general symbol for induced symmetry representations.[7] The index σ for the vertex representations indicates that point vertices are symmetric objects with respect to the symmetry elements that pass through the vertex sites, in the same way as s or p_z orbitals in axially symmetric sites. For the edge representations the symbol $\parallel$ refers to the set of arrows along the edges, while the index $\odot$ in the face-representations refers to the circular arrows on the faces. All these representations are in principle *reducible*, which means that they can be decomposed into standard irreducible representations, which describe the basic symmetry patterns in the point group.

These so-called *irreps* can easily be found using the standard techniques of character theory.[4] As an example for the tetrahedral complex in Table 1, one immediately obtains these representations in the T_d symmetry group, see Equation (9).

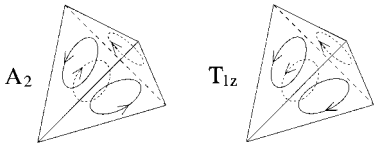
$$\begin{aligned} \Gamma_\sigma(v) &= A_1 + T_2 \\ \Gamma_\parallel(e) &= T_1 + T_2 \\ \Gamma_\odot(f) &= A_2 + T_1 \end{aligned} \tag{9}$$

Of these combinations only the vertex terms are familiar to chemists. They simply represent the SALCs (symmetry-adapted linear combinations of atomic orbitals) of MO (molecular orbitals) theory, and look as follows.



The representations on the edges can be constructed in an entirely similar way, only the constituent objects are not s-like orbitals on the atomic vertices, but with arrows along the edges. As an example we show the z components of T_1 and T_2. In the T_{2z} combination the tetrahedron is oriented in the upright z direction, and the arrows along the four lateral edges are pointing upwards. The same arrows are present in the T_{1z} combination but now their orientation alternates between pointing up and down. The x and y components are oriented in an analogous way along their respective directions.

Finally the face terms correspond to symmetry-adapted linear combinations of circular arrows on the face centres. Here we show the A_2 and T_{1z} components.



In Figure 1 we gather all these components in a schematic overview. We have also added the boundary relations that exist between the different layers, to this figure. It is very important to realise that taking the boundaries of faces or edges will *not* alter the symmetries. This operation indeed simply corresponds to the expansion of the circular face arrows to the bordering edges and the edge arrows to the head and tail vertices. As a result, the T_1 face terms will be bordered by the equisymmetric T_1 edge terms, while the T_2 edge modes indeed are bordered by the equisymmetric T_2 vertex combinations.

Two combinations stand on their own, not being bordered by a lower ranking component, nor being themselves borders of some higher component: the A_1 vertex combination and the A_2 face combination. Indeed by taking the boundary of the latter, we generate on all edges pairs of opposite arrows, which therefore cancel. Similarly, the former cannot be the boundary of an edge mode, since all vertices have the same weight, implying no net changes along edges.

Hence by using symmetry and elimination we have found combinations, which are very special topological invariants: they cannot be the origin or image of the boundary mapping.

These combinations can easily be filtered out by taking the alternating sum of all three representations, Equation (10).

$$\Gamma_\sigma(v) - \Gamma_\parallel(e) + \Gamma_\odot(f) = A_1 + T_2 - T_1 - T_2 + A_2 + T_1 = A_1 + A_2 \tag{10}$$

Indeed in this way all terms which are taking part in the boundary will cancel.

Obviously, the structure of Equation (10) involves the familiar Euler theorem for a surface of genus zero. Indeed if we ignore all symmetry elements, or equivalently suppose that the only symmetry element is the trivial unit element of the point group, all representations in Equation (10) would reduce to multiples of the trivial A representation of the C_1 point group, and the multiplication factor would simply

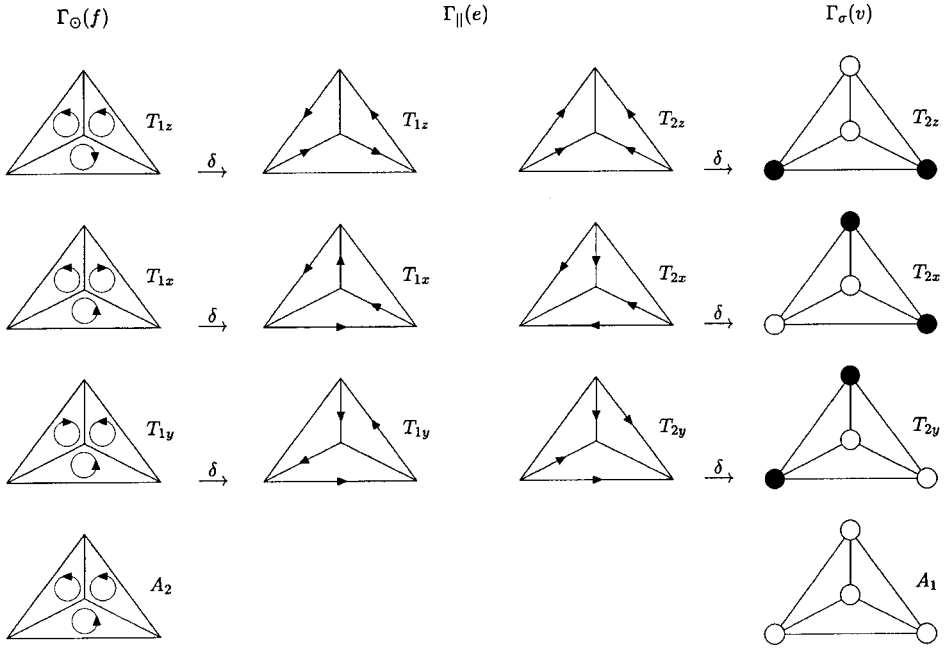


Figure 1. SALCs for the tetrahedral complex

equal the number of vertices, edges, or faces, see Equation (11).

$$\begin{aligned} \Gamma_\sigma(v) &= v.A \\ \Gamma_\parallel(e) &= e.A \\ \Gamma_\odot(f) &= f.A \end{aligned} \tag{11}$$

With $A_1 + A_2 \rightarrow 2\ A$, Equation (10) then reduces to a purely dimensional formula, $v - e + f = 2$, which is exactly Euler's result. Hence, by bringing together symmetry and topology, it is possible to reveal the topological aspects of Euler's rule:

1. We understand now that, not only are the numbers of the polyhedral structure elements related, but also their symmetries. In this respect the number rule is just the (dimensional) top of a symmetry iceberg.

2. The topological invariants, which appear as the remainders of the alternating sum over the structural layers, are characterised by irreducible symmetry representations. These symmetries are keys to relating the topological invariants to chemical and physical properties.

For polyhedra, which can be mapped on the surface of a sphere, the result in Equation (10) can be cast in the general form as given in Equation (12).

$$\Gamma_\sigma(v) - \Gamma_\parallel(e) + \Gamma_\odot(f) = \Gamma_0 + \Gamma_\epsilon \tag{12}$$

The representations Γ_0 and Γ_ε, which appear here on the right-hand side are, respectively, the totally symmetric and pseudo-scalar representation, which is symmetric under proper rotations and antisymmetric under improper rotations. In Mulliken's notation for the point groups, the Γ_0 representation receives labels such as: A_1, A_{1g}, or $A_1{}'$, while the corresponding Γ_ε representation is denoted as A_2, A_{2u}, or $A_2{}''$. A general proof of this result has been given,[8] and its connection to the abstract theory of homology groups has been explained.[9]

Similar results can be obtained for polyhedra with other Euler characteristics. In each case the alternating sum of representations will generate a characteristic set of homologies.

In Table 3 we give an overview of the different topologies we have examined so far. The final two items in the table concern polyhedra that are embedded on a 3D surface. In this case a further structural element must be added, which is the cell or chamber. In the same way as faces are defined as rings of edges, cells are closed regions of space surrounded by faces. In this case the Euler theorem must be extended to include the number of cells, c: Equation (13).

$$v - e + f - c = \chi \tag{13}$$

As an example in the case of a body-centred tetrahedron one has $v = 5$, $e = 10$, $f = 10$, $c = 4$, resulting in the Euler characteristic $\chi = 1$, as indicated in Table 3 for polyhedra with the topology of a solid sphere.

Table 3. Overview of topological structures for which symmetry relationships have been derived

4. Applications

In this section we review two typical cases of polyhedral electronic structures and identify the topologically determined properties.

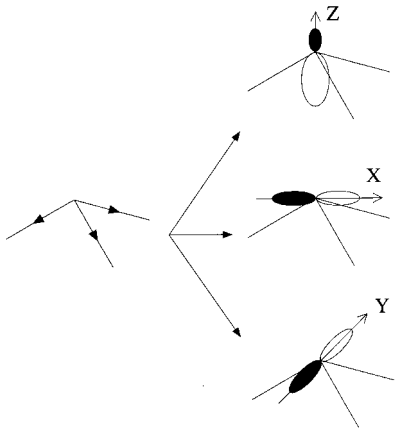
4.1 The Antibonding Orbitals in Trivalent Clusters

Electron counting rules are an important tool for addressing the problem of cluster bonding, and new developments continue to appear.[14,15] Here we will examine a straightforward application of the general graph-theoretical result, which is encountered in the electronic structure of so called "electron-precise" trivalent clusters.[8]

In a trivalent polyhedral cage, each cluster atom has three neighbours. From each vertex radiate three edges, while in turn every edge is linked to two vertices, see Equation (14).

$$3v = 2e \tag{14}$$

The cluster will be completely edge-bonding if each cluster atom has three valence orbital hybrids, which point along the edges and are each occupied by one electron. This requires one inward pointing (radial) hybrid and a tangential $\{p_x, p_y\}$ pair.



In this way one obtains a saturated or "electron-precise" electronic structure with precisely $3v/2$ valence electron pairs, forming an equal number of σ bonds along the edges. Examples are the polyhedranes C_vH_v such as tetrahedrane ($v = 4$), cubane ($v = 8$), or dodecahedrane ($v = 20$), or the equivalent transition-metal clusters, built on the isolobal $Co(CO)_3$ or $Ir(CO)_3$ fragments.[16]

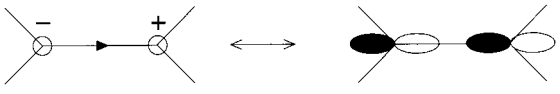
The electronic levels of such compounds were investigated by Johnston and Mingos.[17,18] The $3v/2$ occupied bonding orbitals have precisely $3v/2$ antibonding counterparts. These empty orbitals on the edges can be grouped together in $[v/2] + 1$ strongly antibonding face-combinations and $v - 1$ less antibonding vertex-localised orbitals, Equation (15).

$$3v/2 = [v/2 + 1] + [v - 1] \tag{15}$$

Since in a trivalent cage one has $3v = 2e$ [Equation (14)] and $f = v/2 + 2$, Equation (15) is just a manifestation of Euler's rule, written as in Equation (16).

$$e = [f - 1] + [v - 1] \tag{16}$$

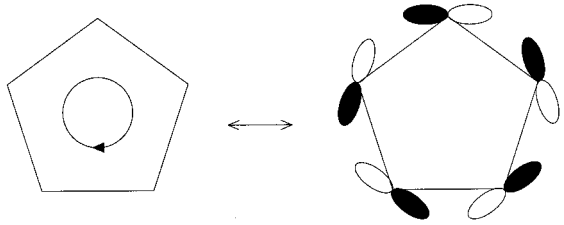
We can now extend this rule to the symmetries of these antibonds. Antibonds along edges with a positive head and a negative tail have precisely the same symmetry as arrows along edges, hence the symmetries of the antibonding shell correspond to $\Gamma_{\|}(e)$.



The symmetry result then predicts Equation (17).

$$\begin{array}{rcccc} e & = & [f-1] & + & [v-1] \\ \Gamma_{\|}(e) & = & [\Gamma_{\odot}(f) - \Gamma_{\epsilon}] & + & [\Gamma_{\sigma}(v) - \Gamma_0] \end{array} \tag{17}$$

The first term on the right-hand side of dimension $(f - 1)$ refers to symmetries of faces in the polyhedral complex. We have represented these earlier as circular arrows, which indeed precisely correspond to the face antibonds of Mingos and Johnston.



The topological basis of this result clearly explains why the number of these highly antibonding orbitals is one less than the number of faces. Indeed if we set up an antibonding combination in which all the face antibonds are rotating in the same direction, there will be two opposite arrows along every edge, which will therefore exactly cancel.

The second term of the equation contains the remaining $v - 1$ terms, which are vertex-localised and therefore less antibonding, as was found by the previous model calculations of Johnston and Mingos.[17] Again the topology of the polyhedron explains why the number of these is one less than the number of vertices. The combination that is lacking transforms as Γ_0, and simply corresponds to the sum of all vertex orbitals of σ-type. This combination is of course completely bonding, and cannot be contained in the edge-antibonding orbitals.

We thus have found important features of the electronic structure of trivalent clusters, which clearly belong to the polyhedral state of molecular matter. The repartitioning of the edge antibonds in face-related and vertex-related parts is entirely based on the polyhedral relationships, as expressed by the symmetry extension of Euler's rule. In electron-precise compounds both sets are empty, yielding an electron count of $3v/2$ skeletal pairs.

4.2 Electronic Properties of Toroidal Polyhedra

The invariants, which arise in the abstract topological treatment, can be understood very simply in terms of densities and currents on a polyhedral surface.

As a simple physical example we take a model of fluid flow on a polyhedral surface. One could think of a flooded polyhedron, with observers on the vertices, edge centres, and face centres. The observers on the vertices measure the net increase or decrease in density which is taking place at the vertices during a given time interval. They thus report a scalar quantity, which stands for the vertex term in the expression. The observers on the edges measure the fluid flow along the edges. The quantity that they report is a vectorial component of flow pointing along the direction of the edge; this is precisely the edge term in the expression. Finally, the observers on the faces measure net circular currents going around the face centres. This corresponds to a component of a rotor, perpendicular to the face, as is expressed by the face term. The theorem then makes a comparison of these three reports: it finds that the flow along the edges exactly accounts for the net changes of density on

the vertices and net circulation around the face centres, except for two modes, which leave no trace in the bookkeeping of the edge currents: the simultaneous increase of density on all vertices, the Γ_0 term, and the simultaneous rotatory currents on all faces in the same sense, as expressed by the Γ_ε term.

If the fluid consists of electrons, the first term represents changes of the total electrical charge of the polyhedron. This mode will be zero if charge is conserved. It cannot give rise to charge flows over the network.

The second mode is less trivial, but in fact equally fundamental. It represents the total magnetic charge of the polyhedral cluster. Electromagnetism requires this charge to be zero, in the absence of magnetic monopoles. Hence both modes refer to conserved quantities which cannot be generated or annihilated by external fields.

In this respect toroidal polyhedra, i.e. polyhedral networks that can be mapped on the surface of a torus or doughnut, offer far more interesting perspectives, since they have topological invariants that have the symmetry of electric and magnetic dipoles.

For a toroidal polyhedron, the Euler theorem reads as in Equation (18).

$$v - e + f = 0 \tag{18}$$

The zero on the right-hand side hides no less than four topological invariants, which make their appearance when the theorem is written in symmetry form, Equation (19).

$$\Gamma_\sigma(v) - \Gamma_\parallel(e) + \Gamma_\odot(f) = \Gamma_0 + \Gamma_\epsilon - \Gamma(T_z) - \Gamma(R_z) \tag{19}$$

The two negative terms on the right-hand side that were absent in the globular polyhedra, are the irreducible symmetry representations of the translation along the central symmetry axis of the torus (T_z), and of the rotation about the same axis (R_z). Both these terms refer to special combinations of edge arrows which have no boundaries at the vertices, and do not interfere with face circulations.[11] These modes are represented by circular motions going around the torus as shown in Figure 2. The $\Gamma(T_z)$ mode corresponds to a circulation linking the inside and outside of the toroidal ring. It is antisymmetric with respect to the inversion centre and horizontal symmetry plane, and symmetric under the principal rotational symmetry axis, exactly as a translation mode in the z direction. On the other hand the $\Gamma(R_z)$ mode constitutes a circulation about the principal axis. It is also symmetrical under this axis, as well as under the inversion centre and the horizontal symmetry plane.

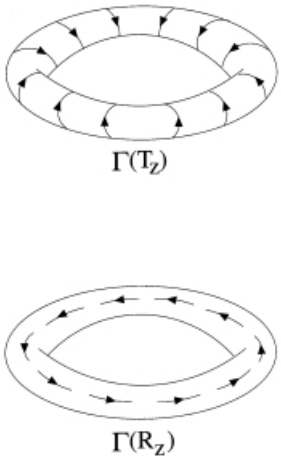


Figure 2. Topologically invariant edge currents on a torus, transforming as translation $\Gamma(T_z)$ and rotation $\Gamma(R_z)$

In ideal cylindrical symmetry, $D_{\infty h}$, these terms match the symmetry representations Σ_u^+ and Σ_g^- which are, respectively, the symmetries of the electric and magnetic dipole. Interestingly, both these invariants can be introduced by external fields. If one places a toroidal polyhedron in a homogeneous magnetic field, with its z axis parallel to the direction of the field, one will indeed induce circular bond currents on the torus, which correspond to the $\Gamma(R_z)$ mode. Open-shell molecules can furthermore sustain spontaneous currents that have precisely this topology.

In contrast, the second mode, $\Gamma(T_z)$, is much subtler. It introduces a moment that is known from nuclear physics[19] as an "anapole" moment. If one simply places the torus in a homogeneous magnetic field along the z direction it would not generate a permanent circulation of the type shown in Figure 2. What is required in order to induce such an anapole is a magnetic field that would run along the spine or internal loop of a torus. Such a field is necessarily inhomogeneous and requires specially designed magnet geometries.[20] However, if the toroid is chiral the two types of motion will belong to the same Σ representation and can therefore be coupled. A homogeneous magnetic field along the z axis is then sufficient to induce an anapole moment: physically this means that in chiral tubes the current which goes around the central hole of the torus follows a spiral pattern, which includes a whirling of the $\Gamma(T_z)$-type. These effects have indeed been demonstrated by model calculations on small toroidal carbon cages.[21]

Chemistry has made steady progress towards the development of toroidal polyhedra, formed by a molecular network that can be mapped on the surface of a torus or doughnut. First Liu et al.[22] reported the observation of closed tubular structures in a batch of multiwalled nanotubes. Later on it was shown by Martel et al.[23] that single-walled carbon nanotubes could be bent by treatment with ultrasonic waves. The STM images of these structures show nice toroidal shapes, but the authors warn that these are very likely coils rather than tori. Very recently Sano et al.[24]

have managed to induce chemical bonds between the functionalised edges of a nanotube.

5. Complexes and Bundles

So far we have defined a polyhedral complex as a set of vertices with edge and face relationships. We now come to the next step, which is to define functions, which are centred at the vertex positions. As an example we may be interested in the elastic properties of clusters. In that case we define on each cluster atom, three Cartesian displacement coordinates and solve the equation of motion in this space of $3v$ displacements.

The special mathematical structure which is created in this way has the following ingredients: i) the set of vertex points or nodes of the complex, referred to as the base space B, ii) a unitary model space of functions, W, representing the object which will be associated with the individual vertices, in our example W contains the three Cartesian displacements, $W = (\Delta x, \Delta y, \Delta z)$, and $W_i = (\Delta x_i, \Delta y_i, \Delta z_i)$ then corresponds to the Cartesian displacements of vertex v^i, iii) the total function space containing all $3v$ displacements of the complex, $E = \{W_i\}_{i=1,v}$ and finally iv) the projection p which connects a given object to its node, $pW_i = v^i$. This link constitutes a fibre, and the total structure (E, B, W, p) is a fibre bundle.[25] With this structure our next task is to find out what happens to the topological invariants, which we have detected in the base space. Hence, what will be the functional forms they connect to?

Again this question can be solved by group-theoretical means. We first derive the symmetry representations of the functional space, and then insert in these expressions the symmetry relations of section 3.

We will illustrate this for the case of the displacement space. To obtain the answer we need to look at a fundamental result of the theory of induced representations.[7,26] It states that the representation of the $3v$ displacements of a cluster with v vertices or atoms is simply given by the direct product of the vertex representation, $\Gamma_\sigma(v)$, with the symmetry of the three translations, $\Gamma(T)$; Equation (20).

$$\Gamma_{x,y,z}(v) = \Gamma_\sigma(v) \times \Gamma(T) \tag{20}$$

This product representation is usually called the mechanical representation, while the vertex representation is obviously the positional representation. The connection in this case is obviously very simple, since it takes the form of a direct product.

We can now substitute the vertex term to yield Equation (21).

$$\Gamma_{x,y,z}(v) = [\Gamma_\parallel(e) - \Gamma_\odot(f)] \times \Gamma(T) + [\Gamma_0 + \Gamma_\epsilon] \times \Gamma(T) \tag{21}$$

The invariants in this equation are both multiplied by $\Gamma(T)$. These products can easily be evaluated, since multiplication with the totally symmetric representation, Γ_0, is a unit operation, while multiplication with the pseudo-scalar representation, Γ_ε, changes the parity and thus turns translations into rotations, see Equation (22).

$$\begin{aligned} \Gamma_0 \times \Gamma(T) &= \Gamma(T) \\ \Gamma_\epsilon \times \Gamma(T) &= \Gamma(R) \end{aligned} \tag{22}$$

Hence the forms in the displacement space, which correspond to the topological invariants of the positional space, are found to transform as the translations and rotations. The topological invariants of the complex thus connect to the collective motions that form the six external degrees of freedom of the cluster. In view of this special topological connection, these are indeed separate solutions of the displacement problem that cannot mix with the internal elastic modes.

In the next section we will show how the mechanical representation can further be resolved in the case of deltahedral clusters. In a further application we will also meet these special functional forms in the Fermi region of fullerene clusters.

6. Applications

Here we review two applications where functions are defined on a complex. One concerns atomic displacements, and the other atomic orbitals.

6.1 The Complete Force Field of Deltahedral Clusters

A deltahedral cluster is made up of triangles. The prototype is the closoborane series, $B_nH_n^{2-}$. Through the isolobal analogy several carbonyl transition-metal clusters have been synthesised with similar structures.

Deltahedral polyhedra are the dual forms of the trivalent polyhedra, discussed in section 4.1. The Euler relationship for trivalent cages, $3v = 2e$ [Equation (14)], can thus be converted into its dual form, which is valid for deltahedral cages; Equation (23).

$$3f = 2e \tag{23}$$

By combining this expression with Euler's theorem, we obtain a relationship between numbers of vertices and edges; Equation (24).

$$3v - 6 = e \tag{24}$$

One immediately recognises in this equation the number of internal degrees of freedom $3v - 6$ of a molecule with v atoms. This number is equal to the number of edges, e. The necessary and sufficient condition that the set of all stretch-

ings of edges would form a nonredundant set of vibrational coordinates is that not only the number but also the symmetries coincide. This equivalence of the vibrational and edge representation is indeed a fact for all deltahedra that can be mapped on the surface of a sphere. The proof is contained in the following fibre equation,[8] that is valid for deltahedra; Equation (25).

$$\Gamma_\sigma(v) \times \Gamma(T) - \Gamma(T) - \Gamma(R) = \Gamma_\sigma(e) \tag{25}$$

On the left the first term of dimension $3v$ is the representation of all Cartesian displacements of all atoms. From this we subtract the six external modes, comprising the translations and rotations. On the right $\Gamma_\sigma(e)$ is the symmetry representation of the set of edge centres. The stretching of an edge is σ-symmetric with respect to all symmetry elements going through the edge, and therefore is also covered by $\Gamma_\sigma(e)$. This expression is highly relevant for the force field of deltahedral clusters. It states that the symmetries of the displacements of the cluster atoms span the symmetries of the edge stretchings plus the six external degrees of freedom. Hence the edge stretchings exactly match the internal degrees of freedom. By putting a spring on every edge of a deltahedral cluster we construct a complete force field. The potential energy of this cluster can thus be written as given in Equation (26), where $\langle ij \rangle$ is the edge between atoms i and j and the summation runs over all edge pairs.

$$2V = \sum_{\langle ij \rangle \langle mn \rangle} k_{\langle ij \rangle \langle mn \rangle} \Delta r_{\langle ij \rangle} \Delta r_{\langle mn \rangle} \tag{26}$$

This equation is a typical example of a polyhedral relationship: a property of the vertices, in this case a displacement, is related to a property of a higher structural component, here the stretching of an edge. A mechanical proof of this property was already known to the famous French engineer and geometrician, Cauchy.[27] Boyle and Parker,[28] in their study of force fields in dodecaborane, noted the peculiar identity of the symmetries of the internal modes and the edge stretchings, but did not realise it was a general result for all deltahedra, which derives directly from the symmetry extension of Euler's theorem.

Table 4. Force constants for B_{12} in N/m

constant		value
k_1	$\langle ij \rangle \langle ij \rangle$	221.48
k_2	$\langle ij \rangle \langle im \rangle$	-33.12
k_3	$\langle ij \rangle \langle ik \rangle$	41.46
k_4	$\langle ij \rangle \langle km \rangle$	-29.57
k_5	$\langle ij \rangle \langle lm \rangle$	-17.36
k_6	$\langle ij \rangle \langle kl \rangle$	17.56
k_7	$\langle ij \rangle \langle kn \rangle$	0.88
k_8	$\langle ij \rangle \langle ln \rangle$	-3.95
k_9	$\langle ij \rangle \langle no \rangle$	8.06

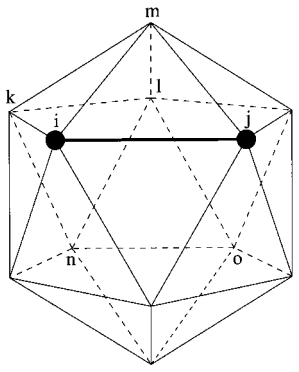

Figure 3. Vertex labelling for the boron skeleton in dodecaborane

In a recent study,[29] we have calculated the Hessian for $B_{12}H_{12}^{2-}$, using DFT techniques, and then derived the force constants. The results are listed in Table 4, following the bond labelling in Figure 3. It can be seen that the interactions between the bond stretchings decrease when the bonds are further apart, but quite remarkably, even bonds that do not have a common atom, still interact significantly. This confirms the delocalised nature of the bonding in these electron-deficient compounds.

6.2 The Frontier Orbitals of Fullerenes

In the innumerable fullerene family, Buckminsterfullerene, C_{60}, stands out in several ways. It is the smallest cage where all pentagons are isolated, and this contributes greatly to its stability, but in addition it is also a closed-shell molecule. In this respect it is the smallest member of the leapfrog class of closed-shell fullerenes.[30] A leapfrog fullerene, C_{3v}, is constructed from a smaller fullerene, C_v, by first capping all of its faces and then taking the dual of the resulting polyhedron. Since the smallest fullerene is the dodecahedron with twenty carbon atoms, the smallest leapfrog fullerene will indeed be C_{60}.[31]

The leapfrog construction (Figure 4) implies that the vertices in the parent will be transformed into hexagonal faces in the leapfrog. As a result all original faces will be surrounded by a ring of hexagons. This corresponds precisely to the "dilution" of the dodecahedron by hexagons to produce the familiar football shape.

The edges of the parent are also present in the leapfrog but are rotated by 90°. In C_{60} they correspond to the thirty edges separating the hexagons.

As a result the π-bonding in a leapfrog can be described by two extreme bonding schemes: either we put ethylenic bonds on all edges, that are derived from the edges of the parent cage, or we put aromatic sextets to all faces that are derived from the parent faces.

In Figure 5 these bonding extremes are connected in a Walsh-like correlation diagram, where we can move from the left to the right by gradually increasing the double-bond lengths and decreasing the single-bond lengths.[32]

On the left we have thirty isolated double bonds and thus thirty π-bonding orbitals and an equal number of π-anti-

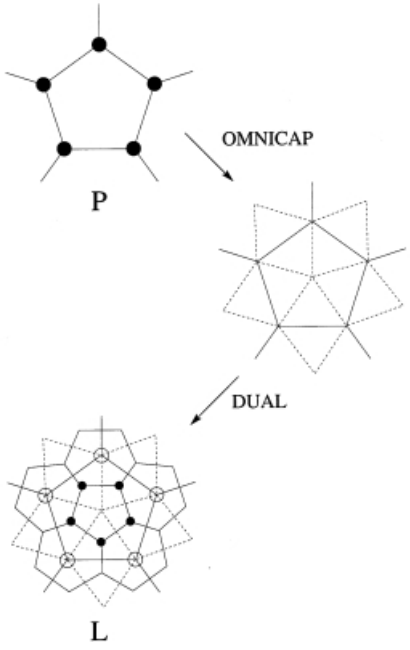

Figure 4. The leapfrog transformation; P is a piece of the parent, L is the leapfrog; vertices in P are hexagon centres in L; faces in P remain faces in L

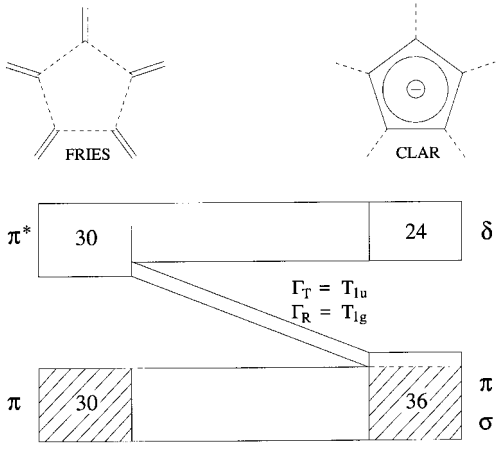

Figure 5. Walsh diagram for C_{60} with correlation between two bonding extremes: a "Fries" structure on the left with localised double bonds between pentagons, and a "Clar" structure on the right with aromatic sextets on the pentagon

bonding orbitals. On the right we recognise the bonding orbitals of twelve isolated pentagons, with the bonding σ and π shells that form the aromatic sextet, and antibonding δ-type orbitals. When we move away from the bonding extremes the localised levels broaden and become the molecular orbitals of C_{60}. Quite remarkably, the *symmetries* of all thirty bonding combinations on the left are present in the thirty-six bonding combinations on the right. The six remaining combinations will correlate with the π* orbitals on the left, and cross the nonbonding line almost halfway between the two extremes. As a result C_{60} has a closed shell of thirty bonding orbitals, followed by a set of low-lying almost nonbonding orbitals. These transform in icosahedral symmetry as T_{1u} and T_{1g} representations, which happen to be the representations of translation and rotation.

This pattern is characteristic for all leapfrog fullerenes. There is always a set of six low-lying frontier orbitals with the $\Gamma(T) + \Gamma(R)$ symmetry. For a general leapfrog fullerene the number of bonding orbitals on the left will be equal to the number of edges, *e*, in the parent. Similarly, the number of bonding orbitals on the right will be equal to three times the number of faces, 3*f*, in the parent. These numbers indeed differ by six, see Equation (27), which follows from Euler's rule, for trivalent cages.

$$e = 3f - 6 \tag{27}$$

As in the previous example, for the correlation in the Walsh diagram to hold, more is required than a simple dimensional agreement. The symmetries of the bonding orbitals on the left should match the symmetries on the right. This is indeed the case according to the following fibre rule for trivalent cages, which is of course the dual of the fibre rule for deltahedra in Equation (25), see Equation (28).

$$\Gamma_\sigma(e) = \Gamma_\sigma(f) \times \Gamma(T) - \Gamma(T) - \Gamma(R) \tag{28}$$

The $\Gamma_\sigma(e)$ term in this equation precisely corresponds to the symmetries of ethylenic bonding orbitals on the edges of the parent, since these are symmetric combinations of the p_z orbitals at either end of the edge. The left-hand side of the expression thus describes the symmetries of the bonding combinations on the left of the Walsh diagram. Similarly, the term $\Gamma_\sigma(f) \times \Gamma(T)$ spans the symmetries of the aromatic sextets on the right of the diagram: each aromatic sextet comprises three orbitals which transform as σ, π_x, and π_y with respect to the centre of the pentagon: i.e. a set which transforms as the three Cartesian components. The direct product $\Gamma_\sigma(f) \times \Gamma(T)$ then generates the bonding orbitals on all twelve pentagons. The group-theoretical results then state that for any fullerene which is a leapfrog, matching of the two bonding extremes will provide a closed-shell structure, with a set of low-lying orbitals transforming as $\Gamma(T) + \Gamma(R)$.

These special frontier orbitals are once again defined as the fibre, which connects to the topological invariances of the polyhedral complex.

A similar analysis can also be extended to other trivalent cages containing triangular or quadrilateral defects. It has also been performed for the graphene sheet.[12] In this case the topologically relevant orbitals are identified as the four semi-occupied nonbonding orbitals in the K-point of the honeycomb lattice.

Conclusion

In many respects molecules are graph-like objects. The Hückel model is essentially based on the molecular graph. Probably in the whole of quantum chemistry, there isn't a

single theory that can compete with this model in terms of minimal effort for maximum relevance.

In this review we point to the existence of equally general molecular relationships, which go beyond the vertex-edge picture, and imply face structures. Especially in the area of clusters and network molecules this leads to useful new insights, both for the description of electronic and elastic properties. In the polyhedral complex steric aspects of molecular structure are taken into account. Note that the elements of a complex are not spatial coordinates, but relationships between atomic nodes.

Further theoretical efforts are certainly needed to expand the theoretical framework. The fibre bundles that we have considered in section 6 are indeed trivial examples, where the connection is a straightforward product. More intricate problems are offered by the description of tunnelling between Jahn−Teller minima on a surface. These await further analysis.

We finally hope the present microreview will invite chemists to acquire a practical understanding of topological concepts. Our main ally in applying these concepts to molecular properties clearly is group theory. Group theory and topology are not rival mathematical disciplines but go admirably together, reinforcing each others results.

A 1,3-Sigmatropic Rearrangement Revealed in the Solid and Solution State Structures of a Chiral Sodium 1-Azaallyl Complex Derived from (*S*)-*N*-(α-Methylbenzyl)allylamine

Philip C. Andrews,*[a] Simone M. Calleja,[a] Melissa Maguire,[a] and Peter J. Nichols[a]

Keywords: Sodium / N ligands / Chirality / Amines / Sigmatropic rearrangement / Structure elucidation

The reaction of *n*BuNa with (*S*)-*N*-(α-methylbenzyl)allylamine, followed by the addition of tmeda, gives a chiral sodium 1-azaallyl complex, $\{[(S)\text{-}\alpha\text{-}[PhC(H)MeN^{\cdot\cdot}C(H)^{\cdot\cdot}CHCH_3)]Na\cdot tmeda\}_2$, as confirmed by single crystal X-ray diffraction and solution NMR spectroscopy, and is most likely the result of a 1,3-sigmatropic rearrangement and subsequent delocalisation within the resulting enamide.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

There is significant interest in the solution and solid state structures of alkali metal amides and in relating this structural knowledge to explanations of the degree of selectivity that can be achieved when used in enantioselective reactions.[1a−1k] In particular, the successful utilisation of chiral lithium amides in conjugate addition and selective deprotonation reactions with consequent high *ee* values has attracted considerable attention.[2a−2i] In contrast, there have been relatively few investigations into the synthetic utility of Na or K amides in such reactions,[3] not because of unexpected internal structural rearrangements but mainly because these reagents are expected to behave in a similar manner to their Li counterparts, although with greater reactivity and reduced selectivity.

Through recent investigations into the alkali metal complexes derived from commonly used chiral amines, such as α-(methylbenzyl)benzylamine[4a,4b] and α-bis(methylbenzyl)-amine,[5] we have discovered the surprising structural transformations that can occur in the amide moiety on changing the metal from lithium to sodium; α-(methylbenzyl)benzylamine was found to undergo transformation to a 2-azaallyl complex while α-bis(methylbenzyl)amine was cleaved to give a metallated primary enamide. In extending this work we have turned our attention to an analogous amine, (*S*)-*N*-(α-methylbenzyl)allylamine which, because of the ease with which the allyl group is cleaved, has been shown by Davies to be often superior to lithium α-(methylbenzyl)benzylamide in the formation of β-amino acids and β-lactams.[6a−6c] With the allyl group essentially being a less-constrained fragment of a benzyl group we were particularly interested in: (i) whether there would be any close interactions of the metal and the $C(H)=CH_2$ unit, and (ii) the possibility of any β-H elimination processes and the formation of 2-azaallyl species as observed for α-(methylbenzyl)benzylamide and dibenzylamide complexes.[7]

To-date, mono-lithiation reactions of the chiral allylamine in the presence of several typical Lewis donors has produced only a series of deep red and orange coloured oils. However, on moving to studying the heavier metal complexes we found that reaction with *n*BuNa, followed by addition of tmeda (*N*,*N*,*N*′,*N*′-tetramethylethylenediamine), is one of the few reactions which has, so-far, produced a crystalline product.

The large yellow crystals isolated from the reaction have been identified by single crystal X-ray diffraction to be the dimeric azaallyl complex $\{[(S)\text{-}\alpha\text{-}[PhC(H)MeN^{\cdot\cdot}C(H)^{\cdot\cdot}CHCH_3)]Na\cdot tmeda\}_2$ (**1**), with ^1H and ^{13}C NMR spectroscopy indicating that this configuration is retained in solution.

Results and Discussion

The two methods by which crystals of **1** were obtained are outlined in Scheme 1. The addition of the amine to *n*BuNa produces a pale brown suspension. Subsequent addition of tmeda causes dissolution to a red solution from which crystals are obtained over several days at 4 °C. Since we have not yet been able to obtain a crystalline product using the typical tridentate donor pmdta (*N*,*N*,*N*′,*N*′,*N*′′-pentamethyldiethylenetriamine), one equivalent of THF was added in an attempt to deaggregate the dimer in order to study possible 2-azaallyl formation. However, this again resulted in crystals of **1** as the exclusive product. We did note, though, that if more than one equivalent of THF is

[a] School of Chemistry, Monash University, Clayton, Melbourne, Vic. 3800, Australia

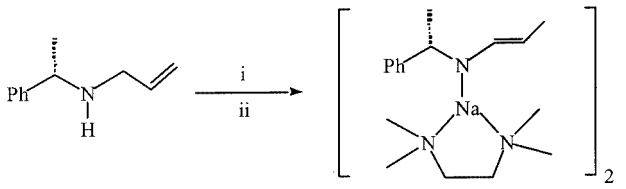
E-mail: p.andrews@sci.monash.edu.au

added it can be difficult to obtain a solid product. Over time this solution becomes very dark red and may indicate some further reaction including the base-catalysed ring opening of the THF.



Scheme 1. Syntheses of [{(*S*)-α-[PhC(H)MeN⋯CH⋯CHCH$_3$]}Na·tmeda]$_2$ (**1**); i) *n*BuNa, hexane, tmeda, room temp; ii) *n*BuNa, hexane, tmeda/thf, room temp.

The crystal structure of **1**, shown in Figure 1, is a noncentrosymmetric dimer (monoclinic, $P2_1$) in which each of the two "monomers" adopts a different configuration. These are shown in Figure 2 and differ with respect to the positional exchange of the Ph and Me groups within the benzylmethyl moiety. An analysis of the bond lengths in the N1−C9−C10 [1.365(3), 1.345(3) Å] and N2−C20−C21 [1.370(3), 1.331(3) Å] fragments indicates that **1** is best described as an η^1-*N*-azaallyl complex, and most likely results from a 1,3-sigmatropic rearrangement to an enamide and subsequent delocalisation of the negative charge (Figure 3).

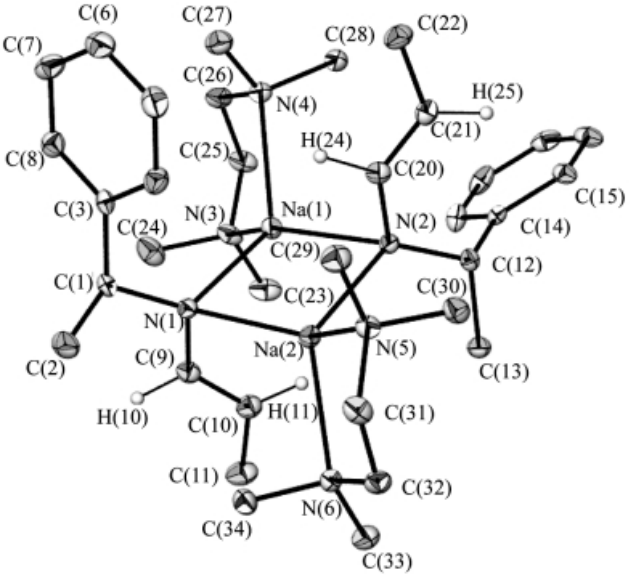


Figure 1. Molecular structure of [{(*S*)-α-[PhC(H)MeN⋯C(H)⋯CHCH$_3$]}Na·tmeda]$_2$ (**1**); thermal ellipsoids at 30% probability; selected bond lengths (Å) and angles (°); Na1−N1 2.410(2), Na1−N2 2.408(2), Na1−N3 2.480(2), Na1−N4 2.516(2), Na2−N1 2.411(2), Na2−N2 2.389(2), Na2−N5 2.500(2), Na2−N6 2.512(2), N1−C1 1.468(3), N1−C9 1.365(3), C9−C10, 1.345(3), C10−C11 1.510(4), N2−C12 1.451(3) N2−C20 1.370(3), C20−C21 1.331(3) C21−C22 1.519(3); N1−Na1−N2 96.78(7), N1−Na2−N2 97.27(7), Na1−N1−Na2 82.43(6), Na1−N2−Na2 82.94(6), C1−N1−C9 112.83(19), N1−C9−C10 128.8(2), C9−C10−C11 123.7(3), N2−C20−C21 134.1(2), C20−C21−C22 123.0(2)

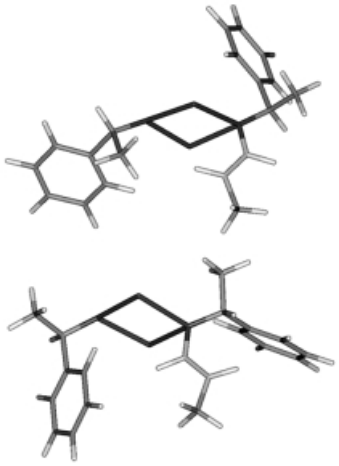

Figure 2. View relative to the $(NaN)_2$ ring of the relationship of the two different "monomers" found in dimeric **1**; tmeda has been omitted for clarity

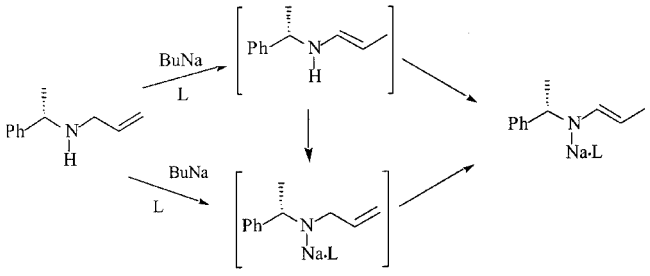

Figure 3. Possible routes of formation for **1**; 1,3 sigmatropic rearrangement and enamide and azaallyl configurations; L = tmeda

The core feature of **1** is the common structural motif of a central four-membered $(NaN)_2$ ring about which the amido moieties are in a *trans* arrangement.[8] However, on this occasion the four-membered ring is not planar but adopts a very shallow butterfly conformation, deviating from the plane by 5.7°. A more general analysis of the structure shows that one phenyl ring adopts an orientation almost co-planar with the $(NaN)_2$ ring and almost perpendicular to the other phenyl ring. This places C13 close to Na2 but, at about 3.4 Å, is beyond what would be considered a reasonable bonding distance (the sum of the van der Waals radii is 3.2 Å). The tetrahedral environment at each N is extremely distorted, most likely for steric reasons, with the azaallyl groups forming acute angles in relation to the $(NaN)_2$ ring. Thus, N2−N1−C9 and N1−N2−C20 are 103.7° and 96.6°, respectively, while the concomitant angles to the benzylic carbon are 142.9° for N2−N1−C1 and 149.0° for N1−N2−C12. So, while the formal coordination number of each Na centre is four, each is able to engage in very short compensatory agostic contacts with nearby C and H atoms of the azaallyl groups. The closest contacts for Na1 are 2.921(3) Å to C9 and 2.818(3) Å to C20, while the comparable distances for Na2 are 3.012(3) Å (C20), 2.923(3) Å (C9) and 3.022(3) Å (C10). Similar close con-

tacts have recently been observed in the uncomplexed sodium amide dimer $[(PhMe_2Si)(Me_3Si)NNa]_2$.[8] The orientation of the azaallyl groups, which deviate from an ideal C20−N2−N1−C1 plane by 14.8°, are nonsymmetrical in relation to the $(NaN)_2$ ring. The hydrogen (H24) on C20 overhangs the $(NaN)_2$ ring, dissecting the two metal centres at distances of 2.75 Å (Na1−H24) and 3.01 Å (Na2−H24), while hydrogen H10 on C9 points away from the ring leaving the hydrogen (H11) on C10 to sit between the two Na cations at distances of 2.74 Å (Na1) and 2.57 Å (Na2). Within the ring the Na−N bond lengths are shorter than those typically observed for dimeric sodium amides {c.f. $[(i\text{Pr})_2\text{NNa·tmeda})]_2$,[9] 2.441(2)-2.453Å; [Cy(*i*Pr)-NNa·tmeda]$_2$ [9] 2.438(2), 2.443(2) Å} but are similar to those observed for $[(PhCH_2)_2\text{NNa·tmeda})]_2$ [10] (2.397, 2.412 Å), which tends to be a reflection of the steric nature of the groups in the amide moiety.

Solution NMR spectra (^{1}H, ^{13}C, COSY and HMQC) were obtained in three solvents; [D$_6$]benzene, [D$_8$]toluene and [D$_8$]THF with variable temperature experiments conducted in [D$_8$]toluene (down to −80 °C) and in [D$_8$]THF (down to −90 °C). At 30 °C the same basic spectra were observed in all three cases, with each confirming that the complex had undergone a 1,3-sigmatropic rearrangement and that the azaallyl configuration, observed in the crystal structure, is retained in solution. In comparing the ^{1}H spectra in [D$_8$]THF of **1**, shown in Figure 4, and the starting allylamine the most telling features are the complete disappearance of the signals of the NCH_2 protons of the amine and the appearance of a doublet at δ = 1.57 ppm (CH_3), which, from 2D experiments, correlates with a doublet of quadruplets at δ = 3.25 ppm (1 H), which in turn correlates with a new doublet at δ = 6.59 ppm ($J_{H,H}$ = 13 Hz, 1 H), which we have assigned to the single H remaining from the transformed NCH_2 group. While this doublet is very sharp in [D$_8$]THF, in spectra obtained in [D$_8$]benzene and [D$_8$]toluene it is slightly broader and is partially obscured by the aromatic signals.

The retention of the azaallyl configuration in solution is supported by an analysis of the change in chemical shift for the central H in the former allyl group (now H25 and H11 in **1**). An upfield shift of 3 ppm is observed relative to its position in the free amine, while the associated C, which now appears at δ = 74.2 ppm, has shifted upfield by almost 60 ppm, both indicating a significant reduction in double bond character and charge distribution. All of the *C*H signals in the ^{13}C spectrum at 30 °C are weak and broad with a large downfield shift observed for the new N*C*H, which ^{1}H/^{13}C correlation and coupling experiments showed to be directly under the signal for the quaternary carbon at δ = 154.1 ppm.

Variable temperature experiments in [D$_8$]THF and [D$_8$]toluene did reveal slightly different solution behaviour for each complex, most likely resulting from deaggregation occurring in THF and retention of the dimer in toluene. As such the [D$_8$]THF spectra are slightly less complex. Looking first at the toluene spectra. At 30 °C the Ph(Me)C*H* protons appear at δ = 4.2 ppm and the C*H* protons (H11 and H25) in the azaallyl group at δ = 3.7 ppm. By −60°C 2D ^{1}H/^{1}H correlation indicates that these split into six distinct signals, four relating to Ph(Me)C*H* protons and two for the azaallyl protons. All the other protons also show substantially differing environments at low temperature. In THF at −60°C the corresponding central azaallylic proton, which is located at δ = 3.25 ppm at 30 °C, splits in two, shifting to δ = 2.86 ppm and δ = 3.57 ppm, with integrals indicating a 2:1 ratio. The Ph(Me)C*H* protons also split in two in a similar ratio, although the signals are not distinct but overlap. The azaallylic protons N⋯C(*H*)⋯C (H10 and H24), initially observed at δ = 6.59 ppm, are also split in two though one is very sharp and the other broad. The Me signals simply broaden.

In attempting to understand the low temperature spectra we undertook some basic molecular modelling experiments.[11] These indicated that the dimer is extremely crowded with very little opportunity for internal reorganisation of the molecule. The *trans* configuration observed within the azaallyl moiety in the crystal structure, and confirmed in solution, is retained due to a significantly restricted rotation around both the azaallyl C⋯N and C⋯C bonds, and the C_{chiral}−N bond, with the latter being a lower energy process. As such, the low temperature spectra in [D$_8$]toluene is consistent with the crystal structure and the two different "monomer" configurations highlighted in Figure 2. The complexity is a consequence of the two different azaallyl environments, with each of the four possible conformations of the benzylmethyl groups resulting from restricted 120° rotations.

In [D$_8$]THF the NMR spectra are consistent with deaggregation to a monomer containing coordinated THF. A model monomer with a single tmeda and a THF was only marginally less restricted than the dimer. However the lower energy barriers to rotation at each of the N−C bonds means that the various more simple possible configurations caused by rotation of the benzylmethyl group are not evident until lower temperatures. And, in fact, they do begin to appear in the spectrum obtained at −90 °C.

1-Azaallyl complexes of the alkali metals are almost exclusively formed by deprotonation of ketimines or aldimines, or by the 1,2-addition to nitriles. The variety of complexes and their bonding modes formed have been reviewed recently.[12] However, it is only in the last few years that an η^1 structural arrangement has been observed with characterisation of the complexes $[\{CH_3CH_2CH_2C(H)C⋯(t\text{Bu})⋯N(H)Li·(hmpa)\}]_n$ and $[\{CH_3CH_2CH_2C(H)C⋯(t\text{Bu})⋯N(H)Na·(hmpa)_2\}]_n$, formed in the reaction of either *n*BuLi or *n*BuNa with *t*BuCN followed by a 1,3-sigmatropic H shift.[13] The azaallyl arrangement in these complexes is calculated as the most stable configuration and is retained in solution, as we observed for **1**. In contrast, though, **1** is formed by deprotonation and metallation of a secondary allylamine leading to the formation of a metal enamide. Several studies have indicated that the base-catalysed isomerisation of *N*,*N*-allylamines in the presence of *t*BuOK, LDA or KH to give the corresponding enamine is energetically favourable.[14a−14e] Whether this isomerisation can oc-

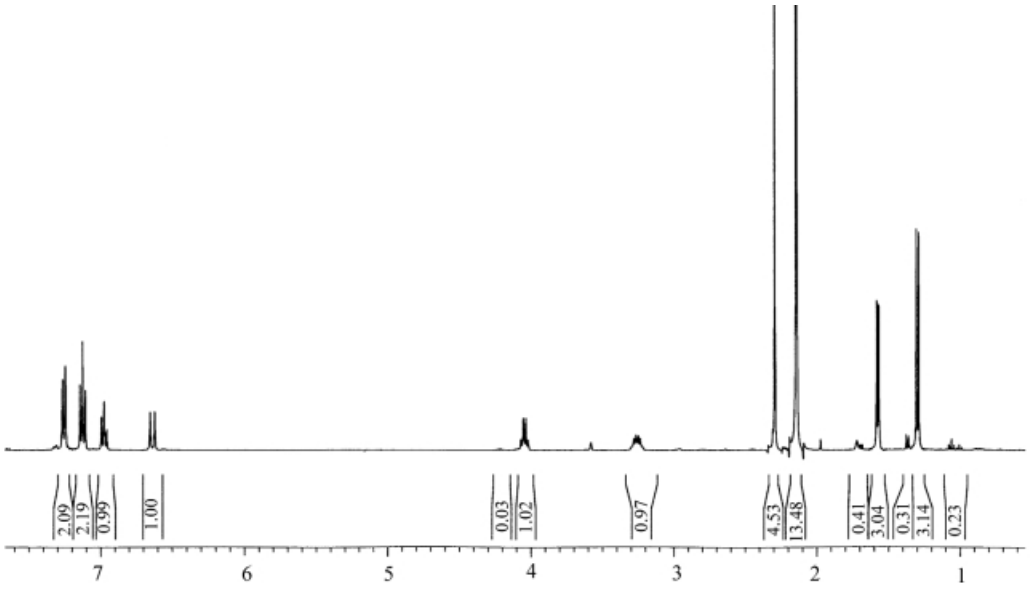

Figure 4. ^{1}H NMR of **1** in [D_8]THF showing the new CH_3 (δ = 1.57 ppm) and CH (δ = 6.59 ppm) signals from the rearrangement of the allyl group

cur with secondary allylamines prior to deprotonation taking place or occurs after metallation requires further study. We did not observe any isomerisation of the (*S*)-*N*-(α-methylbenzyl)allylamine prior to addition of the metallating reagent.

Evidence from the use of adducts of lithium *N*-(α-methylbenzyl)allylamide in conjugate addition reactions suggests that the amide moiety is in the allylic form prior to final deallylation, although cleavage of the allyl group requires ketimine formation prior to hydrolysis.[6,15] In light of this we are continuing our attempts to structurally characterise a lithium complex in the hope of discovering whether this rearrangement is general for the alkali metals and whether there are any important synthetic implications.

Experimetal Section

General Remarks: All compound manipulations were carried out under inert atmosphere and dry conditions using a vacuum/argon line, Schlenk techniques and a high purity argon gas recirculating dry box. Prior to use, solvents were dried by reflux over Na/K alloy and stored over 4 Å molecular sieves. (*S*)-*N*-(α-Methylbenzyl)allylamine was prepared by a literature procedure.[16] *n*BuNa was prepared from the metathesis reaction of *n*BuLi and NaO*t*Bu in hexane and stored as a solid. (Note: this solid is extremely pyrophoric). Tmeda was refluxed over CaH_2, distilled and stored over 4 Å molecular sieves. NMR spectra were obtained on a Bruker DRX-400 spectrometer with chemical shifts referenced to the appropriate deuterated solvent. Elemental analyses were carried out by CMAS, Australia.

Synthesis of 1: (*S*)-*N*-(α-Methylbenzyl)allylamine (0.81 g, 5.0 mmol) was added dropwise to a suspension of *n*BuNa (0.43 g 5 mmol) in hexane (20 mL) at room temperature resulting in a light brown coloured suspension. After 30 min tmeda (0.76 mL, 5.0 mmol) was added causing dissolution of the suspension and formation of a deep red solution. On filtration and cooling to 4 °C over several days pale yellow crystals of X-ray quality were produced. Yield 0.91 g, 61% (not maximised), m.p. 85−87 °C. ^{1}H NMR (400 MHz, 30 °C, [D_8]THF): δ = 7.25 (d, ^1J = 7.06 Hz, 2 H, *o*-H), 7.13 (t, ^1J = 7.45, 2 H, *m*-H), 6.97 (t, ^1J = 7.27, 1 H, *p*-H), 6.65 [d, ^1J = 12.54 Hz, 2 H, N-C(*H*)=C], 4.06 (q, ^1J = 6.56, 1 H, PhC(*H*)CH_3], 3.25 (dq, ^1J = 5.78, ^2J = 11.76, 2 H, C-C(*H*)=CH_3), 2.29 (s, 4 H, NCH_2), 2.14 (s, 12 H, NCH_3), 1.57 (d, ^1J = 5.86 Hz, 3 H, C=CH_3), 1.29 [d, ^1J = 6.62 Hz, 3 H, PhC(H)CH_3] ppm. ^{13}C NMR (100.6 MHz, 30 °C, [D_8]THF): δ = 17.2 (CH_3), 27.3 [PhC(H)CH_3], 46.1 (CH_3N), 58.8 (NCH_2), 62.7 [PhC(H)CH_3], 74.2 [C=C(H)-CH_3], 125.3 (*p*-*C*), 127.4 (*m*-*C*), 128.1 (*o*-*C*), 154.1 [*q*-*C*, N-*C*(H)=C] ppm. $C_{34}H_{60}N_6Na_2$ (598.9): calcd. C 68.2, H 10.1, N 14.0; found C 68.4, H 9.8, N 13.8.

Crystallographic Data for 1: $C_{34}H_{60}N_6Na_2$, M = 598.86, T = 123 K, monoclinic $P2_1$, a = 11.006(2), b = 12.009(2), c = 14.255(3) Å, β = 96.51(3)°, V = 1871.9(7) Å^3, D_c = 1.062 g·cm^{-3}, Z = 2; F(000) = 656, $\mu_{Mo\text{-}K_\alpha}$ = 0.83 cm^{-1}, $2\theta_{max}$ = 56.6°, final R, R_w = 0.052, 0.094. N_o = 5318 observed reflections [$I > 2\sigma$ (I)] out of N = 9213, R_{int} = 0.057. GooF = 0.955. The Flack parameter was indeterminate and the final stereochemistry was based on that of the starting amine. The crystal was coated in oil,[17] mounted on a fibre and data collected at 123 K on an Enraf Nonius Kappa CCD diffractometer equipped with Mo-K_α radiation (λ = 0.71073Å). The structure was solved by direct methods (SHELXS-97)[18] and refined by full-matrix least-squares on F^2. All H atoms were located in the difference map and refined isotropically. All other atoms were refined anisotropically.

A Self-Assembled Dinuclear Double-Stranded Helicate Based on a Square-Planar Coordination Geometry

Mauro Isola,*[a] Vincenzo Liuzzo,[a] Fabio Marchetti,[b] and Andrea Raffaelli[c]

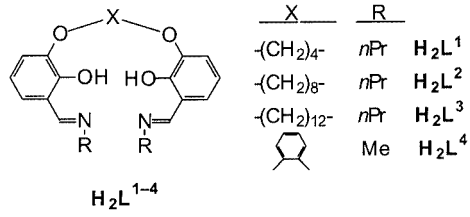
Keywords: Nickel / Schiff-base ligands / Self-assembly / N,O ligands / Supramolecular chemistry

The nickel(II) complex of a new bis-*N,O*-bidentate Schiff base, in which two salicylaldiminate units are connected by an α,α′-dioxo-*ortho*-xylidene spacer via the 3-position of salicyl moieties, was structurally characterised in the solid state and in solution as a dinuclear double helicate based on a square-planar coordination geometry.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

In the field of supramolecular chemistry, intense research activities have been focused on the helicates.[1] Almost all supramolecular structures of this type have been prepared by using neutral ligands containing nitrogen donor sets, so that the helical metal moieties have positive charges.[2]

Only in a few cases have anionic ligands been used, thus leading to neutral[3a−3f] or negatively charged helical structures.[3g,3h] Furthermore, in the four-coordinate helicates, the metal ions are invariably tetrahedral, suggesting that such a geometry is a requisite for generating a helicate with tetracoordinated metals.

Recently, we reported a facile preparation of nickel(II) complexes (Scheme 1) derived from a new class of bis-bidentate Schiff-base ligands capable of generating supramolecular architectures.[4] These new ligands contain two *N,O*-bidentate chelating moieties linked through a flexible polymethylene spacer (**H_2L^{1-3}**).



Scheme 1

In particular, by a self-assembly process the base with the octamethylene bridge yields the double-helical dinuclear complex $[Ni_2(L^2)_2]\cdot THF$, where each metal atom is linked in a *trans*-square-planar geometry by two *N,O*-coordination sites of different ligands. As far as we are aware, this is the first example of a structurally characterised helicate based on a square-planar geometry.[5] However, in $CHCl_3$ solution this supramolecular structure undergoes a disassembly process resulting in an equilibrium mixture in which the mononuclear species is largely predominant.

In light of these results, we started an investigation in order to explore the role of the spacers and the substituent on the imine nitrogen in determining the outcome of self-assembly reactions. To favour the formation of stable helicates, an ideal candidate for the replacement of the polymethylene bridging unit was envisaged to be the more rigid *ortho*-xylidene group, in which the flexibility is restricted to the methylene groups and the *ortho*-linkage is suitable for helication. On the basis of this premise, H_2L^4 was prepared following the general procedure previously described.[4] Reaction of H_2L^4 with $[Ni(OAc)_2]\cdot 4H_2O$ in a 1:1 molar ratio in ethanol at room temperature yielded olive green microcrystals after recrystallization from chloroform that analysed as $[Ni_2(L^4)_2]\cdot CHCl_3$.

Single crystals of the compound were obtained by slow evaporation of a chloroform solution. The X-ray structural analysis clearly shows that the compound has a dinuclear helical structure in the solid state. The molecular structure is sketched in the two projections of Figure 1. Each metal atom is linked in a *trans*-square-planar geometry by *N,O*-coordination sites from two different ligands, winding in a helical loop from Ni(1) to Ni(2). The nickel atoms and chelating groups lie approximately(± 0.25 Å) on two parallel planes, with a Ni(1)···Ni(2) distance of 3.554 Å. The two phenylene rings of the bridges are approximately perpendicular to the previous ones. The concurrence of ligand sizes with the distance between the coordination planes makes

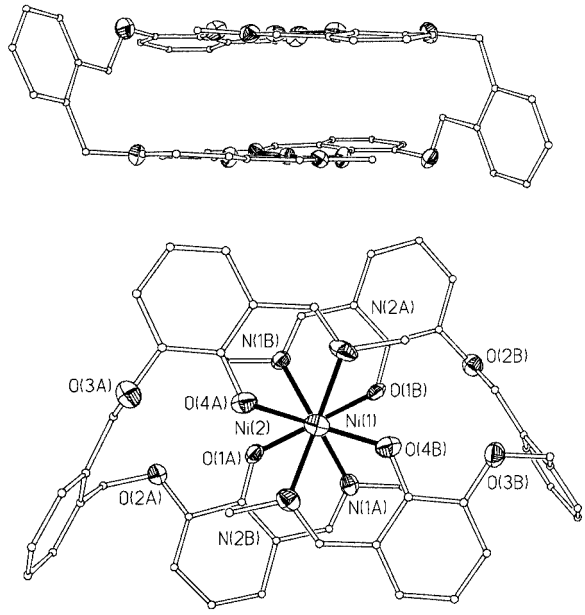

Figure 1. Two projections of the molecular structure of $[Ni_2(L^4)_2]$ along the pseudo-twofold axis (up) and down the coordination planes (down); Ni, O and N atoms are represented by 30% probability thermal ellipsoids; C atoms are represented by small spheres and H atoms are omitted for clarity; relevant bond lengths (Å) and angles (°): Ni(1)−O(1A) 1.82(1), Ni(1)−O(1B) 1.84(1), Ni(1)−N(1A) 1.89(2), Ni(1)−N(1B) 1.92(1), Ni(2)−O(4B) 1.82(1), Ni(2)−O(4A) 1.84(1), Ni(2)−N(2A) 1.90(2), Ni(2)−N(2B) 1.92(1); O(1A)−Ni(1)−O(1B) 177.2(5), O(1A)−Ni(1)−N(1A) 92.8(5), O(1B)−Ni(1)−N(1A) 87.7(5), O(1A)−Ni(1)−N(1B) 86.7(5), O(1B)−Ni(1)−N(1B) 92.8(5), N(1A)−Ni(1)−N(1B) 179.0(6), O(4B)−Ni(2)−O(4A) 176.2(5), O(4B)−Ni(2)−N(2A) 87.5(7), O(4A)−Ni(2)−N(2A) 92.4(7), O(4B)−Ni(2)−N(2B) 93.5(6), O(4A)−Ni(2)−N(2B) 86.8(6), N(2A)−Ni(2)−N(2B) 177.1(7)

the nickel coordination squares almost exactly staggered with an O(1A)−Ni(1)···Ni(2)−O(4A) dihedral angle of 43.7°. The molecule does not possess any crystallographic symmetry, but it shows nearly local symmetry 2(C_2), with the twofold axis parallel to the coordination planes and passing between the two metals. One chloroform molecule, not shown in Figure 1, is also present in the solid, with its hydrogen atom pointing towards a position between O(1B) and O(2B).

A mass spectrometry analysis using electrospray ionization suggests the presence of the dinuclear species as the only molecular species in solution. The main signal observed at m/z = 921 in the ESI-MS spectrum is indeed due to the protonated dinuclear complex, whereas the other important ions present in the spectrum at m/z = 405, 461 and 865 are attributable to the free ligand, to the mononuclear species and to the $[Ni_2(L^4)_2]-Ni^{II}$ species, respectively. MS-MS experiments suggest that these three ions are due to the fragmentation of the main peak at m/z = 921.

The ^{1}H NMR spectrum of the complex in $CDCl_3$ confirms the presence of a unique molecular species and the persistence in solution of the helical arrangement. In general, all the resonances of the complex are shifted upfield relative to the free ligand, and some resonances undergo significant changes upon coordination, giving important information regarding intramolecular interactions. The largest coordination shifts observed are the upfield shifts of the iminic protons (≈ 1.5 ppm) and of the methyl groups (≈ 1.2 ppm). In the crystal structure of the helicate, these protons lie above the salicyl moiety of the other ligand and are in the shielding region generated by the aromatic ring. The signal of the methylene groups of the bridge is a singlet at δ = 5.33 ppm in the free ligand, but upon complexation appears as doublets at δ = 5.21 and 5.01 ppm. On the whole, these spectral changes, particularly the manifestation of the diastereotropism, provide strong evidence for the persistence of the helical structure in solution.

Reaction of H_2L^4 with $[Cu(OAc)_2]\cdot 4H_2O$ in a 1:1 molar ratio, followed by usual treatment, yielded a light brownish-green compound, whose elemental analysis indicates a 1:1 metal:ligand ratio. Also in this case the ESI mass spectroscopic data are consistent with a dinuclear complex, i.e., $[Cu_2(L^4)_2]$. Despite several attempts, we could not isolate X-ray quality crystals, but the 2:2 metal:ligand stoichiometry suggests that, like the nickel(II) complex, the copper(II) complex is a double helicate. Efforts to elucidate the structure are in progress.

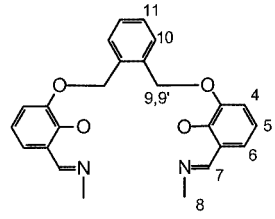
To summarise, we have shown that by careful selection of spacer sub-unit the behaviour of related ligands in the self-assembly process may be controlled. Applying this principle, we have tailored a new ligand to construct a dinuclear double-stranded helical nickel(II) complex, which is the second example of a helicate based on a square-planar geometry, but the first to be stable both in the solid state and in solution.

We are currently exploring the potential of this new class of ligands and investigating alternative linkage strategies for modelling supramolecular structures.

Experimental Section

IR spectra were collected on a Perkin−Elmer Paragon 500 FTIR spectrophotometer and electronic absorption spectra with a Perkin−Elmer Lambda 9 spectrophotometer in chloroform; λ_{max} in nm and ε in $M^{-1}\,cm^{-1}$. ESI mass spectra were recorded on a PE Sciex API III plus triple quadrupole mass spectrometer equipped with an Atmospheric Pressure Ionization source and an articulated Ionspray interface. The sample was dissolved in chloroform (1 mg/mL) and diluted 1:100 with acetonitrile.

NMR measurements were performed on a Varian VXR-300 spectrometer in $CDCl_3$ as solvent and were referred to TMS as external standard.



Preparation of Precursor Dialdehyde α,α′-Bis(3-formyl-2-hydroxy)-phenoxy-*o*-xylene: This compound was prepared in 74% yield from

2,3-dihydroxybenzaldehyde and α,α′-dibromo-*o*-xylene according to our previously reported procedure.[4] M.p. 176−180 °C. IR (Nujol): $\tilde{\nu}$ = 1646 cm^{-1} (C=O). ^1H NMR ($CDCl_3$): δ = 5.34 (s, 2 H), 6.84−7.51 (m, 5 H), 9.86 (s, 1 H), 11.03 (s, 1 H) ppm. $C_{22}H_{18}O_6$ (378.38): calcd. C 69.83, H 4.79; found C 69.62, H 4.61.

Preparation of the Ligand H_2L^4: This Schiff base was synthesised following standard procedures.[4] A mixture of dialdehyde (0.30 g, 0.79 mmol) and methylamine (40 wt.-% solution in water; 1 mL, 12.9 mmol) in ethanol (20 mL) was heated to reflux for 2 h. After cooling, a yellow solid precipitated out on addition of water. Recrystallisation from $CHCl_3$/hexane yielded a yellow crystalline material (0.26 g, 81%). M.p. 169−172 °C. IR (Nujol): $\tilde{\nu}$ = 1634 cm^{-1} (C=N). ^1H NMR ($CDCl_3$): δ = 3.47 (d, *J* = 1.6 Hz, 3 H, H8), 5.33 (s, 2 H, H9+H9′), 6.69 (dd, *J* = 7.6, 7.6 Hz, 1 H, H5), 6.84 (dd, *J* = 7.6, 1.6 Hz, 1 H, H6), 6.97 (dd, *J* = 7.6, 1.6 Hz, 1 H, H4), 7.28 (m, 1 H, H11), 7.51 (m, 1 H, H10), 8.29 (q, *J* = 1.6 Hz, 1 H, H7), 13.89 (s, 1 H, OH) ppm. $C_{24}H_{24}N_2O_4$ (404.46): calcd. C 71.27, H 5.98, N 6.93; found C 71.02, H 5.85, N 6.71. UV/Vis ($CHCl_3$): λ_{max} (10^{-3} ε) = 261 (24.6), 327 (6.53), 425 (0.85).

Preparation of the Complexes: A solution of H_2L^4 (0.74 mmol) in EtOH (20 mL) was added dropwise to a solution of $[Ni(CH_3COO)_2]\cdot 4H_2O$ or $[Cu(CH_3COO)_2]\cdot 4H_2O$ (0.74 mmol) in EtOH (20 mL). After stirring at room temperature for 2 h, solid complexes were collected by filtration, washed with diethyl ether and dried in vacuo. Yields ≥ 90%. Recrystallisation from $CHCl_3$ or $CHCl_3$/diethyl ether led to olive-green crystals of $[Ni_2(L^4)_2]\cdot CHCl_3$ or brownish-green crystals of $[CuL^4]$, respectively.

$[Ni_2(L^4)_2]\cdot CHCl_3$: M.p. 192−195 °C. IR (Nujol): $\tilde{\nu}$ = 1618 cm^{-1} (C=N). ESI-MS: *m*/*z* (%) = 405 (75) $[H_2L^4 + H]^+$, 461 (60) $[NiL^4 + H]^+$, 865 (40) $[Ni(L^4)_2 + 3H]^+$, 921 (100) $[Ni_2(L^4)_2 + H]^+$. ^1H NMR ($CDCl_3$): δ = 2.34 (s, 3 H, H8), 5.01 (d, *J* = 13.6 Hz, 1 H, H9), 5.21 (d, *J* = 13.6 Hz, 1 H, H9′), 6.36 (dd, *J* = 8.0, 7.6 Hz, 1 H, H5), 6.59 (dd, *J* = 8.0, 1.3 Hz, 1 H, H6), 6.78 (dd, *J* = 7.6, 1.3 Hz, 1 H, H4), 6.79 (br. s, 1 H, H7), 7.26 (m, 1 H, H11), 7.52 (m, 1 H, H10) ppm. $C_{48}H_{44}N_4Ni_2O_8\cdot CHCl_3$ (1041.65): calcd. C 56.50, H 4.35, N 5.38; found C 56.25, H 4.20, N 5.18. UV/Vis ($CHCl_3$): λ_{max} (10^{-3} ε) = 269 (88.1), 334 (15.9), 417 (7.05), 625 (0.10).

$[CuL^4]$: M.p. 210 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 1628 cm^{-1} (C=N). ESI-MS *m*/*z* (%) = 405 (35) $[H_2L^4 + H]^+$, 466 (30) $[CuL^4 + H]^+$, 931 (60) $[Cu_2(L^4)_2 + H]^+$, 948 (50) $[Cu_2(L^4)_2 + NH_4]^+$, 953 (50) $[Cu_2(L^4)_2 + Na]^+$. $C_{24}H_{22}CuN_2O_4$ (465.99): calcd. C 61.86, H 4.76, N 6.01; found C 62.18, H 4.96, N 5.73. UV/Vis ($CHCl_3$): λ_{max} (10^{-3} ε) = 276 (42.8), 365 (14.7).

X-ray Crystallographic Study: X-ray diffraction measurements were carried out with a Bruker P4 diffractometer equipped with Mo-K_α radiation (λ = 0.71073 Å).

$[Ni_2(L^4)_2]\cdot CHCl_3$: olive green prismatic crystals, $C_{49}H_{45}Cl_3N_4Ni_2O_8$; *M* = 1041.66; *T* = 293(2) K, monoclinic, space group *C*2/*c* (No. 15); *a* = 50.056(15), *b* = 11.309(3), *c* = 16.340(5) Å, β = 95.92(2)°, *U* = 9201(5) $Å^3$; *Z* = 8; μ = 1.052 mm^{-1}; crystal size (mm) 0.22 × 0.18 × 0.15. 6604 reflections collected, 5631 independent, R_{int} = 0.1010. Such a high R_{int} value is probably due to the long *a* axis and the consequent difficulty in neatly resolving adjacent reflections and to the low diffraction power of the crystal characterised by a large fraction of weak intensities. The structure was solved by standard automatic direct methods and refined by full-matrix least-squares methods. Hydrogen atoms were located in calculated positions and in the final refinement cycles anisotropic thermal factors were used for all non hydrogen atoms.

The solution and refinement were performed by means of the SHELX-97 program.[6] The final reliability factors for 595 refined parameters were: R_1 = 0.0954 calculated for 2606 reflections with $I > 2\sigma(I)$, wR_2 = 0.2818 for all 5631 reflections in the refinement; *GOF* = 1.076.

Synthesis, Crystal Structure and Third-Order Nonlinear Optical Behavior of a Novel Dimeric Mixed-Ligand Zinc(II) Complex of 1,3-Dithiole-2-thione-4,5-dithiolate

Cai-Ming Liu,[a] De-Qing Zhang,*[a] Ying-Lin Song,[b] Chuan-Lang Zhan,[a] Yu-Liang Li,[a] and Dao-Ben Zhu*[a]

Keywords: Zinc / N ligands / S ligands / Crystal structure / Nonlinear optics

The first dimeric mixed-ligand zinc(II) complex of 1,3-dithiole-2-thione-4,5-dithiolate (dmit) $[Zn(dmit)(2,2'\text{-bpy})]_2$ (2,2′-bpy = 2,2′-bipyridine) (**1**), which exhibits a good third-order nonlinear refraction effect, was synthesized by a ligand exchange reaction between $[(Et_4N)_2Zn(dmit)_2]$ and $[Cu(2,2'\text{-bpy})(NO_3)_2]\cdot 2H_2O$. A Z-scanning measurement of complex **1** gives the third-order nonlinear refraction index $n_2 = 3.72 \times 10^{-18}$ m²/W and the real part $Re\chi^{(3)} = 1.01 \times 10^{-12}$ esu. Crystal data for **1**: monoclinic, $P2_1/c$ (No.14), a = 11.556(2) Å, b = 9.141(2) Å, c = 15.020(3) Å, β = 109.55(3)°, Z = 4.

Introduction

Metal bis-dithiolene complexes have aroused more and more interest over the past decades due to their potential applications as precursors for electrical conductors and superconductors;[1] the optical properties of these compounds are also very interesting. For example, in 1972 Drexhage and co-workers discovered that transition metal dithiolene complexes are very stable to intense irradiation in the near-infrared region and are particularly suitable for Q-switching lasers.[2,3] Recently, more and more symmetrical bis-dithiolene complexes with third-order optical nonlinearity or optical limiting effects have been explored.[4] Because of the large values of their third-order nonlinear susceptibility $\chi^{(3)}$ [1a,5] and negative molecular first hyperpolarizability(β),[1a,6] unsymmetrical dithiolene complexes have also become promising candidates for nonlinear optical materials. Herein we report the synthesis, crystal structure and third-order nonlinear optical behavior of a novel dimeric mixed-ligand zinc(II) complex of 1,3-dithiole-2-thione-4,5-dithiolate (dmit) $[Zn(dmit)(2,2'\text{-bpy})]_2$ (**1**). To the best of our knowledge, this is the first example of a dimeric mixed-ligand complex of dmit.

Results and Discussion

$[(Et_4N)_2Zn(dmit)_2]$ and $[Cu(2,2'\text{-bpy})(NO_3)_2]\cdot 2H_2O$ were successfully employed for the preparation of complex **1**. This result illustrates that even complexes with different metal ions can be utilized for ligand-exchange reactions with transition metal dithiolene complexes.[1a,7] As we know, the metal ions are usually the same when a ligand exchange reaction, which takes place between symmetrical metal bischelate of dmit and that of the other ligand,[7c,7d] was used.

In the IR spectra of **1** the C=S and S−C−S stretching bands of the dmit ligand show no significant differences from the symmetrical dmit complexes.[1,8] The electronic spectrum of **1** in DMF exhibits two bands in the 270−700 nm region: the sharp band at 286 nm is assigned to a π-π* transition and the broad band at 497 nm to an n-π* transition of the dmit ligand. Both bands show blue shifts relative to those in $[Na_2(dmit)]$ (316, 514 nm in MeOH),[9] $[NBu_4]_2[Zn(dmit)_2]$ (300, 530 nm in MeCN)[9] and $[NMe_4]_2[Zn(dmit)(Sph)_2]$ (327, 512 nm).[1a]

The crystal structure of **1** consists of discrete neutral dmit complex dimers $[Zn(dmit)(2,2'\text{-bpy})]_2$. As shown in Figure 1, each zinc atom is coordinated in a distorted square-pyramidal geometry, with two nitrogen atoms from the 2,2′-bipyridine ligand and two sulfur atoms from one dmit ligand forming the base of the pyramid and one sulfur from the other dmit ligand occupying the apical site. One of the two sulfur atoms in each dmit ligand therefore acts as a μ_2-bridge to link two zinc atoms; a similar μ_2-S bridging mode of dmit was also observed in the symmetrical dmit complexes $[NnBu_4][Fe(C_3S_5)_2]$ and $[Fe(C_5Me_5)_2][Fe(C_3S_5)_2]$.[10]

The Zn−N and Zn−S bond lengths [average 2.136(2) and 2.4424(9) Å, respectively] are a little longer than those in another dimeric zinc complex $[Zn_2(i\text{-MNT})_2(4\text{-mpy})_4]\cdot CHCl_3$ (*i*-MNT = isomaleonitrile dithiolate) [average 2.056(4) and 2.319(1) Å, respectively].[11] The Zn−Zn distance (3.357 Å) is also a little longer than the Fe−Fe distances in $[NnBu_4][Fe(C_3S_5)_2]$ (3.17 Å) and $[Fe(C_5Me_5)_2]$-$[Fe(C_3S_5)_2]$ (3.169 and 3.164 Å).[10] It is noteworthy that complex **1** is, to the best of our knowledge, the first dimeric mixed-ligand complex with dmit, although dimers with metal-sulfur bonds in symmetrical bis-dithiolene complexes are common.[12]

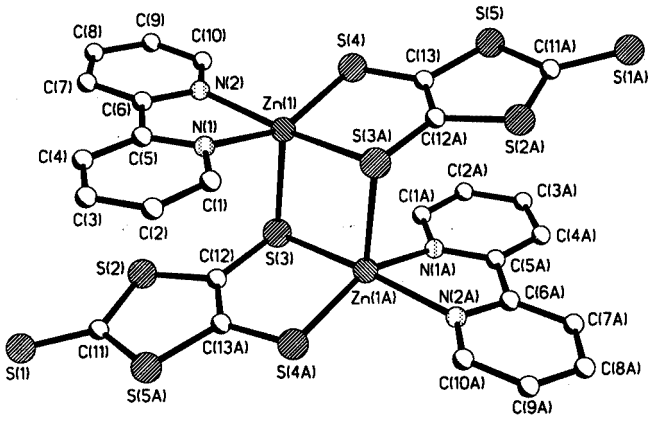

Figure 1. Molecular structure of complex **1**; selected bond lengths (Å) and angles (°): Zn(1)−N(1) 2.104(2), Zn(1)−N(2) 2.168(2), Zn(1)−S(4) 2.3374(8), Zn(1)−S(3) 2.4902(9), Zn(1)−S(3A) 2.4995(11); N(1)−Zn(1)−N(2) 76.06(8), S(3A)−Zn(1)−S(4) 91.18(3), N(2)−Zn(1)−S(4) 93.80(7), N(1)−Zn(1)−S(3A) 94.04(6), N(1)−Zn(1)−S(3) 97.26(6), N(2)−Zn(1)−S(3) 95.57(6), S(4)−Zn(1)−S(3) 106.94(3), S(3A) −Zn(1)−S(3) 95.42(3)

Another interesting structural feature is the molecular arrangement of the $[Zn(dmit)(2,2'\text{-bpy})]_2$ dimers (Figure 2). Unlike other metal bis-dithiolene dimers,[10,12] the $[Zn(dmit)(2,2'\text{-bpy})]_2$ dimers link each other through short S···Zn contacts rather than through short S···S contacts. These S···Zn contacts (3.676 Å) also suggest that there are π-π stacking interactions among dmit groups rather than 2,2′-bipyridine ligands from neighboring $[Zn(dmit)(2,2'\text{-bpy})]_2$ dimers. The center-to-center distance between the C_3S_2 five-membered rings of two adjacent dmit groups is 3.745 Å. Therefore, discrete $[Zn(dmit)(2,2'\text{-bpy})]_2$ dimers are further extended into an interesting one-dimensional supermolecular array by π-π stacking interactions between dmit groups.

Complex **1** crystallizes in the centrosymmetric space group $P2_1/c$, which cannot meet the essential requirement of electronic asymmetry for second-order nonlinear optical (NLO) effects.[13] However, complex **1** does possess third-order nonlinear optical behaviour. The third-order optical nonlinearity of complex **1** was determined by using the *Z*-scan technique.[14−16] These results are shown in Figure 3, where the filled and open circles were measured with and without the aperture, respectively. The valley/peak pattern of the normalized transmittance shows a characteristic self-focusing behavior of the propagating light in the sample.

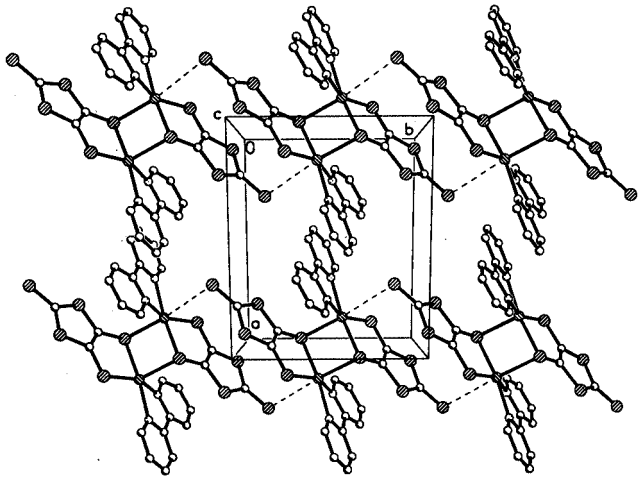

Figure 2. A packing diagram of the unit cell of complex **1** looking down the *c* axis showing how the discrete $[Zn(dmit)(2,2'\text{-bpy})]_2$ dimers are further extended into interesting one-dimensional supermolecular arrays through short S···Zn contacts or π-π stacking interactions between dmit groups

According to the method described in literature,[14−16] the value of the third-order nonlinear refraction index n_2 is calculated to be 3.72×10^{-18} m²/W and the real part of the third-order nonlinear susceptibility $Re\chi^{(3)}$ to be 1.01×10^{-12} esu. The value of $Re\chi^{(3)}$ of **1** is similar to other promising NLO media such as phthalocyanine, porphyrin and pentaazadentate and stilbazolium derivatives,[15] indicating that complex **1** is a good candidate for a nonlinear optical material.

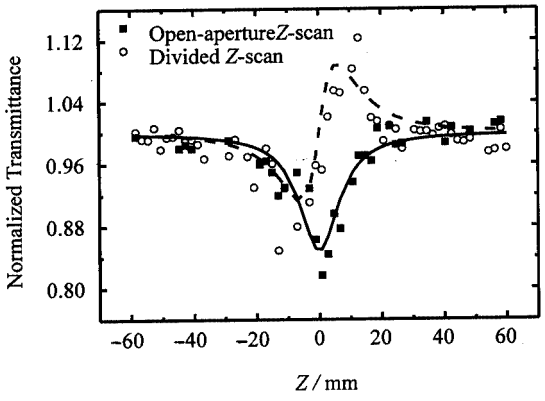

Figure 3. *Z*-scan measurement of complex **1** in a 4.05×10^{-5} mol·dm^{-3} solution of DMF at 532 nm with $I_0 = 0.6$ GW/cm²; the data collected under the closed-aperture configuration show the self-focusing effect

In conclusion, an interesting dimeric mixed-ligand zinc(II) complex of dmit $[Zn(dmit)(2,2'\text{-bpy})]_2$, which exhibits good third-order nonlinear refraction effect, was synthesized by a ligand-exchange reaction between $[Et_4N]_2[Zn(dmit)_2]$ and $[Cu(2,2'\text{-bpy})(NO_3)_2]\cdot 2H_2O$. This demonstrates that the ligand-exchange reaction method for preparing mixed-ligand complexes of dmit is also feasible when the metal ions of the two reactants are different.

Experimental Section

All reagents were obtained from commercial sources and used without further purification. The elemental analyses were performed on a Heraeus Chn-Rapid elemental analyzer. The infrared spectra were recorded on a Perkin−Elmer 2000 spectrophotometer with pressed KBr pellets. Bis(tetraethylammonium) bis(1,3-dithiole-2-thione-4,5-dimercapto)zincate {$[Et_4N]_2[Zn(dmit)_2]$} was prepared according to the literature method.[8]

Synthesis of 1: Single crystals were grown in a test tube. Solid $[Cu(2,2'\text{-bpy})(NO_3)_2]\cdot 2H_2O$ (0.2 mmol) was dissolved in 3 mL of water and 5 mL of MeOH, and to this solution was added carefully a solution of $[Et_4N]_2[Zn(dmit)_2]$ (0.2 mmol) in Me_2CO (10 mL). The test tube was then allowed to stand undisturbed at room temperature for three days, yielding a dark red block of **1** on the tube wall (8.4 mg, ca. 20% yield based on Zn) together with some unknown black amorphous materials at the bottom. $C_{26}H_{16}N_4S_{10}Zn_2$ (835.8): calcd. C 37.37, H 1.93, N 6.70; found C 37.29, H 1.98, N 6.62. IR (KBr): $\tilde{\nu}$ = 1595(m), 1566(w), 1489(w), 1472(m), 1440(s), 1429(s), 1315(m), 1249(w), 1171(w), 1158(w), 1059(s), 1031(vs), 891(m), 765(s), 733(m), 652(w), 629(w), 529(w), 465(m), 415(w) cm^{-1}. UV (1×10^{-4} M DMF): λ_{max} = 286 nm ($\varepsilon = 3.73 \times 10^4$ $M^{-1}cm^{-1}$), 497 nm ($\varepsilon = 1.49 \times 10^4$ $M^{-1}cm^{-1}$). ^1H NMR (300 MHz, $[D_6]$DMSO): δ = 8.73 (br, 1 H, Hpy), 8.43 (br, 1 H, Hpy), 8.02(br, 1 H, Hpy), 7.52 (br, 1 H, Hpy) ppm.

Crystallographic Analysis: A dark-red single crystal with dimensions of 0.2 × 0.1 × 0.1 mm was mounted on a Bruker SMART CCD diffractometer equipped with Mo-K_α radiation (λ = 0.71073 Å) at room temperature and data were collected with the ω-scan technique. Cell parameters were obtained by the global refinement of the positions of all collected reflections. A total of 13737 data of which 5504 independent reflections (R_{int} = 0.0417) were collected in the range of $5.30° \le 2\theta \le 66.92°$($-15 \le h \le 17$, $-13 \le k \le 12$, $-22 \le l \le 22$), and 3043 with $I > 2\sigma(I)$ were used in the refinement of the structure. The data were corrected for Lorentz-polarization effects during data reduction using XSCANS.[17a] Empirical absorption corrections based on Ψ-scan measurements were applied ($T_{min,max}$: 0.759012, 1.000000).

μ (Mo-K_α), mm^{-1}	2.331
R_1, wR_2 [$I > 2\sigma(I)$][a]	0.0452, 0.0583

[a] $R_1 = ||F_o| - |F_c||/|F_o|$, $wR_2 = [w(F_o^2 - F_c^2)^2/w(F_o^2)^2]^{1/2}$.

The structure was solved by direct methods and refined by a full-matrix least-squares technique based on F^2 using the SHELXL-97 program.[17b] All non-hydrogen atoms were refined anisotropically and all hydrogen atoms were treated as riding atoms. Selected crystallographic data and structure determination parameters for complex **1** are given in Table 1.

CCDC-176197 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Non-Linear Optical Measurements: The NLO properties of a solution of **1** in DMF were determined by using a standard *Z*-scan setup with a Q-switched, frequency-doubled Nd:YAG laser.[18] The pulse-repetition rate was 10 Hz. The transmittance of the aperture in front of the detector for a closed-aperture measurement was 0.1. The solution was contained in a 2 mm thick quartz cell.

A Novel Nickel(II) Complex Adopting a *cis*-Configuration: Solvothermal Synthesis and Crystal Structure of $[NiL_2(H_2O)_4]$ (L = 1,4-Dihydropyrazine-2,3-dione-5,6-dicarboxylate)

Cai-Ming Liu,[a] De-Qing Zhang,*[a] An-Jun Qin,[a] Chen Ye,[a] Huai-Ming Hu,[a] and Dao-Ben Zhu*[a]

Keywords: Nickel / Solvothermal synthesis / Carboxylate ligands / Crystal structure

Under solvothermal reaction conditions, the reaction of 5,6-dichloropyrazine-2,3-dicarbonitrile and $[Ni(ClO_4)_2]\cdot 6H_2O$ produces a novel *cis*-nickel(II) complex $[NiL_2(H_2O)_4]$ (**1**) (L = 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate), whereas only hydrated 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylic acid (**2**) was obtained as a single phase when $[Cd(ClO_4)_2]\cdot 6H_2O$ was used instead of $[Ni(ClO_4)_2]\cdot 6H_2O$.

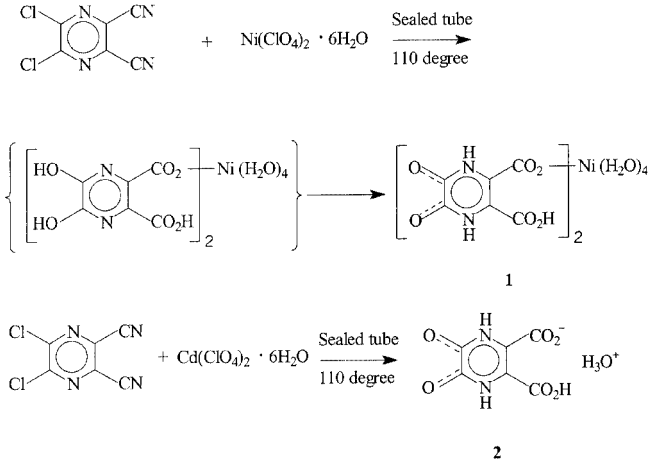
Introduction

Recently, the use of hydro(solvo)thermal techniques for synthesizing coordination compounds with interesting optical and/or magnetic properties has attracted increasing interest.[1,2] Most examples focus on high-dimensional coordination polymers, and the hydrolysis of substituted cyano, ester or aldehyde groups into a carboxylate group has often been used as the key step in designing such functionalized coordination polymers. However, rare examples have involved the hydrolysis of other substituted groups under hydro(solvo)thermal conditions. Here we present the hydro(solvo)thermal synthesis and crystal structure of a novel nickel(II) complex $[NiL_2(H_2O)_4]$ (**1**) (L = 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate), which adopts an unusual *cis*-configuration. Interestingly, no cadmium complex could be isolated from the reaction when $[Cd(ClO_4)_2]\cdot 6H_2O$ was used instead of $[Ni(ClO_4)_2]\cdot 6H_2O$ under the same solvothermal conditions: only hydrated 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylic acid (**2**) was formed. The cyano groups of the reactant 5,6-dichloropyrazine-2,3-dicarbonitrile were found to have been hydrolyzed into carboxylate groups and the chloro groups into hydroxyl groups (there is an autoisomerization from the enol form into the ketone form) during the hydro(solvo)thermal reaction in both cases (Scheme 1).



Scheme 1

Results and Discussion

Green crystals of **1** were obtained by treating 5,6-dichloropyrazine-2,3-dicarbonitrile and $[Ni(ClO_4)_2]\cdot 6H_2O$ under solvothermal conditions. Two strong peaks at $\tilde{\nu}$ = 1688 and 1555 cm^{-1} in the IR spectrum of complex **1** could be assigned to the antisymmetric C=O stretching vibrations of uncoordinated and coordinated carboxylate groups, respectively. The absence of characteristic peaks for cyano groups in the region of 2200 cm^{-1} indicates the formation of carboxylate groups by the hydrolysis of the precursor ligand.[1c] Two strong and sharp peaks around $\tilde{\nu}$ = 3551 and 3448 cm^{-1} indicate the presence of coordinated water

molecules.[3] The strong and sharp peak at $\tilde{\nu}$ = 3373 cm^{-1} is assigned to the N−H stretching mode of ammonium while the broad strong band around $\tilde{\nu}$ = 3116 cm^{-1} can be assigned to the O−H stretching mode of a protonated carboxylate group. A TGA study shows that **1** is thermally stable to about 155 °C and decomposes with the loss of four molecules of water and two molecules of CO_2 over the temperature range 155−290 °C; this also indicates that all four water molecules are coordinated to metal center.[4]

As shown in Figure 1, the crystal structure of **1** consists of isolated 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylatonickel(II) tetrahydrate molecules $[NiL_2(H_2O)_4]$, where the two 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate ligands adopt an unusual *cis*-configuration. To the best of our knowledge, this is the first mononuclear *cis* complex of carboxylate-substituted pyrazine derivatives, although the *cis*-configuration is quite normal for molybdenum complexes of 3,6-di-*tert*-butylcatechol,[5] and the two-dimensional copper complex $[Cu_2(pzdc)_2(pyz)]_n$ (pzdc = pyrazine-2,3-dicarboxylate, pyz = pyrazine) also exhibits such a *cis*-coordination.[6a] This coordination mode is quite similar to that in $[Co^{II}\{OOC(CH_2)_{10}COO\}]\cdot 2H_2O$,[7] where each cobalt atom is coordinated by three carboxylate groups from three *n*-dodecane-α,ω-dioate ligands from one side and two water molecules, in a *cis*-orientation. Generally, there is a chelating interaction involving the nitrogen atom and the oxygen atom of adjacent deprotonated carboxylate ligands in complexes of singly and doubly deprotonated 2,3-pyrazinedicarboxylic acid ($pyzdcH_2$).[4,6] However, the hydrogen atoms bonded to the nitrogen atoms of the pyrazine rings in complex **1** prevent the formation of such a chelate.

The nickel atom has a distorted octahedral environment. It is coordinated by four water molecules and two oxygen atom from the carboxylate groups of two 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate ligands, which are found in a *cis*-orientation. The uncoordinated carboxylate groups of the 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate ligands are still protonated. The O2···O3 distance of 2.412 Å indicates that there is no intramolecular hydrogen bond involving the carboxylate hydrogen and O2. This is quite different from complexes of singly deprotonated 2,3-pyrazinedicarboxylic acid $[Co\{pz(COO)COOH\}_2(H_2O)_2]$[6b] and $[Ni(pyzdcH)_2(H_2O)_2]$,[4] both of which show a *trans*-configuration, a chelate interaction and a strong intramolecular hydrogen bond between the carboxylate hydrogen and the nearest oxygen atom of the deprotonated carboxylate group. The $Ni-O_{carboxylate}$ bond length [2.046(2) Å] is a little longer than that in $[Ni(pyzdcH)_2(H_2O)_2]$ [2.021(1) Å],[4] whereas the Ni−Ow bond lengths [average 2.050(3) Å] are a little shorter than those in $[Ni(pyzdcH)_2(H_2O)_2]$ [2.091(1) Å].[4] The C5−O5 and C6−O6 bond lengths [1.234(3) and 1.227(3) Å, respectively] are shorter than those of C−O single bonds, indicating that the 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate ligands are present as their ketone tautomers.

The intermolecular hydrogen bonds play an important role in the stabilization of the structure of **1**. As shown in Figure 2, there are extensive hydrogen bonds between coordinated water molecules and uncoordinated carboxylate groups ($Ow\cdots O_{carboxylate}$ = 2.774 Å), coordinated water molecules and dione groups ($Ow\cdots O_{dione}$ = 2.885Å), uncoordinated carboxylate groups and dione groups ($O_{dione}\cdots O_{carboxylate}$ = 2.862 Å), and also between dione groups and the nitrogen atoms of the pyrazine rings ($O_{dione}\cdots N$ = 2.887 or 2.954 Å) from neighboring molecules. Consequently, a two-dimensional supramolecular structure is formed.

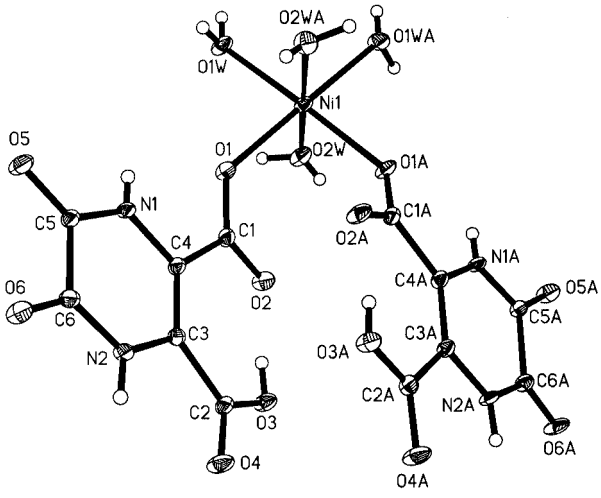

Figure 1. ORTEP drawing of complex **1** with labeling scheme and thermal ellipsoids at the 50% probability level for C, N and O atoms; the spheres of the hydrogen atoms have been arbitrarily reduced; selected bond lengths (Å) and angles (°): Ni(1)−O(1w) 2.041(3), Ni(1)−O(1) 2.046(2), Ni(1)−O(2w) 2.059(3); O(1)−Ni(1)−O(1w) 84.86(10), O(1)−Ni(1)−O(1a) 93.94(13)

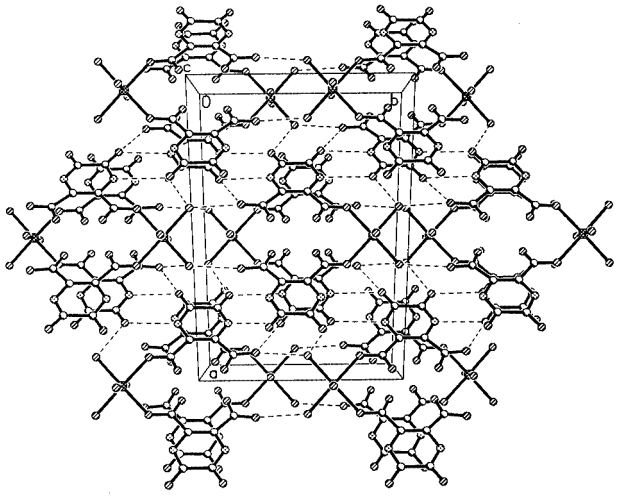

Figure 2. Projection down the *c*-axis of complex **1**

Only one carboxylate group of compound **2** is deprotonated. The hydrogen atom position indicates the two carboxylate groups in compound **2** share a single proton (Figure 3); a similar trend has also been observed in the complex $[Co\{pz(COO)COOH\}_2(H_2O)_2]$.[6b] The other proton is combined with a water molecule to form the cation H_3O^+. The crystal structure of **2** is therefore composed of discrete H_3O^+ cations and singly deprotonated 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate anions. The C1−O3 bond length [1.214(2) Å] is a little smaller than the $C-O_{dione}$ bond lengths in the 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate ligands of **1** [the C5−O5 and C6−O6 bond lengths are1.234(3) and 1.227(3) Å, respectively]. There are extensive hydrogen bonds between protonated water molecules and the oxygen atoms of the dione groups ($Ow\cdots O_{dione}$ = 2.879 Å) and also the carboxylate groups from neighboring singly deprotonated 1,4-dihydropyrazine-2,3-dione-5,6-dicarboxylate anions ($Ow\cdots O_{carboxylate}$ = 2.874 Å). These hydrogen bonding interactions force the structure into an interesting two-dimensional layered supramolecular array, as shown in Figure 4.

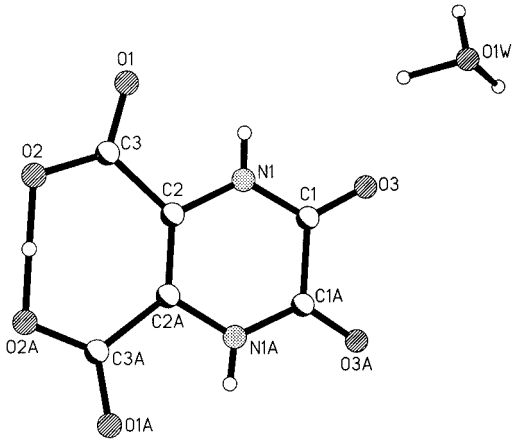

Figure 3. ORTEP drawing of complex **2** showing 50% probability displacement ellipsoids and the atom numbering scheme

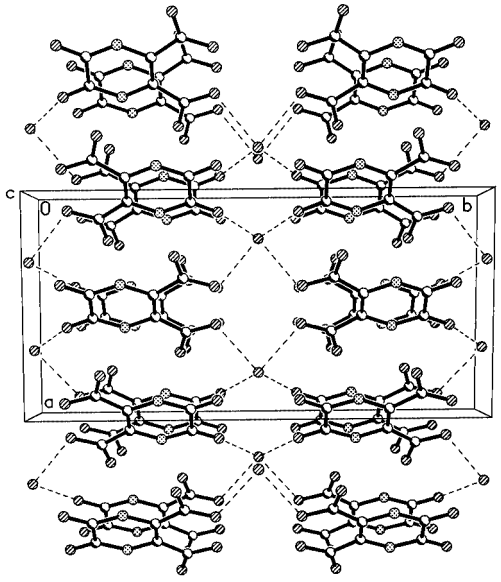

Figure 4. Projection down the *c*-axis of complex **2**

In conclusion, this study illustrates that chloro groups can also undergo a hydrolysis reaction under hydro(solvo)-thermal conditions. This new reaction could be useful for designing structures with a novel topology. Furthermore, such a reaction may also find potential applications in organic synthesis. More investigations are currently underway.

Experimental Section

Synthesis of 1: 5,6-Dichloropyrazine-2,3-dicarbonitrile (80 mg, 0.4 mmol) and $[Ni(ClO_4)_2]\cdot 6H_2O$ (73 mg, 0.2 mmol) were placed in a thick Pyrex tube (ca. 20 cm long). After addition of 0.2 mL of water and 0.8 mL of ethanol, the tube was frozen with liquid N_2, evacuated under vacuum and sealed with a torch. The tube was then heated at 110 °C for three days to give pure green rod-shaped crystals of **1** in 60% yield (63 mg) based on 5,6-dichloropyrazine-2,3-dicarbonitrile. Compound **1** is insoluble in common organic solvents. $C_{12}H_{14}N_4NiO_{16}$ (529.0): calcd. C 27.25, H 2.67, N 10.59; found C 27.12, H 2.81, N 10.47. IR (KBr): $\tilde{\nu}$ = 3551(s), 3448(s), 3373(s), 3116(s), 1688(vs), 1555(s), 1459(s), 1370(s), 1250(w), 1159(m), 1103(m), 889(m), 805(w), 767(m), 702(w), 500(w), 464(m) cm^{-1}.

Synthesis of 2: This compound was prepared as brown tablet-shaped crystals from 5,6-dichloropyrazine-2,3-dicarbonitrile and $[Cd(ClO_4)_2]\cdot 6H_2O$ by the procedure described above for **1**. Yield: 65 mg (75%). $C_{12}H_{12}N_4O_{14}$ (436.2): calcd. C 66.08, H 5.55, N 25.69; found C 65.94, H 5.62, N 25.39%. IR (KBr): $\tilde{\nu}$ = 3444(b, m), 3204(vs), 1718(vs), 1587(s), 1497(s), 1434(vs), 1367(s), 1233(m), 1150(w), 1095(w), 981(w), 857(m), 798(w), 771(w), 709(w), 669(m), 589(w), 461(w) cm^{-1}.

Caution: *$Ni(ClO_4)_2\cdot 6H_2O$ and $Cd(ClO_4)_2\cdot 6H_2O$ are potentially explosive and should be handled with care!*

X-ray Crystal Structure Determination: Crystal data collection was carried out using a Rigaku RAXIS RAPID IP imaging plate system with Mo-K_α radiation (λ = 0.71073Å). The data were corrected for Lorentz-polarization effects, and absorption corrections were applied. The structure was solved by direct methods and refined by a full-matrix least-squares technique based on F^2 using the SHELXL-97 program.[8] All non-hydrogen atoms were refined anisotropically and all hydrogen atoms were located in difference Fourier maps.

Crystal Data For 1: $C_{12}H_{14}N_4NiO_{16}$, monoclinic, space group *C*2/*c*, *Mr* = 528.98, *a* = 17.858(4), *b* = 11.098 (2), *c* = 9.869(2) Å, β = 119.87(3)°, *V* = 1696.1(6) $Å^3$, *Z* = 4, *Dc* = 2.072 g·cm^{-3}, *T* = 293(2)K, μ = 1.254 mm^{-1}, R_1 = 0.0441, wR_2 = 0.0875 for 1356 observed reflections [$I > 2\sigma(I)$] from 1927 independent reflections, GOF = 0.962.

Crystal Data For 2: $C_{12}H_{12}N_4O_{14}$, monoclinic, space group *C*2/*m*, *Mr* = 218.13, *a* = 8.8928(18), *b* = 18.176(4), *c* = 5.0350 (10) Å, β = 96.65(3)°, *V* = 808.4(3) $Å^3$, *Z* = 4, *Dc* = 1.792 g·cm^{-3}, *T* = 293(2)K, μ = 0.168 mm^{-1}, R_1 = 0.0510, wR_2 = 0.1587 for 848 observed reflections [$I > 2\sigma(I)$] from 954 independent reflections, GOF = 1.083.

CCDC-178134 (**1**) and CCDC-178135 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union

Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Evidence Based on Crystal Structures and Calculations of a C−H···π Interaction Between an Organic Moiety and a Chelate Ring in Transition Metal Complexes

Goran A. Bogdanović,[a,b] Anne Spasojević-de Biré,[a] and Snežana D. Zarić*[c]

Keywords: C−H···π interactions / Chelates / Noncovalent interactions / Density functional calculations / Weak hydrogen bonds

Structural and computational evidence is given for a special type of C–H···π interaction where the C–H group interacts with the π-system of a six-membered chelate ring. An investigation of crystal structures shows that these interactions take place in quite a number of metal complexes, including organometallic compounds; in the CSD we found over 1200 structures with these interactions. These interactions exist in complexes of different metals and various chelate rings. DFT calculations on three model systems show that the energy of these interactions is about 1 kcal/mol.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Noncovalent interactions involving π-systems have been extensively studied in the last few years and the importance of these interactions has been shown in different molecular systems from molecular biology to crystal engineering.[1−8]

Noncovalent interactions in metal complexes between π-systems and ligands with X−H groups (X = N, O, C) have been found and investigated by searching databases of crystal structures[9−11] and by quantum chemical calculations.[11−14] It has been shown that these interactions play a role in crystal engineering[7−9] and in the stability of metalloproteins, and it has been proposed that they can play a role in the mechanism of enzymatic reactions.[10] In metal complexes, the partial positive charge of the hydrogen atom belonging to the ligand, gained upon coordination to the metal cation, makes the interactions with the π-system stronger.[8−14] The stabilization energy of the metal ligand aromatic cation − π (MLAC-π) interactions in crystal structures, where ligands coordinated to a metal interact with aromatic groups, was evaluated by quantum chemical calculations to be between 4 and 10 kcal/mol.[10,11]

C−H···π interactions are the weakest among X−H···π interactions. C−H groups are very abundant in organic and biomolecules therefore these interactions appear very frequently and are very important for molecular recognition.[6,15,16] Theoretical calculations have shown the energy and the nature of these interactions,[6,15−18] leading to calculated values close to 1 kcal/mol. C−H···π interactions have also been found in metal complexes.[9,11,16,19−23] However, a C−H···π interaction, where a C−H group belonging to an organic moiety interacts with the π-system of a chelate ring containing a metal atom, have not been reported before. In this article we will give evidence for this type of interaction.

Results and Discussion

Searching crystal structures of transition metal complexes from the Cambridge Structural Database (CSD) shows that specific C−H···π interactions — interactions between C−H groups and the π-systems of chelate ring — can be observed in many crystal structures. It is supposed that the metal atom in these chelate rings is involved in π-delocalisation.[24] In the CSD, we found 5091 structures containing almost planar chelate rings, with delocalised π-bonds. Among these structures, there are 1265 structures[25] with a weak C−H···π interaction ($\alpha > 110°$, $\beta < 16°$, and H···Ω distance < 3.0 Å; α, β, and Ω are defined in Figure 1) and 151 structures with a very strong interaction ($\alpha > 145°$, $\beta < 12°$, and H···Ω distance < 2.6 Å). For many of these structures there is more than one interaction per molecule. The geometrical parameters for some examples are shown

in Table 1. All these examples have a very short H···Ω distance (H···Ω < 2.6 Å), the H atom is almost centered over the chelate ring center (β < 12.5°) and the X−H···Ω line is not too bent (α < 145°). From a geometrical point of view, interactions in these structures are similar to strong C−H···π interactions in organic molecules.[6,16] An example from Table 1 is shown in Figure 2.

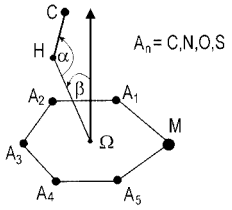

Figure 1. Geometric parameters used for the determination of the C−H···π interaction

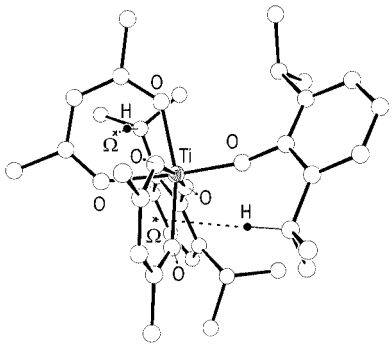

Figure 2. Perspective view of ACIPTI[26] as a selected example for a C−H···π interaction with the π-system of the chelate rings; the carbon atoms are unlabelled

From Table 1, it is clear that these interactions occur in metal complexes — including organometallic compounds — of different metals and various chelate rings. In the interactions shown in Table 1, some of the C donor atoms are sp^3 hybridized and some of them are sp^2. For all the $C_{sp}{}^3$ cases, the carbon atom is bonded to two or three other non-hydrogen atoms, therefore the position of the H atom which is directed toward the chelate ring is reliable. Most of these interactions are intermolecular, and only the ACIPTI compound presents an intramolecular interaction.

It is very interesting to notice that in all the examples shown in Table 1 the complexes are neutral and both the chelate ring and the C−H group are in the same molecule. In the case of intermolecular interactions, the interaction occurs between two identical molecules: the C−H group from one molecule interacting with the chelate ring from the other molecule. For this type of interaction, we assume that the neutrality of the complexes is important, as, on the one hand, the chelate ring should not have any partial positive charge, which would be the case if the complex were positively charged, and, on the other hand, the π-system from the chelate ring should not interact with a negatively charged complex. In the case of a neutral complex the interacting H atom has a partial positive charge, which is enough for a weak C−H···π interaction.

[a] Data for normalised H-atom positions. [b] α is the C−H···Ω angle (Figure 1). [c] β is the angle between the normal of the chelate ring and the Ω···H line (Figure 1). [d] H···Ω is the distance between the normalised H-atom position and the center of the ring (Figure 1). [e] $C_{sp}{}^2$ is bonded to two non-hydrogen atoms. $C_{sp}{}^3$ is bonded to two or three non-hydrogen atoms. [f] *R* is the reliability factor taken from CSD.

In order to evaluate the energy of this type of interaction, DFT calculations were performed on model systems made from the structures JOXGIM, YINLUC and ZOPYUY. Since the molecules in which these interactions occur are rather large, and there are at the same time other intermolecular interactions, we chose the structures where we were able to separate the C−H···π interaction from other interactions, and the calculations were performed on smaller model systems. These model systems were built from the crystal structures by substituting all groups that are not important for the interaction with hydrogen atoms. The model systems for YINLUC and ZOPYUY contain two complex molecules that interact with each other, whereas the model system for JOXGIM has one complex molecule interacting with a molecule of methane (Figure 3). In the JOXGIM model system we used a methane molecule instead of the second molecule of complex as other intermolecular interactions could exist between two complex molecules in the crystal structure, and therefore the calculated energy of interaction of these two molecules would not be only the energy of the C−H···π interaction. The geometries of the interactions were kept the same as they were in the crystal structures. The calculated energies of interactions are 0.89, 1.33, and 1.38 kcal/mol for model systems from JOXGIM, YINLUC and ZOPYUY, respectively. The calculated energies depend upon the H···Ω distance: the distance is the largest in JOXGIM and the shortest in ZOPYUY (Table 1). The calculated values for interacting energies are similar to calculated values of C−H···π interactions in organic molecules.[6]

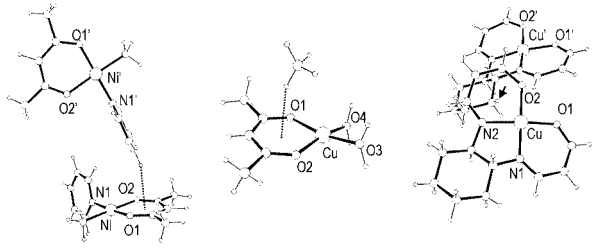

Figure 3. Model systems used for DFT calculations of the energy of C−H···π interactions with a chelate ring; YINLUC (left), JOXGIM (middle), ZOPYUY (right); the carbon atoms are unlabelled

Conclusion

The results presented here show that there is another noncovalent interaction that cannot exist in organic molecules but only in metal complexes. This interaction, where metal-containing chelate rings can be involved in C−H···π interactions, is widespread in metal complexes, including organometallic compounds. It has been estimated by DFT calculations that the energy of this interaction is about 1 kcal/mol. This kind of interaction, like other noncovalent interactions, can be used in nonorganic crystal engineering to design crystals with desired structures and properties. We are continuing our extensive investigations into this kind of interaction using a more detailed analysis of crystal structures from the CSD, enhanced by quantum chemical calculations.

Data Screening and Computational Methods

The Cambridge Structural Database (CSD)[44] was screened in order to find C−H···π interactions with a chelate ring. We searched for the crystal structures of metal complexes that have six-membered, almost-planar chelate rings with delocalized bonds and with N, S, or O atoms coordinated to a transition metal atom, and we found 5091 such structures. In these structures we demanded that there is an hydrogen atom at a distance shorter than 3.0 Å from Ω, the center of the six-membered ring, and presenting an X−H···Ω axis in a narrow cone perpendicular to the ring ($\alpha > 110°$, $\beta < 16°$) (Figure 1). These screening criteria are more restrictive than criteria used previously for similar screenings.[45,46] All C−H distances were normalized to 1.083 Å. In this way we obtained 1265 crystal structures.

Quantum chemical calculations were performed on model systems built from crystal structures using the B3LYP method and 6−31g** basis set on all atoms, except for the metal atoms, where the LANL2DZ basis set was used. The calculations were perfomred with Gaussian-98.[47]

Acknowledgments

Unusual Magnetic Behavior in the Layered Ferromagnet $[Ni(C_6H_{14}N_2)_2]_3[Fe(CN)_6]_2 \cdot 2H_2O$

Frederic Bellouard,[a] Miguel Clemente-León,[a] Eugenio Coronado,*[a] José R. Galán-Mascarós,[a] Carlos J. Gómez-García,[a] Francisco Romero,[a] and Kim R. Dunbar[b]

Keywords: Molecular magnets / Ferromagnetism / Cyanides / Nickel / Magnetic properties

The cyano-bridged molecular complex $[Ni(C_6H_{14}N_2)_2]_3[Fe(CN)_6]_2 \cdot 2H_2O$, with a rectangular 2D structure, displays long-range ferromagnetic ordering at 14 K, and exhibits unusual magnetic properties for this type of material, as confirmed by the appearance of two different peaks in the AC magnetic susceptibility plot, and a high coercive field (2.3 kOe) and remnant magnetization (6.8 μ_B).

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Cyanide-bridged bimetallic assemblies based upon hexacyanometalate building blocks, $[M(CN)_6]^{n-}$, constitute an extensive family of molecular-based materials with interesting magnetic and magneto-optical properties.[1–9] Bimetallic Prussian blue solids behave as magnets with high critical temperatures;[1] however, the face-centered cubic structures adopted by these phases result in a low magnetic anisotropy, and, furthermore, it is very difficult to obtain single crystals. One approach to overcome these problems is to synthesize materials based on $[M(CN)_6]^{n-}$ building blocks condensed with coordinatively unsaturated transition metal complexes such as $[Ni(L)_2]^{2+}$ (L = ethylenediamine derivative) or $[NiL]^{2+}$ (L = polyaza macrocyclic ligand). The resulting Ni_3M_2 (M^{III} = Fe, Cr) based polymeric complexes exhibit a remarkably diverse structural chemistry and a variety of cooperative properties including ferro-, ferri-, and metamagnetism. In fact, a slight modification of the ligand is sufficient to alter the structure, and hence the magnetic properties, completely. For instance, when ethylenediamine is used, a 1D rope-ladder structure is obtained, while the use of *N*-methylethylenediamine affords a 2D honeycomb sheet structure.[10] Interestingly, in the layered materials, a tuning of the bulk magnetic properties can be achieved by changing the interlayer spacing: the behavior can be tuned from metamagnetic for a small spacing (less than 10 Å), to ferromagnetic for a larger spacing, due to the competition between intralayer ferromagnetic interactions with the interlayer antiferromagnetic dipolar interactions. This versatility encouraged us to explore the structure-directing role of diamine ligands exhibiting a larger spatial extension, for example 1,2-diaminocyclohexane, which should favor a larger interlayer spacing and thus a ferromagnetic ordering.

Slow interdiffusion of $K_3[Fe(CN)_6]$ and $[Ni(L)_2]Cl_2$ (L = *trans*-1,2-diaminocyclohexane) in water afforded large brown crystals of $[Ni(C_6H_{14}N_2)_2]_3[Fe(CN)_6]_2 \cdot 2H_2O$.[11] The structure consists of a neutral network of bimetallic cyanide layers that are decorated with organic cyclohexane groups projecting above and below into the interlamellar region.[12] This double layer of bulky diamine ligands imposes a large intersheet separation, with Ni–Ni or Fe–Fe interlayer distances equal to 12.639 Å and a shorter Ni–Fe interlayer distance of 10.889 Å (Figure 1, top). The layers are composed of deformed rectangular grids of twelve octahedral metal sites in which alternating *trans*-$[Ni(C_6H_{14}N_2)_2]^{2+}$ cations and $[Fe(CN)_6]^{3-}$ anions are linked by CN^- bridges (Figure 1, center). Water molecules occupy the free space within these rectangular grids. In contrast with the other 12-gon motifs reported recently,[13] in the present case there are two distinct $[Fe(CN)_6]^{3-}$ units, situated at the corners and at the center of the sides of the grid, which act as tetradentate and bidentate ligands connecting four and two *trans*-$[Ni(C_6H_{14}N_2)_2]^{2+}$ complexes, respectively. Another unusual feature is the extremely bent Ni–N–C bond angles. In related compounds reported so far, the lowest values have been found to be around 148°.[14] Only copper-containing compounds have shown a lower angle for bridging cyanides, near 120°.[15] However, values as low as 128.69° and 122.53° for Ni1–N2–C2 and Ni2–N3–C3, respectively, are observed in the title compound (Figure 1, bottom).

The magnetic susceptibility of the bimetallic compound, measured on polycrystalline samples in the temperature

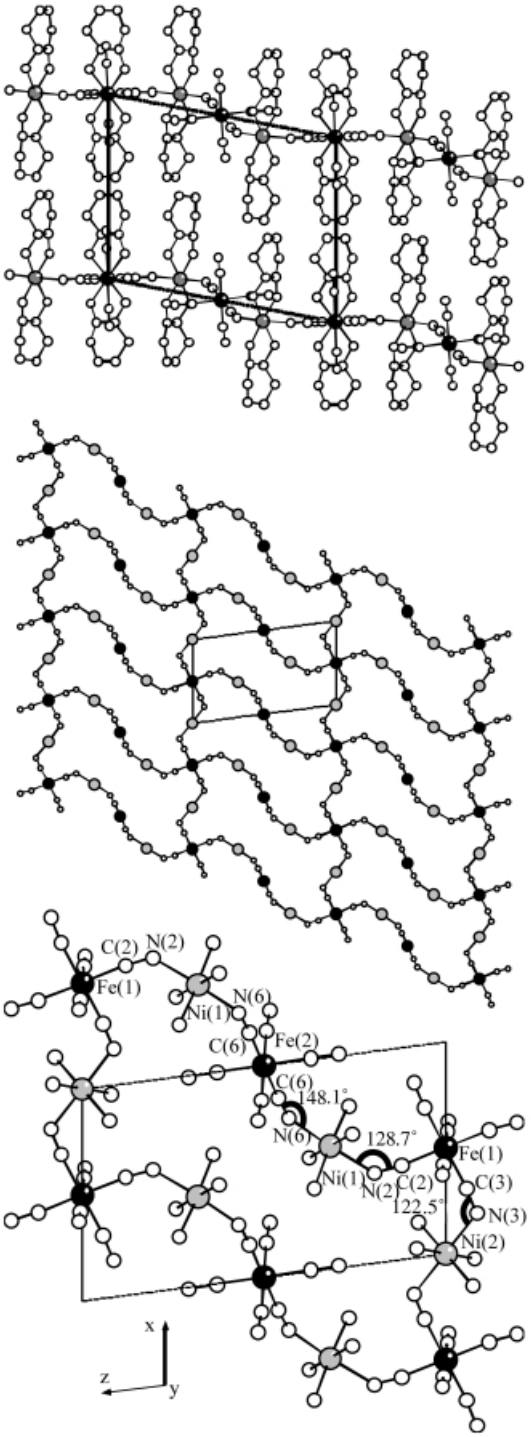

Figure 1. Top: View of the structure of the title compound showing the layers in the *ac* plane. Center: Schematic view of the layers in the *ab* plane. Bottom: View of the Fe_6Ni_6 ring showing the distortions in the bridging Ni−N−C bridges; the cyclohexane rings have been omitted for the sake of clarity (Fe atoms in black and Ni atoms in gray); selected distances in Å: Fe(1)−C(2) 2.088(3), Fe(1)−C(3) 1.916(4), Ni(1)−N(2) 2.168(3), Ni(1)−N(6) 2.088(3), Ni(2)−N(3) 2.154(3), Fe(2)−C(6) 1.931(4)

range 2−300 K under a field of 1000 Oe, follows a Curie−Weiss law above 50 K with a Weiss constant θ of 21.1 K. The positive sign of θ indicates the presence of dominant ferromagnetic interactions between neighboring Fe^{III} and Ni^{II} ions. Below 15 K, χ_m increases sharply and saturates at a lower temperature. In addition, the zero field cooled (ZFC) and field cooled (FC) measurements of the DC magnetic susceptibility deviate from each other at 14 K (Figure 2, inset), with the remnant magnetization disappearing below this temperature. This behavior suggests the onset of a long-range ferromagnetic transition.

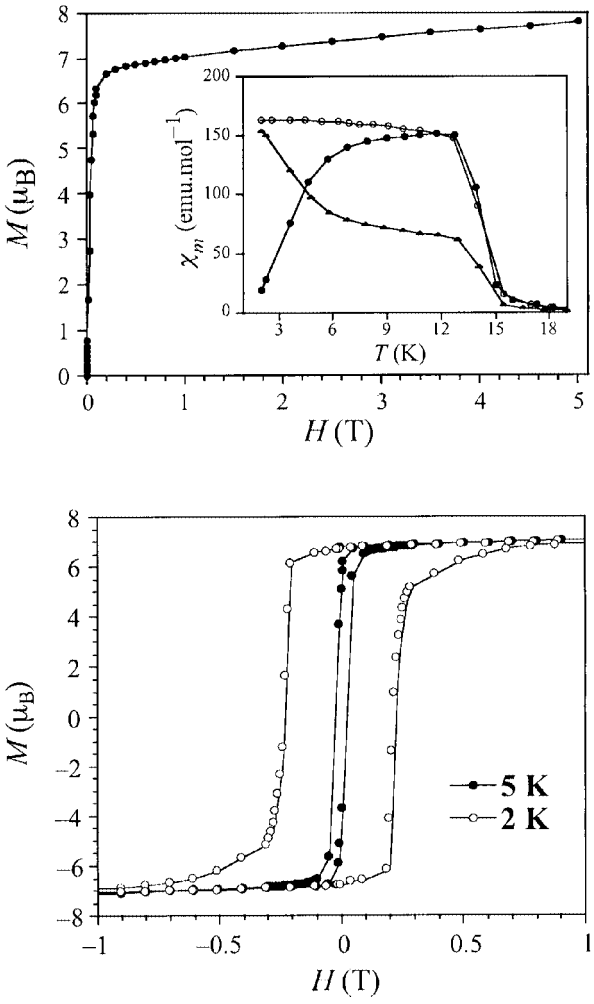

Figure 2. Top: Field dependence of the magnetization at 2 K for the title compound; inset: zero-field cooled (full circles) and field cooled (empty circles) plots of the DC magnetic susceptibility at 1 G, and remnant magnetization (triangles). Bottom: Hysteresis loop for the title compound at 2 and 5 K

The nature of the magnetic transition was confirmed by the field dependence of the isothermal magnetization performed at 2 K (Figure 2). In fact, a rapid increase of the magnetization to a value of ca. 6.5 μ_B is observed at 1 kOe, and increases to 7.7 μ_B at 50 kOe. This latter value is slightly smaller than, but very close to, 8 μ_B, which is the expected value for a ferromagnetic alignment of the interacting spins in the Ni_3Fe_2 unit ($S_{Ni} = 1$, $S_{Fe} = 1/2$; $S = 4$ per Ni_3Fe_2 unit). Hence, the compound behaves as a ferromagnet, although the lower than expected saturation value suggests the presence of some spin canting.

At 2 K this ferromagnet exhibits magnetic hysteresis with a coercive field as large as 2.3 kOe and a high remnant magnetization of 6.8 μ_B per Ni_3Fe_2 unit. This leads to an energy product of 7.3 $kJ\cdot m^{-3}$, which is similar to that obtained in very hard magnetic materials. To the best of our knowledge, the only precedent for a structurally characterized Ni_3Fe_2 ferromagnet is the recently reported layered compound $[NiL]_3[Fe(CN)_6]_2\cdot 12H_2O$ (L = 3,10-diethyl-1,3,5,8,10,12-hexaazacyclotetradecane),[13a] which orders ferromagnetically at 9.1 K. At T = 1.6 K, the material exhibits a coercive field of 1.5 kOe and a remnant magnetization of 1.36 μ_B. In our new layered magnet, the coercivity is larger and the energy product is about one order of magnitude bigger.

One main feature of note in this study is the observation that the Ni^{II} and Fe^{III} centers are ferromagnetically coupled, in spite of the fact that the Ni−N−C angles are much more acute than those reported for known cyanide compounds of these two metals.[14] Our findings underscore the fact that there is a wide range of angles that stabilize a ferromagnetic $Ni^{II}-Fe^{III}$ coupling through a CN^- bridge.

In order to determine precisely the critical temperature at which this transition occurs AC magnetic measurements were performed (Figure 3). We observed a sharp increase below ca. 15 K and a broad and asymmetric maximum in the real part of the susceptibility, χ_m', at about 13.5 K. This signal is accompanied by an out-of-phase signal, χ_m'', that becomes non-zero below a temperature of 14.0 K, which defines T_c. Interestingly, the χ_m'' signal displays a shoulder at ca. 12 K, which is frequency independent, and a maximum at ca. 4 K which is strongly frequency dependent (Figure 3). This result, together with the observation that the compound behaves as a hard magnet only below 5 K (at higher T the coercive field is very small), indicates that the movement of the domain walls is strongly hindered below this temperature. The very same features were observed when measurements were performed on a single crystal. This proves that the anomalous behavior is actually intrinsic for this compound, and not sample dependent.

A plausible explanation of this behavior would be that the magnetic transition at 14.0 K corresponds to a ferromagnetic ordering within the magnetic layer that it is triggered by the magnetic anisotropy of the metallic ions. At lower temperatures (below 5 K), the dipolar coupling between layers becomes relevant and induces an anchoring of the domain walls. If this is the case, the frequency dependence of χ'' can be related to the activation energy required to unblock these domain walls.[16] Fortunately, since this compound can be grown as well-shaped single crystals, a more detailed physical characterization, including neutron diffraction, can be performed that will provide detailed information on the anisotropy and magnetic phase diagram of this novel molecule-based ferromagnet. The unusual features observed in the AC magnetic susceptibility measurements are similar to those observed in other layered magnets with large interlayer separations,[17] suggesting that these effects should be related to the low dimensionality of these systems. Molecular layered magnets are ideal to study this novel behavior since the interlayer separation of a given system can easily be tuned simply by changing the spacers in each case.

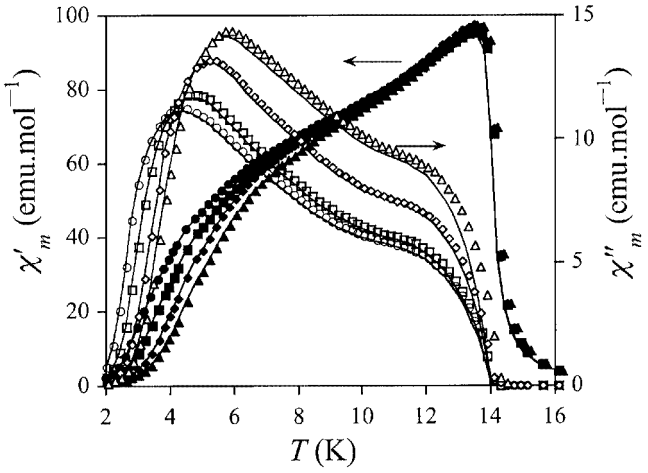

Figure 3. Thermal variation of the molar AC magnetic susceptibility for the title compound (χ': filled symbols, χ'': empty symbols) at frequencies of 1, 10, 110 and 332 Hz (circles, squares, diamonds and triangles, respectively) showing the frequency dependence of χ'' in the peak around 4 K and the appearance of a χ'' signal below 14.0 K

Finally, it is worth mentioning that a racemic mixture of the ligand *trans*-1,2-diaminocyclohexane was used for the synthesis of the title compound and therefore both stereoisomers are present, yielding a centrosymmetric solid state structure. The organic ligands are disordered in two different crystallographic positions corresponding to the two stereoisomers, due to statistical distribution. More work is in progress to obtain a pure enantiomeric structure that would be of interest to study possible magneto-chiral effects.[10] In this case the chirality appears only in the organic ligand and not in the metallic complexes, therefore more subtle effects could be expected.

Experimental Section

Synthesis: The precursor $[Ni(C_6H_{14}N_2)_2]Cl_2$ was prepared by the literature method developed for ethylenediamine complexes.[19] All reagents were of commercial grade and used without further purification.

$[Ni(C_6H_{14}N_2)_2]_3[Fe(CN)_6]_2\cdot 2H_2O$ (1): A solution containing 1,2-diaminocyclohexane (2 mmol, 245 mL) in 40 mL of methanol was added to an aqueous solution of $NiCl_2\cdot 6H_2O$ (2 mmol, 476 mg) in 60 mL of water. A solution of $K_3[Fe(CN)_6]$ (1.3 mmol, 439 mg) in 60 mL of water was then added dropwise to the resulting brown solution,. A brown precipitate was filtered off and the yellow filtrate was allowed to stand in the dark overnight. Brown plates were collected by suction filtration and washed with water and ethanol. Single crystals suitable for X-ray single crystal analysis were obtained after a week by slow diffusion of $[Ni(C_6H_{14}N_2)_2]Cl_2$ (102 mg, 0.28 mmol) and $K_3[Fe(CN)_6]$ (94 mg, 0.28 mmol) placed in the sides of an H-type diffusion tube. Water (55 mL) was used as solvent.

Physical Measurements: X-ray data sets were collected on a SMART 1K area detector diffractometer equipped with graphite monochromated Mo-K_α radiation (λ = 0.71073 Å). The frames were integrated in the Siemens SAINT[20] software package and the data were corrected for absorption using the SADABS program.[21] The structure was solved by direct methods followed by Fourier synthesis (SIR-97),[22] and refined on F^2 (SHELXL-97).[23] Variable temperature susceptibility measurements were carried out in the temperature range 2−300 K at a magnetic field of 0.1 T on polycrystalline samples with a magnetometer (Quantum Design MPMS-XL-5) equipped with a SQUID sensor. Susceptibility data were corrected from the diamagnetic contributions of the compound as deduced from Pascal's constant tables. Isothermal magnetization measurements at low temperatures were carried out up to 5 T on the same apparatus.

Synthesis, Structures and Reactivity of *N*-Borane-Protected 1,1′-Bisimidazoles with Different Bridging Functions

Andre Weiss,[a] Hans Pritzkow,[a] and Walter Siebert*[a]

Dedicated to Prof. Dr. Otto J. Scherer

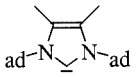
Keywords: Boranes / Carbenes / Carbene complexes / Nitrogen heterocycles / Macrocycles

The bridging functions Me_2Si, $[(CH_2)_3(CMe_2)_2N]B$ and CH_2 have been used to connect two imidazoles in the 1,1′-position. The bisimidazolyl compounds were treated with BH_3 or BEt_3, and the resulting *N*,*N*′-bisborane-protected products **1**, **3b**, **4a**, and **5b** were characterized by X-ray structure analyses. Reaction of 1,1′-bis(4,5-dimethylimidazolyl)methane with BBr_3 yielded the macrocyclic dicationic tetraimidazolyl compound **6**. The behavior of the N-protected bisimidazoles **1** and **3**–**5** towards deprotonating agents was investigated and it was found that 1,1′-bis(3-borane-4,5-dimethylimidazolyl)methane (**5b**) is deprotonated to give a dianionic dicarbene compound. Its reaction with Cp_2MCl_2 allowed the formation of the corresponding titanocene and zirconocene complexes **8** and **9**, which were characterized by X-ray structure analyses. In **9** a 3c,2e B–H–Zr bond is present.

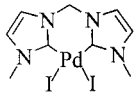
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

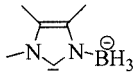
The coordination behavior of *N*-heterocyclic carbenes has been studied very intensely since the isolation of 1,3-bis(adamantyl)imidazolin-2-ylidene **A** by Arduengo et al. in 1991.[1] Many *N*,*N*-methylene- and -ethylene-bridged bis(imidazolin-2-ylidene)metal complexes have since been prepared.[2] Recently the catalytic activity in Heck and Suzuki coupling reactions of the diiodopalladium(II) complex of 1,1′-methylenebis(3-methylimidazolin-2-ylidene) **B** has been investigated.[3]



A



B



C (= L)

Addition of BH_3 to 1-alkylimidazoles leads to neutral *N*-borane adducts, which are deprotonated by butyllithium to give anionic 3-borane-1-alkylimidazol-2-ylidenes **C** (L). These anions were found to be excellent ligands to form transition metal complexes of manganese[4] (**D**), titanium[5] (**E**), iron[4−6] (**F**−**H**) and the distorted tetrahedral anionic complexes of vanadium[5,6] (**I**) and scandium[6] (**J**). In the latter case the formation of four 3c,2e B−H−Sc bonds was observed.

The dinuclear compound **K**[7] is the only structurally characterized imidazol-2-ylidene complex of titanium.

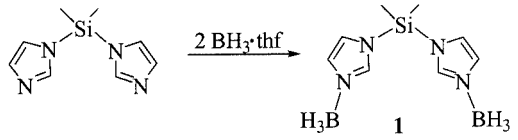
Results and Discussion

Formation and Reactivity of Bisimidazolyl Compounds 1, 2a−b, 3a−b, 4a, and 5a−b

The addition of two equivalents of BH_3·thf to a solution of 1,1′-bis(imidazolyl)dimethylsilane[8] yields the colorless *N*,*N*-bis-borane adduct **1**, which crystallizes from a saturated THF solution (Scheme 1).



Scheme 1

The ^{11}B NMR spectrum shows a quadruplet at $\delta = -21.5$; three imidazole signals in the proton NMR spectrum and one singlet for the methyl groups prove the symmetry of the molecule. In the crystal, **1** has a twofold rotation axis (Figure 1). The N2−B1 distance [1.580(2) Å] is typical for borane adducts of nitrogen compounds. The coordination geometry at the silicon atom is distorted tetrahedral with N1−Si−N1A and C4−Si−C4A angles of 104.4(1)° and 117.7(1)°, respectively. Attempts to doubly deprotonate **1** in the 2,2′-positions with alkyllithium compounds (MeLi, *t*BuLi, *n*BuLi) to generate a dicarbene were unsuccessful due to decomposition.

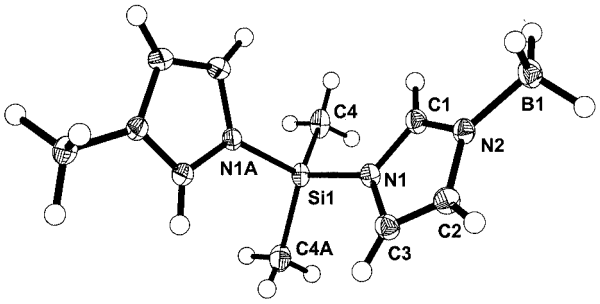


Figure 1. Structure of **1** in the crystal; selected bond lengths [Å] and angles [°]: Si−N1 1.776(1), N1−C3 1.392(1), C2−C3 1.350(2), C2−N2 1.381(1), N2−C1 1.315(1), C1−N1 1.356(1), N2−B1 1.580(2); N1−Si−N1A 104.4(1), C4−Si−C4A 117.7(1), Si−N1−C1 126.0(1), N1−C1−N2 111.2(1)

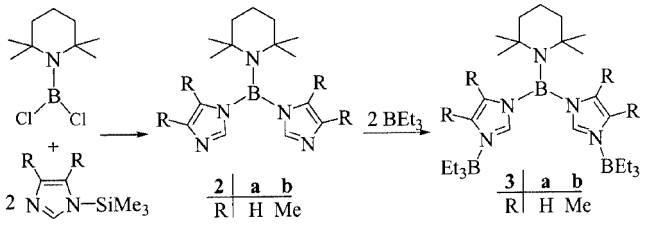
We have shown that attempts to synthesize imidazolylboranes by reaction of 1-trimethylsilylimidazoles with haloboranes lead to polymeric or (under certain conditions) oligomeric products.[9] This is caused by donor/acceptor interactions of the electron pair at the nitrogen in the 3-position with the empty p_z orbital at the boron atom. Formation of oligomeric adducts is avoided when the borane compound is substituted by a sterically demanding and electron-donating group such as 2,2′,6,6′-tetramethylpiperidide (TMP): reactions of (tmp)BCl_2 with two equivalents of 1-trimethylsilylimidazole or 4,5-dimethyl-1-trimethylsilylimidazole yielded the first monomeric bis(imidazolyl)boranes **2a** and **2b**, respectively (Scheme 2).



Scheme 2

The ^{11}B NMR chemical shifts [δ = 28.2 (**2a**), 28.5 (**2b**)] indicate a trigonal coordination at the boron atoms. Compound **2a** shows the expected set of signals in the proton NMR spectrum (three imidazolic protons, one singlet for methyl groups and a multiplet for methylene groups of TMP), whereas the methyl groups of the TMP substituent in **2b** appear as two singlets ($|\nu_a - \nu_b| = 14.8$ Hz), caused by restricted rotation at the N−B bond. Proton NMR spectra at different temperatures (Figure 2) provide a coalescence temperature of 26 °C. The resulting free activation enthalpy of rotation ($\Delta G^{\#}$) at the B−N bond is 64.6 kJ/mol, calculated by the Eyring equation.[10]

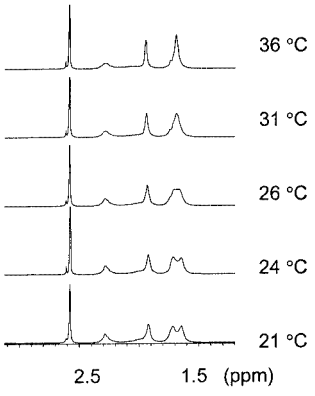


Figure 2. ^1H NMR spectra of **2b** at different temperatures

Attempts to alkylate **2a** in the 3,3′-positions (with CH_3I, 2-iodopropane, or Me_3OBF_4) led to decomposition products, and treatment with Me_3SiBr or BH_3·thf to quaternization of the boron atoms. The reaction of **2a** and **2b** with two equivalents of BEt_3 yields the 3,3′-bis(triethylborane) adducts **3a** and **3b** (Scheme 2), as indicated by an additional signal in the ^{11}B NMR spectra at $\delta \approx -1$. Restricted rotation at the B−N bond also exists in **3b**; there are two signals for the methyl groups.

The X-ray structure analysis of a single crystal of **3b** confirms the steric demand of the substituents coordinated at B1 (Figure 3). The angle of 55° between the C23−N5−C27 and N1−B1−N3 planes is a compromise between the mutual repulsion of the TMP and imidazolyl substituents and donation of the electron pair of N5 to the p_z orbital of B1. The planarity around N5 and the bond length of B1−N5 [1.405(2) Å] show that an effective overlap of the p_z orbitals is possible even at a torsion angle of 55°. Electron donation to the central boron atom from the imidazole rings is negligible because the B1−N1,3 distances (1.476 Å) are in a range typical of B−N single bonds. The N1−B1−N3 angle [115.1(1)°] is smaller than the two neighboring angles [N1−B1−N5: 121.9(2)°; N3−B1−N5: 123.0(1)°].

Treatment of **3a** and **3b** with *n*BuLi or *t*BuLi to yield bisimidazol-2-ylidenes always led to decomposition (quaternisation of the central boron atom is observed by ^{11}B NMR spectroscopy). Further reactions of **3a,b** with metal compounds such as $M(OAc)_2$ (M = Zn, Ni, Pd) and $Ti(NMe_2)_4$ to give metal carbene complexes were unsuccessful.

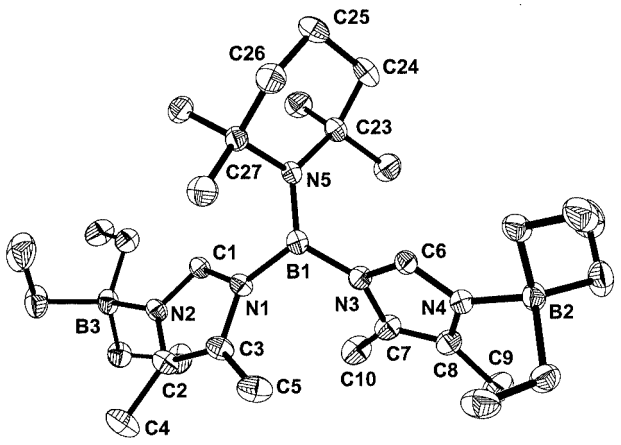

Figure 3. Structure of **3b** in the crystal; the hydrogen atoms have been omitted for clarity; selected bond lengths [Å] and angles [°]: N1−C1 1.352(2), N1−C3 1.401(2), N1−B1 1.475(2), N2−C1 1.307(2), N2−C2 1.406(2), N2−B3 1.645(2), N3−B1 1.477(2), N5−B1 1.405(2), C2−C3 1.364(3), C2−C4 1.486(3); C1−N1−C3 106.2(1), C1−N1−B1 122.1(1), N5−B1−N1 121.9(2), N5−B1−N3 123.0(1), N1−B1−N3 115.1(1), N2−C1−N1 112.4(1)

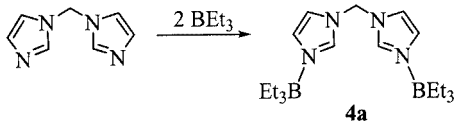
Addition of two equivalents of BEt_3 to 1,1′-bis(imidazolyl)methane yields the crystalline bis(triethylborane) adduct **4a** (80%; Scheme 3).



Scheme 3

The ^{11}B NMR signal of **4a** ($\delta = -1.6$) is in the same region as that of **3a,b**. In the ^1H NMR spectrum the signals of the ethyl groups appear at $\delta = 0.30$ (CH_2) and 0.58 (CH_3), the methylene signal is at $\delta = 6.09$ and the signals of imidazolic protons are at $\delta = 7.06$, 7.23 and 7.91. These shifts show that the imidazolic protons are not as strongly deshielded when forming a triethylborane adduct as when they are alkylated to form imidazolium cations.

The molecular structure of **4a** is shown in Figure 4. In the crystal, **4a** has a C_2 symmetry. The N1−C1−N1A angle [110.6(1)°] is smaller than the comparable angle of **3b** as a result of the tetrahedral bridging function. The coordination geometry at the boron atoms is distorted tetrahedral. While the average C−B1−C angle is 112.5°, the angles C−B1−N2 [av. 106.3(1)°] are smaller. The imidazole rings are nearly symmetric: the C2−N2 and N2−C3 distances barely deviate from those of C2−N1 and N1−C4.

Treatment of 1,1′-bis(imidazolyl)methane or 1,1′-bis(4,5-dimethylimidazolyl) methane with BH_3·thf gives the corresponding 3,3′-bisborane adducts **5a,b** as air- and moisture-sensitive solids in quantitative yields.

In the mass spectra, the molecular peak of **5a** could not be found as it easily loses a BH_3 ligand under EI-MS conditions to give $m/z = 161$ $[M - H - BH_3]^+$. The ^1H NMR spectrum of **5a** shows four signals of equal intensity. The methylene signal ($\delta = 6.32$) and the imidazole protons at

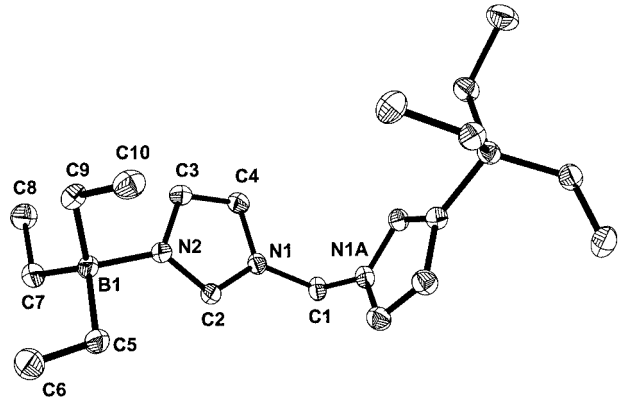


Figure 4. Structure of **4a** in the crystal; the hydrogen atoms have been omitted for clarity; selected bond lengths [Å] and angles [°]: C1−N1 1.454(1), N1−C2 1.349(1), C2−N2 1.322(1), N2−C3 1.384(1), C3−C41.349(2), C4−N11.380(1), N2−B11.649(1); N1−C1−N1A 110.6(1), C1−N1−C2125.6(1), C2−N2−B1127.1(1), N2−B1−C5106.1(1)

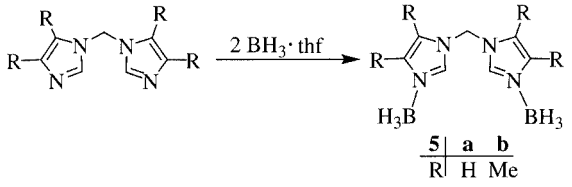

Scheme 4

C4,5 ($\delta = 7.10$, 7.67) have almost the same chemical shifts as in **4a**. In contrast, however, the signal for the proton at C2 is shifted toward lower field ($\delta = 8.64$). A very broad signal at $\delta = 2$ indicates the presence of boron-bonded hydrogen atoms. No proton coupling was observed to the ^{11}B NMR signal at $\delta = -18.4$. Similar spectroscopic results were obtained for **5b**: an ^{11}B NMR signal at $\delta = -20.3$ indicates addition of BH_3, and the ^1H NMR spectrum confirms the formation of **5b**. Its structure was determined by an X-ray diffraction analysis (Figure 5).

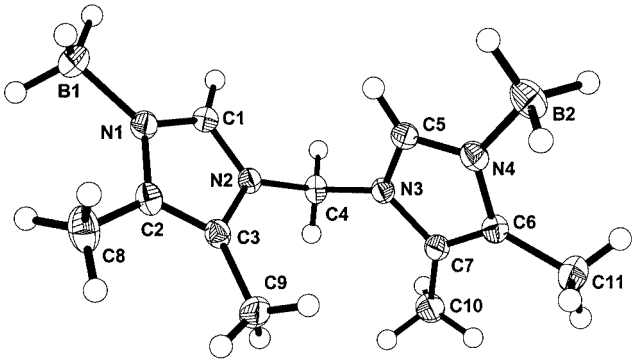

Figure 5. Structure of **5b** in the crystal; selected bond lengths [Å] and angles [°]: B1−N1 1.577(1), N1−C1 1.318(1), C1−N2 1.346(1), N2−C3 1.395(1), C2−C3 1.359(1), N1−C2 1.392(1), N2−C4 1.448(1), C2−C8 1.488(1); B1−N1−C1 125.9(1), N1−C1−N2 109.8(1), N2−C4−N3 110.9(1)

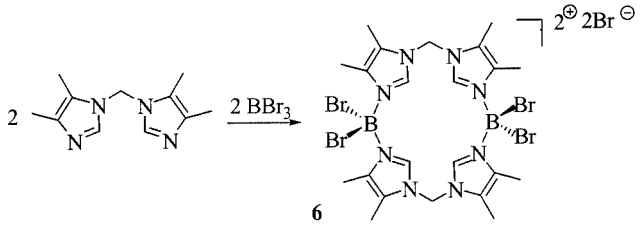
The bond lengths and angles in **5b** are similar to those of **4a**. The N1−C1−N3 angle is 110.9(1)°, and the tetrahedral coordination geometry at the boron atoms is not as strongly distorted as in **4a** [av. angle H−B−H: 111.4(1)°; N−B−H: 107.5(1)°]. The imidazole rings are not symmetric, the N2−C2 and N4−C5 bonds are 0.03(1) Å shorter than N1−C2 and N3−C5.

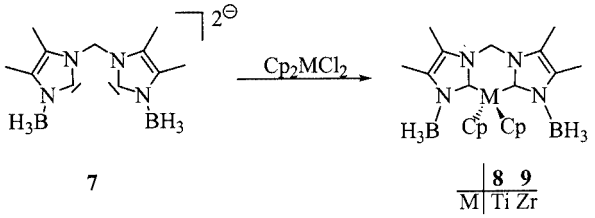
When 1,1′-bis(4,5-dimethylimidazolyl)methane is allowed to react with BBr_3 in a 1:1 ratio, a yellow solid is obtained that is soluble only in Me_2SO (Scheme 5). The ^{11}B NMR spectrum shows one signal at δ = −12.3, and the ^1H NMR spectrum indicates the formation of a highly symmetric product: two signals are observed for the methyl groups at δ = 2.21 and 2.23, a singlet for the methylene protons is at δ = 6.70 and a signal for the proton at the C2 position is detected at δ = 9.38. In comparison with the compounds **4** and **5** this signal is shifted significantly towards low-field, and is found in a region typical of imidazolium cations rather than borane adducts. This observation together with the very high polarity and symmetry of the product indicate the formation of the cyclic diboronium dibromide **6**.



Scheme 5

The signals for the carbon atoms of the imidazole rings are observed at δ = 135.4, 126.4 and 126.1, the methylene bridging carbon atoms at δ = 55.7 and the methyl groups at δ = 9.1 and 8.0. The FAB mass spectrum exhibits peaks derived from the cation of **6** at *m*/*z* = 749 $[M - H]^+$ and *m*/*z* = 579 $[M - BBr_2]^+$.

Attempts to generate dianionic bis(imidazol-2-ylidene) species were unsuccessful starting either from borane adducts of bis(imidazolyl)silane **1** or from the bis(imidazolyl)-boranes **3**. However, the reaction of **5b** with two equivalents of butyllithium at −78 °C causes the ^1H NMR signal of the C2 bonded hydrogen atoms to disappear when the reaction is carried out in $[D_8]$thf and the solution is kept cold. After warming to 20 °C only decomposition products of the dianionic dicarbene **7** were detected, and these could not be characterized. In order to stabilize **7** the titanium complex **8** and the zirconium complex **9** were synthesized by adding a freshly prepared solution of **7** to a solution of the corresponding metallocene dichloride at −78 °C (Scheme 6). Bis(imidazol-2-ylidene)titanium complexes have been prepared previously.[1b]



Scheme 6

Compound **8** is an extremely air- and moisture-sensitive red solid. On exposure to air the color changes to green immediately. Remarkably, in the proton NMR spectrum two signals for the Cp rings are observed at δ = 6.45 and 6.53 and two signals for the methylene bridge at δ = 6.08 and 6.31. In the ^{13}C NMR spectrum two signals for Cp rings are found at δ = 109.9 and 111.8, the signal of the methylene carbon is located at δ = 42.1, and the imidazole carbons (C4,4′ and C5,5′) are observed at δ = 132.9 and 134.1. No signal was found for the metal-bonded carbon atoms. In the EI-MS the molecular peak $[M - H]^+$ is detected at *m*/*z* = 407 as well as a peak for $[M - BH_2]^+$ at *m*/*z* = 395. A different fragmentation pattern was found for the colorless **9**: $[M]^+$ was not observed but rather $[M - Cp - H]^+$ at *m*/*z* = 384. More differences are seen in the NMR spectra: **8** exhibits one ^{11}B NMR signal at δ = −22.3, whereas **9** shows two signals at δ = −17.8 and −20.9, respectively. In the proton NMR spectrum of **9**, only one signal is observed for the methylene bridge (δ = 5.47) and for the Cp rings (δ = 6.27). The zirconium-bonded carbon atoms show a signal at δ = 173.6.

The differences in the NMR spectra of **8** and **9** can be explained on results of their X-ray structure analyses. Compound **8** crystallizes with two independent, and almost identical, molecules in the unit cell (Figure 6). The methylene bridge of **8** is turned out of the coordination plane formed by the imidazole rings and the titanium, and, subsequently, the methylene protons become different, one be-

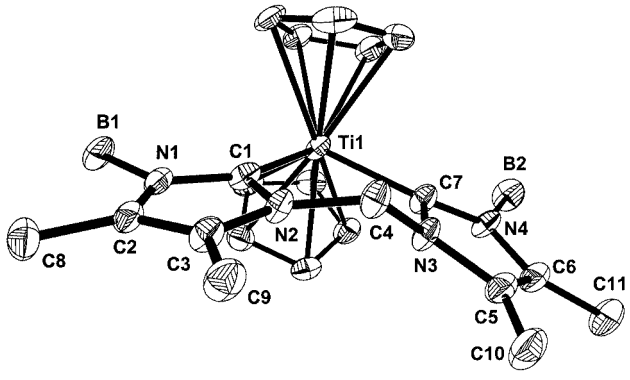


Figure 6. Structure of **8** in the crystal; the CH_2Cl_2 molecule and the carbon-bonded hydrogen atoms have been omitted for clarity; selected bond lengths [Å] and angles [°]: C1−Ti 2.210(5), C7−Ti 2.215(5), N1−B1 1.574(6), N1−C1 1.347(6), C1−N2 1.369(6), N2−C3 1.400(6), C2−C3 1.345(7), N1−C2 1.391(6); N2−C4 1.442(6); C1−Ti−C7 88.3(2), Ti−C1−N2 122.7(3), C1−N2−C4 124.9(4), N2−C4−N3 113.0(4), B1−N1−C1 127.3(4)

coming axial and the other equatorial. The ligand is folded along the C1−Ti axis. A similar behavior of bisimidazolyl ligands has been described by Herrmann et al.[2c] and of a palladium(II) carbene complex of a bistriazole ligand by Diez-Barra et al.[11] Flipping up and down of the methylene bridge does not occur in solution at 20 °C, and this rigid six-membered ring is obviously also the reason for the two different signals of the Cp rings. The C2−Ti−C5 angle is 88.3(2)°, and the N1−C1−N3 angle is a little larger than in **5b** [113.0(4)° vs. 110.9(1)°]. The carbene-carbon to titanium distances are between 2.202(5) and 2.215(5) Å (values for both independent molecules).

The methylene bridge of **9** in the crystal is weakly turned out of the coordination plane and there is no folding observed along the C1−Zr axis (Figure 7). That is the reason why only one signal is found for the methylene protons and for the Cp rings in the ^{1}H NMR spectrum. The C2−Zr−C5 angle is smaller than in **8** (75.4°), and the N1−C1−N3 angle is similar (114.2°), although the carbene-carbon to zirconium distances are quite different: 2.38 (C2−Zr) and 2.30 Å (C5−Zr). This difference is caused by a 3c,2e interaction between B2−H2A−Zr which is non-fluxional in solution at 20 °C according to the two signals in ^{11}B NMR spectrum. Because of this bond compound **9** is an 18-electron complex, while **8** has only 16 valence electrons, which may be the reason for its lower stability.

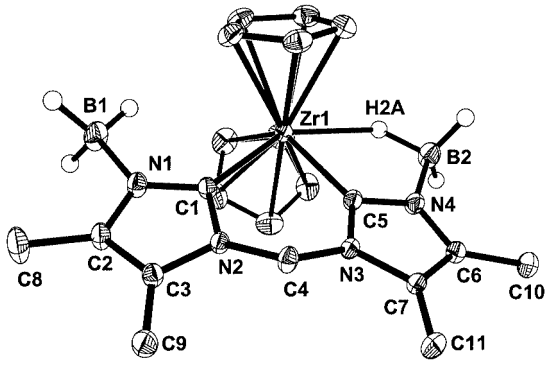

Figure 7. Structure of **9** in the crystal; the carbon-bonded hydrogen atoms have been omitted for clarity; selected bond lengths [Å] and angles [°]: C1−Zr 2.383(1), C5−Zr 2.299(1), N1−B1 1.577(2), N1−C1 1.357(2), C1−N2 1.379(2), N2−C3 1.396(1), C2−C3 1.353(2), N1−C2 1.394(2), N2−C4 1.455(1), B2−H2A 1.23(2), H2A−Zr 2.16(2); C1−Zr−C5 75.4(1), Zr−C1−N2 128.7(1), C1−N2−C4 128.7(1), N2−C4−N3 114.2(1), B1−N1−C1 129.9(1), B2−N4−C5 117.5(1)

Conclusion

It is possible to synthesize monomeric bis(imidazolyl)-boranes when a large, electron-donating substituent such as tetramethylpiperidide is used. Due to the steric requirements of TMP a restricted rotation at the B−N bond is observed for **2b** and **3b**. Treatment of *N*,*N*′-borane-protected bis(4,5-dimethylimidazolyl)methane (**5b**) with butyllithium yields a dianionic dicarbene which coordinates to titanocene and zirconocene complex fragments to form the neutral compounds **8** and **9**. Different coordination numbers at the titanium and the zirconium atom are observed in the X-ray structure analyses of the complexes **8** and **9**.

Experimental Section

General: All reactions were carried out under dry argon, using standard Schlenk techniques. Solvents were dried, distilled and saturated with nitrogen. Glassware was dried with a heat-gun under high vacuum. 1,1′-Bis(imidazolyl)dimethylsilane,[8] 2,2′,6,6′-tetramethylpiperidyldichloroborane,[12] 1,1′-bis(imidazolyl)methane,[13] 1,1′-bis(4,5-dimethylimidazolyl)methane,[13] and 4,5-dimethyl-1-trimethylsilylimidazole[14] were prepared according to literature procedures.

1,1′-Bis(3-borane-imidazolyl)dimethylsilane (1): A 1 M solution of BH_3·thf (20.5 mL) in THF was added dropwise at −78 °C to a solution of 1,1′-bis(imidazolyl)dimethylsilane (1.93 g, 10.0 mmol) in 60 mL of THF. After warming to 20 °C the solvent was removed and the residue washed with pentane, CH_2Cl_2 and recrystallized from a hot saturated solution in THF at −20 °C. The yield was increased by further concentration of the solution to give colorless cubes (1.77 g, 80%). ^{1}H NMR (200 MHz, [D$_8$]THF): δ = 1.11 (s, 6 H, CH_3), 2.2 (br., 6 H, BH_3), 7.15 (s, 2 H, CH=C*H*−N), 7.27 (s, 2 H, C*H*=CH−N), 8.19 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, [D$_8$]THF): δ = −21.5 (q, $^1J_{B\text{-}H}$ = 91 Hz). ^{13}C NMR (50.3 MHz, [D$_8$]THF): δ = −5.9 (CH_3), 119.9 (*C*H=CH−N), 127.9 (CH=*C*H−N), 139.2 (N=CH−N).

1,1′-Bis(imidazolyl)-1-(2,2′,6,6′-tetramethylpiperidyl)borane (2a): 1-Trimethylsilylimidazole (5.25 g, 37.5 mmol) was added to a solution of 2,2′,6,6′-tetramethylpiperidyldichloroborane (4.10 g, 18.7 mmol) in 100 mL of CH_2Cl_2 at −30 °C. After stirring for 2 h the mixture was allowed to warm to 20 °C and the solvent was removed under vacuum. The product was washed with hexane and dried to give a colorless **2a**. Yield: 4.00 g (75%), m.p. 122 °C. ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 1.15 (s, 12 H, CH_3), 1.60 (m, 4 H, CH_2), 1.85 (m, 2 H, CH_2), 7.04 (s, 2 H, CH=C*H*−N), 7.13 (s, 2 H, C*H*=CH−N), 7.79 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, CD_2Cl_2): δ = 28.2. ^{13}C NMR (50.3 MHz, CD_2Cl_2): δ = 17.6 ($CH_2CH_2CH_2$), 32.2 (CH_3), 39.6 ($CH_2CH_2CH_2$), 56.5 [$C(CH_3)_2$], 121.9 (*C*H=CH−N), 131.4 (CH=*C*H−N), 142.8 (N=CH−N). EI-MS: *m*/*z* (%) = 285 (2) [M]$^+$, 270 (1) [M − CH_3]$^+$. HR EI-MS ($C_{15}H_{24}{}^{11}BN_5$): calcd. 285.2125; found 285.2111; Δ*m* = 1.4 mmu.

1,1′-Bis(4,5-dimethylimidazolyl)-1-(2,2′,6,6′-tetramethylpiperidyl)-borane (2b): The synthesis of this compound was carried out analogously to **2a** with 4,5-dimethyl-1-trimethylsilylimidazole. Yield: 74%. ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 1.19 (s, 6 H, CH_3-TMP), 1.25 (s, 6 H, CH_3-TMP), 1.47 [s, 6 H, CH_3 (Im)], 1.55 (m, 2 H, CH_2), 1.83 (m, 4 H, CH_2), 2.08 [s, 6 H, CH_3 (Im)], 7.55 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, CD_2Cl_2): δ = 28.5. ^{13}C NMR (50.3 MHz, CD_2Cl_2): δ = 9.0 [CH_3(Im)], 12.9 [CH_3(Im)], 17.0 ($CH_2CH_2CH_2$), 32.8 (CH_3-TMP), 35.3 (CH_3-TMP), 38.6 ($CH_2CH_2CH_2$), 56.3 [$C(CH_3)_2$], 125.2 (*C*Me=CMe−N), 138.2 (CMe=*C*Me−N), 140.3 (N=CH−N). EI-MS: *m*/*z* (%) = 341 (17) [M]$^+$, 326 (88) [M − CH_3]$^+$. HR EI-MS ($C_{19}H_{32}{}^{11}BN_5$): calcd. 341.2751; found 341.2738; Δ*m* = 1.4 mmu. $C_{19}H_{32}BN_5$ (341.3): calcd. C 66.86, H 9.45, N 20.52; found C 65.52, H 9.37, N 20.09.

1-(2,2′,6,6′-Tetramethylpiperidyl)-1,1′-bis(3-triethylborane-imidazolyl)borane (3a): Triethylborane (2.54 g, 25.9 mmol) was added dropwise to a solution of **2a** (3.71 g, 13.0 mmol) in 60 mL of CH_2Cl_2 at −60 °C. After warming to 20 °C the solution was stirred overnight. The solvent was removed under vacuum and the product

washed with hexane. Recrystallization from CH_2Cl_2 at −20 °C yielded 3.06 g (49%) of a pale-yellow solid, m.p. 114 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 0.34 (q, $^3J_{H-H}$ = 7 Hz, 12 H, CH_2CH$_3$), 0.61 (t, $^3J_{H-H}$ = 7 Hz, 18 H, CH$_2$CH_3), 1.19 (s, 12 H, CH$_3$), 1.65 (m, 4 H, CH$_2$), 1.88 (m, 2 H, CH$_2$), 6.91 (s, 2 H, CH=C*H*−N), 7.28 (s, 2 H, C*H*=CH−N), 7.89 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 28.2 (br.,BN$_3$), −0.8 (br., N-BEt$_3$). ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 9.6 (CH$_2$*C*H$_3$), 14.8 (br., *C*H$_2$CH$_3$), 16.9 (CH$_2$*C*H$_2$CH$_2$), 32.7 (CH$_3$), 39.2 (*C*H$_2$CH$_2$*C*H$_2$), 56.4 [*C*(CH$_3$)$_2$], 121.6 (*C*H=CH−N), 127.5 (CH=*C*H−N), 139.9 (N=CH−N).

1-(2,2′,6,6′-Tetramethylpiperidyl)-1,1′-bis(3-triethylborane-4,5-dimethylimidazolyl)borane (3b): Compound **3b** was prepared from **2b** analogously to **3a**. Yield: 57% colorless cubes. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 0.41 (q, $^3J_{H-H}$ = 7 Hz, 12 H, CH_2CH$_3$), 0.56 (t, $^3J_{H-H}$ = 7 Hz, 18 H, CH$_2$CH_3), 1.15 (s, 6 H, CH$_3$), 1.35 (s, 6 H, CH$_3$), 1.48 (s, 6 H, CH$_3$), 1.56 (m, 2 H, CH$_2$), 1.89 (m, 4 H, CH$_2$), 2.22 (s, 6 H, CH$_3$), 7.73 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 29.7 (br., BN$_3$), − 0.9 (br., N-BEt$_3$). ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 8.5 [CH$_3$(Im)], 9.7 (CH$_2$*C*H$_3$), 10.9 [CH$_3$(Im)], 13.48 (br., *C*H$_2$CH$_3$), 15.4 (CH$_2$*C*H$_2$CH$_2$), 32.2 (CH$_3$-TMP), 35.1 (CH$_3$-TMP), 37.1 (*C*H$_2$CH$_2$*C*H$_2$), 60.0 [*C*(CH$_3$)$_2$], 126.1 (*C*Me=CMe−N), 135.0 (CMe=*C*Me−N), 138.6 (N=CH−N). EI-MS: *m*/*z* (%) = 341 (66) [M − 2BEt$_3$]$^+$, 326 (100) [M − 2BEt$_3$ − CH$_3$]$^+$.

1,1′-Bis(3-triethylboraneimidazolyl)methane (4a): Compound **4a** was prepared from 1,1′-bis(imidazolyl)methane in THF analogously to **3a**. Yield: 80% colorless crystals, m.p. 96 °C. ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 0.30 (q, $^3J_{H-H}$ = 7 Hz, 12 H, CH_2CH$_3$), 0.58 (t, $^3J_{H-H}$ = 7 Hz, 18 H, CH$_2$CH_3), 6.09 (s, 2 H, CH$_2$), 7.06 (s, 2 H, CH=C*H*−N), 7.23 (s, 2 H, C*H*=CH−N), 7.91 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, CD_2Cl_2): δ = −1.6 (br.). ^{13}C NMR (50.3 MHz, CD_2Cl_2): δ = 9.4 (CH$_2$*C*H$_3$), 14.4 (br., *C*H$_2$CH$_3$), 58.2 (CH$_2$), 118.6 (*C*H=CH−N), 126.9 (CH=*C*H−N), 134.6 (N=CH−N).

1,1′-Bis(3-boraneimidazolyl)methane (5a): A solution of 1,1′-bis-(imidazolyl)methane (1.42 g, 9.58 mmol) in 50 mL of THF was cooled to −78 °C. At this temperature 19.2 mL of BH$_3$·thf (as a 1 M solution in THF) was added through a dropping funnel. The reaction mixture was allowed to warm and stirred for 4 h at 20 °C. During this period a precipitate was formed, which was filtered and washed with pentane. Yield: 1.65 g (98%) white solid. ^{1}H NMR (200 MHz, [D$_6$]DMSO): δ = 2.10 (br., 6 H, BH$_3$), 6.32 (s, 2 H, CH$_2$), 7.10 (s, 2 H, CH=C*H*−N), 7.67 (s, 2 H, C*H*=CH−N), 8.64 (s, 2 H, N=CH−N). ^{11}B NMR (64.2 MHz, [D$_6$]DMSO): δ = −18.4 (br.). ^{13}C NMR (50.3 MHz, [D$_6$]DMSO): δ = 56.8 (CH$_2$), 120.9 (*C*H=CH−N), 127.5 (CH=*C*H−N), 137.9 (N=CH−N). EI-MS: *m*/*z* (%) = 161 (1) [M − BH$_3$ − H]$^+$, 148 (16) [M − 2BH$_3$ + 2H]$^+$.

1,1′-Bis(3-borane-4,5-dimethylimidazolyl)methane (5b): Compound **5b** was prepared from 1,1′-bis(4,5-dimethylimidazolyl)methane analogously to **5a**. Yield: 97%, white solid, m.p. 193 °C. ^{1}H NMR (200 MHz, [D$_6$]DMSO): δ = 2.03 (s, 6 H, CH$_3$), 2.10 (s, 6 H, CH$_3$), 6.25 (s, 2 H, CH$_2$), 8.49 (s, 2 H, N=CH−N). ^{13}C NMR (50.3 MHz, [D$_6$]DMSO): δ = 8.9 (CH$_3$), 9.9 (CH$_3$), 54.6 (CH$_2$), 125.1 (*C*Me=CMe−N), 131.4 (CMe=*CMe*−N), 137.2 (N=CH−N). ^{11}B NMR (64.2 MHz, [D$_6$]DMSO): δ = −20.3 (br.).

Cyclic Diboronium Dibromide 6: 1,1′-Bis(4,5-dimethylimidazolyl)-methane (186 mg, 0.91 mmol) and tribromoborane (228 mg, 0.91 mmol) were each dissolved in 20 mL of CH_2Cl_2. Both solutions were added simultaneously within 45 min to 100 mL of CH_2Cl_2 through dropping funnels. After addition the suspension was stirred for 1 h, the precipitate was filtered off, washed with pentane and dried to yield 133 mg (32%) of **6** as a colorless solid. ^{1}H NMR (200 MHz, [D$_6$]DMSO): δ = 2.21 (s, 12 H, CH$_3$), 2.23 (s, 12 H, CH$_3$), 6.70 (s, 4 H, CH$_2$), 9.38 (s, 4 H, N=CH−N). ^{11}B NMR (64.2 MHz, [D$_6$]DMSO): δ = −12.3. ^{13}C NMR (50.3 MHz, [D$_6$]DMSO): δ = 8.0 (CH$_3$), 9.1 (CH$_3$), 55.7 (CH$_2$), 126.1 (*C*Me=CMe−N), 126.4 (CMe=*C*Me−N), 135.4 (N=CH−N). FAB-MS: *m*/*z* (%) = 749 (1) [M − H]$^+$, 579 (11) [M − BBr$_2$]$^+$.

1,1′-Methylene-(3-borane-4,5-dimethylimidazolyl)-2-diylidene (7): In a Teflon sealed NMR tube, 0.08 mL (0.20 mmol) of *n*BuLi (as a 2.5 M solution in hexane) were evaporated to dryness. At −78 °C 20 mg of **5b** (0.09 mmol) was added, followed by 1 mL of cold [D$_8$]THF. The yellow reaction mixture was shaken and the NMR spectrum measured directly (without warming to 20 °C). ^{1}H NMR (200 MHz, [D$_8$]THF): δ = −1.14 (br.), −0.15 (br.), 0.89 (br.), 1.26 (br.) (signals from BuH and BuLi), 1.79 (s, 6 H, CH$_3$), 1.92 (s, 6 H, CH$_3$), 6.00 (s, 2 H, CH$_2$).

[1,1′-Methylene-(3-borane-4,5-dimethylimidazolyl)-2-diylidene]-dicyclopentadienyltitanium (8): Compound **5b** (220 mg, 0.95 mmol) in 30 mL of THF was treated with 0.8 mL (2.00 mmol) of *n*BuLi (2.5 M solution in hexane) at −78 °C to yield a solution of **7**. After 30 min this solution was added to a stirred mixture of Cp_2TiCl_2 (250 mg, 1.00 mmol) in 10 mL of THF at −78 °C with a transfer cannula. Within 4 h the reaction mixture was allowed to warm to 20 °C. Evaporation of the solvent, washing of the residue with hexane and drying yielded 291 mg (75%) of dark-red **8**. ^{1}H NMR (200 MHz, [D$_6$]DMSO): δ = 2.02 (s, 6 H, CH$_3$), 2.10 (s, 6 H, CH$_3$), 6.08 and 6.31 (br., 2 H, CH$_2$), 6.45 (s, 5 H, C$_5$H$_5$), 6.53 (s, 5 H, C$_5$H$_5$). ^{11}B NMR (64.2 MHz, [D$_6$]DMSO): δ = −22.3 (br.). ^{13}C NMR (50.3 MHz, [D$_6$]DMSO): δ = 8.9 (CH$_3$), 9.9 (CH$_3$), 42.1 (CH$_2$), 109.9 (C$_5$H$_5$), 111.8 (C$_5$H$_5$), 132.9 (*C*Me=CMe−N), 134.1 (CMe=*C*Me−N). EI-MS: *m*/*z* (%) = 407 (2) [M − H]$^+$, 395 (58) [M − BH$_2$]$^+$. HR EI-MS ($C_{21}H_{29}{}^{11}B_2N_4Ti$) [M − H]$^+$: calcd. 407.2058; found 407.2079; Δ*m* = 2.1 mmu.

[1,1′-Methylene-(3-borane-4,5-dimethylimidazol)-2-diylidene]-dicyclopentadienylzirconium (9): Compound **9** was prepared analogously to **8** with Cp_2ZrCl_2. Yield: 80%, white solid. ^{1}H NMR (200 MHz, CD_2Cl_2): δ = 2.08 (s, 6 H, CH$_3$), 2.20 (s, 6 H, CH$_3$), 5.47 (s, 2 H, CH$_2$), 6.27 (s, 10 H, C$_5$H$_5$). ^{11}B NMR (64.2 MHz, [D$_6$]DMSO): δ = −17.8, −20.9. ^{13}C NMR (50.3 MHz, CD_2Cl_2): δ = 9.2 (CH$_3$), 9.3 (CH$_3$), 57.4 (CH$_2$), 110.8 (C$_5$H$_5$), 124.7 (*C*Me=CMe−N), 131.9 (CMe=*C*Me−N), 173.6 (N−C−N). EI-MS: *m*/*z* (%) = 384 (100) [M − Cp − H]$^+$.

Crystal Structure Determinations of 1, 3b, 4a, 5b, 8 and 9: Crystal data and details of the structure determinations are listed in Table 1 and 2. Intensity data were collected at 173 K (**3b**, **4a**), at 190 K (**1**, **8** and **9**) or at 293 K (**5b**) with a Bruker AXS area detector (Mo-K_α radiation λ = 0.71073 Å, graphite monochromator, ω-scan). The structures were solved by direct methods (SHELXS-86)[15] and refined by least-squares methods based on F^2 with all measured reflections (SHELXL-97).[16] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located in difference Fourier maps and refined.

Salicylaldimine Dizinc Complexes: Activation of Water Molecules and Fixation of CO_2 in the Coordination Sphere of Zinc

Manfred Döring,*[a] Michael Ciesielski,[a] Olaf Walter,[a] and Helmar Görls[b]

Dedicated to Prof. Ernst Anders on the occasion of his 60th birthday

Keywords: Zinc / N ligands / N,O ligands / Carbon dioxide fixation / Enzyme models

Bi- and tetranuclear zinc complexes of the tridentate N,N,O ligand [{[2-(2-pyridyl)ethyl]imino}methyl]phenol (HL) and their enzyme-like reactions are described. The coordinated water molecules in a dizinc complex of this ligand can be deprotonated reversibly similar to those in the resting states of zinc enzymes. The resulting tetranuclear complex bearing bridging hydroxide ions allows the reversible uptake of CO_2. Whereas the coordination of hydrogen carbonate has not been observed, a tetranuclear carbonate complex with a unique structure was isolated. Its carbonate ion is coordinated to all four zinc atoms. The X-ray structures of the reported complexes are discussed.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Zinc-containing enzymes accelerate the reversible hydration of carbon dioxide, the cleavage of peptide bonds, the hydrolysis of phosphate monoesters, and many other hydrolytic processes in biological systems with a high efficiency. The catalytic function of the zinc enzymes is not only essential for organisms but also of great theoretical interest. The activation of carbon dioxide and cleavage of amide and ester bonds in the coordination sphere of a metal also represent important reactions in synthetic chemistry. It is not surprising, therefore, that many efforts have been made to synthesize zinc-containing complexes that mimic the structural and functional features of the active centres in zinc enzymes.

Recent investigations revealed a distorted tetrahedral ligand geometry around the zinc ions in many zinc enzymes. Three coordination sites at their metal centres are coordinated by various amino acid residues (imidazolyl, -COOH, -SH), depending on the specific functions of the enzymes.[1] In the resting states of the enzymes, the fourth coordination site is occupied by a water molecule, which can be easily deprotonated, thus providing the catalytically active hydroxide form of the enzyme.

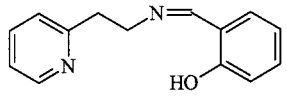
To synthesize zinc complexes by mimicking the active centres of mononuclear zinc enzymes, encapsulating tripodal hydrotris(pyrazolyl)borates (Tp ligands) and cyclen ligands are most frequently used. Vahrenkamp et al.[2–4] have developed the "Freiburg enzyme model" — zinc complexes with the aforementioned Tp ligands bearing sterically demanding substituents. Such complexes possess structural parameters similar to those of the active centre of the hydroxide and the water form of the zinc enzyme carbonic anhydrase (CA). The tetrahedral geometries around the zinc ions in these compounds are enforced by the pocket-like rigid Tp ligands. Parkin et al.[5] converted such a tetrahedral TpZnOH complex into the corresponding aqueous form by protonation and were even able to reverse this process. Tetrahedral zinc complexes with tripodal cyclen ligands like 1,5,9-triazacyclododecane have been reported to be some of the best functional models for CA.[6–10] Apart from the above examples, other more flexible unsymmetrical ligands with mixed N_xO_y donor environments have been established.[11–14] These ligands have been made to reproduce structural and functional properties of biologically relevant enzymes with more than one zinc ion in their active sites.

Zinc complexes with enzyme-analogous hydrolytic activities could be valuable in synthetic chemistry, too. However, the application of zinc complexes as catalysts for hydrolytic processes requires a deeper insight into their structure-reactivity relationship, and, especially, additional information about the reactivity of water molecules in the coordination sphere of zinc. In the present article, we describe bi- and tetranuclear zinc complexes of the Schiff base 2-[{[2-(2-pyridyl)ethyl]imino}methyl]phenol HL.



HL

Although the tridentate ligand chosen is not sufficiently rigid to enforce a tetrahedral geometry around the zinc centre, a zinc complex with coordinated and reactive water molecules is readily accessible. The Zn-OH_2 unit in this binuclear complex can be deprotonated by the addition of sodium hydroxide. Even the uptake of carbon dioxide is performed as a reversible pH-dependent process. However, attempts to isolate a complex with coordinated hydrogen carbonate were not successful. Only a carbonate-containing complex with an unusual structural motif was obtained. The above reactions were found to be very sensitive, and other products could be obtained under slightly different conditions. The complexes were characterized by X-ray structural determinations.

Results and Discussion

The binuclear complex **1** is formed by the reaction of equivalent amounts of HL, zinc perchlorate and sodium hydroxide in aqueous methanol. Compound **1** bears the deprotonated ligand L and a water molecule at both zinc ions. With less water in the solvent, the complexation yields the binuclear complex **2** with zinc-coordinated methanol molecules instead of the complexed water.

$[\mathbf{L}\ Zn(H_2O)]_2\,(ClO_4)_2$ **1**

$[\mathbf{L}\ Zn(CH_3OH]_2\,(ClO_4)_2$ **2**

Both complexes were subjected to X-ray structural determinations. The X-ray structural analysis of **1** and **2** revealed distorted square-pyramidal environments around the metal centres, which are linked by phenolate bridges (see Figure 1 and 2).

The coordinated water molecules in **1** are arranged in a *cis* configuration, whereas the methanol molecules in **2** are in a *trans* configuration. Both configurations are possible in dizinc complexes of L because of the flexibility of the ligand and the flexibility of the phenolate links. The water molecules in the coordination sphere of **1** are acidified in a similar manner to those in the Zn-OH_2 units of zinc enzymes. Therefore, this complex is accessible to a number of conversions.

In a methanolic solution of **1** with half an equivalent of sodium hydroxide at moderate temperatures (20−50 °C) under anaerobic conditions, one water molecule in **1** is deprotonated and the tetranuclear complex **3** is formed by dimerization.

$[(\mathbf{L}\ Zn)_2OH]_2\,(ClO_4)_2$ **3**

Figure 1. Figure 2. Molecular structure of **2** (cation only) with selected bond lengths [Å] and angles [°]: Zn1−O1 2.0154(10), Zn1−O2 2.0564(12), Zn1−O1A 2.0618(10), Zn1−N1 2.0697(12), Zn1−N2 2.0641(13), Zn1−Zn1A 3.1511(4); O1−Zn1−O2 114.96(5), O1−Zn1−O1A 78.78(4), O2−Zn1−O1A 95.63(5), O1−Zn1−N2 122.08(5), O2−Zn1−N2 122.92(5), O1A−Zn1−N2 96.88(5), O1−Zn1−N1 89.93(5), O2−Zn1−N1 89.62(5), O1A−Zn1−N1 168.70(5), N2−Zn1−N1 88.59(5)

Compound **3** has a dimeric structure with two identical binuclear halves linked via two Zn−OH−Zn bridges between the zinc ions. In **3**, all zinc ions are in distorted square-pyramidal coordination spheres and the metal centres in the halves are linked by phenolates as in complex **1**. The bond lengths and angles in the dizinc units of **3** are very similar to those in **1**. Therefore, **3** can be considered an OH-bridged dimer of **1**. Zinc complexes containing Zn−OH−Zn bridging moieties have been reported previously.[14−18]. The nonbonding distances between the zinc ions in the Zn−O−Zn moieties of **3** are 3.5 Å. Very similar Zn−Zn separations (3.55 Å, 3.61 Å) have been reported for other zinc complexes with only one hydroxide bridge between the zinc centres.[15,18] Compound **3** can be reprotonated to the water complex **1**. In the presence of a larger amount of sodium hydroxide the conversion of **1** becomes irreversible. Under these conditions, a ligand distribution reaction occurs. Zinc hydroxide is precipitated from the mixture and complex **4** is formed.

$$[L_2\,Zn]_2\,[Na\,(MeOH)\,ClO_4]$$

4

Its molecular structure is shown in Figure 3. Compound **4** can be considered as a dimer with two mononuclear complexes. The mononuclear halves of **4** are only linked by a fivefold coordinated sodium ion. In contrast to the other complexes reported here, two molecules of the deprotonated ligand are bound to each metal in **4**. The zinc ions in **4** are also fivefold coordinated and appear in a strongly distorted square-pyramidal geometry.

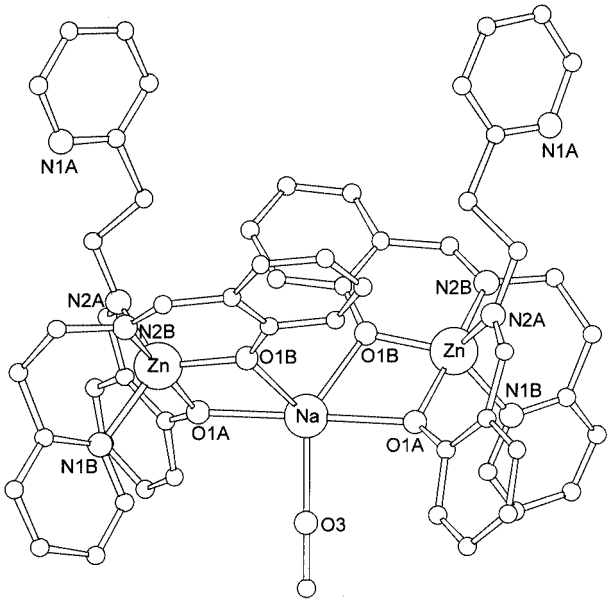

Figure 3. Molecular structure of **4** (cation only) with selected bond lengths [Å] and angles [°]: Zn−O1A 2.035(4), Zn−O1B 1.986(3), Zn−N1B 2.125(5), Zn−N2A 2.094(5), Zn−N2B 2.144(5), Na−O3 2.297(11), Na−O1A 2.385(3), Na−O1B 2.392(4); O1A−Zn−O1B 84.4(1), O1A−Zn−N1B 91.7(2), O1A−Zn−N2A 89.1(2), O1A−Zn−N2B 170.6(2), O1B−Zn−N1B 121.6(2), O1B−Zn−N2B 89.7(2), O1B−Zn−N2A 122.7(2), N2A−Zn−N1B 115.5(2), N1B−Zn−N2B 85.2(2)

The reactivity of **1** towards air and carbon dioxide has also been investigated. Carbon dioxide is taken up by deprotonated **1** in the presence of air. The gas is released again after the mixture has been acidified carefully. Similar to the hydration of CO_2 in the catalytic cycle of CA, this reaction is found to be reversible at moderate temperatures and is pH-dependent. The CA mechanism involves the formation of an intermediate with a Zn-CO_2H unit. It turned out to be impossible to isolate a complex with coordinated hydrogen carbonate. In the reaction of **1** with CO_2 from air and half an equivalent of NaOH, only the complex **3a** is obtained at moderate temperatures.

$$[(L\,Zn)]_2\,(OH)]_2\,(ClO_4)_{2-x}\,(CO_3H)_x \qquad (0 < x < 1)$$

3a

Its X-ray structure is presented in Figure 4. Compound **3a** contains the same coordination sphere as described for **3**. Only one perchlorate anion is partially replaced by hydrogen carbonate. The content of HCO_3^- in **3a** depends on the partial pressure of CO_2 in the atmosphere. The hydrogen carbonate is not formed by a simple absorption of carbon dioxide in an alkaline solution, because the reaction mixture does not contain any excess of hydroxide ions. The uptake of carbon dioxide can be explained by an intermediate interaction of CO_2 with the zinc centres in **3**.

At higher temperatures and in the presence of pure carbon dioxide, the CO_2 is incorporated into the coordination sphere of zinc, and the reaction provides the carbonate complex **5**.

$$[(L\,Zn)_4\,CO_3\,(MeOH)_4]\,(ClO_4)_2$$

5

Most revealing is the molecular structure of **5** (Figure 5), which was obtained by X-ray structural analysis. Complex **5** has a binuclear substructure, two mononuclear units, and a carbonate anion, which is encapsulated inside the molecule. Carbonate-containing zinc complexes of polydentate ligands are well known[9,13,19−21] and, usually, three identical metal centres are attached to the carbonate oxygen atoms. In **5** the carbonate is coordinated to four zinc ions. Furthermore, the carbonate acts as a bridging ligand linking both mononuclear units of the molecule with an oxygen atom. Two differently bound zinc ions are six-coordinated with slightly distorted octahedral geometries. One zinc ion is surrounded by the tridentate ligand L, two methanol molecules, and a carbonate oxygen. The other zinc ion is incorporated into the binuclear substructure of **5** and bears two molecules of the ligand, a methanol molecule, and a carbonate oxygen. One L acts as a bridging ligand, and only its phenolate oxygen is bound to this zinc. The remaining two zinc ions in **5** are fivefold coordinated with a different bonding. One of these zinc ions belongs to the binuclear substructure of **5**. It bears two molecules of L as well as a carbonate oxygen. It is the only zinc ion in **5** without any coordinated methanol. The geometry around this zinc can be described as highly distorted square pyramidal. Whereas

Figure 4. one L molecule is bound to this zinc ion by its three donor atoms, the second one only occupies one coordination site with its phenolate oxygen. The phenolate oxygen acts as bridging atom and links the two metal centres in this substructure. The other fivefold coordinated zinc ion in **5** is the centre of a mononuclear unit and has a slightly distorted square-pyramidal geometry. The coordination sphere contains three donor atoms of L as well as a methanol oxygen and a carbonate oxygen.

Generally, the insertion of CO_2 into Zn−OH−Zn bridges does not occur. However, Karlin et al.[20] reported an exceptional case of a dinuclear zinc hydroxide complex that absorbed atmospheric carbon dioxide. Our experimental results indicate that complexes **3** and **3a** are not sufficiently reactive to bind the carbon dioxide in the coordination sphere of zinc, although it could be possible that the bonds in the Zn−OH−Zn bridges of **3** or **3a** are weakened at higher temperatures, leading to the insertion of water molecules. Complexes with the resulting Zn−OH···H_2O−Zn unit are reported to be more reactive towards CO_2 [18] and able to coordinate it as hydrogen carbonate. The last step of this reaction cascade would consist of the conversion of the hydrogen carbonate containing complex into **5**. Unfortunately we were not able to isolate any of the intermediates proposed.

Solutions of the zinc complexes of L show a remarkably intense blue fluorescence if irradiated with UV light.

Conclusion

The Schiff base L shows a great variety in its complex chemistry with zinc. The key to the successful exploitation of its synthetic potential is the smooth access to the binuclear water-containing complex **1**, which was found to be a suitable starting material for subsequent conversions. Our intention of performing enzyme-like biomimetic reactions with **1** was fulfilled in some respects. Like the resting states in zinc enzymes, **1** could be activated by deprotonation of its coordinated water molecules. The resulting hydroxide-containing complex was subjected to further conversions. Unfortunately, a complex with a highly reactive Zn-OH unit such as is found in the active form of the natural zinc enzymes has not been obtained. The OH ions in the isolated complexes of **3** and **3a** are involved in Zn−OH−Zn bridges and are significantly less reactive. Therefore, the hydroxide function in **3** was found to be unreactive towards carbon dioxide at moderate temperatures. The reaction of **3** was effected at higher temperatures but resulted in the carbonate-containing complex **5**. Thus, a complex with the Zn-OCO_2H motif has not been obtained. Nevertheless, the unique structural features of the carbonate complex **5** reveal the extraordinary synthetic capacity of L in zinc complex chemistry. One property of L is its capability to form multinuclear shell-like systems that encapsulate small molecules like carbonate.

Figure 5. A systematic variation of the ligand structure should enable the synthesis of hydroxide-containing zinc complexes with a higher hydrolytic reactivity than **3**.

If the Zn−OH−Zn bridges in **3** are sufficiently weakened, they might become more reactive towards CO_2 and other substrates even at ambient temperatures. With the flexibility of the ligand being maintained, a better reaction pathway of the substrate would be achieved, as for the carbonate ion in **5**. Furthermore, an additional activation of the coordinated substrate by an adjacent zinc centre in bi- or multinuclear complexes would also be advantageous. The challenge of designing zinc complexes with an enzyme-like hydrolytic activity towards carbon dioxide and amide bonds persists.

Experimental Section

Starting materials were obtained commercially and used without purification.

1: 2-(2-Aminoethyl)pyridine (1.83 g, 15 mmol) in 10 mL of methanol and salicylaldehyde (1.83 g, 15 mmol) in 15 mL of methanol were combined at ambient temperature to give a deep yellow solution. Then, zinc perchlorate hexahydrate (5.59 g, 15 mmol) in 25 mL of aqueous 90% methanol was added. The solution was warmed to 35 °C, and sodium hydroxide (0.6 g, 15 mmol) in 20 mL of methanol was added while stirring. After stirring at 35 °C, the mixture was filtered. A strong fluorescent pale-yellow solution and yellow crystals of the product were obtained. Yield 78%. $C_{28}H_{30}Cl_2N_4O_{12}Zn_2$ (816.24): calcd. C 41.20, H 3.70, Cl 8.69, N 6.86; found C 40.80, H 3.45, Cl 8.55, 7.05 N.

2: 2-(2-Aminoethyl)pyridine (1.83 g, 15 mmol) and salicylaldehyde (1.83 g, 15 mmol) were combined in 50 mL of dry methanol, and zinc perchlorate hexahydrate (5.59 g, 15 mmol) in 20 mL of dry methanol was added. After warming to 35 °C, a solution of sodium hydroxide (0.6 g, 15 mmol) in 20 mL of methanol was added while stirring. The mixture was then filtered. Yellow crystals of the product were formed from the pale-yellow fluorescent solution. Yield 75%. $C_{32}H_{42}Cl_2N_4O_{12}Zn_2$ (908.34): calcd. C 42.31, H 4.66, Cl 7.81, N 6.17; found C 41.88, H 4.87, Cl 7.69, N 5.99.

3: A solution of **1** in 100 mL of methanol freshly prepared from 2-(2-aminoethyl) pyridine (1.83 g, 15 mmol), salicylaldehyde (1.83 g, 15 mmol), zinc perchlorate hexahydrate (5.59 g, 15 mmol), and sodium hydroxide (0.6 g, 15 mmol) was heated to reflux, and sodium hydroxide (0.3 g, 7.5 mmol) was added. Whilst heating at reflux for 30 min under argon the NaOH dissolved and a product precipitated. The mixture was filtered hot, and the volume of the pale-yellow filtrate was reduced. The solution was then cooled slowly in a closed vessel. Compound **3** precipitated as large colourless crystals. Yield about 70%. $C_{56}H_{54}B_2F_8N_8O_6Zn_2$ [22] (1239.46): calcd. C 54.27, H 4.39, N 9.04; found C 54.19, H 4.35, N 9.11.

3a: A solution of **3** in 100 mL of methanol was freshly prepared from salicylaldehyde (1.83 g, 15 mmol), 2-(2-aminoethyl)pyridine (1.83 g, 15 mmol), zinc perchlorate hexahydrate (5.59 g, 15 mmol), and sodium hydroxide (0.9 g, 15 mmol). The mixture was then stirred at 60 °C for 45 min in the presence of air. The mixture was filtered hot and slowly cooled to 5 °C. Compound **3a** was obtained as large colourless crystals. Yield about 70%.[23]

Reaction of 3 with Perchloric Acid: Compound **3** (2.05 g, 1.5 mmol) was dissolved in 100 mL of methanol. 5% aqueous perchloric acid (6.03 mL, 3 mmol) was then added within a period of 10 min at room temperature. The mixture was stirred for 30 min. Crystals of **1** were obtained upon reducing the volume of the solution slowly.

Reaction of 3a with Perchloric Acid: In an analogous manner, **3a** was treated with 5% aqueous perchloric acid. Crystals of **1** were obtained upon reducing the volume of the solution slowly.

4: A solution of **1** in 100 mL of aqueous methanol freshly prepared from salicylaldehyde (1.83 g, 15 mmol), 2-(2-aminoethyl)pyridine (1.83 g, 15 mmol), zinc perchlorate hexahydrate (5.59 g, 15 mmol), and sodium hydroxide (0.6 g, 15 mmol) was heated to reflux. Then, sodium hydroxide (0.6 g, 15 mmol) was added, and the mixture was

[a] Compound **3a** crystallizes from a mixture of 0.5 equivalents of methanol and 0.5 equivalents of water; the anions were found: 1.5 equivalents of perchlorate and 0.5 equivalents of hydrogencarbonate. [b] Compound **5** crystallizes from a mixture of 3.7 equivalents of methanol and 2 equivalents of water (OH atoms are missing in the formula).

stirred under reflux for 30 min. As the sodium hydroxide dissolved a precipitate of zinc hydroxide separated from the mixture. The precipitate was then filtered off and the filtrate was cooled slowly. Compound **4** crystallised as a colourless solid. Yield 76%. $C_{57}H_{55}ClN_8NaO_9Zn_2$ (1185.32): calcd. C 57.76, H 4.68, Cl 2.99, N 9.45; found C 57.69, H 4.65, Cl 2.67, N 9.50.

5: Salicylaldehyde (1.83 g, 15 mmol) was dissolved in 50 mL of methanol and 2-(2-aminoethyl)pyridine (1.83 g, 15 mmol) in 20 mL of methanol was added at room temperature. After 10 min, zinc perchlorate hexahydrate (5.59 g, 15 mmol) in 50 mL of methanol was added, and the mixture was heated to 60 °C. A solution of sodium hydroxide (0.90 g, 22.5 mmol) in 50 mL of methanol was added and a cloudy mixture was obtained. Then, a stream of carbon dioxide was passed through the mixture for 45 min at 60 °C; most of the reaction products dissolved. The remaining undissolved solid was filtered off and the filtrate was cooled in a closed flask to 0 °C under a CO_2 atmosphere. After a few days, compound **5** crystallised as a colourless solid. Yield 55%. $C_{61}H_{68}Cl_2N_8O_{19}Zn_4 \cdot 3.7CH_3OH \cdot 2.5\,H_2O$ (1713.27): calcd. C 45.36, H 5.17, Cl 4.14, N 6.54; found C 45.77, H 4.76, Cl 4.32, N 6.88.

X-ray Crystallographic Study: Data for complexes **1** and **4** were collected on a NONIUS Kappa CCD diffractometer (Mo-K_α, λ = 0.71073 Å, and ω scans), at 183 K, up to Θ = 27.44°. The structures were solved by direct methods (refinement by least-squares against F^2, SHELX program[24]). Diffraction data for the complexes **2**, **3**, **3a**, and **5** were recorded at 200 K with a Siemens SMART 1000 CCD diffractometer fitted with a molybdenum tube (Mo-K_α, λ = 0.71073 Å) and a graphite monochromator. The structures were solved by direct methods and refined anisotropically with the SHELX program. The structural parameters were refined against F^2. Figures were produced with the winray program.[25] Table 1 lists the crystallographic data[26] of the complexes **1**, **2**, **3a**, **4**, and **5**.

Gas-Phase Reactions of Chromium and Chromium Fluoride Cations CrF_n^+ ($n = 0-4$) with Water and Nitrous Oxide

Ulf Mazurek,[a] Detlef Schröder,[a] and Helmut Schwarz*[a]

Dedicated, with admiration and in friendship, to Fulvio Cacace

Keywords: Chromium / Chromium fluorides / Hydrolysis / Gas-phase ion chemistry / Thermochemistry

The reactions of atomic chromium and chromium fluoride monocations CrF_n^+ (n = 0–4) with water and nitrous oxide were investigated by Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometry. Besides slow condensation, Cr^+ is unreactive towards water, whereas all chromium fluoride cations undergo at least one Cr–F bond hydrolysis yielding the corresponding hydroxide concomitant with loss of neutral HF. While hydrolysis is complete for CrF^+ and CrF_2^+, proton transfer and HF losses compete with the hydrolysis of the second Cr–F bond in CrF_3^+ and CrF_4^+. Nevertheless, complete Cr–F bond hydrolysis is observed for the latter two cations as well. The results for the ion-molecule reactions with nitrous oxide are as follows: With the exception of CrF_3^+, which gives CrF_3O^+ in a good yield, all species investigated were found to be essentially unreactive towards N_2O. The ionisation energy of CrF_3O has been determined, IE = 11.3 ± 0.2 eV. In addition, limits for the standard heats of formation of several chromium-containing cations have been derived.

Introduction

In previous studies, we investigated the formation of chromium and chromium fluoride monocations CrF_n^+ (n = 0−4) and their reactions with alkanes C_1 through C_4,[1] and phosphane.[2] The appearance of the species $Cr(OH)^+$, $CrF(OH)^+$, $Cr(OH)_2^+$, $CrF_2(OH)^+$, $CrF(OH)_2^+$, $Cr(OH)_3^+$ and CrF_3O^+ was detected, and attributed to the reactions of the chromium fluoride cations with water from the background of the mass spectrometer's high-vacuum system. As the presence of water is a widespread nuisance in mass spectrometry, we wanted to establish sound kinetic models for the reactions of chromium and chromium fluoride monocations with this neutral species. When investigating reactions of chromium and chromium fluoride cations with neutral species other than water, the kinetic models established here would allow for a more accurate description of the reaction systems as the contributions of background water could then be accounted for quantitatively.

In addition, we wanted to establish a firm basis for the formation of CrF_3O^+ hitherto attributed to a reaction of CrF_4^+ with water,[1] but not fitting into the general Cr−F bond hydrolysis scheme:

$$CrF_n^+ \xrightarrow[-HF]{+H_2O} CrF_{n-1}(OH)^+$$

Furthermore, we intended to expand our study to the generation of other chromium oxyfluoride cations and to investigate their gas-phase chemical properties.

Results and Discussion

Reactions with Water

The reactions of the CrF_n^+/H_2O systems are summarised in Figure 1. Species given in square brackets in this comprehensive reaction scheme were not observed experimentally but postulated, (i) as necessary intermediates in an observed reaction sequence [e.g., $CrF_2(OH)_2^+$] or, (ii) as products of reactions assumed to be reasonable by analogy to observed ones. A detailed discussion with regard to the parent ions CrF_n^+ (n = 0−4) follows below.

Cr^+

For argon-thermalised Cr^+ cations, only slow condensation yielding mono and di adducts was observed. However, for methane-thermalised Cr^+ cations, the di adduct $Cr(H_2O)_2^+$ was not detected. Consequently, this species is given in square brackets in Figure 1. Besides the water mono adduct $Cr(H_2O)^+$, a number of minor products that cannot be formed directly from Cr^+ and water [namely H_3O^+, CrO^+, $Cr(OH)^+$, CrO_2^+, and $Cr(OH)_2^+$] were observed. From these results, we draw the following conclusions: (i) Ground-state (^6S) bare chromium cations ($3d^5$) are essentially unreactive towards water. The only reaction ob-

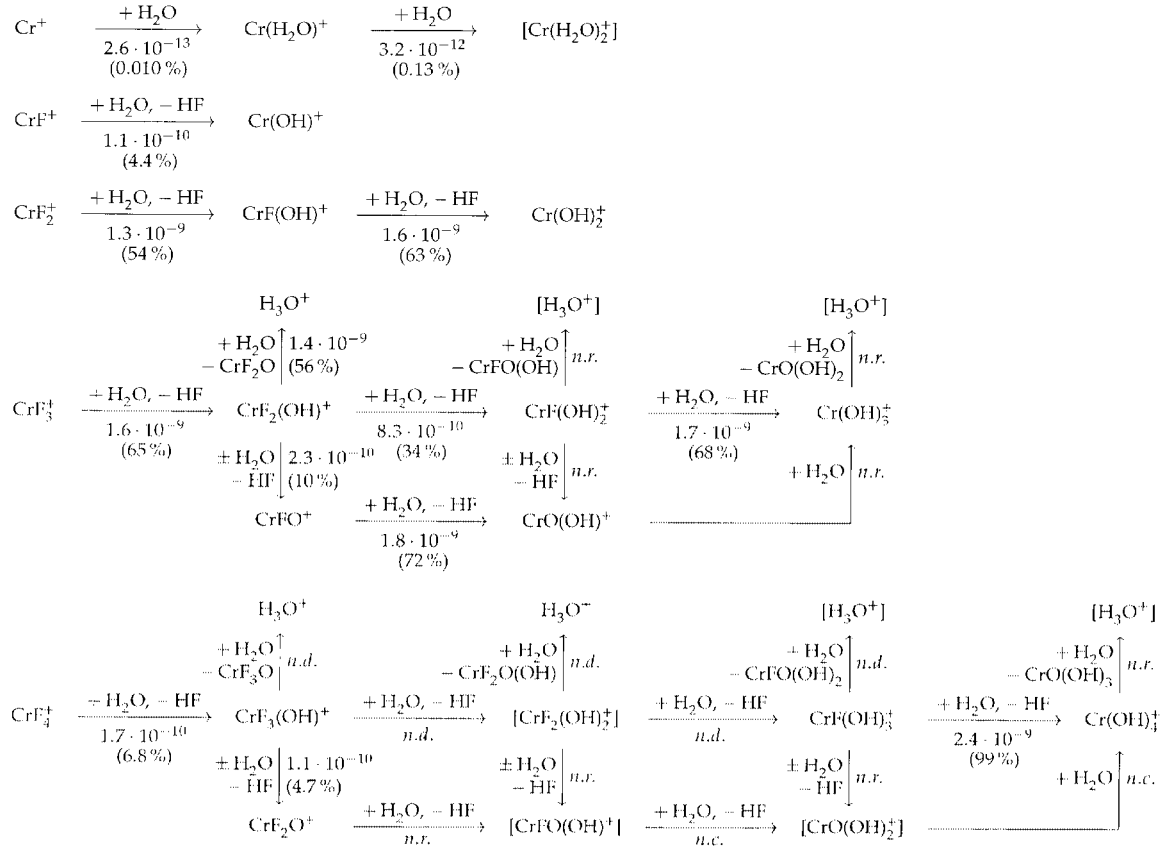

Figure 1. Reactions of CrF_n^+ ($n = 0-4$) with water; rate constants and reaction efficiencies φ (values in parentheses) are given as defined in the Exp. Sect.; for discussion, see text; abbreviations: *n.d.* = not determined (see text), *n.r.* = "no reactivity" indicating a reaction efficiency $\varphi < 0.05\%$, *n.c.* = not covered by this study because the reactant ion was not observed, see text

served is the slow mono adduct formation similar to that observed by Buckner et al. for the Cr^+/NH_3 system,[3] and by us for the CrF_n^+/PH_3 systems.[2] The failure of Cr^+ to activate O−H bonds parallels previous experimental findings for C−H[1,4] and N−H[3] bonds. (ii) Most probably, the condensation of ground-state Cr^+ by H_2O involves termolecular processes. In addition to water, prime candidates for third-body interactions are hydrocarbons and molecular oxygen present in the background of the mass spectrometer; the presence of the latter is supported by the formation of the cations CrO^+ and CrO_2^+. Interestingly, in a mass-spectrometric study of CrO_2^+ isomers, water was observed to catalyse the conversion of $Cr(O_2)^+$ to the chromyl cation.[5] Thus, the interplay between water and molecular oxygen is likely to exert a cooperative effect on the reactivity of Cr^+ cations. (iii) Based on this cooperative effect, we assume that the formation of $Cr(H_2O)_2^+$ from $Cr(H_2O)^+$ is outnumbered by reactions of the latter ion with O_2 rather than with H_2O. (v) The rate constants and reaction efficiencies, given in Figure 1, apply to argon-thermalised chromium cations. Due to the unknown influence of third-body interactions, they should be taken as upper limits of the effective bimolecular rate constants.

CrF^+

The only product of the reaction of CrF^+ with H_2O is $Cr(OH)^+$, corresponding to the loss of neutral HF, whose thermochemical stability may be considered as the driving force for the Cr−F bond hydrolysis. The reaction is rather inefficient compared with the corresponding reactions of CrF_2^+ and CrF_3^+ (see below).

CrF_2^+

In a reaction roughly twelve times as fast as that of CrF^+, CrF_2^+ reacts with water to form $CrF(OH)^+$ which, in turn, undergoes fast hydrolysis of the remaining Cr−F bond. Interestingly, the formal Cr^{III} species $CrF(OH)^+$ and $Cr(OH)_2^+$ do not undergo proton transfer to water, whereas several of their formal Cr^{IV} and Cr^V congeners (see below) do so.

CrF_3^+

CrF_3 reacts with water even faster than CrF_2^+, and undergoes facile hydrolysis of the first Cr−F bond. However, once $CrF_2(OH)^+$ has been formed, three different reaction channels exist as shown in Figure 1. First, $CrF_2(OH)^+$ may

undergo further Cr−F bond hydrolysis, thus following the reaction scheme already observed for $CrF(OH)^+$. In addition, proton transfer from $CrF_2(OH)^+$ to water is facile, and the loss of HF yielding $CrFO^+$ is also observed. The latter reaction shall be discussed in more detail. At a first glance, HF loss from $CrF_2(OH)^+$ can proceed as a unimolecular reaction, thus apparently indicating that $CrF_2(OH)^+$ is a metastable ion. Otherwise, the activation energy needed to form a weakly binding HF ligand would have to be acquired by collision with another molecule. The actual observation of $CrF_2(OH)^+$ on the time scale of an FT-ICR experiment, however, implies that this cannot hold true. Limited to both a maximum of 10^3-10^4 ions for all species detected and a lower detection limit of 10^2 ions for *one* species,[6] the population of an ionic species is too small to be detected by an FT-ICR mass spectrum if that species undergoes unimolecular decay with rate constants of typically some 100 s^{-1}. Furthermore, the intramolecular formation of HF from two ligands pointing away from each other seems to be rather unlikely. For geometrically comparable cations, e.g. $HO-Fe^+-OH$[7−9] and $HO-V^+-OH$,[10] considerable energy barriers were determined for the 1,3-H shifts, and it is fair to assume comparable barriers to be associated with an unimolecular HF formation. By reference to the results for the iron and vanadium systems, we conclude that the loss of HF from $CrF_2(OH)^+$ proceeds as a water-mediated reaction as indicated in Figure 2.

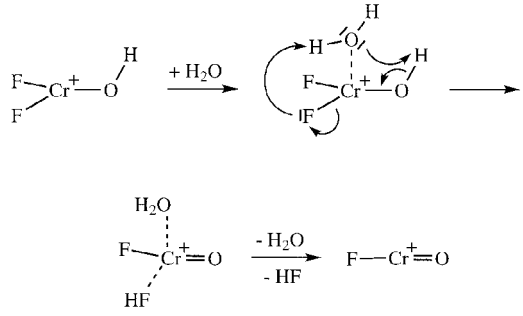

Figure 2. Conceptual illustration of water-mediated HF loss from $CrF_2(OH)^+$

It is suggested that water acts as a "proton shuttle" [11,12] in this reaction sequence, and that the intermediate is a metastable van-der-Waals complex of ionic $CrFO^+$, water, and HF, which looses both ligands easily. Notably, similar water-molecule participation has also been observed for the $Cr(O_2)^+$ cation,[5] the isomerisation of iron-coordinated cyclohexadienone to phenol,[13] and several metal-free systems.[14−16] While HF is known to be a weakly bound ligand and to "boil off" readily, the loss of H_2O from the intermediate complex can only be postulated from the observation of $CrFO^+$. The intermediate $CrFO^+\cdots H_2O$ cannot be distinguished from the long-lived cation $CrF(OH)_2^+$ by mass analysis only, because both cations have the same elemental composition.

At a first glance, the reaction mechanism depicted in Figure 2 may also explain the absence of the formal reaction $CrF(OH)^+ \rightarrow CrO^+ + HF$. If the O−Cr−F part of the $CrF(OH)^+$ cation was linear, the water molecule could no longer bridge the distance between the OH group and the fluoride ligand. However, based on its estimated endothermicity of at least 35 kcal mol^{-1}, this reaction can be ruled out a priori on thermochemical grounds.

In contrast to the variety of reactions observed for its predecessor $CrF_2(OH)^+$, ionic $CrF(OH)_2^+$ only undergoes hydrolysis of the remaining Cr−F bond. Both HF loss and proton transfer to water, as included in Figure 1, were ruled out on kinetic grounds. For an explanation of this different behaviour, we considered the electronic properties of $CrF(OH)_2^+$.

In a broader sense, the different effects of a fluorine atom and a hydroxy group on an adjacent atom shall be discussed with the help of Equation (1).

	CH_3OH		$CH_2F^\bullet$	→	$CH_2OH^\bullet$	+	CH_3F
$\Delta_f H°_{298}$ (kcal mol^{-1}):[17]	−48.2 ± 0.1		−8 ± 2		−6.2 ± 1.5		−59

(1)

The overall reaction enthalpy of $\Delta_r H°_{298} = -9 \pm 2.5$ kcal mol^{-1} indicates a comparable influence of the substituent X (X = F, OH) on a C−H bond. However, as the two corresponding cations require an ionisation energy of 9.1 eV and 7.6 eV, respectively, they are clearly distinct as far as thermochemistry is concerned. Delocalisation of the positive charge in CH_2OH^+ is a prime explanation for the lower *IE* of the corresponding neutral species. As a consequence, the corresponding reaction of cations, rather than radicals, [Equation (2)] strongly favours the formation of CH_2OH^+ as indicated by $\Delta_r H°_{298} = -41.8 \pm 0.1$ kcal mol^{-1}.

	CH_3OH	+	CH_2F^+	→	CH_2OH^+	+	CH_3F
$\Delta_f H°_{298}$ (kcal mol^{-1})[17]	−48.2 ± 0.1		199		168		−59

(2)

With respect to the chromium systems, we can conclude that the hydroxochromium cation can also be described as protonated chromium oxide, thus allowing for a considerable reduction of the formal charge on the metal centre compared with the chromium fluoride cation. From this explanation, it is evident that the stabilising effects of an OH group on a metal cation is much larger than the mere difference between the electronegativities of OH and F. Consequently, it is reasonable to assume that the metal centre in $CrF(OH)_2^+$ is less electron-deficient than in $CrF_2(OH)^+$. Thus, the tendency to increase the electron density at the metal centre in $CrF(OH)_2^+$ by the formation of a Cr−O double bond is less pronounced.

The oxyfluoride $CrFO^+$ undergoes facile hydrolysis of the remaining Cr−F bond, thus yielding $CrO(OH)^+$. This ion, in turn, could undergo addition of water similar to that investigated both experimentally and theoretically for various vanadium[10] and iron[9,18,19] oxides and oxohydroxide

monocations. However, the kinetic data suggest that addition of water to $CrO(OH)^+$ is slow, if it occurs at all, in the pressure region examined. Thus, for the reactions of CrF_3^+ with water, three terminal product ions are observed with decreasing abundances; H_3O^+, $Cr(OH)_3^+$, and $CrO(OH)^+$. Regardless of their actual way of formation, the cationic chromium fragments eventually underwent hydrolysis of all Cr−F bonds originally present in CrF_3^+.

CrF_4^+

On reaction with water, $CrF_3(OH)^+$ is formed as the initial product. One might expect a further increase in the reaction rate relative to CrF_3^+; however, this hydrolysis reaction is remarkably slow. This "passive" behaviour of *thermalised* CrF_4^+ has already been observed in the reactions of this ion with methane and NF_3;[1] any excited CrF_4^+ cations can safely be assumed to have been hydrolysed during the period necessary to isolate CrF_4^+ due to the fact that they are much more reactive. However, the overall behaviour of the CrF_4^+/H_2O system resembles that of its CrF_3^+/H_2O congener: (i) The terminal reaction product, H_3O^+ (obtained by proton transfer from hydrolysed CrF_4^+ to H_2O) dominates over $Cr(OH)_4^+$ (complete Cr−F bond hydrolysis) and CrF_2O^+ where the latter is, by analogy, assumed to be formed by water-mediated HF loss from $CrF_3(OH)^+$. While CrF_2O^+ might be expected to undergo at least one further Cr−F bond hydrolysis, the product $CrFO(OH)^+$ could not be detected in our study, and the kinetic data suggest that CrF_2O^+ is indeed a terminal reaction product. (ii) Three different reaction pathways can be accessed from the first intermediate, $CrF_3(OH)^+$: proton transfer to water, further Cr−F bond hydrolysis, and water-mediated HF loss. While the latter reaction has already been addressed, the other two reaction channels shall be discussed in more detail here. The generation of H_3O^+ from CrF_4^+ and H_2O may occur, in principle, by two different reaction pathways [Equations (3) and (4)].

$$CrF_4^+ \xrightarrow[-HF]{+H_2O} CrF_3(OH)^+ \xrightarrow[-CrF_3O]{+H_2O} H_3O^+ \quad (3)$$

$$CrF_4^+ \xrightarrow[-CrF_4]{+H_2O} H_2O^+ \xrightarrow[-OH]{+H_2O} H_3O^+ \quad (4)$$

However, both the ionisation energies of CrF_4 and water (see Table 1), the failure to observe cationic H_2O^+ during the decay of CrF_4^+ and the concurrent increase in H_3O^+ disfavour the second reaction channel [Equation (4)]. Furthermore, in a double-resonance experiment, ejection of $CrF_3(OH)^+$ from the reaction cell caused the signal of H_3O^+ to vanish completely. Thus, the generation of H_3O^+ is attributed to the first reaction channel [Equation (3)]. However, additional formation of H_3O^+ from further-hydrolysed ions $CrF_2(OH)_2^+$ and $CrF(OH)_3^+$, cannot be ruled out so far and will be discussed in more detail below.

Remarkably, the signal for putative intermediate $CrF_2(OH)_2^+$ did not surpass the noise level in the kinetic investigation, while the signals for its supposed Cr−F bond hydrolysis products $CrF(OH)_3^+$ and $Cr(OH)_4^+$ did so; the latter species is a terminal product of the reaction sequence. The failure to observe $CrF_2(OH)_2^+$ turns the kinetic analysis into a nontrivial problem as is discussed as follows: (i) There is no single source for the protons transferred to water. If proton transfer from both $CrF_3(OH)^+$ and the formal Cr^{IV} species $CrF_2(OH)^+$ (see the CrF_3^+ section above) to water was allowed, it would be rather arbitrary to rule out a similar reaction for the formal Cr^V species $CrF_2(OH)_2^+$ and $CrF(OH)_3^+$. Whilst an F/OH ligand exchange reduces the electron deficiency at the chromium centre, the influence of this exchange on the OH proton acidity is not necessarily large. In contrast, the mere existence of two or even three OH groups in $CrF_2(OH)_2^+$ or $CrF(OH)_3^+$, respectively, compared with one in $CrF_3(OH)^+$ may, on statistical grounds, even increase the rate of proton transfer to water. On the other hand, proton abstraction from $Cr(OH)_4^+$ could be ruled out because the latter ion was found to be a terminal product of the reaction sequences. Thus, a gradual decrease in proton transfer relative to further Cr−F bond hydrolysis is likely. The overall picture is that for $CrF_n(OH)_m^+$, the acidity of the OH protons increases with n but decreases with m. However, it is impossible to establish the particular step sizes of that decrease a priori. (ii) If $CrF_2(OH)_2^+$ could have been observed in the kinetic study, the distribution between proton abstraction and further Cr−F bond hydrolysis could be determined on the basis of the evolution of the ion concentrations over time. However, as $CrF_2(OH)_2^+$ had to be regarded as a reactive intermediate formed in very low steady-state concentrations, any distribution ratio could occur between the two reaction pathways. If proton abstraction from $CrF_3(OH)^+$ is favoured, then proton abstraction for $CrF_2(OH)_2^+$ is not favoured, and vice versa. Similarly, if proton abstraction from $CrF_2(OH)_2^+$ is favoured, then proton abstraction for $CrF(OH)_3^+$ is not favoured, and again, vice versa.

The kinetic analysis was made easier by the following: (i) CrF_2O^+ was found to be a terminal product of the reaction system. In addition, the cations $CrFO(OH)^+$ and $CrO(OH)_2^+$ were not observed. Consequently, the reaction sequence $CrF_4^+ \rightarrow CrF_2O^+ \rightarrow Cr(OH)_4^+$ can be ruled out. (ii) While the $CrF_2(OH)_2^+$ ion, which is not observed, is to be considered as a reactive intermediate, its consumption by one or more reactions with water cannot be faster than the collision rate. (iii) The very same argument applies to $CrF(OH)_3^+$; regardless of its actual rate of formation, the cation cannot be consumed at a reaction rate exceeding the collision limit. (iv) In turn, the temporal evolutions of $CrF(OH)_3^+$, and especially $Cr(OH)_4^+$, set upper limits to the reaction rates in question.

However, one cannot determine without additional experiments (namely exposing isolated intermediates to water or double-resonance experiments) the extent to which H_3O^+ is formed from $CrF_3(OH)^+$, $CrF_2(OH)_2^+$, and perhaps $CrF(OH)_3^+$. In parallel, the fraction of $CrF_3(OH)^+$ which yields $CrF_2(OH)_2^+$ remains unknown as do the fractions of $CrF_2(OH)_2^+$ and $CrF(OH)_3^+$, which yield

$CrF(OH)_3^+$ and $Cr(OH)_4^+$, respectively. However, these additional experiments would be adversely affected by the unfavourable signal-to-noise ratios already hampering the present investigations. As a consequence, isolation of intermediates was not attempted, and we ceased the investigation and determined only the rate constants reported in Figure 1.

Relative Reaction Rates of Hydrolysis

Remarkably, the reaction rate of the first Cr−F bond hydrolysis (see Figure 1) increases by about one order of magnitude from CrF^+ to CrF_2^+. While the rates of the first hydrolysis reactions are similar for CrF_2^+ and CrF_3^+, a subsequent decrease by about one order of magnitude is observed when going from CrF_3^+ to CrF_4^+. We think that the interplay of the effective charge on the chromium centre, the steric hindrance exerted by the increasing number of fluorine atoms attached to the metal centre, and the "surface charge" (originating from the high electron density on the fluorine atoms constituting the ligand sphere of the chromium cation) of the different CrF_n^+ cations provides an appropriate explanation for the observed differences in the rate constants.We will discuss this interplay in more detail: (i) The increased rate of hydrolysis of CrF_2^+ compared with CrF^+ can be explained by the threefold influence of the higher effective charge on the chromium centre on increasing fluorination. First, the formation of the collision complex between the ion and the polar water molecule should be much more facile. Secondly, the resulting collision complex should possess a longer life-time due to the larger ion-dipole interaction. Finally, assuming a four-centre transition state, the increased effective charge at the chromium centre can be assumed to favour the actual Cr−OH bond formation/HF abstraction from the collision complex. (ii) While all arguments mentioned above hold true for the change from CrF_2^+ to CrF_3^+ as well, the increase in the rate constant is much less pronounced. Steric hindrance exerted by the three fluorine atoms attached to the chromium cation can be assumed to slow down the formation of the initial collision complex, irrespective of whether CrF_3^+ keeps the trigonal-planar structure of neutral CrF_3 (Cr−F bond length 1.732 Å[20,21]) or not. (iii) We suppose that the formal Cr^V species CrF_4^+ more or less keeps the tetrahedral structure of neutral CrF_4 (Cr−F bond length 1.704 Å[21,22]), since the formal Cr^V species CrF_3O forms a trigonal-pyramidal structure, i.e. a slightly distorted tetrahedral structure.[21] Thus, the outer-sphere of the CrF_4^+ ion is assumed to be dominated by four electron-rich fluorine atoms, such that formation of the collision complex with water proceeds rather slowly while the actual hydrolysis reaction should proceed at a rate similar to that for CrF_2^+ and CrF_3^+. Accordingly, we conclude that the retardation of the hydrolysis of the "inert" CrF_4^+ cation is not due to the actual F/OH exchange but to the formation of the initial collision complex.

In the preceding discussion, the focus was placed on the structural properties of the chromium fluoride cations. However, spin restrictions[23] discussed in more detail in the Thermochemistry Section below may contribute to the hydrolysis rate differences as well. For example, hydrolysis of a Cr−F bond in CrF_n^+ allows for the above-mentioned delocalisation of the positive charge of the reaction product. This delocalisation, in turn, might allow for a spin inversion on the chromium centre, thus giving rise to a considerable reaction barrier. However, the results of quantum-chemical calculations would be needed to discuss this point in more detail.

Reactions with Nitrous Oxide

The observation of several oxochromium fluoride cations during the hydrolysis reactions reported above prompted our interest in looking for a more facile way of generating them. Our results are described below.

Initial Experiments

When a mixture of chromium and chromium fluoride monocations CrF_n^+ ($n = 0-4$) was subjected to an oxygen pressure of $1.0 \cdot 10^{-8}$ mbar for a period of 24 s, at least 95% of the total ion intensity was due to the cations CrF_n^+ ($n = 0-4$) and their hydrolysis and/or charge-transfer products. Oxochromium fluorides and ions originating from them included $CrFO^+$ (max. 1%), its supposed hydrolysis product $CrO(OH)^+$ (max. 2%), CrF_3O^+ (max. 1%), and the possible hydrolysis product of CrF_2O^+, $CrO(OH)_2^+$ (max. 1%). Therefore, O_2 deemed inappropriate and was replaced by N_2O as a putatively more suitable oxidant. From a thermochemical point of view, the latter should be a much better oxygen-atom donor, irrespective of the substrate present [see Equations (5) and (6)].

$$O_2 \rightarrow O + O \qquad \Delta_f H^\circ_{298} = 119.2 \text{ kcal mol}^{-1}\ [17] \qquad (5)$$

$$N_2O \rightarrow N_2 + O \qquad \Delta_f H^\circ_{298} = 40.0 \text{ kcal mol}^{-1}\ [17] \qquad (6)$$

In a second initial experiment, subjecting a mixture of chromium and chromium fluoride monocations to nitrous oxide pressures of $2.0 \cdot 10^{-8}$ mbar and $5.0 \cdot 10^{-7}$ mbar for 32 s allowed for the detection of substantial amounts of CrF_3O^+. In addition, both NO^+, NF_2O^+ [24] and small amounts of $CrO(OH)^+$ (probably from $CrFO^+$), $CrFN_2O_2^+$, and $CrF_2N_2O_2^+$ were detected.

Reactions of Mass-Selected Ions

(i) Based on the already observed inertness of ground-state (^6S) bare chromium cations towards nitrous oxide[25,26] and the outcome of the initial experiments, no further attempts were undertaken to generate CrO^+. (ii) In the reaction of isolated CrF^+ and N_2O, the desired species $CrFO^+$ could not be detected, whereas $Cr(OH)^+$ formed by hydrolysis with background water dominated the product ion spectrum. Traces of H_3O^+ and NO^+ (not surmounting 3% of the total ion concentration) were attributed to the presence of excited CrF^+ cations. (iii) When isolated CrF_2^+ was

exposed to N_2O, CrF_2O^+ was formed with a reaction efficiency of φ = 0.16%, and the abundance of the ion was not more than 2% of the total ion concentration. Besides hydrolysis products and NO^+ (not exceeding 1% of the total ion concentration), the intermediate N_2O^+ and the final product H_3O^+, accounting for 2% of the total ion concentration, were detected (see the Thermochemistry Section below for discussion). Due to the low abundance of CrF_2O^+, isolation of this cation was not attempted. (iv) When isolated CrF_3^+ was subjected to N_2O pressure of $1.0 \cdot 10^{-8}$ mbar for a period of 20 s, CrF_3O^+ was formed with a reaction rate of $(7 \pm 1)\ 10^{-11}$ cm^3 molecules^{-1} s^{-1} (φ = 9 ± 1%), regardless of whether CrF_3^+ was generated from Cr^+ by NF_3/Ar or pure NF_3 pulses. Note that the small error bars reported here are based on good agreement between two experiments, whereas the systematic error introduced by the pressure measurement (see the Exp. Sect.) has not yet been considered. The only other oxofluoride species observed was $CrFN_2O_2^+$, which accounted for 3% of the total ion concentration. One might suppose $CrFN_2O_2^+$ to be generated by addition of N_2O to $CrFO^+$, which, in turn, is generated from CrF_3^+ by a single Cr−F bond hydrolysis and subsequent HF abstraction (see above). However, double-resonance experiments revealed that $CrFN_2O_2^+$ is formed from $CrF_2(OH)^+$ exclusively, and not at all from $CrFO^+$. Consequently, the generation of $CrFN_2O_2^+$ from $CrF_2(OH)^+$ is attributed to the water-assisted rearrangement of $CrF_2(OH)^+$ into $(HF)CrFO^+$, and subsequent HF/N_2O ligand exchange to yield $(N_2O)CrFO^+$. Note that ligand-mediated H−F bond formation and subsequent ligand loss have already been referred to in the above discussion of the formal reactions $CrF_2(OH)^+ \rightarrow CrFO^+ + HF$ and $CrF_3(OH)^+ \rightarrow CrF_2O^+ + HF$. As N_2O is a weakly bound ligand,[27] subsequent ligand exchange with background water yields $(H_2O)CrFO^+$. Supposedly, the latter rearranges, probably assisted by a neutral water molecule in a reaction sequence similar to that in Figure 2, to its isomer $CrF(OH)_2^+$, which finally undergoes hydrolysis of the remaining Cr−F bond to yield $Cr(OH)_3^+$. Rate constants for both the formation and consumption of $CrFN_2O_2^+$ could not be determined due to the low signal-to-noise ratio of the ion. With regard to Cr−F bond hydrolysis of the observed species, CrF_3O^+ was found to be remarkably inert towards water, but the reaction of its predecessor ion CrF_3^+ with background water was found to be fast and hence limited the yield of CrF_3O^+ to a maximum of about 15% of the total ion concentration. (v) In order to achieve a good signal-to-noise ratio, CrF_4^+ was not mass-selected. When a mixture of CrF_4^+ (23%) and the noninterfering CrF_3O^+ (77%) was subjected to N_2O pressure of $1.0 \cdot 10^{-6}$ mbar for 8 s, CrF_4O^+ could not be detected. This result is in agreement with chemical intuition which suggests that it is unlikely that oxidation of the formal Cr^V species CrF_4^+ would be observed since the reaction product CrF_4O^+ would constitute a formal Cr^{VII} cation, i.e. a hypervalent cation.

The reactions of mass-selected chromium and chromium fluoride monocations with nitrous oxide are summarised in Figure 3. As in Figure 1, possible but experimentally not observed oxidation products are given in square brackets, and both reaction rate constants and reaction efficiencies φ (values in parentheses) are given as defined in the Exp. Sect.

$$Cr^+ \xrightarrow[n.r.]{+N_2O,\ -N_2} [CrO^+]$$

$$CrF^+ \xrightarrow[n.r.]{+N_2O,\ -N_2} [CrFO^+]$$

$$CrF_2^+ \xrightarrow[1.2 \cdot 10^{-12}\ (0.16\,\%)]{+N_2O,\ -N_2} CrF_2O^+$$

$$CrF_3^+ \xrightarrow[7.5 \cdot 10^{-11}\ (9.9\,\%)]{+N_2O,\ -N_2} CrF_3O^+$$

$$CrF_4^+ \xrightarrow[n.r.]{+N_2O,\ -N_2} [CrF_4O^+]$$

Figure 3. Reactions of CrF_n^+ (n = 0−4) with nitrous oxide; for discussion, see text; abbreviation: *n.r.* = "no reactivity" indicating a reaction efficiency φ < 0.05%

Gas-Phase Generation of CrF_3O^+

While the absence of efficient oxygen transfer to chromium and chromium fluoride monocations CrF_n^+ (n = 0−2, 4) limited the present study to CrF_3^+, it simplified the experiments to a great extent. In contrast to requiring the use of two pulse valves, isolating a hydrolysis-sensitive intermediate, and optimising gas pressures and pulse lengths for two pulse valves,[2] good CrF_3O^+ intensities could be achieved by optimising the generation of CrF_3^+ from bare Cr^+ and pulsed-in NF_3, and then adding N_2O to the pulse valve already filled with NF_3. Subsequent optimisation of the length of the combined NF_3/N_2O pulse was not necessary; furthermore, isolation of CrF_3O^+ did not impose any problems.

Ionisation Energy

Chromium fluorides show a strong correlation between the number of electron-withdrawing fluorine atoms connected to the metal centre and the respective ionisation energies (see Table 1). However, the presence of doubly bonded oxygen does not necessarily affect the *IE*. On one hand, an oxygen ligand will withdraw electron density from the metal centre, and on the other hand, it may even donate electron density when the metal centre is already highly electron-deficient. Consequently, we wanted to establish a sound value for the yet unknown ionisation energy of CrF_3O. Exposures of CrF_3O^+ to ethylene [*IE* = 10.5 eV, charge-transfer (CT) reaction efficiency φ = 170%] and to molecular oxygen (*IE* = 12.1 eV, CT reaction efficiency φ < 0.05%) provide lower and upper limits, respectively, for the ionisation energy in question. The reaction with ethylene appears to proceed faster than the rate at which the reactants collide according to the capture theory.[28,29] While the agreement between rate constant determined by experiment and by this theory is very good for electron-

transfer processes between species of similar *IE*s,[30] some pitfalls seem to exist when describing outer-sphere electron transfer between species with large *IE* differences. Most probably, the cross-section is underestimated in the latter case.

Unfortunately, a more precise determination of the ionisation energy of CrF_3O was adversely affected by the following facts: (i) For a large variety of readily available compounds, e.g. alkanes (C_2H_6, *IE* = 11.5 eV; C_3H_8, *IE* = 11.0 eV),[17] haloalkanes (CH_3Cl, *IE* = 11.2 eV; CH_2Cl_2, *IE* = 11.3 eV; CH_2ClF, *IE* = 11.7 eV),[17] and SiH_4 (*IE* = 11.6 eV),[17] dissociative ionisation is preferred and the yields of stable radical cations on removal of an electron are rather poor. (ii) The readily available cyano-substituted ethylenes, which yield stable radical cations (acrylonitrile, *IE* = 10.9 eV; both 1,2-dicyanoethylenes, *IE* = 11.2 eV; 1,1-dicyanoethylene, *IE* = 11.4 eV; tricyanoethylene, *IE* = 11.6 eV; tetracyanoethylene, *IE* = 11.7 eV),[31] are either difficult to handle or are insufficiently volatile to be employed in an FT-ICR experiment. (iii) Hexafluoroacetone (*IE* = 11.6 eV), which forms a stable radical cation and is sufficiently volatile undergoes α cleavage instead of charge-transfer when reacting with CrF_3O^+. Thus, for the determination of the *IE* of CrF_3O, the use of the "bracketing method", while relying largely on only one charge-transfer reaction [namely $CrF_3O^+ + COS$ (*IE* = 11.2 eV) → $CrF_3O + COS^+$; reaction efficiency φ = 80%], deemed not indicated. Consequently, we correlated the efficiency of the presumably barrier-free reaction to the ionisation energy difference, [32] thus estimating the ionisation energy of CrF_3O to be 11.3 eV ± 0.2 eV (rounded up, and the error bar was based on the reaction rate uncertainty mentioned in the Exp. Sect.). Interestingly, this value is considerably lower than the ionisation energies of CrF_2O_2, as well as of CrF_4, and even slightly lower than the ionisation energy of the oxygen-free species CrF_3 (though within the experimental error margins, Table 1). Two reasons can account for the similarity of the ionisation energies of CrF_3 and CrF_3O. (i) In the formal Cr^{III} species CrF_3, the central chromium atom is already highly electron-deficient which disfavours additional electron withdrawal. (ii) Oxygen is not as electronegative as fluorine, thus it does not necessarily withdraw electron density from the chromium atom; in contrast, doubly bound oxygen may even donate electron density to the electron-deficient metal centre. However, in order to account for the influence of a Cr=O double bond on the ionisation energy quantitatively, the ionisation energies of CrF_nO (n = 1, 2) are needed as well.

Table 1. Ionisation energies (*IE*) of CrF_3O and other species of interest[a]

Species	*IE* (eV)	Ref.
C_2H_4	10.5	[17]
COS	11.2	[17]
CF_3COCF_3	11.6 ± 0.1	[31]
O_2	12.1	[17]
H_2O	12.6	[17]
N_2O	12.9	[17]
Cr	6.8	[17]
CrF	8.4 ± 0.3	[17]
CrF_2	10.1 ± 0.3	[17]
CrF_3	11.5 ± 0.4	[1]
CrF_4	12.3 ± 0.3	[1]
CrO	7.9	[17]
CrO_2	10.3 ± 0.5	[17]
	9.7 ± 0.2	[66][b]
CrO_3	11.6 ± 0.5	[17]
CrF_2O_2	12.9	[31]
CrF_3O	11.3 ± 0.2	this work

[a] Values and error bars are rounded off to multiples of 0.1 eV; error bars are not given when they are less than 0.1 eV. [b] OCrO.

Reactions

As CrF_3^+ is relatively easily oxidised to CrF_3O^+, we wondered if that property of the system could be employed in a catalytic oxidation cycle. First, we were interested in the oxidation of small alkanes. Kang and Beauchamp[33] found CrO^+ to selectively oxidise alkanes except methane. While the higher valency of the metal in CrF_3O^+ may help to fulfil this task, no reactions with methane were observed. In contrast, replacing methane by ethane caused the formal transfer of a hydride anion from the hydrocarbon to CrF_3O^+; products indicative of the cleavage of the Cr−O bond were not observed. One might argue that unsaturated hydrocarbons like toluene or buta-1,3-diene could be suitable substrates for oxidation. While this might be perfectly true, it seems unlikely that CrF_3O^+ would transfer oxygen to them, rather than abstract hydride anions or capture electrons from the π-systems, simply because the *IE*s of these substrates are considerably lower than the *IE* of CrF_3O^+. The failure to transfer oxygen atoms to organic substrates has already been observed for other transition-metal complexes of higher oxidation states. For example, both MoO_3^+ and MoS_3^+ show exclusive electron capture and hydride abstraction from toluene,[34] and for the PtO_2^+/ethane system, electron and hydride anion transfer dominate the reactivity (40% and 15% of the reaction products, respectively).[35] Further, OsO_n^+ (n = 3, 4) exclusively abstracts one or two hydrogen atoms from methane, ethane, and propane.[36] From these previous and our present results, we inferred that CrF_3O^+ would also abstract hydride anions from higher alkanes, but is not suited for selectively oxidising them. Thus, we ceased this particular investigation and addressed the oxidation of carbon monoxide. Again, we were not successful: Carbon monoxide does not react with CrF_3O^+. A summary of the investigated reactions is given in Table 2.

Table 2. Reactions of CrF_3O^+ investigated in this study[a] [b] [c] [d]

IE determination							
CrF_3O^+	+	C_2H_4	(*IE* = 10.5 eV)	$\xrightarrow{170\,\%}$	$[Cr,F_3,O]$	+	$C_2H_4^+$
	+	COS	(*IE* = 11.2 eV)	$\xrightarrow{80\,\%}$	$[Cr,F_3,O]$	+	COS^+
	+	C_3F_6O[e]	(*IE* = 11.6 eV)	$\xrightarrow{n.d.}$	$[Cr,F_6,C,O]$	+	$C_2F_3O^+$
	+	O_2	(*IE* = 12.1 eV)	$\xrightarrow{n.r.}$			
Potential applications							
CrF_3O^+	+	CH_4		$\xrightarrow{n.r.}$			
	+	C_2H_6		$\xrightarrow{50\,\%}$	$[Cr,F_3,O,H]$	+	$C_2H_5^+$
				$\xrightarrow{3.4\,\%}$	$[Cr,F_3,O,H_2]$	+	$C_2H_4^+$
	+	CO		$\xrightarrow{n.r.}$			

[a] Reaction efficiencies φ are given as defined in the text. [b] For reaction efficiencies φ apparently greater than unity, see text. [c] *n.d.* = reaction efficiency φ not determined because the observed reaction is unsuited to determine the ionisation energy of CrF_3O. [d] *n.r.* = "no reactivity" indicating a reaction efficiency $\varphi < 0.05\%$. [e] Hexafluoroacetone.

Thermochemistry

Finally, we address the investigated reactions from a thermochemical point of view. Unless otherwise noted, two assumptions shall be made throughout this section: (i) The reactants are properly thermalised and (ii) severe kinetic barriers or spin restrictions[23] do not exist. Assumption (i) allows for the exclusion of endothermic reactions while assumption (ii) limits the reasons for a reaction's nonoccurrence to endothermicity (or the existence of at least one other, more exothermic reaction channel). As a consequence, the mere occurrence or absence of a reaction allows for establishing a $\Delta_fH°_T$ limit for one of the species involved, provided the standard heats of formation of all other species are known. To be more precise, the occurrence of a reaction at a temperature T allows for establishing a lower limit of a reactant's $\Delta_fH°_T$ value or an upper limit of a product's $\Delta_fH°_T$ value, whereas the absence of a reaction allows for establishing an upper limit of a reactant's $\Delta_fH°_T$ value or a lower limit of a product's $\Delta_fH°_T$ value. Maximum $\Delta_fH°_T$ values of reaction products can be utilised in follow-up reactions. Unfortunately, that does not hold true for minimum $\Delta_fH°_T$ values which makes an "inherited" bracketing impossible. However, the procedure is straightforward, and the limits are derived in Table 3 and presented together with those of their neutral counterparts in Table 4. From the heats of formation bond dissociation energies (*BDE*s) may be calculated in a straightforward manner. However, we do not report *BDE*s in this work because $\Delta_fH°_T$ *limits* allow for deriving bond-dissociation energy *limits* only, whereas other experimental techniques are available to determine the actual values.

Chromium Fluoride Hydrolysis Products

For $Cr(OH)^+$, a double upper limit of $\Delta_fH°_{298}$ can be derived (Table 3, Entries 1 and 2). While both results agree with each other and the literature value [(185.8 ± 3.0) kcal mol^{-1}[17,37]], their significance is low. Further, the smaller error bar of the higher value does not provide an advantage. A lower limit for $\Delta_fH°_{298}[Cr(OH)^+]$ cannot be derived on the basis of the reactions investigated here. Similar arguments apply to $\Delta_fH°_{298}[CrF(OH)^+]$ (Table 3, Entries 3 and 4) and to $\Delta_fH°_{298}[Cr(OH)_2{}^+]$ (Table 3, Entries 5 and 6). However, for $CrF(OH)^+$, the $\Delta_fH°_{298}$ limit obtained from the absence of proton transfer is more precise from the point of both its error bar and value, and for $Cr(OH)_2{}^+$, the difference between the two values is less pronounced and mostly due to the decrease in the size of the error bar.

For the hydrolysis of $CrF_3{}^+$ and its follow-up products, deriving the maximum $\Delta_fH°_{298}$ values for the hydrolysis products (Table 3, Entries 7, 9, and 10) is straightforward. Based on the *observed* proton transfer from $CrF_2(OH)^+$ to H_2O (Table 3, Entry 8), a *lower* limit for the heat of formation of the reactant ion can be determined for the first time in this study. In turn, the failure to observe proton transfer from both $CrF(OH)_2{}^+$ and $Cr(OH)_3{}^+$ (Table 3, Entry 11) to H_2O allows, in principle, for re-evaluating maximum $\Delta_fH°_{298}$ values for these cations but fails, in practice, for $CrF(OH)_2{}^+$ because the standard heat of formation of the

[a] Unless otherwise noted, data in kcal mol^{-1}. [b] For discussion, especially of multiple and/or seemingly contradicting entries, see text. [c] The table entries are numbered consecutively beginning with one. In order to avoid confusion with reactions given in the text, those given in this table will be referred to as, e.g., "Table 3, Entry 1". [d] Value considered to be more reliable. For discussion, see text.

corresponding neutral oxochromium hydroxide CrFO(OH) is unknown.

In addition, having established the upper limit for $\Delta_f H^\circ_{298}[CrF_2(OH)^+]$, the maximum standard heats of formation for both $CrFO^+$ and its hydrolysis product $CrO(OH)^+$ can be derived (Table 3, Entries 12 and 13, respectively). However, these two limits should be used with care: all reactions discussed so far involved the same number of reactants and products thus allowing, by and large, for the neglecting of entropic terms. With the number of molecules changing in the course of the HF abstraction reaction (Table 3, Entry 12), this does not apply any longer, and uncertainties in the range of several kcal mol^{-1} may be introduced by neglecting entropic factors. The absence of proton transfer from $CrO(OH)^+$ to water (Table 3, Entry 14) does not allow for deriving a more precise $\Delta_f H^\circ_{298}$ limit for that species.

The discussion of the CrF_4^+/H_2O system essentially parallels that of the CrF_3^+/H_2O system. The only remarkable difference is the occurrence of a second proton transfer reaction $CrF_2(OH)_2^+ + H_2O \rightarrow CrF_2O(OH) + H_3O^+$ which would have allowed for the determination of another minimum $\Delta_f H^\circ_{298}[CrF_2(OH)_2^+]$ value provided $\Delta_f H^\circ_{298}[CrF_2O(OH)]$ had been known.

Oxidation by Nitrous Oxide

As mentioned above, CrO^+ could not be generated from Cr^+ and N_2O, although the reaction is thermochemically favourable. We attribute this to a considerable twofold reaction (activation) barrier introduced by (i) the need to break the $3d^5$ configuration of the chromium cation and (ii) the missing electronic correlation between reactants and products of the reaction, N_2O ($^1\Sigma^+$) + Cr^+ (^6S) → N_2 ($1\Sigma_g^+$) + CrO^+ ($^4\Pi$[38]), already pointed out by Armentrout et al.[39]

We would like to discuss this absence of a thermochemically favourable reaction in more detail. From the point of the experimentalist, assuring proper thermalisation of the reactants is a mere question of careful experimental set-up. Thus, a "false positive" (a reaction occurring despite its endothermicity) can be prevented. In contrast, activation barriers and spin restrictions are *intrinsic* properties of the sys-

Table 4. Heats of formation of chromium fluoride cations and other species of interest[a] [b] [c]

[a] All data in kcal mol^{-1}. [b] This work unless otherwise noted. [c] We report only "best values" here. For data evaluation, see the limits reported in Table 3 and the discussion in the text. [d] Calculated from the heat of formation[21] and the ionisation energy.[1,17] [e] Calculated from the heat of formation[21] and the ionisation energy.[1] [f] Calculated from the heat of formation[21] and the ionisation energy.[17] [g] OCrO. [h] Calculated from the heats of formation of Cr^+ and OH[17] and the bond dissociation energy (*BDE*) of Cr^+-OH.[37]

tem and cannot be circumvented by any experimental condition. Thus, a "false negative" (a reaction not occurring despite its exothermicity) cannot be detected without an independent determination of the thermochemical data.

Finally, one more point regarding oxidation by nitrous oxide shall be discussed here. Due to an orbital reorganisation,[40] linear N_2O needs to get bent in order to facilitate oxygen-atom transfer onto its reaction partner.[41,42]

The failure to generate $CrFO^+$ from CrF^+ and N_2O can be explained by the following. (i) The oxidation reaction is endothermic corresponding to $\Delta_f H^\circ_{298}(CrFO^+) > 217.9 \pm 7.3$ kcal mol^{-1} (Table 3, Entry 22). However, this limit contradicts that derived from the decomposition of $CrF_2(OH)^+$, $\Delta_f H^\circ_{298}(CrFO^+) < 137.8 \pm 9.8$ kcal mol^{-1} (Table 3, Entry 12), and this explanation cannot hold true. (ii) $CrFO^+$, once formed, is readily oxidised to yield $CrFO_2^+$. However, as the formal Cr^{VI} species $CrFO_2^+$ was not observed, it would have to be a fast-reacting intermediate, thus posing the question of its reaction partners and the resulting products. While traces of H_3O^+ and NO^+ were detected, the direct formation of H_3O^+ from $CrFO^+$ and background water is impossible, and the transfer of the nitride anion from N_2O appears rather unlikely. In parallel, hydride anion abstraction from H_2O would yield HO^+, which cannot be observed by our mass spectrometer (thus allowing for both facile formation and consumption of $CrFO_2^+$). However, the formation of HO^+ is highly unlikely on thermochemical grounds. Hence, this second explanation is excluded as well. (iii) The above-mentioned spin-inversion phenomena prevent the reaction from proceeding, i.e. assumption (ii) introduced in the first paragraph of this section does not apply. In this particular case, however, an upper limit for $\Delta_f H^\circ_{298}(CrFO^+)$ could be derived independently from a reaction that does take place (Table 3, Entry 12), thus allowing for the ruling out of an erroneous $\Delta_f H^\circ_{298}(CrFO^+)$ limit derivation (Table 3, Entry 22).

While CrF_2O^+ could be obtained in traces, it was impossible to isolate it from the mixture of hydrolysis products, which included traces of NO^+, the intermediate N_2O^+ and the final product H_3O^+. For a discussion, we apply the three-item scheme already utilised for $CrFO^+$: (i) Endothermicity of the reaction (Table 3, Entry 23) can be ruled out (Table 3, Entry 21). (ii) Facile oxidation of CrF_2O^+ by N_2O would yield $CrF_2O_2^+$, i.e., a formal Cr^{VII} species, which could explain the observation of N_2O^+ and H_3O^+ when CrF^+_2 is exposed to N_2O according to Equations (7)−(11). Furthermore, it should be noted that $CrF_2O_2^+$ has been generated and its *IE* value determined.[43]

$$CrF_2 + N_2O \rightarrow CrF_2O^+ + N_2 \quad (7)$$

$$CrF_2O^+ + N_2O \rightarrow CrF_2O_2^+ + N_2 \quad (8)$$

$$CrF_2O_2^+ + N_2O \rightarrow CrF_2O_2^+ + N_2O^+ \quad (9)$$

$$N_2O^+ + H_2O \rightarrow N_2O + H_2O^+ \quad (10)$$

$$H_2O^+ + H_2O \rightarrow H_3O^+ + OH \quad (11)$$

While the generation of H_3O^+ from N_2O^+ via H_2O^+ is consistent with established thermochemical data (Table 4), and its temporal evolution appeared to be properly modelled, the temporal evolution of N_2O^+ could not be reproduced on the basis of Equations (7)−(11). Furthermore, the value of k_{11} obtained by modelling was about two orders of magnitude smaller than the literature value.[44] Consequently, the generation of N_2O^+ was attributed to a par-

ent ion or ions activated during the mass selection of CrF_2^+, and the formation of the formal Cr^{VII} species $CrF_2O_2^+$ from properly thermalised precursors was ruled out. (iii) As in CrF^+, the spin-inversion problem is a prime candidate for preventing the oxidation reaction of CrF_2^+.

In contrast to the CrF_n^+ cations discussed so far, CrF_3^+ reacts with N_2O to give CrF_3O^+ in good yields. Hence, an upper limit of $\Delta_f H°_{298}(CrF_3O^+)$ can be derived (Table 3, Entry 24). On combination with the ionisation energy of the corresponding neutral species (see Table 1), an upper limit of $\Delta_f H°_{298}(CrF_3O) < -177.9$ kcal mol^{-1} is obtained. Basically, our value is in agreement with literature data;[21] however, it is about 40 kcal mol^{-1} too large. Thus, the inverted procedure, i.e. combining the literature value of $\Delta_f H°_{298}(CrF_3O)$ with the *IE* determined in this study, provides a reasonable value for $\Delta_f H°_{298}(CrF_3O^+)$ as given in Table 4.

Another conclusion is that the spin conservation requirement no longer hampers the transfer of the oxygen atom to the chromium fluoride cation. This could be explained by the fact that as the oxidation state of the chromium centre increases, the spin-orbit coupling increases, thus enabling a more facile intersystem crossing (spin inversion) and, consequently, a lower reaction barrier. This explanation may also account for the trend in the oxidation efficiencies from Cr^+ and CrF^+ (no reactivity observed) via CrF_2^+ (traces of CrF_2O^+ generated) to CrF_3^+ (facile reaction), which parallels, at least qualitatively, the increasing formal oxidation state of the chromium centre.

Conclusion

In this study, we have investigated the reactions of chromium and chromium fluoride monocations CrF_n^+ (n = 0−4) with water. Besides slow condensation, Cr^+ is unreactive, whereas progressive hydrolysis of the Cr−F bonds proceeds for CrF^+, CrF_2^+, CrF_3^+, and CrF_4^+. However, for the species $CrF_2(OH)^+$, efficient proton abstraction parallels the hydrolysis of the next Cr−F bond, and in the case of $CrF_3(OH)^+$, that proton transfer is even preferred over further Cr−F bond hydrolysis.

Furthermore, we have investigated the reactions of chromium and chromium fluoride monocations with the established oxygen-transferring agent nitrous oxide. Significant transfer of oxygen was observed for CrF_3^+ only. The ionisation energy of CrF_3O is 11.3 ± 0.2 eV. Attempts to transfer the oxygen atom from CrF_3O^+ to small alkanes or to carbon monoxide failed.

Experimental Section

Reactants: Nitrogen trifluoride (Praxair, 99.99%), nitrous oxide (Linde, 99.5%), argon (AGA Gas, 99.996%), and solid chromium (Balzers, > 99.9%) were used as purchased. Tap water was used without further purification. The water was put into a half-micro test tube directly connected to the gas-inlet system of the mass spectrometer and degassed by two freeze-evacuate-thaw cycles. Hexafluoroacetone, C_3F_6O, was liberated from its sesquihydrate (Merck-Schuchardt, > 97%) by reaction with phosphoric anhydride, P_4O_{10}, in analogy to literature procedures.[45−47] The dehydration reaction was carried out in a half-micro test tube directly connected to a leak valve of the mass spectrometer. Due to the differences between the boiling points of hexafluoroacetone (−28 °C/p_0)[46] and its water-containing hydrate (55−56 °C/107 mbar),[48] we assumed the dehydration process to be complete in the sense that no hexafluoroacetone hydrate was admitted into the reaction cell from the leak valve. However, the admission of water itself to the reaction cell could not be prevented in this "on-line" preparation of hexafluoroacetone. All reactant gases not mentioned so far were purchased from Linde and used without further purification.

Mass Spectrometer: All experiments were performed with a Bruker Spectrospin CMS-47X Fourier transform ion-cyclotron resonance (FT-ICR) mass spectrometer. The setup and operation have been described previously.[49,50] In brief, chromium monocations were generated from targets of pure chromium by laser desorption/laser ionisation[51,52] in the external ion source of the spectrometer using an Nd:YAG laser (Spectron Systems, λ_{max} = 1064 nm). The chromium ions were extracted from the source and transferred into the analyser cell via a system of electrostatic potentials. Next, the most abundant isotope ^{52}Cr (relative abundance 83.8%[53]) was mass-selected using FERETS,[54] a computer-controlled ion-ejection protocol that combines frequency sweeps and single-frequency pulses to optimise resonant excitation and ejection of all unwanted ions. After mass-selection, $^{52}Cr^+$ cations were allowed to react with pulsed-in reactant gas mixtures as described below.

Reactions with Water: After mass-selection, $^{52}Cr^+$ ions were exposed to pulsed-in nitrogen trifluoride/argon mixtures. Both the composition of the gas mixture and the length of the gas pulse were adjusted to maximise the yield of the desired chromium fluoride cation, CrF_n^+ (n = 1−4). Subsequently, the ion of interest was mass-selected using FERETS. Electronically excited Cr^+ ions, which are known to be efficiently thermalised by collision with methane[55] rather than argon,[1] were allowed to multiply collide with pulsed-in methane. In an additional series of experiments, however, Cr^+ cations were allowed to react with water after multiple collisions with argon rather than with methane. CrF^+ ions which are known to require thermalisation as well[1] were allowed to undergo multiple collisions with water and re-isolated using FERETS. Thermalisation deemed unnecessary for CrF_n^+ (n = 2−4) due to the purely exponential decays of their intensities during the reactions investigated. Water was admitted to the cell via a leak valve at a constant pressure measured by a calibrated[56] BALZERS IMG 070 ion gauge. The effective water pressures were $7.7\cdot10^{-9}$ mbar, $4.7\cdot10^{-9}$ mbar, $2.5\cdot10^{-9}$ mbar, and $7.7\cdot10^{-9}$ mbar for CrF^+, CrF_2^+, CrF_3^+, and CrF_4^+, respectively. For Cr^+, the pressure was in the range of $6.5\cdot10^{-9}$ to $1.0\cdot10^{-5}$ mbar.

Reactions with Nitrous Oxide: After mass selection, $^{52}Cr^+$ ions were exposed to pulsed-in nitrogen trifluoride/argon or nitrogen trifluoride/nitrous oxide mixtures, respectively. Both the composition of the gas mixtures and the length of the gas pulse were adjusted to maximise the yield of the desired chromium fluoride cation, CrF_n^+ (n = 1−4), or oxochromium fluoride cation, CrF_nO^+ (n = 1−4). The ion of interest was isolated using FERETS. Reactant gases were admitted to the cell via a leak valve at a constant pressure in the order of 10^{-8} to 10^{-7} mbar while the background pressure in the analyser cell of the spectrometer was in the range of $(2-4)\cdot10^{-9}$ mbar. To generate the ions of interest, we employed, in that order, (i) the established methodology of generating chromium fluoride monocations using nitrogen trifluoride, NF_3, as the fluorinating

agent[1,2] and (ii) the time-honoured use of nitrous oxide, N_2O, for the transfer of the oxygen atoms. The latter has been proven to transfer oxygen to a wide variety of metal cations like Ti^+,[25] V^+,[25] Fe^+,[18,25] Zr^+,[25] Nb^+,[25] Mo^+ [57] and U_2^+.[58] It was not indicated to use the alternative approach of first generating chromium oxide monocations, CrO^+, and subsequently transferring fluorine atoms to them, due to the inefficient oxygen transfer to bare chromium ions, Cr^+,[25] which requires CrO^+ to be generated from CrO_2Cl_2.[33] CrF^+ ions, which are known to need thermalisation,[1] were allowed to multiply collide with nitrous oxide and re-isolated using FERETS. All other ions CrF_n^+ ($n = 2-4$) did not require thermalisation as mentioned above.

Analysis of Experimental Results: Elemental compositions of ions were determined by high-resolution mass spectrometry. Reaction sequences were derived from the temporal evolution of ion intensities and complementary double-resonance experiments.[59] In a double-resonance experiment, a supposed intermediate [e.g., $^{52}CrF(OH)^+$, $m/z = 87.94165$] is continuously ejected from the reaction cell by employing a constant radio-frequency pulse for a certain period of time. The resulting spectrum is compared with a reference spectrum originating from the very same experimental conditions, except that ejecting the supposed intermediate is replaced by "ejecting" a nonexisting hypothetical ion (e.g., $m/z = 500$). The disappearance of the signal of a product ion indicates that this ion originates, directly or indirectly, from the ejected one. Reaction kinetics were analysed using a computer program that determines rate constants and distribution ratios based on the experimentally observed evolution of ion intensities over time, and a flexible kinetic model.[60] The reported rate constants are measured bimolecular rate constants given in units of cm^3 $molecules^{-1}$ s^{-1}, whereas reaction efficiencies φ are given as fractions of the measured bimolecular rate constants and the gas-kinetic collision rates according to the capture theory.[28,29] The parameters used for H_2O were: dipole moment 1.854 D,[61] polarisability $1.45 \cdot 10^{-24}$ cm^3,[61] relative ion gauge sensitivity 0.97.[62] The parameters used for N_2O were: dipole moment 0.161 D,[61] polarisability $3.03 \cdot 10^{-24}$ cm^3,[61] relative ion gauge sensitivity 1.20.[62] The absolute error of the experimentally determined rate constants is in the range of ± 30%, while the relative rates are more precise (± 10%).[56] However, for reactions of CrF_n^+ ($n = 2-4$) ions with H_2O, the error is estimated to be in the range of ± 40% for the rate constants and ± 15% for their ratios due to the lower signal intensities. Ionisation energies can be determined by the "charge-transfer bracketing" method described in the following: In a series of experiments, the ion of interest is allowed to react with neutral species of known ionisation energies. Then, a *synopsis* of the ionisation energies of the reaction partners and the experimentally observed presence or absence of charge-transfer (CT) between the ion and the reaction partners allows for an estimation of the ionisation energy. Alternatively, the reaction efficiency φ of a charge-transfer reaction is correlated to the ionisation energy difference between the ion and its reaction partner: $\Delta_r G = \Delta_r G° - RT \ln K$ with $K = k_{CT}/k_{reverse\ CT}$, $k_{CT} = \ln(\varphi/\varphi_{max})$, and $k_{reverse\ CT} = 1 - \ln(\varphi/\varphi_{max})$.[32] Both methods rely on the reasonable assumption that the activation barriers associated with the charge-transfer reactions are negligible. Heats of formation $\Delta_f H°$ given in this publication, are in thermochemical kilocalories ($kcal_{th}$) unless otherwise stated. When converting published values given in kilojoules, a conversion factor of 1 $cal_{th} = 4.184$ J[63] was applied. Ionisation energies (*IE*) are given in electron volts (eV), the conversion factors are 1 eV = 96.48534 kJ mol^{-1} = 23.06055 kcal mol^{-1}.[64] On calculating ion heats of formation from heats of formation and ionisation energies of the corresponding neutral species, the "stationary electron" or "ion" convention[65] was applied. To convert the data obtained at 298 K so that they are consistent with the "thermal electron" or "electron" convention, the amount of 1.481 kcal mol^{-1} needs to be added.[65]

Synthesis and Coordination Chemistry of the New Unsymmetrical Ligand $Ph_2PCH_2NHC_6H_4PPh_2$

Qingzhi Zhang,[a] Stephen M. Aucott,[a] Alexandra M. Z. Slawin,[a] and J. Derek Woollins*[a]

Keywords: Unsymmetrical ligands / Phosphanes / Chelates / Monodentate complexes / Heterometallic complexes

Condensation of Ph_2PCH_2OH with 2-(diphenylphosphanyl)-aniline in toluene gave the new unsymmetrical ligand $Ph_2PCH_2NHC_6H_4PPh_2$ (**1**) in good yield. Oxidation of **1** with H_2O_2 or elemental sulfur led to the oxidised products $Ph_2P(O)CH_2NHC_6H_4P(O)Ph_2$ (**2**) and $Ph_2P(S)CH_2NHC_6H_4P(S)Ph_2$ (**3**). The new ligand **1** demonstrates three distinct modes of coordination. Reaction of compound **1** with $[MX_2(cod)]$ (M = Pd, Pt; X = Cl, Br, Me) or $[Mo(CO)_4(pip)_2]$ gave the chelate complexes $[PdCl_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**4**), $[PdBr_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**5**), $[PtCl_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**6**), $[PtMe_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**7**) and $[Mo(CO)_4(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**8**). Coordination of **1** with $[\{RuCl(\mu\text{-}Cl)(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})\}_2]$ or $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ gave the monodentate complexes $[RuCl_2(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**9**) and $[RhCl_2(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**10**). Reaction of **1** with $[\{IrCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ led to a mixture from which the monodentate complex $[IrCl_2(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**11**) and the chelate cationic complex $[IrCl(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)][Cl]$ (**12**) were separated. Abstraction of the chloride ligands from complexes **9** and **10** with $AgClO_4$ gave the cationic chelate complexes $[RuCl(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)][ClO_4]$ (**13**) and $[RhCl(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A][ClO_4]$ (**14**). Compound **1** also functions as a bridging ligand when reacted with two molar equivalents of [AuCl(tht)] or one molar equivalent of $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ to give the bimetallic complexes $[Ph_2P\{AuCl\}CH_2NHC_6H_4PPh_2\{AuCl\}]$ (**15**) and $[\{RhCl_2(\eta^5\text{-}C_5Me_5)\}_2(Ph_2PCH_2NHC_6H_4PPh_2)]$ (**16**). The dioxidised compounds **2** and **3** and several typical complexes **8**, **9**, **11** and **14** were structurally characterised by X-ray diffraction.

Introduction

Chemically symmetrical bisphosphane ligands have been intensively investigated in all aspects of inorganic and organometallic chemistry, and $Ph_2PCH_2PPh_2$ [bis(diphenylphosphanyl)methane (dppm)], $Ph_2PCH_2CH_2PPh_2$ [bis(diphenylphosphanyl)ethane (dppe)], and its $-(CH_2)_n-$ backboned homologues, the aromatic $Ph_2PC_6H_4PPh_2$ [1,2-phenylenebis(diphenylphosphane)] and the ferrocene backboned 1,1′-bis(diphenylphosphanyl)ferrocene are all well-known examples of this class of ligand.[1−9] Unsymmetric bisphosphanes, with the notable exception of chiral aminophosphane-phosphinites,[10] have received relatively little attention (for recent examples see refs.[11−15]). We recently described the synthesis of $Ph_2PC_6H_4NHPPh_2$ an unsymmetrical diphosphane derived from 2-(diphenylphosphanyl)-aniline[16] in which the two phosphorus atoms demonstrated different coordination activities.[17,18] Herein we report another unsymmetrical diphosphane $Ph_2PCH_2NHC_6H_4PPh_2$ which has an additional methylene spacer group between the NH and the PPh_2 moieties giving the ligand a flexible $PCNC_2P$ spine. Other rare literature examples of $PCNC_2P$ backboned ligand systems include diphenyl[3-(2-diphenylphosphanylphenylsydonyl)-phosphane[19] **A**, the substituted quinazolinone ligand **B**[20] and the bis(diphenylphosphanyl)- and bis(dicyclohexylphosphanyl)pyrrole-derived diphosphanes **C** and **D**[21] (Scheme 1). The synthesis of $Ph_2PCH_2NHC_6H_4PPh_2$ and its reactivity towards a variety of late transition metals are described. The products from these reactions have been characterised principally by multi-element NMR spectroscopy and X-ray crystallography.

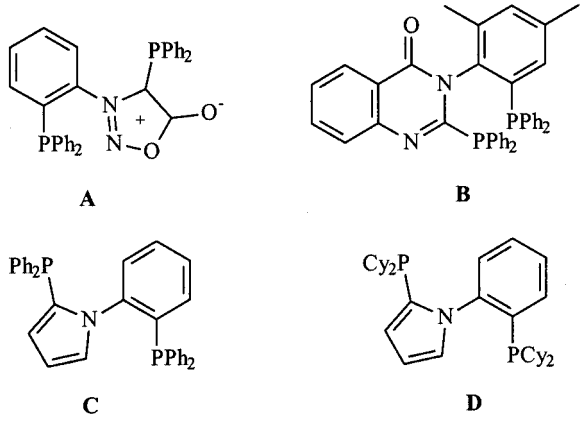
Results and Discussion

Preparation and Characterisation of the Ligand

The condensation of equimolar quantities of diphenylphosphanylmethanol and 2-(diphenylphosphanyl)aniline in toluene at 90−95 °C gave the unsymmetrical bisphosphane $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**) in excellent yield (84.4%) (Scheme 2). The white solid product was stable to moisture and air. The $^{31}P\{^1H\}$ NMR spectrum of **1** in $CDCl_3$ shows two distinct singlets at $\delta_P = -18.77$ and $\delta_P = -22.30$. Although it is not easy to assign the signals in reference to



Scheme 1. Examples of $PCNC_2P$ backboned ligands

the starting reactant 2-(diphenylphosphanyl)aniline[16] (**17**) or the previously reported $Ph_2PNHC_6H_4PPh_2$ [17] (**18**) (Scheme 2, Table 1), the resonance at $\delta_P = -18.77$ was assigned to the phosphorus (P_X) of the $NHCH_2PPh_2$ group and the other signal at $\delta_P = -22.30$ to the triarylphosphane moiety (P_A) by comparing the $^{31}P\{^1H\}$ NMR spectra of its monodentate complexes **9**−**11**, which will be discussed below. These assignments are also in accordance with those in other reported molecules (**19**−**22**)[22−25] shown below (Scheme 3, Table 1).

19[b]	−18.16	−			

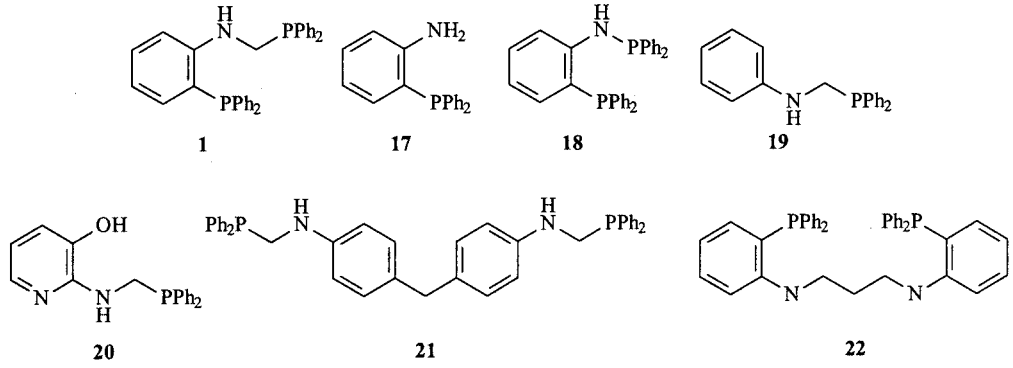
[a] P_X is the phosphorus of either $NHCH_2PPh_2$ or $NHPPh_2$ groups and P_A is the phosphorus of triarylphosphane. [b] Literature compounds.

In the ^1H NMR spectrum, the resonances of the aromatic protons are found between $\delta_H = 7.40$ and 6.64. The NH proton appears as a broad singlet at $\delta_H = 4.97$. The triplet at $\delta_H = 3.83$ was assigned to the methylene group, with equal couplings ($^3J_{P,CH} = {}^3J_{CH,NH} = 5$ Hz). The infrared spectrum of **1** shows ν_{NH} at 3345 cm^{-1}. Attempts to grow crystals of **1** suitable for X-ray analysis were not successful. However, the structures of its oxidised counterparts **2** (Figure 1, Table 2) and **3** (Figure 2, Table 2) were obtained. Compound **2** was prepared by the oxidation of **1** with H_2O_2 and compound **3** by oxidation of **1** with elemental sulfur.

Compounds **2** and **3**, like their parent compound **1**, gave good microanalysis and the expected FAB-MS spectral patterns. The $^{31}P\{^1H\}$ NMR spectrum of **2** (in CD_2Cl_2) exhibits two singlets at higher frequency than those of **1**. The singlet at $\delta_P = 36.38$ was assigned to the triarylphosphane (P_A) and that at $\delta_P = 28.58$ to the phosphorus (P_X) of the $NHCH_2PPh_2$ moiety by comparison with the signals of compounds **23** and **24** (Scheme 4, Table 3). The two singlets of compound **3** at $\delta_P = 39.35$ and 38.46 in CD_2Cl_2 were too close to be assigned unambiguously, but we have assigned the singlet at $\delta_P = 39.35$ to the triarylthiophosphinoyl (P_A) and that at $\delta_P = 38.46$ to the $NHCH_2P(S)Ph_2$ moiety (P_X) by comparing the signals with those of compounds **25** and **26** (Scheme 4, Table 3). The synthesis and complex formation of compounds **23**−**26** in Scheme 4 will be reported elsewhere.

The ^1H NMR spectra of **2** and **3** show similar aromatic proton signals to that of **1**. However, the NH resonance in **2** was obscured by the aromatic proton resonances; the ^1H-^1H COSY spectrum reveals that the NH signal lies at ca. $\delta_H = 7.30$. In compound **3** the NH signal was confirmed by an H/D exchange reaction. In both cases, the NH resonances are shifted to higher frequency by ca. 2 ppm relative to **1**. In the IR spectra, the ν_{NH} absorption was also shifted to lower frequency by 30 cm^{-1} for **2** and 138 cm^{-1} for **3**. This is attributed to the intramolecular hydrogen bonding interactions that occur in compounds **2** and **3**, as seen in the crystal structures.

In the solid state, **2** and **3** (Figure 1a and 2, respectively) both form an envelope-like pseudo six-membered ring via intramolecular hydrogen bonding interactions between the H(13n) and the O(2) or S(2) at P(2). The O(2) atom in compound **2** is 0.60 Å out of the P(2)−C(15)−C(14)−H(13n)−N(13) mean plane (mean deviation of 0.07 Å) with a fold angle of 32°. In compound **3**, the deviation of S(2) from the P(2)−C(15)−C(14)−H(13n)−N(13) mean plane (mean deviation from each other 0.05 Å) of −1.27 Å is bigger than that in compound **2** due to the different bond lengths of P=O and P=S (Table 2), as well as the strength of the H bonding [H(13n)···O(2): 1.98 Å; O(2)···H(13n)−N(13): 144°; H(13n)···S(2): 2.47 Å; S(2)···H(13n)−N(13): 144°]. The hinge angle between the S(2)−P(2)−H(13) plane and the P(2)−C(15)−C(14)−H(13n)−N(13) mean plane along the P(2)−H(13n) axis is 46°. In addition to the intramolecular hydrogen bonding, compounds **2** and **3** share other common features: the two P=E (E = O, S) groups lie in an *anti*-position; the geometry around each phosphorus atom is approximately tetrahedral; the main skeleton of molecules **2** and **3** — P(2)−C(15)−C(14)−N(13)−C(13) — lies in a mean plane with a mean deviation of 0.04 Å and 0.02 Å, respectively. The planar skeleton can be explained from the sp^2 hybrid state of C(15) and C(14) as well as the conjugation of N(13) with the aromatic ring. The C(14)−N(13)−C(13) bond angle is 124.5(4)° and 126.0(2)° in **2** and **3**, respectively. There is one additional feature in



Scheme 3. Compound **1** and other related molecules

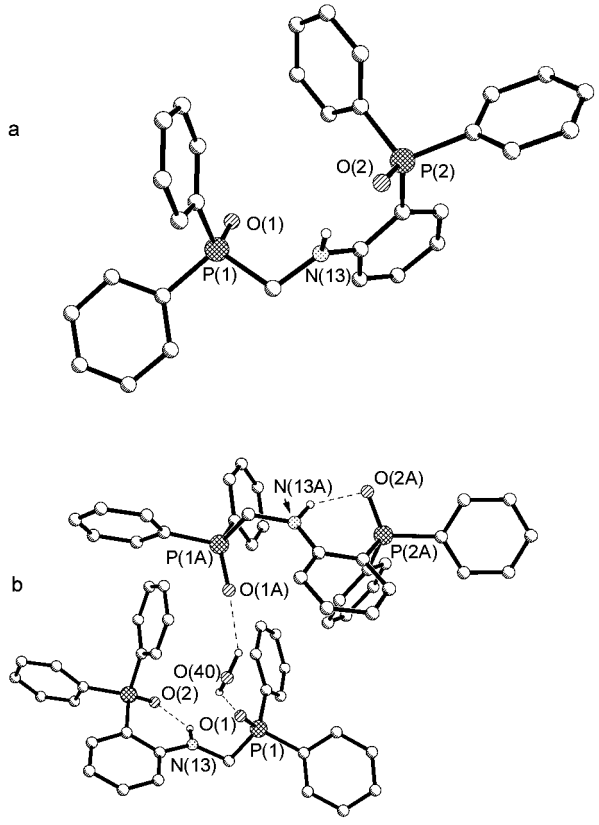


Figure 1. (a) Crystal structure of $Ph_2P(O)CH_2NHC_6H_4P(O)Ph_2$ (**2**): a single molecule; (b) crystal structure of $Ph_2P(O)CH_2NHC_6H_4P(O)Ph_2$ (**2**) showing the hydrogen bonded dimer pairs

compound **2** (Figure 1b) that is not observed in compound **3**: each molecule of **2** crystallises with 0.5 molecules of water. The water links two molecules of **2** through weak intermolecular hydrogen bonding interactions with the oxygen atom of the $NCH_2P(O)Ph_2$ moiety and O(1) and O(1A) [O(1)···H(40): 2.49 Å; O(1)···H(40)−O(40): 102°]. Therefore, it is not surprising to see that there is little difference between the two P=O bond lengths [P(1)−O(1): 1.487(3) Å; P(2)−O(2): 1.483(4) Å] in compound **2**, while, in contrast, P(2)−S(2) [1.9719(11) Å] is longer than P(1)−S(1) [1.9443(12) Å] in **3**.

Coordination Chemistry of Compound 1

Both of the phosphorus atoms of **1** can coordinate with late transition metals. When reacted with Pd^{II}, Pt^{II} or Mo^0, **1** functions as a bidentate ligand to give the seven-membered chelate complexes **4**−**8** (Scheme 5). However, due to their different chemical environments the reactivity of the two phosphorus atoms is different. The less bulky and less

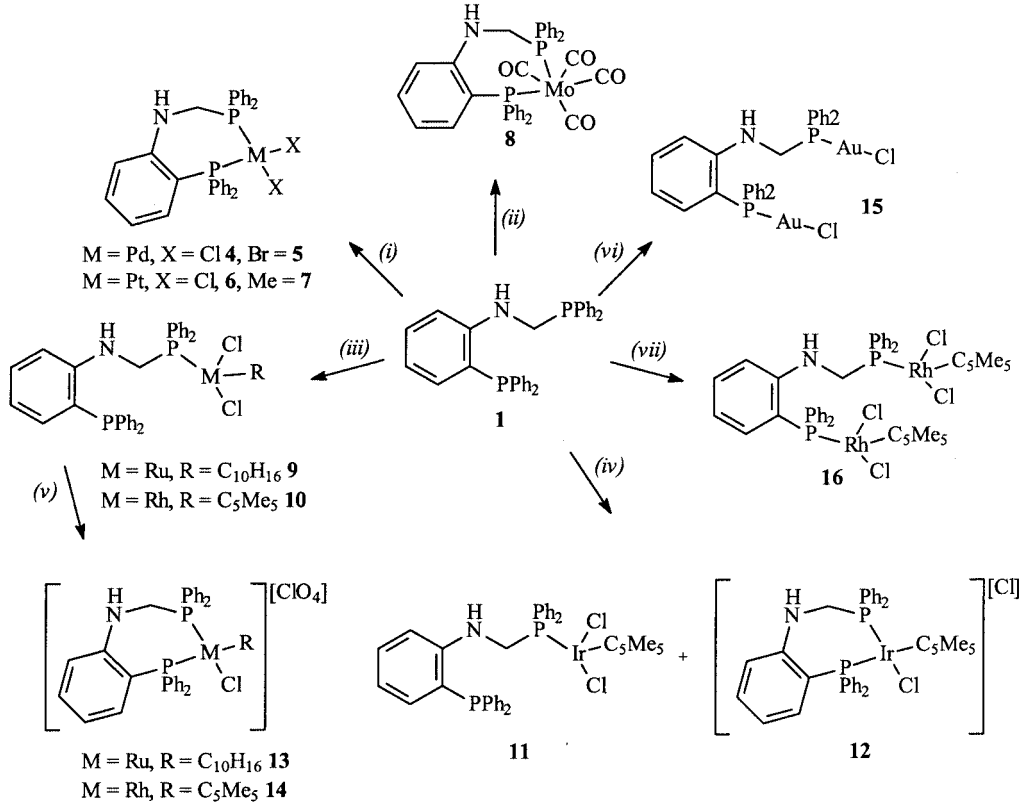
[a] P_X is the phosphorus of $NHCH_2PPh_2$ groups and P_A is the phosphorus of triarylphosphane.

electron-delocalized phosphorus (P_X) of the $NHCH_2PPh_2$ group is more reactive than triarylphosphane (P_A). When **1** reacts with Rh^{III}/Ru^{IV} chloride-bridged dimers in a 2:1 molar ratio, the "dangling" monodentate complexes **9** and **10** were obtained (Scheme 5). However, reaction of **1** with $[\{IrCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ in a 2:1 molar ratio led to the cationic chelate complex **12** together with monodentate **11**. Abstraction of chloride from **9** and **10** with silver perchlorate gave the cationic chelate complexes **13** and **14**. When [AuCl(tht)] was employed, both (P_X) and (P_A) in **1** coordinate to the gold centre. We believe that steric effects control the reaction. Changing the reactants molar ratio also change the products: when two molar equivalents of [AuCl(tht)] or one molar equivalent of $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ was reacted with ligand **1**, the bidentate bridging complexes **15** and **16** were obtained (Scheme 5).

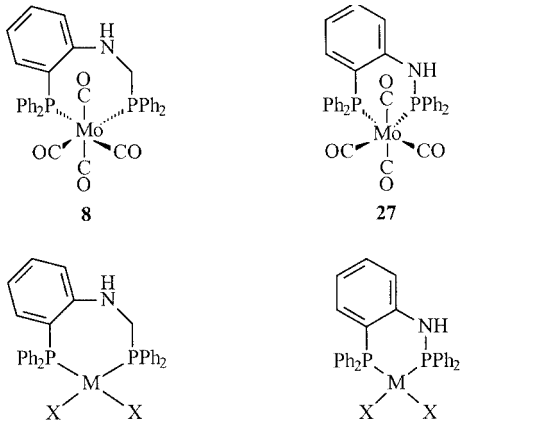
Bidentate Chelate Complexes

Reactions of equimolar quantities of ligand **1** and $[PdCl_2(cod)]$, $[PdBr_2(cod)]$, $[PtCl_2(cod)]$, $[PtMe_2(cod)]$ or $[Mo(CO)_4(pip)_2]$ gave the corresponding seven-membered ring chelate complexes $[PdCl_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**4**), $[PdBr_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**5**), $[PtCl_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**6**), $[PdMe_2(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**7**) and $[Mo(CO)_4(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**8**), respectively. All of the



Scheme 5. (i) $[MX_2(cod)]$ (M = Pd, X = Cl or Br; M = Pt, X = Cl or Me); (ii) $[Mo(CO)_4(pip)_2]$; (iii) 0.5 equiv. of $[\{RuCl(\mu\text{-}Cl)(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})\}_2]$ or $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$; (iv) 0.5 equiv. of $[\{IrCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$; (v) $AgClO_4$; (vi) 2 equiv. of [AuCl(tht)]; (vii) $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$

complexes gave satisfactory microanalysis and the expected fragmentation patterns in their positive ion FAB mass spectra. In the $^{31}P\{^1H\}$ NMR spectra of **4** and **5** no ^{31}P-^{31}P coupling was observed, both compounds displayed two singlets at around $\delta_P = 42$ and $\delta_P = 21$. The $^{31}P\{^1H\}$ NMR spectra of the platinum complex **6** exhibited a two-bond ^{31}P-^{31}P coupling and the expected platinum satellites at $\delta_P = 20.25$ (d, $^1J_{Pt,P} = 3647$ Hz, $^2J_{P,P} = 18$ Hz) and $\delta_P = 1.80$ (d, $^1J_{Pt,P} = 3573$, $^2J_{P,P} = 18$ Hz). The large one-bond ^{31}P-^{195}Pt coupling constants are in agreement with the proposed *cis*-geometry of **6**. In compound **7**, two doublets at $\delta_P = 30.73$ and 11.91 ($^2J_{P,P} = 12$ Hz) with platinum satellites are observed. The coupling constants $^1J_{Pt,P} = 1853$ Hz and $^1J_{Pt,P} = 1720$ Hz are in agreement with those coupling constants found in compounds in which phosphane ligands are *trans* to methyl groups. The molybdenum complex **8** also displays coupling of the two phosphorus atoms at $\delta_P = 41.43$ and $\delta_P = 28.31$ ($^2J_{P,P} = 25$ Hz) in the $^{31}P\{^1H\}$ NMR spectrum. The assignment of the phosphorus resonances in the above chelate complexes is not straightforward. However, by comparing them with the corresponding complexes of $PPh_2C_6H_4NHPPh_2$ [18] (Scheme 6, Table 4), we assigned the signal at higher frequency in the $^{31}P\{^1H\}$ NMR spectra of each chelate complex to the phosphorus of the $NHCH_2PPh_2$ group (P_X) and the lower frequency resonance to the triarylphosphane (P_A). The ^1H NMR spectra of **4**–**8** show similar patterns for the aromatic proton resonances, although the NH and CH_2 signals are slightly different depending upon the nature of the solvent and the complexes. The NH resonances of **4** and **5** appear as broad doublets of triplets in [D$_6$]DMSO at $\delta_H = 5.53$ ($^3J_{PN,CH} = 10$, $^3J_{NH,CH} = 3$ Hz) and $\delta_H = 5.44$ ($^3J_{PN,CH} = 25$, $^3J_{NH,CH} = 3$ Hz), respectively. Their CH_2 signals were found at ca. $\delta_H = 3.9$ as a triplet ($^2J_{P,CH} = {}^3J_{NH,CH} = 3$ Hz).



Scheme 6. Chelate complexes of **1** and $Ph_2NHC_6H_4PPh_2$

In the ^1H NMR spectrum of **6**, the doublet of triplets signal of NH was observed at $\delta_H = 3.55$ ($^3J_{NH,CP} = 16$ Hz). The doublet of doublets with two platinum satellites ($^3J_{Pt,CH} = 36$ Hz) at $\delta_H = 3.96$ was assigned to CH_2. The coupling constants $^2J_{P,CH} = 3$ Hz and $^3J_{NH,CH} = 6$ Hz were determined by an exchange reaction with D_2O.

Table 4. Chemical shifts of complexes **4**–**8** and those from $Ph_2PNHC_6H_4PPh_2$

Complex	Chemical shifts $\delta(P_X)$[a]	$\delta(P_A)$[a]	Complex	Chemical shifts $\delta(P_X)$[a]	$\delta(P_A)$[a]
8	41.43	28.31	**27**[b]	91.7	33.6
4	42.72	22.98	**28**[b]	77.8	18.1
5	41.93	20.55			
6	20.25	1.80	**29**[b]	53.8	−0.4
7	30.73	11.91	**30**[b]	70.6	10.7

[a] P_X is the phosphorus of either $NHCH_2PPh_2$ or $NHPPh_2$ groups and P_A is the phosphorus of triarylphosphane. [b] Literature complexes.[8]

In the ^1H NMR spectrum of complex **7**, the NH and CH_2 resonances overlap at $\delta_H = 3.99$. Addition of D_2O to the $CDCl_3$ solution of **7** gives a $^2J_{P,CH}$ coupling constant of 9 Hz. Other information obtained from this compound is the two doublets of doublets at $\delta_H = 0.60$ and 0.34 with platinum satellites for two CH_3 groups. Although the coupling constants are available ($^3J_{P,CH} = 7$, $^3J_{P',CH} = 9$, $^2J_{Pt,CH} = 70$, $^2J_{Pt,CH'} = 69$ Hz) the accurate assignment of the two doublets is impossible. The resonance for the NH proton in complex **8** was obscured by aromatic multiplets. The CH_2 group in **8** appears as a broad singlet at $\delta_H = 4.04$.

In the infrared spectra, compounds **4**, **5** and **6** show the ν_{NH} absorption at around 3250 cm^{-1}, shifted to lower frequency relative to **1**. Metal-halide stretches at ca. 320 cm^{-1} and 290 cm^{-1} are in agreement with the *cis*-geometry of the complexes. However, the ν_{NH} absorption at 3337 cm^{-1} in compound **7** and 3389 cm^{-1} in **8** occurs at a significantly higher frequency than in **4**–**6**. Obviously there is less opportunity for hydrogen bonding between the NH proton of the ligand and the methyl or carbonyl groups of **7** and **8**, respectively, than between the metal-bound chlorides and the amine protons of complexes **4**–**6**. The infrared spectrum of compound **8** also displayed $\nu_{C\equiv O}$ absorption bands at 2013 cm^{-1}, 1914 cm^{-1}, 1892 cm^{-1} and 1878 cm^{-1}.

Pale yellow crystals of **8** suitable for X-ray analysis (Figure 3, Table 5) were obtained by layering methanol onto a dichloromethane solution of **8** for four days. As shown in Figure 3, the coordination geometry around Mo(1) is approximately octahedral, with P(1) and P(2) occupying the *cis* positions. The bite angle of the ligand is 87.47(2)°, slightly less than the expected 90° for a regular octahedron. The *cis* bond angles at Mo(1) are 84.29(2)–91.51(11)°, while the *trans* angle are in the range 172.59(10)–176.66(8)°. The seven-membered chelate ring is twisted, with N(13)–C(14)–C(15)–P(1)–P(2) coplanar (mean deviation 0.01 Å) and C(13) lying 0.96 Å above, and Mo(1) 1.49 Å below, the mean plane. The fold angles between the N(13)–C(14)–C(15)–P(1)–P(2) mean plane and the N(13)–C(13)–P(1) and P(2)–Mo(1)–P(1) planes are 54° and 88° respectively. The N(13)–C(14)–C(15) [124.7(2)°] and C(14)–C(15)–P(2) [124.6(2)°] bond angles are slightly more open than those in compounds **2** and **3**.

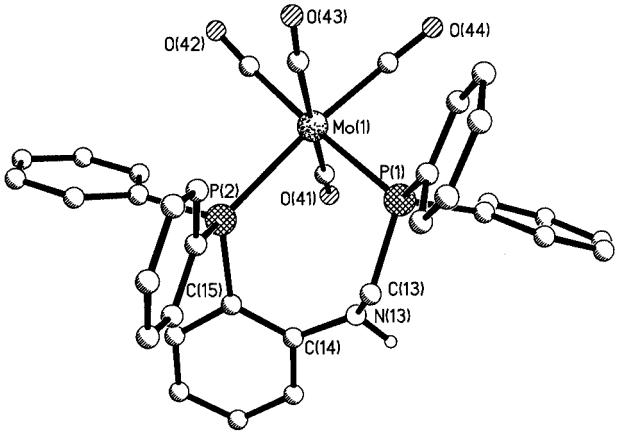

Figure 3. Crystal structure of $[Mo(CO)_4(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**8**)

Monodentate Complexes

Monitoring of the reaction between **1** and either $[\{RuCl(\mu\text{-}Cl)(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})\}_2]$ or $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ by $^{31}P\{^1H\}$ NMR spectroscopy showed that the monodentate complexes $[RuCl(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**9**) and $[RhCl(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**10**) are readily formed. The reaction of $[\{IrCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ and **1**, however, is not so straightforward. Several singlets between $\delta_P = 0.0$ and $\delta_P = -22$ appear in the crude reaction mixtures. Longer reaction times do not affect the product distribution. After several attempts to separate this mixture a monodentate complex $[IrCl(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**11**) was isolated as well-formed crystals from dichloromethane/acetone in low yield. Also obtained was the chelate cationic complex $[Ir(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)]$ (**12**), although in much lower purity.

All of the monodentate complexes gave satisfactory microanalysis and the expected fragmentation patterns and molecular ions in the positive ion FAB mass spectra. Compound **9**−**11** have similar $^{31}P\{^1H\}$ NMR spectra, with the coordinated phosphorus resonance shifted to higher frequency and that of the dangling phosphorus at ca. $\delta_P = -22.5$ unmoved. For the rhodium complex **10**, a typical $^1J_{Rh\text{-}P}$ coupling constant of 141 Hz was observed at $\delta_P = 32.74$. The higher-frequency signal was assigned to the phosphorus of the $NHCH_2PPh_2$ group (P_X) and the unshifted $\delta_P = -22.5$ to triarylphosphane (P_A). This assignment was confirmed by single-crystal X-ray diffraction studies of complexes **9** and **11** (see below).

The ^1H NMR spectra of **9**−**11** show aromatic proton resonances close to the values for the free ligand. The signals for the NH and methylene protons of the complexes are slightly different. Complexes **10** and **11** display a slightly broad quadruplet for NH at ca. $\delta_H = 4.9$ ($^3J_{NH,CH} = {}^3J_{NH,CP} = 7$ Hz) and a doublet at $\delta_H = 4.48-4.66$ for CH_2. No coupling between the CH_2 protons and the phosphorus was observed. In complex **9**, the NH proton signal is a well-resolved multiplet at $\delta_H = 4.95$. The CH_2 group was observed as a doublet of doublets at $\delta_H = 4.59$. The coupling constants were verified by H/D exchange with D_2O ($^2J_{P,CH} = 2$, $^3J_{NH,CH} = 6$ Hz). Complexes **10** and **11** show coupling between (P_X) and the methyl protons of the pentamethylcyclopentadienyl group, [$J_{P\cdots CH} = 3$ Hz]. The complicated signals of complex **9** were also assigned by a ^1H-^1H COSY spectrum. The IR spectra of **9**−**11** show the ν_{NH} absorption at about 3320 cm^{-1}, implying little hydrogen bonding.

Slow evaporation of a dichloromethane solution of **9** gave well-formed deep purple crystals suitable for X-ray analysis. The crystal structure of **9** (Figure 4, Table 6) reveals a monodentate complex coordinated by the $NHCH_2PPh_2$ phosphorus atom, whilst the triarylphosphane moiety remains unbound. The Ru(1) centre adopts an approximately trigonal bipyramidal geometry with Cl(1) and Cl(2) occupying the axial sites while P(1) and the two allylic groups occupy the equatorial positions. The arrangement of the allylic groups, which have local C_2 symmetry, is similar to that found in related complexes.[26] The ligand backbone

P(2)−C(15)−C(14)−N(13), as observed in **2**, **3**, and **8**, is coplanar (mean deviation 0.01 Å). The dangling phosphorus P(2) remains pyramidal as expected.

C(15)−P(2)−C(26)	103.4(6)	102.2(3)

The X-ray structure of **11** (Figure 5) shares many common features with **9**: the pendant triarylphosphane P(2) adopts a pyramidal geometry; the main backbone of the ligand extends in a mean plane P(2)−C(15)−C(14)−N(13) (mean deviation 0.06 Å); the bond lengths and angles (Table 6) are in the expected range; no hydrogen bonding is observed. The geometry around Ir(1) can be viewed as a three-legged "piano stool" with the two chlorides and the phosphorus P(1) supporting the pentamethylcyclopentadienyl top. The bond angles between the "legs" are approximately 90°.

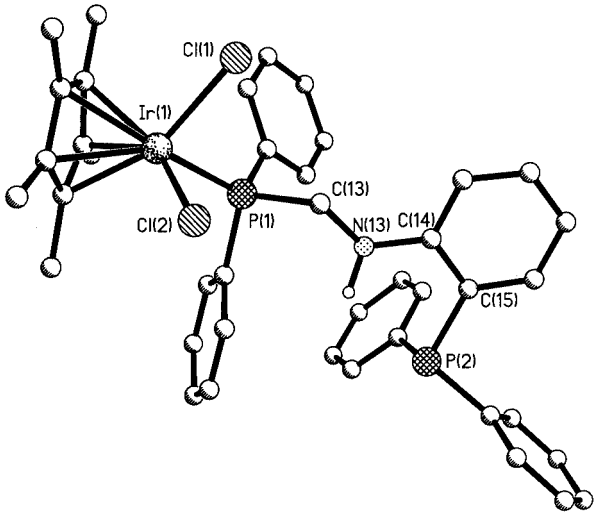

Figure 5. Crystal structure of $[IrCl_2(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X)]$ (**11**)

Cationic Chelate Complexes

As mentioned above, a cationic chelate complex of iridium(III) **12** formed together with the monodentate species **11**. Other cationic chelate complexes of ligand **1** can be obtained by abstraction of a chloride ligand from the monodentate complexes. For example, abstraction of one chloride from complexes **9** and **10** with $AgClO_4$ gave the chelate cationic complexes $[RuCl(\eta^3{:}\eta^3\text{-}C_{10}H_{16})(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)][ClO_4]$ (**13**) and $[RhCl(\eta^5\text{-}C_5Me_5)(Ph_2PCH_2NHC_6H_4PPh_2\text{-}P_X,P_A)][ClO_4]$ (**14**), respectively. Both complexes gave satisfactory microanalysis and positive FAB mass spectra. Their IR spectra displayed the ν_{NH} at 3272 cm^{-1} and 3332 cm^{-1}, respectively, and the strong band of ClO_4^- at ca. 1095 cm^{-1}. The $^{31}P\{^1H\}$ NMR spectrum of **13** showed two singlets at $\delta_P = 36.89$ and $\delta_P = 21.86$ in $CDCl_3$, which were assigned to the phosphorus atoms of the $NHCH_2PPh_2$ (P_X) and the triarylphosphane (P_A) groups, respectively, by reference to the other chelate complexes mentioned above. The ^1H NMR spectrum of **13** showed a broad singlet at $\delta_H = 5.02$ for NH and a doublet of doublet of doublets at $\delta_H = 4.67$ for the ligand methylene protons with $^3J_{NH,CH} = 6$, $^3J_{P,CH} = 15$ Hz and $^2J_{P,CH} = 52$ Hz. Characterisation of **14** by multinuclear NMR proved unsuccessful. The $^{31}P\{^1H\}$ NMR spectrum of **14** exhibited very broad peaks around $\delta_P = 31$ and $\delta_P = 37$, and the ^1H NMR spectrum of this compound also contains broad resonances. The low solubility of **14** in common organic solvents precludes a low temperature NMR study. In solution we believe that there may be an exchange process between several species taking place, possibly the cationic chelate, a monodentate species and perhaps even a cationic bidentate bridging species.

In spite of the uninformative NMR spectroscopic data we were able to obtain single crystals of compound **14** enab-

ling characterisation by X-ray crystallography (Figure 6, Table 7). The crystal structure of **14** reveals that the complex adopts a chair-like seven-membered chelate ring with a ligand bite angle P(1)−Rh(1)−P(2) of 95.12(4)°. The top mean plane of the "chair", C(14)−C(15)−P(2)−N(13) (mean deviation 0.02 Å), is 123° folded back from the "back of the chair", N(13)−P(2)−C(13)−Rh(13) mean plane (mean deviation 0.12 Å). The "bottom of the chair", P(1)−Rh(1)−C(13), is 144° folded forward from the N(13)−P(2)−C(13)−Rh(13) mean plane. Again, the coordination around the rhodium adopts a three-legged "piano stool" geometry. The crystal structure also displays two weak hydrogen bonding interactions between the NH and two of the oxygen atoms of the tetrahedral ClO_4^- anion [H(13n)···O(1): 2.42 Å; H(13n)···O(3): 2.44 Å; N(13)−H(13n)···O(1): 145°; N(13)−H(13n)···O(3): 157°]. The crystal structure also reveals that each molecule of complex **14** crystallises with 0.25 molecules of dichloromethane.

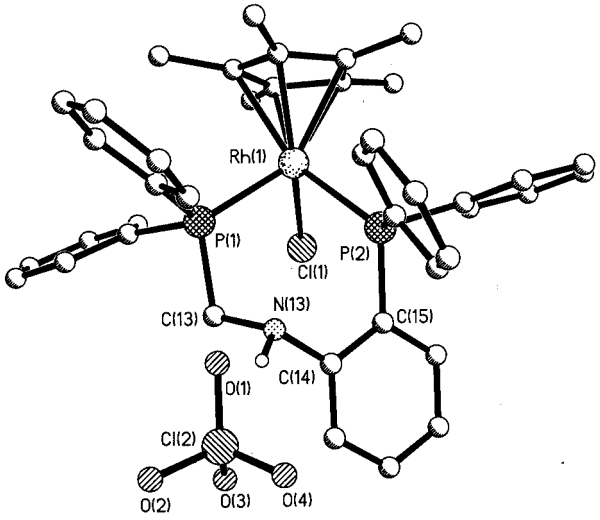

Figure 6. Crystal structure of [RhCl(η^5-C_5Me_5)($Ph_2PCH_2NHC_6H_4PPh_2$-P_X,P_A][ClO_4] (**14**); the solvent of crystallisation is omitted for the sake of clarity

Bimetallic Complexes

While the Ru^{IV} or Rh^{III} metal centres of the bulky dimers [{RuCl(μ-Cl)(η^3:η^3-$C_{10}H_{16}$)}$_2$] and [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] selectively coordinate through the (P_X) or $NHCH_2PPh_2$ moiety of ligand **1**, [AuCl(tht)] displays no such selectivity for either (P_A) or (P_X) of ligand **1**. The reaction between [AuCl(tht)] and **1** in a 1:1 ratio showed two broad peaks at δ_P = 33.4 and 25.0 in the $^{31}P\{^1H\}$ NMR spectrum, implying that both (P_X) and (P_A) were involved in some type of coordination. Workup of this mixture was not attempted. Addition of one more molar equivalent of [AuCl(tht)] to this mixture led to the same bidentate bridging complex **15** as in the one step reaction of [AuCl(tht)] with **1** in a 2:1 molar ratio. Complex **15** exhibits two sharp singlets at δ_P = 24.95 and δ_P = 18.64 which are assigned to (P_X) of the $NHCH_2PPh_2$ group and the (P_A) of the triarylphosphane according to the general trend of the complexes discussed in this paper. The ^1H NMR spectrum of **15** showed a well-resolved and well-shaped multiplet at δ_H = 4.94 for the NH proton and a doublet of doublets at δ_H = 4.34 for CH_2. A ^1H-^1H COSY spectrum of the compound in $CDCl_3$ showed no coupling between the NH and aromatic proton 6-H. Therefore it was concluded that both of the phosphorus atoms coupled with the NH group. The coupling constants were obtained through a D_2O exchange reaction in $CDCl_3$ solution ($^2J_{P,CH}$ = 3, $^3J_{NH,CH}$ = 6, $^3J_{PC,NH}$ = $^4J_{PCCNH}$ = 3 Hz).

The reaction of [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] with **1** in a 1:1 molar ratio gave another bimetallic complex [{$RhCl_2$(η^5-C_5Me_5)}$_2$($Ph_2PCH_2NHC_6H_4PPh_2$)] (**16**). The $^{31}P\{^1H\}$ NMR spectrum of **16** displays two doublets at δ_P = 32.44 ($^1J_{Rh,P}$ = 138 Hz) and δ_P = 27.79 ($^1J_{Rh,P}$ = 144 Hz). Upon comparison with the $^{31}P\{^1H\}$ NMR spectrum of **9**, the doublet at δ_P = 32.44 was assigned to the $NHCH_2PPh_2$ group (P_X), and the other at δ_P = 27.79 to the triarylphosphorus atom (P_A). The ^1H NMR spectrum of **16** displayed two doublets for the two pentamethylcyclopentadienyl groups. The NH resonance appears at δ_H = 5.33 as a broad triplet and that of the ligand methylene protons at δ_H = 4.90 as a broad doublet of doublets ($^3J_{NH,CH}$ = 5, $^2J_{P,CH}$ = 16 Hz). Both bridging complexes gave satisfactory microanalysis and the anticipated FAB mass spectral patterns. Their IR spectra show vibrations for ν_{NH} at 3309 and 3280 cm^{-1} and $\nu_{M\text{-}Cl}$ at 329 and 398 cm^{-1}, respectively.

Conclusion

We have shown that the unsymmetrical bisphosphane ligand $Ph_2PCH_2NHC_6H_4PPh_2$ is readily prepared by the condensation of diphenylphosphanylmethanol (Ph_2PCH_2-OH) and 2-(diphenylphosphanyl)aniline ($Ph_2PC_6H_4NH_2$), and that treatment of $Ph_2PCH_2NHC_6H_4PPh_2$ with H_2O_2 or elemental sulfur gives rise to the dioxide and disulfide. In addition, we have clearly demonstrated that $Ph_2PCH_2NHC_6H_4PPh_2$ has the potential to ligate in a variety of bonding modes. The different steric properties or ba-

sicities of the two phosphorus centres can be exploited to obtain mononuclear complexes where $Ph_2PCH_2NHC_6H_4PPh_2$ is monodentate (via the Ph_2PCH_2 moiety) or chelating, and this latter bonding mode can also be induced by the use of a halide abstracting agent such as Ag^I.

Binuclear complexes where $Ph_2PCH_2NHC_6H_4PPh_2$ adopts a bidentate bridging coordination mode are also readily accessible. The compounds described represent rare examples of either complexes containing $PCNC_2P$ pendant ligands or $MPCNC_2P$ metallacycles. Further studies are currently in progress into the synthesis of heterobimetallic complexes of late transition metals of $Ph_2PCH_2NHC_6H_4PPh_2$ and the coordination properties of its dichalcogen derivatives $Ph_2P(O)CH_2NHC_6H_4P(O)Ph_2$ and $Ph_2P(S)CH_2NHC_6H_4P(S)Ph_2$.

Experimental Section

General: All solvents and reagents were purchased from Aldrich and Lancaster. Dichloromethane was heated to reflux over powdered calcium hydride and distilled under nitrogen. Diethyl ether and tetrahydrofuran were purified by reflux over sodium/benzophenone and distillation under nitrogen. Ligand preparations were performed under an oxygen-free nitrogen atmosphere using standard Schlenk techniques. Coordination reactions and workup were performed in dry solvents. 2-(Diphenylphosphanyl)aniline,[16] diphenylphosphanylmethanol,[27] $[MX_2(cod)]$ (M = Pt, X = Cl or Me; M = Pd, X = Cl, Br; cod = cycloocta-1,5-diene),[28−30] $[Mo(CO)_4(pip)_2]$ (pip = piperidine),[31] [AuCl(tht)] (tht = tetrahydrothiophene),[32] $[\{MCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (M = Rh, Ir),[33] and $[\{RuCl(\mu\text{-}Cl)(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})\}_2]$[34] were prepared using literature procedures.

Infrared spectra were recorded (KBr discs) on a Perkin−Elmer system 2000 spectrometer, and ^1H NMR spectra (300 MHz) on a Varian Gemini 2000 spectrometer, $^{31}P\{^1H\}$ NMR spectra at 101.3 MHz with δ referenced to external 85% H_3PO_4. Microanalysis were performed by the University Service within this Department and fast atom bombardment (FAB) or chemical ionization (CI) mass spectra by the Swansea Mass Spectrometer Service. Precious metal salts were provided on loan by Johnson Matthey plc.

2-$Ph_2PC_6H_4NHCH_2PPh_2$ (1): Ph_2PCH_2OH (3.00 g, 13.87 mmol) was added to a solution of 2-(diphenylphosphanyl)aniline (3.84 g, 13.85 mmol) in toluene (150 cm^3). The reaction mixture was stirred at 90−95 °C for 20 h. The solvent was removed in vacuo and the sticky residue was dissolved in 20 cm^3 of Et_2O. Degassed absolute ethanol (100 cm^3) was then added to the ether solution and the mixture was concentrated in vacuo until a white solid began to precipitate. Storage in the fridge overnight and filtration gave the product as a white solid. Yield: 5.46 g (84.4%). $C_{31}H_{27}NP_2$ (475.5): calcd. C 78.30, H 5.72, N 2.95; found C 77.17, H 5.48, N 2.75. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −22.30 (s, P_A), −18.77 (s, P_X). ^1H NMR ($CDCl_3$): δ = 3.83 (t, $^2J_{P,CH} = {}^3J_{CH,NH}$ = 5 Hz, 2 H, CH_2), 4.97 (br. s, 1 H, NH), 6.64 (t, 1 H, ArH), 6.80 (m, 2 H, ArH), 7.40−7.20 (m, 21 H, ArH). IR (KBr disc): ν_{NH} = 3345m cm^{-1}. CI-MS: *m*/*z* = 476 $[M + H]^+$.

$Ph_2P(O)CH_2NHC_6H_4P(O)Ph_2$ (2): Aqueous hydrogen peroxide (30% w/w, 0.17 cm^3, 1.5 mmol) was added dropwise to a solution of **1** (0.355 g, 0.75 mmol) in THF (20 cm^3) and the mixture was stirred for 1.5 hours at 0−5 °C. The solvent was then removed in vacuo to give a viscous oil which was taken up in dichloromethane (20 cm^3) and dried over magnesium sulfate. The drying agent was removed by filtration and the filtrate was evaporated to dryness. Addition of diethyl ether to the residue precipitated the product. The product was collected by suction filtration and dried in vacuo. Yield: 0.275 g (73%). $C_{31}H_{27}NO_2P_2$ (507.5): calcd. C 73.37, H 5.36, N 2.76; found C 71.01, H 5.29, N 2.74. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 28.58 (s, P_X), 36.38 (s, P_A). ^1H NMR ($CDCl_3$): δ = 4.04 (dd, $^3J_{NH,CH}$ = 6, $^2J_{P,CH}$ = 9 Hz, 2 H, CH_2), 6.59−6.53 (m, 1 H, ArH), 6.78−6.70 (m, 2 H, ArH), 7.68−7.26 (m, 22 H, NH + ArH). IR (KBr disc): ν_{NH} = 3315m cm^{-1}, $\nu_{P=O}$ = 1179vs, 1167vs, 1118vs cm^{-1}. FAB: *m*/*z* = 508 $[M + H]^+$, 530 $[M + Na]^+$.

$Ph_2P(S)CH_2NHC_6H_4P(S)Ph_2$ (3): Compound **1** (0.582 g, 1.224 mmol) and elemental sulfur (0.079 g, 2.47 mmol) were stirred in THF (20 cm^3). A white solid began to precipitate in 10 minutes. Stirring was continued overnight and the product was collected by suction filtration, washed with diethyl ether (3 × 1 cm^3) and dried in vacuo. Yield: 0.519 g (78.6%). $C_{31}H_{27}NS_2P_2$ (539.6): calcd. C 69.00, H 5.04, N 2.60; found C 69.09, H 4.94, N 2.68. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = 38.46 (s, P_X), 39.35(s, P_A). ^1H NMR (CD_2Cl_2): δ = 4.12 (dd, $^3J_{NH,CH}$ = 5, $^2J_{P,CH}$ = 7 Hz, 2 H, CH_2), 6.75−6.33 (m, 3 H, ArH), 7.03 (br. q, $^3J_{NH,CH} = {}^3J_{NH,CP}$ = 5 Hz, 1 H, NH), 7.67−7.27 (m, 21 H, ArH). IR (KBr disc): ν_{NH} = 3287m cm^{-1}. FAB: *m*/*z* = 540 $[M + H]^+$, 562 $[M + Na]^+$.

[$PdCl_2$($Ph_2PC_6H_4NHCH_2PPh_2$-P_X,P_A)] (4): $[PdCl_2(cod)]$ (109 mg, 383 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 183 mg, 385 μmol) in CH_2Cl_2 (20 cm^3). The reaction mixture was stirred for 25 min and then concentrated in vacuo to about 1 cm^3 whereupon diethyl ether (10 cm^3) was added to precipitate the product as an orange powder. Yield: 244 mg (98.0%). $C_{31}H_{27}Cl_2NP_2Pd$: calcd. C 57.12, H 4.17, N 2.15; found C 56.51, H 3.77, N 2.18. $^{31}P\{H\}$ NMR ([D_6]DMSO): δ = 22.98 (s, P_A), 42.72 (s, P_X). ^1H NMR ([D_6]DMSO): δ = 3.96 (t, $^2J_{P,CH} = {}^3J_{NH,CH}$ = 3 Hz, 2 H, CH_2), 5.53 (br. dt, $^3J_{NH,PC}$ = 10 Hz, 1 H, NH), 6.12−6.07 (m, 1 H, ArH), 6.28 (m, 1 H, ArH), 6.85−6.80 (m, 1 H, ArH), 7.23−7.19 (m, 1 H, ArH), 7.56−7.35 (m, 20 H, ArH). IR (KBr disc): ν_{NH} = 3253s cm^{-1}, $\nu_{Pd\text{-}Cl}$ = 312m, 293w cm^{-1}. FAB: *m*/*z* = 616 $[M - Cl]^+$, 580 $[M - 2Cl]^+$, 674 $[M + Na]^+$.

[$PdBr_2$($Ph_2PC_6H_4NHCH_2PPh_2$-P_X,P_A)] (5): $[PdBr_2(cod)]$ (77 mg, 206 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 100 mg, 210 μmol) in CH_2Cl_2 (5 cm^3) and the reaction mixture was stirred for 30 min. The orange suspension of $[PdBr_2(cod)]$ dissolved immediately and a yellow solid product precipitated gradually. This precipitate was collected by suction filtration, washed with petroleum ether (60−80, 3 × 1 cm^3) and diethyl ether (3 × 1 cm^3), yield: 196 mg (68%). $C_{31}H_{27}Br_2NP_2Pd$ (741.7): calcd. C 50.27, H 3.67, N 1.89; found C 50.11, H 3.89, N 1.86. $^{31}P\{^1H\}$ NMR ([D_6]DMSO): δ = 20.55 (s, P_A), 41.93 (s, P_X). ^1H NMR ([D_6]DMSO): δ = 3.92 (br. t, $^2J_{P,CH} = {}^3J_{NH,CH}$ = 3 Hz, 2 H, CH_2), 5.44 (br. d, $^3J_{P,NH}$ = 25 Hz, 1 H, NH), 6.08 (m, 1 H, ArH), 6.80 (m, 1 H, ArH), 7.16 (m, 1 H, ArH), 7.55−7.33 (m, 21 H, ArH). IR (KBr disc): ν_{NH} = 3246s cm^{-1}, $\nu_{Pd,Cl}$ = 332m, 302vw cm^{-1}. FAB: *m*/*z* = 663 $[M - Br]^+$.

[$PtCl_2$($Ph_2PC_6H_4NHCH_2PPh_2$-P_X,P_A)] (6): This colourless complex was prepared in the same manner as compound **4** using $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 80 mg, 168 μmol) in CH_2Cl_2 (20 cm^3) and $[PtCl_2(cod)]$ (62 mg, 168 μmol). Yield: 120 mg (96.0%). $C_{31}H_{27}Cl_2NP_2Pt$ (741.5): calcd. C 50.21, H 3.67, N 1.89; found C 51.42, H 3.70, N 1.75. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 1.80 (d, $^1J_{Pt,P_A}$ = 3573 Hz, P_A), 20.25 (d, $^1J_{Pt,P_X}$ = 3647 Hz; $^2J_{P_A,P_X}$ = 18 Hz, P_X). ^1H NMR (CD_2Cl_2): δ = 3.55 (dt, $^3J_{NH,CP}$ = 16 Hz, 1 H, NH),

3.96 (dd, $^3J_{NH,CH}$ = 6, $^2J_{P,CH}$ = 3, $^3J_{Pt,CH}$ = 36 Hz, 2 H, CH_2), 6.29−6.25 (m, 1 H, ArH), 6.78−6.72 (m, 1 H, ArH), 7.09−7.06 (m, 1 H, ArH), 7.53−7.27 (m, 17 H, ArH), 7.74−7.66 (m, 4 H, ArH). IR (KBr disc): ν_{NH} = 3265m cm^{-1}, ν_{Pt-Cl} = 316m, 293m cm^{-1}. FAB: *m/z* = 741 $[M]^+$, 705 $[M - Cl]^+$, 764 $[M + Na]^+$.

[PtMe$_2$(Ph$_2$PC$_6$H$_4$NHCH$_2$PPh$_2$-*P*$_X$,*P*$_A$)] (7): [$PtMe_2$(cod)] (50 mg, 149 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 71 mg, 149 μmol) in CH_2Cl_2 (5 cm^3). The reaction mixture was stirred for 30 min and then concentrated in vacuo to about 0.5 cm^3 and diethyl ether (1 cm^3) and petroleum ether (3 cm^3, 60−80) were added to precipitate the product as an off-white powder. Yield: 85 mg (82.0%). $C_{33}H_{33}NP_2Pt$ (700.7): calcd. C 56.57, H 4.75, N 2.00; found C 55.68, H 4.49, N 1.93. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 11.91 (d, $^1J_{Pt,P_A}$ = 1720 Hz, P_A), 30.73 (d, $^1J_{Pt,P_X}$ = 1853 Hz; $^3J_{P_A,P_X}$ = 12 Hz, P_X). ^1H NMR ($CDCl_3$): δ = 0.34 (dd, $^3J_{P',CH}$ = 7, $^3J_{P,CH}$ = 9, $^2J_{PtCH'}$ = 69 Hz, 3 H, CH_3), 0.60 (dd, $^3J_{P,CH}$ = 7, $^3J_{P'CH}$ = 9, $^2J_{Pt,CH}$ = 70 Hz, 3 H, CH_3), 3.99 (m, $^2J_{P,CH}$ = 9 Hz, 3 H, CH_2 + NH), 6.23 (m, 1 H, ArH), 6.55 (m, 1 H, ArH), 6.80 (m, 1 H, ArH), 6.93 (t, 1 H, ArH), 7.66−7.20 (m, 20 H, ArH). IR (KBr disc): ν_{NH} = 3337m cm^{-1}. FAB: *m/z* = 700 $[M]^+$, 685 $[M - CH_3]^+$, 670 $[M - 2CH_3]^+$.

[Mo(CO)$_4$(Ph$_2$PC$_6$H$_4$NHCH$_2$PPh$_2$-*P*$_X$,*P*$_A$)] (8): [$Mo(CO)_4(pip)_2$] (119 mg, 315 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 150 mg, 315 μmol) in CH_2Cl_2 (25 cm^3). The reaction mixture was stirred at reflux for 3 h and then filtered through Celite. MeOH (10 cm^3) was added to the filtrate, which was then concentrated under vacuum until trace amounts of solid appeared. The solution was stored in a fridge overnight. Filtration, washing with cold MeOH (0.5 cm^3) and Et_2O (3 × 0.5 cm^3) gave the product as a grey solid. Yield: 105 mg (53%). $C_{35}H_{27}MoNO_4P_2$ (683.5): calcd. C 61.50, H 3.98, N 2.05; found C 61.15, H 3.86, N 2.14. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = 28.31 (d, P_A), 41.43 (d, $^3J_{P_A,P_B}$ = 25 Hz, P_X). ^1H NMR (CD_2Cl_2): δ = 4.04 (br. s, 2 H, CH_2), 6.63−6.56 (m, 1 H, ArH), 6.78−6.71 (m, 2 H, ArH), 7.55−7.26 (m, 22 H, ArH + NH). IR (KBr disc): ν_{NH} = 3389w cm^{-1}, $\nu_{C\equiv O}$ = 2013vs, 1914vs, 1878vs, 1892vs cm^{-1}. FAB: *m/z* = 684 $[M]^+$, 656 $[M - CO]^+$, 628 $[M - 2CO]^+$, 600 $[M - 3CO]^+$, 572 $[M - 4CO]^+$.

[RuCl$_2$(η^3:η^3-C$_{10}$H$_{16}$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$)] (9): [{RuCl(μ-Cl)(η^3:η^3-$C_{10}H_{16}$)}$_2$] (80 mg, 130 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 124 mg, 261 μmol) in THF (5 cm^3). The mixture was stirred for 1.5 h and then concentrated to ca. 0.5 cm^3. Addition of Et_2O (2 cm^3), filtration and washing with Et_2O (3 × 1 cm^3) gave the product as a pale brown solid. Yield: 179 mg (88%). $C_{41}H_{43}Cl_2NP_2Ru$ (783.7): calcd. C 62.84, H 5.53, N 1.79; found C 62.61, H 5.72, N 1.71. $^{31}P\{H\}$ NMR ($CDCl_3$): δ = −22.51(s, P_A), 16.80 (s, P_X). ^1H NMR (CD_2Cl_2): δ = 2.15 (s, 6 H, CH_3), 2.65 (m, 2 H, CH_2), 3.18 (m, 2 H, CH_2), 3.43 (d, 2 H, CH), 4.03 (d, 2 H,CH), 4.59 (dd, $^3J_{NH,CH}$ = 6, $^2J_{P,CH}$ = 2 Hz, 2 H, CH_2), 4.95 (m, 1 H, NH), 5.13 (br. m, 2 H, CH), 6.73−6.54 (m, 3 H, ArH), 7.38−6.99 (m, 17 H, ArH), 7.76−7.59 (m, 4 H, ArH). IR (KBr disc): ν_{NH} = 3314w cm^{-1}. FAB: *m/z* = 784 $[M]^+$, 748 $[M - Cl]^+$, 713 $[M - 2Cl]^+$.

[RhCl$_2$(η^5-C$_5$Me$_5$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$)] (10): [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] (68 mg, 110 μmol) was suspended in THF (4 cm^3) and $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 105 mg, 220 μmol) was added to the stirred suspension as a solid in one portion. The suspension dissolved and after 15 minutes stirring, an orange solid deposited from the deep red solution. After stirring for a total of 2 h the orange solid was collected by suction filtration, washed with diethyl ether (3 × 1 cm^3) and dried in vacuo. Yield: 145 mg (87%). $C_{41}H_{42}Cl_2NP_2Rh$ (784.5): calcd. C 62.77, H 5.40, N 1.79; found C 62.72, H 5.38, N 1.84. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = −22.84 (s, P_A), 32.74 (d, $^1J_{Rh,P_X}$ = 141 Hz, P_X). ^1H NMR (CD_2Cl_2): δ = 1.33 (d, $^4J_{P...CH}$ = 3 Hz, 15 H, CH_3), 4.66 (d, $^3J_{NH,CH}$ = 7 Hz, 2 H, CH_2), 4.97 (br. q, $^3J_{NH,CH}$ = $^3J_{PC,NH}$ = 7 Hz, 1 H, NH; no $^2J_{P,CH}$ observed), 6.30 (m, 1 H, ArH), 6.40 (m, 1 H, ArH), 6.60 (m, 1 H, ArH), 6.85 (m, 1 H, ArH), 7.77−7.04 (m, 20 H, ArH),. IR (KBr disc): ν_{NH} = 3326w cm^{-1}. FAB: *m/z* = 748 $[M - Cl]^+$, 713 $[M - 2Cl]^+$.

[IrCl$_2$(η^5-C$_5$Me$_5$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$)] (11) and [IrCl(η^5-C$_5$Me$_5$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$, *P*$_A$)]Cl (12): [{IrCl(μ-Cl)(η^5-C_5Me_5)}$_2$] (70 mg, 88 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 84 mg, 176 μmol) in THF (5 cm^3). The mixture was stirred for 1.5 h and the solvent was removed in vacuo. The yellow solid residue was dissolved in CH_2Cl_2 (0.5 cm^3) followed by addition of acetone (0.5 cm^3). Storage of this solution at room temperature overnight led to the formation of well-shaped orange crystals of **11**. The crystals were collected by suction filtration and washed with acetone (0.5 cm^3). Addition of Et_2O (2.0 cm^3) to the filtrate caused the precipitation of **12** as an orange powder.
11: Yield: 30 mg (19.5%). $C_{41}H_{42}Cl_2IrNP_2$ (873.9): calcd. C 56.35, H 4.84, N 1.60; found C 56.52, H 4.78, N 1.54. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = −22.80 (s, P_A), 0.10 (s, P_X). ^1H NMR (CD_2Cl_2): δ = 1.33 (d, $^4J_{P...CH}$ = 3 Hz, 15 H, CH_3), 4.66 (d, 2 H, CH_2; no $^2J_{PCH}$ observed), 4.91 (q, $^3J_{NH,CH}$ = $^3J_{PCNH}$ = 7 Hz, 1 H, NH), 6.34 (m, 1 H, ArH), 6.42 (m, 1 H, ArH), 6.61 (m, 1 H, ArH), 7.71−6.91 (m, 21 H, ArH). IR (KBr disc): ν_{NH} = 3328w cm^{-1}. FAB: *m/z* = 838 $[M - Cl]^+$, 803 $[M - 2Cl]^+$.
12: Yield: 29 mg (19%). $C_{41}H_{42}Cl_2IrNP_2$ (873.9): calcd. C 56.35, H 4.84, N 1.60; found C 48.67, H 4.33, N 1.08. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = −0.32 (s), 0.48 (s). IR (KBr disc): ν_{NH} = 3283w cm^{-1}. FAB: *m/z* = 838 $[M - Cl]^+$, 803 $[M - 2Cl]^+$.

[RuCl(η^3:η^3-C$_{10}$H$_{16}$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$,*P*$_A$)][ClO$_4$] (13): [{RuCl(μ-Cl)(η^3:η^3-$C_{10}H_{16}$)}$_2$] (64 mg, 103 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 99 mg, 208 μmol) in THF (5 cm^3). The mixture was stirred for 1.5 h and then $AgClO_4$ (43 mg, 207 μmol) was added. Stirring was continued overnight and the precipitated AgCl was removed by filtration through Celite. The dark filtrate was concentrated in vacuo to ca. 0.5 cm^3. Addition of Et_2O (5 cm^3), filtration and washing with Et_2O (3 × 1 cm^3) gave the product as a black solid. Yield: 162 mg (92%). $C_{41}H_{43}Cl_2NO_4P_2Ru$ (847.7): calcd. C 58.09, H 5.11, N 1.65; found C 56.88, H 4.85, N 2.05. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 21.86 (s, P_A), 36.89 (s, P_X). ^1H NMR ($CDCl_3$): δ = 2.14 (s, 6 H, CH_3), 2.64 (br. m, 2 H, CH_2), 3.22 (d, 2 H, CH), 3.43 (m, 2 H, CH_2), 4.12 (d, 2 H, CH), 4.67 (ddd, $^2J_{P,CH}$ = 52, $^3J_{P,CH}$ = 15, $^3J_{CH,NH}$ = 6 Hz, 2 H, CH_2), 5.02 (br. s, 1 H, NH), 5.13 (br. m, 2 H, CH), 6.42 (m, 2 H, ArH), 6.63 (m, 1 H, ArH), 7.75−7.05 (m, 21 H, ArH). IR (KBr disc): ν_{NH} = 3272w cm^{-1}, $\nu_{ClO_4^-}$ = 1099 vs cm^{-1}. FAB: *m/z* = 748 $[M - ClO_4]^+$.

[RhCl(η^5-C$_5$Me$_5$)(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$-*P*$_X$,*P*$_A$)][ClO$_4$] (14): This orange product was prepared in the same way as the ruthenium compound **13** from [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] (25 mg, 40 μmol), $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 39 mg, 82 μmol) and $AgClO_4$ (17 mg, 82 μmol). Yield: 63 mg (93%). Red crystals suitable for X-ray analysis were obtained by layering THF and petroleum ether (60−80) on a dichloromethane solution of **14** for four days. $C_{41}H_{42}Cl_2NO_4P_2Rh$ (848.5): calcd. C 58.03, H 4.99, N 1.65; found C 57.49, H 4.87, N 1.52. IR (KBr disc): ν_{NH} = 3332m cm^{-1}, $\nu_{ClO_4^-}$ = 1095vs cm^{-1}. FAB: *m/z* = 748 $[M - ClO_4]^+$.

[Ph$_2$P{AuCl}CH$_2$NHC$_6$H$_4${AuCl}PPh$_2$] (15): [AuCl(tht)] (135 mg, 420 μmol) was added to a solution of $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**;

[{RhCl$_2$(η^5-C$_5$Me$_5$)}$_2$(Ph$_2$PCH$_2$NHC$_6$H$_4$PPh$_2$)] (16): This compound was prepared in the same way as compound **10** from a 1:1 molar ratio of [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] (93 mg, 150 μmol) and $Ph_2PC_6H_4NHCH_2PPh_2$ (**1**; 73 mg, 151 μmol). Yield: 148 mg (90%). $C_{51}H_{57}Cl_4NP_2Rh$ (1093.6): calcd. C 54.33, H 5.25, N 1.28; found C 56.01, H 4.66, N 1.16. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 27.79 (d, $^1J_{Rh,P_A}$ = 144 Hz, P_A), 32.44 (d, $^1J_{Rh,P_X}$ = 138 Hz, P_X). ^1H NMR ($CDCl_3$): δ = 1.23 (d, $^4J_{P,CH}$ = 3 Hz, 15 H, CH_3), 1.27 (d, $^4J_{P,CH}$ = 3 Hz, 15 H, CH_3), 4.90 (dd, $^3J_{NH,CH}$ = 5, $^2J_{P,CH}$ = 16 Hz, 2 H, CH_2), 5.33 (br. s, 1 H, NH), 5.78 (m, 1 H, ArH), 6.28 (m, 1 H, ArH), 6.52 (m, 1 H, ArH), 6.70 (m, 1 H, ArH), 7.89−6.90 (m, 20 H, ArH). IR (KBr disc): ν_{NH} = 3280m cm^{-1}. FAB: *m*/*z* = 1056 [M − Cl]$^+$.

X-ray Crystallography: Table 8 lists details of data collections and refinements for **2**, **3**, **8**, **9**, **11** and **14**. Data were collected at room temperature using Mo-K_α radiation with a SMART system. Intensities were corrected for Lorentz polarisation and for absorption. The structures were solved by the heavy atom method or by direct methods. The positions of the hydrogen atoms were idealised. Refinements were by full-matrix least-squares based on F^2 using SHELXTL.[35] CCDC-172648−172653 (corresponding to compounds **2**, **3**, **8**, **9**, **11**, and **14**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We wish to thank the JREI for equipment grants and Johnson Matthey plc for the loan of precious metals. Qingzhi Zhang is indebted to St Andrews University for financial support.

(Alkenylalkylidene)(indenyl)ruthenium(II) Complexes: Synthesis by Protonation of Alkenyl Derivatives

Klaus Bieger,[a] Josefina Díez,[a] M. Pilar Gamasa,*[a] José Gimeno,[a] Martin Pavlišta,[a] Yolanda Rodríguez-Álvarez,[a] Santiago García-Granda,[b] and Rafael Santiago-García[b]

Keywords: Ruthenium / Hydride ligands / Alkenyl complexes / Alkylidene complexes / P ligands

The alkenyl complexes [Ru{(*E*)-C(CO_2Me)=C(H)R}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] [R = CO_2Me (**3**), H (**4**)], [Ru{(*E*)-CH=C(H)Ph}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (**5**) have been prepared by reaction of the hydride complex [RuH(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (**2**) [(*S*)-peap = (–)-(*S*)-*N,N*-bis(diphenylphosphanyl)(1-phenylethyl)amine] with an equimolar amount of dimethyl acetylenedicarboxylate, or with an excess of the terminal alkynes methyl propiolate or phenylacetylene. Similarly, vinylalkenyl complexes **6a**–**d** have been synthesized by the regio- and stereoselective reaction of the hydride complex **2** with 1-ethynylcycloalkynols. Protonation of the vinylalkenyl moiety of complexes **6a**,**c**,**d** with HBF_4·OEt_2 in diethyl ether afforded the cationic alkenylalkylidene complexes **7a**–**c**. The structures of complexes [RuH(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (**2**) and [Ru{(*E*)-C(CO_2Me)=CH(CO_2Me)}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (**3**) have been determined by X-ray diffraction methods. The catalytic activity of (alkenylalkylidene)(indenyl)ruthenium(II) complexes **7a**–**c**, **8** and **9** in the ring-closing metathesis (RCM) of diethyl diallylmalonate has been examined.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The discovery of (alkylidene)ruthenium(II) five-coordinate complexes [Ru{=C(H)R′}Cl_2(PR_3)$_2$] (R = Ph, Cy; R′ = Ph, CH=CPh_2) by Grubbs and co-workers[1] as efficient catalysts of olefin metathesis[2] has been the most important cornerstone in the remarkable development of the chemistry of (carbene)ruthenium complexes. A relevant feature of these catalysts is their tolerance towards most functional groups and protic media. The search for novel species, aiming at reproducing or increasing the performance of the Grubbs catalysts, has been an important goal during the last few years. Besides benzylidene,[3] benzyl or methylcarbene[4] complexes **A** and alkenylalkylidene complexes **B** (Scheme 1) are genuine examples of this type of catalysts. The parent complexes **A** and **B** (R = Ph) were originally obtained from the reaction of [$RuCl_2$(PPh_3)$_3$] with either phenyldiazomethane[1c] or 3,3-diphenylcyclopropene.[1a] A few derivatives of **B**, obtained through triphenylphosphane exchange processes or halide metathesis, are also known. These include [Ru(=CH−CH=CPh_2)X_2(PR_3)$_2$] (X = Cl, Br, I; PR_3 = PCy_3, PCy_2Ph, P*i*Pr_3, P*i*Pr_2Ph)[5] and [Ru(=CH−CH=CPh_2)X_2(PPh_3)$_2$] (X = CF_3CO_2).[6] However, other synthetic approaches, which have been designed as alternative procedures in order to avoid the relatively difficult access of the carbene source, are currently known: i) Reaction of *gem*-dichloride $PhCHCl_2$ with [Ru(cod)(cot)] in the presence of PCy_3 gives the complex **A** [Ru(=CHPh)Cl_2(PCy_3)$_2$].[7] A multi-step procedure starting from [$RuCl_2$(cod)], using phenylacetylene as the carbene source,[3a] and a new general synthetic method involving sulfur ylides[3b] have also been recently reported. ii) Reaction of the (hydrido)dihydrogen complex [Ru(Cl)(H)(H_2)(PCy_3)$_2$] with propargyl or vinyl halides gives vinylcarbene complexes [Ru(=CH−CH=CR_2)Cl_2(PCy_3)$_2$].[8] iii) Treatment of the dinuclear hydrido complex [Ru(H)(μ-Cl)(P−P)]$_2$ (P−P = *t*$Bu_2$$PCH_2$P*t*$Bu_2$) with dimethylpropargyl chloride gives [Ru{=CHCH=CMe_2}Cl_2(P−P)]. The related cationic derivative [Ru(=CHCH=CMe_2)Cl(solvent)(P−P)][OTf], which is formed by the treatment of the parent alkenylalkylidene complex with Me_3SiOTf, is also known.[9] iv) Reaction of [$RuCl_2$(PPh_2)$_3$] with diphenylpropargyl alcohol leads to the phenylindenylidene complex [Ru(3-phenylindenylid-1-ene)Cl_2(PPh_3)$_2$] (**C**, Scheme 1). The PPh_3 ligands can be substituted by better donor ligands such as PCy_3, and to the best of our knowledge only one mixed-phosphane-substituted derivative is known, namely the complex [Ru(3-phenylindenylid-1-ene)-Cl_2(PR_3)L] (R = Ph, Cy; L = 1,3-diarylimidazol-2-ylidene).[10]

We have reported a systematic route for the synthesis of a series of (alkenylalkylidene)ruthenium(II) complexes

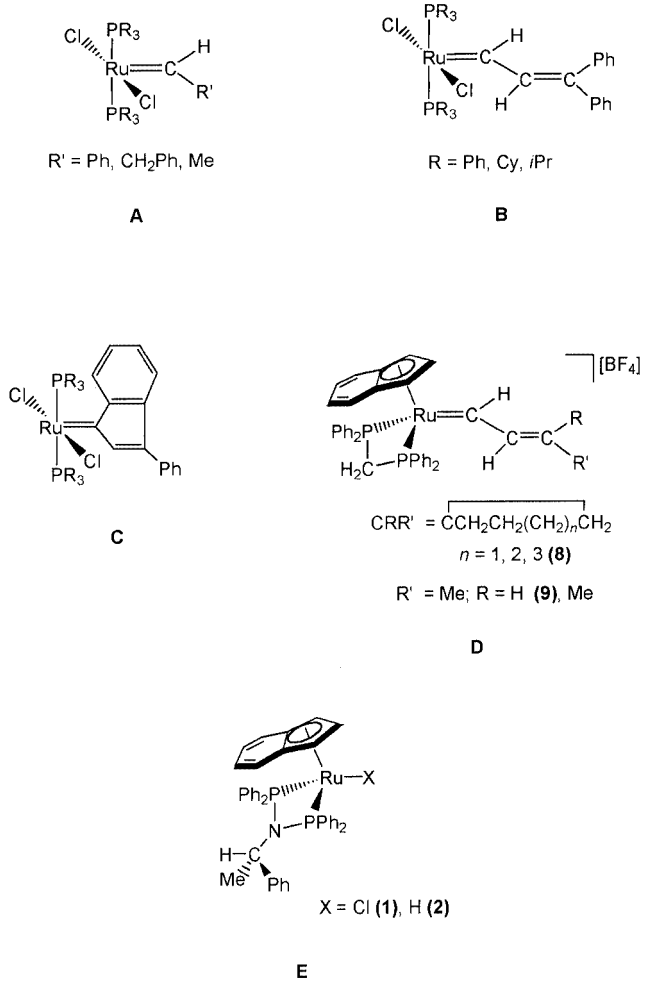

Scheme 1

[Ru(=CH−CH=CR_2)(η^5-C_9H_7)(dppm)][BF_4] [**D**, Scheme 1; dppm = bis(diphenylphosphanyl)methane] in which the unsaturated carbene group is bound to an (indenyl)(phosphane)ruthenium(II) fragment.[11] They have been obtained in high yields by protonation of the vinylalkenyl complexes [Ru{(*E*)-CH=CH−CHR_2)(η^5-C_9H_7)(dppm)]. More recently, this procedure has also been used as an alternative synthetic route for Grubbs catalyst **B** (Scheme 1).[12] Since access to these precursors {by reactions of the hydride complex [RuH(η^5-C_9H_7)(dppm)] with propargyl alcohols} is limited to the presence of the small bite chelate ligand dppm in the hydride precursor, we believed it would be of interest to investigate the applicability of this synthetic methodology using an analogous chelate ligand.

In this paper we report on the synthesis of novel ruthenium(II) precursors **E** (Scheme 1) in which the metal fragment bears the diphosphazane chelate ligand (*S*)-peap [(*S*)-peap = (−)-(*S*)-*N*,*N*-bis(diphenylphosphanyl)(1-phenylethyl)amine], which has a similar small bite angle as dppm. Further, their use as convenient starting materials for the synthesis of alkenylalkylidene complexes is investigated. The synthetic route involves two steps; the synthesis of alkenyl precursors, which are prepared by insertion reactions of the corresponding propargyl alcohol into the Ru−H bond of the hydride complex [RuH(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}], followed by the protonation with HBF_4·OEt_2 to give the desired alkenylalkylidene complexes. Moreover, we have also investigated the ability of the starting hydride complex to undergo insertion at the terminal or internal alkynes, and the catalytic activity of some (alkenylalkylidene)(indenyl)ruthenium(II) in the RCM of olefins (diethyl diallylmalonate). The X-ray crystal structures of the complexes [RuH(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] and [Ru{(*E*)-(CO_2Me)C=CH(CO_2Me)}(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] are also reported.

Results and Discussion

Synthesis of the Precursor Complexes [RuX(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] [X = Cl (1), H (2); (*S*)-peap = (−)-(*S*)-*N*,*N*-bis(diphenylphosphanyl)(1-phenylethyl)amine]

The starting material is the complex [RuCl(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] (**1**), which has been synthesized (83%) by heating a mixture of [RuCl(η^5-C_9H_7)(PPh_3)$_2$] and the diphosphazane (*S*)-peap in toluene under reflux [Equation (1)]. Complex **1** was isolated as an air-stable red solid and characterized by means of spectroscopic methods and elemental analysis (see Exp. Sect. for details). In particular,

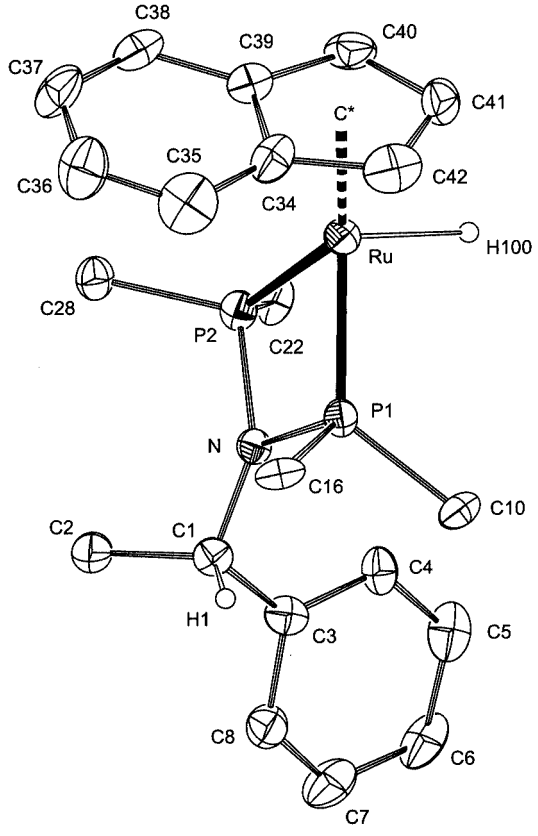

Figure 1. ORTEP-type diagram of [RuH(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] (**2**) with ellipsoids drawn at a 30% probability; phenyl rings of the Ph_2P groups in the diphosphazane have been omitted for clarity

[a] Δ = *d*[Ru−C(34),C(39)] − *d*[Ru−C(40),C(42)]. [b] HA (hinge angle) = angle between normals to least-squares planes defined by [C(40), C(41), C(42)] and [C(34), C(39), C(40), C(42)]. [c] CA (conformational angle) = angle between normals to least-squares planes defined by [C**, C*, Ru] and [C*, Ru, H]. C* = centroid of C(34), C(39), C(40), C(41), C(42); C** = centroid of C(34), C(35), C(36), C(37), C(38), C(39). [d] FA (fold angle) = angle between normals to least-squares planes defined by [C(40), C(41), C(42)] and [C(34), C(35), C(36), C(37), C(38), C(39)].

its $^{31}P\{^1H\}$ NMR spectrum shows two doublet signals at δ = 83.2 and 91.4 ($^2J_{P,P'}$ = 112.7 Hz) of an AB system, which is in agreement with the presence of two diastereotopic phosphorus nuclei from the chiral chelate ligand. The ^1H and $^{31}C\{^1H\}$ NMR spectra also display resonances revealing the presence of the indenyl group and the diphosphazane ligand (see Exp. Sect.).

$$[RuCl(\eta^5\text{-}C_9H_7)(PPh_3)_2] + (S)\text{-peap} \rightarrow [RuCl(\eta^5\text{-}C_9H_7)\{\kappa^2\text{-}P,P\text{-}(S)\text{-peap}\}] + 2\ PPh_3 \quad (1)$$

According to the classical route for the synthesis of transition metal hydride derivatives based on the β-hydrogen elimination from a methoxide complex,[13] the hydride complex [RuH(η⁵-C_9H_7){κ²-*P*,*P*-(*S*)-peap}] (**2**) has been prepared (85% yield) by treatment of complex **1** with an excess of NaOMe in refluxing methanol, see Equation (2).

$$[RuCl(\eta^5\text{-}C_9H_7)\{\kappa^2\text{-}P,P\text{-}(S)\text{-peap}\}] + NaOMe \rightarrow [RuH(\eta^5\text{-}C_9H_7)\{\kappa^2\text{-}P,P\text{-}(S)\text{-peap}\}] + H_2C{=}O + NaCl \quad (2)$$

Complex **2** was isolated as an air-stable yellow solid and has been characterized by elemental analysis, IR and NMR (^1H,$^{13}C\{^1H\}$ and $^{31}P\{^1H\}$) spectroscopy, which support the proposed formulation. The most significant signals arise from the presence of the two nonequivalent phosphorus nuclei: a) the hydride resonance which appears in the ^1H NMR spectrum as a triplet at δ = −14.33 (t, $^2J_{H,P}$ = $^2J_{H,P'}$ = 29.8 Hz) and b) two doublet resonances in the $^{31}P\{^1H\}$ spectrum at δ = 101.22 and 101.73 ($^2J_{P,P'}$ = 87.6 Hz) typical of an AB system. The structure of complex **2** has also been determined by X-ray diffraction. An ORTEP-type view of the molecular structure is shown in Fig-

[a] Spectra were recorded in C_6D_6. δ in ppm and *J* in Hz. Abbreviations: s, singlet; d, doublet; t, triplet; m, multiplet; bs, broad singlet. [b] $J_{H,H}$ in parentheses. [c] Legend for indenyl and alkenyl skeletons. [d] $^2J_{P,P'}$ in parentheses. [e] *C = asymmetric carbon atom of (*S*)-peap ligand. [f] Signal overlapped by aromatic signals. [g] ^1H NMR spectrum recorded in CD_2Cl_2. [h] Spectra recorded in $CDCl_3$.

ure 1 and selected bond lengths and angles are presented in Table 1. The complex shows the typical pseudo-octahedral three-legged piano-stool geometry of indenylruthenium(II) complexes,[14] in which the metal atom is bonded to the η^5-indenyl group, the two phosphorus atoms of the chelate diphosphazane and the hydrogen atom. Significantly, the bite angle P(1)−Ru−P(2) [70.44(12)°] of the chelate (*S*)-peap ligand shows a value that is quite similar to that seen in the complex [$PdCl_2\{\kappa^2$-*P,P*-(*S*)-peap}] [71.5(1)°][15] and by the analogous chelate dppm ligand in the complex [$RuH(\eta^5$-C_9H_7)(dppm)] [dppm = bis(diphenylphosphanyl)methane] [71.28(2)°].[16] The rest of the main structural parameters [i.e. Ru−P(1) = 2.199(3) Å, Ru−P(2) = 2.234(3) Å, Ru−C* = 1.97(2) Å (C* = centroid of the five-membered indenyl ring), hinge angle (HA) = 2.5(10)°, fold angle (FA) = 6.8(9)°, slippage parameter (Δ) = 0.089(12) Å) are rather similar to those found for analogous (indenyl)(phosphane)ruthenium(II) complexes reported by us,[14] and therefore do not merit further comments.

Synthesis of Alkenyl Complexes [Ru{(*E*)-C(CO_2Me)=C(H)R}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] [R = CO_2Me (3), H (4)], [Ru{(*E*)-CH=C(H)Ph}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (5) and Vinylalkenyl Complexes 6a−d

The hydride complex **2** reacted with an equimolar amount of dimethyl acetylenedicarboxylate in refluxing diethyl ether to give the (*E*)-alkenyl complex **3** (71% yield). Similarly, complex **2** reacted with an excess of the terminal alkynes methyl propiolate or phenylacetylene in toluene at 60 and 110 °C, respectively, affording the alkenyl complexes **4** (66% yield) and **5** (73% yield), respectively (Scheme 2). They have been isolated as orange solids and their analyt-

[a] Assigned by using DEPT 135 data. [b] Signal overlapped by aromatic signals. [c] Spectrum recorded in $CDCl_3$. [d] 141.56, 141.64 (s, *CC_{ipso}, C_β*C*$_{ipso}$). [e] Spectrum recorded in CD_2Cl_2.

ical and spectroscopic data (IR and ^1H, ^{13}C and $^{31}P\{^1H\}$ NMR) are in accordance with these formulations. The IR spectra of complexes **3** and **4** show ν(C=O) absorptions in the range of 1675−1699 cm^{-1}, which are typical of uncoordinated CO_2Me groups. The NMR spectroscopic data are shown in Table 2 (^1H and $^{31}P\{^1H\}$) and in Table 3 ($^{13}C\{^1H\}$), and are in agreement with the proposed structures. The $^{13}C\{^1H\}$ and ^1H NMR spectra show the expected resonances of the alkenyl groups which can be compared with those of the analogous (alkenyl)(dppm)ruthenium(II) complexes.[17] In particular, some resonances of the ^1H NMR spectra show coupling constants arising from a *cis* (geminal) arrangement for complex **4** (the relatively small $J_{H,H}$ = 2.3 Hz of the nonequivalent vinylic protons indicates α-metalation) and an (*E*) configuration for complex **5** (the large proton coupling constant $J_{H,H}$ = 15.9 Hz indicates the mutually *trans* arrangement). In order to confirm the stereochemistry of complex **3**, an X-ray crystal structure determination has been carried out. An ORTEP-type view of the molecular structure is shown in Figure 2; selected bond lengths and angles are presented in Table 4. The pseudo-octahedral geometry around the ruthenium atom is quite similar to that found for complex **2**, where the alkenyl group has occupied the hydride position of **2**. The bond lengths Ru−C* = 1.937(13) Å, Ru−P(1) = 2.248(3) Å, Ru−P(2) = 2.259(13) Å, the chelating bite angle P(1)−Ru−P(2) = 70.53(9)° and all the distortion parameters of the indenyl group (HA, FA and Δ) are similar to those shown by complex **2** (see Table 1). The most remarkable feature of the structure is the (*E*) configuration of the alkenyl group which exhibits an Ru−C(1) bond length of 2.030(12) Å that can be compared with the reported values in other alkenylruthenium(II) complexes with the two CO_2Me groups in a mutually *cis* configuration, e.g. 2.07(1) Å and 2.096(7) Å in the complexes [Ru{(*E*)-C(CO_2Me)=CH(CO_2Me)}(η^5-C_5H_5)(dppm)][18] and [Ru{(*E*)-C(CO_2Me)=CH(CO_2Me)}(η^5-Ph_4C_4COH)$(CO)_2$],[19] respectively. The C(1)−C(2) bond length of 1.373(17) Å (typical of a carbon−carbon double bond) and all the remaining values involving the ester functionalities of the alkenyl group are as expected.

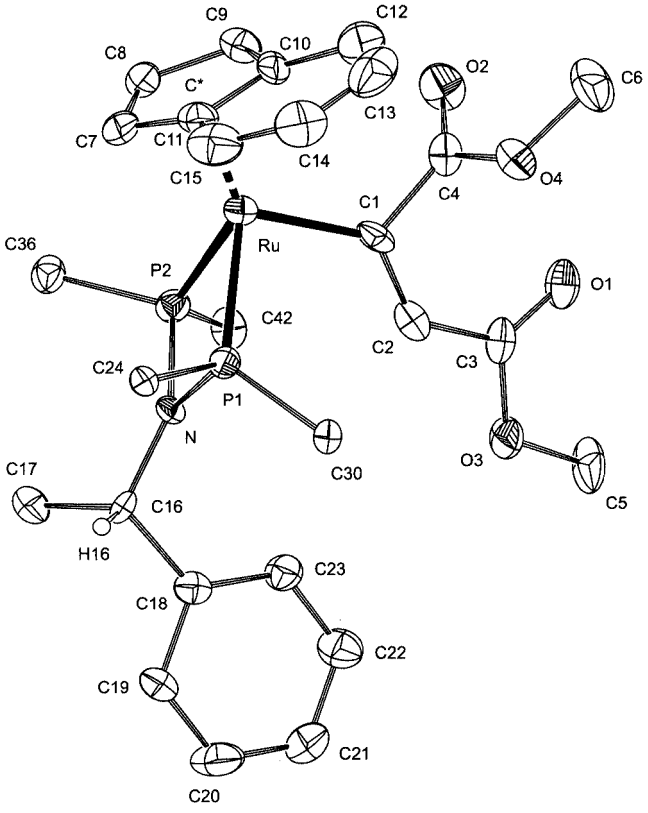

Figure 2. ORTEP-type diagram of [Ru{C(CO_2Me)=CH(CO_2Me)}(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] (**3**) with ellipsoids drawn at a 30% probability; phenyl rings of the Ph_2P groups in the diphosphazane have been omitted for clarity

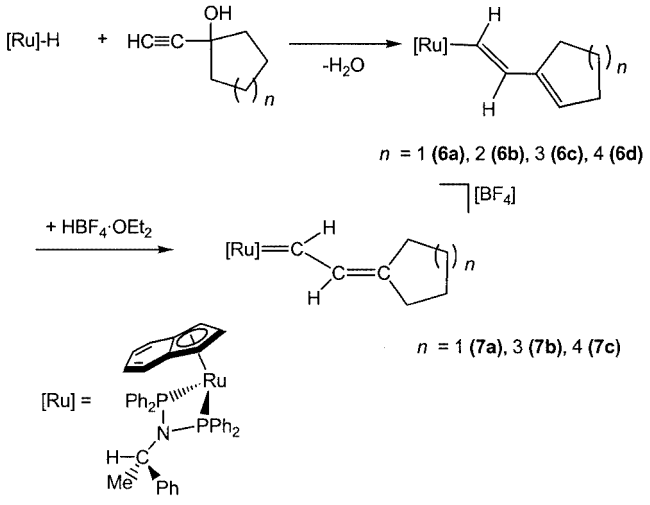
Complex **2** also reacted with 1-ethynylcycloalkynols in toluene at 100 °C affording the vinylalkenyl complexes **6a**−**d** (Scheme 3). Although no attempts to isolate the intermediate species have been made, the reactions proceed stereo- and regioselectively in a *cis*- (*syn*) and *anti*-Markovnikov fashion through the formation of the corresponding hydroxyalkenyl complexes,[11,20,21] that dehydrate spontaneously to give the desired complexes (69−74% yield). All the alkenyl complexes are isolated as air-stable red-orange solids and have been characterized by elemental analysis, mass spectra (FAB) and NMR spectroscopy (Tables 2 and 3). The $^{31}P\{^1H\}$ NMR spectra show, as for complexes **3**−**5**, doublet signals due to the nonequivalent nature of the two

phosphorus atoms of the chiral diphosphazane. The ^1H and $^{13}C\{^1H\}$ NMR spectroscopic data are consistent with those reported for similar α,β-unsaturated alkenylruthenium(II) complexes.[11,21,22] Significant features are the $^3J_{H,H}$ coupling constants (15.7−16.4 Hz) which support the *trans* stereochemistry for the RuC*H*=C*H*R double bond. The $^{13}C\{^1H\}$ NMR spectra exhibit all the resonances corresponding to the α,β-unsaturated alkenyl ligands. Significantly, the Ru*C*H=*C*HR carbon resonances appear as triplet ($^2J_{C,P} = {}^2J_{C,P'}$ = 14.3−15.1 Hz) and singlet signals at δ = 145.59−156.33 and 141.81−149.27, respectively. The spectra also exhibit resonances of the indenyl and (*S*)-peap ligand, along with the rest of the expected resonances for the alkenyl groups (see Tables 2 and 3).



Scheme 3

Synthesis of Alkenylalkylidene Complexes 7a−c

In accordance with the well-established reactivity of alkenyl complexes towards electrophiles[11] which leads to the formation of carbene complexes (theoretical studies support the nucleophilic nature of the C_β atom of the alkenyl group),[23] the treatment of solutions of complexes **6a**, **c** and **d** in diethyl ether with $HBF_4{\cdot}Et_2O$ at −40 °C gave, by precipitation, the alkylidene complexes **7a−c**, respectively (Scheme 3). They were isolated as air-sensitive orange tetrafluoroborate salts (87−92%). They are soluble in chlorinated solvents and acetone. The conductivity data in acetone show values that are expected for 1:1 electrolytes and the IR spectra exhibit the typical ν(B−F) strong absorptions (see Exp. Sect.). All the complexes are characterized by mass spectra (FAB) which support the formulations, and by NMR spectroscopy (Tables 5 and 6). The ^1H and $^{13}C\{^1H\}$ NMR spectra reveal the presence of the alkenylalkylidene groups, which are formally generated from the protonation at the C_δ atoms of the alkenyl chain. The most relevant data arise from the $^{13}C\{^1H\}$ NMR spectra which show the typical low-field carbene resonance at δ = 290.99−294.60 ($^2J_{C,P} = {}^2J_{C,P'}$ = 10.1−12.6 Hz). Resonances that appear more upfield are assigned to the remaining carbon atoms of the hydrocarbon chain [e.g. 142.67−146.27 (C_β); 159.41−165.93 (C_γ)]. The ^1H NMR spectra also show downfield resonances at δ = 13.84−14.09, which are characteristic of the Ru=C*H* proton. The $^{31}P\{^1H\}$ NMR spectra display, as expected, two doublet resonances more upfield than those of the precursor complexes (δ = 91.26−92.20; 94.25−95.20). Similar spectroscopic data have been reported for analogous (alkenylalkylidene)(dppm)(indenyl)ruthenium(II) complexes.[11]

The catalytic activity of **7a−c** and the analogous dppm complexes **8** and **9**[11] (see Scheme 1, **D**) in the RCM of diethyl diallylmalonate was investigated (Scheme 4). The reactions were performed in a sealed tube containing a solution of 5 mol % of the catalyst precursor in CD_2Cl_2 and monitored by ^1H NMR spectroscopy. No transformation of the substrate was observed over 24 h at room or higher temperatures (limited by the thermal stability of the catalyst ca.

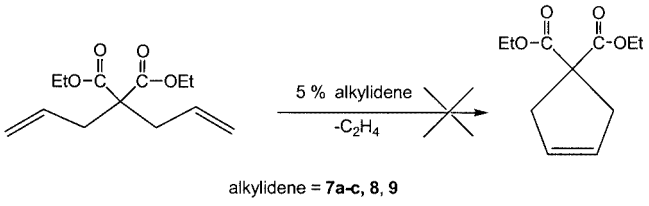
90−100 °C). The substrate also remained unchanged when the reactions were performed in $[D_8]$THF, as well as in the presence of CuCl (10 equiv. with respect to the catalyst) under similar conditions. The addition of CuCl as a co-catalyst has proven to activate the ring-closing metathesis of the substrate with other ruthenium(II) catalysts.[24]



Scheme 4

Conclusions

A series of novel alkenyl- and (vinylalkenyl)ruthenium(II) complexes [Ru{(*E*)-CR=CHR′)(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] [R = CO_2Me; R′= CO_2Me (**3**); R = CO_2Me; R′= H (**4**); R = H; R = Ph (**5**)], **6a−d** containing the chelate diphosphazane ligand (−)-(*S*)-*N*,*N*-bis(diphenylphosphanyl)(1-phenylethyl)amine [(*S*)-peap], have been prepared in good yields. The latter complexes have proven to be good precursors for the synthesis of cationic alkenylakylidene complexes **7a−c** that are synthesized in good yields by protonation of the alkenyl derivatives. Disappointingly, these complexes (along with the dppm analogues **8** and **9**) are completely unreactive towards diethyl diallylmalonate under reaction conditions similar to those used for other ruthenium(II) complexes active in the ring-closing metathesis of olefins.[2,25] Analogous pseudo-octahedral cationic ruthenium complexes, namely [Ru(=CHPh)Tp(S)(PCy_3)]$^+$ [Tp = hydrotris(pyrazolyl)borate; S = H_2O, Py, Me_3CN],[24] have also shown no catalytic activity. Although substitution reactions have been reported in other indenylruthenium(II) complexes favored by a dissociative *indenyl effect*,[26] the cationic nature of the complexes leads to a substantial decrease of the lability of the ligand which is required to allow the coordination of the diolefin substrate.

Experimental Section

General Remarks: The reactions were carried out under dry nitrogen using standard Schlenk techniques. The solvents were dried by standard methods and distilled under nitrogen before use. The complexes [RuCl(η^5-C_9H_7)(PPh_3)$_2$],[27] **8** and **9**[11] and the diphosphazane ligand $(Ph_2P)_2N$[(*S*)-*CHMePh],[15] were prepared by published methods. Dimethyl acetylenedicarboxylate, methyl propiolate, phenylacetylene, propargylic alcohols, HBF_4·OEt_2 and dimethyl diallylmalonate were used as received. Infrared spectra were recorded with a Perkin−Elmer FT-1720-Y spectrometer. C, H and N analyses were carried out with a Perkin−Elmer 240-B microanalyzer (inconsistent analyses are found for complexes **7a−c** due to incomplete combustion). Mass spectra (FAB) were recorded using a VG-Autospec spectrometer, operating in the positive mode; 3-nitrobenzyl alcohol (NBA) was used as the matrix. The conductivities were measured at room temperature, in ca. 10^{-3}·mol·dm^{-3} acetone solutions, with a Jenway PCM3 conductimeter. NMR spectra were recorded with a Bruker DPX-300 or AC-300 instrument operating at 300 MHz (^1H), 121.5 MHz (^{31}P) and 75.4 MHz (^{13}C) or a Bruker AC-200 instrument operating at 200 MHz (^1H), 81.01 MHz (^{31}P) and 50.32 MHz (^{13}C), using $SiMe_4$ or 85% H_3PO_4 as the standard. ^1H, $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectroscopic data for some complexes are presented in Tables 2, 3, 5 and 6.

[RuCl(η^5-C_9H_7){κ^2-*P*,*P*-(*S*)-peap}] (1): A mixture of [RuCl(η^5-C_9H_7)(PPh_3)$_2$] (1 g, 1.29 mmol) and a slight excess of the diphosphazane ligand $(Ph_2P)_2N$[(*S*)-*CHMePh] [(*S*)-peap)] (0.79 g, 1.61 mmol) in 20 mL of toluene was heated under reflux for 8 h. The removal of toluene gave a solid residue which was purified by flash chromatography on silica gel. The triphenylphosphane and the excess diphosphazane were eluted with a mixture of hexane and diethyl ether (10:1), and the red product **1** was eluted with a mixture of dichloromethane and methanol (10:1). The solvent was

evaporated and the dark red oil obtained was recrystallized from diethyl ether, yielding 0.793 g of the red solid **1** (83%). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 83.20 (d), 91.40 (d, $^2J_{P,P'}$ = 112.7 Hz). ^1H NMR ($CDCl_3$): δ = 0.77 (d, $J_{H,H}$ = 7.1 Hz, 3 H, Me), 4.24, 4.27 and 4.48 (s, 1 H each, 1,2,3-H), 4.59 (m, 1 H, *CH), 6.85−7.93 (m, 29 H, PPh_2, *CPh, 4,5,6,7-H). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 21.19 (t, $^3J_{C,P} = {}^3J_{C,P'}$ = 2.2 Hz, Me), 62.21 (t, $^2J_{C,P} = {}^2J_{C,P'}$ = 6.5 Hz, *C), 65.42 (m, C-1 and C-3), 92.56 (s, C-2), 110.07 (m) and 111.51 (d, $^2J_{C,P}$ = 3.6 Hz) (C-3a and C-7a), 123.47, 124.12, 125.29 and 126.11 (s, C-4,5,6,7), 127.00−134.69 (m, PPh_2, *C*Ph*, PC_{ipso}), 137.45−139.41 (m, PC_{ipso}), 141.07 (s, *CC_{ipso}). $C_{41}H_{36}ClNP_2Ru$ (741.22): calcd. C 66.44, H 4.90, N 1.89; found C 66.88, H 5.15, N 1.89.

[RuH(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (2): An excess of NaOMe (ca. 5:1, prepared in situ from NaH and MeOH) was added to a suspension of **1** (0.74 g, 1 mmol) in MeOH (100 mL). The mixture was heated under reflux for 1 h and the color of the solution changed from red to yellow. The solution was cooled at ambient temperature, the liquid decanted and the yellow-orange solid obtained was washed with methanol (3 × 20 mL) and vacuum-dried to yield 0.60 g of **2** (85%). IR (KBr): $\tilde{\nu}$ = 1992 cm^{-1} [w, ν(Ru−H)]. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 101.22 (d), 101.73 (d, $^2J_{P,P'}$ = 87.6 Hz). ^1H NMR ($CDCl_3$): δ = −14.33 (t, $^2J_{H,P} = {}^2J_{H,P'}$ = 29.8 Hz, Ru−H), 0.58 (d, $J_{H,H}$ = 6.9 Hz, 3 H, Me), 4.24 (m, 1 H, *CH), 5.01, 5.06 and 5.36 (s, 1 H each, 1,2,3-H), 6.27−8.01 (m, 29 H, PPh_2, *CPh, 4,5,6,7-H). $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 21.87 (s, Me), 61.05 (t, $^2J_{C,P} = {}^2J_{C,P'}$ = 6.9 Hz, *C), 66.89 (t, $^2J_{C,P} = {}^2J_{C,P'}$ = 4.6 Hz) and 68.56 (t, $^2J_{C,P} = {}^2J_{C,P'}$ = 4.6 Hz) (C-1 and C-3), 88.43 (s, C-2), 106.29 and 107.69 (s, C-3a and C-7a), 121.97, 122.58, 123.26 and 126.33 (s, C-4,5,6,7), 127.39−135.83 (m, PPh_2, *C*Ph*), 139.05−140.87 (m, PC_{ipso}), 143.11 (s, *CC_{ipso}). $C_{41}H_{37}NP_2Ru$ (706.78): calcd. C 69.67, H 5.28, N 1.98; found C 69.47, H 5.47, N 1.96.

[Ru{(*E*)-C(CO_2Me)=CH(CO_2Me)}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (3): A mixture of **2** (0.25 g, 0.35 mmol) and an equimolar amount of dimethyl acetylenedicarboxylate (43 μL, 0.35 mmol) in diethyl ether (40 mL) was heated under reflux for 3 h. The solvent was evaporated and the solid obtained was dried under vacuum, yielding 0.21 g (71%) of **3** as an orange solid. IR (KBr): $\tilde{\nu}$ = 1688 s, 1699 cm^{-1} (s, 2 CO_2Me). $^{31}P\{^1H\}$, ^1H and $^{13}C\{^1H\}$ NMR spectroscopic data are presented in Tables 2 and 3. $C_{47}H_{43}NO_4P_2Ru$ (848.89): C 66.50, H 5.11, N 1.65; found C 65.50, H 5.03, N 1.53.

[Ru{C(CO_2Me)=CH_2}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (4): A mixture of **2** (0.25 g, 0.35 mmol) and an excess of methyl propiolate (95 μL, 1.05 mmol) in toluene (40 mL) was heated at 60 °C for 6 h. The solvent was removed under vacuum and the solid obtained was washed with pentane (3 × 10 mL) and dried under reduced pressure to yield 0.183 g (66%) of **4** as an orange solid. MS (FAB): *m*/*z* = 791 [M$^+$], 760 [M$^+$ − OMe], 706 [M$^+$ − R], 629 [M$^+$ − R − Ph], 590 [M$^+$ − R − C_9H_7 − 1]; R: CH_2=C(CO_2Me) (correct isotope patterns observed for each fragment). IR (KBr): $\tilde{\nu}$ = 1675 cm^{-1} (s, CO_2Me). $^{31}P\{^1H\}$, ^1H and $^{13}C\{^1H\}$ NMR spectroscopic data are presented in Tables 2 and 3.

[Ru{(*E*)-CH=CHPh}(η^5-C_9H_7){κ^2-*P,P*-(*S*)-peap}] (5): A mixture of **2** (0.25 g, 0.35 mmol) and a large excess of phenylacetylene (385 μL, 3.5 mmol) in toluene (40 mL) was heated at 110° C for 4 h. The solvent was removed under vacuum and the solid obtained was washed with pentane (3 × 10 mL) and dried under reduced pressure to yield 0.207 g (73%) of **5** as an orange solid. $C_{49}H_{43}NP_2Ru$ (808.91): calcd. C 72.76, H 5.36, N 1.73; found C 72.52, H 5.44, N 1.46. $^{31}P\{^1H\}$, ^1H and $^{13}C\{^1H\}$ NMR spectroscopic data are presented in Tables 2 and 3.

Complexes 6a−d: A solution of **2** (0.25 g, 0.35 mmol) and an excess of the corresponding propargylic alcohol (3.5 mmol) in toluene (40 mL) was heated at 100 °C for 3 h. The solvent was evaporated to dryness and the resulting red-orange solid was washed with pentane (3 × 20 mL) and dried under vacuum to give **6a−d**. NMR spectroscopic data are presented in Tables 2 and 3. Yield, analytical data and mass spectrum (FAB, correct isotope patterns observed for each fragment) are as follows. **6a:** 71%. $C_{48}H_{45}NP_2Ru$ (798.92): calcd. C 72.16, H 5.68, N 1.75; found C 71.72, H 5.66, N 1.65. **6b:** 69%. $C_{49}H_{47}NP_2Ru$ (812.94): calcd. C 72.39, H 5.83, N 1.72; found C 70.66, H 6.10, N 1.33. *m*/*z* = 813 [M$^+$], 706 [M$^+$ − C_8H_{11}], 590 [M$^+$ − C_8H_{11} − C_9H_7 − 1], 401 [M$^+$ − C_8H_{11} − (*S*)-peap]. **6c:** 73%. $C_{50}H_{49}NP_2Ru$ (826.97): calcd. C 72.62, H 5.97, N 1.69; found C 71.29, H 6.33, N 1.31. *m*/*z* = 827 [M$^+$], 706 [M$^+$ − C_9H_{13}], 590 [M$^+$ − C_9H_{13} − C_9H_7 − 1], 401 [M$^+$ − C_9H_{13} − (*S*)-peap]. **6d:** 74%. $C_{51}H_{51}NP_2Ru$ (841.00): calcd. C 72.84, H 6.11, N 1.66; found C 71.81, H 6.08, N 1.46.

Complexes 7a−c: A dilute solution of HBF_4 in diethyl ether (0.13 mmol) was added dropwise to a stirred solution of the corresponding vinylalkenyl complex (**6a**, **c**, **d**; 0.12 mmol) in 20 mL of diethyl ether, cooled at − 40 °C. Immediately, an orange solid precipitated. The liquid was decanted and the solid washed with diethyl ether (3 × 20 mL) and vacuum-dried. NMR spectroscopic data are presented in Tables 5 and 6. Yield, IR (KBr), conductivity (acetone, 20 °C) and mass spectrum (FAB, correct isotope patterns observed for each fragment) are as follows: **7a:** 87%. $\tilde{\nu}$ = 1062 cm^{-1} [b, s, ν(BF_4^-)]. 134 Ω^{-1}cm^2 mol^{-1}. *m*/*z* = 800 [M$^+$], 706 [M$^+$ − C_7H_{10}]. **7b:** 90%. $\tilde{\nu}$ = 1063 cm^{-1} [b, s, ν(BF_4^-)]. 128 Ω^{-1}cm^2 mol^{-1}. *m*/*z* = 828 [M$^+$], 706 [M$^+$ − C_9H_{14}], 401 [M$^+$ −C_9H_{14} − (*S*)-peap]. **7c:** 92%. $\tilde{\nu}$ = 1060 cm^{-1} [b, s, ν(BF_4^-)]. 117 Ω^{-1}cm^2 mol^{-1}. *m*/*z* = 842 [M$^+$], 706 [M$^+$ − $C_{10}H_{16}$].

Procedure for Ring-Closing Metathesis of Diethyl Diallylmalonate: Solutions of the complexes **7a−c**, **8** or **9** (5 μmol) and diethyl diallylmalonate (0.1 mmol, 24 μL) in CD_2Cl_2 (0.4 mL) were combined in a sealed tube. The reaction mixtures were stirred at room temperature and under more drastic conditions (heating the solutions until 100 °C in an oil bath) for 24 h. The development of the reactions was monitored by ^1H NMR spectroscopy. The diene signals appeared intact in the spectra. In addition, CuCl (10 equiv. based on **7c**) was added to a solution of complex **7c** as a co-catalyst under similar reaction conditions, but we have found that the mixture of alkylidene/CuCl is inactive for olefin metathesis.

X-ray Crystallographic Study of 2 and 3: Data were collected with a Nonius CAD4 single-crystal diffractometer. The intensities were measured using the ω-2θ scan technique with a scan angle of 1.5° intensity of the primary and a variable scan rate with a maximum scan time of 60 s per reflection. The beam was checked throughout the collection by monitoring three standard reflections every 60 min. Profile analysis was performed on all reflections.[28] Some double measured reflections were averaged and Lorentz and polarization corrections were applied. The structures were solved by Patterson interpretation and phase expansion using DIRDIF.[29] Isotropic least-squares refinement on F^2 using SHELXL97.[30] During the final stages of the refinements, all positional parameters and the anisotropic temperature factors of all the non-H atoms were refined. The H atoms were geometrically located and riding with common isotropic thermal parameters, except the hydride H atom (H100) in complex **2** which was located by Fourier difference synthesis and isotropically refined. The function minimized was $([\Sigma w F_o^2 - F_c^2)/\Sigma w(F_o^2)]^{1/2}$ where $w = 1/[\sigma^2(F_o^2) + (nP)^2]$ (n = 0.0337 for **2** and n = 0.0467 for **3**) with $\sigma(F_o^2)$ from counting statistics and $P = [\mathrm{Max}(F_o^2,0) + 2F_c^2]/3$. Atomic scattering factors were taken

Optically Active Phospholes: Synthesis and Use as Chiral Precursors for Phosphinidene and Phosphaferrocene Complexes

Xavier Sava,[a] Angela Marinetti,*[b] Louis Ricard,[a] and François Mathey*[a]

Keywords: Phosphorus heterocycles / Asymmetric catalysis / P ligands / Phosphinidene complexes / Chiral phospholes / Phosphaferrocenes

Phospholes bearing chiral menthyl, myrtanyl, and (4-isopropyloxazolino)phenyl groups at the phosphorus atom were prepared. They were used as precursors for 7-phosphanorbornadienes and phosphinidene complexes. Unexpectedly, the [(4-isopropyloxazolino)phenyl]phosphinidene gave an intramolecular adduct with the imine moiety, which behaved as a 1,3-dipole in cycloaddition reactions. This afforded a new, general approach to 7-aza-1-phosphanorbornadiene and norbornene derivatives. The (4-isopropyloxazolino)phenyl-substituted phosphole was also used for the synthesis of new chiral phosphaferrocene complexes bearing oxazoline moieties.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The organic chemistry of phospholes is extremely rich and varied, as has been shown by the work of many groups during the last decades.[1] Besides simple modifications of the phosphole ring substituents, three main transformations giving access to other classes of phosphorus derivatives are known: these are [4+2] cycloaddition reactions at the dienic system, which afford 7-phosphanorbornenes[2,3] or 7-phosphanorbornadiene[4] derivatives; [1,5] sigmatropic shifts of the aryl, vinyl, or other labile phosphorus substituents around the phosphole nucleus, which lead to 1-phosphanorbornadienes;[5] and finally, the reactivity of either phospholes themselves or phospholyl anions towards suitable transition metal derivatives, which affords an easy access to phosphacyclopentadienyl complexes and phosphametallocenes.[6,7]

Despite the wide synthetic potential of phosphole chemistry, the use of chiral species as synthetic tools has barely been considered. A few optically active phospholes, mainly dibenzophosphole derivatives, have been applied as chiral auxiliaries in transition metal promoted reactions.[8] Recent reports from T. Hayashi disclose the synthesis of enantiomerically pure 2,5-dimenthyl-1-phenylphosphole and its use for the preparation of phosphaferrocene, phosphacymantrene, and diphosphole derivatives.[9]

According to an analogous strategy, i.e. taking advantage from the reactivity of nonracemic phospholes to prepare chiral phosphanes with nonconventional structures and potential interest in catalysis, we started the work presented herein. This includes the synthesis of some new chiral phospholes and their use as precursors for phosphirenes, phosphaferrocenes, and new azaphosphanorbornadiene derivatives.

Results and Discussion

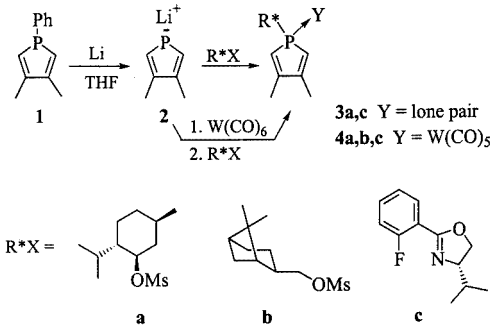
Synthesis of Chiral Phospholes

Chirality in phospholes could be provided by optically pure substituents on either the carbon or the phosphorus atoms. The phosphole ring itself has a low phosphorus inversion barrier (ca. 16 kcal/mol), so it racemizes at room temperature. From a synthetic point of view, the most attractive compounds seem to be phospholes bearing a chiral group on the phosphorus atom, whose easy preparation from phospholyl anions and chiral electrophiles contrasts with the restricted availability of optically active diene moieties.

In this work, two kinds of chiral auxiliaries were considered as phosphorus substituents: alkyl groups derived from chiral pool terpene alcohols (menthol and myrtanol), and valine-derived phenyloxazoline moieties. Both terpene alcohols and amino acids can be conveniently used as stoichiometric chiral auxiliaries because of their large-scale availability.

Chiral phospholes are obtained from 3,4-dimethyl-1-phenylphosphole (**1**)[10] via the corresponding phospholyl anion by substitution on the phosphorus atom, as shown

in Scheme 1. After cleavage of the phosphorus−phenyl bond of **1** with lithium, the phospholyl anion **2** gives nucleophilic substitution reaction on the mesylate of (−)-menthol to afford the *P*-neomenthyl-substituted phosphole **3a**.

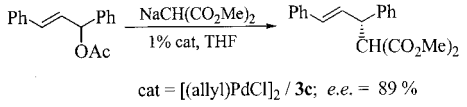


Scheme 1. Synthesis of chiral phospholes

The analogous reaction between the phospholyl anion and the mesylate of (1*S*)-myrtanol[11,12] afforded the corresponding, highly air-sensitive *P*-myrtanylphosphole compound. It was isolated only as its $W(CO)_5$ complex **4b**.

Reaction of **2** with the (−)-(*S*)-2-(2-fluorophenyl)-4-isopropyloxazoline gave the air-stable phosphole **3c** in good yield (61%). The (fluorophenyl)oxazoline has already been used as an electrophile in the analogous *P*-arylation of a dibenzophospholyl anion.[8e]

The optically active phospholes **3a** and **3c** provide new chiral ligands for transition metal promoted asymmetric catalysis. Their potential applications are likely to be those where other phospholes have already been used successfully: for example hydroformylation, hydrogenation, and carbonylation reactions. Moreover, phosphole **3c** should find applications in a number of catalytic reactions usually promoted by phosphanyloxazoline ligands.[13] As a very preliminary test, we checked the effectiveness of phosphole **3c** as chiral ligand in the palladium-catalyzed substitution of 1,3-diphenylpropenyl acetate with sodium malonate under standard conditions. As expected, the observed catalytic activity, as well as the enantioselectivity, is quite satisfactory (Scheme 2).

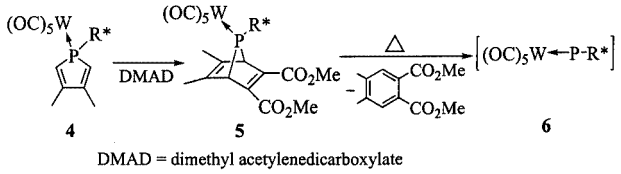


Scheme 2. Palladium-catalyzed allylic substitution

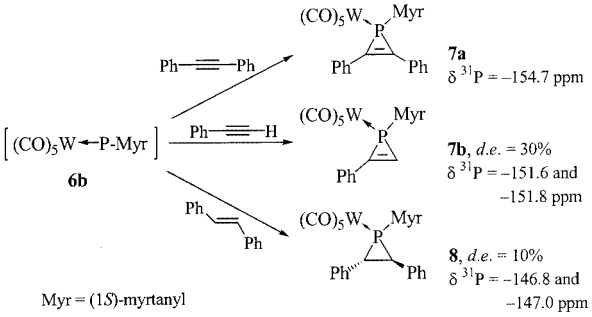
Exhaustive catalytic screening of phospholes **3** lies beyond the scope of this work and will be reported later. Indeed, the main purpose of this work was to check the use of phospholes **3** as chiral intermediates for the synthesis of new phosphorus derivatives through either Diels−Alder cycloaddition reactions on the dienic system or [1,5] sigmatropic shifts of the aryl moiety of **3c**. Results are given hereafter.

Synthesis of (7-Phosphanorbornadiene)$W(CO)_5$ Complexes − Generation of Chiral Phosphinidenes

(7-Phosphanorbornadiene)$W(CO)_5$ complexes are easily accessible from the corresponding phosphole complexes by Diels−Alder cycloadditions with activated alkynes.[4] These compounds were mainly used as synthetic precursors for terminal phosphinidene complexes, which are highly reactive intermediates with carbene-like behavior.[14,15] For instance, addition of (phosphinidene)$M(CO)_5$ complexes to olefins and alkynes leads to the corresponding phosphirane and phosphirene complexes, respectively. When the phosphinidene phosphorus atom bears an optically pure substituent, chiral induction can be expected in its addition to unsymmetrical olefins and acetylenes. To verify this theory, we examined the preparation of the 7-phosphanorbornadiene complexes **5**, as well as their thermolysis and the subsequent phosphinidene trapping reactions, as shown in Schemes 3 and 4.



Scheme 3. Generation of phosphinidene complexes



Scheme 4. Trapping reactions of transient phosphinidene complexes

The phosphole complexes **4a−c** could be obtained by treating the preformed phospholes **3** with the (THF)$W(CO)_5$ complex. For the air-sensitive phosphole **3b**, the most convenient procedure[16] included complexation of the phospholyl anion, followed by reaction of the phospholyltungsten complex with myrtanyl mesylate to give **4b** (see Exp. Sect.).

The course of the reaction between **4** and DMAD was largely dependent on the nature of the phosphorus substituent R*. When R* = neomenthyl, the Diels−Alder cycloaddition was prevented by the steric hindrance of the phosphorus substituent. When R* = myrtanyl, the steric hindrance around the phosphorus atom was greatly reduced and the Diels−Alder reaction with DMAD leads to the expected 7-phosphanorbornadiene **5b**, which was isolated and fully characterized.

The generation and trapping of the pentacarbonyl(*P*-myrtanylphosphinidene)tungsten complex from **5b** was checked in small-scale experiments by ^{31}P NMR spectroscopy on crude reaction mixtures (Scheme 4). Diphenylacetylene, phenylacetylene, and *trans*-stilbene were used as trapping reagents because, in such cases, the anticipated complexed phosphirene and phosphirane products should give very characteristic ^{31}P NMR signals at high-field shifts.[14,17]

These experiments show that thermolysis of **5b** under the usual experimental conditions,[14,17] affords the pentacarbonyl(*P*-myrtanylphosphinidene)tungsten complex **6b**, which displays the expected electrophilic behavior toward olefins and alkynes. Phosphirane and phosphirene complexes are obtained as the only reaction products, by [2+1] cycloaddition reactions.

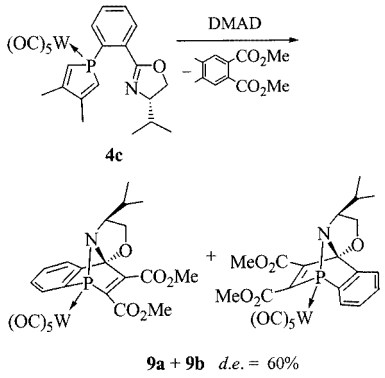
In the case of unsymmetrical alkynes and olefins, chiral induction from the optically active myrtanyl substituent should give diastereoselective addition reactions. Unfortunately, mixtures of diastereomers, with rather poor diastereomeric excesses, are obtained upon cycloaddition of **6b** with phenylacetylene and *trans*-stilbene, leading to **7b** and **8**, respectively. To be stereoselective, the reaction with phenylacetylene requires diastereoselective formation of a chiral phosphorus center, while the diastereoselective addition of **6b** on *trans*-stilbene requires enantiofacial selectivity. The low efficiency of the myrtanyl group as chiral auxiliary in both these reactions is probably due to the presence of the flexible CH_2 spacer between the phosphorus atom and the chiral centers of the myrtanyl moiety. The diastereoselectivity is likely to be improved by using chiral auxiliaries bearing stereogenic centers closer to the phosphorus atom.[18]

Finally, trapping reactions of the *P*-myrtanylphosphinidene **6b** should give a convenient access to optically pure phosphirane[19] and phosphirene derivatives, but only when symmetrically substituted unsaturated substrates are used, as shown by the synthesis of **7a**. Otherwise, separation of the diastereomeric mixtures would be required.

Given that several procedures are known for removing phosphirenes and phosphiranes from their pentacarbonyltungsten or -molybdenum complexes,[20−22] reactions in Scheme 4 should represent new potential sources of chiral ligands for enantioselective catalysis.

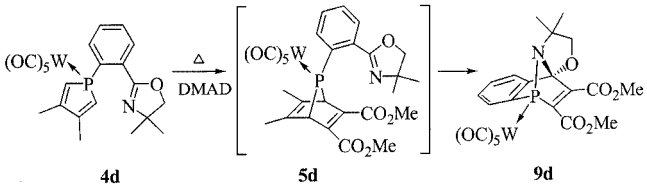
In the reaction of the phosphole complex **4c** {R* = 2-[(*S*)-4-isopropyloxazolino]phenyl} with DMAD, the expected 7-phosphanorbornadiene derivative **5c** was not detected. Nevertheless, a clean reaction occurred to give a new phosphorus derivative as a mixture of two isomers. Spectroscopic data and NMR analysis of the crude reaction mixture showed formation of dimethyl phthalate. This suggests that the Diels−Alder reaction took place as expected, but that the 7-phosphanorbornadiene complex decomposed instantaneously to generate the corresponding phosphinidene **6c** (Scheme 3). The excess DMAD was suspected to be the trapping reagent for the intermediate phosphinidene.

This hypothesis is supported by spectroscopic analysis of the pure final product, which was in agreement with the bicyclic structure **9** shown in Scheme 5. Nevertheless, an unambiguous assignment was prevented by the presence of the two inseparable isomers **9a** and **9b**, in a 4:1 ratio.



Scheme 5. Reaction of the {3,4-dimethyl-1-[2-(4-isopropyl-4,5-dihydro-1,3-oxazol-2-yl)phenyl]phosphole}$W(CO)_5$ complex **4c** with dimethyl acetylenedicarboxylate

To confirm the structural assignment, we decided to perform the same reaction starting from the achiral (oxazolylphenyl)phosphole complex **4d**, which should lead to a single isomer of the final product and thus facilitate its purification and characterization (Scheme 6).



Scheme 6. Reaction of the {3,4-dimethyl-1-[2-(4,4-dimethyl-4,5-dihydro-1,3-oxazol-2-yl)phenyl]phosphole}$W(CO)_5$ complex **4d** with dimethyl acetylenedicarboxylate

The expected reaction between the phosphole complex **4d** and DMAD led to the 7-aza-1-phosphanorbornadiene **9d**, which was easily isolated and fully characterized. An X-ray diffraction study of **9d** confirmed the proposed structure (Figure 1).

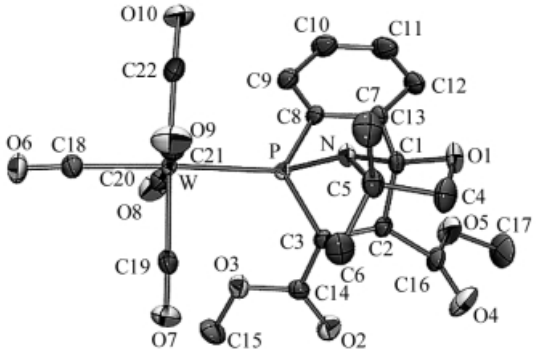


Figure 1. ORTEP diagram for complex **9d**; selected bond lengths [Å]: W−P 2.4495(7), P−N 1.707(2), P−C(8) 1.845(3), P−C(3) 1.890(3), N−C(1) 1.474(3); selected bond angles [°]: P−W−C(18) 172.13(9), C(3)−P−C(8) 94.4(1), P−N−C(1) 100.0(2), C(1)−N−C(5) 106.9(2), O(1)−C(1)−N 106.1(2)

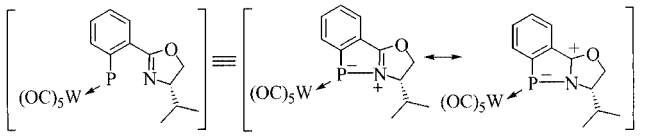
To date, only one example of a 7-aza-1-phosphanorbornadiene has been reported,[23] which was obtained by trapping a (pentamethylcyclopentadienyl)phosphinidene complex with a nitrile. The first formed adduct rearranges through a [4+2] cycloaddition to give the norbornadiene.

In the reactions of Schemes 5 and 6, formation of the 7-aza-1-phosphanorbornadiene complexes **9** can be explained as follows. The [4+2] cycloaddition between **4c** (or **4d**) and excess DMAD gives the 7-phosphanorbornadiene complex **5c** (or **5d**), which instantaneously generates the corresponding phosphinidene complex. The easy decomposition of these 7-phosphanorbornadiene complexes can be explained by the intramolecular interaction between the phosphorus atom and the nitrogen lone pair of the oxazoline moiety, as it has already been shown that amines and strongly basic phosphanes catalyze such reactions.[24] The phosphinidene complex is thus generated as an adduct between the imine nitrogen atom and the electron-deficient phosphorus atom, which can be described by the two resonance structures **I** and **II** in Scheme 7.



Scheme 7. {*P*-[2-(4-Isopropyl-4,5-dihydro-1,3-oxazol-2-yl)phenyl]-phosphinidene}$W(CO)_5$ complex **6c**

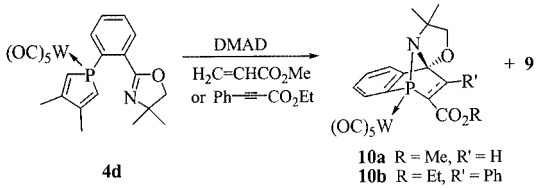
Structure **II** clearly emphasizes the 1,3-dipolar nature of the adduct and explains its [3+2] cycloaddition with DMAD leading to **9**. The reaction intermediate of Scheme 7, can be considered as a phosphaazomethine ylide.

As far as we know, phosphinidene−imine adducts have never been described before. However, other P/N adducts are known. A pyrazolyl−phosphinidene complex has been reported by Cowley. In this case, the coordination of the nitrogen lone pair substantially reduced the electrophilicity of the phosphinidene, thus permitting its isolation.[25] Phosphinidene−nitrile adducts have been generated as reactive intermediates and their reactivity in 1,3-dipolar cycloadditions has been studied by Streubel.[26−28]

Azomethine ylides,[29] as well as (iminomethylene)phosphoranes and analogs[30] were found to be useful as synthetic building blocks through [3+2] cycloadditions. Thus, the use of the phosphaazomethine ylides above as synthetic tools can be envisaged.

Results given in Schemes 5 and 6 point out the strongly nucleophilic behavior of the (2-oxazolylphenyl)phosphinidene complexes, which contrasts with that of simple alkyl- or aryl-substituted pentacarbonyl(phosphinidene)tungsten complexes. Further experiments showed that the [3+2] cycloaddition with DMAD took place preferentially even in the presence of excess diphenylacetylene, an usually efficient phosphinidene trapping reagent.

Preliminary tests (^{31}P NMR analysis of crude reaction mixtures) show that electron-deficient olefins and alkynes other than DMAD can be used as trapping reagents (Scheme 8). In the presence of methyl acrylate (or ethyl phenylpropionate), diastereomeric mixtures of the bicyclic derivatives **10a** (or **10b**) were obtained. However, complex **9** is still formed in some amount (**10/9** ≈ 80:20), even when a threefold excess of the trapping reagent was used, showing that DMAD competes well with the other reagents. The whole reaction sequence can be improved by using ethyl phenylpropionate as the only cycloaddition partner for both the Diels−Alder reaction on phosphole **4d** and the phosphinidene trapping. Under such conditions, the crude reaction mixture contains complex **10** as the major product.



Scheme 8. Reactivity of the {3,4-dimethyl-1-[2-(4,4-dimethyl-4,5-dihydro-1,3-oxazol-2-yl)phenyl]phosphole}$W(CO)_5$ complex **4d**

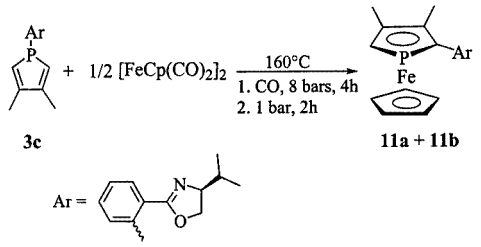
To summarize, the cycloaddition reactions shown in Schemes 6 and 8 demonstrate the generation of new phosphinidene intermediates, which display an unprecedented 1,3-dipolar behavior. Their reactivity allows the synthesis of new tricyclic 7-aza-1-phosphanorbornadiene derivatives.

Application of such reactions to the preparation of new optically pure ligands for transition metal catalysis should be possible, provided that the separation of the diastereoisomers of **9** (or **10**) and the removal of the azaphosphanorbornadienes from their tungsten complexes could be performed. Although 7-aza-1-phosphanorbornadienes are new compounds whose catalytic properties are difficult to predict, the use of 1-phosphanorbornadienes as auxiliaries in transition metal catalysis, including asymmetric catalysis, is already well documented.[31]

Studies on the synthetic applications of the 1,3-dipolar cycloadditions above are in progress.

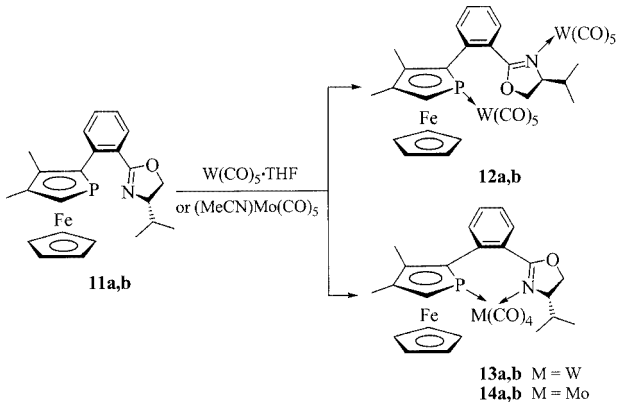
Synthesis of Chiral Phosphaferrocene Derivatives

Phosphaferrocenes[32] are usually obtained from phospholes by two different procedures: 1) lithium-induced cleavage of the phosphorus substituent and reaction of the phospholyl anion with either iron halides[33,34] or arene(cyclopentadienyl)iron derivatives;[35] and 2) thermal [1,5] sigmatropic shift of the phosphorus substituent and subsequent trapping of the intermediate 2*H*-phosphole by suitable iron complexes.[36,37] The second approach was selected for the synthesis of phosphaferrocenes starting from phosphole **4c** and $[CpFe(CO)_2]_2$ (Scheme 9).



Scheme 9. Synthesis of the phosphaferrocene derivatives **11**

Under the usual reaction conditions, the aryl group of **4c** underwent a [1,5] sigmatropic shift, followed by deprotonation of the 2*H*-phosphole and complexation to the cyclopentadienyliron moiety to afford **11** as a mixture of two isomers in a 1:2 ratio and in a moderate yield. The α-substituted phosphaferrocenes display planar chirality, so the formation of two diastereoisomers was expected. Chiral induction from the oxazoline moiety favors one of them, but the diastereoselectivity level is not yet satisfactory.



Scheme 10. Tungsten and molybdenum complexes of the phosphaferrocene **11**

Purification of the final products **11** and separation of isomers, proved to be difficult because of their air sensitivity. Thus, complexation of the phosphaferrocenes by pentacarbonyltungsten or -molybdenum was envisaged and furnished stable, easily isolable species (Scheme 10).

The main product obtained by reaction of **11** with an excess of the tungsten complex $(THF)W(CO)_5$, was the dimetallic complex **12**, where both the phosphorus and nitrogen atoms are complexed by a $W(CO)_5$ group. The major

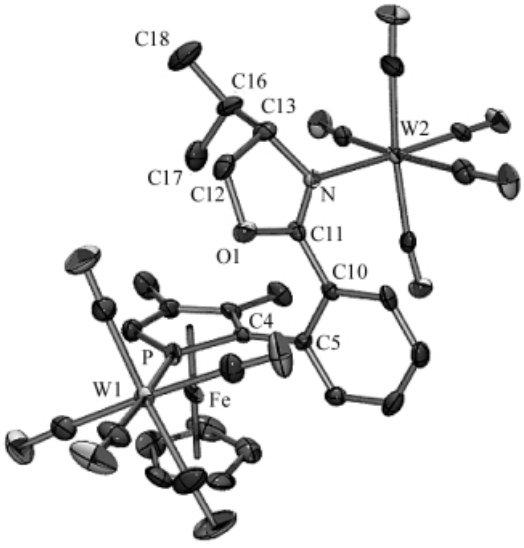


Figure 2. ORTEP diagram for the tungsten complex **12a**; selected bond lengths [Å]: W(1)−P 2.462(2), W(2)−N 2.284(5), Fe−P 2.253(2); selected bond angles [°]: C(1)−P−C(4) 91.8(3), C(11)−N−C(13) 107.7(5), W(2)−N−C(11) 130.0(4), W(2)−N−C(13) 122.2(4)

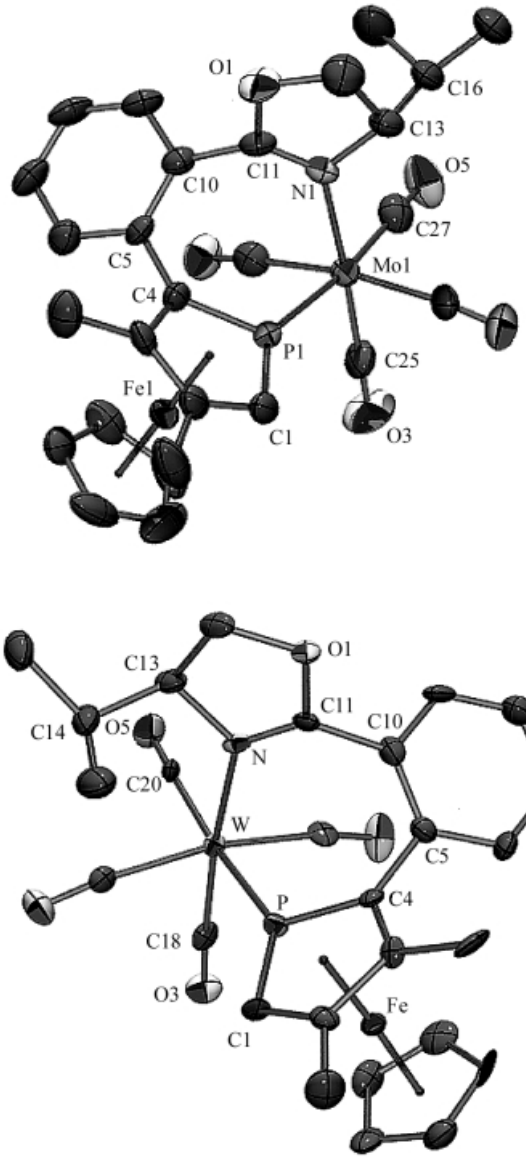

Figure 3. ORTEP diagrams for the molybdenum and tungsten complexes **14a** and **13b**; selected bond lengths [Å]: **14a**: Mo−P 2.475(1), Mo−N 2.277(4), Fe−P 2.240(2); **13b**: W−P 2.425(3), W−N 2.274(8), Fe−P 2.231(3); selected bond angles [°]: **14a**: P−Mo−N 79.4(1), C(1)−P−C(4) 90.6(3), C(11)−N−C(13) 106.9(4), Mo−N−C(11) 130.1(4), Mo−N−C(13) 122.6(3); **13b**: P−W−N 79.5(2), C(1)−P−C(4) 91.9(5), C(11)−N−C(13) 107.7(8), W−N−C(11) 128.4(7), W−N−C(13) 123.8(6)

diastereomer, (*S*,*S*)-**12a** (M = W), was obtained in pure form after crystallization. Its structure was confirmed by X-ray crystallography, as shown in Figure 2.

Minor amounts of the chelate derivative **13** (M = W) were also present in the reaction mixture. Crystals of one diastereomer (**13b**) were isolated and analyzed by X-ray crystallography (Figure 3, bottom). Its absolute configuration was determined as (*S*,*S*).

In the reaction with the molybdenum complex $(THF)Mo(CO)_5$, the P,N-bidentate phosphaferrocene **11** exclusively formed the chelate derivative **14** (M = Mo) as an isomeric mixture. The main isomer was obtained in pure form after crystallization and was characterized by X-ray diffraction studies. The ORTEP drawing for **14a** as well as selected bond angles and distances are given in Figure 3 (top). From the X-ray data, an (*R*,*S*) absolute configuration can be assigned to the isolated complex.

Isolation of complexes **13** and **14** shows that the geometry of the P,N-bidentate ligand **11** is suitable for chelate formation. This is a key feature of the ligand, as far as its use as a chiral auxiliary in catalysis is concerned. The high catalytic efficiency of oxazolines coupled with phosphanylferrocene moieties is well established to date,[38] and the use of phosphaferrocenes in catalysis is a field of growing interest.[39] Thus, ligands **11**, which associates the phosphaferrocene and the oxazoline moieties, should find interesting applications in organometallic asymmetric catalysis. Nevertheless, improvement of the synthetic approach and an efficient separation procedure for the two diastereomers **11a** and **11b** is required.

An alternative synthetic approach to the phosphaferrocenes **11** and other metallocene analogs could be the formation of the corresponding phospholylpotassium derivative after [1,5] shift of the aryl group.[40] The phospholyl anion could be treated with various metal halide complexes under milder conditions, and would hopefully be more diastereoselective in its outcome.

Conclusion

This work shows that phospholes bearing various optically pure substituents at the phosphorus atom are easily accessible species. They can either be applied as chiral auxiliaries in asymmetric transition metal catalysis or used as versatile synthons. As a very preliminary study, we have shown here that chiral phosphinidene complexes and phosphaferrocene derivatives can be obtained from these phospholes. The (oxazolylphenyl)phosphole **3c** seems to be a particularly promising starting material. On one hand, an unprecedented, [1,3]-dipole-like reactivity of the corresponding terminal phosphinidene complex has been demonstrated, and on the other hand, phosphole **3c** underwent a [1,5]-sigmatropic shift of the phosphorus substituent and should allow application of the well-known 2*H*-phosphole chemistry to the asymmetric synthesis of phosphorus derivatives.

Experimental Section

General: All reactions were routinely performed under nitrogen by using Schlenk technique and dry deoxygenated solvents. NMR spectra were obtained at 25 °C with a Bruker AC 200 SY spectrometer operating at 200.13 MHz for ^{1}H, 50.32 MHz for ^{13}C, and 81.01 MHz ^{31}P. Chemical shifts are expressed in ppm downfield from external TMS (^{1}H and ^{13}C) and 85% H_3PO_4 (^{31}P), and coupling constants are given in Hz. Mass spectra were obtained at 70 eV with an HP 5989 B spectrometer coupled with an HP 5890 chromatograph by the direct inlet method. IR spectra were obtained with a Perkin−Elmer 297. Elemental analyses were performed by the Service d'Analyse du CNRS at Gif sur Yvette, France.

1-(2-Isopropyl-5-methylcyclohexyl)-3,4-dimethylphosphole (3a): A solution of lithium 3,4-dimethylphospholide in 30 mL of THF was prepared by treating 3,4-dimethyl-1-phenylphosphole (3 g, 16 mmol) with excess lithium at room temperature. Menthyl mesylate (3.7 g, 16 mmol) was added, and the solution was allowed to reflux for 1 h. After hydrolysis, evaporation of THF, and extraction of the aqueous layer with diethyl ether, the organic phase was dried with $MgSO_4$. The product was purified by chromatography on silica gel with hexanes, affording **3a** as a colorless oil. Yield: 25% (1.0 g). ^{31}P NMR ($CDCl_3$): δ = −3.0. ^{1}H NMR ($CDCl_3$): δ = 0.85 (d, $^3J_{H,H}$ = 6.1 Hz, 3 H, Me), 0.94 (d, ^3J = 6.4 Hz, 3 H, Me), 0.95 (d, ^3J = 6.5 Hz, 3 H, Me), 1.04−1.99 (m, 9 H), 2.08 [s, 3 H, $C(CH_3)$], 2.09 [s, 3 H, $C(CH_3)$], 2.56 (m, 1 H), 6.41 (d, $^2J_{P,H}$ = 36.9 Hz, 2 H, 2-H and 5-H). ^{13}C NMR ($CDCl_3$): δ = 17.75 (Me), 17.81 (Me), 21.2 (Me), 21.5 (Me), 22.7 (Me), 26.5 (d, *J* = 8.7 Hz, CH_2), 28.7 (d, *J* = 6.1 Hz, CH), 31.2 (d, *J* = 7.8 Hz, CH), 36.1 (CH_2), 38.8 (d, *J* = 4.6 Hz, CH), 42.6 (CH_2), 48.8 (d, *J* = 11.6 Hz, CH), 129.1 (CH=), 146.5 (CH=), 146.7 (s, C).

(*S*)-2-[2-(3,4-Dimethyl-1*H*-phosphol-1-yl)phenyl]-4-isopropyl-4,5-dihydro-1,3-oxazole (3c): A mixture of lithium 3,4-dimethylphospholide (96 mmol), prepared from lithium metal and 3,4-dimethyl-1-phenylphosphole (18.0 g, 96 mmol), and (*S*)-2-(2-fluorophenyl)-4-isopropyl-4,5-dihydrooxazole (14.8 g, 72 mmol) in THF was heated at 45 °C for 48 h. After hydrolysis and extraction of the aqueous layer with diethyl ether, the organic phase was dried with $MgSO_4$. After evaporation of the solvent, the residue was purified by chromatography on silica gel with a hexane/ether (95:5) mixture, giving **3c** as a colorless oil. Yield: 61% (13.0 g). ^{31}P NMR ($CDCl_3$): δ = 0.9. ^{1}H NMR ($CDCl_3$): δ = 0.99 [d, *J* = 6.7 Hz, 3 H, $CH(CH_3)_2$], 1.10 [d, *J* = 6.7 Hz, 3 H, $CH(CH_3)_2$], 1.87 [m, *J* = 6.6 Hz, 1 H, $CH(CH_3)_2$], 2.10 (d, $^4J_{P,H}$ = 4.2 Hz, 6 H, CH_3), 4.29 (m, 3 H, CHN and OCH_2), 6.62 (d, $^2J_{P,H}$ = 34.3 Hz, 2 H, P−CH), 7.24−7.31 (m, 2 H, Ar-H), 7.35−7.41 (m, 1 H, Ar-H), 7.79−7.86 (m, 1 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 17.8 (d, ^3J = 2.3 Hz, 2 CH_3), 18.7 [$CH(CH_3)_2$], 19.1 [$CH(CH_3)_2$], 33.1 [$CH(CH_3)_2$], 70.4 (OCH_2), 73.5 (CHN), 127.6 (CH), 128.9 (d, *J* = 13.8 Hz, CH), 129.1 (CH), 130.4 (CH), 130.7 (d, ^2J = 18.6 Hz, C), 133.5 (CH), 136.4 (d, ^1J = 21.4 Hz, C), 147.7 (d, ^2J = 9.5 Hz, C), 147.9 (d, ^2J = 10.5 Hz,), 162.8 (C=N). MS: *m*/*z* (%) = 299 (78) [M^+], 230 (100). $C_{18}H_{22}NOP$ (299.35): calcd. C 72.22, H 7.41, N 4.68; found C 71.88, H 7.54, N 4.51. $[\alpha]_D$ = +64 (*c* = 1, toluene).

2-[2-(3,4-Dimethyl-1*H*-phosphol-1-yl)phenyl]-4,4-dimethyl-4,5-dihydro-1,3-oxazole (3d): A mixture of lithium 3,4-dimethylphospholide (48 mmol), prepared from lithium metal and 3,4-dimethyl-1-phenylphosphole (9.0 g, 48 mmol), and 2-(2-fluorophenyl)-4,4-dimethyl-4,5-dihydrooxazole (8.9 g, 46 mmol) in 40 mL of THF was heated at 45 °C for 48 h. After hydrolysis, evaporation of THF, and extraction of the aqueous layer with diethyl ether, the solution was

dried with $MgSO_4$. After concentration, the residue was purified by chromatography on a silica gel column with hexane/ether (95:5) as the eluent. Yield: 70% (9.2 g). ^{31}P NMR ($CDCl_3$): δ = 0.2. ^1H NMR ($CDCl_3$): δ = 1.43 [s, 6 H, $C(CH_3)_2$], 2.09 (dd, $^4J_{P,H}$ = 4.0, ^4J = 0.5 Hz, 6 H, CH_3), 4.13 (s, 2 H, OCH_2), 6.59 (dd, $J_{P,H}$ = 34.6, ^4J = 0.5 Hz, 2 H, P−CH), 7.2−7.3 (m, 3 H, Ar-H), 7.7−7.8 (m, 1 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 17.7 (d, ^3J = 2.8 Hz, CH_3), 28.5 [$C(CH_3)_2$], 68.4 [$C(CH_3)_2$], 79.0 (OCH_2), 127.7 (CH-Ar), 128.9 (P−CH), 129.1 (d, ^2J = 4.3 Hz, C), 130.3 (CH-Ar), 131.2 (d, ^2J = 19.6 Hz, C), 133.4 (CH-Ar), 135.1 (d, ^1J = 21.4 Hz, C), 147.9 (d, ^2J = 10.6 Hz), 161.8 (s, C=N).

{1-(2-Isopropyl-5-methylcyclohexyl)-3,4-dimethylphosphole}W-(CO)$_5$ (4a): A solution of hexacarbonyltungsten (1.55 g, 4.4 mmol) in 250 mL of THF was irradiated under UV light for 30 min. To this solution was added a solution of **3a** (1.0 g, 4 mmol) in 10 mL of THF. After 1 h of stirring, the solvent was evaporated. The product was then purified by chromatography on silica gel, with hexane as eluent (R_f = 0.25), affording **4a** as a yellow powder. Yield: 91% (2.1 g). ^{31}P NMR ($CDCl_3$): δ = 11.4 ($^1J_{P,W}$ = 203.2 Hz). ^1H NMR ($CDCl_3$): δ = 0.80 (d, ^3J = 6.0 Hz, 3 H, Me), 0.92 (d, ^3J = 6.0, Hz, 3 H, Me), 0.93 (d, ^3J = 6.1 Hz, 3 H, Me), 1.14−1.80 (m, 8 H), 2.15 (s, 6 H, CH_3), 2.32−2.45 (m, 1 H), 2.77 (s, 1 H), 6.43 (d, $^2J_{P,H}$ = 37.2 Hz, 1 H, PCH), 6.53 (d, $^2J_{P,H}$ = 36.7 Hz, 1 H, PCH). ^{13}C NMR ($CDCl_3$): δ = 17.8 (d, ^3J = 3.4 Hz, Me), 17.1 (d, ^3J = 4.4 Hz, Me), 21.6 (Me), 21.8 (Me), 22.24 (Me), 26.0 (d, J = 2.8 Hz, CH_2), 28.8 (CH), 30.13 (CH), 35.4 (CH_2), 39.8 (d, J = 5.9 Hz, CH_2), 42.1 (d, J = 14.6 Hz, CH), 50.9 (d, J = 6.0 Hz, CH), 131.3 (d, ^1J = 38.1 Hz, PCH), 131.8 (d, ^1J = 35.2 Hz, PCH), 146.3 (d, ^2J = 9.3 Hz, C), 146.5 (d, ^2J = 9.0 Hz, C), 197.0 (d, ^2J = 6.2 Hz, 4 CO_{cis}), 199.3 (d, ^2J = 16.8 Hz, CO_{trans}). MS (EI): m/z (%) = 574 (7) [M^+], 192 (100).

{1-[(6,6-Dimethylbicyclo[3.1.1]hept-2-yl)methyl]-3,4-dimethyl-1*H*-phosphole}W(CO)$_5$ (4b): A mixture of lithium 3,4-dimethylphospholide (56 mmol), prepared from lithium metal and 3,4-dimethyl-1-phenylphosphole (10.5 g, 56 mmol) in 60 mL of THF, and hexacarbonyltungsten (19.7 g, 56 mmol) was stirred for 24 h at room temperature. Then 13.0 g (56 mmol) of myrtanyl mesylate were added and the mixture was stirred again for 48 h. After hydrolysis, the THF was evaporated under vacuum. The residue was extracted with diethyl ether, and the organic layer dried with $MgSO_4$. The product was then purified by chromatography on silica gel with hexane as eluent. Yield: 42% (13.5 g). ^{31}P NMR ($CDCl_3$): δ = 5.8 ($J_{P,W}$ = 206.9 Hz). ^1H NMR ($CDCl_3$): δ = 0.85 (d, J = 12.3 Hz, 1 H), 0.94 [s, 3 H, $C(CH_3)_2$], 1.19 [s, 3 H, $C(CH_3)_2$], 1.2−1.4 (m, 1 H), 1.8−2.1 (m, 8 H), 2.16 (s, 6 H, CH_3), 2.2−2.3 (m, 1 H), 6.28 (d, $^2J_{P,H}$ = 36.7 Hz, 1 H, P-CH), 6.33 (d, $^2J_{P,H}$ = 36.7 Hz, 1 H, P−CH). ^{13}C NMR ($CDCl_3$): δ = 17.1 (Me), 17.3 (Me), 23.3 (CH_3), 23.9 (d, ^3J = 4.7 Hz, CH_2), 26.1 (CH_2), 27.8 (CH_3), 32.9 (CH_2), 38.4 (P−CH_2−*C*H), 38.5 [$C(CH_3)_2$], 38.7 (d, ^1J = 22.9 Hz, P−CH_2), 40.8 (CH), 48.1 (d, ^3J = 10.3 Hz, CH), 129.3 (d, ^1J = 17.0 Hz, P−CH), 130.1 (d, ^1J = 18.1 Hz, P−CH), 149.8 (d, ^2J = 7.8 Hz, C), 150.2 (d, ^2J = 7.8 Hz, C), 196.4 (d, ^2J = 7.2 Hz, 4 CO_{cis}), 199.3 (d, ^2J = 16.7 Hz, CO_{trans}). MS: m/z (%) = 572 (26) [M^+], 407 (100). $C_{21}H_{25}O_5PW$ (572.23): calcd. C 44.08, H 4.40; found C 43.69, H 4.41.

{(*S*)-2-[2-(3,4-Dimethyl-1*H*-phosphol-1-yl)phenyl]-4-isopropyl-4,5-dihydro-1,3-oxazole}W(CO)$_5$ (4c): A solution of hexacarbonyltungsten (0.89 g, 2.5 mmol) in 250 mL of THF was irradiated under UV for 30 min. To this solution was added a solution of **3c** (0.76 g, 2.5 mmol) in 10 mL of THF. After 30 min of stirring, the solvent was evaporated. The product was then purified by chromatography on silica gel with a hexane/diethyl ether gradient (from 24:1 to 9:1) affording **4c** as a yellow powder (R_f = 0.4 in hexane/diethyl ether, 3:2),. Yield: 85% (1.34 g). ^{31}P NMR ($CDCl_3$): δ = 9.2 ($^1J_{P,W}$ = 213 Hz). ^1H NMR ($CDCl_3$): δ = 1.00 [d, J = 6.7 Hz, 3 H, $CH(CH_3)_2$], 1.09 [d, J = 6.7 Hz, 3 H, $CH(CH_3)_2$], 2.08 [m, J = 5.3 Hz, 1 H, $CH(CH_3)_2$], 2.12 (s, 3 H, CH_3), 2.18 (s, 3 H, CH_3), 4.22−4.53 (m, 3 H, CHN and OCH_2), 6.64 (d, $J_{P,H}$ = 33.0 Hz, 1 H, P−CH), 6.90 (d, $J_{P,H}$ = 32.9 Hz, 1 H, P−CH), 7.39−7.45 (m, 2 H, Ar-H), 7.57−7.67 (m, 1 H, Ar-H), 8.0−8.1 (m, 1 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 17.1 (d, ^3J = 10.1, Me), 17.3 (d, ^3J = 11.1 Hz, Me), 17.6 [$CH(CH_3)_2$], 19.0 [$CH(CH_3)_2$], 32.3 [$CH(CH_3)_2$], 69.6 (OCH_2), 72.7 (CHN), 129.1 (d, J = 10.5 Hz), 129.6, 129.7, 130.0 (d, J = 6.0 Hz), 130.6, 130.7, 131.8 (d, J = 7.0 Hz), 134.0 (d, ^1J = 35.1 Hz, PCH), 148.9 (d, ^2J = 9.8 Hz, C), 149.1 (d, ^2J = 10.2 Hz, C), 162.1 (C=N), 196.9 (d, ^2J = 7.1 Hz, 4 CO_{cis}), 200.0 (d, ^2J = 18.5 Hz, CO_{trans}). MS: m/z (%) = 623 (1) [M^+], 595 (33) [M − CO], 380 (100).

{2-[2-(3,4-Dimethyl-1*H*-phospholyl)phenyl]-4,4-dimethyl-4,5-dihydro-1,3-oxazole}W(CO)$_5$ (4d): A solution of hexacarbonyltungsten (1.85 g, 5.2 mmol) in 250 mL of THF was irradiated under UV light for 30 min. To this solution was added a solution of **3d** (1.5 g, 5.2 mmol) in 10 mL of THF. After 30 min of stirring, the solvent was evaporated. The product was then purified by chromatography on silica gel, with a hexane/diethyl ether gradient. Complex **4c** was obtained as a yellow powder (R_f = 0.35 in hexane/diethyl ether, 3:2). Yield: 80% (2.54 g). ^{31}P NMR ($CDCl_3$): δ = 11.8 ($^1J_{P,W}$ = 214 Hz). ^1H NMR ($CDCl_3$): δ = 1.50 [s, 6 H, $C(CH_3)_2$], 2.12 (s, 6 H, CH_3), 4.19 (s, 2 H, OCH_2), 6.72 (dd, $J_{P,H}$ = 33.2, ^4J = 0.8 Hz, 2 H, P−CH), 7.37−7.47 (m, 2 H, Ar-H), 7.53−7.63 (m, 1 H, Ar-H), 7.98−8.04 (m, 1 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 17.3 (d, ^3J = 11.8 Hz, CH_3), 28.3 [$C(CH_3)_2$], 68.8 [$C(CH_3)_2$], 79.2 (OCH_2),129.3 (d, J = 5.1 Hz, C), 128.8, 129.4, 129.7, 130.5, 130.7, 130.8, 131.9, 132.0, 134.1 (d, ^1J = 35.1 Hz, PCH), 149.1 (d, ^2J = 10.7 Hz, C), 160.9 (C=N), 197.2 (d, ^2J = 7.2 Hz, CO_{cis}), 200.4 (d, ^2J = 19.6 Hz, CO_{trans}).

{Dimethyl 7-[(6,6-dimethylbicyclo[3.1.1]hept-2-yl)methyl]-5,6-dimethyl-7-phosphabicyclo[2.2.1]hepta-2,5-diene-2,3-dicarboxylate}W(CO)$_5$ (5b): To a solution of **4b** (11.4 g, 20 mmol) in 50 mL of toluene was added 15 mL (120 mmol) of dimethyl acetylenedicarboxylate. The solution was heated to 84 °C for 30 h. The solvent was evaporated under vacuum. The residue was purified by chromatography on silica gel with hexane/diethyl ether (95:5) as the eluent. Recrystallization afforded pure **5b** as yellow crystals. Yield: 74% (10.5 g). ^{31}P NMR ($CDCl_3$): δ = 217.5 ($^1J_{P,W}$ = 234.3 Hz). ^1H NMR ($CDCl_3$): δ = 0.90 (d, J = 9.9 Hz, 1 H) 0.97 [s, 3 H, $C(CH_3)_2$], 1.16 [s, 3 H, $C(CH_3)_2$], 1.40 (m, 1 H), 1.72−1.80 (m, 1 H), 1.83−1.90 (m, 3 H), 1.94 (s, 3 H, CH_3), 1.95 (s, 3 H, CH_3), 2.19−2.58 (m, 5 H), 3.56 (m, $^2J_{P,H}$ = 3.0, ^4J = 3.0 Hz, 2 H, P−CH), 3.82 (s, 3 H, OCH_3), 3.84 (s, 3 H, OCH_3). ^{13}C NMR ($CDCl_3$): δ = 15.9 (Me), 16.0 (Me), 22.6 (d, ^3J = 4.5 Hz, CH_2), 22.6 (CH_3), 26.2 (CH_2), 27.9 (CH_3), 33.8 (CH_2), 38.3 (d, ^1J = 17.9 Hz, P−CH_2), 38.5 [$C(CH_3)_2$], 41.0 (CH), 43.1 (P−CH_2*C*H), 47.3 (d, ^3J = 7.7 Hz, CH), 52.5 (OMe), 59.9 (d, ^1J = 19.6 Hz, P-CH), 60.3 (d, ^1J = 18.4 Hz, P-CH), 138.9 (d, ^2J = 2.6 Hz, C), 139.1 (d, ^2J = 14.6 Hz, C), 145.3 [d, ^2J = 5.1 Hz, *C*(CO_2Me)], 146.0 [d, ^2J = 4.8 Hz, *C*(CO_2Me)], 165.0 [d, ^3J = 3.0 Hz, C(*C*O_2Me)], 165.4 [d, ^3J = 2.7 Hz, C(*C*O_2Me)], 196.2 (d, ^2J = 6.6 Hz, 4 CO_{cis}), 197.8 (d, ^2J = 25.7 Hz, CO_{trans}). MS: m/z (%) = 714 (4) [M^+], 191 (100).

(7-Aza-1-phosphabicyclo[2.2.1]hept-2-ene)W(CO)$_5$ Complexes 9a and 9b: A solution of **4c** (0.66 g; 1.0 mmol) and dimethyl acetylenedicarboxylate (0.26 mL; 2.1 mmol) in 3 mL of toluene was heated under reflux for 15 h. The crude mixture was purified directly by chromatography on silica gel with toluene as eluent. Two diastereo-

mers were obtained in a 4:1 ratio. Yield: 63% (0.43 g). ^{31}P NMR (toluene): δ = 38.5 (minor diastereomer), 41.8 (major diastereomer). The mixture was dissolved in toluene and layered with hexane. Storage of the solution at 6 °C gave orange crystals of the main diastereomer. ^{31}P NMR ($CDCl_3$): δ = 42.1 ($^1J_{P,W}$ = 289 Hz). ^{1}H NMR ($CDCl_3$): δ = 0.68 [d, *J* = 7.0 Hz, 3 H, $CH(CH_3)_2$], 0.71 [d, *J* = 6.6 Hz, 3 H, $CH(CH_3)_2$], 2.00 [m, *J* = 3.5 Hz, 1 H, $CH(CH_3)_2$], 3.33 (m, *J* = 14.9 et 3.5 Hz, 1 H, CHN), 3.54 (s, 3 H, OMe), 3.59 (s, 3 H, OMe), 4.00 (AB, *J* = 7.7 Hz, 2 H, OCH_2), 6.91−7.14 (m, 2 H, Ar-H), 7.33−7.38 (m, 1 H, Ar-H), 7.41−7.53 (m, 1 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 14.5 (Me), 19.8 (Me), 29.0 [$CH(CH_3)_2$], 52.6 (OMe), 52.7 (OMe), 58.6 (d, ^2J = 2.6 Hz, N−CH), 72.9 (d, ^3J = 7.6 Hz, OCH_2), 115.8 (N−C−O), 121.3 (d, *J* = 3.0 Hz, CH-Ar), 126.4 (d, *J* = 12.3 Hz, CH-Ar), 128.5 (d, *J* = 15.6 Hz, CH-Ar), 129.5 (CH-Ar), 142.6 (C-Ar), 146.4 [P−C=*C*(CO_2Me)], 148.8 [d, ^1J = 44.2 Hz, P−*C*(CO_2Me)], 160.4 (d, *J* = 6.8 Hz, P−C-Ar), 164.0 [d, ^2J = 14.3 Hz, P−C(*C*O_2Me)], 164.2 [d, *J* = 12.1 Hz, P−C=C(*C*O_2Me)], 194.2 (d, ^2J = 8.1 Hz, W−CO_{cis}), 195.9 (d, ^2J = 30.3 Hz, W−CO_{trans}).

(7-Aza-1-phosphabicyclo[2.2.1]hept-2-ene)W(CO)$_5$ (9d): A solution of **4d** (2.0 g; 3.3 mmol) and dimethyl acetylenedicarboxylate (0.9 mL; 7.3 mmol) in 8 mL of toluene was heated under reflux for 14 h. The crude mixture was purified directly by chromatography on silica gel with toluene as eluent. The product was dissolved in toluene and layered with hexane. Storage of the solution at 6 °C gave **9d** as orange crystals. Yield: 54% (1.2 g). ^{31}P NMR ($CDCl_3$): δ = 32.2 ($^1J_{P,W}$ = 286 Hz). ^{1}H NMR ($CDCl_3$): δ = 1.16 [s, 3 H, $C(CH_3)_2$], 1.24 [s, 3 H, $C(CH_3)_2$], 3.53 (s, 3 H, OMe), 3.60 (s, 3 H, OMe), 3.98 (AB, 2 H, OCH_2), 6.92−7.14 (m, 2 H, Ar-H), 7.34−7.44 (m, 2 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 25.8 [d, *J* = 6.3 Hz, C(*C*H_3)$_2$], 28.3 [C(*C*H_3)$_2$], 52.4 (OMe), 52.7 (OMe), 60.1 [*C*(CH_3)$_2$], 85.9 (d, ^3J = 4.7 Hz, OCH_2), 115.0 (s, N−C), 121.0 (d, *J* = 3.8 Hz, CH-Ar), 126.1 (d, *J* = 12.2 Hz, CH-Ar), 127.7 (d, *J* = 15.6 Hz, CH-Ar), 128.95 (CH-Ar), 145.2 (C-Ar), 149.2 [d, *J* = 5.9 Hz, P−C=*C*(CO_2Me)], 149.3 [d, *J* = 43.8 Hz, P−*C*(CO_2Me)], 160.9 (d, *J* = 5.9 Hz, P−C(Ar)], 163.4 [d, *J* = 14.0 Hz, P−C(*C*O_2Me)], 164.1 [d, *J* = 11.2 Hz, P−C=C(*C*O_2Me)], 194.4 (d, *J* = 8.1 Hz, W−CO_{cis}), 195.9 (d, *J* = 30.2 Hz, W−CO_{trans}). $C_{22}H_{18}NO_{10}PW$ (671.19): calcd. C 39.37, H 2.70; found C 39.33, H 2.67.

2-{2-[(*S*)-4-Isopropyl-4,5-dihydro-1,3-oxazol-2-yl]phenyl}-3,4-dimethyl-1-phosphaferrocene (11a and 11b): A solution of **3c** (0.73 g, 2.4 mmol) and dicarbonyl(η^5-cyclopentadienyl)iron dimer (0.42 g, 1.2 mmol) in 40 mL of toluene was heated at 160 °C for 4 h under 8 bar of CO. The carbon monoxide pressure was then released and the solution heated for additional 3 h. The solution was then allowed to cool to room temperature. The final products **11a** and **11b** were characterized only by ^{31}P NMR as the crude mixture. Two diastereomers were present in a 2:1 ratio. ^{31}P NMR (toluene): δ = −67.1 (minor diastereomer), −68.0 (major diastereomer).

(μ-{2-{2-[(*S*)-4-Isopropyl-4,5-dihydro-1,3-oxazol-2-yl]phenyl}-3,4-dimethyl-1-phosphaferrocene})[W(CO)$_5$]$_2$ (12a and 12b): A solution of W(CO)$_5$(THF), prepared from 1.70 g (4.8 mmol) of hexacarbonyltungsten in 250 mL of THF, was poured into the crude mixture of **11a**,**b**. The solution was stirred at room temperature for 0.5 h. After evaporation of the solvent, the mixture was purified by chromatography on silica gel with toluene, affording **12a** and **12b** as an orange powder. The chelate compounds **13a** and **13b** were also isolated from the reaction mixture. Yield of **12a**,**b** from **3c** was 60% (1.53 g). The major diastereomer [(*S*,*S*)-**12a**] was obtained in pure form after crystallization from hexane. **12a**: ^{31}P NMR ($CDCl_3$): δ = −34.5 ($^1J_{P,W}$ = 263, $^2J_{P,H}$ = 32.4 Hz). ^{1}H NMR ($CDCl_3$): δ = 0.42 [d, *J* = 6.7 Hz, 3 H, $CH(CH_3)_2$], 0.88 [d, *J* = 7.0 Hz, 3 H, $CH(CH_3)_2$], 2.11 (s, 3 H, CH_3), 2.20 (s, 3 H, CH_3), 2.63 [m, 1 H, C*H*(CH_3)$_2$], 3.70 (d, $J_{P,H}$ = 32.4 Hz, P−CH), 3.93−4.34 (m, 3 H, CHN, OCH_2), 4.51 (s, 5 H, Cp), 7.49−7.61 (m, 4 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 12.9 [$CH(CH_3)_2$], 15.4 (d, *J* = 3.0 Hz, Me), 16.2 (d, *J* = 4.5 Hz, Me), 19.0 [$CH(CH_3)_2$], 29.9 [*C*$H(CH_3)_2$], 67.8 (OCH_2), 69.9 (P−CH), 74.1 (Cp), 77.5 (CHN), 93.1 (C), 93.12 (C), 93.7 (d, *J* = 2.2 Hz, P−C), 127.7 (CH-Ar), 130.1 (CH-Ar), 130.9 (d, *J* = 3.2 Hz, C), 131.3 (CH-Ar), 133.9 (d, *J* = 3.5 Hz, CH-Ar), 134.4 (d, *J* = 13.8 Hz, C-2′), 171.6 (C=N), 194.5 (d, *J* = 8.0 Hz, CO_{cis}-P), 197.8 (CO_{cis}-N), 197.8 (d, *J* = 32.0 Hz, CO_{trans}-P), 200.8 (CO_{trans}-N). $C_{33}H_{26}FeNO_{11}PW_2$ (1067.06): calcd. C 37.14, H 2.46; found C 37.22, H 2.33. [α]$_D$ = −249 (*c* = 1, toluene). The structure of **12a** has been confirmed by X-ray diffraction studies. The minor diastereomer (*R*,*S*)-**12b** was characterized only by ^{31}P NMR ($CDCl_3$): δ = −31.4 ($^1J_{P,W}$ = 261.6, $^2J_{P,H}$ = 31.8 Hz).

(2-{2-[(*S*)-4-Isopropyl-4,5-dihydro-1,3-oxazol-2-yl]phenyl}-3,4-dimethyl-1-phosphaferrocene)W(CO)$_4$ (13a and 13b): These compounds were obtained as side products during the synthesis of **12a**,**b** and were isolated by chromatography on silica gel. Crystals of the major diastereomer (**13b**) were obtained from a hexane solution. Yield (**13a** and **13b**): 3% (50 mg). ^{31}P NMR (toluene): δ = −0.7 (main diastereomer), −9.6 (minor diastereomer). The structure of **13b** was established by X-ray diffraction studies.

(2-{2-[(*S*)-4-Isopropyl-4,5-dihydro-1,3-oxazol-2-yl]phenyl}-3,4-dimethyl-1-phosphaferrocene)Mo(CO)$_4$ (14a and 14b): To a crude solution of **11a**,**b**, prepared from 2 g (6.7 mmol) of **3c**, was added 1 equiv. of the (MeCN)Mo(CO)$_5$ complex [prepared from 1.76 g (6.7 mmol) of hexacarbonylmolybdenum and 0.74 g (6.7 mmol) of trimethylamine *N*-oxide in 30 mL of acetonitrile]. The solution was stirred at room temperature for 1 h. After evaporation of the solvent, the mixture was purified by chromatography on silica gel with hexane/toluene (4:1), affording an isomeric mixture of the chelate complexes **14a** and **14b** as an orange powder. Yield over two steps: 47% (1.96 g). The minor diastereomer was characterized by ^{31}P NMR ($CDCl_3$): δ = 8.6. The major diastereomer [(*R*,*S*)-**14a**] was obtained in pure form by crystallization in hexane. **(*R*,*S*)-14a:** ^{31}P NMR ($CDCl_3$): δ = 1.5. ^{1}H NMR ($CDCl_3$): δ = 0.86 [d, *J* = 6.7 Hz, 3 H, $CH(CH_3)_2$], 0.93 [d, *J* = 7.0 Hz, 3 H, $CH(CH_3)_2$], 2.27 (s, 6 H, CH_3), 2.80 [m, 1 H, C*H*(CH_3)$_2$], 3.71 (d, $J_{P,H}$ = 34.0 Hz, P−CH), 4.05−4.20 (m, 3 H, CHN, OCH_2), 4.34 (s, 5 H, Cp), 7.11−7.45 (m, 4 H, Ar-H). ^{13}C NMR ($CDCl_3$): δ = 13.5 [$CH(CH_3)_2$], 13.9 (Me), 16.9 (d, *J* = 2.8 Hz, Me), 18.9 [$CH(CH_3)_2$], 29.4 [*C*$H(CH_3)_2$], 67.4 (OCH_2), 68.8 (d, *J* = 17.5 Hz, P−CH), 74.5 (Cp), 76.4 (CHN), 90.0 (d, *J* = 13.1 Hz, P−C), 92.4 (C), 94.1 (d, *J* = 2.6 Hz, C), 126.4 (CH-Ar), 128.4 (CH-Ar), 129.9 (CH-Ar), 130.1 (d, *J* = 16.0 Hz), 133.1 (d, *J* = 5.4 Hz, CH-Ar), 136.9 (d, *J* = 13.4 Hz, C), 169.5 (C=N), 204.9 (d, *J* = 12.1 Hz, CO_{cis}-P), 208.4 (d, *J* = 10.5 Hz, CO_{cis}-P), 215.7 (d, *J* = 47.0 Hz, CO_{trans}-P), 219.8 (d, *J* = 9.2 Hz, CO_{cis}-P). IR (ν_{CO}): $\tilde{\nu}$ = 2017 (m), 1895 (s), 1846 cm^{-1} (s). $C_{27}H_{26}FeMoNO_5P$ (627.26): calcd. C 51.70, H 4.18; found C 51.87, H 4.05.

[18] Bringing stereogenic centers closer to the phosphorus atom could lower the reactivity of the corresponding phospholes with DMAD and thus preclude the generation of phosphinidene complexes by this method. In such cases the phosphinidene complexes bearing chiral phosphorus substituents could be better generated by thermolysis of the corresponding phosphirane complexes (see: A. Marinetti, C. Charrier, F. Mathey, J. Fischer, *Organometallics* **1985**, *4*, 2134−2138), which are easily accessible through cyclization reactions (see ref.[19b]).

Investigation of the Enantioselectivity Observed in Epoxidation Reactions Catalysed by Bis-Strapped Chiral Porphyrins Derived from L-Proline

Bernard Boitrel,*[a][‡] Valérie Baveux-Chambenoît,[a] and Philippe Richard[a]

Keywords: L-Proline / Epoxidations / Porphyrins / Enantioselectivity / Iron

The enantiomeric excesses obtained during the epoxidation reactions of *p*-chlorostyrene or 1,2-dihydronaphthalene catalysed by two different series of chiral porphyrins are reported. An attempt is made to correlate the enantioselectivity with the steric hindrance generated by the straps of these catalysts. It is shown that this steric hindrance is influenced by the nature of the strap and that it can be approximated. Additionally, the same strap is tethered in two different fashions on each side of the porphyrin, leading to either D_2- or C_2-symmetrical catalysts, for which the two sides are identically functionalised.

Introduction

Metalloporphyrins have been well known, for two decades, to be effective catalysts for unfunctionalised alkene epoxidation[1−3] or alkane hydroxylation.[4] More recently, they have also been investigated as effective catalysts for cyclopropanation[5] and aziridination[6] reactions. Indeed, when compared with metallosalens, porphyrinoid catalysts are expected to exhibit much higher turnover numbers.[7] This criterion is of course extremely important in any catalysis, but may be much more important in the case of "destructive" catalysis, such as oxidation. In the case of chiral molecules, although different encouraging results have been reported, the obtained enantioselectivities are generally lower than those described for metallosalens, and also much more difficult to rationalise. This observation can be partially explained by the fact that the complete series of these latter catalysts have been synthesised and extensively studied.[8−10] We believe that the study of a series of potential catalysts can help our understanding of how the enantioselectivity can be achieved.[11−13] Indeed, for oxidation reactions, although the use of aromatic structures such as BINAP-related straps lead to a robust catalyst, it is difficult to predict the effectiveness of the same catalyst in terms of selectivity.[7]

Recently, we have reported on the synthesis of a complete family of potential chiral catalysts for epoxidation reactions. We were able to obtain an X-ray structure of one of the catalysts metallated by zinc(II) and hence have a precise image of the chiral superstructure. Moreover, the ^{1}H NMR spectroscopic studies of the same molecule indicated that the solution structure was in agreement with the structure in the solid state.[14] In this paper, we now report on the catalytic activity of two different series of iron(III) chiral catalysts, related by the point of attachment of the chiral straps, in the asymmetric epoxidation of *p*-chlorostyrene and 1,2-dihydronaphthalene by iodosylbenzene.

Results and Discussion

In previous studies, excellent enantiomeric excesses (*ee*) and good turnover numbers have been reported on. The main goal of this study is to determine if the enantioselectivities observed for a given reaction, namely the epoxidation of an unfunctionalised olefin, can be directly correlated with the steric hindrance of the strap in a D_2-symmetrical environment, as in the first series of porphyrins **1**−**6** (Figure 1, left column). For that purpose, we needed to make use of several potential catalysts for which we have a precise representation of the catalyst in solution.

We have already published the crystal structure of the zinc counterpart of porphyrin **1**.[14] In Figure 2 we have represented two other views of the same molecule in order to describe a structural parameter that we have defined as *R*, the ratio of the steric hindrance of the chiral strap and the steric hindrance of the porphyrin core itself (R = S/P). This ratio gives an unbiased representation of the steric hindrance of the strap whilst taking into account the planarity of the porphyrin. It is graphically measured as indicated in Figure 2, with a spatial extent limited to the carbon atoms. Indeed, this ratio has been evaluated by molecular mechanics modelling for six different bis-strapped porphyrins,

and is found to range from 0.20 to 0.51 (Table 1).[15] For our study, we have assumed that the conformation observed for the zinc(II)−porphyrin is not very different from that in the iron(III) complex used in the epoxidation reaction. Furthermore, we have validated our results by modelling and comparing the *R* value calculated theoretically with the experimental value in the case of **1Zn**; the values of 0.49 and 0.51, respectively, are strikingly similar. This also proves that the intramolecular coordination of the zinc atom does not significantly influence this parameter.

The results of the modelling of the six chiral porphyrins synthesised in the first αβαβ series are depicted in Figure 3. They are represented according to the same point of view as in Figure 2.[16] It is obvious that the *R* value increases as we examine the catalysts from (a) to (f). This means that if the enantioselectivity is a function of the steric hindrance during the approach of the olefin, we should obtain increasing values of *ee* as we examine the catalysts through the series **6**, **4**, **5**, **1**, **2**, and **3**. Different results emerged from the observation of the first four lines of Table 1. First of all, the different *ee* values are extremely low, as long as the straps of the catalyst are composed of a non-aromatic linker, and independent of the olefin. Indeed, with linkers such as the succinyl, fumaryl, adipyl, or glutaryl moieties, the *ee* values range from 1 to 7% in the case of a terminal olefin. Obviously, these linkers are attached just above the iron−oxo species generated by the action of iodosylbenzene on the iron(III)−porphyrin, and are likely to be easily oxidised instead of the olefin. These low *ee* values are also to be compared with those reported by Rose and Collman[17] with their "blank picket" porphyrins, for which they reported that the *ee* values vary inversely to the number of chiral pickets. It seems that our catalysts, although not at all comparable, are as poor catalysts as these picket porphyrins. On the other hand, the explanation advanced by the authors for their picket catalysts could also be valid for our

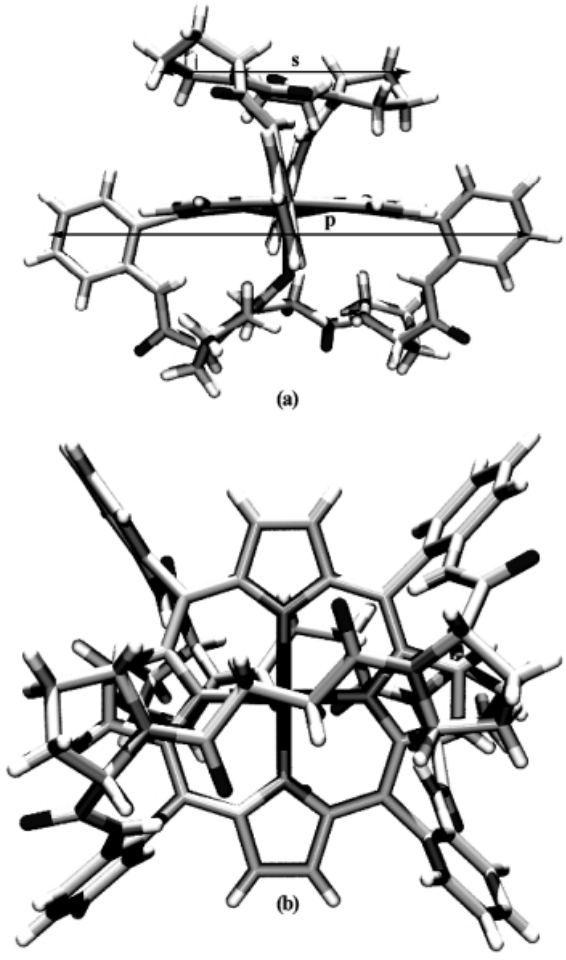

Figure 2. Stick representation (including hydrogen atoms) of the crystal structure of **1Zn**; (a) "*meso*-C_5-C_{15}" lateral view, (b) apical view

Table 1. Enantiomeric excesses obtained with the iron catalysts for two different olefins with the characteristic steric ratio *R* for catalysts **1**−**6**

Catalyst[a]	*p*-Chlorostyrene[b]	1,2-Dihydronaphthalene[b]	*R*[c]

Difum-αβαβ (**4**)	2	2	0.26
Ditere-αβαβ (**5**)	18	3	0.36
Diiso-αβαβ (**6**)	5	19	0.20
Disucc-ααββ (**7**)	26	3	−
Diglut-ααββ (**8**)	20	8	−
Diadip-ααββ (**9**)	31	26	−
Diiso-ααββ (**10**)	28	14	−

[a] Reaction conditions: catalyst (1 μmol), substrate (1000 μmol), and PhIO (100 μmol) react at room temperature in CH_2Cl_2 (2 mL).[b] Determined by GC with a Cyclodex-B chiral column. [c] In the case of **1Zn** (Figure 2), calculated equal to 0.51.

strap catalysts because the lowest *ee* value was obtained with the catalyst Disucc-αβαβ (**1**), for which the *R* value is almost the highest calculated and equal to 0.49. Now, if we

compare the side views (d) of Disucc-αβαβ (**1**) (R = 0.49) and (b) of Difum-αβαβ (**4**) (R = 0.26) (Figure 3), and if the *ee* value was to follow the lateral steric hindrance, the *ee* value should be found to be much lower in the case of Difum-αβαβ (**4**). Actually, they are almost the same. This means that either there is no relationship between this steric hindrance and the enantioselectivity or, this relation is not applicable in this case for other reasons. Indeed, the oxidative degradation of the catalyst could be consistent with this observation. The straps in catalysts such as **1**−**4** are so close to the metal centre and so sensitive to oxidation that they are oxidised immediately, and in fact, the measured *ee* value could reflect the enantioselectivity of the resulting mixture of degraded compounds. This explanation is consistent with previous results[17] for which it is believed that providing more access to the metal centre could increase the selectivity. The results obtained in the case of a (*Z*)-disubstituted olefin (1,2-dihydronaphthalene) follow the same trend and are as disappointing as in the case of the terminal olefin. Undeniably, the approach of such an encumbered olefin must be very limited and the *ee* values are even lower than for *p*-chlorostyrene.

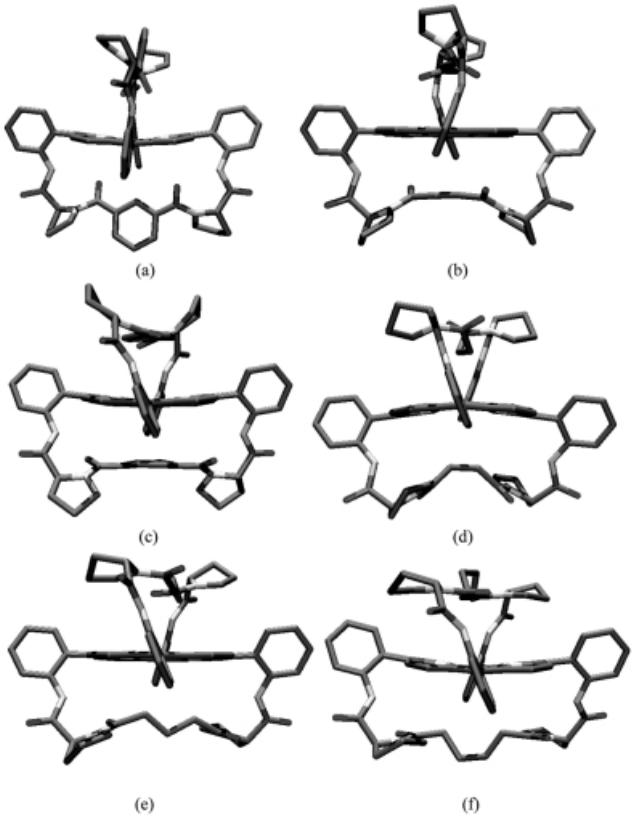

Figure 3. Stick representations of (a) **6**, (b) **4**, (c) **5**, (d) **1**, (e) **2**, and (f) **3** obtained by molecular mechanics modelling[15]

In a second study, we investigated a similar type of catalyst, but for which the linker is based on an aromatic diacyl dichloride, namely the porphyrins Ditere-αβαβ (**5**) and Diiso-αβαβ (**6**). The results of this comparison are much more informative, since the correlation between steric hindrance and enantioselectivity appears to be verified, but only for the terminal olefin. Actually, the results are contradictory when one compares the *ee* values obtained for the terminal olefin and the (*Z*)-disubstituted alkene. For porphyrin Ditere-αβαβ (**5**), which exhibits a greater R value than Diiso-αβαβ (**6**) (0.36 vs. 0.20), the observed *ee* value is 18% with *p*-chlorostyrene, but only 3% for 1,2-dihydronaphthalene. Conversely, for the catalyst Diiso-αβαβ (**6**), the *ee* value is 5% with *p*-chlorostyrene, but increases to 19% for 1,2-dihydronaphthalene. It clearly appears that with the terminal olefin, the steric hindrance is a pertinent parameter with a positive effect, whereas for a disubstituted olefin, the opposite effect is observed. This result, a priori difficult to anticipate, can be rationalised by considering two major facts. Firstly, the olefin cannot approach from the top of the catalyst,[18] but only from the side with its aromatic ring parallel to the mean plane of the porphyrin (side approach).[19] Secondly, it is striking that the aromatic rings of the straps in these two catalysts are in two extreme perpendicular positions. This observation is particularly visible in Figure 3 [views (a) and (c), bottom strap]. For catalyst Diiso-αβαβ (**6**) (a), the aromatic ring is perpendicular to the mean plane of the porphyrin whereas, for porphyrin Ditere-αβαβ (**5**) (c), it is parallel to the porphyrin plane. In the case of **5**, the enantioselectivity is much better for *p*-chlorostyrene because the olefin can introduce its double bond just above the iron−oxo species and perpendicular to the strap, with its aromatic ring avoiding the steric bulk of the L-proline ring. In the case of 1,2-dihydronaphthalene, this approach is not possible, and therefore its double bond remains parallel to the strap, resulting in no real discrimination by steric hindrance. Furthermore, in the case of **5**, the aromatic ring of the strap, parallel to the porphyrin plane, actually decreases the apparent hindrance of the five-membered ring of the L-proline. On the other hand, for catalyst **6** [Figure 3, view (a), top strap], there is a slight steric effect, mainly because the aromatic cycle remains in the plane of the strap (R = 0.20). Apparently, this subtle modification is sufficient to discriminate between the two different approaches of the disubstituted olefin, but not at all in the case of the terminal one. This explanation is in agreement with previous studies related to chiral picket porphyrins.[17] This particular comparison of two closely related catalysts with two different types of olefins is another example of how a fine difference in conformation can induce dramatic changes in the enantioselectivity, and also demonstrates that there should be a relation between the steric hindrance and the observed enantioselectivity, whether this relation is favourable or not. Furthermore, our catalyst Ditere-αβαβ (**5**), the L-prolinoyl analogue of Rose's L-alanine bis(handle) porphyrin,[20,21] must be compared with Mansuy's catalyst[22,23] that involves L-phenylalanine. In the L-phenylalanine series, an *ee* value of 50% was reported for the epoxidation of *p*-chlorostyrene, a value 2.5 times higher than the 18% *ee* obtained with **5**. This result, again, points out that a non-flexible structure such as the ring of L-proline is not a good structural feature for efficient enantioselectivity, and that L-phenylalanine, even with the possible rotation of the phenyl group around the methylene group of the lateral

chain, is a much better chiral inducer. This criterion has to be considered for further developments of chiral catalysts that involve L-proline.

In light of these instructive but relatively low enantioselectivities, we decided to extend our approach to another family of catalysts. Since 1995, we were aware of a study involving the four atropisomers of a chiral catalyst, synthesised by the condensation of a BINAP-type aldehyde with pyrrole,[24] leading to the aromatic analogues of the well-known "chiroporphyrins".[25] It was shown in this report that the iron−αααββ atropisomer was the most enantioselective catalyst among the four atropisomers for the epoxidation of styrene (59% *ee* vs. 7.5% *ee* for the αβαβ atropisomer). At a later stage this result was published,[13] and successfully generalised for a porphyrin bearing BINAP straps.[7] Thus, we have prepared the four new catalysts **7**−**10**, the analogues of **1**−**3** and **6**, respectively, with the αααββ geometry (Figure 1, right column). The lack of a crystal structure prevented us from evaluating the steric hindrance of the strap above the metal centre of the porphyrin as precisely as we did in the αβαβ series. However, we were able to estimate the steric hindrance in solution by examining the proton NMR spectra.

The ^{1}H NMR spectra of the two catalysts obtained by condensation of the glutaryl dichloride, **8** (top trace) and **2** (bottom trace) with the αααββ and αβαβ geometry, respectively, are represented in Figure 4. Clearly, in the case of **2**, the three multiplets that appear between δ = 0 and −3.5 can be assigned unambiguously to the three methylene groups of the glutaryl residues. However, an unexpected result can be seen for the chemical shifts of these three methylene groups with an αααββ geometry: their signals should be more downfield since the straps do not cross over the ring current of the porphyrin. The methylene protons with this geometry are as shielded as the methylene protons in the αβαβ geometry, and this seems to indicate that they are close to the porphyrin plane in both cases.

The results of the asymmetric epoxidation for the two olefins are interesting. The most obvious difference is represented by the *ee* values themselves. Indeed, for the epoxidation of the terminal olefin, they are much higher than for the first series. In addition, they seem to be almost the same (about 30% *ee*) for the three catalysts **7**, **9**, and **10**. Our preliminary modelling results seem to indicate that the bending of the straps over the porphyrin centre does not differ significantly when the length of the strap is varied from one methylene group to three groups. This could explain why the observed enantioselectivities are of the same order of magnitude in the case of *p*-chlorostyrene. For the disubstituted alkene, the *ee* value of one obtained for catalyst Diadip-αααββ (**9**) appears significantly different (26% *ee*) from that for the other catalysts, but is almost the same as that for the terminal olefin. This second observation can be explained by the fact that the structural feature that favours the discrimination between the two types of olefins for the catalysts in the αβαβ family, does not apply in the αααββ family. Indeed, during a side approach, the crevasse built by the bending of the straps over the porphyrin core can accommodate both types of olefins, with a slightly better selectivity for the terminal one. The two low *ee* values obtained by catalysts Disucc-αααββ (**7**) (3% *ee*) and Diglut-αααββ (**8**) (8% *ee*) for the disubstituted olefin can occur as

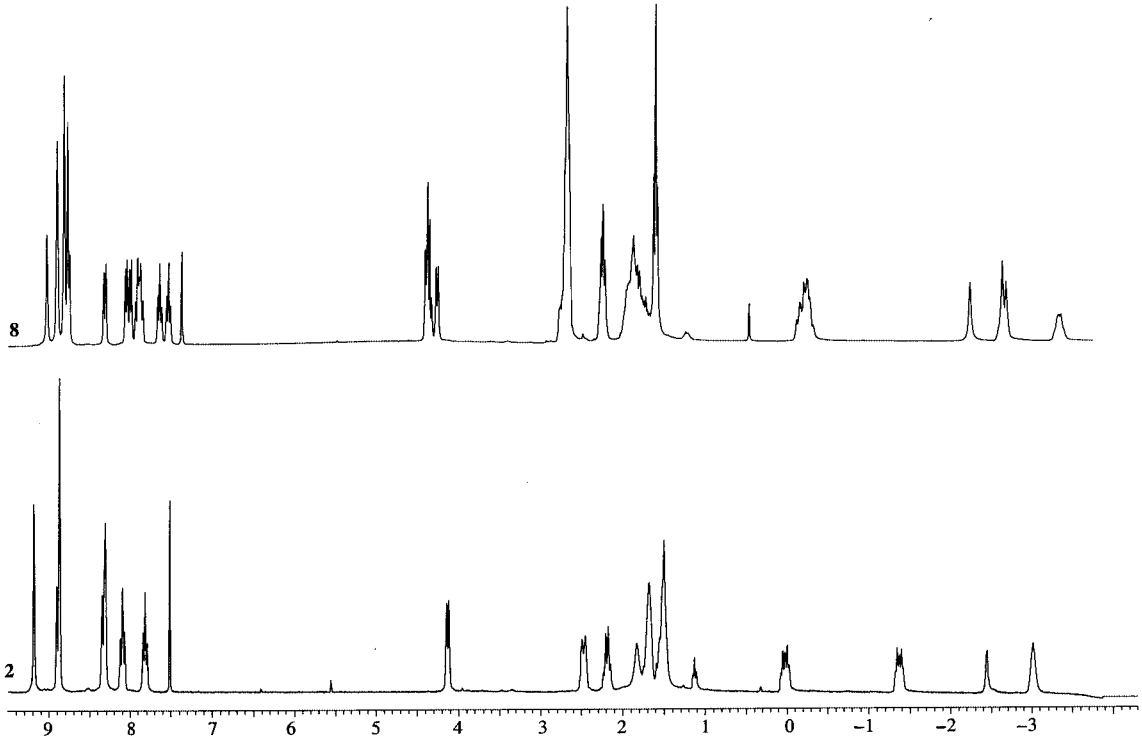

Figure 4. ^{1}H NMR spectra of porphyrins **8** and **2** ($CDCl_3$, 300 MHz, 300 K)

result of a less pronounced bending over the porphyrin, which is logical for catalysts with shorter straps than for the porphyrins Diiso-ααββ (**10**) or Diadip-ααββ (**9**). Globally, we can summarise this second part by the fact that if the linker (the diacyl dichloride employed in the last step of the synthesis) is long enough to allow the strap to bend over the metal centre, the enantioselectivity should not be decreased by switching from the αβαβ to the ααββ geometry. This phenomenon is observed only in the case of catalyst **9**, prepared with adipoyl dichloride.

Conclusion

We have reported and discussed the enantioselectivity of two closely related series of chiral bis(strapped) porphyrins, synthesised from L-prolinoyl residues. The first family, with an αβαβ geometry, with a strap crossing the porphyrin over the metal centre on each side, has been prepared to study the relationship between the steric hindrance of the strap and the observed enantiomeric excesses. For most of the catalysts under investigation, we found that congestion around the metal centre could not induce good enantioselectivities. In fact, these catalysts are poor in terms of reaction yield, and the measured enantiomeric excess does not reflect the activity of the initially designed molecule but rather of some degradation intermediates. It is important to underline that this hypothesis has already been reported for very different chiral catalysts and can now be generalised. For some well-defined catalysts, we have been able to establish that the enantioselectivity was correlated to the steric hindrance, but not always as expected. The molecules for which such a relationship exists are rather rare and deserve to be studied exhaustively. However, it must be underlined that this direct relationship between the steric hindrance and the *ee* value does not exist from a general point of view, the observed *ee* values may be influenced by many different factors. The comparison of the second series of catalysts with the first one confirms the previous explanation, namely that the enantioselectivity increases as the congestion around the metal centre decreases. Additionally, it also confirms that similar chiral inducers are more efficient with the ααββ geometry than with the αβαβ geometry. This was already known for picket structures, and is now applicable to strapped catalysts. Further studies are under investigation with these catalysts, both to evaluate them for asymmetric processes for which the catalyst is not destroyed, and to obtain a more accurate perception of their real structure in solution.

Experimental Section

General Remarks: Unless otherwise stated, the analytical facilities were provided by the Université de Bourgogne (C.S.M.) in Dijon. ^{1}H (500.13 MHz or 300.14 MHz) and ^{13}C (125.05 MHz or 75.47 MHz) NMR spectra were recorded with Bruker Avance DRX 500 or Avance 300 spectrometers and referenced to the residual protonated solvents. Mass spectra were performed with a MS/MS ZABSpec TOF spectrometer at the Université de Rennes I (C.R.M.P.O.). UV/Vis spectra were recorded with a Varian Cary 1E spectrometer. IR spectra were recorded with a Bruker IFS 66 spectrometer. All solvents (ACS for analysis) were purchased from Carlo Erba. THF was distilled from potassium metal. CH_2Cl_2 was used as received. Triethylamine and *N*-methylpiperidine were distilled from CaH_2. The starting materials were generally used as received (Acros, Aldrich) without any further purification. All reactions were performed under argon and monitored by TLC (silica, CH_2Cl_2/CH_3OH). Column flash chromatography was performed on silica gel (Merck TLC-Kieselgel 60 H, 15 μm). Enantiomeric excesses were determined by gas chromatography with a Chirasil-Dex CB as chiral capillary column (25 m × 0.25 mm, Chrompack). Compounds **1**, **4**, **5**, **6**, and **1Zn** have already been characterised. The two following porphyrins were prepared as previously reported, by reaction of a diacyl dichloride with the known α-5,15:β-10,20-tetrakis[2-(L-prolinoylamido)phenyl]porphyrin under high-dilution conditions.[14]

α-5,15:β-10,20-Bis{2,2′-[*N,N*′-bis(1,5-dioxo-1,5-pentanediyl)-L-prolinoyldiamido]diphenyl}porphyrin (2): This compound was prepared from glutaryl dichloride and obtained in 27% (37 mg) yield. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ = −3.24 (m, 4 H, glut), −2.67 (s, 2 H, NH_{pyr}), −1.60 (m, 4 H, glut), −0.21 (m, 4 H, glut), 1.29 (m, 8 H, Pro), 1.45 (m, 8 H, Pro), 1.95 (m, 4 H, Pro), 2.25 (m, 4 H, Pro), 3.90 (d, ^3J = 7.3 Hz, 4 H, Pro*), 7.58 (t, ^3J = 7.3 Hz, 4 H, aro), 7.86 (t, ^3J = 7.5 Hz, 4 H, aro), 8.09 (m, 8 H, aro + β-pyr), 8.64 (s, 4 H, NHCO), 8.66 (d, ^3J = 8.2 Hz, 4 H, aro), 8.95 (s, 4 H, β-pyr). ^{13}C NMR (75 MHz, $CDCl_3$, 300 K): δ = 15.0, 24.6, 27.3, 31.4, 46.4, 60.6, 115.4, 122.4, 123.6, 129.3, 130.3, 131.9, 134.4, 139.3, 169.6, 171.6. MS (MALDI-TOF): *m*/*z* = 1254.34 $[M]^+$. $C_{74}H_{70}N_{12}O_8{\cdot}CH_3OH{\cdot}CH_2Cl_2$ (1372.40): calcd. C 66.51, H 5.58, N 12.25; found C 66.52, H 6.05, N 11.88. UV/Vis (CH_2Cl_2): λ (10^{-3} ε [$M^{-1}{\cdot}cm^{-1}$]) = 421 (280.1), 516 (15.1), 549 (3.4), 588 (4.6), 643 nm (1.7). IR (KBr): ν̃ = 3477 (NH), 1691, 1631 cm^{-1} (CO).

α-5,15:β-10,20-Bis{2,2′-[*N,N*′-bis(1,6-dioxo-1,6-hexanediyl)-L-prolinoyldiamido]diphenyl}porphyrin (3): This compound was prepared from the adipoyl dichloride and obtained in 11% (15 mg) yield. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ = −3.95 (m, 4 H, adip), −2.52 (m, 6 H, adip + NH_{pyr}), −1.79 (m, 4 H, adip), −0.05 (m, 4 H, adip), 1.42 (m, 4 H, Pro), 1.70 (m, 4 H, Pro), 1.88 (m, 4 H, Pro), 2.29 (m, 8 H, Pro), 2.58 (m, 4 H, Pro), 4.33 (d, ^3J = 7.3 Hz, 4 H, Pro*), 7.42 (m, 8 H, aro), 7.82 (td, 4 H, ^3J = 7.7, ^4J = 2.1 Hz, aro), 8.47 (d, 4 H, ^3J = 8.1 Hz, aro), 8.67 (s, 4 H, β-pyr), 8.85 (s, 4 H, β-pyr), 9.69 (s, 4 H, NHCO). ^{13}C NMR (75 MHz, $CDCl_3$, 300 K): δ = 19.9, 24.9, 26.4, 31.2, 46.6, 60.4, 115.8, 124.2, 124.7, 129.5, 129.9, 133.4, 134.0, 135.5, 137.7, 169.9, 172.1. HR-MS (LSI-MS); *m*/*z*($C_{76}H_{75}N_{12}O_8$ [M + H]$^+$): calcd. 1283.5831; found 1283.5848. UV/Vis (CH_2Cl_2): λ (10^{-3} ε [$M^{-1}{\cdot}cm^{-1}$]) = 424 (288.5), 519 (15.2), 553 (3.9), 592 (4.7), 651 nm (2.2). IR (KBr): ν̃ = 3473 (NH), 1689, 1621 cm^{-1} (CO).

Typical Procedure for the Synthesis of Porphyrins 7−10: These porphyrins were synthesised according to the above-mentioned procedure, fully described for α-5,15:β-10,20-tetrakis[2-(L-prolinoylamido)-phenyl]porphyrin. Obviously, to obtain porphyrins **7**−**10**, the procedure was applied to the ααββ atropisomer, namely α-5,10:β-15,20-tetrakis[2-(L-prolinoylamido)phenyl]porphyrin. Thus, a solution of the former porphyrin, freshly prepared in 10 mL of THF, and a solution of the desired diacyl dichloride (0.264 mmol, 2.4 equiv.) in 10 mL of THF were added over 5 h with a syringe pump to a solution of NEt_3 (1.37 mL, 9.8 mmol, 90 equiv.) in 120 mL of THF placed under argon in an ice bath. The solution was stirred for 10 h. THF was removed under vacuum and the product was

chromatographed on silica gel. A CH_2Cl_2/CH_3OH mixture (98:2) was used for the elution.

α-5,10:β-15,20-Tetrakis[2-(*N*-*tert*-butoxycarbonyl-L-prolinoylamido)phenyl]porphyrin (11): *N*-Boc-L-proline (19.46 g, 90.4 mmol, 100 equiv.) was dissolved in dry THF (120 mL) under argon at −20 °C. *N*-Methylpiperidine (16.5 mL, 135 mmol, 150 equiv.) and then isobutyl chloroformate (11.15 mL, 85.9 mmol, 95 equiv.) were added. Immediately, a white precipitate appeared. A solution of TAPP ααββ (610 mg, 0.9 mmol) in 50 mL of THF, maintained at −20 °C, was then added. The reaction mixture was stirred for 3 h at this temperature and then warmed to room temperature. The mixture was filtered and the precipitate washed with diethyl ether. The solution was concentrated under vacuum and the residue was chromatographed on silica gel [elution with a CH_2Cl_2/CH_3OH (98:2)]. 1.18 g of pure product was obtained (89% yield). ^{1}H NMR (500 MHz, $CDCl_3$, 300 K): δ = −2.68 (s, 2 H, NH_{pyr}), −1.96 (s, 1 H, Pro), −1.63 (m, 1 H, Pro), −0.99 (m, 1 H, Pro), −0.44 (m, 2 H, Pro), −0.12 (m, 4 H, Pro), 0.63 (m, 4 H, Pro), 0.89 (m, 6 H, Pro), 1.17 (m, 36 H, Boc), 1.61 (s, 3 H, Pro), 2.66 (m, 2 H, Pro), 3.49 (m, 4 H, Pro*), 7.18 (s, 2 H), 7.64 (d, ^3J = 7.0 Hz, 2 H), 7.90 (m, 4 H), 8.00 (d, ^3J = 7.5 Hz, 4 H), 8.10 (s, 2 H), 8.16 (m, 4 H), 8.61 (d, ^3J = 6.5 Hz, 2 H), 8.71 (s, 2 H), 8.80 (s, 4 H, NHCO), 8.87 (s, 2 H). ^{13}C NMR (125 MHz, $CDCl_3$, 300 K): δ = 28.7, 28.9, 30.1, 43.9, 46.4, 59.5, 61.7, 114.5, 117.7, 120.6, 123.7, 124.6, 125.0, 127.3, 127.5, 130.2, 130.6, 131.8, 133.2, 134.0, 136.09, 139.1, 145.9, 152.9, 154.3, 170.5, 171.5. MS (FAB): *m*/*z* = 1463.0 $[M]^+$. HR-MS (LSI-MS); *m*/*z*($C_{84}H_{94}N_{12}NaO_{12}$ $[M + Na]^+$): calcd. 1485.7012; found 1485.6994. UV/Vis (CH_2Cl_2): λ (10^{-3} ε [$M^{-1}\cdot cm^{-1}$]) = 419 (308.2), 513 (16.8), 546 (3.9), 587 (4.9), 642 nm (1.7). IR (KBr): ṽ = 3383 (NH), 1698 cm^{-1} (CO). For the removal of the Boc group, **11** (0.16 g, 0.11 mmol) was dissolved in 10 mL of CH_2Cl_2 under argon. 1 mL of TFA was added. After 30 min, the solvent was removed under vacuum. The reaction was almost quantitative (0.11 g) and α-5,10:β-15,20-tetrakis[2-(L-prolinoylamido)phenyl]porphyrin used without any further purification.

α-5,10:β-15,20-Bis{2,2′-[*N,N*′-bis(1,4-dioxo-1,4-butanediyl)-L-prolinoyldiamido]diphenyl}porphyrin (7): This compound was prepared from succinyl dichloride and obtained in 45% (57 mg) yield. ^{1}H NMR (500 MHz, [D_5]pyridine, 383 K): δ = −1.78 (s, 2 H, NH), −1.52 (s, 2 H), −0.19 (s, 2 H), 0.12 (s, 2 H), 0.92 (s, 2 H), 1.08 (m, 8 H), 1.28 (m, 2 H), 1.43 (m, 2 H), 1.58 (m, 2 H), 1.79 (m, 2 H), 2.12 (m, 2 H), 2.46 (s, 2 H), 2.70 (m, 2 H), 2.85 (m, 2 H), 3.91 (m, 2 H, Pro*), 4.29 (m, 2 H, Pro*), 7.43 (t, ^3J = 7.5 Hz, 2 H, aro), 7.84 (m, 8 H), 8.04 (d, ^3J = 7.0 Hz, 2 H, aro), 8.34 (s, 2 H), 8.84 (d, ^3J = 4.5 Hz, 2 H, β-pyr), 8.89 (d, ^3J = 4.5 Hz, 2 H, β-pyr), 8.95 (s, 2 H), 9.04 (m, 4 H), 9.12 (s, 2 H), 9.63 (s, 2 H). ^{13}C NMR (500 MHz, $CDCl_3$, 300 K): δ = 24.2, 25.1, 25.7, 26.2, 27.6, 28.7, 45.2, 46.9, 60.1, 61.1, 114.2, 117.0, 119.7, 121.3, 122.4, 123.7, 130.1, 130.4, 131.5, 133.5, 135.1, 136.8, 138.1, 140.0, 169.7, 170.7. Typical Procedure for the Insertion of Iron Ions in Porphyrins: 50 mg of **2**−**3**, or **7**−**10** was dissolved in toluene (10 mL) inside a glove box maintained under 1 ppm of dioxygen. 2,6-Lutidine and an excess of $FeBr_2$ were added to the mixture. The solution was heated at reflux for 12 h until the reaction was complete as indicated by UV/Vis spectroscopy. The product was oxidised by air for 1 h. The solvent was removed under vacuum. The residue was dissolved in CH_2Cl_2, and washed with brine. The product was chromatographed on silica gel. A CH_2Cl_2/CH_3OH mixture (95:5) was used for the elution. The yield was almost quantitative (95%).

General Procedure for Asymmetric Olefin Epoxidation: The catalyst (1 μmol) and the olefin (1000 μmol) were dissolved in degassed CH_2Cl_2 (2 mL) in a Schlenk tube. While stirring under N_2, PhIO (100 μmol) was added in one portion. The mixture was stirred at room temperature for 30 min and then quenched with 2% PPh_3 in CH_2Cl_2. The solvent was removed under reduced pressure. Pentane was added and the mixture was filtered. Dodecane (10 μL, GC standard) was added. Enantiomeric excesses were determined by GC on a Chirasil-Dex CB capillary column. The GC conditions were as follows (epoxide, oven temperature, retention time): *p*-chlorostyrene oxide, 120 °C, 22.5 and 24.3 min; 1,2-dihydronaphthalene oxide, 130 °C, 18.9 and 20.4 min.

Structural Chemistry and Magnetism of Tb^{3+}-β′′-Alumina ($Tb_{0.46}Al_{10.62}Mg_{0.38}O_{17}$)

Frank Soetebier[a] and Werner Urland*[a]

Keywords: Aluminum / Magnesium / Terbium / Ion exchange / Crystal structure / Magnetic properties

The structure of completely exchanged Tb^{3+}-β′′-Al_2O_3 ($Tb_{0.46}Al_{10.62}Mg_{0.38}O_{17}$) crystals has been investigated by single crystal X-ray diffraction methods at room temperature [trigonal, $R\bar{3}m$, $Z = 3$, $a = 560.91(8)$ pm, $c = 3330.3(8)$ pm]. The terbium ions are found to occupy BR (49.2%) and mO positions (50.8%) in nearly the same amount. The structural results are discussed in relation to magnetic measurements on crushed single crystals, where ligand field calculations applying the angular overlap model have been taken into account.

Introduction

The fast ion conductor Na^+-β′′-Al_2O_3, so-called β′′-alumina, is generally described by the formula given by Bettman and Peters as $Na_{1+x}Mg_xAl_{11-x}O_{17}$ ($x = 0.24-0.7$).[1] It crystallizes in the trigonal space group $R\bar{3}m$ and consists of close-packed spinel blocks separated by conduction planes containing the mobile Na^+ cations. Covalent Al−O−Al bonds and Coulomb attraction forces of the in-plane cations to the spinel bock anions connect the blocks. Due to the high mobility of the Na^+ ions they can be replaced by other mono-, di- and trivalent cations, especially by lanthanide ions (Ln^{3+}).[2,3] There are two possible crystallographic positions for the cations within the conduction plane: the sevenfold coordinated (smaller) Beevers−Ross (BR) site (C_{3v} symmetry, 6c Wyckoff notation in $R\bar{3}m$) and the eightfold coordinated (larger) mid-Oxygen (mO) site (C_{2h} symmetry, 9d Wyckoff notation in $R\bar{3}m$). The content of Na^+ cations affects the height of the conduction slabs and therefore the lattice constant c.[4]

Previous investigations on Ln^{3+}-exchanged compounds like La^{3+}-β′′-Al_2O_3,[5] Pr^{3+}-β′′-Al_2O_3,[6] Nd^{3+}-β′′-Al_2O_3, Eu^{3+}-β′′-Al_2O_3 and Gd^{3+}-β′′-Al_2O_3 [7] show a main occupation of the higher coordinated mO site. In this paper the structure and the magnetic behaviour of completely exchanged Tb^{3+}-β′′-Al_2O_3 single crystals are presented. The determination of the ionic distribution within the conduction plane is important to understand the mobility of trivalent cations.[8,9] The observed occupancy is correlated with susceptibility measurements on crushed Tb^{3+}-β′′-Al_2O_3 crystals where ligand-field calculations applying the angular overlap model (AOM) for f-electrons[10−12] have been taken into account.

Results and Discussion

The structure of the spinel blocks (Mg/Al distributions, vacancies, etc.) is similar to other β′′-aluminas studied before and will therefore not be discussed in further detail. The ion distribution within the conduction planes (*ab*-planes) is of main interest. The structural refinements lead to a distribution of 49.2% Tb^{3+} cations on the smaller BR site and 50.8% on the larger mO site. Due to the nearly equal atomic form factors, Mg^{2+} and Al^{3+} ions within the spinel blocks were not distinguishable. Because of charge neutrality the Mg^{2+} content could be estimated from the refined cationic/anionic occupancy ratio. This results in the formula $Tb_{0.46}Al_{10.62}Mg_{0.38}O_{17}$. The site multiplicities, fractional atomic coordinates, site occupation factors and equivalent displacement parameters are given in Table 1, some interatomic distances are shown in Table 2.

Al2−O2 (1x)	185.2(9)
Al3−O1 (2x)	199.4(4)
Al3−O2 (1x)	196.4(5)
Al3−O3 (1x)	184.3(4)
Al3−O4 (2x)	182.9(3)
Al4−O4 (3x)	177.6(5)
Al4−O5 (1x)	161.0(4)

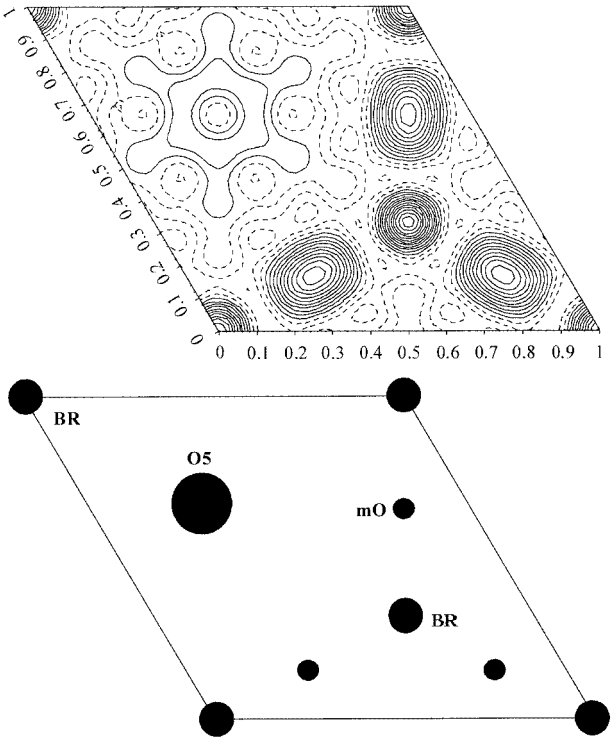

Figure 1. Electron density map (ρ_{obs}) of the conduction plane (z = 1/6); the contour intervals are 1 e·Å^{-3}; a schematic representation of the occupied sites is given beneath

As can be seen from Figure 1 the electron density is extended for all positions in the conduction plane, indicating large local disordering induced by Coulomb interactions between the ions. The Tb^{3+} ions in the mO sites are shifted towards neighbouring empty BR positions. The sites of the column oxygens O5 are influenced by the local cation environment, leading to large displacement parameters.

We observed that the size and the ionic distribution (BR/mO ratio) of the lanthanide ions are correlated with each other. The larger cations such as Nd^{3+} ions prefer the eightfold coordinated mO site (93%)[7] and the smaller ones (for example Ho^{3+} ions) the sevenfold coordinated BR site (84%).[13] Thus the BR/mO ratio of 49.2:50.8 found here for the terbium ion distribution is in line with previous findings.

From these results the ionic conductivity of La^{3+}-β′′-Al_2O_3,[5] Pr^{3+}-β′′-Al_2O_3 [14] and Ho^{3+}-β′′-Al_2O_3,[15,16] which differs in the temperature at which lanthanide ion mobility begins (574 K for La^{3+}, 564 K for Pr^{3+} and 496 K for Ho^{3+}), can be explained: the decrease of this temperature is due to an easier occupation of the BR site with smaller cations.

Magnetic susceptibility measurements on crushed single crystals were performed with a SQUID magnetometer in the 2.0−300.0 K temperature range at field strengths of 2 and 5 kOe. The magnetic susceptibilities are practically independent of the magnetic field (see Figure 2). In order to interpret the measured susceptibilities we carried out ligand-field calculations applying the angular overlap model within the basis set ^7F for Tb^{3+} and using the spin-orbit coupling constant of 1705 cm^{-1}.[17] The angular overlap parameters e_σ and e_π (Table 3) representing σ- and π-bonding between terbium ions and coordinated oxygen atoms were obtained by fitting procedures using the spiral algorithm.[18] The theoretical susceptibilities for both sites (BR and mO site) were calculated and fitted to the measured data. These were added up according to the occupancy ratio obtained from the structural investigation. The good agreement between the observed and calculated (fitted) inverse susceptibilities (R value:[19] 0.62%) of Tb^{3+}-β′′-Al_2O_3 is shown in Figure 2.

Table 3. Angular overlap parameters e_σ and e_π [cm^{-1}] for $Tb_{0.46}Al_{10.62}Mg_{0.38}O_{17}$

	e_σ	e_π
Tb1(BR)−O_S [a]	630	270
Tb1(BR)−O_C	536	142
Tb2(mO)−O_S	252	73
Tb2(mO)−O_C	341	79

[a] O_S: spinel block oxygen atoms (O3, O4), O_C: conduction plane oxygen atoms (O5).

The calculated e_σ/e_π ratios range between 2.3 and 4.3, in line with values for other lanthanide compounds (2.66 for $LaCl_3$:Tb^{3+},[20] 2.89 for $CaWO_4$:Tb^{3+},[21] 3.4 for $TbAl_3Cl_{12}$ [17]). Assuming a d^{-7} dependency of e_σ [21] (where d represents the distance between Tb^{3+} and coordinated oxygen atom) and taking d[Tb^{3+}(BR)−O_S] = 251 pm and d[Tb^{3+}(mO)−O_S] = 278 pm (averaged from Table 2) we obtain from Table 3 values for d[Tb^{3+}(BR)−O_C] = 257 pm and d[Tb^{3+}(mO)−O_C] = 266 pm. These calculated distances are smaller than the crystallographic ones (cf. Table 2). This is because the partial occupation of the BR and mO sites leads to a local coordination of the Tb^{3+} ions because of Coulomb attraction and this differs from the

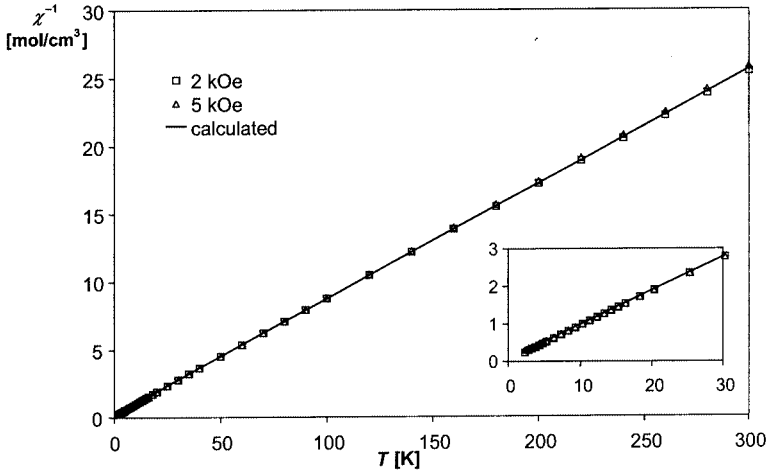

Figure 2. Observed inverse magnetic susceptibilities at different field strengths and calculated values for $Tb_{0.46}Al_{10.62}Mg_{0.38}O_{17}$ (−)

averaged coordination observed by X-ray investigation. This expresses itself in the low displacement parameters of O_S (see O3, O4 in Table 1) and the large ones of O_C (see O5 in Table 1).

Experimental Section

Na^+-β′′-Al_2O_3 (1): Na^+-β′′-alumina crystals were grown by flux evaporation from a mixture of 32.4 mol % Na_2O (from Na_2CO_3, Chempur, 99.99%), 8.0 mol % MgO (Chempur, 99.99%) and 59.6 mol % Al_2O_3 (Chempur, 99.99+%). The Na_2O-rich flux was heated for 19 days in a platinum foil coated crucible of corundum at 1680 °C according to an empirical temperature program.[22]

Tb^{3+}-β′′-Al_2O_3 (2): For the ion-exchange reaction a platinum net containing clear and colourless crystals of **1** was immersed under an argon atmosphere in an anhydrous $TbCl_3$ melt (Aldrich, 99.99%). To ensure a nearly complete exchange the crystals were exposed to the melt for 72 hours at 650 °C. No further heat treatments were applied after quenching the crystals to room temperature.

Magnetic Measurements: Measurements of the magnetic susceptibility were performed with a SQUID magnetometer (MPMS5, Quantum Design) in the 2.0 to 300 K temperature range at field strengths of 2 and 5 kOe. A polycrystalline sample of crushed single crystals was placed in a gelatine capsule and fixed with conventional cotton wool. The raw magnetic data were corrected for diamagnetism by measuring susceptibilities of Na^+-β′′-Al_2O_3.

X-ray Crystallographic Study: Crystallographic data were collected with a Stoe-IPDS diffractometer at room temperature. An optical clear single crystal was chosen for X-ray measurements. For details of the measurement see Table 4. The initial parameters used in the least-squares refinement of the spinel blocks and the bridging oxygen ions (O5) were taken from published parameters of Na^+-β′′-Al_2O_3.[1] BR and mO positions were occupied with Tb^{3+} ions (Tb1 and Tb2, respectively). The final refinement results in a distribution of 49.2% Tb^{3+} cations on the smaller BR site and 50.8% on the larger mO site. Due to the nearly equal atomic form factors, Mg^{2+} and Al^{3+} ions within the spinel blocks were not distinguishable. Because of charge neutrality the Mg^{2+} content could be estimated from the refined cationic/anionic occupancy ratio. The atomic sites, coordinates, site occupation factors, equivalent displacement parameters and selected interatomic distances are shown in Table 1 and 2.

Further details of the crystal-structure investigation may be obtained from the Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository number CSD-412282.

Synthesis and Properties of a Novel Series of Organometallic Merocyanines Combining the Potent Electron-Donating [(CpFeCO)$_2$(μ-CO)(μ-C=CH−)] Fragment with Tropylium-Type Acceptors

Tony Farrell,*[a] Anthony R. Manning,*[a] Gemma Mitchell,[a] Jürgen Heck,*[b] Timo Meyer-Friedrichsen,[b] Maik Malessa,[b] Christian Wittenburg,[b] Marc H. Prosenc,[b] Des Cunningham,[c] and Pat McArdle[c]

Dedicated to Prof. Dr. Gottfried Huttner on the occasion of his 65th birthday

Keywords: Organometallic compounds / Merocyanines / Azulenes / Bond length alternation / Solvatochromism / Nonlinear optics (NLO) / Long-wavelength hyper-Rayleigh scattering (HRS)

The potent electron-donating group [(CpFeCO)$_2$(μ-CO)(μ-C=CH–)] was combined with different tropylium-based acceptors yielding the push-pull complexes [(CpFeCO)$_2$(μ-CO)(μ-C=CH–CH=A)][BF$_4$] where =A represents [=CH–(η^7-C$_7$H$_6$)Cr(CO)$_3$]$^+$ (**5**), [={C$_{10}$H$_7$}]$^+$ (azulenylium) (**7**) [={C$_{10}$H$_4$Me$_2$*i*Pr}]$^+$ (guaiazulenylium) (**8**). Crystal structures of the precursor complexes [(CpFeCO)$_2$(μ-CO)(μ-C=CH–CH=CH–C$_7$H$_7$)] (**3**), [(CpFeCO)$_2$(μ-CO){μ-C=CH–CH=CH–(η^6-C$_7$H$_7$)Cr(CO)$_3$}] (**4**) and the push-pull derivative **5** are presented. Whereas complexes **3** and **4** demonstrate localised carbon–carbon double and single bonds in the π-bridge between the diiron moiety and the seven-membered ring a small but distinct π-bond delocalisation can be observed in the π-linker of the cationic derivative **5**. From the NMR spectroscopic results a correlation between the ^{13}C NMR shift of the bridging carbon atom μ-C of the diiron unit and the coupling constant J(^{1}H-^{1}H) of the β- and γ-protons of the π-bridge was found. This correlation indicates an increased π-bond delocalisation throughout the conjugated bridge with respect to the electron-accepting capability in the order tricarbonyl(η^7-cycloheptatrienylium)chromium < guaiazulenylium < azulenylium implying a predominantly charge-delocalised form in the case of the azulenylium complex **7**. Considerably large first hyperpolarisabilities β were determined for **5** and **8** by means of hyper-Rayleigh scattering. Based on the two-level model β$_0$ values were calculated and related to the bond-length alternation in the π-linker.

Introduction

A major feature of the research into materials capable of doubling the frequency of incident light (second harmonic generation, SHG), a second-order nonlinear optical (NLO) property, is the determination of the first hyperpolarisability β.[1] Dipolar chromophores of the form D−π−A are the most important class of compounds capable of frequency doubling, where D represents an electron donor, A an electron acceptor and a π-bridge of unsaturated bonds providing the electronic communication between the termini. One of our approaches has been to synthesise organometallic merocyanine complexes which utilise the cationic diiron [(CpFeCO)$_2$(μ-CO)(μ-C−)]$^+$moiety as an electron acceptor[2] and the related μ-vinylidene [(CpFeCO)$_2$(μ-CO)(μ-C=CH−)] fragment as an electron donor[3] in candidates for SHG. The rationale being that theoretical[4] and experimental[5] research have demonstrated that electronic interaction between the Fe$_2$μ-C component and the conjugated system is maintained throughout rotation of the μ-C−vinyl bond.

Azulene displays many of the criteria essential for the exhibition of large first hyperpolarisabilities: it has an asymmetric charge distribution (azulene has a dipole moment of 0.8 D)[6] and it is noncentrosymmetric. Also unlike conventional organic donors such as *para*-(dialkylamino)-phenyl substituents which lose resonance stabilisation upon charge separation, azulene and their alkylated derivatives are quite unique in that the disruption of aromaticity on going from the neutral to the charged form is counterbal-

anced by the gain of resonance energy upon formation of the azulenylium carbocation, a 6π-electron aromatic tropylium analogue (Figure 1).[7] Thus, azulene appears to be an extremely novel and versatile system and it is surprising that there are very few reports to date of azulenic NLO chromophores.[7–10] The present study focuses on the synthesis and charcterisation of a novel series of organometallic merocyanines linking the [(CpFeCO)$_2$(μ-CO)(μ-C=CH−)] fragment to tropylium-based electron acceptors.

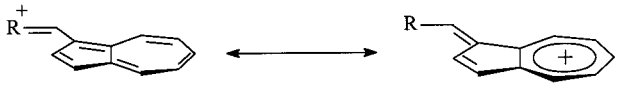

Figure 1. Resonance forms of a substituted azulenylium carbocation

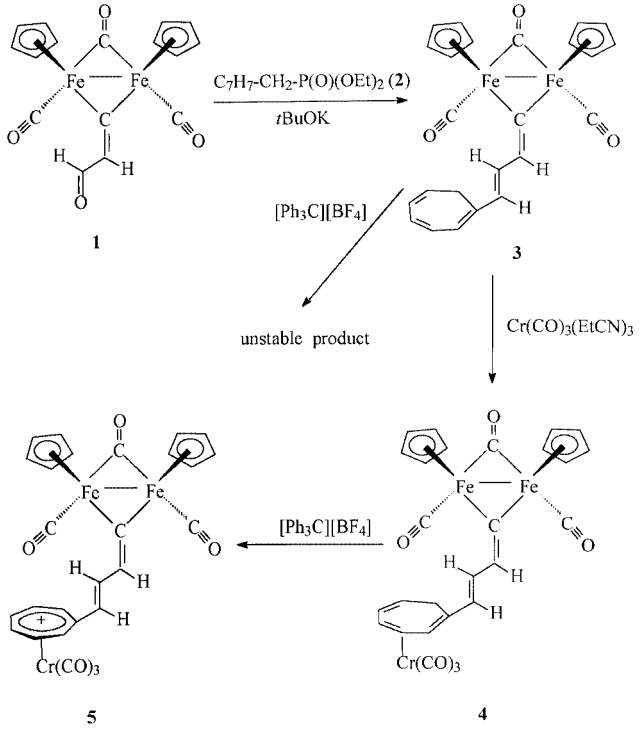
Results and Discussion

Synthesis

Previous work revealed that the presence of the strong electron-donating dinuclear carbene reduces the reactivity of the formyl-substituted diiron complex [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CHO)][11] (**1**) towards phosphorane nucleophiles but that extended μ-vinylidene complexes of the type [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH=CH−R)] are available using the more reactive Wittig−Horner−Wadsworth−Emmons (WHWE) reagents.[3] The diethyl (cycloheptatrienylmethyl)phosphonate (**2**) was prepared in a Michaelis−Arbuzov reaction from 1-chlormethyl-1,3,5-cycloheptatriene,[12] and treated with **1** in THF using *t*BuOK to yield the μ-vinylidene complex [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH=CH−C$_7$H$_7$)] (**3**) (Scheme 1). The



Scheme 1. Synthesis of the cationic dimetallic D−π−A complex **5**

trityl salt [Ph$_3$C][BF$_4$] was added to a solution of **3** in CH_2Cl_2 in order to abstract a hydride and to produce the tropylium derivative [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH=CH−C$_7$H$_6$)][BF$_4$]. A colour change from red-brown to blue was observed during the reaction and the IR spectrum of the reaction mixture showed the expected ν(CO) modes (2030, 1997, 1845 cm^{-1}), which are strongly shifted to higher energies compared to the corresponding ν(CO) modes of **3** (1996, 1960, 1795 cm^{-1}). However, the reaction mixture discoloured quickly and attempts to isolate the pure product were unsuccessful.

It was expected that coordination of the Cr(CO)$_3$ fragment to the seven-membered ring would greatly enhance the stability of the tropylium derivative and this was achieved by first treating **3** with Cr(CO)$_3$(EtCN)$_3$ (Scheme 1) to generate the neutral heterometallic complex [(CpFeCO)$_2$(μ-CO){μ-C=CH−CH=CH−(η^6-C$_7$H$_7$)Cr(CO)$_3$}] (**4**) as a mixture of the isomers **4a** and **4b** (Figure 2). As before, the addition of the trityl cation to a solution of the complex **4** in CH_2Cl_2 was accompanied by a dramatic colour change from red-brown to deep blue indicating a strong enhancement in the electronic communication between the diiron terminus and the cationic tricarbonyl(tropylium)chromium moiety. By layering the reaction mixture with diethyl ether a microcrystalline solid was obtained which was characterised as the cationic heterometallic merocyanine [(CpFeCO)$_2$(μ-CO){μ-C=CH−CH=CH-(η^7-C$_7$H$_6$)Cr(CO)$_3$}][BF$_4$] (**5**).

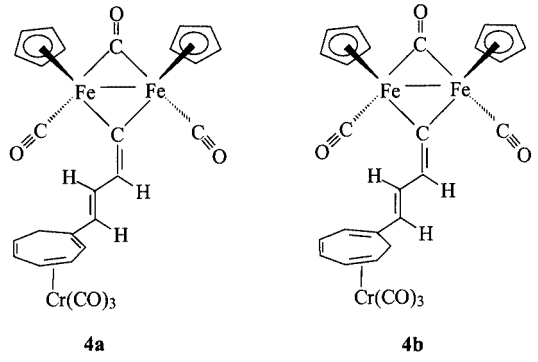


Figure 2. Different diastereoisomers of the neutral complex **4**

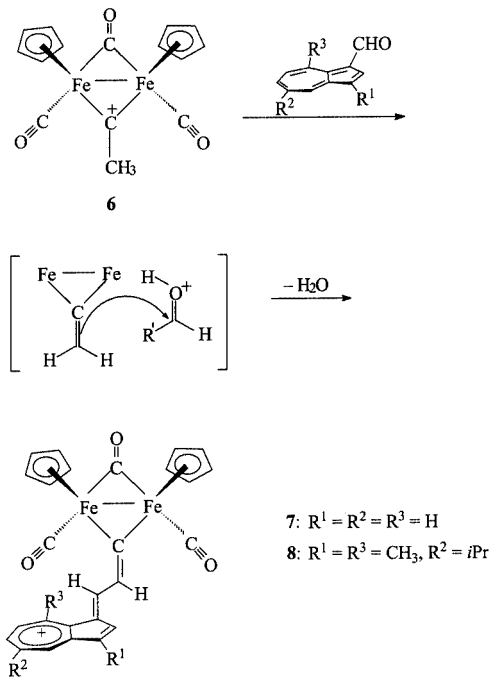
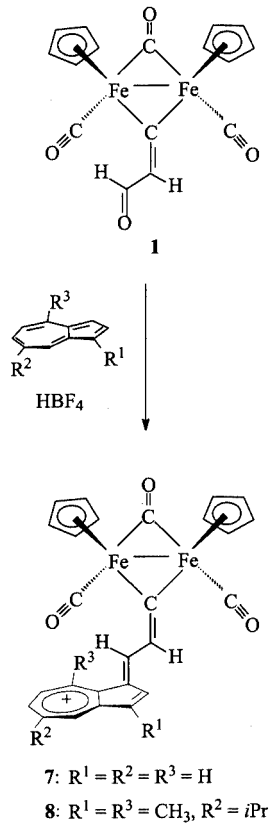
The reaction of the μ-ethylidyne complex [(CpFeCO)$_2$(μ-CO)(μ-C−CH$_3$)][BF$_4$][13] (**6**) with aldehydes has been found to be a facile methodology towards the preparation of cationic diiron chromophores.[2] Nonetheless, purification problems have been experienced when longer reaction periods were necessary due to the formation of [CpFe(CO)$_3$][BF$_4$] which was extremely difficult to remove.[2a] Consequently, two complimentary procedures were attempted in order to isolate the organometallic azulenylium [{C$_{10}$H$_7$}]$^+$ and guaiazulenylium [{C$_{10}$H$_4$Me$_2$*i*Pr}]$^+$ merocyanines [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH={C$_{10}$H$_7$})][BF$_4$] (**7**) and [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH={C$_{10}$H$_4$Me$_2$*i*Pr})][BF$_4$] (**8**), and also to provide versatile access to a wide range of other vinyl−carbene/carbyne complexes. Azulene- and guaiazulene-1-carboxaldehyde[14] are readily available by literature procedures and

these aldehydes were condensed with **6** in CH_2Cl_2 at 40 °C overnight giving intensely coloured reaction mixtures (Scheme 2). The air-stable merocyanine salts **7** and **8** were isolated upon filtering the reaction mixture and layering the filtrate with diethyl ether.



Scheme 2. Synthesis of the azulenylium and guaiazulenylium D−π−A complexes **7** and **8**

As organic[15] and organometallic[7] aldehydes have been found to react with azulenes under acidic conditions to form azulenylium based carbocationic complexes, an alternative synthetic route towards **7** and **8** was envisaged by the reaction of the formyl-substituted μ-vinylidene complex **1** with azulene and guaiazulene (Scheme 3). Condensation of **1** with an equimolar amount of azulene or guaiazulene in THF with a large excess of HBF_4 was indeed successful and again led to the isolation of **7** and **8** in high yields.



Scheme 3. Alternative synthetic route to **7** and **8**

Crystal Structures of 3, 4 and 5

Crystal and structure refinement data for the X-ray analyses are presented in Table 1 and selected bond lengths and angles are listed in Table 2. Views of the molecular structures are illustrated in Figures 3−5 along with atom labelling. The $Fe_2(\eta\text{-}C_5H_5)(CO)_2(\mu\text{-}CO)(\mu\text{-}C)$ moiety has a *cis* structure while the π-linker displays an all-*trans* geometry in all of the structures. Of note is the similarity between the bond lengths across the all-$C_{sp2}-C_{sp2}$ π-bridge (C14−C17) in **3** and **4**, whereas **5** displays slightly shorter carbon−carbon single and elongated double bonds. This suggests a predominantly μ-carbene structure in **3** and **4** with little interaction between the diiron and cycloheptatriene moiety as depicted by the olefinic mesomeric form **I** in Figure 6. In **5** the alternation in the bond lengths of the π-bridge indicates an increased electronic interaction between the termini in the solid state, which can be rationalised as a distinct contribution of the vinylcarbyne mesomeric form **II** to the electronic ground state (GS).

The extent of the bond length alternation (BLA), which is defined as the difference between the average lengths of carbon−carbon single and double bonds, has been established as a useful indicator of high first hyperpolarisabilities.[16] Several attempts to relate β to both the molecular electronic and structural parameters led to the prediction that optimal NLO activity is achieved when BLA = 0.03−0.05 Å. The BLA across the π-bridge of complexes **3** and **4** is 0.10 Å and ca. 0.11 Å, respectively, whereas for **5** the BLA is 0.07 Å, which implies a medium first hyperpolarisability value for **5**.

Another notable feature of the X-ray diffraction study, which fortifies the evidence for the strong π-communication between the termini, especially in the case of the push-pull chromophore **5**, are the calculated dihedral angles. The larger angle between the planes made by Fe_2μ-C and C14−C16 for **5** denotes a more flexible C14−C15 bond with a relatively lower bond order than for both **3** and **4**. Furthermore, the angle between the planes C14−C16 and C15−C17 increases in the order **5** < **4** < **3** (but are nonetheless quite low), attesting to the π-interaction of the entire conjugated linker.

Analysis of IR, ^{13}C and ^{1}H NMR spectra

One of the main considerations when characterising D−π−A-type compounds is the electronic configuration of

the molecules and how this affects the properties of the material. The systematic modification of a system coupled with the detailed analysis of the resulting changes may allow us to formulate a relationship between the molecular structure and the properties. This would greatly enhance our ability to tune a system structurally in order to maximise a particular output. In the case of these μ-vinylidene complexes the GS electronic constitution is easily evaluated by considering (i) the carbonyl stretching frequencies,

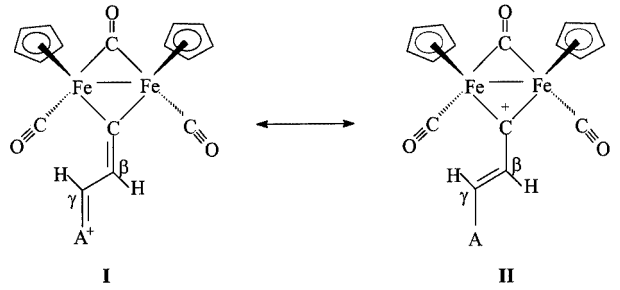

Figure 6. Mesomeric forms of the cationic donor−acceptor complexes $[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-}CH{=}A^+)]$ where A^+ = $[CH{-}(\eta^7\text{-}C_7H_6)Cr(CO)_3]^+$ (**5**), $[C_{10}H_7]^+$ (azulenylium) (**7**), $[C_{10}H_4Me_2iPr]^+$ (guaiazulenylium) (**8**)

(ii) the number of Cp signals in both the ^1H and ^{13}C NMR spectra, (iii) the ^1H-^1H coupling constants across the unsaturated bridging ligand, and (iv) the chemical shift of the μ-carbon signal in the ^{13}C NMR spectra.

The solution IR spectra of all the complexes prepared reveal one bridging and two terminal carbonyl stretching modes, the relative intensities of which are consistent with a *cis* arrangement of these CO ligands. The wavenumbers of these ν(CO) bands are very informative in determining the extent of electronic coupling between the $Fe_2\mu$-C=CH- and the tropylium-based termini (Table 3). A predominant μ-vinylidene resonance contribution to the GS (**I**, Figure 6), can be concluded from ν(CO) bands at lower wavenumbers [ν(CO): ca. 1992, 1953 cm^{-1}].[3,17] On the other hand, charge delocalisation throughout the molecule due to increased contribution from the mesomeric form **II** to the GS (Figure 6), decreases the electron density at the $Fe_2\mu$-C core reducing the degree of M→CO back donation. The resulting ν(CO) shift to higher wavenumbers tends towards that of **6** [ν(CO): 2046, 2000 cm^{-1}][2,18] where the positive charge is fully localised on the diiron end group. As expected, the neutral fragment $[(\eta^6\text{-}C_7H_7)Cr(CO)_3]$ is the weakest electron acceptor with ν(CO) bands at 1997, 1961 cm^{-1}, followed by the corresponding cation $[(\eta^7\text{-}C_7H_6)Cr(CO)_3]^+$ with the CO stretching modes at 2007 and 1975 cm^{-1}. As expected, the azulenylium-type end groups are stronger electron acceptors due to the resonance stabilisation in both extreme mesomeric forms and display increased contribution from the μ-vinyl−carbyne resonance forms **II** to the overall GS structure. Alkylation of the azulenylium moiety results in a more stable carbocation and a weaker electron acceptor with the result that the azulenylium complex **7** exhibits the highest ν(CO) modes.

An excellent diagnostic of the degree of charge delocalisation is the chemical shift of the μ_2-carbon atom of the π-bridge between the donor and acceptor in the ^{13}C NMR spectra (Table 3).[2,3] Increasing the potency of the electron acceptor augments the electronic interaction between the termini and the contribution from the (vinylcarbyne)diiron mesomeric form **II**. The reduction of electron density at the diiron framework results in the bridging carbon signal occurring at lower field strengths. From the position of these μ-C signals we can conclude that the azulenylium carbocations are by far the strongest electron acceptors within the presented series.

Comparing the ^1H-^1H coupling constants across the bridging $C_\beta{-}C_\gamma$ (Figure 6) bond should also aid in elucidating the GS electronic arrangement with $J(^1H_\beta\text{-}^1H_\gamma)$ increasing as the bond order increases (Table 3). Considering

the limiting mesomeric form **I** (Figure 6), which contains an sp^2-carbon−sp^2-carbon single bond between C_β and C_γ, $^1H_\beta$-$^1H_\gamma$ coupling constants of about 10 Hz are to be expected.[3,19] For **3** and **4** the structural data are in agreement with a $C_\beta-C_\gamma$ localised carbon−carbon single bond and the neutral "true" μ-vinylidene compound **3** exhibits the lowest coupling constant at $J = 10.1$ Hz. For compound **4** the $^1H_\beta$-$^1H_\gamma$ coupling value is slightly larger and the μ-^{13}C nucleus is deshielded to a smaller extent compared to **3**, demonstrating a small increase in the electron-withdrawing capability of the cycloheptatriene moiety due to the $Cr(CO)_3$ coordination. Consequently, the $C_\alpha-C_\beta$ bond remains predominantly a carbon−carbon double bond with a restricted rotation about the μ-C=CH bond. Hence, the Cp and terminal CO ligands are formally in different environments, and **3** as well as **4** exhibit two Cp and two CO signals in the ^1H and ^{13}C NMR spectra, respectively. When the bond order between C_β and C_γ displays increased C−C double bond character, as occurs in (μ-vinylcarbyne)diiron cations (mesomeric form **II** in Figure 6), the $^1H_\beta$-$^1H_\gamma$ coupling constants increase to 14.9 Hz and only one Cp and CO signal appear in the NMR spectra.[2]

The increase in $J(^1H_\beta$-$^1H_\gamma)$ agrees with the general downfield shift of the μ-C_α resonance signal of the diiron moiety and a graphic displays a linear correlation between $\delta(\mu$-$^{13}C)$ and $J(^1H_\beta$-$^1H_\gamma)$ (Figure 7). These results present strong indications that in solution there exists an increasing charge delocalisation in the order **3** < **4** << **5** << **8** < **7** for the electronic ground state, which concurs with the ordering of electron-accepting strength from the IR data. It is noteworthy that only one Cp and one CO signal are observed in the NMR spectra for all of the cationic chromophores. This is in accordance with the structural data of **5**, which displays a marked decrease of the μ-$C_\alpha-C_\beta$ double-bond character and increase of $C_\beta-C_\gamma$ bond order in the solid state. This effect may be augmented by the ion-pair separation in solution whereas in the solid state the inter ion-pair Coulomb interaction will diminish the D−A interaction within the entire cation. The correlation between $\delta(\mu$-$^{13}C)$ and $J(H_\beta$-$H_\gamma)$ indicates a considerable contribution of the μ-vinylcarbyne mesomeric form **II** to the electronic ground states for **7** and **8** in solution, which even dominates for **7**. Hence, the diiron derivatives under study represent a rare example of organometallic D−π−A complexes wherein the electronic ground state can be varied from an organometallic merocyanine-type species, in which the positive charge is mainly localised on the seven-membered ring moiety as in **5**, to a merocyanine wherein the positive charge is mainly localised on the diiron terminus as in **7**. A suitable selection of the cationic acceptor would enable the development of an organometallic polymethine with a complete delocalisation of the positive charge.

Electronic Absorption Spectra

A commonly used model called the two-level approximation relates β to the molecular optical properties and predicts that large first hyperpolarisabilities are favoured by molecules possessing intense, low-energy and highly solvatochromic charge transfer (CT) transitions.[20] These fundamental parameters cannot be optimised independently and may not be weighted equally for a particular system. For example, for the series of compounds $[(CpFeCO)_2(\mu$-$CO)(\mu$-$C-\{\pi$-bridge$\}-Fc)][BF_4]$[2b] (Fc = ferrocenyl) it was found that a large solvatochromic shift and extinction coefficient upon photoexcitation were more important to the enhancement of β than the energy of the transition.

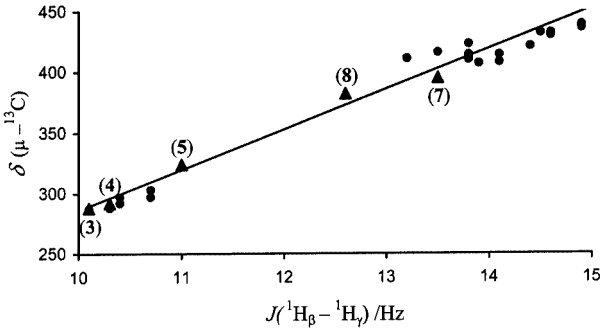

Figure 7. Correlation between $\delta(^{13}C)$ of the μ-C atom and the J coupling constants between H_β and H_γ of the π-bridge (•: data points from refs.[2,3])

The optical absorption data for the chromophores are presented in Table 4. The electronic spectra of the merocyanine salts display an intense asymmetric absorption in the visible region between 570 and 635 nm indicating a superimposition of different transitions. The two azulenylium chromophores also reveal a much weaker transition at lower energies (Figure 8). We assign the stronger absorption band to a donor−acceptor charge-transfer (DACT) transition and propose that the lower energy band is an azulene-localised π−π* transition. The strong electronic transitions are governed by medium negative solvatochromism which points towards a slightly more charge delocalised photoexcited state. However, the negative solvatochromism is much smaller than that observed for other cationic diiron NLO chromophores,[2a] confirming a certain degree of charge delocalisation in the electronic ground state as already concluded from the NMR results. This finding is also corroborated in that the solvatochromism and thus dipole change Δμ between the ground and the excited state decreases with increasing charge delocalisation: **5** > **8** > **7**. Also of note is that increasing the electron-accepting capabilities of the tropylium-based termini results in a blue shift to the CT bands (Figure 9). This is consistent with an energetically lower lying molecular orbital being involved in the CT transition as a consequence of higher GS charge delocalisation.

Hyperpolarisability Measurements

The complexes **5**, **7** and **8** were subjected to hyper-Rayleigh scattering (HRS) studies[21] but as they absorb substantially in the area of 532 nm [i.e. $I(2\omega)$ when the incident light has a wavelength of $I(\omega) = 1064$ nm], the stimulating laser light was shifted to a higher wavelength (1500 nm). Thus, the superposition of a strong absorption and the HRS signal is minimised, which makes the calculated static

Table 4. Linear and nonlinear optical data of the complexes for the complexes $[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-}A)]$

Acceptor		λ_{max} (ε) [nm (M^{-1} cm^{-1})][a] CH_2Cl_2	CH_3CN	$\Delta\tilde{\nu}$[b] (cm^{-1})	β[a] (10^{-30} esu)	β_0 esu
	(**7**)	579 (55621)	571 (41437)	–242	nd[d]	–

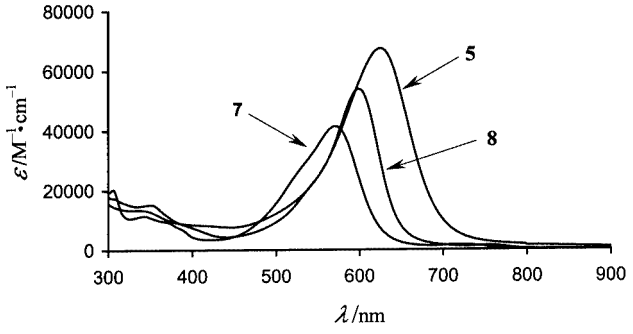

Figure 9. Electronic absorption spectra of **5**, **7** and **8** in CH_3CN

hyperpolarisability (β_0)[20] more reliable.[22,23] Another important reason for using the higher wavelength incident beam, is an attempt to discriminate between a true SHG signal and a two-photon absorption-induced fluorescence (TPAF) enhanced signal[24–26] The 1500-nm incident-beam HRS examinations were achieved using a tuneable optical parametric oscillator (OPO) based set-up.[23] All measurements were carried out using Desperse Red 1 (DR1) as an external standard. The reference hyperpolarisability β of DR1 in CH_2Cl_2 was calculated by comparing the slopes of the standard in CH_2Cl_2 and $CHCl_3$ to obtain the ratio of β_{solute}.[27] Using the value $\beta(CHCl_3) = 80 \times 10^{-30}$ esu[24] the hyperpolarisability of DR1 in CH_2Cl_2 is estimated to be 70×10^{-30} esu. The effect of the refractive indices of the solvents was corrected using the simple Lorentz local field.[28]

The first hyperpolarisability β could only be obtained for the cationic dimetallic complex **5** (451×10^{-30} esu) and the guaiazulenylium derivative **8** (274×10^{-30} esu) (Table 4), complex **7** did not show any intensity in the HRS experiment. The obtained β values are in the order of magnitude of β values found for the neutral diiron donor-based complexes containing dicyanovinyl-substituted arenes as electron acceptors ($\beta = 156 \times 10^{-30}$ esu and $\beta = 227 \times 10^{-30}$ esu, Table 4).[3] The very low extinction coefficients for the complexes **5** and **8** at λ = 750 nm allows a reliable calculation of the static hyperpolarizability β_0 using the two-level model[20b] [β_0(**5**) = 117×10^{-30} esu and β_0(**8**) = 79×10^{-30} esu]. It is noteworthy that the static hyperpolarisabilities of the four diiron donor-based NLO chromophores in Table 4 can be correlated with $J(H_\beta\text{-}H_\gamma)$, which is a measure of the carbon–carbon bond order between C_β and C_γ (vide supra) and thus, synonymous to the carbon–carbon bond length (Figure 10). The β_0 values improve with increasing $J(H_\beta\text{-}H_\gamma)$ values beyond 11 Hz and then decreases distinctly for $J(H_\beta\text{-}H_\gamma)$ = 12.6 Hz for **8**, and for complex **7** with $J(H_\beta\text{-}H_\gamma)$ = 13.5 Hz the first hyperpolarisability even vanishes. This behaviour very much resembles the correlation between the static hyperpolarizability β_0 and the bond-length alternation (BLA) in donor–acceptor-substituted polyenes found by Marder et al.[16] Therefore, the small β_0 value for **8** may be explained by the smaller BLA due to the large contribution of the μ-vinylcarbyne mesomeric form **II** to the ground state. Since the X-ray data demonstrate that in the solid state the BLA for **5** is still beyond the optimum value of 0.03–0.05, we suggest that a maximum of the β_0 values in the diiron-based NLO chromophores may be obtained, when the accepting capability of the seven-membered ring moiety is slightly enhanced compared to the $[(\eta^7\text{-}C_7H_6)Cr(CO)_3]^+$ acceptor but less potent than for the guaiazulenylium or even azulenylium electron acceptors.

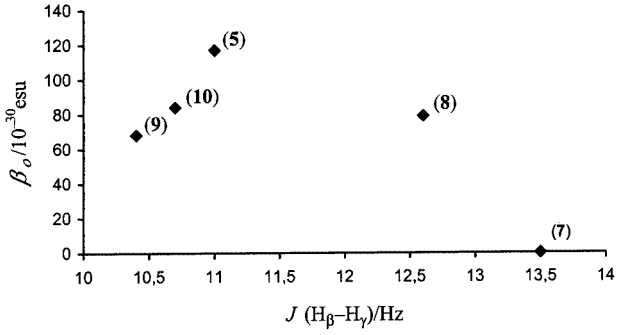

Figure 10. Correlation between the first static hyperpolarisability β_0 and the coupling constants $J(H_\beta\text{-}H_\gamma)$

The NLO properties of a series of organometallic merocyanines utilising the $[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-})]$ fragment as an electron donor linked to thiobarbituric acid by olefinic units, demonstrated the effectiveness of the diiron unit.[27] The second-order optical nonlinearities were determined using electric-field-induced second harmonic generation (EFISH). However, as there exist problems in comparing results obtained from different techniques[25,26] no correlations will be attempted. Static hyperpolarisabilities from 1500-nm HRS experiments have been reported for organic 1D, 2D and 3D NLO chromophores.[27,28] An extremely large β_0 value was reported for the 2D NLO truxenone derivative ($\beta_0 = 169 \times 10^{-30}$ esu)[29] which is still larger than the value of β_0(**5**). However, in terms of their static hyperpolarisability to molecular mass ratio β_0/M, which is often used as a figure of merit, values of β_0/M(**5**) $= 0.153 \times 10^{-30}$ (esu·mol^{-1}·g^{-1}) and β_0/M(**8**) $= 0.149 \times 10^{-30}$ (esu·mol^{-1}·g^{-1}) were calculated for the present organometallic merocyanines, which compare well with the corresponding value of the truxenone chromophore $\beta_0/M = 0.124 \times 10^{-30}$ (esu·mol^{-1}·g^{-1}).

Conclusion

The facile synthesis is presented for a series organometallic merocyanines based on the diiron moiety $[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-})]$ as the electron donor and the cationic tropylium derivatives $[-C{=}CH(\eta^7\text{-}C_7H_6)Cr(CO)_3]^+$ and azulenylium and guaiazulenylium as electron-accepting units, which tune the electronic properties of these D−A complexes. In ^{13}C NMR spectroscopic studies an increased deshielding of the μ-C atom of the π-bridge is observed in the order **5** < **8** < **7**, thus demonstrating the increased electron-accepting capability of the cationic seven-membered ring units in that order. Additionally, a correlation between $\delta(\mu\text{-}^{13}C)$ and $J(H_\beta\text{-}H_\gamma)$ is found which indicates a slightly stronger contribution of the μ-vinylcarbyne mesomeric form **II** to the ground state in solution for the azulenylium and guaiazulenylium congeners **7** and **8**, whereas for the tropylium derivative **5** the ground state displays extensive contribution from the μ-vinylidene mesomeric form **I**. The cationic complexes reveal a strong absorption band in UV/Vis spectra around 600 nm due to a DA−CT transition, which undergoes a medium negative solvatochromic shift. The analysis of the nonlinear optical properties by means of HRS measurements was successful for **5** and **8** and reveals that the combination of the diiron donor and the tricarbonyl(η^7-tropylium)chromium cation provides the larger experimental and static first hyperpolarisabilities β and β_0, respectively. A correlation between $J(H_\beta\text{-}H_\gamma)$ and the static hyperpolarisability β_0 very much resembles the dependence of β_0 on the bond length alternation (BLA). Hence, although the guaiazulenylium cation is a considerably stronger electron acceptor, the smaller β_0 value of **8** may be explained by a smaller bond length alternation due to the larger contribution of the μ-vinylcarbyne mesomeric form **II**.

Experimental Section

Solvent Purification and Instrumentation: Dichloromethane, diethyl ether and THF were dried by refluxing in the presence of calcium hydride and distillation prior to use. THF was further distilled from sodium/benzophenone. Infrared spectra were recorded with a Perkin−Elmer Paragon 1000 spectrometer. UV/Vis spectra were recorded with a Perkin−Elmer Lambda 6 spectrometer and a Perkin−Elmer model 554. NMR spectra were recorded with JEOL JNM-GX 270 FT and Varian Gemini 200 BB spectrometers using TMS as an internal standard. Elemental analyses were carried out by the Microanalytical Laboratory, University College, Dublin and the Institut für Anorganische und Angewandte Chemie, Universität Hamburg.

$[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-}CH{=}CH{-}C_7H_7)]$ (3): *t*BuOK (0.13 g, 1.16 mmol) was added to a solution of $[(CpFeCO)_2(\mu\text{-}CO)(\mu\text{-}C{=}CH{-}CHO)]$[11] (**1**) (0.3 g, 0.79 mmol) and diethyl (cycloheptatrienylmethyl)phosphonate (**2**)[12] (1.1 equiv.) in dry THF (50 mL). Stirring was continued for 1 h under nitrogen, water (30 mL) was added and the mixture was extracted with dichloromethane. The organic layer was dried with $MgSO_4$ and the solvent was removed. The residue was taken up in dichloromethane and chromatographed on alumina. Product **3** eluted with dichloromethane and was recrystallised from CH_2Cl_2/hexane. Yield: 0.30 g (82%). ^1H NMR ($CDCl_3$): δ = 8.17 (d, *J* = 10.1 Hz, 1 H, μ-C=C*H*), 7.03 (dd, *J* = 10.1, 15.2 Hz, 1 H, μ-C=CH−C*H*), 6.62 (m, 1 H, C_7H_7), 6.46 (m, 1 H, C_7H_7), 6.20 (m, 3 H, μ-C=CH−CH=C*H*, C_7H_7), 5.44 (m, 1 H, C_7H_7), 4.90 (s, C_5H_5), 4.81 (s, C_5H_5), 2.74 (m, 2 H, C_7H_7) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 288.3 (μ-C), 270.8 (μ-CO), 210.7, 210.6 (CO), 144.3, 132.8 124.9 (μ-C=CH−CH=CH), 134.0 (C_q, C_7H_7), 131.6, 129.3, 128.1, 124.2, 122.1 (C_7H_7), 88.4, 87.8 (C_5H_5), 29.1 (C_7H_7) ppm. IR (CH_2Cl_2): $\tilde{\nu}$ = 1996 (vs), 1960 (m) [ν(CO)]; 1795 (s) [ν(μ-CO)]; 1607 (m), 1558 (w) [ν(C=C)] cm^{-1}. $C_{24}H_{20}Fe_2O_3$ (468.10): calcd. C 61.58, H 4.31; found C 61.04, H 4.68.

$[(CpFeCO)_2(\mu\text{-}CO)\{\mu\text{-}C{=}CH{-}CH{=}CH{-}(\eta^6\text{-}C_7H_7)Cr(CO)_3\}]$ (4): Compound **3** (0.3 g, 0.64 mmol) and $Cr(CO)_3(EtCN)_3$[29] (0.19 g, 0.63 mmol) were stirred in dry THF (40 mL) overnight under N_2. The solvent was removed and the residue taken up in the minimum volume of dichloromethane and chromatographed on alumina. The column was washed with toluene to remove traces of unreacted **3**. Product **4** eluted with dichloromethane and was recrystallised from CH_2Cl_2/hexane. Yield: 0.28 g (73%). ^1H NMR ($CDCl_3$, only one isomer given): δ = 8.21 (d, *J* = 10.3 Hz, 1 H, μ-C=C*H*), 6.86 (dd, *J* = 10.4, 15.0 Hz, 1 H, μ-C=CH−C*H*), 5.89 (m, 2 H, η^6-C_7H_7), 5.74 (d, *J* = 15.2 Hz, 1 H, μ-C=CH−CH=C*H*), 5.13 (m, 1 H, η^6-C_7H_7), 4.96 (s, C_5H_5), 4.86 (s, C_5H_5), 4.85 (hidden, 2 H, η^6-C_7H_7), 3.35 (m, 2 H, η^6-C_7H_7) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 292.1 (μ-C), 269.6 (μ-CO), 232.6 [$Cr(CO)_3$], 209.9, 209.8 (CO), 143.3, 134.1 123.3 (μ-C=CH−CH=CH), 100.7, 98.0, 97.6, 96.8, 96.3 (η^6-C_7H_7), 88.0, 87.5 (C_5H_5), 23.7 (η^6-C_7H_7) ppm. IR (CH_2Cl_2): $\tilde{\nu}$ = 1997 (vs), 1961 (m), 1898 (vs), 1869 (s) [ν(CO)]; 1796 (s) [ν(μ-CO)]; 1607 (m), 1558 (w) [ν(C=C)] cm^{-1}. $C_{27}H_{20}CrFe_2O_6$ (604.13): calcd. C 53.68, H 3.34; found C 53.09, H 3.60.

$[(CpFeCO)_2(\mu\text{-}CO)\{\mu\text{-}C{=}CH{-}CH{=}CH{-}(\eta^7\text{-}C_7H_6)Cr(CO)_3\}][BF_4]$ (5): $[Ph_3C][BF_4]$ (0.10 g, 0.30 mmol) was added to a solution of **4** (0.2 g, 0.33 mmol) in dry CH_2Cl_2 (50 mL) at −70 °C. The reaction mixture was allowed to warm to room temperature and then filtered. Product **5** was obtained by layering the filtrate with dry diethyl ether (50 mL) and cooling overnight. Yield: 0.16 g (70%). ^1H NMR [$(CD_3)_2CO$]: δ = 8.69 (d, *J* = 11.0 Hz, 1 H, μ-

C=C*H*), 8.04 (dd, *J* = 11.0, 14.6 Hz, 1 H, μ-C=CH−C*H*), 6.95 (m, 2 H, η^7-C_7H_6), 6.70 (m, 4 H, η^7-C_7H_6), 6.39 (d, 1 H, μ-C=CH−CH=C*H*), 5.22 (s, 10 H, C_5H_5). $^{13}C\{^1H\}$ NMR [$(CD_3)_2CO$]: δ = 323.7 (μ-C), 265.6 (μ-CO), 225.1, [$Cr(CO)_3$], 211.6 (CO), 146.9, 145.7 116.5 (μ-C=CH−CH=CH), 135.3 (C_q, η^7-C_7H_6), 106.0, 103.5, 98.4 (η^7-C_7H_6), 89.8 (C_5H_5) ppm. IR (CH_2Cl_2): ṽ = 2043 (s), 2007 (vs), 1970 (sh) [ν(CO)]; 1812 (m) [ν(μ-CO)]; 1606 (w), 1562 (m), 1468 (vs), 1456 (s) [ν(C=C)] cm^{-1}. $C_{27}H_{19}BCrF_4Fe_2O_6 \cdot CH_2Cl_2$ (774.86): calcd. General Procedure for the Condensation of Azulenic Aldehydes with [(CpFeCO)$_2$(μ-CO)(μ-C−CH$_3$)][BF$_4$] (6): Complex **6** (0.25 g, 0.57 mmol) and an excess of aldehyde (1.2 equiv.) were stirred in CH_2Cl_2 (50 mL) at 35 °C for 12 h. The reaction mixture was filtered and the product precipitated from the filtrate by carefully adding diethyl ether (25 mL) and cooling overnight.

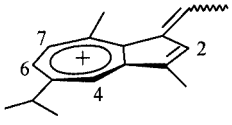
[(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH={C$_{10}$H$_7$})][BF$_4$] (7): Yield: 0.23 g (70%). ^1H NMR ($CDCl_3$): δ = 9.88 (d, *J* = 13.5 Hz, 1 H, μ-C−C*H*=CH), 9.24 (d, *J* = 9.6 Hz, 1 H, 4-H), 8.74 (d, *J* = 9.9 Hz, 1 H, 8-H), 8.71 (d, *J* = 4.2 Hz, 1 H, 2-H), 8.38 (d, *J* = 13.5 Hz, 1 H, μ-C−CH=C*H*), 8.23 (t, *J* = 9.6 Hz, 1 H, 6-H) 8.02 (m, 2 H, 5-H, 7-H), 7.77 (d, 1 H, *J* = 4.22 Hz, 3-H), 5.34 (s, 10 H, C_5H_5) ppm. $^{13}C\{^1H\}$ NMR (CD_3CN): δ = 394.5 (μ-C), 258.9 (μ-CO), 209.5 (CO), 149.1, 146.2 (μ-C−CH=CH), 152.2, 148.7, 127.1 (C_q, $C_{10}H_7$), 143.9, 141.5, 138.5, 135.2, 134.0, 127.3 ($C_{10}H_7$), 91.1 (C_5H_5) ppm. IR (CH_2Cl_2): ṽ = 2024 (vs), 1993 (m) [ν(CO)]; 1832 (s) [ν(μ-CO)]; 1605 (m), 1546 (m), 1518 (vs), 1464 (m) [ν(C=C)] cm^{-1}. $C_{26}H_{19}BF_4Fe_2O_3$ (577.92): C 53.98, H 3.29; found C 54.19, H 3.62.



[(CpFeCO)$_2$(μ-CO)(μ-C=CH−CH={C$_{10}$H$_4$Me$_2$*i*Pr})][BF$_4$] (8): Yield: 0.29 g (80%). ^1H NMR ($CDCl_3$): δ = 9.66 (d, *J* = 12.6 Hz, 1 H, μ-C−C*H*=CH), 8.61 (d, *J* = 12.6 Hz, 1 H, μ-C−CH=C*H*), 8.50 (s, 1 H, 2-H), 8.44 (s, 1 H, 8-H), 8. (m, 2 H, 6-H, 7-H), 5.26 (s, 10 H, C_5H_5), 3.4 [m, 1 H, CH, *i*Pr], 3.34 (s, 3 H, CH_3), 2.65 (s, 3 H, CH_3), 1.42 [d, 1 H, *J* = 7.03 Hz, $(CH_3)_2$, *i*Pr]. $^{13}C\{^1H\}$ NMR (CD_3CN): δ = 382.0 (μ-C), 259.8 (μ-CO), 209.7 (CO), 152.7, 148.9 (μ-C−CH=CH), 153.6, 151.2, 150.4, 144.8, 142.2, 129.3 (C_q, $C_{10}H_4Me_2$*i*Pr), 140.6, 139.9, 136.7, 135.9 ($C_{10}H_4Me_2$*i*Pr), 90.4 (C_5H_5), 39.2, 13.8 (CH_3), 29.7 (CH, *i*Pr), 24.7 [$(CH_3)_2$, *i*Pr] ppm. IR (CH_2Cl_2): ṽ = 2017 (vs), 1990 (m) [ν(CO)]; 1829 (s) [ν(μ-CO)]; 1605 (m), 1552 (m), 1534 (s), 1501 (s) [ν(C=C)] cm^{-1}. $C_{31}H_{29}BF_4Fe_2O_3$ (648.05): C 57.45, H 4.51; found C 57.81, H 4.90.

Reaction of azulene and guaiazulene with [(CpFeCO)$_2$(μ-CO)(μ-C=CH−CHO)] (1): An excess of HBF_4 (54% solution in diethyl ether) was added to an equimolar solution of azulene or guaiazulene and **1** (0.25 g, 0.57 mmol) in dichloromethane (50 mL). The reaction mixture was concentrated until a colour change occurred and then stirred for 2 h. The products were precipitated from the solution by adding diethyl ether (75 mL) and cooling overnight. The resulting precipitates were filtered off and washed well with diethyl ether. The yields were 0.28 g (85%) of **7** and 0.30 g (83%) of **8**.

X-ray Structure Determination: Crystals suitable for an X-ray structure analysis were obtained by diffusion of Et_2O into a CH_2Cl_2 solution of **5** and by layering a CH_2Cl_2 solution of **3** and **4**, respectively with hexane. Complex **5** crystallises with three independent molecules of CH_2Cl_2. The data for structures **3** and **4** were obtained with a Bruker SMART-APEX diffractometer with an Mo-K_α X-ray tube as radiation source. The data for the structure of **5** was collected on a four-circle diffractometer Hilger & Watts, Mo-K_α, λ = 0.71073 Å. Complex **4** crystallises as a merohedral twin with two perpendicular monoclinic unit cells (with opposite oriented *z* axes) leading to a nearly orthorhombic cell. Symmetry-absence conditions did not give any suitable orthorhombic space group. The structure was solved and refined as a twin in the monoclinic space group $P2_{1/c}$ with β = 90.449°. Refinement in the same space group without the TWIN option leads to an R_1 value above 19% and worse standard deviations for geometric parameters. All structures were resolved by direct methods (SHELXL-86).[30] Refinement on F^2 was carried out by full-matrix least-squares techniques (SHELXL-93, SHELXL-97).[31,32] All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were refined by the riding-model method with a fixed isotropic thermal parameter related by a factor of 1.2 to the value of the equivalent isotropic thermal parameter of their carrier atoms. Weights were optimised in the final refinement cycles. CCDC-178112 (**3**), -178111 (**4**), -178113 (**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

HRS Measurements of the First Hyperpolarisabilities: The measurements at a wavelength of 1500 nm were carried out as described in ref.[23] Instead of the third harmonic (355 nm) generated from an Nd:YAG laser with a wavelength of 1064 nm the optical parametric oscillator (OPO)[33] in use was pumped with the second harmonic (532 nm). The signal intensity at 824 nm and the fundamental at 532 nm were removed from the Idler using dichroic mirrors (HR 650−850 and HR 532), a green light and a silicon filter (transparent > 1000 nm). An additional Glan-Taylor polarizer ensured the vertical polarisation of the beam into the measurement cell. Measurements were performed with ca. 10^{-4} to 10^{-6} M solutions of **5**, **7** and **8** in CH_2Cl_2. The validity of Beer's law was proven by UV/Vis measurements of samples with corresponding concentration. Disperse Red 1 (DR1) was used as an external standard with a value of β_{1500}(DR1) = 70 × 10^{-30} esu. This value was obtained by comparing the slopes of the reference in CH_2Cl_2 and $CHCl_3$ to obtain the ratio of β_{solute}.[27] Using the value β($CHCl_3$) = 80 × 10^{-30} esu[24] the hyperpolarisibility of DR1 in CH_2Cl_2 is estimated to be 70 × 10^{-30} esu. The effect of the refractive indices of the solvents was corrected using the simple Lorentz local field.[28]

Kinetics and Mechanism of the Copper-Catalysed Oxygenation of 2-Nitropropane

Éva Balogh-Hergovich,[a] Zoltán Gréczi,[b] József Kaizer,[a] Gábor Speier,*[a] Marius Réglier,[c] Michel Giorgi,[c] and László Párkányi[d]

Keywords: 2-Nitropropane / Copper nitronates / Oxygenation / Copper / Kinetics / Dioxygenase

Primary and secondary nitro compounds react with dioxygen in the presence of copper metal and N ligands such as *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (tmeda), 2,2′-bipyridine (bpy), and 1,10-phenantroline (phen) in various solvents to form aldehydes or ketones. More coordinating solvents as well as donor N ligands accelerate the reaction remarkably. The oxygenolysis of 2-nitropropane (NPH) in the presence of copper and tmeda in DMF results in acetone and acetone oxime. The amount of tmeda influences the chemoselectivity, higher tmeda concentrations preferentially lead to the formation of the oxime. The kinetics of the reaction, measured at 90 °C, resulted in a rate equation of first-order dependence on copper and dioxygen and second-order dependence on 2-nitropropane. The rate constant, activation enthalpy, and entropy at 363.16 K are as follows: k_{cat} = (5.37 ± 0.34) × 10^{-2} mol^{-3} dm^9 s^{-1}, E_a = 131 ± 4 kJ mol^{-1}, $\Delta H^{\ddagger}$ = 127 ± 4 kJ mol^{-1} and $\Delta S^{\ddagger}$ = 80 ± 13 J mol^{-1} K^{-1}. The catalytically active intermediates $Cu^{II}(NP)_2$(tmeda) and $Cu^{II}(NO_2)_2$(tmeda) in the catalytic cycle were isolated and their structures determined by X-ray crystallography. The kinetics of the stoichiometric oxygenation of $Cu^{II}(NP)_2$(tmeda) to $Cu^{II}(NO_2)_2$(tmeda) and acetone resulted in the overall second-order rate equation with a rate constant, activation enthalpy, and entropy at 313.16 K of k_s = 0.46 ± 0.02 mol^{-1} dm^3 s^{-1}, E_a = 38 ± 1 kJ mol^{-1}, $\Delta H^{\ddagger}$ = 35 ± 1 kJ mol^{-1} and $\Delta S^{\ddagger}$ = −142 ± 13 J mol^{-1} K^{-1}, respectively.

Introduction

The transformation of primary and secondary aliphatic nitro compounds to aldehydes or ketones is a reaction often used in organic chemistry and in biological processes as well. The Nef reaction, the classical method for this conversion, involves the hydrolysis of the conjugate bases of nitroalkanes with sulfuric acid [Equation (1)].[1]

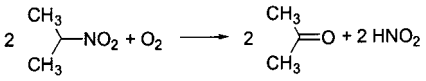
Supporting information for this article is available on the WWW under http://www.eurjic.com or from the author.

There are also a fair number of stoichiometric reagents for this conversion. Treatment of nitroalkanes with aqueous $TiCl_3$,[2] cetyltrimethylammonium permanganate,[3] tin complexes and $NaHSO_3$,[4] activated dry silica gel,[5] 30% H_2O_2/K_2CO_3,[6] $KMnO_4$,[7] ceric ammonium nitrate (CAN),[8] MoO_5/pyridine/HMPA,[9] ozone[10] or singlet oxygen[11] leads to oxo compounds; *t*BuOOH and a catalyst provide a catalytic process for the transformation.[12]

Biochemical degradation of aliphatic nitro compounds is also known in the literature. Glucose oxidase and D- and L-amino acid oxidase accept nitroalkane anions as substrates.[13] The flavoenzyme-catalysed oxidation of nitroalkanes and its mechanism has been established.[14,15] Electron-deficient flavins also oxidise nitroalkane anions in model reactions.[16,17]

Extracts of *Neurospora crassa* and pea seedlings oxidatively metabolise nitroethane and nitropropane,[18] and those from the hyphae of a nitrifying strain of *Aspergillus flavus* produce nitrite and nitrate from 2-nitropropane.[19] 2-Nitropropane and some other nitroalkanes are oxidatively denitrified by an intracellular enzyme of Hansenula mraki.[20] 2-Nitropropane dioxygenase has been purified and characterised as an iron-containing metalloenzyme.[21] It belongs to the peculiar class of intermolecular dioxygenases catalysing the reaction according to Equation (2).[22] That means

that the two oxygen atoms of dioxygen are incorporated into two molecules of the substrate.



(2)

In order to gain more insight into the mechanism of these reactions we initiated studies on copper- and iron-mediated oxygenations of nitroalkanes. We could show that isopropyl nitronate, ligated to a copper ion, can be oxygenated to (nitrito)copper species and acetone,[23] and in the presence of copper metal, as a precursor, nitroalkanes are easily transformed to aldehydes or ketones by dioxygen.[24] In this paper we present kinetic and spectroscopic data on this reaction, the X-ray structures of intermediates and propose a plausible mechanism for the oxygenation as a 2-nitropropane dioxygenase mimicking reaction.

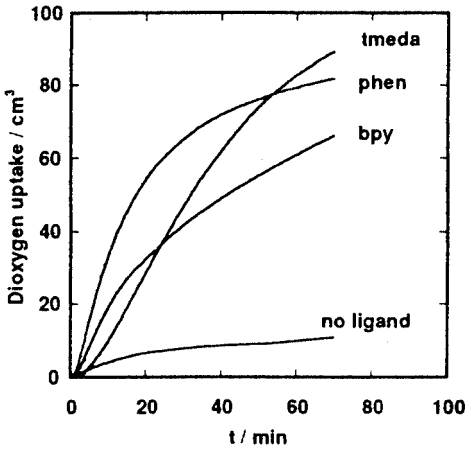


Figure 1. Time course for the stoichiometric oxygenation of 2-nitropropane in the presence of copper metal and N-containing ligands (bpy, phen, tmeda); Cu^0 = L = 1.5 mmol, NPH = 3 mmol, 90 °C, 30 mL DMF

Results and Discussion

Stoichiometric Oxygenation

To a 2-nitropropane (NPH) solution in DMF, copper metal powder was added under dioxygen. The colour of the solution slowly turned reddish and further dissolution of the solid copper resulted in a green homogeneous solution. If coordinating N ligands, such as *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (tmeda), 2,2′-bipyridine (bpy), or 1,10-phenanthroline (phen) were also present, the dissolution of the copper metal proceeded even faster. According to parallel gas-volumetric (O_2), titrimetric (NO_3), spectrophotometric (NO_2) and GC (acetone) measurements (Table 1), the stoichiometry of the oxygenation reaction corresponds to Equation (3). Figure 1 shows typical dioxygen uptake vs. time curves for the oxidation process obtained by the gas-volumetric method.

$$Cu^0 + L + 2\ NPH + 2\ O_2 = Cu^{II}(L)(NO_2)(NO_3) + 2\ (CH_3)_2CO + H_2O \quad (3)$$

Table 1. Stoichiometric oxygenation of 2-nitropropane in DMF solution in the absence and presence of N ligands

Expt. no.	Ligand	Conv.[a] %	NO_3 [b] mmol	NO_2 [c] mmol	Conv.[d] %	Conv.[e] %
1	–	12	0.22	0.09	9.3	10
2	tmeda	98	0.98	1.20	73	87
3	phen	91	0.89	1.01	63	78
4	bpy	73	0.99	1.06	68	72

[a] Conversions were determined by gas volumetry. [b] Yields were determined by titrimetry. [c] Yields were determined by spectrophotometry. [d] Conversions were determined from [b] and [c]. [e] Conversions were determined by GLC.

The presence of the intermediate H_2O_2 in the reaction mixture could be demonstrated either by iodometry or oxidising triphenylphosphane to triphenylphosphane oxide. We believe that in the first step copper metal, in the presence of N ligands, reacts with the *aci* form of the secondary nitro compound to give copper nitronate complexes and H_2O_2 [Equation (4)]. Similar reactions were reported for the reaction of copper metal with acidic compounds in the presence of air.[25]

$$Cu^0 + L + 2\ NPH + O_2 = Cu^{II}(L)(NP)_2 + H_2O_2 \quad (4)$$

In the presence of molecular oxygen both copper(I) and copper(II) nitronates are probably first formed, the former is then transformed to $Cu^{II}(L)(NP)_2$, which can be oxygenated to the desired products [Equation (5)].

$$Cu^{II}(L)(NP)_2 + O_2 = Cu^{II}(L)(NO_2)_2 + 2\ (CH_3)_2CO \quad (5)$$

This is then followed by the fast consecutive formation of $Cu^{II}(L)(NO_2)(NO_3)$, which is assumed to be obtained as a product of the oxidative process between $Cu^{II}(L)(NO_2)_2$ and H_2O_2 [Equation (6)].

$$Cu^{II}(L)(NO_2)_2 + H_2O_2 = Cu^{II}(L)(NO_2)(NO_3) + H_2O \quad (6)$$

Copper-Catalysed Oxygenation of 2-Nitropropane

Previously we have reported that primary and secondary nitro compounds in the presence of copper metal and N ligands can be transformed to aldehydes or ketones and HNO_2. The reaction can also be carried out catalytically in

the presence of tmeda at high 2-nitropropane/copper ratios in a very efficient way (Figure 2).

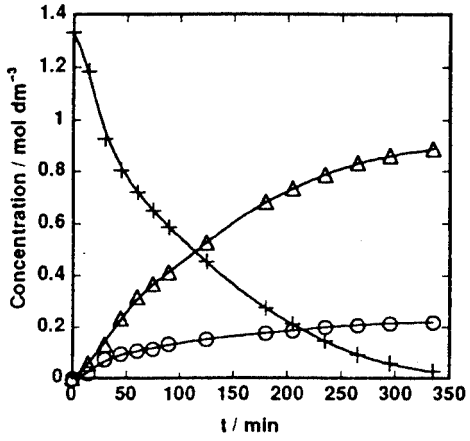

Figure 2. Time course for the copper-catalysed oxygenation of 2-nitropropane (+) [acetone (Δ); acetone oxime (o)] in DMF using tmeda as ligand (Experiment 3, Table 4)

In these experiments Cu^0, tmeda, and 2-nitropropane are first pretreated with O_2 to give a homogeneous solution in about 10−15 min and thereafter the reaction takes place in a homogeneous phase. According to simultaneous gas-volumetric and GC measurements the stoichiometry of the oxidation reaction corresponds to that shown in Equation (7).

$$2\,NPH + O_2 = 2\,HNO_2 + 2\,(CH_3)_2CO \quad (7)$$

In the reaction mixture the presence of acetone oxime is also detected (10−20%). The formation of acetone oxime is favoured at high tmeda concentrations (Figure 3). We believe that excess tmeda acts as a base and in the presence of HNO_2 the salt tmeda·HNO_2 is formed, which reacts with 2-nitropropane resulting in the oxime [Equation (8)].

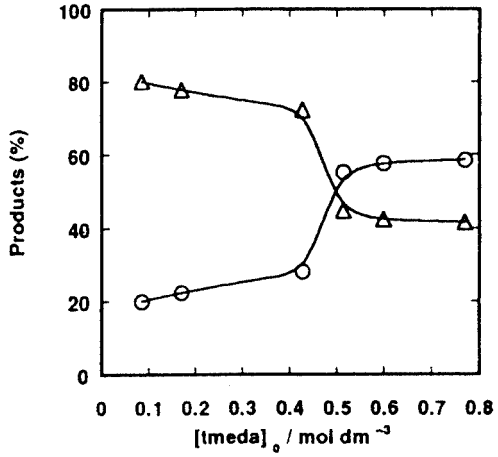

Figure 3. Plots of amounts of acetone (Δ) and acetone oxime (o) formed vs. the initial tmeda concentration at the copper-catalysed oxygenation of 2-nitropropane in DMF (Experiment 15, Table 4)

(8)

On addition of ether to the reaction mixture, a green solid precipitated from which, after recrystallisation from ethanol, green crystals of $Cu^{II}(NO_2)_2$(tmeda) were obtained. The presence of $Cu^{II}(NO_2)_2$(tmeda) in the reaction mixture clearly suggests that the first step in the catalytic oxygenation of 2-nitropropane is the formation of the fairly stable $Cu^{II}(NP)_2$(tmeda) complex from copper powder, 2-nitropropane, tmeda and dioxygen, which further rapidly reacts with dioxygen to form the more stable nitrito species $Cu^{II}(NO_2)_2$(tmeda). The complex $Cu^{II}(NP)_2$(tmeda) was prepared by the stoichiometric reaction of $Cu^{II}(OMe)_2$, 2-nitropropane and tmeda in THF under Ar.

Characterisation of $Cu^{II}(NO_2)_2$(tmeda)

$Cu^{II}(NO_2)_2$(tmeda) displays three bands at 1360, 1286 and 808 cm^{-1} in its IR spectrum assigned to the asymmetric and symmetric stretching and bending frequencies of the nitro group. There are three additional bands at 953, 845 and 593 cm^{-1} due to deformation and bending frequencies of the nitro group. Three bands at 2983, 2941 and 2899 cm^{-1} can be assigned to the ligand tmeda coordinated to the copper ion. The electronic absorption spectrum of $Cu^{II}(NO_2)_2$(tmeda) in acetonitrile showed two intense bands at 271 and 222 nm, which were assigned to LMCT bands. Further, the LMCT bands for the nitro complex at 271 nm may include contributions from the n→π* transition as well.[26] Crystallographic characterisation of Cu^{II}-(NO_2)(tmeda) shows that the molecule is monomeric. The view of the molecule depicted in Figure 4 shows that the copper(II) centre has an elongated rhombic octahedral geometry with a $CuO_2N_2O_2$ chromophore and a (4+2*)-type coordination involving two off-the-*z*-axis bonds.

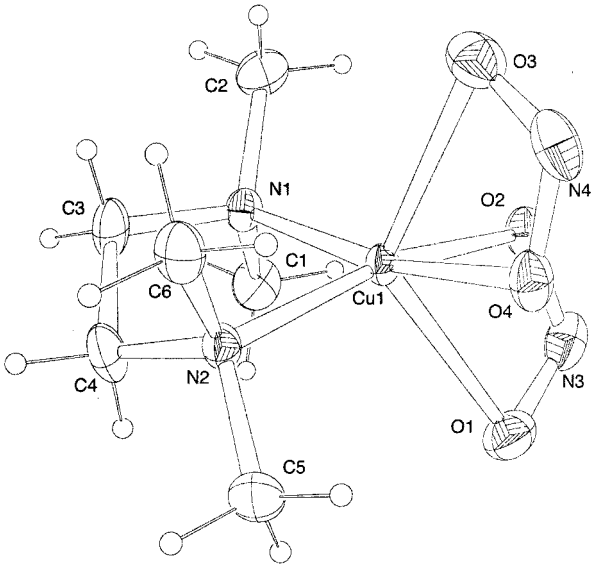

Figure 4. Molecular structure and numbering scheme of [Cu^{II}(NO_2)$_2$(tmeda)] (**1**); only one molecule is shown; hydrogen atoms are omitted for clarity, the ellipsoids represent a probability of 40%

Selected bond lengths and angles given in Table 2 show that two N atoms of the bidentate *N*,*N*,*N*′,*N*′-tetramethylethylenediamine ligand with Cu−N distances of 2.0291(4) and 2.0242(4) Å, and two O atoms of the NO_2 ligands with Cu−O distances of 2.0052(4) and 2.0087(4) Å, occupy basal positions, the other two O atoms of the NO_2 ligands with Cu−O distances of 2.3992(5) and 2.4693(5) Å being in apical positions. This is associated with the bidentate bonding mode of oxyanions to the copper(II) ion, such as the nitrite and nitrate anions, all of which form good primary ligands to the copper(II) ion as in $[Cu^{II}(pyrazine)_2(O_2NO)_2]$[27] and $[Cu^{II}(bipy)(ONO)_2]$.[28] Asymmetric bidentate copper nitrite coordination was also found in other complexes with N-donor ligands.[29,30]

Characterisation of $Cu^{II}(NP)_2$(tmeda)

The green complex $Cu^{II}(NP)_2$(tmeda) was prepared in 85% yield. The IR spectrum of the complex shows intense sharp bands corresponding to the coordinated *aci*-2-nitropropanate ligands at 1612 [ν(C=N)], 1162 and 1123 [$\nu_{as}(NO_2)$], and 943 [$\nu_s(NO_2)$] cm^{-1}. The electronic spectrum of the complex shows an absorption band at 727 nm due to d-d transitions. A higher energy band at 314 nm is associated with charge transfer transition. Room-temperature magnetic measurements yielded a value of μ_{eff} = 1.92 BM for the complex consistent with a copper(II) ion. The view of the molecule in Figure 5 shows that the geometry around the copper(II) centre is similar to that of the Cu^{II}-(NO_2)(tmeda) complex with an elongated rhombic octahedral $CuO_2N_2O_2$ chromophore and a (4+2*)-type coordination, involving two off-the-*z*-axis bonds. Selected bond lengths and angles given in Table 3 show that two N atoms of the bidentate *N*,*N*,*N*′,*N*′-tetramethylethylenediamine ligand, with Cu−N distances of 2.0665(14) Å, and two O atoms of the nitronate ligands, with Cu−O distances of 1.9997(13) Å, occupy basal positions, while the other two O atoms of the nitronate ligands, with Cu−O distances of 2.3615(13) Å, are in apical positions. The carbon−nitrogen bond [1.290(2) Å] in the nitronate ligand is essentially double bond in character (C−N 1.47 Å, C=N 1.27 Å).[31] This is similar to the findings for the structures of $Cu^{I}(NP)(PPh_3)_2$ [23] and $Fe^{III}(NP)_3$.[32] The C−N distances are somewhat longer in $Cu^{II}(NP)_2$ (1.34−1.35 Å), however, its structure consists of chains of $Cu^{II}(NP)_2$ units.[33]

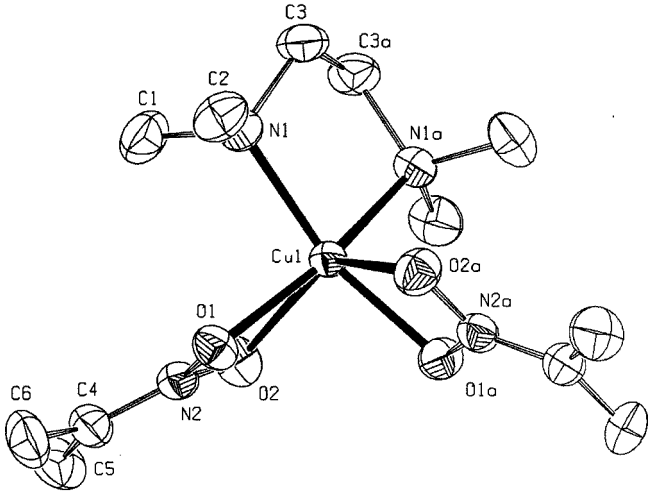

Figure 5. Molecular structure and numbering scheme of $[Cu^{II}$-$(NP)_2$(tmeda)] (**2**); only one molecule is shown; hydrogen atoms are omitted for clarity, the ellipsoids represent a probability of 40%

Kinetic Measurements

The reaction between 2-nitropropane and dioxygen in the presence of a catalytic amount of copper and tmeda were performed in DMF solution and examined in the temperature range 363.16 to 373.16 K with a ratio between initial concentrations of copper and 2-nitropropane in the range

1:6−33. Experiments were also carried out at different dioxygen concentrations. Experimental conditions are summarised in Table 4.

A simple rate law for the catalytic reaction between 2-nitropropane and dioxygen catalysed by copper in the presence of tmeda is given in Equation (9).

$$-\mathrm{d[NPH]}/\mathrm{d}t = \mathrm{d[acetone]}/\mathrm{d}t = k_{cat}[\mathrm{NPH}]^m[\mathrm{Cu}]^n[\mathrm{O_2}]^q \quad (9)$$

In order to determine the rate dependence on the various reactants, oxygenation runs were performed at different substrate concentrations (Table 4; Experiments 1−4), catalyst concentrations (Table 4; Experiments 3, 5−9), and at different dioxygen pressures (Table 4; Experiments 10−14). Assuming a constant concentration of the catalyst during each reaction, as well as a constant dioxygen pressure for the experiments, the pseudo-first-order rate law according to Equation (10) is obtained, where $k_{cat}' = k_{cat}[\mathrm{Cu}]^n[\mathrm{O_2}]^q$.

$$-\mathrm{d[NPH]}/\mathrm{d}t = k_{cat}'[\mathrm{NPH}]^m \quad (10)$$

Plots of $[\mathrm{NPH}]^{-1}$ vs. time were linear in Experiments 1−14, indicating that the reaction is second order with respect to substrate concentration. Columns k_{cat}' and R in Table 4 report slopes and the correlation coefficients obtained by the least-squares method for these linear regressions. From variations of the reaction rates, plots of $-\mathrm{d[NPH]}/\mathrm{d}t$ vs. the second exponent of the initial NPH concentration $[\mathrm{NPH}]_0^2$ (Figure S1, Supporting Information) were also linear ($R = 99.41$), reinforcing that the reaction is indeed second-order with respect to the 2-nitropropane concentration (Table 4; Experiments 1−4). This means that $m = 2$ in Equation (9).

Kinetic measurements of the reaction rate with respect to catalyst concentration (Table 4; Experiments 3, 5−9) indic-

[a] In 30 mL of DMF, the amount of tmeda is equimolar to copper. [b] Correlation coefficients of least-squares regressions. [c] Mean value of the kinetic constant k and its standard deviation $\sigma(k)$ were calculated as $k = (\Sigma_i w_i k_i/\Sigma_i w_i)$ and $\sigma(k) = [\Sigma_i w_i(k_i - k)^2/(n-1)\Sigma_i w_i]^{1/2}$, where $w_i = 1/\sigma_i^2$. [d] $Cu^{II}(NO_2)_2$(tmeda) was used as catalyst instead of Cu^0. [e] $Cu^{II}(NP)_2$(tmeda) was used as catalyst instead of Cu^0.

ate a first-order dependence. Plots of k_{cat}' vs. [Cu] for the above experiments gave a straight line with a correlation coefficient of 99.10% (Figure S2, Supporting Information).

The experiments performed at different dioxygen concentrations (calculated from literature data assuming the validity of Dalton's law, the dissolved concentration of O_2 being 8.25×10^{-3} mol dm^{-3} at 90 °C and 760 Torr O_2 pressure) show that the reaction is first order with respect to the dioxygen concentration (Table 4; Experiments 3, 10−14). Plotting k_{cat}' against [O_2] for the above experiments resulted in a straight line with a correlation coefficient of 99.61% (Figure S3, Supporting Information). According to the kinetic data obtained the oxygenation of 2-nitropropane obeys an overall fourth-order reaction rate with $m = 2$, $n = q = 1$ in Equation (9), from which a mean value of the kinetic constant k_{cat} of $(5.37 \pm 0.34) \times 10^{-2}$ mol^{-3}·L^3 s^{-1} at 363.16 K was obtained (Table 4).

The catalytic oxygenation reactions of 2-nitropropane by $Cu^{II}(NO_2)_2$(tmeda) and $Cu^{II}(NP)_2$(tmeda) complexes as catalysts were also carried out (Table 4; Experiments 17−18). It can be seen that the mean value of the kinetic constant for $Cu^{II}(NO_2)_2$(tmeda) and $Cu^{II}(NP)_2$(tmeda) complexes are very similar to those found in the reactions, where the catalyst was prepared "in situ", suggesting that the two complexes above were involved in the catalytic process when copper metal was used as the catalyst precursor.

The activation parameters for the catalytic oxygenation reaction were determined from the temperature dependence of the kinetic constant k_{cat}. The Arrhenius plot of log k_{cat} vs. $1/T$ (Figure S4, Supporting information) using the k_{cat} values at 363.16, 368.16 and 373.16 K (Table 4; Experiments 1−14, 15−16) was linear with a correlation coefficient of 99.27%. From the slope and the ordinate intercept of this line the parameters $E_a = 131 \pm 4$ kJ mol^{-1}, $\Delta H^{\ddagger} = 127 \pm 4$ kJ mol^{-1} and $\Delta S^{\ddagger} = 80 \pm 13$ J mol^{-1} K^{-1} were calculated.

In order to shed light on the kinetic scenery of the elementary steps of these catalytic reactions we also studied the kinetics of the oxygenation of the proposed intermediate $Cu^{II}(NP)_2$(tmeda). The oxygenation of [Cu^{II}-$(NP)_2$(tmeda)] affords a stoichiometry corresponding to Equation (11) by the use of parallel gas-volumetric and GC measurements.

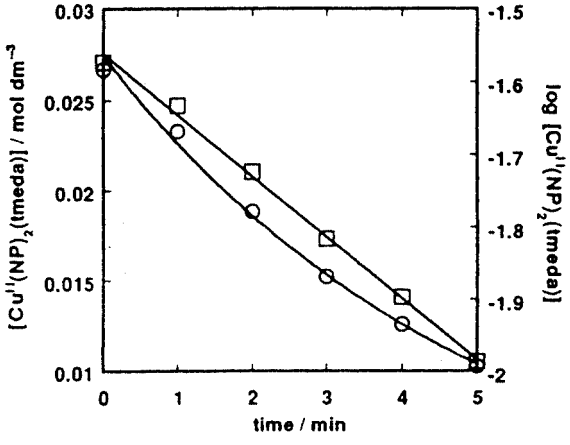

Figure 6. The time course for the oxygenation of [Cu^{II}-$(NP)_2$(tmeda)] (o) and plot of log[$Cu^{II}(NP)_2$(tmeda)] vs. time for the oxygenation of [$Cu^{II}(NP)_2$(tmeda)] (Experiment 4, Table 5)

$$Cu^{II}(NP)_2(tmeda) + O_2 = Cu^{II}(NO_2)_2(tmeda) + 2\,(CH_3)_2CO \quad (11)$$

Figure 6 shows a typical concentration vs. time curve for [$Cu^{II}(NP)_2$(tmeda)] obtained by the measured dioxygen uptake. The reaction between [$Cu^{II}(NP)_2$(tmeda)] and dioxygen was performed in DMF solution and examined in the temperature range 303.16 to 318.16 K. Experiments were also carried out at different dioxygen concentrations. The experimental conditions are summarised in Table 5.

A simple rate law for the stoichiometric reaction between [$Cu^{II}(NP)_2$(tmeda)] and dioxygen is given in Equation (12).

$$-d[Cu^{II}(NP)_2(tmeda)]/dt = k_s[Cu^{II}(NP)_2(tmeda)]^m[O_2]^n \quad (12)$$

In order to determine the rate dependence on the various reactants, oxygenation runs were performed at different [$Cu^{II}(NP)_2$(tmeda)] concentrations (Table 5; Experiments 1−4), and at different dioxygen pressures (Table 5; Experiments 4−7). Assuming a constant concentration of the dioxygen during each reaction the pseudo-first-order rate law according to Equation (13) is obtained, where $k_s' = k_s[O_2]^n$.

$$-d[Cu^{II}(NP)_2(tmeda)]/dt = k_s'[Cu^{II}(NP)_2(tmeda)]^m \quad (13)$$

Plots of log[$Cu^{II}(NP)_2$(tmeda)] vs. time were linear in Experiments 1−10, indicating that the reaction is first-order with respect to the $Cu^{II}(NP)_2$(tmeda) concentration. Columns k_s' and R in Table 5 report slopes and the correlation coefficients obtained by the least-squares method for these linear regressions. A typical first-order plot is shown in Figure 6 (Table 5; Experiment 4).

From variations of the reaction rates, plots of $-d[Cu^{II}(NP)_2(tmeda)]/dt$ (v_0) vs. [$Cu^{II}(NP)_2$(tmeda)] (Figure S5, Supporting Information) were also linear ($R = 98.46$), reinforcing that the reaction is indeed first-order with respect to the $Cu^{II}(NP)_2$(tmeda) concentration (Table 5; Experiments 1−4). This means that $m = 1$ in Equation (12).

Experiments carried out at different dioxygen concentrations (calculated from literature data assuming the validity of Dalton's law, the dissolved concentration of O_2 being 5.36×10^{-3} mol dm^{-3} at 40 °C and 760 Torr O_2 pressure) show that the reaction is first-order with respect to the dioxygen concentration (Table 5; Experiments 4−7). Plotting $-d[Cu^{II}(NP)_2(tmeda)]/dt$ (v_0) against [O_2] for the above four experiments resulted in a straight line with a correlation coefficient of 99.41% (Figure S6, Supporting Information). According to the kinetic data obtained, the oxygenation of $Cu^{II}(NP)_2$(tmeda) obeys an overall second-order rate equation with $m = n = 1$ in Equation (12), from which a mean value of the kinetic constant k_s of (0.46 ± 0.02) mol^{-1} dm^3 s^{-1}, at 313.16 K, was obtained (Table 5).

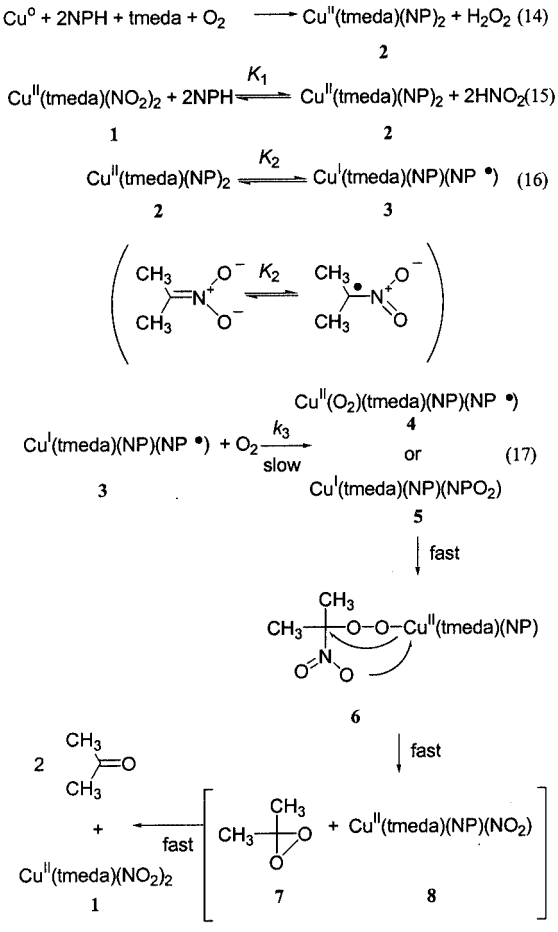
[a] In 30 mL of DMF. [b] Correlation coefficients of least-squares regressions. [c] Mean value of the kinetic constant k and its standard deviation $\sigma(k)$ were calculated as $k = (\Sigma_i w_i k_i/\Sigma_i w_i)$ and $\sigma(k) = [\Sigma_i w_i(k_i - k)^2/(n-1)\Sigma_i w_i]^{1/2}$, where $w_i = 1/\sigma_i^2$.

The activation parameters for the stoichiometric oxygenation reaction were determined from the temperature dependence of the kinetic constant k_s. The Arrhenius plot of log k_s vs. $1/T$ (Figure S7, Supporting Information) using the k_s values at 303.16, 308.16, 313.16 and 318.16 K (Table 5; Experiments 4, 8−10) was linear with a correlation coefficient of 99.48%. From the slope and the ordinate intercept of this line the parameters $E_a = 38 \pm 1$ kJ mol^{-1}, $\Delta H^{\ddagger} = 35 \pm 1$ kJ mol^{-1} and $\Delta S^{\ddagger} = -142 \pm 13$ J mol^{-1} K^{-1} were calculated. Values of the activation parameters indicate that the oxidation of $Cu^{II}(NP)_2(tmeda)$ is a bimolecular reaction involving the associative transition state of $Cu^{II}(NP)_2(tmeda)$ and molecular oxygen; k_{cat} is substantially smaller than k_s since in the former the pre-equilibrium constants K_1 and K_2 are also involved, and K_1 and K_2 are small. The equilibria according to Equations (15) and (16) are shifted to the left side. A comparison of the activation enthalpies and entropies of the catalytic and stoichiometric reactions clearly shows that the stoichiometric reaction is enthalpy-driven while in the case of the catalytic reaction the positive $\Delta S^{\ddagger}$ and the larger $\Delta H^{\ddagger}$ values show a different situation. Here the contribution of the entropy seems to be more and the enthalpy less dominant. This may be explained by the effect of the pre-equilibrium according to Equation (15), since K_1 is involved in k_{cat} thus causing this difference.

Based on the kinetic data on the copper-catalysed oxygenation of 2-nitropropane to acetone, a probable mechanism is proposed as shown in Scheme 1. According to that, the first step is the formation of the complex Cu^{II}(tmeda)$(NP)_2$ (**2**) from copper powder, 2-nitropropane, tmeda, and dioxygen [Equation (14)] or from $Cu^{II}(tmeda)(NO_2)_2$ through substitution of NO_2^- by NP^- in a pre-equilibrium in the catalytic cycle [Equation (15)]. This is then followed by an intramolecular electron transfer [Equation (16)] from the ligand 2-nitropropanate to the copper(II) ion resulting in a (2-nitropropyl radical)copper(I) complex $Cu^{I}(tmeda)(NP)(NP^{\bullet})$ (**3**). This equilibrium is largely shifted to the left (K_2 is rather small). All attempts to detect the radical by EPR spectroscopy failed. The 2-nitropropanate anion does not react with $^3O_2$.[34] The absence of the electron transfer from $Cu^{II}(tmeda)(NP)_2$ to dioxygen could also be proved by the test for free $O_2^{\bullet-}$ with nitroblue tetrazolium (NBT), where no reduction of the added dye to the blue formazan took place excluding the formation of free $O_2^{\bullet-}$.[35]

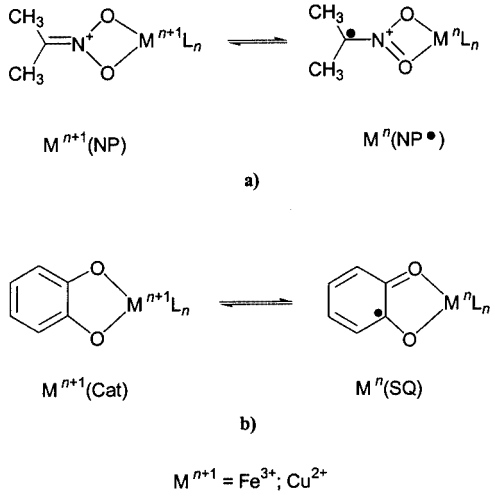


Scheme 1

In the complex Cu^{I}(tmeda)(NP)(NP$^{\cdot}$) (**3**) there are two redox-active centres, namely the nitropropanyl radical NP$^{\cdot}$ and the copper(I) ion.

The biradical dioxygen may react at both redox-active sites of the complex Cu^{I}(tmeda)(NP)(NP$^{\cdot}$), in a radical-radical reaction with the coordinated radical ligand NP$^{\cdot}$ leading to the peroxo intermediate **5**, or in an oxidative addition of O_2 to the copper(I) ion giving the (superoxo)copper(II) complex **4**, as found in the case of many other copper(I) complexes.[36] Both mechanistic assumptions satisfy the kinetic data, but we believe that the reaction of the copper(I) centre of **3** with O_2 is more probable. We have observed earlier that radical ligands bound to metal ions that cannot be oxidised (e.g. Cu^{II}, Fe^{III}, etc)[37] do not react with O_2 at all, or undergo very slow reactions only. The (superoxo)copper(II) complex **4** then undergoes an intramolecular radical-radical reaction of the coordinated ligands $O_2^{\cdot-}$ and NP$^{\cdot}$ resulting in the peroxide species **6**. This then decomposes to the mixed-ligand copper(II) complex **8** and 1,1-dimethyldioxirane (**7**). The 1,1-dimethyldioxirane (**7**) then oxygen ates the coordinated NP^{-} in **8** resulting in Cu^{II}(tmeda)-$(NO_2)_2$ and acetone. The 2-nitropropane once again replaces the nitrito ligand in **1** and so closes the catalytic cycle. Previous studies have shown, that dimethyldioxirane oxidation of nitronate anions affords the corresponding carbonyl product.[38]

As a conclusion it can be said, that the present work provides further support to the key role of redox-active ions in these oxygenation reactions, which may be regarded as functional models for 2-nitropropane dioxygenase. We believe that there is a valence tautomerism between Cu^{II}(NP) and Cu^{I}(NP$^{\cdot}$) due to intramolecular electron transfer from the ligand to the metal ion (Scheme 2a). In this sense of the activation process the ligand is transformed to a radical and copper(II) to copper(I). The latter then reacts with dioxygen to form a peroxidic species, which transforms to the (nitrito)copper(II) complex and acetone. At the intradiol cleavage of catechols either by iron-[39] or copper-containing[40] catechol 1,2-dioxygenases along with model studies[41] it has been proven that valence isomerism plays an important role (Scheme 2b). The molecular orbitals involved in this process are close to each other in energy and so the electron transfer is easily feasible. The equilibrium depends of course on auxiliary ligands as shown in the case of copper catecholate complexes, whereas soft ligands prefer the lower oxidation state of the metal ion.[42] A similar behaviour with (nitropropane)iron complexes is also to be expected as a key step in these oxygenations. Further work is in progress on the design and elucidation of iron-containing functional 2-nitropropane dioxygenase models.



Scheme 2

Experimental Section

Materials and Methods: Analytical-grade reagents were used throughout. Copper powder (Aldrich), 2-nitropropane (Fluka), *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (Aldrich), 2,2′-bipyridine (Aldrich), and 1,10-phenanthroline (Aldrich) were used as supplied. DMF (Aldrich) was purified by azeotropic distillation with benzene and water and stored under argon.[43] Gaseous dioxygen from Messer Griesheim was 99.6% and passed through P_2O_5 and Blaugel in order to remove traces of water and other impurities. IR spectra were recorded with a Specord IR-75 (Carl Zeiss) spectrometer on either Nujol or KBr pellets. Electronic spectra were measured with a Shimadzu UV-160A spectrophotometer using quartz cells. GC analyses were performed with HP 5830A and HP 5890 gas chromatographs equipped with a flame ionisation detector and CP SIL 8CB column. GC-MS measurements were recorded with an HP 5890II/5971 GC/MSD instrument at 75 eV.

Stoichiometric Oxygenation: In a typical stoichiometric reaction 2-nitropropane (0.36 mL, 3 mmol), copper metal (0.10 mg, 1.5 mmol) and tmeda (0.225 mL, 1.5 mmol) in DMF (30 mL) were stirred at 90 °C under dioxygen for 60 min. The stoichiometry of the reactions was investigated by gas volumetric (O_2), spectrophotometric (NO_2),[44] titrimetric (NO_3)[45] and GC measurements (acetone), and the presence of H_2O_2 was determined by iodometry[46] (Table 1.). Then diethyl ether was layered on the solution and left at −20 °C for 2 h to afford a green solid, which was filtered off and recrystallised from acetonitrile to give [Cu(tmeda)$(NO_3)(NO_2)$] as green crystals (0.11 g, 25%). M.p. 172 °C (dec.). $C_6H_{16}CuN_4O_5$ (287.7): calcd. C, 25.03, H 5.60, Cu 22.07, N 19.46; found C 25.4, H 5.49, Cu 22.43, N 19.31. UV/Vis (DMF): λ_{max} (log ε/mol^{-1} dm^3 cm^{-1}) = 276 (3.66), 365 (3.16), 642 nm (2.300). IR (KBr): $\tilde{\nu}_{max}$ = 2976 m, 2938 w, 2888 w, 1567 m, 1470 vs, 1387 s, 1361 vs, 1284 m, 1161 vs, 1046 s, 1020 s, 1001 m, 956 s, 846 m, 814 s, 769 cm^{-1} m. μ_{eff} = 2.07 BM. The ratio NO_3^-/NO_2^- in the complex was 1:1.2.

Preparation of [$Cu^{II}(NP)_2$(tmeda)]: [$Cu(OMe)_2$] (3.14 g, 25 mmol) was dissolved in MeOH (20 mL); tmeda (3.78 mL, 25 mmol) and 2-nitropropane (4.5 mL, 50 mmol) were added and the mixture was stirred under argon at room temperature for 20 h. The solvent was then removed in vacuo and the remaining oily residue was treated with diethyl ether, filtered off and dried to give a green powder (7.60 g, 85%). M.p. 95 °C (dec.). $C_{12}H_{28}CuN_4O_4$ (355.9): calcd. C 39.88, H 7.45, N 15.49; found C 40.50, H 7.93, N 15.74. IR (KBr): $\tilde{\nu}$ = 2925 w, 1612 vs, 1464 vs, 1393 w, 1291 w, 1162 vs, 1123 vs, 1059 m, 1033 m, 956 m, 943 s, 814 s, 782 m, 634 m, 402 cm^{-1} m. UV/Vis (DMF): λ_{max} (ε/ʟ mol^{-1} cm^{-1}) = 314 (978.5), 727 nm (76.7). μ_{eff} = 1.92 BM. On recrystallisation from THF green single

crystals of $[Cu^{II}(NP)_2(tmeda)]$ were formed suitable for X-ray diffraction.

Kinetic Experiments: Kinetic measurement were carried out at atmospheric pressure, at constant partial pressure of dioxygen with vigorous stirring in a thermostatted reaction vessel equipped with a syringe inlet for taking samples at regular time intervals. The samples taken were chilled, stored at dry-ice temperature and then submitted for GC or GC-MS analysis. Dioxygen uptakes were also measured in a constant-pressure gas-volumetric apparatus. The volume of absorbed dioxygen was read periodically using a gas burette. The amount of nitrous acid was determined spectrophotometrically[44] after diazotization of sulfanylic acid and successive coupling with 1-aminonaphthalene, and was found in each case to be nearly equal to that of acetone. The catalytic reactions were carried out by preparing the catalyst from copper metal, tmeda, and 2-nitropropane in DMF under dioxygen. After about 10−15 min, the mixture gave a green homogeneous solution by dissolving the copper metal. Thereafter, the reaction was monitored by analysing the amount of products (acetone and acetone oxime) and the starting 2-nitropropane by GLC. In a typical oxygenation of 2-nitropropane to acetone and acetone oxime, the copper metal (191 mg, 3 mmol), 2-nitropropane (3.6 mL, 40 mmol), tmeda (0.45 mL, 3 mmol) and DMF (30 mL) were stirred under dioxygen at 95 °C. After dissolution of the copper powder (10 min), samples were taken at ca. 10-min intervals, cooled to dry-ice temperature and then subjected to GLC analysis. The solubility of dioxygen in DMF at 95 °C was taken as 8.56×10^{-3} M.[47] The validity of Dalton's law was assumed for the calculation of dioxygen concentration at different partial pressures.[48] Diethyl ether was layered on the solution and left at −20 °C for 2 h to afford a green solid, which was filtered off and recrystallised from ethanol to give $[Cu^{II}(tmeda)(NO_2)_2]$ as green crystals. M.p.197 °C (dec.). $C_6H_{16}CuN_4O_4$ (271.7): calcd. C 26.51, H 5.93, N 20.62; found C 25.7, H 5.72, N 19.91. UV/Vis (DMF): λ_{max} (log ε/mol^{-1} dm^3 cm^{-1}) = 271 (3.66), 222 (3.43) and 648 nm (2.17). IR (KBr): $\tilde{\nu}_{max}$ = 2983 m, 2941 m, 2899 m, 1477 s, 1468 s, 1360 vs, 1286 m, 1249 m, 1165 vs, 1101 m, 1041 m, 1021 m, 1000 m, 953 s, 845 m, 808 s, 770 m, 593 cm^{-1} m. The stoichiometric oxygenation of $[Cu^{II}(NP)_2(tmeda)]$ was carried out in a thermostatted constant-pressure gas-volumetric apparatus. The volume of absorbed dioxygen was read periodically using a gas burette.

X-ray Crystallography: Crystallographic and experimental details of the data collection and refinement of the structures of $Cu^{II}(NO_2)_2(tmeda)$ and $Cu^{II}(NP)_2(tmeda)$ are reported in Table 6, while the molecular structures are depicted in Figures 4 and 5. The intensity data of $Cu^{II}(NO_2)_2(tmeda)$ were collected with a KappaCCD single-crystal diffractometer, using the graphite-monochromated Mo-K_α radiation and φ-scan technique. The structure was solved by direct and difmap methods (SIR92),[49] and refined on F^2 using full-matrix least-squares methods (Maxus).[50] The intensity data of $Cu^{II}(NP)_2(tmeda)$ were collected with an Enraf−Nonius CAD-4 single-crystal diffractometer, using graphite-monochromated Mo-K_α radiation and ω/2θ-scan technique. The structure was solved by direct and difmap methods (SHELXS-97),[51] and refined with full-matrix least-squares refinement on F^2 (SHELXL-97).[52] CCDC-167599 (**1**) and -167598 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of Dihydrogen(olefin)osmium Complexes with (E)-$Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2$

Sheng Hua Liu,[a] Xin Huang,[a] Zhenyang Lin,*[a] Chak Po Lau,*[b] and Guochen Jia*[a]

Keywords: Dihydrogen / Diphosphane / Hydride / Osmium

Treatment of $[OsClH_3(PPh_3)_3]$ with (*E*)-$Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2$ produced $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]$, which reacted with HOTf to give the dihydrogen(olefin) complex $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$. Treatment of the latter complex with H_2 did not result in hydrogenation of the olefin double bond, but gave the (hydrido)dihydrogen complex $[OsH(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$. A density functional theory study suggested that hydrogenation of the double bond in $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$ was thermodynamically feasible but kinetically unfavorable.

Introduction

Since the first report of dihydrogen complexes by Kubas and his co-workers in 1984,[1] this unique class of complexes has been intensively investigated, especially with regard to their preparation, characterization, and structural and catalytic properties.[2−4] Previous studies have established that dihydrogen complexes may have their own individual reactivity and play active roles in catalytic reactions. In catalytic hydrogenation reactions, there are several possible ways in which dihydrogen complexes may play active roles. Among them, intramolecular hydrogen transfer from a coordinated dihydrogen ligand to the α-carbon atom of a σ-bonded carbon ligand has been recognized as one of the key steps in the catalytic cycles. In particular, (alkyl)dihydrogen and (alkenyl)dihydrogen complexes have been proposed or inferred as the key intermediates in the hydrogenation of olefins and acetylenes under catalysis by group-8 metal complexes such as $[MH(H_2)(PP_3)]^+$ [M = Fe, Ru; PP_3 = $P(CH_2CH_2PPh_2)_3$],[5] $[OsClH(CO)\{P(iPr)_3\}_2]$,[6] $[RuClH(PPh_3)_3]$,[7] and $[RuH(Tp)(L)(PPh_3)]$ [Tp = hydrotris(1-pyrazolyl)borate; L = PPh_3, CH_3CN].[8] As model complexes for reactions involving intramolecular hydrogen transfer from a coordinated dihydrogen ligand to the α-carbon atom of a σ-bonded carbon ligand, several well-characterized dihydrogen complexes containing σ-bonded carbon ligands (such as alkynyl,[9] alkenyl,[10] and aryl[11]) have been synthesized in recent years.

In addition, there are reports that hydrogenation may also proceed through hydrogen transfer from a coordinated dihydrogen ligand to an olefin ligand. The complexes $[M(H_2)(\eta^4\text{-NBD})(CO)_3]$ and $[M(H_2)(\eta^2\text{-NBD})(CO)_4]$ (M = Cr, Mo, and W) have been proposed as the intermediates in the photocatalytic hydrogenation of norbornadiene with $[M(CO)_6]$.[12,13] Dihydrogen(olefin) complexes have also been proposed (but not detected) as the intermediates in catalytic hydrogenation of olefins with $[Ru(Tp)(PPh_3)_x(CH_3CN)_{3-x}]^+$ (x = 1, 2),[8] and in the protonation reaction of [Ru(Cp*)H(NBD)].[14a] However, well-characterized dihydrogen(olefin) complexes are rare.[12−14] Reported dihydrogen(olefin) complexes include $[M(H_2)(\eta^2\text{-NBD})(CO)_4]$ (M = Mo and W),[12] $[M(H_2)(\eta^4\text{-NBD})(CO)_4]$ (M = Cr, Mo, and W),[12] and $[Fe(H_2)(CO)_3(MeO_2CCH{=}CHCO_2Me)]$,[13] which have been detected by IR spectroscopy, and $[Ru(Cp^*)(H_2)(COD)]^+$, which has been detected by NMR spectroscopy.[14a] In this paper we wish to report the synthesis and characterization of new dihydrogen(olefin) complexes.

Results and Discussion

Synthesis and Characterization of $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]$

Complexes of the type $[MCl(H_2)L_4]^+$ (M = Ru, Os; L = phosphane, CO, pyridine) are known to contain a dihydrogen ligand.[15,16] One might therefore expect that protonation of $[MClH(olefin)(PR_3)_3]$ might produce dihydrogen complexes $[MCl(H_2)(olefin)(PR_3)_3]^+$. To test this possibility, we prepared the hydrido(olefin) complex $[OsClH(PPh_3)(Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2]$, hoping that subsequent protonation would produce the corres-

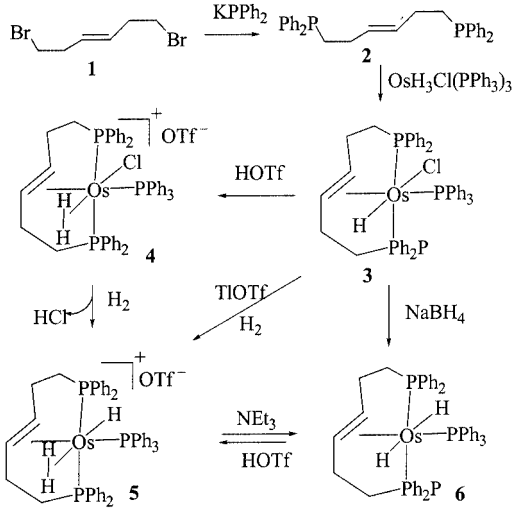
Hung Hom, Kowloon, Hong Kong

ponding dihydrogen(olefin) complex. Osmium metal and the bidentate phosphane ligand with an olefinic functionality in the backbone were used in the project because of the expectation that such systems may give thermally stable dihydrogen(olefin) complexes.

The ligand (*E*)-$Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2$ (**2**)[17] was prepared by treatment of (*E*)-$Br(CH_2)_2CH{=}CH(CH_2)_2Br$ (**1**) with excess $KPPh_2$ in THF (Scheme 1). Ligand **2** was characterized by ^1H, $^{13}C\{^1H\}$, and $^{31}P\{^1H\}$ NMR spectroscopy and by elemental analysis. In particular, the ^1H NMR spectrum (in C_6D_6) showed the olefinic proton signal at $\delta = 5.4$ ppm, while the $^{31}P\{^1H\}$ NMR spectrum (in C_6D_6) showed a singlet at $\delta = -17.0$ ppm. The closely related ligand (*E*)-$(t\mathrm{Bu})_2P(CH_2)_2CH{=}CH(CH_2)_2P(t\mathrm{Bu})_2$ has also been reported previously.[18]



Scheme 1

Treatment of a benzene solution of $[OsClH_3(PPh_3)_3]$ with ligand **2** for 5 h produced $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]$ (**3**), which was isolated as a gray solid in ca. 79% yield. The structure of complex **3** could readily be assigned by its ^1H, $^{13}C\{^1H\}$, $^{31}P\{^1H\}$, and ^1H-^{31}P-COSY NMR spectra and by elemental analysis. The $^{31}P\{^1H\}$ NMR spectrum (in C_6D_6) showed three doublets of doublets at $\delta = -7.7$, 7.3, and 23.8 ppm. A large $^2J_{P,P}$ coupling (290.6 Hz) for the ^{31}P signals at $\delta = 7.3$ and 23.8 ppm was observed, indicating that two of the phosphorus atoms in **3** were *trans* to each other. A ^1H-^{31}P-COSY NMR experiment suggested that the two *trans*-disposed phosphorus atoms were associated with the two PPh_2 groups of ligand **2**. In the ^1H NMR spectrum (in C_6D_6), the olefinic proton signals appeared at $\delta = 3.88$ ppm, significantly upfield from their counterparts in free ligand **2**, confirming that the olefin double bond was coordinated to the osmium center. Complex **3** exhibited a hydride signal at $\delta = -16.40$ ppm (dt, $^2J_{P,H} = 27.0$, 15.0 Hz). The magnitude of the coupling constants indicated that the hydride ligand was *cis* to the three phosphorus atoms. The chemical shift of the hydride signal was quite strongly upfield, consistently with a structure in which the hydride ligand is *trans* to a chloride ligand. During the course of this work, the closely related complex $[OsClH(PPh_3)(Ph_2P{-}C_6H_3Me{-}CH{=}CH{-}C_6H_3Me{-}PPh_2)]$ was reported.[19]

Synthesis and Characterization of $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$

Protonation of complex **3** with HOTf produced the dihydrogen(olefin) complex $[OsCl(H_2)(PPh_3)(Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2)]OTf$ (**4**). Complex **4** was unstable and decomposed under vacuum. The compound could therefore not be isolated as a pure solid, so it was characterized in situ. The $^{31}P\{^1H\}$ NMR spectrum of complex **4** (in CD_2Cl_2) exhibited the PPh_3 signal at $\delta = -8.9$ ppm and the PPh_2 signals at $\delta = 14.2$ and 16.8 ppm. The ^{31}P signals of the PPh_2 groups at $\delta = 14.2$ and 16.8 ppm had a large $^2J_{P,P}$ coupling constant (243.6 Hz), indicating that the PPh_2 groups were *trans* to each other in **4**. The ^1H NMR spectrum (in CD_2Cl_2) exhibited a broad signal attributable to a dihydrogen ligand at $\delta = -9.57$ ppm. The broad hydride signal had a T_1 (min) of 27.0 ms (at 300 MHz) at 258 K. The short T_1 (min) value strongly suggested that complex **4** contained a dihydrogen ligand. Further support for the existence of the dihydrogen ligand in **4** was provided by the ^1H NMR spectrum of the HD isotopomer $[OsCl(HD)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]^+$, which was generated in situ by protonation of complex **3** with DOTf. The ^1H NMR spectrum of the HD isotopomer (in CD_2Cl_2) displayed the HD signal as a 1:1:1 triplet at $\delta = -9.58$ ppm, with a $^1J(HD)$ coupling constant of 14.1 Hz. A $d(HH)$ of 1.18 Å was obtained by application of the relationship $d(HH) = -0.0167J(HD) + 1.42$ and $^1J(HD) = 14.1$ Hz.[15a] On the basis of the T_1 (min) of 27 ms, the H−H bond length was calculated to be 1.13 Å for a nonspinning H_2 or 0.98 Å for a spinning dihydrogen ligand.[20]

Treatment of $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$ with H_2

We tried to hydrogenate the coordinated olefin double bond in **4** by storing a solution of **4** in CD_2Cl_2 under H_2. However, the expected hydrogenated product $[OsClH_x(PPh_3)\{Ph_2P(CH_2)_6PPh_2\}]^+$ was apparently not produced from the reaction, as indicated by in situ NMR studies. Instead, the fluxional (hydrido)dihydrogen complex $[OsH(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]OTf$ (**5**) was slowly produced under these reaction conditions. A molecule of HCl in **4** was thus apparently replaced by a H_2 molecule in the reaction. Mechanistically, complex **5** could be formed by initial displacement of Cl^- in **4** with an H_2 molecule to give the dicationic dihydrogen complex $[Os(H_2)_2(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]^{2+}$, followed by deprotonation.

The presence of a coordinated CH=CH moiety in **5** was supported by the ^{13}C NMR spectrum (in CD_2Cl_2), which displayed the coordinated olefinic CH carbon signals at $\delta = 56.9$ and 65.7 ppm. The $^{31}P\{^1H\}$ NMR spectrum (in CD_2Cl_2) at 230 K showed the PPh_3 signal at $\delta = 4.0$ ppm

and the PPh_2 signals at δ = 29.1 and 36.5 ppm. The two PPh_2 groups in **5** had to be *trans* to each other for the large $^2J_{P,P}$ coupling constant (201.7 Hz) observed for the PPh_2 signals at δ = 29.1 and 36.5 ppm. In the room-temperature ^1H NMR spectrum (in CD_2Cl_2), a broad hydride signal was observed at δ = −5.30 ppm. When the temperature was below 275 K, the hydride signal was split into two with a relative intensity ratio of 1:2. For example, the ^1H NMR spectrum at 230 K showed a doublet of triplets at δ = −6.70 ppm ($^2J_{P,H}$ = 33.0, 19.5 Hz) and a broad singlet at δ = −4.74 ppm, corresponding to one and two hydrogen atoms, respectively. T_1 measurements showed that the broad hydride signal at δ = −4.74 ppm had a T_1 (min) of 10.1 ms (on 300 MHz) at 232 K. The short T_1 (min) value strongly suggested that complex **5** contained a dihydrogen ligand. Furthermore, a partially deuterated sample of $[OsD_{3-x}H_x(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]^+$ (in CD_2Cl_2 at 235 K) showed a 1:1:1 triplet at δ = −4.69 ppm with a ^1J(HD) coupling constant of 26.7 Hz. The *d*(HH) value in **5** was estimated to be 0.97 Å by application of the relationship *d*(HH) = −0.0167 *J*(HD) + 1.42 and ^1J(HD) = 26.7 Hz.[15a] On the basis of the T_1 (min) of 10.1 ms, the H−H bond length was calculated to be 1.04 Å for a nonspinning H_2 or 0.83 Å for a spinning H_2 ligand.[20] The H−H distance in the (hydrido)dihydrogen complex **5** was shorter than that in the (chloro)dihydrogen complex **4**; a similar trend has been observed for $[MX(H_2)(dppe)_2]^+$ (M = Ru, Os; X = H, Cl).[15a]

Deprotonation of complex **5** with NEt_3 produced the neutral dihydride complex *trans*-$[OsH_2(PPh_3)\{Ph_2P(CH_2)_2CH{=}CH(CH_2)_2PPh_2\}]$ (**6**), which could also be obtained by treatment of complex **3** with $NaBH_4$. Complex **5** was regenerated when **6** was treated with HOTf. The geometry of complex **6** could readily be assigned from its NMR spectroscopic data. In particular, the ^1H NMR spectrum (in CD_2Cl_2) displayed only one hydride signal at δ = −9.13 ppm, indicating that the molecule had high symmetry. Consistently with the structure, the $^{31}P\{^1H\}$ NMR spectrum (in CD_2Cl_2) showed a doublet at δ = 41.2 ppm for the PPh_2 groups and a triplet at δ = 17.6 ppm for the PPh_3 ligand; the $^{13}C\{^1H\}$ NMR showed the coordinated olefinic CH carbon signal at δ = 37.6 ppm.

Structural Study Using Quantum Chemical Calculations

To obtain a better understanding of the interesting chemistry described above, we calculated the structures of complexes $[OsClH(PH_3)\{H_2P(CH_2)_2CH{=}CH(CH_2)_2PH_2\}]$ (**3′**), $[OsCl(H_2)(PH_3)\{H_2P(CH_2)_2CH{=}CH(CH_2)_2PH_2\}]^+$ (**4′**), and $[OsH(H_2)(PH_3)\{H_2P(CH_2)_2CH{=}CH(CH_2)_2PH_2\}]^+$ (**5′**), by the density functional theory B3LYP technique. The calculated structures of complexes **3′**, **4′**, and **5′** should provide enlightening geometric information regarding complexes **3**, **4**, and **5**. We also calculated the structure of $[OsCl(H_2)(PH_3)\{H_2P(CH_2)_6PH_2\}]^+$ (**7′**), a model complex for a hydrogenated product of complex **4**. The optimized structures are shown in Figure 1. Complex **3′** is a typical hydrido(olefin) complex with strong Os−olefin interaction. The protonated species **4′** is confirmed to be a dihydrogen complex. The H−H distance in the dihydrogen complex is calculated to be 1.011 Å, which is close to the experimentally predicted value in **4** based on the ^1J(HD) coupling constant and T_1 (min) value. In a similar manner to complex **4′**, complex **5′** is another dihydrogen(olefin) species. In **5′**, the H−H distance is significantly shorter (0.853 Å), due to the presence of the strongly *trans*-influencing hydride ligand, which gives weaker Os−H_2 interaction.

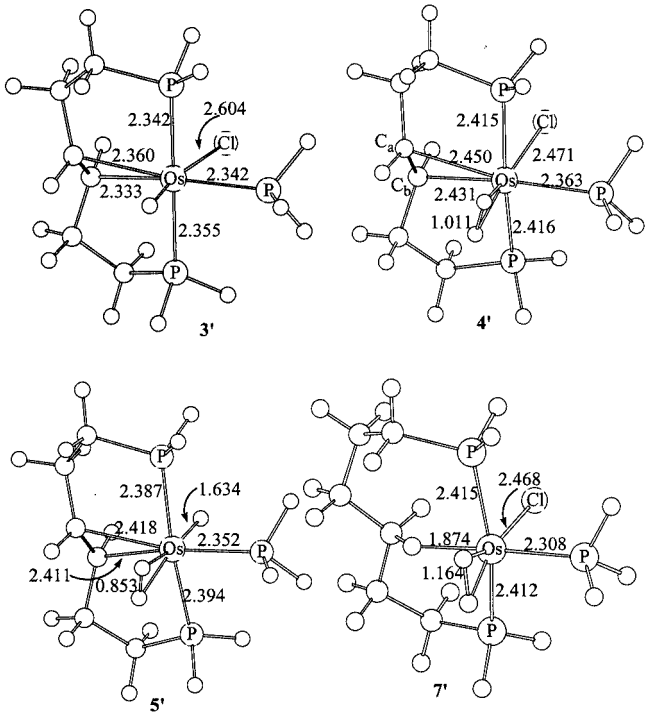


Figure 1. Optimized structures together with selected bond lengths [Å]

Experimentally, it is interesting that under H_2 the coordinated η^2-H_2 did not hydrogenate the olefin unit. The calculated free energy change (ΔG^0) for the process of **4′** + H_2 → **7′** (see Figure 1 for **7′**, the hydrogenated product featuring an agostic interaction) is ca. −1.0 kcal/mol. This result suggests that the hydrogenation is thermodynamically feasible, and we therefore feel that kinetic factors are probably responsible for the hydrogenation not occurring. Careful examination of the structure of complex **4′** (Figure 1) allows one to see that the orientation of the coordinated −HC=CH− unit is in such a manner that one olefinic carbon atom (C_a) is closer to the η^2-H_2 ligand while the other is further away. The hydrogenation of a coordinated olefin by an η^2-H_2 unit can occur through the formation of an agostic intermediate by transfer of one hydrogen atom of the H_2 ligand to one of the two olefinic carbon atoms. A reductive elimination then follows, to complete the hydrogenation process. If the transfer of one H atom from the η^2-H_2 ligand to the closer olefinic carbon atom (C_a) in **4′** is regarded as the first step, it is found that the assumed agostic species does not correspond to a stationary point in the potential energy surface. An agostic structure can be calculated (optimized) by fixing the C_a−H bond length at 1.20 Å.

However, the partially optimized structure is 20 kcal/mol higher in energy than complex **4′** and adopts a pseudopentagonal-bipyramidal (PB) structure in which the equatorial plane is formed by one hydride ligand, the chloride ion, the PH_3 molecule, the C_a-H agostic ligand, and the bonded C_b alkyl moiety. In the PB structure, the hydride ligand and the bonded C_b alkyl moiety are separated by the C_a-H agostic ligand. In such a ligand arrangement, reductive elimination starting from the high-energy partially optimized structure is difficult. Considering the PB structure, one might also take account of the possibility of pushing the C_a-H agostic ligand away and then binding an additional H_2 molecule so that reductive elimination becomes possible. Calculations showed that such a structure was again not a stationary point and had an even higher energy, due to the crowded ligand environment. When the transfer of one H atom from the η^2-H_2 ligand to the further olefinic carbon atom (C_b) was considered as the first step, we found that the activation energy (50 kcal/mol) was too high for such a transfer under the given reaction conditions. The high activation energy for such a process was not surprising, because of the geometric separation of the H and the C_b atoms. A concerted process in which both hydrogen atoms in the η^2-H_2 ligand would transfer simultaneously to the two olefinic carbon atoms seemed unlikely on the basis of our previous calculations on related systems.[21]

Conclusion

The dihydrogen(olefin) complex $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ has been prepared and characterized by NMR spectroscopy. Treatment of $[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ with H_2 produced the (hydrido)dihydrogen complex $[OsH(H_2)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ rather than the hydrogenated products. A computational study suggested that the hydrogenation was thermodynamically feasible but kinetically unfavorable. This work provides rare examples of dihydrogen(olefin) complexes that are characterizable by NMR spectroscopy.

Experimental Section

General: All manipulations were carried out at room temperature under nitrogen by standard Schlenk techniques unless otherwise stated. Solvents were distilled under nitrogen from sodium/benzophenone (hexane, diethyl ether, THF, benzene) or calcium hydride (dichloromethane, $CHCl_3$). The starting materials $Br(CH_2)_2CH=CH(CH_2)_2Br$[22] and $[OsClH_3(PPh_3)_3]$[23] were prepared by literature methods. Microanalyses were performed by M-H-W Laboratories (Phoenix, AZ). ^1H, $^{13}C\{^1H\}$, and $^{31}P\{^1H\}$ NMR spectra were measured with a Bruker ARX 300 spectrometer (300 MHz). ^1H and ^{13}C NMR chemical shifts are relative to TMS, and ^{31}P NMR chemical shifts are relative to 85% H_3PO_4.

(*E*)-$Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2$ (2): A THF solution of $KPPh_2$ (50 mL, 0.50 M, 25 mmol) was added slowly to a solution of (*E*)-$Br(CH_2)_2CH=CH(CH_2)_2Br$ (3.00 g, 12.4 mmol) in 30 mL of THF. The reaction mixture was stirred at room temperature for 3 h. A deep red solid was obtained after the solvent had been removed. Addition of water (10 mL) and methanol (40 mL) to the reaction mixture gave a pale yellow solid. The solid was collected on a filter frit, washed with MeOH/H_2O (4:1, 6 × 50 mL) and MeOH (4 × 40 mL), and dried under vacuum. Yield, 4.2 g, 76%. ^1H NMR (300.13 MHz, C_6D_6): δ = 2.03−2.08 (m, 4 H, $CH_2CH_2PPh_2$), 2.14−2.24 (m, 4 H, CH_2PPh_2), 5.38−5.41 (m, 2 H, *H*C=C*H*), 7.12−7.52 ppm (m, 20 H, Ph). $^{31}P\{^1H\}$ NMR (121.5 MHz, C_6D_6): δ = −17.0 ppm (s, PPh_2). $^{13}C\{^1H\}$ NMR (75.48 MHz, C_6D_6): δ = 28.0 (d, $J_{P,C}$ = 12.8 Hz, $CH_2CH_2PPh_2$), 28.9 (d, $J_{P,C}$ = 17.7 Hz, $CH_2CH_2PPh_2$), 128.1 (s, *p*-Ph), 128.2 (d, $J_{P,C}$ = 6.2 Hz, *m*-Ph), 130.2 (d, $J_{P,C}$ = 13.3 Hz, =CH), 132.6 (d, $J_{P,C}$ = 18.6 Hz, *o*-Ph), 139.2 ppm (d, $J_{P,C}$ = 14.6 Hz, *ipso*-Ph). $C_{30}H_{30}P_2$ (452.52): calcd. C 79.63, H 6.68; found C 79.72, H 6.56.

$[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (3): A mixture of $[OsClH_3(PPh_3)_3]$ (1.37 g, 1.35 mmol) and (*E*)-$Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2$ (0.71 g, 1.6 mmol) in benzene (110 mL) was stirred for 5 h. The volume of the reaction mixture was reduced to ca. 7 mL under vacuum. A gray solid was formed when hexane (60 mL) was added. The solid was collected by filtration, washed with hexane (3 × 15 mL), and dried under vacuum. Yield: 1.0 g, 79%. ^1H NMR (300.13 MHz, C_6D_6): δ = −16.40 (dt, $J_{P,H}$ = 27.0, 15.0 Hz 1 H, Os−*H*), 1.96−3.88 [m, 10 H, $Ph_2PCH_2)_2CH=CH(CH_2)_2PPh_2$], 6.87−8.55 ppm (m, 35 H, Ph). $^{31}P\{^1H\}$ NMR (121.50 MHz, C_6D_6): δ = −7.7 (dd, $J_{P,P}$ = 15.0, 14.2 Hz PPh_3), 7.3 (dd, $J_{P,P}$ = 290.6, 15.0 Hz, PPh_2), 23.8 ppm (dd, $J_{P,P}$ = 290.6, 14.2 Hz, PPh_2). $^{13}C\{^1H\}$ NMR (75.48 MHz, C_6D_6): δ = 28.1−33.5 (m, $CH_2CH_2PPh_2$), 56.4 (m, H*C*=), 56.7 (d, $J_{P,C}$ = 21.9 Hz, =*C*H), 126.8−143.0 ppm (m, Ph). $C_{48}H_{46}ClP_3Os$ (941.47): calcd. C 61.24, H 4.93; found C 61.06, H 5.13.

$[OsCl(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ (4): Because of its low stability, the compound was not isolated but was characterized in situ. HOTf (5 μL, 0.06 mmol) was added to a CD_2Cl_2 solution (0.5 mL) containing $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (20 mg, 0.021 mmol) in an NMR tube. ^1H, ^{13}C, and ^{31}P NMR spectra were measured immediately. ^1H NMR (300.13 MHz, CD_2Cl_2): δ = −9.57 (br, Os−H_2), 2.15−3.10 (m, 8 H, $CH_2CH_2PPh_2$), 4.77 (br, 1 H, *H*C=), 5.58 (br, 1 H, =C*H*), 6.86−7.82 ppm (m, 35 H, Ph). $^{31}P\{^1H\}$ NMR (121.50 MHz, CD_2Cl_2): δ = −8.9 (dd, $J_{P,P}$ = 14.1, 15.5 Hz, PPh_3), 14.2 (dd, $J_{P,P}$ = 243.6, 15.5 Hz, PPh_2), 16.8 ppm (dd, $J_{P,P}$ = 243.6, 14.1 Hz, PPh_2). $^{13}C\{^1H\}$ NMR (75.48 MHz, CD_2Cl_2): δ = 28.6−37.4 (m, $CH_2CH_2PPh_2$), 89.0 (br, H*C*=), 96.0 (br, =*C*H), 118.8−137.2 ppm (m, Ph). T_1 [ms] of Os(H_2) (300 MHz, CD_2Cl_2) (temperature) = 35.2 (298 K), 31.3 (273 K), 29.1 (263 K), 27.0 (258 K), 27.5 (253 K), 29.5 (243 K), 32.5 (233 K).

$[OsCl(HD)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ ($[D_1]$-4): The compound was prepared similarly, except that DOTf was used instead of HOTf. The η^2-HD signal was observed after cancellation of the η^2-H_2 peak at δ = −9.57 ppm by the inversion-recovery method. ^1H NMR (300.13 MHz, CD_2Cl_2): δ = −9.58 ppm [1:1:1 triplet, J(HD) = 14.1 Hz, Os(HD)].

Characterization of $[OsH(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]OTf$ (5): Because of its low stability, this compound was not isolated but was characterized in situ. **Method A:** HOTf (5 μL, 0.06 mmol) was added to a CD_2Cl_2 solution (0.5 mL) containing $[OsH_2(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (20 mg, 0.020 mmol) in an NMR tube. NMR spectra were then measured immediately. **Method B:** A CD_2Cl_2 solution (0.5 mL) containing $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (20 mg,

0.021 mmol) and TlOTf (20 mg, 0.057 mmol) in an NMR tube was stored under H_2 for 5 h. ^1H, ^{13}C, and ^{31}P NMR spectra were then measured. **Method C:** A CD_2Cl_2 solution of **4** was stored under H_2 for 18 h, and ^1H and $^{31}P\{^1H\}$ NMR spectra were then measured. ^1H NMR (300.13 MHz, CD_2Cl_2, 230 K): δ = −6.70 (dt, $J_{P,H}$ = 33.0, 19.5 Hz, 1 H, Os−*H*), −4.74 (br, 2 H, OsH_2), 1.60−3.80 [m, 10 H, $Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2$], 6.86−7.70 ppm (m, 35 H, Ph). ^1H NMR (300.13 MHz, CD_2Cl_2, 298 K): δ = −5.30 (br, 3 H, Os−*H*, Os−H_2), 1.60−3.80 [m, 12 H, $Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2$], 6.86−7.64 ppm (m, 35 H, Ph). $^{31}P\{^1H\}$ NMR (121.50 MHz, CD_2Cl_2, 230 K): δ = 4.0 (dd, $J_{P,P}$ = 11.0, 12.8 Hz, PPh_3), 29.1 (dd, $J_{P,P}$ = 201.7, 12.8 Hz, PPh_2), 36.5 ppm (dd, $J_{P,P}$ = 201.7, 11.0 Hz, PPh_2). $^{31}P\{^1H\}$ NMR (121.50 MHz, CD_2Cl_2, 298 K): δ = 4.4 (dd, $J_{P,P}$ = 12.4, 12.5 Hz, PPh_3), 29.8 (br. d $J_{P,P}$ = 181.5 Hz, PPh_2), 36.2 ppm (br. d, $J_{P,P}$ = 181.5 Hz, PPh_2). $^{13}C\{^1H\}$ NMR (75.48 MHz, CD_2Cl_2, 233 K): δ = 28.6−35.1 (m, CH_2CH_2P), 56.9 (br, H*C*=), 65.7 (br, =*C*H), 128.2−138.8 ppm (m, Ph). T_1 [ms] (300 MHz, CD_2Cl_2) (temperature): δ = −4.80: 13.8 (272 K), 12.2 (252 K), 10.1 (232 K), 14.2 (213 K); δ = −6.58: 14.9 (272 K), 65.16 (252 K), 204.9 (232 K), 301.5 (213 K).

$[OsD_{3-x}H_x(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]BF_4$: CD_3OD (0.05 mL) was added to a solution of $[OsH(H_2)(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]BF_4$ in CD_2Cl_2, prepared by protonation of **6** (20 mg, 0.020 mmol) with $HBF_4{\cdot}Et_2O$ (5 μL, 0.04 mmol). The mixture was stored at room temperature for 2 h, and ^1H NMR spectrum was measured at 235 K. The η^2-HD signal was observed after cancellation of the η^2-H_2 peak at δ = −4.74 ppm by the inversion-recovery method. ^1H NMR (300.13 MHz, CD_2Cl_2, 235 K): δ = −4.69 ppm [1:1:1 triplet, J(HD) = 26.7 Hz, Os(HD)].

***trans*-$[OsH_2(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (6):** A mixture of $NaBH_4$ (0.20 g, 5.3 mmol) and $[OsClH(PPh_3)\{Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2\}]$ (0.50 g, 0.53 mmol) in 20 mL of ethanol was stirred at room temperature for 30 min. The solvent was removed under vacuum and the residue was extracted with benzene (20 mL). The volume of the extracted solution was reduced to ca 3 mL. A yellow solid was formed when hexane (40 mL) was added. The solid was collected by filtration, washed with hexane (3 × 15 mL), and dried under vacuum. Yield: 0.25 g, 52%. The complex was also produced when complex **5** was treated with NEt_3. ^1H NMR (300.13 MHz, CD_2Cl_2): δ = −9.13 (dt, $J_{P,H}$ = 29.7, 12.6 Hz, 2 H, Os−*H*), 1.80−2.74 [m, 10 H, $Ph_2P(CH_2)_2CH=CH(CH_2)_2PPh_2$], 6.74−7.80 ppm (m, 35 H, Ph). $^{31}P\{^1H\}$ NMR (121.50 MHz, CD_2Cl_2): δ = 17.6 (t, $J_{P,P}$ = 15.1 Hz, PPh_3), 41.2 ppm (d, $J_{P,P}$ = 15.0 Hz, PPh_2). ^{13}C NMR (75.48 MHz, CD_2Cl_2): δ = 30.4 (t, $J_{P,C}$ = 13.5 MHz, CH_2P), 34.2 (t, $J_{P,C}$ = 7.3 MHz, CH_2CH_2P), 37.6 (d, $J_{P,C}$ = 12.1 MHz, H*C*=), 126.8−143.1 ppm (m, Ph). $C_{48}H_{47}P_3Os{\cdot}3H_2O$ (961.06): calcd. C 59.99, H 5.56 (the water was probably from the solvents); found C 59.98, H 6.00.

Computational Details: In our calculations, the Ph group on the phosphorus ato was modeled by an H atom. Geometry optimizations and frequency calculations were carried out for all species involved in the reactions with the Gaussian 98 program[24] installed on Pentium III personal computers with Linux (Red Hat) operating systems. Molecular geometries of the model complexes were optimized at the Becke3LYP (B3LYP) level of density functional theory.[25] The LANL2DZ effective core potentials and basis sets[26] were used to describe Os, P, and Cl. Polarization functions [ξ(*d*) = 0.340][27] were added for P and [ξ(*d*) = 0.514][27] for Cl. Additionally, better to describe the electronic properties of both hydride and dihydrogen ligands, polarization functions with ξ(p) = 0.11[27] were also added to the standard basis set for H atoms of these two ligands. The standard 6−31G basis set was used for all other atoms.

Kinetics and Equilibria of Nickel(II)−Schiff Base Adducts Formation

Ivo Cacelli,[a] Laura Carbonaro,*[a] and Piero La Pegna[a]

Keywords: Kinetics / Nickel / Schiff base / Adducts / Substituent effects

The interactions between Ni^{II} cations and bidentate Schiff base ligands, *N*-alkyl-5-X-salicylaldimine HL (X = H; R = Et, *n*Pr, *t*Bu; X = Cl, OMe, NO_2; R = *n*Pr), and bis(*N*-*n*-alkyl-5-X-salicylaldiminato)nickel(II) complexes [NiL_2] (X = H; R = Et, *n*Pr, *n*Bu; X = Cl, OMe, Me; R = *n*Pr) were investigated by UV/Vis spectrophotometry in acetonitrile. The kinetics for the formation of Ni^{II}/HL 1:1 adducts was studied by stopped-flow techniques, which showed that the process followed a two-consecutive mechanism. Experimental evidence and theoretical calculations indicated the formation of an unidentate intermediate in the first step, according to a dissociative interchange mechanism. Ring-closure occurs in the second step and its rate is slower for electron-withdrawing-substituted Schiff bases. Nickel(II) cations interact with [NiL_2] affording $[NiL]^+$ and $[Ni_2L_3]^+$ species; the associated equilibrium constants were found to be related to the electronic effects of the 5-X ligand substituents.

Introduction

Metal adducts of Schiff bases are an important class of compounds. Metal complexes [ML_2] of Schiff bases derived from salicylaldehyde can form adducts with different ions,[1,2] and even with DNA.[3] Examples of $MA_n{\cdot}mHL$ adducts (A = anion) between neutral HL Schiff base ligands and metal ions have also been reported.[4] The nature and the factors influencing the observed stoichiometries of individual adducts have been investigated mainly with regard to the steric hindrance of the imine group. In spite of the interest in these compounds, not much information is available on both the stability constants and the kinetics for the formation of these compounds. This is the first investigation of the mechanism for the formation of 1:1 Ni^{II}/HL adducts in acetonitrile, and of the equilibria between Ni^{II} cations and [NiL_2] complexes (HL = 5-X-salH-R) for various 5-X aromatic ring substituents and nitrogen-bound aliphatic chains R of the Schiff base ligand, see Scheme1.

The mechanism of solvent exchange and ligand substitution involving octahedral nickel(II) ions has been shown to be dissociative in character and generally to proceed by the fast formation of an outer-sphere complex followed by the loss of a solvent molecule in the rate-determining step,[5] see Equations (1a and b). Thus, the pseudo-first-order rate constant is generally expressed by Equation (2), where K_0 is the equilibrium constant for the formation of the outer-sphere complex, k_2 can be approximated to the rate constant for solvent exchange k_{ex}, and k_{-2} is the first-order rate constant for the reverse dissociation process.

$$Z{\cdots}Y + [NiS_6]^{2+} \overset{K_0}{\rightleftharpoons} [NiS_6{\cdot}Z{\cdots}Y]^{2+} \quad (1a)$$

$$[NiS_6{\cdot}Z{\cdots}Y]^{2+} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} [S_5Ni{-}Z{\cdots}Y]^{2+} + S \quad (1b)$$

$$[S_5Ni{-}Z{\cdots}Y]^{2+} \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} [S_4Ni\begin{matrix}Z\\|\\Y\end{matrix}]^{2+} + S \quad (1c) \qquad (1)$$

$$k_{obs} = k_f[Ni^{2+}] + k_d = K_0k_2[Ni^{2+}] + k_{-2} \qquad (2)$$

This mechanism can be extended to bidentate ligands by introducing an additional, usually fast, ring-closure step, see Equation (1c). It can be anticipated that bidentate 5-X-salH-R ligands give rise to ring-closure inhibition in the coordination reaction to nickel(II) cations, as they can form hydrogen bonds between their chelating sites, and may exist[6,7] in zwitterionic forms $HL^{\pm}$ in polar solvents (see Scheme 1). Differing from most of the kinetics studies reported in the literature on solvent substitution reactions by bidentate ligands, the steps according to Equations (1b and c) can be studied kinetically, and the substituent effects on the ring-closure step can be examined.

The interactions between [NiL′] tetradentate complexes (Scheme 1) and alkaline, alkaline-earth or Ni^{II} cations were previously studied by our group.[8] Adducts of stoichiometry 1:1 and/or 1:2 form in acetonitrile, see **1** and **2** of Scheme 2. Metal ions are coordinated by means of the O···O bite offered by the [NiL′] complex.

Solid-state examples of adducts formed between metal ions and bidentate [NiL_2] complexes (Scheme 1) are re-

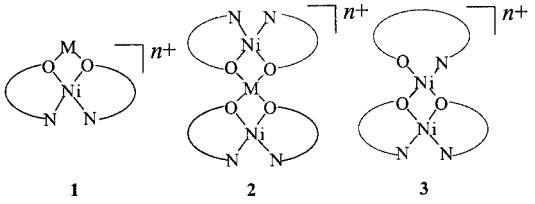

Scheme 2. Schematic representation of the interactions between tetradentate [NiL'] (N−N bridge is omitted) or bidentate $[NiL_2]$ complexes with different ions (M = alkali, alkaline earth or Ni^{II} ions; n = 1 or 2)

stricted to a few cases.[8] In solution *trans*-planar $[NiL_2]$ complexes are in equilibrium with their tetrahedral isomers when R is a bulky substituent.[9] The formation of adducts with metal ions may induce a *cis* geometry having an oxygen bite similar to that of tetradentate complexes. It has been confirmed[10,11] that 1:1 adducts are formed with Na^+ and Ba^{2+}, and 2:1 adducts with Ba^{2+} (**1** and **2** of Scheme 2) in the solid state, as well as in solution when R = H and a second pendant arm is *ortho* to the phenolato oxygen atom. From the present study it appears that $[NiL_2]$ complexes with R = alkyl group and *para* aromatic-ring substituents, may exhibit a different behaviour in the presence of Ni^{II} cations.

Results and Discussion

Reaction between HL = 5-X-salH-R and Ni^{II} Cations

The equilibrium between solvated octahedral nickel(II) and 5-X-salH-R Schiff bases for R = Et, X = H was studied in an acetonitrile solution. The spectrophotometric data were consistent with the formation of a 1:1 Ni^{II}/ligand adduct at high Ni^{II}/ligand molar ratios. A value of $\log K$ = 2.3 ± 0.01 was determined for the apparent equilibrium constant for the formation of the adduct.[12] Values of $\log K$ = 1.21 ± 0.02 and $\log K$ = 1.98 ± 0.03 were found for the formation of 1:1 adducts with Ba^{2+} and Sr^{2+}, respectively. On the basis of these findings and of the kinetic results (see below), only a 1:1 Ni^{II}/ligand product was assumed to form at the concentrations used in the kinetic measurements.

UV/Vis spectra recorded during the reaction of Ni^{II} cations with 5-X-salH-R Schiff bases (X = H, R = Et, *n*Bu; X = H, Cl, OMe, R = *n*Pr) showed different isosbestic points for the initial and final spectra, see Figure 1. At the initial reaction times a band at about 400 nm appears, while the final spectrum exhibits a maximum in the 360−370 nm range, depending on the 5-X substituent.

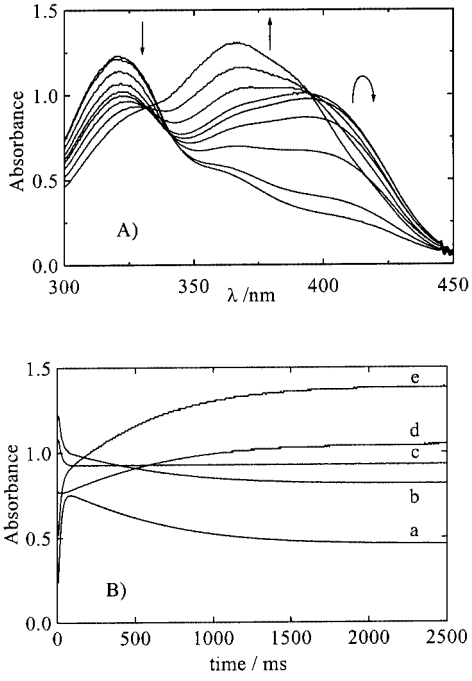

Figure 1. Spectral changes A) and kinetic traces B) at different wavelengths recorded for the reaction of 5-MeO-salH-*n*Pr (3×10^{-4} M) and nickel cations ($[Ni(CH_3CN)_6(ClO_4)_2] = 3.3 \times 10^{-2}$ M) in acetonitrile within 2500 ms at 25.0 °C (optical path = 1 cm); A) following the arrows, the spectra were recorded at 5, 10, 25, 50, 100, 250, 500, 1000, 2500 ms after mixing the reactants; B) λ = a) 416 nm, b) 332 nm, c) 322 nm, d) 394 nm, e) 366 nm

The kinetic traces could be fitted to the two-exponential Equation (10) (Exp. Sect.), which is characteristic of a two-consecutive step reaction.[13] The sum and the product of the exponential constants λ_1 and λ_2 were found to be linearly dependent on the nickel(II) concentration, Figures 2 and 3 (Figures 1*i* and 2*i*, Supporting Information). These kinetic results are in agreement with Equation (1): in the first step [Equation (1b)] the Schiff base replaces one solvent ligand leading to a mono-chelating complex; in the second step [Equation (1c)] ring closure occurs. Assuming $K_0[Ni^{2+}] << 1$, the rate constants of Equation (1) can be calculated from the slopes and the intercepts of Equations (3) and (4) (see Table 1).

$$\lambda_1 + \lambda_2 = k_f[Ni^{2+}] + (k_{-2} + k_3 + k_{-3}) \quad (3)$$

$$\lambda_1\lambda_2 = k_f(k_3 + k_{-3})[Ni^{2+}] + k_{-2}k_{-3} \quad (4)$$

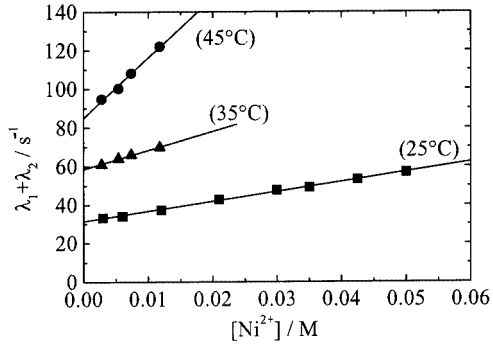

Figure 2. Plots of $\lambda_1 + \lambda_2$ [Equations (3) and (10)] against [Ni^{2+}] for the reaction between 5-H-salH-*n*Pr (ca. 10^{-4} M) and nickel(II) cations in acetonitrile at three different temperatures

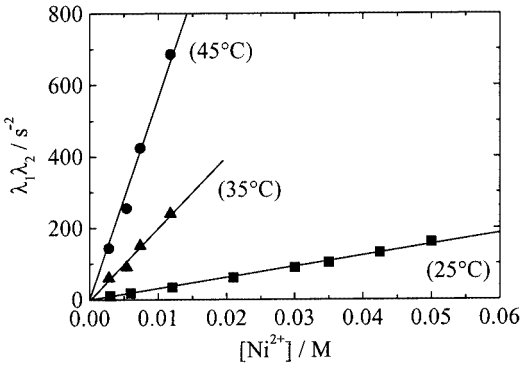

Figure 3. Plots of $\lambda_1\lambda_2$ [Equations (4) and (10)], against [Ni^{2+}] for the reaction between 5-H-salH-*n*Pr (ca. 10^{-4} M) and nickel(II) cations in acetonitrile at three different temperatures

As expected for a dissociative mechanism, the k_f rate constants were only slightly dependent on the substituent 5-X, and are close to those found for other uncharged monodentate ligands, e.g. pyridine[14] (k_f = 830 $M^{-1}s^{-1}$) and isoquinoline[15] (k_f = 709 m^{-1} s^{-1}).

The equilibrium constants K_0 for the outer-sphere complex formation were calculated from the measured k_f values as $k_f = fK_0k_{ex}$, where $k_{ex} = 3.1 \times 10^3$ s^{-1} is the rate constant of acetonitrile exchange[16] between the nickel(II) cations and the bulk solvent, and f = 3/4 is a statistical factor taking into account the number of solvent molecules in the outer-sphere complex competing with the entering ligand.[17] The theoretical K_0 values derived from the electrostatic theory, see Table 2, as well as from theoretical calculations, vide infra, were in excellent agreement.

Table 2. Calculated dipole moments of HL= 5-X-salH-R ligands, interaction energies, and theoretical and experimental equilibrium constants related to the formation of the outer-sphere complex between Ni^{II} cations and Schiff bases [Equation (1a)]

X	R	μ/Debye[a]	U[b]/kJ mol^{-1}	K_0 [c]/M^{-1}	K_0 [d]/M^{-1}
H	Et	2.44	−0.679	0.21	0.24
H	*n*Pr	2.89	−0.760	0.22	0.22
H	*t*Bu	3.63	−0.735	0.22	0.12
Cl	*n*Pr	3.31	−0.463	0.20	0.22
O_2N	*n*Pr	5.45	−0.642	0.21	0.18
MeO	*n*Pr	3.56	−0.774	0.22	0.19

[a] Dipole moment of the ligand (see text). [b] Interaction electrostatic energy between the dipole of the ligand and the charge of the nickel(II) cation. See Equation (15). [c] Theoretical K_0 values calculated by Equations (14) to (16). [d] Experimental K_0 values calculated from the ratio k_f/fk_{ex} (the values of k_f are from Table 1).

For the reaction of 5-H-salH-*n*Pr with Ni^{II} cations (Table 1), the activation parameters were $\Delta H^{\neq}$ = 34.7 ± 1.7 kJ mol^{-1} and $\Delta S^{\neq}$ = −100.4 ± 4.2 J mol^{-1} K^{-1} for k_{-2}, and $\Delta H^{\neq}$ = 71.1 ± 4.2 kJ mol^{-1}, $\Delta S^{\neq}$ = 38.5 ± 3.3 J mol^{-1} K^{-1} for k_f. The latter values compare quite satisfactorily with the activation parameters reported for solvent exchange:[17] $\Delta H^{\neq}$ = 60.8 ± 1.1 kJ mol^{-1} and $\Delta S^{\neq}$ = 25.8 J ± 2.8 J mol^{-1} K^{-1}, thus confirming a dissociative mechanism.

For X = NO_2 two well-distinct pseudo-first-order steps were confirmed. The pseudo-first-order kinetic rate constant for the first step is linearly dependent on the nickel(II) concentration, see Equation (2). For the second step, by neglecting k_{-3} and with $K_2 = k_2/k_{-2}$, Equation (5) was applied along with Equation (1). Thus the rate constants for Equation (1b) and Equation (1c) could be determined, see

Table 1. Rate constants (errors expressed as standard deviations) for the formation of 1:1 adducts between Ni^{II} cations and Schiff bases HL = 5-X-salH-R, see Equation (1)

X	R	T/°C	k_f/M^{-1} s^{-1}	k_{-2}/s^{-1}	k_3/s^{-1}	k_{-3}/s^{-1}	ΔpK_a[a]

H	*t*Bu	35.0	(7.7 ± 0.6) × 10^2 [e]	19.3 ± 0.5[e]			
H	*t*Bu	45.0	(19.5 ± 0.7) × 10^2 [e]	31.8 ± 0.6[e]			

[a] $\Delta pK_a = (pK_{OH} - pK_{NH^+})$, difference between the pK_a of *p*-X-phenols[18] and *m*-X-benzylammonium[19] in water at 25 °C. [b] Calculated by Equations (10), (3) and (4). [c] Calculated according to Equations (9), (2) and (5). [d] The value of k_{-3} was neglected within the experimental error. [e] Calculated by Equations (9) and (2).

Figure 4 and Table 1, and their values confirmed the previous assumptions made on Equations (3) and (4) for the other ligands.

$$1/k_{obs(2)} = 1/(K_0K_2k_3[Ni^{2+}]) + 1/k_3 \quad (5)$$

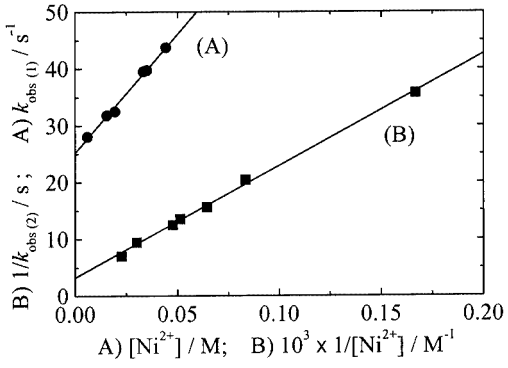

Figure 4. Plot of (A) $k_{obs(1)}$ against [Ni^{2+}] for the first reaction step [Equation (1b)] according to Equations (2) and (9), and plot of (B) $1/k_{obs(2)}$ against 1/[Ni^{2+}] for the second reaction step [Equation (1c)] according to Equations (5) and (9), for the reaction between 5-NO_2-salH-*n*Pr (ca. 10^{-4} M) and nickel(II) cations in acetonitrile at 25.0 °C

For X = H, R = *t*Bu, only one rate-determining step was seen, the final spectrum exhibits a maximum at about 390 nm. The observed pseudo-first-order rate constant depends linearly on the Ni^{II} concentration (see Figure 5) and, according to Equation (2), it could be related to the formation of the unidentate complex. The values of k_f and k_{-2} at different temperatures (Table 1) are slightly smaller than the rate constants quoted for the other ligands examined. The activation parameters, $\Delta H^{\neq}$ = 75.3 ± 1.2 kJ mol^{-1} and $\Delta S^{\neq}$ = 54.4 ± 4.2 J mol^{-1} K^{-1} for k_f and $\Delta H^{\neq}$ = 34.3 ± 2.1 kJ mol^{-1} and $\Delta S^{\neq}$ = −108.8 ± 8.4 J mol^{-1} K^{-1} for k_{-2}, are close to those found for the 5-H-salH-*n*Pr ligand. Ring closure for R = *t*Bu might be insignificant due to steric hindrance.

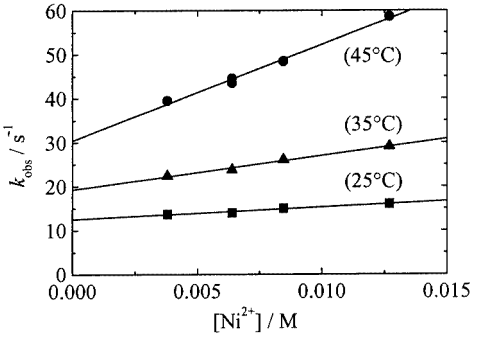

Figure 5. Plot of k_{obs} [Equations (2) and (9)] against [Ni^{2+}] for the reaction between 5-H-salH-*t*Bu (ca. 10^{-4} M) and nickel(II) cations in acetonitrile at three different temperatures

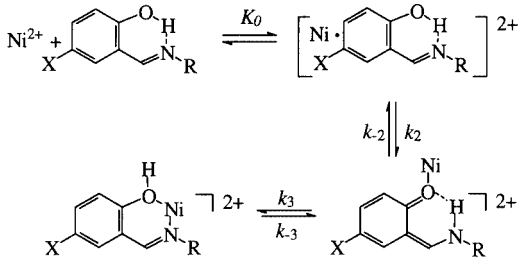
From Table 1, the rate constant k_3 for the ring-closure step depends on the substituents 5-X and increases with increasing electron-donor properties of 5-X. A linear relationship was found (slope = 0.58; correlation coefficient r = 0.999) when logk_3 is plotted vs. ΔpK_a ($\Delta pK_a = pK_{OH} - pK_{NH^+}$, where pK_{OH} [18] and pK_{NH^+} [19] are the pK_a values in water of the *p*-substituted phenols and of the *m*-substituted benzylammonium ions related to the 5-X-salH-R ligand, respectively). The positive slope suggests that migration of hydrogen from nitrogen to oxygen occurs in the ring-closure step. This agrees with a quinonic structure for the unidentate intermediate, rather than an enolic structure. The band at about 400 nm identified in the early stages of the reaction, which is characteristic[20] of the quinonic form of the ligand, confirms this proposal. Nickel(II) may be coordinated to the oxygen or the nitrogen atom of the quinonic form of the ligand, while an NH···O or N···HO intramolecular hydrogen bond is retained, respectively. Both these structures have been documented for some $MA_n \cdot mHL$ (A = anion)[4] Schiff base adducts similar to the present ones. Theoretical calculations on 5-X-salH-R ligands indicated that Ni^{II} coordination to oxygen is favoured (vide infra). A plausible mechanism for the formation of 5-X-salH-R adducts with Ni^{II} cations is depicted in Scheme 3, where solvent molecules are omitted for clarity. It is worth noting that for X = NO_2, a strong resonance stabilisation of the quinonic intermediate may account for the significantly smaller k_3 value than that observed for the other ligands.



Scheme 3

Theoretical Results

The quantum-mechanical geometry optimisation shows that all the free ligands have a virtually planar geometry and that the O−H and N−H distances are 0.99 Å and 1.75−1.77 Å, respectively. These are consistent with the enolic form of HL, see Scheme 1. The computed dipole moments for the 5-X-salH-R ligands are reported in Table 2.

The most favourable arrangements for the Ni^{II}/HL outer-sphere complexes are depicted in Figure 6. In all cases the centre of the cation sphere (R = 4 Å) almost lies on the plane of the aromatic ring.

When X is an electron-donating group, the dipole moment is roughly parallel to the (HO)C−C(CH=NR) bond and the cation sphere approaches the molecule toward the oxygen atom. When X = Cl, and more so when X = NO_2, the dipole moment is rotated toward the R group and the most favourable position of the cation moves toward the aromatic ring.

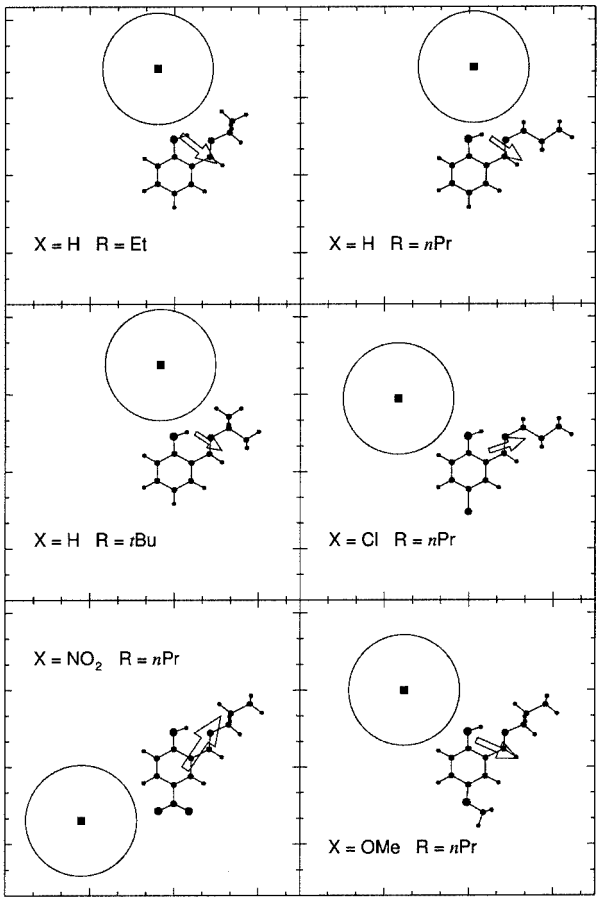


Figure 6. Schematic representation of the 5-X-salH-R/Ni^{II} outer-sphere complexes as determined by theoretical calculations; the distance between two nearest ticks of both axes is 2 Å; the molecular geometry is projected on the aromatic plane; the length of the arrow on the ligand is proportional to the dipole moment vector and indicates its position as specified in the text

When using Equations (6) and (7), a good agreement between the experimental and theoretical K_0 values (Table 2) was found. The overestimation of the theoretical K_0 value for X = H, R = *t*Bu may be of significance. The R groups are far away from the sphere of the Ni^{II} ion; nevertheless, the formation of a tighter inner-sphere complex requires the steric hindrance, that arises as a result of R, to be reduced by assuming a more favourable conformation. This cannot be achieved for R = *t*Bu.

$$K_0 = \frac{4\pi}{3000} Na^3 \times \exp(-U/k_B T) \quad (6)$$

$$U = -\frac{\mu Q \cos\alpha}{Dd^2} \quad (7)$$

In order to gain some information about the structure of the monodentate intermediate of Equation (1), we carried out a theoretical calculation on the 5-HsalH-Et ligand interaction with a cation. The effect of metal ion coordination by the ligand was studied by a simplified model system in which the NiS_5^{2+} cation was mimicked by the Na^+ cation. The cation was initially assumed to be equidistant (9 Å) from both the O and N atoms in the molecular plane of the enolic ligand. As expected, during the geometry optimisation the cation moves towards the O−H−N group, the H atom simultaneously migrates towards the N atom. The final optimised geometry (O−H = 2.09 Å, N−H = 1.03 Å) clearly shows that the presence of a cation such as Na^+ favours the quinonic form of the ligand.

Equilibria between $[NiL_2]$ = [Ni(5-X-sal-R)$_2$] Complexes and Ni^{II} Cations

The equilibria between the $[NiL_2]$ complexes and the Ni^{II} cations were studied spectrophotometrically in acetonitrile solution. On increasing the amounts of Ni^{II} cations, the characteristic MLCT and $\pi\rightarrow\pi\delta$ absorption bands[21] at ca. 400 and ca. 330 nm decrease and a new band at 370 nm appears. At high metal/ligand ratios the observed maximum shifts to longer wavelengths. (Figure 3*i*, Supporting Information). For the 5-O_2N-substituted complex, absorbance changes were too small to obtain reliable results.

Several equilibrium schemes were tested by refining the spectrophotometric data by a nonlinear least-squares program, and the formation of 1:1 or 1:2 $Ni^{II}/[NiL_2]$ adducts similar to those mentioned[2] in the introduction (see Scheme2) could be excluded. Fit residues were within the absorbance measurement error, and gave a statistical distribution at all the wavelengths examined only by applying Equation (8) (solvent molecules are omitted for clarity). In the equilibrium according to Equation (8a) the starting complex dissociates into two $[NiL]^+$ moieties. In the equilibrium according to Equation (8b) a dinuclear species $[Ni_2L_3]^+$ is formed by the interaction of $[NiL_2]$ and $[NiL]^+$.

$$[NiL_2] + Ni^{2+} \overset{K_4}{\rightleftharpoons} 2[NiL]^+ \quad (8a)$$

$$[NiL]^+ + [NiL_2] \overset{K_5}{\rightleftharpoons} [Ni_2L_3]^+ \quad (8b)$$

The related equilibrium constants, calculated as average values for at least three independent experiments, are reported in Table 3. In the present measurements, according to these values, the concentration of $[Ni_2L_3]^+$ was at most 8−10% of the total concentration of the other species.

Figure 7 shows an example of calculated spectra for the species involved in the equilibria of Equation (8) for the $Ni^{II}/[Ni(5\text{-MeO-sal-}n\text{Pr})_2]$ system; the spectrum of $[Ni_2L_3]^+$ is similar to that of $[NiL]^+$ but shows a threefold absorptivity, which is in agreement with three nearly equivalent ligands.

The ^1H NMR spectra of acetonitrile solutions of $[NiL_2]$ and Ni^{II} cations did not show detectable signals, most likely due to the presence of paramagnetic species.

A linear free energy relationship was found between the equilibrium constants $\log K_4$ of Equation (8a) and Taft's substituent constant[22] σ_p° which is related to the Schiff base oxygen atom, but not to the imine site (slope ρ° = +2.04; correlation coefficient r = 0.995) (Table 3). It is likely that an initial charge−dipole interaction between Ni^{II}

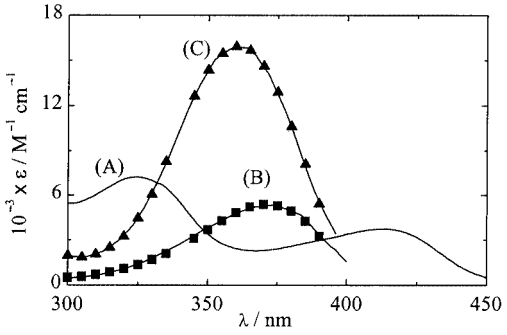

Figure 7. Experimental absorbance spectrum of $[NiL_2]$ = [Ni(5-MeO-sal-*n*Pr)$_2$] (A) and calculated absorbance spectra of $[NiL]^+$ (B), and $[Ni_2L_3]^+$ (C) in acetonitrile at 25.0 °C

cations like that in **1** in Scheme 2, yields two $[NiL]^+$ species, with electron-withdrawing substituents favouring their formation.

For logK_5, a good linear correlation was found by using the equation $\log K_5 = \rho(\sigma^\circ_p - \sigma^+)$ (slope = 0.973; r = 0.999). The interpretation of this behaviour is not straightforward since the $[Ni_2L_3]^+$ structure in solution is not known. It is likely that $[Ni_2L_3]^+$ forms by direct interaction of the starting complex $[NiL_2]$, by means of its O···O bite with the charged species $[NiL]^+$, see Scheme 2 (species **3**). This might be achieved by adopting a hindered *cis*-planar, or more likely a tetrahedral geometry. Hence, electron-withdrawing substituents on $[NiL]^+$ (which can be related to the σ^+ term) and electron-donor substituents on $[NiL_2]$ (which can be related to the σ°_p term) favour the right side of the equilibrium according to Equation (10b), accounting for the above logK_5 equation.

Experimental Section

Physical Measurements: IR and UV/Vis spectra were recorded with Perkin−Elmer 983 and Perkin−Elmer Lambda9 instruments, respectively. A Dionex Chromatograph S4000 instrument and an ICP/AES Varian Liberty 200 instrument were used for ionic chromatographic and plasma analyses, respectively. ^{1}H NMR spectra were recorded with a Varian Gemini 200 instrument.

Materials: Bis(*N*-alkyl-5-X-salicylaldiminato)nickel(II) = [Ni(5-X-sal-R)$_2$] complexes (X = H, R = Et, *n*Pr, *n*Bu; X = Cl, OMe, Me, NO_2; R = *n*Pr) were prepared and purified according to the literature.[23] *N*-Alkyl-5-X-salicylaldimine Schiff bases,[24] 5-X-salH-R (X = H; R = Et, *n*Pr, *t*Bu; X = Cl, OMe, NO_2; R = *n*Pr), were prepared by condensation of salicylaldehyde with the appropriate amine and purified by distillation under reduced pressure. Acetonitrile was purified and dried by standard methods.[25]

Caution!*: Perchlorates are potentially explosive. Only small amounts should be dried and used at once.* Alkaline earth perchlorates (Aldrich products) were dried at 100 °C under reduced pressure. Ionic HPLC and plasma analyses confirmed the purity of each salt. $[Ni(CH_3CN)_6](ClO_4)_2$ was prepared and purified according to literature methods[26] and characterised by elemental and plasma analyses.

Equilibrium and Kinetic Measurements: Spectrophotometric kinetic measurements were carried out by a stopped-flow technique previously described[27] (dead time = 6−7 ms) under dry nitrogen at different temperatures (± 0.2 °C). $[Ni(CH_3CN)_6](ClO_4)_2$ was used in a large excess (from 3×10^{-3} to 5×10^{-2} M) relative to the Schiff base ligand (ca. 10^{-4} M). The reactions were monitored by a diode-array detector (time resolution 5 ms) or a photomultiplier in the 300−500-nm UV/Vis region (time resolution 0.1 ms). Experimental kinetic traces were selected at one or more wavelengths (365, 383, 430 nm) corresponding to the largest absorbance changes. Up to six traces of absorbance (A) vs. time (t) for each kinetic run were computer-fitted to the appropriate one-exponential Equation (9), or two-exponential Equation (10). A_0 and A_∞ are the initial and final absorbances respectively, and A_1 and A_2 are pre-exponential factors. Kinetic experiments with different amounts of (nBu$_4$N)-(ClO_4) showed that the rates were not affected by ionic strength.

$$A = A_\infty + (A_0 - A_\infty) \exp(-k_{obs}t) \quad (9)$$

$$A = A_\infty + A_1 \exp(-\lambda_1 t) + A_2 \exp(-\lambda_2 t) \quad (10)$$

Equilibrium measurements were carried out as previously described.[2] 20−40 solutions of the $[NiL_2]$ complex at constant concentration (ca. 10^{-4} M) and increasing concentrations of $[Ni(CH_3CN)_6](ClO_4)_2$ were used. An inverse procedure was adopted to determine the equilibria between 5-H-salH-Et Schiff base (up to ca. 10^{-4} M) and the metal ions (ca. 10^{-3} M). The experimental absorbance $A(\lambda)$ was expressed as a function of the total concentrations C of the reactants, the absorptivities ε_λ of the species in solution and the equilibrium constants K_i according to the equilibrium scheme to be tested. Equilibrium constants and molar absorptivities at about 25 wavelengths in the range of 300 to 500 nm were simultaneously optimised using a nonlinear least-squares program.[28] Standard deviations accepted were less than 2.5×10^{-3}. Equilibria involving species at concentrations less than 2% of the total reactant were rejected.

According to Equation (8), the absorbance of an $Ni^{II}/[NiL_2]$ solution at a given wavelength λ is expressed by Equation (11), where the dependence of the ε values on the wavelength has been omitted for brevity. The mass balance equations allow to relate the concentrations of the Ni^{II} cations and $[NiL_2]$ to the total concentrations $C_{[NiL]_2}$ and $C_{[Ni^{2+}]}$.

$$A(\lambda) = \varepsilon_{Ni^{2+}}[Ni^{2+}] + \varepsilon_{NiL_2}[NiL_2] + \varepsilon_{(NiL)^+}(K_4[NiL_2][Ni^{2+}])^{1/2} + \varepsilon_{(Ni_2L_3)} + K_5[NiL_2](K_4[NiL_2][Ni^{2+}])^{1/2} \quad (11)$$

Ion pairs involving ClO_4^- anions were neglected in the acetonitrile solution.[29] In order to evaluate the activity coefficients of the charged species, the Debye−Hückel law was applied in its complete form, by taking the distance for the closest approach of the ions as $a = 5$ Å. Hence, the effect of ionic strength can be neglected for the present measurements on complexation reactions of neutral macrocyclic ligands with cations,[2] and/or for total $M(ClO_4)_2$ concentrations not exceeding 0.001 M.

Computational Details: The geometry of the 5-X-salH-R ligands was optimised by employing the Density Functional Theory based on the B3LYP functional.[30]The triple zeta with polarisation 6−311G* basis set was employed and the calculations were carried out with the Gaussian98[31] package. Other calculations concerning some species involved in the reaction of Ni^{II} cations with HL ligands were performed in the same way.

With the aim to evaluate the $[NiS_6]^{2+}$/HL (S = solvent) interaction energy of the outer-sphere complex, we resorted to the Fuoss association theory[32,33] (originally developed for ions in a solvent), represented as a polarizable continuum and adapted to the case of an ion interacting with a dipole. If the cation is considered as a point charge at the centre of a sphere of radius a, then the equilibrium constant K_0 can be approximated as in Equation (6), where a is expressed in cm, N is the Avogadro number, and U is the charge−dipole electrostatic interaction energy. By considering the solvent as a continuum of permittivity D, the energy U may be approximated to the lowest power of the charge−dipole distance d as in Equation (7), where μ is the dipole moment and α is the angle between the dipole vector and the electric field generated by the charge Q at the dipole centre. Unfortunately, this simple theoretical approach, in which the ligand dipole is placed at a fixed distance from the positive sphere and is directed towards the more favourable direction, cannot properly account for the geometrical factors of the ligands. Thus, we use a more sophisticated approach, in which each atom both of the $[NiS_6]^{2+}$ and of the ligand has been represented as a hard sphere with the appropriate van der Waals radius. The energy was calculated again using Equation (7), by placing the ligand dipole in the middle of the segment connecting the centre of the charge originated by the positively charged atoms of the ligand, to the centre of the charge arising from the negatively charged atoms [Equation (12)], where c is the centre of the dipole and k runs over the positively charged ligand atoms.

$$\vec{c} = 2\left(\sum_j^{pos} q_j\right)^{-1} \sum_k^{all} q_k \vec{R}_k \quad (12)$$

The atomic charges q were determined by the Mulliken population analysis method. The most favourable conformations were determined by starting from a large number of geometrical arrangements of the cation−ligand system and moving the molecules along the energy gradient until an energy minimum was found.

Rate and Mechanism of the Oxidative Addition of Benzoic Anhydride to Palladium(0) Complexes in DMF

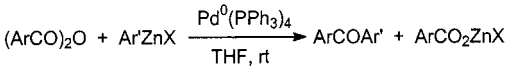
Anny Jutand,*[a] Serge Négri,[a] and Johannes G. de Vries[b]

Keywords: Palladium / Kinetics / Electrochemistry / Benzoic anhydride / Oxidative addition

The rate constant of the oxidative addition of the benzoic anhydride $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$ has been determined in DMF and compared to that of phenyl halides and phenyl triflate. The following reactivity order has been established: PhI >> $(PhCO)_2O$ > PhOTf > PhBr. The oxidative addition of $(PhCO)_2O$ proceeds by activation of one C–O bond. Two acyl-Pd^{II} complexes are formed: a neutral complex *trans*-$[(PhCO)Pd(OCOPh)(PPh_3)_2]$ and a cationic complex *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ (S = DMF) showing that the decarbonylation process is highly endergonic. The exchange of PPh_3 by the bidentate ligand dppp does not favor the decarbonylation process.

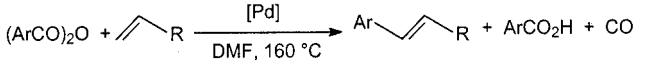
Introduction

Aromatic carboxylic anhydrides $(ArCO)_2O$ were first used by Sakamoto et al. as *acylating* agents in palladium-catalyzed cross-coupling reactions [Equation (1)]:[1]



(1)

Recently, they have also been used by de Vries et al. as *arylating* agents in palladium-catalyzed Heck reactions [Equation (2)]:[2]



(2)

When compared to the aryl halides or triflates more commonly used as arylating agents in Heck reactions,[3–5] aromatic carboxylic anhydrides appear to be more attractive since they are a cheap aryl source and they do not lead to the formation of environmentally wasteful halide salts. Moreover, no base is required, as it usually is in Heck reactions, since benzoate anions are released in the reaction. They serve as a base by forming aromatic carboxylic acid, which can be recycled back to the aromatic carboxylic anhydride. CO is then the only by-product of the Heck reaction [Equation (2)].

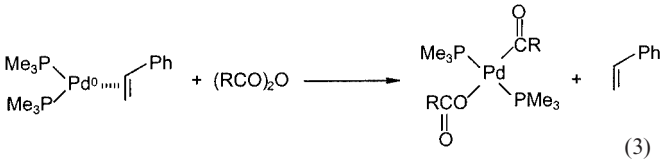
By analogy to aryl halides and triflates,[3–5] the first step of the catalytic cycle of the Heck reaction must be an oxidative addition of the aromatic carboxylic anhydride to the palladium(0) catalyst, giving a palladium(II) complex. Further transformation of this complex gives an intermediate aryl-Pd^{II} complex able to react with the alkene. The oxidative addition of carboxylic anhydrides to palladium(0) complexes has been reported by Yamamoto et al.[6–8] It proceeds by cleavage of one C–O bond and *trans*-acyl(carboxylato)palladium(II) complexes have been isolated and characterized with the PMe_3 ligand [Equation (3), (R = alkyl or phenyl)].[6,7]



(3)

The reactivity of such complexes has been investigated by the same group. Hydrogenation gives RCHO and RCO_2H, establishing that no decarbonylation occurs in the acyl(carboxylato)palladium(II) complex formed in the oxidative addition.[6,7] Hydrogenation of $(PhCO)_2O$ to form PhCHO and $PhCO_2H$ has been successfully developed in THF with $[Pd^0(PPh_3)_4]$ as a catalyst.[6–8] Only one reaction in the aromatic series is reported (phthalic anhydride, PMe_3 as the ligand), where CO is released from the acyl(carboxylato)-palladium(II) complex, giving rise to the formation of an aryl(carboxylato)Pd^{II} complex.[7]

Grushin and Alper have characterized in solution the complex *trans*-$[(PhCO)Pd(OCOPh)(PCy_3)_2]$ formed by reacting $(PhCO)_2O$ with $[Pd^0(PCy_3)_2]$ (Cy = cyclohexyl).[9] Decarbonylation was observed in the course of the oxidative addition as a very minor process (5–10%).

We report here a mechanistic investigation of the oxidative addition of benzoic anhydride $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$ in DMF (solvent of the Heck reaction). The objective is to compare its reactivity to that of phenyl halides and phenyl triflate and to characterize the Pd^{II} complex(es) generated in the oxidative addition.

Results and Discussion

Rate of the Oxidative Addition of Benzoic Anhydride $(PhCO)_2O$ to $Pd^0(PPh_3)_4$ in DMF

The kinetics of the oxidative addition of $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$ (C_0 = 1.33 mM) in DMF (containing nBu$_4$NBF$_4$, 0.3 M) was monitored by amperometry at a rotating gold disk electrode, as reported for aryl halides[10] and triflates.[11] $[Pd^0(PPh_3)_3]$, the main complex generated in DMF from $[Pd^0(PPh_3)_4]$ [Equation (4)], exhibited an oxidation peak at +0.11 V vs. SCE. The rotating disk electrode was polarized at +0.35 V, on the plateau of the oxidation wave of $[Pd^0(PPh_3)_3]$. The kinetics of the oxidative addition of $(PhCO)_2O$ was monitored by recording the decay of the oxidation current, i, of $[Pd^0(PPh_3)_3]$ (proportional to the Pd^0 concentration) as a function of time, up to 100% conversion. The reaction was rather slow at 25 °C and the kinetic investigation was then performed at 40 °C.

$$Pd^0(PPh_3)_4 \longrightarrow Pd^0(PPh_3)_3 + PPh_3 \quad (4)$$

It is well established that when $[Pd^0(PPh_3)_4]$ is the Pd^0 precursor, any oxidative addition (e.g. of aryl halides or triflates) proceeds from the 14-electron complex $[Pd^0(PPh_3)_2]$ [Equation (5) and (6)].[10,11] The Pd^{II} complex formed in the oxidative addition is tentatively written as [(PhCO)Pd(OCOPh)$(PPh_3)_2$] after cleavage of one C−O bond, by analogy to the complex obtained when the Pd^0 is ligated by PMe_3 [6,7] or by PCy_3.[9] Its structure will be established in the second part of this work.

$$Pd^0(PPh_3)_3 \underset{}{\overset{K}{\rightleftharpoons}} Pd^0(PPh_3)_2 + PPh_3 \quad (5)$$

$$Pd^0(PPh_3)_2 + (PhCO)_2O \xrightarrow{k} (PhCO)Pd(OCOPh)(PPh_3)_2 \quad (6)$$

Overall reaction:

$$Pd^0(PPh_3)_4 + (PhCO)_2O \xrightarrow{k_{app}} (PhCO)Pd(OCOPh)(PPh_3)_2 + 2\,PPh_3 \quad (7)$$

The kinetic investigation allows the determination of the apparent rate constant k_{app} of the overall oxidative addition [Equation (7)]. Due to the continuous release of PPh_3 in the fast equilibrium (5) during the course of the oxidative addition, the kinetic law is expressed in Equation (8) {C_0: initial concentration of $[Pd^0(PPh_3)_4]$, $(PhCO)_2O$ in large excess}.[10]

$$2\ln([Pd^0]/[Pd^0]_0) + 1 - [Pd^0]/[Pd^0]_0 = -Kk[(PhCO)_2O]t/C_0 = -k_{app}[(PhCO)_2O]t = -k_{obs}t \quad (8)$$

The plot of $2\ln(i/i_0) + 1 - i/i_0 = 2\ln([Pd^0]/[Pd^0]_0) + 1 - [Pd^0]/[Pd^0]_0$ versus time is a straight line (Figure 1a) (i: oxidation current of Pd^0 at t; i_0: initial oxidation current). The value of k_{obs} was calculated from the slope of the regression line [Equation (8)]. The benzoic anhydride concentration was varied in the range 0.01−0.4 M and the plot of the corresponding k_{obs} value versus the benzoic anhydride concentration gave a straight line (Figure 1b). The reaction order in benzoic anhydride is thus +1 [Equation (8)]. This establishes that the mechanism of the oxidative addition of the benzoic anhydride to $[Pd^0(PPh_3)_4]$ [Equations (4−7)] is the same as that already established for aryl halides and triflates.[10,11] The value of $Kk = 3.6 \times 10^{-5}\ s^{-1}$ was calculated from the slope of the regression line of Figure 1b and allows the calculation of the apparent rate constant of the overall reaction [Equation (7)]: $k_{app} = Kk/C_0$ (in $M^{-1}s^{-1}$)

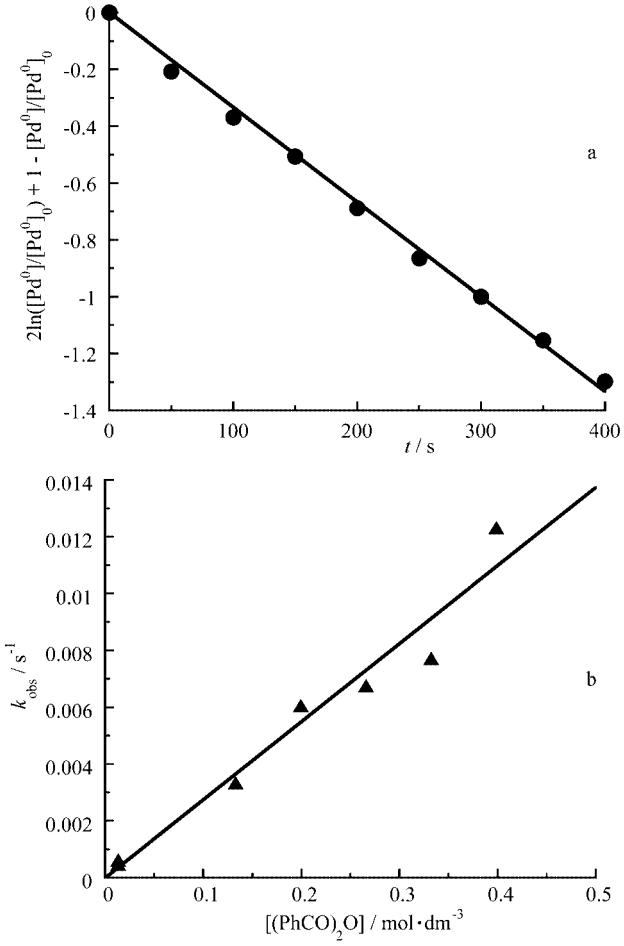


Figure 1. Oxidative addition of $(PhCO)_2O$ in DMF (containing nBu$_4$NBF$_4$ 0.3 M) to $[Pd^0(PPh_3)_4]$ (1.33 mM) at 40 °C, monitored by amperometry at a rotating gold disk electrode (diameter: 2 mm, ω = 105 rad s^{-1}) polarized at +0.35 V vs. SCE; a) $[(PhCO)_2O]$ = 0.133 M; plot of $2\ln(i/i_0) + 1 - i/i_0 = 2\ln([Pd^0]/[Pd^0]_0) + 1 - [Pd^0]/[Pd^0]_0$ *versus* time (i: oxidation current of $[Pd^0(PPh_3)_3]$ at t; i_0: initial oxidation current). k_{obs} (s^{-1}) is calculated from the slope [Equation (8)]; b) Plot of k_{obs} (s^{-1}) *versus* $(PhCO)_2O$ concentration

Table 1. Comparative reactivity of $(PhCO)_2O$, PhI, PhBr and PhOTf in their oxidative addition to $[Pd^0(PPh_3)_4]$ (2 mM) in DMF [Equation (7) for $(PhCO)_2O$]

	T (°C)	PhI	$(PhCO)_2O$	PhOTf	PhBr
k_{app} ($M^{-1}s^{-1}$)	25	25	3.1×10^{-3}	–	–
k_{app} ($M^{-1}s^{-1}$)	40	–	1.8×10^{-2}	1.2×10^{-2}	10^{-2}

[Equation (8)], for any value of C_0 (Table 1). It is worthwhile to note that, even at the lowest benzoic anhydride concentration investigated here (0.013 M), the oxidation current of Pd^0, and therefore the concentration of Pd^0, dropped to almost zero. This indicates that the oxidative addition went to completion and that the reverse reaction, the formation of $(PhCO)_2O$ and a Pd^0L_2 complex by reductive elimination from $[(PhCO)Pd(OCOPh)(PPh_3)_2]$,[9,12] was much slower than the rate of the oxidative addition and did not interfere in the kinetics investigated herein.

Since aromatic carboxylic anhydrides appear to be an alternative to the use of aryl halides and triflates in Heck reactions,[2] it was of interest to compare their reactivity in the oxidative addition, which may be rate determining in the case of poorly reactive aryl derivatives. The apparent rate constant k_{app} of the oxidative addition of PhOTf and PhBr to $[Pd^0(PPh_3)_4]$ has also been determined at 40 °C, in DMF, to allow comparison with that of $(PhCO)_2O$ (Table 1). The order of reactivity in DMF has been established to be:

$$PhI >> (PhCO)_2O > PhOTf > PhBr$$

When considering the oxidative addition, $(PhCO)_2O$ is thus slightly more reactive than PhOTf and PhBr and may therefore be a good alternative to the use of PhOTf or PhBr in any reaction where the oxidative addition is rate determining, provided the subsequent decarbonylation takes place.

Palladium(II) Complexes Generated in the Oxidative Addition of Benzoic Anhydride $(PhCO)_2O$ to $Pd^0(PPh_3)_4$ in DMF

The oxidative addition of $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$ in DMF at 40 °C was monitored by conductivity measurements, which allows the characterization of ionic complexes as well as their rate of formation.[11] Starting with a residual conductivity $\kappa_0 = 5\ \mu S{\cdot}cm^{-1}$, we observed that the conductivity of the solution increased as soon as $(PhCO)_2O$ (100 equiv.) was added to $[Pd^0(PPh_3)_4]$ (C_0 = 1.33 mM) in DMF, attesting that an ionic complex was formed in the very first stages of the oxidative addition (Figure 2). From the kinetic curve of Figure 2, we see that at least two different ionic species are formed successively, at different time scales, the first complex being formed on a shorter time scale ($t < 800$ s) than the second one. The first time scale is compatible with that of the oxidative addition when monitored independently by amperometry ($t_{1/2}$ = 250 s, see Figure 1a). This suggests that the neutral complex $[(PhCO)Pd(OCOPh)(PPh_3)_2]$, initially formed in the oxidative addition [Equation (7)], dissociates to give a cationic complex $[(PhCO)PdS(PPh_3)_2]^+$ (S = DMF) [Equation (9)] in a reaction which is faster than the oxidative addition.[13,14] A second ionic species is then generated in a subsequent reaction. This latter might be a decarbonylation as in Equation (10) or any decomposition process leading to more conductive ionic species {e.g., formation of a phosphonium salt $PhCOO\text{-}PPh_3^+$ via a reductive elimination from $[(PhCO)Pd(OCOPh)(PPh_3)_2]$,[15] reaction of dioxygen with $[(PhCO)PdS(PPh_3)_2]^+$,[16] etc.}.

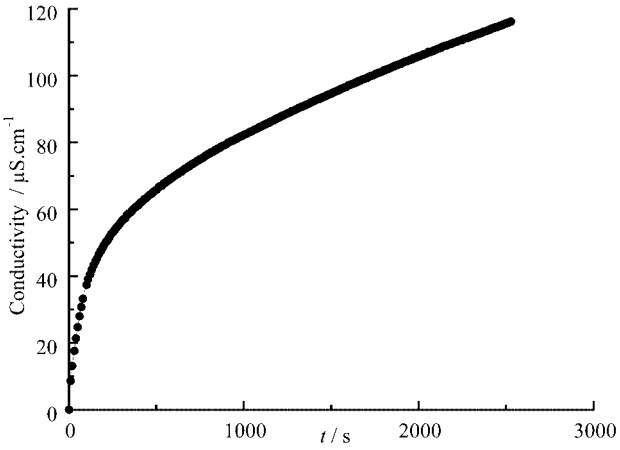

Figure 2. Oxidative addition of $(PhCO)_2O$ (0.133 M) to $[Pd^0(PPh_3)_4]$ (1.33 mM) in DMF at 40 °C, monitored by conductivity measurements; variation of the conductivity *versus* time

$$(PhCO)Pd(OCOPh)(PPh_3)_2 \rightleftharpoons (PhCO)PdS(PPh_3)_2^+ + PhCO_2^- \quad (9)$$

$$(PhCO)PdS(PPh_3)_2^+ \rightleftharpoons CO + PhPdS(PPh_3)_2^+ \quad (10)$$

To test the hypotheses formulated in Equation (9) and (10), the oxidative addition of $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$ was monitored by ^{31}P NMR spectroscopy[17] in DMF to characterize the formed Pd^{II} complexes. The ^{31}P NMR spectroscopy was first investigated after the amperometry experiment, i.e., when the oxidative addition, performed with $[Pd^0(PPh_3)_4]$ (C_0 = 1.33 mM) and $(PhCO)_2O$ (100 equiv.) in DMF at 40 °C, was over (experiment A). The ^{31}P NMR spectrum exhibited three main singlets: one singlet at $\delta = -5.4$ ppm characteristic of free PPh_3 released during the oxidative addition [Equation (7)], one singlet at $\delta = 25.6$ ppm characteristic of $(O)PPh_3$ [16] and one singlet at δ_1 = 19.9 ppm, which then characterizes the major complex formed in the oxidative addition. Two smaller singlets were also observed at δ_2 = 20.4 ppm and δ_3 = 24.1 ppm (each with a magnitude of ca. 15% of that of the singlet at δ_1). In a second experiment, the oxidative addition was monitored in an NMR tube at room temperature, starting from a more concentrated solution of $[Pd^0(PPh_3)_4]$ (C_0 = 7 mM) and $(PhCO)_2O$ (100 equiv.) in DMF (experiment B). After 30 min, the ^{31}P NMR spectrum exhibited, besides some un-

changed $[Pd^0(PPh_3)_3]$ (δ = 10.7 ppm), the two singlets δ_1 and δ_2 already observed in experiment A, although here the singlet at δ_2 was the major one (relative integration of 0.4:1). After 3 hours, the two singlets δ_1 and δ_2 had almost the same magnitude. This indicates that the signal at δ_2 = 20.4 ppm characterizes the first complex formed in the oxidative addition, which then gives a second complex at δ_1 = 19.9 ppm. Those two complexes are ligated by two PPh_3 ligands sitting in a *trans* position in the Pd^{II} complexes because only singlets were detected. The signal at δ_3 = 24.1 ppm was also detected with a magnitude of half that of δ_1, i.e., in larger amount than in experiment A.

In order to assign the signals at δ_1 and δ_2 to the complexes postulated in Equation (9) and (10), i.e., [(PhCO)-Pd(OCOPh)$(PPh_3)_2$], $[(PhCO)PdS(PPh_3)_2]^+$ or $[PhPdS(PPh_3)_2]^+$, these complexes were synthesized independently in DMF following known procedures. An oxidative addition was performed with PhOTf (100 equiv.) and $[Pd^0(PPh_3)_4]$ (C_0 = 7 mM) in DMF and monitored by ^{31}P NMR spectroscopy. Such a reaction is known to give, in DMF, the cationic complex *trans*-$[PhPdS(PPh_3)_2]^+ \cdot [OTf]^-$ [Equation (11)].[11] This complex exhibits a singlet at δ = 21.9 ppm (Table 2, entry 1) different from δ_1 and δ_2. We can already assume, therefore, that the cationic complex *trans*-$[PhPdS(PPh_3)_2]^+$, postulated in Equation (10), is not formed in the oxidative addition of $(PhCO)_2O$ under the experimental conditions used above. When CO was bubbled into the NMR tube, a new singlet appeared at higher field at δ = 20.0 ppm and was assigned to *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ [Equation (12), Table 2, entry 2].[18,19] This latter signal is very similar to the signal at δ_1 observed when the oxidative addition was performed with $(PhCO)_2O$ (experiments A and B, Table 2, entry 3). When $PhCO_2^- \cdot Li^+$ was then added in large excess into the NMR tube, a singlet appeared at δ = 20.4 ppm and was assigned to *trans*-[(PhCO)Pd(OCOPh)$(PPh_3)_2$] [Equation (13)].[20] This latter signal is the same as the signal at δ_2 observed when the oxidative addition was performed with $(PhCO)_2O$ (experiment A and B, Table 2, entry 4).

$$Pd^0(PPh_3)_4 + PhOTf \longrightarrow \textit{trans}\text{-}PhPdS(PPh_3)_2^+ + TfO^- + 2PPh_3 \quad (11)$$

$$\textit{trans}\text{-}PhPdS(PPh_3)_2^+ + CO \longrightarrow \textit{trans}\text{-}(PhCO)PdS(PPh_3)_2^+ \quad (12)$$

$$\textit{trans}\text{-}(PhCO)PdS(PPh_3)_2^+ + PhCO_2^- \rightleftharpoons \textit{trans}\text{-}(PhCO)Pd(OCOPh)(PPh_3)_2 \quad (13)$$

Consequently, two complexes are formed in the oxidative addition of $(PhCO)_2O$ to $[Pd^0(PPh_3)_4]$: *trans*-[(PhCO)-Pd(OCOPh)$(PPh_3)_2$] and *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ {see Equation (5) and Equation (14) and (15) for the mechanism of the oxidative addition of benzoic anhydride to $[Pd^0(PPh_3)_4]$ in DMF}.

$$Pd^0(PPh_3)_3 \overset{K}{\rightleftharpoons} Pd^0(PPh_3)_2 + PPh_3 \quad (5)$$

$$Pd^0(PPh_3)_2 + (PhCO)_2O \overset{k}{\longrightarrow} \textit{trans}\text{-}(PhCO)Pd(OCOPh)(PPh_3)_2 \quad (14)$$

$$\textit{trans}\text{-}(PhCO)Pd(OCOPh)(PPh_3)_2 \rightleftharpoons \textit{trans}\text{-}(PhCO)PdS(PPh_3)_2^+ + PhCO_2^- \quad (15)$$

The fact that *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ was detected in larger amounts than *trans*-[(PhCO)Pd(OCOPh)$(PPh_3)_2$] in experiment A as opposed to experiment B (vide supra) is due to the difference of concentration. In experiment B, the concentration of $[Pd^0(PPh_3)_4]$ was higher than that in experiment A. Consequently the concentration of the released $PhCO_2^-$ was higher in experiment B and Equation (15) was shifted more towards the left hand-side, i.e., to the formation of *trans*-[(PhCO)Pd(OCOPh)$(PPh_3)_2$]. This is why *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ appeared as the major complex at low $[Pd^0(PPh_3)_4]$ concentration (experiment A).

The singlet at δ = 24.3 ppm remained unassigned. Two phenyl-Pd^{II} complexes *trans*-$[PhPdS(PPh_3)_2]^+$ and *trans*-[PhPd(OCOPh)$(PPh_3)_2$] could have been formed by decarbonylation of *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ and *trans*-[(PhCO)Pd(OCOPh)$(PPh_3)_2$], respectively, but the cationic complex *trans*-$[PhPdS(PPh_3)_2]^+$ was not detected in the NMR spectrum (vide supra). We have independently

Table 2. ^{31}P NMR shifts δ (101 MHz, DMF, [D_6]acetone (10%), H_3PO_4) of phenyl- and acyl-palladium(II) complexes

Entry	Complexes (S = DMF)	δ

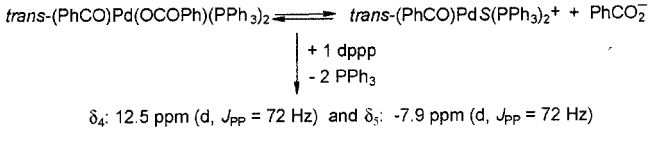
[a] Authentic sample with OTf^- as the counter anion. [b] Formed by reaction (12) with OTf^- as the counter anion. [c] Formed in the oxidative addition of benzoic anhydride and $[Pd(PPh_3)_4]$ with $PhCO_2^-$ as the counter anion. [d] Formed in the oxidative addition of benzoic anhydride and $[Pd(PPh_3)_4]$ [Equation (7)] and by reaction (13). [e] Formed by reaction of benzoate anion with $[PhPdBr(PPh_3)_2]$. [f] Authentic sample with BF_4^- as the counter anion. [g] Formed by reaction (16) with BF_4^- as the counter anion. [h] Formed by reactions (17−19) with $PhCO_2^-$ as the counter anion. [i] Formed by ligand exchange (Scheme 1) and by reaction (18). [j] Formed by reaction (17).

checked that the complex *trans*-[PhPd(OCOPh)(PPh_3)$_2$] was not formed in the oxidative addition, by reacting *trans*-[PhPdBr(PPh_3)$_2$] (δ = 24.2 ppm) with $PhCO_2^-\cdot Li^+$ in DMF to induce the $Br^-/PhCO_2^-$ substitution.[21] Indeed, a new singlet assigned to *trans*-[PhPd(OCOPh)(PPh_3)$_2$][23] appeared at δ = 21.6 ppm (Table 2, entry 5), which was never observed in the course of the oxidative addition of the benzoic anhydride. Consequently, the decarbonylation must be a very endergonic process, since even at 100 °C for 1 h, under continuous degassing, none of the signals of either *trans*-[PhPd(OCOPh)(PPh_3)$_2$] or *trans*-[PhPd*S*(PPh_3)$_2$]$^+$ were detected. In contrast, carbonylation of [PhPd(OCOPh)(PPh_3)$_2$][20] or *trans*-[PhPd*S*(PPh_3)$_2$]$^+$ [Equation (12)] proved to be efficient.[22] Consequently, the singlet at δ = 24.3 ppm, which must be due to a decomposition product, remains unassigned.

The influence of the ligand on the decarbonylation process was tested by switching from the monodentate ligand PPh_3 investigated above to the bidentate bisphosphane ligand 1,3-bis(diphenyl)phosphanylpropane (dppp). Whereas the acyl group of acyl-Pd^{II} complexes ligated by two monophosphane ligands sits in a *cis* position relative to each monophosphane ligand, it must sit in a *trans* position relative to one P of a bidentate bisphosphane ligand. This may affect the decarbonylation process. The oxidative addition of $(PhCO)_2O$ to [Pd^0(dba)(dppp)] generated from Pd^0(dba)$_2$ + 1 equiv. dppp was very sluggish. Consequently, one equiv. dppp was added to the solution of *trans*-[PhCOPd*S*(PPh_3)$_2$]$^+$ and *trans*-[PhCOPd(OCOPh)(PPh_3)$_2$], generated from the oxidative addition of $(PhCO)_2O$ to [Pd(PPh_3)$_4$], in DMF, to test the effect of the bidentate ligand on the decarbonylation process. The two singlets δ_1 = 19.9 ppm and δ_2 = 20.4 ppm of *trans*-[PhCOPd*S*(PPh_3)$_2$]$^+$ and *trans*-[PhCOPd(OCOPh)(PPh_3)$_2$], respectively, disappeared. The signal of free PPh_3 was observed at δ = −5.4 ppm but not that of dppp (δ = −17.0 ppm), confirming the ligand exchange. As a result of this exchange, a single complex was observed, characterized by two doublets at δ_4 = 12.5 ppm (d, J_{PP} = 72 Hz) and δ_5 = 7.9 ppm (d, J_{PP} = 72 Hz) (Scheme 1).



Scheme 1. Exchange of two PPh_3 ligands by one dppp in DMF

At least four complexes might be formed in DMF: [(PhCO)Pd(OCOPh)(dppp)], [(PhCO)Pd*S*(dppp)]$^+$ and the complexes formed by decarbonylation {[PhPd(OCOPh)(dppp)] and/or [PhPd*S*(dppp)]$^+$}. The ^{31}P NMR signals of an authentic sample of [PhPd*S*(dppp)]$^+$[BF_4]$^-$ in DMF (two doublets at δ = 25.2 ppm and δ = −2.2 ppm, Table 2, entry 6) showed that such a complex was not formed in the exchange reaction of Scheme 1. When CO was bubbled into an NMR tube containing the authentic sample of the cationic complex [PhPd*S*(dppp)]$^+$[BF_4]$^-$ in DMF, two new broad doublets were detected at δ = 5.1 and −8.4 ppm (Table 2, entry 7) and assigned to [(PhCO)Pd*S*(dppp)$^+$] [Equation (16)].[24] Such a complex did not appear when PPh_3 was exchanged by dppp in Scheme 1.

(16)

In order to discriminate between [(PhCO)Pd(OCOPh)(dppp)] and [PhPd(OCOPh)(dppp)], a series of experiments was then performed independently. To a solution of [PhPdI(PPh_3)$_2$] in DMF was first added one equiv. of dppp to generate [PhPdI(dppp)] characterized by two ^{31}P NMR doublets (δ = 12.4 ppm, $J_{P,P}$ = 53 Hz and δ = −8.6 ppm, $J_{P,P}$ = 53 Hz). Addition of 10 equiv. $PhCO_2^-\cdot Li^+$ to the NMR tube resulted in the formation of a new complex assigned to [PhPd(OCOPh)(dppp)][21] (2 doublets at δ = 18.9 ppm and δ = −6.5 ppm, Table 2, entry 10) [Equation (17)]. This complex did not appear when PPh_3 was exchanged by dppp in Scheme 1.

(17)

(18)

(19)

When CO was bubbled into the NMR tube, the two doublets of [PhPd(OCOPh)(dppp)] disappeared, confirming the CO insertion [Equation (18)]. Two sets of two doublets were detected (relative integration of 1:4): a first set of two major doublets at δ_4 = 12.5 ppm and δ_5 = −7.9 ppm, assigned to [(PhCO)Pd(OCOPh)(dppp)] [Equation (18)] and already observed after the ligand exchange in Scheme 1, and a second set of two minor doublets at δ = 5.1 ppm and δ = −8.8 ppm (Table 2, entry 8) similar to [(PhCO)Pd*S*(dppp)$^+$] previously characterized [vide supra, Table 2, entry 7, Equation (19)].

Consequently, the ligand exchange in Scheme 1 generated an acyl-Pd^{II} complex [(PhCO)Pd(OCOPh)(dppp)] but no phenyl-Pd^{II} complexes [PhPd(OCOPh)(dppp)] or [PhPd*S*(dppp)]$^+$ that would be formed by a decarbonylation process. The decarbonylation is definitively an endergonic process when phosphane ligands (monodentate or bidentate) are considered, which strongly stabilize neutral and cationic acyl-Pd^{II} complexes in DMF.

Conclusion

In DMF, the oxidative addition of benzoic anhydride to [Pd(PPh_3)$_4$] is slower than that of PhI but slightly faster than that of PhOTf and PhBr. This reaction gives two acyl-Pd^{II} complexes: the cationic complex *trans*-[(PhCO)Pd*S*(PPh_3)$_2$]$^+$ and the neutral complex *trans*-[(PhCO)Pd(OCOPh)(PPh_3)$_2$]. Aryl-Pd^{II} complex(es)

formed by decarbonylation of the two above acyl-Pd^{II} complexes have not been detected. Changing the monodentate PPh_3 ligand to the bidentate dppp does not favor the decarbonylation process either. This is why the Heck reaction, which requires the formation of an aryl-Pd^{II} complex, is much more efficient using catalytic Pd salts (in the absence of ligand) than catalytic phosphane-ligated Pd complexes when it is performed from benzoic anhydride.[2] The phosphane-ligated aryl-Pd^{II} complex must be present at very low concentration in an endergonic equilibrium with the major acyl-Pd^{II} complex(es) but be nevertheless more reactive with alkenes than the acyl-Pd^{II} complex(es). The decarbonylation of the acyl-Pd^{II} complex(es) ligated to the alkene, before the carbopalladation steps, appears more improbable.

Experimental Section

General Remarks: ^{31}P NMR spectra were recorded on a Bruker spectrometer (101 MHz) using H_3PO_4 as an external reference. Amperometry was performed with a generator Tacussel GSTP4. Conductivity was measured on a Radiometer Analytical CDM210 conductivity meter (cell constant: 1 cm^{-1}).

Chemicals: DMF was distilled from calcium hydride under vacuum. Commercial benzoic anhydride, phenyl triflate, PPh_3 and dppp (Acros) were used without any purification. $[Pd(PPh_3)_4]$,[25] $[PhPdBr(PPh_3)_2]$,[26] $[PhPdI(PPh_3)_2]$,[26] and $[PhPd(dppp)]^+[BF_4]^-$ [27] were prepared according to described procedures.

Electrochemical Set-Up and Procedure for Kinetic Measurements: Experiments were carried out in a thermostatted three-electrode cell connected to a Schlenk line. The counter electrode was a platinum wire of ca. 1 cm^2 apparent surface area. The reference was a saturated calomel electrode (Radiometer Analytical) separated from the solution by a bridge filled with 3 mL of DMF containing n-$Bu_4N{\cdot}BF_4$ (0.3 M). The kinetic measurements were performed at a rotating gold disk electrode (Radiometer analytical, EDI 65109, diameter: 2 mm, angular velocity: 105 $rad{\cdot}s^{-1}$) polarized at +0.35 V vs. SCE. $[Pd(PPh_3)_4]$ (23.1 mg, 0.02 mmol) was introduced into 15 mL of DMF containing n-$Bu_4N{\cdot}BF_4$ (0.3 mol dm^{-3}) followed by the appropriate amount of benzoic anhydride. The decay of the oxidation current was recorded as a function of time, up to 100% conversion.

[12] Reductive elimination with formation of $(PhCO)_2O$ would occur from a *cis*-$[(PhCO)Pd(OCOPh)(PPh_3)_2]$ complex first formed in the oxidative addition before its isomerization to the *trans* complex, the final complex (see the second part of this work). Reductive elimination is usually inhibited by extra phosphanes, which favor the *cis*/*trans* isomerization. For a reductive elimination from $[(PhCO)Pd(OCOPh)(PPh_3)_2]$ synthesized in situ by reacting CO with $[PhPd(OCOPh)(PPh_3)_2]$ in the absence of extra phosphane, see ref.[9] and the comments on the deceleration of the reductive elimination due to the release of PPh_3 by decomposition of $[Pd^0(PPh_3)_2]$ also generated in the course of the reductive elimination process. In the present work, free phosphanes were generated as the oxidative addition proceeded [Equation (7)]. Moreover, it seems that the reductive elimination is favored in the presence of CO for PPh_3 or PCy_3 ligands.[9]
[13] This situation has been observed in the oxidative addition of aryl triflates to $[Pd(PPh_3)_4]$.[11]
[14] The kinetic treatment of the curve in Figure 2, featuring the kinetics of formation of the ionic species could not be done with high accuracy, since the value of the intrinsic conductivity κ_{lim} of *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ could not be determined, due to the equilibrium (9) and to the "decomposition" process occurring at longer times. The first part of the curve ($t < 500$ s) featuring the kinetics of formation of the cationic complex *trans*-$[(PhCO)PdS(PPh_3)_2]^+$ was nevertheless analyzed after an estimation of $\kappa_{lim} = 110$ $\mu S{\cdot}cm^{-1}$ and by neglecting the reverse reaction of equilibrium (9) over short time periods. The plot of $\ln((\kappa_{lim} - \kappa)/\kappa_{lim})$ *versus* time was not a straight line (κ: conductivity at t). The first linear part of the curve ($t < 100$ s) gives a value of $k_{obs} = 0.0039$ s^{-1}, not far from the value of $k_{obs} = 0.0034$ s^{-1} determined for the oxidative addition by amperometry (see a in Figure 1).
[15] For reductive elimination in Pd^{II} complexes ligated by a carboxy group and PPh_3, see: C. Amatore, E. Carré, A. Jutand, A. M. M′Barki, G. Meyer, *Organometallics.* **1995**, *14*, 5605−5614.

[17] Acyl or arylcarboxy groups ligated to Pd^{II} complexes may be characterized by ^{31}P, ^{13}C NMR and IR spectroscopy.[6,7,9] However, our purpose was to investigate the structure of the complexes formed in the oxidative addition in the conditions of a Heck reaction, i.e., in solution in DMF. ^{13}C NMR spectroscopy cannot be performed in DMF. Moreover, since the oxidative addition was slow, a large excess of benzoic anhydride was required. The presence of DMF and benzoic anhydride in large amount excludes any characterization of the complexes formed in solution by IR spectroscopy.
[18] For a reaction of CO with cationic monoorgano-Pd^{II} complexes ligated by monodentate phosphanes, see ref.[8] and references therein.
[19] Cationic MeCO-Pd^{II} complexes formed by reaction of CO with the corresponding cationic Me-Pd^{II} complexes exhibit ^{31}P NMR signals at higher field than the starting complex, see: P. Braunstein, C. Frison, X. Morise, *Angew. Chem. Int. Ed.* **2000**, *39*, 2867−2870 and references therein.
[20] Grushin and Alper have reported that the ^{31}P NMR signal of $[(PhCO)Pd(OCOPh)(PPh_3)_2]$ synthesized in situ by reacting CO with a $[D_6]$benzene solution of $[PhPd(OCOPh)(PPh_3)_2]$ was

a singlet at δ = 18.3 ppm.[9] In our case (solvent: DMF containing 10% [D_6]acetone) the singlet of [(PhCO)Pd(OCOPh)(PPh_3)$_2$] was located at δ = 20.4 ppm. This difference is due to the solvent since we observed that the singlet of *trans*-[PhPd(OCOPh)(PPh_3)$_2$] at δ = 23 ppm in [D_6]benzene reported by Grushin and Alper[9] was located at δ = 21.6 ppm in DMF containing 10% [D_6]acetone (Table 2, entry 5).

[21] For the substitution of X by carboxylate anions in *trans*-[PhPdX_2] (X = I, Br) see the reference given in ref.[15] and I. Ishiyama, M. Murata, N. Miyaura, *J. Org. Chem.* **1995**, *60*, 7508−7510.

[22] Reaction of CO with monoorgano-Pd^{II} complexes to form acyl-Pd^{II} complexes has been widely developed and is reported to be faster with cationic complexes than with neutral complexes.[8,19]

[23] Grushin and Alper have reported the synthesis of [PhPd(OCOPh)(PPh_3)$_2$] by reacting [PhPd(μ-OCOPh)(PPh_3)]$_2$ with 2 PPh_3.[9] For its ^{31}P NMR characterization see the last part of the note in ref.[20].

Keywords: Bioinorganic chemistry / Charge-transfer complexes / Iodine / S ligands / Sulfur heterocycles

Direct reaction of thiazolidine-2-thione (tzdtH), an anti-thyroidal agent with diiodine in a molar ratio of 1:2 caused the heterolytic cleavage of diiodine and formation of $[\{(tzdtH)_2I^+\}\cdot I_3^-\cdot 2I_2]$ (**1**), whereas the reaction of benzothiazole-2-thione (bztzdtH) with diiodine in a molar ratio of 1:2 and 1:1 resulted in the formation of the $[\{(bztzdtH)I_2\}\cdot I_2]$ (**2**) and $[(bztzdtH)I_2]$ (**3**) charge-transfer (c.t.) complexes. In addition, the reaction between benzimidazole-2-thione (bzimtH) with diiodine in a molar ratio 1:2 yielded the c.t. complex $[\{(bzimtH)I_2\}_2\cdot I_2\cdot 2H_2O]$ (**4**). All reactions were carried out in dichloromethane. The molecules have been characterized by m.p., elemental analyses, and FT-Raman, FT-IR, UV/Vis and ^{1}H NMR spectroscopy. Crystal structures of the named complexes have been determined by X-ray diffraction at –103 °C (**1**), 20 °C (**2** and **3**) and –168 °C (**4**). The charge-transfer nature of the bonds of the adducts (**1**–**4**) has been verified by the lengthening of the I–I bond lengths as compared to the S–I bond lengths, by the characteristic c.t. bands observed in the UV spectra and by the shifts of frequencies measured for the I–I bond vibration in the FT-Raman spectra of the complexes. Compound **1** ($C_3H_5NS_2I_4$) is monoclinic with a space group $P2_1/n$ and a = 9.145(2) Å, b = 13.259(2) Å, c = 10.615(2) Å, β = 106.30(2)°, Z = 4. The complex is ionic, containing an S–I$^+$–S linkage and an I_3^- counter anion. Compound **2** [$C_7H_5NS_2I_4$, monoclinic, space group $P2_1/n$, a = 8.357(2) Å, b = 17.829(4) Å, c = 9.603(2) Å, Z = 4, β = 94.39(3)°] consists of a benzothiazole-2-thione ligand bonded with an iodine atom through a sulfur atom. A neutral diiodine molecule is also co-crystallized. A benzothiazole-2-thione ligand is also bonded through its sulfur atom to an iodine atom in molecule **3** [$C_7H_5NS_2I_2$, orthorhombic, space group $P2_12_12_1$, a = 4.189(1) Å, b = 9.770(3) Å, c = 27.704(8) Å, Z = 4]. Extended intramolecular N–H···I contacts link the molecules forming a supramolecular assembly. The crystal structure of **4** ($C_7H_6N_2SI_3\cdot H_2O$) reveals a monoclinic space group $P2_1/c$ and a = 13.4828(14) Å, b = 4.6704(4) Å, c = 21.267(2) Å, β = 101.029(8)°, Z = 4. It consists of a benzimidazole-2-thione ligand bonded to an iodine atom through a sulfur atom. An extended intramolecular linkage via I(2)···H(4)[C(4)] leads to the formation of dimers, while an extended hydrogen-bonding network {H(12w)[O(12)w]···N(3), O(1w)···N(3)} links the alternate parallel dimers forming a supramolecular assembly. Attempts to draw conclusions on the behavior of a thione, when used as an anti-thyroidal agent, towards diiodine have been made.

1. Introduction

Among the most widely anti-thyroidal agents used for the treatment of hyper-thyroidism (Graves' decease) over the years are thioamides such as *N*-methylimidazoline-2-thione (methimazole), 3-methyl-2-thioxo-4-imidazoline-1-carboxylate (carbimazole) and propylthiouracil.[1] Mercaptothiazoline (thiazolidine-2-thione) has also been used[1] for this purpose. Thioamides inhibit the formation of 3,5,3′-triiodothyronine (T3) and 3,5,3′,5′-tetraiodothyronine (T4) hormones by depressing the incorporation of oxidized iodides to tyrosine, a precursor of T3 and T4 hormones.[2] In addition, a good correlation between the anti-thyroid activity in vivo and the formation constants of diiodine complexes with organic bases has been found.[2c] Therefore, there is an increasing interest in the study of the charge transfer complexes of iodine with thioamides or thiones [3–18] not

only for the clarification of the iodine-binding mechanism but also for the development of new anti-thyroidal agents as well. Moreover, the sulfur−iodine charge transfer complexes have been shown to possess promising electrical properties such as superconducting ability.[14,16,19]
