27b: ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.53−1.75 (m, 2 H, PhCH$_2$CH_2), 2.44 (s, 3 H, CH_3), 2.43−2.53 (m, 2 H, PhCH_2), 4.10 (d, $^2J_{H,H}$ = 15.4 Hz, 1 H, PhCH_2N), 4.37 (ddd, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 7.7 Hz, 1 H, CHN), 4.60 (d, $^2J_{H,H}$ = 15.4 Hz, 1 H, PhCH_2N), 4.99 [ddd, $^4J_{H,H}$ = 1.1, $^2J_{H,H}$ = 1.5, $^3J_{H,H}$ = 17.3 Hz, 1 H, *anti*-(=CH_2)], 5.10 [ddd, $^4J_{H,H}$ = 1.1, $^2J_{H,H}$ = 1.5, $^3J_{H,H}$ = 10.7 Hz, 1 H, *syn*-(=CH_2)], 5.47 (ddd, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 10.7, $^3J_{H,H}$ = 17.3 Hz, 1 H, CH= CH_2), 6.78−6.84 (m, 2 H, *arom.* H), 7.08−7.21 (m, 3 H, *arom.* H), 7.24−7.35 (m, 5 H, *arom.* H), 7.38−7.45 (m, 2 H, *arom.* H), 7.70 [d, $^3J_{H,H}$ = 8.7 Hz, 2 H, *m*-(1-SO_2-4-Me-C_6H_4)] ppm. ^{13}C{^{1}H} NMR (75.48 MHz, $CDCl_3$, 25 °C): δ = 21.5 (CH_3), 32.6 (Ph*C*H$_2$), 34.1 (PhCH$_2$*C*H$_2$), 48.2 (Ph*C*H$_2$N), 60.3 [*C*H(NTs)(Bzl)], 118.6 (=CH_2), 125.7, 127.3, 127.5, 128.2, 128.3, 128.5, 128.6, 129.6 (all CH *arom.*), 135.8 (*C*H=CH_2), 138.1, 138.1, 141.6, 143.1 (s, all C *arom.*) ppm. MS (FAB): *m*/*z* (%) = 406 (60) [M^+ + H], 300 (100) [M^+ − PhCH$_2$CH$_2$], 262 (99) [M^+ − Ts]. $C_{25}H_{27}NO_2S$ (405.55): calcd. C 74.04, H 6.71, N 3.45, S 7.91; found C 74.03, H 6.74, N 3.51, S 7.76.

(5,7-Dioxa-6-phosphadibenzo[a,c]cyclohepten-6-yl)dimethylamine (L3): A mixture of 2,2′-dihydroxybiphenyl (1.00 g, 5.4 mmol), NH_4Cl (8.0 mg, 0.1 mmol) and [P(NMe_2)$_3$] (976 μL, 5.4 mmol) and toluene (15 mL) was stirred for 18 h at 80 °C and then concentrated in vacuo to give a yellow oil which was purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 98:2). Colourless oil. Yield: 29% (400 mg). ^{1}H NMR (500.13 MHz, $CDCl_3$, 25 °C): δ = 2.66 (d, $^3J_{H,P}$ = 9.4 Hz, 6 H, CH_3), 7.18 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, *arom.* H), 7.22−7.26 (m, 2 H, *arom.* H), 7.32−7.37 (m, 2 H, *arom.* H), 7.46 (br. d, $^3J_{H,H}$ = 8.0 Hz, 2 H, *arom.* H) ppm. ^{13}C{^{1}H} NMR (125.76 MHz, $CDCl_3$, 25 °C): δ = 35.9 (d, $^2J_{P,C}$ = 10.7 Hz, CH_3), 121.9 (*arom.* C), 124.5 (*arom.* C), 129.2 (*arom.* C), 129.6 (*arom.* C), 131.1 (d, $^2J_{P,C}$ = 2.8 Hz, *arom.* C), 151.5 (*arom.* C) ppm. ^{31}P NMR (202.46 MHz, $CDCl_3$, 25 °C): δ = 149.74 (s) ppm. $C_{14}H_{14}NO_2P$ (259.24): calcd. C 64.86, H 5.44, N 5.40, P 11.95; found C 64.95, H 5.37, N 5.45, P 11.91.

[IrCl(η^4-1,5-COD){(a*R*)-L2}] (29): THF (4 mL) was added to a mixture of $[IrCl(COD)]_2$ (20 mg, 0.03 mmol) and phosphorus amidite (*R*)-**L2** (21.3 mg, 0.06 mmol) at room temperature. Formation of complex **29** was observed by ^{1}H and ^{31}P NMR spectroscopy within 10 min. Recrystallization from diethyl ether furnished orange crystals of **29**. Yield: 90% (37.5 mg). ^{1}H NMR (500.13 MHz, $CDCl_3$, 25 °C): δ = 1.22−1.44 (m, 2 H, CH_2-COD), 1.74−1.84 (m, 2 H, CH_2-COD), 1.81−1.91 (m, 2 H, CH_2-COD), 1.93−2.04 (m, 1 H, CH_2-COD) 2.09−2.19 (m, 1 H, CH_2-COD), 2.20−2.30 (m, 1 H, CH-COD), 2.45−2.52 (m, 1 H, CH-COD), 2.79 (d, $^3J_{P,H}$ = 10.7 Hz, 6 H, CH_3), 3.35−3.42 (m, 1 H, CH-COD), 5.30−5.45 (m, 1 H, CH-COD), 7.27 (dd, $^3J_{H,H}$ = 8.4, $^3J_{H,H}$ = 8.7 Hz, 2 H, CH *arom.*), 7.30 (d, $^3J_{H,H}$ = 8.7 Hz, 1 H, CH *arom.*), 7.32 (d, $^3J_{H,H}$ = 8.4 Hz, 1 H, CH *arom.*) 7.42 (d, $^3J_{H,H}$ = 8.4 Hz, 1 H, CH *arom.*), 7.39−7.47 (m, 2 H, CH *arom.*), 7.89 (d, $^3J_{H,H}$ = 7.4 Hz, 1 H, CH *arom.*), 7.91 (d, $^3J_{H,H}$ = 8.7 Hz, 1 H, CH *arom.*) 7.95 (d, $^3J_{H,H}$ = 8.35 Hz, 2 H, CH *arom.*), 8.01 (d, $^3J_{H,H}$ = 9.0 Hz, 1 H, CH *arom.*) ppm. ^{13}C{^{1}H} NMR (125.77 MHz, $CDCl_3$, 25 °C): δ = 29.7 (d, $^4J_{P,C}$ = 1.9 Hz, CH_2-COD), 29.0 (d, $^4J_{P,C}$ = 2.8 Hz, CH_2-COD), 32.5 (d, $^4J_{P,C}$ = 2.8 Hz, CH_2-COD), 34.2 (d, $^4J_{P,C}$ = 3.8 Hz, CH_2-COD), 38.2 (d, $^3J_{P,C}$ = 10.36 Hz, CH_3), 52.2 (d, $^3J_{P,C}$ = 1.9 Hz, CH-COD), 55.3 (d, $^3J_{P,C}$ = 1.88 Hz, CH-COD), 102.7 (d, $^3J_{P,C}$ = 17.9 Hz, CH-COD), 103.22 (d, $^3J_{P,C}$ = 19.1 Hz, CH-COD), 121.1 (*C*H *arom.*), 122.1 (d, $^4J_{C,P}$ = 1.88 Hz, *C*-*arom.*), 122.9 (d, $^4J_{C,P}$ = 2.86 Hz, *C*-*arom.*), 123.9 (d, $^4J_{C,P}$ = 2.83 Hz, *C*H-*arom.*), 125.2,

126.1, 126.5, 126.8, 127.1, 128.3, 128.4, 129.9, 130.3 (s, all CH *arom.*), 131.0, 131.6 (both s, *C-arom.*), 132.2 (d, $^3J_{C,P}$ = 1.88 Hz, *C-arom.*), 132.5 (s, *C-arom.*), 148.4 (d, $^2J_{C,P}$ = 4.7 Hz, O*C-arom.*), 149.5 (d, $^2J_{C,P}$ = 12.9 Hz, O*C-arom.*) ppm. ^{31}P NMR (202.46 MHz, $CDCl_3$, 25 °C): δ = 116.3 (s) ppm. $C_{30}H_{30}ClIrNO_2P$ (694.4): calcd. C 51.79, H 4.35, N 2.01, P 4.46; found C 52.01, H 4.47, N 2.06, P 4.40.

[Ir(η^3-CH$_2$CHCHPh)(Cl)$_2$(η^4-1,5-COD)] (30): Cinnamyl chloride (83 μL, 91 mg, 0.596 mmol) was added to a solution of $[IrCl(COD)]_2$ (100 mg, 0.149 mmol) in THF (2 mL) and the mixture stirred for 18 h at 50 °C. A yellow precipitate of **30** was formed, which was isolated by filtration, washed with hexane and dried in vacuo. Yield: 82% (119.3 mg). A 2:1 mixture of two isomers was observed in solution at between −60 and −40 °C.

Major isomer: ^{1}H NMR (300.13 MHz, CD_2Cl_2, −60 °C): δ = 1.45−1.65 (m, 1 H, CH_2-COD), 1.65−1.83 (m, 1 H, CH_2-COD), 2.25−2.55 (m, 3 H, CH_2-COD), 2.60−3.00 (m, 2 H, CH_2-COD), 2.95−3.15 (m, 1 H, CH_2-COD), 3.72 3.87 (m, 1 H, CH-COD), 4.07 [d, $^3J_{H,H}$ = 8.8 Hz, 1 H, *anti*-(*allyl* CH_2)], 4.45 [d, $^3J_{H,H}$ = 6.8 Hz, 1 H, *syn*-(*allyl* CH_2)], 4.59−4.86 (m, 3 H, CH-COD), 4.93 [d, $^3J_{H,H}$ = 14.0 Hz, 1 H, *anti*-(*allyl* C*H*Ph)], 6.06 (ddd, $^3J_{H,H}$ = 6.8, $^3J_{H,H}$ = 8.8, $^3J_{H,H}$ = 14.0 Hz, 1 H, *allyl* CH), 7.20−7.90 (m, 5 H, -C_6H_5) ppm. ^{13}C{^{1}H} NMR (75 MHz, CD_2Cl_2, −60 °C): δ = 26.6 (CH_2-COD), 28.6 (CH_2-COD), 35.5 (CH_2-COD), 37.6 (CH_2-COD), 40.9 (*allyl* CH_2), 81.9 (CH-COD), 83.0 (CH-COD), 92.7 (CH-COD), 93.3 (CH-COD), 110.6 (*allyl* CH), 111.1 (*allyl C*HPh), 129.0, 130.3, (C_6H_5), 134.8 (C_{ipso}-C_6H_5) ppm.

Minor isomer: ^{1}H NMR (300.13 MHz, CD_2Cl_2, −60 °C): δ = 1.26−1.36 (m, 1 H, CH_2-COD), 1.45−1.65 (m, 1 H, CH_2-COD), 1.93−2.10 (m, 1 H, CH_2-COD), 2.25−2.55 (m, 2 H, CH_2-COD), 2.60−3.00 (m, 3 H, CH_2-COD), 4.13−4.26 (m, 1 H, CH-COD), 4.31−4.55 (m, 2 H, CH-COD and *allyl* CH_2), 4.59−4.86 (m, 2 H, CH-COD and *allyl* CH_2), 5.22−5.32 (m, 1 H, CH-COD), 5.55−5.74 (m, 1 H, *allyl* CH), 6.33 [d, $^3J_{H,H}$ = 14.1 Hz, 1 H, *anti*-(*allyl* C*H*Ph)], 7.20−7.90 (m, 5 H, -C_6H_5) ppm. ^{13}C{^{1}H} NMR (75 MHz, CD_2Cl_2, −60 °C): δ = 27.0 (CH_2-COD), 28.8 (CH_2-COD), 33.6 (CH_2-COD), 37.9 (CH_2-COD), 42.6 (*allyl* CH_2), 80.8 (CH-COD), 81.7(CH-COD) 89.4 (CH-COD), 92.6 (CH- COD), 102.2 (*allyl* CH), 123.0 (*allyl C*HPh), 128.5, 128.9, 130.8 (C_6H_5), 147.6 (C_{ipso}-C_6H_5) ppm. $C_{17}H_{21}Cl_2Ir$ (488.52): calcd. C 41.80, H 4.34; found C 41.84, H 4.37.

[Ir(Br)$_2$(η^3-C$_3$H$_5$)(η^4-1,5-COD)] (31). Method A: A solution of $[IrCl(COD)]_2$ (50 mg, 0.07 mmol) and allyl bromide (28.6 μL, 36.0 mg, 0.3 mmol) in THF (1 mL) was stirred for 18 h at 50 °C. A yellow precipitate of **31** formed which was washed with diethyl ether and recrystallised from dichloromethane/pentane. Yield: 81% (60 mg).

Method B: $[IrCl(COD)]_2$ (150 mg, 0.2 mmol) was treated with an excess of *anhydrous* LiBr (155.1 mg, 1.8 mmol) in acetone (15 mL). After stirring for 18 h, the solvent was removed under vacuum and the product $[IrBr(COD)]_2$ extracted three times with dichloromethane. Removal of the solvent gave an orange oil which was further treated with allyl bromide (57 μL, 79.8 mg, 0.7 mmol). After 18 h, a crystalline yellow precipitate had formed, which was isolated by filtration and washed with diethyl ether. Yield: 66% (145 mg). NMR spectroscopy at −60 °C showed a 9:1 mixture of two isomers.

Major isomer: ^{1}H NMR (500.13 MHz, CD_2Cl_2, −60 °C): δ = 1.46−1.59 (m, 1 H, CH_2-COD), 1.75−1.88 (m, 1 H, CH_2-COD), 2.23−2.35 (m, 1 H, CH_2-COD), 2.40−2.50 (m, 1 H, CH_2-COD), 2.50−2.61 (m, 1 H, CH_2-COD), 2.60−2.72 (m, 1 H, CH_2-COD), 3.00−3.10 (m, 1 H, CH_2-COD), 3.12 [d, $^3J_{H,H}$ = 13.3 Hz, 1 H, *anti*-(*allyl* CH_2)], 3.22−3.34 (m, 1 H, CH_2-COD), 3.33−3.41 (m, 1 H, CH-COD), 3.83 [d, $^3J_{H,H}$ = 10.0 Hz, 1 H, *anti*-(*allyl* CH_2)], 4.48 [d, $^3J_{H,H}$ = 6.7 Hz, 1 H, *syn*-(*allyl* CH_2)], 4.75−4.84 (m, 1 H, CH-COD), 4.93 [d, $^3J_{H,H}$ = 8.7 Hz, 1 H, *syn*-(*allyl* CH_2)], 4.95−5.03 (m, 1 H, CH-COD), 5.10−5.17 (m, 1 H, CH-COD), 5.74−5.87 (m, 1H. *allyl* CH) ppm. ^{13}C{^{1}H} NMR (125.76 MHz, CD_2Cl_2, −60 °C): δ = 26.4, 27.2, 36.4, 37.1 (all CH_2-COD), 44.6 (*allyl* CH_2), 83.2, 85.5 (both CH-COD), 79.7 (*allyl* CH_2), 91.8, 92.7 (both CH-COD), 114.5 (*allyl* CH) ppm.

Table 9. Crystal data and details of the structure refinement for compounds **12**, **29**, **30**, and **31**

Minor isomer: ^{1}H NMR (500.13 MHz, CD_2Cl_2, −60 °C): δ = 1.09−1.20 (m, 1 H, CH_2-COD), 1.57−1.67 (m, 1 H, CH_2-COD), 2.11−2.20 (m, 1 H, CH_2-COD), 2.24−2.35 (m, 1 H, CH_2-COD), 2.40−2.50 (m, 1 H, CH_2-COD), 2.69−2.79 (m, 1 H, CH_2-COD), 2.93−3.00 (m, 1 H, CH_2-COD), 3.00−3.10 (m, 1 H, CH_2-COD), 4.23−4.30 (m, 1 H, CH-COD), 4.62−4.70 (m, 3 H, CH-COD and *allyl* CH_2), 4.75−4.84 (m, 1 H, CH-COD), 4.90−4.97 (m, 1 H, *allyl* CH), 5.20−5.30 (m, 2 H, *allyl* CH_2), 5.58−5.63 (m, 1 H, CH-COD) ppm. $^{13}C\{^1H\}$ NMR (125.76 MHz, CD_2Cl_2, −60 °C): δ = 26.7, 27.2, 35.3, 37.7 (all CH_2-COD), 44.9 (*allyl* CH_2), 83.6, 85.4, 87.1 (all CH-COD), 89.6 (*allyl* CH_2), 93.9 (both CH-COD), 107.9 (*allyl* CH) ppm. $C_{11}H_{17}Br_2Ir$ (501.28): calcd. C 26.36, H 3.42; found C 26.30, H 3.56.

Stoichiometric Reaction of Complex 30 with Dimethyl 2-Sodiomalonate in the Presence of (*R*)-L2: A 0.24 M solution of $NaCH(CO_2Me)_2$ (0.4 mL, 0.1 mmol) in THF was syringed into a Schlenk tube and the solvent was removed under vacuum. To the residual white solid were added complex **30** (49.9 mg, 0.1 mmol) and the stoichiometric quantity of ligand (*R*)-**L2** (36.2 mg, 0.1 mmol), then $[D_8]THF/CD_2Cl_2$ (2:1; 1.5 mL) was added at −78 °C. The mixture was stirred for a few minutes at this temperature to give a clear light yellow solution that was transferred into a pre-cooled (−60 °C) NMR tube. The ^{1}H and ^{31}P NMR spectra of this solution, recorded at −60 °C, showed complete reaction to give exclusively a 1:1 mixture of *rac*-**3a** and complex **29** which were separated by flash column chromatography (silica gel, hexane/diethyl ether 9:1). Yield: 64% (16 mg) of **3a** (purity > 99% by GCMS) and 32% (22.6 mg) of **29** as orange crystals.

X-ray Crystallographic Studies: Crystals of compound **12** were obtained as needles by slow evaporation of solvent from a saturated solution in ethyl acetate. Single crystals of complex **29** were grown as orange needles by slow concentration of a saturated solution in diethyl ether. Single crystals of complexes **30** and **31** were grown, both as yellow needles, by slow diffusion of diethyl ether into a saturated solution in dichloromethane.

The measurements were made on a Bruker SMART-CCD diffractometer with graphite monochromated Mo-K_α radiation (0.71073 Å) at 200 K. Frames corresponding to a sphere of data were collected. 20 s exposures of 0.3 degree scans in omega were taken. An absorption correction was applied using SADABS (G. M. Sheldrick, SADABS, Bruker AXS, Inc.: Madison, WI, 1996) based on the laue symmetry of the reciprocal space. The structures were solved by direct methods and expanded using Fourier techniques. All non-hydrogen atoms were refined with anisotropic displacement parameters, most hydrogen atoms could be located in the Fourier map, in **12** all hydrogens were refined isotropically, in **29** and **30** only the allylic hydrogens and the olefinic hydrogens of the COD were refined isotropically, in **30** the allylic hydrogens were not included in the structure model due to the disorder, all the rest of the hydrogen atoms was taken into account at calculated positions. The full-matrix least-squares refinement against F^2 converged. All calculations were performed using the SHELXTL crystallographic software package of Bruker (G. M. Sheldrick, SHELXTL V5.10, Bruker AXS, Inc.: Madison, WI, 1997). For details and crystal data see Table 9.
CCDC-181254 (**12**), -181255 (**29**), -181256 (**30**) and -181257 (**31**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk)

Isomerically Pure α_1-Monosubstituted Tungstodiphosphates: Synthesis, Characterization and Stability in Aqueous Solutions

Roland Contant,[b] Martine Richet,[b] Yu Wei Lu,[a] Bineta Keita,[a] and Louis Nadjo*[a]

Keywords: Polyanions / Phosphates / Tungsten

Isomerically pure samples of α_1-$P_2W_{17}O_{61}M$ were prepared, in which M represents Ca^{II} and mainly the first-row transition metal cations: Mn^{II}, Fe^{III}, Co^{II}, Ni^{II}, Cu^{II}, Zn^{II}. The formula is α_1-$P_2W_{17}O_{62}M$ for V^{V} and Mo^{VI}. The compounds were characterised by elemental analysis, IR, UV/Vis and ^{31}P NMR spectroscopy. The stability of these complexes was monitored by cyclic voltammetry and/or UV/Vis spectroscopy. All the compounds proved to be stable for at least 24 h in a pH = 3 medium, even in the presence of 0.2 M Na^+, except for the precursor lacunary species itself and the Ca^{II}-substituted derivative. In this medium, the transformation of the lacunary heteropolyanion yielded a mixture of α-$[P_2W_{18}O_{62}]^{6-}$ and $[H_2P_2W_{12}]^{12-}$. The same species were obtained, but at a much slower rate, through the decomposition of α_1-$P_2W_{17}O_{61}Ca$. This difference in stability between the lacunary and the Ca^{II}-substituted derivatives might be ascribed to size and charge effects, along with the rigidity of the vacant site. At pH = 5, the final product of the transformation of α_1-$[P_2W_{17}O_{61}]^{10-}$ is α_2-$[P_2W_{17}O_{61}]^{10-}$. The presence of Li^+ appears to be more favourable than Na^+ for the stability of these complexes.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

It is well established that numerous electrocatalytic processes can be triggered by heteropolyanions (HPA).[1] Specifically, sustained catalytic several-electron reduction processes demand that the necessary number of electrons be accumulated in the framework of the HPA and then delivered to the substrate in potential regions where neither structure change of the HPA nor derivatisation of the electrode might occur.[1d,2] In our continuing efforts to systematically examine the parameters and combinations of parameters that could favour or counteract the merging of the first several waves in the electrochemical study of heteropolyanions, two main parameters were identified. The pH of the solution is one obvious parameter, which can be combined successfully with the second parameter, namely substitution effects, to reveal the rich redox behaviour of HPAs.[3−5] This last parameter is particularly important because it will determine, at least in part, the stability domain of the substituted HPA. Furthermore, the location of the heterometal in the framework and the nature and the number of the substituents are likely to influence the interactions between the electroactive centres in the molecule. In this context, our present efforts are aimed at illustrating such ideas with compounds of the Dawson series. It can be recalled that the Dawson structure is an elongated ellipsoid that consists of six addenda atoms of one kind and twelve of another. The six metal atoms are assembled in two groups of edge-shared M_3O_{13} octahedra that occupy the two "polar" positions of the ellipsoid; the remaining twelve metal atoms form two rings of six alternately edge- and corner-shared MO_6 octahedra in what is usually termed the equatorial position. The metal atoms in the "cap" occupy what is termed α_2-positions and those in the "belt" α_1-positions. With regard to the α_2-series, the synthesis involved first-row transition metal ion substituted complexes[4] derived from $[(1,)2,3\text{-}P_2Mo_2W_{15}O_{61}]^{10-}$. Among other remarkable results, the electrochemistry of this series of compounds shows that the interplay of the pH effect facilitates the build-up of an overall three-electron process on the first wave of the Fe^{III}-substituted complex.[4a,6] Another, possibly complementary direction involves positional isomerism. Perusal of the literature on simple Dawson-type tungstodiphosphates reveals that the α_2-isomer and its substituted derivatives were the preferred,[5] owing presumably to the instability of lacunary α_1-$[P_2W_{17}O_{61}]^{10-}$ which isomerises easily to the α_2-form[7] and reconstitutes the parent $[P_2W_{18}O_{62}]^{6-}$. However, we have succeeded in obtaining previously pure samples of several compounds of the α_1-series.[6]

The aim of the present paper is to describe the synthesis and characterisation of pure samples of the lacunary and

first-row transition metal ion substituted compounds of the α_1-series. In particular, their transformation in solution as a function of pH and time were monitored by cyclic voltammetry and/or UV/Vis spectroscopy. The interplay of ion-pairing remains a subject of interest,[8] and is obvious in several instances below. In a preceding paper[6c] devoted to the electrochemistry of these compounds and based on the present syntheses, we have demonstrated, by cyclic voltammetry, the successful synthesis of these metal ion substituted derivatives from the α_1-lacunary species. Thus, the conditions under which α_1-$[P_2W_{17}O_{61}]^{10-}$ is fairly stable could be determined. The metal cation substituted derivatives of α_1-$[P_2W_{17}O_{61}]^{10-}$ could then be obtained and studied. Further, in a pH = 3 medium, a characteristic fingerprint for the α_2-series has been found that allows us to distinguish them unequivocally from the corresponding α_1-isomers.[6c] Here, the details of the syntheses are given, with a full characterisation by elemental analysis, ^{31}P NMR, UV/Vis and IR spectroscopy. A further incentive for this work stems from the desire to study the influence of positional isomerism on the redox properties. It has been proposed,[9a][9b] and experimental evidence supports [8c] the fact that α-P_2W_{18} is initially reduced at one of the twelve equivalent tungsten atoms. Substitution in the α_1-position should then markedly influence electron transfer processes relative to the α_2-series.

^{31}P NMR Spectroscopy

In the following, the oxygen atoms and the negative charges are omitted when no confusion is possible.The following species, α-$[P_2W_{18}O_{62}]^{6-}$, α_1-$[P_2W_{17}O_{61}]^{10-}$, and α_2-$[P_2W_{17}O_{61}]^{10-}$, will be abbreviated as α-P_2W_{18}, α_1-P_2W_{17}, and α_2-P_2W_{17}, respectively.

Table 1 presents the ^{31}P NMR spectroscopic features obtained in the present work for α_1- and α_2-derivatives. Jorris et al.[10] have published ^{31}P NMR spectroscopic data on some compounds of the same families. Their results were confirmed, under slightly different experimental conditions, by Finke et al.[5b] on derivatives of the α_2-series. More recently, Francesconi et al.[7a] have published the data pertaining to the lithium salt of α_1-P_2W_{17} and to several other lanthanide complexes of this lacunary species. To the best of our knowledge, Jorris et al.[10] were the first to study the NMR spectroscopic behaviour of paramagnetic element containing HPAs of P_2W_{17} derivatives. Even though their syntheses resulted in mixtures of α_1- and α_2-isomers, their pioneering work constitutes a valuable basis for the interpretation of the present observations. In these complexes, it is convenient to designate the phosphorus atom nearer the substituent (eventually paramagnetic ion) as P(1), and the phosphorus atom further away from this element as P(2). From the ^{31}P NMR spectra of several Dawson structures substituted in the α_2-position, it can be seen that the chemical shift assigned to P(2) is practically unaffected by the nature of the substituent element. The only exception is when Co^{II} is the substituent. Such an observation is confirmed in Table 1. Provisionally, it is worth mentioning that the same observation (with the same exception) was also made for compounds of the $K_8P_2W_{15}Mo_2MO_{61}$ series, where M represents the divalent substituent cation.[4b] Table 1 shows that the same conclusions remain true for the chemical shifts assigned to P(2) in the α_1-$P_2W_{17}M$ derivatives, with the exceptions also extended to cases where M is Ni^{II} and Mn^{II}. As expected, the signal assigned to the P atom closest to the substitution site is shifted downfield considerably in the presence of paramagnetic cations. The shift is larger for α_1-derivatives. The ^{31}P NMR line widths depend on the nature of the particular substituent atom, and especially on its electronic ground state configuration. Usually, as can be seen in Table 1, very narrow or relatively narrow signals are observed for P(2), in contrast to that observed for the P(1) signal, which becomes exceedingly broadened in the case of the Mn^{II} derivative, whose ground state is orbitally nondegenerate. As a whole, it can be considered that satisfactory agreement with the observations of Jorris et al.,[9] and other literature results, [5b][7a] is obtained in the present work, provided the difference in medium composition is taken into account. The same reasoning is also applied to the interpretation of the spectra of the Mg^{II}-, Ca^{II}- and Cu^{II}-substituted derivatives. From the electronic configurations of Mg^{II} and Ca^{II}, no dramatic chemical shifts are expected for either P(2) or P(1) compared with those observed in the diamagnetic Zn^{II} isomorphs. The results in Table 1 validate this reasoning. In contrast, Cu^{II} is a paramagnetic d^9 ion that has a dramatic effect on the observed chemical shift, as expected.

IR Spectroscopy

The characteristic IR peaks were recorded. The assignments were made by taking into account those established in the literature.[11] As in related studies,[6a] introduction of a substituent metal cation in the vacancy basically restores the symmetry of the PO_4 tetrahedron, at least as far as the IR spectra are concerned. Consequently, the IR spectra are very similar from one complex to the next, thus preventing any reliable identification of a given anion. However, it is worth noting that the peak assigned to the $P-O_a-W$ vibration, where W is one of the "belt" atoms, is not observed in the Co^{II} and Ni^{II} derivatives.

Stability of α_1-P_2W_{17} and Its Substituted Derivatives: Electrochemistry and UV/Vis Spectroscopy

A constant observation in the transformation of α-P_2W_{18} as a function of pH and time, is that the nature of the resulting species depends strongly on the pH of the solution and on the identity and concentrations of the cations present in the solution.[9] Such a dependence is also expected in the cases of interest here. The evolution of α_1-P_2W_{17} is monitored by cyclic voltammetry at pH = 3 and 5. The

[a] From ref.[7a] [b] From ref.[10]

voltammograms are limited to the first several waves spanning the potential region in which no derivatisation of the electrode surface is encountered.[3n] These waves appear to serve as sufficiently clear fingerprints for the various compounds. The stability of the substituted derivatives was studied by UV/Vis spectroscopy, complemented by cyclic voltammetry when necessary. A sodium medium was selected for a detailed study, since the presence of this cation gives an intermediate rate of transformation, suitable for correct monitoring by cyclic voltammetry.

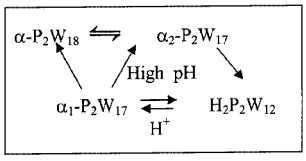
Cyclic Voltammetric Monitoring of α_1-P_2W_{17} at pH = 3 and 5 in an Na^+ Medium

Table 2 summarises the evolution of the main observed cathodic peak potentials as a function of time. The significance of these values is indicated below.

Table 2. Evolution of the reduction peak potentials of the first three waves of $\alpha_1P_2W_{17}$ as a function of pH and time; for the compositions of the electrolytes and other details, see text

Duration/h	$-E_{p1}$/mV	pH = 3 $-E_{p2}$/mV	$-E_{p3}$/mV
0	310	580	925
168	30 and 210	635	902
		pH = 5	
0	500	656	1042
72	530	658	922

At pH = 3, the first three waves, run on a freshly prepared solution of α_1-P_2W_{17}, are initially considered. After a period of 2 h, transformation is already significant: the cathodic peak current intensity of the first wave decreases to 75% of its initial value; concomitantly, two new waves appear and begin to grow at a more positive potential than that observed for the former initial first wave. The initial first wave completely disappears after 26 h, after which the cyclic voltammogram remains practically the same and is composed of a four-wave system. The transformation scheme, as a function of pH, established previously for α-P_2W_{18} by Contant and Ciabrini[5k,12] and sketched in Scheme 1, is very helpful for identifying the possible species responsible for the observed voltammogram and for their quantitative determination.



Scheme 1. Decomposition pathways of α_1-P_2W_{17}

The cyclic voltammograms of authentic samples of α-P_2W_{18} and P_2W_{12} are superimposed in Figure 1 (A). Key to the identification of the decomposition products is the observation that the single wave of P_2W_{12} in the explored potential region appears to be very close to the third wave of α-P_2W_{18} in Figure 1 (A). As a result, when a cyclic voltammogram is run on a sample of a mixture of the two species, the third wave is broad and composite, and is clearly different to the third wave observed in the voltammogram of α-P_2W_{18} alone.

Based on the cyclic voltammograms of these authentic samples of α-P_2W_{18} and P_2W_{12}, the decomposition pathways of α_1-P_2W_{17} could be described quantitatively in Figure 1 (B and C), which also shows a representative selection of the cyclic voltammograms of the mixture. It is assumed when calculating the percentages of the various species that

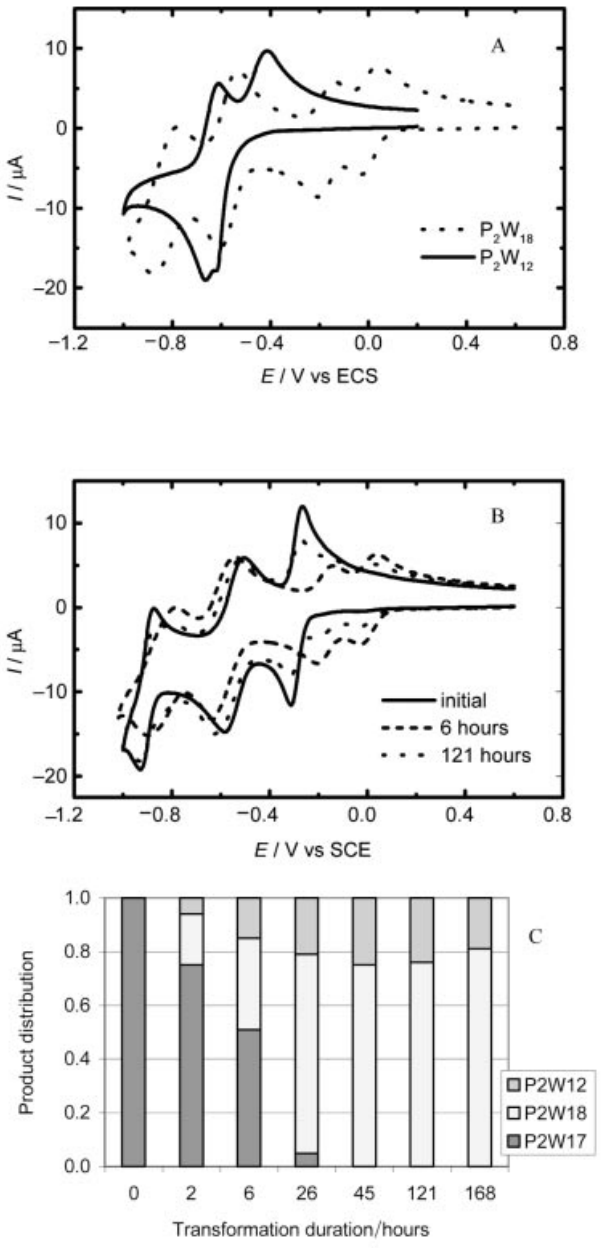


Figure 1. Identification of the decomposition pathway of α_1-P_2W_{17} in a pH = 3 medium (0.2 M Na_2SO_4 + H_2SO_4); (A) Cyclic voltammograms of authentic samples of α-P_2W_{18} and P_2W_{12}; (B) selection of representative cyclic voltammograms of α_1-P_2W_{17}, as a function of time; (C) electroactive products distribution, as a function of transformation duration; for further details, see text

only negligibly small amounts of possible non-electroactive species might exist in the mixture. Finally, the solution obtained after completion of the transformation of α_1-P_2W_{17} at pH = 3 contains α-P_2W_{18} and P_2W_{12}. This is in agreement with previous work.

Parallel experiments were performed at pH = 5 in sodium acetate buffer. The initial cyclic voltammogram is restricted to the three redox peaks observed between +0.6 and −1.1 V; the last two waves are composite. The initial and final reduction peak potential values are presented in Table 2. Cyclic voltammetry reveals that after only a few minutes the formation of the first two waves of α-P_2W_{18} can be seen, while the initial wave system is only slightly different, except for current intensities. However, after standing for 72 h, the waves of α-P_2W_{18} have completely disappeared and a new voltammetric pattern is observed, which can be ascribed to a pure electroactive product. Comparison of the cyclic voltammogram of α_2-P_2W_{17} with that obtained after completion of the transformation of α_1-P_2W_{17} at pH = 5, indicates unambiguously that α_1-P_2W_{17} is initially converted into a mixture of α_2-P_2W_{17} and α-P_2W_{18}, and that the final product at pH = 5 is pure α_2-P_2W_{17}.

The cyclic voltammetric monitoring of the species appearing in solution has allowed for the clarification of the transformation pathways of α_1-P_2W_{17} at pH = 3 and 5, as sketched in Scheme 1. Qualitatively, it is worth noting that the transformations are much slower at pH = 3 than at pH = 5.

Study of the Stability of α_1-$P_2W_{17}M$ Complexes (M = Ca^{II}, V^{V}, Mn^{II}, Fe^{II}, Co^{II}, Ni^{II}, Cu^{II}, Zn^{II} and Mo^{VI})

A sodium sulfate solution at pH = 3 was selected as the medium for this study. For each complex, the concentration in solution was approximately 2×10^{-5} M, and two spectra were run with the same sample with a time interval of 24 h. All the spectra are relatively featureless, almost identical to each other, and show a shoulder. The characteristic features are presented in Table 3. Not unexpectedly, large magnification of the absorbance scale indicates differences in the onsets of the absorption spectra.

On careful comparison of the spectra, only two complexes are not completely stable after 24 h in the pH = 3 medium: α_1-P_2W_{17} and α_1-$P_2W_{17}Ca$. The corresponding spectra can be seen in Figures 2 and 3. For the lacunary species, this observation is in agreement with the results of the cyclic voltammetric study. Provisionally, we note the close similarity between the spectra of the two complexes after 24 h at pH = 3, which could suggest similar transformation pathways for them. Therefore, a complementary voltammetric examination of α_1-$P_2W_{17}Ca$ as a function of time was carried out. In the sodium sulfate medium at pH = 3, and as observed for other complexes in the previous section, the relevant cyclic voltammogram consists of

three chemically reversible waves. Their cathodic peak potentials are at − 0.320, − 0.570 and − 0.916 V. Figure 4 shows the cyclic voltammograms of α_1-$P_2W_{17}Ca$. Comparison of the voltammograms obtained after 15 d with that of α_1-P_2W_{17} after 7 d indicates that α-P_2W_{18} and P_2W_{12} are indeed the transformation products of α_1-$P_2W_{17}Ca$. However, the transformation is distinctly slower in the case of the latter complex; for instance, the transformation of α_1-P_2W_{17} gives 73% α-P_2W_{18} after 26 h, while the percentage obtained from α_1-$P_2W_{17}Ca$ after 15 d is only 67%. These observations agree with the previously discussed trends[4,6b] involving the cyclic voltammograms associated with the tungsten framework in monosubstituted Dawson heteropolyanions. It has been demonstrated that appropriate comparisons among cyclic voltammograms involve those of

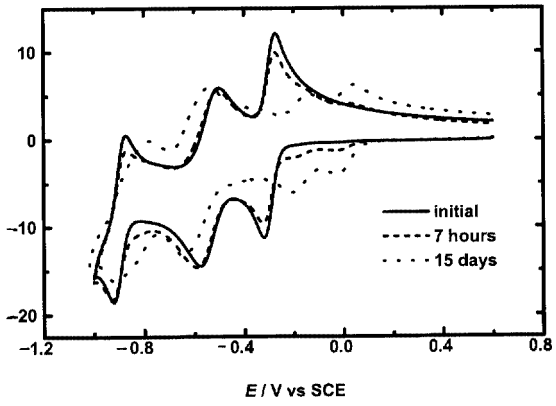

Figure 4. Selection of representative cyclic voltammograms observed during the transformation of α_1-$P_2W_{17}Ca$ in a pH = 3 medium (0.2 M Na_2SO_4 + H_2SO_4); for further details, see text

the monosubstituted species with that of the precursor lacunary complex, except for the cases of substitution by $Mo^{6+/5+}$ and $V^{5+/4+}$. Looking at the present example which is particularly remarkable, it can readily be seen that the reduction peak potentials of the Ca^{II}-substituted complex are very similar to the corresponding ones of the lacunary species. The following rationale, based on the respective charges of Na^+ and Ca^{2+}, can also be used to explain the greater stability of α_1-$P_2W_{17}Ca$ than α_1-P_2W_{17}. On dissolution of α_1-P_2W_{17} (α_1-$LiK_9P_2W_{17}O_{61}$) in 0.2 M Na_2SO_4 + H_2SO_4 (pH = 3), the relatively fast replacement of Li^+ by Na^+ might be favoured by the large concentration of the latter, which is known to be deleterious to the stability of the complex. Owing to the difference in charge, the corresponding replacement of Ca^{2+} by Na^+ is much slower for α_1-$P_2W_{17}Ca$, even though the two cations have approximately the same radius. In other words, the local negative charge of the vacancy is better compensated by Ca^{2+} which is therefore, more difficult to displace than Li^+.

A study was also carried out to compare the stability of α_1-$P_2W_{17}Ca$ in Li^+ (0.2 M Li_2SO_4/H^+, pH = 3) and Na^+ media. The transformation is slower in the presence of lithium, quantified by a percentage of 43% decomposition in Li^+ medium compared with 63% in Na^+ medium after 2 d. Thus, it appears that the relative stability of α_2-$P_2W_{17}Ca$ and α_1-$P_2W_{17}Ca$ might be explained in terms of steric reasons,[5k,6,13] but in combination with the effect of the charge of the substituent cation. It should be noted that the ideal size for a cation to fit in the vacancy should be very similar to the usually accepted size of W^{6+} ion (0.74 Å). The radii of Ca^{2+} (1.14 Å) and Na^+ (1.16 Å) collected from the literature[14] are similar, but are larger than that of W^{6+} (0.74 Å); hence the relative order of the stabilities of the corresponding species. However, the charge of the substituent cation also plays a part as discussed previously. For a further confirmation of this size hypothesis, Mg^{2+} (0.86 Å), which has the same charge but a smaller radius than Ca^{2+}, was selected for comparison with the latter. In the sodium solution at pH = 3, α_1-$P_2W_{17}Mg$ is remarkably more stable than α_1-$P_2W_{17}Ca$. This observation gives further support to the preceding assumptions. Another aspect of the steric effect must be traced to the location of the vacancy in the α_1- or α_2-position in the tungsten framework.[5k,6,13] The vacancy is distinctly more rigid in the α_1- than in the α_2-position. Therefore, the deformability of the latter vacancy makes it larger and favours the accommodation of a large cation. As a result, it is expected that α_2-$P_2W_{17}Ca$ is more stable than α_1-$P_2W_{17}Ca$. The test in the sodium medium at pH = 3 confirms the hypothesis. The decomposition of α_2-$P_2W_{17}Ca$ begins after 4 d compared with 7 h for α_1-$P_2W_{17}Ca$. After a period of 15 d, the percentage of α-P_2W_{18} formed from α_2-$P_2W_{17}Ca$ is only 20%.

Concluding Remarks

One of the aims of this work is to further investigate the parameters that could influence electron transfer processes

involving the first wave of heteropolyanions and, eventually, favour the apparently simultaneous uptake of several electrons. Positional isomerism is likely to be one of these parameters. It has been proposed, and experimental evidence supports the fact that α-P_2W_{18} is initially reduced at one of the twelve equivalent tungsten atoms. With the assumption that this behaviour remains valid in substituted compounds, substitution in the α_1-position should markedly influence electron transfer processes compared with the α_2-series. Conditions were found in which the lacunary ligand α_1-$[P_2W_{17}O_{61}]^{10-}$ is fairly stable. This result was achieved through the use of AcOLi for the dissolution of the complex, or by taking advantage of the favourable kinetics of addition vs. degradation when the solid lacunary HPA was added to a solution of the salt of the substituent cation. Its metal cation-substituted derivatives could then be obtained and studied. To the best of our knowledge, this work constitutes the first systematic synthesis and study of first-row transition metal cation monosubstituted complexes of the α_1-lacunary ligand. ^{31}P NMR spectroscopy and cyclic voltammetry were used to demonstrate the successful synthesis of these species. Their stability was monitored in pH = 3 and 5 media by cyclic voltammetry and UV/Vis spectroscopy. It is worth noting that even the relatively labile α_1-P_2W_{17} and α_1-$P_2W_{17}Ca$ are sufficiently stable to permit NMR spectroscopic and electrochemical characterisations. Relevant comparisons with the same derivatives in the α_2-series were carried out.

Experimental Section

Preparation: The potassium salts of α-$[P_2W_{18}O_{62}]^{6-}$, α_1-$[P_2W_{17}O_{61}]^{10-}$ and α_2-$[P_2W_{17}O_{61}]^{10-}$ were prepared by published methods.[5a] The compounds of the α_2-series have received extensive attention and their syntheses will not be described further.[5] In the α_1-series, the synthesis of Fe^{III}-substituted derivatives was described in detail previously.[6a] The synthesis of Mo- and V-substituted compounds were also described previously by one of the present authors.[5k−5m,7b,8c] The water contents were measured by gravimetric methods. Elemental analyses were performed by the Laboratoire Central d'Analyse of CNRS (Vernaison, France) and checked, except for the metallic cations, by standard methods.[6a] The precision of these analyses is not excellent, as is not unusual in the literature on polyoxometalates.

$\alpha_1K_8P_2W_{17}ZnO_{61}$, 16 H_2O: A sample of $\alpha_1K_9LiP_2W_{17}O_{61}$, 18 H_2O (10 g) was dissolved in 100 mL of acetate buffer at pH = 4.7, 0.5 M in lithium acetate AcOLi. The solution was not perfectly clear. $Zn(NO_3)_2$ (3 mL of a 1 M solution) was added whilst stirring. The solution was filtered through an ashless pleated filter and left to settle. The clear part of the solution (70 mL) was collected and treated with KCl (7 g). The precipitate was filtered, washed with ethanol and diethyl ether and air-dried; recovered: 7.5 g; yield: 75%. $\alpha_1K_8P_2W_{17}ZnO_{61}$, 16 H_2O (4830): calcd. K 6.48, P 1.28, Zn 1.35, W 64.71, H_2O 5.60; found K 6.70, P 1.24, Zn 1.25, W 62.60, H_2O 5.55.

$\alpha_1K_8P_2W_{17}MgO_{61}$, 17 H_2O: $Mg(NO_3)_2$ (5 mL of a 1 M solution) was added to 100 mL of water. $\alpha_1K_9LiP_2W_{17}O_{61}$, 18 H_2O (10 g) was then added whilst stirring, and the solution was filtered if necessary. The clear solution was treated with KCl (10 g) to obtain a white precipitate. The precipitate was filtered, washed with ethanol and diethyl ether and air-dried. Note that the same result could be obtained by starting with $MgCl_2$ instead of the nitrate; recovered: 7.9 g; yield: 80%. $\alpha_1K_8P_2W_{17}MgO_{61}$, 17 H_2O (4807): calcd. K 6.51, P 1.29, Mg 0.51, W 65.02, H_2O 6.00; found K 6.68, P 1.28, Mg 0.48, W 64.20, H_2O 6.02.

$\alpha_1K_8P_2W_{17}CaO_{61}$, 19 H_2O: The synthesis is the same as that of the Mg^{2+} derivative. The magnesium salt is replaced by $Ca(NO_3)_2$; recovered: 8.0 g; yield: 80%. $\alpha_1K_8P_2W_{17}CaO_{61}$, 19 H_2O (4877): calcd. K 6.41, P 1.27, Ca 0.82, W 64.09, H_2O 7.02; found K 6.60, P 1.24, Ca 0.79, W 62.67, H_2O 6.98.

$\alpha_1K_8P_2W_{17}NiO_{61}$, 16 H_2O: Ni^{2+} (2 mL of a 1 M $Ni(NO_3)_2$ solution) was added to LiCl (50 mL of a 0.2 M solution). $\alpha_1K_9LiP_2W_{17}O_{61}$, 18 H_2O (5 g) was then added whilst stirring, and the solution was filtered if necessary. The clear solution was treated with 30 mL of a saturated KCl solution. The precipitate was filtered, washed with ethanol and diethyl ether and air-dried. The same synthesis could be carried out in an acetate buffer containing 0.5 M AcOLi; recovered: 3.7 g; yield: 75%. $\alpha_1K_8P_2W_{17}NiO_{61}$, 16 H_2O (4823): calcd. K 6.49, P 1.28, Ni 1.22, W 64.80, H_2O 5.60; found K 6.74, P 1.25, Ni 1.25, W 62.42, H_2O 5.75.

$\alpha_1K_8P_2W_{17}CoO_{61}$, 16 H_2O: The synthesis is the same as that of the Zn^{2+} derivative; recovered: 7.5 g; yield: 75%. $\alpha_1K_8P_2W_{17}CoO_{61}$, 16 H_2O (4823): calcd. K 6.48, P 1.28, Co 1.22, W 64.80, H_2O 5.60; found K 6.75, P 1.24, Co 1.13, W 63.83, H_2O 5.71.

$\alpha_1K_8P_2W_{17}MnO_{61}$, 15 H_2O: A sample of $\alpha_1K_9LiP_2W_{17}O_{61}$, 18 H_2O (10 g) was dissolved in 100 mL of acetate buffer pH = 4.7, 0.5 M in lithium acetate AcOLi. The solution was not perfectly clear. Mn^{2+} (1.87 mL of a 1.6 M solution) was then added whilst stirring. The solution was filtered through an ashless pleated filter and left to settle. The clear part of the solution was collected and treated with KCl (10 g). The precipitate was filtered, washed with ethanol and diethyl ether and air-dried; recovered: 8.0 g; yield: 85%. $\alpha_1K_8P_2W_{17}MnO_{61}$, 15 H_2O (4819): calcd. K 6.51, P 1.29, Mn 1.14, W 65.09, H_2O 5.25; found K 6.53, P 1.24, Mn 1.13, W 64.01, H_2O 5.44.

$\alpha_1K_8P_2W_{17}CuO_{61}$, 19 H_2O: The synthesis is the same as that of the Zn^{2+} derivative; recovered: 7.5 g; yield: 75%. $\alpha_1K_8P_2W_{17}CuO_{61}$, 19 H_2O (4882): calcd. K 5.41, P 1.27, Cu 1.30, W 64.02, H_2O 6.64; found K 6.50, P 1.21, Cu 1.36, W 61.14, H_2O 6.65.

NMR, IR and UV/Vis Measurements: ^{31}P NMR spectra were recorded using a Bruker VM 250 apparatus operating at 101.2 MHz, in the Fourier transform mode. The ^{31}P chemical shifts were measured on 0.02 M solutions of the polyanions in aqueous 0.5 M LiCl (50% D_2O) solutions, and were referenced to external 85% H_3PO_4 by the substitution method. IR spectra were recorded with a Bio-Rad FTS 165 FTIR spectrophotometer. UV/Vis spectra were recorded with a Perkin−Elmer Lambda 19 spectrophotometer.

Electrochemical Experiments. Chemicals, Equipment and Apparatus: Pure water was used throughout. It was obtained by passing it through a Milli-RO_4 unit and subsequently through a Millipore Q water purification set. All the chemicals were of high-purity grade and were used as received. H_2SO_4 and Na_2SO_4 were commercial products (Prolabo). The pH = 3 electrolyte was usually made up of 0.2 M Na_2SO_4 + H_2SO_4, and will be abbreviated as Na_2SO_4/H^+ (pH = 3), except for the case where sodium is replaced by lithium, i.e. Li_2SO_4/H^+ (pH = 3). The pH = 5 medium was prepared with 0.4 M CH_3COONa + CH_3COOH and abbreviated CH_3COONa/

H^+ (pH = 5). The solutions were deaerated thoroughly for a least 30 min with pure argon and kept under a positive pressure of this gas during the experiments. The source, mounting and polishing of the glassy carbon (GC, Le Carbone Lorraine, France or Tokai, Japan) electrodes have been described.[3p] The glassy carbon samples had a diameter of 3 mm. The electrochemical set-up was an EG & G 273 A driven by a PC with the 270 software. The data were recorded using the computer, and then printed, when necessary to an HP DeskJet 560 C printer. Potentials are quoted against a saturated calomel electrode (SCE). The counter electrode was a platinum gauze of large surface area. Experiments were performed at laboratory temperature.

Stereochemical Exploitation of the Chiral (+)-9-Phenyldeltacyclanyl Substituent in Diphosphanes and Their Ni, Pd and Pt Complexes[‡]

Henri Brunner,*[a] Stephan Dormeier,[a] and Manfred Zabel[a]

Dedicated to Professor Dr. Gottfried Huttner on the occasion of his 65th birthday

Keywords: Deltacyclenes / Chiral ligands / Phosphanes / Nickel / Palladium / Platinum

The (+)-9-phenyldeltacyclanyl moiety as a chiral phosphorus substituent contains eight configurationally fixed asymmetric carbon atoms. It is easily obtained from the reaction of norbornadiene and phenylacetylene via a Co-catalyzed enantioselective homo-Diels–Alder reaction, to give (+)-8-phenyldeltacyclene. In the reaction of (+)-8-phenyldeltacyclene with 1,2-$(H_2P)_2C_6H_4$ the trisubstitution product *P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl)-1,2-bis(phosphanyl)benzene, **(+)$_\delta$-LH**, is obtained, in which a single P–H bond at the stereogenic phosphorus atom is left. **(+)$_\delta$-LH** crystallizes as a pure diastereomer, which isomerizes in solution with respect to the secondary phosphorus atom at –20 °C resulting in a 64:36 diastereomer mixture. Substitution of the P–H hydrogen atom in **(+)$_\delta$-LH** by benzyl, 3-bromobenzyl, 6-bromo-*n*-hexyl and 3-(diphenylphosphanyl)phenyl gave the bis(tertiary) diphosphanes **(+)$_\delta$-LR^1**–**(+)$_\delta$-LR^4**. $NiBr_2$, $PdHal_2$ (Hal = Cl, Br, I) and $PtHal_2$ (Hal = Cl, Br) complexes of **(+)$_\delta$-LH** and **(+)$_\delta$-LR^1**–**(+)$_\delta$-LR^4** have been synthesized. The complexes form two diastereomers differing in the configuration of the chiral P atom. X-ray structure analyses have been carried out with **(+)$_\delta$-LH**, **[(+)$_\delta$-LR^2]NiBr$_2$**, **[(+)$_\delta$-LH]PdI$_2$** and **[(+)$_\delta$-LCl]PdI$_2$**. Interestingly, for **[(+)$_\delta$-LH]PdI$_2$** both diastereomers are found in the same crystal lattice in a 1:1 ratio. In **[(+)$_\delta$-LH]PdI$_2$** and **[(+)$_\delta$-LCl]PdI$_2$** the configuration at the secondary phosphorus atom is stable in solution at room temperature, whereas in the free ligand **(+)$_\delta$-LH** it is configurationally labile.

Introduction

2,5-Norbornadiene undergoes thermal [2+2+2] homo-Diels−Alder reactions with acetylenes to give deltacyclenes, provided the acetylene carries strongly electron-withdrawing groups such as NO_2.[2] Non-reactive acetylenes form deltacyclenes with 2,5-norbornadiene only in the presence of transition metal catalysts, although other products may also be formed.[3] In 1978, a procedure was published to transform terminal acetylenes into deltacyclenes in high yield using a combination of $Co(acac)_3$, triphenylphosphane and a reducing agent.[4] This reaction was rendered chiral by replacing the achiral triphenylphosphane by optically active phosphanes.[5,6] Further investigations showed that the catalyst $Co(acac)_3$ together with norphos and the reducing agent Et_2AlCl in the solvent THF gave nearly enantiopure deltacyclenes.[7] (+)-8-Phenyldeltacyclene, used in the present work, can be prepared in this way from 2,5-norbornadiene and phenylacetylene in a reliable enantiomeric excess of *ee* > 97.5%. Subsequently, other catalytic systems, allowing the extension to substituted acetylenes, and other enantioselective studies have appeared.[8−15]

The double bond of (+)-8-phenyldeltacyclene enables further derivatization by addition reactions, e.g. of P−H bonds. Ph_2PH has been added to give a monodentate chiral phosphane.[13] The aim of the reaction of 1,2-bis(phosphanyl)benzene with a fourfold excess of (+)-8-phenyldeltacyclene was to synthesize a chelate ligand with four deltacyclanyl substituents at the two phosphorus atoms. However, the tetrasubstituted product, albeit detected in the mass spectrum, could not be obtained.[13] Obviously, the reaction of 1,2-$(H_2P)_2C_6H_4$ with (+)-8-phenyldeltacyclene stops after 3 P−H additions. Due to steric hindrance the fourth P−H bond does not add to another (+)-8-phenyldeltacyclene. The resulting trisubstitution product **(+)$_\delta$-LH** is a tertiary/secondary diphosphane open to further derivatization reactions at the chiral phosphorus atom. **(+)$_\delta$-LH** is the starting material for the studies described in the present and succeeding paper.[16]

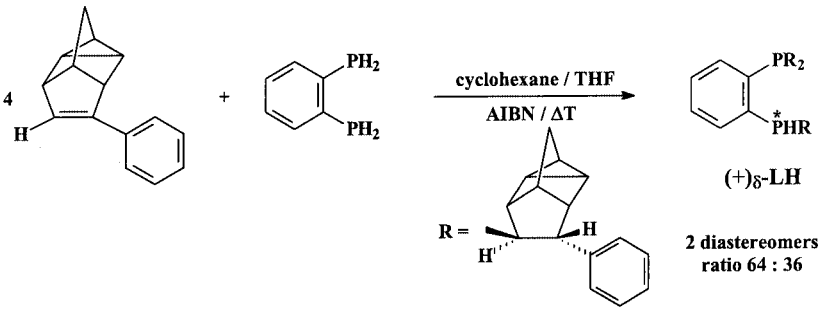

Scheme 1. Reaction of (+)-8-phenyldeltacyclene and 1,2-bis(phosphanyl)benzene to give *P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene, **(+)$_\delta$-LH**

Results and Discussion

P,P,P′-Tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene, (+)$_\delta$-LH

The tertiary/secondary diphosphane **(+)$_\delta$-LH** was obtained under radical conditions from (+)-8-phenyldeltacyclene and 1,2-bis(phosphanyl)benzene in boiling THF/cyclohexane in the presence of AIBN (Scheme 1).

After recrystallization from ethanol, **(+)$_\delta$-LH** was isolated as fine colorless needles in 45% yield. The ^{31}P NMR spectrum, in $CDCl_3$ at room temperature, showed that **(+)$_\delta$-LH** consists of two diastereomers with respect to the chiral P atom in a ratio of 64:36 (*de* = 28%). Interestingly, the needles obtained in the crystallization from ethanol contained only one of the two possible diastereomers of **(+)$_\delta$-LH**, as shown by low-temperature ^{31}P NMR spectroscopy (Figure 1). The cooled solution (−80 °C) of **(+)$_\delta$-LH** in [D_8]THF afforded only two doublets at δ = −15.0 and −29.9 ppm, the signals of the major isomer in the equilibrium mixture. The formation of the second diastereomer (δ = −10.8 and −31.7 ppm) was observed by warming up to temperatures around −20 °C. At room temperature the diastereomer ratio of 64:36 was obtained. The fast epimerization is in agreement with the known configurational lability of secondary phosphanes.[17−20]

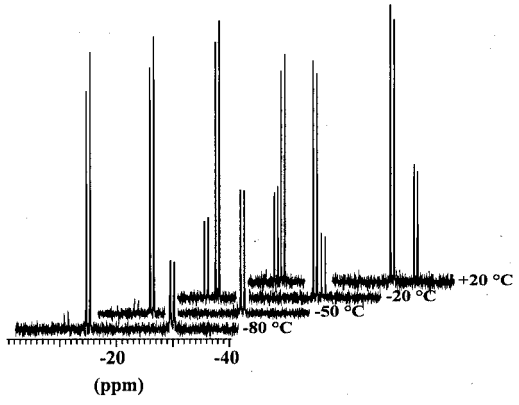

Figure 1. ^{31}P NMR spectrum of crystallized **(+)$_\delta$-LH** at −80 °C in [D_8]THF and equilibration of the diastereomers of **(+)$_\delta$-LH** on warming

A structural study performed with the needles of **(+)$_\delta$-LH** confirmed the presence of only one diastereomer (Figure 2). The phosphorus atom is *exo*-bonded to the 9-phenyldeltacyclan-8-yl substituent, pointing away from the deltacyclane cage, whereas the 9-phenyl group is *endo*-arranged beneath the deltacyclane cage. In principle, there are six alternatives to the addition of a P−H bond to (+)-8-phenyldeltacyclene.[13] However, in the structure of **(+)$_\delta$-LH** and the structures reported subsequently only one of them, 9-*exo*-P and 8-*endo*-Ph, is found, confirming former ^{1}H NMR assignments and calculations.[13] Note that in the P−H addition carbon atoms 8 and 9 of the deltacyclene skeleton change priorities. Thus, (+)-8-phenyldeltacyclene becomes the 9-phenyldeltacyclan-8-yl substituent. The symbol **(+)$_\delta$** in the ligand **(+)$_\delta$-LH** (and in its complexes) indicates that the 9-phenyldeltacyclan-8-yl substituents derived from (+)-8-phenyldeltacyclane are formed in a highly enantioselective homo-Diels−Alder reaction. The configuration of the chiral phosphorus atom could not be determined since the hydrogen atom at the secondary phosphorus atom was not localized in the X-ray structure analysis. As it is also labile in solution at room temperature, no configura-

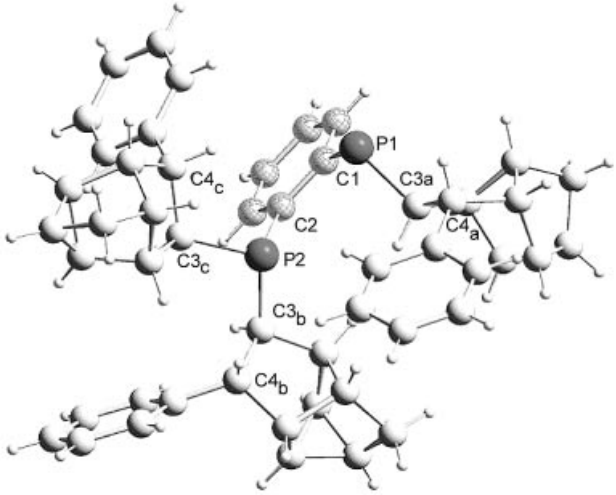

Figure 2. Molecular structure of **(+)$_\delta$-LH**, crystallized from ethanol; selected bond lengths [Å] and angles [°]: P1···P2 3.197(6), P1−C1 1.827(5), P2−C2 1.847(4), P1−$C3_a$ 1.853(5), P2−$C3_b$ 1.858(4), P2−$C3_c$ 1.842(3); C1−P1−$C3_a$ 102.01(16), C2−P2−$C3_b$ 100.14(19), C2−P2−$C3_c$ 98.85(18), $C3_b$−P2−$C3_c$ 102.80(14)

tional symbol for the secondary phosphorus atom in the ligand **(+)$_\delta$-LH** is used. However, in the complexes of **(+)$_\delta$-LH** the configuration of the secondary phosphorus atom is stabilized. Therefore, it is added for all the compounds that could be characterized by X-ray crystallography. The torsion angle P2−C2−C1−P1 of 2.41(44)° shows that the chelate ligand **(+)$_\delta$-LH** is nearly planar.

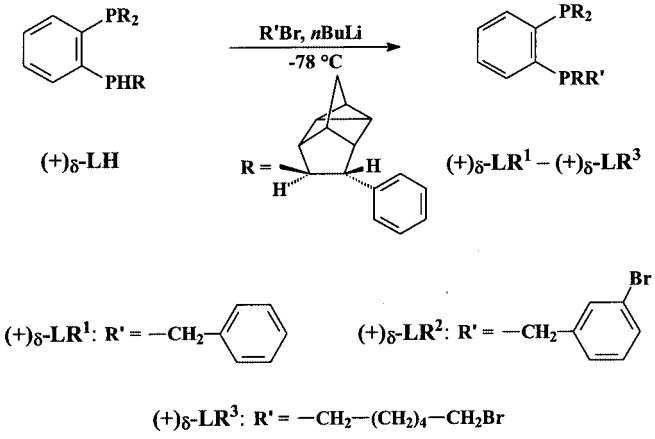
The synthesis of chiral building blocks frequently starts from amino acids and carbohydrates of the natural pool. Due to its easy accessibility from norbornadiene and phenylacetylene, (+)-8-phenyldeltacyclene is a promising artificial chiral building block. It contains six chiral carbon atoms, which are stereospecifically built up in the deltacyclene formation. After P−H addition to the double bond of (+)-8-phenyldeltacyclene, the number of asymmetric carbon atoms increases to eight in the (+)-9-phenyldeltacyclan-8-yl substituent. The trisubstitution product **(+)$_\delta$-LH** comprises 24 chiral centers (8 × 3) in the three deltacyclanyl substituents. The 25th stereogenic center in **(+)$_\delta$-LH** is the secondary phosphorus atom. In the present paper, **(+)$_\delta$-LH** is exploited for the synthesis of unsymmetrical bis(tertiary) phosphanes and mononuclear complexes with transition metal halides.[16] Di- and trinuclear complexes of **(+)$_\delta$-LH** will be described in the succeeding paper.

The Unsymmetrical Bis(tertiary) Diphosphanes (+)$_\delta$-LR^1 to (+)$_\delta$-LR^4

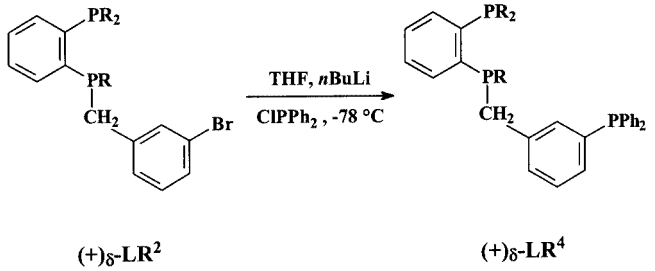
As the P−H bond of the trisubstitution product **(+)$_\delta$-LH** did not add to another (+)-8-phenyldeltacyclene due to steric reasons, sterically less demanding groups, to be used as the fourth substituent, were taken into consideration. Deprotonation of the P−H bond and reaction with the bromo derivative of the desired substituent seemed to be a suitable methodology.[12−14] Deprotonation of **(+)$_\delta$-LH** with *n*BuLi provides an achiral phosphide anion. Therefore, the diastereomeric excess obtained in consecutive reactions is independent of the diastereomer ratio of the secondary phosphane **(+)$_\delta$-LH**. However, the new phosphorus configuration will be influenced by the chirality of the 24 asymmetric centers of the three deltacyclane substituents.

Benzyl bromide is a reactive bromo derivative having only one coupling site. Treatment of a THF solution of **(+)$_\delta$-LH** with *n*BuLi at −78 °C followed by addition of benzyl bromide afforded the bis(tertiary) diphosphane **(+)$_\delta$-LR^1** in nearly 40% yield (Scheme 2). The ^{31}P NMR spectrum of **(+)$_\delta$-LR^1** in $CDCl_3$ displayed an AB system for each of the two diastereomers, the diastereomer ratio being 93:7 (*de* = 86%). Ligand **(+)$_\delta$-LR^2** is formed in 42% yield with a diastereomeric excess of *de* = 72% by using 1-bromo-3-(bromomethyl)benzene, which has an extra less reactive bromo substituent in the *meta* position of the benzyl group (Scheme 2). The best diastereomeric excess (*de* = 90%) was achieved with 1,6-dibromohexane. Ligand **(+)$_\delta$-LR^3** was isolated in 45% yield (Scheme 2). Formation of the disubstituted product was not observed.[16]

Halogen/metal exchange in **(+)$_\delta$-LR^2** with *n*BuLi, followed by reaction with chlorodiphenylphosphane, provided **(+)$_\delta$-LR^4** as a diastereomeric mixture with *de* = 56%



Scheme 2. Formation of the unsymmetrical bis(tertiary) diphosphanes **(+)$_\delta$-LR^1** to **(+)$_\delta$-LR^3**



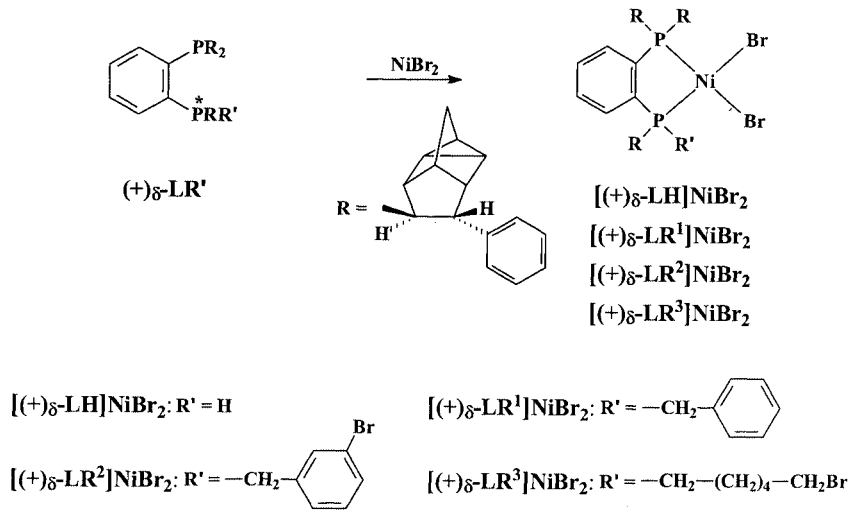
Scheme 3. Synthesis of **(+)$_\delta$-LR^4**

(Scheme 3). In addition to the signals of the AB system of the chelating unit, the ^{31}P NMR spectrum of **(+)$_\delta$-LR^4** showed singlets at δ = −4.73 and −5.09 ppm belonging to the phosphorus atoms of the PPh_2 group of the two diastereomers.

The $NiBr_2$ Complexes of the Diphosphanes (+)$_\delta$-LH and (+)$_\delta$-LR^1 to (+)$_\delta$-LR^3

Reaction of anhydrous $NiBr_2$ with **(+)$_\delta$-LH** in boiling ethanol provided the expected square-planar mononuclear dibromo(diphosphane)nickel(II) complex **[(+)$_\delta$-LH]$NiBr_2$** (Scheme 4). Crystallization of **[(+)$_\delta$-LH]$NiBr_2$** from a mixture of acetone, CH_2Cl_2, toluene and pentane gave fine red needles, which were amorphous in the X-ray structure analysis. The ^{31}P NMR spectrum showed two AB systems (δ = 72.34/43.27 and 74.70/49.76 ppm) resulting from the two diastereomers differing in the configuration of the secondary phosphorus atom in a ratio of 84:16. The splitting of the PHR signals at δ = 43.27 ppm (400.5 Hz) and δ = 49.76 ppm (408.2 Hz) in the proton-coupled ^{31}P NMR spectrum clearly proves that the hydrogen atom is still bonded to the secondary phosphorus atom. The tendency of **[(+)$_\delta$-LH]$NiBr_2$** to HBr elimination and the formation of dinuclear complexes will be discussed in the succeeding paper.

In the reaction of anhydrous $NiBr_2$ with the bis(tertiary) diphosphanes **(+)$_\delta$-LR^1** to **(+)$_\delta$-LR^3** mononuclear complexes are expected and found (Scheme 4). The ^{31}P NMR spectrum of **[(+)$_\delta$-LR^1]$NiBr_2$** showed two AB systems (δ =



Scheme 4. Synthesis of the dibromonickel(II)-diphosphane complexes **[(+)$_\delta$-LH]NiBr$_2$**, **[(+)$_\delta$-LR^1]NiBr$_2$**, **[(+)$_\delta$-LR^2]NiBr$_2$** and **[(+)$_\delta$-LR^3]NiBr$_2$**

82.37/66.39 and 74.99/72.13 ppm, ratio 8:92) caused by the two possible diastereomers in a ratio which is similar to that of the free ligand **(+)$_\delta$-LR^1**. Compared to the ^{31}P NMR spectrum of **(+)$_\delta$-LR^1** the signals of the diamagnetic square-planar complex **[(+)$_\delta$-LR^1]NiBr$_2$** are shifted to higher ppm (coordination shift).

Using ligand **(+)$_\delta$-LR^2**, the corresponding mononuclear dibromonickel(II) complex **[(+)$_\delta$-LR^2]NiBr$_2$** could also be isolated as a mixture of two diastereomers. Evaluation of the ^{31}P NMR spectrum of **[(+)$_\delta$-LR^2]NiBr$_2$** provided two AB systems (δ = 82.79/67.02 and 74.77/72.57 ppm) with a 16:84 ratio of the two diastereomeric forms. From a mixture of CH_2Cl_2 and ethanol, fine orange plates of **[(+)$_\delta$-LR^2]NiBr$_2$**, suitable for X-ray structure analysis, were obtained.

The structural study confirmed the mononuclear character of the complex (Figure 3) and proved the presence of only one of the two possible diastereomeric forms. The configuration of the chiral phosphorus atom was determined as (*R*). The ^{31}P NMR spectrum of a solution of these crystals showed that only one diastereomer was present, indicating configurational stability of the chiral phosphorus atom in the complex, whereas the free ligand **(+)$_\delta$-LH** already isomerized at −20 °C. The diastereomer in the isolated crystals corresponded to the major diastereomer formed in the synthesis described above. The dihedral angles P1−C1−C2−P2 [2.66(60)°] and P1−P2−Br2−Br1 [2.82(4)°] showed that in **[(+)$_\delta$-LR^2]NiBr$_2$** the chelate ring and the nickel square were only slightly deformed. In the crystal of **[(+)$_\delta$-LR^2]NiBr$_2$** the bromobenzyl substituent was disordered. The conformation shown in Figure 3 had 92.3% probability. In the conformation with 7.7% probability, the benzyl substituent was rotated by 180° with respect to the C5−C$_{ipso}$ bond.

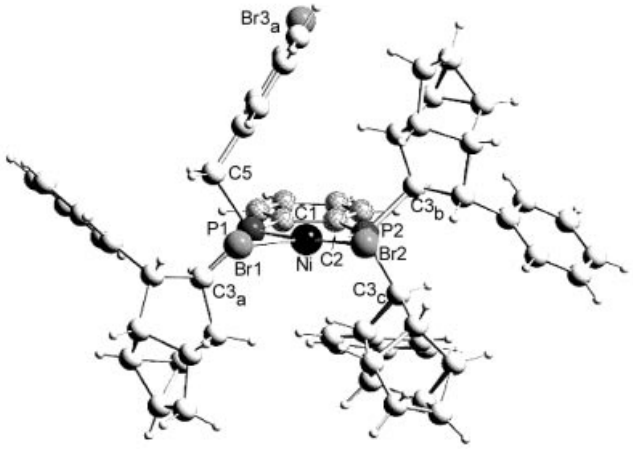


Figure 3. Molecular structure of **[(+)$_\delta$-LR^2]NiBr$_2$**, crystallized from CH_2Cl_2/ethanol; selected bond lengths [Å] and angles [°]: Ni−Br1 2.342(1), Ni−Br2 2.334(2), Ni−P1 2.151(2), Ni−P2 2.172(2), P1−C1 1.817(6), P2−C2 1.841(6), P1−C3$_a$ 1.858(7), P1−C5 1.839(7), P2−C3$_b$ 1.844(7), P2−C3$_c$ 1.842(7); C1−P1−C3$_a$ 103.20(23), C1−P1−C5 102.24(29), C5−P1−C3$_a$ 101.66(29), C3$_b$−P2−C3$_c$ 104.95(28), C2−P2−C3$_b$ 100.52(22), C2−P2−C3$_c$ 100.61(26), P1−Ni−Br1 86.13(5), P1−Ni−P2 89.24(6), P2−Ni−Br2 92.21(4), Br2−Ni−Br1 92.44(3)

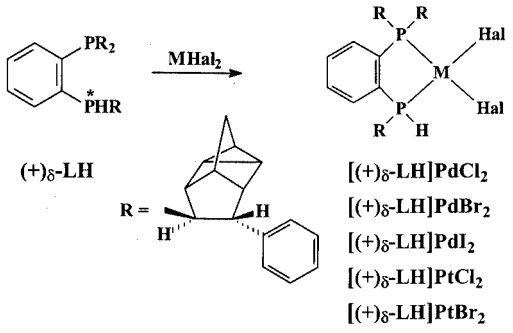
In the complex **[(+)$_\delta$-LR^3]NiBr$_2$**, the ligand of which carried an aliphatic chain as the fourth substituent, there were two diastereomers (^{31}P NMR: δ = 78.14/68.92 (minor) and 73.82/71.85 ppm (major), ratio 4:96).

Palladium and Platinum Complexes of the Secondary Diphosphane (+)$_\delta$-LH

The first products of the reaction of **(+)$_\delta$-LH** with palladium and platinum dihalides were the corresponding mononuclear square-planar complexes (Scheme 5). Their

HHal elimination to afford di- and trinuclear complexes will be discussed in the succeeding paper.



Scheme 5. Preparation of palladium and platinum dihalide complexes of **(+)$_\delta$-LH**

The diastereomeric excess in the preparation of **[(+)$_\delta$-LH]PdCl$_2$** depended on the reactants and the reaction conditions. Heating of **(+)$_\delta$-LH** and $PdCl_2$ in toluene in the presence of a small amount of concentrated HCl provided **[(+)$_\delta$-LH]PdCl$_2$**, the ^{31}P NMR spectrum of which showed two diastereomers in a ratio of 55:45. Using Na_2PdCl_4 in boiling ethanol, the diastereomer present in excess (δ = 76.75/41.10 ppm) was enriched to *de* = 84% (minor diastereomer: δ = 74.83/38.82 ppm). If the reaction was started in THF at −78 °C with $(PhCN)_2PdCl_2$ and diastereomerically pure **(+)$_\delta$-LH** as the starting material, the ^{31}P NMR spectrum of the product also showed the signals of the two diastereomers. However, in this case the diastereomer, which was the minor before, dominated with a ratio of 91:9. In **[(+)$_\delta$-LH]PdCl$_2$** the P−P couplings were typical for (diphosphane)palladium chelate complexes ($^2J_{PP}$ = 9.0 and 11.8 Hz), the P−H couplings were 405 and 410 Hz.

The syntheses of **[(+)$_\delta$-LH]PdBr$_2$** was succeeded by stirring a suspension of $PdBr_2$ and **(+)$_\delta$-LH** in CH_2Cl_2 for 4 d. The ^{31}P NMR spectrum of **[(+)$_\delta$-LH]PdBr$_2$** showed two isomers (major: δ = 79.10/43.96; minor: δ = 76.52/39.45 ppm; ratio 55:45). For **[(+)$_\delta$-LH]PdBr$_2$** the P−P couplings (14.5 and 17.6 Hz) and the P−H couplings (409 and 414 Hz) were larger than for **[(+)$_\delta$-LH]PdCl$_2$**.

A suspension of **(+)$_\delta$-LH** and PdI_2 was refluxed in benzene. After 4 h, all the PdI_2 had reacted and a dark red powder was isolated in nearly quantitative yield. The ^{31}P NMR spectrum of **[(+)$_\delta$-LH]PdI$_2$** showed two diastereomers, δ = 80.09/45.29 and 75.77/38.02 ppm in a ratio of 58:42 with P−P couplings (13.5 and 16.5 Hz) and P−H couplings (407 and 405 Hz). After putting a layer of methanol over a solution of **[(+)$_\delta$-LH]PdI$_2$** in CH_2Cl_2, red crystals of X-ray quality were obtained (Figure 4).

In the structural study the hydrogen atoms of the secondary phosphorus atoms could be localized. To our surprise from a solution of the two diastereomers of **[(+)$_\delta$-LH]PdI$_2$**, differing in the configuration at the secondary phosphorus atom in the ratio 58:42, single crystals could be obtained which contained both diastereomers exactly in a 1:1 ratio. This is extremely unusual, because normally each diastereomer crystallizes in its own lattice. In the case of **[(+)$_\delta$-LH]PdI$_2$** the (S_P) diastereomer and the (R_P) diastereomer

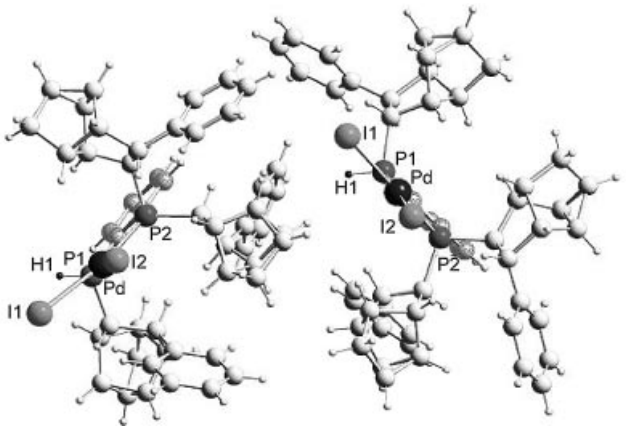


Figure 4. Molecular structures of the two diastereomers of **[(+)$_\delta$-LH]PdI$_2$**, crystallized from CH_2Cl_2/methanol; (R_P) diastereomer on the right, (S_P) diastereomer on the left; selected bond lengths [Å] and angles [°] of the (S_P) diastereomer of **[(+)$_\delta$-LH]PdI$_2$**: Pd−I1 2.659(1), Pd−I2 2.646(1), Pd−P1 2.244(1), Pd−P2 2.269(2), P1−C1 1.818(5), P2−C2 1.835(5), P1−C3$_a$ 1.842(3), P1−H1 1.219(47), P2−C3$_b$ 1.842(6), P2−C3$_c$ 1.844(3); H1−P1−C3$_a$ 99.87(202), C1−P1−C3$_a$ 112.15(15), C1−P1−H1 105.52(234), C3$_c$−P2−C3$_b$ 104.89(15), C2−P2−C3$_c$ 99.57(15), C2−P2−C3$_b$ 101.26(16), P1−Pd−P2 86.15(3), P2−Pd−I2 95.73(3), I2−Pd−I1 90.66(1), I1−Pd−P1 87.47(2)

formed a pair that was repeated in the lattice (Figure 4), a rare case of molecular recognition and supramolecular chemistry.[21] The ^{31}P NMR spectrum of the solution of the crystals showed the two diastereomers in a 50:50 ratio. Thus, the configuration at the secondary P atoms in the diastereomeric complexes was stable. In this specific case diastereomer enrichment on crystallization did not occur in the crystals but in the supernatant mother liquor. Whereas in **[(+)$_\delta$-LH]PdCl$_2$** the palladium square was only slightly deformed [dihedral angle P1−P2−I2−I1 1.28(2)°], the chelate ring was appreciably puckered [dihedral angle P1−C1−C2−P2 11.11(41)°].

In addition to the signals of **[(+)$_\delta$-LH]PdI$_2$** the ^{31}P NMR spectrum of the reaction mixture of PdI_2 and **(+)$_\delta$-LH** in CH_2Cl_2 exhibited many signals of other compounds. Within 12 h dark red crystals of **[(+)$_\delta$-LCl]PdI$_2$** of X-ray quality crystallized from a CH_2Cl_2/Et_2O solution. The X-ray structure analysis of **[(+)$_\delta$-LCl]PdI$_2$** (Figure 5) showed that the hydrogen atom, bonded to the secondary phosphorus atom in the ligand **(+)$_\delta$-LH**, had been replaced by a chlorine atom which must have come from the solvent CH_2Cl_2. The configuration of the chiral phosphorus atom was determined as (*S*). The ^{31}P NMR spectrum of the dissolved crystals exhibited only signals of one diastereomer at δ = 123.29 and 68.87 ppm. With the torsion angle P1−C1−C2−P2 [4.15(89)°] there was a slight puckering of the chelate ring. On the other hand the square-planar arrangement of the four atoms bonded to the palladium atom in **[(+)$_\delta$-LCl]PdI$_2$** was heavily distorted [dihedral angle P1−P2−I2−I1 13.78(5)°].

To synthesize the mononuclear platinum complex **[(+)$_\delta$-LH]PtCl$_2$**, K_2PtCl_4 was dissolved in a small amount of concentrated HCl. The dark brown solution was diluted with ethanol and heated to reflux. After dropwise addition of a

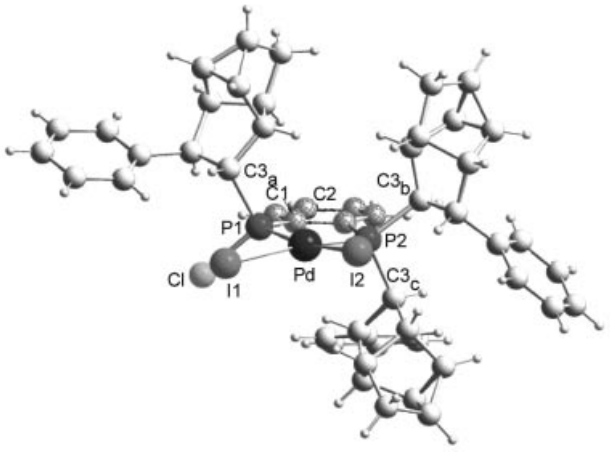

Figure 5. Molecular structure of **[(+)$_\delta$-LC]$_2$PdI$_2$**, crystallized from CH_2Cl_2/methanol; selected bond lengths [Å] and angles [°]: Pd−I1 2.647(2), Pd−I2 2.653(2), Pd−P1 2.228(2), Pd−P2 2.275(3), I1···Cl 3.901(4), P1−C1 1.818(10), P2−C2 1.836(9), P1−$C3_a$ 1.815(8), P1−Cl 2.231(14), P2−$C3_b$ 1.838(13), P2−$C3_c$ 1.828(8); Cl−P1−$C3_a$ 103.70(29), C1−P1−$C3_a$ 110.10(38), C1−P1−Cl 100.16(28), $C3_c$−P2−$C3_b$ 103.79(37), C2−P2−$C3_c$ 102.67(37), C2−P2−$C3_b$ 101.46(38), P1−Pd−P2 85.84(8), P2−Pd−I2 97.66(6), I2−Pd−I1 90.07(2), I1−Pd−P1 88.19(6)

toluene solution of **(+)$_\delta$-LH**, the complex **[(+)$_\delta$-LH]PtCl$_2$** could be isolated. The ^{31}P NMR spectrum of **[(+)$_\delta$-LH]PtCl$_2$** showed the signals of two different isomers. The diastereomer present in excess (δ = 48.67/15.90 ppm) was enriched to 80% (minor diastereomer: δ = 47.20/15.23 ppm). The P−P couplings (2.5 and 3.1 Hz) were much smaller for **[(+)$_\delta$-LH]PtCl$_2$** than for **[(+)$_\delta$-LH]PdCl$_2$**. In addition to P−H couplings (414 and 416 Hz) Pt−P couplings were observed (3508 and 3531 Hz), typical for mononuclear (diphosphane)platinum complexes.

The corresponding platinum bromide complex **[(+)$_\delta$-LH]PtBr$_2$** was obtained from Pt(cod)Br$_2$ and **(+)$_\delta$-LH** in benzene at room temperature. The ^{31}P NMR spectrum showed two diastereomers, the major diastereomer (δ = 49.77/18.19 ppm) being enriched to nearly 70% (minor diastereomer: δ = 51.81/21.49 ppm). The P−P couplings were smaller (2.2/2.4) and the P−H couplings larger (417/419) than those of the platinum chloride complex **[(+)$_\delta$-LH]PtCl$_2$** with the Pt−P couplings (3322/3504) in the expected range.

Experimental Section

General Remarks: All reactions were performed under dry nitrogen using standard Schlenk techniques. Solvents were purified and dried by standard procedures. (+)-8-Phenyldeltacyclene[7] and 1,2-bis(phosphanyl)benzene[22−24] were prepared as described in the literature. Mass spectra: Finnigan Mat 95 for field desorption (FD) and fast atom bombardment (FAB), Thermo Quest TSQ 7000 for electron spray injection (ESI), M^+ = the most intense peak of the isotope cluster of M. ^{1}H NMR spectra: Bruker ARX 400 spectrometer (400 MHz). ^{31}P NMR spectra: Bruker ARX 400 spectrometer (162 MHz). Melting points: Büchi SMP 20. Elemental analyses: Heraeus Elementar Vario EL III.

***P,P,P′*-Tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)-benzene, (+)$_\delta$-LH:** To the boiling solution of (+)-8-phenyldeltacyclene (4.90 g, 25.0 mmol) in 20 mL of cyclohexane, 1,2-bis(phosphanyl)benzene (1.00 g, 7.0 mmol), AIBN (0.16 g, 1.0 mmol) in 20 mL of cyclohexane and 20 mL of THF was added dropwise. After heating for 16 h, the solvents were evaporated and the residue was suspended in 50 mL of pentane. The mixture was cooled to −20 °C for 1 h. Filtration gave the crude product. Recrystallization from hot ethanol provided **(+)$_\delta$-LH** (3.05 g) as thin colorless needles in 45% yield, m.p. 105−110 °C. Crystals of **(+)$_\delta$-LH**·0.75C_2H_5OH (colorless needles) were obtained from ethanol at −40 °C. $[\alpha]_D^{20}$ = +85 (*c* = 1; CH_2Cl_2). ^{1}H NMR ($CDCl_3$): δ = 3.76−0.39 (m, 30 H, aliph. H), 4.27 (m, $^1J_{PH}$ = 213.8 Hz, 1 H, PH), 7.63−6.43 (m, 19 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = −11.3 (d, $^3J_{PP}$ = 116.8 Hz, 36% PR_2), −12.3 (d, $^3J_{PP}$ = 105.9 Hz, 64% PR_2), −32.3 (d, $^3J_{PP}$ = 105.9, $^1J_{PH}$ = 213.8 Hz, 64% PHR), −38.8 (d, $^3J_{PP}$ = 116.8, $^1J_{PH}$ = 213.8 Hz, 36% PHR) ppm. MS-FD (CH_2Cl_2): *m*/*z* = 724.3 [M^+]. $C_{51}H_{50}P_2$ (724.9): calcd. C 84.50, H 6.95; found C 84.19, H 7.25.

Preparation of the Tertiary Diphosphanes (+)$_\delta$-LR^1 to (+)$_\delta$-LR^3: A solution of **(+)$_\delta$-LH** in abs. THF (20 mL) was treated with a small excess of a 1.6 M solution of *n*BuLi in *n*-hexane. After stirring at room temperature for 1 h, the deep red solution was cooled to −78 °C. The appropriate bromo compound [1 equiv. relative to **(+)$_\delta$-LH**] was then dissolved in THF (5 mL) and added dropwise to the solution of the deprotonated phosphane. The solution was allowed to warm up to room temperature and stirred for 16 h. Removal of the solvent and purification by crystallization or chromatography provided the pure product.

***P′*-Benzyl-*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene, (+)$_\delta$-LR^1: (+)$_\delta$-LH** (1.30 g, 1.7 mmol) was treated with *n*BuLi (1.26 mL, 1.8 mmol, 1.6 M solution in hexane) and (bromomethyl)benzene (0.30 g, 1.7 mmol) as described above. Recrystallization from petroleum ether/toluene provided **(+)$_\delta$-LR^1** (0.53 g) as a colorless powder in 38% yield, m.p. 129−132 °C. ^{1}H NMR ($CDCl_3$): δ = 4.07−0.34 (m, 32 H, aliph. H), 7.54−5.95 (m, 24 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = −12.65 (d, $^3J_{PP}$ = 178.1 Hz, 7% PR_2), −13.37 (d, $^3J_{PP}$ = 170.0 Hz, 93% PR_2), −16.56 (d, $^3J_{PP}$ = 170.0 Hz, 93% PRR′), −19.93 (d, $^3J_{PP}$ = 178.1 Hz, 7% PRR′) ppm. MS-FD (CH_2Cl_2): *m*/*z* = 814.1 [M^+]. $C_{58}H_{56}P_2$ (815.0): calcd. C 85.47, H 6.93; found C 84.73, H 7.67.

***P′*-(3-Bromobenzyl)-*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene, (+)$_\delta$-LR^2: (+)$_\delta$-LH** (3.30 g, 4.6 mmol) was treated with *n*BuLi (3.55 mL, 5.1 mmol, 1.6 M solution in hexane) and 1-bromo-3-(bromomethyl)benzene (1.17 g, 4.6 mmol). Recrystallization from petroleum ether/toluene provided **(+)$_\delta$-LR^2** (1.63 g) as a colorless powder in 42% yield, m.p. 121−127 °C. ^{1}H NMR ($CDCl_3$): δ = 3.67−0.43 (m, 32 H, aliph. H), 7.54−5.95 (m, 23 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = −12.59 (d, $^3J_{PP}$ = 179.8 Hz, 14% PR_2), −12.89 (d, $^3J_{PP}$ = 167.5 Hz, 86% PR_2), −16.21 (d, $^3J_{PP}$ = 167.5 Hz, 86% PRR′), −19.48 (d, $^3J_{PP}$ = 179.8 Hz, 14% PRR′) ppm. MS-FD (CH_2Cl_2): *m*/*z* = 892.3 [M^+]. $C_{58}H_{55}BrP_2$ (893.9): calcd. C 77.93, H 6.20; found C 77.88, H 6.80.

After 2 h, the red solution was filtered through silica gel and the solvents were evaporated to provide **$[(+)_\delta$-LR²]$NiBr_2$** (0.46 g) as a red powder in 93% yield, m.p. 162−165 °C. Crystals of **$[(+)_\delta$-LR²]$NiBr_2$** (orange plates) were obtained from a mixture of CH_2Cl_2 and ethanol at room temperature. ^{1}H NMR ($CDCl_3$): δ = 3.91−0.28 (m, 32 H, aliph. H), 8.18−5.57 (m, 23 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 67.02 (d, $^2J_{PP}$ = 49.6 Hz, 16% PRR′), 72.57 (d, $^2J_{PP}$ = 47.9 Hz, 84% PRR′), 74.77 (d, $^2J_{PP}$ = 47.9 Hz, 84% PR_2), 82.79 (d, $^2J_{PP}$ = 49.6 Hz, 16% PR_2) ppm. MS-FD (CH_2Cl_2): *m/z* = 1112.3 [M^+]. $C_{58}H_{55}Br_3NiP_2$ (1112.4): calcd. C 62.62, H 4.98; found C 62.27, H 4.91.

Dibromo{*P′*-(6-bromohexyl)-*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bisphosphanylbenzene}nickel(II), $[(+)_\delta$-LR³]$NiBr_2$: A suspension of **$(+)_\delta$-LR³** (0.18 g, 0.20 mmol) and anhydrous $NiBr_2$ (0.044 g, 0.2 mmol) was heated in ethanol (20 mL) for 1 h. After cooling to room temperature and evaporating the solvent, the red residue was dissolved in CH_2Cl_2 and filtered through silica gel. Concentration provided **$[(+)_\delta$-LR³]$NiBr_2$** (0.19 g) as a dark red powder in 84% yield, m.p. 160−163 °C. ^{1}H NMR ($CDCl_3$): δ = 3.21−0.60 (m, 40 H, aliph. H), 3.14 (t, ^1J = 6.7 Hz, 2 H, CH_2Br), 7.51−6.53 (m, 19 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 68.92 (d, $^2J_{PP}$ = 50.1 Hz, 4% PRR′), 71.85 (d, $^2J_{PP}$ = 48.5 Hz, 96% PRR′), 73.82 (d, $^2J_{PP}$ = 48.5 Hz, 96% PR_2), 78.14 (d, $^2J_{PP}$ = 50.1 Hz, 4% PR_2) ppm. MS-FD (CH_2Cl_2): *m/z* = 1106.3 [M^+]. $C_{57}H_{61}Br_3NiP_2$ (1106.5): calcd. C 61.87, H 5.56; found C 61.76, H 5.66.

Dichloro{*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene}palladium(II), $[(+)_\delta$-LH]$PdCl_2$: $(+)_\delta$-LH (0.50 g, 0.70 mmol) was dissolved in THF at −78 °C. $Pd(NCPh)_2Cl_2$ (0.27 g, 0.70 mmol), dissolved in THF and cooled down to −78 °C, was added dropwise to the solution of the phosphane. The pale yellow solution was stirred while warming to room temperature. Washing several times with *n*-hexane and subsequent drying gave **$[(+)_\delta$-LH]$PdCl_2$** (0.62 g) as a yellow powder in 98% yield, m.p. 169 °C. ^{1}H NMR ($CDCl_3$): δ = 3.62−0.05 (m, 30 H, aliph. H), 7.67−5.33 (m, 19 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 38.82 (d, $^2J_{PP}$ = 11.8, $^1J_{PH}$ = 406.5 Hz, 91% PHR), 41.10 (d, $^2J_{PP}$ = 9.0, $^1J_{PH}$ = 410.6 Hz, 9% PHR), 74.83 (d, $^2J_{PP}$ = 11.8 Hz, 91% PR_2), 76.75 (d, $^2J_{PP}$ = 9.0 Hz, 9% PR_2) ppm. MS-FAB (CH_2Cl_2): *m/z* = 900.8 [M^+]. $C_{51}H_{50}Cl_2P_2Pd$ (902.2): calcd. C 67.89, H 5.59; found C 68.11, H 5.62.

Dibromo{*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene}palladium(II), $[(+)_\delta$-LH]$PdBr_2$: $(+)_\delta$-LH (0.37 g, 0.51 mmol) and $PdBr_2$ (0.14 g, 0.51 mmol) were stirred in CH_2Cl_2 for 4 d at room temperature. Filtration and concentration provided **$[(+)_\delta$-LH]$PdBr_2$** (0.49 g) as an orange powder in 97% yield, m.p. 175 °C. ^{1}H NMR ($CDCl_3$): δ = 3.70−0.19 (m, 30 H, aliph. H), 7.53−5.19 (m, 19 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 39.45 (d, $^2J_{PP}$ = 17.6, $^1J_{PH}$ = 410.6 Hz, 45% PHR), 43.96 (d, $^2J_{PP}$ = 14.5, $^1J_{PH}$ = 419.0 Hz, 55% PHR), 76.52 (d, $^2J_{PP}$ = 17.6 Hz, 45% PR_2), 79.10 (d, $^2J_{PP}$ = 14.5 Hz, 55% PR_2) ppm. MS-FAB (CH_2Cl_2): *m/z* = 990.4 [M^+]. $C_{51}H_{50}Br_2P_2Pd$ (991.1): calcd. C 61.80, H 5.08; found C 61.16, H 5.72.

Diiodo{*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene}palladium(II), $[(+)_\delta$-LH]PdI_2: $(+)_\delta$-LH (0.50 g, 0.70 mmol) and PdI_2 (0.25 g, 0.70 mmol) were suspended in benzene and refluxed for 4 h. After cooling to room temperature the solution was filtered and the solvent evaporated. **$[(+)_\delta$-LH]PdI_2** (0.49 g) remained as a red powder in 99% yield, m.p. 183 °C. Crystals of **$[(+)_\delta$-LH]PdI_2**·CH_2Cl_2 (orange plates) were obtained from a mixture of CH_2Cl_2 and methanol at room temperature. ^{1}H NMR ($CDCl_3$): δ = 3.35−0.08 (m, 30 H, aliph. H), 4.45 (m, 1 H, $^1J_{PH}$ = 404.9 Hz, 1 H, PH, 42%), 7.63−6.29 (m, 19 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 38.02 (d, $^2J_{PP}$ = 16.5, $^1J_{PH}$ = 404.9 Hz, 42% PHR), 45.29 (d, $^2J_{PP}$ = 13.5, $^1J_{PH}$ = 413.8 Hz, 58% PHR), 75.77 (d, $^2J_{PP}$ = 16.5 Hz, 42% PR_2), 80.09 (d, $^2J_{PP}$ = 13.5 Hz, 58% PR_2) ppm. MS-FAB (CH_2Cl_2): *m/z* = 1084.5 [M^+]. $C_{51}H_{50}I_2P_2Pd$ (1085.1): calcd. C 56.45, H 4.64; found C 56.43, H 4.86.

{*P′*-Chloro-*P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl)-1,2-bis(phosphanyl)benzene}diiodopalladium(II), $[(+)_\delta$-LCl]PdI_2: $(+)_\delta$-LH (0.59 g, 0.81 mmol) and PdI_2 (0.29 g, 0.81 mmol) were suspended in CH_2Cl_2 and stirred for 3 d followed by filtration and evaporation of the solvent. Crystallization from a 1:2 mixture of CH_2Cl_2/diethyl ether gave **$[(+)_\delta$-LCl]PdI_2** (0.08 g) as dark red-brown crystals in nearly 10% yield, m.p. 188 °C. ^{1}H NMR ($CDCl_3$): δ = 3.50−0.08 (m, 30 H, aliph. H), 7.65−6.38 (m, 19 H, arom. H) ppm. ^{31}P NMR

X-ray Crystallographic Studies: The data were collected with a STOE-IPDS diffractometer with Mo-K_α radiation and graphite monochromator at a temperature of 173(1) K. Crystal data, data collection, structure refinement and CCDC numbers for **$(+)_\delta$-LH**, **$[(+)_\delta$-LR^2]NiBr$_2$**, **$[(+)_\delta$-LH]PdI$_2$** and **$[(+)_\delta$-LCl]PdI$_2$** are given in Table 1. The structures were solved by direct methods (SIR-97) and refined by full-matrix least squares on F^2 (SHELXL-97). The H atoms were calculated geometrically and a riding model was applied during the refinement process. Absorption corrections, when necessary, were carried out numerically from the crystal shape (x-RED).[25] CCDC numbers given in Table 1 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Dinuclear and Trinuclear Ni−, Pd−, and Pt−Halide Complexes of the Easily Accessible Chiral Ligand *P,P,P′*-Tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)benzene[‡]

Henri Brunner,*[a] Stephan Dormeier,[a] Ilias Grau,[a] and Manfred Zabel[a]

Dedicated to Professor Dr. Gottfried Huttner on the occasion of his 65th birthday

Keywords: Nickel complexes / Palladium complexes / Platinum complexes / Phosphido bridges / Phosphorus configuration

The synthesis of seven dinuclear complexes **[(+)$_\delta$-LMHal]$_2$** (M = Ni, Pd, Pt; Hal = Cl, Br, I) is described, in which **(+)$_\delta$-L$^-$** represents the deprotonated chiral chelate ligand *P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl]-1,2-bis(phosphanyl)-benzene, easily accessible in a highly enantioselective homo-Diels–Alder reaction. All the dinuclear complexes are bent at the phosphido bridges which connect the two square-planar halves of the molecules. The phosphorus atoms of the phosphido bridges are stereogenic centers. For **[(+)$_\delta$-LNiBr]$_2$** and **[(+)$_\delta$-LPdCl]$_2$** both diastereomers with (S_P,S_P) and (R_P,R_P) configuration were observed, whereas for **[(+)$_\delta$-LPdBr]$_2$**, **[(+)$_\delta$-LPdI]$_2$**, and **[(+)$_\delta$-LPtCl]$_2$** only the (S_P,S_P) isomers could be obtained. Furthermore, the synthesis of eight trinuclear complexes **[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** (M = Pd, Pt; Hal = Cl, Br) is reported, which contain unusual three-square arrays. In the trinuclear complexes all the halogens are oriented to one side. Halogeno and phosphido bridges connect the three squares leading to chair configurations (opposite scaffold chirality possible) and boat configurations. For **[(+)$_\delta$-L$_2$Pd$_3$Cl$_4$]**, **[(+)$_\delta$-L$_2$Pd$_3$Br$_4$]**, and **[(+)$_\delta$-L$_2$Pt$_3$Cl$_4$]** the two diastereomers with (S_P,S_P) and (R_P,R_P) configuration and for **[(+)$_\delta$-L$_2$Pt$_3$Br$_4$]** the diastereomers with (S_P,S_P) and (S_P,R_P) configuration could be isolated. In addition, the dinuclear complex **[(+)$_\delta$-LPt$_2$Br$_3$(cod)]** (cod = 1,5-cyclooctadiene) containing a single phosphido bridge was obtained.

Introduction

In the previous paper the synthesis of the chiral ligand *P,P,P′*-tris[(+)-9-phenyldeltacyclan-8-yl)-1,2-bis(phosphanyl)benzene **(+)$_\delta$-LH** and its mononuclear complexes was reported. **(+)$_\delta$-LH** is formed in the enantioselective homo-Diels−Alder reaction of norbornadiene with phenylacetylene[2,3] and the subsequent addition of 3 PH bonds of 1,2-bis(phosphanyl)benzene to the double bonds of (+)-8-phenyldeltacyclene.[1,4] **(+)$_\delta$-LH** contains 3 × 8 = 24 asymmetric carbon atoms in its three deltacyclanyl substituents and a stereogenic secondary phosphorus atom which is configurationally labile in the free ligand but stabilized in its mononuclear complexes **[(+)$_\delta$-LH]MHal$_2$**, M = Ni, Pd, Pt.[1] The symbol **(+)$_\delta$** in the ligand **(+)$_\delta$-LH** and in its complexes indicates the 24 asymmetric carbon atoms of a given configuration in the deltacyclane substituents built up in the highly enantioselective homo-Diels−Alder reaction. Here, the dinuclear and trinuclear compounds will be described, which form on HHal elimination from the complexes **[(+)$_\delta$-LH]MHal$_2$**.[5] The dinuclear complexes have roof-shaped structures with bridging phosphorus atoms. In the trinuclear compounds three square-planar units are connected in an uncommon way. In addition to the 48 asymmetric carbon atoms of fixed configuration both dinuclear and trinuclear complexes contain two stereogenic phosphorus atoms of the phosphido bridges. As the phosphorus atoms may occur in (S_P,S_P) as well as (R_P,R_P) in one case even (S_P,R_P) configuration series of diastereomers could be isolated and characterized differing only in the configuration of the phosphido bridges. Thus, the dinuclear compounds **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-MHal]$_2$** and the trinuclear compounds **(S_P,S_P)-**, **(R_P,R_P)-** and **(S_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** are not enantiomers but diastereomers.

All the molecules shown in Schemes 1 and 2 and discussed in Tables 1−6 {except **(R_P)-[(+)$_\delta$-L$_2$Pt$_3$Br$_3$(cod)]**} are C_2-symmetric. However, only for **(S_P,S_P)-[(+)$_\delta$-L$_2$Pd$_3$Br$_4$]**, **(R_P,R_P)-[(+)$_\delta$-L$_2$Pd$_3$Br$_4$]**, and **(S_P,S_P)-[(+)$_\delta$-L$_2$Pt$_3$Br$_4$]** the C_2 axis of the molecule is also a symmetry element of the unit cell. Consequently, in all the other cases the two halves of the molecules are different. Nevertheless, throughout the paper only one half of each molecule is described and discussed (the left halves in Figures 1−5).

Reaction of a dinuclear complex **[(+)$_\delta$-LMHal]$_2$** and $MHal_2$ to give trinuclear compounds **[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** (top) and the three possible isomers **(S_P,S_P)-**, **(R_P,R_P)-**, and **(S_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** of the trinuclear phosphido- and halo-bridged complexes having all the halides on one side (bottom)

The Dinuclear Phosphido-Bridged Complexes [(+)$_\delta$-LMHal]$_2$

Although most of the syntheses of the dinuclear complexes **[(+)$_\delta$-LMHal]$_2$** given in the Exp. Sect. started from the ligand **(+)$_\delta$-LH** and suitable metal precursors, the intermediacy of the corresponding mononuclear complexes **[(+)$_\delta$-LH]MHal$_2$** must be assumed.[1] As indicated in Scheme 1 two mononuclear complexes give the dinuclear phosphido-bridged compounds by twofold HHal elimination. Some of the dinuclear complexes were obtained in attempts to recrystallize the mononuclear compounds **[(+)$_\delta$-LH]MHal$_2$** demonstrating their tendency to loose HHal.

In the dinuclear complexes **[(+)$_\delta$-LMHal]$_2$** two square-planar units are connected by bridging phosphorus atoms. The phosphorus atoms of these phosphido bridges are stereogenic centers, as they have four different substituents: the palladium atom which is part of the chelate ring, the palladium atom which is not part of the chelate ring, the chelate ring, and the (+)-9-phenyldeltacyclanyl substituent. This priority sequence is the basis for the assignment of (*R*) and (*S*) configuration to these stereogenic phosphido phosphorus atoms. In all the dinuclear complexes **[(+)$_\delta$-LMHal]$_2$** the (+)-9-phenyldeltacyclanyl substituents have the same stereochemistry. It is the configuration of the bridging phosphorus atoms which differentiates the diastereomers.

At the bottom of Scheme 1 the three possible isomers for the dinuclear complexes are shown. In combination with the enantiomerically pure deltacyclane substituents abbreviated by **(+)$_\delta$** the configuration of the bridging phosphorus atoms can be (S_P,S_P), (R_P,R_P), or (S_P,R_P) giving rise to three diastereomers. Obviously, the **(S_P,S_P)-[(+)$_\delta$-LMHal]$_2$** diastereomers are highly favored. However, for the fragments NiBr and PdCl both diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-LMHal]$_2$** could be isolated and characterized. The **(S_P,R_P)-[(+)$_\delta$-LMHal]$_2$** isomer, *meso*-configurated with respect to the central core (excluding the deltacyclanyl substituents), was never observed.

Dinuclear complexes in which two square-planar units are connected by bridges can be coplanar or bent.[6,7] Diphenylphosphido-bridged complexes usually are planar, e.g. [Hal(PPh$_2$H)M(μ-PPh$_2$)$_2$M(PPh$_2$H)Hal] (M = Pd, Pt; Hal = Cl, I).[8−10] On the other hand complexes containing unsymmetrically substituted phosphido bridges PRR′ are bent.[6] Consequently, the bridging phosphido groups discussed here, in which the phosphorus atoms have a phenylene and a deltacyclanyl substituent, are expected to be bent, the roof angle depending on the type of diastereomer.

Reaction of anhydrous NiBr$_2$ with **(+)$_\delta$-HL** and Na$_2$CO$_3$ in boiling ethanol provided a crude product, the ^{31}P NMR spectrum of which showed the signals of several compounds including those of the dinuclear complexes **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$** (main product) and **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** (see below). Crystallization from CH$_2$Cl$_2$ gave red needles suitable for X-ray structure analysis. The ^{31}P NMR spectrum exhibited the AA′XX′ system of only one of the possible diastereomers. The structural study confirmed the dinuclear character of the complex (Figure 1) proving the presence of only one of the possible isomers.

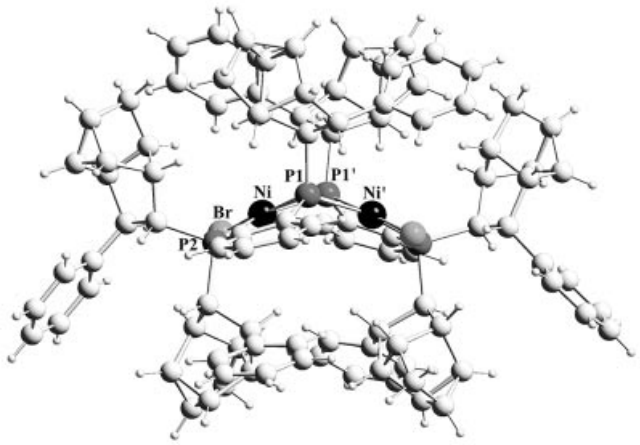

Figure 1. Molecular structure of **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$**, crystallized from CH$_2$Cl$_2$; selected bond lengths [A], bond angles [°], and dihedral angles [°]: Ni···Ni′ = 3.277(12), P1···P1′ = 2.689(8), Ni−Br = 2.349(1), Ni−P1 = 2.181(3), Ni−P1′ = 2.217(1), Ni−P2 = 2.207(3); Br−Ni−P1′ = 97.60(3), P1′−Ni−P1 = 75.39(4), P1−Ni−P2 = 88.39(4), P2−Ni−Br = 98.30(3), P1−Ni−Br = 172.95(3), P1′−Ni−P2 = 160.29(4); Ni−P1′−P1−Br = 0.53(2), Ni−P1′−P1−P2 = 8.24(3), P2−P1−P1′−Br = 7.71(3), Ni−P1−P1′−Ni′ = 140.84(4), Ni−P1−P2/C1−C2 = 10.5(2): δ

The configuration of the two bridging chiral phosphorus atoms was determined as (S_P,S_P). **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$** is bent at the phosphido bridges. The "roof angle" between the two square-planar units is 140.84°. The dihedral angle of the metal substituents P2−P1−P1′−Br (of the left half of the molecule) shows that there is a small deformation of the square-planar arrangement of 7.71°. The chelate ring Ni−P1−C1−C2−P2 is slightly puckered indicated by the inclination of the bond C1−C2 of the benzene ring with respect to the plane Ni−P1−P2. The angle of this inclination is a measure of the chirality of the helix defined by the two skew lines C1−C2 and P1−P2 (which is part of the plane Ni−P1−P2). The chirality of the chelate ring Ni−P1−C1−C2−P2 is induced by the given chirality of the deltacyclanyl substituents and the configuration of the bridging phosphorus atoms. In **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$** the inclination angle of C1−C2 with respect to the plane Ni−P1−P2 is 10.5°, defining δ helicity. The parameters discussed for **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$** are typical for the (S_P,S_P) diastereomers. They differ for the (R_P,R_P) diastereomers (Table 1).

Reaction of anhydrous NiBr$_2$ with **(+)$_\delta$-HL** and *n*BuLi in CH$_2$Cl$_2$, followed by crystallization from acetone, afforded brown crystals of **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** suitable for X-ray structure analysis (Figure 2).

The diastereomer **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** is also bent at the phosphido bridges. However, the roof angle of 156.53° shows a flattening compared to **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$**, which is also obvious from the lengthening of the nonbonding Ni−Ni distance from 3.28 to 3.45 Å (Table 1). In **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** the plane of the metal substituents P2−P1−P1′−Br is heavily deformed by 25.97°. This strong deformation, which is typical for all (R_P,R_P) isomers

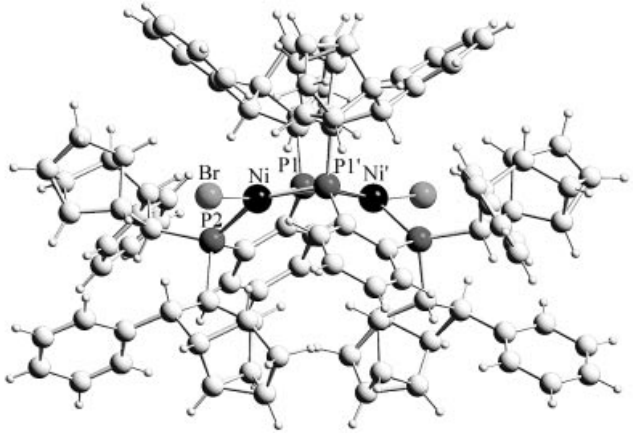

Figure 2. Molecular structure of **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$**, crystallized from acetone; selected bond lengths [Å], bond angles [°], and dihedral angles [°]: Ni···Ni′ = 3.454(21), P1···P1′ = 2.650(11), Ni−Br = 2.344(4), Ni−P1 = 2.181(4), Ni−P1′ = 2.223(10), Ni−P2 = 2.201(4); Br−Ni−P1′ = 102.93(10), P1′−Ni−P1 = 73.96(1), P1−Ni−P2 = 90.19(2), P2−Ni−Br = 97.36(10), P1−Ni−Br = 168.28(11), P1′−Ni−P2 = 149.42(11); Ni−P1′−P1−Br = 7.43(7), Ni−P1′−P1−P2 = −18.54(9), P2−P1−P1′−Br = −25.97(10), Ni−P1−P1′−Ni′ = 156.53(15), Ni−P1−P2/C1−C2 = 0.9(6): λ

(Table 1), may be the reason for their discrimination compared to the (S_P,S_P) isomers. On the other hand, the chelate rings are almost planar in the (R_P,R_P) diastereomers. In **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** the inclination angle is only 0.9° with λ helicity (Table 1).

Similar to the NiBr series, it was possible in the PdCl series to isolate and characterize both diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-LPdCl]$_2$** (Tables 1 and 3). The structural parameters (roof angle, nonbonding M−M distance, square deformation, inclination angle, and helicity) for the diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-LPdCl]$_2$** link up with those of the diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$**. Similar to the NiBr system, the two diastereomers of the PdCl system do not interconvert in solution, because their ^{31}P NMR spectra are different and stay different.

Using Na_2PdCl_4/LiBr, PdI_2, and **[(+)$_\delta$-LH)PtCl$_2$** as starting materials the dinuclear complexes **(S_P,S_P)-[(+)$_\delta$-LPdBr]$_2$**, **(S_P,S_P)-[(+)$_\delta$-LPdI]$_2$**, and **(S_P,S_P)-[(+)$_\delta$-LPtCl]$_2$** (Table 4) were isolated and characterized. They all belong to the (S_P,S_P) diastereomer series and resemble the (S_P,S_P) diastereomers described above in having roof angles

about 140°, dihedral angels of the metal substituents between 7 and 12° and δ helicity in the slightly puckered chelate rings (Table 1).

The complex **(R_P)-[(+)$_δ$-LPt$_2$Br$_3$(cod)]** was obtained during crystallization of **[(+)$_δ$-LH)PtBr$_2$** which had been prepared from Pt(cod)Br$_2$ (Figure 3). The compound has only one **(+)$_δ$-L$^-$** substituent which connects two platinum atoms by a single phosphido bridge. The configuration of this phosphorus atom was determined as (R_P). To one of the platinum atoms a cod molecule is coordinated, left over from the starting material Pt(cod)Br$_2$.

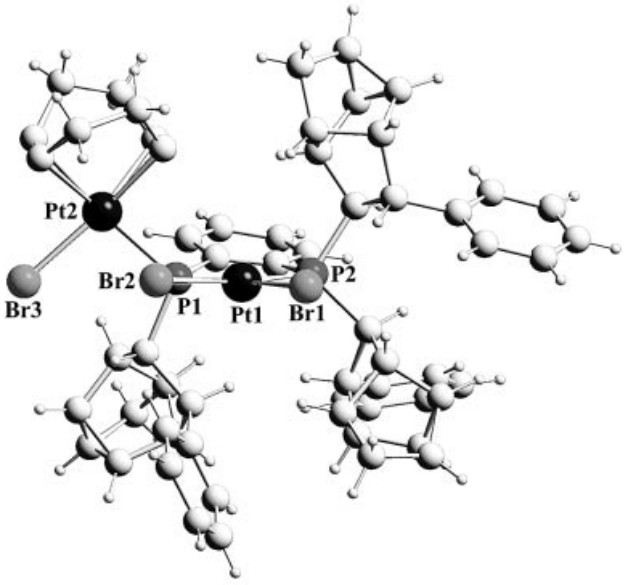

Figure 3. Molecular structure of **(R_P)-[(+)$_δ$-LPt$_2$Br$_3$(cod)]**, crystallized from CH_2Cl_2/methanol; selected bond lengths [Å], bond angles [°], and dihedral angles [°]: Pt1···Pt2 = 3.832(2), Pt1−Br1 = 2.449(1), Pt1−Br2 = 2.507(1), Pt1−P1 = 2.249(2), Pt1−P2 = 2.239(2), Pt2−Br3 = 2.430(1), Pt2−P1 = 2.339(2); P1−Pt1−Br2 = 85.89(5), Br2−Pt1−Br1 = 88.98(3), Br1−Pt1−P2 = 97.11(5), P2−Pt1−P1 = 88.30(6), P1−Pt1−Br1 = 174.36(5), P2−Pt1−Br2 = 170.18(5), Pt1−P1−Pt2 = 113.27(7), P1−Pt2−Br3 = 94.98(4); Pt1−P1−Br2−P2 = 5.69(4), Pt1−P1−Br2−Br1 = −1.66(4), P1−Br2−Br1−P2 = 6.46(5), Pt1−P1−Br2−Pt2 = 140.28(7), Pt1−P1−Br2/Pt2−P1−Br3 = 78.18(8), Pt1−P1−P2/C1−C2 = 6.0(4): λ

The Unusual Trinuclear Phosphido-Bridged Complexes [(+)$_δ$-L$_2$M$_3$Hal$_4$]

The dinuclear compounds **[(+)$_δ$-LMHal]$_2$** discussed above are ubiquitous in the chemistry of palladium(II) and platinum(II). However, the trinuclear compounds **[(+)$_δ$-L$_2$M$_3$Hal$_4$]** discussed here are extremely rare. Formally MX_2 is inserted into the dinuclear compounds **[(+)$_δ$-LMHal]$_2$** as shown in Scheme 2.

Seven of the eight characterized trinuclear complexes were isolated during crystallization attempts of the mononuclear complexes **[(+)$_δ$-LH]MHal$_2$**. Only the (R_P,R_P) isomer of the palladium chloride series was obtained by heating **(+)$_δ$-LH** and $PdCl_2$ in toluene. As indicated in Scheme 2 (top) two mononuclear complexes in combination with $MHal_2$ give the trinuclear phosphido- and halide-bridged compounds by twofold HHal elimination.

Many isomers are possible for trinuclear compounds of the type **[(+)$_δ$-L$_2$M$_3$Hal$_4$]**. All halogens can be oriented to one side and the two stereogenic phosphido phosphorus atoms may have the configurations (S_P,S_P), (R_P,R_P), and also (S_P,R_P). All three isomers have been isolated. In addi-

Figure 4. tion, there should be isomers having the halogens on different sides. Such isomers have not been observed up to now. The (+)-9-phenyldeltacyclanyl substituents in the trinuclear compounds have the same stereochemistry. It is the configuration of the two stereogenic phosphorus atoms which gives rise to the differences between the diastereomers.

The three isomers for the trinuclear complexes having all the halides on one side are shown at the bottom of Scheme 2. In the PdCl, PdBr, and PtCl series the diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** could be isolated and characterized. In the PtBr series the diastereomers **(S_P,S_P)-** and **(S_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** were obtained.

All the new complexes are bent at the phosphido and halo bridges. This bending leads to chair and boat configurations for the three-square arrays in the trinuclear complexes **(S_P,S_P)-**, **(R_P,R_P)-**, and **(S_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]**. The chair configurations contain a C_2 axis passing through the central metal atoms. They subdivide into the diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-L$_2$M$_3$Hal$_4$]** differing only in the phosphorus configuration. The isomer **(S_P,R_P)-[(+)$_\delta$-L$_2$Pt$_3$Br$_4$]** has a symmetry plane passing through the central Pt atom (without consideration of the chiral deltacyclanyl substituents). It is *meso*-configurated with respect to its central core.

Trinuclear compounds consisting of an array of three square-planar units connected by bridges are peculiar and rare. Whereas mononuclear compounds, such as $(PPh_3)_2PdCl_2$, and their chloro-bridged dinuclear pendants, e.g. $(PPh_3)ClPd(\mu\text{-}Cl)_2PdCl(PPh_3)$, are common, the corresponding trinuclear compound $(PPh_3)ClPd(\mu\text{-}Cl)_2Pd(\mu\text{-}Cl)_2PdCl(PPh_3)$ is unknown. For trinuclear phosphido-bridged complexes there is precedent in the literature.[11] In 2001 a series of new trinuclear complexes was described, which in contrast to our compounds (two phosphido and

two halide bridges) contained four diphenylphosphido bridges.[12] An X-ray structural analysis of one of the trinuclear complexes showed a chair configuration with regard to the three-square array. The roof angles between the squares were 152.7° in agreement with our results.

The trinuclear compounds **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-$L_2Pt_3Cl_4$]** were isolated in attempts to crystallize **[(+)$_\delta$-LH)PtCl$_2$]** from CH_2Cl_2 and CH_2Cl_2/EtOH, respectively. Both compounds were characterized by X-ray crystallography. A comparison of the structural parameters of the diastereomeric platinum chloride complexes **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-$L_2Pt_3Cl_4$]** shows that there are no large differences (Figures 4 and 5). The roof angles are very similar (121.42 and 128.96°, respectively) and the deformations of the peripheral and central squares P2−P1−Cl2−Cl1 and P1−P1′−Cl2′−Cl2 are insignificant (Table 2). The chelate rings Pt1−P1−C1−C2−P2 of the diastereomeric complexes are only slightly disturbed (2.7 and 1.5° respectively) both having δ chirality. Obviously, four chloride ligands on one side and four phosphorus atoms on the other side do not result in distinct distortions of the two diastereomers with opposite chair chirality.

With respect to structural aspects palladium compounds are similar to their platinum analogues. Accordingly, the palladium chloride diastereomers **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-$L_2Pd_3Cl_4$]** closely resemble their platinum congeners (Tables 2, 5 and 6).

In contrast to the platinum chloride and palladium chloride series, the two (S_P,S_P) and (R_P,R_P) diastereomers in the palladium bromide system show large differences (Tables 2 and 5). The roof angle of **(S_P,S_P)-[(+)$_\delta$-$L_2Pd_3Br_4$]** is more than 30° smaller than the roof angle of **(R_P,R_P)-[(+)$_\delta$-$L_2Pd_3Br_4$]**, which inversely affects the Pd−Pd distances. With 12.41 and 17.44°, respectively, the deformations of the peripheral and central squares P2−P1−Br2−Br1 and P1−P1′−Br2′−Br2 of the (S_P,S_P) diastereomer are strong but similar. In the (R_P,R_P) diastereomer, however, the peripheral squares are nearly undisturbed (3.73°), whilst the central square P1−P1′−Br2′−Br2 is extremely distorted (29.29°) as obvious from the formula in the upper right-hand corner of Table 2. The chelate rings in **(S_P,S_P)-** and **(R_P,R_P)-[(+)$_\delta$-$L_2Pd_3Br_4$]** are almost planar having opposite helicity (Table 2).

Similar to the trinuclear palladium bromide compounds the trinuclear platinum bromide complexes exhibited strong distortions. Table 2 shows that **(S_P,S_P)-[(+)$_\delta$-$L_2Pt_3Br_4$]** closely resembles the corresponding palladium derivative (Table 6) but the diastereomer **(R_P,R_P)-[(+)$_\delta$-$L_2Pt_3Br_4$]**, which would have been expected to be heavily distorted, could not be obtained at all. Instead, the only boat isomer **(S_P,R_P)-[(+)$_\delta$-$L_2Pt_3Br_4$]** was isolated (Figure 6, Table 2 bottom right).

In the boat isomer **(S_P,R_P)-[(+)$_\delta$-$L_2Pt_3Br_4$]** the left side (Table 2) and the right side of the molecule were appreciably different. Whereas the peripheral square on the right side was nearly planar (0.60°), the left and the central squares were distorted (13.90 and 11.97°, respectively). The boat isomer also had two unequal roof angles (left side 144.01°, right side 132.77°) resulting in a difference of the metal−metal distances of approximately 0.2 Å. The chelate rings Pt1−P1−C1−C2−P2 and Pt1′−P1′−C1′−C2′−P2′ on the two sides are only slightly disturbed (1.5 and 5.9°, respectively) both having δ chirality.

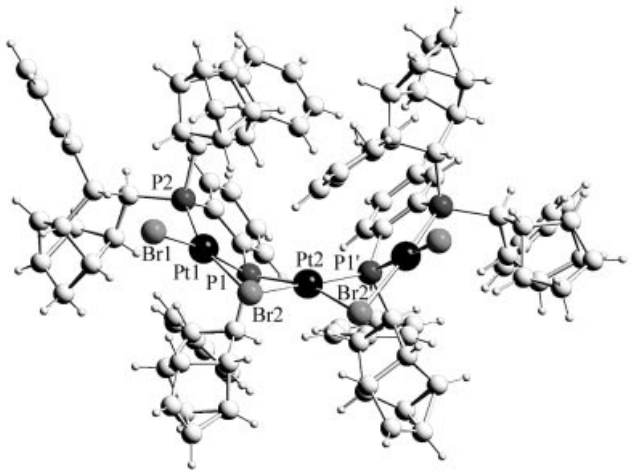

Figure 6. Molecular structure of **(R_P,S_P)-[(+)$_\delta$-$L_2Pt_3Br_4$]**, crystallized from benzene; selected bond lengths [Å], bond angles [°], and dihedral angles [°]: Pt1···Pt2 = 3.258(1), P1···Cl2 = 3.258(1), Pt1−P1 = 2.213(2), Pt1−Br1 = 2.483(2), Pt1−Br2 = 2.528(2), Pt1−P2 = 2.200(3), Pt2−P1 = 2.253(3), Pt2−Br2 = 2.575(2); P2−Pt1−P1 = 89.64(11), P1−Pt1−Br2 = 84.02(8), Br2−Pt1−Br1 = 89.82(5), Br1−Pt1−P2 = 96.41(9), P2−Pt1−Br2 = 173.37(9), P1−Pt1−Br1 = 173.19(9), P1−Pt2−Br2 = 82.15(8), P1−Pt2−P1′ = 113.87(11), Br2−Pt2−Br2′ = 84.68(5), P1−Pt2−Br2′ = 160.80(9); Pt1−P1−Br2−P2 = 1.37(6), Pt1−P1−Br2−Br1 = 2.05(6), P1−Br2−Br1−P2 = −0.60(8), Pt2−P1−Br2−Br2′ = −5.96(6), Pt2−P1−Br2−P1′ = 6.01(6), P1−P1′−Br2′−Br2 = −12.09(8), Pt1−P1−Br2−Pt2 = 132.77(11), Pt1−P1−P2/C1−C2 = 1.5(8): δ; Pt1′−P1′−P2′/C1′−C2′ = 5.9(7): δ

Experimental Section

General Remarks: All reactions were performed under dry nitrogen using standard Schlenk techniques. Solvents were purified and dried by standard procedures. *P,P,P′*-Tris[(+)-9-phenyldeltacyclan-8-yl)-1,2-bis(phosphanyl)benzene **[(+)$_\delta$-LH]** was prepared as described in the previous paper. Spectroscopy and analyses as in the previous paper. For the AA′XX′ systems in the ^{31}P NMR spectra the chemical shifts of the signals are given.

(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$: A suspension of **(+)$_\delta$-LH** (0.57 g, 0.77 mmol) and anhydrous $NiBr_2$ (0.18 g, 0.77 mmol) was heated for 30 min in ethanol (150 mL) in the presence of 2 g of Na_2CO_3. After cooling to room temperature, the red solution was concentrated, the residue dissolved in acetone and filtered through silica gel. Evaporation of the solvent and crystallization of the residue from CH_2Cl_2 provided **(S_P,S_P)-[(+)$_\delta$-LNiBr]$_2$** (0.20 g) as red crystals in 30% yield, m.p. > 250 °C. ^{1}H NMR ($CDCl_3$): δ = 3.48−0.38 (m, 60 H, aliph. H), 7.91−6.34 (m, 38 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 45.42, 44.99, 44.36, 43.93 (PR_2); −52.73, −53.17, −53.80, −54.23 (PR) ppm. MS (FD, CH_2Cl_2): *m*/*z* = 1724.6 [M^+].

(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$: A suspension of **(+)$_\delta$-LH** (0.32 g, 0.44 mmol) and anhydrous $NiBr_2$ (0.10 g, 0.44 mmol) was heated in CH_2Cl_2 (50 mL) for 1 h. After the addition of *n*BuLi (0.5 mL, 0.74 mmol, 1.6 M solution in hexane), the solution was heated for

another 30 min, cooled to room temperature, filtered through silica gel, and concentrated. Crystallization from acetone provided **(R_P,R_P)-[(+)$_\delta$-LNiBr]$_2$** (0.20 g) as brown crystals in 54% yield, m.p. > 250 °C. ^{1}H NMR ($CDCl_3$): δ = 3.73−0.64 (m, 60 H, aliph. H), 7.90−5.90 (m, 38 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 44.78, 44.22, 43.68, 43.11, (PR_2); −69.86, −70.43, −70.98, −71.53 (PR) ppm. MS (FD, CH_2Cl_2): *m*/*z* = 1724.3 [M^+].

(S_P,S_P)-[(+)$_\delta$-LPdCl]$_2$: A suspension of **(+)$_\delta$-LH** (0.34 g, 0.47 mmol) and Na_2PdCl_4 (0.14 g, 0.47 mmol) in ethanol was stirred at room temperature for 36 h, followed by filtration through silica gel and concentration. Crystallization from CH_2Cl_2/Et_2O gave **(S_P,S_P)-[(+)$_\delta$-LPdCl]$_2$** (0.39 g) as pale yellow crystals in 95% yield, m.p. > 250 °C. $C_{102}H_{98}Cl_2P_4Pd_2$ (1731.5): calcd. C 70.75, H 5.70; found C 70.57, H 5.88. ^{1}H NMR ($CDCl_3$): δ = 4.95−0.20 (m, 60 H, aliph. H), 7.87−6.39 (m, 38 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 54.72, 54.00, 53.44, 51.96, 51.40, 50.71 (PR_2); −49.35, −50.07, −50.63, −52.11, −52.67, −53.37, (PR) ppm. MS (FAB, CH_2Cl_2): *m*/*z* = 1731.3 [M^+].

(R_P,R_P)-[(+)$_\delta$-LPdCl]$_2$: Compound **(+)$_\delta$-LH** (0.18 g, 0.25 mmol) and KO*t*Bu (0.028 g, 0.25 mmol) were stirred in THF. After 1 h, $(PhCN)_2PdCl_2$ (0.095 g, 0.25 mmol) was added to the pale yellow solution which was then stirred at room temperature for another 16 h. Evaporation of the solvent provided **(R_P,R_P)-[(+)$_\delta$-LPdCl]$_2$** (0.20 g) as a dark orange powder in 93% yield, m.p. > 250 °C. $C_{102}H_{98}Cl_2P_4Pd_2$ (1731.5): calcd. C 70.75, H 5.70; found C 70.52, H 5.93. ^{1}H NMR ($CDCl_3$): δ = 5.06−0.34 (m, 60 H, aliph. H), 7.94−6.28 (m, 38 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 60.73, 60.01, 56.31, 57.92, 57.22, 56.49 (PR_2); −72.25, −72.97, −73.66, −75.06, −75.75, −76.47, (PR) ppm. MS (FAB, CH_2Cl_2): *m*/*z* = 1731.3 [M^+].

(S_P,S_P)-[(+)$_\delta$-LPdBr]$_2$: Na_2PdCl_4 (0.094 g, 0.32 mmol) and a twelvefold excess of LiBr (0.34 g) were suspended at room temperature in 20 mL of ethanol. After 30 min, **(+)$_\delta$-LH** (0.23 g, 0.32 mmol) was added to the dark red solution, which was stirred for another 16 h. Filtration through silica gel and evaporation of the solvent gave **(S_P,S_P)-[(+)$_\delta$-LPdBr]$_2$** (0.27 g) as an orange powder in 94% yield, m.p. > 250 °C. $C_{102}H_{98}Br_2P_4Pd_2$ (1820.4): calcd. C 67.30, H 5.43; found C 67.05, H 5.59. ^{1}H NMR ($CDCl_3$): δ = 5.05−0.15 (m, 60 H, aliph. H), 7.86−6.36 (m, 38 H, arom. H) ppm. ^{31}P NMR ($CDCl_3$): δ = 55.11, 54.45, 53.90, 52.41, 51.86, 51.21 (PR_2); −51.73, −52.40, −52.95, −54.44, −54.99, −55.66 (PR) ppm. MS (ESI, CH_3OH): *m*/*z* = 1820.2 [M^+].

(S_P,S_P)-[(+)$_\delta$-LPdI]$_2$: Compound **(+)$_\delta$-LH** (0.24 g, 0.33 mmol) and PdI_2 (0.12 g, 0.33 mmol) were suspended in toluene and stirred at

X-ray Crystallographic Studies: The data were collected with a STOE-IPDS diffractometer with Mo-K_α radiation and graphite monochromator at a temperature of 173(1) K. Crystal data, data collection, structure refinement, and CCDC numbers for all complexes are given in Tables 3−6. The structures were solved by direct methods (SIR-97) and refined by full-matrix least squares on F^2 (SHELXL-97). The H atoms were calculated geometrically and a riding model was applied during the refinement process. Absorption corrections, when necessary, were carried out numerically from crystal shape (x-RED)[13] or emperical (PLATON)[14]. CCDC numbers given in Tables 3−6 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre 12 Union Road Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Chiral Mono- and Bidentate Ligands Derived from D-Mannitol and Their Application in Rhodium(I)-Catalyzed Asymmetric Hydrogenation Reactions

Alexander Bayer,[a] Petra Murszat,[a] Ulf Thewalt,[b] and Bernhard Rieger*[a]

Keywords: Chiral pool / P ligands / Rhodium / Asymmetric catalysis / Hydrogenation

The new monodentate phosphoramidites **8a**–**g** and bidentate phospholanes **13a**–**e** are prepared in an ex-chiral-pool synthesis from D-mannitol. Chiral diols **7a**–**g**, obtained via nucleophilic ring opening of bis(epoxides) **6a**–**b**, are the key intermediates for the production of both classes of ligands. Treatment of **8a**–**g** or **13a**–**e** with $[PdCl_2(COD)]$ or $[Rh(COD)_2][SO_3CF_3]$ yield the corresponding Pd (**10a, 10f, 15a**) and Rh compounds (**9a**–**g** and **14a**–**e**), respectively. The C_2 symmetry of the complexes in the solid state is demonstrated by X-ray structure investigations performed on **10a**, **10f** and **15a**. Surprisingly high enantioselectivities in the asymmetric hydrogenation of itaconic acid (94% *ee*) and α-acetamidocinnamic acid (89% *ee*) are observed on using the Rh complex **9g** bearing two monodentate phosphoramidite ligands. Although the chelating bis(phospholanes) described herein are more effective, the adjustable synthesis of the monodentate phosphoramidites may permit the optimization of asymmetric catalytic reactions.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The enantioselective hydrogenation of prochiral olefins plays an important role in the application of homogeneous catalysts. The development of suitable ligands for rhodium(I) species started in 1968 with Wilkinson-type complexes.[1,2] They used chiral monophosphane ligands, e.g. methyl(phenyl)(*n*-propyl)phosphane, which led to poor enantioselectivities in rhodium(I)-catalyzed hydrogenation reactions (3−15% *ee*). Also, other monodentate ligands failed to produce high enantioselectivities, while cyclohexyl(*o*-anisyl)methylphosphane (CAMP) was one of the rare exceptions (90% *ee* for hydrogenation of dehydroamino acids).[3] With the introduction of Kagan's DIOP, the first chiral diphosphane,[4] the research focussed on bidentate ligands. Knowles et al. showed that DIPAMP, another chelating diphosphane, is superior to PAMP, the corresponding monodentate species, with respect to rhodium-catalyzed hydrogenation reactions.[5] The use of bidentate ligands such as BINAP[6] and DuPHOS,[7] have also led to extremely high enantiomeric excess values. These chelating compounds are supposed to be superior because of the resulting rigid catalysts which favor effective chiral induction.[8] Monodentate ligands have been neglected in asymmetric hydrogenation reactions until Pringle et al. questioned the superiority of the bidentate species. They found higher enantioselectivities (92% *ee*) when using an asymmetric monophosphonite compared with the corresponding C_2-symmetric diphosphonite in the hydrogenation of methyl 2-(acetamido)acrylate.[9] Excellent enantioselectivities (> 99% *ee*) are also reported with monodentate phosphites[10] and phosphoramidites.[11] These new monodentate ligands have an enantiomerically pure binaphthol fragment in common. Based on the X-ray data of a platinum(II) complex, Pringle showed that the *cis* coordination of two sterically demanding monophosphonite ligands favors one stable conformation at the metal center, so that rotation about the M−P bond is prevented. Quadrant diagrams demonstrate the edge-on conformation of the bulky binaphthol moiety, presumably causing the asymmetric induction.[9]

Our approach to achieve high enantioselectivities in asymmetric hydrogenation reactions is not based on a single chiral auxiliary group. We present a highly variable ex-chiral-pool synthesis in order to generate monodentate phosphoramidites bearing four stereogenic centers, differing in the absolute configuration of carbon atoms and the steric demand of the substituents. This synthetic protocol also offers access to functionalized bidentate DuPHOS derivatives. Both types of ligands were tested in the rhodium(I)-catalyzed hydrogenation reaction of itaconic and α-(acetamido)-cinammic acid. The hydrogenation results can be explained with the help of quadrant diagrams based on X-ray data of corresponding palladium(II) complexes.

Ligand and Complex Synthesis

Our approach starts with the chiral building block D-mannitol[12] (**1**, Figure 1), which is converted into the

1,2;3,4;5,6-tri-*O*-isopropylidene (**2**) and the 3,4-*O*-isopropylidene derivative (**3**).[13,14] The syntheses of 1,2;5,6-dianhydro-3,4-*O*-isopropylidene-D-mannitol (**6a**),[15] the corresponding chiral diols **7a**−**e**,[16,17] the monodentate phosphoramidites **8a**−**e**, the Rh complexes **9a**−**e** and the Pd complex **10a** were recently reported by us.[18]

The highly variable synthetic strategy allows for the conversion of compound **3** (Figure 1) to the diastereomeric bis(epoxide) 1,2;5,6-dianhydro-3,4-*O*-isopropylidene-L-iditol (**6b**, Figure 2), with a changed configuration at carbon atoms C2 and C5 (dibenzoylation of **3**, ditosylation of **4**, subsequent transesterification with concomitant intramole-

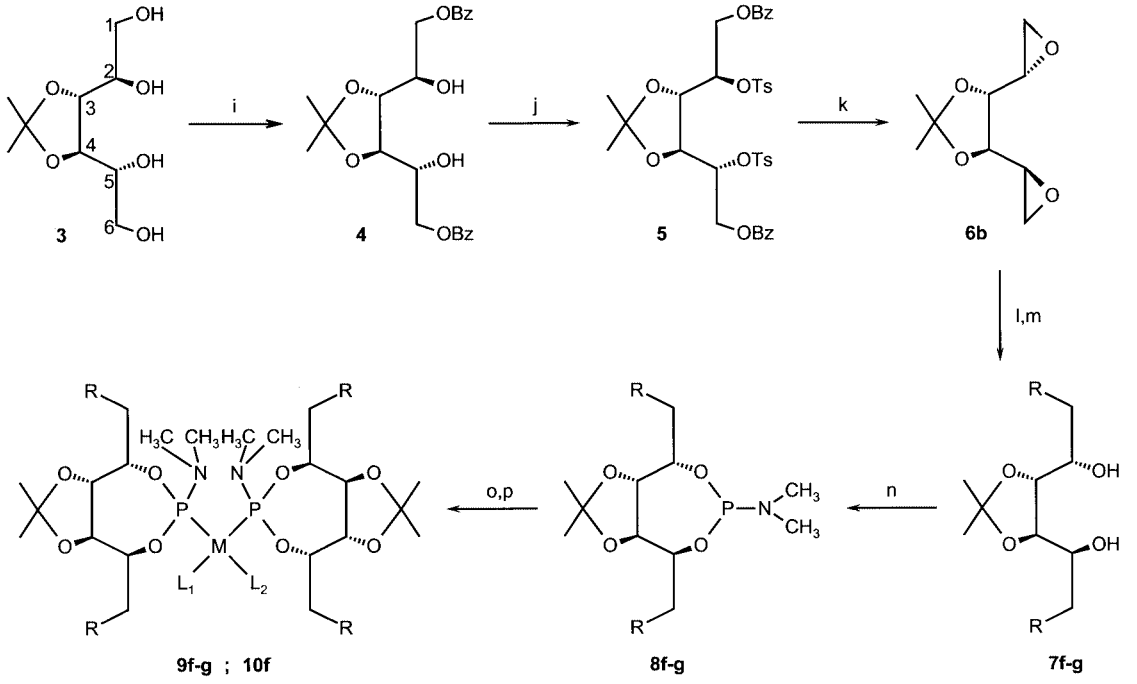

Figure 2. i) benzoyl chloride, pyridine, CH_2Cl_2, −80 °C; j) tosyl chloride, NEt_3, 4-(dimethylamino)pyridine, CH_2Cl_2; k) K_2CO_3, MeOH; l) $LiAlH_4$, Et_2O, R = H (**7f**); m) CuBr·SMe_2, PhMgBr, THF/Et_2O, −40 °C, R = C_6H_5 (**7g**); n) HMTAP, toluene, reflux; o) $[Rh(COD)_2][SO_3CF_3]$, CH_2Cl_2, **9f**−**g**: M = Rh, L_1-L_2 = COD; p) $[PdCl_2(COD)]$, CH_2Cl_2, **10f**: M = Pd, $L_1 = L_2$ = Cl

cular S_N2 reaction of **5**).[13] Nucleophilic attack of $LiAlH_4$ opens the epoxide rings of **6b** to form (2*S*,3*R*,4*R*,5*S*)-3,4-*O*-isopropylidene-2,3,4,5-hexanetetraol (**7f**) in a clean reaction.[16,19] Larger substituents [e.g. (2*S*,3*R*,4*R*,5*S*)-3,4-*O*-isopropylidene-1,6-diphenyl-2,3,4,5-hexanetetraol, **7g**, R = phenyl] can be introduced by nucleophilic ring-opening of **6b** with organocuprate reagents generated from the copper(I) bromide−dimethylsulfide complex and suitable Grignard reagents in diethyl ether.[17,20] Subsequently, the monodentate phosphoramidites **8f**−**g** were synthesized in high yields by refluxing **7f**−**g** and hexamethyltriaminophosphane (HMTAP) in toluene. The corresponding orange Rh complexes **9f**−**g** and the pale yellow Pd compound **10f** were prepared by stirring 2 equiv. of monodentate ligand **9f**−**g** with $[Rh(COD)_2][SO_3CF_3]$ or $[PdCl_2(COD)]$ in dichloromethane.

Access to functionalized DuPHOS ligands was offered by branching off from the key intermediates **7a**−**e** (Figure 3), which were readily converted into the corresponding cyclic sulfates **11a**−**e** by reaction with thionyl chloride, followed by in situ oxidation of the intermediate cyclic sulfite with catalytic amounts of RuO_4.[21,22] The 1,2-bis(phospholano)-benzenes **12a**−**e** were prepared by successive treatment of 1,2-bis(phosphanyl)benzene with 2 equiv. of *n*BuLi, followed by the addition of 2 equiv. of the corresponding cyclic sulfate **11a**−**e** and an additional 2.2 equiv. of *n*BuLi.[8] The chiral bis(phospholanes) **13a**−**e** bearing four free hydroxy groups were synthesized by cleavage of the protecting groups (refluxing **12a**−**e** with methanesulfonic acid in water/methanol).[23−25] The resulting chiral bis(phospholanes) **13a**−**e** were converted into the corresponding yellow-orange Rh complexes **14a**−**e** and the pale yellow Pd analog **15a** by stirring 1 equiv. of **13a**−**e** with $[Rh(COD)_2][SO_3CF_3]$ or $[PdCl_2(COD)]$ in tetrahydrofuran or dichloromethane, respectively.

Structure of $PdCl_2$ Complexes

We were not able to grow suitable crystals of the rhodium complexes for X-ray analysis, but we succeeded in crystallizing the isoelectronic $PdCl_2$ species **10a**, **10f** (from methanol) and **15a** (from acetone/ethyl acetate). The crystallographic data of **10a** (Figure 4) were already reported on in our latest report.[18] The X-ray structure of **10a** (C2, C11, C5, C14: *R*; C3, C12, C4, C13: *S*; "*RSSR*") indicates the *cis* coordination of the two monodentate ligands **8a**, and the expected square-planar coordination environment of Pd^{II} [see (a) in Figure 4, front-view] with a chiral, C_2-symmetric arrangement of both ligands [see (b) in Figure 4, side-view]. Furthermore, Figure 4 (b) clearly shows that the tunable substituents (Figure 1, CH_2−R) of the monodentate phosphoramidites (Figure 4; C1, C10: R = H) occupy the top-left and bottom-right quadrants [see (c) in Figure 4], thereby defining a chiral cage around the metal center. The size of the cage is influenced by the nucleophile (R) used for the epoxide ring opening.

The diastereomeric $PdCl_2$ complex **10f** (C2−C5, C11−C14: *S*; "*SSSS*") also bears two *cis*-coordinated monodentate phosphoramidites **8f**. The C_2 symmetry and the square-planar geometry around the Pd^{II} center was determined by an X-ray structure investigation (Figure 5). The corresponding crystallographic data are listed in Table 1

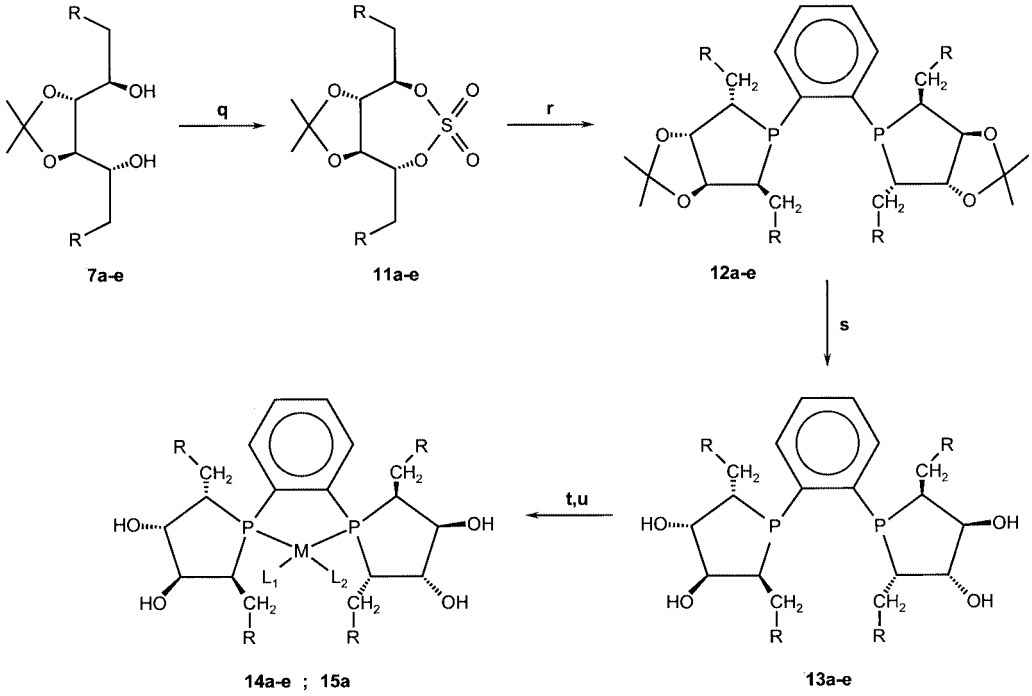

Figure 3. q) (i) $SOCl_2$, NEt_3, CH_2Cl_2; (ii) $NaIO_4/RuCl_3$, $CH_2Cl_2/MeCN/H_2O$; r) (i) 1,2-bis(phosphanyl)benzene, *n*BuLi, THF; (ii) *n*BuLi, THF; s) CH_3SO_3H, MeOH/H_2O, reflux; t) $[Rh(COD)_2][SO_3CF_3]$, THF, **14a**−**e**: M = Rh, L_1-L_2 = COD; u) $[PdCl_2(COD)]$, CH_2Cl_2, **15a**: M = Pd, $L_1 = L_2$ = Cl

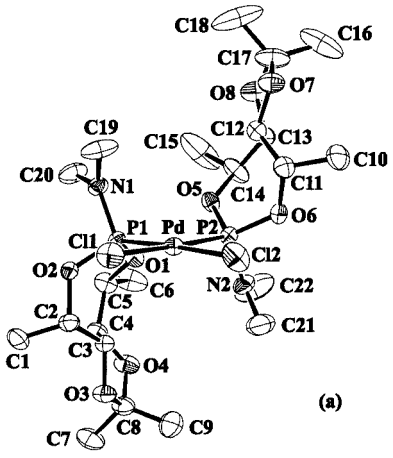

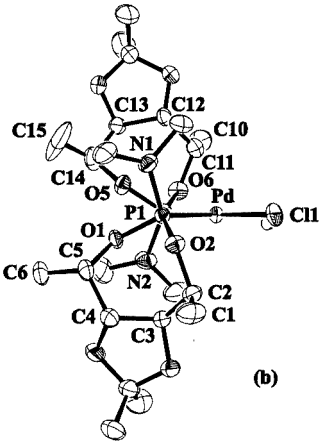

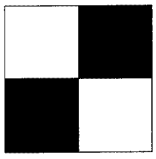

Figure 5. Molecular structure of **10f** (*SSSS*); (a) front-view: square-planar environment of Pd^{II}; (b) side-view: C_2-symmetric arrangement; hydrogen atoms have been omitted for clarity; (c) quadrant diagram

and 3. The side-view shows that the tunable substituents (Figure 2, CH_2-R) of the monodentate ligands (Figure 5; C1, C10: R = H) now occupy the top-right and bottom-left quadrants less effectively than in **10a** [see (c) in Figure 5].

In contrast to **10a** and **10f**, which bear two monodentate ligands each, the Pd^{II} complex **15a** (C2−C5, C8−C11: *S*; "*SSSS*") consists of a chelating bis(phospholane) (**13a**). Figure 6 (a) shows the five-membered phospholane rings and the planarity of the 1,2-phenylene moiety. The top view in Figure 6 (b) verifies the almost perpendicular orientation of the substituents (C1, C6, C7, C12 = CH_3) in the equatorial positions of the phospholane ring relative to the square-planar Pd^{II} environment. The effective occupation of the top-right and bottom-left quadrants is especially due to the free hydroxy groups (O2, O4) in the axial positions of the five-membered rings [Figure 6 (c); Table 2 and 3].

Results in the Asymmetric Hydrogenation Reactions

The synthesized Rh^{I} complexes bearing two monodentate phosphoramidite ligands (**9a**−**g**) or a chelating bis(phospholan)e (**14a**−**e**) were tested in the asymmetric hydrogenation reactions of α-(acetamido)cinnamic acid (**16**) and itaconic acid (**18**). Complexes **9a**−**e** ["*RSSR*", see (A) in Figure 7] produce a small excess of *N*-acetyl-(*R*)-phenylalanine in the hydrogenation of **16** (Table 4, Entries 1−5), ranging

from 3 to 36% *ee*. The highest value in this series (36% *ee*) is achieved with **9e** which bears the sterically most demanding benzyl substituent. The absolute configuration (*R*) of our hydrogenation products is in accordance with the prediction of Knowles[26] that the reaction to form (*R*)-amino acids is favored if the top-right quadrant of the catalyst's chiral cage is not occupied [Figure 4 (c)]. On the other hand, the diastereomeric Rh^{I} complexes **9f−g** ["*SSSS*", Figure 7 (B)], with the opposite quadrant geometry [cf. Pd^{II} complex **10f**, Figure 5 (c)], deliver an excess of the (*S*) form of *N*-acetylphenylalanine (**17**) (Entries 6−7). Complex **9g** remarkably yields an 89% *ee* (*S*) due to the benzyl groups, whereas the methyl-substituted analog **9f** only gives a 14% *ee* (*S*).

The methyl substituents in **9a** [Figure 7 (a), *RSSR*, C1, C10] occupy the "front-side" of the catalyst, whereas the same groups in **9f** [Figure 7 (B), *SSSS*, C1, C10] are oriented "sidewards". This leads to overall low enantioselectivities in the case of the methyl derivatives **9a**, **9f** (R = H), but with a trend to better results for **9a**. This situation changes completely for the benzyl-substituted species **9e** [Figure 7 (A)] and **9g** [Figure 7 (B)]. Computer models suggest that the sterically demanding benzyl groups (R = Ph) in **9e** are most probably oriented away from the P1−Pd−P2 plane, pointing into the "free-areas" above and below the coordination plane [Figure 7 (A)]. The changed stereochemistry of C2 and C11 (both *S*) in **9g** provides a "tight chiral cage" in the case of the demanding benzyl substituents in

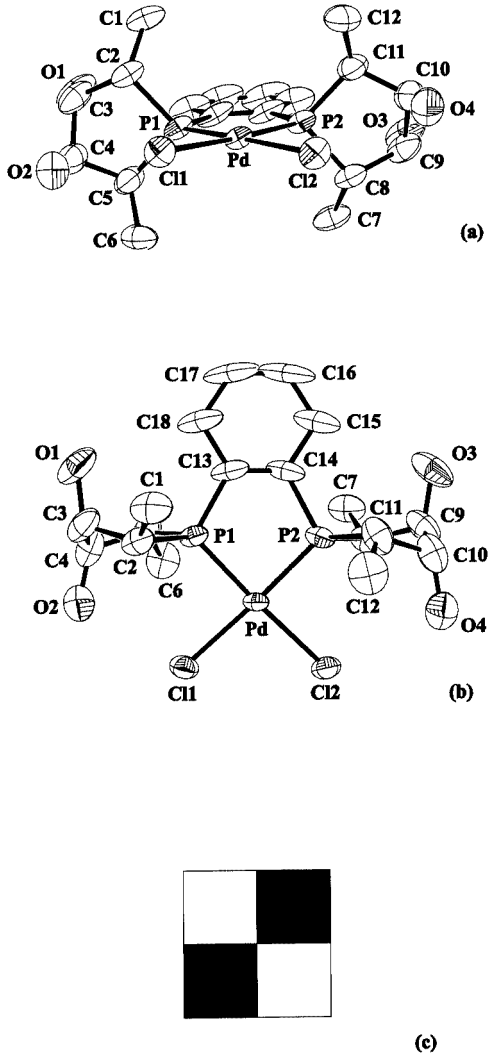

Figure 6. Molecular structure of **15a** (*SSSS*); (a) front-view: square-planar environment of Pd^{II}; (b) top-view: C_2-symmetric arrangement; hydrogen atoms have been omitted for clarity; (c) quadrant diagram

9g, and induces high enantioselectivities due to the "front orientation" of the phenyl fragments. In contrast, the small methyl substituents in **9f** lead to an "open chiral cage" of low enantioselectivity.

Itaconic acid (**18**), our second test olefin, gave the (*S*)-configured product after hydrogenation with **9a−e** ("*RSSR*"). The % *ee* values are higher with increasing steric demand of the substituents at the stereogenic centers C2 and C11 (Table 5, Entries 1−5). Therefore, **9e** gives the best result (61% *ee*) in this series; **9f** also produces a small excess (10% *ee*) of (*S*)-methylsuccinic acid (**19**); **9g** follows the opposite quadrant geometry relative to the former diastereomeric complexes, yielding **19** in an outstanding 94% *ee* (*R*) (Entries 6−7). This indicates that the steric arguments used above (Figure 7) also hold true for other substrates.

The Rh^{I} complexes **14a−e** bearing bidentate ligands once again demonstrate their outstanding ability to induce excellent enantioselectivities in asymmetric hydrogenation reactions. Compounds **14a−e**, with a quadrant diagram ident-

ee values obtained with the hydroxy-substituted bis(phospholanes) **13a**−**e** are as high as that for the DuPHOS case, but we did not find a maximal enantioselectivity for the *n*-propyl derivative.[8] An increase in the steric demand of our tunable ligands **13a**−**e** lowers the resulting enantiomeric excess of the amino acids produced. Figure 6 (b) shows that mainly the free hydroxy groups in the axial positions claim the top-right and bottom-left quadrant. Raising the steric demand of the equatorial substituents cannot improve the occupation of the crucial areas.

The (*R*) form of methylsuccinic acid (**19**) is produced throughout with very high enantiomeric excess values (up to > 99% *ee*) (Table 5, Entries 8−12). The best enantioselectivities are again produced with the catalysts **14a**,**b** with the smallest substituents in the 2,5-positions of the phospholane moiety.

Conclusion

Recently developed chiral monodentate P-ligands based on binaphthol as the chiral building block show remarkable selectivities in asymmetric hydrogenation reactions. Here, we presented an efficient ex-chiral-pool synthesis starting from D-mannitol, which allows for the tailoring of monodentate phosphoramidites and bidentate phospholanes. The diastereoisomers of these new monodenate ligands allow the exact positioning of substituents with a defined steric demand at the stereogenic centers. The benzyl-substituted Rh^I complex **9g** (up to 94% *ee*) proved that monodentate ligands can be designed for high enantioselectivities in asymmetric catalytic reactions of different substrates. This opens the possibility to fine-tune our ligands and the corresponding metal complexes for given prochiral substrates. A suitable design strategy can be based on relatively simple steric considerations, e.g. the "quadrant model" of Knowles et al. Our results were in accordance with the carefully drawn structure-selectivity relations based on such quadrant diagrams derived from X-ray structures of the corresponding Pd^{II} species.

Experimental Section

General Remarks: All reactions and manipulations were performed using standard Schlenk techniques. The reagents were obtained from Aldrich, Fluka, Merck and Strem and used without purification. Diethyl ether, tetrahydrofuran, toluene and pentane were distilled from $LiAlH_4$, dichloromethane was distilled from CaH_2 under nitrogen. Dry methanol (secco solv) was purchased from Merck. Melting points were determined using a Büchi Melting Point B-540 apparatus and are uncorrected. Optical rotations were obtained using a POLAR monitor from IBZ Messtechnik. Elemental analyses were carried out using an Elementar Vario EL. Mass spectrometry was performed using a Finnigan MAT, TSQ 7000 (FAB; matrix: 2-nitrophenyl octyl ether) and a Finnigan MAT, SSQ 7000 (CI: CH_4; EI: 70 eV). ^1H, ^{13}C, ^{31}P NMR spectra were recorded with a Bruker DRX 400 spectrometer. Chemical shifts are reported in ppm downfield from tetramethylsilane, with the solvent as the internal standard or 85% H_3PO_4 as the external standard. Enantiomeric excess (% *ee*) values were measured using Daicel chiral HPLC columns Chiralcel OD and Chiralpak WH 10 μ m (250 mm × 4.6) with a Waters HPLC 2690 with a Knauer variable UV/Vis detector. Hydrogen (5.0) was purchased from mti. All compounds shown in Figure 1 were reported in our latest report.[18]

Synthesis of Chiral Diols 7f−g

(2*S*,3*R*,4*R*,5*S*)-3,4-*O*-Isopropylidene-2,3,4,5-hexanetetraol (7f): A solution of **6b** (8.85 g, 47.5 mmol) in 50 mL of diethyl ether was slowly added to a stirred suspension of $LiAlH_4$ (3.61 g, 95.1 mmol) in 130 mL of diethyl ether. After refluxing for 3 h, the reaction mixture was carefully hydrolyzed at 0 °C, subsequently with water and diluted sulfuric acid until the white precipitate dissolved. Extraction with diethyl ether, washing the organic layer with $NaHCO_3$, drying with Na_2SO_4 and evaporation of the solvent yielded **7f** as a colorless oil. Yield: 5.60 g, 62.0%. $[\alpha]_D^{25}$ = +26.1 (*c* = 0.44, $CHCl_3$). ^1H NMR (400 MHz, $CDCl_3$): δ = 1.21 (d, 6 H, CH_3), 1.40 (s, 6 H, CH_3), 3.68−3.75 (m, 2 H, CH), 3.76−3.78 (m, 2 H, CH) ppm. ^{13}C NMR: δ = 20.1, 27.4, 67.1, 81.4, 109.4 ppm. MS (CI): *m*/*z* = 335 [MH^+] (+MSTFA). $C_9H_{18}O_4$ (190.24): calcd. C 56.82, H 9.54; found C 54.43, H 9.31.

(2*S*,3*R*,4*R*,5*S*)-3,4-*O*-Isopropylidene-1,6-diphenyl-2,3,4,5-hexanetetraol (7g): $CuBr{\cdot}SMe_2$ (0.62 g, 3 mmol) was added to a stirred suspension of phenylmagnesium bromide (120 mmol) in 100 mL of diethyl ether at −40 °C. After stirring at −40 °C for 2 h, a solution of **6b** (5.59 g, 30 mmol) in 30 mL of tetrahydrofuran was added. After 1 h of stirring at room temp., the mixture was poured into a saturated NH_4Cl solution. The organic layer was extracted, washed with water, dried with Na_2SO_4 and the solvents were evaporated to dryness to give **7g**, after flash chromatography (eluting with hexane/EtOAc, 7:3), as a colorless oil. Yield: 7.82 g, 76.1%. $[\alpha]_D^{21}$ = +10.2 (*c* = 0.53, $CHCl_3$). ^1H NMR (400 MHz, $CDCl_3$): δ = 1.43 (s, 6 H, CH_3), 2.70−2.83 (m, 4 H, CH_2), 3.66−3.71 (m, 2 H, CH), 3.95−3.99 (m, 2 H, CH), 7.13−7.26 (m, 10 H, $CH_{arom.}$) ppm. ^{13}C

NMR: δ = 27.1, 41.1, 70.9, 78.6, 109.3, 126.4, 128.4, 129.2, 137.9 ppm. MS (CI): *m*/*z* = 343 [MH$^+$]. $C_{21}H_{26}O_4$ (342.4): calcd. C 73.66, H 7.65; found C 72.44, H 7.62.

General Procedure for the Synthesis of 8f−g: Chiral diols **7f−g** (6.2 mmol) and NH_4Cl (10 mg) were refluxed in 150 mL of toluene. HMTAP (1.24 mL, 6.8 mmol) was added to this refluxing solution and stirred for a further 8 h. The mixture was concentrated under reduced pressure affording colorless oils.

(4*S*,5*S*,6*S*,7*S*)-5,6-*O*-Isopropylidene-2-(dimethylamino)-4,7-dimethyl-1,3,2-dioxaphosphepane-5,6-diol (8f): Yield: 1.59 g, 97.3%. $[\alpha]_D^{23}$ = −67.1 (*c* = 0.41, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.24 (d, 3 H, CH_3), 1.36 (s, 3 H, CH_3), 1.37 (s, 3 H, CH_3), 1.42 (d, 3 H, CH_3), 2.57 (s, 3 H, N−CH_3), 2.60 (s, 3 H, N−CH_3), 4.24−4.27 (m, 1 H, CH), 4.41−4.56 (m, 3 H, CH) ppm. ^{13}C NMR: δ = 15.0, 16.4, 27.2, 34.8, 35.0, 68.4, 69.8, 75.7, 76.3, 110.3 ppm. ^{31}P NMR: δ = 140.48 (s) ppm. MS (CI): *m*/*z* = 264 [MH$^+$]. $C_{11}H_{22}NO_4P$ (263.3): calcd. C 50.18, H 8.42, N 5.32; found C 48.38, H 8.41, N 6.21.

(4*S*,5*S*,6*S*,7*S*)-5,6-*O*-Isopropylidene-2-(dimethylamino)-4,7-dibenzyl-1,3,2-dioxaphosphepane-5,6-diol (8g): Yield: 2.38 g, 92.4%. $[\alpha]_D^{21}$ = −50.0 (*c* = 0.01, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.49 (s, 6 H, CH_3), 2.45 (s, 3 H, N−CH_3), 2.48 (s, 3 H, N−CH_3), 2.70−2.78 (m, 1 H, CH_2), 3.09−3.25 (m, 3 H, CH_2), 4.43−4.61 (m, 3 H, CH), 4.73−4.79 (m, 1 H, CH), 7.17−7.29 (m, 10 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 27.0, 27.2, 34.3, 34.8, 35.0, 36.7, 73.3, 74.8, 76.4, 77.3, 110.6, 126.09, 126.13, 128.1, 128.2, 129.6, 129.8, 138.8, 139.1 ppm. ^{31}P NMR: δ = 140.24 (s) ppm. MS (CI): *m*/*z* = 417 [MH$^+$]. $C_{23}H_{30}NO_4P$ (415.5): calcd. C 66.49, H 7.28, N 3.37; found C 62.56, H 7.07, N 3.56.

General Procedure for the Synthesis of Rhodium(I) Complexes 9f−g: A solution of 2 equiv. of the corresponding monodentate phosphoramidite **8f−g** in 20 mL of dichloromethane was added to a stirred solution of $[Rh(COD)_2][SO_3CF_3]$ (300 mg, 0.64 mmol) in 30 mL of dichloromethane at 0 °C. After stirring for 2 h at room temp., the solvent was removed under reduced pressure. The resulting orange solid was washed twice with 50 mL of pentane and dried in vacuo.

{Bis[(4*S*,5*S*,6*S*,7*S*)-5,6-*O*-isopropylidene-2-(dimethylamino)-4,7-dimethyl-1,3,2-dioxaphosphepane]Rh^I(COD)} Trifluoromethanesulfonate (9f): Yield: 528 mg, 93.0%. ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.23 (d, 6 H, CH_3), 1.33 (d, 6 H, CH_3), 1.38 (s, 12 H, CH_3), 2.31−2.57 (m, 8 H, $CH_{2,COD}$), 2.97−3.01 (m, 12 H, N−CH_3), 4.29−4.35 (m, 2 H, CH), 4.41−4.46 (m, 2 H, CH), 4.52−4.64 (m, 4 H, CH), 5.10−5.17 (m, 2 H, CH_{COD}), 5.52−5.59 (m, 2 H, CH_{COD}) ppm. ^{31}P NMR: δ = 117.06 (d) ppm. MS (FAB): *m*/*z* = 737 [(M − $SO_3CF_3^-$)$^+$]. $C_{31}H_{56}F_3N_2O_{11}P_2RhS$ (886.7): calcd. C 41.99, H 6.37, N 3.16; found C 41.87, H 6.48, N 2.55.

{Bis[(4*S*,5*S*,6*S*,7*S*)-5,6-*O*-isopropylidene-2-(dimethylamino)-4,7-dibenzyl-1,3,2-dioxaphosphepane]Rh^I(COD)} Trifluoromethanesulfonate (9g): Yield: 734 mg, 96.2%. ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.37 (s, 6 H, CH_3), 1.39 (s, 6 H, CH_3), 2.17−2.54 (m, 8 H, CH_{2COD}), 2.38−2.44 (m, 12 H, N−CH_3), 2.60−2.75 (m, 4 H, CH_2), 2.95−3.06 (m, 4 H, CH_2), 4.10−4.16 (m, 2 H, CH), 4.26−4.31 (m, 2 H, CH), 4.45−4.53 (m, 2 H, CH), 4.53−4.59 (m, 2 H, CH), 4.78−4.86 (m, 2 H, CH_{COD}), 5.45−5.53 (m, 2 H, CH_{COD}), 7.05−7.32 (m, 20 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = 116.60 (d) ppm. MS (FAB): *m*/*z* = 1041 [(M − $SO_3CF_3^-$)$^+$]. $C_{55}H_{72}F_3N_2O_{11}P_2RhS$ (1191.1): calcd. C 55.46, H 6.09, N 2.35; found C 54.28, H 6.22, N 2.31.

{Bis[(4*S*,5*S*,6*S*,7*S*)-5,6-*O*-isopropylidene-2-(dimethylamino)-4,7-dimethyl-1,3,2-dioxaphosphepane]}PdCl$_2$ (10f): A solution of 2 equiv. of the monodentate ligand **8f** in 50 mL of dichloromethane was added to a stirred solution of $[PdCl_2(COD)]$ (500 mg, 1.75 mmol) in 70 mL of dichloromethane at 0 °C. After stirring at room temp. for 2 h, the solvent was removed under reduced pressure. Washing of the residue twice with 50 mL of diethyl ether and drying in vacuo resulted in a pale yellow powder. Yield: 1.13 g, 91.7%. ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.34 (d, 6 H, CH_3), 1.37 (s, 12 H, CH_3), 1.38 (d, 6 H, CH_3), 2.86−2.89 (m, 12 H, N−CH_3), 4.34−4.44 (m, 4 H, CH), 4.73−4.81 (m, 2 H, CH), 5.20−5.28 (m, 2 H, CH) ppm. ^{13}C NMR: δ = 15.4, 16.7, 26.7, 26.9, 38.1, 72.9, 74.4, 75.4, 75.9, 111.8 ppm. ^{31}P NMR: δ = 101.47 (s) ppm. MS (FAB): *m*/*z* = 669 [(M − Cl$^-$)$^+$]. $C_{22}H_{44}N_2O_8P_2PdCl_2$ (703.9): calcd. C 37.54, H 6.30, N 3.98; found C 35.66, H 6.45, N 4.18.

General Procedure for the Synthesis of the Cyclic Sulfates 11a−e: **11a**,**b** have already been reported.[24] A solution of thionyl chloride (1.91 mL, 26 mmol) in 20 mL of dichloromethane was added to a stirred solution of the corresponding chiral diol **7c−e** (24 mmol) and pyridine (4.26 mL, 53 mmol) in 100 mL of dichloromethane at 0 °C. After 3 h at room temp., the reaction mixture was washed with water and the organic layer extracted, dried with Na_2SO_4 and the solvents were evaporated to dryness. The resulting oil was redissolved in 40 mL of dichloromethane and 40 mL of acetonitrile, and $NaIO_4$ (10.25 g, 48 mmol) and $RuCl_3{\cdot}nH_2O$ (34 mg) in 60 mL of water were then added. After 1 h at room temp., the organic layer was extracted with dichloromethane, washed with brine, dried with Na_2SO_4 and the solvents were evaporated to dryness. The products were isolated by filtration through silica (eluent: dichloromethane). After concentration to dryness, the cyclic sulfates **11c−d** were obtained as colorless crystals, **11e** as a pale yellow oil.

(4*R*,5*S*,6*S*,7*R*)-5,6-*O*-Isopropylidene-4,7-di-*n*-propyl-1,3,2-dioxathiepane 2,2-Dioxide (11c): Yield: 5.48 g, 74.2%; m.p. 36−38 °C. $[\alpha]_D^{24}$ = +45.4 (*c* = 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 0.94 (t, 6 H, CH_3), 1.38 (s, 6 H, CH_3), 1.41−1.49 (m, 2 H, CH_2), 1.55−1.64 (m, 2 H, CH_2), 1.81−1.86 (m, 4 H, CH_2), 3.98−4.04 (m, 2 H, CH), 4.25−4.31 (m, 2 H, CH) ppm. ^{13}C NMR: δ = 13.5, 18.0, 26.7, 34.2, 79.6, 84.6, 110.5 ppm. MS (CI): *m*/*z* = 309 [MH$^+$]. $C_{13}H_{24}O_6S$ (308.4): calcd. C 50.63, H 7.84; found C 49.81, H 7.69.

(4*R*,5*S*,6*S*,7*R*)-4,7-Diisopentyl-5,6-*O*-isopropylidene-1,3,2-dioxathiepane 2,2-Dioxide (11d): Yield: 7.22 g, 82.6%; m.p. 36−38 °C. $[\alpha]_D^{24}$ = +45.3 (*c* = 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 0.88−0.90 (m, 12 H, CH_3), 1.23−1.34 (m, 2 H, CH_2), 1.39 (s, 6 H, CH_3), 1.42−1.50 (m, 2 H, CH_2), 1.51−1.61 (m, 2 H, CH), 1.77−1.93 (m, 4 H, CH_2), 3.99−4.04 (m, 2 H, CH), 4.22−4.28 (m, 2 H, CH) ppm. ^{13}C NMR: δ = 22.2, 22.5, 26.8, 27.7, 30.2, 33.6, 79.7, 85.3, 110.6 ppm. MS (CI): *m*/*z* = 365 [MH$^+$]. $C_{17}H_{32}O_6S$ (364.5): calcd. C 56.02, H 8.85; found C 55.41, H 8.89.

(4*R*,5*S*,6*S*,7*R*)-4,7-Dibenzyl-5,6-*O*-isopropylidene-1,3,2-dioxathiepane 2,2-Dioxide (11e): Yield: 8.07 g, 83.2%. $[\alpha]_D^{23}$ = +54.2 (*c* = 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.44 (s, 6 H, CH_3), 3.07−3.18 (m, 4 H, CH_2), 4.02−4.07 (m, 2 H, CH), 4.39−4.45 (m, 2 H, CH), 7.18−7.28 (m, 10 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 26.8, 38.1, 78.7, 84.5, 110.9, 127.1, 128.5, 129.6, 135.1 ppm. MS (CI): *m*/*z* = 405 [MH$^+$]. $C_{21}H_{24}O_6S$ (404.49): calcd. C 62.39, H 5.98; found C 59.56, H 5.95.

General Procedure for the Synthesis of the Bis(phospholanes) 12a−e: **12a**,**b** have already been reported.[24] A solution of 1.6 M *n*-butyllithium (8.0 mL, 12.8 mmol) in *n*-hexane was added to a stirred solution of 1,2-bis(phosphanyl)benzene (0.91 g, 6.4 mmol) in 50 mL of

tetrahydrofuran. After 2 h at room temp., the corresponding cyclic sulfate **11c−e** (12.8 mmol) in 50 mL of tetrahydrofuran was added. After an additional 4 h at room temp., *n*-butyllithium (8.8 mL of 1.6 M solution, 14.1 mmol) in *n*-hexane was added. After 16 h at room temp., the excess *n*-butyllithium was hydrolyzed with 3 mL of methanol. The reaction solvents were evaporated to dryness. The resulting yellow oil was extracted twice with 50 mL *n*-pentane. After concentrating to dryness, the bidentate ligands were obtained as a white powder (**12d−e**) or a colorless oil (**12c**).

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-*O*-isopropylidene-2,5-diisopropylphospholanyl]benzene (12c): Yield: 2.37 g, 65.8%. $[\alpha]_D^{24}$ = +189.3 (*c* = 0.783, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 0.57 (t, 6 H, CH_3), 0.69−0.78 (m, 2 H, CH_2), 0.85 (t, 6 H, CH_3), 0.95−1.05 (m, 2 H, CH_2), 1.23−1.35 (m, 6 H, CH_2), 1.37−1.42 (m, 2 H, CH_2), 1.44 (s, 6 H, CH_3), 1.45 (s, 6 H, CH_3), 1.47−1.56 (m, 2 H, CH_2), 1.81−1.97 (m, 2 H, CH_2), 2.24−2.29 (m, 2 H, CH), 2.61−2.73 (m, 2 H, CH), 4.33−4.46 (m, 4 H, CH), 7.30−7.38 (m, 4 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 13.90, 13.91, 21.6, 22.9, 27.2, 27.3, 29.8, 29.9, 30.6, 30.9, 81.3, 82.2, 117.0, 129.2, 131.1, 141.2 ppm. ^{31}P NMR: δ = 35.95 (s) ppm. MS (CI): *m*/*z* = 563 [MH^+]. $C_{32}H_{52}O_4P_2$ (562.7): calcd. C 68.30, H 9.31; found 64.18, H 8.56.

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-2,5-diisopentyl-3,4-*O*-isopropylidenephospholanyl]benzene (12d): Yield: 3.00 g, 69.3%; m.p. 125−130 °C. $[\alpha]_D^{23}$ = +136.5 (*c* = 0.31, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 0.48 (d, 6 H, CH_3), 0.59 (d, 6 H, CH_3), 0.72−0.81 (m, 4 H, CH), 0.85 (d, 12 H, CH_3), 0.85−0.90 (m, 2 H, CH_2), 1.04−1.13 (m, 4 H, CH_2), 1.15−1.24 (m, 2 H, CH_2), 1.26−1.42 (m, 4 H, CH_2), 1.46 (s, 6 H, CH_3), 1.47 (s, 6 H, CH_3), 1.47−1.56 (m, 2 H, CH_2), 1.87−2.00 (m, 2 H, CH_2), 2.15−2.20 (m, 2 H, CH), 2.54−2.66 (m, 2 H, CH), 4.32−4.49 (m, 4 H, CH), 7.31−7.37 (m, 4 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 22.3, 22.4, 22.6, 22.7, 25.2, 26.1, 27.31, 27.33, 28.2, 28.4, 31.3, 31.4, 38.3, 38.9, 81.3, 82.4, 117.1, 129.2, 131.3, 141.2 ppm. ^{31}P NMR: δ = 36.71 (s) ppm. MS (CI): *m*/*z* = 676 [MH^+]. $C_{40}H_{68}O_4P_2$ (674.9): calcd. C 71.18, H 10.15; found C 67.24, H 9.69.

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-2,5-dibenzyl-3,4-*O*-isopropylidenephospholanyl]benzene (12e): Yield: 2.64 g, 54.6%; m.p. 136−140 °C. $[\alpha]_D^{23}$ = +28.1 (*c* = 0.089, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.47 (s, 12 H, CH_3), 2.05−2.10 (m, 2 H, CH_2), 2.49−2.55 (m, 2 H, CH_2), 2.67−2.73 (m, 2 H, CH_2), 2.79−2.88 (m, 2 H, CH_2), 3.12−3.26 (m, 4 H, CH), 4.43−4.63 (m, 4 H, CH), 6.89−7.44 (m, 24 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 27.3, 27.4, 30.9, 32.2, 24.0, 35.1, 81.0, 81.9, 117.8, 125.6, 126.0, 127.8, 128.2, 128.6, 128.9, 129.0, 129.7, 130.8, 141.3, 141.4 ppm. ^{31}P NMR: δ = 42.39 (s) ppm. MS (CI): *m*/*z* = 755 [M^+]. $C_{48}H_{52}O_4P_2$ (754.9): calcd. C 76.37, H 6.94; found C 75.04, H 6.65.

General Procedure for the Synthesis of the Bis(phospholanes) 13a−e: 13a,**b** have already been reported.[24,25] Methanesulfonic acid (1 mL of a 70% solution) in water was added to a stirred solution of the corresponding bis(phospholane) **12c−e** (2.11 mmol) in 50 mL of methanol at room temp. After 2.5 h of stirring under reflux, the reaction solvents were evaporated to dryness. The residue was dissolved in 30 mL of ethyl acetate and 30 mL of water. K_2CO_3 was then added until neutral reaction of litmus. After stirring for several hours, the organic layer was separated and dried with Na_2SO_4. Concentration to dryness yielded bis(phospholanes) **13c−e** as white solids.

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-di-*n*-propylphospholanyl]benzene (13c): Yield: 0.73 g, 71.9%; m.p. 100−103 °C. $[\alpha]_D^{26}$ = +103.7 (*c* = 0.52, MeOH). ^{1}H NMR (400 MHz, MeOD): δ = 0.69−0.72 (t, 6 H, CH_3), 0.77−0.82 (t, 6 H, CH_3), 1.12−1.36 (m, 12 H, CH_2), 1.53−1.66 (m, 2 H, CH_2), 1.68−1.83 (m, 2 H, CH_2), 2.53−2.66 (m, 2 H, CH), 2.82−2.89 (m, 2 H, CH), 4.14−4.19 (m, 4 H, CH), 7.18−7.22 (m, 2 H, $CH_{arom.}$), 7.89−7.93 (m, 2 H, $CH_{arom.}$) ppm. ^{13}C NMR: δ = 14.9, 15.0, 23.8, 24.4, 30.6, 32.9, 41.7, 45.3, 80.0, 81.0, 129.1, 135.3, 144.8 ppm. ^{31}P NMR: δ = −10.36 (s) ppm. MS (CI): *m*/*z* = 483 [MH^+]. $C_{26}H_{44}O_4P_2$ (482.5): calcd. C 64.72, H 9.19; found C 62.77, H 9.00.

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-diisopentylphospholanyl]benzene (13d): Yield: 1.13 g, 90.2%; m.p. 150−155 °C. $[\alpha]_D^{24}$ = +89.2 (*c* = 0.25, MeOH). ^{1}H NMR (400 MHz, MeOD): δ = 0.68−0.81 (m, 24 H, CH_3), 0.83−0.90 (m, 4 H, CH), 1.04−1.27 (m, 6 H, CH_2), 1.31−1.40 (m, 4 H, CH_2), 1.42−1.52 (m, 2 H, CH_2), 1.53−1.65 (m, 2 H, CH_2), 1.77−1.91 (m, 2 H, CH_2), 2.50−2.63 (m, 2 H, CH), 2.77−2.87 (m, 2 H, CH), 4.16−4.20 (m, 4 H, CH), 7.18−7.22 (m, 2 H, $CH_{arom.}$), 7.88−7.92 (m, 2 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = −10.04 (s) ppm. MS (CI): *m*/*z* = 595 [M^+]. $C_{34}H_{60}O_4P_2$ (594.7): calcd. C 68.67, H 10.17; found C 66.22, H 9.89.

1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-2,5-dibenzyl-3,4-dihydroxyphospholanyl]benzene (13e): Yield: 0.81 g, 56.9%; m.p. 178−183 °C. $[\alpha]_D^{24}$ = +37.9 (*c* = 0.174, MeOH). ^{1}H NMR (400 MHz, MeOD): δ = 2.05−2.27 (m, 2 H, CH_2), 2.75−2.85 (m, 2 H, CH_2), 2.89−3.04 (m, 4 H, CH_2), 3.06−3.18 (m, 2 H, CH), 3.31−3.43 (m, 2 H, CH), 3.83−3.93 (m, 2 H, CH), 3.99−4.06 (m, 2 H, CH), 6.80−7.37 (m, 24 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = −11.13 (s) ppm. MS (CI): *m*/*z* = 675 [M^+]. $C_{42}H_{44}O_4P_2$ (674.7): calcd. C 74.77, H 6.57; found C 73.34, H 6.58.

General Procedure for the Synthesis of the Rhodium(I) Complexes 14a−e: A solution of 1 equiv. of the corresponding bis(phospholane) **13a−e** in 30 mL of tetrahydrofuran was added to a solution of $[Rh(COD)_2][SO_3CF_3]$ (400 mg, 0.85 mmol) in 50 mL of tetrahydrofuran at room temp. After 3 h of stirring at room temp., the reaction solvents were evaporated to dryness. The orange residue was washed twice with 50 mL of diethyl ether and dried in vacuo.

[{1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-dimethylphospholanyl]benzene}Rh^I(COD)] Trifluoromethanesulfonate (14a): Yield: 582 mg, 93.3%. ^{1}H NMR (400 MHz, MeOD): δ = 0.91−0.96 (m, 6 H, CH_3), 1.34−1.40 (m, 6 H, CH_3), 2.17−2.64 (m, 8 H, CH_{2COD}), 2.79−2.89 (m, 4 H, CH), 4.06−4.14 (m, 2 H, CH), 4.16−4.24 (m, 2 H, CH), 5.54−5.61 (m, 2 H, CH_{COD}), 5.95−6.04 (m, 2 H, CH_{COD}), 7.55−7.58 (m, 2 H, $CH_{arom.}$), 8.62−8.66 (m, 2 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = 78.20 (d) ppm. MS (FAB): *m*/*z* = 581 [(M − $SO_3CF_3^-$)$^+$]. $C_{27}H_{40}F_3O_7P_2RhS$ (730.5): calcd. C 44.39, H 5.52; found C 43.36, H 5.78.

[{1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,4-diethylphospholanyl]benzene}Rh^I(COD)] Trifluoromethanesulfonate (14b): Yield: 615 mg, 91.5%. ^{1}H NMR (400 MHz, MeOD): δ = 0.85−0.88 (t, 6 H, CH_3), 0.93−0.96 (t, 6 H, CH_3), 1.43−1.54 (m, 2 H, CH_2), 1.81−1.91 (m, 2 H, CH_2), 1.91−2.04 (m, 2 H, CH_2), 2.14−2.22 (m, 2 H, CH_2), 2.29−2.65 (m, 8 H, CH_{2COD}), 2.57−2.65 (m, 2 H, CH), 2.67−2.75 (m, 2 H, CH), 4.18−4.34 (m, 4 H, CH), 5.53−5.58 (m, 2 H, CH_{COD}), 5.89−5.95 (m, 2 H, CH_{COD}), 7.54−7.57 (m, 2 H, $CH_{arom.}$), 8.65−8.69 (m, 2 H, $CH_{arom.}$). ^{31}P NMR: δ = 71.50 (d) ppm. MS (FAB): *m*/*z* = 637 [(M − $SO_3CF_3^-$)$^+$]. $C_{31}H_{48}F_3O_7P_2RhS$ (786.6): calcd. C 47.33, H 6.15; found C 46.7, H 6.13.

[{1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-di-*n*-propylphospholanyl]benzene}Rh^I(COD)] Trifluoromethanesulfonate (14c): Yield: 679 mg, 94.4%. ^{1}H NMR (400 MHz, MeOD): δ = 0.74−0.80 (m, 12 H, CH_3), 0.82−1.68 (m, 10 H, CH_2), 1.79−1.98 (m, 4 H, CH_2),

2.13−2.26 (m, 2 H, CH_2), 2.27−2.67 (m, 8 H, CH_{2COD}), 2.68−2.76 (m, 2 H, CH), 2.79−2.88 (m, 2 H, CH), 4.12−4.33 (m, 4 H, CH), 5.46−5.57 (m, 2 H, CH_{COD}), 5.88−5.99 (m, 2 H, CH_{COD}), 7.55−7.60 (m, 2 H, $CH_{arom.}$), 8.65−8.69 (m, 2 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = 71.87 (d) ppm. MS (FAB): *m*/*z* = 693 [(M − $SO_3CF_3^-$)$^+$]. $C_{35}H_{56}F_3O_7P_2RhS$ (842.7): calcd. C 49.89, H 6.70; found C 50.31, H 6.75.

[{1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-diisopentylphospholanyl]benzene}Rh^I(COD)] Trifluoromethanesulfonate (14d): Yield: 763 mg, 93.5%. ^{1}H NMR (400 MHz, MeOD): δ = 0.66−0.69 (m, 12 H, CH_3), 0.78 (d, 6 H, CH_3), 0.83 (d, 6 H, CH_3), 0.86−0.95 (m, 4 H, CH), 0.99−1.66 (m, 12 H, CH_2), 1.71−1.83 (m, 2 H, CH_2), 2.00−2.14 (m, 2 H, CH_2), 2.14−2.65 (m, 8 H, CH_{2COD}), 2.65−2.80 (m, 4 H, CH), 4.15−4.34 (m, 4 H, CH), 5.50−5.57 (m, 2 H, CH_{COD}), 5.94−6.03 (m, 2 H, CH_{COD}), 7.53−7.61 (m, 2 H, $CH_{arom.}$), 8.62−8.69 (m, 2 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = 73.36 (d) ppm. {1,2-Bis[(2*S*,3*S*,4*S*,5*S*)-3,4-dihydroxy-2,5-dimethylphospholanyl]benzene}Pd^{II}Cl$_2$ (15a): A solution of **12a** (2.10 g, 4.66 mmol) in 50 mL of dichloromethane was added to a solution of [$PdCl_2$(COD)] (1.10 g, 3.85 mmol) in 50 mL of dichloromethane. The yellow solution was stirred for 1 h at room temp. and the solvents were evaporated to dryness. The residue was washed twice with 50 mL of *n*-pentane and dissolved in 50 mL of dichloromethane. On addition of 20 mL of water, and a small amount of hydrochloric acid, a pale yellow powder precipitated. After stirring for 1 h at room temp., the precipitate was filtered off, washed with dichloromethane and dried in vacuo. Yield: 1.87 g, 88.6%. ^{1}H NMR (400 MHz, MeOD): δ = 0.91−0.99 (m, 6 H, CH_3), 1.35−1.44 (m, 6 H, CH_3), 3.09−3.19 (m, 2 H, CH), 3.51−3.60 (m, 2 H, CH), 3.97−4.08 (m, 2 H, CH), 4.15−4.25 (m, 2 H, CH), 7.73−7.79 (m, 2 H, $CH_{arom.}$), 8.49−8.55 (m, 2 H, $CH_{arom.}$) ppm. ^{31}P NMR: δ = 104.99 (s) ppm. MS (FAB): *m*/*z* = 513 [(M − Cl^-)$^+$]. $C_{18}H_{28}Cl_2O_4P_2Pd$ (547.7): calcd. C 39.47, H 5.15; found C 39.47, H 5.09.

General Procedure for the Asymmetric Hydrogenation: Hydrogenation reactions were performed using standard Schlenk techniques. Methanol Secco Solv was purchased from Merck and stored over molecular sieves. In a Schlenk tube, the corresponding Rh^I complex, **9a**−**g**, **14a**−**e**, (10 μmol) and **16** (500 mg, 2.44 mmol) or **18** (250 mg, 1.92 mmol) were dissolved in 5 mL of methanol. After three vacuum/nitrogen cycles, followed by one vacuum/hydrogen cycle (1.3 bar), the reaction mixture was stirred at room temp. for 20 h. The reaction products were filtered through a short silica column and subjected to *ee* determination. Conversions were determined by means of ^{1}H NMR spectroscopy.

X-ray Crystallography of 15a and 10f: The crystals used in this study were mounted onto the ends of glass fibers. X-ray data were collected with a STOE IPDS unit (Imaging Plate Diffraction System). Graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å) was used. Crystal data are listed in Table 3, together with refinement details. The lattice constants correspond to the temperatures indicated there. Absorption corrections were not applied. The structures were solved by the Patterson method with the SHELXS-86 program.[27] The atomic coordinates and anisotropic thermal parameters of the non-hydrogen atoms were refined using the SHELXL-97 program;[28] full-matrix method on F^2 data. Hydrogen atoms were included in the final refinement cycles, except those of atoms C15, C16, C18, C19 and C22 of **10f**, since these were highly anisotropic. The riding model was used for the hydrogen atoms. By using the absolute structure parameter[29] as a criterion, it could be decided which of the enantiomers in both cases corresponds to the crystal investigated, and that in the case of **15a**, $P3_121$ is the correct space group and not $P3_221$. CCDC-177475 and -177476 for **15a** and **10f** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Metal Complexes of the Tetradentate Ligands *rac*- and *meso*-N,P,P,N: Synthesis, Separation and Structural Characterization

Gabi Müller,[a] Martti Klinga,[b] Markku Leskelä,[b] and Bernhard Rieger*[a]

Keywords: N ligands / P ligands / Iron / Palladium / Cobalt

The N,P,P,N ligand 1,2-bis[(2-quinolinemethyl)(phenyl)phosphanyl]ethane (**2**) which contains two stereogenic phosphane units in the ligand backbone [***rac*-2** (*R*/*R*, *S*/*S*) and ***meso*-2** (*R*/*S*)] and two pendant quinaldine moieties was synthesized. The diastereomeric forms were separated after conversion of the ligands to the corresponding palladium(II) diiodide complexes (***rac*-3**, ***meso*-3**). The structure of both compounds was determined by X-ray structure analysis and revealed a bidentate coordination through phosphorus leading to the expected square-planar geometry. The free ligands were regenerated by treatment of the palladium(II) diiodides with potassium cyanide and the coordination behavior of ***rac*-2** and ***meso*-2** towards iron(II) and cobalt(II) dichloride (***rac*-5, *meso*-5**, M = Fe; ***rac*-6, *meso*-6**, M = Co) was investigated by the means of IR and UV/Vis spectroscopy. The results indicate that in the case of Fe^{II} and Co^{II} the quinaldine moieties are not coordinated to the metal center and the ligands therefore act, as in the case of Pd^{II}, as bidentate systems. UV/Vis investigations suggest a tetrahedral coordination environment for the Co^{II} complexes. The Fe^{II} and Co^{II} derivatives were tested for ethene polymerization and the bis(acetonitrile)-palladium compounds (***rac*-4**, ***meso*-4**) for ethene/CO copolymerization reactions.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

A variety of late-transition-metal polymerization catalysts with different ligand (mono-, bi-, tri- or tetradentate)-metal combinations are known in the literature.[1–3] Bidentate ligands are often used in nickel-catalyzed olefin homopolymerization and palladium-catalyzed olefin/CO copolymerization reactions. Highly active iron and cobalt complexes with tridentate pyridyl-diimine systems were discovered recently.[4,5] However less attention has been directed towards iron and cobalt complexes with tetradentate ligands.

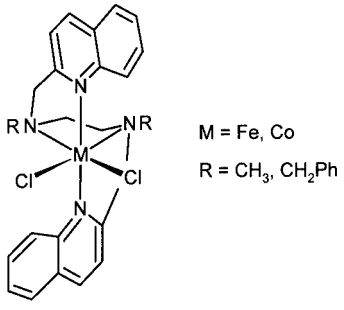

Figure 1. Octahedral C_2-symmetric complexes containing ligand **1**

Recently, our group reported the synthesis of a tetradentate quinaldine-amine ligand **1** and on the application of the corresponding palladium complexes for norbornene polymerization.[6,7] When coordinated to iron(II) or cobalt(II) dichloride, **1** exclusively forms an octahedral, C_2-symmetric complex [**(1)Fe/CoCl$_2$**, Figure 1].

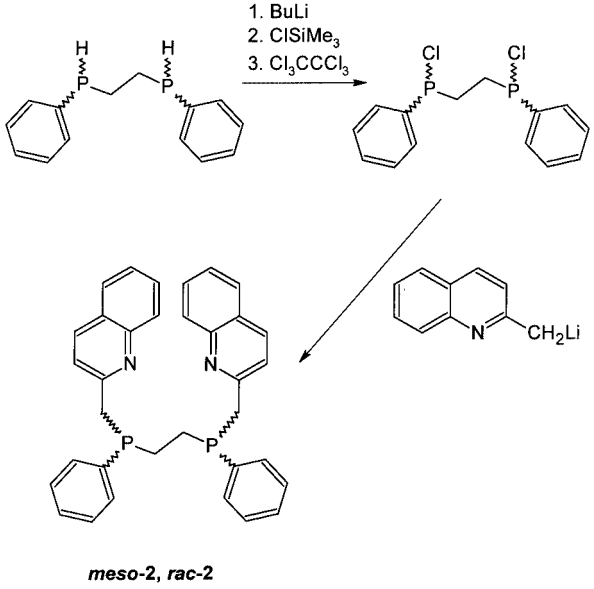

Figure 2. Synthesis of the N,P,P,N ligand **2** (***rac*-2** and ***meso*-2**)

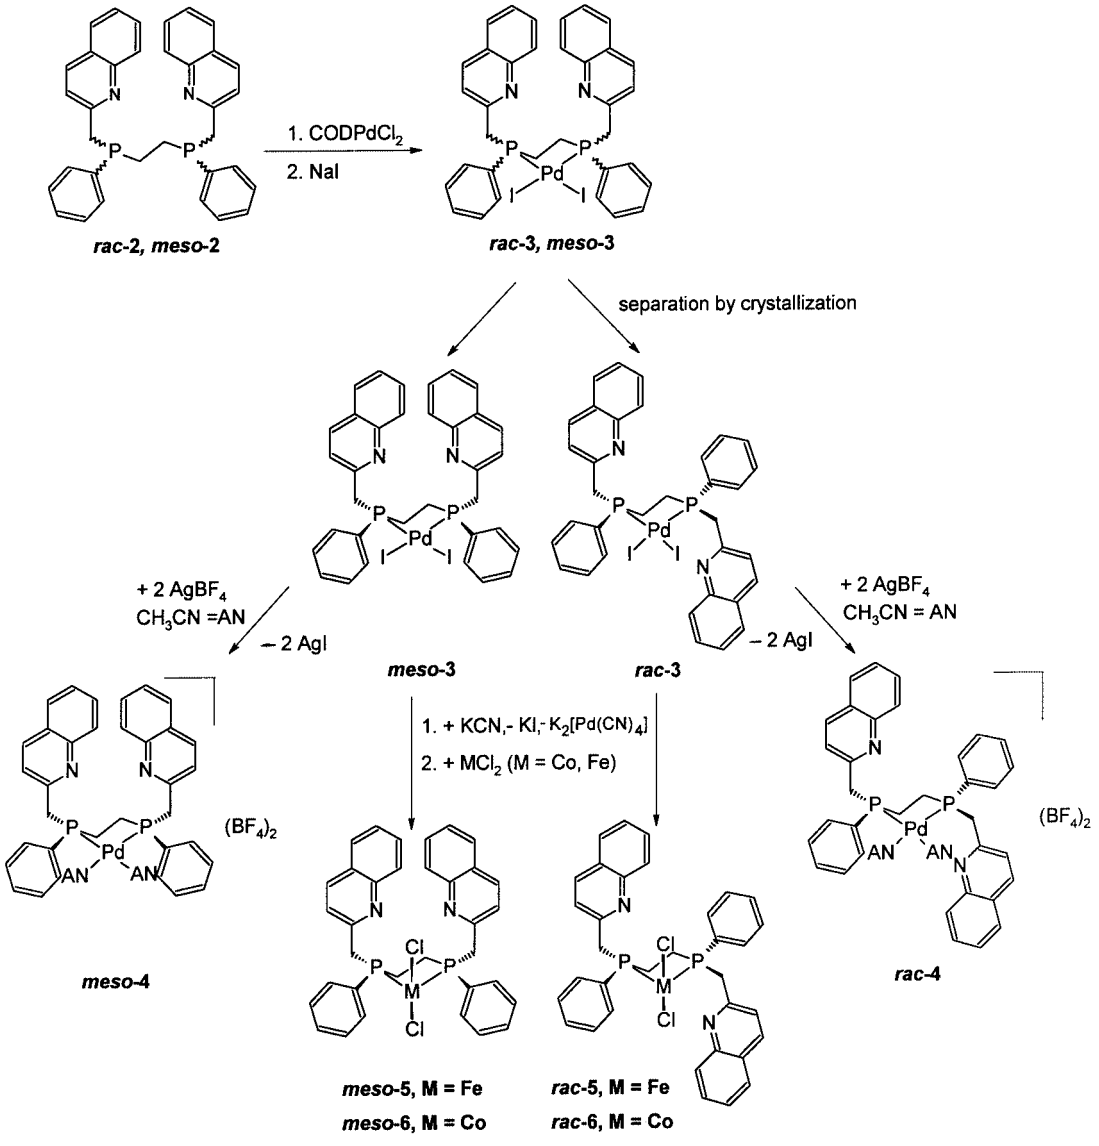
After activation with MAO, **(1)CoCl$_2$** (R = CH_2Ph) forms an active catalyst for the polymerization of ethene.[8] The molecular weight of the product is relatively high ($M_w \approx 1.5 \times 10^6$ g/mol), however the activity (10 kg PE/[Co]h) of this system is poor due to the low stability of the activated complex.[8] We report here on the synthesis of a tetradentate, mixed nitrogen/phosphorus-containing ligand **2** which, instead of the donor-amine groups of ligand **1**, carries donor/acceptor phosphane functionalities in the ligand backbone. The overall arrangement with the pendant quinaldine moieties was left unchanged to ensure the formation of the C_2-symmetric, octahedral coordination compound. Pd^{II}, Fe^{II} and Co^{II} complexes bearing the new N,P,P,N ligands were synthesized and tested in ethene and ethene/CO copolymerization reactions.

Results and Discussion

Ligand and Complex Synthesis

The ligand **2** (***rac*-2** and ***meso*-2**) was prepared following the synthetic pathway depicted in Figure 2.[9]

1,2-Bis(phenylphosphanyl)ethane was converted into 1,2-bis(chlorophenylphosphanyl)ethane by treating the bis(Li phosphide) with $ClSiMe_3$, followed by the addition of hexachloroethane. Subsequent reaction of Li-quinaldine with 1,2-bis(chlorophenylphosphanyl)ethane afforded the tetradentate N,P,P,N ligand **2** which was isolated as a mixture of two diastereoisomers due to the two stereogenic phosphorus atoms [***rac*-2** (*R*/R and *S*/*S*) and ***meso*-2** (*S*/*R*)]. The ratio of ***rac*-2**/***meso*-2** was 1.7:1, indicating a preferred



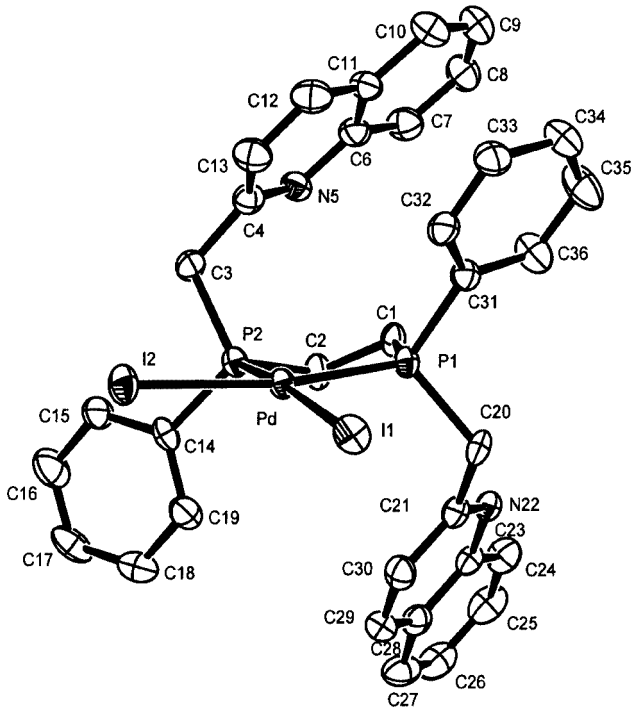
Scheme 1

formation of the *rac*-form. Attempts to separate the two ligands were unsuccessful.

The mixture of ***rac*-2** and ***meso*-2** was converted into the corresponding, air-stable palladium(II) diiodide complexes (Scheme 1, ***rac*-3**, ***meso*-3**) by treatment with [$PdCl_2$(COD)] in the presence of sodium iodide.[10] After purification of the mixture by column chromatography, ***rac*-3** could be separated by repeated crystallization from CH_2Cl_2/EtOAc. A pure sample of ***meso*-3** was isolated by crystallization from hot acetone.

To investigate the catalytic properties of our diastereomeric Pd^{II} complexes for ethene/CO copolymerizations the palladium diiodide compounds were converted into the bis(acetonitrile) complexes ***rac*-4** and ***meso*-4** by treating the diiodides with silver tetrafluoroborate in acetonitrile.

The diastereomeric ligands ***rac*-2** and ***meso*-2** were isolated in pure form after treatment of the corresponding PdI_2 species with aqueous KCN solution. The iron(II) and cobalt(II) dichloride complexes of ***rac*-2** and ***meso*-2** were synthesized by treatment of the free ligands with the appropriate metal(II) salt (***rac*-5**, ***meso*-5**, M = Fe; ***rac*-6, *meso*-6**, M = Co). Elemental analysis and FAB-MS indicated a 1:1 metal to ligand ratio.



Structural Characterization

Solid State Structures

Single crystals of the palladium(II) diiodide compounds suitable for an X-ray structure determination were obtained by crystallization from CH_2Cl_2/EtOAc (***rac*-3**) or from acetone/toluene (***meso*-3**) (Figure 3).

For both complexes a water molecule was located in the unit cell which forms intermolecular hydrogen bonds to neighboring quinaldine moieties. Both compounds crystallize in the monoclinic form. The two iodides (I1 and I2) and the two phosphorus units (P1 and P2) form the expected square-planar coordination sphere around the palladium center. Small deviations might result from crystal packing (Table 1). Bond lengths and angles are within the range expected for this type of complex (Table 2).[11–13] In ***rac*-3** one of the quinaldine moieties is located above, and the second below, the Pd–P1–P2–I1–I2 coordination plane, while in ***meso*-3** both units lie on the same side of the plane. Considering this geometrical arrangement it is obvious that only the *rac*-form of the ligand is able to coordinate as a tetradentate ligand in a manner identical to the N,N,N,N ligand **1** (see Figure 1), with the quinaldine fragments occupying both axial positions.[6] Attempts to obtain single crystals of ***rac*-5,6** or ***meso*-5,6** suitable for an X-ray structure analysis were unsuccessful.

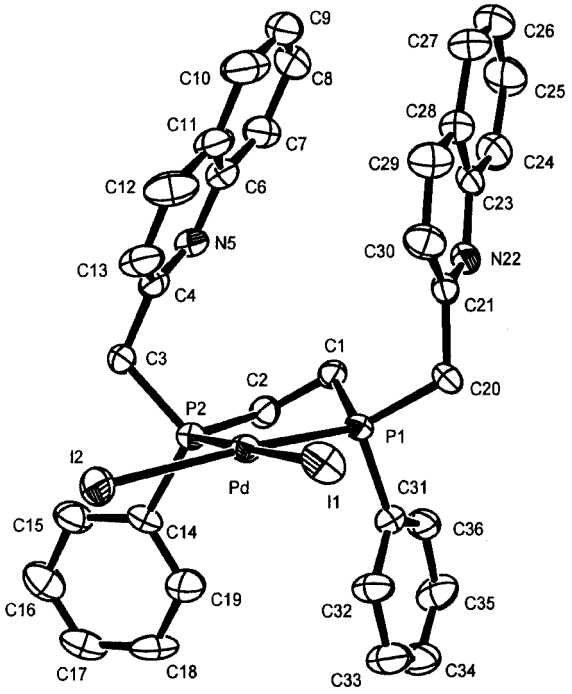


Figure 3. The structure of ***rac*-3** (upper) and ***meso*-3** (lower)

IR Analysis

For structure elucidation IR analysis was performed on the free ligands **1**, ***rac*-2** and ***meso*-2** as well as on the corresponding Fe^{II} and Co^{II} complexes. Coordination of an N-heteroaromatic unit to a metal center is indicated by a frequency shift of the heteroaromatic ring vibrations.[14–16] The IR spectra of the octahedral Fe^{II} and Co^{II} complexes of ligand **1** [**(1)$FeCl_2$** and **(1)$CoCl_2$**] were used as references, since in this case the coordination of the quinaldine moieties has been confirmed by an X-ray structure determination.[6,8]

The high frequency region (1700−1400 cm^{-1}) of the ring deformations of the aromatic and heteroaromatic units is depicted in Figure 4.[17,18] The IR diagrams **1** (ligand **1** and complexes), **2** (***rac*-2** and complexes) and **3** (***meso*-2** and complexes) show the spectra of the free ligand (top), and the iron (middle) and cobalt (bottom) complexes. The ring vibration of the free ligands at 1614 cm^{-1} and 1595 cm^{-1} (**1**), 1617 cm^{-1} and 1597 cm^{-1} (***rac*-2**), 1614 cm^{-1} and 1595 cm^{-1} (***meso*-2**) were attributed to the quinaldine moiety.[17]

The spectra of the Fe^{II} and Co^{II} complexes of ligand **1** show a high frequency band at 1647 and 1648 cm^{-1}, respectively, which is not present in the spectrum of the free ligand. Also, a distinct shift of the bands in the 1400−1570 cm^{-1} region is detectable upon coordination of the quinaldine moiety. No differences of band positions and intensities in the spectra of the Fe^{II} and Co^{II} complexes were observed.

In the case of the Fe^{II} and Co^{II} complexes of the N,P,P,N ligands ***rac*-2** and ***meso*-2** no band at higher frequencies is detectable, which would indicate a coordination of the quinaldine moiety. The slight variation in the 1400−1570 cm^{-1} region might be due to the coordination of the phosphane units to the metal center. These investigations imply that, in contrast to **1**, which coordinates as a tetradentate ligand, ***rac*-2** and ***meso*-2** form Fe^{II} and Co^{II} complexes where the heteroaromatic unit is not coordinated to the metal center and the ligands therefore act as bidentate systems.

UV/Vis Spectroscopy

To support this hypothesis, UV/Vis measurements were performed on the Co^{II} complexes ***rac*-6** and ***meso*-6** in solution (Figure 5). The spectra of both isomers show a similar structure of band positions and intensities, suggesting the

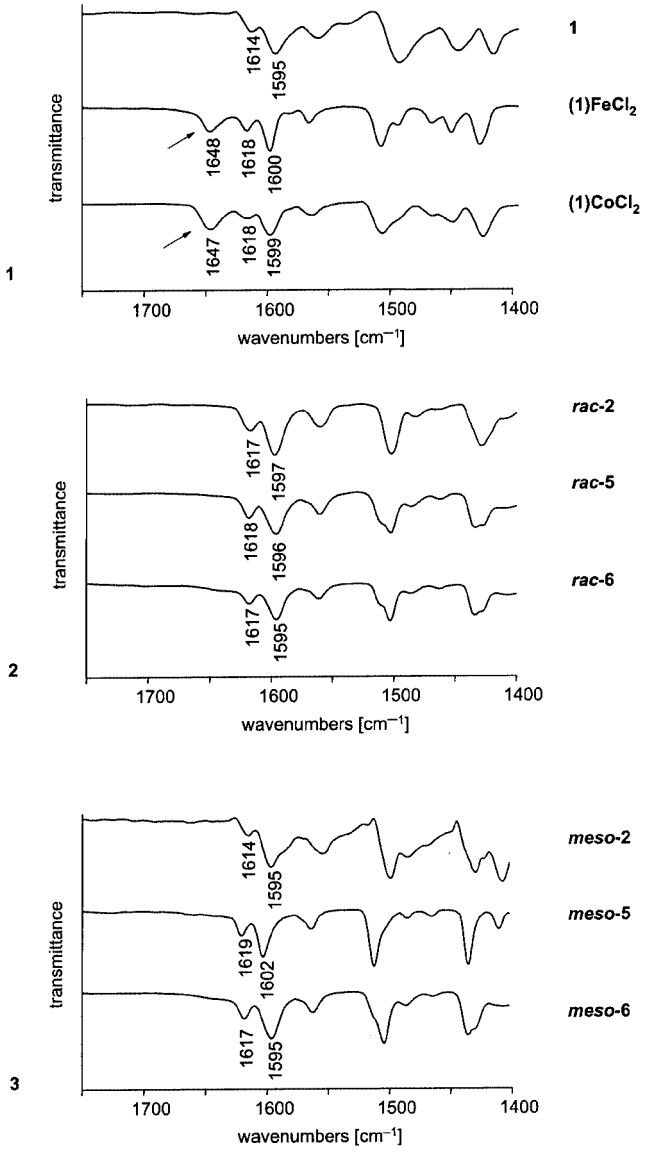

Figure 4. IR spectra of the free ligands (top), the Fe^{II} (middle) and the Co^{II} (bottom) complexes of the ligands **1** (diagram 1), ***rac*-2** (diagram 2) and ***meso*-2** (diagram 3)

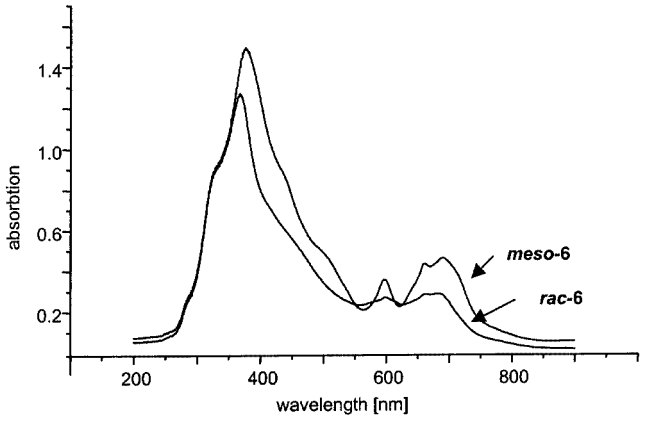

Figure 5. UV/Vis spectra of a solution of ***rac*-6** and ***meso*-6** in CH_2Cl_2

same overall coordination geometry for both complexes (Table 3).

Table 3. Positions of the band maxima and molar extinction coefficient of the UV/Vis spectra of a solution of ***rac*-6** and ***meso*-6** in CH_2Cl_2

	λ_{max} [nm] (ε_{max} [L·mol^{-1}·cm^{-1}])			
***rac*-6**	368 (852)	599 (329)	663 (375)	683 (381)
***meso*-6**	377 (985)	597 (316)	661 (390)	690 (414)

UV/Vis investigations on other tetrahedral $CoCl_2L_2$ complexes (L = P donor) have shown that the absorption in the 500−800 nm region can be attributed to the spin-allowed transition $^4A_2 \rightarrow {}^4T_1$.[19−25] The observed absorption spectra for ***rac*-6** and ***meso*-6** resemble the reported spectra for the tetrahedral complex $[CoCl_2(PPh_3)_2]$, indicating a bidentate coordination of ***rac*-2** and ***meso*-2** (through the P units) to give the corresponding tetrahedral $CoCl_2$ complexes (Figure 6).[20,24] We assume a similar coordination behavior for the Fe^{II} complexes.

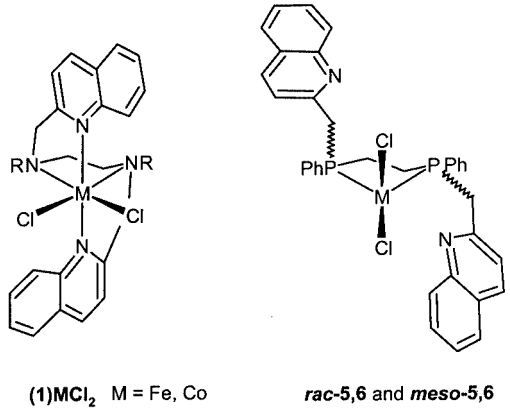

Figure 6. Coordination behavior of **1** and proposed coordination behavior of ***rac*-2** and ***meso*-2** in their Fe^{II} and $Co^{II}Cl_2$ complexes

Analysis of the bond lengths and angles found for the strained, octahedral complex **(1)$FeCl_2$** revealed an Fe−N(R)−CH_2 angle of 107°.[6] This angle, together with the N(R)−Fe bond length determines the distance of the quinaldine moiety from the axial coordination site in the complexes. The strained structure of **(1)$FeCl_2$** indicates that an angle of 107° together with an N−Fe bond length of 2.25 Å is necessary to allow coordination of the quinaldine moieties.[6] In the square-planar Pd^{II} complexes ***rac*-3** and ***meso*-3**, where the quinaldine moieties are not coordinated to the metal center, a Pd−P−CH_2 angle of 116° was observed. It is likely that bidentate coordination of the N,P,P,N ligands stabilizes the tetrahedral $CoCl_2P_2$ complexes (P−Co ≈ 2.2 Å [26]) sufficiently so that there is no need to diminish this angle considerably, forming a highly constrained ring systems.

The Fe^{II} and Co^{II} complexes were tested for the polymerization of ethene. However, in contrast to the octahedral **(1)$CoCl_2$**, the tetrahedral complexes ***rac*-5,6** and ***meso*-5,6** of the present study decomposed upon addition of MAO to

give a suspension of the complexes in toluene (black precipitate, most likely Fe^0 or Co^0). Initial experiments showed that the diastereomeric bis(acetonitrile)palladium complexes ***rac*-4** and ***meso*-4** are suitable catalyst precursors for the copolymerization of ethene and CO using methanol as cocatalyst. Further investigations on the behavior of the diastereomeric complexes towards the polymerization of 1-olefins and CO are in progress.

Conclusion

Exchanging the backbone nitrogen functionalities in the tetradentate N,N,N,N ligand **1** for phosphorus leads to the formation of two stable diastereoisomers ***rac*-2** and ***meso*-2**. At the same time a distinct variation in the coordination behavior of the new N,P,P,N ligands is induced. While the N,N,N,N ligand **1** forms octahedral Fe^{II} and Co^{II} complexes, a tetrahedral environment is suggested for the Fe^{II} and Co^{II} complexes of ***rac*-2** and ***meso*-2**. Whereas **(1)$CoCl_2$** shows some activity for ethene polymerization, the tetrahedral ***rac*-5,6** and ***meso*-5,6** complexes undergo fast decomposition upon treatment with MAO. However, the Pd^{II} analogues ***rac*-4** and ***meso*-4** show some activity in the ethene/CO copolymerization reaction; this will be investigated further.

Experimental Section

General Remarks: All manipulations except the handling of the palladium diiodide complexes were carried out in dry solvents under an inert atmosphere of argon using standard Schlenk techniques. THF, diethyl ether and toluene were distilled from $LiAlH_4$, and CH_2Cl_2 and petroleum ether were distilled from CaH_2. All solvents were stored over molecular sieves. Commercially available anhydrous acetonitrile and ethanol, BuLi (1.6 M in hexane), hexachloroethane, KCN, anhydrous $FeCl_2$ and $CoCl_2$ were used without further purification. Quinaldine and chlorotrimethylsilane were purified by distillation. (*cis*,*cis*-Cycloocta-1,5-diene)dichloropalladium,[27] 1,2-bis(phenylphosphanyl)ethane,[28] ligand **1**, as well as the corresponding iron and cobalt complexes,[6] were prepared according to literature procedures.

Polymerization experiments were performed in a 100 mL steel autoclave (Roth) with a glass inlet and mechanical stirring. Ethene (BASF, 2.7) and CO (BASF, 2.0) were used without further purification. MAO (10% in toluene) was purchased from Witko.

NMR measurements were conducted on a Bruker DRX 400 spectrometer at 400 MHz (^1H) and 162 MHz (^{31}P). Chemical shifts are reported in ppm. Tetramethylsilane and 85% phosphoric acid were used as references. IR spectra were measured on a Bruker IFS 113v spectrometer, FAB-MS spectra on a Finnigan MAT TSQ 7000 spectrometer using *meta*-nitrobenzyl alcohol (*m*-NBA), 2,3,4-trimethoxyacetophenone (TMAP) or 2-nitrophenyloctyl ether (2-NPOE) as matrices. Elemental analysis were measured on an Vario EL elementar. UV/Vis absorption spectra were conducted on a J & M spectrometer using 2 mm solutions in CH_2Cl_2.

Synthesis of *rac*-2, *meso*-2: BuLi (55.2 mL, 88 mmol) was added slowly to a solution of 1,2-bis(phenylphosphanyl)ethane (10.9 g, 44 mmol) in THF (300 mL) cooled to −78 °C. The reaction mixture was warmed to 0 °C and chlorotrimethylsilane (11.4 mL, 90 mmol) was added slowly with a syringe. The solvent was removed under reduced pressure and CH_2Cl_2 (300 mL) was added. The reaction mixture was cooled to 0 °C and hexachloroethane (20.9 g, 88 mmol) was added in small portions. The reaction mixture was stirred at room temperature for 72 hours. The solvent was removed under reduced pressure and the solid was suspended in THF (250 mL). In a separate flask BuLi (55.2 mL, 88 mmol) was added slowly to a solution of quinaldine (12 mL, 88 mmol) in 200 mL of THF cooled to −78 °C. The dark red solution of the quinaldine anion was allowed to reach room temperature and was then added to the suspension of the chlorophosphane at −78 °C until the red color of the quinaldine anion remained. A further 10 mL of quinaldine solution was added to ensure the complete transformation of the chlorophosphane. The reaction mixture was allowed to reach room temperature and was stirred overnight. Water (10 mL) was added and the solvent was removed under reduced pressure. The remaining solid was dissolved in water (300 mL) and CH_2Cl_2 (500 mL). The organic layer was separated and the water layer was extracted with two 200 mL portions of CH_2Cl_2. The organic layers were dried over sodium sulfate. Evaporation of the solvent left a red oil which contained a 1:1.7 *meso*:*rac* mixture of the ligand. The crude product was used without further purification. Yield: 80% (18.6 g).

Synthesis of *rac*-3, *meso*-3: [$PdCl_2$(COD)] (10.5 g, 36.7 mmol) was added to a solution of the ligand (36.7 mmol) in CH_2Cl_2 (300 mL). NaI (22 g, 1.47 mol) was added after 10 minutes and the reaction mixture was stirred for 12 hours. CH_2Cl_2 (500 mL) was added and the solution was stirred for a further 24 hours. The reaction mixture was filtered and the solvent was removed under reduced pressure. The product was purified by column chromatography on silica using a 10:1 (v:v) mixture of CH_2Cl_2 and ethyl acetate as eluent. The *rac* form was separated by crystallization of the diastereomeric mixture from CH_2Cl_2 and ethyl acetate. A pure sample of the *meso*-isomer was obtained by crystallization of a *meso*-enriched fraction from hot acetone. Overall yields: 37% (12.1 g) ***rac*-3**, 25% (8.1 g) ***meso*-3**.

***rac*-3:** ^1H NMR ($CDCl_3$): δ = 2.13 (m, 1 H), 2.22 (m, 1 H), 2.50 (m, 2 H), 4.14 (dd, J_1 = 15.9, J_2 = 13.1 Hz, 2 H), 4.80 (dd, J_1 = 12.9, J_2 = 10.1 Hz, 2 H), 6.80 (m, 4 H), 7.12 (dd, 2 H), 7.24 (m, 4 H), 7.53−7.61 (m, 4 H), 7.65 (d, J = 8.1 Hz, 2 H), 7.83 (d, J = 8.1 Hz, 2 H), 8.08 (d, J = 8.4 Hz, 2 H), 8.15 (d, J = 8.7 Hz, 2 H) ppm. ^{31}P NMR ($CDCl_3$): δ = 69.48 ppm. ***meso*-6**: FAB-MS (matrix: 2-NPOE): *m*/*z* (%) = 622 (100) [$M^+ - Cl$], 587 (35) [$M^+ - 2Cl$]. $C_{34}H_{30}Cl_2CoN_2P_2 \cdot H_2O$ (676.4): calcd. C 60.37, H 4.77, N 4.14; found C 59.86, H 4.85, N 4.05.[30]

Ethene/CO Copolymerization: A 100 mL stainless steel autoclave equipped with a glass inlet and a stirring bar was purged with argon. The appropriate amount of the complex (50 μmol catalyst), solvent (50 mL of CH_2Cl_2) and methanol (Cat.:Cocat. = 1:200) were added and the autoclave was pressurized with the ethene (20 bar) and CO (60 bar). After stirring for 1 h at room temp. the gases were vented off and the polymer was isolated by filtration. Yields: 50 mg (***meso*-4**), 65 mg (***rac*-4**). IR: ECO (***meso*-4**): 2912.3 cm^{-1} (ν CH_2), 1693.6 (ν C≡O); ECO (***rac*-4**): 2912.3 cm^{-1} (ν CH_2), 1693.9 (ν C≡O)

X-ray Crystallographic Study: Crystal data of the compounds ***rac*-3** and ***meso*-3** were collected with a Rikagu AFC7S single-crystal diffractometer at 193(2) K using Mo-K_α radiation (graphite monochromator, λ = 0.71073 Å; omega scans). Intensities were corrected for Lorentz and polarization effects.[30] A psi-scan absorption correction was performed, $0.592 < T < 1.000$ (***rac*-3**), $0.920 < T < 1.000$ (***meso*-3**).[31] Solution and refinement: SHELX97 (Sheldrick, 1997).[32,33] The structure was solved by direct methods. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were refined isotropically with their displacement factors 1.2-times that of the host atom. The hydrogen atoms of the lattice water were picked up from the final electron density map and were not further refined. The solid-state structures are stabilized by hydrogen bonds. The water molecule in both compounds is H-bonded to N5 and N22, the nitrogen acceptor atoms being situated in different complex molecules. In ***meso*-3** a toluene molecule is present in the unit cell which lies on a twofold rotation axis and is slightly disordered. All the final electron densities greater than one lie within one angsterom unit from palladium or iodine atoms.

CCDC-175209 (***rac*-3**) and -175208 (***meso*-3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Structural and Chemical Characterization of Unsaturated C_4- and C_{10}-Bridged Group-4 *ansa*-Metallocenes Obtained Through a Ring-Closing Olefin Metathesis Reaction

Doris Hüerländer,[a] Nina Kleigrewe,[a] Gerald Kehr,[a] Gerhard Erker,*[a] and Roland Fröhlich[a][‡]

Keywords: Carbenes / Metallocenes / Metathesis / Olefins / Ruthenium / Zirconium

Bis[(5-hexenyl)cyclopentadienyl]zirconium dichloride (**3**) underwent ring-closure olefin metathesis with loss of ethylene when treated with 10 mol % of the $[Cl_2(PCy_3)_2Ru{=}CHPh]$ catalyst in refluxing dichloromethane, to yield the large *ansa*-zirconocene complex [dec-5-ene-1,10-diylbis(η^5-cyclopentadienyl)]$ZrCl_2$ (*trans*-**4**). Characterization by NMR and by X-ray diffraction revealed that the isolated complex contained a *trans*-C=C double bond inside the *ansa* bridge. Similarly, bis[(allyl)cyclopentadienyl]$ZrCl_2$ (**7**) gave the *ansa*-metallocene [but-2-ene-1,4-diylbis(η^5-cyclopentadienyl)]zirconium dichloride (*cis*-**8**) when treated with the same ruthenium metathesis catalysts (10 mol %) under similar conditions, except that a *cis*-C=C double bond was now found to be present (shown by NMR and X-ray diffraction). The *cis*-**8** complex was used as a homogeneous Ziegler–Natta catalyst for ethylene polymerization [after activation of the metallocene dichloride **8** with MAO (methylalumoxane) or treatment of the corresponding dimethylmetallocene complex **9** with $B(C_6F_5)_3$]. Complex **8** was also converted into a mixture of (*s-cis*- and *s-trans*-η^4-butadiene)-*ansa*-metallocene complexes (*s-cis*-**15**/*s-trans*-**15** = 4:5) by treatment with (butadiene)-magnesium. The C=C double bond of *cis*-**8** could be hydroborated with 9-BBN or with the $H{-}B(C_6F_5)_2$ reagent. $Li^+[B(C_6F_5)_4^-]$ added to *cis*-**8** to yield an interesting solid-state chain structure in which the $[Zr]Cl_2$ unit and the *o*-/*m*-F pairs of two $-C_6F_5$ groups were found to be in contact with the central lithium cation in a distorted octahedral coordination environment (as shown by X-ray diffraction).

Introduction

ansa-Metallocenes of the Group 4 metals have become of great importance, especially as components of homogeneous Ziegler−Natta catalyst systems.[1] Their synthesis in most cases involves nucleophilic substitution routes with Cp-anion equivalents and the respective bis(electrophile) of the bridging unit to build up the ligand framework before it is attached to the transition metal atom. This synthetic scheme has been followed in many cases, providing the ubiquitous *ansa*-metallocenes with small bridging units (e.g. SiR_2, $CH_2{-}CH_2$ etc.)[2−6] as well as the few examples of "large *ansa*-metallocenes" so far described in the literature.[7−10] A sizeable number of alternatives of linked bis(Cp) ligand syntheses has been reported in the literature,[11−19] but only very few in which selective organic transformations were carried out by coupling functional groups at the Cp ligands at the Group 4 metallocene stage.[20,21]

The C=C double bonds of alkenyl side chains at the Cp rings are functional groups compatible with many Group 4 metallocene features, and are easily introduced.[8,9,22−25] Modern variants of the olefin metathesis reaction, employing defined molecular Group 6 or Group 8 alkylidene complexes, can efficiently use alkenyl functional groups for carbon−carbon coupling.[26−28] Intramolecular variants ("ring-closure metathesis", RCM) has become an especially useful tool in organic synthesis.[29−36] We have employed such an olefin metathesis reaction for the intramolecular C−C coupling of bis[(ω-alkenyl)cyclopentadienyl]$ZrCl_2$ complexes to yield the respective C=C unsaturated *ansa*-metallocene complexes. Two representative examples are described, including their structural characterization and some chemical features of these easily available new systems.[37]

Results and Discussion

Synthesis and Characterization of the *ansa*-Metallocenes

Bis[(5-hexen-1-yl)cyclopentadienyl]zirconium dichloride (**3**) was prepared by a procedure analogous to that described by us in the literature: treatment of Cp−sodium

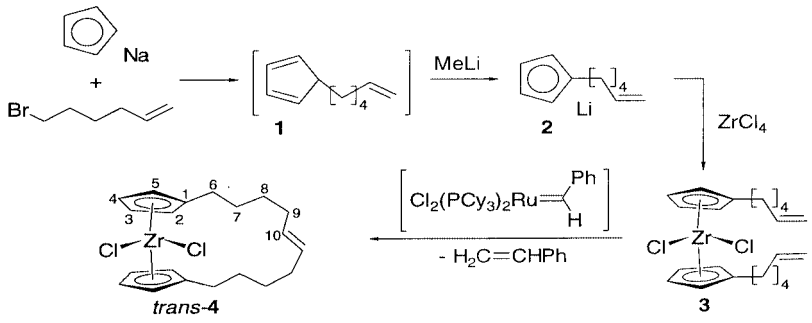

Scheme 1

with hexenyl bromide, followed by deprotonation (MeLi) and transmetallation furnished complex **3** in 38% yield (see Scheme 1).[8,22] Intramolecular olefin metathesis was carried out catalytically on **3** by treatment with 10 mol % of the "Grubbs catalyst" benzylidenedichlorobis(tricyclohexylphosphane)ruthenium.[38,39] In dilute solution, with use of a syringe pump for addition of **3** in dichloromethane to the metathesis catalyst, the reaction can largely be kept in the intramolecular regime. Crystallization from toluene gave the "large *ansa*-zirconocene dichloride complex" as a white crystalline solid in 25% yield.

Single crystals of **4** suitable for X-ray crystal structure analysis were obtained from [D_6]benzene at room temperature. The crystals were very thin needles, and the diffraction power was therefore weak, giving data of limited accuracy. The structure features an *ansa*-metallocene containing a *trans*-C=C double bond [C10−C11: 1.291(18) Å] in its centre. The large "13-membered" ring displays a crown-shaped conformation. The metallocene conformation is such that the bridging ring system is completely oriented toward a lateral sector of the bent metallocene wedge ["bis(lateral) *syn*" conformation, see Figure 1].[10,40,41] The zirconium atom in complex **4** is pseudotetrahedrally coordinated by the two η^5-Cp rings [Cp(centroid)−Zr: 2.193 and 2.216 Å, Cp(centroid)−Zr−Cp(centroid) angle 129.4°, Zr−Cl2 2.430(3) Å, Zr−Cl1 2.437(3) Å, Cl1−Zr−Cl2 angle: 98.2(1)°] in a largely unstrained fashion.

In the NMR spectra the signals of a major (> 95%) and a minor component could be seen. Whereas the minor compound has remained unidentified so far (it could be the *cis* isomer or an oligomer), the major product is likely to be identical to *trans*-**4** as identified by X-ray diffraction. This is indicated by the typical ^{13}C NMR shift of the allylic $-CH_2-CH=$ resonance (C-9) at δ = 31.9 ppm [δ(C-10) = 131.5 ppm]. The remaining CH_2 shifts of the bridging hydrocarbyl chain are found at δ = 29.3 (C-6), 26.4 (C-7) and 28.5 (C-8) ppm (for atom numbering scheme see Scheme 1). The corresponding ^1H NMR resonances occur at δ = 2.52 (6-H), 1.22 (7-H), 1.30 (8-H), 2.01 (9-H) and 5.25 (olefinic 10-H) ppm.

The synthesis of bis(allylcyclopentadienyl)zirconium dichloride (**7**) was carried out analogously to the procedure described by us previously (Scheme 2).[22] The ring-closing metathesis reaction was carried out by treatment of **7** with $Cl_2(PCy_3)_2Ru=CHPh$ under high-dilution reaction conditions. Oligomeric by-products were removed by filtration and the product **8** was purified by fractional crystallization. Eventually, the isomerically pure complex *cis*-**8** was obtained as a colourless, crystalline material in ca. 50% yield.

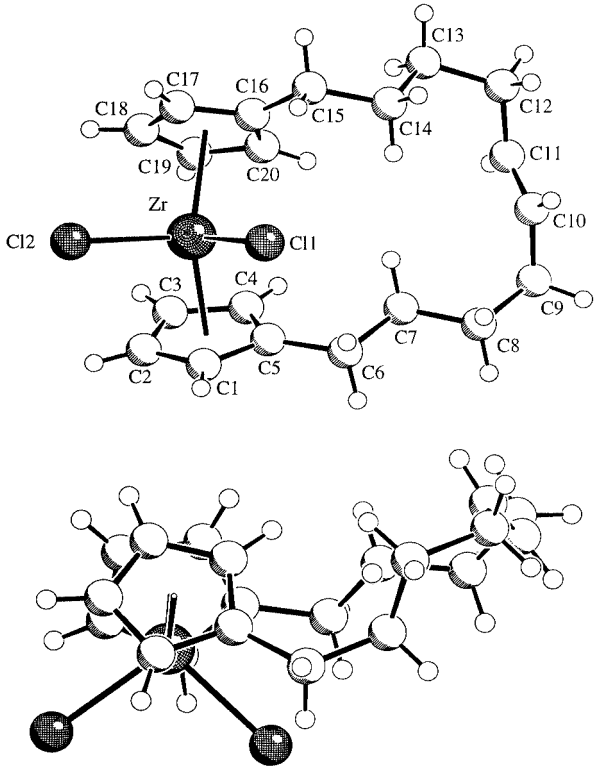

Figure 1. Two views of the organometallic olefin metathesis product **4**; selected bond lengths [Å] and angles [°]: Zr−Cl1 2.437(3), Zr−Cl2 2.430(3), C5−C6 1.526(14), C6−C7 1.489(14), C7−C8 1.516(14), C8−C9 1.500(17), C9−C10 1.472(19), C10−C11 1.291(18), C11−C12 1.455(23), C12−C13 1.538(22), C13−C14 1.505(20), C14−C15 1.528(19), C15−C16 1.510(16); Cl1−Zr−Cl2 98.2(1), C5−C6−C7 113.6(9), C6−C7−C8 113.8(9), C7−C8−C9 112.3(9), C8−C9−C10 111.7(11), C9−C10−C11 128.0(15), C10−C11−C12 126.7(16), C11−C12−C13 114.0(13), C12−C13−C14 112.0(12), C13−C14−C15 116.3(13), C14−C15−C16 118.0(11); C5−C6−C7−C8 −175.4(10), C6−C7−C8−C9 179.2(11), C7−C8−C9−C10 71.2(14), C8−C9−C10−C11 -107.6(15), C9−C10−C11−C12 176.2(14), C10−C11−C12−C13 -108.4(16), C11−C12−C13−C14 65.1(19), C12−C13−C14−C15 -175.6(13), C13−C14−C15−C16 74.4(18)

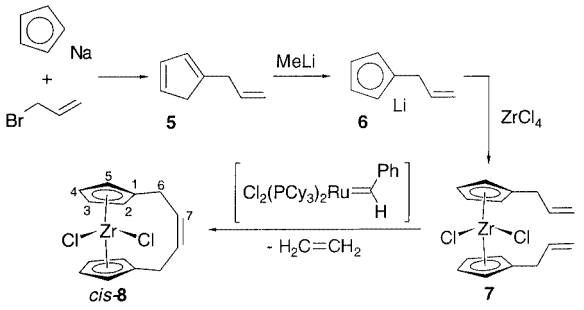
The X-ray crystal structure analysis of **8** (single crystals were obtained from [D_6]benzene at room temperature) again shows the presence of an unconstrained *ansa*-metallo-



Scheme 2

cene framework. The metal−C(Cp) bond lengths are in a rather narrow range between 2.486(2) Å (Zr−C13) and 2.536(2) Å (Zr−C11). The Cp(centroid)−Zr−Cp(centroid) angle amounts to an ideal bent metallocene value of 130.0°.[42] The Cl1−Zr−Cl2 angle in **8** [95.95(2)°] is only marginally smaller than that in the parent compound Cp_2ZrCl_2.[43] Zr−Cl1 [2.437(1) Å] and Zr−Cl2 [2.455(1) Å] are very similar in lengths.

The *ansa*-metallocene complex **8** features an endocyclic *cis*-carbon−carbon double bond [C16−C26 1.319(3) Å]. This value is in the range typical for an uncoordinated C=C bond.[44] Close inspection reveals that there is no immediate coordinative interaction between the *cis*-C=C double bond inside the *ansa* bridge and its adjacent, slightly electron-deficient Group 4 metal centre. The observed Zr···C16/C26 distances of ca. 4 Å rule out any significant direct interaction. Consequently, an eclipsed metallocene conformation is attained in complex *cis*-**8**, with the C10−C15 and C20−C25 vectors oriented to the same lateral sector of the bent metallocene wedge and the $-CH_2-CH=CH-CH_2-$ unit bent back towards the back side of the metallocene framework (as illustrated by the top view projection of *cis*-**8** in Figure 2).

In solution one finds a single set of NMR signals, indicating that there is only one isomer present. This shows a ^{13}C NMR signal of the allylic C-6 $CH_2-CH=$ carbon centre (see Scheme 1) at δ = 24.8 ppm, consistent with the *cis*-**8** structure (*trans*-**4** shows the analogous $-CH_2-CH=$ signal at δ = 31.9 ppm, see above). In addition, there are the olefinic −CH= resonance at δ = 129.7 ppm and three Cp signals at δ = 119.3, 115.3 (both *C*H) and δ = 121.2 ppm (*C*). The pairwise identical C-2/C-5 and C-3/C-4 resonances indicate rapid conformational equilibration of *cis*-**8** on the NMR timescale. Probably both the Cp−Zr rotation *and* the inversion of the metallacycle that includes the *ansa* bridge atoms are fast.[45] Consequently, only two C_5H_4 resonances are observed in the ^1H NMR spectrum of *cis*-**8** at "high" temperatures. In a $CDFCl_2/CDF_2Cl$ mixture[46] at 253 K this pair of ^1H NMR Cp signals is observed at δ = 6.32 and 6.66 ppm. On lowering the temperature these signals each decoalesce to a new pair of Cp signals that at 128 K have become separated by 517 and 128 Hz, respectively (see Figure 7). From these temperature-dependent ^1H NMR spectra an averaged activation barrier has been calculated as $\Delta G^{\ddagger}_{inv}$ (128 K) = 5.1 ± 0.3 kcal mol^{-1}.[47] We assume

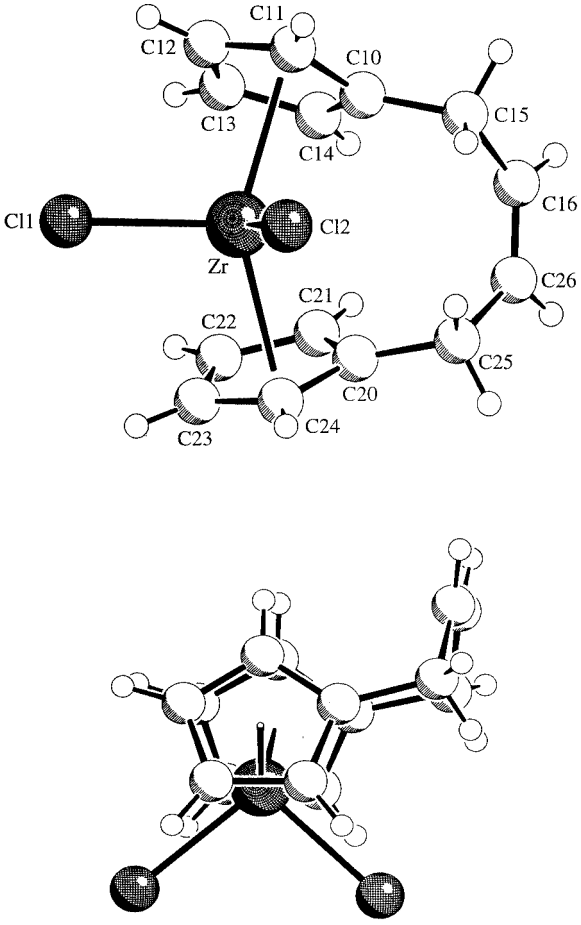


Figure 2. Top and side views of the molecular structure of complex *cis*-**8**; selected bond lengths [Å] and angles [°]: Zr−Cl1 2.437(1), Zr−Cl2 2.455(1), C10−C15 1.513(3), C15−C16 1.496(3), C16−C26 1.319(3), C26−C25 1.503(3), C25−C20 1.518(3); Cl1−Zr−Cl2 95.95(2), C10−C15−C16 114.7(2), C15−C16−C26 126.2(2), C16−C26−C25 126.1(2), C26−C25−C20 112.5(2); C10−C15−C16−C26 −83.5(3), C15−C16−C26−C25 0.9(3), C16−C26−C25−C20 86.0(3)

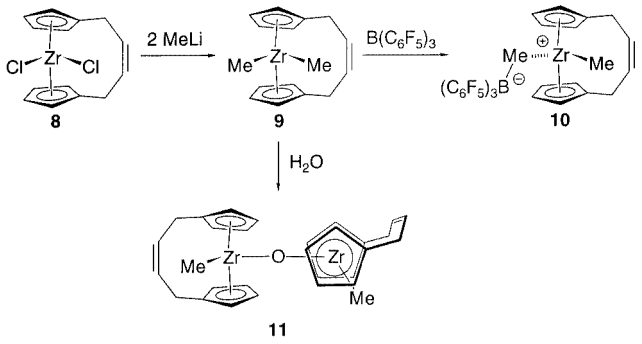
that this Gibbs activation energy primarily characterises the inversion barrier of the *ansa*-metallacycle, but it is in principle possible that this has coincided with "freezing" of the Cp−M rotation on the NMR timescale at this very temperature.[48−50]

Reactions of the *ansa*-Metallocenes

Treatment of the *ansa*-zirconocene dichloride **8** with methyllithium (2 equiv.) gave the corresponding dimethylmetallocene complex **9** {$^1H/^{13}C$ NMR of [Zr]$(CH_3)_2$: δ = −0.05/31.0 ppm ($^1J_{CH}$ = 117 Hz) in [D_6]benzene}. Treatment of **9** with $B(C_6F_5)_3$ in [D_8]toluene with NMR monitoring generated the ion-pair **10** {^1H NMR of [Zr]CH_3/[B]CH_3: δ = 1.34/0.94}. Compound **10** separated from the solution as a red oil after some time. An attempt to crystallise **10** from [D_6]benzene resulted in partial hydrolysis of the moisture-sensitive complex, and we isolated single crystals of the corresponding dinuclear μ-oxobis(*ansa*-metallo-

cene) compound **11** suitable for an X-ray crystal structure determination (see Scheme 3 and Figure 3).



Scheme 3

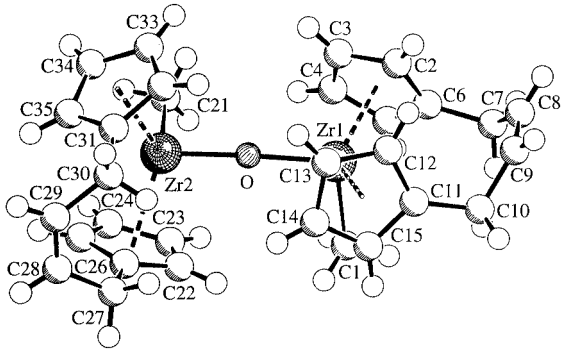


Figure 3. A projection of the molecular structure of the μ-oxobis(*ansa*-metallocene) complex **11**; selected bond lengths [A] and angles [°]: Zr1−O 1.951(2), Zr1−C1 2.294(3), Zr2−O1 1.954(2), Zr2−C21 2.291(3), C6−C7 1.509(4), C7−C8 1.499(4), C8−C9 1.312(4), C9−C10 1.503(4), C10−C11 1.502(4), C26−C27 1.514(4), C27−C28 1.483(4), C28−C29 1.317(4), C29−C30 1.489(4), C30−C31 1.503(4); Zr1−O−Zr2 170.53(9), C1−Zr1−O 97.55(9), C21−Zr2−O 97.97(9), C6−C7−C8 113.7(2), C7−C8−C9 124.4(3), C8−C9−C10 123.8(2), C9−C10−C11 112.8(2), C26−C27−C28 114.7(3), C27−C28−C29 124.0(3), C28−C29−C30 124.0(3), C29−C30−C31 113.6(2); C6−C7−C8−C9 84.3(3), C7−C8−C9−C10 −0.9(5), C8−C9−C10−C11 −88.9(3), C26−C27−C28−C29 −81.7(4), C27−C28−C29−C30 0.2(5), C28−C29−C30−C31 88.8(4)

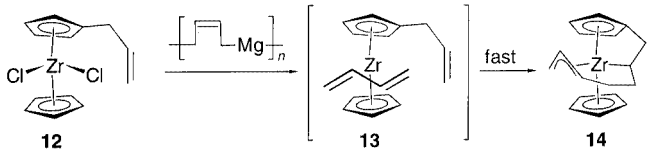
The X-ray crystal structure analysis of **11** shows the presence of two C_4-*ansa*-metallocene subunits, bridged by a close to linear μ-oxobridge [angle Zr1−O−Zr2: 170.53(9)°]. Both the zirconium−oxygen bonds are rather short, at 1.951(2) Å (Zr1−O) and 1.954(2) Å (Zr2−O), respectively. This indicates considerable μ-oxygen ligand-to-metal π-backbonding,[51] making use of the available acceptor orbital at the (formally) 16-electron metal centre.[52] Consequently, the overall structural arrangement of the two metallocene subunits of **11** along the metal-oxygen-metal vector is close to perpendicular (dihedral angle C1−Zr1···Zr2−C21 −85.8°). The conformational arrangement of the strongly bent *ansa*-bridge is noteworthy, as it is different in the two metallocene subunits. On both sides the $-CH_2-CH=CH-CH_2-$ bridge is oriented toward a lateral sector of the bent metallocene wedge, and this is toward the oxygen side in both cases, but the *ansa* bridge at Zr1 is bent in the direction toward the front side of the bent metallocene, whereas at Zr2 this hydrocarbyl bridge is bent away from the μ-oxygen atom and prefers to point toward the narrow back side of the bent metallocene wedge.

Both the complexes **8** and **9** were used as starting materials for the generation of active homogeneous Ziegler−Natta catalysts. In the case of the dimethylzirconium complex, activation was achieved by treatment with $B(C_6F_5)_3$ in a close to equimolar ratio (the active species probably being **10**, see Scheme 3).[53] The *ansa*-metallocene dichloride **8** was activated by treatment with a large excess of methylalumoxane in toluene solution (Al/Zr > 1000).[1,54] Both systems turned out to be excellent ethylene polymerization catalysts (see Table 1). They also polymerized propene at room temperature, although not with high activities (a = 38). The obtained polypropylene was atactic.

We had previously shown that Cp-bound alkenyl groups can undergo a C−C coupling reaction with metal-coordinated butadiene ligands at the Group 4 metallocene frameworks.[22] The formation of **14** from **12** via **13** is a typical example.



We were curious to see whether there would be any interaction between the endocyclic *cis*-C=C double bond in the *ansa*-metallocene framework and a butadiene ligand attached at, for example, the framework of complex **8**. We therefore treated complex **8** directly with 1 mol-equiv. of the (butadiene)Mg·(THF)$_n$ reagent[55] in [D_8]toluene at room temperature. Formation of the (butadiene)metallocenes took place. NMR analysis revealed the presence of the (*s-cis*- and *s-trans*-η^4-butadiene)[Zr] complex isomers (*s-cis*-**15**;

Table 1. Ethylene polymerization with homogeneous Ziegler−Natta catalysts derived from the complexes **8** and **9**

Cat. precursor[a]	Activator	Al(B)/Zr ratio	T [°C]	Reaction time [min]	PE [g]	M.p. [°C]	Act.[b]

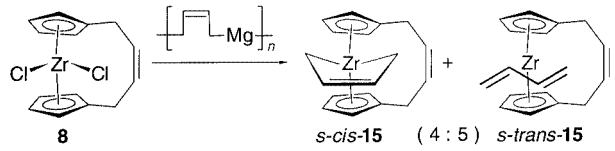
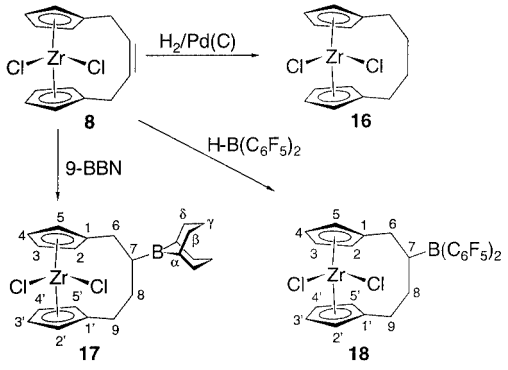


Scheme 4

s-trans-**15**, see Scheme 4) in a 4:5 ratio. The *s-cis* isomer is easily identified by its dynamic NMR behaviour, due to a rapid inversion of its five-membered σ^2,π-metallacyclopentene core on the NMR timescale at room temperature, becoming frozen at low temperature.[56] This results in the observation of a 1:1 pair of ^{1}H NMR singlets at 298 K (δ = 5.09, 4.88 ppm) that decoalesces to a set of four Cp signals of equal intensity at 213 K in the [D_8]toluene solvent (δ = 5.55, 4.91, 4.78, 4.53 ppm). In contrast, the chiral (averaged C_2-symmetric) *s-trans*-**15** isomer exhibits temperature-invariant NMR spectra showing four separate ^{1}H NMR Cp resonances (213 K: δ = 4.87, 4.85, 4.53, 4.35 ppm) throughout this temperature range. The ^{1}H/^{13}C NMR shifts of the (*s-cis*-η^4-butadiene)[Zr] complex [213 K: δ = 4.76, 3.42, −0.59 (H_{meso}, H_{syn}, H_{anti})/112.1, 49.7 (C-2/3, C-1/4) ppm] and its *s-trans*-**15** isomer [213 K: δ = 3.04, 3.14, 1.38 ppm (^{1}H)/96.7, 59.1 ppm (^{13}C)] are characteristically different.[56] The *s-cis*- and *s-trans*-**15** complexes are stable as such in the examined temperature range. We have so far found no evidence of the occurrence of a C−C coupling reaction with the disubstituted C=C double bond of the adjacent *ansa* bridge.

The C=C double bond in *cis*-**8** undergoes reactions typical of olefins, however. Catalytic hydrogenation (H_2, Pd/C) cleanly yields the saturated tetramethylene-bridged *ansa*-



Scheme 5

zirconocene dichloride complex **16** (see Scheme 5). Hydroboration takes place equally facilely and also leaves the metallocene nucleus untouched. We have used two sterically and electronically quite different boranes for this purpose. 9-BBN[57,58] adds to the endocyclic double bond in *cis*-**8** to yield the product **17**. The borylated complex **18** was formed by treatment of *cis*-**8** with the electrophilic borane H−B(C_6F_5)$_2$.[59,60] As expected, each of these products now shows eight ^{1}H NMR signals of the pair of monosubstituted Cp ligands [**17**: δ = 6.53, 6.45 (2 H), 6.42, 6.40, 6.35, 6.33, 6.25 ppm]. It is interesting to note that complex **18** has an electrophilic −B(C_6F_5)$_2$ unit covalently bonded to its *ansa*-metallocene framework. Future studies should show if this can be utilized as an internal activator component for the generation of an active single-component metallocene Ziegler−Natta catalyst system.[61,62]

L_nM^+ cations can sometimes be generated by treatment of the respective metal halide complexes (e.g., L_nM−Cl) with alkali metal cations in combination with anions of low nucleophilicity.[63] An interesting alternative reaction, namely Li^+ addition, was observed in one case starting from **8**. When we treated the *ansa*-metallocene complex *cis*-**8** with $Li^+[B(C_6F_5)_4^-]$ in [D_8]toluene at room temperature, the crystalline adduct **19** was obtained. Its rather interesting structure was determined by X-ray diffraction (see Figures 4 and 5).

The X-ray crystal structure analysis revealed that the Li^+ cations of two independent molecules are (electrostatically) coordinated to the pair of chloride ligands[64,65] at the zirconium center in a chelate fashion. The coordination sphere around the lithium ion is complemented by two additional

Figure 4. Figure 5. A projection of the chain structure of the adduct **19** in the crystal

chelate interactions, each with a pair of *ortho*- and *meta*-fluorine atoms of one C_6F_5 substituent from two different adjacent $[B(C_6F_5)_4^-]$ anions. This complements a distorted octahedral coordination sphere around the alkali metal cation (see Figure 4). The octahedral geometry is, however, markedly distorted. Of the (idealised) three 180° bonding angles around the central (alkali) metal ion, only two are close to linear [F135−Li2−Cl22: 165.9(3)° and Cl21−Li2−F203: 160.8(2)°; only the data of one of the crystallographically independent units (here around Li2) are given, those around Li1 are similar], whereas the third is markedly smaller at 147.0(3)° (F202−Li2−F136). Most of the remaining twelve bonding angles at the origin of the distorted octahedron are reasonably close to the expected 90° [F202−Li2−F135: 84.1(2)°, F202−Li2−Cl21: 96.9(2)°, F135−Li2−Cl21: 86.1(2)°, F136−Li2−Cl22: 93.3(2)°, Cl21−Li2−Cl22: 92.7(2)°, F136−Li2−F203: 93.8(2)°, Cl22−Li2−F203: 83.4(2)°], with the exception of the two narrow internal *o*-/*m*-F chelate angles [F136−Li2−F135: 73.5(2)° and F202−Li2−F203: 67.2(2)°] and some secondary deviation, caused by this chelate effect [F136−Li2−Cl21: 105.2(2)°, F202−Li2−Cl22: 110.0(2)°, F135−Li2−F203: 102.1(2)°].

The lithium chloride contact lengths in the adduct **19** amount to 2.379(6) Å (Li2−Cl21) and 2.420(6) Å (Li2−Cl22). The Li−F distances cover a wider range [Li2−F202: 2.045(5) Å, Li2−F136: 2.052(5) Å, Li2−F135: 2.223(6) Å, and Li2−F203: 2.567(6) Å]. Each $[B(C_6F_5)_4^-]$ anion in the adduct **19** contains two C_6F_5 units that exhibit chelate contacts to two different Li^+ cations, whereas the remaining C_6F_5 pair of substituents is oriented away from the alkali metal centres. This results in a chain-type suprastructure of **19**, depicted in Figure 5.

The electrostatic Li^+ coordination has changed the $[Zr]Cl_2$ geometry slightly. In comparison with the starting material **8**, the Zr−Cl bond lengths in the adduct **19** are slightly longer [Zr1−Cl11: 2.479(1) Å, Zr1−Cl12: 2.487(1) Å, Zr2−Cl21: 2.454(1) Å, Zr2−Cl22: 2.477(1) Å; see for comparison: *cis*-**8** Zr−Cl1: 2.437(1) Å, Zr−Cl2: 2.455(1) Å]. Consequently, the Cl11−Zr1−Cl12 angle in **19** is markedly smaller [87.53(2)°; Cl21−Zr2−Cl22: 89.50(3)] than in *cis*-**8** [Cl1−Zr2−Cl2: 95.95(2)°].

It is also noteworthy that the conformational arrangement of the $-CH_2-CH=CH-CH_2-$ *ansa* bridge in *cis*-**8** and in the adduct **19** are quite different. In the former, the C=C double bond in the strongly bent structural subunit is oriented toward the back side (Zr···C=C separation ca. 4 Å), whereas in the latter it is found in the inverted position (see Figure 6), which brings the C=C π-system closer to the electron-deficient d^0-configurated Group 4 metal centre (in **19** the Zr···C=C separation is only ca. 3.5 Å).

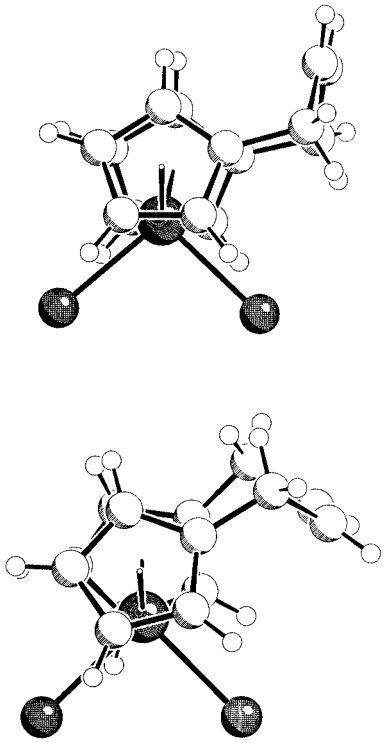

Figure 6. A comparison of the *ansa*-metallocene core conformation as found in *cis*-**8** (top) and the adduct **19** (bottom)

We conclude that olefin metathesis at the Cp−alkenyl unit of Group 4 metallocenes can easily be carried out intramolecularly, cleanly yielding the respective unsaturated *ansa*-metallocenes with loss of ethene. The C=C bond inside the *ansa*-metallocene bridge undergoes a variety of typical reactions without affecting the Group 4 metallocene backbone. Such combinations of reactions may potentially open up new synthetic pathways to functionalized bent metallocene complexes that may turn out to be useful for the development of improved catalysts for rapid and selective C−C coupling reactions and/or for use as reagents in organic synthesis. Studies aimed at finding out about such properties are being carried out in our laboratory.

Experimental Section

General: All reactions were carried out under dry argon in Schlenk-type glassware or in a glove-box. Solvents, including deuterated solvents used for NMR spectroscopy, were dried and distilled prior to use. For additional general conditions, including a list of instruments used for physical characterization of the compounds, see

ref.[41b] or ref.[66] NMR assignments were usually secured by carrying out a variety of 2D NMR experiments.[67] The starting materials **3** and **7** were prepared according to literature procedures.[8,22]

Preparation of [Dec-5-ene-1,10-diylbis(η⁵-cyclopentadienyl)]zirconium Dichloride (*trans*-4): A solution containing [$Cl_2(PCy_3)_2Ru$=CHPh] (45.3 mg, 0.06 mmol, 10 mol %) in 400 mL of dichloromethane was brought to reflux temperature in a three-necked flask, equipped with stirrer, reflux condenser and a septum. Over 6 h a solution of bis[η⁵-(5-hexen-1-yl)cyclopentadienyl]$ZrCl_2$ (**3**, 250 mg, 0.55 mmol) in 100 mL of dichloromethane was added by syringe pump. The mixture was heated under reflux for an additional 3 h, and then cooled to room temperature and filtered. Solvent was removed in vacuo, and the residue was washed with pentane (2 × 20 mL). Fractional crystallization from toluene (10 mL) gave 58.9 mg (25%) of *trans*-**4** as a white solid, m.p. 162 °C. IR (KBr): $\tilde{\nu}$ = 3103 w, 2929 m, 2856 w, 2387 w, 1497 w, 1263 m, 1102 s, 1035 s, 969 w, 841 w, 828 s, 825 vs cm^{-1}. ^1H NMR ([D_6]benzene, 599.9 MHz, 298 K): δ = 5.97 (m, 4 H, 3,4-H), 5.73 (m, 4 H, 2,5-H), 5.25 (m, 2 H, 10-H), 2.52 (m, 4 H, 6-H), 2.01 (m, 4 H, 9-H), 1.30 (m, 4 H, 8-H), 1.22 (m, 4 H, 7-H) ppm. $^{13}C\{^1H\}$ NMR ([D_6]benzene, 150.8 MHz, 298 K): δ = 139.3 (C, C-1), 131.5 (CH, C-10), 115.1 (CH, C-3,4), 111.0 (CH, C-2,5), 31.9 (CH_2, C-9), 29.3 (CH_2, C-6), 28.5 (CH_2, C-8), 26.4 (CH_2, C-7) ppm. $C_{20}H_{26}Cl_2Zr$ (428.5): calcd. C 56.05, H 6.12; found C 56.35, H 6.63.

X-ray Crystal Structure Analysis of *trans*-4: Single crystals were obtained from [D_6]benzene at ambient temperature. $C_{20}H_{26}Cl_2Zr$, M = 428.53, yellow crystal, 0.30 × 0.04 × 0.03 mm, a = 6.581(1), b = 20.480(1), c = 14.451(1) Å, β = 97.47(1)°, V = 1931.2(3) $Å^3$, $\rho_{calcd.}$ = 1.474 g cm^{-3}, μ = 8.43 cm^{-1}, empirical absorption correction by SORTAV (0.786 ≤ T ≤ 0.975), Z = 4, monoclinic, space group $P2_1/c$ (no. 14), λ = 0.71073 Å, T = 198 K, ω and φ scans, 5920 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.59 $Å^{-1}$, 3401 independent (R_{int} = 0.066) and 2048 observed reflections [$I \geq 2\sigma(I)$], 209 refined parameters, R = 0.094, wR^2 = 0.165, max. (min.) residual electron density 1.46 (−1.19) e $Å^{-3}$, weakly diffracting crystal due to its shape; therefore the accuracy of the resulting data is poor, hydrogen atoms calculated and refined as riding atoms.

Synthesis of [But-2-ene-1,4-diylbis(η⁵-cyclopentadienyl)]zirconium Dichloride (*cis*-8): Analogously to the procedure described above, bis[η⁵-(2-propen-1-yl)cyclopentadienyl]$ZrCl_2$ (**7**, 1.60 g, 4.30 mmol) was metathesized by treatment with [$Cl_2(PCy_3)_2Ru$=CHPh] (248 mg, 0.30 mmol, 7 mol %) in a total of 500 mL of dichloromethane under high-dilution conditions. The mixture was heated under reflux for an additional 6 h, cooled to room temperature and filtered. The volume of the resulting solution was reduced to 20 mL in vacuo. Crystallization at −30 °C overnight gave a crystalline precipitate that was washed with pentane (15 mL) and dried in vacuo to give 740 mg (50%) of *cis*-**8** as a microcrystalline solid, m.p. 182 °C. IR (KBr): $\tilde{\nu}$ = 3117 w, 2968 w, 2922 w, 2848 w, 2373 w, 1487 w, 1447 m, 1430 w, 1269 m, 1098 w, 1046 s, 960 w, 903 m, 829 s, 817 vs, 795 s cm^{-1}. ^1H NMR ([D_6]benzene, 599.9 MHz, 298 K): δ = 6.02 (m, 4 H, 2,5-H), 6.00 (m, 4 H, 3,4-H), 5.61 (m, 2 H, 7-H), 2.74 (m, 4 H, 6-H) ppm. ^1H NMR ($CDFCl_2/CDF_2Cl$, 599.9 MHz): δ (253 K) = 6.66, 6.32 (each m, each 4 H, 2,5-H, 3,4-H), 6.31 (m, 2 H, 7-H), 3.35 (m, 4 H, 6-H); δ (128 K) = 6.83/6.61, 6.74/5.87 (each br., each 2 H, 2,5-H, 3,4-H), 6.33 (br., 2 H, 7-H), 3.29, 3.25 (each br., each 2 H, 6-H) ppm. $^{13}C\{^1H\}$ NMR ([D_6]benzene, 150.8 MHz, 298 K): δ = 129.7 (CH, $^1J_{CH}$ = 145 Hz, C-7), 121.2 (C, C-1), 119.3 (CH, $^1J_{CH}$ = 176 Hz, C-2,5), 115.3 (CH, $^1J_{CH}$ = 175 Hz, C-3,4), 24.8 (CH_2, $^1J_{CH}$ = 129 Hz, C-6) ppm. $C_{14}H_{14}Cl_2Zr$ (344.4): calcd. C 48.83, H 4.10; found C 48.70, H 4.84. The dynamic behaviour of *cis*-**8** was monitored by ^1H NMR over a temperature range of 253 to 128 K (Figure 7). The AA′BB′ spin system of the Cp protons at high temperature changed to an ABCD spin system at low temperature. The activation energies were estimated as $\Delta G^{\neq}_{inv}$ [T_c: 153 K; Δν (128 K): 517 Hz] = 5.22 kcal·mol^{-1} for one group of protons and $\Delta G^{\neq}_{inv}$ [T_c: 138 K; Δν (128 K) = 128 Hz] = 5.07 kcal·mol^{-1} for the other. The average activation energy was calculated as $\Delta G^{\neq}_{inv}$ = 5.1 ± 0.3 kcal·mol^{-1}.

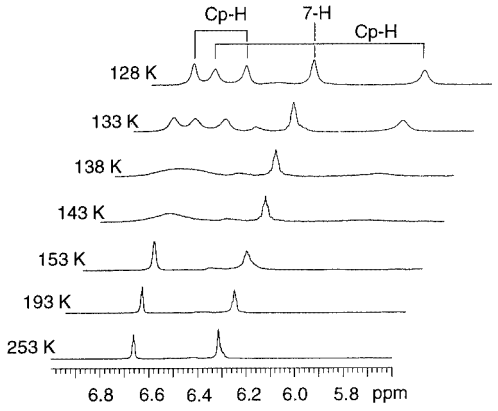

Figure 7. Dynamic ^1H NMR spectrum of *cis*-**8** (in $CDFCl_2$/CDF_2Cl)

X-ray Crystal Structure Analysis of *cis*-8: Single crystals of the *ansa*-metallocene were obtained from [D_6]benzene at room temperature. $C_{14}H_{14}Cl_2Zr$, M = 344.37, light yellow crystal, 0.40 × 0.20 × 0.10 mm, a = 7.798(1), b = 12.887(1), c = 13.044(1) Å, V = 1310.8(2) $Å^3$, $\rho_{calcd.}$ = 1.745 g cm^{-3}, μ = 12.19 cm^{-1}, empirical absorption correction by SORTAV (0.641 ≤ T ≤ 0.888), Z = 4, orthorhombic, space group $P2_12_12_1$ (no. 19), λ = 0.71073 Å, T = 198 K, ω and φ scans, 10,955 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.67 $Å^{-1}$, 3159 independent (R_{int} = 0.037) and 3025 observed reflections [$I \geq 2\sigma(I)$], 156 refined parameters, R = 0.020, wR^2 = 0.043, max. (min.) residual electron density 0.29 (−0.40) e $Å^{-3}$, refined as racemic twin, Flack parameter 0.17(3), hydrogen atoms calculated and refined as riding atoms.

[But-2-ene-1,4-diylbis(η⁵-cyclopentadienyl)]dimethylzirconium (9): [But-2-ene-1,4-diylbis(η⁵-cyclopentadienyl)]zirconium dichloride (**8**, 50 mg, 0.15 mmol) and methyllithium (6.4 mg, 0.3 mmol) were suspended in 2 mL of toluene, precooled to −78 °C. The suspension was allowed to warm up to room temperature and stirred overnight. The reaction mixture was filtered through Celite. After removal of the solvent in vacuo, product **9** was isolated as a brown solid (yield: 32 mg, 72%), m.p. 48 °C. IR (KBr): $\tilde{\nu}$ = 3115 w, 2961 m, 2926 w, 2869 w, 1458 w, 1412 w, 1269 vs, 1097 s, 1028 s, 965 w, 867 w, 793 vs, 729 m cm^{-1}. ^1H NMR ([D_6]benzene, 599.9 MHz, 298 K): δ = 6.01, 5.62 (each m, each 4 H, Cp-H), 5.58 (m, 2 H, 7-H), 2.66 (m, 4 H, 6-H), −0.05 (s, 6 H, CH_3) ppm. $^{13}C\{GATED\}$ NMR ([D_6]benzene, 150.8 MHz, 298 K): δ = 129.6 (dm, $^1J_{CH}$ = 158 Hz, C-7), 120.8 (s, C-1), 111.9 (d, $^1J_{CH}$ = 172 Hz, Cp), 110.2 (d, $^1J_{CH}$ = 171 Hz, Cp), 31.0 (q, $^1J_{CH}$ = 117 Hz, CH_3), 24.4 (t, $^1J_{CH}$ = 128 Hz, C-6) ppm. $C_{16}H_{20}Zr$ (303.56): calcd. C 63.31, H 6.64; found C 61.64, H 6.72. Single crystals of the partial hydrolysis product **11**, suitable for X-ray diffraction, were obtained from a concentrated [D_6]benzene solution of **9**.

X-ray Crystal Structure Analysis of 11: $C_{30}H_{34}OZr_2$, M = 593.01, colourless crystal 0.60 × 0.20 × 0.08 mm, a = 8.218(1), b =

10.985(1), c = 27.805(1) Å, β = 94.07(1)°, V = 2503.8(4) Å^3, $\rho_{calcd.}$ = 1.573 g cm^{-3}, μ = 8.53 cm^{-1}, empirical absorption correction by SORTAV (0.629 ≤ T ≤ 0.935), Z = 4, monoclinic, space group $P2_1/c$ (no. 14), λ = 0.71073 Å, T = 198 K, ω and φ scans, 17976 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.66 Å^{-1}, 5886 independent (R_{int} = 0.048) and 4599 observed reflections [I ≥ 2 σ(I)], 300 refined parameters, R = 0.035, wR^2 = 0.061, max. (min.) residual electron density 0.39 (−0.52) e Å^{-3}, hydrogen atoms calculated and refined as riding atoms.

Ethene Polymerization Reactions: These were carried out in a 1-L Büchi glass autoclave, charged with 300 mL of toluene. In the cases in which the *ansa*-metallocene dichloride *cis*-**8** was used as a precursor, methylalumoxane (MAO) in toluene (10.5%, 20 mL, 9.05 mmol) was added. In the case of the dimethylmetallocene/$B(C_6F_5)_3$ catalysts, triisobutylaluminium (0.5 mL) was added instead as a water scavenger. The autoclave was brought to the desired temperature and the solution was then saturated with ethene at a 2 bar pressure with stirring (800 rpm) for ca. 40 min. Either *cis*-**8** or the **9**/$B(C_6F_5)_3$ mixture (see Table 1 for details) was injected. To end the polymerization reaction, the ethene addition was terminated, excess monomer was allowed to vent, and the mixture was quenched by injection of 40 mL of a solution of dilute aqueous HCl/methanol (1:1). After 20 min of stirring, 100 mL of H_2O was added. The precipitated polyethylene was collected by filtration, and washed with 50 mL of 2 N aqueous HCl and then with water. The polymer was dried in vacuo for 24 h. The observed ethene polymerization activities of the homogeneous Ziegler−Natta catalyst derived from **8** or **9** (Table 1) are in a range similar to those obtained with related unbridged systems under similar conditions (e.g., **7**/MAO: a ≈ 2400 kg PE/mol [Zr]·h·bar at 25 °C). Propene polymerization reactions were carried out analogously (2 bar propene pressure). The **9**/$B(C_6F_5)_3$ system gave atactic polypropylene (stereochemical analysis by ^{13}C NMR spectroscopy) with a catalyst activity of a = 38 kg PP/mol [Zr]·h·bar at 25 °C. The **8**/MAO catalyst system produced atactic polypropylene at 25 °C with a = 38 (Al/Zr = 800) at 60 °C with a = 40 (Al/Zr = 1050).

Preparation of (Butadiene)metallocene Complexes *s-cis*-15 and *s-trans*-15: Samples of [but-2-ene-1,4-diylbis(η^5-cyclopentadienyl)]-zirconium dichloride (**8**, 80 mg, 0.23 mmol) and 2-butene-1,4-diylbis(tetrahydrofuran)magnesium (95.1 mg, 0.23 mmol) were mixed as solids and then dissolved in 3 mL of toluene. The reaction mixture spontaneously changed colour to deep red, and a white precipitate was formed. Because of the rapid decomposition of the product upon filtration, all volatile components were removed in vacuo to obtain the product **15**·$MgCl_2(THF)_n$ (112 mg, 85%) as a red solid (in [D_8]toluene solution at 298 K both the *s-cis*-**15** and the *s-trans*-**15** isomers were detected in a 4:5 ratio). $(C_{18}H_{20}Zr)\cdot(THF)_2MgCl_2$ (327.58 + 239.42 = 567.00): calcd. C 55.08, H 6.40; found C 53.22, H 6.43. IR (KBr): $\tilde{\nu}$ = 2962 w, 2915 m, 2849 m, 1635 w, 1449 m, 1262 m, 1042 s, 797 s, 729 m cm^{-1}. *s-cis*-**15**: ^1H NMR ([D_8]toluene, 599.9 MHz, 298 K): δ (298 K) = 5.81 (m, 2 H, 7-H), 5.09 (br., 4 H, Cp-H), 4.88 (br. m, 4 H, Cp-H), 4.73 (m, 2 H, H_{meso}), 2.91 (m, 4 H, 6-H), 1.24 (br., 4 H, H_{syn}, H_{anti}) ppm; δ (213 K) = 5.89, 5.75 (each m, each 1 H, 7-H), 5.55, 4.91, 4.53 (each br., each 2 H, Cp-H), 4.78 (m, 2 H, Cp-H), 4.76 (m, 2 H, H_{meso}), 3.42 (m, 2 H, H_{syn}), 2.97 (m, 2 H, 6-H), 2.81 (m, 2 H, 6-H), −0.59 (m, 2 H, H_{anti}) ppm. $^{13}C\{^1H\}$ NMR ([D_8]toluene, 150.8 MHz): δ (298 K) = 130.2 (CH, $^1J_{CH}$ = 157 Hz, C-7), 118.6 (C, C-1), 112.8 (CH, $^1J_{CH}$ = 157 Hz, butadiene-CH), 100.9 (CH, $^1J_{CH}$ = 173 Hz, Cp), 25.8 (CH_2, $^1J_{CH}$ = 121 Hz, C-6) ppm; δ (213 K) = 130.5, 129.4 (each CH, C-7), 121.5, 115.1 (each C, C-1), 112.1 (CH, butadiene-CH), 107.9, 101.1, 101.1(4) (each CH, Cp), 96.0 o. 97.6 (CH, Cp), 49.7 (butadiene-CH_2), 25.3, 25.0 (each CH_2, C-6) ppm. ***s-trans*-15:** ^1H NMR ([D_8]toluene, 599.9 MHz): δ (298 K) = 5.81 (m, 2 H, 7-H), 4.96, 4.93, 4.57, 4.39 (each m, each 2 H, Cp-H), 3.02 (m, 2 H, H_{syn}), 2.99 (m, 4 H, 6-H), 2.97 (m, 2 H, H_{meso}), 1.24 (m, 2 H, H_{anti}); δ (213 K) = 5.79 (m, 2 H, 7-H), 4.87, 4.85, 4.53, 4.35 (br) (each m, each 2 H, Cp-H), 3.14 (m, 2 H, H_{syn}), 3.04 (m, 2 H, H_{meso}), 2.97 (m, 4 H, 6-H), 1.38 (m, 2 H, H_{anti}) ppm. $^{13}C\{^1H\}$ NMR ([D_8]toluene, 150.8 MHz, 298 K): δ = 130.2 (CH, $^1J_{CH}$ = 157 Hz, C-7), 112.1 (C, C-1), 104.4 (CH, $^1J_{CH}$ = 170 Hz, C-Cp), 101.7 (CH, $^1J_{CH}$ = 172 Hz, C-Cp), 98.0 (CH, $^1J_{CH}$ = 174 Hz, C-Cp), 96.1 (CH, $^1J_{CH}$ = 149 Hz, butadiene-CH), 95.9 (CH, $^1J_{CH}$ = 175 Hz, C-Cp), 59.5 (CH_2, $^1J_{CH}$ = 157, $^1J_{CH}$ = 146 Hz, butadiene-CH_2), 25.5 (CH_2, $^1J_{CH}$ = 125 Hz, C-6); δ (213) = 129.8 (CH, C-7), 111.1 (C, C-1), 104.0, 101.1(4) (CH, Cp), 97.6 o. 96.0 (CH, Cp), 95.7 (CH, butadiene-CH), 95.3 (CH, Cp), 59.1 (CH_2, butadiene-CH_2), 24.9 (CH_2, C-6) ppm.

Catalytic Hydrogenation of *cis*-8. Preparation of 16: Complex *cis*-**8** (77 mg, 0.22 mmol) was dissolved in dichloromethane (20 mL). Heterogeneous Pd(C) catalyst (10% palladium, 80 mg) was added. Hydrogen was passed through the solution through a frit at 1 bar with stirring for 2 h. The catalyst was removed by filtration and the solvent was evaporated in vacuo to yield 43 mg (56%) of the *ansa*-metallocene **16**. ^1H NMR ([D_2]dichloromethane, 599.9 MHz, 298 K): δ = 6.40 (m, 4 H, 2,5-H), 6.38 (m, 4 H, 3,4-H), 2.84 (br. m, 4 H, 6-H), 1.90 (m, 4 H, 7-H) ppm. $^{13}C\{^1H\}$ NMR ([D_2]dichloromethane, 150.8 MHz, 298 K): δ = 128.1 (C, C-1), 118.5 (CH, C-3,4), 117.6 (CH, C-2,5), 27.5 (CH_2, C-6), 26.1 (CH_2, C-7) ppm.

Treatment of *cis*-8 with 9-BBN. Preparation of 17: A mixture of [but-2-ene-1,4-diylbis(η^5-cyclopentadienyl)]zirconium dichloride (**8**, 50 mg, 0.15 mmol) and 9-borabicyclo[3.3.1]nonane (17.7 mg, 0.15 mmol) was dissolved in 2 mL of dichloromethane at room temperature. The solution was stirred for 12 h and then concentrated to dryness in vacuo. The product (67.1 mg, 96%) was isolated as a white solid, m.p. 170 °C. IR (KBr): $\tilde{\nu}$ = 3094 w, 2911 m, 2837 m, 2362 w, 1492 w, 1452 m, 1355 w, 1309 w, 1195 w, 1012 m, 880 w, 817 vs cm^{-1}. ^1H NMR ([D_2]dichloromethane, 599.9 MHz, 298 K): δ = 6.53, 6.33 (each m, each 1 H, 2,5-H), 6.45, 6.25 (each m, each 1 H, 3,4-H), 6.45, 6.35 (each m, each 1 H, 2′,5′-H), 6.42, 6.40 (each m, each 1 H, 3′,4′-H), 3.03 (*A*BM, ^2J = 16.1, ^3J = 2.3 Hz, 1 H, 6-H), 2.99 (*A*BMN, ^2J = 16.2, ^3J = 3.0, ^3J = 7.1 Hz, 1 H, 9-H), 2.89 (A*B*MN, ^2J = 16.2, ^3J = 2.6, ^3J = 10.9 Hz, 1 H, 9-H′), 2.75 (A*B*M, ^2J = 16.1, ^3J = 9.0 Hz, 1 H, 6-H′), 2.09 (m, 1 H, 8-H), 1.88 (m, 1 H, 8-H′), 1.94, 1.72 (each m, each 4 H, β, δ-H), 1.93, 1.28 (each m, each 2 H, γ-H), 1.82 (m, 2 H, α-H), 1.71 (m, 1 H, 7-H) ppm. $^{13}C\{^1H\}$ NMR ([D_2]dichloromethane, 150.8 MHz, 298 K): δ = 129.4 (C, C-1), 128.1 (C, C-1′), 122.0, 115.1 (each CH, C-2,5), 120.5, 113.6 (each CH, C-2′,5′), 120.4, 117.4 (each CH, C-3,4), 118.4, 117.3 (each CH, C-3′,4′), 34.0, 33.9 (each CH_2, C-β, δ), 31.3 (br. CH, C-7), 30.7 (br. CH, C-α), 27.8 (CH_2, C-9), 27.4 (CH_2, C-6), 26.4 (CH_2, C-8), 23.5 (CH_2, C-γ) ppm. $^{11}B\{^1H\}$ NMR ([D_6]benzene, 64.2 MHz, 298 K): δ = 87 ($\nu_{1/2}$ = 329 Hz) ppm. $C_{22}H_{29}BCl_2Zr$ (466.41): calcd. C 56.65, H 6.27; found C 55.72, H 6.16.

Treatment of *cis*-8 with H-B(C_6F_5)$_2$. Preparation of 18: A mixture of [but-2-ene-1,4-diylbis(η^5-cyclopentadienyl)]zirconium dichloride (**8**, 50 mg, 0.15 mmol) and bis(pentafluorophenyl)borane (50.2 mg, 0.145 mmol) was dissolved in 2 mL of dichloromethane at room temperature. The solution was stirred for 1 h. Solvent was removed in vacuo to yield 90.3 mg (90%) of the product as a light brown solid, m.p. 238 °C. IR (KBr): $\tilde{\nu}$ = 3103 w, 2934 m, 2861 m, 1648 m, 1520 s, 1467 vs, 1386 m, 1316 m, 1288 w, 1094 m, 974 s, 813 s cm^{-1}. ^1H NMR ([D_2]dichloromethane, 599.9 MHz, 298 K): δ = 6.56, 6.43

(each m, each 1 H, 2,5-H), 6.49, 6.38 (each m, each 1 H, 3′,4′-H), 6.48, 6.47 (each m, each 1 H, 2′,5′-H), 6.40, 6.28 (each m, each 1 H, 3,4-H), 3.12 (*A*BMN, ^2J = 16.8, ^3J = 2.7, ^3J = 10.5 Hz, 1 H, 9-H), 3.05 (d, $^{2\text{ or }3}J$ = 15.9 Hz, 1 H, 6-H), 2.92 (A*B*MN, ^2J = 16.8, ^3J = 2.8, ^3J = 7.7 Hz, 1 H, 9-H′), 2.85 (m, 1 H, 6-H′), 2.56 (m, 1 H, 7-H), 2.16 (m, 1 H, 8-H), 1.96 (m, 1 H, 8-H′) ppm. $^{13}C\{^1H\}$ NMR ([D$_2$]dichloromethane, 150.8 MHz, 298 K): δ = 148.3 [dm, ^1J = 247.2 Hz, B(C_6F_5)$_2$], 139.4 [dm, ^1J = 253.0 Hz, B(C_6F_5)$_2$], 145.0 (dm, ^1J = 265.0 Hz, B(C_6F_5)$_2$], 128.4 (C, C-1), 128.3 (C, C-1′), 124.5, 117.9 (each CH, C-2,5), 121.5, 121.2 (CH, C-2′,5′), 120.4, 114.6 (each CH, C-3′,4′), 119.4, 118.6 (each CH, C-3,4), 115.0 [br., B(C_6F_5)$_2$], 30.2 (CH_2, C-9), 29.9 (CH_2, C-6), 27.5 (CH_2, C-8), (C-7 not observed) ppm. $^{11}B\{^1H\}$ NMR ([D$_6$]benzene, 64.2 MHz, 298 K): δ = 76 ($\nu_{1/2}$ = 340 Hz) ppm. ^{19}F NMR ([D$_6$]benzene, 563.6 MHz, 298 K): δ = −127.3 (br. m, 4 F, *o*-C_6F_5), −146.2 (br. m, 2 F, *p*-C_6F_5), −159,4 (br. m, 4 F, *m*-C_6F_5) ppm. $C_{26}H_{15}BCl_2F_{10}Zr$ (690.33): calcd. C 45.24, H 2.19; found C 45.02, H 2.42.

Adduct Formation between *cis*-8 and $Li^+[B(C_6F_5)_4^-]$. Generation of 19: In an NMR experiment, *cis*-**8** (23 mg, 0.07 mmol) was mixed with $Li^+[B(C_6F_5)_4^-]$ (46 mg, 0.07 mmol), and [D$_8$]toluene (1.0 mL) was then added. NMR spectra of the mixture were not distinguished from those of the single components, but the coordination product **19** crystallised from the mixture after ca. 1 d at ambient temperature to allow an X-ray crystal structure analysis.

X-ray Crystal Structure Determination of 19: $C_{14}H_{14}Cl_2Zr{\cdot}LiBC_{24}F_{20}$, M = 1030.36, colourless crystal, 0.50 × 0.40 × 0.15 mm, a = 13.8212(1), b = 14.7217(1), c = 18.2205(2) Å, α = 88.406(1), β = 77.278(1), γ = 89.484(1)°, V = 3614.92(5) Å^3, $\rho_{calcd.}$ = 1.893 g cm^{-3}, μ = 5.88 cm^{-1}, empirical absorption correction by SORTAV (0.758 ≤ T ≤ 0.917), Z = 4, triclinic, space group $P\bar{1}$ (no. 2), λ = 0.71073 Å, T = 198 K, ω and φ scans, 26503 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.67 Å^{-1}, 17598 independent (R_{int} = 0.025) and 14617 observed reflections [$I \geq 2\sigma(I)$], 1135 refined parameters, R = 0.043, wR^2 = 0.105, max. (min.) residual electron density 1.24 (−1.44) e Å^{-3}, hydrogen atoms calculated and refined as riding atoms.

Data sets were collected with a Nonius KappaCCD diffractometer, equipped with a Nonius FR591 rotating anode generator. Programs used: data collection COLLECT[68], data reduction DenzoSMN[69], absorption correction SORTAV[70], structure solution SHELXS-97[71], structure refinement SHELXL-97[72], graphics SCHAKAL[73]. CCDC-180478 to -180481 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Supporting Information Available: 2D NMR spectroscopic data of the complexes *trans*-**4**, *cis*-**8**, **9**, *s-cis*-/*s-trans*-**15**, **16**, **17** and **18** (see also the footnote on the first page of this article).

Bismuthanides and Bismuthanediides − Synthesis and Structural Characterization of $[R_2Bi]^-$ and $[(RBi)_{12}Na_{21}]^{3-}$ Salts with Bulky Silyl Substituents

Gerald Linti,*[a] Wolfgang Köstler,[a] and Hans Pritzkow[a]

Dedicated to Prof. Dr. Gottfried Huttner on the occasion of his 65th birthday

Keywords: Bismuth / Lithium / Sodium / Silicon / Cluster compounds

The reaction of bismuth trihalides with the bulky alkali metal silanides $[(THF)_3LiSi(SiMe_3)_3]$ and $[(THF)_2NaSi(CMe_3)_3]$ affords the cyclotetrabismuthanes $(RBi)_4$ **1** and **3**, the alkali metal bismuthanides $[Li(THF)_4][Bi\{Si(SiMe_3)_3\}_2]$ (**2**) and $Na(THF)_3[Bi\{Si(CMe_3)_3\}]_2$ (**4**) and the bismuthanediide $Na_3(THF)_{14}[Na_{21}\{BiSi(CMe_3)_3\}_{12}]$ (**5**). Compound **2** features a two-coordinate bismuth atom. The core of **5** is a Bi_{12} icosahedron which is face-capped by 20 sodium atoms. The cluster is filled with a sodium atom. All structures were confirmed by single crystal X-ray crystallography. In addition, the bismuthanides and bismuthanediides were investigated by quantum chemical calculations.

Introduction

Alkali metal amides, phosphides and arsanides are common reagents, and their structural chemistry, especially that of the heavier homologous, has been explored recently.[1] This interest focused mainly on lithiated species and, consequently, relatively little is known about heavier alkali metal derivatives.[2] The structural chemistry of doubly metalated phosphanes and arsanes M_2PR revealed a high diversity of cluster compounds.[3,4]

Metalated bismuthanes have been known for 60 years, when the synthesis of $MBi(C_6H_5)_2$ (M = Li, Na, K) by reduction of $(C_6H_5)_2BiI$ with alkali metals in liquid ammonia was described.[5] About 40 years later, the first lithium bismuthanide $[(dme)LiBi(SiMe_3)_2]$ was structurally characterized.[6] MER_2 and M_2ER (E = P, As) compounds are normally prepared by metalation of phosphanes and arsanes and the lack of stable hydrogen compounds of bismuth might have caused the low interest in metalated bismuthanes;[7] only very recently was the first stable diarylbismuthane reported.[8] We report here on the reduction of bismuth halides with alkali metal silanides resulting in cyclotetrabismuthanes[9] and bismuthanides and bismuthanediides. The reaction of $SbCl_3$ with $NaSi(CMe_3)_3$ leads to the isolation of the cyclotetrastibane $[(Me_3C)_3SiSb]_4$.[10]

Results and Discussion

Reactions

The reaction of $BiBr_3$ with three equivalents of $[(THF)_3LiSi(SiMe_3)_3]$ in toluene affords the cyclotetrabismuthane **1** in good yields [Equation (1)].[9] If $BiCl_3$ in THF is used instead, **1** forms as the main product of the reaction, too. Initially a green solution is observed during warming of the reaction mixture from −78 °C to ambient temperatures. On stirring at room temperature the color changes to brown. Workup allows isolation of **1** as pentane soluble red crystals. The green component is soluble in THF. The dark green crystals obtained proved to be **2** [Equation (1), nonstoichiometric]. If $NaSi(CMe_3)_3$ dissolved in THF is reacted with $BiBr_3$ [Equation (2), nonstoichiometric] the reaction proceeds similarly to Equation (1).

$$BiBr_3 + 3\ Na(THF)_2Si(CMe_3)_3 \xrightarrow[-\ LiBr]{THF} \begin{array}{l} (Me_3C)_3Si{-}Si(CMe_3)_3 \\ + \\ 0.25\ [BiSi(CMe_3)_3]_4 \\ \mathbf{3} \\ + \\ Na(THF)_3Bi[Si(CMe_3)_3]_2 \\ \mathbf{4} \\ + \\ Na_3(THF)_{14}[Na_{21}Bi_{12}\{Si(CMe_3)_3\}_{12}] \\ \mathbf{5} \end{array} \quad (2)$$

The cyclotetrabismuthane **3** is formed predominantly. In addition, the bismuthanide **3** and the bismuthanediide **4** can be isolated. Compound **4** is the first example of a bismetalated bismuthane and a highly aggregated structure is expected as alkali metal phosphanediides and arsanediides form a large variety of cage compounds.[3]

Crystal Structure Analysis

The molecule structure of **3** resembles that of **1**.[9] The tetrabismuthane **3** crystallizes in the monoclinic space group $C2/c$ (Table 1, Figure 1) together with two molecules of THF. No direct intermolecular contacts are observed. The molecule of **3** with a folded Bi_4 core resides on a crystallographic twofold axis (angle between Bi_3 planes: 150°). This folding angle is even flatter than in **1** (angle between Bi_3 planes 138°). $[(Me_3Si)_2CHBi]_4$ [11] with less bulky substituents than **1** and **3** has a more folded Bi_4 core (angle between Bi_3 planes: 113°). The Bi–Bi–Bi bond angles are near 90°, as expected. The Bi–Bi–Si angles are wider, and

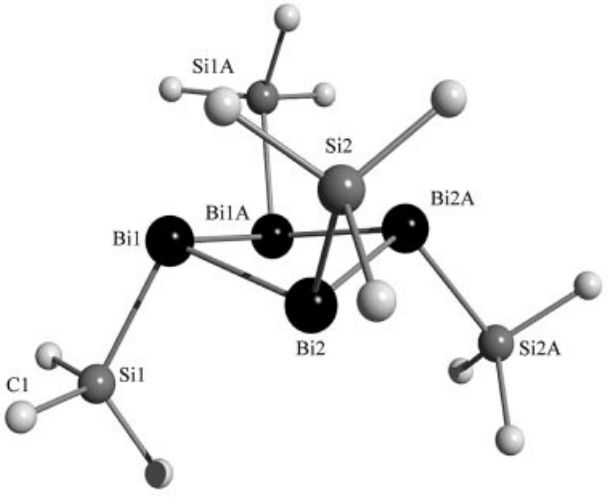

Figure 1. View of a molecule of **3**; disordered methyl groups are omitted from the plot for clarity; selected bond lengths [pm] and angles [°]: Bi(1)–Bi(2) 301.3(1), Bi(1)–Bi(1A) 303.1(2), Bi(2)–Bi(2A) 303.8(2), Bi(1)–Si(1) 275.0(6), Bi(2)–Si(2) 276.5(5); Bi(1)–Bi(2)–Bi(2A) 87.97(2), Bi(2)–Bi(1)–Bi(1A) 88.10(2), Bi(2)–Bi(1)–Si(1) 100.3(1), Bi(1A)–Bi(1)–Si(1) 101.4(1), Bi(1)–Bi(2)–Si(2) 108.9(1), Bi(2A)–Bi(2)–Si(2) 105.8(1)

range from 100° to 109° due to the steric demand of the substituents.

The Bi−Bi distances [(d_{Bi-Bi} = 301.3(1)−303.8(2) pm)] are similar to those in **1**. $[(Me_3Si)_2CHBi]_4$ has more alternating Bi−Bi bonds [d_{Bi-Bi} = 297.0(5)−304.4(2) pm]. The Bi−Si bond lengths (d_{BiSi} = 275.8 pm on average) are longer than those in **1** by approx. 5 pm. This difference is typical for the substituents under consideration and is observed in other cases, too.[12] This difference in the Bi−Si bond lengths and the increasing flattening of the Bi_4 cores in the known cyclotetrabismuthanes is due to the increased steric demand of the substituents.

Compound **2** crystallizes in the monoclinic space group $P2_1/a$. In this $LiBiR_2$ compound, the ions are separated. The lithium cation is coordinated by four THF molecules in a distorted tetrahedral manner. The BiR_2 anion (Figure 2) has a two-coordinate Bi atom. The shortest nonbonding intramolecular distances (except H) are 390 pm (for Bi−C_{methyl}), and the nearest Bi atom of a neighboring anion is 1100 pm away. The Bi−Si distances [d_{Bi-Si} = 267 pm on average] are shorter than those in **1** by 4 pm. This is due to the lower coordination number at the Bi atom. The Si−Bi−Si angle (114.4°) is larger than 90°, the usual angle observed in BiR_3 compounds. The wide range for the Si−Si−Si and Si−Si−Bi angles observed makes the distortion of the hypersilyl group obvious.

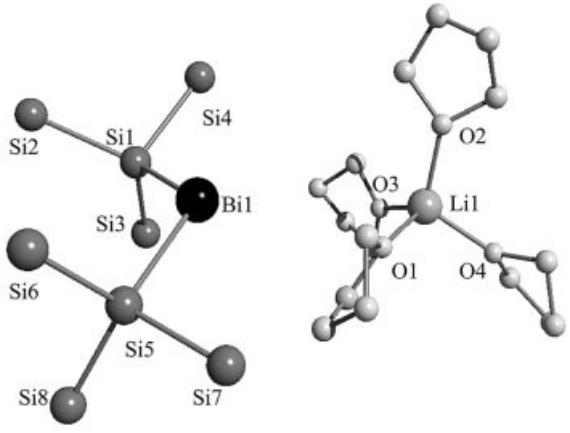

Figure 2. View of a molecule of **2**; disordered methyl groups are omitted from the plot for clarity; selected bond lengths [pm] and angles [°]: Bi(1)−Si(1) 266.8(5), Bi(1)−Si(5) 267.2(4), Si(1,5)−Si 234.2 (aver.); Si(1)−Bi(1)−Si(5) 112.2(1), Si−Si(1,5)−Si 103.1(3)−110.1(3), Bi(1)−Si(1)−Si(4) 123.1(3), Bi(1)−Si(1)−Si(3) 113.1(3), Bi(1)−Si(1)−Si(2) 99.5(2), Bi(1)−Si(5)−Si(6) 115.2(2), Bi(1)−Si(5)−Si(7) 120.6(2), Bi(1)−Si(5)−Si(8) 92.8(2)

For $[Bi(SiH_3)_2]^-$ an Si−Bi−Si angle of 93.4° is calculated by MP2 calculations.[13] This angle is nearly unaffected by the coordination of a lithium or sodium atom to the bismuth atom (see Table 2, Figure 3).[13] $[(dme)LiBi(SiMe_3)_3]$[6] is the only structurally characterized lithium bismuthanide so far. In this polymeric structure the Bi atom is tetracoordinated by two Si and two Li atoms, with an Si−Bi−Si angle of 91.8(4)°.

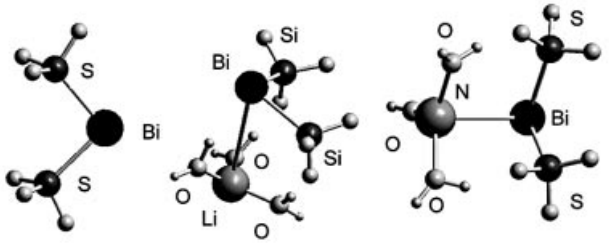

Figure 3. Calculated structures of $[(H_3Si)_2Bi]^-$ and $[(H_3Si)_2Bi-M(OH_2)_3]$ (M = Li, Na)

Compound **4** crystallizes in the trigonal space group $P3_1$ with Z = 3. Here, unlike **2**, a separated ion pair is not present. The alkali metal ion is coordinated by three THF molecules and the fourth coordination site is occupied by the Bi atom of the $BiSi_2$ unit. Thus, the Bi atom in **4** (Figure 4) is three-coordinated by two Si atoms (d_{BiSi} = 271.7 pm on average) and a sodium atom [d_{Bi-Na} = 311(1) pm]. Similar to the differences in **1** and **2**, the Bi−Si distances in **4** are

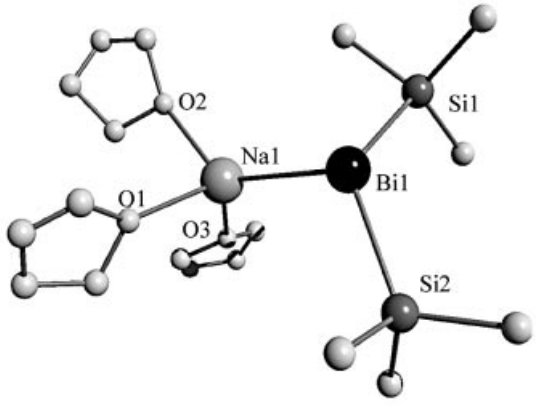

Figure 4. View of a molecule of **4**; disordered methyl groups are omitted from the plot for clarity; selected bond lengths [pm] and angles [°]: Bi(1)−Si(1) 272.6(10), Bi(1)−Si(2) 270.7(8), Bi(1)−Na(1) 311(1); Si(1)−Bi(1)−Si(2) 122.3(2), Na(1)−Bi(1)−Si(1) 113.7(4), Na(1)−Bi(1)−Si(2) 98.6(3)

Table 2. Results of MP2 calculations on bismuthanides

	d(Bi-Si) [pm]	*d*(Bi−M) [pm]	Si−Bi−Si [°]	M−Bi−Si [°]	M−Bi/Si−Bi−Si [°]

$(H_3Si)_2BiNa(OH_2)_3$	267.4	367.3	92.7	74.9, 85.0	80
for comparison: crystal structure of $(Me_3Si)_2BiLi(dme)$[6] (c.n. Bi and Li = 4)	263 (1)	292(3)	91.8	96(1), 106(1)	

shorter than those in **3** by 4 pm. The Si−Bi−Si angle is even wider (122.3°) than that in **2**. Here, the higher steric demand of the $Si(CMe_3)_3$ group compared to the $Si(SiMe_3)_3$ group becomes obvious again. The line Bi(1)−Na(1) is not orthogonal to the Si_2Bi plane, as might be expected, and as proposed by the quantum chemical calculations (Table 2). The angle of the line Bi(1)−Na(1) to the Si_2Bi plane is 143.8°, which means that the Bi atom is only 82 pm above the Si_2Na plane.

Compound **5** crystallizes in the trigonal space group $R\bar{3}$ with $Z = 3$, and is the sodium salt of an RBi^{2-} ion, which means that a highly aggregated structure can be expected. In fact, **5** forms an RBi dodecamer (Figure 5a) in which 12 bismuth atoms and 20 sodium atoms form a ball-like cage. Of the remaining four sodium atoms two show up as $[Na(THF)_4]^+$ and one as $[Na(THF)_6]^+$. In the structural model applied, the fourth is in a disordered position in the center of the $Bi_{12}Na_{20}$ cage. The disordered sodium atom takes the positions of an internal icosahedron.

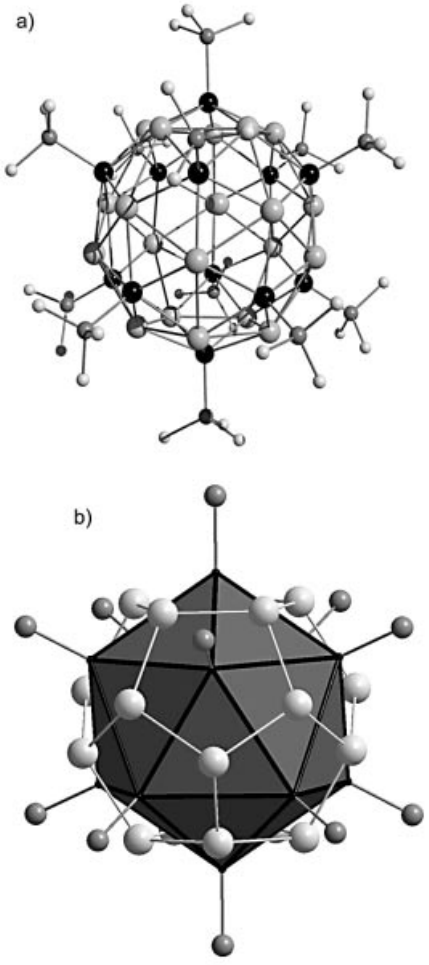

Figure 5. View of the cluster anion of **5**: a) showing only one position of the disordered central sodium atom (methyl groups are omitted for clarity); b) polyhedral representation of the Bi_{12} icosahedron with capping sodium atoms in pentagon dodecahedral arrangement; only the silicon atoms are shown for the $Si(CMe_3)_3$ substituents; selected bond lengths [pm] and angles [°] Bi(1)−Si(1) 263.0(4), Bi(2)−Si(2) 264.4(4), Bi−Na 317.2(6)−324.4(6); Si(1)−Bi(1)−Na 106.8(1)−113.5(1)

In the cage, 12 Bi atoms form an icosahedron (d_{BiBi} = 527−536 pm), whose faces are capped by 20 sodium atoms (Figure 5b). These sodium atoms themselves form a pentagonal dodecahedron ($d_{Na\text{-}Na}$ = 351−363 pm). All Bi atoms are bonded to the central silicon atom of a $Si(CMe_3)_3$ substituent (d_{BiSi} = 263.7 pm on average), which is severely disordered, as usual. The Bi−Si bond is even shorter than in **3** and **4**, which is expected in the series $R-BiX_2$, R_2Bi^- and RBi^{2-}. The $(RBi)_{12}Na_{20}$ cage is unique in the chemistry of bismuth, although $(R'P)_{12}Li_{20}$ and $(R'As)_{12}R_{20}$ (R = Li, Na) clusters with an analogous arrangement of the pnicogen and alkali metal atoms as in **5** are known.[3] These clusters are filled, too. In most cases M_nO (n = 2,6) units are present in the center of the cages. RI-DFT calculations[14] were performed on an empty $[(HBi)_{12}Na_{20}]^{4-}$ shell (Figure 6a). The resulting structure was quite similar to the observed structure of **5**. If a sodium cation is placed in the center of this $[(HBi)_{12}Na_{20}]^{4-}$ shell, the final position for this cation is out of the center of the shell and in a position similar to that of one position for the disordered encapsulated sodium atom. Adding this additional positive charge inside the cage results in a shrinking of the cage. This means the diameter of the $Bi_{12}Na_{20}$ shell decreases from 1044 pm to 1020 pm (Figure 6b). The Bi−Na interactions in **5**, as well as the Bi-(Li, Na) contacts in **2** and **4**, are mostly ionic, as is revealed by Aldrich−Heinzmann population analyses.[15] This is expressed in the shared electron numbers, which are as low as 0.22 to 0.29 for the Bi−Na interactions.

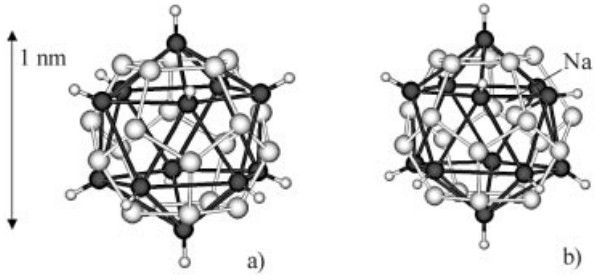

Figure 6. View of a) $[(HBi)_{12}Na_{20}]^{4-}$ and b) $[(HBi)_{12}Na_{21}]^{3-}$ as derived from RI-DFT calculations; average selected bond lengths [pm] a) Bi−Na 330.7, Bi−H 184.5, Bi···Bi 548.0, Na···Na 364.0; b) Bi−Na 328.6, Bi−H 184.0, Bi···Bi 545.0, Na···Na 361.6

Conclusion

The reaction of bismuth halides with bulky silanides has proved to be a valuable entry to the chemistry of bismuth ring compounds as well as for the synthesis of anionic bismuthanides R_2Bi^- and RBi^{2-}. In particular, the latter opens a novel field for bismuth. Whether these compounds are useful for synthetic applications will depend on their improved availability.

Experimental Section

General: All experiments were performed under purified nitrogen or in vacuo with Schlenk techniques. All yields are referenced to

BiX_3. Chemical analysis for **3** gave unreliable results, due to the partial loss of THF from the crystals, and for the ionic species **2**, **4** and **5** due to their sensitivity. NMR: Bruker ACP 250; Mass spectra: Varian MAT 711; X-ray crystallography: Suitable crystals were mounted with a perfluorinated polyether oil on the tip of a glass fiber and cooled immediately on the goniometer head. Data collections were performed with Mo-K_α radiation on a Bruker AXS (**2**), STOE IPDS (**3**, **5**) or a STOE STADI4 diffractometer (**4**). Absorption correction was performed numerically with XRED (STOE) for **3,5** and empirically using equivalent reflections for **2**. Structures were solved and refined with the Bruker AXS SHELXTL 5.1 program package. Refinement in full-matrix against F^2. All hydrogen atoms were included as a riding model with fixed isotropic U values in the final refinement. For further data see Table 1. The structures of **4** and **5** are influenced by disorder of the CMe_3 groups. In part, we attempted to describe this by a split model. The crystal structure of **4** was refined as a merohedral twin (BASF 0.49, Flack parameter −0.03). The low parameter/data ratio and the lack of an absorption correction due to decomposition of the crystal together with the severe disorder of the silyl groups allows no detailed discussion of the structure.
CCDC-174922 (**2**), -174923 (**3**) -174924 (**4**) and -174925 (**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Compounds 1 and 2: A solution of $[(THF)_3LiSi(SiMe_3)_3]$[16−18] (2.58 g, 5.49 mmol) in 20 mL THF was added dropwise to a stirred solution of $BiCl_3$ (0.58 g, 1.84 mmol) in 20 mL THF at −78 °C within 10 min. The dark-colored mixture was stirred for an additional 10 min at low temperature and was then quickly warmed to ambient temperature. After stirring for 1 h the dark green solution was stripped down. The residue was extracted with 50 mL of pentane in several portions. After filtration an orange-red solution was obtained, from which **1** was isolated as tiny red crystals by cooling to −20 °C. The solid, dark colored residue after the pentane extraction was treated with 15 mL of THF. After filtration a dark green solution of **2** (pure by NMR spectroscopy) was obtained. Upon cooling to −20 °C, green crystals of **2** formed; yield: 0.92 g (51%; with reference to Bi).
1:[9] ^{1}H NMR (250 MHz, C_6D_6): δ = 0.49 ppm. ^{13}C NMR: δ = 5.6 ppm. ^{29}Si NMR: δ = −124 (Si) −2.2 ($SiMe_3$).
2: ^{1}H NMR (250 MHz, C_6D_6): δ = 0.64 (s, 54 H, $SiMe_3$), 1.66 (m, 16 H, CH_2), 3.40 (m, 16 H, OCH_2) ppm. ^{13}C NMR: δ = 5.9 ($SiMe_3$), 26.0 (CH_2), 68.9 (OCH_2), ppm. ^{29}Si NMR: δ = −110 (Si) −8.6 ($SiMe_3$) (approx. 6% **1** as impurity, as indicated by ^{1}H NMR integration).

Compounds 3, **4 and 5:** $[NaSi(CMe_3)_3]$ (6.80 mmol),[10] dissolved in 10 mL THF, was added dropwise with a syringe into a stirred solution of $BiBr_3$ (1.02 g, 2.27 mmol) in 40 mL of THF at −78 °C. The dark-colored solution was stirred for an additional 30 min at −78 °C. The THF was removed in vacuo before ambient temperature was reached. The residue was extracted with 50 mL of pentane and 20 mL of THF. The pentane solution was reduced to a volume of 10 mL. Upon cooling to −20 °C red crystals of **3** were isolated [yield: 0.30 g (32%)]. From the THF solution dark-red crystals of **4** were isolated, which were accompanied by traces of **3** and several nearly dark black crystals of **5**. Attempts to purify **4** by recrystallization resulted in decomposition of **4** to **3**.
3: ^{1}H NMR (250 MHz; C_6D_6): δ = 1.15 ppm. ^{13}C NMR: δ = 30.9 ppm. MS (EI, 70 eV): *m/z* (%) = 816 (5) $[Bi_2\{Si(CMe_3)_3\}_2]^{+\cdot}$, 607 (4) $[Bi\{Si(CMe_3)_3\}_2]^+$, 550 (2) $[Bi\{Si(CMe_3)_3\}\{Si(CMe_3)_2\}]^{+\cdot}$, 408 (5) $[BiSi(CMe_3)_3]^{+\cdot}$, 57 (100) $[C(CMe_3)_3]^+$.
4: $C_{36}H_{78}BiNaO_3Si_2$ (847.2): calcd. C 51.04, H 9.28; found C 56.53, H 11.30. ^{1}H NMR (250 MHz; C_6D_6): δ = 1.41 (m, 12 H, CH_2), 1.49 (s, 54 H, CMe_3), 3.56 (m, 12 H, OCH_2) ppm. ^{13}C NMR: δ = 25.8 (CH_2), 34.6 (CMe_3), 67.9 (OCH_2).
5: $C_{200}H_{436}Bi_{12}Na_{24}O_{14}Si_{12}$ (6462.2): calcd. C 37.17, H 6.80; found C 36.96, H 7.94.

Evaluation of 3,4-Hydroxypyridinecarboxylic Acids as Possible Bidentate Chelating Agents for Aluminium(III): Synthesis and Metal−Ligand Solution Chemistry

Valerio B. Di Marco,[a] Robert A. Yokel,[b] Maria Grazia Ferlin,[c] Andrea Tapparo,[a] and G. Giorgio Bombi*[a]

Keywords: Aluminium / Carboxylate ligands / Potentiometry / Chelation therapy

In view of a possible application to aluminium(III) chelation therapy, 3-hydroxy-4-pyridinecarboxylic acid (3H4P) and 4-hydroxy-3-pyridinecarboxylic acid (4H3P) were synthesised, and their chemical interactions with the metal ion were investigated in aqueous 0.6 m (Na)Cl at 25 °C by means of potentiometric titrations. Only mononuclear complexes of the type AlL_lH_h (l = 1, 2 and 3; h = 0, 1, ..., l) were formed. The qualitative and quantitative results obtained were confirmed by UV spectrophotometry and ^1H NMR spectroscopy. The efficiencies of the ligands to chelate aluminium(III) were evaluated at physiological pH and ionic strength (in vitro), together with the *n*-octanol/water distribution coefficients of the free ligands and of the ligand–metal complexes. The results suggest that 3H4P and 4H3P lack sufficient chelation efficacy to be proposed as chelation therapy agents for aluminium(III). However, the results do suggest a strategy for the synthesis of more promising compounds.

Introduction

The therapy for metal overload pathologies usually involves the administration of suitable chelating agents to selectively remove the metal from the body. Regarding aluminium(III) and iron(III), medical research continuously emphasises the need for new safe, efficient and orally effective chelators.[1−3] The existing chelating agents, desferrioxamine and deferiprone, have a number of drawbacks, including oral inefficacy and high cost for the former,[4−6] and several toxic side effects and controversial efficiency for the latter.[5−8] An attempt to address this need is the chemical modification of existing chelating agents, to improve their in vivo properties.[9−11] Another important approach is the synthesis of new hexadentate ligands.[12−16] However, although there is some evidence that hexadentate ligands may be more efficient than bidentate and tridentate ligands, they are more expensive and thought to be less absorbed orally.[5,17,18] There are very few attempts to synthesise new tridentate ligands[19] and, to the best of our knowledge, no attempts to synthesise new bidentate ones other than deferiprone analogues.

Hydroxypyridinecarboxylic acids (HPs) represent a class of compounds that have not been considered for metal chelation therapy. The limited data in biomedical literature seems to demonstrate their lack of toxicity. Some have been proposed as drugs.[20−23] Their structure suggests a good ligating capability towards aluminium(III) and iron(III). The interactions between 2-hydroxy-3-pyridinecarboxylic acid (2H3P) and 3-hydroxy-2-pyridinecarboxylic acid (3H2P) with aluminium(III) have been investigated.[24] Although complexes with reasonably high stability constants form in solution, their stability is much lower than those of the corresponding desferrioxamine and deferiprone complexes. Therefore, neither 2H3P nor 3H2P appear to be good candidates for chelation therapy.

It is known, for hydroxypyridinones, that the 3,4 derivatives form significantly more stable complexes with aluminium(III) and iron(III), than the 2,3 derivatives.[25] The same behaviour is expected for HPs, which are structurally very similar to hydroxypyridinones. Therefore, an investigation of the stability of the metal complexes of 3,4-HPs is advisable.

In this work, the formation of complexes of aluminium(III) and 3-hydroxy-4-pyridinecarboxylic acid (3H4P),

and 4-hydroxy-3-pyridinecarboxylic acid (4H3P) (Figure 1) have been studied in aqueous solutions by means of potentiometric titrations. The speciation data obtained has been integrated and confirmed by UV/Vis spectrophotometry, NMR spectroscopy and elemental analysis. The efficiency of the ligands to chelate aluminium(III) at physiological pH and ionic strength in vitro, and the octanol/water distribution of both the free ligands and the metal−ligand complexes, have been determined according to a method developed by Yokel et al.[26] For comparison, the efficiency and the octanol/water distribution of 2H3P and 3H2P have also been analysed.

Results And Discussion

Synthesis of the Ligands

Among the methods proposed for the synthesis of 3H4P,[27,28−31] we selected the three-step procedure starting from 4-methylpyridine described by Dejarden.[27] The advantage of this pathway lies in the bromination of the starting material, which gives the precursor 3-monobromo derivative of 3H4P as the main reaction product as a result of the deactivation caused by the bromine atom itself. In all cases the yields were lower than those reported; for the hydrolysis of the bromo acid of 3H4P, no product was obtained under the literature conditions;[27] the use of a water/methanol mixture (6:4, v:v) for 12−24 h yielded over 40% of pure 3H4P (ref.[27] 80%).

The synthesis of 4H3P was accomplished via butadienedicarbonitriles according to the method of Mittelbach,[32] that produces the desired isomeric compound. This pathway, although requiring five steps, is quite straightforward and has proven to be more convenient (17% overall yield) than others.[33−36]

Thermodynamic Study

Acidity Constants of the Ligands

The pK_a values for H_2L and HL (here and in the following, charges are omitted for simplicity), corresponding to the deprotonation of the pyridine nitrogen atom and the phenol oxygen atom, respectively, were computed for the potentiometric titration data of the free ligands (Table 1).[24,37]

Table 1. Acidic properties of 3H4P and 4H3P, at 25 °C in aqueous (Na)Cl 0.6 m

Species	3H4P pK_a	n[a]	4H3P pK_a	n[a]	Source
H_3L	0.64 ± 0.03	4	−0.06 ± 0.04	3	UV
H_2L	4.713 ± 0.001	30	5.955 ± 0.002	24	pot.
HL	10.300 ± 0.004	15	10.85 ± 0.01	12	pot.

[a] n is the number of experiments from which the data were obtained; the reported uncertainty is the standard deviation of the mean.

Accurate potentiometric measurements at pH values lower than ca. 1.5 cannot be executed, because under these conditions the pH modification induced by the acid-base equilibria is negligible. Therefore, the more acidic pH region has been explored by means of UV spectrophotometric measurements, which allowed for the detection of H_3L and the calculation of its pK_a value (Table 1). This deprotonation has been assigned to the carboxylic group.[37] It may be noted that for the carboxylic group in nicotinic acid, $pK_{a1} \approx 2$;[38] as the *ortho*-phenol group can be expected to produce a significant increase in the acidity (for example, the carboxylic pK_a of salicylic acid is ca. 1.2 units lower than that of benzoic acid[38]), the values obtained for H_3L appear to be reasonable.

Metal−Ligand Complexes − Potentiometric Results

The potentiometric titrations of solutions containing both the metal ion and the ligand allowed for the identification of a large number of complexes, 9 in the case of 3H4P and 8 in the case of 4H3P; their stoichiometries are reported in Table 2, together with the values of their stability constants. The distribution diagrams for the two systems, containing an excess ligand concentration, are reported in Figure 2. It is worth noting that the precipitation of aluminium hydroxide was not observed in any systems in the presence of an excess ligand concentration (at least three-

1, 3, 0	26.09 ± 0.07		6	25.76 ± 0.09		7

[a] n is the number of experiments from which the data were obtained; the reported uncertainty is the standard deviation of the mean.

fold), due to the high affinity of the ligands towards the metal ion.

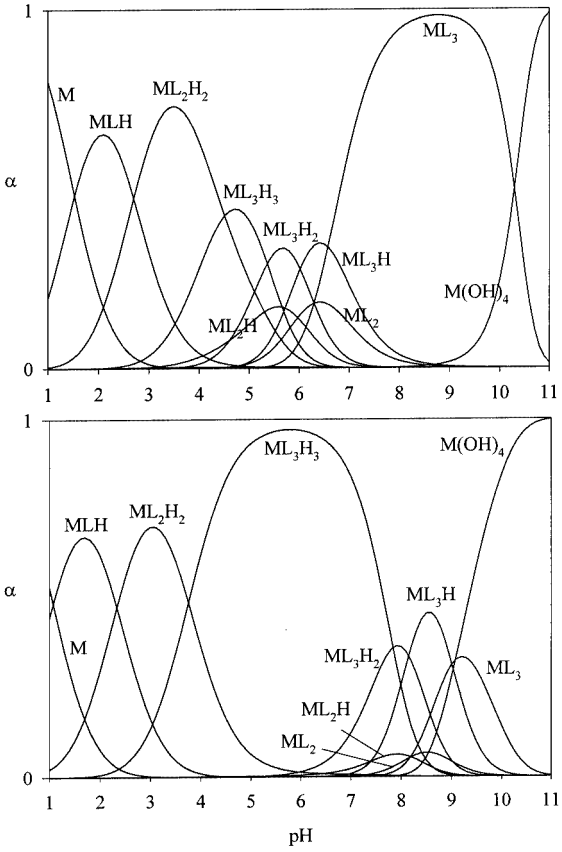

Figure 2. Distribution diagrams of the most important aluminium species in the presence of 3H4P (above) and 4H3P (below) in aqueous (Na)Cl 0.6 m, $T = 25$ °C; $[Al]_0 = 5{\cdot}10^{-4}$ m, $[ligand]_0 = 4{\cdot}10^{-3}$ m

Owing to the large number of species, the simultaneous optimisation of the metal−ligand complexation constants led to strong correlations between the various values. Therefore, the data has been elaborated in a sequential manner, considering the titrations with large metal/ligand ratios (1:1, 1:2) separately from the others. In this way, some of the complexes could be neglected in the former titrations and optimised only in the latter, and most of the correlations could be avoided. Of course the consistency of the above procedure needed to be verified a posteriori: distribution diagrams like those reported in Figure 2 have been drawn for the actual metal and ligand concentrations adopted for the former titrations in order to verify that the species rejected were actually negligible.

In some of the titrations of the system Al^{III}/3H4P, the precipitation of a white powder was observed (for $[Al]_0 >$ ca. $8{\cdot}10^{-4}$ m, $[Al]_0/[L]_0 \leq 1{:}3$ and pH > ca. 5−6). The solid was examined by elemental analysis (C = 37.9, H = 3.1, Al = 6.92, N = 7.1, Na = 4.22). The relative mol ratios between aluminium, carbon and nitrogen were calculated. The values obtained, 1:12.3:1.96, are in close agreement with the theoretical ratios 1:12:2 expected for an AlL_2 species (= $C_{12}H_8AlN_2O_6$). The 1:2 metal/ligand stoichiometry is also suggested by the observation that in all the titrations, the precipitation occurred when the concentration of the neutral species AlL_2H (as calculated from the stability constants reported in Table 2) reached a value of about $3{\cdot}10^{-4}$ m. The solid obtained is likely to be coordinated with water molecules (elemental analysis suggests two) and with NaCl (elemental analysis suggests Na/Al = 0.7). Unfortunately, the stoichiometry and the structure of this solid cannot be defined exactly because no crystals suitable for X-ray analysis could be obtained.

The distribution curves in Figure 2 show that the speciation in the two aluminium−ligand systems is very similar at acidic pH values, where only the free metal ion and the complexes AlLH and AlL_2H_2 exist in solution. At pH > 4, 3H4P forms a large number of complexes, which include AlL_3H_3 and the deprotonation products of the 1:2 and 1:3 metal/ligand species; AlL_3 and $Al(OH)_4$ are the only existing metal species at pH values larger than ca. 8. On the contrary, 4H3P forms only one main species, AlL_3H_3, in the pH range 4−6, and the deprotonation products only appear at higher pH values; among these, AlL_3 is not as predominant as in 3H4P. The different behaviour of 3H4P and 4H3P is due to the different acidity of the pyridine hydrogen atom of the two ligands (pK_{a2}, Table 1), the pK_a value of 3H4P is 1.2 log units lower. This acidity difference is further increased in the metal complexes (pK_a values, Table 2), and therefore, the deprotonation products of the Al/3H4P species are more stable than those of Al/4H3P. For the same reason, the species AlL is not present in a significant amount in the Al/4H3P system.

Two interesting properties regarding the acidity of the complexes in both aluminium/ligand systems should be noted. (i) For the Al/3H4P system, the acidity decreases systematically (i.e. pK_a increases) in the order $H_2L >$ AlLH > $AlL_2H_2 > AlL_3H_3$ (Table 2). For the Al/4H3P system, no pK_a value for AlLH is available, but the acidity order for the other species is the same. The decrease in the acidities is less marked for 4H3P than for 3H4P. (ii) The increase in the pK_a values of the complexes having the same number of ligands (namely AlL_2H_2 and AlL_2H; AlL_3H_3, AlL_3H_2 and AlL_3H) by decreasing the number of acidic protons is close to that expected on statistical grounds (for example, the K_a ratio of the 3H4P complexes AlL_2H_2/AlL_2H is 4.6, the statistical value is 4). All these results are very similar to those obtained for the complexes formed by 2H3P and 3H2P with aluminium(III)[24] and iron(III).[39] In ref.[24] an explanation is given for both the effects.

In order to confirm the potentiometric results with some independent techniques, UV spectrophotometric quantitative data and NMR spectroscopic qualitative and semiquantitative data have also been obtained.

Metal−Ligand Complexes − UV Spectrophotometric Results

UV spectra for the Al/4H3P system at several pH values are reported in Figure 3. The following value was obtained

for log β (AlLH): log $\beta_{1,1,1}$ = 18.03 ± 0.10 (fitting of 5 spectra, values at three λs). This value compares well (*t*-test) with the corresponding potentiometric value (18.19 ± 0.09). The agreement between these results suggests the absence of any bias on final results.

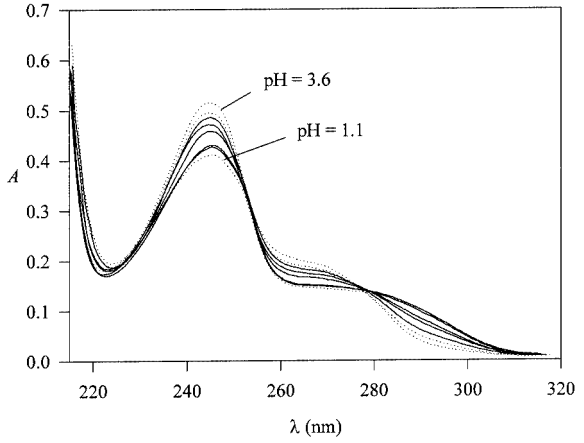

Figure 3. UV spectrophotometric study for Al/4H3P; see Table 6 for experimental details; dashed curves were excluded for the log β calculation

Metal−Ligand Complexes − NMR Spectroscopic Results

^{1}H NMR spectra were collected for both 4H3P and 3H4P systems at various pD values in D_2O solutions containing only the free ligand or the ligand with the metal ion. As an example, the spectra obtained for the 4H3P system are shown in Figure 4.

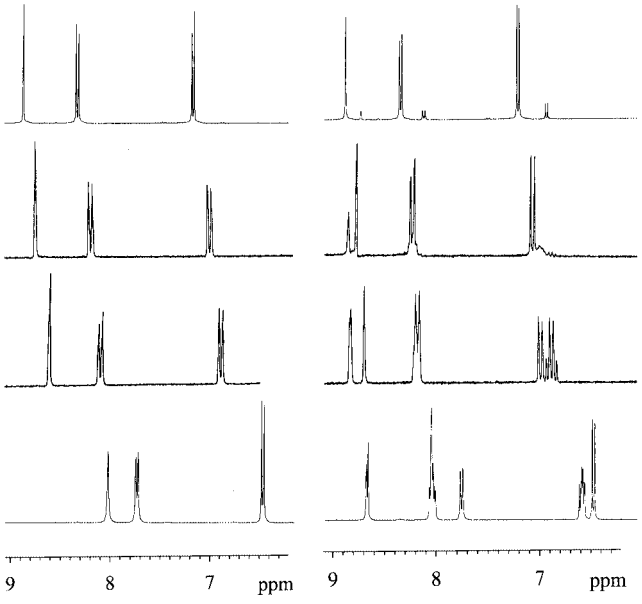

Figure 4. Left side: ^{1}H NMR spectra of 4H3P alone (0.050 m); right side: ^{1}H NMR spectra of Al^{III} (0.010 m) + 4H3P (0.050 m); from top to bottom: pD = 0.11, 1.73, 5.20, 8.58

On complexation with aluminium, three new groups of peaks in addition to those of the free ligand are observed. At pD = 0.11 the multiplicity and the shape of the "new" peaks are almost identical to those of the free ligand; according to the potentiometric data, these signals can be assigned to the AlLH complex. On increasing the pH, the peaks of the complexes become more complicated, since under these conditions different species coexist in solution (AlL_2H_x and AlL_3H_x). Furthermore, as the ligands are not symmetric and may chelate the metal ion in different spatial configurations, AlL_2H_x and AlL_3H_x can form with 4 and 2 different diastereoisomers, respectively, each with a slightly different NMR response. At pD = 5.20 and 8.58, the patterns of the signals become more simple, because, according to potentiometric data, only the AlL_3H_x species (and therefore fewer diastereoisomers) exist in solution.

The dependence of the chemical shift of the different signals on the pD can be explained by the acid-base properties of the ligand and the complexes: deprotonation of the pyridine nitrogen atom causes a shift of the ligand signals towards lower ppm values; this shift is maximal at pD = pK_a. However, for a correct interpretation it is necessary to take into account the difference in the pK_a values of the acid in D_2O and in H_2O due to isotopic effects. In order to estimate the pK_a difference, the empirical equation p$K_a(D_2O)$ = 0.41 + 1.02·p$K_a(H_2O)$ has been proposed[40] (for example, the pK_a values for 4H3P in heavy water are: pK_{a1} ≈ 0.3, pK_{a2} ≈ 6.5 and pK_{a3} ≈ 11.5). Considering the NMR spectra in the light of the above, the lowest-field signal at pD = 0.11 is due to the free ligand, whereas the signals at pD = 1.73 and 5.20 are assigned to the complexes since the free ligand deprotonates between pD = 0.11 and 1.73 ($H_3L \rightarrow H_2L$) and the complex species do not [for example, for AlL_2H_2 p$K_a(D_2O)$ ≈ 6.9]. For a similar reason, at pD = 8.58 the chemical shift difference between the same lowest-field signals of the complexes and of the free ligands become significantly larger than in the spectrum at pD = 5.20. This is because in this pD range the free ligand further deprotonates ($H_2L \rightarrow HL$), whereas the complexes deprotonate only partially [for example, for AlL_3H_3 p$K_a(D_2O)$ ≈ 8.4]. These semi-quantitative data are in good agreement with the potentiometric results.

The integration of the signals of the free ligand and of the complexes gives the relative amount of free and complexed ligand; the values obtained are reported in Table 3, together with the corresponding values calculated from the stability constants reported in Table 1 and Table 2. The agreement between the two sets of data is good, in view of the uncertainties of the NMR integration values, and of the presence of isotopic and solvent effects introduced by the change in solvent from H_2O to D_2O.

n-Octanol/Water Distribution and Chelation Efficacy Study

The results obtained for each ligand are summarised in Table 4. 2H3P and 3H2P have also been analysed for comparison.

A significant increase in efficiency can be observed for the 3,4-HPs, and especially for 4H3P, with respect to the

Table 3. Percentages of free and complexed ligand (Al/4H3P spectra)

pD	from NMR spectroscopic data		from potentiometric/UV results	
0.11	free ligand	88.8	$H_3L + H_2L$	90.4
	complexed ligand	11.2	$AlLH + 2\ AlL_2H_2$	9.6
1.73	free ligand	61.5	$H_3L + H_2L$	64.2
	complexed ligand	38.5	$AlLH + 2\ AlL_2H_2 + 3\ AlL_3H_3$	35.8
5.20	free ligand	42.7	$H_2L + HL$	40.1
	complexed ligand	57.3	$2\ AlL_2H_2 + 3\ AlL_3H_3 + 3\ AlL_3H_2$	59.9
8.58	free ligand	44.2	$H_2L + HL + L$	40.3
	complexed ligand	55.8	$3\ AlL_3H_3 + 3\ AlL_3H_2 + 3\ AlL_3H + 3\ AlL_3$	59.7

Table 4. Octanol/water distribution coefficients, and Al^{III} chelation efficiencies

Ligand	$D_{o/w}$ free ligand	$D_{o/w}$ Al complexes	Chelation efficiency (%)
3H4P	0.014 ± 0.001	0.005	20 ± 2
4H3P	0.004 ± 0.001	0.002	43 ± 6
2H3P	0.0006 ± 0.0001	–	4 ± 1
3H2P	0.006 ± 0.001	–	13 ± 2

2,3-HPs. This is in agreement with the thermodynamic data. The very low lipophilicity of all the ligands and the metal−ligand complexes at physiological pH values should be noted; in fact, from thermodynamic data it is known that at pH = 7.4 both the free ligand and the metal−ligand complexes are predominantly in the charged form (HL^- and deprotonated $AlL_3H_x^{(3-x)-}$ species, respectively). Actually, the octanol/water distribution of the Al ligand complexes could not accurately be calculated from its distribution in the presence and the absence of Al borate, because a significant (if not predominant) percentage of the ligand was not complexed with Al, as evidenced by the generally low efficiency obtained. The values obtained for 3H4P and 4H3P suggest that the metal−ligand complexes are slightly more hydrophilic than the free ligand.

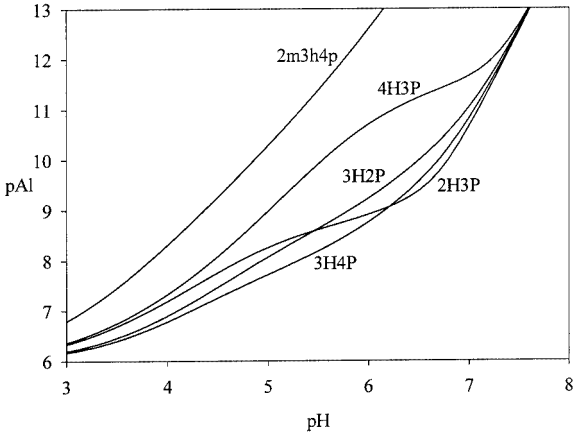

Figure 5. pAl for several ligands (see text); $[Al]_0 = 10^{-6}$ m, $[ligand]_0 = 5{\cdot}10^{-5}$ m

Conclusions

Both 3H4P and 4H3P form strong complexes in solution with aluminium(III) such that no metal hydroxide precipitates at neutral pH in the presence of a threefold (or higher) ligand excess. The speciation patterns of the two ligands with aluminium(III) are similar, and a number of 1:1, 1:2 and 1:3 metal/ligand species are formed in solution.

In order to compare the affinities of the various HPs (3H4P, 4H3P, 3H2P and 2H3P) for the metal, the direct analysis of the data reported in Table 2 (and in the corresponding Table of ref.[24]) is not useful since the competition arising from the proton (i.e. the basicity of the ligand) cannot be taken into account. The comparison could be accomplished by computing the conditional stability constants of the complexes, however, in the literature the calculation of pAl (= $-\log [Al^{3+}]$) vs. pH at a given metal and ligand concentration is much more common. Generally,[41] the pAl is computed at a metal concentration of 10^{-6} m and at a ligand concentration of $5{\cdot}10^{-5}$ m. For different systems, the higher the pAl, the stronger the complexes. In Figure 5, pAl plots for the four HPs are shown, together with that of a deferiprone-like molecule (2-methyl-3-hydroxy-4-pyridinone, 2m3h4p, data taken from ref.[42]). It is evident that 4H3P forms significantly more stable complexes with aluminium than the other HPs, especially at slightly acidic and neutral pH values. This result is as expected (see Introduction) and confirms that 3,4-HPs are more promising chelating agents than 2,3-HPs. Surprisingly, the pAl of 3H4P is quite low, similar to those of the 2,3-HPs; this latter data cannot be explained as yet. However, it is important to note from Figure 5 that the pAl of 4H3P is significantly lower than that of the deferiprone-like molecule at all pH values.

The chelation efficiencies give an indication of the ability of the ligands to solubilise aluminium(III) at physiological pH. The data obtained correlate well with the thermodynamic results, and a reasonably high efficiency, 43%, was obtained for only 4H3P.

Table 5. Potentiometric titrations (titrant: NaOH)

Titrations	Conditions			
	$[Al]_0/10^{-3}$ m	$[L]_0/10^{-3}$ m	$[Al]_0/[L]_0$	pH
1.				
3H4P + HCl	–	0.51–1.27	–	2.7–10.5
4H3P + HCl	–	0.36–2.98	–	2.1–10.5
2.				
Al + HCl	0.50–2.88	–	–	2.4–3.5
	1.01–3.39	–	–	
3.				
Al + 3H4P + HCl	0.50–3.81	1.88–4.01	1:1;1:2;1:4;1:8	1.7–10.0
Al + 4H3P + HCl	0.31–3.01	1.58–4.95		

The octanol/water distribution coefficients $D_{o/w}$ indicate that all HPs and their aluminium complexes show a marked hydrophilic behaviour. Porter[43] has suggested that an orally effective Fe (or Al) chelator should probably have a $D_{o/w}$ of 0.2 or greater to be absorbed. However, in our evaluation of a series of 3,4-hydroxypyridinones we found that some compounds with a $D_{o/w}$ much lower were among the most orally bioavailable and effective chelators of Al.[44–46]

In conclusion, the thermodynamic data and the chelation efficiencies suggest that the HPs considered in this work cannot be regarded as possible alternatives to desferrioxamine and deferiprone in the chelation therapy of aluminium(III). The synthesis of more lipophilic HPs with higher stability constants towards the metal ion is advisable. For deferiprone-like molecules, both of these characteristics have been obtained by introducing electron-donating, lipophilic groups into the pyridinic ring. The synthesis of 1- and 2-methyl HP derivatives is therefore now in progress.

Experimental Section

Synthesis of the Ligands: The ligands 3H4P and 4H3P (which are not commercially available) were prepared acording to reported multi-step methods,[27,32] with some modifications. All chemicals and solvents were obtained from Aldrich Chimica or Janssen Chimica (now Acros). The identity and purity of all intermediates and final compounds were checked by melting point (m.p.) measurements (Gallenkamp MFB 595 010 M/B capillary m.p. apparatus), ^{1}H NMR spectra (Bruker 300 MHz), TLC (Merck silica gel 60 F-254 glass plates), mass spectrometry (Mat 112 Varian Mat Bremen mass spectrometer) and elemental analyses (Perkin–Elmer Elemental Analyzer Model 240B).

3H4P: White needles. Yield 24% (4 g). M.p. 321 °C (ref.[32] 316–319 °C). ^{1}H NMR (in [D$_6$]DMSO), δ = 7.83 (d, $J_{5,6}$ = 5.2 Hz, 1 H, 5-H), 8.10 (d, $J_{6,5}$ = 5.2 Hz, 1 H, 6-H), 8.39 (s, 1 H, 2-H) ppm. $C_6H_5NO_3$ (139.11): calcd. C 51.80, H 3.62, N 10.07; found C 51.72, H 3.65, N 9.97.

4H3P: White needles. Yield 17% (4 g). ^{1}H NMR ([D$_6$]DMSO): δ = 6.73 (d, $J_{5,6}$ = 5 Hz, 1 H, 5-H), 8.07 (d, $J_{6,5}$ = 5 Hz, 1 H, 6-H), 8.61 (s, 1 H, 2-H), 12.99 (s, 1 H, OH), 15.70 (s, 1 H, COOH) ppm. EI MS (70 eV): *m/z* (%) = 139 (100) [M$^+$], 122 (80.66) [M$^+$ – OH], 94 (63.94) [M$^+$ – COOH]. $C_6H_5NO_3$ (139.11): calcd. C 51.80, H 3.62, N 10.07, found C 51.74, H 3.59, N 10.00.

Thermodynamic Study: The experimental apparatus, reagents and measurement methods were almost the same as those reported previously.[47] In the following, a summary will be given; details are reported only when different from those described previously.

Apparatus: All potentiometric measurements were performed using a Radiometer ABU93 Triburette apparatus. UV spectra were recorded using Perkin–Elmer Lambda 20 and Lambda 5 instruments, ^{1}H NMR spectra using Varian Gemini 200 MHz and Bruker 300 MHz instruments. The elemental analyses were performed using an Iris Intrepid ICP-AES for Al and Na, and a Perkin–Elmer Elemental Analyzer Model 240B for C, N and H.

Reagents: All analyte concentrations were expressed using the molality scale (mol/kg of water). For potentiometric and UV spectrophotometric measurements, working solutions of HCl (0.1 m), NaOH (0.1 m) and $AlCl_3$ (0.05 m, containing HCl 0.01 m) were prepared and standardised as described previously;[47] 3H4P and 4H3P were used as synthesised to prepare 0.004 m and 0.05 m working solutions, respectively, (the concentrations correspond to about 80% of their water solubility). The ionic strength of all the solutions was adjusted to 0.6 m (≈ 0.594 M) (Na)Cl. Solutions for ^{1}H NMR spectroscopic measurements were prepared by dissolving weighted amounts of ligand, $AlCl_3$ (Fluka, ≥ 99%) and NaCl in D_2O.

Potentiometric Measurements: Titrations were carried out at 25 ± 0.1 °C; duplicate potentiometric measurements were performed using two different glass electrodes (Radiometer pHG201 and BDH 309/1015/02) and an Ag/AgCl/0.6 m NaCl reference electrode,[48,49] with a J-shaped junction; its acidic liquid junction potential has been determined previously[39] and can be represented by the equation[49] $E_j = -S\cdot\log(1 + J\cdot[H^+])$, with J = 4.251 ± 0.003. Besides the calibration and the base standardisation experiments,[47] the titrations reported in Table 5 were performed. All stability constants were calculated using the computer program PITMAP.[50] The hydroxometal species reported by Öhman[51] have been considered and the corresponding log β values were kept constant during the processing of the data. After the addition of the metal ion and either of the two ligands to an acidic solution (pH < 3), the measured e.m.f. drifted and reached a constant value only after ca. 1 h, suggesting a low complex formation rate. The kinetics of the aluminium–ligand reaction became "normal" (equilibration after ca. 1 min) at pH values > 3. These findings are in agreement with previous results with 2,3-HPs.[24,52] Experimental details regarding the treatment of the slow kinetics during the titrations are reported.[24]

UV Spectrophotometric Measurements: The measurements reported in Table 6 were performed. The pH of the solutions was computed

Table 6. UV spectrophotometric measurements

System	Conditions				
	$[Al]_0/10^{-4}$ m	$[L]_0/10^{-4}$ m	pH	λ [nm] for calculation	Cell length [cm]
3H4P	–	6.00	0.30–2.90	215; 245; 322; 346	0.1
4H3P	–	6.61	0.23–1.80	226; 248; 283	0.1
Al + 4H3P	0.806	1.16	1.10–3.60	245; 262; 290	1

from the stoichiometric concentration of HCl,[53] because the changes in $[H^+]$ produced by the other species were always negligible under the chosen conditions. The pK_a for the equilibrium $H_3L^+ \leftrightarrows H_2L + H^+$ (for both ligands) and the log β for the equilibrium $H_2L + Al^{3+} \leftrightarrows AlLH^{2+} + H^+$ (for 4H3P only) were computed using a described method.[24,47]

^{1}H NMR Spectroscopic Measurements: Spectra were obtained in D_2O for solutions containing only the ligand (0.0041 m in the case of 3H4P and 0.050 m in the case of 4H3P) and for solutions also containing aluminium (0.010 m and 0.0012 m, respectively, with the same ligand concentration as before) at various pH values, in the presence of (Na)Cl 0.6 m. The pH was adjusted with small additions of concentrated HCl or NaOH solutions (prepared in D_2O), and was measured with a glass electrode BDH 309/1025/02 previously calibrated in aqueous solutions containing (Na)Cl 0.6 m and known concentrations of HCl. 0.41 pH units were added to the pH-meter readings to correct for isotopic and solvent effects,[54] i.e. "pD" rather than "pH" values were measured.

***n*-Octanol/Water Distribution and Chelation Efficacy Studies**

Materials: NaCl, KCl, $NaHCO_3$, H_3BO_3 and *n*-octanol were obtained from EM, Fisher, or Sigma; Al borate from Pfaltz and Bauer (Waterbury, CT) and an Al atomic absorption standard from Sigma. Polypropylene test tubes (10 mL) with polyethylene caps were purchased from VWR.

Method: The octanol/water distribution of the ligands (3H4P, 4H3P, 2H3P and 3H2P), their ability to solubilise Al as an indicator of chelation potential, and the octanol/water distribution of the aluminium–ligand complex were assessed in an octanol/aqueous system, as described previously;[26] 4 mL of *n*-octanol and 4 mL of an aqueous buffer were added to 10-mL test tubes. The tubes also contained Al borate, ligand or Al borate + ligand. Al borate (7–8 mg) was added as a source of Al, which is quite insoluble, but not kinetically inert. The ligand was introduced in the aqueous phase at $1 \cdot 10^{-3}$ M. The aqueous phase contained 125 mM NaCl, 25 mM $NaHCO_3$, 5 mM KCl and 100 mM H_3BO_3 at pH = 7.4. The tubes were shaken overnight at room temperature in order to achieve equilibrium. Al was quantitated in the aqueous and octanol phases of tubes that contained Al borate, using a Perkin–Elmer 4100 ZL atomic absorption spectrophotometer, S-70 sampler and DEC workstation. All samples were analysed at least twice at λ = 309.3 nm. The concentration of the ligand, both in the presence and absence of Al borate, was determined in the aqueous and octanol phases using a Shimadzu UV2501PC recording spectrophotometer. Samples were compared, at the isosbestic point of absorbance of the ligand (λ = 306.0, 298.3, 257.0 and 305.4 nm for 3H4P, 4H3P, 2H3P and 3H2P, respectively), to aqueous standards containing the ligand in the absence of Al borate. The amount of Al in each phase in the absence of ligand was subtracted from the amount of Al in the presence of ligand, as a measure of the Al solubilised by the chelator. Since 1:3 complexes form for all compounds (see thermodynamic results above and ref.[24]), the efficiency of the test compound to solubilise (chelate) Al was calculated as threefold the sum of the increase in Al (in mol) in the two phases in the presence of ligand, divided by the molar concentration of the ligand introduced into the aqueous phase ($1 \cdot 10^{-3}$ M). The octanol/water distribution of each ligand was determined from its concentration in the octanol/aqueous phase (in the absence of Al borate). The octanol/water distribution of the Al–ligand complex was calculated from the total ligand concentration in each phase (determined by UV spectrophotometry in the presence of Al borate) minus the calculated free ligand concentration, as described.[55] The total free ligand concentration was calculated from (1-% efficiency/100) × the total chelator concentration. The free ligand concentration in each phase was calculated from the octanol/water distribution of the ligand. The results are the mean of three or four independent experiments containing duplicate observations for each aluminium–ligand system.

Acknowledgments

We would like to thank Professor Gianfranco Chiarelotto for helpful suggestions for the synthesis, the graduate students Alessandro Gnocchi, Angela M. Peagler and Maria Rosa Trestin for their careful work, and Chelab S. r. l. (Resana, Treviso, Italy) for the ICP analysis.

(Tetramethylcyclobutadiene)cobalt Complexes − Syntheses of Tris(ligand) Derivatives and Structures of $[(C_4Me_4)Co(CO)_3]BF_4$ and $[(C_4Me_4)Co(NCMe)_3]PF_6$

Mikhail V. Butovskii,[a] Ulli Englert,[a] Alexei A. Fil'chikov,[b] Gerhard E. Herberich,*[a] Ulrich Koelle,[a] and Alexander R. Kudinov*[b]

Keywords: Cobalt / Cyclobutadiene complexes / Metallo-electrophiles

Photolysis of $[Cb^*Co(C_6H_6)]PF_6$ (**6**) ($Cb^* = C_4Me_4$) in acetonitrile solution produces the red solvento complex $[Cb^*Co(NCMe)_3]PF_6$ (**8**) in quantitative yield. Alternatively, heating of the acetonitrile solution to reflux temperature may effect the displacement of the benzene ligand. Photolysis of **6** in liquid ammonia gives $[Cb^*Co(NH_3)_3]PF_6$ (**9**). Compound **8** is substitution-labile and reacts with a wide variety of Lewis bases to produce substitution products $[Cb^*CoL_3]PF_6$ with L = $P(OMe)_3$ (**10**), py (**11**), CN*t*Bu (**12**), and the related compound $(NEt_4)_2[Cb^*Co(CN)_3]$ (**13**). Thermal reaction of $[Cb^*Co(CO)_3]BF_4$ (**7**) with PMe_3 takes place spontaneously at ambient temperature and produces the monosubstitution product $[Cb^*Co(CO)_2(PMe_3)]BF_4$ (**14**), while irradiation combined with a purging stream of N_2 effects an exhaustive decarbonylation and affords $[Cb^*Co(PMe_3)_3]BF_4$ (**16**). Irradiation of **7** in acetonitrile produces mixtures of the mono- and disubstitution products; if a purging stream of N_2 is applied, $[Cb^*Co(CO)(NCMe)_2]BF_4$ (**18**) is formed with a small admixture of $[Cb^*Co(NCMe)_3]BF_4$. The iodide $Cb^*CoI(CO)_2$ reacts with 2,2′-bipyridine to produce the monocarbonyl complex $[Cb^*Co(CO)(bipy)]I$ (**15**). Single-crystal structure determinations of $[Cb^*Co(CO)_3]BF_4$ (**7**) with Co–Cb(ring plane) 1.777(2) Å (av.) and of $[Cb^*Co(NCMe)_3]PF_6$ (**8**) with Co–Cb(ring plane) 1.68(1) Å (av.) are reported. Synthetic procedures for the preparation of $[Cb^*Co(CO)_3]BF_4$ (**7**), $Cb^*CoI(CO)_2$ (**2**), and $[Cb^*Co(C_6H_6)]PF_6$ (**6**) are also given. An electrochemical study of the compounds **8**, **10**–**13**, and **16** reveals chemically fully reversible oxidation reactions. Hard σ-donor ligands (CN^-, py, NCMe) stabilize the corresponding 17e species much more so than soft donor ligands [PMe_3, CN*t*Bu, and $P(OMe)_3$].

Introduction

Electrophilic complex fragments or metallo-electrophiles of the general type $[L_xM(solv)_y]^{n+}$ are useful synthons in organometallic chemistry. Our interest in metallo-electrophiles developed during our quest for new triple-decker complexes.[1,2] Early examples of metallo-electrophiles are the 1,5-cyclooctadiene complex $[(COD)Rh(THF)_x]^+$ [3] and the cation $[Cp^*Rh(OCMe_2)_3]^{2+}$.[4] These species are usually generated from corresponding chlorides by dehalogenation with Ag^+ or Tl^+ salts with nonbasic anions such as BF_4^-, PF_6^-, or $CF_3SO_3^-$. Weakly coordinating solvents such as nitromethane, dichloromethane, THF, acetone, or acetonitrile are used in the generation of the metallo-electrophiles to provide a maximum reactivity and a minimal stabilization. The number of coordinated solvent units is often unknown, especially in the cases of the most weakly bonded solvent molecules. On the other hand, the acetonitrile ligand provides sufficient stabilization to the electrophilic metal center to allow the isolation of less reactive, but well-defined compounds. The species $[CpFe(NCMe)_3]^+$,[5,6] $[Cp^*Fe(NCMe)_3]^+$,[7] $[CpRu(NCMe)_3]^+$,[6,8] $[Cp^*Ru(NCMe)_3]^+$,[9] and $[CpOs(NCMe)_3]^+$ [10] are pertinent examples, and the more recently discovered species $[Cb^*Co(solv)_x]^+$ ($Cb^* = C_4Me_4$, solv = inter alia MeCN)[11] is related to these by virtue of the isolobal analogy.

Complex fragments of the (cyclobutadiene)cobalt type are well known in complexes with Cp counterligands, e.g. Cb^*CoCp,[12] or $(C_4Ph_4)CoCp$,[13] whereas comparatively little is known about (cyclobutadiene)cobalt complexes with counterligands other than Cp. There are several general reviews on (cyclobutadiene)metal complexes,[14] and also specialized reviews that center on the chemistry of (cyclobutadiene)cobalt complexes.[15]

In pioneering work Pauson et al.[16] have shown that the zwitterionic cyclobutenyl species $Me_4C_4AlCl_3$ [17] readily re-

acts with $Co_2(CO)_8$ to form the cation $[Cb^*Co(CO)_3]^+$ ($\mathbf{1}^+$). On this basis they developed syntheses of $Cb^*Co-I(CO)_2$ (**2**), and $[Cb^*Co(C_6H_6)]^+$ ($\mathbf{3}^+$). The goal of the present work is the further development of the chemistry of the (tetramethylcyclobutadiene)cobalt complex fragment and especially of the new metallo-electrophile $[Cb^*Co(NCMe)_3]^+$ ($\mathbf{4}^+$). We also present the first structural characterizations of tris(ligand) species $[Cb^*CoL_3]^+$ with L = CO and MeCN.

$\mathbf{4}^+$

Results and Discussion

Starting Materials

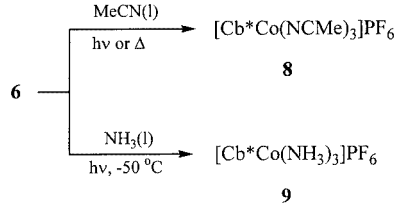
In the work of Pauson et al.[16] the salt $[Cb^*Co(CO)_3]PF_6$ (**5**) was isolated from the reaction of $Me_4C_4AlCl_3$ [17] and $Co_2(CO)_8$. In a second step, this salt was treated with Me_3NO/Bu_4NI in dichloromethane or with K_2CO_3/Bu_4NI in dichloromethane to afford the iodide **2**. In a further transformation the iodide **2** was heated with $AlCl_3$ in benzene, and the resulting cation $\mathbf{3}^+$ was isolated as hexafluorophosphate **6** [≡ (**3**)PF_6].[16]

In part of our work we used the tetrafluoroborate **7** [≡ (**1**)BF_4] which was synthesized by a straightforward adaptation of the published synthesis of the hexafluorophosphate **5**. The iodide **2** was prepared by a simplified procedure that combines the two steps of the original work into a single protocol. After hydrolysis of the primary reaction mixture, Me_3NO and NaI were added to the raw aqueous solution containing $\mathbf{1}^+$, producing the uncharged iodide **2** as a brown precipitate. This procedure gave a somewhat lower yield (37%; ref.[16] 45−52%), but requires less work.

When we repeated the synthesis of the benzene complex **6**, we found that some tricarbonyl cation $\mathbf{1}^+$ was also formed as was readily seen from the product IR spectrum or from ^{1}H NMR spectra in nitromethane or dichloromethane solution. It is recommendable to use a tenfold excess of $AlCl_3$, to add petroleum ether (octane fraction, 60% by volume), and to run the reaction at ca. 130 °C. Under these conditions the CO formed is removed more efficiently from the reaction mixture, and the formation of $\mathbf{1}^+$ is largely suppressed. The by-product may also be removed during workup of the reaction mixture, by adding a little Me_3NO and NaI to the aqueous solution. The yield of **6** varies somewhat erratically between 50 and 80% (ref.[16] 25%), presumably because traces of water seem to be favorable while larger amounts of water are detrimental.

Photolysis of $[Cb^*Co(C_6H_6)]PF_6$ (6) and Alternative Thermal Ligand Displacement

The sandwich cation $\mathbf{3}^+$ is rather light-sensitive, and solutions of **6** can be photolyzed with any light source at hand (cf. Exp. Sect.). In this context the most useful solvent is acetonitrile. During irradiation, the color changes from yellow to red, and subsequent removal of the volatiles affords the product $[Cb^*Co(NCMe)_3]PF_6$ (**8**) as red crystalline solid in quantitative yield. When acetonitrile solutions of **6** are heated, the benzene ligand is displaced almost completely. This thermal ligand displacement reaction may be forced to go to completion if the volatiles are largely pumped off and the reaction mixture is heated once more in fresh solvent (Scheme 1). The number of acetonitrile units in **8** was determined by elemental analysis and from the relative intensities of the ^{1}H NMR spectrum in [D_6]acetone; these were found to be 8.95:12 for the methyl signals of acetonitrile and Cb*, respectively. It was also finally confirmed by a single-crystal structure analysis (see below). The new compound **8** is sensitive to air, especially in solution. It undergoes slow oxidation by CH_2Cl_2 that is seen as a fast deterioration in the NMR spectra performed in the same solvent.



Scheme 1. Substitution reactions of $[Cb^*Co(C_6H_6)]PF_6$ (**6**)

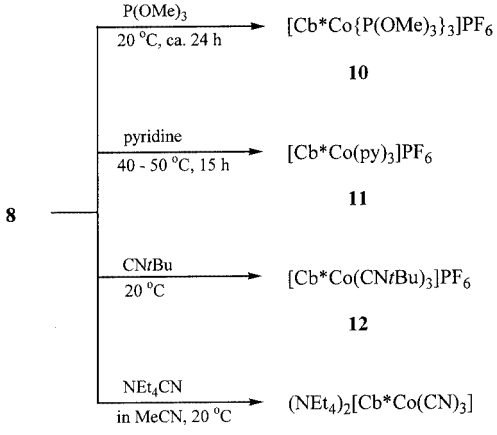
^{1}H NMR spectra of **8** in [D_3]acetonitrile, measured at 200 MHz and at ambient temperature, show a single signal for the methyl groups of acetonitrile. An ^{1}H NMR spectrum in [D_6]acetone/[D_3]acetonitrile mixtures (with comparable quantities of free and coordinated acetonitrile), taken at 500 MHz, showed line-broadening at ambient temperature, decoalescence at −10 °C, and below two signals corresponding to a low-temperature exchange regime; at −84 °C, these two signals were sharp with chemical shifts of δ = 2.50 ppm for coordinated acetonitrile and of δ = 2.12 ppm for free acetonitrile.

The photolysis of **6** works equally well in liquid ammonia and affords the red crystalline salt $[Cb^*Co(NH_3)_3]PF_6$ (**9**). The crystals of **9** are sensitive to air and humidity and smell of ammonia; they melt at about 170 °C, apparently without

decomposition. NMR spectra could be recorded in [D_6]acetone that was charged with gaseous NH_3.

Ligand Substitution Reactions of [Cb*Co(NCMe)$_3$]PF$_6$ (8)

Complex **8** readily undergoes ligand substitution reactions with a wide variety of neutral and anionic reagents. The in situ reaction with the carbaborane anion [9-(Me_2S)-7,8-$C_2B_9H_{10}$]$^-$ to give the metallacarbaborane Cb*Co[9-(Me_2S)-7,8-$C_2B_9H_{10}$] has been described in previous work,[11] and sandwich complexes with bora- and boratabenzene counter-ligands have been made with complex **8** as the starting material.[18] Herein we describe the new compounds **10**−**13** (Scheme 2). In the cases of pyridine and of the phosphorus ligands $P(OMe)_3$ and PMe_3, the third substitution step is slow, and gentle heating may be required to complete the substitution. We treated, for instance, compound **8** with an excess of PMe_3 at only ambient temperature. After removal of the volatiles under vacuum, the solid residue showed a virtual triplet for the protons of the *P*-methyl groups, thereby indicating the presence of two PMe_3 ligands. Similarly, treatment of **8** with excess pyridine at 20 °C for 3 h and subsequent removal of all volatiles left a red solid whose ^{1}H NMR spectroscopic data showed a pyridine/acetonitrile ratio of 2:1. Substitution of the third acetonitrile ligand required prolonged heating at temperatures of 40−50 °C. On the other hand, the slim and strong carbon nucleophiles CN*t*Bu and Et_4NCN readily effected substitution of all three acetonitrile ligands.

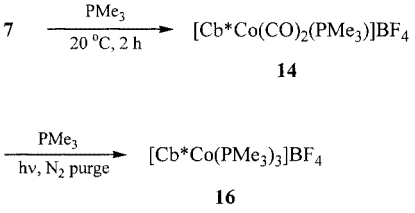


Scheme 2. Thermal ligand substitution reactions of [Cb*Co(NCMe)$_3$]PF$_6$ (**8**)

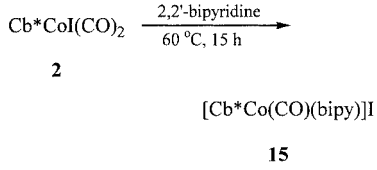
There are some obvious limitations to this method. The ligand to be introduced should either bind strongly to the metal atom or should be less volatile than acetonitrile. For instance, it is not possible to replace acetonitrile with dimethyl sulfide.

Ligand Substitution Reactions of [Cb*Co(CO)$_3$]BF$_4$ (7) and Cb*CoI(CO)$_2$ (2)

The cation **1**$^+$ is prone to thermal ligand substitution reactions. In favorable cases product formation is highly chemoselective. Thus, the tetrafluoroborate **7** reacts with trimethylphosphane in dichloromethane at ambient temperature with spontaneous evolution of CO to give the monosubstitution product [Cb*Co(CO)$_2$(PMe_3)]BF$_4$ (**14**) in good yield (Scheme 3). In contrast to this simple case, the analogous reaction with the weaker donor ligand $P(OMe)_3$ showed little selectivity. When **7** was treated with $P(OMe)_3$ in [D_6]-acetone, warming to 40−50 °C was required to effect the reaction, and in ^{1}H NMR spectra signals of the mono- and the disubstitution product were observed besides those of the starting material. Thermal substitution of **1**$^+$ with 2,2′-bipyridine (bipy), at somewhat elevated temperatures, produced the cation [Cb*Co(CO)(bipy)]$^+$; the same cation can be obtained more conveniently from the reaction of the iodide **2** to give the iodide [Cb*Co(CO)(bipy)]I (**15**) (Scheme 4).



Scheme 3. Trimethylphosphane derivatives of [Cb*Co(CO)$_3$]BF$_4$ (**7**)



Scheme 4. An ionic 2,2′-bipyridine derivative of Cb*CoI(CO)$_2$ (**2**)

Photochemically induced ligand substitution reactions provide a synthetic alternative. Irradiation of **7** in CH_2Cl_2 in the presence of PMe_3 or $P(OMe)_3$ effects the stepwise replacement of one, two and, much more slowly, even of all three carbonyl groups. For practical purposes it is necessary to purge the reaction mixture with a slow stream of dinitrogen. We used this method to produce the salt [Cb*Co(PMe_3)$_3$]BF$_4$ (**16**) by exhaustive decarbonylation (Scheme 3). The closely related trimethyl phosphite compound **10** can be prepared analogously; however, the synthesis from **8** described above seems more convenient.

We were especially interested in the replacement of the CO ligands of cation **1**$^+$ with acetonitrile. The first substitution step has already been described by Pauson et al.[16] to give the red salt [Cb*Co(CO)$_2$(NCMe)]BF$_4$ (**17**). Irradiation of an acetonitrile solution of **7** effects a slow second substitution and affords mixtures of **17** and the disubstitution product [Cb*Co(CO)(NCMe)$_2$]BF$_4$ (**18**). If a slow stream of dinitrogen purges the reaction mixture, the rates of these reactions are greatly increased. After a few hours, complex **17** is completely consumed, but the monocarbonyl complex **18** is now contaminated by an admixture of the

tris(acetonitrile) complex $[Cb^*Co(NCMe)_3]BF_4$ (**19**) (typically 10%). The monocarbonyl complex **18** is highly reactive and rather sensitive to traces of air and humidity.

Structure Determinations

To the best of our knowledge no tris(ligand) complex of the Cb*Co fragment has yet been structurally characterized. Therefore, the structure of **7** was elucidated. Crystallization from acetone/THF gave small light-yellow crystals that turned out to be systematically twinned platelets. This situation is expected to limit the quality of the final structural model. The crystals possess the monoclinic space group $P2_1/m$ with two very similar independent formula units in the elemental cell. Both cations and anions display crystallographic mirror symmetry. One of the cations (cation 1, all labels beginning with a leading 1) is shown in Figure 1.

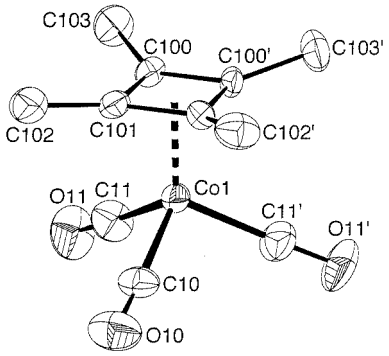


Figure 1. Structure of one of two independent cations $\mathbf{1}^+$ (PLATON plot, see ref.[19] at the 50% probability level) in the crystal of **7**; selected bond lengths [Å]: Co1−C10 1.826(13), Co1−C11/Co1−C11′ 1.852(10), Co1−C100/Co1−C100′ 2.061(8), Co1−C101/Co1−C101′ 2.048(8), Co2−C22 1.739(13), Co2−C21/Co2−C21′ 1.817(10), Co2−C200/Co2−C200′ 2.029(8), Co2−C201/Co2−C201′ 2.061(8)

The cation $\mathbf{1}^+$ possesses the expected piano-stool structure. The planes defined by the cyclobutadiene carbon atoms (plane C_4), the carbonyl carbon atoms (plane C_3), and the carbonyl oxygen atoms (plane O_3) are roughly parallel [largest deviation 3.8(6)° between the two carbon planes C_4 and C_3 of cation 1]. The metal-to-ring distance amounts to 1.769(2) for cation 1 and 1.785(2) Å for cation 2, and is remarkably long. In the family of CoCbCp complexes this distance ranges from 1.68 to 1.70 Å,[20a] and is 1.681 Å for the parent complex CoCbCp[20b] and 1.692 Å for $Co(C_4Ph_4)Cp$.[20a] With reference to the general bonding characteristics of (cyclobutadiene)metal complexes such as $Fe(CO)_3(C_4H_4)$,[21] we expect that the lower energy of the 2e valence orbital set of the $Co(CO)_3^+$ fragment, as compared to that of the uncharged CoCp fragment, results in an e MO set of more metal character and hence weaker Co−Cb bonding in the cation $\mathbf{1}^+$.

Crystals of **8**, that were suitable for a structural study, were obtained by crystallization of **8** from an acetonitrile/ether mixture. The structure determination of **8** (Figure 2) was hampered by disorder of the cyclobutadiene rings. In the final structural model this disorder is largely resolved showing two dispositions of the rings with almost equal (0.52 and 0.48) occupancies. The best ring planes C_4 (with the atoms C1, C2, C3, C4) and C_4B (with C1B, C2B, C3B, C4B; not shown in Figure 2) of the minor orientation display an interplanar angle of 6.8(16)°. The metal-to-ring distance amounts to 1.680(10) for the major disposition and to 1.670(10) Å for the minor disposition. In this case the weak π-acceptor property of the acetonitrile ligands allows for a much stronger Co−Cb interaction as compared to **7**.

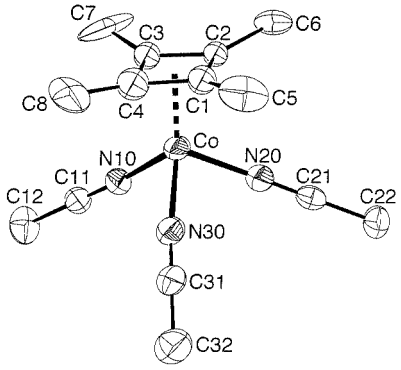

Figure 2. Structure of the major disposition of cation $\mathbf{4}^+$ (PLATON plot, see ref.[19] at the 30% probability level) in the crystal of **8**; for details of the disorder problem see text; selected bond lengths [Å]: Co−N10 1.943(6), Co−N20 1.951(7), Co−N30 1.957(7), Co−C1 1.95(4), Co−C2 2.043(12), Co−C3 1.989(13), Co−C(4) 1.856(19); the positional coordinates of C1 are most severely affected by the disorder of the Cb* ring

Electrochemical Studies

The redox behaviour of the complexes **8**, **10**−**13**, and **16** was studied by cyclic voltammetry. All these complexes show a chemically fully reversible oxidation. No reduction was found down to the solvent/electrolyte limit at about −2 V. Table 1 lists the electrochemical data obtained, with the compounds arranged in order of increasing oxidation potential. The data show that hard donor ligands tend to ease oxidation; in other words, hard donor ligands stabilize the $CbCo^{2+}$ fragment more than the soft donors PMe_3, CN*t*Bu, and $P(OMe)_3$. The 17e acetonitrile cation $\mathbf{4}^{2+}$ shows a second irreversible oxidation at about 0.8 V. The 17e monoanion $[Cb^*Co(CN)_3]^-$, derived from monoelectronic oxidation of **13**, is not further oxidized up to about 0.4 V, i.e. it exhibits a stability window of at least 1 V. The dianion of **13** is highly air-sensitive. However, the green air oxidation product seems to be different from the electrochemical oxidation product since it cannot be re-reduced electrochemically. Further investigation of the cyano compounds would seem desirable and rewarding.

The redox behaviour classifies the Cb^*Co^+ fragment as a relatively hard organometallic metallo-electrophile, similar to $CpFe^+$. This feature is illustrated by the fact that complexes $[Cb^*CoL_3]^{n+}$ could be prepared with ligands of predominant σ-donor character as well as with π-acceptor ligands. However, in both cases of Cb^*Co^+ and $CpFe^+$,

Table 1. Cyclovoltammetric data for **8**, **10**−**13**, and **16**

Electroactive species	Solvent	$E_{1/2}$/V vs. SCE	ΔE/mV	v/mV s^{-1}
$[Cb^*Co(CN)_3]^{2-}$ in **13**	acetonitrile	−0.616	146	50
$[Cb^*Co(py)_3]^+$ in **11**	acetonitrile	0.155	80	100
$[Cb^*Co(NCMe)_3]^+$ in **8**	acetonitrile	0.23	77	50
$[Cb^*Co(PMe_3)_3]^+$ in **16**	CH_2Cl_2	0.70	65	100
$[Cb^*Co(CNtBu)_3]^+$ in **12**	CH_2Cl_2	0.97	94	100
$[Cb^*Co\{P(OMe)_3\}_3]^+$ in **10**	CH_2Cl_2	1.02	74	100

ligands placed to the left of ammonia and acetonitrile in the spectrochemical series, such as water, lead to decomplexation of the carbocyclic ligand.

Conclusions

This paper documents an improved access to the (tetramethylcyclobutadiene)cobalt complexes $Cb^*CoI(CO)_2$ (**2**) and $[Cb^*Co(C_6H_6)]^+$ ($\mathbf{3}^+$) (as hexafluorophosphate **6**) which may serve as versatile starting materials in this chemistry. Photolysis of the salt **6** in solution produces synthetically useful, reactive metallo-electrophiles of the type $[Cb^*Co(solv)_x]^+$. The generation of a very reactive species of this type in dichloromethane allowed the synthesis of triple-decker sandwich complexes with a bridging cyclopentadienyl ligand.[22] One main aim of this paper was the full characterization of the cation $[Cb^*Co(NCMe)_3]^+$ ($\mathbf{4}^+$). This species is not only prepared from $\mathbf{3}^+$ by the photolytic method, but also by thermal ligand displacement in acetonitrile solution. With the improved accessibility of Cb*Co complexes achieved in this work the metallo-electrophiles $[Cb^*Co(solv)_x]^+$ should from now on belong to the standard armory of the synthetic organometallic chemist.

Experimental Section

General Remarks: Reactions were carried out under dinitrogen by means of conventional Schlenk techniques. THF and Et_2O were distilled from sodium benzophenone ketyl, acetonitrile and CH_2Cl_2 from CaH_2. A 400-W Philips sodium lamp SON-T or the pyrex-filtered output of a 150-W mercury lamp were used in photolytic reactions. Elemental analyses were performed by Analytische Laboratorien Prof. Dr. H. Malissa und G. Reuter GmbH, 51789 Lindlar, Germany. Melting points were determined with a Büchi 510 melting point apparatus and are uncorrected. NMR spectra were recorded with a Varian 200 (^{1}H, 200 MHz. $^{13}C\{^1H\}$, 50.29 MHz. $^{31}P\{^1H\}$, 80.96 MHz) or, in special cases, with a Varian Unity 500 (^{1}H, 499.6 MHz. ^{13}C, 125.6 MHz) instrument. Chemical shifts are given in ppm; they were measured at ambient temperature and are referenced to internal TMS for ^{1}H and ^{13}C, and relative to H_3PO_4 (85%) as external reference for ^{31}P. IR spectra were measured with a Nicolet Avatar 360 FT IR instrument.

$[Cb^*Co(CO)_3]BF_4$ (7): A suspension of anhydrous aluminium chloride (16.5 g, 124 mmol) in CH_2Cl_2 (40 mL) was cooled to 0 °C. A solution of 2-butyne (8.93 mL, 114 mmol) in dichloromethane (25 mL) was added dropwise while stirring for 30 min. After addition of more CH_2Cl_2 (35 mL), the mixture was allowed to warm to 20 °C and stirred for 1 h at 20 °C. Octacarbonyldicobalt (9.78 g, 28.6 mmol) was then added and stirring was continued for 80 h. The reaction mixture was hydrolyzed with cold water at 0 °C. The organic phase was removed and the water phase was filtered. $NaBF_4$ (8.0 g, 73 mmol) was added and the mixture was cooled to 0 °C overnight. The precipitate was collected and dried under vacuum. The raw product was dissolved in acetone, and the solution was passed through a 2-cm layer of alumina. Concentration of the filtrate and addition of ether gave **7** (6.67 g, 19.7 mmol, 35%) as a pale yellow powder. $C_{11}H_{12}CoF_4O_3$ (338.0): calcd. C 39.09, H 3.58; found C 39.09, H 3.60. $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ = 9.9 ($C_4\mathit{Me}_4$), 106.6 (C_4Me_4), 197.8 (br, CO) ppm.

$Cb^*CoI(CO)_2$ (2): To the aqueous solution from a similar preparation [$AlCl_3$ (10.6 g, 80 mmol) in CH_2Cl_2 (40 mL), 2-butyne (5.74 mL, 73.5 mmol) in CH_2Cl_2 (25 mL), $Co_2(CO)_8$ (6.29 g, 18.4 mmol)] were added trimethylamine *N*-oxide $Me_3NO{\cdot}2H_2O$ (1.99 g, 17.9 mmol) and NaI (18 g, 0.12 mol). The mixture was stirred for 15 h. The brown precipitate that formed was collected and dried under vacuum; the filtrate did not form any more product when further Me_3NO was added. The raw product was dissolved in CH_2Cl_2, and the solution was passed through a 4-cm layer of alumina. After concentration of the filtrate and addition of a sixfold volume of octane, the solution was kept at −30 °C for 15 h to give **2** (4.79 g, 37%) as dark brown crystals. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 10.2 ($C_4\mathit{Me}_4$), 94.2 (C_4Me_4) ppm; signals of CO groups not observed. For further data see ref.[16]

$[Cb^*Co(C_6H_6)]PF_6$ (6): A round-bottomed flask was charged with benzene (20 mL), octane (30 mL), iodide **2** (3.5 g, 10 mmol), and anhydrous aluminium chloride (13.4 g, 100 mmol). The mixture was stirred and heated under reflux at ca.130 °C for 8 h. After cooling to 20 °C, the reaction mixture was carefully hydrolyzed with ca. 100 mL of cold water. The organic phase was separated and the water phase was filtered. Addition of NH_4PF_6 (1.63 g, 10 mmol) to the filtrate gave a yellow precipitate. For further purification, the solution of the dry raw product was passed through a 2-cm layer of alumina. Concentration of the filtrate and addition of a large volume of ether gave **6** (2.44 g, 63%) as a pale yellow powder. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 10.1 ($C_4\mathit{Me}_4$), 94.7 (C_4Me_4), 99.8 (C_6H_6) ppm. For further data see ref.[16]

$[Cb^*Co(NCMe)_3]PF_6$ (8). By Photochemical Synthesis: A solution of **6** (390 mg, 1.00 mmol) in acetonitrile (20 mL) was irradiated with a sodium lamp at ambient temperature for 2 h. The color of the solution changed from yellow to red. Removal of the solvent under vacuum afforded **8** (434 mg, 100%) as an air-sensitive, red crystalline solid; m.p. 175 °C (dec.). $C_{14}H_{21}CoF_6N_3P$ (435.2): calcd. C 38.63, H 4.86, N 9.65; found C 38.51, H 4.83, N 9.66. **By Thermal Ligand Displacement:** A solution of **6** (392 mg, 1.00 mmol) in acetonitrile (20 mL) was heated to reflux temperature for 2.5 h. After removal of the volatiles, fresh acetonitrile (20 mL) was added, and the solution was re-heated for 1 h. The volatiles were pumped

off to leave **8** (436 mg, 100%) as spectroscopically pure (^{1}H NMR) product. **Data:** ^{1}H NMR ([D$_6$]acetone): δ = 0.91 (s, Cb*), 2.41 (s, 3 Me) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 2.9 (*Me*CN), 8.9 (C$_4$*Me*$_4$), 74.8 (*C*$_4$Me$_4$), 124.6 (CN) ppm.

[Cb*Co(NH$_3$)$_3$]PF$_6$ (9): A Schlenk tube with a suspension of complex **6** (195 mg, 0.5 mmol) in liquid ammonia (20 mL) was irradiated with a sodium lamp, while the reaction mixture was stirred at −50 °C. The color of the reaction mixture changed to red and finally, when all the starting material had dissolved, it was a transparent solution (5−7 h). The ammonia was removed by allowing the system to slowly warm to ambient temperature, thus affording **9** (180 mg, 99%) as an air-sensitive, red crystalline solid; m.p. 170 °C, dec. 240 °C. $C_8H_{21}CoF_6N_3P$ (363.2): calcd. C 26.46, H 5.83, N 11.57; found C 26.41, H 5.67, N 11.37. ^{1}H NMR ([D$_6$]acetone, saturated with NH$_3$): δ = 0.84 (s, Cb*), 1.44 (s, 3 NH$_3$) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone, saturated with NH$_3$): δ = 8.9 (C$_4$*Me*$_4$), 61.7 (*C*$_4$Me$_4$).

[Cb*Co{P(OMe)$_3$}$_3$]PF$_6$ (10): Trimethyl phosphite (3 mL, 27 mmol) was added to the tris(acetonitrile) complex **8** (434 mg, 1 mmol) in acetonitrile (10 mL). The mixture was stirred at room temperature overnight. The solution was then concentrated in a gentle vacuum to ca. 3 mL, and stirring was continued for 24 h. Addition of ether (20 mL) precipitated a crystalline powder, which was collected on a frit, washed with ether (20 mL), and dried under vacuum to give **7** (680 mg, 100%) as a yellow powder; dec. 210−230 °C. $C_{17}H_{39}CoF_6O_9P_4$ (684.3): calcd. C 29.84, H 5.74; found C 29.81, H 5.83. ^{1}H NMR ([D$_6$]acetone): δ = 1.51 (q, J_{PH} = 5.4 Hz, Cb*), 3.80 [m, 3 P(OMe)$_3$] ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 9.4 [q, not well resolved, J_{PC} = 1.4 Hz, C$_4$*Me*$_4$), 53.8 [vq, J_{PC} = 2.7 Hz, P(OMe)$_3$], 86.6 [q, not well resolved, J_{PC} = 2 Hz, *C*$_4$Me$_4$] ppm. ^{31}P{^{1}H} NMR ([D$_6$]acetone): δ = −140.8 (sept, PF_6^-), 163.0 [s, P(OMe)$_3$] ppm.

[Cb*Co(py)$_3$]PF$_6$ (11): A solution of **8** (434 mg, 1 mmol) in pyridine (10 mL) was stirred at 40−50 °C overnight. The solution was then concentrated to 2−3 mL under vacuum at the same temperature. Addition of ether precipitated **11** in large crystal blocks, which were washed with ether (40 mL), and dried under vacuum to afford **11** (547 mg, 100%) as a dark red, crystalline solid; dec. 90 °C, very air-sensitive. Sharp NMR spectra could only be recorded when a trace of [D$_5$]pyridine was added. $C_{23}H_{27}CoF_6N_3P$ (549.4): calcd. C 50.28, H 4.95, N 7.65; found C 49.83, H 5.08, N 7.55. ^{1}H NMR ([D$_6$]acetone with a drop of [D$_5$]pyridine): δ = 0.62 (s, Cb*), 7.41 (m, 6 H$_\beta$), 7.76 (tt, 3 H$_\gamma$), 8.79 (d, 6 H$_\alpha$) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone with a drop of [D$_5$]pyridine): δ = 8.8 (C$_4$*Me*$_4$), 70.4 (*C*$_4$Me$_4$), 125.0 (C$_\beta$), 136.0 (C$_\gamma$), 150.6 (C$_\alpha$) ppm.

[Cb*Co(CN*t*Bu)$_3$]PF$_6$ (12): Preparation similar to that of **10**; with *tert*-butyl isocyanide (1.0 mL, 9 mmol) the reaction was completed in 2 h and gave **12** (560 mg, 100%) as a yellow crystalline solid; m.p. 178 °C, dec. 192 °C. $C_{23}H_{39}CoF_6N_3P$ (561.5): calcd. C 49.20, H 7.00, N 7.48; found C 49.31, H 7.14, N 7.48. ^{1}H NMR ([D$_6$]acetone): δ = 1.56 (s, 3 *t*Bu), 1.57 (s, Cb*) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 9.6 (C$_4$*Me*$_4$), 30.0 (C*Me*$_3$), 58.5 (*C*Me$_3$), 87.1 (*C*$_4$Me$_4$), 155.8 (CN) ppm. IR (MeCN): $\tilde{\nu}$ = 2140, 2174 [ν(CN)] cm^{-1}.

(NEt$_4$)$_2$[Cb*Co(CN)$_3$] (13): A solution of **8** (515 mg, 1.18 mmol) in acetonitrile (20 mL) was added to a stirred solution of Et$_4$NCN (555 mg, 3.55 mmol) in acetonitrile (15 mL). The yellow color of the mixture indicates completion of the reaction immediately after mixing. The solvent was removed under vacuum to afford a brownish yellow crystalline material. The product was separated from Et$_4$NPF$_6$ by two recrystallizations from MeCN (0.5 mL)/dry acetone (10 mL), keeping the solution at −30 °C for 18 h, to give **13** (518 mg, 87%) as a spectroscopically pure, brownish-yellow, crystalline solid; m.p. 187 °C, dec. 194 °C, very air-sensitive. $C_{27}H_{52}CoN_5$ (505.7): calcd. C 64.13, H 10.37, N 13.85; found C 63.6, H 10.0, N 14.1 (average of two determinations). ^{1}H NMR (CD$_3$CN): δ = 1.23 [tt, ^3J(^{1}H-^{1}H) = 7.3, ^3J(^{14}N-^{1}H) = 1.9 Hz, 8 Me], 1.27 (s, Cb*), 3.27 [q, br, ^3J(^{1}H-^{1}H) = 7.3 Hz, 8 CH$_2$N] ppm. ^{13}C{^{1}H} NMR (CD$_3$CN): δ = 7.8 (*C*H$_3$CH$_2$N), 10.9 (C$_4$*Me*$_4$), 53.0 [t, ^1J(^{14}N-^{13}C) = 3.0 Hz, CH$_2$N], 71.0 (*C*$_4$Me$_4$), 165.1 (CN) ppm.

[Cb*Co(CO)$_2$(PMe$_3$)]BF$_4$ (14): A solution of PMe$_3$ in CH$_2$Cl$_2$ (1 M, 20 mL, 20 mmol) was added to **5** (342 mg, 1.01 mmol), and the mixture was stirred at room temperature until the spontaneous evolution of CO had completely ceased (ca. 2 h). The solution was concentrated in a gentle vacuum to ca. 2−3 mL. Addition of ether (10 mL) precipitated the raw product that was then collected on a frit, washed with ether (20 mL), and dried under vacuum. In a further purification step, the product was dissolved in CH$_2$Cl$_2$, passed through a 0.5-cm layer of alumina, and recovered by addition of ether to give **14** (270 mg, 69%) as a pale yellow, crystalline solid; dec. 245 °C. $C_{13}H_{21}BCoF_4O_2P$ (386.0): calcd. C 40.45, H 5.48; found C 40.68, H 5.42. ^{1}H NMR ([D$_6$]acetone): δ = 1.73 (d, J_{PH} = 10.1 Hz, PMe$_3$), 1.89 (d, J_{PH} = 4.0 Hz, Cb*) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 9.5 (s, C$_4$*Me*$_4$), 17.7 (d, J_{PC} = 31.1 Hz, PMe$_3$), 96.9 (s, *C*$_4$Me$_4$) ppm. ^{31}P{^{1}H} NMR ([D$_6$]acetone): δ = 7.6 ppm. IR (CH$_2$Cl$_2$): $\tilde{\nu}$ = 2025 and 2064 [ν(CO)] cm^{-1}.

[Cb*Co(CO)(bipy)]I (15): A solution of complex **2** (349 mg, 1.00 mmol) and 2,2′-bipyridine (156 mg, 1.00 mmol) in acetonitrile (5 mL) was stirred overnight at 50−60 °C. The product was precipitated by addition of ether (40 mL), washed with ether (40 mL), and dried under vacuum to afford **15** (471 mg, 99%) as a crystalline powder; dec. 130−140 °C. $C_{19}H_{20}CoIN_2O$ (478.2): calcd. C 47.72, H 4.22, N 5.86; found C 47.79, H 4.29, N 6.05. ^{1}H NMR ([D$_6$]acetone): δ = 1.32 (s, Cb*), 7.86 (m, 4-/4′-H), 8.28 (m, 5-/5′-H), 8.81 (m, 6-/6′-H), 9.04 (m, 3-/3′-H) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 9.1 (C$_4$*Me*$_4$), 89.6 (*C*$_4$Me$_4$), 124.3 (C-6,6′), 127.9 (C-4,4′), 139.6 (C-5,5′), 154.8 (C-3,3′), 155.9 (C-2,2′). Assignments within the 2,2′-bipyridine ligand were made on the basis of COSY and HETCOR spectra. IR (KBr): $\tilde{\nu}$ = 1960.3 [ν(CO)] cm^{-1}.

[Cb*Co(PMe$_3$)$_3$]BF$_4$ (16): A solution of PMe$_3$ in CH$_2$Cl$_2$ (1 M, 20 mL, 20 mmol) was added to **14** (180 mg, 0.46 mmol) in a Schlenk tube, equipped with a capillary as a gas outlet, and irradiated with a mercury lamp at ambient temperature. A very slow stream of N$_2$ was passed through the solution for 5 h. Concentration of this solution to 5 mL and addition of diethyl ether (20 mL) afforded the raw product which was collected, washed with ether (20 mL) and dried under vacuum to give **16** (210 mg, 93%) as a deep yellow powder; dec. 150−160 °C. $C_{17}H_{39}BCoF_4P_3$ (540.3): calcd. C 42.35, H 8.15; found C 42.15, H 8.05. ^{1}H NMR ([D$_6$]acetone): δ = 1.48 (q, J_{PH} = 3.1 Hz, Cb*), 1.50 (d, J_{PH} = 7.2 Hz, PMe$_3$) ppm. ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 10.5 (s, C$_4$*Me*$_4$), 21.6 (8 lines between 21.3 and 21.9, PMe$_3$), 78.5 (s, *C*$_4$Me$_4$) ppm. ^{31}P{^{1}H} NMR ([D$_6$]acetone): δ = 7.3.

[Cb*Co(CO)(NCMe)$_2$]BF$_4$ (18): A sample of **7** (338 mg, 1.00 mmol) in a Schlenk tube, equipped with a capillary as a gas outlet, was dissolved in acetonitrile (20 mL). The solution was photolyzed while N$_2$ was passed through the solution for 8 h. Product formation was monitored by ^{1}H NMR spectroscopy in CD$_3$NO$_2$ on samples taken from the reaction mixture. The acetonitrile was removed completely under vacuum. The residue was dissolved in CH$_2$Cl$_2$, and the product was precipitated with ether and dried under vacuum; yield not determined. $C_{13}H_{18}BCoF_4N_2O$ (364.0): calcd. C 42.89, H 4.98 N 7.70; found C 43.01, H 5.13, N 6.54. ^{1}H

NMR ([D$_6$]acetone): δ = 1.33 (s, Cb*), 2.50 (s, 2 Me) ppm. ^{1}H NMR ([D$_6$]MeNO$_2$): δ = 1.33 (s, Cb*), 2.39 (s, 2 Me) ppm. ^{13}C{^{1}H} NMR ([D$_3$]nitromethane): δ = 3.6 (*Me*CN), 9.2 (C$_4$*Me*$_4$), 92.2 (*C*$_4$Me$_4$), 128.9 (CN), 202.7 (CO) ppm.

X-ray Crystal Structure Determinations:[23] Diffraction intensity data were collected with ENRAF-Nonius CAD4 diffractometers, equipped with graphite monochromators. Crystal data, data collection parameters, and convergence results are listed in Table 2. Numerical absorption corrections[24] were applied before averaging symmetry-equivalent data. The structures were solved by direct methods[25] and refined on F^2.[26] Hydrogen atoms were calculated in standard geometry and treated as riding on the corresponding C atoms. In the case of **7** all crystals tested proved to be twinned. In the diffraction pattern reflections of the type *hkl*, *l* = 0 for both domains coincide, and reflections *hkl*, *l* = 10 show partial overlap and were omitted from the refinement. Despite this modest loss of information, the final completeness of the data set amounts to 0.94. The structure suffers from strongly anisotropic displacement parameters, especially for the methyl substituents on the Cb* rings and the BF_4^- anion; rigid bond[27] restraints and, in the case of the fluorine atoms, additional distance restraints were introduced to ensure a physically reasonable model. The Cb* ligand in **8** shows disorder; C atoms belonging to this moiety were assigned isotropic displacement parameters, and distance restraints were used to ensure a stable refinement of the alternative orientations.

Table 2. Crystal data, data collection parameters, and convergence results for **7** and **8**

	7	**8**
Empirical formula	$C_{11}H_{12}BCoF_4O_3$	$C_{14}H_{21}CoF_6N_3P$

Electrochemical Measurements: The redox behaviour of the complexes **8**, **10**−**13**, and **16** was investigated by cyclic voltammetry with an IJ Cambria Scientific CHI630A potentiostat at the Pt electrode in the solvents indicated in Table 1 using tetrabutylammonium hexafluorophosphate as the supporting electrolyte. Potentials are vs. SCE and have been standardized towards a ferrocene/ferrocenium potential vs. SCE of 0.400 V in either solvent.

Synthesis and Structural Characterization of Trinuclear, Amidate-Bridged Heterobimetallic Complexes $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]X_n$ (M = Mn, Fe, Co, Ni, Cu; X = BF_4^-, ClO_4^-; *n* = 2 or 3)

Wanzhi Chen[a] and Kazuko Matsumoto*[a]

Keywords: N ligands / Bridging ligands / Platinum / Manganese / Iron / Cobalt / Nickel / Copper

A family of trinuclear heterometallic complexes of the formula $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]X_n$ (M = Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}; X = BF_4^-, ClO_4^-) have been prepared by reacting $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$ and the corresponding metal ions in water. They were characterised by elemental analysis, and their structures were determined by X-ray crystallography. The crystal structures of all the complexes consist of trinuclear $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]^{n+}$ (M = Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}) cations with M located at the centre. The platinum atoms are linked to the central metal atom through their amidate ligands also by Pt–M interactions. The coordination sphere of the Pt atom is completed by two NH_3 and two amidate ligands in *cis* positions to each other. The central heterometal ions are coordinated by four oxygen atoms of the amidate ligands, adopting either a square-planar or a tetrahedral conformation. Crystal structure determinations of all the complexes revealed extensive systems of N–H···O hydrogen bonds between the coordinated NH_3 ligands and the counteranions.

Introduction

Heterometallic cluster complexes containing direct M−M interactions are expected to create a new era of transition metal chemistry, especially in the fields of multimetallic catalysis and functional materials, due to their versatile chemical and physical properties, and thus the chemistry of heterotransition metal complexes has received great attention in recent years.[1] Multimetallic complexes are also promising precursors in developing nanostructured materials, including molecular-scale electronic, optical, and chemical devices.[2] A number of these complexes have been shown to exhibit unique spectroscopic properties that are associated with the metal-metal interactions.[3]

We became interested in $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$[4] because this compound is the core of a number of amidate-bridged dimeric and oligomeric platinum complexes containing metal-metal interactions and mixed oxidation states of the metals.[5] Partially oxidized tetranuclear platinum complexes have been applied to the activation of C−H bonds of ketones to give ketonylplatinum(III) dinuclear complexes, and the coordination of olefins in water to give hydroxyalkylplatinum complexes.[6] It was also found that amidate-bridged Pt^{III} complexes catalyze the oxidation of terminal olefins to ketones in acidic water and promote the dihydroxylation of alkenes in neutral aqueous solutions.[7] We have recently described the preparation and structural characterization of $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$, which acts as a versatile building block for the construction of dinuclear platinum and platinum-palladium complexes.[4] In addition, many transition metal ions of the first row are known to play an important role in oxidation reactions. Therefore, it was of interest to prepare amidate-bridged heterometallic compounds with the transition metal ions of the first row, and to study their redox chemistry and catalysis. As a continuation of our work on the platinum amidate chemistry, we report here the preparation and X-ray structural characterization of heterometallic trinuclear complexes of the formula $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]X_n$ (M = Mn^{2+} **1**, Fe^{3+} **2**, Co^{2+} **3**, Ni^{2+} **4**, Cu^{2+} **5** and **6**; X = BF_4^-, ClO_4^-).

Results and Discussion

Synthesis

The square-planar platinum complex $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$, readily prepared by basic hydrolysis of $[Pt(NH_3)_2(NCtBu)_2](ClO_4)_2$, reacts with Mn^{2+}, Fe^{2+}, Co^{2+}, Ni^{2+} or Cu^{2+} salts in water to form trinuclear complexes with the formula $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]X_n$, where X is either perchlorate or tetrafluoroborate. Remarkably, regardless of the Pt:M ratio (1:1 or 2:1) the trinuclear Pt_2M complexes were formed exclusively in high yield. Attempts to prepare the platinum-copper dimeric complex with the formula $[Pt(NH_3)_2(NHCOtBu)_2Cu(en)](ClO_4)_2$ by reacting $[Cu(en)_2(H_2O)](SO_4)$ with $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$ in a 1:1 ratio were not successful, and $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Cu](ClO_4)_2$ was the only isolated complex. However, both dimeric *cis*-$[(NH_3)_2Pt(1\text{-}MeU)_2Cu(H_2O)_2]SO_4\cdot 4.5H_2O$,[8] and trimeric *cis*-$[(NH_3)_2Pt(1\text{-}MeU)_2Cu(1\text{-}MeU)_2Pt(NH_3)_2]^{2+}$ (1-MeU = 1-methyluracilato)[9] have long been known. Reaction of $FeSO_4\cdot 7H_2O$ with $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$ did afford the red $Pt_2^{II}Fe^{III}$ complex rather than $Pt_2^{II}Fe^{II}$, and a gradual colour change in water was observed from light green to red.

Structural Characterisation

Since the NMR spectroscopic data of the paramagnetic complexes were not particularly informative, suitable single crystals were grown by slow evaporation and cooling of an H_2O/acetone solution. All of the complexes were characterised by X-ray diffraction analysis.

The crystal structures of all of the complexes consist of trinuclear $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2M]^{n+}$ (M = Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}) cations with M located at the centre. Within the cations each platinum atom is linked to the central heterometal atom through two amidate ligands and a Pt−M interaction. The coordination sphere of the Pt atom is completed by two NH_3 and two amidate ligands in *cis* positions to each other. The central metal atoms are coordinated by four oxygen atoms of the amidate ligands. Two pairs of pivalamidate ligands are arranged head-to-head. The head-to-head orientation of the amidate ligands in these complexes is not straightforward from X-ray crystallographic arguments, but is reasonable on the basis of the method of preparation and the properties of the central metal ions. The Pt−N bond lengths and N−Pt−N angles are normal and similar to the values found in the starting compound $[Pt(NH_3)_2(NHCOtBu)_2]\cdot 2H_2O$. These data as well as the M−O distances and O−M−O angles are listed in Table 1 and 2. The Pt−M−Pt axes in **1b, 4−7** are roughly perpendicular to both of the coordination planes of Pt and M. In complex **1b**, **4−7**, the Pt−M−Pt axes are virtually linear with a Pt−M−Pt angle of 180°, whereas in **1a** and **3**, the Pt−M−Pt axes are bent with a Pt−M−Pt angle of 114.13(7)° and 176.39(8)° for **1a** and **3**, respectively. The structures of the complexes with the linearly ordered Pt−M−Pt cores are essentially the same.

Crystal Structures of $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Mn](ClO_4)_2\cdot 4H_2O$ (1)

Crystallographic analysis of the manganese complex revealed that the asymmetric unit comprises of one molecule of **1a** and half of a molecule of **1b**. The structure of **1b** is generated by the inversion centre (1/2, 0, 1/2) at Mn(2). The structure of the cations of **1a** and **1b** are illustrated in Figure 1a and 1b. It is interesting to note that in **1a** the central Mn atom adopts a tetrahedral geometry, which is completed by the four amidate oxygen atoms, or a bicapped tetrahedron when the two rather long Pt−Mn contacts are considered. In **1b**, however, the Mn ion adopts a square-planar geometry, or it may be viewed as octahedrally coordinated with the platinum atoms sitting above and below the coordination plane. The distance between the Pt and Mn

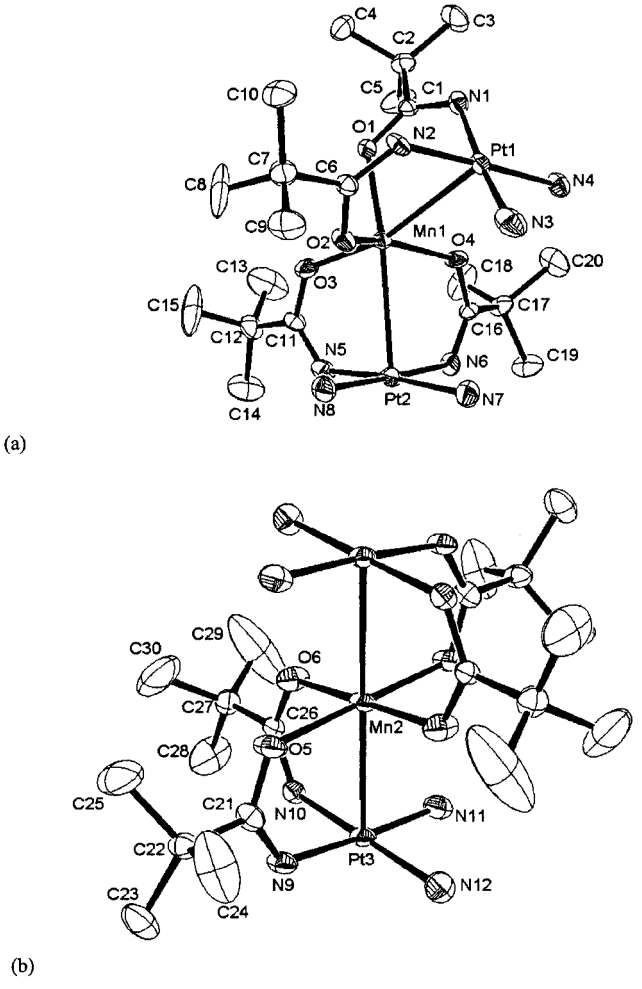

Figure 1. (a) ORTEP view of the bent $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Mn]^{2+}$ cation in complex **1a**, showing the numbering of the atoms; (b) ORTEP view of the linear $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Mn]^{2+}$ cation in complex **1b**, showing the numbering of the atoms; thermal ellipsoids are drawn at the 30% probability level

atoms within the cation of **1b** [2.6644(5)] is much shorter than those in the cation of **1a** [2.8807(18) Å and 2.9995(18) Å]. The Pt−Mn distance in **1b** is also shorter than that in $[(NH_3)_2Pt(1\text{-}MeT)_2Mn(1\text{-}MeT)_2Pt(NH_3)_2]^{2+}$ (1-Met = 1-methylthymine) [2.704(1) Å],[10] which has a similar Mn^{II} coordination environment, and it is even shorter than that in $[(dppe)(CH_3)PtMn(CO_5)]$ (2.795 Å),[2a] in which the Pt−Mn bond is thought to be typical of a covalent single bond. The shorter Pt−Mn distance in **1b** is probably a consequence of the square-planar coordination of the Mn^{II} atoms which enables a closer approach to the square-planar Pt atoms than the Mn^{II} ion in the tetrahedral arrangement in **1a**. The Mn−O distances in both **1a** and **1b** fall in the range of 2.044(8)−2.110(9) Å, and are consistent with those found for octahedral complexes with oxygen atoms coordinated to Mn^{II} ions. The Pt−Mn−Pt axis in **1b**, which is linear by space group symmetry, is approximately perpendicular to both of the coordination planes of Pt and Mn. These coordination planes are tilted towards each other by an angle of 17.34°.

Crystals containing both **1a** and **1b** have four lattice water molecules in the unit cell. All of the water molecules and perchlorate ions participate in short contacts with the coordinated NH_3. The N−H···O contacts fall in the range of 3.011(15)−3.49(3) Å, suggesting hydrogen bonding. These hydrogen bonds link the cations, counteranions and the lattice water molecules into a two-dimensional network structure. Selected hydrogen bonds are listed in Table 3.

Crystal Structure of $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Fe](ClO_4)_3$ (2)

The crystal structure of **2** is shown in Figure 2. The Pt_2Fe complex crystallises in a chiral orthorhombic space group $P2_12_12_1$. The platinum(II) and iron(III) atoms are held together through the four bridging pivalamidate ligands. The Pt−Fe−Pt is slightly bent with an angle of 176.40(8)°, but still close to a linear arrangement. The Pt−Fe distances are rather short [2.5566(15) Å and 2.5718(15) Å], and are similar to the values [2.5062(9)−2.673(4) Å] in the dppm-bridged Pt−Fe complexes.[11,12] The short Pt−Fe distances are attributed to the smaller Fe^{III} radius and the geometry requirement of the pivalamidate ligands. The coordination sphere of the Fe^{III} ion is completed by the four equatorial

oxygen atoms of the amidate ligands and the two platinum atoms sitting above and below the FeO_4 coordination plane, if the two Pt−Fe interactions are taken into account. The Pt−N and Fe−O bond lengths are normal and not very different from those observed in **1**. The whole molecules are also organized in the two-dimensional structure involving hydrogen bonds both of intercationic and between cations and perchlorate anions. Some hydrogen bonds are collected in Table 3.

Crystal Structure of $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Co](ClO_4)_2$ (3)

Crystal data and selected bond lengths and angles are presented in Table 1 and 2. The structure of **3** consists of a centrosymmetric trinuclear Pt−Co−Pt core and two perchlorate counteranions (Figure 3). The Pt−Co bond length [2.6197(4) Å] within the cation is longer than those found in the Pt−Co clusters $[PtCo_2(CO)_7(cod)]$ [2.515(1) Å and 2.514(1) Å] and $[Pt_2Co_2(CO)_8(\mu_3\text{-}EtC_2Et)]$ [2.551(1) Å and 2.556(1) Å],[13] and is also longer than in the $(Ph_2P)_2NH$-

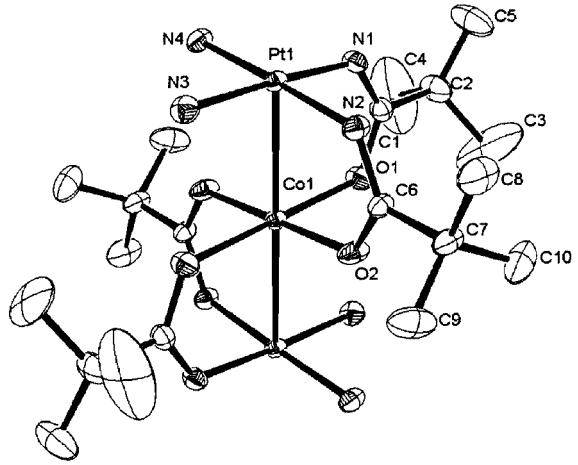

Figure 3. ORTEP view of the $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Co]^{2+}$ cation in complex **3**, showing the numbering of the atoms; thermal ellipsoids are drawn at the 30% probability level

bridged Pt−Co carbonyl complexes [2.531(2)−2.508(2) Å].[14] The cation and the counteranions are linked by hydrogen bonds between the coordinated NH_3 and the perchlorate oxygens. Intermolecular hydrogen bonds between the NH_3 and amidate oxygen atoms are also observed, and thus form two-dimensional networks.

Crystal Structure of $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Ni](ClO_4)_2$ (4)

The asymmetric unit of the Pt_2Ni complex comprises four half units of a molecule of the complex, and their structures are generated by the inversion centre (1/2, 1, 0; 1/2, 1/2, 1/2; 1, 1/2, 0; 1, 1, 1/2) at Ni(1), Ni(2), Ni(3) and Ni(4), respectively. The four molecules are essentially the same, and one of the structures of the four cations is shown in Figure 4. The Pt−Ni−Pt angles in all of the four independent molecules are 180°. The platinum and nickel centres are bridged by triatomic NCO groups of the amidate ligands. Each nickel ion is coordinated to four oxygen and two platinum atoms at the axial sites. The *cis* O−N−O angles lie within the range 89.0(3)°−91.3(3)°. The *trans* O−Ni−O angles are both 180°. The Ni−O bond lengths [2.005(7) Å and 2.008(7) Å] are almost identical. The Pt−Ni distance within the cation is 2.5870(4) Å. The hydrogen atoms of the coordinated NH_3 ligands are engaged in hydrogen bonding interactions with the oxygen atoms of the perchlorate anions, resulting in the formation of a three-dimensional network.

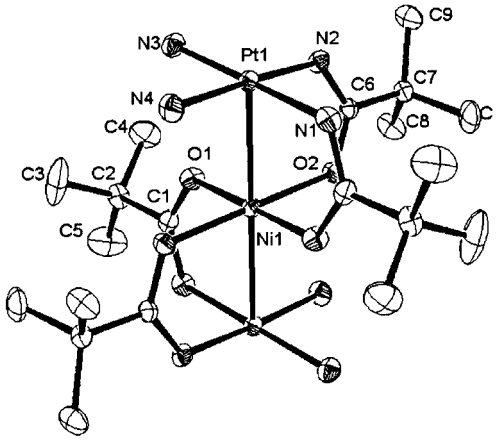

Figure 4. ORTEP view of the $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Ni]^{2+}$ cation in complex **4**, showing the numbering of the atoms; thermal ellipsoids are plotted at the 30% probability level

Crystal Structure of $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Cu](ClO_4)_2$ (5) and $[\{Pt(NH_3)_2(NHCOBu)_2\}_2Cu](BF_4)_2$ (6)

Although the two complexes crystallise in different space groups, their structures are essentially the same. A molecular view of **5** is shown in Figure 5. Within the trimers, the Cu atoms are located at the special position (1/2, 0, 1/2) for both **5** and **6**. The Pt−Cu distances are 2.6795(3) Å and 2.6955(2) Å in **5** and **6,** respectively, and are therefore shorter than that in the Pt/Cu dimer, *cis*-$[(NH_3)_2Pt(1\text{-}MeU)_2Cu(H_2O)_2]^{2+}$,[9] and the Pt_2Cu trimer, *cis*-$[(NH_3)_2Pt(1\text{-}MeU)_2Cu(1\text{-}MeU)_2Pt(NH_3)_2]^{2+}$ (1-MeU = 1-methyluracilato),[10] and much shorter than those in the platinum-copper complexes bridged by alkynyl ligands.[15]

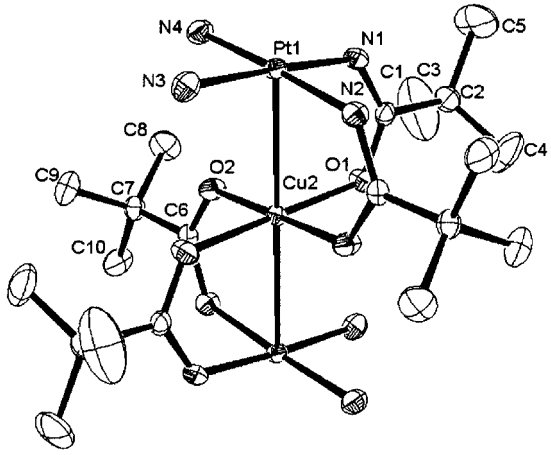

Figure 5. ORTEP view of the $[\{Pt(NH_3)_2(NHCOtBu)_2\}_2Cu]^{2+}$ cation in complex **5**, showing the numbering of the atoms; thermal ellipsoids are plotted at the 30% probability level

Similar to the complexes described above, the trinuclear cations and counteranions in **5** and **6** are connected by N−H···O and N−H···F hydrogen bonding, with N···O distances in the range from 2.983(6) Å to 3.221(8) Å, and the N−H···F distances from 2.961(9) to 3.092(13) Å. Short N−H···F and N−H···O contacts are presented in Table 3. The short contacts indicate strong hydrogen bonds between the hydrogen atoms of the NH_3 ligands and the fluorine or oxygen atoms of the anions. These interactions make two- and three-dimensional hydrogen bond networks for **5** and **6,** respectively.

All of the complexes presented here have provided unequivocal evidence for the formation of Pt−M (2:1) amidate-bridged complexes. X-ray diffraction analysis showed that the Pt atoms have an essentially planar conformation, and the central metal ions are similarly coordinated by four equatorial oxygen atoms with two platinum atoms occupying the two axial sites in **1b**, and **2**−**7**. The metal-metal distances in these complexes with linear Pt−M−Pt conformation are found to follow the order: Pt−Cu > Pt−Mn > Pt−Co > Pt−Ni > Pt−Fe. The metal-metal distances between the platinum and Mn^{II} (d^5), Fe^{III} (d^5), Co^{II} (d^7), Ni^{II} (d^8) and Cu^{II} (d^9) are rather short in complexes **2**−**7**. It was thought that these short intermetallic distances within the cations do not reflect a significant electronic interaction between the Pt and heterometals, and they are rather attributed to the geometric requirement caused by the two bridging ligands.[9] Most probably this also applies to our complexes. However, a weak metal-metal interaction should probably not be ruled out, on the basis of the Pt and the heterometal radii. The redox chemistry of these cationic trinuclear heterometallic complexes is currently being explored.

Experimental Section

General Remarks: $[Pt(NH_3)_2(NHCOtBu)_2{\cdot}2H_2O]$ was prepared according to our published procedure.[4] All other chemicals and solvents were purchased and used as received.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Mn](ClO$_4$)$_2$·4H$_2$O (1): A solution of $MnCl_2·4H_2O$ (20 mg, 0.10 mmol) in 2 mL of water was added to a solution of [Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$]·2H$_2$O (93 mg, 0.20 mmol) in 1 mL of water. A pale-yellow precipitate was formed immediately by the addition of $NaClO_4$ (50 mg) to the pale-yellow solution. Yield: 95 mg (83%). $C_{20}H_{52}Cl_2N_8MnO_{12}Pt_2·4H_2O$ (1148.70): calcd. C 20.28, H 5.10, N 9.46; found C 20.42, H 5.03, N 9.46.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Fe](ClO$_4$)$_3$ (2): This compound was prepared from $FeSO_4·7H_2O$ (27.8 mg, 0.10 mmol), [Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$·2H$_2$O], and $NaClO_4$ (50 mg) as for **1**, and was isolated as red crystals. Yield: 98 mg (81%). $C_{20}H_{52}Cl_3FeN_8O_{16}Pt_2$ (1213.08): calcd. C 19.80, H 4.32, N 9.24; found C 19.90, H 4.15, N 9.26.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Co](ClO$_4$)$_2$ (3): This compound was prepared from $Co(NO_3)_2·6H_2O$, [Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$·2H$_2$O] and $NaClO_4$ (50 mg) as for **1**, and was isolated as blue crystals. Yield: 102 mg (91%). $C_{20}H_{52}Cl_2CoN_8O_{12}Pt_2$ (1116.71): calcd. C 21.51, H 4.69, N 10.03; found C 21.36, H 4.55, N 9.78.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Ni](ClO$_4$)$_2$ (4): This compound was prepared from $Ni(NO_3)_2·6H_2O$ (18.2 mg, 0.1 mmol), [Pt(NH$_3$)$_2$(NHCOBu)$_2$]·2H$_2$O (46 mg, 0.1 mmol), and $NaClO_4$ (50 mg) as for **1**, and was isolated as light-green crystals. Yield: 80 mg, (72%). $C_{20}H_{52}Cl_2N_8NiO_{12}Pt_2$ (1116.49) C, 21.52, H 4.69, N 10.04; found C 21.75, H 4.88, N 9.70.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Cu](ClO$_4$)$_2$ (5): This compound was prepared from [Cu(en)(H$_2$O)](SO$_4$) (25 mg, 0.1 mmol), [Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$·2H$_2$O] (46 mg, 0.1 mmol), and $NaClO_4$ (50 mg) as for **1**. The compound can also be prepared directly from $Cu(ClO_4)_2·2H_2O$. Yield: 82 mg, (73%). $C_{20}H_{52}Cl_2CuN_8O_{12}Pt_2$ (1121.32): calcd. C 21.42, H 4.67, N 9.99; found C 21.46, H 4.43, N 9.82.

Preparation of [{Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$}$_2$Cu](BF$_4$)$_2$ (6): This compound was prepared from $Cu(BF_4)_2·6H_2O$ (23.7 mg, 0.10 mmol) and [Pt(NH$_3$)$_2$(NHCO*t*Bu)$_2$·2H$_2$O] (93 mg, 0.2 mmol) as for **1** and isolated as light green crystals. Yield: 84 mg (77%). $C_{20}H_{52}B_2CuF_8N_8O_4Pt_2$ (1096.04): calcd. C 21.92, H 4.78, N 10.22; found C 21.89, H 4.79, N 10.21.

X-ray Crystallographic Study: Data collection was performed on a Bruker Smart-CCD diffractometer by using monochromatized Mo-K_α radiation (λ = 0.71073 Å) at room temperature. Data reduction was performed by using the SAINT+ Version 6.02 software.[16] The data were corrected for absorption by using the program SADBAS within the SAINTPLUS package. The structures were solved by direct methods. This solution yielded metal atoms, N O, and some C atoms. Subsequent Fourier synthesis gave the remaining C-atom positions. The hydrogen atoms, except those of the amidate and water hydrogen atoms, were geometrically fixed, allowed to ride on their attached atoms, and refined with the XSHELL software.[17] The final refinement included anisotropic thermal parameters for all of the non-hydrogen atoms and converged to the *R*1 and *wR*2 values listed in Table 4.

Dioxygenation of Sterically Hindered (Ethene)Rh^{I} and -Ir^{I} Complexes to (Peroxo)Rh^{III} and (Ethene)(peroxo)Ir^{III} Complexes

Bas de Bruin,*[a] Theo P. J. Peters,[a] Jos B. M. Wilting,[a] Simone Thewissen,[a] Jan M. M. Smits,[a] and Anton W. Gal*[a]

Keywords: Alkene ligands / Iridium / O−O activation / Oxidations / Peroxo ligands

New cationic, five-coordinate bis(ethene)iridium(I) complexes [(κ^3-Me_3-tpa)Ir^{I}(ethene)$_2$]$^+$ (**12**$^+$) and [(κ^3-Me_2-dpa-Me)Ir^{I}(ethene)$_2$]$^+$ (**13**$^+$) have been prepared {Me_3-tpa = *N*,*N*,*N*-tris[(6-methyl-2-pyridyl)methyl]amine, Me_2-dpa-Me = *N*-methyl-*N*,*N*-bis[(6-methyl-2-pyridyl)methyl]amine}. Complexes **12**$^+$ and **13**$^+$ lose one ethene fragment in solution, yielding the five-coordinate mono(ethene) complex [(κ^4-Me_3-tpa)Ir^{I}(ethene)]$^+$ (**14**$^+$) and the four-coordinate mono-(ethene) complex [(κ^3-Me_2-dpa-Me)Ir^{I}(ethene)]$^+$ (**15**$^+$), respectively. [(κ^4-Me_3-tpa)Rh^{I}(ethene)]$^+$ (**11**$^+$), the rhodium analogue of **14**$^+$, was also prepared. Whereas rhodium complex **11**$^+$ is stable in acetonitrile at room temperature, the iridium analogue **14**$^+$ converts to the cyclometallated (acetonitrile)(hydrido) complex **16**$^+$ within 72 h by dissociation of the unique 6-methylpyridyl fragment and oxidative addition of the 6-methylpyridyl C^3–H bond. The four-coordinate mono(-ethene) complex **15**$^+$ is even less stable in solution; it converts to a mixture of compounds within 18 h. Reaction of the mono(ethene)Rh^{I} complex **11**$^+$ with O_2 yields the peroxo complex **17**$^+$ by ethene displacement. In contrast, the mono(-ethene)Ir^{I} complexes **14**$^+$ and **15**$^+$ bind O_2 without the loss of ethene, leading to unprecedented (ethene)(peroxo)Ir^{III} complexes **18**$^+$ and **19**$^+$. At room temperature, peroxo complex **17**$^+$ does not react with ethene and, quite remarkably, C–O bond formation does not occur in the (ethene)(peroxo) complexes **18**$^+$ and **19**$^+$.

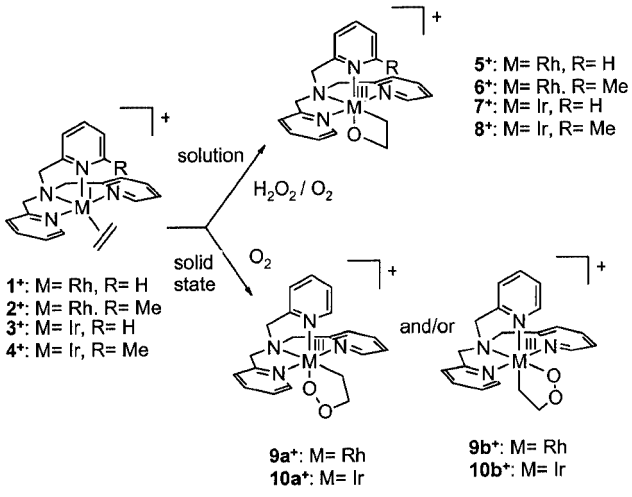
Introduction

Mechanistic aspects of oxygenation reactions with environmentally benign dioxygen are poorly understood. In the late transition metal (LTM) catalyzed oxidation of olefins, peroxo and (olefin)peroxo complexes,[1] 3-metalla-1,2-dioxolanes,[1,2] and 2-metallaoxetanes[3,4] have been proposed as crucial intermediates. In an attempt to collect more mechanistic insight in LTM-mediated oxygenation of olefins we are investigating the stoichiometric oxygenation of rhodium(I)- and iridium(I)-coordinated olefins by O_2.

We have previously observed the selective oxygenation of the cationic (ethene)Rh^{I} and -Ir^{I} complexes **1**$^+$−**4**$^+$ by H_2O_2 *in solution* (various solvents), to give 2-rhoda(III)- and 2-irida(III)oxetanes (1-oxa-2-metalla(III)cyclobutanes) **5**$^+$−**8**$^+$ (Scheme 1).[5,6] Recently, we also observed monooxygenation of cationic (ethene)Ir^{I} complexes by O_2; reaction of **4**$^+$ with air or O_2 in CH_2Cl_2 led to formation of approximately 25% of **8**$^+$.[6]

Furthermore we observed slow, selective dioxygenation of *solid* **1** with air or O_2 to the 3-metalla-1,2-dioxolanes **9a**$^+$ and **9b**$^+$. The ratio between these geometrical isomers proved to be counterion-dependent.[7] Recently, we observed a similar reaction for the iridium analogue **3**$^+$ yielding **10a**$^+$ and **10b**$^+$.[8]



Scheme 1. Mono- and dioxygenation of (ethene)Rh^{I} and -Ir^{I} complexes by O_2

In order to improve our understanding of the mechanisms by which the above reactions proceed, we have now studied the reactivity of [(ethene)(N-ligand)M^{I}]$^+$ (M = Rh, Ir) complexes containing the more bulky N-ligands Me_3-tpa and Me_2-dpa-Me.

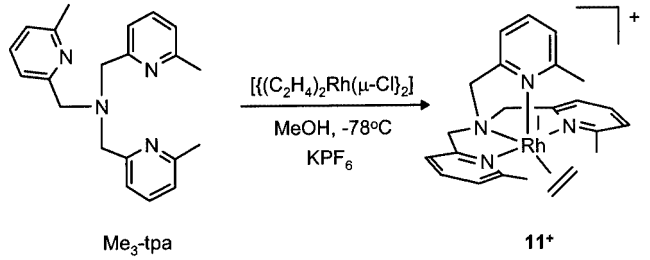
Results and Discussion

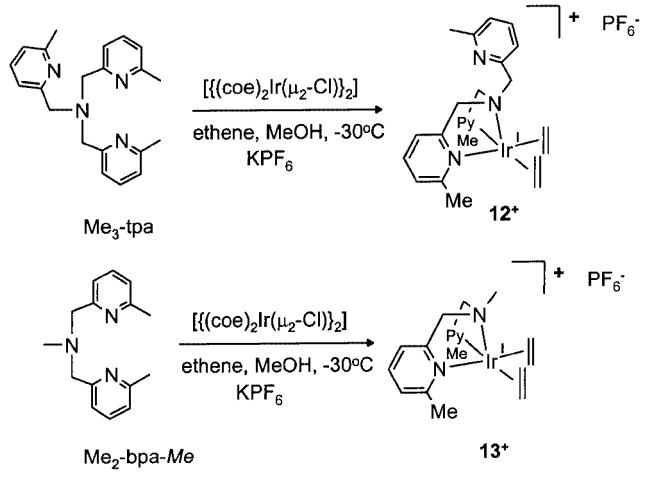
1. Synthesis of (Ethene)Rh^{I} and -Ir^{I} Complexes

We synthesized the cationic ethene complex [(Me_3TPA)-$Rh^{I}(C_2H_4)]^+$ (**11**$^+$) using the route in Scheme 2. Stirring of $[\{(C_2H_4)_2Rh^{I}(\mu\text{-Cl})\}_2]$ with Me_3-tpa in MeOH at −78 °C resulted in the formation of **11**$^+$, which was isolated as [**11**]PF_6 by precipitation with KPF_6.



Scheme 2. Preparation of (ethene)Rh^{I} complex **11**$^+$

A similar reaction of $[(C_2H_4)_4Ir^{I}(Cl)]$[9] (generated in situ from the reaction of $[\{(coe)_2Ir^{I}(\mu\text{-Cl})\}_2]$[10] with ethene; coe = cyclooctene) in MeOH with Me_3-tpa and Me_2-dpa-Me yielded the bis(ethene)iridium complexes [(Me_3-tpa)$Ir^{I}(C_2H_4)_2]^+$ (**12**$^+$) and [(Me_2-dpa-Me)$Ir^{I}(C_2H_4)_2]^+$ (**13**$^+$), respectively (Scheme 3). The cations **12**$^+$ and **13**$^+$ were isolated as PF_6^- salts by precipitation with KPF_6.



Scheme 3. Synthesis of bis(ethene)Ir^{I} complexes **12**$^+$ and **13**$^+$

The ^1H and ^{13}C NMR spectroscopic data of **12**$^+$ and **13**$^+$ reveal two equivalent N-CH_2-Py^{Me} groups. The ^1H NMR methyl signals of these two groups have shifted by approximately 0.7 ppm downfield relative to the free ligand, in both **12**$^+$ and **13**$^+$. As expected, the diastereotopic methylene protons of the two equivalent N-CH_2-Py^{Me} groups give rise to two AB-type doublets. The ^1H NMR methyl signal of the unique N-CH_2-Py^{Me} group of **12**$^+$ at δ = 2.6 ppm is close to the value of that of the free ligand (δ = 2.56 ppm). In the ^1H NMR spectra of **12**$^+$ and **13**$^+$, the ethene fragments are observed as two broad signals between δ = 2.1 and 1.6 ppm at room temperature.

The X-ray structure of **12**$^+$ was determined. Despite of the poor quality of the data set obtained, the X-ray analysis clearly shows the presence of the κ^3-*N,N,N-fac*-coordinated Me_3-tpa ligand with a noncoordinated 6-methylpyridyl group. The structure is in good agreement with the NMR spectroscopic data in solution (Figure 1).

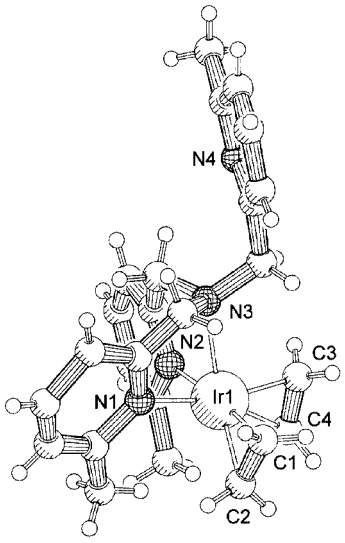


Figure 1. X-ray structure of **12**$^+$

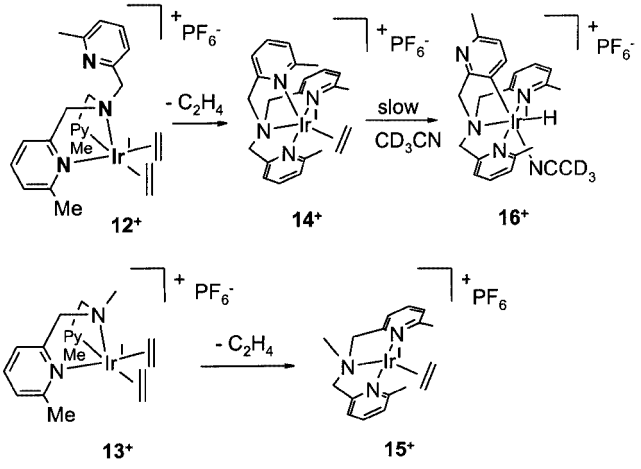
The coordination mode of **12**$^+$ is best described as pseudo square-pyramidal (sqpy). Analogously, complex **13**$^+$ will most probably be square-pyramidal, too.

2. Ethene Dissociation from Bis(ethene)Ir^{I}

Solutions of the bis(ethene) complexes **12**$^+$ and **13**$^+$ are not stable. One of the two ethene fragments dissociates in [D_6]acetone, CD_2Cl_2, or MeCN within 4 h at room temperature (Scheme 4). For **12**$^+$, substitution of the ethene fragment by the unique 6-methylpyridyl group results in the mono(ethene) complex [(κ^4-Me_3-tpa)Ir^{I}(ethene)]$^+$ (**14**$^+$), which is the iridium analogue of **11**$^+$. Ethene dissociation from **13**$^+$ results in the four-coordinate mono(ethene) complex **15**$^+$.



Scheme 4. Ethene dissociation from bis(ethene)Ir^{I} complexes **12**$^+$ and **13**$^+$ resulting in the mono(ethene) complexes **14**$^+$ and **15**$^+$ and the cyclometallated complex **16**$^+$

At room temperature the ^{1}H and ^{13}C NMR spectra of **14^{+}** show two equivalent and one unique N-CH_2-Py^{Me} fragment, consistent with a κ^4-coordination mode of the Me_3-tpa ligand. The ^{1}H and ^{13}C NMR spectra of **15^{+}** show signals for two equivalent N-CH_2-Py^{Me} groups. The ethene signals of both **14^{+}** and **15^{+}** are observed as two sharp triplets, indicating that the ethene fragment does not rotate on the NMR time scale.

The ^{1}H NOE patterns of **15^{+}** are characteristic of a *mer*-coordination mode of the Me_2-dpa-Me ligand; clear NOE contacts are observed between N-*CH_3* and the equatorial N-*CH_2*-Py^{Me} methylene protons (one of the two AB-type doublets). The latter also show NOE contacts with the Py-H^3 protons. The axial N-*CH_2*-Py^{Me} methylene protons (the other AB-type doublet) do not show NOE contacts with either N-*CH_3* or Py^{Me}-*H^3*.

The mono(ethene) complexes **14^{+}** and **15^{+}** are only moderately stable at room temperature, in solution. Complex **14^{+}** is in marked contrast with the less substituted tpa and (Me-tpa)Ir^{I}(ethene) complexes **3^{+}** and **4^{+}**, which are stable in solution over a period of days. Complex **15^{+}** decomposes in CD_2Cl_2 or CD_3CN to a complex mixture of products within 18 h. In CD_3CN, complex **14^{+}** selectively converts in 72 h to cyclometallated complex **16^{+}**, presumably by chelate ring opening, oxidative addition of the 6-methylpyridyl C^3−H bond to the Ir^{I} center and substitution of ethene by CD_3CN (Scheme 4). The hydride in **16^{+}** is observed as a sharp ^{1}H NMR signal at $\delta = -18.6$ ppm. The presence of a coordinated CD_3CN was confirmed by ESI-MS and elemental analysis. The observed cyclometallation also occurs in acetone or CH_2Cl_2. In these solvents, however, ^{1}H NMR spectroscopy indicates that the 6th coordination site is still occupied by ethene.

A solution of **15^{+}** in CD_2Cl_2 contains only **15^{+}**. In CD_3CN, however, **15^{+}** and **15^{+}**(CD_3CN) are present in a ratio of 3:1. Although they have separate ^{1}H NMR signals, they show exchange signals in the EXSY spectrum, indicating that **15^{+}** and **15^{+}**(CD_3CN) are in slow exchange on the ^{1}H NMR time scale. The ethene ^{1}H NMR signals of **15^{+}**(CD_3CN) are very similar to those of **14^{+}**. The ethene signals of **15^{+}**, both in CD_3CN and CD_2Cl_2, have clearly shifted downfield relative to those of **14^{+}**. Computer-generated space-filling models of **15^{+}** indicate that the methyl substituents on the pyridyl fragments must hinder a true square-planar coordination geometry (see also Figure 4 and the discussion of the structure of complex **19^{+}**). Therefore, we propose that **15^{+}** has a distorted square-planar geometry, in which the ethene fragment has moved to a position below the *mer*-(Me-dpa-Me)Ir plane, away from the N_{amine}-Me and the Py-6-Me substituents (Scheme 4). From MO calculations it is known that such a distortion towards a mono-vacant trigonal-bipyramidal coordination geometry increases the reactivity of d^8-metal centers towards oxidative addition of a C−H bond.[11] This could explain the apparent reactivity of **15^{+}** in solution at room temperature. Dissociation of the unique 6-methyl-pyridyl fragment of **14^{+}** would lead to a similar distorted square-planar geometry, thus accounting for its intramolecular C−H activation.

3. Electrochemical Oxidation of the (Ethene)Rh^{I} and -Ir^{I} Complexes

The electrochemical oxidation of the ethene complexes **11^{+}**−**15^{+}** (Schemes 2 and 3) was studied by means of cyclic voltammetry. Table 1 summarizes the electrochemical data.

Table 1. Electrochemical data for complexes **11^{+}**−**15^{+}** [measured in MeCN (0.1 M TBAH); potentials in mV vs. the Fc/Fc^{+} couple]

	M	E^{p}_{anode}	$E^{p}_{cathode}$	$E_{1/2}$	I_b/I_f	ΔE
12^{+}	Ir	188	57	124[a]	0.53	114
13^{+}	Ir	156	90	123	1.00	66
11^{+}	Rh	−272	−426	−349[a]	0.48	154
14^{+}	Ir	−330	−399	−365	1.00	69
15^{+}/15^{+}(MeCN)	Ir	−226	−	−	0.00	−

[a] Quasi-reversible.

Clearly, the mono(ethene) complexes **11^{+}**, **14^{+}**, and **15^{+}**/**15^{+}**(MeCN) are oxidized at much lower potentials (−226 to −330 mV vs. Fc/Fc^{+}) than the bis(ethene) complexes **12^{+}** and **13^{+}** (+156 to +188 V vs. Fc/Fc^{+}). This presumably stems from an increased electron density at the metal center (due to decreased π-back donation) as a result of the loss of one ethene fragment. As expected, the (N_4-ligand)-Rh^{I} complex **11^{+}** is oxidized at a higher potential than the (N_4-ligand)Ir^{I} complex **14^{+}**.

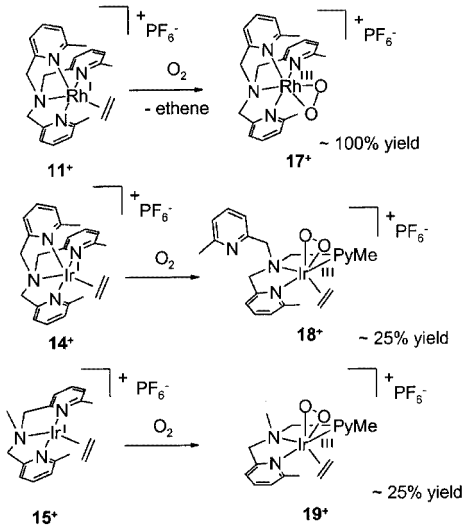
The five-coordinate bis- and mono(ethene)Ir^{I} complexes **13^{+}** and **14^{+}** (Scheme 4) undergo reversible one-electron oxidation at 100 mV/s in MeCN (0.1 M TBAH). The five-coordinate mono(ethene)Rh^{I} complex **11^{+}** and bis(ethene)Ir^{I} complex **12^{+}** both undergo quasi-reversible one-electron oxidation. In contrast, the mono(ethene) complex **15^{+}**/**15^{+}**(MeCN) is oxidized irreversibly in MeCN at 100mV/s.

During conversion of the bis(ethene) complexes **12^{+}** and **13^{+}** to the mono(ethene) complexes **14^{+}** and **15^{+}**, respectively, the redox pairs **12^{+}**/**14^{+}** and **13^{+}**/**15^{+}** are both seen as separate waves in the cyclic voltammogram. Therefore the bis(ethene) complexes are not in equilibrium with the mono(ethene) complexes on the electrochemical time scale.

4. Oxidation of the (Olefin)Rh^{I} and -Ir^{I} Complexes by O_2

The reactivity of the (ethene)rhodium complex **11^{+}** and the (ethene)iridium complexes **12^{+}**−**15^{+}** towards O_2 has been investigated. For the rhodium complex **11^{+}**, we observed clean ethene displacement by O_2. In contrast, the iridium complexes **14^{+}** and **15^{+}** react aselectively. For 25% the complexation of O_2 occurs without dissociation of ethene, giving **18^{+}** and **19^{+}** (Scheme 5).

Treatment of a CD_2Cl_2 solution of the Rh^{I} complex **11^{+}** with O_2 resulted in selective formation of the (peroxo)Rh^{III} complex **17^{+}**, according to ^{1}H NMR spectroscopy and ESI-MS. Loss of ethene was confirmed by ^{1}H NMR spectroscopy. The ^{1}H and ^{13}C NMR spectroscopic data of **11^{+}**, showing two equivalent and one unique N-CH_2-Py^{Me} frag-



Scheme 5. Reaction of (ethene)Rh^{I} and -Ir^{I} complexes to (peroxo)Rh^{III} and (ethene)(peroxo)Ir^{III} complexes

ment, are in accordance with a κ^4-coordination mode of the Me_3TPA ligand. ^{1}H NMR and ESI-MS indicate that the reaction of [(Me_2-tpa)Rh^{I}(ethene)]$^+$ with O_2 also results in selective formation of the (peroxo)Rh^{III} complex [(Me_2-tpa)$Rh^{II}(O_2)$]$^+$. In solution, Me_x-tpa complexes with less Me substituents, viz. [(Me_x-tpa)Rh^{I}(ethene)]$^+$ (x = 0, 1) lose ethene upon contact with O_2 or air in an aselective reaction.

Upon reaction of (mono)etheneIr^{I} complex **14**$^+$ with 1.2 bar O_2 in CD_2Cl_2, the ^{1}H NMR spectrum showed intense signals from the (ethene)(peroxo) complex **18**$^+$ and very broad signals, probably from paramagnetic species (Scheme 5). Based on the intensity of the ^{1}H NMR signals of **18**$^+$ relative to the internal standard dichloroethane, the starting complex **14**$^+$ has been converted into **18**$^+$ for approximately 25%, and approximately 70% of (a) paramagnetic compound(s). The reaction of complex **15**$^+$ with 1.2 bar O_2 in CD_2Cl_2 proceeds similarly to that of **14**$^+$. Again, approximately 25% of the (ethene)(peroxo) complex **19**$^+$ and approximately 70% of unidentified paramagnetic species are formed (Scheme 5). Any attempts to improve the selectivity of these reactions, e.g. by treatment of [**14**]PF_6 or [**15**]PF_6 with only 1 equiv. O_2 or by performing the reactions at lower temperatures, were not successful. Nevertheless, we succeeded in the isolation of pure [**18**]PF_6 and [**19**]PF_6 through crystallization.

The ^{1}H and ^{13}C NMR spectra of **18**$^+$ and **19**$^+$ show signals for two equivalent N-CH_2-Py^{Me} groups. The equatorial N−CH_2−Py^{Me} group of **18**$^+$ gives rise to a ^{1}H NMR methyl signal at δ = 2.65 ppm, close to the value for the free ligand (δ = 2.56 ppm). The methyl signals of the two equivalent 6-methylpyridyl groups of **18**$^+$ and **19**$^+$ are approximately 0.4 ppm downfield from those in the free ligand. The diastereotopic methylene protons of the two equivalent N-CH_2-Py^{Me} groups give rise to two AB-type doublets.

On going from (ethene)Ir^{I} compounds **14**$^+$ and **15**$^+$ to the (ethene)(peroxo)Ir^{III} species **18**$^+$ and **19**$^+$ the rate of ethene rotation increases. In the 200 MHz ^{1}H NMR spectra of **18**$^+$ and **19**$^+$ at room temperature, the ethene fragments are observed as very broad signals at δ = 4.48 and 4.22 ppm, respectively. At 500 MHz, the broad signals have split into two sharp triplets at 233 K for both **18**$^+$ (δ = 4.84 and 4.14 ppm, $^3J_{H,H}$ = 9.70 Hz) and **19**$^+$ (δ = 4.56 and 3.77 ppm, $^3J_{H,H}$ = 9.40 Hz). For both **18**$^+$ and **19**$^+$, at 500 MHz, coalescence of these triplets into one signal occurs at T_c = 273 K. From these data, the free energy of activation ($\Delta G_c^{\neq}$) for ethene rotation in **18**$^+$ and **19**$^+$ at T_c was estimated to be ca. 12 kcal/mol. The ethene fragments of **14**$^+$ and **15**$^+$ do not rotate on the ^{1}H NMR time scale at room temperature (298 K, 200 MHz). The free energy of activation for ethene rotation ($\Delta G_c^{\neq}$) of **14**$^+$ and **15**$^+$, as estimated from line-width analysis of the ethene ^{1}H NMR signals, must be at least 17 kcal/mol.

The structures of [**18**]PF_6 (Figure 2) and [**19**]PF_6 (Figure 3) were determined by single-crystal X-ray diffraction.

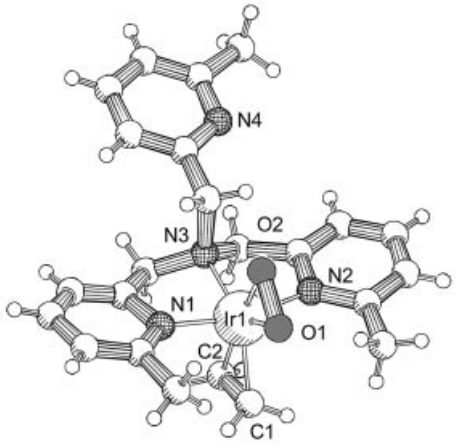


Figure 2. X-ray structure of **18**$^+$; selected bond lengths [Å] and angles [°]: Ir1−N1 2.071(12), Ir1−N2 2.085(12), Ir1−N3 2.073(11), Ir1−O1 2.014(10), Ir1−O2 2.011(9), Ir1−C1 2.119(14), Ir1−C2 2.162(14), O1−O2 1.430(13), C1−C2 1.40(2); N1−Ir1−N2 162.3(5), N1−Ir1−N3 80.7(5), N2−Ir1−N3 81.6(5), O1−Ir1−N3 136.7(4), O2−Ir1−N3 95.1(4), C1−Ir1−N3 128.4(5), C2−Ir1−N3 90.1(5), O1−Ir1−C1 94.9(5), O1−Ir1−C2 133.1(5), O2−Ir1−C1 136.5(5), O2−Ir1−C2 174.6(5)

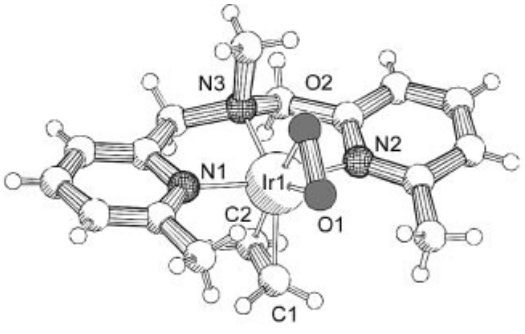

Figure 3. X-ray structure of **19**$^+$; selected bond lengths [Å] and angles [°]: Ir1−N1 2.083(6), Ir1−N2 2.076(5), Ir1−N3 2.098(5), Ir1−O1 2.046(5), Ir1−O2 2.023(5), Ir1−C1 2.122(7), Ir1−C2 2.136(7), O1−O2 1.446(8), C1−C2 1.404(11); N1−Ir1−N2 164.0(2), N1−Ir1−N3 81.5(2), N2−Ir1−N3 82.7(2), O1−Ir1−N3 136.0(2), O2−Ir1−N3 94.4(2), C1−Ir1−N3 127.1(3), C2−Ir1−N3 88.8(3), O1−Ir1−C1 96.8(3), O1−Ir1−C2 135.1(3), O2−Ir1−C1 138.4(3), O2−Ir1−C2 176.1(5)

The X-ray structure of **18**$^{+}$ reveals a κ^3-*mer*-coordinated Me_3-tpa ligand with a noncoordinated 6-methylpyridyl group, in accordance with the NMR spectroscopic data. Thus, dissociation of the unique pyridyl group probably precedes the reaction of **14**$^{+}$ with O_2. It is therefore not surprising that the reaction of **15**$^{+}$ with O_2 proceeds similarly.

The O−O distances in **18**$^{+}$ [1.430(13) Å] and **19**$^{+}$ [1.446(8) Å] indicate that the coordinated η^2-O_2 is best described as an η^2-peroxo fragment. Consequently the iridium center is formally in the +III oxidation state. The Ir−C and C−C distances for coordinated ethene in **18**$^{+}$ and **19**$^{+}$, however, fit well within the Ir−C and C−C ranges reported for (ethene)Ir^{I} complexes (ranges found in the Cambridge Structural Database: Ir^{I}−C: 2.036−2.191 Å, C−C: 1.351−1.444 Å).

Viewing the stick representation of (ethene)(peroxo) complex **19**$^{+}$ along the N1−Ir1−N2 axis reveals that folding of Me_2-dpa-Me to its *mer*-coordination mode leaves a relatively small compartment for *cis* coordination to the N3-Me fragment and a relatively large compartment for *trans* coordination to the N3-Me fragment (*cis* and *trans* with respect to the Ir1−N3 axis, Figure 4).

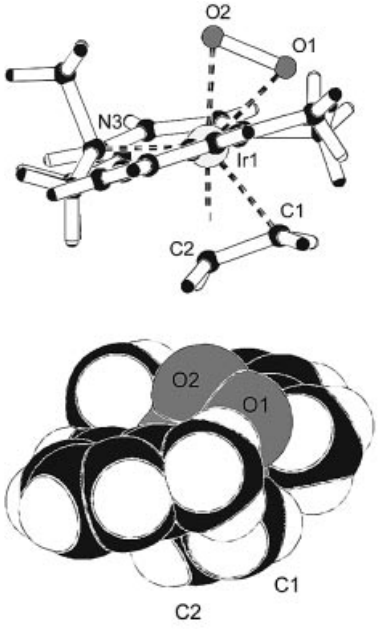

Figure 4. X-ray structure of **19**$^{+}$; top: stick representation; bottom: CPK representation

Viewing the CPK representation of **19**$^{+}$ (Figure 4, right) suggests that *mer*-Me_2-dpa-Me in the ethene complex **15**$^{+}$ allows ethene coordination neither in the small *cis* compartment (resulting in a mono-vacant trigonal-bipyramidal geometry) nor at a position *trans* to N3, in between the Py-Me groups (resulting in a square-planar geometry). It is therefore tempting to assume that **15**$^{+}$ (Scheme 4) has a mono-vacant trigonal-bipyramidal coordination geometry, with ethene coordinated *trans* to the N3-Me fragment, close to the structure of **19**$^{+}$ without the peroxo fragment. Binding of O_2 to **15**$^{+}$ would thus involve only small structural rearrangements.

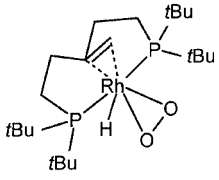
5. π-Back Bonding in (Ethene)Rh^{I}, -Ir^{I} and -Ir^{III} Complexes

The ethene signals of four-coordinate **15**$^{+}$ have shifted down-field relative to those of five-coordinate **14**$^{+}$, both in ^{1}H NMR (**15**$^{+}$: δ = 3.54 and 2.34 ppm; **14**$^{+}$: δ = 1.85 and 1.37 ppm) and ^{13}C NMR (**15**$^{+}$: δ = 37.0 and 25.1 ppm; **14**$^{+}$: δ = 3.7 and 0.2 ppm). The ethene signals of the five-coordinate Rh^{I} complex **11**$^{+}$ (^{1}H NMR: δ = 2.41 and 2.11 ppm; ^{13}C NMR: δ = 29.5 and 26.3 ppm) have also shifted down-field relative to those of its Ir^{I} analogue **14**$^{+}$. Furthermore, the (N_4-ligand)Rh^{I} complex **11**$^{+}$ is oxidized at a potential 60 mV higher than that of the (N_4-ligand)Ir^{I} complex **14**$^{+}$. These data are consistent with weaker M→C=C π-back donation upon removal of a donor atom (from **14**$^{+}$ to **15**$^{+}$) and upon substitution of rhodium(I) for iridium(I) (from **14**$^{+}$ with **11**$^{+}$).

The increased rate of ethene rotation on going from (ethene)Ir^{I} compounds **14**$^{+}$ and **15**$^{+}$ to (ethene)(peroxo)Ir^{III} species **18**$^{+}$ and **19**$^{+}$ (vide infra) most likely results from decreased Ir→C=C π-back bonding for Ir^{III} relative to Ir^{I}.

Discussion and Conclusions

Complexes **18**$^{+}$ and **19**$^{+}$ are very rare examples of (olefin)(peroxo) complexes. In the only other structurally characterized (peroxo)(olefin)transition-metal complex **20**, the olefin fragment is part of the stabilizing P-ligand (Figure 5).[12] Olefin coordination in **20** must be promoted by the chelate effect, in contrast to ethene coordination in **18**$^{+}$ and **19**$^{+}$.

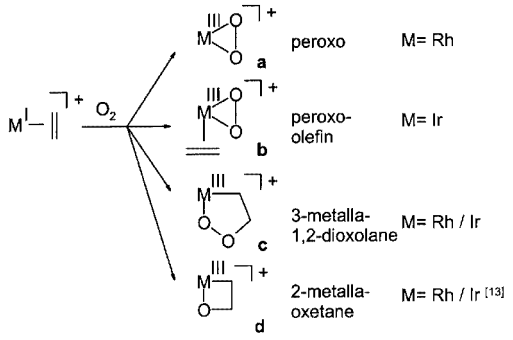


20

Figure 5. (Olefin)(peroxo)rhodium complex **20**[12]

For **18**$^{+}$, **19**$^{+}$, and **20** it is quite remarkable that the olefin fragment does not insert into the M−O bond of the η^2-peroxo fragment. The approach of the peroxo fragment by the olefin fragment might be hindered by geometrical constraints, i.e. the fixed position of the olefin in the rigid chelating diphosphane ligand in **20** and for steric reasons in **18**$^{+}$ and **19**$^{+}$. However, there seems to be no obvious geometrical constraint for the peroxo fragment to move towards the olefin. Nevertheless, intramolecular C−O bond formation is not observed.

The (peroxo)Rh^{III} complex **17**$^{+}$ and the unprecedented (ethene)(peroxo)Ir^{III} complexes **18**$^{+}$ and **19**$^{+}$ add to the list of species observed upon reaction of [(N-ligand)M^{I}(ethene)]$^{+}$ (M = Rh, Ir) with O_2 (**a** and **b** in



Scheme 6. Observed oxygenations of $[(\text{N-ligand})\text{M}^{\text{I}}(\text{olefin})]^+$ (M = Rh, Ir) by O_2

Scheme 6). The reactivity of (ethene)Rh^{I} and -Ir^{I} fragments towards dioxygen thus varies from ethene displacement (**a**) and formation of mixed (ethene)(O_2) complexes (**b**) to C−O bond formation (to give a 3-metalla-1,2-dioxolane; **c**) and to C−O bond formation plus O−O bond breaking (to give a 2-metallaoxetane; **d**).[13] Apparently, the outcome of the oxygenation reaction subtly depends on the metal and the N-ligand (Scheme 6).

The remarkable effects of variation of metal and N-ligand on the obtained products are best demonstrated by comparing **11**$^+$ (Scheme 5), **14**$^+$ (Scheme 5), and **4**$^+$ (Scheme 1) in their solution-phase reactivity towards O_2. Changing the metal from rhodium in **11**$^+$ to iridium in **14**$^+$ results in (η^2-ethene)(η^2-peroxo) complex **18**$^+$ instead of η^2-peroxo complex **17**$^+$. Apparently ethene binds stronger to iridium(III) than to rhodium(III).[14] Changing the ligand from Me_3-tpa in **14**$^+$ to Me-tpa in **4**$^+$ results in 2-iridaoxetane **8**$^+$, instead of the (ethene)(peroxo) complex **18**$^+$, as the observed product.

One could imagine peroxo species of type **a** (analogues of **17**; Scheme 5) to react with olefins, yielding 3-metalla-1,2-dioxolanes **c** (analogues of **9**$^+$ or **10**$^+$; Scheme 1) or 2-metallaoxetanes **d** (analogues of **1**−**4**; Scheme 1). Insertion of ethene into the Ir−O bond of (ethene)(peroxo) complexes **b** (analogues of **18**$^+$ or **19**$^+$; Scheme 5) would seem a simple and viable route to 3-metalla-1,2-dioxalanes **c**. However, at room temperature, the (peroxo)Rh^{III} species **17**$^+$ shows no further reactivity towards ethene, and the (ethene)(peroxo)Ir^{III} complexes **18**$^+$ and **19**$^+$ do not undergo insertion of ethene into the Ir−O bond. The 3-metalla-1,2-dioxolane isomers **9**$^+$ and **10**$^+$ (Scheme 1) are only formed from **1**$^+$ and **3**$^+$ in the *solid state*, whereas *in solution* very aselective reactions yield other products without any indication for the formation of **9**$^+$ or **10**$^+$. It is hard to believe that chelate ring opening, which would be required to form a (ethene)(peroxo) complex analogous to **18**$^+$, plays a role in the *solid state* reactions. Therefore, 3-metalla-1,2-dioxolanes **c** probably form by alternative routes in the *solid state*.

In **14**$^+$, relieving the steric strain by the Me substituents in the κ^4-coordination mode of the Me_3-tpa ligand through dissociation of a 6-methylpyridyl fragment apparently opens up the "κ^3-route" to the formation of **18**$^+$. As such strain is absent in the Me-tpa complex **4**$^+$, formation of 2-iridaoxetane **8**$^+$ might proceed by a "κ^4-route". However, we cannot exclude that the formation of the (ethene)-(peroxo) complex **18**$^+$, instead of an analogue of 2-iridaoxetane **8**$^+$ (Scheme 1), merely reflects a thermodynamic preference, resulting from the weaker N-donor capacity of the Me_3-tpa ligand.

Experimental Section

General Methods: All procedures were performed under N_2 using standard schlenk techniques unless otherwise indicated. Solvents (p.a.) were deoxygenated by bubbling a stream of N_2 through the solvent or by the freeze-pump-thaw method. Room temperature corresponds to ca. 20 °C. NMR spectroscopic experiments were carried out with a Bruker DPX200 (200 MHz and 50 MHz for ^{1}H and ^{13}C, respectively), a Bruker AC300 (300 MHz and 75 MHz for ^{1}H and ^{13}C, respectively), a Varian Inova 400 (400 MHz and 100 MHz for ^{1}H and ^{13}C, respectively) and a Bruker AM500 (500 MHz and 125 MHz for ^{1}H and ^{13}C, respectively). Solvent shift reference for ^{1}H NMR spectroscopy: [D_6]acetone δ_H = 2.05, CD_3CN δ_H = 1.94, CD_2Cl_2 δ_H = 5.31. For ^{13}C NMR: [D_6]acetone δ_C = 29.50, CD_3CN δ_C = 1.25, CD_2Cl_2 δ_C = 54.20. Abbreviations used are s = singlet, d = doublet, dd = doublet of doublets, t = triplet, dt= doublet of triplets, q = quadruplet, dq = doublet of quadruplets, m = multiplet and br = broad. Py^A represents the two equivalent 6-methylpyridyl groups, Py^B represents the unique 6-methylpyridyl group. Elemental analyses (C,H,N) were carried out with a Carlo Erba NCSO analyzer. Mass spectra (FAB, ESI) were recorded with a MAT 900 XL mass spectrometer or a JEOL JMS SX/SX102A four-sector mass spectrometer. Cyclic voltammetry measurements were performed using an Eco Chemie Autolab PGSTAT20. A conventional three-electrode cell, with Pt working and auxiliary electrodes and 0.1 M [(nBu)$_4$N]PF_6 (TBAH) electrolyte was used. An Ag/AgI reference electrode (grain of AgI, 0.02 M [(nBu)$_4$N]I (TBAI) and 0.1 M TBAH) was employed. Me_3-tpa,[15] [{(C_2H_4)$_2$Rh(μ-Cl)}$_2$],[16] and [{(coe)$_2$Ir(μ-Cl)}$_2$][10] were prepared according to literature procedures. All other chemicals were commercially available and were used without further purification, unless otherwise stated.

X-ray Diffraction: Single crystals were mounted in air on glass fibers. Intensity data were collected at room temperature. An Enraf−Nonius CAD4 single-crystal diffractometer was used, applying graphite-monochromatized Cu-K_α or Mo-K_α radiation. Unit cell dimensions were determined from the angular setting of 22 reflections for [**12**]PF_6, 24 reflections for [**18**]PF_6 and 25 reflections for [**19**]PF_6. Intensity data were corrected for Lorentz and polarization effects. Semiempirical absorption correction (ψ-scan) was applied for all compounds.[17] The structures were solved by the program system DIRDIF[18] using the program PATTY[19] to locate the heavy atoms. All structures were refined with standard methods (refinement against F^2 of all reflections with SHELXL-97[20]) with anisotropic parameters for the non-hydrogen atoms. Hydrogen atoms were placed at calculated positions and were subsequently refined isotropically in riding mode. For [**18**]PF_6 and [**19**]PF_6 geometrical data with regard to O1, O2, C1, and C2 are rather similar. The assignment of atomic species has been made on the basis of prior occupancy factor refinement and comparison of thermal displacement parameters. Selected bond lengths and angles are summarized in Figures 1−3. Drawings were generated with the program PLATON.[21] Other relevant crystal data are summarized in Table 2. Crystallographic data (excluding structure factors) for the

structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-176106 for [**12**]PF_6, -176105 for [**18**]PF_6, and -176104 for [**19**]PF_6. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

[12]PF_6: The structure determination was hampered by the poor quality of the data caused by the inferior quality of the crystals, which was, unfortunately, the best that could be achieved. The crystal diffracted very weakly, and no reliable data could be collected at θ > 55° (resolution 0.95 Å). Moreover a more than average crystal decay was observed, up to 17%. No attempt was made to locate the hydrogen atoms attached to the disordered CH_3OH and partially occupied H_2O moieties; they cannot be calculated and no indication whatsoever of their location was found in the difference fourier map. From the anisotropic thermal displacement parameters for the PF_6 moiety it is clear that these atoms show a large positional disorder. Although it is possible to use several partially occupied positions for these atoms, no physically reasonable model results from these parameters, at least not any better than the model presented here. Because the EMPABS procedure,[17] by itself, was not adequate enough, presumably caused by the poor quality of the data and hence the ψ-scans, an additional absorption correction was applied using the DIFABS procedure.[22] Even then it was necessary to use the SIMU option in the least-squares refinement to end up with physically acceptable anisotropic thermal displacement parameters. Geometrical calculations (PLATON-93)[21] revealed neither unusual geometric features, nor unusual short intermolecular contacts. The calculations revealed no higher symmetry and no (further) solvent accessible areas.

[18]PF_6: Unfortunately the crystal structure determination was influenced by a rather severe but regular crystal decay of up to 43%. From the anisotropic thermal displacement parameters for the PF_6 moiety it is clear that these atoms show a large positional disorder. Although it is possible to use several partially occupied positions for these atoms, no physically reasonable model results from these parameters, at least not any better than the model presented here. Moreover, the model presented here was the only one that was stable by itself without the need for additional restraints. Calculations (PLATON-93)[21] showed a small void of 162 Å^3, containing at least 6 electrons, around 0,1/2,0. This electron density is assumed to be a disordered water molecule, and the SQUEEZE (PLATON-93) procedure was applied to account for this electron density. This assumption accounts for the physical molecular properties as given in Table 2.

[19]PF_6: Geometrical calculations (PLATON-93)[21] revealed neither unusual geometric features, nor unusual short intermolecular contacts. The calculations revealed no higher symmetry and no solvent accessible areas.

Syntheses

Methylbis[(6-methyl-2-pyridyl)methyl]amine (Me_2-dpa-Me): To CH_3CN (300 mL), 2-(chloromethyl)-6-methylpyridine·HCl[23] (7.98

g, 44.8 mmol), CH_3NH_2·HCl (2.27 g, 33.6 mmol), Na_2SO_4 (25.00 g), and Na_2CO_3 (47.50 g) were added. The resulting suspension was heated to reflux for 16 h. The mixture was filtered and the filtrate was concentrated yielding a brown oil, to which Et_2O (100 mL) was added. Partial evaporation of the solvent resulted in precipitation of Me_2-dpa-Me as a white solid (> 95% pure according to GC), which was crystallized as white crystals from a saturated hexane solution at −20 °C. Yield 2.52 g (16.8 mmol, 50%). An alternative synthetic route to Me_2-dpa-Me has been reported, mentioning its melting point and C,H,N analysis.[24] ^{1}H NMR (200.13 MHz, $CDCl_3$, 289 K): δ [ppm] = 7.54 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H^4), 7.34 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H^3), 7.00 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H^5), 3.74 (s, 4 H, N-*CH*$_2$-Py^{Me}), 2.54 (s, 6 H, Py-*CH*$_3$), 2.30 (s, 3 H, N-*CH*$_3$). ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 289 K): δ [ppm] = 158.6 (Py-C^2), 157.4 (Py-C^6), 136.4 (Py-C^4), 121.2 (Py-C^5), 119.6 (Py-C^3), 63.6 (N-*C*H$_2$-Py^{Me}), 42.6 (N-*C*H$_3$), 24.3 (Py-*C*H$_3$).

[(κ^4-Me$_3$-tpa)Rh^I(C$_2$H$_4$)]PF$_6$ ([11]PF$_6$): [(C$_2$H$_4$)$_2$Rh(μ-Cl)]$_2$ (270 mg, 0.69 mmol) and Me_3-tpa (375 mg, 1.13 mmol) were stirred in MeOH (55 mL) at −78 °C for about 4 h until a clear solution was obtained. Subsequently, KPF_6 (127 mg, 0.69 mmol) was added. Partial evaporation of the solvent caused the precipitation of [**11**]PF_6 as a yellow powder, which was collected by filtration and dried under vacuum. Yield 370 mg (0.61 mmol, 63%). ^{1}H NMR 200.13 MHz, CD_2Cl_2, 298 K): δ [ppm] = 7.42 (t, $^3J_{H,H}$ = 7.8 Hz, 3 H, Py^A-H^4 and Py^B-H^4), 7.16 (d, $^3J_{H,H}$ = 7.3 Hz, 1 H, Py^B-H^3 or Py^B-H^5), 7.04 (d, $^3J_{H,H}$ = 7.6 Hz, 2 H, Py^A-H^3 or Py^B-H^5), 6.89 (d, $^3J_{H,H}$ = 7.6 Hz, 3 H, Py^B-H^3 or -H^5 or Py^A-H^3 or -H^5), 5.63 (d[AB], $^2J_{H,H}$ = 15.3 Hz, 2 H, N-*CH*$_2$-Py^A), 4.80 (d[AB], $^2J_{H,H}$ = 15.3 Hz, 2 H, N-*CH*$_2$-Py^A), 4.41 (s, 2 H, N-*CH*$_2$-Py^B), 3.71 (s, 3 H, Py^B-*CH*$_3$), 2.87 (s, 6 H, Py^A-*CH*$_3$), 2.54−2.34 (m, 2 H, *CH*$_2$=CH$_2$), 2.25−2.05 (m, 2 H, CH$_2$=*CH*$_2$). ^{13}C{^{1}H} NMR (50.32 MHz, CD_2Cl_2, 289 K): δ [ppm] = 163.8 (Py^B-C^2), 163.6 (Py^A-C^2), 161.0 (Py^B-C^6), 159.6 (Py^A-C^6), 138.0 (Py^B-C^4), 137.8 (Py^A-C^4), 125.5 (Py^A-C^3), 124.5 (Py^B-C^3), 120.5 (Py^A-C^5), 119.9 (Py^B-C^5), 70.5 (N-*C*H$_2$-Py^A), 63.7 (N-*C*H$_2$-Py^B), 31.7 (Py^B-*C*H$_3$), 29.5 (d, $^1J_{Rh,H}$ = 16.9 Hz, *CH*$_2$=CH$_2$), 28.2 (Py^A-*C*H$_3$), 26.3 (d, $^1J_{Rh,H}$ = 19.9 Hz, CH$_2$=*CH*$_2$). FAB$^+$-MS: *m*/*z* = 463 [M − PF$_6$]$^+$. $C_{23}H_{28}F_6N_4PRh$ (608.37): calcd. C 45.41, H 4.64, N 9.21; found C 45.18, H 4.71, N 9.40.

[(κ^3-Me$_3$-tpa)Ir^I(C$_2$H$_4$)$_2$]PF$_6$ ([12]PF$_6$): [Ir(coe)$_2$Cl)$_2$ (350 mg, 0.39 mmol) was dissolved in methanol (14 mL). Ethene was bubbled through the solution until a clear solution was obtained. The solution was cooled to −30 °C and Me_3-tpa (260 mg, 0.78 mmol) was added under ethene. The reaction mixture was stirred until the Me_3-tpa had dissolved. Subsequently, KPF_6 (170 mg, 0.92 mmol) was added and the solution was stirred for 1 h at −30 °C, after which the solution was cooled to −78 °C causing the precipitation of [**12**]PF_6. A second portion was obtained by adding KPF_6 (25 mg, 0.14 mmol) to the filtrate, stirring for 1 h at −50 °C, and leaving overnight at −20 °C. The yellow solid thus obtained was collected by filtration, washed three times with cold methanol (−78 °C) under nitrogen and dried under vacuum. Yield: 311 mg (0.43 mmol, 55%). ^{1}H NMR (200.13 MHz, CD_2Cl_2, 289 K): δ [ppm] = 7.80 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, Py^B-H^4), 7.71 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^4), 7.38 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py$^{A/B}$-H$^{3/5}$), 7.34 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py$^{A/B}$-H$^{3/5}$), 7.24 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py$^{A/B}$-H$^{3/5}$), 5.26 (d[AB], $^2J_{H,H}$ = 16.0 Hz, 2 H, N-*CH*$_2$-Py^A), 4.94 (s, 2 H, N-*CH*$_2$-Py^B), 3.92 (d[AB], $^2J_{H,H}$ = 16.0 Hz, 2 H, N-*CH*$_2$-Py^A), 3.28 (s, 6 H, CH$_3$-Py^A). 2.62 (s, 3 H, CH$_3$-Py^B), 2.02 (br, 4 H, CH$_2$=CH$_2$), 1.81 (br, 4 H, CH$_2$=CH$_2$). $C_{25}H_{32}F_6IrN_4P$ (725.74): calcd. C 41.38, H 4.44, N 7.72, found C 41.19, H 4.20, N 7.80.

[(κ^3-Me$_2$-dpa-Me)Ir^I(C$_2$H$_4$)$_2$]PF$_6$ ([13]PF$_6$): [Ir(coe)$_2$Cl]$_2$ (350 mg, 0.39 mmol) was dissolved in methanol (14 mL), ethene was bubbled through the solution until a clear solution was obtained. The solution was cooled to −30 °C and Me_2-dpa-Me (190 mg, 0.79 mmol) was added under ethene. The reaction mixture was stirred until the Me_2-dpa-Me had dissolved. Subsequently, KPF_6 (170 mg, 0.92 mmol) was added and the solution was stirred for 1 h at −30 °C, after which the solution was cooled to −78 °C causing precipitation of [**13**]PF_6. A second portion was obtained by adding KPF_6 (25 mg, 0.14 mmol) to the filtrate, stirring for 1 h at −50 °C, and leaving overnight at −20 °C. The resulting yellow solid was collected by filtration, washed three times with cold methanol (−78 °C) under nitrogen and dried under vacuum. Yield: 234 mg (0.37 mmol, 47%). ^{1}H NMR (200.13 MHz, CD_3CN, 289 K): δ [ppm] = 7.73 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H^4), 7.37 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H$^{3/5}$), 7.27 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H$^{3/5}$), 4.64 (d[AB], $^2J_{H,H}$ = 15.8 Hz, 2 H, CH$_2$-Py), 4.10 (d[AB], $^2J_{H,H}$ = 15.8 Hz, 2 H, CH$_2$-Py), 3.34 (s, 3 H, CH$_3$-N), 3.18 (s, 6 H, CH$_3$-Py), 1.83 (br, 4 H, CH$_2$=CH$_2$), 1.67 (br, 4 H, CH$_2$=CH$_2$). $C_{19}H_{27}F_6IrN_3P$ (634.63): calcd. C 35.96, H 4.29, N 6.62; found C 35.66, H 4.10, N 6.39.

[(κ^4-Me$_3$-tpa)Ir^I(C$_2$H$_4$)]PF$_6$ ([14]PF$_6$): Compound [**12**]PF_6 (100 mg, 0.14 mmol) was dissolved in acetone (5 mL) and stirred for 4 h under nitrogen at room temp. The gas phase was flushed with fresh nitrogen every hour. Subsequently, 25 mL of hexane was added causing precipitation of [**14**]PF_6. The resulting orange solid was collected by filtration, washed 3 times with cold hexane and dried under vacuum. Yield 42 mg (0.07 mmol, 50%). ^{1}H NMR (200.13 MHz, CD_3CN, 289 K): δ [ppm] = 7.54 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, Py^B-H^4), 7.50 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^4), 7.24 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^3/Py^B-H$^{3\&5}$), 7.09 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H$^{5/3}$/Py^B-H$^{3\&5}$), 7.02 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^5/Py^B-H$^{3\&5}$), 5.29 (d[AB], $^2J_{H,H}$ = 15.3 Hz, N-*CH*$_2$-Py^A), 4.85 (d[AB], $^2J_{H,H}$ = 15.3 Hz N-*CH*$_2$-Py^A), 4.64 (s, N-*CH*$_2$-Py^B), 3.65 (s, 3 H, Py^B-CH$_3$), 2.85 (s, 6 H, Py^A-CH$_3$), 1.85 (t, 2 H, $^3J_{H,H}$ = 8.6 Hz, *CH*$_2$=CH$_2$), 1.37 (t, 2 H, $^3J_{H,H}$ = 8.58 Hz, CH$_2$=*CH*$_2$). ^{1}H NMR (400.14 MHz, [D$_6$]acetone, 289 K): δ [ppm] = 7.72 (t, $^3J_{H,H}$ = 7.8 Hz, 1 H, Py^B-H^4), 7.60 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py^A-H^4), 7.35 (d, $^3J_{H,H}$ = 7.2 Hz, 1 H, Py^B-H^3), 7.26 (d, $^3J_{H,H}$ = 7.6 Hz, 2 H, Py^A-H^3), 7.15 (d, $^3J_{H,H}$ = 7.3 Hz, 1 H, Py^B-H^5), 7.81 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py^A-H^5), 5.49 (d[AB], $^2J_{H,H}$ = 15.2 Hz, N-*CH*$_2$-Py^A), 5.11 (d[AB], $^2J_{H,H}$ = 15.2 Hz, N-*CH*$_2$-Py^A), 4.90 (s, N-*CH*$_2$-Py^B), 3.75 (s, 3 H, Py^B-*CH*$_3$), 2.94 (s, 6 H, Py^A-*CH*$_3$), 1.89 (t, 2 H, $^3J_{H,H}$ = 8.6 Hz, *CH*$_2$=CH$_2$), 1.47 (t, 2 H, $^3J_{H,H}$ = 8.79 Hz, CH$_2$=*CH*$_2$). ^{13}C{^{1}H} NMR (100.61 MHz, [D$_6$]acetone, 289 K): δ [ppm] = 164.6 (Py^A-C^6), 163.2 (Py^A-C^2), 161.8 (Py^B-C^6), 160.2 (Py^B-C^2), 138.4 (Py^B-C^4), 136.9 (Py^A-C^4), 124.7 (Py^A-C^5), 123.5 (Py^B-C^5), 119.8 (Py^A-C^3), 118.9 (Py^B-C^3), 71.7 (N-*C*H$_2$-Py^A), 65.2 (N-*C*H$_2$-Py^B), 32.5 (Py^B-*C*H$_3$), 27.2 (Py^A-*C*H$_3$), 3.7 (*C*H$_2$=CH$_2$), 0.2 (CH$_2$=*C*H$_2$). ESI$^+$-MS: *m*/*z* = 553 [M − PF$_6$]$^+$. $C_{23}H_{28}F_6IrN_4P$ (697.69): calcd. C 39.60, H 4.04, N 8.03; found C 39.43, H 4.17, N 8.20.

[(κ^3-Me$_2$-dpa-Me)Ir^I(C$_2$H$_4$)]PF$_6$ ([15]PF$_6$): Dissolving [**13**]PF_6 in CD_2Cl_2 resulted in the formation of [**15**]PF_6 within 2 h. ^{1}H NMR (200.13 MHz, CD_2Cl_2, 289 K): δ [ppm] = 7.59 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py-H^4), 7.17 (d, $^3J_{H,H}$ = 7.5 Hz, 2 H, Py-H^3), 7.05 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, Py-H^5), 5.07 (d[AB], $^2J_{H,H}$ = 14.9 Hz, N-*CH*$_2$-Py), 4.75 (d[AB], $^2J_{H,H}$ = 14.9 Hz, N-*CH*$_2$-Py), 3.59 (t, $^3J_{H,H}$ = 9.7 Hz, 2 H, *CH*$_2$=CH$_2$), 3.15 (s, 3 H, N-CH$_3$), 2.66 (s, 6 H, Py-CH$_3$), 2.36 (t, $^3J_{H,H}$ = 9.7 Hz, 2 H, CH$_2$=*CH*$_2$). ^{1}H NMR (400.14 MHz, CD_3CN, 289 K): δ [ppm] = 7.63 (t, $^3J_{H,H}$ = 7.9 Hz, 2 H, Py-H^4), 7.18 (d, $^3J_{H,H}$ = 7.4 Hz, 2 H, Py-H^3), 7.11 (d, $^3J_{H,H}$ = 7.9 Hz, 2

H, Py-H^5), 5.06 (d[AB], $^2J_{H,H}$ = 15.1 Hz, N-*CH*$_2$-Py), 4.71 (d[AB], $^2J_{H,H}$ = 15.1 Hz, N-*CH*$_2$-Py), 3.54 (t, $^3J_{H,H}$ = 9.7 Hz, 2 H, *CH*$_2$=CH$_2$), 3.11 (s, 3 H, N-CH$_3$), 2.64 (s, 6 H, Py-CH$_3$), 2.34 (t, $^3J_{H,H}$ = 9.7 Hz, 2 H, CH$_2$=*CH*$_2$). ^{13}C{^{1}H} NMR (75.47 MHz, CD$_3$CN, 289 K): δ [ppm] = 166.6 (Py-C^6), 164.4 (Py-C^2), 138.7 (Py-C^4), 127.2 (Py-C^5), 121.9 (Py-C^3), 72.2 (N-*C*H$_2$-Py), 52.4 (N-*C*H$_3$), 37.0 (*C*H$_2$=CH$_2$), 27.1 (Py-*C*H$_3$), 25.1 (CH$_2$=*C*H$_2$). Due to the instability of [**15**]PF$_6$, reliable elemental analytical data were not obtained.

[(κ^3-Me$_2$-dpa-Me)Ir^{I}(C$_2$H$_4$)]PF$_6$ ([15(MeCN)]PF$_6$): Dissolving [**13**]PF$_6$ in CD$_3$CN resulted in a 3:1 mixture of [**15**]PF$_6$ and [**15**(MeCN)]PF$_6$ within 2 h. ^{1}H NMR (400.14 MHz, CD$_3$CN, 289 K): δ [ppm] = 7.63 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py-H^4), 7.20 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, Py-H^3), 7.16 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py-H^5), 4.95 (d[AB], $^2J_{H,H}$ = 14.9 Hz, N-*CH*$_2$-Py), 4.57 (d[AB], $^2J_{H,H}$ = 14.9 Hz, N-*CH*$_2$-Py), 2.91 (s, 6 H, Py-CH$_3$), 2.78 (s, 3 H, N-CH$_3$), 1.94 (t, $^3J_{H,H}$ = 8.7 Hz, 2 H, *CH*$_2$=CH$_2$), 1.28 (t, $^3J_{H,H}$ = 8.7 Hz, 2 H, CH$_2$=*CH*$_2$). ^{13}C{^{1}H} NMR (75.47 MHz, CD$_3$CN, 289 K): δ [ppm] = 166 (Py-C^6), 164 (Py-C^2), 137.0 (Py-C^4), 127.2 (Py-C^5), 120.0 (Py-C^3), 72.6 (N-*C*H$_2$-Py), 51.4 (N-*C*H$_3$), 27.6 (Py-*C*H$_3$). ^{13}C NMR signals of the ethene fragment could not be observed at 289 K. Due to the instability of [**15**(MeCN)]PF$_6$, reliable elemental analytical data were not obtained.

[(κ^4-C,*N*,*N*′,*N*′′-Me$_3$-tpa)Ir(H)(CD$_3$CN)]PF$_6$ ([16]PF$_6$): Compound [**14**]PF$_6$ (20 mg, 0.03 mmol) was dissolved in MeCN (1 mL) and was kept for 3 d under nitrogen. Sample prepared in CD$_3$CN: CPy represents the unique cyclometallated pyridyl group (at C^3). ^{1}H NMR (500 MHz, CD$_3$CN, 289 K): δ [ppm] = 7.81 (d, $^3J_{H,H}$ = 7.7 Hz, CPy-H^5), 7.63 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^4), 7.25 (d, $^3J_{H,H}$ = 7.2 Hz, 2 H, Py^A-H^3), 7.23 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^5), 6.48 (d, $^3J_{H,H}$ = 7.7 Hz, CPy-H^4), 5.09 (d[AB], $^2J_{H,H}$ = 15.3 Hz, 2 H, N-*CH*$_2$-Py^A), 5.04 (d[AB], $^2J_{H,H}$ = 15.3 Hz, 2 H, N-*CH*$_2$-Py^A), 4.41 (s, 2 H, N-*CH*$_2$-CPy), 2.81 (s, 6 H, Py^A-CH$_3$), 2.13 (s, 3 H, CPy-CH$_3$), −18.58 (s, Ir-H). ^{13}C{^{1}H} NMR (75.47 MHz, CD$_3$CN, 289 K): δ [ppm] = 169.6 (CPy-C^6), 167.0 (Py^A-C^6), 164.6 (CPy-C^2), 151.8 (CPy-C^5), 151.2 (Py^A-C^2), 139.0 (Py^A-C^4), 127.3 (CPy-C^3-Ir), 124.9 (Py^A-C^5), 121.9 (CPy-C^4), 121.7 (Py^A-C^3), 70.4 (N-*C*H$_2$-Py^A), 68.8 (N-*C*H$_2$-CPy), 31.6 (*C*H$_3$-Py^A), 23.2 (*C*H$_3$-CPy). ESI-MS: *m*/*z* = 569 [M − PF$_6$]$^+$. Sample prepared in CH$_3$CN: ESI-MS: *m*/*z* = 566 [M − PF$_6$]$^+$. C$_{23}$H$_{27}$F$_6$IrN$_5$P (710.68): calcd. C 38.87, H 3.83, N 9.85; found C 39.07, H 4.01, N 9.99.

[(κ^4-C,*N*,*N*′,*N*′′-Me$_3$TPA)Ir(H)(C$_2$H$_4$)](PF$_6$): [**14**]PF$_6$ (10 mg, 0.015 mmol) was dissolved in CD$_2$Cl$_2$ (1 mL) and kept for 3 d under nitrogen. ^{1}H NMR: (200 MHz, CD$_2$Cl$_2$): δ [ppm] = 8.23 (d, CPy-H^5, $^3J_{H,H}$ = 7.4 Hz), 7.58 (t, 2 H, Py^A-H^4, $^3J_{H,H}$ = 7.9 Hz), 7.22 (d, 2 H, CPy-H^3, $^3J_{H,H}$ = 7.7 Hz), 7.13 (d, 2 H, Py^A-H^5, $^3J_{H,H}$ = 7.7 Hz), 6.70 (d, CPy-H^4, $^3J_{H,H}$ = 7.7 Hz), 5.50 (d[AB], N-*CH*$_2$-Py^A, $^2J_{H,H}$ = 16.0 Hz), 5.27 (d[AB], N-*CH*$_2$-Py^A, $^2J_{H,H}$ = 16.0 Hz), 4.68 (s, 2 H, N-*CH*$_2$-CPy), 3.53 (s, 4 H, *CH*$_2$=*CH*$_2$), 2.75 (s, 6 H, Py^A-*CH*$_3$), 2.22 (s, 3 H, CPy-*CH*$_3$), -15.87 (s, Ir-*H*).

[(k^4-Me$_3$-tpa)Rh^{III}(O$_2$)]PF$_6$ ([17]PF$_6$): A solution of [**11**]PF$_6$ (50 mg, 0.082 mmol) in CH$_2$Cl$_2$ (2 mL) was vigorously stirred at room temperature in contact with O$_2$ for about 30 min. The peroxo complex **17** was formed in 100% yield. Addition of hexane to the solution caused precipitation of [**17**]PF$_6$ as a light-brown solid, which was collected by filtration and dried under vacuum. ^{1}H NMR (200.13 MHz, CD$_2$Cl$_2$, 298 K): δ [ppm] = 7.63 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, Py^A-H^4), 7.60 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, Py^B-H^4), 7.34 (d, $^3J_{H,H}$ = 7.6 Hz, 1 H, Py^B-H^3 or -H^5), 7.24 (d, $^3J_{H,H}$ = 7.6 Hz, 2 H, Py^A-H^3 or -H^5), 7.11 (d, $^3J_{H,H}$ = 7.8 Hz, 1 H, Py^B-H^3 or -H^5), 7.10 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, Py^A-H^3 or -H^5), 5.64 (d[AB], $^2J_{H,H}$ = 15.5 Hz, 2 H, N-C*H*$_2$-Py^A), 5.15 (d[AB], $^2J_{H,H}$ = 15.5 Hz, 2 H, N-C*H*$_2$-Py^A), 4.68 (s, 2 H, N-C*H*$_2$-Py^B), 3.56 (s, 3 H, Py^B-C*H*$_3$), 3.03 (s, 6 H, Py^A-C*H*$_3$). ^{13}C{^{1}H} NMR (50.31 MHz, CD$_2$Cl$_2$, 298 K): δ [ppm] = 165.4, 162.7, 162.6, 160.3 (Py^B- and Py^A-C^2, Py^B- and Py^A-C^6), 139.8 (Py^A-C^4), 139.5 (Py^B-C^4), 127.6 (Py^A-C^3), 126.3 (Py^B-C^3), 120.8 (Py^A-C^5), 119.9 (Py^B-C^5), 72.0 (N-*C*H$_2$-Py^A), 67.5 (N-*C*H$_2$-Py^B), 31.3 (Py^B-*C*H$_3$), 24.2 (Py^A-*C*H$_3$). FAB$^+$-MS: *m*/*z* = 467 [M − PF$_6$]$^+$: *m*/*z* = 1079 [2 M − PF$_6$]$^+$. ESI-MS with argon as a collision gas: *m*/*z* = 467 [M − PF$_6$]$^+$. C$_{21}$H$_{24}$F$_6$N$_4$O$_2$PRh (612.32): calcd. C 41.19, H 3.95, N 9.15; found C 40.29, H 4.72, N 8.46.

[(κ^3-Me$_3$-tpa)Ir^{III}(C$_2$H$_4$)(O$_2$)]PF$_6$ ([18]PF$_6$): Compound [**14**]PF$_6$ (40 mg, 0.06 mmol) was dissolved in dichloromethane (4 mL) and placed under 1.6 bar of O$_2$ for 30 min. The solution was filtered and dried under vacuum. Yellow/brown crystals of [**18**]PF$_6$, suitable for X-ray diffraction, were obtained by vapor-vapor diffusion of diethyl ether and a solution of [**18**]PF$_6$ in MeCN. A separate volumetric gas-uptake measurement indicated consumption of 1 mol of O$_2$ per mol of [**14**]PF$_6$. During this reaction [**14**]PF$_6$ (150 mg, 0.15 mmol) consumed ca. 3.40 mL of O$_2$ (0.14 mmol). Isolated yield 7.3 mg (0.01 mmol, 16%). ^{1}H NMR (400.14 MHz, [D$_6$]acetone, 289 K): δ [ppm] = 7.97 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py^A-H^4), 7.82 (t, $^3J_{H,H}$ = 7.6 Hz, 1 H, Py^B-H^4), 7.63 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py^A-H^3), 7.43 (d, $^3J_{H,H}$ = 7.4 Hz, 1 H, Py^B-H^5), 7.41 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py^A-H^5), 7.37 (d, $^3J_{H,H}$ = 7.6 Hz, 1 H, Py^B-H^3), 5.79 (d[AB], $^3J_{H,H}$ = 16.0 Hz, 2 H, Py^A-*CH*$_2$-N), 5.05 (d[AB], $^3J_{H,H}$ = 16.0 Hz, 2 H, Py^A-*CH*$_2$-N), 4.80 (s, 2 H, Py^B-*CH*$_2$-N), 4.48 (br, 4 H, *CH*$_2$=*CH*$_2$), 2.96 (s, 6 H, Py^A-CH$_3$), 2.65 (s, 3 H, Py^B-CH$_3$). ^{13}C{^{1}H} NMR (75.47 MHz, [D$_6$]acetone, 289 K): δ (ppm) = 166 (Py^A-C^2), 166 (Py^A-C^2), 165 (Py^A-C^6), 159.5 (Py^B-C^6), 151 (Py^B-C^2), 140.2 (Py^A-C^4), 137.9 (Py^B-C^4), 128 (Py^A-C^5), 124.5 (Py^B-C^3), 124 (Py^B-C^5), 122 (Py^A-C^3), 65.5 (N-*C*H$_2$-Py^A), 62.7 (N-*C*H$_2$-Py^B), 22.0 (Py^A-*C*H$_3$ & Py^B-*C*H$_3$). ^{13}C NMR signals of the ethene fragment could not be observed at 289 K. ESI-MS: 585 [M − PF$_6$]$^+$, 557 [M − PF$_6$ − C$_2$H$_4$]$^+$, 553 [M − PF$_6$ − O$_2$]$^+$, 566 [M − PF$_6$ − O$_2$ − C$_2$H$_4$ + CH$_3$CN]$^+$. C$_{23}$H$_{28}$F$_6$IrN$_4$O$_2$P (729.68): calcd. C 37.86, H 3.87, N 7.68; found C 38.05, H 4.03, N 7.85.

[(κ^3-Me$_2$-dpa-Me)Ir^{III}(C$_2$H$_4$)(O$_2$)]PF$_6$ ([19]PF$_6$): [**15**]PF$_6$ (40 mg, 0.112 mmol) was dissolved in 4 mL of dichloromethane and placed under of 1.6 bar of O$_2$ for 30 min. The solution was filtered and dried under vacuum. Light-brown crystals of [**19**]PF$_6$, suitable for X-ray diffraction, were obtained by vapor-vapor diffusion of hexane and a solution of [**19**]PF$_6$ in acetone. Isolated yield 7.7 mg (0.012 mmol, 16%). ^{1}H NMR (400.14 MHz, CD$_3$CN, 289 K): δ [ppm] = 7.78 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py-H^4), 7.35 (d, $^3J_{H,H}$ = 7.8 Hz, 1 H, Py-H^3), 7.22 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, Py-H^5), 4.93 (d[AB], $^2J_{H,H}$ = 15.6 Hz, 2 H, N-*CH*$_2$-Py), 4.86 (d[AB], $^2J_{H,H}$ = 15.6 Hz, 2 H, N-*CH*$_2$-Py), 4.22 (br, 4 H, C$_2$H$_4$), 3.23 (s, 3 H, N-CH$_3$), 2.82 (s, 6 H, Py-CH$_3$). ^{1}H NMR (400.14 MHz, [D$_6$]acetone, 289 K): δ [ppm] = 7.93 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py-H^4), 7.56 (d, $^3J_{H,H}$ = 7.8 Hz, 1 H, Py-H^3), 7.37 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, Py-H^5), 5.53 (d[AB], $^2J_{H,H}$ = 15.6 Hz, 2 H, N-*CH*$_2$-Py), 5.21 (d[AB], $^2J_{H,H}$ = 15.6 Hz, 2 H, N-*CH*$_2$-Py), 4.36 (br, 4 H, *CH*$_2$=*CH*$_2$), 3.41 (s, 3 H, N-*CH*$_3$), 2.92 (s, 6 H, Py-*CH*$_3$). ^{13}C{^{1}H} NMR (75.47 MHz, CD$_3$CN, 289 K): δ [ppm] = 166.1 (Py-C^2), 165.5 (Py-C^6), 140.7 (Py-C^4), 128.6 (Py-C^5), 122.5 (Py-C^3), 71.3 (N-*C*H$_2$-Py), 52.7 (N-*C*H$_3$), 23.0 (Py-*C*H$_3$). ^{13}C NMR signals of the ethene fragment could not be observed at 289 K. C$_{17}$H$_{23}$F$_6$IrN$_3$O$_2$P (638.57): calcd. C 31.98, H 3.63, N 6.58; found C 32.14, H 3.61, N 6.38.

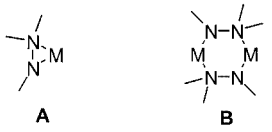
New Aspects in the Coordination Chemistry of Magnesium Hydrazides

Hermann Sachdev[a]

Keywords: Hydrazides / Coordination chemistry / Magnesium / N ligands

The coordination chemistry of alkaline earth metal hydrazides has been investigated, and the synthesis and crystal structures of monomeric magnesium bis[*N*-phenyl-*N*′,*N*′-bis-(trimethylsilyl)hydrazide] (**1**) and dimeric magnesium bis[*N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazide] (**2**) are presented. An unusual coordination sphere of the magnesium atom was observed in the first structurally characterized monomer magnesium hydrazide **1**, a highly reactive compound with side-on coordinated hydrazide ligands forming a bent butterfly-type structure. The Mg–N distances range from 1.92 to 2.45 Å and intramolecular C–H···Mg interactions in the range 2.42 to 2.63 Å are observed. This structural motif is unprecedented in the coordination chemistry of magnesium hydrazides.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Low-coordinated compounds of main-group metals are highly desired to study their structural chemistry and reactivity. They are considered to be potential candidates for the synthesis of ceramic composite materials by CVD techniques. Different ligand systems have been investigated to achieve low-coordinated, volatile compounds.[1,2] Hydrazines are interesting ligands due to an additional donor atom in the α-position, and metalated hydrazines exhibit a different coordination chemistry than the corresponding amides. Due to a second nitrogen atom in the adjacent α-position, intramolecular (**A**), as well as intermolecular (**B**) coordination of the metal centers is possible by the ligands.



The structural chemistry of the amides of group-1, -2 and -13 metals has already been widely characterized and indicates the formation of oligomeric or polymeric ring and cage structures.[3–5] Some recent aspects of the coordination chemistry of alkali metal hydrazides have been reported,[6–8] and the syntheses of aluminium and gallium hydraziedes were studied as possible precursors for AlN[3] and GaN.[10,11] These metal hydrazides share some common features with the corresponding amides, but also show significant differences in their coordination chemistry. Monomeric magnesium complexes containing monoanionic bidentate ligands are rare and the coordination chemistry of alkaline earth metal hydrazides is quite unexplored. The alkaline earth metal hydrazides were studied in order to compare the structures with the corresponding alkali metal hydrazides.

In this report, the structures of two magnesium hydrazides are presented. The aim was to investigate the coordination chemistry of alkaline earth metal hydrazides without the influence of donor solvents on the coordination sites at the metal atoms, hence a straightforward synthesis of the corresponding compounds was carried out. The deprotonation of the hydrazines was achieved by a solution of dibutylmagnesium in hexane according to Equations (1) and (2). This gave magnesium bis[*N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazide] (**1**) and magnesium bis[*N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazide] (**2**).

$$2\,(Me_3Si)_2N-N(H)Ph + MgBu_2 \rightarrow [(Me_3Si)_2N-N-Ph]_2Mg\,(\mathbf{1}) + 2\,Bu\text{-}H \quad (1)$$

$$2\,Me_2N-N(H)SiMe_3 + MgBu_2 \rightarrow [Me_2N-N-SiMe_3]_2Mg\,(\mathbf{2}) + 2\,Bu\text{-}H \quad (2)$$

In the case of hydrazide **1**, two isomers (**C**, **D**) are likely since migration of the silyl groups is a common feature of silylated hydrazines.[12] Silyl group migration also occurs during metalation and the resulting isomers are sometimes difficult to predict, as indicated by the formation of mixed isomers in lithiated silylhydrazines.[7,8] Structural characterizations of metalated phenylhydrazines have shown that a phenyl group is able to stabilize the negative charge of a hydrazide nitrogen atom better than a silyl group leading to an η^n coordination of the metal center ($n = 2-6$) by the π-electron system, hence the formation of isomer **C** is expected.[7b–7d]

Compound **1** was obtained from the reaction of *N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazine and dibutylmagnesium in hexane in a 73% yield in the form of colorless platelets according to Equation (1). It was characterized by ^{1}H, ^{13}C, and ^{29}Si NMR spectroscopy and X-ray crystallography.

The ^{29}Si NMR spectrum in hexane solution, as well as the spectrum of the isolated crystals of **1** in C_6D_6, exhibits only one resonance at $\delta = 8.70$ ppm. The ^{1}H and ^{13}C NMR data reveal a single resonance for the silyl groups, and four signals in the ^{13}C NMR for the phenyl group, which indicates the free rotation of the aryl unit. The data reveal a high symmetry for compound **1**.

The magnesium hydrazide **1** could be isolated from a hexane solution and it crystallizes in the monoclinic system (space group $P2_1/n$) containing four molecules per unit cell. The most remarkable feature of compound **1** is that it is monomeric in the solid state and no intermolecular interactions could be observed. The molecular structure of **1** is depicted in Figure 1.

In spite of the tetrahedral coordination geometry of the magnesium atom, which is common in e.g. donor-coordinated magnesium amides, an unprecedented type of coordination is adopted by the magnesium atom of compound **1** which displays an unusual arrangement of the hydrazide ligands. The magnesium atom Mg(1) exhibits four bonds with the nitrogen atoms of two side-on-coordinated hydrazide ligands giving a butterfly-shaped conformation. The individual molecule reveals a symmetry close to C_2. There are two types of Mg–N distances, short ones to the atoms N(1) and N(3) [Mg(1)–N(1) 1.918(2) Å, Mg(1)–N(3) 1.917(2) Å], both linked to the phenyl groups of the hydrazide ligands and which can be considered equal, and longer distances to the nitrogen atoms N(2) and N(4) of the NSi_2 groups [Mg(1)–N(4) 2.399(2) Å, Mg(1)–N(2) 2.448(2) Å]. The structural features of **1** resemble an sp^2-type hybridization for all nitrogen atoms in each hydrazide unit [sum of the bond angles at N(1) 360.0°, N(2) 359.9°, N(3) 359.8°, N(4) 359.4°], indicating that the basicity of the atoms N(2) and N(4) is low and an sp^3-type hybridization does not occur from the coordinative interaction of the $-NSi_2-$ nitrogen atoms with the magnesium atom. The nearest C–H···Mg interactions occur with the trimethylsilyl groups of the atoms Si(2) and Si(4), involving the carbon atoms C(6) and C(12), and are in the range of 2.417 to 2.625 Å. The shortest Mg–C distances [Mg(1)···C(6) 2.688 Å, Mg(1)···C(12) 2.696 Å] are longer than those reported for a monomeric dialkylmagnesium compound $Mg[CH(SiMe_3)_2]_2$ [Mg···C 2.535(4) Å],[13] but are of comparable magnitude as those found in a monomeric magnesium diamide $Mg[N(SiPh_2Me)_2]_2$,[14] and can be considered as quite weak. The Si–N distances involving the silyl groups Si(2) and Si(4) [1.760(2), 1.771(2) Å, respectively] are significantly longer than the distances involving the silyl groups Si(1) and Si(3) without C–H···Mg contacts [1.745(2), 1.749(2) Å], and are in general longer than the Si–N distances of tetrameric $[Ph(Li)N-N(SiMe_3)_2]_4$ and of the ether adducts of $Ph(Na)N-N(SiMe_3)_2$, which all exhibit coordinative metal–aryl interactions.[7b–7d] According to the solid-state structure of **1**, the silyl groups of the $-NSi_2$ unit are different, but the ^{29}Si NMR spectrum displays only one signal indicating a more symmetric species in solution.

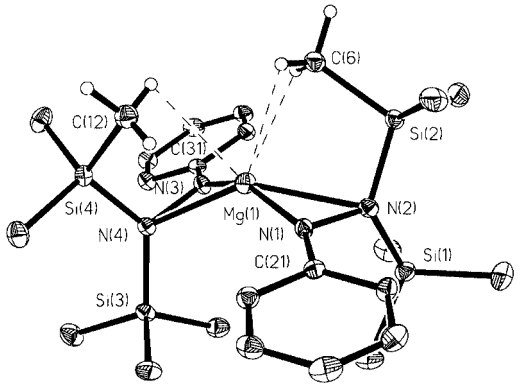

Figure 1. Molecular structure of monomeric magnesium bis[*N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazide] (**1**); thermal ellipsoids are shown at a 25% probability level and only hydrogen atoms at C(6) and C(12) are shown; selected atom distances [Å] and angles [°]: N(1)–N(2) 1.497(2), N(3)–N(4) 1.493(2), Mg(1)–N(3) 1.917(2), Mg(1)–N(1) 1.918(2), Mg(1)–N(4) 2.399(2), Mg(1)–N(2) 2.448(2), Si(1)–N(2) 1.760(2), Si(2)–N(2) 1.745(2), Si(3)–N(4) 1.771(2), Si(4)–N(4) 1.749(2), N(1)–C(21) 1.372(2), N(3)–C(31) 1.372(2); N(3)–Mg(1)–N(1) 151.17(8), N(3)–Mg(1)–N(4) 38.47(6), N(1)–Mg(1)–N(4) 128.78(6), N(3)–Mg(1)–N(2) 130.34(6), N(1)–Mg(1)–N(2) 37.70(6), N(4)–Mg(1)–N(2) 144.85(6), C(21)–N(1)–N(2) 117.77(13), C(21)–N(1)–Mg(1) 151.48(12), N(2)–N(1)–Mg(1) 90.75(10), N(1)–N(2)–Si(2) 111.03(11), N(1)–N(2)–Si(1) 118.25(11), Si(2)–N(2)–Si(1) 130.61(9), N(1)–N(2)–Mg(1) 51.56(7), C(31)–N(3)–N(4) 117.72(13), C(31)–N(3)–Mg(1) 153.56(12), N(4)–N(3)–Mg(1) 88.51(9), N(3)–N(4)–Si(4) 110.82(11), N(3)–N(4)–Si(3) 118.64(11), Si(4)–N(4)–Si(3) 129.96(9), N(3)–N(4)–Mg(1) 53.02(7)

The Si–N–Si and C–N–Mg planes are almost orthogonal to each other [C(21)N(1)Mg(1)/Si(1)N(2)Si(2) 81.1°, C(31)N(3)Mg(1)/Si(3)N(4)Si(4) 98.8°], but the tilt is greater than in the corresponding lithium hydrazide (cf. 87.6°/92.3°).

The interplanar angle of the phenyl group and the N–N–Mg plane is quite small (4.2°), indicating a π interaction between the aromatic ring system and the lone pair of electrons at the nitrogen atom.

The N–Mg–N angles resulting from the side-on-coordinated hydrazide ligands are small [N(1)Mg(1)N(2) 37.70(6)°, N(3)Mg(1)N(4) 38.47(6)°], whereas the N(1)–Mg(1)–N(3) angle of 151.17(8)°, involving the deprotonated nitrogen atoms N(1) and N(3) of the hydrazide ligands, is in a similar range as reported for the monomeric magnesium bis(amide) $Mg[N(SiPh_2Me)_2]_2$ [N–Mg–N 162.8(3)°],[14] or the monomeric dialkylmagnesium com-

pound $Mg[CH(SiMe_3)_2]_2$ [C−Mg−C 140.0(2)°].[13] The angle N(2)−Mg(1)−N(4), involving both NSi_2 groups is 144.85(6)°, and the N−Mg−N angles involving different hydrazide nitrogen atoms are in the range of ca. 130° [N(1)Mg(1)N(4) 128.78(6)°, N(2)Mg(1)N(3) 130.34(6)°]. There are two types of N−N−Mg angles of comparable magnitude, those centered at the deprotonated nitrogen atoms N(1) [90.75(10)°] and N(3) [88.51(10)°], and those involving the sp^2-type $-NSi_2$ groups at N(2) [51.56(7)°] and N(4) [53.02(7)°].

A significant difference in the coordination chemistry of comparable alkali metal phenylhydrazides, where the aromatic ring system may act as an η^n ligand ($n = 2-6$) to the metal atom, is the fact that the phenyl groups do not participate in the coordinative saturation of the magnesium atom. This difference is also the reason for the larger C−N distances between the nitrogen atom of the hydrazide unit and the *i*-C of the phenyl group [1.372(2) Å] than the corresponding C−N distances of the tetrameric lithium hydrazide $[Ph-N(Li)-N(SiMe_3)_2]_4$ [1.346(5), 1.349(5) Å] or of the ether adducts of the corresponding sodium hydrazides (1.34−1.36 Å).[7c][7d]

Table 1 depicts an overview of the bond lengths involving the $Ph-N^{-}-N(SiMe_3)_2$ hydrazide ligand and different metal atoms. Although the N−N distances of the *N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazides of lithium, sodium, cesium[7b−7d] and magnesium are of comparable magnitude, a significant difference is seen in the C−N and Si−N bond lengths.

Compound **2** was obtained from the reaction of *N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazine and dibutylmagnesium in hexane in a 86% yield, in the form of colorless crystals according to Equation (2). It was characterized by ^1H, ^{13}C and ^{29}Si NMR spectroscopy and X-ray crystallography.

The ^{29}Si NMR spectrum of the hexane solution indicates two peaks at $\delta = -2.62$ and -9.43 ppm, which is identical to the spectrum of the isolated crystals in C_6D_6. The ^1H and ^{13}C NMR spectra reveal two resonances each for the silyl groups and methyl groups, and indicate two different hydrazide ligands. No change was observed up to a temperature of 60 °C in the high-temperature ^{29}Si NMR spectra. The resonances observed in the ^{29}Si NMR spectrum can be interpreted as silyl groups located at three- and four-coordinated deprotonated nitrogen atoms.

Single crystals of the magnesium hydrazide **2** could be obtained from a hexane solution and they crystallize in the monoclinic system and space group $P2_1/n$ with four formula units per unit cell.

The crystal structure of the hydrazide **2** is shown in Figure 2. It is aggregated in the form of centrosymmetric dimers in the solid state with terminal and bridging hydrazide units. The magnesium atoms are coordinated by five nitrogen atoms with Mg−N distances ranging from 1.971(2) to 2.232(2) Å.

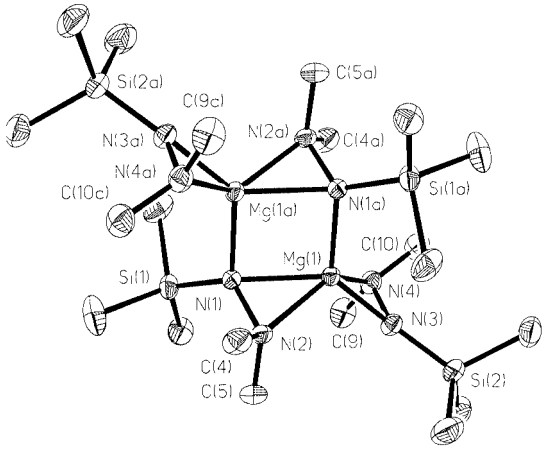

Figure 2. Molecular structure of dimeric magnesium bis[*N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazide] (**2**); thermal ellipsoids are shown at a 25% probability level and hydrogen atoms are omitted for clarity; selected atom distances [Å] and angles [°]: Mg(1)−N(3) 1.971(2), Mg(1)−N(1a) 2.107(2), Mg(1)−N(2) 2.125(2), Mg(1)−N(1) 2.139(2), Mg(1)−N(4) 2.232(3), Mg(1)−Mg(1a) 2.9659(18), Si(1)−N(1) 1.726(2), N(1)−N(2) 1.501(3), N(1)−Mg(1a) 2.107(2), N(2)−C(4) 1.463(4), N(2)−C(5) 1.473(4), Si(2)−N(3) 1.696(2), N(3)−N(4) 1.474(3), N(4)−C(10) 1.451(5), N(4)−C(9) 1.469(5), Mg(1)−Mg(1a) 2.966(2); N(3)−Mg(1)−N(1a) 132.28(10), N(3)−Mg(1)−N(1) 136.19(10), N(2)−Mg(1)−N(4) 132.05(10), N(1a)−Mg(1)−N(1) 91.40(9), Mg(1a)−N(1)−Mg(1) 88.60(9), N(1)−Mg(1)−N(4) 121.53(10), N(3)−Mg(1)−Mg(1a) 176.87(9), N(2)−N(1)−Si(1) 124.59(16), N(2)−N(1)−Mg(1a) 111.70(15), N(2)−N(1)−Mg(1) 68.88(12), N(1)−N(2)−Mg(1) 69.91(12), N(4)−N(3)−Si(2) 126.58(18), N(4)−N(3)−Mg(1) 79.34(14), Si(2)−N(3)−Mg(1) 151.56(15), C(4)−N(2)−C(5) 109.6(3), C(10)−N(4)−C(9) 109.3(3)

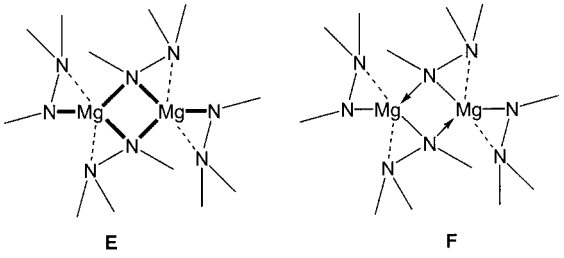
If the coordination sphere of the magnesium atoms is considered with respect to the deprotonated hydrazine nitrogen atoms only, they exhibit a trigonal-planar coordination sphere [sum of the bond angles at Mg(1) involving N(1), N(1a) and N(3): 359.9°], indicating that the coordination of the NMe_2 groups to the magnesium atoms does not cause a tetrahedron-type coordination. The coordination sphere of the nitrogen atoms N(3) and N(3a) of the ter-

Table 1. Bond lengths of *N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazides

Compound	$Mg[N(Ph)-N(SiMe_3)_2]_2$	$LiN(Ph)-N(SiMe_3)_2$ [7c]	$NaN(Ph)-N(SiMe_3)_2 \cdot nOR_2$ [7d]	$Cs(Ph)-N(SiMe_3)_2$ [7c]
Aggregation	monomeric	tetrameric	monomeric to polymeric	polymeric
N−N [Å]	1.497(2), 1.493(2)	1.486(5), 1.493(5)	1.47−1.51	1.501(8)
N−Si [Å]	1.760(2), 1.745(2), 1.771(2), 1.749(2)	1.733(4), 1.736(4)	1.71−1.74	1.724(6), 1.735(6)
M−N [Å]	1.917(2), 1.918(2)	1.881(9), 1.883(9)	2.30−2.33	2.991(6)
C−N [Å]	1.372(2)	1.346(5), 1.349(5)	1.34−1.36	1.351(9)

minal hydrazide units are almost trigonal-planar (sum of the bond angles: 357.5°), whereas the remaining nitrogen atoms are four-coordinate. The N−N bond length of the terminal hydrazide ligand [N(3)−N(4) 1.474(3) Å] is slightly shorter than the bond length of the hydrazide ligand bridging the magnesium atoms [N(1)−N(2) 1.501(3) Å], due to the different coordination geometries of the nitrogen atoms involved. The N−Mg−N angles of the terminal and bridging hydrazide ligands are of comparable magnitude [N(1)Mg(1)N(2) 41.21(8)°, N(3)Mg(1)N(4) 40.47(9)°], and are only slightly larger as the corresponding N−Mg−N angles of **1**. The N−N−Mg angles range from 60.2 to 79.34°, and the angles of the central Mg_2N_2 unit are close to 90° [N(1)Mg(1)N(1a) 91.40(9)°, Mg(1a)N(1)Mg(1) 88.60(9)°]. The NMR spectra of the solution are in accordance with the dimeric structure of **2**.

The dimeric structure of **2** can be explained either as an association of two molecules with both side-on- and end-on-coordinated hydrazide units each (**E**), or as an arrangement of two monomeric hydrazide units with bent, side-on-coordinated ligands (**F**). The latter explanation arises since the structural unit of the bent coordination sphere in the monomer magnesium hydrazide **1** is also detected in the structure of the dimeric molecule **2**.



E **F**

The structural arrangement of the nitrogen atoms in dimeric **2** ($\mathbf{2}_2$) reveals some strong similarities with the corresponding dimeric magnesium amides.[15] When only the deprotonated hydrazide nitrogen atoms N(1), N(3), N(1a) and N(3a) are considered, the remaining core structure of $\mathbf{2}_2$ is almost planar, with the exocyclic nitrogen atoms inclined by 3.1° from the central Mg_2N_2 plane. This structural motif is related to the structure of the dimeric magnesium amide $Mg[N(SiMe_3)_2]_2$, and the Mg−N and Si−N distances, as well as the N−Mg−N angles of the core structure of **2** and the latter magnesium amide are similar.

In spite of an expected tetrahedral coordination geometry, the magnesium atom in compound **1** displays a side-on coordination of the hydrazine ligands, whereas magnesium bis[*N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazide] (**2**) reveals a dimeric structure in the solid state. The unusual coordination sphere of **1** explains its high reactivity, e.g. towards ethers or toluene. In the case where these solvents are used, a reaction of **1** with the solvents occurs with the formation of phenylbis(trimethylsilyl)hydrazine, which is identified using NMR spectroscopy,[7c] and other reaction products. It has been reported that magnesium amides are able to generate arene anions, which might also be likely to react with these low-coordinated magnesium hydrazides.[16]

Since the substituents of the hydrazine unit are not extremely bulky, the bent coordination sphere at the magnesium center can result from a weak Mg···H−C interaction involving the methyl groups of the silyl substituents. Regarding heavier alkaline earth metals, a bent coordination sphere of the two-coordinate species is due to core polarization effects, as indicated by theoretical investigations.[17] The aryl ligand does not coordinate to the metal center in the magnesium hydrazide **1**, which is in contrast to the corresponding alkali metal hydrazides. Further investigations with other ligands leading to low-coordinate magnesium compounds need to be carried out in order to explain the different coordinative behavior and the bent N−Mg−N moiety.

Experimental Section

General: All reactions were performed by using modified Schlenk techniques under argon. Solvents were freshly distilled from an Na/K alloy. Dibutylmagnesium (1 M in heptane) was obtained from commercial suppliers and used as received, and starting materials were prepared according to literature methods. NMR spectra were recorded in C_6D_6 solution by using a Bruker ACP 200 spectrometer (TMS as external standards; ^{1}H: 200 MHz; ^{13}C: 55.0 MHz; ^{29}Si: 39.7 MHz). Compounds **1** and **2** react with ethers and toluene and can ignite when exposed to air. Deviations in elemental analyses are attributed to the formation of silicon carbide during combustion. The data for the crystal structure of compound **1** were collected with a Siemens P4 automated four-circle diffractometer with CCD detector and LT2 cooling device (Mo-K_α, λ= 0.71073 Å, graphite monochromator). For the X-ray structure determination of **2**, a STOE IPDS diffractometer was used (Mo-K_α, λ= 0.71073 Å, graphite monochromator). The programs XS, SHELXTL Plus and SHELX97 were used for data collection, structure solution and refinement.[18] The structures of the compounds were solved by direct methods and refined by full-matrix least-square methods. Anisotropic thermal parameters for all non-hydrogen atoms in the final cycles, isotropic refinement for hydrogen atoms positioned by geometry. CCDC-168700 and -168701 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Magnesium Bis[*N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazide] (1): A solution of freshly distilled *N*-phenyl-*N*′,*N*′-bis(trimethylsilyl)hydrazine (0.84 g, 3.3 mmol) in 15 mL of hexane was allowed to react at room temperature with dibutylmagnesium (1.7 mL of a 1 M solution; 1.7 mmol) in heptane. The mixture became light yellow and colorless crystals were formed at −18 °C within several days. Yield: 0.65 g (73%); m.p. 93−95 °C (dec.). ^{1}H NMR (C_6D_6): δ = 0.10 (s, Me_3Si, 18 H), 6.63−7.17 (m, Ph-N, 5 H) ppm. ^{13}C NMR: δ = 1.00 (Me_3Si), 112.58, 129.27 (o, *m*-C), 118.60 (*p*-C), 151.9 (*i*-C1) ppm. ^{29}Si NMR: δ = 8.70 ppm. $C_{24}H_{46}MgN_4Si_4$ (527.32): calcd. C 54.67, H 8.79, Mg 4.61, N 10.63; found C 52.64, H 8.29, Mg 4.36, N 10.99.

Magnesium Bis[*N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazide] (2): Dibutylmagnesium (3.0 mL of a 1 M solution; 3.0 mmol) in heptane was added dropwise to a stirred solution of *N*,*N*-dimethyl-*N*′-(trimethylsilyl)hydrazine (0.79 g, 6.0 mmol) in 15 mL of hexane at am-

bient temperature. The evolution of butane occurred immediately. Colorless crystals separated from the solution within several days at room temperature. Yield 0.74 g (86%), m.p. 107−109 °C (dec.). ^{1}H NMR (C_6D_6): δ = 0.30 (s, Me_3Si, 9 H), 0.36 (s, Me_3Si, 9 H), 2.58 (s, Me_2N−, 6 H), 2.61 (s, Me_2N−, 6 H) ppm. ^{13}C NMR: δ = 4.77 (Me_3Si), 5.65 (Me_3Si), 52.17 (Me_2N−), 53.39 (Me_2N−) ppm. ^{29}Si NMR: δ = −2.62 [$^1J(^{13}C^{29}Si)$ = 54.0 Hz], −9.43 [$^1J(^{13}C^{29}Si)$ = 52.4 Hz] ppm. $C_{10}H_{30}MgN_4Si_2$ (286.87): calcd. C 41.87, H 10.54, Mg 8.47, N 19.53; found C 41.24, H 10.22, Mg 8.33, N 19.38.

Crystal Data and Data Collection Parameters: 1: $C_{24}H_{46}MgN_4Si_4$, M_r = 527.32, crystal size 0.22 × 0.36 × 0.48 mm, monoclinic, $P2_1/n$, a = 11.0017(2), b = 12.4958(2), c = 22.5633(4) Å, β = 96.119(1)°, V = 3084.22(9) Å^3, Z = 4, $\rho_{calcd.}$ = 1.136 Mg/m^3, μ = 0.232 mm^{-1}, F(000) = 1144, index range: $-14 \le h \le 10$, $-16 \le k \le 16$, $-27 \le l \le 28$, 2θ = 57.96°, T = 193 K, refl. collected 17422, refl. unique 5969, refl. observed (4σ) 5324, R(int.) = 0.0352, no. of variables 367, weighting scheme x/y = 0.0272/2.5741, GOOF = 1.226, final R(4σ) = 0.0476, final $wR2$ = 0.1039, largest residual peak 0.281 e/Å^3, with: $w^{-1} = \sigma^2F_o^2 + (xP)^2 + yP$; $P = (F_o^2 + 2F_c^2)/3$. **2:** $C_{10}H_{30}MgN_4Si_2$, M_r = 286.87, T = 293(2) K; monoclinic, $P2_1/n$, a = 10.320(2), b = 12.755(3), c = 14.102(3) Å, β= 98.19(3)°, V = 1837.3(7) Å^3, Z = 4, $\rho_{calcd.}$ = 1.037 Mg/m^3, μ = 0.217 mm^{-1}, F(000) = 632, crystal size: 0.35 × 0.5 × 0.5 mm, θ range for data collection: 2.16−22.51°, index ranges: $0 \le h \le 11$, $-13 \le k \le 0$, $-15 \le l \le 15$; reflections collected: 2400, independent reflections: 2400; refinement method: full-matrix least squares on F^2; data/restraints/parameters: 2400/0/274; GOOF on F^2: 1.193; final R indices [$I > 2\sigma(I)$]: $R1$ = 0.0410, $wR2$ = 0.0946; R indices (all data): $R1$ = 0.0627, $wR2$ = 0.1095; largest difference peak and hole: 0.166 and −0.179 e/Å^3.

Acknowledgments

H. S. is grateful to Prof. Dr. H. Nöth for collecting data of a low-temperature X-ray analysis of compound **1** and acknowledges financial support of the Fonds der Chemischen Industrie and the Deutsche Forschungsgemeinschaft, as well as Chemetall for the donation of alkyllithium compounds. Experimental assistance of S. Scholl is also acknowledged.

Synthesis, Variable Temperature and Pressure ^{17}O NMR Study of Bis(alkylamide) Derivatives of $[(Gd\text{-}DTPA)(H_2O)]^{2-}$ − An Assessment of the Substitution Effect on Water Exchange Kinetics

François Botteman,[a] Gaëlle M. Nicolle,[b] Luce Vander Elst,[a] Sophie Laurent,[a] André E. Merbach,[b] and Robert N. Muller*[a]

Keywords: Water exchange / MRI contrast agents / DTPA-bis(amide) derivatives / Substituent effects / ^{17}O

In this work, primary, secondary and tertiary bis(amide) derivatives of DTPA have been synthesized and the residence time of the water molecule coordinated to their gadolinium complexes has been measured by variable temperature ^{17}O NMR spectroscopy. The influence of substituent characteristics (molecular mass, hydrophobicity, volume) has been studied. For the primary and secondary bis(amide) complexes, increasing the length of the lateral chains decreases the water residence time. It varies from 1171±38 ns for [Gd(DTPA-BA)(H_2O)] to 673±32 ns for [Gd(DTPA-BHeptA)(H_2O)]. The activation volumes of 5 bis(amide) complexes {[Gd(DTPA-BA)(H_2O)], [Gd(DTPA-BEA)(H_2O)], [Gd(DTPA-BnBA)(H_2O)], [Gd(DTPA-BAA)(H_2O)], and [Gd(DTPA-BHA)(H_2O)]} have been measured by a variable pressure ^{17}O NMR spectroscopic study. No change in the activation volume is observed when the substituent size is increased. The inner sphere is therefore not disturbed by the substitution on the amide groups. The slight decrease in water residence time can be attributed to the hydrophobicity increase of the complexes which, in turn, leads to a hydrophobic environment favorable to water molecule exchange. The water residence time of tertiary bis(amide) complexes is similar to the fastest secondary bis(amide) complex. For the tertiary bis(amide) complexes, a length increase by the substituent does not change the residence time. According to these results, we suspect that a disruption of the hydration shell of the complexes by amide substituents occurs that can influence coordinated water exchange by a factor of two, at most.

Introduction

Most of the contrast agents used in Magnetic Resonance Imaging (MRI) are paramagnetic complexes of gadolinium. Their efficiency, expressed by their relaxivity, r_1 (water proton relaxation rate enhancement induced by 1 millimole per liter of paramagnetic complex), depends on water exchange kinetics, electronic relaxation, and molecular tumbling, as well as on the number of water molecules in the first coordination sphere of the gadolinium cation (q). The influence of these parameters has been extensively described and the ways in which to modify some of them, for instance the rotational correlation time of the complex (τ^r) and the number q, are well known.[1] By comparison, the strategies towards changing the electronic relaxation times (τ_{Si}, $i = 1, 2$) and the residence time of the water-coordinated molecule (τ_M) are poorly understood.

τ_M is not a limiting factor for the relaxivity of commercially available T_1 low molecular weight agents, like Magnevist® (Schering, Berlin, Germany), Omniscan® (Amersham Health, Amersham, United Kingdom), Dotarem® (Guerbet, Aulnay, France) or Prohance® (Bracco, Milan, Italy), at physiological temperatures and magnetic fields normally used in MRI, but this parameter may play an important role when covalent or noncovalent coupling to a macromolecule is involved.[2,3] Indeed, in order to improve the relaxivity, high molecular weight contrast agents have been developed. To reach optimal relaxivity, the residence time must, however, fulfil the condition: $T_{1M} > \tau_M > \tau_{Si}$, τ_R, where T_{1M} is the longitudinal relaxation time of nuclei in the first coordination sphere. The adjustment of τ_M is therefore of paramount importance.

Up to now, it has been reported that the water exchange rate of monoaquagadolinium chelates decreases by several orders of magnitude as compared to the aqueous ion.[4] Micksei et al. showed that the water exchange rate of $[Gd(DTPA)(H_2O)]^{2-}$ is about 200 times slower than that for aqueous gadolinium $[Gd(H_2O)_8]^{3+}$.[5] The presence of amide groups further decreases the exchange rate of Ln^{III}-DTPA derivatives.[6−9] The determination of water exchange rates for a set of lanthanide complexes of DTPA-

BMA (from Nd^{3+} to Ho^{3+}) has shown that the exchange rate increases when the ionic radius of the lanthanide decreases.[10] These two latter observations show the importance of steric hindrance in the coordination cage on the water exchange rate. Furthermore, the charge has also been invoked as a factor affecting residence times which are particularly long, as for $[Gd(DTMA)(H_2O)]^{3+}$ (τ_M= 17 μs at 278 K),[11] or short, as for $[Gd(PCTP\text{-}[13])(H_2O)]^{3-}$ (τ_M = 8 ns at 278 K).[12] Further substitution of the DTPA backbone on the ethylene bridge decreases the residence time by about 30% as compared to $[Gd(DTPA)(H_2O)]^{2-}$ at 310 K as is the case for the Gd^{III} chelates of EOB-DTPA and MS-325.[13,14]

From the literature, no simple relationship can be clearly established between the structure of Gd complexes and water exchange kinetics. To unravel some relationship, we have studied a series of equally charged but diversely amide-substituted chelates of Gd-DTPA bis(amide) derivatives (Table 1). Proton and oxygen-17 relaxometry at variable temperatures and pressures have been carried out to analyze the influence of the lengthening of the amide substituent on the water residence time.

Results and Discussion

Primary and Secondary Bis(amide) DTPA Gd^{III}-Chelates

The proton relaxivity of primary and secondary chelates measured at 20 MHz and 310 K is given in Table 2. The data for the variable temperature study is presented in Figure 1. The proton longitudinal relaxivity reflects the molecular mass increase of the complexes as expected by the Solomon−Bloembergen theory.[15,16] The relaxivity is the sum of inner- and outer-sphere contributions. The outer-sphere relaxation is not influenced by the residence time of water and increases when the temperature decreases due to the reduction of the water molecule translational diffusion. On the contrary, the inner-sphere contribution depends on the water residence time as expressed in Equations (1) and (2).

When the water residence time is short as compared to T_{1M} ($\tau_M << T_{1M}$), the inner-sphere contribution increases and the total relaxivity is enhanced when the temperature decreases, as for $[Gd(DTPA)(H_2O)]^{2-}$.[17] If the water exchange is slow, the inner-sphere contribution decreases when the temperature is reduced, as is the case for [Gd(DTPA-BMA)(H_2O)]. As a result, the total relaxivity may remain approximately constant or decrease at low temperature. The proton relaxivity of all the bis(amide) complexes studied in this work is clearly limited at low temperatures and reflects a long water residence time (Figure 1).

For the determination of the residence time from ^{17}O NMR spectroscopic measurements, the experimental ^{17}O NMR spectroscopic data were fitted assuming q = 1 (the temperature dependence of the logarithm of the ^{17}O reduced transverse relaxation rates is shown in Figure 2 for four of the studied complexes). This assumption was supported by the values of the hyperfine-coupling constant ($A/\hbar$) and relaxivities that are similar to those measured for DTPA complexes with one coordinated water molecule. Table 2 shows the parameters obtained by the fitting of the experimental points. Since the ^{17}O transverse relaxation rates have been measured at one magnetic field (7.05 T in this study), the electronic parameters obtained are relatively

[a] See ref.[15] [b] The reduced ^{17}O transverse relaxation rates measured at variable temperature have been refitted with the equations used in this study.

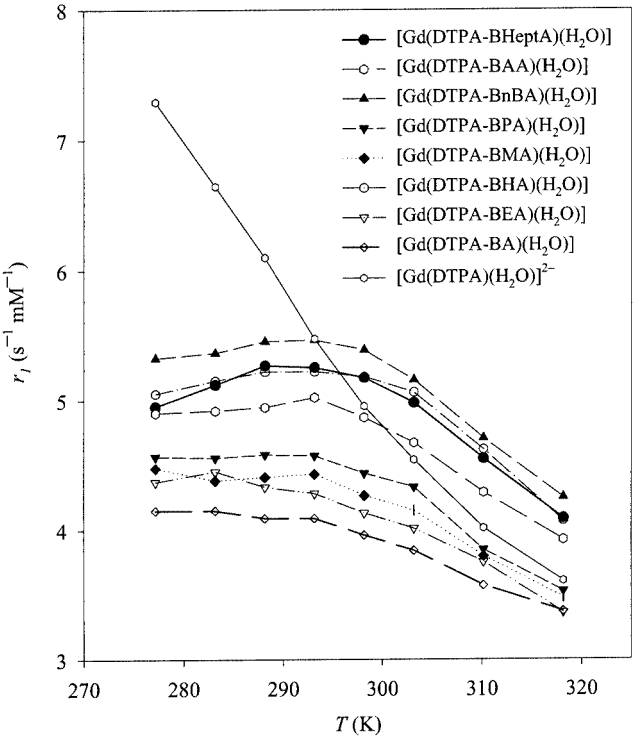

Figure 1. Temperature dependence of the proton relaxivity of linear bis(amide) complexes of $[Gd(DTPA)(H_2O)]^{2-}$ and of the parent compounds at 20 MHz

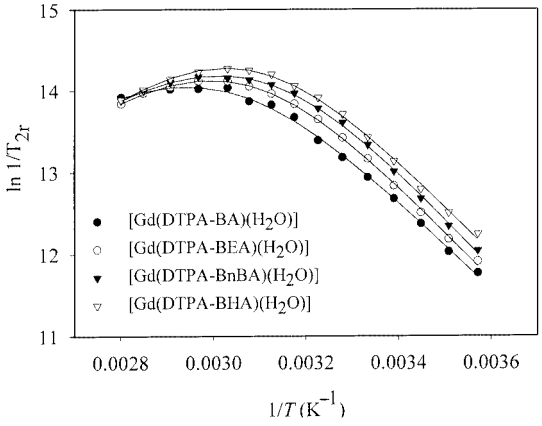

Figure 2. Temperature dependence of the reduced transverse ^{17}O relaxation rate for four linear bis(amide) complexes at 7.05 T; the straight lines represent the fitted curves

less reliable. Nevertheless, this is not a problem for the determination of the water residence time, which is nearly unaffected by the value of the electronic parameters. Table 2 indicates that the substituent size (or the substituent mass in Figure 3) has an effect on the water residence time: the larger the substituent, the faster the water exchange rate. The energy difference between the initial state and the transition state of the exchange seems thus to be reduced for a larger substituent. Steric hindrance can be invoked since it could reduce the energy necessary to reach the transition state assumed to have identical energy whatever the complex.

The ^{17}O transverse relaxation rate of the paramagnetic solutions, $1/T_2^r$, and of the acidified water reference, $1/T_2^{dia}$, were also measured at high pressure. This allows the calculation of the reduced transverse relaxation rate as described above in the variable temperature section. For the fitting of the high pressure data, T_{2M} was then fixed to the value calculated at 400 MHz with the parameters obtained at 300 MHz in the variable temperature study using Equations (7)−(10). The pressure dependence of $1/T_2^r$ at 298.15 K is presented in Figure 4 for five of the studied complexes. The decrease of $1/T_2^r$ as pressure increases, indicates a slowing down of the water exchange process, which has been checked to be reversible for all the studied Gd^{III} chelates. The fitted parameters are given in Table 3. The replacement of two carboxylic groups by two amide groups induces a nearly twofold decrease in the activation volume, as seen by

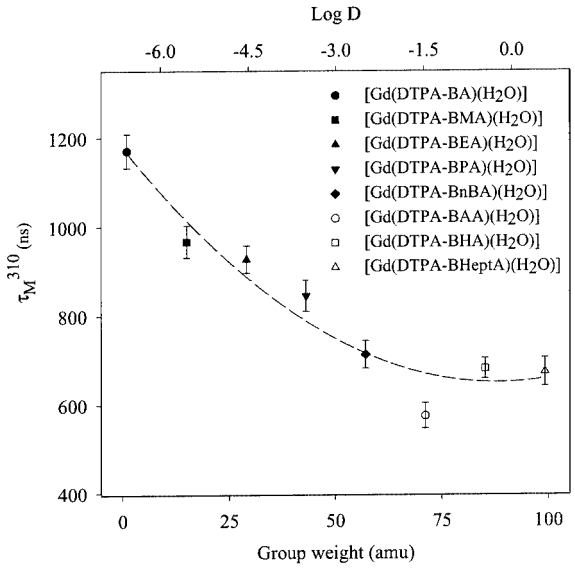

Figure 3. Dependence of the water residence time for linear bis(amide) complexes as a function of the group mass and of the hydrophobicity of the ligand (log D)

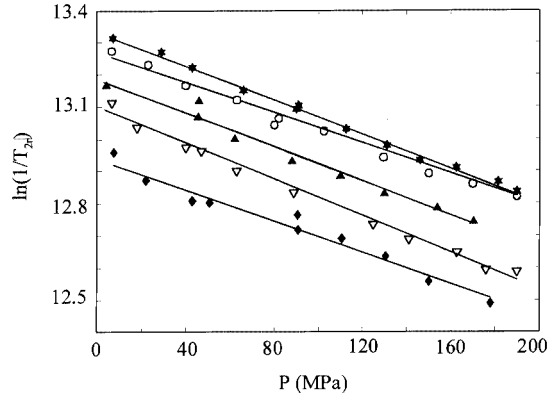

Figure 4. Pressure dependence of the reduced transverse ^{17}O relaxation rate at 298.15 K and 9.4 T for $[Gd(DTPA\text{-}BA)(H_2O)]$ (black diamonds), $[Gd(DTPA\text{-}BEA)(H_2O)]$ (white triangles), $[Gd(DTPA\text{-}BnBA)(H_2O)]$ (black triangles), $[Gd(DTPA\text{-}BAA)(H_2O)]$ (black stars) and $[Gd(DTPA\text{-}BHA)(H_2O)]$ (white circles);the straight lines represent the fitted curves

comparing $[Gd(DTPA\text{-}BA)(H_2O)]$ to $[Gd(DTPA)(H_2O)]^{2-}$. For the $[Gd(DTPA\text{-}BA)(H_2O)]$ complex, the incoming water molecule is therefore more implicated in the water exchange process than it is for the $[Gd(DTPA)(H_2O)]^{2-}$ complex. The decrease of the water exchange rate constant for $[Gd(DTPA\text{-}BA)(H_2O)]$ compared to $[Gd(DTPA)(H_2O)]^{2-}$, by one order of magnitude, therefore is not interpretable in terms of activation volume but could be attributed to the difference between their entropy of activation (see Table 2). The variation of the substituent site, on going from the methyl to the hexyl group, does not affect the value of the activation volume within the experimental errors. The activation volumes are in accordance with the one obtained for the $[Gd(DTPA\text{-}BMA)(H_2O)]$ complex in a previous study (< 7.5 cm^3 mol^{-1}) and indicates a dissociative interchange I_d mechanism.[4] The activation volume is therefore independent of the nature of the alkyl substituent. This shows in turn that the substituent does not have a major influence on the first coordination sphere nor on its steric crowding.

As stated above, the similar values obtained for the activation volumes for the series have revealed that the inner sphere is not affected by the substitution on the amide group. This result is in agreement with the available crystallographic data of various Gd-DTPA-bis(amide) complexes.[18−21] In fact, it shows that as compared to $[Gd(DTPA)(H_2O)]^{2-}$, the formation of an amide bond does not markedly modify the distances between Gd^{III} and its coordinates (Table 4). A folding of lateral chains in solution, however, is not excluded. The decrease of the residence time when the lateral chain is lengthened could be explained by such a folding due to the hydrophobic repulsion between the complex and the bulk. This phenomenon could disrupt the hydration shell of the complexes and favor the water exchange by modifying the hydrogen bonds between the exchanging water molecule and the hydration shell. For instance, the presence of a hydroxy group in $[Gd(DTPA\text{-}(R,S)BHPA)(H_2O)]$ causes an increase of about 30% of the water residence time (Table 2) as compared to $[Gd(DTPA\text{-}BnPA)(H_2O)]$. Furthermore, this folding occurs outside of the coordination cage and this could thus explain why the

activation volume is not affected by the nature of the substituent.

In order to characterize the hydrophobicity of our bis(amide) complexes carrying aliphatic linear chains, the log D coefficient of the corresponding ligands was used.[22] At a fixed pH, this log D coefficient reflects the hydrophobicity for the different ligands in solution and takes into account the contribution of ionizable groups. For the calculation of log D, the pH was set to 12 since the ligand structure is similar to the one in the complex (the carboxylate groups and nitrogen atoms are not protonated). The calculated hydrophobicity of bis(amide) ligands is reported in Figure 3. The residence time decreases with increasing hydrophobicity and remains quite similar for larger groups. This plateau could be explained due to the fact that only the first carbon atoms of the chain disturb the hydration shell that contributes to the exchange process.

The influence of the substituent volume on the water residence time was also investigated. The volumes of 4 substituents (R_1 = hydrogen, methyl, isopropyl, *tert*-butyl) were calculated using the van der Waals radii of atoms. The volumes of linear chains were not calculated because their flexibility does not allow a correct description of their volumes. The evolution of the residence times shown in Figure 5 is similar to the one observed in Figure 3. The measured values for [Gd(DTPA-BiPA)(H_2O)] and [Gd(DTPA-BtBA)(H_2O)] (Table 2) confirm a fact previously observed in this study: the only hindrance arising from the first carbon atoms of the substituent leads to a shortening of the residence time.

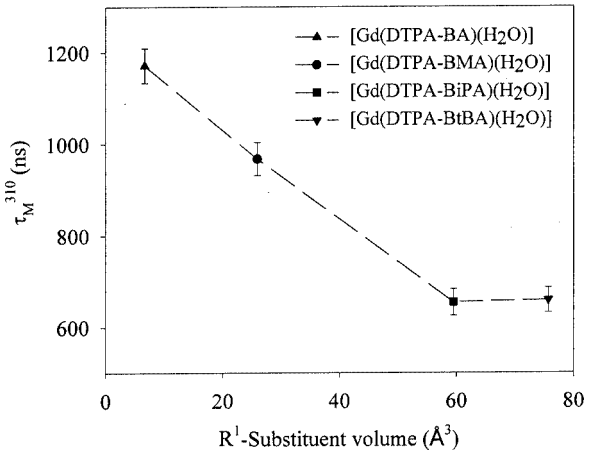

Figure 5. Volume substituent dependence of the residence time for bis(amide) complexes

An alternative explanation can be proposed. The bis(alkylamide) DTPA derivatives present four diastereoisomers in solution.[23] It has been shown for the complex $[Eu(DOTAM)(H_2O)]^{3+}$ that the diastereoisomers have different exchange rates.[24] Recently, the study of interconversion mechanisms between the diastereoisomers proved that the global value of the residence time was mainly fixed by the minor stereoisomer.[25] The exchange rates measured for the bis(alkylamide) derivatives are therefore averages weighted by the molar fractions of the stereoisomers. Like for tetrakis(amide) DOTA derivatives,[26] the alkyl chains could influence the equilibrium between the stereoisomers. According to Figure 3, the lengthening of lateral chains could favor the faster stereoisomer, but this must still be demonstrated.

Study of Tertiary Bis(amide) DTPA Complexes

For the tertiary bis(amides), the evolution of proton relaxivity at varying temperatures also demonstrates a limitation by the residence time (Figure 6). The values of the residence times are similar to those measured for the larger linear bis(amide) complexes [Gd(DTPA-BnBA)(H_2O)], [Gd(DTPA-BAA)(H_2O)], [Gd(DTPA-BHA)(H_2O)], and [Gd(DTPA-BHeptA)(H_2O)] (Table 2). The reduction of the

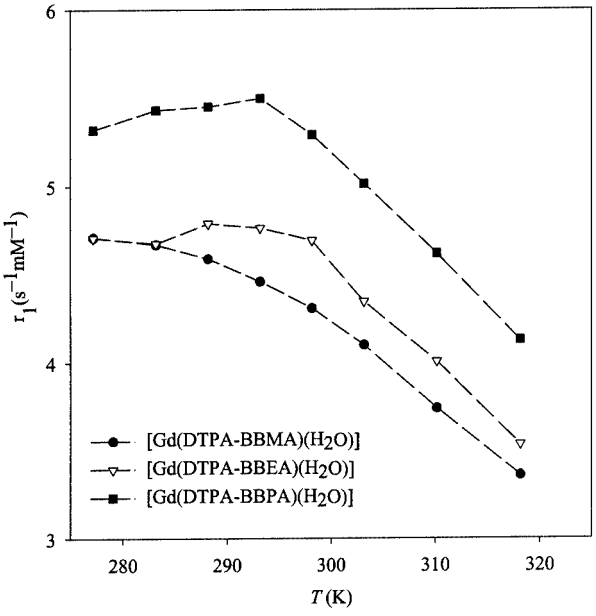

Figure 6. Temperature dependence of the proton relaxivity for tertiary bis(amide) complexes of $[Gd(DTPA)(H_2O)]^{2-}$

residence time of [Gd(DTPA-BBMA)(H_2O)] compared to [Gd(DTPA-BMA)(H_2O)], as well as the similarity of the residence time of the tertiary bis(amides), once again confirm the importance of steric hindrance at the level of the nitrogen atom from the amide group.

Conclusions

For the first time an extensive series of Gd-DTPA bis(amide) derivatives has been studied to assess the influence of the amide substituents on the water exchange rate. ^{17}O NMR spectroscopic studies carried out at variable temperatures and high pressures reveal that the substituents, which are close to the first coordination sphere, influence the residence time of bis(amide) DTPA derivatives without modifying the activation volume. However, this influence is relatively weak since the water exchange rate is doubled, at the most, for [Gd(DTPA-BA)(H_2O)] as compared to [Gd(DTPA-BHeptA)(H_2O)] and does not reach the exchange rate of $[Gd(DTPA)(H_2O)]^{2-}$. To explain the decrease of τ_M along the series, both the hydrophobicity and the hindrance of the complexes have been addressed, since these complexes are all neutral. The relative influence of these factors depends on the complexes studied. However, another hypothesis is that the lengthening of alkyl substituents favors the stereoisomers with the faster exchange rates and therefore influences the global exchange rate.

Experimental Section

Chemicals: DTPA-BMA was provided by Nycomed (Amersham Health, Amersham, United Kingdom). All chemicals and $GdCl_3 \cdot 6H_2O$ were purchased from Aldrich (Bornem, Belgium).

Ligand Synthesis: The bis(amide) derivatives of DTPA were synthesized by adding an excess of amine to DTPA-bis(anhydride).[19,27] Amine (16.8 mmol) was added to a stirred suspension of DTPA-bis(anhydride) (2 g, 5.6 mmol) in anhydrous DMF (50 mL) and heated at 325 K. After 12 h, the yellow solution was concentrated under reduced pressure. The residue was dissolved in water (50 mL) and the pH of the aqueous phase was adjusted to 7 with saturated $NaHCO_3$ solution. The aqueous phase was extracted with diethyl ether (5 × 30 mL). The organic phase was discarded and the pH of the aqueous solution was adjusted to 2−3 with 3 M HCl and the solvents evaporated once again. The residue was dissolved in a minimum of methanol and filtered. Solvent A (Table 5) was slowly added whilst stirring. The white precipitate was filtered, suspended in solvent B (Table 5) and heated until dissolution. The warm solution was filtered and cooled to 273 K. Cold solvent C (Table 5) was then slowly added whilst stirring to precipitate the ligand. The ligand was filtered, washed with diethyl ether and dried under vacuum. The yields are reported in Table 5. For the synthesis of DTPA-BHeptA, when the pH of the aqueous phase was adjusted to 7 with saturated $NaHCO_3$ solution, the aqueous phase was continuously extracted with diethyl ether for 48 h (to avoid emulsion formation). The purity and structure of the compounds were identified by ^1H, ^{13}C NMR spectroscopy with a Bruker AMX-300 (Bruker, Karlsruhe, Germany) and by LSIMS mass spectrometry (VG Analytical Autospec 6F, Manchester, UK). For this technique, samples were dissolved in water and deposited on a glycerol matrix.

NMR Spectroscopic Data

DTPA-BnPA (4): $C_{20}H_{37}N_5O_8$: 475.54 amu. ^1H NMR (D_2O, 298 K, pH ≈ 6): δ = 0.55 (t, 6 H, 2 × CH_3), 1.2 (sext, 4 H, 2 × CH_2), 2.8 (t, 4 H, 2 × CH_2), 2.9 (t, 4 H, 2 × CH_2), 3.0 (t, 4 H, 2 × CH_2), 3.1 (m, 8 H, 4 × CH_2), 3.55 (s, 2 H, 1 × CH_2) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 6, reference pyridine): δ = 10.0, 21.1, 40.1, 49.6, 51.9, 53.6, 58.1, 58.2, 169.5, 172.2, 177.8 ppm.

DTPA-BAA (6): $C_{24}H_{45}N_5O_8$: 531.64 amu. ^1H NMR (D_2O, 298 K, pH ≈ 13): δ = 0.75 (t, 6 H, 2 × CH_3), 1.1−1.3 (m, 8 H, 4 × CH_2), 1.4 (quint, 4 H, 2 × CH_2), 2.3−2.6 (m, 8 H, 4 × CH_2), 2.9−3.2 (m, 14 H, 2 × CH_2 + 5 × CH_2) ppm. ^{13}C NMR (D_2O at 298 K, pH ≈ 13, reference MeOH): δ = 14.0, 22.4, 28.9, 32.6, 39.3, 52.1, 52.6, 58.6, 59.1, 59.4, 173.4, 179.2, 179.6 ppm.

DTPA-BHeptA (8): $C_{28}H_{53}N_5O_8$: 587.75 amu. ^1H NMR (D_2O, 298 K, pH ≈ 11): δ = 0.7 (t, 6 H, 2 × CH_3), 1−1.3 (m, 16 H, 8 × CH_2), 1.3−1.5 (quint, 4 H, 2 × CH_2), 1.8 (m, 4 H, 2 × CH_2), 2.3−2.6 (m, 6 H, 3 × CH_2), 2.9−3.3 (m, 12 H, 6 × CH_2) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 11, reference pyridine): δ = 13.5, 22.2, 23.1, 23.2, 26.6, 28.7, 28.8, 31.5, 38.8, 52.1, 52.6, 57.9, 58.3, 58.9, 172.6, 178.5, 181.2 ppm.

DTPA-BBEA (10): $C_{22}H_{41}N_5O_8$: 503.59 amu. ^1H NMR (D_2O, 298 K, pH ≈ 6): δ = 1−1.2 (dt, 12 H, 4 × CH_3), 3.15 (t, 4 H, 2 × CH_2), 3.2−3.4 (m, 8 H, 4 × CH_2), 3.45 (s, 2 H, 1 × CH_2), 3.65 (s, 4 H, 2 × CH_2), 4.05 (s, 4 H, 2 × CH_2) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 6, reference pyridine): δ = 14.9, 15.1, 15.9, 16.1, 43.9, 44.7, 53.4, 54.9, 58.2, 58.7, 60.6, 169.8, 176.4, 178.1 ppm.

DTPA-BBPA (11): $C_{26}H_{49}N_5O_8$: 559.70 amu. ^1H NMR (D_2O, 298 K, pH ≈ 1): δ = 0.6 (dt, 12 H, 4 × CH_3), 1.3 (m, 8 H, 4 × CH_2), 2.7−3.1 (m, 10 H, 5 × CH_2), 3.3 (m, 8 H, 4 × CH_2), 4.05 (s, 4 H, 2 × CH_2), 4.25 (s, 4 H, 2 × CH_2) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 6, reference pyridine): δ = 6.9, 7.2, 16.6, 17.5, 44.4, 45.1, 45.5, 45.6, 50.0, 52.6, 53.4, 160.9, 165.8, 168.8 ppm.

DTPA-BiPA (13): $C_{20}H_{37}N_5O_8$: 475.54 amu. ^1H NMR (D_2O, 298 K, pH ≈ 3): δ = 0.9 (d, 12 H, 4 × CH_3), 2.95 (t, 4 H, 2 × CH_2), 3.3 (t, 4 H, 2 × CH_2), 3.4 (s, 2 H, 1 × CH_2), 3.7 (2 H, sept,

Table 5. Solvents used and yields for the syntheses of bis(amide) derivatives

Ligands	Solvent A	Solvent B	Solvent C	Yield (%)
DTPA-BnPA	acetone	2-propanol	diethyl ether	69
DTPA-BAA	acetone	ethanol	diethyl ether	51
DTPA-BHeptA	ethyl acetate	ethanol/ethyl acetate (2:2)	acetone	55
DTPA-BBEA	diethyl ether	ethanol	diethyl ether	57

2 × CH), 3.9 (s, 4 H, 2 × CH_2), 4.0 (s, 4 H, 2 × CH_2) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 6, reference pyridine): δ = 17.9, 38.7, 47.1, 48.6, 51.0, 53.3, 53.5, 162.7, 168.1, 169.2 ppm.

DTPA-(R,S)BHPA (14): $C_{20}H_{37}N_5O10$: 507.53 amu. ^1H NMR (D_2O, 298 K, pH ≈ 6: δ = 0.9 (d, 6 H, 2 × CH_3), 2.8 (t, 4 H, 2 × CH_2), 2.9−3.0 (m, 8 H, 4 × CH_2), 3.0−3.2 (m, 8 H, 4 × CH_2), 3.55 (s, 2 H, 1 × CH_2), 3.65 (2 H, sext, 2 × CH) ppm. ^{13}C NMR (D_2O, 298 K, pH ≈ 6, reference pyridine): δ = 18.9, 45.3, 49.7, 52.3, 53.8, 58.2, 63.2, 65.4, 169.7, 172.8, 178.0 ppm.

Preparation of the Gadolinium Complexes: The gadolinium complexes were prepared by mixing a slight excess (5%) of ligand with gadolinium chloride. The pH of the solution was adjusted to 6−7. The absence of free gadolinium ions was checked with xylenol orange indicator.[28] In order to eliminate the excess of ligand, the bis(amide) complexes were filtered through a Sep-Pak Vac 6cc cartridge, OH^- form from Waters (Brussels, Belgium) and eluted with demineralized water. The mass was confirmed by ElectroSpray spectrometry (Micromass, Manchester, UK) and the purity of the chelates was checked by HPLC (Waters, Milford, USA), C18 column, inverse phase, pH = 6.5, triethylammonium buffer 0.05 M, flow 1 mL/min, diode array and fluorescence detectors. The concentration of the Gd complex solutions was measured by proton relaxometry after decomplexation of Gd^{3+} and by Induced Coupled Plasma methods (Jobin-Yvon 38+, Jobin-Yvon ISA, Longjumeau, France).

Variable Temperature and High Pressure ^{17}O NMR Spectroscopy: Variable temperature ^{17}O NMR spectroscopic measurements were recorded with a Bruker AMX-300 spectrometer (7.05T, 40.65 MHz). The temperature was controlled by a BVT-2000 unit. ^{17}O NMR spectroscopic measurements at natural abundance were performed in 2-mL samples contained in 10-mm (o.d.) tubes. The concentration of the solutions was lower than 30 mM. ^{17}O diamagnetic transverse relaxation times of water were measured using a Carr-Purcell-Meiboom-Gill sequence (90° and 180° pulse lengths were 25 and 50 μs, respectively). All ^{17}O NMR spectra were proton-decoupled. ^{17}O transverse relaxation times of water in solutions containing Gd complexes were calculated from the spectral linewidth. High pressure ^{17}O NMR spectroscopic measurements were performed up to 200 MPa at 298.15 K and with a Bruker ARX 400 spectrometer (9.4T, 54.2 MHz) equipped with a homebuilt probe head.[29] The Gd^{III} complex solutions were enriched to 3%, using in all cases 10% ^{17}O-enriched water (Yeda R&D Co., Rehovot, Israel). Their Gd^{III} concentration was checked as previously described. The pH of the solutions, measured with a combined glass electrode, was between 4.0 and 6.1. The reference used was 2% ^{17}O-enriched bidistilled water acidified with perchloric acid. The temperature was externally controlled by a circulating flow from an external temperature bath and measured using a built-in Pt resistor. The transverse relaxation times were obtained by the CPMG spin-echo technique.[30]

Proton Relaxometry: The relaxivities were measured at 0.47T with a Bruker Minispec PC-120 thermostatted by a tetrachloroethylene flow at temperatures between 278.15 and 318.15 K. To avoid prototropic exchange, measurements were carried out at pH = 6−7.

Data Analysis: Fitting of variable temperature ^{17}O NMR spectroscopic data was performed with Minuit software (CERN library). Least-squares fits of the ^{17}O high pressure data were performed by Scientist for Windows. The log D coefficients were calculated using log D Suite developed by Advanced Chemistry Development (Toronto, Canada). The volumes of substituents were calculated with the software Molecular Modeling Pro (ChemSW Software, Fairfield, USA). All the equations that are used in the treatment of ^{17}O NMR spectroscopic data and relaxivity measurements are given here.

Relaxivity Measurement: The measured proton relaxivities contain both inner- and outer-sphere contributions [Equation (1)].

$$r_1 = r_1^{is} + r_1^{os} \tag{1}$$

The inner-sphere term is given by Equation (2), where P is the molar fraction of paramagnetic centers and q is the number of coordinated water molecules.

$$\frac{1}{T_1^{is}} = \frac{Pq}{T_{1M} + \tau_M} \tag{2}$$

Variable Temperature ^{17}O NMR Spectroscopy: The residence time of inner-sphere water molecules can be estimated by the analysis of the temperature dependence of the ^{17}O transverse relaxation rate. The observed transverse relaxation rate is the sum of a paramagnetic ($1/T_2^p$) and a diamagnetic ($1/T_2^{dia}$) contribution [Equation (3).]

$$\frac{1}{T_2} = \frac{1}{T_2^p} + \frac{1}{T_2^{dia}} \tag{3}$$

The paramagnetic term itself arises from outer-sphere ($1/T_2^{os}$) and inner-sphere ($1/T_2^{is}$) mechanisms [Equation (4)].

$$\frac{1}{T_2^p} = \frac{1}{T_2^{os}} + \frac{1}{T_2^{is}} \tag{4}$$

The inner-sphere contribution is given by the classical Equation (5), where $\Delta\omega_M$ is the chemical shift difference between bound and bulk water and T_{2M} is the transverse relaxation time of the bound water.

$$\frac{1}{T_2^{is}} = \frac{Pq}{\tau_M} \frac{T_{2M}^{-2} + \tau_M^{-1} T_{2M}^{-1} + \Delta\omega_M^2}{\left(\tau_M^{-1} + T_{2M}^{-1}\right)^2 + \Delta\omega_M^2} \tag{5}$$

It has been shown that for gadolinium complexes the outer-sphere contribution is negligible.[4] $\Delta\omega_M$ is defined by Equation (6), where g_L is the Landé factor (equal to 2 for Gd^{3+}), μ_B is the Bohr magneton, S is the electron spin (3.5 for Gd^{3+}), k_B is the Boltzmann constant, $A/\hbar$ is the hyperfine coupling constant, and T is the temperature.

$$\Delta\omega_M = \frac{g_L \mu_B S(S+1) B_o}{3 k_B T} \frac{A}{\hbar} \tag{6}$$

The transverse relaxation rate of ^{17}O coordinated to the gadolinium ion is predominantly described by the scalar interaction [Equation (7)]. The dipolar and quadrupolar contributions can be neglected since their contribution to the relaxation is 5% at the most.[4] Therefore, T_{2M} is given by Equation (7), where ω_S is the resonance frequency of the electron.

$$\frac{1}{T_{2M}} = \frac{S(S+1)}{3} \left(\frac{A}{\hbar}\right)^2 \left(\tau_{e1} + \frac{\tau_{e2}}{1 + \omega_S^2 \tau_{e2}^2}\right) \tag{7}$$

The scalar correlation times τ_{ei} are defined by Equation (8).

$$\frac{1}{\tau_{ei}} = \frac{1}{\tau_M} + \frac{1}{\tau_{Si}} \text{ with } i = 1,2 \tag{8}$$

The electronic relaxation times (τ_{Si}) are described by the contribution of the zero-field splitting interaction (no contribution of the spin rotation has been considered) and are expressed by Equation (9) and (10), where τ_v is the correlation time related to the modulation of the zero-field splitting (ZFS) and B is a parameter related to the ZFS and is independent of the temperature.

$$\frac{1}{\tau_{S1}} = B \tau_V \left[\frac{1}{1 + \omega_S^2 \tau_V^2} + \frac{4}{1 + 4\omega_S^2 \tau_V^2}\right] \tag{9}$$

$$\frac{1}{\tau_{S2}} = \frac{B\,\tau_V}{2}\left[3 + \frac{5}{1+\omega_S{}^2\,\tau_V{}^2} + \frac{2}{1+4\,\omega_S{}^2\,\tau_V{}^2}\right] \quad (10)$$

At high magnetic fields, $\omega_S\tau_{e2} >> 1$ and Equation (7) becomes Equation (11).

$$\frac{1}{T_{2M}} = \frac{S(S+1)}{3}\left(\frac{A}{\hbar}\right)^2 \tau_{e1} \quad (11)$$

A reduced relaxation rate given by Equation (12) was used in this study, where f is the ratio [paramagnetic complexes]/[water].

$$\frac{1}{T_2^r} = \frac{\left(\frac{1}{T_2^{is}}\right)}{f \times q} \quad (12)$$

The reduced transverse relaxation depends thus on the electronic relaxation time τ_{S1}, the hyperfine coupling constant $A/\hbar$, and the water residence time τ_M. The parameters $A/\hbar$ and B are independent of temperature. The temperature dependence of the water residence time and of the correlation time τ_v can be described according to the theories of Eyring and Arrhenius [Equation (13) and (14)], where $\Delta S^{\neq}$ and $\Delta H^{\neq}$ are the entropy and enthalpy of activation, respectively, for the water exchange process and E_v is the activation energy related to τ_v; τ_v^{298} is the correlation time for the modulation of the zero-field splitting interaction at 298.15 K.

$$\frac{1}{\tau_M} = \frac{k_B\,T}{h}\exp\left(\frac{\Delta S^{\neq}}{R} - \frac{\Delta H^{\neq}}{RT}\right) \quad (13)$$

$$\tau_v = \tau_v{}^{298}\exp\left(\frac{E_V}{R}\left(\frac{1}{T} - \frac{1}{298.15}\right)\right) \quad (14)$$

The temperature dependence of the ^{17}O reduced transverse relaxation rate, $1/T_2^r$, can thus be used to determine the water residence time and the related activation parameters ($\Delta S^{\neq}$ and $\Delta H^{\neq}$).

Variable Pressure ^{17}O NMR Spectroscopy: By neglecting $\Delta\omega_M$ in Equation (5) and using Equation (12), the reduced transverse relaxation rate, $1/T_2^r$, can be simplified by Equation (15), where $1/T_{2M}$ is expressed as in Equation (7).[21]

$$\frac{1}{T_2^r} = \frac{1}{T_{2M} + \tau_M} \quad (15)$$

Previous studies have shown that the logarithm of the water exchange rate varied almost linearly with pressure, as long as the compressibility coefficient of activation is negligible, as expressed by Equation (16),[31] where $\Delta V^{\ddagger}$ is the activation volume independent of pressure and $(k_{ex})_0^T$ is the water exchange rate at zero pressure and temperature T; $1/T_{2M}$ is small and therefore can be assumed to be independent of the pressure since a pressure dependence of $1/T_{2M}$ with a $\Delta V_M^{\ddagger}$ between +5 and −5 cm^3mol^{-1} does not affect the value of $\Delta V^{\ddagger}$ within the experimental errors.

$$\frac{1}{\tau_M} = k_{ex} = (k_{ex})_0^T \exp\{-\frac{\Delta V^{\ddagger}}{RT}P\} \quad (16)$$

A Study of the Method of Synthesis and Chromatic Properties of the Cr-SnO_2 Pigment

Beatriz Julián,[a] Héctor Beltrán,[a] Eloisa Cordoncillo,[a] Purificación Escribano,*[a] José Vicente Folgado,[b] Maria Vallet-Regí,[c] and Rafael P. del Real[c]

Keywords: Ceramics / Chromium / Chromium-tin pigment / Solid-state reactions / Tin

Chromium-doped tin dioxide has long been used as a violet pigment in the ceramic industry. However, traditional ceramic synthesis involves slow diffusion processes, high processing temperatures and serious environmental problems due to the use of carcinogenic Cr^{VI} precursors. This paper addresses the synthesis of Cr-SnO_2 by a novel, wet route that uses $Cr(acac)_3$ and $Sn(OiPr)_4$ as raw materials. The new wet method does not require handling of Cr^{VI} reagents and allows a reduction in the heat-treatment temperature from 1400 to 800 °C, which are promising economic and environmental improvements. The coloring mechanism in this pigment, currently the subject of debate, was also studied. The results indicate that the violet color is produced by the chromium ions incorporated in the cassiterite structure (SnO_2), while the quantity of chromium exceeding the network dissolution limit gives rise to Cr_2O_3 segregation, producing a greenish color. Electron spin resonance (ESR) and magnetic measurements show that chromium ions are present in the pigment in various oxidation states, reduced chromium species such as Cr^{III} and/or Cr^{IV} being responsible for the violet color.

Introduction

Cr-doped structures have been widely studied as ceramic pigments.[1−3] The influence of the host structure in the chromium ion crystal field produces a different coloring of the solid in which it acts as a chromophore.

Tin dioxide (cassiterite) exhibits a rutile structure consisting of infinite chains of octahedral SnO_6 linked by sharing of edges and corners to form a three-dimensional framework. This lattice has attracted attention as a host lattice for the incorporation of coloring metal ions such as transition metals, and also as a sealant for the inclusion of glaze-unstable colored pigments. When chromium ions are introduced into the SnO_2 structure in low quantities, they produce a violet color, yielding a pigment classified by DCMA (Dry Colour Manufacturer's Assn.) as 11-23-5.[4]

This pigment is usually synthesized by the conventional ceramic method, involving mixture dispersion of the metal oxides in a planetary ball mill and heat treatment of the mixture at 1200−1500 °C for a solid-state reaction. This procedure presents some drawbacks. Since the product formation rate is controlled by slow diffusion processes,[5] high reaction temperatures are required, with the energy costs entailed. These high temperatures produce losses of volatile reagents and hence departure from starting system stoichiometric conditions. To improve these interdiffusion processes, small quantities of various additives (mineralizers) need to be introduced. These mineralizers often contain toxic components. Furthermore, the Cr^{VI} precursors[6−9] used in Cr^{III} synthesis or oxidation to more oxidized species during heat treatment are highly toxic carcinogens.

To avoid the above disadvantages of the traditional ceramic method, a new method of synthesis for obtaining the reaction mixture has been tested. In this method the reagents are dissolved and begin to react at very low temperatures (70 °C). This synthesis route provides a high degree of homogeneity and low particle size, raising diffusion process efficiency, reducing heat-treatment temperature and avoiding the use of toxic mineralizers.

The Cr-SnO_2 pigment is an economically important material with a long history in the ceramic industry. However, its coloring mechanism is essentially unknown and a subject of debate.[9] The main difficulty could be related to determination of the oxidation states of the chromium ions in the network. Thus, little information on Cr-doped tin(IV) oxide materials is available.

To attempt to clarify some of these aspects, a study was undertaken, (i) to determine the optimum chromium content in the structure that yields the best color development by the traditional ceramic method, (ii) to design a new method of synthesis to reduce thermal treatment, and (iii) to determine the chromium oxidation states responsible for the violet color.

Results and Discussion

A preliminary study was carried out on five samples synthesized by the ceramic method (Method 1, see Table 5) to determine the relation between chromium starting quantity in synthesis and the resulting color after heat treatment. Phase evolution in the 1000−1400 °C range was studied by X-ray diffraction (XRD). Figure 1 shows the evolution of the crystalline phases for sample SC2.

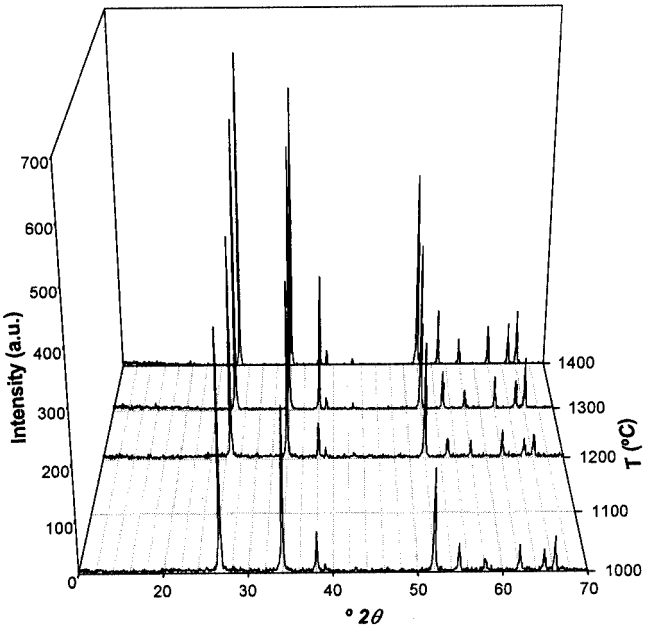

Figure 1. XRD diffractograms of sample SC2 after heat treatment at 1000, 1200, 1300 and 1400 °C for 6 h

SnO_2 (cassiterite) is the major phase in all the samples, the crystallinity of which increases with temperature. Some of the samples also exhibit peaks attributable to Cr_2O_3. The tin dioxide phase content in each sample was approximately estimated from the cassiterite (110) and Cr_2O_3 (012) peak intensities (JCPDS patterns no. 41-1445 and 38-1479, respectively) from Equation (1).

$$\%_{SnO_2} = \frac{I_{SnO_2}}{I_{SnO_2} + I_{Cr_2O_3}} \text{x}100 \quad (1)$$

Of course, for accurate analysis, a calibration curve is required for this method. XRD analysis showed a single SnO_2 phase for compositions SC1 and SC2 at all temperatures, while Cr_2O_3 was also detected for compositions SC3−SC5. In these last samples, the chromium(III) oxide phase content decreased when the temperature increased. Figure 2 plots these results. It shows that, in the samples in which the chromium content rises, high temperatures are required to produce a single phase, 1200 °C for sample SC3, 1300 °C for sample SC4, etc.

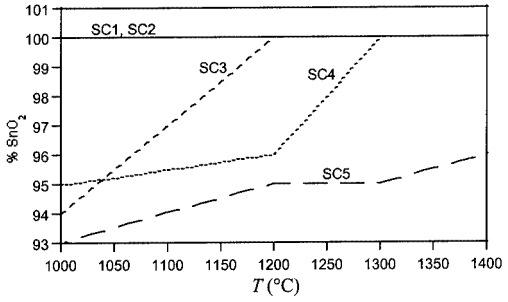

Figure 2. SnO_2 content (%) versus temperature for samples SC1, SC2, SC3, SC4 and SC5

Table 1. Colours of the samples produced by the dry method after heat treatment

Sample	1000 °C/6 h	1200 °C/6 h	1300 °C/6 h	1400 °C/6 h
SC1	pale pink	pale pink	pink-violet	violet
SC2	pale pink	pink	violet	intense violet
SC3	grey	pink-grey	pink-grey	violet-grey
SC4	grey-green	grey-pink	grey-pink	grey-pink
SC5	green	grey-green	grey-green	grey-green

Table 1 details the color of the ceramic samples heat-treated at different temperatures. For compositions with chromium contents lower than that in SC3, the violet color develops after heat treatment at 1300−1400 °C for 6 h, the SC2 composition having the most intense color. However, in samples with a chromium quantity exceeding that in SC2, a greenish shade overlies the characteristic violet color, giving rise to a greyish color for compositions SC3 and SC4, and greenish colors for SC5 at all temperatures.

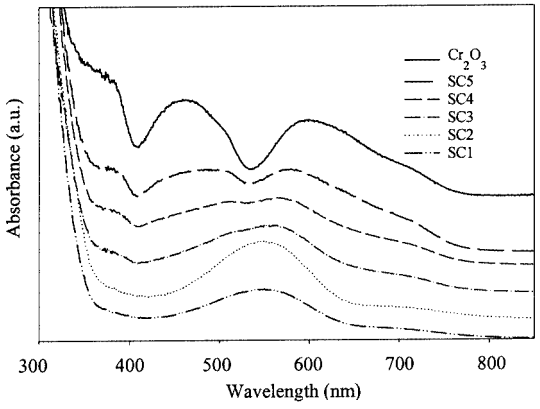

Figure 3. Diffuse reflectance spectra of ceramic samples calcined at 1400 °C for 6 h and of Cr_2O_3

Figure 3 depicts the diffuse reflectance spectra of the ceramic samples after calcination at 1400 °C for 6 h, showing the evolution of the bands with chromium content (from SC1 to SC5). The Cr_2O_3 spectrum is also included as a

reference. It is to be noted that the color of pure chromium(III) oxide is green.

In the Cr_2O_3 spectrum, two bands at 460 and 600 nm can be observed. The Cr^{III} ion, with a $3d^3$ electronic configuration, tends to an octahedral coordination. According to the Tanabe-Sugano diagram these bands can be attributed to $^4A_{2g} \rightarrow {}^4T_{2g}$ and $^4A_{2g} \rightarrow {}^4T_{1g}(F)$ spin-allowed transitions, respectively. SC1 and SC2 sample spectra exhibit a wide absorption band centerd at 18182 cm^{-1} (550 nm) and a shoulder at 14286 cm^{-1} (700 nm). In the samples with higher Cr content, however, a progressive twofold splitting of the wide absorption band can be seen. Thus, as sample SC2 developed the most intense color, the violet shade can be associated with absorption at 550 nm.

The above results indicate that, under the working conditions used, SC2 is the optimum composition. A doping ion quantity higher than that contained in $Sn_{0.985}Cr_{0.02}O_2$ cannot be fully accommodated by the host lattice, resulting in Cr_2O_3 segregation (detected by XRD), causing the greenish shade in the pigment.

It is difficult to establish where and how the chromium ion is located in the pigment, due especially to the small doping content in the violet samples (SC1 and SC2). The fact that XRD spectra of these samples detected a single tin dioxide phase at all temperatures could suggest the formation of a solid solution.

From a review of the experimental results on alloy formation, it is suggested that a difference of 15% in the radii of the metal atoms that are replacing each other is the most that can be tolerated if a substantial solid solution range is to be formed. For solid solutions in nonmetallic systems, the limiting acceptable difference in size appears to be rather larger than 15%, although difficult to quantify because it is difficult to quantify the sizes of the ions themselves.[10]

If a solid solution were formed in this system, a shift in the SnO_2 diffraction peaks should be detected, because the idealized cation radii of chromium(III) and tin(IV) ions in octahedral coordination are 75.5 and 83 pm, respectively.[11] However, comparison of XRD spectra of doped and undoped tin dioxide showed no deviations in peak positions. On the other hand, if there is free Cr_2O_3 outside the tin dioxide lattice, the amount must be below the sensitivity threshold of the instrument. XRD analysis therefore does not enable solid solution formation to be established.

The Cr-SnO_2 pigment composition was thus optimized (sample SC2) by the ceramic method. This composition was therefore prepared by the wet method (sample referenced SC6). Undoped tin dioxide was also synthesized as a reference under the same conditions (sample S2).

XRD characterization of the powders produced by Method 2 (after heating under reflux and evaporation of the solvent) showed that they were amorphous. To determine the cassiterite crystallization temperature and to design an appropriate heat treatment to remove organic matter, differential thermal (DTA) and thermogravimetric (TG) analyses were performed. Figure 4 shows the DTA/TG data for sample SC6 in the 25−1200 °C range.

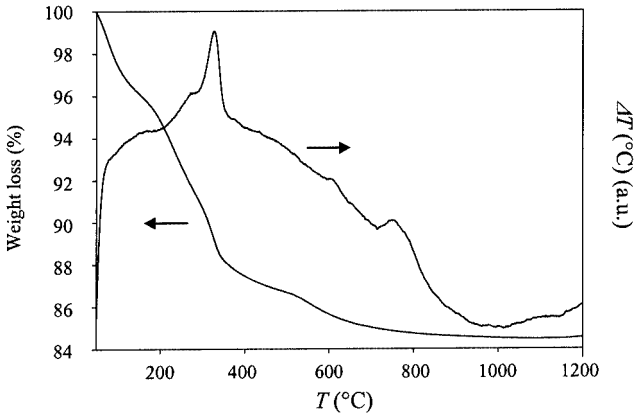

Figure 4. DTA/TG curves found for sample SC6

The DTA curve of SC6 displayed several broad exothermic peaks below 650 °C, which were accompanied by a gradual weight loss of 15% as detected by TG measurements. These bands can be assigned to solvent evaporation (below 150 °C) and decomposition/combustion of the organic groups. An exothermic peak without weight loss at 750 °C was also detected. This latter peak could be tentatively associated with cassiterite crystallization. To confirm this, the sample was heat-treated at several temperatures below and above 750 °C, followed by XRD analysis. The resulting XRD patterns indicated that SnO_2 crystallization occurred at 400 °C. The crystallization peak in the DTA curve is probably overlapped by organic matter burnout (between 150 and 650 °C) and cannot be detected. Moreover, the same peak was also observed in the undoped sample (SC2). This exothermic peak was therefore associated with SnO_2 phase transformation.

In spite of the detection of SnO_2 crystallization at 400 °C, heat-treatment design needed to ensure complete removal of organic matter. Taking this into account and also to enable comparison of the results of the two methods of synthesis, the following heat-treatment schedule was adopted. Samples SC2 and SC6 (with the same composition but synthesized by different methods) were calcined in air at a heating rate of 10 °C/min at 800, 1000, 1200, 1300, and 1400 °C for 6 h, with a hold at 500 °C for 1 h. The diffractograms of the samples indicate the presence of SnO_2 as single phase, while the diffraction peak intensity increases with temperature.

Table 2 shows the color and CIELAB (L*a*b*) parameters of samples SC2 and SC6 after heat treatment at several temperatures.

In Table 2 the same color evolution can be observed for both samples from 1000 to 1400 °C. However, at 800 °C the ceramic sample exhibited a yellow color, whereas sample SC6 exhibited a violet color with L*a*b* parameters similar to those found for the SC2 sample after calcination at 1400 °C for 6 h. The wet method thus reduced the synthesis temperature by 600 °C.

The diffuse reflectance spectra of the SC2 and SC6 samples under different heat-treatment conditions are dis-

Table 2. L* a* b* parameters for SC2 and SC6 samples heat treated at different temperatures

	800 °C/6 h		1000 °C/6 h		1200 °C/6 h		1400 °C/6 h

played in Figure 5, part a) (ceramic method) and part b) (dissolution method).

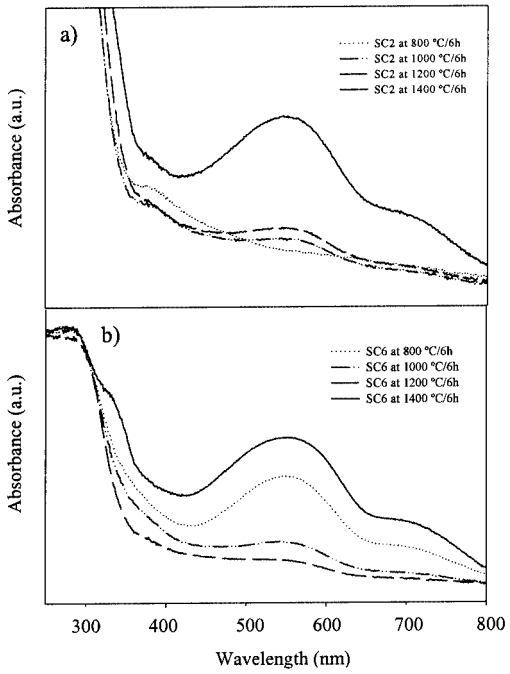

Figure 5. Diffuse reflectance spectra of samples (a) SC2 and (b) SC6 heat-treated at 800, 1000, 1200 and 1400 °C for 6 h

All the spectra show a strong absorption band in the ultraviolet zone (from 200 to around 350 nm) but different behavior is observed in the two synthesis methods. The most remarkable fact is the similarity between the spectra of the SC2 sample, calcined at 1400 °C for 6 h, and the SC6 sample calcined at 800 °C for 6 h, producing the same color in the two samples (Table 2). The spectrum of sample SC6 heat treated at 1400 °C shows a high intensity for the band centerd at 550 nm, which explains the very intense violet color exhibited by this sample.

Although exhaustive study for thorough understanding of the pigment-coloring mechanism is still pending, exploratory studies were performed to determine the origin of the differences found in the colors of samples SC2 and SC6 heat-treated under the same conditions.

The first explanation advanced was that the violet color was related to the quantity of chromium introduced into the SnO_2 framework. This would allow a ready explanation of the violet color found in the sample prepared by the wet method at 800 °C, since the degree of homogeneity and the reaction rate are much higher than in the ceramic method.

An estimation was therefore made of the Cr content inside and outside the framework for the SC2 and SC6 samples calcined at 800 and 1200 °C for 6 h. These two temperatures were chosen because at 800 °C/6 h the colors of the two samples were quite different, while at 1200 °C/6 h the color was the same. The samples were washed by the procedure described in the Exp. Sect. Acid attack and oxidation to Cr^{VI} were performed to remove the unretained chromium in the SnO_2 lattice. The Cr^{VI} content in the washing liquids was determined by atomic absorption spectrometry (AAS), and the Cr content in the washed powders was analysed by X-ray fluorescence (XRF). The values, expressed in mol Cr/g pigment, are summarized in Table 3.

Table 3. Cr^{VI} content in washing liquids and Cr content in washed powders

Sample	800 °C/6 h	1200 °C/6 h
SC2 (washing liquids)	3.034×10^{-5}	1.283×10^{-5}
SC2 (powders)	1.171×10^{-4}	1.355×10^{-4}
SC6 (washing liquids)	2.657×10^{-5}	1.794×10^{-5}
SC6 (powders)	1.118×10^{-4}	1.013×10^{-4}

The initial chromium content was 1.334×10^{-4} mol/g pigment. Table 3 shows that the Cr^{VI} content in the washing liquids is slightly higher in samples heat-treated at 800 °C for 6 h. This is a reasonable finding, if it is taken into account that the introduction of chromium into the SnO_2 structure requires slow diffusion processes, which improve with increasing temperature. However, no significant difference in Cr^{VI} content, that could be responsible for the drastic difference in color (at 800 °C), was found between the washing liquids of samples SC2 and SC6. Moreover, the color of the washed and unwashed samples does not differ significantly. On the other hand, the Cr content detected in the solid by XRF for both samples at the two temperatures is also similar (it is to be noted that measurement was at the detection limit of this technique).

Due to the similarity of the Cr content in both samples, the differences in color can be considered mainly due to variations in the oxidation state of the chromium ions, and not to the chromium content introduced into the SnO_2 structure.

In order to analyse the chromium oxidation states, electron spin resonance (ESR) analysis was performed for samples SC2 and SC6 heat-treated at 800 and 1200 °C. The ESR spectra found are depicted in Figure 6.

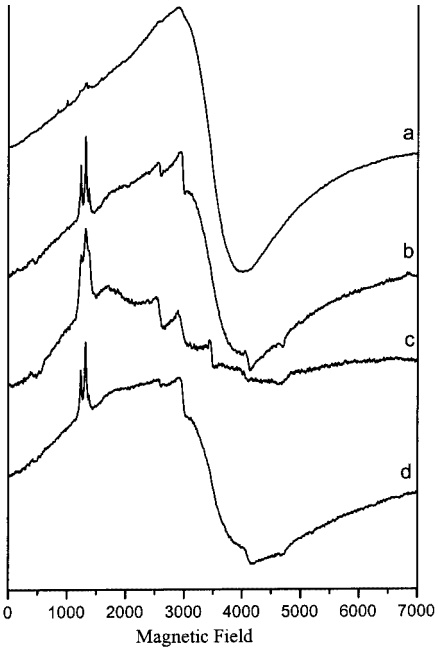

Figure 6. ESR spectra of sample SC2 heat-treated at 800 °C/6 h (a) and 1200 °C/6 h (b), and sample SC6 heat-treated at 800 °C/6 h (c) and 1200 °C/6 h (d)

The four spectra are each dominated by a very broad signal centerd at a g value of ca. 2, with other, narrower, superimposed peaks. The ratio between the narrow and the broad signals depends on the method of synthesis and the heat-treatment temperature. These facts indicate the presence of Cr^{3+} in the samples. The broad isotropic signal can be attributed to Cr_2O_3-like clusters, whereas the narrow signals correspond to isolated Cr^{3+} ions (i.e., diluted in a diamagnetic lattice[12−14]). Broad signals at $g = 2$ have also been observed in mixed-valence trimers of the type $Cr^{VI}-O-Cr^{III}-O-Cr^{VI}$ with an average oxidation state of +5.[15,16]

The spectra of sample SC2 at 800 °C/6 h are dominated by the signal at $g = 2$, indicating that the chromium ions are predominantly forming clusters. In contrast, for sample SC6 at the same temperature, the chromium ions basically appear as isolated species and the relative quantity of clusters is smaller. Moreover, in the latter sample, a very weak sharp signal at $g = 2$ may indicate the presence of a small quantity of Cr^{V} or tetrahedrally coordinated Cr^{IV} ions.[17] Almost identical spectra were found for the SC2 and SC6 samples heat-treated at 1200 °C for 6 h. In these samples, isolated Cr^{3+} ions and clusters are observed and, although the cluster fraction is still significant, it is lower than that in SC2 at 800 °C for 6 h.

With regard to the set of signals associated with isolated Cr^{3+} ions, at least seven features are observed in each spectrum. Careful study of these signals indicates that they are due to the presence of Cr^{3+} in two different polyhedral coordinations, both corresponding to orthorhombically distorted octahedra.[12−14] Cr^{III} is an $S = 3/2$ ion and exhibits a zero field splitting (characterized by D and E parameters), which is very sensitive to small variations of the local crystal field. In our case, the spectra are typical of $2D >> h\nu$ and $E \neq 0$, and two groups of five signals should be expected under the experimental conditions used. Although no accurate calculations can be performed, due to overlapping and poor resolution of the signals, a value of $D > 0.6$ cm^{-1} and an E/D ratio of ca. 0.22 and 0.28 can be estimated for the two slightly different sites. The higher E value corresponds to a major orthorhombic distortion of the site. These values are very similar to those found in Cr^{3+} diluted in TiO_2-rutile,[12−14] and suggest that Cr^{3+} is incorporated into the Sn sites in the SnO_2 lattice.

This study reflects the tendency of paramagnetic chromium ions to form clusters with strong Cr−Cr interactions. Since no remarkable differences in chromium oxidation states were found in the different samples and no clear signal associated with isolated Cr^{V} species and Cr^{IV} ions was detected, the color difference could be related to the quantity of chromium in each oxidation state. The clustering effect may modify the color slightly, but would not be expected to produce the drastic changes in color found in these samples.

To confirm the presence of Cr^{III} in the two different distorted octahedral environments, the band observed in the UV/Vis spectra at 550 nm was deconvoluted by a Gaussian function. Figure 7 shows that this band can be resolved into two bands centerd at 578 and 510 nm, which matches ESR results.

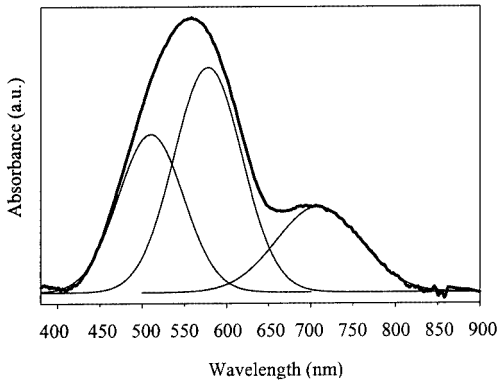

Figure 7. Deconvolution in Gaussian functions of the band centerd at 550 nm

According to the Tanabe-Sugano diagram, two other bands should be observed in the UV/Vis region. The most energetic band should appear in the UV zone and cannot be detected. The second band associated with a $^4A_{2g} \rightarrow {}^4T_{2g}$ transition should appear at around 380 nm, but is overlapped by a broad charge-transfer band in the UV zone.

The presence of Cr^{IV} ions was also studied in the absorption spectra, but no characteristic signals of this species were found (in the IR region, at 1000−1200 nm).[18] If any Cr^{IV} ions are contained in the pigment, they must be in

small quantities as they are not detected within the sensitivity limits of the instrument.

As the presence of Cr^{II} ions was precluded under the synthesis conditions used, the existence of chromium ions in more than one oxidation state (Cr^{VI}, Cr^{V}, Cr^{IV} and Cr^{III}) was determined from measurements of magnetic moment (*m*) vs. magnetic field (*H*) at a constant temperature of 77 K. For this purpose the magnetic response of a sample is assumed to be generated from the paramagnetic contributions of the chromium ions in each oxidation state. It was further assumed that the chromium ions in a sample are only contained in two oxidation states, Cr^{VI} (with no magnetic response) and Cr in another oxidation state (III, IV or V, each having its own magnetic response). Table 4 summarizes the calculated quantity of Cr^{VI} contained in the structure for each pair of oxidation states (Cr^{III} and Cr^{VI}, Cr^{IV} and Cr^{VI}, or Cr^{V} and Cr^{VI}).

Table 4. Cr^{VI} content (%) in the samples for each pair of oxidation states

	Cr^{VI} (%)			
Oxidation state	SC2 at 800 °C/6 h	SC6 at 800 °C/6 h	SC2 at 1200 °C/6 h	SC6 at 1200 °C/6 h
Cr^{III}	82	40	91	81
Cr^{IV}	66	0	84	64
Cr^{V}	8	−	57	5

The Cr^{VI} content (%) was found from the slope (*m* vs. *H*) and quantity of Cr in the samples.[19]

The data indicate that all samples contain chromium ions in different oxidation states. Sample SC6 at 800 °C shows a high magnetic response, which could be attributable to all the chromium ions being in oxidation state IV (and no Cr^{VI} would be present). However, since Cr^{III} was detected by ESR, it must also contain Cr^{VI}, so that this sample must mainly contain species in low oxidation states (Cr^{III} and Cr^{IV}) and a minor quantity of Cr^{VI}. All the other samples show low magnetization values indicating a very high Cr^{VI} content, this being especially notable for sample SC2 at 1200 °C for 6 h. Samples SC2 at 800 °C and SC6 at 1200 °C exhibit the same magnetic behavior, but different colors. This can be explained by the assumption of a different distribution of chromium ions in the various oxidation states.

The ESR results and magnetic measurements therefore indicate that differences in color are directly related to the quantity of chromium in each different oxidation state, and must be mainly generated by reduced species such as Cr^{III} and Cr^{IV}. Emission measurements are currently under further investigation in order to achieve a better understanding of the coloring mechanism.

Conclusion

A new synthesis method to prepare chromium-doped tin dioxide from a mixture of Sn^{IV} and Cr^{III} precursors has been devised, and compared with the traditional ceramic method. The composition that developed the best violet color under the working conditions used was $Sn_{0.985}Cr_{0.02}O_2$. The great advantage of this dissolution method is that the intense violet color can be produced after heat treatment at 800 °C for 6 h, whereas the traditional method requires heat treatment at 1400 °C for 6 h. An excess of chromium content in the SnO_2 structure causes the segregation of Cr_2O_3, giving rise to a greenish shade.

ESR studies reflect the tendency of paramagnetic chromium ions to form clusters with strong Cr−Cr interactions and reveal that the main chromium oxidation state in all the samples is Cr^{III}. The presence of Cr^{IV} ions was also studied by diffuse reflectance spectra but no characteristic signals of this species were found.

All the studies performed to establish the coloring mechanism indicate that the origin of the violet color is unrelated to the quantity of chromium introduced in the structure, but is directly associated with the quantity of chromium present in different oxidation states, the reduced chromium species (Cr^{III} and/or Cr^{IV}) being mainly responsible for the violet color.

This new synthesis method presents promising results for the ceramic industry from an economic and environmental standpoint.

Experimental Section

General Remarks: Two different synthesis routes for preparing the precursor mixture for the solid-state reaction were developed, the traditional ceramic method from Sn^{IV} and Cr^{III} oxides (Method 1) and a method in which the Sn^{IV} and Cr^{III} reagents are dissolved (Method 2). The nominal compositions and references of the samples synthesized are summarized in Table 5. In a first step, the optimum Cr content was established for samples produced by the ceramic method and the best composition (SC2 sample) was also synthesized by the dissolution method (SC6 sample). In Method 1, the following precursors were used: SnO_2 (Panreac, analytical grade) and Cr_2O_3 (Merck, analytical grade). These samples were prepared by mixing and homogenizing stoichiometric amounts of each precursor in a planetary ball mill, with acetone used as a dispersant. After evaporation of the dispersant at room temperature, the samples were dried under infrared lamps. In Method 2, synthesis was performed by heating the appropriate amount of $Cr(acac)_3$ (Merck, pure grade) under reflux in a 2-propanol solution of $Sn(OiPr)_4 \cdot i$PrOH adduct (ABCR, analytical grade). Sample

Table 5. Nominal composition of the samples

Sample	Composition	Method of synthesis
SC1	$Sn_{0.992}Cr_{0.01}O_2$	1
SC2	$Sn_{0.985}Cr_{0.02}O_2$	1
SC3	$Sn_{0.956}Cr_{0.06}O_2$	1
SC4	$Sn_{0.927}Cr_{0.1}O_2$	1
SC5	$Sn_{0.86}Cr_{0.2}O_2$	1
S2	SnO_2	2
SC6	$Sn_{0.985}Cr_{0.02}O_2$	2

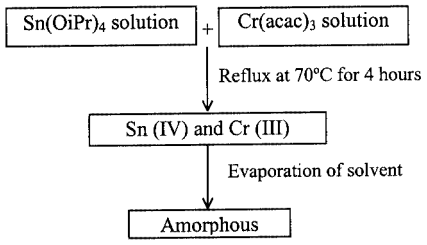

Figure 8. Synthesis diagram of S2 and SC6 samples

preparation is set out in the flow diagram in Figure 8. As an SnO_2 structure is generated during heat treatment in this method of synthesis, an undoped sample (referenced S2) was prepared by the same experimental procedure. All the samples were heat-treated in an electric furnace at different temperatures (from 800 to 1400 °C for 6 h) at a heating rate of 10 °C/min. In order to refine and homogenize the particle size after calcination, the resulting product was ground in an agate mortar with acetone, followed by sieving to 50 μm.

Instrumentation: Crystalline phase evolution of the calcined powders was monitored by X-ray powder diffraction (XRD) with a SIEMENS D5000 diffractometer with Cu-K_α radiation. Data were collected by step-scanning from $2\theta = 10$ to 70° with a step size of $2\theta = 0.050°$ and 1 s counting time per step. The automatic diffractometer was controlled by "SIEMENS DIFFRACT plus" software, which records diffraction peak positions and intensities. Differential thermal (DTA) and thermogravimetric (TG) analyses were performed in a Mettler Toledo model SDTA 851^e. All experiments were run in air from 25 to 1200 °C with a heating rate of 10 °C/min. UV/Vis spectra (diffuse reflectance) and CIELAB parameters were determined at room temperature with a spectrophotometer (CARY 500 SCAN) and a coupled analytical software for color measurements. The data were registered from 200 to 1400 nm with a PTFE blank as reflecting standard. CIELAB color parameter measurements were conducted using a D65 standard illuminant. ESR experiments were performed at 100 K with a Bruker spectrophotometer (ER200D) in the X-band at 9.5 GHz. Magnetic susceptibilities were recorded as a function of the magnetic field at 20 K with a SQUID magnetometer ($H_{max} = 5$ T). In view of the high carcinogenicity of Cr^{VI} ions, the Cr^{VI} content in the washing liquids of the samples was determined by atomic absorption. 1 g of sample was subjected to successive washings with hot 0.3 M HNO_3 until 100 mL of solution was obtained. Measurements were conducted with a Varian Spectra 640 atomic absorption spectrophotometer. Besides these analyses, the chromium content was determined on solid samples by X-ray fluorescence spectrometry with a PHILIPS instrument (Model PW 2400) fitted with an Rh tube and eight single crystals for analysis: LiF200, LiF220, GE(111), InSn, PE, TLAP, PX1 and PX3.

Synthesis and Structures of Triorganotelluronium Pseudohalides

Thomas M. Klapötke,*[a] Burkhard Krumm,[a] Peter Mayer,[a][‡] Holger Piotrowski,[a][‡] Ingo Schwab,[a] and Martin Vogt[a][‡]

Dedicated to Professor D. Naumann on the occasion of his 60th birthday

Keywords: Tellurium / Azides / NMR spectroscopy / Noncovalent interactions

The syntheses of $[(CH_3)_3Te]X$ {X = N_3 (**1**), OCN (**2**), SCN (**3**), SeCN (**4**), $[Ag(CN)_2]$ (**5**)} and $[(C_6H_5)_3Te]X$ {X = N_3 (**6**), SeCN (**7**), $[Ag(CN)_2]$ (**8**)}, their NMR spectroscopic data, vibrational spectra and single crystal structures are described. Compounds **1**–**4** are the first trimethyltelluronium pseudohalides, while the known compounds **6** and **7** have been prepared for completion of their analytical and structural properties. The occurrence of intermolecular Te···N, Te···O, Te···S and Te···Se contacts is thoroughly studied. The dicyanoargentates **5** and **8** were obtained in an attempt to prepare telluronium cyanides. Low-temperature ^{13}C NMR spectroscopy of the $[Ag(CN)_2]^-$ ion in solution has been carried out, with determination of the ^{13}C–$^{107/109}Ag$ coupling.

Introduction

Telluronium salts $[R_3Te]X$ have been known for more than a hundred years.[1,2] Some experimental work has been carried out since then, synthesizing telluronium cations with various substituents. In the 1970s Ziolo reported on the first telluronium pseudohalides $[(C_6H_5)_3Te]X$ (X = N_3, CN, OCN, SCN, SeCN),[3,4] with no NMR spectroscopic characterization, but single-crystal X-ray data for $[(C_6H_5)_3Te]OCN$ and $[(C_6H_5)_3Te]SCN$.[5–7]

The preparation and characterization of tris(perfluorophenyl)tellurium(IV) halides $(R_F)_3TeCl$ and $(R_F)_3TeBr$ (R_F = C_6F_5, $CF_3C_6F_4$) was achieved recently.[8] Their X-ray crystallographic analysis and properties revealed structures consistent with a rather covalent constitution.

Telluronium halides and pseudohalides bearing nonfluorinated substituents are in most cases widely ionic and show strong electrolyte behavior in solution.[9,10] Dihalotelluranes R_2TeX_2 feature intermolecular interactions in the solid state, whose distances lie between those of the sum of covalent and van der Waals radii.[11–13] Similar secondary interactions[14] have also been found in telluronium salts.[15,16]

To the best of our knowledge, no trimethyltelluronium pseudohalide has been reported, and continuing our efforts to explore the chemistry of main-group element azides, we report here on the first single-crystal structural determination of telluronium azides. $[(CH_3)_3Te]N_3$ (**1**) and $[(C_6H_5)_3Te]N_3$ (**6**) complete the series $R_nTe(N_3)_{4-n}$ (R = CH_3 or C_6H_5; n = 1, 2, 3), of which both $(CH_3)_2Te(N_3)_2$ and $CH_3Te(N_3)_3$, as well as $(C_6H_5)_2Te(N_3)_2$ and $C_6H_5Te(N_3)_3$ were recently synthesized and characterized.[17,18]

Pursuing the work of Ziolo, we intended to complete his examinations of **6** and **7** with modern spectroscopic and crystallographic methods. Moreover, the scope of telluronium pseudohalides should be extended to the smallest compounds, trimethyltelluronium salts. Thus, the preparation of a series of trimethyltelluronium chalcogenocyanates **2**–**4** was of further interest.

An attempt to prepare telluronium cyanides, omitting the use of an anion exchange resin,[4] will be reported. This work can be seen in context with a very recent report, dealing with structural investigations of several triphenyltelluronium transition metallates.[19]

Results and Discussion

Synthesis

Suitable precursors for the synthesis of telluronium compounds $[R_3Te]X$ are the corresponding telluronium halides. These can be obtained either by the reaction of Grignard reagents with tellurium tetrachloride,[2] or the aqueous ha-

logenation of tetraalkyl- or tetraaryltelluranes, generated in situ [Equation (1)].[20]

$$TeCl_4 + 4\,RLi \xrightarrow[-4\,LiCl]{Et_2O,\ -70\ ^\circ C} R_4Te \xrightarrow[-RH]{H_2O/KI} [R_3Te]I \qquad R = CH_3, C_6H_5 \qquad (1)$$

Another method for the preparation of $[(C_6H_5)_3Te]Cl$ is the Friedel−Crafts type arylation of tellurium tetrachloride with benzene and aluminum trichloride.[21] Some references stated this as a method suitable for the preparation of $[(C_6H_5)_3Te]Cl$. However, it was found by tracing this reaction at different temperatures up to 90 °C, that the latter approach is somewhat slower than reported.[21] Additionally, minor impurities of $(C_6H_5)_2TeCl_2$ are always present in the isolated product, which was proven by ^{125}Te NMR spectroscopy with a resonance at $\delta = 920$ ppm.

The synthesis of trimethyltelluronium pseudohalides **1**−**4** is achieved by reaction of the corresponding silver pseudohalides with trimethyltelluronium iodide in aqueous or ethanolic solutions [Equation (2)].

$$[(CH_3)_3Te]I + AgX \xrightarrow[-AgI]{H_2O\ or\ EtOH} [(CH_3)_3Te]X \qquad X = N_3, OCN, SCN, SeCN \qquad (2)$$
$$(1)\quad (2)\quad (3)\quad (4)$$

The trimethyltelluronium pseudohalides are colorless salt-like substances which slowly release dimethyltellane as a product of their reductive decomposition [Equation (3)].

$$[(CH_3)_3Te]X \xrightarrow{slow\ dec.,\ 25\ ^\circ C} (CH_3)_2Te + CH_3X \qquad (3)$$

Another method of preparation of telluronium pseudohalides is employed for the preparation of **6** and **7**. As previously described,[4] they can be obtained by a two-phase exchange reaction of $[(C_6H_5)_3Te]Cl$ with an excess of NaN_3 (**6**), and by simply precipitating a hot aqueous solution with excess KSeCN (**7**) [Equation (4)]. Since **6** and **7** are known compounds, they have been prepared for further spectroscopic and structural characterization and in order to compare the properties of telluronium pseudohalides with different cations.

$$[(C_6H_5)_3Te]Cl \xrightarrow[-NaCl]{NaN_3/H_2O/CHCl_3} [(C_6H_5)_3Te]N_3\ (6) \qquad [(C_6H_5)_3Te]Cl \xrightarrow[-KCl]{KSeCN/H_2O} [(C_6H_5)_3Te]SeCN\ (7) \qquad (4)$$

Of further interest in this study would be a telluronium cyanide. The only report of such a compound was also given by Ziolo, who stated that its synthesis had succeeded with the use of an anion exchange resin.[4] Applying the methods mentioned before, mostly led to the formation of an unidentified red decomposition product, after trimethyl- or triphenyltelluronium chloride had been treated with excess of KCN and evaporated subsequently. The use of silver cyanide produced the highly stable dicyanoargentate salts $[(CH_3)_3Te][Ag(CN)_2]$ (**5**) and $[(C_6H_5)_3Te][Ag(CN)_2]$ (**8**), since the complex dicyanoargentate anion formed during the reaction is more stable than the corresponding silver halides [Equation (5)]. Although their synthesis was not an initial goal, they were fully characterized including X-ray crystallography.

$$[R_3Te]I + 2\,AgCN \xrightarrow[-AgI]{H_2O} [R_3Te][Ag(CN)_2] \qquad R = CH_3, C_6H_5 \qquad (5)$$
$$(5)\quad (8)$$

Vibrational Spectra

In their IR (strong), as well as their Raman (weak) spectra, the antisymmetric stretching vibration $\nu_{as}N_3$ is visible for both telluronium azides **1** and **6**. They are found in the region of 2030−2000 cm^{-1} similar as found for the $\nu_{as}N_3$ of covalent tellurium(IV) azides.[17,18] Since **1** and **6** exhibit ionic character, the difference between their $\nu_{as}N_3$ frequencies and that of ionic azide ion in NaN_3 ($\nu_{as}N_3 = 2041$ cm^{-1}, $\nu_sN_3 = 1344$ cm^{-1})[22] is negligible. The symmetric stretching vibration, ν_sN_3, is visible in the Raman spectra at 1376 cm^{-1} for **1**, and 1328 cm^{-1} for **6** with medium intensity and in the IR spectra with weak intensity.

Compounds **2**−**4** and **7** are chemically related and may be described together. Again, comparison of their vibrational spectra, namely the $\nu_{as}XCN$ vibration, shows only minor differences from the precursors. As found for **1** and **6**, the telluronium chalcogenocyanates exhibit ionic nature as well. No coordination effects in solution have been proven (NMR section), but the coordination in the solid state shows a significant effect, accounting for a shift of 20 cm^{-1} on the S−C stretching vibration of the SCN^- moiety in the Raman spectrum of **3** (732 cm^{-1}), compared to 749 cm^{-1} in KSCN (Table 1).

Table 1. IR/Raman vibrational frequencies of trimethyltelluronium pseudohalides

[a] **1**−**5** in D_2O, **6**−**8** in $CDCl_3$. [b] J and $\Delta\nu_{1/2}$ in Hz. [c] ^{109}Ag shift δ = 593 ppm.

Comparison of the Raman spectra of $[(CH_3)_3Te][Ag(CN)_2]$ (**5**) and $[(C_6H_5)_3Te][Ag(CN)_2]$ (**8**) with the Raman spectrum of crystalline $K[Ag(CN)_2]$ (νCN = 2140 cm^{-1})[27] shows that νCN is slightly shifted to 2132 cm^{-1} (**5**) and 2135 cm^{-1} (**8**). Further deviations are not detected.

The vibrational data indicate that all compounds consist of discrete ions in the solid state.

NMR Spectra

The NMR spectroscopic data (Table 2) confirm the salt-like nature of the compounds. In case of the azides, two resonances were observed in the ^{14}N NMR spectra at δ = −132 (N_β) and −266 ($N_{\alpha\gamma}$) ppm for **1** and δ = −132 (N_β) and −272 ($N_{\alpha\gamma}$) ppm for **6**. This strongly suggests, that in solution **1** and **6** are completely dissociated into telluronium cations and azide anions, since for covalently bound azides, three distinct ^{14}N resonances are observed.[17,18] The ^{125}Te NMR spectra show resonances at δ = 443 ppm (D_2O) and δ = 456 ppm ($CDCl_3$) for **1** and δ = 795 ppm ($CDCl_3$) for **6**, which, as expected, are very similar to the shifts of the starting materials $[(CH_3)_3Te]I$ [δ = 441 ppm (D_2O)] and $[(C_6H_5)_3Te]Cl$ [δ = 759 ppm ($CDCl_3$)], respectively. The corresponding triorganoselenonium azides are discrete ions in solution as well.[28]

For compounds **2**−**5**, **7**, and **8**, only minor variations of the ^{125}Te chemical shift are found, proving the negligible effect of the counterion on the telluronium cation in solution. This is consistent with the ^{125}Te NMR spectroscopic data of $[(C_6H_5)_3Te]_2[MCl_6]$ (M = Ir, Pt) and $[(C_6H_5)_3Te][AuCl_4]$.[19]

The ^{77}Se NMR shift of $[(CH_3)_3Te]SeCN$ (**4**) in D_2O is δ = −324 ppm, which is very similar to that of KSeCN in D_2O (δ = −340 ppm) and $[(CH_3)_3Se]SeCN$ [δ(SeCN) = −328 ppm],[28] but notably different to that of $[(C_6H_5)_3Te]$-SeCN (**7**) in $CDCl_3$ (δ = −144 ppm). This is believed to be mainly a solvent effect.[10] On going from cyanate **2** to thiocyanate **3** and selenocyanate **4**, the linewidth of the ^{14}N NMR resonance increases with the chemical shift. This reflects the change in electronegativity and shielding properties of the chalcogen atom in the chalcogenocyanate moiety.

An interesting temperature-dependent behavior is observed for the ^{13}C NMR resonance of $[(C_6H_5)_3Te][Ag(CN)_2]$ (**8**). At 25 °C, a single resonance at δ = 143 ppm is detected for the cyano resonance. Variable-temperature measurements of the ^{13}C NMR spectra of **8** between −100 °C and 60 °C in $[D_8]THF$ show, that below 25 °C the CN resonance broadens, and at ca. −80 °C two resonances become visible (Figure 1a). Finally, at −100 °C, both the $^{1}J^{13}C-^{107}Ag$ (J = 183 Hz) and the $^{1}J^{13}C-^{109}Ag$ (J = 209 Hz) coupling is resolved (Figure 1b). A similar feature has been reported for $K[Ag(CN)_2]$ in DMF upon cooling below −50 °C.[29]

The coupling with silver isotopes ^{107}Ag (I = −1/2, 51.82%) and ^{109}Ag (I = −1/2, 48.18%)[30] can be observed only at low temperatures, often explained as a result of fast exchange mechanisms.[31−34] For **8**, the calculated ratio of the coupling constants 0.876 is very close to that predicted by the theoretical ratio of the gyromagnetic constants $\gamma^{107}Ag/\gamma^{109}Ag$ = 0.869.

Crystal Structures

As indicated earlier, the crystal structures of $[Ph_3Te]X$ (X = OCN, SCN)[5−7] are known, but for X = N_3 (**6**) and X = SeCN (**7**) only powder diffraction data existed.[3] Hence, for all compounds described in the synthesis section, single-crystal structure determinations have been carried out. Our focus has been set especially on the interactions between the telluronium cations and the different anions, leading to an extended coordination sphere around the tellurium centre (Table 3). The concept of secondary interactions[14] also applies for telluronium compounds[5,6,19,35,36] and was subject to a detailed study.[15,16]

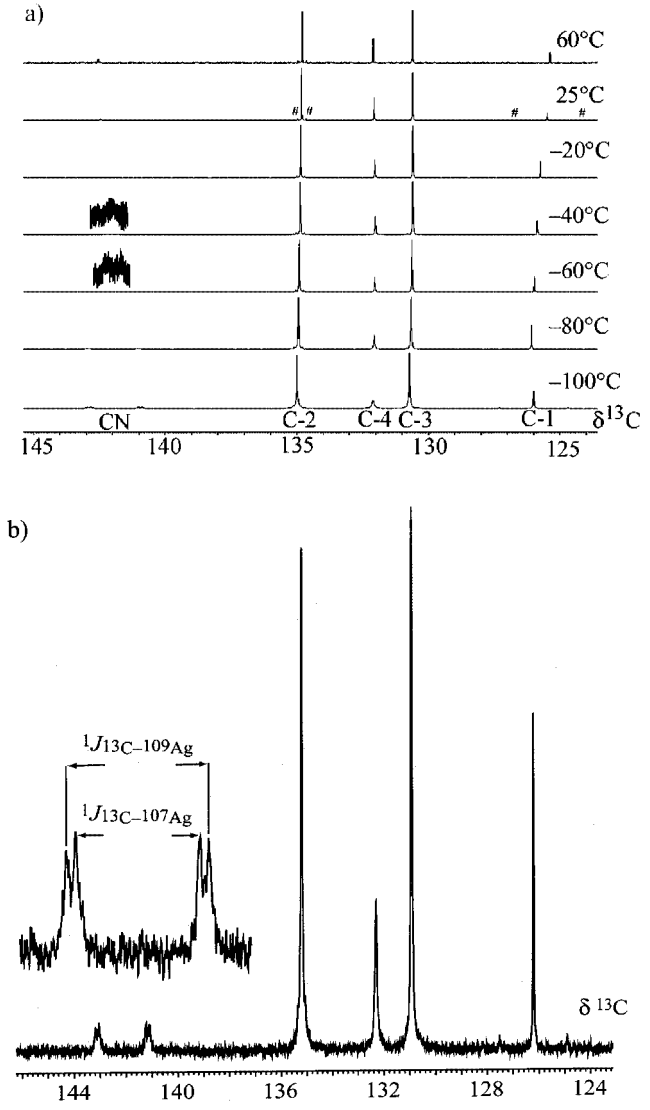

Figure 1: (a) Variable-temperature ^{13}C NMR spectra of $[Ph_3Te][Ag(CN)_2]$ (**8**) in $[D_8]$THF; asterisks denoting ^{125}Te satellites; (b) ^{13}C NMR spectrum of **8** in $[D_8]$THF at −100 °C

In covalent tellurium azides, $R_2Te(N_3)_2$ and $RTe(N_3)_3$, including the free electron pair at the tellurium centre, hepta- and octacoordination of Te is found,[17,18] containing almost linear azide groups connected to the tellurium ion with Te−C bond lengths of ca. 2.2 Å. The interatomic Te···N distances are in the range of 2.7−3.5 Å.

In contrast, the structures of $[(CH_3)_3Te]N_3$ (**1**) (Figure 2) and $[(C_6H_5)_3Te]N_3$ (**6**) (Figure 3) show almost perfectly linear azide groups connected on both sides to different layers of telluronium cations. The azide **6** crystallizes as a chloroform solvate (see Table 4). In both azides **1** and **6**, the N−N bond lengths (1.15−1.18 Å) differ only slightly from each other. This is in agreement with the crystal structure of the azide anion in $[(CH_3)_4N]N_3$, and demonstrates the minor influence of the secondary bonds on the bonding situation of the azide group.[26] The average secondary bonding Te···N distances amount to 3.0 Å, which is well below the sum of the tellurium−nitrogen van der Waals radii (ΣvdWr Te−N 3.61 Å).[37] This leads mostly to a monocapped distorted octahedral AX_3Y_3E environment and a complex three-dimensional network of cations and anions (Figure 2).

The Te−C bond lengths for the telluronium cations $[(CH_3)_3Te]^+$ (in **1**−**5**) and $[(C_6H_5)_3Te]^+$ (in **6**−**8**) span ranges between 2.11 and 2.14 Å, and are together with the resulting bond angles in good agreement with those of $[(CH_3)_3Te]I$[38] and $[(C_6H_5)_3Te]SCN$.[7] Regarding only Te−C bonds, a typical AX_3E trigonal-pyramidal arrangement around the tellurium centre is formed.

Similarly, the C−N and C−O(S)(Se) bond lengths in the chalcogenocyanate anions of **2**−**4** and **7** exhibit only marginal deviations to those found in the potassium salts. The bond lengths of the cyanate anions in **2** [C−N 1.168(4) Å, C−O 1.217(4) Å] are very similar to those of $[(C_6H_5)_3Te]OCN{\cdot}1/2CHCl_3$[5] and KOCN.[39] For $[(CH_3)_3Te]SCN$ (**3**), the distances are very similar, the C−N [1.143(8) Å] and C−S [1.662(5) Å] bonds being negligibly shortened when compared to KSCN [C−N 1.15(1) Å, C−S 1.69(1) Å].[40] The selenocyanate ions in **4** [C−N 1.146(7) Å, C−Se 1.816(5) Å] and **7** [C−N 1.142(8)/1.148(6) Å, C−Se 1.804(5)/1.817(6) Å] feature bond lengths, which also cannot be considered significantly different from those in KSeCN.[41] As discussed for AgSeCN,[42] this is in agreement with a slightly elongated C−N triple bond and a C−Se bond with minor multiple bond contribution.

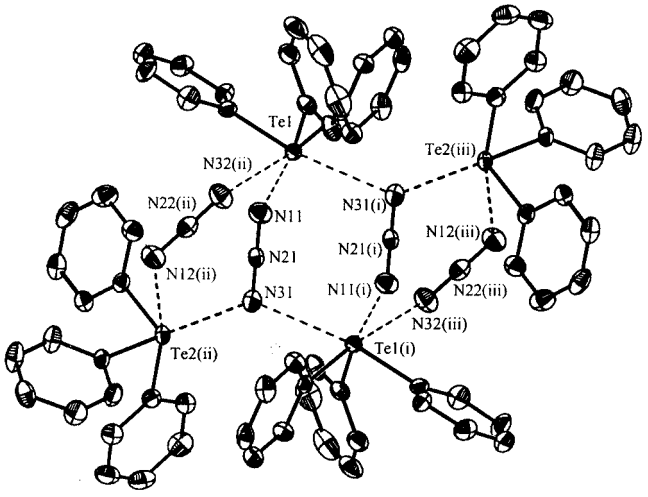

Figure 3. ORTEP plot of **6**; solvate molecules and H atoms omitted for clarity; selected bond lengths [Å] and angles [°]: Te−C 2.121(4)−2.146(4), N11−N21 1.181(5), N21−N31 1.161(5), N12(*ii*)−N22(*ii*) 1.184(5), N22(*ii*)−N32(*ii*) 1.170(5), Te1···N11 2.867(4), Te2(*ii*)···N12(*ii*) 2.772(4), Te2(*ii*)···N31 3.027(4), C−Te−C 92.6(2)−98.8(2), N11(*ii*)−N21(*ii*)−N31(*ii*) 179.6(5), N12−N22−N32 179.1(5); with $i = -x, -y, 1 - z$; $ii = -1 + x, y, z$; $iii = 1$

For compounds **2**−**4** and **7** (Figure 4−7), similar network-like structures as for the azides **1** and **6** exist. Distorted monocapped octahedral AX_3Y_3E environments indicate secondary bonding between cations and anions as well. An analogous structure was reported for β-[TeCl_3][$AlCl_4$], considering primary Te−Cl and secondary Te···Cl bonds.[15] As chalcogenocyanates are ambidentate ligands, it is of interest, whether Te···X [X = O, S, Se; ΣvdWr TeO(S)(Se) 3.58, 3.86, 3.96 Å)], or Te···N contacts or both are preferred. The crystal structures show, that Te···N as well as Te···X coordination is present. Compounds **3**, **4** and **7** exhibit two Te···S(Se) and one Te···N contact each, **3** and **4** crystallize isotypically. The cyanate ion in **2**, which has the oxygen atom as its "hard end", shows an inverted situation. This can be explained according to the HSAB concept,[43,44] considering a telluronium cation as a rather weak acid, preferring coordination to the softer ends of the particular anions. In the solid state the N···Te contacts in **2**−**4**

and in **7** are always shorter than the Te···O/S/Se contacts. The latter have approximately the same distance as reported for Te···Se contacts in $[R_3Te][SeR]$.[36] The coordination sphere of azide **1**, and the other pseudohalides **2**−**4** and **7** are very similar, with all anions being threefold coordinated (e.g. in **1**: Te1···N11, Te2···N11, Te3···N31 (Figure 2)].

The crystal structures of the dicyanoargentates $[(CH_3)_3Te][Ag(CN)_2]$ (**5**) and $[(C_6H_5)_3Te][Ag(CN)_2]$ (**8**) contain short Ag···Ag contacts that account for 3.167 Å and 2.985 Å, respectively, which is at the lower distance limit of known Ag···Ag contacts (2.99−4.2 Å),[45−47] but no significant effect on the bonding parameters of both the telluronium cation and the dicyanoargentate anion are found. The rod-like dicyanoargentate anions are able to mediate interactions between ions in the crystal which are far away from each other. In the structure of the methyl derivative **5** (Figure 8), infinite chains of two crystallographically independent perfectly linear $[Ag(CN)_2]^-$ ions (C−Ag−C 180°) are oriented staggered in an angle of 75° to each other, alternately coordinated to telluronium cations. In the phenyl derivative **8**, the corresponding angle is 84° (Figure 9). The coordination sphere around tellurium consists of two shorter and one longer Te···N contacts, the latter being only 0.1 Å below the sum of the van der Waals radii of Te−N 3.61 Å. This again can be regarded as a distorted monocapped octahedral AX_3Y_3E arrangement.

Conclusion

The syntheses, spectroscopic, and structural studies of triorganotelluronium azides, pseudohalides, and dicyanoargentates have been described. Multinuclear NMR spectroscopy established that total dissociation occurs in solution. Variable-temperature ^{13}C NMR studies of the $[Ag(CN)_2]^-$ ion in solution revealed discrete couplings of ^{13}C to both silver isotopes (^{107}Ag and ^{109}Ag). In the crystal structures of all compounds, secondary interactions, Te···N(O)(S)(Se), are present between cations and anions.

Experimental Section

General Remarks: Commercially available chemicals ($TeCl_4$, 1.6 M MeLi in diethyl ether, 1.8 M PhLi in cyclohexane/diethyl ether) were used without further purification. The silver salts AgX (X = N_3, OCN, SCN, SeCN) were obtained by precipitation of aqueous solutions of silver nitrate with the corresponding Na/K pseudohalides. $[Me_3Te]I$ was prepared according to a standard procedure,[20,48] $[Ph_3Te]Cl$ by a similar reaction or according to ref.[21] IR: Perkin−Elmer Spektrum One FT-IR or Nicolet 520 FT-IR Spektrometer (as KBr pellets or between KBr plates). Raman: Perkin−Elmer Spectrum 2000 NIR FT-Raman (Nd:YAG laser, 1064 nm, 200 mW). NMR spectroscopy: JEOL Eclipse 400 and EX400 instruments; chemical shifts are reported with respect to $(CH_3)_4Si$ (^1H, 399.8 MHz; ^{13}C, 100.5 MHz), CH_3NO_2 (^{14}N, 28.9 MHz), $(CH_3)_2Se$ (^{77}Se, 76.3 MHz), aqueous $AgNO_3$ (^{109}Ag, 18.6 MHz), $(CH_3)_2Te$ (^{125}Te, 126.1 MHz). The ^{77}Se and ^{125}Te spectra were recorded at 25 °C. All chemical shifts are presented in Table 2. MS: JEOL MStation JMS 700 Spektrometer. Multi-isotope containing fragments refer to the isotope with the highest natural abundance (for example ^{130}Te). The FAB mass spectra were recorded using 3-nitrobenzyl alcohol (NBA) as matrix. Elemental analyses: in-house.

X-ray Crystallography: For compounds **1**−**4** and **8** a Nonius Kappa CCD, and for **5**−**7** a STOE IPDS area detector device was employed for data collection using Mo-K_α radiation. All structures were solved by direct methods using SIR97[49] (**1**−**4**, **7**, **8**) and SHELXS (**5**, **6**) and refined by means of the full-matrix least-squares procedures using SHELXL-97[50] (Table 4). CCDC-184294 (**1**), -184288 (**2**), -184289 (**3**), -184293 (**4**), -184290 (**5**), -184295 (**6**), -184291 (**7**) and -184292 (**8**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

CAUTION! Silver azide is potentially explosive. This necessitates meticulous safety precautions during its preparation and handling. Although both azides **1** and **6** reported in this section are ionic, they do exhibit a noticeable fizzling when exposed to heat!

Trimethyltelluronium Azide, $[Me_3Te]N_3$ (1): Into a solution of 3 mmol of trimethyltelluronium iodide in 40 mL of H_2O, was added 4.2 mmol of moist AgN_3 in one portion. After stirring for 4 h at ambient temperature, the mixture was filtered and the solvent removed from the filtrate in vacuo. After recrystallization from ethanol/diethyl ether, **1** was obtained as colorless, hygroscopic powder (84%), m.p. 110 °C. IR (KBr): $\tilde{\nu}$ = 3009 s, 2027 vs/1998 s ($\nu_{as}N_3$), 1416 m, 1376 m, 1216 w, 1115 vs, 1054 s, 906 s, 618 s, 594 w, 543 m, 439 w cm^{-1}. Raman: $\tilde{\nu}$ = 3023 (5), 2924 (20), 1999 (5, $\nu_{as}N_3$), 1990 (5), 1414 (5), 1323 (35, ν_sN_3), 1225 (5), 1042 (5), 546 (100), 528 (90), 226 (10), 135 (25) cm^{-1}. FAB^+ MS: *m*/*z* (%) = 328 (10) [Me_3Te^+ + NBA], 175 (100) [Me_3Te^+]. $C_3H_9N_3Te$ (214.72): calcd. C 16.8, H 4.2, N 19.6; found C 16.5, H 4.1, N 18.3.

Trimethyltelluronium Cyanate, $[Me_3Te]OCN$ (2): Into a solution of 1 mmol of trimethyltelluronium iodide in 50 mL of H_2O, was added

FAB$^+$ MS: *m/z* (%) = 328 (10) [Me_3Te^+ + NBA], 175 (100) [Me_3Te^+]. C_4H_9NSTe (230.79): calcd. C 20.8, H 3.9, N 6.1, S 13.9; found C 20.7, H 4.0, N 5.9, S 13.2.

Trimethyltelluronium Selenocyanate, [Me_3Te]SeCN (4): Into a solution of 1 mmol of trimethyltelluronium iodide in 100 mL of H_2O, was added 2 mmol of freshly precipitated AgSeCN in one portion. After stirring for 8 h at ambient temperature, the mixture was filtered and the solvent removed from the filtrate in vacuo. After recrystallization from methanol/chloroform/diethyl ether, **4** was obtained as slightly pinkish powder (58%), m.p. 106−109 °C. IR (KBr): $\tilde{\nu}$ = 3421 (br), 3011 m, 2065 vs/2018 m (ν_{as}SeCN), 1757 w, 1640 w, 1503 w, 1409 s, 1385 m, 1249 m, 1226 m, 1215 s, 890 vs, 826 w, 816 m, 540 s, 530 s, 414 m cm^{-1}. Raman: $\tilde{\nu}$ = 3014 (5), 2918 (15), 2065 (40, ν_{as}SeCN), 1217 (5), 542 (85), 531 (100), 227 (br, 10), 120 (br, 5) cm^{-1}. FAB$^+$ MS: *m/z* (%) = 328 (10) [Me_3Te^+ + NBA], 175 (100) [Me_3Te]$^+$. C_4H_9NSeTe (277.68): calcd. C 17.3, H 3.2, N 5.0; found C 17.5, H 3.3, N 4.9.

Trimethyltelluronium Dicyanoargentate, [Me_3Te][Ag(CN)$_2$] (5): Into a solution of 1 mmol of trimethyltelluronium iodide in 100 mL of H_2O, was added 2 mmol of AgCN in one portion. After stirring for 20 h at 50 °C, the mixture was filtered and the solvent removed from the filtrate in vacuo; **5** was obtained as slightly grayish crystals (85%), m.p. 118−122 °C. IR (KBr): $\tilde{\nu}$ = 3007 m, 2962 m, 2929 m, 2873 m, 2135 s/2126 s (νCN), 1728 m, 1563 m, 1416 m, 1290 m, 1251 m, 1222 m, 1125 w, 898 s, 832 m, 550 m, 537 m, 391 s cm^{-1}. Raman: $\tilde{\nu}$ = 3027 (20), 2932 (50), 2132 (70, νCN), 1412 (10), 1226 (10), 550 (90), 540 (100), 213 (30) cm^{-1}. FAB$^+$ MS: *m/z* (%) = 328 (10) [Me_3Te^+ + NBA], 175 (100) [Me_3Te]$^+$. FAB$^-$ MS: *m/z* (%) = 427 [$Ag_3(CN)_4^-$], 292 [$Ag_2(CN)_3^-$], 159 [$Ag(CN)_2^-$]. $C_5H_9AgN_2Te$ (332.6): calcd. C 18.1, H 2.7, N 8.4; found C 20.9, H 3.1, N 7.6.

Triphenyltelluronium Azide, [Ph_3Te]N_3 (6): Into a solution of 2.5 mmol of triphenyltelluronium chloride in 50 mL of chloroform, was poured in one portion a solution of 20 mmol of NaN_3 in 50 mL H_2O. After stirring for 45 min at ambient temperature, the chloroform extract was separated and dried with anhydrous $MgSO_4$. After removal of the solvent, recrystallization from chloroform or 2-propanol yielded **6** as colorless crystals (82%), m.p. 155 °C (ref.[4] 155.5−156.5 °C). IR (KBr): $\tilde{\nu}$ = 3293 w, 3051 w, 2017 vs/1993 s ($\nu_{as}N_3$), 1572 w, 1478 w, 1434 w, 1182 w, 1055 w, 996 w, 735 m, 688 w cm^{-1}. Raman: $\tilde{\nu}$ = 3145 (10), 3058 (70), 1989 (25, $\nu_{as}N_3$), 1574 (35), 1478 (10), 1328 (40), 1240 (5), 1188 (10), 1160 (10), 1056 (15), 1020 (55), 1001 (100), 655 (50), 614 (10), 464 (5), 365 (10), 284 (45), 269 (40), 258 (70), 233 (40), 134 (70) cm^{-1}. FAB$^+$ MS: *m/z* (%) = 361 (100) [Ph_3Te^+], 284 (10) [Ph_2Te^+], 207 (5) [$PhTe^+$]. $C_{18}H_{15}N_3Te\cdot 1/2CHCl_3$ (460.62): calcd. C 48.2, H 3.4, N 9.1, Cl 11.6; found C 48.7, H 3.4, N 9.0, Cl 11.3.

Triphenyltelluronium Selenocyanate, [Ph_3Te]SeCN (7): Into a solution of 0.5 mmol of triphenyltelluronium chloride in 10 mL of H_2O, was added 1 mL of a hot aqueous solution of 2 mmol of KSeCN in one portion. After stirring for 15 min at 50 °C, filtration of the residue and subsequent rinsing with diethyl ether yielded **7** as a colorless powder (98%), m.p. 164.5−165.5 °C (ref.[4] 164.5−165.5 °C). IR (KBr): $\tilde{\nu}$ = 3048 w, 2960 m, 2077 vs/2062 vs (ν_{as}SeCN), 1572 m, 1477 s, 1436 vs, 1331 w, 1313 w, 1262 s, 1180 w, 1160 w, 1096 vs, 1064 s, 1056 s, 1017 vs, 995 s, 802 vs, 746 s, 730 vs, 685 s, 467 m, 452 m, 403 m cm^{-1}. Raman: $\tilde{\nu}$ = 3142 (10), 3053 (8), 2079 (75, ν_{as}SeCN), 1574 (35), 1479 (10), 1332 (40), 1271 (5), 1188 (10), 1162 (10), 1056 (15), 1020 (55), 1000 (100), 657 (50), 613 (10), 570 (5), 550 (5), 470 (5), 452 (5), 281 (95), 270 (60), 255 (90), 228 (75), 179 (30), 117 (45) cm^{-1}. FAB$^+$ MS: *m/z* (%) = 361 (100) [Ph_3Te^+], 284 (10) [Ph_2Te^+], 207 (5) [$PhTe^+$]. $C_{19}H_{15}NSeTe$ (463.89): calcd. C 49.2, H 3.3, N 3.0; found C 49.0, H 3.2, N 3.0.

Triphenyltelluronium Dicyanoargentate, [Ph_3Te][Ag(CN)$_2$] (8): Into a solution of 1 mmol of triphenyltelluronium chloride in 40 mL of H_2O, was added 1.5 mmol of KI in one portion. The resulting precipitate was collected and washed with water and diethyl ether. To a suspension of this precipitate in 50 mL of H_2O was added 2 mmol of AgCN. After stirring for 20 h at 50 °C, the mixture was filtered and the solvent removed from the filtrate in vacuo. Recrystallization from chloroform/hexane yielded **8** as colorless crystals (42%), m.p. 130−132 °C. IR (KBr): $\tilde{\nu}$ = 3055 w, 2921 w, 2126 s/1999 s (νCN), 1573 s, 1477 w, 1436 s, 1384 m, 1250 m, 1182 w, 1149 w, 1042 m, 1016 s, 994 s, 958 s, 915 m, 817 s, 732 s, 6685 s, 649 s, 502 m cm^{-1}. Raman: $\tilde{\nu}$ = 3056 (55), 2135 (30), 1575 (40), 1020 (45), 1000 (100), 658 (55), 613 (20), 263 (50), 231 (50) cm^{-1}. FAB$^+$ MS: *m/z* (%) = 361 (100) [Ph_3Te^+], 284 (10) [Ph_2Te^+], 207 (5) [$PhTe^+$]. FAB$^-$ MS: *m/z* (%) = 427 [$Ag_3(CN)_4^-$], 292 [$Ag_2(CN)_3^-$], 159 [$Ag(CN)_2^-$].

Synthesis, Structure and Characterisation of New Phenolato-Bridged Manganese Complexes $[L_2Mn_2]^{2+}$ − Formation by Ligand Oxidation in L_aH [L_aH = *N*-(2-hydroxybenzyl)-*N*,*N*′-bis(2-pyridylmethyl)ethane-1,2-diamine]

Christelle Hureau,[a] Elodie Anxolabéhère-Mallart,[a] Martine Nierlich,[b] Florence Gonnet,[d] Eric Rivière,[a] and Geneviève Blondin*[a]

Keywords: Manganese / N,O ligands / Electrochemistry / EPR spectroscopy

A mononuclear $[L_aMn^{III}OAc](ClO_4)\cdot 0.5H_2O$ [**2**$(ClO_4)\cdot 0.5H_2O$] complex with a new amino-containing pentadentate ligand L_aH with a $[N_4O]$ coordination sphere has been obtained. Magnetic susceptibility measurements of **2**$(ClO_4)\cdot 0.5H_2O$ indicated a high spin electronic configuration for the Mn^{III} ion. In cyclic voltammetry the reversible wave observed at $E_{1/2}$ = 0.15 V vs. SCE was attributed to the reduction of Mn^{III} into Mn^{II}. In acetonitrile solution complex **2** spontaneously evolved into phenolato-bridged $Mn^{II}Mn^{II}$ dimeric complexes with the concomitant oxidation of the ligand. X-ray diffraction structures revealed that there is indeed a 1:1 mixture of two closely related complexes: in one case both ligands L_a^- have been oxidised to the imine form leading to the $[L_iMn^{II}Mn^{II}L_i]^{2+}$ cation (**1a**), whereas in the other, only one ligand has been oxidised, leading to the $[L_aMn^{II}Mn^{II}L_i]^{2+}$ cation (**1b**). In both **1a** and **1b**, Mn^{II} ions are in a distorted octahedral environment. Crystallographic data indicated that the Mn_2O_2 core is similar for **1a** and **1b.** The complete spectroscopic and electrochemical studies performed on powder samples and on acetonitrile solutions did not allow one to distinguish between the two cations. The magnetic susceptibility measurements performed on a powder sample of **1**$(BPh_4)_2\cdot 2CH_3COCH_3$ was characteristic of a weak antiferromagnetic coupling interaction between the two high-spin Mn^{II} ions (g = 1.95 and J = –1.5 cm^{-1}). Similar behaviour was observed for the powder sample of **1**$(ClO_4)_2\cdot H_2O$ (g = 1.96 and J = –2.9 cm^{-1}). Powder samples of **1**$(BPh_4)_2\cdot 2CH_3COCH_3$ and **1**$(ClO_4)_2\cdot H_2O$ showed EPR intensity variations with temperature indicating that the signal was mainly due to the S = 2 spin state. EPR spectra run on the acetonitrile solutions indicated that the dinuclear structure of **1** is maintained. In cyclic voltammetry, complex **1**$(ClO_4)_2\cdot H_2O$ exhibited a quasi-reversible wave in oxidation at E_p = 0.71 V vs. SCE, attributed to the slow electron transfer of the $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ redox process ($k_s^{app} = 1.10^{-4}$ $cm^2\cdot s^{-1}$).

Introduction

Manganese is involved in several essential processes of life.[1] One famous example is the oxidation, under light, of water into dioxygen that is catalysed by the tetranuclear (oxo)Mn cluster of the Oxygen Evolving Complex (OEC) located in the photosystem II of green plants.[2,3] Dinuclear manganese clusters are present in several metalloproteins.[4,5] Among them, one can quote the manganese catalases, arginase and manganese ribonucleotide reductase.

In the last decade, X-ray diffraction studies were performed on an increasing number of metalloproteins, allowing new insight into the active sites. Resolution may, however, not be sufficient to predict either, the nature of the ligands[6] or the spatial arrangement of the metal ions.[7,8] The determination of the nature of the active sites still relies on the analysis of spectroscopic data. For instance, different hypotheses are formulated for the Mn_4 cluster of the OEC based on X-ray absorption investigations in conjunction with electronic spin resonance techniques (EPR, ENDOR, ESEEM).[3,9−11] Another example is the magnetisation studies run on catalases.[12]

Synthesising new complexes is still a challenge for the chemists along with the investigation of spectroscopic characteristics of such molecules and the perspective of elaborating new catalysts.

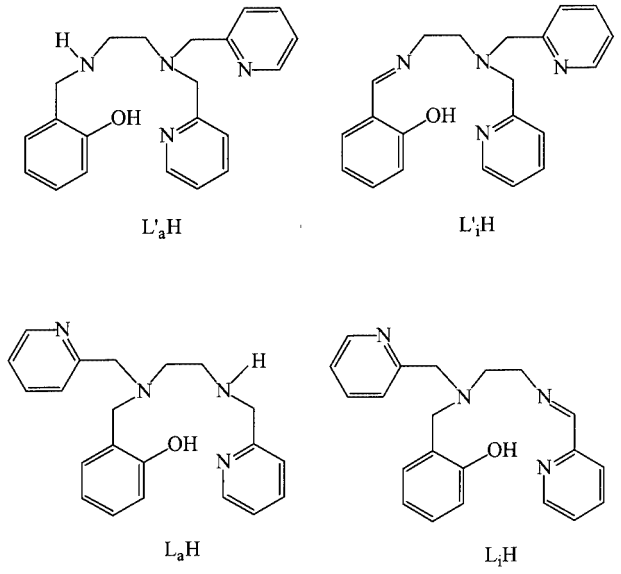
In relation to the OEC, we are interested in the EPR signatures of mixed-valent dinuclear $Mn^{III}Mn^{IV}$ systems for which the chemical nature of the bridge appears to have a great influence on the EPR signature. At the X-band, both the $[Mn^{III}-(\mu\text{-}O)_2-Mn^{IV}]^{3+}$ [13,14] and $[Mn^{III}-(\mu\text{-}O)_2(\mu\text{-}OAc)-Mn^{IV}]^{2+}$ [15,16] core systems present 16-line spectra that differ in their relative line intensities while the only mono(μ-oxo) complex reported in the literature, $[L'_iMn^{III}-(\mu\text{-}O)-Mn^{IV}L'_i]^{3+}$ (see Scheme 1), exhibits a peculiar 18-line spectrum.[17] In order to synthesise a new $Mn^{III}-(\mu\text{-}O)-Mn^{IV}$ system, we designed a ligand very similar to the one (L'_iH) used by Horner et al. In the laboratory, we previously used these ligands in the amine form (noted L_aH and L'_aH in Scheme 1) to synthesise $Fe^{III}-(\mu\text{-}O)-Fe^{III}$ systems and found that both ligands behave the same.[18,19] We will show here that this is not the case when the trivalent metal used is manganese. Following the same synthetic route reported for the formation of $[L'_iMn^{III}-(\mu\text{-}O)-Mn^{III}L'_i]^{2+}$, a mononuclear Mn^{III} complex is isolated when ligand L_aH is used instead of L'_aH. We found that this complex evolves into a bis(μ-phenolato)bis(Mn^{II}) complex with the concomitant dehydrogenation of the amine function of the ligand. Only three out of four ligands are indeed oxidised and we will designate LH to the mixture of L_aH and L_iH present in the isolated dinuclear Mn^{II} complex.



Scheme 1

Results and Discussion

Starting from $Mn(OAc)_3{\cdot}nH_2O$ and the ligand L_aH, a mononuclear Mn^{III} complex **2** was isolated as a perchlorate salt. No X-ray structure could be obtained, but the entire characterisation allows us to propose the formula $[L_aMnOAc]^+$ for **2**, which is in good agreement with all the measurements that were taken. Complex **2** evolves spontaneously in solution and leads to the formation of the dinuclear Mn^{II} complex **1** that was isolated using BPh_4^- or ClO_4^-. The two powdered samples $[\mathbf{1}](BPh_4)_2{\cdot}2CH_3COCH_3$ and $[\mathbf{1}](ClO_4)_2{\cdot}H_2O$ were characterised. Crystals were only obtained with tetraphenylborate as a counterion. Based on the whole characterisation of $[\mathbf{1}](BPh_4)_2{\cdot}2CH_3COCH_3$ and $[\mathbf{1}](ClO_4)_2{\cdot}H_2O$ discussed below, it is shown that the cation is the same in the two complexes. The dehydrogenation of the secondary amine which goes with the conversion of **2** into **1** is corroborated by the IR spectra. The vibration detected at 1665 cm^{-1} for $[\mathbf{1}](BPh_4)_2{\cdot}2CH_3COCH_3$ or 1661 cm^{-1} for $[\mathbf{1}](ClO_4)_2{\cdot}H_2O$ may be assigned to a coordinated imine function. No such vibration is detected for **2** indicating that the ligand remains as introduced.

X-ray Crystal Structure of $[L_2Mn_2](BPh_4)_2{\cdot}2CH_3COCH_3$

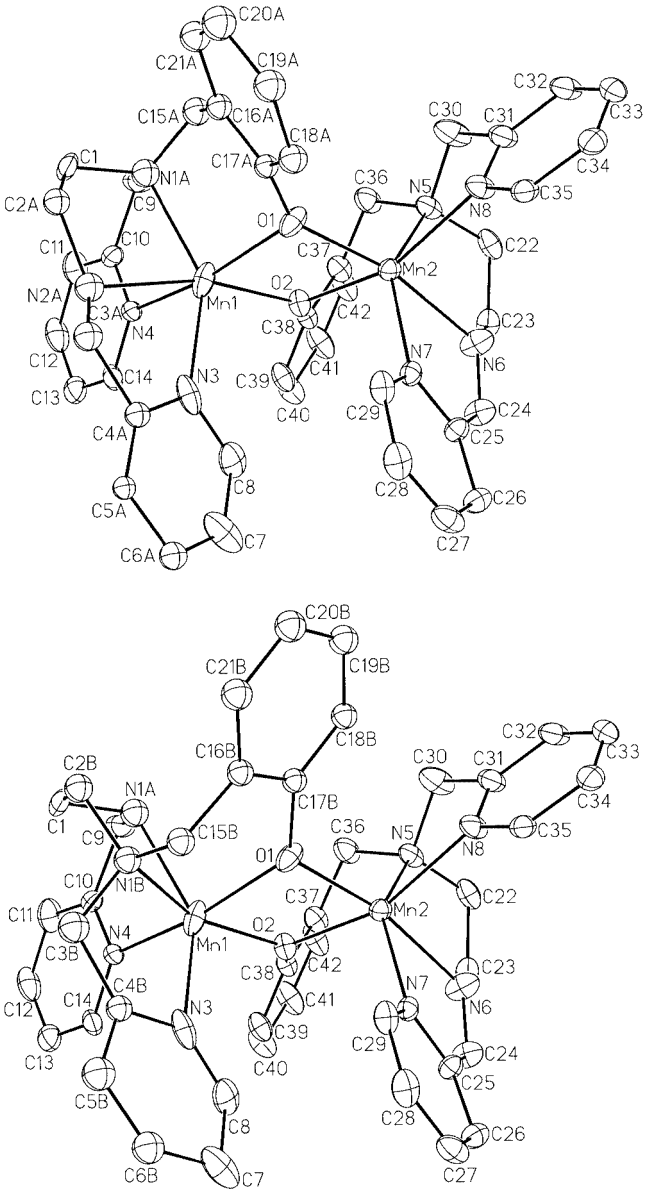
The structure consists of one $[LMn^{II}Mn^{II}L]^{2+}$ complex cation, two tetraphenylborate anions and two acetone molecules. The structure reveals that the complex is indeed a mixture of two closely related complexes in a 1:1 ratio. In complex **1a**, both ligands have been oxidised and exhibit an imine function conjugated to one pyridine group in place of the secondary amine function present in L_a^-. In complex **1b**, only one ligand has been oxidised while the second is the unchanged amine. A view of the cations is presented in Figure 1 and selected bond lengths and angles are listed in Table 1.

In both cations **1a** and **1b**, the two manganese ions are coordinated by the four nitrogen atoms of one ligand and by two oxygen atoms from phenolato groups, one belonging to the same ligand, and the other to the ligand coordinating the other metallic site. The metallic ions in **1a** and **1b** are in a distorted octahedral environment as shown by the angle values listed in Table 1. Such angle values are commonly observed in hexacoordinated Mn^{II} complexes.

The imine function is identified by the short C24−N6 and C3A−N2A bond lengths [1.310 (8) Å and 1.32 (2) Å] in the ligand coordinated to the Mn2 and Mn1 sites respectively. Moreover, the sum of the angles around the nitrogen atoms N6 or N2A approaches 360° (351° around N6, 343° around N2A), clearly demonstrating the sp^2 hybridisation of the nitrogen atoms.

The $Mn^{II}-N$ bond lengths in **1a** and **1b** are close to the values commonly observed for Mn^{II} complexes[20−26] except for the Mn1−N2A distance (2.375 Å) in **1a**. This distance is longer than the observed $Mn^{II}-N$ bond lengths (2.20−2.32 Å) where the nitrogen atom belongs to a phenolate conjugated imine function.[27−29]

The Mn2 moiety is common to the cations **1a** and **1b**. A comparison of the Mn1 moieties is shown in Figure 2. The folding of the ligand L_i^- around the metal centre is the same for Mn1 and Mn2 in complex **1a**, but the folding of the ligand L_a^- is not the same, leading to a different environment around the Mn1 atom in **1b**: (i) the phenolate ring planes are almost orthogonal (81°), (ii) the tertiary amine nitrogen atom to which this phenolate group is linked (N1A in **1a** and N1B in **1b**) is *cis* to the bridging phenolate O2



Fiugre 1. Views of the cations **1a** (top) and **1b** (bottom)

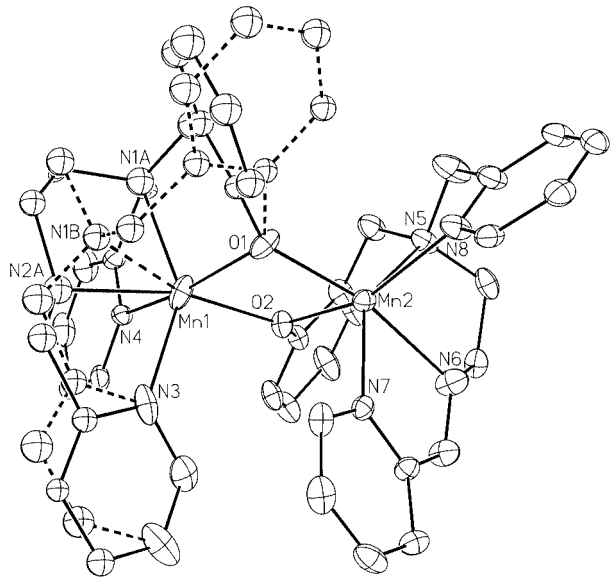

Figure 2. Comparison of the cations **1a** and **1b**, showing the differences in the Mn1 moieties; N1A of **1a** and N2B of **1b** are superimposed

atom in **1a** [N1A−Mn1−O2 113.8(2)°] while it is in the *trans* position in **1b** [N1B−Mn1−O2 156.7(3)°], (iii) the pyridine ring, slightly different in its orientation in the two Mn1 moieties, which contains the N3 atom, is linked to the imine nitrogen atom N2A atom in **1a** but to the tertiary amine N1B atom in **1b**, (iv) consequently, the two aromatic group substituents of the tertiary amine are *cis* to each other in **1b** [O1−Mn1−N3 102.7(2)°] while they are *trans* to each other in **1a** [O1−Mn1−N4 160.4(2)°] as it is around the Mn2 site [O2−Mn2−N8 156.2(2)°].

Such foldings can be compared to the ones of the same or closely related pentadentate ligands around Mn^{III} or Fe^{III} dinuclear complexes. The complexes $[L'_iMn-(\mu\text{-}O)-MnL'_i]^{n+}$ (n = 2, 3) have been characterised by X-ray crystallography.[17] The folding of the isomeric ligand L'^{-}_{i} presents the same characteristics as that of the ligand L^{-}_{i}, that is (i) the two aromatic groups anchored to the tertiary amine nitrogen atom are *trans* to each other, (ii) the tertiary amine nitrogen atom is *trans* to the group linked to the imine nitrogen atom (the phenolate ring in L'^{-}_{i}) and (iii) the imine nitrogen atom is *trans* to the exogeneous ligand. The same folding is observed for the ligand L'^{-}_{a} around the Fe^{III} ion in the complex $[L'_aFe-(\mu\text{-}O)-FeL'_a]^{2+}$,[18,19] and the secondary amine nitrogen atom in L'^{-}_{a} and the imine nitrogen atom in L'^{-}_{i} behave the same. In contrast, the ligand L^{-}_{a} adopts another folding in the complex $[L_aFe-(\mu\text{-}O)-FeL_a]^{2+}$.[18,19] The common features observed with the coordination around the Mn1 site just described in **1b** are (i) the two aromatic rings linked to the tertiary amine nitrogen atom are *cis* to each other and (ii) the tertiary amine nitrogen atom is *trans* to the extra ligand. The main difference lies in the ligation of the secondary amine nitrogen atom that is *trans* to the phenolate group. The variety of foldings observed when the ligand is in the reduced form (L^{-}_{a} and L'^{-}_{a}) compared to the unique ligating mode ob-

served when the ligand is oxidised (L_i^- and L'^-_i) is a signature of the greater flexibility when the conjugated imine function is absent.

Both Mn_2O_2 diamond core structures in **1a** and **1b** formed by the two metallic sites and the two oxygen atoms of the phenolate rings present features characteristic of such a motif. The $Mn^{II}-O$ distances (average 2.110 Å), and the $Mn^{II}-O-Mn^{II}$ bridging angles (average 101.4°) with a Mn···Mn separation of 3.280 Å, lie in the range observed for similar complexes.[20,21,25,27–34] One can note that the Mn_2O_2 diamond core structure is not planar and has a dihedral angle of 11.5°. Owing to the similarities in the Mn_2O_2 core in **1a** and **1b**, the two cations were considered identical in the following solid state studies.

Solution studies of **1** are prepared from powder samples [**1**$(ClO_4)_2$·H_2O or **1**$(BPh_4)_2$·$2CH_3COCH_3$]. One expects the same mixture of complex **1a** and **1b** observed in the crystals to exist in the powder samples and in solution.

Magnetic Susceptibility Measurements

The molar magnetic susceptibility χ_M of a powder sample of **1**$(BPh_4)_2$·$2CH_3COCH_3$ was measured as a function of temperature. The $\chi_M T$ value as a function of T is reported in Figure S1 in the Supporting Information (see also footnote on the first page of this article), together with the values obtained for **1**$(ClO_4)_2$·H_2O. For **1**$(BPh_4)_2$·$2CH_3COCH_3$, $\chi_M T$ decreases very slowly from 8.13 $cm^3 \cdot mol^{-1} \cdot K$ at 300 K to 7.91 $cm^3 \cdot mol^{-1} \cdot K$ at 100 K. Below 100 K, $\chi_M T$ decreases more rapidly to 0.9 $cm^3 \cdot mol^{-1} \cdot K$ at 2 K. This behaviour suggests a weak antiferromagnetic coupling interaction between the two high-spin Mn^{II} ions ($S_1 = S_2 = 5/2$). The best fit was obtained assuming identical parameters for the cations **1a** and **1b**: $g = 1.95$ and $J = -1.5$ cm^{-1}. These values are in agreement with those reported in the literature for complexes where two Mn^{II} ions are bridged by two phenolate ligands.[27,29,31,34]

Comparable results are obtained for **1**$(ClO_4)_2$·H_2O: $g = 1.96$ and $J = -2.9$ cm^{-1}. Small deformations of the $[Mn_2O_2]$ diamond core unit could lead to the slight differences in the g and J values determined for compound **1**, depending on the counterion.

The product of the molar magnetic susceptibility χ_M and the temperature T for a powder sample of **2**(ClO_4)·$0.5H_2O$ has a constant value of 3 $cm^3 \cdot mol^{-1} \cdot K$ from room temperature down to 30 K (see Figure S1 in the Supporting Information; see also footnote on the first page of this article). This indicates a +III oxidation state and a high-spin electronic configuration for the manganese ion ($S_{Mn^{III}} = 2$). $\chi_M T$ decreases below 30 K to reach 1.8 $cm^3 \cdot mol^{-1} \cdot K$ at 2 K. This behaviour is the signature of the zero-field splitting on the high-spin Mn^{III} ion. The best fits were obtained with a g factor close to 2 with either a positive or a negative D parameter: $g = 2.008$ and $D = +4.3$ cm^{-1} or $g = 2.006$ and $D = -4.5$ cm^{-1}. A weak intermolecular antiferromagnetic coupling between high-spin Mn^{III} ions can also contribute to the drop of $\chi_M T$ below 30 K. Mn^{III} complexes usually present an elongated octahedral geometry which corresponds to a negative D parameter.[35] The g and D values deduced here are in agreement with those determined by high-frequency EPR spectroscopy on other Mn^{III} complexes.[36–39]

EPR Spectroscopy

X-band EPR spectra of a powder sample of **1**$(BPh_4)_2$·$2CH_3COCH_3$ were recorded at several temperatures between 4.2 and 50 K using the perpendicular detection mode. The series is shown in Figure S2 in the Supporting Information (see also footnote on the first page of this article). All spectra exhibit features extending from 0 to 800 mT. Increasing temperature from 4.2 to 50 K does not affect the line positions but only their relative intensities. In addition, the signal intensity calculated as the double integral of the recorded spectrum does not follow a Curie law and reaches a maximum at 10 K.

The overall shape of the detected signals in conjunction with the deviation from the Curie law of the temperature dependence of the intensity is typical of dinuclear Mn^{II} complexes.[23,24,27,40–43] As previously reported in the literature, the complexity of the EPR spectra originating from weakly coupled dinuclear Mn^{II} complexes comes from the superposition of the signatures of the various paramagnetic spin states ($S = 1-5$) weighted by the Boltzmann distribution. Deconvolution procedures have been performed on systems presenting a relatively large antiferromagnetic exchange interaction.[44,45] In such systems, only the $S = 1$ and $S = 2$ excited spin states are sufficiently populated at low temperature to contribute to the EPR signal. In the present study, the exchange interaction is too small to allow for such an analysis.

A powder sample of the compound **1**$(ClO_4)_2$·H_2O was also tested in X-band EPR at 4.2 K and the observed spectrum is almost superimposable with the one of **1**$(BPh_4)_2$·$2CH_3COCH_3$.

The EPR was also run on frozen acetonitrile solutions of both compounds, either in the absence or in the presence of 0.1 M tetrabutylammonium perchlorate. The spectra recorded at 4.2 K present the same features as the ones detected on powder samples using the perpendicular or the parallel detection mode. This proves that the dinuclear structure of complex **1** is maintained in solution.

No X-band EPR signal was detected using the perpendicular detection mode on a powder sample of compound [**2**](ClO_4)·$0.5H_2O$. This is expected for integer spin states presenting a zero-field splitting much larger than the microwave quantum as is usually the case for monomeric Mn^{III} systems.

The EPR spectrum recorded on a freshly prepared acetonitrile solution of **2** displays a characteristic signature of **1**, together with signatures of free Mn^{II} ions (6 lines) and mixed valent $Mn^{III}Mn^{IV}$ species as impurities. These observations are the first indications that complex **2**(ClO_4)·$0.5H_2O$ is not stable in acetonitrile solution (vide infra).

Electrochemical Properties

The cyclic voltammogram of [**1**]$(ClO_4)_2 \cdot H_2O$ at 4×10^{-3} M in acetonitrile containing 0.1 M tetrabutylammonium perchlorate under argon is shown in Figure 3a. **1**$(BPh_4)_2 \cdot 2CH_3COCH_3$ was also investigated under reduction and showed similar results. The counterion BPh_4^- being easily oxidised, this sample was not investigated in the high potential ranges.

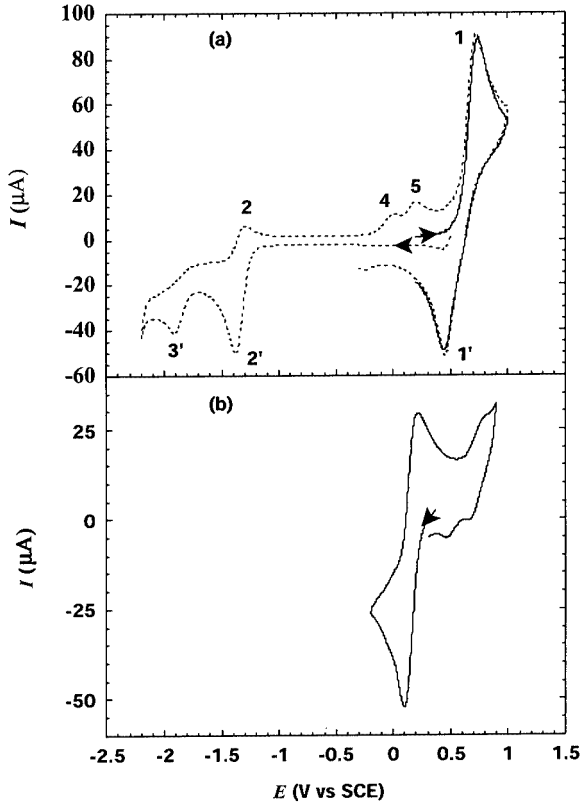

Figure 3. Cyclic voltammograms of **1**$(ClO_4)_2 \cdot H_2O$ (a) and **2**$(ClO_4)_2 \cdot 0.5H_2O$ (b) in acetonitrile containing 0.1 M of tetrabutylammonium perchlorate, $T = 20$ °C and scan rate = 100 mV·s^{-1}

The cyclic voltammetry trace of [**1**]$(ClO_4) \cdot H_2O$ shows a well-defined anodic wave (labelled wave 1 in Figure 3a) at $E_p = 0.710$ V vs. SCE, accompanied on the reverse scan by a well-defined cathodic wave (labelled 1′, $E_p = 0.450$ V vs. SCE). This oxidation process is attributed to the oxidation of the Mn^{II} ion being complexed by the imine form of the ligand in both **1a** and **1b**. This Mn^{II} oxidation potential is fairly high. $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ oxidation potentials have been reported in the literature at about 0.35 V vs. SCE for the $[LMn_2Cl_2]$[30] or $[L'Mn_2(OAc)]^{2+}$ [46] cation where LH_2 and L′H are related to L_aH.[47] In complex **1**, the higher potential value is related to the lower number of the charged ligand around the Mn^{II} ion. A value of 0.598 V vs. SCE is reported in the literature for the $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ oxidation potential in the case of the neutral bis(phenolato)-bridged $[Mn_2^{II}(SALPS)_2]$ dinuclear complex.[27,48] The Mn^{II} ion complexed by the amine ligand is expected to be oxidised at a higher potential. Indeed other oxidation waves are detected when scanning the potential up to 1.7 V vs. SCE. Those irreversible, ill defined cyclic voltammetry traces are attributed to oxidation of the ligand (phenolic part) and overlay with the oxidation trace of the Mn^{II} ion complexed by the amine ligand.

The cyclic voltammogram displayed in Figure 3a shows a large difference in peak potential ($\Delta E_p = 260$ mV) for wave 1/1′. This indicates that the associated electron transfer is slow. In the case of slow electron transfer, determination of n, the number of electrons involved in the redox process, is not easy. For a system undergoing irreversible charge transfer kinetics (i.e. slow electron transfer), it has been shown that $|E_p - E_{p/2}|$[49] is related to αn through Equation (1), where α is the charge transfer coefficient.[50]

$$\alpha n = \frac{0.048}{|E_p - E_{p/2}|} \quad (1)$$

In the present case, considering the symmetrical shape of the entire wave, a value of 0.5 can be taken for α. At this point one must be concerned with the influence of solution resistance since it can affect the position of the peak potential. Therefore particular care was taken to insure that the present ohmic drop was correctly compensated. From $|E_p - E_{p/2}|$ values listed in Table 2, one can establish that $n = 1$. This value was confirmed by chronocoulometry measurements. A step potential ($E = +1$ V vs. SCE, $t = 500$ ms or 250 ms) was applied to the working electrode of known surface area.[51] The chronocoulometry response gives the total charge passed Q vs. time t from the initial step. From the linear relationship[52] between Q and $\sqrt{t}$, a value of 1.2 was found for n. Thus, at the time scale of cyclic voltammetry (v range 50−500 mV·s^{-1}), or for chronocoulometry with time steps shorter than 1 s, the first oxidation step corresponds to Equation (2).

Table 2. Potential peak values and electron transfer rate constants for the $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ oxidation in **1**$(ClO_4)_2 \cdot H_2O$

v [mV·s^{-1}]	E_{pa} [a] [V vs. SCE]	$E_{pa/2}$ [a] [V vs. SCE]	E_{pc} [a] [V vs. SCE]	ΔE_p [b] [mV]	k_s^{app} [c] [cm·s^{-1}]
50	0.705	0.595	0.460	245	7.7×10^{-4}
75	0.705	0.600	0.465	240	9.9×10^{-4}
100	0.710	0.610	0.450	260	9.4×10^{-4}
200	0.730	0.625	0.435	295	9.4×10^{-4}
300	0.730	0.625	0.445	285	1.3×10^{-3}
400	0.725	0.625	0.435	290	1.4×10^{-3}
500	0.730	0.630	0.440	290	1.5×10^{-3}
1000	0.750	0.650	0.410	340	1.4×10^{-3}

[a] E_{pa} and E_{pc} are the values of the anodic and of the cathodic peak potential, respectively, of the wave of interest. [b] ΔE_p is defined as the difference between the anodic and the cathodic peak potentials. [c] k_s^{app} is calculated according to Equation (3) given in the text with $\alpha = 0.5$, $D = 15 \times 10^{-6}$ cm$^2 \cdot$ s^{-1} and $T = 298$ K.

$$Mn^{II}Mn^{II} \rightarrow Mn^{II}Mn^{III} + e^- \quad (2)$$

It was not possible to confirm this stoichiometry by controlled potential electrolysis at $E = +1$ V vs. SCE, due to the instability of the $Mn^{II}Mn^{III}$ state on the electrolysis time

scale, even when lowering the temperature down to −30 °C. The quasi-reversibility of this oxidation step was studied by cyclic voltammetry, which showed that the peak separation, ΔE_p, for the redox couple $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ varied between ca. 240 and 340 mV as the scan rate was increased from v = 50 to 2000 mV·s^{-1}. Table 2 gives the measured ΔE_p values for a series of voltammograms at different scan rates. Values of the apparent charge transfer rate constant (k_s^{app}) can be obtained using the procedure of Nicholson[50] for peak separations smaller than 210 mV. When ΔE_p exceeds this value, k_s^{app} [cm^{-1}] can be calculated using Equation (3), where D is the diffusion coefficient of the species of interest [cm^2·s^{-1}] and v the scan rate [m^{-1}].

$$k_s^{app} = 2.18\sqrt{\frac{D\alpha nFv}{RT}}\exp\left(\alpha^2\frac{nF}{RT}\Delta E_p\right) \quad (3)$$

Values of k_s^{app} obtained for different values of v are listed in Table 2 and a mean value of 1.2×10^{-3} cm·s^{-1} is found. This is in agreement with what is found in the literature for slow electron transfer in inorganic compounds. For example, a value of 10^{-3} cm·s^{-1} is found for the electron transfer constant of the reduction of a (porphyrin)Mn^{III} compound in dimethyl sulfoxide.[53]

This low value of the electron transfer can mainly be attributed to the fact that the oxidation process requires structural reorganisation of the original $Mn^{II}Mn^{II}$ cation. Indeed the geometry around the Mn^{III} ion should become axially distorted, due to the Jahn−Teller effect. The constraint of the structure imposed by the phenolato bridges makes this reorganisation difficult. Moreover, it was never possible to generate an $Mn^{II}Mn^{III}$ species that is stable in solution when running exhaustive electrolysis at E = +1 V vs. SCE. EPR spectra recorded on such an electrolysed solution did not show the expected $Mn^{II}Mn^{III}$ signature. Indeed, the observed signal is characteristic of monomeric Mn^{II} species, suggesting that most of the complexes remaining in solution are monomeric EPR-silent Mn^{III} entities. These observations sustain the fact that the phenolato bridges cannot support the dimeric structure in a mixed-valent state.

When scanning towards low potentials, two cathodic waves (noted as 2′ and 3′, see a in Figure 3) are observed. The first appears at E_p = −1.380 V vs. SCE and the second at −1.910 V vs. SCE. When scanning back to the oxidative potential, a first anodic wave is observed at E_p = −1.300 V vs. SCE (wave 2) and is related to the cathodic wave 2′. Scanning back towards higher potentials generates two new anodic waves (denoted 4 and 5) at E_p = 0.005 V and E_p = 0.190 V, respectively. The waves 2′ and 3′ are attributed to the [2e$^-$,1H$^+$] reductive process of the imine function of the ligand. Indeed the addition of perchloric acid to the solution results in the shift of the peak potentials towards positive values (not shown). Increasing the scan rate results in the increase of reversibility of wave 2′/2, thus showing that the reduction process associated with wave 2 generates a very reactive species. We propose this first reduced species to be an anion radical, the unpaired electron being located on the nitrogen atom of the imine part of the ligand. This very reactive anion radical is immediately protonated and further reduced at −1.910 V (wave 3′). Waves 4 and 5 are tentatively attributed to monomeric Mn^{II} species, most likely generated consecutively by the reduction process 2′ and 3′. Indeed, the monomeric **2**$(ClO_4)_2$ species exhibits an Mn^{II}/Mn^{III} redox process in the potential range of waves 4 and 5.

The cyclic voltammogram of **2**$(ClO_4)_2$·H_2O in acetonitrile containing 0.1 M tetrabutylammonium perchlorate under Ar is shown in Figure 3b. The most intense wave at $E_{1/2}$ = 0.150 V vs. SCE [$E_{1/2} = (E_{pa} + E_{pc})/2$, ΔE_p = 180 mV] is attributed to the reduction of the Mn^{III} into Mn^{II} species. This value lies between the ones measured on acetonitrile solutions of {[$py_2(NMe)_2$]$Mn^{II}Cl_2$} ($E_{1/2}$ = 0.55 V vs. SCE) and {[$py_2(NMe)_2$]$Mn^{III}F_2$}$^+$ ($E_{1/2}$ = −0.07 V vs. SCE) where $py_2(NMe)_2$ stands for *N*,*N*′-dimethyl-2,11-diaza[3,3]-(2,6)pyridinophane.[38] The fairly low value for the reduction potential of **2** agrees with the coordination of two negatively charged ligands, the phenolate and the acetate, to the Mn^{III} site. In the anodic part of the voltammogram, a second and less intense wave is observed at $E_{1/2}$ = 0.770 V and is related to the conversion of **2** into **1** (vide infra).

UV/Vis Spectroscopy

The UV/Vis spectrum of complex **2** was recorded on a freshly prepared acetonitrile solution and is reproduced in Figure 4 [curve (a)]. Three bands are found at 373 (ε = 1770 M^{-1}·cm^{-1}), 502 (940) with a shoulder at 475 (1050),

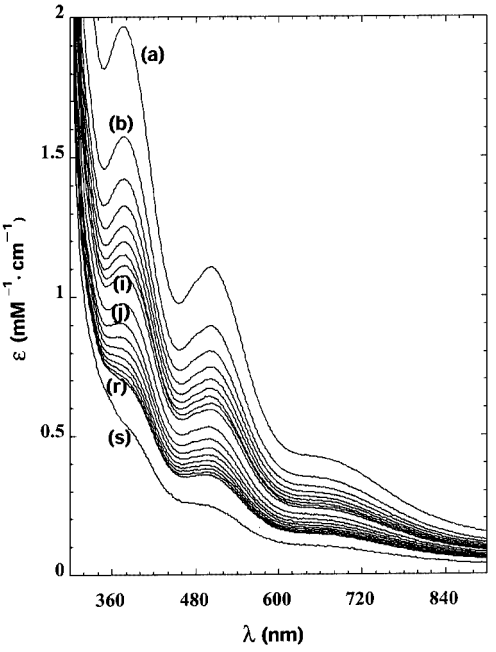

Figure 4. Time evolution of the UV/Vis spectrum of **2**$(ClO_4)_2$·0.5H_2O, 10^{-3} M in acetonitrile; spectrum (a) corresponds to the freshly prepared solution (t = 0); spectra (b) to (i) are recorded every 15 min (t = 15−120 min) and spectra (j) to (r) every hour (t = 180−660 min); spectrum (s) was recorded 46 h after spectrum (a)

and 670 nm (330). The more intense band detected in the near UV region is also observed in Mn^{III}-based complexes containing phenolato ligands and may be assigned to a phenolato-to-Mn^{III} charge transfer (LMCT) transition.[46,54,55] The last two transitions may be attributed to d-d transitions of the Mn^{III} ion according to the literature.[56,57] The low extinction coefficient measured at 670 nm enforces such an attribution. The greater absorption detected around 500 nm suggests that this band does not arise only from a d-d transition and may overlap with other LMCT bands. Resonance Raman experiments performed on dinuclear Mn^{III} complexes presenting the bis(μ-acetato)(μ-oxo) core unit suggest that the acetato-to-Mn^{III} charge transfer transition occurs in the range 450 to 500 nm rather than around 400 nm.[58] We thus propose that the absorption observed in **2** could originate from the $AcO^- \rightarrow Mn^{III}$ LMCT transition but we cannot reject a contribution from a phenolato $\rightarrow Mn^{III}$ LMCT transition.[59]

Complex **1** presents features only in the UV region [282 (ε = 2850 $cm^{-1}\cdot M^{-1}$), 262 (3960), 238 (6000) and 210 nm (15400)] associated with π-π* transitions of the ligand, in agreement with the +II oxidation state of the manganese ions.

Evolution of 2 into 1

All the attempts to obtain crystals of complex **2** ineluctably led to the formation of crystals of complex **1**. Thus, we decided to investigate the transformation of **2** into **1**, using different techniques.

A freshly prepared acetonitrile solution of **2** was allowed to evolve at room temperature and the UV/Vis spectra were recorded every 15 min. The evolution is presented in Figure 4. 36% of the initial absorption is lost in 1 h. It was not possible to interpret the series of spectra assuming the existence in solution of only two chromophores. Indeed, the band at 502 nm and the shoulder at 475 nm do not obey the same kinetic law. This implies the formation of at least one intermediate species (not identified).

The transformation was also monitored by EPR spectroscopy. As mentioned above, a signal attributed to **1** was detected on the freshly prepared acetonitrile solution of **2**, which significantly increased with time. Cyclic voltammetry and mass measurements confirmed the fast generation of **1** from **2**.

Electrospray mass spectra were recorded on freshly prepared acetonitrile solutions of complexes **1** and **2**. For complex **1**, peaks at *m*/*z* values of 901 and 903 are detected and attributed to the $\{[L_iMn^{II}Mn^{II}L_i](ClO_4)\}^+$ and $\{[L_iMn^{II}Mn^{II}L_a](ClO_4)\}^+$ entities, respectively. For complex **2**, no peak was detected at the expected *m*/*z* value of 461 for the monocationic $[L_aMn^{III}(OAc)]^+$ species. On the other hand, the above-mentioned peaks at *m*/*z* values of 901 and 903 were well observed, clearly indicating the conversion of **2** into **1** in acetonitrile solution.

Conclusion

Mn^{III} coordination chemistry has been investigated with a new pentadentate ligand L_aH with an $[N_4O]$ coordination sphere. It was expected to form a new dimeric $Mn^{III}-(\mu\text{-}O)-Mn^{IV}$ system, as has previously been obtained with an isomeric $[N_4O]$ ligand[17] (L_i'), but a mononuclear $[L_aMn^{III}]^{2+}$ complex **2** was obtained. It was found that this monomeric complex spontaneously evolves in acetonitrile solution into phenolato-bridged $Mn^{II}Mn^{II}$ dimeric complexes with the concomitant oxidation of the ligand. The formation of this bridge is made possible owing to the fairly flexible phenolate arm, when the conjugated imine function is absent in contrast to what has been observed in $[L_i'Mn-(\mu\text{-}O)-MnL_i']^{n+}$ (n = 2, 3). X-ray crystal structure analyses revealed that there is indeed a mixture of two closely related complexes: in one case both ligands L_a have been oxidised to the imine form leading to the $[L_iMn^{II}Mn^{II}L_i]^{2+}$ cation **1a**, whereas in the other only one ligand has been oxidised leading to the $[L_aMn^{II}Mn^{II}L_i]^{2+}$ cation **1b**. One can note that the oxidation of the ligand L_aH into L_iH is a $(2e^-,2H^+)$ process, while the concomitant reduction of Mn^{III} into Mn^{II} implies only one electron. We thus propose that the mononuclear complex **2** evolves in solution according to Equation (4).

$$6\ [L_aMn(OAc)]^+ \rightarrow [L_iMnMnL_i]^{2+} + [L_iMnMnL_a]^{2+} + [L_aMnMnL_a]^{2+} + 6\ OAc^- + 6\ H^+ \quad (4)$$

The three complexes would present the same bis(μ-phenolato)-bridged core unit and would be indistinguishable by EPR spectroscopy for instance. Complex $[L_aMn^{II}Mn^{II}L_a]^{2+}$ would remain in solution during the crystallisation process. Further investigation on the mechanism of this evolution was not pursued. A complete study would require controlling the pH value and the amount of acetate ions during the synthesis and crystallisation processes. In order to avoid the oxidation of the secondary amine of the L_aH ligand, methylation of the nitrogen atom has been performed. Manganese coordination chemistry of both the Mn^{II} and Mn^{III} oxidation states with this pentadentate ligand is under investigation.

Experimental Section

General Remarks: Reagents and solvents were purchased commercially and used as received. Elemental analysis: Analyses were performed by the Service Central d'Analyse du CNRS (Vernaison-France) for C, H, B, Cl, Mn, N. Infrared spectroscopy: Spectra were recorded on KBr pellets in the range of 4000 to 200 cm^{-1} with a Perkin–Elmer Spectrum 1000 spectrophotometer. The synthesis of L_aH has been described previously.[18]

Caution: *Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small quantities of these compounds should be prepared and handled behind suitable protective shields.*

Syntheses

[1](BPh$_4$)$_2$·2CH$_3$COCH$_3$: An ethanol solution (5 mL) of L_aH (348 mg, 1.0 mmol) and triethylamine (0.2 mL, 2.0 mmol) was added to an ethanol solution (5 mL) of Mn(OAc)$_3$·2H$_2$O (268 mg, 1.0 mmol) while stirring. The resulting brown solution was stirred for an extra hour and filtered at least twice in order to eliminate the remaining Mn(OAc)$_3$·2H$_2$O. To the filtrate sodium tetraphenylborate (342 mg, 1.0 mmol) was added. The brownish powder thus obtained, was then washed with ethanol, dried on a frit, and redissolved in acetone. Crystals suitable for X-ray crystallography were obtained by slow evaporation of acetone. 170 mg (ρ = 11%) of crystallised complex was collected by filtration. IR (KBr): $\tilde{\nu}$ = 3461 (w), 3254 (w), 3053 (m), 1710 (m), 1665 (s), 1597 (w), 1580 (m), 1569 (m), 1479 (w), 1453 (m), 1443 (m), 1360 (s), 1265 (w), 1220 (m), 1156 (s), 1101 (s), 1031 (s), 1015 (s), 974 (s), 882 (s), 841 (s), 751 (m), 733 (w), 706 (w), 643 (s), 624 (s), 611 (m), 581 (s), 528 (s), 470 (s), 412 (s) cm^{-1}. $C_{96}H_{95}B_2Mn_2N_8O_4$ (1556.3): calcd. C 74.09, H 6.15, B 1.36, Mn 7.06, N 7.20; found C 73.68, H 6.11, B 2.06, Mn 7.00, N 6.97.

[1](ClO$_4$)$_2$·H$_2$O: An ethanol solution (5 mL) of L_aH (348 mg, 1.0 mmol) and triethylamine (0.2 L, 2 mmol) was added to an ethanol solution (5 mL) of Mn(OAc)$_3$·2H$_2$O (268 mg, 1.0 mmol) while stirring. The resulting brown solution was stirred for several hours and filtered at least twice in order to eliminate the remaining Mn(OAc)$_3$·2H$_2$O. To the filtrate sodium perchlorate (122 mg, 1.0 mmol) was added. The pale brownish powder thus obtained, was then washed with ethanol, and dried on a frit. IR (KBr): $\tilde{\nu}$ = 3440 (s), 3278 (m), 3059 (w), 2912 (m), 1661 (w), 1595 (s), 1570 (m), 1479 (s), 1453 (m), 1442 (m), 1294 (m), 1265 (s), 1152 (m), 1094 (s), 1017 (m), 884 (w), 838 (w), 769 (m), 762 (m), 725 (w), 636 (w), 624 (w), 611 (m), 579 (w), 472 (w), 412 (w) cm^{-1}. $C_{42}H_{45}Cl_2Mn_2N_8O_{11}$ (1018.6): calcd. C 49.52, H 4.45, Cl 6.96, N 11.00; found C 49.61, H 4.63, Cl 7.33, N 10.82.

[2](ClO$_4$)·0.5H$_2$O: An ethanol solution (5 mL) of L_aH (348 mg, 1.0 mmol) was added to an ethanol solution (5 mL) of Mn(OAc)$_3$·2H$_2$O (268 mg, 1.0 mmol) while stirring. The resulting dark purple solution was stirred for 5 min and filtered at least twice in order to eliminate the remaining Mn(OAc)$_3$·2H$_2$O. To the filtrate sodium perchlorate (122 mg, 1.0 mmol) was added. The solution was stirred for an extra hour and the purple powder thus obtained, was then washed with ethanol, and dried on a frit. IR (KBr): $\tilde{\nu}$ = 3416 (s), 3148 (m), 2970 (w), 2926 (w), 1607 (w), 1568 (m), 1479 (s), 1450 (s), 1445 (s), 1428(m), 1375(s), 1327 (s), 1283 (m), 1263 (s), 1160 (w), 1088 (s), 1017 (m), 974(w), 944 (w), 930 (w), 887 (w), 852 (w), 783 (s), 765 (s) 56 (s), 724 (w), 658 (w), 640 (m), 623 (s), 584 (w), 579 (w), 415 (w) cm^{-1}. $C_{23}H_{27}ClMnN_4O_{7.5}$ (569.9): calcd C 48.48, H 4.78, Cl 6.22, N 9.83; found C 48.35, H 4.72, Cl 6.65, N 9.58.

Crystallographic Data Collection and Refinement of the Structure of [1](BPh$_4$)$_2$·2CH$_3$COCH$_3$: The crystal data of [**1**](BPh$_4$)$_2$·2CH$_3$COCH$_3$ and the parameters of data collection are summarized in Table 3. A honey-colored crystal of approximate dimensions 0.30 × 0.20 × 0.15 mm was selected. The diffraction collection was carried out with a Nonius diffractometer, equipped with a CCD detector. The lattice parameters were determined from ten images recorded with 2° Φ-scans and later refined on all data. The data were recorded at 123 K. A 180° Φ-range was scanned with 2° steps with a crystal-to-detector distance fixed at 30 mm. Data were corrected for Lorentz polarisation. The structure was solved by direct methods and refined by full-matrix least squares on F^2 with anisotropic thermal parameters for all non-H atoms. One ligand was found disordered on two positions with a 0.5 occupation factor. H atoms were introduced at calculated positions (except for atoms of the disordered ligands) and constrained to ride on their parent C atom. All calculations were performed with an O2 Silicon Graphics Station with the SHELXTL package.[60] Crystal data are summarized in Table 3. CCDC-178266 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.ac.uk].

Table 3. Crystallographic data for [**1**](BPh$_4$)$_2$·2CH$_3$COCH$_3$

Empirical formula	$C_{96}H_{95}B_2Mn_2N_8O_4$
Formula mass	1556.3
Temperature [K]	123
Wavelength [Å]	0.71073
a [Å]	24.502(5)
b [Å]	14.805(3)
c [Å]	25.626(5)
β [°]	115.86(3)
Volume [Å^3]	8365(3)
Z	4
Density [g·cm^{-3}]	1.236
μ [mm^{-1}]	0.359
θ_{max} [°]	24.69
hkl ranges	$0 \le h \le 28$ $0 \le k \le 17$ $-30 \le l \le 27$
Reflections measured	51714
Reflections independent	14126
Reflections with $I > 2\sigma(I)$	7772
Parameters	962
$R1 = \Sigma\|\|F_o\| - \|F_c\|\|/\Sigma\|F_o\|$	0.1004
$wR2 = \{\Sigma[w(F_o^2 - F_c^2)^2]^2/\Sigma w(F_o^2)^2]\}^{1/2}$ $w = 1/[\sigma^2(F_o^2) + (0.1000P)^2]$ where $P = (F_o^2 + 2F_c^2)/3$	0.2120
(Δ/σ)max	0.016
$\Delta\rho_{max}$ [e·Å^{-3}]	0.566
$\Delta\rho_{min.}$ [e·Å^{-3}]	−0.475

Magnetic Susceptibility Measurements: Magnetic susceptibility data were recorded with an MPMS5 magnetometer (Quantum Design, Inc.). The calibration was made at 298 K using a palladium reference sample furnished by Quantum Design, Inc. The data were collected over a temperature range of 2−300 K at a magnetic field of 0.5 or 1 T and were corrected for diamagnetism. In the case of **1**, the $\chi_M T$ vs. T curves were fitted using the van Vleck formula and assuming the same g factor for each spin state S. The energies appearing in the exponential arguments are derived from the Heisenberg−Dirac-van Vleck Hamiltonian $-JS_1 \cdot S_2$. The total spin S runs from $|S_1 - S_2|$ to $S_1 + S_2$ by unit steps. The fitting procedure used for complex **2** is derived from magnetisation calculations described previously.[61]

EPR Spectroscopy: EPR Spectra were recorded with a Bruker 200D spectrometer at the X-band. For low-temperature studies, an Oxford Instrument continuous-flow liquid helium cryostat and a temperature control system were used.

Cyclic Voltammetry and Chronocoulometry: Cyclic voltammetry and chronocoulometry measurements were recorded with an EGG PAR potentiostat (M273 model). The counter electrode was an Au wire, the working electrode, a glassy carbon disk, was carefully polished before each voltammogram with a 1 μm diamond paste, sonicated in an ethanol bath and then washed carefully with eth-

anol. It is worth noting that in the absence of such treatment of the working electrode surface, the successive cyclic voltammograms were not reproducible. The reference electrode was an $Ag/AgClO_4$ electrode (0.530 V vs. NHE electrode), isolated in a fritted bridge. The solvent used was distilled acetonitrile where tetrabutylammonium perchlorate was added to obtain a 0.1 M supporting electrolyte, when the experiments were carried out at room temperature, or 0.2 M, when the experiments were carried out at low temperature (below 10 °C). Low-temperature regulation was insured by a Julabo circulation cryostat.

UV/Vis Spectroscopy: UV/Vis spectra were recorded with a Cary 300 Bio spectrophotometer at 20 °C with 1-cm quartz cuvettes.

Electrospray Ionisation Ion Trap Mass Spectrometry: All experiments were performed with an ESQUIRE ion trap (Bruker-Franzen Analytic GmbH, Bremen, Germany). The used instrument has a fundamental RF frequency of 781 kHz and was used here in the *standard* mode with a mass-to-charge ratio up to 2000 Th, using a 260.3 kHz frequency as axial modulation. The ion trap operated at an uncorrected partial He buffer gas pressure of 3.4×10^{-5} Torr ($4.5\ 10^{-3}$ Pa). A differentially pumped interface transferred the ions from the electrospray source (Analytica of Brandford, Inc., Brandford, CT) to the mass spectrometer. No Ion Current Control (ICC) was used, allowing the adjustment of the ion accumulation time. Some applied parameters were unchanged for all experiments, such as the RF frequency amplitude of the hexapole (700 V), and the voltage applied on the electron multiplier (−1500 V). The dynode voltage of the electron multiplier was −5 kV, the delay before scanning 10 ms and the exit lens voltage −50 V, with the low *m/z* cutoff value at 50 Th.

Infused Solutions: The complexes were analysed in the positive-ion mode. Diluted samples (ca. 10^{-4} M) in pure acetonitrile were infused into the ESI source using a Cole−Parmer Instrument Company (74900 series) syringe pump at a flow rate of 120 μL/h. The capillary entry voltage was about −3500 V. The N_2 drying gas temperature was 150 °C with a flow rate of 200 L/h.

Syntheses, Crystal Structure, and Nuclease Activity of Oxalato-Bridged Dicopper(II) Complexes with Planar N-Donor Heterocyclic Bases

Anitha M. Thomas,[a] Girish Neelakanta,[b] Subramony Mahadevan,[b] Munirathinam Nethaji,[a] and Akhil R. Chakravarty*[a]

Keywords: Catalysis / Copper / Crystal structure / Magnetic properties / Nuclease activity

Oxalato-bridged dicopper(II) complexes [{CuL(H_2O)}$_2$(μ-ox)]-(ClO_4)$_2$ (**1**–**4**), where L is a bidentate chelating heterocyclic base such as 2,2′-bipyridine (bpy, **1**), 1,10-phenanthroline (phen, **2**), dipyridoquinoxaline (dpq, **3**) and dipyridophenazine (dppz, **4**), were prepared by treatment of copper(II) perchlorate hexahydrate with sodium oxalate and L in aqueous ethanol. Complex **3** has been structurally characterised. The coordination geometry of the copper centres is essentially square-pyramidal. The {CuL(H_2O)} units are bridged by an oxalate moiety to form the discrete dimeric core. Magnetic studies in the 20–300 K temperature range show the presence of an antiferromagnetically coupled dicopper(II) unit, giving $-2J$ values in the 346–384 cm^{-1} range. The redox-active complexes retain the dimeric core in solution, and two quasireversible Cu^{II}/Cu^{I} couples are observed in the potential range from 0.2 to –0.4 V vs. SCE in a DMF/tris–HCl/0.1 M KCl buffer system (1:1, v/v, pH = 7.2) with a glassy carbon working electrode. The binding and cleavage of DNA by the complexes have been studied. The intercalating ability of the planar bases, determined from the decrease of the fluorescence intensity of ethidium bromide bound calf thymus DNA on addition of the complex, gave the order: **3** > **4** > **2** >> **1**. The nuclease activity of the complexes with supercoiled pUC19 DNA in DMF/tris–HCl/NaCl buffer (pH = 7.2) in the presence of ascorbic acid follows the order: **3** > **2** >> **4** ≈ **1**. The dpq complex exhibits the most efficient DNA binding and cleavage activity. The dppz complex shows good binding ability but poor nuclease activity.

Introduction

Coordination complexes that oxidatively cleave DNA under physiological conditions are of current interest in the development of artificial nucleases.[1−3] In view of the important role played by copper ions in enzymatic catalysis, efforts to develop the chemistry of redox-active copper complexes as chemical nucleases are underway.[1−6] It has been suggested that metallointercalators such as the bis(1,10-phen) complex of copper(I), on activation by hydrogen peroxide in the presence of a reducing agent, cleave DNA through the formation of a hydrogen-abstracting active oxygen species.[6] It has also been postulated that the active oxo species react with the H1′ or H4′ deoxyribose protons of the nucleotide in the vicinity of the binding site at the minor groove to initiate a series of reactions resulting in the cleavage of DNA.[5a,7] The cleavage efficiency is generally dependent on the DNA binding ability and the metal-based redox potential of the complex.

Supporting information for this article is available on the WWW under http://www.eurjic.org or from the author.

Although the true binding mode of the bis(phen) complex to DNA is currently unknown, it has been indicated by several research groups that the nuclease activity of the complex is related to the partial intercalation or binding of one phen ligand to the minor DNA groove, with the other phen ligand making favourable contacts within the groove.[8−11] Rill and co-workers have observed that the phen complex displays efficient nuclease activity at a phenanthroline/copper ratio of greater than 2:1, regardless of the reducing agent used in the cleavage reaction.[8] This current work stems from our interest in covalently linking two mono(phen) and related copper units through an oxalate moiety to form a dinuclear complex with an N-donor base/copper ratio of 1:1 and studying the DNA binding and nuclease activity of the complexes. The objective of the use of the oxalate as a linker is to provide a planar skeleton in the {LCu−ox−CuL} moiety. In addition, the bio-relevant oxalate ligand is an oxidized product of ascorbic acid (vitamin C), used extensively in copper-mediated enzymatic reactions.[12] An essentially planar $N_4O_4Cu_2$ unit with planar N-donor bases should be expected to show good binding ability to the DNA minor groove. Previous studies on oxalato-bridged dicopper(II) complexes have shown that an estimate of the planarity of the core can readily be obtained from the singlet-triplet energy gap, which varies over a wide range depending upon the nature of the terminal

ligands.[13−17] Here we report the synthesis, structure and nuclease activity of the dicopper(II) complexes $[\{CuL(H_2O)\}_2(\mu\text{-ox})](ClO_4)_2$ (**1**−**4**) with planar heterocyclic bases as terminal ligands [L: 2,2′-bipyridine (bpy), **1**; 1,10-phenanthroline (phen), **2**; dipyrido[3,2-*d*:2′,3′-*f*]quinoxaline (dpq), **3**; and dipyrido[3,2-*a*:2′,3′-*c*]phenazine (dppz), **4**]. The significant result of this study is the observation of varied DNA binding and nuclease activity of the structurally similar complexes **1**−**4**. A preliminary report on the crystal structure of complex **1** has already appeared.[18]

Results and Discussion

Synthesis and Characterization

Complexes **1**−**4**, prepared by treatment of $Cu(ClO_4)_2\cdot 6H_2O$ with the bidentate N-donor heterocyclic base (L) and sodium oxalate in aqueous ethanol, belong to the general class of oxalato-bridged dicopper(II) complexes of formulation $[LCu(\mu\text{-}C_2O_4)CuL]X_n$, where X is a counteranion or solvent molecule.[13] The physicochemical data for **1**−**4** are given in Table 1. The complexes are moderately soluble in methanol and MeCN, soluble in DMF or DMSO. While the bpy and phen complexes are moderately water-soluble, the dpq and dppz complexes show poor solubility in water. They display characteristic infrared bands in the 1651−1662 and 1077−1098 cm^{-1} ranges for the oxalate and perchlorate, respectively. The complexes show a d-d band in the 650−710 nm range in aqueous DMF solution.

Crystal Structure and Magnetic Properties

Complex **3**, crystallised as $[Cu_2(ox)(dpq)_2(H_2O)_2](ClO_4)_2\cdot 2H_2O$, has been structurally characterised by single-crystal X-ray diffraction. A perspective view of the complex is shown in Figure 1. The crystallographic data and the data collection parameters are summarized in Table 5 and the selected bond lengths and angles are given in Table 2. The structure consists of a centrosymmetric complex in which $Cu(dpq)(H_2O)$ units are bridged by oxalate to give a copper−copper distance of 5.138 Å. Each copper centre is essentially in a 4 + 1 coordination environment, with the N(1), N(2), O(1), and O(2) atoms forming a basal plane and the Ow(1) atom of the bound water occupying the axial position. The perchlorate anion, involved in the hydrogen-bonding interactions with the water molecules, also shows a very weak axial contact to the copper centre through oxygen atom O(11) [Cu(1)···O(11), 2.696 Å]. The planar dpq ligand exhibits a bidentate chelate mode of bonding and non-involvement of the quinoxaline moiety in any metal−ligand interaction. The deviation of the copper atom from the basal plane is 0.062 Å, which is the shortest among known copper−oxalate species.[14] The angle formed between the basal plane containing the copper atom and the oxalate plane is 2.55°. This angle gives a measure of the coplanarity, an important factor for derivation of the orbital topologies.

The complexes **1**−**4** are antiferromagnetically (AF) coupled dimeric species. Magnetic susceptibility measurements from 20 to 300 K with polycrystalline samples of the complexes gave a singlet-triplet separation ($-2J$) in the 346−384 cm^{-1} range from theoretical fitting of the $\chi_M T$ vs. T plots (Figure 2; Table 1). It has been theoretically predicted that, for a coplanar orbital topology with the $d_{x^2-y^2}$-type orbital coplanar with the oxalate molecule [i.e., both singly occupied molecular orbitals (SOMOs) being in the

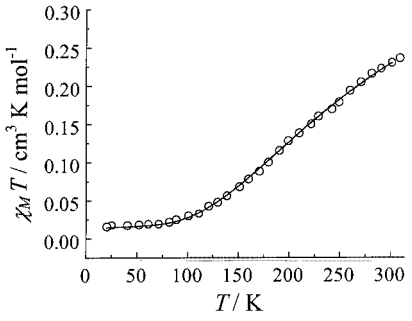

Figure 2. Plot of $\chi_M T$ vs. T for a polycrystalline sample of [{(phen)Cu(H$_2$O)}$_2$(μ-ox)](ClO$_4$)$_2$ (**2**); the solid line shows a theoretical fit to the experimental data

plane of the oxalate bridge], the $-2J$ (S-T gap) value should fall in the 300−400 cm^{-1} range, with the singlet being the ground state.[13] The observed $-2J$ values for the complexes **1**−**4** suggest a coplanar orbital topology in which the copper(II) $d_{x^2-y^2}$ orbitals, being in the plane of the oxalate molecule, result in the strong overlap of both SOMOs and the oxalate-based molecular orbitals.

Electrochemical and Catalytic Properties

In a DMF−50 mM tris−HCl/0.1 M KCl (1:1, v/v) buffer (pH = 7.2) and with a glassy carbon working electrode, complexes **1**−**3** show two cyclic voltammetric responses attributable to the $Cu_2^{II}/Cu^{II}Cu^{I}$ and $Cu^{II}Cu^{I}/Cu_2^{I}$ couples in the 0.2 to −0.4 V (vs. SCE) potential range (Figure 3; Table 3). The observation of these redox couples, with similar current heights, suggests a dimeric nature of the complexes in solution. The ratio of unity of the cathodic to anodic peak currents (i_{pc}/i_{pa}) at different scan rates and the ΔE_p values in the 100−250 mV range at 50 mV·s^{-1} indicate the quasireversible nature of the electron-transfer processes. Because of poor solubility, the redox chemistry of the dppz complex was studied by differential pulse voltammetry (DPV). The electrochemical data suggest the stability order for the copper(I) species as: **4** (dppz) > **3** (dpq) > **2** (phen) > **1** (bpy). The observed differences in the $E_{1/2}$ values could be due to the effect of the quinoxaline and phenazine moieties in dpq and dppz ligands, stabilizing the copper(I) state. When the potential is scanned up to −1.7 V, the complexes show an irreversible reduction peak in the range of −1.0 to −1.5 V and two anodic counterparts, with the one near −0.1 V showing high anodic current indicating absorption of the reduced species on the electrode surface.

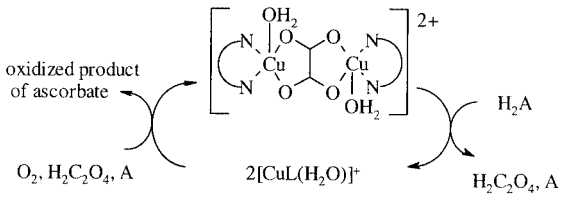
The complexes undergo facile reduction with ascorbic acid (H$_2$A) in a DMF/50 mM tris−HCl buffer medium (1:1, v/v, pH = 7.2) to form an unstable brown copper(I) species, which converts into the oxidized species on exposure to dioxygen (Scheme 1). The catalytic cycle is effective with mol ratios of H$_2$A and the complex of ca. 100 for **1** and **2** and ca. 60 for **3** and **4**. The product from such a reaction in the presence of excess ascorbic acid has been analysed as polymeric copper(II) oxalate by the powder X-ray diffraction method.[19] The oxalic acid is formed by hydrolytic ring-rupture and oxidation of dehydroascorbate through the formation of L-threonic and 2,3-diketo-L-gulonic acids.[12] Additionally, the reduced species of **3** and **4** are susceptible to dimer formation through the extended aromatic rings of the quinoxaline and phenazine moieties.[8] Attempts to isolate the cuprous complex of **1** under anaerobic condition over a period of 7 d were unsuccessful. The brown single crystals formed in low yield were analysed from the unit cell dimensions as the bis(bpy) complex of copper(I).[20] The reduced species isolated by rapid precipitation of the solid from the reaction mixture was tentatively analysed as [Cu(bpy)(H$_2$O)(ClO$_4$)]. The solid mass did not show any IR band for the oxalate ion. We believe that the dicopper cores in **1**−**4** undergo cleavage due to a concomitant two-electron and two-proton transfer process by ascorbic acid [H$_2$A → A + 2 H$^+$ + 2 e$^-$]. The reduced monomeric species regenerates the dimeric core on exposure to dioxygen in the presence of oxalic acid in solution.



Scheme 1. Catalytic oxidation reaction of ascorbic acid (H$_2$A) by dioxygen, mediated by [{LCu(H$_2$O)}$_2$(μ-ox)](ClO$_4$)$_2$ (L = bpy, **1**; phen, **2**; dpq, **3**; dppz, **4**) in a DMF/tris−HCl buffer (1:1, v/v, pH = 7.2)

DNA Binding and Cleavage Studies

The binding of the complexes **1**−**4** and $[Cu(phen)_2(H_2O)](ClO_4)_2$ to calf thymus DNA was studied by fluorescence spectroscopy. Measurements were made with ethidium bromide bound (EB-bound) DNA, and showed enhanced emission intensity relative to the free EB. Competitive binding of the copper complex to CT DNA results in the displacement of the bound EB. This causes a reduction in the emission intensity, due to fluorescence quenching of the free EB by the solvent molecules.[21−23] Figure 4 shows the decrease in the emission intensity of EB on addition of the complexes, including the bis(phen)copper(II) complex. Complexes **3** and **4**, showing higher slopes than the bis(phen) complex, indicate significant binding abilities of the dpq and dppz complexes (Figure 4). The bpy complex, with a near zero slope, does not show any binding affinity to CT DNA. The binding ability of the complexes to the CT DNA follows the order: **3** ≥ **4** > **2** ≥ $Cu(phen)_2^{2+}$ >> **1**. The

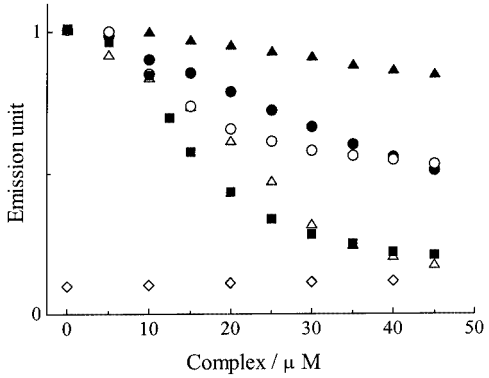


Figure 4. Effect of addition of $[\{LCu(H_2O)\}_2(\mu\text{-ox})](ClO_4)_2$ (L = bpy, black triangle; phen, whithe circles; dpq, black squares; dppz, whithe triangles) and the bis(phen)copper(II) species (black circles) on the emission intensity of the CT DNA bound ethidium bromide (12.5μM) at different complex concentrations in 5 mM tris−HCl + 50 mM NaCl buffer (pH = 7.2) containing 3% DMF at 25 °C; the concentration of CT DNA was 125 μM; the emission intensity of EB (in the absence of DNA) at various concentrations of the $[\{(dpq)Cu(H_2O)\}_2(\mu\text{-ox})](ClO_4)_2$ complex is also shown (whithe diamonds)

binding constant (K_b) for the bis(phen)copper(I) complex is known to be 5×10^4 M^{-1} (base pairs).[9] The K_b value for the copper(II) species is 2.7 times lower, as evidenced by differential pulse voltammetric (DPV) studies.[23] Although it was not possible for us to estimate the K_b values for **1**−**4**, due to the absence of any intense band in the visible spectra of the complexes, the emission data suggest a significantly higher binding constant for **3** and **4** than for the bis(phen)-copper(II) species.

The nuclease activity of **1**−**4**, together with that of the bis(phen)copper complex, was studied with pUC19 DNA in a medium of DMF/tris−HCl buffer (1:1, v/v, pH = 7.2) in the presence of ascorbic acid. The cleavage efficiency of the complexes was determined by gel electrophoresis, from their ability to convert supercoiled (SC) to nicked circular

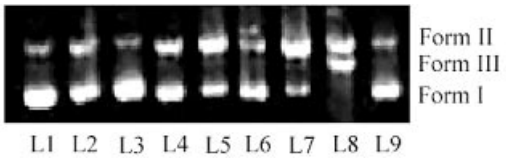

Figure 5. Cleavage of supercoiled pUC19 DNA (0.5 μg) by $[\{LCu(H_2O)\}_2(\mu\text{-ox})](ClO_4)_2$ (**1**−**4**) in DMF in the presence of ascorbic acid (H_2A, 100 μM) in a 50 mM tris−HCl + 50 mM NaCl buffer at 37 °C; cleavage by the mono- and bis(phen) complexes of copper are also shown for comparison; Lane 1, DNA control; Lane 2, DNA + H_2A; Lane 3, DNA + complex **3**; Lane 4, DNA + H_2A + mono(phen)copper(II) complex; Lane 5, DNA + H_2A + bis(phen)copper(II) complex; Lane 6, DNA + H_2A + **1**; Lane 7, DNA + H_2A + **2**; Lane 8, DNA + H_2A + **3**; Lane 9, DNA + H_2A + **4**; complex concentration was 30 μM; forms I−III are supercoiled, nicked circular and linear, respectively

(NC) DNA (Table 4; Figure 5).[24] The dpq complex has the greatest ability to cleave DNA. The mechanistic aspects of the cleavage reactions are of importance. Oxalato-bridged dicopper(II) complexes containing terminal 2,2′-bipyridyl or 2,2′:6′,2"-terpyridyl ligands (L) are known to exist in equilibria with two mononuclear complexes of formulations CuL^{2+} and CuL(ox) at pH values ranging between 2.0 and 6.0.[25,26] At pH values higher than 7.5, the mononuclear

[a] The serial numbers correspond to the lanes shown in Figure 5. [b] Concentration: H_2A 100 μM; copper complexes 30 μM. Reaction medium: DMF−50 mM tris−HCl/50 mM NaCl buffer (1:1, v/v, pH = 7.2). Forms I−III are supercoiled (SC) pUC19, nicked circular and linear DNA, respectively.

[Cu(L)(ox)] species predominates. Such mononuclear copper(II) complexes, with one terminal ligand, show poor cleavage activity when L is an intercalating ligand such as 1,10-phen. Although we cannot exclude the possibility of such an equilibrium involving the present complexes, the cleavage efficiency data indicate that the dimeric structure in **1**−**4** is generally retained in pH = 7.2 DMF/tris−HCl buffer.

There are several important findings in this study pertaining to the binding and cleavage of DNA. Complexes **1**−**4** are dicationic and have a Cu/heterocyclic base ratio of 1:1. The bpy complex has been found to be nuclease-inactive and a poor binder to DNA. This suggests that DNA binding in the form of intercalation could be an important factor for the cleavage activity. The luminescence experiments monitoring the emission of the DNA-bound ethidium bromide strongly support an intercalative binding mode for the copper(II) complexes. Complexes **2**−**4** are powerful binders to DNA. The high affinities of the dpq and dppz ligands for intercalative binding could be related to the presence of extended aromatic rings, making noncovalent interactions between the π-system of the ligand and the DNA base pairs more favourable. The ability of the dppz ligand to approach deep into the DNA helix would be expected to be greater than that of the dpq ligand. However, the emission data indicate equal CT DNA helix binding affinities for both complexes. The complexes differ drastically in their abilities to cleave DNA in the presence of a reducing agent such as ascorbic acid. The anomalous nuclease activity of **4** could be related either to the difference in groove selectivity[27−32] or to an enhancement of the stability of the cuprous complex in the presence of hydrophobic interactions.

Conclusions

Four dicopper(II) complexes with $[Cu(\mu\text{-ox})Cu]^{2+}$ cores and planar N-donor heterocyclic bases as terminal ligands show interesting DNA-binding and -cleavage properties. The phen, dpq and dppz complexes were found to be powerful binders to CT DNA. While the phen and dpq complexes show good cleavage properties, the dppz complex is nuclease-inactive. The results are explained in terms of intercalative binding of the complexes to DNA. The cleavage activity of the dpq complex is significantly greater than that of the phen complexes. The results are of significance, as the dpq complex may find use as a new DNA-binding and -cleaving agent in nucleic acids chemistry.

Experimental Section

General Methods: All reagents and chemicals were purchased from commercial sources and used without further purification. Solvents were purified by standard procedures. The calf thymus (CT) DNA and supercoiled (SC) pUC19 DNA were purchased from Bangalore Genie (India). Agarose (molecular biology grade) and ethidium bromide were from Sigma (USA). Tris−HCl buffer solution was prepared with deionised, sonicated, triply distilled water. Dipyridoquinoxaline and dipyridophenazine ligands were prepared by literature methods.[24,33] The elemental analyses were done with a Perkin−Elmer 2400 CHN analyser. The infrared, electronic and fluorescence spectra were recorded with Bruker Equinox 55, Hitachi U-3000 and Perkin−Elmer LS 50B spectrophotometers, respectively. Variable-temperature magnetic susceptibility data in the 20−300 K range were obtained for polycrystalline samples with a George Associates Inc. Lewis-coil-force magnetometer system equipped with a closed-cycle cryostat (Air products) and a Cahn balance. $Hg[Co(NCS)_4]$ was used as a calibrant. Experimental susceptibility data were corrected for diamagnetic contributions[34] and temperature-independent paramagnetism ($N\alpha = 60\times10^{-6}$ $cm^3\cdot mol^{-1}$ per copper). The molar magnetic susceptibilities were fitted by the modified Bleaney−Bowers expression[35,36] based on the isotropic form of the Heisenberg−Dirac−van Vleck (HDvV) model with a spin Hamiltonian $H = -2JS_1S_2$ ($S_1 = S_2 = 1/2$ for d^9-d^9 configuration): $\chi_{Cu} = [Ng^2\beta^2/kT][3 + \exp(-2J/kT)]^{-1}(1 - \rho) + (Ng_{\parallel}^2\beta^2/4kT)\rho + N\alpha$, where ρ is the fraction of monomeric impurity and $-2J$ is the singlet-triplet energy separation, with the singlet being the ground state. The magnetic moments at various temperatures were calculated in μ_B units [$\mu_B \approx 9.274\cdot10^{-24}$ $J\cdot T^{-1}$]. Electrochemical measurements were made at 25 °C with an EG&G PAR Model 253 Versastat Potentiostat/Galvanostat with electrochemical analysis software 270 for voltammetric work with a three-electrode set-up comprising a glassy carbon working electrode, a platinum wire auxiliary electrode and a saturated calomel reference (SCE) electrode. The electrochemical data were uncorrected for junction potentials.

Preparation of $[\{CuL(H_2O)\}_2(\mu\text{-ox})](ClO_4)_2$ (1−4): The complexes were prepared by a general procedure in which the heterocyclic base (L, 1.0 mmol; 156 mg bpy; 198 mg phen; 232 mg dpq; 282 mg dppz) was treated with $Cu(ClO_4)_2\cdot6H_2O$ (1.0 mmol; 371 mg) in aqueous ethanol (70 cm^3), followed by addition of an aqueous solution (5 mL) of sodium oxalate (0.5 mmol; 67 mg). The reaction mixture was stirred for 10 min. Complexes were isolated as pale blue solids after washing with ethanol and water followed by drying in vacuo over P_4O_{10} (yield: 70%). ***Caution!*** Perchlorate salts are potentially explosive and should be handled in small quantities with care. Single crystals of **3**, suitable for X-ray studies, were obtained by slow concentration of an aqueous methanolic solution of the complex $C_{22}H_{16}Cl_2Cu_2N_4O_{12}$ (**1**) (726.38): calcd. C, 36.36, H 2.20, N 7.71; found C 36.51, H 2.48, N 7.62. $C_{26}H_{20}Cl_2Cu_2N_4O_{14}$ (**2**) (810.45): calcd. C, 38.52, H 2.47, N 6.91; found C 38.92, H 2.23, N 6.93. $C_{30}H_{20}Cl_2Cu_2N_8O_{14}$ (**3**) (914.55): calcd. C, 39.36, H 2.19, N 12.25; found C 38.97, H 2.34, N 11.96. $C_{38}H_{24}Cl_2Cu_2N_8O_{14}$ (**4**) (1014.64): calcd. C, 44.97, H 2.37, N 11.05%; found C 44.71, H 2.63, N 10.86.

X-ray Crystal Structure Analysis: All geometric and intensity data were collected with an automated Enraf−Nonius CAD4 diffractometer equipped with Mo-K_α radiation (λ = 0.71073 Å) with a crystal mounted on a fibre by epoxy cement (Table 5). Intensity data, collected by an ω-2θ scan technique, were corrected for Lorentz polarisation effects and for absorption.[37] The structure was solved by the combination of Patterson and Fourier techniques and refined by full-matrix least squares. During refinement, positional disorder of the oxygen atoms of the perchlorate anion were observed. The four oxygen peaks concerned were refined with restraints. The ClO_4 moiety refined well, but showed a highest peak of 1.01 e·Å^{-3} near the O(11) atom ($x = 0.7932$; $y = 0.2161$; $z = 0.3594$). All the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located from the difference Fourier map and

[a] $w = 1/[\sigma^2(F_o^2) + (0.0690\ P)^2 + (3.0700\ P)]$ where $P = [\mathrm{Max}(F_o^2,0) + 2\ F_c^2]/3$.

were refined isotropically, except for those attached to the water oxygen atoms, which were treated as rigid groups. All calculations were performed with PC versions of the SHELX system of programs.[38] The perspective view of the complex was obtained by use of ORTEP.[39] CCDC-159021 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

DNA-Binding and -Cleavage Experiments: The concentration of the CT DNA was determined by recording the absorption intensity at 260 nm, with a known molar extinction coefficient value of 6600 dm^3 mol^{-1} cm^{-1}.[40] The experiments were performed with 0.1 mM complex solution in the absence and in the presence of CT DNA, varying from 0 to 250 μM. In order to compare the relative binding of the complexes to DNA with that of the bis(phen) complex of copper(II), ethidium bromide bound CT DNA solution in tris−HCl/NaCl buffer (pH = 7.2) was treated with an increasing amount of the complex solution. The fluorescence intensities of the ethidium bromide in the bound form at 601 nm (510 nm excitation) were plotted against the complex concentration. The cleavage of DNA was monitored by agarose gel electrophoresis. Supercoiled pUC19 DNA (6 μL, ca. 500 ng) in tris−HCl buffer (50 mM) with 50 mM NaCl (pH = 7.2) was treated with the metal complex (30 μM) and ascorbic acid (100 μM), followed by dilution with the tris−HCl buffer to a total volume of 20 μL. The samples were incubated for 1 h at 37 °C, loading buffer [25% bromophenol blue, 0.25% xylene cyanol, 30% glycerol (3 μL)] was added and then loaded on 0.8% agarose gel containing 1.0 μg/mL ethidium bromide. Electrophoresis was carried out at 40 V for 3 h in TBE buffer. Bands were viewed under UV light and photographed. The cleavage efficiency was measured by determining the ability of the complex to convert the supercoiled DNA (SC) to nicked circular form (NC). After electrophoresis, the proportion of DNA in each fraction was estimated quantitatively from the intensities of the bands by use of the BIORAD Gel Documentation System. The fraction of the original supercoiled DNA, converted into the NC (nicked circular) at the end of the reaction, was calculated after correction for the low level of NC present in the original sample and the low affinity of ethidium bromide binding to SC compared to NC and linear forms of DNA.[24]

Acknowledgments

We thank the Department of Science and Technology, Government of India, and the Council of Scientific and Industrial Research, New Delhi, for financial support. Thanks are due to the Alexander von Humboldt Foundation, Germany, for the donation of an electroanalytical system. We also thank Mr. P. A. N. Reddy for his help in DNA-binding and -cleavage studies and the Bioinformatic Center of the Indian Institute of Science, Bangalore, for a database search.

A New Oligomeric Complex of Cyclic Hydrogenphosphonates with Calcium Perchlorate

Elsa Sutra,[a] Lydia Lamandé,[a] Heinz Gornitzka,[b] and Jacques Bellan*[a]

Keywords: Phosphorus heterocycles / Calcium / P ligands / Self-assembly / Noncovalent interactions

A hybrid organic/inorganic material is obtained with calcium as the structural building block. The structure of this new oligomeric complex was confirmed by a single crystal X-ray diffraction, which shows the bridging position of the calcium ions between four dioxazaphosphocane moieties.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Methylenebisphosphonates, also known as geminal bisphosphonates, are analogues of pyrophosphates and are also characterized by a P−C−P bond. These compounds with various side chains linked to the central carbon atom, like Etidronate® or Clodronate®, have been extensively studied and widely used in treating various diseases of bone and calcium metabolism.[1−3]

Whereas monophosphonates have been reported to be inactive with respect to calcium related disorders,[4] the presence of a potential donor group adjacent to the phosphonate moiety (as in α-acylphosphonates or α-hydroxyiminophosphonates) restores this activity.[5] Despite the large number of bis-phosphonates investigated for their biological activity or even used clinically, structural studies of their calcium complexes are very limited. However, a common feature of the few structural studies reported is that the Ca ion forms bidentate chelates with two oxygen atoms.[6−7]

In this field, we have synthesized, in the past few years, new eight-membered cyclic hydrogenophosphonates named dioxazaphosphocanes. These cyclic and nonionizable phosphodiesters, with two donor groups (carbonyl and phosphoryl) in the same molecule, display interesting complexing properties towards alkaline earth metal cations.[8]

The complexing properties of the dioxazaphosphocane moiety have been demonstrated in the solid state by an X-ray structure determination. It revealed an original polymeric arrangement which is in accordance with the previously claimed stoichiometry and the data obtained by classical physical methods (NMR and IR spectroscopy).

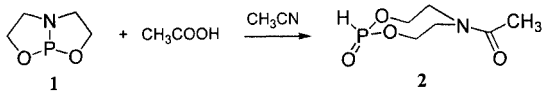
The synthesis of dioxazaphosphocanes, based on the reactivity of a constrained bicyclophosphane, was developed in our laboratory.[9] Scheme 1 shows the synthesis of compound **2**, studied in this paper, which is obtained by an oxidative addition reaction of acetic acid to the bicyclophosphane **1**.[10]



1 **2**

Scheme 1

By a single crystal X ray diffraction analysis, we have recently demonstrated that the dioxazaphosphocane **2** adopts a crown conformation in the solid state.[11] This conformation is retained in solution according to the ^{1}H and ^{13}C NMR spectra, thus meaning that the phosphoryl and carbonyl groups are in favourable positions for complexation.

We have already observed the formation of a well-defined complex from the reaction of dioxazaphosphocane **2** with calcium perchlorate. Comparison of the IR spectra of the free ligand and of the complex shows shifts to lower frequencies for the carbonyl ($\Delta\nu_{C=O}$ = 22 cm^{-1}) and phosphoryl ($\Delta\nu_{P=O}$ = 14 cm^{-1}) stretching vibrations; hence they are both involved in the complexation. Moreover, interaction of the phosphoryl group with calcium was confirmed by ^{31}P NMR spectroscopy ($\Delta\delta^{31}{}_{P}$ = 0.9 ppm; $\Delta^{1}{}_{JPH}$ = 32 Hz). The chemical formula of complex **3** [$CaL_2{\cdot}(ClO_4)_2$ (with L = compound **2**)] is consistent with a 1:2 stoichiometry (one calcium atom for two heterocycles) as determined by elemental analysis, and from these results we previously proposed a sandwich-type structure, with the calcium atom being located between two dioxazaphosphocane moieties.

A single crystal X-ray diffraction analysis of this complex (Figure 1) confirmed that the complexation actually involves the phosphoryl and carbonyl groups.

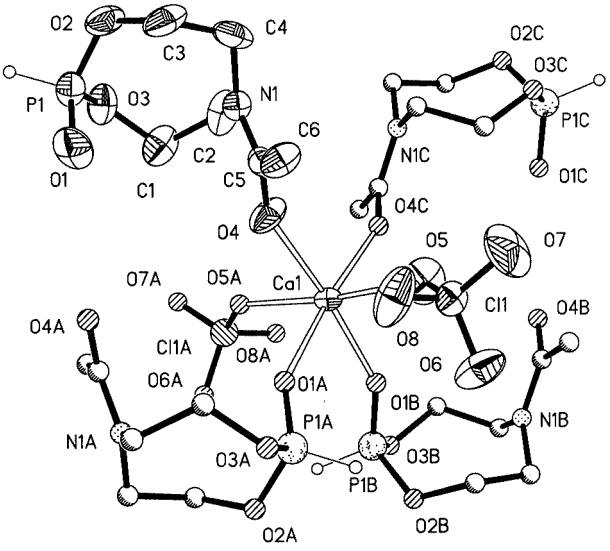


Figure 1. Structure of **3** in the solid state; the asymmetric unit is drawn as a thermal ellipsoid diagram at the 50% probability level; the figure shows the coordination environment of the Ca cation; except for the hydrogen atom bonded to the phosphorus, all others hydrogen atoms have been omitted for clarity; selected bond lengths [Å] and angles [°]: Ca−O1A 2.280(6), Ca−O4 2.281(5), Ca−O5 2.36(4), O1A−Ca−O1B 85.0(4), O1A−Ca−O4 92.5(2), O1A−Ca−O4C 174.3(2), O1A−Ca−O5 91.5(5), O1A−Ca−O5C 92.9(5)

However, calcium is not located between two dioxazaphosphocane moieties, but is bridged between four heterocycles leading to the formation of a one-dimensional polymeric material in which the metal plays the role of a template element. However, and in contrast to the solid state, the sandwich-type structure is not unlikely in solution. It is important to notice that in complex **3** the dioxazaphosphocane moieties retain the crown conformation previously determined for the free ligand.

Ca^{2+} generally accepts a coordination number of eight or nine,[12] and its coordination shell is either full, or completed with one molecule of solvent (e.g. H_2O, CH_3CN, THF). A coordination number of six, while less common, leads to well-defined octahedral complexes.[13] This latter arrangement is found in antibiotics like Benastatine A[14] or Griseocheline.[15] In complex **3** the calcium atom is coordinated to six oxygen atoms, four from four different dioxazaphosphocane moieties and two from perchlorate anions. The charge neutrality of the complex is maintained by perchlorate anions located on both parts of the mean plane formed by the other complexing oxygen atoms from two carbonyl groups and two phosphoryl groups for each calcium ion. The Ca−O distances are in the range 2.37−2.26 Å and there are no other Ca−O contacts less than 3.2 Å to indicate any additional coordination of Ca.

The most prominent common structural feature is the arrangement of the $[CaL_2]\cdot(ClO_4)_2$ units (L = dioxazaphosphocane **2**) in polymeric chains, where the metal centers are connected by bridging dioxazaphosphocane groups (Figure 2).

An examination of Ca/dioxazaphosphocane complex formation under physiological conditions is in progress, because in many biomineralizing systems organized organic assemblies serve as inductive templates for mediating the nucleation and growth of inorganic crystals.

Experimental Section

3: $[Ca(ClO_4)_2\cdot 6H_2O]$ (0.37 g, 1.08 mmol) in MeCN (30 mL) was added to a solution of dioxazaphosphocane **2** (0.42 g, 2.17 mmol) in MeCN (50 mL). The mixture was stirred at room temperature for 10 min. Slow evaporation of the solvent produced colorless crystals of **3** (0.48 g, 70%). ^{31}P NMR (80.96 MHz, CH_3CN, 298 K): $\delta = 8.8$ ($^1J_{PH} = 760$ Hz) ppm. $C_{12}H_{24}CaCl_2N_2O_{16}P_2$ (624.98): calcd. C 23.04, H 3.84, N 4.48; found C 23.13, H 3.65, N 4.49.

Crystal Data for 3: $C_{12}H_{24}CaCl_2N_2O_{16}P_2$, $M = 625.25$, monoclinic, $C2/c$, $a = 15.067(5)$ Å, $b = 12.271(4)$ Å, $c = 13.564(4)$ Å, $\beta = 94.792(6)°$, $V = 2499.2(13)$ Å^3, $Z = 4$, $\rho_c = 1.662$ Mg m^{-3}, $F(000) = 1288$, $\lambda = 0.71073$ Å, $T = 193(2)$ K, μ(Mo-K_α) = 0.669 mm^{-1}, crystal size 0.2 × 0.2 × 0.05 mm, $2.14° < \Theta < 23.25°$, 4459 reflections (1761 independent with $R_{int} = 0.0638$) were collected at low temperatures with an oil-coated shock-cooled crystal on a Bruker-AXS CCD 1000 diffractometer. The structure was solved by direct methods (SHELXS-97)[16] and 209 parameters were refined using the least-squares method on F^2.[17] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the molecules were idealized geometrically and refined using a riding model. The hydrogen atom bonded to the phosphorus atom was located by a difference Fourier procedure. A disorder of the ClO_4 anion was refined anisotropically with the help of 202 ADP and distance restraints. Largest electron density residue: 0.599 e·Å^{-3}, R_1 [for $I > 2\sigma(I)$] = 0.0711 and $wR_2 = 0.1795$ (all data) with $R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{0.5}$.

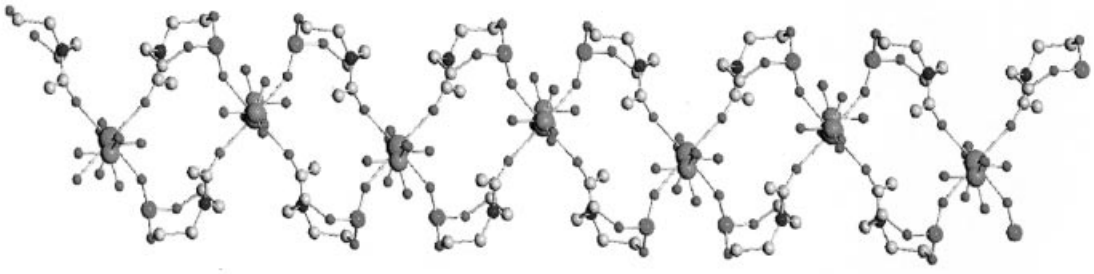

Figure 2. Ball-and-stick view showing the polymeric nature of **3**

The Structure and Fluorescence Properties of Two Novel Mixed-Ligand Supramolecular Frameworks with Different Structural Motifs

Zhi-Yong Fu,[a,b] Xin-Tao Wu,*[a] Jing-Cao Dai,[a] Sheng-Min Hu,[a] Wen-Xin Du,[a] Han-Hui Zhang,[c] and Rui-Qing Sun[c]

Keywords: Crystal engineering / Cobalt / Fluorescence / Supramolecular chemistry

Two novel coordination polymers formed by cobalt nitrate and 1,2-bis(4-pyridyl)ethane with the homologous ligands 2-aminoterephthalic acid and terephthalic acid, respectively, have been prepared. One displays a fivefold diamond-type feature while the other exhibits a twofold interpenetrating structural motif. The thermal and photoluminescence properties associated with their structures have been characterized and studied.

Introduction

The construction of functional metal-organic frameworks is of great interest due to their intriguing network topologies and their potential applications as microporous,[1] magnetic,[2] nonlinear optical[3] and fluorescent materials.[4] Molecular self-assembly has been proven as an effective way of constructing various fascinating supramolecular frameworks. The basic building blocks recognize each other in a reaction system and aggregate to form the bulk structure.[5] Lots of supramolecular frameworks have already been produced in the past decade based upon the principle of crystal engineering.[6] However, the mechanism of molecular self-assembly is unclear and the result of self-assembly is unpredictable, therefore an understanding of the factors that govern the assembly process is necessary for technological development. Recently, considerable attention has been focused on the influence of the factors involved in molecular self-assembly processes, such as the solvent system,[7] template,[8] counterion,[9] and the conformational freedom of the ligands.[10] We are particularly interested in self-assembly and the functionalities associated with different coordination conformations. Here, we report two novel mixed organic ligand supramolecular compounds [Co{1,2-bis(4-pyridyl}ethane)(2-aminoterephthalate)] (**1**) and [Co{1,2-bis(4-pyridyl)ethane}(terephthalate)] (**2**). The O,O′-donor ligands adopt different coordination modes forming different kinds of building blocks, which finally aggregate to generate different supramolecular architectures, due to the influence of the substituent groups. These different structures show similar fluorescence spectra: they both display strong fluorescence emission at 400 nm.

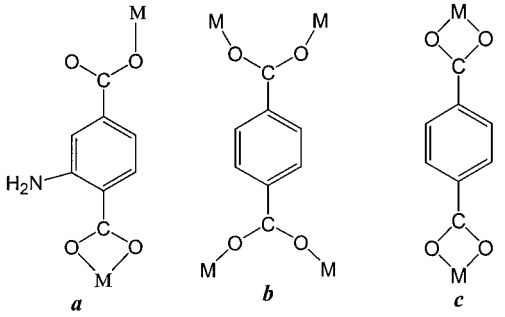
Results and Discussion

2-Aminoterephthalic acid and terephthalic acid were chosen as starting materials as one has a substituted amino group while the other has none. These two organic acids react with 1,2-bis(4-pyridyl)ethane and cobalt nitrate in a 1:1:1 ratio under the same conditions. The O-donors accept different coordination modes (Scheme 1), which finally results in different coordination frameworks.



Scheme 1. The coordination modes of the carboxylate group: *a*) unidentate and chelating bis-bidentate; *b*) bidentate; *c*) chelating bidentate

Crystal Structures

An ORTEP view of a Co center of compound **1** is shown in Figure 1. The Co atom has a distorted tetrahedral coordination geometry, being coordinated by two N atoms of two 1,2-bis(4-pyridyl)ethane molecules [Co1−N2b = 2.101(11) Å, Co1−N3 = 2.063(11) Å], two O atoms from one chelating bis-bidentate carboxylate group [Co1−O1a = 2.050(10) Å, Co(1)−O2a = 2.224(10) Å], and one O atom of one unidentate carboxylate group [Co1−O3 = 2.024(9) Å], which provide the four connecting nodes resulting in an unsymmetrical adamantane-type unit (Figure 2). No guest molecules were found in the cage of the adamantane unit and distortions of the unit can arise from the application of different ligands. Four 2-aminoterephthalate ligands and two 1,2-bis(4-pyridyl)ethane ligands bridge six Co atoms to form a hexagonal circuit. The distance between the Co centers is determined by the length of 2-aminoterephthalate (10.729 Å) or 1,2-bis(4-pyridyl)ethane (13.349 Å). Figure 3 shows that five independent equivalent networks are interpenetrated within the structure (fivefold diamondoid mode). The nodes of four other nets are arranged between the top-most and bottom-most extremities of an adamantane unit of the first net. Although many diamond-related nets displaying various interpenetration modes ranging from two- to ninefold have been reported,[13] the fivefold interpenetration of **1** is novel in the presence of the mixed organic ligands with different lengths. To the best of our knowledge, with coordination polymers only two other examples of a fivefold diamond-type net have been previously observed. They are $[Cu(L_2)](BF_4)$ (L = 1,4-dicyanobenzene) and $[Cu(bpe)_2](BF_4)$ generated by the reaction of $CuBF_4$ with 1,4-dicyanobenzene and bpe, respectively.[14]

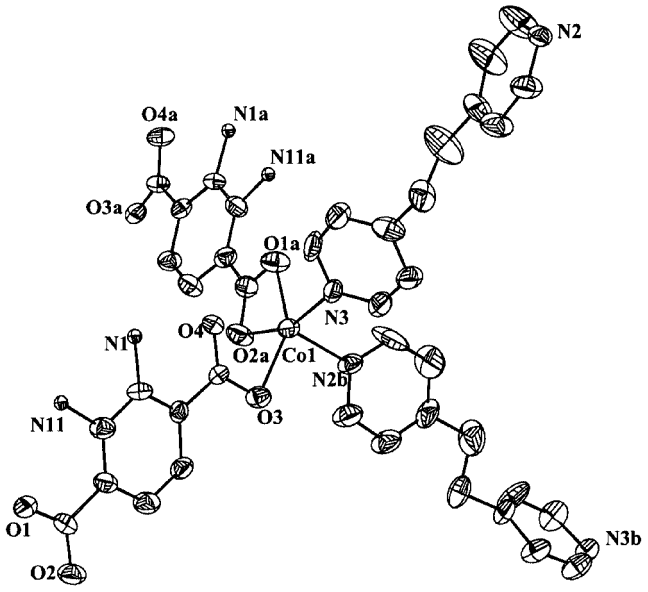


Figure 1. ORTEP drawing of **1** around the Co center (ellipsoids at 30% probability); the hydrogen atoms are omitted for clarity; the N1 and N11 atoms of compound **1** were located from the E-map directly, and the displacement parameters of them were of 0.5 to 0.5 statistically; symmetry codes: $a = -x, 1 + y, z - 1/4$; $b = x, 2 - y, z + 1/4$

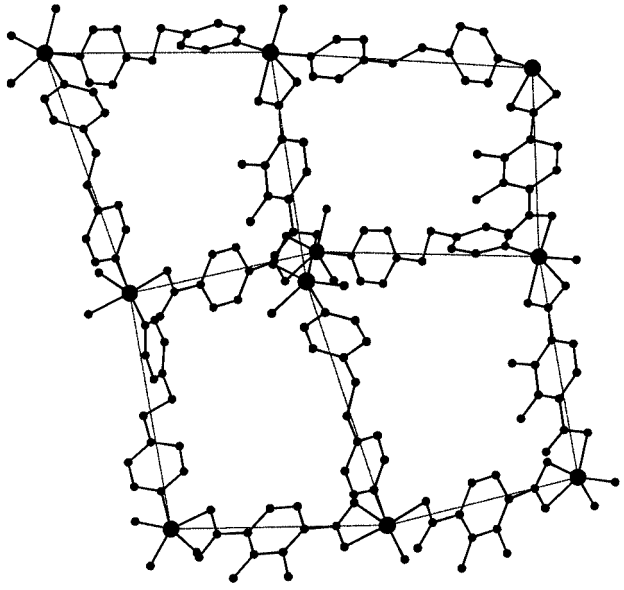

Figure 2. View of the adamantane units of **2**; the large black balls represent the Co atoms

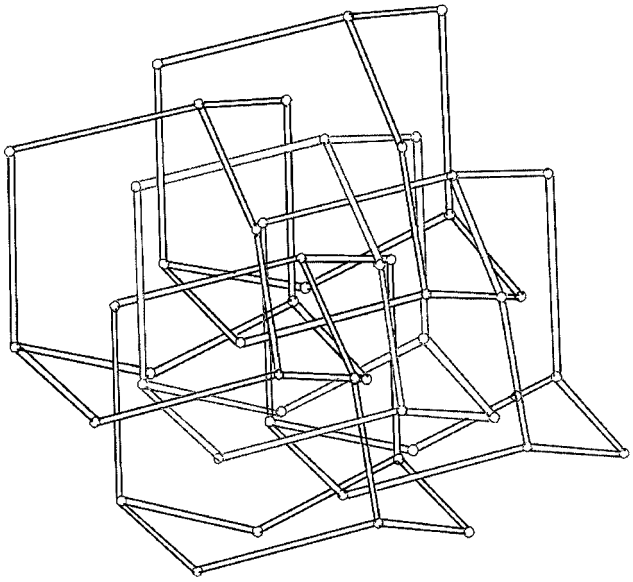

Figure 3. The interpenetration model for complex **1**

For the preparation of compound **2**, the terephthalate ligand was used instead of 2-aminoterephthalate ligand. The Co center has a distorted octahedral coordination geometry, with two oxygen donors of one chelating bis-bidentate carboxylate group [Co1−O1 = 2.200(3) Å, Co1−O2 = 2.192(3) Å] and two oxygen donors of two bridging bidentate carboxylate groups in the horizontal direction (Co1−O3 = 2.017 Å, Co1−O4a = 2.028 Å). The coordination sphere is completed by two nitrogen donors of 1,2-bis(4-pyridyl)ethane [Co1−N1 = 2.163(3) Å, Co1−N2b =

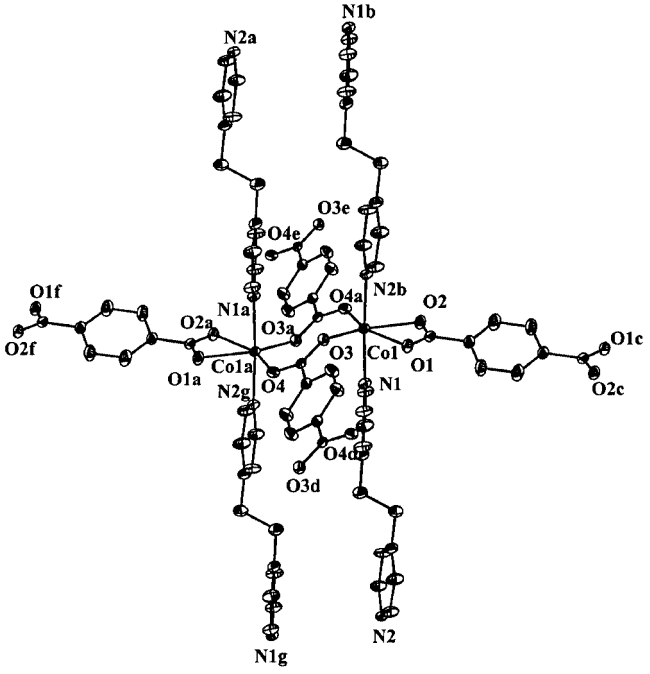

Figure 4. View of the dimetal unit of **2**; hydrogen atoms have been omitted, and the ellipsoids at 30% probability represent C, N O, and Co; symmetry codes: $a = -x, -y, -z$; $b = x, y + 1, z - 1$; $c = 1 - x, -1 - y, -1 - z$; $d = 1 - x, -y, -z$; $e = -1 + x, y, z$; $f = -1 + x, 1 + y, 1 + z$; $g = -x, -1 - y, 1 - z$

2.152(3) Å] in the axial direction (Figure 4). The coordination mode in compound **2** generates a novel cuboidal building block (Figure 5). Each corner of the cuboidal block is occupied by a binuclear subunit and the Co···Co separation in the binuclear subunit is 4.27 Å. Eight terephthalate ligands form the length and width of the cuboidal block while eight 1,2-bis(4-pyridyl)ethane ligands make up the height of it. No guest molecule is included in the cuboidal box. The aggregation of the building blocks results in a 3-D framework, and the 3-D networks interlock with each other displaying a twofold-interpenetrating mode. As shown in Figure 6, in the axial direction every two rods (rod a and b) in the cuboidal block are associated with one particular quadrate ring (ring 1) of the other framework through which they pass, while in the horizontal direction one rod (rod c) is associated with two particular quadrate rings (ring 2 and 3) of the other framework through which it penetrates.

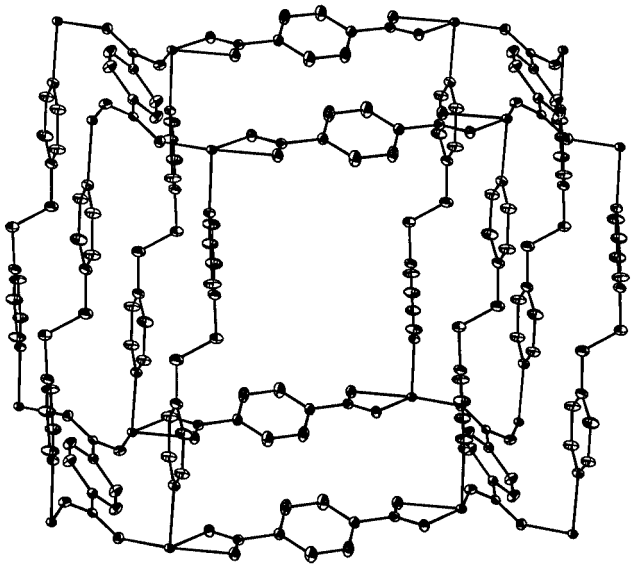

Figure 5. Structure of the cuboidal block of **2**, showing eight Co2 units linked by eight terephthalate anions and eight 1,2-bis(4-pyridyl)ethane units

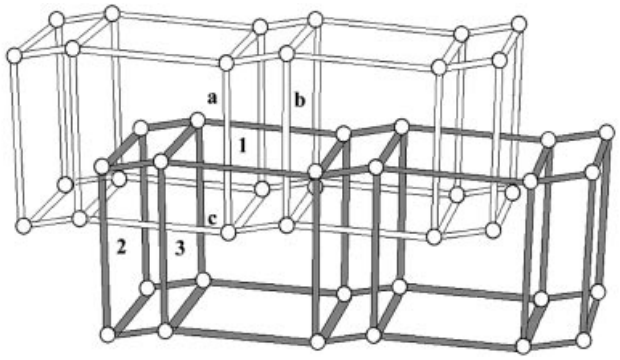

Figure 6. The interpenetration model for complex **2**

Under the same reaction conditions, compounds **1** and **2** exhibit different structural motifs. The coordination mode of the carboxylate group is an essential factor in affecting the bulk structures of **1** and **2**. One of the characteristics of these reactions is that the substituent groups in the homologous O,O′-donor ligands are slightly different, which affects the pH values in the reaction systems (obsd. 6.22 in **1** and 5.13 in **2**). These different basicities, which most probably make the carboxylate groups in **1** and **2** accept different coordination modes, lead to different supramolecular architectures.

IR Spectroscopy

The IR spectrum of compound **1** shows the characteristic bands of the dicarboxylate groups of the 2-aminoterephthalate ligands at 1618−1549 cm^{-1} for the asymmetric vibration and at 1421−1396 cm^{-1} for the symmetric vibration. While the IR spectrum of compound **2** shows the characteristic bands of the dicarboxylate groups of the terephthalate ligands at 1610−1552 cm^{-1} for the asymmetric vibration and at 1410−1394 cm^{-1} for the symmetric vibration. The splitting of $\nu_{asym}(CO_2)$ in compound **1** and compound **2** confirms that the carboxylate groups have two different coordination modes,[15] in agreement with their crystal structures. The absence of the expected characteristic bands at 1730−1690 cm^{-1} for the protonated carboxylate groups indicates the complete deprotonation of 2-aminoterephthalic acid and terephthalic acid in the reaction with Co ions.[16]

Thermal and Fluorescent Properties

Compounds **1** and **2** were heated to 600 °C under N_2. Their thermal decomposition behavior (Figure 7) is very similar. No obvious decomposition was observed in until ca 430 °C. The TGA data show that **1** has an obvious weight loss starting at about 435 °C (437 °C for **2**).

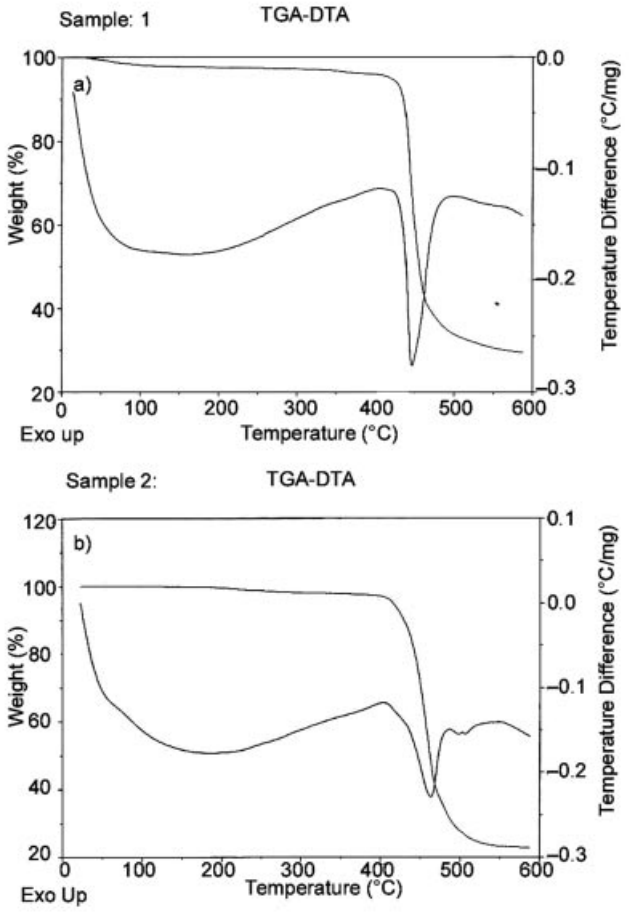

Figure 7. The TGA-DTA diagram for the coordination polymers: *a*) compound **1**; *b*) compound **2**

The emission spectra of compounds **1** and **2** in the solid state at room temperature are shown in Figure 8. It can be seen that **1** exhibits an intense photoluminescence emission at 400 nm (Figure 8a, λ_{ex} = 300 nm) while **2** also exhibits an intense photoluminescence emission at 400 nm (Figure 8b, λ_{ex} = 310 nm). These emissions may be assigned as ligand-to-metal charge transfer (LMCT).[17] Due to their high thermal stability, **1** and **2** may be good candidates for emitting diode devices.

It is very interesting to note that **1** and **2** exhibit similar thermal behaviors and photoluminescence spectra despite having different structural motifs. What is the reason for these phenomena? Due to the fact that thermal behaviors and photoluminescence behavior are closely associated with the metal ions and the ligands coordinated around them, we decided to look again at the coordination environments of the metal ions in **1** and **2**. In **1** the Co atom has a distorted tetrahedral coordination geometry while in **2** the Co

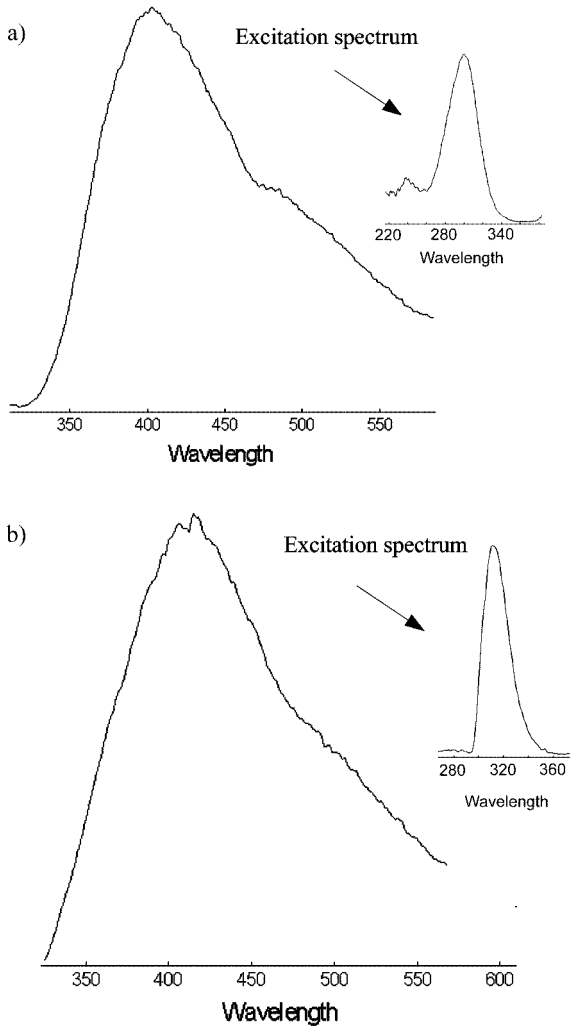

Figure 8. Solid-state emission spectra of the coordination polymers at room temperature: *a*) compound **1**; *b*) compound **2**

atom has a distorted octahedral coordination geometry. However, despite this distinct disparity, the ligands coordinated around the metal ions in **1** and **2** are similar (Figure 1 and Figure 4). The Co center in **1** has one chelating bis-bidentate carboxylate group, one unidentate carboxylate group, and two 1,2-bis(4-pyridyl)ethane ligands while in **2** there are one chelating bis-bidentate carboxylate group, two bridging bidentate carboxylate groups, and two 1,2-bis(4-pyridyl)ethane ligands. These similar environments may be the reason, for the similar thermal and photoluminescence behaviors (Figure 7 and 8).

Conclusion

Two novel coordination polymers formed by cobalt nitrate and 1,2-bis(4-pyridyl)ethane with the homologous ligands 2-aminoterephthalic acid and terephthalic acid have been prepared and characterized. Compound **1** displays a fivefold diamond-type net while compound **2** exhibits a twofold-interpenetrating structural motif. The two com-

pounds have similar thermal behaviors and photoluminescence spectra. In this paper, we have shown that the amino group in 2-aminoterephthalic acid plays an important role in affecting the coordination mode of the carboxylate group, causing **1** to have a structural motif that is clearly different from that of **2**. Their thermal and photoluminescence properties are closely associated with the coordination environments around the metal centers.

Experimental Section

General Remarks: All reactions were carried out in hydrothermal conditions. All chemicals are commercially available and used as received without further purification. The C, H and N microanalyses were carried out with a Vario EL III elemental analyzer. Infrared spectra (KBr pellets) were recorded in the range from 4000−400 cm^{-1} on a Nicolet Magna 750 FT-IR spectrometer. Thermogravimetric analyses (**TGA**) were performed under nitrogen with a heating rate of 10 °C·min^{-1} using a TA5200/MDSC2910 system. Fluorescent spectra were measured with an Edinburgh FL-FS90 TCSPC system at the Spectroscopy Lab of Fuzhou University.

Synthesis of [Co{1,2-bis(4-pyridyl)ethane}(2-aminoterephthalate)] (1): An aqueous mixture (10 cm^3) containing $Co(NO_3)_2·6H_2O$ (0.292 g, 1 mmol), 1,2-bis(4-pyridyl)ethane (0.184 g, 1 mmol), 2-aminoterephthalic acid (0.181 g, 1 mmol) and NaOMe (0.108 g, 2 mmol) was placed in a Parr Teflon-lined stainless steel bomb (25 cm^3). The bomb was heated at 5 °C·min^{-1} to 160 °C; after 24 h at 160 °C it was cooled to 90 °C at the rate of 0.1 °C·min^{-1}, then maintained at that temperature for 12 h. Finally, it was cooled at 0.1 °C·min^{-1} to 20 °C. The bomb was opened to give red block crystals in 62% yield. $C_{20}H_{17}CoN_3O_4$ (422.3): calcd. C 56.86, H 4.06, N 9.95; found C 56.96, H 4.01, N 9.97. IR (KBr): $\tilde{\nu}$ = 3442m, 3338m, 3055w, 2945w, 1618s, 1564s, 1549s, 1498m, 1446m, 1421s, 1396s, 1375m, 1333w, 1261s, 1072w, 1028s, 847s, 816m, 768s, 702w, 536w, 517w cm^1.

Synthesis of [Co{1,2-bis(4-pyridyl)ethane}(terephthalate)] (2): An aqueous mixture (10 cm^3) containing $Co(NO_3)_2·6H_2O$ (0.292 g, 1 mmol), 1,2-bis(4-pyridyl)ethane (0.184 g, 1 mmol), terephthalic acid (0.166 g, 1 mmol) and NaOMe (0.108 g, 2 mmol) was placed in a Parr Teflon-lined stainless steel bomb (25 cm^3). The bomb was heated at 5 °C·min^{-1} to 160 °C; after 24 h at 160 °C it was cooled to 90 °C at the rate of 0.1 °C·min^{-1}, then maintained at that temperature for 12 h. Finally, it was cooled at 0.1 °C·min^{-1} to 20 °C. The bomb was opened to give red block crystals in 75% yield. $C_{20}H_{16}CoN_2O_4$ (407.3): calcd. C 58.98, H 3.96, N 6.88; found C 58.87, H 3.92, N 6.89. IR (KBr): $\tilde{\nu}$ = 3057w, 2933w, 1610s, 1568s, 1552s, 1510m, 1500m, 1427m, 1410s, 1394s, 1306w, 1221w, 1018m, 841s, 818m, 748s, 550s, 523m cm^1.

X-ray Crystallographic Study: Crystallographic data for compound **1** and compound **2** are listed in Table 1. For compound **1**, a red block crystal with dimensions of 0.40 × 0.14 × 0.14 mm was used. For compound **2**, a red block crystal with dimensions of 0.30 × 0.22 × 0.12 mm was used. Data for **1** and **2** were collected at room temperature on a Siemens SMART-CCD area-detector diffractometer with Mo-K_α radiation (λ = 0.71073 Å) and a graphite monochromator using the ω-scan mode. Data reductions and absorption corrections were performed with SMART and SADABS software, respectively. For all structural analyses, all calculations were performed on an indy workstation from Silicon Graphics with the program SHELXTL.[11] The structures were solved by direct methods. The refinement of structures was performed by full-matrix least-squares techniques on F^2 using SHELXL-97.[12] All non-hydrogen atoms were treated anisotropically. The nitrogen atoms of 2-aminoterephthalate exhibit disorder. They were located from

Keywords: Palladium / Platinum / N ligands / Bridging ligands / Structure elucidation

New dimetallic palladium and platinum complexes containing the tetrakis(pyrazol-1-yl)borate ligand of the type $[\{(C_6F_5)_2M\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^-$ (M = Pd, Pt), $[\{(C_6F_5)(L)Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^+$ (L = CN*t*Bu, NCPh, PR_3, AsR_3) and $[\{(C_6F_5)(Cl)Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^-$ have been prepared using the benzonitrile complexes *cis*-$[(C_6F_5)_2M(NCPh)_2]$ (M = Pd, Pt) or the halide bridged complexes $[\{(C_6F_5)LPd(\mu\text{-}X)\}_2]$ (L = CN*t*Bu, NCPh, PR_3, AsR_3, tht; X = Cl or Br), and $[B(pz)_4]^-$ as starting materials. The monometallic $[(C_6F_5)(t\text{BuNC})Pd(\mu\text{-}pz)_2B(pz)_2]$ and the asymmetric dinuclear $[(C_6F_5)_2Pd(\mu\text{-}pz)_2B(\mu\text{-}pz)_2Pd(\eta^3\text{-}C_4H_7)]$ complexes have also been prepared. The crystal structures of $[\{(C_6F_5)_2Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^-$, $[\{(C_6F_5)(t\text{BuNC})Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^+$ and $[(C_6F_5)_2Pd(\mu\text{-}pz)_2B(\mu\text{-}pz)_2Pd(\eta^3\text{-}C_4H_7)]$ have been established by X-ray diffraction.

Introduction

Poly(pyrazolyl)borates have become an important class of ligands with unique properties, as indicated by the variety of species they form with most metals and metalloids,[1,2] including those of palladium and platinum.[3] This family of ligands has found great favor in studies of structure and reactivity[1−6] relevant to catalysis[7,8] and inorganic biochemistry.[5,9] From a structural coordination chemistry point of view, these polydentate nitrogen-donor ligands offer unique opportunities to look into the detailed dynamic behavior in solution, particularly by use of NMR spectroscopy.[10] Although an important number of monomeric palladium(II) poly(pyrazol-1-yl)borate complexes that have already been structurally characterized by X-ray crystallography exists ($[Pd(COMe)\{(Me_2pz)_2BH\text{-}N,N'\}(PCy_3)]$,[11] $[Pd(CH_2SiMe_3)\{(Me_2pz)_2BH\text{-}N,N'\}(PMe_3)]$,[12] $[Pd(\eta^3\text{-}C_3H_5)\{(pz)_3BH\text{-}N,N'\}]$, $[PdPh\{(pz)_3BH\text{-}N,N'\}]$, $[PdR\{(pz)_4B\text{-}N,N'\}(PPh_3)]$ (R = Me, Ph),[13] $[Pd\{2\text{-}(NMe_2CH_2)C_{10}H_6\text{-}C,N\}\{(pz)_3BH\text{-}N,N'\}]$,[14] $[Pd\{2\text{-}CH_2\text{-}C_6H_4P(o\text{-tolyl})_2\text{-}C,P\}\{(pz)_3BH\text{-}N,N'\}]$, $[Pd(C_6H_4C_5H_4N\text{-}C^2,N)\{(pz)_3BH\text{-}N,N'\}]$[15]), surprisingly, to the best of our knowledge (3D Search using the Cambridge Structural Database, October 2001 release) there are no dimeric palladium complexes yet fully characterized by X-ray diffraction.

Here, we describe the synthesis and characterization of some new dimetallic palladium and platinum complexes with the tetrakis(pyrazol-1-yl)borate ligand. The crystal structures of $[\{(C_6F_5)_2Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^-$, $[\{(C_6F_5)(t\text{BuNC})Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]^+$ and $[(C_6F_5)_2Pd(\mu\text{-}pz)_2B(\mu\text{-}pz)_2Pd(\eta^3\text{-}C_4H_7)]$ have been established by X-ray diffraction. The benzonitrile complexes *cis*-$[(C_6F_5)_2M(NCPh)_2]$ (M = Pd, Pt) and the halide-bridged complexes $[\{(C_6F_5)LPd(\mu\text{-}X)\}_2]$ (L = CN*t*Bu, NCPh, PR_3, AsR_3, tht; X = Cl or Br) have been shown to be good precursors for the synthesis of the binuclear compounds reported herein.

Results and Discussion

Homodimetallic Complexes 1 and 2

The ready reaction of *cis*-$[(C_6F_5)_2M(NCPh)_2]$ (M = Pd, Pt) in CH_2Cl_2 with $K[B(pz)_4]$ (pz = pyrazolyl) in a 2:1 molar ratio gives the dimetallic complexes **1** and **2** (Scheme 1). The replacement of PhCN by $[B(pz)_4]^-$ takes place without isomerization, and the reaction products are the *cis* isomers. The complexes are air-stable, both in the solid state and in solution, and they are white. The new complexes have been characterized by partial elemental analyses and spectroscopic (IR and ^1H and ^{19}F NMR)

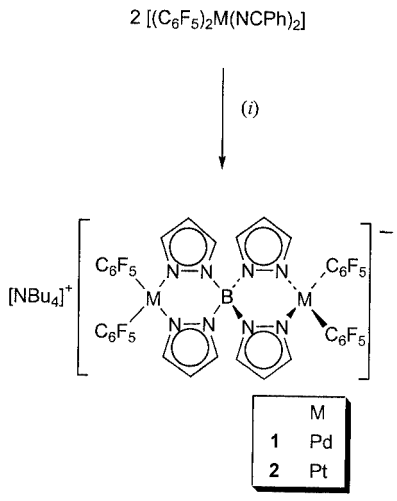
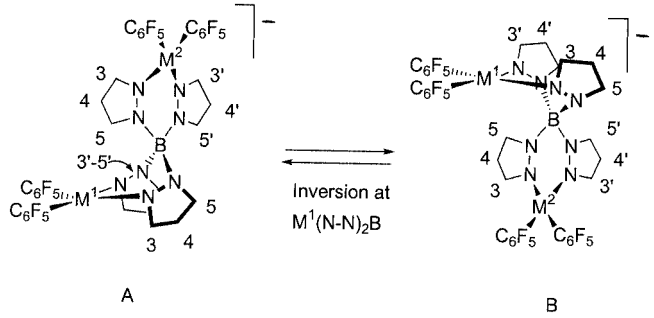
methods. In an acetone solution, these complexes behave as 1:1 electrolytes.[16]



Scheme 1. (*i*) $K[B(pz)_4]/Bu_4NCl$

The IR spectra of complexes **1** and **2** show the characteristic absorptions of the C_6F_5 group [17] at 1630, 1490, 1450, 1050, 950 cm^{-1}, and a split band at ca. 800 cm^{-1}, derived from the so-called X-sensitive mode in C_6F_5 halogen molecules, which is characteristic of the *cis*-$M(C_6F_5)_2$ fragment[18,19] and behaves like a ν(M−C) band.[20]

The ^1H NMR spectra of **1** and **2** at room temperature show a unique set of three resonances for the pyrazolyl ring protons, which suggests the occurrence of a very fast intramolecular interconversion between the conformational isomers **A** and **B** that arises from the boat like $M(N-N)_2B$ ring inversions of these compounds (Scheme 2) for which a spiro structure is expected. The same spectra are observed when the temperature is lowered to −90 °C in CD_2Cl_2. The 3-H and 5-H resonances of complex **1** appear as doublets, owing to coupling with 4-H. The resonance assigned to 4-H appears as a pseudo-triplet. Assignment of the signals to the 3-H and 5-H protons of complex **1** was possible by comparison with the spectrum of complex **2**, for which the 3-H resonance is flanked by satellites (1:4:1) arising from a small hydrogen-platinum coupling. Furthermore, the assignment is also in accordance with the usual criterion for pyrazoles where $^3J_{45} > {}^3J_{34}$.[21]



Scheme 2

We have performed ^1H-^{13}C COSY on **1** in order to examine the Onishi criterion[22] for the pyrazolyl C-3 and C-5 NMR assignments in transition-metal poly(1-pyrazolyl)borate complexes, and we have also found that the resonance assigned to the pyrazolyl C-3 CH carbon atoms is at a lower field than that of C-5.

The ^{19}F NMR spectra of **1** and **2** show the presence of four equivalent freely rotating C_6F_5 rings giving three resonances with relative intensities of 2:1:2, due to the *ortho*-, *para*- and *meta*-F atoms, respectively. As expected, the *ortho*-F signal of complex **2** is flanked by satellites due to coupling to ^{195}Pt.

The structure of **1** is shown in Figure 1 and selected bond lengths and angles in Table 1. Insofar as we know, this is the first dipalladium tetrakis(pyrazol-1-yl)borate species to be structurally characterized. The X-ray structure determination of **1** shows the existence of the spiro structure. Both six-membered chelate $Pd(1)N_4B$ and $Pd(2)N_4B$ rings adopt a boat conformation. Each of the palladium atoms essentially has a square-planar geometry. The four distances Pd−N [2.089(2), 2.098(2), 2.068(2) and 2.100(3) Å] are very similar and are in the range found for other Pd−N distances in polypyrazolylborate complexes [e.g., 2.113(3) and 2.079(2) Å in $[PdPh\{(pz)_4B\text{-}N,N'\}(PPh_3)]$].[13] The bridging tetrakis(pyrazolyl)borate ligand forms chelate angles of 91.04(9) and 89.43(9)° at Pd(1) and Pd(2), respectively. The Pd−C_6F_5 distances [2.003(3), 2.006(6), 2.002(3), 2.005(3) Å] are in the range found in the literature.[23,24]

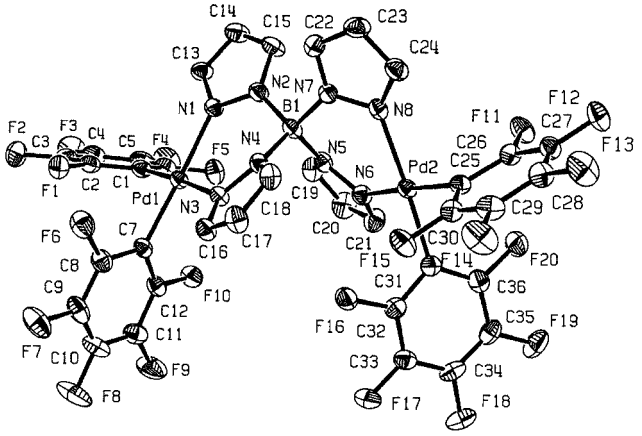


Figure 1. Structure of the anion of **1** showing the atom numbering scheme; hydrogen atoms have been omitted for clarity

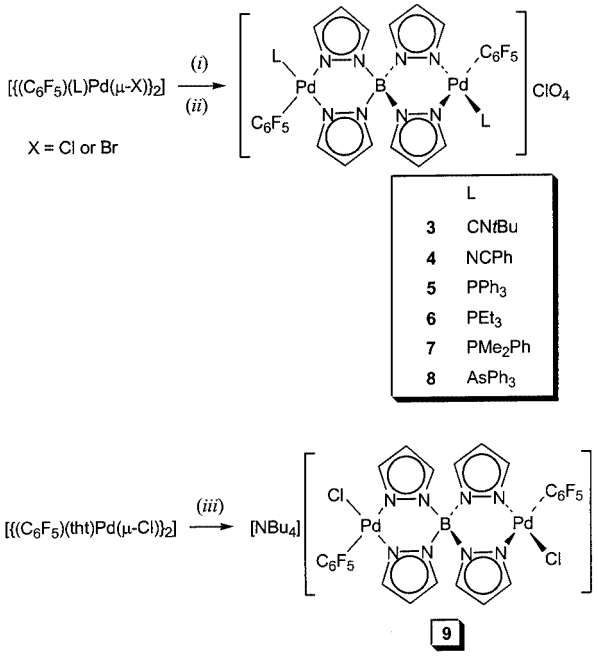
Homodimetallic Complexes 3−9

The reaction of $[\{(C_6F_5)LPd(\mu\text{-}X)\}_2]$ (X = Cl, L = *t*BuNC, PhCN, PPh_3, $AsPh_3$; X = Br, L = PEt_3, PMe_2Ph) with $AgClO_4$ (1:2 molar ratio) in acetone, followed by the addition of $K[B(pz)_4]$ (1:1 molar ratio) gives the corresponding dimetallic complexes **3**−**8** (Scheme 3). The reaction of $[\{(C_6F_5)LPd(\mu\text{-}Cl)\}_2]$ [L = tetrahydrothiophene (tht)] with $K[B(pz)_4]$ and Bu_4NCl (1:1:1 molar ratio) leads to the formation of complex **9** (Scheme 3). In an acetone solution, complexes **3**−**9** behave as 1:1 electrolytes.[16]

Table 1. Selected bond lengths [Å] and angles [°] for complex **1**

Bond lengths		Bond angles	
Pd(1)−C(7)	2.003(3)	C(7)−Pd(1)−C(1)	85.13(12)
Pd(1)−C(1)	2.006(3)	C(7)−Pd(1)−N(3)	91.90(10)
Pd(1)−N(3)	2.089(2)	C(1)−Pd(1)−N(3)	177.00(11)
Pd(1)−N(1)	2.098(2)	C(7)−Pd(1)−N(1)	176.98(11)
Pd(2)−C(25)	2.002(3)	C(1)−Pd(1)−N(1)	91.93(11)
Pd(2)−C(31)	2.005(3)	N(3)−Pd(1)−N(1)	91.04(9)
Pd(2)−N(6)	2.068(2)	C(25)−Pd(2)−C(31)	86.73(12)
Pd(2)−N(8)	2.100(3)	C(25)−Pd(2)−N(6)	175.03(11)
		C(31)−Pd(2)−N(6)	90.49(11)
		C(25)−Pd(2)−N(8)	93.59(11)
		C(31)−Pd(2)−N(8)	176.64(11)
		N(6)−Pd(2)−N(8)	89.43(9)



Scheme 3. (*i*) 2 $AgClO_4$; (*ii*) $K[B(pz)_4]$; (*iii*) $K[B(pz)_4]/Bu_4NCl$

The IR spectra of complexes **3**−**9** show an absorption at 790 cm^{-1} that is observed as a single band for the so-called X-sensitive mode,[20] as expected from the presence of only one C_6F_5 group in the coordination sphere of the palladium atom. Two absorptions at 1100 and 620 cm^{-1}, which are typical of the uncoordinated ClO_4^- (T_d) anion are observed for complexes **3**−**8**.[25] IR spectra of **3** and **4** also show an absorption assigned to ν(CN) at ca. 2230 cm^{-1} (*t*BuNC group[26−28] for **3**) or at 2280 cm^{-1} (PhCN ligand[28,29] for **4**). Complex **9** exhibits a Pd−Cl stretching vibration at 326 cm^{-1}.[30] The NMR spectroscopic data show that they exist in solution in a unique arrangement. Thus, the ^{19}F NMR spectra of **3**−**9** exhibit only one resonance for the *para*-fluorine atoms corresponding to only one type of pentafluorophenyl ring, and the ^{31}P NMR spectra of complexes **5**−**7** only show a resonance for the phosphane ligands. The ^1H NMR spectrum of complex **3** shows a singlet resonance for the *t*BuNC groups at δ = 1.56 ppm. On the other hand, the ^1H NMR spectra of complexes **3**−**9** exhibit two distinct sets of pyrazolyl signals of equal intensities, one assigned to the pyrazolyl group *trans* to C_6F_5 and the other to the pyrazolyl group *trans* to L (with three resonances 1:1:1 each). This suggests the occurrence of a very fast intramolecular interconversion between the conformational isomers that arises from the boat like $M(N-N)_2B$ ring inversions of these compounds for which a spiro structure is expected. The resonances assigned to the pyrazolyl groups in the ^1H NMR spectrum of complex **3** are assigned by considering the NOE between the 3′-H and the *t*BuNC singlet, the usual criterion for pyrazoles where $^3J_{45} > {}^3J_{34}$,[21] and from two-dimensional ^1H-^1H COSY experiments. Furthermore, we have also performed ^1H-^{13}C COSY on **3** (Figure 2), and we have also found that the resonance assigned to the pyrazolyl C-3 CH carbon atoms is at a lower field than that of C-5.[22]

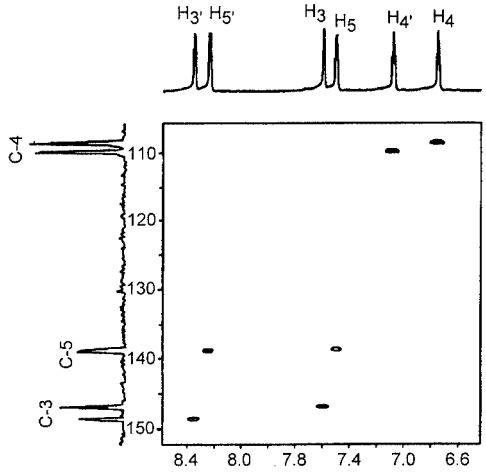


Figure 2. ^1H-^{13}C COSY of **3** in $[D_6]$acetone at 25 °C

The *ortho*- and *meta*-fluorine resonances of complexes **3**−**9** are duplicated, suggesting hindered rotation around the Pd−C_6F_5 bond.

The structure of **3** is shown in Figure 3 and selected bond lengths and angles in Table 2. The Pd(1)−N(2) bond length (*trans* to the C_6F_5 group) is longer (ca. 0.06 Å) than the Pd(1)−N(6) bond (*trans* to the *t*BuNC ligand), reflecting the stronger *trans* influence of the aryl group relative to the carbon donor group of the *t*BuNC ligand. The Pd−CN*t*Bu distances are very similar to those observed in the related complexes $[\{(C_6F_5)LPd(\mu\text{-}X)\}_2]$ (L = *t*BuNC; X = HNPh,[27] N=CPh_2 [26] and PhNNNPh[28]).

Monometallic Complexes 10−12

The reaction of $[\{(C_6F_5)(L)Pd(\mu\text{-}X)\}_2]$ (X = Cl, L = CN*t*Bu) with $AgClO_4$ (1:2 molar ratio) in acetone, followed by the addition of $K[B(pz)_4]$ (1:2 molar ratio) gives the monometallic complex **10** (Scheme 4). The IR spectrum shows an absorption assigned to ν(CN) of the *t*BuNC group[26−28] at ca. 2230 cm^{-1}. The ^{19}F NMR spectrum at room temperature shows a unique set of sharp resonances, indicating the presence of only one type of C_6F_5 group.

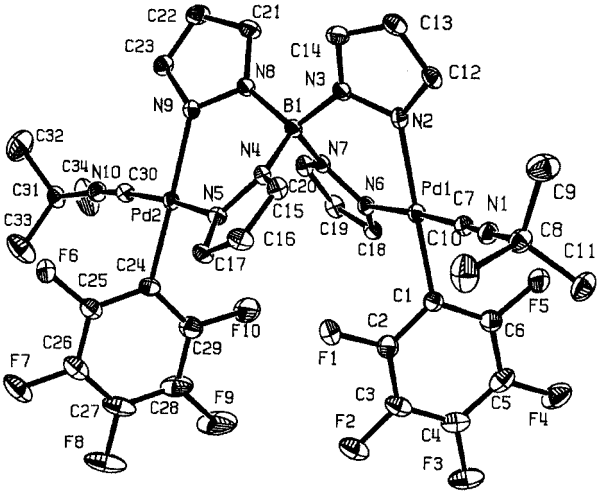

Figure 3. Structure of the cation of **3** showing the atom numbering scheme; hydrogen atoms have been omitted for clarity

Table 2. Selected bond lengths [Å] and angles [°] for complex **3**

Bond lengths		Bond angles	
Pd(1)−C(7)	1.946(4)	C(7)−Pd(1)−C(1)	87.59(16)
Pd(1)−C(1)	2.000(4)	C(7)−Pd(1)−N(6)	175.25(15)
Pd(1)−N(6)	2.026(3)	C(1)−Pd(1)−N(6)	90.71(14)
Pd(1)−N(2)	2.088(3)	C(7)−Pd(1)−N(2)	92.26(15)

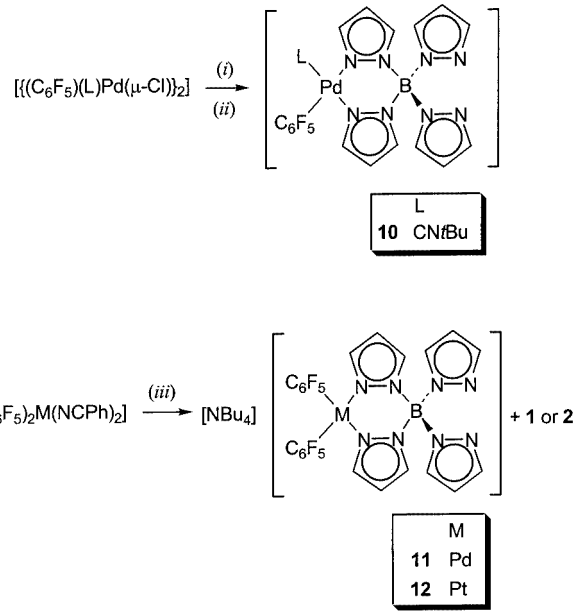
		C(24)−Pd(2)−N(9)	178.54(15)
		N(5)−Pd(2)−N(9)	89.87(12)



Scheme 4. (*i*) 2 $AgClO_4$; (*ii*) 2 K[B(pz)$_4$]; (*iii*) 2 K[B(pz)$_4$]/2 *n*Bu$_4$Cl

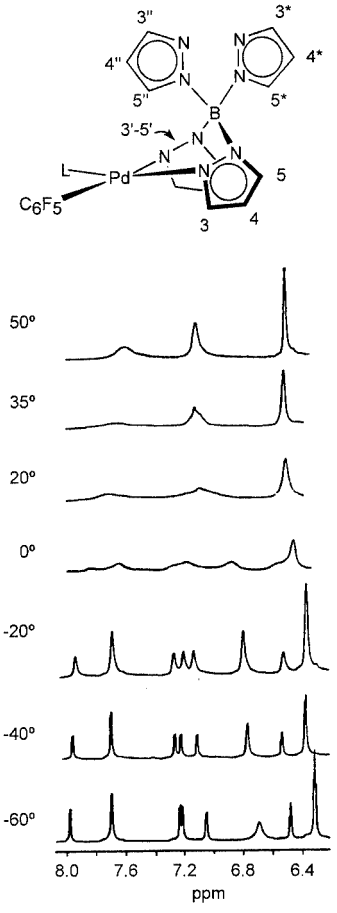


Figure 4. Temperature-dependent ^{1}H NMR (300 MHz) of pyrazolyl protons in **10** in [D$_6$]acetone

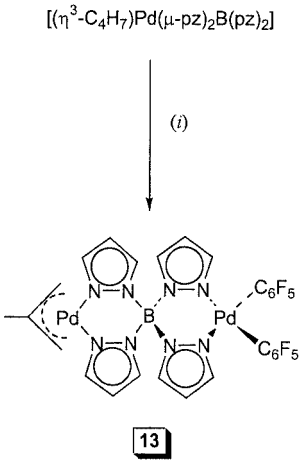
However, in the ^{1}H NMR spectrum broad bands are observed due to exchanges between the four pyrazolyl groups. Fluxional motions of (η^2-BPz$_4$)palladium(II) complexes have been considered to involve the additional coordination of one uncoordinated pyrazolyl group near the palladium atom [via a tridentate tetrakis(pyrazolyl)borate−palladium structure], dissociation of one pyrazolyl group coordinated previously, and inversion of the boat-like six-membered Pd−(N−N)$_2$−B ring.[22] Variable-temperature ^{1}H NMR spectra of **10** have been recorded (Figure 4). At −60 °C the ^{1}H NMR spectrum exhibits eight different resonances in the pyrazolyl region with relative intensities of 1:2:1:1:1:2:1:3 (the two coordinated and the two uncoordinated pyrazolyl groups should all be nonequivalent, although casual overlaps of some signals are observed). The ^{1}H signals (nearly apparent triplets) at δ = 6.7−6.3 are readily assigned to 4-H protons of the BPz$_4$ ligand. A singlet resonance is observed for the *t*BuNC group at δ = 1.6 ppm.

The reaction of *cis*-[(C$_6$F$_5$)$_2$M(NCPh)$_2$] (M = Pd or Pt) in CH_2Cl_2 with K[B(pz)$_4$] (pz = pyrazolyl) in a 1:1 molar ratio was attempted, in order to obtain the corresponding mononuclear complexes. However, mixtures containing both the dimetallic and the monometallic complexes **1** and **11** (for palladium), or **2** and **12** (for platinum), respectively,

were obtained (Scheme 4). All attempts to separate them were unsuccessful.

Asymmetric Dinuclear Complex 13

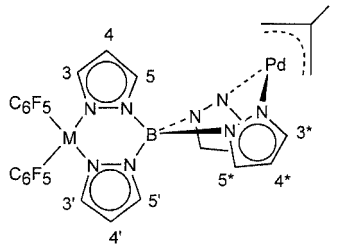
The reaction of *cis*-$[(C_6F_5)_2Pd(NCPh)_2]$ with the monomeric palladium tetrakis(pyrazol-1-yl)borate complex $[(\eta^3\text{-}CH_2CCH_3CH_2)Pd(\mu\text{-}pz)_2B(pz)_2]$[31] in a 1:1 molar ratio yields the asymmetric dinuclear complex **13** (Scheme 5).



Scheme 5

The new complex has been characterized on the basis of partial elemental analysis and spectroscopic data. A split absorption located at ca. 800 cm^{-1} in the IR spectrum is observed, which indicates that the *cis* arrangement[18,19] of the $Pd(C_6F_5)_2$ fragment is kept in the reaction. The ^1H NMR spectrum at room temperature shows the presence of three types of pz groups in a 2:1:1 ratio (Figure 5). No changes are observed in the temperature range −70 to + 50 °C. The ^{19}F NMR spectrum exhibits two resonances for the *para*-fluorine atoms, which is indicative of the existence of two different C_6F_5 rings. ^1H NMR resonances are assigned on the basis of a strong NOE between H_{syn} and 3*-H,[10] and selective decoupling experiments, and assuming that the 5′-H proton will be in a magnetic environment that is most similar to that of the 5*-H proton (Figure 5).[31,32] These findings are reconcilable with a structure where one ring is undergoing rapid inversion even at low temperatures, and the other is puckered in a boat conformation (Figure 5). Presumably, the puckered system is the $B(\mu\text{-}pz)_2Pd(\eta^3\text{-}CH_2CRCH_2)$ ring. The same pattern has been found previously in the *B*,*B*-bis(1-pyrazolyl)pyrazabole complexes $[(Et_2B(\mu\text{-}pz)_2B(\mu\text{-}pz)_2Pd(\eta^3\text{-}CH_2CRCH_2)]^+$ (R = Me or Ph).[31]

The structure of **13** has been established by X-ray diffraction and is shown in Figure 6 and selected bond lengths and angles in Table 3. Each of the palladium atoms essentially has a square-planar geometry. The Pd−N distances are very similar for Pd(1) and Pd(2), these values are similar to the distances found in polypyrazolylborate complexes of Pd^{II}.[13] The bridging tetrakis(pyrazolyl)borate ligand forms chelate angles of 88.9(2) and 88.7(2) Å at Pd(1) and Pd(2),



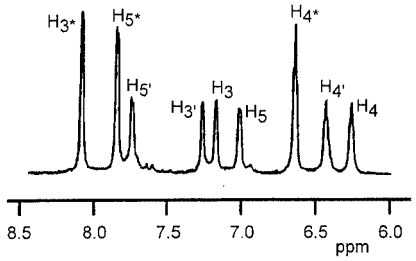


Figure 5. ^1H NMR (300 MHz) of pyrazolyl protons in **13** in $[D_6]$acetone

respectively. The $Pd(2)N_4B$ ring adopts a shallow boat conformation, the palladium and boron atoms are on the same side of the plane defined by the nitrogen atoms; in $Pd(1)N_4B$ the boat is distorted giving a twist-like conformation.

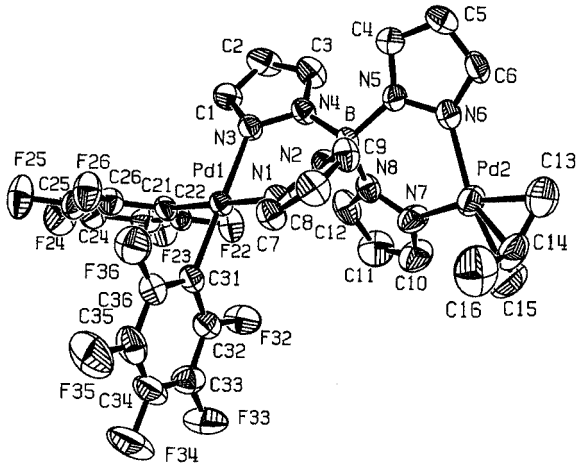

Figure 6. Structure of complex **13** showing the atom numbering scheme; hydrogen atoms have been omitted for clarity

The geometry of the allyl group is similar to that usually found in (η^3-allyl)palladium(II) complexes.[24,32] Thus, the allyl plane is not normal to the "$Pd(1)N_2$" plane, giving a dihedral angle of 114.5(5)°. The methyl group on the central carbon atom is 0.29(3) Å out of the allyl plane, on the same side as the Pd atom. The central carbon atom lies 0.55(1) Å to one side of the plane. The three carbon atoms bonded to the palladium atom are approximately equidistant from Pd [2.084(8), 2.121(7) and 2.127 (7) Å], and the carbon−carbon bond lengths of the η^3-allyl group are al-

Table 3. Selected bond lengths [Å] and angles [°] for complex **13**

		C(13)−Pd(2)−C(14)	38.5(3)

most equal [1.397(12), 1.401(12) Å]. The Pd−C(1) bond lengths [2.013(6) and 2.012(6) Å] are similar to the values observed in other (pentafluorophenyl)palladium complexes.[23,24]

Experimental Section

General Methods: Calcd. C, H, N analyses were performed with a Carlo Erba model EA 1108 microanalyzer. Decomposition temperatures were determined with a Mettler TG-50 thermobalance at a heating rate of 5 °C min^{-1}. Conductance measurements were performed in an acetone solution ($c \approx 5 \times 10^{-4}$ mol L^{-1}) with a Crison 525 conductimeter. The NMR spectra were recorded with a Bruker AC 200E (^1H) or Varian Unity 300 (^1H, ^{19}F) spectrometer, using $SiMe_4$ or $CFCl_3$ as standards, respectively. NOE difference spectra were recorded with the following acquisition parameters: spectral width 4000 Hz, acquisition time 2.5 s, pulse width 5 μs (45°), relaxation delay 10 s, irradiation power 35−251 L, number of scans 100. Infrared spectra were recorded with a Perkin−Elmer 16F PC FT-IR spectrophotometer using Nujol mulls between polyethylene sheets. The compounds $[(C_6F_5)_2M(NCPh)_2]$ (M = Pd,[29] Pt[34]) and $[\{(C_6F_5)(L)Pd(\mu\text{-}Cl)\}_2]$ (L = PPh_3, tht, CN*t*Bu),[35,36] $K[B(pz)_4]$[37] were prepared as described elsewhere.

Safety Note: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of material should be prepared, and these should be handled with great caution.

$[Bu_4N][\{(C_6F_5)_2M\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]$ [M = Pd (1) or Pt (2)]: $K[B(pz)_4]$ (19.6 mg, 0.06 mmol), followed by $[Bu_4N]Cl$ (16.7 mg, 0.06 mmol) was added to a solution of $[(C_6F_5)_2M(NCPh)_2]$ (M = Pd or Pt) (0.12 mmol) in dimethylformamide (DMF) (5 mL) . The resulting solution was stirred for 30 min at room temperature. Addition of water caused the precipitation of a white solid, which was collected by filtration and air-dried. It was recrystallized from dichloromethane/hexane.

1: Yield 73%. $C_{52}H_{48}BF_{20}N_9Pd_2$ (1402): calcd. C 44.5, H 3.4, N 9.0; found C 44.1, H 3.3, N 8.9. M.p. 300 °C (dec.). Λ_M = 84 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 794, 784 cm^{-1} (Pd−C_6F_5). ^1H NMR ([D$_6$]acetone, TMS): δ = 7.75 (d, J_{45} = 2.5 Hz, 4 H, 5-H,), 7.23 (d, J_{34} = 1.4 Hz, 4 H, 3-H), 6.42 (pseudo-t, 4 H, 4-H) ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone, TMS): δ = 145.7 (C-3), 138.2 (C-5), 107.6 (C-4) ppm. ^{19}F NMR ([D$_6$]acetone, $CFCl_3$): δ = −114.7 (m, 8 F_o), −163.7 (t, 4 F_p, J_{mp} = 19.7 Hz), −165.4 (m, 8 F_m) ppm.

2: Yield 77%. $C_{52}H_{48}BF_{20}N_9Pt_2$ (1580): calcd. C 39.5, H 3.1, N 8.0; found C 39.1, H 3.2, N 7.7. M.p. 288 °C (dec.). Λ_M = 86 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 806, 798 cm^{-1} (Pt−C_6F_5). ^1H NMR ([D$_6$]acetone, TMS): δ = 7.73 (d, J_{45} = 2.5 Hz, 4 H, 5-H), 7.33 (d, J_{34} = 1.7 Hz, J_{HPt} = 10 Hz, 4 H, 3-H), 6.29 (pseudo-t, 4 H, 4-H) ppm. ^{19}F NMR ([D$_6$]acetone, $CFCl_3$): δ = −118.4 (d, J_{om} = 25.9 Hz, J_{PtF_o} 456 Hz, 8 F_o), −163.7 (t, J_{mp} = 19.7 Hz, 4 F_p), −165.3 (m, 8 F_m) ppm.

$[\{(C_6F_5)(L)Pd\}_2(\mu\text{-}pz)_2B(\mu\text{-}pz)_2]ClO_4$ [L = CN*t*Bu (3), NCPh (4), PPh_3 (5), PEt_3 (6), PMe_2Ph (7), $AsPh_3$(8): $AgClO_4$ (53.0 mg, 0.26 mmol) was added to a solution of $[\{(C_6F_5)(L)Pd(\mu\text{-}X)\}_2]$ (X = Cl, L = CN*t*Bu, PhCN, PPh_3, $AsPh_3$; X = Br, L = PEt_3, PMe_2Ph) (0.13 mmol) in acetone (15 mL). The solution was stirred at room temperature for 30 min, while it was protected from light. The white AgCl was then filtered off. $K[B(pz)_4]$ (40.0 mg, 0.13 mmol) was then added to the resulting solution. The solution was stirred for 30 min at room temperature and concentrated under vacuum. The addition of ether/hexane caused the precipitation of a white solid, which was collected by filtration and air-dried. The complexes were recrystallized from dichloromethane/hexane.

3: Yield 80%. $C_{34}H_{30}BClF_{10}N_{10}O_4Pd_2$ (1092): calcd. C 37.4, H 2.8, N 12.8; found C 37.1, H 2.6, N 12.8. M.p. 157 °C (dec.). Λ_M = 117 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 2234 cm^{-1} [ν(CN)], 798 cm^{-1} (Pd−C_6F_5 str). ^1H NMR ([D$_6$]acetone, TMS): δ = 8.34 (d, $J_{3'4'}$ = 1.6 Hz, 2 H, 3′-H), 8.23 (d, $J_{4'5'}$ = 2.6 Hz, 2 H, 5′-H), 7.39 (d, J_{34} = 1.6 Hz, 2 H, 3-H), 7.30 (d, J_{45} = 2.6 Hz, 2 H, 5-H), 6.87 (pseudo-t, 2 H, 4′-H), 6.55 (pseudo-t, 2 H, 4-H), 1.56 (s, 18 H, *t*BuNC) ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone, TMS): δ = 148.5 (C-3′), 146.7 (C-3), 138.8 (C-5′), 138.6 (C-5), 109.7 (C-4′), 108.5 (C-4), 30.1 (Me_3C) ppm. ^{19}F NMR ([D$_6$]acetone, $CFCl_3$): δ = −119.1 (m, 4 F_o), −159.6 (t, 2 F_p, J_{mp} = 19.7 Hz), −163.6 (m, 4 F_m) ppm.

4: Yield 81%. $C_{38}H_{22}N_{10}BClF_{10}O_4Pd_2$ (1132): calcd. C 40.3, H 2.0, N 12.4; found C 39.9, H 1.8, N 12.4. M.p. 122 °C (dec.). Λ_M = 125 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 2280 cm^{-1} [ν(CN)], 798 cm^{-1} (Pd−C_6F_5 str). ^1H NMR ($CDCl_3$, TMS): δ = 8.07 (unresolved d, 4 H, 3′-H + 5′-H), 7.72 (m, 4 H_m + 2 H_p), 7.57 (m, 4 H_o), 7.10 (m, 4 H, 3-H + 5-H), 6.87 (pseudo-t, 2 H, 4′′-H), 6.43 (pseudo-t, 2 H, 4-H) ppm. ^{19}F NMR ($CDCl_3$, $CFCl_3$): δ = −121.1 (m, 2 F_o, J_{om} = 25.9 Hz), −122.5 (m, 2 F_o, J_{om} = 29.0 Hz), −157.4 (t, 2 F_p, J_{mp} = 19.7 Hz), −162.0 (m, 4 F_m) ppm.

5. Yield 84%. $C_{60}H_{42}BClF_{10}O_4N_8P_2Pd_2$ (1450): calcd. C 49.7, H 2.9, N 7.7; found C 49.4, H 2.8, N 7.6. M.p. 278 °C (dec.). Λ_M = 106 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 796 (Pd−C_6F_5 str). ^1H NMR ([D$_6$]acetone, TMS): δ = 7.83 (unresolved d, 2 H, 3′-H), 7.5 (m, 34 H, PPh_3 + 2 5′-H + 2 × 3-H), 7.09 (unresolved d, 2 H, 5-H), 6.67 (unresolved pseudo-t, 2 H, 4′-H), 6.48 (unresolved pseudo-t, 2 H, 4-H) ppm. ^{19}F NMR ([D$_6$]acetone, $CFCl_3$): δ = −117.9 (m, 4 F_o), −160.1 (t, 2 F_p, J_{mp} = 19.7 Hz), −161.2 (m, 2 F_m), −161.9 (m, 2 F_m) ppm. ^{31}P NMR ([D$_6$]acetone, H_3PO_4): δ = 30.9 (s) ppm.

6: Yield 75%. $C_{36}H_{42}N_8BClF_{10}O_4P_2Pd_2$ (1162): calcd. C 37.2, H 3.6, N 9.6; found C 36.9, H 3.8, N 9.8. M.p. 271 °C (dec.). Λ_M = 110 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 800 cm^{-1} (Pd−C_6F_5 str). ^1H NMR ([D$_6$]acetone, TMS): δ = 8.22 (unresolved d, 2 H, 3′-H), 8.03 (unresolved m, 2 H, 3-H), 7.32 (unresolved d, 2 H, 5′-H), 7.19 (unresolved d, 2 H, 5-H), 6.76 (unresolved pseudo-t, 2 H, 4′-H), 6.57 (unresolved m, 2 H, 4-H), 1.8 (m, 12 H, CH_2P), 1.1 (m, 18 H,

CH_3CH$_2$P) ppm. ^{19}F NMR ([D$_6$]acetone, CFCl$_3$): δ = −117.4 (m, 4 F$_o$), −159.3 (t, J_{mp} = 19.7 Hz, 2 F$_p$), −161.7 (m, 2 F$_m$), −162.3 (m, 2 F$_m$) ppm. ^{31}P NMR ([D$_6$]acetone, H$_3$PO$_4$): δ = 29.7 (s) ppm.

7: Yield 84%. $C_{40}H_{34}BClF_{10}N_8O_4P_2Pd_2$ (1202): calcd. C 40.0, H 2.9, N 9.3; found C 39.6, H 3.1, N 9.1. M.p. 244 °C (dec.). Λ_M = 115 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 792 cm^{-1} (Pd−C$_6$F$_5$ str). ^{1}H NMR ([D$_6$]acetone, TMS): δ = 7.95 (unresolved m, 2 H, 3-H), 7.83−7.73 (m, 4 H, Ph), 7.65 (unresolved d, 2 H, 5′-H), 7.60−7.54 (m, 8 H, Ph + 2 × 3′-H), 7.36 (unresolved d, 2 H, 5-H), 6.71 (unresolved pseudo-t, 2 H, × 4′-H), 6.61 (unresolved m, 2 H, 4-H), 1.64 (d, J_{HP} = 19.5 Hz, 6 H, Me), 1.57 (d, J_{HP} = 19.6 Hz, 6 H, Me) ppm. ^{19}F NMR ([D$_6$]acetone, CFCl$_3$): δ = −117.9 (m, 2 F$_o$), −118.3 (m, 2 F$_o$), −159.6 (t, 1 F$_p$, J_{mp} = 20.0 Hz), −161.9 (m, 2 F$_m$), −162.5 (m, 2 F$_m$) ppm. ^{31}P NMR ([D$_6$]acetone, H$_3$PO$_4$): δ = 6.49 (s) ppm.

8: Yield 77%. $C_{60}H_{42}As_2BClF_{10}N_8O_4Pd_2$ (1538): calcd. C 46.7, H 2.7, N 7.3; found C 49.8, H 3.6, N 6.4. M.p. 213 °C (dec.). Λ_M = 120 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 796 cm^{-1} (Pd−C$_6$F$_5$ str). ^{1}H NMR ([D$_6$]acetone, TMS): δ = 7.94 (d, $J_{4'5'}$ = 2.4 Hz, 2 H, 5′-H), 7.62 (unresolved d, 2 H, 3′-H), 7.5−7.3 (m, 32 H, AsPh$_3$ and 5-H), 7.27 (unresolved d, 2 H, 3-H), 6.69 (pseudo-t, 2 H, 4′-H), 6.55 (pseudo-t, 2 H, 4-H) ppm. ^{19}F NMR ([D$_6$]acetone, CFCl$_3$): δ = −117.0 (m, 4 F$_o$), −159.2 (t, J_{mp} = 19.7 Hz, 2 F$_p$), −160.7 (m, 2 F$_m$), −161.2 (m, 2 F$_m$).

[Bu$_4$N][{(C$_6$F$_5$)(Cl)Pd}$_2$(μ-pz)$_2$B(μ-pz)$_2$] (9): K[B(pz)$_4$] (32.0 mg, 0.10 mmol), followed by [Bu$_4$N]Cl (29.6 mg, 0.10 mmol) was added to a solution of [{(C$_6$F$_5$)LPd(μ-Cl)}$_2$] [L = tetrahydrothiophene (tht)] (80.0 mg, 0.10 mmol) in acetone (15 mL).The resulting solution was stirred for 30 min at room temperature and concentrated under vacuum. The addition of ethanol/water caused the precipitation of a yellow solid, which was collected by filtration and air-dried. Yield 84%. $C_{40}H_{48}BCl_2F_{10}N_9Pd_2$ (1139): calcd. C 42.2, H 4.3, N 11.1; found C 41.8, H 4.0, N 11.2. M.p. 246 °C (dec.). Λ_M = 90 S cm^2 mol^{-1}. IR (nujol): $\tilde{\nu}$ = 796 cm^{-1} (Pd−C$_6$F$_5$ str), 326 cm^{-1} [ν(Pd−Cl)]. ^{1}H NMR ([D$_6$]acetone, TMS): δ = 8.43 (d, $J_{3'4'}$ = 1.6 Hz, 2 H, 3′-H), 7.95 (d, $J_{4'5'}$ = 2.6 Hz, 2 H, 5′-H), 7.35 (d, J_{34} = 1.6 Hz, 2 H, 3-H), 7.15 (d, 2 H, 5-H, J_{45} = 2.6 Hz), 6.60 (pseudo-t, 2 H, 4′-H), 6.37 (pseudo-t, 2 H, 4-H) ppm. ^{19}F NMR ([D$_6$]acetone, CFCl$_3$): δ = −118.7 (m, 4 F$_o$), −163.9 (t, 2 F$_p$, J_{mp} 19.7 Hz), −166.1 (m, 4 F$_m$) ppm.

[(C$_6$F$_5$)(CN*t*Bu)Pd(μ-pz)$_2$B(pz)$_2$] (10): AgClO$_4$ (46.0 mg, 0.20 mmol) was added to a solution of [{(C$_6$F$_5$)(*t*BuNC)Pd(μ-Cl)}$_2$] (80.0 mg, 0.10 mmol) in acetone (15 mL). The solution was stirred at room temperature for 30 min, while it was protected from light. The white AgCl was then filtered off. K[B(pz)$_4$] (64.8 mg, 0.20 mmol) was then added to the resulting solution. The solution was stirred for 30 min at room temperature and concentrated under vacuum. The addition of ether/hexane caused the precipitation of a white solid, which was collected by filtration and air-dried. The complex was recrystallized from dichloromethane/hexane. Yield 90%. $C_{23}H_{21}BF_5N_9Pd$ (636): calcd. C 43.5, H 3.3, N 19.8; found C 43.8, H 3.5, N 19.8. M.p. 182 °C (dec.). IR (nujol): $\tilde{\nu}$ = 2230 cm^{-1} [ν(CN)], 796 (Pd−C$_6$F$_5$ str). ^{1}H NMR ([D$_6$]acetone, TMS, 20 °C): δ = 7.7 (br, 3 H), 7.0 (br, 5 H), 6.3 (br, 4 H). ^{1}H NMR ([D$_6$]acetone, TMS, −60 °C): δ = 7.98 (d, J = 1.8 Hz, 1 H), 7.69 (unresolved d, 2 H), 7.23 (d, J = 2.4 Hz, 1 H), 7.21 (d, J = 2.1 Hz, 1 H), 7.05 (d, J = 2.4 Hz, 1 H), 6.69 (br, 2 H), 6.48 (pseudo-t, 1 H), 6.31 (pseudo-t, 3 H), 1.6 (s, 18 H, *t*BuNC) ppm. ^{19}F NMR ([D$_6$]acetone, CFCl$_3$, 20 °C): δ = −117.2 (m, 2 F$_o$), −159.7 (t, 1 F$_p$, J_{mp} 20.3 Hz), −163.5 (m, 4 F$_m$) ppm.

[(C$_6$F$_5$)$_2$Pd(μ-pz)$_2$B(μ-pz)$_2$Pd(η^3-C$_4$H$_7$)] (13): [(C$_6$F$_5$)$_2$Pd(NCPh)$_2$] (88.0 mg, 0.14 mmol) was added to a solution of [(η^3-CH$_2$CCH$_3$CH$_2$)Pd(μ-pz)$_2$B(pz)$_2$] (60.0 mg, 0.14 mmol) in acetone (10 mL). The resulting solution was stirred for 30 min at room temperature and concentrated under vacuum. The addition of ethanol/water caused the precipitation of a white solid, which was collected by filtration and air-dried. Yield 88%. $C_{28}H_{19}F_{10}N_8Pd_2$ (870): calcd. C 38.2, H 2.2, N 12.7; found C 38.2, H 2.3, N 12.5. M.p. 185 °C (dec.). IR (nujol): $\tilde{\nu}$ = 782, 808 (Pd−C$_6$F$_5$ str) cm^{-1}. ^{1}H NMR ([D$_6$]acetone, TMS): δ = 8.06 (unresolved d, 2 H, 3*-H), 7.82 (d, J_{4*5*} = 2.4 Hz, 2 H, 5*-H), 7.72 (d, $J_{4'5'}$ = 2.2 Hz, 1 H, 5′-H), 7.26 (unresolved d, 1 H, 3-H), 7.22 (unresolved d, 1 H, 3-

[a] $R1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $wR2 = [\Sigma[w(F_o^2-F_c^2)^2]/\Sigma\, w(F_o2)^2]^{0.5}$. [b] $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = (2F_c^2 + F_o^2)/3$ and *a* and *b* are constants set by the program.

H), 7.02 (d, J_{45} = 2.4 Hz, 1 H, 5-H), 6.65 (unresolved pseudo-t, 2 H, 4*-H), 6.45 (unresolved pseudo-t, 1 H, 4′-H), 6.28 (unresolved pseudo-t, 1 H, 4-H), 4.04 (s, 2 H, H_{syn}), 3.23 (s, 2 H, H_{anti}), 2.12 (s, 3 H, CH_3) ppm. ^{19}F NMR ([D$_6$]acetone, $CFCl_3$): δ = −114.0 (m, 4 F_o), −162.8 (m, 2 F_p), −164.7 (m, 4 F_m) ppm.

Determination of the X-ray Crystal Structures of 1, 3 and 13: Crystals of **1**, **3**·CH_2Cl_2 and **13**·CH_2Cl_2 suitable for X-ray diffraction studies were grown from dichloromethane/toluene/hexane solution, mounted on glass fibers, and transferred to the diffractometer (Siemens P4) as summarized in Table 4. Cell constants were refined from 82 (**1**), 57 (**3**) and 44 (**13**) reflections in the 2θ range of 9.5−25°. The structures were solved by direct methods (**1**, **13**) and by the Patterson method (**3**) using the SHELXS-97 program,[38] and refined anisotropically on F^2 (program SHELXL-97[38]). Hydrogen atoms were included using a riding model. CCDC-182373 (**1**), -182374 (**3**) and -182372 (**13**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK 9Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

This work was supported by the Dirección General de Investigación del Ministerio de Ciencia y Tecnología (Project No. BQU2001-0979-C02-01), Spain, and the Fundación Séneca de la Comunidad Autónoma de la Región de Murcia (Project No. PI-72-00773-FS-01 and a grant to V. R.). F. F. thanks the University of Murcia for a research grant. We thank Dr. M. D. Santana, Dr. G. García and Mr. A. Lozano for helpful discussions.

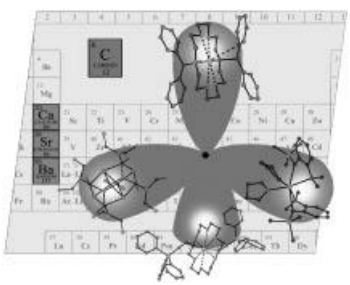
COVER PICTURE

The cover picture shows the familiar depiction of an sp^3-hybrid orbital. Each lobe highlights an example of one of the emerging classes of heavy alkaline earth organometallic compounds, specifically those in which the central metal (calcium, strontium and barium) displays direct metal–carbon bonds. Clockwise around the orbital, these classes are: di- and triphenylmethanides, dibenzyl species, acetylides, and "ate" complexes. Atoms in green depict the alkaline earth metal centers, carbon atoms are black, silicon atoms pink, oxygen atoms red and nitrogen atoms blue. Details are discussed in the Microreview by J. S. Alexander and K. Ruhlandt-Senge on pp. 2761 ff. The cover image was generated by Dr. Jesse Taylor (Syracuse University).



MICROREVIEW

Contents

Not Just Heavy "Grignards": Recent Advances in the Organometallic Chemistry of the Alkaline Earth Metals Calcium, Strontium and Barium

Jacob S. Alexander[a] and Karin Ruhlandt-Senge*[a]

Keywords: Calcium / Strontium / Barium / σ-bound organometallics / Synthesis / Structural characterization

Since their initial development in the early 1900's, Grignard reagents have proven to be immensely useful and are among the most common organometallic reagents. The nature of the reagents in solution is complex and depends on substituents, solvent, concentration and temperature. Despite continuing questions about their solid state and solution composition and conformation, organomagnesium reagents find new applications continually. In contrast, little information about the heavier alkaline earth organometallic compounds RMX and R_2M (R = alkyl, aryl; M = Ca, Sr, Ba, X = halide) exists. High reactivity due to the predominantly ionic character of the metal-ligand bond and increased lability complicates synthetic access.

Recent interest in the organometallic chemistry of the alkaline earth metals calcium, strontium and barium has been sparked by the realization that heavy alkaline earth metal organometallics play unique roles in synthetic applications, such as polymerization initiators and as reagents to modify polymers. As a result, the organometallic chemistry of calcium, strontium and barium has received significant attention over the last few years. This article summarizes recent results in this emerging area of chemistry.

Jacob S. Alexander was born in Nashville, Tennessee in 1975. He obtained his B.S. in Chemistry from Tennessee Technological University in 1997. He received his M.S. in inorganic chemistry in 2000 and is currently pursuing his Ph.D. at Syracuse University where he studies organometallic main group chemistry and crystallography with Karin Ruhlandt-Senge. His research interests include a wide range of issues concerning alkali and alkaline earth metal organometallics, including structural chemistry and applications in organic synthesis.

Karin Ruhlandt-Senge studied chemistry at the Gutenberg University in Mainz (Germany) and the Philipps University in Marburg, Germany. She received her doctorate in 1991 working with Ulrich Müller (Marburg) on transition metal chemistry and crystallography, and with Philip P. Power and Håkon Hope at the University of California, Davis (U.S.A.) where she was concerned with main group III chemistry and crystallography. After her return to Davis for postdoctoral work in P.P. Power's group (1992−1993), she started her independent career in fall 1993 at Syracuse University (U.S.A.). Her current research interests focus on various aspects of alkali and alkaline earth metal chemistry.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

1. Introduction

The organometallic chemistry of the heavy alkaline earth metals dates back to the early 1900's, with the intent to synthesize highly reactive "Grignard analogs" for synthetic applications.[1] The assumption that the organometallic chemistry of these metals roughly resembles that of the lighter congener, magnesium, prompted attempts to synthesize candidate molecules bearing small organic ligands. However, the formation of either unstable and/or sparsely soluble compounds with little opportunity to be utilized for synthesis discouraged further efforts. These compounds continued to be viewed as obscure, and rather recently a popular organometallic textbook remarked: "Since the heavier alkaline earth organometallics do not offer any advantages over Grignard reagents, their chemistry has not been studied extensively [..]."[2] In consideration of the recent prominence organometallic calcium, strontium, and barium derivatives have received, this view is now changing. Still, most applications rely on the preparation of reagents in situ, and little information exists with regard to the reactive species.

Organometallic derivatives of the heavy alkaline earth metals have been most intensely studied for cyclopentadienyl systems, dating back to 1956 with the preparation of $(C_5H_5)_2Ca$.[3] Since then, many related derivatives have been prepared due to the unique capability of this system to stabilize the alkaline earth metal centers both sterically and electronically.[4−6] Similar work has been extended to fluorenyl, indenyl and related π-ligand systems.[7−10]

This progress did not however extend towards σ-bonded ligand systems and, aside from the early studies mentioned above and some activity in the latter part of the last century,[9,11−21] little attention has been devoted to them. High reactivity and low solubility complicated the isolation and detailed characterization of these systems, resulting in reports of the in situ preparation of the candidate molecules, whose identity was predominantly verified by the products from chemical reactions.

Examples of well-characterized σ-bonded organometallic calcium, strontium, and barium derivatives are heavily based on heteroleptic compounds, incorporating cyclopentadienyl (Cp) ligation in addition to a σ-bonded organometallic ligand system, taking advantage of the stabilizing effect provided by the Cp ligand.[4−6,22] Well-characterized organometallic compounds relying purely on σ-bonded ligands remain scarce, the original examples being the now familiar $[Ca\{CH(SiMe_3)_2\}_2(1,4\text{-dioxane})_2]$,[23] available by co-condensation of metal and ligand at 77 K, and $Ca[C(SiMe_3)_3]_2$, prepared by treatment of CaI_2 with two equivalents of $KC(SiMe_3)_3$.[24] Treatment of the latter with diethyl ether results in immediate ether scission and formation of the parent hydrocarbon and $Ca(OEt)_2$, illustrating the problems associated with the organometallic chemistry of these elements: severe limitation of synthetic variables due to high reactivity, low solubility caused by the high ionic character of the metal-ligand bond, high lability, and a prominent tendency towards the formation of oligomeric or polymeric species associated with a dramatic reduction of solubility.

The ability to reproducibly and cleanly prepare organometallic derivatives in good yield and purity and analyze their structure and function is critical for the progress of this emerging area of chemistry. Several recent studies have provided much needed information to improve the performance and utility of existing applications while establishing a new branch of organometallic chemistry with room for considerable growth.

2. Scope of This Microreview

This review examines recent examples of structurally characterized σ-bound and charge-separated organometallic complexes of calcium, strontium and barium with a focus on synthetic access strategies and structural features. Compounds of magnesium and beryllium will not be addressed. Numerous π-bound calcium, strontium and barium derivatives are now known, such as the families of cyclopentadienyl-, fluorenyl- and indenyl-stabilized organometallics; with a few exceptions these lie outside of the chemistry reviewed here. Similarly, allyl or vinyl systems will not be discussed; instead we refer to the several excellent review articles on these subjects.[4−6,25]

3. Synthetic Strategies

Multiple synthetic strategies towards the target compounds have been explored; among the most successful are transamination, direct metallation, alkane/arene elimination and transmetallation.

3.1 Transamination

The ready availability of the alkaline earth metal amides $M[N(SiMe_3)_2]_2$,[26] their solubility in many different solvent systems, and the easy removal of $HN(SiMe_3)_2$ make this an attractive route for the synthesis of alkaline earth metal organometallics [Equation (1)].[27]

$$M[N(SiMe_3)_2]_2 + 2\,HR \longrightarrow MR_2 + 2\,HN(SiMe_3)_2 \quad (1)$$

R = alkyl, aryl M = Ca, Sr, Ba

A limiting factor in this reaction is the pK_a range of hydrocarbon sources: only those with a higher acidity than $HN(SiMe_3)_2$ can be utilized. Highly acidic substrates, however, induce a competing side reaction involving protonation of the liberated secondary amine and formation of the silane [Equation (2)].

$$HN(SiMe_3)_2 + HR \longrightarrow Me_3SiR + 2\,H_2NSiMe_3 \quad (2)$$

R = alkyl, aryl

This side reaction may be suppressed by careful and dilute addition of the acid.[28] An additional complication stems from the basic amide starting material promoting ether cleavage. This may be avoided using low temperature conditions.

3.2 Direct Metallation

The ease of the reaction and ready availability of precursors adds to the attractive nature of this route [Equation (3)].

$$2\,HR + M_{act} \longrightarrow MR_2 + H_2 \quad (3)$$

R = alkyl, aryl, Act.= activated, M = Ca, Sr, Ba

Necessary requirements for this reaction include the presence of highly active and pure alkaline earth metal. Activation methods include the distillation or sublimation of the metals,[29] the reduction of metal iodides with alkali metals,[30] or by dissolving the metals in anhydrous, deoxygenated liquid ammonia.[31] The reactivity of the metals plays a major role: barium will react smoothly, while the less reactive strontium and calcium generally require reflux conditions in liquid ammonia.

Problems associated with the ammonia route focus on difficulties in evolving a viable solvent system. Often, cosolvent systems are necessary along with the ammonia, but the sparse solubility of many organometallic complexes upon removal of NH_3 precludes crystallographic and spectroscopic characterization, and, more importantly, use of the target compound as a soluble precursor. If the system allows, this obstacle may be overcome by using donor systems in addition to the ammonia.

3.3 Arene Elimination

Until recently, this method was not applicable for the synthesis of heavy alkaline earth organometallics due to the unavailability of suitable precursor materials. The widely known and easily available cyclopentadienyl (Cp) complexes as basic substrates are not suitable due to the inherent stability of the Cp^- anion. In addition, the tendency of liberated C_5H_6 to dimerize causes significant difficulties in separation and purification. Fortunately, during the last few years several dibenzyl derivatives of calcium,[32,33] strontium[34] and barium[35] have become available, making arene elimination an attractive route. This method takes advantage of the strong thermodynamic drive towards the formation of toluene (and/or substituted phenylmethanes), resulting in the facile metallation of a variety of acidic hydrocarbons [Equation (4)].[52]

$$M(C_7H_7)_2(THF)_2 + 2HR \longrightarrow MR_2 + 2C_7H_8 \quad (4)$$

R = alkyl, aryl M = Ca, Sr, Ba

This method is particularly attractive as it forms simple hydrocarbons as the reaction products that can be easily removed from the reaction mixture. Again, similar pK_a limitations as discussed above apply (see section 3.1), as well as the lack of flexibility in solvent selection for some of the heavier analogs. Particularly for the heavier metal congeners, the high ionic character of the complexes precludes solvation in all but the most polar solvents, such as THF. This limitation makes the separation of the two solid reaction products difficult due to the lack of differentiation in solubility. In addition, great care must be applied to choose the appropriate reaction conditions as alkaline earth metal arene systems are extremely basic and will readily promote ether scission.

3.4 Transmetallation/Metal Exchange

Several possible variations of these schemes may be considered: the use of organomercury reagents in conjunction with activated alkaline earth metals [Equation (5)], or the reaction of organolithium compounds with alkaline earth metal alkoxides, aryloxides [Equation (6)], or amides [Equation (7)]. The chemistry as successfully employed in Equation (6) and (7) has been applied in the synthesis of dibenzylcalcium, -strontium and -barium derivatives [Equation (8)],[32−35] whereas organomercury chemistry [Equation (5)] has been employed to prepare the related organolanthanides.[36]

$$HgR_2 + M_{act} \longrightarrow MR_2 + Hg \quad (5)$$

$$2LiR + M(OR)_2 \longrightarrow MR_2 + 2LiOR \quad (6)$$

$$M[N(SiMe_3)_2]_2 + 2\,LiR \longrightarrow MR_2 + 2\,LiN(SiMe_3)_2 \quad (7)$$

$$M[N(SiMe_3)_2]_2 + 2\,LiCH_2Ph \longrightarrow M(CH_2Ph)_2 + 2LiN(SiMe_3)_2 \quad (8)$$

R = alkyl, aryl M = Ca, Sr, Ba

Although these reactions often proceed smoothly and with few side products, the toxicity of mercury and its compounds make this route less attractive, and have therefore not been applied extensively towards the alkaline earth metal systems. In the case of the reactions shown in Equation (6) and (7), the separation of the two solid reaction products remains the key challenge. Necessary for successful separation are sufficient differences in the solubility of the products, sometimes achievable by careful choice of ligands or by addition of donors.[37]

4. Historical Examples

Successful structurally authenticated investigations into the area of σ-bonded organometallic compounds of the heavy alkaline earth metals opened in 1991 with the now-familiar isolation and structural characterization of $[Ca\{CH(SiMe_3)_2\}_2(C_4H_8O_2)_2]$ (**1**).[23] This four-coordinate complex arose from a co-condensation of calcium vapor and bis(trimethylsilyl)bromomethane in THF at 77 K, presumably to give $RCaBr(THF)_n$, with subsequent formation of the target compound via a Schlenk-type equilibrium. This calcium compound was a starting point for observing

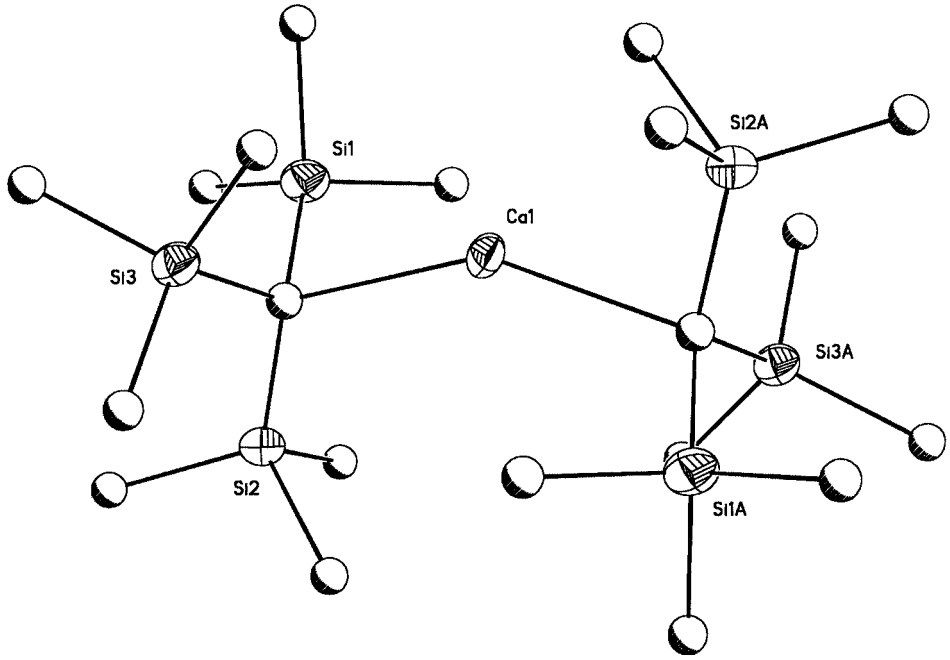

Figure 1. Molecular structure of **2**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

σ-type alkaline earth metal-carbon interactions in Group 2 organometallics.

The first, and to date only, example of an unsolvated, two-coordinate complex of a heavy Grignard analog came with the report of the remarkable calcium bis(tristrimethylsilyl)methanide (**2**; Figure 1).[24] Reaction of the potassium methanide with calcium iodide in benzene over extended periods of time, followed by recrystallization from benzene/heptane, led to the isolation of extremely thin plates suitable for X-ray diffraction. While considerable disorder exists in the structure, the structural information is reliable and agrees well with other σ-bonded alkaline earth organometallics. Interestingly, there is little evidence for strong agostic interactions, although the compound still adopts the bent geometry predicted for compounds of this type.[38]

5. Dibenzyl Derivatives of the Heavy Alkaline Earth Compounds

Early studies on alkaline earth metal benzyl derivatives focussed on the use of organomercury reagents; the reaction products were solely characterized by NMR studies and no definitive structural information exists. Very recently, a facile synthesis of homoleptic dibenzylbarium became available by treatment of barium bis[bis(trimethylsilyl)]amide or barium *tert*-butoxide with two equivalents of the TMEDA (*N*,*N*,*N*′,*N*′-tetramethylethylenediamine) adduct of benzyllithium in diethyl ether.[35] This promising result, coupled with the known activity of dibenzylbarium as a polymerization initiator, led to intense efforts to provide a wider array of derivatives of this type, as summarized in Table 1. Major impediments in this chemistry lie in the relative insolubility of dibenzylbarium in hydrocarbons, in addition to difficulties separating pure compounds for the lighter metals, calcium and strontium, from a mixture of reaction products of varying solubility. These problems were addressed by altering the substitution pattern of the benzyl moiety in an attempt to tune the solubility of the resulting compounds.

As a result, the first benzylcalcium complex (**3**; Figure 2) was reported from the reaction of the potassium salt of an α,α-bis(trimethylsilyl)-substituted toluene derivative with calcium iodide.[32] This compound crystallizes as the bis-THF adduct with a four-coordinate metal center with some additional weak π-contacts to the attendant phenyl rings. Interestingly, beyond these contacts (2.89−2.95 Å) no agostic interactions to the trimethylsilyl moieties are seen, probably as a result of the THF-metal interaction.

A related approach improved the solubility properties with intramolecular stabilization by means of a tethered dimethylamino moiety to give the diastereomeric benzylcalcium complex as its bis-THF adduct (**4**; Figure 3).[33] This benzene soluble derivative exhibits a six-coordinate distorted octahedral metal center with slightly shorter $Ca-C_\alpha$ distances than the α,α-disubstituted benzylide **3** as well as mixed hybridization of the α-carbons, with angles summing to 342(1)° and 346(1)°. Unlike **3**, this bidentate compound shows no additional aryl interactions. In solution, a temperature- and concentration-dependant exchange between diastereomers is observed; the addition of THF assists this exchange.

The first example of a heteroleptic benzylcalcium derivative displays fluorenyl stabilization with a distorted η^5 coordination (**5**).[39] One additional THF completes the coordination sphere of the metal. The metal-C_α distance of 2.50 Å is noticeably shorter than the purely σ-bound species **3**

and **4**, and is rationalized as a result of the π-stabilization afforded by the fluorenyl system.

Currently, the only example of a simple homoleptic dibenzylstrontium complex is the well-defined bis[(2-dimethylamino-α-trimethylsilyl)benzyl]strontium (**6**).[34] Like the calcium congener, this internally stabilized compound crystallizes as the bis-THF adduct. Unlike the calcium compound, however, there are several close contacts to the aryl rings, which may indicate an η^3-interaction. The geometry around the metal is strongly distorted, and takes up a nearly trigonal prismatic arrangement, with a bridging $C_\alpha-Sr-C_\alpha'$ angle of 143.5°, versus 157.5° for the calcium congener. This compound also crystallizes as a set of diastereomers, and shows slow exchange from the heterochiral to the homochiral orientation similar to that of the calcium compound. As in that example, the extra intramolecular stabilization afforded by the NMe_2 ligation and the added bulk of the $SiMe_3$ moiety result in a low coordination number at the metal center and good solubility, although apparently at the expense of the efficacy of the compound as a polymerization initiator. There appears to be a clear connection between the steric bulk and the reactivity of these compounds for polymerization; for detailed discussions on this topic we refer the reader to the original literature.[32−35]

The concept of internal stabilization and modification of the benzyl group was also utilized in the synthesis of two closely related organometallic complexes of calcium.[40] The first uses the stabilization of PPh_2' (Ph′ = *p*-tolyl) on the α-carbon along with internal coordination from a methoxy substituent on the benzyl ring to afford an example of a benzylcalcium complex (**7**; Figure 4). The parent hydrocarbon was lithiated in Et_2O, then transmetallated with sodium *tert*-butoxide followed by salt elimination with CaI_2. This compound assumes a coordination number of six, with the geometry around the metal lying between octahedral and trigonal prismatic. There are several agostic interactions be-

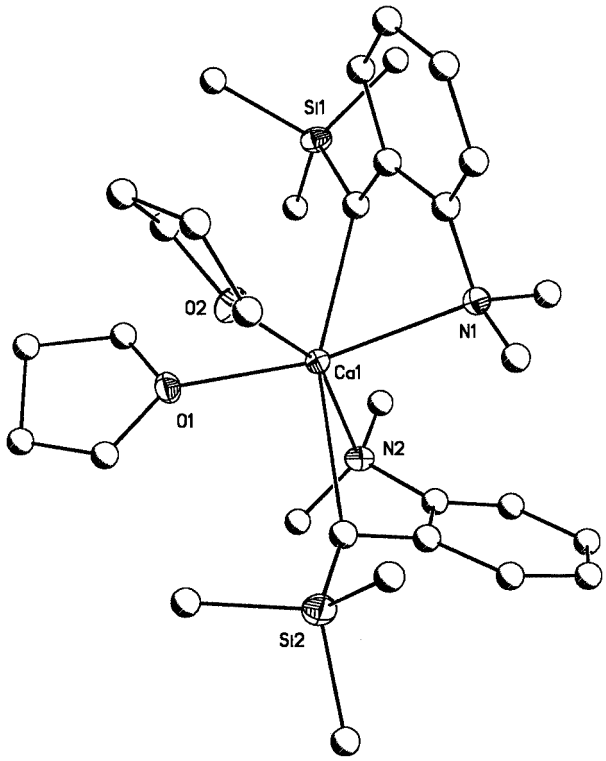

Figure 3. Molecular structure of **4**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

tween H_α and the metal center of 2.41 Å, possibly as a consequence of the calcium being situated out of the plane of the π-bound benzyl moieties. The phosphanyl groups do not coordinate to the calcium, but rather to the sodium counterion.

If the salt elimination reaction is instead carried out in THF, an ether cleavage occurs on the methoxy substituent leading to the formation of a tetrameric benzyl alkoxide derivative (**8**; Figure 5) in very low yield. The mechanism is explained by nucleophilic attack of the iodide ion at the carbon of the calcium-coordinated methoxy group. The resulting compound displays a distorted cuboidal structure with the oxygen atoms at alternate corners. This reaction illustrates one of the most prevalent problems in the organometallic chemistry of the heavy group 2 metals: ether cleavage is a common occurrence, limiting solvent and donor choices.

Another example of the use of phosphorus-bearing substituents is observed in barium phosphonium dibenzylide (**9**; Figure 6).[41] This example of a heavy organoalkaline earth metal compound is accessible through the reduction of the phosphonium ylide bromide with potassium amide followed by addition of 0.5 equivalents of barium amide. The ylidic ligand easily fills the coordination sphere of barium with numerous η^2- and η^3-interactions; the added bulk of the substituents affords a complex which is readily soluble in toluene, benzene and THF. The benzyl planes occupy four different orientations with respect to the metal, and the contact distances vary. For all four ylidic carbons, the angles add up to perfectly planar sp^2-bonding geometries.

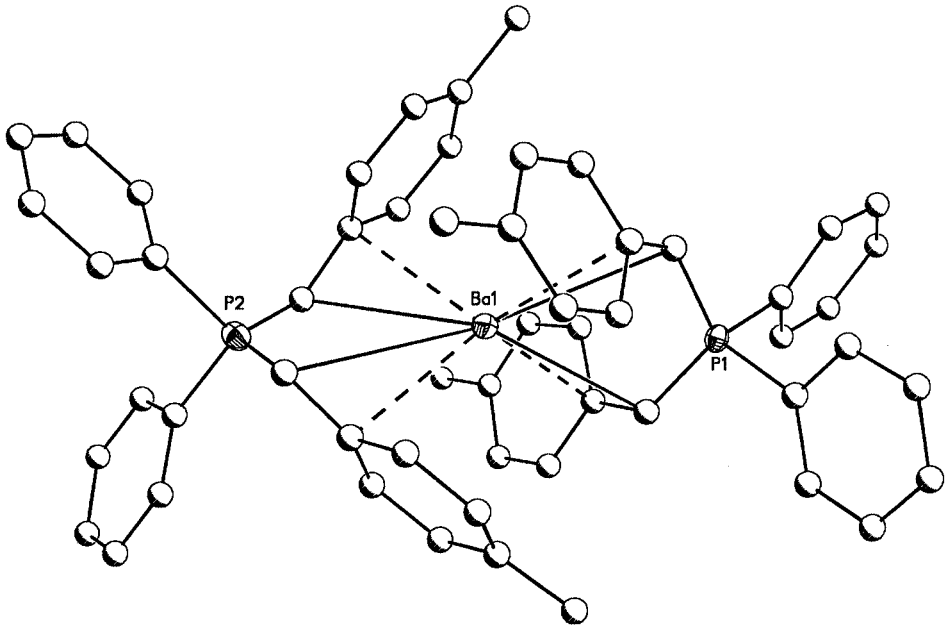

Figure 6. Molecular structure of **9**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

The solubility of the dibenzyl derivatives can be adjusted by a careful choice of substituents, allowing for increased utility of these organometallics in an array of synthetic applications. The internal stabilization appears to play a key role in isolation and characterization.

6. "Ate" Complexes of Calcium, Strontium and Barium

The structural chemistry of "ate" complexes of the alkaline earth metals has been mostly limited to compounds of magnesium and beryllium.[42] There are many examples of anionic transition and main group organometallic compounds with beryllium and magnesium counterions, usually with a coordinating donor, but rarely in these cases do the metals display metal-carbon contacts. Several recent examples of such complexes involving heavy alkaline earth cations displaying metal-carbon bonds have been reported, as summarized in Table 2.

The addition of tris(trimethylsilylmethyl)alane and unsolvated calcium bis[bis(trimethylsilyl)amide] in a 2:1 molar ratio in toluene affords the dimeric calcium bis(trimethylsilyl)amide-tetrakis(trimethylsilylmethyl) aluminate (**10**; Figure 7).[43] The central Ca_2N_2 core of the complex is planar. The complex exhibits calcium-carbon distances of 2.68 and 2.64 Å. The close calcium-aluminum contact (3.25 Å) and the small Ca−C−Al angles (85.5° and 86.3°) might indicate the presence of three-center, two-electron bonding. There are several agostic interactions from the methylene hydrogens, also explaining the short Ca−Al contacts.

Several "ate" complexes have been obtained by the reaction of bis[(trimethylsilyl)methyl]zinc with freshly distilled alkaline earth metals with extrusion of elemental zinc. Utilizing this route, the reaction of freshly distilled strontium metal with bis[(trimethylsilyl)methyl]zinc in THF at room temperature over 24 hours yielded the strontium zincate (**11**; Figure 8).[44] This complex assumes a coordination number of six at the strontium center in a slightly distorted octahedral geometry as a result of the small chelation angle

afforded by the anion. The somewhat longer strontium-carbon contacts, as compared to other organostrontium compounds, are probably the result of the higher coordination number of the strontium as well as the result of a proposed Sr−C−Zn three-center, two-electron bonding mode through the core of the complex.

An analogous reaction between freshly distilled barium metal and a dialkylzinc derivative in THF affords the barium congener (**12**).[44] The larger radius of barium allows for an expanded coordination sphere filled by two additional THF donor molecules. Overall, the barium center possesses a coordination number of eight in a rather irregular geometry. As a result, the barium-carbon contacts are considerably longer than those of the strontium congener.

Repeating the reaction in toluene affords the bis-toluene adduct (**13**) of the zincate, with the toluene molecules π-bound to the barium metal center.[44] If each toluene is counted as filling one coordination site, then the coordination number of the barium is six, allowing a slightly distorted octahedral metal environment. This low coordination state, coupled with the steric shielding provided by the closely coordinated toluene donors also allows for shorter metal-carbon contacts than in the THF adduct (3.05 vs. 3.23 Å).

An attempt to obtain donor-free derivatives by using *n*-heptane as the solvent did not lead to a crystalline product. However, dropwise addition of THF to the reaction mixture led to a barium zincate/oxide (**14**; Figure 9).[44] This barium complex features a dimeric barium oxide with numerous contacts to THF donors and silyl substituents. An apparent rearrangement and elimination leads to the concurrent formation of a zinc silanide in situ, indicating the possibility of water or oxygen contamination causing the unexpected side reactions. The low coordinate zinc centers exhibit very short contacts to the oxygen atoms, while the barium-carbon distances are extremely long due to the lack of anionic charge located in these carbon centers.

A complex reaction of barium bis[tris(trimethylsilylmethyl)zincate] with excess barium, with extrusion of zinc metal, leads to the formation of a proposed alkylbarium moiety in situ. This highly reactive substrate reacts immediately with subsequently added metal and excess zincate to form the unique barium cubane (**15**; Figure 10) with extrusion of tetramethylsilane.[45] This distorted, face-sharing double cube possesses agostic interactions between the methylene groups and the nearby barium centers, in addition to metal-carbon σ-bonds within the range observed for other σ-bonded compounds.

In addition, this complex shows carbon ligands in the unusual coordination state of six, resulting in rather long contacts to the nearly trigonal planar environments of the zinc centers.

7. Acetylides of the Heavy Group 2 Metals

The first examples of homoleptic heavy alkaline earth metal acetylides were reported recently;[46] these examples are summarized in Table 3.

The heavy Group 2 acetylides were prepared by transamination: reacting triphenylsilylethyne with a metal amide in THF at −78 °C with the addition of 18-crown-6. The geometry of these acetylides (**16**−**18**; the structure of **18** is shown in Figure 11) can be envisioned as distorted, pseudo-octahedral with the crown ether occupying the equatorial plane and the ligands filling the axial positions. The presence of the crown ether is critical for the formation of the acetylides. The complexes react with trace amounts of water to form siloxides and acetylene.[47]

The structural composition of the calcium, strontium and barium derivatives reveals a number of interesting trends, beginning with a smooth increase of metal-C_α distances with increasing size of the metal. Of particular note is an unexpected bend angle through the presumably sp-hybridized *ipso*-carbon, with a value of 168° for the calcium congener decreasing to 127° for the barium complex. This unexpected geometry led to several suggestions to explain the surprising results, including a lack of directionality in the ethyne sp orbital and subsequent freedom of motion. Other possibilities include the potential for partial rehybridization of the acetylide moiety, a possible side-on π-interaction of the ligand with the heavier metals, or crystal packing effects.

To further probe these trends, the effects of the ligands on the structural features were examined with the synthesis of less sterically demanding acetylides. Utilization of the same transamination pathway with *para-tert*-butylphenylethyne led to the formation of the strontium and barium acetylides (**19**; Figure 12) and **20**.[48] It was expected that the smaller phenyl substituents would experience a reduced steric repulsion with the crown ether ring and allow for more flexibility and perhaps an even closer approach of the ligand to the crown ether than in the bulkier triphenylsilyl analogs.

Intriguingly, very similar geometrical features were observed for both groups of acetylides, suggesting that simple steric models do not satisfactorily explain the unexpected geometry. DFT calculations to shed further light on this topic are currently underway.[49]

8. Di- and Triphenylmethanides

Organometallic di- and triphenylmethanide complexes of the alkali metals are well-known.[50] In contrast, such compounds of the heavier alkaline earth metals are rare; only the compounds shown in Table 4 have been structurally characterized.[51] Of particular interest in these systems is the structural geometry about the methyl carbon, as the

level of resonance through the phenyl rings can be derived from studies of this type.

Early attempts to synthesize group 2 triphenylmethanides focussed on the transamination route employed successfully to prepare the acetylides (**16**−**20**). Reaction of triphenylmethane and barium bis[bis(trimethylsilyl)]amide in the presence of 18-crown-6 in THF at low temperature did not afford the desired product; instead, cleavage of the crown ether and subsequent elimination of free amine led to the formation of the heteroleptic vinyl ether amide (**21**; Figure 13).[52]

This heteroleptic barium amide exists as a dimer, with two slightly asymmetrically bridging alkoxide moieties connecting the two metal centers. The opposite face is filled by an amide ligand, and the vinyl ether wraps around the equator of the barium atom giving four additional metal-oxygen interactions for a total coordination number of seven. This reproducible product continued to form even with the switch to an arene elimination route utilizing dibenzylbarium. It was not until the addition of HMPA (HMPA = hexamethylphosphoramide) in conjunction with the arene elimination route that charge separation was induced and the desired product observed.

The barium triphenylmethanide crystallizes as a separated ion pair, with the metal center occupying a center of symmetry (**22**; Figure 14). The crown ether fills the equatorial plane, while two HMPA molecules occupy the axial sites. The metal lies almost directly at the center of the crown ether ring, at an average M−O distance of 2.78 Å. The triphenylmethanide anions exhibit a "propeller" geometry, with the center of the anion fully planarized, suggesting considerable resonance through the phenyl rings. The rings are too sterically demanding to be coplanar and so twist out of the plane by an average of 31.1°. One of the phenyl substituents exhibits a slightly longer bond length to the methyl center; this ring possesses the greatest twist angle, reducing the possible orbital overlap and subsequent resonance stabilization. It is noteworthy that the crown ether is cleaved rather than the THF solvent.

Similarly, the strontium congeners (**23**) and (**24**) of these complexes can be prepared.[53] Reaction of triphenylmethane with strontium bis[bis(trimethylsilyl)]amide with 18-crown-6 in THF at low temperatures leads to the heteroleptic vinyl ether amide (**23**). This compound adopts the same basic geometry as the barium congener, with a similar bridged dimeric structure. As expected, the bonds in the strontium complex overall are slightly shorter than those in the barium compound. The metal centers are still seven coordinate with the cleaved ether wrapping around to complete the coordination sphere.

The strontium triphenylmethanide can be synthesized analogously to the barium congener.[53] Preparation via arene elimination with dibenzylstrontium in the presence of triphenylmethane and HMPA in THF at low temperature

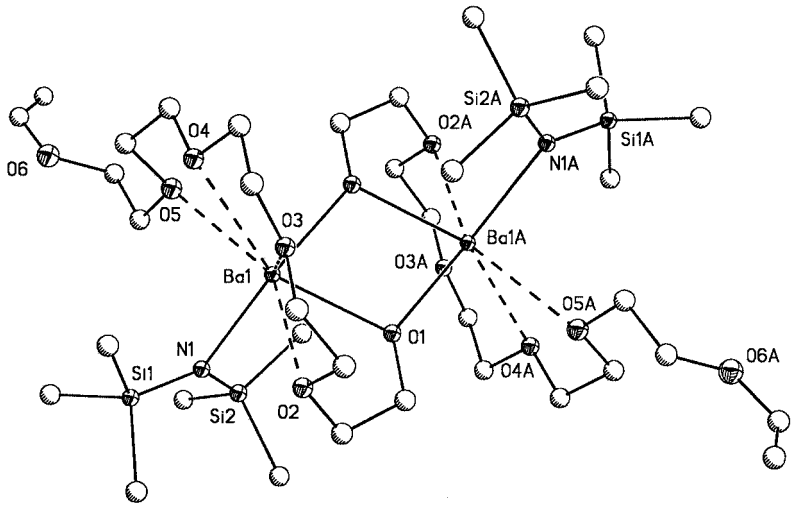

Figure 13. Molecular structure of **21**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

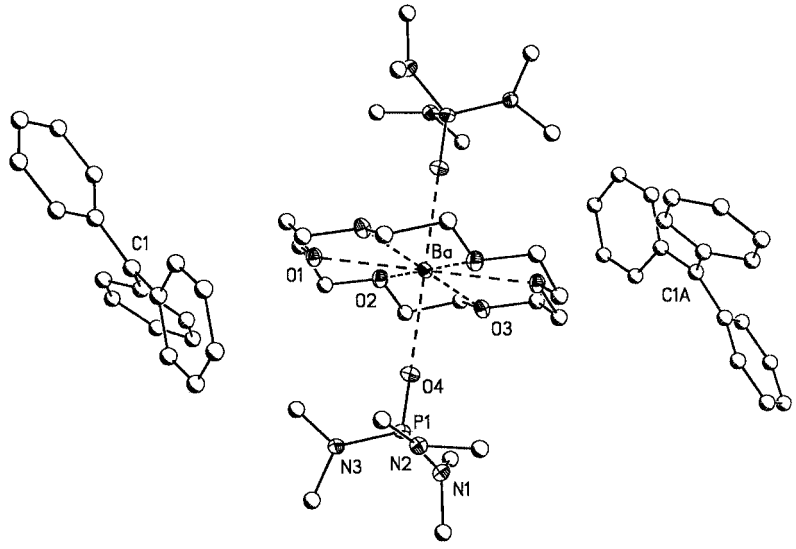

Figure 14. Molecular structure of **22**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

leads to the charge-separated strontium triphenylmethanide (**24**). This complex adopts a structure analogous to the barium congener, with the anions exhibiting a "propeller" geometry. The methyl center is planar, and the phenyl rings twist out of the plane by an average of 30.6°. The ring showing the greatest twist angle leads to the longest C-C distance. If dibenzylbarium is treated with diphenylmethane in the presence of 18-crown-6, the contact barium diphenylmethanide (**25**; Figure 15) stabilized by 18-crown-6 is observed.[54]

Compound **25** crystallizes out of warm THF as a nine-coordinate distorted pseudo-octahedron with the methanide anions capping the axial positions over the crown ether encapsulated metal. The α-carbons in the ligand are slightly pyramidal. The phenyl rings are not coplanar, and are twisted slightly away from the methyl center by an average of 5.5°. Curiously, this compound is stable enough in THF to allow for recrystallization without any of the ether cleavage reactions observed for the triphenylmethanide system. It is possible that the lower steric demand of the diphenylmethanide anion plays a key role. Similar chemistry using dibenzylbarium, diphenylmethane and six equivalents of HMPA led to a charge-separated diphenylmethanide compound with six HMPA donors stabilizing the barium cation. Insufficient crystal quality has thus far prevented a satisfactory structure elucidation.[55]

An earlier example of a heavy alkaline earth dibenzyl system comes with the metallation of 2-pyridylphenylmethane in liquid NH_3/THF with barium and the addition of diglyme (**26**; Figure 16).[56] This "open metallocene" has the potential to add stabilization through coordination of the pyridyl moiety. The metal center is saturated with two η^3-contacts, two pyridyl contacts, one diglyme and one THF molecule. Although the ligands show conjugation through

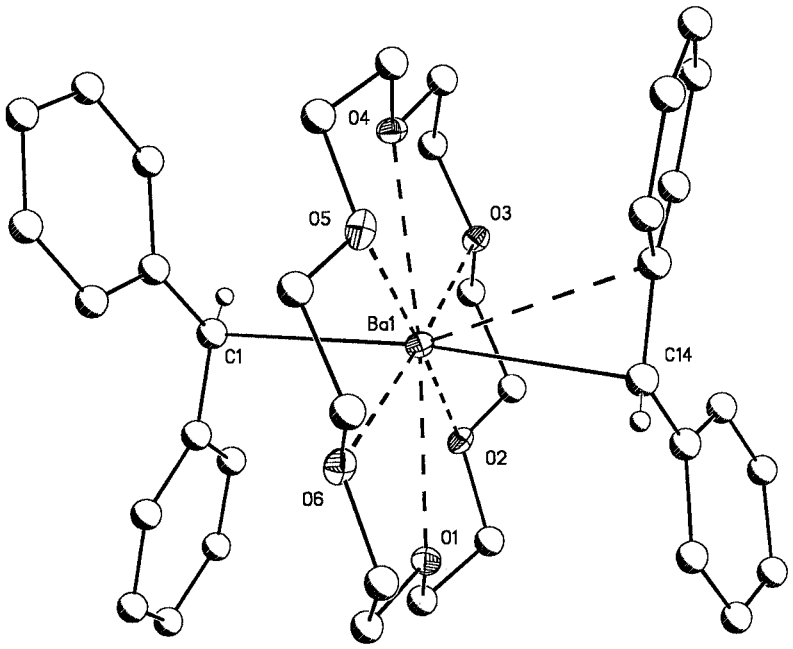

Figure 15. Molecular structure of **25**; heavy atoms displayed anisotropically with ellipsoids at 30% probability; hydrogen atoms except those on the *ipso* carbons have been omitted for clarity

the *ipso*-carbons (C_{ipso}−C distances of 1.41−1.43 Å) the rings are tilted away from the metal center (dihedral angles of 16.0°, 21.8°). Interestingly, the steric bulk of the ligands appears to be of little consequence, as they are pushed quite near each other by the approach of the donor.

9. Conclusions

With the advent of new synthetic methods and an array of possible applications the once sparsely investigated organometallic chemistry of calcium, strontium and barium

is coming to the forefront of main group chemistry. A wide variety of compounds once thought inaccessible are now being prepared simply and efficiently, and the interesting structural features of these complexes and the questions they raise demand further examination. With the synthesis and structural characterization of new targets, information on the relationship between structure and reactivity is slowly becoming clear. This will have a profound effect on the possible applications of the target molecules. Future investigations will extend to new ligand systems and alternative synthetic pathways to probe the fascinating geometry, unusual chemical properties and various applications exhibited by this exciting new collection of compounds.

Note added in proof (July 24, 2002): After submission of this article we became aware of two publications which are of importance to this review.[57,58]

Theoretical Study of an Isolable Compound with a Short Silicon-Silicon Triple Bond, $(t\mathrm{Bu_3Si})_2\mathrm{MeSiSi{\equiv}SiSiMe}(\mathrm{Si}t\mathrm{Bu_3})_2$

Nozomi Takagi[a] and Shigeru Nagase*[a]

Keywords: Silicon / Multiple bonds / Substituent effects / Density functional calculations

The effects of a very bulky silyl group [R**, -SiMe(Si-tBu$_3$)$_2$] — developed recently by Wiberg and co-workers — on silicon-silicon triple bonding have been investigated by density functional theory in search of a stable disilyne. These calculations predict that R**Si≡SiR** is stable enough to be isolated and has a short Si-Si bond length of 2.072 Å that is short enough to be a triple bond.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Since the first isolation of a stable disilene ($R_2Si{=}SiR_2$) in 1981,[1] a variety of synthetic methods have been developed for the synthesis of silicon-silicon doubly bonded compounds, as summarized in recent reviews.[2−4] However, stable silicon-silicon triply bonded compounds [disilynes (RSi≡SiR)] are still unknown, despite several attempts to isolate them,[5] except for their transient existence as intermediates.[6,7] It is the focus of much current interest whether disilynes are synthetically accessible and isolable as stable compounds.[3,4,8,9] The major difficulty in synthesizing and isolating disilynes is due to their high reactivities, especially toward isomerization and dimerization.[10−14] To suppress these reactivities, substituent effects have been extensively investigated.[10−14] Bulky aryl groups such as Tbt [C_6H_3-2,4,6-{$CH(SiMe_3)_2$}$_3$] and Ar* [C_6H_3-2,6-(C_6H_2-2,4,6-iPr$_3$)$_2$][15] have been suggested as sterically promising substituents.[12,13]

According to theoretical investigations,[10,11] substitution by electropositive silyl groups is electronically much more effective in realizing a less trans-bent disilyne structure with a short silicon-silicon multiple bond. Thus, silyl groups such as SitBu$_3$ and SiDep$_3$ (Dep = 2,6-diethylphenyl) have been tested as bulky candidates.[10,11] However, it has been found that they are not sufficiently bulky to make disilynes isolable under normal conditions.[12,16] Therefore, the availability of much bulkier silyl groups has been anticipated. In this context, it is worthy to note that Wiberg and co-workers have very recently developed the extremely bulky silyl group R** [SiMe(SitBu$_3$)$_2$] and succeeded in synthesizing and isolating a stable 1,2-dichlorodisilene, R**ClSi=SiClR**, with the R** groups in trans positions, as reported in this journal.[17] It has been suggested that dechlorination of R**ClSi=SiClR** could lead to an isolable disilyne, R**Si≡SiR**. To confirm this interesting suggestion, we have performed theoretical calculations on R**Si≡SiR**.

Results and Discussion

Hybrid density functional calculations at the B3LYP level[18] were performed with the 3-21G* basis set,[19] as in a series of previous studies,[10−14] using the Gaussian 98 program.[20] Since the structure of R**ClSi=SiClR** has been determined by X-ray crystal analysis,[17] its geometry optimization was first carried out to calibrate the B3LYP/3-21G* calculations. As found for the X-ray crystal structure, it was calculated that R**ClSi=SiClR** has a planar structure around the Si-Si double bond with C_i symmetry. The calculated bond lengths and angles were R**-Si = 2.397 Å, Cl−Si = 2.116 Å, R**-Si-Si = 135.9°, and Cl−Si−Si = 108.0°. These values agree very well with the X-ray crystal data of R**-Si = 2.401 Å, Cl−Si = 2.091 Å, R**-Si-Si = 132.0°, and Cl−Si−Si = 106.8°. The Si-Si double bond length was calculated to be 2.171 Å, this being only 0.008 Å longer than the X-ray crystal structure value of 2.163 Å.

The optimized structure of R**Si≡SiR** is shown in Figure 1; it has C_2 symmetry. Owing to the two bulky R** groups, the skeleton of R**Si≡SiR** is only twisted around the central Si-Si bond by 1.0°, as shown by the dihedral R**-Si-Si-R** angle (ω) of 179.0°. However, the two bulky R** groups help to protect the central Si-Si bond from the attack of reactive reagents (see Figure 1). Silicon has a low tendency to form an ideal hybrid orbital because of the size difference between valence s and p orbitals.[10,11,21] For this reason, it is normal that disilynes prefer a highly trans-bent structure with some lone pair character at each Si atom, in contrast to the well-known linear

[a] Department of Theoretical Studies, Institute for Molecular Science,
Okazaki 444-8585, Japan

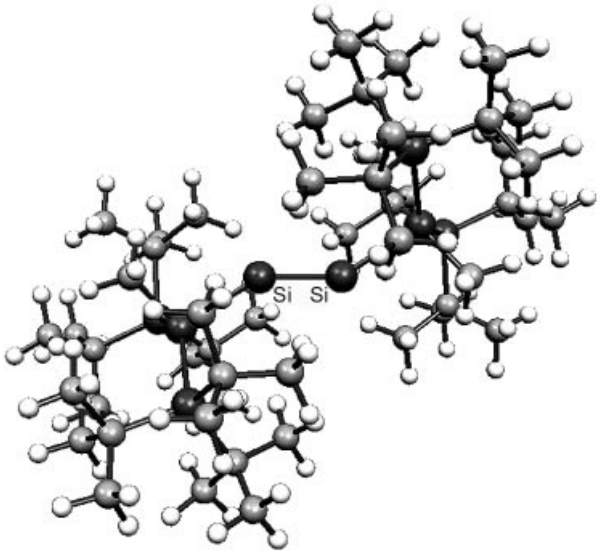

Figure 1. Optimized structure of R**Si≡SiR**; Si-Si = 2.072 Å and R**-Si-Si = 148.0°

structure of the carbon analogues. For R**Si≡SiR**, the R**-Si-Si bond angle (θ) was calculated to be 148.0°. It is noticeable that the trans-bending is 23.1° smaller than that for HSi≡SiH (θ = 124.9°). In addition, the energy difference between trans-bent and linear structures is only 5.5 kcal/mol for R**Si≡SiR**, while it is 20.3 kcal/mol for HSi≡SiH.

More interesting is the central Si-Si bond length of 2.072 Å calculated for R**Si≡SiR**, which is shorter than that of 2.093 Å for HSi≡SiH and considerably shorter than those of 2.121 and 2.136 Å calculated at the same level of theory for TbtSi≡SiTbt (θ = 130.9° and ω = 180.0°)[12] and Ar*Si≡SiAr* (θ = 129.0° and ω = 171.2°),[13b] owing to the much less trans-bent structure. The advantage of the R** group in the Si-Si bond shortening and skeletal linearization for R**Si≡SiR** is due to the fact that the SiR** components have a very small doublet-quadruplet energy difference of 28.5 kcal/mol because of the electropositive character of R**, as compared with the values of 42.6, 50.1, and 55.1 kcal/mol for SiH, SiTbt, and SiAr*, respectively; for the importance of the small doublet-quadruplet energy gap, see refs.[10,11]

The Si-Si bond length of 2.072 Å for R**Si≡SiR** is 0.1 Å shorter than the Si-Si double bond length of R**ClSi=SiClR** and 0.13−0.18 Å shorter than those of 2.202−2.251 Å determined for tetrasilyldisilenes $R_2Si=SiR_2$ (R = $SiMe_2t$Bu, $SiMei$Pr$_2$, and SiiPr$_3$).[22] These results clearly suggest that R**Si≡SiR** possesses an additional bond between the Si atoms, as compared with disilenes; it is interesting that the Si-Si distance is very close to an "idealized" Si-Si triple bond length of 2.025 Å in the linear structure of R**Si≡SiR**.[23] In an attempt to reduce the crowding of the substituents, the Me group in R** [$SiMe(Sit$Bu$_3)_2$] was replaced by an H atom. After this replacement the Si-Si distance increased to 2.081 Å, and the trans-bending and twisting were enhanced by 4.6 and 6.1°, respectively, thus showing that even the small Me group in R** plays an important role.[24]

The bulk of the R** group helps to destabilize the 1,2-R**-shifted isomer SiSiR**R**, because the two R** groups crowd more around one end of the Si-Si bond, as is apparent from Figure 2. Thus, R**Si≡SiR** was calculated to be 33.4 kcal/mol more stable than SiSiR**R**. This energy difference is large enough to prevent the 1,2-R** shift in R**Si≡SiR**. The corresponding energy differences are 18.5 and 37.9 kcal/mol for TbtSi≡SiTbt[12] and Ar*Si≡SiAr*,[13b] while they are only 9.8 and 12.0 kcal/mol for tBu$_3$SiSi≡SiSitBu$_3$ [10] and Dep$_3$SiSi≡SiSiDep$_3$,[10] respectively.

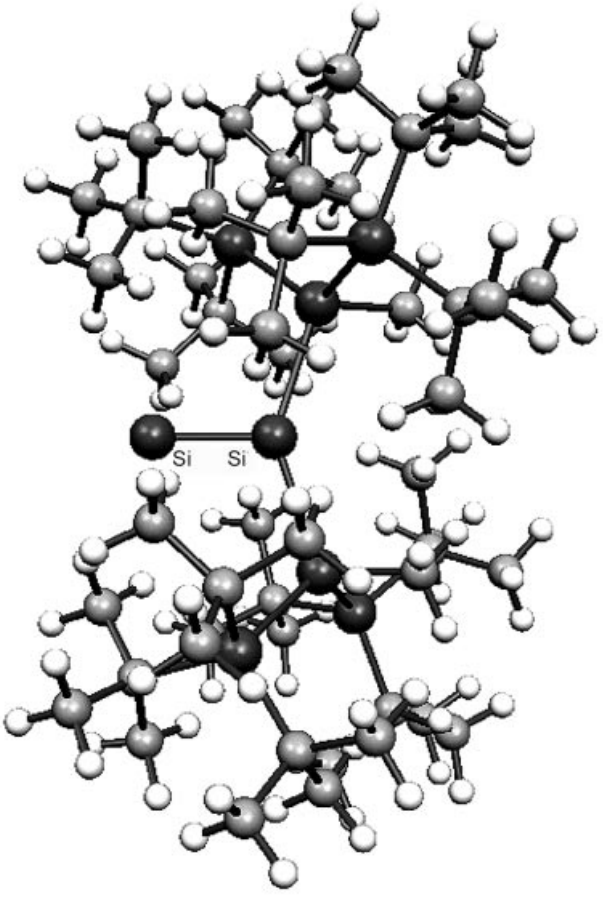

Figure 2. Optimized structure of the SiSiR**R** isomer; Si-Si = 2.187 Å and R**-Si-R** = 143.9°

Because of the bulk of the R** group, it may be argued that R**Si≡SiR** dissociates readily in solution. However, the energy required to cleave the central Si-Si bond (leading to two SiR** fragments in the doublet ground-state) was calculated to be 55.1 kcal/mol, this value being larger than those of 51.8 and 37.9 kcal/mol calculated for TbtSi≡SiTbt[12] and Ar*Si≡SiAr*,[13b] respectively. The dissociation energy of R**Si≡SiR** is 20.3 kcal/mol larger than the value of 34.8 kcal/mol calculated for R**ClSi=SiClR** (leading to two SiClR** fragments in the singlet ground-state), confirming that the two central Si atoms are strongly bonded in R**Si≡SiR**. According to orbital analysis, the

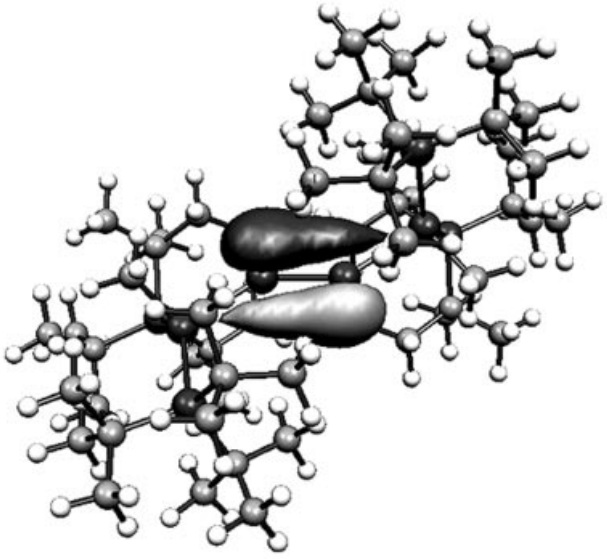

Figure 3. The Si-Si π-bonding orbital in the R*-Si-Si-R* plane of R**Si≡SiR** plotted with a value of 0.05 au

Figure 4. Optimized tetrasilabutadiene structure of the R**Si≡SiR** dimer; Si−Si = 2.227−2.534 Å and Si−Si−Si = 88.7−91.0°

Si≡Si bonding consists of a slightly distorted σ-bond, an out-of-plane π-bond, and a slipped in-plane π-bond due to the σ* mixing.[23] There has been much debate on the bonding contribution of a slipped π-bond.[3,5,8] As Figure 3 shows, however, the slipped in-plane π-orbital of R**Si≡SiR** has considerable bonding character between the Si atoms and helps to form a strong triple bond, though it is localized on each Si atom and becomes nonbonding as the trans-bending increases.

The most important obstacle to the isolation of disilynes is their facile dimerization to form tetrasilatetrahedrane or more stable tetrasilacyclobutadiene structures. To investigate to what extent R**Si≡SiR** is stable towards dimerization, calculations were carried out for a dimer of large size (a total of 1660 basis functions at the B3LYP/3-21G* level). Up to now, it has been predicted that the dimerization of tBu$_3$SiSi≡SiSitBu$_3$ [12] and Dep$_3$SiSi≡SiSiDep$_3$ [16] to form tetrasilatetrahedrane structures is exothermic by 80 and 32 kcal/mol, respectively. In this context, it is interesting to note that a stable tetrasilatetrahedrane has been synthesized using a reaction that involves most probably tBu$_3$SiSi≡SiSitBu$_3$ as a transient intermediate.[25] In contrast, the dimerization of R**Si≡SiR** to a tetrasilacyclobutadiene structure (Figure 4) was calculated to be endothermic by 49.9 kcal/mol owing to the steric congestion of four bulkier R** groups. This large endothermicity confirms that R**Si≡SiR** is highly unlikely to dimerize.

In conclusion, R**Si≡SiR** is very stable towards both isomerization and dimerization. In addition, it has the least trans-bent structure and the shortest triple bond among isolable silicon analogues of alkynes that have ever been investigated.[10−14] It is expected that R**Si≡SiR** will soon be successfully isolated[26] and open up a new area in silicon chemistry.

[26] It has been reported that the reduction of R**ClSi=SiClR** with LiC$_{10}$H$_8$ in THF leads to a reaction mixture containing a Cl-free product that shows a low field ^{29}Si NMR signal at δ = 91.5 ppm.[17] In an attempt to estimate ^{29}Si NMR chemical shifts of triply bonded Si atoms, GIAO-B3LYP calculations were carried out using B3LYP/3-21G* optimized structures; a larger 6-311G(3d) basis set was employed only for Si because of the size of molecules. At this level, the ^{29}Si NMR chemical shifts of H$_3$SiSi≡SiSiH$_3$ and MeSi≡SiMe were calculated at δ = 95.0 and 26.9 ppm, respectively. It may be informative that the ^{29}Si NMR chemical shift at δ = 111.2 ppm calculated for R**Si≡SiR** is much closer to the observed signal than that at δ = 180.4 ppm calculated for R**ClSi=SiClR**.

A Robust, Reactive, and Remarkably Simple to Prepare Sterically Encumbered *meta*-Terphenyl Ligand

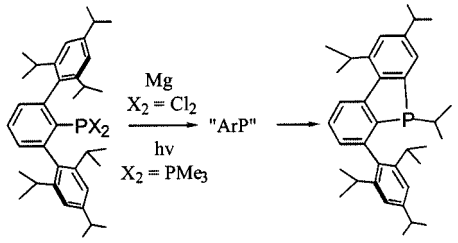
Rhett C. Smith,*[a] Tong Ren,[b] and John D. Protasiewicz*[a]

Keywords: Terphenyl / Diphosphene / Insertion / Phosphaalkene

A cost-efficient, high yield and simple one-pot route to the sterically encumbered iodoterphenyl DcpI [Dcp = 2,6-(2,6-$Cl_2C_6H_3)_2C_6H_3$] is developed in which the necessary addition of external Grignard reagent is avoided. This material is employed as a convenient precursor to low-coordinate phosphorus compounds, such as DcpP=PDcp (**1**), DcpP=C(H)Ph (**4**), and DcpP=PMe_3. The resultant aryl is found to provide robust steric protection for **1** and **4** once in place, but reactive intermediates leading to insertion chemistry must be avoided in the course of their synthesis. A new bis(dibenzophosphole) **2** resulting from insertion of a phosphorus atom into vicinal C–Cl bonds was isolated and characterized. The single crystal X-ray structures of **1**, **2**, and **4** are presented.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Sterically encumbered *meta*-terphenyl ligands represent an exciting class of protective groups. Recent reviews have detailed their widespread success for stabilizing new compounds having novel element−element multiple bonds, generating interesting molecular geometries and coordination environments, and synthesis of models for biological systems.[1] Yet despite their great success in stabilizing reactive functional groups, these types of ligands can be susceptible to intramolecular attack by high-energy intermediates. For example, it was recently noted that both reduction of 2,6-$Trip_2C_6H_3PCl_2$ with magnesium, and photolysis of $Trip_2C_6H_3P{=}PMe_3$, lead to the same phosphafluorene [Equation (1)].[2−4]



(1)

Presumably, the phosphinidene ("ArP"), generated from either process, inserts into an Ar−*i*Pr carbon−carbon bond to account for the final product. While phosphinidenes, the phosphorus analogues of carbenes, have been invoked in many reactions to justify a variety of products, direct evidence for such species is still quite limited.[5−7]

Our interest in examining the scope of this type of process and finding more convenient and economical variations of *meta*-terphenyl ligands led us to investigate systems based upon the 2,6-bis(2,6-dichlorophenyl)phenyl (Dcp) group. This terphenyl was first isolated in 22% yield by Kress from the black sludge that resulted from the thermal decomposition (exothermic) of 2,6-dichlorophenyllithium at temperatures above −45 °C (Scheme 1).[8] Hart subsequently found that the corresponding Grignard reagent was much more stable and could be used to prepare 2,6-bis(2,6-dichlorophenyl)benzene (DcpH) in moderate yields (44%).[9] This discovery led to the development of a convenient route to a range of terphenyls (2,6-$Ar_2C_6H_3E$, Scheme 1) using *meta*-dichlorobenzene and various Grignard reagents. The maximum steric screening provided by terphenyl ligands for reactive atoms and functional groups is largely defined by the *ortho* substituents on the outer aromatic rings. Hence, another particularly attractive facet of the Dcp terphenyl is its steric similarity to the widely used terphenyl 2,6-$Mes_2C_6H_3$ (Dmp). Because of the similar van der Waals radii for chlorine and methyl groups, one should be able to obtain the same steric coverage as the Dmp system at reduced cost and effort. We now report that the modification of the original Kress reaction and subsequent quenching with iodine leads to a high yield and convenient synthesis of DcpI, as well as its unusual stability and reactivity in low-coordinate phosphorus compounds.

The reaction first reported to yield DcpH was thus modified by not allowing the initial dichlorobenzene/butyllithium mixture to warm above −50 °C, and by the subsequent addition of I_2. A 65% yield of DcpI is achieved

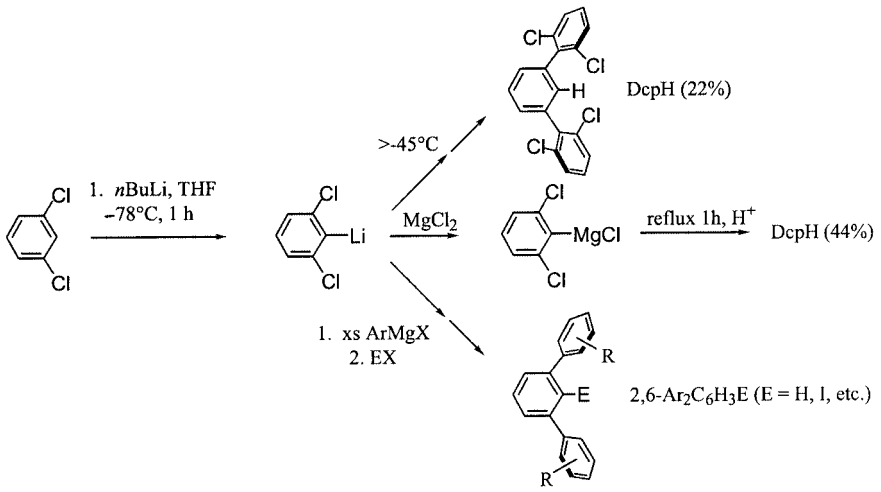
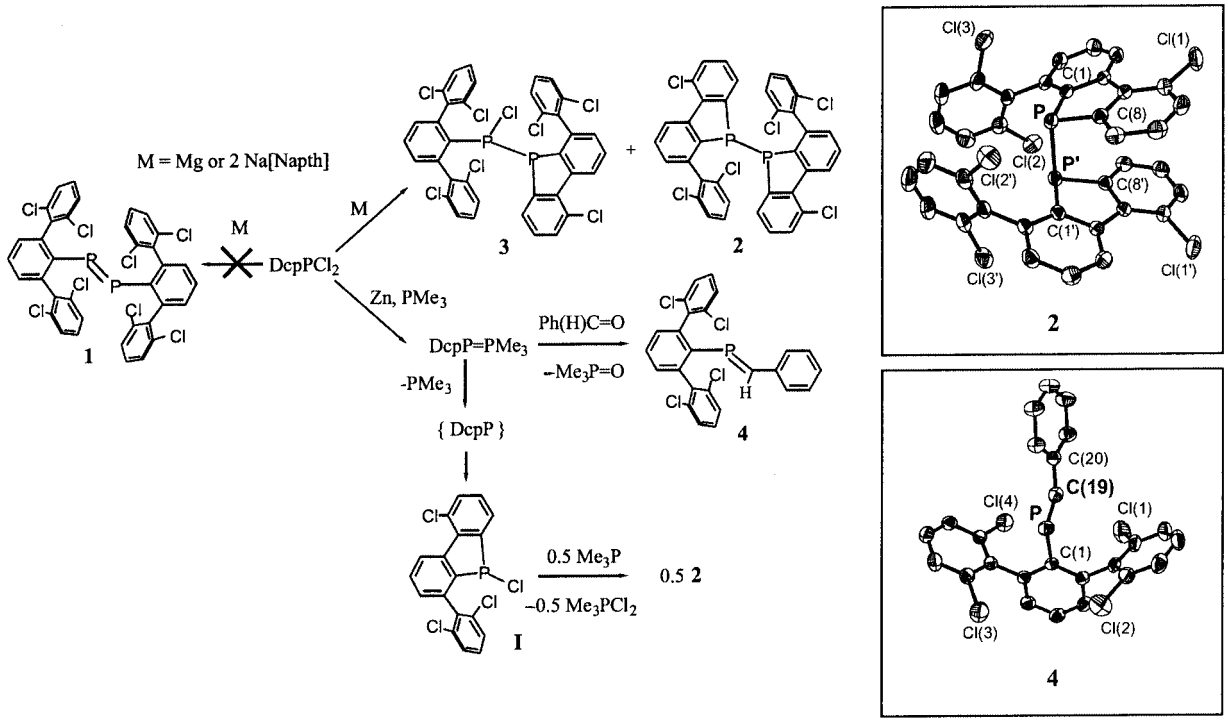


Scheme 1

after single recrystallization by an exceptionally convenient and simple procedure that provides better yields than many conventional iodoterphenyl syntheses (Scheme 1). With this pure material in hand, the synthesis of $DcpPCl_2$ was effected by standard methods (metallation of DcpI by *n*BuLi at −78 °C in THF, followed by addition of three equivalents of PCl_3 and warming to room temperature).

Synthesis of the diphosphene DcpP=PDcp (**1**) was then undertaken to assess the steric screening capabilities of the Dcp ligand. Attempts to prepare this material by reduction of $DcpPCl_2$ by proven and established methods[10] (by either ultrasound/magnesium or 2 equiv. Na[Napth]) surprisingly failed to provide any evidence of the desired diphosphene. Instead, two other major products (**2** and **3**) were observed in about equal amounts (Scheme 2, top). This result was puzzling, since the diphosphene bearing the nearly isosteric terphenyl Dmp ligand is quite robust and stable.[11] The identity (and perhaps the origins) of **2** became clearer when the synthesis of the phosphanylidene-σ^4-phosphorane $DcpP{=}PMe_3$ was undertaken (Scheme 2). Reduction of $DcpPCl_2$ by either Zn/PMe_3 or excess PMe_3 cleanly leads to $DcpP{=}PMe_3$ [^{31}P NMR (THF): δ = 6.7, −121.1 ppm, J_{PP} = 573 Hz] having NMR spectroscopic properties similar to its $DmpP{=}PMe_3$ analogue.[12] This material,



Scheme 2. Selected bond lengths [Å] and angles [°] for **2**: P−C(8) 1.810(2), P−C(1) 1.813(2), P−P′ 2.248(1), C(8)−P−C(1) 89.3(1), C(8)−P−P′ 101.69(8), C(1)−P−P′ 97.36(9); selected bond lengths [Å] and angles [°] for **4**: P−C(19) 1.634(3), P−C(1) 1.841(3), C(19)−P−C(1) 102.9(1), C(20)−C(19)−P 125.4(2)

however, quickly (10−15 min) and cleanly transforms to **2** [^{31}P NMR (THF): δ = −27.6 ppm].

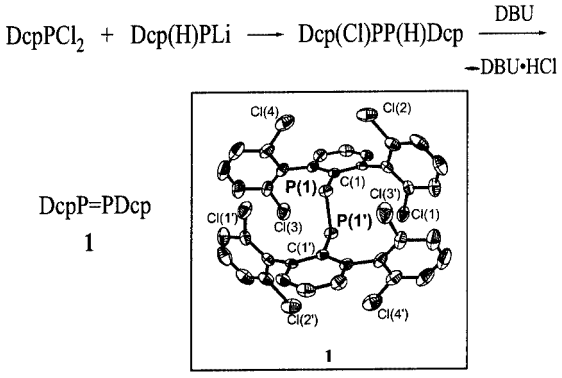
Interestingly, as the results of an X-ray diffraction study show (Scheme 2), two phosphorus atoms have inserted into the carbon−chlorine bonds of two terphenyl ligands and coupled to one another to provide bis(dibenzophosphole) **2**.[13] Despite the crowded nature about the P−P bond, a relatively normal P−P single bond length of 2.248(1) Å is found. The structure of **2** is remarkably similar to the disilane postulated to arise by insertion of a silylene into the carbon−carbon bonds of a Dmp terphenyl.[14]

The nature of **2** makes it tempting to speculate that the unstable phosphanylidene-σ^4-phosphorane loses PMe_3 in an initial step to generate a highly reactive phosphinidene (Scheme 2, bottom). This behavior would stand in contrast to the related phosphanylidene-σ^4-phosphoranes ArP=PMe_3 (Ar = Dmp, Mes*, 2,6-$Trip_2C_6H_3$) that are thermally stable at room temperature, but extrude PMe_3 upon photolysis.[3] The presumed product of phosphinidene insertion into the carbon−chlorine bond, chlorophosphafluorene **I**, has, however, proven to be much more difficult to detect than the analogous product derived from phosphinidene insertion into a carbon−carbon bond [Equation (1)]. It appears that the P−Cl bond in **I** must be more susceptible to further reduction than $DcpPCl_2$. For example, reactions of $DcpPCl_2$ and either 1 equiv. of Na[Napth] or 1/2 equiv. of Mg yield mixtures of **2** and unchanged $DcpPCl_2$. Likewise, the proposed intermediate **I** must also be very susceptible to trialkylphosphane-promoted dehalogenation and P−P coupling processes.[15]

The unstable DcpP=PMe_3 was trapped by excess benzaldehyde to give the new phosphaalkene DcpP=C(H)Ph [**4**, ^{31}P NMR ($CDCl_3$): δ = 233.0] (> 95% by ^{31}P NMR, 62% isolated yield) by our version of a phospha-Wittig reaction (Scheme 2).[12,16] Scheme 2 also shows the results of a single-crystal X-ray diffraction study of **4**.[13] The main feature of interest, the P=C bond length of 1.634(3) Å, is at the shorter end of the spectrum of reported values for such compounds.[17−21] The phosphaalkene unit itself resides within the protective cleft of the large Dcp ligand.

The other major product produced by reduction of $DcpPCl_2$ by magnesium has been assigned as **3**, based on its ^{31}P NMR spectrum [δ = 96.3 ppm (d, J_{PP} = 305 Hz), −5.0 (d, J_{PP} = 305 Hz)]. The identity of this product was more firmly established by its independent synthesis. Bis(dibenzophosphole) **2** was reductively cleaved by excess Na metal to a dibenzophospholide anion[22,23] [^{31}P NMR (THF): δ = 21.9 ppm], which was treated with $DcpPCl_2$ to give **3** as the main product. Interestingly, this material does *not* appear to be an intermediate to **2** during the thermal decomposition of DcpP=PMe_3, as it does not react with Zn or PMe_3.

Though the Dcp ligand might be very susceptible to attack by phosphinidene (or other) intermediates, it is a very effective protective unit once in place. In fact, the diphosphene **1** is very stable and robust. Compound **1** was readily prepared by the stepwise process described in Scheme 3, which avoids potential generation of phosphinidenes. While



Scheme 3. Selected bond lengths [Å] and angles [°] for **1**; (only one of two independent molecules shown); P(1)−C(1) 1.847(4), P(1)−P(1′) 2.039(2), C(1)−P(1)−P(1′) 98.46(15)

1 exhibits a typical ^{31}P NMR chemical shift value of δ = 500.3 ppm, the compound has two notable features that distinguish it from the Dmp analogue. First, the presumed π-π* electronic transition of **1** is blue-shifted by approximately 19 nm compared to DmpP=Dmp (solid **1** is yellow, while DmpP=PDmp is orange). Secondly, the structure of **1** (Scheme 3) reveals a different orientation of the terphenyl groups.[13] Specifically, the two central rings of each terphenyl are nearly parallel to one another (and related by an inversion center). Similar orientations of the terphenyl groups of DmpPE=EDmp (E = As, Sb) are adopted in the solid state.[2]

For the phosphorus species, it appears that the smaller central atom size and bond lengths disfavor this orientation due to steric clashes between Dmp groups across the P=P unit. Compound **1** lacks the *para* substituents present on the Dmp system, and thus interactions of the Dcp groups across the P=P unit are not as severe. Average P−P distances of 2.030 Å (two independent molecules in unit cell) and C−P−P bond angles spanning 98.5(2) to 98.9(1)° are otherwise unexceptional for **1**.

The facile self-destruction reactions of the Dcp ligand (as in **2** and **3**) bear some likeness to similar reactions of low-coordinate phosphorus compounds bearing the Mes* (Mes* = 2,4,6-$tBu_3C_6H_2$) group. In these materials the phosphorus atoms insert into the vicinal C−H bonds of the *tert*-butyl groups. For example, reduction of Mes*PCl_2 with activated magnesium gives rise to a phosphaindane.[4] In addition, photolysis of the diphosphene Mes*P=PMes* readily leads to such products, and therefore it was anticipated that under photolysis **1** would yield products such as **2** or **3**.[24] The remarkable stability of **1** is amply demonstrated by its complete inertness to continued photolysis (by either irradiation in a 254-nm photochemical reactor or by 355-nm laser light). In this regard, **1** behaves like the terphenyl-protected diphosphenes DmpP=PDmp[3] and ArP=PAr[25] (Ar = 2,6-Mes_2-4-MeC_6H_2).

We have thus shown that a relatively inexpensive and sterically encumbered *meta*-terphenyl ligand can rapidly be constructed for applications in low-coordinate phosphorus chemistry. Highly reactive phosphorus centers can insert into the carbon−chlorine bonds of the Dcp ligand and pro-

vide access to novel phosphafluorene-derived materials. If these high-energy intermediates can be avoided, then the resulting materials bearing the Dcp unit are very robust. This finding should also serve as another reminder for others searching for new compounds having multiply bonded elements, that the size of the ligand is not everything. In other applications, where an economically more desirable sterically demanding protecting group is required, the Dcp unit should also be useful.

Experimental Section

General: Air sensitive materials were handled in a dry box or using modified Schlenk line techniques under dry nitrogen. Solvents were obtained by distillation from Na-benzophenone ketyl under nitrogen. ^{1}H NMR and ^{31}P NMR spectra were acquired on a Varian Gemini 300 MHz spectrometer and are referenced to TMS and 85% H_3PO_4, respectively.

DcpI: 54.8 mL of *n*BuLi (2.5 M in hexanes, 138 mmol) was added dropwise to a solution of 1,3-dichlorobenzene (20.0 g, 136 mmol) in THF (250 mL) at −78 °C. The resulting white suspension was stirred for 1.5 h at −78 °C (dry ice/acetone bath), and then warmed to −50 °C (bath temperature) over a 30 min period. Elemental iodine (14.0 g, 55.2 mmol) was added under positive pressure of N_2 and the mixture was allowed to warm to room temperature over a 2 h period. Excess iodine was quenched with aqueous Na_2SO_3, and the organic products were extracted with diethyl ether. The combined organic layers were washed with water and then dried with Na_2SO_4. Removal of all volatiles under reduced pressure yielded a sticky light brown solid. Recrystallization from hot EtOH gave 14.9 g (65% yield) of pure white DcpI; m.p. 176−178 °C. ^{1}H NMR ($CDCl_3$): δ = 7.56 (t, J = 7.0 Hz, 2 H), 7.43 (d, J = 7.0 Hz, 4 H), 7.29 (t, J = 8.0 Hz, 1 H) 7.22 (d, J = 8.0 Hz, 2 H) ppm. ^{13}C NMR (300 MHz, $CDCl_3$): δ = 143.5, 141.9, 135.0, 129.6, 129.1, 128.6, 127.8, 104.8 ppm. HR-MS (FAB): calcd. for $C_{18}H_9Cl_4I$: 491.8503; found 491.8509 [M + H$^+$].

DcpPCl$_2$: Prepared in 52% yield using literature methods.[11] ^{1}H NMR (C_6D_6): δ = 7.09 (t, J = 8.0 Hz, 1 H), 6.97 (d, J = 8.0 Hz, 4 H), 6.81 (dd, $^3J_{H,H}$ = 8, $^4J_{PH}$ = 3 Hz, 2 H), 6.55 (d, J = 8.0 Hz, 2 H) ppm. ^{31}P NMR (C_6D_6): δ = 155.4 (s) ppm.

DcpPH$_2$: Prepared in 47% yield using literature methods.[11] ^{1}H NMR (C_6D_6): δ = 7.13 (t, J = 8.0 Hz, 1 H), 7.02 (d, J = 8.0 Hz, 4 H), 6.96 (d, $J_{H,H}$ = 8, $^4J_{PH}$ = 2 Hz, 2 H), 6.57 (t, J = 8.0 Hz, 2 H), 3.23 (d, J_{PH} = 208 Hz) ppm. ^{31}P NMR (C_6D_6): δ = −148.1 (t, J_{PH} = 208 Hz) ppm.

2: To a stirred mixture of DcpPCl$_2$ (0.30 g, 0.60 mmol) and Zn dust (0.05 g, 0.76 mmol) in 10 mL of THF was added a solution of PMe_3 (0.19 g, 2.5 mmol) in 5 mL of THF. The solution immediately turned bright yellow, and a ^{31}P NMR spectrum of an aliquot, run after 5 min of reaction, indicated complete conversion into DcpP=PMe$_3$. After 20 min, the solvent was removed in vacuo, and the solids were extracted with hexanes. Removal of hexanes in vacuo yielded 0.16 g of **3** as a white solid (70% yield). Crystals suitable for X-ray structure determination were grown from hexanes/$CDCl_3$. ^{1}H NMR (C_6D_6): δ = 8.83 (d, J = 8.0 Hz, 2 H), 7.33 (t, J = 8.0 Hz, 2 H), 7.14 (d, J = 8.0 Hz, 4 H), 6.94 (d, J = 8.0 Hz, 2 H), 6.84 (d, J = 8.0 Hz, 2 H), 6.63 (t, J = 8.0 Hz, 2 H), 6.34 (t, J = 8.0 Hz, 2 H), 6.00 (d, J = 8.0 Hz, 2 H) ppm. ^{31}P NMR (THF): δ = −27.6 ppm. HR-MS (FAB):calcd. for $C_{36}H_{19}Cl_6P_2$ 722.9093; found 722.9128 [M + H$^+$].

DcpP=C(H)Ph (4): To a stirred mixture of DcpPCl$_2$ (0.10 g, 0.21 mmol), zinc dust (0.02 g, 0.3 mmol), and benzaldehyde (0.090 g, 0.85 mmol) in 5 mL of THF in a 20-mL vial was added a solution of PMe_3 (0.10 g, 1.32 mmol) in 3 mL of THF. After 1 h of stirring, the solvent was removed in vacuo. The solid was extracted with hexanes, and the hexanes were evaporated to yield 0.060 g of **4** as a white powder (62%). Crystals suitable for X-ray structure determination were grown by slow concentration of a $CDCl_3$ solution. ^{1}H NMR ($CDCl_3$): δ = 9.08 (d, J = 24.0 Hz, 1 H), 7.49 (t, J = 7.0 Hz, 1 H), 7.27 (d, J = 7.0 Hz, 4 H), 7.20−7.08 (m, 10 H) ppm. ^{31}P NMR ($CDCl_3$): δ = 233.0 ppm. HR-MS (FAB): calcd. for $C_{25}H_{16}Cl_4P$ 486.9743; found 486.9718 [M + H$^+$].

DcpP=PDcp (1): To a rapidly stirred solution of DcpPCl$_2$ (0.87 g, 1.9 mmol) in ether (50 mL), a suspension of DcpPH[Li·OEt$_2$] (0.90 g, 2.0 mmol) in 50 mL of diethyl ether was added dropwise over 30 min. After 1 h, a solution of DBU (0.26 g, 1.7 mmol) in 5 mL of diethyl ether was added and the mixture stirred for 2 h. The bright yellow mixture was then filtered and the solvent removed in vacuo to afford a crude yellow solid. The solid was taken up in THF/hexanes (4:1) and cooled to −35 °C to yield **1** as a yellow powder (0.31 g, 23%). ^{1}H NMR (C_6D_6): δ = 7.02 (t, J = 8.0 Hz, 1 H), 6.97 (d, J = 8.0 Hz, 4 H), 6.88 (d, J = 8.0 Hz, 2 H), 6.61 (t, J = 8.0 Hz, 2 H) ppm. ^{31}P NMR (C_6D_6): δ = 500.3. UV/Vis (THF): ε (448 nm) = 626 cm^{-1} M^{-1}; ε (352 nm) = 8551 cm^{-1} M^{-1}. $C_{36}H_{18}P_2Cl_8$: calcd. C 54.31, H 2.28; found C 53.91, H 2.53.

Crystal data for **2**·*n*-C_6H_{14}: $C_{42}H_{18}Cl_6P_2$, M_r = 797.20, monoclinic, space group $C2/c$, a = 21.271(3), b =

12.587(2), c = 14.940(2) Å, β = 103.499(2)°, V = 3889.4(9) Å^3, Z = 4, $\rho_{calcd.}$ = 1.361 g cm^{-3}, $2\theta_{max}$ = 50°, Mo-K_α radiation, λ = 0.71073 Å, μ = 0.554 mm^{-1}. Crystal data for **4**: $C_{25}H_{15}Cl_4P$, M_r = 488.14, monoclinic, space group $C2/c$, a = 30.200(7), b = 8.335(2), c = 18.698(4) Å, β = 91.947(4)°, V = 4704(2) Å^3, Z = 8, $\rho_{calcd.}$ = 1.379 g cm^{-3}, $2\theta_{max}$ = 50°, Mo-K_α radiation, λ = 0.71073 Å, μ = 0.581 mm^{-1}. All data sets were collected with a Bruker SMART CCD diffractometer at 300(2) K. Lorentz polarization and empirical (SADABS) absorption corrections were applied. The structures were solved by direct methods and refined using SHELXTL. Non-hydrogen atoms were refined with anisotropic displacement parameters, and hydrogen atoms were placed in idealized positions and included as riding with U_{iso}(H) =1.3 U_{eq}(non-H). Of 17736 collected reflections for **1**, 6090 were unique (R_{int} = 0.0663). Final figures of merit for **1**: R = 0.0568 [$I > 2\sigma(I)$], Rw = 0.1142 (F^2, all data). Of 9341 collected reflections collected for **2**, 3360 were unique (R_{int} = 0.0326). Final figures of merit for **2**: R = 0.0425 [$I > 2\sigma(I)$], Rw = 0.1196 (F^2, all data). Of 11278 collected reflections for **4**, 4086 were unique (R_{int} = 0.0563). Final figures of merit for **4**: R = 0.0540 [$I > 2\sigma(I)$], Rw = 0.1161 (F^2, all data). The highest peaks in the final difference map were 0.609, 0.318 and 0.318 e Å^{-3} for **1**, **2** and **4**, respectively. CCDC-184750 (**1**), -184749 (**2**), and -184748 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of Group 14 1-Haloazametallatranes

Pavel L. Shutov,[a] Sergey S. Karlov,*[b] Klaus Harms,[a] Andrei V. Churakov,[c] Judith A. K. Howard,[c] Jörg Lorberth,*[a] and Galina S. Zaitseva[b]

Keywords: Azametallatranes / Silicon / Germanium / Tripodal ligands / Tin

The reaction between $MHal_4$ (M = Ge, Sn; Hal = Cl, Br) and $N(CH_2CH_2NRLi)_3$ (R = Me, $SiMe_3$) yields 1-haloazametallatranes **1**–**8**, $N(CH_2CH_2NR)_3M$–Hal (**1**, M = Ge, Hal = Cl, R = Me; **2**, M = Ge, Hal = Br, R = Me; **3**, M = Ge, Hal = Cl, R = $SiMe_3$; **4**, M = Ge, Hal = Br, R = $SiMe_3$; **5**, M = Sn, Hal = Cl, R = Me; **6**, M = Sn, Hal = Br, R = Me; **7**, M = Sn, Hal = Cl, R = $SiMe_3$; **8**, M = Sn, Hal = Br, R = $SiMe_3$). The composition and structures of the new compounds were established by elemental analyses, ^1H and ^{13}C NMR spectroscopy and mass spectrometry. Single crystal structures of **1** and **3** were determined by X-ray diffraction studies: both compounds show transannular Ge–N_{ax} interactions.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The chemistry of pentacoordinate complexes of the group 14 elements has attracted much attention, mostly from a theoretical point of view, with the nature of the intramolecular interaction the main subject of interest.[1–4] In addition, these species are ideal models for the investigation of nucleophilic substitution pathways in group 14 element chemistry.[5] During the last decade we have focussed our research interests on metallatranes containing symmetrical tripodal ligands of type **A** (Scheme 1).[4,6–10]

Metal derivatives of tripodal amines — azametallatranes (type **B**) — have greater chemical and structural flexibility than the "usual" metallatranes (type **C**) due to the influence of various substituents R (for example, R = H, Me, $SiAlk_3$, C_6F_5 etc.) on the structure and the chemical properties of these derivatives. Although azasilatranes have been known for some twenty years,[2] azagermatranes and azastannatranes are compounds which have been very little studied.[11–19]

Compounds containing an $SiAlk_3$ group apart from the equatorial nitrogen atoms (N_{eq}) of the azatrane skeleton are the subject of special interest among the group 14 element azametallatranes (**B**). Due to the extremely long Si–N_{ax} distance in the only structurally characterized example $[N(CH_2CH_2NSiMe_3)_3Si{-}CH_3]$[20] Verkade et al. coined the term "*quasi-azasilatranes*" for these rare silicon species.[2] The corresponding azastannatranes (**B**, R = $SiMe_3$) are as yet unknown and for germanium only $N(CH_2CH_2NSiMe_3)_3Ge$–allyl has been reported amongst the $N(CH_2CH_2NSiMe_3)_3Ge$–X derivatives prior to this work.[12]

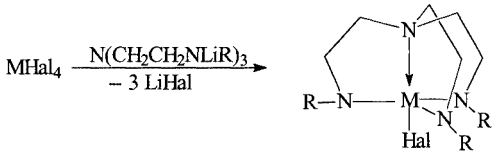
In this paper we report on the synthesis of 1-haloazametallatranes (M = Ge, Sn) by metathetical exchange reactions between $MHal_4$ (M = Ge, Sn; Hal = Cl, Br) and the trilithium salts of the parent amines $N(CH_2CH_2NHMe)_3$ (Me_3-tren) and $N(CH_2CH_2NHSiMe_3)_3$ (TMS_3-tren). Details of the X-ray crystal and molecular structures of $N(CH_2CH_2NMe)_3GeCl$ (**1**) and $N(CH_2CH_2NSiMe_3)_3GeCl$ (**3**) are also described.

Results and Discussion

Our aim was to obtain 1-haloazametallatranes as precursors for further synthetic applications and to find a new

improved method of preparation for azametallatranes of group 14 elements. 1-Haloazatranes of group 14 elements are those bearing reactive apical groups which have the possibility for further derivatization at the metal centre. Verkade et al. reported only a relatively complicated multistep procedure involving $N(CH_2CH_2NMe)_3Si-H$ and $N(CH_2CH_2NMe)_3Sn-NMe_2$ as intermediate products leading finally to 1-chloro-*N*,*N*′,*N*′′-trimethylazasilatranes and 1-chloro(bromo)-*N*,*N*′,*N*′′-trimethylazastannatranes.[16,21] We prepared azagermatranes **1** and **2** by transamination reactions of $HalGe(NMe_2)_3$ with Me_3-tren.[13]

Another method for building the main group element azatrane framework was previously only used for transition metals.[22] Tetrahalides (Hal = Cl, Br) of germanium and tin react readily with the trilithium salts of Me_3-tren and TMS_3-tren (in toluene at room temperature) to give 1-haloazametallatranes **1**−**8** in high yield (Scheme 2). The derivatives with Me_3-tren were purified by recrystallization from toluene/*n*-pentane while those of TMS_3-tren were purified by recrystallization from *n*-pentane. Lithium salts of Me_3-tren and TMS_3-tren are conveniently generated in situ by treatment of Me_3-tren or TMS_3-tren with the equivalent amount of *n*BuLi.



M = Ge; **1**, R = Me, Hal = Cl; **2**, R = Me, Hal = Br
3, R = $SiMe_3$, Hal = Cl; **4**, R = $SiMe_3$, Hal = Br
M = Sn; **5**, R = Me, Hal = Cl; **6**, R = Me, Hal = Br
7, R = $SiMe_3$, Hal = Cl; **8**, R = $SiMe_3$, Hal = Br

Scheme 2

The structures of **1**−**8** were confirmed by ^1H and ^{13}C NMR spectroscopy. In the ^1H NMR spectra of **1**−**8** the signals of the methylene protons of the azatrane skeleton appear as a set of two pseudo-triplets, forming an AA′BB′ spin system. This pattern is a general feature of the "atrane" framework for a variety of metallatranes.[1,2,4]

The reaction of silicon derivatives ($SiCl_4$, $SiBr_4$) with lithium salts of Me_3-tren and TMS_3-tren resulted in unidentifiable polymeric products.

To the best of our knowledge, compounds **1** and **3** (Figure 1 and 2, respectively) are the first structurally characterized azagermatranes. Molecules of **1** lie on a crystallographic threefold axis, while molecules of **3** possess approximate C_3 symmetry. The coordination polyhedron of the germanium atom in both compounds is a distorted trigonal bipyramid with the N(4) [for compound **3**; N(1) for compound **1**] and Cl atoms in the axial positions and the three nitrogen atoms in equatorial sites. The germanium atoms are displaced by 0.25 Å (for **3**) and by 0.22 Å (for **1**) from a plane defined by the three equatorial nitrogen atoms towards the chlorine substituent. The $N_{ax}-Ge-Cl$ angles are exactly 180° for **1** and 179.53(7)° for **3**. The Ge−Cl distances observed in **3** [2.2727(8) Å] and in **1** [2.2968(9) Å] are significantly longer than in the closely related 1-chlorogermatrane $N(CH_2CH_2O)_3Ge-Cl$ (**9**) [2.209(1) Å].[23] The $Ge-N_{ax}$ bonds [2.278(2) Å for **3** and 2.167(4) Å for **1**] are also longer than in **9** [2.096(3) Å]. Thus, a formal substitution of the oxygen atom in molecule **9** by a NCH_3 group (molecule **1**) results in a simultaneous increase of the Ge−Cl and $Ge-N_{ax}$ distances by 0.088 Å and 0.051 Å, respectively. With the same formal substitution in silatranes this leads to the opposite change in the Si−X and $Si-N_{ax}$ bond lengths, as found previously for the compounds $N(CH_2CH_2O)_3Si-OEt$ [$d(Si-O_{ax})$ = 1.699(2) Å, $d(Si-N_{ax})$ = 2.135(2) Å] and $N(CH_2CH_2NMe)_3Si-OEt$

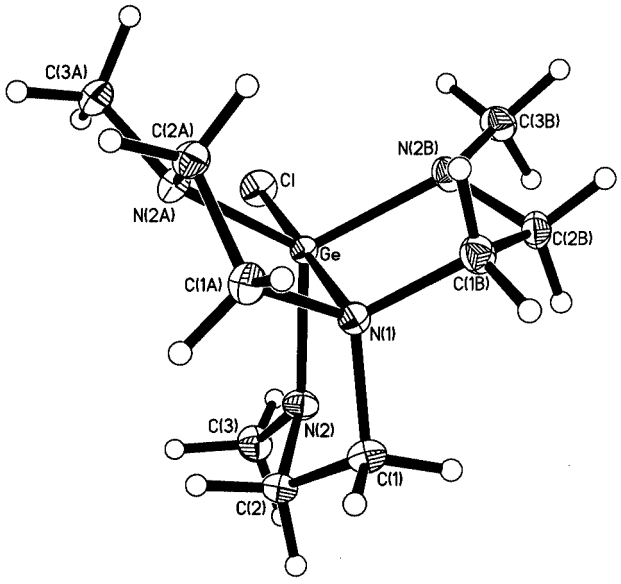


Figure 1. Molecular structure of compound **1**

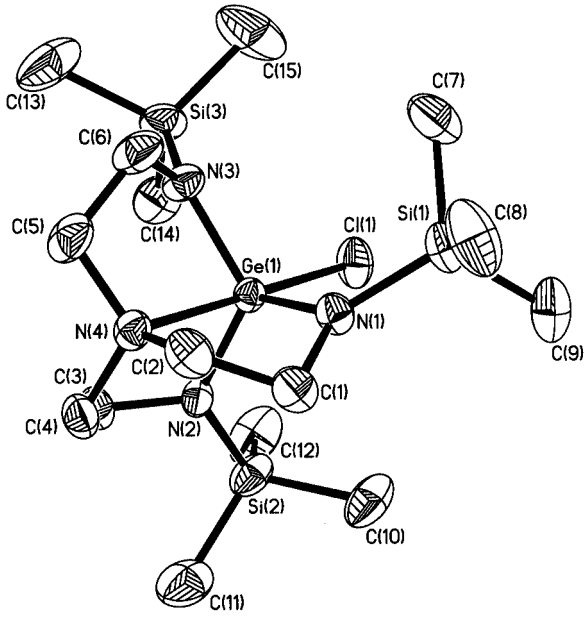

Figure 2. Molecular structure of compound **3**; hydrogen atoms have been omitted for clarity

[d(Si−O_{ax}) = 1.658 Å, d(Si−N_{ax}) = 2.152 Å (averaged for two independent molecules)].[24,25] The Ge−N_{ax} distance in **3** [2.278(2) Å] lies within the typical range for germatranes [2.081(5)−2.32(1) Å][26,27] and clearly verifies the existence of a Ge−N transannular bond in **3**. In contrast, the Si analogue of **3**, $N(CH_2CH_2NSiMe_3)_3Si-CH_3$, possesses an extremely long Si−N_{ax} bond [2.775(7) Å].[20] The Ge−N_{ax} bond length in **1** [2.167(4) Å] is noticeably shorter than that in **3** [2.278(2) Å]; the Ge−N_{eq} distances are 1.837(2) Å, 1.838(2) Å and 1.838(2) Å for **3** and 1.858(1) Å for **1**.

The environment at the N_{ax} atoms is approximately tetrahedral with C−N_{ax}−C and C−N_{ax}−Ge angles ranging between 104.1(2)° and 114.4(3)° for **3** and 106.3(2)° and 112.5(2)° for **1**. The axial nitrogen atoms are displaced by 0.37 Å (for **3**) and by 0.42 Å (for **1**) from a plane defined by the three carbon atoms towards germanium.

All five-membered rings of the atrane skeleton in **1** and **3** adopt an ''envelope''-like conformation; for both **1** and **3** all carbon atoms in the positions β to the N_{ax} atom occupy ''flap'' sites, while the C-α atoms form the base of an envelope plane, the latter being unusual for germatranes without C-β substituents.[9]

Conclusion

In summary, metathetical exchange reactions between $MHal_4$ (M = Ge, Sn; Hal = Cl, Br) and the lithiated parent amines afford compounds **1**−**8** in good yields. The presence of a transannular Ge←N interaction in **1** and **3** was confirmed by X-ray diffraction analyses. Further studies on the application of this reaction for the synthesis of main group element azametallatranes and an investigation of their chemical behaviour are in progress.

Experimental Section

General Remarks: All manipulations were performed under dry, oxygen-free argon atmosphere using standard Schlenk techniques. Solvents were dried by standard methods and distilled prior to use. $MHal_4$ (M = Si, Ge, Sn; Hal = Cl, Br) (Aldrich) were used as supplied. Starting materials Me_3-tren[28] and TMS_3-tren[12] were prepared according to the literature. C_6D_6 was obtained from Deutero GmbH and dried over sodium. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AC200 spectrometer. ^{1}H and ^{13}C chemical shifts are reported in ppm relative to Me_4Si as external standard. Elemental analyses were carried out by the Microanalytical Laboratory of the Chemistry Department of the Moscow State University and by that of the Fachbereich Chemie of the Philipps-University of Marburg (Heraeus-Rapid-Analyser). Mass spectra (EI-MS) were recorded on a VARIAN CH-7a device using electron impact ionization at 70 eV; mass spectra (FD-MS) were recorded on a HP-5989B device; all assignments were made with reference to the most abundant isotopes.

1-Chloro-*N*,*N*′,*N*′′-trimethylazagermatrane (1): A 1.6 M *n*BuLi solution (4.88 mL, 7.8 mmol) in hexane at room temperature was added dropwise to a stirred solution of Me_3-tren (0.48 g, 2.6 mmol) in 40 mL of toluene. The reaction mixture was stirred for 5 h and a solution of $GeCl_4$ (0.55 g, 2.6 mmol) in 10 mL of toluene was added dropwise at room temperature. After stirring for a further 24 h a white precipitate of LiCl was filtered off. Most of the volatiles were then evaporated in vacuo and 10 mL of *n*-pentane was added. A white crystalline solid was separated by filtration, washed with cold *n*-pentane (3 × 5 mL) and dried in vacuo. Yield: 0.50 g (65%). ^{1}H NMR and ^{13}C NMR spectroscopic data were consistent with those already reported.[13]

1-Bromo-*N*,*N*′,*N*′′-trimethylazagermatrane (2): Following the same experimental procedure as above for **1** using Me_3-tren (0.50 g, 2.7 mmol), a 1.6 M *n*BuLi solution in hexane (5.06 mL, 8.1 mmol) and $GeBr_4$ (1.04 g, 2.7 mmol), colourless crystals (0.63 g, 69%) were obtained. ^{1}H NMR, ^{13}C NMR and EI MS data were consistent with those already reported.[13]

1-Chloro-*N*,*N*′,*N*′′-tris(trimethylsilyl)azagermatrane (3): A 1.6 M *n*BuLi solution in hexane (4.67 mL, 7.5 mmol) at room temperature was added dropwise to a stirred solution of TMS_3-tren (0.90 g, 2.5 mmol) in 40 mL of toluene. The reaction mixture was stirred for 5 h and a solution of $GeCl_4$ (0.53 g, 2.5 mmol) in 10 mL of toluene was added dropwise at room temperature. The mixture was stirred for another 24 h. Removal of all volatiles in vacuo followed by extraction of the residue with 20 mL of *n*-pentane gave a yellowish extract. The solution was reduced in volume by 50% and stored at −30 °C to obtain colourless crystals **3** (0.81 g, 70%). ^{1}H NMR (C_6D_6, 200.13 MHz): δ = 0.40 (s, 27 H, $SiCH_3$), 1.81 (t, ^1J = 6 Hz, 6 H, CH_2N), 2.59 (t, ^1J = 6 Hz, 6 H, CH_2NSi) ppm. ^{13}C NMR (C_6D_6, 50.32 MHz): δ = 2.41 ($SiCH_3$), 41.03 (CH_2N), 58.79 (CH_2NSi) ppm. EI MS: *m*/*z* (%) = 468 (13) [M^+], 453 (21) [M^+ − CH_3], 433 (7) [M^+ − Cl], 367 (100) [M^+ − Me_3SiNCH_2], 353 (17) [M^+ − $Me_3SiNCH_2CH_2$]. $C_{15}H_{39}ClGeN_4Si_3$ (467.8): calcd. C 38.51, H 8.40, N 11.98; found C 38.21, H 8.63, N 11.73.

1-Bromo-*N*,*N*′,*N*′′-tris(trimethylsilyl)azagermatrane (4): Using the same experimental procedure as above for **3** employing TMS_3-tren (1.85 g, 5.1 mmol), 9.56 mL of a 1.6 M *n*BuLi solution (15.3 mmol) in hexane and $GeBr_4$ (2.00 g, 5.1 mmol), colourless crystals **4** (1.72 g, 66%) were obtained from an *n*-pentane solution at −30 °C. ^{1}H NMR (C_6D_6, 200.13 MHz): δ = 0.43 (s, 27 H, $SiCH_3$), 1.82 (t, ^1J = 6 Hz, 6 H, CH_2N), 2.59 (t, ^1J = 6 Hz, 6 H, CH_2NSi) ppm. ^{13}C NMR (C_6D_6, 50.32 MHz): δ = 2.63 ($SiCH_3$), 41.34 (CH_2N), 59.14 (CH_2NSi). FD-MS: *m*/*z* (%) = 512 (21) [M^+], 433 (100) [M^+ − Br]. $C_{15}H_{39}BrGeN_4Si_3$ (512.3): calcd. C 35.17, H 7.67, N 10.94; found C 35.43, H 7.49, N 11.15.

1-Chloro-*N*,*N*′,*N*′′-trimethylazastannatrane (5): The procedure was analogous to that for **1**: reaction of Me_3-tren (1.06 g, 5.6 mmol) with 10.56 mL of a 1.6 M *n*BuLi solution (16.9 mmol) in hexane and then with $SnCl_4$ (1.46 g, 5.60 mmol) gave **5** as a white crystalline solid. Yield: 1.31 g (69%). ^{1}H NMR and ^{13}C NMR spectroscopic data were consistent with those already reported.[16]

1-Bromo-*N*,*N*′,*N*′′-trimethylazastannatrane (6): The procedure was analogous to that for **1**: reaction of Me_3-tren (1.77 g, 9.4 mmol) with 17.63 mL of a 1.6 M *n*BuLi solution (28.2 mmol) in hexane and then with $SnBr_4$ (4.12 g, 9.4 mmol) gave **6** as a white crystalline solid. Yield: 2.58 g (71%). ^{1}H NMR and ^{13}C NMR spectroscopic data were consistent with those already reported.[16]

1-Chloro-*N*,*N*′,*N*′′-tris(trimethylsilyl)azastannatrane (7): The procedure was analogous to that for **3**: reaction of TMS_3-tren (0.93 g, 2.6 mmol) with 4.81 mL of a 1.6 M *n*BuLi solution (7.7 mmol) in hexane and then with $SnCl_4$ (0.68 g, 2.6 mmol) gave **7** as a white crystalline solid. Yield: 0.84 g (63%). ^{1}H NMR (C_6D_6, 200.13 MHz): δ = 0.38 (s, 27 H, $SiCH_3$), 1.81 (t, ^1J = 6 Hz, 6 H, CH_2N), 2.71 (t, ^1J = 6 Hz, 6 H, CH_2NSi) ppm. ^{13}C NMR (C_6D_6,

The Reaction of (Butadiene)zirconocene with Imines

Carsten Höltke,[a] Gerhard Erker,*[a] Gerald Kehr,[a] Roland Fröhlich,[a][‡] and Olga Kataeva[a][‡]

Keywords: Template synthesis / Zirconium / Metallocenes / Polymerizations

(Butadiene)zirconocene (*s-trans-*/*s-cis-***1** equilibrium mixture) reacts with the imine MeN=CHPh (**7a**) to form the 1:1 carbon-coupling product [κ*N*-MeN–CHPh–CH_2–η^3-(CHCHCH_2)]ZrCp_2 (**8a**). The X-ray crystal structure analysis of **8a** revealed a metallacyclic structure featuring a distorted π-allyl moiety and a planar-tricoordinate nitrogen atom. Only one of the two possible diastereoisomers is found in the crystal (*cis*-**8a**) as well as in solution. Treatment of **1** with the more bulky aldimine $PhCH_2N$=CHPh (**7b**) selectively gave the corresponding 1:1 addition product *trans*-**8b**. Ketimines $PhCH_2N=C(CH_2)_4$ (**7c**), HN=CPh_2 (**7d**), or Δ^1-2-methylpyrroline (**7e**) also reacted selectively with (butadiene)zirconocene to yield the analogous metallacyclic C–C coupling products **8c**–**e**. Treatment of **8e** with $B(C_6F_5)_3$ proceeded cleanly by abstraction of a hydride anion from the carbon atom α to the nitrogen atom to form the intramolecularly coordinated imine product **10a** {with the [$HB(C_6F_5)_3^-$] anion}. Similarly, Ph_3C^+ abstracts a hydride ion from **8e** to yield **10b** {isolated with the [$B(C_6H_5)_4^-$] anion}. Proton addition from HNR_3^+ reagents takes place selectively at the Zr–amido nitrogen atom of the complexes **8a** or **8d** to yield the substituted (π-allyl)zirconocene cation complexes **11** or **12**, respectively, The cationic complexes **10**, **11**, and **12** polymerize ethene at room temperature/2 bar of ethene with moderate catalytic activities.

Introduction

(Butadiene)zirconocene (**1**) has been used repeatedly as a reagent in organometallic and organic synthesis[1] as well as in catalysis.[2] Compound **1** is remarkable since it exists as a mixture of the two stereoisomers, (*s-cis-*) and (*s-trans-*η^4-C_4H_6)ZrCp_2.[3] It is readily prepared by treatment of the metallocene dihalide with "butadiene−magnesium".[4,5] Several alternative syntheses of **1** have been described in the literature.[3,6]

The (η^4-butadiene)zirconocene system reacts with a variety of unsaturated organic or organometallic reagents with carbon−carbon coupling. In many cases 1:1 or 1:2 addition products were obtained selectively. Their further transformation including hydrolytic workup has opened attractive synthetic pathways to novel Fischer carbene complexes,[1,7] stable conjugated primary enamines,[8] β,γ-unsaturated ε-hydroxycarboxylic acids,[9] and other organic building blocks.[10] Typical examples of organometallic products formed in these addition reactions are shown in Scheme 1.

It is noteworthy that the addition of organic carbonyl compounds leads to seven-membered metallacycles **4** that exhibit a strong metal−oxygen interaction caused by a marked oxygen-to-Zr π-backbonding component,[11] whereas the formally related zirconoxycarbene complexes **3** typically show a metallacyclic π-allyl structure.[7] Five-mem-

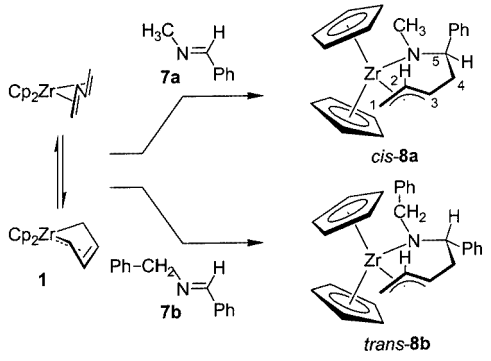
bered tautomeric mixtures (**5** ⇄ **6**) were observed in the case of the 1:1 addition products between **1** and nitriles.[8] The metallacyclic structural type actually favored in such systems thus seems to depend strongly on the specific electronic features of the subunits involved, especially on the π-backbonding ability of the heteroatom that is σ-attached to the zirconocene unit.[2,5] We have now treated (butadiene)-zirconocene with a variety of organic imines and found that the formation of metallacyclic 1:1 addition products is favored. The systems were structurally characterized and their remarkable reaction with some electrophiles was studied.

Results and Discussion

Addition of Aldimines

We have employed the benzaldimines **7a** and **7b** for the addition reaction with (butadiene)zirconocene (**1**). The reactions were carried out in toluene solution at ambient temperature. Both addition reactions required ca. 2 d of reaction time under these conditions to go to completion. The 1:1 addition products **8a** and **8b** were formed selectively (see Scheme 2). We did not observe the formation of any 1:2 addition products, even in the presence of excess imine.[12] The products were isolated as yellow to orange-colored solids in 60% (**8a**) and 45% (**8b**) yield.



Scheme 2

Single crystals of **8a** were obtained from dichloromethane (Figure 1). The structure shows that a new C−C connection has been formed between the heterocarbonyl carbon atom of the imine reagent **7a** and a terminal sp^2-carbon center of the butadiene ligand in **1** [C4−C5: 1.525(4) Å]. The metallocene complex **8a** contains a metallacyclic substructure located in the bent metallocene σ-plane, that contains a distorted η^3-allyl moiety. It exhibits short Zr−C1 [2.472(3) Å] and Zr−C2 [2.487(3) Å] bonds and a markedly longer Zr−C3 contact [2.618(3) Å]. The carbon−carbon bond lengths inside the π-allyl unit are distorted towards a σ,π-type structure [C1−C2: 1.417(4) Å; C2−C3: 1.356(4) Å].[13] The Zr−N bond in **8a** is rather short at 2.157(2) Å. The nitrogen center in complex **8a** is trigonally planar coordinated (sum of bonding angles at N: 354.7°).

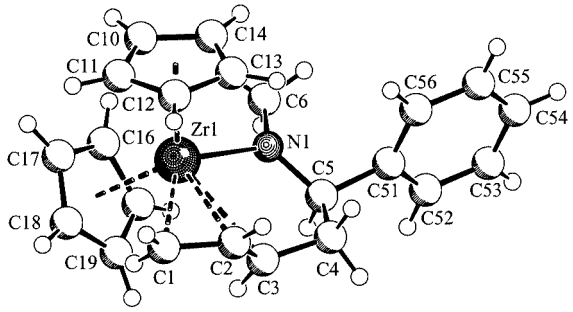


Figure 1. Molecular structure of **8a**; selected bond lengths [Å] and angles [°]: Zr1−N1 2.157(2), Zr1−C1 2.472(3), Zr1−C2 2.487(3), Zr1−C3 2.618(3), C1−C2 1.417(4), C2−C3 1.356(4), C3−C4 1.481(4), C4−C5 1.525(4), C5−N1 1.459(3), N1−C6 1.453(3); N1−Zr1−C1 123.9(1), N1−Zr1−C2 91.7(1), N1−Zr1−C3 67.4(1), C1−Zr1−C2 33.2(1), C1−Zr1−C3 57.3(1), C2−Zr1−C3 30.7(1), Zr1−N1−C5 128.0(2), Zr−N1−C6 116.6(2), Zr1−C1−C2 74.0(2), C1−C2−Zr1 72.8(2), C3−C2−Zr1 80.0(2), C2−C3−Zr1 69.3(2), C4−C3−Zr1 109.1(2), C1−C2−C3 123.7(3), C2−C3−C4 124.3(3), C3−C4−C5 107.6(2), C4−C5−N1 108.0(2), C5−N1−C6 110.1(2); C1−C2−C3−C4 160.9(3)

The formation of a new bond to the former imine sp^2-carbon atom has created a chiral center (C5) in **8a**. In addition, the substituted (π-allyl)$ZrCp_2$ subunit contains an element of planar chirality. Thus, two diastereoisomers could have been formed. However, only one is observed in the crystal. It is characterized by a *cis* orientation of the phenyl group at C5 and the π-allyl "*meso*"-hydrogen atom at C2 (*cis*-**8a**).

Single crystals of **8b** suitable for an X-ray crystal structure analysis were obtained from a toluene solution. In the asymmetric unit there are two crystallographically almost identical enantiomeric molecules. It exhibits an analogous metallacyclic framework to that of **8a**, containing a σ,π-distorted π-allyl unit [Zr−C1: 2.479(5) Å; Zr−C2: 2.511(4) Å; Zr−C3: 2.597(3) Å; C1−C2: 1.409(7) Å; C2−C3: 1.370(6) Å; values taken from molecule A]. The Zr−N σ-bond length in **8b** is found to be 2.185(3) Å and the nitrogen center is coordinated in a trigonally planar manner (sum of bonding angles: 358.0°). The major difference from **8a** is that the phenyl substituent of **8b** at C5 is *trans*-oriented relative to the 2-H at the π-allyl unit (see Figure 2). This may derive from a steric basis: in **8b**, the bulky C_6H_5 group of the *N*-benzyl substituent is found clearly oriented away from the C5 phenyl group.

In solution, only a single diastereoisomer of **8a** was observed, which is probably the *cis*-**8a** isomer. It exhibits a diastereotopic pair of ^{1}H NMR Cp singlets at δ = 5.87 and 5.82 ppm (in CD_2Cl_2 at 298 K). The (*E*)-configured monosubstituted π-allyl unit of **8a** is characterized by ^{13}C NMR signals at δ = 42.9 (C1), 124.7 (C2), and 110.5 (C3) as well as ^{1}H NMR resonances at δ = 2.19/1.89 (1-H, 1-H′), 5.80 (2-H), and 5.02 (3-H) with a characteristic set of coupling constants [^2J(1-H, 1-H′) = 3.0 Hz, ^3J(1-H_{syn}, 2-H) = 8.0 Hz, ^3J(1-H_{anti}, 2-H) = 14.5 Hz, and ^3J(2-H, 3-H) = 15.0 Hz]. The proton 5-H (δ = 4.60 ppm) shows a

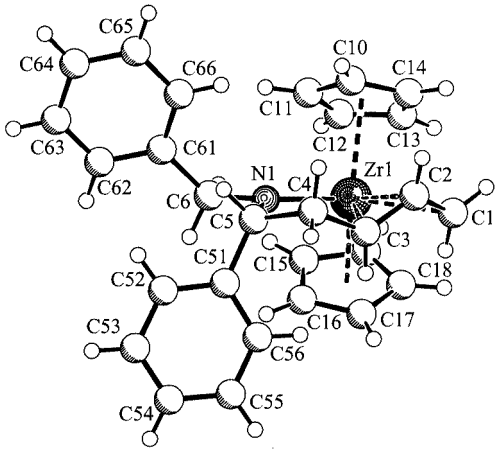

Figure 2. A view of the molecular structure of *trans*-**8b**; selected bond lengths [A] and angles [°] (molecule A): Zr1−N1 2.185(3), Zr1−C1 2.479(5), Zr1−C2 2.511(4), Zr1−C3 2.597(4), C1−C2 1.409(7), C2−C3 1.370(6), C3−C4 1.487(6), C4−C5 1.535(5), C5−N1 1.473(5), N1−C6 1.462(5); N1−Zr1−C1 123.7(2), N1−Zr1−C2 92.4(2), N1−Zr1−C3 67.2(2), C1−Zr1−C2 32.8(2), C1−Zr1−C3 57.0(2), C2−Zr1−C3 31.1(1), Zr1−N1−C5 129.9(2), Zr−N1−C6 118.2(2), Zr1−C1−C2 74.9(3), C1−C2−Zr1 72.3(3), C3−C2−Zr1 77.9(2), C2−C3−Zr1 71.0(3), C4−C3−Zr1 110.5(3), C1−C2−C3 121.3(5), C2−C3−C4 125.9(4), C3−C4−C5 110.1(3), C4−C5−N1 107.3(3), C5−N1−C6 109.9(3); C1−C2−C3−C4 −162.5(4)

large (anti-periplanar) coupling of ^3J(4-H′, 5-H) = 11.5 Hz and a small (gauche) coupling of ^3J(4-H, 5-H) = 7.2 Hz. Together with the coupling constants at 4-H/4-H′ of ^2J(4-H′, 4-H) = 12.0 Hz, ^3J(4-H′, 3-H) = 11.5 Hz, and ^3J(4-H, 3-H) = 3.5 Hz, this places the C5 phenyl substituent of complex **8a**, in solution, in a *cis* orientation relative to the 2-H *meso*-proton, just as it is found in the solid state structure. The NMR spectroscopic features of complex **8b** are similar (see Tables 1 and 2), but in detail specifically different. In **8b**, the 5-H proton shows only small coupling to 4-H/4-H′ (ca. 7 Hz) which indicates the presence of the *trans*-**8b** isomer in solution, analogously as it is found in the solid state (see Scheme 2).

Table 1. Selected ^{1}H NMR spectroscopic features of the complexes **8**, **10** and **11**

[a] Chemical shifts in CD_2Cl_2 at 298 K. [b] 253 K. [c] 273 K. [d] In [D_5]bromobenzene at room temperature. [e] Room temperature [D_6] benzene/[D_8] THF (4:1).

Reaction of (Butadiene)zirconocene with Ketimines

The reaction of **1** with imine **7c** of *N*-benzylcyclopentanone in toluene at room temperature required 2 d to go to completion. Again, only a 1:1 addition product was detected (**8c**), which was isolated in ca. 80% yield. Single crystals of **8c** were obtained from toluene. There are two crystallographically independent but chemically equivalent molecules of **8c** in the asymmetric unit; the values given below correspond to molecule A. The X-ray crystal structure analysis showed the presence of the typical metallacyclic framework (see Figure 3), featuring a nitrogen center that is close to being sp^2-hybridized [sum of bonding angles: 355.3°; angle Zr−N−C5: 128.5(2)°] and bonded to the zirconium atom [Zr−N: 2.178(3) Å], and a distorted η^3-allyl moiety [Zr−C1: 2.473(4) Å; Zr−C2: 2.491(4) Å; Zr−C3: 2.635(4) Å; C1−C2: 1.406(6) Å; C2−C3: 1.373(5) Å] inside a rigid metallacycle. The benzyl substituent at the nitrogen atom in **8c** attains a similar conformational orientation as was observed for **8b** (see above). The spiro-annelated carbocyclic five-membered ring at C5 occupies a pseudoaxial and a pseudoequatorial substituent position with its C−C bonds at the slightly crown-shaped central heterometallacycle.

In solution, complex **8c** shows the typical ^{1}H/^{13}C NMR spectroscopic features of the metallacyclic π-allyl complex systems (see Tables 1 and 2), so we can assume that the structures of **8c** in solution are similar to that of the solid state.

Imine **7d** of benzophenone also adds cleanly to (butadiene)zirconocene. The reaction takes only ca. 7 h to go to completion. The metallacyclic 1:1 addition product **8d** was

Molecular structure of complex **8c**; selected bond lengths [Å] and angles [°]: Zr1−N1 2.178(3), Zr1−C1 2.473(4), Zr1−C2 2.491(4), Zr1−C3 2.635(4), C1−C2 1.406(6), C2−C3 1.373(5), C3−C4 1.476(5), C4−C5 1.534(5), C5−N1 1.487(5), N1−C6 1.476(5); N1−Zr1−C1 123.3(1), N1−Zr1−C2 91.4(1), N1−Zr1−C3 67.2(1), C1−Zr1−C2 32.9(1), C1−Zr1−C3 57.1(1), C2−Zr1−C3 30.9(1), Zr1−N1−C5 128.5(2), Zr−N1−C6 115.0(2), Zr1−C1−C2 74.3(2), C1−C2−Zr1 72.8(2), C3−C2−Zr1 80.3(2), C2−C3−Zr1 68.8(2), C4−C3−Zr1 108.8(2), C1−C2−C3 123.2(4), C2−C3−C4 125.7(4), C3−C4−C5 110.0(3), C4−C5−N1 105.2(3), C5−N1−C6 111.8(3); C1−C2−C3−C4 −160.5(4)

isolated in 74% yield as a pale yellow solid. The ^{1}H NMR spectrum of **8d** (in CD_2Cl_2) shows a large separation of the signals of the diastereotopic Cp ligands (δ = 5.85 and 5.26 ppm). The typical π-allyl resonances of **8d** are listed in Tables 1 and 2. The broad NH ^{1}H NMR resonance of **8d** is found at δ = 1.71 ppm (in CD_2Cl_2). Figure 4 shows a typical ^{1}H NMR spectrum of complex **8d**.

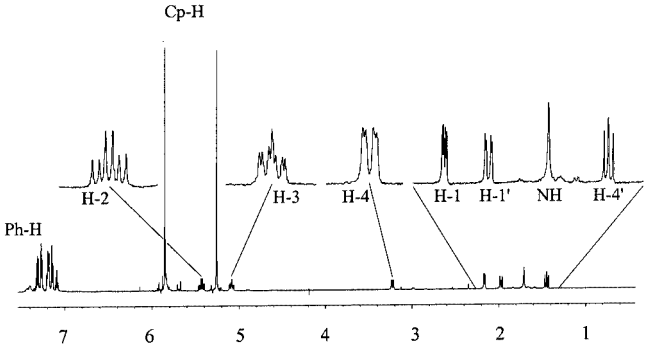

Figure 4. ^{1}H NMR spectrum of **8d** (CD_2Cl_2, 600 MHz, 298 K, δ in ppm)

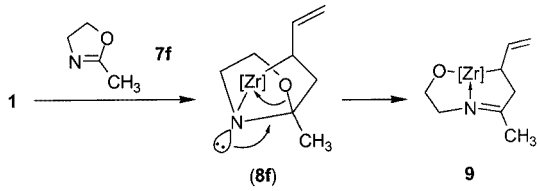
Addition of the cyclic imine Δ^1-2-methylpyrroline (**7e**) to **1** at room temperature gave **8e** (single diastereomer, 60% isolated, for characterization see Tables 1 and 2, and the Exp. Sect.). The complexes **8c**−**e** were also characterized by ^{15}N NMR spectroscopy.[14] They showed ^{15}N NMR resonances at δ = −279 (**8c**), δ = −254 (**8d**), and δ = −249 ppm (**8e**) (external reference: nitromethane, δ = 0 ppm). These values are in a range that is typical for trigonal-planar nitrogen derivatives[15] including zirconocene-bound amido ligands.[16]

Reaction of 2-Methyl-2-oxazoline with (Butadiene)zirconocene

The reaction of **1** with the oxazoline reagent **7f** takes place slowly at room temperature in toluene solution (see Scheme 4). Workup after 20 h of reaction time gave the product **9** in ca. 80% yield, which was different from the expected simple addition product **8f**. Single crystals were obtained from toluene solution that allowed **9** to be structurally characterized by X-ray diffraction. The result of the X-ray crystal structure analysis (see Figure 5) revealed that the oxazoline heterocycle had been opened in the course of the reaction, and that a thermodynamically favorable zirconium−oxygen bond had been formed. Related ring-opened products have previously been obtained by Rosenthal et al. in the reaction of a [η^2-bis(trimethylsilyl)acetylene]zirconocene complex with thiazoles or benzoxazole.[17]



Scheme 4

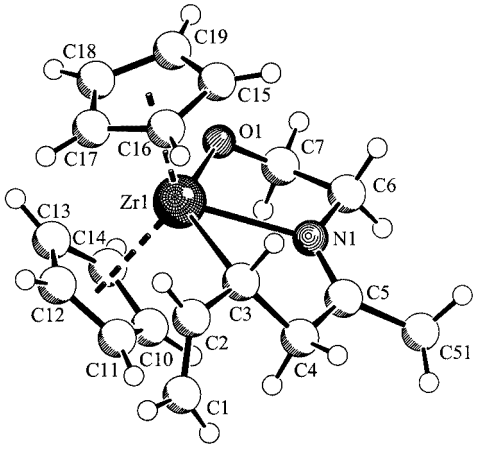


Figure 5. Molecular structure of complex **9**; selected bond lengths [Å] and angles [°]: Zr1−O1 2.094(2), Zr1−N1 2.378(2), Zr1−C3 2.448(2), C1−C2 1.336(4), C2−C3 1.470(3), C3−C4 1.517(3), C4−C5 1.491(4), C5−N1 1.279(3), N1−C6 1.467(3), C6−C7 1.492(4), C7−O1 1.365(3); O1−Zr1−N1 69.8(1), O1−Zr1−C3 135.2(1), N1−Zr1−C3 66.2(1), C7−O1−Zr1 123.4(2), Zr1−N1−C5 122.9(2), Zr−N1−C6 114.6(2), C2−C3−Zr1 118.8(2), C4−C3−Zr1 110.5(2), C1−C2−C3 128.3(3), C2−C3−C4 114.0(2), C3−C4−C5 110.6(2), C4−C5−N1 115.9(2), C5−N1−C6 121.8(2), N1−C6−C7 106.2(2), C6−C7−O1 111.2(2); C1−C2−C3−C4 −13.3(4)

In the reaction a metallabicyclic framework has been formed. The structural core is made up of an eight-membered ring comprising the zirconium atom, the −O−CH_2−CH_2−N=C(CH_3)− core of the oxazoline reagent, and two butadiene carbon atoms. The metallabicyclic structure is formed from building up a close transannular

zirconium−nitrogen contact. In **9** the Zr−O bond length is 2.094(2) Å, which is rather long and indicates the absence of a significant O→Zr π-interaction.[18] Consequently, the Zr−O−C7 bond angle is in the "normal" range at 123.4(2)°.

The N−C5 bond length is 1.279(3) Å, which clearly indicates the presence of an imine-type N=C double bond.[19] Consequently, the remaining lone pair on the N atom is used to coordinate to the zirconium atom [Zr−N: 2.378(2) Å]. The coordination geometry at the nitrogen atom in **9** is trigonal-planar (sum of bonding angles: 359.3°) as is the adjacent sp^2-hybridized carbon atom C5 (360°). The lateral Zr−C σ-bond length is 2.448(2) Å. The σ-ligand angle at the five-coordinate zirconium atom in **9** is rather large [O−Zr−C3: 135.2(1)°]. It is divided almost equally by the central N−Zr dative bond [O−Zr−N: 69.8(1)°; N−Zr−C3: 66.2(1)°]. The remaining vinyl group at C3 does not interact with the zirconium atom. It is pointing away from the metal center and is rotated out of the σ-plane [dihedral angle C4−C3−C2−C1: −13.3(4)°]. Consequently, a typical $C(sp^3)-C(sp^2)$ σ-bond length is observed for C2−C3 [1.470(3) Å]. The C1−C2 length [1.336(4) Å] denotes the presence of a C=C double bond.[19]

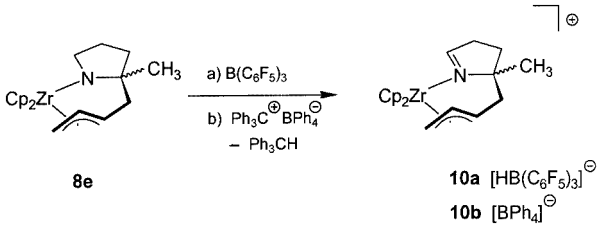
The ^{13}C NMR spectrum of complex **9** shows a typical imine carbon resonance of the N=C unit at δ = 187.2 ppm and a corresponding ^{15}N NMR signal at δ = −105.6.[14] The C4 ^{13}C NMR resonance of **9** is observed at δ = 48.8 ppm with a $^1J_{CH}$ coupling constant of 121 Hz, similar to the C3 resonance (δ = 52.6 ppm, $^1J_{CH}$ = 125 Hz). The C1 (δ = 97.5 ppm, $^1J_{CH}$ = 157 Hz and 151 Hz) and C2 (δ = 147.9 ppm, $^1J_{CH}$ = 144 Hz) signals indicate the presence of a σ-allyl group [^1H NMR signals at δ = 6.23 (2-H), 4.36, and 4.19 (1-H/1-H′) ppm]. Complex **9** exhibits a pair of equal-intensity ^1H NMR signals for the diastereotopic Cp ligands at δ = 5.95 and 5.70 ppm.

It is conceivable that the reaction of **1** with the oxazoline **7f** initially takes the usual course, and the addition product **8f**, that already contains the essential newly formed carbon−carbon bond, is actually formed. The applied reaction conditions probably favor thermodynamically controlled product formation. A subsequent β-oxygen elimination pathway that transforms **8f** to the more stable product **9** is viable (see Scheme 4).

Reactions of the Complexes 8 with Electrophiles

The reaction of alkylzirconocene complexes with activator Lewis acids, such as $B(C_6F_5)_3$[19,20] or the salt $[Ph_3C^+][B(C_6H_5)_4^-]$,[21] mostly proceeds with abstraction of an alkyl anion equivalent from the metal center with formation of a metallocene-derived cation.[22] Such cations often serve as very active homogeneous Ziegler−Natta catalysts for α-olefin polymerization.[23] In this context we were interested to learn about the favored reaction pathways that might be followed upon treatment of the heteroatom-functionalized metallacycles **8** with such electrophilic reagents.

We first reacted the bicyclic (butadiene)zirconocene/imine addition product **8e** with tris(pentafluorophenyl)borane (Scheme 5). The starting materials were dissolved in dichloromethane at 0 °C, and their reaction was then allowed to go to completion over 1 h at room temperature. The resulting product **10a** was isolated as an amorphous solid in greater than 80% yield. The NMR spectroscopic analysis showed that the $B(C_6F_5)_3$ electrophile had not attacked the Zr−allyl group (see Table 1). Instead, the borane had selectively abstracted a hydride from the C8 methylene group adjacent to the nitrogen atom, with formation of a κ*N*-coordinated imine.[24] The ^{11}B NMR spectrum of the salt shows a characteristic doublet (δ = −24.9 ppm, $^1J_{BH}$ = 85 Hz) of the $[HB(C_6F_5)_3^-]$ anion. In addition, the typical $^1H/^{13}C$ NMR spectroscopic features of the metal−imine moiety are observed at δ = 7.42 (8-H) and 183.5 ppm (C8), which were shifted drastically from the respective resonances of the starting material [**8e**: δ = 3.22, 2.90 (8-H); δ = 56.0 ppm (C8)].



Scheme 5

An even more pronounced $\Delta\delta^{15}N$ value was observed upon transforming the neutral starting material **8e** ($\delta^{15}N$ = −249 ppm) to the salt **10a** ($\delta^{15}N$ = −89 ppm). Figure 6 shows the characteristic appearance of the ^1H NMR spectrum of complex **10a** in [D_5]bromobenzene (the *H*BAr_3^- ^1H NMR resonance was not observed).

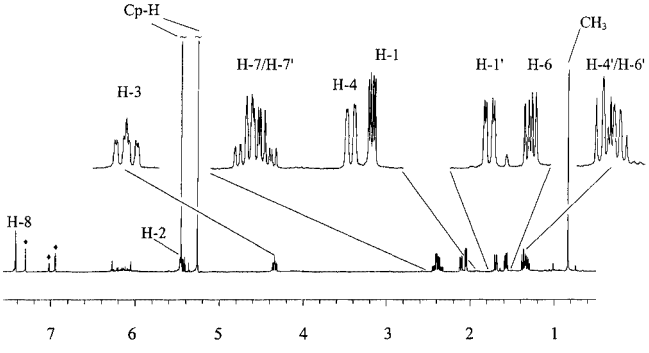


Figure 6. ^1H NMR spectrum of **10a** in [D_5]bromobenzene (600 MHz, 298 K, δ in ppm, black diamonds = solvent peaks)

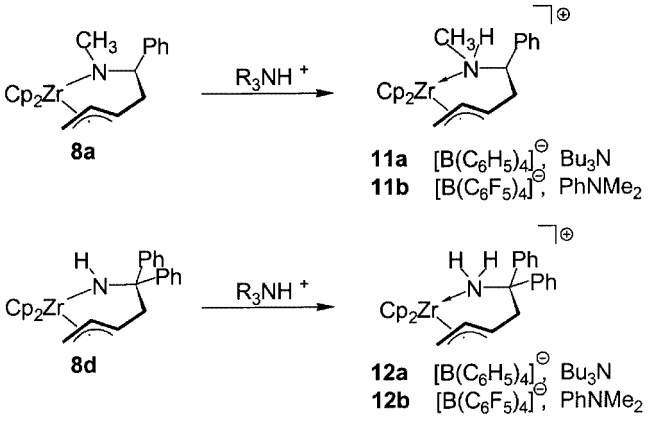
Treatment of **8e** with trityl tetraphenylborate proceeded similarly. Hydride abstraction[25] from C8 takes place cleanly with formation of triphenylmethane and the organometallic salt **10b**.

We then treated the complexes **8a** and **8d** with both the ammonium Brønsted acids $[Bu_3NH^+][B(C_6H_5)_4^-]$ and $[PhNMe_2H^+][B(C_6F_5)_4^-]$.[26,27] Again, the Zr(π-allyl) moiety proved to be inert to electrophilic attack. Instead, in both cases it is the amido nitrogen atom that picks up the proton. We isolated the respective salts **11** and **12** [with

BPh_4^- (**a**) or $B(C_6F_5)_4^-$ (**b**) anions, respectively, see Scheme 6]. Both systems show the typical ^1H and ^{13}C NMR spectroscopic features of the remaining substituted (η^3-allyl)zirconocene moiety (see Tables 1 and 2). Protonation at the nitrogen atom has resulted in characteristic ^1H NMR spectroscopic features of **11b**, such as the $N-CH_3$ doublet at $\delta = 2.27$ ppm and the characteristic triplet of doublets of 5-H at $\delta = 4.09$ ppm (see Figure 7).



Scheme 6

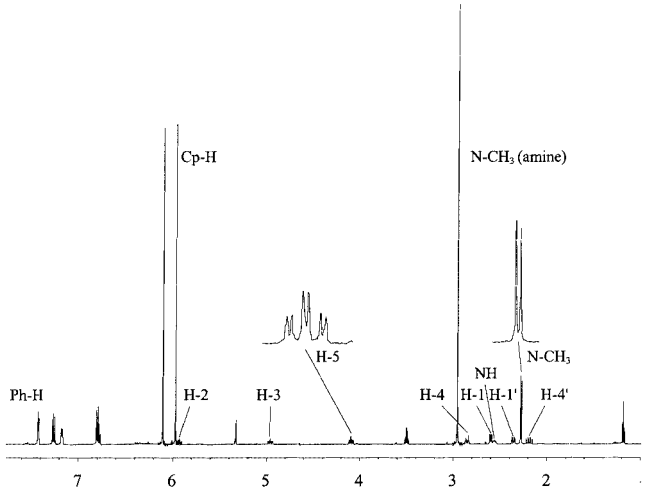


Figure 7. ^1H NMR spectrum of the salt **11b** [with $B(C_6F_5)_4^-$ anion]; the sample contains ca. 1 mol-equiv. of *N*,*N*-dimethylaniline (δ in ppm)

All the isolated samples of the complexes **11** and **12** contained ca. 1 mol-equiv. of the respective tertiary amine base, which could not readily be removed during the workup procedure. This has led us to assume an equilibrium of intra- and intermolecular amine coordination to the strongly electrophilic group-4 transition metal in these systems. For simplicity, the structures with intramolecular amine coordination to the zirconocene cation moiety are drawn in Scheme 6, although this has not been strictly proven.

We have employed the complexes **10a**, **11b**, and **12b** {all with $[HB(C_6F_5)_3^-]$ or $[B(C_6F_5)_4^-]$ anions} in polymerization experiments. Ethene polymerization was carried out with these systems in toluene solution (200 mL) at room temperature (2 bar of ethylene). The solution contained 0.5 mL of triisobutylaluminum as a "scrubbing agent" to prevent hydrolysis of the very sensitive homogeneous Ziegler–Natta catalyst systems at the very low concentrations that were used. The organometallic single component catalyst systems were injected as bromobenzene/toluene solutions to the pre-equilibrated reaction mixtures. All three systems turned out to be catalysts with moderate activity in the ethene polymerization experiments. Linear polyethylenes were obtained in all three cases (see Table 3).

Table 3. Ethene polymerization with the metallocene cation complexes **10**, **11**, and **12**

[a]	Catalyst [mg]	PE [g]	Activity[b]	M.p. [°C]
10a	15.0	2.24	65	129
11b	15.0	2.74	110	129
12b	15.0	4.30	177	131

[a] In 200 mL of toluene/0.5 mL of Bu_3Al, 1 h, room temperature, 2 bar of ethene. [b] Catalyst activities in kg(polymer)/[mol(cat.)·h·bar(ethene)].

We conclude that the (butadiene)zirconocene reagent is just reactive enough to add to the organic imines. It seems that in these cases the limit of the reactivity of these organometallic reagents is approached, since a subsequent carbon–carbon coupling at the other former diene terminus could not be achieved in these reactions. The nitrogen lone pair of the resulting metal amides does not seem to be substantially involved in bonding to the zirconocene unit.[26] This becomes apparent from the structural data of the complexes characterized here, which all feature relatively long Zr–N bonds. It also shows up in the reactions of these (π-allyl)zirconacycles: protonation occurs at the rather basic Zr–N bond, but not at the allyl carbanion equivalent, and hydride abstraction α to the nitrogen atom is also a favorable reaction of the systems **8**. Overall, this provides interesting selectivity features. We will explore whether the resulting cationic systems **10**, **11**, **12** can be used in selective stoichiometric carbon–carbon coupling reactions with functionalized unsaturated organic reagents. The observed moderate ethene polymerization activity of these systems allows us to believe that this can be achieved.

Experimental Section

General: Reactions with organometallic compounds were carried out under argon using Schlenk-type glassware or a glove-box. Solvents were dried and distilled under argon before use. NMR spectroscopic experiments were carried out with a Varian Unity plus 600 or a Bruker AC 200 NMR spectrometer. The NMR assignments were usually secured by carrying out a series of 2D NMR spectroscopy experiments.[29] For details see the Supporting Information. The following instruments were used for additional physical characterization: IR spectroscopy: Nicolet 5DXC FT-IR spectrometer; melting points: DSC 2010 (TA instruments); elemental analyses:

Foss Heraeus CHN-O-Rapid. (Butadiene)zirconocene (**1**)[3] and tris(pentafluorophenyl)borane[20] were prepared according to literature procedures. Commercially available imines [imine of benzophenone, Δ^1-2-methylpyrroline, benzylidene(methyl)amine, benzyl(benzylidene)amine] were distilled under argon prior to use. The other imines used in this study were prepared by condensation reactions of the respective carbonyl compound with the amine using 4 Å molecular sieves. The molecular sieves were activated by heating them to approx. 600 °C in vacuo, prior to use. The aldehyde or ketone (50.0 mmol) and the amine (50.0 mmol) were dissolved in dry toluene (150 mL) and stirred overnight with the activated molecular sieves at ambient temperature under argon. The molecular sieves were filtered off and the solvent removed in vacuo. The remaining crude imine was then purified by distillation and kept at 7 °C under argon.

Reaction of (Butadiene)zirconocene with Benzylidene(methyl)amine. Formation of 8a: Benzylidene(methyl)amine (**7a**, 0.24 g, 2.00 mmol) was added to a solution of (butadiene)zirconocene (**1**) (0.55 g, 2.00 mmol) in toluene (150 mL). After stirring at room temperature for 40 h the mixture was filtered and the solvent evaporated in vacuo. The crude residue was then treated with pentane (40 mL) to precipitate the insertion product (**8a**) as a yellow amorphous solid. The product was collected by filtration, washed with pentane (20 mL) and dried in vacuo. Yield: 0.60 g (75%). M.p. 194 °C. IR (KBr): $\tilde{\nu}$ = 3088 w, 2897 w, 2840 m, 2754 s, 1450 m, 1004 s, 999 s, 979 s, 877 m, 804 vs, 763 s, 703 s cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 7.25 (pt, 2 H, ph-H$_{meta}$), 7.14 (pt, 1 H, ph-H$_{para}$), 7.12 (pd, 2 H, ph-H$_{ortho}$), 5.87 (s, 5 H, cp-H), 5.8 (m, 1 H, 2-H), 5.82 (s, 5 H, cp-H), 5.04 (m, 1 H, 3-H), 4.60 (dd, $^3J_{H,H}$ = 11.5, $^3J_{H,H}$ = 4.5 Hz, 1 H, 5-H), 2.41 (m, 1 H, 4-H), 2.24 (s, 3 H, 6-H), 2.19 (dd, $^3J_{H,H}$ = 8.0, $^2J_{H,H}$ = 2.5 Hz, 1 H, 1-H), 1.89 (dd, $^3J_{H,H}$ = 14.5, $^2J_{H,H}$ = 2.5 Hz, 1 H, 1′-H), 1.72 (m, 1 H, 4′-H) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 148.1 (ph-C$_{ipso}$), 128.3 (ph-C$_{meta}$), 127.2 (ph-C$_{ortho}$), 126.4 (ph-C$_{para}$), 124.7 (C-2), 110.5 (C-3), 108.4 (cp-C), 106.6 (cp-C), 96.4 (C-5), 46.6 (C-4), 45.6 (C-6), 42.9 (C-1) ppm.

X-ray Crystal Structure Analysis of 8a: Crystals were obtained by slow concentration of a dichloromethane solution. Formula $C_{22}H_{25}NZr$, M = 394.65, green-yellow crystal 0.35 × 0.10 × 0.05 mm, a = 20.995(1), c = 8.039(1) Å, V = 3543.5(5) Å^3, ρ$_{calcd.}$ = 1.480 g·cm^{-3}, μ = 6.23 cm^{-1}, empirical absorption correction (0.812 ≤ T ≤ 0.970), Z = 8, tetragonal, space group $I\bar{4}$ (no. 82), λ = 0.71073 Å, T = 198 K, ω and φ scans, 6355 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.65 Å^{-1}, 3654 independent (R_{int} = 0.032) and 3400 observed reflections [$I \geq 2\sigma(I)$], 218 refined parameters, R = 0.028, wR^2 = 0.054, Flack parameter −0.02(4), max. residual electron density 0.27 (−0.25) e·Å^{-3}, hydrogen atoms calculated and refined as riding atoms.

Reaction of (Butadiene)zirconocene with Benzyl(benzylidene)amine. Formation of 8b: Benzyl(benzylidene)amine (**7b**, 1.97 g, 10.0 mmol) was added to a solution of (butadiene)zirconocene (**1**) (2.26 g, 10.0 mmol) in toluene (200 mL). After stirring for 60 h, the mixture was filtered and the solvent evaporated in vacuo. The crude residue was then treated with pentane (150 mL) to precipitate the insertion product as a yellow powder. The product was collected by filtration, washed twice with pentane (50 mL) and dried in vacuo. Yield: 2.12 g (45%). M.p. 114 °C. IR (KBr): $\tilde{\nu}$ = 3078 w, 3024 w, 2892 m, 2831 m, 2796 m, 2767 m, 1598 m, 1570 s, 1489 s, 1450 s, 1344 s, 1261 s, 1190 m, 1024 vs, 875 m, 811 vs, 740 vs, 702 s cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 253 K): δ = 7.34 (pt, 2 H, ph-H$_{meta/B}$), 7.24 (pt, 2 H, ph-H$_{meta/A}$), 7.1 (m, 4 H, ph-H$_{para/A}$, ph-H$_{para/B}$, ph-H$_{ortho/B}$), 7.01 (pd, 2 H, ph-H$_{ortho/A}$), 6.06 (m, 1 H, 2-H), 5.83 (s, 5 H, cp-H), 5.80 (s, 5 H, cp-H), 5.67 (m, 1 H, 3-H), 4.91 (m, 1 H, 5-H), 4.24 (d, $^2J_{H,H}$ = 17.2 Hz, 1 H, 6-H), 3.48 (d, $^2J_{H,H}$ = 17.2 Hz, 1 H, 6′-H), 2.39−2.28 (m, 3 H, 4-H/4′-H/1-H), 1.88 (m, 1 H, 1′-H) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 253 K): δ = 146.9 (ph-C$_{ipso/A}$), 142.4 (ph-C$_{ipso/B}$), 128.1 (ph-C$_{meta/B}$), 127.9 (ph-C$_{meta/A}$), 127.6 (ph-C$_{ortho/A}$), 127.5 (ph-C$_{ortho/B}$), 126.9 (C-2), 126.2 (ph-C$_{para/A}$), 125.7 (ph-C$_{para/B}$), 112.7 (C-3), 108.4 (cp-C), 106.7 (cp-C), 88.4 (C-5), 60.0 (C-6), 44.0 (C-1), 40.9 (C-4) ppm. $C_{28}H_{29}NZr$ (470.7): calcd. C 71.44, H 6.21, N 2.98; found C 71.21, H 6.32, N 2.66.

X-ray Crystal Structure Analysis of 8b: Crystals were obtained from a saturated toluene solution. Formula $C_{28}H_{29}NZr$, M = 470.74, yellow crystal 0.15 × 0.15 × 0.05 mm, a = 11.516(1), b = 17.227(1), c = 22.510(1) Å, V = 4465.7(5) Å^3, ρ$_{calcd.}$ = 1.400 g·cm^{-3}, μ = 5.07 cm^{-1}, empirical absorption correction (0.928 ≤ T ≤ 0.975), Z = 8, orthorhombic, space group $P2_12_12_1$ (no. 19), λ = 0.71073 Å, T = 198 K, ω and φ scans, 37107 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.66 Å^{-1}, 10611 independent (R_{int} = 0.077) and 7135 observed reflections [$I \geq 2\sigma(I)$], 541 refined parameters, R = 0.050, wR^2 = 0.080, Flack parameter 0.01(4), max. residual electron density 0.33 (−0.51) e·Å^{-3}, hydrogen atoms calculated and refined as riding atoms, two almost identical independent molecules in the asymmetric unit, being enantiomers of each other.

Reaction of (Butadiene)zirconocene with Benzyl(cyclopentylidene)-amine. Formation of 8c: Benzyl(cyclopentylidene)amine (**7c**, 0.87 g, 5.0 mmol) was added to a solution of (butadiene)zirconocene (**1**) (1.38 g, 5.0 mmol) in toluene (120 mL). After stirring for 16 h, the mixture was filtered and the solvent was evaporated in vacuo. The crude residue was then treated with pentane (100 mL) to precipitate the insertion product **8c** as a yellow powder. The product was collected by filtration, washed with pentane (50 mL) and dried in vacuo. Yield: 1.82 g (81%). M.p. 130 °C. IR (KBr): $\tilde{\nu}$ = 3072 w, 2951 m, 2863 m, 2792 w, 1575 w, 1446 m, 1087 m, 1017 s, 803 vs, 736 s cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 273 K): δ = 7.34 (pd, 2 H, ph-H$_{ortho}$), 7.29 (pt, 2 H, ph-H$_{meta}$), 7.15 (t, $^3J_{H,H}$ = 7.5 Hz, 1 H, ph-H$_{para}$), 5.83 (ddd, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 7.2 Hz, 1 H, 2-H), 5.81 (s, 5 H, cp-H), 5.66 (s, 5 H, cp-H), 4.87 (ddd, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 11.5, $^3J_{H,H}$ = 3.5 Hz, 1 H, 3-H), 4.41 (d, $^2J_{H,H}$ = 18.5 Hz, 1 H, 8-H), 3.91 (d, $^2J_{H,H}$ = 18.5 Hz, 1 H, 8′-H), 2.44 (dd, $^3J_{H,H}$ = 3.5, $^2J_{H,H}$ = 11.5 Hz, 1 H, 4-H), 2.22 (dd, $^3J_{H,H}$ = 7.2, $^2J_{H,H}$ = 2.5 Hz, 1 H, 1-H), 1.88 (dd, $^3J_{H,H}$ = 14.5, $^2J_{H,H}$ = 2.5 Hz, 1 H, 1′-H), 1.81−1.73 (m, 1 H, 6-H$_a$), 1.68 (m, 1 H, 4′-H), 1.65−1.50 (m, 3 H, 6-H$_b$/7-H$_{a+b}$), 1.45−1.27 (m, 2 H, 7′-H$_{a+b}$), 1.09−0.93 (m, 2 H, 6′-H$_{a+b}$) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 273 K): δ = 148.6 (ph-C$_{ipso}$), 127.5 (ph-C$_{meta}$), 127.2 (ph-C$_{ortho}$), 125.3 (C-2), 124.8 (ph-C$_{para}$), 109.4 (C-3), 108.1 (cp-C), 106.2 (cp-C), 97.2 (C-5), 55.8 (C-8), 44.9 (C-1), 44.0 (C-4), 40.7 (C-6′), 29.6 (C-6), 23.5 (C-7′), 21.1 (C-7) ppm. X-ray Crystal Structure Analysis of 8c: Single crystals were obtained from a saturated toluene solution. Formula $C_{26}H_{31}NZr$, M = 448.74, light yellow crystal 0.15 × 0.10 × 0.03 mm, a = 8.206(1), b = 25.367(1), c = 20.260(1) Å, β = 90.84(1)°, V = 4216.9(6) Å^3, ρ$_{calcd.}$ = 1.414 g·cm^{-3}, μ = 5.33 cm^{-1}, empirical absorption correction (0.924 ≤ T ≤ 0.984), Z = 8, monoclinic, space group $P2_1/c$ (no. 14), λ = 0.71073 Å, T = 198 K, ω and φ scans, 42299 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.66 Å^{-1}, 9977 independent (R_{int} = 0.124) and 5583 observed reflections [$I \geq 2\sigma(I)$], 505 refined parameters, R = 0.060, wR^2 = 0.086, max.

residual electron density 0.57 (−0.77) e·Å^{-3}, hydrogen atoms calculated and refined as riding atoms, two almost identical independent molecules in the asymmetric unit.

Reaction of (Butadiene)zirconocene with the Imine of Benzophenone. Formation of 8d: Imine **7d** (0.91 g, 5.0 mmol) of benzophenone was added to a solution of (butadiene)zirconocene (**1**) (1.38 g, 5.0 mmol) in toluene (150 mL). After stirring for 7 h, the solvent was evaporated in vacuo and the crude residue was treated with pentane (100 mL) to precipitate the insertion product **8d** as a light-yellow powder. The product was collected by filtration, washed with pentane (50 mL) and dried in vacuo. Yield: 1.69 g (74%). M.p. 129 °C. IR (KBr): $\tilde{\nu}$ = 3052 s, 2936 m, 2912 s, 2849 m, 1643 s, 1604 s, 1576 s, 1493, 1450 s, 1228 m, 1173 s, 1064 s, 1020 s, 800 vs, 712 s, 611 s cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 7.47−7.06 (m, 10 H, ph-H), 5.85 (s, 5 H, cp-H), 5.43 (ddd, $^3J_{H,H}$ = 14.8, $^3J_{H,H}$ = 14.8, $^3J_{H,H}$ = 8.1 Hz, 1 H, 2-H), 5.26 (s, 5 H, cp-H), 5.08 (ddd, $^3J_{H,H}$ = 14.8, $^3J_{H,H}$ = 11.2, $^3J_{H,H}$ = 3.8 Hz, 1 H, 3-H), 3.22 (dd, $^3J_{H,H}$ = 3.8, $^2J_{H,H}$ = 12.7 Hz, 1 H, 4-H), 2.16 (dd, $^3J_{H,H}$ = 8.1, $^2J_{H,H}$ = 3.2 Hz, 1 H, 1-H), 1.97 (dd, $^3J_{H,H}$ = 14.8, $^2J_{H,H}$ = 3.2 Hz, 1 H, 1′-H), 1.71 (br, 1 H, NH), 1.45 (dd, $^3J_{H,H}$ = 11.2, $^2J_{H,H}$ = 12.7 Hz, 1 H, 4′-H) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 155.4, 151.6, 128.2, 127.8, 127.5, 126.1, 125.7, 125.6 (ph-C), 124.8 (C-2), 114.2 (C-3), 108.6, 106.3 (cp-C), 97.3 (C-5), 47.6 (C-4), 41.2 (C-1). (^{1}H-^{15}N)-GHMBC (599.9 MHz/60.0 MHz, CD_2Cl_2, 273 K): δ^{1}H/δ^{15}N = 1.71/−254.3 (d, $^1J_{HN}$ = 62 Hz) ppm. $C_{27}H_{27}NZr$ (456.74): calcd. C 71.00, H 5.96, N 3.07; found C 71.14, H 5.93, N 2.93.

Reaction of (Butadiene)zirconocene with Δ^1-2-Methylpyrroline. Formation of 8e: Δ^1-2-Methylpyrroline (**7e**, 0.84 g, 10.0 mmol) was added to a solution of (butadiene)zirconocene (**1**) (2.76 g, 10.0 mmol) in toluene (200 mL). After stirring for 16 h, the mixture was filtered and the solvent evaporated in vacuo. The residue was washed with three portions of pentane (3 × 50 mL). The filtrate was concentrated in vacuo until precipitation of the product occurred, and then stored at −18 °C overnight. The resulting product was collected by filtration and washed with cold pentane (20 mL). Subsequent concentration of the mother liquor and crystallization gave a combined yield of 2.15 g (60%) of the insertion product **8e**. M.p. 70 °C. IR (KBr): $\tilde{\nu}$ = 3088 w, 2951 m, 2863 m, 1628 w, 1441 w, 1015 s, 797 vs, 740 vs cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 5.79 (s, 5 H, cp-H), 5.71 (s, 5 H, cp-H), 5.68 (ddd, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 7.7 Hz, 1 H, 2-H), 5.22 (ddd, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 11.5, $^3J_{H,H}$ = 3.5 Hz, 1 H, 3-H), 3.22 (m, 1 H, 8-H), 2.90 (m, 1 H, 8′-H), 2.27 (dd, $^3J_{H,H}$ = 3.5, $^2J_{H,H}$ = 11.5 Hz, 1 H, 4-H), 2.12 (dd, $^3J_{H,H}$ = 7.7, $^2J_{H,H}$ = 3.2 Hz, 1 H, 1-H), 1.83 (dd, $^3J_{H,H}$ = 14.5, $^2J_{H,H}$ = 3.2 Hz, 1 H, 1′-H), 1.68−1.61 (m, 2 H, 7-H/7′-H), 1.53 (m, 1 H, 6-H), 1.35 (m, 1 H, 4′-H), 1.26 (m, 1 H, 6′-H), 1.06 (s, 3 H, 9-H) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 125.2 (C-2), 117.4 (C-3), 109.2 (cp-C), 107.7 (cp-C), 98.9 (C-5), 56.0 (C-8), 49.1 (C-4), 42.9 (C-6), 41.7 (C-1), 28.0 (C-7), 24.1 (C-9, s, $^1J_{CH}$ = 124 Hz) ppm. (^{1}H-^{15}N)-GHMBC (599.9 MHz/60.0 MHz, CD_2Cl_2, 273 K): δ^{1}H/δ^{15}N = 3.22, 2.90/−249.3 ppm. $C_{19}H_{25}NZr$ (358.64): calcd. C 63.63, H 7.03, N 3.91; found C 62.42, H 6.80, N 3.56.

Reaction of (Butadiene)zirconocene with 2-Methyl-2-oxazoline. Formation of 9: 2-Methyl-2-oxazoline (**7f**, 171 mg, 2.00 mmol) was added to a solution of butadiene(zirconocene) (**1**) (551 mg, 2.00 mmol) in toluene (50 mL). After stirring for 17 h, the mixture was filtered and the solvent evaporated in vacuo. The crude residue was then treated with pentane (20 mL) to precipitate the insertion product as a light brown powder. The product was collected by filtration, washed twice with pentane (10 mL) and dried in vacuo. Yield: 613 mg (85%). IR (KBr): $\tilde{\nu}$ = 3060 m, 2826 m, 2673 w, 1654 s, 1589 s, 1448 w, 1368 w, 1106 s, 1015 s, 821 s, 795 vs, 765 m cm^{-1}. ^{1}H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 6.23 (ddd, $^3J_{H,H}$ = 10.5, $^3J_{H,H}$ = 16.9, $^3J_{H,H}$ = 5.4 Hz, 1 H, 2-H), 5.95 (s, 5 H, cp-H), 5.70 (s, 5 H, cp-H), 4.36 (ddd, $^3J_{H,H}$ = 10.5, $^2J_{H,H}$ = 2.2, $^4J_{H,H}$ = 2.1 Hz, 1 H, 1-H), 4.19 (ddd, $^3J_{H,H}$ = 16.9, $^2J_{H,H}$ = 2.2, $^4J_{H,H}$ = 2.1 Hz, 1 H, 1′-H), 3.90 (ddd, $^3J_{H,H}$ = 5.7, $^3J_{H,H}$ = 5.8, $^2J_{H,H}$ = 9.8 Hz, 1 H, 7-H), 3.71 (ddd, $^3J_{H,H}$ = 5.4, $^3J_{H,H}$ = 6.6, $^2J_{H,H}$ = 9.8 Hz, 1 H, 7′-H), 3.28 (m, 1 H, 6-H), 3.11 (m, 1 H, 6′-H), 2.95 (m, 1 H, 4-H), 2.80 (m, 1 H, 4′-H), 2.53 (m, 1 H, 3-H), 2.03 (s, 3 H, 8-H) ppm. ^{13}C{^{1}H} NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 187.2 (C-5, s), 147.9 (C-2, d, $^1J_{CH}$ = 144 Hz), 111.0 (cp-C, d, $^1J_{CH}$ = 171 Hz), 110.6 (cp-C, d, $^1J_{CH}$ = 171 Hz), 97.5 (C-1, dd, $^1J_{CH}$ = 151, $^1J_{CH}$ = 157 Hz), 69.0 (C-7, t, $^1J_{CH}$ = 139 Hz), 56.4 (C-6, t, $^1J_{CH}$ = 137 Hz), 52.6 (C-3, d, $^1J_{CH}$ = 125 Hz), 48.8 (C-4, t, $^1J_{CH}$ = 121 Hz), 20.2 (C-8, q, $^1J_{CH}$ = 128 Hz) ppm. (^{1}H-^{15}N)-GHMBC (599.9 MHz/60.0 MHz, CD_2Cl_2, 273 K): δ^{1}H/δ^{15}N = 3.28, 3.11/−105.6 ppm. $C_{18}H_{23}NOZr$ (360.61): calcd. C 59.95, H 6.43, N 3.88; found C 58.74, H 6.53, N 3.48.

X-ray Crystal Structure Analysis of 9: Single crystals were obtained from a saturated toluene solution. Formula $C_{18}H_{23}NOZr$, M = 360.59, light yellow crystal 0.15 × 0.15 × 0.10 mm, a = 10.486(1), b = 13.273(1), c = 11.591(1) Å, β = 94.73(1)°, V = 1607.7(2) Å^3, $\rho_{calcd.}$ = 1.490 g·cm^{-3}, μ = 6.83 cm^{-1}, empirical absorption correction (0.905 ≤ T ≤ 0.935), Z = 4, monoclinic, space group $P2_1/c$ (no. 14), λ = 0.71073 Å, T = 198 K, ω and φ scans, 13970 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.66 Å^{-1}, 3845 independent (R_{int} = 0.048) and 3039 observed reflections [$I \geq 2\sigma(I)$], 191 refined parameters, R = 0.033, wR^2 = 0.072, max. residual electron density 0.63 (−0.61) e·Å^{-3}, hydrogen atoms calculated and refined as riding atoms.

Data sets were collected with a Nonius Kappa CCD diffractometer, equipped with a rotating anode generator Nonius FR591. Programs used: data collection COLLECT (Nonius B.V., **1998**), data reduction Denzo-SMN (Z. Otwinowski, W. Minor, *Methods Enzymol.* **1997**, *276*, 307−326), absorption correction SORTAV (R. H. Blessing, *Acta Crystallogr.* **1995**, *A51*, 33−37; R. H. Blessing, *J. Appl. Crystallogr.* **1997**, *30*, 421−426), structure solution SHELXS-97 (G. M. Sheldrick, *Acta Crystallogr.* **1990**, *A46*, 467−473), structure refinement SHELXL-97 (G. M. Sheldrick, Universität Göttingen, **1997**), graphics SCHAKAL (E. Keller, Universität Freiburg, **1997**). CCDC-183380 to -183383 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Reaction of 8e with Tris(pentafluorophenyl)borane. Formation of 10a: Compound **8e** (0.36 g, 1.0 mmol) was treated with tris(pentafluorophenyl)borane (0.51 g, 1.0 mmol) in dichloromethane (20 mL) at 0 °C for 1 h. Evaporation of the solvent yielded a semi-solid material, which was suspended in pentane (30 mL) and stirred for 2 d at ambient temperature to precipitate the reaction product. Filtration gave 0.77 g (88%) of complex **10a**. M.p. 244 °C (decomp.). IR (KBr): $\tilde{\nu}$ = 3124 w, 2973 m, 2368 m, 1643 m, 1511 s, 1461 vs, 1272 m, 1103 s, 968 s, 821 s cm^{-1}. ^{1}H NMR (599.9 MHz, C_6D_5Br, 298 K): δ = 7.42 (s, 1 H, 8-H), 5.45 (s, 5 H, cp-H), 5.44 (ddd, $^3J_{H,H}$ = 15.2, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 7.8 Hz, 1 H, 2-H), 5.26 (s, 5 H, cp-H), 4.34 (ddd, $^3J_{H,H}$ = 15.2, $^3J_{H,H}$ = 11.9, $^3J_{H,H}$ = 2.9 Hz, 1 H, 3-H), 2.46-2.32 (m, 2 H, 7-H, 7′-H), 2.11 (dd, $^3J_{H,H}$ = 2.9, $^2J_{H,H}$ = 13.0 Hz, 1 H, 4-H), 2.05 (dd, $^3J_{H,H}$ = 7.8, $^2J_{H,H}$ = 3.7 Hz, 1 H, 1-H), 1.70 (dd, $^3J_{H,H}$ = 14.5, $^2J_{H,H}$ = 3.7 Hz, 1 H, 1′-

H), 1.58 (m, 1 H, 6-H), 1.37−1.30 (m, 2 H, 4′-H, 6′-H), 0.84 (s, 3 H, 9-H) ppm. The $H-B(C_6F_5)_3^-$ resonance was not observed. $^{13}C\{^1H\}$ NMR (150.8 MHz, C_6D_5Br, 298 K): δ = 183.5 (C-8, d, $^1J_{CH}$ = 181 Hz), 127.6 (C-2), 107.9 (cp-C), 107.3 (cp-C), 102.0 (C-3), 98.8 (C-5), 45.2 (C-1), 43.1 (C-4), 38.1 (C-7), 36.9 (C-6), 23.4 (C-9) ppm. ^{11}B NMR (64.2 MHz, C_6D_5Br, 298 K): δ = −24.9 (d, $^1J_{BH}$ = 85 Hz) ppm. (^1H-^{15}N)-GHMBC (599.9 MHz/60.0 MHz, CD_2Cl_2, 273 K): $\delta^1H/\delta^{15}N$ = 7.42/−88.8 ppm. HRMS (EI): calcd. for $C_{19}H_{24}NZr^+$ 356.0956, found 356.0965.

Reaction of Complex 8e with Trityl Tetraphenylborate. Formation of 10b: A sample of **8e** (0.36 g, 1.00 mmol) was treated with trityl tetraphenylborate (0.57 g, 1.00 mmol) in dichloromethane (20 mL) at −78 °C. The mixture was then warmed to ambient temperature and stirred overnight. Evaporation of the solvent yielded a white, solid material, which was suspended in pentane (30 mL) and stirred for 17 h at ambient temperature to precipitate the product and to dissolve triphenylmethane. Filtration and washing with pentane yielded 0.58 g (85%) of complex **10b**. M.p. 215 °C (decomp.). ^1H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 7.45−7.40 (m, 8 H, ph-H_{borate}), 7.23 (m, 1 H, 8-H), 7.08 (pt, 8 H, ph-H_{borate}), 6.93 (pt, 4 H, ph-H_{borate}), 5.93 (m, 1 H, 2-H), 5.88 (s, 5 H, cp-H), 5.62 (s, 5 H, cp-H), 4.89 (ddd, $^3J_{H,H}$ = 2.8, $^3J_{H,H}$ = 11.5, $^3J_{H,H}$ = 14.9 Hz, 1 H, 3-H), 2.59−2.53 (m, 3 H, 4-H, 7-H, 7′-H), 2.47 (dd, $^3J_{H,H}$ = 7.7, $^2J_{H,H}$ = 3.6 Hz, 1 H, 1-H), 2.14 (dd, $^3J_{H,H}$ = 14.1, $^2J_{H,H}$ = 3.6 Hz, 1 H, 1′-H), 1.99 (m, 1 H, 6-H), 1.78 (dd, $^3J_{H,H}$ = 11.5, $^2J_{H,H}$ = 13.0 Hz, 1 H, 4′-H), 1.65 (m, 1 H, 6′-H), 1.25 (s, 3 H, 9-H) ppm. $^{13}C\{^1H\}$ NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 184.6 (C-8), 164.5 (q, ph-$C_{ipso/borate}$, $^1J_{BC}$ = 49.5 Hz), 136.2 (ph-$C_{ortho/borate}$), 128.2 (C-2), 126.3 (q, ph-$C_{meta/borate}$, $^3J_{BC}$ = 2.8 Hz), 122.4 (ph-$C_{para/borate}$), 108.6 (cp-C), 108.0 (cp-C), 102.6 (C-3), 99.6 (C-5), 46.1 (C-1), 44.0 (C-4), 38.9 (C-7), 37.7 (C-6), 24.4 (C-9) ppm. HRMS (EI): calcd. for $C_{19}H_{24}NZr^+$ 356.0956, found 356.0987.

Reaction of 8a with Tri(*n*-butyl)ammonium Tetraphenylborate. Formation of 11a: A sample of **8a** (0.39 g, 1.00 mmol) was treated with tri(*n*-butyl)ammonium tetraphenylborate (0.51 g, 1.00 mmol) in diethyl ether (20 mL) at −78 °C. The mixture was then warmed to ambient temperature and stirred overnight. Evaporation of the solvent yielded a white solid, which was suspended in pentane (30 mL) and stirred for 17 h at ambient temperature. Filtration gave 0.79 g (88%) of complex **11a**. M.p. 204 °C. ^1H NMR (599.9 MHz, C_6D_6/[D_8]THF ≈ 4:1, 298 K): δ = 7.39−7.33 (m, 3 H, ph-H), 7.31−7.27 (m, 8 H, ph-H_{borate}), 7.27−7.24 (m, 2 H, ph-H), 6.86 (pt, 8 H, ph-H_{borate}), 6.72 (pt, 4 H, ph-H_{borate}), 6.04 (s, 5 H, cp-H), 5.93 (s, 5 H, cp-H), 5.90 (dt, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 8.2 Hz, 1 H, 2-H), 4.92 (ddd, $^3J_{H,H}$ = 14.5, $^3J_{H,H}$ = 11.2, $^3J_{H,H}$ = 3.5 Hz, 1 H, 3-H), 4.11 (m, 1 H, 5-H), 2.89 (m, 1 H, NH), 2.64 (m, 1 H, 4-H), 2.47 (dd, $^3J_{H,H}$ = 8.2, $^2J_{H,H}$ = 3.2 Hz, 1 H, 1-H), 2.43 (br, 6 H, α-H_{amine}) 2.27−2.24 (m, 1 H, 1′-H), 2.20 (m, 1 H, 4′-H), 2.15 (d, $^3J_{H,H}$ = 6.2 Hz, 3 H, 6-H), 1.40 (m, $^3J_{H,H}$ = 7.4 Hz, 6 H, β-H_{amine}), 1.31 (m, $^3J_{H,H}$ = 7.4 Hz, 6 H, γ-H_{amine}), 0.90 (t, $^3J_{H,H}$ = 7.4 Hz, 9 H, δ-H_{amine}) ppm. $^{13}C\{^1H\}$ NMR (150.8 MHz, [D_6]benzene/[D_8]THF ≈ 4:1, 298 K): δ = 165.2 (q, $C_{ipso/borate}$, $^1J_{BC}$ = 50.2 Hz), 139.0 (ph-C), 137.2 ($C_{ortho/borate}$), 129.8, 128.2, 127.9 (ph-C), 128.9 (C-2), 125.8 (q, $C_{meta/borate}$, $^3J_{BC}$ = 2.5 Hz), 121.9 ($C_{para/borate}$), 110.3 (cp-C), 109.8 (cp-C), 103.6 (C-3), 82.5 (C-5), 54.6 (α-C_{amine}), 47.6 (C-1), 41.6 (C-4), 39.6 (C-6), 29.6 (β-C_{amine}, only visible in the 50 MHz spectrum), 21.2 (γ-C_{amine}), 14.3 (δ-C_{amine}) ppm. Reaction of Complex 8d with Tri(*n*-butyl)ammonium Tetraphenylborate. Formation of 12a: A sample of complex **8d** (457 mg, 1.00 mmol) and tri(*n*-butyl)ammonium tetraphenylborate (0.51 g, 1.00 mmol) was suspended in diethyl ether (20 mL) at −78 °C. The mixture was then warmed to ambient temperature and stirred overnight. Evaporation of the solvent yielded a white solid, which was stirred in pentane (30 mL) for 17 h at ambient temperature. Filtration gave 0.71 g (74%) of complex **12a**. M.p. 247 °C (decomp.). Due to rapid decomposition of compound **12a** in solution only ^1H and $^1H/^1H$-correlation NMR spectra were recorded. ^1H NMR (599.9 MHz, C_6D_6/[D_8]THF = 2:1, 298 K): δ = 7.72 (m, 8 H, Ph-H_{borate}), 7.25 (m, 1 H, Ph-H), 7.23 (m, 1 H, Ph-H), 7.19 (pt, 8 H, Ph-H_{borate}), 7.17 (m, 4 H, Ph-H), 7.09 (pt, 2 H, Ph-H), 7.03 (pt, 4 H, Ph-H_{borate}), 6.90 (pd, 2 H, Ph-H), 5.46 (ddd, $^3J_{H,H}$ = 14.2, $^3J_{H,H}$ = 15.1, $^3J_{H,H}$ = 8.0 Hz, 1 H, H-2), 5.39 (s, 5 H, Cp-H), 5.09 (s, 5 H, Cp-H), 4.63 (m, 1 H, H-3), 3.69 (d, $^2J_{H,H}$ = 12.3 Hz, 1 H, NH), 3.27 (d, $^2J_{H,H}$ = 14.5 Hz, 1 H, H-4), 3.01 (d, $^2J_{H,H}$ = 12.3 Hz, 1 H, NH′), 2.17 (dd, $^3J_{H,H}$ = 8.0, $^2J_{H,H}$ = 3.3 Hz, 1 H, H-1), 2.10 (br, 6 H, α-H_{amine}) 1.93 (dd, $^3J_{H,H}$ = 14.2, $^2J_{H,H}$ = 3.3 Hz, 1 H, H-1′), 1.86 (dd, $^3J_{H,H}$ = 11.9, $^2J_{H,H}$ = 14.5, 1 H, H-4′), 1.02 (br, 6 H, γ-H_{amine}), 0.98 (br, 6 H, β-H_{amine}), 0.90 (br, 9 H, δ-H_{amine}) ppm.

Reaction of Complex 8d with *N,N*-Dimethylanilinium Tetrakis(pentafluorophenyl)borate. Formation of 12b: A mixture of compound **8d** (457 mg, 1.00 mmol) and *N,N*-dimethylanilinium tetrakis(pentafluorophenyl)borate (800 mg, 1.00 mmol) was suspended in diethyl ether (50 mL) at −78 °C. The mixture was then warmed to ambient temperature and stirred overnight. Evaporation of the solvent yielded a white solid, which was suspended in pentane (30 mL) and stirred for 17 h at ambient temperature. Filtration gave 1.02 g (81%) of complex **12d**. M.p. 288 °C (decomp.). ^1H NMR (599.9 MHz, CD_2Cl_2, 298 K): δ = 7.60 (m, 2 H, Ph-H_{meta}), 7.52 (m, 1 H, Ph-H_{para}), 7.43 (m, 2 H, Ph-H_{ortho}), 7.38 (m, 2 H, Ph-H_{meta}), 7.32 (m, 1 H, Ph-H_{para}), 7.26 (m, 2 H, Ph-H_{amine}), 7.03 (m, 2 H, Ph-H_{ortho}), 6.81 (m, 3 H, Ph-H_{amine}), 5.98 (m, 1 H, H-2), 5.96, 5.54 (s, each 5 H, Cp-H), 5.13 (ddd, $^3J_{H,H}$ = 14.9, $^3J_{H,H}$ = 11.9, $^3J_{H,H}$ = 2.8 Hz, 1 H, H-3), 3.76 (dd, $^3J_{H,H}$ = 14.9, $^2J_{H,H}$ = 15.6 Hz, 1 H, H-4), 3.57, 3.30 (d, $^2J_{H,H}$ = 12.5 Hz, each 1 H, NH, and NH′), 2.95 [s, 6 H, $N(CH_3)_{amine}$], 2.60 (dd, $^3J_{H,H}$ = 8.2, $^2J_{H,H}$ =

3.7 Hz, 1 H, H-1), 2.38 (dd, $^3J_{H,H}$ = 14.2, $^2J_{H,H}$ = 3.7 Hz, 1 H, H-1′), 2.31 (dd, $^3J_{H,H}$ = 11.9, $^2J_{H,H}$ = 15.6 Hz, 1 H, H-4′) ppm. $^{13}C\{^1H\}$ NMR (150.8 MHz, CD_2Cl_2, 298 K): δ = 149.9 (C, Ph-$C_{ipso/amine}$), 148.6 (CF, dm, Ph-$C_{ortho/borate}$, $^1J_{C,F}$ = 242 Hz), 146.4, 140.1 (C, Ph-C_{ipso}), 138.7 (CF, dm, Ph-$C_{para/borate}$, $^1J_{C,F}$ = 242 Hz), 136.7 (CF, dm, Ph-$C_{meta/borate}$, $^1J_{C,F}$ = 248 Hz), 130.5 (CH, Ph-C), 130.3 (CH, C-2), 129.9, 129.7 (CH, Ph-C), 129.6 (CH, Ph-$C_{meta/amine}$), 128.7, 126.8, 124.2 (CH, Ph-C), 124.0 (C, br, Ph-$C_{ipso/borate}$), 118.7 (CH, Ph-$C_{para/amine}$), 113.8 (CH, Ph-$C_{ortho/amine}$), 108.7, 108.4 (CH, Cp-C), 102.1 (CH, C-3), 85.9 (C, C-5), 46.6 (CH_2, C-1), 44.6 (CH_2, C-4), 41.6 [CH_3, $N(CH_3)_{amine}$] ppm. HRMS (EI): calcd. for $C_{27}H_{28}NZr^+$ 456.1269, found 456.1231.

Polymerization Experiments: The polymerization experiments were carried out in a thermostatted 1-L Büchi glass autoclave. The reaction mixtures contained toluene (200 mL) and triisobutylaluminum (0.5 mL) as the scavenger. The stirred (700 rpm) solution was saturated with ethylene at 2 bar for 45 min before the polymerization reactions were started by injection of the group-4 metal catalyst precursors, dissolved in 3−7 mL of a toluene/bromobenzene mixture. The polymerization reactions were stopped after 1 h by the addition of ca. 20 mL of a 1:1 mixture of 1 N aqueous HCl in methanol after the pressure had been released and the excess ethylene vented. The mixture was stirred for an additional 30 min. The polymer formed was collected by filtration, washed with aqueous HCl and water and dried in vacuo at an elevated temperature. Further information is provided in Table 3.

[12] Rosenthal et al. have observed coupling of two benzaldimines at Cp_2Ti or Cp_2Zr in the reaction of the respective [η^2-bis(tri-

methylsilyl)acetylene]metallocene complexes with PhN=CHPh.[12a,12b] We have some indication that in the reaction of the bulky ansa-metallocene complex $Me_2Si(C_5Me_4)CpZr$(butadiene) with MeN=CHPh such imine coupling (with extrusion of butadiene) is competing with the imine/butadiene addition reaction. Simultaneous Cation/Anion Coordination by Bifunctional 1,2-Diimine/1,2-Diamine Type Ligands: Synthesis, Structures, and Properties of Tight Ion Pair Complexes of Ruthenium and Iron

Sven Rau,[a] Lars Böttcher,[a] Sebastian Schebesta,[a] Michael Stollenz,[a] Helmar Görls,[a] and Dirk Walther*[a]

Keywords: Iron / Hydrogen bonds / N ligands / Ruthenium

The reaction between $[(\eta^6\text{-}p\text{-cymene})RuCl_2]_2$ and tetra-*p*-tolyloxalic amidine (*oxam1*) results in a coupled cation/anion coordination forming the ion-paired complex $[(\eta^6\text{-}p\text{-cymene})RuCl(oxam1)Cl]$ (**1a**). According to an X-ray single crystal diffraction analysis the Ru moiety is coordinated at the 1,2-diimine part yielding a five-membered chelate ring. Furthermore, the 1,2-diamine group on the opposite side binds to a chloride anion via two N–H groups. Exchange of the chloride anion by trifluoractetate yields $[(\eta^6\text{-}p\text{-cymene})RuCl(oxam1)CF_3CO_2]$ (**1c**) in which the C=O group is bonded to the diamine part. Similarly, bis(mesityl)bis(pyridylmethyl)oxalic amidine (*oxam2*) reacts with FeX_2 to yield the ion-paired complexes **3a** (X: Cl), and **3b** (X: Br). X-ray diffraction studies of both compounds reveal that the oxalic amidine ligand acts as a four-dentate chelating ligand. One halide is fixed in the same way as in **1a**. The complex **1a** reacts with $Pd(acac)_2$ (acac: acetylacetonate) to give the tetranuclear heterobimetallic complex $[(\eta^6\text{-}p\text{-cymene})RuCl(oxam1)PdCl]_2$ (**2**). The related complexes $[(tbbpy)_2Ru(bbimH_2)(OOC\text{–}CF_3)](PF_6)$ (**4**), $[(tbbpy)_2Ru(bbimH_2)\{OOC(CF_2)_7CF_3\}][OOC(CF_2)_7CF_3]$ (**5**), $[\{(tbbpy)_2Ru(bbimH_2)\}_2(OOC\text{–}C_6F_4\text{–}COO)](PF_6)_2$ (**6**), and $[\{(tbbpy)_2Ru(bbimH_2)\}_2(OOC\text{–}C_6F_4\text{–}COO)]$ (**7**), ($bbimH_2$: bibenzimidazole; tbbpy: 4,4′-di-*tert*-butyl-2,2′-bipyridine) also form ion-paired compounds. According to the X-ray diffraction analyses of **4**–**6** both oxygen atoms of the carboxylate ions are coordinated to the two N–H functions via strong N–H···O bonds. Although **5** contains a dication, the compound is soluble in solvents of low polarity, even in supercritical carbon dioxide.

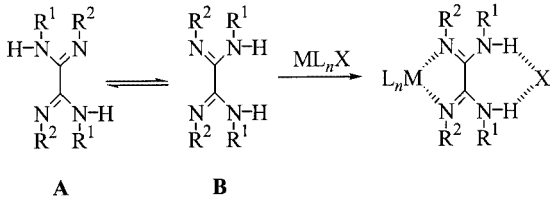
Introduction

Oxalic amidines containing the structural element **A** are not only variable building blocks for bi- and oligonuclear complexes[1–8] but can also be considered as bifunctional ligands which should be capable of coupled cation/anion coordination forming tight contact ion-paired complexes according to Scheme 1.



Scheme 1. Formation of ion-paired complexes by coupled cation/anion coordination

Structure **B**, the tautomer of **A** can be stabilized by formation of a 1,2-diimine metal compound provided a suitable metal complex fragment is used. Additionally, anion bonding via hydrogen bonds on the opposite 1,2-diamine side of the oxalic amidine system may stabilize the mononuclear complex preventing undesired coordination polymerization.

The general principle behind this process is strongly reminiscent of anion recognition events in supramolecular chemistry between cationic diamine-based hosts and anionic guests.[9] The stability of the resulting aggregates is commonly influenced by steric and electronic tuning of the host molecule with regard to the guest. The application of these construction principles in metallorganic and coordination chemistry is still relatively underdeveloped even so multinuclear supramolecular aggregates are promising candidates for multistep catalytic processes or biomimetic analogues, such as light harvesting complexes.

Simultaneous cation/anion coordination could therefore result in the generation of "supramolecularly" protected metalloligands, useful as starting products for the construction of heterobi- or oligometallic complexes, but also for the formation of ion-paired metal complexes with untypical high solubilities in solvents of low polarity. In addition, in-

teraction of dicarboxylates as dianions with appropriately designed 1,2-diamine containing complexes should result in the formation of hydrogen-bonded stable dimers. Furthermore, this type of reaction may be used to force ligands bearing additional donor groups in R^1 into untypical coordination modes. Additionally, the generation of 1,2-diimine metal species containing cationic electrophilic parts may be of special interest because of their well-known catalytic potential.[10,11]

We describe here the first examples for simultaneous cation/anion bonding using oxalic amidines as ligands and investigate the structures and properties of the new compounds. Furthermore, we report on ion-paired complexes consisting of the photoactive fragment $(tbbpy)_2Ru(bbimH_2)^{2+}$ and carboxylates that are hydrogen bonded to the related bibenzimidazole ligand. Although in these complexes a dication is part of the tight ion-paired compound, these compounds show surprisingly high solubilities in nonpolar solvents if long chained perfluoro-substituted carboxylates are coordinated to the N−H groups.

Results and Discussion

Reaction between $[(\eta^6\text{-}p\text{-cymene})RuCl_2]_2$ and tetra-*p*-tolyloxalic amidine (*oxam1*) in refluxing toluene resulted in the formation of $[(\eta^6\text{-}p\text{-cymene})RuCl(oxam1)Cl]$, **1a**, which was isolated as an orange-red crystalline compound at room temperature. Elemental analysis and a mass spectrum confirmed its composition. In the ESI-mass spectrum the complex ion $[\mathbf{1a} - Cl]^+$ (m/z =716) was detected. The ^1H NMR spectrum of **1a**, recorded in $[D_8]$THF at room temperature supports the assumption of a C_s symmetrical complex. It showed one doublet belonging to the methyl protons of the isopropyl group at δ = 1.14 and 1.17 ppm and a singlet for the methyl group of coordinated cymene at δ = 2.27 ppm. Two singlets for the methyl groups of the coordinated *oxam1* were detected at δ = 2.09 and 2.18 ppm. The relative intensities of these resonances are, as expected, (1:1):(1:2):2. The multiplet corresponding to the CH proton of the isopropyl group was detected at δ = 2.50 ppm. The aromatic protons of the *p*-cymene ligand (δ = 4.59 ppm), and the protons of the aromatic substituents (δ = 6.66 and 7.60 ppm) were detected with the expected intensities. Furthermore, the ^1H NMR spectrum shows one sharp singlet for both NH groups at δ = 12.83 ppm, which is in agreement with a strong chloride binding to the N−H functions according to Figure 1. The ^{13}C NMR spectrum for **1a** in $[D_8]$THF also showed the expected simple pattern corresponding to a symmetrical complex.

The molecular structure of compound **1a** has been confirmed by X-ray crystallography (Figure 1). The compound consists of a cationic portion in which the metal center is surrounded by the *p*-cymene, the diimine part of the oxalic amidine ligand and one chloride to form a typical "piano stool" complex in which the arene acts as the "bench" and the other ligands form "the legs" of the stool. The ruthenium coordination environment is best described as a distorted trigonal pyramidal geometry considering the aromatic ring as a unique coordination site, represented by the middle of the benzene unit, occupying one position of the polygon. The second chloride is bonded to the two N−H groups of the 1,2 diamine part of the oxalic amidine via two hydrogen bonds. Bond lengths and angles are listed in the figure caption and lie within typical ranges (see Figure 1 caption). The C1−N1 and C2−N2 bond lengths of 1.301(4), and 1.298(4) Å clearly indicate that the ligand coordinates with the 1,2-diimine part. Typically, due to the partial delocalization of the double bonds of the coordinated 1,2 diimine, the C1−C2 bond length 1.497(4) Å is shorter than that of a C−C single bond. The N3−Cl2 and N4−Cl2 distances of 3.077(2) and 3.088(2) Å, respectively, are in the accepted range for these distances. Furthermore, the angles for the N3−H···Cl group, and the N4−H···Cl group (167 and 170°, respectively) show very little deviation from linearity. These findings clearly indicate a strong bonding between the N−H functions of the 1,2-diamine system and the chloride counterion. In the related compound tris(*N*,*N*′-diphenyloxalic amidine−*N*,*N*′)cobalt(II) dichloride, the peripheral primary amine functions form tight hydrogen bonds to one chloride anion resulting in a polymeric three-dimensional network.[12]

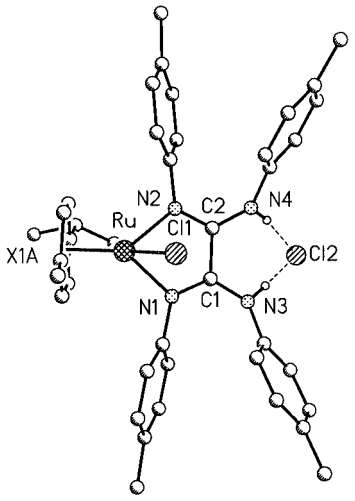

Figure 1. Molecular structure of complex **1a**, selected distances [Å] and bond angles [deg]: Ru−Cl1 2.398(1), Ru−X1A 1.692(4), Ru−N1 2.088(3), Ru−N2 2.079(3), C1−N1 1.301(4), C1−N3 1.436(4), C1−C2 1.497(4), C2−N2 1.298(4), C2−N4 1.350(5), Cl2−N3 3.077(2), Cl2−N4 3.088(2); X1A−Ru−Cl1 128.60(7), X1A−Ru−N1 83.9(2), X1A−Ru−N2 83.5(2), Cl1−Ru−N1 83.93(9), Cl1−Ru−N2 83.54(8), N1−Ru−N2 75.9(1), N1−C1−N3 127.2(3), N2−C2−N4 127.4(3), C1−C2−N2 114.1(3), C1−C2−N4 118.2(3), C2−C1−N1 114.1(3), C2−C1−N3 118.6(3)

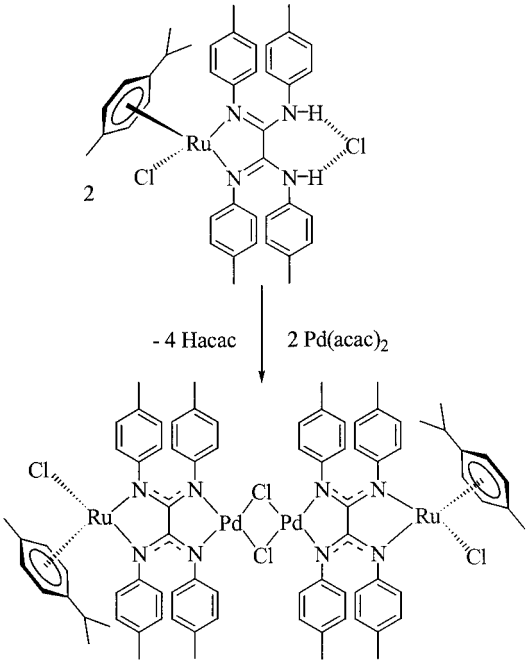
The complex **1a** has been proven to be a suitable "protected" ligand for the construction of oligonuclear complexes containing different metals. For example, reaction with $Pd(acac)_2$ resulted in the formation of the tetranuclear complex **2** containing palladium atoms in the inner part and two ruthenium centers on the peripheries (Scheme 2). Elemental analysis and a mass spectrum confirmed its composition. In the ESI-mass spectrum the complex cation [M

$- Cl]^+$ $m/z = 1679$ was detected and the obtained isotope pattern agrees well with the calculated molecular formula $C_{80}H_{84}Cl_3N_8Pd_2Ru_2$. Furthermore, the ^1H NMR and the ^{13}C NMR spectra of **2** ([D$_8$]THF at room temperature) show the expected signals for a symmetrical complex and are similar to those of **1a**, except for the absence of the signals of the N−H protons. Red single crystals of compound **2** obtained from toluene were subjected to an X-ray diffraction analysis. Figure 2 displays the molecular structure of **2**.



Scheme 2. Formation of the tetranuclear heterobimetallic complex **2**

The Ru(*oxam1*)PdCl$_2$Pd(*oxam1*)Ru core of **2** is essentially planar and the peripheral ligands cymene and chloride are *trans* with respect towards each other. The coordination geometry around the ruthenium centers is the same as in **1a**.

Exchange of the hydrogen bonded chloride in **1a** by BF_4^- or trifluoroacetate anions in THF resulted in the formation of the complexes [(η^6-*p*-cymene)RuCl(*oxam1*)BF$_4$] (**1b**), and [(η^6-*p*-cymene)RuCl(*oxam1*)OOCCF$_3$] (**1c**). The ^1H NMR spectra of both compounds in [D$_8$]THF showed nearly identical signals for all of the CH groups; however the signals for the NH protons were very different. In **1b** this signal appeared at $\delta = 9.05$ ppm as a sharp singlet. The magnitude of this upfield shift ($\delta = 3.8$ ppm) is indicative of a weaker hydrogen bond interaction compared with **1a**. In contrast, the trifluoroacetate complex **1c** showed very broad NH signals between $\delta = 11$ and $\delta = 12$ ppm, characteristic of a fast proton exchange or rotational effect. At lower temperature the signal became sharper at around $\delta = 11.6$ ppm. This low-field shift is indicative of a stronger hydrogen bond than that in **1b**.

The solid-state structure of **1b** and **1c** could be determined by X-ray analyses. Both ruthenium cymene moieties

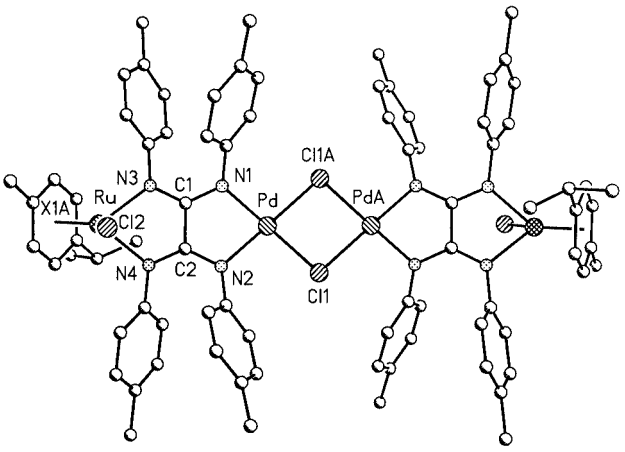


Figure 2. Molecular structure of complex **2**, selected distances [Å] and bond angles [deg]: Ru−Cl2 2.431(1), Ru−X1A 1.681(4), Ru−N4 2.104(3), Ru−N3 2.082(3), Pd−Cl1 2.333(1), Pd−Cl1A 2.341(1), Pd−N1 1.989(4), Pd−N2 2.011(3), C1−N1 1.342(5), C1−N3 1.312(5), C1−C2 1.495(5), C2−N2 1.332(5), C2−N4 1.318(5); X1A−Ru−Cl2 127.8(1), X1A−Ru−N3 86.5(2), X1A−Ru−N4 83.8(2), Cl2−Ru−N3 86.8(1), Cl2−Ru−N4 83.8(1), N3−Ru−N4 76.7(1), Cl1−Pd−Cl1A 82.99(4), Cl1−Pd−N1 179.4(1), Cl1−Pd−N2 97.7(1), N1−Pd−N2 81.7(1), N1−Pd−Cl1A 97.6(1), N2−Pd−Cl1A 179.3(1), N1−C1−N3 129.8(4), N2−C2−N4 130.9(4), C1−C2−N2 114.9(3), C1−C2−N4 114.2(3), C2−C1−N1 114.7(3), C2−C1−N3 115.5(3)

(**1b** not depicted) are identical to **1a** within experimental errors. One fluoro substituent of the BF_4^- anion does form a hydrogen bond to both NH function [N3−F4 2.825(4) and N4−F4 3.034(4) Å]. The surprisingly short N3−F4 distance might be due to packing effects. Similar N−H···F hydrogen bond patterns have been observed in related copper azophenine complexes.[13]

The trifluoroacetate anion in **1c** does form a hydrogen bond with both NH functions of the coordinated oxalic amidine (Figure 3). However, in contrast to the usual bonding mode of carboxylate anions in previously reported related metal complexes containing a diimine/diamine[14–16] in **1c** only the oxygen of the C=O group [C41−O2 = 1.176(7) Å] is involved in the hydrogen bond network. The relatively short N−H···O distances of 2.771(3), and 2.761(3) Å, respectively suggest a very strong interaction.

The formation of the complexes **3a** and **3b** between bis(mesityl)bis(pyridylmethyl)oxalic amidine (*oxam2*) and FeX_2 (X: Cl, Br) clearly demonstrates that coupled cation/anion coordination can also be used for realizing untypical coordination modes (Scheme 3). Whereas in transition metal complexes containing additional coordinating anionic chelate ligands (such as acetylacetonate), *oxam2* typically acts as a three-dentate bridging ligand in dinuclear complexes[18−20] whereas it forms mononuclear tetradentate complexes with iron halides.

The solid-state structure of **3a** determined by X-ray diffraction analysis shows the oxalic amidine ligand to be coordinated as tetradentate ligand in its prototropic form (Figure 4). The 1,2-diimine now residing on the picolyl based nitrogens is coordinated together with the pyridine donor sites to the five-coordinated Fe^{II} with the chloride ligand in the apical position resulting in a square-planar

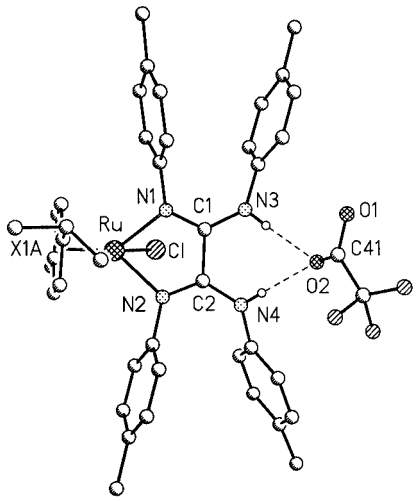

Figure 3. Molecular structure of complex **1c**, selected distances [Å] and bond angles [deg]: Ru−Cl 2.406(1), Ru−X1A 1.687(4), Ru−N1 2.079(3), Ru−N2 2.084(3), C1−N1 1.304(5), C1−N3 1.344(5), C1−C2 1.513(6), C2−N2 1.308(5), C2−N4 1.347(5), O2−N3 2.761(3), O2−N4 2.771(3); X1A−Ru−Cl 128.3(1), X1A−Ru−N1 85.4(2), X1A−Ru−N2 84.4(2), Cl−Ru−N1 85.2(1), Cl−Ru−N2 84.4(1), N1−Ru−N2 75.8(1), N1−C1−N3 129.0(4), N2−C2−N4 127.5(4), C1−C2−N2 113.5(4), C1−C2−N4 118.9(4), C2−C1−N1 113.6(3), C2−C1−N3 117.4(4)

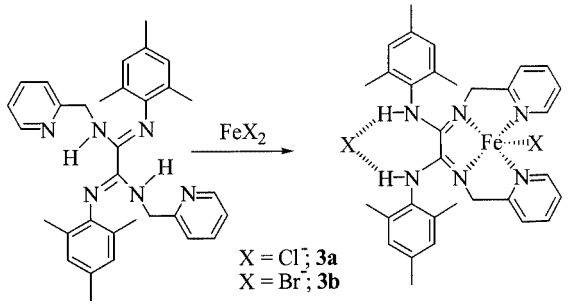

Scheme 3. Structure of the free ligand bis(mesityl)bis(pyridylmethyl)-oxalic amidine, and coordination mode in the iron complexes **3a** and **3b**

pyramidal coordination environment. Similarly to complex **1a**, one halide is coordinated to the two N−H groups on the opposite side of the oxalic amidine frame yielding a zwitterionic complex [Cl2−N5 = 3.051(1) Å, Cl2−N6 = 3.152(1) Å]. Other relevant bond lengths and angles fall in the range of typical values. The internal bond length and angles of the central oxalic amidine are similar to those in **1a**. In contrast to **1a**, the plane arranged by the four nitrogen donor atoms of the central oxalic amidine frame of **3a** is slightly distorted. More significant are the differences between the bond angles Cl1−Fe−N2 [104.27(7)°] and Cl1−Fe−N4 [107.66(7)°] respectively to Cl1−Fe−N1 [109.27(7)°] and Cl1−Fe−N3 [114.36(7)°]. These differences result in a distorted square pyramidal coordination arrangement in **3a**. In this arrangement the iron center is "out of plane" coordinated similar to well-known hem iron systems. According to X-ray structural analysis, **3b** has the same ion-paired structure as **3a**.

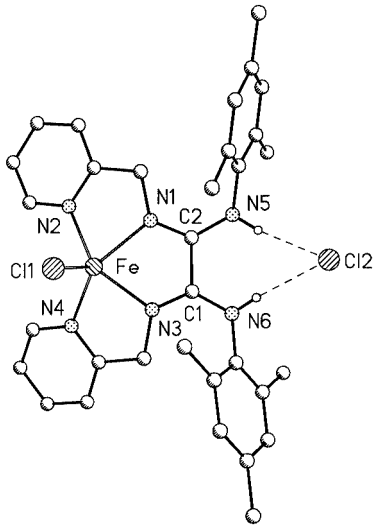

Figure 4. Molecular structure of complex **3a**, selected distances [Å] and bond angles [deg]: Fe−Cl1 2.663(9), Fe−N1 2.091(2), Fe−N2 2.148(2), Fe−N3 2.089(2), Fe−N4 2.181(2), C1−N3 1.296(3), C1−N6 1.336(3), C1−C2 1.535(4), C2−N1 1.284(3), C2−N5 1.350(3), Cl2−N5 3.051(1), Cl2−N6 3.152(1); Cl1−Fe−Nl 109.27(7), Cl1−Fe−N2 104.27(7), Cl1−Fe−N3 114.36(7), Cl1−Fe−N4 107.66(7), Nl−Fe−N2 76.98(9), N1−Fe−N3 75.64(9), N1−Fe−N4 140.04(9), N2−Fe−N3 138.13(9), N2−Fe−N4 108.03(9), N3−Fe−N4 75.70(9), N6−C1−N3 128.8(3), N1−C2−N5 128.5(3), C1−C2−N1 113.6(2), C1−C2−N5 117.9(2), C2−C1−N3 112.7(2), C2−C1−N6 118.5(2)

The cores of bibenzimidazole (*bbimH*$_2$) and biimidazole (*bimH*$_2$) are structurally related to the oxalic amidine ligand family. However, electronic differences exist which manifest themselves in different pK_a values of the coordinated ligands.[3,17] Since ruthenium polypyridyl complexes of these ligands are photoactive it was our aim to use the coupled cation/anion coordination for the formation of tight ion-paired, photoactive complexes. The appropriate choice of anions should lead to stable assemblies of potentially higher nuclearity and in addition a tuning of their solubility in nonpolar solvents could be envisaged.

It is known that some biimidazole (*bimH*$_2$) can form complexes in which one anion is linked to the imidazole based NH groups via hydrogen bonds;[21−28] however, in most cases polymeric networks resulted.[21,22−24] In contrast, well-defined mononuclear ion-paired bibenzimidazole complexes are rare. Ag^I and Cu^I complexes containing associated chloride or acetate anions have been characterized by de Souza Lemos.[25,26] Iron(II) complexes with *bbimH*$_2$ exhibit complex hydrogen bonding patterns where cationic complexes are linked via hydrogen bonds to their respective anions.[15] Recently, Beauchamp et al. have shown that some *bimH*$_2$ Re^{III} complexes form hydrogen bonds with halides or benzoate anions resulting in ion pairs that are stable in organic solvents.[16,27,28]

In an initial work we have shown that N−H groups of *bbimH*$_2$ Ru complexes bind water molecules resulting in hydrogen bonded networks. The variation of the noncoordinating anion determined the supramolecular aggregation in these compounds.[29]

Based on these observations we choose to employ carboxylate anions in an attempt to obtain stable aggregates. The trifluoroacetate complex $[(tbbpy)_2Ru(bbimH_2)(OOC-CF_3)](PF_6)$ (**4**), could easily be prepared by deprotonation of $[(tbbpy)_2Ru(bbimH_2)](PF_6)_2$ followed by reaction of the deprotonated complex with the trifluoroacetic acid. $[(tbbpy)_2Ru(bbimH_2)\{OOC(CF_2)_7CF_3\}][OOC(CF_2)_7CF_3]$ (**5**) was prepared by deprotonation of $[(tbbpy)_2Ru(bbimH_2)](Cl)_2$ followed by reaction of the fully deprotonated complex with the corresponding acid. The ^1H NMR spectra of both **4** and **5** show a new signal at δ = 16.4 ppm in deuterated acetone in addition to the other signals for the complex cation (see Exp. Sect.). Its broadness and extreme low-field shift suggests that it corresponds to the N−H protons. Since a signal for these protons in other ruthenium polypyridyl complexes with $bbimH_2$ as ligand has never been observed,[29] we assume that strong ion paring may explain this effect. The ESI-mass spectroscopical investigation confirmed the nature of the complex cation.

The solid-state structure of **4** elucidated by an X-ray diffraction study showed the expected complex cation where the bibenzimidazole ligand coordinates via the 1,2-diimine part to the Ru^{II} atom that exhibits distorted-octahedral geometry. The peripheral NH functions form hydrogen bonds to the carboxylate anion resulting in an ion-paired structure (Figure 5). The distances between hydrogen atoms of the N−H functions and the oxygens of the carboxylate [N3−O1 = 2.703(3), N4−O1 = 2.659(3) Å] are in the range of strong hydrogen bonds.[29] In contrast to the hydrogen bond association in **1c**, *both* NH function interact with both carboxylate oxygens in **4**. The complementary topology of the secondary amines of coordinated bibenzimidazole and the carboxylate anions allows a more efficient interaction between both parts leading to two strong N−H···O bonds (see also Figure 3).

In order to understand why the two strongly related complexes, **1c** and **4**, form different hydrogen bonding networks with trifluoroacetate the central cores of **1b** and **4** were superimposed on each other (Figure 6). It is clearly evident from Figure 6 that the steric demand of the aryl substituents at the nitrogens in **1c** determines the C1−N3−H angle in such a way that a favorable hydrogen bond interaction is only possible with one hydrogen bond acceptor. In contrast, the bibenzimidazole ligand in **4** is bent around the ruthenium center[29] that results in the orientation of the two NH functions towards two hydrogen bond acceptors.

Although the diffraction data for complex **5**, containing perfluorooctylcarboxylate instead of trifluoroacetate, were insufficient for satisfactory refinement of all parameters, the data show without doubt that the perfluorooctylcarboxylate is anchored via the two imidazole NH to the complex cation, as is similar in **4** (O1−N4 = ca. 2.660 Å, O2−N3 = ca. 2.706 Å). The structural motif of **5** is displayed in Figure 7.

Complex **5** contains a twofold positively charged cation as part of the ion-paired unit but also a discrete anion. Surprisingly, **5** is even soluble in supercritical CO_2, which is known to be an extremely poor solvent for ionic compounds. This suggests that the tight ion-paired compound **5** is also stable in such nonpolar solvents. This could be explained by the interaction of the hydrophilic moieties, cationic 1,2-diamine and carboxylate with each other in such a way that only the lipophilic *tert*-butyl- and perfluorooctyl moieties interact with the solvent. In contrast, the ionic complex $[(tbbpy)_3Ru][OOC(CF_2)_7CF_3]_2$, which can be obtained by simple anion-exchange, is completely insoluble in $scCO_2$. Due to the lack of N−H functions in this complex no hydrogen bonds can be formed, additionally confirming that the supramolecular association via hydrogen bonds is essential for this unexpected effect.

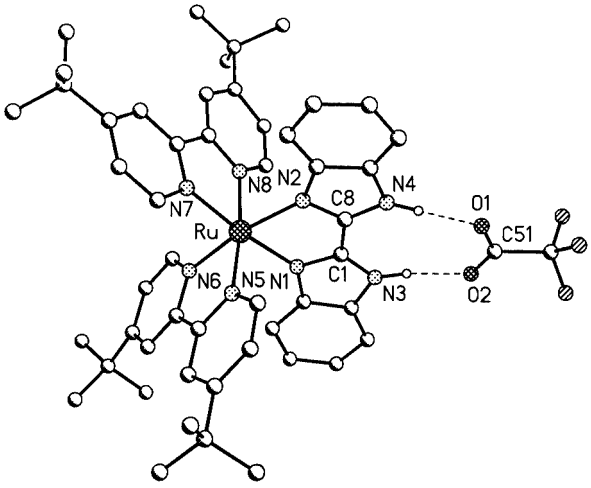

Figure 5. Molecular structure of complex **4**, selected distances [Å] and bond angles [deg]: Ru−N1 2.086(3), Ru−N2 2.109(3), Ru−N5 2.038(2), Ru−N6 2.037(3), Ru−N7 2.042(3), Ru−N8 2.074(3), C1−N11.332(5), C1−N3 1.336(6), C1−C8 1.433(6), C8−N2 1.328(6), C8−N4 1.359(6), N4−O1 2.659(3), N3−O2 2.703(3), O1−C51 1.257(6), O2−C51 1.223(6), N1−Ru−N2 77.5(1); N1−Ru−N5 88.3(1), N1−Ru−N6 93.6(1), N1−Ru−N7 173.4(1), N1−Ru−N8 97.2(1), N1−C1−N3 114.0(4), C1−C8−N2 117.3(4), C1−C8−N4 129.1(4), C8−C1−N1 115.9(4), C8−C1−N3 130.0(4), O1−C51−O2 131.2(5)

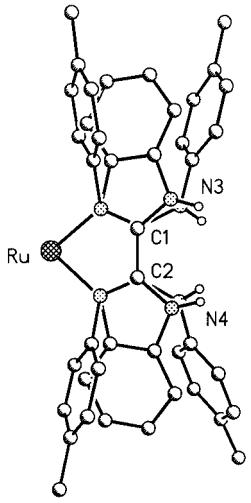

Figure 6. Least square fit of parts of complex **1c** and **4**, torsion angles N3−C1−C2−N4: for **1c** −1.2° and for **4** −2.4°; distance N3−N4: for **1c** 2.784(4) Å and for **4** 3.184(4) Å

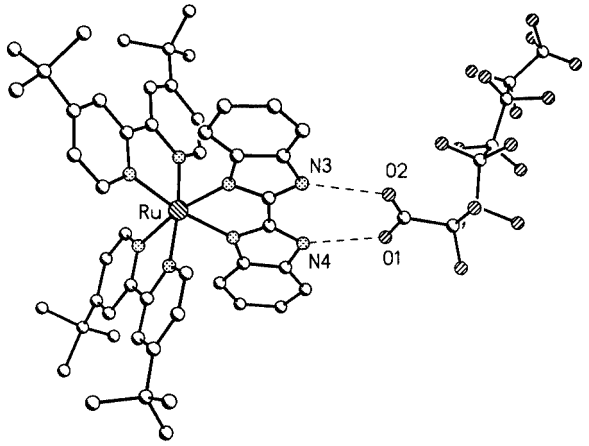

Figure 7. Structural motif of complex **5**

Deprotonation of $[(tbbpy)_2Ru(bbimH_2)](PF_6)_2$ and subsequent reaction with tetetrafluoroterephthalic acid in a molar ratio 2:1 in acetone/water resulted in the formation of complex **6**. Upon recrystallization of **6** from acetonitrile/water the deep red complex **7** was obtained. Both complexes could be isolated as single crystals.

Figure 8 shows the molecular structure for compound **6** and lists relevant bond lengths and angles in the figure captions.

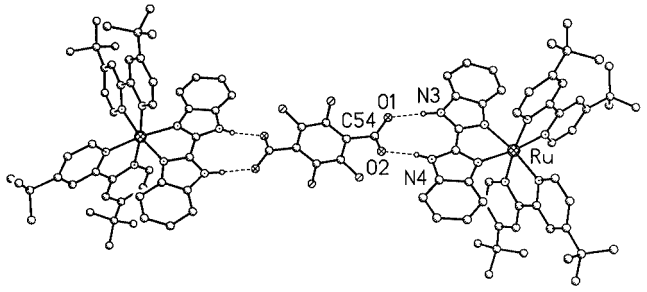

Figure 8. Molecular structure of complex **6**, selected distances [Å] and bond angles [deg]: O1−N3 2.673(5), O2−N4 2.652(5), O1−C54 1.240(5), O2−C54 1.232(5); O1−C54−O2 128.5(4)

In the solid state two ruthenium bibenzimidazole units are connected via a deprotonated tetrafluoroterephthalic acid dianion. Two PF_6 anions remain isolated. Both imidazole based NH functions interact with both oxygen atoms of one carboxylate function, resulting in N···O distances of 2.673(5) and 2.652(5) Å, respectively. The interaction between the ruthenium complex units and the carboxylate moiety is very similar to that observed in **4**. Both ruthenium complexes are twisted out of the plane defined by the two coplanar carboxylate moieties by 152.8°. The Ru···Ru distance defined by this supramolecular arrangement is 1.957 nm. Although the combination of two inherently chiral ruthenium complexes may lead to a mixture of diastereomers[3] the crystals of **6** only contained the MESO isomer.

According to the X-ray analysis of single crystals, **7** contains two monodeprotonated ruthenium units, also connected by the terephthalate bridge (Figure 9 and Scheme 4). However, only the protonated imidazole nitrogen forms a hydrogen bond to one oxygen of the carboxylate group [N3−O2 = 2.693(5) Å] whereas the deprotonated imidazole nitrogen acts as a hydrogen bond acceptor for an additional water molecule [N4−O3 = 2.871(5) Å].

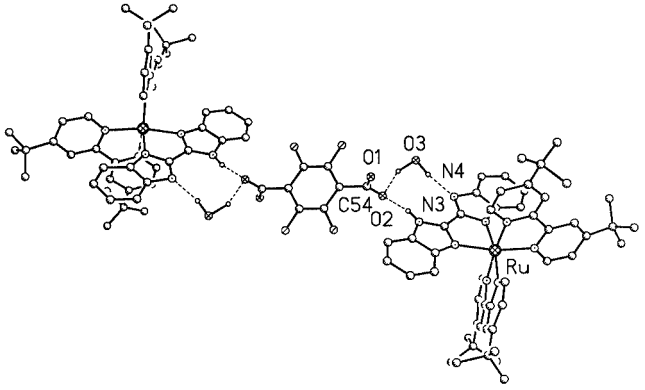

Figure 9. Molecular structures of complex **7**, selected distances [Å] and bond angles [deg]: O3−N4 2.871(5), O2−N3 2.693(4), O2−O3 2.926 (5), O1−C54 1.230(5), O2−C54 1.248(5); O1−C54−O2 127.9(4)

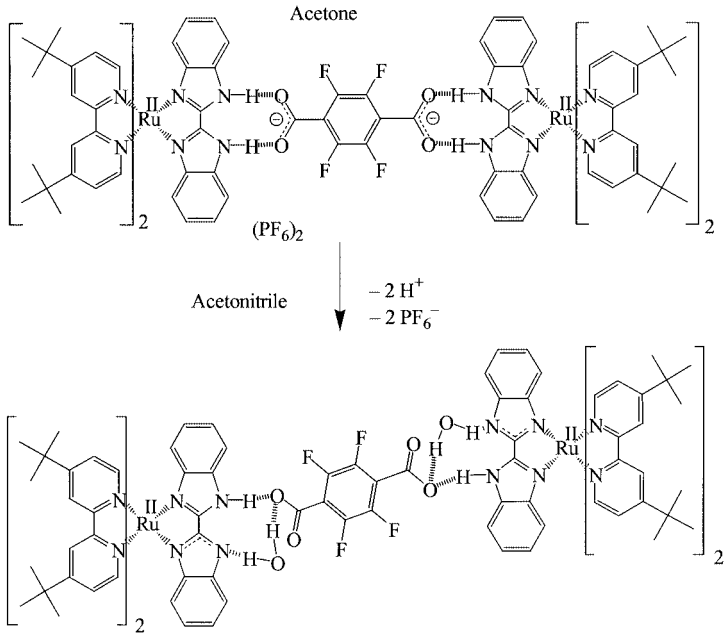
The ruthenium complexes are consequently twisted out of the plane defined by the two carboxylate moieties by 65.0°. This is a difference of 87.8° compared with the value obtained for **6**. As expected, the Ru···Ru distance in **7** (2.025 nm) is longer than in **6** (1.957 nm). The isolated compound **7** contains, as in **6**, only the MESO isomer.

The dimeric arrangement is therefore stable even if the essential ruthenium based NH functions are monodeprotonated.

Conclusion

Tight ion-paired complexes with different anions can be synthesized using diimine/diamine type bridging ligands, which are able to split M−X bonds under formation of a coupled cation/anion coordination. The resulting ion-paired complexes can be considered as ''protected metalloligands'' useful for the construction of oligonuclear organometallic complexes, as demonstrated by the reaction of **1a** with $Pd(acac)_2$ resulting in the formation of the tetranuclear mixed metal complex **2**. The hydrogen bonded anion in **1** can be varied in a wide range. The novel hydrogen bonding pattern displayed in **1a−c** between the cationic oxalic amidine fragment and one specific spatially well defined point opens the possibility of designing supramolecular compounds using new, ''single point'' bridging components such as the redox active 1,4-benzoquinone and similar systems.

The connection of chromophores such as ruthenium polypyridyl complexes employing supramolecular construction principles is strongly reminiscent of the building principles of the naturally occurring Light Harvesting Complexes (LHA). Additionally, the simple building blocks em-



Scheme 4. Structural formula of complexes **6** and **7**

ployed here, as in **6**, would allow a wide variation of the structures obtained, for example simply by switching the coordination mode by altering the pH values. Furthermore, the enhanced solubility of **5** offers the interesting possibility of investigating reactions of the photoactive complex **5** and related complexes in supercritical CO_2. Further studies along these lines are now in progress.

Experimental Section

General: *p*-Tolyl oxalic amidine ligand (*oxam1*);[30] the ligand *N*,*N*′-bis(2-pyridylmethyl)-1,2-bis(2,4,6-trimethylphenylimino)ethane-1,2-diamine (*oxam2*),[20,31] and [(tbbpy)$_2$Ru]Cl$_2$ and [(tbbpy)$_2$Ru-(bbimH$_2$)](X)$_2$ (X = Cl, PF$_6$)[3,29] were prepared according to described methods. The complexes (η^6-*p*-cymene)RuCl$_2$, PdCl$_2$(CH$_3$CN)$_2$, and trifluoroacetic acid (Aldrich) and perfluorooctylcarboxylic acid (ABCR) were used without additional purification. All manipulations were carried out under Argon using standard Schlenk techniques and the solvents used were dried and distilled.

^{1}H NMR and ^{13}C NMR spectra were recorded at ambient temperature unless otherwise stated on a Bruker AC 200 MHz spectrometer. All spectra were referenced to TMS or deuterated solvent as an internal standard. FAB-mass spectra were obtained on a Finnigan MAT SSQ 710 system (2,4-dimethoxybenzyl alcohol as matrix), ESI-mass spectra were recorded on a Finnigan MAT, MAT 95 XL. IR measurements were carried out on a Perkin−Elmer System 2000 FT-IR.

Complex 1a: A solution of *oxam1* (1.30 g, 2.92 mmol) in toluene (30 mL) was added to a suspension of [(η^6-*p*-cymene)RuCl$_2$]$_2$ (0.89 g, 1.46 mmol) in toluene (30 mL) and the mixture was refluxed for 2 hours. After cooling to room temperature, the orange-red microcrystalline solid was filtered, washed with diethyl ether (20 mL) and dried in vacuo. Single crystals of **1** were obtained by recrystallization from hot toluene. Yield: 1.75 g (79%). $C_{40}H_{44}Cl_2N_4Ru$ (752.8): calcd.: C 63.82, H 5.89, N 7.44, Cl 9.42; found C 63.52, H 6.23, N 7.05, Cl 9.24. ^{1}H NMR ([D$_8$]THF): δ = 1.14, 1.17 [d, $^3J_{H\text{-}H}$ = 6.9 Hz, 6 H, −CH(CH_3)$_2$ cymene], 2.09, 2.18 (2 s, 6 H each, −CH$_3$ tolyl), 2.27 (s, 3 H, −CH$_3$ cymene), 2.50 [five lines, $^3J_{H\text{-}H}$ = 7.0 Hz, 1 H, −C*H*(CH$_3$)$_2$ cymene], 4.55, 4.58, 4.60, 4.64 (2 d, $^3J_{H\text{-}H}$ = 6.2 Hz, 2 H each, H^{2,3,5,6} cymene), 6.62, 6.66, 6.74, 6.78 [2 d$_{AA'BB'}$, $^3J_{H\text{-}H}$ = 8.3 Hz, 6 H each, −CH tolyl), 7.02, 7.60 (2 s$_{broad}$, 2 H each, −CH tolyl), 12.83 (s, 2 H, −NH) ppm. ^{13}C NMR ([D$_8$]THF): δ = 15.5 (−CH$_3$ cymene), 20.9 (−CH$_3$ tolyl), 22.6 (−CH(**C**H$_3$)$_2$ cymene), 31.0 [−*C*H(CH$_3$)$_2$ cymene], 84.8, 86.5 (C^{2,3,5,6} cymene), 102.0, 104.3 (C^{1,4} cymene), 123.9, 126.2, 128.6, 129.3 (CH tolyl), 124.7, 126.3 (**C**−CH$_3$ tolyl), 138.3 (NH−C tolyl), 148.8 (=N−C tolyl), 155.6 (C$_{bridge}$) ppm. MS (ESI in THF): *m*/*z* (%) = 716 (100) [M − Cl]$^+$, 680 (20) [M − 2 Cl]$^+$.

The red-orange complex **1b** was prepared by reaction of **1a** in THF with equimolar amounts of NaBF$_4$. yield: 80% $C_{40}H_{44}BClF_4N_4Ru$ (804.2) calcd.: C 59.74, H 5.52, N 6.97; found C 58.63, H 5.43, N 6.53. ^{1}H NMR ([D$_8$]THF): δ = 1.13, 1.17 [d, $^3J_{H,H}$ = 6.9 Hz, 6 H, −CH(CH_3)$_2$ cymene], 2.10 (s, 12 H, −CH$_3$ tolyl), 2.19 (s, 3 H, −CH$_3$ cymene), 2.63 [m, $^3J_{H,H}$ = 6.8 Hz, 1 H, −C*H*(CH$_3$)$_2$ cymene], 4.63 (s, 4 H, H^{2,3,5,6} cymene), 6.69, 6.84, 6.96, 7.17, 7.50 (four broad signals, one s, 16 H overall, −CH tolyl), 9.05 (s$_{broad}$, 2 H, −NH) ppm. ^{13}C NMR ([D$_8$]THF): δ = 15.9 (−CH$_3$ cymene), 20.7 (−CH$_3$ tolyl), 22.5 [−CH(*C*H$_3$)$_2$ cymene], 31.7 [−*C*H(CH$_3$)$_2$ cymene], 84.7, 87.3 (C^{2,3,5,6} cymene), 102.0, 104.3 (C^{1,4} cymene), 123.7, 128.8 (CH tolyl), 134.2 (*C*−CH$_3$ tolyl), 136.5 (NH−C tolyl), 149.7 (=N−C tolyl), 156.7 (C$_{bridge}$).

Analogously, **1c** was synthesized by reaction of **1a** in THF with an equimolar quantity of Ag(OOCCF$_3$). yield: nearly quantitative $C_{42}H_{44}ClF_3N_4O_2Ru$ (830.4) calcd.: C 60.75 H 5.33 N 6.75 Cl 4.27 found C 60.01 H 5.13 N 6.44. ^{1}H NMR ([D$_8$]THF): δ = 1.14, 1.18 [d, $^3J_{H,H}$ = 6.9 Hz, 6 H, −CH(CH_3)$_2$ cymene], 2.10 (s, 12 H, −CH$_3$ tolyl), 2.18 (s, 3 H, −CH$_3$ cymene), 2.51 [m, 1 H, −C*H*(CH$_3$)$_2$ cymene], 4.57, 4.60, 4.62, 4.65 (s, 1 H each, $^3J_{H,H}$ = 4.3 Hz, H^{2,3,5,6} cymene), 6.67, 6.87, 7.56 (m, 16 H, −CH tolyl), 11−12 (s$_{very\ broad}$, 2 H, −NH).

Single crystals of these complexes, suitable for an X-ray diffraction analysis, were obtained from THF or toluene.

Complex 2: Complex **1** (0.38 g, 0.5 mmol) and $Pd(acac)_2$ (0.154 g, 0.5 mmol) were suspended in toluene (20 mL) and refluxed for 4 h or until a clear, dark red solution resulted. The solution was concentrated to 5 mL and pentane (20 mL) was added. The red microcrystalline solid was filtered, washed with pentane (20 mL) and dried in vacuo. Single crystals of **2** were obtained by recrystallization from diethyl ether or toluene. Yield: 0.28 g (65%). $C_{80}H_{84}Cl_4N_8Pd_2Ru_2$ (1714.35) calcd.: C 56.04, H 4.94, N 6.53, Cl 8.27; found C 55.63, H 5.49, N 5.90, Cl 8.25. ^{1}H NMR (400 MHz, [D$_8$]THF): δ = 1.11, 1.13 [d, $^3J_{H\text{-}H}$ = 6.9 Hz, 6 H, −CH(CH_3)$_2$ cymene], 2.00 (s, 24 H, −CH_3 tolyl), 2.09 (s, 6 H, −CH_3 cymene), 2.43 [m, $^3J_{H\text{-}H}$ = 7.0 Hz, 2 H, −CH(CH$_3$)$_2$ cymene], 4.07, 4.09, 4.21, 4.23 (2 d, $^3J_{H\text{-}H}$ = 5.9 Hz, 4 H each, H^{2,3,5,6} cymene), 6.45, 6.47, 6.49, 6.51 (2 $d_{AA'BB'}$, $^3J_{H\text{-}H}$ = 8.0 Hz, 8 H each, −CH tolyl), 6.65, 6.68, 7.22, 7.24 (2 $d_{AA'BB'}$, $^3J_{H\text{-}H}$ = 8.0 Hz, 8 H each, −CH tolyl) ppm. ^{13}C NMR (100.6 MHz, [D$_8$]THF): δ = 19.0 (−CH_3 cymene), 20.8, 21.0 (2 s, −CH_3 tolyl), 22.7 [−CH(CH_3)$_2$ cymene], 31.5 [−CH(CH$_3$)$_2$ cymene], 82.7, 85.5 (C^{2,3,5,6} cymene), 100.2, 101.6 (C^{1,4} cymene), 125.9, 127.5, 127.7, 128.6 (CH tolyl), 132.9, 133.3 (C−CH_3 tolyl), 144.7, 151.1 (−N−C tolyl), 167.8 (C_{bridge}) ppm. MS (ESI in toluene + methanol): *m*/*z* (%) = 1679 (46) [M − Cl]$^+$ (isotope pattern found), 854 (100) [M − $C_{40}H_{42}N_4Cl_2RuPd]^+$, 680 [M − $C_{40}H_{42}N_4Cl_4Pd_2Ru]^+$.

Complex 3a: This compound was prepared as a crystalline bright orange solid analogously to **3b** from $FeCl_2$ (66 mg, 0.52 mmol) using *N*,*N*′-bis(2-pyridylmethyl)-1,2-bis(2,4,6-trimethylphenylimino)-ethane-1,2-diamine (*oxam2*) (262 mg, 0.52 mmol). Single crystals suitable for X-ray determination were obtained from THF. Yield: 286 mg (87%). $C_{36}H_{44}Cl_2FeN_6O$ (703.6) calcd.: C 61.46, H 6.30, N 11.95; found C 61.91, H 6.55, N 12.15. MS (FAB in NBA): *m*/*z* (%) = 630 (1) [M]$^+$, 595 (58) [M − Cl]$^+$, 560 (33) [M − 2 Cl]$^+$, 559 (83) [M − 2 Cl]$^+$.

Complex 3b: $FeBr_2$·2THF (181 mg, 0.50 mmol) and *N*,*N*′-bis(2-pyridylmethyl)-1,2-bis(2,4,6-trimethylphenylimino)ethane-1,2-diamine (*oxam2*) (261 mg, 0.52 mmol) were dissolved in THF (40 mL) and stirred overnight, at room temperature. After concentrating the solution to 10 mL, the precipitate was filtered off, washed with THF (3 × 10 mL) and dried by oil pump vacuum (9 h) at room temperature. A light orange solid was obtained. Yield: 317 mg (88%). Single crystals suitable for X-ray-determination were obtained from THF. $C_{32}H_{36}Br_2FeN_6$ (720.33): calcd. C 53.36; H 5.04; N 11.67; found C 52.44; H 5.22; N 11.07. IR (Nujol): $\tilde{\nu}$ = 3127 (m, NH), 1605, 1622, 1554 cm^{-1}. MS (FAB in NBA): *m*/*z* (%) = 639 (17) [M − Br]$^+$, 560 (14)[M − 2 Br]$^+$, 559 (83)[M − 2 Br−H]$^+$.

Complex 4: [(tbbpy)$_2$Ru(bbimH$_2$)](PF$_6$)$_2$ (500 mg, 0.43 mmol) was dissolved in predistilled THF. Freshly prepared NaOMe (0.43 mmol) in MeOH was then added, resulting in a bathochromic shift of the absorption. The solution was stirred for 20 min. CF_3COOH (49 mg, 0.43 mmol,) was added to this solution, which resulted in a hypsochromic shift of absorption, the solution was stirred for 20 min, the solvent removed and the precipitate recrystallized from acetone/water resulting in single crystals. ^{1}H NMR spectra were recorded in deuterated acetone. Yield: 410 mg (84.4%). $C_{55}H_{64}F_9N_8O_3PRu$ (1188.21): calcd. C 55.59, H 5.43, N 9.43; found C 55.87, H 5.13, N 8.84. ^{1}H NMR ([D$_6$]acetone): δ = 16.4 (s, 1 H, NH), 8.85 (s, 2 H, 3a-H), 8.75 (s, 2 H, 3b-H), 8.04 (m, 2 H, 6a-H), 8.04 (m, 2 H, 6b-H), 7.76 (d, 2 H, 6-H), 7.61 (d, 2 H, 5a-H), 7.45 (d, 2 H 5b-H), 7.37 (t, 2 H, 5-H) 7.01 (t, 2 H, 4-H), 5.72 (d, 2 H, 3-H), 1.47 (s, 18 H, C_4H_9), 1.35 (s, 18 H, C_4H_9) ppm. MS (ESI in methanol): *m*/*z* (%) = 871 (100) [M − H − PF$_6$ − $CF_3COO]^+$ (isotope pattern found) IR (Nujol): $\tilde{\nu}$ = 3060 (m, NH), 1776 (s, C=O), 1614 (s, C=N) cm^{-1}.

Complex 5: [(tbbpy)$_2$Ru(bbimH$_2$)](Cl)$_2$ (405 mg, 0.43 mmol) was dissolved in predistilled THF. Freshly prepared NaOMe (0.87 mmol) in MeOH was then added, resulting in a bathochromic shift of the absorption. The solution was stirred for 30 min. $C_7F_{15}COOH$ (358 mg, 0.87 mmol) was added to this solution, which resulted in a hypsochromic shift of the absorption, the solution was stirred for 20 min, the solvent removed and the precipitate recrystallized from acetone/water. ^{1}H NMR spectra were recorded in deuterated acetone. Yield 705 mg, 92%, ^{1}H NMR ([D$_6$]acetone): δ = 16.4 (s, 1 H, NH), 8.85 (s, 2 H, 3a-H), 8.75 (s, 2 H, 3b-H), 8.04 (m, 2 H, 6a-H), 8.04 (m, 2 H, 6b-H), 7.76 (d, 2 H, 6-H), 7.61 (d, 2 H, 5a-H), 7.45 (d, 2 H, 5b-H), 7.37 (t, 2 H, 5-H) 7.01 (t, 2 H, 4-H), 5.72 (d, 2 H, 3-H), 1.47 (s, 18 H, C_4H_9), 1.35 (s, 18 H, C_4H_9) ppm. MS (ESI in methanol): *m*/*z* (%) = 871 (100) [M − H − 2 $C_7F_{15}COO]^+$ (isotope pattern found) IR (Nujol): $\tilde{\nu}$ = 3060 (m, NH), 1730 (s, C=O), 1612 (s, C=N) cm^{-1}.

Complex 6: [(tbbpy)$_2$Ru(bbimH$_2$)](PF$_6$)$_2$ (500 mg, 0.43 mmol) was dissolved in THF. Freshly prepared NaOMe (0.43 mmol) in MeOH was then added, resulting in a bathochromic shift of the color. After stirring for 20 min $COOHC_6F_4COOH$ (0.43 mmol, 103 mg) was added to this solution resulting in a hypsochromic shift of the color. The solution was then stirred for 20 min, the solvent removed and the precipitate recrystallized from acetone/water. Yield 404 mg, 75%, ^{1}H NMR ([D$_6$]acetone): δ = 8.85 (s, 2 H, 3a-H), 8.75 (s, 2 H, 3b-H), 8.04 (m, 2 H, 6a-H), 8.04 (m, 2 H, 6b-H), 7.76 (d, 2 H, 6-H), 7.61 (d, 2 H, 5a-H), 7.45 (d, 2 H, 5b-H), 7.37 (t, 2 H, 5-H) 7.01 (t, 2 H, 4-H), 5.72 (d, 2 H, 3-H), 1.47 (s, 18 H, C_4H_9), 1.35 (s, 18 H, C_4H_9) ppm. MS (ESI in methanol): *m*/*z* (%) = 871 (100) [M − (tbbpy)$_2$Ru(bbimH$_2$) − H − 2 PF$_6$ − $COOC_6F_4COO]^+$ (isotope pattern found) IR (Nujol): $\tilde{\nu}$ = 3410 (w, OH), 3177 (m, NH), 1704 (m, C=O), 1613 (s, C=N) cm^{-1}.

Complex 7: Compound **6** (200 mg) was dissolved in acetonitrile/water (80:20). The color of the solution changed from bright orange to red. The solvent was allowed to evaporate slowly and the small crystals that appeared were collected by filtration. X-ray suitable crystals were obtained by recrystallization from acetonitrile/water. Yield 110 mg 55%, ^{1}H NMR ([D$_6$]acetonitrile): δ = 8.51 (s, 2 H, 3a-H), 8.42 (s, 2 H, 3b-H), 7.87 (d, 2 H, 6a-H), 7.76 (m, 4 H, 6b/6-H), 7.48 (d, 2 H, 5a-H), 7.43 (t, 2 H, 5-H) 7.35 (d, 2 H, 5b-H), 7.06 (t, 2 H, 4-H), 5.68 (d, 2 H, 3-H), 1.47 (s, 18 H, C_4H_9), 1.35 (s, 18 H, C_4H_9) ppm. MS (ESI in methanol): *m*/*z* (%) = 871 (100) [M − (tbbpy)$_2$Ru(bbimH$_2$) − H − $COOC_6F_4COO]^+$ (isotope pattern found) IR (Nujol): $\tilde{\nu}$ = 3460 (m, OH), 3177 (m, NH), 1674 (m, C=O), 1607 (s, C=N) cm^{-1}.

(tbbpy)$_3$Ru(C$_7$F$_{15}$COO)$_2$: Triethylamine (45 mg, 0.44 mmol) was added to a solution of perfluorooctanoic acid (177 mg, 0.44 mmol) in CH_2Cl_2 while stirring. After 15 minutes this solution was poured into a suspension of [(tbbpy)$_3$Ru](PF$_6$)$_2$ (250 mg, 0.21 mmol in CH_2Cl_2/H_2O, 50:50). This mixture was stirred rapidly for 48 hours. The bright orange-red organic layer was separated and the solvent was removed. The remaining solid was recrystallized from acetone/water (10:1). The absence of the PF_6^- anion was established via ^{31}P NMR spectroscopy. Yield 363 mg, quantitative $C_{70}H_{72}F_{30}O_4N_6Ru$ (1732.4) calcd.: C 48.53, H 4.19, N 4.85 found C 46.33, H 3.93, N 4.42. ^{1}H NMR (298 K, 400 MHz, CD_2Cl_2): δ = 1.410 (s, 9 H, CH_3), 7.436 (dd, 1 H, CH-arom.), 7.605 (d, 1 H, CH-arom.), 8.529 (s, 1 H, CH-arom.) ppm. IR (Nujol): $\tilde{\nu}$ = 1695 (s, C=O), 1237, 1202 cm^{-1} (s, CF). MS (ESI in methanol): *m*/*z* (%) = 1319 (100) [M − $C_7F_{15}COO$ + 1]$^+$, 905 (16) [M − 2 $C_7F_{15}COO]^+$.

Crystal Structure Determination: The intensity data for the compounds were collected on a Nonius−Kappa CCD diffractometer, using graphite-monochromated Mo-K_α radiation. Data were corrected for Lorentz and polarization effects, but for absorption were only corrected for **3b**.[32,33] The structures were solved by direct methods (SHELXS[34]) and refined by full-matrix least-squares techniques against F_o^2 (SHELXL-97[35]). The diffraction data obtained for compound **5** were insufficient for satisfactory refinement of the structure parameters. However, the data were sufficient to show the structural motif of the molecule (Figure 7), the hydrogen-bridging system, and the crystallographic data. The data for compound **5** were not deposited in the Cambridge Crystallographic Data Centre.

For all compounds the hydrogen atoms of the diamine groups and the hydrogen atoms of the water molecule of **7** were located by difference Fourier synthesis and refined isotropically. All other hydrogen atoms were included at calculated positions with fixed thermal parameters. All non-hydrogen atoms (without the acetone and the disordered $[PF_6]^-$) were refined anisotropically.[36] XP (SIEMENS Analytical X-ray Instruments, Inc.) was used for structure representations.

Crystal Data for 1a:[36] $C_{40}H_{44}Cl_2N_4Ru$, Mr = 752.76 g·mol^{-1}, orange prism, size 0.10 × 0.10 × 0.09 mm, monoclinic, space group $P2_1/n$, a = 12.0053(3), b = 18.2083(4), c = 17.2697(3) Å, β = 95.763(2)°, V = 3756.01(14) Å^3, T= −90 °C, Z = 4, $\rho_{calcd.}$ = 1.331 g·cm^{-3}, μ(Mo-K_α) = 5.92 cm^{-1}, F(000) = 1560, 15215 reflections in h (−15/15), k (−23/21), l (−22/22), measured in the range 2.27° ≤ Θ ≤ 27.50°, completeness Θ_{max} = 98.8%, 8535 independent reflections, R_{int} = 0.036, 7120 reflections with $F_o > 4\sigma(F_o)$, 427 parameters, 0 restraints, $R1_{obs.}$ = 0.0547, $wR^2_{obs.}$ = 0.142, $R1_{all}$ = 0.067, wR^2_{all} = 0.152, GOOF = 1.085, largest difference peak and hole: 1.219/−1.074 e·Å^{-3}.

Competitive Insertion of Isocyanide into Tantalum−Amido and Tantalum−Methyl Bonds

Francisco Amor,[a] Javier Sánchez-Nieves,[a] Pascual Royo,*[a] Heiko Jacobsen,[b] Olivier Blacque,[b] Heinz Berke,[b] Maurizio Lanfranchi,[c] Maria Angela Pellinghelli,[c] and Antonio Tiripicchio[c]

Keywords: Tantalum / Competitive insertion / Isocyanide insertion / Density functional calculations

The (amido)methyl complexes [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NR_2)] [R = Ph (**3**), $SiMe_3$ (**4**)] were prepared by reaction of [Ta(η^5-C_5Me_5)(N*t*Bu)ClMe] (**1**) with the appropriate lithium amides. Attempts to isolate the analogous NHMe derivative afforded a mixture of complexes [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NHMe)] (**5**) and [Ta(η^5-C_5Me_5)(NMe)Me(NH*t*Bu)] (**6**), resulting from hydrogen exchange between the amido and imido ligands. Insertion of CN(2,6-$Me_2C_6H_3$) into the Ta–Me bond of complexes **3** and **4** gave the η^1-iminoacyl derivatives [Ta(η^5-C_5Me_5)(N*t*Bu)(NR_2){η^1-C(Me)=N(2,6-$Me_2C_6H_3$)}] [R = Ph (**7**), $SiMe_3$ (**8**)], while insertion into the Ta–NRMe (R = H, Me) bond of the complexes [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NRMe)] [R = H (**5**), Me (**2**)] gave the η^2-iminocarbamoyl compounds [Ta(η^5-C_5Me_5)(N*t*Bu)Me{η^2-C(NRMe)=N(2,6-$Me_2C_6H_3$)}] [R = H (**10**), Me (**9**)]. All of the new compounds were characterized by ^{1}H and ^{13}C NMR spectroscopy. The X-ray crystal structure of **9** is reported. DFT calculations were carried out to justify the preference of the insertion either into the Ta–C or the Ta–N bond.

Introduction

It is well known that isocyanides can be inserted into early transition metal−alkyl[1−5] and metal−amido[1,6−10] bonds to give η^2-iminoacyl and η^2-iminocarbamoyl compounds, respectively. These are versatile and potentially useful reagents in many synthetic applications.[1]

We reported[11] the insertion of isocyanide into the tantalum−methyl bond of various (η^5-pentamethylcyclopentadienyl)(imido) complexes of the type [Ta(η^5-C_5Me_5)(NR)MeX] to verify that this insertion takes place into the tantalum−methyl bond[12] not only for X = Cl, OR (R = Me, *t*Bu), noncompetitive ligands, but also for X = NH*t*Bu, which could behave as a competitive ligand to give η^2-iminocarbamoyl derivatives. We concluded that the steric demands of the X substituent influence these reactions more significantly than its π-donor capacity, the reaction being easier for X = Cl, Me, OMe (immediate at room temperature) than for X = O*t*Bu (7 h at room temperature) and X = NH*t*Bu (3 d at 75 °C). We also observed that the double insertion of isocyanide into the tantalum−iminoacyl bond is preferred over the insertion into the Ta−NH*t*Bu bond, allowing for the isolation of [Ta(η^5-C_5Me_5)(N*t*Bu)(NH*t*Bu){η^2-C(CMe=NR)=NR}] (R = 2,6-$Me_2C_6H_3$) complexes. Consequently, formation of η^2-iminocarbamoyl derivatives by insertion into tantalum−amido bonds would only be possible if no alkyl substituent were present, as observed for [Ta(η^5-C_5Me_5)(N*t*Bu)Cl{NH*t*Bu)][12] and related (amido)niobium compounds.[13]

However, an unexpected behaviour was observed when [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NMe_2)], which contains a less bulky dimethylamido ligand, was used. This reaction was immediate at room temperature affording the η^2-iminocarbamoyl derivative with preferential insertion into the tantalum−amido rather than the tantalum−methyl bond. For this reason we decided to thoroughly investigate these insertion reactions using different amido ligands. Meanwhile, a similar preferential insertion into a metal−dimethylamido bond was reported for related [Nb(η^5-$C_5H_4SiMe_3$){N(2,6-$Me_2C_6H_3$)}Me(NMe_2)] and [Ta(η^5-C_5Me_5){N(2,6-$Me_2C_6H_3$)}Me(NMe_2)] complexes.[14]

Here we report the synthesis of new (amido)methyltantalum complexes [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NR_2)] [R_2 = HMe, Ph_2, $(SiMe_3)_2$] and the competitive insertion of

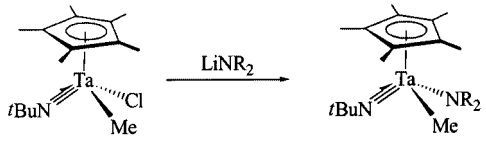
$CN(2,6\text{-}Me_2C_6H_3)$ into their Ta−Me and Ta−NR_2 bonds. The X-ray molecular structure of the η^2-iminocarbamoyl complex $[Ta(\eta^5\text{-}C_5(CH_3)_5](NtBu)Me\{\eta^2\text{-}C(NMe_2)=N(2,6\text{-}Me_2C_6H_3)\}]$ is also reported, as well as DFT calculations carried out to justify the notion of preferential insertion into Ta−dimethylamido bonds.

Results and Discussion

As previously reported[15] the dimethylamido complex $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me(NMe_2)]$ (**2**) was isolated in high yield as a dark yellow oil by addition of $LiNMe_2$ to an ethereal solution of the (chloro)(methyl) derivative $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)ClMe]$ (**1**). As shown in Equation (1), the same procedure afforded complex $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me(NPh_2)]$ (**3**) as a yellow oil in 90% yield. It is an air-sensitive compound that can be stored for long periods under an inert gas. The complex $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me\{N(SiMe_3)_2\}]$ (**4**), which was not isolated as a solid, was prepared in quantitative yield by the same reaction in a sealed NMR tube, and is stable in C_6D_6 solution for long periods.

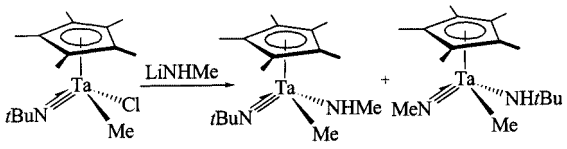


(1)

1 R = Ph, **3**; $SiMe_3$, **4**

It was found[15] that **2** shows dynamic NMR spectroscopic behaviour, indicating free rotation of the amido ligand and making the two methyl groups equivalent, to give a unique broad signal in both ^1H and ^{13}C NMR spectra at room temperature. Dynamic NMR spectroscopy experiments showed a coalescence temperature of ca. 302 K and a Gibbs activation energy $\Delta G^{\neq}$ of 58.15 kJ/mol for this process, in agreement with reported values for analogous complexes.[16] However, the ^1H NMR spectra of complexes **3** and **4** show the presence of two nonequivalent phenyl- and silylamido substituents, respectively, every aryl ring proton of **3** appearing as a sharp signal (δ = 6.7−7.2 ppm) while two sharp signals for the $SiMe_3$ groups of **4** were observed at δ = 0.18 and 0.50 ppm. Resonances for the methyl, *tert*-butyl and pentamethylcyclopentadienyl groups in complexes **3** and **4** appear in the usual region (see Exp. Sect.).

In an attempt to complete the series of (amido)(imido) complexes analogous to **2**, we tried the reaction of **1** with LiNHMe in THF. This reaction was not so simple and gave a mixture of $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me(NHMe)]$ (**5**) and $[Ta(\eta^5\text{-}C_5Me_5)(NMe)Me(NHtBu)]$ (**6**) in ca. 1:1 ratio [Equation (2)], as a pale yellow oil from which they could not be separated. No interconversion between **5** and **6** was observed when the mixture was heated up to 80 °C in the NMR tube, indicating that the temperature does not substantially modify the equilibrium.



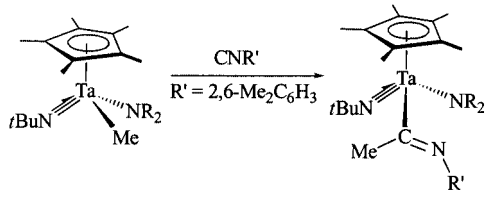
(2)

1 **5** **6**

Complexes **5** and **6** were easily distinguished by their ^1H NMR spectrum, which shows the methyl resonance of the amido ligand as a doublet (δ = 3.63 ppm, $^3J_{H,H}$ = 7 Hz) whereas that of the imido ligand appears as a singlet (δ = 3.77 ppm). Two sets of signals for the methyl, *tert*-butyl and pentamethylcyclopentadienyl groups were observed for the mixture of complexes **5** and **6**. The amido proton of the corresponding NHMe and NH*t*Bu appears as a broad signal at δ = 4.62 and 4.88 ppm, respectively. The values of $\Delta\delta$ ($\Delta\delta = \delta_{quat} - \delta_{Me}$) observed in the ^{13}C NMR spectra of **5** (30.2 ppm) and **6** (21.6 ppm) are consistent with the presence of the *tert*-butylimido and *tert*-butylamido ligands, respectively.[17]

Therefore, formation of **5**, followed by proton transfer from the methylamido to the more basic *tert*-butylimido ligand,[16,18−25] affords complex **6**, and the kinetic barrier for interconversion between **5** and **6** must be high.

Treatment of complexes **3** and **4** with $CN(2,6\text{-}Me_2C_6H_3)$ resulted in insertion into the Ta−Me bond, to give the η^1-iminoacyl compounds $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)(NPh_2)\{\eta^1\text{-}C(Me)=N(2,6\text{-}Me_2C_6H_3)\}]$ (**7**) and $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)[N(SiMe_3)_2]\{\eta^1\text{-}C(Me)=N(2,6\text{-}Me_2C_6H_3)\}]$ (**8**), after heating at 80 °C for 8 h and 20 h, respectively [Equation (3)]. This is the same behaviour previously observed for $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me(NHtBu)]$.[12]

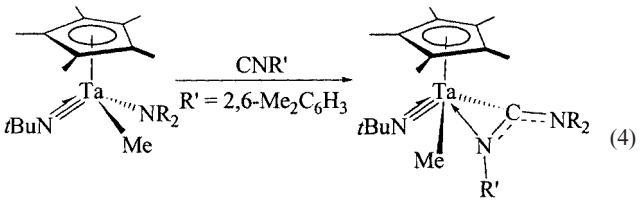


(3)

R_2 = Ph_2, **3**; $(SiMe_3)_2$, **4** R_2 = Ph_2, **7**; $(SiMe_3)_2$, **8**

Formation of the iminoacyl compounds **7** and **8** was confirmed by the low-field shift ($\delta > 1$ ppm) of the ^1H NMR signal of the migrated methyl group and the ^{13}C resonance of the iminoacyl sp^2-carbon atom observed at δ = 249.3 (**7**) and 251.9 ppm (**8**), as expected for complexes of this type.

In contrast, an almost immediate and complete reaction of the dimethylamido complex **2** with 1 equiv. of $CN(2,6\text{-}Me_2C_6H_3)$ took place at room temperature in hexane to afford the η^2-iminocarbamoyl compound $[Ta(\eta^5\text{-}C_5Me_5)(NtBu)Me\{\eta^2\text{-}C(NMe_2)=N(2,6\text{-}Me_2C_6H_3)\}]$ (**9**) [Equation (4)], which was recrystallized from pentane and isolated as colourless air-stable crystals soluble in all the usual organic solvents. Its crystal structure was determined by X-ray diffraction methods.



(4)

$R_2 = Me_2$, **2**; HMe, **5** $R_2 = Me_2$, **9**; HMe, **10**

Addition of 2 equiv. of CN(2,6-$Me_2C_6H_3$) to a C_6D_6 solution of a ca. 1:1 mixture of **5** and **6** proceeded with darkening of the solution and isocyanide insertion into the Ta−NHMe bond of complex **5** to give [Ta(η^5-C_5Me_5)(N*t*Bu)Me{η^2-C(NHMe)=N(2,6-$Me_2C_6H_3$)}] (**10**) after 24 h at room temperature [Equation (4)]. Under these conditions complex **6** remained unaltered. No insertion into the Ta−Me bond was observed even after heating to 80 °C, which caused complex **6** to decompose, while **10** remained unchanged.

Formation of the η^2-iminocarbamoyl compounds **9** and **10** was confirmed by the high-field shift ($\delta \approx 1$ ppm) of the methylamido signal, the very slight displacement of the Ta-Me resonance and the presence in the ^{13}C NMR spectra of a low-field signal ($\delta > 200$ ppm) due to the iminocarbamoyl sp^2-carbon atom.[26] Three ν(C=N) IR stretching vibrations were observed[6] for the η^2-iminocarbamoyl complex **9**.

The transformation of the (benzyl)(η^2-iminocarbamoyl) species into the corresponding (amido)(η^2-iminoacyl) derivative, typical in related (amido)niobium compounds,[13] was not observed for complex **9**, which decomposed on heating to over 100 °C. It can therefore be concluded that insertion occurred directly into the Ta−NMe_2 rather than the Ta−Me bond.

An X-ray diffraction study of complex **9** confirms that the isocyanide was inserted into the tantalum−amido bond. A view of the molecular structure of complex **9**, together with the atomic labeling system, is shown in Figure 1. Selected bond lengths and angles are given in Table 1.

The tantalum atom shows a four-legged piano stool arrangement involving the pentamethylcyclopentadienyl ring [Ta−CE(1) = 2.182(6) Å], [CE(1) being the centroid of the ring], the methyl carbon atom [Ta−C(11) = 2.230(5) Å], the nitrogen atom of the *tert*-butylimido ligand [Ta−N(3) = 1.785(4) Å], and the carbon and nitrogen atoms of the η^2-iminocarbamoyl ligand [Ta−C(12) = 2.146(5) and Ta−N(1) = 2.164(4) Å]. The dihedral angle between the cyclopentadienyl ring and the N(3)C(11)N(1)C(12) mean plane is 5.2(2)°. This arrangement can also be viewed as a three-legged piano-stool if the midpoint [M(1)] of the N(1)−C(12) bond is taken into consideration [Ta−M(1) = 2.054(5) Å]. The coordination geometry around the Ta atom can be described also as pseudotetrahedral if the centroid CE(1) and the midpoint M(1) are considered as coordination sites. The complex is chiral, and both enantiomers are present in the crystals. The insertion of CN(2,6-$Me_2C_6H_3$) into the coordinated dimethylamido group is stereoselective; in fact the η^2-iminocarbamoyl shows the N atom in a *cis* position with respect to the coordinated methyl group. Only one of the two possible stereoisomers is so formed. This stereoselectivity is probably mainly due to steric factors.

The *inside* coordination of the N(1) iminocarbamoyl nitrogen atom located between C(12) and C(11) is similar to that found for similar (chloro)(iminoacyl)(imido)(pentamethylcyclopentadienyl)- or (iminoacyl)(imido)(methyl)(pentamethylcyclopentadienyl)tantalum complexes[11,12,14,27] in which the N(1) iminoacyl nitrogen atom is located between the iminoacyl carbon atom and the chlorine atom or the methyl carbon atom. The values of the Ta−N(3) bond length, consistent with triple bond character, and of the nearly linear Ta−N(3)−C(23) bond angle of 176.8(4)° are as expected for an imido ligand and compare well with

those found in other (imido)(pentamethylcyclopentadienyl)-tantalum complexes.[11,12,14,27−30] The Ta−C(11) bond length presents the normal value for a $Ta-CH_3$ bond. The Cp* (C_5Me_5) ring is bound to the Ta atom in a nearly symmetric η^5-fashion; a slight trend towards η^3-coordination is observed, as indicated by three short [Ta−C(2) = 2.485(6), Ta−C(3) = 2.441(6), Ta−C(4) = 2.406(6) Å] and two long $Ta-C_{Cp^*}$ ring carbon distances [Ta−C(1) = 2.567(5) and Ta−C(5) = 2.503(6) Å], involving the C(1)−C(5) bond nearly *trans* to the imido group[30] {τ[N(3)−Ta−CE(1)−C(1)] = 159.7(4), τ[N(3)−Ta−CE(1)−C(5)] = −128.6(6), τ[N(3)−Ta−CE(1)−C(3)] = 17.3(7)°}. The midpoint of the N(1)−C(12) bond nearly eclipses the C(5) atom of Cp* {τ[M(1)−Ta−CE(1)−C(5)] = 10.3(7)°}. The Ta−N(1) and Ta−C(12) bond lengths are similar to those found in (η^2-*C*,*N*-iminoacyl)Ta complexes.[11,12,14,27] The N(1)−C(12) [1.303(5) Å], and the C(12)−N(2) [1.339(6) Å] bond lengths reveal π delocalizaton in the η^2-*C*,*N*-iminocarbamoyl moiety. The N(1)C(12)N(2)C(21)C(22) fragment is quite planar {max. dev. 0.050(7) Å for C(21), τ[N(1)−C(12)−N(2)−C(21)] = 173.4(5), τ[N(1)−C(12)−N(2)−C(22)] = −6.8(8)°} and forms dihedral angles of 4.5(2) and 81.7(2)° with the TaN(1)C(12) and the aryl groups, respectively.

The close similarity between the symmetry properties of the frontier orbitals of (cyclopentadienyl)(imido)metal [Ta(η^5-C_5Me_5)(N*t*Bu)] and the metallocene [Ti(η^5-C_5Me_5)$_2$] fragments[30] suggests that the $1a_1$ metal orbital is used for π-bonding by the NMe_2 ligand. The dynamic behaviour observed for **2** at room temperature indicates that this $1a_1$ orbital is energetically accessible for ligand binding, allowing the isocyanide to be located at any of the two positions appropriate for insertion into either the Ta−Me or $Ta-NMe_2$ bonds. Insertion into the Ta−NRMe (R = H, Me) bonds is the most favorable, being followed by rotation around the Ta−C bond to give the η^2-iminocarbamoyl compound, and similar behaviour should be expected for the NH*t*Bu derivatives **6** and [Ta(η^5-C_5Me_5)(N*t*Bu)-Me(NH*t*Bu)].[12] However steric effects from the presence of the bulky *tert*-butyl substituent are more important than the electronic effects and probably prevent this reaction, leaving the energetically less favorable insertion into the Ta−Me bond as the only possible pathway, which requires heating at 75 °C for 3 d in the case of [Ta(η^5-C_5Me_5)-(N*t*Bu)Me(NH*t*Bu)].[12] Complexes **3** and **4** favor preferential insertion into the Ta−Me bond when heated at 80 °C for 8 and 20 h, respectively, probably due to electronic effects of the amido substituents.

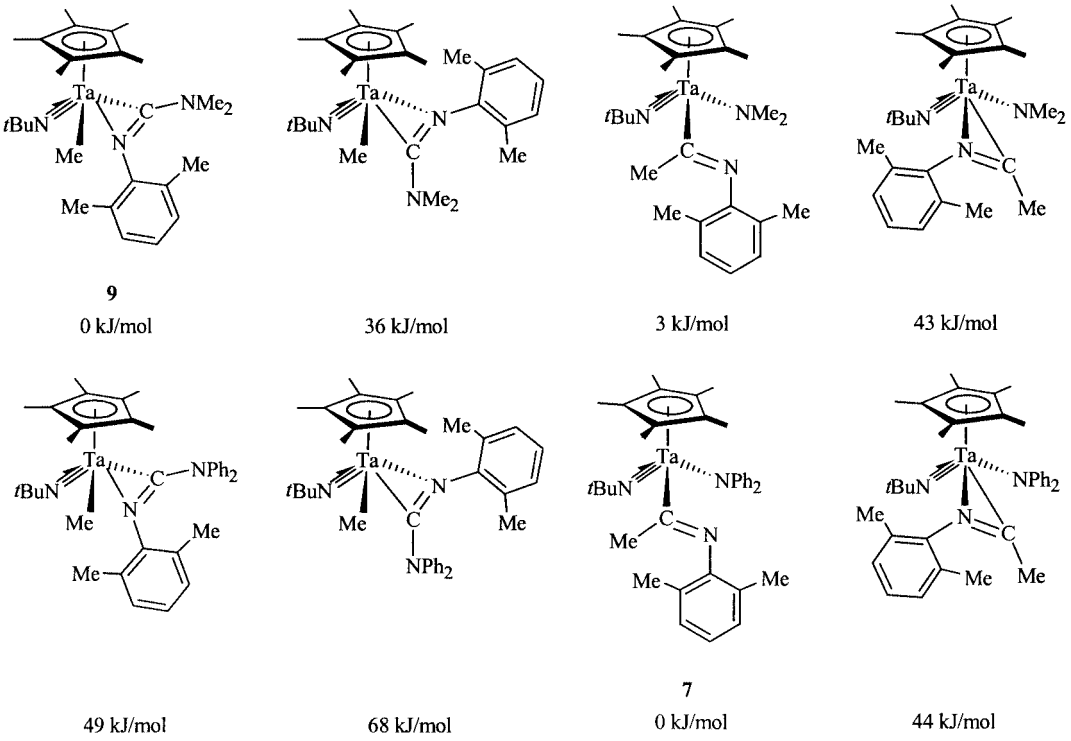
To help answer the question why compound **3** shows a preference for insertion into the tantalum−methyl bond, rather than insertion into the tantalum−amido bond, as observed for compound **2**, we performed density functional calculations on possible insertion products of the reaction of **2** and **3** with CN(2,6-$Me_2C_6H_3$). The relative energies and coordination geometries are collected in Scheme 1.

According to our calculations, the most stable insertion product for compound **2** is the η^2-iminocarbamoyl complex **9** based on the approach of the isocyanide between the alkyl and the amido ligands. However, the corresponding iminoacyl derivative is only 3 kJ/mol higher in energy. Furthermore, the optimized geometry shows that the iminoacyl ligand is bound in an η^1-fashion, with the two N groups in a *cis* position with respect to the Ta−C bond. A rotation around the latter bond leads to a complex with an η^2-iminoacyl ligand. This compound, however, is 40 kJ/mol higher in energy than the one bearing an η^1-iminoacyl ligand. The possibility of an attack of the isocyanide from the other "side" of the amido ligand (between the amido and imido ligands) has also been investigated but the η^2-iminocarbamoyl insertion product is about 36 kJ/mol higher in energy.

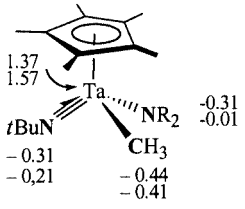
Turning to the insertion products for compound **3**, the calculations show that the iminoacyl complex **7** is the energetically favored insertion product. Again, the iminoacyl group acts as an η^1-ligand, and the corresponding η^2 complex is 44 kJ/mol higher in energy. Also, the η^2-iminocarbamoyl complexes are energetically disfavored by 49 and 68 kJ/mol.

An analysis of the charge distributions in complexes **2** and **3** holds an answer for the observed preferences in coordination geometry. Charges (in a.u.) at the atoms forming the Ta−C and Ta−N bonds of **2** and **3** are displayed in Scheme 2.

For both compounds, the imido N atom as well as the methyl C atom carry a negative charge, whereas the metal center is positively charged. However, whereas for compound **2** the electron-rich dimethylamido ligand carries a sizeable amount of negative charge at the N atom, the N atom of the diphenlyamido group of compound **3** carries almost no charge at all. Also, in this compound, the central metal atom as well as the imido N atom are more positively charged by 0.2 and 0.1 a.u., when compared with **2**. This suggests that the diphenylamido ligand possesses some electron-withdrawing properties, since charge can be effectively delocalized over the two aromatic phenyl groups. This assumption is supported when the total charge on the NMe_2 and NPh_2 in compounds **2** and **3** is analyzed. Summing up the individual contributions of all atoms of the NMe_2 group, we find a charge value of +0.10 a.u., indicating that the dimethylamido group is acting as an electron-donating group. On the other hand, the total charge of the NPh_2 group amounts to −0.61 a.u. This indicates that electron delocalization over the phenyl groups indeed induces some electron-withdrawing properties. The same behaviour should be expected for compound **4** by electron delocalization onto the silicon d orbitals. Thus, the isocyanide ligand will insert into that Ta−R (R = C, N) bond, in which R carries a sizeable amount of negative charge. In this case, the attack of R at the LUMO of the CN(2,6-$Me_2C_6H_3$) molecule, which is the first step in the formation of the new R−CN(2,6-$Me_2C_6H_3$) bond, is facilitated. We also note that when steric bulk is provided by alkyl groups, the sterically most hindered M−C bond can also be expected to contain the C atom with the largest amount of negative charge.



Scheme 1



R = Me, **2**
R = Ph, **3**

Scheme 2

Comparing the small energy difference between **9** and the corresponding η^1-iminoacyl complex, it becomes clear that thermodynamic considerations do not explain the preference for insertion into the Ta−NMe_2 bond. In order to gain further insight into the nature of the frontier orbitals, we carried out an orbital analysis of the (amido)(imido) compound **2**. As expected, the lone pair of the amido ligand interacts in a π-fashion with the empty $1a_1$ metal orbital. The π-bonding interaction takes place in the highest occupied molecular orbital of the complex (Figure 2), while the corresponding π-antibonding interaction is mainly localized in the LUMO.

The resulting metal−nitrogen π-bonding interaction leads to a more stable orientation with one of the amido substituents pointing towards the Cp* ring. For the real insertion process of the $CN(2,6\text{-}Me_2C_6H_3)$ molecule into the Ta−amido bond, we may then take the attack of the lone pair of the amido group in the HOMO (π-bonding orbital) on the π* LUMO of the isocyanide molecule as the major orbital transformation of this process (Scheme 3). The preference of Ta−N over Ta−C insertion is therefore governed by frontier orbital arguments, and is preferred on kinetic, rather than thermodynamic, grounds.

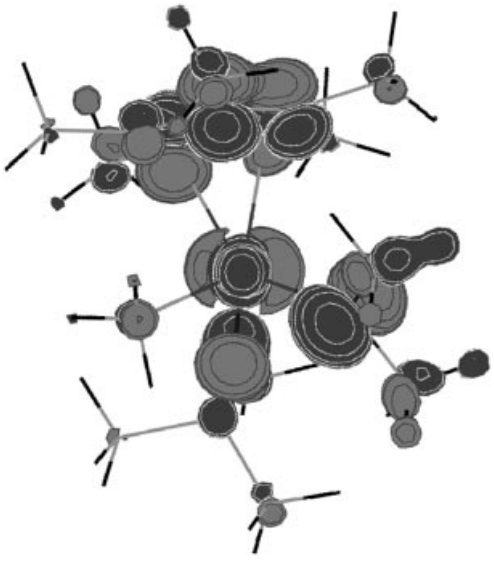


Figure 2. Calculated HOMO of the amido imido complex **2** showing the π-bonding interaction between the metal orbital and the amido lone pair

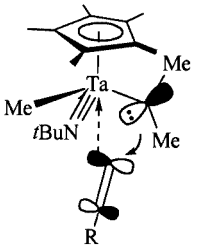

Scheme 3

Conclusions

Various (amido)methyltantalum complexes [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NR_2)] [R_2 = HMe, Ph_2, $(SiMe_3)_2$] were prepared by reaction of the (chloro)(methyl) derivative with appropriate lithium amides Li(NR_2). Easy hydrogen exchange between methylamido (NHMe) and the more basic *tert*-butylimido (N*t*Bu) groups was observed.

According to density functional calculations, coordination of isocyanide CN(2,6-$Me_2C_6H_3$) followed by nucleophilic attack initiates the insertion, either into Ta−amido or Ta−methyl bonds, that is governed by kinetic factors. Insertion into Ta−methyl bonds is preferred for amido NR_2 [R_2 = Ph_2, $(SiMe_3)_2$] complexes to give the η^1-iminoacyl [Ta(η^5-C_5Me_5)(N*t*Bu)(NR_2){η^1-C(Me)=N(2,6-$Me_2C_6H_3$)}] derivatives, whereas stereoselective insertion into the Ta−amido bonds is preferred for NRMe (R = H, Me) yielding *inside-N*-coordinated η^2-iminocarbamoyl [Ta(η^5-C_5Me_5)(N*t*Bu)Me{η^2-C(NRMe)=N(2,6-$Me_2C_6H_3$)}] complexes.

Experimental Section

General: All operations were performed under argon using standard Schlenk-line or glovebox techniques. Hexane and pentane were distilled from a sodium/potassium alloy and diethyl ether from sodium benzophenone ketyl. H_2NMe (Aldrich), $HNPh_2$ (Aldrich), $HN(SiMe_3)_2$ (Aldrich), CN(2,6-$Me_2C_6H_3$) (Fluka) were used as received. LiBu (Aldrich) was titrated prior to use.[31] Complexes [Ta(η^5-C_5Me_5)(N*t*Bu)ClMe] (**1**)[12] and [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NMe_2)] (**2**)[15] were prepared by known procedures. IR: Perkin−Elmer 583 spectrophotometer (4000−200 cm^{-1}). ^{1}H and ^{13}C NMR: Varian Unity 300 MHz spectrometer (^{1}H, 299.95 MHz; ^{13}C, 75.43 MHz). Chemical shifts (in ppm) were referenced internally using the residual solvent resonances and were reported relative to tetramethylsilane. Elemental analyses: Perkin−Elmer 2400 CHNO.

Preparation of [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NPh_2)] (3): Cooled THF (30 mL) was added to a solid mixture of **1** (1.36 g, 3.11 mmol) and $LiNPh_2$ (0.59 g, 3.42 mmol) at 0 °C. The mixture was allowed to warm slowly to room temperature. All volatiles were removed and pentane (2 × 15 mL) was added to give a brown-yellow solution. The solution was filtered and the solvent was completely removed to give **3** as a yellow oil. Yield 1.60 g (90%). IR (Nujol, CsI): $\tilde{\nu}$ = 1273 (s) cm^{-1}. ^{1}H NMR ($CDCl_3$, 298 K): δ = 0.39 (s, 3 H, Ta*Me*), 0.79 (s, 9 H, NC*Me*$_3$), 1.89 (s, 15 H, C_5Me_5), 6.7−7.2 (s, 10 H, N*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$, 298 K): δ = 11.2 (C_5Me_5), 28.0 (Ta*Me*), 32.0 (NC*Me*$_3$), 64.5 (N*C*Me$_3$), 115.4 (C_5Me_5), 122.8, 125.3, 128.1, 129.3 (N*Ph*$_2$) ppm. $C_{27}H_{37}N_2Ta$ (570.55): calcd. C 56.84, H 6.49, N 4.91; found C 56.59, H 6.25, N 4.52.

NMR Tube Scale Preparation of [Ta(η^5-C_5Me_5)(N*t*Bu)Me{N($SiMe_3$)$_2$}] (4): C_6D_6 was added to a solid mixture of **1** (0.034 g, 0.077 mmol) and $LiN(SiMe_3)_2$ (0.013 g, 0.077 mmol) in a sealed NMR tube and the mixture was monitored by ^{1}H NMR spectroscopy. After 24 h at 90 °C, the signals of complex **1** disappeared leaving a solution that contained **4** in quantitative yield. ^{1}H NMR (C_6D_6, 298 K): δ = 0.18 [s, 9 H, N(Si*Me*$_3$)$_2$], 0.47 (s, 3 H, Ta*Me*), 0.5 [s, 9 H, N(Si*Me*$_3$)$_2$], 1.32 (s, 9 H, NC*Me*$_3$), 1.91 (s, 15 H, C_5Me_5) ppm. ^{13}C{^{1}H} NMR (C_6D_6, 298 K): δ = 6.6, 7.7 [N(Si*Me*$_3$)$_2$], 12.2 (C_5Me_5), 20.3 (Ta*Me*), 33.5 (NC*Me*$_3$), 65.5 (N*C*Me$_3$), 116.4 (C_5Me_5) ppm.

Preparation of [Ta(η^5-C_5Me_5)(N*t*Bu)Me(NHMe)] (5) and [Ta(η^5-C_5Me_5)(NMe)Me(NH*t*Bu)] (6): According to a similar procedure to that used for **3**, compound **1** (1.06 g, 2.42 mmol) was treated with LiNHMe (0.11 g, 2.91 mmol) in hexane (30 mL) at −78 °C, to give a ca. 1:1 mixture of **5** and **6** as a pale yellow oil. Yield 0.76 g (72%). **5:** ^{1}H NMR (C_6D_6, 298 K): δ = 0.33 (s, 3 H, Ta*Me*), 1.37 (s, 9 H, NC*Me*$_3$), 1.84 (s, 15 H, C_5Me_5), 3.63 (d, $^3J_{H,H}$ = 7 Hz, 3 H, NH*Me*), 4.62 (br, 1 H, N*H*Me) ppm. ^{13}C{^{1}H} NMR (C_6D_6, 298 K): δ = 11.1 (C_5Me_5), 20.4 (Ta*Me*), 33.9 (NC*Me*$_3$), 45.5 (NH*Me*), 64.1 (N*C*Me$_3$), 114.0 (C_5Me_5) ppm. **6:** ^{1}H NMR (C_6D_6, 298 K): δ = 0.29 (s, 3 H, Ta*Me*), 1.35 (s, 9 H, NHC*Me*$_3$), 1.82 (s, 15 H, C_5Me_5), 3.77 (s, 3 H, N*Me*), 4.88 (br, 1 H, N*H*CMe$_3$) ppm. ^{13}C{^{1}H} NMR (C_6D_6, 298 K): δ = 10.6 (C_5Me_5), 20.4 (Ta*Me*), 34.7 (NHC*Me*$_3$), 45.9 (N*Me*), 56.3 (NH*C*Me$_3$), 113.3 (C_5Me_5) ppm.

Preparation of [Ta(η^5-C_5Me_5)(N*t*Bu)(NPh_2){η^1-C(Me)=N(2,6-$Me_2C_6H_3$)}] (7): A solution of **3** (1.79 g, 3.14 mmol) in toluene (20 mL) was treated with CN(2,6-$Me_2C_6H_3$) (0.42 g, 3.20 mmol) and the mixture was heated (80 °C) and stirred for 8 h. The solution was filtered and the solvent completely removed. The residue was washed with hexane (2 × 15 mL) to give **7** as a brown oil. Yield 1.65 g (75%). IR (Nujol CsI): $\tilde{\nu}$ = 1594 (s), 1260 (s) cm^{-1}. ^{1}H NMR ($CDCl_3$, 298 K): δ = 1.0 (s, 9 H, NC*Me*$_3$), 1.91 [s, 3 H, C(*Me*)=N], 1.98 (s, 3 H, 2,6-*Me*$_2$C$_6$H$_3$), 2.12 (s, 15 H, C_5Me_5), 2.46 (s, 3 H, 2,6-*Me*$_2$C$_6$H$_3$), 6.5−7.3 (m, 13 H, 2,6-Me$_2$C$_6$*H*$_3$, N*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$, 298 K): δ = 12.3 (C_5Me_5), 18.9, 19.3 (2,6-*Me*$_2$C$_6$H$_3$), 22.5 [C(*Me*)=N], 33.2 [NC*Me*$_3$], 65.8 [N*C*Me$_3$], 115.7 (C_5Me_5), 117.7, 120.9, 124.9, 125.0, 127.5, 127.9, 128.1, 129.3, 130.9, 142.0 (2,6-Me$_2$*C*$_6$H$_3$, N*Ph*$_2$), 249.3 [*C*(Me)=N] ppm. $C_{36}H_{46}N_3Ta$ (701.73): calcd. C 61.63, H 6.61, N 5.99; found C 61.33, H 6.39, N 5.66.

NMR Tube Scale Preparation of [Ta(η^5-C_5Me_5)(N*t*Bu){N($SiMe_3$)$_2$}{η^1-C(Me)=N(2,6-$Me_2C_6H_3$)}] (8): CN(2,6-$Me_2C_6H_3$) (0.015 g, 0.114 mmol) was added to an NMR tube containing a C_6D_6 solution of **4** (0.114 mmol) and the mixture was monitored by ^{1}H NMR spectroscopy. After ca. 20 h at 80 °C, the signals of complex **4** disappeared leaving a solution that contained **8** in quantitative yield. ^{1}H NMR (C_6D_6, 298 K): δ = 0.17, 0.63 [s, 9 H, N(Si*Me*$_3$)$_2$], 1.19 (s, 9 H, NC*Me*$_3$), 2.01 (s, 15 H, C_5Me_5), 2.04 [s, 3 H, C(*Me*)=N], 2.22, 2.38 (s, 3 H, 2,6-*Me*$_2$C$_6$H$_3$), 6.92 (m, 3 H, 2,6-Me$_2$C$_6$*H*$_3$) ppm. ^{13}C{^{1}H} NMR (C_6D_6, 298 K): δ = 8.3, 8.9 [N(Si*Me*$_3$)$_2$], 12.8 (C_5Me_5), 18.6, 19.9 (2,6-*Me*$_2$C$_6$H$_3$), 24.0 [C(*Me*)=N], 34.4 (NC*Me*$_3$), 66.3 (N*C*Me$_3$), 116.0 (C_5Me_5), 125.8, 128.5, 128.9, 132.2, 134.9, 144.0 (2,6-Me$_2$*C*$_6$H$_3$), 251.9 [*C*(Me)=N] ppm.

Preparation of [Ta(η^5-C$_5$Me$_5$)(N*t*Bu)Me{η^2-C(NMe$_2$)=N(2,6-Me$_2$C$_6$H$_3$)}] (9): A solution of **2** (1.0 g, 2.24 mmol) in hexane (20 mL) was added to CN(2,6-Me$_2$C$_6$H$_3$) (0.30 g, 2.26 mmol) and the mixture was stirred for 1 h at room temperature. The solution was filtered and the solvent was removed to give **9** as a white solid. Recrystallization from pentane gave **9** as colourless crystals. Yield 1.14 g (88%). IR (KBr pellets): $\tilde{\nu}$ = 1606 (s), 1586 (s), 1267 (s) cm^{-1}. ^{1}H NMR (CDCl$_3$, 298 K): δ = −0.29 (s, 3 H, Ta*Me*), 1.03 (s, 9 H, NC*Me*$_3$), 1.96, 2.0 (s, 3 H, 2,6-*Me*$_2$C$_6$H$_3$), 2.04 (s, 15 H, C$_5$*Me*$_5$), 2.59, 3.39 [s, 3 H, C(N*Me*$_2$)=N], 6.87 (m, 3 H, 2,6-Me$_2$C$_6$*H*$_3$) ppm. ^{13}C{^{1}H} NMR (CDCl$_3$, 298 K): δ = 11.8 (C$_5$*Me*$_5$), 14.2 (Ta*Me*), 19.7 (2,6-*Me*$_2$C$_6$H$_3$), 33.7 (NC*Me*$_3$), 36.8, 45.3 [C(N*Me*$_2$)=N], 64.1 (N*C*Me$_3$), 112.4 (*C*$_5$Me$_5$), 123.7, 127.0, 127.4, 132.0, 132.5, 143.8 (2,6-Me$_2$*C*$_6$H$_3$), 206.6 [*C*(NMe$_2$)=N] ppm. C$_{26}$H$_{42}$N$_3$Ta (577.59): calcd. C 54.07, H 7.33, N 7.28; found C 54.26, H 7.46, N 7.48.

NMR Tube Scale Preparation of Ta(η^5-C$_5$Me$_5$)(N*t*Bu)Me{η^2-C(NHMe)=N(2,6-Me$_2$C$_6$H$_3$)} (10): C$_6$D$_6$ was added to a mixture of **5** and **6** (0.054 g, 0.125 mmol) and CN(2,6-Me$_2$C$_6$H$_3$) (0.016 g, 0.125 mmol) in a sealed NMR tube and the mixture was monitored by ^{1}H NMR spectroscopy. After ca. 24 h at room temperature, the signals of complex **5** disappeared leaving a solution that contained **10**, **6** and excess isocyanide. **10:** ^{1}H NMR (C$_6$D$_6$, 298 K): δ = 0.44 (s, 3 H, Ta*Me*), 1.29 (s, 9 H, NC*Me*$_3$), 2.04 (s, 15 H, C$_5$*Me*$_5$), 2.14, 2.21 (s, 3 H, 2,6-*Me*$_2$C$_6$H$_3$), 2.66 [d, $^3J_{H,H}$ = 7 Hz, 3 H, C(NH*Me*)=N], 4.68 [br, 1 H, C(N*H*Me)=N], 6.95 (m, 3 H, 2,6-Me$_2$C$_6$*H*$_3$) ppm. ^{13}C{^{1}H} NMR (C$_6$D$_6$, 298 K): δ = 12.0 (C$_5$*Me*$_5$), 16.6 (Ta*Me*), 19.3, 19.5 (2,6-*Me*$_2$C$_6$H$_3$], 34.1 (NC*Me*$_3$), 64.3 (N*C*Me$_3$), 67.8 [C(NH*Me*)=N], 112.8 (*C*$_5$Me$_5$), 125.0, 128.8, 132.5, 132.9, 141.8, 143.6 (2,6-Me$_2$*C*$_6$H$_3$), 208.4 [*C*(NHMe)=N] ppm.

Crystal Structure Determination of 9: Crystals of compound **9** were obtained by crystallization from pentane. A suitably sized crystal in a Lindemann tube was mounted on a Philips PW 1100 diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Crystallographic and experimental details are summarized in Table 2. A semi-empirical method of absorption correction was applied (maximum and minimum values for the transmission coefficient were 1.000 and 0.582).[32] A decay of 15% was observed during the data collection. The structure was solved by direct methods (SIR92)[33] and refined by least squares against F_o^2 (SHELXL-97).[34] All non-hydrogen atoms were refined anisotropically except for the methyl carbon atoms of the Cp* ring and of the *t*Bu group. These last methyl groups were found to be disordered in two positions and refined with s.o.f. of 0.5. All hydrogen atoms were introduced from geometrical calculations and refined using a riding model. All calculations were carried out with the DIGITAL AlphaStation 255 of the "Centro di Studio per la Strutturistica Diffrattometrica del C.N.R.", Parma. The programs PARST[35] and ORTEP[36] were also used. CCDC-187149 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Details: Gradient-corrected density functional calculations were carried out with corrections for exchange and correlation according to Becke[37] and Perdew,[38] respectively (BP86). Geometries were optimized using the program system TURBOMOLE[39] within the framework of the RI-*J* approximation.[40] The geometry was pre-optimized using a triple-ζ valence basis plus polarization TZVP[41] for Ta, and a split-valence basis set with one set of polarization functions for the non-H atoms SV(P)[42] for the remaining elements. In the final steps of the geometry optimization, all elements were treated with the TZVP basis. Atomic charges were obtained from a population analysis based on occupation numbers, and include multicenter corrections.[43] Optimized geometries and final energies are presented in the Supporting Information (see also footnote on the first page of this article).

Table 2. Summary of crystallographic data for compound **9**

Empirical formula	C$_{26}$H$_{42}$N$_3$Ta
Formula mass	577.58
Crystal system	triclinic
Space group	$P\bar{1}$
Radiation (λ [Å])	Mo-K_α (0.71073)
a [Å]	8.592(5)
b [Å]	9.874(4)
c [Å]	16.940(9)
α [°]	101.55(2)
β [°]	93.04(2)
γ [°]	102.50(2)
V [Å^3]	1367.7(12)
Z	2
$D_{calcd.}$ [Mg m^{-3}]	1.403
μ(Mo-K_α) [mm^{-1}]	4.034
F(000)	584
Crystal size [mm]	0.49 × 0.30 × 0.15
Diffractometer	Philips PW 1100
θ range [°]	3.20−30.01
Scan type	θ/2θ
Index ranges	$-12 \le h \le 12$, $-13 \le k \le 13$, $0 \le l \le 23$
No. of reflections measured	7954
No. of unique total data	7954
No. of unique observed data	6016 [$I > 2\sigma(I)$]
Data/restraints/parameters	7954/0/253
Goodness-of-fit on F^2	0.955
*R*1 [$I > 2\sigma(I)$]	0.0385
*wR*2 [$I > 2\sigma(I)$]	0.0947
*R*1 (all data)	0.0572
*wR*2 (all data)	0.1023

Collapsed Molecular Rectangles Based on Rhenium(I) Coordination of Ethynylpyridyl Porphyrins − Synthesis, Structure, and Bending-Induced Charge-Transfer Behavior

Kurt D. Benkstein,[a] Charlotte L. Stern,[a] Kathryn E. Splan,[a] Robert C. Johnson,[a] Keith A. Walters,[a] Frederick W. M. Vanhelmont,[a] and Joseph T. Hupp*[a]

Keywords: Porphyrins / Rhenium / Supramolecular chemistry / Molecular rectangles / Electroabsorption spectroscopy

Efforts to synthesize extremely large rectangle-shaped porphyrin systems have yielded an unusual and unexpected collapsed structure that brings the porphyrin walls into van der Waals contact. The bent geometry of the nominally rigid ethynylpyridyl porphyrin ligand edges, mandated by the collapse of the rectangle, imparts significant charge-transfer character to the rectangles' Soret and Q-region electronic transitions, as shown experimentally by Stark spectroscopy and transient DC photoconductivity measurements, and replicated by electronic structure calculations. In contrast to lower symmetry porphyrin-like pairs found in naturally occurring photosystems, however, the light-induced charge transfer is an intra-porphyrin rather than inter-porphyrin process.

Introduction

Cyclic molecular host compounds — squares, triangles, pentagons, hexagons, cylinders, prisms and other structures — featuring transition-metal-ion corners and multifunctional aromatic ligands as edges hold substantial promise for applications entailing selective chemical sensing, reaction catalysis, or nanoscale molecular transport.[1] As a logical next step beyond the now ubiquitous molecular-square motif, we recently reported the synthesis of tetrametallic molecular rectangles featuring frameworks of modest size: ca. 6 × 11 Å.[2,3] The resulting cavities are too narrow to host even a planar aromatic guest molecule. Nevertheless, by packing in a fashion that creates intermolecular cavities, neutral versions of the rectangles have proven effective in the solid state as hosts for selected volatile organic chemical guests (arenes)[2b] and as shape-selective thin-film coatings for condensed-phase molecular transport.[4] Here we describe the synthesis of new and much larger rectangles **2** and **3** featuring lengthy dihexyl derivatives of [5,15-bis(4-ethynylpyridyl)porphyrinato]zinc(II) (**1**) as walls. Intermolecular voids, potentially suitable for guest uptake, were again expected in the solid state. Additionally, however, our hope was that the extended walls would prove sufficiently flexible, especially in solution, to permit the rectangles to encapsulate polyaromatic guests in an intramolecular fashion. We further envisioned that the available pair of zinc sites could be used to bind a difunctional ligand axially, thereby propping open the porphyrin walls and resulting in a well-defined, but smaller, cavity. We instead found that the cavities are collapsed such that the porphyrinic walls approach within van der Waals distances and that the collapsed cavities strongly resist functionalization via Zn^{II} ligation. In addition we found that the cavity collapse alters the rectangle's electronic structure and imparts significant porphyrin-localized charge-transfer character to both B- and Q-band transitions, as evidenced by electronic Stark effect (electroabsorption) measurements, transient DC photoconductivity measurements, and electronic structure calculations.

Results and Discussion

Reaction of **1** with either $[Re_2(CO)_6Cl_2(\mu\text{-bipyrimidine})]$ or $[Re_2(CO)_8\{\mu\text{-bis(benzimidazolate)}\}]$ leads readily to the desired rectangles **2** and **3**.[5] The single-crystal X-ray structure for **3** is shown in Figure 1. Especially striking is the pronounced inward bowing of two of the four ethynylpyridine linkages (15.6° angle between the plane of the pyridine and the plane of the porphyrin + second pyridine). Thus, while the rhenium atoms define a framework 24.6 Å long and 5.7 Å wide, the porphyrins approach within 3.4 Å, slightly less than the estimated van der Waals contact distance (3.6 Å). A "top" view of the structure shows that the porphyrins are significantly laterally slipped — the zinc centers, for example, being laterally displaced from each other by 1.0 Å to give a slip angle of 19°. This offset is consistent with strong porphyrin/porphyrin π-stacking in-

teractions and is similar to the displacements reported for other cofacial metalloporphyrin assemblies.[6] Another factor may be an intrinsic predisposition at the rhenium center for angles of less than 90° between the chelating short-edge ligand and the Re−N(imine) bond; crystal structures of closely related *Z*-shaped molecules such as *trans*-[(pyridine)$_2$Re$_2$(CO)$_8${μ-bis(benzimidazolate)}] feature angles of 82 to 84°.[7]

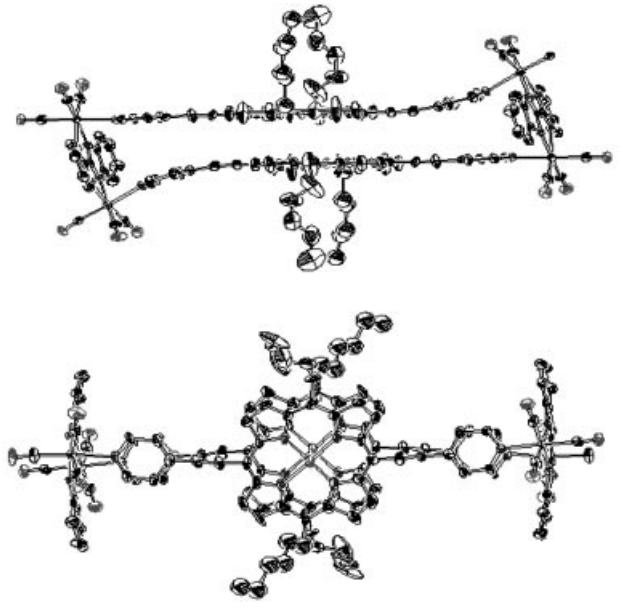

Figure 1. ORTEP representations of **3** showing the side view (top) and top view (bottom) of the co-facial porphyrin systems; hydrogen atoms have been omitted for clarity; the thermal ellipsoids represent 50% occupancy

While the collapsed cavity is too narrow for guest incorporation, as evidenced by the crystal structure, we reasoned that the flexible nature of the porphyrin walls may allow for cooperative interior binding of a single bridging ligand by the pair of Zn^{II} centers. To this end, DABCO (1,4-diazobicyclo[2.2.2]octane), a strong Lewis base, might be expected to bind inside the cavity despite being larger than the framework defined by the rhenium corners. However, DABCO is observed to bind to **3** in a 2:1 stoichiometry with no detectable preferential binding of the first equivalent ($K_b = 5 \times 10^4$ M^{-1} in $CHCl_3$) — an observation that clearly implies exterior binding. Furthermore, quinuclidine, a monofunctional, exterior-binding ligand also binds to **3** in a 2:1 stoichiometry, with $K_b = 2 \times 10^5$ M^{-1}, four times larger than the binding constant of DABCO. With other bis(porphyrinato)zinc(II) systems, the di-functionality of DABCO can favor inside binding (double ligation of a single ligand) over outside binding by as much as 300-fold, despite estimated π-stacking enthalpies of as great as −48 kJ mol^{-1}.[8] The absence of significantly favored inside binding suggests, but does not prove, even greater interactions here.

The visible-region electronic absorption spectra for **2** and **3** are dominated by porphyrin-based B- and Q-bands (Figure 2). In particular, the Q-bands for **2** and **3** are red-shifted by 20 and 10 nm, respectively, versus the Q-band for **1**, consistent with expected electron-withdrawing effects due to metal-cation coordination. Electroabsorption measurements at 77 K for **3** in a 2-methyl-THF glass (Figure 3) show that excitation in either region entails charge transfer.

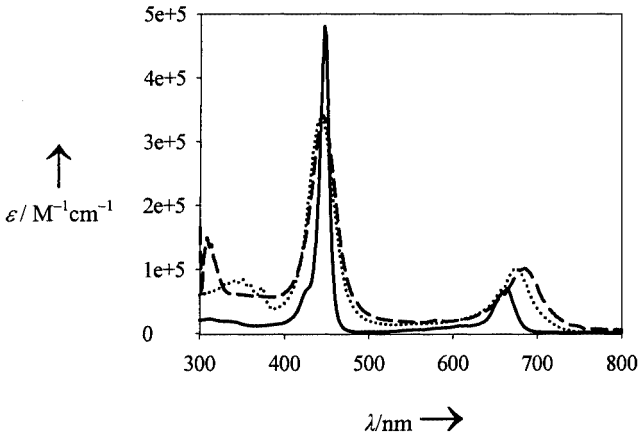

Figure 2. Electronic absorption spectra of **1** (−), **2** (---), and **3** (···) in $CHCl_3$

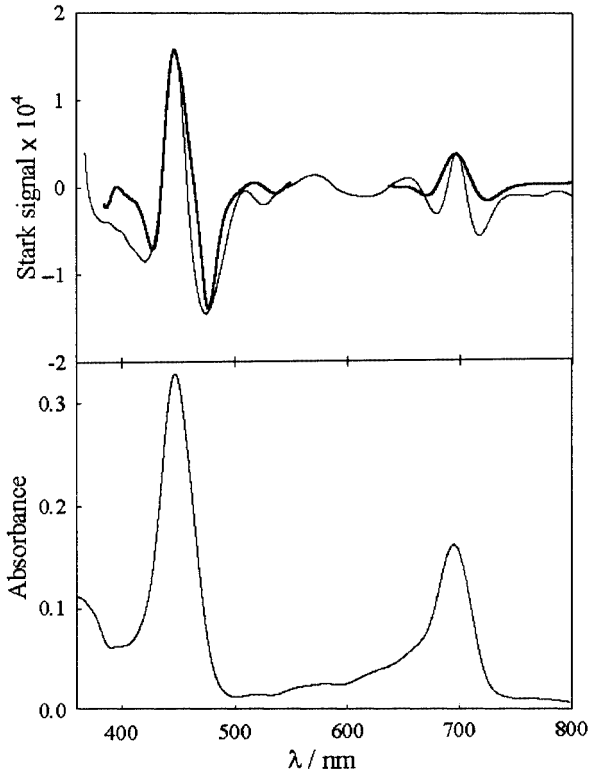

Figure 3. Electroabsorption (Stark) spectrum (top) at 77 K for **3** in a 2-methyl-THF glass at a field strength (r.m.s.) of 4.5×10^7 V/m; both B- and Q-regions of the Stark spectrum display substantial components of the second derivative (bold line) of the absorption spectrum, indicating charge-transfer character in these regions; dipole moment changes were obtained by fitting the spectra to appropriately weighted sums of zeroth-, first-, and second derivative spectra

A standard Liptay analysis of the electroabsorption spectrum,[9] neglecting local field corrections, yields ground-state to excited-state vector-dipole-moment changes, $|\Delta\mu|$, of 5 debeye for the B transition and 2 debeye for the Q transition. No charge transfer is seen in Stark measurements of **1**. That the charge-transfer observation is not peculiar to the glass environment is evidenced by liquid-phase transient DC photoconductivity measurements[10] (not shown) that demonstrate that the scalar dipole moment of the emissive excited state of **3** exceeds that of the ground state.

It is tempting, by analogy to the known low-energy charge-transfer behavior of various versions of the bacteriachlorophyl dimer (the "special pair") in photosynthetic reaction systems, to ascribe this unusual electric-field-effect behavior to photo-induced porphyrin-to-porphyrin charge-transfer. Nevertheless, the result would be most surprising given the inversion symmetry of **3**.[11] A comparison of Stark measurements made at electric-field/electromagnetic-field angles of 55° and 90° shows that in both the B- and Q-regions the change in dipole moment (charge-transfer vector) is essentially collinear with the transition dipole moment (absorption vector). This unequivocally rules out porphyrin-to-porphyrin charge-transfer, for which a vector offset of close to 90° would be expected. The behavior instead is ascribed to the remarkable structural distortions occurring in one of the two ethynylpyridines attached to each porphyrin. Bending partially attenuates electron withdrawal by the rhenium-cation-appended linkage, thereby reducing the symmetry of the porphyrin in an electronic sense and creating a porphyrin-localized dipole moment. AM1 calculations (HyperChem. 5.02), using a bent and doubly-pyridyl-protonated ligand **1** as a surrogate for one-half of **3** (in the absence of parameters for Re), corroborate the explanation. The anti-parallel arrangement of the porphyrins, of course, leads to a net molecular dipole moment of zero in the ground electronic state. Local excitation of only one of the two available porphyrins eliminates the inversion symmetry, leaving **3** with a calculated net charge-transfer polarization of 2 debeye in the lowest singlet excited state.

Finally, ambient temperature photo-excitation of **1**, **2**, and **3** in THF leads to singlet emission. Corrected emission maxima are red-shifted for the rectangles in comparison to free porphyrin: $\lambda_{em}(\mathbf{1}) = 677$ nm, $\lambda_{em}(\mathbf{2}) = 694$ nm, $\lambda_{em}(\mathbf{3}) = 714$ nm. Emission lifetimes are: $\tau(\mathbf{1}) = \tau(\mathbf{2}) =$ 1.3 ns, with emission too weak for reliable assessment of $\tau(\mathbf{3})$. Cyclic voltammetry in THF yielded the following reversible reduction potentials, measured vs. Ag/AgCl, for **1**: −0.96 and −1.39 V; for **2**: −0.70, −0.95, −1.06, −1.18 V; and for **3**: −0.89, −1.08, and −1.20 V. All are assigned as porphyrin reductions, except the first and fourth reductions for **2**; these are multi-electron reductions and are assigned as overlapping one-electron reductions of the widely separated pair of bipyrimidine ligands.[12] The relatively good reductive accessibility of the coordinated bipyrimidine edges suggests redox quenching and may account for the attenuation of the fluorescence of **2**. The splitting of nominally equivalent one-electron porphyrin reduction waves, on the other hand, suggests significant Por^-/Por^- electrostatic repulsion and/or Por^-/Por^0 electronic interactions. Combining the voltammetry and emission data, the estimated excited-state reduction potentials for **1** and **3** are both approximately +0.87 V; with less certainty, because of the intervening bipyrimidine reduction, the excited-state reduction potential for **2** is approximately +0.82 V.

To summarize, coordination chemistry based molecular-rectangle construction using lengthy bis(4-ethynylpyridyl)-porphyrins as two of the edges yields an unusual collapsed structure that places the porphyrin faces in very close proximity and substantially distorts two of the four nominally rigid ethynylpyridyl linkages. These distortions, in turn, polarize the porphyrins sufficiently that electronic transitions in both the B- and Q-band regions develop significant charge-transfer character. While we have emphasized here the special structural and photophysical features of the new rectangles, there are also interesting prospects for chemical catalysis, particularly if reactive metals are used in place of zinc and if added oxidizing or reducing equivalents lead to porphyrin-porphyrin electrostatic repulsion, thereby opening up the collapsed cavity for substrate binding.

Experimental Section

General: $[Re_2(CO)_6Cl_2(\mu\text{-bipyrimidine})]$,[2a] $[Re_2(CO)_8\{\mu\text{-bis(benzimidazolate)}\}]$,[2b] and **1**[13] were synthesized according to literature methods. THF was dried with Na/benzophenone. All other chemicals and solvents were reagent grade and used as received. ^{1}H NMR spectra were recorded with a 400 MHz Varian Mercury spectrometer. FAB mass spectra were obtained in the Mass Spectrometry Laboratory, School of Chemical Sciences, University of Illinois. Electroabsorption experiments were performed at 77 K in neat 2-methyltetrahydrofuran glass with a Cary-14 spectrophotometer. Full experimental procedures and the data reduction method have been described in detail elsewhere.[14]

1: ^{1}H NMR ([D$_5$]pyridine/$CDCl_3$): δ = 1.04 (t, J = 7 Hz, 6 H), 1.45 (m, 4 H), 1.59 (m, 4 H), 2.65 (m, 4 H), 5.13 (t, 4 H), 8.03 (d, J = 6 Hz, 4 H), 8.98 (d, J = 6 Hz, 4 H), 9.79 (d, J = 5 Hz, 4 H) 10.05 (d, J = 5 Hz, 4 H) ppm. LR ES-MS: calcd. for $[M + H^+]$: m/z = 743; found 743. HR FAB-MS: calcd. for $[M + H^+]$: m/z = 743.2841; found 743.2840 l. UV/Vis (THF): λ_{max} = 446, 664 nm.

2: Porphyrin rectangle **2** was formed by first refluxing 15.5 mg (0.0201 mmol) of $[Re_2(CO)_6Cl_2(\mu\text{-bipyrimidine})]$ with slightly more than two equivalents of AgOTf (10.9 mg, 0.424 mmol) in 20 mL of acetone under N_2 for 4 hours. The solution was passed through celite and concentrated to leave a red film. This film, $[OTf(CO)_3Re]_2(\mu\text{-bipyrimidine})$, was refluxed for two days with 14.8 mg (0.0199 mmol) of **1** in 20 mL of deoxygenated THF. The desired product precipitated as a dark red power (11.3 mg, 0.0032 mmol) in 33% yield. ^{1}H NMR ([D$_6$]DMSO): δ = 0.088 (t, J = 7 Hz, 12 H), 1.31 (m, 16 H), 1.57 (m, 8 H), 1.94 (m, 8 H), 4.28 (m, 8 H), 7.98 (d, J = 6 Hz, 8 H), 8.52 (d, J = 6 Hz, 8 H), 8.66 (m, 12 H), 9.06 (d, J = 4 Hz, 8 H), 10.16 (d, J = 6 Hz, 8 H) ppm. LR ES-MS: calcd. for [M − 2OTf]: m/z = 1592.0; found 1591.6. UV/Vis (THF): λ_{max} = 446, 686 nm.

3: Equimolar amounts of $[Re_2(CO)_8\{\mu\text{-bis(benzimidazolate)}\}]$ (22.2 mg, 0.0268 mmol) and **1** (25.5 mg, 0.0255 mmol) were refluxed in 30 mL of THF for two days. Upon addition of hexanes the desired product precipitated as a dark green powder (35.4 mg, 0.0117 mmol) in 91% yield. ^{1}H NMR ($CDCl_3$): δ = 0.879 (t, J = 7 Hz, 12 H), 1.32 (m, 16 H), 1.55 (m, 8 H), 1.92 (m, 8 H), 4.34 (t, J = 8 Hz, 8 H), 7.50 (d, J = 6 Hz, 8H0, 7.60 (q, J = 3 Hz, 8 H), 8.04 (q, J = 3 Hz, 8 H), 8.24 (d, J = 6 Hz, 8 H), 8.66 (d, J = 5 Hz, 8 H), 8.92 (d, J = 5 Hz, 8 H) ppm. FTIR ($CHCl_3$): ν_{CO} = 1901, 1922, 2022, 2028 cm^{-1}; ν_{cc} =2188 cm^{-1}. LR FAB-MS: calcd. m/z = 3034.0; found 3033.4. UV/Vis (THF): λ_{max} = 444, 686 nm. X-ray quality crystals of **3** were grown by slow evaporation from a THF/toluene solution (1:1, v:v) at ambient temperature.

Crystal Data for 3·4C$_7$H$_8$: $C_{150}H_{74}N_{20}O_{12}Zn_2Re_4$; crystal dimensions 0.5 × 0.20 × 0.48 mm; triclinic; space group $P\bar{1}$ No. 2; a = 10.877 (2), b = 17.501 (2), c = 19.230 (3) Å, α = 88.657 (2)°, β = 82.615 (2)°, γ = 88.943 (2)°, V = 3628.6 (8) Å^3; Z = 1; $\rho_{calcd.}$ = 1.487 g cm^{-3}; $2\theta_{max}$ = 56.8°; Mo-K_α radiation, λ = 0.7101 Å; T = 153 K; 33040 reflections, of which 16692 were unique; 9224 of these were included in the refinement; data corrected for Lorentz polarization effects; solution by direct methods (G. M. Sheldrick, SHELX 1997) and refinement on $|F^2|$ by full-matrix least-squares procedures (TeXsan for Windows version 1.03, Molecular Structure Corporation, Texas, USA); 781 parameters; isotropic refinement of disordered solvent molecules and C61−C66, the remaining non-hydrogen atoms were refined anisotropically; methyl groups for toluene and half the disordered hexyl group were not found in the difference Fourier map. H atoms were included, except in disordered solvent molecules and the constrained carbons, but not refined; R = 0.063, R_w = 0.141.

CCDC-176672 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

[5] Based on the successful synthesis of molecular squares from alkyl-functionalized dipyridyl porphyrins lacking ethynyl groups (P. J. Stang, J. Fan, *Chem. Commun.* **1997**, *15*, 1453−1454; R. V. Slone, J. T. Hupp, *Inorg. Chem.* **1997**, *36*, 5422−5423) rectangle construction was initially attempted using the same porphyrins as long edges. Unfortunately, discrete rectangles could not be isolated. In retrospect, the problem almost certainly is steric, stemming from the ca. 90° orientation of the rhenium-coordinating pyridyl functionalities with respect to the porphyrin itself and the subsequent crowding likely accompanying rectangle formation. The elimination of pyridine-proximal alkyl groups and the addition of ethynyl spacers at the 5- and 15-positions permits co-planarization of the porphyrin and appended pyridines and allows for formation of the desired rectangles.

Synthesis and Characterization of a Novel Modular Cadmium-Organic Framework with Biphenyl-4,4′-dicarboxylate

Filipe A. Almeida Paz,[a] Yaroslav Z. Khimyak,[a] Andrew D. Bond,[a] João Rocha,[b] and Jacek Klinowski*[a]

Keywords: Coordination polymers / Cadmium / Supramolecular chemistry / O ligands

We report the synthesis and structural characterization of a thermally stable and highly crystalline novel metal-organic framework with cadmium(II) ions. The crystal structure is formed by a threefold interpenetration of identical three-dimensional modular frameworks, assembled by the repetition of a binuclear secondary building unit. This unit contains 1,2-bis(4-pyridyl)ethane and introduces biphenyl-4,4′-dicarboxylate as an effective rigid large spacer between metal centres. Water molecules are hydrogen bonded to carboxylate groups and act as bridges between each independent framework. To the best of our knowledge, CUmof-1 is the first structure in which the paddlewheel motif is associated with a distribution of cavities in a concertina manner.

Introduction

Crystal engineering of polymeric coordination networks has advanced significantly since Hoskins and Robson reported the first such compounds.[1] The design and synthesis of highly ordered, porous, multi-dimensional metal-organic frameworks (MOFs) combining organic and inorganic properties is possible through the assembly of metal centres with di- or multitopic organic ligands. Consequently, features typical of purely inorganic frameworks, such as robustness, high thermal stability and a large variety of coordination geometries, can be achieved through very strong metal-to-ligand bonds (several hundreds of $kJ \cdot mol^{-1}$).[2] By closely controlling the molecular properties of the ligands, such as shape, functionality, flexibility and symmetry, frameworks with interesting and desirable properties can be created. A number of MOFs with attractive new topologies and containing several different metal centres (Cd, Co, Cu, Ni, Pt, Sn, Zn) have been reported. Many of these exhibit interesting properties, such as shape selectivity, clathration, molecular recognition, chirality, photoluminescence and unusual magnetic behaviour, and have potential applications in nonlinear optics, catalysis, and semiconductor physics.[2–23]

N,*N*′-donor spacer ligands with rod-like characteristics, such as 4,4′-bipyridine (BPY), have been extensively used.[24–30] 1,2-Bis(4-pyridyl)ethane (BPE),[6,31–33] can adopt the *gauche* and *anti* conformations which may induce supramolecular isomerism in coordination polymers.[34] Multifunctional organic molecules with one or more *exo* carboxylic acid groups have also been widely used as ligands, due to their rigidity and ability to coordinate to several metal centres in various modes.[9,22,35–37] The most common coordination forms are the unidentate, the chelating bidentate (both symmetrical and asymmetrical), several bridging systems and the free carboxylate anion.[38] Deprotonation of biphenyl-4,4′-dicarboxylic acid (H_2BPhDC) gives rise to a linear symmetrical ligand (BPhDC), which coordinates to metal ions in aqueous solutions. This ligand can serve as a bridge between metal centres because of its rigidity along the C_2 symmetry axis.

The use of large ligands such as BPhDC (ca. 10 Å between carboxylate groups) or BPE (ca. 9 Å between N-donor atoms) in MOFs increases the average distance between metal centres, leading to frameworks with large channels, cavities or windows. However, the presence of large cavities commonly leads to unusual materials, where the voids of one network are filled by one or more independent networks, which do not necessarily need to be identical or to have the same dimensionality.[27,39] Several structures reflecting these properties and containing BPE have been reported.[6,33,40–43] The design and synthesis of porous modular materials assembled by discrete aggregates (referred to as secondary building units, SBUs) has become an area of increasing interest.[12,36,44,45] This approach facilitates the design of crystal structures by selectively controlling the experimental conditions. For instance, optimal porosity of interpenetrated networks is achieved by controlling

not only the length of the spacer but also the diameter of the repeat unit.[44]

In contrast to the extensive research focused on the use of mononuclear centres, coordination polymers containing bimetallic units (both homo- and heteronuclear) are little explored. These structural units have predictable coordination environments according to the type of ligands used, and can also exhibit attractive properties due to close metal-metal interactions. Cotton and co-workers made a contribution to this field,[46] and an unusual twofold interpenetrated $4^6 6^4$ network containing copper and the $Cr_2O_7^{2-}$ ion has been reported.[47]

Here we report the synthesis and crystal structure of a novel MOF (CUmof-1) containing cadmium(II). The combination of H_2BPhDC with BPE and a cadmium(II) salt under hydrothermal conditions, and in the presence of a stoichiometric amount of triethylamine (TEA), gives a product containing a bimetallic SBU which self-assembles into a porous modular framework, interpenetrating in a threefold manner. The highly crystalline product was obtained in high yield (86.3%) using a carefully controlled temperature program for the synthesis. This was designed in order to overcome the limitations of hydrothermal synthesis, such as the formation of poorly crystalline products caused by the irreversible nature of the process,[24] and the fast kinetics of nucleation and crystal growth.[45]

Results and Discussion

Crystallography

Single-crystal X-ray diffraction revealed a remarkable extended 3D structure with the molecular formula $[Cd(BPhDC)(BPE)(H_2O)]_n$ (CUmof-1) (Figure 1 and Table 1), which reflects the molar ratios in the synthesis mixture. The structure contains only one crystallographically unique metal centre coordinated to two BPE and three BPhDC ligands, in a geometry which is best described as a distorted octahedron (Figure 1 and Table 2). BPhDC acts as a bridging ligand with two different coordination modes. It also exhibits rod-like properties despite the internal rotations about the C_2 axis. In one of the coordination modes, each carboxylate group is coordinated to only one metal centre, forming an asymmetric chelate and imposing a Cd···Cd separation of 15.554(2) Å. Hydrogen bonds to the free water molecule maintain the C−O equivalence, although the respective Cd−O distances are slightly different (Table 2). The O−C−O angle [122.4(9)°] is also close to the expected value.[38] The aromatic rings in the chelating BPhDC are coplanar, forming an average dihedral angle of 16.1(9)° with the two crystallographically equivalent carboxylate groups. The second mode has each carboxylate forming a *syn-syn* bidentate bridge between the two cadmium centres with the Cd···Cd distance being 4.375(1) Å. This leads to the formation of a binuclear SBU with a paddlewheel-like structure, with the two bridging BPhDC ligands occupying the equatorial positions (Figure 1). The minimum separation between cadmium centres

Figure 1. dihedral angle between the two aromatic rings is 44.4(3)°. Although one carboxylic group is essentially coplanar with the benzene residue to which it is bound, the other is tilted by 25.6(3)° to the respective aromatic ring. The BPE ligands are *trans*-coordinated to the metal centres acting as axial linkers in a distorted *anti* conformation. The dihedral angle between the 4-pyridyl groups is 50.4(3)°.

The 3D assembly of the binuclear SBU gives a coordinatively bonded open framework (Figure 2). This structure has decorated square-grid perforated layers formed by dicarboxylate and cadmium ions, with each pair of opposite sides of the cavity containing one of the two previously discussed types of BPhDC (Figure 2, bottom perspective). The layers can be described as a 4.8^2 net,[48] a topology common to structures with the paddlewheel motif.[44] However, to the best of our knowledge, CUmof-1 is the first structure where this motif is associated with a distribution of the cavities in a concertina manner. The BPE axial linkers act as pillars between the 4.8^2 sheets, producing several types of channels. The most prominent channels run along the *b* direction of the unit cell and have a cross-section of ca. 8.0 × 12.1 Å^2 (Figure 2). A second type of perforated sheet can be described as a distorted rectangular 4^4 net, again presented in a concertina manner (Figure 2, top perspective). A BPE molecule acting as a pillar has also been found in other structures.[6,33]

The open framework can be seen as the [ABAB...] alternation, in the *ac* plane, of two different highly distorted cuboidal [$Cd_{16}(BPhDC)_8(BPE)_6$] units (Figure 3), which are mirror images of one another. Tao et al. have reported three frameworks resembling the CUmof-1 structure, with one of the structures containing cadmium ions.[49] However, in those cases the cuboidal units are significantly more regular, possibly due to the use of the 4,4′-bipyridine ligand, which is a more rigid pillar between the acid sheets.

Interpenetration occurs in CUmof-1 as in several other structures, and involves two identical frameworks filling the voids in another framework (Figure 4). This threefold inter-

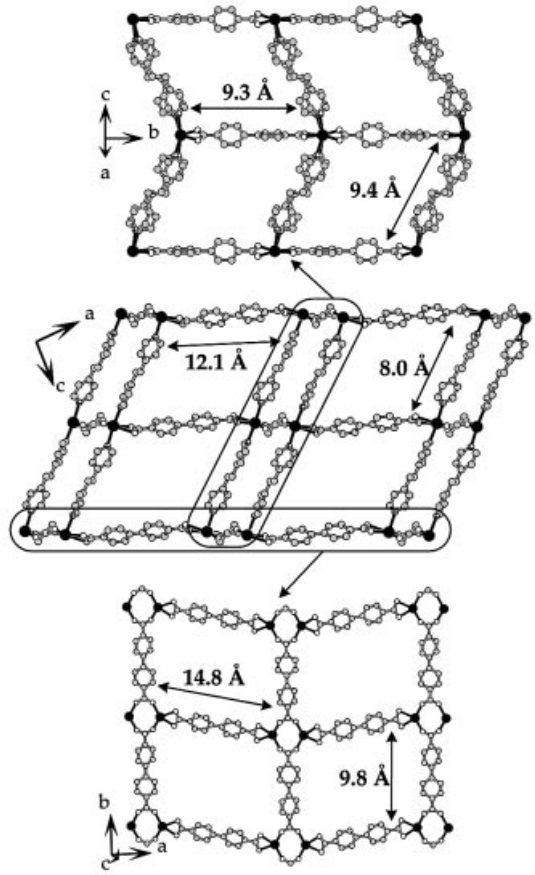

Figure 2. Overhead view along the crystallographic *b* axis of the framework constructed by assembly of the SBU; the structure has two types of perforated and interconnected concertina layers running along this axis, creating a porous 3D network; cavities inside each layer are shaded grey, and their dimensions are based on van der Waals radii; hydrogen atoms have been omitted for clarity

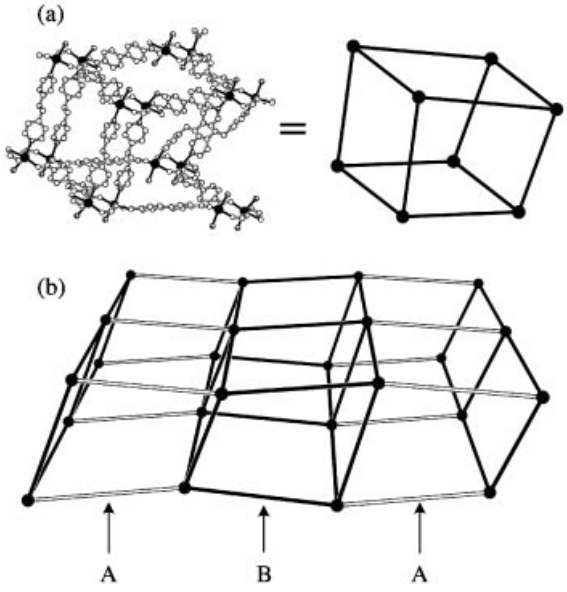

Figure 3. (a) The highly distorted cuboidal [$Cd_{16}(BPhDC)_8(BPE)_6$] unit and its simplified representation (a node is taken in the centre of each SBU); (b) The framework is constructed by [ABAB...] alternation in the *ac* plane of the two cuboidal units

penetration gives a nonporous material, as confirmed by nitrogen adsorption measurements (the adsorption isotherm of evacuated CUmof-1 reveals a BET surface area of about 2 m^2/g). The existence of an additional interpenetrating framework in CUmof-1 rather than the twofold interpenetration in the Cd-based compound reported by Tao et al.,[49] is probably the result not only of the greater length of the ligands, but also of the higher flexibility of BPE, which allows it to bend inside the cavities (Figure 4c). Such flexibility occurs in other MOF structures containing the BPE ligand: in NbO-like[42] and adamantoid networks,[43] layers[4,41] and chains.[32,41] We believe that this property of the BPE ligand is also responsible for the high distortion of the cuboidal units.

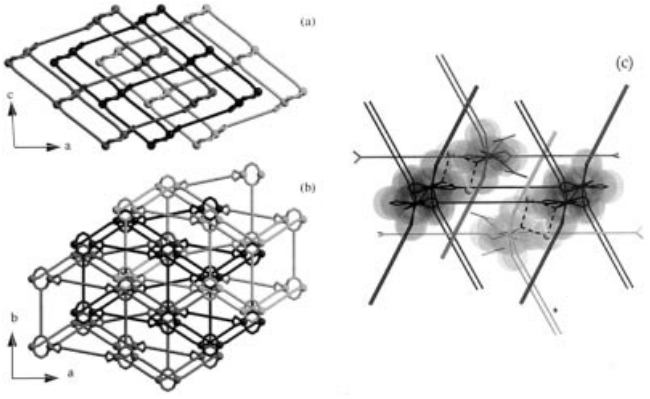

Figure 4. Crystal structure of CUmof-1, showing the presence of three interpenetrated networks, viewed along the (a) *b* and (b) *c* crystallographic axes; in view of the complexity of the structure, the aromatic rings have been omitted for clarity; for BPE the nitrogen atoms were connected directly one to each other [N(31) to N(32)], for BPhDC the connection is between the carboxylate carbon atoms [C(27) to C(27*x*), where *x* represents a different symmetry operation; C(11) to C(110)]; (c) projection showing two frameworks filling the voids of the third one; the van der Waals volume of the SBUs is also represented, along with the bridging water molecules and hydrogen bonds (dashed black lines)

Another remarkable feature of CUmof-1 is the structural function of the solvent molecules. Each individual framework is bridged to the other two by hydrogen bonding between the free water molecules and the O(271) bifurcated acceptor atoms (Figure 4c and Figure 5). These two strong O−H···O hydrogen bonds create an $R_4^2(8)$ motif with two different O···O distances (Table 2).

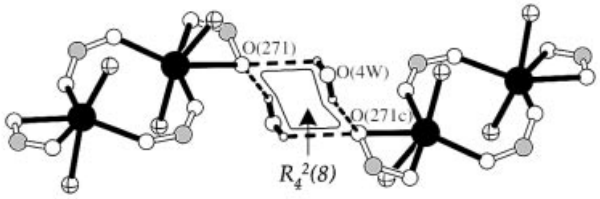

Figure 5. The chemical environment of the free solvent molecules, showing their function as bridges between different interpenetrated networks; bond lengths are given in Table 2

Other Techniques

The phase purity and crystallinity of the bulk were confirmed by a direct comparison between the experimental high-resolution PXRD pattern and a simulation based on the single-crystal X-ray diffraction results (see Supporting Information). This was also confirmed by elemental analysis. ^{113}Cd MAS NMR spectroscopy confirms the existence of only one cadmium site in CUmof-1, with a chemical shift of $\delta = 21.3$ ppm.

TGA shows a very slow and gradual release of approximately 0.71 water molecules per formula unit in the 28−140 °C temperature range. The slow kinetics of dehydration, along with the fact that not all the molecules were released, implies that the water is either strongly bonded or trapped inside the compact structure of CUmof-1. The two most significant weight losses occur between 330 and 440 °C, and are attributable to the complete oxidation of the sample to cadmium(II) oxide. This conclusion is supported by the 23.7% of residue which agrees with the expected value, considering the formation of a stoichiometric amount of CdO (23.1%). DSC analysis is in good agreement with the TGA, showing three endothermic processes corresponding to thermal decomposition of the MOF.

FT-IR and FT-Raman confirm the presence of the water molecule hydrogen bonded to the structure, and also the two organic ligands used in the synthesis. The typical antisymmetric (1577 cm^{-1}) and symmetric (1526 and 1400 cm^{-1}) stretching bands of carboxylate ions are also evident in the FT-IR spectrum. The respective $\Delta[\nu_{assym}(CO_2) - \nu_{sym}(CO_2)]$ values clearly indicate the presence of chelate (51 cm^{-1}) and bridging coordination modes (177 cm^{-1}) in CUmof-1 (Table 2), as is shown by the crystal structure.[38,50]

Conclusions

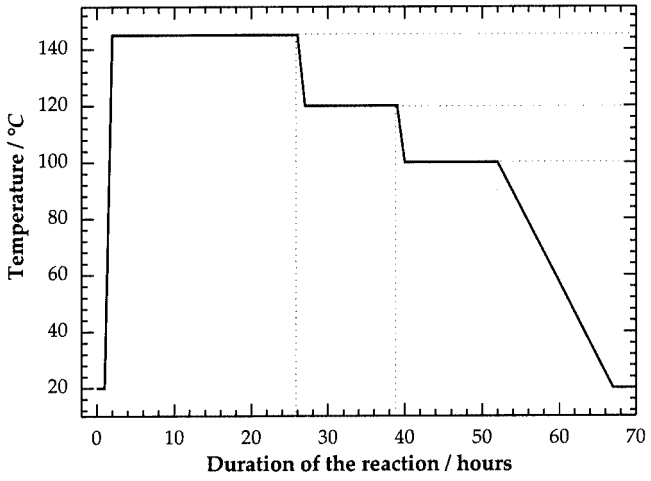
A novel modular coordination polymer with cadmium(II) ions was synthesised using a new organic bridging ligand, BPhDC, and a well-known flexible bidentate bridging molecule with two 4-pyridyl donor groups, BPE. A highly crystalline product was obtained using close control of the temperature in hydrothermal synthesis. The structure contains a single framework, assembled by the repetition of a binuclear SBU, which leads to the formation of BPhDC layers pillared by the BPE ligand. A cuboidal unit can also be isolated from the framework. Its distorted nature is attributed to the high flexibility of the BPE ligand. A threefold interpenetration leads to the formation of a nonporous compound, CUmof-1.

Experimental Section

Elemental analysis for C, N and H was performed on an Exeter Analytical CE-440 Elemental Analyser. The sample was combusted under oxygen at 975 °C for 1 minute, with He as the purge gas. TGA was carried out using Shimadzu TGA-50 and DSC on Shim-

adzu DSC-50 analyzers. Measurements were performed with a heating rate of 5 °C/min under a nitrogen atmosphere with a flow rate of 20 cm^3/min. The FT-IR spectrum was acquired using KBr pellets (Aldrich 99% +, FT-IR grade) on a Mattson 7000 FT-IR spectrometer. The FT-Raman spectrum was measured on a Bruker RFS 100 spectrometer with a Nd: YAG coherent laser (λ = 1064 nm). ^{113}Cd MAS NMR spectra were recorded at 88.71 MHz using a Chemagnetics CMX-400 spectrometer equipped with a 9.4 T magnet and zirconia rotors 7.5 mm in diameter spun in nitrogen at 5.0 kHz, using 6 μs pulse length and 180 s repetition time. Chemical shifts are quoted in ppm with respect to a 0.1 M aqueous solution of $Cd(NO_3)_2$.

Reagents: All chemicals are available from commercial sources and were used as received. The synthesis was carried out in a Teflon-lined autoclave under autogeneous pressure and static conditions (8 cm^3 total volume, filling rate 70%). The autoclave was obtained from Parr Instruments. The temperature profile used for the synthesis is described in Scheme 1.



Scheme 1

Characterization: A suitable single crystal of CUmof-1 was mounted on a glass fibre, directly from the autoclave solution, using perfluoropolyether oil.[51] Data were collected on a Nonius Kappa CCD diffractometer with Mo-K_α graphite-monochromated radiation (λ = 0.7107 Å). The crystals were very thin needles and diffracted weakly: data were collected only to θ = 22.5° (equivalent to 0.93 Å resolution) and weak data at high angle contributes to a relatively large R_{int} value of 0.238). The structure was solved by direct methods and refined by full-matrix least-squares on F^2 with anisotropic displacement parameters for all non-hydrogen atoms,[52,53] with multi-scan absorption corrections also being applied.[54] All hydrogen atoms bound to carbon were placed geometrically, and refined using a riding model with an isotropic displacement parameter fixed at 1.2-times U_{eq} for the atom to which they are connected. Bond length restraints were not applied, except for H(1O) and H(2O), associated with the water molecule, for which the O−H distances were restrained to be 0.85(1) Å and the H−O−H angle was also restrained to be 1.39(2) Å. These restraints ensure a chemically reasonable geometry for the water molecule. Cavity dimensions were calculated by overlapping rigid spheres with van der Waals radii for each element: Cd^{2+} 2.20 Å; O 1.52 Å; N 1.55 Å; C 1.7 Å. Hydrogen atoms were omitted in all cases for simplicity. Information concerning crystallographic data collection and structure refinement for CUmof-1 is summarised in Table 1, while selected bond lengths and angles are presented in Table 2. CCDC-178338 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The PXRD pattern was measured at ambient temperature on a STOE STADI-P high-resolution diffractometer with Ge(111)-monochromated Cu-K_α radiation (λ = 1.5406 Å) and a position-sensitive detector covering 6° 2θ angle (40 kV, 40 mA). Data were collected using the step counting method (step 1.0°, time 150 s) in the 2° ≤ 2θ ≤ 60° range. Theoretical PXRD calculations were performed using the STOE Win XPOW software package.[55]

Synthesis of CUmof-1: 1,2-Bis(4-pyridyl)ethane (BPE, 0.188 g, Aldrich), biphenyl-4,4′-dicarboxylic acid (H_2BPhDC, 0.244 g, Fluka) and triethylamine (TEA, 0.211 g, Avocado) were added to a solution of $Cd(NO_3)_2{\cdot}4H_2O$ (0.318 g, Aldrich) in distilled water (6.15 g) and the mixture was stirred thoroughly for 1 hour at ambient temperature. The suspension, with a composition of 1.00 H_2BPhDC:1.02 Cd^{2+}:1.01 BPE:2.07 TEA:339 H_2O, was autoclaved at 145 °C. A white crystalline product was obtained. Crystals suitable for single-crystal X-ray diffraction were separated manually and preserved in a portion of the autoclave aqueous solution. The powder was washed with 50 cm^3 distilled water and three times with 50 cm^3 absolute ethanol, and air-dried at 70 °C to give crystalline CUmof-1. This MOF proved to be air- and light-stable, as well as insoluble in distilled water and common organic solvents (ethanol, acetone, dichloromethane and toluene). The elemental composition found was: C 55.91%, H 3.85%, N 4.92%. The calculated composition was: C 56.30%, H 4.00%, N 5.05%. TGA (weight loss for an initial sample of 11.82 mg): 28−140 °C 2.3%; 330−380 °C 31.8% (DTG peak at 368 °C); 380−440 °C 41.6% (DTG peak at 435 °C). DSC data: three endothermic processes with peaks at 63, 371 and 433 °C. Selected FT-IR data (cm^{-1}): ν(O−H) 3664w and 3426 m,vb; ν(C−H) 3070w; overtones and combinations in substituted benzene rings, 1940w and 1815w; *p*-disubstituted benzene and pyridine rings ν(C=C) 1608vs, 1577vs, 1526vs, 1400vs,vb; ν(C−O) 1230m and 1175m; 1103w; 1071m; δ(=C−H) 1016m and 1006m; 963w; γ(O−H) 877w; *p*-substituted pyridine ring γ(C−H) 851s, 829s, 816s and 800m; *m*-substituted benzene ring ω(C−H) 773s; γ(C=O) 703m, 685m and 672m; pyridines δ(=C−H) 629w; *p*-disubstituted benzene ring δ and γ(=C−H) 547m, 528m; ρ[(C=O)−O] 493m; substituted benzenes γ(C−H) 420s. Selected FT-Raman data (cm^{-1}): ν(C−H) 3067 m; ν(C=C, pyridines and aromatic compounds) 1608vs; δ(O−H) 1415m; ν(C−O) 1295m and 1280m; 1141m; δ(=C−H) 1016w; γ(C−H) 861m and 846m; depolarized δ(C=C) 667w; 628w; 412w; 335w.

Electrochemical and Spectroelectrochemical Investigations of "Figure-Eight" Octapyrrolic Macrocycles, Free Bases, and Their Mononuclear, Homo- and Heterodinuclear Complexes with Divalent Transition Metals

Jordi Bley-Escrich,[a] Jean-Paul Gisselbrecht,[a] Emanuel Vogel,[b] and Maurice Gross*[a]

Keywords: Macrocyclic ligands / Octaphyrins / Transition metal complexes / Electrochemistry

This work reports on electrochemical investigations of "figure-eight"-shaped cyclooctapyrrolic macrocycles (octaphyrins) **1**–**3** and of some of their mono- and dinuclear transition metal complexes. The octaphyrins **1**–**3** differ mainly in the size of the main conjugation pathway, which involves either $4n$ π-electrons for **1** and **3**, or $(4n + 2)$ π-electrons for **2**. All species studied undergo six redox steps, namely two reductions and four oxidations. The two reductions and the first three oxidations are reversible one-electron transfers. The fourth oxidation is either reversible, or irreversible due to a subsequent chemical reaction. Depending on the complex studied, the third and fourth oxidations occur either at similar potentials, so that a global two-electron step is observed, or at distinct potentials, leading to two well-separated signals. Spectroelectrochemical investigations demonstrate that all redox processes are ligand centred. The reported results clearly indicate that the redox potential changes in these new octapyrrolic macrocycles depend much more on structural contributions, due to their figure-eight topography, than on characteristics such as ionic radius or electronegativity of the coordinated metal. The HOMO-LUMO gap in the series of octaphyrins studied is rather small (about 1 eV), and is not only related to the macrocyclic ring size, but also depends on whether the main conjugation pathway involves $4n$ or $(4n + 2)$ π-electrons.

Introduction

Expanded porphyrinoids with five or more conjugated pyrrolic rings have attracted interest since the discovery of the pentapyrrolic sapphyrin by Woodward, Dolphin, and Johnson.[1−3] Subsequent to this early work, various cyclopolypyrroles, namely penta- and hexapyrrolic ring systems[4−8] have been prepared and identified. More recently, a new cyclodecapyrrole called turcasarin,[9] and a family of cyclooctapyrroles, named octaphyrins,[10−12] belonging to figure-eight-shaped cyclopolypyrroles have been obtained. Giant cycles containing up to 16 pyrrole units have also been synthesised and identified very recently.[13−15]

Despite this very large set of polypyrrolic macrocycles now available, the complexing abilities of these new expanded macrocycles have only been investigated for a few compounds,[16] and electrochemical studies remain scarce.[17]

The cyclooctapyrroles (COP) presently known,[10−12] i.e., **1** {[32]COP(1.0.1.0.1.0.1.0)},[18] **2** {[34]COP(1.1.1.0.1.1.1.0)},[18] and **3** {[36]COP(2.1.0.1.2.1.0.1)}[18] (all three series studied in this publication), are employed as hexadecaethyl derivatives (Figure 1) for reasons of solubility. A characteristic feature of these cyclooctapyrroles is that they are folded in such a way so as to adopt figure-eight conformations with approximate D_2 symmetry, both in solution and in the solid state as confirmed by NMR spectroscopic studies and X-ray crystallographic analysis.[19−20] NMR spectroscopic studies of these cyclooctaphyrin free bases confirmed their nonaromatic character, whether they possess $(4n + 2)$ [**2** (34)] or $4n$ [**1** (32) and **3** (36)] π-electrons in their main conjugation pathway. The figure-eight-shaped structure of cyclooctaphyrins provides two equivalent porphyrin-sized cavities for metal complexation, enabling the generation of mononuclear, homodinuclear and heterodinuclear complexes. However, depending on the ring size, all three types of complexes could be prepared with **1** and **2**. On the other hand, only homodinuclear complexes could be obtained and identified with ligand **3**.[21]

Until now, electrochemical investigations of macrocyclic polypyrroles containing more than four pyrrole units remain rather scarce,[17] and studies on octapyrrolic macrocycles are restricted to preliminary studies on the free bases and some complexes of **1** and **3** in CH_2Cl_2.[22] In the present paper the electrochemical behaviour of a new series of cyclooctaphyrins, namely **2**, has been investigated in dry benzonitrile. Its behaviour will be compared with previously

published data[22] involving **1** and **3**. However, to obtain a better insight into the redox behaviour of the three series of COP and to allow consistent comparison, the previously studied COP (**1**, **3**−**10**, **16**−**18**) have been reinvestigated here in dry benzonitrile by hydrodynamic voltammetry, by cyclic voltammetry, and by UV/Vis spectroelectrochemistry.

Results and Discussion

Results

In order to obtain useful information on the redox properties of the cyclooctaphyrins **1**, **2**, and **3** and their complexes (Figure 1), studies were carried out by cyclic voltammetry (CV) and hydrodynamic voltammetry on a platinum RDE in dry PhCN + 0.1 M Bu_4NPF_6 solutions at 25 °C on the three series of cyclooctaphyrins.

Hydrodynamic voltammetry of **1** and its complexes **4**−**10** show similar redox behaviour. Indeed, all species exhibit, as illustrated for the Pd−Pd complex **7** (Figure 2), two reduction waves of equal amplitude, as well as three oxidation waves. The first two oxidation waves have the same limiting current as the reduction waves, whereas the current for the third oxidation is twice that of the previous steps. For the complexes **4**−**10**, this later wave is broader, depending on the complex studied. Wave analysis, using Tomeš criteria,[23] give slopes $|E_{3/4} - E_{1/4}|$ close to 56.4 mV for the two reductions and the first two oxidations, whereas the third oxidations have slopes ranging from 60 to 170 mV, depending on the coordinated metal ion(s). For the two reductions and the first two oxidations, the observed slopes are consistent with reversible one-electron exchanges, whereas the slope for the third oxidation, involving two electrons will be studied by CV to obtain more information on its electron transfer mechanism. The potentials obtained by hydrodynamic voltammetry are in agreement with those observed by CV, and they are reported in Table 1.

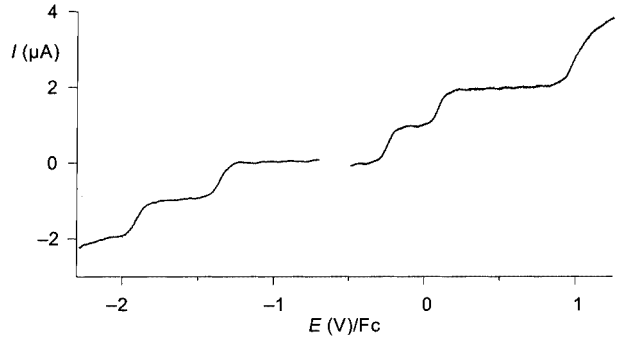

Figure 2. Hydrodynamic voltammetry of **7** in PhCN + 0.1 M Bu_4NPF_6, on Pt working electrode; scan rate: 0.01 V/s (potentials vs. Fc)

The CVs for **1** and its complexes are given in Figure 3 and their redox potentials are reported in Table 1. For the free base, as well as for the complexes studied, two one-electron reversible reductions are observed. For the oxidations, the first two electron transfers are also one-electron reversible oxidations, as confirmed by the monitoring of their peak current (I_p) and peak potentials (E_p) with scan rate. The corresponding peak potentials are constant with scan rates of up to 5 V/s, the peak current ratio I_{pa}/I_{pc} is close to unity at any v, the peak potential difference $\Delta E = E_{pc} - E_{pa}$ is approximately 60 mV up to 5 V/s, and a linear correlation intercepting the origin is observed by plotting I_p vs. $v^{1/2}$.

Further oxidation steps deserve specific comments. The free base **1** and the mononuclear complexes **4**−**6** exhibit a third oxidation step, which is irreversible at scan rates lower than 1 V/s. At scan rates higher than 1 V/s, this third step becomes reversible for complexes **4**−**6**, and reversible only at scan rates higher than 5 V/s for **1**. Analysis of the peak characteristics show that the plot I_{pa} vs. $v^{1/2}$ is a straight line intercepting the origin for scan rates lower than 0.2 V/s. Its slope is twice that of the first and second oxidation, consistent with a two-electron transfer, as indicated from the results obtained in hydrodynamic voltammetry. At scan rates higher than 0.2 V/s, the peak current evolution was slightly curved to the x axis. In addition, the peak current ratio I_{pa}/I_{pc} increases with scan rate to unity. The peak shape ($E_p - E_{p/2}$) is specific to the species studied (45 mV for **1**, 100 mV for **4** and 60 mV for **5** at v = 0.1 V/s) and increases with scan rate. Although no clear conclusion

could be drawn from these data from known criteria,[24] these results are fully consistent with a third oxidation obeying an $E_{rev}E_{rev}C_{irr}$ mechanism. Such a mechanism is indeed observed for complex **6** (belonging to the same series of species studied), with distinct potentials for both steps. Actually, the NiH_2 complex **6** undergoes distinct third and fourth one-electron oxidations. Reversing the scan after the third oxidation confirms the reversibility of the third oxidation, whereas the fourth oxidation remains irreversible at scan rates lower than 1 V/s. Digital simulation using DIGISIM software[25] confirms the proposed mechanism, as illustrated for **1** in Figure 4, and allows us to access to the corresponding potentials. The final species generated could not be identified. However, the species generated is electroactive and could be identified by its reduction around +0.7 V/Fc on the reverse scan.

The complexes **7**−**10** exhibit a two-electron, reversible third oxidation at all scan rates. The redox potentials are presented in Table 1. For this third step, wave analysis gives slopes close to 60 mV in hydrodynamic voltammetry, and the peak potential difference $\Delta E_p = E_{pa} - E_{pc}$ is close to 60 mV up to 1 V/s. These characteristics are in agreement with two overlapping reversible one-electron transfers, whose redox potentials are separated by 35.6 mV, as predicted by Savéant[26] for hydrodynamic voltammetry and Shain[27] for CV. The latter transfers occur at two independent redox centres whose potentials are given in Table 1.

For **2** and its homo- and heterodinuclear complexes **11**−**15**, the redox behaviour is similar to the results reported above. All these species undergo two one-electron reversible reductions. Oxidation of the free base **2** gives four well-separated one-electron reversible steps, whereas for complexes **11** and **12** the fourth oxidation is irreversible as shown by CV (Figure 5). Oxidation of **13**, **14** and **15** occurs in three steps, the first two are one-electron reversible oxidations, and the third step is a reversible two-electron step. Analysis of the peak characteristics indicate that the third oxidation involves two reversible overlapping one-electron steps whose potentials are reported in Table 1.

Ligand **3** and its homodinuclear complexes **16**−**18** all have similar redox behaviour, namely two one-electron reduction steps, as well as three oxidations as shown in Figure 6. The first two oxidations are reversible one-electron transfers, whereas the third oxidation has the characteristics of two overlapping one-electron reversible transfers. Indeed, wave analysis of the third oxidation step gives a slope close to 60 mV by hydrodynamic voltammetry, whereas the peak potential difference in CV, $E_{pc} - E_{pa}$, is approximately 60 mV at scan rates up to 1 V/s. As two electrons are involved in the third step, these characteristics are in agreement with two one-electron transfers separated by 35.6 mV,[26,27] which occur at two independent redox centres. In order to identify the electron-transfer sites, spectroelectrochemical studies have also been carried out.

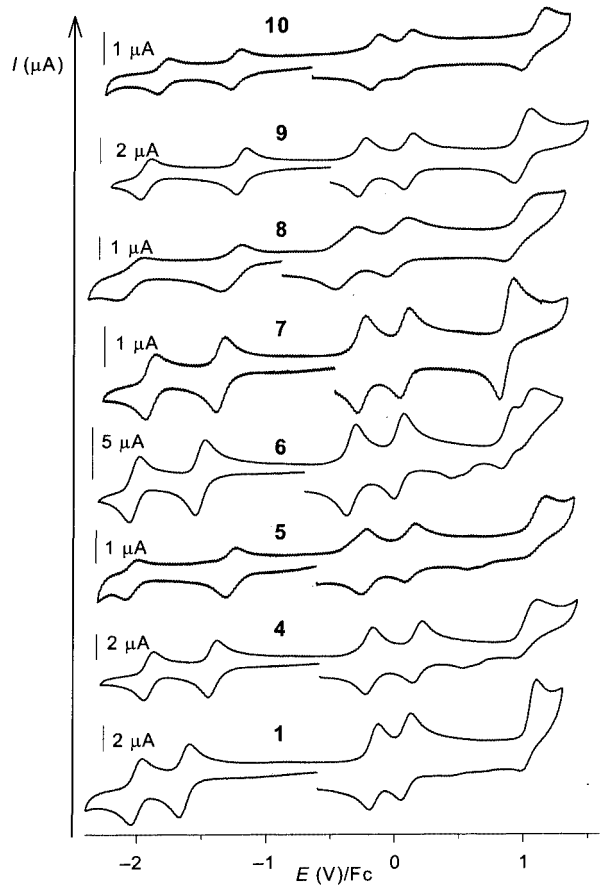

Figure 3. Cyclic voltammetry of **1** and **4**−**10** in PhCN + 0.1 M Bu_4NPF_6, on Pt working electrode; potential vs. Fc; scan rate: 1 V/s for **1** and 0.2 V/s for **4**−**10**

Figure 4. Spectroelectrochemistry

Spectroelectrochemistry was carried out on each compound. The spectra showing the two reduction steps and the four oxidations exhibit, in general, well-defined isosbestic points. During the two reductions and the first two oxidations, the species generated exhibit specific absorbance bands. The initial spectrum could be recovered quantitatively by stepwise electrochemical restoration of the initial cyclooctaphyrin. This indicates that the two electroreduced and the two electrooxidised species are chemically stable on the time scale of the spectroelectrochemical experiments, i.e. about 30 min, a good indication of the high stability of the electrogenerated species under the experimental conditions.

In general, the third and fourth oxidations do not revert to the initial spectrum after spectroelectrochemical measurements, due to the chemical reaction coupled to the fourth oxidation step, hence leading to global irreversibility. When the third and fourth oxidations occur at quite distinct potentials (i.e. for the Zn_2 and Cu_2 complexes **11** and **12**), allowing for the trioxidised and the tetraoxidised species to be obtained separately, the trioxidised species quantitatively reverts to the initial spectrum by stepwise electrochemical restoration of the initial species.

The spectral changes during electrolysis are similar for **1** and its complexes **4**−**10**, as well as for **3** and its complexes **16**−**18**. Therefore, the behaviour of one representative compound, Pd_2 complex **16**, will be described for these two series (**a**, **b** in Figure 7). The neutral species presents a main absorbance band at 660 nm, and no bands are detected

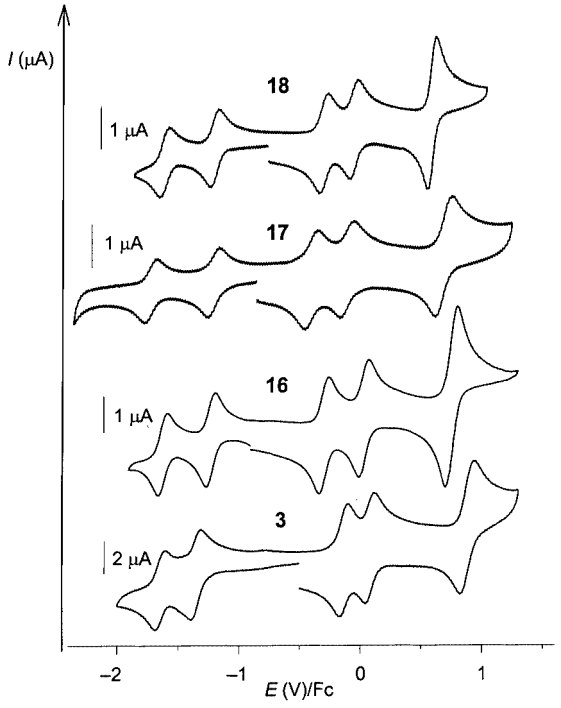

Figure 6. Cyclic voltammetry of **3** and **16**−**18** in PhCN + 0.1 M Bu_4NPF_6, on Pt working electrode; scan rate: 1 V/s for **3** and 0.2 V/s for **16**−**18** (potentials vs. Fc)

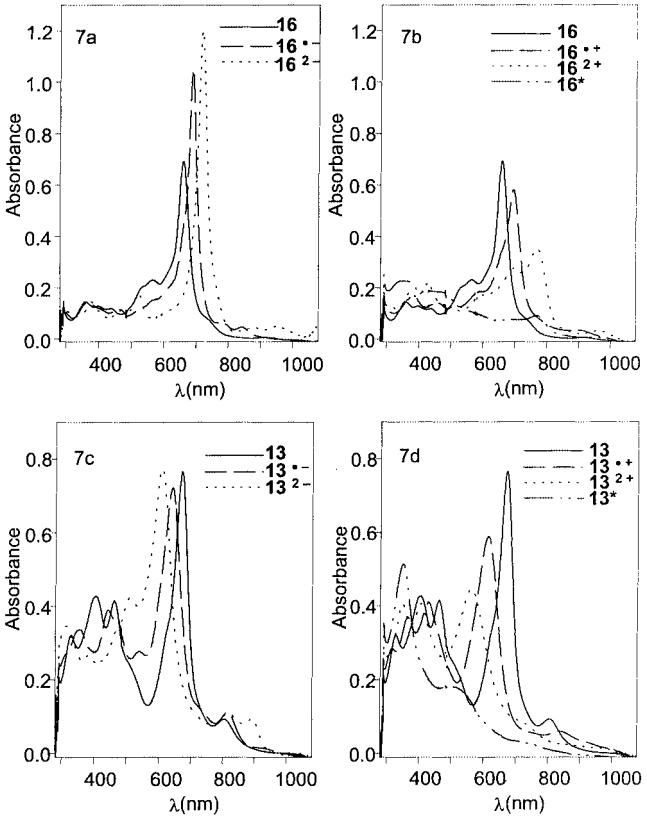

Figure 7. Spectroelectrochemistry of COP **16** and **13**, in PhCN + 0.1 M Bu_4NPF_6; reductions (see **a**) and oxidations (see **b**) of **16**; reductions (see **c**) and oxidations (see **d**) of **13**; *: spectrum corresponding to the species resulting from the irreversible chemical reaction following the fourth oxidation

from 800 to 1100 nm. During electrolysis on the plateau potential corresponding to the first reduction, the main band shifts to the red (691 nm) and its intensity increases by 75%, while some small bands appear between 800 and 900 nm. The main band shifts to a lower energy (720 nm) and its intensity increases again by 20%, after further electrolysis at the potential of the second reduction. Small bands appear between 900 and 1000 nm and an absorbance band is detected at 1078 nm. Spectra of the neutral, mono- and di-reduced species are presented in Figure 7 (see **a**). For the oxidation, the behaviour is quite similar for the first and second steps: the main absorbance band undergoes a red shift during the first oxidation electrolysis (696 nm), while its intensity decreases relative to the intensity of the neutral compound. The electrolysis at the second oxidation potential leads to a spectrum in which the main absorbance band also undergoes a red shift (771 nm) and is less intense.

During the third oxidation step, the intensity of all bands beyond 550 nm decreases considerably, or the bands completely disappear. This step is not reversible on the time scale of spectroelectrochemistry. Spectra characterising the species generated during oxidative electrolysis are presented in Figure 7 (see **b**).

The spectroelectrochemical behaviour of **2** and its complexes **11**−**15** is similar to the results presented above. However, a blue shift of the main absorbance band is observed during reduction, as well as during oxidation, as illustrated in the case of complex **13** (see **c**, **d** in Figure 7). The most intense main absorbance band is observed in the neutral compound spectrum, and not for the di-reduced species as observed previously with **1**, **3**, and their respective complexes.

These redox and spectral characteristics unambiguously indicate that the metal complexes of the cyclooctaphyrins studied undergo redox processes very similar to those of the free bases. Comparison of these reduction and oxidation potentials of the free bases with those of their metal complexes, as well as the spectral modifications associated with electron transfer in each redox step, lead to the reasonable conclusion that the electron transfer processes occur on the cyclooctapyrrolic ligand in the free bases and also in the complexes studied.

Discussion

The present electrochemical investigations clearly demonstrate that all the free bases and complexes studied above undergo six one-electron transfers on the conjugated cyclooctapyrrolic ring, namely two well-separated reversible one-electron reduction and four oxidation steps. The first three oxidations are reversible one-electron steps, whereas the fourth oxidation is either reversible, in most cases, or is irreversible in the species **1**, **4**, **5**, **6**, **11**, and **12**. For almost all the species studied, the last two oxidations occur at fairly close potentials ($Eox_4 - Eox_3 = 35.6$ mV), giving, macroscopically, a unique two-electron transfer, except in **2**, **6**,

11, **12** where the third and fourth oxidation potentials are separated by more than 80 mV. The third oxidation step observed, involving two-electron transfers separated by 35.6 mV and corresponding to oxidations at almost independent redox centres, is not well understood for COP. It could either result from non-interacting redox centres in the ligand, or from geometric changes occurring after the third electron exchange, which raises the energy level of the HOMO, making the removal of the fourth electron easier.[28] Theoretical approaches should be undertaken in order to obtain a better insight into these new families of compounds. Nevertheless, it should be stressed that unlike other polypyrrolic macrocycles, such as porphyrins, the COP ligands studied here are not planar[19,20] and do not possess an aromatic π-electron system, although they are fully conjugated. Therefore, it is possible that the removal of two electrons from the same HOMO orbital, occurring at two distant sites in the ligand, avoiding any coulombic repulsion, occurs in a unique step. However, until further information is made available, conformational changes triggered by the third oxidation thus allowing for the removal of the fourth electron at the same potential may not be ruled out, since geometric and steric factors contribute to the electrochemical behaviour, as pointed out hereafter.

Comparison of the redox potentials lead to interesting observations. Disregarding the species involving **3**, for which the number of complexes studied is too small (free base **3** and complexes **16**−**18**) to allow significant comparisons, it may be observed from Table 1 that **2** and its complexes **11**−**15**, possessing ($4n$ + 2) π-electrons in the main conjugation pathway, present very close mean reduction potentials values ($E\text{red}_1$ = −1.36±0.04 V, $E\text{red}_2$ = −1.89±0.03 V/Fc). In contrast, **1** and its complexes **4**−**10**, possessing $4n$ π-electrons, present a greater spread in their mean reduction potentials values ($E\text{red}_1$ = −1.35±0.09 V, $E\text{red}_2$ = −1.98±0.08 V/Fc). However, the difference between these two values remain similar for **2** and its complexes ($E\text{red}_1 - E\text{red}_2$ = +0.52±0.03 V) and for **1** and its complexes ($E\text{red}_1 - E\text{red}_2$ = +0.53±0.03 V), except for the complexes of **1** that contain copper (0.75 V). The similarity in these values is a good indication that all the reductions occur on the ligand, and they are also consistent with the possible explanation that the potential difference corresponds to the energy repulsion between two electrons filling the same orbital.[29]

The same conclusions are observed for the oxidation processes. For **2** and its complexes, the first two oxidation potentials are quite similar ($E\text{ox}_1$ = −0.37±0.02 V, $E\text{ox}_2$ = +0.10±0.03 V), whereas **1** and its complexes present more dispersed mean potential values ($E\text{ox}_1$ = −0.29±0.09 V, $E\text{ox}_2$ = +0.06±0.10 V). The potential difference between the first and second oxidations in each series are also quite similar. Indeed $E\text{ox}_1 - E\text{ox}_2$ = +0.46±0.03 V for **2** and its complexes, and $E\text{ox}_1 - E\text{ox}_2$ = +0.36±0.03 V for **1** and its complexes, except for **10** (0.24 V). As observed recently by Guyard et al.,[30] who studied the oxidation behaviour of several pyrrole oligomers, namely pyrrole to tetrapyrrole, the longer the chain, the easier the oxidations. The tetrapyrrole was easily oxidised (stepwise) at −0.16 and +0.12V/Fc like COP. The low potentials associated with the first two oxidations of COP agree with those results, assuming that COP behave like polypyrroles, independent of their cyclic or conjugation characteristics. It has to be mentioned that in the present set of cyclooctaphyrins studied, no correlation between the observed redox potentials and the electronegativity of the complexed metals could be established, in contrast with results observed with porphyrins or porphyrin isomers.[31−33] This suggests that geometric and steric factors contribute in good part to the electrochemical behaviour of COP.

In a given set of molecules, advantage may be taken from the existing correlation between the energy of the HOMO orbital and at least the first oxidation potential, and also between the LUMO and the first reduction potential. In such a case the difference $E\text{ox}_1 - E\text{red}_1$ may be taken as a good approximation of the energy gap between the HOMO and the LUMO orbitals.[32,34] The energy gaps for cyclooctaphyrins are relatively low (Table 1), compared with aromatic polypyrrolic macrocycles like porphyrins (2.25±0.15 V)[32] or porphycenes (1.85±0.15 V),[33,35−37] but they are similar to that of expanded porphycenes containing 26 π-electrons (1.01 V).[38] This low energy gap observed in cyclooctaphyrins is therefore related to the extension of the π-conjugation pathway. However, as observed in free bases **1**−**3**, the gap does not decrease on increasing the size of the conjugated macrocycle. Indeed, the highest value belongs to the smallest cyclooctaphyrin **1** (ΔE = 1.46 V), followed by the largest macrocycle **3** (ΔE = 1.22 V), and finally the smallest gap corresponds to the middle-sized cyclooctaphyrin **2** (ΔE = 1.10 V). These values are in agreement with the observed lowest energy bands observed in CH_2Cl_2, as shown in Figure 8. Indeed, **2** gives well-defined bands, the less energetic band being located at 1280 nm (0.97 eV). In contrast, both free-bases **1** and **3** only exhibit small amplitude absorbance bands at 865 (1.43 eV) and 932 nm (1.33 eV), respectively. However, this is parallel to the energy sequence of the most intense bands in the UV/Vis spectra of these macrocycles (λ = 534 nm for **1**, λ = 596 nm for **3**, and λ = 660 nm for **2**), illustrated in Figure 8.

For the species studied (Figure 9), **2**, **11**−**15** [($4n$ + 2) π-electrons] exhibit an almost constant gap within the series of the five complexes studied (ΔE =1.00±0.10 V). In complexes of **1** and **3** ($4n$ π-electrons), this difference decreases drastically from the free base to mononuclear complexes, and further to dinuclear complexes (Figure 9). For example, in mononuclear complexes **4**−**6** these values change drastically in the series, the highest belonging to **4** and the lowest to **5**. These variations could not successfully be correlated to any metal characteristics (electronegativity, ionization potential, ionic radius, ...), and therefore we are inclined to conclude that this evolution is basically related to geometric and steric parameters characterising the cations in the cavity of cyclooctaphyrins.

The results obtained from spectroelectrochemical studies on cyclooctaphyrins confirm that all redox steps occur on the ligand, and that no metal-centred transfer is observed

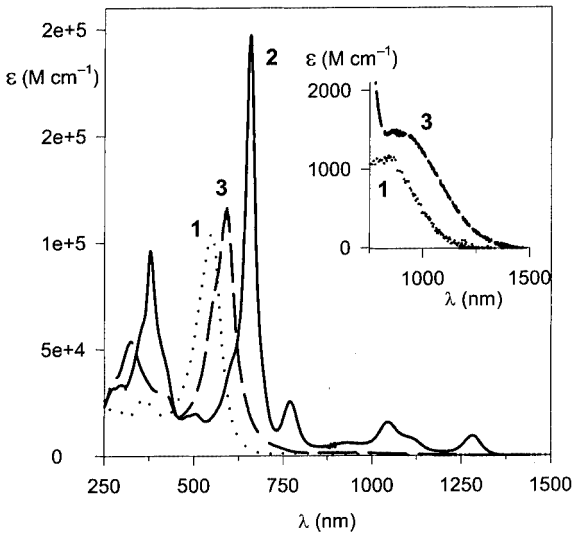

Figure 8. UV/Vis absorbance spectra of the three free bases **1**, **2**, and **3**, in CH_2Cl_2

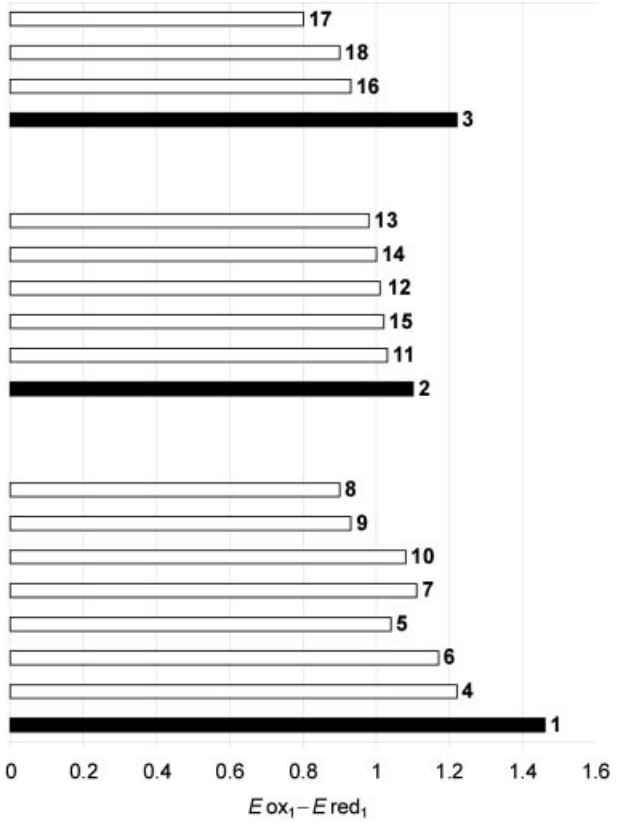

Figure 9. Potential difference $E\text{ox}_1 - E\text{red}_1$ [V], estimation of the HOMO−LUMO gap, for the three cyclooctaphyrin series

in the series studied. Some unexpected trends within the three series of compounds studied are observed. Indeed, although none of the species studied involves an aromatic ligand (even though they have 34 or 38 π-electrons [(4*n* + 2) π-electrons]),[11,39] the observed spectra obtained from spectroelectrochemistry are markedly different, depending on whether the ligands possess 4*n* or (4*n* + 2) π-electrons.

Such unexpected spectral changes are documented from comparison among the three COP families, more specifically when comparing the families with 4*n* π-electrons with the family with (4*n* + 2) π-electrons. Indeed, the spectra of the families with 4*n* π-electrons show a red shift during the two reductions and the first two oxidations, both corresponding to changes from 4*n* to (4*n* + 2) π-electrons. More explicitly, the species with (4*n* + 2) π-electrons exhibit a narrow and intense band whose wavelength depends on the family studied: this absorbance band is located close to 660 nm for the neutral species **2** and its complexes, and close to 725 nm for the di-reduced species **1**, **3**, and their complexes. The intensity and the geometry of this band is reminiscent of the characteristics of a Soret band, although the species are not aromatic.[11,39] On the contrary, the spectra of the family initially possessing (4*n* + 2) π-electrons shifts to the blue during the reductions and the oxidations, i.e. when changing from (4*n* + 2) to 4*n* π-electrons. Based on such related 4*n* or (4*n* + 2) π-electron numbers, the two evolutions are consistent. Another interesting observation was carried out for cyclooctaphyrins containing (4*n* + 2) π-electrons, including di-reduced **1** and **3**, as well as the neutral ligands **2**, and their respective metal complexes: all exhibit a particular similarity in their UV/Vis absorbance spectra. On the contrary, the absorbance band wavelength of the species having 4*n* π-electrons in their main conjugation pathway depends to a large extent on the chemical nature of the complexed metal(s).

The presence of this intense and sharp band in the species possessing (4*n* + 2) π-electrons is surprising for these macrocycles, in particular because of their twisted ("figure-eight") conformation. Still more surprising is the observation that the absorbance bands of the neutral ligand **2** and its complexes and those of the di-reduced species **3** and its complexes are perfectly located on the linear correlation (established previously by Franck et al. for aromatic planar expanded porphyrins)[40] between the wavelength of the Soret-like band and the number of conjugated π-electrons belonging to expanded macrocycles, named Babuška Porphyrins.

In the absence of any study or review available on macrocyclic polypyrroles analysing their spectral evolution with the size of the conjugated macrocycles, we plotted the wavelength of the most intense band of known polypyrrolic macrocycles, versus the number of π-electrons in the main conjugation pathway. The data collected, shown in Figure 10, involve species containing (4*n* + 2) π-electrons as well as 4*n* π electrons, their conformation being either planar or twisted "figure-eight". Two linear correlations are obtained (Figure 10) for species with (4*n* + 2) and with 4*n* π-electrons, respectively. These two correlations differ in their slopes. A greater slope is obtained for the correlation involving macrocycles with (4*n* + 2) π-electrons. Both correlations intercept at a common point, which has no physical meaning. Such correlations were never reported previously on polypyrrolic macrocycles. However, the same kind of

correlation has been established by Märkl et al.[41] for tetraoxaporphyrins, possessing (4*n* + 2) π-electrons, and also for tetraepoxyannulenes with 4*n* π-electrons. The two correlations were linear and differed mainly in their slopes. It has to be mentioned here that the two linear correlations with macrocycles involving (4*n* + 2) π-electrons containing either N or O heteroatoms overlap, whereas for macrocycles containing 4*n* π-electrons the two correlations possess similar slopes, but with different ordinates (the wavelength of the macrocycles with O heteroatoms is blue-shifted relative to the polypyrrolic macrocycles).[41]

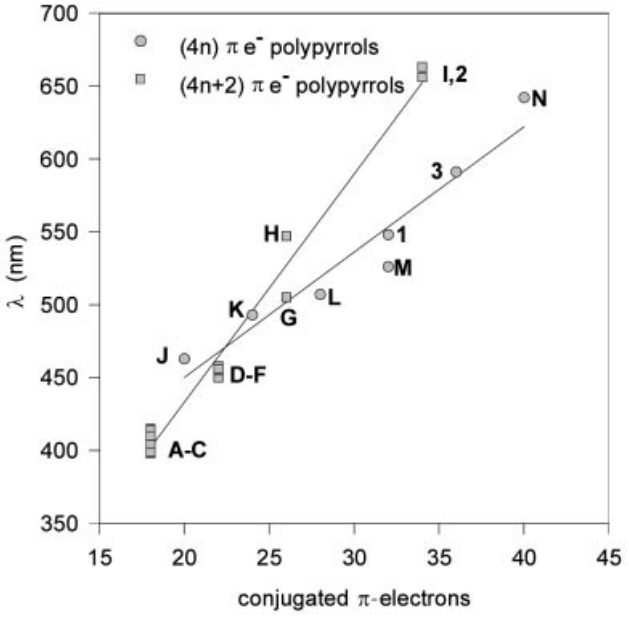

Figure 10. Correlation established for the main absorbance bands in UV/Vis spectra of polypyrrolic macrocycles versus the number of π-electrons involved in the main conjugation pathway; **A**: porphyrin;[40,42] **B**: corrphycene;[43,44] **C**: hemiporphycene;[45,46] **D**: sapphyrin;[3,42,47,48] **E**: pentaphyrin;[4] **F**: smaragdyrine;[49] **G**: rubyrine;[7] **H**: (3.3.3.3)porphyrin;[40] **I**: (5.5.5.5)porphyrin;[40] **J**: orangarin;[50] **K**: amethyrin;[50] **L**: heptaphyrin;[12] **M**: octaphyrin(1.0.0.0.1.0.0.0);[12] **N**: turcasarin;[9] **1**;[10] **2**;[11] **3**[11]

The observed correlations (Figure 10) with two different slopes rationalise the results of the spectroelectrochemical experiments. As reported above, the spectra from cyclooctaphyrins possessing 4*n* π-electrons undergo a red shift after two one-electron reductions, generating (4*n* + 2) π-electron species. Spectral evolutions for cyclooctaphyrins with (4*n* + 2) π-electrons undergo a blue shift under the same conditions, which is in agreement with the observed evolutions given in Figure 10, above the intercept.

The data reported above and correlations clearly indicate that the polypyrrolic macrocycles containing (4*n* + 2) π-electrons exhibit greater homogeneous characteristics. For instance, the redox potentials of **2** and its complexes **11**−**15** are identical, and the observed HOMO−LUMO gap is very similar for the series. Also their UV/Vis spectra give strong Soret-like bands at similar wavelengths. The homogeneity of such data for macrocycles containing (4*n* + 2) π-electrons most likely results from a stabilised structure, due to the presence of (4*n* + 2) π-electrons in cyclooctaphyrins. From the spectroelectrochemical studies, the dianion of **1**, **3**, and of their complexes also exhibit well-resolved sharp bands located at 725 nm.

Conclusion

The studied cyclooctaphyrins undergo six redox steps, two one-electron reversible reductions and four one-electron oxidations, the first three oxidations are one-electron reversible transfers. For some derivatives, the fourth oxidation is irreversible. The potential difference between the third and fourth oxidation is rather small in most of the species studied (close to 40 mV), resulting in a unique reversible two-electron exchange on the time scale of the experiments. The latter step, involving two overlapping electron transfers, involves two independent redox centres. Spectroelectrochemical studies confirm that all electron transfers are ligand-centred and that the species generated are stable on the time scale of the spectroelectrochemical measurements, namely for at least 30 min, except for the species generated by the fourth oxidation. This tetracation generated undergoes further chemical reaction(s) and renders the fourth oxidation irreversible on the spectroelectrochemical time scale.

The present study also demonstrates that cyclooctaphyrins with (4*n* + 2) π-electrons possess more homogeneous electrochemical and spectral characteristics, whereas cyclooctaphyrins with 4*n* π-electrons exhibit a greater spread in the redox potentials and UV/Vis absorbance bands. The spectra of the species with (4*n* + 2) π-electrons exhibit an intense and sharp absorbance band, clearly resulting from an intense conjugation in the ligand.

Further studies are under way, especially on cyclooctaphyrins containing electroactive metals that are, up to now, rather scarce. Also, more insight into these new classes of compounds will be provided by theoretical approaches.

Experimental Section

General: All of the presently studied cyclooctapyrroles were, for reasons of solubility, employed as hexadecaethyl derivatives. The synthesis of compound **1**, namely 2,3,6,7,11,12,15,16,20,21,24,25,29,30,33,34-hexadecaethylcyclooctapyrrol-(1.0.1.0.1.0.1.0), and for species **2**, namely 2,3,7,8,12,13,16,17,21,22,26,27,31,32,35,36-hexadecaethylcyclooctapyrrol-(1.1.1.0.1.1.1.0), and **3**, namely 2,3,6,7,11,12,17,18,22,23,26,27,31,32,37,38-hexadecaethylcyclooctapyrrol-(2.1.0.1.0.2.1.0.1), have been published previously.[10,11] The figure-eight conformation confers two coordination sites on these molecules, and it has been shown that **1** and **2** are able to coordinate diverse transition metal ions to afford complexes of all three types, namely mononuclear, homo- and hetero-dinuclear complexes according to classical procedures.[19,20] Ligand **3** gave only some homodinuclear complexes according to published procedures.[20,21] The electrochemical measurements were carried out in a glove box (less than 3 ppm of H_2O and less than 2 ppm of O_2) at room temperature (25±2 °C) in PhCN containing 0.1 M Bu_4NPF_6 in a classical three-electrode cell. The electrochemical cell was con-

nected to a computerised multipurpose electrochemical device (PAR 273) interfaced with a PC computer. The working electrode was a platinum (Pt) disc electrode (diameter: 2 mm) used either motionless for cyclic voltammetry (v = 20 mV/s to 5 V/s) or as a rotating disc electrode. The auxiliary electrode was a platinum wire, and the pseudo-reference electrode was also a platinum wire. All potentials are referred to the ferrocenenium/ferrocene (Fc^+/Fc) couple used as an internal standard. Benzonitrile (PhCN, Aldrich, 99%) was dried, before use, for 2 d with $CaCl_2$ (anhydrous, Fluka, 97%), and distilled from P_2O_5 (Prolabo) under reduced pressure and argon. The main fraction was collected under argon and transferred into the glove box. The supporting electrolyte, Bu_4NPF_6 (Fluka − electrochemical grade) was dried in an oven (65 °C) under vacuum for 2 d. Bu_4NPF_6 was solubilised in PhCN inside the glove box and the solution was then percolated over activated aluminia. The available potentials on a platinum working electrode ranged from −2.5 to +1.8 V/Fc. Spectroelectrochemical measurements were carried out in PhCN in a home-made quartz cell, having an optical pathway of 1 mm. The working electrode was a platinum grid (1000 mesh) placed in the optical pathway. The reference and the auxiliary electrodes were platinum wires in individual compartments, separated from the solution by cotton. The cell was filled in the glove box, and hermetically closed, it was then placed in a diode array spectrophotometer (Hewlett−Packard 8453) and spectra were recorded during electrolysis. UV/Vis spectra were recorded in CH_2Cl_2 (Merck, spectroscopy grade, used as received) with a Varian Cary 05E UV/Vis/NIR spectrophotometer, at room temperature.

The First Aluminophosphonate Cluster Analogue of the 4=1 SBU of Zeolites: Structure and Multinuclear Solid-State NMR Study, Including ^{1}H NMR

Thierry Azaïs,[a] Laure Bonhomme-Coury,[b] Jacqueline Vaissermann,[c] Jocelyne Maquet,[a] and Christian Bonhomme*[a]

Keywords: Aluminium / Cluster compounds / NMR spectroscopy / Phosphorus / Solid state

The first Al–O–P analogue of the so-called 4=1 Secondary Building Unit (SBU) of zeolites is presented and characterized by single-crystal X ray diffraction (compound **1**). The 4=1 building unit structure is very rarely encountered in zeolites and microporous materials. Compound **1** was carefully studied by ^{31}P and ^{27}Al solid-state MAS NMR, resulting in the precise spectroscopic description of the phosphorus and aluminium sites. Unusual ^{27}Al quadrupolar parameters were measured. Moreover, we also present a high-resolution solid-state ^{1}H NMR study of **1** at 600 MHz and 33 kHz MAS; a remarkable improvement in resolution is observed, allowing definite assignments. The new opportunities offered by very high speed ^{1}H NMR at high field were further demonstrated with the study of a cubane-shaped Al–O–P cluster (compound **2**) and of phenylphosphonic acid.

Introduction

Description of zeolites and porous aluminophosphate derivatives in terms of Secondary Building Units (SBUs) is now well established.[1] The geometrical features of each structural type are adequately described by connecting these small portions of solids. The synthesis of clusters mimicking SBUs[2] remains a great chemical challenge for the following reasons: (i) the SBUs may be considered as intermediates in the synthesis of microporous materials, and so it follows that reactions between these well-defined entities could give rise to new framework structures, and (ii) these clusters are suitable for fine spectroscopic studies, including solid-state NMR. Interactions such as the chemical shift anisotropy (CSA) or the quadrupolar interaction (for nuclei with $I > 1/2$) can be related to structural features around nuclei. These parameters are therefore of prime importance for NMR studies of more complex derivatives, such as microporous compounds.

Among the 18 SBUs described in the literature,[1] six types have synthetic analogues. If we restrict the list to Al−O−P-containing entities, only five types of clusters mimicking the following SBUs have been reported: the S4R (or 4) ring,[3] the S6R (or 6) ring,[4] the cubane-shaped D4R (or 4−4),[3c,3h,5] the prismatic D6R (6−6),[3h,5c] and the 6≡1 SBU.[6] Here we present the first cluster involving Al−O−P bonds to mimic the so-called 4=1 SBU: [(μ$_2$-hydroxo)bis{μ$_3$-phenylphosphonato(2−)-*o*,*o*′,*o*"}-decaethanoltrialuminium](4+) chloride·water(1:1): $[Al_3(\mu_2\text{-}OH)(\mu_3\text{-}C_6H_5PO_3)_2(C_2H_5OH)_{10}]Cl_4\cdot H_2O$ (compound **1**). The 4=1 SBU is encountered only very rarely; only three zeolites can be considered as derivatives of 4=1 units: natrolite ($Na_2Al_2Si_3O_{10}\cdot 2H_2O$), thomsonite ($NaCa_2Al_5Si_5O_{20}\cdot 6H_2O$), and edingtonite ($Ba_{2.02}Al_{4.03}Si_{5.07}O_{20}\cdot 7.8H_2O$).[1,7−9] These compounds exclusively involve Al−O−Si bonds. No aluminophosphate (-onate, -inate) derivative containing the 4=1 SBU has ever been described. We conjecture that it might be possible to synthesize such a derivative, as compound **1** definitely shows that the 4=1 Al−O−P architecture is realistic. Only two clusters involving Ga−O−P bonds and resembling the 4=1 SBU have previously been reported in the literature.[10] Finally, we stress the fact that compound **1** is an analogue of the 4=1 SBU but differs in terms of Al coordination: Al atoms are sixfold coordinated in compound **1**, whereas the Al atoms in zeolites are fourfold coordinated.

Cluster analogues of SBUs have generally been characterized by IR and solution NMR (^{1}H, ^{13}C, ^{27}Al, ^{31}P) techniques, after dissolution. Surprisingly, these compounds have never been studied by solid-state NMR, whereas this technique has been extensively applied to the structural characterization of microporous aluminophosphates (such as $AlPO_4$-*n*). Very recently, we have fully characterized

S4R[11] and D4R[12] Al−O−P analogues by high-resolution ^{27}Al and ^{31}P MAS NMR spectroscopy. In this paper we present the structure of compound **1**, which was obtained as single crystals, and a multinuclear solid-state study, ^{31}P and ^{27}Al NMR for the inorganic core, and ^{13}C and ^{1}H NMR for the organic part. We have extracted precise data related to CSA (^{31}P) and quadrupolar interaction (^{27}Al) for compound **1** and analyze them in terms of the crystallographic structure. We also introduce (for the first time in the field of the study of inorganic clusters) ^{1}H MAS experiments at high field (600 MHz, 14 T) and at very high rotation frequency (up to 33 kHz). Spectacular improvements have been observed in terms of resolution, and these allow clear interpretation of spectra. These new opportunities in solid-state ^{1}H NMR are further illustrated by results obtained for the cubane-shaped Al−O−P cluster $[Al_4(HPO_4)_4(C_2H_5OH)_{12}]Cl_4{\cdot}4C_2H_5OH$ (compound **2**)[12] and phenylphosphonic acid [$C_6H_5PO(OH)_2$, precursor of **1**]. One original insight of this paper concerns the solid-state ^{1}H MAS experiments.

Results and Discussion

The structure of compound **1** is presented in Figure 1, a). It presents a very unusual geometry. Two Al atoms (Al2, Al3) and two P atoms (P1, P2), linked through oxo bonds, form a ring. On one side, this ring is capped with a third Al atom (O2Al1O3) between P atoms, and there is a hydroxo bridge (O5) on the other side between Al atoms [Figure 1, b)]. All Al atoms are sixfold coordinated, involving three (Al2, Al3) or four (Al1) ethanol ligands. Selected bond lengths are reported in Table 1. Average bond lengths involving oxo bridges are 1.84 Å around Al2 and Al3 atoms and 1.80 Å around Al1. Distances between O of ethanol ligands and Al atoms are much longer: 1.94 Å (Al2, Al3) and 1.93 Å (Al1). The mean bond length for the μ-OH bridge is about 1.85 Å. Distortions of polyhedra are discussed quantitatively below. P atoms are fourfold coordinated; in addition to three O atoms, each P atom is bonded to one phenyl ring (C11→C16 and C21→C26). The average P−O bond length is 1.52 Å, whereas the mean P−C bond length is about 1.79 Å. Cl^- counter-ions (Cl1→Cl4) are present in the structure. H···Cl hydrogen bonds are strongly suggested by O···Cl distances shorter than 3.35 Å.[13] All Cl atoms are involved in several hydrogen bonds, two for Cl1 (with O11 and O12) and for Cl4 (with O15 and O17), three for Cl2 (with O8, O14, and O16), and four for Cl3 (with O5, O9, O10, and O13). The inorganic core of **1** strongly mimics the geometry of the 4=1 SBU [Figure 1, c)]. In the case of compound **1**, however, a μ-OH bridge is observed between Al2 and Al3, although there is no such bridge in the 4=1 SBU. We note that the Ga−O cluster,[10] which also looks like the 4=1 SBU, has a marked difference with the SBU; a phosphonate group links two Al atoms, as does the μ-OH bridge in compound **1**.

Compound **1** was fully characterized by solid-state ^{31}P, ^{27}Al, and ^{13}C MAS NMR spectroscopy (Figure 2). The ^{31}P CP (cross polarization from ^{1}H) MAS spectrum of **1** exhibits two sharp lines located at δ = 1.7 and 2.8 ppm, in agreement with the crystallographic data. At 3 kHz, numerous spinning sidebands are observed, allowing the principal values of the chemical shift tensors δ_{ii} to be determined. All data are reported in Table 2. In terms of NMR parameters (δ_{iso}, η_{CSA}, and $\Delta\delta$), the two sites are clearly distinguished, whereas crystallographic data show that the chemical environments of the P atoms are very similar. The next challenge is therefore to correlate NMR spectroscopic data with slight distortions of polyhedra around P atoms by ab initio CSA calculations. In other words, the next step of our research is to assign P1 and P2 definitely to the two observed ^{31}P lines.

2.8	0.75	73.1	1.5 (Al2,3)	<< 1[a]	–

[a] The quadrupolar interaction for (Al2, Al3) is very small(see text).

The ^{27}Al MAS spectrum of **1** [Figure 2, b)] exhibits two major lines. The first one is centered at $\delta \approx 1.5$ ppm and is narrow. The second is strongly broadened and exhibits the characteristic features of a second-order quadrupolar broadened line (i.e. "horns" at $\delta \approx -15$ and -35 ppm). Quantitative experiments[14] show that the two lines are in the ratio 2:1. Therefore, the line centered at $\delta \approx 1.5$ ppm is assigned to Al2 and Al3, the other to Al1. At low rotation frequency (4.5 kHz), the sub-spectrum corresponding to Al1 is a complex superposition of the central transition, spinning sidebands of the central transition (full square), and spinning sidebands of satellite transitions (open square) [Figure 3, a)]. However, the full spectrum can be satisfactorily simulated by the SIMPSON program, available on the web (see the Exp. Sect.).[15] The quadrupolar parameters are very precisely determined (see Table 2), as all the discontinuities of the spectrum are sensitive to (C_Q, η_Q). For instance, the calculated shift of one particular discontinuity (boxed **1**) versus η_Q is plotted in Figure 3, b). The experimental shift unambiguously gives $\eta_Q = 0.2 \pm 0.02$. The final set of quadrupolar parameters for Al1, including second-order corrections for the chemical shift,[16] is: Al1 ($\delta_{iso} = -2.2$ ppm; $C_Q = 4.92$ MHz; $\eta_Q = 0.2$). Chemical shifts for Al2 and Al3 are located at $\delta_{iso} = 1.5$ ppm. The C_Q values for (Al2, Al3) are very small, as shown in Figure 3 (a). Indeed, only two spinning sidebands corresponding to (Al2, Al3) are observed at a rotation frequency of 4.5 kHz (open circle). At this stage, the C_Q parameters can be analyzed in terms of the correlation established by Ghose et al:[17] C_Q of octahedrally coordinated aluminium atoms increases with the longitudinal strain $|\alpha|$ with

$$|\alpha| = \sum_{i=1}^{6} |\ln(l_i / l_0)|$$

where l_i are the individual Al−O bond lengths and l_0 is the ideal bond length for a perfect octahedron with the same volume as the distorted polyhedron.

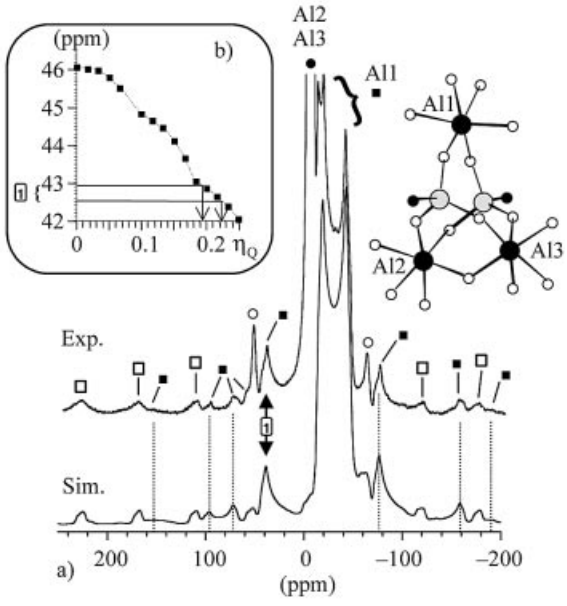

Figure 3. a) ^{27}Al MAS {^{1}H dec} spectrum of compound **1** at moderate spinning frequency (4.5 kHz); full circle: central transition of (Al2,Al3); open circle: spinning sidebands related to the satellite transitions; full square: central transition of Al1 and corresponding sidebands; open square: spinning sidebands related to the satellite transitions; simulation obtained by use of the SIMPSON program with: $\delta_{iso} = -2.2$ ppm, $C_Q = 4.92$ MHz, and $\eta_Q = 0.2$; b) calculated shift of the discontinuity (boxed **1**) versus η_Q; the experimental shift (with uncertainty) is shown by boxed **1** {; arrows indicate the derived values of η_Q

From the crystallographic data of compound **1**, the following calculated longitudinal strains are obtained: $|\alpha|$ = 0.155 and 0.165 for Al1 and Al2, respectively; $|\alpha|$ = 0.182 for Al3. These values are high and should be connected to $C_Q > 8$ MHz, as stated by Ghose et al. for aluminium oxide derivatives.[12,17] Obviously, the extracted experimental data are not in agreement with the previously reported results: (i) the C_Q values for Al1, Al2, and Al3 are much lower than 8 MHz, and (ii) C_Q(Al1,Al2) << C_Q(Al3) although $|\alpha|$ is almost identical for Al1, Al2, and Al3. This study proves unambiguously that a simple approach of the electric field gradient, taking into account only the first oxygen neighbors of Al atoms, is not suitable for the fine description of clusters such as **1**.

The ^{13}C CP MAS spectrum of **1** [Figure 2, c)] shows three main groups of resonances centered at δ = 17.3, 60.2, and 132.5 ppm and corresponding to $^{13}CH_3$, $^{13}CH_2$, and aromatic groups, respectively. The resolution is not high enough to count C atoms in the asymmetric unit (ten $^{13}CH_3$, ten $^{13}CH_2$, and twelve aromatic C). Experiments at higher field (up to 17.5 T) should allow a much improved resolution of spectra, and therefore direct counting of C atoms.

The ^{1}H MAS NMR spectra of phenylphosphonic acid [$C_6H_5PO(OH)_2$] and of compound **1** are presented in Figure 4. At $\nu_0(^1H)$ = 300 MHz and high rotation frequency (up to 14 kHz), the spectra are broad and almost featureless [Figure 4, a) and c)]. This is mainly due to the homogeneous character of the strong ^{1}H-^{1}H homonuclear dipolar interaction.[18] In the case of inhomogeneous interactions, such as CSA or first-order quadrupolar interaction, MAS is efficient even at low spinning frequency: sharp isotropic lines and sharp spinning sidebands are obtained [see, for instance, the ^{31}P CP MAS spectrum of compound **1** in Figure 2, a)]. It follows that high resolution is obtained. In contrast, slow MAS is inefficient to remove the broadening due to strong homonuclear coupling, unless the MAS frequency equals or exceeds the magnitude of the interaction. The problem was partially circumvented by the use of the so-called Combined Rotation And Multi Pulse Spectroscopy (CRAMPS), combining MAS and multi-pulse irradiation during the acquisition of the ^{1}H signal.[19] CRAMPS is a very demanding technique and is rarely implemented in laboratories. In this paper we present a second approach, involving a high field [14 T, $\nu_0(^1H)$ = 600 MHz] − to increase resolution − and a very high rotation frequency (33 kHz) − to average the homonuclear interaction efficiently. The observed increase of resolution is indeed dramatic [Figure 4, b) and d)]. In the case of the phenylphosphonic acid, two main lines located at δ = 8 ppm and 12 ppm [experimental intensity ratio: 5.6:2; calculated ratio for $C_6H_5PO(OH)_2$: 5:2] are observed and can safely be assigned to phenyl and P−OH groups, respectively. In the case of compound **1**, three main groups of resonances located at δ = 1.5, 4.5, and ca. 8 ppm are observed. The first two lines are attributable to CH_3 and CH_2 groups of ethanol molecules, respectively. The line at δ ≈ 8 ppm is complex, and involves several resonances. These are related to phenyl groups, OH (ethanol and μ-OH), and H_2O. Deconvolution of groups of resonances at δ = 1.5, 4.5, and ca. 8 ppm by Gaussian lines gives the following experimental integration: 30 (CH_3):16 (CH_2):16 (OH, H_2O, phenyl); the integrals of signals include the contributions of the first spinning sidebands, which represent ca. 10% of the total signal. The calculated integral for compound **1** gives: 30 (CH_3):20 (CH_2):23 (OH, H_2O, phenyl). The experimental results therefore indicate good general trends. The noted discrepancies between calculated and experimental data may be attributed to the strong overlapping of lines in the δ = 7−12 ppm region.

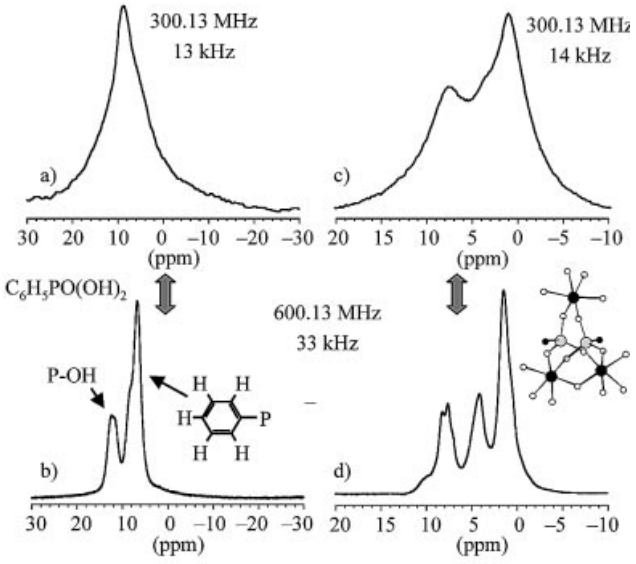

Figure 4. ^{1}H MAS NMR spectra (single pulse experiment) of phenylphosphonic acid: at $\nu_0(^1H)$ = 300.13 MHz and ν_{rot} = 13 kHz [a)]; at $\nu_0(^1H)$ = 600.13 MHz and ν_{rot} = 33 kHz [b)]; compound **1**: at $\nu_0(^1H)$ = 300.13 MHz and ν_{rot} = 14 kHz [c)]; at $\nu_0(^1H)$ = 600.13 MHz and ν_{rot} = 33 kHz [d)]

In order to highlight the new possibilities offered by ^{1}H very fast MAS NMR, we present experimental data (Figure 5) related to the cubane-shaped Al−O−P cluster $[Al_4(HPO_4)_4(C_2H_5OH)_{12}]Cl_4{\cdot}4C_2H_5OH$ (compound **2**).[12] For compound **2**, four types of protons may be distinguished, namely CH_3 and CH_2 groups from ethanol ligands and solvates, OH groups from ethanol, and OH groups from P−OH entities. Once again, at $\nu_0(^1H)$ = 600 MHz and 33 kHz, a spectacular gain in resolution is demonstrated. Assignments can be safely proposed (Figure 5). Experimental integration of lines at δ = 1.2 (CH_3), 3.9 (CH_2), 7.4 (OH), and 8.7 ppm (P-OH) gives 48:32.3:13.7:2. The calculated values for compound **2** are 48:32:16:4. An excellent agreement is noted between experimental and calculated data.

The examples presented above clearly show that solid-state ^{1}H NMR is now available as an analytical tool for the study of Al−O−P clusters, or more generally, for inorganic cores linked to organic groups. Very high MAS frequencies (up to 33 kHz) result (in these particular cases), in sufficient

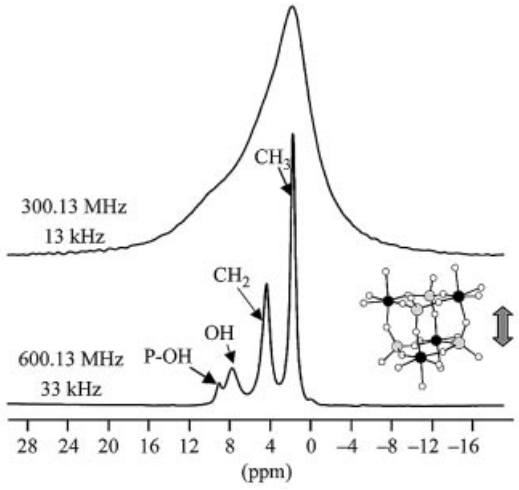

Figure 5. ^{1}H MAS NMR spectra (single pulse experiment) of compound **2** at [$\nu_0(^1H)$ = 300.13 MHz, ν_{rot} = 13 kHz] and [$\nu_0(^1H)$ = 600.13 MHz and ν_{rot} = 33 kHz]; each Al atom is coordinated to three ethanol ligands; four ethanol solvate molecules (per each cube) are present; each P atom is bonded to an OH group; see ref.[12]

averaging of the strong ^{1}H-^{1}H homonuclear interaction. Caution must be taken to ensure that no degradation due to high rotation frequency (heating[20] and gigantic pressure inside the rotor) occurs in samples. Spectra were first recorded at low rotation speeds, and the frequency of rotation was then increased. After high rotation speed experiments, checking of the integrity of the products was performed by recording spectra at low speed, and comparing them to the initial spectra.

Solid-state NMR therefore offers a two-level approach for the study of Al−O−P clusters. Firstly, the inorganic core can be studied by standard ^{31}P and ^{27}Al MAS NMR. The latest developments in ab initio calculation of chemical shifts and quadrupolar interaction[21] show that it is now possible to calculate these parameters safely for structures involving a reasonable number of atoms per cell. SBUs could act as good candidates for precise comparison between calculated and experimental data. Secondly, the organic part of the cluster, which acts as a link between inorganic cores, may now be investigated by high-resolution ^{1}H MAS NMR.

Finally, we believe that compound **1** could serve as a valuable precursor for the direct synthesis of complex aluminophosphonate frameworks. Our experience is that such a compound is slightly soluble in ethanol (see Exp. Sect.) and that the structure is preserved in solution (as checked by solution-state ^{31}P NMR). The compound may appear much more soluble in other solvents such as DMF, CH_3CN, etc., but the structure is usually not preserved in solution (several resonances with various intensities are observed in the corresponding ^{31}P spectra; see also refs.[11,12]). However, we note that treatment of **1** under solvothermal conditions (with ethanol) resulted in highly crystalline compounds with interesting solid-state NMR features. These compounds are under investigation in the laboratory.

Experimental Section

Synthesis of $[Al_3(\mu_2\text{-}OH)(\mu_3\text{-}C_6H_5PO_3)_2(C_2H_5OH)_{10}]Cl_4\cdot H_2O$ (1): Anhydrous $AlCl_3$ (4.33 g, 32.5 mmol) was slowly added to cooled ethanol (25 mL, 0 °C, exothermic reaction). $C_6H_5PO(OH)_2$ (5.14 g, 32.5 mmol) was then added to the solution. After 48 h at 5 °C, colorless crystals were obtained. Yield: 65%. Elemental analysis (Vernaison, France): $C_{32}H_{73}Al_3Cl_4P_2O_{18}$ (1030.6): calcd. C 37.29, H 7.14, Al 7.85, Cl 13.76, P 6.01; found C 35.87, H 6.63, Al 7.60, Cl 14.48, P 6.35. Chemical analyses were hardly reliable due to the extreme instability of compound **1** to air and moisture (several attempts were made).

Simultaneous Differential Thermal and Thermogravimetric Analyses: TA Instrument SDT 2960; air flow, 5 °C·min^{-1}, 25 °C up to 1250 °C; 25 to 1250 °C, TGA, 71.3 wt% loss (calcd. 71.4%); 25 to 160 °C: 50.3 wt% loss, endothermic event: ethanol loss; 500 to 650 °C: 11.3 wt% loss, complex exothermic event: phenyl decomposition/combustion; 1035 °C: weak exothermic event: poor crystallization into cristobalite and tridymite ($AlPO_4$) (powder XRD); 1180 to 1240 °C, 3.0 wt% loss, exothermic event: residual carbon combustion. End of DTA-TGA: gray powder containing traces of carbon, poorly crystallized (cristobalite and tridymite); no crystalline alumina detected.

Crystal Data for 1: $[Al_3(\mu_2\text{-}OH)(\mu_3\text{-}C_6H_5PO_3)_2(C_2H_5OH)_{10}]Cl_4\cdot H_2O$, (0.1 × 0.1 × 0.1 mm, rapidly brought out of the mother liquor, put in a capillary with oil), Enraf−Nonius MACH-3, monoclinic, $P2_1/a$, a = 20.083(5), b = 12.011(4), c = 24.36(1) Å, β = 114.00(3)°, V = 5368(3) Å^3, $\rho_{calcd.}$ = 1.28 ·cm^{-3}, Mo-K_α (λ = 0.71069 Å), ω/2θ, θ = 1−26°, T = 200 K, measured reflections: 11383, independent reflections: 10524, reflections included in the refinement: 6484 with $(F_o)^2 > 3\sigma(F_o)^2$, data corrected for Lorentz and polarization effects, no absorption correction, 534 parameters, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.0812$; $wR = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2]^{1/2} = 0.0985$, $w = w'\,[1 - (||F_o| - |F_c||/6\sigma(F_o)^2]^2$ with $w' = 1/\Sigma_r A_r T_r(X)$ with 3 coefficients 12.1, 5.48, and 8.53 for the Chebyshev series for which X is $F_C/F_{C(max)}$, Δρ(min.) = −0.81, Δρ(max.) = 1.85 e·Å^{-3}. Scattering factors corrections for anomalous absorption were taken from ref.[22] Structures were solved by direct methods (SHELXS)[23] and refined by full-matrix, least-squares with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were introduced in calculated positions as fixed contributors in the last refinement. CCDC-182720 (**1**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Solid-State NMR: All ZrO_2 rotors were filled under argon in a dried glove-box, as compounds **1** and **2** were very sensitive to air moisture. ^{31}P CP MAS: Ξ^{31}P: 121.44 MHz; δ = 0 ppm: H_3PO_4 (85%); diameter of rotor (φ): 4 mm; MAS: ν_{rot} = 3−5 kHz. ^{1}H 90° pulse duration: 4 μs; for each ν_{rot}, the Hartmann−Hahn (H-H) condition was matched with compound **2**; contact time: 3 ms; relaxation delay (RD): 15 s, number of scans (NS): 40. ^{31}P (in ethanol-OD): Ξ^{31}P: 161.92 MHz, δ = 2.3 ppm (relative to H_3PO_4). ^{13}C CP MAS: Ξ^{13}C: 75.43 MHz; spectra referenced to TMS via solid adamantane; φ: 4 mm; MAS: 4 kHz. ^{1}H 90° pulse duration: 5 μs; H-H condition was matched with adamantane; contact time: 3 ms; RD = 15 s; NS = 2000. ^{27}Al MAS: Ξ^{27}Al: 78.17 MHz; δ = 0 ppm: $Al(NO_3)_3$, HNO_3 (1 M); φ: 4 mm; flip angles ≤ π/12; MAS-{^{1}H} high power decoupling: 4.5−15 kHz; RD = 1 s; NS = 7200.

^{1}H MAS: Ξ^1H: 600.13 MHz; spectra referenced to TMS via solid adamantane; φ: 2.5 mm; very high speed Bruker probe; MAS: 33 kHz; RD = 15 s; NS = 8.

Simulation of Spectra: See the SIMPSON package, available on the web.[15] Simulations of second-order ^{27}Al spectra (Figure 3) include the following parameters: ^{27}Al frequency, MAS frequency, quadrupolar Hamiltonian up to second-order, central transition and all satellite transitions, isotropic chemical shift δ_{iso} (no CSA), quadrupolar parameters (C_Q, η_Q), powder averaging type.

Acknowledgments

Professor G. Bodenhausen is warmly thanked for access time on the 600 MHz spectrometer of the Ecole Normale Supérieure (Paris).

Keywords: Radical ions / S ligands / Magnetic properties / Crystal engineering / Non-covalent interactions

The structure of the iodo-substituted tetrathiafulvalene derivative EDT-TTF-I is described, with neutral molecules associated into inversion-centred dyads; no short intermolecular I···I contacts are observed. Electrocrystallisation of EDT-TTF-I (**1**) or EDT-TTF-I_2 (**2**) in the presence of $[nBu_4N][Ni(mnt)_2]$ afforded 2:1 salts, formulated as $[\mathbf{1}]_2[Ni(mnt)_2]$ and $[\mathbf{2}]_2[Ni(mnt)_2]$. In both salts the organic donor molecules **1** or **2** are associated into inversion-centred dyads, connected to the $[Ni(mnt)_2]$ species through a short, directional CN···I interaction. The dyads alternate with the nickel dithiolene complex into mixed ...DDADDADDA... stacks. Comparisons in both salts of intramolecular bond lengths, intra-dyad overlap modes, and magnetic susceptibilities, indicate a full charge-transfer in $[\mathbf{1}]_2[Ni(mnt)_2]$, formulated as $[\mathbf{1}]_2^{2+}[Ni(mnt)_2]^{2-}$, while a mixed-valence state is observed in $[\mathbf{2}]_2^{+\cdot}[Ni(mnt)_2]^{-\cdot}$.

Introduction

Intermolecular CN···I interactions[1,2] have been known for a long time in the solid state chemistry of organic molecules[3] and were recently investigated theoretically.[4] Mainly associated with the most polarisable halogens (Br, I), they are characterised by a N···Hal distance far shorter than the sum of the van der Waals radii [N···I = 3.0−3.15 Å; Σ_{vdW}(N···I) = 3.53 Å] together with a strong tendency to linearity.[5,6] Recent ab initio intermolecular perturbation theory calculations showed that the attractive nature of the N···I interaction is mainly due to electrostatic effects while its directionality can be explained by the anisotropic electron distribution around the halogen atom.[4] This directional interaction has been used deliberately in the synthesis of several organic salts derived from iodinated tetrathiafulvalenes such as TTF-I,[7] EDT-TTF-I,[8,9] EDO-TTF-I_2,[10] or DIETS[11] and cyano-containing anions such as $Ag(CN)_2^-$, $Pd(CN)_4^{2-}$ or $[Pd(mnt)_2]^{2-}$. It is also elegantly used in a TTF molecule containing both a pyrazino and two iodo moieties,[12] or by the inclusion in the anionic layer of neutral iodinated molecules.[13] Among those various cyanide-containing counterions, only one example has been described which involves an open-shell anion, namely the $[Ni(mnt)_2]^{-\cdot}$ nickel dithiolene complex, in a 2:1 salt with EDO-TTF-I_2.[14] In this salt, the metallic conductivity is due to the one-dimensional chains of EDO-TTF-I_2, while the localised spins of the $[Ni(mnt)_2]^-$ anions behave as a one dimensional ferromagnet, and interact with conduction electrons. In a search for similar systems where localised and itinerant spins coexist and eventually interact,[15] we investigated the salts derived from the mono- and diiodo-substituted tetrathiafulvalene derivatives EDT-TTF-I (**1**) and EDT-TTF-I_2 (**2**) with the open-shell anion $[Ni(mnt)_2]^{-\cdot}$ and describe here their structural and electronic properties, paying special attention to the CN···I and the magnetic organic/inorganic interactions.

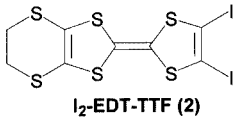
I-EDT-TTF (1)



I_2-EDT-TTF (2)

Results and Discussion

Solid-State Structures

Compounds **1** and **2** were prepared as described previously[16] and recrystallised from toluene. Molecule **1**, in the neutral state, crystallises in the triclinic system, space group $P\bar{1}$ with two crystallographically independent molecules in the unit cell (Figure 1). One of these exhibits strong distortions from planarity with folding angles along the S···S hinge of the two dithiole rings of 14.3(1) and 14.0(1)° for the dithiole rings bearing the dithioethylene and iodo substituents, respectively. The other crystallographically independent molecule is almost planar,[17] except for the dithioethylene bridge, which is also disordered over two positions with a 55:45 distribution. The intramolecular bond lengths and angles differ only slightly from those observed in the unsubstituted EDT-TTF.[18] The molecules are associated into inversion-centred dyads with plane-to-plane distances of 3.43(2) and 3.51(2) Å in the two independent dyads, respectively, while the shortest intermolecular I···I contacts are observed at 4.47 Å, thus excluding the presence of I···I interactions in the solid state.[16,19,20] (NB The structure of the neutral diiodo derivative **2** could not be fully determined due to the poor quality of the crystals.[21]) Electrocrystallisation of **1** and **2** in the presence of [nBu$_4$N][Ni(mnt)$_2$] afforded in both cases a 2:1 salt, formulated as [**1**]$_2$[Ni(mnt)$_2$] and [**2**]$_2$[Ni(mnt)$_2$]. They crystallise in the triclinic system, space group $P\bar{1}$, and exhibit almost identical gross structural features (Figure 2 and 3), with the organic donor molecules **1** or **2** associated into inversion-centred dyads connected to the [Ni(mnt)$_2$] moiety through a short, directional CN···I interaction with the following characteristics: N···I = 2.926(4) Å, C≡N···I = 177.9(2)° in [**1**]$_2$[Ni(mnt)$_2$]; N···I = 2.949(9) Å, C≡N···I = 171.6(9)° in [**2**]$_2$[Ni(mnt)$_2$]. It should be stressed that the CN···I distances observed here are much shorter than the distances observed in the neutral *p*-iodobenzonitrile, for example (3.0−3.15 Å). This striking shortening suggests an enhanced interaction due to the electrostatic nature of the CN···I interaction. Indeed, in those systems where the iodine atom is covalently linked to the *cationic* tetrathiafulvalene and the nitrile group is part of an *anionic* dithiolene complex, this polarised interaction is expected to be enhanced, as observed here and in the salts of the iodinated TTF's mentioned above. Such an activation of iodinated molecules has also been performed by the incorporation of neighbouring electron-withdrawing fluorinated groups, leading to enhanced N···I interactions.[22,23] To further demonstrate the electrostatic character of this interaction, the *reverse polarisation*, which involves a cyanide-bound tetrathiafulvalene cation and halogenated anions, has recently been addressed:[24] the interaction was completely suppressed in these cases.

In both salts, as shown in Figure 4, the oxidised donor molecules are associated into inversion-centred dyads which alternate with the nickel dithiolene complex into mixed ...DDADDADDA... stacks. This alternating structure is in sharp contrast with the EDO-TTF-I$_2$ salt described by Enoki et al.,[14] where segregated stacks were observed.

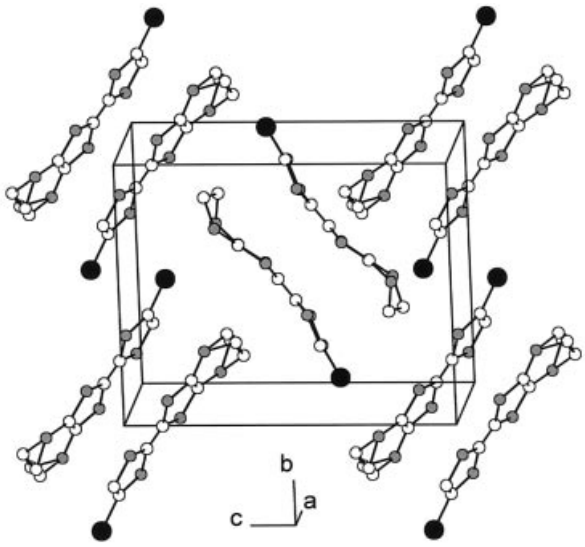


Figure 1. A view of the unit cell of neutral EDT-TTF-I (**1**); sulfur atoms are in dark grey, iodine atoms in black; note the folding of the dithiole rings of the molecule located at the centre of the unit cell

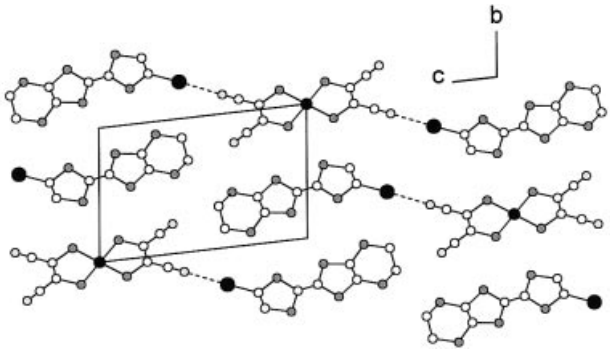

Figure 2. Projection view (along *a*) of a molecular plane in [**1**]$_2$[Ni(mnt)$_2$] showing the CN···I interaction (dotted line)

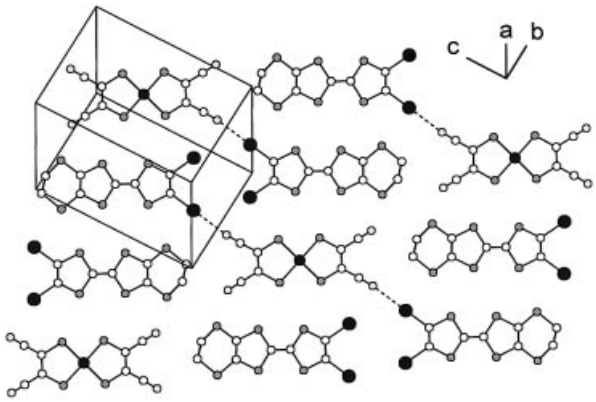

Figure 3. View of a molecular plane in [**2**]$_2$[Ni(mnt)$_2$] showing the CN···I interaction (dotted line)

The magnetic susceptibilities of both salts, as determined from SQUID measurements, are very different (Figure 5).

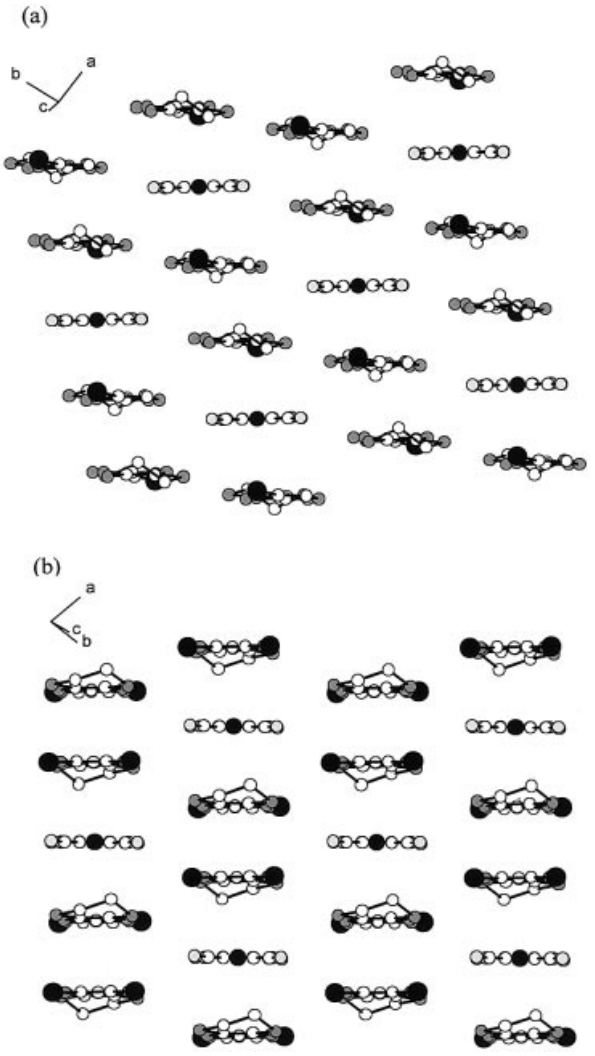

Figure 4. Views along the long molecular axis of the mixed ...DDADDADDA... chains arranged into slabs in $[\mathbf{1}]_2[Ni(mnt)_2]$ (a) and $[\mathbf{2}]_2[Ni(mnt)_2]$ (b)

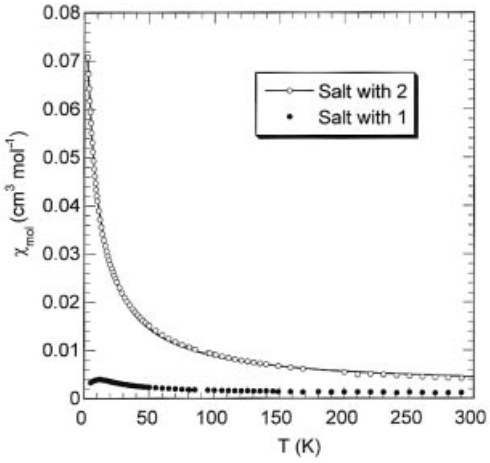

Figure 5. Temperature dependence of the magnetic susceptibility in $[\mathbf{1}]_2[Ni(mnt)_2]$ and $[\mathbf{2}]_2[Ni(mnt)_2]$; the solid line for $[\mathbf{2}]_2[Ni(mnt)_2]$ is the fit to the Curie−Weiss model, $\chi_{mol} = \chi_0 + C/(T - \theta)$, with $\chi_0 = 0.002$ cm^3·mol^{-1}, C = 0.71 cm^3·K·mol^{-1} and $\theta = -8$ K

Indeed, $[\mathbf{2}]_2[Ni(mnt)_2]$ follows a Curie−Weiss-type law, $\chi = C/(T\text{-}\theta)$, with $C = 0.71$ and $\theta = -8$ K — the signature of two localised, weakly interacting spin carriers — while $[\mathbf{1}]_2[Ni(mnt)_2]$ exhibits a weak paramagnetism (see below). Single crystal conductivity measurements performed on $[\mathbf{2}]_2[Ni(mnt)_2]$ show a semi-conducting behaviour with a low room-temperature conductivity ($\sigma_{RT} = 6 \times 10^{-3}$ S cm^{-1}) and an activation energy of 1700 K (0.14 eV).[25] These contrasting behaviours raise several questions concerning the actual oxidation state of both the donor molecules and the nickel dithiolene complex in the two salts. A precise examination of the two structures and their differences is expected to reveal the actual nature of these salts. Are we in presence of mixed-valence organic dyads, $[\mathbf{1}]_2^{+\cdot}$ or $[\mathbf{2}]_2^{+\cdot}$, together with a paramagnetic $[Ni(mnt)_2]^{-\cdot}$ radical anion, or in the presence of fully oxidised donor molecules, $[\mathbf{1}]_2^{2+}$ or $[\mathbf{2}]_2^{2+}$ with the reduced diamagnetic $[Ni(mnt)_2]^{2-}$ complex?

A comparison of the redox potentials favours the mixed-valence solution. Indeed, as shown in Scheme 1, both donor molecules oxidise at potentials far above the $Ni(mnt)_2^{2-/1-}$ couple, and **1** oxidises at a slightly lower potential than **2**, illustrating the electron-withdrawing effect of the iodine atom. The evolution of the bond lengths within the donor molecules and the dithiolene complexes is also a very efficient tool for evaluating the degree of charge transfer. As observed in Table 1, the lengthening of the central C=C bond and shortening of the C−S bonds within the TTF cores upon oxidation is observed to a larger extent in $[\mathbf{1}]_2[Ni(mnt)_2]$ than in $[\mathbf{2}]_2[Ni(mnt)_2]$. Similarly, the bond lengths' evolution within the $Ni(mnt)_2$ complex in both salts (Table 2) more clearly reveals that the monoanionic[26] $Ni(mnt)_2^{-\cdot}$ is present in $[\mathbf{2}]_2[Ni(mnt)_2]$, while most probably the dianionic $Ni(mnt)_2^{2-}$ moiety[27] is found in $[\mathbf{1}]_2[Ni(mnt)_2]$. This assignment is further confirmed by the ν_{CN} stretching frequency (Table 2). We are therefore faced here with two totally different electronic distributions: mixed-valence organic $[\mathbf{2}]_2^{+\cdot}$ dyads alternating with an anionic $[Ni(mnt)_2]^{-\cdot}$ moiety in $[\mathbf{2}]_2[Ni(mnt)_2]$, and dicationic $[\mathbf{1}]_2^{2+}$ dyads alternating with a dianionic $[Ni(mnt)_2]^{2-}$ moiety in $[\mathbf{1}]_2[Ni(mnt)_2]$.

Besides the intramolecular bond length variations, this electronic distribution is also reflected in the overlap geometry within the organic dyads. Indeed, as shown in Figure 6, the overlap interaction between two donor molecules within a dyad in $[\mathbf{1}]_2[Ni(mnt)_2]$ is of the eclipsed type, with a short plane-to-plane distance at 3.396(1) Å, characteristic of a fully oxidized $[\mathbf{1}]_2^{2+}$ dyad. The eclipsed configuration indeed favours the best overlap between SOMOs and, as a consequence, the pairing of the two spin carriers in their bonding combination. The corresponding calculated $\beta_{HOMO\cdots HOMO}$ overlap interaction amounts to 1.03 eV, a large value which also confirms the dicationic character of the dyad. On the other hand, a so-called bond-over-ring overlap is observed in the dyads in $[\mathbf{2}]_2[Ni(mnt)_2]$ together with a larger plane-to-plane distance [3.418(1) Å] and a much reduced $\beta_{HOMO\cdots HOMO}$ overlap interaction

(0.435 eV) — another confirmation of its mixed-valence character. Note also that the calculated β values for the interactions between the mixed-valence dyads are much smaller albeit not negligible (≈ 40 meV).

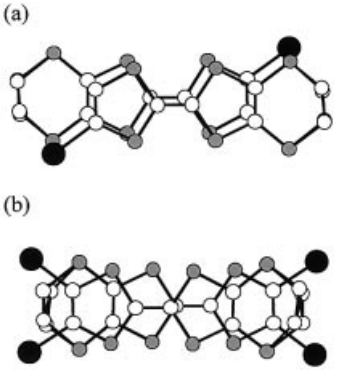

Figure 6. The overlap within each donor dyad in [**1**]$_2$[Ni(mnt)$_2$] (a) and [**2**]$_2$[Ni(mnt)$_2$] (b)

All these results confirm the above-mentioned formulations, i.e. a full charge-transfer in [**1**]$_2^{2+}$[Ni(mnt)$_2$]$^{2-}$ and a mixed-valence state in [**2**]$_2^{+\cdot}$[Ni(mnt)$_2$]$^{-\cdot}$. A fully oxidised dyad has already been observed in [TTF-I]$_2$[Pd(mnt)$_2$], a similar system described by Bryce et al. with a closely related structure and CN··I interaction.[7] In this salt, TTF-I is more easily oxidised than **1** while [Pd(mnt)$_2$]$^{2-}$ oxidises at higher potentials than Ni(mnt)$_2^{2-}$. It is therefore understandable that this salt was formulated as [TTF-I]$_2^{2+}$[Pd(mnt)$_2$]$^{2-}$. The same formulation in [**1**]$_2^{2+}$[Ni(mnt)$_2$]$^{2-}$ appears more surprising given the potential difference between the two redox centres (−0.40 V, Scheme 1). Furthermore, from the [TTF-I]$_2^{2+}$[Pd(mnt)$_2$]$^{2-}$ and [**1**]$_2^{2+}$[Ni(mnt)$_2$]$^{2-}$ formulations, one would expect a fully diamagnetic behaviour, in contrast to the temperature dependence of the magnetic susceptibility in both salts. [TTF-I]$_2^{2+}$[Pd(mnt)$_2$]$^{2-}$ was indeed reported to behave as a one-dimensional Heisenberg chain with an isotropic nearest-neighbour exchange interaction of $J \approx -50$ K. The temperature dependence of the magnetic susceptibility in [**1**]$_2$[Ni(mnt)$_2$] (Figure 5) shows a similar shape even though the fits we performed with the Bonner−Fisher model[28] are consistent with a J value of −18 K but with a contribution of only 0.25 mol of $S = 1/2$, a behaviour which we cannot explain at present, although one possibility would be the contribution of a sizeable TIP arising from the inorganic moiety. However, a control susceptibility measurement performed on [Et$_4$N]$_2$[Ni(mnt)$_2$] confirmed the diamagnetic character of the dianionic [Ni(mnt)$_2$]$^{2-}$ component with a χ_{mol} value of -340×10^{-6} cm^3·mol^{-1}, attributable to the diamagnetic contribution of the different atoms, as evaluated from the Pascal constants (-290×10^{-6} cm^3·mol^{-1}). This observation of a paramagnetic contribution in Bryce's [TTF-I]$_2$[Pd(mnt)$_2$] complex as well as in [**1**]$_2$[Ni(mnt)$_2$] could also originate from a minority polymorph. However, an X-ray powder diagram of the polycrystalline sample used for the magnetic susceptibility measurements confirmed the identity of [**1**]$_2$[Ni(mnt)$_2$] as determined from the single-crystal diffraction experiment.

The observation of a mixed-valence salt in [**2**]$_2$[Ni(mnt)$_2$] is confirmed by the SQUID magnetic susceptibility, which shows that both paramagnetic entities, the [**2**]$_2^{+\cdot}$ dyad and the [Ni(mnt)$_2$]$^{-\cdot}$ complex, contribute to the susceptibility, hence the Curie−Weiss law for two almost-independent spin carriers. The weak, negative θ value (−8 K) found in the temperature dependence of the magnetic susceptibility of [**2**]$_2$[Ni(mnt)$_2$] cannot find its origin in a ZFS of the nickel complex since the [Ni(mnt)$_2$]$^{-\cdot}$ moieties have a spin of 1/2; it must therefore stem from weak intermolecular in-

teractions between the $[\mathbf{2}]_2^{+\cdot}$ moieties since the $[Ni(mnt)_2]^{-\cdot}$ moieties are fully isolated from each other in the structure. Indeed, as mentioned above, the calculated $\beta_{HOMO\cdots HOMO}$ overlap interaction between donor molecules pertaining to neighbouring dyads amounts to approximately 40 meV and can explain the Curie−Weiss behaviour observed here. Preliminary EPR measurements at room temperature performed on a polycrystalline sample of $[\mathbf{2}]_2[Ni(mnt)_2]$ show a single asymmetric line centred at $g = 2.032$ with a ΔH value of 240 G (Figure 7). Taking into account the presence of two types of spin carriers in the salt, the line can be tentatively decomposed as the sum of two lines of equal intensity, centred at the g values of 2.012 and 2.062. These values compare favourably with those reported in the literature for similar TTF dyads ($g = 2.005-2.008$)[29] and for $[Ni(mnt)_2]^{-\cdot}$ ($g = 2.0633$).[30]

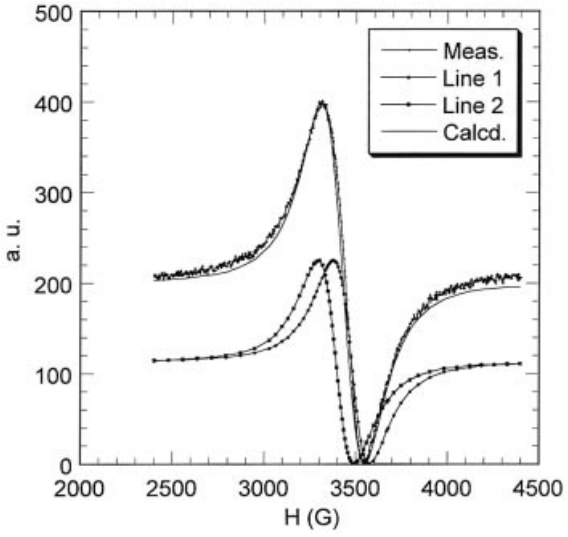

Figure 7. EPR signal obtained for $[\mathbf{2}]_2[Ni(mnt)_2]$; the solid line is the sum of the line 1 and line 2 components

Experimental Section

Synthesis: The donor molecules **1** and **2** were prepared as previously described. Electrocrystallization experiments were performed in two-compartment cells in 1,1,2-trichloroethane (10 mL) with $[n Bu_4N][Ni(mnt)_2]$ (20 mg) as electrolyte and **1** or **2** (4 mg). Crystals were obtained on the anode after galvanostatic electrolysis (0.25 μA, 16 days for **1** and 0.5 μA, 12 days for **2**).

Crystallography: Details of the data collection and structure refinement are given in Table 3. For neutral **1** and $[\mathbf{1}]_2[Ni(mnt)_2]$ data were collected on a Stoe-IPDS or an Enraf−Nonius Mach3 diffractometer at 293 K with graphite-monochromatized Mo-K_α radiation ($\lambda = 0.71073$ Å). The Stoe software was used for data collection and reduction, and numerical absorption correction using crystal faces. For $[\mathbf{2}]_2[Ni(mnt)_2]$ data were collected on an Enraf−Nonius Mach 3 diffractometer, reduction of the data was performed with XCAD4 (Harms, 1986) and absorption correction from a ψ-scan (SHELXPREP). The structures were solved by direct methods (SHELXS-86) and refined using SHELXL. All atoms were refined anisotropically except hydrogen atoms and some carbon atoms of the disordered ethylene bridge (C15B in neutral **1**, C7, C7′, C8, C8′ in $[\mathbf{1}]_2[Ni(mnt)_2]$ and $[\mathbf{2}]_2[Ni(mnt)_2]$). Hydrogen atoms were introduced at calculated positions (riding model) and not refined. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-178087, -178088 and -178089 for **1**, $[\mathbf{1}]_2[Ni(mnt)_2]$ and $[\mathbf{2}]_2[Ni(mnt)_2]$ respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Magnetic Measurements: Magnetic susceptibility measurements were performed on a Quantum Design MPMS5 SQUID magnetometer operating in the range 5−300 K with polycrystalline samples. Data were corrected for Pascal diamagnetism and sample holder contribution. Room temperature EPR measurements were obtained from a Bruker ER200D spectrometer operating in X-band (9.782 GHz) with a modulation of 1.25 G.

Novel Complexes *trans*(Cl)-[Os(bpy)(CO)(CH_3CN)Cl_2]^n (n = 0, +1; bpy = 2,2′-Bipyridine): Photo- and Electrochemical Syntheses and Comparative Study of Their Bonding and Redox Properties

Sylvie Chardon-Noblat,*[a] Philippe Da Costa,[a] Alain Deronzier,*[a] Taasje Mahabiersing,[b] and František Hartl*[b]

Keywords: Osmium / N ligands / Charge-transfer photochemistry / Electrochemical oxidation / Decarbonylation

Photoirradiation of the complex *trans*(Cl)-[Os(bpy)($CO)_2Cl_2$] in acetonitrile with $\lambda \geq 320$ nm light gives rise to substitution of a CO ligand, with the formation of *trans*(Cl)-[Os(bpy)-(CO)(CH_3CN)Cl_2]. The bonding properties and redox reactions of the novel photoproduct were thoroughly investigated by several methods such as nanosecond time-resolved UV/Vis absorption and resonance Raman spectroscopy, cyclic voltammetry, and IR and UV/Vis spectroelectrochemistry. Its one-electron electrochemical oxidation in acetonitrile produces the stable cation *trans*(Cl)-[Os(bpy)(CO)(CH_3CN)Cl_2]$^+$. This complex is also formed as the major product during one-electron oxidation of the dicarbonyl precursor *trans*(Cl)-[Os(bpy)($CO)_2Cl_2$] in acetonitrile at room temperature. By contrast, the initial dicarbonyl oxidation product *trans*(Cl)-[Os(bpy)($CO)_2Cl_2$]$^+$ remains stable in dry noncoordinating dichloromethane and in butyronitrile at low temperatures. The CO-loss reactivity of *trans*(Cl)-[Os(bpy)($CO)_2Cl_2$], induced by the partial oxidation of the formally osmium(II) centre, is dramatically lower compared to the corresponding ruthenium(II) complex due to the stronger Os–CO bonds. Replacement of one CO or Cl ligand in *trans*(Cl)-[Os(bpy)-($CO)_2Cl_2$] by a stronger σ-donor CH_3CN or isopropoxycarbonyl [–C(O)O*i*Pr] ligands strengthens the Os–CO bond(s) and results in photostable derivatives.

Introduction

In the past two decades considerable attention has been paid to the synthesis,[1−3] electrochemistry,[4−6] photochemistry[7−10] and (photo-, electro-)catalytic properties[11−17] of the complex *trans*(Cl)-[Ru(bpy)($CO)_2Cl_2$] (bpy = 2,2′-bipyridine) and its derivatives. The active species in the electrocatalytic reduction of CO_2 with this complex is the insoluble polymer [Ru(bpy)($CO)_2$]$_n$ resulting from a two-electron reduction pathway. Its physicochemical properties and reactivity can be finely tuned by attachment of different substituents at the bpy rings.[5] We have been particularly interested whether a major difference in this regard can be achieved by replacement of the ruthenium centre by the heavier osmium. In general, osmium complexes are less reactive and therefore better suited for mechanistic studies. The properties of the corresponding precursor osmium complex *trans*(Cl)-[Os(bpy)($CO)_2Cl_2$] (**1**) have been relatively unexplored. Apart from its synthesis and brief spectroscopic characterisation,[18] only a preliminary electrochemical study has recently been reported.[19] In addition, an analogous complex **1a** with 4,4′-dimethyl-2,2′-bipyridine (dmb) was prepared as a precursor of the luminescent complex *trans*($SnPh_3$)-[Os(dmb)($CO)_2$($SnPh_3$)$_2$].[20−22] As a part of our continued studies of bonding properties and reactivity of complex **1** and its derivatives, we describe in the present work its charge-transfer photochemical reactivity [Equation (1)] and electrochemical oxidation [Equation (2)], both promoting CO substitution reaction by the donor solvent acetonitrile. The studied osmium complexes will also be compared with the corresponding ruthenium compounds.

$$[Os(bpy)(CO)_2Cl_2] \xrightarrow[CH_3CN]{h\nu} [Os(bpy)(CO)(CH_3CN)Cl_2] + CO \quad (1)$$

$$[Os(bpy)(CO)_2Cl_2] \xrightarrow[CH_3CN]{-e^-} [Os(bpy)(CO)(CH_3CN)Cl_2]^+ + CO \quad (2)$$

Results and Discussion

Photochemical Formation and Characterization of [Os(bpy)(CO)(CH_3CN)Cl_2] (2)

Irradiation of *trans*(Cl)-[Os(bpy)(CO)$_2$Cl$_2$] (**1**) in CH_3CN with a 250-W Xe lamp into its predominantly Os-to-bpy charge transfer band at 364 nm produces within a few hours exclusively the photostable monocarbonyl complex *trans*(Cl)-[Os(bpy)(CO)(CH_3CN)Cl_2] (**2**) (Figure 1). The composition of the photoproduct has been verified by mass spectrometry and elemental analysis. Its *trans*(Cl) geometry can be deduced from the corresponding ^{1}H NMR spectrum, in particular from the coinciding signals of the 2,2′-bipyridine hydrogen atoms 6-H and 6′-H at δ = 9.05 ppm (see Scheme 1 and Exp. Sect.).[23] The identity of complex **2** has further been confirmed by IR spectroscopy. During the irradiation, the two ν(CO) bands of the parent complex **1** (2038 and 1968 cm^{-1}; CH_3CN) are replaced by a single band at 1933 cm^{-1}. Such a large wavenumber drop is quite normal for CO substitution in a dicarbonyl complex, resulting in considerably increased π-back-bonding to the remaining CO ligand. For comparison, a similar situation applies for *cis*(Cl)-[Ru(bpy)(CO)$_2$Cl$_2$] [ν(CO) at 2067 and 2001 cm^{-1}; CH_3CN] and *cis*(Cl)-[Ru(bpy)(CO)(CH_3CN)Cl_2] [ν(CO) at 1969 cm^{-1}; CH_3CN].[9] The typically smaller ν(CO) wavenumbers for the osmium(II) compounds compared to their ruthenium(II) derivatives [$\Delta\nu$(CO) $\approx$ 30 cm^{-1} for corresponding bands] reflect the stronger bond between CO and the 5d metal atom.

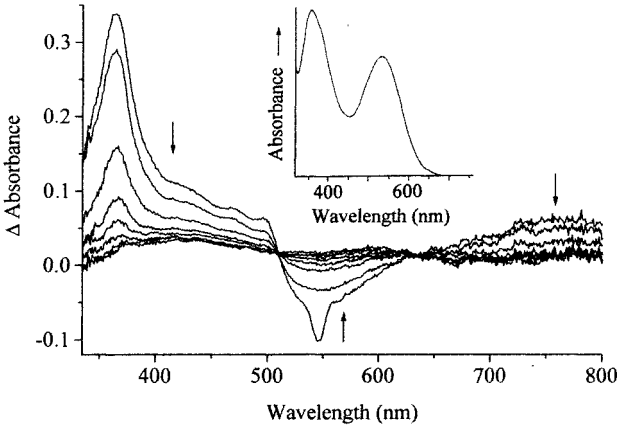

Figure 1. Nanosecond TA spectra of complex **2** in acetonitrile (λ_{exc} = 545 nm, time increment 5 ns, 50 accumulations); the MLCT/XLCT (X = Cl; L = 2,2-bipyridine) excited-state lifetime τ = 12.6 ns at 293 K; inset: UV/Vis spectrum of complex **2** in acetonitrile

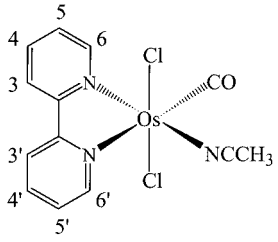

Scheme 1. Schematic molecular structure of complex **2** with numbering of 2,2′-bipyridine proton nuclei for assignment of ^{1}H NMR signals

In the course of the photoreaction the initially yellow solution of **1** (λ_{max} = 364 nm in acetonitrile) turns progressively purple due to the appearance of a new visible absorption band of complex **2** at λ_{max} = 535 nm; in addition, a new band also grows at 362 nm (Figure 1, in set). This spectral change is consistent with a significantly higher energy of the largely d_π(Os)-centred highest occupied molecular orbital (HOMO) of complex **2** compared to that of precursor **1**. The higher energy of the HOMO is evidenced by the much less positive $E_{1/2}(Os^{II}/Os^{III})$ oxidation potential for **2** (see below), reflecting sensitively the substitution of the π-acceptor carbonyl ligand by the stronger σ-donor acetonitrile ligand. On the other hand, the lowest unoccupied π^* (bpy) orbital (LUMO) rises by much less energy upon the photosubstitution than the HOMO, as can be concluded from the close $E_{1/2}$(bpy/bpy$^{\cdot-}$) reduction potentials for **1** and **2** (see below).

In order to assign the lowest-energy electronic transition of complex **2**, nanosecond time-resolved absorption (TA) spectra (Figure 1) and resonance Raman spectra (Figure 2) were recorded upon irradiation into the visible absorption band at 535 nm. The difference UV/Vis absorption spectra in Figure 1 show a bleaching between 500 and 630 nm due to the disappearance of complex **2** (inset to Figure 1) that completely regenerates in 35 ns after the laser pulse. The transient absorption between 630 and 800 nm can be ascribed to the lowest π^*-π^* transitions of the aromatic [bpy]$^{\cdot-}$ ligand;[24] another set of π^*-π^* transitions is observed as a band with two characteristic absorption maxima at 467 and 497 nm. The strong transient band at 363 nm probably belongs to the π-π^* transition of [bpy]$^{\cdot-}$. The shoulder at 418 nm may reflect the presence of the formally Os^{III} centre in the excited transient, as a similar absorption band appears in the UV/Vis spectrum of the electrochemically one-electron-oxidised Os^{III} species **2**$^+$ (see below and Figure 3). The TA data thus indicate that the lowest optically accessible excited state has an osmium(II)-to-bpy charge-transfer (MLCT) character. On the other hand, resonance Raman spectra of nonluminescent **2**, dispersed in KNO_3 and irradiated with 514.5 nm (Figure 2) and 543 nm light, show only a weak rR effect of ν_s(CO) at 1917 cm^{-1}. [For comparison, the ν(CO) band of complex **2**, dispersed in KBr, occurs at 1927 cm^{-1}, i.e. lower by 6 cm^{-1} than found in acetonitrile, see above]. This implies that the Os-to-CO π-back-bonding is not strongly affected by this electronic transition. Characteristic resonance-enhanced Raman bands of the bpy ligand are found at 1606, 1557 [both ν(C=C)], 1493, 1325 [both ν(C=N)], 1278 [ν(C−C) inter-ring], 1177 [δ(CCH) in-plane], 1031 (ring breathing) and 669 [δ(CCC) inter-ring] cm^{-1}. Importantly, an apparent Raman band due to ν_s(Os−Cl) is observed at 302 cm^{-1}, consistent with a relatively strong rR effect on the Os−Cl bonds. However, the overall rR effect is rather weak and,

hence, the normal coordinates of complex **2** are less affected by the electron transfer to π*(bpy) than would be expected for an MLCT transition. Instead, the rR spectra of complex **2** agree with a mixed MLCT/XLCT (X = Cl) character of the lowest optically accessible excited state. Its lifetime τ = 12.6 ns at 293 K has been determined from the TA data (see above).

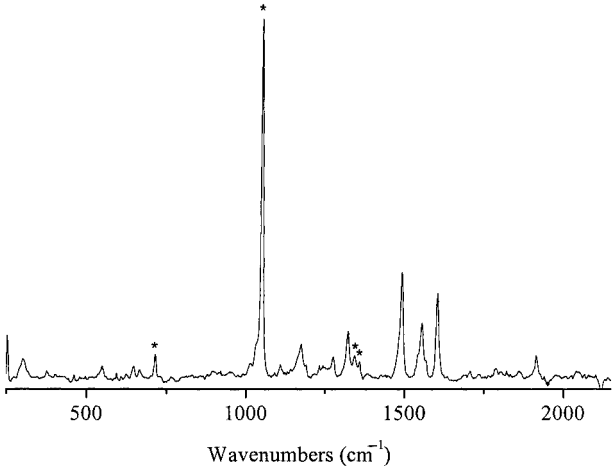

Figure 2. Resonance Raman spectrum of complex **2** dispersed in a KNO_3 pellet; λ_{exc} = 514.5 nm; bands due to KNO_3 indicated by an asterisk

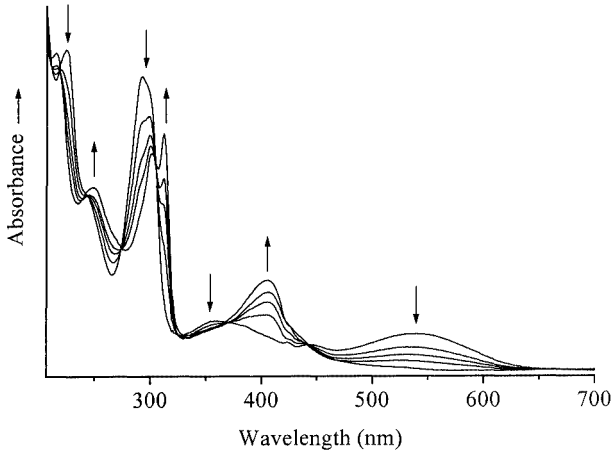

Figure 3. UV/Vis spectral changes recorded during the one-electron oxidation of complex **2** (10^{-3} M) in acetonitrile; electrolysis within an OTTLE cell[38] at 293 K

Unfortunately, the CO-loss photoreactivity and luminescence of complex **1** prevented the recording of both TA and resonance Raman spectra for this complex and comparison with complex **2**.

A similar difference in the CO-loss reactivity was also observed between the corresponding cations $\mathbf{1}^+$ and $\mathbf{2}^+$ produced by electrochemical oxidation (see below). This observation is consistent with removal of electron density from the highest occupied molecular orbital, similarly to the situation in the mixed lowest-energy charge-transfer excited state of the Os^{II} complexes **2**. The cyclic voltammogram (CV) of the photoproduct **2** dissolved in $CH_3CN/10^{-1}$ M TBAP indeed shows a completely reversible Os^{II}/Os^{III} redox couple at $E_{1/2}$ = 0.45 V vs. Ag/Ag^+ that is positioned less positively by 0.80 V than the one-electron oxidation of parent complex **1**.[19] This observation agrees with the strong σ-donor ability of the CH_3CN ligand compared to the expulsed π-acceptor carbonyl ligand, thereby stabilizing the formal osmium(III) oxidation state in $\mathbf{2}^+$. Exhaustive oxidation of complex **2** at 0.55 V upon bulk electrolysis or within a thin-layer spectroelectrochemical cell produced the corresponding inherently stable cation $\mathbf{2}^+$ quantitatively. The UV/Vis spectrum of the oxidised product exhibits a low-energy absorption band at 406 nm (ε_{max} = 5500 M^{-1} cm^{-1}) tailing down to 550 nm. The UV/Vis spectral changes accompanying the formation of $\mathbf{2}^+$ within an OTTLE cell are shown in Figure 3. In the infrared region the single ν(CO) band of $\mathbf{2}^+$ (2047 cm^{-1}) is shifted to larger wavenumbers by 114 cm^{-1} compared to parent complex **2** (1933 cm^{-1}). The large ν(CO) difference testifies to the predominantly Os-localised oxidation, resulting in strongly diminished Os-to-CO π-back-bonding.[25]

Unlike the completely irreversible reduction of the dicarbonyl precursor **1** in CH_3CN electrolyte at room temperature and moderate cyclic voltammetric scan rates,[19] complex **2** is reduced under the same experimental conditions in a nearly chemically reversible one-electron step at $E_{1/2}$ = −1.80 V (I_{pa}/I_{pc} = 0.93 at v = 100 mV s^{-1}). As mentioned above, the π*(bpy) LUMO energy for complex **2** is slightly higher than complex **1**, which is reversibly reduced at a less negative potential: $E_{1/2}$ −1.64 V (THF, 293 K)[19] and −1.62 V (PrCN, 273 K). Exhaustive electrolysis of **2** in acetonitrile at −1.90 V leads to the formation of a dark film, weakly adherent to the working electrode surface, together with a green solution containing 1 mol-equiv. of free chloride ions, as revealed by voltammetry on a rotating disk electrode.[29] In situ IR spectroelectrochemical study of this cathodic process in acetonitrile/10^{-1} M TBAP at room temperature showed disappearance of the ν(CO) band of **2** at 1933 cm^{-1} and formation of a new reduced complex **2R**, absorbing at 1890 cm^{-1}. The parallel thin-layer cyclic voltammetric scan shows that **2R** is not the one-electron-reduced radical anion $\mathbf{2}^{\cdot-}$ [stable in PrCN at 253 K, ν(CO) at 1895 cm^{-1}], as its reverse oxidation occur 0.45 V less negatively than the initial reduction of precursor **2**. Further reduction of **2R** is chemically reversible ($E_{1/2}$ = −1.96 V), causing a shift of the ν(CO) band to 1857 cm^{-1}. This behaviour of complex **2** upon reduction closely resembles that of complex **1**,[19] pointing to the formation of an Os−Os-bonded species. Detailed experimental studies of the reduction paths of complexes **1** and **2** are in progress and will be published in a separate paper.

Electrochemical Formation of [Os(bpy)(CO)(CH_3CN)Cl_2] (2)

Electrochemical oxidation of complex **1** to the formally osmium(III) species $\mathbf{1}^+$ ($E_{1/2}$ = 1.23 V vs. Ag/Ag^+ in acetonitrile[19]) is completely reversible on the time scale of cyclic voltammetry at room temperature, independently of the solvent used {acetonitrile [see Figure 4 (a)], butyronitrile, dichloromethane}. The less positive oxidation potential

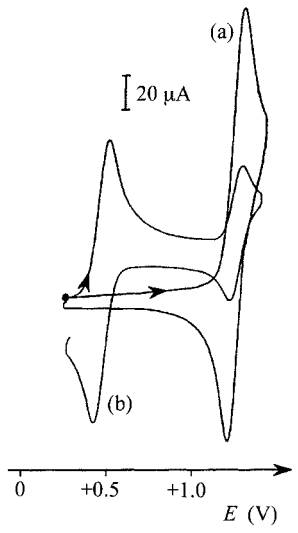

Figure 4. Cyclic voltammograms recorded (a) before and (b) after exhaustive one-electron oxidation of complex **1** (2.71×10^{-3} M) at 1.35 V and subsequent back reduction of the oxidised species $\mathbf{1}^+$ and $\mathbf{2}^+$ at 0.25 V at a Pt sheet electrode; conditions: acetonitrile containing 10^{-1} M TBAP and 1 μL of H_2O per 10 mL of CH_3CN, Pt disk electrode (5 mm diameter), scan rate 100 mV s^{-1}, T = 293 K

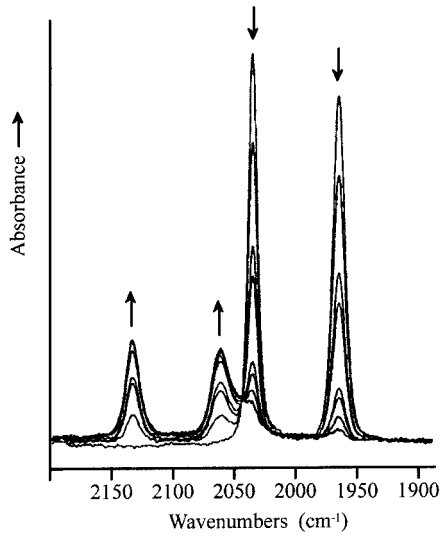

Figure 5. Spectral changes in the IR ν(CO) region recorded during the reversible oxidation of complex **1** (ca. 5×10^{-3} M) to $\mathbf{1}^+$ in butyronitrile; electrolysis within an OTTLE cell[39] at 273 K

of complex **1** compared to *trans*(Cl)-[Ru(bpy)($CO)_2Cl_2$] ($E_{1/2}$ = 1.45 V vs. Ag/Ag^+)[4,5] is generally encountered also for other types of Ru^{II} and Os^{II} complexes, such as classical $[M(bpy)_3]^{2+}$ (M = Ru, Os) and their numerous derivatives.[30] Bulk electrolysis of **1** at +1.35 V, carried out in acetonitrile containing a small amount of water (0.01%),[4] produced a mixture of $\mathbf{1}^+$ and $\mathbf{2}^+$ in 30% and 70% yield, respectively. Their quantitative back reduction at 0.25 V gave the corresponding neutral complexes **1** and **2** that were analysed by cyclic voltammetry [Figure 4 (b)]. Notably, both cations $\mathbf{1}^+$ and $\mathbf{2}^+$ are unstable during the bulk electrolysis in dry acetonitrile.

On the other hand, cation $\mathbf{1}^+$ could be completely stabilised in dry noncoordinating dichloromethane (at 293 K) or in dry butyronitrile electrolyte (at 273 K). The corresponding IR spectroelectrochemical studies showed the complete conversion of **1** [ν(CO) at 2037, 1967 cm^{-1} in dichloromethane (293 K); 2036, 1966 cm^{-1} in butyronitrile (273 K)], into $\mathbf{1}^+$ [ν(CO) at 2129 and 2056 cm^{-1} in dichloromethane (293 K); 2144 and 2063 cm^{-1} in butyronitrile (273 K)]. Notably, the ν(CO) bands of the cationic product $\mathbf{1}^+$ possess much lower intensity than those of the parent complex (see Figure 5). The large CO-stretching wavenumbers for $\mathbf{1}^+$ again imply one-electron oxidation predominantly localised on the osmium centre.[25] The UV/Vis spectrum of $\mathbf{1}^+$ in dichloromethane is very similar to that of the electrochemically oxidised photoproduct $\mathbf{2}^+$ in acetonitrile (see Figure 3), the maximum of the new lowest-lying absorption band of $\mathbf{1}^+$ being merely shifted to 385 nm. Apparently, the corresponding electronic transition in the formally osmium(III) complexes $\mathbf{1}^+$ and $\mathbf{2}^+$ with *trans*(Cl) geometry is not much affected by the substitution of the CO ligand by acetonitrile. Its assignment, however, has not been attempted, as support from theoretical MO studies is needed for a precise description of the molecular orbitals involved.

In contrast, when the butyronitrile electrolyte is replaced with acetonitrile, the oxidation of complex **1** within the IR OTTLE cell at 273 K produces besides $\mathbf{1}^+$ [ν(CO) at 2135, 2063 cm^{-1}] also CO-substituted $\mathbf{2}^+$ [ν(CO) at 2048 cm^{-1}] as the minor secondary product ($\mathbf{1}^+/\mathbf{2}^+ \approx 3:1$). At room temperature $\mathbf{2}^+$ becomes the major product ($\mathbf{1}^+/\mathbf{2}^+ \approx 1:4$). When the one-electron oxidation of complex **1** is nearly completed, two additional secondary products begin to form both at 293 and 273 K. At the same time the concentrations of $\mathbf{1}^+$ and $\mathbf{2}^+$ decrease. These cations are apparently in equilibrium. One of the ultimate products can be assigned as $[Os^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$ [ν(CO) at 2066 and 2003 cm^{-1}], based on the comparison with $[Ru^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$ [ν(CO) at 2091 and 2035 cm^{-1}][31] and taking into account the likely ν(CO) wavenumber difference of ca. 30 cm^{-1} (see above). The other tertiary product [ν(CO) at 2058 and 1991 cm^{-1}] has remained unassigned. Possibly, two different structural isomers of $[Os^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$ are formed in similar amounts. As a plausible explanation of the observed anodic behavior, CO liberated during the formation of $\mathbf{2}^+$ cannot escape from the thin electrolyte layer within the spectroelectrochemical cell and remains dissolved in the vicinity of the working electrode. At the end of the electrolysis the CO concentration increased sufficiently to trigger the reaction with cations $\mathbf{1}^+$ or $\mathbf{2}^+$ and the replacement of one chloride ligand with the formation of $[Os^{III}(bpy)(CO)_2(CH_3CN)Cl]^{2+}$. Importantly, the thin-layer cyclic voltammetric scan recorded during the oxidation of complex **1,** has proven that $[Os^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$ is not further oxidised to the corresponding dication before the anodic limit of the potential "window" of the acetonitrile electrolyte is reached. The generation of the oxidised transient $[Os^{III}(bpy)(CO)_2(CH_3CN)Cl]^{2+}$ from complex $\mathbf{2}^+$, even though inefficient,

must therefore be coupled to its instantaneous one-electron reduction at the applied electrode potential of the **1/1**$^+$ redox couple, resulting in the stable complex $[Os^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$. In this way $[Os^{II}(bpy)(CO)_2(CH_3CN)Cl]^+$ is formed at the expense of **1**$^+$ and **2**$^+$ until the process becomes inhibited owing to decreased CO concentration.

Comparison of the CO-Loss Reactivity of Complexes $[M(bpy)(CO)_n(CH_3CN)_{2-n}Cl_2]$ (M = Ru, Os; n = 1, 2)

It is important to recall that electrochemical oxidation of the complex *trans*(Cl)-$[Ru(bpy)(CO)_2Cl_2]$ in acetonitrile, containing a small amount of water, induces decoordination of one CO and one Cl ligand, producing the Ru^{III} complex $[Ru(bpy)(CO)(CH_3CN)_2Cl]^{2+}$. The completely decarbonylated Ru^{III} compound $[Ru(bpy)(CH_3CN)_2Cl_2]^{2+}$ is also formed in low yield (5%) in this medium.[4] In contrast to this, for the corresponding Os^{II} complex **1** it proved possible to substitute merely a single CO ligand, by electrochemical one-electron oxidation producing the cationic species **2**$^+$. Moreover, the CO substitution is incomplete even in aqueous CH_3CN electrolyte at ambient temperature and a mixture of cations **1**$^+$ and **2**$^+$ is produced. Substitution of a chloride ligand in the course of the oxidation of complex **1**, producing ultimately the Os^{II} complex $[Os(bpy)(CO)_2(CH_3CN)Cl]^+$, could only be achieved under special conditions of locally increased CO concentration in the acetonitrile electrolyte. These results point to much stronger Os−CO bonds in complex **1**$^+$, but also in **2**$^+$, compared to the corresponding ruthenium derivatives. This conclusion is supported by the lower ν(CO) frequencies for the Os^{II} complexes (see above). The σ,π-donation from the chloride ligands is assumed to play an important role in the stabilization of the formal metal(III) oxidation state, strengthening the metal-to-CO π-backbonding and, hence, the metal(III)−CO bonds. A comparison of ν(CO) frequencies for the corresponding Os^{III} and Ru^{III} complexes would be useful in this regard. Unfortunately, the oxidised Ru^{III} complexes *trans*(Cl)-$[Ru(bpy)(CO)_2Cl_2]^+$ and $[Ru(bpy)(CO)(CH_3CN)Cl_2]^+$ have not been characterised so far by IR spectroscopy.

Similar arguments can be used to explain the relatively slow dissociative photosubstitution reaction of complex **1** in acetonitrile, producing the monocarbonyl complex *trans*(Cl)-$[Os(bpy)(CO)(CH_3CN)Cl_2]$ (**2**). Resonance Raman spectra of the latter photostable complex have shown that its lowest-energy optically populated excited state has a mixed MLCT/XLCT character. This unreactive excited state apparently does not interact with any reactive state from which a CO-loss reaction would occur [e.g. ligand-field (LF) or metal-to-CO charge-transfer (MLCT) states[10,32]. In contrast to this, the related 4d-ruthenium complex *cis*(Cl)-$[Ru(bpy)(CO)(CH_3CN)Cl_2]$ is readily photoreactive and converts into $[Ru(bpy)(CH_3CN)_2Cl_2]$.[7] Time-resolved spectroscopic studies and theoretical MO calculations are needed to describe the reactive (dissociative) state in the latter case.

Time-dependent DFT calculations on the complex *trans*(Cl)-$[Ru(Me\text{-}DAB)(CO)_2Cl_2]$ (Me-DAB = *N*,*N*′-dimethyl-1,4-diaza-1,3-butadiene) have revealed a mixed XLCT/MLCT character of its lowest-energy allowed electronic transition, while CASSCF/CASPT2 ab initio calculations favour its predominant MLCT assignment.[33] The CO-loss reactions of the analogous ruthenium complex *trans*(Cl)-$[Ru(bpy)(CO)_2Cl_2]$ and the studied complex **1** probably occur upon optical preparation of a similar Franck-Condon excited state. Upon light absorption and electron transfer to the π*(bpy) orbital the metal centre becomes partly oxidised, resulting in diminished π-backbonding toward the CO ligands bound in the equatorial metal−bpy plane. The stabilization of the metal−CO bonds by increased donation of electron density to the $M(CO)_2$ unit from the axial donor ligands plays a crucial role in tuning the photoreactivity. Thus, incorporation of a stronger σ-donor isopropoxycarbonyl [−C(O)O*i*Pr] ligand instead of chloride results in a photostable complex $[Os(bpy)(CO)_2\{C(O)OiPr\}Cl]$.[34] Under identical experimental conditions, the isomeric ruthenium(II) photoproduct *cis*(Cl)-$[Ru(bpy)(CO)(CH_3CN)Cl_2]$ is formed from *trans*(Cl)-$[Ru(bpy)(CO)_2Cl_2]$ markedly more rapidly (within a few minutes),[7,9] again consistent with weaker Ru−CO bonds in the reactive excited state and in analogy with the electrochemical oxidation. It is also possible that for the less photoreactive 5d-Os complex **1** a branching of the Franck-Condon excited state evolution occurs, resulting in a competition between CO-loss reactivity from the dissociative state and parallel population of an unreactive excited state.[10,32] Again, time- and temperature-dependent studies and theoretical support are needed. The CO-loss-induced photoisomerisation is characteristic for this class of dicarbonylruthenium and -osmium complexes with the lowest-energy optically accessible XLCT/MLCT excited states. Another example is the complex *trans*,*cis*-$[Ru(CO)_2(dmb)(Me)I]$ (dmb = 4,4′-tetramethyl-bpy) isomerising via the monocarbonyl transient [Ru(CO)(dmb)(Sv)(Me)I] (Sv = donor solvent) to *cis*,*cis*-$[Ru(CO)_2(dmb)(Me)I]$.[36] In this regard it is remarkable that both complex **1** and its ultimate photoproduct **2** are *trans*(Cl) isomers; although, the proposed stucture of complex **2** (see above) has not been yet confirmed by a single-crystal X-ray diffraction study.

Experimental Section

General Remarks: The supporting electrolyte Bu_4NClO_4 (TBAP; Fluka) and HPLC-grade acetonitrile (Rathburn) were used as received. Analytical-grade acetontrile and butyronitrile (purchased from Acros) were distilled from CaH_2. All syntheses and measurements were performed under dry nitrogen or argon, in a dry-box and/or using standard Schlenk techniques. For photolysis experiments, the samples were placed in a pyrex glass vessel and irradiated under argon with unfiltered light of Oriel Instruments 500-W Hg or Osram XBO 250-W Xe discharge lamps. Cyclic voltammetric measurements and bulk electrolyses were performed using a PAR Model 173 potentiostat. All cyclic voltammograms were recorded with a conventional single-compartment three-electrode cell in a

dry box (Jaram). All electrode potentials reported in this work are given relative to Ag/Ag^+ (10^{-2} M in CH_3CN containing 10^{-1} M TBAP). Conversion into the ferrocene/ferrocenium reference system can be easily done by adding −0.087 V.[37] The working electrodes for cyclic voltammetry were platinum or glassy carbon (GC) discs (active surface areas of 0.19 and 0.07 cm^2, respectively), polished carefully with a 2 μm diamond paste (Mecaprex Presi). Exhaustive electrolyses were carried out in the same cell on a platinum sheet (2 cm^2). The auxiliary electrode was a Pt wire in acetonitrile/10^{-1} M TBAP. The electrolysed solutions of complex **1** were handled in the dark to avoid photoreactions. IR and UV/Vis spectroelectrochemical experiments at variable temperatures were carried out with home-made OTTLE cells[38,39] equipped with a Pt minigrid working electrode (32 wires/cm) and CaF_2 windows. The spectroelectrochemical samples typically contained 3×10^{-3} M osmium complex and 3×10^{-1} M supporting electrolyte. The working electrode potential of the OTTLE cells was controlled with PA4 (EKOM, Czech Republic) or PAR Model 173 potentiostats. Electronic absorption spectra were recorded with Hewlett−Packard 8452 A or 8453 diode array spectrophotometers, IR spectra with Perkin−Elmer Spectrum GX FTIR or Bio-Rad FTS 7 spectrometers, and ^1H NMR spectra with a Bruker AC 250 MHz spectrometer. Mass spectra (FAB^+) were obtained with a ZAB-HF-VB analytical apparatus in a *m*-nitrobenzyl alcohol matrix. Nanosecond time-resolved absorption (TA) spectra of complex **2** were obtained by irradiating the sample with 5-ns pulses (fwhm) of a 545 nm line of a continuously tunable (360−700 nm) Coherent Infinity XPO laser. The employed experimental setup has been described previously.[40] Resonance Raman (rR) spectroscopic measurements were performed with a Dilor XY spectrometer, equipped with a Wright Instruments CCD detector. A Spectra Physics 2040E argon ion laser in combination with Coherent CR490 and CR590 dye lasers (with Coumarine 6 and Rhodamine 6G dyes) served as excitation sources under a 180° backscattering geometry. Data acquisition was controlled by Dilor Labspec 2.08 software. Wavenumbers of the resonance-enhanced Raman bands were calibrated with respect to the Raman bands of NO_3^- at 1051 and 716 cm^{-1}. Baseline deviations were corrected by using Grams software. Elemental analyses (C, H, N) were carried out in the Microanalytisches Laboratorium of Dornis & Kolbe, Mülheim a. d. Ruhr, Germany. Determination of Cl was performed argentometrically after pyrolysis according to the method of Schöniger.[41,42]

Synthesis of *trans*(Cl)-[Os(bpy)(CO)(CH_3CN)Cl_2] (2): The precursor complex *trans*(Cl)-[Os(bpy)(CO)$_2Cl_2$] (**1**) was prepared as previously described.[19] A solution of complex **1** (20 mg, 4.2×10^{-5} mol) in acetonitrile (20 mL) was illuminated with unfiltered light of a 250-W Xe lamp with continuous stirring and incidental purging with argon gas. The progress of the photoreaction was monitored by UV/Vis and IR spectroscopy. Under these conditions the complete photochemical conversion of **1** into **2** was achieved in 18 h (Figure 1). The resulting solution of **2** was concentrated to dryness, leaving behind a purple powder. Yield: ca. 18 mg (90%). ^1H NMR (250 MHz, CD_3CN, 298 K): δ = 1.96 (s, 3 H, CH_3CN), 7.40 (td, ^3J = 5.6, ^4J = 1.6 Hz, 1 H, 5′-H), 7.75 (2 td, 2 H, 4′,5-H), 8.17 (td, ^3J = 5.6, ^4J = 1.6 Hz, 1 H, 4-H), 8.33 (d, ^3J = 8.7 Hz, 1 H, 3′-H), 8.41 (d, ^3J = 8.7 Hz, 1 H, 3-H), 9.05 (d, ^3J = 5.6 Hz, 2 H, 6,6′-H) ppm. IR (CH_3CN): $\tilde{\nu}$ = 1933 [vs, ν(CO)] cm^{-1}; CsI pellet: $\tilde{\nu}$ = 1929 [vs, ν(CO)], 317 (w, ν(Os-Cl)] cm^{-1}. UV/Vis (CH_3CN): λ_{max} = 362, 534 nm. FAB-MS: *m*/*z* = 487.4 $[M + H]^+$, 446.3 $[M + H - CH_3CN]^+$, 418.3 $[M + H - CH_3CN - CO]^+$. $C_{13}H_{11}Cl_2N_3OOs$ (486.36): calcd. C 32.10, H 2.28, Cl 14.58, N 8.64; found C 31.90, H 2.19, Cl 14.81, N 8.39.

Acknowledgments

We gratefully acknowledge the Ministère des Affaires Etrangères and the Netherlands Organization for Scientific Research (NWO; project VGP 71-126) for the financial support of this work undertaken as a part of the bilateral Dutch-French Van Gogh Programme. Many thanks are owed to Mr. Frank W. Vergeer and Mr. Theo L. Snoeck (both University of Amsterdam) for recording the nanosecond TA and resonance Raman spectra, respectively.

[34] The complex [Os(bpy)$(CO)_2${C(O)O*i*Pr}Cl] is usually formed as a minor side product (yield 15−20%) during the synthesis of complex **1** conducted in 2-propanol.[19] Its purification was not attempted. A similar side reaction has also been reported for the corresponding ruthenium complexes.[35] [Os(bpy)$(CO)_2${C(O)O*i*Pr}Cl] was characterised in a mixture with complex **1**. IR (in CH_3CN): ν(CO) at $\tilde{\nu}$ = 2012, 1933 cm^{-1}. MS (FAB^+): m/z = 527 $[M + H]^+$, 491 $[M + H - Cl]^+$, 467 $[M + H - C(O)OiPr]^+$. The smaller ν(CO) wavenumbers of [Os(bpy)$(CO)_2${C(O)O*i*Pr}Cl] compared to complex **1** testify to stronger donation of electron density from the isopropoxycarbonyl ligand compared to Cl, resulting in stronger Os−CO bonds. Indeed, in contrast to complex **1**, [Os(bpy)$(CO)_2${C(O)O*i*Pr}Cl] is photostable in acetonitrile at ambient temperature and CO substitution does not occur.

Dioxygen Activation Using Schiff Base Macrocyclic Dinuclear Copper(I) Complexes: Structurally Characterized Dioxygen Reaction Products

Haiyan Ma,[a] Markus Allmendinger,[a] Ulf Thewalt,[b][‡] Axel Lentz,[c] Martti Klinga,[d][‡‡] and Bernhard Rieger*[a]

Keywords: Macrocyclic ligands / Dinuclear copper complexes / Oxygenation reactions / O−O activation / X-ray crystal structures

Schiff-base condensation of diethylenetriamine with a series of dialdehydes [isophthalaldehyde (**2a**), 5-*tert*-butylisophthalaldehyde (**2b**), 2-methylisophthalaldehyde (**2c**), and *p*-phthalaldehyde (**2d**)] affords four hexaaza macrocyclic ligands [$L^{H,H}$ (**3a**), $L^{tBu,H}$ (**3b**), $L^{H,Me}$ (**3c**), $L^{p\text{-}H,H}$ (**3d**)] bearing different substituents on the aromatic units that connect the two metal ion binding sites. The dinuclear copper(I) complexes $[L^{H,H}Cu_2(MeCN)_2](ClO_4)_2$ (**4a**), $[L^{tBu,H}Cu_2(MeCN)_2](ClO_4)_2$ (**4b**), $[L^{H,Me}Cu_2(MeCN)_2](ClO_4)_2$ (**4c**), and $[L^{p-H,H}Cu_2(MeCN)_2](CF_3SO_3)_2$ (**4d**) are obtained in good yields by reaction with Cu^I salts. X-ray diffraction studies performed on **4a** and **4d** reveal a distorted tetrahedral coordination geometry around each Cu^I ion, which is constructed by three nitrogen donors of the macrocyclic ligand and one acetonitrile solvent molecule. Treatment of these complexes with molecular dioxygen shows that their reactivity can be fine-tuned by the nature of the aromatic unit of the dialdehyde building blocks. Thus two different dinuclear Cu^{II} complexes resulting from the reaction of **4a** and **4b** with dioxygen were isolated and characterized by single crystal X-ray diffraction, XPS and magnetic measurements. The introduction of a methyl group in the 2-position of the aromatic spacers in **4c** hinders such oxygen transfer reactions but may allow the characterization of stable dioxygen binding species.

Introduction

The study of copper-dioxygen interactions and reactivity is of great interest in chemical systems that involve redox activity or oxidative transformations. In biological systems copper proteins are known to provide a variety of functions including dioxygen transport by hemocyanin (Hc), oxygenation and dehydrogenation of substrates combined with the transformation of O_2 to either H_2O_2 or water.[1−3] With the hope of mimicking the mild and selective biological oxygenation reactions,[4−10] a great variety of mononuclear[11−15] and dinuclear[16−21] copper(I) complexes ligated by polydentate N-ligands (containing amine or imine groups) have been synthesized and investigated. In most cases, two interacting copper centers were found to be included in dioxygen binding and activation process just as hemocyanins and tyrosinases do in the natural systems.[4,10,22]

Tolman and co-workers[22−25] suggested an equilibrium between $Cu_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-peroxo})$ and $Cu_2(\mu\text{-oxo})_2$ cores using mono- or binucleating 1,4,7-3R-1,4,7-triazacyclonoanes ligands (R = alkyl or aryl), which was strongly influenced by ligand geometry, solvent donor ability and temperature. It was further found that either of the cores might be responsible for oxygenation of substrates. Karlin and coworkers thoroughly investigated the reaction of dioxygen with a series of dinuclear Cu^I complexes ligated by alkyl- or aryl-bridged bis[2-(pyrid-2-yl)ethyl]amine.[26−30] The alkyl bridge afforded in some cases the reversible binding of dioxygen to the copper centers, identified by UV/Vis or resonance Raman spectroscopy.[26−28] The replacement of the alkyl bridge by an aryl group, however, usually resulted in hydroxylation at the 2-position of the arene spacer, leading to $[Cu_2^{II}(R-XYL-O^-)(OH^-)]^{2+}$ (XYL: *m*-xylylene) species.[20,29,30] Surveying back the development of copper(I) complexes used in the oxygenation reaction, much of the research work has been focused on the use of "open" (non-macrocyclic) ligands. Only a few macrocyclic copper com-

[‡] X-ray diffraction (**4a**, **5a** and **5b**).

plexes have been reported for oxygenation reactions during the past several decades.[31−35]

According to the active sites of type III copper proteins (hemocyanins, tyrosinases), two copper ions coordinated by two or three nitrogen ligands per Cu unit and a suitable copper-copper distance for dioxygen binding are necessary aspects for the formation of stable copper-dioxygen adducts.[1−3] In our opinion, Schiff-base macrocyclic ligands fulfil these requirements. At the same time, a freely adjustable Cu···Cu distance can be realized by designing ligands of various sizes. Martell, Schindler et al. reported the first example of oxygenation reaction of a copper(I) complex ligated by a Schiff-base macrocyclic ligand. A possible oxygenation mechanism[32] and kinetic details[34] were provided in their work. However, they did not provide structural characterization of Cu^{I} or Cu^{II} complexes, leaving many structural and mechanistic questions unanswered. It is found that a minor modification of the ligand environment around the copper center will lead to a dramatic variation in oxygenation activity of the copper(I) complexes.[26,27] For a better understanding of the relation between a complex's structure and its reactivity towards dioxygen, we report here a series of Schiff-base macrocycles of different size and substitution, which provide structural insight into a tyrosinase model system.

Results and Discussion

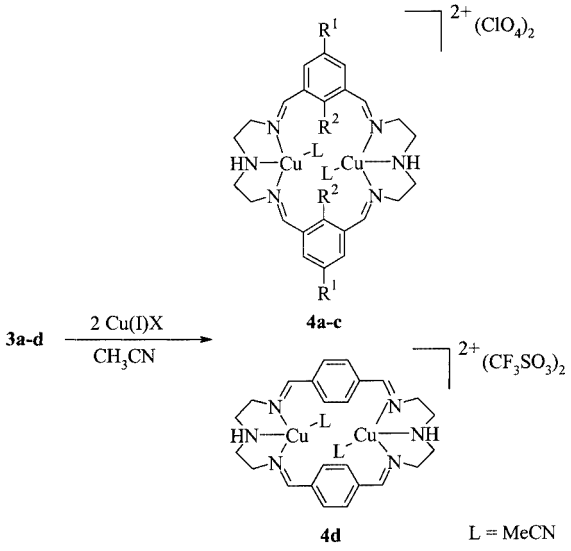
Syntheses of Ligands

The macrocyclic compounds used in our investigations (Scheme 1) were prepared by a Schiff-base condensation reaction of diethylenetriamine (**1**) with four different aromatic aldehydes (**2a**−**d**) under dilute conditions.[36]

The dropwise addition of aldehydes in acetonitrile to a solution of amine in the same solvent affords the formation of macrocycles, which precipitate as white crystalline solids. This one step procedure gives all [2+2][37] cycles in good to quantitative yields. The products were characterized by a combination of different MS techniques (CI, FAB, MALDI-Tof: size distribution), by elemental analysis, and by IR and NMR spectroscopy. The ^{1}H NMR spectra of the macrocycles **3a**−**c** suggest the existence of isomers in solution. This can be explained by a facile nucleophilic attack of an NH group to one of the neighboring imine fragments, leading to the reversible formation of 18-membered diimine imidazolidine macrocycles.[33] According to ^{1}H and ^{13}C NMR spectroscopy at 25 °C, **3b** exists predominantly in the form of the bisimidazolidine isomer, while for **3a** and **3c** no preference can be found.

Syntheses and Characterization of Copper(I) Complexes

Cu^{I} complexes of the macrocycles **3a**−**d** were obtained by an addition of in situ generated Cu^{I} perchlorate[38] or Cu^{I} triflate to the ligand solution in dichloromethane (Scheme 2).



Scheme 2. Formation of dinuclear Cu^{I} complexes

The yellow to red crystalline compounds obtained were isolated and in selected cases characterized by single-crystal X-ray analysis. Suitable crystals of **4a** and **4d** were obtained by diffusion of diethyl ether into an acetonitrile solution

of the complex. The crystallographic analysis of **4a** and **4d** (Table 1) confirms in both cases the coordination of two copper atoms to the hexadentate macrocycle. Additionally, a coordinated acetonitrile molecule completes the distorted tetrahedral coordination geometry of the copper centers (Figures 1 and 2). In the case of **4a** the *meta*-substituted aromatic spacer units afford a C_2-symmetric arrangement of both copper(I)-containing subunits relative to each other leading to a short Cu···Cu distance of 4.28 Å, which is indeed similar to that found in tyrosinase (ca. 3.6 Å) and in the solid state of oxygenated and deoxygenated haemocyanin (3.6 and 4.6 Å).[1−3] Thereby the two copper centers are pointing towards each other, enforced by a pocket-like orientation of the macrocyclic ligand array (Figure 1).

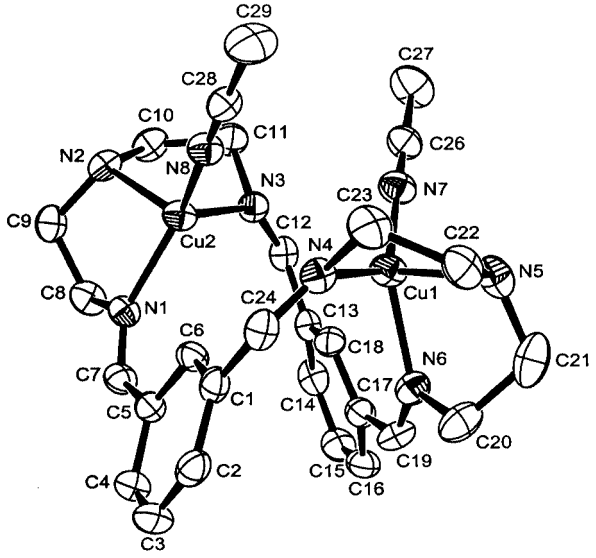

Figure 1. An ORTEP view of $[L^{H,H}Cu_2(MeCN)_2](ClO_4)_2$ (**4a**); hydrogen atoms and anions are omitted for clarity

Compound **4d** contains two tridentate metal binding sites that are separated by *para*-substituted aromatic spacer units. This leads to a "linear" arrangement of the two copper sub-structures with a larger Cu···Cu distance (relative to **4a**) of 6.86 Å. The two triflate anions show no direct interaction with the metal centers. In contrast to a recently published crystal structure of a similar complex with perchlorate anions,[35] the metal centers in **4d** are oriented to the same side of the plane defined by the macrocycle (Figure 2).

Reaction of Copper(I) Complexes with O_2

The dinuclear copper(I) complexes **4a**−**d** were exposed to oxygenation reactions.[39] Dioxygen was bubbled directly via a gas releasing apparatus into the solution of **4a** in a mixture of acetonitrile, dichloromethane and methanol at room temperature. A clear green solution developed gradually. After workup, green prismatic crystals of **5a** could be isolated by recrystallization from acetonitrile. Single crystal analysis indicates **5a** to be a dinuclear bis(μ-methoxy)-copper complex still bearing the initial macrocyclic ligand (Scheme 3). This is a clear difference to the bis(μ-hydroxo)dicopper(II) complex or the aromatic hydroxylation Cu^{II} complex proposed by Menif et al.[32,34] Complex **5a** displays sharp signals for the aromatic units of the ligand in the ^{1}H NMR spectrum. A broad peak appears at δ = 5−6 ppm which could be assigned to the bridging methoxy groups. Thus the existence of two strongly-coupled copper(II) centers is suggested for **5a**. This hypothesis is further supported

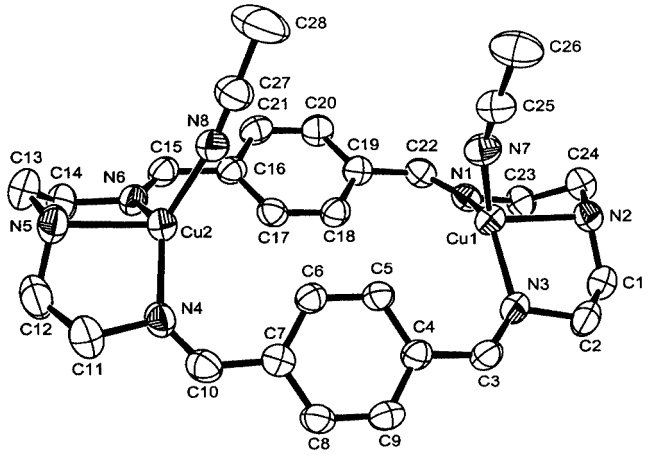

Figure 2. An ORTEP view of $[L^{p\text{-}H,H}Cu_2(MeCN)_2](CF_3SO_3)_2$ (**4d**); hydrogen atoms and anions are omitted for clarity

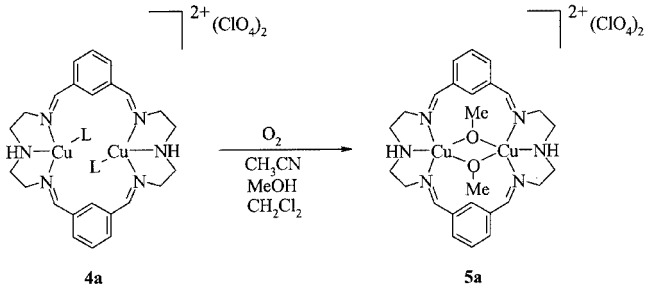
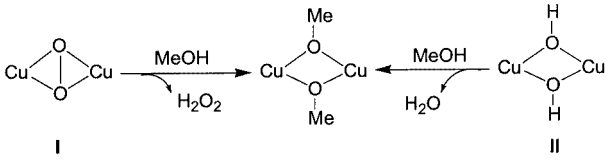


Scheme 3

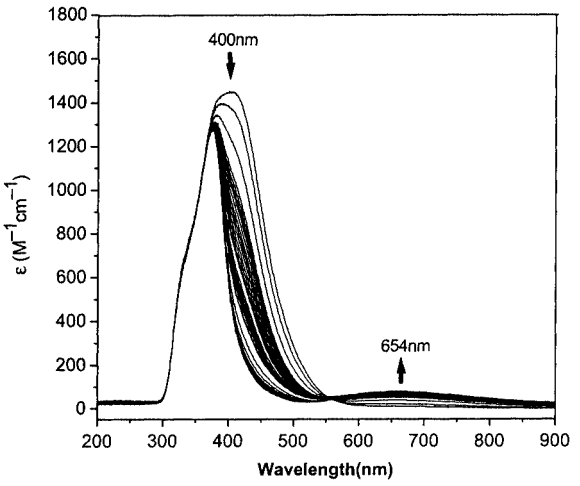
by temperature-dependent magnetic susceptibility measurements and by X-ray photoelectron spectroscopy.

Compound **5a** is not the first example of a methoxy-bridged Cu^{II} complex. The isolation of similar Cu^{II} species from the reaction of Cu^{I} precursors bearing noncyclic ligands with dioxygen has been reported by other groups [7,16,40,41]. However, the formation process is still not understood. We assume here that the formation of **5a** occurs most likely via the reaction of the oxygenated species [either the dioxygen-binding species **I** or the bis(μ-hydroxo)dicopper complex **II**, Scheme 4] with solvent molecules.[42] Unfortunately, we were not able to demonstrate the formation of hydrogen peroxide or water. Direct synthesis of the bis(μ-hydroxo)dicopper(II) species from Cu^{II} salts also failed due to the decomposition of the Schiff-base ligands in the presence of water or a base.

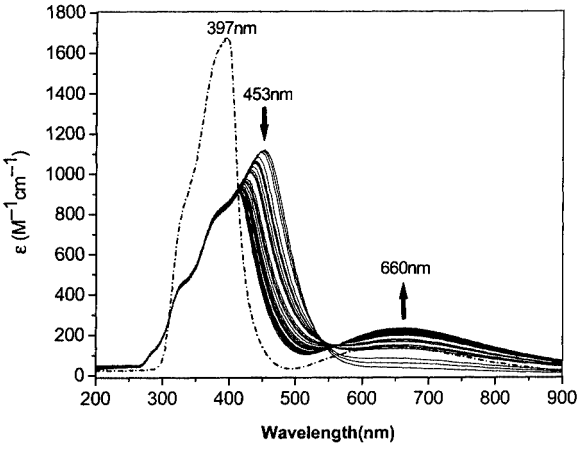


Scheme 4

To gain a better understanding, the reaction of **4a** with dioxygen was further investigated by UV/Vis spectroscopy in *N*,*N*-dimethylformamide. A single absorption at 400 nm is displayed initially for **4a**. By bubbling dioxygen into this



(A)

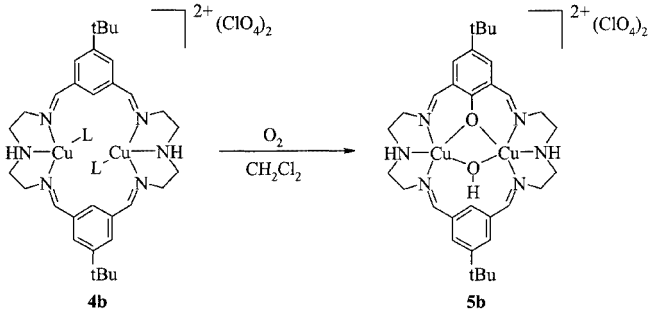


(B)

Figure 3. Reaction of (A) $[L^{H,H}Cu_2(MeCN)_2](ClO_4)_2$ (**4a**), (B) $[L^{tBu,H}Cu_2(MeCN)_2](ClO_4)_2$ (**4b**) with dioxygen in dry *N*,*N*-dimethylformamide; the initial trace shows the electronic spectrum of **4a** or **4b**; the subsequent traces were obtained upon adding dioxygen continually at room temperature for 2 h; the dashed line in (B) is the spectrum of $[(L^{tBu,H}O)Cu_2(\mu\text{-}OH)](ClO_4)_2$ (**5b**) in DMF

solution continually, this absorption shifts gradually to shorter wavelength with decreasing intensity. At the same time, a new absorption around 650−700 nm appears with lower intensity [Figure 3 (A)]. The final trace (after oxygenation is complete) shows a strong absorption at 375 nm and a weak one at 654 nm, which are only slightly different from the data reported by Menif (362 nm and 620 nm).[32] However, it suggests the formation of phenoxo- hydroxo-bridged dinuclear copper(II) complexes in DMF.[1,17,27,32] The absorption at 375 nm can be assigned to the ligand to metal charge transfer transition (from phenoxide to the Cu^{II} center). The high wavelength absorption at 654 nm is due to the d-d transition band, which is characteristic for Cu^{II} complexes.[1,7] The existence of the proposed bis(μ-hydroxo)dicopper complex[32−34] could not be identified definitely, however, the deviation of the low energy absorption (654 nm instead of 620 nm) might indicate its formation.

The reaction of **4b** with dioxygen in dichloromethane proved to be even faster than **4a**. Complex **5b**, which was



Scheme 5

isolated from this reaction in high yield, is the product of an intramolecular oxygen transfer and bears the dioxygen molecule after reductive O−O bond cleavage (Scheme 5, Figure 6). Such aromatic hydroxylation products obtained from noncyclic Cu^{I} precursors and dioxygen are already well known.[29,30] However, to the best of our knowledge, **5b** is the first characterized structure obtained from the reaction of a Schiff-base macrocyclic Cu^{I} complex and O_2.

An electrophilic attack of the μ-η^2:η^2-peroxo moiety to the aryl part of the ligand is proposed for the formation of such hydroxylation products.[29,30] This suggestion is supported by our observation that *tert*-butyl substitution at the 5-position of the aromatic spacer unit increases the rate of the C−H activation process in the 2-position and leads to higher yields of the insertion product **5b**. It is further found that a lower reaction temperature or addition of toluene inhibits the hydroxylation reaction. However, the presence of benzyl alcohol[43] increases the ratio of **5b** to the rest of oxidation products up to 88%. This is consistent with the result of Casella et al.[44] whereby the increase of the proton donor ability of the reaction medium favors the formation of the hydroxylation products (Table 2).

The UV spectrum of **4b** in the presence of dioxygen displays a similar reactivity to complex **4a**. The initial absorption at 453 nm of **4b** is gradually replaced by new absorptions at 397 nm and 660 nm, indicating the formation of the phenoxo- hydroxo-bridged dicopper complex **5b** [Figure 3, (B), solid lines)]. Nevertheless, the proposed dioxygen adduct intermediates which are responsible for the formation of **5b**, are again undetectable due to fast subsequent oxygen transfer.[1−10,14] By comparing the UV spectrum of pure **5b** [isolated crystals, Figure 3 (B), dashed line] with the final trace of **4b** after oxygenation, a good agreement is obtained except for the low energy region. Compound **5b** displays a d-d transition band at 640 nm (in contrast to the absorption at 660 nm of the reaction mixture), indicating most probably the formation of some other Cu^{II} species during the oxygenation reaction. One suitable suggestion might be the formation of bis(μ-hydroxo)dicopper(II) complexes. This is supported by the findings of Karlin and co-workers on dinuclear Cu^{I}−dioxygen reaction products ligated by substituted pyridine ligands.[19,20,29,30]

The reaction of **4c**, bearing methyl substituents on the aromatic rings of the macrocyclic frame, with dioxygen shows a completely different reactivity than **4a** and **4b** (Figure 4 vs. Figure 3). The initial absorption at 433 nm shifts gradually to *longer* wavelength with *increasing* intensity and a weaker absorption appears at ca. 550 nm. Furthermore the intensity of this new absorption ($\varepsilon \approx 800$ $M^{-1}cm^{-1}$) is significantly higher than the comparable d-d bands in Figure 3 ($\varepsilon < 200$ $M^{-1}cm^{-1}$). This suggests the formation of new species [instead of phenoxo- hydroxo-bridged dicopper complex or bis(μ-hydroxo)dicopper complex] by reaction with dioxygen.[1,11]

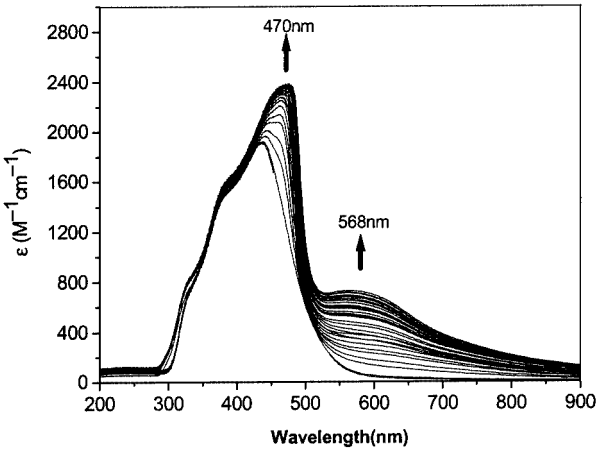


Figure 4. Reaction of $[L^{H,Me}Cu_2(MeCN)_2](ClO_4)_2$ (**4c**) with dioxygen in dry *N*,*N*-dimethylformamide; the initial trace shows the electronic spectrum of **4c**; the subsequent traces were obtained upon continuous addition of dioxygen at room temperature for 2 h

The features depicted in Figure 4 are more similar to what was reported for μ-peroxo-bridged complexes. These species show absorptions near 550 nm with moderate molar

Table 2. Aspects influencing the reaction of **4b** with O_2

	Conc. [mM]	Solvent	BzOH (BzOH/Cu)	Temp. [°C]	Time [h]	**5b**[a] (%)
1	0.58	CH_2Cl_2/toluene (20:1)	-	-80/25	5/15	13

5	1.45	CH_2Cl_2	1:1	25	20	88
6	10	CH_2Cl_2	1:1	25	24	80[b]
7	10	CH_2Cl_2	2:1	25	24	79[b]

[a] Determined after hydrolysis of the reaction mixture by the ratio of hydroxylated dialdehydes to their nonhydroxylated counterparts.[32] [b] Dioxygen was bubbled for 1 min.

absorbance of about 1000 $M^{-1}cm^{-1}$,[42] which is similar to the observed absorption at 568 nm. The absorption at ca. 470 nm (ca. 2000 $M^{-1}cm^{-1}$) after oxygenation of **4c** is again assigned to a ligand to metal charge transfer transition. The relatively low intensity[42] of this band can result either from a generally low absorption of our macrocyclic ligands or − most probably − from a low concentration of the peroxo species, which seems to be stable for hours even at room temperature.

The reaction of **4c** with dioxygen was also performed on a synthetic scale in dichloromethane at room temperature. The color of the solution changed gradually to yellow-greenish and a solid of the same color precipitated. No pure green color developed as in the cases of **4a** and **4b**. After workup, a yellow-greenish powder was isolated, which shows the existence of a $[L^{H,Me}Cu_2(O_2)]^{2+}$ fragment by means of MS spectrometry. Unfortunately, all attempts to purify the products by crystallization failed, due to the poor solubility in suitable solvents. The analysis of products obtained after hydrolysis by addition of 4 N HCl and subsequent extraction with dichloromethane gave the original dialdehyde, 4-hydroxy-2-methylisophthalaldehyde, and a tetraaldehyde coupling product (Scheme 6).[45] Thus, the introduction of 2-methyl substituents in **4c** has not blocked the binding of dioxygen but has effectively inhibited the intramolecular hydroxylation reactions. The formation of 4-hydroxy-2-methylisophthalaldehyde might be explained by assuming that an intermolecular hydroxylation process occurs. If an electrophilic attack is suggested for this process,[29,40,46] the hydroxylation should happen in the 5-position of the aromatic unit. Thus 4-hydroxy-2-methylisophthalaldehyde and even the coupling product are most likely formed via a free radical process before or during acidic decomposition.[47]

Compared to the oxygenation activity of **4a**−**c**, the *para*-subsituted Cu^I complex **4d** is completely inert to dioxygen. No oxygenation or even decomposition was observed in solution or in the solid state after exposure to dioxygen.[35] This surprising effect becomes clear by comparing the Cu···Cu distances in the *meta*-bridged complex **4a** and the "linear", *para*-bridged complex **4d**. The *para*-substituted aromatic units restrict the free location of the two Cu^I centers relative to each other and leads to a separation of the Cu centers (Cu···Cu: 6.86 Å). This implies that no dioxygen can be activated. The *meta*-aromatic bridges force the two copper(I) centers into a chiral, "pocket-like" arrangement (cf. Figure 1) with a short Cu···Cu distance (4.28 Å) allowing both copper centers to bind and activate the dioxygen molecule simultaneously.[4−10]

Characterization of Copper(II) Complexes

Solid State Structures

Single crystals of dinuclear copper(II) complexes **5a** (Figure 5) and **5b** (Figure 6) were obtained and characterized

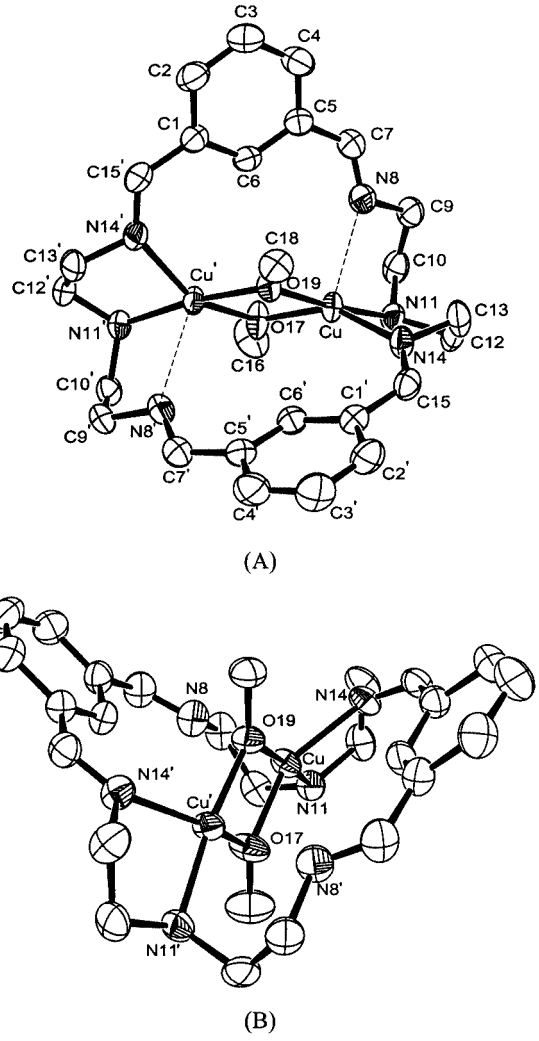

Figure 5. Two ORTEP views of $[L^{H,H}Cu_2(\mu\text{-}OMe)_2](ClO_4)_2$ (**5a**); hydrogen atoms and anions are omitted for clarity

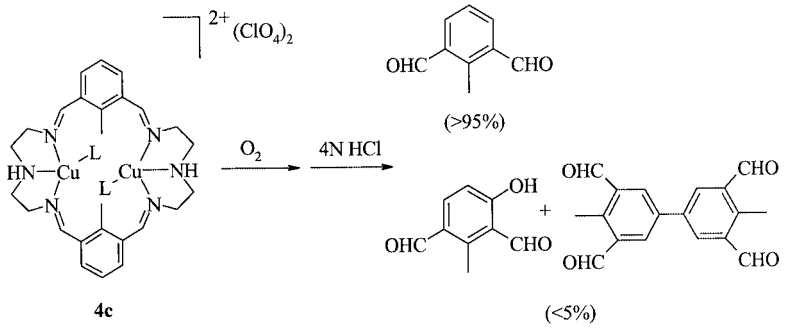

Scheme 6

by X-ray diffraction (Table 3). The dicationic portion of **5a** shows a chiral, C_2-symmetric coordination around the dinuclear Cu^{II} core in the solid state. Compared to the quasi-tetrahedral coordination adopted by **4a**, the coordination geometry around each Cu^{II} ion in **5a** is most likely distorted square planar with a Cu···Cu separation of about 3.03 Å. This distance is typical for dinuclear copper complexes containing two single-atom bridging ligands.[23,27] The $Cu-N_{imine}$, $Cu-N_{amine}$ distances in **5a** do not differ from each other and are in the expected region for nitrogen-coordinated copper complexes of that type (Table 4).[10,11,22,27]

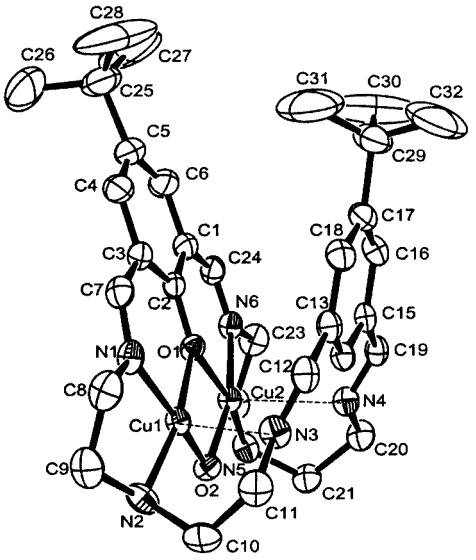

Figure 6. ORTEP view of $[(L^{tBu,H}O)Cu_2(\mu\text{-}OH)](ClO_4)_2$ (**5b**); hydrogen atoms and anions are omitted for clarity

However, the imine nitrogen atoms N8 (N8′) are also relatively close to the respective copper centers (N8−Cu, N8′−Cu′: 2.62 Å), thus a distorted square pyramidal environment can be assumed for both Cu centers[29,30] [Figure 5 (A)]. The $[Cu_2(\mu\text{-}OMe)_2]^{2+}$ core unit forms an ideal plane (torsion angle O19−Cu−O17−Cu = 0°), which is located perpendicular to the "macrocyclic pocket" structure [Figure 5 (B)] and N8, N8′ are disposed *anti* relative to it.

The nonsymmetric complex **5b** is the product of an intramolecular oxygenation reaction bearing bridging phenoxide and hydroxy units (Figure 6). Each Cu^{II} ion adopts a slightly distorted square pyramidal coordination environment. The nitrogen atom N1 (N6), N2 (N5) and the two oxygen atoms O1, O2 form the basal equatorial plane (the sum of the angles is 358°). In contrast to **5a**, the two axial imine donors (N3, N4) are deposited *cis* with respect to the Cu_2O_2 plane, which leads to the observed unusual "U"-form of the macrocyclic ligand system. However, this coordination is less pronounced than in literature reports of five-coordinated species (2.409−2.437 Å relative to 2.0 −2.3 Å, Table 4).[20,22,46] The effect is probably due to repulsive steric interactions of the bulky *tert*-butyl substituents of **5b**.

Magnetic Measurements

The magnetic susceptibilities of complexes **5a** and **5b** from 2 to 400 K (or 300 K) were determined by variable temperature magnetic susceptibility measurements. The curve of complex **5a** shows a pronounced antiferromagnetic behavior over the whole temperature range, due to the coupling of the two copper(II) ions in the same molecule, where the superexchange is mediated by the bridging me-

thoxy groups (Figure 7). The effective magnetic moment per copper (μ_{eff}/Cu) is about 1.2 μ_B in solid state. A value of $-2J = 587\ cm^{-1}$ is obtained at room temperature, indicating a strong coupling between the two copper ions even at room temperature. This is however in accordance with the result of the ^1H NMR spectra.

The magnetic behavior of the phenoxo- hydroxo-bridged dicopper complex **5b** is significantly different from **5a**, despite the relatively similar Cu···Cu distance. The data obtained for **5b** suggest that the copper ions are essentially independent centers or, at best, very weakly coupled (Figure 8). In the low temperature range, the molar susceptibility of **5b** is in a good agreement with the Curie−Weiss law[48,49] as indicated by the linear relation of $1/\chi$ over T below 100 K.

Conclusion

Our results show that macrocycles containing suitable sites for transition metal coordination can be designed to hold two metal centers at a well-defined distance and orientation relative to each other. In agreement with natural oxidation catalysts, such as monooxygenase tyrosinase, this seems to be a major requirement to fine-tune the reactivity of artificial cyclic di- or multinuclear structures. In our case, *meta*-substituted dialdehyde building blocks resulted in macrocyclic complexes with Cu···Cu distances that allowed the activation and transfer of molecular dioxygen. It has been shown that subsequent oxygen transfer reactions can follow multiple pathways from which one intra- and one intermolecular reaction product could be isolated and characterized. Interestingly, the unwanted intramolecular reaction could be blocked effectively by introduction of methyl substituents in the 2-position of the bridging aromatic spacer, favoring other oxygen-transfer routes. This gives good hope that macrocyclic complexes can be designed to bind oxygen and allow selective transfer to substrates of technical importance.

Experimental Section

General Remarks: All operations concerning air- or moisture sensitive substances were performed under argon with standard Schlenk

techniques. Reagents and solvents were purchased from commercial sources and were used as received unless stated otherwise. Acetonitrile and methanol were purchased as dry solvents (water <0.005%) and were subsequently kept together with activated 3 Å or 4 Å molecular sieves. Dichloromethane and diethyl ether were refluxed with CaH_2 and $LiAlH_4$, respectively, and stored over activated molecular 4 Å sieves. All dry solvents were degassed prior to use. 2-Methylisophthalaldehyde[50], 5-*tert*-butylisophthalaldehyde[51] as well as **3a**[33] and **3d**[35] were prepared according to literature methods[32]. ^{1}H NMR and ^{13}C NMR spectra were recorded with a Bruker AMX400. Infrared measurements were obtained on KBr pellets using a Bruker IFS 113V and IFS 66V instrument. UV/Vis scan spectra were recorded with a J&M detector connected to a TIDAS spectrometer at room temperature. MS measurements were carried out using a Finnigan SSQ 7000 spectrometer with the methods of CI, FAB and MALDI. Magnetic measurement was carried out with a SQUID Magnetometer with constant field of 10000 Gauss. Elemental analyses were determined in the Microanalytical Laboratory of the University of Ulm.

Caution! *Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of material should be prepared and handled with great care.*

General Synthesis of Macrocyclic Imine Ligands: In a typical reaction the aldehyde (1 mmol) in 20 mL of acetonitrile was added dropwise to a stirred solution of the amine (1 mmol) in about 30 mL of acetonitrile. The addition was done over 1−2 h at room temperature. After stirring the reaction mixture for 24 h the crystalline precipitates were filtered and washed with acetonitrile in small portions. If necessary the products can be recrystallized from chloroform/acetonitrile. The compounds were characterized by ^{1}H NMR, ^{13}C NMR, IR spectroscopy, and by MS and elemental analysis.

$L^{tBu,H}$ (3b): Yield 78%. FT IR (KBr): ν(C=N) = 1650 (s) cm^{-1}. $C_{32}H_{46}N_6$ (514.76): calcd. C 74.67, H 9.01, N 16.33; found C 74.51, H 8.98, N 16.25. ^{1}H NMR ($CDCl_3$): δ = 8.1 (d, 2 H), 7.83 (m, 2 H), 7.44 (m, 2 H), 7.35 (m, 2 H), 3.13−4.0 (m, 14 H), 2.25−2.39 (m, 4 H), 1.85 (s, 2 H), 1.21 (m, 18 H) ppm. ^{13}C NMR ($CDCl_3$): δ = 160.8, 150.3, 140.1, 135.9, 128.2, 126.0, 120.6, 83.4, 58.4, 51.4, 51.1, 43.9, 33.6, 30.3 ppm. CI-MS, FAB-MS, MH$^+$: 515 (2+2 macrocycle), MALDI-Tof (dithranol): *m*/*z* = 514.38.

$L^{H,Me}$ (3c): Yield 79%. FT IR (KBr): ν(C=N) = 1629 (s) cm^{-1}. $C_{26}H_{34}N_6$ (430.34): calcd. C 72.50, H 7.90, N 19.52, found C 72.09, H 7.74, N 19.48. CI-MS, FAB-MS, MH$^+$: 431 (2+2 macrocycle), minor amount 646 (3+3 macrocycle), MALDI-Tof (dithranol): *m*/*z* = 514.38. The ^{1}H and ^{13}C NMR spectra in $CDCl_3$ are complex, suggesting the presence of isomers of the macrocycle.

General Preparation Method for Cu^I Complexes: Cu^I precursors were synthesized from Cu^{II} salts according to literature procedures in a mixture of oxygen-free methanol/acetonitrile (1:1). This solution was filtered directly into a degassed solution of the ligand in dichloromethane. After stirring for several hours at room temperature, the complexes can be either isolated by evaporating the solvent to dryness or by precipitating the product with degassed diethyl ether after concentration of the solution. The yellow to orange products were characterized by a combination of ^{1}H NMR and IR spectroscopy and elemental analysis.

$[L^{H,H}Cu_2(MeCN)_2](ClO_4)_2$ (4a): Yield 95%. FT IR (KBr): ν(C=N) = 1640 (s) cm^{-1}; ν(ClO_4^-) = 1111 (s), 1091 (s), 624 (s) cm^{-1}. $C_{28}H_{36}N_8Cu_2Cl_2O_8$ (810.26): calcd. C 41.46, H 4.44, N 13.82, found C 41.38, H 4.46 N 13.79. ^{1}H NMR (CD_3CN): δ = 9.3−8.3 (m, 6 H), 7.65 (s, 4 H), 7.1 (s, 2 H), 3.5 (s, 8 H), 3.25 (s, 2 H), 2.85 (m, 8 H) ppm. ^{13}C NMR (CD_3CN): δ = 164.2, 152.2, 135.9, 132.0, 129.6, 60.3, 48.5 ppm.

$[L^{tBu,H}Cu_2(MeCN)_2](ClO_4)_2$ (4b): Yield 93%. FT IR (KBr): ν(C=N) = 1621(s) cm^{-1}; ν(ClO_4^-) = 1111 (s), 1091 (s), 624 (s) cm^{-1}. $C_{36}H_{52}Cu_2Cl_2N_8O_8$ (922.08): calcd. C 46.85, H 5.64, N 12.15, found C 46.49, H 5.68, N 12.27. ^{1}H NMR (CD_3CN): δ = 9.24 (s, 2 H), 8.25 (s, 4 H), 7.62 (s, 4 H), 3.45 (m, 8 H), 3.2 (s, 2 H), 2.9 (m, 8 H), 1.3 (m, 18 H) ppm.

$[L^{H,Me}Cu_2(MeCN)_2](ClO_4)_2$ (4c): Yield 90%. FT IR (KBr, cm^{-1}): ν(C=N) = 1619 (s), ν(ClO_4^-) = 1111 (s), 1091 (s), 624 (s). $C_{30}H_{40}Cu_2Cl_2N_8O_8$ (838.4): calcd. C 42.94, H 4.77, N 13.36, found C 41.66, H 4.85, N 13.51. ^{1}H NMR spectra could not be obtained, due to the very low solubility of the complex.

$[L^{p\text{-}H,H}Cu_2(MeCN)_2](CF_3SO_3)_2$ (4d): Yield 95%. FT IR (KBr, cm^{-1}): ν(C=N) = 1626 (s). $C_{30}H_{36}Cu_2F_6N_8O_6S_2$ (909.14): calcd. C 39.59, H 3.96, N 12.32, found C 39.84, H 4.18, N 12.12. ^{1}H NMR (CD_3CN): δ = 8.5 (s, 4 H), 8.0 (s, 8 H), 3.6 (m, 8 H), 3.3 (s, 2 H), 2.9 (m, 8 H) ppm.

Isolation of $[L^{H,H}Cu_2(\mu\text{-}OMe)_2](ClO_4)_2$ (5a): Blue crystals of $Cu(ClO_4)_2{\cdot}6H_2O$ (0.370 g, 1 mmol) were added to a suspension of excess Cu powder in acetonitrile (25 mL) and methanol (25 mL). The reaction mixture was stirred for 3 h. After filtration, the obtained clear colourless solution was added dropwise to a solution of macrocyclic ligand **3a** (0.402 g, 1 mmol) in dichloromethane (30 mL). An orange solution was obtained at once and was stirred overnight. Dioxygen was then bubbled gently via a gas releasing apparatus into the above solution at room temperature for 2 days. The solution became green within the first 10 minutes. After removal of the solvents, 50 mL of acetonitrile was injected to dissolve the dark green powder. Trace amounts of impurities were removed by filtration. The clear solution was concentrated to about 15 mL (warming the solution during this process slightly), and kept at room temperature for one day. Green prismatic crystals were separated from the solution (50 mg), and characterized as **5a**. MS (*m*/*z*, FAB): 627 (52) [M + H − ClO_4^- − Cu^{2+}], 565 (22) [M + H − ClO_4^- − 2 MeO^-] 527 (30) [M − 2 ClO_4^- − Cu^{2+}], 500 (19) [M − $HClO_4$ − 2 Cu^{2+} − 2 MeO^-], 465 (100) [M − 2 ClO_4^- − Cu^{2+} − 2 MeO^-]. IR (KBr): $\tilde{\nu}$ = 3436 br, 3270 m, 3077 w, 2930 m, 2819 m, 1642 s, 1604 sh, 1580 sh, 1456 m, 1434 sh, 1336 m, 1294 w, 1258 w, 1232 m, 1011 s, 1081 s, 1054 s, 967 m, 891 m, 794 m, 685 m, 622 s, 538 m, 450 m cm^{-1}. $C_{26}H_{36}Cl_2Cu_2N_6O_{10}$: calcd. C 39.50, H 4.58, N 10.63; found C 39.69, H 4.44, N 10.89. ^{1}H NMR (CD_3CN): δ = 10.6 (br, 4 H), 8.2 (s, 2 H, Ar-*H*), 7.85 (m, 2 H, Ar-*H*), 7.4 (d, 4 H, Ar-*H*), 4.8−6.2 (br, 6 H, C*H*$_3$O), 3.2 (d, 8 H), 2.1 (s, 2 H, N-*H*), 1.8 (m, 8 H) ppm.

Isolation of $[(L^{tBu,H}O)Cu_2(\mu\text{-}OH)](ClO_4)_2$ (5b): Dioxygen was bubbled gently through a violently stirred solution of **4b** (500 mg, 0.54 mmol) in dichloromethane (150 mL) at room temperature. The solution turned green immediately and some green precipitate appeared. After 24 h, the reaction mixture was concentrated to dryness to afford a green powder. Acetonitrile (15 mL) was added to dissolve it and a trace amount of impurities was removed by filtration. The filtrate was then concentrated to about 3−4 mL (warming the solution during this process slightly), and kept at room temperature. Green planar crystals were obtained in a yield of 45% (190 mg), which were characterized as complex **5b**. MS (FAB): *m*/*z* = 655 (100) [M − 2 ClO_4^- − OH], 672 (31) [M − 2 ClO_4^-]. IR (KBr): $\tilde{\nu}$ = 3566 s, 3267 s, 2960 s, 2871 m, 1647 s, 1597 w, 1559 m, 1455 m, 1395 w, 1366 w, 1399 m, 1287 w, 1238 m, 1098 s, 1010 m, 968 m, 889 w, 766 w, 706 w, 621 s, 575 w, 481 w, 445 m cm^{-1}.

$C_{32}H_{46}Cl_2Cu_2N_6O_{10}$: calcd. C 44.04, H 5.31, N 9.63; found C 44.62, H 5.30, N 9.71.

Magnetic Susceptibility Measurements: Solid-state magnetic susceptibility measurements of copper complexes **5a** and **5b** were obtained at a constant field of 10KOe on a SHE SQUID magnetometer operating between 2 and 400 K. Determinations were made on crystalline samples loaded into gelatine capsules. Diamagnetic corrections for the capsules were made by direct measurements, while corrections for the ligands were calculated by use of Pascal's constants.[49] A fixed TIP correction of 60×10^{-6} cm^3/mol was adopted.[48]

X-ray Photoelectron Spectroscopy: Measurements for **5a** were carried out under the conditions of 5.85 eV, 250.0 W at 45.0° over 83.33 min for the Cu2p energy region. The same curve was also obtained by combining the energy bands reported for $CuCl_2$ and CuO.

X-ray Crystallographic Study: The crystal data of copper(I) complexes **4a** and **4d** and copper(II) complexes **5a** and **5b** were collected on a Rigaku AFC7S four-circle diffractometer or a STOE IPDS unit (Imaging Plate Diffraction System) using graphite monochromatized Mo-K_α radiation, $\lambda = 0.71073$ Å, ω-scans. Intensities were corrected for Lorentz and polarization effect.[52] A psi-scans absorption correction was applied for **4d**.[53] The structures of **4a** and **5b** were solved by the Patterson method (SHELXS-86 program), while the structures of **4d** and **5a** were solved primarily by direct methods. A refinement of full-matrix least-squares on F^2 was performed for all reflections with the SHELXL-97 program. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in the final refinement cycle in a riding mode except for those of the methoxy bridges in **5a** and the *tert*-butyl groups of **5b**. In the case of **4d**, one triflate anion is disordered with site occupation factors of 0.25 and 0.75. DFIX was needed to refine both ordered and disordered triflate anions, which stabilize the structure by H bonds through oxygen atom with the macrocycle or its symmetry equivalent.[54,55] The perchlorate anions in **5a** are also disordered. Four oxygen atoms were represented by eight half-populated oxygen atoms. Crystal data of **4a**, **4d**, **5a** and **5b**, details about data collection, analysis and refinement were listed in Tables 1 and 3. CCDC-182382, -182229, -182383 and -182384 for **4a**, **4d**, **5a,** and **5b** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

(Phenylalkyl)palladium Complexes Containing β-Hydrogen Atoms: Synthesis and Characterization of [PdR_2(dppe)], [PdR(SPh)(dppe)] (R = CH_2CH_2Ph, $CH_2CH_2CH_2Ph$, $CH_2CHMePh$), and [Pd($CH_2CH_2CH_2Ph$)X(dppe)] (X = I, Br, Cl)

Thomas Spaniel,[a] Harry Schmidt,[a] Christoph Wagner,[a] Kurt Merzweiler,[a] and Dirk Steinborn*[a]

Keywords: Phenylalkyl complexes / Palladium / β-Hydrogen-containing alkyl ligands / P ligands

Reactions of HgR_2 (R = CH_2CH_2Ph, **1a**; $CH_2CH_2CH_2Ph$, **1b**; $CH_2CHMePh$, **1c**) (prepared from $HgCl_2$ and the requisite Grignard compounds) with lithium in toluene afforded (phenylalkyl)lithium compounds LiR (**2a**–**c**) in yields of between 64 and 81%. At –30 °C, they react with [$PdCl_2$(dppe)] [dppe = 1,2-bis(diphenylphosphanyl)ethane] yielding bis(phenylalkyl)palladium(II) complexes [PdR_2(dppe)] (**3a**–**c**) which were isolated (T_{dec} = 159 °C, **3a**; 80 °C, **3b**; 145 °C, **3c**) and fully characterized by ^1H, ^{13}C, and ^{31}P NMR spectroscopy. Single-crystal X-ray diffraction of [Pd(CH_2CH_2Ph)$_2$(dppe)] (**3a**) showed that the palladium atom is square-planar coordinated by two 2-phenylethyl ligands and the dppe ligand. The two CH_2CH_2Ph ligands exhibite nearly a fully staggered conformation. Overall, a good approximation for the complex is that it has C_2 symmetry with the C_2 axis defined by the Pd atom and the midpoint of the central C–C bond of the dppe ligand. Bis(phenylalkyl)palladium complexes **3a** and **3b** reacted with PhSH in a 1:1 ratio yielding [PdR(SPh)(dppe)] (R = CH_2CH_2Ph, **5a**; $CH_2CH_2CH_2Ph$, **5b**), whereas in the case of complex **3c**, besides [Pd($CH_2CHMePh$)(SPh)(dppe)] (**5c**), a considerable amount of [Pd(SPh)$_2$(dppe)] (**6a**) was formed. Reactions of **3b** with the less acidic alkanethiols *i*PrSH and *t*BuSH resulted in the formation of [Pd($CH_2CH_2CH_2Ph$)(SR′)(dppe)] (R′ = *i*Pr, **5d**; *t*Bu, **5e**) along with smaller amounts of [Pd(SR′)$_2$(dppe)] (**6**) and [Pd(dppe)$_2$] (**7**). Furthermore, complex **3b** was found to react in THF with disulfides R′SSR′ (R′ = Ph, Bz, Me), yielding [Pd($CH_2CH_2CH_2Ph$)(SR′)(dppe)] (R′ = Ph, **5b**; Bz, **5f**, Me, **5g**) with small amounts (3–13%) of [Pd(SR′)$_2$(dppe)] (**6**) as side products. The corresponding reaction with MeSeSeMe afforded [Pd($CH_2CH_2CH_2Ph$)(SeMe)(dppe)] (**8a**) and 3% of [Pd(SeMe)$_2$(dppe)] (**9a**) and [Pd(dppe)$_2$] (**7**). Reactions of complex **5b** with MeI and H_2C=$CHCH_2Br$ in tetrahydrofuran and with neat H_2C=$CHCH_2Cl$ readily proceeded at –30 °C to give halo(3-phenylpropyl)palladium complexes [Pd($CH_2CH_2CH_2Ph$)X(dppe)] (X = I, **10a**; Br, **10b**; Cl, **10c**). They were isolated as pale yellow powdery/microcrystalline substances and fully characterized by ^{13}C and ^{31}P NMR spectroscopy. Solutions of complexes **10** in THF decompose rapidly above –30 °C.

1. Introduction

The Heck reaction has been proven to be a powerful method for the arylation and vinylation of olefins (Scheme 1).[1] Despite the continuous debate on its mechanism,[2] oxidative addition of RX (R = aryl, vinyl, heteroaryl, ...; X = halide, tosylate, triflate, ...) to the Pd catalyst complex yielding an $L_xPd(R)X$ complex (**I**, Scheme 1) followed by olefin insertion (**II**, Scheme 1) are crucial reaction steps in the classic Heck cycle. The reactions of ethene with phenyl and benzyl halides yielding styrene and allylbenzene, respectively, can be considered as the most simple prototypic model reactions for Heck reactions. Complexes of type **I** in Scheme 1 (R = Ph, Bz) are well known.[3] Contrary to type **I**, those of type **II**, (2-phenylethyl)- and (3-phenylpropyl)palladium complexes, have not yet been described. Due to β-hydrogen atoms in the phenylalkyl ligands the thermal stability of these complexes can be expected to be low. Facile β-hydride elimination reactions, in Heck-type catalysts, are discussed as a reason for the alkylation of olefins being restricted to special cases. Alkyl halides R′CH−CH_2X react to form intermediates **I** [$L_xPd(CH_2-CHR')X$], which undergo β-hydride elimination more easily than insertion of the olefin, giving intermediate **II** and opening the reaction channel to the desired products.

Several mononuclear palladium complexes with β-hydrogen-containing acyclic alkyl ligands have been isolated as solids and characterized. These include: (i) dialkyl− and alkyl/aryl−Pd^{II} complexes [PdR_2L_2] [R = Et, *n*Pr, *n*Bu; L_2 = (PR′$_3$)$_2$, dppe, bpy, ...; R_2 = Et/Ar, *n*Bu/Ar, Ar = Aryl],[4] (ii) monoalkyl−Pd^{II} complexes with an anionic

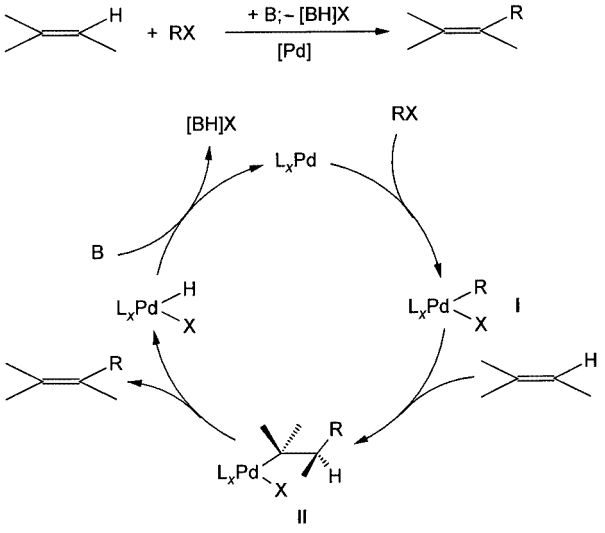


Scheme 1

ligand *trans*-[PdEt(X)(PR′$_3$)$_2$] (X = Cl, Br, I, SPh, OPh, O$_2$CR′),[5] [Pd(CH$_2$CH$_2$CH=CH$_2$)Cl(dppe)],[6] and [PdR(S$_2$CNR′$_2$)(PR′$_3$)] (R = *n*Pr, *i*Pr, *n*Bu, *s*Bu, ...),[7] and (iii) cationic Pd^{II} complexes [PdR{N(CH$_2$CH$_2$PPh$_2$)$_3$}]X (R = Et, *n*Pr, *n*Bu; X = I, BPh$_4$)[8] and [PdEt(η^2-C$_2$H$_4$)(phen)][B{C$_6$H$_3$(CF$_3$)$_2$}$_4$];[9] furthermore, (iv) alkyl-(Et, *n*Pr)–Pd^{IV} complexes with tripodal N-donor and bipyridine co-ligands have been synthesized.[10] Only a few of these complexes could be structurally characterized, namely *trans*-[PdEt(X)(PMe$_3$)$_2$] (X = Br,[5b] SPh[5c]), [PdR{S$_2$CN-(CH$_2$)$_4$}(PEt$_3$)] (R = *n*Pr, *i*Pr),[7b] and [PdEtMe$_2$-{(pz)$_3$BH}].[10d]

Palladium complexes with acyclic β-hydrogen-containing alkyl ligands cover a wide range of stability: PdEtI without supporting ligands already decompose at −100 °C[11] whereas toluene solutions of complexes with dithiocarbamato[7] and tris(pyrazolyl)borate[10d] co-ligands were found to be stable to 60 °C and to at least 80 °C, respectively. On the other hand, many of the above-mentioned complexes are unstable in solution even at room temperature. Preferred decomposition pathways are β-hydrogen elimination and/or reductive elimination in the case of dialkyl complexes. For stereoelectronic reasons organopalladium complexes with β-hydrogen-containing cycloalkyl ligands are thermally more stable.[4b,4c,4f,6,12]

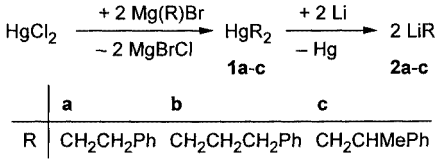
(Phenylalkyl)palladium complexes containing the structural unit Pd–[CH$_2$]$_n$Ph with $n > 1$ [benzyl complexes (n = 1), for which β-hydrogen elimination is lacking, will not be considered here] have not yet been synthesized. Pd(CH$_2$CH$_2$Ph)Cl was proposed as an intermediate in reactions of PdCl$_2$/HgPhCl with ethene and [PdCl$_4$]$^{2-}$ with Hg(CH$_2$CH$_2$Ph)Cl followed by cleavage of the Pd–C bond with CuCl$_2$/LiCl.[13] Furthermore, complexes with CH$_2$–CH$_2$Ph and CHPh–CH$_2$Ph ligands were detected by NMR spectroscopy as intermediates in reactions of phenylpalladium complexes with ethene and styrene, respectively.[14]

Here we report on the synthesis and characterization of (2-phenylethyl)- as well as (2- and 3-phenylpropyl)palladium complexes with bis(diphenylphosphanyl)ethane (dppe) as a stabilizing co-ligand. Reactions of [PdCl$_2$(dppe)] with LiR (R = CH$_2$CH$_2$Ph, CH$_2$CH$_2$CH$_2$Ph, CH$_2$CHMePh) afforded the diorgano complexes [PdR$_2$(dppe)]. Partial protolysis with phenylthiol resulted in formation of mono(phenylalkyl) complexes [PdR(SPh)-(dppe)], whose reactions with organo halides, disulfides and diselenides are described. Furthermore, the molecular structure of the first palladium complex with two β-hydrogen-containing alkyl ligands, [Pd(CH$_2$CH$_2$Ph)$_2$(dppe)], is presented.

2. Results and Discussion

2.1. Synthesis and Characterization of (Phenylalkyl)lithium and -mercury Compounds

The synthesis of (2-phenylethyl)lithium was described in the literature by either a direct synthesis (PhCH$_2$CH$_2$Br + Li),[15] or a lithium/iodide exchange reaction (PhCH$_2$CH$_2$I + *t*BuLi)[16] in diethyl ether. We and others[16b] failed to obtain LiCH$_2$CH$_2$Ph by direct synthesis. By a lithium/iodide exchange reaction we succeeded to obtain LiCH$_2$CH$_2$Ph, although severe impurities due to ether cleavage prevented its use as starting material for the synthesis of organopalladium complexes. Thus, we prepared (phenylalkyl)lithium compounds by transmetalation according to Scheme 2.



Scheme 2

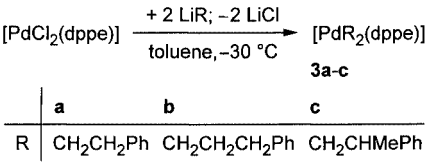
The bis(phenylalkyl)mercury compounds **1a–c** were obtained (Scheme 2) by reaction of the Grignard compounds with mercury chloride in THF/diethyl ether as colorless liquids in moderate to good yields (66–84%). They were characterized by ^{1}H and ^{13}C NMR spectroscopy; all chemical shifts and couplings ($^nJ_{Hg,H}$ and $^nJ_{Hg,C}$, see Exp. Sect.) are in full agreement with expectations. Due to its two equivalent substituted stereogenic centers, the ^{13}C NMR spectrum of Hg(CH$_2$*C*HMePh)$_2$ (**1c**) shows two sets of signals of equal intensity corresponding to *rac* and *meso* forms. Comparison of the $^1J_{Hg,C}$ coupling constants (706 Hz, **1a**; 692 Hz, **1b**; 720 Hz, **1c**) with those of the corresponding non-phenyl-substituted compounds HgEt$_2$ (647 Hz)[17] and Hg(*n*Pr)$_2$ (660 Hz),[17] shows that phenyl substitution in the 2- (**1a**/**1c**) and 3-position (**1b**) gives rise to an increase of the $^1J_{Hg,C}$ coupling constants by 59/60 Hz and 32 Hz, respectively. In terms of Bent's model[18] this indicates a higher electronegativity of phenylalkyl ligands compared with their pure alkyl analogues.

Reactions of bis(phenylalkyl)mercury compounds **1a−c** with lithium in toluene resulted in the formation of (phenylalkyl)lithium compounds **2a−c** in moderate to good yields (64−81%) (Scheme 2). The compounds are stable in toluene at room temperature for days. Despite the use of highly toxic organomercury compounds these transmetalation reactions are superior to all other methods[15,16] because they essentially proceed without side reactions and can be performed in a solvent (toluene) in which the organolithium reagents **2a−c** are stable.

Instead of toluene as a solvent, *n*-pentane can be used for the synthesis of (3-phenylpropyl)lithium (**2b**). This is due to the excellent solubility of **2b** in aliphatic hydrocarbons at room temperature. Without obvious reason the homologous compounds **2a** and **2c** are insoluble in aliphatic hydrocarbons and the transmetalation in these solvents failed. The ^{13}C NMR spectrum of **2b** in perdeuterated *n*-hexane gave evidence for its identity. The signal of the carbon atom attached to the lithium atom is broadened ($b_{1/2} \approx 75$ Hz) due to dynamic processes and/or the quadrupole moment of Li (^{7}Li: $I = 3/2$, 92.6% rel. abund.). Its chemical shift ($\delta = 10.1$ ppm) is in the expected range as compared with other alkyllithium compounds [$\delta(^{13}C_\alpha)$, median: 12.5 ppm; lower/upper quartile: 10.2/17.0 ppm; 17 observations[19]]. The lithium-induced shift in **2b** [$\delta(^{13}C_\alpha)$ in LiR − $\delta(^{13}C_\alpha)$ in HR] amounts to $\delta = 10.1-14.6$ ppm[20] $= -4.5$ ppm, and is somewhat larger than expected for the correlation given in ref.[19] The $^1J_{C,H}$ coupling constant (ca. 94 Hz) is in the range expected for alkyllithium compounds ($^1J_{C,H}$ in $LiCH_3$: 98 Hz[21]).

2.2. Synthesis and Characterization of Bis(phenylalkyl)palladium Complexes

The (phenylalkyl)lithium compounds **2a−c** reacted with [$PdCl_2$(dppe)] in toluene at −30 °C to give bis(phenylalkyl){bis(diphenylphosphanyl)ethane}palladium complexes **3a−c** (Scheme 3). Addition of *n*-pentane resulted in the precipitation of complexes **3a−c**. Note that the choice of solvent determins the success of the synthesis: Despite its low vapor pressure at −30 °C, resulting in a long-lasting procedure to remove it in vacuo at that temperature, toluene is the most preferable one. The (phenylalkyl)lithium compounds **2** are freely soluble in toluene even at −78 °C and they are indefinitely stable in toluene, which is not the case for ethereal solvents.



Scheme 3

Complexes **3a−c** were isolated in yields between 68 and 84% as colorless (**3a/b**) and yellowish (**3c**) microcrystalline substances that are moderately air-sensitive. Heating by a rate of about 4 K/min resulted in decomposition at about 159 °C (**3a**), 80 °C (**3b**) and 145 °C (**3c**). Solutions of these complexes in toluene are stable at −30 °C for several days although decomposition occurs at room temperature within several hours.

The identities of complexes **3** were unambiguously confirmed by ^1H, ^{13}C and ^{31}P NMR spectroscopy and also by X-ray crystallography for **3a**. Selected NMR spectroscopic data are shown in Table 1 along with the data of the dimethyl complex [$PdMe_2$(dppe)] (**4**) for comparison. As for the mercury compound **1c**, ^1H, ^{13}C, and ^{31}P NMR spectra of the 2-phenylpropyl complex [$Pd(CH_2CHMePh)_2$(dppe)] (**3c**) show two sets of signals in a 1:1 ratio due to the existence of *rac* and *meso* forms. Furthermore, in the ^{13}C NMR spectrum of **3c** a further signal splitting for the phenyl carbon atoms of the dppe ligand (e.g. four different C_o signals with coupling to the phosphorus atom, see Exp. Sect.) was observed indicating a pairwise inequivalence of the phenyl groups of the dppe ligand. This was expected as the two asymmetric carbon atoms reduce the symmetry (C_{2v} in terms of the NMR time scale) of simple [PdR_2(dppe)] complexes to C_2 in the *rac* form and C_s in the *meso* form.

Coupling with the magnetically inequivalent P atoms resulted in higher order multiplets of AA′X or − taking into account the isotopic shift of ^{13}C − ABX spin systems (A, B = ^{31}P; X = ^{13}C) for the ^{13}C resonances. For the dimethyl compound [$PdMe_2$(dppe)] (**4**) a complete set of $^nJ(^{31}P,^{13}C)$ coupling constants was obtained by spectral analysis using the program package PERCH[22] (cf. Table 1 and Exp. Sect.). For the methyl carbon atoms (signal pattern 'dd', pseudo-doublet of doublet with roof effect) and the methylene carbon atoms (signal pattern 't', pseudo-triplet) the results obtained by computer analysis are very similar to the results obtained when the signals are handled as first-order multiplets: CH_3: $^2J(P,C_{trans}) = 107.3$ Hz vs. 107.5 Hz, $^2J(P,C_{cis}) = 10.1$ Hz vs. 9.7 Hz; CH_2: $^{1+4}J_{P,C}/^{2+3}J_{P,C} = 19.7/21.9$ Hz (with opposite sign, assignment tentative) vs. 21.5 Hz. Thus, it seems to be justified to obtain approximate coupling constants by a "first-order treatment" as was done for complexes **3** (cf. Table 1).

The α-carbon signals in (phenylalkyl)palladium complexes **3a−c** are strongly lowfield-shifted compared with that in [$PdMe_2$(dppe)] (**4**) ($\delta = 24.9-33.6$ ppm vs. 1.9 ppm). In the couplings of α-carbon atoms to phosphorus atoms ($^2J_{P,C}$) only smaller differences between **3a−c** (*trans* coupling 100−101 Hz; *cis* coupling 9 Hz) and the dimethyl complex **4** (*trans* coupling 107.3 Hz; *cis* coupling 10.1 Hz) were found. The phosphorus chemical shifts are in the order 2-phenyl-substituted alkyl (**3a/c**: $\delta = 38.6-40.3$ ppm) < 3-phenyl-substituted alkyl (**3b**: $\delta = 43.6$ ppm) < Me (**4**: $\delta = 45.6$ ppm).

Single crystals of the 2-phenylethyl complex **3a**, which were suitable for X-ray diffraction analysis were grown from THF/pentane. The molecular structure of complex **3a** is shown in Figure 1, and selected bond lengths and angles are compiled in Table 2. Complex **3a** crystallizes as separate molecules without unusual intermolecular interactions; the shortest ones between non-hydrogen atoms are C···C distances of more than 3.5 Å. The palladium atom, to a good

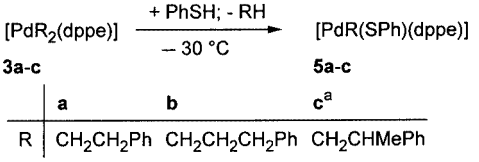
approximation, is square-planar coordinated by two carbon atoms and two phosphorus atoms [greatest deviation of the least-squares plane: Pd 0.018(1) Å]. The five-membered PdP_2C_2 ring is twisted about C17−C18. The phenyl rings of the dppe ligand are arranged in a typical "face-to-edge"[23] position (face: Ph37/Ph19; edge: Ph31, Ph25; phenyl groups are designated by Ph*x*, where *x* is the number of the *ipso*-carbon atom). The bite of the dppe ligand [P1−Pd−P2 85.53(8)°] is as expected (median: 85.0°; lower/higher quartile: 84.3/85.6°; number of values: 52[24]). The opposite C1−Pd−C9 angle [85.8(2)°] is also markedly smaller than 90°.

As shown by the torsion angles Pd−C1−C2−C3 [178.0(4)°] and Pd−C9−C10−C11 [165.0(4)°] the two 2-phenylethyl ligands exhibit a nearly fully staggered conformation. The Pd−C1−C2/Pd−C9−C10 [112.6(4)/111.2(3)°] and C1−C2−C3/C9−C10−C11 [112.6(5)/114.8(4)°] angles are nearly tetrahedral. The phenyl groups of the 2-phenylethyl ligands are nearly parallel to the complex plane [Ph3/PdP_2C_2 10.8(2)°; Ph11/PdP_2C_2 14.2(3)°] and nearly perpendicular to the face-positioned phenyl groups of the dppe ligand [Ph3/Ph19 80.7(3)°; Ph11/Ph37 89.8(3)°]. Thus, the complex, to a good approximation, is C_2-symmetric with the C_2 axis defined by the Pd atom and the midpoint of the central C17−C18 bond of the dppe ligand.

2.3. Synthesis and Characterization of (Phenylalkyl)(thiolato)palladium Complexes

Yamamoto[5b,25] showed that *trans*-$[PdEt_2(PMe_3)_2]$ and $[PdMe_2(dppe)]$ react selectively with equimolar amounts of PhSH with protolytic cleavage of one of the two Pd−C bonds yielding *trans*-$[PdEt(SPh)(PMe_3)_2]$ and [PdMe(SPh)(dppe)], respectively. The analogous reaction of bis(phenylalkyl)palladium complexes **3a−c** proceeded according to Scheme 4. In the case of the 2-phenylethyl (**3a**) and 3-phenylpropyl (**3b**) complexes the protolytic cleavage of the first Pd−C bond proceeded faster than that of the second one. Thus, at −30 °C using a 1:1 ratio of **3a/3b** and PhSH the desired (phenylalkyl)(thiolato) complexes **5a** and **5b** were obtained. On the other hand, under the same reaction conditions the 2-phenylpropyl complex **3c** reacted with PhSH (1:1) to yield both the mixed complex **5c** (15%) and $[Pd(SPh)_2(dppe)]$ (**6a**) to a remarkable extent (16%) as shown by ^{31}P NMR spectroscopy. Successive additions of further quantities of PhSH (calculated 1:1 in relation to the amount of unchanged starting complex **3c** detected in the



Scheme 4. [a] $[Pd(SPh)_2(dppe)]$ (**6a**) was also formed

^{31}P NMR spectrum) until **3c** had been completely consumed resulted in a mixture of **5c** and **6a** of about 3:1.

The less acidic alkanethiols *i*PrSH and *t*BuSH reacted slower with the 3-phenylpropyl complex **3b** than with PhSH (Scheme 5): At −30 °C the reaction was incomplete even after six days of reaction time. Increasing the temperature to −15 °C for one day and to 0 °C for eight days, resulted in the formation of [Pd($CH_2CH_2CH_2Ph$)(SR′)(dppe)] in 77% (R′ = *i*Pr, **5d**) and 82% yield (R′ = *t*Bu, **5e**). Side products were the bis(thiolato) complexes **6b** (R′ = *i*Pr; 13%) and **6c** (R′ = *t*Bu; 8%), and [Pd(dppe)$_2$] (**7**; 2% for R′ = *i*Pr; 7% for R′ = *t*Bu) as the reduction product. Comparing *i*PrSH and *t*BuSH, the protolytic cleavage of the second Pd−C bond yielding **6c** is less favoured, although the reduction yielding **7** is more favoured with *t*BuSH, which might be explained because of its lower acidity *and* its greater bulkiness.

[PdR$_2$(dppe)] + R′SH → [PdR(SR′)(dppe)] + [Pd(SR′)$_2$(dppe)] + [Pd(dppe)$_2$]

8 d, 0 °C	8/3	77/82	13/8	2/7

Scheme 5. R = $CH_2CH_2CH_2Ph$; [a] temperature regime, see text; [b] composition of reaction mixture in % for R′ = *i*Pr/*t*Bu

The (phenylalkyl)(thiolato) complexes **5a** and **5b** were isolated as colorless (**5a**) and pale pink (**5b**) slightly air-sensitive, microcrystalline substances. The solids decomposed at 145 °C (**5a**) and 90 °C (**5b**). Solutions in tetrahydrofuran were stable at −30 °C; at room temperature they decomposed slowly. The identities of (phenylalkyl)(thiolato) complexes **5a** and **5b** were confirmed by ^{1}H, ^{13}C and ^{31}P NMR spectroscopy. The bis(thiolato) complexes **6** were characterized by ^{31}P NMR spectroscopy and by comparison with authentic samples prepared by reaction of [PdCl$_2$(dppe)] with LiSR′. Substitution of a phenylalkyl ligand by PhS (**3a/b** → **5a/b**) gives rise to a slight (δ = 1.5/4.1 ppm) lowfield shift of the C1 signal of the remaining phenylalkyl ligand. In complexes **5a/b** the signals of the P atoms *trans* to the carbon atoms are shifted to higher field [**5a/b**: δ($^{31}P_{trans\ to\ C}$) = 34.5/34.0 ppm] relative to those in the analogous bis(phenylalkyl) complexes [**3a/b**: δ(^{31}P) = 40.3/43.6 ppm] and those *trans* to sulfur atoms are lowfield-shifted [**5a/b**: δ($^{31}P_{trans\ to\ S}$) = 53.2/53.1 ppm]. Very similar to the latter one is the phosphorus shift in the bis(thiolato) complex [Pd(SPh)$_2$(dppe)] (**6a**) (δ = 55.4 ppm).

Apart from protolytic cleavage of the Pd−C bonds with alkanethiols (vide supra), reactions of bis(phenylalkyl)palladium complexes **3** with diorgano disulfides are another access to (phenylalkyl)(thiolato)palladium complexes **5**. Thus, reactions of R′SSR′ (R′ = Ph, Bz, Me) with the (3-phenylpropyl)palladium complex **3b** were performed (Scheme 6). PhSSPh exhibited the highest reactivity. It reacted already at −30 °C (to a small extent even at −50 °C) whereas for reactions of BzSSBz and MeSSMe, the temperature had to be increased to 0 °C and 15 °C, respectively. Side products were the bis(thiolato) complexes [Pd(SR′)$_2$(dppe)] (**6**) in all cases.

[PdR$_2$(dppe)] (**3b**) + R′SSR′ → [PdR(SR′)(dppe)] (**5b, 5f, 5g**) + [Pd(SR′)$_2$(dppe)] (**6a, 6d, 6e**)

R′	*t*, *T*	**3b**	**5**	**6**
Ph	5 d, -30 °C	7[a]	90 (**5b**)	3 (**6a**)
Bz	19 d, 0 °C	75	17 (**5f**)	8 (**6d**)
Me	6 d, 15 °C	64	22 (**5g**)	13 (**6e**)[b]

Scheme 6. R = $CH_2CH_2CH_2Ph$; [a] composition of reaction mixture in %; [b] small amounts of [Pd(dppe)$_2$] (**7**) were formed

In analogous reactions diorgano diselenides exhibited a higher reactivity than diorgano disulfides. Thus, at −30 °C, in tetrahydrofuran, reactions of MeSeSeMe with [Pd($CH_2CH_2CH_2Ph$)$_2$(dppe)] (**3b**) afforded the formation of [Pd($CH_2CH_2CH_2Ph$)(SeMe)(dppe)] (**8a**) (73%) and [Pd(SeMe)$_2$(dppe)] (**9a**) (3%), within one day. Formation of 3% [Pd(dppe)$_2$] (**7**) after a further day of reaction indicated a relatively low stability of **8a**. [PdMe$_2$(dppe)] (**4**) reacted with PhSeSePh at −30 °C completely, yielding 91% [PdMe(SePh)(dppe)] (**8b**) and 9% [Pd(SePh)$_2$(dppe)] (**9b**), within one day. No indication for the formation of organopalladium(IV) complexes as intermediates was found in any of the reactions. Analogous reactions between [PdMe$_2$L$_2$] (L$_2$ = bpy, phen) and PhEEPh (E = S, Se) afforded complexes [PdMe$_2$(EPh)$_2$L$_2$] that are unstable for E = S and moderately stable for E = Se.[26] This is further support for the far greater versatility of nitrogen-donor ligands in stabilizing palladium(IV) than that of phosphane ligands.[27]

2.4. Synthesis and Characterization of Halo(3-phenylpropyl)palladium Complexes

The (3-phenylpropyl)(phenylthiolato) complex **5b** reacted with organo halides RX with substitution of the phenylthiolato ligand by the halide yielding halo(3-phenylpropyl)palladium complexes **10a−c** (Scheme 7). Due to the low thermal stability of the products, reactions were performed at −30 °C in tetrahydrofuran as solvent or in neat RX. The reactivity of RX followed the expected order of X (I > Br > Cl) and R (allyl > alkyl). To obtain a complete degree

[Pd($CH_2CH_2CH_2Ph$)(SPh)(dppe)] (**5b**) + RX; − RSPh (thf; −30 °C) → [Pd($CH_2CH_2CH_2Ph$)X(dppe)] (**10a-c**)

	a	**b**	**c**
X	I	Br	Cl
R	Me	$H_2C{=}CHCH_2$	$H_2C{=}CHCH_2$

Scheme 7

of conversion, a threefold excess of methyl iodide was necessary; ethyl bromide did not react at all. Allyl bromide reacted quantitatively when a 50-fold excess was used. In neat allyl chloride complex **10c** was obtained with a 94% degree of conversion whereas allyl fluoride did not react at all. *trans*-[PdEt(SPh)(PMe_3)$_2$] proved to be more reactive than complex **5b** and reacted with MeI, $PhCH_2Br$ and $H_2C{=}CHCH_2Cl$ in a 1:1 ratio yielding *trans*-[PdEt(X)(PMe_3)$_2$] (X = I, Br, Cl) in > 80% yields.[5b]

The iodo (**10a**), bromo (**10b**) and chloro (**10c**) complexes were isolated as yellow (**10a**) and pale yellow (**10b**, **c**) powdery/microcrystalline substances that are moderately air-sensitive. Heating by about 4 K/min results in a decomposition at about 80 °C (**10b**) and 140 °C (**10c**). Solids can be handled at room temperature without noticeable decomposition for a short period of time. Solutions in tetrahydrofuran decompose rapidly above −30 °C, turning intensively violet.

The identities of complexes **10** were confirmed by ^{13}C and ^{31}P NMR spectroscopy. Selected values are shown in Table 3. Substitution of the 3-phenylpropyl ligand by bromide and chloride (**3b** → **10b/c**) gives rise to a lowfield shift of C1 by 4.1 and 6.1 ppm, respectively, whereas substitution by iodide (**3b** → **10a**) leaves the C1 chemical shift practically unchanged. Analogous to mono(phenylalkyl)(thiolato) complexes **5**, P atoms *trans* to the carbon atom resonate at higher fields than those *trans* to the halide ligand (δ = 27.7−30.2 vs. 56.1−59.5 ppm).

In the present investigation (2- and 3-phenylalkyl)palladium complexes have been prepared and fully characterized for the first time. All of them contain β-hydrogen atoms and proved to be − at least in solution − of low thermal stability. This is especially pronounced in the *cis*-halo(3-phenylpropyl)palladium complexes [Pd($CH_2CH_2CH_2Ph$)X(dppe)] (**10a**−**c**; X = I, Br, Cl) that are − most likely − intermediates in the catalytic Heck cycle.[1b]

Experimental Section

1. General Comments: All reactions were performed under argon using standard Schlenk techniques. Solvents were dried prior to use: Et_2O, THF, and toluene with Na/benzophenone, *n*-hexane, *n*-pentane and [D_8]THF with $LiAlH_4$. ^1H, ^{13}C, and ^{31}P NMR spectra were recorded with Gemini 200, VXR 400 and Unity 500 NMR spectrometers (Varian). For ^1H and ^{13}C NMR spectra the protio impurities of the deuterated solvent or the solvent signals were used as internal references. For ^{31}P NMR spectra H_3PO_4 (85%) was used as the external reference. In higher order multiplets *N* gives the distance between the two most intense lines. In pseudo-triplets ('t') and pseudo-doublets of doublets ('dd') *N* was derived like couplings in first-order triplets and doublets of doublets, respectively. A CP9000 chromatograph (Chrompack) was used for chromatographic analyses. GC/MS investigations were carried out with an HP 5890 Series II/HP 5972 (Hewlett−Packard). [$PdCl_2$(dppe)] and [Pd(dppe)$_2$] were prepared according to literature methods.[28,29] Reactions of LiSR (R = Ph, *i*Pr, *t*Bu, Bz, Me) [obtained from RSSR and (*n*BuLi)] with [$PdCl_2$(dppe)] afforded complexes [Pd(SR)$_2$(dppe)] (**6a**−**e**) in yields between 40 and 85%. ^{31}P NMR (81 MHz, [D_8]THF): δ = 55.4 (in $CDCl_3$; R = Ph, **6a**), 56.7 (R = *i*Pr, **6b**), 54.3 (R = *t*Bu, **6c**), 58.2 (R = Bz, **6d**), 57.6 (R = Me, **6e**) ppm. Other chemicals were commercially available.

2. HgR_2 (R = CH_2CH_2Ph, 1a; $CH_2CH_2CH_2Ph$, 1b; $CH_2CHMePh$, 1c): Solutions of Grignard compounds RMgBr in diethyl ether (0.7−0.9 M) were prepared following a standard procedure[30] from Mg and RBr. Yields (93−97%) were determined by acidimetric titration. Only solutions of Grignard compounds free from unchanged RBr (checked by GC/MS) were used. These solutions of RMgBr (40.5 mmol) were added dropwise to a solution of $HgCl_2$ (5.0 g, 18.4 mmol) in THF (20 mL) at −78 °C. The reaction mixture was slowly warmed to room temperature and stirred for 2 days. At −78 °C, water (20 mL) was added dropwise. The organic phase was separated, washed with water and dried with Na_2SO_4. The solvent was removed in vacuo. Finally, the temperature was raised to 50 °C (0.1 Torr) to remove all volatile substances. ***Warning!*** All manipulations with the highly toxic organomercurials were done in a separate fume hood using appropriate safety requirements, above all, a special combination of gloves.[31] All glassware used in these syntheses was treated with a solution of bromine in methanol to convert highly toxic organomercurials into less toxic $HgBr_2$.

Compound 1a (R = CH_2CH_2Ph): Colorless oil. Yield: 5.3 g (70%). ^1H NMR (200 MHz, $CDCl_3$): δ = 1.29 ('t' + dt, *N* = 7.7, $^2J_{Hg,H}$ = 96.7 Hz, 4 H, $HgCH_2$), 3.05 ('t' + dt, *N* = 7.7, $^3J_{Hg,H}$ = 112.3 Hz, 4 H, $HgCH_2CH_2$), 7.12−7.33 (m, 10 H, Ph) ppm. ^{13}C NMR (100 MHz, $CDCl_3$): δ = 34.8 (s, $HgCH_2CH_2$), 45.0 (s + d, $^1J_{Hg,C}$ = 706.5 Hz, $HgCH_2$), 125.4 (s, *m*-*C*),[32] 127.9 (s, *p*-*C*), 128.4 (s, *o*-*C*), 147.3 (s, *i*-*C*).

Compound 1b (R = $CH_2CH_2CH_2Ph$): Colorless oil. Yield: 5.3 g (66%). ^1H NMR (400 MHz, $CDCl_3$): δ = 0.77 ('t' + dt, *N* = 7.2, $^2J_{Hg,H}$ = 100.0 Hz, 4 H, $HgCH_2$), 2.13 ('quint' + dt, *N* = 7.2, $^3J_{Hg,H}$ = 112.3 Hz, 4 H, $HgCH_2CH_2$), 2.58 ('t', *N* = 7.2 Hz, 4 H, $HgCH_2CH_2CH_2$), 7.13−7.19 (m, 6 H, Ph), 7.27−7.30 (m, 4 H, Ph) ppm. ^{13}C NMR (100 MHz, $CDCl_3$): δ = 30.5 (s + d, $^2J_{Hg,C}$ = 33.2 Hz, $HgCH_2CH_2$), 40.2 (s + d, $^3J_{Hg,C}$ = 83.8 Hz, $HgCH_2CH_2CH_2$), 41.7 (s + d, $^1J_{Hg,C}$ = 692.0 Hz, $HgCH_2$), 125.7 (s, *p*-*C*), 128.3/128.6 (s/s, *o*-, *m*-*C*), 142.9 (s, *i*-*C*) ppm.

Compound 1c (R = $CH_2CHMePh$, 1:1 Mixture of Two Diastereomers): Colorless oil. Yield: 6.8 g (84%). ^1H NMR (400 MHz, $CDCl_3$): δ = 1.22 (d, $^3J_{H,H}$ = 7.0 Hz, 2 × 6 H, CH_3), 1.28 (centered, m, 2 × 4 H, $HgCH_2$), 3.41−3.52 (m, 2 × 2 H, $HgCH_2CH$), 7.11−7.18, 7.22−7.28 (m, 2 × 10 H, Ph) ppm. ^{13}C NMR (100 MHz, $CDCl_3$): δ = 26.50/26.51 (s/s, CH_3), 39.46/39.49 (s/s, $HgCH_2CH$), 54.46/54.49 (s + d/s + d, $^1J_{Hg,C}$ = 720.2/720.2, $HgCH_2$), 2 × 125.6 (s, *p*-*C*), 2 × 126.3/128.3/128.4 (s/s/s, *o*-, *m*-*C*), 151.66/151.68 (s/s, *i*-*C*) ppm.

3. Synthesis of LiR (R = CH_2CH_2Ph, 2a; $CH_2CH_2CH_2Ph$, 2b; $CH_2CHMePh$, 2c): A solution of HgR_2 (**1**) (ca. 7 mmol) in toluene (ca. 15 mL) was stirred for 2 days with freshly cut lithium chips (ca. 75 mmol) at room temperature. The lithium amalgam formed was allowed to settle and the supernatant was filtered [yield (acidimetric): 64%, **2a**; 81%, **2b**; 80%, **2c**]. For isolation of compound **2b**, the reaction was performed in *n*-pentane. Removal of solvent in vacuo resulted in an orange oil that was dissolved in $[D_{14}]$*n*-hexane for NMR spectroscopic investigations.

Compound 2b (R = $CH_2CH_2CH_2Ph$): ^{13}C NMR (100 MHz, $[D_{14}]$*n*-hexane): δ = 10.1 (br., t, $^1J_{C,H} \approx 94$ Hz, Li*C*H_2), 31.0 (t, $^1J_{C,H}$ = 121.8 Hz, LiCH$_2$*C*H_2), 44.2 (t, $^1J_{C,H}$ = 126.6 Hz, LiCH$_2$CH$_2$*C*H_2), 125.7 (dt, $^1J_{C,H}$ = 159.9, $^2J_{C,H}$ = 7.4 Hz, *p*-*C*), 128.3 (dd, $^1J_{C,H}$ = 158.9, $^2J_{C,H}$ = 7.6 Hz, *o*-*C*), 128.7 (dt, $^1J_{C,H}$ = 156.3, $^2J_{C,H}$ = 5.9 Hz, *m*-*C*), 142.6 (s, *i*-*C*). Couplings refer to H-coupled spectrum.

4. [PdR$_2$(dppe)] (R = CH_2CH_2Ph, 3a; $CH_2CHMePh$, 3c): At −78 °C, 1.9 equiv. of LiCH_2CH_2Ph (**2a**) or Li$CH_2CHMePh$ (**2c**) in toluene (20−25 mL) was added to [PdCl$_2$(dppe)] (ca. 3 mmol). The reaction mixture was slowly warmed to −30 °C and stirred overnight. The filtered solution was concentrated to about 5 mL in vacuo at −30 °C. Cooling to −78 °C and addition of *n*-pentane (ca. 25 mL) resulted in precipitation of **3a** or **3c**, respectively, that were filtered off, washed with *n*-pentane (2 × 5 mL) and dried in vacuo at −30 °C.

Complex 3a (R = CH_2CH_2Ph): Colorless microcrystalline powder. Yield: 68%. ^1H NMR (400 MHz, $[D_8]$THF): δ = 1.62 (m, 4 H, PdCH_2), 2.25 (m, *N* = 17.8 Hz, 4 H, PCH_2), 2.65 (m, 4 H, PdCH$_2$CH_2), 6.87 (m, 6 H, Ph), 7.01 (m, 4 H, Ph), 7.43 (m, 12 H, Ph), 7.65 (m, 8 H, Ph) ppm. ^{13}C NMR (125 MHz, −30 °C, $[D_8]$THF): 27.9 ('t', *N* = 21.2 Hz, P*C*H$_2$), 28.6 ('dd', *N* = 101.4/9.3 Hz, Pd*C*H$_2$), 39.7 (s, PdCH$_2$*C*H$_2$), 124.7 (s, *p*-C_{Ph}), 128.4/128.6 (s/s, *o*-C_{Ph}/*m*-C_{Ph}), 129.5 (m, *N* = 8.7 Hz, *m*-C_{dppe}), 130.9 (s, *p*-C_{dppe}), 134.3 (m, *N* = 12.6 Hz, *o*-C_{dppe}), 134.4 (m, superposed, *N* = 29.4 Hz, *i*-C_{dppe}), 150.3 (m, *N* = 10.7 Hz, *i*-C_{Ph}) ppm. ^{31}P NMR (202 MHz, −30 °C, $[D_8]$THF): δ = 40.3 (s) ppm.

Complex 3c (R = $CH_2CHMePh$; 1:1 Mixture of Two Diastereomers): Yellow microcrystalline powder. Yield: 69%. ^1H NMR (200 MHz, $CDCl_3$): δ = 0.92/0.99 (m/m, *N*/*N* = 6.8/6.8 Hz, 6/6 H, CHCH_3), 1.22−2.49 (m, 2 × 8 H, PCH_2 + PdCH_2), 3.05 (m, 2 × 2 H, C*H*Me), 6.9−7.2, 7.3−7.7 (m, 2 × 30 H, Ph) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 25.9/26.6 (s/s, CH*C*H$_3$), 26.9/26.9 ('t', *N* = 20.9 Hz, P*C*H$_2$), 33.5/33.6 ('dd'/'dd', *N* = 99.7/9.0 Hz/100.8/8.9 Hz, Pd*C*H$_2$), 42.4/42.5 (s/s, PdCH$_2$*C*H), 124.1/124.2 (s/s, *p*-*C*), 126.5/126.6/127.6/127.7 (s/s/s/s, *o*-*C*, *m*-*C*), 128.4/128.5/128.6/128.7 (m/m/m/m, *N* = 9.0/9.0/9.0/9.0 Hz, *m*-C_{dppe}), 129.5/2 × 129.9/130.4 (s/s/s, *p*-C_{dppe}), 132.5/133.3/133.5/134.3 (m/m/m/m, *N* = 10.9/11.9/13.9/13.9 Hz, *o*-C_{dppe}), 132.7/133.9 (m, *N* = 29.0/30.0 Hz, *i*-C_{dppe}, 2 × *i*-C_{dppe} not found due to superposition), 154.0/154.2 (m/m, *N* = 8.0/9.0 Hz, *i*-*C*) ppm. ^{31}P NMR (81 MHz, $CDCl_3$): δ = 38.6/39.7 (s/s) ppm.

5. [Pd(CH$_2$CH$_2$CH$_2$Ph)$_2$(dppe)] (3b): At −78 °C, a solution of Li$CH_2CH_2CH_2Ph$ (**2b**) (34.2 mmol) in toluene (50 mL) was added to [PdCl$_2$(dppe)] (3.30 g, 5.73 mmol). The reaction mixture was slowly warmed to −30 °C and stirred overnight. The colorless precipitate was filtered off and washed at room temperature with *n*-pentane as long as the filtrate remained colorless (ca. 20 mL). The precipitate was dissolved in toluene (100 mL) at room temperature and immediately filtered. At −30 °C, the solution was concentrated in vacuo to about 10 mL. Cooling to −78 °C and addition of *n*-pentane (ca. 50 mL) resulted in the formation of **3b** as a colorless microcrystalline precipitate that was filtered off, washed with *n*-pentane (2 × 5 mL) and dried in vacuo at −30 °C. Yield: 3.56 g (84%). ^1H NMR (400 MHz, $[D_8]$THF): δ = 1.44 (m, 4 H, PdCH_2), 1.67 (m, 4 H, PdCH$_2$CH_2), 2.20 (m, *N* = 17.8 Hz, 4 H, PCH_2), 2.31 ('t', *N* = 7.8 Hz, 4 H, PdCH$_2$CH$_2$CH_2), 6.87−7.60 (m, 30 H, Ph) ppm. ^{13}C NMR (125 MHz, $[D_8]$THF, −30 °C): δ = 24.9 ('dd', *N* = 100.7/9.1 Hz, Pd*C*H$_2$), 28.2 ('t', *N* = 20.9 Hz, P*C*H$_2$), 35.9 (s, PdCH$_2$*C*H$_2$), 44.0 (m, *N* = 10.9 Hz, PdCH$_2$CH$_2$*C*H$_2$), 125.3 (s, *p*-C_{Ph}), 128.3/129.1 (s/s, *o*-C_{Ph}, *m*-C_{Ph}), 129.3 (m, *N* = 9.9 Hz, *m*-C_{dppe}), 130.6 (s, *p*-C_{dppe}), 134.1 (m, *N* = 12.9 Hz, *o*-C_{dppe}), 134.9 (m, *N* = 26.9 Hz, *i*-C_{dppe}), 145.1 (s, *i*-C_{Ph}) ppm. ^{31}P NMR (81 MHz, $[D_8]$THF): δ = 43.6 (s) ppm.

6. [PdMe$_2$(dppe)] (4): In a modified synthesis to that described in ref.[33], a solution of MeLi (6.25 mmol) in diethyl ether (24 mL) was added to [PdCl$_2$(dppe)] (2.00 g, 3.47 mmol) at −78 °C. The reaction mixture was slowly warmed to −30 °C, stirred overnight and filtered. At −30 °C the solvent was distilled off in vacuo and toluene (20 mL) was added to the residue. The precipitated LiCl was filtered off and the solution was concentrated to about 5 mL in vacuo at −30 °C. At −78 °C the addition of *n*-pentane (ca. 30 mL) resulted in the formation of **4** as a colourless precipitate that was filtered off, washed with *n*-pentane (2 × 10 mL) and dried in vacuo at −30 °C. Yield: 0.95 g (51%). ^1H NMR (400 MHz, $CDCl_3$): δ = 0.41 (m, *N* = 0.8 Hz, *N*′ = 14.1 Hz, 6 H, PdCH_3; *N*′: distance of the two outer lines lower in intensity), 2.22 (m, *N* = 18.2 Hz, 4 H, PCH_2), 7.32−7.42 (m, 12 H, Ph), 7.57−7.83 (m, 8 H, Ph) ppm. ^{13}C NMR (100 MHz, $[D_8]$THF), for analysis PERCH[22] program package was used: δ = 1.95 (m, *trans*-$^2J_{P,C}$ = 107.3 Hz, *cis*-$^2J_{P,C}$ = 10.1 Hz, Pd*C*H$_3$), 28.5 (m, $^{1+4}J_{P,C}$/$^{2+3}J_{P,C}$ = 19.7/21.9 Hz, P*C*H$_2$; with opposite signs, assignment tentative), 129.5 (m, $^3J_{P,C}$ = 8.6, $^5J_{P,C}$ = 0.5 Hz, *m*-*C*), 130.9 (s, *p*-*C*), 134.2 (m, $^2J_{P,C}$ = 13.6, $^4J_{P,C}$ = −1.1 Hz, *o*-*C*), 135.0 (m, $^1J_{P,C}$ = 28.8 Hz, $^{3+4}J_{P,C}$ = 1.9 Hz, *i*-*C*) ppm. ^{31}P NMR (81 MHz, $[D_8]$THF): δ = 45.6 (s) ppm.

7. [Pd(CH$_2$CH$_2$Ph)(SPh)(dppe)] (5a): At −78 °C, PhSH (77 mg, 0.70 mmol) in THF (15 mL) was added to a solution of [Pd(CH$_2$CH$_2$Ph)$_2$(dppe)] (**3a**) (500 mg, 0.70 mmol) in THF (15 mL). After warming to −30 °C, the reaction mixture was stirred overnight. At −30 °C, the precipitate formed was filtered off, washed with pentane (2 × 10 mL) and dried in vacuo. Yield: 251 mg (50%). ^1H NMR (200 MHz, $CDCl_3$): δ = 1.53 (m, 2 H, PdCH_2), 2.00−2.48 (m, 4 H, PCH_2), 2.22 (m, 2 H, PdCH$_2$CH_2), 6.0−6.2, 6.8−7.0, 7.2−7.8 (m, 30 H, Ph) ppm. ^{13}C NMR (100 MHz, $CDCl_3$): δ = 26.1 (dd, $^{1+4}J_{P,C}$ = 24.7 Hz, $^{2+3}J_{P,C}$ = 14.7 Hz, P*C*H$_2$), 29.4 (dd, $^{1+4}J_{P,C}$ = 28.2 Hz, $^{2+3}J_{P,C}$ = 22.0 Hz, P*C*H$_2$), 30.1 (d, $^2J_{Ptrans,C}$ = 91.6 Hz, Pd*C*H$_2$), 37.0 (d, $^3J_{Ptrans,C}$ = 4.2 Hz, PdCH$_2$*C*H$_2$), 122.9 (s, *p*-C_{SPh}), 124.2 (s, *p*-C_{Ph}), 127.3/127.4/128.0 (s/s/s, *o*-C_{Ph}, *m*-C_{Ph}, *m*-C_{SPh}), 128.8 (d, $^3J_{P,C}$ = 9.6 Hz, *m*-C_{dppe}), 129.0 (d, $^3J_{P,C}$ = 10.4 Hz, *m*-C_{dppe}), 130.3 (d, $^1J_{P,C}$ = 43.1 Hz, *i*-C_{dppe}), 130.4 (d, $^4J_{P,C}$ = 2.5 Hz, *p*-C_{dppe}), 131.0 (d, $^4J_{P,C}$ = 2.5 Hz, *p*-C_{dppe}), 132.1 (d, $^1J_{P,C}$ = 28.6 Hz, *i*-C_{dppe}), 133.3 (d, $^2J_{P,C}$ = 12.5 Hz, *o*-C_{dppe}), 133.7 (d, $^2J_{P,C}$ = 12.0 Hz, *o*-C_{dppe}), 135.7 (d, $^4J_{Ptrans,C}$ = 1.6 Hz, *o*-C_{SPh}), 144.5 (m, *i*-C_{Ph}), 147.0 (dd, $^3J_{Ptrans,C}$ = 13.1, $^3J_{Pcis,C}$ = 3.1 Hz, *i*-C_{SPh}) ppm. ^{31}P NMR (81 MHz, $CDCl_3$): δ = 34.5 (d, $^{2+3}J_{P,P}$ = 26.9 Hz, P_{trans} to CH_2CH_2Ph), 53.2 (d, $^{2+3}J_{P,P}$ = 26.9 Hz, P_{trans} to SPh) ppm.

8. [Pd(CH$_2$CH$_2$CH$_2$Ph)(SPh)(dppe)] (5b): At −78 °C, PhSH (244 mg, 2.21 mmol) in THF (90 mL) was slowly added to a solution of [Pd(CH$_2$CH$_2$CH$_2$Ph)$_2$(dppe)] (**3b**) (1.644 g, 2.21 mmol) in THF (90 mL). After warming to −30 °C, the reaction mixture was stirred overnight. At −30 °C the solution was concentrated in vacuo to 5 mL and at −78 °C pentane (25 mL) was added. At −30

°C the pale pink precipitate that formed was filtered off, washed with pentane (2 × 10 mL) and dried in vacuo. Yield: 1.54 g (95%). ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.12 (m, 2 H, PdCH_2), 1.37 (m, 2 H, PdCH$_2$CH_2), 1.71 (m, 2 H, PdCH$_2$CH$_2$CH_2), 1.94−2.43 (m, 4 H, PCH_2), 6.6−6.7, 6.9−7.2, 7.4−7.8 (m, 30 H, Ph) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 25.9 (dd, $^{1+4}J_{P,C}$ = 25.0 Hz, $^{2+3}J_{P,C}$ = 15.0 Hz, P*C*H$_2$), 28.9 (dd, $^{1+4}J_{P,C}$ = 27.9 Hz, $^{2+3}J_{P,C}$ = 22.0 Hz, P*C*H$_2$), 29.0 (d, $^{2}J_{Ptrans,C}$ = 90.8 Hz, Pd*C*H$_2$), 33.3 (d, $^{3}J_{Ptrans,C}$ = 4.0 Hz, PdCH$_2$*C*H$_2$), 41.3 (dd, $^{4}J_{Ptrans,C}$ = 14.9, $^{4}J_{Pcis,C}$ = 3.0 Hz, PdCH$_2$CH$_2$*C*H$_2$), 122.6 (s, *p*-C_{SPh}), 124.5 (s, *p*-C_{Ph}), 126.8 (s, *m*-C_{SPh}), 127.5/128.2 (s/s, *o*-C_{Ph}, *m*-C_{Ph}), 128.5 (d, $^{3}J_{P,C}$ = 9.0 Hz, *m*-C_{dppe}), 128.7 (d, $^{3}J_{P,C}$ = 11.0 Hz, *m*-C_{dppe}), 130.1 (s, *p*-C_{dppe}), 130.3 (d, $^{1}J_{P,C}$ = 42.9 Hz, *i*-C_{dppe}), 130.7 (s, *p*-C_{dppe}), 132.0 (d, $^{1}J_{P,C}$ = 27.9 Hz, *i*-C_{dppe}), 133.1 (d, $^{2}J_{P,C}$ = 12.0 Hz, *o*-C_{dppe}), 133.3 (d, $^{2}J_{P,C}$ = 12.1 Hz, *o*-C_{dppe}), 135.4 (s, *o*-C_{SPh}), 143.2 (s, *i*-C_{Ph}), 144.6 (d, $^{3}J_{Ptrans,C}$ = 9.9 Hz, *i*-C_{SPh}) ppm. ^{31}P NMR (81 MHz, $CDCl_3$): δ = 34.0 (d, $^{2+3}J_{P,P}$ = 26.8 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 53.1 (d, $^{2+3}J_{P,P}$ = 25.6 Hz, P_{trans} to SPh) ppm.

9. [Pd(CH$_2$CHMePh)(SPh)(dppe)] (5c)/[Pd(SPh)$_2$(dppe)] (6a): At −78 °C, PhSH (115 mg, 1.04 mmol) was added to a solution of [Pd(CH$_2$CHMePh)$_2$(dppe)] (**3c**) (770 mg, 1.04 mmol) in THF (50 mL). After stirring overnight at −30 °C, the degree of conversion was determined by ^{31}P NMR spectroscopy. Then, PhSH was added in a quantity that corresponded to the unchanged amount of **3c** and stirring (−30 °C) was continued. This procedure was repeated until all of **3c** had been consumed (final ratio **3c**/PhSH = 1:6). At −30 °C, THF was removed in vacuo. The residue was taken up in toluene (10 mL). Addition of pentane (50 mL) at −78 °C resulted in the precipitation of a mixture of **5c/6a** (74/26%) that was filtered, washed with pentane and dried in vacuo at −30 °C.

Complex 5c: ^{31}P NMR (81 MHz, [D$_8$]THF): δ = 35.6 (d, $^{2+3}J_{P,P}$ = 25.7 Hz, P_{trans} to CH$_2$CHMePh), 51.3 (d, $^{2+3}J_{P,P}$ = 25.7 Hz, P_{trans} to SPh) ppm.

Complex 6a: ^{31}P NMR (81 MHz, $CDCl_3$): δ = 55.4 ppm.

10. [Pd(CH$_2$CH$_2$CH$_2$Ph)X(dppe)] (X = I, 10a; Br, 10b; Cl, 10c): At −78 °C, MeI (290 mg, 2.04 mmol), H$_2$C=CHCH$_2$Br (4.12 g, 34.1 mmol), or H$_2$C=CHCH$_2$Cl (10 mL, without THF) was added to [Pd(CH$_2$CH$_2$CH$_2$Ph)(SPh)(dppe)] **5b** (500 mg, 0.68 mmol) in THF (10 mL). After stirring overnight at −30 °C, solvent and unchanged RX compound were removed in vacuo. The residue was taken up in toluene (10 mL) and cooled to −78 °C. Addition of pentane (ca. 30 mL) resulted in precipitation of complexes **10** that were filtered off, washed with pentane (2 × 5 mL) and dried in vacuo. All manipulations were performed at a maximum temperature of −30 °C.

Complex 10a (X = I): Yellow solid. Yield: 500 mg (98%). ^{13}C NMR (125 MHz, −30 °C, [D$_8$]THF): δ = 24.3 (d, $^{2}J_{Ptrans,C}$ = 100.6 Hz, Pd*C*H$_2$), 30.2 (dd, $^{1+4}J_{P,C}$ = 30.0 Hz, $^{2+3}J_{P,C}$ = 22.6 Hz, P*C*H$_2$; other P*C*H$_2$ not found, probably beneath solvent signal), 35.8 (s, PdCH$_2$*C*H$_2$), 42.9 (d, $^{4}J_{Ptrans,C}$ = 13.9 Hz, PdCH$_2$CH$_2$*C*H$_2$), 125.6 (s, *p*-C_{Ph}), 128.5/128.9 (s/s, *o*-C_{Ph}, *m*-C_{Ph}), 129.2 (d, $^{3}J_{P,C}$ = 9.2 Hz, *m*-C_{dppe}), 129.9 (d, $^{3}J_{P,C}$ = 10.3 Hz, *m*-C_{dppe}), 130.2 (d, $^{1}J_{P,C}$ = 47.4 Hz, *i*-C_{dppe}), 131.1 (s, *p*-C_{dppe}), 132.1 (s, *p*-C_{dppe}), 133.6 (d, $^{1}J_{P,C}$ = 28.9 Hz, *i*-C_{dppe}), 134.5 (d, $^{2}J_{P,C}$ = 11.8 Hz, *o*-C_{dppe}), 134.7 (d, $^{2}J_{P,C}$ = 11.7 Hz, *o*-C_{dppe}), 143.8 (s, *i*-C_{Ph}) ppm. ^{31}P NMR (202 MHz, −30 °C, [D$_8$]THF): δ = 30.2 (d, $^{2+3}J_{P,P}$ = 29.3 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 56.1 (d, $^{2+3}J_{P,P}$ = 29.3 Hz, P_{trans} to I) ppm.

Complex 10b (X = Br): Pale yellow solid. Yield: 456 mg (95%). ^{13}C NMR (125 MHz, −30 °C, [D$_8$]THF): δ = 24.0 (dd, $^{1+4}J_{P,C}$ = 25.6 Hz, $^{2+3}J_{P,C}$ = 11.9 Hz, P*C*H$_2$), 29.0 (d, $^{2}J_{Ptrans,C}$ = 100.4 Hz, Pd*C*H$_2$), 30.4 (dd, $^{1+4}J_{P,C}$ = 31.3 Hz, $^{2+3}J_{P,C}$ = 24.1 Hz, P*C*H$_2$), 34.6 (s, PdCH$_2$*C*H$_2$), 42.4 (d, $^{4}J_{Ptrans,C}$ = 15.3 Hz, PdCH$_2$CH$_2$*C*H$_2$), 125.5 (s, *p*-C_{Ph}), 128.5/129.0 (s/s, *o*-C_{Ph}, *m*-C_{Ph}), 129.3 (d, $^{3}J_{P,C}$ = 9.7 Hz, *m*-C_{dppe}), 129.8 (d, $^{3}J_{P,C}$ = 9.7 Hz, *m*-C_{dppe}), 130.6 (d, $^{1}J_{P,C}$ = 49.0 Hz, *i*-C_{dppe}), 131.0 (s, *p*-C_{dppe}), 132.0 (s, *p*-C_{dppe}), 134.0 (d, $^{1}J_{P,C}$ = 27.3 Hz, *i*-C_{dppe}), 134.5 (d, $^{2}J_{P,C}$ = 9.7 Hz, *o*-C_{dppe}), 144.1 (s, *i*-C_{Ph}) ppm. ^{31}P NMR (202 MHz, −30 °C, [D$_8$]THF): δ = 28.9 (d, $^{2+3}J_{P,P}$ = 29.5 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 59.5 (d, $^{2+3}J_{P,P}$ = 29.5 Hz, P_{trans} to Br) ppm.

Complex 10c (X = Cl): Pale yellow solid. Yield: 420 mg (94%). ^{13}C NMR (125 MHz, −30 °C, [D$_8$]THF): δ = 23.2 (dd, $^{1+4}J_{P,C}$ = 26.3 Hz, $^{2+3}J_{P,C}$ = 11.0 Hz, P*C*H$_2$), 30.3 (dd, $^{1+4}J_{P,C}$ = 32.7 Hz, $^{2+3}J_{P,C}$ = 23.9 Hz, P*C*H$_2$), 31.0 (d, $^{2}J_{Ptrans,C}$ = 101.2 Hz, Pd*C*H$_2$), 34.0 (d, $^{3}J_{P,C}$ = 4.5 Hz, PdCH$_2$*C*H$_2$), 42.2 (dd, $^{4}J_{Ptrans,C}$ = 15.3, $^{4}J_{Pcis,C}$ = 3.2 Hz, PdCH$_2$CH$_2$*C*H$_2$), 125.5 (s, *p*-C_{Ph}), 128.5/129.0 (s/s, *o*-C_{Ph}, *m*-C_{Ph}), 129.4 (d, $^{3}J_{P,C}$ = 8.8 Hz, *m*-C_{dppe}), 129.7 (d, $^{3}J_{P,C}$ = 10.1 Hz, *m*-C_{dppe}), 130.7 (d, $^{1}J_{P,C}$ = 49.0 Hz, *i*-C_{dppe}), 131.0 (s, *p*-C_{dppe}), 131.9 (s, *p*-C_{dppe}), 134.1 (one line of d, other one superposed, *i*-C_{dppe}), 134.3 (d, $^{2}J_{P,C}$ = 11.3 Hz, *o*-C_{dppe}), 134.5 (d, $^{2}J_{P,C}$ = 11.3 Hz, *o*-C_{dppe}), 144.2 (s, *i*-C_{Ph}) ppm. ^{31}P NMR (202 MHz, −30 °C, [D$_8$]THF): δ = 27.7 (d, $^{2+3}J_{P,P}$ = 29.5 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 59.4 (d, $^{2+3}J_{P,P}$ = 29.5 Hz, P_{trans} to Cl) ppm.

11. Experiments Monitored by ^{31}P NMR Spectroscopy: The corresponding amounts of sulfur or selenium compounds were added with a syringe to solutions of the palladium complex in THF/[D$_8$]THF (ca. 4:1). The reaction mixtures were transferred to NMR tubes that were then sealed. The reactions were monitored by ^{31}P{^{1}H} NMR spectroscopy.

[Pd(CH$_2$CH$_2$CH$_2$Ph)(SPh)(dppe)] (5b) from 3b and PhSSPh: ^{31}P NMR (81 MHz): δ = 34.0 (d, $^{2+3}J_{P,P}$ = 25.6 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 53.1 (d, $^{2+3}J_{P,P}$ = 25.6 Hz, P_{trans} to SPh) ppm.

[Pd(CH$_2$CH$_2$CH$_2$Ph){S(*i*Pr)}(dppe)] (5d) from 3b and *i*PrSH: ^{31}P NMR (81 MHz): δ = 40.7 (d, $^{2+3}J_{P,P}$ = 22.0 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 55.9 [d, $^{2+3}J_{P,P}$ = 22.0 Hz, P_{trans} to S(*i*Pr)] ppm.

[Pd(CH$_2$CH$_2$CH$_2$Ph){S(tBu)}(dppe)] (5e) from 3b and tBuSH: ^{31}P NMR (81 MHz): δ = 35.3 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 56.9 [d, $^{2+3}J_{P,P}$ = 22.0 Hz, P_{trans} to S(*t*Bu)] ppm.

[Pd(CH$_2$CH$_2$CH$_2$Ph)(SBz)(dppe)] (5f) from 3b and BzSSBz: ^{31}P NMR (81 MHz): δ = 41.9 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 56.6 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to SBz) ppm.

[Pd(CH$_2$CH$_2$CH$_2$Ph)(SMe)(dppe)] (5g) from 3b and MeSSMe: ^{31}P NMR (81 MHz): δ = 41.3 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 55.6 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to SMe) ppm.

[Pd(CH$_2$CH$_2$CH$_2$Ph)(SeMe)(dppe)] (9a) from 3b and MeSeSeMe: ^{31}P NMR (81 MHz): δ = 46.1 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to CH$_2$CH$_2$CH$_2$Ph), 52.4 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to SeMe) ppm.

[PdMe(SePh)(dppe)] (9b) from 4 and PhSeSePh: ^{31}P NMR (81 MHz): δ = 45.0 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to Me), 56.8 (d, $^{2+3}J_{P,P}$ = 23.2 Hz, P_{trans} to SePh) ppm.

12. X-ray Structure of [Pd(CH$_2$CH$_2$Ph)$_2$(dppe)] (3a): Single crystals of complex **3a** suitable for X-ray diffraction analysis were grown at −30 °C by slow diffusion of *n*-pentane into a solution of **3a** in THF. Intensity data for complex **3a** were collected at 200(2) K with a Stoe STADI4 diffractometer with Mo-K_α radiation (0.71073 Å, graphite monochromator). A summary of crystallographic data, data collection parameters, and refinement parameters is given in

Table 4. The structure was solved by direct methods with SHELXS-86[34] and refined using full-matrix least-squares routines against F^2 with SHELXL-93.[34] Non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were found in the difference Fourier map and were refined isotropically. CCDC-184402 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 4. Crystal data and details of the structure determination for complex **3a**

Empirical formula	$C_{42}H_{42}P_2Pd$
Formula mass	715.10
Crystal system	orthorhombic
Space group	*Pbca*
a [Å]	12.97(2)
b [Å]	22.000(5)
c [Å]	25.545(6)
Z	8
V [Å^3]	7290(12)
$D_{calcd.}$[g cm^{-3}]	1.303
F(000)	2960
μ(Mo-K_α) [cm^{-1}]	6.24
2θ range [°]	1.59−26.04
Recip. latt. segment (*h*, *k*, *l*)	0 → 8, 0 → 27, 0 → 31
Measured reflections	7659
Independent reflections [$R_{int.}$]	4775 [0.0387]
Observed reflections	3590
Parameters	575
*R*1, *wR*2 [$I > 2\sigma(I)$]	0.0387, 0.0794
*R*1, *wR*2 (all data)	0.0647, 0.0930
Goodness-of-fit on F^2	1.108
Min. and max. resd. electron density [e·Å^{-3}]	−0.558 and 0.333

Studies of Aryl Substituent and Solvent Donor Imposed Structural Diversity in *N*,*N*′-Diarylformamidinate Complexes of Lithium[‡]

Jens Baldamus,[a][+] Christiane Berghof,[a][+] Marcus L. Cole,[a] Evamarie Hey-Hawkins,[b] Peter C. Junk,*[a] and Lance M. Louis[c]

Keywords: Lithium / Formamidinates / Coordination modes / N ligands

Treatment of *N*,*N*′-bis(2,4,6-trimethylphenyl)formamidine, (2,4,6-$Me_3C_6H_2$)NC(H)NH(2,4,6-$Me_3C_6H_2$) (HFMes) with *n*-butyllithium in DME leads to deprotonation of the amidine affording the dimeric compound [{Li(FMes)(dme)}$_2$] (**1**). Similar treatment of the less sterically encumbered formamidine *N*,*N*′-bis(*o*-tolyl)formamidine, (2-MeC_6H_4)NC(H)NH(2-MeC_6H_4) (HFTolO) in DME (1,2-dimethoxyethane) or HFMes in hexane/TMEDA (*N*,*N*,*N*′,*N*′-tetramethylethylenediamine) yields the compounds [Li(dme)$_3$][Li(FTolO)$_2$] (**2**) and [Li(FMes)(tmeda)] (**3**), respectively. Both the anion of **2** and **3** are the first monomeric group 1 formamidinates to exhibit η^2-chelation in the solid state, and **3** is the first Lewis base stabilised mononuclear group 1 formamidinate complex. Complexes **1**–**3** have been characterised by spectroscopy (^{1}H and ^{13}C NMR, FTIR) and X-ray crystallography, and are discussed herein vis-à-vis formamidinate binding modes exhibited by *N*,*N*′-diarylformamidinates of smaller steric size, e.g. *N*,*N*′-bis(*p*-tolyl)formamidine, (4-MeC_6H_4)NC(H)NH-(4-MeC_6H_4) (HFTolP).

Introduction

The fundamental role of group 1 amido complexes, particularly those of lithium, as synthetic reagents in inorganic chemistry and strong Bronsted bases or nucleophiles in organic synthesis[1−5] has led to considerable advances in the field of metal amide chemistry.[6] Within this arena, knowledge of reagent structure both in solution and in the solid state is crucial, permitting the synthetic chemist to tailor syntheses or transformations. In both, association is to be expected due to the high polarity of the Li−N bond.[7−13] However, aggregation can be frustrated if ligands of adequate steric bulk are employed.[14]

In contrast to the actively investigated area of transition metal formamidinate chemistry (formamidinate = [RNC(H)NR]$^-$, R = aryl, alkyl, silyl),[15,16] literature detailing the full characterisation of s-block systems has been conspicuously absent.[17] As a result there is a scarcity of structural data pertaining to this class of amidinate complex, which are generally perceived as metathesis reagents, their isolation and characterisation largely being ignored. It has been suggested that this shortage of structural data, there being just one structurally authenticated lithium formamidinate complex ([{Li(FTolP)(Et_2O)}$_2$]), results from the facility by which group 1 formamidinates lose solvent.[18] However, to compliment the vast array of coordination modes observed for formamidinates in d-block systems we have engaged in a program of s-block metal formamidinate structural characterisation using solvent donors that either chelate or have recognised strong donor characteristics. Thus far, this has identified several group 1 diarylformamidinate bonding motifs, e.g. μ_2:η^2:η^1 (in [{Li_2(FTolP)$_2$(tmeda)}$_\infty$])[17] and η^6:η^1 (in [K(FMes)(HFMes)]),[19] that are either rare or unprecedented in transition metal chemistry. To date several known bonding motifs like discrete η^2-chelation, have not been observed in group 1 systems. Furthermore, there is potential for new binding modes, e.g. η^3-diazaallyl, as seen for η^3-*N*-aryl diarylketeneiminates,[20] where the carbon atom of the NCN backbone would interact with a metal centre that sits perpendicular to the NCN plane either as part of symmetrical NCN donation or as a discrete C=N π-donor. In order to assess the likelihood of these, and advance our study, we have now chosen to focus our attention on formamidine ligands of greater steric bulk, in this case *N*,*N*′-bis(2,4,6-trimethylphenyl)formamidine, (2,4,6-$Me_3C_6H_2$)NC(H)NH(2,4,6-$Me_3C_6H_2$) (HFMes). Herein we present a preliminary lithium study employing HFMes and relate the findings to new and archival structural data.

Results and Discussion

Treatment of HFMes with *n*-butyllithium in the coordinating solvent DME (1,2-dimethoxyethane) results in clean deprotonation of the amino group (see Scheme 1), after moderate heating, yielding a colourless crystalline product that characterises as [Li(FMes)$(dme)_{3/2}$] (**1**) by ^{1}H NMR (C_6D_6). Spectroscopic evidence confirms deprotonation via the absence of a resonance attributable to the amino proton of HFMes and the lack of an N−H stretch at ca. 3200−3300 cm^{-1} [^{1}H NMR (C_6D_6): δ = 5.71 ppm (NH); FTIR: $\tilde{\nu}$ = 3228 cm^{-1} (HFMes N−H stretch)].[21] The appearance of a broad NC(*H*)N resonance at δ = 7.60 ppm is also indicative of deprotonation, that of the ligand appearing at δ < 7.07 ppm.[21] Similarly, the NCN backbone carbon resonance at δ = 157.6 ppm (C_6D_6) is suggestive of deprotonation, the analogous resonance of HFMes appearing at δ = 145.0 ppm. Attempts to obtain ^{7}Li NMR spectroscopic data for **1** were thwarted by low solubility in nondonating solvents (employed to preclude further solvation). Overall, NMR resonances for **1** compare favourably to those of the FTolP ligands in the ionic complex [Li$(dme)_3$][$Li_2(\mu_2{:}\eta^1{:}\eta^1$-FTolP$)_3$] (**4**) although the NC(*H*)N resonance is shifted to lower frequency, that of **4** appearing at δ = 8.88 ppm.[17] This intimates a differing structural preference for **1** viz. **4**, as does the abated decomposition temperature of 112 °C, which would intuitively be in excess of that for **4** were they to assume a congruent solid-state motif (**4**: dec. At 130 °C).[17]

To assess this, X-ray quality crystals of **1**, which proved extremely air-sensitive and prone to solvent loss, were isolated and a structure determination undertaken. A POV-RAY depiction of **1** can be seen in Figure 1 (30% thermal ellipsoids), whilst selected bond lengths and angles are listed in the caption. Crystallographic data for compounds

each lithium centre. This results from the increased steric bulk of FMes with respect to FTolP, which not only inhibits discrete ion formation, as in **4**, but also precludes μ_2:η^2:η^1-formamidinate coordination as seen for both [{$Li_2(\mu_2$:η^2:η^1-FTolP)$_2$(μ_2-tmeda)}$_\infty$] (**5**)[17] and [{Li(μ_2:η^2:η^1-FTolP)(Et_2O)}$_2$],[18] the Li(1)#−N(1) distance of 3.3723(60) Å testifies to this. Interestingly, the donation of two singular DME ligands in **1** is representative of the overall steric coordination number[22] of [$Li_2(\mu_2$:η^1:η^1-FTolP)$_2$(THF)$_2$(μ_2-thf)],[17] which exhibits analogous formamidinate binding modes with one chelating and one bridging THF interaction completing each lithium coordination sphere. The lithium atoms of **1** sit in a distorted tetrahedral environment [N(1)−Li(1)−N(2)# 133.5(3)°, N(2)#−Li(2)−O(2) 115.6(3)°, O(1)−Li(1)−O(2) 78.9(2)°, whilst the Li−N bond lengths of 2.035(6) Å and 2.033(6) Å are abated relative to those deposited in the Cambridge structural database (mean 2.082 Å),[23] extended with respect to those of **4** (mean 1.992 Å)[17] and similar to those displayed by the similarly dimeric lithium amide complex [{Li[NHC_6H_4(*o*-$AsMe_2$)](THF)$_2$}$_2$] [24] (mean 2.064 Å). As per **4**, the considerable strain involved in formamidinate bridging to two separate metal atoms has repercussions regarding ligand geometry. This includes the opening of the NCN backbone angle to 127.7(3)° (**4**: mean 123.0°) and the C(19)−N(1)−Li(1) angle to 129.7(3)° (**4**: mean 122.2°), these are in stark contrast to the comparatively acute angles of the bis(η^2-chelate) complex [Mg(FTolP)$_2$(THF)$_2$] (mean 117.0 and 90.14°, respectively).[25] Consequently, C(19) sits 0.023 Å out of the N_4 plane, whilst the Li centres sit 0.670 Å out of the N_4 plane [N(2)#−Li(1)−N(1) plane at 56.55(33)° to the N_4 plane). Given the orthogonal orientation of the FMes ligands to the lithium−lithium vector, these projections are insignificant regarding possible Li(1)/Li(1)#···C(19) interactions. Intriguingly, the structural motifs of **1** and **4** are reminiscent of the "lantern-type" structures popularised by the transition metal studies of Cotton and Murillo et al.,[15,16,26] e.g. [Mo_2(PhNC(Ph)NPh)$_4$],[27] the lower ratio of ligand/metal resulting from the restricted space in which the formamidinate ligands can orientate themselves around the diminutive dilithium core. Conversely, unlike the close-contact-enforced metal−metal bonding observed for d-block systems, which lead to magnetic and electronic phenomena,[15,16] the metal−metal distance of complex **1** [3.508(11) Å] precludes similar interaction (**4**: mean 2.580 Å). Furthermore, the steric congestion of **1** is exemplified by the near orthogonal torsion angle of the mesityl rings to one another [87.19(12)°] and the large dihedral angles of both rings to the NCN plane [C(1) ring 66.5(3)°, C(10) ring 66.6(3)°]. These impose a differing structural motif and lower formamidinate aggregation for **1**, with respect to **4**, which necessitates augmentative DME donation to achieve an equivalent degree of coordinative saturation. Meanwhile, the formamidinate backbone N−C bond lengths of 1.312(4) and 1.314(4) Å are indicative of symmetrical amidinate ligation (**4**: mean 1.326 Å; HFTolP dimer mean C−N bonds: imino 1.294 Å and amino 1.347 Å).[17] Lastly, the symmetrical dilithium di-β-dinitrogen ligand eight-membered metallacycle exhibited by **1** is not an uncommon feature of lithium structural chemistry (22 examples),[23] however, the lithium−lithium distance described (listed above) does testify to significant steric congestion about the core, there being just two polymetallacyclic examples wherein the distance of **1** is exceeded; [(Li{*t*BuNC(*t*Bu)N*t*Bu})$_4$] (max. Li···Li 3.809 Å)[28] and [Li_2\{1,2-*trans*-[NC(*para*-Tol)N(*para*-Tol)]$_2C_6H_{10}$\}] (max. Li···Li 4.391 Å).[29]

If complex **1** represents double *o*-methylaryl substitution (i.e. 2,6-dimethyl) and **4** represents no *o*-methylaryl substitution, the considerable variation in the solid-state motifs of **1** and **4** invites speculation as to the likely solid-state

nature of a singularly *o*-methylated *N*,*N*′-diarylformamidinate lithium complex. As such, an identical preparation to that of **1** was undertaken employing *N*,*N*′-bis(*o*-tolyl)formamidine (HFTolO), see Scheme 1. As per the synthesis of **1**, treatment of HFTolO in DME with *n*-butyllithium renders a colourless crystalline compound devoid of amino-attributable resonances or stretches (^{1}H NMR and FTIR), with a composition that indicates two formamidinate ligands to three DME molecules; [Li(FTolO)(dme)$_{3/2}$] (**2**) (^{1}H NMR). The NC(H)N-attributable resonances of **2** at δ = 8.72 ppm and 160.4 ppm (^{1}H and ^{13}C NMR, respectively) are representative of **4** rather than **1** (^{1}H NMR: **4**: δ = 8.88 ppm; **1**: δ = 7.60 ppm) as is the decomposition temperature of 122 °C (**1**: 112 °C; **4**: 130 °C).[17] Correspondingly, block-like crystals of **2** were grown from DME and an X-ray structure determination undertaken (Figure 2; POV-RAY illustration, 30% thermal ellipsoids, relevant bond lengths and angles listed in the caption).

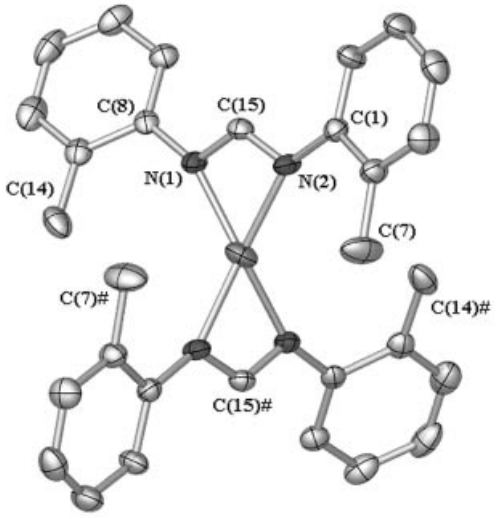

Figure 2. Molecular structure of the anion of **2** [Li(η^1:η′-FTolO)$_2$], all hydrogen atoms omitted for clarity; selected bond lengths [Å] and angles [°]: N(1)−Li(1) 2.063(11), N(2)−Li(1) 2.073(10), N(1)−C(15) 1.323(8), N(2)−C(15) 1.315(8), N(1)−Li(1)−N(1)# 135.5(8), N(1)−Li(1)−N(2)# 130.7(3), N(1)−Li(1)−N(2) 67.3(3), N(1)−C(15)−N(2) 120.6(7), NCN−NCN# 82.5(4), C(1) ring−NCN 13.3(7), C(8) ring−NCN 33.1(6), C(1) ring−C(8) ring 28.0(4)

Akin to complex **4**, compound **2** crystallises in the space group *C*2/*c* as discrete anions and cations, of which there is half an anion/cation pair in the asymmetric unit. The cationic lithium unit, which is solvated by three DME molecules to form a distorted octahedron (mean O−Li−O bite 76.34°), is not uncommon,[23] structurally unexceptional and will not be discussed further. However, the anion (see Figure 2) is a mononuclear [Li(FTolO)$_2$] unit that presents two η^2-FTolO ligands forming a distorted tetrahedral geometry about a lithium centre without solvent interaction [N(1)−Li(1)−N(2) bite 67.3(3)°, N(1)−Li(1)−N(1)# 135.5(8)°]. The Li−N bond lengths vary in the range 2.063(11)−2.073(10) Å and are therefore closer to the mean average Li−N bond length deposited in the Cambridge structural database (2.082 Å)[23] than the appropriate bonds of **1** and **4**. This perhaps results from lessened steric strain and the absence of bridging interactions. Likewise, the NCN backbone angle of 120.6(7)° bares a closer resemblance to the analogous angles of [Mg(FTolP)$_2$(THF)$_2$] (mean: 117.0 Å),[25] than those of **1** [127.7(3)°] due to the chelate motif described. The depreciated tolyl−tolyl steric buttressing described by **2** vis-à-vis **1** can be seen in the dihedral angle of either tolyl ring to the NCN backbone plane [C(1) ring 13.3(7)°, C(8) ring 33.1(6)°] and the relative torsion angle of 28.0(4)°. Thus, in complex **2** we can state that whilst the imposition of two *o*-methyl groups upon the formamidinate frame, as in FMes, results in nonionic **1**, the addition of a singular *o*-methyl group renders an ionic complex, similar to **4**, with lower anion aggregation. This modification creates a complex devoid of formamidinate bridging interactions, which cannot merely result from *o*-methyl addition relative to **4** because complex **1** exhibits similar μ$_2$:η^1:η^1 interactions. To rationalise this, it appears that the relative cation and anion sizes of **2** and **4** are comparable, thereby presenting lattice energies of adequate magnitude for salt formation. Meanwhile, an ionic composition for complex **1** is thermodynamically unfavourable due to the sheer steric bulk of the included amidinate ligands. These create a cation/anion size disparity. This has precedent in group 1 cyclopentadienide crown ether chemistry[30,31] where the ionic complex [K{15-crown-5}$_2$][Cp] forms whilst use of 18-crown-6 yields solely the monomer [K(18-crown-6)Cp].[32] Irrespective, it remains that the ionic nature of **2** introduces a new type of lithium-based formamidinate anion.

To increase the steric encumbrance observed for complex **1**, and thereby potentially frustrate bridging interactions and generate new bonding motifs, a bulkier solvent donor; *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (TMEDA) was utilised in a preparative procedure similar to that for **1** using hexane as solvent. Treatment of HFMes with *n*-butyllithium in hexane resulted in instant deposition of an insoluble colourless material, presumably polymeric in nature, which dissolved upon addition of excess TMEDA (see Scheme 1). Subsequent recrystallisation of the reaction mother liquor yielded colourless prisms that characterised as [Li(FMes)(tmeda)] (**3**) by ^{1}H NMR, and were devoid of the resonances and stretches (NMR and FTIR, respectively) attributable to the HFMes ligand. Unlike compounds **1** and **2**, compound **3** appears to be stable to solvent loss but is extremely air-sensitive decomposing to a dark brown material upon brief exposure to air. Solid samples of **3** are thermally robust decomposing above 145 °C (cf. **1**: 112 °C; **2**: 122 °C; **4**: 130 °C).[17] The spectroscopic data for **3** bare a resemblance to those of both **4** and the related TMEDA compound [{Li$_2$(μ$_2$:η^2:η^1-FTolP)$_2$(μ$_2$-tmeda)}$_\infty$] (**5**) in that compound **3** possesses a ^{1}H NMR resonance at δ = 8.02 ppm (**4**: δ = 8.88 ppm; **5**: δ = 8.25 ppm, respect-

ively);[17] however, the solvent/formamidinate ligand ratios of 1:1 mitigate against a solid-state motif analogous to **5** unless half an equivalent of TMEDA is contained as lattice solvent. In order to evaluate the above, an X-ray structure determination of **3** was undertaken (Figure 3; POV-RAY illustration, 30% thermal ellipsoids, selected bond lengths and angles listed in the caption).

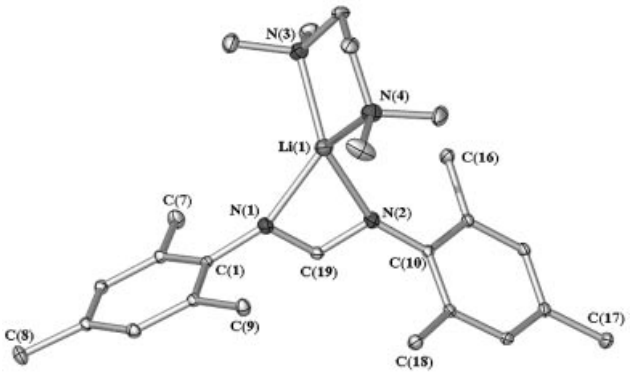

Figure 3. Molecular structure of [Li(η^1:η^1-FMes)(tmeda)] (**3**), all hydrogen atoms omitted for clarity; selected bond lengths [Å] and angles [°]: Li(1)−N(1) 2.036(3), Li(1)−N(2) 2.011(3), Li(1)−N(3) 2.087(3), Li(1)−N(4) 2.057(3), N(1)−C(19) 1.314(2), N(2)−C(19) 1.328(2), $NLiN_{FMes}$−$NLiN_{TMEDA}$ 72.95(6), N(1)−Li(1)−N(2) 68.84(10), N(3)−Li(1)−N(4) 86.94(12), N(1)−Li(1)−N(3) 125.52(15), N(2)−Li(1)−N(4) 112.57(14), N(1)−C(19)−N(2) 120.04(15), C(1) ring−NCN 86.9(2), C(10) ring−NCN 50.6(1), C(1) ring−C(10) ring 58.07(5)

Compound **3** represents the first structurally authenticated lithium formamidinate complex that displays neither μ_2:η^2:η^1/μ_2:η^1:η^1-bridging interactions or an ionic composition. It appears that the added steric buttressing of TMEDA relative to DME imposes enough hindrance to cause **3** to exist as discrete [Li(FMes)(tmeda)] units without intermolecular contacts. Inspite of this, the tetrahedral geometry about the metal centre of **3** is deficient in symmetry [N(1)−Li(1)−N(4) 131.94(15)°, N(2)−Li(1)−N(3) 137.92(15)°, N(3)−Li(1)−N(4) 86.94(12)°]. For example, the N−Li−N planes of the two dinitrogen ligands exist at a dihedral angle of 72.95(6)° to one another, this exacerbates the interaction of the C(11)-bound mesityl ring with the tmeda C(23)-bound NMe_2 group. This group counterintuitively leans toward the N(2) side of the formamidinate ligand [N(2)−Li(1)−N(4) 112.57(14)°, N(1)−Li(1)−N(3) 125.52(15)°]. In the absence of an apparent energetic benefit to this, such an anomaly must surely result as a crystal-packing phenomenon. Correspondingly, the disparate dihedral angles of the mesityl rings to the NCN plane [C(1) ring 86.92(15)°, C(11) ring 50.61(14)°] cannot be explained by intramolecular interactions alone. Indeed, one would expect the two mesityl groups to lie orthogonal to the NCN plane, and therefore flat to one another, thereby minimising interaction with the TMEDA ligand. Instead, the mesityl rings exist at a relative torsional angle of 58.07(5)°, which seemingly decries the rationale proposed for the structure exhibited. Reassuringly, the NCN FMes backbone of **3** displays nearly equivalent C−N bond lengths of 1.314(2) and 1.328(2) Å (symptomatic of symmetrical η^2-chelation) without interaction of C(19) to the metal centre [C(19) projects 0.024 Å above/below the NCN plane). Lastly, the bond lengths N(1)−Li(1) and N(2)−Li(1) [2.036(3) and 2.011(3) Å, respectively) are similar to other symmetrically bonded FMes compounds (**1**, mean: 2.034 Å), whilst the FMes backbone angle of **3** is acute with respect to the μ_2:η^1:η^1-bound FMes ligands of **1** [120.04(15)°; **1**: 127.7(3)°], and comparable those of the μ_2:η^2:η^1-formamidinate complexes **5** [120.8(3)°][17] and [{Li(μ_2:η^2:η^1-FTolP)(Et_2O)}$_2$] [120.0(4)°],[18] and hence closer to the sp^2-hybridised ideal of 120°.

Conclusion

The solid-state structures of **1**−**3** exhibit structural diversity borne out of the rational exchange and substitution of both solvent and aryl substituents. In tandem with archival structural data, we can assert that *N*,*N*′-diarylformamidinates are versatile ligands for lithium, exhibiting an ever increasing number of binding modes and structural motifs. In particular, we have identified the first complexes to display solely η^2-formamidinate chelation (**2** and **3**), and the first mononuclear Lewis base stabilised group 1 formamidinate to be structurally authenticated (**3**). These studies expand our understanding of the structural ramifications of increased diaryl steric bulk in group 1 systems, which in the extreme negate the interaction of solvent donors, as in the anion of **2**, or frustrate salt formation, as in **1**. In summary, with respect to known FTolP complexes,[17,18] it appears that the presence of *o*-methyl group(s) upon the aryl substituents frustrate, and to a certain extent limit, dimer formation such that μ_2:η^2:η^1-formamidinate bridging is not viable (lithium−lithium proximity hindered). This enforces either supplementary solvent coordination or, as seen for **2**, low aggregate lithium−formamidinate anion composition. We are presently extending these studies to ligands of greater steric bulk, e.g. *N*,*N*′-bis(2,6-diisopropylphenyl)formamidine (HFIso), and heavy group 2 and f-block metals. The outcome of these will form the basis of forthcoming publications.

Experimental Section

General: The formamidinate ligand precursors *N*,*N*′-bis(2,4,6-trimethylphenyl)- and *N*,*N*′-bis(*o*-tolyl)formamidine, HFMes and HFTolO, respectively, were synthesised according to published procedures.[18,33] *n*-Butyllithium (1.6 M solution in hexanes) was purchased from Aldrich. 1,2-Dimethoxyethane (DME/dme) and hexane were dried with sodium, freshly distilled from sodium/benzophenone, and freeze-thaw-degassed prior to use. *N*,*N*,*N*′,*N*′-Tetramethylethylenediamine (TMEDA/tmeda) was dried with sodium, freshly distilled from sodium, and freeze-thaw-degassed prior to use. All manipulations were performed using conventional Schlenk or glovebox techniques under high-purity argon or dinitrogen in flame-dried glassware. Infrared spectra were recorded as Nujol mulls using sodium chloride plates with a Nicolet Nexus FTIR

spectrophotometer. ^{1}H NMR spectra were recorded at 300.13 MHz and ^{13}C NMR spectra were recorded at 75.46 MHz using Bruker BZH 300/52 and DPX 300 spectrometers with Varian or Bruker consoles and chemical shifts were referenced to the residual ^{1}H or ^{13}C resonances of the deuteriobenzene solvent employed. Melting points were determined in sealed glass capillaries under argon or dinitrogen and are uncorrected. The high aerobic and moisture sensitivity of compounds **1**−**3**, combined with the facile loss of solvent from both **1** and **2** (as seen for [{Li(μ_2:η^2:η^1-FTolP)(Et_2O)}$_2$], see ref.[18]), frustrated the acquisition of meaningful mass spectrometric and C,H,N microanalytical data. Microanalyses for **1** and **2** were consistently high in carbon and nitrogen, and low in hydrogen, whilst those of **3** were repeatedly low in nitrogen.

[{Li(μ_2:η^1:η^1-FMes)(dme)}$_2$].DME (1): *n*-Butyllithium (0.80 mL, 1.28 mmol) was added dropwise to a stirred ambient-temperature solution of HFMes (0.36 g, 1.28 mmol) in DME (30 mL). Heating of the resultant clear colourless solution to 50 °C for 1 h yielded an opaque-white slurry that was filtered and the filtrate placed at −20 °C. This yielded the title compound as small colourless needles (0.36 g, 67%), m.p. 112 °C (dec.). ^{1}H NMR (C_6D_6, 300 K): δ = 2.24 (s, 12 H, *p*-CH_3), 2.32 (s, 24 H, *o*-CH_3), 3.04 (s, 18 H, OCH_3), 3.11 (s, 12 H, OCH_2), 6.85 (s, 8 H, *m*-H), 7.60 [br. s, 2 H, NC(H)N] ppm. ^{13}C NMR (C_6D_6, 300 K): δ = 18.4 (s, *p*-CH_3), 19.6 (s, *o*-CH_3), 57.4 (s, OCH_3), 70.6 (s, OCH_2), 127.7 (s, *m*-C), 128.0, 128.1, 130.7 (s, Ar-C), 157.6 [s, NC(H)N] ppm. IR (Nujol): $\tilde{\nu}$ = 850 m, 872 m, 1022 m, 1090 m, 1124 m, 1146 m, 1209 s, 1246 w, 1294 w, 1564 s, 1614 m, 1639 m cm^{-1}.

[Li(dme)$_3$][Li(η^2-FTolO)$_2$] (2): *n*-Butyllithium (0.80 mL, 1.28 mmol) was added dropwise to a stirred solution of HFTolO (0.29 g, 1.29 mmol) in DME (30 mL) producing an opaque-yellow solution. Cessation of stirring after 2 h, followed by filtration gave a solution that yielded colourless crystals of the title compound (upon storage at −30 °C) as large solvent-dependent blocks (0.33 g, 71%), m.p. 122 °C (dec.). ^{1}H NMR (C_6D_6, 300 K): δ = 2.13 (s, 12 H, *o*-CH_3), 2.86 (s, 18 H, OCH_3), 2.88 (s, 12 H, OCH_2), 6.94 (m, 4 H, Ar-H), 7.03 (m, 4 H, Ar-H), 7.15 (m, 8 H, Ar-H), 8.72 [br. s, 2 H, NC(H)N] ppm. ^{13}C NMR (C_6D_6, 300 K): δ = 19.2 (s, *o*-CH_3), 58.9 (s, OCH_3), 71.1 (s, OCH_2), 118.2, 120.1, 127.1, 129.9, 130.6, 150.7 (s, Ar-C), 160.4 [s, NC(H)N] ppm. IR (Nujol): $\tilde{\nu}$ = 811 m, 831 m, 867 m, 921 w, 995 w, 1028 w, 1083 s, 1122 m, 1178 w, 1205 m, 1222 m, 1245 w, 1549 s, 1568 m, 1664 w cm^{-1}.

[Li(η^2-FMes)(tmeda)] (3): *n*-Butyllithium (1.10 mL, 1.76 mmol) was added dropwise to a stirred solution of HFMes (0.48 g, 1.71 mmol) in hexane (60 mL), instantly yielding a white precipitate. Addition of TMEDA (300 μL, 1.99 mmol) resulted in dissolution of the precipitate, rendering a clear yellow solution that was concentrated in vacuo (ca. 40 mL) and filtered. Placement of the filtrate at −5 °C for one week yielded the title product as a microcrystalline powder and a small quantity of colourless prisms (single product by ^{1}H NMR, 0.49 g, 71%), m.p. 145 °C (dec.). ^{1}H NMR (C_6D_6, 300 K): δ = 1.80 (s, 4 H, NCH_2), 1.92 (s, 12 H, NCH_3), 2.29 (s, 6 H, *p*-CH_3), 2.38 (s, 12 H, *o*-CH_3), 6.97 (s, 4 H, *m*-H), 8.02 [br. s, 1 H, NC(H)N] ppm. ^{13}C NMR (C_6D_6, 300 K): δ = 20.0 (s, *o*-CH_3), 21.0 (s, *p*-CH_3), 45.3 (s, NCH_3), 56.5 (s, NCH_2), 129.0 (s, *m*-C), 129.4, 131.0, 140.4 (s, Ar-C), 166.1 [br. s, NC(H)N] ppm. IR (Nujol): $\tilde{\nu}$ = 792 m, 851 m, 944 m, 998 m, 1018 m, 1061 w, 1158 m, 1212 m, 1285 s, 1302 m, 1536 s, 1609 w, 1644 w cm^{-1}.

X-ray Crystallography: Crystalline samples of compounds **1** and **3** were mounted upon glass fibres in silicone grease at −150 °C (123 K). A crystalline sample of **2** was mounted in a 0.5 mm capillary and sealed under argon at ambient temperature. Crystal data for compounds **1** and **3** were obtained using an Enraf−Nonius Kappa CCD. Data for **2** were obtained with a Bruker SMART CCD diffractometer. Data were corrected for absorption using the SADABS program.[34] Structural solution and refinement was carried out using SHELXL-97[35] and SHELXS-97[36] utilising the graphical interface X-Seed.[37] Crystal data and refinement parameters for all complexes are compiled in Table 1. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-186011 (**1**), -186013 (**2**) and -186012 (**3**). Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Self-Assembly of Cobaloximes and Rhodoximes with 3-Aminophenylboronic Acid: A Molecular Triangle and a Polymer

Renata Dreos,*[a] Giorgio Nardin,[a] Lucio Randaccio,*[a] Patrizia Siega,[a] and Giovanni Tauzher[a]

Keywords: Cobalt / Rhodium / Boronic acid / Self assembly

The reactions of methylaquacobaloxime and ethylaquacobaloxime with 3-aminophenylboronic acid in water produce supramolecular triangles **3a** and **3b** respectively, through the reaction of boron with the oxime oxygens of the alkylcobaloxime and the coordination of pyridine to cobalt. The reaction is reversible and strongly pH dependent. The complexes **3a** and **3b** precipitate immediately from the solution at pH 7, but dissolve quickly at both acidic (below 4) and basic (above 9) pH values. The aggregates are re-formed by readjusting the pH to neutrality and the precipitation-dissolution cycle may be repeated several times without an apparent decrease in yield. The complexes were fully characterised by ^{1}H and ^{13}C NMR spectroscopy. The X-ray structure shows that the neutral chiral supramolecule **3a** is a triangle of cobalt atoms with an approximate C_3 symmetry. The side of the triangle is about 9.5 Å. The ring closure is ensured by the torsion angles around the B–C and C–NH_2 bonds, which vary in the range 25–30° and 97–109°, respectively. The reaction of methylaquarhodoxime with 3-aminophenylboronic acid in water at pH 7 results in the displacement of H_2O by 3-aminophenylboronic acid only. The polymeric form **4** precipitates from CD_3OD in the NMR tube with time. The X-ray structure shows that **4** is a polymeric species with a zig-zag chain arrangement, with Rh···Rh distances of 9.2 Å. The chain arrangement is characterized by torsion angles around the B–C and C-NH_2 bonds of 61° and 92°, respectively.

Introduction

Use of the metal-ligand interaction to form inorganic supramolecules from mononuclear building blocks is a rapidly developing field in supramolecular chemistry.[1] Transition metal-directed self-assembly has been used to construct a large variety of molecular polygons and polyhedra, but molecular triangles with metal ions in vertex positions are still relatively rare, mainly due to the impossibility of generating the required 60° angle in a metal fragment of common coordination number. The majority of molecular triangles with metal ions at the corners are based on the square-planar geometry of Pt^{II} and Pd^{II} complexes [2] and display right-angled vertices. The closure of the triangle is made possible by ligands with appropriate coordinate vectors or by rather flexible ligands. The latter approach often results in low yields, owing to the formation of equilibrium mixtures, in which larger species, typically squares, are also present.[1] We report here the selective formation, in high yield, of neutral supramolecular triangles by reaction of octahedral organoaquacobaloximes with 3-aminophenylboronic acid. Furthermore, we show that changing the metal atom from Co to Rh causes a dramatic change in the structure and an inorganic polymer is formed.

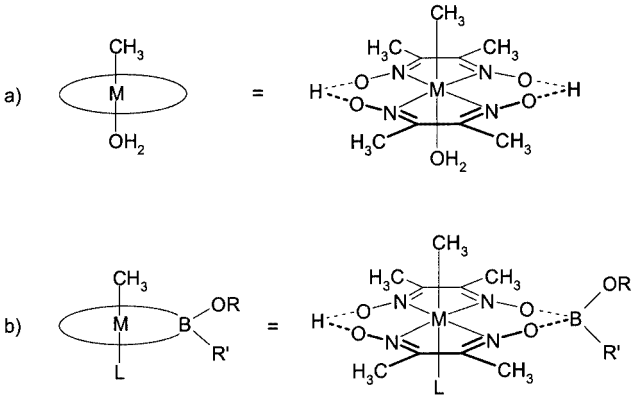
Results and Discussion

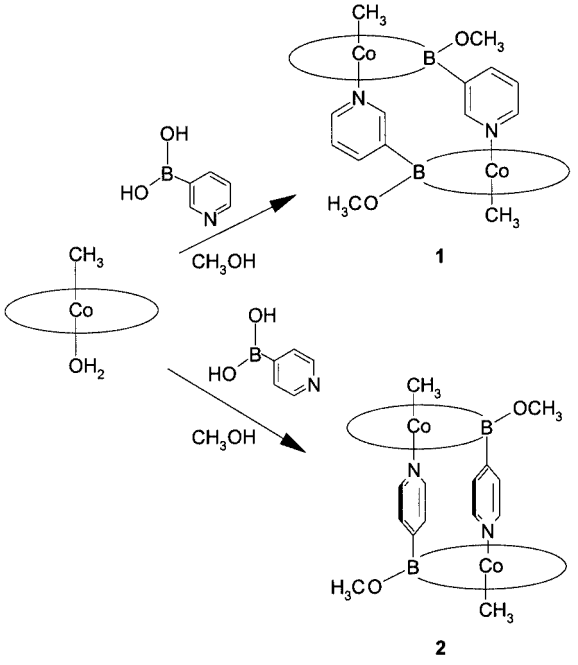
Synthesis

Alkylaquabis(dimethylglyoximates) of Co^{III} (alkylaquacobaloximes, Scheme 1) have already been shown to be suit-



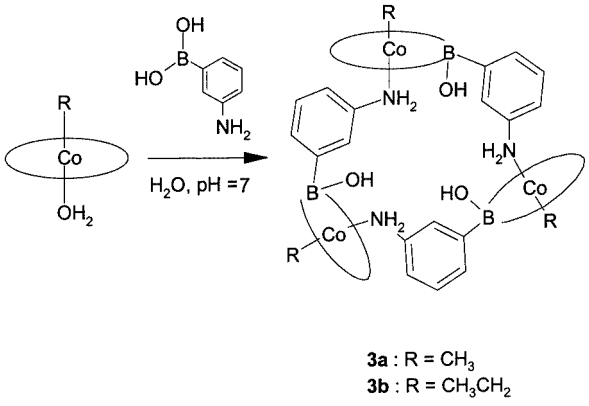
Scheme 1. Structural (right) and schematic (left) representation of a) alkylaquabis(dimethylglyoximate) (M = Co, Rh); b) monoborylated alkylbis(dimethylglyoximate)

able for self-assembly with functionalized arylboronic acids, such as 3- and 4-PyB(OH)$_2$.[3] In fact, similar to *cis*-diols,[4] the oxime bridges are very reactive towards boronic acids and the axial water ligand can easily be replaced by the pyridinyl group. The reaction of methylaquacobaloxime with 3-pyB(OH)$_2$ gives cyclic dimer **1**, with coplanar pyridinyl moieties, whereas the reaction with 4-pyB(OH)$_2$ gives cyclic dimer **2**, with parallel pyridinyl rings (Scheme 2). The reactions are strongly pH dependent, because the formation of the dinuclear species **1** and **2** requires the neutral (or zwitterionic) form of the boronic acid.[3b]



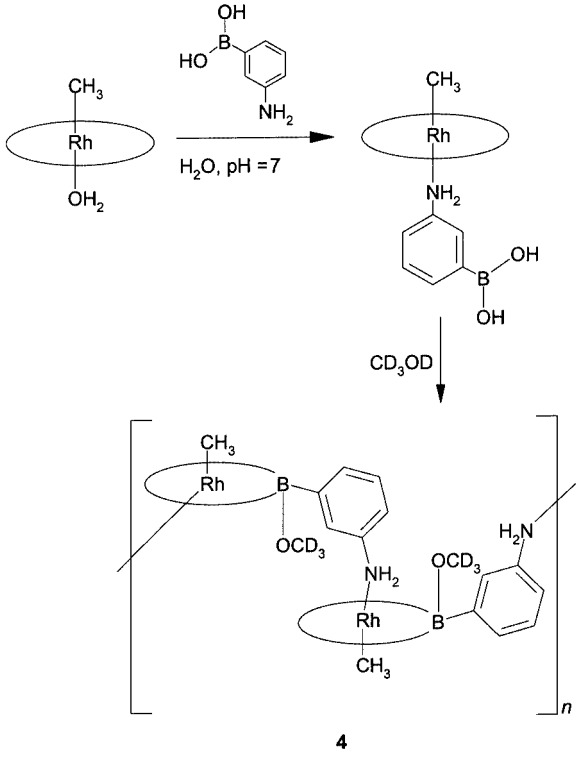
Scheme 2

The macroscopic pK_a values for the first and the second deprotonation of the 3-aminophenylboronic acid, determined by spectrophotometric titration, are 9.14 and 4.56, respectively. These values suggest, by analogy with the reactions with pyridinylboronic acids, that self-assembly should occur within this pH range. Indeed, when the pH of an aqueous solution of organoaquacobaloxime containing 3-aminophenylboronic acid in slightly less than an equimolar amount is adjusted to about 7, complexes **3a** and **3b** precipitate immediately from the solution (Scheme 3). Further acidification of the solution to below pH 4 results in the dissolution of the precipitate. The aggregate is re-formed by restoring the pH of the solution back to neutrality and is redissolved at alkaline pH values (above pH 9). The precipitation/dissolution cycle may be repeated at least twenty times without an apparent decrease in yield. The same trimer **3a** can be synthesized in methanol, without esterification of the B(OH) groups, provided the reagent concentration is sufficiently high to induce an immediate precipitation. If the precipitation occurs after a longer time, or if the precipitate is left in contact with the solution, the ^{1}H NMR spectrum shows a mixture of several products.



Scheme 3

The reaction of [CH$_3$Rh(DH)$_2$H$_2$O] with 3-aminophenylboronic acid in water at pH 7 (Scheme 4) results in the displacement of H$_2$O by 3-aminopheylboronic acid only, as suggested by an incomplete X-ray structural analysis and by the ^{1}H NMR spectrum in CD$_3$OD. The polymeric form **4** precipitates from CD$_3$OD in the NMR tube with time (Scheme 3). A ^{1}H NMR study in D$_2$O of a solution containing [CH$_3$Rh(DH)$_2$H$_2$O] and 3-aminophenylboronic acid in equimolar amounts does not give any evidence of a condensation reaction between the oxime bridge and the boronic acid in the pH range 9.5−0.6.



Scheme 4

X-ray Structure Determination of 3a

The structure of one enantiomer of the racemic crystal of **3a** is depicted in Figure 1. The molecule has an approx-

imate C_3 symmetry, with the threefold axis perpendicular to the plane of the cobalt atoms. Each B−OH group makes an intramolecular H-bond with the amino group coordinated to Co (Figure 1), with relatively short NH···O distances in the range 2.95(1)−3.04(1) Å. The conformational freedom of B and the torsion around the Co−NH_2 bond are thereby "frozen", so that the structure is essentially defined by the values of the torsion angles around the B−C and C−NH_2 bonds, which have very similar values in the three independent units. The torsion angles HO−B−C−C_α and Co−NH_2−C−C_α (where C_α = C40, C46, and C52, Figure 1) vary in the ranges 25−30° and 97−109°, respectively. The mean plane of the three carbon atoms of the methyl groups, each from one bis(dimethylglyoximate) moiety, is nearly parallel to that of the Co triangle [at an interplanar distance of 1.35(1) Å]. The Co plane is 1.76 Å from the approximately parallel mean plane of the O atoms of the boron OH groups. Therefore, one side of **3a** is hydrophilic (OH groups), while the other side is hydrophobic. A water molecule (O2W) is H-bonded to the three boron OH groups at distances in the range 2.82(1)−2.85(1) Å (Figure 1) and lies approximately at the mid-point of the three hydroxyl O atoms. It is interesting to note that the trimer/OW2 aggregates are held together by a network of H-bonds between the $(OH)_3$···OW2 grouping of one aggregate and that of the neighbouring aggregate, related by a crystallographic twofold axis along z (at x = 1/2, y = 1/4). Figure 2 shows the H-bond network, with O···O distances in the range 2.82−3.02 Å. Two distributions of the H atoms with half occupancy, related by the twofold axis, are represented. Each O atom has a distorted tetrahedral arrangement with four O···O H-bonds around OW2 and with two O···O, one NH···OH, and one O−B bond around each O atom of the boron (OH) groups.

Characterization of 3a and 3b by NMR Spectroscopy

The ^{1}H NMR spectrum of **3a** in $CDCl_3$ is in agreement with the trimeric structure of Figure 1. Four signals are observed for the equatorial methyl groups of each cobaloxime moiety, due to the loss of equivalence caused by the self-assembly process. One signal is shifted considerably upfield (δ = 1.39 ppm) in comparison with the usual range found for alkylcobaloximes.[5] This signal has been assigned to the protons on C18, C21 and C31, which lie above the plane of the phenyl rings and in the cone of their magnetic shielding. The protons of the NH_2 groups are diastereotopic and give rise to two doublets, one of which is in the aromatic part of the spectrum and the other in the range δ = 3.0−3.5 ppm. The protons on B(OH) and the oximic protons give rise to two singlets at δ = 4.48 and 18.0 ppm, respectively. In the spectrum of complex **3b**, the methylene protons of the ethyl groups are diastereotopic and give rise to the AB part of an ABM_3 pattern. All the other signals are almost superimposable onto those of **3a**. The strong similarity of the spectra suggests a trimeric structure also for **3b**.

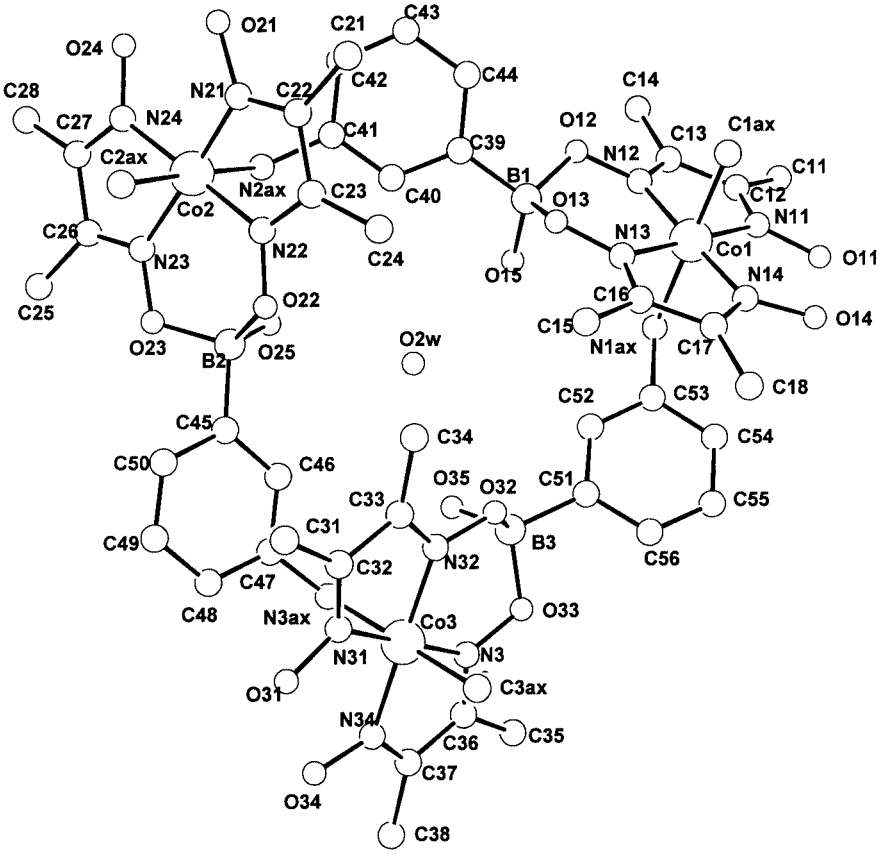


Figure 1. Molecular structure of one enantiomer of **3a**, with the labelling scheme for the atoms

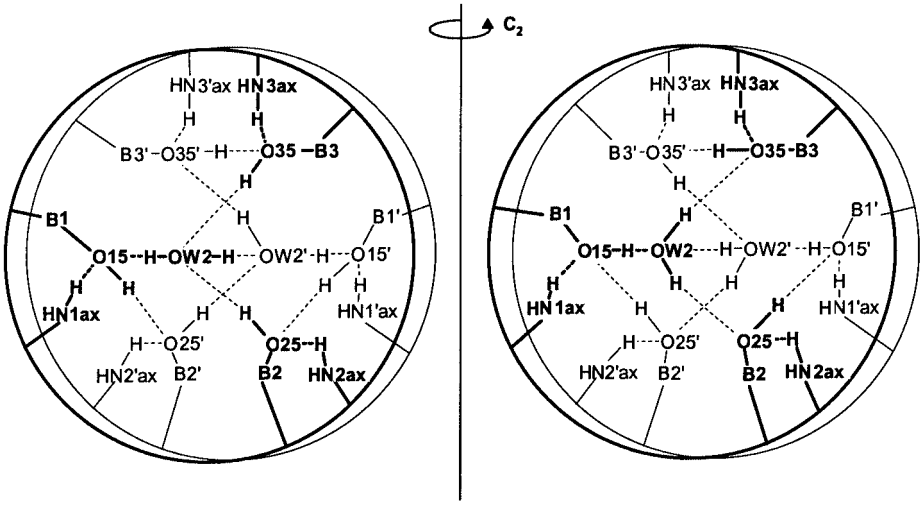

Figure 2. Two H-bond distributions, with half occupancy H atoms, in the network involving OW2 and boron OH groups; the superimposition of the two schemes has C_2 symmetry

The spectra show little variation with concentration (except for the NH_2 protons) in the range 2×10^{-2} to 1×10^{-3} M or with temperature in the range −60 to +50 °C. Therefore, the trimers are very stable in $CDCl_3$ solution and do not coexist in equilibrium with other species, even if a model inspection suggests that a tetranuclear square species is sterically allowed.

X-ray Structure Determination of 4

The structure of **4** is shown in Figure 3. In spite of the increase of about 0.1 Å in the coordination distances of rhodoximes with respect to those of the analogous cobaloximes, the local geometry of each unit is very similar to that of the unit in **3a**. An intramolecular H-bond between the coordinated amino group and the axially directed OCD_3 group, arising from the esterification of B(OH) in CD_3OD [NH···OCD_3 distance of 2.88(1) Å], is still present. Conformational changes, essentially due to a significant variation in the B−C and C−NH_2 torsion angles with respect to **3a**, lead to the chain arrangement shown in Figure 3, with a Rh···Rh distance of 9.159(4) Å. The O5−B1−C9−C10 and Rh−N5−C11−C12 torsion angles are 61(1) and 92(1)°, respectively. The polymer **4** is too insoluble in non-coordinating solvents to be studied by ^{1}H NMR spectroscopy.

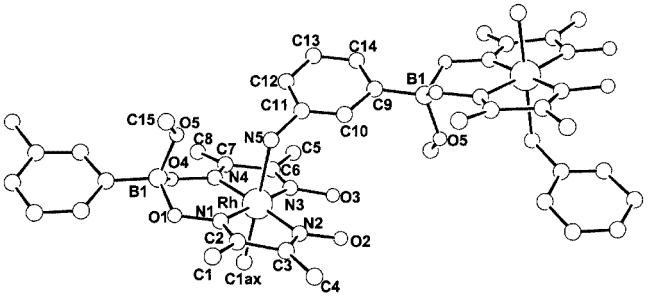

Figure 3. The chain arrangement of the polymeric species **4** with the labelling scheme for the atoms

Conclusion

The neutral trimers **3a** and **3b** are one of the few examples of triangular supramolecular structures based on an octahedral metal centre,[6] and show some novel elements. The fast assembly/disassembly process is reversible and "triggered" by a pH variation.[7] Furthermore, the 3-aminophenylboronic acid does not connect the cobaloxime units through two direct metal-ligand interactions, as occurs in most of the reported triangles.[1,2] The connection is created, on one side, by the reaction of the $B(OH)_2$ group with the oxime bridge at the periphery of the equatorial ligand and, on the other side, by the coordination of the amino group to cobalt. The chirality of **3** is a consequence of this way of binding. A further consequence of the use of the asymmetric linker is the complete diastereoselectivity in the formation of **3** and **4**. The ^{1}H NMR spectra of **3** do not show epimerization even at elevated temperatures ($CDCl_3$, 50 °C).

Methylaquacobaloxime and methylaquarhodoxime give very different products under similar conditions. As both the geometry and the coordination properties of the complexes are very similar, we believe that the relevant point is the esterification of the OH groups in **4**, due to their prolonged contact with deuterated methanol. This hypothesis is supported by evidence that complex **3a** can be recovered from methanol, without esterification of the B(OH) groups, but decomposes if left in contact with the solvent for a longer time. Probably, esterification reduces the stabilization arising from the H-bonds between the water molecule (OW2) and the three boron OH groups in the cyclic form **3** (Figure 2). The steric hindrance of OCH_3 could contribute to prevent the cyclization in **4**.

Experimental Section

General Remarks: NMR spectra were recorded on a Jeol EX-400 spectrometer (^{1}H at 400 MHz and ^{13}C at 100.4 MHz) with TMS

as internal standard. $[CH_3Co(DH)_2H_2O]$, $[CH_3CH_2Co(DH)_2H_2O]$[8] and $[CH_3Rh(DH)_2H_2O]$[9] were prepared according to literature procedures. All other reagents were reagent grade and used without further purification.

Synthesis of 3a and 3b: The appropriate alkylaquacobaloxime (0.40 mmmol) was dissolved in an aqueous alkaline solution (10 mL) with a pH of about 11 and 3-aminophenylboronic acid (0.37 mmol) was added. After filtration, the pH of the solution was lowered to about 7.0 with concentrated $HClO_4$. A highly insoluble yellow precipitate formed immediately, which was filtered and washed with water. X-ray quality crystals of **3a** were obtained by slow diffusion of a solution of the complex into CH_2Cl_2 in *n*-heptane.

3a: Yield: 70 mg (40%). $C_{45}H_{75}B_3Co_3N_{15}O_{18}$ (1323, with $3H_2O$): calcd: C 40.8, H 5.71, N 15.8; found C 40.4, H 5.51, N 15.2. ^{1}H NMR (400 MHz, $CDCl_3$, TMS): δ = 0.64 (s, 9 H, axial CH_3), 1.39 (s, 9 H, eq. CH_3), 1.90 (s, 9 H, eq. CH_3), 2.13 (s, 9 H, eq. CH_3), 2.27 (s, 9 H, eq. CH_3), 3.26 (d, $^2J_{H\text{-}H}$ = 8.3 Hz, 3 H, NH_2), 4.48 (s, 3 H, BOH), 6.67 (d, $^3J_{H\text{-}H}$ = 7.8 Hz, 3 H, ar. H), 6.88 (d, $^2J_{H\text{-}H}$ = 8.3 Hz, 3 H, NH_2) 7.04 (m, 3 H, ar. H), 7.09 (s, 3 H, ar. H), 7.35 (d, $^3J_{H\text{-}H}$ = 7.1 Hz, 3 H, ar. H), 18.01 (s, 3 H, OHO) ppm. ^{13}C NMR (100.4 MHz, $CDCl_3$, TMS): δ = 11.46, 12.18, 13.10, 14.60 (equatorial CH_3), 118.74, 124.36, 126.49, 129.44, 137.38 (aromatic carbons), 148.77, 149.62, 154.27, 156.69 (C=N).

3b: Yield: 90 mg (50%). $C_{48}H_{81}B_3Co_3N_{15}O_{18}$ (1365, with $3H_2O$): calcd: C 42.2, H 5.98, N 15.4; found C 41.0, H 5.60, N 15.0. ^{1}H NMR (400 MHz, $CDCl_3$, TMS): δ = 0.24 (t, $^3J_{H\text{-}H}$ = 7.6 Hz, 9 H, CH_3 of ethyl), 1.37 (s, 9 H, eq. CH_3), 1.57 (m, $^2J_{H\text{-}H}$ = 7.6 Hz, 6 H, CH_2 of ethyl), 1.87 (s, 9 H, eq. CH_3), 2.09 (s, 9 H, eq. CH_3), 2.26 (s, 9 H, eq. CH_3), 3.38 (d, $^2J_{H\text{-}H}$ = 8.3 Hz, 3 H, NH_2), 4.47 (s, 3 H, BOH), 6.66 (d, $^3J_{H\text{-}H}$ = 7.6 Hz, 3 H, ar. H), 6.73 (d, $^2J_{H\text{-}H}$ = 8.3 Hz, 3 H, NH_2), 7.03 (m, 3 H, ar. H), 7.09 (s, 3 H, ar. H), 7.32 (d, $^3J_{H\text{-}H}$ = 7.1 Hz, 3 H, ar. H), 17.87 (s, 3 H, OHO) ppm. ^{13}C NMR (100.4 MHz, $CDCl_3$, TMS): δ =15.83 (axial CH_3), 25.63 (axial CH_2) 11.47, 12.24, 13.20, 14.77 (equatorial CH_3), 118.75, 124.46, 126.56, 129.31, 137.60 (aromatic carbons), 148.80, 149.73, 154.42, 156.86 (C=N).

Synthesis of 4: Methylaquarhodoxime (0.10 mmmol) was dissolved in an aqueous alkaline solution (3 mL) with a pH of about 11 and 3-aminophenylboronic acid (0.12 mmol) was added. The pH of the solution was lowered to about 7.0 with concentrated $HClO_4$ and the solution left to stand. After some days yellow needle crystals were collected. Both an incomplete X-ray structure (due to the very low resolution) and the ^{1}H NMR spectrum in CD_3OD strongly suggested that the yellow product was a rhodoxime with coordinated aminophenylboronic acid. After some days, X-ray quality crystals of **4** were collected from the CD_3OD solution in the NMR tube. Yield: 10 mg (20%) $[C_{16}H_{25}N_5BO_5Rh + 1H_2O]_n$: calcd. C 38.5, H 5.45, N 14.0; found C 37.8, H 5.10, N 13.9. The polymer **4** is too insoluble in non-coordinating solvents to be studied by ^{1}H or ^{13}C NMR spectroscopy.

Equilibrium Studies: The deprotonation constants of the 3-aminophenylboronic acid were determined by spectrophotometric titration as previously described.[3b]

Structure Determination of 3a and 4: Single crystals, suitable for X-ray data collection, were obtained as reported above. X-ray diffraction data for **3a** and **4** were collected at room temperature with a Nonius DIP 1030 H System, using graphite-monochromated Mo-K_α radiation. For all compounds a total of 36 frames were collected, using the Xpress program,[10] over a half of reciprocal space, with a rotation of 5° about the axis. A Mac Science Image Plate (diameter = 300 mm) was used and the crystal-to-plate distance was fixed at 90 mm. The determination of unit-cell parameters, integration of reflection intensities and data scaling were performed using MOSFLM and SCALA from the CCP4 program suite.[11] Reflections, which were measured on previous and later frames, were used to scale the frames onto each other, a procedure that partially eliminated absorption effects, taking into account also any crystal decay. The structures were solved by direct methods,[12] followed by Fourier syntheses, and refined by full-matrix least-squares (on F^2) cycles.[13] Compounds **3a** and **4** co-crystallized with water molecules and 0.5 molecules of CH_2Cl_2 in the case of **3a**, and 1.5 molecules of CD_3OD in the case of **4**. All solvent molecules were refined isotropically. The H atoms were not refined but were included at calculated positions in the final refinements. The solvent H atoms and the disordered hydrogen of the B−OH were not included. A suite of programs[14] was also used for the geometrical and final calculations. Crystal and refinement data are given in Table 1. CCDC-175792 (**3a**) and CCDC-175793 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

An Iron(II) Complex with an N_4S Ligand − A Novel Model Compound to Mimic Cytochrome P450 Activity

Oliver Fazio,[a] Manuel Gnida,[b,c] Wolfram Meyer-Klaucke,[b] Walter Frank,[a] and Wolfgang Kläui*[a]

Dedicated to Prof. Dr. K. Wieghardt on the occasion of his 60th birthday

Keywords: Metalloenzymes / Tetrapodal pentadentate ligand / Iron / Homogeneous catalysis / O−O activation / N,S ligands / Epoxidation / EXAFS spectroscopy

The ligand 2,5-Bis[hydroxybis(2-pyridyl)methyl]thiophene (bhpmt) was designed to mimic the coordination sphere of cytochrome P450. With the ligand's four coplanar nitrogen atoms and an axial sulfur donor group it is the first nonporphyrin model compound to form a similar arrangement. The structure of the corresponding iron(II) perchlorate complex was determined by EXAFS and XPS measurements. The bond lengths of the first coordination sphere are remarkably similar to known porphyrin-based P450 model compounds. It is shown that the iron complex of bhmpt is able to perform epoxidation reactions with open-chain olefins and aqueous hydrogen peroxide (30%) as the oxidizing agent.

Introduction

Iron complexes are widely known in nature and play an essential part as biological redox catalysts in almost all life forms. Especially the heme proteins are of importance. Aside from hemoglobin, a great number of structurally related compounds, such as the cytochromes in the oxidative chain, are known.[1] Designing ligands that can mimic the structural aspects and, consequently, the catalytic properties of an enzyme has been the subject of extensive research in the field of biomimetic chemistry. It is one such model that we would like to report here. As a natural counterpart for our model system we have chosen the ubiquitous enzyme cytochrome P450, one of a class of heme-containing enzymes that catalyze the hydroxylation of C−H bonds, epoxidation of carbon−carbon double bonds, and the oxidation of heteroatoms.[2] Unlike many of the other heme-containing enzymes, P450 features a thiolate function at the apical position of the octahedral iron complex rather than another nitrogen donor group. It appears that thiolate ion ligation of the metal center is the main reason for the different reactivity of P450 compounds compared to other heme-based enzymes.[3] To understand the extraordinary properties of this enzyme many model compounds have been developed to date. While these mostly porphyrin-based complexes can sufficiently mimic the exact steric properties of the natural counterpart, their catalytic activities are limited.[4] So far only the Woggon group has developed a system that is able to perform oxygen insertion with dioxygen into nonactivated C−H bonds. Since the insertion occurs at a side chain of the model compound, the functional properties of P450 cannot be sufficiently mimicked.[4e] Simple, non-porphyrin iron-containing model compounds with an N_4S-donor set are unknown to the best of our knowledge. In contrast to the few known pentadentate ligands that usually carry N_5-donor sets,[5,6] we wanted to introduce a sulfur atom to occupy one axial position in an octahedral metal complex. However, the introduction of a thiolate moiety into a metal complex proves to be difficult, since it readily forms disulfides in the presence of O_2. In nature this problem is circumvented by creating hydrophobic cavities to protect the sulfur atom from oxidation.[4b] Trading stability for higher donor strength, we chose thiophene instead of thiolate as the axial donor group. Here we report the synthesis of the novel ligand 2,5-bis[hydroxybis(2-pyridyl)methyl]thiophene (bhmpt), the iron perchlorate complex of bhmpt, its catalytic properties in the epoxidation of simple olefins, and the structural characterization of its active site.

Results and Discussion

According to a procedure recently published by Feringa,[6a] who created a similar N_5-ligating system, bhpmt can be synthesized by treating 2,5-thiophenedicarbonyl dichloride with 2-lithiopyridine. However, treatment of 2,5-dilithiothiophene with bis(2-pyridyl) ketone gives much higher yields (Figure 1).

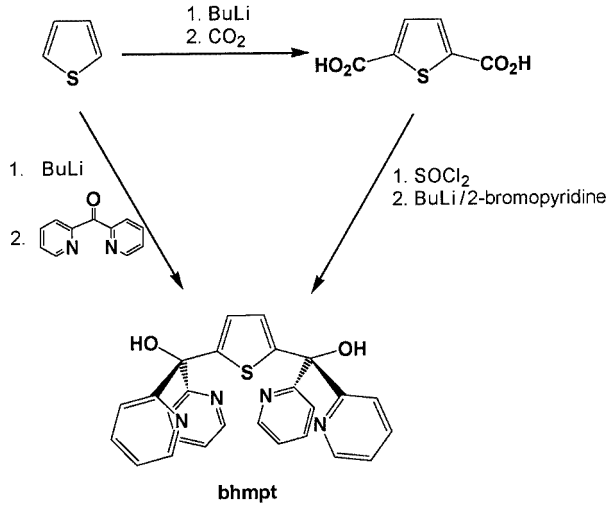

Figure 1. Synthesis of 2,5-bis[hydroxybis(2-pyridyl)methyl]thiophene (bhpmt)

The ligand is well soluble in halogenated solvents, toluene, THF as well as methanol and displays a high stability towards oxidation and hydrolysis.

Reaction of bhpmt with anhydrous iron(II) perchlorate in THF gives the corresponding metal complex. The compound is a yellow solid, paramagnetic and solely soluble in acetonitrile and dimethyl sulfoxide (DMSO). Due to disorder problems we have not been able to solve the crystal structure of the complex. The same problems were observed with the complexes of other divalent metal ions such as Co^{2+}, Ni^{2+} and Zn^{2+}. Only the corresponding copper perchlorate complex of bhpmt gave crystals suitable for X-ray analysis. It would not be reasonable to expect iron to exhibit the same coordination geometry as the copper complex. However, as is shown below, the X-ray data of the copper complex have helped to interpret the XPS and EXAFS data of the iron complex in the solid state and in solution.

The crystal structure of the copper complex shows that the thiophene moiety does not participate in the coordination of the metal center. Instead a dimer of two units of $[Cu(bhmpt)]^{2+}$ is formed, which allows the copper atoms to adopt the preferred square arrangement of four donor atoms. Both copper atoms are coordinated in a nearly planar fashion by three nitrogen atoms and one oxygen atom (Figure 2).

Vapour-pressure osmometric measurements, as well as conductivity measurements, suggest that the dimer is cleaved in solution to give monomers of as-yet-unknown structure.

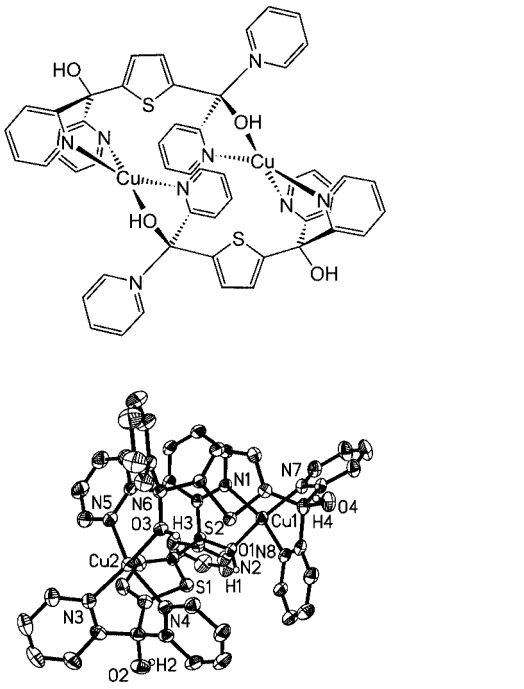

Figure 2. Molecular structure of the cation $[\{Cu(bhpmt)\}_2]^{4+}$; selected bond lengths [Å]: Cu1−O1 1.877(3), Cu1−N1 2.001(3), Cu1−N7 1.980(3), Cu1−N8 2.022(2), Cu1−O33′ 2.716(6) (perchlorate O), Cu2−O3 1.869(2), Cu2−N3 1.974(3), Cu2−N4 2.022(3), Cu2−N5 1.998(3), Cu2−O12 2.691(4) (perchlorate O); ′: $-x$, $2-y$, $-z$; selected H atoms, perchlorate anions and solvent molecules have been omitted for clarity; two of the perchlorate ions are weakly bonded to the two copper metal ions; by way of moderate hydrogen bonding two THF molecules are bonded to the OH moieties O2 and O4; additional disordered water and THF is situated among the ionic groups; displacement ellipsoids are drawn at the 25% probability level

Since the crystal structure of the corresponding iron complex of bhpmt could not be solved, spectroscopic measurements were used. X-ray photoelectron spectroscopy (XPS) measurements of $[Fe(bhpmt)](ClO_4)_2$ show four equivalent nitrogen atoms with binding energies in the range of coordinated pyridine, whereas for the corresponding copper complex the signal is broadened, indicating different electronic environments for the pyridine groups. According to the crystal structure of $[Cu_2(bhpmt)_2](ClO_4)_4$ the thiophene moiety does not participate in the coordination of the metal center. The XPS signal of thiophene is found at 164.3 eV. For the iron complex this signal is shifted to 164.0 eV. This decrease of binding energy at the sulfur atom is probably due to coordination of the sulfur atom to the iron atom.

The binding of bhmpt to the iron atom was investigated by means of Fe-*K*-edge X-ray absorption spectroscopy (XAS). The iron coordination environment was determined for solid $[Fe(bhpmt)](ClO_4)_2$·thf as well as for the metal complex dissolved in acetonitrile. Comparison of the normalized absorption edges for both samples shows that the step-like edge jump for the dissolved compound appears at lower energies than for the solid complex (Figure 3, separation of about 2−3 eV over the entire edge). Its energetic position is connected to the charge on the absorbing ion,[7]

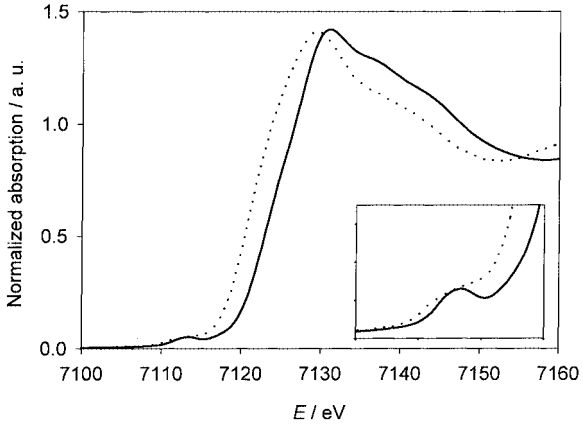

Figure 3. Normalized Fe-*K*-absorption edges of the solid compound (−) and the compound in solution (···); the inset displays the enlarged pre-edge region; abbreviations: a.u. = arbitrary units; *E* = X-ray energy

allowing the assignments of Fe^{II} for the solution and Fe^{III} for the solid-state complex. The Fe^{III} state is presumably a result of aerobic handling of the solid during sample preparation (see Exp. Sect.).

Both edge spectra exhibit a pre-edge peak at about 7113 eV (inset in Figure 3). It is due to a formally dipole-forbidden 1s → 3d electronic transition and its intensity is related to the coordination number and geometry of the iron site.[8] For both complexes the pre-edge peak areas (solid: 10.1 units; dissolved: 9.7 units; 1 unit = 10^{-2} eV) are in between the typical ranges for five- and six-coordinate complexes, indicating a significant distortion from octahedral symmetry.[8,9]

Further information on the iron coordination environment is derived from the extended X-ray absorption fine structure (EXAFS) of the absorption edge. Fourier transformation of the EXAFS signal allows the radial distribution of neighbouring atoms around the central absorbing metal ion to be explored (Figure 4, Table 1).

The structural composition of the first coordination shell of the iron atom is summarized in Table 1. In the solid as well as in the solution sample, the iron atom is coordinated by four nitrogen atoms (solid: 2.13 Å; solution: 2.11 Å) and one sulfur donor (solid: 2.29 Å; solution: 2.27 Å). Thus, the ligand binds in the desired pentadentate fashion with thiophene occupying the apical position (Figure 5). The sixth coordination site is most likely occupied by THF (Fe−O: 1.90 Å) and acetonitrile (Fe−N: 2.21 Å) in the solid state and in solution, respectively. No indication was found that dimerization occurs, as is the case for the corresponding Cu^{II} complex.

Comparison of the obtained data with EXAFS data of a heme-based P450-model compound by Higuchi's group shows very similar bond lengths (Fe−S 2.20 Å, Fe−N 2.00 Å).[4d] This indicates that the structural aspects of P450 can be adequately mimicked even by a simple model compound such as bhmpt in the solid state as well as in solution.

Epoxidation reactions were performed in order to investigate the catalytic activity, and consequently the ability of

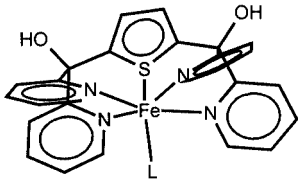

Figure 5. Molecular structure of the P-450 mimic investigated in this study; in the solid L is THF whereas CH_3CN binds to the iron ion in the dissolved complex

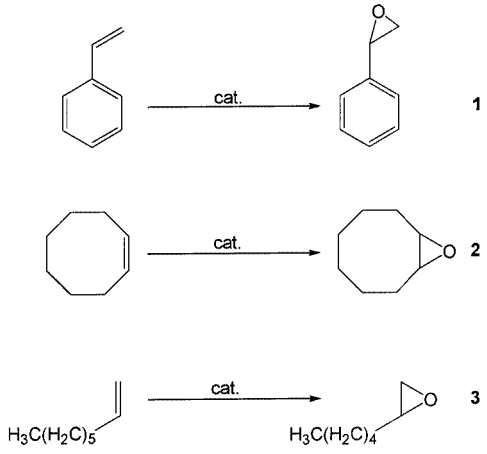

Figure 6. Performed epoxidation reactions

[Fe(bhpmt)]$^{2+}$ to mimic its biological counterpart (Figure 6).

For all reactions the catalyst was charged with a 50-fold excess of the substrate and the same amount of aqueous hydrogen peroxide (30%). The course of the catalytic reaction was monitored by gas chromatography (GC) and the resulting products were identified by gas chromatography/mass spectrometry (GC/MS). Surprisingly, the catalysis with a relatively unreactive olefin such as 1-octene displays similar efficiencies to that of more reactive substrates like styrene and cyclooctene (Figure 7).

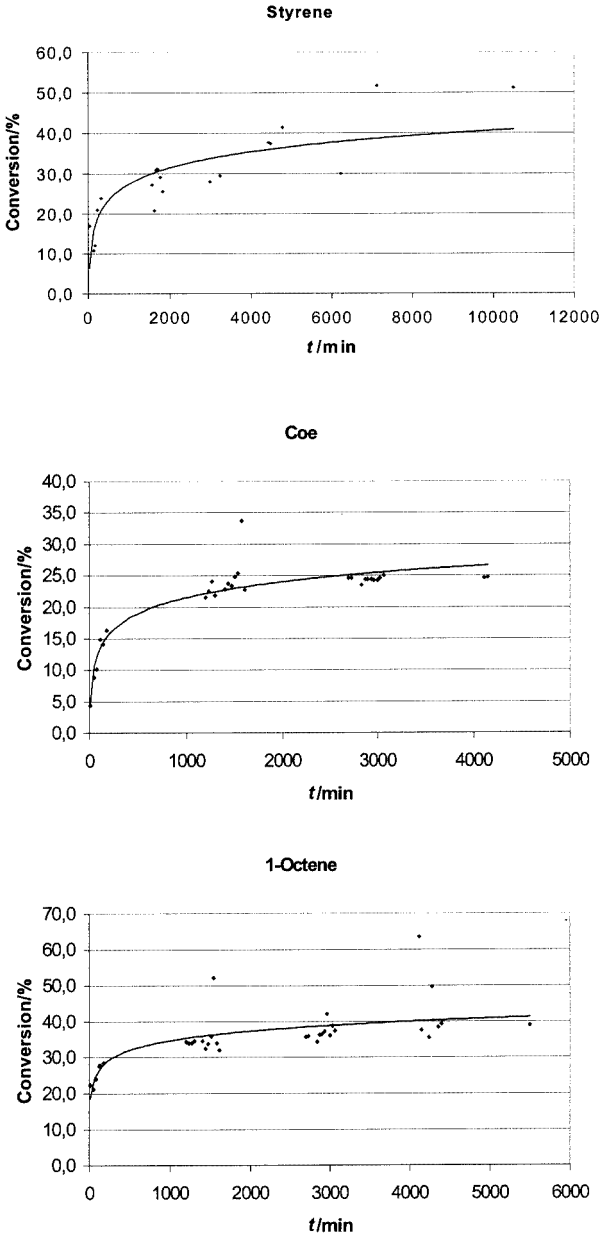

Figure 7. Conversion vs. time plots of the epoxidation reactions with styrene, cyclooctene (coe) and 1-octene

When norbornene is used as a substrate, significantly less epoxide is formed. This leads to the conclusion that the steric demands of the substrate and thus accessibility to the metal center determine the conversion rate, while the electronic properties of the substrate only have a minor effect on the catalysis. Since none of the other model compounds of P450 have been reported to show similar behavior we cannot decide whether this is typical for these types of iron complexes.

The only other iron complex to catalyze the epoxidation of open-chain olefins has been reported by Valentine. In this case, however, the ligand system is based on cyclam, thus having only four nitrogen donor groups. With a turnover of 20 for [Fe(bhpmt)]$(ClO_4)_2$, the epoxidation of 1-

octene shows significantly higher turnover numbers based on the iron complex than the one obtained with [Fe(cyclam)]$(CF_3SO_3)_2$ which reaches only 7 turnovers (Table 2).[11]

Table 2. Substrates used and resulting conversions to the corresponding epoxides

Substrate	Conversion	Turnover[a]
Styrene	51%	25
1-Octene	40%	20
Cyclooctene	25%	13
Norbornene	10%	5

[a] mmol of epoxide per mmol of catalyst.

The catalytic reactions proceed slowly with moderate conversions of the substrates. After approximately one day, the termination stage of each reaction is reached and the efficiency cannot be increased by further addition of either substrate or hydrogen peroxide. This suggests that the catalyst, which displays an unusually high durability in an aqueous medium for an iron(II) complex, does decompose after a while, forcing the catalytic activity to subside. At present, we do not know the nature or structure of the decomposition products. We believe that the ligand is oxidized after a while, releasing iron perchlorate. This is known to catalyze the decomposition of hydrogen peroxide, which could be another reason for the comparatively low efficiency of the catalyst. When using $Fe(ClO_4)_2$ as the catalyst in a control experiment, no epoxidation product could be detected.

Conclusions

With the iron complex of bhpmt we were able to mimic the structural aspects as well as the catalytic activity of cytochrome P450. We believe the latter is possible due to sulfur ligation of the central atom. Unusually for iron(III) complexes, which mostly form insoluble hydroxides in the presence of water, the metal complex of bhpmt displays a high tolerance for small amounts of water and is able to perform the catalysis with aqueous hydrogen peroxide. We discovered that higher conversion rates are obtained with sterically less demanding (albeit less strained) substrates. Therefore, styrene and 1-octene display conversion rates in the same range, whereas substrates with considerably higher ring strain, such as cyclooctene, are much harder to epoxidize. Norbornene, with the highest steric demand shows hardly any conversion into the corresponding epoxide. This is unlike the reactivity of other epoxidation catalysts such as porphyrin−iron complexes[12] and manganese[13] and chromium[14] complexes of salen-type ligands, where electronic factors play a more important role than the steric factor.

Experimental Section

CAUTION! Although no problems were encountered in this work, transition metal perchlorate complexes with organic ligands are potentially explosive and should be handled with due precaution. All reagents were commercial samples and were used as received.

Materials and Instrumentation: When not stated otherwise, experiments were performed under nitrogen using standard Schlenk techniques and freshly dried solvents. Filtration was done with 1-μm membrane filters (regenerated cellulose, Schleicher & Schuell). Infrared spectra were recorded by using a Bruker IFS 66 FT spectrometer. GC analysis was done with an HP-5890 series II chromatograph with an FID detector and an MSD 5970 integrator. As a standard for gas chromatography 0.8 mL of mesitylene was added to each catalysis experiment. Elemental analyses were performed using a Perkin−Elmer CHN-2400/II elemental analyzer.

2,5-Bis[hydroxybis(2-pyridyl)methyl]thiophene (bhpmt): *n*-Butyllithium (8.0 mL, 3 mmol) was dissolved in *n*-hexane (40 mL) and treated with an equimolar amount of tetramethylethylenediamine (tmeda; 1.5 g). After slow addition of freshly distilled thiophene (0.43 g, 5.1 mmol) in *n*-hexane (50 mL), the reaction mixture was heated to reflux for 1 h. The mixture was then transferred to a flask, containing bis(2-pyridyl) ketone (2.4 g, bis 13 mmol) in diethyl ether, and stirred overnight. After hydrolyzing with iced water and neutralization with hydrochloric acid, the precipitate was filtered off and washed with diethyl ether until a white solid remained. Recrystallization from THF/*n*-hexane yielded 1.1 g (47%). ^{1}H NMR (500 MHz, $CDCl_3$, 298 K): δ = 6.95 (s, 2 H, C_4H_2S), 7.19 (dt, $^3J_{H,H}$ = 6, $^4J_{H,H}$ = 1 Hz, 4 H, C_5H_4N), 7.94 (dt, $^3J_{H,H}$ = 8, $^4J_{H,H}$ = 2 Hz, 4 H, C_5H_4N), 7.98 (d, $^3J_{H,H}$ = 8 Hz, 4 H, C_5H_4N), 8.49 (d, $^3J_{H,H}$ = 5 Hz, 4 H, C_5H_4N) ppm. $^{13}C\{^1H\}$ NMR (500 MHz, $CDCl_3$, 298 K): δ = 78.7 (s, COH), 122.6 (s, C_5H_4N), 122.8 (s, C_5H_4N), 125.9 (s, C_4H_2S), 137.1 (s, C_5H_4N), 147.7 (s, C_5H_4N), 150.6 (s, C_5H_4N), 162.7 (s, C_4H_2S) ppm. IR (KBr): $\tilde{\nu}$ = 3375 br, 1585 vs, 1569 s, 1463 vs, 1432 vs, 1363 br, 1328 m, 1190 s, 1154 m, 1142 m, 1104 s, 1068 m, 967 w, 864 m, 774 s, 749 s, 700 s, 674 s, 662 s, 627 m, 513 w cm^{-1}. UV/Vis (THF): λ_{max} (ε) = 259 nm (22000), 210 nm (28000). MS (FAB+NBA): *m*/*z* (%) = 453 (61) [M^+ + H], 435 (92) [M^+ − OH], 268 ([M − $py_2COH]^+$). $C_{26}H_{20}N_4O_2S$ (452.5): calcd. C 69.0, H 4.4, N 12.4; found C 68.6, H 3.9, N 11.9.

[Fe(bhpmt)]$(ClO_4)_2$·thf: bhpmt (0.36 g, 0.65 mmol) was treated with anhydrous iron(II) perchlorate (0.17 mg, 0.65 mmol) in THF and stirred overnight. The resulting solid was filtered and recrystallized from acetonitrile/THF. Yield 0.31 g (60%). IR (KBr): $\tilde{\nu}$ = 3431 br, 3098 w, 1602 s, 1521 w, 1468 m, 1437 m, 1297 w, 1096 vs, 772 s, 624 s cm^{-1}. Conductivity Λ = 234 S·cm^2·mol^{-1} (acetonitrile). $C_{30}H_{28}Cl_2FeN_4O_{11}S$ (779.4): calcd. C 46.2, H 3.6, N 7.2; found C 46.8, H 3.5, N 7.5.

[Cu_2(bhpmt)$_2$]$(ClO_4)_4$: The compound was prepared according to the procedure described for the iron complex; bhpmt (0.13 g, 0.29 mmol), copper(II) perchlorate dihydrate (0.11 g, 0.29 mmol), recrystallization from acetonitrile/THF. Yield 0.12 g (80%). IR (KBr): $\tilde{\nu}$ = 3429 br, 1602 s, 1514 w, 1469 m, 1441 m, 1294 w, 1121 vs, 1101 m, 1090 w, 772 s, 627 s cm^{-1}. $C_{64}H_{67}Cl_4Cu_2N_8O_{24.5}S_2$ (1673.2):calcd. C 45.9, H 4.0, N 6.7; found C 42.7, H 3.4, N 7.0.

Crystal Structure Analysis of [Cu_2(bhmpt)$_2$]$(ClO_4)_4$·3C_4H_8O·1.5H_2O: M_r = 1673.26; crystal dimensions: 0.32 × 0.45 × 0.61 mm, *a* = 13.787(3) Å, *b* = 15.753(2) Å, *c* = 19.182(4) Å, α = 89.69(2)°, β = 81.12(2)°, γ = 65.85(2)°, *V* = 3748.2(12) $Å^3$, *Z* =

2, $\rho_{calcd.}$ = 1.483 Mg/m^3, triclinic, space group $P\bar{1}$. Stoe IPDS, Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator, T = 20 °C, Θ_{max} = 30.31°, $-19 < h < 16$, $-20 < k < 18$, $-27 < l < 27$, 76976 reflections were detected, 20254 independent (R_{int} = 0.0595), 7640 were classified as "observed" with $I > 2\sigma(I)$, μ = 0.847 mm^{-1}, Direct method (SHELXS-97) and difference Fourier syntheses (SHELXL-97), minimizing of $\Sigma w(F_o^2 - F_c^2)^2$ with $w = 1/[\sigma^2(F_o^2) + 0.03P^2]$ and $P = (F_o^2 + 2F_c^2)/3$, 1048 refined parameters, R_1 = 0.0592, wR_2 = 0.1131, $(\Delta/\sigma)_{max}$ = 0.001, $\Delta\rho_{max}/\Delta\rho_{min}$ = 0.615/−0.358 e Å^{-3}. CCDC-190219 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

General Preparation for the Synthesis of Epoxides: [Fe(bhpmt)](ClO$_4$)$_2$ (8.4 mg, 1.0 μmol) and the substrate (50 μmol) were dissolved in acetonitrile (15 mL) and treated with 30% hydrogen peroxide (50 μL, 50 μmol). This mixture was stirred for 3 d at room temperature. The substrates used and resulting conversions are displayed in Table 2.

XAS Samples: Solution sample: A 3.2 mM solution of Fe(bhpmt)(ClO$_4$)$_2$ in acetonitrile (75 μL), with 5 vol.% glycerine, was poured into a sample cell of HESAR glass, covered with Kapton windows. Solid sample: In order to avoid "thickness effects" in the X-ray absorption spectrum, [Fe(bhpmt)](ClO$_4$)$_2$ (28 mg) in THF was mixed with boron nitride (59 mg, under aerobic conditions) in order to obtain an absorbance less than unity.[15] The mixture was pasted homogeneously into a sample cell of HESAR glass and was sealed with Kapton windows.

XAS Data Collection: Data were collected at the EMBL bending magnet EXAFS beam line D2 at DESY (Hamburg, Germany) using an Si(111) double crystal monochromator and a double focusing mirror. As detectors ionization chambers (absorption mode for solid sample) and a 13-element solid-state Canberra fluorescence detector (fluorescence mode for solution sample) were used. Absolute energy calibration of the spectra was achieved recording Bragg reflections of a static Si(220) crystal in back-reflection geometry.[16] During data collection, the samples were kept in an He closed-cycle cryostat (modified Oxford instruments) at temperatures below 55 K.

XAS Data Analysis: Data reduction such as background removal and extraction of the EXAFS signal was performed using the EXPROG program package (H. F. Nolting, C. Hermes, EMBL Hamburg) and assuming an Fe-K-edge position of E_0 = 7112 eV. EXAFS data were analyzed with EXCURV98,[10] considering multiple scattering from the units of pyridine, tetrahydrofuran, thiophene, and acetonitrile. Pre-edge peak areas were determined by fitting one (solid) or two (solution) Gaussians to the X-ray absorption spectra (solid: 7100−7121 eV; solution: 7100−7118). In addition, a Lorentzian was used as background function (rising edge).

Acknowledgments

We thank Dr. P. Albers and Dr. M. Pfeifer at dmc^2 for their kind support and XPS measurements. The authors are grateful to Dr. G. Barone (Department of Inorganic Chemistry, University of Palermo, Italy) for providing us with optimized structures of the multiple scattering units used in the EXAFS analysis. We gratefully acknowledge the Fonds der Chemischen Industrie for supporting our research.

Manganese Oxidation Catalysts with 2-(2′-Hydroxyphenyl)oxazoline Ligands: Catalyst Intermediates and Degradation Products − Crystal Structure of Bis[{2-(2′-oxazolinyl)phenolato}bis(1-methylimidazole)manganese(III)] Perchlorate

Marcel Hoogenraad,[a] Huub Kooijman,[b] Anthony L. Spek,[b] Elisabeth Bouwman,[a] Jaap G. Haasnoot,[a] and Jan Reedijk*[a]

Keywords: Catalysis / Manganese / Mass spectrometry / Oxazolines / Oxidation

Manganese complexes with phox ligands [Hphox = 2-(2′-hydroxyphenyl)oxazoline] act as oxidation catalysts with dihydrogen peroxide. Their catalytic efficiency is strongly affected by the presence of a base, such as 1-methylimidazole (1-Meim). The crystal structure of an Mn–phox complex with two axial 1-Meim ligands, $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$, is reported. The $[Mn(phox)_2]^+$ and $[Mn(phox)_2(1\text{-}Meim)]^+$ species have been detected in catalytic reaction mixtures by electrospray mass spectrometry. In the catalytic oxidation of styrene, turnover numbers of 428 and 456 have been obtained for styrene oxide in the presence of $[Mn(phox)_3]$ and of $[Mn(5'\text{-}NO_2phox)_3]$, respectively. During these reactions, catalyst degradation occurs, and is the main obstacle to obtaining higher turnover numbers. GC-MS analysis of the degradation products of $[Mn(5'\text{-}Clphox)_3]$ after catalytic reactions indicates that the oxazoline group is decomposed. The same decomposition products are also observed with electrospray mass spectrometry at higher ionisation potentials.

Introduction

Oxidations are versatile reactions for the synthesis of various fine chemicals and pharmaceuticals.[1] Traditionally, these reactions are performed with stoichiometric amounts of inorganic oxidants such as chromium or manganese oxides. However, the use of such reagents is environmentally unacceptable and there is an increasing demand for clean synthetic methods.[2,3] A very attractive method for oxidation reactions is the use of manganese catalysts with clean and cheap oxidants such as molecular oxygen or dihydrogen peroxide. Various manganese complexes with, for example, substituted tacn (1,4,7-triazacyclononane), porphyrin, salen [H_2salen = bis(salicylidene)ethylenediamine] or phox [Hphox = 2-(2′-hydroxyphenyl)oxazoline] ligands, have successfully been used in oxidation reactions and bleaching processes with dihydrogen peroxide.[4,5] In most reactions with these complexes, however, catalyst degradation results in loss of catalytic activity. Catalyst degradation is often a problem in oxidation catalysis,[6] and provision of increased stability in the manganese catalysts is therefore of great interest. A significant increase in stability has been accomplished by modification of the ligands. For instance, the introduction of halogen or nitro groups onto porphyrin catalysts results in a higher resistance towards oxidative degradation.[7] Similarly, the stability, and thus the catalytic efficiency, of Mn−salen complexes (or Jacobsen−Katsuki catalysts) has been reported to be improved by introduction of electron-withdrawing nitro substituents,[8] although in catalysed asymmetric epoxidation reactions this change results in significantly lower enantiomeric excesses (*ee*s) in the epoxides.[9] Alternatively, the addition of *N*-oxides[10] or, for reactions with dihydrogen peroxide,[11] of bases improves the catalytic efficiency without significantly reducing the *ee*s of the products. A base effect[12] and a substituent effect[13] have also been found for oxidations catalysed by the Mn−phox complexes. The didentate Hphox ligands, like the salen ligands, have a mixed N,O-donor set and are readily accessible. They are also known to be more stable to hydrolysis than the salen ligands.[14] However, the Mn−phox complexes also show a loss of catalytic activity over time during oxidation reactions.

The reactions causing the degradation of the complexes with the salen and similar phox ligands are not yet clearly understood. Dual-mode EPR spectroscopy has been used to gain insight into the mechanism of catalyst degradation of Mn−salen epoxidation catalysts.[15] This paper reports studies of the Mn−phox complexes during oxidation reac-

tions, showing the effect of the reaction conditions on the catalytic efficiency, and the identification of various catalyst intermediates and degradation products.

Results and Discussion

Molecular Structure of $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$

X-ray analysis of $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$ (1-Meim = 1-methylimidazole) shows two similar independent molecules present in the unit cell, with $Z = 2$.

The structure of these molecules consists of a C_i-symmetric manganese(III) ion with two phox ligands *trans*-coordinated in the equatorial plane and two monodentate axial 1-Meim ligands (Figure 1), together with a noncoordinating perchlorate anion. Selected bond lengths and angles are given in Table 1.

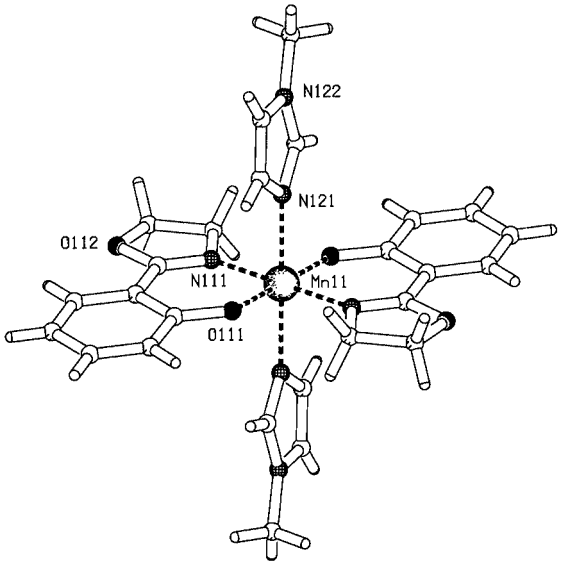

Figure 1. PLATON projection of the structure of one of the $[Mn(phox)_2(1\text{-}MeIm)_2]^+$ ions

Table 1. Selected bond lengths [Å] and angles [°] of one of the molecules of $[Mn(phox)_2(1\text{-}MeIm)_2](ClO_4)_2$; symmetry operation: $'$: $-x, -y, 1 - z$

Mn11−O111	1.867(2)	Mn11−N121	2.235(3)
Mn11−N111	2.045(3)		
O111−Mn11−N111	90.59(11)	O111−Mn11−N121′	89.88(10)
O111−Mn11−N111′	89.41(11)	N111−Mn11−N121	89.40(10)
O111−Mn11−N121	90.12(10)	N111−Mn11−N121′	90.60(10)

The differences in the ligand-to-metal bond lengths between the independent units are within 0.03 Å, while the differences in the bond angles are within 0.06°. The axial bonds of 2.235(3) (Mn1−N121) and 2.261(3) Å (Mn2−N221) are longer than the coordination bonds between the manganese ion and the phox ligands, as is to be expected for a Jahn−Teller-distorted d^4 ion. The Mn1−O111 and Mn−O211 bond lengths are similar to the bond lengths found in the $[Mn(phox)_2(MeOH)_2]^+$ units of the other Mn−phox complexes,[16] while the bonds of the manganese ion to the oxazoline nitrogen atoms are slightly longer.

Manganese(III) complexes with similar N_4O_2 coordination have been characterised for various Mn−salen complexes with pyridine molecules as axial ligands.[17] The main differences are the longer axial coordination bonds (between 2.30[18] and 2.48 Å[19]) for these complexes, as compared to $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$. A manganese(III) complex with two axially coordinated imidazole groups from 1,4-di(1-imidazolyl)butane has been synthesised; in this case the two imidazole groups of one ligand coordinate to different manganese atoms, resulting in a network structure.[20] The bond lengths of the Mn−N bonds in this complex (2.28 and 2.29 Å) are only slightly longer than those in $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$.

Catalysis

The solvent employed has a large effect on $[Mn(phox)_3]$-catalysed oxidation reactions;[13] the most interesting solvents were found to be methanol and acetone. The catalytic efficiency in the reactions in acetone (similarly to that in the reactions in methanol[12]) is increased by the addition of a base such as 1-Meim. In acetone, however, much higher turnover numbers have been obtained. It has been proposed that an acetone adduct of dihydrogen peroxide would be formed under these conditions, and that this would slowly release dihydrogen peroxide during the reaction,[21] although the adduct itself might also act as the actual oxidant. Gas evolution due to dihydrogen peroxide decomposition is visible during the reactions in acetone, and hydrogen peroxide decomposition is the limiting factor for these reactions. In methanol, ligand degradation limits the cumulative turnover numbers; after 15 min, hydrogen peroxide is still present and activity can be restored by addition of fresh quantities of the ligand. The amounts of dihydrogen peroxide used were varied to study the result on the turnover numbers, as well as the efficiency, relative to the oxidant (Table 2).

The results in Table 2 clearly show that the use of only 2.1 mmol of dihydrogen peroxide (10% of the standard amount) already results in a turnover number of 22 in methanol, an efficiency of 14.7% relative to dihydrogen peroxide. With larger amounts of dihydrogen peroxide, the turnover numbers level off, with a concomitant decrease in the efficiency based on the oxidant. This efficiency and the turnover number can be slightly increased by slow addition of the oxidant (five times 4.2 mmol in 15 min), resulting in a turnover number of 40 towards styrene oxide (efficiency of 2.7% based on H_2O_2) and of 4 towards benzaldehyde.

In acetone, contrary to the situation in methanol, an increase in the amount of oxidant from 5.3 mmol to 21 mmol results in a significant increase in the turnover numbers. The highest efficiency (15.8%) towards the oxidant is obtained on addition of 15.8 mmol of dihydrogen peroxide. At higher amounts of the oxidant, added at once, the turnover

Table 2. Effect of the amount of 1-Meim and dihydrogen peroxide on the turnover numbers and efficiency towards H_2O_2 in the [Mn(phox)$_3$]-catalysed oxidation of styrene

1-Meim Amount [mmol]	H_2O_2 Amount [mmol]	Turnover numbers towards styrene oxide[a] Methanol	Acetone	Yield of styrene oxide based on H_2O_2 (%) Methanol	Acetone

2.0	4 × 21.0[c]	34	428	0.6	7.1

[a] Reactions in methanol were carried out with stirring by dissolving [Mn(phox)$_3$] (14 μmol) in methanol (20 mL) at room temperature; subsequently, the substrate (14 mmol), 1-MeIm (2.0 mmol) and the indicated amount of dihydrogen peroxide were added (t = 0); turnover numbers are the total turnover numbers at t = 15 min; reactions in acetone were carried out by stirring acetone (10 mL) and the indicated amount of dihydrogen peroxide at 0 °C for 30 min; subsequently, the substrate (14 mmol), 1-MeIm (2.0 mmol) and [Mn(phox)$_3$] (14 μmol) were added (t = 0); turnover numbers are the total turnover numbers at t = 15 min. [b] Slow addition of the oxidant (five times 4.2 mmol in 15 min); n.d. = not determined. [c] 21.0 mmol was added before the reaction; additional amounts of 21.0 mmol of the oxidant, dissolved in 5 mL of acetone, were added, at t = 15, 30 and 45 min.

numbers appear to reach a maximum. It may be that a maximum activity is found at a certain dihydrogen peroxide concentration, or it may indicate that by this time most of the extra dihydrogen peroxide added is decomposed into water and dioxygen. In contrast to the reactions in methanol,[12] the catalytic activity could not be restored by addition of fresh Hphox ligand. Subsequent addition of extra dihydrogen peroxide instead of the ligand, however, results in an increase in the total turnover number. After three consecutive additions of quantities of 21 mmol of dihydrogen peroxide in 5 mL of acetone at t = 15, 30, and 45 min (by which time the solution had turned colourless), a turnover number of up to 428 was obtained. The addition of even more dihydrogen peroxide did not result in any further increase in the turnover number, but gas evolution still continued. To regain catalytic epoxidation activity at this point, addition of fresh Hphox ligand appeared to be necessary, indicating that the catalyst had been degraded by this time.

Higher turnover numbers have been obtained with the more stable [Mn(5′-NO_2phox)$_3$] catalyst, similarly to the case of the reactions in methanol.[13] For [Mn(5′-NO_2phox)$_3$], the obtained turnover number of 456 towards styrene oxide obtained for the reaction in acetone (4×21 mmol H_2O_2) corresponds to a yield of 46% relative to styrene. The addition of extra dihydrogen peroxide increases the turnover numbers, but lowers the efficiency relative to the oxidant to 7.1% (reaction with [Mn(phox)$_3$]) and 7.6% (reaction with [Mn(5′-NO_2phox)$_3$]).

Catalyst Degradation

The major obstacle to the obtainment of higher turnover numbers in the Mn−phox-catalysed oxidation reactions is catalyst degradation. It has been reported that the decrease in catalytic activity during the reactions in methanol coincides with a change in the original green colour of the solution to pale yellow or colourless and the appearance of a manganese(II) EPR signal, while the addition of fresh free ligand results in regeneration both of the green solution and of the catalytic activity, indicating that the ligand decomposes during the catalytic reactions.[12] Similarly, the appearance of the manganese(II) EPR signal and decolouration of the solution also occur for the reactions in acetone, although loss of the catalytic activity due to catalyst degradation and the related decolouration of the solution both proceed less quickly (45 min) than in methanol (15 min, see above).

ES-MS studies were performed during the oxidation of styrene with [Mn(phox)$_3$] and [Mn(5′-NO_2phox)$_3$] in methanol and in acetone. In the absence of the oxidant, the main fragments detected for the [Mn(phox)$_3$] and [Mn(5′-NO_2phox)$_3$] complexes (both in the methanol and in the acetone solutions) are the $[MnL_2]^+$ and the $[MnL_2(1\text{-Meim})]^+$ ions. These two fragments may originate from species of the type $[MnL_3]$ or $[MnL_2L'_xL''_y]^+$ (with L′ and L″ being, for instance, 1-methylimidazole or solvent molecules) after dissociation of one or two coordinating groups. After addition of dihydrogen peroxide, the $[MnL_2]^+$ and $[MnL_2(1\text{-Meim})]^+$ fragments are still the most important species observed in

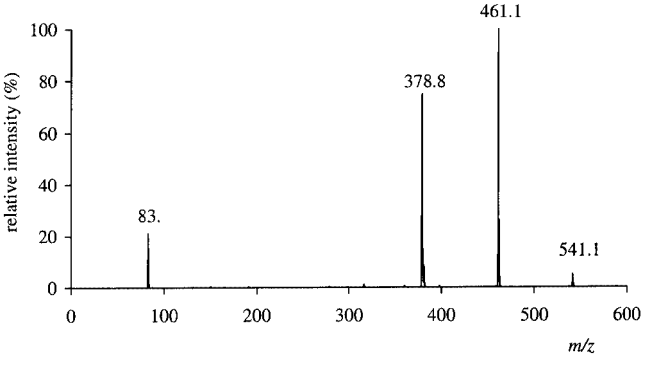

Figure 2. Electrospray mass spectrum at the start (t = 1 min) of the oxidation of styrene with [Mn(phox)$_3$] and dihydrogen peroxide in methanol: m/z = 83.0 [1-MeIm + H^+], 378.8 $[Mn(phox)_2]^+$, 461.1 $[Mn(phox)_2(1\text{-MeIm})]^+$, 541.1 $[Mn(phox)_3]^+$

both solvents during the first minutes of the reaction (Figure 2).

A few minutes after the start of the reaction, the ES-MS spectra of all reaction mixtures show decreases in the intensities of the $[MnL_2]^+$ and $[MnL_2(1\text{-Meim})]^+$ peaks. In these spectra, the parent peak originates from the [1-Meim + H^+] fragment, while various other peaks of low intensity are also present; these could not be clearly assigned. In mass spectra of reaction mixtures taken towards the end of all reactions, only various small peaks are observed. Apart from the peaks already assigned, no other peaks that could be clearly assigned to a manganese-containing species or a ligand degradation product have been observed.

In order to try to identify the ligand degradation products, catalysis experiments were performed. During these, an excess of fresh ligand (2×30 equiv. with respect to Mn) was added. GC-MS analysis of the oxidation products of H-5′-Clphox in an ethanol/methanol solution showed nearly quantitative conversion of the ligand. The main product appeared to be 5-chlorosalicylic acid; the secondary products methyl 5-chlorosalicylate and ethyl 5-chlorosalicylate, which are due to the acidic alcoholic conditions used for GC-MS, are also observed. The formation of these products indicates degradation of the catalyst at the oxazoline moiety. No traces of derivatives of the $-NCH_2CH_2-$ part of the oxazoline group were found.

Further indications that the oxazoline group is the part of the ligand most susceptible towards degradation are obtained by analysis of the ES-MS spectra of the pure $[Mn(5'\text{-Clphox})_3]$, $[Mn(phox)_3]$ and $[Mn(phox)_2(MeOH)_2]$-$[Mn(phox)_2(ClO_4)_2](H_2O)_2$ complexes. With a +70 V nozzle ionisation potential, the main fragments observed are the $[MnL_2]^+$ and the $[HL + H]^+$ fragments. Additional information can be obtained by use of other ionisation potentials. For $[Mn(5'\text{-Clphox})_3]$, $[Mn(phox)_3]$ and $[Mn(phox)_2(MeOH)_2][Mn(phox)_2(ClO_4)_2](H_2O)_2$, the application of a +170 V nozzle ionisation potential results in mass spectra showing fragments that might be related to catalyst degradation products. In the mass spectra of $[Mn(phox)_3]$ and $[Mn(phox)_2(MeOH)_2][Mn(phox)_2(ClO_4)_2](H_2O)_2$ (Figure 3), the $[Mn(phox)_2]^+$ fragments can be observed at m/z = 379.0. The mass difference of m/z = 42.2 between this signal and the signal at m/z = 336.8 corresponds to the loss of an $-NCH_2CH_2-$ fragment. A small signal at m/z = 121.0, corresponding to the $(Ar-C=O)^+$ fragment (see Figure 4) of a decomposed ligand, can also be observed.

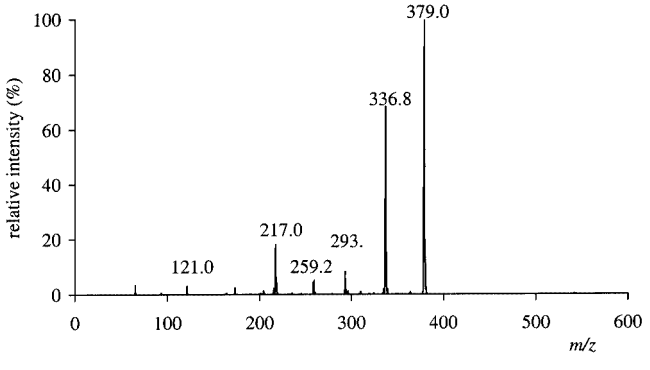

Figure 3. Ligand degradation observed in the electrospray mass spectrum of $[Mn(phox)_2(MeOH)_2][Mn(phox)_2(ClO_4)_2](H_2O)_2$ at a 170 V nozzle ionisation potential: m/z = 121.0 $[Ar\text{-}C=O]^+$, 217.0 $[Mn(phox)]^+$, 259, 293 unidentified, 336.8 $[Mn(phox)(Ar-C=O)]^+$, 379.0 $[Mn(phox)_2]^+$

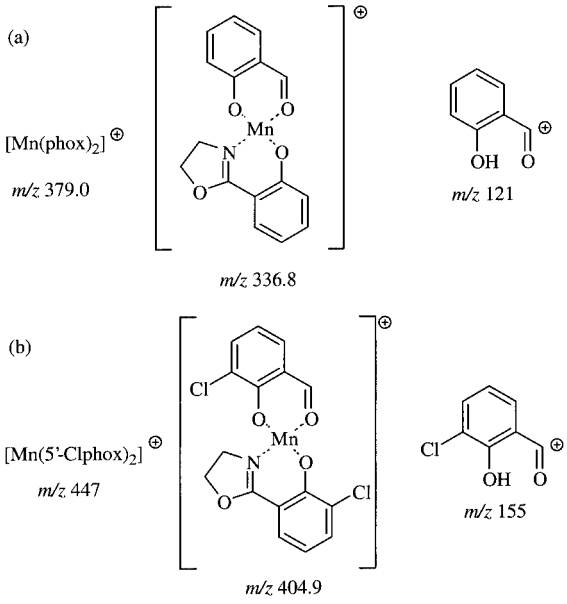

Figure 4. Schematic overview of degradation products (with m/z) observed in the ES-MS spectra of: (a) $[Mn(phox)_3]$, (b) $[Mn(5'\text{-Clphox})_3]$

A similar complex degradation pattern is found in the mass spectrum of $[Mn(5'\text{-Clphox})_3]$. The degradation of the $[MnL_2]^+$ fragment (m/z = 447.0) results in the $[Mn(5'\text{-Clphox})(Ar-C=O)]^+$ ion, which is clearly observed at m/z = 404.9. The isotope pattern of the latter fragment confirms the presence of two chlorine atoms. The $(Ar-C=O)^+$ fragment in this mass spectrum is observed at m/z = 155 (Figure 4). The reaction of the $(Ar-C=O)^+$ fragment, found in the ES-MS measurements, with water or an alcohol results in salicylic acid or one of its esters, which are the ligand decomposition products identified after the oxidation reaction with $[Mn(5'\text{-Clphox})_3]$ and excess of the H-5′-Clphox ligand (see above). Fragments containing the $-NCH_2CH_2-$ part of the oxazoline group were not identified.

The $\{[MnL_2]^+ - 42\}$ fragment is present with higher relative intensities in the mass spectra of $[Mn(phox)_2(MeOH)_2][Mn(phox)_2(ClO_4)_2](H_2O)_2$ and $[Mn(phox)_3]$ than in the spectra of $[Mn(5'\text{-Clphox})_3]$. In the mass spectrum of $[Mn(5'\text{-}NO_2phox)_3]$, no such signal is observed at all. In the reactions in methanol, $[Mn(5'\text{-}NO_2phox)_3]$ remains active for a longer time than the other catalysts.[12] This indicates that the complexes containing Hphox ligands with electron-withdrawing substituents are more resistant towards oxidative degradation, which is similar to the trend found for manganese complexes with porphyrin[7] and Mn−salen[8] ligands.

Conclusion

The most important reactions occurring during oxidation catalysis with the Mn−phox complexes are substrate oxidation, dihydrogen peroxide decomposition and catalyst degradation. The choice of the catalyst and the reaction conditions have considerable influence on all these reactions and therefore also on the catalyst efficiency. For instance, the addition of a base such as 1-Meim to the reaction mixtures is required to improve the catalytic efficiency. 1-Meim can coordinate to the manganese complex, as shown by the crystal structure of $[Mn(phox)_2(1\text{-}Meim)_2](ClO_4)$. The presence of $[Mn(phox)_2(1\text{-}Meim)]^+$ species during the catalytic reactions has been observed with ES-MS. Furthermore, coordination of 1-Meim significantly influences the electrochemical properties of the complexes containing the $Mn(phox)_2$ unit, as indicated by the changes in the cyclic voltammograms.[16] Therefore, the higher catalytic efficiency observed in the presence of 1-Meim is likely to be caused by coordination of 1-Meim to manganese atoms, thus resulting in a more active or stable catalyst.

In the reactions in acetone, oxygen evolution caused by dihydrogen peroxide decomposition is visible. Upon addition of extra dihydrogen peroxide, higher turnover numbers can be obtained in styrene oxidation, but the efficiency relative to dihydrogen peroxide is decreased. Despite the addition of extra dihydrogen peroxide, the reactions finally cease completely because of catalyst degradation, and the maximum turnover numbers obtained are 428 with $[Mn(phox)_3]$ and 456 with $[Mn(5'\text{-}NO_2phox)_3]$ as catalysts.

Changes in the solvent used or the addition of a base notwithstanding, the catalytic reactions cease in the end due to ligand degradation, which is the main obstacle to obtaining high turnover numbers. The decolouration of the reaction solution, and the appearance of an Mn^{II} EPR signal coincide with decreasing catalytic activity.[12] In methanol, the activity could easily be regenerated by addition of fresh Hphox ligand, which simultaneously restored the green colour of the solution. ES-MS measurements and analysis of the oxidation products of H-5′-Clphox indicate that the oxazoline group is the part of the Mn−phox catalysts most susceptible towards oxidative degradation. The introduction of a nitro substituent resulted in a more stable catalyst, as shown by the catalytic experiments and the ES-MS studies. The higher catalytic efficiency and the prolonged catalytic activity of $[Mn(5'\text{-}NO_2phox)_3]$ in styrene oxidation in methanol[13] directly reflects higher stability of the catalyst, as shown by electrochemistry (the irreversible oxidation of $[Mn(5'\text{-}NO_2phox)_3]^+$ occurs at the highest potentials)[13] and ES-MS, which is in accordance with the disappearance of the green colour being slower than in the reactions with the other catalysts. These results indicate that the introduction of strongly electron-withdrawing substituents decreases the susceptibility of the oxazoline group towards degradation. The first step of ligand degradation is presumably an oxidation reaction. In the literature, decomposition of oxazoline groups has been reported in reactions with the oxidants *m*-chloroperbenzoic acid (*m*-CPBA)[22] and sodium hypochlorite.[23] The oxidation products may be the oxaziridine and the oxazoline *N*-oxide,[22] with the ring still intact, as well as ring-opening products such as various esters,[22,23] which have also been found after oxidation of the excess H-5′-Clphox, indicating that similar oxazoline degradation reactions occur.

As shown in this study, Mn−phox- and Mn−salen-catalysed oxidation reactions with hydrogen peroxide have similar characteristics. Examples are the decolouration of the reaction solutions, the beneficial effect of the addition of bases on the catalytic efficiency and the increased stability upon introduction of electron-withdrawing substituents. Two oxidative conversions of Mn−salen complexes have been reported. Treatment of an Mn−salen complex in pyridine with dioxygen resulted in the oxidation of one imine group to an amide,[24] while complex degradation by visible light photolysis resulted in 2-(2′-hydroxyphenyl)benzimidazole, salicylaldehyde and a manganese(II) ion.[25] The products formed in the latter reaction, salicylaldehyde and manganese(II), are similar to the observed Mn−phox degradation products after the oxidation reactions. These results emphasise that for the Mn−phox complexes, the oxazoline group is the most oxidation-sensitive, while it is indicated that the imine group is the most sensitive position of the Mn−salen catalysts. Replacement of these groups should therefore be required to enhance the catalyst stability and indeed, for a similar catalyst system, the replacement of an imine by a tertiary amine group has resulted in a significantly more stable catalyst.[26] Given the potential of the Mn−salen complexes as asymmetric (ep)oxidation catalysts, further studies of stabilisation of these complexes are of paramount importance.

Experimental Section

General Remarks: All manganese complexes were synthesised by published procedures.[12,13,16] Solvents were used as technical grade, p.a. grade or, for acetonitrile, as HPLC grade (Rathburn) and, unless noted otherwise, were used as received. All p.a. grade solvents were purchased from Baker, except for acetone (Acros). Dihydrogen peroxide (35% in water) and styrene were supplied by Merck, all other chemicals used were obtained from Acros.

Equipment: A Varian Star 3400CX gas chromatograph with a J&W Scientific/Fisons DB-1701 (14% cyanopropylphenyl-methylpolysiloxane) column was used for analysis of the oxidation experiments. UV/Vis/NIR measurements were performed with a Perkin−Elmer Lambda 900 UV/Vis/NIR spectrometer. EPR measurements were performed at 77 K with a Jeol Esprit RE-2X spectrometer with a Jeol Esprit 330 ESRE data system. EPR *g* values were determined relative to DPPH as an external "*g*-mark" (g = 2.0037). GC-MS analysis of the ligand degradation products was recorded with a Finnigan MAT ITD 700 (EI mode) coupled with a Hewlett−Packard 438a GC. Electrospray mass spectra at higher ionisation potentials and before and during the oxidation reactions were performed at the Pharmacy department of the University of Groningen and were recorded with a NERMAG R 3010 triple quadrupole mass spectrometer equipped with an in-house atmospheric pressure ionisation source and ion spray interface.[27,28] The

PE-Sciex API 3 data system with an in-house and digital interface was used for data acquisition and data processing.

Catalysis: The catalytic reactions were carried out in methanol and in acetone, usually with a catalyst/substrate/oxidant ratio of 1:1000:1500. All flasks and stirrer bars used were thoroughly cleaned with acid to remove traces of metal, after which they were washed with an aqueous sodium carbonate solution. The turnover numbers given are the total turnover numbers per manganese ion after the indicated period of time. All reactions were performed at least in duplicate. ***Caution!*** The combination of acetone and dihydrogen peroxide is potentially explosive, especially under acidic conditions.[29] However, it can be handled safely by performing reactions on a small scale at 0 °C under slightly alkaline conditions, as used in the experiments described below.

In Methanol: The catalyst (14 μmol) was dissolved with stirring in 20 mL of methanol at room temperature. Styrene (14 mmol), chlorobenzene (5.0 mmol) and 1-methylimidazole (1-Meim, 2.0 mmol) were added to the resulting green solution, followed (at $t = 0$ min) by dihydrogen peroxide (35% in water, 21 mmol). Except for the reaction mixture with [Mn(5′-NO_2phox)], which slowly started to turn pale yellow after $t = 10$ min, the colours of the reaction mixtures changed to slightly yellow to colourless within the first few minutes of the reactions. At $t = 15$ min, a sample was taken and analysed by gas chromatography, with chlorobenzene as the internal standard.

In Acetone: Dihydrogen peroxide (35% in water, 21 mmol) and acetone (10 mL) were stirred for 30 min at 0 °C. Next, styrene (14 mmol), chlorobenzene (5.0 mmol) and 1-Meim (2.0 mmol) were added, followed by the powdered catalyst (14 μmol, $t = 0$). The green solution became slightly red-brown within the first few minutes of the reactions. After 10 min, the solution slowly turned pale green-yellow. At $t = 15$ min, a sample was taken and analysed by gas chromatography, with chlorobenzene as the internal standard.

Addition of Extra Dihydrogen Peroxide to the Oxidation of Styrene with [Mn(phox)$_3$] and [Mn(5′-NO_2phox)$_3$]: Dihydrogen peroxide (35% in water, 21 mmol) and acetone (10 mL) were stirred for 30 min at 0 °C. Styrene (14 mmol) and 1-Meim (2.0 mmol) were then added, followed by [Mn(phox)$_3$] (14 μmol, $t = 0$ min). At $t = 15$ min, a sample was taken from the pale green-yellow solution and analysed by gas chromatography, with chlorobenzene as the internal standard. Subsequently, 5 mL of a solution of dihydrogen peroxide (42 mmol) in acetone (20 mL), which had been stirring for 30 min at 0 °C, was added. At $t = 30$ and 45 min, a sample was taken for analysis, after which an additional 5 mL of the dihydrogen peroxide solution was added. At this time, the solution had turned almost colourless to pale yellow. A final sample was taken at $t = 60$ min.

Oxidation of the H-5′-Clphox Ligand: [Mn(5′-Clphox)$_3$] (14 μmol) was dissolved at room temperature, with stirring, in a mixture of methanol (10 mL) and ethanol (10 mL). Styrene (1.4 mmol) was added to this green solution, followed by dihydrogen peroxide (35% in water, 21 mmol). After 15 min, during which the solution turned from green to colourless, a sample was taken and analysed by gas chromatography, with chlorobenzene as the internal standard. Next, H-5′-Clphox (0.42 mmol) was added, resulting in the regeneration of the green color of the reaction solution. Samples were taken each 15 min and were analysed by gas chromatography, with chlorobenzene as the internal standard. The H-5′-Clphox peak could be clearly detected. The reaction was monitored over time by gas chromatography until the solution had become almost colourless and most of the ligand had disappeared. Further H-5′-Clphox (0.42 mmol) and dihydrogen peroxide (21 mmol) were added. After disappearance of most of the ligand, a sample was taken and analysed by GC-MS.

Electrospray Mass Spectrometry: Electrospray mass spectra of [Mn(phox)$_3$], [Mn(5′-phox)$_3$], [Mn(5′-NO_2phox)$_3$] and [Mn(phox)$_2$-(MeOH)$_2$][Mn(phox)$_2$(ClO_4)$_2$](H_2O)$_2$ were recorded in methanol and acetone, both in the absence and in the presence of water and/or 1-Meim. Mass spectra were also recorded on samples taken during the oxidation of styrene with [Mn(phox)$_3$] or [Mn(5′-NO_2-phox)$_3$] and dihydrogen peroxide. For these reactions, the standard conditions in methanol and acetone were used, with exception of the use of 10.5 mmol of dihydrogen peroxide instead of 21 mmol.

X-ray Data Collection and Structure Determination of [Mn(phox)$_2$(1-Meim)$_2$](ClO_4): The data were collected with an Enraf−Nonius Kappa CCD area detector on a rotating anode, with graphite-monochromated Mo-K_α radiation ($\lambda = 0.71073$ Å). The crystallographic data of the complex are presented in Table 3. The unit cell parameters were checked for the presence of lattice symmetry.[30] The structures were solved by automated direct methods (SHELXS-86).[31] Refinement on F^2 was carried out by full-matrix, least squares (SHELXL-97-2).[32] Neutral atom scattering factors and anomalous dispersion corrections were taken from the International Tables for Crystallography.[33] Geometrical calculations and illustrations were performed with PLATON.[34] All calculations were performed with a DEC Alpha 255. Hydrogen atoms were included in the refinement on calculated positions riding on their carrier atoms. All non-hydrogen atoms were refined with anisotropic thermal parameters; hydrogen atoms were refined with a fixed isotropic thermal parameter related to the value of the equivalent isotropic displacement parameter of their carrier atoms. CCDC-181805 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses and Crystal Structures of Five Cadmium(II) Complexes Derived from 4-Aminobenzoic Acid

Ruihu Wang,[a] Maochun Hong,*[a] Junhua Luo,[a] Rong Cao,*[a] Qian Shi,[a] and Jiabao Weng[a]

Keywords: Cadmium / Hydrogen bonds / N,O ligands / Supramolecular chemistry

Five cadmium(II) complexes, $[CdClL\cdot H_2O]_n$ (**1**), $[CdBrL\cdot H_2O]_n$ (**2**), $CdI_2(HL)_2$ (**3**), $\{[Cd(dca)_2(HL)_2]\cdot 2H_2O\}_n$ (dca^- = dicyanamide) (**4**), and $(H_2L)_2[CdCl_4(H_2O)_2]$ (**5**), have been synthesized by the reaction between 4-aminobenzoic acid (HL) and Cd^{2+}. In **1** and **2**, L^- serves as a tridentate ligand and bridges six-coordinate Cd^{II} centers to form $[Cd^{II}–L]_n$ chains; halide anions link adjacent chains into two-dimensional layers. Complex **3** is a typical metallic carboxylic acid synthon. In **3**, HL acts as a monodentate ligand coordinating to Cd^{II} through the nitrogen atom, and the head-to-tail hydrogen bonds of carboxylic groups result in a zigzag chain. The weak Cd···I interactions between adjacent chains extend the zigzag chain-like structure into a two-dimensional structure. Complex **4** consists of $[Cd(dca)_2(HL)_2]_n$ chains and free water molecules. The twelve-membered rings formed by water molecules and carboxylic groups through hydrogen bonds link the adjacent chains to yield a two-dimensional layer. Complex **5** consists of discrete $[CdCl_4(H_2O)_2]^{2-}$ anions and H_2L^+ organic cations, which are linked by intermolecular hydrogen-bonding interactions to form a three-dimensional structure.

Introduction

The design and synthesis of novel complexes with unusual and tailorable structures are fundamental steps for the discovery and fabrication of various functional supramolecular devices or technologically useful materials.[1] Recently, a great deal of attention has been paid to the design and construction of organic-inorganic hybrid frameworks from synthons or building blocks, owing to their fascinating structural diversity and promising potential application in chemistry, biology, and material science.[2,3] Coordination covalent bonds, hydrogen bonds, and combinations of the two have been powerful tools for linking synthons or building blocks into extended structural topologies;[2–5] likewise, organic counterions are frequently used as templating agents – based on their shape and hydrogen-bonding capability – to form frameworks such as perovskites.[6] Through careful selection of organic ligands with hydrogen-bonding functionalities, structural frameworks can be confidently established and predicted, and their physical properties, such as magnetic, optical, and electronic properties, can be controlled and tailored.[2,4–6] By the aforementioned synthetic methods, it is possible to prepare and modify complexes with different structural frameworks through control of synthetic conditions such as counterions, pH value, reaction temperature, solvent, template, and the ratio of metal/ligand.

In previous studies, we have synthesized a series of novel organic-inorganic hybrid complexes based on covalent bonds through the use of simple organic ligands such as pyridine-2-thiol and pyrimidine2-thiol.[7] Recently, we have extended our work by the selection of multifunctional organic ligands that may form both coordination covalent bonds and hydrogen bonds as synthons or building blocks. 4-Aminobenzoic acid (HL) has been extensively studied in coordination chemistry, thanks to the richness of its coordination modes (Scheme 1, **a–i**): 1) HL can act as a carboxylic acid synthon and also as a good monodentate ligand through the amine group.[8] 2) deprotonated 4-aminobenzoic acid (L^-) can act as a monodentate ligand through a carboxylate oxygen atom,[9] chelating and/or bridging ligands through its amide and/or carboxylate groups,[10,11] and 3) HL may be protonated to form organic cation templating agents. Previous reports showed that the association of d^{10}-configured cadmium(II) with HL resulted in two kinds of complexes, in which HL acts as a carboxylic acid synthon[8] and as a bridging ligand.[11] Our aim is to study self-assembly processes of Cd^{II}–HL complexes, especially the influence of co-ligand and reaction medium on the coordination behaviour of HL and thereby the structural topology of the complexes obtained. Here we report the syntheses and crystal structures of five cadmium complexes: $[CdClL\cdot H_2O]_n$ (**1**), $[CdBrL\cdot H_2O]_n$ (**2**), $CdI_2(HL)_2$ (**3**),

$\{[Cd(dca)_2(HL)_2]\cdot 2H_2O\}_n$ (**4**), and $(H_2L)_2[CdCl_4(H_2O)_2]$ (**5**).

Results and Discussion

Syntheses and IR Spectra

Treatment of L^- with $CdCl_2\cdot 2.5H_2O$ and $CdBr_2\cdot 4H_2O$ in MeOH/H_2O (2:1) resulted in the formation of the corresponding mixed-anion cadmium(II) complexes **1** and **2**, respectively. However, treatment of L^- with CdI_2 under the same conditions failed to produce the expected complex containing mixed-anion ligands. Instead, a straightforward reaction between HL and CdI_2 in MeOH/H_2O (2:1) yielded a two-dimensional complex **3**, formed by head-to-head carboxylic acid hydrogen bonding (Scheme 1, **j**) and weak Cd···I interactions. The successful isolation of **3** prompted us to replace I^- with bridging ligands, such as SCN^-, dca^-, and N_3^-, in order to obtain layer complexes containing head-to-head carboxylic acid hydrogen bonds. Use of $Cd(NO_3)_2\cdot 6H_2O$, NH_4SCN, and HL in MeOH/H_2O (2:1) generated the expected complex $[Cd(SCN)_2(HL)_2]_n$,[8b] but employment of $Cd(NO_3)_2\cdot 6H_2O$, Na(dca), and HL in MeOH/H_2O (2:1) produced complex **4**, comprising twelve-membered rings made up of water molecules and carboxylic groups through hydrogen bonds (Scheme 1, **k**). Isolation of $[Cd(N_3)_2(HL)_2]_n$ from the reaction between $Cd(NO_3)_2\cdot 6H_2O$, NaN_3, and HL in EtOH/H_2O (2:1) was not successful; instead, HL was deprotonated by NaN_3 and a known compound $[(CdL_2\cdot H_2O)\cdot 2H_2O]_n$ [11] was obtained. As mentioned above, HL may be protonated to form an organic ammonium ion H_2L^+, which can act as an organic cation templating agent for perovskite complexes. When the reaction between $CdCl_2\cdot 2.5H_2O$ and HL was carried out in aqueous HCl solution, HL did accept a proton to form H_2L^+ and produced a perovskite-type complex **5**.

The IR spectra of complexes **1** and **2** confirm the presence of the carboxylate group, by the strong peaks at 1608 and 1398 cm^{-1} for **1** and at 1610, 1597, 1414 and 1402 cm^{-1} for **2**. The separations (Δ) between the antisymmetric stretching ν_{asym}(COO) and the symmetric stretching ν_{sym}(COO) are 210 cm^{-1} for **1**, and 197 and 195 cm^{-1} for **2**. The characteristic carboxylic acid group bands are observed at 1684, 1441, and 1423 cm^{-1} for **3** and at 1678, 1626, 1443 (m), and 1423 (m) cm^{-1} for **4**. Moreover, the IR spectrum in complex **4** displays a very strong absorption band at 2175 cm^{-1}, indicating the presence of C≡N in dca^-. The carboxylic group in complex **5** is characterized by the presence of strong peaks at 1701 and 1678 cm^{-1} for antisymmetric stretching and at 1487 and 1433 cm^{-1} for symmetric stretching. Several strong bands in the 3550 to 2750 cm^{-1} range may be assigned to N−H and O−H stretching frequency in H_2L^+.

Structures

[CdClL·H₂O]ₙ (1)

Complex **1** consists of two-dimensional layers formed by interconnection of neighboring $[Cd^{II}-L]_n$ chains through bridging Cl^- in a *trans* mode. As shown in Figure 1 (a), each Cd^{II} is coordinated by two chelating carboxylate oxygen atoms from one L^- ligand, a nitrogen atom from the other L^- ligand, two bridging Cl^- ions, and one coordinated water molecule in a distorted octahedral geometry. The two bridging Cl^- ions stand at the apical positions [Cd−Cl = 2.580(1) and 2.646(1) Å, Cl−Cd−Cl(A) = 171.13(2)°], while the two carboxylate oxygen atoms [O(1) and O(2)], the nitrogen atom [N(0B)], and the water oxygen atom (O_w) form the equatorial plane. Cd^{II} is approximately coplanar with the mean plane of O1, O2, O_w, and N(0B), with a deviation of 0.0625 Å. L^- adopts a chelating/

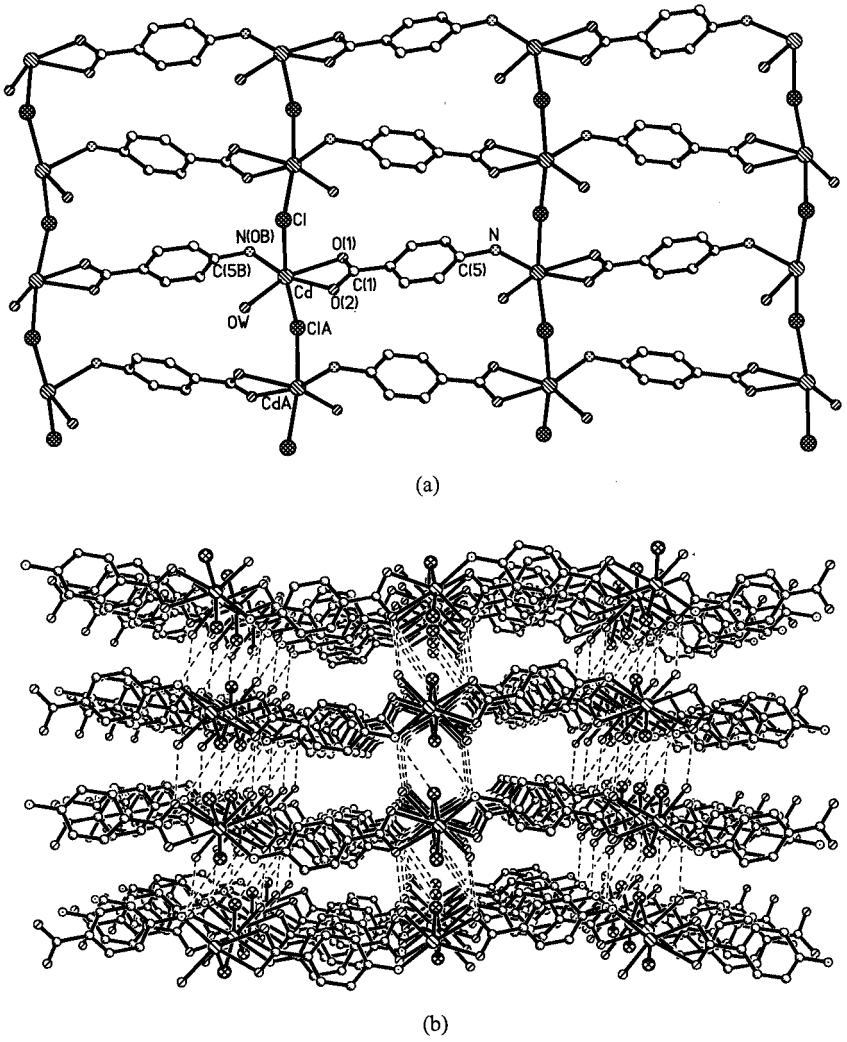

Figure 1. (a) View of the two-dimensional layer in **1** along the *b* axis with atomic numbering; (b) view of a packing diagram showing the three-dimensional structure of **1** along the *a* axis

bridging coordination mode to link two Cd^{II} centers (Scheme 1, **f**), similar to those in reported Cd^{II} complexes.[11] Cl^- acts as a μ_2-bridge and lies at the apical site occasionally reported in Cd^{II} complexes with mixed carboxylate and Cl^- ligands.[12] The Cd^{II} components can thus be viewed as linkers connecting L^- and Cl^- to form a two-dimensional layer consisting of rectangular grids with dimensions of 4.397 × 9.881 Å based on Cd···Cd distances. It should be noted that the water ligand forms hydrogen bonds with carboxylate oxygen atoms of L^- [O_w−H···O(1)^i 2.776(4) Å and O_w−H···O(2)^{ii} 2.773(5) Å; symmetry modes: i: $x + 1/2, -y + 1/2, -z + 1$; ii: $-x + 1, -y + 1, -z + 1$], and the amide of L^- also forms a hydrogen bond with Cl^- [N−H···Cl^{iii} 3.186(4) Å; symmetry mode: iii: $-x + 1/2, -y + 1, z - 1/2$]. Such hydrogen bonding interactions consolidate the structural architecture and further extend the two-dimensional layers into a three-dimensional structure (Figure 1, b).

[CdBrL·H$_2$O]$_n$ (2)

Complex **2** consists of two-dimensional layers formed by the interconnection of neighboring $[Cd^{II}-L]_n$ chains through bridging Br^- in a *cis* mode. As shown in Figure 2 (a), each Cd^{II} is coordinated by two chelating carboxylate oxygen atoms of one L^-, a nitrogen atom of the other L^-, two bridging Br^- moieties, and one coordinated water molecule in a highly distorted octahedral geometry; the equatorial plane is formed by the two carboxylate oxygen atoms [O(1) and O(2)], a nitrogen atom [N(0A)], and one bromide ion (Br) [with the shorter Cd−Br distance of 2.787(1) Å], while the water oxygen atom (O_w) and the other bromide ion [with the longer Cd−Br(B) distance of 2.829(1) Å] occupy the axial positions. The deviation of Cd^{II} from the equatorial plane defined by O(1), O(2), N(0A), and Br is 0.197 Å. Two adjacent Cd^{II} atoms are bridged by two Br^- moieties to form a Cd_2Br_2 four-membered ring[13] with a Cd···Cd separation of 3.795 Å. Such four-membered rings

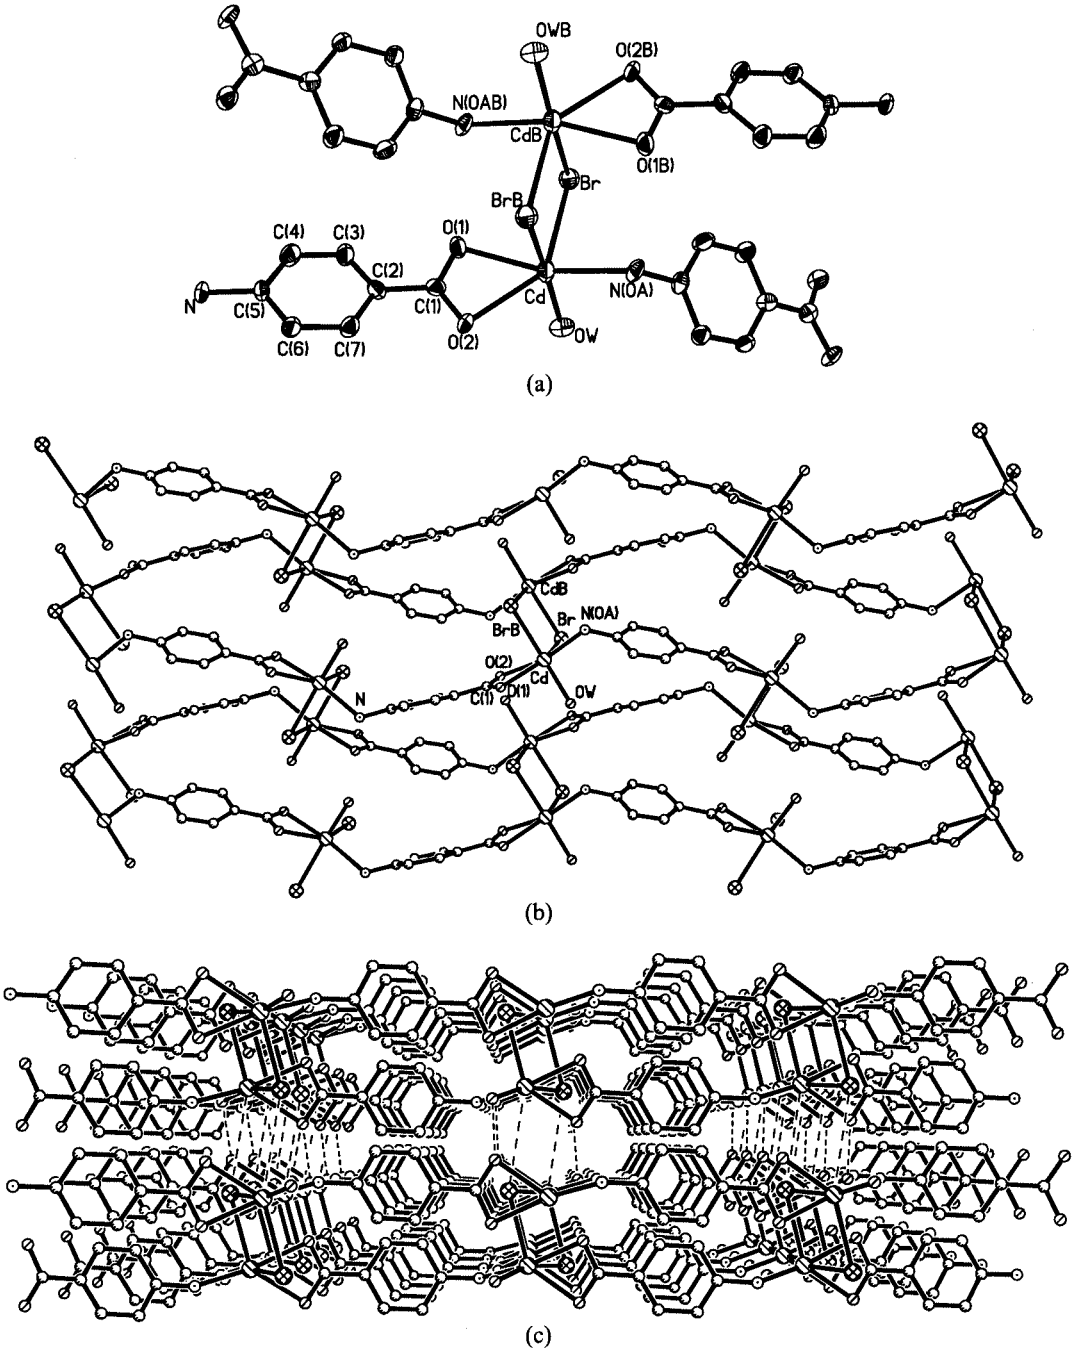

Figure 2. (a) The coordination geometry of Cd^{II} in **2**, thermal ellipsoids are shown with 50% probability; (b) view of the two-dimensional layer in **2** along the *a* axis; (c) view of the stacking layers in **2** along the *b* axis

act as nodes, and L^- links the nodes to yield a two-dimensional layer. The coordination mode of L^- is the same as in **1** (Scheme 1, **f**), but the layer is very different from that of **1** owing to the *cis* orientations of Br^- in **2**. The Cd···Cd distance separated by L^- (9.907 Å) is close to that in **1** (9.881 Å). It is noteworthy that the weak inter-layer Br···Cd interaction (3.798 Å) and hydrogen bonding interactions may play important roles in consolidating the crystal architecture. As shown in Figure 2 (c), hydrogen bonds of the water ligand and two oxygen atoms of different L^- ligands [$O_w-H\cdots O1^{i}$ 2.716(7) and $O_w-H\cdots O2^{ii}$ 2.818(7) Å; symmetry modes: i: $1-x$, $1-y$, $-z$; ii: $-x$, $1-y$, $-z$], and of Br^- and amide [$Br\cdots H-N^{iii}$ 3.376(6) Å; symmetry mode: iii: $-x$, $y-0.5$, $-0.5-z$] along with the weak Br···Cd interaction extend the two-dimensional layers into a three-dimensional structure.

$CdI_2(HL)_2$ (3)

The structure of complex **3** is made up of $HL-CdI_2-HL$ metallic synthons. As shown in Figure 3 (a), each Cd^{II} is coordinated by two I^- and two nitrogen atoms of HL in a distorted tetrahedral geometry [Cd–N = 2.347(5) Å,

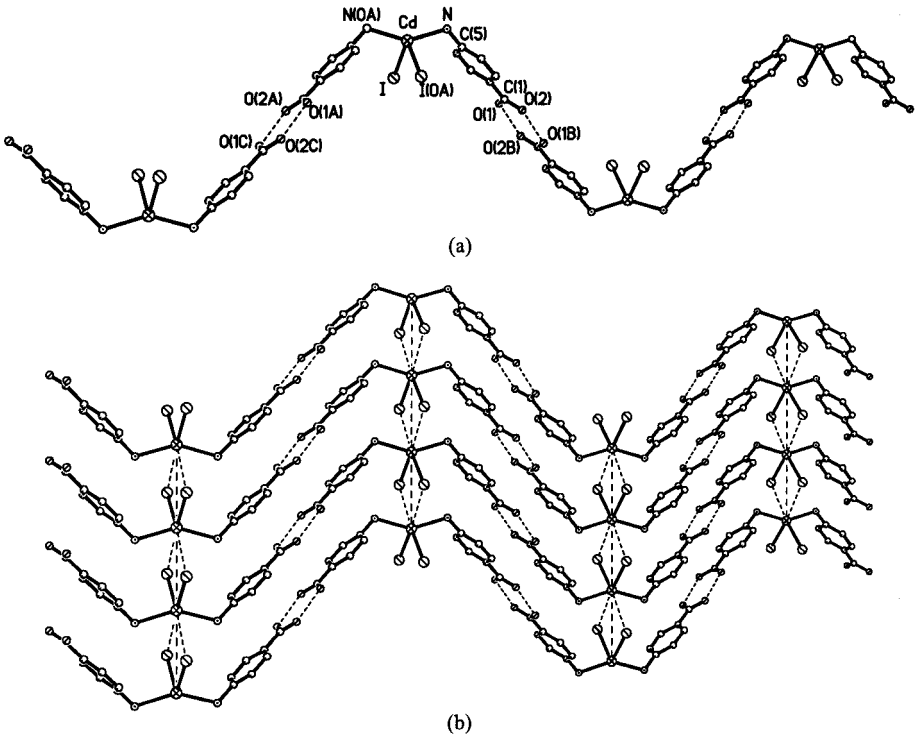

Figure 3. (a) One-dimensional hydrogen bonding zigzag chain in **3**; (b) two-dimensional layer is formed through weak Cd−I and hydrogen bonding interactions in **3**

Cd−I = 2.8276(8) Å, N−Cd−N(0A) = 148.8(3)°]. Each HL acts as a monodentate ligand, coordinating to Cd^{II} through its amine nitrogen atom, and forms hydrogen bonds through the carboxylic group (Scheme 1, **h**). The two HL components coordinated to the same Cd^{II} atom are approximately perpendicular, with a dihedral angle of 83.8°, similar to those in synthons of four-coordinate metal centers and pyridine derivatives.[5] In **3**, HL−CdI_2−HL units propagate by head-to-head hydrogen bonds between the carboxylic acid groups of HL (Scheme 1, **j**) into a zigzag chain [O(1)···H−O(2)^{i} 2.631(7) Å; symmetry code: i: $-x + 1/2, -y + 5/2, -z + 1$]. Such zigzag chains are further extended into a two-dimensional network through weak inter-chain Cd···I interactions [I···Cd^{ii} 3.3365(9) Å, Cd−I···Cd^{ii} 93.727(13)°; symmetry code: ii: $x, y + 1, z$] (Figure 3, b). The inter-chain adjacent Cd···Cd separation is 4.511 Å.

{[Cd(dca)$_2$(HL)$_2$]·2H$_2$O}$_n$ (4)

The crystal structure of complex **4** consists of one-dimensional cadmium chains and free water molecules (Figure 4, a). Each Cd^{II} is coordinated by six nitrogen atoms in a distorted octahedral geometry, in which four nitrogen atoms of different dca^- moieties form the equatorial plane [average $Cd-N_{dca}$ = 2.326(3) Å] and the nitrogen atoms of two HL units [$Cd-N_{HL}$ = 2.377(3) Å] occupy the apical positions. Each adjacent Cd^{II} pair is bridged by two inversely related dca^- units to form a neutral one-dimensional cadmium−dca chain consisting of twelve-membered $(N-C-N-C-N-Cd)_2$ rings with a Cd···Cd separation of 7.737 Å, which is slightly larger than those in the complexes comprising this type of bridge.[14] The HL ligands are situated at the two sides of the chain to saturate the six-coordinate Cd^{II} centers, adopting a monodentate coordination mode through the nitrogen atoms and forming hydrogen bonds through the carboxylic groups (Scheme 1, **h**). Unlike in **3**, adjacent one-dimensional chains in **4** are interconnected by hydrogen bonds between free water molecules and carboxylic groups to produce a two-dimensional structure [O_w···O(2) 2.608(3), O_w−H···O(1)^{i} 2.783(4) Å; symmetry code: i: $-x + 1, -y + 2, -z + 1$] (Figure 4, b). The O(2)−C(11) bond of 1.327(4) Å in HL is longer than those in **3**, $[Cd(SCN)_2(HL)_2]_n$,[8b] and the free HL ligand.[15] Formula **k** in Scheme 1 shows the twelve-membered ring formed by hydrogen bonds of water molecules and carboxylic acid groups. To the best of our knowledge, this is a unique structural motif in supramolecular chemistry. As shown in Figure 4 (c), the two-dimensional layers are further extended into a three-dimensional framework through weak inter-layer hydrogen bonds between free water molecules and oxygen atoms from HL [O_w···O(2)^{ii} 2.924(4) Å; symmetry code: ii: $-x + 1, y + 1/2, -z + 1/2$].

(H$_2$L)$_2$[CdCl$_4$(H$_2$O)$_2$] (5)

Complex **5** consists of discrete octahedral $[CdCl_4(H_2O)_2]^{2-}$ anions linked by H_2L^+ organic cations through extensive intermolecular hydrogen bonding interactions. As shown in Figure 5 (a), cadmium(II) is coordinated by four Cl^- ions [Cd−Cl = 2.5687(7) or 2.5699(7) Å] and two water oxygen atoms [$Cd-O_w$ = 2.364(2) Å] in a compressed octahedral geometry, in which the Cl^- units lie in the equatorial plane and the oxygen atoms are situated at

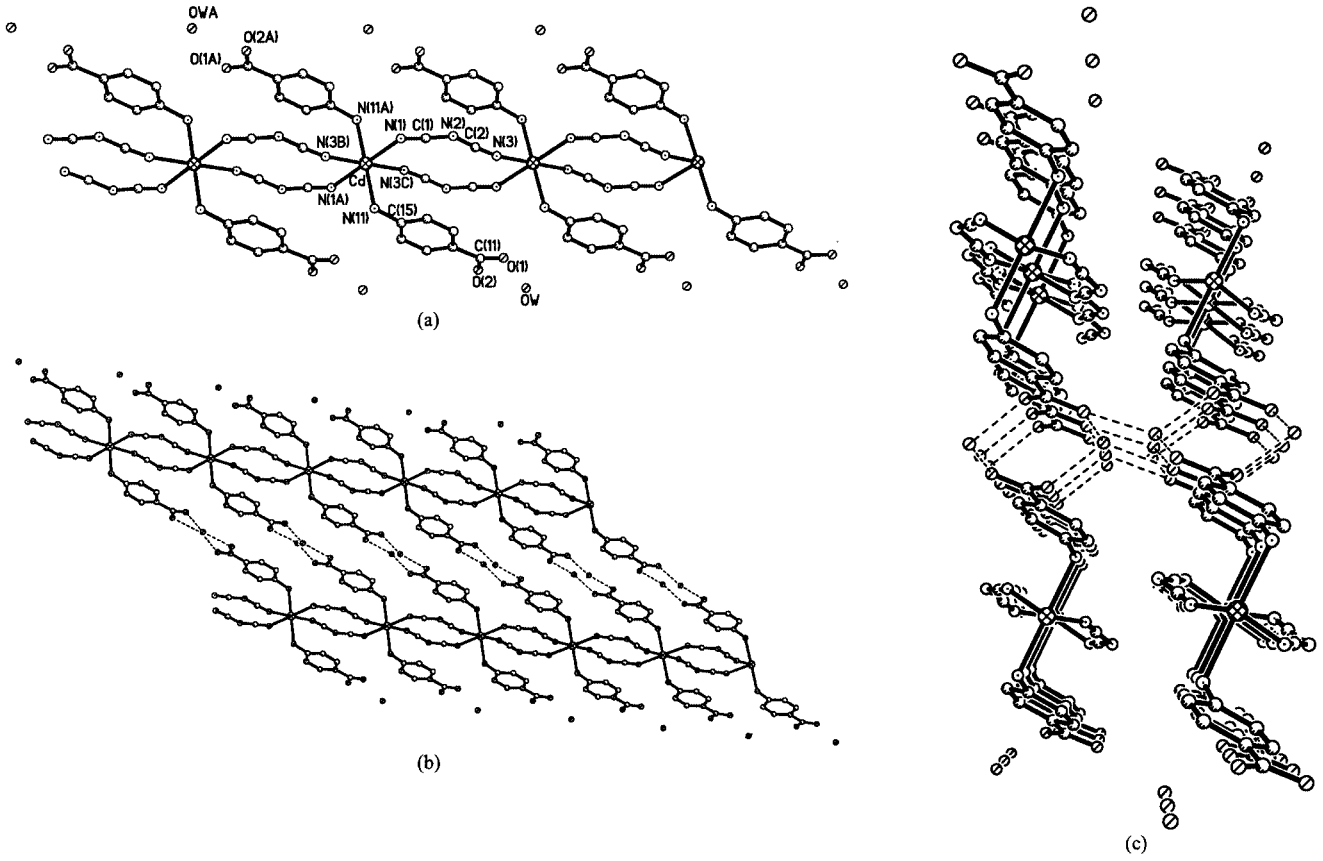

Figure 4. (a) View of one-dimensional chain and lattice water molecules in **5** with atomic numbering; (b) view of the hydrogen bonding between adjacent chains to form a two-dimensional layer along the *c* axis; (c) view of three-dimensional structure in **4** along the *a* axis

the axial positions. The coordination environment around Cd^{II} is similar to that in $[CdCl_2(H_2O)_2{\cdot}2Cyt]_n$ (Cyt = cytosine).[16] Cd^{II} is coplanar with the four Cl^- units and lies in the center of the equatorial plane. The bond lengths and angles are very similar to those in $[CdCl_2(H_2O)_2{\cdot}2Cyt]_n$.[16] As shown in Figure 5 (b), H_2L^+ cations act as linkers to link discrete $[CdCl_4(H_2O)]^{2-}$ units into a three-dimensional supramolecular structure through hydrogen bonding. There is no interaction between adjacent $[CdCl_4(H_2O)]^{2-}$ units, and the shortest Cd−Cd separation is 5.833 Å. Formula **i** in Scheme 1 shows the hydrogen bonds formed by H_2L^+: $-NH_3^+$ is surrounded by three Cl^- units [N−H···Cl(2) 3.228(3), N−H···Cl(2)^{i} 3.193(3), N−H···Cl(2)^{ii} 3.233(3) Å; symmetry codes: i: x, $y + 1$, z; ii: $-x + 1$, $y + 1/2$, $-z + 1/2$], −OH forms a hydrogen bond with a Cl^- ion [O(1)−H···Cl^{iii} 3.031(3) Å; symmetry code: iii: $-x + 2$, $y + 1/2$, $-z + 1/2$], and −C=O forms a hydrogen bond with a coordinated water molecule (O_w) [O_w−H···O(2)^{iv} 2.753(4) Å; symmetry code: iv: $x - 1$, $-y + 3/2$, $z - 1/2$]. To the best of our knowledge, this is the first complex comprising discrete $[CdCl_4(H_2O)]^{2-}$ anions and the first complex to use protonated 4-aminobenzoic acid (H_2L^+) as an organic cation templating agent.

Conclusion

Through the use of the multifunctional 4-aminobenzoic acid (HL) ligand and different synthetic strategies, we have successfully synthesized five Cd^{II} complexes that display hydrogen-bonding interactions. Complexes **1** and **2** may be regarded as extensions of the one-dimensional chain structure of $[(CdL_2{\cdot}H_2O){\cdot}2H_2O]_n$ [11] into two-dimensional networks through bridging Cl^- or Br^- instead of L^- and are further extended into three-dimensional structures by interlayer hydrogen bonding interactions. Moreover, Cl^- and Br^-, occupying different coordination sizes around Cd^{II}, result in two completely differentstructural topologies. Complex **3** is a typical metallic carboxylic acid synthon. The twelve-membered ring formed by H_2O and the carboxylic acid group of HL through hydrogen bonding in **4** is a unique structural motif in supramolecular chemistry. In complex **5**, N−H···Cl, O−H···Cl, O_w−H···Cl, and O_w−H···O hydrogen bonds link compressed octahedral $[CdCl_4(H_2O)]^{2-}$ anions and H_2L^+ cations into a three-dimensional structure. To the best of our knowledge, this is the first complex comprising discrete $[CdCl_4(H_2O)]^{2-}$ anions and the first complex to use protonated 4-aminobenzoic acid (H^2L^+) as an organic cation templating agent. In summary, this work demonstrates that the combination of coordination covalent bonds and hydrogen bonds is an important tool for the construction of supramolecular architectures, and that the presence of counterions or co-ligands in the synthetic reaction plays an important role in the formation of different structures.

Experimental Section

General: All reagents are commercially available and were used as purchased without further purification. The IR spectra were recorded with a Magna 750 FT-IR spectrophotometer from KBr disks. Elemental analyses were recorded with an Elementar Vario ELIII elemental analyzer.

$[CdClL\cdot H_2O]_n$ (1): A solution of $CdCl_2\cdot 2.5H_2O$ (0.11 g, 0.5 mmol) in H_2O (5 mL) was added slowly to a solution of HL (0.07 g, 0.5 mmol) in MeOH (10 mL). Aqueous NaOH (1 mol·L^{-1}) was then added dropwise to the reaction mixture until a small amount of precipitate had formed. The precipitate was filtered off and the clear filtrate was allowed to stand at room temperature. After one week, light yellow crystals were obtained. Yield: 68%. $C_7H_8CdClNO_3$ (302.0): calcd. C 27.84, H 2.65, N 4.64; found C 28.27, H 2.76, N 4.52. IR (KBr): $\tilde{\nu}$ = 3329 (s), 3280 (s), 3217 (s), 3134 (m), 1928 (vw), 1693 (vw), 1637 (vw), 1608 (vs), 1597 (m), 1520 (s), 1518 (s), 1433 (m), 1398 (vs), 1327 (w), 1302 (w), 1240 (w), 1176 (w), 1142 (w), 1076 (s), 1034 (m), 964 (w), 856 (m), 843 (vw), 787 (m), 777 (m), 702 (vw), 636 (m), 617 (vw), 517 (vw), 503 (vw) cm^{-1}.

$[CdBrL\cdot H_2O]_n$ (2): The procedure was similar to the synthesis of complex **1**, except that $CdBr_2\cdot 4H_2O$ (0.17 g, 0.5 mmol) was used instead of $CdCl_2\cdot 2.5H_2O$. Yield: 53%. $C_7H_8BrCdNO_3$ (346.5): calcd. C 24.27, H 2.31, N 4.04; found C 24.32, H 2.43, N 4.12. IR (KBr): $\tilde{\nu}$ = 3286 (br, vs), 1923 (vw), 1911 (vw), 1668 (w), 1610 (vs), 1597 (vs), 1502 (vs), 1414 (vs), 1402 (vs), 1302 (m), 1246 (s), 1184 (m), 1146 (w), 1101 (m), 1055 (vs), 951 (w), 868 (s), 852 (s), 785 (s), 702 (m), 636 (s), 596 (m), 530 (m) cm^{-1}.

$CdI_2(HL)_2$ (3): A solution of CdI_2 (0.09 g, 0.25 mmol) in H_2O (5 mL) was added slowly to a solution of HL (0.07 g, 0.5 mmol) in MeOH (10 mL). The reaction mixture was stirred for 30 min and the resulting colourless solution was filtered. Light yellow crystals of complex **3** were obtained by allowing the filtrate to stand in air for one week. Yield: 56%. $C_7H_7Cd_{0.5}INO_2$ (320.2): calcd. C 26.25, H 2.19, N 4.37; found C 26.37, H 2.24, N 4.43. IR (KBr): $\tilde{\nu}$ = 3460 (s), 3363 (s), 3329 (s), 3215 (m), 2978 (m), 2669 (m), 2551 (m), 1684 (s), 1605 (s), 1574 (m), 1512 (vw), 1441 (m), 1423 (m), 1387 (w), 1319 (s), 1290 (s), 1261 (m), 1174 (s), 1128 (w), 1097 (vw), 1012 (w), 1018 (w), 964 (w), 899 (vw), 843 (w), 773 (m), 694 (vw), 617 (w), 550 (vw), 499 (vw) cm^{-1}.

$\{[Cd(dca)_2(HL)_2]\cdot 2H_2O\}_n$ (4): A solution of $Cd(NO_3)_2\cdot 6H_2O$ (0.15 g, 0.5 mmol) and Na(dca) (0.09 g, 1 mmol) in H_2O (5 mL) was added slowly to a solution of HL (0.07 g, 0.5 mmol) in MeOH (10 mL). The reaction mixture was stirred for 30 min and gave a colourless solution. After filtration, the filtrate was allowed to stand in air for two weeks to give light yellow crystals of complex **4**. Yield: 50%. $C_9H_9Cd_{0.5}N_4O_3$ (277.4): calcd. C 38.97, H 3.24, N 20.19; found C 39.02, H 3.27, N 20.23. IR (KBr): $\tilde{\nu}$ = 3575 (vw), 3460 (m), 3383 (w), 3365 (m), 3307 (w), 3165 (vw), 2663 (vw), 2291 (m), 2268 (m), 2235 (w), 2175 (vw), 1678 (s), 1626 (s), 1605 (s), 1576 (vw), 1518 (vw), 1443 (w), 1423 (w), 1365 (vw), 1327 (s), 1315 (s), 1292 (s), 1263 (w), 1176 (m), 1128 (vw), 1012 (vw), 964 (vw), 943 (vw), 918 (vw), 845 (vw), 771 (vw), 698 (vw), 619 (vw), 553 (vw), 509 (vw) cm^{-1}.

$(H_2L)_2[CdCl_4(H_2O)_2]$ (5): An aqueous solution (10 mL) of $CdCl_2\cdot 2.5H_2O$ (0.11 g, 0.5 mmol) was added slowly to a solution of HL (0.07 g, 0.5 mmol) in HCl (6 mol·L^{-1}, 20 mL). After stirring for 30 min, the colourless reaction mixture was filtered. Light yellow crystalline complex **5** was obtained by keeping the filtrate in

X-ray Crystallography: Intensity data for the five complexes were measured with a Siemens Smart CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) at 298 K. Empirical absorption corrections were applied by use of the SADABS program. The structures were solved by direct methods and all calculations were performed with the aid of the SHELXL PC program. The positions of H atoms in complexes **1**−**4** were generated geometrically (C−H bond fixed at 0.96 Å) and the positions of H atoms in complex **5** were generated from difference Fourier maps, assigned isotropic thermal parameters, and allowed to ride on their parent carbon atoms before the final cycle of refinement. The structures were refined by full-matrix, least-squares minimization of $\Sigma(F_o - F_c)^2$ with anisotropic thermal parameters for all atoms except the H atoms. The crystallographic data for complexes **1**−**5** are listed in Table 1, selected bond lengths and angles in Table 2. CCDC-180374 to -180376 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Structural and Single Crystal EPR Studies of the Complex Copper L-Glutamine: A Weakly Exchange-Coupled System with *syn-anti* Carboxylate Bridges

José M. Schveigkardt,[a] Alberto C. Rizzi,[a] Oscar E. Piro,[b] Eduardo E. Castellano,[c] Ricardo Costa de Santana,[d] Rafael Calvo,[a,e] and Carlos D. Brondino*[a]

Keywords: EPR spectroscopy / Carboxylate ligands / Through bond interactions / Copper / Magnetic Properties / Layered compounds

We report the molecular structure and a single crystal EPR study at 9.8 and 33.9 GHz of a new copper(II) compound with the amino acid L-Glutamine, $Cu[NH_2CO_2CH(CH_2)_2CONH_2]_2$. The Cu^{II} ion is in an elongated octahedral environment equatorially *trans*-coordinated by two glutamine molecules acting as bidentate ligands through the nitrogen atom and one oxygen atom of each amino acid group, and axially by two carboxylate oxygen atoms of two neighboring glutamine molecules. Copper ions are arranged in layers connected by *syn-anti* carboxylate bridges that provide equatorial and apical ligands to the copper ions. Neighboring layers are connected by long chemical paths, which include two amino acid side chains connected by H bonds. Single crystal EPR spectra show a single exchange-collapsed resonance at both microwave frequencies for any magnetic field orientation. The evaluation of the molecular ***g***-tensor from the angular variation of the EPR line position yielded $g_\perp = 2.051$ and $g_\parallel = 2.248$, which indicates a $d_{x^2-y^2}$ ground orbital for the Cu ions. The angular variation of the EPR line width displays a contribution that is typical of a 2-D magnetic system, and another contribution depending on the microwave frequency, which is attributed to the incomplete collapse of the resonances corresponding to magnetically nonequivalent copper ions. A quantitative analysis of the line width data allowed us to estimate a mean exchange coupling constant $|J/k| = 0.42(2)$ K, which is assigned to the *syn-anti* carboxylate chemical path that connects neighboring copper ions within a layer. The results are discussed and compared with those observed in similar systems.

Introduction

Copper complexes with amino acids are appropriate compounds for the study of magnetic properties of weakly exchange-coupled systems. They are also of biological interest as amino acids provide ligands to the metal ions in metalloproteins.[1] Additional biological interest arises because chemical paths for superexchange interactions, such as carboxylate bridges, saturated and nonsaturated sigma bonds, hydrogen bonds, stacking of aromatic rings, or mixed paths integrated by fragments of the previous ones, have been identified as possible pathways for electron transfer in several biological systems.[2] These paths are responsible for the transmission of weak exchange interactions ($0.0005\ K \leq |J/k| \leq 2\ K$) that have been related to the matrix element for electron transfer between redox centers in metalloproteins.[3] Small exchange interactions are difficult to evaluate by standard magnetic susceptibility measurements, but they can be accurately and selectively measured employing EPR spectroscopy.[4−6]

Most solid copper compounds with α-amino acids have the Cu^{II} ions coordinated to the nitrogen and one of the carboxylate oxygen atoms of the amino acid group of two amino acid molecules, while the remaining carboxylate oxygen atoms are bonded to copper ions of neighboring molecules. This gives rise to copper ion networks having 1-, 2-, or 3-D structures, connected by carboxylate bridges of the *syn-anti* type that provide equatorial and apical ligands to the copper ions.[7−12] A different situation occurs in the copper complexes with aspartic acid,[13,14] glutamic acid,[15,16] and asparagine.[17] In these compounds, the copper ions are coordinated to one amino acid molecule as

in the compounds described above, and, in addition, are coordinated to the side chain carboxylate group of the other amino acid molecule in the case of aspartic and glutamic acids, and by the side chain amide in the case of asparagine. This coordination gives rise to polymeric chains, where the sigma skeleton of the amino acid molecule connects two neighboring copper ions.

We report herein the crystal and molecular structure and a single-crystal EPR study of the copper complex with the amino acid L-glutamine. According to the information given above, this compound was expected to exhibit a polymeric structure. However, our results indicate that this complex has a molecular structure and a magnetic behaviour different from that observed in polymeric compounds.

Results and Discussion

Molecular Structure

X-ray structural characterizations of the title compound reveal that it crystallizes in the monoclinic space group *C*2. The copper ion has an elongated octahedral coordination, trans coordinated by two glutamine molecules with a nearly square planar equatorial N_2O_2 ligand group. Figure 1 is an ORTEP[18] drawing of the complex showing the coordination around the Cu^{II} ion, hereafter called $Cu(gln)_2$. Selected bond lengths and angles are given in Table 1. The axial ligands are the carboxylate oxygen atoms O22 and O12, each belonging to one of two symmetry related neighboring glutamine molecules.

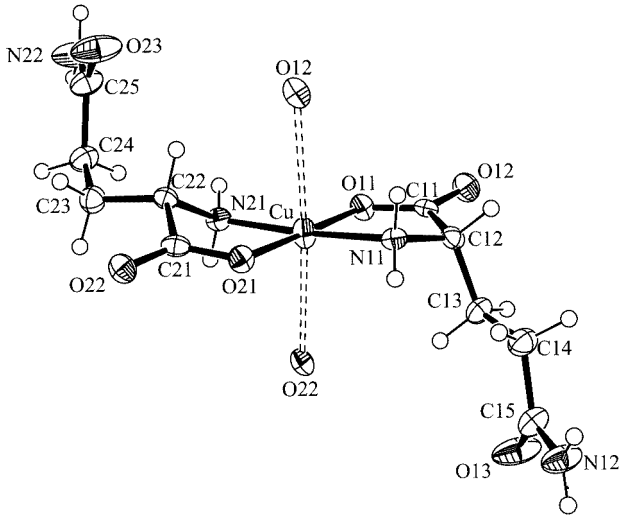

Figure 1. Drawing of the $Cu(gln)_2$ molecule showing the coordination around Cu^{II}, the labeling scheme of the non-H atoms and their displacement ellipsoids at 50% probability level; full lines indicate copper-ligand bonds

The four symmetry related copper ions in the unit cell of $Cu(gln)_2$ lie in two layers parallel to the *cb* plane 14.1 Å apart . One of them, shown in Figure 2, contains the copper atoms in the general positions (*x,y,z*) and ($-x + 1/2$, $y + 1/2$, $-z$) (positions I and IV, respectively, of the crystallographic space group *C*2). The other one contains the copper atoms in positions ($-x$, y, $-z$) and ($x + 1/2$, $y + 1/2$, z) (positions II and III, respectively).[19]

Table 1. Selected bond lengths (Å) and angles (deg) around copper(II) for $Cu(gln)_2$; symmetry code: (i) $3/2-x$, $y-1/2$, $2-z$; (ii) $3/2-x$, $y + 1/2$, $1-z$.

Bond lengths		Bond angles	
Cu−O(11)	1.941(2)	O(21)−Cu−O(11)	179.10(7)
Cu−O(21)	1.951(2)	O(11)−Cu−N(11)	84.39(7)
Cu−N(11)	1.985(2)	O(11)−Cu−N(21)	95.62(8)
Cu−N(21)	1.984(2)	O(21)−Cu−N(21)	84.11(7)
Cu−O(12^{i})	2.848(3)	N(11)−Cu−N(21)	175.44(9)
Cu−O(22^{ii})	2.778(3)	O(12^{i})−Cu- O(22^{ii})	176.11(13)

Two different types of chemical paths connect copper ions within each layer. Cu^{I} and Cu^{IV} are connected by two similar carboxylate bridges of the *syn-anti* type ($-Cu-O_{ap}-C-O_{eq}-Cu-$), which gives rise to a 2-D network of copper ions (see Figure 2). The same situation occurs for Cu^{II} and Cu^{III} in the other layer (not shown). A similar equatorial-apical copper interaction in the layered compounds has been observed in the copper complexes with the amino acids phenylalanine,[7] methionine,[8] leucine,[9] alanine,[10,11] and α-aminobutyric acid.[12] The second path is provided by double hydrogen bonds N−H···O that connect the copper ions with identical spatial orientation (Figure 2). This connection, which involves equatorial ligands to the copper ions, gives rise to infinite polymeric chains along the *b* crystal axis. Copper ions having the same spatial orientation, but in neighboring layers, are connected by chemical paths that involve the skeleton of two amino acid molecules and double N−H···O hydrogen bonds (see Figure 3).

Crystal and Molecular *g*-Factor

The room temperature EPR spectra of $Cu(gln)_2$ display a single Lorentzian-shaped resonance line for any magnetic field orientation at the microwave frequencies of 9.8 and 33.9 GHz. Figure 4 shows the angular variation of the squared *g*-factor [$g^2(\theta,\varphi)$] observed at 9.8 GHz. A similar result is obtained at 33.9 GHz (data not shown). Since Cu^{I} and Cu^{III} sites [as well as Cu^{II} and Cu^{IV}] are related by a [1/2, 1/2, 0] translation, they have identical spatial orientation and consequently give rise to identical EPR spectra for any magnetic field orientation. Within each layer Cu^{I} and Cu^{IV} sites [as well Cu^{II} and Cu^{III}] are related by a C_{2b} rotation, and consequently the angular variation of their EPR spectra will also be related by the same symmetry operation. Therefore, two-symmetry related EPR spectra associated with copper ion pairs I−III and II−IV are expected for any magnetic field orientation except in the *ca* plane and along the *b* crystal axis, in which the four copper ions are magnetically equivalent. These resonance lines should be split by hyperfine interactions with the copper nuclear spin ($I = 3/2$) and the nitrogen ligands ($I = 1$). The fact that a single Lorentzian-shaped resonance line is observed for the

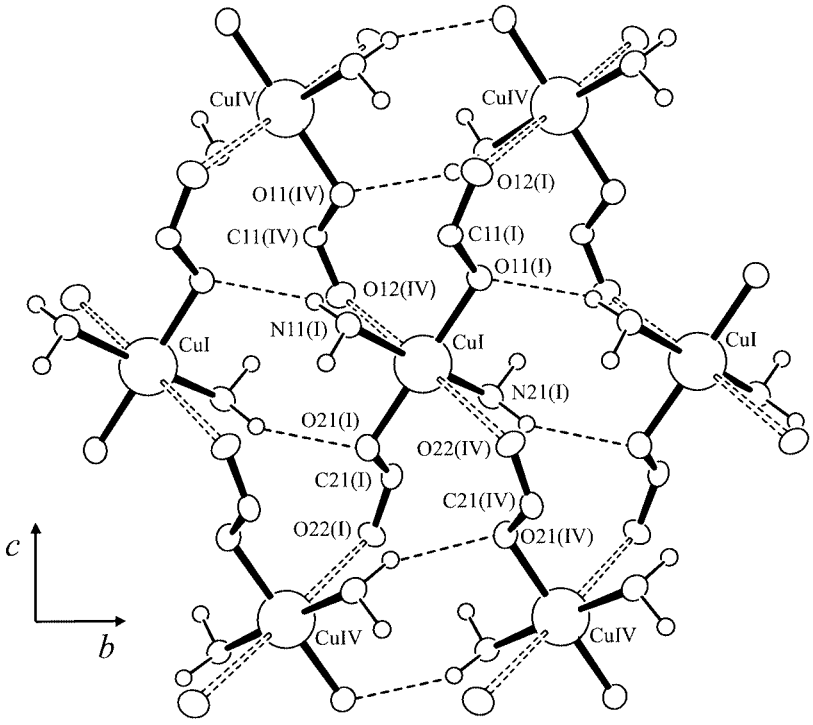

Figure 2. Orthogonal projection of $Cu(gln)_2$ along $a^* = b \times c$ crystal axis showing a copper atom and its six nearest copper neighbors within a layer; only the layer containing copper ions at symmetry positions I and IV is shown

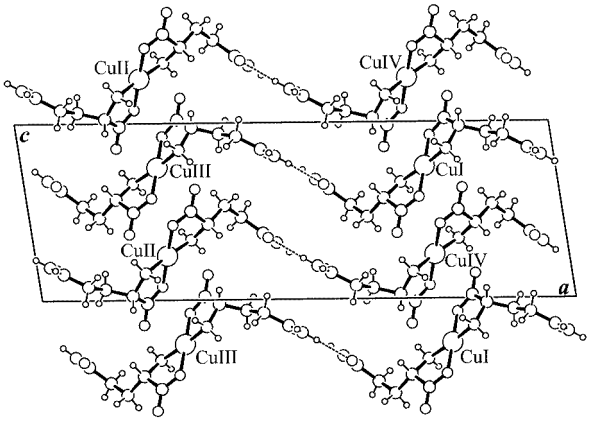

Figure 3. Orthogonal projection of $Cu(gln)_2$ along the b crystal axis showing the copper atom layers and the chemical paths connecting them

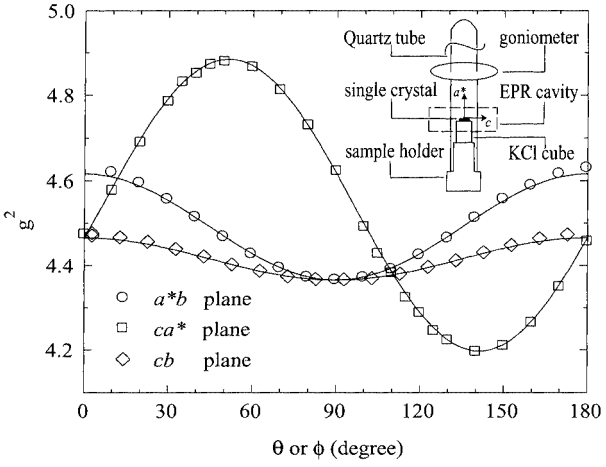

Figure 4. Angular variation of the squared g-factor measured at 298 K and 9.8 GHz in three orthogonal crystalline planes of $Cu(gln)_2$; the solid lines were obtained by fitting a symmetric $\boldsymbol{g}^2$ second-order tensor to the data; the parameters of the fit are included in Table 2; the inset schematizes the orientation of the sample for the EPR experiment

measured crystal planes, even at 33.9 GHz, indicates that the exchange interaction between the Cu^{II} ions is large enough to collapse both the expected hyperfine splitting and the resonance lines due to magnetically nonequivalent Cu^{II} ions.

For a magnetic system showing a single exchange-collapsed resonance line, the position of the observed resonance lines is described by the Zeeman Hamiltonian in Equation (1) where μ_B is the Bohr magneton, **S** is the effective spin operator ($S = 1/2$), $\boldsymbol{g}$ is the crystal $\boldsymbol{g}$-tensor defined as the average of the molecular $\boldsymbol{g}_i$-tensors (i = I,···IV), and **B** is the applied magnetic field.

$$H = \mu_B \mathbf{S} \cdot \boldsymbol{g} \bullet \mathbf{B} \quad (1)$$

The components of the crystal $\boldsymbol{g}$-tensor defined in Equation (1) were obtained by least-squares fitting the function $g^2(\theta,\phi) = \mathbf{h}\cdot\boldsymbol{g}^2\cdot\mathbf{h}$ to the experimental data, where $\mathbf{h} = \mathbf{B}/|\mathbf{B}| = (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)$ is the direction of the applied magnetic field **B**. The components of $\boldsymbol{g}^2$ at both microwave frequencies, its eigenvalues and eigenvectors, are

given in Table 2. They were employed to calculate the solid lines shown in Figure 4.

Table 2. Values of the components of the g^2 tensor obtained by least-squares analyses of the data at both microwave frequencies. $(g^2)_1$, $(g^2)_2$ and $(g^2)_3$ and α_1, α_2 and α_3 are the eigenvalues and eigenvectors of the g^2 tensor in the $xyz = a^*bc$ coordinates system ($a^* = b\times c$); the values of $g_\perp$ and $g_\parallel$, the polar and azimuthal angles θ_m and ϕ_m of the normal to the square of ligands to copper ion in site I, and the angle 2α between the normals to copper ions in sites I and IV (identical to those of sites II and III) were calculated like in ref.[20]

9.8 GHz	33.9 GHz
$(g^2)_{xx} = 4.616(1)$	$(g^2)_{xx} = 4.6036(5)$

$\alpha_1 = [0.625(1), 0, 0.7808(1)]$	$\alpha_1 = [0.6415(3), 0, 0.7672(3)]$
$\alpha_2 = [0.7808(1), 0, -0.625(1)]$	$\alpha_2 = [0.7672(3), 0, -0.6415(3)]$
$\alpha_3 = [0, 1, 0]$	$\alpha_3 = [0, 1, 0]$
$g_\perp = 2.049$	$g_\perp = 2.053$
$g_\parallel = 2.248$	$g_\parallel = 2.248$
$2\alpha = 127.3°$	$2\alpha = 125.2°$
$\theta_m = 124.1$	$\theta_m = 124.7$
$\phi_m = 32.3$	$\phi_m = 34.0$

The components and principal directions of the copper molecular g_i-tensor shown in Table 2 were evaluated following the procedure described elsewhere assuming axial symmetry.[20] θ_m and φ_m are, respectively, the polar and azimuthal angles of the symmetry axis of the Cu^I site [identical to Cu^{III} site] referred as to the a^*bc crystal system, and 2α is the angle between the normals to the Cu^I and Cu^{IV} sites [identical to $Cu^{II}-Cu^{III}$]. The values for θ_m, φ_m and 2α are in a good agreement with the crystallographic ones ($\theta_c = 120.4°$, $\varphi_c = 29.0°$, and $2\alpha_c = 130.4°$), supporting the assumption of axial symmetry for this copper complex. The result obtained for the molecular g-tensor (Table 2) indicates a $d_{x^2-y^2}$ ground state orbital situated in the equatorial ligand plane of the Cu^{II} ion.[21]

EPR Line Width and Superexchange Paths

Figure 5 shows the angular variation of the peak-to-peak line width $[\Delta B_{pp}(\theta,\phi)]$ at 9.8 and 33.3 GHz. To analyze the variation of the line width with the magnetic field orientation, the data shown in Figure 5 were least-squares fitted with the function presented in Equation (2), where θ_n is the angle between the applied external magnetic field and the normal to the layers ($\cos\theta_n = \sin\theta\cos\phi$). The a_i coefficients, given in Table 3, were used to obtain the solid lines shown in Figure 5.

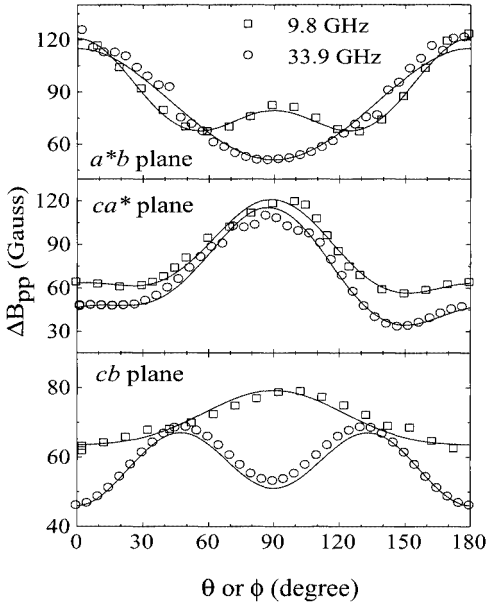

Figure 5. Angular variation of the peak-to-peak line width measured at 9.8 GHz and 33.9 GHz and 298 K in three orthogonal crystalline planes of $Cu(gln)_2$; the solid lines were obtained by fitting the data with Equation (2); the parameters of the fit are included in Table 3

a_6	n.d.[a]	1801(81)

[a] n.d. not detectable

$$\Delta B_{pp}(\theta,\phi) = a_1 \sin^2\theta\cos^2\phi + a_2 \sin^2\theta\sin^2\phi + a_3\cos^2\theta + a_4 \sin\theta\cos\theta\cos\phi + a_5(1-3\cos^2\theta_n)^2 + a_6[g_I(\theta,\phi) - g_{IV}(\theta,\phi)]^2 \quad (2)$$

Several mechanisms, such as dipolar interactions and incomplete collapse of the hyperfine splitting and/or the resonances corresponding to nonequivalent copper ions, contribute to the EPR line width in copper amino acid complexes.[22–25] The terms a_{1-4} in Equation (2) consider the contributions to the EPR line width of interactions having a second order angular variation, like the crystal g-tensor, such as the incomplete collapse of the hyperfine structure, as well as other smaller interactions (e.g. anisotropic and antisymetric exchange).[4] They are not important in our study, and therefore will not be analyzed further.

The term a_5 describes the dipolar contribution for a 2-D magnetic system.[26] The typical angular variation originat-

ing from this interaction can be visualized at the X-band in Figure 5. At the Q-band, the contribution of the dipolar interaction in both *a*b* and *cb* planes is masked by the contribution described by the term a_6, which is negligible at the X-band but not at the Q-band (see below).

The term a_6 in Equation (2) takes into account the contribution to the line width arising from the presence of two magnetically nonequivalent copper sites in the crystal lattice of $Cu(gln)_2$. As discussed elsewhere,[27,28] this interaction depends on both the microwave frequency and the number of neighboring nonequivalent Cu^{II} ions connected by the bridge. Its contribution can be identified at the Q-band in the *cb* and, though less noticeable, *a*b* crystal planes (see Figure 5 and Table 3). On the contrary, in the *ca** crystal plane, where the four copper ions are magnetically equivalent, the line width does not show significant differences at both frequencies, except for a small constant shift. This shift is attributed to nonsecular terms of the Zeeman interaction that only make a contribution at the X-band.[29]

For a system having two magnetically nonequivalent copper ions per unit cell, the coefficient a_6 in Equation (2) is given by Equation (3),[28,30] where $g = 1/3\ \mathrm{tr}(\boldsymbol{g})$ is the isotropic *g*-factor, ω_o is the Larmor frequency, and ω_e is the exchange frequency.

$$a_6 = (2/3\pi)^{1/2}\, \omega_o^2\, \hbar/4\, g^3\, \omega_e\, \mu_B \qquad (3)$$

Using Equation (3) and the a_6 value obtained from the fitting (Table 3 and Figure 5) we calculated $\omega_e = 1.089 \times 10^{11}\ s^{-1}$, which is related to the exchange parameters through Equation (4)[28] where J_i's are the exchange parameters associated with the chemical paths connecting magnetically nonequivalent copper ion pairs and z_i is the number of the nearest neighboring copper ions connected by the ith chemical path.

$$\hbar\,\omega_e = (\Sigma_i z_i J_i^2)^{1/2} \qquad (4)$$

As shown in Figures 2 and 3, each copper ion is connected to only four nonequivalent neighboring copper ions through two similar *syn-anti* carboxylate bridges. Further, since line-width data indicate a 2-D magnetic behaviour, it is reasonable to assume $J_1 \approx J_2$, where J_1 and J_2 are the exchange parameters associated with each carboxylate bridge. Then, from Equation (4) we obtain a mean exchange parameter $|J|/k = 0.42(2)$ K for the intralayer bridge connecting magnetically nonequivalent copper ions (Figure 2).[31] This value is supported by the lowest limit $|J|/k \geq 0.13$ K estimated from the collapse condition $J \geq \Delta g\, \mu_B\, B$ at Q-band. The model employed to analyze the EPR data does not allow for the measurement of exchange couplings between magnetically equivalent copper ions associated with intra- or interlayer bridges (Figures 2 and 3). However, the observed 2-D spin dynamic indicates that the interlayer exchange couplings are negligible (Figure 3). Thermodynamic measurements at very low temperatures (< 1 K) performed on the copper compounds with the amino acids L-alanine[32,33] and α-aminobutyric acid[34] indicate that *syn-anti* carboxylate bridges involving equatorial and apical ligands to the copper ions transmit antiferromagnetic interactions. Therefore, a similar magnetic behaviour is expected for all copper amino acid compounds that show this characteristic.

Levstein and Calvo observed that the magnitude of *J* decreases linearly with an increase in the $Cu-O_{ap}$ bond length for three Cu^{II} amino acid complexes.[35] According to their results, the *J* value for $Cu(gln)_2$ should be smaller than 0.1 K. A similar discrepancy was obtained for the copper complexes with L-alanine[32] and L-α-aminobutyric acid.[12] Thus, the length of the $Cu-O_{ap}$ bond is not the only factor that determines the magnitude of the magnetic interactions, but other structural factors should also be considered. Table 4 shows the *J* values, the $Cu-O_{ap}$ distances and the dihedral angles between the plane of the carboxylate bridge and the planes (eq and eq′) of the equatorial ligands of the two magnetically nonequivalent Cu^{II} ions connected by the bridge for six layered Cu^{II} L-amino acid complexes. As seen in Table 4, the compounds studied in ref.[35] have similar dihedral angles, deviating by about two degrees from the mean value. Meanwhile, the compounds that do not follow the proposed dependence of the magnitude of *J* with the $Cu-O_{ap}$ length have smaller dihedral angles when the longer $Cu-O_{ap}$ bond is taken into account. For the shorter $Cu-O_{ap}$ bond, there is a dual behaviour: on the one hand no significant changes are observed for the higher angles (< eq−OCO in Table 4); on the other hand, a slight increase of the angle value is observed for the lower angles (< eq′−OCO in Table 4). Consequently, the results in Table 4 suggest that the values of the angles between the magnetic orbitals of the Cu^{II} ion and the OCO plane, play a key role regarding the *J* value. They indicate that the higher the planarity of the Cu−OCO−Cu bridge, the larger the magnitude of the exchange interaction. This is in line with previous observations for some copper dimers, which yielded the same conclusion.[36]

Table 4. *J*-values, copper-apical ligand bond lengths, and angles between the carboxylate group bridging equatorial ligand planes of two nearest magnetically nonequivalent Cu^{II} ions (eq and eq′) in six layered Cu^{II}-L-amino acid complexes

Conclusion

This work demonstrates that $Cu(gln)_2$ belongs to the family of copper amino acid complexes in which the amino acid R group is not involved in the Cu^{II} coordination resulting in a layered structure of copper ions connected by equatorial-apical *syn-anti* carboxylate bridges. Cu^{II} complexes of amino acids are among the few examples of equatorial-apical *syn-anti* carboxylate-bridged compounds magnetically characterized so far.[37] In this work we show that the magnitude of the exchange interaction depends on both the $Cu-O_{ap}$ distance and the angles between the equatorial ligand plane and the bridging ligand plane. The larger the co-planarity between the Cu^{II} equatorial ligand plane and the OCO plane, the larger the J value.

Experimental Section

Sample Preparation: All commercially available chemicals were reagent grade and used without further purification. Single crystals of $Cu(gln)_2$, $Cu[NH_2CO_2CH(CH_2)_2CONH_2]_2$, were obtained by dissolving L-glutamine (730.5 mg, 5 mmol) and basic copper carbonate (276.4 mg, 2.5 mmol) in ion-exchanged water (40 mL). This solution was stirred for a few minutes until a light-blue colour developed, and the solid was filtered out, using a 0.22 μm Millipore filter. The pH of the resulting solution was adjusted to 9 and left to evaporate at room temperature. Thin blue plates were obtained after one week. The crystals are elongated along the b direction and show well defined bc lateral faces.

X-ray Structural Determination. Data Collection, Solution, and Refinement of the Structure. X-ray data were collected at 120 and 293 K on an Enraf−Nonius KappaCCD diffractometer with Mo-K_α (λ = 0.71073 Å) graphite monochromated radiation. Diffraction data were reduced and corrected using the DENZO and SCALEPACK Programs.[38] Structures were solved by direct methods with the help of the SHELXS-97 program[39] and refined on reflection intensities (F^2) using the SHELXL-97 program.[40]

Crystal data, structure determination methods and refinement results at 120 K are summarized in Table 5. All H atoms were located among the first 18 peaks of a difference Fourier map. As expected, the terminal amine H atoms were found close to the OCN plane. These hydrogen atoms were therefore positioned stereochemically on the corresponding planes and refined with the riding model. The hydrogen atoms of the amine group coordinated to the copper(II) ion were refined isotropically with N−H bond lengths restrained to a target value of 0.89(1) Å. The remaining glutamine H atoms were also positioned on a stereochemical basis and refined with the riding model. The room temperature solid is isomorphous to that of the low temperature one.

CCDC-179785 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

EPR Measurements: EPR spectra at 9.8 GHz (X-band) and 33.9 GHz (Q-band) were acquired on Bruker ER-200 and Bruker ESP300 spectrometers, respectively, using a Bruker rectangular cavity ER4102ST (X-band) and a cylindrical cavity ER5101Q (Q-band). The field modulation was 100 kHz in both cases. All the experiments were carried out at room temperature.

The samples were oriented by gluing the single crystal bc face to a cleaved KCl cubic holder, which defines a set of x,y,z orthogonal axes with the x axis along the $a^* = b\times c$ direction, and the y and z directions along the b and c crystal axes, respectively. For the X-band measurements, the sample holder was positioned on the horizontal plane at the top of a pedestal, which was introduced into a 4 mm OD Quartz tube (see inset on Figure 4). For the Q-band measurements, the samples were mounted only on the pedestal. Both devices were introduced into the cavity, and the EPR spectra were taken with the magnetic field along several directions of the crystal planes a^*b, ca^* and cb of the sample. Positions and peak-to-peak line widths (ΔB_{pp}) of the resonance lines were obtained by least-squares fitting of the spectra to a Lorentzian derivative line.

The stereochemistry of a new class of models of the vitamin B_{12} system, containing tridentate pyridyl-imino-oxime [$C_6H_5N(CH_2)_nNC(CH_3)C(CH_3)NO^-$; n = 1, L^1; n = 2, L^2] and pyridyl-amino-oxime [$C_6H_5N(CH_2)_nNHCH(CH_3)$-$C(CH_3)NO^-$; n = 1, L^3; n = 2, L^4] ligands, has been investigated through molecular mechanics calculations based on a specific force field. It is shown that, among all the possible diastereomers of the imino complexes $[Co(L^{1,2})_2]^+$, the minimum strain energy is exhibited in a *mer* configuration. For the amino complexes $[Co(L^{3,4})(HL^{3,4})]^{2+}$, the minimum is exhibited in a *fac* configuration, with the amino nitrogen atoms all having the same chirality, opposite to that of the adjacent carbon atoms. Furthermore, comparison of the effect of five- (L^1, L^3) or six-membered (L^2, L^4) chelate rings on the complexes indicates that the strain energy decreases upon passing from L^1 to L^2 complexes, while it increases upon passing from L^3 to L^4 complexes. The effect of rotation around the axial pyridyl Co–N bond on the coordination geometry has also been studied through a conformational analysis of the methyl (R = Me) and adamantyl (R = Adam) organocobalt derivatives $[RCo(L^4)(HL^4)]^+$. The most important result is that the rotation is rather hindered in the case of the bulky Adam group, while in the Me case the pyridyl group can rotate across a wide angular range. In both cases, the rotation causes a significant change in the Co–N bond length, while the Co–C distance is almost unaffected. It is also shown that the aromatic base is oriented with respect to the equatorial ligand in a fashion quite different from other B_{12} models.

Introduction

In recent years,[1−3] tridentate imino- and amino-oxime ligands, obtained by condensation of biacetyl monoxime with 2-(aminomethyl)pyridine and 2-(2-aminoethyl)pyridine (see Scheme 1), have been used to prepare stable alkylcobalt complexes, which differ in a number of respects from the widely studied tetradentate ligand derivatives.[4] Thus, it has recently been shown[3] that organocobalt(III) complexes of formula $[RCo(L^4)(HL^4)]^+$ (Figure 1, a), containing the tridentate 3-[2-(2-pyridyl)ethylamino]butane-2-one-oximato ligand (L^4) and its protonated form (HL^4), constitute a new type of model of alkylcobalamins (vitamin B_{12} system).[5] Their geometry is reminiscent of the lariat-type complexes (Figure 1, b),[6] which combine the corrin-like features of iminocobaloximes with an appended axial base, but differs by having a more crowded equatorial moiety. Structural evidence[3] indicates that their properties are closer to those of alkylcobalamins (particularly for the C−Co−N axial fragment) than that of any of the other previously reported models,[7] such as the well documented alkylcobaloximes, $RCo(DH)_2L$ (DH = monoanion of dimethylglyoxime). This has been attributed to the more crowded nature of the equatorial moiety (planar in cobaloximes), which would cause stronger steric interactions with the axial ligands.[2,3] Therefore, these compounds offer the opportunity to study the influence of the electronic and steric factors on the axial Co−C and Co−N bonds, thereby extending the previous molecular mechanics (MM) investigation on alkylcobaloximes.[8]

Structural investigations of lariat-type complexes[6] and alkylcobaloximes[7,8] have shown that the Co−N axial bond length is significantly affected by the relative orientation of the N and equatorial ligands. This feature becomes relevant in light of the evidence of substitution in some B_{12} enzymes of the Co-bound benzimidazole residue with a histidine group of the protein chain.[9] Therefore, the study of the nature of the Co−N bond in simple models,[6a,10] and particularly of the influence of the orientation of the nitrogen base with respect to the equatorial ligand, is of special interest.[8,11]

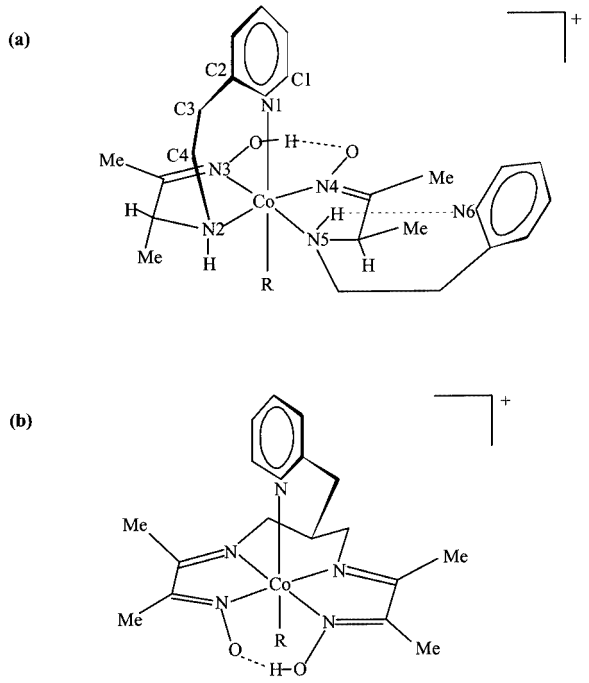

Figure 1. (a) Sketch of the structure of $[RCo(L^4)(HL^4)]^{2+}$ with a numbering scheme for the relevant atoms. (b) Sketch of the structure of a lariat type complex

$[RCo(L^4)(HL^4)]^+$ species may be obtained from $[Co(L^4)(HL^4)]^{2+}$ by reduction and successive oxidative alkylation.[3] In turn, the latter complex may be obtained by hydrogenation of the imino-oxime derivative $[Co(L^2)_2]^+$ (Figure 2).[2] Interestingly, starting from the 2-(aminomethyl)pyridine complex $[Co(L^1)_2]^+$ and under the same conditions, the metal reduction and alkylation reactions do not occur and only the hydrogenation product $[Co(L^3)(HL^3)]^{2+}$ is obtained.[2] This difference has been attributed to a more strained coordination in the L^1 complex with respect to that in the L^2 derivative.[2]

In order to provide some insight into the different strain energies of the $[Co(L^1)_2]^+ - [Co(L^2)_2]^+$ and $[Co(L^3)(HL^3)]^{2+} - [Co(L^4)(HL^4)]^{2+}$ complexes, a stereochemical investigation has been carried out through MM calculations, by implementation of the previously derived cobaloxime force field.[8] Furthermore, the present investigation includes an analysis of all the possible diastereomers of these complexes, denoted as $[Co(A\hat{}B\hat{}C)_2]$, where A^B^C represents the tridentate ligand with its three different nitrogen donors, A, B, and C (Figure 3). In the cases of the L^3 and L^4 complexes, ligand chirality, arising from the presence of stereogenic nitrogen and carbon centres in the equatorial ligand (N2, N5, and their adjacent C atoms, see Figure 2, b), has also been taken into account. This appears to be of some interest for an investigation of the possible species present in solution, considering that the $[Co(L^1)_2]^+$ [12] and $[Co(L^2)_2]^+$ complexes have been found in the solid state in a *mer* configuration, while the $[Co(L^3)(HL^3)]^{2+}$ and $[Co(L^4)(HL^4)]^{2+}$ complexes have been isolated in the *fac* configuration with *trans* pyridyl groups and *cis* amino and oxime nitrogen atoms.[2]

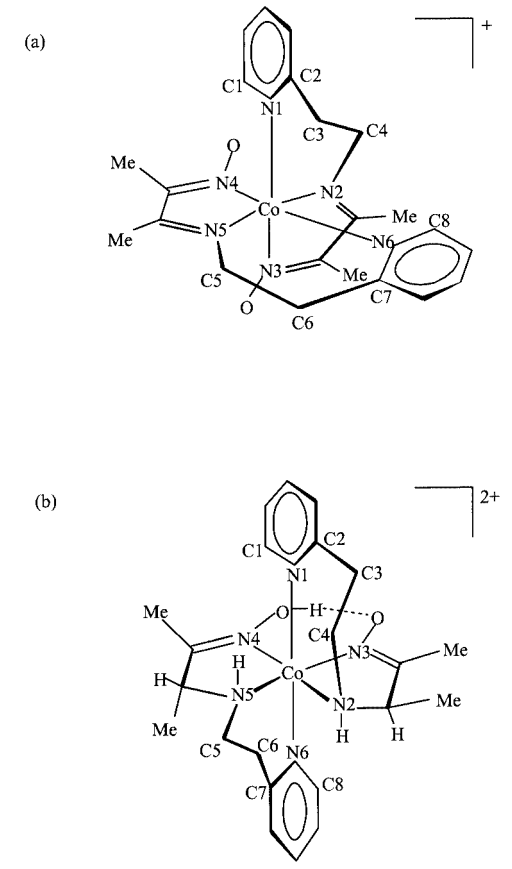

Figure 2. Sketch of the structure of $[Co(L^2)_2]^+$ (a) and $[Co(L^4)(HL^4)_2]^{2+}$ (b), with a numbering scheme for the relevant atoms. Hydrogen atoms are shown for H bonds and the chiral C and N atoms

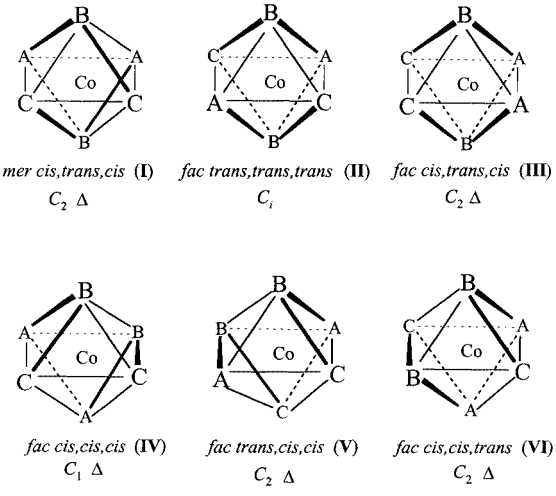

Figure 3. Schematic depiction of the six possible diastereomers for octahedral cobalt complexes containing two tridentate ligands A^B^C. Point symmetry and complex chirality are also shown. Larger letters define the octahedron upper triangular face. Thick lines represent the ligand bites

After validation of the force field, the effect of rotation around the axial Co−N bond on the metal coordination geometry has been investigated for the $[MeCo(L^4)(HL^4)]^+$

complex. The study has also been extended to the much bulkier adamantyl (Adam) derivative, even if not thus far isolated, in order to address the effects of the alkyl bulkiness. The results of the conformational analysis are also useful for a comparison between sterically different equatorial ligands, such as $(L^4)(HL^4)$ and $(DH)_2$.[4,5]

Results

Methods

Energy calculations have been performed with a Pentium III PC, using the HyperChem 6.01 molecular modelling system.[13] The Polak−Ribiere version of the conjugate gradient method was used in all energy minimisation calculations with a convergence criterion of 0.001 kcal·mol^{-1}·Å^{-1}.

The AMBER force field,[14] already implemented for the stereochemical investigation of cobaloximes,[8] has been used after further addition of the new atom types, NP_R, NI_R, NH_R, NE_R, and NO_R (R = X, Y, Z) for the pyridyl (py), imino (im), amino (am), protonated and nonprotonated oximato (ox) nitrogen atoms, respectively. The relative stretching and bending force field constants (Table 1) have been derived by the methods and optimisation procedure previously described,[8,15] which are based on the crystal structure atom parameters of the Co−L^{1-4} complexes.[3] The minimised function is GOF = $[\Sigma_i w_i \Delta_i^2/(n_{obsd.} - n_p)]^{1/2}$, where $n_{obsd.}$ is the number of observables (388 in the present case) with weights $w_i = 1/\sigma_i^2$, n_p is the number of variable parameters (11), the summation being extended to all the differences, Δ_i, between each observed and calculated value. In order to simulate crystal packing effects that can affect the torsion angles and yield to strained geometries, the pyridyl endocycle N−Co−N−C and N−C−C−C torsion angles were restrained to the observed values by force constants of 20 kcal·mol^{-1}. In order to estimate the electrostatic contribution to the total strain energy, E, the dielectric constant D = 7.8 has been used, as for cobaloximes.[8]

Table 1. Optimised force field stretching [k^d (kcal·mol^{-1}·Å^{-2}), d^o (Å)] and bending [k^θ (kcal·mol^{-1}·rad^{-2}), θ^o (°)] constants

CO3−NO_R	108.27	1.9602
NO_R−O1	647.61	1.2713
	k^θ	θ^o
CO3−NH_R−CT	61.89	110.40
CO3−NI_R−CDH	53.22	120.10
CO3−NI_R−CT	48.36	125.50
CO3−NO_R−CDH	51.15	122.50
CO3−NO_R−O1	65.57	121.10

[a] R = X, Y, Z.

Atomic charges for each molecule have been calculated by the semi-empirical ZINDO/1 method, using restricted Hartree Fock functions,[13] and then averaged over chemically equivalent atoms. At convergence GOF was 4.786, with a difference between the lowest and highest GOF values of less than 0.0001.

In order to explore, as thoroughly as possible, the conformational space of the complexes of type $[Co(L)_2]^+$ and $[Co(L)(HL)]^{2+}$ (L = L^3, L^4), all possible stereoisomers have been built using HyperChem, considering all combinations of nitrogen and carbon chiralities. The strain energies of all these diastereomers have been calculated by molecular energy minimisation, without any torsion restraint and with $D = r_{ij}$, in order to simulate solvent effects.[14]

Because of the uncertainty in the location of the oxime bridge hydrogen atoms, it has been assumed, as in the case of cobaloximes,[8] that the hydrogen atom (atom type HDH) lies on the median of the O···O segment (atom types ODH). The energy of the H-bonding interaction is given by electrostatic interactions and by the stretching of the ODH−HDH bond (d^o = 1.269, k^d = 198.9 kcal·mol^{-1}·Å^{-2}). Where it has been assumed that this H bond is not present (L^o ligands), one ODH−HDH bond has been substituted by an ODH−HO bond (d^o = 0.96 Å, k^d = 553.0 kcal·mol^{-1}·Å^{-2}) and the other oxygen atom treated as type O1. In this case, when properly oriented, the O1 atom can give rise to a hydrogen bond interaction with HO only through electrostatic interactions.

For the conformational analysis of the alkyl derivatives $[RCo(L^4)(HL^4)]^+$, with R = Me and Adam, the strain energy has been minimised (D = 7.8) by rotating about the Co−N(py) bond (torsion angle φ_1 = N2−Co−N1−C2, see Figure 1) in steps of 5°, with a restraint constant of 1000 kcal·mol^{-1}. For these complexes, the force field constants derived for the axial ligands of the relative alkyl/pyridine cobaloxime have been adopted.[8] The Δ isomer with S and R configurations for the nitrogen and carbon atoms, respectively, has been used in the calculations, maintaining the intramolecular N5···N6 hydrogen bond (Figure 1, a) present in the solid state.

In all calculations, the same improper torsion parameters have been assigned to trigonal carbon atoms (atom type CA) and trigonal nitrogen atoms, taking the parameters of CA given in AMBER.[14] As in previous calculations,[8] torsion barriers around the coordination bonds have not been considered.

A local program[16] has been used for all the geometrical calculations, including the ring puckering parameter Q,[17] and the conformation discriminator Δ_c.[18]

Validation of the Force Field

As shown in Table 2, the agreement between observed and calculated bond lengths and angles for the Co−L^{1-4} complexes is quite satisfactory, on the basis of the values of the average differences $<\Delta>$ and the root-mean-square deviations, rms = $[(\Sigma_i \Delta_i^2)/n]^{1/2}$.

Moreover, the consistency of the force field is well illustrated (Table 3) by its ability to reproduce the observed vari-

Table 2. Average differences, <Δ>, between observed and calculated bond lengths [Å] and angles [°], together with rms values (Å) and number of observations, *n*; X, Y, and Z represent generic non-metal atoms

[a] C_α and C_β represent, respectively, the pyridyl carbon atoms like C1, C2 and C8, C7 in Figure 2. [b] The first line refers to the pyridyl bridge, the second one to the oxime ring. [c] The first line refers to the pyridyl bridge, the second one to the equatorial ring.

ations[2] of both bond lengths and angles on passing from $[Co(L^1)_2]^+$ to $[Co(L^2)_2]^+$, as well as from $[Co(L^3)(HL^3)]^{2+}$ to $[Co(L^3)(HL^3)]^{2+}$, that is on passing from complexes with ligands L^1, L^3 [$-(CH_2)-$ bridges] to complexes with ligands L^2, L^4 [$-(CH_2)_2-$ bridges]. The conformational parameters of the calculated structures are also in good agreement with those observed (Table 4).

In the case of the methyl derivative, $[MeCo(L^4)(HL^4)]^+$, the agreement between observed and calculated coordination bond lengths (Table 5) is not as good (rms = 0.033 Å) as that found in the Co−L^{1-4} complexes (rms = 0.019 Å). This indicates that the force field is not completely transferable to the organometallic derivatives. However, for the limited scope of this work, it is sufficient that the trend in the Co−N bond lengths, Co−N(ox) < Co−N(am) < Co−N(py), as well as the deviations from 90° of the coordination bond angles involving the coordinated pyridyl ligand (Table 5), are well reproduced. Furthermore, it is to be stressed that the perchlorate anion and the methyl group in the crystal structure are affected by thermal motion, reducing the accuracy of the crystal structure determination.[3] Correction of the experimental distances for this effect (riding model) reduces the rms deviation of the Co−X distances to 0.022 (Table 5).

Table 4. Conformational parameters of the two pyridyl chelate rings for $[Co(L)_2]^+$ (L = L^1, L^2) and $[Co(L)(HL)]^{2+}$ (L = L^3, L^4). The two rings are defined by the bites N1−N2 and N5−N6, respectively

[a] The *cis*/*trans* descriptors refer, in the order, to the pairs of the nitrogen atoms of the tridentate ligands, N(py), N(am)/N(im), and N(ox), labelled, respectively, A, B, and C in Figure 3.

Diastereomers of Complexes Co−L$^{1-4}$

The relative minimum energies for the six possible diastereomers of the [Co(L)$_2$]$^+$ (L = L^1, L^2) and [Co(L)(HL)]$^{2+}$ (L = L^3, L^4) complexes are reported in Table 6. Structures **I**−**VI** refer to those depicted in Figure 3, that is, the bis-tridentate ligand octahedral complexes [Co(A^B^C)$_2$], where A = N(pyridyl), B = N(imine), and C = N(nonprotonated oxime) for L^1 and L^2, and A = N(pyridyl), B = N(amine), and C = N(protonated oxime) for L^3 and L^4.

It is evident that the L^1 and L^2 complexes are stable only in the *mer cis,trans,cis* configuration (**I**), the *cis*/*trans* descriptors referring, respectively, to the pairs of A, B, and C nitrogen atoms of the tridentate ligands in [Co(A$_2$B$_2$C$_2$)]. On the other hand, the L^3 and L^4 complexes have a minimum strain energy in the *fac trans,cis,cis* configuration (**V**). In order to address the possibility of the opening of the O···H···O oxime hydrogen bond, especially in the highly strained configurations with *trans* NE atoms, Table 6 also lists the relative strain energies for the [Co(HL^{3o})$_2$]$^{2+}$ and [Co(HL^{4o})$_2$]$^{2+}$ complexes, where HL^{3o} and HL^{4o} represent the HL^3 and HL^4 ligands without the symmetric oxime intramolecular hydrogen bond.

It should be noted that the high values of the strain energies of some diastereomers (Table 6) are merely indicative of highly distorted improbable structures, having been calculated by the harmonic force field functionals of AMBER.[14]

Δ/Λ descriptors can be applied to designate the chirality of the complexes, on the basis of the 'skew lines' convention.[19] In this work, because of the different nature of the three donor atoms and the different number of skew lines, the descriptor is defined by the orientation of the two lines AB, or, when they are parallel as in **VI**, by the skew lines AB and BC. This convention is applied to the descriptors given in Figure 3.

Conformational Analysis of [RCo(L^4)(HL^4)]$^+$

Figure 4 shows the variation of the total strain energy E for the methyl and adamantyl derivatives as a function of the rotation angle φ = C1−N1−Co−N*, where N* represents the midpoint between the oxime nitrogen atoms (N3, N4 in Figure 1, a). Moreover, according to the usual convention, the sign of φ, as well as of all torsion angles, is positive for anticlockwise rotations and negative for clockwise rotations. According to the definition of the two torsion angles, (φ_1 − φ) is approximately 50°, that is, half the N3−Co−N4 bond angle (Figure 1, a).

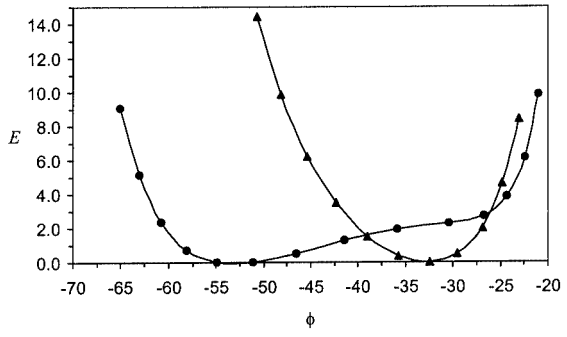

Figure 4. Plot of the scaled strain energy (E, kJ·mol^{-1}) as a function of the rotation angle φ around the axial Co−N bond for [RCo(L^4)(HL^4)]$^+$ with R = Me (circles) and Adam (triangles)

The E/φ plot of the methyl derivative is characterised by a broad asymmetric minimum (E < 2.5 kJ·mol^{-1}), in the range −60° < φ < −25°, with E = 0 at φ = −53°. For the adamantyl derivative, the energy plot is nearly symmetric, with a narrower minimum (−42° < φ < −26°, for E < 2.5 kJ mol^{-1}) centred at φ = −32°.

Figure 5 shows the variation of the axial Co−C and Co−N bond lengths as a function of the rotation angle φ. Figure 6 (see a) reports the α/φ plot, where α is the dihedral angle between the two moieties of the equatorial ligand (Figure 1, a), while Figure 6 (see b) shows the trend of the cobalt out-of plane displacement (d) from the least-squares plane defined by the four equatorial nitrogen atoms. The plots refer to the φ range corresponding to low energy regions of the methyl and adamantyl derivatives.

Tables S1 and S2 in the Supplementary Information (see also footnote on the first page of this article), report for R = Me and R = Adam, respectively, the scaled total strain

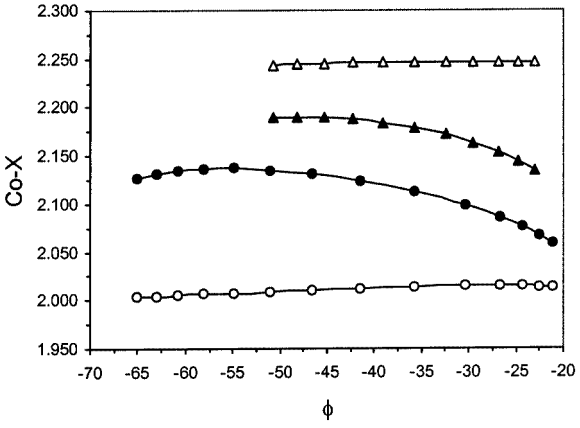

Figure 5. Plot of the axial Co−X distances [Å] as a function of the rotation angle φ [°] for $[RCo(L^4)(HL^4)]^+$. Circles refer to R = Me, with open circles for X = C, and full circles for X = N. Triangles refer to R = Adam, open for X = C, full for X = N

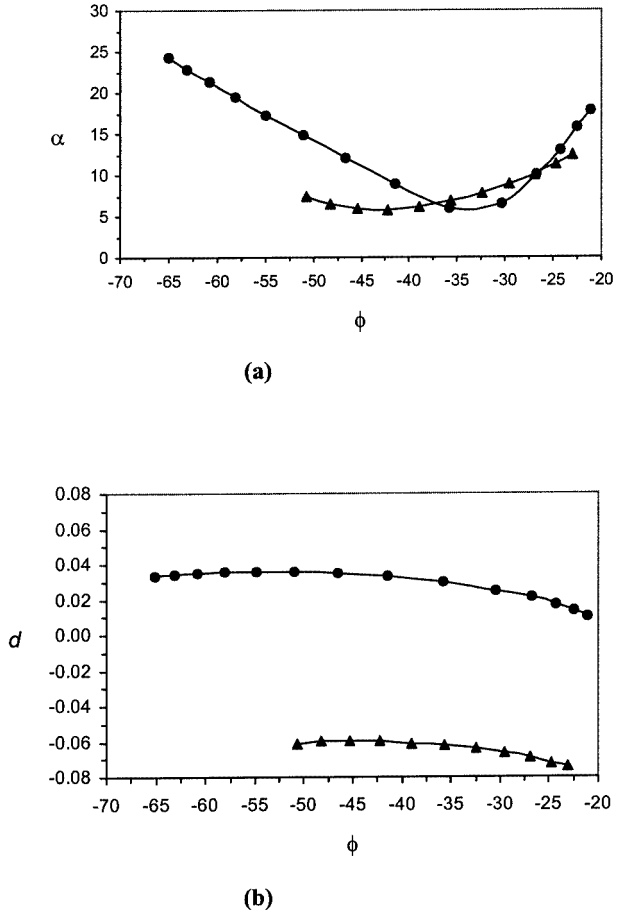

Figure 6. Plot of the dihedral angle α [°] (a), and of the cobalt out-of-plane displacement *d* [Å] (b), as a function of the rotation angle φ (°) for $[RCo(L^4)(HL^4)]^+$. Circles refer to R = Me, triangles to R = Adam

energy (*E*) calculated as a function of the torsion angle φ_1 (C2−N1−Co−N2), together with the rotation angle φ, the ethylene bridge torsion angle φ_2 (C2−C3−C4−N2), the cobalt out-of-plane displacement (*d*), the dihedral angle α, and the axial Co−C and Co−N bond lengths.

Discussion

Stereochemical Features of the Bis(tridentate ligand)cobalt Complexes

Octahedral metal complexes with bis-tridentate ligands of the type $[M(A\hat{}B\hat{}C)_2]$, where A, B, and C represent three different coordinating atoms, can in principle[19b,20] give rise to the six diastereomers illustrated in Figure 3 for M = Co, where A = N(py), B = N(im, or am), and C = N(ox). Of these, only the facial isomer **II**, with its C_i point symmetry, is achiral (ignoring the possible inherent ligand chirality), while all the others are chiral and exist as Δ/Λ enantiomeric pairs (Table 6).[19b,20]

The different stability of the six isomers depends on the nature of the donor atoms and on the length of the chelate bridge. Thus, in the case of $[Co(L^1)_2]^+$ it is evident from molecular models that all the *fac* isomers (**II**−**VI**) can be built only with great difficulty because of the trigonal nature of the imino nitrogen atoms (B) and the short A−(CH_2)−B bridge. In fact, MM calculations show (Table 6) that the *mer cis,trans,cis* arrangement (**I**) has the lowest strain energy, with the closest *fac* arrangement *trans,trans,trans* (**II**) at a significantly higher energy (117.3 kJ·mol^{-1} higher), thereby corresponding to an unrealistic structure. Owing to the longer bridge A−$(CH_2)_2$−B, the $[Co(L^2)_2]^+$ complex is more flexible and the energy difference between the minimum energy isomer (**I**) and the closest *fac* isomer *cis,trans,cis* (**III**) is reduced to 49.3 kJ·mol^{-1}, although this difference is still rather high. These results are in perfect agreement with the observation that, both in the solid state and in solution, only isomer **I** has been detected.[2]

Isomer stability is more complicated in the case of the L^3 and L^4 derivatives, $[Co(L^3)(HL^3)]^{2+}$ and $[Co(L^4)(HL^4)]^{2+}$, because of the presence of tetrahedral amino nitrogen atoms at B. Moreover, in this case, chiral centres are present at the positions of the amine nitrogen atoms (N2, N5) and of their adjacent carbon atoms in the equatorial five-membered rings (Figure 2, b), which gives rise to further possible diastereomers. On the other hand, molecular model inspection suggests that the nitrogen atom chirality is a crucial factor for the ring closure, so that a limited number of reasonable diastereomers is to be expected. Further restriction arises from formation of intramolecular hydrogen bonds involving the oxime nitrogen atoms (atom type NE, atom C in Figure 3). If these are to be maintained, all structures with *trans* NE atoms would be highly strained with respect to those with *cis* NE atoms.

The results of the present MM calculations show that both $[Co(L^3)(HL^3)]^{2+}$ and $[Co(L^4)(HL^4)]^{2+}$ complexes exhibit minimum strain energy in the configuration *fac trans,cis,cis* (isomer **V**), with *S* and *R* configurations for the nitrogen and carbon atoms, respectively (see Table 6). All other diastereomers have markedly higher energies. As expected, isomers **II** and **VI**, with *trans* oxime nitrogen atoms have exceedingly high energies, indicating that they cannot exist. When the constraint on the oxime hydrogen bond is re-

moved, the energy values decrease on passing from $L^{3,4}$ to $L^{3o,4o}$ ligands, but again isomers of type **V** have the lowest energy.

Data in Table 6 show that in the minimum energy structures of the $[Co(L^3)(HL^3)]^{2+}$ and $[Co(L^4)(HL^4)]^{2+}$-complexes the chirality of the nitrogen and carbon atoms depends on the isomer type. Nevertheless, any change from the *SSRR* chirality to the other configurations does not significantly lower the energy of the nonminimum energy isomers.

Further elements of chirality could derive from the helicity of the chelate rings. However, the oxime five-membered rings are essentially planar and the helicity of the metallacycles formed by the pyridyl ligands, as defined by the IUPAC rules,[19] is rather small (pseudo-torsion angles, defined by the N···N and C···C skew lines, of 10°−12°). Therefore, it seems likely that in solution the helicity can be easily reversed, so this factor can be neglected.

Another important conformational feature is defined by the torsion angle (φ_2) around the C−C bonds of the six-membered rings in the L^2 and L^4 complexes. MM calculations show that for $[Co(L^2)_2]^+$ inverting the sign of both the torsion angles increases the strain energy by only 1.0 kJ·mol^{-1}, while a significant increase (28.7 kJ·mol^{-1}) occurs by changing the sign of one only. On the contrary, for $[Co(L^4)(HL^4)]^{2+}$ all changes in the torsion angles cause a significant increase in the strain energy.

As experimentally observed and confirmed by the present MM calculations (Table 3), passage from N(py)−(CH_2)−N(am,im) to N(py)−$(CH_2)_2$−N(am,im) bridges (that is, on meeting the ring closure condition by passing from five- to six-membered chelate rings) causes a lengthening of about 0.10 Å of the Co−N(py) bond lengths together with significant angular changes in the pyridyl metallacycles. The largest effect, observed in both the L^1, L^2 and L^3, L^4 pairs, is the narrowing of the pyridyl exo-cycle bond angles (av. calcd. Co−N(py)−C_α, from 127.0(3)° to 120(1)°], which is paralleled by a widening of the endo-cycle angles (av. calcd. Co−N(py)−C_β, from 113.4(5)° to 123(2)°]. These observations are in very good agreement with the experimental X-ray data (see Table 3, where C_α and C_β represent, respectively, the pyridyl carbon atoms like C1, C2 and C8, C7 in Figure 2)

However, the total strain energy of $[Co(L^1)_2]^+$ is 19.1 kJ·mol^{-1} higher than that of $[Co(L^2)_2]^+$, while in $[Co(L^3)(HL^3)]^{2+}$ it is 67.9 kJ·mol^{-1} lower than in $[Co(L^4)(HL^4)]^{2+}$, paralleling the ring strain energies (sum of only stretching and bending contributions). These results suggest that the pyridyl ring closure introduces a severe strain in the $[Co(L^1)_2]^+$ (five-membered rings) and $[Co(L^4)(HL^4)]^{2+}$ (six-membered rings) complexes with respect to their L^2 and L^3 analogues.

Stereochemical Features of the Organometallic Complexes $[RCo(L^4)(HL^4)]^+$

The results of the conformational analysis of the organocobalt methyl derivative $[MeCo(L^4)(HL^4)]^+$ (see Figure 4 and Table S1 show that the pyridyl group can rotate around the axial Co−N bond across a rather wide range ($-60° < \varphi \leq -25°$) while maintaining the total strain energy within a limit of 2.5 kJ·mol^{-1}. This is in agreement with the observation that in the solid state two crystallographically independent molecules are present, with φ values of −38° and −48°, and that similar values were also found for the ethyl and trifluoroethyl derivatives, with φ = −36° and −44°, respectively.[3] This corresponds to the pyridyl ring being more or less parallel to the N2−Co−N4 axis ($-15° < \varphi_1 < 24°$).

In the case of the adamantyl group, the minimum strain energy is also observed at a similar torsion angle ($\varphi \approx -32°$), but the MM calculations show that, in the case of this much bulkier alkyl group, the pyridyl rotation is rather restricted ($\Delta\varphi \approx \pm 8°$ with $\Delta E < 2.5$ kJ·mol^{-1}) (Figure 4, Table S2).

Thus, the present results confirm the observation that in complexes with tridentate amino-oxime ligands the orientation of the planar nitrogen base is quite different from that commonly found in cobaloximes and lariat-type complexes ($\varphi \approx 0°$),[6] and in iminocobaloximes ($\varphi \approx 90°$).[3]

Interestingly, the variation of φ is accompanied by significant changes in the geometry of the pyridyl metallacycle, such as the variation of the torsion angle φ_2. Of particular interest is the significant increase of the Co−N(py) bond length with decrease (more negative values) of the rotation angle φ (Figure 5). This confirms the appreciable effect of steric factors in determining the *trans* influence of an alkyl group.[3]

On the contrary, the Co−C bond length of both the Me and Adam derivatives show negligible variations (Figure 5), in agreement with FT-Raman studies which do no detect any change in the Co−C force constants even in base-on and base-off cobalamins.[10a]

In order to maintain the total strain energy around its minimum, the variation of φ also causes distortions in the equatorial ligand, as shown by the variation of the dihedral angle α between its two moieties. This is the combination of bending and twisting deformations of the two equatorial five-membered rings. Inspection of molecular diagrams shows that when α is less than 7° ($-36° < \varphi < -30°$ for R = Me; $-46° < \varphi < -35°$ for R = Adam) the two rings are essentially twisted without significant bending, while for higher values the latter component becomes more appreciable. The calculations indicate that this effect is stronger in the methyl derivative (see Figure 6, a), in which the equatorial ligand is bent away from the axial alkyl group when φ increases from −30°. This trend is in good agreement with that experimentally observed.[3] The opposite bending occurs when φ is less than −36°. The variation of α with φ (in the low strain energy region) is much lower in the adamantyl derivative (Figure 6, a) because the bending towards the alkyl group is hindered by the alkyl bulkiness.

Finally, it is interesting to observe that while in the Me derivative the cobalt atom is displaced towards the pyridyl nitrogen atom, in the Adam derivative the displacement is nearly doubled and reversed, the Co atom moving towards the carbon atom (Figure 6, b).

Syntheses and Molecular Structures of Chromium(IV) Halides and Pseudohalides Bearing a Triamidoamine Ligand

Alexander C. Filippou,*[a] Sven Schneider,[a] and Burkhard Ziemer[a]

Keywords: Chromium / Tripodal ligands / N ligands / Halides / Pseudohalides / Oxidations

A general method for the synthesis of chromium(IV) halides and pseudohalides of the general formula [Cr(N_3N)X] (**2**: X = F; **3**: X = Cl; **4**: X = Br; **5**: X = I; **6**: X = CN) is presented. It involves the one-electron oxidation of the Cr^{III} triamidoamine complex [Cr(N_3N)] {($(N_3N)^{3-}$ = [($Me_3SiNCH_2CH_2)_3N]^{3-}$} (**1**) with silver(I) salts. The oxidation of **1** with one equivalent of $AgBF_4$ or [Ag(CN*t*Bu)$_2$](BF_4) (**7**) affords the chromium(IV) fluoride [Cr(N_3N)F] (**2**), and treatment of **1** with AgX (X = Cl, Br, I, CN) gives the complexes **3**–**6**. Alternatively, the complexes **4** and **5** can be obtained by halogenation of **1** with 0.5 equivalents of X_2 (X = Br, I). The magnetic moments of **2**–**6** range from 2.7–3.0 μ_B at 297 K, indicating the presence of high spin d^2 chromium complexes, and their ^1H NMR spectra suggest an averaged C_{3v} symmetry in solution. X-ray crystallography shows that complexes **4** and **6** have a distorted trigonal-bipyramidal coordination geometry, with the halide(pseudohalide) ligand and the bridgehead amine nitrogen atom occupying the apical positions. The triamidoamine ligand is disposed, approximately with a three-fold symmetry about the chromium centre. The chromium centre is displaced out of the equatorial plane defined by the three amido nitrogen atoms towards the halide(pseudohalide) ligand, by 0.212 (**4**) and 0.191 Å (**6**). The molecular structures of **4** and **6** are compared with that of **3** and other chromium(IV) triamidoamine complexes and show a strong effect of the ligand X on the conformation of the N_3N ligand and the $Cr–N_{amine}$ bond length.

Introduction

The coordination and organometallic chemistry of chromium(IV) is much less developed than that of chromium in the oxidation states +II, +III, and +VI.[1] This can be traced back to the greater oxidising power of most chromium(IV) compounds and their inclination to valence disproportionation or reductive elimination.[2] Most of the isolable chromium(IV) complexes are stabilised by electronegative and strong σ- or π-donor ligands as exemplified by [CrF_4],[3] the ionic fluorides $M^I[CrF_5]$, $M^I_2[CrF_6]$, and $M^{II}[CrF_6]$ (M^I = Li, K, Rb, Cs, Ag; M^{II} = Mg, Ca, Sr, Ba, Zn, Cd, Hg),[4] and the homoleptic chromium(IV) alkyls [CrR_4] {R = CH_2SiMe_3, CH_2tBu, CH_2CMe_2Ph, CH_2CPh_3, 1-adamantylmethyl, *i*Pr, Cy (cyclohexyl), 2-adamantyl, *t*Bu, 1-camphyl, 1-norbornyl},[5] dialkylamides [Cr(NRR′)$_4$] (R, R′ = Et, Pr; R = Me, R′ = Bu; RR′ = C_5H_{10})[6] and alkoxides [Cr($OR)_4$] {R = C(H)(Me)*t*Bu, $CHtBu_2$, *t*Bu, CMe_2Et, $CMeEt_2$, CEt_3, 1-adamantyl, $SiEt_3$}.[7]

Some chromium(IV) imido-,[8] oxo-,[9] peroxo-,[10] sulphido-,[11] pentamethylcyclopentadienyl-,[8c,9f,11a,12] and carbaborane complexes[13] are also known. Representative examples are the compounds [Cr^{IV}Cl(NEt)(dmpe)$_2$]OTf {dmpe = 1,2-bis(dimethylphosphanyl)ethane, OTf = CF_3SO_3},[8a] [Cr^{IV}(NAr)$_2L_2$] (Ar = C_6H_3-2,6-*i*Pr_2; L = PMe_3, PMe_2Ph),[8e] [Cr^{IV}(O)(porphyrinato)],[9a–9e] [$Tp^{tBu,Me}Cr^{IV}$(O)OPh] {$Tp^{tBu,Me}$ = hydridotris(3-*tert*-butyl-5-methylpyrazol-1-yl)borate},[9h] [$Cr^{IV}(O_2)_2(NH_3)_3$],[10a] [{Cr^{IV}-(NRR′)$_2$}$_2$(μ-S)$_2$] (R, R′ = Cy; R = 1-adamantyl, R′ = C_6H_3-3,5-Me_2)[11b] and [(Cp*$Cr^{IV}Me_2)_2$(μ-O)] (Cp* = C_5Me_5).[9f] In comparison, chromium(IV) halides (halide = Cl, Br, I) and pseudohalides are rare and include the hydroxo derivatives [{Cr($OH)_2(X)_2$(pyridine)}$_2$] (X = Cl, Br, I),[14] the cyanochromate(IV) K_2[Cr($CN)_4$(O)(pyridine)]·H_2O,[15] and the Cr^{IV} iodide [Cr($I)_2$($NRAr_F)_2$] {R = $C(CD_3)_2CH_3$, Ar_F = C_6H_3-2,5-F,Me}.[16]

Chromium(IV) halides are promising starting materials for the preparation of chromium(IV) alkyls. These compounds have attracted considerable interest since the recent reports of S. L. Scott et al. on the polymerization of α-olefins by silica-supported Cr^{IV} species,[17] and the theoretical studies of T. Ziegler et al. which predict that the chromium(IV) model compounds [$Cr(NR_2)_2R']^+$ (R = H, Me, SiH_3; R′ = Me Et) should be active ethylene polymerization catalysts.[18] Therefore, a general approach to stable chromium(IV) halides bearing amido ligands would be very valuable.

We have recently described the synthesis and molecular structure of the triamidoamine complex [Cr(N_3N)Cl] {($(N_3N)^{3-}$ = [($SiMe_3NCH_2CH_2)_3N]^{3-}$} (**3**), which is a remarkably stable chromium(IV) chloride (m.p. 155–158

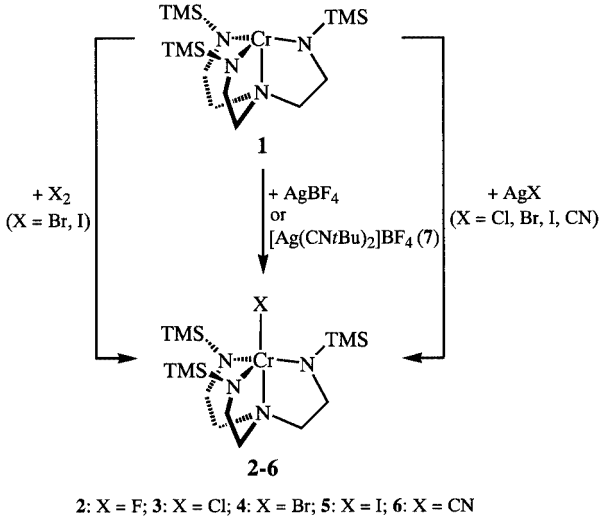
°C),[19] considering the thermal instability of $CrCl_4$.[1a] In continuation of our studies in this field, here, we present a general method for the synthesis of chromium(IV) halides and pseudohalides of the general formula $[Cr(N_3N)X]$ (X = F, Br, I, CN) and describe their spectroscopic properties, as well as the molecular structures of the bromo and cyano derivatives.

Results and Discussion

Syntheses and Characterisation

The starting material for the reactions described below was the Cr^{III} triamidoamine complex $[Cr(N_3N)]$ (**1**), which was obtained from $CrCl_3(THF)_3$ and $Li_3(N_3N)$, as described recently.[19] Treatment of **1** with one equivalent of $AgBF_4$ in THF at −78 °C resulted in the rapid precipitation of elemental silver and a colour change from green to dark brown, indicating the fast oxidation of **1**. After evaporation of the solvent and extraction of the residue with pentane, the chromium(IV) fluoride $[Cr(N_3N)F]$ (**2**) was isolated as a dark brown/black crystalline solid in a 43% yield (Scheme 1).[20]



Scheme 1. Syntheses of $[Cr(N_3N)X]$ (X = F, Cl, Br, I, CN) (**2**−**6**) (TMS = $SiMe_3$)

The formation of **2** suggests that a cationic species $[Cr(N_3N)]^+$, which was expected as the primary product of the one-electron oxidation of **1** with Ag^+, is electrophilic enough (as other inorganic electrophiles[21]) to abstract a fluoride ion from BF_4^-. In an attempt to trap such a species with *t*BuNC, the oxidation of **1** with the silver(I) isocyanide complex $[Ag(CNtBu)_2](BF_4)$ (**7**) was investigated. Complex **7** was synthesised for this purpose by the reaction of $AgBF_4$ with two equivalents of *t*BuNC in CH_2Cl_2 and was isolated as a white solid in a 89% yield. It was characterised by elemental analysis and spectroscopic methods (vide infra). Treatment of **1** with **7** in THF at −78 °C also led to the rapid precipitation of elemental silver and a reddish-black solution indicating the fast oxidation of **1**, as in the case of $AgBF_4$. IR spectroscopic monitoring of the reaction revealed the fast replacement of the ν(C≡N) absorption of $[Ag(CNtBu)_2](BF_4)$ at 2212 cm^{-1} by that of uncoordinated *t*BuNC at 2134 cm^{-1}, and gave no evidence for the formation of any stable Cr^{IV} isocyanide complexes even at low temperatures. Workup of the reaction mixture afforded $[Cr(N_3N)F]$ (**2**) as the only pentane-soluble product in a 52% yield (Scheme 1, Table 1).

Table 1. Preparation of **2**−**6** by oxidation of $[Cr(N_3N)]$ (**1**)

Oxidant	Product	Yield (%)
$AgBF_4$	$[Cr(N_3N)F]$ (**2**)	43
$[Ag(CNtBu)_2](BF_4)$		52
AgCl	$[Cr(N_3N)Cl]$ (**3**)[a]	54
$CrCl_3(THF)_3$		50
$PhICl_2$		28
AgBr	$[Cr(N_3N)Br]$ (**4**)	64
Br_2		16
AgI	$[Cr(N_3N)I]$ (**5**)	71
I_2		29
AgCN	$[Cr(N_3N)CN]$ (**6**)	57

[a] Ref.[19]

Oxidation of **1** with Ag^I salts has proven to be a versatile route for obtaining chromium(IV) triamidoamine complexes as shown by the syntheses of $[Cr(N_3N)X]$ (**4**: X = Br; **5**: X = I; **6**: X = CN) via the reactions of **1** with AgX (X = Br, I, CN) in THF (Scheme 1). Complexes **4**−**6** were isolated after crystallisation from diethyl ether or pentane as black crystalline solids in good yields (Table 1). The chloro complex **3** was previously obtained using the same method (Scheme 1, Table 1).[19] Alternatively, the halides **4** and **5** can be prepared by halogenation of **1** with 0.5 equivalents of X_2 (X = Br, I) in THF, albeit in lower yields (Table 1). The chromium(IV) complexes **2**−**6** are moderately air-sensitive solids, and their melting points are 159 (**2**), 155−158 (**3**), 175 (**4**), 177 (**5**), and 166 °C (**6**). They are very soluble in pentane, diethyl ether, toluene, and THF, giving dark brown (**2**), dark red (**3**, **6**), reddish-black (**4**), and yellowish-black (**5**) solutions. The thermal stability of the halides **3**, **4**, and **5** is remarkable, given the very low thermodynamic stability of CrX_4 (X = Cl, Br).[1a] This can be attributed to the strong π-donating ability of the N_3N ligand.

Complexes **2**−**6** have very similar IR spectra in nujol, indicating the structural similarity of these compounds. It is worth noting that the IR spectrum of **6** in nujol lacks an absorption for the ν(C≡N) vibration of the cyano ligand, as was previously observed for the analogous molybdenum and tungsten complexes $[M(N_3N)(CN)]$.[22] The Ag^I isocyanide complex **7** is stable in CH_2Cl_2 and THF solutions at ambient temperature, as shown by the IR spectra, which display only one intense absorption band for the ν(C≡N) vibrations of the isocyanide ligands at 2225 and 2212 cm^{-1}, respectively. This absorption is assigned to the Σ_u^+ mode

and indicates a local $D_{\infty h}$ symmetry of the Ag(C≡N−C)$_2$ core in **7**.[23] In comparison, the IR spectrum of **7** in KBr shows two ν(C≡N) absorption bands at very different wavenumbers (2245 and 2185 cm^{-1}) from that in solution, which indicates that **7** reacts with the KBr matrix under pressure.[24] The opposite behaviour is shown by [Ag(CN*t*Bu)$_4$](BF$_4$) (**8**), which is stable in pressed KBr discs but unstable in CH_2Cl_2 solution, in which it exists in a dissociation equilibrium with [Ag(CN*t*Bu)$_3$](BF$_4$) (**9**) and *t*BuNC.[25] Thus, in KBr complex **8** gives rise to only one ν(C≡N) absorption band at 2184 cm^{-1}, which is assigned to the T_2 stretching mode and suggests a local T_d symmetry of the Ag(C≡N−C)$_4$ core of the cation.[23] However, in CH_2Cl_2 two ν(C≡N) absorption bands are observed at 2200 and 2140 cm^{-1}, in addition to the band at 2183 cm^{-1} assigned to **8**, which by comparison with authentic samples are assigned to **9** and *t*BuNC, respectively.[25]

The effective magnetic moments of **2**−**6** were determined in C_6D_6 solution at 297 K by the method of Evans (Table 2).[26,27] These range from 2.8−3.0 μ_B, and are similar to the spin-only value for a d^2 high-spin configuration (2.83 μ_B). The ^{1}H NMR spectra of **2**−**6** in C_6D_6 at 297 K display three very broad, strongly shifted signals due to the presence of the two unpaired electrons. On the basis of integration of these signals, two are assigned to the backbone methylene groups and one to the trimethylsilyl groups of the N_3N ligand. This suggests an averaged C_{3v} symmetry of these complexes in solution on the ^{1}H NMR spectroscopic time scale (Table 2).

Table 2. ^{1}H NMR spectroscopic data and magnetic moments of **2**−**6**

Compound[a]	δ(Si*Me*$_3$)[b]	δ(C*H*$_2$)[b]	δ(C*H*$_2$)[b]	μ_{eff} [μ_B]
[Cr(N_3N)F] (**2**)	3.28 (190)	−33.1 (1400)	−208 (5100)	3.0
[Cr(N_3N)Cl] (**3**)[c]	4.47 (220)	−40.8 (1300)	−211 (6000)	2.6

[Cr(N_3N)I] (**5**)	5.88 (150)	−54.1 (950)	−145 (2100)	3.0
[Cr(N_3N)CN] (**6**)	3.49 (220)	−39.0 (1400)	−188 (6900)	2.9

[a] ^{1}H NMR spectra and magnetic moments in C_6D_6 at 297 K. [b] Chemical shifts in ppm relative to the residual proton resonance of the deuterated solvent [δ(C_6D_5H) = 7.15 ppm], $\Delta\nu_{1/2}$ [Hz] in parentheses. [c] Ref.[19]

Molecular Structures

The solid-state structures of **4** and **6** were determined by single-crystal X-ray diffraction.[28] Complex **6** is the first chromium(IV) cyano complex to be structurally characterised. DIAMOND plots of the molecular structures of **4** and **6** are shown in Figures 1 and 2, respectively, and selected bond lengths and angles are listed in Table 3. For comparative purposes, the corresponding bonding parameters of complex **3**[19] are also summarised in Table 3.

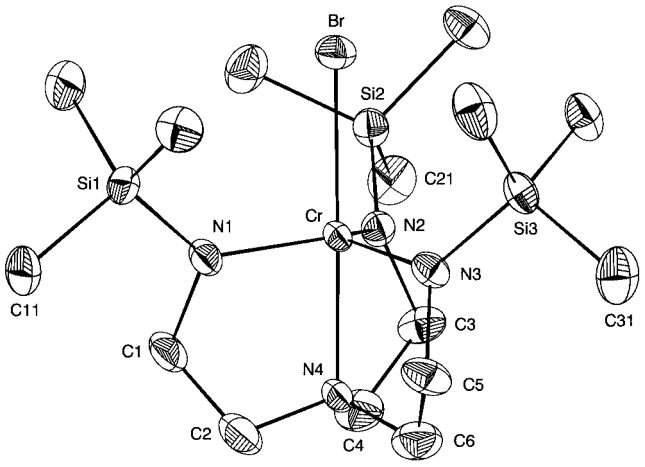

Figure 1. DIAMOND plot of the molecular structure of [Cr(N_3N)Br] (**4**) with thermal ellipsoids drawn at the 50% probability level; hydrogen atoms are omitted for clarity

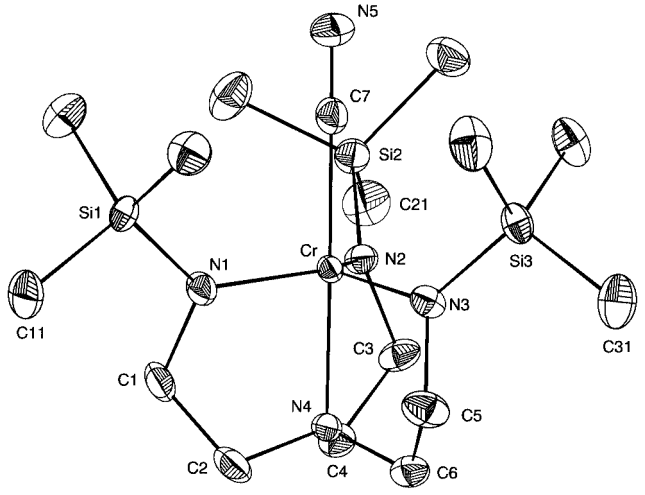

Figure 2. DIAMOND plot of the molecular structure of [Cr(N_3N)CN] (**6**) with thermal ellipsoids drawn at the 50% probability level; hydrogen atoms are omitted for clarity

As for the case of **3**, both complexes are distorted trigonal-bipyramidal, with the bridgehead amine nitrogen atom N4 of the tetradentate N_3N ligand and the bromo (**4**) or cyano ligand (**6**) residing at the apexes of the trigonal bipyramid. Distortion arises as a result of the displacement of the chromium atom out of the equatorial plane defined by the three amido nitrogen atoms N1−N3, toward the halide (pseudohalide) ligand. The distance of the chromium atom from the equatorial plane is 0.212 (**4**) and 0.191 Å (**6**), larger than that in the chloro complex **3** (0.189 Å). This results in a slightly smaller mean $N_{amido}-Cr-N_{amine}$ bond angle of 83.5(2) (**4**) and 84.13(6)° (**6**), compared with that of **3** [84.2(2)°] (Table 3). In **4** and **6**, as in **3**, the amido groups approach an "upright" conformation, as shown by the torsion angles N4−Cr−N1−Si1, N4−Cr−N2−Si2 and N4−Cr−N3−Si3 (Table 3). The amido nitrogen atoms are sp^2 hybridised, as shown by the mean sum of the bond

Table 3. Selected bond lengths, bond angles and dihedral angles of complexes **4** and **6** (corresponding bonding parameters of **3** are also listed for comparative purposes).

	4	**6**	**3**[19]
Bond Lengths [Å]			
Cr−X	2.440(1)	2.062(2)	2.269(2)
Cr−N1	1.875(3)	1.869(2)	1.886(3)
Cr−N2	1.868(3)	1.870(2)	1.869(4)
Cr−N3	1.877(3)	1.876(2)	1.877(4)
Cr−N4	2.135(3)	2.140(2)	2.043(3)
Bond Angles [deg]			
N4−Cr−X	179.0(1)	179.06(7)	179.4(1)
N1−Cr−N4	83.8(2)	83.90(6)	84.2(2)
N2−Cr−N4	83.6(2)	84.53(6)	84.2(2)
N3−Cr−N4	83.1(2)	83.96(6)	84.3(2)
N1−Cr−N2	119.3(2)	119.15(7)	120.6(2)
N2−Cr−N3	118.2(2)	118.65(7)	117.9(2)

N4−Cr−N2−Si2	158.2(3)	160.3(2)	162.2(3)
N4−Cr−N3−Si3	156.4(2)	159.7(2)	163.8(3)

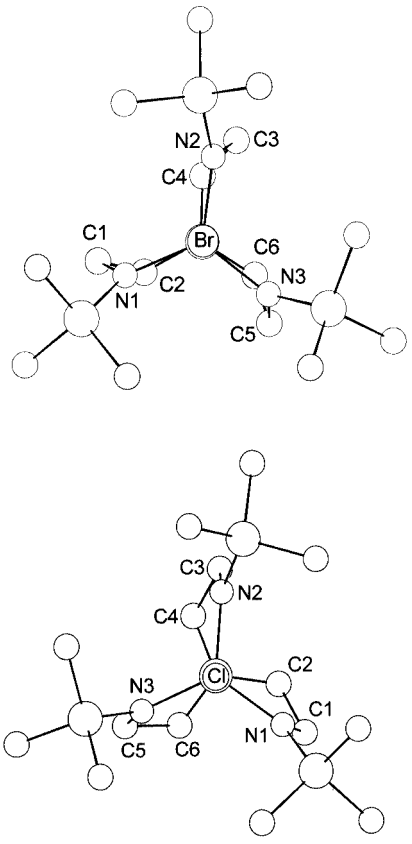

Figure 3. View of **4** (top) and of **3** (bottom) down the X−Cr−N4 axis showing the different conformation of the N_3N ligand in the two complexes

angles at the atoms N1−N3, which is 360.0° in both compounds (**3**: 359.1°). In addition, the $Cr-N_{amido}$ bond lengths have an average value of 1.873(3) Å in the bromo complex **4** and 1.872(2) Å in the cyano complex **6**, which is similar to that of **3** [1.877(4) Å], but are considerably shorter than the $Cr-N_{amine}$ bond lengths in these compounds, e.g. **4** [$Cr-N_{amine}$ = 2.135(3) Å] (Table 3). All these structural features indicate extensive π-electron donation of the N_3N ligand to the chromium centre.

In complexes **4**, **6**, and **3** the tetradentate N_3N ligand is disposed with an approximate C_3 symmetry about the chromium centre. The nearly linear $N_{amine}-Cr-X$ atom sequence corresponds to the principal axis. The $SiMe_3$ groups form a pocket in which the ligand X is located, as shown by the torsion angles Cr−N1−Si1−C11, Cr−N2−Si2−C21, and Cr−N3−Si3−C31 of −155.8(3), −164.6(3), and −160.2(2)° (**4**), and −156.5(2), −166.5(2), and −161.6(2)° (**6**), respectively. However, complexes **4** and **6** differ from **3** by the envelope conformation of the three five-membered chelate rings (Cr−N1−C1−C2−N4, Cr−N2−C3−C4−N4, and Cr−N3−C5−C6−N4) (Figure 3). In complexes **4** and **6** the N_{amido}-bonded methylene carbon atoms C1, C3, and C5 form the "flap" of the envelope, whereas in complex **3** the N_{amine}-bonded methylene carbon atoms C2, C4, and C6 are "tipped up" (Figure 3).

It is suggested that this conformational change results from the increased steric repulsion as the auxiliary ligand becomes more sterically demanding. This causes the $SiMe_3$ groups to twist out of the apical pocket, as shown by the mean torsion angle $N_{amine}-Cr-N_{amido}-Si$ (**4**: 157.8°; **6**: 160.4°; **3**: 163.3°). Additional evidence for the influence of steric strain on the conformation of the N_3N ligand is also found in other chromium(IV) and related molybdenum(IV) triamidoamine complexes. For example, a similar conformation as in [Cr(N_3N)Cl] (**3**) is adopted by the N_3N ligand in [Cr(N_3N)H][29] containing the 'small' hydrido ligand, or in [Mo(N_3N)Cl],[30a] whereas the complexes [Cr(N_3N)Me],[29] [Mo(N_3N)CD_3],[30b] and [Mo(N_3N)OTf][30b] bearing "large" auxiliary ligands have the same N_3N ligand conformation as in **4** and **6**.

The Cr−Br distance of 2.440(1) Å in **4** is similar to that found in [$Cr^{IV}Br(\eta^5$-Cp*)(μ-NCy)]$_2$·toluene [Cr−Br = 2.470(2) Å],[8c] and the Cr−CN bond length of 2.063(2) Å in **6** is similar to those of six-coordinate Cr^{III} and Cr^{V} cyano complexes.[31] The $Cr-N_{amine}$ bond length depends on the *trans*-influence[32] of the ligand X, as seen by the longer $Cr-N_{amine}$ bond of [Cr(N_3N)Me] [$Cr-N_{amine}$ = 2.250(2) Å][29] relative to that of **4** [$Cr-N_{amine}$ = 2.135(3) Å] or **6** [$Cr-N_{amine}$ = 2.140(2) Å], and the longer $Cr-N_{amine}$ bond of [Cr(N_3N)H] [$Cr-N_{amine}$ = 2.140(2) Å][29] relative to that of **3** [$Cr-N_{amine}$ = 2.043(3) Å] (Table 3). The steric repulsion between the ligand X and the $SiMe_3$ groups, which is transmitted via the chelate backbone (see different conformations of **4** and **3** in Figure 3), also seems to affect the $Cr-N_{amine}$ bond length, as indicated, for example, by the larger $Cr-N_{amine}$ distance of **4** relative to that of **3** (Table 3).

Conclusion

The one-electron oxidation of the chromium(III) triamidoamine complex [Cr(N_3N)] {($(N_3N)^{3-}$ = [(Me_3Si-$NCH_2CH_2)_3N]^{3-}$} (**1**) with silver(I) salts is a very valuable method for the synthesis of rare, thermally stable chromium(IV) halides and pseudohalides of the general formula [Cr(N_3N)X] (X = F, Cl, Br, I, CN). Their molecular structures, magnetic moments, and ^{1}H NMR spectra show the presence of distorted trigonal-bipyramidal, high-spin d^2 chromium complexes with threefold symmetry, in which the bridgehead amine nitrogen atom of the tetradendate N_3N ligand and the halide (pseudohalide) ligand occupy the apical positions. The strong π-donating ability of the N_3N ligand is expected to reduce the oxidising power of these compounds making them promising starting materials for the development of the organometallic chemistry of chromium(IV).

Experimental Section

General Remarks: All syntheses and sample manipulations were carried out under an atmosphere of argon using Schlenk and glovebox techniques.[33] The solvents were dried using standard methods (pentane with CaH_2 or sodium wire/benzophenone/tetraglyme, diethyl ether and THF with sodium wire/benzophenone and CH_2Cl_2 with Sicapent (Merck) and Na/Pb alloy), and freshly distilled and deoxygenated prior to use. Complex **1** was prepared as described recently.[19] AgBr and AgI were dried under exclusion of light in vacuo for 4 h at 70 °C. Br_2 was dried with concentrated sulphuric acid and distilled. $SiMe_4$ was dried with sodium, trap-to-trap distilled in vacuo and stored over 4 Å molecular sieves. All other commercially available chemicals were used as purchased. Elemental analyses were obtained from the Central Analytical Group of the Chemistry Department of the Humboldt-Universität zu Berlin. The IR spectra of the compounds were recorded on a Bruker IFS-55 spectrometer either in solution using a cell of NaCl plates, as dispersions in pressed KBr discs or as nujol mulls between KBr plates (**6** - between NaCl plates). The following abbreviations are used for the intensities and the shape of the absorption bands: vs = very strong, s = strong, m = medium, w = weak, vw = very weak, br = broad, sh = shoulder. The ^{1}H, ^{13}C{^{1}H}, and ^{19}F NMR spectra were recorded on a Bruker AM-300 spectrometer in dry deoxygenated C_6D_6 and CD_2Cl_2. The ^{1}H and ^{13}C{^{1}H} NMR spectra were calibrated against the internal residual proton resonance and the natural abundance ^{13}C resonance of the solvent, respectively (C_6D_6, δ_H = 7.15 and δ_C = 128.0 ppm; CD_2Cl_2, δ_H = 5.32 and δ_C = 53.8 ppm). The ^{19}F NMR spectra were calibrated against external $CFCl_3$. Magnetic moments were determined in C_6D_6 at 297 K by the Evans method as modified by Sur[26,27] using the shift of the proton resonance of internal $SiMe_4$. The diamagnetic correction was performed using Pacault's method.[34] Melting points were determined using a Büchi 530 melting point apparatus and are corrected. The samples were sealed under vacuum in capillary tubes and heated slowly until the compounds melted.

Preparation of [Cr(N_3N)F] (2) by Oxidation of 1 with $AgBF_4$: A precooled solution (−78 °C) of [Cr(N_3N)] (**1**) (0.356 g, 0.86 mmol) in 25 mL of THF was rapidly added, via a double ended needle, to a stirred solution of $AgBF_4$ (0.168 g, 0.86 mmol) in 20 mL of THF that was kept in the dark at −78 °C. The green solution of **1** quickly turned dark brown and elemental silver precipitated out of the solution. The reaction mixture was allowed to warm to ambient temperature and stirred in the dark for 15 h. The solvent was evaporated to dryness and the residue extracted twice with 25 mL of pentane. The red-brown extracts were filtered through a filter cannula and the filtrate was evaporated to dryness leaving 180 mg of a dark brown microcrystalline residue. The residue was recrystallised from pentane at −78 °C affording **2** as a black crystalline solid. Yield 0.16 g (43%). $C_{15}H_{39}CrFN_4Si_3$ (430.75): calcd. C 41.83, H 9.13, N 13.01; found C 42.39, H 9.15, N 12.63. The product was shown by ^{1}H NMR spectroscopy to be identical to that obtained from oxidation of **1** with **7** (vide infra).

Preparation of [Cr(N_3N)F] (2) by Oxidation of 1 with 7: Under exclusion of light, a solution of [Ag(CN*t*Bu)$_2$](BF_4) (**7**) (0.36 g, 1.00 mmol) in 50 mL of THF was slowly added, via a double ended needle, to a stirred solution of [Cr(N_3N)] (**1**) (0.42 g, 1.02 mmol) in 50 mL of THF, at −78 °C. The green solution of **1** rapidly turned reddish-black and elemental silver started to precipitate. The suspension was stirred at −78 °C for 0.5 h and then allowed to warm to ambient temperature in the dark. IR spectra of the reaction solution were recorded in the region of 2300−1500 cm^{-1} to monitor the progress of the reaction. These revealed the fast replacement of the ν(C≡N) absorption of [Ag(CN*t*Bu)$_2$](BF_4) at 2212 cm^{-1} by that of uncoordinated *t*BuNC at 2134 cm^{-1}. In addition, a weak ν(C≡N) absorption band of an intermediate was observed at 2203 cm^{-1}, which disappeared after stirring the reaction mixture for ca. 3.5 h at ambient temperature. All volatiles were removed after 4 h in vacuo. The residue was extracted twice with 40 mL of pentane and the extract filtered through a filter cannula. The filtrate was evaporated to dryness and the residue was washed with a minimum amount of pentane at −78 °C affording **2** as a dark brown microcrystalline solid (0.17 g). A second crop of **2** was obtained from the wash solution on crystallisation at −78 °C (0.06 g). Overall yield 0.23 g (52% relative to **1**), m.p. 159 °C. IR (nujol mull): $\tilde{\nu}$ [cm^{-1}] = 2726 vw, 2655 vw, 1458 m, 1450 m, 1421 w, 1408 vw, 1400 vw, 1344 w, 1331 w, 1310 vw, 1286 w, 1259 sh, 1245 sh, 1238 s, 1210 vw, 1180 vw, 1151 vw, 1131 w, 1090 m, 1077 m, 1062 m, 1025 w, 958 s, 944 s, 922 s, 887 m, 840 vs br, 793 s br, 756 m, 748 sh, 724 sh, 685 sh, 679 m, 632 w, 593 s, 577 m, 535 w, 493 m. ^{1}H NMR (300.1 MHz, C_6D_6, 297 K): δ [ppm] = 3.28 [s, $\Delta\nu_{1/2}$ = 190 Hz, 27 H, 3 × Si(CH_3)$_3$], −33.1 (s, $\Delta\nu_{1/2}$ = 1400 Hz, 6 H, 3 × CH_2), −208 (s, $\Delta\nu_{1/2}$ = 5100 Hz, 6 H, 3 × CH_2). μ_{eff} = 3.0 μ_B. $C_{15}H_{39}CrFN_4Si_3$ (430.75): calcd. C 41.83, H 9.13, N 13.01; found C 41.47, H 8.85, N 13.13.

Preparation of [Cr(N_3N)Br] (4) by Oxidation of 1 with AgBr: [Cr(N_3N)] (**1**) (0.42 g, 1.02 mmol) was dissolved in 40 mL of THF, the solution was cooled to −60 °C and transferred via a double ended needle to a Schlenk tube, which was charged with AgBr (0.192 g, 1.02 mmol) and cooled to −60 °C. The suspension was allowed to warm to ambient temperature and stirred in the dark for 16 h. During this time the colour of the solution turned from green to reddish-black and a black precipitate of elemental silver was formed. The volatiles were removed in vacuo and the residue was extracted with 30 mL of diethyl ether. The extract was filtered through a filter cannula and the filtrate was concentrated to approximately 5 mL. Crystallisation was completed by storing the solution at −35 °C, affording **4** as a brown-black microcrystalline solid. Yield 0.32 g (64%), m.p. 175 °C. IR (nujol mull): $\tilde{\nu}$ [cm^{-1}] = 2724 vw, 2642 vw, 1448 m, 1400 vw, 1366 w, 1335 w, 1325 w, 1302 vw br, 1262 m, 1245 s, 1212 vw, 1181 vw, 1150 vw, 1132 w, 1119 sh, 1066 m, 1052 s, 1030 w, 942 s, 919 s, 905 m, 841 vs br, 796 m, 777 s, 753 s, 742 m, 689 w, 671 m, 632 w, 602 m, 575 m, 563 w, 545

vw, 482 w. ^{1}H NMR (300.1 MHz, C_6D_6, 297 K): δ [ppm] = 5.17 [s, $\Delta\nu_{1/2}$ = 250 Hz, 27 H, 3 × Si(CH_3)$_3$], −47.4 (s, $\Delta\nu_{1/2}$ = 1000 Hz, 6 H, 3 × CH_2), −185 (s, $\Delta\nu_{1/2}$ = 2700 Hz, 6 H, 3 × CH_2). μ_{eff} = 2.8 μ_B. $C_{15}H_{39}BrCrN_4Si_3$ (491.66): calcd. C 36.64, H 8.00, Br 16.25, N 11.40; found C 36.66, H 7.65, Br 16.32, N 11.28.

Preparation of [Cr(N$_3$N)Br] (4) by Oxidation of 1 with Br$_2$: A solution of [Cr(N$_3$N)] (**1**) (0.26 g, 0.63 mmol) in 50 mL of pentane was treated at −78 °C with a solution of Br_2 (0.016 mL, 0.31 mmol) in 1 mL of pentane. The colour of the reaction solution instantly turned black. After stirring for 2.5 h at ambient temperature, the solution was concentrated in vacuo to half of its volume and filtered from a black solid through a glass frit. The brownish-red filtrate was evaporated to dryness to yield 0.16 g of an oily residue. Crystallisation of the crude product from diethyl ether at −78 °C afforded **4** as black cubes. A second crop of **4** could be obtained after evaporation of the mother liquor to dryness and crystallisation of the residue from pentane at −78 °C. Overall yield 0.05 g (16%). The product was shown by ^{1}H NMR spectroscopy to be identical to that obtained from oxidation of **1** with AgBr.

Preparation of [Cr(N$_3$N)I] (5) by Oxidation of 1 with AgI: A mixture of [Cr(N$_3$N)] (**1**) (0.41 g, 1.00 mmol) and AgI (0.24 g, 1.02 mmol) was treated in the dark with 40 mL of THF at −78 °C. On warming to room temperature, the green solution of **1** turned yellowish-black and elemental silver precipitated out of the solution. After stirring for 16 h at room temperature in the dark, the solvent was removed in vacuo and insoluble material was removed by extraction of the residue with 40 mL of diethyl ether and filtration. The filtrate was concentrated to approximately 5 mL, then 10 mL of pentane was added and the volume of the solution was reduced in vacuo again to approximately 5 mL. Crystallisation of the product was completed by storing the solution overnight at −78 °C, thus providing **5** as black crystals, which were found by ^{1}H NMR spectroscopy to be more than 95% pure. Yield: 0.46 g (86%). Analytically pure **5** was obtained after recrystallisation of the crude product from diethyl ether and washing of the obtained crystals with pentane at −78 °C. Yield 0.38 g (71%), m.p. 177 °C. IR (nujol mull): $\tilde{\nu}$ [cm^{-1}] = 2635 w, 2080 w br, 2014 w, 1992 vw, 1925 w br, 1871 w br, 1447 m, 1401 w, 1366 vw, 1358 w, 1331 w, 1321 w, 1304 w, 1261 s, 1246 vs, 1211 w, 1136 m, 1115 w, 1069 m, 1050 sh, 1044 vs, 1024 m, 938 vs, 912 vs, 840 vs br, 781 vs br, 753 s, 740 s, 689 m, 674 m, 630 w, 574 s. ^{1}H NMR (300.1 MHz, C_6D_6, 297 K): δ [ppm] = 5.88 [s, $\Delta\nu_{1/2}$ = 140 Hz, 27 H, 3 × Si(CH_3)$_3$], −54.1 (s, $\Delta\nu_{1/2}$ = 950 Hz, 6 H, 3 × CH_2), −145 (s, $\Delta\nu_{1/2}$ = 2100 Hz, 6 H, 3 × CH_2). μ_{eff} = 3.0 μ_B. $C_{15}H_{39}CrIN_4Si_3$ (538.66): calcd. C 33.45, H 7.30, I 23.56, N 10.40; found C 33.16, H 7.36, I 23.32, N 10.25.

Preparation of [Cr(N$_3$N)I] (5) by Oxidation of 1 with I$_2$: A solution of I_2 (0.127 g, 0.50 mmol) in 30 mL of THF was added dropwise to a solution of **1** (0.42 g, 1.02 mmol) in 50 mL of THF at −78 °C. The colour of the solution instantly changed to yellowish-black. The resulting reaction mixture was stirred at room temperature for 15 h. The volatiles were removed in vacuo and the residue was extracted with 40 mL of pentane and then with 10 mL of diethyl ether. The extracts were filtered and evaporated to dryness in vacuo providing 0.48 g of a brown-black sticky solid. This was crystallised from 10 mL of diethyl ether at −78 °C affording black crystals of **5**. Yield: 0.16 g (29% relative to **1**). $C_{15}H_{39}CrIN_4Si_3$ (538.66): calcd. C 33.45, H 7.30, I 23.56, N 10.40; found C 32.21, H 7.17, I 23.88, N 10.37. The product was shown by ^{1}H NMR spectroscopy to be identical to that obtained from the oxidation of **1** with AgI.

Preparation of [Cr(N$_3$N)CN] (6): A solution of **1** (0.59 g, 1.43 mmol) in 30 mL of THF was added to a suspension of AgCN (0.22 g, 1.64 mmol) in 30 mL of THF at −50 °C. The reaction mixture was allowed to warm to ambient temperature under the exclusion of light. The colour of the solution slowly changed to red, and a black precipitate of elemental silver was formed. The suspension was stirred overnight at room temperature in the dark. The volatiles were removed in vacuo and the residue was extracted with 70 mL of diethyl ether. The blood-red extract was filtered, the filtrate was concentrated to approximately 15 mL and stored overnight at −78 °C to complete crystallisation of the product. After decanting the supernatant solution, the black crystals were washed with a minimum amount of diethyl ether at −78 °C and dried in vacuo. Yield: 0.36 g (57%), m.p. 166 °C. IR (nujol mull): $\tilde{\nu}$ [cm^{-1}] = 2642 vw, 1929 vw, 1871 vw, 1402 m, 1367 m, 1335 w, 1323 m, 1309 w, 1265 m, 1259 m, 1246 s, 1211 w, 1180 vw, 1169 vw, 1150 vw, 1132 m, 1118 sh, 1069 sh, 1051 s, 1029 m, 1015 sh, 941 vs, 919 vs, 841 vs br, 778 vs br, 750 s, 743 s, 732 sh, 687 m, 676 m, 633 m, 629 w, 601 m, 575 s, 562 m, 490 m, 466 m, 444 w, 417 m. ^{1}H NMR (300.1 MHz, C_6D_6, 297 K): δ [ppm] = 3.49 (s, $\Delta\nu_{1/2}$ = 220 Hz, 27 H, 3 × Si(CH_3)$_3$], −39.0 (s, $\Delta\nu_{1/2}$ = 1400 Hz, 6 H, 3 × CH_2), −188 (s, $\Delta\nu_{1/2}$ = 6900 Hz, 6 H, 3 × CH_2). μ_{eff} = 2.9 μ_B. $C_{16}H_{39}CrN_5Si_3$ (437.77): calcd. C 43.90, H 8.98, N 16.00; found C 44.14, H 9.06, N 15.75.

Preparation of [Ag(CN*t*Bu)$_2$](BF$_4$) (7): A suspension of $AgBF_4$ (0.625 g, 3.21 mmol) in 15 mL of CH_2Cl_2 was treated in the dark with *t*BuNC (0.72 mL, 6.37 mmol) and the reaction mixture was stirred at room temperature. After 5 min, an IR spectrum of the solution was recorded in the region of 2300−1500 cm^{-1} to follow the progress of the reaction. This showed two strong ν(C≡N) absorptions at 2225 and 2200 cm^{-1}, indicating the formation of the cations $[Ag(CNtBu)_2]^+$ and $[Ag(CNtBu)_3]^+$. After stirring for 30 min at ambient temperature, the IR spectrum of the reaction solution revealed that the ν(C≡N) absorption of $[Ag(CNtBu)_3]^+$ at 2200 cm^{-1} had disappeared. The solution was then filtered and the filtrate was concentrated in vacuo to a few millilitres and pentane was added to precipitate complex **7**. The supernatant solution was discarded and the precipitate washed once with pentane and dried in vacuo to afford **7** as a white solid. Yield 1.03 g (89%). IR (CH_2Cl_2): $\tilde{\nu}$ [cm^{-1}] = 2225 vs [ν(*t*BuN≡C)]. IR (THF): $\tilde{\nu}$ [cm^{-1}] = 2212 vs [ν(*t*BuN≡C)]. IR spectra in KBr showed extensive decomposition of **7** due to reaction with the matrix. ^{1}H NMR (300.1 MHz, CD_2Cl_2, 248 K): δ [ppm] = 1.52 (s, 18 H, 2 × CMe_3). ^{13}C{^{1}H} NMR (75.5 MHz, CD_2Cl_2, 222 K): δ [ppm] = 29.3 (s, 2 × CMe_3), 58.6 (s, 2 × CMe_3), 132.7 (s, 2 × CNCMe_3). ^{19}F NMR (282.4 MHz, CD_2Cl_2, 248 K): δ [ppm] = −152.65 (s, $^{11}BF_4$), −152.60 (s, $^{10}BF_4$). $C_{10}H_{18}AgBF_4N_2$ (360.94): calcd. C 33.28, H 5.03, N 7.76; found C 33.24, H 4.99, N 7.59.

X-ray Crystallographic Study: Suitable single crystals of **4** and **6** were grown by slow cooling of a saturated pentane (**4**) or diethyl ether (**6**) solution from ambient temperature to −35 °C. A summary of the crystal data, data collection and refinement is given in Table 4.

Data collection was performed on a STOE IPDS diffractometer (area detector) equipped with a low- temperature device (Cryostream, Oxford Cryosystems) using graphite monochromated Mo-K_α radiation (λ = 0.71073 Å). Unit cell parameters of **4** and **6** were determined from least-squares analyses using 5000 reflections (5.6° < 2θ < 50.0°). Intensities were measured by φ-oscillation scans and corrected for background, polarisation and Lorentz effects. DIFABS was applied for absorption correction of the data set of **4**.[35] The structures were solved by direct methods and refined anisotropically by the least-squares procedure implemented in the SHELX program system.[36] Hydrogen atoms were included iso-

[23] I.-P. Lorenz, *Gruppentheorie und Molekülsymmetrie*, Attempto Verlag, Tübingen, Germany, **1992**.

[24] The lower-energy ν(C≡N) absorption band of **7** in KBr appears at nearly the same position as that of analytically pure $[Ag(CN\textit{t}Bu)_4](BF_4)$ (**8**) in KBr (2184 cm^{-1}). This let us suggest that **8** might be one of the products of the reaction of **7** with KBr under pressure. It is interesting to note, that $[Ag(CN\textit{t}Bu)_3](PF_6)$ has been previously reported to give two ν(C≡N) absorption bands in KBr at positions (2241 and 2184 cm^{-1}) very close to those of **7**: Y. Yamamoto, K. Aoki, H. Yamazaki, *Inorg. Chim. Acta* **1982**, *68*, 75−78.

[25] Complexes **8** and **9** were prepared in CH_2Cl_2 by the reaction of $AgBF_4$ with four and three equivalents of *t*BuNC, respectively. These were isolated as analytically pure, white solids in very high yields and were fully characterised: D. Wössner, Dissertation, **1997**, Humboldt-Universität zu Berlin, Cuviller Verlag, Göttingen, Germany, **1997**.

Two New Layered Thioantimonate(III) Compounds: Solvothermal Syntheses, Crystal Structures, and Properties of (*trans*-1,4-$C_6N_2H_{15}$)Sb_3S_5 and (*trans*-1,2-$C_6N_2H_{15}$)$Sb_3S_5 \cdot H_2O$

Lars Engelke,[a] Christian Näther,[a] and Wolfgang Bensch*[a]

Keywords: Crystal structure / Hydrogen bonds / Solvothermal synthesis / Thioantimonate

Two new thioantimonate(III) compounds (*trans*-1,4-chxnH)Sb_3S_5 (**I**) and (*trans*-1,2-chxnH)$Sb_3S_5 \cdot H_2O$ (**II**) (chxn = diaminocyclohexane = $C_6N_2H_{14}$) were prepared under solvothermal conditions. Structure-directing arrangements of the organic molecules are formed under the conditions of synthesis; these consist of hydrogen-bonded chains (**I**) and of double chains of the amine molecules indirectly joined by water molecules through hydrogen bonding (**II**). In both compounds the structure-directing counter-ions are arranged in a layer-like fashion and because of the similar arrangements the topologies of the thioantimonate(III) layers $^2_\infty[Sb_3S_5]^-$ are nearly identical. The anionic layers are formed by interconnection of SbS_3 trigonal pyramids and SbS_4 moieties. The layers containing Sb_2S_2, Sb_4S_4, and $Sb_{10}S_{10}$ heterorings as secondary building units are stacked parallel to the *b* axis. The anionic layers and the structure-directing aggregates are stacked in a sandwich-like fashion. The water molecule in **II** can be removed at low temperatures, and this process is partially reversible. Interestingly, the removal of water is accompanied by a pronounced colour change from bright yellow to red.

Introduction

Structure-directing molecules such as alkylamines or their ammonium salts are widely used for the solvothermal synthesis of new main group thiometallates. A large number of thioantimonates(III) have been synthesized over recent years. The high flexibility of the coordination behaviour of the Sb^{III} atom, with coordination numbers between 3 and 6[1–4] due to the lone pair effect,[5,6] has allowed the preparation of a large variety of thioantimonate(III) compounds.

With alkali or alkaline metal cations, a size dependence of the anion dimensionality is observed. With decreasing ionic radius the formation of one-dimensional chains,[7] layered anions,[8] or three-dimensional networks[9] is preferred. In cases of transition metal amine complexes[10–12] or pure alkylammonium cations[13–15] no simple relationship between the size and the dimensionality of the thioantimonate(III) anion could be observed; thus, other factors must play a dominant role during the anionic framework formation. Systematic investigations are required in order to obtain a deeper knowledge of the factors influencing the formation and crystallization of thioantimonates(III). One approach to study the influence of the structure-directing molecules is the application of amines of similar size and charge but with their amino groups at different positions. Such an amine pair is *trans*-1,2-diaminocyclohexane and *trans*-1,4-diaminocyclohexane. In this contribution we report the syntheses, crystal structures, thermal stabilities, and optical properties of the two new thioantimonate(III) (chxnH)$[Sb_3S_5]$ species, with chxnH being the protonated amines *trans*-1,2-diaminocyclohexane and *trans*-1,4-diaminocyclohexane.

Results and Discussion

Both (*trans*-1,4-chxnH)Sb_3S_5 (**I**) and (*trans*-1,2-chxnH)$Sb_3S_5 \cdot H_2O$ (**II**) crystallize in the triclinic space group $P\bar{1}$ with two formula units in the unit cell (Table 1). The Sb(1) and Sb(2) atoms in both **I** and **II** are coordinated by three sulfur atoms, forming the well-known SbS_3 pyramids. The Sb–S distances range from 2.396(1) to 2.5993(8) Å in **I** (Table 2) and from 2.393(1) to 2.599(1) Å in **II** (Table 3). In both compounds the Sb(3) atoms are coordinated by four S atoms to form an SbS_4 unit with two shorter Sb–S distances [2.4299(8) and 2.452(1) Å in **I** and 2.435(1) and 2.450(1) Å in **II**] and two significantly longer Sb–S separations [2.684(1) and 2.777(1) Å in **I** and 2.615(1) and 2.908(1) Å in **II**]. Such SbS_4 building units are common, and the two longer Sb–S distances are always in *trans* relationships to each other.[16–19] The coordination spheres of the antimony atoms are completed by S atoms at greater distances, giving coordination numbers of five [Sb–S: 2.978(1) to 3.546(1) and 2.973(1) to 3.519(1) Å, respectively]

to form distorted SbS_5 trigonal bipyramids (Table 4 and Figure 1).

The $Sb(1)S_3$ and $Sb(2)S_3$ pyramids each share a common corner with the $Sb(3)S_4$ moiety, yielding the $Sb_3S_5^-$ anion. Further interconnection to produce the two-dimensional

layered anion is achieved by corner- and edge-sharing in the different primary building units. Two symmetry-related $Sb(1)S_3$ pyramids share a common edge to form a *trans*-Sb_2S_4 unit, and two $Sb(3)S_4$ and two $Sb(2)S_3$ have common corners, yielding a puckered, eight-membered Sb_4S_4 ring (8MR). The 8MR units are condensed into rods running along the *a* axis. Adjacent rods are connected by the *trans*-Sb_2S_4 building units, giving the two-dimensional $[Sb_3S_5]^-$ anion extending within the *a*−*c* plane shown in Figure 2. The connection of the rods by the Sb_2S_4 units gives rise to the formation of ellipsoidal 20-membered $Sb_{10}S_{10}$ heterorings (20MR) with approximate dimensions of 9.2×3 Å (measured from coordinate to coordinate). The layers are stacked perpendicular to the *b* axis (interlayer spacing about 6.9 Å) with a parallel alignment of the 8MR and 20MR units. The thickness of the individual layers is about 3.5 Å.

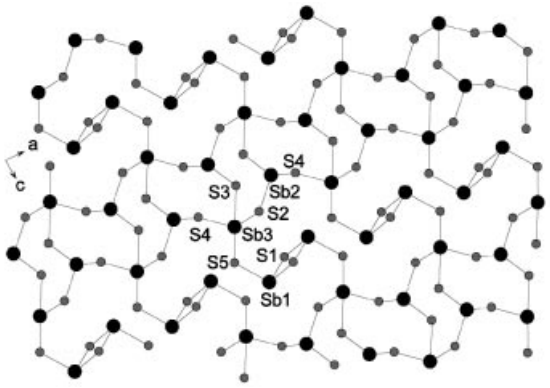

Figure 2. The $[Sb_3S_5^-]_\infty$ layer viewed parallel to [010], with numbering scheme and the four-, eight-, and 20-membered rings

In compound **I**, protonation of one of the two NH_2 groups yields the charge-balancing *trans*-1-amino-4-ammoniocyclohexane cation. Strong hydrogen bonds [N···H distance: 1.86(2) Å; N−H···N angle: 172.26(4)°] between adjacent cations (see Figure 3) force the arrangement of nearly linear chains running parallel to the *a* axis. The chains are oriented parallel to one another to form pseudo-layers within the *a*−*c* plane. As shown in Figure 4, the anionic Sb_3S_5 layers and cationic pseudo-layers are stacked in a sandwich-like manner perpendicular to the *b* axis.

Figure 3. Hydrogen bonds in the *trans*-1-amino-4-ammoniocyclohexane chains; the displacement ellipsoids are drawn at the 50% probability level

In compound **II**, one of the amino groups is again protonated to form the *trans*-1-amino-2-ammoniocyclohexane cation for charge-balancing. Hydrogen bonds between the

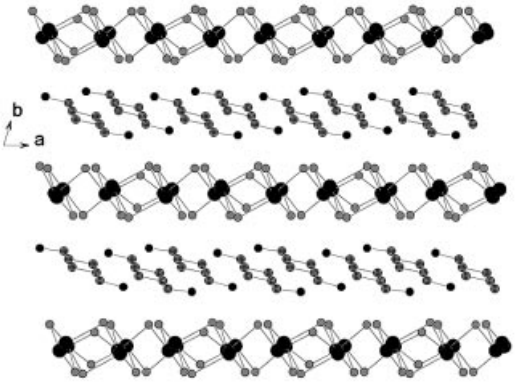

Figure 4. The sandwich-like arrangement of alternating anionic and cationic layers viewed along [001] in compound **I**

NH_2 and NH_3^+ groups in the 1- and 2-positions cannot give rise to the formation of linear chains as observed for the *trans*-1-amino-4-ammoniocyclohexane cation. In this compound, pairs of cations are formed, connected through hydrogen bonds involving two water molecules (Figure 5). The O···H distance of 1.85(5) Å and the N···H distance of 1.87(7) Å, with corresponding angles of 165.5° and 175.6°, are indicative of strong hydrogen bonds. An additional, weaker O···H hydrogen bond between the NH_3^+ groups and the water molecules interconnects the pairs to produce double chains. The O···H distance of 2.03(4) Å, the corresponding angle of 177.4°, and the N···O distance of 2.87(4) Å are common values for weaker hydrogen bonds.[20] The double chains running along the *a* axis are arranged in a layer-like fashion within the *a*−*c* plane. As in compound **I**, a sandwich-like structure consisting of alternating anionic and cationic layers stacked perpendicular to the *b* axis is observed. The differences between the arrangements of the cations in the two compounds are presumably due to the type of H bonding. In compound **I**, the amine molecules are joined by direct hydrogen bonds, whereas the connection in compound **II** involves a bridging water molecule. This acts as a donor and acceptor to two adjacent cations and is an acceptor for a third amine molecule.

At first glance, the two anionic network structures seem to be identical. However, a more detailed analysis reveals several differences, demonstrating the high flexibility of Sb^{III} coordination spheres for optimization of the packing (see Table 4). If only the short Sb−S bonds are taken into account, the average Sb−S distances of 2.526 Å (**I**) and 2.532 Å (**II**) are identical (Table 4). A small difference is observed when the long bonds are also considered [<Sb−S> = 2.771 Å for **I** and 2.783 Å for **II**]. The flexible behaviour can be demonstrated by comparing the environments of Sb(3) in the two compounds. In **I** the Sb(3)−S(3) and Sb(3)−S(5) separations are 2.777(1) Å and 2.684(1) Å, whereas in **II** these values amount to 2.908(1) Å and 2.615(1) Å. Because the bond order of the S(5) atom has to remain constant, the Sb(1)−S(5) bond in **I** [2.460(1) Å] is shorter than in **II** [2.494(1) Å].

Some remarkable differences are also observed for the S−Sb−S angles. In **I**, these values range from about 72.5

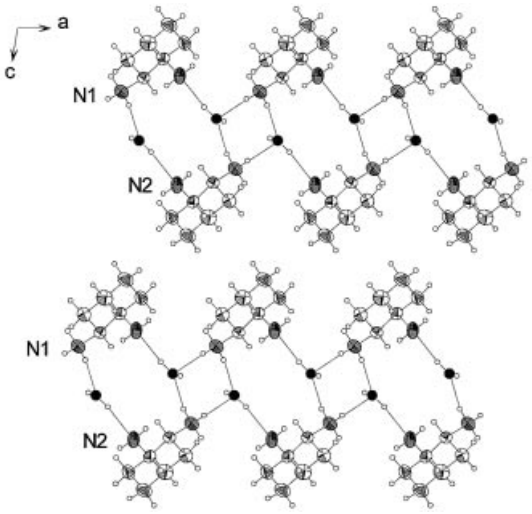

Figure 5. View of the *trans*-1-amino-2-ammoniocyclohexane cations and the water molecules forming double chains in the $a-c$ plane (displacement ellipsoids are drawn at the 50% probability level; hydrogen bonds are shown as dotted lines)

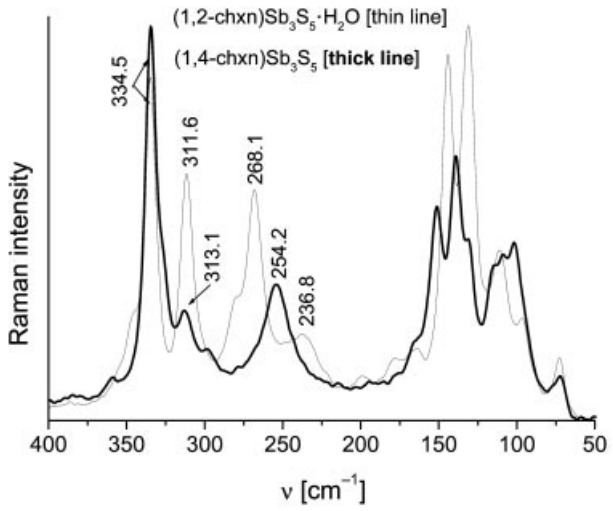

Figure 6. Raman spectra of (*trans*-1,4-chxnH)Sb_3S_5 and (*trans*-1,2-chxnH)$Sb_3S_5{\cdot}H_2O$; the numbers are the frequencies of some of the most intense resonances

to 110.2° whereas in **II** the analogous values extend from 74.7 to 103.7° (note: *trans*-S−Sb−S angles are not considered). Individual angles show differences of up to about 6.5° [S(1)−Sb(3)−S(3)], again demonstrating the flexibility of the thioantimonate(III) network for achievement of optimum packing.

As previously demonstrated, the bonding properties of a lone-pair atom are best detected from changes of the bond angles, whereas interatomic bond lengths are only slightly affected,[21] and the local environment of the Sb^{III} atoms exhibits no significant alterations of the Sb−S distances. Raman spectroscopy is a powerful tool for the detection of differing bonding properties; the Raman spectra are shown in Figure 6. Both compounds show intense bands located at 334.5 cm^{-1} (**I** and **II**) and at 313.1 cm^{-1} (**I**) or 311.6 cm^{-1} (**II**), due to SbS_3 and SbS_4 units.[22] Because of the similar average Sb−S bond lengths in **I** and **II**, the main resonances show only minute differences. However, small shoulders on the high-frequency side of the first band are caused by the different Sb environments in the two compounds. The assignments of the Sb−S modes are in accordance with the results reported by Pfitzner for Cu_3SbS_3 and $(CuI)_2Cu_3SbS_3$.[23] In the former compound, two maxima were observed at 321 and 290 cm^{-1}, reflecting the weaker bonding interaction due to the 3 + 5 environment. In the latter, the [SbS_3^{3-}] anion has no next-nearest S atoms, yielding Raman bands at 362 and 339 cm^{-1}. For $Mn_2Sb_2S_4$, with one Sb^{III} atom in a sixfold environment of S atoms and the other Sb^{III} atom in a sevenfold one, Raman bands occur at even lower frequencies, being located between about 280 and 310 cm^{-1}.[24]

A brief comparison of the crystal structures of **I** and **II** with structures of composition RSb_3Q_5 (R = cation, Q = S, Se) should serve to highlight the uniqueness of the thioantimonate(III) layers in the title compounds. In $RbSb_3S_5{\cdot}H_2O$[16] and $RbSb_3Se_5$,[25] layered anions are found. In these two compounds, however, remarkably different modes of interconnection of the primary building units to form SbS/SbSe heterorings are found. In the selenide, six- and eight-membered rings are formed, while in the sulfide the interconnection yields four- and 16-membered rings. Compounds $[M^{II}(en)_3]Sb_3S_5$ with M = Ni, Co[26] contain isolated $[Sb_3S_5]^-$ anions. With large organic cations such as Tpa [tetrapropylammonium, $(C_3H_7)_4N^+$] or PPh_4 (tetraphenylphosphonium), the SbS_x units are joined to form one-dimensional chains, as found in $(Tpa)Sb_3S_5$ [11] and $(PPh_4)Sb_3S_5$.[27] With the smaller Tma [tetramethylammonium, $(CH_3)_4N^+$] cation, three-dimensional interconnection of the primary units of the Sb_3S_5 anion was proposed.[28] The ternary compound $TlSb_3S_5$ [29] shows a three-dimensional anionic framework. We note that the two title compounds are the first examples of thioantimonate(III) moieties with $[Sb_3S_5]^-$ networks containing 4MR, 8MR, and 20MR components as secondary building units.

With respect to the syntheses of the compounds, several observations are remarkable. Compound **I** forms under a wide range of conditions, with factors such as temperature, amine concentration, and amine/antimony ratio having virtually no influence on product formation. Several unsuccessful attempts were made to introduce transition metal cations into the anionic thioantimonate(III) framework. In all experiments compound **I** was obtained. Hence, we conclude that, under the reaction conditions used, *trans*-1,4-diaminocyclohexane forms a very stable arrangement that forces the growth of $^2_\infty[Sb_3S_5]^-$ layers with the topology found in the title compound. In contrast, the synthesis of **II** requires very precise conditions, suggesting a lower stability of the hydrogen-bonded 1,2-substituted amine. Parameters such as temperature, amine concentration, and amine/antimony ratio were varied in a large number of experiments. Small deviations from the synthesis conditions reported in the Exp. Sect., though, always yield thioanti-

monates of different composition. In addition, application of Mn, Ni, or Co results in the formation of compounds composed of isolated $[M(chxn)_3]^{2+}$ and SbS_4^{3-} ions (M = Co, Ni) or of $[M(chxn)_2(SbS_4)_2]^{4-}$ ions (M = Mn). Obviously, the formation of the structure-directing arrangement of the cations requires precise conditions, and deviations from exact stoichiometric quantities suppress the "template" formation.

Thermal Investigations

The DTA-TG curves are shown in Figure 7. Compound **I** starts to decompose at T_{onset} = 250 °C. A weight loss of 18.9% occurs in one step, and is accompanied by an endothermic signal with a peak temperature T_p of 257 °C. The mass loss is in good agreement with that calculated for the emission of the amine molecules ($-\Delta m_{theo}$ = 17.98%). In the X-ray powder pattern of the decomposition product, the reflections of crystalline Sb_2S_3 as well as of elemental antimony are found. Obviously, the Sb/S ratio in the starting material (0.6) results in a partial reduction of Sb^{III} to elemental Sb and the formation of Sb_2S_3. A C,H,N analysis of the residue yields a very low contamination level of about 0.5%.

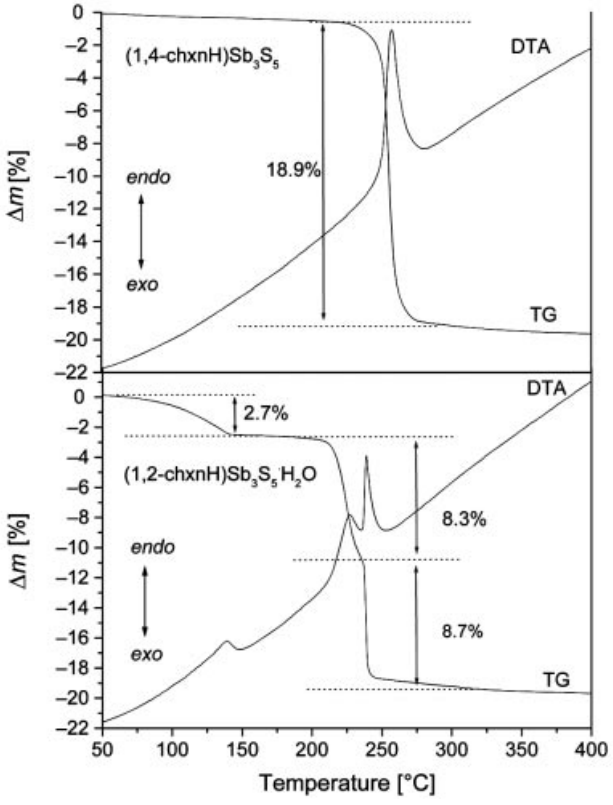

Figure 7. DTA/TG curves for compound **I** (top) and for compound **II** (bottom; mass changes are given in %)

For compound **II** the decomposition reaction is more complex. In the first step, a weight loss of 2.7% is observed at T_{onset} = 80 °C, accompanied by an endothermic signal at T_p = 139 °C. This weight change is in agreement with the emission of the water molecule ($-\Delta m_{theo}$ = 2.7%). On further heating, two strongly endothermic signals occur at T_{onset} = 220 and 230 °C, with DTA signals at T_p = 227 and 239 °C. The total weight loss is about 17.0%, suggesting successive decomposition of the amine. The experimental mass change is close to the value expected for the removal of the amine ($-\Delta m_{theo}$ = 17.4%). The X-ray powder pattern of the final product is identical with that obtained for the decomposition product of **I**.

In a further experiment, thermal decomposition was interrupted after the emission of the water molecule. The formerly yellow compound exhibited a significant darkening to red. The X-ray powder pattern shows a significant shift of the (0*k*0) reflections to larger 2θ values (see Figure 8), representing a reduction of the interlayer distance from 9.95 to 9.52 Å. The removal of H_2O is partly reversible, and the X-ray powder pattern after a few days in humid air is similar to that of the pristine material. The positions of the (010) and (020) reflections shifted to 2θ values very close to those determined for the original material. The alteration of the reflection profiles indicate that the process is not fully reversible. This is further supported by the orange colour of the sample, in comparison to the yellow colour of the pristine material.

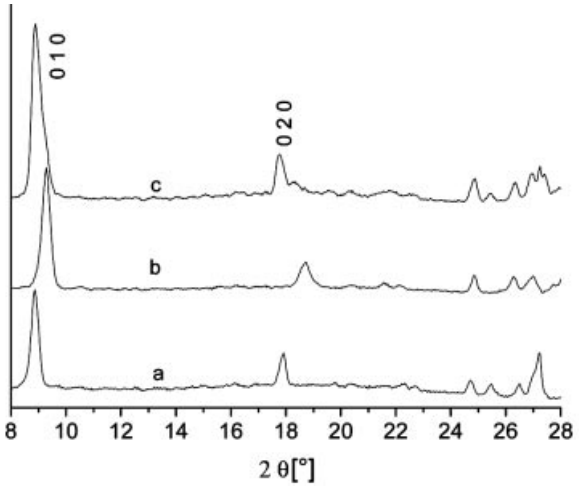

Figure 8. X-ray powder patterns of compound **II**: as prepared (a), after removal of water (b), and after treatment of the water-free sample in humid air (c); for two reflections the indices are given

Conclusion

The crystal structures of the two new thioantimonate(III) compounds are excellent examples demonstrating the structure-directing effect of the amines used under solvothermal conditions. The topologies of the $^2_\infty[Sb_3S_5]^-$ layers in **I** and **II** are very similar, but with some distinct differences demonstrating the high flexibility of Sb^{III} coordination spheres. The structure-directing cations are formed in situ, and the stability seems to be determined mainly by the location of the two amino functions. Compound **I** is formed under a wide range of reaction conditions, strong intermolecular hy-

drogen bonds resulting in the stable arrangement of the cations. In contrast, compound **II** is only formed in a very narrow window of reaction conditions, and water molecules are necessary for the formation of the structure-directing arrangement. The anionic layers and the structure directors are stacked in a sandwich-like manner. The removal of water from **II** is partially reversible and is accompanied by a significant change of the colour from bright yellow to red. We are currently investigating whether the uptake of other polar molecules into the water-free material is possible. In addition, the 1,3-diamino- and 1,3,5-triaminocyclohexane should be used in further solvothermal syntheses to provide information on the influence of the structure-directing molecules on product formation.

Experimental Section

Syntheses of (*trans*-1,4-chxnH)Sb_3S_5 (I) and (*trans*-1,2-chxnH)$Sb_3S_5 \cdot H_2O$ (II) (chxn = Diaminocyclohexane, $C_6H_{14}N_2$): The two compounds were prepared under solvothermal conditions in a Teflon-lined steel autoclave with an inner volume of 30 mL. For **I**, a mixture of elemental antimony (122 mg, 1 mmol) and sulfur (80 mg, 2.5 mmol) was heated with *trans*-1,4-diaminocyclohexane (0.65 g, 5.7 mmol) and water (2.5 mL) to 140 °C for 5 d. For **II**, the same amounts of Sb and S were applied, but a mixture of water (1.5 mL) and *trans*-1,2-diaminocyclohexane (1.5 mL, 12.5 mmol) was used (120 °C for 5 d). The products were filtered and washed with water and acetone. Single crystals suitable for X-ray investigations were obtained under static conditions. Pale yellow, air-stable platelets were obtained in yields of about 75% based on antimony. Both compounds could also be prepared whilst stirring. For **I**, a mixture of Sb (122 mg, 1 mmol), S (64 mg, 2 mmol), amine (0.8 g, 7 mmol), and water (2 mL) was heated in a Teflon-lined autoclave of 7 mL internal volume, while for **II**, the amine (1.5 mL, 12.5 mmol) was diluted with water (0.5 mL). When the slurry was stirred, the reactions were complete after 3 h, with yields of 90% based on antimony. The yellow microcrystalline powders were shown to be phase-pure by X-ray powder diffraction. **I:** (640.75): calcd. C 11.24, H 2.36, N 4.37; found C 11.06, H 2.29, N 4.30. **II:** (658.77): calcd. C 10.94, H 2.58, N 4.25; found C 10.70, H 2.51, N 4.18.

X-ray Crystallography: The intensity data were collected with PHILIPS PW1100 four-circle (**I**) and NONIUS CAD4 (**II**) diffractometers, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by use of SHELXS-97[28] and structure refinements were done against F^2 with SHELXL-97.[29] All non-hydrogen atoms were refined with anisotropic displacement parameters. All H atoms in **I** and those bound to N and O in **II** were located in the difference Fourier maps and were refined with varying coordinates and varying isotropic displacement parameters. In compound **II**, the H atoms bound to carbon atoms were positioned with idealized geometries and refined with fixed isotropic displacement parameters by use of a riding model. The details of data acquisition and some refinement results are listed in Table 1, and atom distances and angles are listed in Tables 2−3. CCDC-178624 (**I**) and -178625 (**II**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

X-ray Powder Diffraction: The X-ray powder patterns were recorded in transmission geometry with a STOE Stadi-P diffractometer with Cu-$K_{\alpha 1}$ radiation (λ = 1.540598 Å).

Thermal Analysis: The thermal investigations were performed with a Netzsch STA 429 DTA-TG device. The samples were heated in Al_2O_3 crucibles, with a heating rate of 3 °C min^{-1}, up to 600 °C and purged in an argon stream (approximately 100 mL min^{-1}). The data were corrected for buoyancy effects.

Raman Spectroscopy: The Raman spectra were measured from 50 to 3500 cm^{-1} with a Bruker IFS 66 Fourier transform Raman spectrometer (wavelength: 1064 nm).

Synthesis and Properties of Bis(2-heteroaryl)borane Derivatives

Thomas Köhler,[a] Jürgen Faderl,[a] Hans Pritzkow,[a] and Walter Siebert*[a]

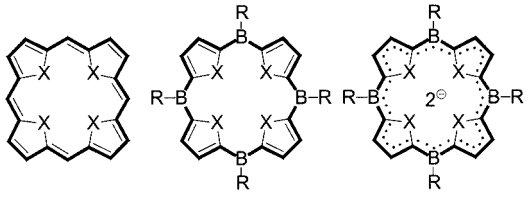
Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Boranes / Porphyrinogens / Lithiation / Grignard reaction / Bromination

The reaction of (isopropyloxy)bis(2-thienyl)borane (**1d**) with Grignard reagents leads to methylbis(2-thienyl)borane (**1e**) and to phenylbis(2-thienyl)borane (**1f**). Treatment of monolithiated heterocycles with dichloroboranes yields the bis(2-heteroaryl)boranes **1b**, **1c**, and **3a**, which are dibrominated with NBS to give the 5,5′-dibromo products **1b**′, **2a**′, and **3a**′. NMR spectroscopic and MS data confirm the composition of the compounds. The [2+2] cyclization of the dibromo derivatives yields, in the case of **2a**′, the macrocycle **4b**, as confirmed by HR-MS data.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

We are interested in the electronic structure and ligand properties of tetraboraporphyrinogens **B**, which formally derive from isophlorins (*N*,*N*′-dihydroporphyrins) **A**[1] (X = NR) by exchange of the *meso*-carbon atoms for boron atoms. In **B** the empty p_z orbitals of the boron atoms may allow macrocyclic conjugation when **B** (16 π-electrons) is reduced to the dianion **C**. As a first example of a tetraboraporphyrinogen we recently synthesized the tetrathia macrocycle **B** (X = S; R = N*i*Pr$_2$) in good yield via the bis(2-thienyl)borane **1a**.[2] Attempts to incorporate the corresponding *N*-methylpyrrole derivative **2a** into **B** (X = NMe) were not successful.[3a,3b] The formation of silyl- and stannyl-bridged macrocycles has been reported.[4a,4b]



A X = NR, O, S **B** X = NR, O, S **C** X = NR, O, S

Bis(2-heteroaryl)boranes were first prepared via tin/boron exchange and characterized by NMR spectroscopic studies.[5a,5b] Recently, we reported the formation of (diisopropylamino)bis(1-methyl-2-pyrrolyl)borane (**2a**) and its *N*-benzyl analogue.[6] Besides **1a**[2] some bis(2-thienyl)boranes are already known.[7,8] For the synthesis of furan- and *N*-methylpyrrole-containing macrocycles we investigated the 5,5′-dibromination of the corresponding bis(heteroaryl)boranes with *N*-bromosuccinimide. In the following we report on the new derivatives **1b**, **1c**, and **3a** of bis(2-heteroaryl)boranes, as well as on a new synthesis for methylbis(2-thienyl)borane (**1e**) and phenylbis(2-thienyl)borane (**1f**), and a high-yield bromination method for bis(2-heteroaryl)boranes and their reactivity in [2+2] cyclizations.

Results and Discussion

1. Syntheses, Spectra of Aminobis(2-heteroaryl)boranes (1b, 1c, 3a), and Structure of 3b

(Dialkylamino)bis(2-thienyl)boranes are obtained when 2-lithiothiophene is treated at low temperatures with dichloro(diethylamino)borane and dichloro(2,2,6,6-tetramethylpiperidino)borane in a 2:1 ratio to give colorless and moisture-sensitive (diethylamino)bis(2-thienyl)borane (**1b**) and (2,2,6,6-tetramethylpiperidino)bis(2-thienyl)borane (**1c**) in yields of 72 and 85%, respectively. Their compositions follow from spectroscopic data. The ^{1}H NMR spectrum of **1b** exhibits a triplet for the CH_3 and a quadruplet for the CH_2 protons. At low field the thienyl protons appear as doublets of doublets. Sharp ^{13}C NMR signals for the heteroaromatic carbon atoms and a broad signal for the boron-bound car-

[a] Anorganisch-Chemisches Institut der Universität,
Im Neuenheimer Feld 270, 69120 Heidelberg, Germany

E-mail: ci5@ix.urz.uni-heidelberg.de

bon atom are observed. Its ^{11}B NMR shift at $\delta = 35$ ppm is similar to that of other aminobis(2-thienyl)boranes.[7,8] Compound **1c** shows similar NMR shifts to that of **1b** in the heteroaromatic region. The 2,2,6,6-tetramethylpiperidino substituent (tmp) of **1c** yields a multiplet for the ring methylene protons and a singlet for the ring-bound methyl protons. The composition of both compounds was confirmed by HR-EI mass spectra.

X	S	S	O	O
R	NEt_2	tmp	$NiPr_2$	C_4H_3O

Addition of a suspension of monolithiated furan to a solution of Cl_2BNiPr_2 yields (diisopropylamino)bis(2-furanyl)borane (**3a**, 45%) as a colorless liquid that is sensitive to air and moisture. When the reaction is carried out by addition of the dichloroborane to monolithiated furan, only a small amount of **3a** is obtained, the main product being tris(2-furanyl)borane (**3b**). The ^1H NMR spectrum of **3a** shows the signals of the isopropyl groups and three doublets of doublets for the ring protons. Because of the coupling constants and the shift, the signal at $\delta = 6.19$ ppm is assigned to 4-H.[5a] Similarly, the ^{13}C NMR signal at $\delta = 110.4$ ppm is assigned to C-4 which is confirmed by a ^1H-^{13}C COSY NMR spectrum. The ^{11}B NMR shift at $\delta = 30$ ppm is in the expected region. The composition of **3a** is confirmed by a high-resolution mass spectrum.

Crystals of **3b** (Figure 1) suitable for X-ray analysis were grown from a hexane solution. Crystal data and structure refinement are shown in Table 1. The B1−C1 bond lengths in **3b** are similar to those in **1g**[9] but significantly shorter than the B−C bonds in triphenylborane[10] (1.585 Å). The O1−C1 bond (1.398 Å) in **3b** is slightly longer than O1−C4 (1.353 Å). This corresponds to **1g**, where the S1−C1 bond is longer than S1−C4. The boron atom in **3b** is tricoordinated and the C−B−C angles are 120°. As in **1g** the bond angle O1−C1−C4 (107.4°) is more acute than O1−C2−C3 (111.0°).

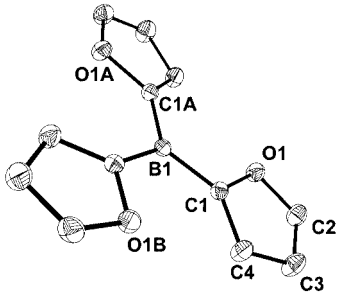

Figure 1. Molecular structure of **3b** in the crystal; selected bond lengths [Å] and angles [°]: O1−C2 1.353(1), O1−C1 1.389(1), B1−C1 1.537 (1), C1−C4 1.368(2), C2−C3 1.338(2), C3−C4 1.415 (2); C1−O1−C2 107.39(9), C4−C1−O1 107.43(9), C4−C1−B1 133.35(9), O1−C1−B1 119.20(8), C3−C2−O1 111.03(10), C2−C3−C4 106.28(11), C1-B1-C1A 120.00(1)

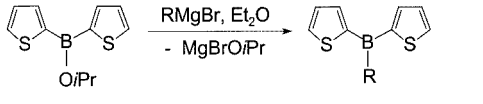
2. Syntheses of Alkylbis(2-thienyl)boranes (1e, 1f)

Methylbis[2-(5-methyl)thienyl]borane[8] (**1e**) was obtained from a redox reaction between 2-iodo-5-methylthiophene and $MeBI_2$ with elimination of elemental iodine. Because of the low yield an alternative approach to **1e** was developed. (Isopropyloxy)bis(2-thienyl)borane[7] (**1d**) was treated with methylmagnesium bromide in diethyl ether to give **1e** in almost quantitative yield. Its NMR spectroscopic and mass spectrometric data are in accordance with those reported previously.[5b,11] The reaction of phenylmagnesium bromide with **1d** analogously yielded phenylbis(2-thienyl)borane (**1f**) (53%). The composition of the colorless air-sensitive solid follows from ^{11}B and ^1H NMR spectroscopic data, the ^{13}C NMR spectrum exhibits six sharp signals for aryl and thienyl carbon atoms and two broad signals for the boron-bound carbon atoms.[12] Attempts to obtain the corresponding furan and pyrrole derivatives were not successful, because the reactions led to tris(1-methyl-2-pyrrolyl)borane (**2b**) and tris(2-furanyl)borane (**3b**), respectively.



1	e	f	g
R	Me	Ph	C_4H_3S

3. 5,5′-Dibromination of 1b, 2a, and 3a with *N*-Bromosuccinimide

For the syntheses of new macrocycles we need reactive *N*-methylpyrrole and furan derivatives as building blocks. Because of the very low tendency of the bis(2-pyrrolyl)borane **2a** and bis(2-furanyl)borane **3a** to yield dilithiated products[3a,3b] the bromination of the heterocycles at C-5 and C-5′ was investigated by using *N*-bromosuccinimide in THF. The bis(2-heteroaryl)boranes **1b**, **2a**, and **3a** react at −78 °C with *N*-bromosuccinimide in THF to give the dibromo derivatives **1b′**, **2a′**, and **3a′** in 89, 75, and 70% yield, respectively. Compound **3a′** is a yellow oil, which decomposes rapidly at room temperature. The ^{11}B NMR spectra exhibit signals for **1b′** at $\delta = 34$ ppm, for **2a′** at $\delta = 35$ ppm, and for **3a′** at $\delta = 29$ ppm. The shifts for the heteroaromatic protons of each compound show a coupling pattern of two doublets (AB spectrum). The three dibromo compounds **1b′**, **2a′**, and **3a′** were identified by EI-mass and HR EI-mass spectrometry.

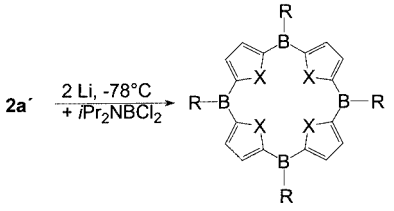
	1b	2a	3a
X	S	NMe	O
R	NEt_2	$NiPr_2$	$NiPr_2$

	1b′	2a′	3a′
X	S	NMe	O
R	NEt_2	$NiPr_2$	$NiPr_2$

4. Formation of 4b

As the [2+2] cyclization of **1b** led only to products with a quaternary boron atom, **1b′** was treated with lithium at

low temperatures and quenched with Cl_2BNiPr_2. However, cyclization did not take place, and only decomposition was noticed. Compound **2a′** reacted in a [2+2] cyclization to yield the first *N*-methylpyrrole-containing tetraboraporphyrinogen **4b**. The ^{11}B NMR shift of δ = 33 ppm and the HR-EI mass spectrometric analysis confirm the existence of macrocycle **4b**, however, purification of the dark brown oil was not successful. The oily residue obtained by performing the same reaction with the furan derivative **3a′** did not contain the macrocycle **4c**.



4b X = NMe, R = N*i*Pr$_2$

Conclusion

Quenching of 2 equiv. of 2-lithioheteroarenes with dichloro(2,2,6,6-tetramethylpiperidino)borane and dichloro(diisopropylamino)borane yields the corresponding aminobis(2-heteroaryl)boranes **1b**, **1c**, and **3a**. Interestingly, the bromination of the aminobis(2-heteroaryl)boranes **1b**, **2a**, and **3a** with 2 equiv. of *N*-bromosuccinimide leads to new dibromo derivatives **1b′**, **2a′**, and **3a′**. Methyl- and phenylmagnesium bromide were treated with (isopropoxy)bis(2-thienyl)borane (**1d**) to give the organyl-substituted bis(2-thienyl)boranes **1e** and **1f**. In summary, new organyl- and amino-substituted building blocks containing heteroarenes of the new tetraboraporphyrinogens are obtained in good yields. The [2+2] cyclization of the dibromo derivatives **1b′**, **2a′**, **3a′** give in the case of **2a′** the first *N*-methylpyrrole-containing tetraboraporphyrinogen **4b**.

Experimental Section

General: Reactions were carried out under dry nitrogen using standard Schlenk techniques. Solvents and chemicals were dried, distilled and saturated with nitrogen. Glassware was dried with a heat-gun under high vacuum. ^1H, ^{11}B, ^{13}C NMR: Bruker DRX 200 spectrometer, shift references are $(CH_3)_4Si$ and $F_3B{\cdot}OEt_2$. Mass spectra were obtained with a ZAB-2F VH Micromass CTD spectrometer, HR mass spectra with a JEOL MS Station JMS 700 spectrometer both using the EI ionization technique. (Isopropyloxy)-bis(2-thienyl)borane (**1d**),[7] dichloro(diisopropylamino)borane,[13] dichloro(diethylamino)borane,[14] and dichloro(2,2,6,6-tetramethylpiperidino)borane[15] were prepared according to literature procedures.

(Diethylamino)bis(2-thienyl)borane (1b): *n*-Butyllithium (2.5 M in hexane; 6 mL, 15 mmol) was added to a solution of thiophene (1.3 g, 15 mmol) in diethyl ether (30 mL) at −25 °C. After warming to room temperature, the reaction mixture was stirred for 1 h and then cooled to −50 °C. Dichloro(diethylamino)borane (1.2 g, 7.6 mmol) in diethyl ether (15 mL) was added dropwise to this solution. The mixture was allowed to warm to room temperature and was stirred overnight. Volatile compounds were removed under vacuum, the residue dissolved in pentane and filtered. The solvent was evaporated under vacuum and the colorless oil crystallized at −15 °C. Yield: 1.4 g (5.5 mmol, 72%) of colorless **1b**, m.p. 103 °C. ^1H NMR ($CDCl_3$, 200 MHz): δ = 1.21 (t, CH_3CH_2, $^3J_{H,H}$ = 7.0 Hz, 6 H), 3.38 (q, CH_3CH_2, $^3J_{H,H}$ = 7.0 Hz), 4 H, 7.10 (m, 4 H, CH_{th}), 7.50 ppm (m, 2 H, CH_{th}). ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 35 ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 16.1 (CH_3CH_2), 44.3 (CH_3CH_2), 127.7, 129.8, 135.2 (CH_{th}), 142 ppm (br, CB). MS: *m*/*z* (%) = 249 (28) [M^+], 234 (78) [$M^+ - CH_3$]. HR-MS: *m*/*z* (%) = 249.0845 [M^+]; calcd. for $^{12}C_{12}{}^1H_{16}{}^{11}B^{14}N^{32}S_2$ 249.0817 (Δmmu = 2.8).

(2,2,6,6-Tetramethylpiperidino)bis(2-thienyl)borane (1c): *n*-Butyllithium (2.5 M in hexane; 6 mL, 15.0 mmol) was added to a solution of thiophene (1.3 g, 15 mmol) in diethyl ether (30 mL) at −25 °C. The reaction mixture was stirred for 1 h at room temperature. At −20 °C a solution of dichloro(2,2,6,6-tetramethylpiperidino)borane (1.7 g, 7.6 mmol) in diethyl ether (15 mL) was added dropwise. The mixture was allowed to warm to room temperature and stirred overnight. Volatile compounds were removed under vacuum, and the residue was dissolved in pentane and filtered. The solvent was evaporated under vacuum leaving a white solid. Yield: 2.1 g (6.5 mmol, 85%) of colorless **1c**, m.p. 116−118 °C. ^1H NMR ($CDCl_3$, 200 MHz): δ = 1.28 (s, 12 H, $CH_{3,tmp}$), 1.68 (m, 6 H, $CH_{2,tmp}$), 6.98 (m, 2 H, CH_{th}), 7.08 (m, 2 H, CH_{th}), 7.41 ppm (m, 2 H, CH_{th}). ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 42 ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 16.1 ($CH_{2,tmp}$), 35.0 ($CH_{3,tmp}$), 37.7 ($CH_{2,tmp}$), 56.3 (C_{tmp}), 127.0, 130.7, 133.5 (CH_{th}), 151 ppm (br, CB). MS: *m*/*z* (%) = 317 (4) [M^+], 302 (100) [$M^+ - CH_3$]. HR-MS: *m*/*z* (%) = 317.1413 [M^+]; calcd. for $^{12}C_{17}{}^1H_{24}{}^{11}B^{14}N^{32}S_2$ 317.1444 (Δmmu = 3.1).

Methylbis(2-thienyl)borane (1e): Methylmagnesium bromide (3.0 M in diethyl ether; 1.7 mL, 5.1 mmol) was added dropwise to a solution of **1d** (1.1 g, 4.7 mmol) in diethyl ether (50 mL) at −25 °C. The mixture was allowed to warm for 30 min and stirred at room temp. for 3 h until a colorless solid was formed. Volatile compounds were removed under vacuum, the residue was dissolved in diethyl ether and filtered. The solvent was evaporated under vacuum and the wax-like residue dried. Yield: 0.9 g (4.5 mmol, 95%) of colorless **1e**. ^1H NMR (C_6D_6, 200.1 MHz): δ = 1.37 (s, 3 H, BCH_3), 6.96 (dd, $^3J_{H,H}$ = 3.6, $^3J_{H,H}$ = 4.7 Hz, 2 H, C4-H_{th}), 7.37 (dd, $^3J_{H,H}$ = 4.7, $^4J_{H,H}$ = 0.9 Hz, 2 H, CH_{th}), 7.87 ppm (dd, $^3J_{H,H}$ = 3.6, $^4J_{H,H}$ = 0.9 Hz, 2 H, CH_{th}). ^{11}B NMR (C_6D_6, 64 MHz): δ = 57. ^{13}C NMR (C_6D_6, 50 MHz): δ = 12.3 (CB), 129.1 [CH_{th} (C-4)], 136.1, 140.0 ppm (CH_{th}), $C_{th}B$ signal not observed. EI-MS: *m*/*z* (%) = 192 (62) [M^+], 177 (100) [$M^+ - CH_3$].

Phenylbis(2-thienyl)borane (1f): Phenylmagnesium bromide (3.0 M in diethyl ether; 1.7 mL, 5.1 mmol) was added dropwise to a solution of **1d** (1.2 g, 5.1 mmol) in diethyl ether (50 mL) at −20 °C. The mixture was allowed to warm for 20 min and stirred at room temperature for 26 h. Volatile compounds were removed under vacuum, the residue was dissolved in hexane/CH_2Cl_2 (1:4) and filtered. The solvent was evaporated under vacuum and the solid recrystallized from hexane at −80 °C. Yield: 0.7 g (2.7 mmol, 53%) of colorless **1f**, m.p. 85 °C. ^1H NMR (C_6D_6, 200 MHz): δ = 7.04 (m, 2 H, CH_{th}), 7.28 (m, 2 H, CH_{th}), 7.59−8.01 ppm (m, 7 H, CH_{ar}). ^{11}B NMR (C_6D_6, 64 MHz): δ = 49 ppm. ^{13}C NMR (C_6D_6, 50 MHz): δ = 128.1, 129.6, 130.5, 136.7, 136.8, 141.8 (CH_{ar}), 146, 149 ppm (2 × br, CB). EI-MS: *m*/*z* (%) = 254 (100) [M^+].

(Diisopropylamino)bis(2-furanyl)borane (3a): *n*-Butyllithium (2.5 M in hexane; 10.0 mL, 25. mmol) was added at room temperature to a solution of TMEDA (2.7 g, 24. mmol) in hexane (50 mL). The solution was stirred for 30 min and furan (1.4 g, 21 mmol) was added at room temperature. After stirring the mixture for 90 min, it was added to a solution of Cl_2BNiPr_2 (2.2 g, 12. mmol) in hexane (100 mL), within 80 min, at −25 °C. The mixture was allowed to warm to room temperature and stirred for 20 h. Volatile compounds were removed under vacuum, the residue was dissolved in hexane and filtered. The solvent was evaporated under vacuum and the crude product was distilled to give colorless **3a** (1.4 g, 5.5 mmol, 45%), b.p. 65 °C/5·10^{-3} mbar. ^{1}H NMR (C_6D_6, 200 MHz): δ = 1.21 [d, $^3J_{H,H}$ = 6.9 Hz, 12 H, CH(CH_3)$_2$], 3.95 [sept, $^3J_{H,H}$ = 6.9 Hz, 2 H, CH(CH$_3$)$_2$], 6.19 (dd, $^3J_{H,H}$ = 1.7, $^3J_{H,H}$ = 3.3 Hz, 2 H, C4-H$_{fu}$), 6.63 (dd, $^3J_{H,H}$ = 3.3, $^4J_{H,H}$ = 0.7 Hz, 2 H, CH$_{fu}$), 7.39 ppm (dd, $^3J_{H,H}$ = 1.7, $^4J_{H,H}$ = 0.7 Hz, 2 H, CH$_{fu}$). ^{11}B NMR (C_6D_6, 64 MHz): δ = 30 ppm. ^{13}C NMR (C_6D_6, 50 MHz): δ = 23.5 [CH(*C*H$_3$)$_2$], 49.4 [*C*H(CH$_3$)$_2$], 110.4 [CH$_{fu}$ (C-4)], 123.4, 145.2 ppm (CH$_{fu}$), CB signal not observed. EI-MS: *m*/*z* (%) = 245 (16) [M$^+$], 230 (100), [M$^+$ − CH$_3$]. HR EI-MS: *m*/*z* (%) = 245.1608 [M$^+$]; calcd. for $^{12}C_{12}{}^1H_{16}{}^{11}B^{14}N^{32}S_2$ 245.1587 (Δmmu = 2.1).

Bis(5-bromo-2-thienyl)(diethylamino)borane (1b′): A solution of **1b** (1.3 g, 5.0 mmol) in THF (65 mL) was cooled to −78 °C and *N*-bromosuccinimide (1.5 g, 10 mmol) was added in portions. The mixture turned yellow to orange and was allowed to warm to room temperature. The solvent was removed under vacuum and pentane was added to the residue. After filtering the succinimide off, the solvent of the yellow solution was evaporated. The yellow viscous oil was crystallized from pentane at −30 °C to give colorless **1b′** (1.5 g, 3.8 mmol, 75%), m.p. 132 °C. ^{1}H NMR (CDCl$_3$, 200 MHz): δ = 1.15 (t, CH_3CH$_2$, $^3J_{H,H}$ = 7.0 Hz, 6 H), 3.28 (q, CH$_3$CH_2, $^3J_{H,H}$ = 7.0 Hz, 4 H), 6.79 (m, 4 H, CH_{th}), 6.90 ppm (m, 2 H, CH_{th}). ^{11}B NMR (CDCl$_3$, 64 MHz): δ = 34 ppm. ^{13}C NMR (CDCl$_3$, 50 MHz): δ = 16.3 (*C*H$_3$CH$_2$), 44.9 (CH$_3$*C*H$_2$), 114.1, 130.0, 135.4 (C$_{th}$), 144 ppm (br, CB). MS: *m*/*z* (%) = 407 (12) [M$^+$], 392 (15) [M$^+$ − CH$_3$].

Bis(5-bromo-1-methyl-2-pyrrolyl)(diisopropylamino)borane (2a′): This compound was prepared analogously to **1b′** from **2a** (1.4 g , 5.0 mmol) and *N*-bromosuccinimide (1.5 g, 10 mmol) of. Yield: 1.9 g (4.5 mmol, 89%) of colorless **2a′**, m.p. 145 °C. ^{1}H NMR (CDCl$_3$, 200 MHz): δ = 1.15 [d, $^3J_{H,H}$ = 6.9 Hz, 12 H, CH(CH_3)$_2$], 3.02 (s, 6 H, NCH$_3$), 3.94 [sept,$^3J_{H,H}$ = 6.9 Hz, CH(CH$_3$)$_2$, 2 H], 6.08 (d, $^3J_{H,H}$ = 3.7 Hz, 2 H, CH$_{py}$), 6.22 ppm (d, $^3J_{H,H}$ = 3.7 Hz, 2 H, CH$_{py}$). ^{11}B NMR (CDCl$_3$, 64 MHz): δ = 35 ppm. ^{13}C NMR (CDCl$_3$, 50 MHz): δ = 25.0 [CH(*C*H$_3$)$_2$], 34.5 (N−CH$_3$), 49.3 [*C*H(CH$_3$)$_2$], 105.2, 110.2, 116.4 (CH$_{py}$), 139 ppm (br, CB). MS: *m*/*z* (%) = 429 (60) [M$^+$], 350 (15) [M$^+$ − Br]. HR-MS: *m*/*z* (%) = 427.0409 [M$^+$]; calcd. for $^{12}C_{16}{}^1H_{24}{}^{11}B^{79}Br_2{}^{14}N_3$ 427.0430 (Δmmu = 2.1).

Bis(5-bromo-2-furanyl)(diisopropylamino)borane (3a′): This compound was prepared analogously to **1b′** from **3a** (1.2 g, 5.0 mmol) and *N*-bromosuccinimide (1.5 g, 10 mmol). The mixture turned dark brown and was allowed to warm to room temp. for 16 h. The solvent was removed under vacuum and pentane was added. After filtering the succinimide off, the solvent of the yellow solution was evaporated. The yellow, viscous oil turned orange and needed no further purification. Yield: 1.4 g (3.5 mmol, 70%) of orange **3a′**. ^{1}H NMR (CDCl$_3$, 200 MHz): δ = 1.16 [d, $^3J_{H,H}$ = 6.9 Hz, 12 H, CH(CH_3)$_2$], 3.82 [sept,$^3J_{H,H}$ = 6.9 Hz, 2 H, CH(CH$_3$)$_2$], 6.21 (d, $^3J_{H,H}$ = 3.7 Hz, 2 H, CH$_{fu}$), 6.41 ppm (d, $^3J_{H,H}$ = 3.7 Hz, 2 H, CH$_{fu}$). ^{11}B NMR (CDCl$_3$, 64 MHz): δ = 29 ppm. ^{13}C NMR (CDCl$_3$, 50 MHz): δ = 23.8 [CH(*C*H$_3$)$_2$], 48.3 [*C*H(CH$_3$)$_2$], 112.0, 125.7, 145.5 ppm (CH$_{fu}$), CB signal not observed . MS: *m*/*z* (%) = 403 (6) [M$^+$], 324 (60) [M$^+$ − Br]. HR-MS: *m*/*z* (%) = 400.9823 [M$^+$]; calcd. for $^{12}C_{14}{}^1H_{18}{}^{11}B^{79}Br_2{}^{14}N^{16}O_2$ 400.9797 (*Δmmu* = 2.6).

Macrocycle 4b: A solution of bis(5-bromo-1-methyl-2-pyrrolyl)(diisopropylamino)borane [**2a′**, 481 mg (1.1 mmol)] was added to a suspension of lithium powder (13 mg, 2.2 mmol) in THF (30 mL) at −78 °C. The color of the suspension changed to bright orange. After 2 h of stirring, the mixture was allowed to warm to −20 °C. Excess lithium was filtered off and the solution cooled to −40 °C. A solution of dichloro(diisopropylamino)borane (0.21 g, 1.2 mmol) in pentane (20 mL) was added over 2 h and warmed overnight to room temperature. Insoluble salts were filtered and the volatile compounds evaporated leaving a brown oily residue that could not be purified by column chromatography or crystallization. ^{11}B NMR (CDCl$_3$, 64 MHz): δ = 33 ppm. MS: *m*/*z* (%) = 760 (13) [M$^+$], 717 (3) [M$^+$ − *i*Pr]. HR-MS: *m*/*z* (%) = 760.6600 [M$^+$]; calcd. for $^{12}C_{44}{}^1H_{76}{}^{11}B_4{}^{14}N_8$ 760.6565 (Δmmu = 3.5).

X-ray Structure Determination of 3b: Crystal data and details of the structure determination are listed in Table 1. Intensity data for **3b** were collected at −83 °C with a Bruker AXS SMART 1000 diffractometer (Mo-K_α radiation, λ = 0.71073 Å, graphite monochromator, ω-scan). An empirical absorption correction was applied. The structure was solved by direct methods (SHELXS-86)[16] and refined by least-squares methods based on F^2 with all measured reflections (SHELXL-97).[16] All non-hydrogen atoms are refined anisotropically. Hydrogen atoms were located in difference Fourier maps and refined isotropically. CCDC-177342 (**3b**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 1. Crystal data and structure refinement for **3b**

Empirical formula	$C_{12}H_9BO_3$
Formula mass	212.00
Crystal system	cubic
Space group	$P2_13$
Unit cell dimensions	a = 10.2961(4) Å
Volume	1091.49(7) Å^3
Z	4
Density (calculated)	1.29 g/cm^3
Absorption coefficient	0.091 mm^{-1}
F(000)	440
Crystal size	0.36 × 0.30 × 0.20 mm
θ_{max}	32.40°
Reflections collected	7894
Independent reflections	1272 [R(int) = 0.0332]
Final R indices [$I > \sigma(I)$]	$R1$ = 0.0387, $wR2$ = 0.1004
R indices (all data)	$R1$ = 0.0463, $wR2$ = 0.1084
Largest diff. peak/hole	0.288/-0.124 e·Å^{-3}

Thermodynamics of Redox Processes and Kinetics and Mechanism of Electron Self-Exchange Reactions in the Bis(*N*,*N*-diethyldithiocarbamato)copper(II)/Iodine/Dichloromethane System

Valery G. Shtyrlin,*[a] Alexey V. Zakharov,*[a] Andrey M. Kuznetsov,[b] Ol'ga V. Kukushkina,[a] and Pavel P. Chernov[a]

Keywords: Copper / Electron-transfer kinetics / Reaction mechanisms / Redox reactions thermodynamics / S ligands

The thermodynamics of complex formation between Et_4NI and I_2 in CH_2Cl_2 and the redox processes in the bis(*N*,*N*-diethyldithiocarbamato)copper(II) $[Cu^{II}L_2]/I_2/CH_2Cl_2$ system have been studied spectrophotometrically. The reversibility of the reactions of formation of copper(III) complexes was established and their thermodynamic parameters determined: $Cu^{II}L_2 + {}^3/_2I_2 \rightleftarrows [Cu^{III}L_2]I_3$ {log$K$ = 5.80 (298 K), ΔH = –35.0 kJ·mol^{-1}, and ΔS = –6.7 J·K^{-1}·mol^{-1}} and $[Cu^{III}L_2]I_3 + I_2 \rightleftarrows [Cu^{III}L_2]I_5$ {log$K$ = 2.02 (298 K), ΔH = –11.1 kJ·mol^{-1}, and ΔS = 1.3 J·K^{-1}·mol^{-1}}. The rate constants and activation parameters for the electron self-exchange reactions between $Cu^{II}L_2$ and $[Cu^{III}L_2]I_n$ (n = 3, 5) in the CD_2Cl_2 solutions were determined by NMR line-broadening of the ligand L protons: $k_e = 3.0 \cdot 10^8$ M^{-1}·s^{-1} (298 K), $\Delta H^{\neq} = 6.1$ kJ·mol^{-1}, and $\Delta S^{\neq} = -62.3$ J·K^{-1} mol^{-1}. To account for the kinetic parameters, an unusual mechanism for the self-exchange reaction was suggested. This mechanism involves the prior formation of the $Cu^{II}L_2I_nCu^{III}L_2$ intermediate, in which considerable delocalization of electron density through the orbitals of copper and bridging iodine atoms is achieved, followed by electron transfer. The formation of the intermediate was supported by ESR data and quantitative analysis of the activation parameters with the use of quantum chemical computations by the DFT method at the B3LYP/3-21G* level.

Introduction

The study of redox reactions of Cu^I, Cu^{II}, and Cu^{III} complexes with sulfur-containing ligands is of interest for fundamental understanding of electron-transfer mechanisms. In this regard, the interconversions of copper(II) and copper(III) dithiocarbamates deserve particular attention. The electrochemical oxidation of the copper(II) dithiocarbamates to copper(III) is a reversible process at a platinum electrode.[1] With a "soft" oxidative agent such as iodine, one would also expect a reversible copper(II)/copper(III) transformation in solution. This would in principle allow one to evaluate both the thermodynamic parameters of the redox processes and the kinetic characteristics of the copper(II)/copper(III) electron self-exchange reactions. A first attempt to turn these possibilities into reality has been undertaken in this work.

We have investigated the thermodynamics of the redox processes and kinetics of the electron self-exchange reactions in the bis(*N*,*N*-diethyldithiocarbamato)copper(II) $[Cu^{II}L_2]/I_2/CH_2Cl_2$ (CD_2Cl_2) system by means of spectrophotometric, NMR, and ESR methods. Moreover, for the characterization of polyiodide anions forming in these solutions, the thermodynamics of complex formation in the $Et_4NI/I_2/CH_2Cl_2$ system have been studied spectrophotometrically.

Previously,[1–5] treatment of copper(II) *N*,*N*-dialkyldithiocarbamates ($Cu^{II}L'_2$) with iodine had resulted in the isolation of copper(III) complexes of compositions $[Cu^{III}L'_2]I_3$[1–5] and $[Cu^{III}L'_2]I_5$[4] as crystals. Two of these, $[Cu^{III}(S_2CNnBu_2)_2]I_3$ and $[Cu^{III}(S_2CNEt_2)_2]I_3$, have been characterized by X-ray data.[3,5] No thermodynamic or kinetic parameters of reactions of this type have been reported in the literature.

To the best of our knowledge, the only directly studied copper(II)/copper(III) electron self-exchange reaction was the electron transfer between the copper complexes with the deprotonated tripeptide tris-α-aminoisobutyrate $[Aib_3H_{(-2)}{}^{3-}]$ in aqueous medium.[6] Those authors[6] had suggested an outer-sphere electron exchange mechanism, but not ruled out bridging by an axially bound water molecule. In this investigation we have attempted to elucidate the mechanism of the electron self-exchange reaction between the copper(II) and copper(III) dithiocarbamates.

Results and Discussion

Thermodynamics of Complex Formation and Redox Processes

For interpretation of the experimental data in the $Cu^{II}L_2/I_2/CH_2Cl_2$ system, previous investigations of complex formation between Et_4NI and I_2 in CH_2Cl_2 are of considerable significance. The I_2 concentration-dependence of the molar absorption coefficient (ε) of Et_4NI in CH_2Cl_2 solutions (Figure 1) is adequately computer-simulated by two equilibria with consecutive addition of two I_2 molecules to Et_4NI, but the first equilibrium constant (K_1) cannot be exactly estimated at these concentration conditions. The K_1 values were therefore deduced from the dependence of the molar absorption coefficient of the I_2 solution ($c_{I_2} = 2\cdot10^{-5}$ M) upon the Et_4NI concentration ($2\cdot10^{-6}$ to $8\cdot10^{-5}$ M) at λ 365 nm (Table S1, Supporting Information), and these values were then fixed at computations of the addition constant of I_2 to Et_4NI_3 (K_2) from the above-mentioned $\varepsilon - c_{I_2}$ dependence at λ 400 nm (Table S2). The enthalpy (ΔH) and entropy (ΔS) of each equilibrium were calculated from the log $K_{1,2}$ magnitudes at different temperatures. The derived $\log K_{1,2}$, $\Delta H_{1,2}$, and $\Delta S_{1,2}$ parameters are given in Table 1. With the aid of the computed mol fractions of the Et_4NI_3 and Et_4NI_5 compounds their electronic absorption spectra were reconstructed (Figure 2).

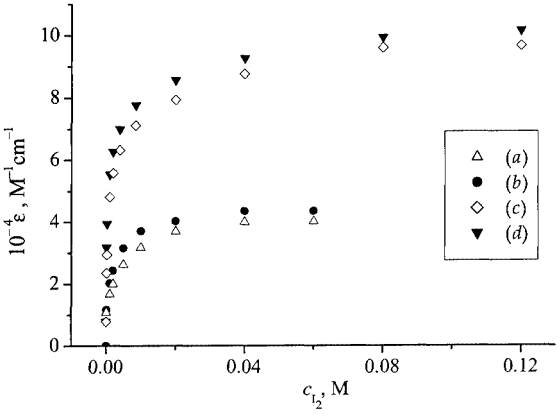

Figure 1. Dependence of the molar absorption coefficient (ε) upon the I_2 concentration in the systems $Et_4NI/I_2/CH_2Cl_2$ (*a*, *b*) and $Cu^{II}L_2/I_2/CH_2Cl_2$ (*c*, *d*) at 298 K (*a*, *c*) and 278 K (*b*, *d*), $c_{CuL_2} = 1\cdot10^{-4}$ M (*a*, *b*), $c_{Et_4NI} = 6.25\cdot10^{-5}$ M (*c*, *d*); λ = 400 nm

Table 1. Thermodynamic parameters of equilibria in the systems $Et_4NI/I_2/CH_2Cl_2$ and $Cu^{II}L_2/I_2/CH_2Cl_2$

Equilibrium	log*K* (298 K)	Δ*H* [kJ·mol^{-1}]	Δ*S* [J·K^{-1}·mol^{-1}]
$Et_4NI + I_2 \rightleftarrows Et_4NI_3$	7.20±0.10	−60.0±4.4	−63.6±15.1
$Et_4NI_3 + I_2 \rightleftarrows Et_4NI_5$	2.33±0.03	−16.8±1.0	−11.6±3.4
$Cu^{II}L_2 + 3/2I_2 \rightleftarrows [Cu^{III}L_2]I_3$	5.80±0.04	−35.0±1.3	−6.7±4.6
$[Cu^{III}L_2]I_3 + I_2 \rightleftarrows [Cu^{III}L_2]I_5$	2.02±0.06	−11.1±1.0	1.3±3.5

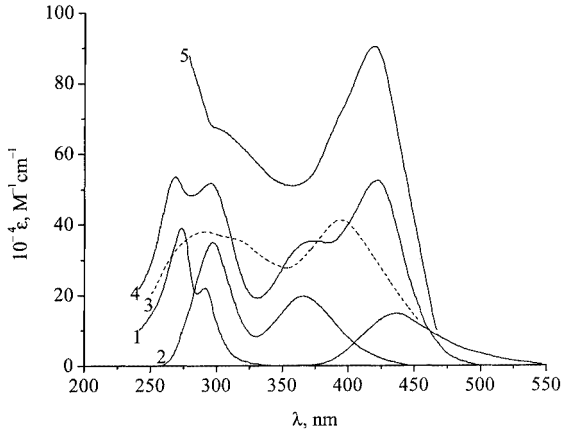

Figure 2. Electronic absorption spectra of $Cu^{II}L_2$ (1), Et_4NI_3 (2), Et_4NI_5 (3), $[Cu^{III}L_2]I_3$ (4), and $[Cu^{III}L_2]I_5$ (5) in CH_2Cl_2 at 298 K

Two absorption bands of the I_3^- spectrum in CH_2Cl_2 have the parameters λ_{max} 363 nm (ε_{max} $2.5\cdot10^4$ M^{-1}·cm^{-1}) and λ_{max} 293 nm (ε_{max} $4.3\cdot10^4$ M^{-1}·cm^{-1}), which are essentially coincident with those reported for triiodide anion in CH_2Cl_2,[7] acetonitrile, and 1,2-dichlorethane[8] and somewhat different from those found for I_3^- in water.[9,10] These two bands correspond[7,11–13] to the allowed singlet-singlet transitions $\pi_g \rightarrow \sigma_u^*$ and $\sigma_g \rightarrow \sigma_u^*$, respectively, for the linear I_3^- anion with nominal $D_{\infty h}$ symmetry (in theoretical studies this symmetry is predicted for the gas phase[11–17] but it can be slightly broken by solvation[18,19]).

The I_5^- spectrum in CH_2Cl_2 exhibits bands at λ_{max} 392 nm (ε_{max} $5.0\cdot10^4$ M^{-1}·cm^{-1}) and λ_{max} 288 nm (ε_{max} $4.6\cdot10^4$ M^{-1}·cm^{-1}) with a "shoulder" at λ_{sh} 312 nm (ε_{sh} $4.4\cdot10^4$ M^{-1}·cm^{-1}); these differ from those in acetonitrile (λ_{max} 390 nm, ε_{max} $2.5\cdot10^4$ M^{-1}·cm^{-1}; λ_{max} 310 nm, ε_{max} $2.1\cdot10^4$ M^{-1}·cm^{-1})[20] and in *tert*-butyl alcohol (λ_{max} 395 nm, ε_{max} $3.1\cdot10^4$ M^{-1}·cm^{-1}; λ_{max} 315 nm, ε_{max} $2.5\cdot10^4$·M^{-1} cm^{-1}).[20] In solid compounds, the I_5^- anion exhibits either a bent structure (symmetry C_{2v})[12,21–23] or a linear structure (symmetry $D_{\infty h}$).[24–28] According to calculations,[15,29] however, interconversions between these I_5^- conformations under vacuum require little or no energy expenditure. In our opinion the band at 392 nm (25510 cm^{-1}) in the I_5^- spectrum can be assigned to the allowed $4\sigma_u \rightarrow 5\sigma_g^*$ transition for the $D_{\infty h}$ symmetry or the $6b_1 \rightarrow 8a_1^*$ transition for the C_{2v} symmetry (see notations in ref.[15]) and the band at 288 nm (34720 cm^{-1}) and the "shoulder" at λ_{sh} 312 nm (32050 cm^{-1}) are attributable to the allowed transitions $3\pi_u \rightarrow 5\sigma_g^*$ ($D_{\infty h}$ symmetry) and $3b_2 \rightarrow 8a_1^*$ (C_{2v} symmetry), respectively. This assignment is in good accordance with the theoretically calculated difference between the $4\sigma_u$ and $3\pi_u$ orbital energies (9130 cm^{-1})[15] or between the $6b_1$ and $3b_2$ orbital energies (7290 cm^{-1}).[15]

The $\log K_1$ value obtained (Table 1) is very similar to the reported values of $\log K_1$ in nitromethane (6.7[30] and 7.4[31] at 293 K), nitrobenzene (8.0),[32] sulfolane (7.4),[33] ethylene carbonate (6.6 at 313 K),[34] propylene carbonate (7.9),[35] acetonitrile (6.6,[30] 7.0,[31] 7.4,[36] 6.85,[37] 6.75,[38] and

6.80[39]), dimethylacetamide (7.4),[39] DMF (7.0),[39] and DMSO (6.9),[39] while differing fundamentally from the $\log K_1$ values in methanol (4.94[38] and 4.30[39]), ethanol (4.13[38] and 4.70[38]), and water (2.85,[9] 2.86,[10] and 2.84[38]). The $\log K_2$ value found (Table 1) is fairly close to the $\log K_2$ values in nitrobenzene (2.7),[32] ethylene carbonate (1.8 at 313 K),[34] propylene carbonate (1.9),[35] acetonitrile (2.0−2.3),[20] and *tert*-butyl alcohol (2.03)[20] (the data for water are contradictory: $\log K_2 = 0.95$[40] or 2.3[41]). As is evident from Table 1, the difference between $\log K_1$ and $\log K_2$ is mainly the result of the enthalpy constituent. This also governs the decrease in $\log K_1$ on going from CH_2Cl_2 to H_2O ($\Delta H_1 = -21.3$[9] or -19.9[10,40] kJ·mol^{-1}). The more positive ΔS_2 value relative to ΔS_1 (Table 1) accounts for the rigid I_3^- structure and the flexible I_5^- structure with interconversions between the bent and linear I_5^- conformers,[15,29] as mentioned above.

Let us consider the $Cu^{II}L_2/I_2/CH_2Cl_2$ system. The excellently reproducible dependence of the molar absorption coefficient of the $Cu^{II}L_2$ solutions on the I_2 concentration can be computer-simulated equally well by two alternative equilibrium models involving formation of the following pairs of complexes: 1) $[Cu^{III}L_2]I$ and $[Cu^{III}L_2]I_3$, or 2) $[Cu^{III}L_2]I_3$ and $[Cu^{III}L_2]I_5$ (Table S3). The electronic absorption spectra were reconstructed for each pair of complexes on the basis of their respective calculated equilibrium constants, and these pointed unambiguously to the suitability of the second model only. Indeed, the reconstructed spectra of $[Cu^{III}L_2]I_3$ and $[Cu^{III}L_2]I_5$ (Figure 2) are superpositions of the I_3^- and I_5^- spectra discussed above and the spectrum of the $[Cu^{III}L_2]^+$ cation produced by the electrochemical oxidation of $Cu^{II}L_2$.[1] Note that the asymmetric band at λ_{max} 435 nm for $Cu^{II}L_2$ (Figure 2) is attributable to the composition of two ligand-to-metal charge-transfer transitions,[42,43] $\pi S \rightarrow 3d_{x^2-y^2}$ (two bands with λ_{max} 270 and 290 nm in the $Cu^{II}L_2$ spectra (Figure 2) correspond to pure ligand $\pi \rightarrow \pi^*$ transitions).[43] By analogy, the band at λ_{max} 418 nm for $[Cu^{III}L_2]^+$ (Figure 2) can be assigned to the $\pi S \rightarrow 3d_{x^2-y^2}$ transitions. Thus, according to the spectrophotometric data, the following equilibria operate in the $Cu^{II}L_2/I_2/CH_2Cl_2$ system:

$$Cu^{II}L_2 + 3/2I_2 \overset{K_3}{\rightleftharpoons} [Cu^{III}L_2]I_3 \quad (1)$$

$$[Cu^{III}L_2]I_3 + I_2 \overset{K_4}{\rightleftharpoons} [Cu^{III}L_2]I_5 \quad (2)$$

The validity of reactions according to Equations (1) and (2) was supported by the isolation of $[Cu^{III}L_2]I_3$ and $[Cu^{III}L_2]I_5$ crystals under suitable concentration conditions (see Exp. Sect.). The reversibility of process (2) is apparent from its similarity to the Et_4NI_5 formation reaction described above. The reversibility of process (1) was established by ESR in the following manner. Dissolution of the diamagnetic $[Cu^{III}L_2]I_3$ crystals in CH_2Cl_2 ($c_{Cu} = 1\cdot10^{-3}$ M) gives rise to the ESR spectrum with the spin-Hamiltonian parameters $g_o = 2.048\pm0.001$ and $A_o = (75.8\pm0.5)\cdot10^{-4}$ cm^{-1} (298 K), which correspond to the $Cu^{II}L_2$ complex. The integral intensity of the ESR signals of the $[Cu^{III}L_2]I_3$ solution in question is 25(±3)% of that for the $Cu^{II}L_2$ solution at the same concentration ($1\cdot10^{-3}$ M). This value is nearly equal to the $Cu^{II}L_2$ fraction (22.1%) calculated for the $[Cu^{III}L_2]I_3$ dissociation from the obtained K_3 and K_4 constants. This leftward shift of equilibrium (1) is suppressed by introduction of iodine into the $Cu^{II}L_2$ solution: at $c_{I_2} = 0.1$ M the ESR spectrum disappeared entirely.

The equilibrium constants of Equations (1) and (2) and the thermodynamic parameters computed from the temperature-dependence of $\log K_3$ and $\log K_4$ are listed in Table 1. The $\log K_3$ constant can be presented as a sum of three contributions [Equation (3)]

$$\log K_3 = -\frac{\Delta G_3^0}{2.3RT} = \frac{nF}{2.3RT}\cdot\Delta E^0 + \log K_{M^+I^-} + \log K_{MI_3} \quad (3)$$

where ΔG_3^0 is the standard free energy of the reaction (1), ΔE^0 is the standard electromotive force[44] of the reaction $Cu^{II}L_2 + {}^1/_2I_2 \rightleftarrows [Cu^{III}L_2]^+ + I^-$, $K_{M^+I^-}$ is the constant of the association process $[Cu^{III}L_2]^+ + I^- \rightleftarrows [Cu^{III}L_2]I$, and K_{MI_3} is the constant of the equilibrium $[Cu^{III}L_2]I + I_2 \rightleftarrows [Cu^{III}L_2]I_3$. With the requirement that replacement of $M^+ = [Cu^{III}L_2]^+$ by $M^+ = Et_4N^+$ has little or no effect on the constants above, it is possible to take $\log K_{MI_3} = K_1 = 7.20$ and $\log K_{M^+I^-} = 4.9$.[44] With these values and $\log K_3 = 5.80$ (Table 1), according to Equation (3), a value of $\Delta E^0 = -0.375$ V (298 K) would be estimated. The ΔE^0 value in CH_2Cl_2 has not been determined by electrochemical methods, but the ΔE^0 value obtained above is reasonably close to the difference between the normal electrode potential for the reaction ${}^1/_2I_2 + e^- \rightarrow I^-$ (0.36 V in acetone)[30] and the half-wave potential for the oxidation process $Cu^{II}L_2 \rightleftarrows [Cu^{III}L_2]^+ + e^-$ (0.70 V in acetone).[1] Thus, the spontaneous course of reaction (2) in dichloromethane is provided by the energy-favorable processes of triiodide anion formation and ionic association.

The thermodynamic description achieved for the $Cu^{II}L_2/I_2/CH_2Cl_2$ system allows one to regulate the Cu^{II} and Cu^{III} contents by varying the I_2 concentration and to study the kinetics of electron self-exchange reactions between the complexes $Cu^{II}L_2$ and $[Cu^{III}L_2]I_n$ ($n = 3, 5$) at different temperatures on this basis.

Kinetics of Electron Self-exchange

^{1}H NMR spectra of the $Cu^{II}L_2$ solutions in CD_2Cl_2 display only the signal of the methyl protons of the coordinated L ligand, with the chemical shift (δ) varying from 0.36 to 0.67 ppm and the line-width ($\Delta\nu_{1/2}$) decreasing from 86 to 46 Hz as the temperature increases from 248 to 298 K; the ^{1}H NMR signal of the L methylene protons is so broad that it defies observation. As iodine is added to the $Cu^{II}L_2$ solution ($c_{I_2} \leq 1\cdot10^{-3}$ M), the NMR signal of the CH_3-protons is progressively narrowed and shifted to low field (the signal of the CH_2-protons remains unobservable). Such a situation corresponds to a "fast exchange"[45] of the L methyl protons between two different environments **A** (dia-

magnetic $[Cu^{III}L_2]I_n$) and **B** (paramagnetic $Cu^{II}L_2$) through electron self-exchange. On a further increase in the I_2 concentration (above $1\cdot10^{-2}$ M), multiplet structures of the ^1H NMR signals appear for both methyl and methylene protons, and their chemical shifts cease to be changed and range up to 1.41−1.43 and 3.81−3.85 ppm, respectively. In the I_2 concentration interval from 0.03 to 0.12 M, with decreasing I_2 content (and correspondingly increasing $Cu^{II}L_2$ fraction), the line-widths of the methyl triplet are essentially unaffected, while the lines of the methylene quadruplet are significantly broadened. The line-widths of the CH_3-protons decrease and those of the CH_2-protons increase with increasing temperature from 268 to 298 K (Figure 3). All these facts clearly attest to the "fast exchange" limiting case being reached for the methyl protons and the "slow exchange" limiting case for the methylene protons (see ref.[45]).

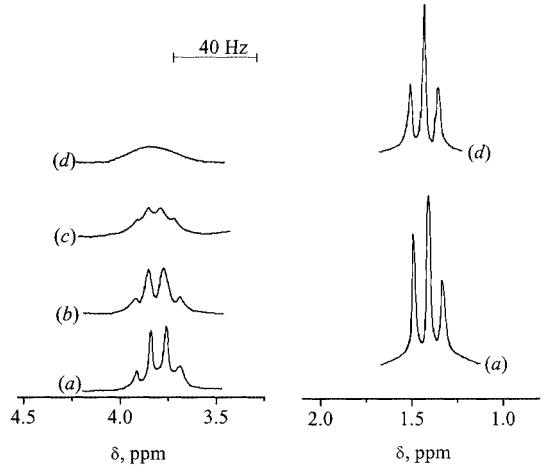

Figure 3. ^1H NMR spectra of the $Cu^{II}L_2$ solutions in CD_2Cl_2 with I_2 (0.04 M) at 268 K (*a*), 278 K (*b*), 288 K (*c*), and 298 K (*d*); $c_{CuL_2} = 1.5\cdot10^{-3}$ M

Under conditions suitable for the quantitative kinetic experiments ($c_{I_2} = 0.03-0.12$ M and $T = 268-298$ K) the mol fractions (P) calculated from the K_3 and K_4 constants change from $3.7\cdot10^{-7}$ to $5.0\cdot10^{-5}$ for $Cu^{II}L_2$, from 0.048 to 0.238 for $[Cu^{III}L_2]I_3$, and from 0.952 to 0.762 for $[Cu^{III}L_2]I_5$. Consequently, the condition [**A**] >> [**B**] is obeyed, and with this the exchange between **A** ($[Cu^{III}L_2]I_n$) and **B** ($Cu^{II}L_2$) is described by the Swift−Connick equation,[46] which at $\Delta\omega_{AB} \approx 0$ is reduced to relation (4)

$$\pi\Delta\Delta\nu_{1/2} = \frac{1}{T_2} = \frac{1}{T_{2A}} + \frac{P_B}{T_{2B} + \tau_B} \qquad (4)$$

where P_B is the mol fraction of $Cu^{II}L_2$, T_{2A} and T_{2B} denote the transverse relaxation times of the protons in the dia- and paramagnetic positions, respectively, and τ_B is the lifetime of the protons in the latter position. Equation (4) holds for the bimolecular electron self-exchange reaction according to Equation (5)

$$Cu^{II}L_2 + [{}^{*}Cu^{III}L_2]I_n \underset{k_e}{\rightleftharpoons} [Cu^{III}L_2]I_n + {}^{*}Cu^{II}L_2 \quad (n = 3, 5) \qquad (5)$$

under the condition that the chemical shifts of the **A** form, the T_{2A} relaxation times, and the electron self-exchange rate constants (k_e) are independent on the size of the I_n^- counter-ion (n = 3, 5) with $\tau_B^{-1} = k_e[Cu^{III}L_2I_n]$ in this case. From the above values of P_B and $\Delta\nu_{1/2} = (\pi\cdot T_{2B}{}^{CH_3})^{-1}$ for the CH_3-protons in $Cu^{II}L_2$ it follows that at c_{I_2} = 0.03−0.12 M the contribution of the last term in Equation (4) to the methyl proton line-widths is negligibly small (< 0.01 Hz). Because of this, for the "slow exchange" of the L methylene protons ($T_{2B}{}^{CH_2} << \tau_B$), the difference of the NMR line-widths of the CH_2- and CH_3-protons ($\Delta\Delta\nu_{1/2}$) can be represented by Equation (6) {with $P_B[Cu^{III}L_2I_n] = [Cu^{II}L_2]$}

$$\pi\Delta\Delta\nu_{1/2} = \pi\left(\Delta\nu_{1/2}^{CH_2} - \Delta\nu_{1/2}^{CH_3}\right) = \left(\frac{1}{T_{2A}^{CH_2}} - \frac{1}{T_{2A}^{CH_3}}\right) + k_e\left[Cu^{II}L_2\right] \qquad (6)$$

The application of the $\pi\Delta\Delta\nu_{1/2}$ parameter has the advantage that this enables one to eliminate almost fully the $\Delta\nu_{1/2}{}^{CH_2}$ contributions from the variation of the solution viscosity, the magnetic field inhomogeneity, the signal acquisition regime, and so on as $T_{2A}{}^{CH_2} << T_{2A}{}^{CH_3}$. As Figure 4 suggests, plots of the $\pi\Delta\Delta\nu_{1/2}$ parameter as a function of $[Cu^{II}L_2]$ are linear, with small intercepts. Therefore, all discussed conditions for the use of Equation (6) are fulfilled. True, it should be pointed out that the k_e constant accounts mainly for the $Cu^{II}L_2/[Cu^{III}L_2]I_5$ exchange because of a predominance of the last form at the kinetic experiment conditions (Table S4). (The experimental relationship $T_{2B}{}^{CH_2} << T_{2B}{}^{CH_3}$, as used above, can reasonably be explained in terms of a dipole−dipole mechanism of the proton relaxation[45] by virtue of a greater distance from the paramagnetic center for the methyl protons of L than for the methylene protons). From the k_e constants derived by Equation (6) at different temperatures (Table S4), the activation enthalpy ($\Delta H^{\neq}$) and entropy ($\Delta S^{\neq}$) of the electron self-exchange reaction were determined by application of the Eyring equation. The obtained values of k_e, $\Delta H^{\neq}$, and

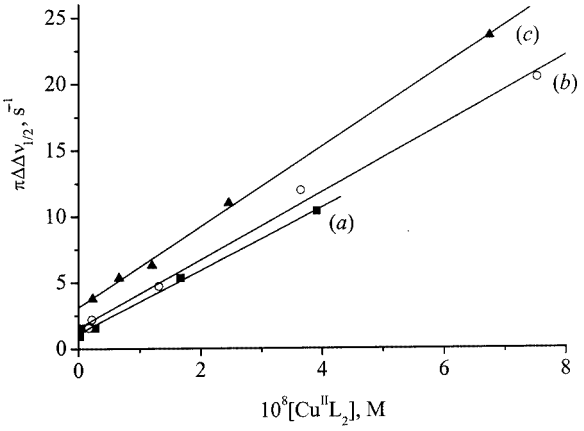

Figure 4. Dependence of the $\pi\Delta\Delta\nu_{1/2}$ parameter on $[Cu^{II}L_2]$ in the $Cu^{II}L_2/I_2/CD_2Cl_2$ system at 278 K (*a*), 288 K (*b*), and 298 K (*c*)

Table 2. Rate constants and activation parameters of the electron self-exchange reaction in the CD_2Cl_2 solution

$$Cu^{II}L_2 + [{}^{*}Cu^{III}L_2]I_n \underset{}{\overset{k_e}{\rightleftharpoons}} [Cu^{III}L_2]I_n + {}^{*}Cu^{II}L_2 \quad (n = 3,5)$$

T, K	k_e [$M^{-1}\,s^{-1}$]	
268	$(2.04\pm0.21)\cdot10^8$	
278	$(2.38\pm0.09)\cdot10^8$	$\Delta H^{\neq} = 6.1\pm0.9$ kJ·mol^{-1}
288	$(2.57\pm0.09)\cdot10^8$	$\Delta S^{\neq} = -62.3\pm3.0$ J·K^{-1}·mol^{-1}
298	$(3.04\pm0.07)\cdot10^8$	

$\Delta S^{\neq}$ are listed in Table 2 and are essentially different from those found for the related electron self-exchange reaction between the copper(II) and copper(III) complexes (with tris-α-aminoisobutyrate as a ligand) in aqueous medium ($k_e = (5.5\pm0.1)\cdot10^4$ M^{-1}·s^{-1} (298 K), $\Delta H^{\neq} = 29\pm2$ kJ·mol^{-1}, and $\Delta S^{\neq} = -54\pm8$ J·K^{-1}· mol^{-1}).[6]

Mechanism of the Electron Self-exchange Reactions

The remarkably high values of the rate constants and some unusual $\Delta H^{\neq}$ magnitude for the exchange of the σ* ($3_{dx^2-y^2}$) electron between the $Cu^{II}L_2$ and $[Cu^{III}L_2]I_n$ complexes are difficult to account for by an ordinary outer-sphere mechanism. We therefore suggest a special outer-sphere mechanism of this process, involving prior formation of a fairly stable associate of reagents (intermediate) − $Cu^{II}L_2I_nCu^{III}L_2$ − in which the essential delocalization of the electron density through the orbitals of the copper and the bridging iodine atoms is achieved, followed by an efficient electron transfer.

Direct evidence of the formation of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate was deduced by us from comparison of the ESR spectra of the $5\cdot10^{-3}$ M $Cu^{II}L_2$ solutions in CH_2Cl_2 (or CH_2Cl_2/toluene 1:1) without and with I_2 ($3.8\cdot10^{-3}$ M). At this I_2 concentration − according to the thermodynamic data (Table 1) − as much $[Cu^{III}L_2]I_3$ complex arises as $Cu^{II}L_2$ remains (ca. $2.5\cdot10^{-3}$ M). In liquid solutions at 293 K, the obtained isotropic spin-Hamiltonian parameters for $Cu^{II}L_2$ without and with I_2 are the same within the limits of experimental error [$g_o = 2.048\pm0.001$ and $A_o = (75.8\pm0.5)\cdot10^{-4}$ cm^{-1}] and close to the literature data for $Cu^{II}L_2$ solutions in other noncoordinating solvents.[47,48] In frozen solutions at 77 K, alternatively, the anisotropic ESR spectra of $Cu^{II}L_2$ without and with I_2 differ from one another markedly [Figure 5 (*a*) and (*b*)]. Computer simulation of the ESR spectra in view of the known relations[49] by the program produced previously[50] enabled the following parameters of the axial-symmetry spin-Hamiltonian to be determined: $g_\parallel = 2.087$, $g_\perp = 2.025$, $A_\parallel^{63} = 163.4\cdot10^{-4}$ cm^{-1}, $A_\parallel^{65} = 174.8\cdot10^{-4}$ cm^{-1}, $A_\perp = 43.1\cdot10^{-4}$ cm^{-1} for the (*a*) spectrum, as well as $g_\parallel = 2.090$, $g_\perp = 2.027$, $A_\parallel^{63} = 160.5\cdot10^{-4}$ cm^{-1}, $A_\parallel^{65} = 171.8\cdot10^{-4}$ cm^{-1}, $A_\perp = 41.0\cdot10^{-4}$ cm^{-1} for the (*b*) spectrum (the *g* and *A* parameters were calculated with an accuracy of ±0.001 and $\pm0.5\cdot10^{-4}$ cm^{-1}, respectively; in parallel orientation the hyperfine lines due to the two isotopes ^{63}Cu and ^{65}Cu are clearly resolved). The anisotropic parameters of the (*a*) spectrum agree closely with those reported for $Cu^{II}L_2$ in noncoordinating solvents.[47,48] Increases in the $g_\parallel$ and $g_\perp$ values and decreases in the $A_\parallel$ and $A_\perp$ values in going from spectrum (*a*) to spectrum (*b*) (Figure 5) are typical both for the axial adduct formation and for the self-association of copper(II) complexes.[47,48] Consequently, the spectrum (*b*) parameters are consistent with the formation of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate with the axial bridging iodine atom or the self-associated complex,[47] which involves fairly strong axial Cu−S interactions, as with the Cu_2L_4 dimeric unit of the $Cu^{II}L_2$ monocrystal.[51] However the comparatively small changes in the *g* and *A* parameters with the $[Cu^{III}L_2]I_3$ present correlate better with the first of the intermediate structures.

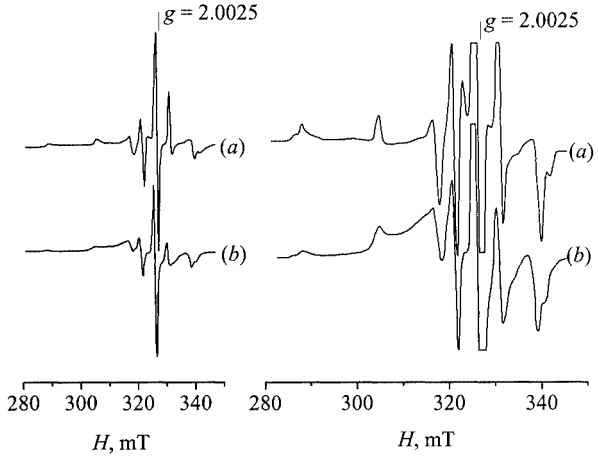

Figure 5. ESR spectra of the $5\cdot10^{-3}$ M $Cu^{II}L_2$ solutions in CH_2Cl_2/toluene 1:1 (*a*) and CH_2Cl_2 (*b*) without (*a*) and with I_2 (*b*) at 77 K, $c_{I_2} = 3.8\cdot10^{-3}$ M

The formation of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate with the bridge coordination of the I_3^- terminal iodine atom was confirmed by density functional theory (DFT) quantum-chemical computations (B3LYP version) with the Gaussian 98 and Jaguar program packages.[52,53] To save computation time, four ethyl groups of the ligands in the copper(II) or copper(III) complexes were in all cases replaced by methyl groups on the assumption that this should not essentially influence the geometry characteristics and electron density distribution in the immediate environment of the metal atom. The calculations were performed in three steps. Initially, optimization of the $Cu^{II}L_2$ and $[Cu^{III}L_2]^+$ geometry in vacuum was carried out by application of the Gaussian 98 program with the use of the standard 3-21G* basis set on the assumption that both complexes have D_{2h} symmetry. Some computation results are given in Table 3. Note that the deduced surroundings of copper in the $Cu^{II}L_2$ and $[Cu^{III}L_2]^+$ species are close to square-planar and the calculated Cu−S bond lengths in $Cu^{II}L_2$ (2.328 Å) and $[Cu^{III}L_2]^+$ (2.194 Å) are in good agreement with those obtained by X-ray structure analysis for crystals of $Cu^{II}L_2$ (2.31 Å[51]) and $[Cu^{III}L_2]I_3$ (2.21 Å[5]). In addition, for the I_3^- anion in vacuum the calculated I−I distances are 2.998 Å and the effective atomic charges are −0.060 and −0.470

Table 3. Total energies (E_0), averaged Cu−S bond lengths (R), effective atomic charges (Q), and atomic spin densities (ASD) computed at the B3LYP/3-21G* level for the $Cu^{II}L_2$, $[Cu^{III}L_2]^+$, $Cu^{II}L_2$*, and $[Cu^{III}L_2$*$]^+$ species in vacuum, as well as for $Cu^{II}L_2$, $Cu^{III}L_2I_3$, and $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate in dichloromethane ($Cu^{II}L_2$* is the $Cu^{II}L_2$ species with the fixed geometry optimized for the Cu^{III} complex and $[Cu^{III}L_2$*$]^+$ is the $[Cu^{III}L_2]^+$ species with the geometry optimized for the Cu^{II} complex)

Species	E_0 [Hartree]	R(Cu−S) [Å]	Q(Cu) [a.u.]	Q(S) [a.u.]	ASD(Cu) [a.u.]
In vacuum					
$Cu^{II}L_2$	−3561.503209	2.328	0.511	−0.125	0.711
$[Cu^{III}L_2]^+$	−3561.287141	2.194	0.357	0.093	0
$Cu^{II}L_2$*	−3561.488716	2.194	0.360	−0.092	0.631
$[Cu^{III}L_2$*$]^+$	−3561.273059	2.328	0.523	0.061	0

[a] For the $Cu^{II}L_2$ fragment. [b] For the $Cu^{III}L_2$ fragment.

a.u. for the central and the terminal iodine atoms, respectively. These results are consistent with the data from previous I_3^- computations.[17−19]

In the second step, the total energy of the $Cu^{II}L_2$ complex at the fixed geometry optimized for the Cu^{III} complex {$Cu^{II}L_2$*} and that of the $[Cu^{III}L_2]^+$ species at the geometry optimized for the Cu^{II} complex {$[Cu^{III}L_2$*$]^+$} were computed with the Gaussian 98 program for vacuum (Table 3). The difference between the $Cu^{II}L_2$* and $Cu^{II}L_2$ species energies gives the inner-sphere reorganization energy[54−56] of the $Cu^{II}L_2$ complex at electron transfer, and amounts to 38.1 kJ/mol (see Table 3). Similarly, the $[Cu^{III}L_2]^+$ inner-sphere reorganization energy is defined as the difference between the $[Cu^{III}L_2$*$]^+$ and $[Cu^{III}L_2]^+$ energies (37.0 kJ/mol, Table 3). By this means the total inner-sphere reorganization energy (λ_{in}) for the electron self-exchange reaction is λ_{in} = 38.1 + 37.0 = 75.1 kJ/mol. Because the values of the $Cu^{II}L_2$ and $[Cu^{III}L_2]^+$ inner-sphere reorganization energies are very close, the λ_{in} magnitude can also be calculated by assuming a parabolic approximation (Marcus equation)[54,55] and starting from the experimental data.

The Marcus equation gives λ_{in} in Equation (7)[54−56]

$$\lambda_{in} = \sum_j \frac{f_j^R f_j^P}{f_j^R + f_j^P} \cdot (\Delta q_j)^2 \qquad (7)$$

where f_j^R is the jth normal mode force constant in the reactants, f_j^P is that in the products, and Δq_j is the difference in equilibrium value of the jth normal coordinate in the oxidized and reduced states. We restrict our consideration only to the full-symmetric vibrations $\nu(a_1)$. For these vibrations, by using the Cu−S stretching frequencies in the dithiocarbamate complexes $Cu^{II}L'_2$ (376−404 cm^{-1}), $[Cu^{III}L'_2]I_3$ (400−402 cm^{-1}), and $[Cu^{III}L'_2]I_5$ (390−404 cm^{-1}),[4] we set $f_j^R \approx f_j^P \approx f$ = 300 N·m^{-1}. On the basis of the X-ray data for $Cu^{II}L_2$ [51] and $[Cu^{III}L_2]I_3$,[5] the Δq_j value is 0.10 Å. At the f and Δq_j values given, from Equation (7) we have: λ_{in} = 72.4 kJ/mol. Hence, the λ_{in} values obtained above by the DFT calculations and Equation (7) are in close agreement. In the third step of the quantum-chemical computations, the full geometry optimization of the $Cu^{II}L_2$ and $[Cu^{III}L_2]I_3$ species and the intermediate $Cu^{II}L_2I_3Cu^{III}L_2$ in dichloromethane solutions was performed by application of the Jaguar program[53] at the B3LYP/3-21G* level, with the Poisson−Boltzman SCRF model. Certain of the computed parameters are given in Table 3. We emphasize that no imaginary frequencies were found either for the initial complexes or for the optimized $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate; this eliminates the possibility of the consideration of the intermediate as a transition state. From the frequency computations, the thermal correction to enthalpies required for going from 0 to 298 K were deduced. The optimized structure of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate is rather intriguing (Figure 6). In particular, two metallo-chelates are not coplanar, with the $Cu^{II}-I_1-Cu^{III}$ angle with the bridging I_3^- iodine atom (I_1) and the dihedral angle $C(S_2)-Cu^{III}-I_1-I_2$ being 153.5° and 87.0°, respectively. The $Cu^{III}-I_1$, $Cu^{II}-I_1$, and $Cu^{II}-Cu^{III}$ distances were found to be 2.978, 4.008, and 6.805 Å, respectively. The $Cu^{III}-I_1$ distance is very close to the length of the axial $Cu^{II}-I$ bond in the crystal of (2,6-diacetylpyridine dihydrazone)diiodocopper(II)·1/2I_2 (2.974 Å),[57] but markedly different from the $Cu^{III}-I$ distance in the $[Cu^{III}L_2]I_3$ monocrystal (3.48 Å),[5] in which each copper(III) atom is axially bound with two terminal iodine atoms of two I_3^- groups. In the bridged I_3^- anion, the I_1-I_2 and I_2-I_3 bond lengths are 3.184 and 3.094 Å, respectively, and differ slightly from those in the optimized $[Cu^{III}L_2]I_3$ complex (3.166 and 3.098 Å), but far exceed the equal I−I distances in the I_3^- anion of the $[Cu^{III}L_2]I_3$ crystal (2.92 Å).[5]

The calculated values of the effective charges on the bridging (I_1), central (I_2), and terminal (I_3) iodine atoms of I_3^- are −0.231, −0.061, and −0.385, respectively, in the intermediate, as compared to −0.292 (I_1), −0.071 (I_2), and −0.391 (I_3) in the initial $[Cu^{III}L_2]I_3$ complex. Hence, part of the bridged I_3^- charge (−0.324) is delocalized on the $Cu^{III}L_2$ fragment (−0.265) and the $Cu^{II}L_2$ fragment (−0.059) of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate. According to the data in Table 3, the formation energy of the intermediate in CH_2Cl_2 is $E_0 = E_0(Cu^{II}L_2I_3Cu^{III}L_2) - E_0(Cu^{II}L_2)$

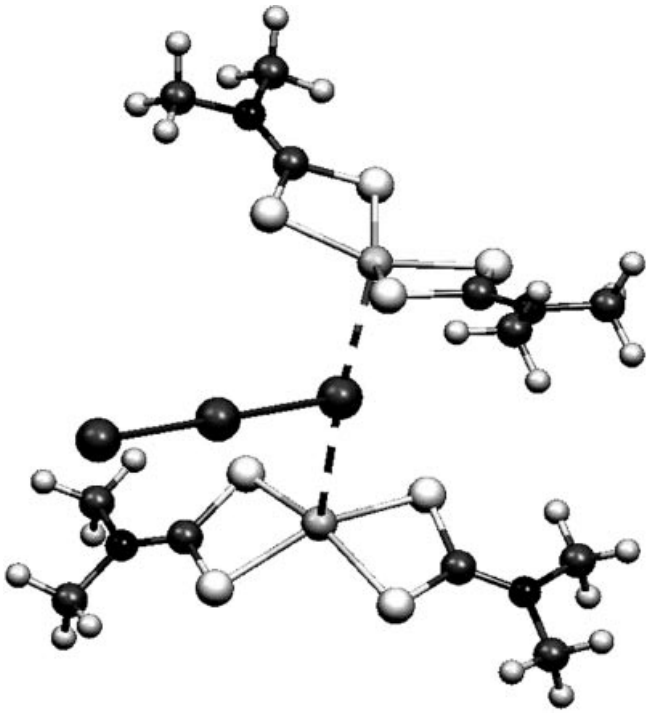

Figure 6. The structure of the $Cu^{II}L_2I_3Cu^{III}L_2$ model intermediate for the copper(II)/copper(III) electron self-exchange reaction optimized by the DFT method (the copper(III) chelate is positioned below)

$- E_0(Cu^{III}L_2I_3) = -0.012175$ a.u. $= -32.0$ kJ/mol. If the thermal correction to enthalpies ($\delta H = 1.8$ kJ/mol) is taken into account, the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate formation enthalpy can be estimated as -30.2 kJ/mol. From similar computations it follows that the alternative intermediate with the 1,3-bridging mode of triiodide at the designed C_i symmetry has a formation enthalpy of only -21.1 kJ/mol and can be regarded as less probable than the above fully optimized intermediate. It should be added that the intermediate of composition $Cu^{II}L_2I_5Cu^{III}L_2$ differs from $Cu^{II}L_2I_3Cu^{III}L_2$ (Figure 6) only by the addition of I_2 to one of the terminal atoms of the I_3^- anion.

It is appropriate to compare the value of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate formation enthalpy discussed above with the estimation of this parameter for the dichloromethane solution following from an analysis of the activation enthalpy (Table 2) under the conditions of adiabatic electron transfer. To do this we examine the relation for the electron self-exchange rate constant k_e[55,56,58]

$$k_e = K_A \nu_n \kappa_{el} \Gamma_\lambda \exp(-\Delta G^*/RT) \quad (8)$$

with

$$\Delta G^* = \Delta G^*_{out} + \Delta G^*_{in} \quad (9)$$

where K_A is the stability constant for the formation of an encounter complex with an appropriately oriented configuration (intermediate), ν_n is an effective nuclear vibration frequency that takes the activated reactants on to products, κ_{el} is an electronic transmission coefficient ($\kappa_{el} \leq 1$), Γ_λ is a nuclear tunneling factor ($\Gamma_\lambda \geq 1$), and ΔG^* is the free energy of activation related to the reorganization energy (λ) for electron transfer ($\lambda = 4\Delta G^*$), including contributions from both the outer-sphere reorganization energy ($\lambda_{out} = 4\Delta G^*_{out}$) and the inner-sphere reorganization energy ($\lambda_{in} = 4\Delta G^*_{in}$). Let us evaluate the ΔG^*_{out} contribution for the reaction under investigation.

From the X-ray data,[5,51] the $[Cu^{III}L_2]I_n$ and $Cu^{II}L_2$ reactants can be thought of as two identical extended ellipsoids with semi-axes $a = 7.5$ Å, $b = 2.5$ Å, and $c = 1.5$ Å (the I_3^- and I_5^- anions are not taken into account because they retain their charges during the course of the electron-transfer reaction and their polarizability may be regarded as approximating the CD_2Cl_2 polarizability). In the framework of the dielectric continuum model, Equations (10) and (11) were obtained for interaction of two conducting non-polarizable ellipsoids contacting along the short semi-axis c.[59]

$$\Delta G^*_{out} = \frac{(\Delta e)^2}{4}\left(\frac{1}{D_{op}} - \frac{1}{D_s}\right)\left(\frac{F(\nu,q)}{\sqrt{a^2-c^2}} - \frac{1}{R}\cdot g\right) \quad (10)$$

$$g = 1 + \frac{2c^2 - a^2 - b^2}{3R^2} + \frac{abc}{R^3} + \frac{4\left[8c^4 + 3\left(a^4+b^4\right) - 8c^2\left(a^2+b^2\right) + 2a^2c^2\right]}{15R^4} \quad (11)$$

In these equations, Δe denotes the charge transferred from one reactant to the other, D_s and D_{op} are the static and optical (square of refractive index) dielectric constants of the solvent, respectively, R is the center-to-center separation distance in the reacting pair during the electron transfer, and $F(\nu,q)$ is the elliptic integral of the first kind[60] with $\nu = \arcsin[(a^2 - c^2)/a^2]^{1/2}$ and $q = [(a^2 - b^2)/(a^2 - c^2)]^{1/2}$. At the ellipsoid parameters specified above, the $F(\nu,q)$ value is 2.03[60] and the $[(a^2 - c^2)]^{1/2}/F(\nu,q)$ ratio is 3.62 Å. For the intermediate in CD_2Cl_2 at $R = 6.8$ Å (Figure 6), $D_s = 8.93$, and $D_{op} = 2.020$[61] (298 K), it follows from Equations (10) and (11) that $\Delta G^*_{out} = 2.2$ kJ/mol. We emphasize that the low value of ΔG^*_{out} for the reaction under consideration is caused both by the moderate magnitude of the $(D_{op}^{-1} - D_s^{-1})$ parameter for dichloromethane and by the close contact of two ellipsoids with quite large volumes.

Thus, according to Equation (9) with the above value λ_{in} (75.1 kJ/mol), we can assume that $\Delta G^* = \Delta G^*_{out} + \Delta G^*_{in} = 2.2 + 18.8 = 21.0$ kJ/mol. Knowledge of ΔG^* enables the enthalpy of the intermediate formation (ΔH_A) to be calculated for the corresponding stability constant K_A. At $\Delta S^* \approx 0$,[55] from relations (8) and $K_A = \exp[(-\Delta H_A + T\Delta S_A)/RT]$, in conjunction with the Eyring equation, we obtain: $\Delta H^{\neq} = \Delta H_A + \Delta G^*$. Hence, with regard to the experimentally determined $\Delta H^{\neq}$ value (Table 2), it follows that $\Delta H_A = \Delta H^{\neq} - \Delta G^* = 6.1 - 21.0 = -14.9$ kJ/mol. The difference between the values of the $Cu^{II}L_2I_3Cu^{III}L_2$ intermediate formation enthalpy calculated by the semiempiric approach (-14.9 kJ/mol) and by the DFT method (-30.2 kJ/mol) can be assigned both to the approximations of the dielectric continuum model[59] and to incomplete accounting for solvation effects in the DFT computations. In any case the reasonable ΔH_A values obtained provide considerable support for the stability of the proposed and found intermediate (Figure 6).

Hence, in terms of the proposed mechanism, the remarkably high values of the electron-transfer rate constants for the system involved derive both from the particular structure of the intermediate and the favorable dielectric properties of dichloromethane. To obtain greater insight into the given mechanism we are performing further investigations of the solvent effects on the kinetics of electron self-exchange reactions between the copper(II) and copper(III) dithiocarbamates.

Experimental Section

Materials. The CH_2Cl_2 and CD_2Cl_2 solvents were purified prior to use by standard method,[62] dried, and stored over 4 Å molecular sieves. Crystal iodine, $CuSO_4 \cdot 5H_2O$, $NaS_2CNEt_2 \cdot 3H_2O$ (analytical grade, Reakhim), and Et_4NI, after recrystallization, were used for preparation of solutions. The $Cu^{II}L_2$ and $[Cu^{III}L_2]I_3$ complexes were synthesized by literature methods.[4,5] For the $Cu^{II}L_2$, $C_{10}H_{20}CuN_2S_4$ (360.08), calcd. C 33.36, H 5.60, N 7.78, S 35.62; found C 32.98, H 5.62, N 7.79, S 35.32; for the $[Cu^{III}L_2]I_3$, $C_{10}H_{20}CuI_3N_2S_4$ (740.80), calcd. C 16.21, H 2.72, N 3.78, S 17.31; found C 16.27 H 2.50, N 3.62, S 17.70. The $[Cu^{III}L_2]I_5$ compound was isolated for the first time.

Synthesis of Bis(*N*,*N*-diethyldithiocarbamato)copper(III) Pentaiodide, $[Cu^{III}L_2]I_5$: A benzene solution (4 mL) of I_2 (20.3 mg, $1.6 \cdot 10^{-4}$ mol) was added to a dichloromethane solution (8 mL) of $Cu^{II}L_2$ (5.8 mg, $1.6 \cdot 10^{-5}$ mol). The resulting solution was allowed to stand in the refrigerator for a week. The grown crystals were collected, washed with hexane, and dried. The product constitutes lustrous brown-black crystals, m.p. 140−141 °C. For the $[Cu^{III}L_2]I_5$, $C_{10}H_{20}CuI_5N_2S_4$ (994.60), calcd. C 12.08; H 2.03; N 2.82; S 12.90; found C 12.02; H 1.92; N 2.73; S 12.94. Unfortunately it was impossible to perform Cu and I elemental analyses for technical reasons.

Investigation Methods: The UV/Vis absorption spectra were obtained on a LOMO Model SF 46 spectrophotometer with a thermostat in the 278−308 K temperature range, in 1.0 and 0.1 cm quartz cells. The optical densities were measured with an accuracy of ±1%. The ^1H NMR spectra were recorded on a Bruker WH 90 spectrometer (ν = 90 MHz) by 400−1000 acquisitions in CD_2Cl_2 solutions at temperatures from 248 to 298 K. Variable-temperature measurements were monitored by a Bruker temperature control unit. Signals from residual solvent protons were used as internal references. Transverse relaxation times (T_2) for protons of the methyl and methylene groups of the coordinated L ligands were evaluated from the NMR line-widths ($\Delta\nu_{1/2}$, Hz) by the relation[45] $T_2^{-1} = \pi\Delta\nu_{1/2}$ with an accuracy of ±5%. ESR spectra were recorded on a Model RE-1306 ESR spectrometer (ν = 9.2 GHz), at 100 KHz magnetic-field modulation.

Constants and thermodynamic parameters of equilibria in the above two systems were determined from the dependence of the molar absorption coefficient (ε) upon the Et_4NI or I_2 concentrations at 5−7 values of temperature and λ = 365 or 400 nm. All calculations of the equilibrium constants were made with the aid of the CPESSP computer program.[63] This program is based on the minimization of a F function,[64] $F = \Sigma_j(X_{exptl,j} - X_{calc,j})^2 \cdot (\sigma X_{exptl,j})^{-2}$, where $X_{exptl,j}$ and $X_{calc,j}$ are the experimental and calculated properties, respectively, j is the experiment number (N experiments), and σ is the relative error of the measurement. The reliability of the results obtained with this procedure was evaluated by the Fisher criterion by using the computed F_{min} value and the experimental error as described.[64]

Rate constants and activation parameters of the electron self-exchange reactions in the $Cu^{II}L_2/I_2/CD_2Cl_2$ system were calculated from the dependence of the NMR line-widths upon the I_2 and $Cu^{II}L_2$ concentrations at several temperatures with regard to the equilibrium constants obtained. Precipitation of a quantity of the copper(III) compounds at low temperatures was controlled by the integral intensity of the NMR signals. A poor solubility of these compounds at $T < 268$ K has given no way of estimating the NMR line widths at lower temperatures.

Electronically Published Supporting Information: Tables of data for the computations of the equilibrium constants with the Et_4NI_3, Et_4NI_5, $[Cu^{III}L_2]I_3$, and $[Cu^{III}L_2]I_5$ formation and the rate constants of the electron self-exchange reactions at different temperatures (4 pages, Tables S1−S4). Ordering information is given on any current masthead page (see footnote on the first page of this article).

Twisting the Porphyrin Ring to Enhance Epoxidation Enantioselectivity

Stéphanie Gazeau,[a] Jacques Pécaut,[a] Raid Haddad,[b] John A. Shelnutt,*[b] and Jean-Claude Marchon*[a]

Keywords: Porphyrinoids / Manganese / Enantioselectivity / Asymmetric catalysis / Epoxidation

A series of bridled chiroporphyrins has been prepared in which the distortion of the porphyrin ring is controlled solely by the length of the bridles. The influence of ring distortion on the enantioselectivity of catalytic epoxidation by their manganese complexes has been investigated. Twisting the porphyrin ring is found to enhance the enantioselectivity of dihydronaphthalene epoxidation.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Despite numerous recent advances in the area of asymmetric catalysis by chiral metal complexes,[1] the specific features (steric, conformational, electronic, etc.) of the chiral ligand that influence the enantiomeric excess (*ee*) are far from being completely understood. Among stereochemical factors, steric exclusion is widely considered a major determinant of asymmetric induction in a host of metal-catalyzed reactions. The influence of conformation is less clear; the impact of the distortion of a nominally planar ligand has been suspected only recently.[2,3] In this report, we examine the influence of porphyrin ring distortion on the enantioselectivity of catalytic epoxidation by manganese chiroporphyrins.

Steric crowding by bulky *meso* substituents is known to result in a ruffling distortion of the porphyrin[4] which influences the spectral and chemical properties of the molecule.[5] The asymmetric epoxidation of dihydronaphthalene by iodosylbenzene induced by ruffled manganese(III) chiroporphyrin complexes was investigated recently in our laboratories: the *ee* of the epoxide product has been found to increase as the porphyrin becomes more ruffled.[6] Since the origin of the ruffled distortion is the congestion induced by the bulky *meso* substituents near the porphyrin ring in an αβαβ conformation, we have not been able to determine whether the asymmetric induction is due to a conformational or a steric effect, or both. In an attempt to resolve these two influences, we have designed a series of chiroporphyrins H_2Bn (Scheme 1) in which the ester functions on adjacent *meso* substituents are linked by a strap of adjustable length (n = 8 to 16 methylene groups). We expected that the ruffling induced by the αβαβ conformation could be restricted by these bridles, and that the resulting distortion could be tuned by the strap length while the substituent volume and electronic effects would remain unchanged. Here we report our investigations of the ruffling of the bridled chiroporphyrin free bases and nickel(II) complexes by ^{1}H NMR and resonance Raman spectroscopy. We show that the ruffling in solution can indeed be controlled by the bridle length, and that it has a positive influence on the epoxidation enantioselectivity.

Results and Discussion

The bridled chiroporphyrins H_2B9−16 were obtained in 3−12% yield following the procedure outlined in Scheme 1, which we designed earlier for the synthesis of H_2B8 from biocartol **1**.[7] In contrast to H_2B8, which is obtained as the αααα isomer,[7] the αβαβ conformation of the free bases with longer bridles (H_2B9−16) is apparent from their D_2-symmetric ^{1}H NMR spectra, with a pair of singlets for the β-pyrrolic protons and a single signal for each group of *meso* protons. The resonances of the methylene protons of H_2B9−16 appear near δ = 1.6−1.8 ppm, indicating that the two straps are directed away from the ring current and connect adjacent substituents on opposite faces of the porphyrin. Metal insertion gave the nickel complexes NiB8−16 as pure αβαβ conformers, and the manganese complexes MnClB8−16 as a mixtures of αβαβ and αααα conformers, which were separated by TLC on silica gel and identified by X-ray crystallography. The more abundant isomer was assigned the αβαβ conformation, and the more polar, less abundant one was assigned the αααα conformation. Single crystals were obtained by slow diffusion of *n*-hexane into a chloroform solution of MnClB10. The determination of the X-ray structure showed that the asymmetric unit contains one αβαβ-MnClB10 complex and two very similar, but crystallographically distinct, αααα-MnClB10 complexes, and it confirmed the assignments made on the basis of the relative polarities observed in TLC. Views of the X-ray structures of the two conformers are illustrated in Figure 1. Notable features of these structures are the ruffled porphyrin conformation of the αβαβ conformer and the two straps connecting adjacent *meso* substituents on opposite faces, and the slightly domed porphyrin conformation of the αααα conformer and the two straps connecting adjacent *meso* substituents on the same face. Also noteworthy is the variable conformation of the four ester moieties, which have their carbonyl group inwardly directed in the αβαβ isomer and outwardly directed in the αααα isomer.

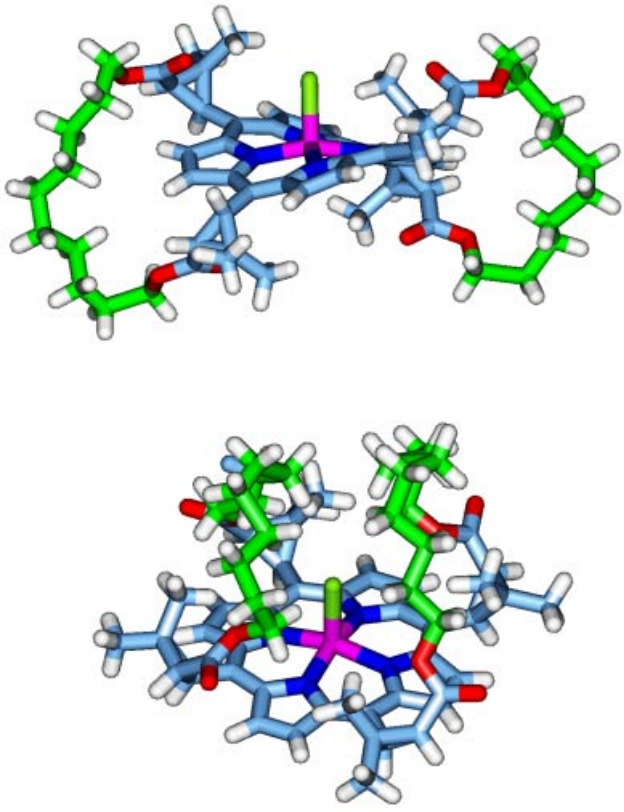

Figure 1. X-ray structures of the bridled manganese(III) complex MnClB10; (top) stick representation of the αβαβ-MnClB10 molecule showing the ruffled porphyrin conformation and the two straps connecting adjacent *meso* substituents on opposite faces; selected bond lengths (Å): Mn(1)−N(1) 1.983(8); Mn(1)−N(2) 1.987(8); Mn(1)−N(3) 1.968(8); Mn(1)−N(4) 1.993(8); Mn(1)−Cl(1) 2.371(3); (bottom) stick representation of one of the two αααα-MnClB10 molecules showing the slightly domed porphyrin conformation and the two straps connecting adjacent *meso* substituents on the same face; selected bond lengths (Å): Mn(2)−N(11) 2.024(9); Mn(2)−N(12) 2.053(8); Mn(2)−N(13) 2.033(8); Mn(2)−N(14) 2.057(8); Mn(2)−Cl(2) 2.365(3). Mn(3)−N(21) 2.019(8); Mn(3)−N(22) 2.014(8); Mn(3)−N(23) 2.018(8); Mn(3)−N(24) 2.037(9); Mn(3)−Cl(3) 2.360(3)

High-frequency Raman lines in the region 1340−1640 cm^{-1} have been shown to be especially sensitive to the ruffling mode of deformation of nickel(II) porphyrins.[5] In the resonance Raman spectra of the bridled nickel(II) complexes NiB8−16 (Figure 2), all of the high-frequency marker lines show a similar frequency dependence on bridle length. The correlation between frequency and the number of methylene groups in a bridle is depicted in Figure 3 for ν_2. At first ($8 \leq n \leq 12$), lengthening the bridle induces a decrease of the line frequency, indicating increased ruffling of the ring as we expected. Apparently the constraints imposed by the bridles, which prevent adjacent *meso* substituents on opposite faces from moving away from each other, are gradually relaxed as the number of methylene groups increases, thus allowing the porphyrin to reach a more distorted conformation until a maximum is attained for n = 12. Further lengthening of the bridles beyond n = 12 unex-

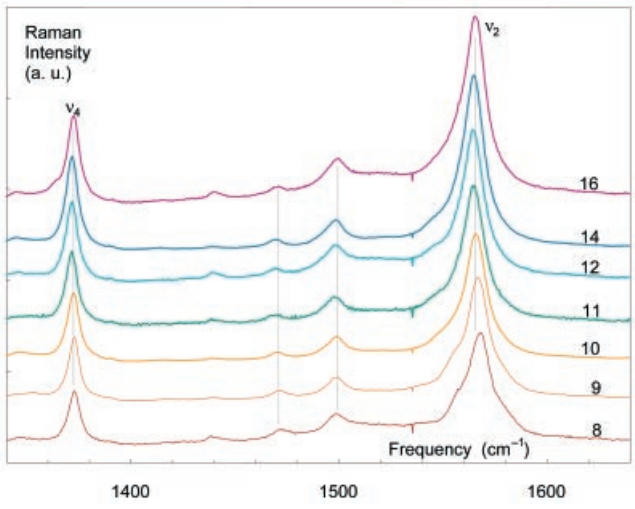

Figure 2. High-frequency region of the resonance Raman spectra for the bridled nickel(II) complexes NiB8−16 obtained at 407.6 nm laser excitation in carbon disulfide; the number on each spectrum refers to the number of methylene groups in a bridle of the complex

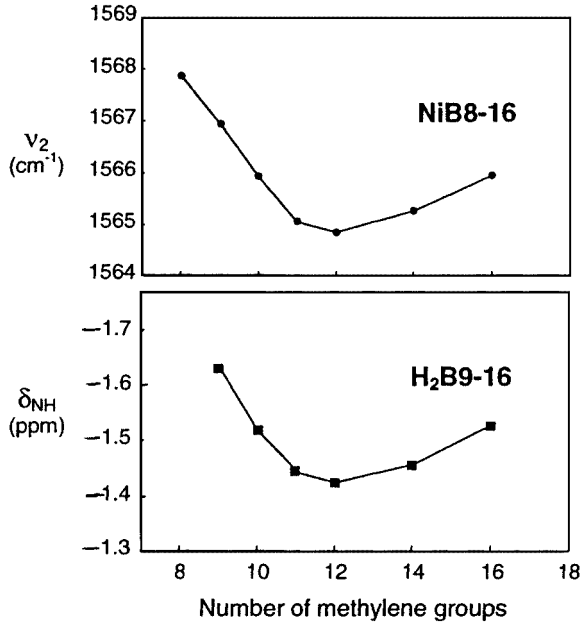

Figure 3. Dependence of the frequency of the structure-sensitive line ν_2 for the nickel(II) complexes αβαβ-NiB8−16 (upper trace), and of the chemical shift of central protons δ_{NH} for the free base chiroporphyrins αβαβ-H_2B9−16 (lower trace) on the number of methylene groups in a bridle

pectedly induces a small decrease in the ruffling, as evidenced by the small increase in the marker line frequencies.

An entirely similar biphasic behavior has been detected for the free bases H_2B9−16 by ^{1}H NMR spectroscopy (Figure 3), using the chemical shift δ_{NH} of the central protons as a probe of the ring current; the latter is directly related to the nonplanar distortion of the porphyrin. The similar trends found for the free bases and their nickel(II) complexes is a strong indication that in these intrinsically ruffled compounds the amount of distortion of the porphyrin ring arises mainly from the restraints imposed by the bridles, and that it is not strongly influenced by the size of the metal center. Molecular dynamics simulations also give average structures for NiB8−16 that indicate a dependence of the magnitude of ruffling similar to that shown in Figure 3.[10]

We surmise that long straps ($n \geq 12$) have sufficient flexibility to allow other conformational states of the ester group to be populated, for example by rotation of their oxo and alkoxy substituents. Conformations in which the carbonyl group is either inwardly or outwardly directed, as seen in Figure 1, have been observed earlier in the X-ray structure of the nickel chiroporphyrin derived from the bornyl ester of **1**.[6] In a chiroporphyrin with long bridles, a change from an outwardly to an inwardly directed carbonyl group would result in an effective shortening of the strap, and therefore to a less-distorted porphyrin ring.[10] In agreement with this proposed mechanism, the conformational flexibility of the 16-methylene chains of H_2B16 is apparent from the presence of a single signal at $\delta = 3.62$ ppm for the two diastereotopic protons of the methyleneoxy groups, which are in fast exchange on the NMR time scale. In contrast, the shorter-chain congeners are more conformationally rigid, as indicated by the anisochronicity of the two diastereotopic protons of the methyleneoxy groups, which give two broad signals. It is also possible that additional flexibility in the straps introduces new ways in which the straps can influence the out-of-plane macrocycle distortion

[a] Reaction conditions: catalyst/substrate/PhIO 1:1000:100 μmol at room temperature in 2 mL CH_2Cl_2. [b] Yield relative to PhIO. [c] Measured by GC on a Cyclodex-B chiral column.

through nonbonding interactions or additional degrees of freedom at the meso substituents.

Each catalyst of the series αβαβ-MnClB8−16 was carefully purified by TLC on silica gel. The yields and *ee*'s obtained in the catalytic epoxidation of 1,2-dihydronaphthalene by iodosylbenzene are collected in Table 1. Figure 4 shows a plot of the enantiomer composition (ec) of the major 1*S*,2*R* epoxide versus the ν_2 frequency of NiB8−16. The observed correlation suggests that similar distortions of the ring are obtained irrespective of the core metal (Ni or Mn). It also indicates that the enantioselectivity induced by the manganese catalysts increases as the ruffling of the porphyrin increases, i.e. that twisting the porphyrin ring is beneficial to the asymmetric induction.

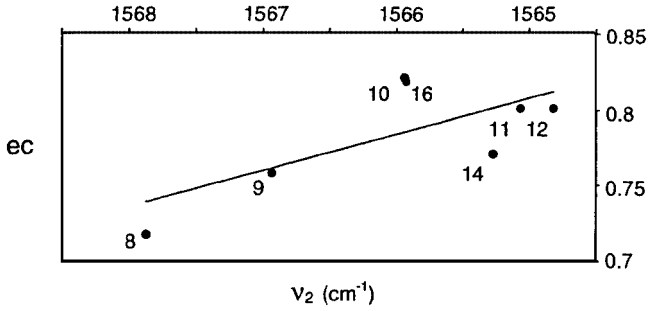

Figure 4. Plot of the enantiomer composition (ec) of the major 1*S*,2*R* epoxide obtained in the asymmetric epoxidation of 1,2-dihydronaphthalene by iodosylbenzene induced by catalysts αβαβ-MnClB8−16 as a function of the frequency of the structure-sensitive line ν_2 of NiB8−16; the number of methylene groups *n* in each bridle is indicated for each data point

The subtle effect by which a conformation change can influence the enantioselectivity of a catalyst is intriguing. We speculate that this influence may be mediated by several factors, either steric or electronic in origin. For example, a folding, or twisting, of the porphyrin ring would put more bulk near the metal center, or induce more asymmetry of charge distribution in the reactive species, respectively. Coming back to the chiroporphyrin catalysts of the first generation,[6] which were the starting point of this investigation, we can now conclude that the extent of their asymmetric induction is the result of several effects. The favorable steric influences of the ester or amide substituents in their various possible conformations are corroborated by the resulting propitious effect of porphyrin ruffling. This finding reveals a novel facet of the origins of stereoinduction in asymmetric catalysis, and it may have implications in catalyst design.

Conclusion

In summary, bridled chiroporphyrins provide the unprecedented possibility of controlling the distortion of the porphyrin ring without substantially modifying the steric and electronic influences of the macrocycle substituents. The dependence of the ruffling on the bridle length shows two opposite trends. Like the structure-sensitive Raman frequencies of the nickel complexes, the ^{1}H NMR chemical shift of the central protons of the free bases is a very sensitive probe of the ruffled distortion of the porphyrin ring in solution. Our finding that this distortion has a positive influence on stereoinduction may open new possibilities for the design or improvement of asymmetric catalysts.

Experimental Section

General Spectroscopic Information: All compounds were characterized by electrospray mass spectrometry (Finnigan MAT LCQ), UV/Vis (Perkin−Elmer Lambda 9), and NMR spectroscopy. The purity of all products was ascertained by TLC, UV/Visible and NMR spectroscopy; elemental analytical data were not obtained due to the generally low yields. ^{1}H NMR spectra of $CDCl_3$ solutions of the compounds (ca. 3 mg in 0.5 mL) were recorded at room temperature on a Bruker AC200 or a Varian Avance 400 NMR spectrometer. Parameters for acquiring proton spectra were the following: 200 MHz, 16 scans, spectral window 4 kHz, 16 K data points; 400 MHz, 8 scans, spectral window 8 kHz, 58.5 K data points. Chemical shifts were measured relative to $CHCl_3$ and they are referenced to tetramethylsilane. Resonance Raman spectra were obtained as reported in a an earlier publication.[8]

Catalytic epoxidations were carried out according to standard procedures.[6,9] Measurements of enantiomeric compositions were carried out at least in triplicate by chiral chromatography on a Cyclodex-B column with a Fisons GC 9000 system.

Synthesis of a Bridle An: A typical procedure is described below for A10. NaH (1.13 g, 28 mmol) was added in small portions to a dry THF (30 mL) solution of biocartol **1** (4 g, 28 mmol) under argon at 10 °C. The mixture was then stirred for 30 min at room temperature and 2.76 mL of 1,10-diiododecane (7 mmol) in dry DMF (120 mL) was added. After stirring for 24 h under argon at room temperature, diethyl ether was added and the organic layer was washed and dried over Na_2SO_4. The solvent was then removed under reduced pressure. The residue was purified by silica gel chromatography with dichloromethane/methanol (97:3) as eluent to afford A10 as a colorless oil (2.96 g, >99% relative to diiododecane). ^{1}H NMR (200 MHz, $CDCl_3$): δ = 9.73 (d, *J* = 6.3 Hz, 2 H, CHO), 4.09 (dt, *J* = 6.8, *J* = 1 Hz, 4 H, OCH_2), 2.10 (d, *J* = 8.8 Hz, 2 H, CH−C(O)O), 1.82 (dd, *J* = 6.3, *J* = 8.8 Hz, 2 H, C*H*−CHO), 1.62 (m, 4 H, O−CH_2−CH_2), 1.54 (s, 6 H, CH_3), 1.28 (b, 12 H, CH_2), 1.25 (s, 6 H, CH_3).

Synthesis of a Bridled Chiroporphyrin H_2Bn: A typical procedure is described below for H_2B10. A degassed dichloromethane (1.9 L) solution containing A10 (3.54 g, 8.4 mmol), 1.4 mL (20 mmol) of pyrrole and 1.55 mL (20 mmol) of TFA was stirred at room temperature under argon for 6 days. The reaction mixture was diluted to 5.7 L by adding 3.8 L of dichloromethane and then oxidized with DDQ (3.8 g, 16.6 mmol). After stirring for 4 h, the solvent was removed under reduced pressure. The residue was chromatographed on an alumina column eluting with dichloromethane/methanol (98:2), then on silica gel plates eluting with the same solvent mixture. The porphyrin H_2B10 was obtained as a purple solid (530 mg, 12%). MS (ES): *m*/*z* = 1035.7 [MH^+]. UV/Vis (CH_2Cl_2): λ_{max} = 429 nm (Soret), 530, 565, 607, 662. ^{1}H NMR (400 MHz, $CDCl_3$): δ = 9.12 and 9.08 (2s, 8 H, Hβ), 4.80 (d, *J* = 8.8 Hz, 4 H, H^2), 4.0 (m, 4 H, OCH_2), 3.55 (m, 4 H, OCH_2), 2.74 (d, *J* = 8.8 Hz, 4 H,

H^1), 1.93 (s, 12 H, CH_3), 1.82 and 1.69 (2b, 32 H, CH_2), 0.79 (s, 12 H, CH_3), −1.52 (b, 2 H, NH) ppm. ^{13}C NMR (200 MHz, $CDCl_3$): δ = 169.8 (C=O), 153.0 (Cα), 149.3 (Cα), 131.3 (Cβ), 127.3 (Cβ), 111.0 (*meso* C^{IV}), 64.3 (OCH_2), 38.4 (CH^2), 32.9 (CH^1), 29.7 (Me), 29.2 (CH_2), 28.9 (CH_2), 28.6 (CH_2), 27.7 (C^{IV}), 27.3 (CH_2), 17.9 (Me) ppm.

MnClBn: A typical procedure is described below for MnClB10. A saturated $MnCl_2{\cdot}4H_2O$ solution (20 mL) in ethanol was added to a solution H_2B10 (20 mg, 19.3 μmol) in 10 mL of chloroform. The mixture was stirred under reflux for 72 h. The solvent was removed under reduced pressure and the residue was purified twice by TLC on silica eluting with dichloromethane/methanol (92:8). The resulting product (20.5 mg, 95%) gave a single spot in TLC on silica. MS (ES): m/z = 1087.5 [M^+ − Cl]. UV/Vis (CH_2Cl_2): λ_{max} = 383, 402, 486, 596, 638 nm.

X-ray Crystallographic Study: Dark green single crystals were obtained by slow diffusion of *n*-hexane into a chloroform solution of the complex. Data collection was carried out on a Bruker AXS Smart CCD area-detector diffractometer. The structure was solved by direct methods using the SHELX-TL software package. Crystal data for MnClB10: $3C_{64}H_{80}N_4O_8MnCl{\cdot}CHCl_3$, M = 3490.50, trigonal, space group $P3_2$, a = 27.3710(8), b = 27.3710(8), c = 23.2007(9) (Å), γ = 120°, V = 15052.6(9) Å^3, T = 193(2) K, Z = 3, μ(Mo-K_α) = 0.329 mm^{-1}, 63323 reflections, 42452 independent reflections (R_{int} = 0.0820) which were used in all calculations. The final R was 0.0965, the final $wR(F^2)$ was 0.2263 [$I > 2\sigma(I)$].

CCDC-156317 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

P−H Activation By Zirconium Amido Complexes: From New Phosphanidozirconium Complexes to the First Zr_2P_6 Cluster with the $[RP-P-PR]^{3-}$ Ligand [R = Me_2(*i*PrMe_2C)Si]

Matthias Driess,*[a] Joachim Aust,[a] and Klaus Merz[a]

Dedicated to Prof. Karl Wieghardt on the occasion of his 60th birthday

Keywords: Phosphanides / Bond activation / Cluster compounds / Zirconium / Phosphanes

A new, efficient and salt-free method to synthesize phosphanidozirconium complexes is reported. Treatment of $[Cp_2Zr(PHR)_2]$ **3** [R = Me_2(*i*PrMe_2C)Si] with $[Zr(NEt_2)_4]$ furnishes the first unsymmetrically substituted 1,3-dizircona-2,4-diphosphetane $[Cp_2Zr(PR)_2Zr(NEt_2)_2]$ (**1**; Cp = η^5-C_5H_5) in quantitative yield, which undergoes intermolecular ligand exchange reactions at 140 °C to form the mixed substituted derivative $[Cp_2Zr(PR)_2ZrCp(NEt_2)]$ (**2**) in 28% yield. An X-ray diffraction analysis of **2** revealed that the four-membered Zr_2P_2 ring is only slightly puckered. The Brønsted acid-base reaction of $[Cp^*Zr(NMe_2)_3]$ (**4**; Cp^* = C_5Me_5) with the P–H acidic silylphosphane RPH_2 affords the corresponding tris-(phosphanido) complex $[Cp^*Zr(PHR)_3]$ (**5**) in the form of a red-brown oil in quantitative yield. Heating of the latter at 140 °C leads to the first dinuclear zirconium phosphanide cluster $[(Cp^*Zr)_2(R_2P_3)_2]$ (**6**), which has been isolated in the form of dark green crystals in 12% yield and structurally characterized by X-ray diffraction analysis.

Introduction

During the last few years substantial progress has been achieved in the development of nucleophilic, and at the same time soft, phosphorus-transfer reagents, in which Zr−P compounds play an excellent role as versatile building blocks for the synthesis of organophosphorus compounds. Since the initial work on phosphanidozirconium compounds by Issleib and Häckert[1] it has become well established that $Cp_2Zr(+4)$ and $Cp_2Zr(+3)$complexes (Cp = η^5-C_5H_5) with bridging and/or terminal phosphanido ligands can serve as soluble, mild and selective PR_2^-, PR^{2-} and P^{3-} equivalents.[2] The latter types of complexes are superior to the respective ionogenic alkali and alkaline earth metal phosphanides since, during their synthesis, they can initiate simultaneous Zr-assisted P−P and/or P−C cross-coupling reactions between several primary organophosphorus moieties, affording new polyphosphorus ligands. This synthetic potential is impressively demonstrated by the $[Cp_2Zr]$-induced cyclooligomerisation of phosphaalkynes[3] and the formation of Zr−P complexes with unsubstituted phosphorus atoms, starting from P_4 and $[Cp_2Zr]$ complex fragments.[4] The formation of Zr−P bonds in phosphanidozirconocene compounds is usually achieved by salt metathesis reactions between lithium phosphanides and $[Cp_2ZrX_2]$ (X = halogen) or through oxidative addition of (oligo)phosphanenes, P−C multiple bonds and P_4 to $[Cp_2Zr]$ fragments as reactive intermediates.[5] The latter methods also frequently involve redox processes at the zirconium and phosphorus atoms, which make product predictions more difficult. Here we report a new method for the synthesis of Zr−P complexes through σ-metathesis reactions, starting from strong Brønsted-basic amidozirconium complexes ($[Zr]-NR_2$) and P−H-acidic silylphosphanenes. Hitherto, only the reverse process, that is, the simple protolytic fission of the Zr−P bond with NH-containing amines, has been described.[6] Furthermore, we report the preparation of the first zirconium tris(silylphosphanido)-complex **5**, which can be converted into the $(ZrP_3)_2$ cluster **6**.

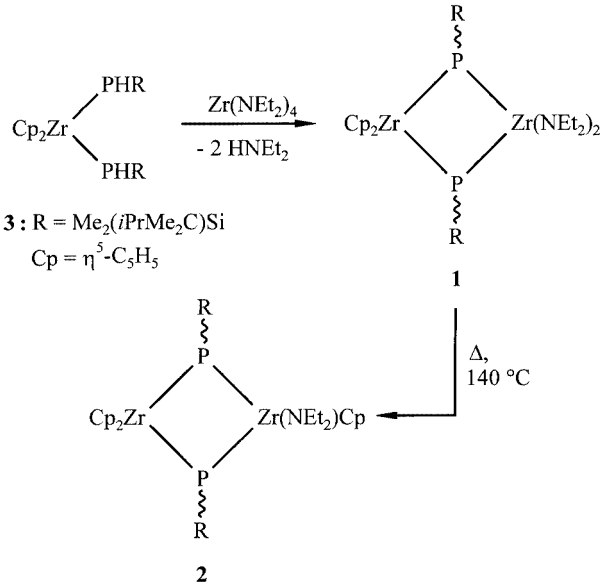
Results and Discussion

The Zr_2P_2 complex **1** is furnished in almost quantitative yield by heating the diphosphanido complex **3** with $[Zr(NEt_2)_4]$ in boiling benzene, while compound **3** is accessible upon reaction of $[Cp_2ZrCl_2]$ with RP(H)Li in 71% yield [molar ratio 1:2, toluene, 0 °C; R = Me_2(*i*PrMe_2C)Si; $\delta(^{31}P)$ = −51.0 (d, $^1J_{P,H}$ = 214 Hz)]. In contrast to the $[Cp_2Zr(PHR)_2]$ derivatives (R = *t*Bu, Aryl) hitherto known,[7] **3** is not only easily accessible and thermally resist-

ant up to 120 °C but also suitable for selective P−H bond activation.

Compound **1** was isolated in the form of a red-brown oil. Its structure can be deduced from the simple features of the ^{1}H and ^{31}P NMR spectra, while its composition is proven by the EI mass spectrum. The ^{31}P NMR spectrum of **1** shows a singlet for both μ_2-bridging P atoms at relatively low field (δ = 287.6 ppm), as expected for Zr_2P_2 complexes.[9]

Surprisingly, **1** undergoes metathesis reactions in boiling xylene at 140 °C to give the unsymmetrical **2**, which contains one $Cp(Et_2N)$- and one Cp_2-substituted Zr atom, in 28% yield (Scheme 1). The mechanism of this unprecedented Cp/NEt_2 exchange reaction at the zirconium atoms is still unknown. However, the formation of **2** probably occurs intermolecularly, as indicated by the strong concentration dependence of the reaction. The complex is formed in only 1.5% yield if **3** is reacted with $[Zr(NEt_2)_4]$ in boiling xylene. The ^{31}P NMR spectrum of **2** at 28 °C shows one singlet at δ = 273.8 ppm which is consistent with an fast inversion of configuration at phosphorus on the time scale of the experiment. This inversion process could not be frozen out at low temperature due to the moderate solubility of **2** in CH_2Cl_2, $CHCl_3$, Et_2O and aromatic solvents. Its ^{1}H NMR spectrum shows, as expected, three anisotropic sets of Cp groups and one type of ethyl protons. Additionally, the constitution of **2** has been corroborated by an single-crystal X-ray diffraction analysis. The four-membered Zr_2P_2 skeleton is slightly puckered (Zr1-Zr2-P1/Zr1-Zr2-P2 = 3.2°). The Zr1−P1 [2.552(3) Å] and Zr1−P2 [2.527(3)] bond lengths are similar to the values for Zr2−P1 [2.550(3) Å] and Zr2−P2 [2.615(3) Å] (Figure 1).



Scheme 1

The Zr−P distances are practically identical to the values observed in other Zr(+4)-phosphanide complexes but ca. 4% shorter than the single bonds in isostructural Zr_2P_2

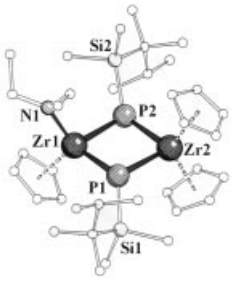


Figure 1. Molecular structure of **2**; hydrogen atoms are omitted for clarity; selected distances [Å] and angles [°]: Zr1−N1 1.958(11), Zr1−P1 2.552(3), Zr1−P2 2.527(3), Zr2−P1 2.550(3), Zr2−P2 2.615(3), P1−Si1 2.225(4), P2−Si2 2.210(4); P2−Zr1−P1 89.8(1), P1−Zr2−P2 87.90(9)

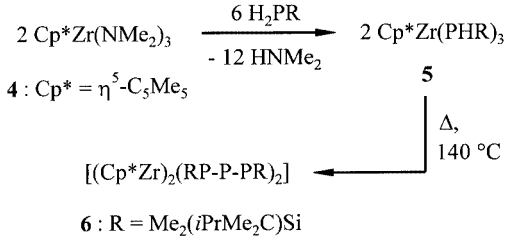
complexes with Zr(+3) centers.[1,9] The Zr−N and Si−P distances are unexceptional. The P atoms are pyramidal coordinated (ΣP1 = 344.5°, ΣP2 = 340.0°) and possess practically identical endocyclic angles at the Zr centers.

In another P−H/Zr−N σ-metathesis reaction, starting from the tris(amido) complex **4** and H_2PR in the molar ratio of 1:3 in boiling toluene, the first zirconium tris(phosphanido) complex $[Cp^*Zr(PHR)_3]$ (**5**; $Cp^* = \eta^5$-C_5Me_5) has been prepared (Scheme 2).



Scheme 2

This compound can be isolated in the form of a red-brown oil in quantitative yield and has been characterized by its ^{1}H and ^{31}P NMR spectra and mass spectrum. Its temperature-independent ^{31}P NMR spectrum shows a shielded ^{31}P nucleus at δ = −173.5 [$^1J_{P,H}$ = 182.4 Hz] with significantly different δ and $^1J_{P,H}$ values compared with $[Cp_2Zr(PHR)_2]$ complexes of type **3** [R = silyl; δ = −51 to −78 ppm, $^1J_{P,H}$ = 204 to 215 Hz].[7,9c] Prolonged heating of a solution of **5** in xylene at 140 °C (four days) furnishes a reaction mixture from which the novel cluster **6** can be isolated by fractional crystallization in 12% yield. The dark green crystals are only sparingly soluble in common organic solvents. Its temperature-invariable ^{31}P NMR spectrum shows an AA′BB′CC′ spin system of higher order which is in accordance with an identical chelating coordination mode of both [RP−P−PR] ligands toward the Zr centers. Since the appearance of the spectrum remains unchanged in polar solvents (THF, DMF) even at low temperature, there is no indication for a dissociation process in solution. However, the structure of **6** could only be established by an X-ray diffraction analysis. This revealed a Zr_2P_6 cluster core with a center of symmetry as a characteristic structural mo-

tif, which can be simply described as a dimer of two butterfly-like ZrP_3 frameworks (Figure 2).

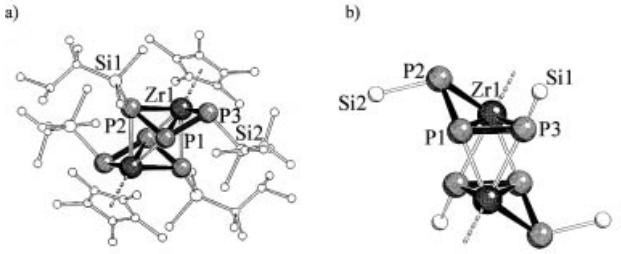


Figure 2. a) Molecular structure of **6**; hydrogen atoms are omitted for clarity; selected distances [Å] and angles [°]: Zr1−P1 2.731(3), Zr1−P2 2.665(3), Zr1−P3 2.593(3), Zr1−P1A 2.617(3), Zr1−P2A 2.796(3), P1−P3 2.175(4), P1−P2 2.184(4), P3−Si2 2.267(4), P2−Si1 2.284(4); P3−Zr1−P2 83.05(9), P3−Zr1−P1 48.14(8), P2−Zr1−P1 47.73(9), P1−P3−Zr1 69.2(1), P3−P1−Zr1 64.57(9), P2−P1−P3 106.2(1); b) view along the distorted octahedral connection between the two hypothetical ZrP_3 halves in **6**; organo groups are omitted for clarity

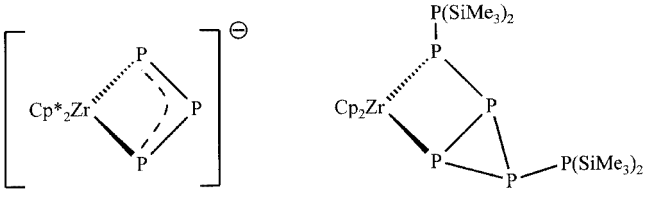
The hypothetical ZrP_3 halves have a distorted octahedral geometry and are connected to each other through the two Zr1−P1−P3 and Zr1A−P1A−P3A triangular faces (see Figure 2b), which leads to significantly different Zr−P distances between the ZrP_3 moieties [Zr1−P2A 2.796(3) Å, Zr1−P1A 2.617(3) Å]. However, the Zr−P distances within the butterfly-like ZrP_3 framework are also quite different: the Zr1−P1 distance of the bridgehead bond [2.731(3) Å] is, as expected, longer than the Zr1−P2 [2.665(3) and Zr1−P3 bonds [2.593(3) Å], due to ring strain. Apparently, a stabilization of the hypothetical ZrP_3 halves is achieved by the formation of Zr,P,P multiple-center bonds and the closing of vacant coordination sites at the Zr atom. While the P1 atom is substituent-free, the P2 and P3 atoms bear terminal silyl groups, which are *exo*,*endo* configured with respect to the hypothetical ZrP_3 butterfly-like framework. The almost equal P-P distances in the ZrP_3 halves [2.175(4) and 2.184(4) Å] lie between the values observed in the related complexes **A** (2.10 Å)[10] and **B** (2.24 Å) shown in



A : Cp* = η^5-C_5Me_5 **B** : Cp = η^5-C_5H_5

Scheme 3

Scheme 3,[11] and they imply, in contrast to the electronic situation in **A**, no contribution of stabilizing P-P π-interactions in the R_2P_3 ligand. The geometric features suggest that **6** is the first zirconium oligophosphanide cluster containing an $[RP-P-PR]^{3-}$ anion. The synthesis of the parent anion $[HP-P-PH]^{3-}$ by reduction of P_4 with alkali metals in liquid ammonia has recently been reported.[12]

Experimental Section

General Remarks: All manipulations were carried out under anaerobic conditions in dry argon using standard Schlenk techniques. Solvents were refluxed over an appropriate drying agent, and distilled and degassed prior to use. NMR spectra were recorded on a Bruker Avance250 spectrometer at ambient temperature operating at 250.1 MHz (^{1}H) and 101.3 MHz (^{31}P). Chemical shifts are reported relative to TMS at 0.00 (^{1}H) and to 85% H_3PO_4 in D_2O at 0.00 (^{31}P). Mass spectra were measured on a Varian MAT CH7 spectrometer. Elemental analyses were performed by the microanalytical service of the department. The starting materials H_2PR [R = Me_2(*i*PrMe$_2$C)Si],[13] [$Zr(NEt_2)_4$] and [Cp*$Zr(NMe_2)_3$] (**4**)[14] were prepared according to literature procedures.

Preparation of 1: [$Zr(NEt_2)_4$] (0.79 g, 2.1 mmol) was added to a solution of **3** (1.21 g, 2.1 mmol) in benzene and refluxed for 8 h. Subsequently, the volatile components of the mixture were evaporated off at 80 °C (10^{-3} Torr), affording the oily red-brown product in pure form according to NMR spectroscopy and EI mass spectrometry. Yield: (1.67 g, 2.07 mmol), 99%. ^{1}H NMR (C_6D_6): δ = 0.53 (d, $^3J_{P,H}$ = 3.7 Hz, 12 H, $SiMe_2$), 1.12 (d, $^3J_{H,H}$ = 6.6 Hz, 12 H, $CHMe_2$), 1.16 (s, 12 H, $SiCMe_2$), 1.98 (t,$^3J_{H,H}$ = 7.4 Hz, 12 H, NCH_2Me), 2.15 (sept., $^3J_{H,H}$ = 6.6 Hz, 2 H, $CHMe_2$), 3.23 (q, $^3J_{H,H}$ = 7.4 Hz, 8 H, NCH_2Me), 5.89 (t, $^3J_{P,H}$ = 1.9 Hz, 10 H, Cp) ppm. ^{31}P NMR (C_6D_6): δ = 287.6 (s) ppm. MS (EI, 70 eV): *m*/*z* (%) = 805 (3) [M^+], 720 (4) [M − (*i*PrMe$_2$C)]$^+$, 65 (100) [Cp^+].

Preparation of 2: A solution of **1** (1.10 g, 1.36 mmol) in xylene was heated at 140 °C for 2 days, affording a deep-brown reaction mixture. After removal of the solvent and other volatile components at 80 °C and 10^{-3} Torr, the resulting residue was taken up in ca. 5 mL hexane. The desired product crystallized after several days at −15 °C in the form of green-brown crystals. Yield: (0.31 g, 0.38 mmol), 28%. ^{1}H NMR (C_6D_6): δ = 0.52 (d, $^3J_{P,H}$ = 3.7 Hz, 12 H, $SiMe_2$), 1.14 (d, $^3J_{H,H}$ = 6.6 Hz, 12 H, $CHMe_2$), 1.15 (s, 12 H, $SiCMe_2$), 2.04 (t,$^3J_{H,H}$ = 7.4 Hz, 6 H, NCH_2Me), 2.15 (sept., $^3J_{H,H}$ = 6.6 Hz, 2 H, $CHMe_2$), 3.31 (q, $^3J_{H,H}$ = 7.4 Hz, 4 H, NCH_2Me), 5.89 (t, $^3J_{P,H}$ = 2.0 Hz, 5 H, Cp), 5.92 (t, $^3J_{P,H}$ = 1.8 Hz, 5 H), 5.97 (t, $^3J_{P,H}$ = 1.1 Hz, 5 H, Cp) ppm. ^{31}P NMR (C_6D_6): δ = 273.8 (s) ppm. MS (EI, 70 eV): *m*/*z* (%) = 720 (4) [M − (*i*PrMe$_2$C)]$^+$, 648(8) [M − (*i*PrMe$_2$C) − NEt_2]$^+$, 65 (80) [Cp^+], 29 (100) [Et^+]. correct C, H-combustion analysis: $C_{35}H_{63}NP_2Si_2Zr_2$ (798.4): calcd. C 52.65, H 7.95; found C 51.98, H 7.90.

Preparation of 3: A solution of LiP(H)R [R = Me_2(*i*PrMe$_2$C)Si] (6.8 mmol) in 20 mL toluene, freshly prepared from H_2PR (1.20 g, 6.8 mmol) and 4.26 mL of a 1.6 M solution of BuLi in hexane (Aldrich) in 50 mL toluene at 0 °C, was added to a solution of [Cp_2ZrCl_2] (1.0 g, 3.4 mmol) in 50 mL toluene at −70 °C. The reaction mixture was allowed to warm to room temperature within 8 h and then stirred for one day. After filtration, the solvent was removed under reduced pressure affording a solid residue. The latter was redissolved in ca. 20 mL hexane from which the desired product crystallized after a few days in the form of pale red crystals. Yield: (1.38 g, 2.41 mmol), 71%. ^{1}H NMR (C_6D_6): δ = 0.54 (s, 12 H, $SiMe_2$), 1.12 (d, $^3J_{H,H}$ = 6.6 Hz, 12 H, $CHMe_2$), 1.14 (s, 12 H, $SiCMe_2$), 2.12 (sept., $^3J_{H,H}$ = 6.6 Hz, 2 H, $CHMe_2$), 2.61 (d $^1J_{P,H}$ = 214 Hz, 2 H, PH,), 5.93 (s, 10 H, Cp) ppm. ^{31}P NMR (C_6D_6): δ = −51.0 (d, $^1J_{P,H}$ = 214 Hz) ppm. MS (EI, 70 eV): *m*/*z* (%) = 394 (9) [M − PH(*i*PrMe$_2$C)$SiMe_2$]$^+$, 143 (98) [*i*PrMe$_2$C)$SiMe_2$]$^+$. Correct C, H combustion analysis: $C_{26}H_{50}P_2Si_2Zr$ (572.0): calcd. C 54.59, H 8.81; found C 54.12, H 8.80.

Preparation of 5: A solution of **4** (1.72 g, 5.24 mmol) in 50 mL toluene was treated with H_2PR [R = Me_2(*i*PrMe$_2$C)Si] (2.76 g,

15.72 mmol) and refluxed at 110 °C for 3 h, resulting in an clear dark solution. After removal of all volatile components at ca. 60 °C and 10^{-3} Torr, the oily red-brown product was isolated in practically quantitative yield. Yield: (3.94 g, 5.23 mmol), 99.8%. ^{1}H NMR (C_6D_6): δ = 0.56 (s, 18 H, $SiMe_2$), 1.14 (d, $^3J_{H,H}$ = 6.6 Hz, 18 H, $CHMe_2$), 1.15 (s, 18 H, $SiCMe_2$), 1.87 (m, $^1J_{P,H}$ = 182.4 Hz, 3 H, PH), 2.13 (sept., $^3J_{H,H}$ = 6.6 Hz, 3 H, $CHMe_2$), 2.22 (s, 15 H, C_5Me_5) ppm. ^{31}P NMR (C_6D_6): δ = −173.5 (d, $^1J_{P,H}$ = 182 Hz) ppm. MS (EI, 70 eV): *m*/*z* (%) = 752 (3) [M^+], 577 (5)[M − PH(*i*PrMe$_2$C)SiMe$_2$]$^+$, 143 (98) [*i*PrMe$_2$C)SiMe$_2$]$^+$, 73 (100) [$SiMe_3^+$].

Preparation of 6: A red-brown solution of **5** (1.36 g, 1.8 mmol) in 10 mL xylene was heated at 140 °C for three days, affording a dark green solution. After removal of all volatile components under vacuum (10^{-3} Torr) at a maximum of 100 °C (oil bath), the solid residue was redissolved in ca. 10 mL hexane, from which dark green crystals precipitated after six days. Yield: (0.26 g, 0.21 mmol), 12%. ^{1}H NMR (C_6D_6): δ = 0.52 (s, 12 H, $SiMe_2$), 0.54 (s, 12 H, $SiMe_2$), 1.11 (d, $^3J_{H,H}$ = 6.6 Hz, 12 H, $CHMe_2$), 1.13 (d, $^3J_{H,H}$ = 6.6 Hz, 12 H, $CHMe_2$), 1.16 (br. s, 24 H, $SiCMe_2$), 2.15 (br. m, 4 H, $CHMe_2$), 2.05 (s, 30 H, C_5Me_5) ppm. ^{31}P NMR (C_6D_6, assignment according to $[RP_A-P_B-P_CR]_2$ and simulations [16]): $\delta(P_A)$ = −123.0 (m, $^1J_{P_A,P_B}$ = 374, $^2J_{P_A,P_C}$ = 68 Hz), $J_{P_A,P_{A'}}$ = 23.0, $J_{P_A,P_{B'}}$ = 3.0, $J_{P_A,P_{C'}}$ = 2.5 Hz; other long-range couplings = 0), δ_{P_B} = −62.6 (m, $^1J_{P_B,P_A}$ = 374, $^1J_{P_B,P_C}$ = 269, $J_{(P_B,P_{B'}}$ = 8.6, $J_{P_B,P_{A'}}$ = 3.0 Hz; other long-range couplings = 0), δ_{P_C} = −85.4 (m, $^1J_{P_C,P_B}$ = 269, $^2J_{P_C,P_A}$ = 68, $J_{P_C,P_{C'}}$ = 4.9, $J_{P_C,P_{A'}}$ = 2.5 Hz; other long-range couplings = 0). Correct C, H combustion analysis: $C_{52}H_{106}P_6Si_4Zr_2$ (1212.0): calcd. C 51.53, H 8.81; found C 51.12, H 8.76.

X-ray Crystallographic Study

1: Triclinic, space group $P\bar{1}$, a = 10.1276(18), b = 21.453(5), c = 17.066(3) Å, α = 83.016(9)°, β = 73.063(9)°, γ = 83.157(9)°, V = 2007.2(4) Å^3, 5230 independent reflections [$I > 2\sigma(I)$], 349 parameters, $R1$ = 0.0823 (observed reflections), $wR2$ = 0.1951 (all data).

6: Monoclinic, space group $P2_1/c$, a = 11.719(8), b = 12.861(9), c = 20.817(14) Å, β = 90.643(15)° Volume = 3137(4) Å^3, 4024 independent reflections [$I > 2\sigma(I)$], 281 parameters, $R1$ = 0.0843 (observed reflections), $wR2$ = 0.2390 (all data).

The intensities were measured with a Bruker-axs-SMART diffractometer. (Mo-K_α radiation, λ = 0.71707 Å, ω-scan, The structures were solved by direct methods (SHELXS 97). Refinements were carried out with the SHELXL-97 package.[16] All non-hydrogen atoms were refined with anisotropic temperature factors. The hydrogen atoms were placed in calculated positions and refined isotropically in riding mode. All refinements were made by full-matrix least-squares on F^2.

CCDC-158194 (**1**) and -158195 (**6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of a Dinuclear Manganese(III,III) Complex with Three Phenolate Ligands

Reiner Lomoth,[a] Ping Huang,[b] Jiutian Zheng,[c] Licheng Sun,*[c] Leif Hammarström,*[a] Björn Åkermark,[c] and Stenbjörn Styring*[b]

Keywords: Manganese / Ligand design / Redox chemistry

A dinuclear manganese complex ($[Mn_2L(\mu\text{-}OAc)_2]PF_6$) has been synthesized, where L is the trianion of 2,6-bis{[(2-hydroxy-3,5-di-*tert*-butylbenzyl)(2-pyridylmethyl)amino]-methyl}-4-methylphenol, a ligand with three phenolate groups. The two pseudo-octahedrally coordinated Mn ions are bridged via the two bidentate acetate ligands and the 4-methylphenolate group of the ligand. We have characterized the complex with electrochemistry, spectroelectrochemistry and EPR spectroscopy. Electrochemically the $Mn_2^{III,III}$ complex undergoes two metal-centered quasi-reversible one-electron reduction steps ($E_{1/2}$ = 0.04 and −0.32 V vs. SCE). Reduction to the $Mn_2^{II,III}$ state results in transformation into a modified complex with slightly different redox properties. One-electron oxidation ($E_{1/2}$ = 0.96 V vs. SCE) affords the $Mn_2^{III,IV}$ state while further one-electron oxidation ($E_{1/2}$ = 1.13 V vs. SCE) presumably involves ligand oxidation. High valent Mn complexes involving Mn^{IV} or Mn^{V} centers are of particular interest as intermediates in catalytic water oxidation. The redox potentials of $[Mn_2L(\mu\text{-}OAc)_2]^+$ show the expected stabilization of higher manganese oxidation states compared with the related complex, $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^+$.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

A major reason for the interest in higher valent multinuclear manganese complexes is the catalytic activity of the $(Mn)_4$ cluster in photosynthetic water oxidation.[1] This is a key reaction in nature that provides the electrons needed for the reduction of CO_2 resulting in energy rich reduced carbon products. Therefore, synthetic Mn complexes have potential importance for the construction of artificial photosynthetic systems to convert solar energy into fuels.[2] The oxygen evolving center (OEC) in photosynthesis, as well as artificial systems aiming for fuel production by light-induced water splitting, has to involve a catalyst that can store four oxidation equivalents generated by subsequent light-induced one-electron oxidations. Finally the catalyst has to retrieve all four electrons from water since oxidation of water can be accomplished at a reasonable potential (0.82 V vs. NHE at pH 7) only in a four-electron process. In photosynthesis catalytic water oxidation is carried out in Photosystem II by the OEC, an oxo-bridged tetranuclear manganese complex that cycles between five redox states.[1]

In our attempts to mimic the electron transfer reactions on the electron donor side of Photosystem II we have, earlier, studied the light-induced oxidation of manganese complexes sensitized by $[Ru(bpy)_3]^{2+}$ (bpy = 2,2′-bipyridine) and we recently observed the light-induced three-step oxidation of the $Mn_2^{II,II}$ dimer $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^+$ [3] to a $Mn_2^{III,IV}$ dimer in an aqueous/acetonitrile medium.[4]

Although the exact mechanism of photosynthetic water oxidation is not solved, it is clear that some of the steps in the cyclic redox reactions (the so called S-cycle) involve Mn-centered oxidations.[5] It is also clear that the Mn ions in the higher oxidation states of the S-cycle are at the Mn^{III} state or higher. A $Mn^{V}{=}O$ moiety has been proposed to play a key-role in O−O bond formation in both photosynthesis[6] as well as in a model complex.[7] With regard to the importance of high-valent manganese species for catalytic water oxidation, we have commenced with the synthesis of manganese complexes with an increased number of negatively charged ligand functions to stabilize higher oxidation states of manganese. In this paper we on report the synthesis and characterization of complex **4**, which is the $Mn_2^{III,III}$ dimer $[Mn_2L(\mu\text{-}OAc)_2]^+$, where L is the trianion of 2,6-bis{[(2-hydroxy-3,5-di-*tert*-butylbenzyl)(2-pyridylmethyl)amino]methyl}-4-methylphenol. The complex con-

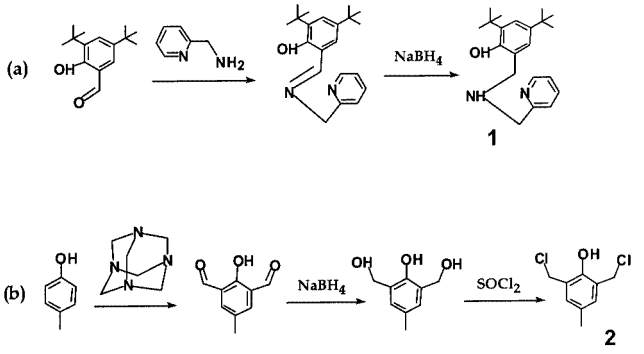
tains a bridging phenolate and two additional phenolate groups that replace two of the pyridyl groups in the $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^+$ complex resulting in considerably lowered redox potentials for the manganese redox couples. Thus, the high valent Mn states that are of interest for water oxidation may also be accessible with photochemical oxidation, using photo-oxidants such as $[Ru(bpy)_3]^{2+}$.

Results and Discussion

Synthesis

A ligand similar to the one used here has been employed for the preparation of $Fe_2^{II,III}$ and $Fe_2^{III,III}$ complexes[8] but no Mn dimer with this type of $(N_2O_2)_2$-μ-O compartmental ligand has been prepared. We have introduced *tert*-butyl substituents on the phenol groups of the ligand to increase their electron donating effect and to improve the solubility of the complex. Apart from that the *tert*-butyl groups seem to ease the isolation of the Mn complex since we were not able to isolate the analogue Mn complexes with unsubstituted or methyl-substituted phenol groups.

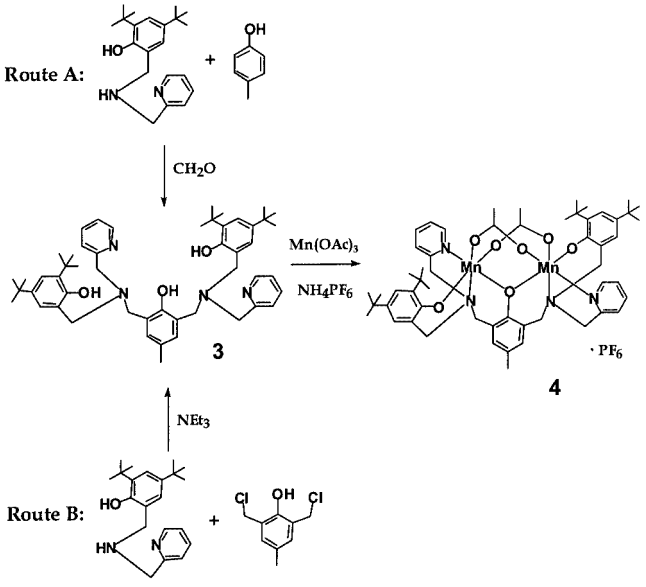
The synthesis of the ligand precursors is shown in Scheme 1. The Schiff base intermediate was made by a condensation reaction of 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde and picolylamine. The reduction of the Schiff base by sodium hydroborate gave the secondary amine **1**. 2,6-dichloromethyl-4-methylphenol **2** was synthesized by reaction of 2,6-dihydroxy-4-methylphenol, which was prepared by the procedure shown in Scheme 1 (see b).



Scheme 1

Two different routes have been used to synthesize the ligand **3** in reasonable yields (Scheme 2). In route A, the secondary amine **1** was reacted directly with *p*-cresol and paraformaldehyde in a modified Mannich reaction in an ethanol/water mixture. Alternatively, **3** was obtained from the reaction of the secondary amine **1** and 2,6-dichloromethyl-4-methylphenol **2** according to route B.

Reaction of manganese(III) acetate in ethanol with **3** gave the manganese(III,III) dimer complex $[Mn_2L(\mu\text{-}OAc)_2]^+$, **4**, where L is the trianion of **3**. Elemental analysis, ESI-MS (see Exp. Sect.), electrochemistry, spectroelectrochemistry, and EPR spectroscopy (see below) were used to characterize the complex. In ESI-MS spectra the base peak was attributed to the mono-charged $Mn_2^{III,III}$ dimer complex.



Scheme 2

In addition to the base peak a minor peak at a higher *m*/*z* region was observed that can be assigned to a trace of a $Mn_4^{III,III,III,III}$ tetramer $[\{Mn_2L(\mu\text{-}OAc)_2\}_2(PF_6)]^+$ with one counterion. The tetramer has exactly twice the mass of the dimer, suggesting either a weak association between two structurally intact dimers, or a true tetramer with acetates crossbridging between the dimer units. The tetramer could be formed during the ionization process in ESI-MS, but the fact that these tetramers may have been formed during the synthesis cannot be excluded.

Complex **4** can be expected to exist in two diastereomeric forms with the pyridine nitrogens *syn* or *anti* to the Mn−O(phenolate)−Mn plane. Within the limits of spectral resolution no indication for a mixture of different diastereomers in the preparation of **4** was obtained by any of the spectroscopic methods applied.

Several attempts to crystallize **4** failed.

Spectroscopic and Electrochemical Characterization of 4

We will begin by describing the spectroscopic and electrochemical characterization of **4**. In the following sections we will then describe the characterization of the different products obtained by reduction or oxidation of **4**.

Magnetic Susceptibility Measurements

The molar magnetic susceptibility χ in a powder sample of **4**(PF_6) was measured as a function of temperature between 2 and 300 K. The product χT amounts to 5.34 $cm^3mol^{-1}K$ at 300 K and decreases to 0.21 $cm^3mol^{-1}K$ at 2 K (not shown). The temperature behavior reveals antiferromagnetic coupling between the Mn^{III} sites and the high value of χT at 300 K indicates a weak coupling interaction. The best fit of the data was obtained with a *g*-factor of 1.99

and a fraction of dimer of $F = 0.961$ and resulted in an exchange coupling constant of $J = -8.5$ cm^{-1}. Weak antiferromagnetic coupling with similar values of $-J = 5-8$ cm^{-1} has been reported for other $Mn_2^{II,III}$ and $Mn_2^{II,II}$ complexes with a (μ-phenoxo)bis(μ-acetato) core.[9] No reference data is available for $Mn_2^{III,III}$ complexes with the same bridging structure but the difference between the $Mn_2^{II,III}$ and $Mn_2^{II,II}$ states of $[Mn_2(bpmp)(\mu\text{-}RCOO)_2]^{+/2+}$ [10] is small and similar behavior might be expected for the $Mn_2^{III,III}$ complex **4**, supporting its (μ-phenoxo)bis(μ-acetato) formulation.

EPR Spectroscopy

The perpendicular mode EPR spectrum of **4** is shown in Figure 1 (see c). This spectrum is essentially silent as expected for a $Mn_2^{III,III}$ dimer with an integral spin. Moreover, no signals were detected with parallel mode EPR (not shown). The absence of a parallel mode signal has been interpreted as an indication for antiferromagnetic coupling between two Mn^{III} ions, resulting in an $S = 0$ singlet ground spin state.[11] Magnetic susceptibility measurements of **4** clearly reveal weak antiferromagnetic coupling between the two Mn^{III} ions (see above). Weak multiline signals centered at $g \approx 2$ in the perpendicular mode spectrum (see c in Figure 1) can be assigned to traces of a $Mn_2^{II,III}$ species (ca. 4100−4600 G) and a $Mn_2^{III,IV}$ species (ca. 2900−4000 G) that amount to $< 5\%$ and $< 1\%$ of the total Mn, respectively (for details of the quantification see Exp. Sect.). Thus, the dominating part ($> 94\%$) of the material is an EPR silent $Mn_2^{III,III}$ dimer, as expected. The $Mn_2^{II,III}$ signal probably arises from the reduced state of **4**.

UV/Vis Spectroscopy

Figure 2 shows the electronic spectrum of **4** and its oxidation and reduction products in acetonitrile. On the basis of similarities with the spectra of other Mn complexes and the spectral changes observed upon oxidation and reduction (see below), the following assignments of the electronic transitions are suggested: The UV absorption with the pronounced peak at $\lambda = 260$ nm is observed with the complex as well as with the protonated ligand (not shown). This can be assigned to LC transitions of the aromatic groups, which are only slightly affected in energy and intensity by the oxidation state of the Mn ions. The band at 400 nm ($\varepsilon = 4600$ M^{-1}cm^{-1}) is presumably a CT transition from the bridging phenolate to Mn^{III} that has been observed between 320 and 400 nm with other phenoxo bridged $Mn_2^{II,III}$ and $Mn_2^{III,III}$ complexes.[9] The intensity of this bridging phenolate-Mn^{III} LMCT band has been reported to amount to as much as $\varepsilon = 2100$ M^{-1}cm^{-1} per phenoxo bond.[12] This value is in good agreement with the spectrum of **4** ($\varepsilon = 2300$ M^{-1}cm^{-1} per bridging phenoxo bond). The additional visible absorption might originate from LMCT transitions from other ligands, i.e. the nonbridging phenolate ligands or the pyridyl ligands, and also from a splitting of the metal d-orbitals due to the reduced symmetry of the complex. LF transitions of six-coordinated Mn^{III} complexes can occur in the visible

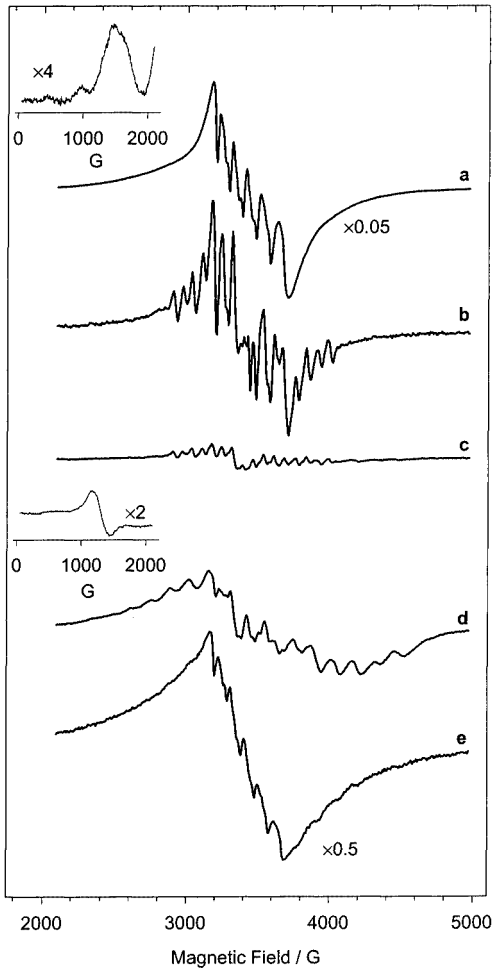


Figure 1. EPR spectra of **4** (1 mm, spectrum c) and its oxidation and reduction products in CH_3CN [0.1 M $N(n\text{-}C_4H_9)_4PF_6$] observed after electrolysis at −0.05 V (d), −0.50 V (e), 0.92 V (b) and 1.25 V (a). EPR parameters. *T*, 4 K; microwave frequency, 9.62 GHz; modulation amplitude, 10 G; microwave power, 3 mW (a, c, d), 0.3 mW (b, e). The spectra are normalized in amplitude (to the same microwave power, number of spectrometer scans, gain etc.) such that their size is approximately similar to facilitate comparison

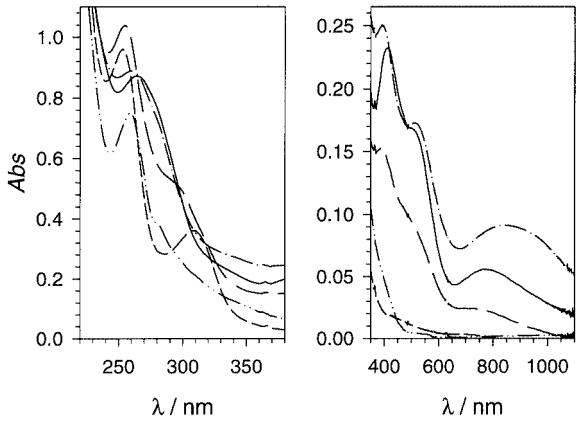

Figure 2. Electronic absorption spectrum of **4** ($5 \cdot 10^{-4}$ M, −) and spectra recorded after electrolysis at −0.05 V (− −), −0.60 V (---), 1.08 V (− · −), and 1.30 V (− · · −) in acetonitrile [0.1 M $N(n\text{-}C_4H_9)_4PF_6$]. $l = 1$ mm

region[13] but are of low intensities (typically $\varepsilon < 500$ $M^{-1}cm^{-1}$ [9a,14]).

IR Spectroscopy

IR spectra of ligand **3** and complex **4** (**4** as PF_6^- salt, see Supplementary Material) were recorded between 4000 and 400 cm^{-1}. Based on characteristic frequencies and comparison with the spectrum of **3,** the following assignments are suggested for the bands observed with **4** in agreement with the composition of the complex: 3082 cm^{-1}(w, ν C−H, aryl); 2954, 2907, 2868 cm^{-1} (s, ν C−H, alkyl); 1579cm^{-1} (s, ν_a C=O, carboxylate); 1605, 1571, 1478 cm^{-1}(m, ν C=C, aryl); 1430 cm^{-1}(m, ν_s C=O, carboxylate); 1384, 1361 cm^{-1} (w, δ C−H, alkyl); 844 cm^{-1}(s, ν_a P−F, PF_6^-); 761, 810 cm^{-1}(m, γ C−H, aryl); 558 cm^{-1} (m, δ P−F, PF_6^-). No assignment could be made for a number of weaker bands at 1247, 1171, 663, 617, 591 cm^{-1} of which the bands at 663 and 591 cm^{-1} were clearly absent in the spectrum of **3** and probably involve metal to ligand modes as ν Mn−O−Mn that were observed between 550 and 750 cm^{-1} with μ-oxo-bis(μ-carboxylato) $Mn^{III,III}$ complexes.[15]

The IR spectrum of **3** shows additional bands at about 3000 cm^{-1} (s, very broad, ν O−H with intramolecular H-bond), 1300 cm^{-1} (m, δ O−H) and 1111 cm^{-1} (m, ν C−O) that are diagnostic for the phenol functions of the ligand. These bands are not observed in the spectrum of **4** providing evidence that all phenol functions are deprotonated and ligated to the metal ions in **4** and that no or very little of the free ligand **3** is present in this preparation of **4**.

The value of Δν between the asymmetric and symmetric C=O stretch modes of the acetate ligands of **4** [$\Delta\nu = (\nu_a$ C=O) − (ν_s C=O) = 149 cm^{-1}], indicates that both acetate ligands are symmetrically bridging the two manganese(III) ions: For monodentate acetate ligands Δν is known to substantially exceed the free ionic value of $\Delta\nu = 164$ cm^{-1}, and for chelating acetate ligands Δν is usually smaller than the value observed with **4**.[16] Asymmetrically bridging carboxylates have been reported to show a greater Δν, similar to monodentate ligands.[17]

Electrochemistry

Cyclic and differential pulse voltammograms of **4** are shown in Figures 3 and 4 and the electrochemical data are summarized in Table 1. All potentials are reported vs. SCE (see Exp. Sect.). The cyclic voltammograms (see a in Figure 3) show two major quasi-reversible reduction waves labeled (1) and (2) and two almost merged oxidation waves labeled (3) and (4) that cannot be fully resolved even in differential pulse voltammetry (see b in Figure 3). A small reverse peak for the first oxidation is already observed with the low sweep rates (10 $mV{\cdot}s^{-1}$, not shown) but the minor reverse peak for the second oxidation only appears at higher sweep rates (≥ 500 $mV{\cdot}s^{-1}$). The one-electron nature of the reductions was confirmed coulometrically. Separate coulometric measurements on the individual oxidations are impeded by the small potential separation but the two oxidations correspond to two electrons in total.

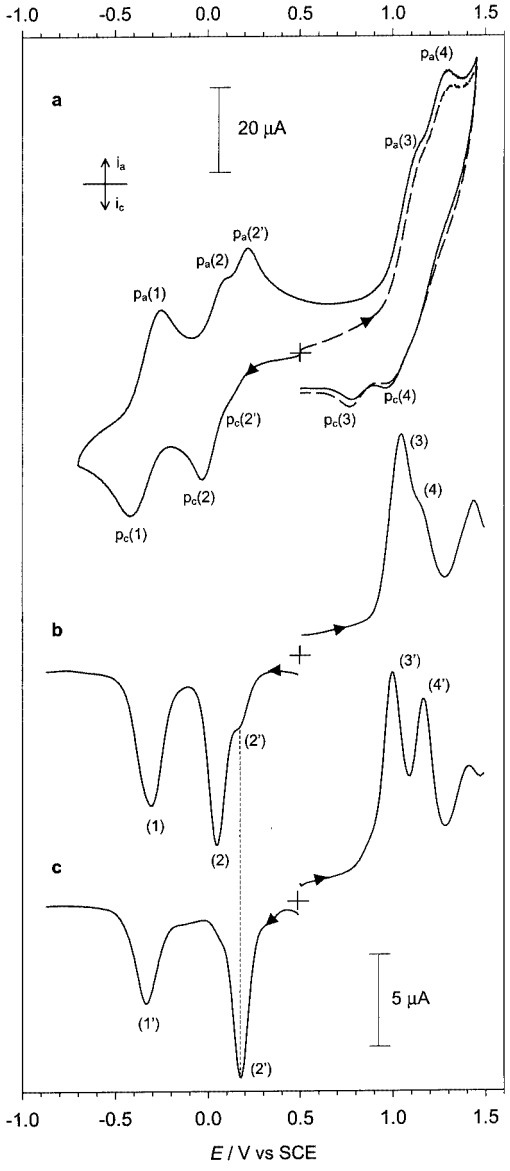

Figure 3. Cyclic voltammograms ($v = 500$ $mV{\cdot}s^{-1}$) (a) and differential pulse voltammogram (b) of **4** (1 mM) in acetonitrile (0.1 M $N(n\text{-}C_4H_9)_4PF_6$). Differential pulse voltammogram of a solution of **4** after exhaustive electrolysis at −0.10 V (c). Arrows indicate scanning direction

The minor quasi-reversible reduction wave (2′) in the cyclic voltammograms, that appears as a shoulder of the first reduction peak (2) in the differential pulse voltammogram (see b in Figure 3), is assigned to a different complex **4′** that is initially present, to a small extent, but is subsequently formed upon one-electron reduction of **4**. Evidence for this assignment comes from voltammograms observed immediately after exhaustive reduction of **4** at −0.10 V showing that the peak for the first reduction has shifted completely from $E(2)$ to $E(2')$ (compare b and c in Figure 3). A corresponding shift is observed for the re-oxidation peak when starting from the reduced complex. The conversion is quantitative (> 95%) as judged from the disappearance of the initial reduction peak (2) of **4**.

Table 1. Electrochemical data in acetonitrile

Complex	$E_{1/2}$ /V[a] (ΔE_p/mV)[b]			
	1	**2**	**3**	**4**
	$Mn_2^{II,III}/Mn_2^{II,II}$	$Mn_2^{III,III}/Mn_2^{II,III}$	$Mn_2^{III,IV}/Mn_2^{III,III}$	[c]
4[d]	−0.32 (140)	0.04 (130)	0.96 (360)	1.13 (340)
4′[d]	−0.34 (275)	0.17 (90)	0.95 (300)	1.13 (300)
$[Mn_2(bpmp)(\mu\text{-}OAc)_2]^{+}$ [e]	0.50 (70[f])	1.06 (120[f])	−[g]	−

[a] From cyclic voltammetry in CH_3CN, ±0.03 V. [b] v = 500 mV·s^{-1}. [c] The final oxidation product is a monomeric Mn^{II} or possibly Mn^{IV} complex. [d] As PF_6^- salt with 0.1 M $N(n\text{-}C_4H_9)_4PF_6$ as supporting electrolyte. [e] As ClO_4^- salt with 0.1 M $N(n\text{-}C_4H_9)_4ClO_4$ as supporting electrolyte. [f] v = 100 mV·s^{-1}. [g] No oxidation to the $Mn_2^{III,IV}$ state in CH_3CN.

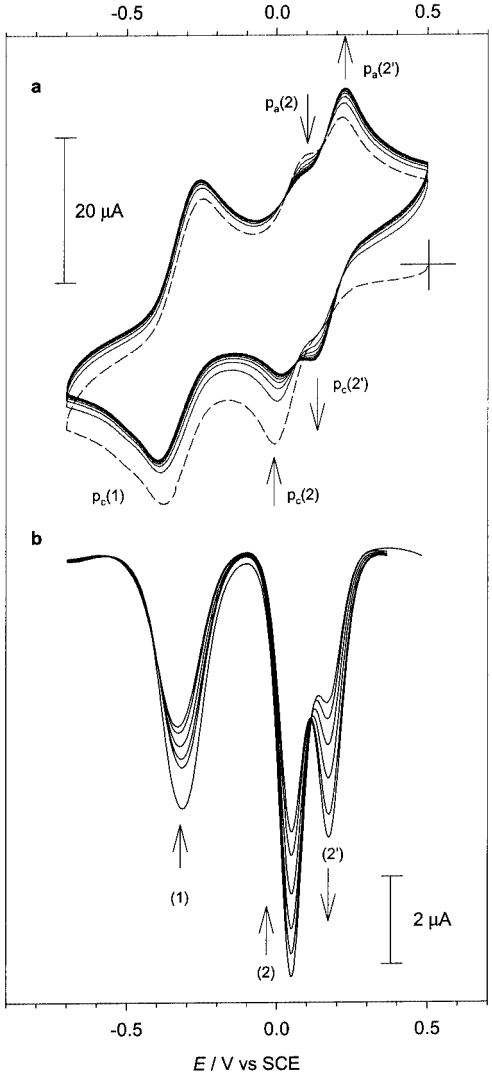

Figure 4. Voltammograms of **4** (1 mm) in acetonitrile [0.1 M $N(n\text{-}C_4H_9)_4PF_6$]. a) Cyclic voltammograms (v = 500 mV·s^{-1}). Scan 1 (- - -) and scans 2 to 10 (−). Arrows indicate the effect of increasing number of scans. b) Differential pulse voltammograms after increasing duration (0, 2, 5, 10, 20, 50 s) of pre-electrolysis at −0.10 V. Arrows indicate the effect of increasing pre-electrolysis time

A set of subsequent cyclic voltammograms of **4** (see a in Figure 4) shows how the reduction wave of **4′** grows with the expense of the reduction wave of **4**, as indicated by the arrows.

The same transformation was followed by differential pulse voltammograms (see b in Figure 4) recorded with increasing time of pre-electrolysis at −0.10 V, providing further evidence that the transformation to **4′** occurs in the one-electron reduced state of **4**.

The effect of this transformation on the potential for the first reduction is $\Delta E_{1/2}$ = 130 mV, while the effect on the second reduction (at −0.3 V) and the two oxidations (around 1 V) is comparatively small ($|\Delta E_{1/2}| \leq 0.05$ V) (see c in Figures 3, 4, Table 1).

The two reductions of both **4** and **4′** exhibit quasi-reversible CV waves (see a in Figure 4) but they are not reversible on the longer time-scale of the bulk electrolysis experiments (see below). For the oxidations of **4′** only small cathodic counter-peaks at $E_{pc}(3')$ = 0.80 V and $E_{pc}(4')$ = 0.98 V are observed on the reverse scan of the cyclic voltammograms (500 mV·s^{-1}, not shown) recorded after exhaustive electrolysis of **4** at −0.10 V. **4′** is unstable in its initial reduced state since well-defined voltammograms of **4′** were obtained only a few minutes after reduction of **4**. This will presumably impede isolation of **4′**. However, spectroscopic characterization of the reduced states of **4′** could be made immediately after reduction of **4**. (see below).

According to its EPR spectrum (see below) **4′** in its one-electron reduced state is a magnetically coupled $Mn_2^{II,III}$ dimer, the exact structure of which we cannot elucidate from our data. The loss of an acetate bridge from **4** as a charge compensating reaction due to reduction of the complex could explain the potential shift of the first reduction. However, with the loss of a negatively charged ligand a larger shift of *all* metal centered reduction and oxidation processes towards higher potentials would be expected. Therefore we suggest that the transformation of **4** into **4′** might instead represent a geometric re-arrangement of the reduced complex rather than loss or exchange of ligands.

Spectroscopic Characterization of the Reduced and Oxidized Products of 4

The products of the two reduction and the two-oxidation processes have been characterized by UV/Vis-spectroelectrochemistry and by EPR spectroscopy on samples prepared by electrolysis of **4** at appropriate potentials. Exhaustive electrolysis in the spectroelectrochemical experiments as well as for preparation of EPR samples occurs on

the time-scale of minutes, i.e. the species observed by these techniques upon *reduction* will be the reduction products of **4′**. The results of these experiments are discussed in the following paragraphs.

First Reduction

The first one-electron reduction of **4** can be assigned to a metal centered process [Equation (1)] resulting in a $Mn_2^{II,III}$ complex as evidenced by EPR spectroscopy.

$$[Mn_2^{III,III}L(\mu\text{-}OAc)_2]^+ + e^- \rightarrow [Mn_2^{II,III}L(\mu\text{-}OAc)_2] \qquad E_{1/2} = 0.04\ V \qquad (1)$$

The EPR spectrum of, **4** after exhaustive reduction at −0.05 V, displays a partially resolved multiline signal centered at $g \approx 2$ and a weak featureless signal at $g \approx 5.3$ (see d in Figure 1). The $g \approx 2$ multiline signal has a total line width of ca. 2300 G. The hyperfine lines are clearly visible but they are somewhat broadened. The relative amplitude of the $g \approx 2$ signal decreases while the $g \approx 5.3$ signal increases with increased temperature (not shown). This indicates that the $g \approx 2$ signal originates from a ground spin state while the $g \approx 5.3$ signal originates from an excited spin state. Similar overall behavior has been reported earlier for the EPR signals from $[Mn_2^{II,III}(bpmp)(\mu\text{-}OAc)_2]^{2+}$ [18], that is weakly antiferromagnetically coupled with a ground spin state $S = {}^1/_2$. In $[Mn_2^{II,III}(bpmp)(\mu\text{-}OAc)_2]^{2+}$ a featureless signal at $g \approx 5.4$ became detectable only above 7.5 K, while the multiline signal centered at $g \approx 2$ dominated at 4 K. In our case, however, the appearance of the relatively large $g \approx 5.3$ signal together with the $g \approx 2$ multiline signal already at 4 K, indicates that the excited spin state is lower in energy than in $[Mn_2^{II,III}(bpmp)(\mu\text{-}OAc)_2]^{2+}$. There are no parallel mode EPR signals of this sample (not shown), which is expected for an $S = {}^1/_2$ system. From EPR spectroscopy we therefore conclude that one electron reduction of **4** gives a weakly antiferromagnetically coupled $Mn_2^{II,III}$ species.

This assignment is in agreement with the spectrophotometrical changes observed during electrolysis at −0.05 V (Figure 2, − −): Upon the first reduction of **4** about half of the visible absorption disappears. Absorption at $\lambda >$ 400 nm has been assigned to the Mn^{III} subunit in the mixed valence $Mn_2^{II,III}$ state[9a] of the similar phenoxo bridged dinuclear manganese complex $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^{2+}$. Therefore, the electronic spectrum corroborates the assignment of the first cathodic process to the formation of a $Mn^{II,III}$ complex. Several isosbestic points are observed in the course of the first reduction (not shown). This suggests that the structural changes of the reduced complex, that lead to the formation of **4′**, as indicated by voltammetry (see above), do not affect the absorption spectrum. Thus, they have a negligible effect on the phenolate to Mn^{III} CT transitions in the visible region and the ligand centered transitions in the UV part of the electronic spectrum.

Re-oxidation of the one-electron reduction product by bulk electrolysis was carried out at 0.60 V after exhaustive reduction at −0.05 V. According to coulometry only 55% of the material could be re-oxidized pointing to a limited stability of the one-electron reduction product. This is supported by the EPR spectrum of the re-oxidized sample (not shown) that can be assigned to uncoupled Mn^{II}, presumably from decomposition of the reduced complex, while the re-oxidized $Mn_2^{III,III}$ species can be expected to be EPR-silent. Note that the time-scale of bulk electrolysis is several minutes, which is much longer than that for the voltammetry experiments (Figures 3 and 4, and above).

Second Reduction

Further one-electron reduction of the $Mn_2^{II,III}$ complex at −0.50 V probably gives rise to both a dimeric $Mn_2^{II,II}$ and a monomeric Mn^{II} complex [Equation (2)].

$$[Mn_2^{II,III}L(\mu\text{-}OAc)_2] + e^- \rightarrow [Mn_2^{II,II}L(\mu\text{-}OAc)_2]^- + \text{monomeric } Mn^{II} \text{ species} \qquad E_{1/2} = -0.32\ V \qquad (2)$$

The EPR spectrum shows a broadened 6-line spectrum in the $g \approx 2$ region (see e in Figure 1) that can be assigned to a monomeric Mn^{II} species. Quantification of the EPR signal reveals that about 48% of the complex was found in the monomeric Mn^{II} form after the second reduction. Since all of the $Mn_2^{II,III}$ signals disappeared it is reasonable to assume that the residual 52% of the complex was kept in the $Mn_2^{II,II}$ state after the second reduction.

This is supported by the observation of an EPR spectrum with parallel mode EPR (Figure 5). This featureless spectrum covers the spectral range from 0−3000 G and indicates the presence of a species with integral spin. Monomeric Mn^{II} species with $S = {}^1/_2$ are not expected to give rise to spectra of this kind. To the best of our knowledge there are no literature reports of parallel mode EPR studies for $Mn^{II,II}$ compounds but spectra of this kind cannot be excluded for antiferromagnetically coupled dimers.

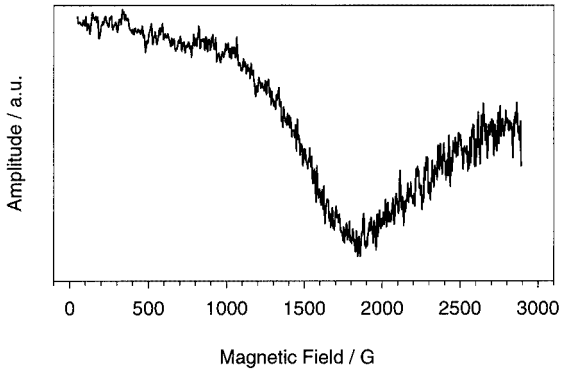

Figure 5. EPR spectrum recorded in parallel mode after bulk electrolysis of **4** at −0.50 V. The spectrum is recorded on the same sample as in Figure 1e. $T = 4$ K; microwave power 16 mW; modulation amplitude 10 G; microwave frequency 9.47 GHz

Reductive degradation of the ligand is unlikely at this potential and presumably a $Mn_2^{II,II}$ complex is formed initially that undergoes some subsequent dissociation reaction giving the monomeric Mn^{II} species observed by EPR.

The assignment of the second reduction to the reduction of Mn^{III} centers to Mn^{II} is in agreement with the spectrophotometric changes: Most of the residual visible absorption of the $Mn_2^{II,III}$ complex disappears upon the second one-electron reduction (Figure 2, ---) as expected from the usually low intensity of MLCT transitions of Mn^{II}. Similar spectral changes have been reported for the reduction of $[Mn_2^{II,III}(bpmp)(\mu\text{-}OAc)_2]^{2+}$ to the $Mn_2^{II,II}$ state.[9a]

First Oxidation

4 can be oxidized in two irreversible one-electron steps that occur very close in potential (Figure 3), making the study of the individual oxidation products of the respective oxidation process more complicated. Still the first oxidation can be assigned to a metal centered process resulting in a $Mn_2^{III,IV}$ dimer [Equation (3)] detected by EPR spectroscopy.

$$[Mn_2^{III,III}L(\mu\text{-}OAc)_2]^{+} \rightarrow [Mn_2^{III,IV}L(\mu\text{-}OAc)_2]^{2+} + e^{-} \qquad E_{1/2} = 0.96\ V \qquad (3)$$

The EPR spectrum in Figure 1 (see b) was observed after partial oxidation of **4** at 0.92 V, i.e. at a potential 40 mV *below* $E_{1/2}$ for the first oxidation. At this potential only a minor fraction of the complex can be expected to be oxidized but further oxidation due to the nearby second anodic process is avoided. The resulting EPR spectrum displays a well-resolved multiline signal (see b in Figure 1). This multiline signal consists of 18−19 lines centered at $g \approx 2$, with an overall line width of 1115 G, and an average hyperfine splitting of ca. 73 G. The spectrum is thus much narrower than that for the one-electron reduced $Mn_2^{II,III}$ product of **4** (see above). A narrow multiline EPR signal of this character (see b in Figure 1) is typical for a $Mn_2^{III,IV}$ dimer that is strongly antiferromagnetically coupled with a resulting spin of $S = {}^1/_2$.[19] Integration of the signal and comparison with a $Mn_2^{III,IV}$ standard (see Exp. Sect.) shows that this multiline spectrum corresponds to about 0.2 mM of $Mn_2^{III,IV}$ after oxidation of a 1 mM solution of **4**. This is similar to the 0.3 charge equivalents determined coulometrically for oxidation of the EPR sample demonstrating that oxidation at 0.92 V is predominantly a metal centered reaction resulting in $Mn_2^{III,IV}$. The multiline signal from the $Mn_2^{III,IV}$ disappeared almost completely (not shown) after re-reduction at 0.50 V. However, for this reduction only 0.04 charge equivalents were consumed, pointing to limited stability of the $Mn_2^{III,IV}$ state. This might also explain that the concentration of $Mn_2^{III,IV}$ after bulk electrolysis is somewhat lower than expected from coulometry.

At higher potentials, such as 1.05 V, electrolysis results in a mixture of oxidation products as the EPR spectra (not shown) are a superposition of a multiline signal from $Mn_2^{III,IV}$ as described above and a 6-line signal that is probably due to monomeric Mn^{II} (see below). Upon re-reduction of this sample at 0.50 V, the multi-line spectrum disappeared while the 6-line spectrum remained, supporting the assignment of the spectra to a $Mn_2^{III,IV}$ complex and Mn^{II}, respectively. Since no 6-line signal was observed upon oxidation at lower potentials, such as 0.92 V (see above), the species giving rise to this signal is presumably a product of the second anodic process.

The spectrophotometrical changes observed upon oxidation of **4** at 1.05 V corroborate the conclusions drawn from the EPR results. The increased absorption in the region 500−1100 nm upon oxidation at 1.08 V (Figure 2, − · −) can be assigned to the $Mn_2^{III,IV}$ complex detected by EPR spectroscopy. Absorption bands observed between 500 and 935 nm have been assigned to phenolate to Mn^{IV} LMCT transitions in Mn^{IV} monomeric complexes[20] as well as $Mn_2^{III,IV}$ and $Mn_2^{IV,IV}$ dimers[21] and bands at $\lambda > 700$ nm have been assigned to intervalence transitions in mixed-valence μ-oxo $Mn_2^{III,IV}$ complexes.[22] Isosbestic points were observed at the outset ($t < 300$ s) of the spectroelectrochemical experiment (not shown). Throughout the course of electrolysis, however, the isosbestic points were not maintained either due to instability of the $Mn_2^{III,IV}$ species or parallel formation of oxidation products from the second oxidation process. This is consistent with the EPR spectroscopic results that show a 6-line spectrum besides the spectrum of the Mn_2III,IV complex after oxidation at this potential (1.05 V).

Second Oxidation

Oxidation at 1.25 V [Equation (4)] gives rise to EPR spectra dominated by a 6-line signal centered at $g \approx 2$ with a hyperfine coupling of ca. 95 G (see a in Figure 1).

$$[Mn_2^{III,IV}L(\mu\text{-}OAc)_2]^{2+} \rightarrow \text{oxidation products} + e^{-} \qquad E_{1/2} = 1.13\ V \qquad (4)$$

The EPR spectrum of the product is identical to the 6-line signal for the sample oxidized at 1.05 V (not shown, see above). A detailed inspection of the lower field region reveals the presence of a very weak signal at g ≈ 4 (inset in Figure 1). The 6-line spectral feature (see a in Figure 1) is very similar to a typical spectrum from monomeric Mn^{II} and we assign this spectrum to Mn^{II}. This assignment is also based on the spectroelectrochemical studies where the complete disappearance of visible and near infrared absorption upon the second oxidation (Figure 2, − · · −) suggests that the second oxidation process generates monomeric Mn^{II} rather than Mn^{IV}, since Mn^{IV} phenolate complexes are known to show intense LMCT transitions in the visible region.[20] Thus, it seems that **4** is degraded during the second oxidation step probably involving ligand oxidation at the relatively high potential that is employed. In the course of the second oxidation isosbestic points are absent (not shown). This is in agreement with a more complicated reaction scheme that possibly involves phenolate ligand oxidation[23] finally resulting in the release of monomeric Mn^{II}.

The very weak EPR signal at $g \approx 4$ might however originate from a trace of Mn^{IV} remaining after the oxidation although the fraction is too small to give a measurable absorption in UV/Vis spectroelectrochemistry (Figure 2). Monomeric Mn^{IV} has been reported to give rise to a 6-line signal around $g \approx 2$, quite similar in shape to the signal

from Mn^{II}, in addition to the weak $g \approx 4$ signal.[20e] It is thus difficult to distinguish Mn^{IV} from Mn^{II} in the $g \approx 2$ region while the $g \approx 4$ region probably is more indicative.

The possible generation of a Mn^{IV} containing state at a high potential in **4** is interesting, although one has to use techniques more rapid than bulk electrolysis to trap and detect it and possibly utilize its oxidative power.

Conclusions

The negative charge of the three phenolate groups in **4** results in a considerable stabilization of higher oxidation states of the Mn ions compared to the case of $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^+$ [9a] that has only one bridging phenoxo group of the bpmp ligand. The stabilization is reflected in the electrochemical potentials summarized in Table 1. The potentials for the $Mn_2^{II,III}/Mn_2^{II,II}$, and $Mn_2^{III,III}/Mn_2^{II,III}$ couples of **4** are lowered by 0.8 and 1.0 V compared with $[Mn_2(bpmp)(\mu\text{-}OAc)_2]^+$, and a third metal centered process attributable to the $Mn_2^{III,IV}/Mn_2^{III,III}$ couple is observed with **4** before oxidative degradation of the complex occurs. With regard to our interest in systems as functional mimics of the water oxidizing complex in Photosystem II, it is worth pointing out that due to the stabilization of high valent Mn states all four of the reported oxidation steps of **4** could be driven with photogenerated $Ru(bpy)_3^{3+}$ ($E_{1/2}$ = 1.32 V). However, accumulation and subsequent use of oxidative equivalents would require a rapid redox cycling in order to outcompete degradation of the less stable states of **4**.

Experimental Section

Materials: Triethylamine and ammonium hexafluorophosphate were purchased from Aldrich and used as received. Silica gel 60 (230−400 mesh) from Merck, Darmstadt, Germany and Aluminum oxide from Aldrich. All solvents were dried by standard methods. 2-aminomethylpyridine was purchased from Lancaster. 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde was purchased from Aldrich and used without further purification.

General Methods: NMR spectra were measured either on Bruker-400 MHz spectrometer for 1D or on a Bruker-500 MHz spectrometer for 2D. The positions of the signals are reported on δ scale in ppm units. The splitting of the signal is described as singlets (s), doublets (d), triplets (t), quadruplets (q), doublets of doublets (dd), or multiplets (m).

The electrospray ionization mass spectrometry (ESI-MS) experiments were performed on a ZacSpec mass spectrometer (VG Analytical, Fisons Instrument). Electrospray conditions were: Needle potential, 3 kV; acceleration voltage, 4 kV; bath and nebulizing gas, nitrogen. The liquid flow was 75 μL per min from a syringe pump (Phoenix 20, Carlo−Erba, Fisons instrument). Solvent, CH_3CN. Accurate mass measurements were obtained by the use of polyethylene glycol (PEG) as an internal standard.

Thin-layer chromatography (TLC) was performed using silica gel (Kieselgel F_{254}) adsorbent.

Column chromatography was performed using silica gel (Kieselgel 60, 0.040−0.063 mm).

Synthesis of *N*-(3,5-Di-*tert*-butyl-2-hydroxy)-*N*-(2-pyridylmethyl)-amine (1): 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde (1.48 g, 6.32 mmol) and picolylamine (0.68 g, 6.32 mmol) were dissolved in MeOH (30 mL) and stirred for 4 hours at 50° C. After cooling to room temperature, $NaBH_4$ (0.34 g, 9 mmol) was added to the solution in small amounts and the solution was stirred for another 4 hours at room temperature. After evaporating the solvent to dryness, the residue was dissolved in CH_2Cl_2 and washed with an aqueous solution of NH_4Cl and dried with Na_2SO_4. 1.20 g (61%) of product was obtained after purification by flash chromatography on silica gel eluting with CH_2Cl_2. ^1H NMR ($CDCl_3$, 400 MHz): δ = 8.58 (d, H-Py); 7.66 (t, H-Py); 7.23 (m, 2 H-Py); 6.84 (d, 2 H-Ph); 3.98 (s, N-CH_2-Py); 3.94 (s, N-CH_2-Ph); 1.43 (s, *tert*-Butyl); 1.28 (s, *tert*-Butyl) ppm.

Synthesis of 2,6-Bis(chloromethyl)-4-methylphenol (2):[24] A solution of 2,6-bis(hydroxymethyl)-4-methylphenol (2.5 g,,15 mmol) in dichloromethane (12.5 mL) was added to a solution of thionyl chloride (7.0 g,60 mmol) in dichloromethane (25 mL). After stirring for 24 hours the mixture was poured over ice (25 mL) and adjusted to pH = 6 with aqueous NaOH. The aqueous solution was extracted with three 25 mL portions of dichloromethane, washed with brine and dried with anhydrous Na_2SO_4. The solution was evaporated to dryness at reduced pressure yielding a pale-yellow solid. By recrystallization from hexane 1.85 g (yield: 60%) of the product was obtained and stored in a freezer. mp: 80° C. ^1H NMR ($CDCl_3$, 400 MHz, ppm): 7.09 (s, 2 H, Ar-H), 4.66 (s, 4 H, Ar-CH_2-Cl), 2.28 (s, 3 H, Ar-CH_3).

Synthesis of 2,6-Bis{[(3,5-di-*tert*-butylbenzyl-2-hydroxy)(2-pyridylmethyl)amino]methyl}-4-methylphenol (3)[25] A solution of (3,5-di-*tert*-butylbenzyl-2-hydroxy)(2-pyridylmethyl)amine (2.1 g, 6.4 mmol) and triethylamine (1.3 g, 13 mmol) in THF (20 mL) was added dropwise to 10 mL of a stirred solution of 2,6-bis(chloromethyl)-4-methylphenol (0.6 g, 3.2 mmol) in THF at 0° C under nitrogen atmosphere. The reaction mixture was stirred for 12 hours at room temperature. Then the solution was filtered to remove the TEA salts, the filtrate was evaporated to dryness and the residue was dissolved in CH_2Cl_2 (80 mL) and washed with brine. The organic phase was dried with anhydrous Na_2SO_4. The product was purified by flash chromatography on silica gel, eluting with CH_2Cl_2. 1.32 g of product was obtained, yield: 52%. ^1H NMR ($CDCl_3$, 400 MHz, ppm): 8.60 (d, H-Py); 7.65 (t, H-Py); 7.31 (d, H-Py); 7.22 (t, H-Ph); 7.16 (d, H-Ph); 6.93 (s, H-Ph); 6.83 (d, H-Ph); 3.83 (s, N−CH_2-Py); 3.78 (s, N−CH_2-Ph); 3.76 (s, N−CH_2-Ph); 2.22 (s, CH_3-Ph); 1.32 (s, *tert*-butyl-Ph); 1.25 (s, *tert*-butyl-Ph).

The Complex of $Mn(OAc)_3(H_2O)_2$ with 2,6-Bis{[(3,5-di-*tert*-butylbenzyl-2-hydroxy)(2-pyridylmethyl)amino]methyl}-4-methylphenol (4):[9a] $Mn(OAc)_3(H_2O)_2$ (95.0 mg, 0.35 mmol) was added to 2,6-bis{[(3,5-di-*tert*-butylbenzyl-2-hydroxy)(2-pyridylmethyl)amino]-methyl}-4-methylphenol (**3**) (135.0 mg, 0.17 mmol) in 85% ethanol (3 mL). The mixture was heated at 50 °C for 30 min and cooled to room temperature. NH_4PF_6 (81 mg, 0.49 mmol) in 85% ethanol (1 mL) was added to the red-brown solution whilst stirring, and the solution was stored in a freezer overnight. The solid was filtered off and washed with 85% ethanol (1.5 mL) at 0° C, H_2O (2 mL) and 99% ethanol (1.5 mL). After drying under vacuum, 151 mg of solid product was obtained. Yield: 86%. ESI-MS: (*m*/*z*): 1009.4 [M − PF_6]$^+$ (calcd. for $C_{55}H_{71}N_4O_7Mn_2$: 1010.06), 2163.8 [2 M − PF_6]$^+$ (calcd. for $C_{110}H_{142}N_8O_{14}F_6PMn_4$: 2165.08); $C_{55}H_{71}F_6Mn_2N_4O_7P$ (1155.02): calcd. C 57.19, H 6.20, N 4.85, Mn 9.51; found C 57.16, H 6.26, N 4.82, Mn 9.44.

Electrochemistry: Cyclic voltammetry, differential pulse voltammetry, and controlled potential electrolysis were performed with an Autolab potentiostat and a GPES electrochemical interface in a 3-electrode cell with the counter electrode separated from the bulk by a fritted disk. The working electrode was a glassy carbon disc (diameter 3 mm) for voltammetry or a platinum grid cylinder (15 mm × 15 mm diameter) for bulk electrolysis, respectively. The reference electrode was a nonaqueous Ag/Ag^+ electrode (10 mM $AgNO_3$ in acetonitrile) of double-junction design. The reference electrode has a potential of −0.08 V vs. the ferrocene/ferrocenium couple in acetonitrile as an external standard. All potentials reported here are vs. the saturated calomel electrode (SCE) and have been converted by adding 0.30 V to the potentials measured vs. the Ag/Ag^+ electrode according to $E_{1/2} = 0.38$ V vs. SCE for the ferrocene/ferrocenium couple.[26]

Electrolyte solutions were prepared from dry acetonitrile (Merck, spectroscopy grade, dried with MS 3 Å) with 0.1 M tetrabutylammonium hexafluorophosphate (Fluka, electrochemical grade, dried at 373 K) as supporting electrolyte. The glassware used was oven dried, assembled and flushed with argon while hot. Before all measurements, the solutions were deoxygenated by bubbling solvent saturated argon through the stirred solutions for 10 minutes. Whilst measuring the samples were kept under an argon atmosphere.

The electrochemical preparation of EPR samples was performed by bulk electrolysis of 1 mm (3 mL) solutions at controlled potentials. The electrolysis was followed by amperometry and coulometry. After electrolysis, samples of 250 μL were taken with an argon filled syringe via a septum from the electrolysis vessel and transferred to argon flushed EPR tubes. The samples were immediately frozen and kept in liquid nitrogen.

UV/Vis Spectroelectrochemistry: Spectroelectrochemical measurements were made in an OTTLE-type quartz cell with an optical path length of 1 mm. A platinum grid of size 10 × 30 mm^2 and 400 meshes per cm^2 was used as working electrode. The counter and reference electrodes were of the same type as described for electrochemistry. Solvent saturated argon was bubbled through samples for 15 min, and they were then transferred to the argon flushed cell with an argon stream. The spectra were recorded on an UV/Vis diode array spectrophotometer (Hewlett Packard 8435).

IR Spectroscopy: IR spectra were recorded on a FT-IR spectrometer (Bruker IFS 66v/S) with the sample as a KBr pellet.

EPR Spectroscopy: All EPR spectra were recorded on a Bruker E580-ELEXSYS spectrometer equipped with an Oxford 900 liquid helium cryostat and an ITC 503 temperature controller. An ER4116DM dual mode X-band resonator of rectangular type (TE_{102} for perpendicular and TE_{012} for parallel mode) was used for all measurements. Data analysis was carried out with either the X-Epr or X-Winpro software packages.

Quantification of **4** in different oxidation states was carried out by double integration of the perpendicular EPR mode signal studied within the selected spectral region. The signal intensity was then converted into spin concentration by comparison with the signal intensity in a standard sample in the same oxidation state with known concentration. All EPR spectra used for the evaluation of the different concentrations were recorded using nonsaturating microwave power.

The amount of $Mn_2^{II,III}$ found in the preparation of **4** was obtained by comparison with the signal in the $g = 2$ region recorded after exhaustive one electron reduction of **4** to the $Mn_2^{II,III}$ state. The reduction was monitored coulometrically providing the exact concentration of $Mn_2^{II,III}$ after electrolysis.

$[Mn_2^{III,IV}(\mu\text{-}O)_2(bpy)_4]^{3+}$ was utilized as the standard for quantification of the $Mn_2^{III,IV}$ complex formed after one-electron oxidation of **4**. The precise concentration of the $[Mn_2^{III,IV}(\mu\text{-}O)_2(bpy)_4]^{3+}$ standard was determined spectrophotometrically at 684 nm.[27]

Mn^{II} acetate (purity > 99.9%) in 10% water/90% acetonitrile was used as standard for quantification of monomeric Mn^{II} species formed, e.g. after two-electron reduction. Mn^{II} acetate was used as purchased.

Magnetic Susceptibility Measurements: Magnetic susceptibility measurements were performed on an MPMS5 magnetometer (Quantum Design Inc.) over a temperature range of 2−300 K and at a magnetic field of 1.0 T. A palladium reference (Quantum Design Inc.) was used for callibration at 298 K. Data were corrected for diamagnetism and the χT vs. T plot was fitted according to the procedure described in ref.[28]

Acknowledgments

Eric Rivière (Université Paris-Sud, Orsay) is gratefully acknowledged for performing and analyzing the magnetic susceptibility measurements. This work was supported by the Knut and Alice Wallenberg Foundation, the Swedish National Energy Administration, the Swedish Research Council, and DESS.

Syntheses, Crystal Structures and Reactivity of Organometallic Tantalum(IV) Phosphinidene Complexes: *trans*-[{Cp*TaCl(μ-PR)}$_2$] (Cp* = C_5Me_5, R = Cy, *t*Bu, Ph), *cis*- and *trans*-[{Cp*TaCl(μ-PMes)}$_2$] (Mes = 2,4,6-$Me_3C_6H_2$) and *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (Cp′ = C_5H_4Me)

Steffen Blaurock[a] and Evamarie Hey-Hawkins*[a]

Keywords: Tantalum / P ligands / Oxo ligands / Isocyanide ligands

The reaction of [Cp*TaCl$_4$] (Cp* = C_5Me_5) with LiPHR (1:1 or 1:2) gives the phosphinidene-bridged tantalum(IV) complexes *trans*-[{Cp*TaCl(μ-PR)}$_2$] [R = Cy (**1**), *t*Bu (**2**), Ph (**3**), 2,4,6-$Me_3C_6H_2$ (Mes) (**4b**)]. When the reaction with LiPHMes is carried out in a 1:1 ratio, *cis*-[{Cp*TaCl(μ-PMes)}$_2$] (**4a**) is also formed besides **4b**. For comparison, *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (**5**) was prepared from [Cp′TaCl$_4$] (Cp′ = C_5MeH_4) and LiPHMes (1:1). **1**–**5** are diamagnetic and were characterised spectroscopically (IR, MS; ^{1}H, ^{31}P, ^{13}C NMR). Crystal structure determinations on **1**–**5** showed the presence of dimeric phosphinidene-bridged Ta^{IV} complexes. The phosphinidene-bridged complexes **1**, **3** and **4b** do not react with acetone, benzophenone, acetonitrile, CS_2 (**1**, **3**), acetaldehyde (**4b**), or ethylaluminum dichloride (**3**). **3** reacts with moist acetone in the presence of traces of air to give the trinuclear cluster [{Cp*TaCl(μ$_2$–O)}$_3$(μ$_3$-O)(μ$_2$-O_2PHPh)] (**6**) in very low yield. With an excess of CyNC, **3** gives [Cp*TaCl(CNCy)$_4$]Cl (**7**), which was characterised by ^{1}H and ^{13}C NMR spectroscopy and by crystal structure determination. As a minor product, [(Cp*TaCl$_2$)$_2$(μ$_2$-O)(η^2,μ$_2$-P_2Cy_2)] (**8**) was also obtained in the reaction of [Cp*TaCl$_4$] with LiPHCy. **6** and **8** were only characterised by crystal structure determination.

Introduction

Organometallic dialkyl- and diarylphosphanido complexes of early transition metals have been studied intensively, while complexes derived from functionalised phosphanes which exhibit a reactive phosphorus-ligand bond have largely been neglected.[1] To date, only a few phosphanido derivatives of organometallic[2,3] and inorganic[4,5] tantalum compounds, one phosphinidene-bridged dimeric Ta^{IV} complex[3] and two stable terminal phosphinidene complexes[5,6] have been described in the literature.

Recently, we reported the syntheses and structures of the primary phosphane complexes [Cp′TaCl$_4$(PH$_2$Tipp)] (Cp′ = C_5H_4Me, Tipp = 2,4,6-*i*Pr$_3$C$_6$H$_2$)[3] and [Cp*MCl$_4$(PH$_2$R)] [Cp* = C_5Me_5; M = Nb, Ta; R = *t*Bu, Ad, Cy, Ph, 2,4,6-$Me_3C_6H_2$ (Mes)],[7] which we expected to be suitable precursors for the preparation of phosphanido and phosphinidene complexes. However, when [Cp*TaCl$_4$(PH$_2$R)] (R = *t*Bu, Cy, Ad, Ph, Mes) were treated with DBU an internal redox reaction occurred with formation of [(DBU)H][Cp*TaCl$_4$] (DBU = 1,8-diazabicyclo[5.4.0]undec-7-ene) and the corresponding diphosphane ($P_2H_2R_2$) or decomposition products thereof.[8] For the aryl-substituted phosphane complexes, there was also an indication from the ^{31}P NMR spectra of the formation of tantalum phosphinidene complexes, which could, however, not be isolated.

We now report the targeted synthesis of these and other dimeric Ta^{IV} phosphinidene complexes, which are accessible from [Cp^{R}TaCl$_4$] (Cp^R = Cp*, Cp′) and LiPHR′, and some reaction products thereof. The related tantalum(IV) phenylimido complex *trans*-[{Cp*TaCl(μ-NPh)}$_2$] is also known.[9]

Results and Discussion

Synthesis and Properties of *trans*-[{Cp*TaCl(μ-PR)}$_2$] [R = Cy (1), *t*Bu (2), Ph (3)], *cis*- and *trans*-[{Cp*TaCl(μ-PMes)}$_2$] (4a,b) and *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (5)

When [Cp*TaCl$_4$][7,10] was treated with two equivalents of LiPHR[11–14] in toluene (to keep the concentration of LiPHR low in solution) at low temperature (to reduce side reactions), the deep red phosphinidene-bridged tantalum(IV) complexes *trans*-[{Cp*TaCl(μ-PR)}$_2$] [R = Cy (**1**), *t*Bu (**2**), Ph (**3**), Mes (**4b**)] were obtained after workup in 73 to 86% yield (based on [Cp*TaCl$_4$]; Scheme 1).

In the ^{31}P NMR spectra of the reaction mixtures, one singlet is observed for the *t*Bu, Ph and Mes derivatives, while for the Cy derivative, two singlets are observed in the low-field region, one of which has only a low intensity [δ = 437.6 (major) and 433.7 (minor) ppm]. The major signal

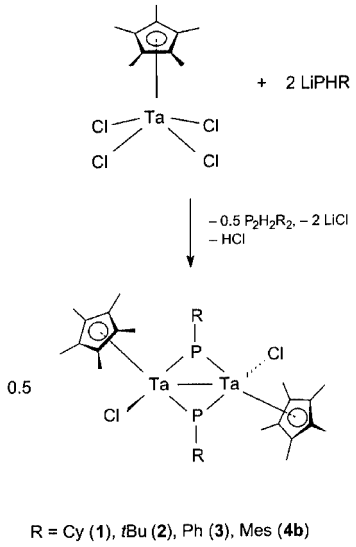

Scheme 1

was shown to belong to the *trans* isomer, while the minor signal presumably belongs to the *cis* isomer.

When the reaction of [Cp*$TaCl_4$] with LiPHMes was carried out in a 1:1 ratio, *cis*-[{Cp*TaCl(μ-PMes)}$_2$] (**4a**) was also formed along with **4b**. An additional signal was observed in the ^{31}P NMR spectrum at δ = 485.8 ppm [ratio ca. 1 (**4a**): 6 (**4b**): 3], which indicates the formation of a terminal phosphinidene complex, [Cp*$TaCl_2$(PMes)] (cf. the stable terminal phosphinidene complex [Cp*$TaCl_2${P(Tipp)}], which shows a singlet at δ = 488.0 ppm).[15] The mesitylphosphinidene complex could, however, not be obtained in its pure form. Complexes **4a** and **4b** could be separated by fractional crystallisation from *n*-hexane.

For comparison, *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (**5**) was prepared from [Cp′$TaCl_4$][16] and LiPHMes (1:1). In the ^{31}P NMR spectrum of the reaction mixture, only one signal was observed, which indicates the exclusive formation of the *cis* isomer.

In these reactions, the lithium reagent acts as a reducing agent, base and substitution reagent. The products of these reactions, that is, the oxidation product $P_2H_2R_2$, the free phosphane RPH_2, and the corresponding Ta^{IV} phosphinidene complex were detected by ^{31}P NMR spectroscopy.

The formation of **1**–**4b** was also observed when only one equivalent of LiPHR was used, but the yield was lower.

Related tantalum phosphinidene complexes include *trans*-[(Cp′TaCl{μ-P(Tipp)})$_2$] (**I**),[3] which was obtained by treating [Cp′$TaCl_4${PH_2(Tipp)}] with DBU (1:2 or 1:3), and the stable terminal phosphinidene complexes [N{$CH_2CH_2N(SiMe_3)$}$_3$Ta=PR] [δ(^{31}P) = 175.1 (R = Cy) and 227.3 (R = *t*Bu) ppm][6] and [(tBu$_3$SiO)$_3$Ta=PPh][5] [δ(^{31}P) = 334.6 ppm]. These ^{31}P chemical shifts indicate the presence of a linear MPR unit (bent MPR unit: δ = 660 to 800 ppm).[17] For **1**–**5** and **I**, ^{31}P chemical shifts of δ = 390.3 ppm (for **4b**) to 482.0 ppm (for **2**) are observed [for **I**, δ(^{31}P) = 391.5 ppm], and Δδ (phosphane vs. phosphinidene complex) ranges from δ = 526 to 562 ppm (Table 1).

Apparently, the influence of the substituted cyclopentadienyl ligand on the ^{31}P NMR chemical shift is negligible, as shown by the similar values for **4b** (Cp* complex) and **I** (Cp′ complex), while alkyl-substituted phosphinidene complexes **1** and **2** exhibit low-field shifts compared to aryl-substituted phosphinidene complexes **3**–**5**. The same trend is observed for the corresponding primary phosphanes (Table 1).

In the ^{13}C NMR spectra of **1**–**4**, the signals of the carbon atoms of the Cp* ring are shifted to high field by Δδ = 16.5–18 relative to the starting material [Cp*$TaCl_4$] (δ = 132.9 ppm).

Molecular ion peaks were observed in the mass spectra of **1**–**4**.[18] For **1**, **3**, and **4a**, signals for monomeric [Cp*TaCl(PR)]$^+$ and fragmentation products thereof were also observed.

In the UV/Vis spectra in pentane, **1**–**4** exhibit four absorptions in the ranges 682 – 753 (ν_1), 473 – 528 (ν_2), 337 – 396 (ν_3), and 313 – 319 nm (ν_4), with molar absorption coefficients of 10^2 – 10^3 (for ν_1, d-d transition), $2{\cdot}10^3$ – 10^4 (for ν_2 and ν_3; CT transitions), and 10^4 – $3{\cdot}10^4$ cm^2/mol (for ν_4, π -π * transition of Cp*).

Molecular Structures of *trans*-[{Cp*TaCl(μ-PR)}$_2$] [R = Cy (1), *t*Bu (2), Ph (3), Mes (4b)], *cis*-[{Cp*TaCl(μ-PMes)}$_2$] (4a) and *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (5)

Single crystals of **1**–**5** were obtained from concentrated solutions in diethyl ether (**1**, **3**), pentane (**2**) or hexane (**4a**,**b**, **5**) at 5 °C. The *trans* complexes **1**–**3** crystallise in the monoclinic space group $P2_1/n$, **4b** in the monoclinic space group $P2_1/c$ and have two formula units per unit cell; the *cis* complexes **4a** and **5** crystallise in the triclinic space group $P\bar{1}$ with two formula units in the unit cell (Table 2). The unit

cell of **1** contains four noninteracting diethyl ether molecules, and that of **4a** two hexane molecules.

The pronounced tendency of Ta^{IV} to form binuclear complexes is also evident in the molecular structures of **1**−**5**. The *trans* complexes **1**−**4b** are centrosymmetric dimers in which two Ta atoms are bound by two bridging phosphinidene [PCy (**1**) (Figure 1), P*t*Bu (**2**) (Figure 2), PPh (**3**) (Figure 3), PMes (Figure 4)] groups. Each Ta atom also bears a terminal chloro ligand, and a Cp* ligand completes the coordination sphere of the Ta atom (Table 3). The four-membered metallacycles Ta−P−Ta′−P′ are planar and almost square (the centres of the planar Ta_2P_2 rings in **1**−**4b** coincide with crystallographic inversion centres); this indicates substantial pπ -dπ backbonding (P→ Ta) of the phosphorus lone pair. Complex **I** exhibits comparable structural parameters.[3]

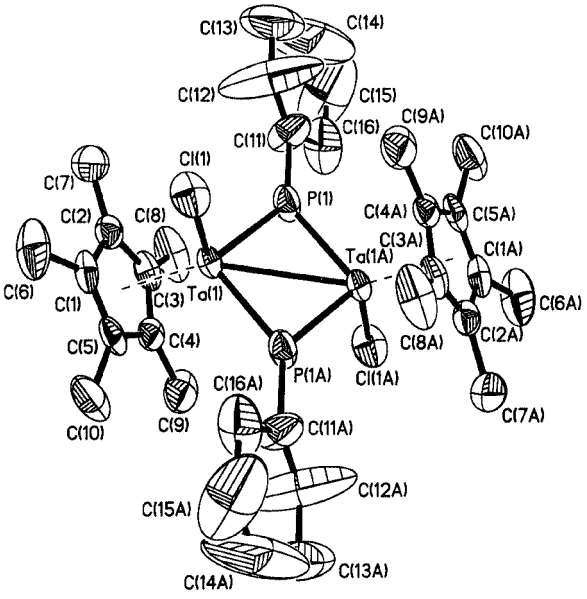

Figure 1. Molecular structure of *trans*-[{Cp*TaCl(μ-PCy)}$_2$] (**1**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

In the *cis* complexes **4a** (Figure 5) and **5** (Figure 6), a butterfly-type central Ta_2P_2 ring is observed [dihedral angle for **4a**: Ta(1)−P(1)−Ta(2)/Ta(1)−P(2)−Ta(2) 27.61(6)°, **5**: Ta(1)−P(1)−Ta(2)/Ta(1)−P(2)−Ta(2) 10.4(2)°]. Due to geometric requirements, the aryl rings in **4a** are almost perpendicular to the Ta_2P planes [dihedral angles 89.9(4)° and 88.9(4)°]. This structure is also retained in solution, as indicated by two signals for the nonequivalent *meta*-H atoms (^{1}H NMR) and the *ortho*-methyl groups in the ^{1}H and ^{13}C NMR spectra. In **5**, both mesityl rings are also almost perpendicular to the Ta_2P planes [dihedral angles 86.6(4)° for P(2)-mesityl and 73.8(4)° for P(1)-mesityl]. However, in this case free rotation around the P−C_{ipso}(Mes) bond is possible in solution, as indicated by the presence of only one broad signal for the equivalent *meta*-H atoms and the *ortho*-methyl groups (^{1}H NMR).

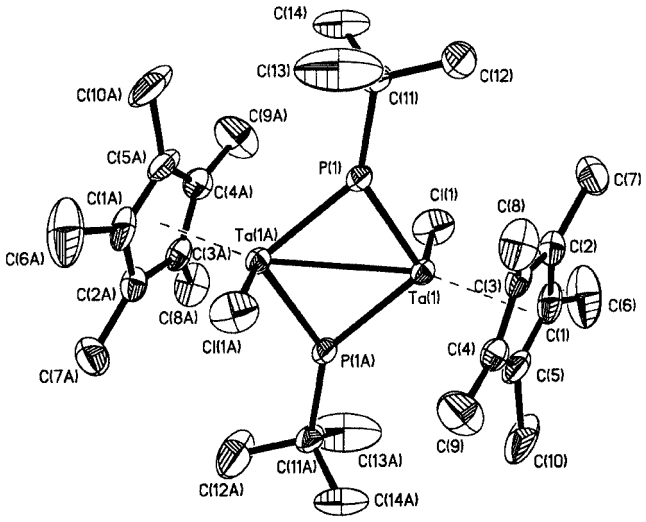

Figure 2. Molecular structure of *trans*-[{Cp*TaCl(μ-P*t*Bu)}$_2$] (**2**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

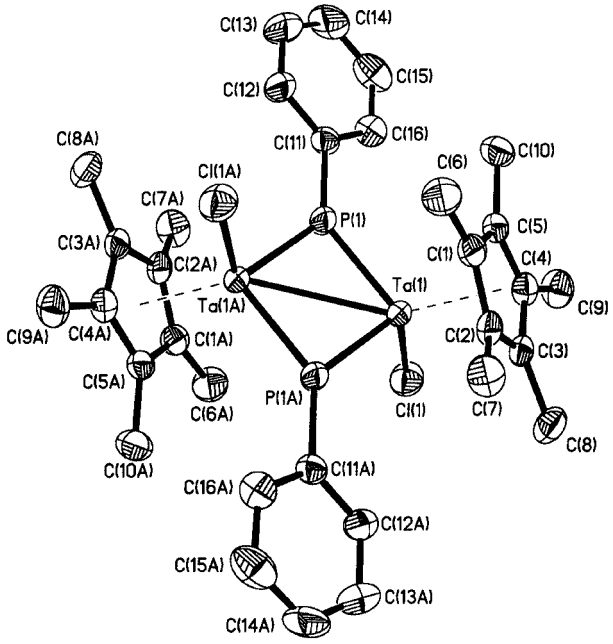

Figure 3. Molecular structure of *trans*-[{Cp*TaCl(μ-PPh)}$_2$] (**3**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

Complexes **1**−**5** are diamagnetic, thus the presence of a Ta−Ta single bond can be assumed. For other dimeric complexes it was observed that the Ta−Ta bond length[19] is strongly dependent on the number and type of ligands (e.g., hydrido-bridged complexes generally have shorter Ta−Ta bonds than comparable halogen-bridged complexes[20]). A comparable value of 3.165 Å was observed for [{$TaCl_3(SMe_2)$(μ-SPh)}$_2$],[21] in which a Ta−Ta single bond is present according to theoretical calculations.[22]

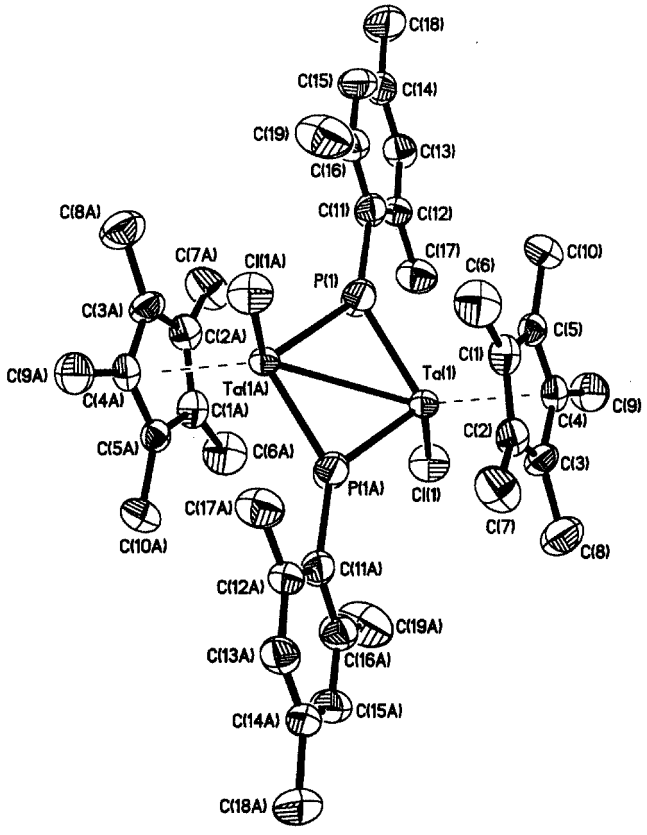

Figure 4. Molecular structure of *trans*-[{Cp*TaCl(μ-PMes)}$_2$] (**4b**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

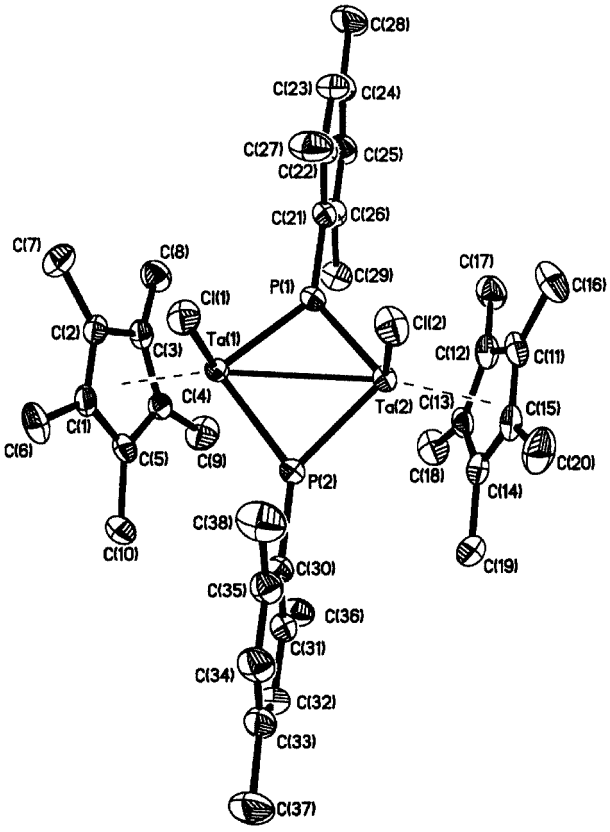

Figure 5. Molecular structure of *cis*-[{Cp*TaCl(μ-PMes)}$_2$] (**4a**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

Table 3. Selected bond lengths [Å] and angles [°] of compounds **1**–**5** and [(Cp′TaCl{μ-P(Tipp)})$_2$] (**I**)[3]

Compound	Ta–P	Ta–Ta	Ta–Cl	Ta–P–Ta	P–Ta–P
1	2.334(2), 2.336(2)	3.132(1)	2.358(2)	84.26(6)	95.74(6)
2	2.354(1), 2.357(1)	3.1759(8)	2.360(1)	84.78(4)	95.22(4)
3	2.345(1), 2.344(1)	3.1957(6)	2.357(1)	85.92(4)	94.08(4)
4a	3 × 2.344(2), 2.349(1)	3.0881(3)	2.347(2), 2.352(2)	82.31(5), 82.39(5)	93.87(5), 94.00(5)
4b	2.328(2), 2.331(2)	3.0773(5)	2.364(2)	82.68(7)	97.32(7)
5	2.348(3), 2.358(3) 2.336(3), 2.357(3)	3.1253(7)	2.351(3), 2.365(3)	83.0(1), 83.7(1)	95.9(1), 96.3(1)
I	2.317(6), 2.338(2)	3.100(3)	2.350(2)	83.51(8)	96.49(8)

The Ta–P bond lengths in **1**–**5** are similar to those of **I**[3] (Table 3) and the terminal phosphinidene complex [(*t*Bu$_3$SiO)$_3$Ta=PPh][5] [2.317(4) Å] with a bent TaPC arrangement [Ta–P–C 110.2(4)°], while [N{CH$_2$CH$_2$N(SiMe$_3$)}$_3$Ta=PCy][6] has a linear TaPC arrangement and a shorter Ta–P bond of 2.145(7) Å. However, all these distances are shorter than the sum of the covalent radii of Ta and P (2.44 Å).[23] Longer bonds are observed for bridging phosphanido ligands (e.g., [{Cp′Ta(PPh$_2$)(μ-PPh$_2$)}$_2$], Ta–P$_{br}$ 2.486(2), 2.458(2) Å].[3]

The trigonal-planar geometry of the P atoms of the bridging phosphinidene group in the *trans* complexes **1**–**4b** (sum of bond angles ca. 360°) indicates that the PR group acts as a three-electron donor. In the *cis* complexes **4a** and **5**, the P atoms also have a trigonal-planar environment [sum of bond angles **4a**: P(1): 358.0(2)°, P(2): 357.8(2)°, **5**: P(1): 356.8(4)°, P(2): 358.8(4)°].

The Ta–Cl bonds in **1**–**5** (Table 3) are shorter than those in the Ta chloro phosphane complexes (e.g., [{TaCl$_2$(μ-Cl)(μ-PMe$_2$CH$_2$PMe$_2$)}$_2$], Ta–Cl (terminal) 2.435(7), 2.457(6) Å;[24] *trans*-[CpTaCl$_2$(CO)(PMe$_2$Ph)$_2$], Ta–Cl 2.518(4), 2.539(4) Å;[25] [Cp*TaCl$_3$(PMe$_3$)], Ta–Cl 2.395(3) to 2.416(3) Å;[26] *cis*-[Cp*TaCl$_2$(CO)$_2$(PMe$_3$)], Ta–Cl 2.504(2), 2.512(2) Å[26]).

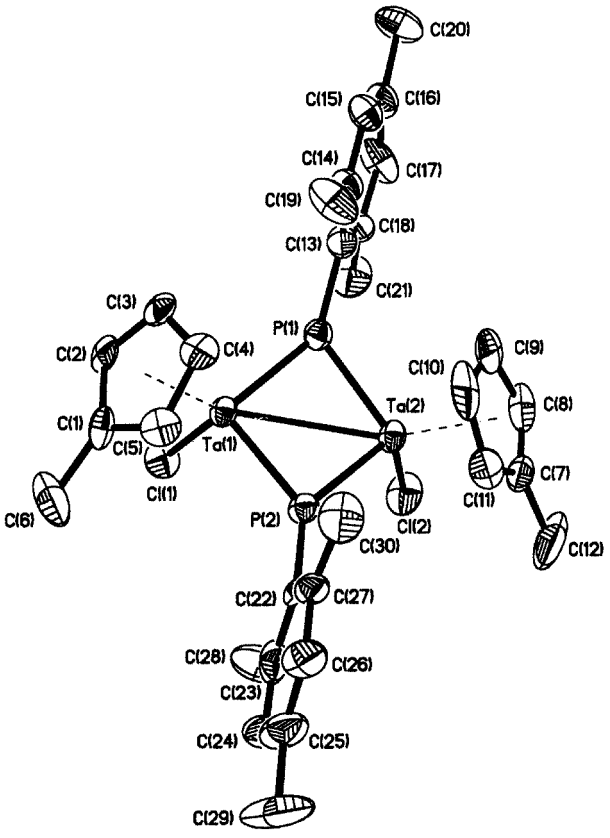

Figure 6. Molecular structure of *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (**5**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity.

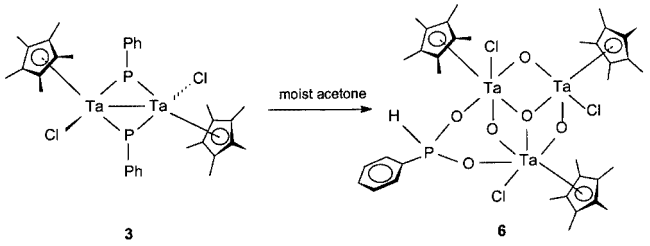
Reactivity of 1, 3 and 4

While terminal electrophilic phosphinidene complexes are highly reactive,[27] **1**−**5** are air-stable as solids for at least several hours. **1**, **3** and **4b** also exhibit a remarkable stability towards acetone, benzophenone, acetonitrile, CS_2 (**1** and **3**), acetaldehyde (**4b**), or $EtAlCl_2$ (**3**), even at elevated temperatures.

Complex **3** reacts with moist acetone (50-fold excess) in the presence of traces of air to give the trinuclear cluster [{Cp*TaCl(μ$_2$-O)}$_3$(μ$_3$-O)(μ-O$_2$PHPh)}] (**6**) in very low yield (Scheme 2). **6** was only characterised by crystal structure determination.



3 6

Scheme 2

Complex **6** crystallises as yellow prismatic crystals in the monoclinic space group $P2_1/n$ with four molecules of acetone in the unit cell. The central structural fragment is a Ta_3O_4 cluster, in which the Ta^V and O atoms alternatingly occupy the corners of a heterocubane with one missing corner (Figure 7). Related clusters have been reported for Zr, Nb, Ta and Mo.[28] Each Ta atom is coordinated by a Cp* and one terminal chloro ligand. Two Ta atoms have a coordination number of six [Ta(1) and Ta(2)]; Ta(3) is five-coordinate. The Ta−Ta distances range from 3.1185(3) to 3.3378(3) Å. There are two types of O atoms: one triply-bridging [O(6)] and three doubly-bridging oxo ligands [O(3), O(4), and O(5); Ta−O 1.910(3) to 2.003(3) Å]. The latter Ta−O bond lengths are in the range for single bonds,[28a,28b] while the Ta−O(6) bond lengths differ by

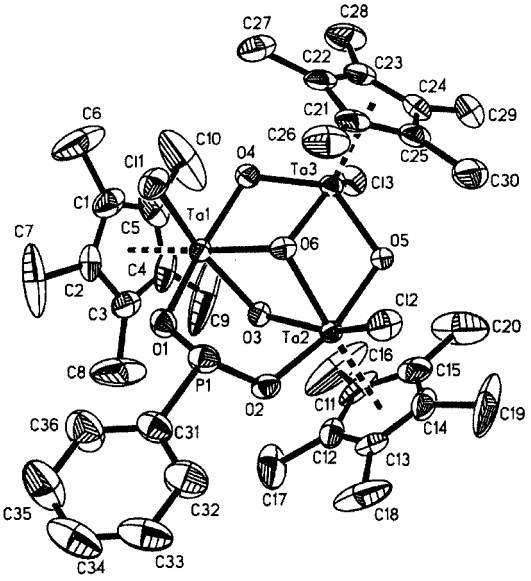


Figure 7. Molecular structure of [{Cp*TaCl(μ$_2$-O)}$_3$(μ$_3$-O)(μ$_2$-O$_2$PHPh)}] (**6**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity. Bond lengths [Å] and angles [°]: Ta(1)−O(4) 1.960(3), Ta(1)−O(3) 1.991(3), Ta(1)−O(1) 2.127(3), Ta(1)−O(6) 2.148(3), Ta(2)−O(5) 1.964(3), Ta(2)−O(3) 2.003(3), Ta(2)−O(2) 2.117(3), Ta(2)−O(6) 2.136(3), Ta(3)−O(5) 1.910(3), Ta(3)−O(4) 1.915(3), Ta(3)−O(6) 2.058(3), Ta(1)−Cl(1) 2.506(1), Ta(2)−Cl(2) 2.491(1), Ta(3)−Cl(3) 2.429(1), Ta(1)−Ta(3) 3.1185(3), Ta(1)−Ta(2) 3.3378(3), Ta(2)−Ta(3) 3.1206(3), P(1)−O(1) 1.510(4), P(1)−O(2) 1.514(4), P(1)−C(31) 1.778(6); O(4)−Ta(1)−O(3) 98.6(1), O(4)−Ta(1)−O(1) 155.9(1), O(3)−Ta(1)−O(1) 86.6(1), O(4)−Ta(1)−O(6) 74.0(1), O(3)−Ta(1)−O(6) 71.2(1), O(1)−Ta(1)−O(6) 85.7(1), O(4)−Ta(1)−Cl(1) 86.9(1), O(3)−Ta(1)−Cl(1) 148.8(1), O(1)−Ta(1)−Cl(1) 77.1(1), O(6)−Ta(1)−Cl(1) 81.05(9), O(5)−Ta(2)−O(3) 97.7(1), O(5)−Ta(2)−O(2) 156.1(1), O(3)−Ta(2)−O(2) 86.2(1), O(5)−Ta(2)−O(6) 74.0(1), O(3)−Ta(2)−O(6) 71.2(1), O(2)−Ta(2)−O(6) 85.1(1), O(5)−Ta(2)−Cl(2) 87.6(1), O(3)−Ta(2)−Cl(2) 148.7(1), O(2)−Ta(2)−Cl(2) 77.5(1), O(6)−Ta(2)−Cl(2) 80.91(9), O(5)−Ta(3)−O(6) 76.9(1), O(4)−Ta(3)−O(6) 77.0(1), O(5)−Ta(3)−Cl(3) 86.0(1), O(4)−Ta(3)−Cl(3) 85.4(1), O(6)−Ta(3)−Cl(3) 136.68(9), O(1)−P(1)−O(2) 112.5(2), O(1)−P(1)−C(31) 109.4(3), O(2)−P(1)−C(31) 109.2(2), P(1)−O(1)−Ta(1) 123.7(2), P(1)−O(2)−Ta(2) 124.8(2), Ta(1)−O(3)−Ta(2) 113.4(2), Ta(3)−O(4)−Ta(1) 107.2(2), Ta(3)−O(5)−Ta(2) 107.3(2), Ta(3)−O(6)−Ta(2) 96.1(1), Ta(3)−O(6)−Ta(1) 95.7(1), Ta(2)−O(6)−Ta(1) 102.4(1), C(36)−C(31)−P(1) 122.1(5), C(32)−C(31)−P(1) 120.0(5).

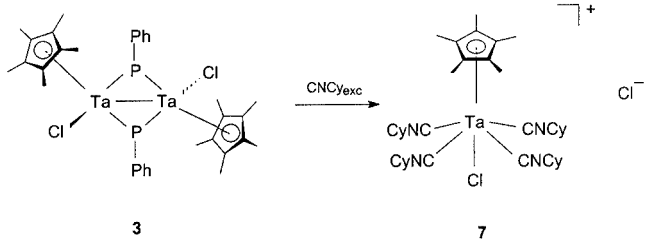
ca. 0.1 Å [Ta(3)−O(6) 2.058(3), Ta(1)−O(6) 2.148(3), Ta(2)−O(6) 2.136(3) Å]. For Ta(1) and Ta(2), the *trans* effect of the Cp* ligand apparently affects the Ta−O bond lengths. Similar structural data were found for [(Cp*TaCl)$_3$(μ_2-Cl)(μ_2−O)$_2$(μ_3-O)(μ-O$_2$Si*t*Bu$_2$)].[28b]

In addition, a P(H)(Ph)O$_2^-$ ligand, the anion of phenyl phosphinic acid, bridges Ta(1) and Ta(2). However, the PH proton could not be localised. Due to the small amount of **6** available, no ^{31}P NMR spectrum could be obtained to verify the presence of the PH proton. However, since tantalum(v) is present in this cluster, the presence of an anionic P(H)(Ph)O$_2^-$ ligand must be assumed. The P−O bond lengths indicate multiple bond character (ca. 1.51 Å).[28f]

While no reaction of **3** with one or two equivalents of CyNC was observed, a 10-fold excess of CyNC gave the tantalum(III) complex [Cp*TaCl(CNCy)$_4$]Cl (**7**) (Scheme 3), which was characterised by ^{1}H, ^{13}C NMR spectroscopy and



Scheme 3

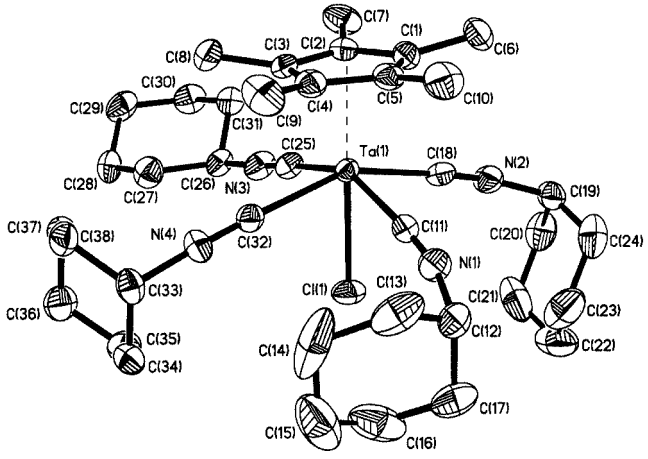


Figure 8. Molecular structure of [Cp*TaCl(CNCy)$_4$]Cl (**7**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Only the cation is shown. Hydrogen atoms are omitted for clarity; selected bond lengths [Å] and angles [°]: Ta(1)−C(11) 2.179(4), Ta(1)−C(32) 2.185(4), Ta(1)−C(18) 2.187(4), Ta(1)−C(25) 2.187(4), Ta(1)−Cl(1) 2.5146(9), N(1)−C(11) 1.151(5), N(1)−C(12) 1.460(5), N(2)−C(18) 1.147(5), N(2)−C(19) 1.452(5), N(3)−C(25) 1.154(5), N(3)−C(26) 1.452(5), N(4)−C(32) 1.152(5), N(4)−C(33) 1.459(5); C(11)−Ta(1)−C(32) 84.69(13), C(11)−Ta(1)−C(18) 87.54(14), C(32)−Ta(1)−C(18) 153.37(13), C(11)−Ta(1)−C(25) 153.23(13), C(32)−Ta(1)−C(25) 86.15(13), C(18)−Ta(1)−C(25) 89.51(14), C(11)−Ta(1)−Cl(1) 76.99(10), C(32)−Ta(1)−Cl(1) 76.98(10), C(18)−Ta(1)−Cl(1) 76.46(10), C(25)−Ta(1)−Cl(1) 76.45(10), C(11)−N(1)−C(12) 165.6(4), C(18)−N(2)−C(19) 166.5(4), C(25)−N(3)−C(26) 174.6(4), C(32)−N(4)−C(33) 175.5(4), N(1)−C(11)−Ta(1) 176.1(3), N(2)−C(18)−Ta(1) 176.0(3), N(3)−C(25)−Ta(1) 177.2(3), N(4)−C(32)−Ta(1) 177.7(3).

by crystal structure determination. A molecular ion peak was observed for the cation in **7** by FAB-MS (3-nitrobenzaldehyde as matrix) at m/z = 786. In the ^{31}P NMR spectrum of the reaction mixture, signals for the oxidation products (PPh)$_n$ (n = 4−6)[29] were observed. In addition, two doublets (δ = −57.8 ppm and −121.4 ppm, $^1J_{PP}$ = 311 Hz) were observed, which we could not assign.

Complex **7** crystallises as orange rhombic crystals from THF in the monoclinic space group $P2_1/n$. In the cation (Figure 8), the NC group occupies the axial position in three of the four cyclohexyl groups of the isocyanide ligands. The reason for this unexpected arrangement is the formation of hydrogen bonds between the hydrogen atom of the α-C atom C(26) of the isocyanide ligand in which the NC group is in the equatorial position and the hydrogen atom on the β-C atom of an isocyanide ligand of a second molecule to a chloride anion (Figure 9). However, in solution the four isocyanide ligands are equivalent (^{13}C NMR).

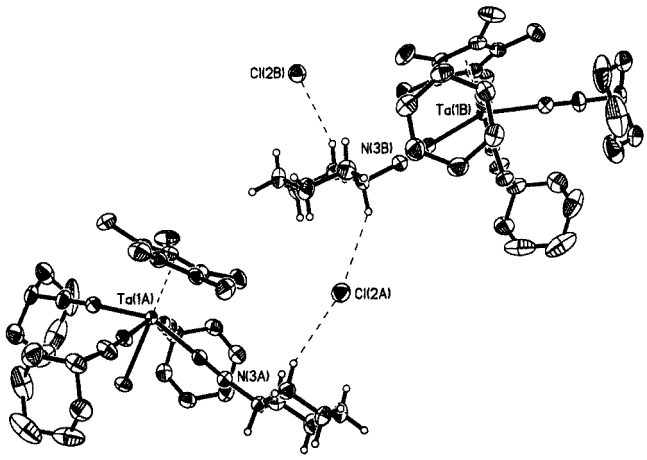

Figure 9. Hydrogen bonding in [Cp*TaCl(CNCy)$_4$]Cl (**7**) (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]).

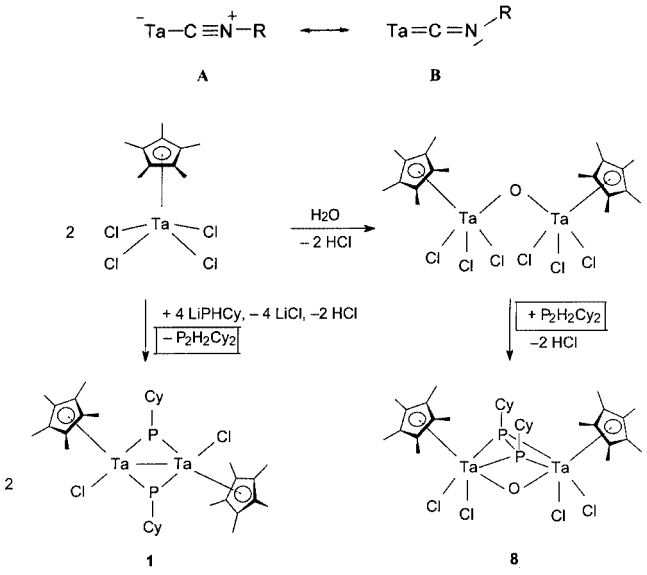
For the TaCN group, two mesomeric structures can be formulated (as for carbonyl groups):



Scheme 4

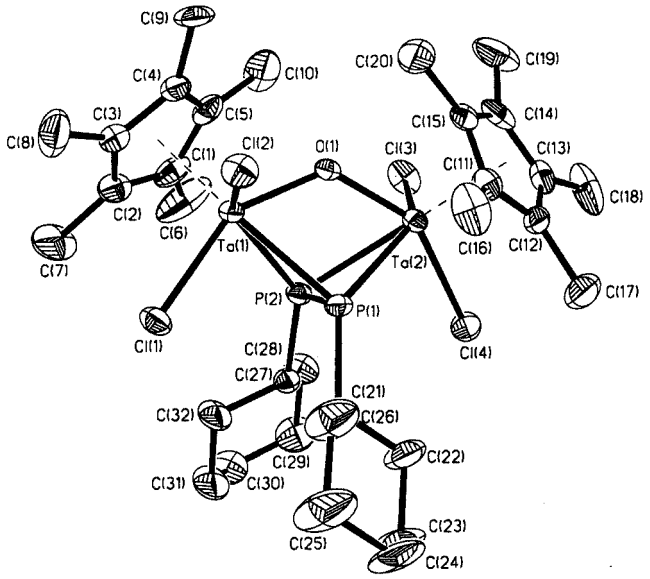


Figure 10. Molecular structure of $[(Cp^*TaCl_2)_2(\mu_2\text{-}O)(\eta^2,\mu_2\text{-}P_2Cy_2)]$ (**8**) showing the atom numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP[37]). Hydrogen atoms are omitted for clarity. Bond lengths [Å] and angles [°]: Ta(2)−O(1) 1.974(6), Ta(2)−Cl(3) 2.413(2), Ta(2)−Cl(4) 2.425(2), Ta(2)−P(1) 2.580(2), Ta(2)−P(2) 2.600(2), Ta(1)−O(1) 1.978(6), Ta(1)−Cl(2) 2.407(2), Ta(1)−Cl(1) 2.413(2), Ta(1)−P(2) 2.578(2), Ta(1)−P(1) 2.602(2), P(1)−C(21) 1.884(9), P(1)−P(2) 2.188(3), P(2)−C(27) 1.864(9); O(1)−Ta(2)−Cl(3) 94.31(18), O(1)−Ta(2)−Cl(4) 148.73(17), Cl(3)−Ta(2)−Cl(4) 88.86(9), O(1)−Ta(2)−P(1) 69.02(17), Cl(3)−Ta(2)−P(1) 137.96(8), Cl(4)−Ta(2)−P(1) 88.01(8), O(1)−Ta(2)−P(2) 67.73(17), Cl(3)−Ta(2)−P(2) 88.14(8), Cl(4)−Ta(2)−P(2) 81.33(8), P(1)−Ta(2)−P(2) 49.97(8), O(1)−Ta(1)−Cl(2) 94.81(17), O(1)−Ta(1)−Cl(1) 148.85(16), Cl(2)−Ta(1)−Cl(1) 90.28(8), O(1)−Ta(1)−P(2) 68.17(17), Cl(2)−Ta(1)−P(2) 137.60(8), Cl(1)−Ta(1)−P(2) 87.57(7), O(1)−Ta(1)−P(1) 68.49(16), Cl(2)−Ta(1)−P(1) 87.88(8), Cl(1)−Ta(1)−P(1) 81.04(8), P(2)−Ta(1)−P(1) 49.97(8), C(21)−P(1)−P(2) 111.3(4), C(21)−P(1)−Ta(2) 138.1(3), P(2)−P(1)−Ta(2) 65.49(9), C(21)−P(1)−Ta(1) 131.2(3), P(2)−P(1)−Ta(1) 64.45(9), Ta(2)−P(1)−Ta(1) 87.02(7), C(27)−P(2)−P(1) 111.2(3), C(27)−P(2)−Ta(1) 138.2(3), P(1)−P(2)−Ta(1) 65.57(9), C(27)−P(2)−Ta(2) 131.0(3), P(1)−P(2)−Ta(2) 64.55(9), Ta(1)−P(2)−Ta(2) 87.10(7), Ta(2)−O(1)−Ta(1) 129.1(3).

As the Ta−C bond lengths of the isocyanide ligands [2.179(4) to 2.187(4) Å] are in the range of Ta−C single bonds and the C−N−C(Cy) groups are almost linear [165.6(4)° to 175.5(4)°], mesomeric structure **A** can be assumed. The Ta atom is located 0.502(2) Å above the plane of the four isocyanide carbon atoms.

As a minor product, $[(Cp^*TaCl_2)_2(\mu_2\text{-}O)(\eta^2,\mu_2\text{-}P_2Cy_2)]$ (**8**) was also obtained in the reaction of $[Cp^*TaCl_4]$ with one equivalent of LiPHCy. **8** was only characterised by crystal structure determination; in the ^{31}P NMR spectrum of the reaction mixture a singlet of low intensity at $\delta = 538.6$ ppm was observed, which could be attributed to **8** or a precursor complex thereof. As two doublets are observed in the high-field region of the ^{31}P NMR spectrum of $[Cp_2TaH(\eta^2\text{-}P_2R_2)]$ (R = Ph:[2a,30] $\delta = -145.1$ ppm and -162.8 ppm, R = Cy:[30] $\delta = -123.1$ ppm and -143.3 ppm) the latter seems more likely.

A possible route for the formation of **8** is hydrolysis of $[Cp^*TaCl_4]$ to give $[(Cp^*TaCl_3)_2(\mu\text{-}O)]$, which can then react with $P_2H_2R_2$ (formed in the redox reaction which gives **1**) to yield the observed product (Scheme 4).

Complex **8** crystallises in the monoclinic space group *Cc*. In **8**, two Cp^*TaCl_2 fragments are bridged by one oxo ligand and a diphosphanediyl group $P_2Cy_2^{2-}$; this indicates the presence of Ta^V (Figure 10). In general, free diphosphenes P_2R_2 are only stable when sterically demanding R groups are present;[31] however, unstable derivatives can be stabilised by coordination to a transition metal.[32] The Ta−P bond lengths [Ta(2)−P(1) 2.580(2), Ta(2)−P(2) 2.600(2), Ta(1)−P(2) 2.578(2), Ta(1)−P(1) 2.602(2) Å] are in the range observed for other tantalum diphosphene complexes [2.602(5) to 2.632(5) Å].[32]

In **8**, the P(1)−P(2) bond length of 2.188(3) Å indicates a single bond. In the tantalum diphosphene complexes $[Cp_2TaH(\eta^2\text{-}P_2R_2)]$ (R = Cy, H) the P−P bond lengths are shorter [2.131(3) and 2.136(6) Å].[30]

Experimental Section

All experiments were carried out under purified dry argon. Solvents were dried and freshly distilled under argon. The NMR spectra were recorded with an AVANCE DRX 400 spectrometer (Bruker), ^1H NMR: internal standard solvent (benzene or $CDCl_3$), external standard $SiMe_4$. ^{13}C NMR: external standard $SiMe_4$, internal standard solvent. ^{31}P NMR: external standard 85% H_3PO_4. The IR spectra were recorded with a FT-IR spectrometer Perkin−Elmer System 2000 in the range 350−4000 cm^{-1}. UV/Vis spectra were recorded in pentane with a LAMBDA 900 (Perkin−Elmer) in an inert-gas cuvette. The melting points were determined in sealed capillaries under argon and are uncorrected. LiPHCy,[11] LiPH*t*Bu,[12] LiPHPh,[13] LiPHMes,[14] [Cp′$TaCl_4$][16] and $[Cp^*TaCl_4]$[10] were prepared by literature procedures.

General Procedure for the Preparation of *trans*-[{Cp*TaCl(μ-PR)}$_2$] [R = Cy (1), *t*Bu (2), Ph (3), Mes (4b)]: A suspension of $[Cp^*TaCl_4]$ in toluene (30 mL) was cooled to −70 °C, and two equivalents of LiPHR were added to the stirred reaction mixture over 2 h. The resulting suspension was slowly warmed to room temperature and stirred overnight. The solvent was removed and the solid dissolved in diethyl ether (**1**, **3**), pentane (**2**), or hexane (**4b**). The mixture was filtered. Deep red crystals were obtained by cooling the filtrate to 5 °C.

The Ta^{IV} phosphinidene complex (Table 1) and the oxidation products $P_2H_2R_2$ (or their decomposition products: cyclic oligophosphanes and the free phosphane RPH_2) were detected by ^{31}P NMR spectroscopy. The following signals were observed for the oxidation products:

*t*Bu: $\delta = -57.5$ ppm [s, $(PtBu)_4$],[29] −71.7 (d) and −108.0 (t) $(PtBu)_3$ ppm.[33]

Cy: $\delta = -68.3$ (s, $PCy)_4$, −84.3 and −87.5 (m, *rac*- and *meso*-$P_2H_2Cy_2$),[29] −111.0 (t, PH_2Cy) ppm.

Ph: δ = ca. 3 [m, $(PPh)_5$], −21.3 [s, $(PPh)_6$], −47.6 [s, $(PPh)_4$][29,34] −67.4, −70.9 (m, *meso*- and *rac*-$P_2H_2Ph_2$; the signal for the unstable diphosphane disappears after two days),[35,36] −122.1 (t, PH_2Ph) ppm.

Mes: $\delta = -43.2$ [s, $(PMes)_4$], −109.3 (d), −143.9 (t) $(PMes)_3$, −110.4, −117.5 (m, *meso*- and *rac*-$P_2H_2Mes_2$), −153.8 (t, PH_2Mes) ppm.

1: (0.45 g, 0.98 mmol) [Cp*$TaCl_4$], (0.48 g, 1.96 mmol) LiPHCy, rhombohedral deep red crystals of **1**·2 Et_2O, yield: 0.40 g (81% rel. [Cp*$TaCl_4$]), m.p. 319 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.12 [t, $^3J_{H,H}$ = 7.0 Hz, 6 H, CH_3 in ether], 1.38 (m, 4 H, 4-H in Cy), 1.46 (m, 8 H, 3-H/5-H in Cy), 1.76 (m, 8 H, 2-H/6-H in Cy), 2.00 (m, 2 H, 1-H in Cy), 2.20 (s, 30 H, CH_3 in Cp*), 3.27 [q, $^3J_{H,H}$ = 7.0 Hz, 4 H, CH_2 in ether] ppm. ^{13}C{^{1}H} NMR (100.61 MHz, C_6D_6, 25 °C): δ = 14.0 (*C*H_3 in C_5Me_5), 16.2 (*C*H_3 in ether), 27.5 (C-4 in Cy), 30.0 [d, $^3J_{P,C}$ = 19 Hz; C-3/C-5 in Cy], 35.9 [d, $^2J_{P,C}$ = 79 Hz; C-2/C-6 in Cy], 52.1 (br; C-1 in Cy), 66.6 (*C*H_2 in ether), 114.9 (*C*$_5$Me$_5$) ppm. Solvent-free **1**, $C_{32}H_{52}Cl_2P_2Ta_2$ (931.51): C 41.3, H 5.6, Cl 7.6; found C 40.4, H 5.3, Cl 7.2.

2: (0.40 g, 0.87 mmol) [Cp*$TaCl_4$], (0.17 g, 1.77 mmol) LiPH*t*Bu, yield: 0.33 g (86% rel. [Cp*$TaCl_4$]), m.p. 341 °C (dec.), prismatic deep red crystals. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.48 [d, $^3J_{P,H}$ = 14 Hz, 18 H, *t*Bu], 2.18 (s, 30 H, CH_3 in Cp*) ppm. ^{13}C{^{1}H} NMR (100.61 MHz, C_6D_6, 25 °C): δ = 14.8 (*C*H_3 in C_5Me_5), 35.1 [C(*C*H_3)$_3$], 35.6 [*C*(CH$_3$)$_3$], 116.4 (*C*$_5$Me$_5$) ppm. $C_{28}H_{48}Cl_2P_2Ta_2$ (879.40): calcd. C 38.3, H 5.5, Cl 8.1; found C 38.8, H 5.6, Cl 8.1.

3: (0.50 g, 1.09 mmol) [Cp*$TaCl_4$], (0.25 g, 2.20 mmol) LiPHPh, yield: 0.42 g (85% rel. [Cp*$TaCl_4$]), m.p. 341 °C (dec.), rhombohedral deep red crystals. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 2.03 (s, 30 H, CH_3 in Cp*), 6.97 (br, 2 H, *p*-H in Ph), 7.36 [pseudo t, $^3J_{H,H}$ = 14, $^3J_{P,H}$ = 14 Hz, 4 H, *o*-H in Ph], 8.17 [t, $^3J_{H,H}$ = 14 Hz, 4 H, *m*-H in Ph] ppm. ^{13}C{^{1}H} NMR (100.61 MHz, C_6D_6, 25 °C): δ = 13.6 (*C*H_3 in C_5Me_5), 115.3 (*C*$_5$Me$_5$), 129.7 (*p*-C in Ph), 125.2 (*m*-C in Ph), 136.0 (*o*-C in Ph), 148.6 (*ipso*-C in Ph) ppm. $C_{32}H_{40}Cl_2P_2Ta_2$ (919.38): calcd. Cl 7.7; found Cl 8.1.

4b: (0.40 g, 0.87 mmol) [Cp*$TaCl_4$], (0.28 g, 1.8 mmol) LiPHMes, yield: 0.32 g (73% rel. [Cp*$TaCl_4$]), m.p. 321 °C (dec.), rhombohedral deep red crystals. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 2.01 (s, 30 H, CH_3 in Cp*), 2.22 (s, 6 H, *p*-Me in Mes), 2.72 (s, 12 H, *o*-Me in Mes), 7.01 (s, 4 H, *m*-H in Mes) ppm. ^{13}C{^{1}H} NMR (100.61 MHz, C_6D_6, 25 °C): δ = 13.3 (*C*H_3 in C_5Me_5), 22.0 (*p*-Me in Mes), 25.9 (*o*-Me in Mes), 115.2 (*C*$_5$Me$_5$), 130.5 (*m*-C in Mes), 132.9 (*p*-C in Mes), 139.4 (*o*-C in Mes), 144.8 (*ipso*-C in Mes) ppm. $C_{38}H_{52}Cl_2P_2Ta_2$ (1003.54): calcd. C 45.5, H 5.2; Cl 7.1; found C 45.9, H 5.4, Cl 7.0.

Synthesis of *cis*-[{Cp*TaCl(μ-PMes)}$_2$] (4a): A suspension of one equivalent of [Cp*$TaCl_4$] (0.5 g, 1.09 mmol) in toluene (30 mL) was cooled to −70 °C, and one equivalent of LiPHMes (0.17 g, 1.09 mmol) was added to the stirred reaction mixture over 3 h. The resulting suspension was stirred at −70 °C for 2 h, and then slowly warmed to room temperature and stirred overnight. The solvent was removed under vacuum, and the solid recrystallised twice from *n*-hexane. Yield: 80 mg (29% rel. LiPHMes); m.p. 289 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 2.05 (s, 30 H, CH_3 in Cp*), 2.26 (s, 6 H, *p*-Me in Mes), 2.39 (s, 6 H, *o*-Me in Mes), 2.56 (s, 6 H, *o*-Me in Mes), 6.91 (s, 2 H, *m*-H in Mes), 6.97 (s, 2 H, *m*-H in Mes) ppm. ^{13}C{^{1}H} NMR (100.61 MHz, C_6D_6, 25 °C): δ = 12.9 (*C*H_3 in C_5Me_5), 21.8 (*p*-Me in Mes), 23.1 (*o*-Me in Mes), 24.3 (*o*-Me in Mes), 115.5 (*C*$_5$Me$_5$), 128.0 (*m*-C in Mes), 130.9 (*m*-C in Mes),139.7 (*p*-C in Mes), 142.1 (*o*-C in Mes), 145.7 (*o*-C in Mes), 149.3 (*ipso*-C in Mes) ppm. $C_{38}H_{52}Cl_2P_2Ta_2$ (1003.54): calcd. C 45.5, H 5.2; Cl 7.1; found C 45.8, H 6.0, Cl 6.8.

Synthesis of *cis*-[{Cp′TaCl(μ-PMes)}$_2$] (5): A suspension of [Cp′$TaCl_4$] (0.4 g, 0.99 mmol) in toluene (20 mL) was cooled to −70 °C, and one equivalent of LiPHMes (0.15 g, 0.98 mmol) was added to the stirred reaction mixture over 3 h. The resulting suspension was stirred at −70 °C for 2 h, and then slowly warmed to room temperature and stirred overnight. The solvent was removed in vacuo, and the solid recrystallised twice from *n*-hexane. Yield: 0.19 g (43.5% rel. LiPHMes), rhombohedral orange-red crystals; m.p. 276 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 2.00 (s, 6 H, C_5MeH_4), 2.34 (s, 6 H, *p*-Me in Mes), 2.49 (br, 12 H, *o*-Me in Mes), 5.72 (t, $J_{H,H}$ = 2.6 Hz, 4 H, C_5MeH_4), 6.27 (t, $J_{H,H}$ = 2.6 Hz, 4 H, C_5MeH_4), 6.64 (br, 4 H, *m*-H in Mes) ppm. $C_{30}H_{36}Cl_2P_2Ta_2$ (891.33): C 40.4, H 4.1, Cl 8.0; found C 40.6, H 4.2, Cl 7.7.

Synthesis of [Cp*TaCl(CNCy)$_4$]Cl (7): Cyclohexyl isocyanide (0.17 g, 1.6 mmol) was added to a solution of **3** (0.15 g, 0.16 mmol) in toluene (20 mL). Over 3 days, the red solution turned orange. The solvent was removed under vacuum, and the solid recrystallised from THF to give **7** as rhombic orange crystals (0.10 g, 38% rel. to **3**); m.p. 345 °C (dec.). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = ca. 1.3 (m, 24 H, 3-H, 4-H, 5-H in Cy), ca. 1.7 (m, 16 H, 2-H, 6-H in Cy), 2.29 (s, 15 H, CH_3 in Cp*), 4.45 (br, 4 H, 1-H in Cy) ppm. ^{13}C{^{1}H} NMR (100.61 MHz, $CDCl_3$, 25 °C): δ = 13.7 (*C*H_3 in C_5Me_5), 23.5 (C-4 in Cy), 26.1 (C-3 and C-5 in Cy), 33.5 (C-2 and C-6 in Cy), 55.4 (C-1 in Cy), 70.3 (*C*NCy) 102.2 (*C*$_5$Me$_5$) ppm. $C_{38}H_{59}Cl_2N_4Ta$ (823.74): C 55.4, H 7.2, Cl 8.6; found C 55.0, H 7.8, Cl 8.4.

Data Collection and Structural Refinement of 1−8: Details of the data collection and crystal structure refinement are summarised in Table 2. Data (Mo-*Kα* , λ = 0.71073 Å) were collected with a Siemens CCD (SMART). All observed reflections were used for determination of the unit cell parameters. The structures were solved by direct methods (SHELXTL PLUS[37]) and subsequent difference Fourier syntheses and refined by full-matrix least-squares on F^2 (SHELXTL PLUS[37]). Restrictions for **1−8**: Ta, Cl, C, O, N and P atoms anisotropic, H atoms located or in calculated positions and refined isotropically. Absorption correction with SADABS[38]. CCDC-181631 (**1**), −181629 (**2**), −181627 (**3**),- 181633 (**4a**), −181635 (**4b**), −181632 (**5**), −181630 (**6**), −181628 (**7**) and CCDC-181634 (**8**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Bis[bis(dialkylamino)phosphanyl]methanes and Bis(trifluoromethyl)acrylonitrile — Reactions and Derivatives

Igor Shevchenko,*[a] Vasyl Andrushko,[a] Enno Lork,[b] and Gerd-Volker Röschenthaler*[b]

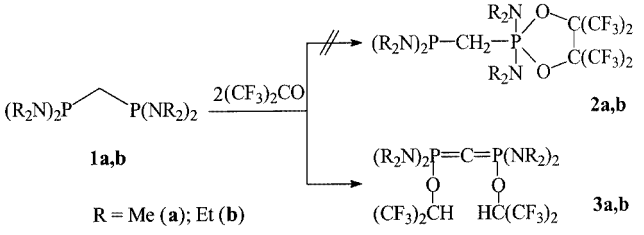
Keywords: Ylides / Phosphanes / Nitriles / Hexafluoroacetone

The reaction of bis[bis(dialkylamino)phosphanyl]methanes **1a,b** with bis(trifluoromethyl)acrylonitrile **8** led to the ylides **10a,b** which showed an interesting ability for self-fluorination involving trifluoromethyl groups to give the P–F derivatives **13a,b**. An X-ray analysis and NMR spectroscopic data showed that molecules of **10a,b** have different conformations in solution and in the crystal. Compounds **10a,b** reacted further with **8** to give either the symmetrical diylide **16a** or the P–F derivative **13b**. The addition of hexafluoroacetone to **10a,b** resulted in the formation of unsymmetrical diylides **19a,b**.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Previously we have described the unusual reaction of hexafluoroacetone (HFA) with bis[bis(dialkylamino)phosphanyl]methanes **1a,b**, which does not lead to the expected phosphoranes **2a,b**,[1–4] in which one of the phosphorus atoms is included into 1,3,2-dioxaphospholane heterocycles, but yields quantitatively the carbodiphosphoranes **3a,b** (Scheme 1).[5,6]



Scheme 1

Taking into account the unusual nature of this reaction we were interested in studying its scope by substituting the carbonyl function of hexafluoroacetone with a C=C double bond. In this paper we describe the reaction of the bis[bis(dialkylamino)phosphanyl]methanes **1a,b** with alkenes in which the C=C double bond is activated by two trifluoromethyl groups.

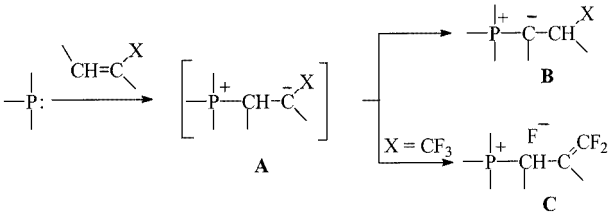
The interaction of tertiary phosphanes with compounds containing activated carbon-carbon double bonds to give phosphorus ylides is well known. The first step of this interaction is the formation of the intermediate zwitterionic compounds **A** (Scheme 2), containing a carbanion in the β-position to the phosphorus atom. Sometimes such intermediates can be isolated as stable compounds.[7–10] Then, a migration of the more acidic α-proton to the β-carbon is observed to give the appropriate ylides **B**. In some cases a similar migration is found for fluorine.[11,12] The forms **A** and **B** are in equilibrium with each other, and this equilibrium is usually shifted completely to the thermodynamically more stable form **B**. When this interconversion is separated by a high barrier, the two forms can be isolated as separate stable isomers.[13]

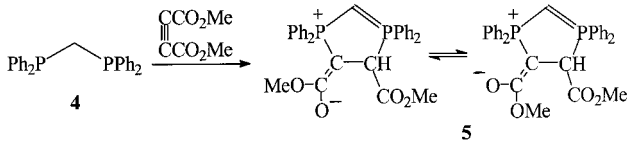


Scheme 2

We reasoned that if the C=C double bond of the starting alkene is activated by a CF_3 group (X = CF_3) the intermediate zwitterionic compound **A** can be alternatively stabilized by the elimination of a fluoride anion to give structure **C**. Such reactions have not been studied yet in the chemistry of phosphorus ylides, although the elimination of F^- from the α-position of a carbanion is well-known in fluorine chemistry.[14–17]

The second objective of the present investigation was to use methylenediphosphanes containing the fragment

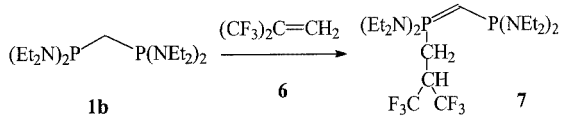
P−C−P. Such compounds have not yet been investigated in their reactions with alkenes, to the best of our knowledge. The only known close example is the reaction of methylenebis(diphenylphosphane) (**4**) with the methyl ester of acetylenedicarboxylic acid,[18] which gave a mixture of *E*/*Z* isomers of the stable cyclic ylide **5** (Scheme 3)



Scheme 3

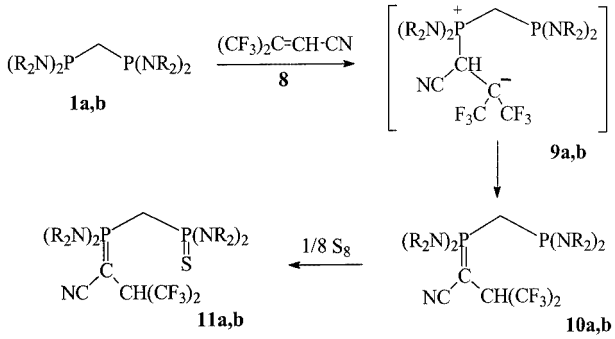
Results and Discussion

The activation of ethylene by two trifluoromethyl groups, as in compound **6**, turned out to be insufficient for the electrophilic attack of the trivalent phosphorus atom. The reaction of **1b** even with a threefold excess of 1,1-bis(trifluoromethyl)ethylene (**6**) proceeded very slowly (Scheme 4). After heating the reaction mixture in hexane in a sealed tube at 60 °C for 18 h, only traces of product **7** were detected by ^{31}P NMR spectroscopy as two characteristic doublets at δ = 34 and 78 ppm ($^2J_{P,P}$ = 76.4 Hz). The reaction rate increased in more polar solvents (CH_2Cl_2, $CHCl_3$), although it still required heating for a long period, which led to substantial decomposition of **7** and prevented its isolation in pure form.



Scheme 4

The presence of a nitrile group at the double bond, as in bis(trifluoromethyl)acrylonitrile (**8**), renders this compound much more reactive towards methylenediphosphanes **1a,b**. The reaction of **8** with **1a,b** proceeds rapidly in hexane solution at −15 °C to give ylides **10a,b** almost quantitatively (Scheme 5)



Scheme 5

The first step of this reaction is the formation of the intermediate betaines **9a,b**. However, at −15 °C the stability of these compounds is determined not by a fluoride ion elimination, but by a standard proton migration to give the ylides **10a,b**. Compounds **10a,b** can be isolated in good yields as colorless crystalline products. The structure of compounds **10a,b** and, in particular, the position of the ylidic bond, have been confirmed by NMR spectroscopy. For example the P−C−P carbon atom of **10a** appears as a doublet of doublets at δ = 26 ppm, whereas the negatively charged ylidic carbon atom P-*C*−CN appears with a characteristic high field chemical shift at δ = 10.8 ppm with a large $J_{P,C}$ coupling constant of 180 Hz. It is interesting to note that unlike the doublet of doublets of the $P-CH_2-P$ carbon atom in the ^{13}C NMR spectrum, the two equivalent protons of this unit appear in the ^1H NMR spectrum as only one doublet, probably because one of the two $^2J_{P,H}$ coupling constants is close to zero.

The second interesting peculiarity of compounds **10a,b** is the "through-space" spin-spin interaction between the $(CF_3)_2CH$ unit and the tricoordinate phosphorus atom. In the $^{31}P\{^1H\}$ NMR spectra the P^{III} phosphorus appears as a doublet of septuplets with $J_{P,F}$ = 3.0 Hz (**10a**) or 2.9 Hz (**10b**). All the fluorine atoms are equivalent and appear as a doublet of doublets in the ^{19}F NMR spectra, one of the doublets having the same $J_{P,F}$ coupling constant. In addition, the *C*H$(CF_3)_2$ carbon atom has a $J_{P,C}$ coupling constant of 6 Hz in the ^{13}C NMR spectrum. It should be noted that this spin-spin through-space interaction does not lead to a rigid cyclic conformation of compounds **10a,b**: the $(CF_3)_2CH$ group have a possibility for rotation, otherwise the equivalence of all fluorine nuclei should be accounted for by the appropriate symmetry of the molecule.

The structure of compound **10a** in the crystal was solved by X-ray analysis (Figure 1).

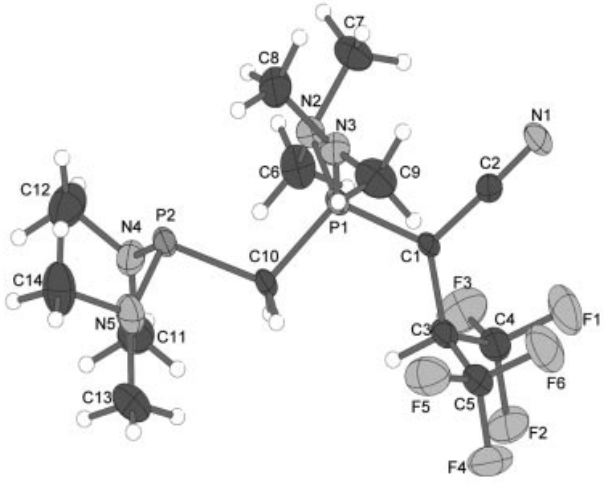


Figure 1. Perspective view and labeling scheme for the molecule **10a**; selected bond lengths [pm] and angles [°]: P(1)−C(1) 172.6(3), P(1)−C(10) 180.2(3), P(1)−N(2) 166.6(3), P(1)−N(3) 164.8(3), C(10)−P(2) 187.6(3), C(1)−C(2) 139.8(5), C(2)−N(1) 116.4(5), C(1)−C(3) 149.6(5); C(1)−P(1)−C(10) 109.07(16), P(1)−C(10)−P(2) 112.05(18), C(2)−C(1)−C(3) 121.3(3), C(2)−C(1)−P(1) 113.8(3), C(3)−C(1)−P(1) 124.9(2), N(1)−C(2)−C(1) 177.8(4); C(1)−P(1)−C(10)−P(2) −179.9(2), C(10)−P(1)−C(1)−C(2) −172.6(3), C(10)−P(1)−C(1)−C(3) 7.5(4)

In crystalline form the molecule of **10a** is rather symmetrical as the C(1), P(1), C(10), P(2) atoms are situated exactly in the same plane. The appropriate dihedral angle has a value of −179.9(2)°. The neighboring C(2) and C(3) atoms are only slightly deviated from this plane. For example, the C(10)−P(1)−C(1)−C(3) dihedral angle is 7.5(4)°. The two adjacent nitrogen atoms N(2) and N(3) have a slightly different configuration. The N(3) atom is almost flat, whereas the N(2) atom has a more pronounced tetrahedral geometry [the sums of angles are 357.3(8)° and 343.6(9), respectively]. In solution, however, both the dimethylamino groups are equivalent and display a common signal at δ = 2.49 ppm in the ^{1}H NMR spectrum.

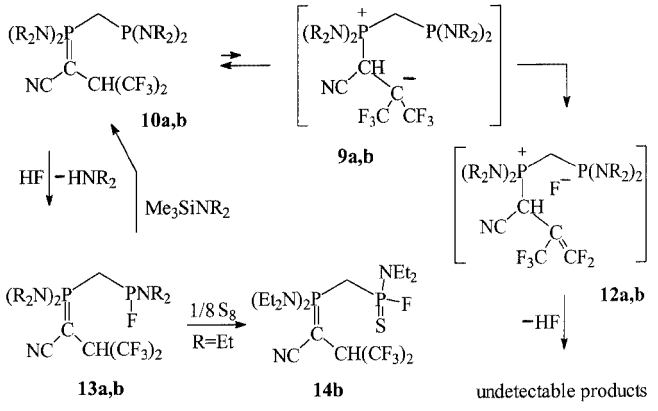
The ylidic carbon C(1) has an ideal flat conformation which is accounted for by the delocalization of the negative charge on the nitrile group; this is why the P(1)−C(1) bond (172.6 pm) is somewhat longer than the normal ylidic bond (168 pm),[19] whereas the C(1)−C(2) distance is considerably shorter (139.8 pm) than the average single C−C bond. These data are consistent with the structure of other nitrile-substituted phosphorus ylides.[20−22]

As is seen from the structure of **10a**, because of the large distance between P(1) and the fluorine atoms their spin-spin through-space interaction is hardly possible in the crystalline form. In solution, however, the molecule should have different conformations in which the bis(dimethylamino)-phosphane unit and the trifluoromethyl groups are close to each other due to rotation around the P(1)−C(10) and C(1)−C(3) bonds. This conclusion is also supported by the fact that the spin-spin through-space interaction in compounds **10a,b** disappears upon sulfuration of the phosphane center. All the fluorine atoms of the thio derivatives **11a,b** are equivalent and appear as one clear doublet in the ^{19}F NMR spectra at δ = −67 ppm ($^3J_{H,F}$ = 8 Hz).

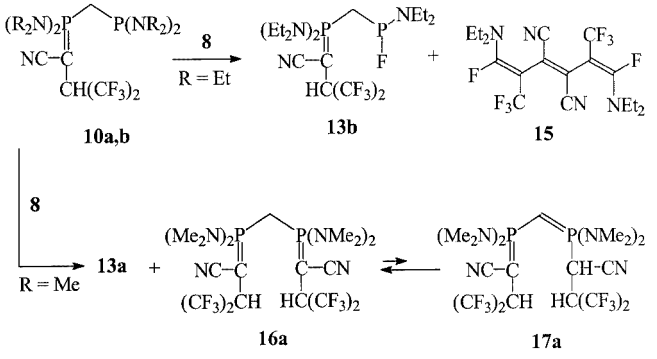
Compounds **10a,b** are rather stable in the crystalline form and in solution at −15 °C. At room temperature, however, they slowly decompose (over several days) into the monofluorides **13a,b** (Scheme 6). At 60 °C this process takes several hours. The stability of **10a,b** is probably determined by the presence of CF_3 groups in the α-position to the carbanion of the equilibrium forms **9a,b**. The elimination of the fluoride ion from the non-phosphorus analogs of **9a,b** can lead, in some cases, to stable products containing a perfluoroisopropenyl unit.[17] However, the elimination of F^- from **10a,b** probably goes via the unstable intermediates **12a,b**, which quickly decompose forming HF and a complex mixture of unidentified products. Thus, one half of the ylide molecules **10a,b** is formally used in their decomposition as a source of HF, which then reacts with the second half to give the monofluoro derivatives **13a,b**. Further transformation of **13a,b** into difluoro derivatives was not observed. The proposed mechanism was confirmed by the addition of HF (as $Et_3N{\cdot}3HF$) to compounds **10a,b**, giving the monofluorides **13a,b**. This result is consistent with the decomposition of carbodiphosphoranes **3a,b** and the formation of P−F bonds.[6]

The structure of compounds **13a,b** was confirmed by NMR spectroscopy and by their reaction with silylated amines, which led to the starting materials **10a,b**. One of the two phosphorus atoms in **13a,b** is asymmetric, which is why these compounds exist as a mixture of enantiomers. The diethylamino derivative **13b** was isolated as a crystalline product. Although the nucleophilicity of the phosphorus atom P^{III} in this compound is substantially reduced, it can be sulfurated with elemental sulfur to give **14b**. This process leads to the disappearance of the free rotation around one of the P−C bonds, hence **14b** was isolated as a mixture of diastereomers. Unlike starting compound **13b** the two trifluoromethyl groups in **14b** are inequivalent and appear as two quadruplets in the ^{19}F NMR spectrum. An interesting peculiarity of the sulfurated derivative is that the P−F fluorine is coupled with only one proton of the P−CH_2−P unit, the second coupling constant being equal or very close to zero. The presence of only one proton between two phosphorus is excluded as the chemical shift of the appropriate carbon atom in the ^{13}C NMR spectrum does not differ from that of compound **13b**.

The trivalent phosphorus of compounds **10a,b** is able to react further with **8**. However, the pathway of this reaction depends on the steric situation in compounds **10a,b**. The diethylamino derivative **10b** reacts slowly with **8** at room temperature and does not give the expected diylide but yields the monofluoro derivative **13b** as the main product (Scheme 7). According to the spectroscopic data the yield of monofluoride **13b** is about 70%, which is why its formation cannot be accounted for by the decomposition of the start-



Scheme 6



Scheme 7

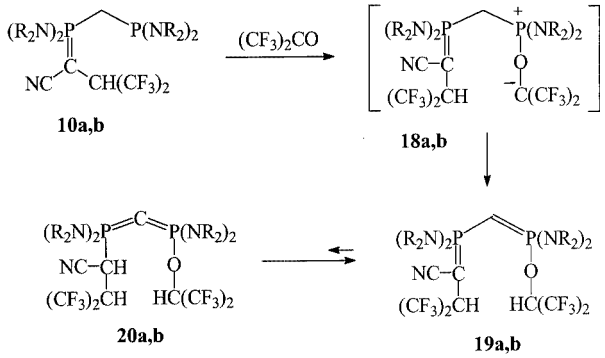
ing material. Bis(trifluoromethyl)acrylonitrile (**8**) acts as a fluorinating agent in this unusual reaction, transforming into the novel fluorinated triene **15**.[23] It is interesting to note that one of the trifluoromethyl groups of the acrylonitrile **8** looses two fluorine atoms and adds one of the diethylamino groups which was initially connected to one trivalent phosphorus atom of **10b**. Triene **15** was isolated as a slightly yellow crystalline product. The detailed structure of this compound was determined by X-ray analysis.[23]

The reaction of the less bulky dimethylamino derivative **10a** with **8** is much easier and gives a mixture of monofluoro derivative **13a** and the expected diylide **16a** in the ratio 35:65. The same result was obtained when two equivalents of **8** were added to the starting bis[bis(dialkylamino)phosphanyl]methane (**1a**). The formation of compound **13a** is not a result of decomposition of **16a**, as this ratio does not change after completion of the reaction. The mechanism of fluorination of **10a** by **8** does not, therefore, include the formation of **16a** as an intermediate product.

Diylide **16a** was isolated as a stable crystalline product, the structure of which was confirmed by NMR spectroscopy. Despite the fact that the $P-CH_2-P$ hydrogen atoms are situated between the two positively charged phosphorus atoms and are therefore rather acidic, the possible unsymmetrical structure **17a** was not detected. Thus, the equilibrium between **16a** and **17a** is completely shifted to the symmetrical form. The NMR spectroscopic data showed that the two phosphorus atoms and all their substituents are equivalent. The methylene group $P-CH_2-P$ appears as a triplet and the two ylidic carbon atoms as a characteristic doublet at $\delta = 12.0$ ppm ($^1J_{P,C} = 197$ Hz) in the ^1H and ^{13}C NMR spectra. Analogously to other symmetrical compounds containing central P−P or P−C−P fragments in which two phosphorus atoms are divided by a plane of symmetry, the diylide **16a** shows characteristic signals of an AA′XX′ spin system. The two tertiary carbon atoms of the $(CF_3)_2CH$ units are equivalent and appear as a clear septet of triplets in the ^{13}C NMR spectrum, each carbon having the same coupling constants with the two phosphorus atoms and vice versa. The two protons of the $(CF_3)_2CH$ groups show the same effect. However, because of the equality of the $^3J_{P,H}$ and $^3J_{H,F}$ coupling constants the spectrum appears as a multiplet of nine lines. Earlier we observed the analogous coupling for the same protons of carbodiphosphoranes **3a,b**.[5]

The presence of ylidic and trivalent phosphorus bridged by a methylene group makes compounds **10a,b** interesting synthons for further investigations. We were interested in the reaction of **10a,b** with hexafluoroacetone as it could answer the question as to whether the formation of carbodiphosphoranes described at the beginning of this paper is an exception or is more common.

We found that HFA reacts easily with ylides **10a,b** giving compounds **19a,b**, which were isolated as stable crystalline products, quantitatively (Scheme 8). The reaction proceeds via the intermediate zwitterionic structure **18a,b**, followed by proton migration from the $P-CH_2-P$ unit to the $(CF_3)_2C^-$ carbanion. As ylidic bonds are extremely polarized, the compounds **19a,b** can be considered as structures with alternating charges $P^+-C^--P^+-C^-$. Compounds **19a,b** should be in equilibrium with the carbodiphosphorane structures **20a,b**, although according to NMR spectroscopic data this equilibrium is shifted towards **19a,b**. For example, the $P-HC^--P$ proton appears in the ^1H NMR spectra as a doublet of doublets at high field ($\delta =$ 0.63 ppm). The two negatively charged ylidic carbon atoms are clearly seen in the ^{13}C NMR spectra at $\delta = 7.6$ and 15.6 ppm. The latter value, corresponding to the $C-CN$ carbon atom, is shifted slightly to low field compared with starting ylides **10a,b** which can be accounted for by the presence of the isomeric forms **20a,b**.



Scheme 8

Experimental Section

General Remarks: All operations were performed under nitrogen in a dry box. The solvents were dried by standard procedures. The NMR spectra were recorded with a JEOL FX-90Q and Varian 300 MHz spectrometers. The ^1H and ^{13}C chemical shifts are referenced to external tetramethylsilane (TMS). The ^{31}P chemical shifts are referenced to 85% aqueous orthophosphoric acid as an external standard. As usual, downfield shifts are given positive signs. The digital resolutions were 0.25, 0.5 Hz and 1.25 Hz for ^1H, ^{13}C and ^{31}P NMR spectra respectively.

Compound 10a: Bis(trifluoromethyl)acrylonitrile (**8**; 400 mg, 2.12 mmol) in 2 mL of diethyl ether was cooled to −15 °C and added to a solution of methylenebis(dimethylaminophosphane) (**1a**; 500 mg, 1.98 mmol) in 10 mL of hexane at the same temperature. The reaction mixture was maintained at −15 °C for 48 h. The colorless crystals of **10a** formed over this time were separated and recrystallized from chloroform/diethyl ether (1:2) at −15 °C, (681 mg, 78%), m.p. 72−74 °C. ^1H NMR ($CDCl_3$): $\delta = 2.13$ [d, $^2J_{P(1),H} = 13.5$, $^2J_{P(2),H} = 0$ Hz, 2 H, $P-CH_2-P$], 2.45 [d, $^3J_{P,H} =$ 10.0 Hz, 12 H, $N(CH_3)_2$], 2.49 [d, $^3J_{P,H} = 10.0$ Hz, 12 H, $N(CH_3)_2$], 3.34 [m, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): $\delta = 10.78$ (dm, $J_{P,C} = 180.0$ Hz, 1 C, PCCN), 26.22 (dd, $^1J_{P,C} = 25.4$, $^1J_{P,C} =$ 85.8 Hz, PCP), 36.60 (d, $^2J_{P,C} = 2.9$ Hz, 2 C, NMe_2), 36.76 (d, $^2J_{P,C} = 3.9$ Hz, 2 C, NMe_2), 40.40 (d, $^2J_{P,C} = 15.6$ Hz, 4 C, NMe_2), 45.62 [sept. dd, $^2J_{P,C} = 16.6$, $J_{P,C} = 5.9$, $^2J_{F,C} = 29.3$ Hz, 1 C, $CH(CF_3)_2$], 124.20 (q, $^1J_{F,C} = 282.9$ Hz, 2 C, CF_3), 125.02 (d, $^2J_{P,C} = 10.8$ Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): $\delta = -67.5$ (dd, $^3J_{H,F} = 8.3$, $J_{P,F} = 3.0$ Hz, 6 F) ppm. ^{31}P NMR ($CDCl_3$): $\delta =$ 66.94 (d, $^2J_{P,P} = 85.3$ Hz), 79.19 (sept. d, $^2J_{P,P} = 85.3$, $J_{F,P} =$

3.0 Hz) ppm. $C_{14}H_{27}F_6N_5P_2$ (441.34): calcd. C 38.10, H 6.17; found C 37.18, H 5.82.

Compound 10b: Bis(trifluoromethyl)acrylonitrile (**8**; 233 mg, 1.23 mmol) in hexane (3 mL) was cooled to −15 °C and added to a solution of methylenebis(diethylaminophosphane) (**1b**; 418 mg, 1.15 mmol) in hexane (5 mL) at the same temperature. The reaction mixture was maintained at −15 °C for 24 h. The colorless or light-yellow crystals of **10b** formed over this time were separated and washed with hexane (2 × 2 mL). Yield 496 mg (78%), 68−72% after crystallization from diethyl ether/hexane at −15 °C, m.p. 62−64 °C. ^{1}H NMR ($CDCl_3$): δ = 1.01 (t, $^3J_{H,H}$ = 7.07 Hz, 12 H, CH_2CH_3), 1.14 (t, $^3J_{H,H}$ = 7.07 Hz, 12 H, NCH_2CH_3), 2.27 [d, $^2J_{P(1),H}$ = 16.1, $^2J_{P(2),H}$ = 0 Hz, 2 H, P−CH_2−P], 3.09 (m, 16 H, N NCH_2CH_3), 3.44 [m, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 13.13 (d, $^3J_{P,C}$ = 1.9 Hz, 4C, NCH_2CH_3), 13.17 (dm, $J_{P,C}$ = 214.6 Hz, 1C, $PCCN$), 13.5 (d, $^3J_{P,C}$ = 3.9 Hz, 4C, NCH_2CH_3), 28.09 (dd, $^1J_{P,C}$ = 21.5, $^1J_{P,C}$ = 80.0 Hz, PCP), 39.19 (d, $^2J_{P,C}$ = 3.9 Hz, 2C, NCH_2CH_3), 39.34 (d, $^2J_{P,C}$ = 2.9 Hz, 2C, NCH_2CH_3), 42.20 (d, $^2J_{P,C}$ = 16.6 Hz, 4C, NCH_2CH_3), 46.40 [sept. dd, $^2J_{P,C}$ = 17.8, $J_{P,C}$ = 9.0, $^2J_{F,C}$ = 29.3 Hz, 1C, $CH(CF_3)_2$], 124.12 (q, $^1J_{F,C}$ = 282.0 Hz, 2C, CF_3), 125.66 (d, $^2J_{P,C}$ = 9.9 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −66.93 (dd, $^3J_{H,F}$ = 7.8, $J_{P,F}$ = 2.9 Hz, 6F) ppm. ^{31}P NMR ($CDCl_3$): δ = 73.78 (d, $^2J_{P,P}$ = 102.4 Hz), 67.18 (sept. d, $^2J_{P,P}$ = 102.4, $J_{F,P}$ = 2.9 Hz) ppm. $C_{22}H_{43}F_6N_5P_2$ (553.56): calcd. C 47.74, H 7.83; found C 47.69, H 7.75.

Compounds 11a, 11b: Sulfur (16 mg) was added to a solution of **10a** or **10b** (0.4 mmol) in 2 mL of CH_2Cl_2 at 20 °C. After 2 h the solution was filtered, the solvent was evaporated and the residue was recrystallized from CH_2Cl_2/hexane (1:2) at −15 °C.

11a: Yield 142 mg (75%), m.p. 125−128 °C. ^{1}H NMR ($CDCl_3$): δ = 2.48 [d, $^3J_{P,H}$ = 12.6 Hz, 6 H, $N(CH_3)_2$], 2.63 [d, $^3J_{PH}$ = 10.3 Hz, 6 H, $N(CH_3)_2$], 2.83 (t, $^2J_{P(1),H}$ = $^2J_{P(2),H}$ = 15.8 Hz, 2 H, P−CH_2−P), 3.54 [m, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 12.81 (dm, $J_{P,C}$ = 186.3 Hz, 1C, $PCCN$), 27.73 (dd, $^1J_{P,C}$ = 88.8, $^1J_{P,C}$ = 90.7 Hz, PCP), 36.56 (d, $^2J_{P,C}$ = 2.9 Hz, 4C, NMe_2), 37.23 (d, $^2J_{P,C}$ = 3.9 Hz, 4C, NMe_2), 46.27 [sept.d , $^2J_{P,C}$ = 14.6, $^2J_{F,C}$ = 29.3 Hz, 1C, $CH(CF_3)_2$], 124.20 [q, $^1J_{F,C}$ = 284.8 Hz, 2(CF_3)], 124.70 (d, $^2J_{P,C}$ = 13.7 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −66.95 (d, $^3J_{H,F}$ = 7.8 Hz, 6F) ppm. ^{31}P NMR ($CDCl_3$): δ = 61.46 ($^2J_{P,P}$ = 1.2 Hz), 72.12 ($^2J_{P,P}$ = 1.2 Hz) ppm. $C_{14}H_{27}F_6N_5P_2S$ (473.40): calcd. C 35.52, H 5.75; found C 35.14, H 5.35.

11b: Yield 176 mg (75%), m.p. 106−109 °C. ^{1}H NMR ($CDCl_3$): δ = 1.11 (t, $^3J_{H,H}$ = 7.03 Hz, 12 H, NCH_2CH_3), 1.16 (t, $^3J_{H,H}$ = 7.03 Hz, 12 H, NCH_2CH_3), 2.7−3.2 (m, 2 H, P−CH_2−P, 16 H, NCH_2CH_3), 3.09 (m, 16 H, NCH_2CH_3), 3.45 [m, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 13.43 (d, $^3J_{P,C}$ = 3.9 Hz, 4C, NCH_2CH_3), 13.67 (d, $^3J_{P,C}$ = 2.9 Hz, 4C, NCH_2CH_3), 13.87 (dm, $J_{P,C}$ = 195.05 Hz, 1C, $PCCN$), 27.74 (dd, $^1J_{P,C}$ = 28.8, $^1J_{P,C}$ = 90.7 Hz, PCP), 39.51 (d, $^2J_{P,C}$ = 2.9 Hz, 4C, NCH_2CH_3), 40.07 (d, $^2J_{P,C}$ = 4.9 Hz, 4C, NCH_2CH_3), 46.27 [sept. d, $^2J_{P,C}$ = 14.6 Hz, $^2J_{F,C}$ = 29.3 Hz, 1C, $CH(CF_3)_2$], 124.23 [q, $^1J_{F,C}$ = 284.8 Hz, 2(CF_3)], 124.70 (d, $^2J_{P,C}$ = 13.7 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −66.70 (d, $^3J_{H,F}$ = 8.0 Hz, 6F) ppm. ^{31}P NMR ($CDCl_3$): δ = 63.71 (d, $^2J_{P,P}$ = 7.3 Hz), 69.77 (d, $^2J_{P,P}$ = 7.3 Hz) ppm. $C_{22}H_{43}F_6N_5P_2S$ (585.62): calcd. C 45.12, H 7.40, N 11.96; found C 44.89, H 6.96, N 11.23.

Compound 13b: Compound **8** (170 mg, 0.90 mmol) was added to a solution of **10b** (400 mg, 0.72 mmol) in toluene (2 mL) and the reaction mixture was left at room temperature for 7 days. If the ^{31}P NMR spectrum showed the residual starting material **10b** the reaction mixture was heated at 70 °C for about 15 min. (NB The reaction can be carried out at elevated temperature, although the yield is then lower.) The solvent was removed in vacuo and the remaining thick dark-brown oil was thoroughly washed with cold hexane (2 × 1 mL) at −15 °C. The product was then extracted with boiling hexane (5 × 3 mL) and the obtained solution was left overnight at −15 °C. Light yellow crystalline product, yield 184 mg (51%), after re-crystallization from hexane 137 mg (38%). M.p. 90−91 °C. ^{1}H NMR ($CDCl_3$): δ = 1.14 (t, $^3J_{H,H}$ = 7.03 Hz, 6 H, NCH_2CH_3), 1.16 (t, $^3J_{H,H}$ = 7.03 Hz, 12 H, NCH_2CH_3), 2.3−2.7 (m, 2 H, P−CH_2−P), 2.9−3.4 [m, 12 H, NCH_2CH_3, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 12.68 (dm, $J_{P,C}$ = 238.9 Hz, 1C, $PCCN$), 13.48 (m, 4C, NCH_2CH_3), 15.13 (m, 2C, NCH_2CH_3), 34.26 (ddd, $^1J_{P,C}$ = 19.5, $^1J_{P,C}$ = 87.8, $^2J_{F,C}$ = 48.8 Hz, PCP), 39.36 (m, 4C, NCH_2CH_3), 42.89 (d, $^3J_{F,C}$ = 18.5 Hz, 2C, NCH_2CH_3), 47.44 [m, 1C, $CH(CF_3)_2$], 124.16 [q, $^1J_{F,C}$ = 281.8 Hz, 2(CF_3)], 124.90 (d, $^2J_{P,C}$ = 12.6 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −67.04 (dd, $^3J_{H,F}$ = 7.8, $^3J_{P,F}$ = 3.6 Hz, 6F), −106 (d, $^1J_{P,F}$ = 958 Hz, 1F) ppm. ^{31}P NMR ($CDCl_3$): δ = 62.23 (dd, $^2J_{P,P}$ = 68.2, $^3J_{P,F}$ = 17.1 Hz,), 155.05 (dd, $^2J_{P,P}$ = 68.2, $^1J_{F,P}$ = 958 Hz) ppm. $C_{18}H_{33}F_7N_4P_2$ (500.42): calcd. C 43.20, H 6.64, N 11.20; found C 44.39, H 6.98, N 12.20.

Compound 14b: Sulfur (10 mg) was added to a solution of **13b** (100 mg, 0.2 mmol) in $CHCl_3$ (1 mL) and the mixture was heated at 60 °C for 3.5 h. The solvent was removed in vacuo and the residue was extracted with diethyl ether (1.5 mL) at −10 °C in order to separate the product from the remaining sulfur. Evaporation of diethyl ether in vacuo yielded 77 mg (72%) of **14b**. M.p. 51−53 °C. ^{1}H NMR ($CDCl_3$): δ = 1.17 (t, $^3J_{H,H}$ = 7.03 Hz, 6 H, NCH_2CH_3), 1.20 (t, $^3J_{H,H}$ = 7.03 Hz, 12 H, NCH_2CH_3), 2.8−3.5 [m, 2 H, P−CH_2−P, 12 H, NCH_2CH_3, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 13.05 (dm, $J_{P,C}$ = 195.03 Hz, 1C, $PCCN$), 13.39 (m, 4C, NCH_2CH_3), 14.17 (m, 2C, NCH_2CH_3), 33.87 (ddd, $^1J_{P,C}$ = 34.1, $^1J_{P,C}$ = 95.6, $^2J_{F,C}$ = 85.8 Hz, PCP), 39.77 (d, 2C, $^2J_{P,C}$ = 4.9 Hz, NCH_2CH_3), 39.99 (d, 2C, $^2J_{P,C}$ = 4.9 Hz, NCH_2CH_3), 40.53 (dd, $^2J_{P,C}$ = 3.9, $^3J_{F,C}$ = 1.9 Hz, 2C, NCH_2CH_3), 47.10 [m, 1C, $CH(CF_3)_2$], 124.33 [q, $^1J_{C,F}$ = 283.8 Hz, 2(CF_3)], 124.52 (d, $^2J_{P,C}$ = 13.7 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −66.52 (q, $^4J_{FF}$ = 8.5 Hz, 3F), −67.04 (q, $^4J_{FF}$ = 8.5 Hz, 3F), −41.80 (dd, $^1J_{P,F}$ = 1063, $^2J_{H,F}$ = 9.8 Hz) ppm. ^{31}P NMR ($CDCl_3$): δ = 59.75 (d, $^2J_{P,P}$ = 4.9 Hz), 84.90 (dd, $^2J_{P,P}$ = 4.9, $^1J_{F,P}$ = 1060.7 Hz) ppm. $C_{18}H_{33}F_7N_4P_2S$ (532.48): calcd. C 40.60, H 6.24, S 6.02; found C 39.86, H 6.21, S 6.24.

Compound 16a: Compound **8** (200 mg, 1.06 mmol) was added to a solution of **10a** (360 mg, 0.82 mmol) in dichloromethane (4 mL) and the reaction mixture was maintained at 20 °C for 16 h. The solvent was then removed in vacuo and compound **13a** was extracted from the residue with diethyl ether (2 × 2.5 mL). The remaining product was dried in vacuo, dissolved in the minimum amount of dichloromethane, diluted with diethyl ether until the solution became turbid and the solution was left at −15 °C. After 2 days colorless crystals of **16a** were separated and dried in vacuo (280 mg, 54%), m.p. 185−186 °C. ^{1}H NMR ($CDCl_3$): δ = 2.66 [m, 2 H, $CH(CF_3)_2$], 2.77 (d, $^3J_{PH}$ = 10.0 Hz, 24 H, NCH_3), 3.18 (t, $^2J_{PH}$ = 16.1 Hz, 2 H, P−CH_2−P) ppm. ^{13}C NMR (CD_3COCD_3): δ = 12.00 (dm, $J_{P,C}$ = 196.8 Hz, 2C, $PCCN$), 26.4 (t, $J_{P,C}$ = 93.0 Hz, PCP), 36.75 (s, 8C, NCH_3), 47.03 [sept. t, $^2J_{P,C}$ = 29.3, $J_{P,C}$ = 6.8 Hz, $CH(CF_3)_2$], 123.0 (t, $^2J_{P,C}$ = 7.1 Hz, 2 C, CN), 124.8 [q, $^1J_{F,C}$ = 279.8 Hz, 2(CF_3)] ppm. ^{19}F NMR ($CDCl_3$): δ = −67.1 (d, $^3J_{H,F}$ = 7.8 Hz, 6F) ppm. ^{31}P NMR ($CDCl_3$): δ = 59.9 (s, 2P) ppm. $C_{19}H_{28}F_{12}N_6P_2$ (630.39): calcd. C 36.20, H 4.48; found C 35.81, H 4.12.

Compounds 19a, 19b: A solution of **10a** or **10b** (0.2 mmol) in toluene (1.5 mL) was placed in a 10 mL flask. The flask was then evacuated slightly and gaseous hexafluoroacetone (4.8 mL, 0.21 mmol) was introduced with a syringe. The mixture was left for 24 h at room temperature, then the solvent was removed in vacuo. The remaining oil was dissolved in minimum amount of diethyl ether (about 2 mL), diluted with hexane and left for two days at −15 °C. Colorless crystals were separated and dried in vacuo.

19a: Yield 80 mg (66%), m.p. 88−90 °C. ^{1}H NMR ($CDCl_3$): δ = 0.64 (dd, $^2J_{P,H}$ = 5.6, $^2J_{P,H}$ = 8.1 Hz, 1 H, P−C*H*−P), 2.56 [d, $^3J_{P,H}$ = 10.0 Hz, 12 H, N(CH_3)$_2$], 2.63 [d, $^3J_{P,H}$ = 10.0 Hz, 12 H, N(CH_3)$_2$], 2.95 [sept. d, $^3J_{H,F}$ = 8.5, $^3J_{PH}$ = 8.5 Hz, 1 H, C*H*(CF$_3$)$_2$], 5.08 [sept. d, $^3J_{H,F}$ = 5.8, $^3J_{P,H}$ = 11.9 Hz, 1 H, C*H*(CF$_3$)$_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 7.67 (dd, $^1J_{P,C}$ = 168.7, $^1J_{P,C}$ = 205.8 Hz, P*C*P), 15.86 (dm, $J_{P,C}$ = 136.5 Hz, 1C, P*C*CN), 36.97 (d, $^2J_{P,C}$ = 3.9 Hz, 4C, NMe$_2$), 37.17 (d, $^2J_{P,C}$ = 4.9 Hz, 4C, NMe$_2$), 48.20 [sept. d, $^2J_{P,C}$ = 12.7, $^2J_{F,C}$ = 29.3 Hz, 1C, *C*H(CF$_3$)$_2$], 70.11 [sept. d, $^2J_{P,C}$ = 2.9, $^2J_{F,C}$ = 34.1 Hz, 1C, *C*H(CF$_3$)$_2$], 120.20 (q, $^1J_{F,C}$ = 285.7 Hz, 2C, CF$_3$), 124.68 (q, $^1J_{F,C}$ = 279.9 Hz, 2C, CF$_3$), 127.63 (d, $^2J_{P,C}$ = 14.7 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −67.29 (d, $^3J_{H,F}$ = 8.5 Hz, 6F), −73.15 (d, $^2J_{H,F}$ = 5.8 Hz, 6F) ppm. ^{31}P NMR ($CDCl_3$): δ = 60.65 ($^2J_{P,P}$ = 39.0 Hz), 63.81 ($^2J_{P,P}$ = 39.0 Hz) ppm. $C_{17}H_{27}F_{12}N_5OP_2$ (607.36): calcd. C 33.61, H 4.48, N 11.53; found C 33.24, H 4.31, N 11.80.

19b: Yield 139 mg (97%), m.p. 79−82 °C. ^{1}H NMR ($CDCl_3$): δ = 0.67 (dd, $^2J_{P,H}$ = 9.7, $^2J_{P,H}$ = 12.3 Hz, 1 H, P−C*H*−P), 1.10 (t, $^3J_{H,H}$ = 7.1 Hz, 24 H, CH_2CH_3), 2.8−3.5 [m, 16 H, CH_2CH_3, 1 H, C*H*(CF$_3$)$_2$], 5.36 [sept, $^3J_{H,F}$ = 5.9 Hz, 1 H, C*H*(CF$_3$)$_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 12.2 (dd, $^1J_{P,C}$ = 173, $^1J_{P,C}$ = 199 Hz, P*C*P), 13.1 (d, $^3J_{P,C}$ = 2.9 Hz, 4 C, NCH$_2$*C*H$_3$), 13.8 (d, $^3J_{P,C}$ = 1.9 Hz, 4 C, NCH$_2$*C*H$_3$), 38.8 (d, $^2J_{P,C}$ = 4.9 Hz, 4 C, N*C*H$_2$CH$_3$), 40.4 (d, $^2J_{P,C}$ = 4.9 Hz, 4 C, N*C*H$_2$CH$_3$), 48.7 [sept. d, $^2J_{P,C}$ = 12.7, $^2J_{F,C}$ = 28.3 Hz, 1 C, *C*H(CF$_3$)$_2$], 70.4 [sept. d, $^2J_{P,C}$ = 2, $^2J_{F,C}$ = 37 Hz, 1C, *C*H(CF$_3$)$_2$], 121.0 (q, $^1J_{F,C}$ = 279 Hz, 2C, CF$_3$), 124.7 (q, $^1J_{F,C}$ = 285 Hz, 2C, CF$_3$), 128.1 (d, $^2J_{P,C}$ = 14.7 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −66.5 (d, $^3J_{H,F}$ = 8.3 Hz, 6 F), −72.6 (d, $^3J_{H,F}$ = 5.8 Hz, 6 F) ppm. ^{31}P NMR ($CDCl_3$): δ = 61.9 (d, $^2J_{P,P}$ = 41 Hz), 64.2 (d, $^2J_{P,P}$ = 41 Hz) ppm. $C_{25}H_{43}F_{12}N_5OP_2$ (719.58): C 41.73, H 6.02, N 9.73; found C 40.89, H 6.56, N 10.23.

X-ray Crystallographic Study: The single-crystal X-ray structure determination was performed at 173(2) K on a Siemens P4 diffractometer using graphite monochromated Mo-K_α radiation (λ = 71.073 pm) and a low temperature LT2 device. The structure was solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELX-97 program suite.[24] Crystal data for **10b** ($C_{14}H_{27}F_6N_5P_2$): M_w = 441.35, monoclinic, space group $P2_1/c$, a = 1195.0(2), b = 1348.9(2), c = 1397.7(4) pm, β = 110.400(10)°, V = 2.1117(8) nm^3, Z = 4, D_c = 1.388 Mg/m^3, μ = 0.266 mm^{-1}; 6078 reflections collected, 256 parameters refined using 4850 unique reflections (R_{int} = 0.0463) to final indices $R1$ [$I > 2\sigma(I)$] = 0.0651 and wR_2 (all data) = 0.1652 [$w = 1/[\sigma^2(F_o^2) + (0.0698P)^2 + P]$ where $P = (2F_c^2 + F_o^2)/3$. All non-hydrogen atoms were refined anisotropically and the position of the hydrogen atoms was calculated as a riding model. The final residual Fourier positive and negative peaks were equal to 0.401 and −0.480 e Å^{-3}.

CCDC-164430 contains the supplementary crystallographic data (for **10a**). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].
