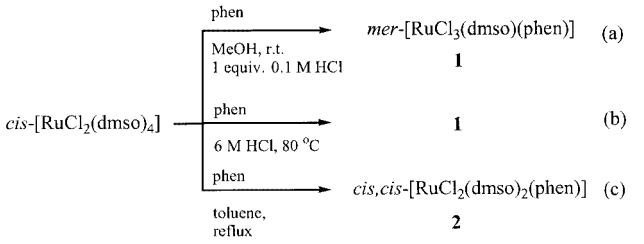
A literature method to prepare the Ru^{II} complex **2**[12] from *cis*-[RuCl$_2$(dmso)$_4$] and phen in CHCl$_3$ gave only low yields in our hands, but changing the solvent to toluene[16] resulted in direct precipitation of the pure product from the reaction mixture [see (c) in Scheme 4]. An additional and vital advantage of this method is the complete absence of bis- and tris(phen)ruthenium complexes. Upon slow concentration of a CHCl$_3$/toluene solution of **2**, red crystals of **1** were obtained; a lead to the synthesis of the analogous Ru^{III} complex **1** was found. CHCl$_3$ is known to contain traces of HCl and recently the syntheses of several complexes with the general formula [RuCl$_3$(dmso)L], where L is triazole, thiadiazole or diamine, by oxidation with HCl were reported.[17,18] Indeed, it proved feasible to prepare **1** by oxidation of *cis*-[RuCl$_2$(dmso)$_4$] with HCl in the presence of phen [see (a) and (b) in Scheme 4]. The formation of an Ru^{III} species from an Ru^{II} precursor can be envisioned to involve simultaneous reduction of the dmso ligand to dimethyl sulfide as proposed by Cingi et al. [see Equation (1)].[17] A general path to the Ru^{II} species that does not invoke ligand participation is discussed below. The room-temperature route [see (a) in Scheme 4] results directly in analytically pure **1**, but the overall yield with the high-temperature route [see (b) in Scheme 4] is higher. It should be noted, however, that at higher reaction temperatures with longer reaction times and using concentrated HCl, other products may precipitate, which are probably oligomeric analogs of **1**.



Scheme 4. Synthesis of **1** (a) (b) and **2** (c) from *cis*-$[RuCl_2(dmso)_4]$

$$2\ cis,cis\text{-}[RuCl_2(dmso)_2(phen)] + 2\ HCl \longrightarrow 2\ mer\text{-}[RuCl_3(dmso)(phen)] + Me_2S + dmso + H_2O \quad (1)$$

Crystal Structure Determination of 1

An ORTEP drawing of **1** is shown in Figure 1. Some selected bond lengths and angles are given in Table 1. The ruthenium center is in a distorted octahedral environment with coordination of one didentate phen ligand, three chloride ions and one *S*-bonded dmso ligand *trans* to one of the phen nitrogen atoms. The S−O bond is in the same plane as the phen ligand. Both ruthenium−nitrogen distances are in the range found for other ruthenium complexes with aromatic nitrogen donor ligands.[13,17] The Ru(1)−S(21) bond is longer than in analogous Ru^{II} complexes,[17] which reflects the smaller degree of π-back donation in this Ru^{III} complex. The S(21)−O(22) bond [1.478(2) Å] is slightly shorter than in free dmso [1.492(1) Å][19] indicating greater S−O double-bond character in the *S*-bonded dmso. The bonds within the phen ligand are similar to those in other (phen)ruthenium complexes.[13]

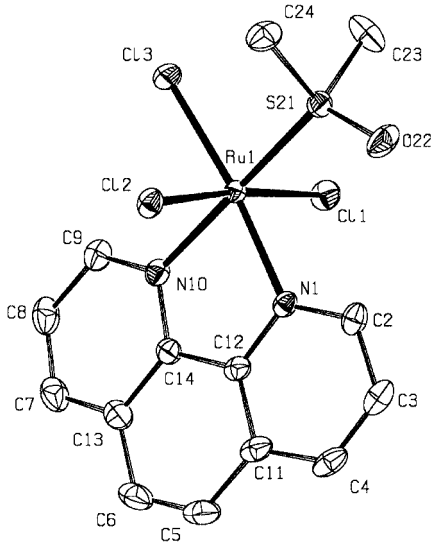


Figure 1. ORTEP plot and numbering scheme of the major component of complex **1**; hydrogen atoms and toluene solvent molecules are omitted for clarity; thermal ellipsoids are drawn at the 50% probability level

Table 1. Selected bond lengths and angles for **1**·toluene

Bond lengths [Å]			
Ru(1)−N(1)	2.099(2)	Ru(1)−Cl(3)	2.3477(8)
Ru(1)−N(10)	2.087(2)	Ru(1)−S(21)	2.2971(8)
Ru(1)−Cl(1)	2.3267(8)	S(21)−O(22)	1.478(2)
Ru(1)−Cl(2)	2.3444(8)		
Angles [°]			
N(1)−Ru(1)−N(10)	78.99(8)	N(10)−Ru(1)−S(21)	178.75(7)
N(1)−Ru(1)−Cl(1)	86.27(6)	S(21)−Ru(1)−Cl(1)	90.73(2)
N(1)−Ru(1)−Cl(2)	87.08(6)	S(21)−Ru(1)−Cl(2)	90.87(2)
N(1)−Ru(1)−Cl(3)	172.34(6)	S(21)−Ru(1)−Cl(3)	87.06(2)
N(1)−Ru(1)−S(21)	100.60(6)	Cl(1)−Ru(1)−Cl(2)	173.34(3)
N(10)−Ru(1)−Cl(1)	90.42(6)	Cl(1)−Ru(1)−Cl(3)	93.49(2)
N(10)−Ru(1)−Cl(2)	87.93(7)	Cl(2)−Ru(1)−Cl(3)	93.05(2)
N(10)−Ru(1)−Cl(3)	93.35(6)		

The Cl(1)−Ru(1)−Cl(2) angle is significantly smaller than 180° due to steric repulsion of the dmso methyl groups; the N(1)−Ru1−N(10) bond angle of 78.99(8)° is contracted compared to the ideal octahedral value by the small phen bite angle, which is somewhat smaller than in the complex where dmso is replaced by CO.[13] In this complex the phen ligand itself is boat-shaped to some extent, with angles between pairs of least-squares planes (through each of the three rings) ranging from 4.97(13) to 10.30(12)°. In the crystal packing a high degree of stacking is observed. Only two rings of each phen ligand are stacked with two rings of a phen ligand on an adjacent complex molecule (generated by symmetry operation $1 - x, -y, 1 - z$), avoiding steric repulsion between neighboring dmso groups. Approximately perpendicular to this, the cocrystallized toluene molecules form dimers, totally enclosed by molecules **1**, through stacking interactions.

Cyclic Voltammetry Studies on 1 and 2

The redox properties of both complexes have been investigated with cyclic voltammetry. In an acetonitrile solution, **1** exhibits two reversible one-electron waves (Figure 2). The first peak ($E_{1/2}$ = 0.11 V, ΔE_p = 60 mV) corresponds to the $Ru^{III/II}$ couple, whereas the second peak ($E_{1/2}$ = 1.73 V, ΔE_p = 54 mV) corresponds to the $Ru^{IV/III}$ couple. The nature of both couples has been corroborated by linear sweep voltammetry that shows the expected signs of the currents. The current for both peaks is linearly dependent on $v^{1/2}$ for the scan rates studied (0.05−1 V s^{-1}) indicating reversible diffusion-controlled processes.[20] The potential of the first wave is evidence for the ease of reduction of **1,** which plays an important role in isomerization catalysis (vide infra).

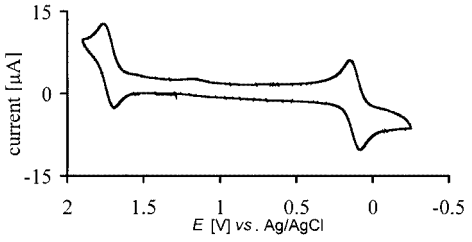

Figure 2. Cyclic voltammogram of **1** in acetonitrile at room temperature; scan rate: 0.1 V s^{-1}

The reversibility of the second peak is remarkable, demonstrating a robust Ru^{IV} complex, this was also observed in the analogous compound *mer*-[$RuCl_3$(dmso)(tmen)] (tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine).[18] From this peak it can be concluded that dmso in **1** is primarily a σ-donor and remains *S*-bonded even with the ruthenium atom in the 4+ oxidation state.

Complex **2** shows one reversible one-electron wave ($E_{1/2}$ = 1.08 V, ΔE_p = 56 mV), corresponding to the $Ru^{III/II}$ couple (Figure 3). In this case, the current for this peak is also linearly dependent on $v^{1/2}$ for the scan rates studied (0.05−1 V s^{-1}) and the oxidation state of **2** has been proven with linear sweep voltammetry. In the reductive part of the voltammogram (at potentials < −1.0 V) an irreversible wave is observed that can be attributed to a ligand-based reduction or reduction of the ruthenium center to Ru^0.

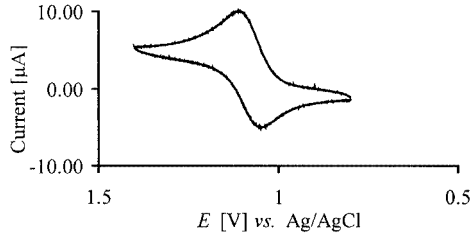

Figure 3. Part of the cyclic voltammogram of **2** in acetonitrile at room temperature showing the $Ru^{III/II}$ wave; scan rate: 0.1 V s^{-1}

Isomerization of 3-Buten-2-ol to MEK

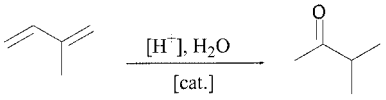
The Influence of a Conjugated Diene

The key step in the direct conversion of 1,3-butadiene to MEK has been identified as the isomerization of 3-buten-2-ol to MEK in the presence of 1,3-butadiene.[3,7] Since 1,3-butadiene is a suspected carcinogenic and due to its high volatility (b.p. −4 °C) it is difficult to handle in standard glassware, so it was decided instead to use isoprene in this study. Isoprene is converted analogously to MIPK [methyl isopropyl ketone, Equation (2)] and can thus function as a reasonable substitute for 1,3-butadiene.[7] The results of isomerization of 3-buten-2-ol to MEK catalyzed by several Ru^{III} (Entries 1−5) and Ru^{II} catalyst precursors (Entries 6−10) both in the absence and presence of isoprene are collected in Table 2.

Table 2. Isomerization of 3-buten-2-ol to MEK catalyzed by Ru^{III} and Ru^{II} complexes

Entry[a]	Catalyst precursor	TON	TON with isoprene[b]
1	[$RuCl_3 \cdot xH_2O$]	285	95
2	[$RuCl_3 \cdot xH_2O$] + 1 equiv. phen	390	300
3	**1**	465	440
4	**1**[c]	n.d.	475
5	**1** + 3 equiv. AgOTs	410	n.d.
6	*cis*-[$RuCl_2(dmso)_4$]	325	110
7	*cis*-[$RuCl_2(dmso)_4$] + 1 equiv. phen	275	75
8	**2**	290	150
9	**2** + 2 equiv. AgOTs	295	n.d.
10	**2**[d]	270	n.d.

[a] Reactions were performed in a 25-mL sealed glass vessel at 130°C; substrate: 3-buten-2-ol (5.8 mmol); catalyst: ruthenium complex (0.011 mmol) plus ligand as appropriate; substrate/catalyst: 530; solvent: water/diglyme (1:3 mL); reaction time: 6 h; n.d. = not determined. [b] 10 mmol of isoprene was added prior to addition of the substrate. [c] 15 mmol of isoprene. [d] In Ar with standard Schlenk techniques.



(2)

It is clear that both Ru^{III} and Ru^{II} complexes are capable of catalyzing the isomerization of 3-buten-2-ol to MEK, but Ru^{III} precursors consistently show higher conversion. The result of Entry 10 demonstrates that exclusion of air is not essential to obtaining good activity. Comparison of Entries 1 and 6 with 2 and 7, respectively, shows that the phen ligand as such is not a necessary requirement for activity. Both in situ mixing of the components and the use of preformed catalyst precursors gave comparable results. If a higher substrate/**1** ratio is applied, a TON of 1025 in 12 h can be obtained with an average TOF of 85 h^{-1}. The negative influence of an increased ligand-redistribution rate is demonstrated by successive removal of chloride ions by Ag^I salts from either **1** or **2**, which results in the same or only slightly lower catalytic activity (Entries 5 and 9). Presumably, the anticipated higher activity, as a consequence of more vacant coordination sites, is counterbalanced by an increased rate of ligand redistribution. Addition of a fourfold excess of Ag^I gives a color change of the reaction mixture to dark blue and almost complete loss of activity.

While a large number of catalysts are able to catalyze the isomerization of allylic alcohols to carbonyl compounds,[2] almost all of these fail to do so in the presence of dienes. The crucial next step therefore is to compare the catalytic systems *in the presence* of isoprene. From Table 2, it becomes apparent that isoprene indeed has a dramatic effect on the catalysis. Two factors are proven to play a role in resistance against isoprene inhibition. First, although phen is not required for activity in the absence of isoprene, the significant difference in activity of the catalyst precursors in Entries 1 and 2 shows that phen is an essential component for catalytic activity in the presence of isoprene. Second, all Ru^{II} catalyst precursors (Entries 6−9) loose 50% or more of their activity with isoprene in the reaction mixture. The presence of phen here (Entry 7) does not lead to resistance against diene inhibition. Thus, both of the requirements, a 3+ oxidation state and one phen ligand, have to be met. Complex **1** remains active, even if more isoprene is added (Entry 4, > 1300 mol-equiv. to ruthenium). These results unambiguously show, for the first time, the crucial influence of the oxidation state of the ruthenium center in allylic alcohol isomerization in the presence of a diene. Comparison of several catalytic precursors lacking or con-

taining various amounts of dmso ligands (cf. Table 2, Entries 2 and 3, 7 and 8), especially in the presence of isoprene, shows that the influence of the ligands on the difference in activity is marginal.

Isomerization Profile in Time

The difference in isomerization activity of Ru^{III} complex **1** and Ru^{II} complex **2** in the absence of isoprene is smaller than suggested by the overall results given in Table 2. The results plotted in Figure 4 clearly indicate that the reaction does not obey clean first-order kinetics. Therefore, *initial* TOFs and *initial* first-order rate constants (k_{ini}) have been calculated for both complexes.[21] The values obtained for **1** (TOF = 295 h^{-1}; k_{ini} = 0.6 h^{-1}) are similar to those found for **2** (TOF = 260 h^{-1}; k_{ini} = 0.5 h^{-1}). Although initial activity is comparable, **2** is deactivated much faster under the reaction conditions. The influence of isoprene is nicely illustrated (Figure 4). In the initial stages of the reaction, complex **2** still catalyzes the formation of MEK, but both initial TOF (75 h^{-1}) and k_{ini} (0.1 h^{-1}) are significantly lower than they are in the absence of isoprene. This remarkable finding may also explain the relatively low conversion reached by Ru^{II} complexes in the absence of isoprene: under the reaction conditions, some reversion (dehydration) occurs [see (a) in Scheme 2] that yields 1,3-butadiene as evidenced by GLC analysis of the gas cap. The increasing concentration of 1,3-butadiene in time causes a decrease of the number of active catalyst centers until finally catalysis is stopped completely.

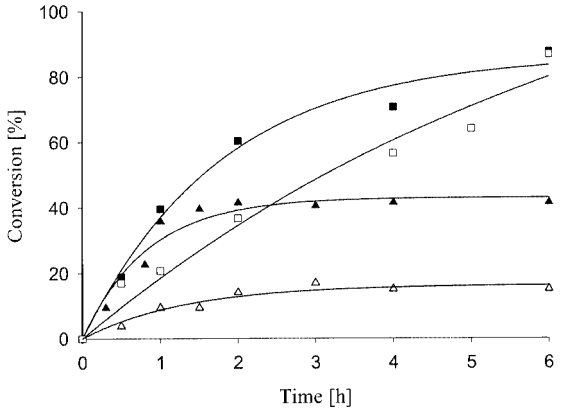


Figure 4. Isomerization of 3-buten-2-ol to MEK catalyzed by complexes **1** (squares) and **2** (triangles) at 130 °C in water/diglyme (1:3 mL) in the absence (filled symbols) and presence (open symbols) of 10 mmol of isoprene; substrate/catalyst precursor = 530

The initial rate of isomerization in the presence of isoprene is also lower with **1** as the catalyst precursor (TOF = 140 h^{-1}, k_{ini} = 0.3 h^{-1}), but deactivation in time does not occur and a high conversion can be attained in 6 h. Previous studies with $Ru(acac)_3$ and phen or bpy likewise showed a decrease in the reaction rate in the presence of 1,3-butadiene, but this system also remained active.[7]

The results of a time-dependent investigation using catalysts formed from [$RuCl_3 \cdot xH_2O$] and varying amounts of phen at 100 °C are shown in Figure 5. In the absence of phen, the isomerization is first order in 3-buten-2-ol with an initial TOF of 500 h^{-1} after a negligible induction period. When 1 equiv. of phen is added, the induction time increases to 40 min. Moreover, the initial TOF drops to 105 h^{-1}. In the original catalytic system with $Ru(acac)_3$, addition of either 1 or 2 equiv. of phen resulted in equal reactivity.[7] In sharp contrast to this, the activity of $RuCl_3$ with 2 equiv. of phen is virtually zero. After more than 16 h of reaction time, a small amount of MEK (60 turnovers) is obtained, but this must have been formed after an induction period of at least 5 h (Figure 5). The variation in lengths of the induction periods most likely originates from a kinetic difference in displacement of the various ligands involved. If isomerization is to occur with [$RuCl_3 \cdot xH_2O$] as the catalyst precursor, water has to be replaced by the substrate, which appears to be reasonably fast. Upon addition of 1 equiv. of phen, [$RuCl_3(H_2O)$(phen)] is formed. In this case, dissociation of one or more chloride ions has to take place prior to catalysis, which is considerably slower.[22] An induction period is not often observed in transition metal catalyzed isomerization of allylic alcohols and it seems to point at a cooperative effect; dissociation of the second and subsequent chloride ions is faster after dissociation of the first chloride ion. A similar effect has also been observed in isomerization of 3-buten-2-ol to MEK catalyzed by [$Ru(MeCN)_6$].[14] Increasing the polarity of the reaction mixture, by doubling the water content, should facilitate dissociation. Indeed, the induction period is reduced to 20 min, while the initial TOF is raised to 215 h^{-1}. At the higher reaction temperatures used with complexes **1** and **2** (Figure 4), chloride dissociation is much faster and only a small induction period is observed. If 2 equiv. of phen are added to $RuCl_3$, [$Ru(phen)_2Cl_2$]Cl is formed. In an analogous isomerization reaction catalyzed by $RuCl_3$ with 2 equiv. of 2,2′-bipyridine, only [$RuCl_2(bpy)_2$]Cl and related dinuclear species are observed with electrospray MS,[15] while complexes with only one bpy ligand are not found under these

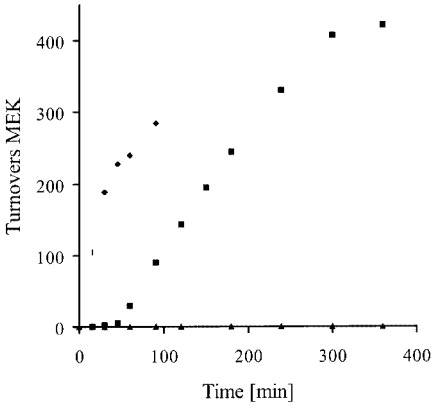

Figure 5. Isomerization of 3-buten-2-ol to MEK with $RuCl_3$ (◆) and $RuCl_3$ plus 1 (■) and 2 (▲) equiv. of phen at 100 °C in water/diglyme (1:3)

conditions. Given the slow dissociation of chloride ions from Ru^{III},[22] catalytic activity is now difficult to achieve.

Direct Conversion of 1,3-Butadiene to MEK

In the presence of *p*-toluenesulfonic acid, the preformed complex **1** is active in the direct conversion of 1,3-butadiene to MEK (Scheme 2). A TON of 2050 is reached in 6 h with a selectivity for MEK of over 95% in water/diglyme at 145 °C. Remarkably, in view of the isomerization results above, **2** also catalyzes the formation of MEK from 1,3-butadiene. The TON of 1300 in 7 h, however, is considerably lower than the TON reached with **1** as the catalyst precursor. The activity of **2** may be ascribed to the in situ oxidation of Ru^{II} to Ru^{III} by the acid present in the reaction mixture for the hydration of 1,3-butadiene. As schematically shown in Equation (3), oxidative addition of a proton initially leads to an Ru^{IV} hydride species. After protonation of the hydride yielding dihydrogen, the resulting Ru^{IV} species may comproportionate with a second Ru^{II} complex to give two Ru^{III} complexes. On the other hand, complex **1** can be reduced, under these reaction conditions, to the inactive Ru^{II} species according to Equation (4). Coordination of a substrate alkoxide followed by β-hydrogen elimination gives an Ru^{III} hydride and an aldehyde. After reductive elimination of 1 equiv. of HCl, the resulting Ru^{I} species may comproportionate with a starting Ru^{III} complex to give two Ru^{II} species.

$$\mathrm{Ru(II) + HCl \longrightarrow HRu(IV)Cl \xrightarrow[-H_2]{HCl} Ru(IV)Cl_2 \xrightarrow{Ru(II)} 2\,Ru(III)Cl} \quad (3)$$

$$\mathrm{Cl_3Ru(III) + {}^{-}OCH_2R \xrightarrow[-Cl^-]{} Cl_2Ru(III)OCH_2R \xrightarrow[-O{=}CHR]{}}$$

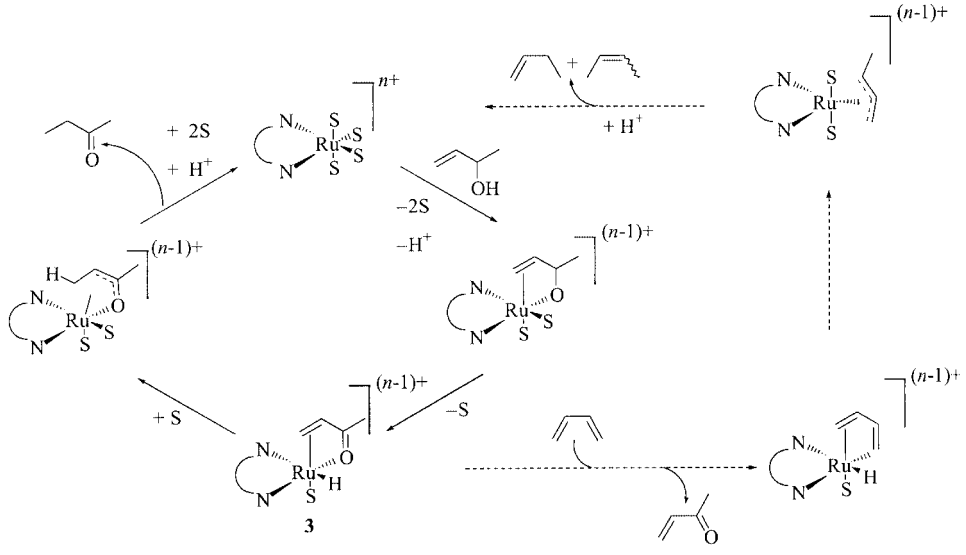
$$\mathrm{HCl_2Ru(III) \xrightarrow[-HCl]{} ClRu(I) \xrightarrow{Cl_3Ru(III)} 2\,Cl_2Ru(II)} \quad (4)$$

Analysis of reaction mixtures containing either catalyst precursors **1** or **2** with electrospray MS clearly shows the presence of Ru^{II} and Ru^{III} species in both cases. Since both catalyst precursors exhibit a significantly different activity, apparently an equilibrium has not been reached during the early stages of the reaction. The formation of Ru^{II} complexes, even to a significant extent in the presence of (oxidizing) acid, is unfortunate and should receive further attention in attempts to maximize catalytic activity. However, simply increasing the acid concentration to keep the ruthenium centers in the 3+ oxidation state results in an increased amount of side reactions such as 1,3-butadiene polymerization.

The direct conversion of 1,3-butadiene was previously shown to also be catalyzed by an in situ mixture of $RuCl_3$ and one phen ligand.[8] In fact, the performance of this system with an initial TOF of 960 h^{-1} and a cumulative TON of 2700 in 5 h is significantly better than the $Ru(acac)_3$/phen system.[7] In connection with the present study it is interesting to recall that electrospray MS spectra showed the presence of species with ruthenium in the oxidation state 3+ or 2+.[8] It can now be concluded that the latter species are inactive under the actual 1,3-butadiene hydration/isomerization reaction conditions used.

Mechanistic Rationale of Diene Inhibition

Two general mechanisms have been proposed for isomerization of allylic alcohols: the intramolecular π-allylmetal hydride mechanism and the intermolecular metal hydride addition/elimination mechanism.[2] Neither mechanism assigns a specific role to the oxygen moiety during the catalytic cycle. However, complexes **1** and **2** are inactive in the isomerization of unsubstituted alkenes such as 1-octene. So, a third, fundamentally different mechanism that invokes coordination of the oxygen moiety was proposed that is shown in Scheme 5.[3,23]



Scheme 5. Mechanism of isomerization of 3-buten-2-ol invoking oxygen coordination; indicated with dotted arrows is a possible deactivation/regeneration route involving a π-allyl species; S = labile ligand or $2e^-$ vacant site; $N_{\cup}N$ = phen, n = 2, 3

The first step is the coordination of 3-buten-2-olate to the ruthenium center after deprotonation of the substrate. This coordination can either be directly didentate as shown in Scheme 5, or occur in two consecutive steps with initial coordination of the double bond.[3] β-Hydrogen abstraction yields the (enone)ruthenium hydride species **3**. After readdition of the hydride ion to give an (oxaallyl)ruthenium complex, protonation affords MEK and regenerates the starting complex.

Two possibilities of catalyst deactivation by conjugated dienes can be envisioned. The simplest mode of action is preferential coordination; if isoprene coordinates much stronger to the ruthenium center than 3-buten-2-ol, no isomerization can take place. Although at this point we cannot completely exclude formation of a stable (isoprene)ruthenium complex with either **1** or **2**, NMR studies with ruthenium(II) complexes in our laboratory indicated a stronger initial coordination of 3-buten-2-ol.[15]

Intermediate **3** forms a second possible handle for diene inhibition as dienes are known to form stable π-allyl complexes after reaction with ruthenium hydrides.[24] Throughout a normal catalytic cycle with extremely fast intramolecular hydrogen transfer no long-lived (“free”) hydride is present. However, if methyl vinyl ketone (MVK) dissociates from **3**, the resulting ruthenium hydride may react with isoprene to form a (presumably inactive) (methylallyl)ruthenium complex. Whereas pure 1-octene is not isomerized in the presence of **1** or **2**, *trans*-2-octene (ca. 10 turnovers with either **1** or **2** as catalyst precursor) can be detected by GLC during the isomerization of 3-buten-2-ol in the presence of 1-octene, a strong support for the presence of free hydrides. Hydrides resulting from direct oxidative addition of acids to the ruthenium atom in **1** or **2** (vide supra) appear to be short-lived as 1-octene isomerization is not observed upon addition of HOTs in the absence of allylic alcohols.

The behavior of both catalyst precursors **1** and **2** is similar with the GLC detection of approximately 30 turnovers of MVK with respect to ruthenium. It should be noted that in both cases a mixture of Ru^{III} and Ru^{II} species is produced and it cannot be determined which of the two is responsible for MVK formation. The higher selectivity to MEK with catalyst precursor **1** suggests a lower rate of MVK dissociation in this case. The amount of MVK formed is more than stoichiometric and there must therefore be a way to regenerate the original catalytically active species from a ruthenium hydride or a (π-allyl)ruthenium species. A tentative route for a ruthenium hydride involves reaction of the hydride with the protic allylic alcohol to generate dihydrogen gas. Alternatively, protonation of an allylruthenium species will yield alkenes. A GLC gas-cap analysis of $RuCl_3$/phen-catalyzed isomerization of 3-buten-2-ol in the presence of isoprene demonstrates the presence of a mixture of C_5 alkenes, which is nicely explained by the protonation of π-allyl species.

Thus, the reaction of a diene with a free ruthenium hydride may explain the deactivation of the catalyst, but at this point no conclusion can be drawn as to why Ru^{III} complexes are much more resistant to this deactivation route and various explanations may be offered. Perhaps ruthenium(III) hydrides are less easily formed, as dissociation of MVK, coordinated through both the oxygen moiety and the double bond, from the higher charged Ru^{III} center may be relatively slower than from Ru^{II}. Alternatively, the removal of a π-allyl species by protonation might be faster with (allyl)Ru^{III} species. We currently favor the former explanation as more plausible, but molecular modeling aided by well-designed experiments should further clarify the peculiar difference in reactivity between Ru^{III} and Ru^{II} complexes.

Conclusion

In conclusion, the novel ruthenium(III) complex **1** has been synthesized and characterized by X-ray diffraction. The comparison with its Ru^{II} analog **2** revealed an important difference in catalytic activity in isomerization of allylic alcohols. Whereas both complexes show high activity in the isomerization of 3-buten-2-ol to MEK, only **1** remains active in the presence of the conjugated diene isoprene. Comparison with other catalyst precursors demonstrated that not only an Ru^{III} oxidation state is required for activity in the presence of isoprene, but also that one phen ligand has to be present in the complex. This is the first time that the role of the oxidation state has been pinpointed, implying that a second major deactivation route is discovered in the ruthenium-catalyzed direct conversion of 1,3-butadiene to MEK, next to ligand redistribution. In fact, while **1** gives high turnovers of MEK (up to 2050), **2** is less active (TON = 1300). The activity of **2** is most likely caused by in situ oxidation to **1** by the acid present in the reaction mixture. The reduction potential of **1** (0.11 V, $Ru^{III/II}$) and the oxidation potential of **2** (1.08 V, $Ru^{III/II}$) indicate that under the applied reaction conditions a delicate balance between both Ru^{III} and Ru^{II} complexes will be present in solution, which is confirmed by MS. Further studies are aimed at complexes with higher redox potentials with ligands that may provide stabilization of Ru^{III}.

Experimental Section

General Remarks: *cis*-$[RuCl_2(dmso)_4]$[12] was prepared according to a literature procedure. $[RuCl_3{\cdot}xH_2O]$ (Aldrich), 3-buten-2-ol (Aldrich), isoprene (Acros) and other reagents and solvents were commercially available and used as received, except 1-octene, from which peroxides were removed by flash chromatography on alumina immediately prior to use. Quantitative gas liquid chromatography (GLC) analyses were carried out with a Chrompack apparatus equipped with a CP wax 58 (FFAP) CB column (25 m × 1.2 μm) with toluene as internal standard. Melting points were measured with a Büchi apparatus and are uncorrected. Matrix Assisted Laser Desorption Ionization (MALDI) Time of Flight (TOF) mass spectra were recorded with a Finnigan MAT Vision 2000 spectrometer. The analytes were mixed with a 2,5-dihydroxybenzoic acid (DHB) or a α-cyano-4-hydroxycinnamic acid (α-CHCA) matrix. Elemental analyses were performed with a Perkin−Elmer series II 2400 CHNS/O analyzer. IR spectra were

obtained with a Perkin−Elmer Paragon 1000 FT-IR spectrophotometer equipped with a golden gate ATR device, using the reflectance technique (4000−300 cm^{-1}). ^1H NMR spectra (300.1 MHz) were measured with a Bruker 300 DPX. Chemical shifts (δ) are reported in ppm. Proton chemical shifts are relative to TMS.

***mer*-[$RuCl_3$(dmso)(phen)] (1):** A bright yellow solution of [$RuCl_2(dmso)_4$] (1.0 g, 2.1 mmol) and phen (0.39 g, 2.2 mmol) in 6 M HCl was heated at 80 °C for 2.5 h, after which time the resulting orange-red mixture was filtered. The filtrate was concentrated in a rotary evaporator. Flash chromatography of the red-brown solid on Al_2O_3 with CH_2Cl_2/MeOH (10:1) as eluent gave **1** as a dark red solid. Yield: 0.71 g, 74%. Alternatively, **1** can be prepared in situ from *cis*-[$RuCl_2(dmso)_4$] and phen at room temperature in MeOH with 1 equiv. of 0.1 M HCl (yield: 30%). Crystals suitable for X-ray analysis can be obtained from slow concentration of an MeOH solution at room temperature. M.p. 182 °C (decomp.). Paramagnetic ^1H NMR ($CDCl_3$): δ = −17.3 (br. s, 6 H, dmso), −8.9 (br. s, 1 H, phen), 2.2 (br. s, 1 H, phen), 8.2 (br. s, 1 H, phen), 8.5 (br. s, 1 H, phen), 11.5 (br. s, 1 H, phen) ppm. Other phen peaks were too broad to be observed. MALDI-TOF MS: *m*/*z* = 497 [M − 2 Cl − dmso + (α-CHCA−H)]$^+$. IR: $\tilde{\nu}$ = 3055 (νC−H), 2923 (νC−H), 1429−1411 (δC−H), 1342−1309 (δC−H), 1106 (νS−O), 1094 (νS−O), 328 (νRu−Cl). $C_{14}H_{14}Cl_3N_2ORuS$ (465.5): calcd. C 36.1, H 3.0, N 6.0, S 6.9; found C 36.9, H 2.9, N 6.0, S 7.0.

***cis*,*cis*-[$RuCl_2(dmso)_2$(phen)] (2):** This complex was prepared analogous to the method described in ref.[16] from *cis*-[$RuCl_2(dmso)_4$] (0.20 g, 0.41 mmol) and phen (0.07 g, 0.4 mmol). Yield: 0.18 g, 86%; m.p. > 300 °C (decomp.). ^1H NMR ($CDCl_3$): δ = 2.44 (s, dmso), 3.12 (s, dmso), 3.59 (s, dmso), 3.62 (s, dmso), 7.76 (dd, 1 H, ArH^3 or ArH^8, ^3J = 5.1, ^3J = 8.1 Hz), 7.87 (dd, 1 H, ArH^3 or ArH^8, ^3J = 5.1, ^3J = 8.1 Hz), 7.92 (d, 1 H, ArH^5 or ArH^6, ^3J = 9.0 Hz), 7.98 (d, 1 H, ArH^5 or ArH^6, ^3J = 9.0 Hz), 8.37 (d, 1 H, ArH^4 or ArH^7, ^3J = 8.1 Hz), 8.47 (d, 1 H, ArH^4 or ArH^7, ^3J = 8.1 Hz), 9.98 (d, 1 H, ArH^2 or ArH^9, ^3J = 5.1 Hz), 10.07 (d, 1 H, ArH^2 or ArH^9, ^3J = 5.1 Hz) ppm. MALDI-TOF MS: *m*/*z* = 435 [M − 2Cl + (DHB−H)]$^+$. IR (cm^{-1}): $\tilde{\nu}$ = 3049 (νC−H), 2924 (νC−H), 1418 (δC−H), 1302 (δC−H), 1082 (νS−O), 930 (νS−O), 328 (νRu−Cl). $C_{16}H_{20}Cl_2N_2O_2RuS_2$·0.1toluene (517.3): calcd. C 38.7, H 4.0, N 5.4, S 12.4; found C 38.4, H 3.9, N 5.7, S 11.5.

Cyclic Voltammetry Experiments: The electrochemistry measurements were performed with an Autolab PGstat 10 potentiostat controlled by GPES4 software. A three-electrode system was used, consisting of a platinum (Pt) working electrode, a platinum (Pt) auxiliary electrode and an Ag/AgCl reference electrode. The experiments were carried out in acetonitrile at room temperature under argon with tetrabutylammonium hexafluorophosphate as electrolyte (0.1 M). Under these conditions the ferrocenium/ferrocene couple was located at +0.436 V with a peak separation of 0.099 V. All potentials are reported relative to Ag/AgCl. Linear voltammograms were obtained with a rotating (500 rpm) platinum disc as working electrode at a scan rate of 0.005 V s^{-1}.

Isomerization Experiments: Catalytic reactions were performed in a closed glass vessel under air. The reaction vessel was charged with ruthenium precursor (0.011 mmol), ligand as appropriate (0.011 mmol, see text) and substrate (5.8 mmol). In some experiments an Ag^I salt (silver tosylate and silver triflate gave identical results) was added in the required stoichiometric amount. After addition of the solvent mixture water/diglyme (1:3 mL) and internal standard (toluene, 0.3 mL), the vessel was closed and the mixture was stirred in a pre-heated oil bath at 130 °C for 6 h. After cooling to room temperature, the mixture was analyzed by GLC. Several time-dependent measurements were performed at 100 °C under argon by using standard Schlenk techniques (see Figure captions). In isoprene inhibition experiments the amount of isoprene [typically 1.0 mL (10 mmol)] was added prior to the addition of the substrate. All reported values for TONs and TOFs are the arithmetic means of two or more reproducible experiments. Experiments are considered reproducible when the deviation of the obtained results are less than 15% of the arithmetic mean.

Direct Conversion of 1,3-Butadiene to MEK: In a typical experiment, a high-pressure autoclave was filled with 0.09 mmol of **1** or **2** and 3.5 mmol of *p*-toluenesulfonic acid (for the acid-catalyzed hydration of 1,3-butadiene). After addition of 100 mL of diglyme/water (70/30) solvent mixture, the autoclave was closed and purged three times with dinitrogen. Next, 1,3-butadiene (10 mL) was added as a liquid using an ISCO high-pressure pump and the autoclave was heated to 145 °C. After 10 h, the autoclave was cooled to room temperature and the contents were analyzed with GLC.

X-ray Crystallographic Study of 1: Crystals of **1** suitable for X-ray analysis were obtained by slow concentration of a $CHCl_3$/toluene solution of **2** at room temperature. Pertinent data for **1**: $C_{14}H_{14}Cl_3N_2ORuS$·C_7H_8, M_r = 557.90, red, block-shaped crystal (0.2 × 0.3 × 0.3 mm), triclinic, space group $P\bar{1}$ with *a* = 7.7503(10), *b* = 12.046(2), *c* = 12.872(3) Å, α = 73.972(10), β = 80.949(10), γ = 79.691(10)°, *V* = 1128.9(4) $Å^3$, *Z* = 2, D_c = 1.641 g cm^{-3}, μ(Mo-K_α) = 1.157 mm^{-1}. 20526 Reflections were measured (5133 independent, R_{int} = 0.0442, 1.6° < θ < 27.48°, *T* = 150 K, Mo-K_α radiation, graphite monochromator, λ = 0.71073 Å) with a Nonius Kappa CCD diffractometer with a rotating anode; no absorption correction was applied. The structure was solved by automated direct methods.[25] The structure displays relatively high residual density peaks in the area around Ru (peak height up to 2.7 e $Å^{-3}$ at 0.78 Å from Ru). The peaks appear to be related to the heavy atoms positions (Ru, Cl and S) by a noncrystallographic twofold rotation, approximately parallel to the local twofold rotation axis of the phenanthroline ligand. The rotation images of some heavy atoms coincide with existing atom sites. Similar peaks were observed in data sets collected on two other crystals. There are no signs of twinning. Rough models, describing these peaks as the result of orientational disorder of the Ru complex, indicated a disorder fraction of approximately 3%. In view of the low occupation factor of the minor component, the disorder model was abandoned. Hydrogen atoms were introduced on calculated positions and included riding on their carrier atoms. Non-hydrogen atoms were described with anisotropic displacement parameters. The isotropic displacement parameters of the hydrogen atoms were coupled to the equivalent isotropic displacement parameters of their carrier atoms. Full-matrix least-squares refinement[26] of 265 parameters on F^2 resulted in a final *R*1 value of 0.0306 [for 4914 reflections with $I > \sigma(I)$], *wR*2 = 0.0729, GoF = 1.044. The final residual density was in the range of −1.09 to 2.66 e $Å^{-3}$. Geometric calculations and molecular graphics were performed with the PLATON package.[27] CCDC-176535 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Acetylides / Copper / N ligands / Zinc

The reaction of the lithium β-diketoiminate complex (dipp)NacNacLi·OEt_2 {(dipp)NacNac = 2-[(2,6-diisopropylphenyl)amino]-4-[(2,6-diisopropylphenyl)imino]pent-2-enyl} with $ZnCl_2$ yielded the corresponding (dipp)NacNacZnCl (**1**) and (dipp)NacNacZn(μ-Cl)$_2$Li$(OEt_2)_2$ (**1a**). Treatment of **1** with LiC≡CPh and $NaBH_4$ in diethyl ether gave (dipp)NacNacZnC≡CPh (**2**) and (dipp)NacNacZn(μ-H)$_2BH_2$ (**3**). The core element of compounds **1a**–**3** is a six-membered ZnN_2C_3 ring. The structure of **1a** shows the β-diketoiminate backbone in a boat conformation with the tetrahedrally coordinated metal centre in **1a** at the prow and the opposing carbon atom at the stern. The zinc atoms in **2** and **3** show a planar arrangement to the β-diketoiminate plane. The zinc atom in **2** is three-coordinated and that in **3** four-coordinated. Treatment of (dipp)NacNacLi·OEt_2 with CuI in diethyl ether yielded {[Li(OEt_2)][(dipp)NacNacCuI]}$_2$ (**4**). In contrast to **1a**–**3**, compound **4** contains a dimetallic system. The core of compound **4** consists of two six-membered LiN_2C_3 rings and one four-membered Cu_2I_2 ring. In addition to bonds to the two iodine atoms, the three-coordinated copper atom has a further bond to the γ-carbon atom of the six-membered LiN_2C_3 ring.

Introduction

Recent reports have indicated increasing interest in the β-diketoiminate ligand, due to its sterically demanding and chelating properties.[1,2] Vinamidines are useful for the stabilization of low oxidation states of group-13 elements. Recently, we reported the preparation of (dipp)NacNacAl^{I}, the first example of a monomeric Al^{I} compound[3] stable at room temperature. Power et al. described the synthesis of the first compound containing a Ga−N double bond, by using a β-diketoiminate ligand.[4] We have also reported on the synthesis of a β-diketoiminate boranate complex of magnesium, in which the magnesium centre is six-coordinated and octahedral.[5]

While the first metals to have a prominent role in organic synthesis were magnesium and lithium, several of the transition metals have also become very important.[6] Organozinc[7] and organocopper[8] complexes are extensively used in both organic and organometallic synthesis. In particular, these complexes offer valuable alternatives to the corresponding magnesium and lithium reagents. Dialkylzinc complexes exist as monomeric molecules with two-coordinate zinc atoms.[9] However, the corresponding dialkylcopper complexes, such as $[LiCuMe_2]_2$, exist as dimers.[10,11] Only discrete R_2Cu^- anions have been observed in crystals in which the lithium cation is complexed by crown ethers.[12] Recent reports have indicated increasing interest in zinc hydrides as reducing agents.[13−15] We have reported the synthesis of $[(dipp)NacNacZnH]_2$ by means of the reaction between $[(dipp)NacNacZnF]_2$ and Et_3SiH.[16]

Although the chemistry of organozinc complexes with four-coordinate zinc atoms has been developed, the synthesis of the corresponding acetylides is not well known. Wright et al. synthesized the first zinc acetylide derivatives in 1996,[17] and Dehnicke et al. have prepared a number of zinc acetylide derivatives.[18,19] Monomeric compounds with three-coordinate zinc are still quite rare; only a few examples have been reported in the literature.[20−27]

Here we report on the formation of a monomeric zinc acetylide complex with a three-coordinate zinc atom. We used the bulky β-diketoiminate 2-[(2,6-diisopropylphenyl)amino]-4-[(2,6-diisopropylphenyl)imino]pent-2-enyl ligand [(dipp)NacNac]. In summary, we prepared four new β-diketoiminate zinc derivatives − (dipp)NacNacZnCl (**1**), (dipp)NacNacZn(μ-Cl)$_2$Li$(OEt_2)_2$ (**1a**), (dipp)NacNacZnC≡CPh (**2**), and (dipp)NacNacZn(μ-H)$_2BH_2$ (**3**) − and also one β-diketoiminate copper derivative, {[Li(OEt_2)][(dipp)NacNacCuI]}$_2$ (**4**).

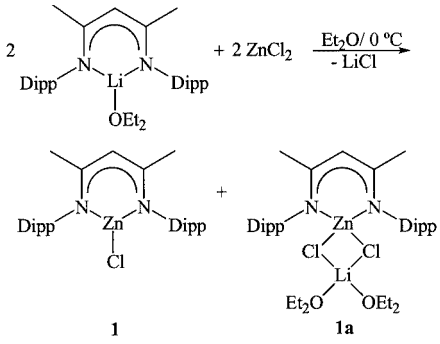
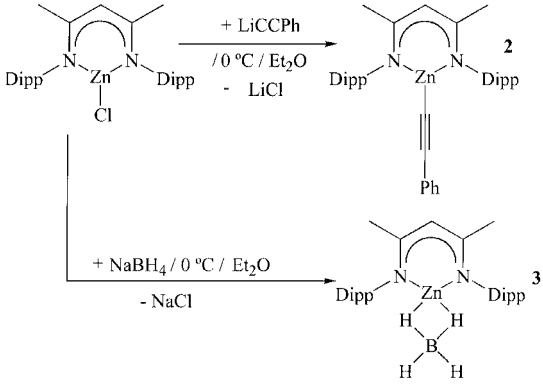
Results and Discussion

Compounds **1** and **1a** were prepared in high yield (92%) by the addition of (dipp)NacNacLi·OEt_2 to a $ZnCl_2$ suspension in diethyl ether (Scheme 1). Compounds **2** and **3** were obtained by addition of LiC≡CPh and $NaBH_4$, respectively, to a solution of **1**. LiCl and NaCl, respectively, were eliminated, and the monomeric zinc complexes **2** and **3** were isolated in high yields (83% **2**, 79% **3**) (Scheme 2).



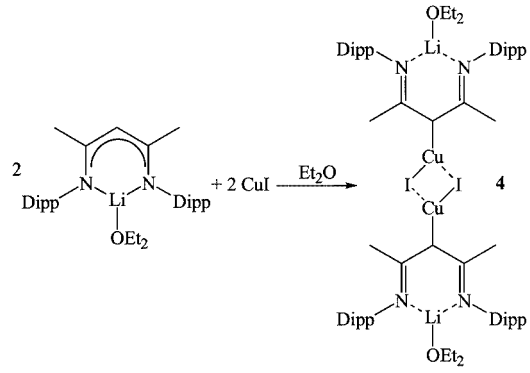
Scheme 1



Scheme 2

Compounds **1**, **2**, and **3** were characterized by EI-MS spectrometry, ^1H and ^{13}C NMR and elemental analysis. All compounds are moisture- and air-sensitive. The ^1H NMR spectra of **1**, **2**, and **3** showed the typical resonances of the β-diketoiminate unit, with two non-equivalent resonances for the methyl groups of the isopropyl substituents due to the hindered rotation about the Ar−N bonds, as observed for related metal systems.[1−3,28] The ^1H NMR spectroscopic data were consistent with the solid-state structures of **2** and **3**. Single crystals suitable for X-ray structural analysis were only obtained for **1a**, but the ^1H NMR spectrum was not consistent with the solid-state structure, with no resonances assignable to protons of the diethyl ether molecules being observed. From the predominance of **1** in the NMR and EI-MS spectra (m/z = 516 [M^+]) **1a** is obviously a by-product that crystallises more rapidly than the main product. The EI-MS spectra of **2** and **3**, however, showed the molecular fragments for **2** (m/z = 582 [M^+]) and for **3** (m/z = 482 [$M - BH_3]^+$), respectively.

Reactions with transition metal compounds are widely used in organic chemistry, organocopper compounds being important starting materials for new reactions in synthetic chemistry.[5] Compound **4** was therefore prepared in high yields (76%) by the addition of (dipp)NacNacLi·OEt_2 to a suspension of CuI in diethyl ether at −78 °C (Scheme 3).



Scheme 3

Compound **4** was characterized by EI-MS spectrometry, ^1H, ^{13}C, and ^7Li NMR and elemental analysis. Like compounds **1**−**3**, compound **4** is air- and moisture-sensitive. The ^1H NMR spectrum of **4** showed the typical resonances of the β-diketoiminate unit, the resonances at δ = 0.75 and 2.98 ppm corresponding with the protons of the coordinated ether molecules. The ^{13}C and ^7Li NMR spectroscopic data were consistent with the solid-state structure of **4**. The EI-MS showed a fragment of **4** minus one iodine atom (m/z = 1251 [$M - I]^+$).

Because of the similarity of compounds **1**−**7** to β-acetylacetonate complexes, a few examples and their physical properties are listed in Table 1 for comparison.

Table 1. Physical data of compounds **1**−**9**; acac = acetylacetonate, tmtch = 3,3,6,6-tetramethyl-1-thia-4-cycloheptyne, Tp* = hydrotris(3-cumyl-5-methylpyrazolyl)borate

	M.p. [°C]	^1H NMR of γ-C*H* (δ [ppm])
(dipp)NacNacZnCl (**1**)	205	4.88
(dipp)NacNacZnC≡CPh (**2**)	154	5.00
(dipp)NacNacZn(μ-H)$_2$BH_2 (**3**)	182−186	4.71
[{Et_2O)Li}{(dipp)NacNacCuI}]$_2$ (**4**)	165	4.24
(dipp)NacNacZnPh (**5**)[2]	155	5.04
(dipp)NacNacMg*i*Pr·Et_2O (**6**)[5]	165	4.85
(dipp)NacNacAl (**7**)[3]	> 150 (dec.)	5.18
(Tp*)Zn(cumoylacetonate) (**8**)[29]	183	5.43
(acac)Cu(tmtch) (**9**)[30]	116	5.37

The compounds **8** and **9** used for the comparison have coordination numbers at their metal centres of three for **8** and of five for **9**. It can be seen that the melting points of the β-acetylacetonate complexes (**8**, **9**) range from 116 to 183 °C, while those of compounds **1**−**4** ranged from 154 to 205 °C. The resonances for γ-CH in **8** and **9** were shifted

downfield [δ = 5.43 (**8**), 5.37 (**9**) ppm] relative to the β-diketoiminate compounds **1**−**7**.

Molecular Structures

The central core of compounds **1a**−**3** is a (dipp)NacNacZn unit. The β-diketoiminate ligand acts as a chelating ligand through its two nitrogen atoms, forming a six-membered ring with the zinc atom. The six-membered ZnN_2C_3 ring in **1a** is not planar, but displays a boat conformation with the metal atom at the prow and the opposite carbon atom at the stern, whereas the ZnN_2C_3 rings in **2** and **3** are planar. This deviation from planarity is imposed by the metal centre, as the planar arrangement implies more distortion of its coordination sphere. Nevertheless, the π-electrons of the β-diketoiminate ligand are delocalised, since the C(1)−C(2), C(2)−C(3), C(1)−N(1), and C(3)−N(2) bond lengths in each compound are equal within experimental errors and correspond to those in conjugated systems.[26] Moreover, the two N−Zn bond lengths are equal as well. The Zn−N distances {**1a**: 1.979(2) and 1.982(2) Å; **2** [$(C_7H_8)_{0.5}$]: 1.941(2) and 1.929(2) Å; **3**: 1.917(6) and 1.911(6) Å} are shorter than those in comparable Zn−N derivatives.[28,32−34] The N−Zn−N angles are 97.8° in compound **1a**, 98.8° in **2** and 101.9° in **3**.

The tetrahedral coordination sphere of the zinc atom is completed in compound **1a** by two chlorine atoms and in compound **3** by two hydrogen atoms, whereas the zinc atom in compound **2** adopts a trigonal-planar environment through an additional bond to one C≡CPh moiety.

The central core of **4** is made up of two (dipp)NacNacLi units. As in **1a**−**3**, the β-diketoiminate ligand acts as a chelating ligand through its two nitrogen atoms, forming a six-membered ring with the lithium atom. The LiN_2C_3 rings in **4** are not planar, but display boat conformations with the metal atom at the prow and the opposite γ-carbon atom at the stern. Surprisingly, the copper atom forms a bond to the γ-carbon atom of the β-diketoiminate ligand. In contrast, Tolman et al. recently reported the preparation of a copper(I) compound with the β-diketoiminate ligand in which the copper formed a six-membered CuN_2C_3 ring.[35] A possible explanation for this different behaviour might be that the soft Cu^{I} prefers coordination with the soft carbon atom while the harder Cu^{II} prefers coordination with the harder nitrogen atoms. The Cu−C bond length of 2.089(6) Å is similar to those found in the literature.[36,37] The trigonal environment of the copper atom is completed by two iodine atoms. The copper atoms form a four-membered Cu_2I_2 ring with the two iodine atoms. The C(1)−C(2) and C(2)−C(3) bond lengths [1.443(8) and 1.455(8) Å] correspond to C−C single bonds, whereas the C−N bond lengths [1.295(8) and 1.299(8) Å] are in the range of C−N double bonds.

The crystallographic data for **1a**, **2**, **3**, and **4** are summarized in Table 6.

Molecular Structure of 1a

Compound **1a** crystallises in the monoclinic space group $P2_1/n$ with one molecule in the asymmetric unit (Figure 1). Selected bond lengths and angles for **1** are given in Table 2.

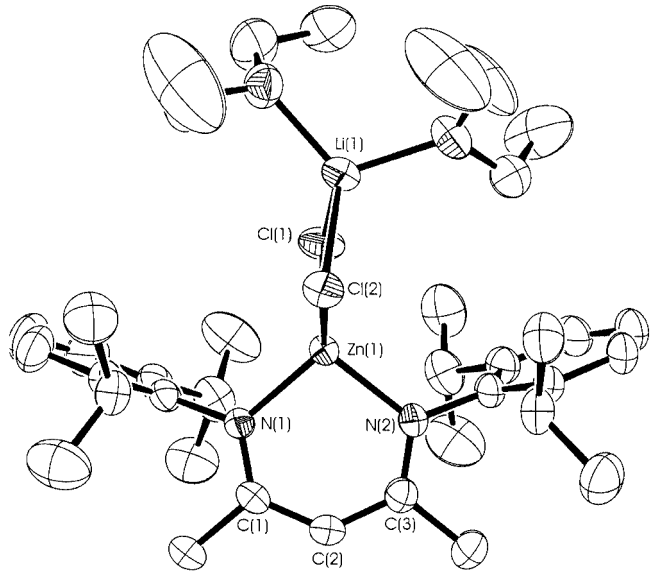


Figure 1. Crystal structure of **1a** (hydrogen atoms are omitted for clarity)

Molecular Structure of 2

Compound **2** crystallises in the monoclinic space group $P2_1/n$ with one molecule in the asymmetric unit. Besides the two nitrogen atoms of the (dipp)NacNac ligand, the zinc atom coordinates to one phenylacetylide group, a trigonal coordination sphere of the zinc atom thus being formed (Figure 2). Furthermore, the Zn−C≡C backbone deviates from linearity [Zn−C(30)−C(31): 168.18(19)°]. This deviation from linearity has been reported for corresponding transition metal complexes[32−34] and also found in aluminium compounds.[38] Selected bond lengths and angles for **2** are given in Table 3.

Molecular Structure of 3

Compound **3** crystallises in the monoclinic space group $P2_1/n$ (Figure 3). The B−H(b1 and b2) bond lengths are nearly equal [1.211(8) and 1.214(8) Å]. Compound **3** is thus

Conclusions

The sterically demanding β-diketoiminate ligand (dipp)NacNac facilitates the stabilization of compounds with low-coordination sites at the metal centre. We have synthesized three zinc β-diketoiminate complexes and one copper β-diketoiminate complex with novel structural motifs generated through substitution of the chlorine and iodine atom, respectively. We are at present investigating these compounds as alternatives for Grignard reagents in organic syntheses.

Experimental Section

General: All reactions were performed by standard Schlenk and dry-box techniques. Solvents were appropriately dried and distilled under dinitrogen prior to use. All NMR spectra were recorded in 5-mm tubes with dry degassed [D_6]benzene as a solvent, referenced externally to $SiMe_4$. Elemental analyses were performed by the Analytisches Chemisches Laboratorium des Instituts für Anorganische Chemie, Göttingen, and (dipp)NacNacH and (dipp)NacNacLi·OEt_2 were prepared by literature procedures.[3]

(dipp)NacNacZnCl (1): A solution of (dipp)NacNacLi·OEt_2 (3.11 g, 1.55 mmol) in Et_2O (20 mL) was slowly added at −78 °C to a suspension of $ZnCl_2$ (420 mg, 1.55 mmol) in Et_2O (20 mL). The mixture was allowed to warm to room temperature and then stirred for an additional 3 h and filtered. The solution was reduced in vacuo to 10 mL and stored at −24 °C to yield **1** and **1a** [(dipp)NacNacZn(μ-Cl)$_2$LiOEt$_2$)$_2$]$_2$ as colourless crystalline solids after 2 d. Data for **1**: Yield 1.48 g, 92%. M.p. 205 °C. ^{1}H NMR (500 MHz, C_6D_6): δ = 1.15 [d, J = 6.8 Hz, 12 H, CH(CH_3)$_2$], 1.16 [d, J = 6.8 Hz, 12 H, CH(CH_3)$_2$], 1.18 [d, J = 6.8 Hz, 12 H, CH(CH_3)$_2$], 1.20 [d, J = 6.8 Hz, 12 H, CH(CH_3)$_2$], 1.70 (s, 6 H, CH_3), 1.75 (s, 6 H, CH_3), 3.02 (sept, J = 6.8 Hz, 3.07 [sept, J = 6.8 Hz, 4 H, CH(CH$_3$)$_2$], 4.87 (s, 1 H, CH), 4.89 (s, 1 H, CH), 7.12 (m, 6 H, ArH) ppm. ^{13}C NMR (125 MHz, C_6D_6): δ = 23.3 [NC(CH$_3$)], 25.4 [CH(CH$_3$)$_2$], 28.8 [CH(CH$_3$)$_2$], 94.2 (γ-C), 123.8 (ArC), 125.2 (ArC), 141.2 (ArC), 142.3 (ArC), 165.4 (NC) ppm. MS (EI): m/z (%) = 481 (21) [M − Cl]$^+$, 516 (100) [M$^+$]. $C_{29}H_{41}ClN_2Zn$ (518.49): calcd. C 67.18, H 7.97, N 5.40; found C 67.0, H 7.6, N 5.3. Molecular mass (cryoscopic in THF in g/mol): calcd. 518.49; found 505. Only single crystals of **1a** were suitable for X-ray structural analysis.

(dipp)NacNacZnC≡CPh (2): A solution of LiC≡CPh (2.34 mL of a 1.0 M solution in THF, 2.34 mmol) was slowly added at −78 °C to a stirred solution of (dipp)NacNacZnCl (1.21 g, 2.34 mmol) in Et_2O (20 mL). The reaction mixture was stirred for an additional 3 h and allowed to warm to room temperature. The residue was filtered and the solution was concentrated to 10 mL under reduced pressure. Storage at −24 °C afforded colourless crystals of **2**: Yield 1.13 g (1.94 mmol), 83%. M.p. 154 °C. ^{1}H NMR (500 MHz, C_6D_6): δ = 1.17 [d, J = 6.8 Hz, 12 H, CH(CH_3)$_2$], 1.40 [d, J = 6.8 Hz,12 H, CH(CH_3)$_2$], 1.67 (s, 6 H, CH_3), 3.19 [sept, J = 6.8 Hz, 4 H, CH(CH$_3$)$_2$], 5.00 (s, 1 H, CH), 6.72−7.28 (m, 11 H, ArH) ppm. ^{13}C NMR (125 MHz, C_6D_6): δ = 20.5 [NC(CH$_3$)], 23.7 [CH(CH$_3$)$_2$], 24.5 CH(CH$_3$)$_2$, 28.3 [CH(CH$_3$)$_2$], 77.7 (C≡C), 83.8 (C≡C), 94.3 (γ-C), 123.3 (ArC), 123.5 (ArC), 124.5 (ArC), 125.1 (ArC), 128.2 (ArC), 139.2 (ArC), 142.6 (ArC), 161.9 (NC) ppm. MS (EI): m/z (%) = 202 (100) [DippNCCH$_3$], 481 (29) [M − C≡CPh]$^+$, 582 (59) [M$^+$]. $C_{37}H_{46}N_2Zn$ (584.16): calcd. C 76.08, H 7.94, N 4.80; found C 75.5, H 7.94, N 4.6.

(dipp)NacNacZn(μ-H)$_2$BH$_2$ (3): A solution of (dipp)NacNacZnCl (1.59 g, 3.10 mmol) in Et_2O (20 mL) was slowly added at −78 °C to a suspension of $NaBH_4$ (0.117 g, 3.10 mmol) in Et_2O (10 mL).

C 57.51, H 7.46, N 4.06; found C 58.7, H 8.5, N 5.2.

Crystal Structure Determination: All crystals were mounted on glass fibres in a rapidly cooled perfluoropolyether.[39] Diffraction data for **1a** and **4** were collected with a Stoe-Siemens-Huber four-circle diffractometer at 203(2) K, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), while diffraction data for **2** and **3** were collected with a Stoe IPDS-II at 133(2) K, again with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by direct methods with SHELXS-97 and refined against F^2 on all data by full-matrix, least squares with SHELXS-97.[40,41] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included in the model at geometrically calculated positions and refined with a riding model if not otherwise stated (Table 6). Atomic coordinates, thermal parameters, bond lengths and angles: CCDC-175030 (**1a**), -175031 (**2**), 175033-(**3**), and -175032 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Formation, Structures, and Magnetic and EPR Spectroscopic Properties of Dicobalt(III)-Dicopper(II) Complexes Featuring Heterotetranuclear Cations of a Puckered Cyclic Structure with Diethanolamine and Diethanolamine(2−) as Bridging Ligands

Valeriya G. Makhankova,[a] Olga Yu. Vassilyeva,*[a] Volodymyr N. Kokozay,[a] Jan Reedijk,[b] Gerard A. van Albada,[b] Julia Jezierska,[c] and Brian W. Skelton[d]

Keywords: Heterometallic complexes / Copper / Cobalt / Amino alcohols / EPR spectroscopy

The compounds $[Cu^{II}_2Co^{III}_2(H_2dea)_2(dea)_4]X_2(Solv)_n$ [X = Cl (**1**), Br (**2**), SCN (**3**), O_2CMe (**4**), I (**5**); Solv = H_2O or/and CH_3OH, DMF, n = 1–4] were synthesised by the reaction of zero-valent copper with cobalt(II) salts in non-aqueous (CH_3OH, DMF, DMSO) solutions of diethanolamine (H_2dea) in air. Crystallographic investigations of **1**–**4** reveal that the complexes contain the centrosymmetric cation $[Cu_2Co_2(H_2dea)_2(dea)_4]^{2+}$ in which the four metal atoms are linked together by bridging oxygen atoms of the six ligand groups to form a parallelogram with the length of the short edge (Cu···Co) being ca. 2.83 Å and a short diagonal distance (Cu···Cu) at approximately 3.23–3.29 Å. The copper atom is five-coordinate with a square-pyramidal geometry; the geometry at the trivalent cobalt ion is almost octahedral. The tetranuclear units are further stabilized by intramolecular O–H···O and N–H···O hydrogen bonds. The hydrogen-bonded network that involves the OH and NH groups of the ligands, uncoordinated anions, and solvent molecules links the tetranuclear units together and results in the formation of extended two- and three-dimensional networks. Variable-temperature magnetic susceptibility measurements of **1**–**3** and **5** show no significant exchange coupling between the copper centres. The frozen-solution and solid-state EPR spectra at 77 K are characteristic of a triplet state with the hyperfine structure distinctly resolved in solution. On the assumption of noncoaxiality of the g and D tensors the spectra were interpreted with the zero-field-splitting parameters D = 0.0560(1) (**2**–**5**) and D = 0.0712(1), E= 0.0028(2) cm^{-1} (**1**). Dominant contributions to the observed EPR zero-field splitting are presumed to be dipole-dipole in origin.

Introduction

The development of new approaches to the preparation of mixed-metal complexes plays an important role in synthetic coordination chemistry. Our current research in this field has been focused on the synthesis of Cu/M (M = Co,[1] Zn,[2] Ni) compounds. Investigation of their physico-chemical and catalytic properties may elucidate features found in polynuclear biologically active molecules, in which copper ions play an essential role in processes such as electron transfer, oxidation and dioxygen transport.[3]

A convenient synthetic pathway to such complexes has proven to be the use of zero-valent copper, a metal salt, and an amino alcohol as starting materials in solution in air. As we showed earlier, metal powders (Cu^0, Ni^0, Zn^0) dissolved to form metal complexes in the presence of an ammonium salt (a proton donating agent) and dioxygen from the air via Equation (1)

$$M^0 + 2\,NH_4^+ + 1/2\,O_2 \rightarrow M^{2+} + H_2O + NH_3 \quad (1)$$

in which copper oxidation occurs in the two-step process $Cu \rightarrow Cu^+ \rightarrow Cu^{2+}$.[4] The concept of the need for a proton-donating agent in syntheses of coordination compounds from elemental metals in air was further developed into a methodology for the preparation of mixed-metal complexes.[5] We believed that coordinatively unsaturated copper aminoalkoxides generated in situ could easily interact with other metal ions present in solution to afford the formation of a mixed-metal compound, due to the estab-

lished ability of amino alcohols to form polynuclear metal complexes.[6]

A unique pentanuclear mixed-valence complex[1a] $[Cu^{II}_2Co^{II}Co^{III}_2(O_2CMe)_4(H_2tea)_2(tea)_2]\cdot 2(HO_2CMe)$ was obtained by the reaction of copper powder with cobalt(II) acetate and triethanolamine (H_3tea) in DMF solution in air. A marked decrease of the χT value below 40 K for this compound was attributed to antiferromagnetic exchange coupling between the Cu^{II} and Co^{II} magnetic centres interacting through the diamagnetic Co^{III} ions. We therefore started systematic investigations into the reactions of zerovalent copper and a cobalt(II) salt in the presence of another amino alcohol, diethanolamine [H_2dea, $NH(C_2H_4OH)_2$], and wish to report here the synthesis, crystal structures, spectroscopic investigations and magnetochemistry of the compounds $[Cu^{II}_2Co^{III}_2(H_2dea)_2(dea)_4]X_2(Solv)_n$ [X = Cl (**1**), Br (**2**), SCN (**3**), O_2CMe (**4**), I (**5**); Solv = H_2O or/and CH_3OH, DMF, n = 1−4].

Results and Discussion

Synthesis

When copper powder and cobalt(II) salts (chloride, bromide, iodide, thiocyanate, or acetate) were treated with nonaqueous (CH_3OH, DMF, DMSO) solutions of diethanolamine in air, dissolution of copper occurred within several hours whilst stirring at 50−60 °C, resulting in the formation of dark green solutions. These solutions slowly precipitated green crystalline products that were isolated as the corresponding solvates or hydrates in high yields. Crystals of an iodide complex formed in methanol appeared to lose solvent and crystallinity within minutes if left to stand exposed to a solvent-free atmosphere. The compounds showed analytical data accounting for the presence of Cu^{II} and Co^{III} in a 1:1 stoichiometry. Their formation can be understood if one considers the reaction scheme in Equation (2).

$$2\,Cu^0 + 2\,CoX_2 + 8\,H_2dea + 1.5\,O_2 + n\,Solv \rightarrow [Cu^{II}_2Co^{III}_2(H_2dea)_2(dea)_4]X_2\cdot n\,Solv + 2\,H_2dea\cdot HX + 3\,H_2O \quad (2)$$

The assumption of neutral and doubly deprotonated amino alcohols that follows from counting the electrostatic charges was verified structurally. A similar tetranuclear cation was found for the mixed-valence dark green cobalt complex $[Co^{II}_2Co^{III}_2(H_2dea)_2(dea)_4](ClO_4)_2$ (**6**),[7] prepared from a Co^{II} salt in air. This observation suggests that the structure and nuclearity of these complexes are governed by the ligand nature of diethanolamine in its interaction with Co^{II} ions in solution. The presence of the amino alcohol facilitates partial air oxidation of the initial Co^{II} to Co^{III} in the case of **6**. When metallic copper is involved the formation of a mixed-metal complex becomes more favourable and all the initial Co^{II} ions oxidise to Co^{III}.

Spectroscopic Characterization

The IR spectra of complexes **1**−**5** in the range 4000−400 cm^{-1} are quite similar, and show all the characteristic ligand peaks. The spectra indicate the presence of hydrogen-bonded (3300−3400 cm^{-1}) OH groups only; free (≈ 3600 cm^{-1}) OH groups are not observed.[8] Compound **3** shows the sharp, intense ν(CN) absorption at 2090 cm^{-1} and a weak band for ν(CS) of a thiocyanate group at 745 cm^{-1}. The δ(NCS) mode is obscured by other vibrations. The frequencies of the observed bands suggest a terminal N-bonded thiocyanate,[9] although this is not supported by the X-ray structural study (vide infra). Participation of the uncoordinated NCS^- group in the intermolecular hydrogen bonding may account for this observation (the $N_{NCS}\cdots O_{solvent}$ contacts of about 2.8 Å support such hydrogen bonding).

The IR spectrum of **4** displays two bands at 1600 and 1380 cm^{-1} of higher and lower intensity (Δ = 220 cm^{-1}), respectively, not observed in the spectra of **1**−**3** and **5** and therefore assigned to ν(CO_2) vibrations. The Δ values above 200 cm^{-1} for the acetato complexes appear generally to be associated with unidentate coordination.[8,10] This criterion is not applicable to **4**, as the results of the X-ray structural study show that the acetate oxygen atoms are not coordinated to metals. However, those oxygens are strongly hydrogen bonded to methanol and the NH groups of the amino alcohol, giving what may be regarded as a "pseudo-bridging" arrangement responsible for the observed spectral pattern. Also, the possibility of anion exchange in a KBr disc and pressure-induced changes cannot be ruled out in the case of **3** and **4**.

The absorption spectra of **1**−**5** in DMF are dominated by the low-energy broad absorption at approximately 600 nm, attributable to a superposition of transitions in the visible region of a low-spin cobalt(III) ion in an octahedral geometry and a five-coordinate copper(II) centre, as revealed in the crystal structure.[11] The high energy, very intense band lower than 330 nm is associated with a charge-transfer transition.

Molecular and Crystal Structures of 1−4

All four complexes consist of the tetranuclear cation $[Cu_2Co_2(H_2dea)_2(dea)_4]^{2+}$, which has a puckered cyclic structure, two anions, and several solvent molecules in the crystal lattice. The overall structural configurations of the cation for **1**−**4** are similar. The important differences show up as relatively small changes in bond lengths and angles (Table 1) as well as in the hydrogen bonding. The molecular diagram and numbering scheme of **1** is shown in Figure 1, which illustrates the general geometry of the compounds.

The existence of an inversion centre induces all metal centres to lie in the same plane. The four metal atoms are linked together by the bridging oxygen atoms of the six diethanolamine groups to form a parallelogram with the length of the short edge [Cu(1)−Co(2)] being ca. 2.83 Å and a short diagonal distance [Cu(1)−Cu(1′)] at approximately 3.23−3.29 Å (Table 1). Our assignments of the positions of the metal ions are based on the relative metal−N(O) bond lengths and the geometric features of the two chromophores. The atom Cu(1) is five-coordinate with a square-pyramidal geometry. The four copper-ligand

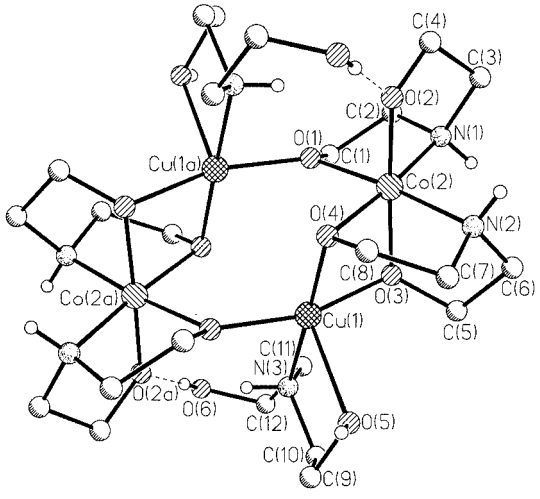

Figure 1. Molecular structure of the tetranuclear cation of **1**

bonds in the plane have normal bond lengths (average Cu−O and Cu−N distances of 1.96 and 2.02 Å, respectively), while the axial Cu−O(5) bond is elongated [2.352(11)−2.408(1) Å] due to the Jahn−Teller effect in the d^9 electronic configuration (Table 1). This long distance also allows one to infer the existence of the hydroxo donor function of the O(5) oxygen atom. The geometry at the trivalent cobalt ion, Co(2), is almost octahedral with Co(2)−O(N) distances in the range 1.885(8)−1.955(2) Å (Table 1), similar to those of low-spin cobalt(III) in an octahedral environment.[12] The structure of the tetranuclear cation is similar to that found for the mixed-valence cobalt complex **6**[7] in which the positions of the Co^{II} ions correspond to those of Cu^{II} in **1**−**4**.

The uncoordinated ethanol group of the neutral diethanolamine ligand forms an intramolecular hydrogen bond with the ethanolato group of the dea^{2-} ligand, as evidenced by the O(6)···O(2′) distances and O−H···O angles (Table 2, Figure 1). There is also a weaker intramolecular H bond between N(3) and O(2′) atoms (Table 2).

[a] Symmetry transformations used to generate equivalent atoms (indicated by ′): $-x + 1$, $-y + 1$, $-z + 1$.

Intermolecular hydrogen bonding involving the OH and NH groups of the ligands, the uncoordinated anions, and solvent molecules, links the tetranuclear units together and results in the formation of extended two- and three-dimensional networks. A fragment of the solid-state structure of **4** is given in Figure 2 as a representative example. We believe that the participation of solvent molecules in the hydrogen-bonded network is essential for the complex integrity in the solid state.

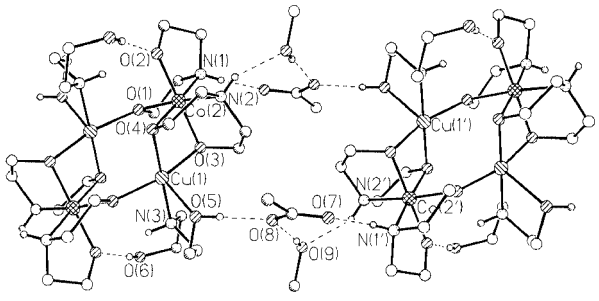

Figure 2. View of **4** showing the hydrogen-bonded network involving the noncoordinating acetate groups and methanol molecules

All bond lengths and angles within neutral and deprotonated diethanolamine are normal, and these data are given as supplementary material. Thiocyanate [d(N−C) 1.14(6), d(S−C) 1.59(4) Å, ∠N−C−S 170(4)°] and acetate groups [d(O−C) ca. 1.256(2), d(C−C) 1.519(2) Å, ∠O−C−O 124.9(1), ∠C−C−O 117.5(1)°] are structurally normal.[12]

Magnetic Properties

Experimental magnetic data for **1**−**3** and **5** are displayed in Figure 3 as μ_{eff} vs. T plots. The experimental data are presented as solid lines to distinguish between different plots. These show that in all cases the magnetic behaviour is paramagnetic. On the assumption that the Co^{III} ions are diamagnetic, the room temperature magnetic moment for each copper atom, ca. 1.8−1.9 B.M., is in the normal range for isolated $S = 1/2$ ions. The drop in the effective magnetic moment below 6 K indicates the onset of a weak antiferromagnetic coupling; this is not unexpected for systems in which H-bond contacts are important. It can be concluded that -O−Co−O- bridges effectively prevent any exchange interactions between copper centres.

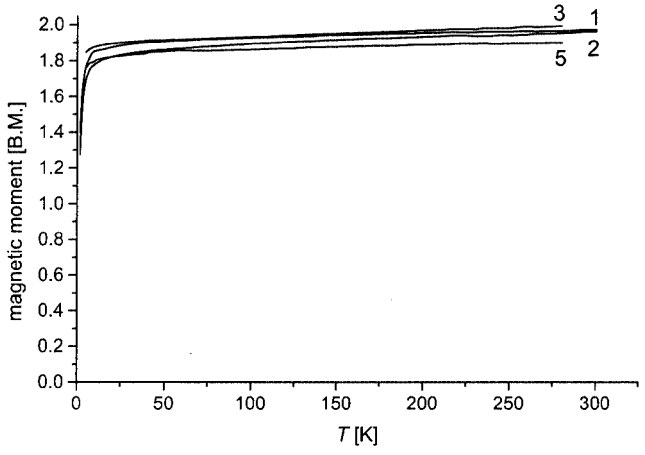

Figure 3. Plots of the effective magnetic moment per copper atom vs. T for **1**−**3** and **5**

The polycrystalline powder EPR spectra of **1**−**5** (Figure 4), which are essentially similar, show characteristic features of the spin-triplet state with the half-field signal observed (ca. 160 mT).[13] Fine structure components due to $\Delta M_S = 1$ transitions are distinctly visible for compounds **2** and **5**, and partly for **3** and **4**. In the case of compound **1** the $\Delta M_S = 1$ triplet-state components are not resolved. The spectra contain an isotropic signal in the $g \approx 2$ region, indicating crystal defects or monomeric impurities of different contribution. No sharpening of the lines or hyperfine splitting was observed upon cooling from room temperature to 77 K.

Nicely resolved spectra of the complexes showing almost identical triplet-state patterns were obtained from fresh solutions in DMF and methanol (77 K) (see Figure 5 for a representative example). The hyperfine structure from the two coupled Cu^{II} centres is clearly observed for the $\Delta M_S = 1$ and $\Delta M_S = 2$ signals and also partly resolved on the line present in frozen solution spectra only at ca. 375 mT, which is attributed to a high-field "parallel" line (Figure 5). Careful examination of the $\Delta M_S = 2$ signals (using the accumulation procedure) reveals two sets of "parallel" orientation lines for compounds **3** and **5** in DMF (Figure 5). One of them corresponds to that observed for all other compounds; the second is most likely associated with the additional spin-triplet line seen at 397 mT for **3** and **5** in DMF, suggesting a very small contribution of other triplet-state species.

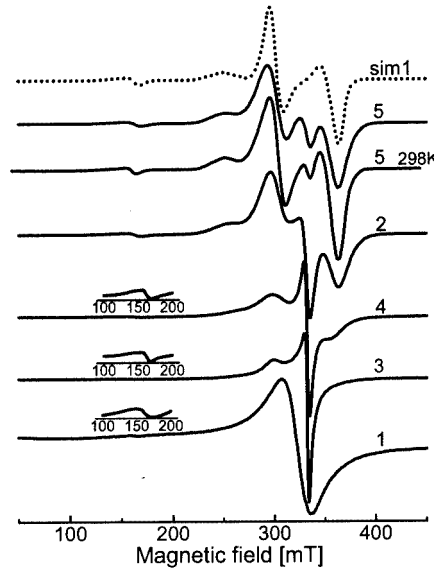

Figure 4. EPR spectra of polycrystalline complexes **1**−**5** measured at 77 K (solid lines), the dotted line being the simulated (sim1) spectrum obtained with parameters reported in the text

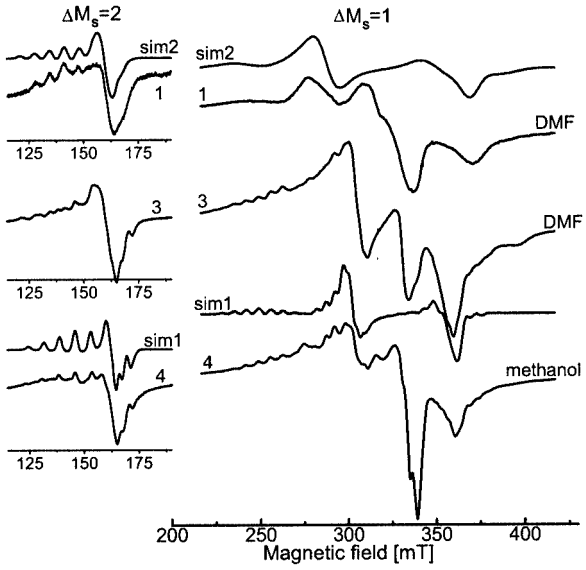

Figure 5. EPR spectra of frozen solutions of **1** and **3** in DMF and **4** in methanol (77 K); sim1 and sim2 are the fits obtained for the frozen solution spectra for **2**−**5** in DMF and methanol and for **1** in DMF, respectively, using parameters reported in the text

No substantial variation of the zero-field splitting for the different complexes was observed in both DMF and methanol frozen solutions, except compound **1**. However, the relative intensities of the fine-structure signals and signals due to paramagnetic species vary for the two solvents. The former signals are much more intense in DMF, indicating that tetranuclear $[Cu_2Co_2(H_2dea)_2(dea)_4]^{2+}$ cations are destroyed by the alcohol to a greater extent. The triplet-state spectra became weaker with time and the paramagnetic species contribution substantially increased.

The triplet EPR spectra are described by the spin Hamiltonian shown in Equation (3):[14]

$$H = \mu_B B\{g\}\, S + I\{A\}S + D[S_z^2 - 1/3\, S(S+1)] + E(S_x^2 - S^2{}_y) \qquad (3)$$

The experimental spectra have been fitted with nonparallel g and D tensors through a computer simulation procedure as described in refs.[15−17] The main features of the solid-state and frozen solution (methanol, DMF) spectra of compounds **2**−**5** were well simulated with the same set of spin-Hamiltonian parameters ("sim1" in Figure 4 and 5), $g_z = 2.305(5)$, $g_x = 2.063(2)$, $g_y = 2.063(2)$, $A_z = 0.0070(2)$, $A_x = 0.0014(4)$, $A_y = 0.0010(4)$ cm^{-1}, $D = 0.0560(1)$ cm^{-1} and an angle (α) between g_{zz} and D_{zz} directions of 25(1)°. In the polycrystalline powder spectrum of **1** the high intensity of the isotropic signal and the low resolution of the triplet signals make a determination of the g and D values impossible. Dissolution of the compound in DMF afforded the triplet-state spectrum (77 K) with the following spin-Hamiltonian parameters ("sim2" in Figure 5): $g_z = 2.350(5)$, $g_x = 2.068(2)$, $g_y = 2.068(2)$, $A_z = 0.0070(2)$, $A_x = 0.0012(4)$, $A_y = 0.0012(4)$ cm^{-1}, $D = 0.0712(1)$ cm^{-1}, $E = 0.0028(2)$ cm^{-1}, $\alpha = 30(1)°$.

These results clearly indicate that the configuration of the tetranuclear cations is retained in solution. Since no significant exchange coupling between copper centres is involved, according to the solid-state magnetic susceptibility studies for the reported compounds, the dominant interaction that brings about the characteristic shape of the EPR spectra is presumed to be dipole-dipole in origin.[13] Assuming only dipolar contributions to the observed EPR zero-field splitting, the empirical formula[18] would yield a separation of 3.4 (**2**−**5**) and 3.2 Å (**1**) for the Cu−Cu distance, which are in nice — although not very accurate — agreement with the solid-state distances (Table 1). The following observation also provides support for such a conclusion. In the case of dominant dipolar effects, the largest component of the zero-field-splitting tensor, D_{zz}, is parallel to the Cu−Cu direction; the largest g value for a square pyramidal copper(II) is expected to be orthogonal to the plane of equatorial ligands.[19] According to the crystallographic studies of compounds **1**−**4** the normal to the least-squares plane provided by N(3), O(3), O(4), and O(1′) makes an angle of ca. 30° with the axis joining the two copper centres. The value obtained is in good agreement with the values of α derived from the assumption of the noncoaxiality of the g and D tensors.

Concluding Remarks

Once again, employing zero-valent metals as a source of one of the metals in the synthesis of mixed-metal compounds allowed the generation of remarkable crystal structures, such as the heterotetranuclear dicobalt(III)dicopper(II) complexes containing diethanolamine.

Magnetic susceptibility measurements and EPR triplet spectra of the complexes showed evidence that the zero-field splitting parameter D originates from dipole-dipole interactions. The structure of the tetranuclear cations is fully preserved in solution and magnetic dipole-dipole coupling between the copper(II) ions is maintained.

Experimental Section

General: All chemicals were of reagent grade, and were used as received. All experiments were carried out in air. Elemental analyses for metals were performed by atomic absorption spectroscopy, and potentiometric titration with a solution of $K_3[Fe(CN)_6]$ for Co^{II},[20] using standard titrimetric methods for anions and a Carlo Erba Strumentazion Analyzer (for C, H and N). Infrared spectra were recorded as KBr discs or as Nujol mulls on a UR-10 spectrophotometer in the 4000−400 cm^{-1} region using conventional techniques. UV/Vis DMF solution spectra were recorded on a Perkin−Elmer Lambda 12 spectrometer. The EPR spectra were recorded on a Bruker ESP 300E (Bruker, Germany) spectrometer operating at X-band and equipped with a Bruker NMR gaussmeter ER 035M and a Hewlett−Packard microwave frequency counter HP 5350B. Variable-temperature magnetic measurements on complexes **1** and **2** in the region 1.8−300 K were made using a SQUID magnetometer (Quantum Design) with samples sealed in capsules. Magnetic susceptibility measurements for compounds **3** and **5** were recorded in the temperature range 4−300 K with a fully automated Manics DSM-8 susceptometer equipped with a TBT continuous-flow cryostat and a Drusch EAF 16 NC electromagnet, operating at ca. 1.4 T. In all cases, diamagnetic corrections for the sample holders were applied to the data. Diamagnetic corrections for the samples were determined from Pascal's constants.[21]

General Procedure for the Synthesis of 1−5: Copper powder (0.32 g, 5 mmol), $Co(X)_2{\cdot}nH_2O$ (5 mmol) (X = Cl, Br, I, NCS, O_2CMe; n = 1−6), CH_3OH (10 cm^3, DMF in the case of **5**) and H_2dea (4 cm^3) were heated to 50−60 °C and stirred magnetically until total dissolution of Cu was observed (several hours). The resulting solutions were allowed to stand at room temperature for one week during which time dark-green crystalline products of **1**−**5** precipitated. They were filtered off, washed with dry 2-propanol and finally dried in vacuo at room temperature.

$[Cu_2Co_2(H_2dea)_2(dea)_4]Cl_2{\cdot}2H_2O$ (1): Mass collected: 1.36 g, yield 56%. IR (KBr): $\tilde{\nu}$ = 3370 br, 3145 s, 3105 s, 2970 sh, 2940 m, 2900 m, 2885 m, 2860 m, 1660 br, 1450 m, 1375 w, 1350 sh, 1340 w, 1270 w, 1250 w, 1235w, 1220 w, 1185 w, 1165 w, 1115 sh, 1105 s, 1080 m, 1060 vs, 1040 sh, 1020 sh, 925 w, 915 w, 900 w, 880 w, 865 w, 830 w, 680 w, 645 m, 600 w, 570 sh, 560 m, 535 m, 500 w, 480 w, 445 w. $C_{24}H_{62}Cl_2Co_2Cu_2N_6O_{14}$ (974.65): calcd. $[Cu_2Co_2(H_2dea)_2(dea)_4]I_2\cdot 2DMF$ (5): Mass collected: 1.53 g, yield 48%. IR (KBr): $\tilde{\nu}$ = 3450 br, 3300−3050 br, 2935 m, 2875 m, 2835 sh, 1660 s, 1440 m, 1400 m, 1370 w, 1350 w, 1250 w, 1185 w, 1160 w, 1110 sh, 1100 m, 1060 vs, 1030 sh, 1020 sh, 920 w, 900 w, 880 w, 855 sh, 830 w, 675 w, 645 m, 600 w, 570 m, 555 m, 525 m, 500 m, 480 w, 450 w cm^{-1}. $C_{30}H_{72}Co_2Cu_2I_2N_8O_{14}$ (1267.73): calcd. Cu 10.03, Co 9.30, I 20.02, C 28.42, H 5.72, N 8.84; found Cu 9.9, Co 9.0, I 20.3, C 29.2, H 5.9, N 8.8.

X-ray Crystallographic Investigations: Diffraction experiments were performed on a Bruker SMART CCD diffractometer (ω rotation scans with narrow frames) (**1**, **4**) and an Enraf−Nonius CAD-4 diffractometer operating in the ω/2θ scan mode (**2**, **3**) equipped with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) (**1**, **2**, **4**) and Cu-K_α radiation (λ = 1.54178 Å) (**3**). The data were corrected for Lorentz polarisation effects and for the effects of absorption [multi-scan (**1**, **4**), Gaussian (**2**, **3**)]. The structures were solved by direct methods using the XTAL3.5[22] (**1**, **4**) and SHELXS-86[23] (**2**, **3**) programs, and refined by full-matrix least-squares methods on *F* using SHELXL-93[24] and XTAL3.5.[22] Details of the structural investigations and crystallographic data are summarized in Table 3.

In most cases (**1**, **2**, **4**), the non-hydrogen atoms were refined anisotropically (full-matrix least-squares). For both **1** and **4** all hydrogen atoms were located in a difference Fourier synthesis and refined isotropically. For **2** hydrogen atoms were included in their calculated positions, except hydroxyl hydrogen atoms, which were located but not refined. The ethanol solvent OH hydrogen atom was not located. For **3**, carbon atoms were refined with isotropic displacement parameters. The solvent methanol was refined with two disordered components with site occupancy factors set at 0.75 and 0.25 after initial trial refinement. Hydrogen atoms were included in

Monitoring the Reactions of the Anticancer Drug Carboplatin with the Chemopreventive Agent Selenomethionine by Electrospray Mass Spectrometry and [^{1}H,^{15}N] HSQC NMR Spectroscopy

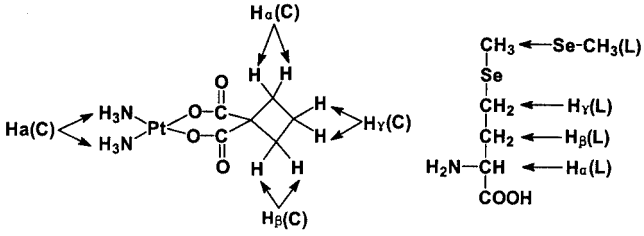
Qin Liu,[a,b] Jun Lin,[a] Pengju Jiang,[a] Junyong Zhang,[a] Longgen Zhu,[a] and Zijian Guo*[a]

Keywords: Antitumor agents / Platinum / L-Selenomethionine / Mass spectrometry / NMR spectroscopy

The reactions of the second-generation platinum anticancer drug carboplatin with L-selenomethionine (L-Se-MetH) and L-methionine (L-MetH) (abbreviations used: L-Se-MetH: L-selenomethionine; L-Se-Met: deprotonated L-selenomethionine; L-MetH: L-methionine; L-Met: deprotonated L-methionine) were studied by ESMS and 2D [^{1}H,^{15}N] HSQC NMR spectroscopy. The combination of the two techniques provided the unambiguous assignment of [Pt(NH_3)$_2$(CBDCA-*O*)(L-Se-MetH-*Se*)] (**1**), the long-lived ring-opened adduct, [Pt(NH_3)(CBDCA-*O*)(L-Se-Met-*Se*,*N*)] (**2**), [Pt(CBDCA-*O*,*O*)(L-Se-MetH-*Se*,*N*)] (**3**) and [Pt(L-Se-Met-*Se*,*N*)$_2$] (**4**). The reaction of carboplatin with L-MetH is very similar to that with L-Se-MetH, except for a slower reaction rate. Interestingly, we observed the dimer and polymer forms of carboplatin in solution by electrospray mass spectrometry. This work demonstrates that carboplatin differs from cisplatin in that both reactions with L-Se-MetH and L-MetH form [Pt(L-Se-Met-*Se*,*N*)$_2$] or [Pt(L-Met-*S*,*N*)$_2$] as the dominant adducts.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Carboplatin, [Pt(NH_3)$_2$(CBDCA)] (CBDCA: cyclobutane-1,1-dicarboxylate, Scheme 1), is now a widely used second-generation platinum anticancer drug. The major advantage of carboplatin compared with cisplatin ([$PtCl_2(NH_3)_2$]) [1] is its much lower toxicity, which may be attributed to its low reactivity caused by the presence of the chelating CBDCA ligand. [2]



Carboplatin **L-Se-MetH**

Scheme 1. Schematic drawing of carboplatin and L-Se-MetH and the labeling scheme used in the ^{1}H NMR spectra

The in vivo activation of carboplatin has been a subject of much interest. [3,4] Although early studies suggested that carboplatin is merely a prodrug of cisplatin, [5] the aquation rate is too slow to account for its in vivo activity. [6] The amino acid L-methionine (L-MetH) has been shown to react rapidly with carboplatin to form long-lived ring-opened complexes. [7] It has been therefore postulated that L-methionine may play a role in the mechanism of the reaction of the platinum drug. [8] More interestingly, a similar ring-opened complex has been detected in the urine of animals treated with carboplatin. [9] Since the complex [Pt(Met-*S*,*N*)$_2$] was identified as the in vivo metabolite of cisplatin, many studies on the interactions of platinum drugs with methionine and its derivatives have been carried out. [10–14]

L-Selenomethionine (L-Se-MetH, Scheme 1), the selenium analogue of L-methionine, is currently on clinical trials as a potential cancer chemopreventive agent in reducing both environmentally and genetically determined cancer. [15,16] It was also recently reported that L-Se-MetH is able to protect against cisplatin-induced renal and other toxicities in mice and rats. [17] We have recently investigated the reactions between cisplatin and L-selenomethionine, and demonstrated that the combination of ESMS and NMR spectroscopy could provide valuable information on the mechanism of the reactions. [18] Here, we extend our study to the interactions of L-selenomethionine and the second-generation anticancer drug carboplatin. The reaction be-

tween carboplatin and L-methionine is also carried out in order to compare the results with those studied by NMR spectroscopy.[7]

Results and Discussion

Results

(1) ESMS Investigation of Carboplatin in Solution: Detection of Dimer and Polymer Forms

A solution of carboplatin (2.68 mmol/mL) was studied at pH = 5.00 (no buffer solution was used) by ESMS. As shown in Figure 1, apart from the positive ion of protonated carboplatin (m/z = 372.1) and {[Pt(NH_3)$_2$(CBDCA)] + Na^+} (m/z = 394.1), three pairs of peaks at m/z = 743.1, 765.1; 1114.1, 1136.1; and 1486.0, 1508.0 were observed. These ions correspond to the formation of the dimer, trimer, and tetramer forms of carboplatin, respectively, and their corresponding sodium adducts (Table 1). These forms of carboplatin have never been detected previously in solution by other methods, although they may be formed only during the ionization process (vide infra). As can be seen from Figure 1, the intensity of the peaks decrease with the increase in the molecular size.

(2) The Time-Dependent Reaction of Carboplatin with L-Se-MetH in a 1:1 Molar Ratio

The reaction between carboplatin and L-Se-MetH was monitored for 22 h. The first ESMS spectrum was measured 2 min after mixing of the solutions of carboplatin and L-Se-MetH. Figure 2 shows the representative spectra of the reaction recorded after 25 min, 3 h and 22 h. As noted, all the isotopic peaks were separated by 1 unit and can be assigned to complexes with one positive charge. After 2 min, two new peaks (peak 1 and 12) appeared in the spectrum. Peak 1 at m/z = 567.9 can be assigned to

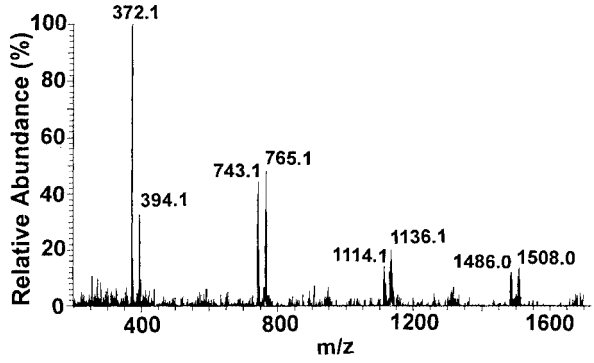

Figure 1. ESMS spectrum of a carboplatin solution (2.68 mmol/mL) at pH = 5.00

[Pt(NH_3)$_2$(CBDCA)(L-Se-MetH)]$^+$ (**1**), in which L-Se-MetH is likely to be coordinated to Pt via the selenium atom and the CBDCA chelate ring is opened. This is confirmed by 2D [^{1}H,^{15}N] HSQC NMR spectroscopy (vide infra). Peak 12 (m/z = 939.9) can be assigned to {[Pt(NH_3)$_2$(CBDCA)]$_2$ (m/z = 742.5) + L-Se-MetH + H^+}. The calculated molecular mass (Table 2) and isotopic distribution match perfectly with the formulae (Figure 1 of Supporting Information). It is worth noting that the intensity of the peak assigned to the carboplatin dimer (m/z = 743.1, 765.1) decreased with time. However, it could still be seen at the end of the reaction (Figure 2c). The intensity of peak 1 increased with time for the first 3 h, then decreased after 4 h, and finally disappeared after 22 h.

Peak 2 (m/z = 553.0), which is assigned to [Pt(NH_3)(CBDCA)(L-Se-MetH)]$^+$ (**2**), appeared 15 min after the reaction began. The intensity of this peak increased gradually, but decreased after 9 h of the reaction. Peak 3 (m/z = 532.3) appeared after 50 min with a low intensity, and is assigned to [Pt(CBDCA)(L-Se-MetH)]$^+$ (**3**). It finally disappeared completely after 12 h of the reaction. Peak 4 (m/z = 587.0), assigned to [Pt(L-Se-MetH)(L-Se-

Table 1. Observed and calculated molecular masses of the complexes for the reaction of carboplatin with L-Se-MetH

Peak	Compound	Observed mass[a]	Calculated mass
1	[Pt(NH_3)$_2$(CBDCA)(L-Se-MetH)] + H^+	564.0−569.9	568.4

11	[Pt(NH_3)$_2$(CBDCA)]$_2$ + Na^+	763.1−769.1	765.5
12	[Pt(NH_3)$_2$(CBDCA)]$_2$ + L-Se-MetH + H^+	933.9−943.9	939.6
13	[Pt(L-Se-MetH)(L-Se-Met)]$^+$ + carboplatin	952.9−964.9	958.3
14	[Pt(NH_3)$_2$(CBDCA)]$_3$ + H^+	1112.0−1118.2	1114.2
15	[Pt(NH_3)$_2$(CBDCA)]$_3$ + Na^+	1132.1−1140.1	1136.2
16	[Pt(NH_3)$_2$(CBDCA)]$_4$ + H^+	1482.9−1491.9	1489.9
17	[Pt(NH_3)$_2$(CBDCA)]$_4$ + Na^+	1502.7−1512.7	1511.9

[a] The Peaks are separated by m/z = 1 in the mass region indicated.

Met)]$^+$ (**4**), began to appear after 1 h 40 min. It had the highest relative intensity after 3 h 10 min (Figure 2b) and became the dominant complex in the final stage of the reaction (Figure 2c). Peaks 6 (m/z = 608.8) and 7 (m/z = 423.1), assigned to the adduct of complex **4** + Na^+ (Figure 2 of the Supporting Information) and complex [$Pt(NH_3)_2$(L-Se-MetH)]$^+$ (**7**), respectively, began to appear after 3 h and could be observed until the end of the reaction (Figures 2b and c). Peak 13 at m/z = 956.9 in the final stage of the reaction (see Figure 2c) can be assigned to {[$Pt(NH_3)_2$(CBDCA)] + [Pt(L-Se-Met)$_2$] + H^+} (Table 1). As shown in Figure 2c, after 22 h of the reaction less products were observed for this reaction than for the reaction of cisplatin with L-Se-MetH,[18] and the major species is peak 4 which corresponds to [Pt(L-Se-MetH)(L-Se-Met)]$^+$ (**4**). This result is rather similar to the reaction of cisplatin with L-Se-MetH in a 1:2 molar ratio, in which the bis(chelated) adduct was the dominant product. No further changes were observed in the ESMS spectra after 22 h. In contrast to the reaction of cisplatin, no dinuclear adducts were observed during the course of the reaction.

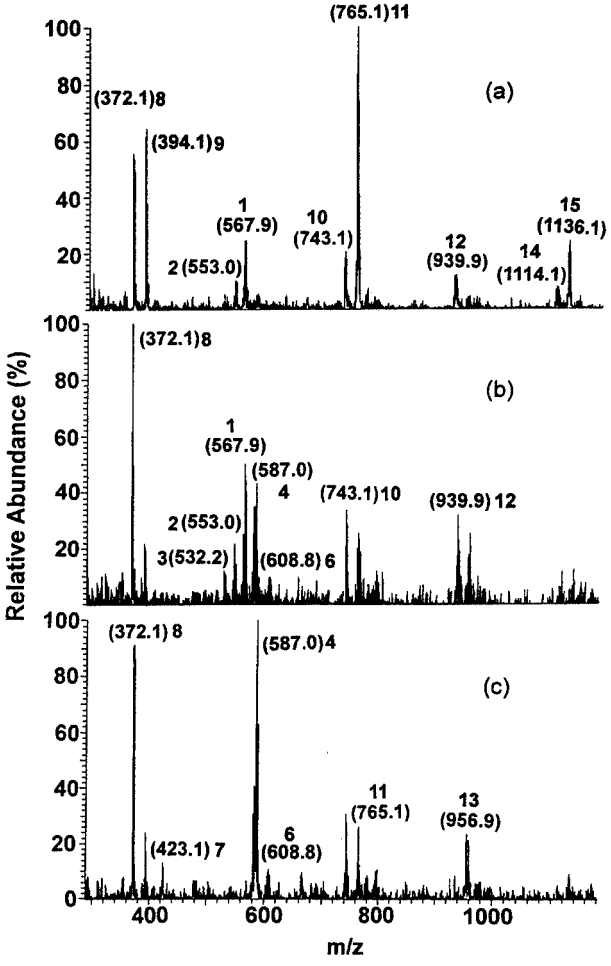

Figure 2. ESMS spectra of the reaction of L-Se-MetH with carboplatin (1:1, 310 K), recorded at different reaction times: (a) 25 min, (b) 3 h, (c) 22 h

(3) ESMS Study of the Time-Dependent Reaction of Carboplatin with L-MetH in a 1:1 Molar Ratio

The above reaction was conducted in order to compare the results with those previously reported.[7] Three typical ESMS spectra recorded after 40 min, 12 h and 38 h of the reaction are shown in Figure 3. Three new peaks (1′, 8′ and 9′) appeared in the spectra immediately after mixing the two reactants. Peak 1′ (m/z = 520.9) corresponds to the ring-opened complex [$Pt(NH_3)_2$(CBDCA)(L-MetH)]$^+$ (**1′**), peak 8′ (m/z = 669.9) is assigned to {[$Pt(NH_3)_2$(CBDCA)(L-MetH)] + L-MetH}$^+$ (Figure 3 of the Supporting Information) and peak 9′ (m/z = 892.0) to {[$Pt(NH_3)_2$(CBDCA)]$_2$ + L-MetH}$^+$ (Figure 4 of the Supporting Information). In these two latter complexes, the existing status of L-MetH is not clear. The hydrogen bonding between the carboxylate and amino groups may play a role in the formation of the two adducts. Peak 1′ remained to be the dominant species for ca. 15 h and then began to decrease in intensity after 18 h, and finally disappeared after 38 h. Peak 2′ (m/z = 504.1), which is assigned to the complex [$Pt(NH_3)$(CBDCA)(L-MetH)]$^+$ (**2′**), appeared after 40 min of the reaction (Figure 3a), and its intensity increased in the following 8 h, then decreased after 10 h. Peak 3′ (m/z = 486.1) is assigned to [Pt(CBDCA)(L-MetH)]$^+$ (**3′**) and appeared after 50 min but remained with a low intensity until it disappeared after 24 h. Peak 7′ (m/z = 377.1), which is assigned to [$Pt(NH_3)_2$(L-Met)]$^+$ (**7′**), appeared after 2 h, reached its maximum intensity after 10 h and then

Table 2. Observed and calculated molecular masses of the complexes for the reaction of carboplatin with L-MetH

Peak	Compound	Observed mass[a]	Calculated mass
1′	[$Pt(NH_3)_2$(CBDCA)(L-MetH)] + H^+	520.0−524.0	521.5
2′	[$Pt(NH_3)$(CBDCA)(L-MetH)] + H^+	503.1−507.1	503.4
3′	[Pt(CBDCA)(L-MetH)] + H^+	486.2−490.1	486.4
4′	[Pt(L-MetH)(L-Met)]$^+$	491.1−495.1	492.5
5′	[$Pt(NH_3)$(L-Met)(L-MetH)]$^+$	−	509.5
6′	[Pt (L-Met)$_2$] + Na^+	513.1−517.1	514.5
7′	[$Pt(NH_3)_2$(L-Met)]]$^+$	376.1−379.1	377.4
8′	[$Pt(NH_3)_2$(CBDCA)(L-MetH)] + H^+ + MetH	668.9−672.9	670.7
9′	[$Pt(NH_3)_2$(CBDCA)]$_2$ + L-MetH + H^+	890.1−898.1	892.7
10′	[Pt(L-MetH)(L-Met)]$^+$ + carboplatin	861.9−867.9	863.8

[a] The Peaks are separated by m/z = 1 in the mass region indicated.

remained constant for 38 h. Peak 4′ (m/z = 491.2), which appeared after 3 h and is assigned to $[Pt(L\text{-MetH})(L\text{-Met})]^+$ (**4′**), increased in intensity with time and became the major species in the final stage. It should be noted that complex $[Pt(NH_3)(L\text{-MetH})(L\text{-Met})]^+$ (**5′**) which is similar to complex **5** and should have an m/z value of 509.5 was not observed in this reaction. Similar to peak 6, peak 6′ at m/z = 514.1 can be assigned to complex **4′** + Na^+. Peak 10′ at m/z = 863.2 (see Figure 3c) can be assigned to $\{[Pt(NH_3)_2(CBDCA)] + [Pt(L\text{-Met})_2] + H^+\}$ (Table 2). Similar to the reaction with L-Se-MetH, the species observed after 38 h were the unchanged carboplatin and the adducts corresponding to peaks 4′ and 7′. From the ESMS results, it can be seen that the final intensity of the peak assigned to carboplatin is much weaker than that of peak 8 in the reaction with L-Se-MetH.

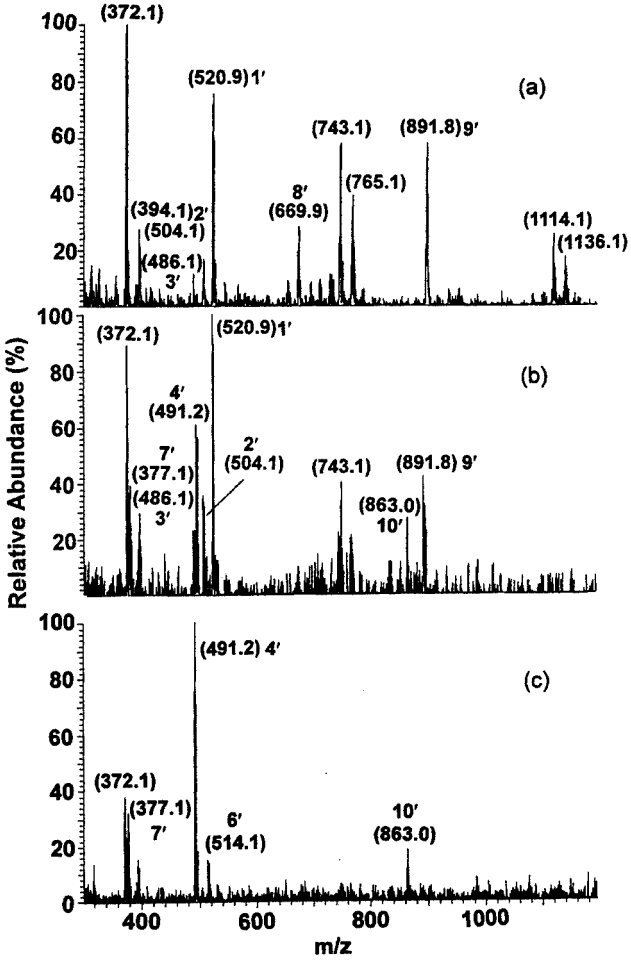

Figure 3. ESMS spectra of the reaction of L-MetH with carboplatin (1:1, 310 K), recorded at different reaction times: (a) 40 min, (b) 12 h, (c) 38 h

We also performed the reactions of carboplatin with L-Se-MetH or L-MetH at 290 K; the spectra recorded after 7 d are shown in Figure 4. As can be seen, complex **7** and **7′** were more abundant than in the reactions at 310 K, suggesting their lower stability at higher temperatures.

(4) NMR Spectroscopic Study of the Reaction of Carboplatin with L-Se-MetH in a 1:1 Molar Ratio

The reaction was initially monitored by ^1H NMR spectroscopy. The spectra recorded at 40 min, 5 h and 10 h are

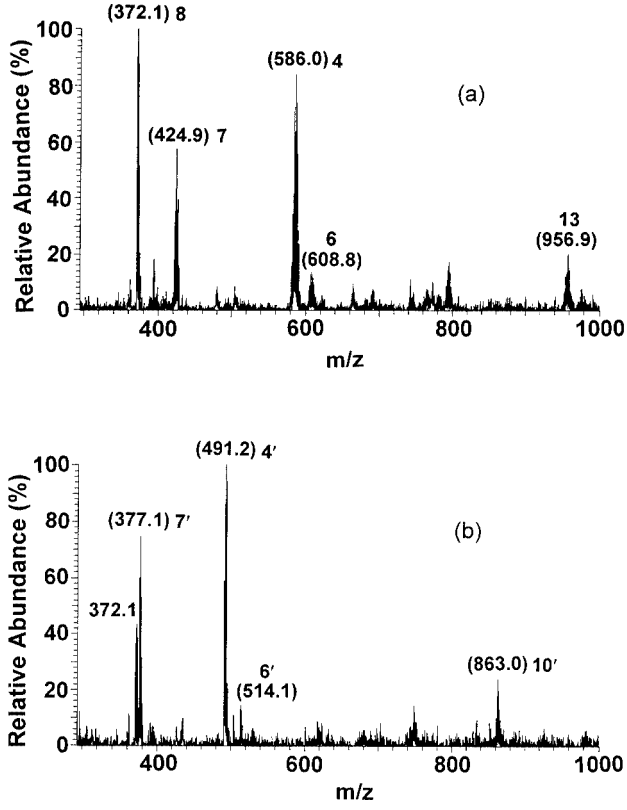

Figure 4. (a) Final ESMS spectra of the reaction of carboplatin with L-Se-MetH (1:1, 290 K); (b) final ESMS spectra of the reaction of carboplatin with L-MetH (1:1, 290 K)

shown in Figure 5. Initially, apart from the signals of free L-Se-MetH and carboplatin, four new singlets appeared between δ = 2.55 and 2.65 ppm. These signals can be assigned to the CH_3 group of the *Se*-bound L-Se-MetH. During the course of the reaction, the signals assigned to free carboplatin and L-Se-MetH decreased in intensity, whilst the signals assigned to free CBDCA increased (Figures 4b, c). After 22 h of the reaction, the signal of the CH_3 group of free L-Se-MetH disappeared completely, while the signals for carboplatin could still be observed (Figure 5 of the Supporting Information). These data are consistent with those observed by ESMS.

The same reaction was then monitored by 2 D [^1H,^{15}N] HSQC NMR spectroscopy. Figure 6 shows the spectra of the reaction recorded after 2 h, 10 h and 22 h. After 1 h, apart from the cross-peak of carboplatin at δ = 4.19/−82.0 ppm (Table 3), four new cross-peaks at δ = 4.33/−84.0 ppm (1a), δ = 4.30/−84.0 ppm (1a′), δ = 4.28/−45.5 ppm (1b), and δ = 4.28/−45.3 ppm (1b′) appeared. The ^{15}N chemical shifts of 1a, 1a′ are consistent with species that have an

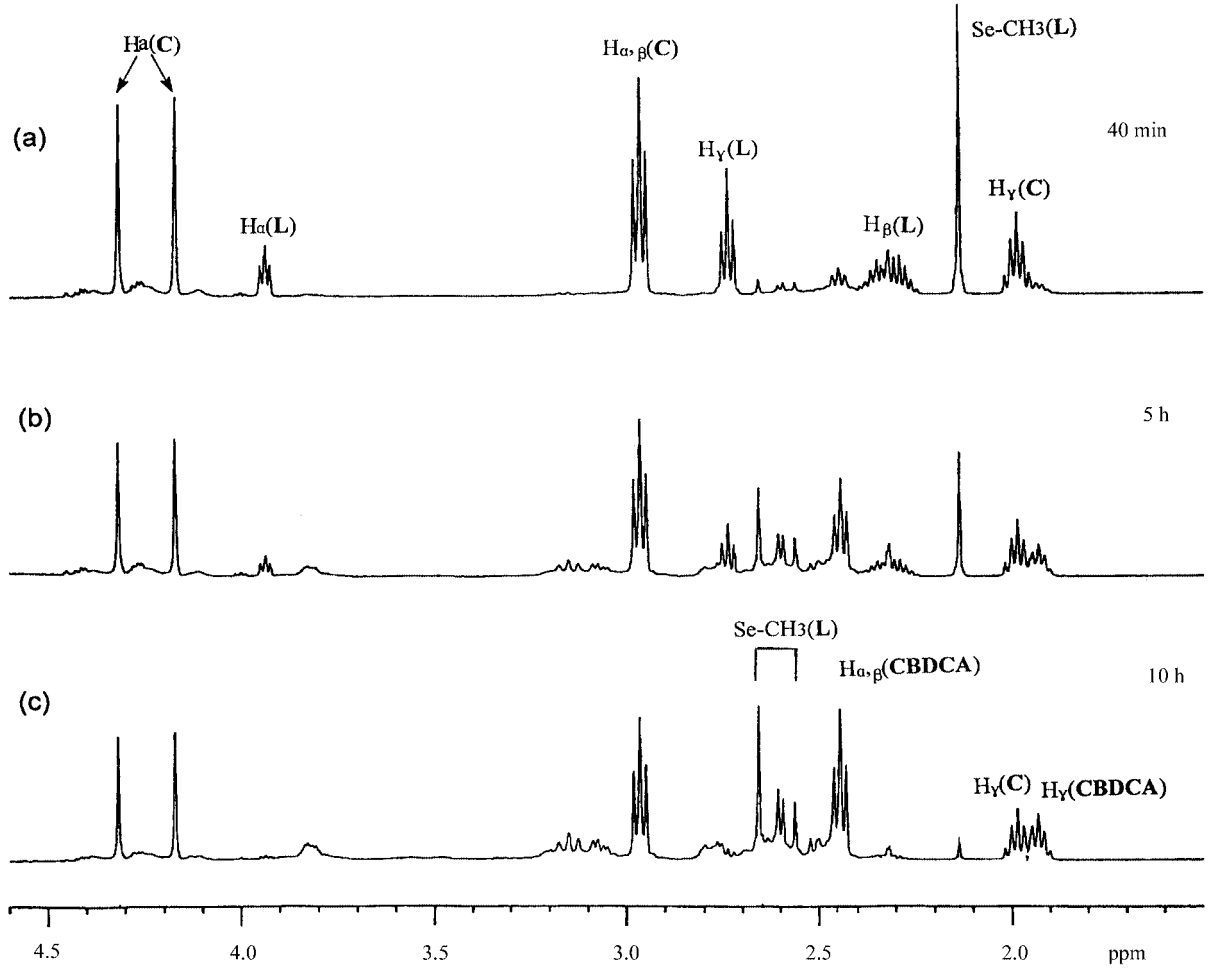

Figure 5. ^{1}H NMR spectra of the reaction of ^{15}N-carboplatin with L-Se-MetH in a 1:1 molar ratio and at 310 K, recorded at different reaction times: (a) 40 min, (b) 5 h, (c) 10 h

amine group *trans* to the oxygen atom, and the ^{15}N chemical shifts of 1b, 1b′ are consistent with species that have an amine group *trans* to the selenium atom. It is likely that these cross-peaks correspond to the formation of $[Pt(NH_3)_2(CBDCA)(L\text{-Se-MetH})]$, which contains a monodentate CBDCA and L-Se-MetH. This agrees well with the ESMS results. The splitting of the cross-peaks (1a and 1a′; 1b and 1b′) in the ^{1}H dimension is similar to that observed in the reaction of carboplatin and L-MetH,[7,19] which can be explained by the slow inversion of the methyl group at the coordinated chiral selenium atom of L-Se-MetH. In the following 3 h, these two cross-peaks increased in intensity, and then disappeared after 14 h. After 1.5 h of the reaction, a new cross-peak at $\delta = 4.16/-67.0$ ppm (2a) appeared, which has a ^{15}N chemical shift in the region of the NH_3 group *trans* to N. After ca 2.5 h, the cross-peaks at $\delta = 4.44/-42.1$ (2b) and $\delta = 4.41/-42.4$ (2b′), which have the NH_3 group *trans* to the selenium atom, began to appear. These cross-peaks were observed even after 22 h. Comparing these with the result of the mass spectrum, cross-peaks 2a and 2b, 2b′ can be assigned to complex $[Pt(NH_3)_2(L\text{-Se-Met})]$ (**7**). However, from the structure of complex **7**, the cross-peak 2a should be split into a doublet in the ^{1}H dimension, similar to the cross-peaks 2b, 2b′, due to the slow inversion of the methyl group at the chiral selenium atom. Therefore, we performed the NMR experiment at 283 K (Figure 5 of the Supporting Information). In the spectrum, cross-peak 2a became two cross-peaks with different chemical shifts in the ^{1}H dimension. The intensity of cross-peaks 2a and 2a′ was equal to that of 2b and 2b′. This showed that the two pairs of cross-peaks are related to the same species. The earlier appearance of cross-peak 2a than cross-peaks 2b, 2b′ may be due to the splitting of cross-peaks 2b, 2b′.

(5) NMR Spectroscopic Study of the Reaction between L-MetH and Carboplatin

An NMR investigation of the reaction between L-MetH and carboplatin was carried out, monitored by 2 D [^{1}H,^{15}N] HSQC NMR spectroscopy. The results obtained could then be compared with the ESMS results and those of a previous NMR study at a different pH. Figure 7 shows the spectra recorded after 2 h, 12 h and 38 h. After 1 h of the reaction,

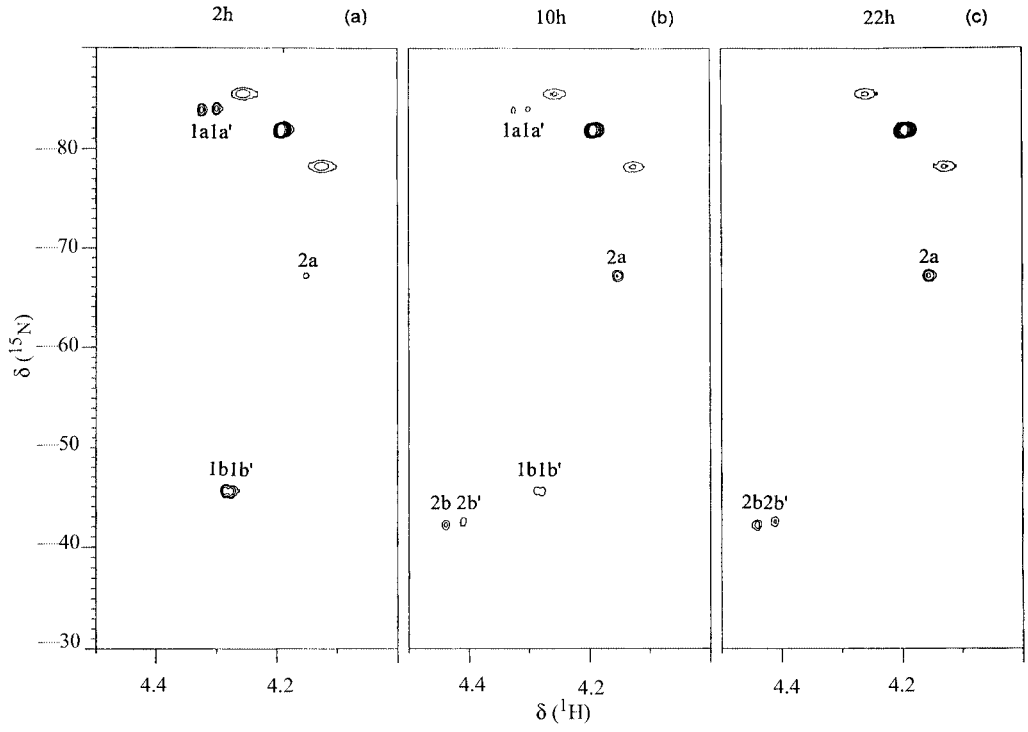

Figure 6. 2D [^{1}H,^{15}N] HSQC NMR spectrum of the reaction of ^{15}N-carboplatin with L-Se-MetH in a 1:1 molar ratio at 310 K, recorded after (a) 2 h, (b) 10 h, (c) 22 h

Table 3. ^{1}H and ^{15}N NMR chemical shifts of carboplatin and its adducts with L-Se-MetH and L-MetH

Complexes	δ(^{1}H)/δ(^{15}N) for Pt−NH_3	Pt−NH_3 *trans* to
[Pt(NH_3)$_2$(CBDCA)]	4.19/−82.0	O
[Pt(NH_3)$_2$(CBDCA)(L-Se-Met)]$^+$	4.33/−84.0; 4.30/−84.0	O
	4.28/−45.5; 4.28/−45.3	Se
[Pt(NH_3)(L-Se-Met)(L-Se-MetH)]$^+$	4.16/−67.0	N
	4.44/−42.1; 4.41/−42.2	Se
[Pt(NH_3)$_2$(CBDCA)(L-Met)]$^+$	4.36/−79.5; 4.34/−79.5	O
	4.29/−46.0	S
[Pt(NH_3)$_2$(L-Met)]$^+$	4.21/62.6; 4.18/−62.5	N
	4.44/−43.0; 4.39/−42.5	S

apart from the cross-peak of carboplatin, two sets of new cross-peaks (1a, 1a′, 1b) with similar intensities appeared at δ = 4.36/−79.5 ppm (1a), δ = 4.34/−79.5 ppm (1a′), and δ = 4.29/−46.09 ppm (1b). These three cross-peaks (1a, 1a′, 1b) can be assigned to [Pt(NH_3)$_2$(CBDCA)(L-MetH)] (**1′**), based on their known shifts.[20] The split of cross-peaks 1a and 1a′ can be attributed to the slow inversion of the coordinated chiral sulfur atom. The intensity of these peaks increased in the following 7 h and decreased after 8 h of the reaction. After 30 h, the peaks disappeared completely, which is consistent with the result by mass spectrometry. After ca. 7 h, two new cross-peaks at δ = 4.21/−62.6 ppm (2a) and δ = 4.44/−43.0 ppm (2b) appeared, and 2 h later another pair of cross-peaks could be seen at δ = 4.18/−62.5 ppm (2a′) and δ = 4.39/−42.5 ppm (2b′). From their ^{15}N chemical shifts these cross-peaks (2a, 2a′ and 2b, 2b′) can be assigned to the NH_3 group *trans* to N and S, respectively. These two pairs of cross-peaks correspond to complex [Pt(NH_3)$_2$(L-Met)] (**7′**), and the splitting of the cross-peaks in the ^{1}H dimension can be attributed to the slow inversion of the methyl group at the coordinated chiral sulfur atom.[7] These adducts could be observed even after 38 h. The final product [Pt(L-Met)(L-MetH)]$^+$ (**4′**) which was observed in the ESMS study could not be observed in the 2 D [^{1}H,^{15}N] HSQC NMR study due to the elimination of ammonia. This result is different from those reported previously[7] in which, apart from the complex **7′**, complexes **1′** and **5′** were also observed even after 3 d at 293 K and at pH = 7.

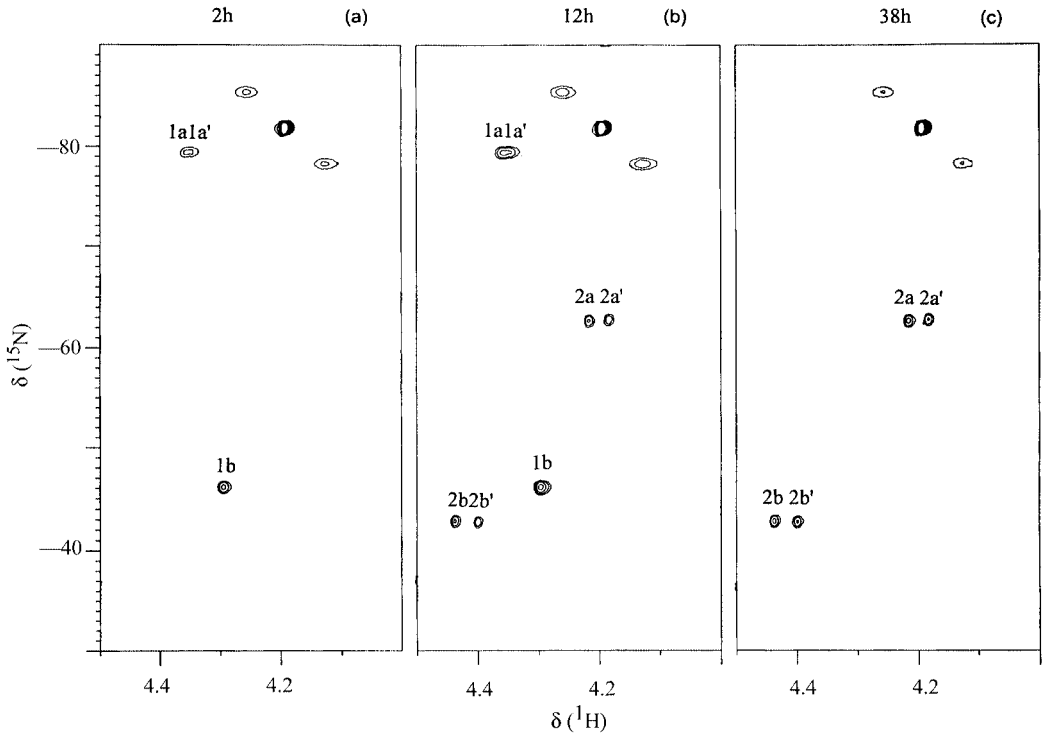

Figure 7. 2D [^{1}H,^{15}N] HSQC NMR spectrum of the reaction of ^{15}N-carboplatin with L-MetH in a 1:1 molar ratio at 310 K, recorded after (a) 2 h, (b) 12 h, (c) 38 h

Discussion

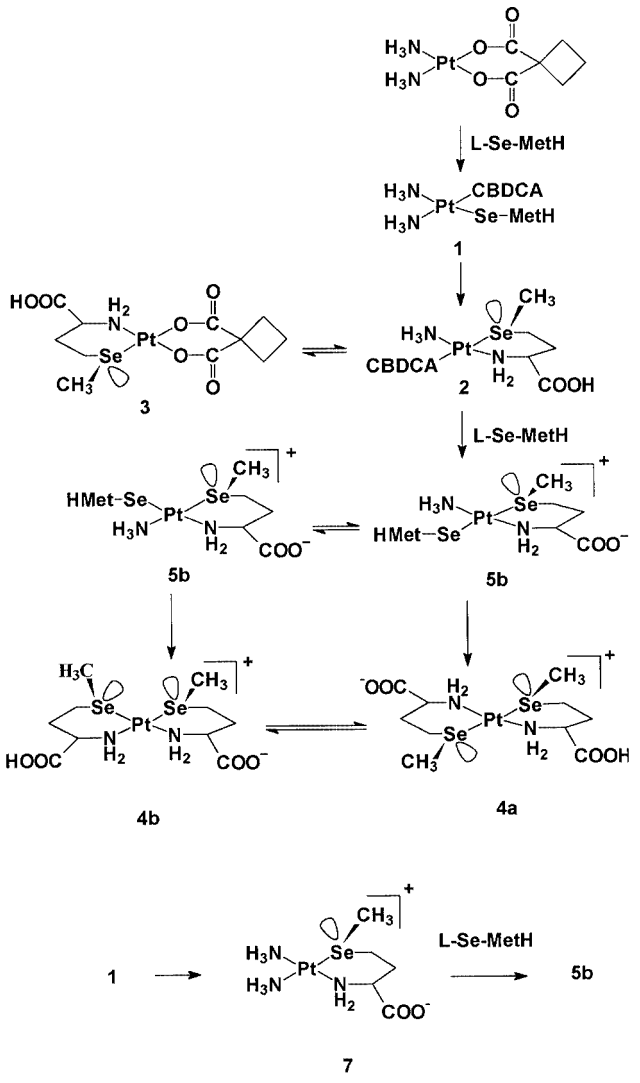
Our recent work on the investigation of the reaction of cisplatin with L-Se-MetH and L-MetH using the combined techniques of ESMS and 2D [^{1}H,^{15}N] NMR has further clarified the reaction pathways.[18] Here we extend our study to the reaction of the second-generation anticancer drug carboplatin with L-Se-MetH and L-MetH, and compared the different reactivities of the two drugs towards the two ligands.

We have detected the dimer, trimer and tetramer forms of carboplatin by ESMS. Although they are not stable in the presence of L-Se-MetH, the dimer form of carboplatin (either as the H^+ or Na^+ form) can be observed for quite a long period of time. Recently, it has been reported that polynuclear Pt complexes can be formed in aqueous solution.[21,22] However, it is possible that these complexes may be formed only in the capillary device of the mass spectrometer due to the high temperature.[23]

Based on the ESMS and 2D [^{1}H,^{15}N] NMR results, the reaction pathway between carboplatin and L-Se-MetH is summarized in Scheme 2.

As can be seen from the ESMS results, the reaction between L-Se-MetH and carboplatin initially gave rise to a ring-opened species [Pt(NH_3)$_2$(CBDCA)(L-Se-MetH)] (**1**) which is very stable and can be observed for ca 18 h in the ESMS experiment (peak 1) and for ca 13 h in the 2D [^{1}H,^{15}N] HSQC NMR experiment (1a, 1a′; 1b, 1b′). The appearance of two pairs of cross-peaks 1a, 1a′, 1b, 1b′ may be due to the hydrogen bonding between the NH_3 group and the oxygen atom of CBDCA similar to that reported in *cis*-[Pt(CBDCA)(NH_3)$_2$(L-Met-*S*)][7] and [Pt(en)(Me-Mal-O)(Ac-Met-*S*)].[24] The high *trans* effect of selenium labilizes the NH_3 group, and L-Se-MetH undergoes ring-closure to form [Pt(CBDCA)(NH_3)(L-Se-Met-*N*,*Se*)] (**2**). The complex [Pt(NH_3)$_2$(L-Se-Met-*Se*,*N*)] (**7**) is also formed. This species corresponds to the cross-peaks 2a and 2b, 2b′ in the 2D NMR spectrum. Most of complex **2** was converted into complex **5**, [Pt(NH_3)(L-Se-MetH-*Se*)(L-Se-MetH-*Se*,*N*)], the rest was converted into complex **3**, [Pt(CBDCA)(L-Se-MetH-*Se*,*N*)] (peak 3 in the ESMS spectrum). Complex **3** could only be observed in the ESMS spectrum with a low intensity for ca. 9 h. However, complex **5** could be observed neither in the ESMS nor in the NMR spectrum, which may be due to its fast conversion into the final product, complex **4**. As can be seen from the ESMS data, the dominant adduct at the end of the reaction is [Pt(L-Se-Met-*Se*,*N*)$_2$] (complex **4**, peak 4 in the ESMS spectrum). There should be two geometrical isomers (*cis* and *trans*) of complex **4**. Previous studies on [Pt(L-Met-*S*,*N*)$_2$] showed that both isomers were present in solution, and that the dominant one was the *cis* isomer. A similar situation may occur in the current work. This result is different from that between cisplatin and L-Se-MetH. In the latter case the final product has one L-Se-MetH coordinated group, i.e. the final product is the complex [Pt(NH_3)Cl(L-Se-MetH)], and there is a low abundance of complex **4**.[18]

Similarly, the reaction of carboplatin with L-MetH gives rise to [Pt(L-Met-*N*,*S*)$_2$] as the final adduct, which is differ-



Scheme 2. Reaction pathway of carboplatin with L-Se-MetH in a 1:1 molar ratio at pH = 5.40

ent from the previous 2D [^{1}H,^{15}N] NMR study.[7] However, it should be noted that the temperature and pH of the two studies are different. The lower temperature and high pH may facilitate the stabilization of the ring-opened adduct and slow down the rate of elimination of the ammonia ligand. It can be concluded from the comparison between the reactions of cisplatin and carboplatin with L-Se-MetH and L-MetH that under the same conditions the bis(chelated) adducts [Pt(L-Se-Met)$_2$] or [Pt(L-Met)$_2$] can be formed more easily in the reaction with carboplatin than in that the reaction with cisplatin.

It is interesting to note that under the same experimental conditions the inversion rate of Se−CH$_3$ in complex **7** is faster than that of S−CH$_3$ in complex **7′**. This is rather intriguing because a reversal of the inversion rate would be expected.

Conclusion

The self-association of carboplatin in aqueous solution was detected by ESMS for the first time. From the ESMS and 2D [^{1}H,^{15}N] HSQC NMR results of this work, the major species [Pt(NH$_3$)$_2$(CBDCA)(L-SeMetH)] (**1**), [Pt(NH$_3$)$_2$(CBDCA)(L-MetH)] (**1′**); [Pt(NH$_3$)(CBDCA)-(L-SeMetH)] (**2**), [Pt(NH$_3$)(CBDCA)(L-MetH)] (**2′**); [Pt(CBDCA)(L-MetH)](**3**), [Pt(CBDCA)(L-MetH)] (**3′**); [Pt(NH$_3$)$_2$(L-SeMet)]$^+$ (**7**), [Pt(NH$_3$)$_2$(L-Met)]$^+$ (**7′**); [Pt (L-Se-Met)$_2$] (**4**) and [Pt(L-Met)$_2$] (**4′**) were found. Due to the elimination of the ammonia group and the abundance of the species, only complex **1**, **1′** and complex **7**, **7′** can be observed by 2D [^{1}H,^{15}N] HSQC NMR spectroscopy. A detailed pathway of the reaction was provided and compared with that of cisplatin. The bis(chelated) adducts [Pt(L-Se-Met)$_2$] or [Pt(L-Met)$_2$] can be formed more easily in the reaction with carboplatin than in the reaction with cisplatin under the same reaction conditions. It remains to be seen whether this observation can be related to in vivo activity and metabolism of the drug.

Experimental Section

General: Carboplatin and [^{15}N]carboplatin were prepared and recrystallized according to a published procedure,[25] L-selenomethionine (L-Se-MetH) and L-methionine (L-MetH) were purchased from Sigma.

Spectroscopy

ESMS: Electrospray mass spectra were recorded using an electron mass spectrometer (ESMS, Finnigan) by loading 1.0 μL of solution into the injection valve of the LCQ unit, and then injecting into the mobile phase solution (50% of aqueous methanol) which was carried through the electrospray interface into the mass analyzer at a rate of 200μL min^{-1}. The voltage employed at the electrospray needles was 5 kV, and the capillary was heated to 200 °C. A maximum injection time of 200 ms, along with 10 scans was set. Positive ion mass spectra were obtained. The predicted isotope distribution patterns for each of the complexes were calculated using the Isopro 3.0 program.[26]

NMR: NMR spectroscopic data were acquired with 500-MHz Bruker DMX and DRX spectrometers. One-dimensional spectra were typically acquired with 128 transients and 32 K data points over a spectral width of 10 kHz by using standard pulse sequences. Two-dimensional [^{1}H,^{15}N] HSQC NMR (Heteronuclear Single Quantum Coherence) data were acquired and processed according to previously reported methods.[27] The ^{15}N chemical shifts are externally referenced to 1.5 M NH_4Cl in 1 M HCl. The indirect referencing method resulted in slightly different ^{15}N chemical shifts to those in previous reports for similar species, and no corrections have been made.

pH Measurements: The pH measurements were carried out using a pHS-3C pH meter equipped with a Phoenix Ag/AgCl reference electrode, calibrated with phosphate buffer solutions at pH = 4.00 and 10.00. The values reported are those measured after the reactions were finished.

Sample Preparations: Samples for the ESMS studies were prepared using double-distilled water. Due to the limitation of the ESMS, no phosphate buffer solution was employed in these studies so as to avoid the potential blockage of the capillary of the instrument. (1) [Pt(NH$_3$)$_2$(CBDCA)] (1.00 mg) was dissolved in 1 mL of water. The pH of the solution was 5.00. The ESMS spectra were recorded

at this pH value. (2) $[Pt(NH_3)_2(CBDCA)]$ (1.00 mg) and L-Se-MetH (0.53 mg) were dissolved in 1 mL of water. The solution was monitored by ESMS for a period of 22 h at 310 K. The pH value after 22 h was 5.40. (3) $[Pt(NH_3)_2(CBDCA)]$ (1.00 mg) was mixed with L-MetH in a 1:1 molar ratio. The reaction was monitored by ESMS for 38 h at 310 K. The pH of the solution after 38 h was 5.41. All the reactions were carried out at 310 K unless otherwise stated. Samples for the NMR study were prepared as follows. $[Pt(NH_3)_2(CBDCA)]$ (2.68 mmol) and L-Se-MetH (2.68 mmol) or L-MetH (2.68 mmol) were dissolved in a 500-μL solution of 90% H_2O and 10% D_2O. The final concentration of carboplatin and L-Se-MetH or L-MetH was 2.68 mmol/mL. To be consistent with the conditions used in the ESMS study, no buffer solution was employed in the NMR study. The reaction was also conducted at 310 K.

Acknowledgments

We thank the National Natural Science Foundation of China for the Distinguished Young Scientists Fund (Grant No. 29925102) and the Major State Basic Research Development Program (Grant No. G200007750). We thank Prof. P. J. Sadler (Edinburgh) for access to his NMR spectrometer with which a part of the experiments were carried out.

Potentially Tridentate Ligands in the Synthesis of Methyl- and Acetylpalladium(II) Complexes

Alessia Bacchi,[a] Mauro Carcelli,[a] Corrado Pelizzi,[a] Giancarlo Pelizzi,[a] Paolo Pelagatti,*[a] and Silvia Ugolotti[a]

Keywords: Carbonylation / Insertion / N ligands / Palladium / Tridentate ligands

The two protic tridentate ligands HNN′O (**1**) and HNN′S (**2**) were treated with [(COD)Pd(Me)Cl], and the corresponding methylpalladium(II) complexes [Pd(η^2-HNN′)(Me)Cl] (**1a** and **2a**) were isolated. The neutral ligands in these complexes coordinated the metal in an NN′ bidentate mode, through the pyridine and imine nitrogens, excluding the O or S atom from the coordination. This behavior was confirmed by X-ray diffraction analysis of the dichloro complex of **1**, [Pd(η^2-HNN′)Cl_2] (**1c**). Complexes **1a** and **2a** easily transformed quantitatively into the corresponding three-coordinate complexes [Pd(η^3-NN′X)(Me)] (**1b**: X = O, **2b**: X = S) in basic medium, with elimination of HCl. The complexes **1a** and **1b** were treated with PPh_3 and $P(CD_3)_3$, respectively, resulting in **1e** and **1h**; **1a** reacted further with a double quantity of PPh_3 to give rise to the diphosphane complex [*trans*-$(PPh_3)_2$Pd(Me)Cl] (**1g**) and free **1**. The three-coordinate complexes **1b** and **2b** were subjected to CO bubbling at room temperature. In the case of **1b**, acylation of the ligand on the phenolic oxygen was observed, with the formation of an organic acetate and release of palladium black. In the case of **2b**, besides the acylated ligand on the thiolic sulfur, the acetylpalladium(II) complex [Pd(η^3-NN′S)(MeCO)] (**2c**) was isolated. The X-ray structures of **1c**·THF, **1b**·1/2$C_6H_6O_2$, **2b**, **2c**·1/2CH_2Cl_2, and **1g** have been solved.

Introduction

There is ongoing interest in the study of CO insertion into Pd−C bonds, because of its importance as a key step in many metal-catalyzed reactions.[1] Much work has been done with both non-hybrid[2] and hybrid[3] bidentate ligands. In contrast, little has been done with tridentate ligands,[4] and there is a lack of data concerning the use of protic tridentate ligands.[5] We have recently shown that the use of protic tridentate HNN′O acylhydrazonic ligands (Scheme 1) resulted in the isolation of two different types of methylpalladium(II) complexes: [Pd(η^2-HNN′)(Me)Cl] and [Pd(η^3-NN′O)(Me)].[6] These complexes showed different reactivities towards CO: the first, in fact, gave rise to the isolation of the corresponding acetyl complexes [Pd(η^2-HNN′)(MeCO)Cl] in excellent yields, whereas the second resulted in the acetylation of the ligands on the hydrazonic nitrogen, with concomitant formation of palladium black; conversion was also quantitative in this case. The presence of the basic hydrazone nitrogen was considered to be responsible for the instability of the complexes under CO atmosphere. With the aim of verifying this hypothesis, we prepared the methylpalladium(II) complexes of the Schiff base ligands 2-[(pyridin-2-ylmethylene)amino]phenol (**1**, HNN′O) and 2-(1-pyridin-2-yl-ethylideneamino)benzenethiol (**2**, HNN′S) (see b in Scheme 1). These chelating agents are potentially tridentate and do not contain a hydrazone nitrogen. Compounds **1** and **2** were treated with [(COD)Pd(Me)Cl], resulting in the isolation, under appropriate conditions, of two different kinds of methylpalladium(II) complexes: [Pd(η^2-HNN′)(Me)Cl] (**1a** and **2a**) and [Pd(η^3-NN′X)(Me)] (**1b**: X = O, **2b**: X = S), which were fully characterized. The reactivity of **1a**−**b** towards phosphanes and, in particular, the reactivity of the three-coordinate complexes **1b** and **2b** towards CO was investigated.

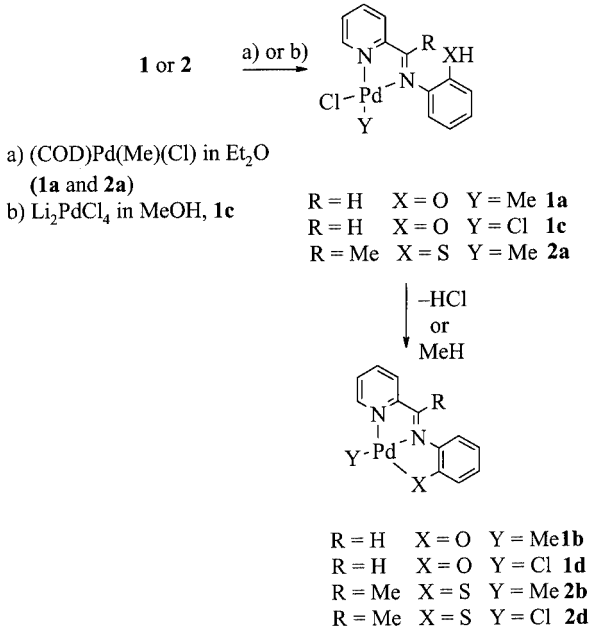
Results and Discussion

Synthesis of the Methyl Complexes 1a and 2a

The ligands HNN′O (**1**) and HNN′S (**2**) reacted with [(COD)Pd(Me)Cl] in diethyl ether at room temperature to afford the complexes [Pd(η^2-HNN′)(Me)Cl] (**1a** and **2a** in Scheme 2). The reactions proceed with rapid displacement of the labile diolefin COD by the incoming chelating pyridylimine ligands. These ligands coordinate to the metal in a bidentate mode through the pyridine and imine nitrogen atoms. The bidentate behavior of the ligand was confirmed by the X-ray structure of the dichloro complex [Pd(η^2-HNN′)Cl_2] (**1c**) (see crystallographic discussion). As previously reported for other methylpalladium(II) complexes containing protic ligands,[6] diethyl ether is the solvent of choice as the fast precipitation of **1a** and **2a** prevents methane elimination caused by ligand deprotonation, a process that takes place easily in solution (vide infra). Complex **1a** is a yellow powder, while complex **2a** is a gray powder. The neutral character of the ligand was indicated by the IR stretching bands of the OH and SH bonds, centered at 3377 cm^{-1} and 3229 cm^{-1}, respectively. The structure of **1a** proposed in Scheme 2 agrees with the ^{1}H NMR spectrum: the sequence of the pyridine protons is normal for pyridylimine ligands in which both nitrogens are involved in coordination.[2b,6] A single isomer was detected, probably that with the methyl ligand *cis* to the imino function. This is in fact the preferred configuration for this type of complex.[2] Moreover, the chemical shift of the methyl group is unusually low (δ = 0.41 ppm in $CDCl_3$ and δ = 0.54 ppm in MeOD, as compared to δ = 0.8−1.1 ppm normally), probably because of the shielding effect of the neighboring aromatic ring.[7] The ^{1}H NMR spectrum of complex **2a** recorded in [D_6]Me_2SO shows a complicated pattern, which prevents unambiguous assignment of the aromatic signals. In the aliphatic region, however, three different species can be distinguished: the expected complex **2a** [singlets at δ = 2.50 and 0.81 ppm, belonging to the C(Me)=N and Pd−Me groups, respectively], and the products of solvent-assisted ligand deprotonation [Pd(η^3-NN′O)(Me)] (**2b**, singlets at δ = 2.70 and 0.20 ppm) and [Pd(η^3-NN′O)Cl] (**2d**, singlet at δ = 2.84 ppm). As far as complex **2a** is concerned, it was not possible to establish the disposition of the methyl and chloride ligands around the metal unequivocally, but we assume that **1a** and **2a** have the same stereochemistry. As a matter of fact, complex **1a** is also not completely stable in solution: in deuterated methanol or dimethyl sulfoxide it slowly converts into the chloride complex [Pd(η^3-NN′O)Cl] (**1d**) with elimination of methane (Scheme 2). This elimination is faster for **2a** than for **1a**, because **2** is more acidic than **1**. Interestingly, methane elimination also takes place in the solid state, as confirmed by TGA analyses (**1a**: 158.3−198.1 °C, weight loss 6%; **2a**, 103.3−149.0 °C, weight loss 5%).



Scheme 2

Synthesis of the Methyl Complexes 1b and 2b

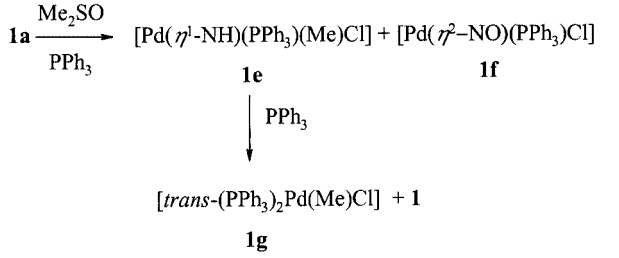
When the reaction between **2** and (COD)Pd(Me)Cl was carried out in THF in the presence of a slight excess of a base, such as NaOMe or Et_3N, elimination of HCl took place and the reaction proceeded with a drastic color change, from yellow to green. During the stirring the solution released the three-coordinate methyl complex [Pd(η^3-NN′S)(Me)] (**2b**) as a green powder (Scheme 2). The anionic character of the ligand was attested to by the disappearance of the IR and ^{1}H NMR signals of the SH group. The methyl ligand resonates at δ = 0.15 ppm, a value similar to those found for other methylpalladium(II) complexes in which the metal is bound to an anionic tridentate ligand.[6]

With **1**, the corresponding process had to be carried out in the presence of *n*BuLi instead of NaOMe or Et_3N. In this way, the deprotonation of the ligand was complete and the reaction was able to proceed smoothly, with a drastic color change from yellow to purple. The three-coordinate methyl complex [Pd(η^3-NN′O)(Me)] (**1b**) precipitated from the solution as a purple solid (Scheme 2). The same product could be obtained by deprotonation of **1a** by *n*BuLi or NaOMe in THF. The tridentate character of the ligand was corroborated by the disappearance of the spectroscopic OH signals; the methyl ligand is found at δ = 0.60 ppm, a higher value than found for **2a**, but still shielded with regard to the value usually found for methylpalladium(II) complexes with bidentate nitrogen ligands.[2b,3,8] The *trans* influence of the methyl attached to palladium is well attested to by the shielding undergone by the imine proton relative to the free ligand: δ = 7.88 ppm for **1b** and δ = 8.71 ppm for **1**.

Single-crystal diffraction analysis of **1b**·1/2$C_6H_6O_2$ and **2b** confirmed the proposed structures (see crystallographic discussion).

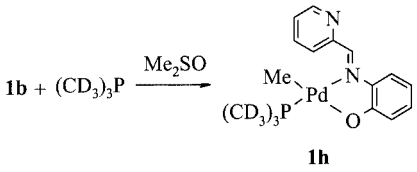
Reactions of 1a and 1b with Phosphanes

In order to investigate the complexation strength of the ligand **1**, and before dealing with the carbonylation reactions, the complexes **1a** and **1b** were treated with PPh_3 and $P(CD_3)_3$. When complex **1a** was treated with a stoichiometric amount of PPh_3 in [D_6]DMSO, an immediate color change took place. The ^{31}P NMR spectrum of the reactant mixture showed a strong signal at $\delta = 40.5$ ppm, a value characteristic for a phosphane coordinated to palladium, and a second, much less intense, singlet at $\delta = 32.5$ ppm. No signals belonging to free PPh_3 were visible. The first resonance was attributable to a species in which the ligand was monodentate through a nitrogen atom and the square-planar coordination was completed by the methyl ligand, the chlorine atom, and PPh_3 (**1e** in Scheme 3). The second signal was tentatively attributed to the chloro(phosphane)-palladium complex **1f** (Scheme 3) , with the deprotonated ligand coordinating palladium through the imine nitrogen and the oxygen, and the square-planar coordination being completed by a PPh_3 molecule and a chlorine atom. Complex **1f** is formed by the reaction between PPh_3 and **1d**, the formation of which has previously been described in Me_2SO solution. The addition of double quantities of PPh_3 resulted in the immediate precipitation of *trans*-[$(PPh_3)_2$Pd(Me)Cl] and the consequent displacement of **1** (Scheme 3). The diphosphane complex is completely soluble in chlorinated solvents, the ^1H NMR spectrum recorded in $CDCl_3$ showing a triplet for the methyl ligand at $\delta = -0.03$ ppm with a $J_{P,H}$ of 5.9 Hz, while in the ^{31}P NMR spectrum the phosphanes generate a singlet centered at $\delta = 27.7$ ppm. The structure of this complex was definitely established by X-ray analysis. Crystals of *trans*-[$(PPh_3)_2$Pd(Me)Cl] were obtained by slow diffusion of *n*-hexane into a refrigerated dichloromethane solution. The methyl is *trans* to the chloride; coordination is planar within 0.08 Å. Relevant coordination features are: Pd−P1 = 2.3272(5), Pd−P2 = 2.3225(6), Pd−Cl = 2.4248(5), Pd−C = 2.0574(4)Å; P1−Pd−P2 = 177.49(2), P1−Pd−Cl = 88.85(1), P1−Pd−C = 91.69(1), P2−Pd−Cl = 89.17(1), P2−Pd−C = 90.43(1), Cl−Pd−C = 174.86(1)°.



Scheme 3

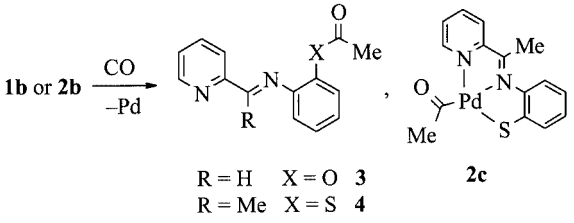
The three-coordinate methyl complex **1b** was treated with a slight excess of $P(CD_3)_3$ in [D_6]DMSO, and the reaction was monitored by ^1H and ^{31}P NMR spectroscopy. After the addition of the phosphane, the signals of an uncoordinated pyridine ring appeared: in fact, the sequence of the hydrogen resonances, from low to high field, was 1-H, 4-H, 3-H, 2-H [Scheme 1(b)].[2b,6] The methyl ligand now resonates at $\delta = 0.25$ ppm ($\delta = 0.60$ ppm in **1b**) as a singlet, while the singlet of a coordinated phosphorus is now present in the ^{31}P NMR spectrum at $\delta = 41.3$ ppm. In conclusion, the phosphane replaces the pyridine ring in the coordination sphere, giving rise to the complex [Pd(η^2-NO){$P(CD_3)_3$}(Me)] (**1h**, Scheme 4). On the basis of literature spectroscopic data,[9] we assume that the methyl is *trans* to the oxygen and the phosphane *trans* to the imine nitrogen (Scheme 4).



Scheme 4

Carbonylation Reactions

Dichloromethane solutions of **1b** and **2b** were subjected to CO bubbling at room temperature. In both cases the formation of palladium black was observed. As in the case of the methyl complexes of NN′O acylhydrazone ligands studied previously,[6] the decomposition of **1b** was very fast, and after 5 min the solution was completely bleached. A different behavior was observed in the case of **2b**: after 3.5 h of exposure to CO the solution was still light purple. After removal of palladium, the resulting solutions were analyzed by mass spectrometry: peaks relating to the acylated ligands [$m/z = 240$ (**3**) and 270 (**4**), respectively] were present in both cases (Scheme 5). In the mass spectrum of the carbonylated solution of **1b**, no signals belonging to the starting complex or to an acetylpalladium complex were observed, whereas the peak of the acetylpalladium complex [Pd(η^3-NN′S)(MeCO)] (**2c** in Scheme 4, $m/z = 378$) was present in the corresponding mass spectrum of **2b**. Such a complex was isolated in a crystalline form by slow diffusion of *n*-hexane into the refrigerated mother liquor; X-ray analysis confirmed the proposed structure (see crystallographic discussion). Unfortunately, the few collected crystals did not allow the spectroscopic characterization of the complex.



Scheme 5

The different reactivities shown by the two three-coordinate methyl complexes are due in the case of **2b** to the presence of a *soft* donor (the S atom), making the isolation of

the acetyl complex **2c** possible. This can definitely be viewed as an intermediate in the acetylation of the ligand, as already proposed by other groups for methyl(alkoxo) and methyl(thiolato)palladium(II) and nickel(II) complexes[10] and by us for hydrazonic palladium(II) complexes.[6] On the basis of the reactivity shown by **1b** toward $P(CD_3)_3$ (see complex **1h**), it is plausible to suppose that the CO coordination occurs with concomitant pyridine displacement. The subsequent step could be the migration of the methyl onto the coordinated CO molecule, followed by coupling between the ligand and the acetyl group.

Structures of Complexes 1c·THF, 1b·1/2$C_6H_6O_2$, 2b, and 2c·1/2CH_2Cl_2

Complex **1c** (Figure 1) crystallizes as a 1:1 THF solvate. The ligand is NN′-bidentate [bite angle N1−Pd−N2: 80.1(2)°], the metal square-planar coordination being completed by two chloride ligands. The OH group is not involved in the coordination. The terminal phenyl ring is nearly perpendicular to the chelation plane [Pd−N−C−C(OH): 72.2(8)°], due to the hindrance of the chloride ligand in the coordination plane [Cl2···O1 3.446(5) Å]. The coordination geometry can be summarized as follows: Pd−N2: 2.018(6) Pd−N1: 2.034(6), Pd−Cl1: 2.290(2), Pd−Cl2: 2.300(2) Å; N2−Pd−N1: 80.1(2), N2−Pd−Cl1: 174.0(2), N1−Pd−Cl1: 94.2(2), N2−Pd−Cl2: 94.8(2), N1−Pd−Cl2: 173.4(2), Cl1−Pd−Cl2: 90.93(8)°.

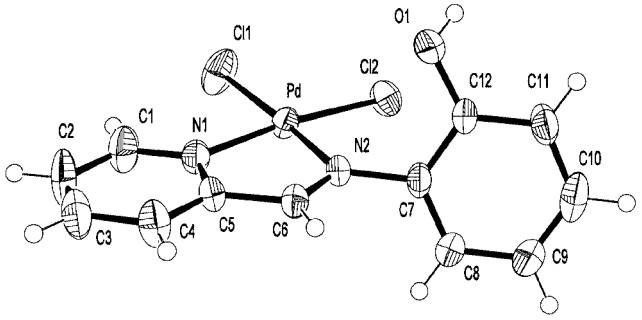


Figure 1. Perspective view of molecule **1c**·THF; thermal ellipsoids are drawn at the 50% probability level; the solvent has been omitted

The molecular structure of **1b**, shown in Figure 2, features NN′O-tridentate coordination for the ligand, with the methyl group *trans* to the iminic nitrogen. The whole complex molecule is perfectly planar (maximum displacement less than 0.08 Å), and two pentaatomic chelation rings are formed upon coordination. Table 1 lists the main bonding features for **1b**. The bite angles involved in the chelation are typical for tridentate chelation in these systems. A survey of the crystal structures of molecules containing a pyridineiminic pentaatomic N(py)−C(py)−C(iminic)−N(iminic)−Pd chelation ring was performed on the Cambridge Crystallographic Database (release of October 2001). The N1−Pd−N2 and Pd−N2−C6 angles appear in the ranges 77.2−82.3° and 108.6−119.2°, respectively, and, as a general trend, they tend to be wider (>80° and >117° respectively) for tridentate NN′X (X = O, S) systems containing two five-membered chelated rings, as in the case of these complexes, than for NN-bidentate systems containing only the Pd−N1−C5−C6−N2 chelation ring (<80° and <116°, respectively). The enlargement of the endocyclic angles upon tridentate coordination correlates well with a shortening of the Pd−N2 bond, ranging between 1.92 and 1.98 Å for tridentate complexes and 1.98 and 2.28 Å for bidentate complexes (with the exception of two NNN-tridentate compounds in which the third donor atom belongs to a flexible six-membered chelation ring). The elongation of the Pd−N2 distance in **1b** [2.009(3) Å] compared to those (1.917−1.944 Å) observed in similar NNO Pd^{II} halogen complexes of phenyl 2-pyridyl ketone benzoylhydrazone[11] is consistent with the *trans* influence of the methyl group, as also attested to by the NMR spectroscopic data. The Pd−O1 distance [2.037(2) Å] is in agreement with those found for the above hydrazone complexes (Pd−O: 2.017−2.033 Å). The growth of good quality crystals of **1b** was favored by co-crystallization with hydroxyquinone, present in traces in the THF used for recrystallization. In the crystal structure, the hydroxyquinone is positioned on a crystallographic center of inversion and bridges two symmetry-related complex molecules through strong O2−H···O1 hydrogen bonds [O2···O1: 2.697(4) Å, O−H···O: 176(3)°], as shown in Figure 3.

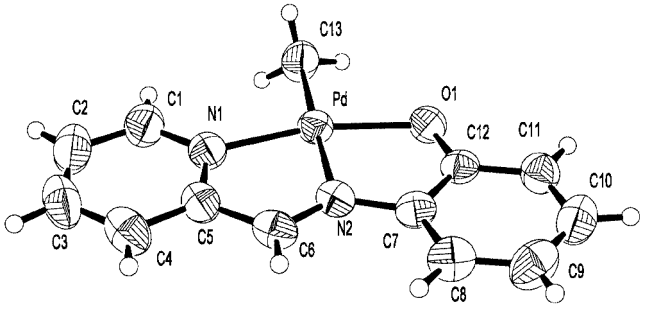

Figure 2. Perspective view of molecule **1b**·1/2$C_6H_6O_2$; thermal ellipsoids are drawn at the 50% probability level

The molecular structure of **2b** is shown in Figure 4, while the most relevant geometric features are listed in Table 1. The coordination is square-planar, with the ligand behaving as NN′S-tridentate, and the methyl *trans* to the iminic N2. The hindrance of the methyl substituent at C6 produces a minor deviation from planarity involving a slight rotation of the benzenethiol group around the C8−N2 bond [C6−N2−C8−C9: −8.0(5)°]. The overall planarity is conserved (maximum deviation 0.16 Å). The presence of the soft and bulkier S donor in the ligand has the effect of opening the S−Pd−N2 angle relative to the analogous O−Pd−N2 angle in **1b** [88.21(6) and 82.7(1)° for **2b** and **1b**, respectively], with a consequent slight weakening of the Pd−N2 bond [2.069(2) for **2b** and 2.009(3) Å for **1b**]. The *trans* effect of the S atom also results in a lengthening of the Pd−N1 bond [2.060(2) in **2b** and 2.033(3) Å for **1b**]. The dimensions of the S atom also seem to induce a compression of the Pd−N2−C6 angle [115.2(2)°] from the usual

Table 1. Selected bond lengths (Å) and angles (°) for compounds **1b**·1/2$C_6H_6O_2$, **2b**, and **2c**·1/2CH_2Cl_2

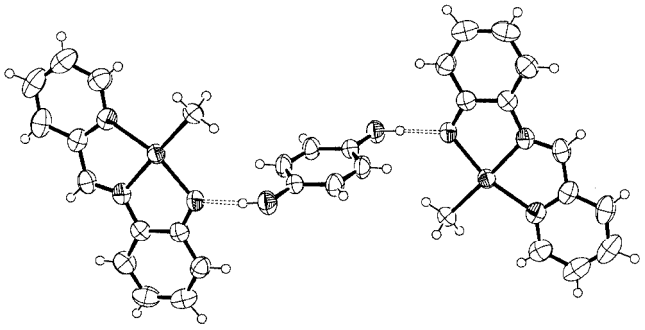

Figure 3. Molecular assembly through hydrogen bonds in the cocrystallization of **1b** with hydroxyquinone

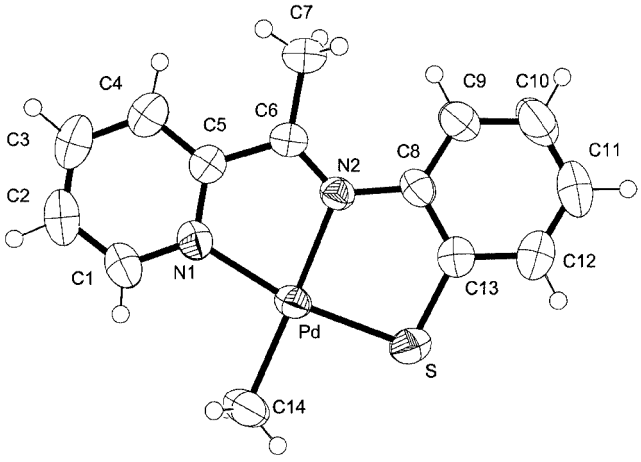

Figure 4. Perspective view of molecule **2b**; thermal ellipsoids are drawn at the 50% probability level

value for tridentate complexes; this has also been observed in some other cases of similar complexes [115.8° in chloro(-pyridine-2-carbaldehyde thiosemicarbazone-*N*,*N*′,*S*)palladium(II),[12] and chloro(2-formylpyridine 3-hexamethylene iminyl thiosemicarbazone-*N*,*N*′,*S*)palladium(II)[13]].

Compound **2c** crystallizes with two independent molecules in the asymmetric unit, one of which is shown in Figure 5. A dichloromethane molecule is also present in the asymmetric unit. The two complex molecules have similar geometries, and their relevant bonding features are listed in Table 1. The insertion of the CO into the Pd−CH_3 bond of **2b** produces a remarkable modification in the geometry of the resulting acylated complex **2c**, the resulting ligand structure being significantly distorted, with deviations from planarity as large as 0.75 Å, due to a rotation of the terminal benzenethiol group around the C−N bond [C6−N2−C8−C9: 33(1) and C21−N4−C23−C24: −30(1)°]. The metal coordination planes (N, N S, C, Pd) are also affected, with maximum deviations from planarity of 0.22 and 0.14 Å, respectively, for the two molecules. The bite geometry of the Pd−N−C−C−S chelation ring is not influenced by this conformational modification, as can be seen by comparison of the corresponding bond angles of **2b** and **2c** (Table 1), whereas angular strains are induced in the Pd−N−C−C−N chelation ring, which in **2c** are generally narrower than in **2b**. In particular, the N−Pd−N bite angle is reduced to values typical for bidentate systems [78.7(3) and 79.1(3)° for the two molecules of **2c**]. The modification

of the coordination geometry upon introduction of the acetyl ligand may be due to a larger *trans* effect determining the elongation of the Pd−N2 bond than in the methyl complex [Pd−C: 2.090(7) and 2.097(7) Å in **2c** and 2.069(2) Å in **2b**], and also to steric reasons involving the orientation of the acetyl group around the Pd−C bond. It has been shown that acetyl groups coordinated to square-planar Pd or Pt atoms tend to orient themselves perpendicularly to the coordination plane, with dihedral angles between the acetyl and the coordination planes varying in the 68−90° range, and Pd−C bonds falling between 1.947 and 2.001 Å.[6] In **2c**, the Pd−C bonds [1.91(1) and 1.936(9) Å] are significantly shorter than average, and the acetyl groups are closer to the coordination planes [dihedral angles of 51.4(4) and 31.7(7)°], thus increasing the steric crowding in the average molecular plane. In both molecules the acetyl optimizes electrostatic interactions with **2** through an orientation of the methyl towards the ligand sulfur atom and the oxygen towards the pyridine C1−H [CH_3(acyl)···S: 3.35(1) and 3.15(1) Å; O(acyl) ···C(py) =3.19(1) and 3.11(1) Å].

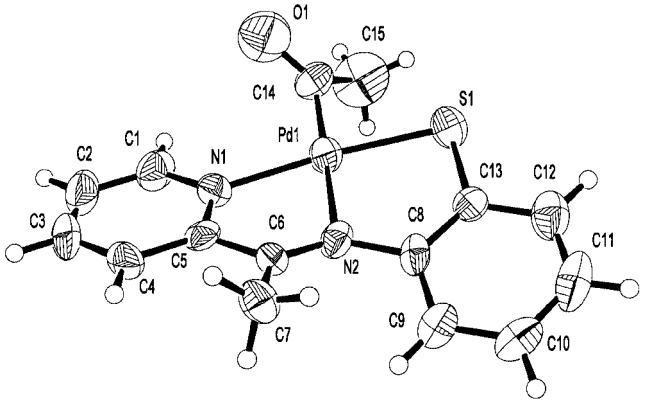

Figure 5. Perspective view of one of the two independent molecules in the crystal structure of **2c**·1/2CH_2Cl_2; thermal ellipsoids are drawn at the 50% probability level; the solvent has been omitted

Conclusions

We have reported the preparation of methylpalladium(II) complexes containing protic tridentate ligands of the HNN′O and HNN′S types. These ligands can adopt two different coordination modes around palladium: η^2-HNN′ when neutral, η^3-NN′X (X = O or S) when deprotonated. The reactivity of the three-coordinate complexes towards phosphanes and CO has been investigated. As far as carbonylation was concerned, in the absence of *soft* donors (**1b**) it was not possible to isolate the corresponding acetyl complex, and the reaction product was an organic molecule derived from the acetylation of the ligand (**3**). In the presence of a *soft* donor (the sulfur atom in **2b**), however, isolation of the carbonylated complex was successful, although the major product of the reaction was the thioacetate **4**, derived from acetylation of the ligand. The formation of the organic derivatives was accompanied by the release of palladium black. According to the results of a study on the reactivity of **1b** toward trimethylphosphane, it seems likely that the CO coordination proceeds by the breaking of the Pd-py bond. The possibility of making such a reaction catalytic is under investigation in our laboratories.

Experimental Section

General: All reactions were performed under an atmosphere of nitrogen by standard Schlenk techniques. Solvents were dried prior to use and stored under nitrogen. Elemental analyses (C, H, N, and S) were performed with a Carlo Erba Mod. EA 1108 apparatus. Infrared spectra were recorded with a Nicolet 5PCFT-IR spectrophotometer in the 4000−400 cm^{-1} range, as KBr disks. ^{1}H NMR spectra were obtained on a Bruker 300 FT spectrometer with $SiMe_4$ as internal standard at 25 °C, while $^{31}P\{^1H\}$ NMR spectra were recorded on a Bruker CPX 200 FT with H_3PO_4 (85%) as external standard at 25 °C. MS-CI spectra (methane) were recorded on a Finnigan SSQ 710 spectrometer, collecting negative ions; the relative intensities are reported in brackets. The thermogravimetric analyses were carried out under nitrogen atmosphere on a Perkin−Elmer Delta Series TGA7 apparatus, with a programmed temperature increment of 5 °C/min. The ligands HNN′O (**1**)[14] and HNN′S (**2**)[15] were synthesized by slightly modified literature procedures. The reagents used in the syntheses of the ligands — PPh_3, $P(CD_3)_3$ and *n*BuLi (1.6 M solution in *n*-hexane) — were commercial grade and were used without further purification. [(COD)Pd(Me)Cl] was synthesized as reported in the literature.[4b]

[Pd(η^2-HNN′)(Me)Cl] (1a): Compound **1** (0.050 g, 0.252 mmol) was dissolved in 30 mL of diethyl ether and [(COD)Pd(Me)Cl] (0.066 g, 0.250 mmol) was added. The immediate precipitation of a yellow powder was observed. The mixture was stirred at room temperature for 1 h and then filtered, and the solid was washed repeatedly with diethyl ether and dried under vacuum. Yield: 0.083 g (94%). ^{1}H NMR ([D_6]Me_2SO): δ = 0.41 (s, 3 H, Pd-Me), 6.89 (t, 1 H, 7-H), 6.98 (d, 1 H, 8-H), 7.08 (d, 1 H, 5-H), 7.16 (t, 1 H, 6-H), 7.91 (t, 1 H, 2-H), 8.14 (d, 1 H, 4-H), 8.27 (t, 1 H, 3-H), 8.82 (d, 1 H, 1-H), 8.88 [s, 1 H, C(H)=N], 9.84 (s, 1 H, O−H) ppm. IR: ṽ = 3377 m (OH), 1597 m−1589 m (C=N) cm^{-1}. $C_{13}H_{13}ClN_2OPd$ (355.1): calcd. C 43.97, H 3.69, N 7.89; found C 44.00, H 3.71, N 7.85.

[Pd(η^2-HNN′)(Me)Cl] (2a): Complex **2** (0.050 g, 0.219 mmol) was dissolved in 20 mL of diethyl ether and [(COD)Pd(Me)Cl] (0.058 g, 0.219 mmol) was added. The rapid formation of a gray powder was observed, and this was filtered off after two hours of stirring at room temperature. The filtered solid was washed repeatedly with diethyl ether and then dried under vacuum. Yield: 0.060 g 71%. ^{1}H NMR ([D_6]Me_2SO): δ = 0.81 (s, Pd-Me), 2.50 [s, C(Me)=N] ppm. The other signals overlapped with the signals of **2b** and **2d**. IR: ṽ = 3229 m (SH), 1587 m (C=N) cm^{-1}. $C_{14}H_{15}ClN_2PdS$ (385.2): calcd. C 43.65, H 3.92, N 7.27, S 8.32; found C 43.63, H 3.85, N 7.19, S 8.17.

[Pd(η^3-NN′O)(Me)] (1b). Method a: Complex **1** (0.050 g, 0.252 mmol) was dissolved in 10 mL of THF and [(COD)Pd(Me)Cl] (0.067 g, 0.252 mmol) was added, resulting in a yellow solution that was stirred at room temperature for 5 min. *n*BuLi (0.016 g, 0.252 mmol, 158 μL) was then added, to produce a purple solution that was stirred for 3 h, filtered, concentrated, and then treated with an excess of *n*-hexane. A purple solid was filtered off, washed with *n*-hexane, and then dried under vacuum. Yield: 0.072 g (90%). On slow evaporation of a THF solution of **1b**,

crystals of **1b**·1/2$C_6H_6O_2$ suitable for X-ray analysis were collected.

Method b: Complex **1a** (0.050 g, 0.141 mmol) was dissolved in 10 mL of THF, and NaOMe (0.011 g, 0.211 mmol) or *n*BuLi (0.008 g, 0.141 mmol, 88 μL) was added; the purple solution was stirred at room temperature for 2 h, then filtered and concentrated, and the product was precipitated with *n*-hexane and worked up as described above. Yield: 0.039 g (85%). ^{1}H NMR ([D$_6$]DMSO): δ = 0.60 (s, 3 H, Pd-Me), 6.37 (t, 1 H, 6-H), 6.72 (d, 1 H, 8-H), 7.00 (m, 2 H, 5-H−7-H), 7.21 (t, 1 H, 2-H), 7.38 (d, 1 H, 4-H), 7.76 (t, 1 H, 3-H), 7.88 [s, 1 H, C(H)=N], 8.15 (d, 1 H, 1-H) ppm. IR: $\tilde{\nu}$ = 1600 s (C=N) cm^{-1}. MS: *m*/*z* (%) = 317 (43) [**1b**]$^-$, 301 (19) [**1b** − Me]$^-$, 198 (100) [**1**]$^-$. $C_{13}H_{12}N_2OPd$ (318.7): calcd. C 49.00, H 3.79, N 8.79; found C 49.09, H 3.85, N 8.75.

[Pd(η^3-NN′S)(Me)] (2b): Complex **2** (0.100 g, 0.438 mmol) was dissolved in 30 mL of THF. [(COD)Pd(Me)Cl] (0.116 g, 0.438 mmol) was then added, and the resulting yellow solution was stirred at room temperature for 5 min. NaOMe (0.035 g, 0.656 mmol) or Et_3N (0.066 g, 0.656 mmol, 91 μL) was added, producing a deep green solution that was stirred for 1.5 h and from which a green solid was released. The solid was filtered off, washed with cold methanol and diethyl ether, and then dried under vacuum. Yield: 0.115 g (75%). On slow evaporation of a THF solution of **2b**, crystals suitable for X-ray analysis were collected. ^{1}H NMR ([D$_6$]DMSO): δ = 0.15 (s, 3 H, Pd-Me), 2.70 [s, 3 H, C(Me)=N], 6.78 (t, 1 H, 7-H), 6.91 (t, 1 H, 6-H), 7.15 (d, 1 H, 5-H), 7.23 (d, 1 H, 8-H), 7.66 (t, 1 H, 2-H), 8.01 (d, 1 H, 4-H), 8.13 (t, 1 H, 3-H), 8.35 (d, 1 H, 1-H) ppm. IR: $\tilde{\nu}$ = 1595 m (C=N) cm^{-1}. MS: *m*/*z* (%) = 349 (100) [**2b**]$^-$. $C_{14}H_{14}N_2PdS$ (348.7): calcd. C 48.21, H 4.05, N 8.03, S 9.19; found C 48.25, H 4.10, N 8.05, S 9.14.

[Pd(η^2-HNN′)Cl$_2$] (1c): 1 (0.076 g, 0.383 mmol) was dissolved in 30 mL of methanol, and a methanol solution (30 mL) of Li_2PdCl_4 (0.100 g, 0.383 mmol) was added. The mixture was stirred at room temperature for 2 h, producing a brown solid, which was filtered off, washed with methanol, and dried under vacuum. Yield: 0.111 g (77%). On slow evaporation of a THF solution of **1c**, crystals of **1c**·THF suitable for X-ray analysis were collected. ^{1}H NMR ([D$_6$]DMSO): δ = 6.83 (t, 1 H, 7-H), 6.92 (d, 1 H, 8-H), 7.19 (m, 2 H, 5-H−6-H), 7.95 (t, 1 H, 2-H), 8.20 (d, 1 H, 4-H), 8.39 (t, 1 H, 3-H), 8.72 [s, 1 H, C(H)=N], 9.06 (d, 1 H, 1-H), 10.01 (s, 1 H, O−H) ppm. IR: $\tilde{\nu}$ = 3423 s (O−H), w (C=N) 1615 cm^{-1}. $C_{12}H_{10}Cl_2N_2OPd$·THF (447.62): calcd. C 42.93, H 4.05, N 6.26; found C 42.95, H 4.10, N 6.24.

[Pd(η^3-NN′O)Cl] (1d): Characterization was performed only in solution. ^{1}H NMR ([D$_6$]DMSO): δ = 6.48 (m, 2 H, 7-H−8-H), 7.05 (t, 1 H, 6-H), 7.39 (d, 1 H, 5-H), 7.61 (t, 1 H, 2-H), 7.77 (d, 1 H, 4-H), 8.16 (t, 1 H, 3-H), 8.43 (d, 1 H, 1-H) ppm; the C(H)=N signal was obscured.

Reactions of 1a and 1b with Phosphanes: The complex (0.020 g, 0.056 mmol for **1a** and 0.063 mmol for **1b**, respectively) was dissolved in 0.75 mL of [D$_6$]DMSO in a 5-mm NMR tube. The desired amount of phosphane was added quickly, with the progress of the reaction being monitored by ^{1}H or ^{31}P NMR spectroscopy at 25 °C.

Treatment of 1a with PPh_3: PPh_3 (stoichiometric, 0.015 g, 0.056 mmol) was added; the solution instantaneously turned from yellow to green. **1e:** ^{31}P NMR: δ = 40.5 (s) ppm. **1f:** ^{31}P NMR: δ = 32.5 (s) ppm; (excess of PPh_3): Additional PPh_3 (0.015 g) was added, resulting in the immediate precipitation of a white solid (*trans*-[$(PPh_3)_2$Pd(Me)Cl]), which was filtered off, washed with Me_2SO and diethyl ether, and then dried under vacuum. Yield: 0.035 g (92%). ^{1}H NMR ($CDCl_3$): δ = −0.03 (t, $J_{P\text{-}H}$ = 5.9 Hz, 3 H, Pd−Me), 7.71−7.38 (m, 30 H, Ph) ppm. ^{31}P NMR ($CDCl_3$): δ = 27.7 (s) ppm. Crystals suitable for X-ray analysis were collected from a refrigerated THF/*n*-hexane mixture of *trans*-[$(PPh_3)_2$Pd(Me)Cl]. $C_{37}H_{33}ClP_2Pd$ (681.5): calcd. C 65.21, H 4.88, N 4.11; found C 65.20, H 4.85, N 4.10.

Treatment of 1b with $P(CD_3)_3$: $P(CD_3)_3$ (0.007 g, 0.112 mmol, 8.7 μL) was added to the complex solution by micropipette, without observation either of color changes or of solid formation. **1h:** ^{31}P NMR: δ = 43.1 (s) ppm. ^{1}H NMR: δ = 0.25 (s, 3 H, Pd-Me), 6.13 (t, 1 H, 6-H), 6.46 (d, 1 H, 8-H), 6.75 (t, 1 H, 7-H), 7.08 (d, 1 H, 5-H), 7.31 (t, 1 H, 2-H), 7.81 (t, 1 H, 3-H), 8.02 (d, 1 H, 4-H), 8.57 (d, 1 H, 1-H), 9.70 [s, 1 H, C(H)=N] ppm.

Carbonylations of 1b and 2b: The complex (0.050 g, 0.157 mmol for **1b** and 0.144 mmol for **2b**) was placed in a Schlenk tube and dissolved under nitrogen in 15 mL of dichloromethane. CO was bubbled through a glass capillary until complete saturation of the solution (at least 5 min), the vessel was closed, and the CO atmosphere was maintained for the required time. The solution was filtered through Celite in order to remove palladium black, and analyzed by mass spectrometry.

Carbonylation of 1b (3): The formation of palladium black was practically instantaneous, as was the bleaching of the solution. The CO was released after 10 min. MS: *m*/*z* (%) = 241 (48) [**3**]$^-$, 199 (32) [**1**]$^-$.

Carbonylation of 2b (2c and 4): The formation of palladium black was much slower then in the case of **1b**. The CO was released after 2 h. MS: *m*/*z* (%) = 378 (2) [**2c**]$^-$, 270 (100) [**4**]$^-$, 228 (37) [**2**]$^-$. A portion of the solution was dried and redissolved in the minimum amount of dichloromethane, and *n*-hexane was slowly diffused into it at −18 °C; crystals of **2c**·1/2CH_2Cl_2 suitable for X-ray analysis were collected.

Crystal Structure Determinations of 1b·1/2$C_6H_6O_2$, 1c·THF, 2b, 2c·1/2CH_2Cl_2, and *trans*-[$(PPh_3)_2$Pd(Me)Cl]: Single crystals were mounted on glass fibers, and X-ray diffraction data were collected at room temperature on a Bruker−Siemens SMART AXS 1000 equipped with a CCD detector for compounds **1b**·1/2$C_6H_6O_2$, **2b**, and **2c**·1/2CH_2Cl_2, and a Philips PW1100 diffractometer equipped with a scintillation counter for compounds *trans*-[$(PPh_3)_2$Pd(Me)Cl] and **1c**·THF. Graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å) was used in all cases. Data collection details for **1b**, **2b**, and **2c** are: crystal to detector distance: 5.0 cm, hemisphere mode, time per frame: 30 s, oscillation Δω = 0.300°. Data reduction was performed by use of the SAINT package[16] and data were corrected for absorption effects by the SADABS[17] procedure. For *trans*-[$(PPh_3)_2$Pd(Me)Cl] and **1c**·THF, data were processed with a peak-profile procedure and corrected for Lorentz, polarization, and absorption effects (Ψ-scan method). Crystal decay was negligible in all cases. The phase problem was solved by direct methods[18] and the structures were refined by full-matrix, least-squares on all F^2,[19] by use of the WinGX package.[20] Anisotropic displacement parameters were refined for all non-hydrogen atoms, while hydrogen atoms were partly located from Fourier maps and refined isotropically, and partly introduced at calculated positions. Use was made of the Cambridge Crystallographic Database[21] facilities for structure discussion. Final maps were featureless. Data collection and refinement results are summarized in Table 2.

CCDC-178202 (**1b**·1/2$C_6H_6O_2$), -178203 (**2b**), -178204 (**2c**·1/2CH_2Cl_2), -178205 (**1g**), and -178206 (**1c**·THF) contain the

Oxidative Addition of Benzyliminium Tetraphenylborate to Pd(dba)(dppe): Synthesis and Catalytic Activity of [(dppe)Pd(dba)-{η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$

Michele Aresta,*[a] Angela Dibenedetto,[a] Eliana Amodio,[a] and Immacolata Tommasi[a]

Keywords: Methyl acrylate / Dimerization / Styrene−methyl acrylate coupling / Palladium

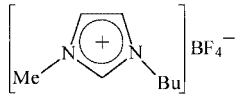
The synthesis and catalytic activity of the new dicationic Pd^{II} complex [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ from the Pd^0 complex Pd(dba)(dppe) and $[(PhCH_2)HN{=}CMe_2]BPh_4$ are described. $[(PhCH_2)HN{=}CMe_2]BPh_4$ adds to Pd(dba)(dppe) under mild conditions through a selective N–H activation. The resulting species further reacts with $[(PhCH_2)HN{=}CMe_2]BPh_4$ and generates *N*-benzyl-*N*-isopropylamine and [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$. The latter catalyzes the dimerization of methyl acrylate (MA) and the co-oligomerization of MA with styrene. Significant changes of the selectivity in the dimerization of MA have been found, e.g. changing the solvent from methyl acrylate (mostly tail-to-tail, T-T, coupling) to the ionic liquid $[bmim]BF_4$ (T-T and head-to-tail, H-T, coupling).
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

We have recently reported that $[(PhCH_2)HN{=}CMe_2]BPh_4$ (**1**)[1] oxidatively adds to $(PCy_3)_2N{-}N{\equiv}NNi(PCy_3)_2$ (**2**)[2] through a selective N−H activation,[3] affording [*trans*-$(H)Ni(PCy_3)_2${η^1(*N*)-$PhCH_2N{=}CMe_2$}]BPh_4 (**3**) [Equation (1)].

$$2\,[(PhCH_2)HN{=}CMe_2]BPh_4\ (\mathbf{1}) + (PCy_3)_2NiN{\equiv}NNi(PCy_3)_2\ (\mathbf{2}) \xrightarrow{293\ K,\ THF,\ N_2} 2\,[(H)Ni(PCy_3)_2(\eta^1(N)\text{-}PhCH_2N{=}CMe_2)]BPh_4\ (\mathbf{3}) + N_2 \quad (1)$$

Compound **3** promotes the head-to-tail (H-T) oligomerization of methyl acrylate (**4**), with 100% selectivity, to give dimethyl 2-methyleneglutarate (**5**), accompanied by traces of the trimer 2,4,6-tris(methoxycarbonyl)-1-hexene (**6**), which is still an H-T coupling product.[4] Conversely, $(CH_2{=}CHCH_2NH_3)BPh_4$ (**7**)[1] adds to Ni^0 complexes, such as **2**[3] or $(PCy_3)_2Ni(\eta^2\text{-}CO_2)$ (**8**),[5] through the selective activation of the C−N allyl bond, affording $[(\eta^3\text{-}C_3H_5)Ni(PCy_3)(NH_3)]BPh_4$ (**9**).[4] Compound **9**, in the presence of dihydrogen (0.1 MPa) as a cocatalyst, shows the same 100% selectivity towards the H-T oligomerization of **4**, affording **5**.[4] As we have demonstrated, in both cases the formation of (hydrido)Ni species is the key factor for catalysis to occur. In order to ascertain if such a reaction also occurs with other metal systems, we have investigated the reaction of **1** with [1,2-bis(diphenylphosphanyl)ethane][(*E*,*E*)-dibenzylideneacetone]palladium (**10**) and found a completely different behavior with respect to Ni^0. Compound **1** reacts with **10** in a multistep reaction, giving the dicationic Pd^{II} complex [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (**11**), that has been proved to catalyze the dimerization of **4** and the co-oligomerization of **4** with styrene (**12**). The reaction takes place in either the neat monomer(s), or in the ionic liquid 1-butyl-3-methylimidazolium tetrafluoroborate ($[bmim]BF_4$) (**13**),[6,7] but with different yields and selectivities (Figure 1).



13

Figure 1. 1-Butyl-3-methylimidazolium tetrafluoroborate, $[bmim]BF_4$ (**13**)

The interest in ionic liquids, such as $[bmim]BF_4$, as solvents in biphasic processes such as Pd-catalyzed oligomerization, hydroformylation and hydrogenation of olefins is growing.[8,9] Most Pd complexes are perfectly stable and soluble in these solvents. Moreover, biphasic systems allow for easier product isolation and catalyst recycling.

Results and Discussion

Reaction of Pd(dba)(dppe) (10) with $[(PhCH_2)HN{=}CMe_2]BPh_4$ (1)

The iminium salt **1** reacts with the palladium(0) species Pd(dba)(dppe) (**10**), in THF at 293 K, to give the dicationic

[a] Dipartimento di Chimica, Campus Universitario, Università di Bari, and Centro METEA,
Via Celso Ulpiani 27, 70126 Bari, Italy

E-mail: aresta@metea.uniba.it

Pd^{II} complex **11** [Equation (2)] as ultimate product. This implies a different reaction pathway to that of the addition of **1** to Ni^0 [Equation (1)].

$$\underset{\mathbf{1}}{2\,[(PhCH_2)HN{=}CMe_2]BPh_4} + \underset{\mathbf{10}}{Pd(dba)(dppe)} \xrightarrow{293\ K,\ THF,\ N_2} \underset{\mathbf{11}}{[(dppe)Pd(dba)(\eta^1(N)\text{-}PhCH_2N{=}CMe_2)](BPh_4)_2} + \underset{\mathbf{20}}{(PhCH_2)HN(CHMe_2)} \quad (2)$$

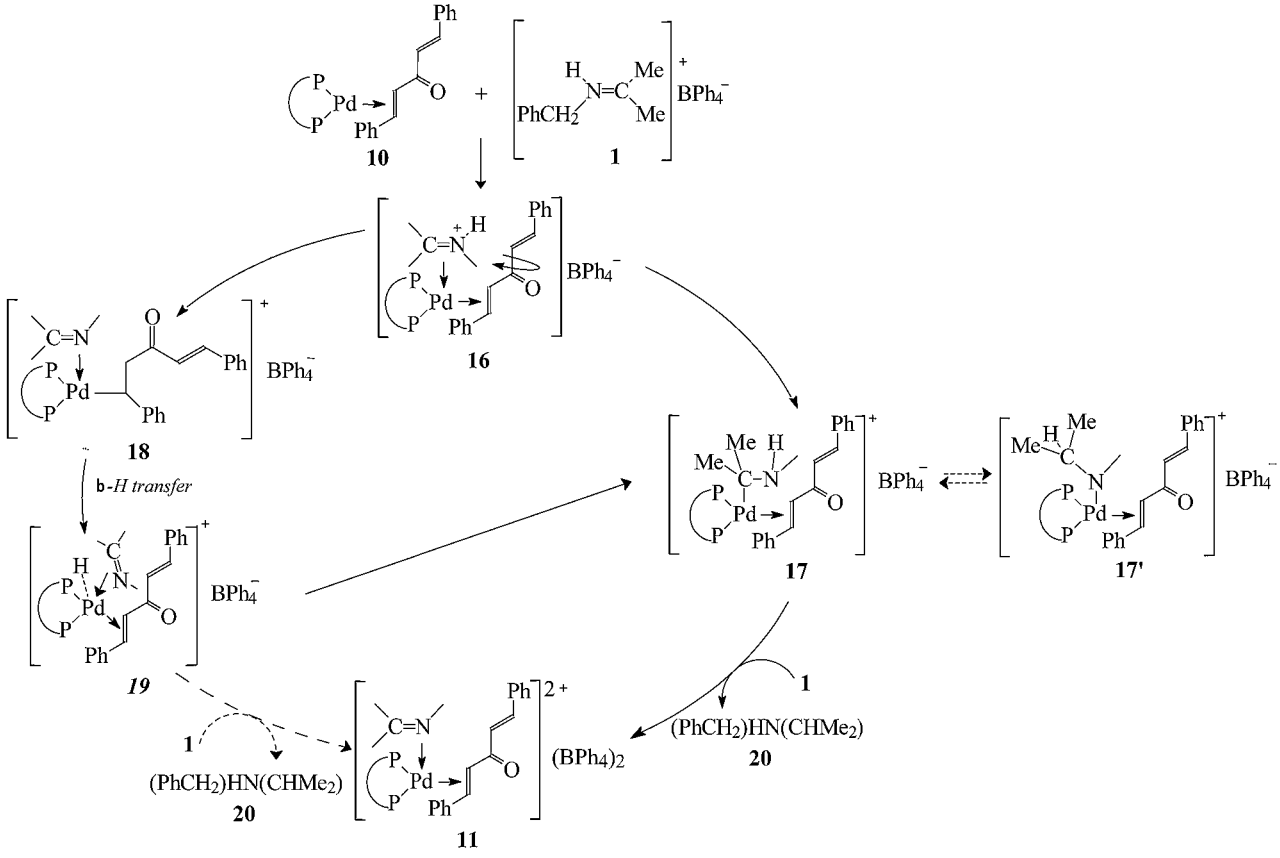
It is known that **10** exists in solution in equilibrium with a small amount of (S)Pd(dppe) (**10′**) (S = solvent) and dba. Compound **10′** undergoes the oxidative addition of reagents such as chloroform (**14**)[10] and phenyl iodide (**15**).[11] Pd(dba)(dppe) also reacts; however, the reaction is slower than that of (S)Pd(dppe). The result is the formation of a Pd^{II} species, with the release of dba [Equations (3) and (4)].

$$Pd(dba)(dppe) + CHCl_3 \rightarrow Pd(dppe)(Cl)(CHCl_2) + dba \quad (3)$$

$$Pd(dba)(dppe) + PhI \rightarrow PhPdI(dppe) + dba \quad (4)$$

In order to ascertain if **11** is formed by an initial addition of **1** to Pd^0 with the formation of a hydride species, we have continuously monitored the reaction depicted in Equation (2) by ^1H NMR spectroscopy at 293 K, over a period of 1 h (Scheme 1).

The iminium tetraphenylborate salt (**1**) does not add to the metal center, as observed with the Ni^0 complexes.[3] As a matter of fact, neither hydrides nor free dba have been detected during the reaction. This excludes the complication added by the presence of **10′** in the addition process. It seems that both the presence of dba as a potential proton acceptor and the lower stability of the palladium hydride species with respect to Ni[3,12b] and Pt,[12] may favor a different reaction path for Pd. Rarely have Pd−H species been isolated,[13] and often the formation of cationic (hydrido)Pd compounds have been inferred on the basis of the products that can originate by H-transfer.[14,15] Recently, we have reported that **1** reacts with $Pd(dppe)_2$ (**21**) to afford the unstable hydride $[HPd(dppe)_2]BPh_4$ (**22**), which has been detected in solution and characterized by ^1H (quint at δ = −7.37 ppm) and ^{31}P NMR spectroscopy (d at δ = 32.98 ppm).[15] The reaction of **1** with Pd(dba)(dppe) (**10**) was monitored by ^1H NMR spectroscopy. Soon after the addition of **1** to Pd(dba)(dppe) (**10**), a new resonance signal appears at δ = 4.75 ppm, which is assigned to an N−H moiety (**16** or **17**), as demonstrated by D_2O exchange. In principle, either the protonation of dba may occur to give **18** or the organometallic species **17** (possibly in equilibrium with the amido complex **17′**), derived from the coordination of the iminium cation to the palladium atom. The appearance of a new signal at δ = 2.65 ppm seems to support the



Scheme 1. The lifetime of **19** is not long enough to record the ^1H NMR spectrum

formation of **18**. This assignment agrees well with the ^1H resonance of alkyl moieties bonded to Pd {such as those in cationic complexes of the type $[(N-N)Pd(CH_3)(acetonitrile)]BF_4$} that commonly fall in the δ = 2.32−2.71 ppm range (CD_3CN, 293 K).[16] Compound **18** can be converted into **17** (or **17′**), probably through the formation of the unstable palladium hydride species (**19**), not observed by ^1H NMR spectroscopy. Compound **17** (or **17′**) can easily be protonated by the benzyliminium salt **1** affording the saturated amine *N*-benzyl-*N*-isopropylamine (**20**), which is found free in solution as revealed by GC-MS analysis, and the final complex **11**, in which dba is π-coordinated to the palladium atom, as suggested by two broad resonances at δ = 4.77 and 5.98 ppm, assigned to the nonequivalent protons of the C=C double bond.[10] Therefore, both Pd(dba)(dppe) and $Pd(dppe)_2$ react with the iminium salt **1**, affording the saturated amine **20** and a dicationic Pd^{II} complex, but by a different reaction path.[15] The ^{31}P NMR spectrum of the isolated complex **11** at 293 K shows that the two original resonances at δ = 34.79 and 37.07 ppm, characteristic of the asymmetric complex Pd(dba)(dppe), shift downfield and are found at δ = 35.31 and 38.00 ppm, respectively. The observed shift agrees with the greater electrophilicity of the metallic center that is oxidized to Pd^{II} after the reaction occurs. During the reaction such signals appear as broad resonances as a result of the dynamic behavior of the system Pd(dba)(dppe)/$[(PhCH_2)HN{=}CMe_2]BPh_4$ in solution. Unfortunately, solubility properties do not allow a low-temperature investigation. Complex **11** is stable in solution at 293 K, while above 353 K it decomposes to give benzene (**23**), generated from the BPh_4^- moiety, as already observed with rhodium[17a] and nickel[4] complexes. The cleavage of the B−C bond may be promoted by the preliminary coordination of the tetraphenylborate unit to the metal atom through one of its phenyl rings. However, **23** can also be formed by the direct protolysis of one of the B−C bonds of BPh_4^- by the iminium cation [Equation (5)]. The latter reaction has been proved to occur when the benzyliminium tetraphenylborate is heated in a solvent in the absence of any metal system.[17b]

$$H^+ + BPh_4^- \rightarrow BPh_3 + PhH \quad (5)$$

We have used **11** as a catalyst in the oligomerization of methyl acrylate (**4**) and discovered that the different properties and reactivity of the system Pd(dba)(dppe)/$[(PhCH_2)HN{=}CMe_2]BPh_4$, relative to the nickel complexes, greatly modifies the catalytic activity towards **4**.

Catalytic Activity of 11 in the Dimerization of Methyl Acrylate (4)

Interest in the dimerization of methyl acrylate (**4**) arises from the utility, at an industrial level, of the products that can be formed by C_3-C_3 or C_3-C_2 coupling (Figure 2).

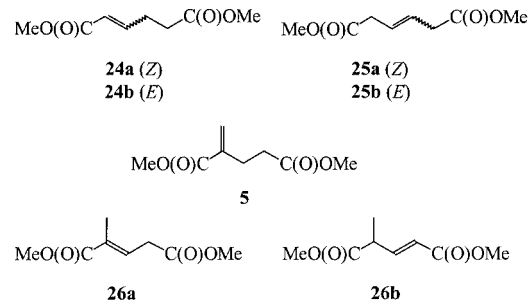


Figure 2. Tail-to-tail (**24a**−**b**, **25a**−**b**) and head-to-tail (**5**, **26a**−**b**) dimers of methyl acrylate

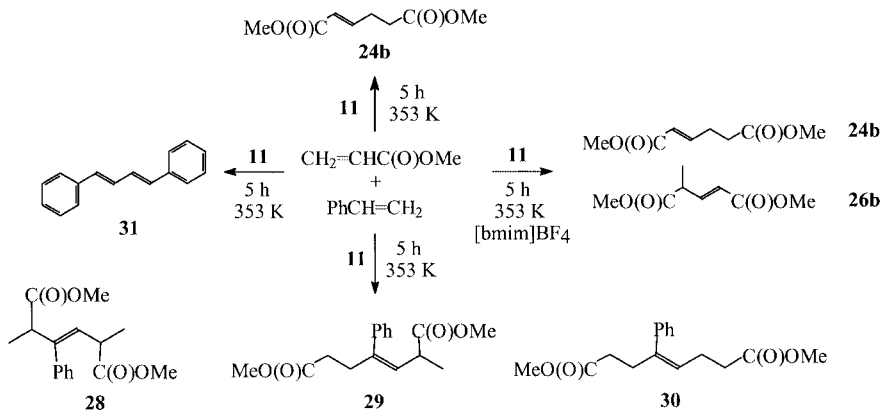
The dimethyl (*Z*)- and (*E*)-hex-2-enedioates (**24a**, **24b**), and dimethyl (*Z*)- and (*E*)-hex-3-enedioates (**25a**, **25b**), obtained by C_3-C_3 coupling of two methyl acrylate units,[18] are used principally as precursors for the synthesis of adipic acid, which is used in the Nylon-6,6 production. Conversely, head-to-tail dimers dimethyl 2-methyleneglutarate (**5**) and dimethyl methylpentenedioates (**26a**, **26b**), obtained by C_3-C_2 coupling of two methyl acrylate units, find their application essentially as monomers in co-polymerization reactions.[19] As mentioned above, in a recent study[4] we have shown that **3**[1] and **9**,[4] in the presence of H_2 as a cocatalyst, catalyze the selective (100%) H-T oligomerization of **4** giving dimer **5** and traces of trimer **6**. We have now studied the catalytic activity of complex **11**; typically, a **4**/**11** ratio of 1000:1 was used either in methyl acrylate as the solvent or in the ionic liquid $[bmim]BF_4$. We have found that the solvent drives both the rate of conversion and the selectivity of the process towards the T-T dimer dimethyl (*E*)-hex-2-enedioate (**24b**). The conversion yield of methyl acrylate in $[bmim]BF_4$ is four times higher than in methyl acrylate as the solvent. In $[bmim]BF_4$, **11** catalyzes the formation of the T-T product dimethyl (*E*)-hex-2-enedioate (**24b**) (41%), followed by the H-T product dimethyl 4-methylpent-2-enedioate (**26b**) (36%). Minor amounts of T-T dimers dimethyl (*Z*)-hex-2-enedioate (**24a**) (4%) and dimethyl (*E*)-hex-3-enedioate (**25b**) (5%), and the H-T dimers dimethyl 2-methyleneglutarate (**5**) (4%) and dimethyl 2-methylpent-2-enedioate (**26a**) (10%) were also obtained. In methyl acrylate, **11** catalyzes the dimerization of **4** affording the T-T dimer dimethyl (*E*)-hex-2-enedioate (**24b**) with a selectivity of 82%. Smaller amounts of the T-T dimer dimethyl (*E*)-hex-3-enedioate (**25b**) (2%) and the H-T dimers dimethyl 2-methyleneglutarate (**5**) (5%), dimethyl 2-methylpent-2-enedioate (**26a**) (9%) and dimethyl 4-methylpent-2-enedioate (**26b**) (2%) were also obtained. In both cases, traces of methyl 3-phenyl-2-propenoate (**27**) are also formed that are produced by the reaction of the phenyl moiety, formed by thermal degradation of complex **11**, with **4**. The trend shown by Pd catalysts is quite different from that characteristic of analogous Ni complexes. It has been proved[4] that the H-T coupling of **4** requires a hydride catalyst[4,20] or monodentate phosphorus ligands.[21] In the present case, the instability of Pd−H represses H-T coupling



Scheme 2

and favors the formation of T-T dimers of **4** that do not require M−H species.[18k] Also the nature of the solvent can favor or disfavor the formation of Pd−H systems and, thus, promote or prevent H-T coupling.

Catalytic Activity of 11 in the Co-Oligomerization of Methyl Acrylate (4) with Styrene (12)

Complex **11** has also been found to be active in the co-oligomerization of **4** with **12** (**11**/**4**/**12** = 1:1000:1000), when both the monomers are used as the solvent, or in [bmim]BF_4. The reaction affords the co-trimers dimethyl 2,5-dimethyl-3-phenylhex-3-enedioate (**28**), dimethyl 2-methyl-4-phenylhept-3-enedioate (**29**) and dimethyl 4-phenyloct-4-enedioate (**30**) (Scheme 2).

These co-oligomerization products are accompanied by the dimers of **4**, dimethyl (*E*)-hex-2-enedioate (**24b**) and dimethyl 4-methylpent-2-enedioate (**26b**) in the presence of [bmim]BF_4, or dimethyl (*E*)-hex-2-enedioate (**24b**) in methyl acrylate and styrene as the solvents. In each case, the dimer of styrene 1,4-diphenyl-1,3-butadiene (**31**) is also formed in traces. In [bmim]BF_4, the conversion of methyl acrylate is higher than in the neat reagents as the solvent, but the **4**/**12** co-trimers are present in minor amounts and the dimers of **4** are the major products. However, when the reagents methyl acrylate and styrene are used as the solvent, **4**/**12** co-trimers are predominantly formed. These results agree with those reported in the literature[22] that showed that the co-dimerization of **12** with **4**, catalyzed by [Pd(C_6H_5CH=CH_2)Cl_2]$_2$, gives the co-dimers of **12** and **4**, and the dimers of **4** or **12**. Ethylbenzene (**32**) is also formed in traces, which is produced by H-transfer to **12**, as a result of the reductive coupling of two units of **12** which gives 1,4-diphenyl-1,3-butadiene (**31**) that is found in the reaction medium. Small amounts of methyl 3-phenyl-2-propenoate (**27**) and stilbene (**33**) are also generated, most likely by the reaction of the phenyl moiety, a thermal degradation product of **11**, with **4** or **12**.[17]

Conclusions

[($PhCH_2$)HN=CMe_2]BPh_4 (**1**) reacts with palladium(0) complex Pd(dba)(dppe) (**10**) to afford the dicationic Pd^{II} complex [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N$=CMe_2}](BPh_4)$_2$ (**11**), through a complex path that starts with the protonation of the coordinated dba. Complex **11** has been proved to be catalytically active in the dimerization of methyl acrylate (**4**) and in the co-oligomerizations of **4** with styrene (**12**). No polymerization products have been observed. In neat methyl acrylate, the selective (84%) T-T coupling of **4** affording dimethyl (*E*)-hex-2-enedioate (**24b**) with a regioselectivity of 82% has been observed. In the ionic liquid [bmim]BF_4, a selectivity of 50% was found towards the T-T coupling of **4**, affording dimethyl (*E*)-hex-2-enedioate (**24b**). The H-T dimethyl 4-methylpent-2-enedioate (**26b**) is formed with a regioselectivity of ca. 40%. In neat methyl acrylate/styrene, co-trimers are formed in higher yields than in [bmim]BF_4, which favors the homocoupling of **4**.

Experimental Section

General Comments: Unless otherwise stated, all reactions and manipulations were conducted under dinitrogen by using vacuum-line techniques. All solvents were dried as described in the literature[23] and stored under N_2. MA was purchased from Fluka and stored under N_2. [($PhCH_2$)HN=CMe_2]BPh_4,[1] Pd(dba)(dppe)[10a,24] and [bmim]BF_4 [6,25] have been prepared as previously reported. Elemental C,H,N microanalyses were performed with an Euro EA 3000 analyser, P analyses were performed using a UV Shimadzu 1601 (λ = 460 nm), Pd was dosed using a Perkin−Elmer Atomic Absorption Spectrometer 3110. NMR spectra were run with a Varian XL-200 instrument. ^{1}H NMR chemical shifts are in ppm vs. TMS and referenced to the solvent peak. ^{31}P NMR chemical shifts are in ppm vs. 85% H_3PO_4. GC-MS analyses were carried out with a Shimadzu GC-17A linked to a Shimadzu GCMS-QP5050 selective mass detector (capillary column: 60 m × 0.25 mm Supelco MDN-5S, 0.25 μm film thickness). Temperature program: 343 K (3 min) → 21 min → 553 K (30 min). GC analyses were performed by using an HP 5890 Series II GC (capillary column: 30 m × 0.25 mm Altech AT-5, 0.25 μm film thickness). Temperature program: 318 K (5 min) → 7.5 min → 393 K (1 min) → 9.5 min → 583 K (30 min).

Synthesis of [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N$=CMe_2}](BPh_4)$_2$ (11): [($PhCH_2$)HN=CMe_2]BPh_4 (0.140 g, 0.30 mmol), dissolved in THF (10 mL), was added to a solution of Pd(dba)(dppe) (0.183 g,

0.25 mmol) in THF (10 mL), prepared under dinitrogen at 293 K. The resulting mixture was stirred at room temperature (293 K) for 5 h, until its color turned to yellowish orange. The reaction mixture was filtered, concentrated in vacuo, and, after addition of diethyl ether (20 mL), cooled to 253 K. The red oil obtained was isolated, washed with diethyl ether (2 × 3 mL), dried in vacuo, and characterized as [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (**11**) (0.219 g, 58%). ^{1}H NMR ([D$_8$]THF, 293 K): δ = 2.02 (s, 3 H, $-CH_3$), 2.07 (s, 3 H, $-CH_3$), 2.50 (br. s, 4 H, $-CH_2CH_2-$), 4.42 (s, 2 H, $-CH_2Ph$), 4.77 (br. s, 1 H, $-HC{=}CH-$), 5.98 (br. s, 1 H, $-HC{=}CH-$), 6.70 (t, J_{ortho} = 7.10 Hz, 2 × 4 H, H_{para} BPh_4^-,), 6.80 (t, J_{ortho} = 7.44 Hz, 2 × 8 H, H_{meta} BPh_4^-), 6.93−7.82 (m, 53 H, 2 × 8 H, H_{ortho} BPh_4^-, $H_{ortho,meta,para}$ $PhCH_2-$, dppe, $H_{aromatic,olefinic}$ dba) ppm. ^{31}P NMR ([D$_8$]THF, 293 K): δ = 35.31 (m), 38.00 (m) ppm. $C_{101}H_{91}B_2NOP_2Pd$ (1524.80): calcd. C 79.56, H 6.02, N 0.92, Pd 6.98, P 4.06; found C 79.77, H 6.05, N 1.08, Pd 6.85, P 4.07. Water must be avoided in order to prevent the hydrolysis of benzyliminium tetraphenylborate to afford acetone and benzylammonium tetraphenylborate.

Reaction of Pd(dba)(dppe) (10) with [(PhCH$_2$)HN=CMe$_2$]BPh$_4$ (1) Monitored by ^{1}H NMR Spectroscopy: A water-free [D$_8$]THF solution (0.75 mL) of Pd(dba)(dppe) (13.20 mg, 0.018 mmol), prepared under N_2, was introduced into an NMR tube, avoiding contact with air. The iminium tetraphenylborate was added (8.20 mg, 0.018 mmol), the tube sealed and the solution continuously monitored by ^{1}H NMR spectroscopy at 293 K (Scheme 1). **18:** ^{1}H NMR ([D$_8$]THF, 293 K): δ = 1.95 (s, 3 H, $-CH_3$), 2.05 (s, 3 H, $-CH_3$), 2.20 (br. s, 4 H, $-CH_2CH_2-$), 2.65 (br. s, Pd−alkyl), 4.43 (s, 2 H, $-CH_2Ph$), 4.75 (br. s, 1 H, N−*H*), 6.70 (t, J_{ortho} = 7.10 Hz, 2 × 4 H, H_{para} BPh_4^-), 6.80 (t, J_{ortho} = 7.44 Hz, 2 × 8 H, H_{meta} BPh_4^-), 6.93−7.82 (m, 53 H, 2 × 8 H, H_{ortho} BPh_4^-, $H_{ortho,meta,para}$ $PhCH_2-$, dppe, $H_{aromatic,olefinic}$ dba) ppm. The formation of *N*-benzyl-*N*-isopropylamine (**20**) was confirmed by analyzing the reaction mixture by GC-MS: $C_{10}H_{15}N$: *m*/*z* = $[M]^+$ (not observed), 134, 106, 91, 77, 65, 41, 39.

Dimerization of Methyl Acrylate (4) Promoted by 11 in Methyl Acrylate: Methyl acrylate (1 mL, 11.10 mmol) was added to [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (13.75 mg, 0.009 mmol) under N_2. The reaction mixture was then stirred at 353 K for 5 h and, after cooling to 293 K, the products were diluted in toluene. They were analyzed by GC and GC-MS, that showed that dimethyl (*E*)-hex-2-enedioate (**24b**) was the main product (82%) and **26a** (9%), **5** (5%), **25 b** (2%) and **26b** (2%) were the minor products. **24b:** GC-MS: $C_8H_{12}O_4$: *m*/*z* = $[M]^+$ (not observed), 157 [$M^+ - CH_3$], 140 [$CH_3O(O)C-CH{=}CH-CH-CH_2-CO$], 108 [$OC-CH{=}CH-CH{=}CH-CO$], 97 [$H_2C{=}CH-CH{=}CH-C(O)O$], 81 [$H_2C{=}CH-CH{=}CH-CO$], 71 [$H_2C{=}CH-C(O)O$], 59 [$C(O)OCH_3$], 53 [$H_2C{=}CH-CH{=}CH$], 41 [$H_2C{=}CH-CH_2$], 39 [$HC-CH{=}CH$], 31 [$OCH_3$].

Dimerization of Methyl Acrylate (4) Promoted by 11 in [bmim]BF$_4$: Methyl acrylate (0.47 mL, 5.22 mmol) and the ionic liquid [bmim]BF_4 (0.25 mL) were added to [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (6.40 mg, 0.004 mmol) under N_2. The reaction mixture was then stirred at 353 K for 5 h and, after cooling to 293 K, the products were isolated by extraction in toluene. They were analyzed by GC and GC-MS, that showed that dimethyl (*E*)-hex-2-enedioate (**24b**) (41%) and dimethyl 4-methylpent-2-enedioate (**26b**) (36%) were the main products and **24a** (4%), **25b** (5%), **5** (4%) and **26a** (10%) were the minor products. **26b:** GC-MS: $C_8H_{12}O_4$: *m*/*z* = $[M]^+$ (not observed), 140 [$M^+ - CH_3OH$], 112 [$H_2C{=}CH-CH{=}CH-C(O)OCH_3$], 97 [$H_2C{=}CH-CH{=}CH-C(O)O$], 85 [$CH{=}CH-C(O)OCH_3$], 81 [$H_2C{=}CH-CH{=}CH-CO$], 71 [$H_2C{=}CH-C(O)O$], 59 [$C(O)OCH_3$], 53 [$H_2C{=}CH-CH{=}CH$], 41 [$H_2C{=}CH-CH_2$], 39 [$HC-CH{=}CH$].

Co-Oligomerization of Methyl Acrylate (4) and Styrene (12) Promoted by 11 in Methyl Acrylate and Styrene: Methyl acrylate (0.46 mL, 5.11 mmol) and styrene (0.59 mL, 5.13 mmol) were added to [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (6.20 mg, 0.004 mmol) under N_2. The reaction mixture was then stirred at 353 K for 5 h and, after cooling to 293 K, the products were diluted in toluene and analyzed by GC and GC-MS. Three different isomers of methyl acrylate/styrene trimers were isolated, dimethyl 2,5-dimethyl-3-phenylhex-3-enedioate (16%) (**28**), dimethyl 2-methyl-4-phenylhept-3-enedioate (14%) (**29**) and dimethyl 4-phenyloct-4-enedioate (35%) (**30**), and the dimer of methyl acrylate dimethyl (*E*)-hex-2-enedioate (32%) (**24b**). **28:** GC-MS: $C_{16}H_{20}O_4$: *m*/*z* = $[M]^+$ (not observed), 244 [$M^+ - CH_3OH$], 216 [$H_2C{=}CH-C(Ph){=}CH-CH(CH_3)C(O)OCH_3$ or $H_2C{=}CH-CH{=}C(Ph)-CH(CH_3)C(O)OCH_3$], 207, 185 [$H_2C{=}CH-C(Ph){=}CH-CH(CH_3)CO$ or $H_2C{=}CH-CH{=}C(Ph)-CH(CH_3)CO$], 143 [$HC-C(Ph){=}CH-CH-CH_3$ or $CH-CH{=}C(Ph)-CH(CH_3)$], 129 ($Ph-C{=}CH-CH{=}CH_2$), 115 ($Ph-C{=}CH-CH$), 96, 77 (C_6H_5), 59 [$C(O)OCH_3$), 51 (C_4H_3). **29:** GC-MS: $C_{16}H_{20}O_4$: *m*/*z* = $[M]^+$ (not observed), 244 [$M^+ - CH_3OH$], 216 [$H_2C{=}CH-CH{=}C(Ph)-CH_2-CH_2C(O)OCH_3$ or $H_2C{=}CH-C(Ph){=}CH-CH(CH_3)C(O)OCH_3$], 207, 185 [$H_2C{=}CH-CH{=}C(Ph)-CH_2-CH_2CO$ or $H_2C{=}CH-C(Ph){=}CH-CH(CH_3)CO$], 143 [$HC-CH{=}C(Ph)-CH_2-CH_2$ or $CH-C(Ph){=}CH-CH-CH_3$], 129 [$HC-CH{=}C(Ph)-CH_2$], 115 [$HC-CH{=}C-Ph$], 96, 77 [C_6H_5], 59 [$C(O)OCH_3$], 51 [C_4H_3]. **30:** GC-MS: $C_{16}H_{20}O_4$: *m*/*z* = $[M]^+$ (not observed), 244 [$M^+ - CH_3OH$], 216 [$H_2C{=}CH-CH{=}C(Ph)-CH_2CH_2C(O)OCH_3$ or $H_2C{=}CH-C(Ph){=}CH-CH_2CH_2C(O)OCH_3$], 207, 157 [$Ph-C{=}CH-CH-CH_2CO$], 141, 129 [$Ph-C{=}CH-CH{=}CH_2$], 115 [$Ph-C{=}CH-CH$], 88, 77 [$C_6H_5$], 59 [$C(O)OCH_3$], 51 [$C_4H_3$].

Co-Oligomerization of Methyl Acrylate (4) and Styrene (12) Promoted by 11 in [bmim]BF$_4$: Methyl acrylate (0.911 g, 10.58 mmol), styrene (1.028 g, 9.87 mmol) and the ionic liquid [bmim]BF_4 (1 mL) were added to [(dppe)Pd(dba){η^1(*N*)-$PhCH_2N{=}CMe_2$}]$(BPh_4)_2$ (12.30 mg, 0.008 mmol) under N_2. The reaction mixture was then stirred at 353 K for 5 h and, after cooling to 293 K, the products were isolated by extraction in toluene and analyzed by GC and GC-MS. Three different isomers of methyl acrylate/styrene trimers were isolated, dimethyl 2,5-dimethyl-3-phenylhex-3-enedioate (4%) (**28**), dimethyl 2-methyl-4-phenylhept-3-enedioate (3%) (**29**) and dimethyl 4-phenyloct-4-enedioate (16%) (**30**), and the dimers of methyl acrylate dimethyl (*E*)-hex-2-enedioate (36%) (**24b**) and dimethyl 4-methylpent-2-enedioate (25%) (**26b**).

Cobalt(II) Complexes with Nitrogen Donors and Their Dioxygen Affinity in Dimethyl Sulfoxide

Clara Comuzzi,*[a] Andrea Melchior,[a] Pierluigi Polese,[a] Roberto Portanova,[a] and Marilena Tolazzi*[a]

Keywords: Cobalt / Amine ligands / Thermodynamics / Solvent effects / Oxygen

The formation of Co^{II} complexes with differently methylated N-donor ligands ethylenediamine (en), *N*,*N*′-dimethylethylenediamine (dmen), *N*,*N*,*N*′-trimethylethylenediamine (trmen), and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (tmen), has been studied at 298 K in both the aprotic solvent dimethyl sulfoxide (dmso) and in an ionic medium set to 0.1 mol dm^{-3} with Et_4NClO_4 under anaerobic conditions. UV/Vis spectrophotometric and calorimetric measurements were carried out to obtain the thermodynamic parameters for the systems investigated. Only mononuclear CoL_j^{2+} complexes were formed (j = 1–3 for en, j = 1, 2 for dmen; and j = 1 for trmen and tmen) where the diamines act as bidentate agents. All the complexes are enthalpy-stabilized whereas the entropy changes counteract the complex formation. The results are discussed in terms of different basicities and steric requirements both of the ligands and the complexes formed. Voltammetric measurements were carried out to correlate the electrochemical properties of the anaerobic complexes with their different dioxygen affinities. The X-ray structure of the starting adduct $[Co(dmso)_6][ClO_4]_2$, determined on a monocrystal, is also reported.

Introduction

A wide variety of cobalt(II) complexes are known to bind dioxygen more or less reversibly and are therefore frequently studied as model compounds for natural oxygen carriers and for their use in O_2 storage, as well as in organic syntheses due to their catalytic properties under mild conditions.[1−7] In this respect, Co^{II} complexes with N-donor ligands containing binding units suitable either for the coordination of a single metal ion or for assembling dimetallic centres have proven to be particularly useful, and have been extensively investigated especially in aqueous solutions.[8−14]

Minor attention has been devoted to the behaviour of such complexes in aprotic solvents[15−21] where their activity as oxidation catalysts can be of great interest. In a previous paper,[21] as result of an initial study focused on thermodynamics of complex formation of Co^{II} with linear, cyclic polyaza or mixed N−O ligands in aprotic solvents, the interactions of Co^{II} with the monoamine *n*-butylamine (n-but) and the triamines diethylenetriamine (dien), *N*,*N*′′-dimethyldiethylenetriamine (dmdien), and *N*,*N*,*N*′,*N*′′,*N*′′-pentamethyldiethylenetriamine (pmdien) were presented in dimethyl sulfoxide (dmso). In this work it was shown that the Co^{II} complex stabilities were greatly dependent on the degree of *N*-alkylation of the triamines, and that their dioxygen affinity varied concomitantly; thus, the tertiary pmdien was not able to take up O_2 whilst dmdien and dien were.

Strong σ-donor ligands are known to increase the dioxygen affinity.[6] In fact, in the oxygenation reaction, the dioxygen donates an electron into the appropriate Co d orbital while the metal centre is thought to donate an electron from the d_{z^2} orbital into the π* orbital of the electrophilic molecular dioxygen, thus forming a complex. This electron transfer should depend on the available electron density at the central metal atom. This density, however, is greatly affected by the electron donor properties of the ligands in the coordination sphere; as the ligand basicity increases, its electron donating ability also increases facilitating such a transfer.[1]

As an extension of the previous work and with the aim of systematically tuning the influence of the introduction of methyl groups on amino groups we have investigated the Co^{II} complex formation in dimethyl sulfoxide (dmso) with the following diamines: ethylenediamine (en), *N*,*N*′-dimethylethylenediamine (dmen), *N*,*N*,*N*′-trimethylethylenediamine (trmen), and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (tmen), which are gradually increasingly methylated, so varying the basicity of the amino group in the order $-NH_2 > -NHR > -NR_2$.[22] The study presented in this paper refers in detail to the determination of the thermodynamic parameter of Co^{II} complex formation under anaerobic con-

ditions, as the knowledge of the properties of the starting complexes are fundamental to extending this investigation to aerobic conditions.

The values of the stability constants of the various systems investigated were determined by UV/Vis spectroscopic measurements using Cd^{II} as auxiliary metal ion,[23] for the reasons discussed in a previous paper.[21] The stability constants of this latter ion with the same ligands were previously determined by potentiometric measurements using the ion-selective cadmium electrode.[24] The enthalpy values were obtained by direct calorimetric titrations.

Also, preliminary remarks concerning dioxygen uptake are reported; in particular voltammetric measurements were carried out in order to obtain a correlation between the electrochemical properties of the anaerobic complexes with the diamines and the triamines previously investigated[21] and their dioxygen affinity in dmso.

All the spectrophotometric, calorimetric, and voltammetric measurements were performed at 298 K and in an ionic medium adjusted to 0.1 mol dm^{-3} with Et_4NClO_4 as the neutral salt, taking extreme care to obtain and maintain the lowest possible water and oxygen contents in the systems.

The X-ray structure of $[Co(dmso)_6][ClO_4]_2$, determined on a monocrystal, is also reported. This structural study is interesting in itself, taking into account the considerable interest of transition metal complexes with dmso for their role as possible intermediates in homogeneous catalysis, as antitumoural agents, or radiosensitizers in medicinal chemistry.[25] Finally, it is important because few X-ray structural evidences are to date available for cobalt−dmso complexes.[26−29]

Results and Discussion

The best fit of the spectrophotometric data was obtained when the species reported in Table 1 were taken into ac-

count. In Table 1, the overall stability constants and the free energies of formation, with the limits of error indicated, are listed for the reactions $Co^{2+} + j\ L \rightleftarrows CoL_j^{2+}$ (where L is the amine concerned and $j = 1-3$). No polynuclear or mixed Co−L−Cd complexes were observed within the concentration range investigated.

As an example, in Figure 1(a) typical UV/Vis spectral changes observed during the reaction of Co^{2+} with dmen are reported in terms of absorbances vs. wavelengths. In Figure 1(b) the spectral modification due to dioxygen uptake is also inserted for the $[Co(dmen)_2]^{2+}$ system.

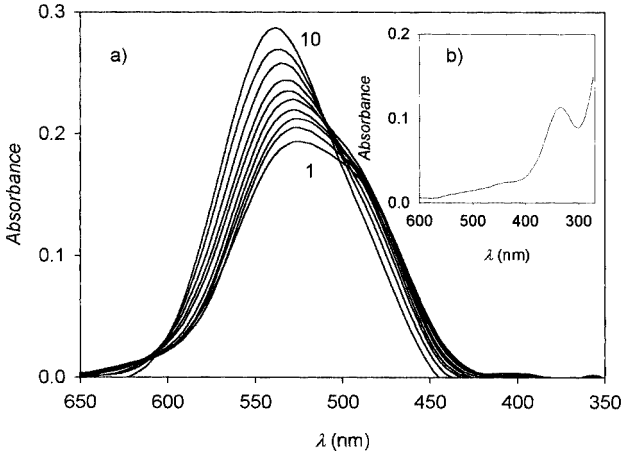

Figure 1. (a) Spectral changes observed during the reaction of Co^{2+} with dmen in dmso: $C^0_{Co} = 25.3$; $C^0_{Cd} = 27.7$ mmol dm^{-3} (spectrum 1); C^0_{dmen} varied from 0 (spectrum 1) to 65.6 (spectrum 10) mmol dm^{-3}; (b) UV/Vis spectrum of a solution of $[Co(dmen)_2]^{2+} = 0.4$ mmol dm^{-3} in air after 5 min

The experimental data obtained from the calorimetric measurements for all the systems investigated are reported in Figure 2 as Δh_t, the total heats of reaction per mol of metal ion, as a function of $R_C = C_L/C_M$, the ratio between the amount (mol) of ligand and the amount (mol) of cobalt(II) in the calorimetric vessel. The enthalpy curves are fully consistent with the information obtained from the analysis of spectrophotometric data. In fact, the curves representing the complexation of Co^{II}−trmen and −tmen indicate formation of complex(es) of relatively low stability(-ies), whereas the Co^{II}−en and −dmen data are consistent with the formation of 3 and 2 complexes, respectively, of relatively high stability.

The lack of evolved heat for $R_C > 2$ for the Co^{II}−dmen system clearly indicates that no more complexes are formed beyond the second one. The fit between experimental and calculated (full lines in Figure 2) curves is quite good.

In Figure 3 the FT-IR spectra of a series of solutions containing the same concentration (about 50 mmol dm^{-3}) of Co^{2+} and different ligand-to-metal ratios R_C, are reported for the Co^{II}−dmen system, chosen as significant example.

In Table 2, the data obtained from electrochemical measurements are summarized in terms of E_{pc}, the cathodic potential at maximum diffusion current, for the Co^{II}/Co^0 redox couple, and in terms of $E_{1/2}$ [$E_{1/2} = (E_{pc} + E_{pa})/2$] for

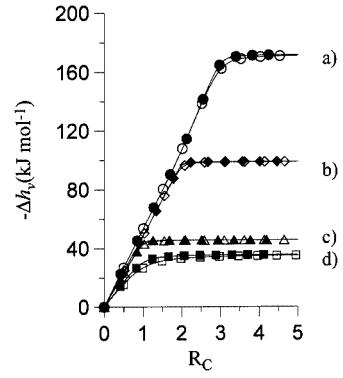

Figure 2. The total molar enthalpy changes, Δh_t, as a function of $R_C = C_L/C_M$ for Co^{II}−diamine systems in dmso: (a) en: (○) 5.05, (●) 19.91 mmol dm^{-3} in Co^{2+}; (b) dmen: (◇) 5.12, (◆) 19.96 mmol dm^{-3} in Co^{2+}; (c) trmen: (△) 5.09, (▲) 19.97 mmol dm^{-3} in Co^{2+}; (d) tmen: (□) 5.04, (■) 20.01 mmol dm^{-3} in Co^{2+}; only some of the experimental points, chosen at random, have been plotted; the solid lines were calculated from the values of β_j and $\Delta H°_{\beta j}$ in Table 1

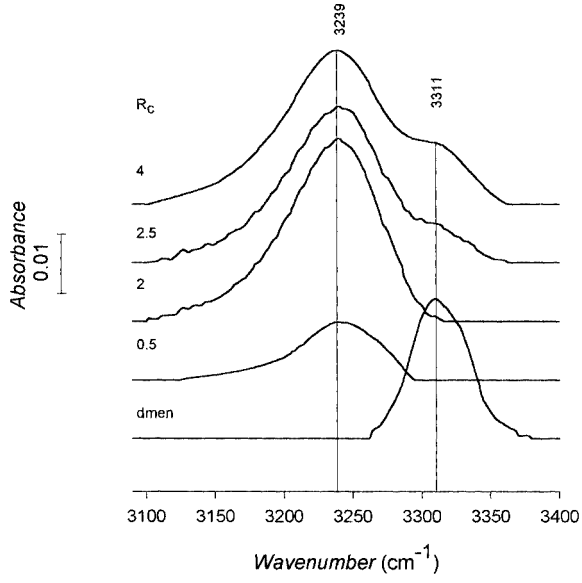

Figure 3. FT-IR spectra of solutions containing 50 mmol dm^{-3} of cobalt(II) and different dmen/metal ratios, R_C

the $Co^{II}L_j/Co^{III}L_j$ couple. The relative reactions [Equations (1) and (2)] are written in the direction in which the experiments were carried out.

$$Co^{II}L_j + 2e \rightarrow Co^0 + jL \quad (1)$$

$$Co^{II}L_j \rightarrow Co^{III}L_j + e \quad (2)$$

For comparison, the measurements have been extended to the triamines dien, dmdien, and pmdien, and the data obtained are also inserted in Table 2. The signals relative to Equation (2) consisted of a pair of irreversible oxidation/reduction waves, but were only detected for some of the systems investigated; no better results could be obtained by

Equilibrium Studies under Anaerobic Conditions

The complexes listed in Table 1 are all characterized by negative enthalpy and entropy values, which is typical of reactions involving complexation of metal ions by neutral ligands in aprotic solvents.[30,31] The desolvation of the species is here rather small and, given the relatively weak ligand−solvent interactions, the enthalpy change associated with the complex formation is therefore essentially a measure of the difference in bond energy toward the metal ion between the ligand and the coordinated molecules of the solvent. Thus, the enthalpy stabilization found here emphasizes the importance of the Co^{II}−nitrogen interaction in the aprotic solvent dmso.

The data for the analogous complexes formed by the Co^{II}−en system in aqueous solution have also been inserted in Table 1;[32] no data in water are available in the literature for the other diamine systems.[33] Lower stabilities are observed in water than in dmso; in a previous work,[21] as no information concerning the heat of transfer of Co^{2+} from water to any other solvent were available,[34] we reasonably supposed that this ion would be more strongly solvated by dmso than by water on the basis of some comparisons between Zn^{2+} and Co^{2+}, characterized by similar charge density.[35] The X-ray structural data reported here for the $[Co(dmso)_6]^{2+}$ species show that, in the solid state, interactions more akin to Co−dmso than to Zn−dmso are at play;

this seems to confirm our previous hypothesis. Therefore, the trend in the complexes stabilities in water and dmso, at variance with what might be expected on the basis of Co^{II} solvation in the two solvents, is to be attributed to a greater solvation of amines in water than in dmso[30] through hydrogen bonding.

The electronic spectra of CoL_j complexes are similar to those observed for the octahedral $[Co(H_2O)_6]^{2+}$ complex[35] and to those previously reported for octahedral $[Co(dmso)_6]^{2+}$ and Co^{II}−triamine systems[21] in dmso [see (a) in Figure 1] and clearly indicate that also for Co^{II}−diamine systems the octahedral structure is retained after the coordination of the ligands. Thermodynamic data confirm that no change of coordination occurs at any step of complexation. If the change occurred, in fact, abnormally less unfavourable entropy and less favourable enthalpy values would be expected.[30]

A comparison between the stability constant associated with the first complexation step for the Co^{II}−en and −n-but systems (Table 1) shows that it is much higher for the former ligand, indicating that the en ligand behaves as bidentate; the very exothermic value of the $\Delta H^\circ_{\beta 1}$ and the unfavourable entropy terms are in line with this hypothesis, which is further confirmed by FT-IR spectra run on solutions containing Co^{II}−en in a molar ratio 1:0.5 where no bands typical of free $-NH_2$ groups[36,37] were detected.

Similar considerations can be applied for the successive complexation steps; coming to the conclusion that hexacoordination is saturated by nitrogen groups when the $[Co(en)_3]^{2+}$ species is formed. It is interesting to note that the third stepwise complexation step is slightly more exothermic than the preceding ones and that the stepwise entropy term is more unfavourable: the coordination of the third en ligand evidently has no great effects on the desolvation of the central metal ion. The data for the other diamines investigated also indicate that bidentation is achieved for all the systems investigated.

The log β_1 values decrease smoothly for Co^{II}−dmen system with respect to the primary en, whereas this decrease is much more evident when one (trmen) or two (tmen) tertiary groups are present. The trend in thermodynamic stabilities primarily reflects the different basicities of the N atoms, which decrease in the order $-NH_2 > -NHR > -NR_2$,[22] whereas, when tertiary amino groups are involved, the greater steric crowding also contributes to a marked elongation of the M−N bonds.[38] In addition, *N*-methylation inhibits the formation of hydrogen bonds of the type M−N−H−O, decreasing the outer-sphere solvation energy of the complexes.[38] It is to note that *N*-alkylation strongly influences not only the stabilities but also the stoichiometry of the species formed; in fact, despite the borderline acid character, cobalt(II) is expected to become harder in dmso,[30] enhancing its affinity for the hard N atom, no more complexes beyond ML_2 or even ML could be detected when dmen or trmen and tmen, respectively, were concerned. In addition to the steric requirements of the more bulky ligands, certainly a role is also played by the small ionic radius of Co^{II} [35] as for example dmen and trmen ligands were found to be able to form three and two complexes, respectively, when octahedral Cd^{II} complexes were considered in dmso. Likely, large metal ions such as Cd^{II} can better minimize steric hindrances and repulsions when more than two bulky $-N(CH_3)_2$ moieties are involved in the complex formation. This is confirmed by the observation that the drop in complex stability by methylation is indeed more evident for Co^{II}− than for Cd^{II}−diamino complexes[24] ($\Delta\log K_{1[Co\text{-}(en)]\rightarrow[Co(trmen)]} = 2.13$; $\Delta\log K_{1[Co(en)]\rightarrow[Co(tmen)]} = 3.34$; $\Delta\log K_{1[Cd(en)]\rightarrow[Cd(trmen)]} = 1.76$; $\Delta\log K_{1[Cd(en)]\rightarrow[Cd(tmen)]} = 2.78$). Also, the increasing soft nature of the nitrogen donors should be responsible of this behaviour in this latter case.[38] The same trend was found for Co^{II} and Cd^{II} complexes with 1,4,8,11-tetraazacyclotetradecane (cyclam) and tetramethylcyclam.[39]

Independent FT-IR measurements were carried out in order to ascertain both the maximum stoichiometry and the coordination mode of the dmen ligand. Figure 3 shows the spectra of a series of solutions containing Co^{II} and different dmen-to-metal ratios, R_C It can be observed that up to $R_C = 2$, only the band due to the bonded secondary amine (at 3239 cm^{-1}) is present, whereas the band due to the free amino groups (at 3311 cm^{-1}) is also present when $R_C > 2$. This confirms both the bidentation in the ML_2 complex and the absence of higher species beyond the ML_2 one, as evidenced also by calorimetry studies.

As mentioned in the introduction, particular interest was devoted to the tuning of the behaviour of different methylated diamines in Co^{II} complexation under anaerobic conditions, in order to clarify their successive role in the affinities for molecular dioxygen. As a matter of fact, it was found[21] that in the case of the Co^{II} complexes with the triamines dien, dmdien, and pmdien, the affinity for dioxygen varied with the number of methyl groups present in the ligands; pmdien was in fact not able to promote dioxygen binding, dmdien promoted a certain amount of binding and release, and dien caused an irreversible dioxygen uptake.[21,40]

A similar behaviour is shown by en, dmen, and tmen; CoL_j complexes with en and dmen ($j \geq 2$) were able to take up dioxygen (see also Electrochemical and UV/Vis Data), with a certain degree of reversibility ascertained for the secondary dmen system, whereas $[Co(tmen)]^{2+}$ was not able to do the same. Unfortunately, the trmen ligand, chosen for its σ-donor properties (intermediate between that of dmen and tmen), was unexpectedly unable to form higher complexes beyond the first one, thus not reaching a minimum of three nitrogen donors per cobalt ion which appears to be necessary to form an oxygenated species as supposed in a previous work[41] and suggested by a comprehensive view of the results reported here and previously.[21] Therefore, we systematically searched for a correlation between the electron density of the metal ion in the complexes and the dioxygen uptake, by means of cyclic voltammetry.

Electrochemical and UV/Vis Data

The signals relative to the $Co^{II}L_j/Co^{III}L_j$ couples were visible only for the $[Co(en)_3]^{2+}/[Co(en)_3]^{3+}$ and $[Co(L)_2]^{2+}/[Co(L)_2]^{3+}$ (L = dien or dmdien) systems (Table 2). Con-

sidering the basicity order of the amino groups,[22] one should expect that the electron density on the cobalt ion decreases in the order $Co(en)_3 > Co(dien)_2 > Co(dmdien)_2$, which is reflected (see Table 2) in the concomitant increase in the $E_{1/2}$ values of the corresponding CoL_j^{2+}/CoL_j^{3+} couples.[38,42,43] This finding agrees with previous reports that *N*-alkylation of amine ligands shifts the redox potentials of the couples $M^{n+1/n}L_m$ anodically relative to those of the corresponding non-alkylated systems.[38] The voltammograms for the other di- and triamine systems should be, according to this trend in electron density, shifted anodically,[38] likely in the potential range where the solvent signals overcome those of the investigated couples.

The values of E_{pc} for reaction (2) are, on the other hand, easily evaluated for all the systems investigated; taking into account that the reaction for the uptake of dioxygen by a given Co^{II} complex is a charge-transfer process, a correlation between E_{pc} values for reaction (1) and Co^{II} charge density, and therefore the $Co^{II}L_j$ dioxygen affinity, should be observed. The higher the charge density is, the more difficult the reduction process to Co^0 should be and the more negative the expected E_{pc} values should be. The E_{pc} values for reaction (1) are in fact shifted anodically as secondary or, even more, tertiary diamines and triamines are considered.

These data are combined with UV/Vis results, obtained both for the Co^{II}−diamine systems studied in this paper and for previously investigated Co^{II}−triamine systems, dien, dmdien, and pmdien,[21] which show that: (i) no changes are observed in the spectra of deaerated and aerated solutions of all the 1:1 Co^{II}−diamine and Co^{II}−triamine (exept dien) species in the range 650−300 nm; (ii) all the aerated spectra of the other complexes show the origin of a charge-transfer band in the range 380−300 nm as shown in Figure 1(b) for the $[Co(dmen)_2]^{2+}$ system. The species mentioned in (i) are clearly not able to bind dioxygen whereas the others are. Therefore, the data reported in Table 2 for reaction (1) suggest an interesting correlation between the E_{pc} values of the Co^{II} complexes related to Equation (1) and their dioxygen affinity; one can in fact foresee that when $E_{pc} \geq -1.54$ V for the $Co^{II}L_j/Co^0$ couple the uptake of dioxygen is not possible in dmso.

Structural Data

Few crystal structures of cobalt(II)−dmso solvates are available in the literature,[26−29] due to the difficulty of obtaining single crystals suitable for X-ray investigation. Despite numerous attempts to improve their quality, also the crystals here investigated show a relative degree of disorder that does not in any case invalidate the overall features of the structure.

Co^{II} is a hard acceptor in dmso preferring hard donor atoms like oxygen, the bonds being mainly of electrostatic character.[30] In the solid-state structure reported in Figure 4, six solvent molecules are coordinated to the metal centre through the oxygen atom in a distorted octahedral geometry. The mean Co−O distance of 2.088(5) Å (Table 3) is consistent with the value found for an octahedral Co^{II}−oxygen coordination[25] and a little shorter than the analogous distance found for the Zn^{II} ion (Zn−O 2.11 Å) in $[Zn(dmso)_6][ClO_4]_2$,[44] shown for comparison for the similar charge density values of these ions. This datum indicates that slightly stronger interactions exist in the solid state between Co and dmso than between Zn and dmso.

Sulfur−oxygen average bond lengths [1.5286(16) Å], are in agreement with those present in the literature[25] for metal−sulfoxide complexes and greater than the S−O bond length in free dmso [1.495(4) Å]. The O−S−C angles [104.08(20)°] are also average for corresponding angles found in the literature for 400 related metal−sulfoxide complexes and less than that in free dmso [105.7(2) °], whereas the C−S−C bond angles (Table 3) are almost similar to the corresponding values in free dmso (98.6°).[25] The perchlorate anions are not coordinated to the central Co^{II} ion and therefore they are not reported in Figure 4. This feature is also maintained in dmso solution as $Co(ClO_4)_2$ has been found to be completely dissociated in dmso.[21]

Concluding Remarks

Important information have been obtained on how different donor properties of the ligands influence the stability and stoichiometry of the Co^{II} complexes; in fact the addition of only one $-CH_3$ group to dmen is shown to cause a drastic change in the number of complexes formed and strongly influence their dioxygen affinity. This result should be taken into account to suitably modify N-donors in order to obtain Co^{II} complexes able to promote a more or less reversible dioxygen binding.

The electrochemical properties, correlated with the number of methyl substituents, point to an interesting result, i.e. that an E_{pc} value of −1.54 V, related to reaction (1), should be at least overcome by the Co^{II}−amino complexes to be able to bind dioxygen. Finally, the structural data of the $[Co(dmso)_6][ClO_4]_2$ adduct are fully consistent with a distorted octahedral geometry of the hexasolvate and provide additional data on cobalt(II)−dmso complexes.

Experimental Section

Warning: Although metal perchlorates solvated by dmso are generally explosive under certain conditions,[45] no problems were encountered when handling $M(ClO_4)_2 \cdot 6dmso$ (M = Co or Cd). Anyway, as a precaution, only small quantities of the salts should be prepared each time. Great caution was exercised when handling dmso solutions of poisonous cadmium salts, since they are easily carried through the skin by dmso, which penetrates lipid tissues at an astonishing rate.

Chemicals: $Co(ClO_4)_2 \cdot 6dmso$ and $Cd(ClO_4)_2 \cdot 6dmso$ were prepared and standardised as before.[21,24] Dimethyl sulfoxide (Fluka; > 99%) was purified by distillation according to the described procedures,[46] degassed by a pumping-freezing procedure and stored over 4-Å molecular sieves. The ligands en, dmen, trmen, and tmen (Aldrich; > 97%) were purified by fractional distillation.[47] Perchlorate

stock solutions of Cd^{II} and Co^{II} ions were prepared by dissolving weighed amounts of the adducts in anhydrous degassed dmso, and their concentrations were checked by titration with EDTA.[48]

The background salt Et_4NClO_4 was recrystallised twice from methanol and dried at 110 °C. Solutions of the ligands were prepared as described.[24] All standard solutions were prepared and stored in an MB Braun 150 glove box under a controlled atmosphere containing less than 1 ppm of water and less than 1 ppm of oxygen. The water content in the solutions, typically 10−20 ppm, was determined by a Metrohm 684 KF Coulometer.

Spectrophotometric Measurements: UV/Vis spectra were recorded with a Varian Cary 50 Spectrophotometer directly inside the glove box using optic fibre probes and a quartz cuvette with a pathlength of 1 cm (117.100 Bracco cell). The data were recorded over the wavelength range 300−650 nm. Different types of titrations were carried out in order to obtain the best competition between Cd^{II} and Co^{II} for the same ligand and/or to evidence possible formation of mixed or polynuclear species. The absorption maximum for $Co(ClO_4)_2$ in dmso occurs at 535 nm with an extinction molar coefficients $\varepsilon = 11.9$ mol^{-1} dm^3 cm^{-1}. The absorption maximum of CoL_j complexes are shifted to lower wavelengths, in line with an increase in the ligand field strength, with the maximum ε values being of the same order of magnitude as that of the starting salt; therefore the dmso solutions always contained at least 20.00 mmol dm^{-3} of the $Co(ClO_4)_2$ starting salt in order to obtain reliable values for absorbance data.[23] The fact that equilibrium was attained was supported by the observation that addition of a titrant solution produced an immediate spectral change with no further change noted after several hours. The absorbance data at about 20 different wavelengths in the range 450−550 nm were analysed and the formation constants of the CoL_j complexes ($j = 1-3$) were determined, together with the molar extinction coefficients of the complexes at each relevant wavelength, using the Hyperquad program.[49]

Calorimetric Measurements: A Tronac model 87-558 precision calorimeter was employed to measure the heats of reaction. The cover of the titration vessel and its connection to the calorimeter were modified in order to make a gas-proof closure. To be sure of operating in absence of O_2, both the vessel and the burette were filled inside the glove box, joined together, taken out of the glove box and connected to the calorimeter for the measurements. The calorimeter was checked by titration of tris(hydroxymethyl)aminomethane (tham) with a standard solution of HCl in water. The experimental value of the heat of neutralization of tham was found to be $\Delta H° = -47.48$ kJ mol^{-1}, in good agreement with the accepted value of -47.53 ± 0.13 kJ mol^{-1}.[33] The procedure for the calorimetric titration was described before.[46] The heats of dilution of the reactants, determined in separate runs, were found to be negligible. The least-squares computer program Letagrop Kalle[50] was used for the calculation of the enthalpy changes.

FT-IR Spectroscopy: The FT-IR spectra were obtained using a Bio-Rad FTS 40 spectrometer (maximum resolution 4 cm^{-1}; 16 scans). A cell with barium fluoride windows (thickness of 25μm) was used. The cells were filled and closed in a glove box and quickly transferred to the spectrometer. The C^0_{Co} in the dmso solutions was about 50 mmol dm^{-3}.

Cyclic Voltammetry: The cyclic voltammograms of CoL_j complexes were carried out using an EG&G Princeton Applied Research Model 263A potentiostat controlled by a Win/PC based program. A saturated Ag/AgCl electrode was employed as reference and a Pt electrode was used as working electrode, being a Pt wire present as auxiliary electrode. The measurements were carried out with a scan rate of 100 mV/s.

X-ray Crystallography: Small violet crystals of the $[Co(dmso)_6][ClO_4]_2$ adduct were obtained from an anhydrous dmso solution of $Co(ClO_4)_2$ by the solvent-diffusion method with acetone. Data collection was carried out on a crystal of dimensions 0.45 × 0.30 × 0.30 mm by using a Nonius DIP-1030H system with Mo-K_α radiation, at 120 K by a nitrogen stream cryo-cooler. A total of 30 frames were collected, each with an exposure time of 10 min, over half of the reciprocal space with a rotation of 6° about , the detector being at a distance of 80 mm from the crystal. Data reduction and cell refinement was carried out by using the program Mosflm.[51] The structure was solved by Patterson and Fourier analyses[52] and refined by the full-matrix least-squares method based on F^2 with all observed reflections.[53] Of three crystallographic independent dmso ligands, two were found to be disordered, and the S−C moiety refined over two positions (occupancies of 88 and 12%, respectively, with hydrogen atoms omitted for the methyl group at lower occupancy). A solvent molecule of dmso and of acetone, sharing the methyl groups and the oxygen atom, were disordered on the same site. Occupancy factor of the S atom (dmso) and of the central C atom (acetone) refined to 0.68 and 0.32, respectively. All the calculations were performed using the WinGX System, Ver 1.64.[54] Additional material is available from the Cambridge Crystallographic Data Center as supplementary material comprising H-atom coordinates, thermal parameters, and remaining bond lengths and angles. CCDC-178439 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Homochiral Self Recognition in Gold-Phosphane-Helicates

Walter Schuh,[a] Holger Kopacka,[a] Klaus Wurst,[a] and Paul Peringer*[a]

Keywords: Self-assembly / Helical structures / Gold / X-ray diffraction / Aurophilicity

Treatment of $Au(SMe_2)Cl$ with a mixture of (R^*,S*)- and (R^*,R*)-(±)-p4 (p4 = 1,1,4,7,10,10-hexaphenyl-1,4,7,10-tetraphosphadecane) and TlOTf produces $[Au_4(R,S\text{-p4})_2](OTf)_4$ (**1**) and a racemic compound of $[Au_4(R,R\text{-p4})_2](OTf)_4$ and $[Au_4(S,S\text{-p4})_2](OTf)_4$ (**2**). Compounds **1** and **2** were isolated as colorless crystals and characterized by single crystal X-ray diffraction. In both **1** and **2**, four gold atoms are bridged by two p4 ligands. The structure of **1** is a *meso*-helicate composed of a P, an M and a central achiral domain. The ligands exhibit a head-to-head arrangement. The structures of **2** consist of a non-palindromic double helix. In both **1** and **2** the *R* centers induce a left-handed (M) and the *S* centers a right-handed (P) helicity. The helical elements of both **1** and **2** are unsaturated and show Au···Au interactions.

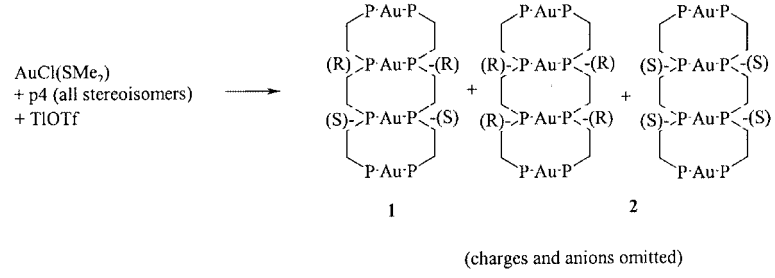
Introduction

Most of the activity in the area of helical complexes has been concentrated on achiral ligands.[1,2] More recently, however, chiral ligands have been used and interest has become focused towards stereoselective helical induction by enantiopure ligands.[3] One report deals with the stereospecific assembly of a racemic compound of homochiral dinuclear helicates from a racemic tetradentate nitrogen donor ligand.[4]

The object of this paper is the investigation of chiral self-recognition during the assembly of double stranded helicates in the presence of all stereoisomers of a ligand containing two chiral centers. The linear tetraphosphane ligand p4 (1,1,4,7,10,10-hexaphenyl-1,4,7,10-tetraphosphadecane, $Ph_2P-CH_2-CH_2-PPh-CH_2-CH_2-PPh-CH_2-CH_2-PPh_2$) exists as ($R$*,S*) and ($R$*,R*)-(±) stereoisomers. In this ligand, the chiral phosphorus centers act as donor atoms, whilst most other chiral ligands used in helicate architecture contain achiral donor atoms and some non-coordinating chiral centers attached to the ligand. We report here on the reaction of $Au(SMe_2)Cl$ with p4 in a stoichiometry that provides two phosphorus donor atoms per gold center. A complex with the ratio Au:P = 2:8, $[Au_2\{(R,R)\text{-p4}\}_2](PF_6)_2$ has been synthesized previously using enantiopure p4.[5] The structure consists of a *parallel helix*,[6] in which the two ligands form two helices whose helical axes are not defined by the metal ions but run parallel to the Au−Au vector. The Au centers are coordinated by four phosphorus atoms. As far as we know this, and the related silver complex,[5] are the sole published complexes containing more than one p4 ligand. A complex of the composition [$(AuCl)_4$(p4)], whose stereochemistry was not specified, has been patented as an antitumor agent.[7]



Scheme 1

Results and Discussion

The reaction of $Au(SMe_2)Cl$ with a mixture of all stereoisomers of p4 and TlOTf in the molar ratio of 4:2:4 in MeOH produces two compounds of the composition [Au_4-

[a] Institut für Allgemeine, Anorganische und Theoretische Chemie, Universität Innsbruck,
Innrain 52a, 6020 Innsbruck, Austria

$(p4)_2](OTf)_4$ which were separated by fractional crystallization from MeOH and isolated as colorless crystals. The less soluble isomer contains exclusively (*R*,*S*)-p4 ligands (**1**) and the other contains p4 with the configurations (*R*,*R*)- or (*S*,*S*)-(**2**) (Scheme 1).

Crystals of **1**·2MeOH or **1**·2EtOH were grown by slow evaporation of solutions of **1** in MeOH or EtOH. The EtOH solvate shows a more compact packing, whilst the structures of the cations are almost identical for both solvates. The cation of **1**·2EtOH (shown in Figure 1, selected distances and angles are presented in Table 1 and the data for **1**·2MeOH are provided as supporting information) contains four gold atoms bridged by two p4 ligands. The assembly is stereoselective in view of the coordination of two (*R*,*S*)-p4 ligands and the head-to-head arrangement of the ligands, i.e. one gold center is coordinated by two *R* phosphorus atoms and another by two *S* phosphorus atoms. The stereoselective coordination of four gold atoms is reflected by a center of symmetry in the cation $[Au_4(\mu^4\text{-}R,S\text{-p4})_2]^{4+}$ in the crystal lattice.

The structure of the cation of **1**·2EtOH shown in Figure 1 is a *meso*-helicate: The two terminal $(Au-P-CC-P)_2$ rings form double helices whose axes pass through the gold atoms. In keeping with the center of symmetry, these domains exhibit opposite helicities: The *R* centers induce an M handedness and the S centers a P sense. The central $(Au-P-CC-P)_2$ element is achiral and adopts a centrosymmetric chair-like geometry. The Au−Au distance of the helical domains [2.9802(4) Å] indicates a 1,6-transannular Au−Au d^{10}-d^{10} interaction in the 10-membered $(Au-P-CC-P)_2$ rings while there is no contact between the inner gold atoms 2 and 2A [4.1062(5) Å]. The axes of the two helical domains are not co-linear.

Crystals of **2**·2MeOH were grown by slow evaporation of a solution of **2** in MeOH. There are two crystallographically

				P22−Au22−Au33−P33	28.61(17)
				P33−Au33−Au44−P44	53.43(17)

independent complexes with very similar structures which are shown in different perspectives in Figure 2 and 3. The structures consist of two ligand strands wrapped as a double helix around a linear Au_4 rod. The helices stereoselectively contain either two *R*,*R*- or two *S*,*S*-p4 ligands.

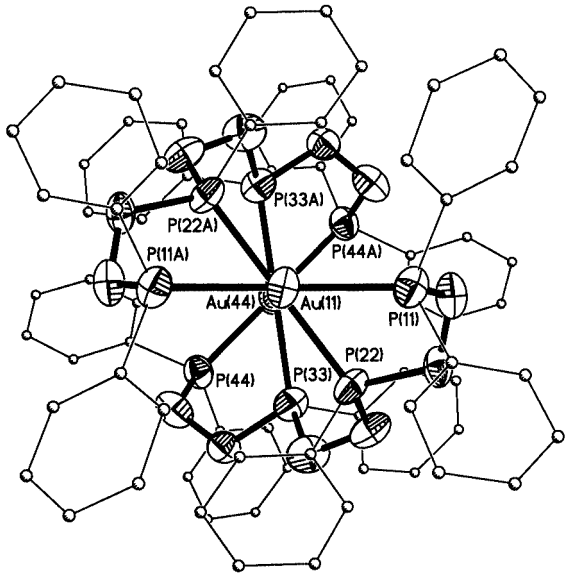

Figure 3. View of the P-$[Au_4(\mu\text{-}(S,S)\text{-p4})_2](OTf)_4$ isomer of the second of two crystallographically independent helicates of **2** along the Au_4 chain

The configuration of the helices is dictated by that of the ligands analogously to **1**: the *R* centers are related to an M helix and the S centers to P. In keeping with the centrosymmetric space group, crystals of **2** are a racemic compound of equal amounts of P and M helices. The helices are nonpalindromic (see Figure 3): the pitch angle of the outer $(Au-P-CC-P)_2$ segments of **2** amounts to 53.2° (mean value), and the inner $(Au-P-CC-P)_2$ segments display a significantly smaller helical twist of 28.6° (mean value). The helical twist in the trinuclear helicate $[Au_3(\mu^3\text{-pp2})_2](OTf)_3$ (pp2 = $PhP(CH_2CH_2PPh_2)_2$] is between 50.66(7)° and 54.57(6)°.[8]

The helicates are unsaturated in view of the gold-gold distances, which all are within the range of Au−Au d^{10}-d^{10} interactions.[9] The separation of the inner Au centers (3.33 Å, mean value) is significantly larger than the contact between inner and outer gold atoms (3.09 Å, mean value).

The stereoselective coordination of the four gold atoms by two ligand strands in **2** is reflected in the symmetry of the complexes in the crystal lattice: The different $[Au_4(\mu^4\text{-}R^*,R^*\text{-p4})_2]^{4+}$ cations in **2** both show internal C_2 symmetry: The twofold axis in one complex is essentially perpendicular to the helical axis bisecting it between the two inner gold atoms; in the other complex it coincides with the Au_4 chain forming the helical axis. Both crystallographically independent cations display idealized D_2 point symmetry. The symmetry of $[Au_4(\mu^4\text{-}R^*,R^*\text{-p4})_2]^{4+}$ in the solid state is remarkable because the existence of different crystallographic symmetry elements in the same helicate seems to be uncommon and because there are no precedents for a twofold symmetry parallel to the helical axis in the space group *C*2/*c*, which is the most frequently occurring space group for helicates.[2]

The crystal packing of **2** is unusual. Because of their cylindrical shape, helicates tend to align themselves along to the helical axis.[2] In contrast, the crystal packing of **2** (Figure 4) produces a sheet of alternatingly parallel and perpendicular helices. Two of the four OTf anions of **2** are located between the terminal gold atoms of one helicate and the two central Au atoms of the neighboring helicates within this sheet; the nearest Au···O and Au···F distances are 3.1 and 3.3 Å, respectively. The sequence of the sheets along *c* is an AB arrangement: In one sheet (A) all helices parallel to the twofold crystallographic axis are built from ligands with an *R*,*R* configuration and the helices perpendicular to the twofold crystallographic axis contain *S*,*S* ligands; the reverse is true for the next sheet (B). The remaining two OTf anions are between the sheets without any contacts to gold atoms.

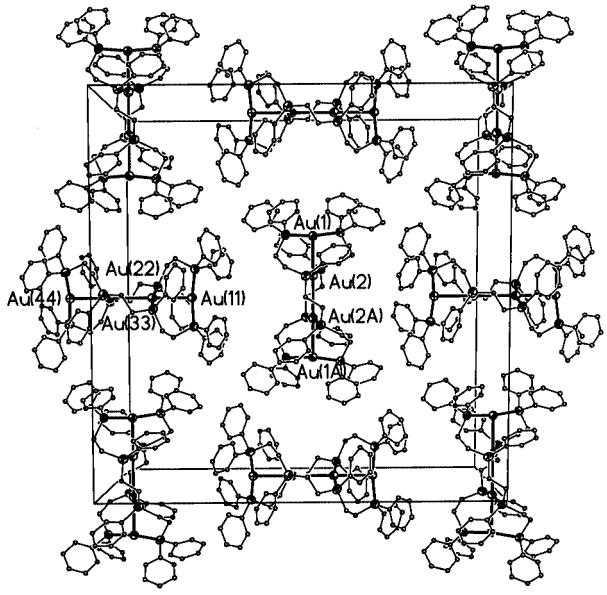

Figure 4. Structure **2** packed along *c*; the anions and solvate molecules have been omitted for clarity

Although the structures of **1** and **2** are essentially different, they display some similarities. The conformation of the substituents of the diagonal phosphorus donor atoms at each gold atom is eclipsed in the view along the P−Au−P axis, the outer phosphorus atoms display a torsion angle C(phenyl)−P−Au−P−C(phenyl) of ca. 0° whereas the inner phosphorus atoms show corresponding angles of approximately 120°. The mean dihedral P−C−C−P angles of the ligand backbone in the different $(Au-P-CC-P)_2$ segments increase in the order 67.9° (**1**, outer segment) < 69.5° (**2**, outer segment) < 104.6° (**2**, inner segment) < 127.14° (**1**, inner segment) and roughly correlate with the Au−Au distances.

Steric reasons may control the formation of helicates or *meso*-helicates: A geometrical extrapolation of $[Au_3(\mu^3\text{-pp2})_2](OTf)_3$ [8] does not exclude the formation of a helical structure from (*R*,*S*)-p4 ligands. In fact, a *meso*-helicate is observed for **1**. Possible factors of strain are different steric requirements concerning the coordination geometry of gold and the conformation of the p4 ligands. A possible indicator of such a strain is that all Au atoms are shifted slightly towards the center of the complex cations (P−Au−P = 173.76−168.0°). This shift is particularly pronounced for the inner gold atoms in compound **2**. Related effects are present in $[Au_3(\mu^3\text{-pp2})_2](OTf)_3$.[8] More data is available on the control of the formation of triple-stranded helicates or *meso*-helicates from achiral ligands. This is related to the rigidity and the form (S or C type) of the ligands, the nature of the spacer (even or odd number of alkylene chains and the chirality of the spacers) and the presence of suitable templates.[10]

Chiral self-recognition has been attributed firstly to the conformational rigidity of the ligand and secondly to the tendency of a more compact structure resulting in maximal intramolecular van der Waals interactions.[4] The first aspect does not apply to the present system in view of the flexibility of the p4 ligand used, whereas the second is thought to control the chiral self-recognition described in this paper.

Experimental Section

The ligand p4 was obtained commercially [(*R**,S*)/(*R**,R*)-(±) ratio ca. 5:1]. Chemical analyses were performed by the Institut für physikalische Chemie, Universität Wien.

Synthesis of 1·2EtOH and 2·2MeOH: A mixture of $Au(SMe_2)Cl$ (58.9 mg, 0.200 mmol), p4 (67.1 mg, 0.100 mmol) and TlOTf (70.7 mg, 0.200 mmol) in MeOH (1 mL) was stirred for 2 h. The TlCl precipitate was removed and the solvent evaporated to a volume of ca. 0.2 mL resulting in a colorless precipitate, which was collected, dried and dissolved in EtOH. Crystals of X-ray quality of **1**·2EtOH were obtained from the first fraction by slow evaporation of this solution. Yield 30 mg (21%, not optimized). $C_{88}H_{84}Au_4F_{12}O_{12}P_8S_4$·2EtOH: calcd. C 39.22, H 3.43; found C 39.1, H 3.3.

The mother liquor mentioned above (MeOH solution) was reduced to a volume of ca. 0.1 mL. Further evaporation of the mother liquor gave X-ray quality crystals of **2**·2MeOH. Yield 6 mg, (4%, not optimized). $C_{88}H_{84}Au_4F_{12}O_{12}P_8S_4$·2MeOH: calcd. C 38.75, H 3.32; found C 38.8, H 3.2.

X-ray Crystallography: The data collection was performed on a Nonius Kappa CCD equipped with graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å) and a nominal crystal-to-area-detector distance of 36 mm. Intensities were integrated using DENZO and scaled with SCALEPACK.[11] Several scans in the φ and ω direction were made to increase the number of redundant reflections, which were averaged over the refinement cycles. This procedure replaces an empirical absorption correction. The structures were solved with direct methods and refined against F^2 using the SHELX program suite.[12,13] Hydrogen atoms were added geometrically and refined using a riding model. All non-hydrogen atoms of compound **1** were refined with anisotropic displacement parameters. In compound **2** nearly all OTf anions and the solvent molecules MeOH are highly disordered and were refined isotropically. Five OTf anions are found in the asymmetric unit, three in a general position and two with occupancy of 0.5 near a crystallographic twofold rotation axis, which passes in a sloping manner through the C−S axis of the OTf anions. Only one OTf anion in a general position is well ordered and could be refined anisotropically. The two others, which are placed between the layers, are 1:1 disordered by a small movement of the complete anion with two common oxygen atoms for both positions. The disorder of these anions leads partly to overlying positions and bond restraints must be used to minimize correlation effects.

CCDC-179094 (**1**·EtOH), -179095 (**1**·2MeOH) and -179096 (**2**·2MeOH) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Four-, Five- and Six-Coordinated Zn^{II} Complexes of OH-Containing Ligands: Syntheses, Structure and Reactivity

Mishtu Dey,[a] Chebrolu Pulla Rao,*[a] Pauli Saarenketo,[b] Kari Rissanen,[b] and Erkki Kolehmainen[b]

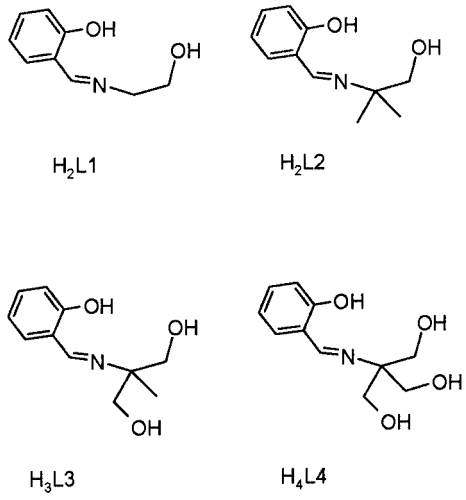
Keywords: N,O ligands / X-ray diffraction / Hydrogen bonds / Metalloenzymes / Zinc

Four-, five- and six-coordinated complexes of Zn^{II} with OH-rich molecules possessing an ONO binding core were synthesized, characterized and their structures were established by single-crystal X-ray diffraction. The corresponding metal ion geometries were found to be distorted tetrahedral, square pyramidal and octahedral, respectively. The complexes exhibit interesting lattice structures such as layered and corrugated sheets owing to the presence of a number of weak intermolecular interactions. The five-coordinated, water-bound Zn^{II} complex was studied because of its putative hydrolysis property towards *p*-nitrophenyl acetate.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Zinc is an essential element for all forms of life and is present at the active site of various enzymes.[1] Zn^{II} is known to exhibit both catalytic and structural roles in its proteins and enzymes.[2−4] The diversity in the functions of Zn^{II} is attributed to its versatile coordination chemistry. Hence, coordination compounds of Zn^{II} are used as biomimetic models.[5−8] It is therefore important to understand how the Zn^{II} center controls the function of metalloenzymes.[9] It may be noted that generally the geometry around the catalytic zinc is distorted and the coordination number varies between four, five and at times even six, along with the presence of labile ligands including a water molecule.[2] While the biological functions of zinc in metalloproteins vary considerably, the active sites exhibit some common structural features.[1] In several zinc enzymes, the metal center is coordinated through the N of histidine and O of aspartic or glutamic acid.[10−12] The role of Zn^{II} in the active centers of hydrolytic metalloenzymes, such as carbonic anhydrase, carboxypeptidase and phosphatase, has constantly been a subject of interest in bioinorganic chemistry.[13−15] Therefore we have chosen a series of hydroxy-rich molecules possessing tridentate ONO donor sites to study their coordination chemistry with Zn^{II}. The coordination behavior of OH-rich molecules has been demonstrated by us in the case of *cis*-VO_2^+, *cis*-MoO_2^{2+} and *trans*-UO_2^{2+} and Ti^{IV}, and by others in the case of iron and manganese, as reported recently in the literature.[16−20] The present paper deals with the results of syntheses, characterization and crystal structure determinations of four-, five-, and six-coordinated Zn^{II} complexes of molecules possessing an ONO core. The ligands used in the study are shown in Scheme 1. A five-coordinated $Zn^{II}-OH_2$ complex was studied for its hydrolytic activity towards *p*-nitrophenyl acetate.



Scheme 1. Schematic representation of the ligands used

Results and Discussions

The reactions of Zn^{II} yielded complexes possessing one or two ligand moieties in its coordination sphere depending

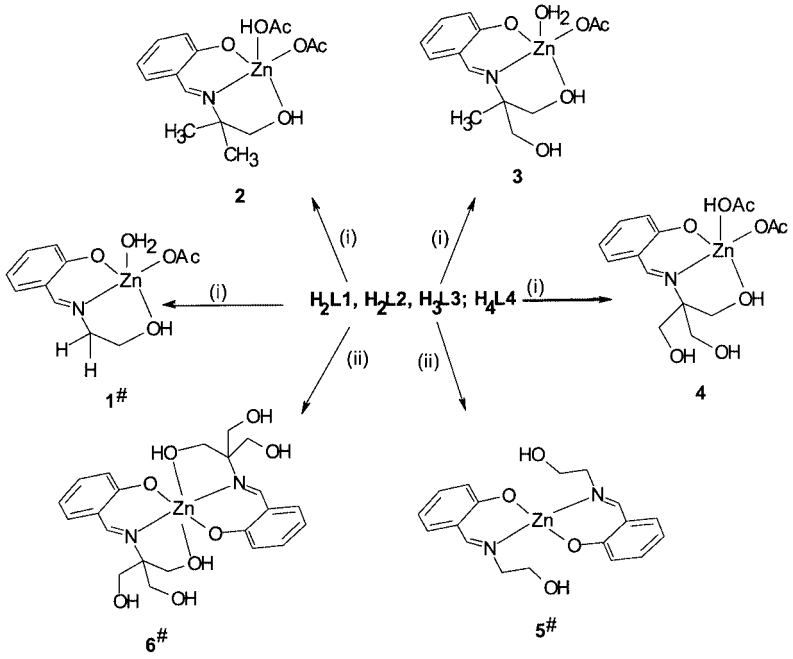

Scheme 2. Zn^{II} complexes of OH-rich molecules; # structure was established by a single crystal XRD study; reaction conditions: (i) $Zn(OAc)_2{\cdot}2H_2O$; Zn/L (1:1), CH_3OH; (ii) $Zn(OAc)_2{\cdot}2H_2O$; Zn/L (1:2), CH_3OH

upon the ratio of metal to ligand (H_2L1 – H_4L4) used (1:1 or 1:2) as shown in Scheme 2. However, H_2L2 and H_3L3 resulted in the formation of the same type of complex, possessing only one ligand per metal ion whether the reaction was carried out in a 1:1 or 1:2 ratio. All the products exhibited similar types of coordination features among the 1:1 reactions no matter how many -OH groups were present in the ligands, H_2L1 (one), H_2L2 (one), H_3L3 (two) and H_4L4 (three). The complexes were all characterized by FTIR, UV/Vis, ^1H and ^{13}C NMR spectroscopy, FAB mass spectrometry, and the structures of **1**, **5** and **6** were also established by single crystal XRD. The crystallographic data is given in Table 1. Further studies were performed on **1** to determine its effect on the hydrolysis of *p*NPA.

IR and UV/Vis Spectra

The IR spectra of the compounds **1**–**6** show ν_{OH} and $\nu_{C=N}$ vibrations at 3321–3390 and 1624–1638 cm^{-1}, respectively and the binding of the imine nitrogen was revealed by the lowering of the frequency (13–15 cm^{-1}). The ν_{asym} and ν_{sym} vibrations of the acetate group were observed in the regions, 1550–1570 and 1407–1445 cm^{-1}, respectively, with $\Delta\nu$ being 105–120 cm^{-1}, suggesting a monodentate binding of the acetate group.[21] These were further confirmed from the single crystal XRD structure of **1**. An intense absorption band around 360 nm, due to the phenolate π-π* transition, was observed in all cases. The π-π* transition associated with the azomethine moiety showed a 10 nm blue shift in the complexes.

^1H NMR Spectroscopic Studies

The phenolic-OH proton signal disappeared from the spectra of all the complexes **1**–**6** due to the binding of this moiety as Ph-O^- to Zn^{II}. The spectra also indicated a downfield shift in the azomethine (–CH=N) proton signal by about 0.2–0.3 ppm, suggesting the binding of this nitrogen to Zn^{II}. Complexes **1**–**4** and **6** exhibited one bound -CH_2OH (δ = 5.2–6.0 ppm, $\Delta\delta$ = 0.5 to 1.3 ppm), **2**, **4** and **6** exhibited one bound -CH_2OH and one or two free -CH_2OH groups (δ = 4.7–5.1 ppm, $\Delta\delta$ = 0.02 to 0.3 ppm), and **5** exhibited one free -CH_2OH (δ = 5.1 ppm). The signal at δ = 1.82 ppm indicates the presence of an acetate moiety in **1**–**4**. Thus, based on ^1H NMR spectra, it was possible to derive the primary coordination about Zn^{II}.

^{13}C NMR Spectroscopic Studies

In **1**–**6** the azomethine (H*C*=N) carbon shifts downfield ($\Delta\delta$ = 6–14 ppm) relative to the corresponding ligand. Downfield shifts were also observed with the tertiary carbon ($\Delta\delta$ = 3–7 ppm) and with the bound -*C*H_2OH signals ($\Delta\delta$ = 0.7–4.2 ppm). In **1**–**4**, the presence of an acetate moiety was identified.

Mass Spectral Studies

The FAB mass spectra of all the complexes showed molecular ion peaks corresponding to their molecular weights as mentioned in the Exp. Sect.. The peak pattern and the intensity ratio confirms the isotopic ratio of M/M + 2/M + 4 peaks as 2.6:1.5:1.

Molecular and Crystal Lattice Structure of 1

Complex **1** is neutral, five-coordinate and has the molecular formula [Zn(HL1)(OAc)(H_2O)], where HL1 acts as a tridentate ligand bound through O_{phen}, O_{alk} and N_{imi} groups. The fourth and fifth coordination sites are occupied

[a] Weighting scheme is as follows: **1:** calcd. $w = 1/[s^2(F_o^2) + (0.0172P)^2 + 1.4009P]$, where $P = (F_o^2 + 2F_c^2)/3$. **5**: calcd. $w = 1/[s^2(F_o^2) + (0.0583P)^2 + 0.8186P]$, where $P = (F_o^2 + 2F_c^2)/3$. **6**: calcd. $w = 1/[s^2(F_o^2) + (0.0275P)^2 + 5.0231P]$, where $P = (F_o^2 + 2F_o^2)/3$.

by an acetate group and a water molecule (Figure 1). The $Zn-O_{phe}$, $Zn-O_{water}$, $Zn-N_{imi}$, $Zn-O_{acetate}$ and $C-O_{acetate}$ distances were found to be consistent with those reported in the literature.[21–24] In **1**, the trans angle [167.5(1)°], the angles in the basal plane [98.0(1) – 143.7(1)°] and the apical to basal angles [76.3(1) – 100.9(1)°], all indicate a distorted square-pyramidal geometry around the Zn^{II} center (Table 2). A $Zn-O_{alk}$ distance of 2.419 Å observed for $Zn-OHCH_2$- binding in **1** is rather long when compared to that generally found in the literature for similar coordination. It is attributable to a weak binding as well as an increase in the coordination number from four to five. It has been noticed from O,N-bound Zn^{II} complexes in the literature that the common coordination number is four and when this number increases the additional coordinations are found to be generally weak with $Zn^{II}\cdots O$ distances ranging from 2.34 to 2.91 Å; the corresponding geometries are highly distorted.[25–29] Such observations include a $Zn^{II}\cdots O_{phosphato}$ distance of 2.71 Å observed in the case of the Zn^{II}-ATP complex[25] (distorted octahedral), $Zn^{II}\cdots O_{carboxylato}$ distances of 2.91 Å and 2.79 Å observed in the case of two Zn^{II}-histidino complexes,[26,27] (distorted octahedral), $Zn^{II}\cdots O_{perchlorato}$ distances of 2.528 and 2.818 Å observed with the two crystallographically independent molecules present in the lattice of a Zn^{II}-triazacyclododecane complex[28] (distorted trigonal bipyramidal), $Zn^{II}\cdots O_{crownether}$ distances of 2.34, 2.56 and 2.60 Å observed in the case of the Zn-crown ether complex[29] (highly distorted trigonal bipyramidal).

Each molecule in the lattice of **1** interacts with three other neighbor molecules via two hydrogen bonds, resulting in a total of six hydrogen bonds. The phenoxy oxygen accepts a hydrogen bond from the $-CH_2OH$ of a neighboring molecule. The Zn^{II}-bound water molecule exhibits two H-bond interactions as donors towards two different neighboring molecules. These H-bonds are accepted by the unbound oxygen of the acetate in the one case and the $-CH_2OH$ group in the other case. Thus, both H_2O and $-CH_2OH$ groups are involved in two H-bonds each (Figure 2). The packing of the molecules in the lattice is reminiscent of a layer type structure where the molecules are arranged to result in columns.

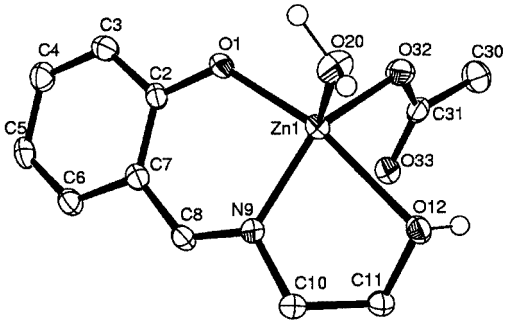

Figure 1. Molecular structure of **1** showing 50% probability thermal ellipsoids (ORTEP)

Molecular and Crystal Lattice Structure of 5

Molecule **5** is neutral, having a molecular formula $[Zn(HL1)_2]$ where each ligand is bidentately bound through O_{phen} and N_{imi} groups, thereby resulting in a distorted tetrahedral geometry around Zn^{II} (Table 2, Figure 3). In this structure, the $-CH_2OH$ groups are not bound to the Zn^{II} center, with $Zn\cdots OH-CH_2$ distances being 3.735 and 4.084 Å. In the crystal lattice of **5**, each Zn^{II} complex is involved in four intermolecular hydrogen bonds with four different

neighbors, of which two are of a donor type and the other two are of an acceptor type. While the O_{phe} acts as an acceptor, the -CH_2OH group acts as a donor in these intermolecular interactions (Figure 4). The lattice structure of **5** shows a corrugated sheet pattern with the presence of channels as shown in Figure 5.

Molecular and Crystal Lattice Structure of 6

Both the H_4L4 ligands act as monoanionic and tridentate binding through the O_{phen}, O_{alk} and N_{imi} groups to result in a distorted octahedral Zn^{II} complex, **6**, with the formula $[Zn(H_3L4)_2]$ (Figure 6). Selected bond lengths and bond angles are shown in Table 2. Of the three -CH_2OH groups, only one is bound to the zinc center (Zn−O distances being 2.259 and 2.315 Å), whereas the other two remain free (Zn−O distances being 4.25 to 5.41 Å); all these -OH groups are involved in hydrogen-bonding interactions in the lattice. In the crystal lattice of **6**, all four of the oxygen atoms of each ligand are involved in hydrogen bond interactions. Compound **6** participates in intermolecular hydrogen bonds of the O−H···O type with five different neighbors in the lattice (Figure 7). While the O_{phe} acts as an acceptor, the -CH_2OH groups act both as a donor and an acceptor. Both of the free CH_2OH groups exhibit two hydrogen bonds each whereas the bound CH_2OH group and O_{phe} exhibit only one hydrogen bond interaction. The lattice MeOH is involved in two H-bond interactions connecting two neighboring zinc complex units. Weak interactions present in all of these complexes exhibited a linear correlation between *d*(D···A) vs. *d*(H···A) as shown in Figure 8.

pH Titration

The potentiometric pH titration curves of H_2L1 in MeOH/water solution in the absence and in the presence of one equivalent of $Zn(OAc)_2$ are shown in Figure 9. A 0.1 M NaOH solution was used to titrate the Zn^{II}-coordinated water. The precursor ligand H_2L1 exhibited one sharp inflection with a pK_a of 9.14 corresponding to the phenolic moiety. On the other hand, the titration of $H_2L1+Zn(OAc)_2$ exhibited two inflection points. The first inflection observed at a pK_a of 6.93 corresponds to the deprotonation of the phenolic-OH followed by formation of a stable complex at pH $>$ 6. This pK_a value for phenolate agrees well with that reported in the literature wherein deprotonation of the phenol was promoted by Zn^{II} coordination, with the pK_a shifting from 9.2 (without zinc) to 6.8 (with zinc).[13] The second inflection point observed at pK_a 8.61 corresponds to the deprotonation of Zn^{II}-bound water in the complex. This value was similar to the pK_a of 8.7 reported for bound H_2O in the case of a macrocyclic tetraamine Zn^{II} complex,[30] a model for carbonic anhydrase. A potentiometric pH titration experiment carried out under similar conditions with the isolated complex **1** also indicated an inflection point at a pK_a of 9.07, corresponding to the deprotonation of the Zn^{II}-bound aquo species.

Kinetics of the Hydrolysis of p-Nitrophenyl Acetate

The kinetics of *p*NPA hydrolysis in the presence and in the absence of zinc complex **1** was studied. The initial rate of the reaction was determined from the slope of a straight line obtained from the plot of the absorbance of *p*-nitrophenolate vs. time. The slope was calculated for the first 10% of the conversion from which the initial rate (v) of the

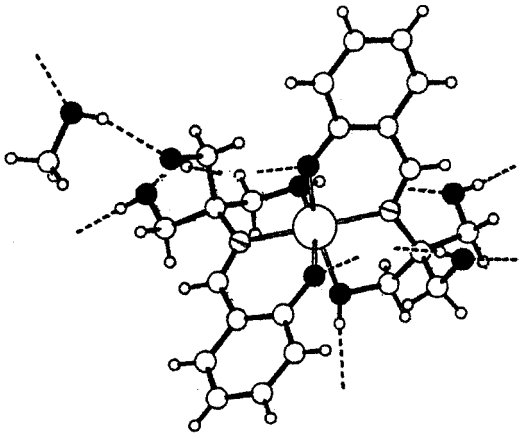

Figure 7. Structure of **6** showing intermolecular hydrogen bond interactions (---); filled circles refer to oxygen, circles with a line refer to nitrogen and the large circles to Zn^{II}

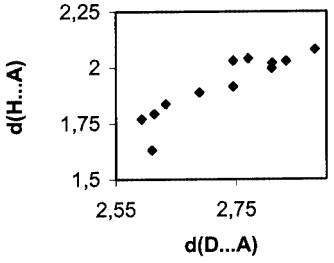

Figure 8. Plot of d(D···A) vs. d(H···A) using the hydrogen bond interaction data obtained in the lattices of **1**, **5** and **6**; d(D···A) and d(H···A) are in Å.

reaction was determined. Thus, these reactions yielded initial rates of 0.183×10^{-4}, 0.80×10^{-4} and 2.28×10^{-4} Ms^{-1} at pH values of 7.2, 8.0 and 9.0, respectively, at 25 °C. The initial rate of hydrolysis increased when the pH of the reaction solution increased, owing to an increase in the concentration of the $Zn-OH^-$ species. The rate of hydrolysis was found to increase to 2.35×10^{-4} Ms^{-1} at 35 °C and pH 8.0 as expected. The experimental results obtained at each stage were compared with the results of the corresponding control experiments.

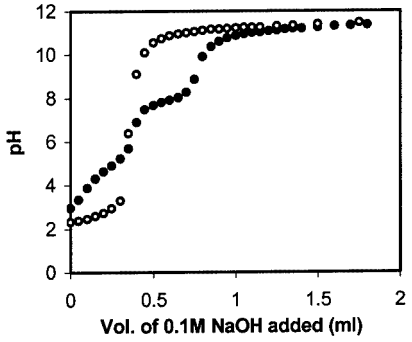

Figure 9. Experimental titration curves of 1.0×10^{-3} M H_2L1 in the presence of 4.0×10^{-3} M HCl in aqueous methanol (33%, v/v) at 25 °C and $I = 0.1$ M ($NaNO_3$); (o) in the absence of Zn^{2+} and (•) in the presence of an equimolar amount of Zn^{2+}

Experiments were also carried out at a fixed concentration of **1** and variable concentrations of *p*NPA (C) and vice versa. The plot of ln v vs. ln C showed that the hydrolysis kinetics is first order with respect to the substrate as well as the zinc complex **1**, and second order overall. The second order rate constants (k_{obs}) were found to be 0.967×10^{-3} and 6.88×10^{-3} $M^{-1}s^{-1}$ at pH 8.0 and 9.0, respectively. Based on the present studies it has been proposed that the water coordinated to the Zn^{II} center plays an important role in the hydrolysis process as indicated in Scheme 3. Four- or five-coordinated mononuclear Zn^{II} complexes of the type $L-Zn-OH_2$ have been used in the literature as model molecules for hydrolytic enzymes.[31,32]

Conclusions

Complexes synthesized from the reaction of Zn^{II} with −OH rich molecules exhibited varied structures and geometry. All these ligands are monoanionic and are bound to the zinc center, either in a bi- or tridentate fashion. This resulted in the formation of distorted geometries of tetrahedral (**5**), square pyramidal (**1**) and octahedral complexes (**6**). Thus, as we go from four- to five- to six-coordinated species, the coordination environment changes from N_2O_2

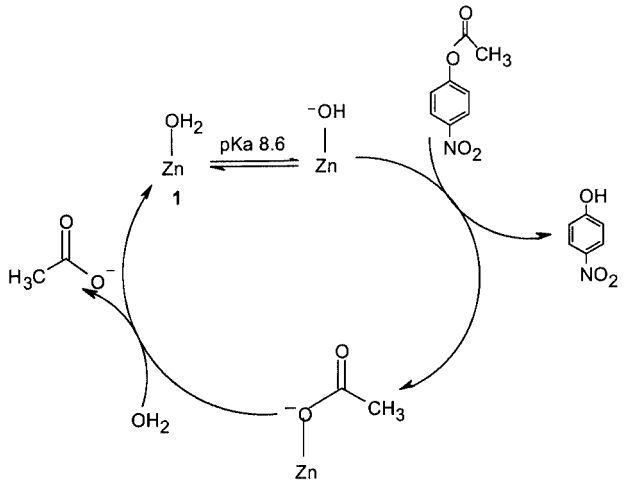

Scheme 3. Possible mechanism for *p*-nitrophenyl acetate hydrolysis by **1**

to NO_4 to N_2O_4 as derived from the crystal structures of **1**, **5** and **6,** respectively. The primary coordination spheres of these complexes are shown in Figure 10 for comparison. The number of chelate rings formed in these complexes increases from two (**5**) to three (**1**) to four (**6**) in the respective complexes. Interestingly, the five-coordinated zinc complex (HL1−Zn−OH_2) (**1**) exhibited an increased rate of hydrolysis of *p*NPA and hence is expected to possess a relationship with the Zn^{II} center, of relevance in zinc hydrolytic enzymes.

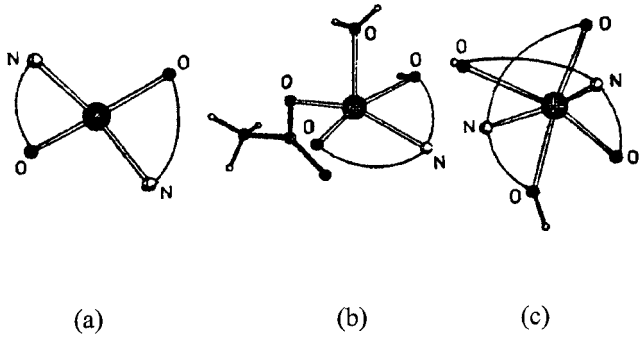

Figure 10. Structures representing primary coordination spheres of **1**, **5** and **6**; (a), (b) and (c) stand for **5**, **1** and **6,** respectively; big circles represent Zn

Experimental Section

General: Elemental analysis was carried out on a Carlo−Erba elemental analyzer. FTIR spectra were recorded on a Nicolet Impact 400 machine in a KBr matrix. UV/Vis spectrophotometric experiments were performed on a Shimadzu UV2101PC instrument equipped with a temperature controlled cell holder (TCC-260). ^1H and ^{13}C NMR spectra were recorded on JEOL JNM GSX-270 FT or Varian XL-300 spectrometer in $(CD_3)_2SO$. The FAB mass spectra were recorded on a JEOL SX 102/DA-6000 Mass Spectrometer/Data System using Argon/Xenon (6 kV, 10 mA) as the carrier gas. The accelerating voltage was 10 kV and the spectra were recorded at room temperature. *m*-Nitrobenzyl alcohol (NBA) was used as the matrix. All the chemicals used were procured from local sources and purified before use. All the solvents were purified and dried immediately before use. All complexes were isolated and purified by recrystallization before performing further studies.

Syntheses

H_2L1: 2-Amino-1-ethanol (1.05 g, 10 mmol) dissolved in MeOH (15 mL) was added to salicylaldehyde (1.0 mL, 10 mmol) in MeOH (15 mL). The reaction mixture was heated to 40 °C for 1 h and then cooled to room temperature followed by concentrating the resulting mixture to a liquid product. FTIR (KBr): $\tilde{\nu}$ = 3411 (ν_{OH}), 1639 ($\nu_{C=N}$) cm^{-1}. ^1H NMR ([D_6]DMSO): δ = 8.50 (s, 1 H, *H*C=N), 7.43 (d, 1 H, Ar *H*), 7.31 (t, 1 H, Ar *H*), 6.87 (m, 2 H, Ar *H*), 4.79 (s, 1 H, CH_2OH), 3.64 (s, 4 H, CH_2OH). The ligands **H_2L2**, **H_3L3** and **H_4L4** were synthesized adopting a similar procedure. The products were obtained as yellow solids by trituration with hexane and were further recrystallized from MeOH and then characterized.[20]

[Zn(HL1)(CH_3COO)(H_2O)] (1): The reaction was carried out using a 1:1 mol ratio of the zinc acetate to the ligand. Zn(acetate)$_2$·$2H_2O$ (0.2195 g, 1.0 mmol) in MeOH (10 mL) was added dropwise to H_2L1 (0.140 mL, 1 mmol) in MeOH (10 mL), and the resultant pale yellow reaction mixture was stirred at room temperature for an hour and then refluxed for 4 h. The reaction mixture was then cooled to room temperature and was concentrated to give a yellow mass, which was triturated with hexane resulting in an off-white product. The crude product was recrystallized from a methanol/hexane mixture (1:2 v/v) resulting in the formation of single crystals of **1** suitable for X-ray diffraction (XRD) studies. Yield: 0.269 g (88%); m.p. 128−132 °C. FTIR (KBr): $\tilde{\nu}$ = 3301 (ν_{OH}), 1638 ($\nu_{C=N}$) cm^{-1}. ^1H NMR ([D_6]DMSO): δ = 8.30 (s, 1 H, *H*C=N), 7.19 (d, 2 H, Ar *H*), 6.60 (d, 1 H, Ar *H*), 6.49 (t, 1 H, Ar *H*), 5.25 (br, 1 H, CH_2OH), 3.54 (m, 4 H, CH_2OH), 1.81 (s, 3 H, CH_3COO) ppm. ^{13}C NMR: δ = 171.5 (H*C*=N), 176.8 (CH_3COO), 170.1, 135.8, 133.9, 122.2, 118.3, 113.1 (six Ar ***C***), 61.4 (CH_2), 60.0 (CH_2OH), 22.6 (CH_3COO). $C_{11}H_{15}NO_5Zn$ (306.6): calcd. C 43.09, H 4.93, N 4.57; found C 42.20, H 4.98, N 4.54%.

[Zn(H_3L4)(CH_3COO)(CH_3COOH)] (2): This compound was synthesized by adopting the procedure given for **1**, except that the ligand used was H_4L4. Yield: 0.445 g (77%); m.p. >200 °C. FTIR (KBr): $\tilde{\nu}$ = 3390 (ν_{OH}), 1638 cm^{-1} ($\nu_{C=N}$). ^1H NMR ([D_6]DMSO): δ = 8.28 (s, 1 H, *H*C=N), 7.14 (m, 2 H, Ar *H*), 6.52 (d, 1 H, Ar *H*), 6.40 (t, 1 H, Ar *H*), 5.99 (br, 1 H, CH_2OH), 5.13 (br, 1 H, CH_2OH), 4.73 (br, 1 H, CH_2OH), 3.47 (s, 6 H, CH_2), 1.82 (s, 3 H, CH_3COO) ppm. ^{13}C NMR: δ = 176.9 (H*C*=N), 170.3 (CH_3COO), 168.3, 136.3, 133.4, 122.3, 118.9, 112.3 (six Ar *C*), 65.4, (*tert C*), 64.6, (CH_2OH), 63.3, (CH_2OH), 23.1, (CH_2OH), 18.4, (CH_3COO). $C_{15}H_{21}NO_8Zn$ (408.7): calcd. C 44.11, H 5.15, N 3.43; found C 44.40, H 4.90, N 3.50. FAB MS: *m*/*z* = 409 (10) [M^+].

[Zn(HL2)(CH_3COO)(H_2O)] (3): Compound **3** was synthesized by adopting the procedure given for **1** but using H_2L2. Yield: 0.240 g (72%); m.p. >200 °C. FTIR (KBr): $\tilde{\nu}$ = 3231, (ν_{OH}), 1634 cm^{-1} ($\nu_{C=N}$). ^1H NMR ([D_6]DMSO): δ = 8.38 (s, 1 H, *H*C=N), 7.21 (d, 1 H, Ar *H*), 7.12 (t, 1 H, Ar *H*), 6.56 (d, 1 H, Ar *H*), 6.42 (t, 1 H, Ar *H*), 5.76 (s, 2 H, CH_2OH, CH_3OH), 3.42 (s, 2 H, CH_2OH), 1.82 (s, 3 H, CH_3COO), 1.20 (s, 6 H, CH_3), 1.09 (s, 3 H, CH_3) ppm. ^{13}C NMR: δ = 170.2 (H*C*=N), 177.9 (CH_3COO), 167.0, 136.3, 133.9, 122.5, 119.3, 113.4 (six Ar C), 68.1 (*tert C*), 60.8 (CH_2OH), 53.4 (CH_3OH), 24.9 (CH_3COO), 24.0, 23.6 (CH_3) ppm. $C_{13}H_{19}NO_5Zn$ (334.7): calcd. C 46.66, H 5.72, N 4.19; found C 46.41, H 5.86, N 4.17. FAB MS: *m*/*z* = 334 (50) [M^+].

[Zn(H$_2$L3)(CH$_3$COO)(CH$_3$COOH)] (4): Compound **4** was synthesized by adopting the procedure given for **1** with the use of H$_3$L3. Yield: 0.354 g (65%); m.p. >200 °C. FTIR (KBr): $\tilde{\nu}$ = 3388 (ν_{OH}), 1637 cm^{-1} ($\nu_{C=N}$). ^{1}H NMR ([D$_6$]DMSO): δ = 8.29 (s, 1 H, *H*C=N), 7.16 (m, 2 H, Ar *H*), 6.57 (d, 1 H, Ar *H*), 6.46 (t, 1 H, Ar *H*), 5.40 (br, 1 H, CH$_2$O*H*), 4.82 (br, 1 H, CH$_2$O*H*), 3.43 (d, 4 H, C*H*$_2$OH), 1.82 (s, 3 H, C*H*$_3$COO), 1.16 (s, 3 H, C*H*$_3$) ppm. ^{13}C NMR: δ = 177.0 (H*C*=N), 170.3, (CH$_3$*C*OO), 167.9, 136.2, 132.7, 122.3, 118.8, 112.5 (six Ar *C*), 65.4, (*tert C*), 64.6, (*C*H$_2$OH), 63.4 (*C*H$_2$OH), 23.2 (CH$_3$COO), 17.9 (CH$_3$). C$_{15}$H$_{21}$NO$_7$Zn (392.6): calcd. C 45.89, H 5.39, N 3.57; found C 46.29, H 5.42, N 4.00. FAB MS: *m*/*z* = 392 (20) [M$^+$].

[Zn(HL1)$_2$] (5): This reaction was carried out using a 1:2 mol ratio of zinc acetate to ligand. Zn(acetate)$_2$·2H$_2$O (0.5 mmol, 0.110 g) in MeOH (25 mL) was added to H$_2$L1 (1 mmol, 0.140 mL) in MeOH (10 mL), and the resultant golden-yellow solution was refluxed for 4 h and then cooled to room temperature. The solvent was removed under vacuum and the resultant yellow residue was redissolved in MeOH (3 mL) and kept at room temperature, whereupon **5** separated out. Single crystals of **5** suitable for X-ray diffraction studies were grown from the methanolic solution of the product. Yield: 0.357 g (91%); m.p. 210−212 °C. FTIR (KBr): $\tilde{\nu}$ = 3328 (ν_{OH}), 1624 cm^{-1} ($\nu_{C=N}$). ^{1}H NMR ([D$_6$]DMSO): δ = 8.38 (s, 1 H, *H*C=N), 7.23 (m, 2 H, Ar *H*), 6.62 (m, 1 H, Ar *H*), 6.53 (m, 1 H, Ar *H*), 5.05 (s, 1 H, CH$_2$O*H*), 3.59 (m, 4 H, C*H*$_2$OH) ppm. ^{13}C NMR: δ = 172.0 (H*C*=N), 170.1, 135.9, 134.1, 122.2, 118.3, 113.4 (Ar *C*), 61.9 (*C*H$_2$OH), 59.9 (*C*H$_2$) ppm. C$_{18}$H$_{20}$N$_2$O$_4$Zn (393.7): calcd. C 54.91, H 5.12, N 7.12; found C 55.40, H 5.21, N 6.74. FAB MS: *m*/*z* = 393 (70) [M$^+$].

[Zn(H$_3$L4)$_2$] (6): A similar procedure was adopted for synthesizing compound **6** using the ligand H$_4$L4. Crystallization of the crude product from methanol resulted in single crystals of **6** suitable for XRD studies. Yield: 0.333 g (65%); m.p. >200 °C. FTIR (KBr): $\tilde{\nu}$ = 3333 (ν_{OH}), 1625 cm^{-1} ($\nu_{C=N}$). ^{1}H NMR ([D$_6$]DMSO): δ = 8.35 (s, 1 H, *H*C=N), 7.10 (m, 1 H, Ar *H*), 6.77 (d, 1 H, Ar *H*), 6.41 (d, 2 H, Ar *H*), 5.16 (br, 1 H, CH$_2$O*H*), 4.74 (br, 1 H, CH$_2$O*H*), 4.11 (br, 1 H, CH$_2$O*H*), 3.62 (s, 6 H, C*H*$_2$) ppm. ^{13}C NMR: δ = 170.1 (H*C*=N), 168.9, 136.2, 132.1, 122.3, 118.5, 112.0 (Ar *C*), 67.1 (*C*H$_2$OH), 61.5 (*C*H$_2$OH), 61.4 (*C*H$_2$OH), 48.6 (*tert-C*) ppm. C$_{22}$H$_{28}$N$_2$O$_8$Zn (513.9): calcd. C 51.43, H 5.49, N 5.45; found C 51.16, H 6.07, N 4.73. FAB MS: *m*/*z* = 513 (95) [M$^+$].

However, when 1:2 reactions were carried out using ligands H$_2$L2 and H$_3$L3 the products obtained were similar to the products of the 1:1 reaction (**3** and **4**).

Potentiometric pH Titration

Titrations were carried out at 25 ± 0.2 °C by means of a Control Dynamics pH meter with a combined glass electrode. The electrode was calibrated using standard aqueous buffers immediately before use. Solutions were made of aqueous methanol (33%, v/v) and the ionic strength was adjusted to 0.1 M using NaNO$_3$. A solution of H$_2$L1 (1.00 mM) with four equivalents of HCl (4.00 mM) in the absence and in the presence of one equivalent of zinc(II) ion was titrated with 0.1 M NaOH aqueous solution. For the titration, every increment of NaOH (50 μL) was added with an equilibration time of 60 s after each addition.

Hydrolysis of *p*-Nitrophenyl Acetate (*p*NPA): The hydrolysis rate of *p*NPA in the presence of [Zn(HL1)(acetate)(H$_2$O)] (**1**) was measured by an initial-slope method following the absorbance increase in the 400 nm band of the released *p*-nitrophenolate species at 25 °C. Such experiments were carried out at a solution pH of 7.2, 8.0 and 9.0 and these were maintained using tris(hydroxymethyl)-aminomethane (20 mM) with an ionic strength of 0.1 mM KNO$_3$. To increase the solubility of *p*NPA, 10% CH$_3$CN/H$_2$O solution was used. In a typical experiment, *p*NPA (c = 0.02−0.5 mM) and the complex, [Zn(HL^1)(acetate)(H$_2$O)] (c = 0.01−0.1 mM) in 10% CH$_3$CN/H$_2$O solution, were mixed at the appropriate pH (the control experiment does not contain the Zn^{II} complex) and the UV/Vis absorption spectra were measured as a function of time until no substantial increase was observed in the absorbance of the 400 nm band. Hydrolysis of *p*NPA was also studied at 35 °C at pH 8.00. Initial slopes were determined from the plots of the measured absorbance at 400 nm versus time.

X-ray Crystallography: Diffraction data were collected for **1** and **6** on a Nonius Kappa CCD machine in the φ scan + ω scan mode (Mo-K_α) and data for **5** were collected on a MACH3 detector in the psi scan mode (Cu-K_α). The structures were routinely solved using SHELXS 97/SIR92 and refined using the SHELXL 97 program packages.[33,34] The diagrams were generated using the ORTEP 3 and PLUTON 98 programs.[35] The data were corrected for empirical absorption. Full-matrix least-squares refinement with anisotropic thermal parameters for all non-hydrogen atoms was used. The hydrogen atoms were treated as riding atoms with fixed thermal parameters. Other details of data collection and structure refinement are provided in Table 1.

CCDC-183936 (**1**), -183937 (**5**) and -183938 (**6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Dedicated to Prof. Joseph Grobe on the occasion of his 70th birthday

Keywords: Copper / Sulfur heterocycles / Phosphane ligands

While the reaction of benz-1,3-imidazole-2-thione ($bzimtH_2$) or benz-1,3-thiazole-2-thione (bztztH) with copper(I) iodide in the presence of two equivalents of triphenylphosphane led to mononuclear complexes of the type $[CuI(PPh_3)_2(L)]$, the reaction of benz-1,3-imidazole-2-thione with copper(I) chloride gave a dimeric complex $[CuCl(PPh_3)(bzimtH_2)]_2$. These three compounds were characterized by IR, UV/Vis, and ^1H NMR spectroscopy, and the crystal structures determined by single-crystal X-ray diffraction methods. Vibrational, electronic, and ^1H NMR spectroscopic data of the complexes are discussed in relation to the structures.

Introduction

The great interest, currently in copper(I) coordination chemistry is due to the participation of this cation in certain biochemical redox reactions,[1] and also because of its ability to adopt various coordination modes.[2] With tertiary phosphanes as ligands, copper(I) halides produce complexes with ligand to copper halide ratios 2:1, 2:2, 3:1, 3:2, 4:2, and 4:4, with the geometry normally being determined by steric rather than by electronic properties of the phosphane ligands.[3]

During our previous work on the interaction of univalent group IB metal cations with biologically interesting molecules, a number of mixed-ligand coordination compounds of copper(I) halides with heterocyclic thiones and triarylphosphanes were prepared and structurally characterized.[4,5] In these complexes, the neutral thione molecules with both nitrogen and sulfur as donating atoms always adopted the monodentate coordination mode, binding the metal centres exclusively through the exocyclic sulfur atom in a terminal or bridging mode. Nonetheless, a remarkable variety of structures ranging from mononuclear three or four-coordinate species with trigonal planar and tetrahedral Cu(I), respectively, to dimers with pseudo-tetrahedral geometry formed by bridging halogen or thione ligands was obtained, even within a closely related series of thione ligands.[6]

As for the factors governing the stoichiometric and structural preferences of these complexes, the bulk of the ligands seemed to be the main factor that determined the coordination number of the metal atom, since the steric demands of the *ortho*-methyl groups clearly lead to three-coordination in the copper(I) halide complexes of tri-*o*-tolylphosphane.[6] On the other hand, the interplay of several other parameters like the geometrical flexibility of the coinage metals, electronic properties on the part of the ligands, as well as the preparation conditions might also be expected to be of major importance, causing significant changes to the coordination geometry of the metal atom. Thus, for example, the cause of dimerization as well as the reasons for the formation of two different types of binuclear copper(I) halide complexes of general formula $[CuX(PR_3)thione]_2$, in which the two copper centers are linked either by a double halide or by a double thione-sulfur bridge, are still not fully understood. On the basis of our earlier observations on dimeric species of the above-mentioned type, the coordination

behavior (terminal or bridging mode) of each ligand seems to depend on the nature of the halogen present. In particular, formation of halogen-bridges has been found to be preferred for the "soft" iodine but not for the "harder" chlorine base,[7,8,9] whereas both bridging and terminal bonding modes were observed for bromo ligands[10,11] since bromide lies on the borderline between soft and hard. However, the information obtained so far is insufficient to establish the above supposition, so we now report on the synthesis and X-ray crystal structure of three novel copper(I) halide complexes in an attempt to obtain further insight into this problem.

Results and Discussion

General Considerations

The complexes were prepared by reacting equimolar quantities of copper(I) halide and triphenylphosphane (PPh_3) followed by the addition of one equivalent of the appropriate thione (L) in dry acetonitrile solution. This procedure, frequently used for the preparation of copper(I) halide complexes containing both heterocyclic thiones and triphenyl- or tritolylphosphane ligands, gave, in the case of copper(I) iodide, the monomeric complexes $[CuI(PPh_3)_2(bzimtH_2)]$ (**1**) and $[CuI(PPh_3)_2(bztztH)]$ (**2**). In contrast, copper(I) chloride, used exactly in the same manner, gave the dimer $[CuCl(PPh_3)(bzimtH_2)]_2$ (**3**) with the two copper centres being double bridged by the thione-S atom.

Crystals of the complexes, prepared by slow evaporation of the solution remaining after filtration of the initial product deposited from the reactions, were coloured solids, soluble in chloroform, methanol, ethanol, acetone, and acetonitrile. They were stable to air and moisture, and could be manipulated in air after their isolation without appreciable decomposition. Their solutions were non-conducting in acetone and chloroform. Room temperature magnetic measurements confirmed the diamagnetic nature of the compounds.

The electronic absorption spectra of the three complexes in chloroform, which are very similar, are dominated by two broad bands with maxima at 240 nm and in the 310−340 nm region. The first one can be attributed to intraligand transitions of the phosphane ligand, since the uncoordinated triphenylphosphane reveals a strong absorption at 245 nm, which usually remains non-shifted upon coordination to Cu^I.[12,13] The lower energy band lies in the region where the free thiones absorb, expressing a small red shift as a consequence of the coordination to Cu^I and should therefore be considered as a thione-originating intraligand transition with some MLCT character.[12,13]

The infrared spectra of the compounds, recorded in the range 4000−250 cm^{-1} show, apart from the existence of strong phosphane bands, the usual four "thioamide bands" required by the presence of the heterocyclic thione ligands, as well as the characteristic NH stretching vibrations observed in the 3050−3160 cm^{-1} region. The shifts observed for these bands due to coordination (upward shifts of 15−35 cm^{-1} for thioamide I, downward shifts of 10−30 cm^{-1} for thioamide II and III) in combination with the lack of ν(SH) bands at ca. 2500−2600 cm^{-1}, signify the exclusive S-coordination mode of the thione ligands.

The prevalence of the thione tautomer in the complexes is further confirmed by the ^1H NMR spectra of the compounds, which display, apart from the signals expected for the phosphane and thione ligands, a single resonance at $\delta \approx 12-14$, attributed to the NH proton.

Description of the Structures

$[CuI(PPh_3)_2(bzimtH_2)]$ (1) and $[CuI(PPh_3)_2(bztztH)]$ (2)

The main bond lengths and angles for compounds **1** and **2** are given in Tables 1 and 2. Molecular plots showing the atom numbering schemes are shown in Figures 1 and 2, re-

spectively, and details of the hydrogen bonding are shown in Table 3. Both complexes are mononuclear with the copper atom being surrounded by two P, one S, and one I atom in a distorted tetrahedral coordination. It should be noted that copper(I) iodide usually tends to form dimeric complexes with two iodine atoms serving as bridges between the two copper atoms, while only one single representative of mononuclear species with a $CuIP_2S$ core exists among the structures characterized by us so far.[5] The largest deviation from the ideal geometry is reflected by the P−Cu−P angles with values of 122.45(4)° (**1**) and 125.33(2)° (**2**). These higher angles are counterbalanced by the bond angles I−Cu−P(1), I−Cu−P(2), S−Cu−P(1), and S−Cu−P(2), whose values are all lower than the tetrahedral value of 109.4°. This tetrahedral distortion may be attributed to steric interactions between the bulky phosphane ligands, which is common among a large series of monomeric copper(I) halide complexes containing one heterocyclic thione

[a] Atom coordinates transposed by: **i**: x, 0.5 − y, 0.5 + z; **ii**: −1 + x, y, z; **iii**: 1 − x, 1 − y, 1 − z; **iv**: −x, 1 − y, −z; **v**: 1 + x, y, z.

slightly shorter than those found in [CuI(PPh_3)$_2$(pymtH)]. This represents, according to the Cambridge Structural Database, a unique known structure of a monomeric, tetrahedrally coordinated copper(I) iodide complex with terminal iodine and thione-sulfur donors.[5] These bond lengths all lie within the range of the corresponding values previously reported for a number of related tetracoordinated copper(I) complexes.

[CuCl(PPh_3)(bzimtH$_2$)]$_2$ (3)

The asymmetric unit of the crystal cell contains two half-molecules. The atoms in molecule **3a** are Cu1, S1, Cl1, C1−C25, H1, H2, H3A, H4A, H5−H24, and their equivalent primed atoms. The atoms in molecule **3b** are Cu2, S2 Cl2, N3, N4, C26−C50, H3, H4, H26−H50, and their equivalent primed atoms. The main bond lengths and angles for both molecules are given in Table 4, and an ORTEP view of molecule **3a** showing the atom numbering is given in Figure 3. There are some significant differences in bond lengths and angles between the two molecules which will be mentioned in the subsequent discussion. The basic structural unit of [CuCl(PPh_3)(bzimtH$_2$)]$_2$ is a dimer in which the two copper atoms are doubly bridged by two S atoms of the thione ligands to form a strictly planar four-membered Cu_2S_2 core. The slightly distorted tetrahedral coordination around copper is completed by one P atom from the phosphane ligand and one chlorine atom.

Three structurally determined analogues, [CuCl(tmtp)(bzimtH$_2$)]$_2$ (tmtp = tri-*m*-tolylphosphane), [CuCl(tptp)(tzdtH)]$_2$ (tptp = tri-*p*-tolylphosphane, tzdtH = 1,3-thiazolidine-2-thione), and [CuCl(tptp)(pmtH)]$_2$ (pmtH = pyrimidine-2-thione) will be used for the subsequent comparative discussion (hereafter referred to as complexes **A**, **B**, and **C**, respectively).

Each of the two non-equivalent Cu−S bonds of 2.332(2) and 2.555(3) Å in **3a** and 2.322(3) and 2.448(3) Å in **3b**, respectively, are within the range expected for binuclear Cu^{I} complexes with double bridging sulfur atoms. The asymmetry in the two bridging distances in molecule **3a**, however, is remarkably larger than in the three already known analogues. As in the other dimers, the two bulky phosphane ligands are *trans* disposed with a Cu−P bond length of 2.236(3) Å, somewhat longer than the values observed in **B** and **C**, but clearly shorter than the "long" one [2.251(1) Å] in **A**. Likewise, the Cu−Cl bond length of 2.347(2) Å in **3a** and 2.357(2) Å in **3b**, lies well above the corresponding values 2.283(1) and 2.300(1) Å found in **C** and **B**, but is significantly shorter than that in **A** [2.391(2) Å]. As previously demonstrated, this Cu−Cl bond appears to be associated with the S−Cu−S angle, namely an opening up of the S−Cu−S angle from 92.48(2)° in **B** to 93.24(2)° in **C** and 110.2(1)° in **A** results in an elongation of the Cu−Cl bond.[16] As for the complex under consideration, it fits well into the above mentioned series, even when the mean values for the Cu−Cl bond length and the S−Cu−S angle for **3a** and **3b** are taken into consideration.

The S−Cu−S and Cu−S−Cu angles [106.79(7) and 73.21(7)° for **3a** and 104.38(8) and 75.62(8)° for **3b**], which are close to the ideal values (109.5 and 70.5°) for symmetric dimers, deviate significantly from those found in **B** and **C**, but are not far from those observed in **A**. The value of the Cl−Cu−S angle of 102.10(10)° in **3b** is similar to the corresponding values observed in the previous complexes **B** and **C**, whereas the same angle in **3a** [93.06(8)°] is strongly distorted and very close to that observed in complex **A**. Finally, the value of the P−Cu−Cl angle of 114.53(9)° in **3a** is similar to the corresponding values observed in the previous complexes **A**, **B**, and **C**, but the same angle in **3b** is surprisingly much smaller [105.96(10)°].

Computational Study

It is generally accepted that the local metal environment in monovalent copper coordination compounds is mainly determined by steric effects as well as by the Lewis basicity of the ligands, but additional considerations may be useful in explaining the situation in some specific cases. The dimerization often realized in copper(I) halide complexes containing heterocyclic thione and triarylphosphane ligands as well as the bridging or terminal bonding mode of each ligand in such dimers, for instance, are of unknown origin. The contribution of electronic factors, however, is suspected to be important. The computations performed in the present paper are an attempt to unravel any such electronic factor.

The lowest unoccupied molecular orbitals (LUMO) for **3A** and **3B** are 3.346 eV and 3.349 eV higher, respectively, than their highest occupied molecular orbitals (HOMO), while the LUMO energies in complexes **2** and **1** are higher than their HOMO energies by 3.518 and 3.432 eV, respect5-ively. This indicates that the monomers are more stable than the dimers. An overlap population of 0.005 e in **3A** and 0.001 e in **3B** between the two metal centres, which are separated by 2.919(2) Å and 2.943(2) Å, respectively, has been calculated for the dimeric structures, whereby the corresponding value for $CuI(pytH)(tmtp)]_2$,[9] with a Cu···Cu distance of 3.119(1) Å, was found to be 0.006 e. The bonding nature of these metal−metal interactions is, of course, too small to be considered as the crucial factor for the domination of the dimeric structures. The stabilizing effect of a metal−metal interaction could be important only for Cu···Cu separations below the value of 2.80 Å proposed to be the sum of two copper covalent van der Waals radii. In the case of $[CuCl(bztzdtH)(tmtp)]_2$ or $[CuBr(pytH)(tmtp)]_2$,[16] where the Cu···Cu distances are 2.764 and 2.691 Å (both shorter than the sum of the copper−copper van der Waals radius by 0.046 and 0.109 Å, respectively), the corresponding overlap populations are 0.019 e and 0.026 e.

The calculated overlap populations for the Cu(1)−S(1) and Cu(1)−S(1)[1] bonds in **3** are 0.384 e and 0.178 e, respectively. The calculated overlap populations for the Cu(1)−P(1) and Cu(1)−Cl(1) bonds are 0.607 and 0.330 e, respectively. The calculated overlap populations, for the Cu(1)−I(1) and Cu(1)−S(1) bonds are 0.244 and 0.348 e, respectively, in complex **2** and 0.255 and 0.344 e in complex **1**, while the values for the overlap population calculated for the two Cu(1)−P(1) and Cu(1)−P(2) bonds are 0.566 and 0.565 e in complex **2** and 0.561 and 0.571 e, respectively, in complex **1**.

Conclusion

The coordination chemistry of copper(I) with heterocyclic thiones and tertiary phosphanes as ligands offers opportunities for the detailed examination of the factors governing the stereochemical preferences of copper(I) compounds. According to our previous investigations, the stoichiometry may be one of these factors, especially in association with the solvent used for the preparation. The three new copper(I) complexes investigated in this work were prepared in an acetonitrile/methanol mixture, whereby two different types of structures were formed, tetrahedral monomeric and pseudo-tetrahedral dimeric with the halogen acting as bridging ligand. However,

since the softness of the halogen decisively affects its donor properties, reaction stoichiometry and solution media cannot be considered as the only reason for the structural preferences of copper(I), at least in the case of complexes investigated in this work. Consequently, this phenomenon needs more extensive studies in consideration of further structures of this series. Finally, extended Hückel calculations could not provide any evidence for significant interaction between the two copper(I) centres, despite the short Cu−Cu distance, in the case of the dimeric complex $[CuCl(PPh_3)(bzimtH_2)]_2$ (**3**).

Experimental Section

Materials and Instruments: Copper(I) chloride, copper(I) iodide, and all solvents are commercially available and were used as obtained, while the thiones (Merck or Aldrich) were recrystallized from hot ethanol prior to their use. Elemental analyses for C, H, N, and S were carried out with a Carlo erba EA MODEL 1108. Melting points were measured in open tubes with a STUART scientific instrument and are uncorrected. Infra-red spectra in the region of 4000−370 cm^{-1} were obtained in KBr discs while far-infrared spectra in the region of 400−50 cm^{-1} were obtained in polyethylene discs, with a Perkin−Elmer Spectrum GX FT-IR spectrometer. A Jasco UV/Vis/NIR V 570 series spectrophotometer was used to obtain the electronic absorption spectra.

Computational: Extended Hückel calculations were performed using the CACAO program.[17] The calculations were carried out using crystallographic data from the studied molecules. The EHT parameters for Cu were those established in the literature.

Synthesis of the Complexes: The complexes were prepared according to the following general procedure. A suspension of copper(I) halide (0.5 mmol) and triphenylphosphane (132 mg, 0.5 mmol) in 10 cm^3 of acetonitrile was stirred until a white precipitation of the intermediate $[Cu_nX_n(PPh_3)_m]$ (X = Cl or I) complex was formed. A solution of the appropriate thione (0.5 mmol beznimidazoline-2-thione (bzimtH) or benzthiazoline-2-thione (bztzdtH) in methanol was then added and the new suspension was stirred until clear (15 min). The resulting solution was filtered off and the clear solution was kept in darkness at room temperature. After 24 hours, crystals of the complexes suitable for single crystal analysis by X-ray crystallography were obtained by filtration.

$[CuI(PPh_3)_2(bzimtH)]$ (1): Pale yellow crystals. Yield 340 mg (72%), m.p. 221−222 °C; $C_{43}H_{36}CuIN_2P_2S{\cdot}CH_3OH{\cdot}0.85CH_3CN{\cdot}0.27H_2O$: C 59.36, H 4.77, N 4.42; found C 59.55, H 4.63, N 4.30%. IR $\tilde{\nu}$ (cm^{-1}): 3050 w, 1619 m, 1493 s, 1434 vs, 1161 s, 1093 s, 742 vs, 694 vs, 603 s, 517 vs, 490 vs; far-IR $\tilde{\nu}$ (cm^{-1}): 218 m, 200 m, 174 s, 162 s, 151vs, 146 m, 121 s. UV-Vis, λ_{max} (logε), $CHCl_3$: 241 (4.373), 310 (4.412).

$[CuI(PPh_3)_2(bztzdtH)]$ (2): Orange crystals. Yield 335 mg (76%), m.p. 218−219 °C; $C_{43}H_{35}CuINP_2S_2$: C 58.54, H 3.99, N 1.59; found C 58.84, H 3.88, N 1.70%. IR $\tilde{\nu}$ (cm^{-1}): 3052 w, 1488 s, 1424 vs, 1322 s, 1094 s, 1029 s, 743 vs, 695 vs, 515 vs, 503 vs; far-IR $\tilde{\nu}$ (cm^{-1}): 219 m, 205 m, 200 m, 174 s, 164 s, 151 vs, 146 m, 121 s. UV-Vis, λ_{max} (logε), $CHCl_3$: 243 (4.471), 329.5 (4.304).

$[CuCl(PPh_3)(bzimtH)]_2$ (3): Pale yellow crystals. Yield 395 mg (77%), m.p. 249−250 °C; $C_{50}H_{42}Cl_2CuN_2P_2S_2$: C 58.71, H 4.13, N 5.48; found C 58.79, H 4.01, N 5.52%. IR $\tilde{\nu}$ (cm^{-1}): 3193 m, 3053 s, 1502 vs, 1459 vs, 1446 s, 1179 vs, 1095 s, 743 vs, 694 vs, 598 s, 520 vs, 501 vs; far-IR $\tilde{\nu}$ (cm^{-1}): 217 w, 200 w, 174 s, 163 s, 151 vs, 146 m, 121 s. UV-Vis, λ_{max} (logε), $CHCl_3$: 240.5 (4.358), 310.5 (4.530).

X-ray Crystallographic Study: The unit cell and intensity data were collected on a Delft Instruments FAST diffractometer using the routines ENDEX, REFINE, and MADONL in the MADNES software suite[18] and processed using ABSMAD;[19] detailed procedures are described by Darr, Drake, Hursthouse, and Malik.[20] Absence of crystal decay in the X-ray beam was confirmed by checking equivalent reflections at the beginning and end of data collection, which lasted about 8 hours. The structures were solved with SIR92[21] and refined with SHELX93.[22] Details are given in Table 5. The copper, bromine, chlorine, iodine, sulfur, phosphorus, nitrogen, and carbon atoms were refined with anisotropic temperature factors. The hydrogen atoms were allowed to ride on their attached atoms with common isotropic temperature factors for methyl and non-methyl hydrogens. An absorption correction was made with DIFABS.[23]

CCDC-174528 (**1**), -174529 (**2**), and -174526 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Half-Sandwich Complexes with Aminocarboxylate Ligands and Their Use as Enantioselective Hydrogen Transfer Catalysts

Daniel Carmona,*[a] María Pilar Lamata,[b] and Luis A. Oro[a]

Keywords: Chiral-at-metal complexes / Asymmetric hydrogen transfer catalysis / Rhodium / Ruthenium / Iridium / Osmium / Aminocarboxylate ligands

Chiral-at-metal half-sandwich complexes of rhodium, iridium, ruthenium, or osmium of the general formula [(η^n-ring)M(Aa)Cl] [(η^n-ring)M = (η^5-C_5Me_5)Rh, (η^5-C_5Me_5)Ir, (η^6-*p*-MeC_6H_4*i*Pr)Ru, (η^6-*p*-MeC_6H_4*i*Pr)Os; Aa = L-α-aminocarboxylate] can readily be prepared from the corresponding dimers [{(η^n-ring)MCl}$_2$(μ-Cl)$_2$]. The compounds have been prepared as diastereomeric mixtures of the two epimers at the metal center. In general, alkynyl aminocarboxylate derivatives [(η^n-ring)M(Aa)(C≡CR)] are obtained by treating the aforementioned chlorides with the corresponding alkynes in basic media. However, the reaction of the (alaninato)rhodium chloride [(η^5-C_5Me_5)Rh(Ala)Cl] with the alkynes HC≡CR (R = Ph, *p*-tolyl) produced the alkynylcyclobutadiene complexes [(η^5-C_5Me_5)Rh(η^4-C_4HR_2C≡CR)] (R = Ph, *p*-tolyl). Treatment of the chlorides [(η^n-ring)M(Aa)Cl] with $AgBF_4$ afforded the cationic trimers [{(η^n-ring)M(Aa)}$_3$](BF_4)$_3$. Trimerization occurs with chiral self-recognition: only the (*R*,*R*,*R*) or (*S*,*S*,*S*) configuration at the metal trimers can be detected. The trimers [{(η^n-ring)M(Aa)}$_3$](BF_4)$_3$ reacted with tertiary phosphanes, leading to the cationic mononuclear complexes [(η^n-ring)M(Aa)(PR_3)](BF_4). The assignment of the configuration at the metal center was accomplished by X-ray diffraction, circular dichroism and NMR spectroscopy. Most of the aminocarboxylate derivatives epimerized at the metal center. On the basis of kinetic and spectroscopic data, a general mechanism is proposed for the epimerization process. Neutral [(η^n-ring)M(Aa)Cl] and cationic [{(η^n-ring)M(Aa)}$_3$](BF_4)$_3$ complexes are active catalysts for the hydrogen transfer reaction from 2-propanol to acetophenone. Conversions of up to 97% and enantioselectivities up to 75% were achieved. A proposal about the origins of the enantioselectivity is given.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

1. Introduction

Organometallic complexes containing stereogenic metal centers are ideally suited to obtain mechanistic information about the stereochemical course of reactions.[1−5] Most of these complexes posses half-sandwich geometries and contain chiral chelating ligands of C_1 symmetry.[6] Among

Daniel Carmona (top, left) obtained his PhD degree in chemistry in 1980 at the University of Zaragoza under the supervision of Prof. Usón. After a postdoctoral stay at the E.T.H. of Zürich with Prof. Venanzi he returned to the University of Zaragoza joining Prof. Oro's group. Since 1988 he is a Research Scientist (Spanish Council for Scientific Research) at the Instituto de Ciencia de Materiales de Aragón. His current research interest is focused on the development of chiral transition metal catalysts, as well as in their application to asymmetric catalysis.

María Pilar Lamata (top, right) obtained her PhD degree in chemistry in 1983 at the University of Zaragoza under the supervision of Drs. Carmona and Oro. In 1986, she was appointed Associate Professor of Inorganic Chemistry at the University of Zaragoza. Her current research interests concern the study of chiral transition metal complexes and their use as enantioselective catalysts.

Luis A. Oro (bottom, left) received his PhD in 1970. After postdoctoral studies at Cambridge University he has served on the faculties of the University of Zaragoza, Madrid Complutense, and Santander. He was appointed to the Chair of Inorganic Chemistry in Zaragoza in 1982. His main research interests are in the field of organometallic and coordination chemistry and homogeneous catalysis, with particular focus on late transition metals. He has been co-author of a book on Homogeneous Hydrogenation, and more recently co-editor of a book on Metal Clusters in Chemistry. He is President of the Spanish Royal Society of Chemistry and member of the editorial board of several scientific journals, including the European Journal of Inorganic Chemistry.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

them, transition-metal complexes with α-aminocarboxylates as ligands constitute an important class of compounds as they are closely related to both biochemistry and organometallic chemistry.[7]

In this context, Dersnah and Baird reported[8] in 1977 that the dimer $[\{(\eta^6\text{-}C_6H_6)RuCl\}_2(\mu\text{-}Cl)_2]$ reacted with glycinate or alaninate anions to form the pseudotetrahedral complexes $[(\eta^6\text{-}C_6H_6)Ru(Aa)Cl]$ (Aa = glycinate, L,D-alaninate), in which the ruthenium ion is chiral. After a strikingly dormant period, over the last decade several (η^6-arene)ruthenium[9–11] or -osmium[12] compounds, as well as (η^5-pentamethylcyclopentadienyl)rhodium,[9,13,14] -iridium[9,13–18] or -ruthenium[19,20] complexes with a variety of α-aminocarboxylate ligands have been reported.

On the other hand, half-sandwich compounds with chiral chelate ligands have been successfully employed as enantioselective catalysts. In particular, chiral (arene)ruthenium(II) complexes with α-aminocarboxylates,[21] L-prolinamide derivatives,[22] or *N*-(*p*-toluenesulfonyl)-1,2-diphenylethylenediamine[23] as chiral ligands have achieved high levels of enantioselectivity in asymmetric transfer hydrogenations with 2-propanol as the hydrogen donor. The prolinamide complexes are also active catalysts for the asymmetric hydrogen transfer reduction of aromatic ketones in aqueous media.[24,25]

Our contribution to this field started with the publication in 1990 of a series of optically active pseudotetrahedral rhodium(III), iridium(III), and ruthenium(II) complexes with L-alaninato and L-prolinato ligands.[26] Since then, we have continued with the study of this type of compounds, including their application in enantioselective hydrogen transfer reactions. This Microreview presents our results in this area.

2. Chloro Complexes

The acetylacetonato complexes $[(\eta^n\text{-ring})M(acac)Cl]$ [$(\eta^n$-ring)M = (η^5-C_5Me_5)Rh, (η^5-C_5Me_5)Ir, (η^6-*p*-MeC_6H_4-*i*Pr)Ru; Hacac = acetylacetone], easily prepared from the corresponding dimer $[(\eta^n\text{-ring})MCl\}_2(\mu\text{-}Cl)_2]$ and Hacac,[27,28] reacted with stoichiometric amounts of free L-α-amino acids to give the neutral complexes $[(\eta^n\text{-ring})M(Aa)Cl]$ as a mixture of epimers at the metal center in an almost quantitative yield [Equation (1), Scheme 1].[29] The osmium analogues $[(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Os(Aa)Cl]$ were prepared starting from $[\{(\eta^6\text{-}p\text{-}MeC_6H_4iPr)OsCl\}_2(\mu\text{-}Cl)_2]$, the amino acid and KOH [Equation (2)].[9,26,30–33]

$$[(\eta^n\text{-ring})M(acac)Cl] + HAa \rightarrow [(\eta^n\text{-ring})M(Aa)Cl] + Hacac \quad (1)$$

$$1/2\,[\{(\eta^6\text{-}p\text{-}MeC_6H_4iPr)OsCl\}_2(\mu\text{-}Cl)_2] + HAa + KOH \rightarrow [(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Os(Aa)Cl] + KCl + H_2O \quad (2)$$

In solution, the diastereomeric composition of these compounds ranges from 0 to 100% *de*. In general, the lowest values correspond to aminocarboxylates such as Ala [*de* = 0 (Rh, Ir), 36% (Ru), 20% (Os)], Abu [*de* = 0 (Rh, Ir)], Val [*de* = 0 (Rh, Ir), 20% (Ru)] or Leu [*de* = 20% (Rh, Ir), 12% (Ru)], and the greatest to the conformationally more rigid cyclic amino acids [Pro = 90% (Rh, Ir), 80% (Ru), 86% (Os); MePro = 100% (Rh, Ir, Ru), 80% (Os)]. However, the complexes are configurationally labile at the metal center.[34] In this regard, the case of iridium prolinate [(η^5-C_5Me_5)Ir(Pro)Cl] is typical. A single crystal of the complex shows the presence of both epimers at the metal center in the unit cell in a 1:1 ratio (Figure 1). Nevertheless, for the same sample, a diastereomeric excess of 90% was measured by ^{1}H NMR spectroscopy in solution at room temperature, as stated above. The composition of the solid is maintained if the crystals are dissolved at −90 °C, but diastereomeric excesses of 30 and 90% were measured immediately after heating the sample to −35 °C and room temperature, respectively. The rhodium analogue [(η^5-C_5Me_5)Rh(Pro)Cl] behaves similarly. These facts indicate that (i) the epimerization process requires a low activation energy and proceeds at a high rate even at low temperatures and (ii) at room temperature, the measurements reflect thermodynamic compositions. A careful analysis of the crystal structures reveals that there is an intermolecular hydrogen-bond network. Thus, for example, in the iridium complex

(Figure 2), this network involves the NH group of the (R_{Ir}) isomer with the oxygen atoms of the carboxylate group of the (S_{Ir}) epimer [N(1b)···O(1a) = 3.196(11) Å, N(1b)H(1b)O(1a) = 140.9(9)°; N(1b)···O(2a) = 3.069(12) Å, N(1b)H(1b)O(2a) = 146.1(8)°], and the chloride ion of the (R_{Ir}) isomer with the NH group of the (S_{Ir}) epimer of the next unit cell [Cl(1b)···N(1a) = 2.510(8) Å, Cl(1b)H(1a)N(1a) = 145.2(7)°]. Most probably, the energy released from the formation of this network is the driving force for the observed epimerization on going from solution to the solid and, therefore, it would be precluded in *N*-substituted prolinates. In fact, we have only detected one diastereomer for the *N*-methylprolinates in both solid state and solution, and determined, from NOE measurements in solution and/or from X-ray diffraction analyses in the crystal, that it has an (*S*) configuration at the metal center for the four metals (Figure 3). On comparison of the circular dichroism (CD) spectrum of the *N*-methylprolinates with those of enriched mixtures of the remaining aminocarboxylates, we propose that the (*S*) configuration at the metal center is adopted for the major component of the mixtures, in all cases.

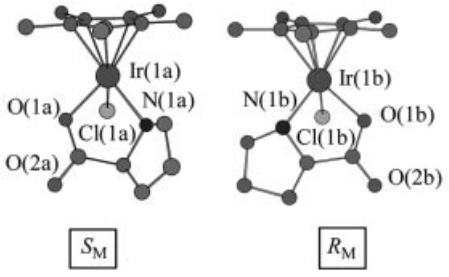

Figure 1. Molecular structure of [(η^5-C_5Me_5)Ir(Pro)Cl]

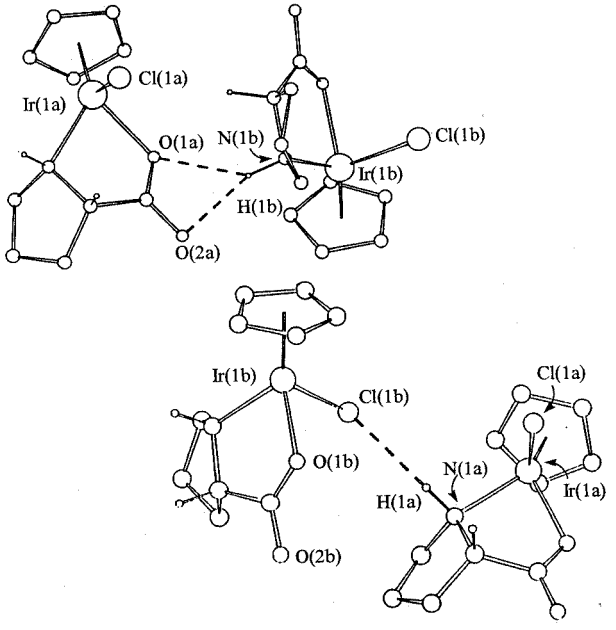

Figure 2. Hydrogen-bond network present in the iridium prolinate [η^5-C_5Me_5)Ir(Pro)Cl]

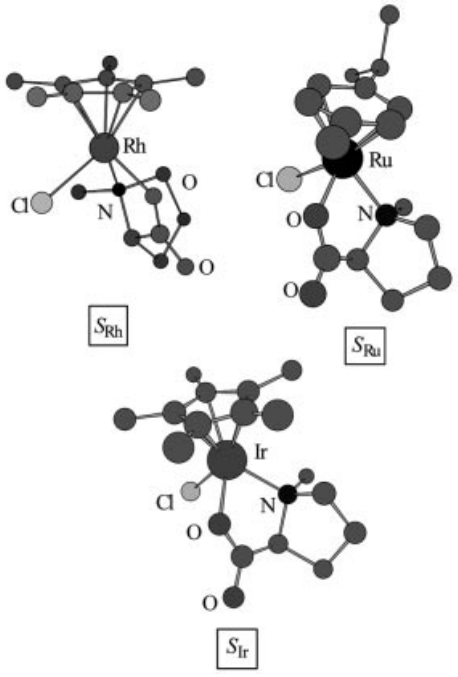

Figure 3. Molecular structures of *N*-methylprolinates

3. Alkynyl Compounds

The aforementioned aminocarboxylate compounds [(η^n-ring)M(Aa)Cl] reacted with terminal alkynes HC≡CR (R = CMe_3, $SiMe_3$, Ph, CO_2Me) in basic media (KOH or NEt_3), affording the corresponding alkynyl compounds [(η^n-ring)M(Aa)(C≡CR)] (Scheme 2).[35,36] In the preparation of the rhodium derivatives, it is necessary that KOH be used as the base. For the rhodium and iridium prolinate complexes, as well as for the ruthenium alaninate [{(η^6-*p*-MeC_6H_4*i*Pr)Ru(Ala)(C≡CPh)] two epimers at the metal center were detected. These complexes slowly epimerize in chloroform, acetone or methanol, the equilibrium composition is dependent on the metal, aminocarboxylate and alkynyl ligand. In particular, the equilibrium constant for the process (R_{Ir},S_C,S_N)-[(η^5-C_5Me_5)Ir(Pro)(C≡$CCMe_3$)] ⇆ (S_{Ir},S_C,S_N)-[(η^5-C_5Me_5)Ir(Pro)(C≡$CCMe_3$)] is 2.70 ± 0.41, in methanol at 20 °C. However, for the other alkynyl complexes only one epimer at the metal center was detected, their CD and NMR spectra remained essentially unchanged over several days.

Although the reaction between aminocarboxylate compounds [(η^n-ring)M(Aa)Cl] and terminal alkynes in basic media usually affords alkynyl compounds of the formula [(η^n-ring)M(Aa)(C≡CR)], the reaction of the (alaninato)-rhodium chloride [(η^5-C_5Me_5)Rh(Ala)Cl] with the monosubstituted alkynes HC≡CR (R = Ph, *p*-tolyl) takes a completely different route. From the reaction medium the alkynylcyclobutadiene complexes [(η^5-C_5Me_5)Rh(η^4-C_4HR_2C≡CR)] (R = Ph, *p*-tolyl) can be isolated (Scheme 3).[37] Their formation implies a novel type of rhodium-mediated trimerization reaction. The most common trimerization process that alkynes undergo is cycloaddition,

$$[(\eta^n\text{-ring})M(Aa)Cl] + HC{\equiv}CR + Base \rightarrow [(\eta^n\text{-ring})M(Aa)(C{\equiv}CR)] \quad (3)$$

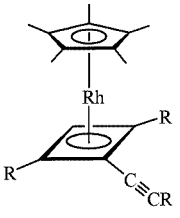
rendering arenes; however, as far as we know, cyclobutadiene-containing transition metal complexes have never been the result of an alkyne trimerization process.[38,39] Figure 4 displays the molecular structure of the phenyl complex. The structure of the cyclobutadiene ligand indicates that both oligomerization and cyclization steps have to be involved in its formation. In agreement with previously reported alkyne oligomerization processes, the pathway shown in Scheme 4 is suggested. The reaction could start with the protonation of the α-alaninato ligand by one alkyne molecule. Subsequently, a second alkyne molecule could substitute the chloride anion. At this point, the reductive tail-to-tail coupling of the two alkynyl ligands at the rhodium center could take place, rendering intermediate **B**. This reductive coupling is a key step since it has been proposed that in the absence of the amino acid ligand, $[(\eta^5\text{-}C_5Me_5)Rh(C_2Ph)_2(NCMe)]$ inserts acetylenes into the rhodium−acetylide bond in a series of stepwise *cis* insertions, which ultimately yields the rhodium complexes depicted in Scheme 5.[40] The substitution of the alanine by an alkyne molecule in **B**, followed by the oxidative coupling of the two alkyne ligands in **C**, may occur to give the unsaturated metallacyclopentadiene **D**. Finally, compound **D** could, through a reductive elimination, give the cyclobutadiene product.



R = Ph, *p*-Tolyl

4. Cationic Trimers

The α-aminocarboxylate chloride complexes $[(\eta^n\text{-ring})M(Aa)Cl]$ (M= Ir, Rh, Ru, Os) were found to behave as ionic conductors in polar solvents such as methanol or

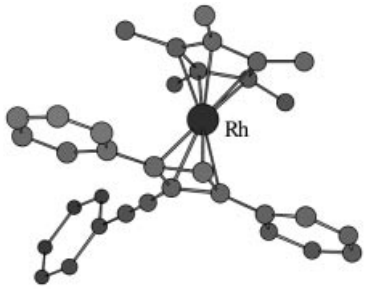

Figure 4. X-ray molecular structure of $[(\eta^5\text{-}C_5Me_5)Rh(\eta^4\text{-}C_4HPh_2C{\equiv}CPh)]$

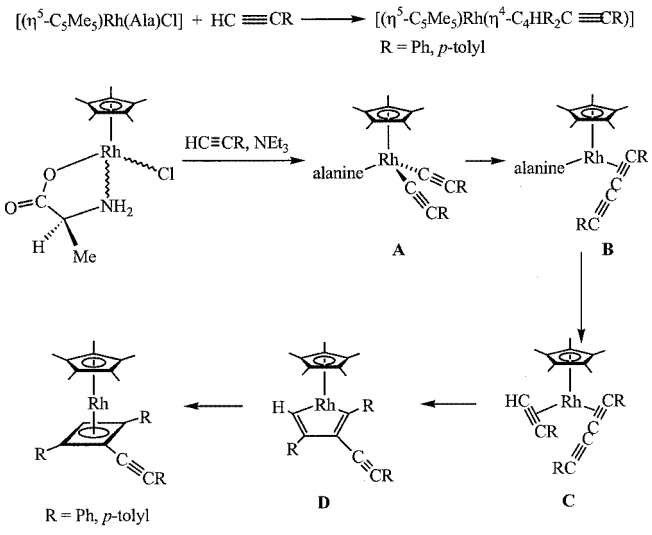
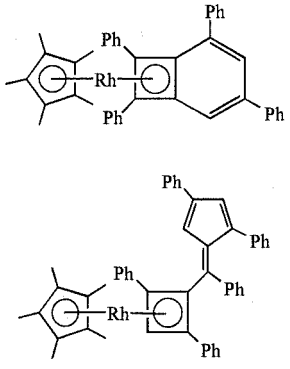


Scheme 4. Suggested pathway for the formation of the (cyclobutadiene)rhodium complexes



Scheme 5. Related (cyclobutadiene)rhodium complexes

water. Molar conductances greater than 60 $\Omega^{-1}cm^2mol^{-1}$ were achieved in the latter solvent. This behavior was explained by assuming a reversible ionization of the chloride ligand.[26,41] However, conductance measurements in water gave values for the slope of the Onsager equation that clearly pointed to a molecular complexity greater than that of univalent electrolytes.[41] To obtain further insights into the actual nature of this ionic species, the reactions of a variety of the aforementioned chloro complexes with $AgBF_4$ were carried out. The reactions resulted in the preparation of a family of chiral-at-metal trimers of the general formula

$[\{(\eta^n\text{-ring})M(Aa)\}_3](BF_4)_3$ (Scheme 6). Two members of this family, namely $[\{(\eta^5\text{-}C_5Me_5)Rh(Phe)\}_3](BF_4)_3$ and $[\{(\eta^5\text{-}C_5Me_5)Ir(Pro)\}_3](CF_3SO_3)_3$, have been previously reported by Beck et al.[42−45] Figure 5 shows the X-ray molecular structures of four members of this series. The aminocarboxylate ligand acts as a tridentate bridging group. The nitrogen atom and one of the carboxylic oxygen atoms of each amino acid are bonded to a metal center in a chelated fashion forming a five-membered metallacycle; the remaining oxygen atom coordinates to a second, different metal center and confers an additional intermetallic bridging nature to the amino acid anion ligand. The coordination environment confers a chiral nature to each metal center and, interestingly, only the two diastereomers with the same absolute configuration for the three metal centers, i.e. the ($R_MR_MR_M$) or the ($S_MS_MS_M$) isomers, were detected. Thus, the cyclization process occurs *with chiral self-recognition* among the mononuclear fragments. Solution studies revealed that in highly polar solvents isomerization of the trimers readily takes place. The rates of diastereomerization are strongly metal-dependent, increasing in the sequence Ru ≈ Os << Ir < Rh. Furthermore, while in solvents of low polarity, such as dichloromethane or acetone, the ($R_MR_MR_M$) isomer is thermodynamically preferred, in water the ($S_MS_MS_M$) isomer is thermodynamically favored. A theoretical analysis carried out at a supramolecular level for the trimer $[\{(\eta^5\text{-}C_5Me_5)Ir(Ala)\}_3](BF_4)_3$ led us to suggest a plausible explanation for the different stabilities encountered: the low number and the relatively restrained localization of the polar groups (amino hydrogen atoms) on the molecular surface of the ($R_{Ir}R_{Ir}R_{Ir}$) diastereomer (Figure 6) could sterically constrain the accessibility of solvent molecules to this area, thus reducing the number of polar trimer−solvent intermolecular interactions formed.[41] On the other hand, for the ($S_{Ir}S_{Ir}S_{Ir}$) diastereomer, the change in the metal configuration is associated to a change in the

Molecular representations of the trinuclear cations of i) $[\{(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Os(Pro)\}_3]^{3+}$, ii) $[\{(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Ru(Pro)\}_3]^{3+}$, iii) $[\{(\eta^5\text{-}C_5Me_5)Ir(Ala)\}_3]^{3+}$, and iv) $[\{(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Os(Pip)\}_3]^{3+}$

localization of amino hydrogen atoms on the surface of the molecule. They are dispersed on the molecular surface allowing interaction with solvent molecules when dissolved, with no apparent steric constrain. This major accessibility of the polar groups in the ($S_MS_MS_M$) diastereomers compared with that of the ($R_MR_MR_M$) isomers seems to be responsible for the greater stability of the ($S_MS_MS_M$) diastereomers in solution as the polarity of the solvent molecules is increased.

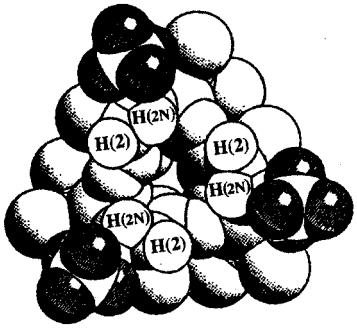

Figure 6. Space-filling model of the ($R_{Ir}R_{Ir}R_{Ir}$)-[{(η^5-C_5Me_5)Ir(Ala)}$_3$](BF_4)$_3$ compound showing the location of one of the amino hydrogen atoms [H(2N)] which is hydrogen-bonded to the BF_4 groups (shaded spheres: carbon atoms; open spheres: hydrogen atoms; black spheres: fluorine atoms of the BF_4 anions)

The equilibrium constant for Equation (5) was determined in methanol, for the range 270−318 K, by integration of corresponding ^{1}H NMR signals of the equilibrated solutions. The equilibrium obeys a simple van't Hoff dependence on the temperature, with $\Delta H^\circ = 23.4 \pm 0.5$ kJ mol^{-1} and $\Delta S^\circ = 80.6 \pm 1.7$ JK^{-1} mol^{-1}.

$$(R_{Rh}R_{Rh}R_{Rh})\text{-}[\{(\eta^5\text{-}C_5Me_5)Rh(Tle)\}_3](BF_4)_3 \leftrightarrows (S_{Rh}S_{Rh}S_{Rh})\text{-}[\{(\eta^5\text{-}C_5Me_5)Rh(Tle)\}_3](BF_4)_3 \quad (5)$$

5. Cationic Phosphane Complexes

Attempts to prepare [(η^n-ring)M(Aa)L]$^+$ compounds by treating [{(η^n-ring)M(Aa)}$_3$]$^{3+}$ trimers with ligands L, such as carbon monoxide, olefins or alkynes, proved to be unsuccessful. However, reaction with tertiary phosphanes readily produces the corresponding cationic monometallic compounds [(η^n-ring)M(Aa)(PR_3)]$^+$ [Equation (6), Scheme 7].[9,26,30,31]

$$1/3\,[\{(\eta^n\text{-ring})M(Aa)\}_3](BF_4)_3 + PR_3 \rightarrow [(\eta^n\text{-ring})M(Aa)(PR_3)]BF_4 \quad (6)$$

The phosphane complexes have been prepared as mixtures of (S_M) and (R_M) epimers. The assignment of the absolute configuration of the metal center was accomplished by a combination of X-ray diffraction (Figure 7), CD and

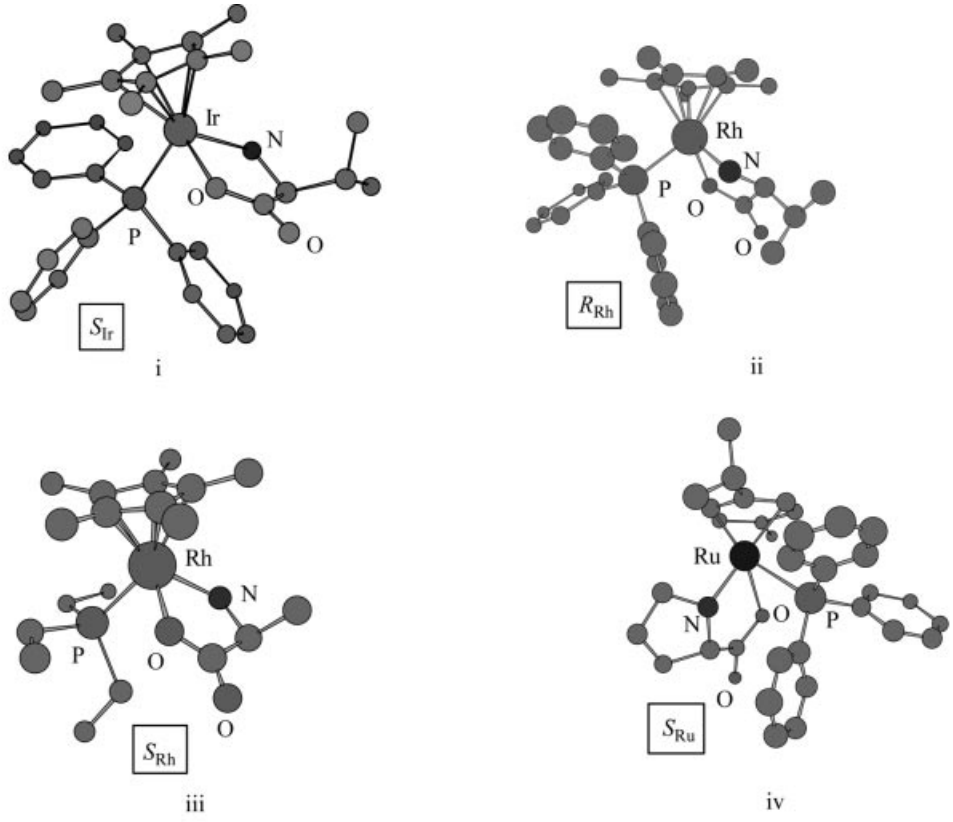

Figure 7. Molecular structures of the cationic phosphane complexes i) [(η^5-C_5Me_5)Ir(Val)(PPh_3)]$^+$, ii) [(η^5-C_5Me_5)Rh(Val)(PPh_3)]$^+$, iii) [(η^5-C_5Me_5)Rh(Ala)(PEt_3)]$^+$, and iv) [(η^6-*p*-MeC_6H_4*i*Pr)Ru(Pro)(PPh_3)]$^+$

NMR spectroscopic measurements. The isolated compounds were always enriched in the (S_M) isomer, which is the kinetically preferred epimer. In alcoholic solutions the (S_M) isomers epimerize at the metal center, the (R_M) isomers are thermodynamically preferred. The kinetic formation of the (S_M) isomers can be accounted for by assuming the preferential attack of the PR_3 ligand through the *Re*-face (hydrogen-shielded), rather than the *Si*-face (R^1- and R^2-shielded),[46] of a planar intermediate derived from the cleavage of the metal−oxygen bridging bonds of the trimers (Scheme 8). Support for this proposal stems from the measured diasteroselectivities. Thus, the kinetic diastereoselectivity in the (triphenylphosphane)rhodium series [(η^5-C_5Me_5)Rh(Aa)(PPh_3)](BF_4), Aa = Ala (R^1, Me), Abu (R^1, Et), Val (R^1, *i*Pr), and Tle (R^1, *t*Bu)] is 46, 50, 70, and 78% *de*, respectively, reflecting the increase in the size of the R^1 group.

The epimerization rate strongly depends on the metal and on the phosphane. Again, it increases in the sequence Ru < Ir < Rh. Table 1 presents the values of the rate constant for a series of (*tert*-leucinato)rhodium complexes with different tertiary phosphanes. The epimerization rate increases as the phosphane basicity decreases. Thus, arylphosphanes with electron-withdrawing substituents have the largest rate constants.

6. Epimerization Processes

As stated above, most of the aminocarboxylate derivatives epimerized at the metal center. To gain a better insight into the epimerization mechanism some kinetic and scrambling experiments have been performed. Thus, for example: (i) Kinetic measurements for the epimerization of (R_{Ir},S_C,S_N)-[(η^5-C_5Me_5)Ir(Pro)(C≡CCMe$_3$)] in chloroform for the temperature range 293−318 K revealed that the epimerization obeys a first-order rate law, with derived rate constants ranging from (2.74 ± 0.02) × 10^{-5} s^{-1} ($t_{1/2}$ = 6 h, 293 K) to (61.7 ± 5.3) × 10^{-5} s^{-1} ($t_{1/2}$ = 0.25 h, 318 K); the activation parameters are $\Delta H^{\neq}$ = 91.4 ± 3.4 kJmol^{-1} and $\Delta S^{\neq}$ = −20.8 ± 10.8 JK^{-1}mol^{-1}. (ii) The rate of isomerization of the iridium compound [{(η^5-C_5Me_5)Ir(MePro)}$_3$](BF_4)$_3$ at 51°C in methanol, was adequate to be monitored by ^{1}H NMR spectroscopy; a first-order rate law was obtained with a rate constant *k* of 2.45 ± 0.01 × $10^{-5}$$s^{-1}$. (iii) Epimerization of the triphenylphosphane complex [(η^5-C_5Me_5)Rh(Tle)(PPh_3)]BF_4 in methanol also follows a first-order rate law, and from the dependence of its rate constant on the temperature in the 296−307 K interval, activation parameters of $\Delta H^{\neq}$= 88.7 ± 0.6 kJmol^{-1} and $\Delta S^{\neq}$ = −24.9 ± 1.7 JK^{-1}mol^{-1} have been obtained.[31]

On the other hand, an equimolar mixture of (R_{Ir},S_C,S_N)-[(η^5-C_5Me_5)Ir(Pro)(C≡CCMe$_3$)] and (S_{Ru},S_C)/(R_{Ru},S_C)-[(η^6-*p*-MeC_6H_4*i*Pr)Ru(Ala)(C≡CPh)] [(S_{Ru},S_C)/(R_{Ru},S_C) = 70:30 molar ratio] was allowed to epimerize in methanol at 22 °C (Scheme 9). The processes were monitored by ^{1}H NMR spectroscopy and this technique clearly showed that both compounds epimerize independently to the corresponding (S_{Ir},S_C,S_N) and (R_{Ru},S_C) derivatives. Thus, no intermolecular processes rendering compounds containing Ru(Pro), Ru(C≡CCMe$_3$), Ir(Ala) or Ir(C≡CPh) moieties have been observed.

However, when equimolar amounts of the cationic complexes with an (*S*) configuration at the ruthenium center, [(η^6-*p*-MeC_6H_4*i*Pr)Ru(Val)(PPh_3)]BF_4 and [(η^6-*p*-MeC_6H_4-

*i*Pr)Ru(Pro){P(4-MeOC$_6$H$_4$)$_3$}]BF_4, were allowed to epimerize, the formation of the (phosphane)metal scrambling products [(η^6-*p*-MeC$_6$H$_4$*i*Pr)Ru(Val){P(4-MeOC$_6$H$_4$)$_3$}]BF_4 and [(η^6-*p*-MeC$_6$H$_4$*i*Pr)Ru(Pro)(PPh$_3$)]BF_4 [(*R*)- and (*S*)-metal epimers] was also observed (Scheme 10). Therefore, epimerization occurs with the dissociation of the phosphane ligand.

In a related experiment, an equimolar mixture of the (*tert*-leucinato)rhodium and -iridium complexes [{(η^5-C_5Me_5)M(Tle)}$_3$]$(BF_4)_3$ was dissolved in CD_3OD at −77 °C and the reaction monitored by ^{1}H NMR spectroscopy. An initial ^{1}H NMR spectrum was immediately recorded at −84 °C and it revealed that only the two starting compounds were present in solution, but after 5 min at the same temperature, new signals emerged in the C_5Me_5 region. At room temperature the spectrum showed nine new resonances in this region (most probably due to a mixture of diastereomers of heterometallic trimers), and an FAB$^+$ mass spectrum of the solution revealed peaks at *m*/*z* values of 828, 1196, and 1285, which are assigned to [(η^5-C_5Me_5)$_2$RhIr(Tle)$_2$]$^+$, [(η^5-C_5Me_5)$_3$Rh$_2$Ir(Tle)$_3$]$^+$, and [(η^5-C_5Me_5)$_3$RhIr$_2$(Tle)$_3$]$^+$ fragments, respectively (Scheme 11). Thus, most likely diastereomerization implies the dissociation of the trimers into monomers.

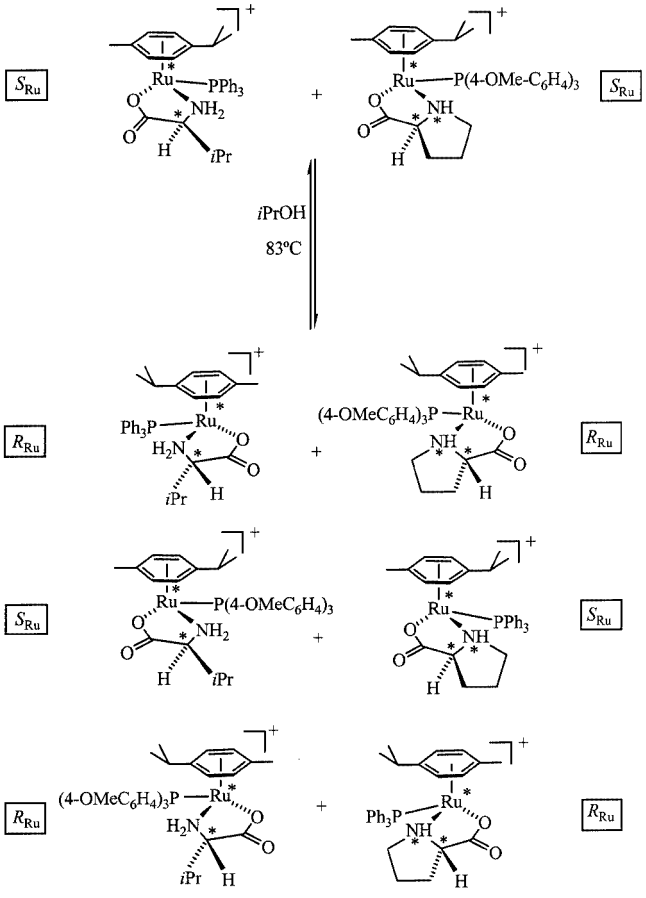
The data collected from all these experiments are compatible with a common epimerization pathway that is outlined in Scheme 12. Dissociation of the chloride ion in the aminocarboxylates [(η^n-ring)M(Aa)Cl], or of the phosphane ligand in the cationic complexes [(η^n-ring)M(Aa)(PR$_3$)]BF_4, and cleavage of the M−O or M−N bonds in the alkynyl compounds [(η^n-ring)M(Aa)(C≡CR)], or of the M−O(bridging) bond in the trimers [{(η^n-ring)M(Aa)}$_3$]$(BF_4)_3$ produce an unsaturated pyramidal species **A** which is in equilibrium with its metal center epimer **C** through a planar achiral intermediate **B**. Subsequent re-coordination of the separated moiety from the other side of the intermediate completes the process. This path accounts for all the experimental observations.

7. Asymmetric Hydrogen Transfer Reactions

Enantioselective transfer hydrogenation of prochiral ketones is a major catalytic procedure for the synthesis of chiral nonracemic secondary alcohols. The results obtained in this field have been reviewed[47] and considerable efforts have recently been paid to elucidate the operating mechanism(s).[48−57]

We have found that both the neutral (aminocarboxylato)(chloro) compounds [(η^n-ring)M(Aa)Cl] and the cationic

trimers $[\{(\eta^n\text{-ring})M(Aa)\}_3](BF_4)_3$ are active catalysts for the hydrogen transfer reaction from 2-propanol to acetophenone (Scheme 13).[41,58] 2-Propanol was used as a hydrogen donor and the solvent; reactions were carried out at refluxing temperature and sodium formate was used as the base. Both conversion and enantioselectivity were measured by gas chromatography. Table 2 presents the results achieved after treating acetophenone under the aforementioned conditions with some selected catalysts.



Scheme 10. Epimerization of an equimolar mixture of (S_{Ru},S_C)-$[(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Ru(Val)(PPh_3)](BF_4)$ and (S_{Ru},S_C,S_N)-$[(\eta^6\text{-}p\text{-}MeC_6H_4iPr)Ru(Pro)\{P(4\text{-}MeOC_6H_4)_3\}](BF_4)$

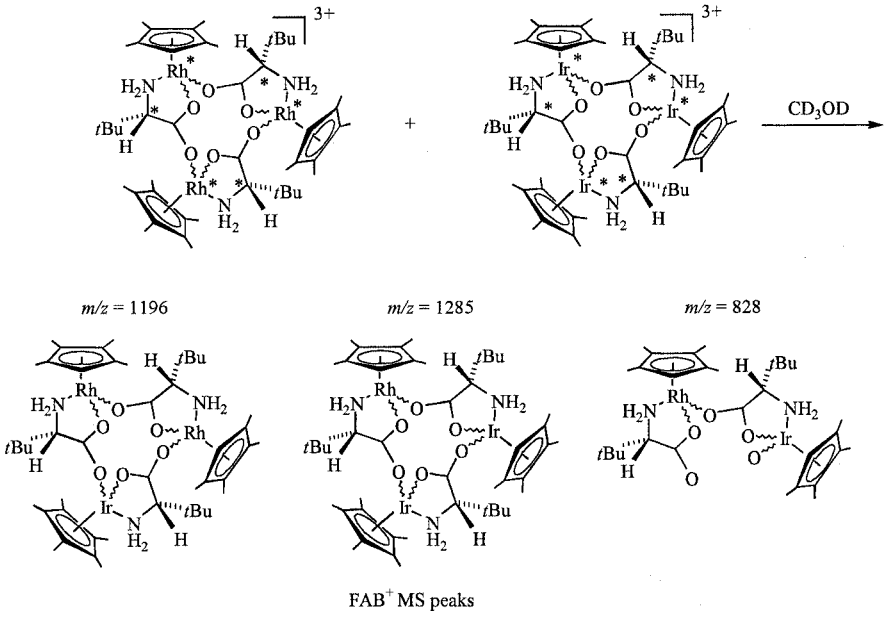
The results deserve some comments:

(i) The best conversions, as well as enantioselectivities were obtained with ruthenium or osmium catalysts. Compare, for example, Entries 1 and 2 (rhodium and iridium prolinate trimers as catalysts) with Entries 3 and 4 (ruthenium and osmium analogues as catalysts).

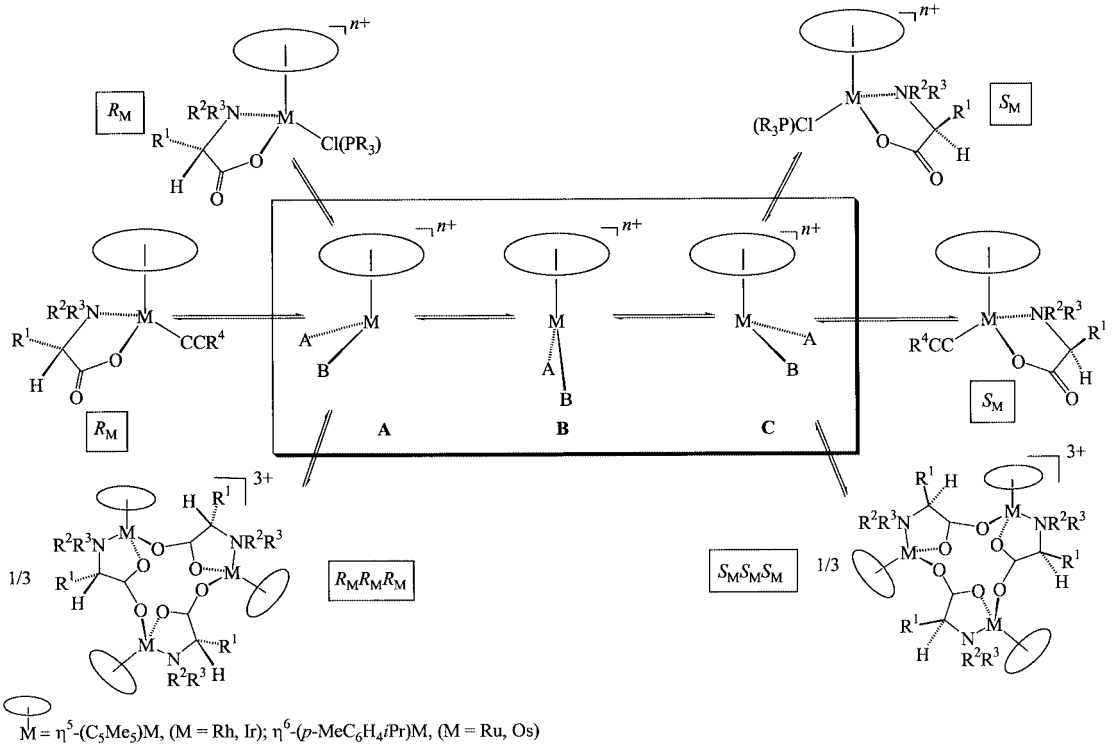
(ii) Catalysts based on cyclic aminocarboxylates produced the best enantioselectivities. Entries 1−4 correspond to cyclic aminocarboxylates, while entries 5−8 correspond to linear aminocarboxylates. Probably, the greater conformational rigidity of the cyclic aminocarboxylates with respect to the linear ones, accounts for the apparent changes in *ee*.

(iii) For a fixed metal and aminocarboxylate, mononuclear chloro complexes and cationic trimers afforded very similar conversions and enantioselectivities. Compare Entries 5 and 7 or Entries 2 and 10. Most probably both species catalyze through a common solvate intermediate $[(\eta^n\text{-ring})M(Aa)S]$, formed by cleavage of the M−O(bridging) bonds in the trimers and halogen abstraction in the chloride ions.

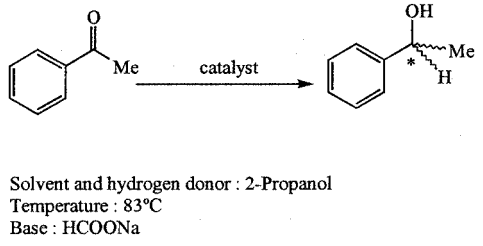
(iv) Catalysts without the NH functionality were almost inactive. Very poor conversions and enantioselectivities have been achieved with *N*,*N*-dimethylphenylalaninate (Entry 15) or *N*-methyl-substituted prolinate (Entries 16 and 17) catalysts. Very recently, Noyori and co-workers have proposed a new metal−ligand bifunctional mechanism that operates for ruthenium-based catalysts containing primary or secondary amines (Scheme 14). The catalyst **A** incorporates hydrogen from the hydrogen donor molecule to form an NH-containing hydride **B** which, in turn, simultaneously transfers the NH proton and RuH hydride to the unsatur-



Scheme 11. Epimerization of a mixture of the complexes $[\{(\eta^5\text{-}C_5Me_5)M(Tle)\}_3](BF_4)_3$ (M = Rh, Ir) in CD_3OD



Scheme 12. Proposed pathway for the epimerization processes



Scheme 13. Standard conditions for the hydrogen transfer reactions

ated substrate through a six-membered cyclic intermediate **C**.[23,59] Probably, this mechanism is operating in the aminocarboxylate catalysts and, therefore, aminocarboxylates, not containing NH groups, are almost inactive.

(v) The (*R*)-alcohols were selectively obtained, except for the piperidine-2-carboxylates (Entries 12 and 14) and *N*-methylphenylalaninate derivatives (Entry 18) which preferentially rendered (*S*)-configured alcohols. When *N*-substituted α-aminocarboxylates coordinate to a metal center through the nitrogen atom, this atom becomes a chiral

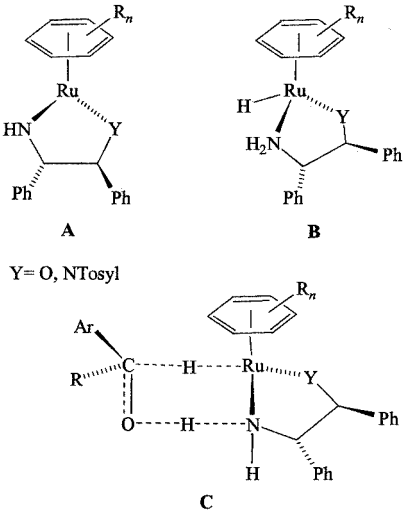
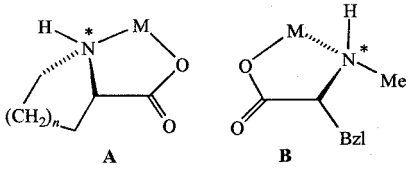
center. This is the case for the metal piperidine-2-carboxylates, prolinates or azetidine-2-carboxylates (Scheme 15A, n = 2, 1, or 0, respectively) or for the *N*-methylphenylalaninates (Scheme 15B).



Scheme 14. Metal−ligand bifunctional mechanism



Scheme 15. Chiral nitrogen centers generated by coordination of *N*-substituted aminocarboxylates

Several molecular structures of prolinato complexes determined by X-ray diffraction have been reported and, interestingly, the nitrogen atom always adopts the same configuration as the asymmetric aminocarboxylate carbon atom.[46] Similarly, only diastereomers with the same configuration at both carbon and nitrogen atoms have been detected in the crystal structures for azetidine-2-carboxylate complexes.[9,60]

In sharp contrast, the molecular structures of the L-piperidine-2-carboxylato-containing osmium compounds, [(η^6-*p*-MeC_6H_4*i*Pr)Os(Pip)Cl] and [(η^6-*p*-MeC_6H_4*i*Pr)Os(Pip)]$_3$[BF_4]$_3$, as well as those of the *N*-methyl-L-phenylalaninates, [(η^6-*p*-MeC_6H_4*i*Pr)M(MePhe)Cl] (M = Ru, Os), show that the nitrogen and the asymmetric carbon atoms of the aminocarboxylate adopt opposite configurations, (S_C,R_N) (Figure 8).[61,62]

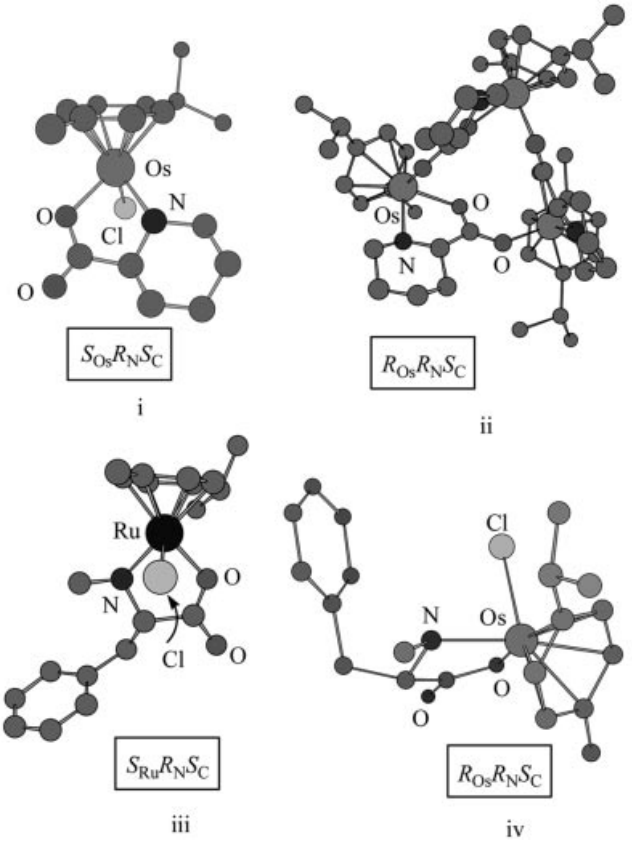


Figure 8. Molecular structures of the (L-piperidine-2-carboxylato)osmium compounds i) [(η^6-*p*-MeC_6H_4*i*Pr)Os(Pip)Cl] and ii) [(η^6-*p*-MeC_6H_4*i*Pr)Os(Pip)]$_3$[BF_4]$_3$, and those of the *N*-methyl-L-phenylalaninates [(η^6-*p*-MeC_6H_4*i*Pr)M(MePhe)]Cl with iii) M = Ru, iv) M = Os

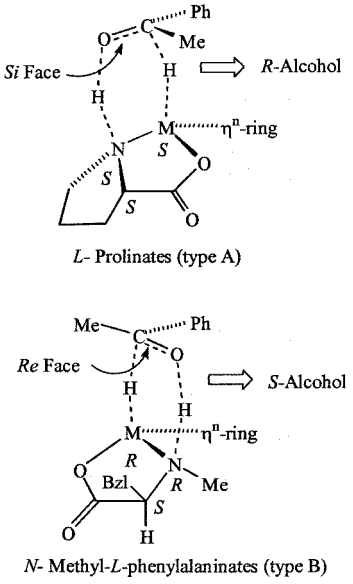
At this point, we suspect that the enantioselection would be related to the different configuration adopted by the nitrogen atom when it coordinates. In fact, we can explain the observed *ee* assuming that the concerted mechanism proposed by Noyori and co-workers is being used.[23,59] Scheme 16 shows the proposed six-membered cyclic intermediate. L-Prolinates (type **A**) and *N*-methyl-L-phenylalaninates (type **B**) have been selected as representative examples of the two types of enantioselection. The cyclic intermediate can only be formed when the metal center and the nitrogen atom adopt the same configuration, i.e. for (S_M) epimers of the **A**-type (S_C,S_N), or for (R_M) epimers of the **B**-type (S_C,R_N). To account for the obtained results [(*R*)-alcohol for the former and (*S*)-alcohol for the latter] the acetophenone phenyl group has to eclipse the *p*-MeC_6H_4*i*Pr ring. In this disposition the carbonyl group interacts with catalysts of type **A** through its *Si* face, but via its *Re* face with those of type **B**, which is in good agreement with the stereochemical outcome. Most probably, recognition of carbonyl enantiofaces is possible through attractive CH−π interactions between the arene ligand and the aromatic acetophenone group, as Noyori et al. have recently proposed, based on theoretical calculations for related (arene)ruthenium systems.[56,57]



Scheme 16. The two possible types of six-membered cyclic intermediates

To obtain further evidence for this proposal we have attempted the reduction of the dialkyl ketone 4-phenyl-2-butanone. Using this substrate, we tried to disrupt the CH−π interactions and then, on the basis of steric grounds, to reverse the enantioselection for both types of catalysts. The results presented in Table 3 strongly support this hypothesis. The L-prolinates [(η^6-*p*-MeC_6H_4*i*Pr)M(Pro)Cl] (M = Ru, Os) afforded (*S*)-4-phenyl-2-butanol, whereas *N*-methyl-L-phenylalaninates produced (*R*)-4-phenyl-2-butanol, preferentially. Thus, the assumption of Noyori's mechanism for the hydrogen transfer reaction from 2-propanol to acetophenone or 4-phenyl-2-butanone, catalyzed by α-aminocarboxylate complexes, explains the *ee* obtained.

Table 3. Reduction of 4-phenyl-2-butanone by hydrogen transfer from 2-propanol

8. Conclusions

In this Microreview, we have described half-sandwich aminocarboxylato compounds of rhodium, iridium, ruthenium or osmium with a chlorine atom, alkynyl groups or tertiary phosphanes as ancillary ligands. The neutral chloro compounds [(η^n-ring)M(Aa)Cl] reacted with $AgBF_4$, most probably yielding the corresponding mononuclear solvates [(η^n-ring)M(Aa)S]$^+$. Whichever metal was used and whatever the aminocarboxylate was, the solvates rearranged to trinuclear compounds through the coordination of the free oxygen atom of the carboxylate group. This trimerization takes place with chiral self-recognition; from the four possible diastereomers only the formation of trimers with equally configured metal centers, that is (*R*,*R*,*R*) or (*S*,*S*,*S*)trimers, was observed. Most of the new aminocarboxylate derivatives epimerized at the metal center following the epimerization pathway outlined in Scheme 12. Chloro compounds [(η^n-ring)M(Aa)Cl] and cationic trimers [{(η^n-ring)M(Aa)}$_3$]$(BF_4)_3$ are active catalysts for the hydrogen transfer reaction from 2-propanol to acetophenone. Finally, it is possible to rationalize that the recognition of the carbonyl enantiofaces of the ketone for the ruthenium catalysts occurs as a result of attractive CH−π interactions between the arene ligand and the aromatic acetophenone group, a mechanistic proposal recently suggested by Noyori et al.

Synthesis and Structure of the new cluster $[Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4]$ and its Conversion into $[Hg_{32}Se_{14}(SePh)_{36}]$

Andreas Eichhöfer*[a] and Emma Tröster[a]

Keywords: Cluster compounds / Mercury / Selenium / UV/Vis spectroscopy

The reaction of $HgCl_2$ and PPh_2nPr with $PhSeSiMe_3$ and $Se(SiMe_3)_2$ in THF at –30 °C results in the formation of yellow octahedral crystals of $[Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4]$. The molecular structure of the cluster is similar to structures of other $[M_{10}Se_4(SePh)_{12}(PR_3)_4]$ (M = Cd, Zn; R = organic group) cluster compounds although it is the first of its type with mercury as the group 12 metal atom. Dissolving $[Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4]$ in benzene at 10 °C leads to the rapid formation of a dark red solution from which red crystals of the larger cluster $[Hg_{32}Se_{14}(SePh)_{36}]$ could be crystallized in 50% yield upon layering with pentane.

Introduction

Systematic studies of the size-dependent optical and electronic properties of CdSe cluster molecules such as $[NPr_4]^+_2[Cd_4(SePh)_6Cl_4]^{2-}$, $[Cd_{10}Se_4(SePh)_{12}(PPr_3)_4]$, $[Cd_{17}Se_4(SePh)_{24}(PPh_2Pr)_4]^{2+}[Cd_8Se(SePh)_{12}Cl_4]^{2-}$ and $[Cd_{32}Se_{14}(SePh)_{36}(PPh_3)_4]$ (Ph = phenyl, Pr = *n*-propyl) show that the absorption and low temperature photoluminescence excitation onset of the clusters shifts systematically to the blue in smaller clusters,[1] thus confirming that the quantum confinement effect that is well-known for larger CdSe nanocrystals is also valid in these small molecular systems. The synthesis and structural characterization of group 12/16 cluster molecules has mostly been focused on ZnS,[2] ZnSe,[3] ZnTe,[4] CdS,[5,6] and CdSe[7] compounds. In contrast, chalcogenide cluster compounds with mercury are rare and $[Hg_{32}Se_{14}(SePh)_{36}]$ (**2**) is, to the best of our knowledge, the only example of such a compound containing selenido ligands as well as selenolato ones.[8] Nonetheless, these materials possess interesting properties as bulk or nano-materials. The alloy $Cd_{1-x}Hg_xTe$ is a well-known material for long-wavelength IR detector technologies, and HgTe nanoparticles have been proposed to act as potential amplifiers operating at wavelengths of 1.3 μm and 1.55 μm for telecommunication device.[9,10] Furthermore, optical investigations on small cluster molecules of bulk materials with smaller band gaps have advantages over those which possess larger ones due to the fact that for smaller clusters the mixing of ligand transitions with those of the cluster core are more pronounced in materials with a large band gap. Therefore in order to extend optical investigations on group 12/16 cluster molecules we began to investigate the synthesis and crystallisation of further mercury selenide cluster molecules.

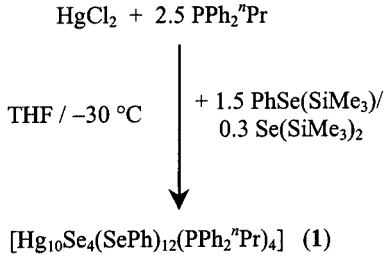
Results and Discussion

The reaction of $HgCl_2$ and PPh_2nPr with $PhSeSiMe_3$ and $Se(SiMe_3)_2$ in THF at −30 °C results in the formation of yellow octahedral crystals of $[Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4]$ (**1**; Scheme 1).



Scheme 1

Figure 1 shows the X-ray crystal structure of the $[Hg_{10}Se_{16}P_4]$ cluster core. The compound crystallizes in the tetragonal space group $I4_1/a$. The core of the cluster, which comprises four HgSe adamantane cages, is a macrotetrahedral fragment of the sphalerite structure, which is also found in HgSe.[11] The tetrahedron with the four phosphane atoms at the apex positions displays edge lengths of 1221.4−1293.4 pm. The Hg atoms Hg1−Hg3 have distorted tetrahedral environments, coordinated by the Se atoms of the μ_2-$SePh^-$ (Se2, Se3, Se4) and the μ_3-Se^{2-} (Se1) atoms as well as the P atoms of the PPh_2nPr (P1) ligands [Se−Hg−Se: 92.17−130.73(5); P−Hg−Se: 103.31−112.98(7)°]. The Hg−SePh bond lengths range

from 262.09 to 277.69(12) pm and the Hg−Se bond lengths from 256.03 to 262.81(10) pm; these distances are similar to those in HgSe (262 pm).[11] The value for the Hg−P1 bond length of the four outer Hg1 atoms coordinated by the PPh_2nPr ligands is 257.5(3) pm. The structure is therefore similar to structures of other $[M_{10}Se_4(SePh)_{12}(PR_3)_4]$ (M = Cd, Zn; R = organic group)[3,7] cluster compounds although it is the first of this type with mercury as the group 12 metal atom.

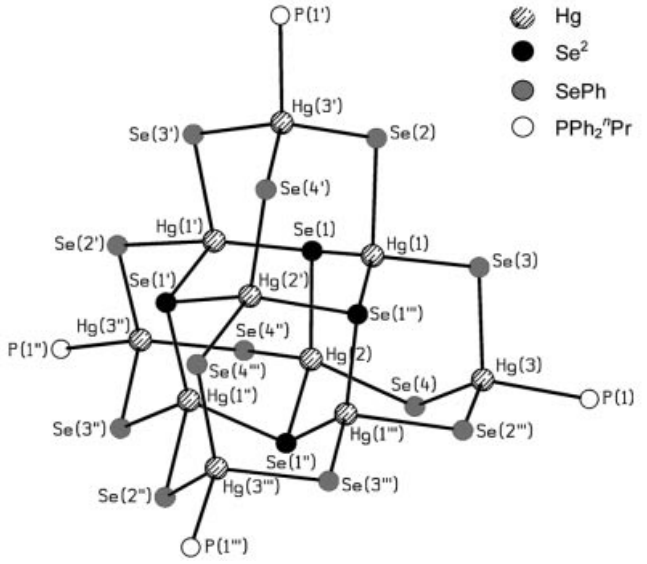


Figure 1. The $Hg_{10}Se_{16}P_4$ cluster core as a section of the molecular structure of **1**; Hg atoms (hatched circles), Se^{2-} atoms (black), $SePh^-$ (grey), P atoms (open circles); C and H atoms are omitted for clarity

Filtration of **1** at −30 °C and subsequent drying under vacuum results in a yellow powder which is stable under nitrogen at room temperature. A reflectance spectrum of microcrystalline **1** between two quartz plates (Figure 2, straight line) displays an absorption onset at 475 nm and two shoulders at approximately 410 nm and 382 nm. If **1** is dissolved in benzene at 10 °C one observes the rapid formation of a deep red solution and a small amount of black precipitate. The UV/Vis absorption spectrum of the supernatant solution (Figure 2, dashed line) displays the bands characteristic of the larger cluster $[Hg_{32}Se_{14}(SePh)_{36}]$ (**2**).[8] Upon concentration at room temperature yellow crystals of $Hg(SePh)_2$ are formed in the red solution. Layering of the filtered solution with pentane yields red crystals of **2**, sometimes accompanied by a small amount of $[Hg(SePh)_2]$. Both compounds were characterized by the determination of the lattice parameters and comparison to literature data {$[Hg(SePh)_2]$,[12] **2**: hexagonal, $a = b = 22.863$, $c = 53.390$ Å, $V = 24256$ Å^3 [8]} and **2** also by elemental analysis. Additionally the UV/Vis absorption spectrum of the red crystalline powder is in perfect agreement with the published one of **2**.[8] The black precipitate displays the three main reflections $2\theta_{111} = 25.4°$, $2\theta_{220} = 42.1°$ and $2\theta_{311} = 49.8°$ of cubic HgSe in its powder diffraction pattern.[13] Following these observations the schematic reaction equation in Scheme 2 can be established.

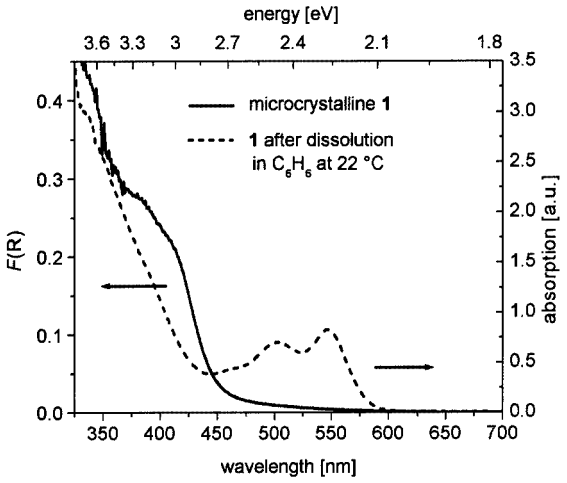

Figure 2. Reflectance spectra of **1** as a microcrystalline powder between two quartz plates (straight line) and UV/Vis absorption spectra of **1** after dissolution in C_6H_6 at 22 °C (dashed line)

$$[Hg_{10}Se_4(SePh)_{12}(PPh_2{}^nPr)_4] \quad \mathbf{(1)}$$

$$\downarrow \; C_6H_6 \,/\, 22\ °C$$

$$[Hg_{32}Se_{14}(SePh)_{36}] \quad \mathbf{(2)}$$

$$+$$

$$Hg(SePh)_2 + HgSe$$

Scheme 2

The conversion of the smaller cluster to the larger one is not induced by light as confirmed by experiments in benzene in the dark. This is in contrast to the experiment of Corrigan et al. who observed the formation of $[Cu_{50}(TePh)_{20}Te_{17}(PEtPh_2)_8][PEtPh_3]$ from $[Cu_6(TePh)_6(PEtPh_2)_5]$ by a light-induced conversion of tellurolate to telluride.[14] Furthermore we could not find any proof for the formation of $SePh_2$ in the reaction solutions similar to the formation of $TePh_2$ in Corrigan's experiment. In the present case temperature seems to play an important role for the induction of the conversion. Because of the high melting point of benzene (5 °C) the progress of the reaction could only be followed in other solvents. Compound **1** is not soluble in toluene at −60 °C. Upon warming, the solution gradually becomes coloured; it is pale yellow at −45 °C, yellow-orange at −15 °C and then becomes turbid at 0 °C with the formation of a black precipitate. The UV/Vis absorption spectrum of the supernatant pale red solution displays the bands typical for **2**. Upon layering with pentane only a few tiny crystals of **2** could be grown. In THF **1** is hardly soluble at −60 °C leading to a pale yellow solution. Upon warming, this solution also gradually turns dark remaining yellow up to −30 °C changing to brown at −10 °C and finally becoming black and turbid at room temperature. This solution shows a strong band at 256 nm prob-

ably originating from transitions related to the phenyl ligands, followed by a continuous decay to 800 nm with no indication of the formation of **2**. These results indicate that the solvent used has also an important influence on the formation of **2**.

Although **2** consists of a core built up from Hg−Se adamantane cages its formation cannot be explained in terms of a direct condensation reaction of the [$Hg_{10}Se_4(SePh)_{12}$] cluster cores of **1**. Because the outer Se−Ph ligands cannot act as bridging ligands inside the cluster cage of **2** larger rearrangements of the cluster core in **1** must take place which could also include the temporary formation of other cluster compounds. These larger rearrangements are also suggested by the formation of $Hg(SePh)_2$ and HgSe, which indicate partial decomposition of **1** during the reorganisation to **2**. The driving force of the conversion reaction could therefore be the complete formation of bulk HgSe and $Hg(SePh)_2$. Accordingly, heating a benzene solution for several hours results in a pale yellow solution with a black precipitate. However the additional formation of elemental mercury and the proof of the formation of $SePPh_2nPr$ by GC-MS and ^{31}P NMR spectroscopy suggests that the decomposition process is a more complex one as is also suggested by the yield of approximately 50% for **2** with respect to the theoretical yield based on the reaction in Scheme 2.

In summary we have shown that the new cluster [$Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4$] (**1**) is a metastable compound that converts to $Hg(SePh)_2$, HgSe and the larger cluster [$Hg_{32}Se_{14}(SePh)_{36}$] (**2**) in benzene at room temperature. This is therefore an interesting example of controlled cluster growth in solution induced by thermal energy and suggests also the possible use of these clusters as precursor compounds in the synthesis of nanoparticles. Whether the treatment of **2** with other solvents such as THF and toluene leads to the formation of different cluster compounds and whether this conversion reaction is also valid for cluster compounds with composition [$M_{10}E_4(EPh)_{12}(PR_3)_4$] (M = Zn, Cd; E = Se, Te; R = organic group) is the focus of current investigations.

Experimental Section

General: Standard Schlenk techniques were employed throughout the syntheses using a double-manifold vacuum line with high purity dry nitrogen. Tetrahydrofuran and benzene were dried over sodium/benzophenone, pentane with $LiAlH_4$ and distilled under nitrogen. Anhydrous $HgCl_2$ was purchased from Aldrich. $PhSeSiMe_3$ [15] and $Se(SiMe_3)_2$ [16] were prepared according to standard literature procedures.

X-ray powder diffraction patterns (XRD) were measured on a STOE STADI P diffractometer (Cu-K_α radiation, Ge monochromator, Debye−Scherrer geometry) in sealed glass capillaries.

Absorption spectra of cluster molecules in solution were measured on a Varian Cary 500 spectrophotometer in quartz cuvettes. Solid-state reflectance spectra were measured on micron-sized crystalline powders between quartz plates with a Labsphere integrating sphere.

Synthesis of 1: $HgCl_2$ (0.18 g, 0.66 mmol) was dissolved in 30 mL of THF and PPh_2nPr (0.30 mL, 1.33 mmol) was added. Then $PhSeSiMe_3$ (0.19 mL, 0.99 mmol) was added at 0 °C and the resulting clear yellow solution stirred overnight at room temperature. Addition of $Se(SiMe_3)_2$ (0.045 mL, 0.2 mmol) at −60 °C led to the formation of a pale yellow solution from which [$Hg_{10}Se_4(SePh)_{12}(PPh_2nPr)_4$] (**1**) could be crystallized at −30 °C (60% yield). $C_{132}H_{128}Hg_{10}P_4Se_{16}$ (5107.6): calcd. C 31.04, H 2.53; $C_{132}H_{128}Hg_{10}P_4Se_{16}{\cdot}6C_4H_8O$: calcd. C 33.8, H 3.02; found C 31.60, H 2.44%. Most of the solvent molecules in the crystal therefore evaporate upon drying under vacuum (10^{-3} mbar). Suitable crystals for X-ray diffraction were obtained by warming the reaction solution to 0 °C and recooling to −35 °C.

Synthesis of 2: Compound **1** (0.18 g, 0.035 mmol) was dissolved in 20 mL of benzene at 10 °C to give a dark red solution with a small amount of black precipitate of HgSe. After two days at room temperature the solution was concentrated to 10 mL. Yellow platelet-like crystals of $Hg(SePh)_2$ grow together with a small amount of red crystals of **2**. These were filtered after two days and subsequent layering of the clear red solution with benzene/pentane led to the formation of red crystals of **2** (yield 49% calculated for Scheme 2). $C_{216}H_{180}Hg_{32}Se_{40}$ (12353.1): calcd. C 19.74, H 1.38; found C 21.87, H 1.58. The deviations in the C H analysis probably indicate the presence of $Hg(SePh)_2$ in the red crystalline powder.

Crystallographic Data for $1{\cdot}6C_4H_8O$: M_r = 5514.91, tetragonal, space group $I4_1/a$ (No. 88), $a = b$ = 23.059(3), c = 37.757(8) Å, V = 20077 Å^3, Z = 4, D_c = 1.825 g·cm^{-3}, μ(Mo-K_α) = 10.59 mm^{-1}. The data collection was carried out on a STOE IPDS II diffractometer using graphite-monochromated Mo-K_α (l = 0.71073 Å) radiation at 170 K. The structure solution and full-matrix least square refinement based on F^2 were performed with the SHELX-97 program package,[17] giving a final $R1$ value of 0.0466 for 406 parameters and 7061 unique reflections with $I \geq 2\sigma(I)$ and a $wR2$ value of 0.1588 for all 37265 reflections.

CCDC-178317 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Diels–Alder Synthesis of Rigid 60° Angular Bridging Ligands and X-ray Crystal Structures of their Silver Nitrate Complexes

Peter J. Steel*[a] and Nicholas C. Webb[a]

Keywords: Silver / Coordination polymers / Bridging ligands / Self-assembly / N ligands

Using Diels–Alder chemistry, three bridging ligands (**2**–**4**) have been synthesised, each of which contains two pyridine nitrogen donors disposed at a 60° angle. X-ray crystal structures are reported for ligand **4** and two coordination polymers formed by the reaction of **2** and **3** with silver nitrate.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The controlled self-assembly of two- and three-dimensional metallosupramolecular species has been the subject of enormous study in recent years.[1] The most common synthetic approach to such compounds has been to employ logical combinations of rigid linear and angular components in order to construct rationally designed architectures.[1] Within this context, molecular squares have proved to be particularly popular synthetic targets as they are readily assembled from combinations of linear, bridging ligands (such as pyrazine or 4,4′-bipyridine) and right-angular (90°) metal linkages (such as is provided by *cis*-coordination in a square-planar metal centre).[2] Similarly, molecular pentagons and hexagons are available using tetrahedral and trigonal linking components.[1] This concept has been extended into the third dimension with reports of molecular cubes,[3] dodecahedra,[4] and other polyhedra.[1]

Of the two-dimensional molecular polygons, triangles pose a particular problem.[1] Metal centres are not suitable for use as the angular components, since the requisite 60° angle is not readily provided by the subset of angular geometries offered by ligand coordination to transition metals. Consequently, the construction of metallosupramolecular triangles necessitates an inversion of approach, such that the metal provides the linear bridge (e.g. *trans* coordination to a square-planar metal centre) and the organic ligand provides the angular component (Figure 1a). A limited number of such species have been reported, the most common of which have employed pyrazolates as angular bridges linking linear metal centres, such as silver or gold (Figure 1b).[5] Intrinsically, the use of pyrazolates as the angular components allows no control over the dimension of the triangles assembled. Loeb and co-workers[6] have used 4,7-naphthyridine to construct larger molecular triangles in which the organic ligand provides the necessary 60° angular bridge linking doubly cyclometallated palladium-based linear bridges. However, such ligands are not amenable to control of the distance between the donor centres, and hence the size of the triangle produced. More recently, a number of isolated examples of metastable distorted triangles have been reported that used pyrazine[7] or larger, more flexible bridging ligands.[8]

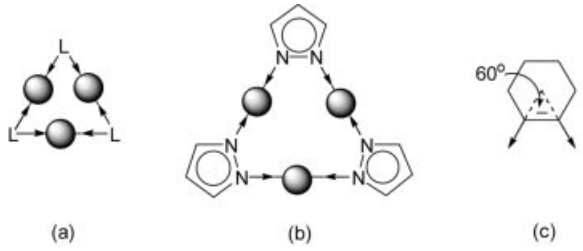

Figure 1. Molecular triangle components

Since the internal angle subtended by adjacent corners of a hexagon is 60°, we reasoned that a diverse range of triangular building blocks would be provided by organic ligands that incorporate donor groups with adjacent substitution in a cyclohexene or benzene ring (Figure 1c). We now report the synthesis of three such ligands that contain two 4-pyridyl substituents, each of which provides two nitrogen donors disposed at a 60° angle. Using a similar conceptual approach, Espinet and co-workers[9] recently reported the synthesis of an organometallic triangle derived from 1,2-phenylene diisocyanide, despite the fact that the corresponding diacetylide had led to an organometallic molecular square.[10] As we,[11] and others,[12] have found, reactions of bridging ligands with silver(I) species have led to a rich array of metallosupramolecular architectures. Thus, we have initially explored the coordination chemistry of these new

ligands by examining their reactions with silver nitrate. Accordingly, we also report the synthesis and X-ray crystal structures of complexes formed from these ligands by reactions with silver nitrate.

Results and Discussion

The three ligands **2**−**4** were prepared by procedures based on the Diels−Alder reaction, as shown in Scheme 1. Di(4-pyridyl)acetylene (**1**) was prepared in 55% overall yield from commercially available 1,2-di(4-pyridyl)ethylene by bromination and dehydrobromination, according to a literature procedure.[13] In order to improve the dienophilicity of this compound, the pyridyl substituents were made more electron-withdrawing by conversion into the pyridinium species, through reaction with tetrafluoroboric acid. This methodology has previously been employed for the Diels−Alder reaction of **1** with cyclopentadiene.[14] Reaction of **1** with cyclohexa-1,3-diene gave the bicyclooctadiene **2**, albeit in a disappointing 12% yield.[15] Since mass spectrometry showed that this compound readily undergoes a retro-Diels−Alder reaction, with expulsion of ethylene, this strategy was used to prepare the disubstituted ligand **3**. Thus, heating **2** to 280 °C resulted in its smooth conversion into ligand **3**, which was isolated in 49% yield. This compound has previously been prepared by a Stille coupling procedure in the course of the synthesis of a large series of poly(4-pyridyl)-substituted aromatics.[16] The tetraphenyl derivative **4** was prepared by reaction of **1** with tetracyclone. In this case the free base was used, as Diels−Alder reactions of tetracyclone are well-known to proceed with inverse electron demand.[17] The intermediate adduct **5** underwent spontaneous expulsion of carbon monoxide to give the new ligand **4**.[18]

In order to confirm the structure of **4**, and to examine the relative orientations of the aryl rings, a single crystal X-ray crystal structure determination was carried out.[19] Figure 2 shows a perspective view of this new ligand, along with selected bond lengths and angles. Whereas the six peripheral aryl rings are all planar (to within 0.007 Å), the central ring displays an interesting distortion into a boat conformation, with C(3) and C(6) each displaced ca. 0.04 Å above the plane of the other four atoms of the ring. This in turn points the two attached phenyl rings above the plane of the central ring. As is the case in the crystal structure of hexaphenylbenzene,[20] the planes of the six external rings display a cooperatively correlated inclination with respect to the central benzene ring. The two pyridine rings are inclined at angles of 63.2 and 68.8° to the central ring, whereas the four phenyl rings are twisted by angles ranging from 65.9 to 76.1°. With respect to the centre of the central ring the two pyridine nitrogen donors subtend an angle of 62.6°.

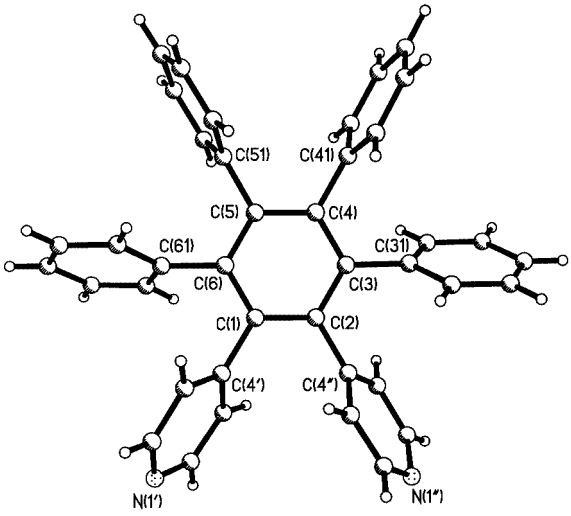

Figure 2. Perspective view of the X-ray crystal structure of ligand **4**; selected bond lengths (Å) and angles (°): C1−C2 1.411(3); C1−C6 1.409(3), C1−C4′ 1.501(3), C2−C3 1.408(3); C2−C4′′ 1.496(3), C3−C4 1.406(3), C3−C31 1.495(3), C4−C5 1.413(3), C4−C41 1.502(3); C5−C6 1.400(3), C6−C61 1.515(3); C2−C1−C6 119.9(2), C1−C2−C3 120.2(2), C2−C3−C4 119.4(2), C3−C4−C5 120.2(2), C4−C5−C6 120.1(2), C1−C6−C5 119.8(2)

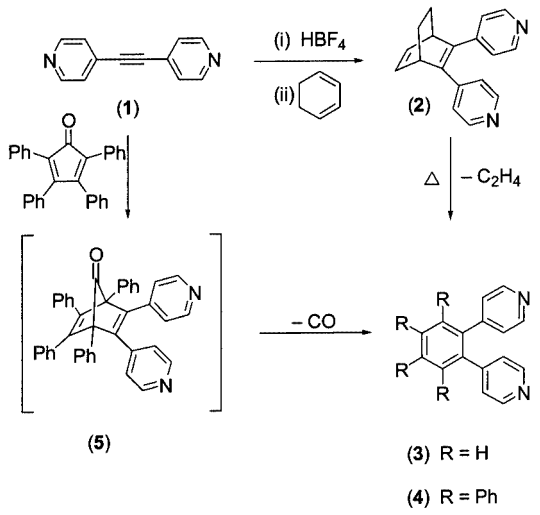

Scheme 1

Ligands **2** and **3** were reacted with silver(I) nitrate in acetonitrile to give quantitative formation of complexes **6** and **7**, respectively, which on slow evaporation of the solutions furnished crystals suitable for an X-ray structure determination. In the case of the hexasubstituted ligand **4**, the low solubility of the ligand in acetonitrile required that the reaction be performed in methanol solution, which did not lead to X-ray quality crystals.

The structure[19] of the complex (**6**) formed from the bicyclo[2.2.2]octa-2,5-diene ligand **2** is surprisingly intricate. Figure 3 shows a perspective view of the contents of the asymmetric unit, which contains two silver atoms, two molecules of **2**, two nitrate anions and an acetonitrile solvate molecule. Each of the two independent ligands is bonded to three silver atoms through its two nitrogen donors and to the endo face of the more exposed double bond of the bicyclo[2.2.2]octa-2,5-diene moiety. Similarly, each silver atom is coordinated to three different ligands and also in-

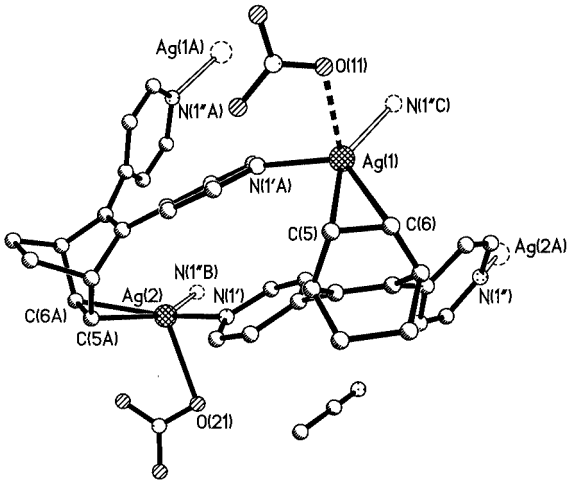

Figure 3. Perspective view of the contents of the asymmetric unit of the crystal structure of **6**; hydrogen atoms have been omitted for clarity; selected bond lengths (Å): Ag1–N1′A 2.328(5), Ag1–N1′′C 2.260(5), Ag1–C5 2.342(7), Ag1–C6 2.468(8), Ag1–O11 2.653(5), C5–C6 1.371(10), Ag2–N1′ 2.328(5), Ag2–N1′′B 2.292(5), Ag2–C6A 2.443(6), Ag2–C5A 2.457(7), Ag2–O21 2.565(5), C5A–C6A 1.403(8)

teracts weakly with one of the oxygen atoms of a nitrate counterion. The bridging nature of both the ligand and the metal results in an extension into a complex coordination polymer that propagates along the *a* axis.

Thus ligand **2** bridges three silver atoms with coordination to both the pyridine donors as well as a double bond of the bicyclooctadiene unit. To the best of our knowledge the only previously reported X-ray crystal structure which incorporates both of these features, is that of an ethylene adduct of a silver complex of a tris-pyrazolylborate.[21] As expected the nitrogen donors subtend angles [66.7(5) and 69.1(5)°] at the centroids of their attached bicyclooctane units which would be compatible with the formation of molecular triangles in the absence of these additional interactions.

The complex (**7**) formed from 1,2-di(2-pyridyl)benzene (**3**) is a zigzag coordination polymer. Figure 4 shows a perspective view of a section of this polymer, with selected atom labelling. In the crystal structure,[19] ligand **2** bridges two silver atoms, with an angle subtended at the centre of the benzene ring of 67.8°. The plane of the benzene ring is inclined to the planes of the attached pyridine rings at angles of 54.1 and 46.9°. By virtue of the coordination to the nitrate anion the silver atom deviates significantly from linear geometry.

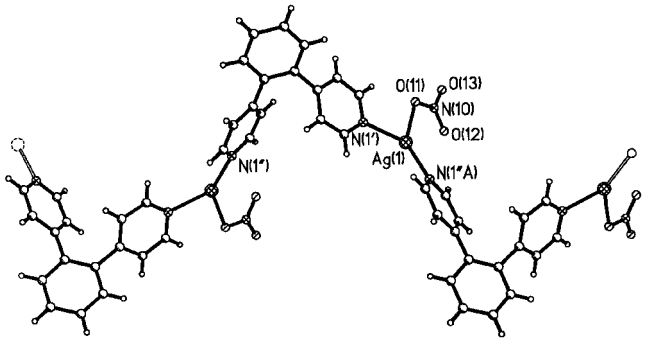

Figure 4. Crystal structure of a segment of the coordination polymer **7**; selected bond lengths (Å) and angles (°): Ag1–N1′ 2.279(2), Ag1–N1′′A 2.210(2), Ag1–O11 2.408(2); N1′–Ag1–N1′′A 132.13(6), N1′–Ag1–O11 87.90(5), N1′′A–Ag1–O11 138.23(5)

[a] $R = \Sigma(|F_0| - |F_c|)/\Sigma|F_0|$. [b] $wR = (\Sigma[w(F_0^2 - F_c^2)^2]/\Sigma[w(F_0^2)^2])^{1/2}$.

In conclusion, we have prepared three bridging ligands, each of which possesses two pyridine nitrogen donors disposed at a 60° angle, suitable for the self-assembly of molecular triangles. In their reactions with silver nitrate coordination polymers are formed as a result of the fact that the silver atoms do not behave as linear bridges due to additional interactions with the nitrate anions.

[15] Preparation of **2**: Di(4-pyridyl)acetylene (500 mg) was converted into its di-HBF_4 salt by addition of 1 mL of 50% HBF_4 solution to a stirred solution of the acetylene in 350 mL diethyl ether. The white precipitate was filtered off, and dried under vacuum. This was added to 3.5 mL of cyclohexa-1,3-diene in 60 mL of dry acetonitrile and the mixture refluxed for 18 h. The solvent was removed in vacuo, leaving a brown/black residue, which was dissolved in 100 mL water, containing a small amount of HBF_4. This was washed with 4 × 45 mL dichloromethane, neutralised with $NaHCO_3$, then extracted with 4 × 60 mL dichloromethane. The dichloromethane solution was dried over $MgSO_4$ and the solvent removed in vacuo. After chromatography on alumina (10% methanol in ethyl acetate) the isolated product was recrystallised from petroleum ether/ethyl acetate to give 86.6 mg of a yellow solid. M.p. 124−126 °C. ^{1}H NMR ($CDCl_3$): δ = 8.44 (d, 4 H), 6.95 (d, 4 H), 6.53 (dd, 2 H), 3.97 (br. s, 2 H), 1.62 (dd, 2 H), 1.53 (dd, 2 H) ppm. ^{13}C NMR ($CDCl_3$): δ = 149.8, 146.7, 141.9, 134.4, 122.8, 43.7, 25.0. $C_{18}H_{16}N_2$ (260.3): calcd. C 83.04, H 6.20, N 10.76; found C 82.97, H 6.18, N 10.92.

Reactivity of Platinum Stanna-*closo*-dodecaborate Complexes: First Hydroformylation Studies

Lars Wesemann,*[a] Siegbert Hagen,[a] Thiemo Marx,[a] Ingo Pantenburg,[a] Markus Nobis,[b] and Birgit Drießen-Hölscher*[b]

Dedicated to Professor Dieter Naumann on the occasion of his 60th birthday

Keywords: Boranes / Cluster compounds / Homogeneous catalysis / Platinum / Tin

The synthesis and characterization of two (dppp)Pt complexes with the stannaborate ligand $SnB_{11}H_{11}$ is described. In the case of the salt $[Bu_3MeN]_2[(dppp)Pt(SnB_{11}H_{11})_2]$ the structure in the solid state was determined by X-ray crystal structure analysis. As a result of comparative catalysis studies between $SnCl_3$ and $[SnB_{11}H_{11}]^-$-substituted platinum complexes we found selective hydroformylation of 1-octene catalysed by the $[(dppp)PtPh(SnB_{11}H_{11})]^-$ and $[(dppp)Pt(SnB_{11}H_{11})_2]^{2-}$ complexes.

Introduction

We are interested in the coordination abilities of the hetero-*closo*-dodecaborate clusters $[EB_{11}H_{11}]^{2-}$ of the group 14 elements.[1,2] The first example of the complexation of these *closo*-borates at a transition metal centre was the copper compound $\{[Bu_4N]_2[ClCu(CB_{11}F_{11})]\}$ reported by Strauss et al.[3] For E = Sn we have synthesised coordination compounds of the type $L_nM\text{-}(SnB_{11}H_{11})$ for a wide variety of transition metals (Fe, Mo, Rh, Ir, Ni, Pd, Pt).[4−7] Characterization of the hydride complex $[Bu_3MeN][trans\text{-}(Et_3P)_2PtH(SnB_{11}H_{11})]$ led us to the conclusion that the stannaborate ligand has a higher *trans* influence than the trichlorostannyl ligand ($SnCl_3$).[7] Furthermore, we found that the tin ligand $[SnB_{11}H_{11}]^-$ activates Pt−C bonds towards isocyanide insertion.[8] In the field of carbonylation hydroformylation is one of the most important reactions catalysed homogeneously by transition metal complexes, with cobalt and rhodium complexes being amongst the most important.[9] The mechanistic aspects of platinum-catalysed hydroformylation have been studied extensively.[10] In particular, the insertion of the carbon monoxide molecule and the effect of the bite angle of the chelating phosphane have been investigated.

Asymmetric hydroformylation using chiral phosphanes has been carried out successfully with platinum complexes.[11] Most of the platinum complexes studied so far in hydroformylation experiments are of the type L_2PtCl_2 and have to be reacted with $SnCl_2$ to provide hydroformylation activity;[12,13] tin(II) chloride inserts into the Pt−Cl bond and forms the trichlorostannyl ligand.[14] The role of this ligand is the subject of many studies and it appears that the lability of the $SnCl_3$ group is one reason for the activation of platinum complexes.[15] Besides these trichlorostannyl complexes several very interesting alternative platinum catalysts have been developed ($[Pt(C_2H_4)$(chelating phosphane)$]/CH_3SO_3H$;[16] platinum-diphenylphosphinous acid complex catalyst).[17] The easily accessible stanna-*closo*-dodecaborate cluster is resistant towards moisture and air and reacts with most of the transition metal electrophiles studied so far by complexation and formation of a metal-tin bond. Since (phosphane)Pt-$(R)SnCl_3$ complexes are well known for their catalytic activity in hydroformylation reactions we started a comparative study on the hydroformylation activity of $SnCl_3$ and $SnB_{11}H_{11}$ complexes of platinum.

Results and Discussion

At the beginning of our stannaborate complex synthesis we decided to use the 1,3-bis(diphenylphosphanyl)propane (dppp) as the chelating ligand. Following our standard procedure two stannaborate complexes were synthesised in high yield by nucleophilic substitution of the chloride anion with the stannaborate dianion (Scheme 1 and 2).

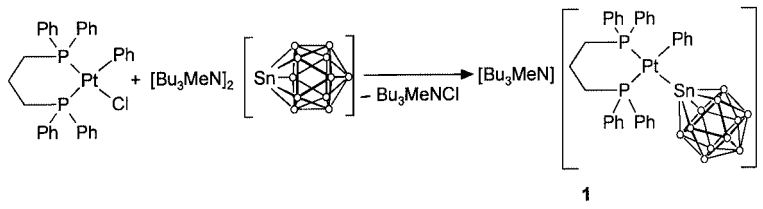
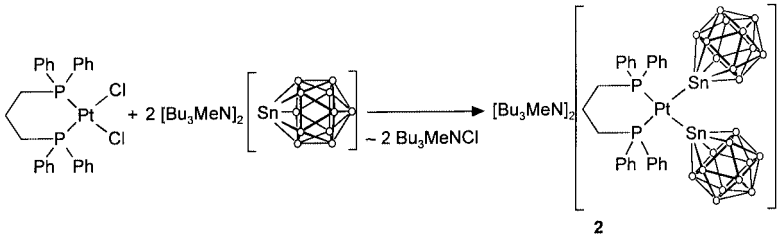


Scheme 1



Scheme 2

The salts **1** and **2** were characterised by elemental analysis, NMR spectroscopy and in the case of **2** by a single-crystal structure analysis. It is well established that the $^2J_{SnP}$ coupling constant permits unambiguous assignment of the stereochemistry in Pt^{II} complexes. Indirect coupling between ligand atoms is known to be much larger for *trans* than for *cis* related ligands.[18] Here the $^2J_{SnP}$ of the signal at $\delta = 2.40$ ppm (*trans* to Sn) is around 10 times larger than the respective coupling of the signal at $\delta = -5.40$ ppm (*cis* to Sn).

Single crystals of complex **2** were obtained at room temperature from acetone and methanol solution. The salt crystallises as yellow-green octahedra in the orthorhombic space group *Pbcn* with the dianion $[(dppp)Pt(SnB_{11}H_{11})]^{2-}$ lying on a twofold rotation axis.[19] Figure 1 shows the molecular structure of the dianion of **2**.

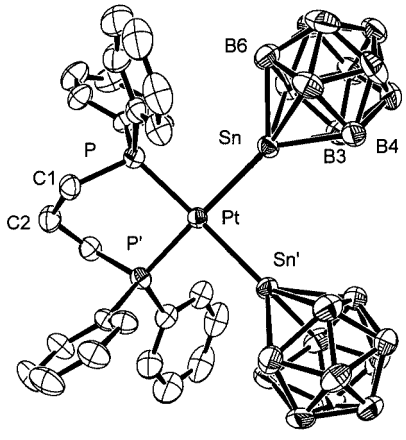


Figure 1. Molecular structure of the $[(dppp)Pt(SnB_{11}H_{11})_2]^{2-}$ dianion in the crystal structure of **2**; bond lengths [Å] and angles [°] (with estimated standard deviations in parentheses): Pt−Sn 2.596(1), Pt−P 2.279(2), Sn−B2 2.288(8), Sn−B3 2.322(8), Sn−B4 2.285(8), Sn−B5 2.308(9), Sn−B6 2.299(9), P−C1 1.821(7), P−Pt−P′ 91.07(8), Sn−Pt−Sn′ 88.87(2), P−Pt−Sn 91.32(4)

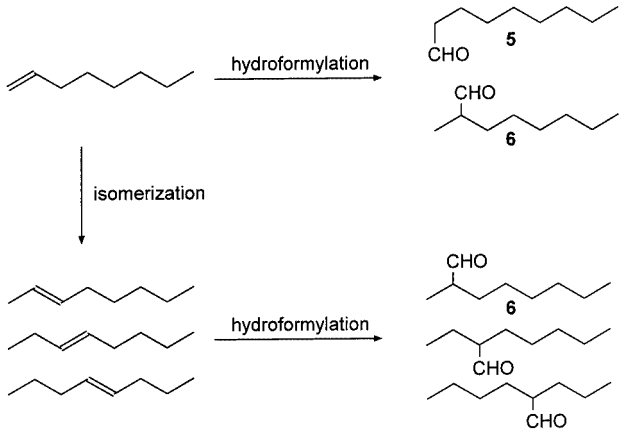
Due to steric crowding around the platinum centre the square-planar coordination is slightly distorted towards a tetrahedral arrangement with a torsion angle (P−P′−Sn−Sn′) of 17°. The interatomic distances are similar to those in other stannaborate complexes.

Hydroformylation experiments were carried out with 1-octene in CH_2Cl_2 with four different (dppp)Pt complexes: **1**, **2**, [(dppp)Pt(Ph)$SnCl_3$] (**3**) and [(dppp)Pt($SnCl_3$)$_2$] (**4**). Due to isomerization of 1-octene during the catalysis four different aldehydes are the expected products of this conversion (Scheme 3).



Scheme 3. Products of the hydroformylation of 1-octene and the olefins 2-, 3- and 4-octene, which result from preceding isomerization (isomerized olefins were drawn without considering the stereochemistry).

Besides other criteria the importance of olefin hydroformylation arises, of course, from the selectivity of the aldehyde formation. The *n*/*iso* ratio, which is always an important parameter in hydroformylation catalysis, refers to the amount of *n*-nonanal (**5**) and *iso*-nonanal (**6**), which is usually determined by gas chromatography. Table 1−4 show the results of the catalysis experiments with complexes

1−**4**. From comparative catalysis studies between $SnCl_3$- and $[SnB_{11}H_{11}]^-$-substituted platinum complexes we found the highest activity at 100 °C for the $SnCl_3$-substituted derivative. However, at 120 °C the activity of the stannaborate complex **1** is the highest and rises upon increasing the temperature. Thus, complexes **1** and **2** are thermally stable at 140 °C whereas their $SnCl_3$ counterparts decompose at this temperatures. In the range of temperature studied the *n*/*iso* selectivity is much higher with the borate complex, although upon increasing the temperature the amount of isomerized olefins also increases. Only a slight pressure dependence of the *n*/*iso* ratio in the case of the reactions with complex **2** was observed (Table 4). In our opinion it is very interesting that the isomerized olefins (Table 3) which were formed during catalysis were not hydroformylated by the stannaborate complexes. Instead 1-octene is selectively transformed into the aldehydes **5** and **6**. The olefin selectivity observed is presumably due to the higher steric crowding in the cluster compounds **1** and **2**. Furthermore, no reaction products from aldol condensation of the produced aldehydes were detected in the experiments with **1** and **2**.

Table 1. Initial TOF[a] [h^{-1}] for the hydroformylation of 1-octene with (dppp)Pt complexes **1**−**4** at different temperatures[b]

Pt compound	100 °C	120 °C	140 °C	160 °C
1	11.0	62.1	72.8	23.6[c]
2	19.3	34.1	73.9	52.7
3	50.5	46.6[c]	[c]	[c]
4	31.6	10.2	[c]	[c]

[a] Turnover frequencies were calculated as mol of aldehyde per mol of Pt per hour. [b] Reactions were carried out in 10 mL of CH_2Cl_2 under 50 bar of CO/H_2 with an octene/Pt catalyst ratio of 250 (0.02 mmol cat.) and reaction times of 2 h. [c] Decomposition of the catalyst.

Table 2. Influence of the temperature of the hydroformylation experiments on the *n*/*iso* ratio of nonanal[a]

Pt compound	100 °C	120 °C	140 °C	160 °C
1	7.8	8.4	8.2	6.0[b]
2	8.8	9.1	9.2	7.8
3	1.7	1.6[b]	[b]	[b]
4	1.4	1.6	[b]	[b]

[a] Reactions were carried out in 10 mL of CH_2Cl_2 under 50 bar of CO/H_2 with an octene/Pt catalyst ratio of 250 (0.02 mmol cat.) and reaction times of 2 h. [b] Decomposition of the catalyst.

Table 3. Degree of isomerization of 1-octene in hydroformylation reaction with complex **1** and **2**[a][b]

Pt compound	100 °C	120 °C	140 °C	160 °C
1	2.5%	13.7%	27.5%	55.3%
2	3.9%	8.5%	26.7%	46.1%

[a] Reactions were carried out in 10 mL of CH_2Cl_2 under 50 bar of CO/H_2 with an octene/Pt catalyst ratio of 250 (0.02 mmol cat.) and reaction times of 2 h. [b] In the case of complexes **3** and **4** the isomerized olefins were partially hydroformylated.

Table 4. Hydroformylation results of 1-octene with complex **2**[a] and their dependence on the CO/H_2 pressure at 140 °C

Pressure [bar]	*n*/*iso*	TOF [h^{-1}]	iso. Olefins[b]
20	8.9	25.4	43.0%
30	10.1	41.4	24.8%
40	9.7	63.7	27.6%
50	9.2	73.9	26.7%

[a] Reactions were carried out in 10 mL of CH_2Cl_2 under 50 bar of CO/H_2 with an octene/Pt catalyst ratio of 250 (0.02 mmol cat.) and reaction times of 2 h. [b] The isomerized olefins were detected by GC analysis.

In order to study the olefin selectivity, in a separate experiment the hydroformylation of *trans*-4-octene at 140 and 160 °C was investigated with complex **2**. Here the formation of 3-propyl-1-hexanal was not detected; olefin isomerization took place. The internal olefins thus formed did not undergo hydroformylation, and the only aldehydes obtained were *n*-nonanal (1-nonanal, **5**) and *iso*-nonanal (2-methyl-1-octanal, **6**).

Conclusion

To conclude, with the stanna-*closo*-dodecaborate dianion we have found a new ligand for the activation of platinum complexes for hydroformylation. The $Pt(SnB_{11}H_{11})$ derivatives studied here have a higher thermal stability and are more selective in hydroformylation experiments than their $SnCl_3$ analogues. *n*- and *iso*-nonanal (**5**, **6**) are the only aldehydes formed during the catalysis.

Experimental Section

General: All manipulations were carried out under dry N_2 in Schlenk glassware; solvents were dried and purified by standard methods and were stored under N_2; NMR Bruker AC 200 (^1H: 200 MHz, int. TMS. $^{31}P\{^1H\}$: 81 MHz, ext. H_3PO_4. $^{11}B\{^1H\}$: 64 MHz, ext. $BF_3{\cdot}Et_2O$); Elemental analysis: Institut für Anorganische Chemie der Universität zu Köln, Heraeus C,H,N,O-Rapid elemental analyser.

$[Bu_3MeN][(dppp)PtPh(SnB_{11}H_{11})]$ (1): At room temperature (dppp)Pt(Ph)Cl (360 mg, 0.50 mmol) was dissolved in 10 mL of CH_2Cl_2 and reacted with a CH_2Cl_2 solution of $[Bu_3MeN]_2[SnB_{11}H_{11}]$ (341 mg, 0.53 mmol). The solution turned yellow immediately and was stirred for 24 h. The solvent was then evaporated and the remaining solid was washed with water to give **1** (493 mg, 87%). Since we were not able to recrystallise this salt, an elemental analysis of the crude product was carried out. ^1H NMR (CD_2Cl_2, 200 MHz, TMS, without the signals for $[Bu_3MeN]^+$): δ = 2.00 (m, 2 H, dppp), 2.50 (m, 4 H, dppp), 6.40 (m, 1 H, Pt-Ph), 6.53 (m, 2 H, Pt-Ph), 6.92 (m, 2 H, Pt-Ph), 7.2−7.4 (m, 12 H, P-Ph), 7.8−7.9 (m, 8 H, P-Ph) ppm. $^{11}B\{^1H\}$ NMR (CD_2Cl_2, 64 MHz, ext. BF_3Et_2O): δ = −16.1 (s, B2−B11), −10.9 (s, B12) ppm. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 81 MHz, ext. H_3PO_4): δ = −5.4 (d, $^2J_{P\text{-}P}$ = 26.2, $^1J_{P\text{-}Pt}$ = 1733.0, $^2J_{P\text{-}Sn}$ = 204.9 Hz), 2.4 (d, $^2J_{P\text{-}P}$ = 26.2, $^1J_{P\text{-}Pt}$ = 3167.3, $^2J_{P\text{-}Sn}$ = 2419.5 Hz) ppm. $C_{46}H_{72}B_{11}NP_2PtSn$

(1133.7): calcd. C 48.73, H 6.40, N 1.24; found C 49.51, H 6.01, N 1.59.

$[Bu_3MeN]_2[(dppp)Pt(SnB_{11}H_{11})_2]$ (2): At room temperature a solution of $[(dppp)PtCl_2]$ (250 mg, 0.37 mmol) in 20 mL of CH_2Cl_2 was added to a solution of $[Bu_3MeN]_2[SnB_{11}H_{11}]$ (479 mg, 0.74 mmol) also in 20 mL of CH_2Cl_2. The colour of the reaction mixture turned orange immediately and after 14 h stirring the solvent was evaporated. The resulting solid was washed with water (two times with 30 mL). Crystallization from acetone/methanol at room temperature yielded yellow-green crystals of **2** (498 mg, 90%). ^1H NMR (CD_2Cl_2, 200 MHz, TMS, without the signals for $[Bu_3MeN]^+$): δ = 2.08 (m, 2 H, dppp), 2.42 (m, 4 H, dppp), 7.48 (m, 12 H, Ph), 7.85 (m, 8 H, Ph) ppm. $^{11}B\{^1H\}$ NMR (CD_2Cl_2, 64 MHz, ext. BF_3Et_2O): δ = −15.8 (s, B2−B11), −9.5 (s, B12) ppm. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 81 MHz, ext. H_3PO_4): δ = −1.1 (s, $^1J_{Pt\text{-}P}$ = 2820.7, $^2J_{P\text{-}Sn}$ = 2127.5 Hz)] ppm. $C_{53}H_{108}B_{22}N_2P_2PtSn$ (1387.0): calcd. C 42.28, H 7.23, N 1.86; found C 42.11, H 7.32, N 2.12.

Experimental Setup: All hydroformylations were carried out in a 75 mL steel autoclave which was built in the workshop of the Institut für Makromolekulare und Technische Chemie der Technischen Hochschule Aachen. The autoclave possesses a 25 mL dropping funnel equipped with a pressure release, a valve connected to a steel capillary with a diameter of 1 mm to take samples, a manometer and two other valves. The reaction mixture was stirred by a cross magnetic stirrer.

Experimental Procedure for Hydroformylations: The reactor was evacuated and filled with argon three times. The catalyst solution, prepared previously in a Schlenk vessel, was then introduced (the exact amount was determined by a syringe). The exact amounts of 1-octene and of GC standard (di-*n*-butyl ether) were transferred to the dropping funnel. The autoclave was pressurized with synthesis gas (CO/H_2) and was heated to reaction temperature by placing it in an oil bath. The reaction mixture was stirred at 750 rpm and kept for 30 minutes at the reaction temperature in order to ensure the preformation of the active catalyst species before the mixture of 1-octene and GC standard was added. Finally the autoclave was cooled in an ice bath, slowly vented and the mixture was analysed by GC.

Analytical Methods for Hydroformylations: The GC chromatograms were recorded on a Sichromat 2 apparatus (Siemens) equipped with a FID detector and an HP-LAS 3359 integrator. Column: 50m Pona-HP-FS; temperature program: 5 min isotherm at 80 °C; 8 °C per minute to 25 °C; temperature of the evaporator: 250 °C; He, 1.5bar; volume of the sample: 0.2 to 1.0 μL.

A New Coordination Mode for the Tripodal $[Te(NtBu)_3]^{2-}$ Dianion: Preparation and Structures of $\{ClIn[Te(NtBu)_3]\}_2$ and $\{LiIn[Te(NtBu)_3]_2\}\cdot LiCl$

Tristram Chivers*[a] and Gabriele Schatte[a]

Keywords: Indium / Tellurium / Imido compound / Tridentate ligand

The complexes $\{ClIn[Te(NtBu)_3]\}_2$ (**1**) and $\{LiIn[Te(NtBu)_3]_2\}\cdot LiCl$ (**2**) are formed from the reaction of $InCl_3$ (or InCl) with $\{Li_2[Te(NtBu)_3]\}_2$ in toluene. The $[Te(NtBu)_3]^{2-}$ dianions in the centrosymmetric dimer **1** act as tridentate [bis(*N*,*N*′-monodentate), μ_2-*N*′′] ligands bridging two indium atoms. Complex **2** involves a spirocyclic indium centre bis(*N*,*N*′-chelated) by two $[Te(NtBu)_3]^{2-}$ ions.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The pyramidal tris(imido) chalcogenite anions $[E(NtBu)_3]^{2-}$ (E = S, Se, Te),[1−3] isoelectronic with EO_3^{2-}, are potentially interesting tridentate ligands.[4] The tellurium congener $[Te(NtBu)_3]^{2-}$ acts as an *N*,*N*′-bidentate ligand in $PhB(\mu\text{-}NtBu)_2TeNtBu$[1] and in the anions $[M(\mu\text{-}NtBu)_2TeNtBu]^-$ (M = Sb, Bi).[5] The formation of coordination complexes is often accompanied by redox processes.[1,6,7] For example, the reaction of $[Te(NtBu)_3]^{2-}$ with $PhPCl_2$ produces the spirocycle $Te[(\mu\text{-}NtBu)_2P(Ph)NtBu]_2$, formally a tellurium(IV) complex of the $[PhP(NtBu)_3]^{2-}$ dianion, and elemental tellurium.[1] More dramatically, the stannatellurone $[tBuNSn(\mu\text{-}NtBu)_2TeNtBu](\mu_3\text{-}SnTe)$ is produced from $[Te(NtBu)_3]^{2-}$ and $SnCl_2$.[8] We report here the synthesis and structures of the neutral, dimeric complex $\{ClIn[Te(NtBu)_3]\}_2$ (**1**), in which the $[Te(NtBu)_3]^{2-}$ dianion adopts a novel, tridentate bonding mode, and the lithium chloride adduct $\{LiIn[Te(NtBu)_3]_2\}\cdot LiCl$ (**2**) with a spirocyclic indium centre.

Results and Discussion

Synthesis

The reaction of $\{Li_2[Te(NtBu)_3]\}_2$ with indium trichloride produces two complexes $\{Cl[InTe(NtBu)_3]\}_2$ (**1**) and $\{LiIn[Te(NtBu)_3]_2\}\cdot LiCl$ (**2**) as extremely moisture-sensitive, yellow solids. The relative amounts of **1** and **2** are determined by the stoichiometry. Thus, **1** is obtained in ca. 60% yield from the 1:2 reaction [Equation (1)] while **2** is best prepared by using a 2:3 stoichiometry. The separation of **1** and **2** is difficult because of their similar solubilities, but **2** may be isolated in modest yields by fractional crystallization from benzene.

$$\{Li_2[Te(NtBu)_3]\}_2 + 2\,InCl_3 \rightarrow \{Cl[InTe(NtBu)_3]\}_2 + 4\,LiCl \quad (1)$$

Complex **1** may also be obtained (ca. 65% yield with respect to Te) from the reaction of $\{Li_2Te(NtBu)_3\}_2$ with indium monochloride. However, this process is inefficient with respect to the use of indium, $^2/_3$ of which is reduced to In metal [Equation (2)].

$$\{Li_2[Te(NtBu)_3]\}_2 + 6\,InCl \rightarrow \{Cl[InTe(NtBu)_3]\}_2 + 4\,In + 4\,LiCl \quad (2)$$

Complexes **1** and **2** were characterised by multinuclear (^1H, ^{13}C, ^{125}Te, ^7Li) NMR spectra. However, the ^1H NMR spectra were structurally uninformative. Thus, both **1** and **2** exhibit singlets at δ = 1.558 and 1.407 ppm, respectively, in $[D_8]THF$ at 23 °C indicative of fluxional processes. These resonances broaden upon lowering the temperature, but resolution of these signals was precluded by the low solubility of **1** and **2** at low temperature.

X-ray Crystal Structures of 1 and 2

An X-ray crystallographic study revealed that **1** is a centrosymmetric dimer with a "deck-chair" structure (Figure 1).[9] As illustrated in Scheme 1, the dimer **1** may be viewed to form by association of the putative monomer $ClIn(\mu\text{-}NtBu)_2TeNtBu$, cf. $PhB(\mu\text{-}NtBu)_2TeNtBu$.[1] The $[Te(NtBu)_3]^{2-}$ dianion in **1** behaves as a tridentate ligand. Two of the nitrogen atoms, N(2) and N(3), are coordinated in a monodentate fashion to different indium atoms, while the third [N(3)] bridges those two indium atoms. Selected bond lengths and angles are given in the Figure caption. The mean Te−N bond length of 198.2 pm may be compared with the values of 208.1 and 187.8 pm for the bridging and terminal Te−N bonds, respectively, in $PhB(\mu\text{-}NtBu)_2TeNtBu$.[1] The Te−N bond length involving the

[a] Department of Chemistry, University of Calgary, Calgary, Alberta T2N 1N4, Canada
E-mail: chivers@ucalgary.ca

bridging (four-coordinate) nitrogen atom is slightly longer (by ca. 4 pm) than those involving three-coordinate nitrogen atoms. The geometry about the indium atom is a highly distorted trigonal bipyramid. The mean axial In−N bond length of 215.4(3) pm is significantly shorter than the mean value of 223.7 pm observed for the related five-coordinate monomeric complex $[CyNC(tBu)NCy]_2InCl$.[10] There is a large disparity in the bridging In−N bond lengths of the four-membered In_2N_2 ring. The In−N(1) distance of 220.5(3) pm is in the range reported for five-coordinate indium,[10,11] whereas the In−N(1)* separation of 250.9(3) pm is typical of a long-range intramolecular interaction.[12] This disparity leads to a substantial difference in the geometries of the two InN_2Te rings. The distortion of the tbp geometry is reflected in the bond angles at the indium centre. The axial bond angle N−In−N of 157.14(13)° deviates substantially from linearity. The sum of the bond angles in the equatorial plane is ca. 359°, but there is a notable difference between the values of Cl−In−N(1) and Cl−In−N(1)*, 164.89(8) and 110.19(9)°. The In−Cl distance of 2.4464(13) Å is slightly longer than the values of 2.383(9) and 2.405(1) Å found for related five-coordinate complexes,[10,11] probably as a result of weak Te···Cl interactions [374.67(13) pm, cf. sum of the van der Waals radii is 381[13a] or 400 pm],[13b] which give rise to a tetrameric array of dimeric molecules in the unit cell.

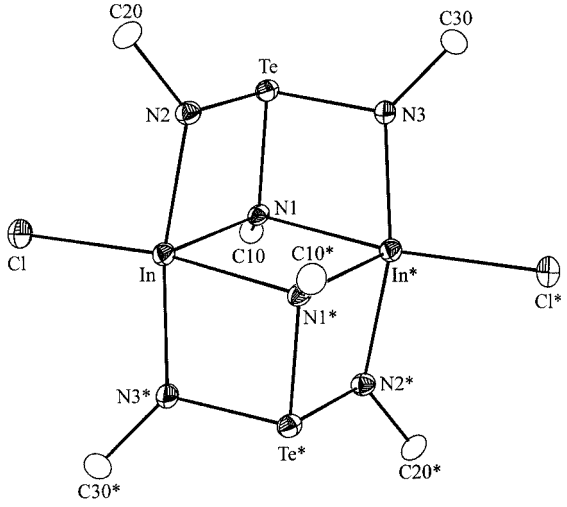

Figure 1. ORTEP diagram (30% probability ellipsoids) for **1**; only the α-carbon atoms of *t*Bu groups are shown; selected bond lengths [pm] and bond angles [°]: Te−N(1) 201.0(3), Te−N(2) 197.3(3), Te−N(3) 196.3(4), In−N(1) 220.5(3), In−N(1)* 250.9(3), In−N(2) 217.3(3), In−N(3)* 213.5(3), In−Cl 244.64(13); N(2)−In−N(3)* 157.14(3), N(1)−In−Cl 110.19(9), N(1)−In−N(1)* 84.90(12), Cl−In−N(1)* 164.89(8); symmetry transformations used to generate equivalent atoms: *: $-x + 1, -y, -z$

An X-ray analysis revealed that $\{Li\{In[Te(NtBu)_3]_2\}\}\cdot LiCl$ (**2**) is a centrosymmetric dimer (Figure 2). Important structural parameters are given in the Figure caption. Each monomeric unit consists of an indium centre bis(*N*,*N*′-chelated) by two $[Te(NtBu)_3]^{2-}$ dianions in a distorted tetrahedral arrangement. Charge balance is provided

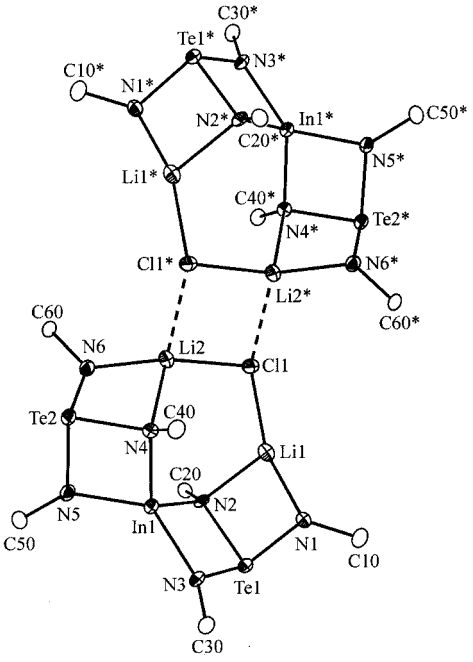

Figure 2. ORTEP diagram (30% probability ellipsoids) for **2** showing the intermolecular Li···Cl interactions; only the α-carbon atoms of *t*Bu groups are shown; symmetry transformations used to generate equivalent atoms: *: $-x + 2, -y + 1, -z + 1$; selected bond lengths [pm] and bond angles [°]: $|Te-N_{endo}|$ 199.2(3), $|Te-N_{exo}|$ 191.8(1), $|In-N_{axial}|$ 216(1), $|In-N_{eq}|$ 208(1), Li−N 195.0(16)−218.4(16), Li(1)−Cl(1) 220.3(15), Li(2)−Cl(1) 238.1(13); N(2)−In(1)−N(3) 77.3(2), N(2)−In(1)−N(5) 130.9(3), N(3)−In(1)−N(5) 131.4(3), N(5)−In(1)−N(4) 78.2(2), N(3)−In(1)−N(4) 131.2(2), N(2)−In(1)−N(4) 114.4(2)

by an Li^+ counterion. In addition, one molecule of LiCl is incorporated into the structure so that an $[Li-Cl-Li]^+$ unit bridges the spirocyclic $\{In[Te(NtBu)_3]_2\}^-$ anion, which is *N*,*N*′-chelated to both lithium centres.[14] The asymmetry in this bridge is the result of dimer formation through a weak Li···Cl interaction [Li(2)···Cl(1) = 247.9(3) pm]. A similar dimeric structural arrangement has been reported recently for $[(THF)_2Li_3Cl\{(NtBu)_3\}S]_2$.[15] The spirocyclic structure of **2**, prior to entrapment of LiCl (Scheme 1), is reminiscent

of the structures of the group-15 derivatives $Li\{M[Te(NtBu)_3]_2\}$ (M = Sb, Bi).[5] However, the bond angles of 84.6(2) and 83.5(3)° subtended at the indium atom are significantly larger than the corresponding bond angles in $Li\{M[Te(NtBu)_3]_2\}$ [72.7(3)° (M = Bi) and 75.4(5)° (M = Sb)].[5] The smaller angles presumably reflect the influence of the lone-electron pair located on the group-15 metal atoms. The geometry at the Te atoms is distorted trigonal-pyramidal with a mean Te−N bond length of 196.7(7) pm, cf. $|d(Te-N)|$ = 197.6(2) pm in $\{Li_2[Te(NtBu)_3]\}_2$.[1] As expected, the Li−N and In−N bond lengths involving the four-coordinate nitrogen atoms, N(2) and N(4), are significantly longer than the corresponding bond lengths involving the three-coordinate nitrogen atoms, N(1)/N(6) and N(3)/N(5), respectively. Curiously, however, this disparity is not observed for the Te−N bonds within the TeN_2In rings, which are equal within the experimental error.

In summary, complex **1** represents the first example of the bridging tridentate bonding mode [bis(*N*,*N*′-monodentate), μ$_2$-*N*′′] for the $[Te(NtBu)_3]^{2-}$ dianion. It is also the first complex of the tris(imidotellurite) dianion that contains an element−halogen bond, which may be utilized for further metathetical reactions.

Experimental Section

General Procedures: Indium(III) chloride and indium(I) chloride (Aldrich, 99.999%) were used as received. $\{Li_2[Te(NtBu)_3]\}_2$ was prepared by a literature procedure.[1,14b] Solvents were dried with the appropriate drying agents and distilled onto molecular sieves before use. All reactions and the manipulation of moisture-sensitive products were carried out under argon or under vacuum. ^{1}H NMR spectra were recorded with Bruker ACE 200 and AM 400 spectrometers, and chemical shifts are reported relative to Me_4Si in $CDCl_3$. ^{13}C and ^{125}Te NMR spectra were measured with a Bruker AM 400 spectrometer using a 5-mm broadband probe operating at 100.594 and 126.393 MHz, respectively. The samples were externally referenced to K_2TeO_3 in D_2O referred to Me_2Te and Me_4Si in $CDCl_3$, respectively. Relaxation delays of 3 and 1.5 s were applied for the measurement of the ^{13}C and ^{125}Te NMR spectra, respectively.

Synthesis of $\{ClIn[Te(NtBu)_3]\}_2$ (1): (a) A suspension of $InCl_3$ (0.250 g, 1.128 mmol) in toluene (20 mL) was added to a pale yellow solution of $\{Li_2[Te(NtBu)_3]\}_2$ (0.400 g, 0.564 mmol) in toluene (10 mL) at −78 °C. THF (10 mL) was added and the yellow slurry was stirred for 10 min at −78 °C and then allowed to reach 23 °C. After 24 h, the intense yellow solution was filtered and the volatile material was removed from the filtrate under vacuum. The solid residue was extracted with *n*-hexane (10 mL) to give **1** as a pale yellow solid (0.339 g, 0.345 mmol, 61%). ^{1}H NMR ([D$_8$]THF): δ = 1.56 [C(C*H*$_3$)$_3$] ppm. ^{13}C NMR ([D$_8$]THF): δ = 37.4 [C(*C*H$_3$)$_3$], 59.9 [*C*(CH$_3$)$_3$] ppm. ^{125}Te NMR ([D$_8$]THF): δ = 1570.6 ppm. $C_{24}H_{54}Cl_2In_2N_6Te_2$ (982.47): calcd. C 29.34, H 5.54, N 8.55; found C 28.64, H 5.98, N 8.09; the product was recrystallised from THF to give **1**·(THF)$_{0.5}$: calcd. C 30.66, H 5.74, N 8.25; found C 30.18, H 6.42, N 8.61. **(b)** A solution of $\{Li_2[Te(NtBu)_3]\}_2$ (0.110 g, 0.155 mmol) in toluene (10 mL) was added to a suspension of InCl (0.093 g, 0.620 mmol) in THF (10 mL) at 23 °C. The formation of indium metal was observed. After 1.5 h, the volume of the solution was reduced to 4 mL and X-ray quality, yellow crystals of **1** (0.098 g, 0.099 mmol, 64% based on Te) were obtained after 1 d at −20 °C.

Synthesis of $\{LiIn[Te(NtBu)_3]_2\}\cdot LiCl$ (2): A suspension of $InCl_3$ (0.169 g, 0.764 mmol) in toluene (10 mL) was added to a pale yellow solution of $\{Li_2[Te(NtBu)_3]\}_2$ (0.400 g, 0.563 mmol) in toluene (10 mL) at −78 °C. The suspension was stirred for 15 min at −78 °C and then allowed to reach 23 °C. After 3 h, the yellow solution was filtered and the solvent was removed from the filtrate under vacuum. The solid residue was extracted with *n*-hexane (5 mL) to give **2** as a yellow solid (0.238 g, 0.109 mmol, 19%). ^{1}H NMR (C_6D_6): δ = 1.29 [C(C*H*$_3$)$_3$, 9 H], 1.38 [C(C*H*$_3$)$_3$, 9 H] ppm. ^{1}H NMR ([D$_8$]THF): δ = 1.41 ppm. ^{13}C NMR ([D$_8$]THF): δ = 38.1 [C(*C*H$_3$)$_3$], 53.7 [*C*(CH$_3$)$_3$] ppm. ^{7}Li NMR ([D$_8$]THF): δ = 2.06 ppm. ^{125}Te NMR ([D$_8$]THF): δ = 1589 ppm. The presence of hexane and small amounts of **1** was evident from the NMR spectra. **2**·(C$_7$H$_{14}$)$_{0.5}$: calcd. C 36.46, H 6.91, N 9.45; found C 35.73, H 7.68, N 9.30.

X-ray Analyses: All measurements were made with a Bruker AXS SMART 1000 CCD. A yellow prismatic crystal of **1** (0.21 × 0.20 × 0.15 mm) was coated with Paratone oil and mounted on a glass fibre. $C_{24}H_{54}Cl_2In_2N_6Te_2$, *M* = 982.47, monoclinic, space group $P2_1/n$, *a* = 10.1689(18), *b* = 15.684(3), *c* = 11.874(2) Å, β = 110.650(2)°, *V* = 1768.0(5) Å, D_c = 1.845 Mg m^{-3}, *Z* = 2, μ(Mo-K_α) = 3.095 mm^{-1}, *T* = 193(2) K. Of a total of 5507 collected reflections 3301 were unique and 2771 had $I > 2\sigma(I)$. The data were corrected for absorption by semi-empirical methods. The structure was solved by direct methods[16] and refined by full-matrix least-squares methods on F^2.[17] A yellow plate-like crystal of **2** (0.21 × 0.16 × 0.10 mm), obtained by fractional crystallization from C_6D_6, was coated with Paratone oil and mounted on a glass fibre. $C_{24}H_{54}ClInLi_2N_6Te_2$, *M* = 846.08, triclinic, space group $P\bar{1}$, *a* = 10.6736(15), *b* = 13.483(2), *c* = 14.357(2) Å, α = 98.885(3), β = 113.036(2), γ = 106.574(2)°, *V* = 1737.5(4) Å^3, D_c = 1.617 Mg m^{-3}, *Z* = 2, μ(Mo-K_α) = 2.424 mm^{-1}, *T* = 193(2) K. Of a total of 14227 collected reflections 6963 were unique and 4782 had $I \geq 2\sigma(I)$. A faced-indexed absorption correction was applied. The structure was solved by the heavy-atom method[18] and refined by full-matrix least-squares methods on F^2.[17] CCDC-183320 (**1**) and -183321 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

1,2-Dichalcogenolylium Ions $(C_3Cl_3E_3)^+$ from Equilibria Involving Dichalcogen Dichlorides E_2Cl_2 (E = S, Se, Te) − Syntheses and Crystal Structures of $(C_3Cl_3S_2)Cl$, $(C_3Cl_3Se_2)Cl$, and $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$

Johannes Beck,*[a] Andreas Hormel,[a] and Michael Koch[a]

Keywords: Chalcogens / Heterocycles / Cations / Solvothermal synthesis

The reaction of tetrachlorocyclopropene with $SeCl_4$ or $TeCl_4$ in CH_2Cl_2 under solvothermal conditions at 120 °C and 90 °C, respectively, is a suitable route to 1,2-dichalcogenolylium ions. Yellow crystals of $(C_3Cl_3Se_2)^+Cl^-$ or red crystals of $\{(C_3Cl_3Te_2)^+\}_2[Te_2Cl_{10}]^{2-}$ are formed in such reactions. The reaction of hexachloropropene with elemental sulfur — the well-known route to 3,4,5-trichloro-1,2-dithiolylium chloride $(C_3Cl_3S_2)Cl$ — turned out not to be transferable to selenium and tellurium chemistry. NMR investigations of the reaction solutions allowed to set up reaction equilibria also involving hexachloropropene and dichalcogen dichlorides E_2Cl_2. The crystal structures of all three compounds were determined by X-ray diffraction. All contain planar, five-membered ring shaped cations $(C_3Cl_3E_2)^+$ (E = S, Se, Te). Short E–E bonds (S–S 201, Se–Se 231, Te–Te 266 pm) indicate substantial π-bonding and charge delocalisation. The anion in $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ consists of two tetragonal pyramidal $[TeCl_5]^-$ units linked by long Te–Cl bridges to centrosymmetric dimers in the form of edge-sharing double octahedra.

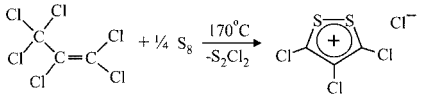
Introduction

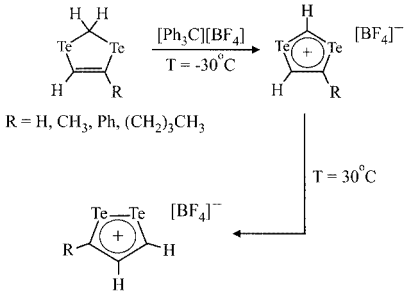
The 1,2-dithiolylium ion is a well-known aromatic planar five-membered ring system. Molecular orbital calculations were carried out on the unsubstituted 1,2-dithiolylium ion by Bergson,[1] and these showed that one 3p electron pair of each sulfur atom is involved in a 6π-electron aromatic system.

Syntheses leading to a variety of differently substituted 1,2-dithiolylium ions have been developed. The reaction of hexachloropropene with sulfur at 160 °C was described by Boberg[2] to yield 3,4,5-trichloro-1,2-dithiolylium chloride (Scheme 1), a stable yellow solid with a decomposition temperature of 235 °C but unknown crystal structure.



Scheme 1. Synthesis of 1,2-dithiolium chloride from hexachloropropene and sulfur

Although a lot of stable 1,2-dithiolylium salts are known much less work has been done on the respective 1,2-ditellurolylium ions. Bender et al. obtained the unsubstituted 1,3-ditellurolylium ion $(C_3H_3Te_2)^+$ by oxidation of 1,3-ditellurol at low temperatures.[3] NMR studies at ambient temperature indicated a rapid rearrangement to the 1,2-ditellurolylium ion (Scheme 2). Alkyl or aryl substituents caused an acceleration of the rearrangement from 1,3- to 1,2-ditelluroles with the consequence that the intermediate 1,3-ditellurolylium ions could not be detected on the NMR time scale. The 1,2-ditellurolylium ion was supposed to be planar with a delocalized positive charge. Above room temperature rapid decomposition with precipitation of tellurium occurs for solutions containing alkyl- or aryl-substituted $(C_3R_3Te_2)^+$ ions. No reports on 1,2-diselenolylium ions have been published.



Scheme 2. Synthesis of 1,3-ditellurolylium salts by oxidation of 1,3-ditelluroles, and their rearrangement to 1,2-ditellurolylium salts

In our studies on the reactivity of tetrachlorocyclopropene toward Lewis acidic metal halides we discovered a straightforward method for the synthesis of 1,2-dichalcogenolylium ions, including the previously unknown diseleno derivative.

Results and Discussion

Synthesis of $(C_3Cl_3E_2)^+$ Ions (E = Se, Te) from Tetrachlorocyclopropene and ECl_4

Heating $SeCl_4$ and tetrachlorocyclopropene in CH_2Cl_2 under solvothermal conditions in a molar ratio of 1:2 yields yellow crystals of 3,4,5-trichloro-1,2-diselenolylium chloride, $(C_3Cl_3Se_2)Cl$, as well as a black precipitate of elemental selenium. The composition of the crystals was checked by energy dispersive X-ray fluorescence. ^{77}Se NMR spectroscopy of the filtered red reaction solution showed one signal with a chemical shift of $\delta = 1257$ ppm, which is ascribed to Se_2Cl_2.[4] The ^{13}C NMR spectrum showed the signals of hexachloropropene ($\delta = 92.7$, 127.4, and 131.8 ppm[5]), and tetrachlorocyclopropene ($\delta = 62.4$ and 122.6 ppm[5]). Due to the very low solubility, signals attributable to the Se atoms of the 1,2-diselenolylium cation could not be detected. A two-step reaction mechanism is supposed: the first step is a redox equilibrium between tetrachlorocyclopropene/$SeCl_4$ and hexachloropropene/selenium (Scheme 3), and the second step yields $(C_3Cl_3Se_2)Cl$ and Se_2Cl_2 analogous to the reaction of hexachloropropene and sulfur described by Boberg.[3]

$$2\,C_3Cl_4 + ECl_4 \rightleftharpoons 2\,C_3Cl_6 + E$$

$$C_3Cl_6 + 4\,E \rightleftharpoons (C_3Cl_3E_2)Cl + E_2Cl_2$$

$$C_3Cl_4 + E_2Cl_2 \rightleftharpoons C_3Cl_6 + 2\,E$$

Scheme 3. Equilibria in the reactions between chalcogen tetrachlorides and tetrachlorocyclopropene (E = Se, Te)

Heating equimolar amounts of $TeCl_4$ and tetrachlorocyclopropene in CH_2Cl_2 yields deep-red 3,4,5-trichloro-1,2-ditellurolylium pentachlorotellurate(IV) $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$. Energy dispersive X-ray fluorescence confirmed the composition. The ^{125}Te NMR spectrum of the deep-red solution shows one signal at $\delta = 1830$ ppm and a second very weak signal at $\delta = 1000$ ppm. It was verified by comparative measurements that the signal occurring at $\delta = 1830$ ppm was not from $TeCl_4$. This signal can therefore be assigned to tellurium in $(C_3Cl_3Te_2)^+$. Only one signal for both tellurium atoms is expected for chemically equivalent nuclei, consistent with the mirror symmetry of the cation. The second signal might be due to Te_2Cl_2 as an intermediate in the reaction equilibrium. Te_2Cl_2 has recently been prepared from Te, $LiBHEt_3$ and $TeCl_4$,[6] and a ^{125}Te NMR resonance at $\delta = 1336$ pm in CS_2 and $\delta = 1287$ ppm in toluene has been reported. Since it is known that ^{125}Te NMR signals are very dependent on the solvent, we can tentatively propose that the reaction of $TeCl_4$ and C_3Cl_4 incorporates the same equilibria as for the reaction of $SeCl_4$ (Scheme 3). In the ^{13}C NMR spectrum four resonances between $\delta = 172.4$ and 160.3 ppm were present, indicating equilibria between cationic species. The unsubstituted dithiolylium cation $(C_3H_3S_2)^+$ shows two signals at $\delta = 142.6$ and 176.7 ppm in this region, corresponding to the central and the terminal carbon atoms of the allylic group.[7]

While $(C_3Cl_3S_2)Cl$ can readily be obtained from hexachloropropene and sulfur, neither $(C_3Cl_3Se_2)Cl$ nor $(C_3Cl_3Te_2)Cl$ could be synthesized in this way with the respective elemental chalcogen; only the reaction of tetrachlorocyclopropene and the respective chalcogen tetrahalide yields the cyclic cations incorporating Se and Te. This is probably caused by the insolubility of selenium and tellurium in organic solvents. The stability of the chalcogen tetrachlorides ECl_4 (E = S, Se, Te) increases from S to Te, while the stability of the dichalcogen dichlorides E_2Cl_2 decreases. The equilibria set up according to Scheme 3 are thus strongly dependent on the kind of chalcogen used. S_2Cl_2 is a favored product in the reaction of C_3Cl_6 with sulfur and it is not reduced to the element by tetrachlorocyclopropene. In the case of selenium this reduction occurs, since a precipitate of finely dispersed elemental selenium is observed. More complex equilibria are present in the case of tellurium. $(C_3Cl_3Te_2)Cl$ could not be isolated, only the less soluble $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$, formed from $(C_3Cl_3Te_2)Cl$ and $TeCl_4$; no precipitation of elemental tellurium was observed at temperatures below 100 °C. Temperatures higher than 110 °C generated a mixture of products which could not be separated or individually characterized.

Crystal Structures

The crystal structures of $(C_3Cl_3S_2)Cl$, $(C_3Cl_3Se_2)Cl$ and $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ all contain nearly planar, five-membered ring shaped cations $(C_3Cl_3E_2)^+$ (E = S, Se, Te; Figure 1). Only $(C_3Cl_3Se_2)^+$ has a crystallographic mirror plane bisecting the ion. $(C_3Cl_3S_2)^+$ and $(C_3Cl_3Te_2)^+$, however, do not deviate substantially from C_s symmetry despite not possessing crystallographic symmetry. In all three ions the C−C and C−Cl bond lengths are almost identical, except for the central C2−Cl2 bond, which increases slightly from S to Te (Table 1). As expected, the chalcogen-C and chalcogen-chalcogen bonds increase in the same direction; they are all shorter than expected for single bonds. In the dithiolylium ion the S−S bond is 200.93(7) pm long, shorter than the expected bond length for a *cis*-planar S−S single bond (210 pm),[8] although it is similar to the bond lengths found in square-planar S_4^{2+} polycations ($S_4[Sb_9F_{39}]$ 197.5−199.5 pm,[9] $S_4[AsF_6]\cdot SO_2$ 201.4 pm[10]) and even shorter than in differently substituted 1,2-dithiolylium ions (3,5-diamino-1,2-dithiolylium iodide 208 pm,[11] 3,5-dimethyl-1,2-dithiolylium tetrachlorocobaltate 202 pm,[12] phenyl-1,2-dithiolylium chloride 202 pm [13]). In the homologous 1,2-diselenolylium ion the Se−Se bond length measures 231.1(2) pm. This is shorter than a normal Se−Se single bond (e.g. 233 pm in Se_8 [14]) and in the typical region for Se_4^{2+} cluster ions ($Se_4[Sb_9F_{39}]$ 224.7−227.6 pm;[15] $Se_4[MoOCl_4]_2$ 226−230 pm[16]). In the 1,2-tellurolylium ion the Te−Te bond is 265.6(2) pm long, which is shorter than in Te_4^{2+} polycations (266−270 pm[17]). The remarkably short chalcogen-chalcogen bonds in this series of trichlorodichalcogenolylium ions indicate bond orders higher than one. The presence of electron-withdrawing substituents strengthens the partial double bond character: on going from E = S to Te in the series $(C_3Cl_3E_2)^+$ the bonding

character changes from an almost equally delocalized system to a separation of a partially localized E−E double bond and the formation of an allylic system [RC=C(R)−CR]$^+$.

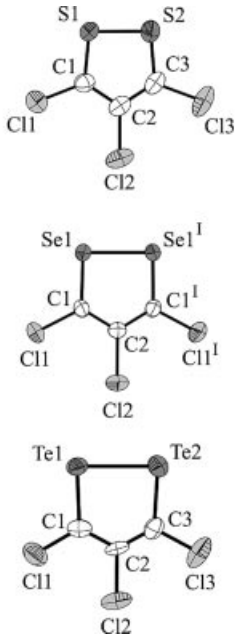

Figure 1. The cations in the structure of $(C_3Cl_3S_2)Cl$ (top), $(C_3Cl_3Se_2)Cl$ (middle), and $(C_3Cl_3Te_2)_2$ $[Te_2Cl_{10}]$ (bottom).; the molecules are drawn to the same scale; the displacement ellipsoids represent a probability density of 50%; the $(C_3Cl_3Se_2)^+$ ion is located with its atoms C2 and Cl2 in a mirror plane, the exponent I refers to the symmetry operation x, $0.5 - y$, z.

In the structure of $(C_3Cl_3S_2)Cl$ the cations are arranged in layers. The chloride ions are located in the layers which are stacked with an interlayer distance of 341 pm along the crystallographic *a*-axis in an ABAB.... sequence (Figure 2). The chloride ion interacts with the cation via short, nearly symmetrical contacts to the sulfur atoms of the disulfide group, with S−Cl distances of 292.5 and 293.3 pm. Additionally, the chloride ion is η^5-coordinated by two cations belonging to adjacent planes with distances of 341 pm to the centres of the rings.

The structure of $(C_3Cl_3Se_2)Cl$ is substantially different from the structure of its sulfur-containing congener. Again, the cations and the chloride anions are located in planes. These planes are stacked along the [101] direction in an ABCABC... sequence with an interlayer distance of 342 pm (Figure 2). Three chloride ions approach the diselenide group of each cation giving rise to triangular Se_2Cl groups with Se−Cl contacts of 305.3 pm lengths and to almost linear $ClSe_2Cl$ groups with Se−Cl distances of 320.7 pm. These interactions link the cations to bands running along the crystallographic *b*-axis. An equivalent arrangement was found in the structure of 4-phenyl-1,2-dithiolylium chloride.[18]

The structure of $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ contains binuclear $[Te_2Cl_{10}]^{2-}$ ions (Figure 3). Two tetragonal pyramidal $[TeCl_5]^-$ units are linked via long Te−Cl bridges (Te3−Cl4 290.0 pm) to centrosymmetric dimers. The Cl−Te3−Cl angles deviate by a maximum of 6° from rectangularity. The Te−Cl bonds, however, show marked differences. There is always a short Te−Cl bond (Te3−Cl6, Te3−Cl7, Te3−Cl8 234.1−244.3 pm) in the *trans* position to a long bond (Te3−Cl4, Te3−Cl4^I, Te3−Cl5 261.6−290.0 pm). The structure of the $[Te_2Cl_{10}]^{2-}$ ion in $(C_3Cl_3Te_2)_2$ $[Te_2Cl_{10}]$ is almost identical to the respective ion in $[Ph_4As]_2$ $[Te_2Cl_{10}]$.[19]

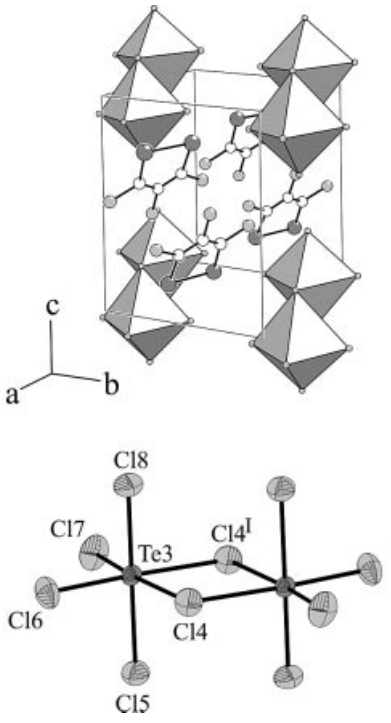

Figure 3. The unit cell of $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ and a detailed view of the dinuclear $[Te_2Cl_{10}]^{2-}$ anion.; the displacement ellipsoids represent a probability density of 50%; the exponent I refers to the symmetry operation $-x + 1, -y, -z$; selected bond lengths [pm] and angles [°]: Te3−Cl4^{I} 290.0(3); Te3−Cl4 274.5(4); Te3−Cl5 261.6(3); Te3−Cl6 238.5(3); Te3−Cl7 234.1(3); Te3−Cl8 244.3(4); Te3−Cl4−Te3^{I} 94.8(1)

Experimental Section

General Techniques: All reactions were carried out in thick-walled glass ampoules of 10 cm length and 10 mm diameter. The ampoules were heated under vacuum to remove traces of water and filled with the starting materials under argon, the solvent was added with a syringe. The contents were frozen with liquid nitrogen, the ampoules were flame-sealed under vacuum and placed in horizontally aligned tube furnaces. Since the products are sensitive towards moisture and oxygen they were opened after the reaction under an argon atmosphere. Liquids were removed with a syringe. Single crystals were prepared under paraffin and mounted in glass capillaries under an argon atmosphere. Tetrachlorocyclopropene (>98%, Fluka) and $SeCl_4$ (Aldrich) were used as purchased. $TeCl_4$ was obtained by chlorinating tellurium powder according to literature procedures.[20] CH_2Cl_2 was dried with P_4O_{10} and freshly distilled before use.

$(C_3Cl_3S_2)Cl$: Heating hexachloropropene (0.1 mL, 7.1 mmol) and sulfur (105 mg, 3.3 mmol) to 170 °C for one day produced yellow needles of $(C_3Cl_3S_2)Cl$. Although the stoichiometry of the reaction (Scheme 1) affords one equivalent of C_3Cl_6 for two equivalents of sulfur, a crystalline product could not be obtained unless a twofold excess of hexachloropropene was used. The yield approached about 70% based on the amount of sulfur used.

$(C_3Cl_3Se_2)Cl$: $SeCl_4$ (270 mg, 1.2 mmol), tetrachlorocyclopropene (0.3 mL, 2.6 mmol), and 1 mL of CH_2Cl_2 were heated slowly at a rate of 10 °C/h to 120 °C. At about 70 °C the $SeCl_4$ dissolved completely with formation of an orange solution. Keeping the temperature at 120 °C for 24 hours and cooling at 10 °C/h to ambient temperature yielded a greyish-black precipitate of elemental selenium and yellow crystals of $(C_3Cl_3Se_2)Cl$. On the basis of $SeCl_4$ the yield reached about 50%.

$(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$: $TeCl_4$ (150 mg, 0.56 mmol), tetrachlorocyclopropene (0.75 mL, 0.65 mmol), and 1.5 mL of CH_2Cl_2 were heated slowly at a gradient of 10 °C/h to 90 °C. After 45 hours the reaction ampoule was cooled to room temperature with a gradient of 5 °C/day. $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ was obtained as dark-red, needle-shaped crystals in low yield (not exceeding 10%). Pure samples could only be obtained by mechanical separation from unchanged starting materials and by-products. UV/Vis (saturated filtered reaction solu-

Crystal Structure Analyses: Crystals of all three compounds were tested for diffraction quality by precession photographs. Data were collected at ambient temperature with a STOE Image Plate diffractometer for $(C_3Cl_3S_2)Cl$ and with a STOE AED 2 four circle diffractometer for $(C_3Cl_3Se_2)Cl$ and $(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$ using graphite monochromated Mo-K_α radiation (λ = 71.073 pm). An empirical absorption correction was applied to the data set of $(C_3Cl_3Se_2)Cl$. Structure models were obtained by direct methods using SHELXS-86[21] and were refined based on F^2 by least-squares full-matrix refinements with anisotropic displacement parameters for all atoms using SHELXL-93.[22] Table 2 contains the crystallographic data and further details of data collection and refinement. CCDC-170239 [$(C_3Cl_3S_2)Cl$], CCDC-170240 [$(C_3Cl_3Se_2)Cl$) and CCDC-170241 [$(C_3Cl_3Te_2)_2[Te_2Cl_{10}]$) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Anion-Dependent Substitution of Zinc by Magnesium in Mononuclear Schiff Base Complexes

Jolante Hermann,[a] Dinah Schumacher,[a] and Andrea Erxleben*[a]

Keywords: Schiff bases / Zinc / Magnesium / Crystal structures

The zinc and magnesium Schiff-base complexes $[ZnL(H_2O)(NO_3)]NO_3$ (**1**) and $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O$ (**2**) (L = Schiff base derived from 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol and glycine) have been prepared and structurally characterized. The reaction of **1** with Mg^{2+} has been studied in water, methanol and DMSO. Substitution of Zn by Mg^{2+} was observed in DMSO and methanol and the amount of Mg complex formed was found to be strongly dependent on the nature and concentration of the anions in solution: Cl^- and $CH_3CO_2^-$ mediate conversion of **1** into **2**, while ClO_4^-, NO_3^-, F^-, Br^-, I^- and SO_4^{2-} are ineffective.

Introduction

In previous papers we outlined our interest in Mg coordination chemistry.[1,2] Mg is an essential cofactor in biology, yet, compared with other biologically relevant metal ions, its coordination chemistry has received little attention.[3−10] Recently, we have studied the reaction of mononuclear Zn complexes derived from binucleating Schiff-base ligands like L′ with $MgCl_2$ and observed substitution of Zn by Mg in DMSO, which appeared to contradict the order of stability predicted by the Irving−Williams series.[11] However, the low solubility of the compounds prevented more detailed studies, for example, the use of different solvents. Furthermore, only $MgCl_2$ was used as the Mg salt, and salts with other anions were not considered. We have now studied the Schiff-base ligand derived from 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol and glycine (L) that forms the mononuclear Zn complex $[ZnL(H_2O)(NO_3)]NO_3$ (**1**) with Zn binding to the glycine side arm, while the protonated ammonium nitrogens render the complex soluble. Besides the effect of the solvent we have also investigated the reaction of **1** with different Mg salts and found that the metal ion exchange is strongly dependent on the anions present in solution.

Results and Discussion

Synthesis and Characterisation of $[ZnL(H_2O)(NO_3)]NO_3$ (1) and $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O$ (2)

The zinc complex $[ZnL(H_2O)(NO_3)]NO_3$ (**1**) was prepared in situ by Schiff base condensation of 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol with glycine in the presence of $Zn(NO_3)_2{\cdot}6H_2O$. X-ray suitable crystals were obtained from methanol/water at pH 5.4. As shown in Figure 1, the ligand coordinates to zinc in a tridentate manner through the deprotonated phenolic oxygen,

the carboxylate group and the imine nitrogen. The amine nitrogens are both protonated and remain uncoordinated. The coordination sphere of Zn is completed by a water molecule and a nitrate ion that binds in an asymmetric chelating mode [Zn(1)−O(4) 2.470(9) Å, Zn(1)−O(5) 2.076(6) Å]. In the crystal packing hydrogen bonding interactions occur that involve the aqua ligand, the carboxylate and nitrate oxygens as well as the ammonium nitrogens (Table 1).

As described below the reaction of **1** with Mg^{2+} leading to the conversion of the Zn complex into the Mg complex of L was studied in solution by NMR spectroscopy; for an unambiguous assignment of the NMR resonances the Mg complex was prepared on a preparative scale. Reaction of 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol with sodium glycinate in the presence of $Mg(NO_3)_2{\cdot}6H_2O$ and NaOH yielded the Schiff-base complex of composition $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O$ (**2**), the X-ray structure of which is depicted in Figure 2. Mg binds to the phenolate oxygen, one carboxylate oxygen and the imine nitrogen and to three water ligands. Again, both amine nitrogens are protonated and noncoordinating. Due to the narrow bite angle of the chelating ligand, Mg adopts a distorted octahedral coordination geometry with the angles around Mg ranging from 76.7 to 100.0° (Table 2).

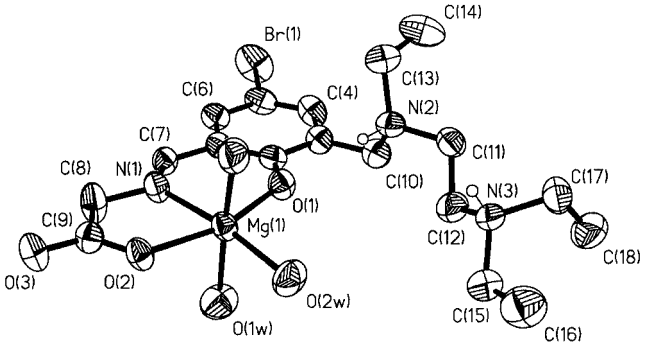

Figure 2. View of the cation of $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O$ (**2**) with atom numbering scheme; except for the ammonium protons, hydrogen atoms are omitted for clarity

Solution Studies

Mg^{2+} shows a strong tendency to bind six water molecules in its inner coordination sphere so that in aqueous solution no reaction of **1** with Mg salts was observed. Consequently it was not unexpected that addition of one equivalent of $Zn(NO_3)_2$ to a solution of **2** in D_2O (pD 9.7) resulted in complete conversion into **1**. Even in the presence of 10 equivalents of $MgCl_2$ (for the choice of Cl^- ions see below) the percentage of **2** is less than 5%. We note that there is no indication for metal binding to the second coordination site of the ligand even under basic conditions.

By contrast, Zn is replaced by Mg when **1** is treated with $MgCl_2$ in DMSO, as observed before for related Schiff-base ligands.[1,2] Addition of three equivalents of $MgCl_2$ leads to approximately 44% conversion of **1** into **2**. The NMR spectra of the reaction solution reveal no change with time. In MeOD 11 equivalents of $MgCl_2$ are required to give an approximately 1:1 mixture of **1** and **2**. Consequently, the concentration of the Mg complex in DMSO is significantly reduced upon addition of MeOD, as shown in Figure 3. In the presence of 10 and 20% MeOD the percentage of **2** decreases to 33 and 22%, respectively. The effect of D_2O is even more pronounced: Upon addition of 20% D_2O the equilibrium is completely shifted towards the Zn complex. Exchange of Zn with Mg in DMSO can be attributed to the low dielectric constant of DMSO that stabilizes Mg binding to the N,O-ligand.

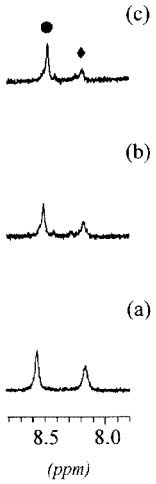

Figure 3. Reaction of **1** with 3 equiv. $MgCl_2$ in [D_6]DMSO solutions containing increasing amounts of MeOD; ^1H NMR spectra (δ = 7.8−8.8 ppm, resonance of the azomethine proton) for (a) 0, (b) 10 and (c) 20% MeOD; (•) $[ZnL]^{2+}$ (◆) $[MgL]^{2+}$

Apart from the effect of the solvent the equilibrium between the Zn and Mg complex is dependent on the anions present in solution. When **1** is treated with $Mg(NO_3)_2$, $Mg(ClO_4)_2$ or $MgSO_4$ instead of $MgCl_2$, no metal-ion substitution is observed in DMSO, while two equivalents of $Mg(CH_3CO_2)_2$ yield 38% of **2**. Addition of NaCl to a 1:1 mixture of **1** and $Mg(ClO_4)_2$ mediates formation of **2**. As shown in Figure 4 the concentration of **2** increases with increasing concentrations of NaCl until ca. 40% of the Mg complex is formed in the presence of 20 equivalents of NaCl.

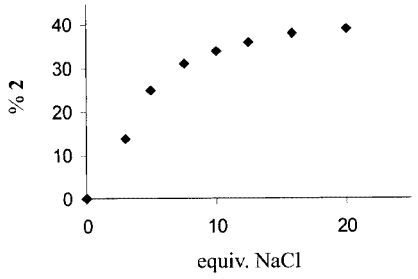

Figure 4. Percentage of **2** upon addition of increasing amounts of NaCl to a 1:1 mixture of **1** and $Mg(ClO_4)_2$ in DMSO

Analogously, addition of $NaCH_3CO_2$ triggers the substitution of Zn by Mg in a 1:1 mixture of $Mg(ClO_4)_2$ and **1**. Acetate is even more effective than Cl^- in promoting replacement of Zn by Mg: Addition of 7.5 equivalents to an equimolar solution of **1** and $Mg(ClO_4)_2$ gives 43% conversion of **1** into **2** in comparison with 31% in the case of Cl^-. Unfortunately, the limited solubility of sodium acetate in DMSO prevents a further increase of the amount of Mg complex formed. No Zn/Mg exchange is observed in the presence of F^-, Br^- and I^- ions. In line with the effect of the anions described so far, Mg is completely substituted by Zn when **2** is treated with one equivalent of $Zn(NO_3)_2$ in the absence of Cl^- or $CH_3CO_2^-$, while treatment of **2** with one equivalent of $Zn(CH_3CO_2)_2$ gives a mixture of 68% **1** and 32% **2**. Elias et al. have studied the replacement of Cu by Ni in [Cu(amben)] [H_2amben = *N,N′*-ethylenebis(2-aminobenzaldimine)].[12] They found a catalytic effect of the anion with the rate of the substitution reaction increasing as follows: $ClO_4^- < Br^- < SCN^- << Cl^-$. In our case, the reaction of **1** with $MgCl_2$ and $Mg(CH_3CO_2)_2$ is fast, the NMR spectra of the reaction mixtures (including those with counterions where no exchange is observed) do not change with time. In other words, the equilibrium is reached immediately and the lack of observation of a reaction in the absence of Cl^- and acetate is clearly not the result of a much slower reaction rate.

The reaction of [$Zn(L'^{2-})(H_2O)_2$] (**3**) with $MgCl_2$ has been described recently by us,[2] and in continuation of this work we have now investigated the anion dependence of the reaction for comparison with the system **1**/Mg^{2+}. Similarly to the reaction behavior of **1**/Mg^{2+}, $MgCl_2$ substitutes Zn in **3**, while $Mg(NO_3)_2$, $Mg(ClO_4)_2$ and $MgSO_4$ are ineffective. Furthermore, no substitution takes place in the presence of iodide, bromide or fluoride ions. Again, the effect of chloride ions can be confirmed by treating mixtures of **3** and $Mg(ClO_4)_2$ with NaCl. Addition of four equivalents of NaCl to a 1:2 mixture of **3** and $Mg(ClO_4)_2$ induces formation of the Mg complex of L′ (**4**) in 67% yield. Complete conversion is achieved with four equivalents of $Mg(ClO_4)_2$ and eight equivalents of NaCl. Thus, as observed for the direct reaction with $MgCl_2$, exchange of Zn with Mg occurs more easily in **3** than in **1**, where the substitution reaction does not go to completion. Investigation of the reaction of **3** with $Mg(CH_3CO_2)_2$ was hampered by the deprotonation of the aromatic carboxylate group by acetate.[13] An NMR spectrum displaying several imine signals indicates the formation of dinuclear complexes that will be isolated and characterized in future work.

Replacement of Zn by Mg in the coordination sphere of the Schiff-base ligand apparently contradicts the order of stability predicted by the Irving−Williams series and, interestingly, the substitution strongly depends on the nature of the anions present in solution. One plausible explanation for the effect of the anions is their interaction with Zn^{2+} in solution. Non- or weakly coordinating ions like ClO_4^-, NO_3^- and SO_4^{2-} do not interact with metal ions in solution — coordination of NO_3^- to Zn in the X-ray structure of **1** is a feature of the solid-state structure and is unlikely to be maintained in solution.[14] By contrast, Cl^- and $CH_3CO_2^-$ do interact with Zn^{2+} in DMSO, and Zn^{2+} is released when a solution of **3** is treated with NaCl as evident from the appearance of a signal set for the free ligand as well as that of **3** in the NMR spectrum. After addition of 2.3 equivalents of NaCl, the intensities of the resonances of **3** and L correspond to a 4:3 ratio of Zn complex and free ligand. The existence of distinct sets of resonances for the free ligand and for the Zn complex shows that the Zn complex is nonlabile on the NMR time-scale in DMSO. This behavior is in contrast to the kinetic properties of the majority of Zn complexes, although it has been observed previously for related Zn Schiff base complexes.[1,15] Coor-

dination of acetate to Zn^{2+} and Mg^{2+} in DMSO solutions can easily be followed by the change in the chemical shift of the acetate resonance in the NMR spectra of solutions of $NaCH_3CO_2$ containing increasing amounts of Mg^{2+} or Zn^{2+} ions. Addition of $Mg(ClO_4)_2$ or $Zn(NO_3)_2$ shifts the methyl signal of the acetate ion to lower fields ($\Delta\delta$ = 0.20 ppm with 1 equiv. Mg^{2+} and 0.24 ppm with 1 equiv. Zn^{2+}). Addition of NaCl to mixtures of $NaCH_3CO_2$ and $Mg(ClO_4)_2$ or $Zn(NO_3)_2$ gives slight upfield shifts of the acetate resonance indicating that Cl^- competes weakly with acetate for metal-ion coordination in DMSO.

In conclusion, in the case of ClO_4^-, NO_3^- and SO_4^{2-} the equilibrium in DMSO

$$[ZnL(DMSO)_x]^{2+} + [Mg(DMSO)_6]^{2+} + nY^- \leftrightarrows [MgL(DMSO)_3]^{2+} + [Zn(DMSO)_m]^{2+} + nY^-$$

lies to the left-hand side due to the coordination properties of Zn and Mg. When coordinating anions are present, the equilibrium

$$[ZnL(DMSO)_x]^{2+} + [Mg(DMSO)_{6-n}X_n]^{(2-n)+} \leftrightarrows [MgL(DMSO)_3]^{2+} + [Zn(DMSO)_mX_y]^{(2-y)+}$$

is to be considered and the position of the equilibrium is determined by the affinities of the metal ions for the Schiff-base ligand *and* for the counterions (solvent effects are also present, see above). For both Zn complexes **1** and **3**, the equilibrium lies further to the right-hand side in the presence of acetate than in the presence of Cl^-. For reaction mixtures containing two equivalents of the respective counterion equilibrium constants of $K = 0.01 \pm 0.03$ (Cl^-) and $K = 0.07 \pm 0.04$ (acetate) can be estimated from the relative intensities of the NMR resonances. In the case of F^-, Br^- and I^-, coordination of Zn to the Schiff-base ligands is favored (100% **1** and **3**).

Although the primary coordination sphere of the metal ion is identical for L and L′ (O_2N), Zn is considerably more susceptible to exchange by Mg in **3** than in **1** as evident from an equilibrium constant of $K \approx 0.18 \pm 0.06$ for the reaction of **3** with Mg^{2+} in the presence of two equivalents of Cl^-. This can be attributed to the presence of the ammonium groups in **1**. Compared with aqueous solutions, the acidity of the ammonium groups is increased in organic solvents, while the acidity of phenols and carboxylic acids decreases significantly.[16] Thus, the metal ions have to compete with the protons of the two tertiary ammonium nitrogens for the binding sites of the ligand. Due to the coordination properties of Zn and Mg, the Mg complex is probably destabilized, while Zn competes efficiently with the protons. This interpretation is in accordance with the observation that upon treating 1:1 mixtures of **1** and **2** with NH_4NO_3 the equilibrium is shifted further towards the Zn complex. On addition of six equivalents of NH_4NO_3 the percentage of **2** is decreased by 25%. Since acetate acts as a relatively strong base in DMSO,[16] deprotonation of the ammonium groups may contribute to the effect of acetate in favoring the formation of the Mg complex.

Conclusions

In conclusion we have isolated and structurally characterized a Zn and Mg complex with the Schiff-base ligand derived from 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol and glycine. These can be interconverted and the position of the equilibrium is determined by the solvent and the nature of the anions added to the reaction mixture.

Experimental Section

Materials and Methods: 4-Bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol was prepared according to the literature procedure.[17] The Zn complex of L′ (**3**) was synthesized as previously described.[1] All chemicals and solvents were reagent grade and used without further purification. ^1H NMR spectra (200.13 MHz) were recorded on a Varian Mercury spectrometer. Spectra were run in [D_6]DMSO, MeOD or D_2O solutions using sodium 3-(trimethylsilyl)propanesulfonate as internal reference. The pD values of D_2O solutions were obtained by use of a glass electrode and addition of 0.4 to the pH meter reading. The CHN analyses were carried out on an Element Analyzer CHNS 932 (LECO). Infrared spectra of KBr pellets were taken on a Bruker IFS 28 FT-spectrometer.

CAUTION: *Perchlorate salts are potentially explosive and should be handled carefully in small quantities only.*

Complex 1: Glycine (141 mg, 1.89 mmol) was dissolved in water (20 mL) and added to a solution of 4-bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol (675 mg, 1.89 mmol) and $Zn(NO_3)_2{\cdot}6H_2O$ (1178 mg, 3.96 mmol) in MeOH (9 mL). The solution was stirred at room temperature for 24 h. Slow evaporation of the solution yielded yellow needles of $[ZnL(H_2O)(NO_3)]NO_3{\cdot}nH_2O$ (elemental analysis $n = 1$, X-ray analysis $n = 0$) in 81% yield. Selected IR data (KBr): $\tilde{\nu}$ = 3002, 1640 (C=N), 1604, 1551, 1452, 1384 (NO_3^-), 1309, 1288, 1201, 1074, 1020, 879, 824 (NO_3^-), 769 cm^{-1}. ^1H NMR [D_2O, pD = 6.8]: δ = 1.14 (t, ^3J = 7.58 Hz, 6 H, CH_3), 1.27 (t, ^3J = 7.58 Hz, 3 H, CH_3), 2.96−3.26 (m, 10 H, CH_2-N), 3.96 (br. s, 2 H, CH_2-COO), 4.21 (s, 2 H Ar-CH_2), 7.49 (s, 1 H, H_{ar}), 7.55 (s, 1 H, H_{ar}), 8.35 (s, 1 H, HC=N). $C_{18}H_{32}BrN_5O_{11}Zn$ (639.78): calcd. C 33.8, H 5.0, N 11.0; found C 33.7, H 4.8, N 11.3.

Complex 2: 4-Bromo-2-[(2-diethylaminoethyl)ethylaminomethyl]-6-formylphenol (258 mg, 0.72 mmol), $Mg(NO_3)_2{\cdot}6H_2O$, (923 mg, 3.60 mmol), sodium glycinate hydrate (105 mg, 0.913 mmol) and NaOH (85 mg, 2.13 mmol) were reacted in methanol/water (5:1, 12 mL) at room temperature. After stirring overnight some insoluble precipitate was filtered off. From the filtrate small needles of composition $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O{\cdot}CH_3OH$ (**2·CH$_3$OH**) were obtained. Yield: 27%. Selected IR data (KBr): $\tilde{\nu}$ = 3391, 1655 (C=N), 1604, 1545, 1384 (NO_3), 1237, 1199, 1147, 1094, 1037, 829 (NO_3^-), 771 cm^{-1}. ^1H NMR [$(CD_3)_2SO$]: δ = 1.03 (br. s, 6 H, CH_3), 1.22 (br. s, 3 H, CH_3), 2.6−3.1 (br. m, 10 H, CH_2-N), 3.92 (br. s, 2 H, CH_2-COO), 4.04 (br. s, 2 H, Ar-CH_2), 7.38 (s, 2 H, H_{ar}), 8.16 (br. s, 1 H, HC=N). $C_{19}H_{40}BrMgN_5O_{14}$ (666.78): calcd. C 34.2, H 6.1, N 10.5; found C 33.9, H 5.7, N 10.1. Recrystallization yielded X-ray suitable crystals of $[MgL(H_2O)_3](NO_3)_2{\cdot}H_2O$ (**2**).

X-ray Crystallography: Crystal data for compounds **1** and **2** (Table 3) were recorded at room temperature on an Enraf−Nonius-KappaCCD diffractometer[18] using graphite-monochromated Mo-K_α radiation ($\lambda = 0.71069$ Å). For data reduction and cell refinement the programs DENZO and SCALEPACK were applied.[19] The structures were solved by conventional Patterson (**1**) and direct methods (**2**) and subsequent Fourier syntheses and refined by full-matrix least-squares on F^2 using the SHELXTL PLUS and SHELXL-93 programs.[20] The scattering factors were those given in the SHELXL programs. Transmission factors were calculated with SHELXL-97.[20] All non-hydrogen atoms except for the oxygen of water of crystallization in **2** were refined anisotropically. Hydrogen atoms were generated geometrically and given fixed isotropic U values.

CCDC-177901 (**1**) and -177902 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving. html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

[13] Deprotonation of the second binding site of the ligand by acetate in aprotic, non-aqueous solution should also take place in the case of ligand L. However, there is no evidence for the formation of homo- or heterodinuclear complexes of L under the reaction conditions used. For acid-base properties in aprotic organic solvents see ref.[16]
[14] Interaction of NO_3^- with Zn^{2+} ions in solution is ruled out, since no dissociation of the complex is observed. As discussed below, interaction with coordinating anions result in the release of Zn^{2+} ions.

Titanocene and Zirconocene Complexes containing Dendrimer-Substituted Cyclopentadienyl Ligands − Synthesis and Ethylene Polymerization

Román Andrés,*[a] Ernesto de Jesús,*[a] F. Javier de la Mata,[a] Juan C. Flores,[a] and Rafael Gómez[a]

Keywords: Metallocenes / Dendrimers / Titanium / Zirconium / Substituent effects

This paper describes the synthesis of a series of titanium and zirconium metallocenes bearing one or two first-generation silane dendritic wedges as bulky substituents at their cyclopentadienyl rings. Wedges $(R_2R'SiCH_2CH_2)_3SiCl$ [R = R′ = Et (**1**); R = Ph, R′ = Me (**2**)] were prepared by hydrosilylation of chlorotrivinylsilane with $R_2R'SiH$. They were reacted with $K(C_5H_5)$ and, subsequently, with KH to give $K[(R_2R'SiCH_2CH_2)_3Si(C_5H_4)]$ [R = R′ = Et (**3**); R = Ph, R′ = Me (**4**)]. The dendronized cyclopentadienides **3** and **4** were the starting materials for preparation of the mixed-ring titanocenes $[\{(R_2R'SiCH_2CH_2)_3SiC_5H_4\}(C_5R''_5)TiCl_2]$ [R = R′ = Et, R′′ = H (**5**), R′′ = Me (**6**); R = Ph, R′ = Me, R′′ = H (**7**), R′′ = Me (**8**)] or the symmetrically substituted metallocenes $[\{(Ph_2MeSiCH_2CH_2)_3SiC_5H_4\}_2MCl_2]$ [M = Ti (**9**), Zr (**10**)]. Cyclic voltammograms and catalytic behavior of all the new metallocenes in ethylene polymerization, using MAO as a cocatalyst, have been studied and compared to that of related non-dendritic complexes. Polyethylene polydispersities increase with the number of dendritic wedges in the catalyst, while activities decrease. Bimodal molecular weight distributions were clearly observed for the bis-dendritic titanocene **9**.

Introduction

The modification of cyclopentadienyl (Cp) ligands has played a crucial role in improving the usefulness of group 4 metallocenes as catalysts in olefin polymerization. It has proved to be especially relevant to the microstructure of polymers obtained from α-olefins.[1] Control of the stereochemistry requires some conformational constraint because it arises mainly from steric interactions between the incoming olefin monomer and the Cp ligand; bridged cyclopentadienyl ligands (*ansa*-metallocenes) have often been used for this purpose.[2] However, some degree of stereocontrol is in principle possible without a rigid ligand framework if rotation of the Cp ligands is hindered,[3] for example by means of sterically demanding substituents.[4]

We are currently studying the chemistry of titanium and zirconium metallocenes located at the focal point of one or two dendritic wedges. Our interest is focused on their use as precursors for olefin polymerization. In these complexes, the dendrimers[5] act as ligand modifiers that introduce steric hindrance around the cyclopentadienyl rings, and their behavior can be compared to that of other sterically encumbered metallocenes.

Cyclopentadienyl complexes have been employed for the peripheral functionalization of dendrimers and, in particular, group 4 derivatives have been already synthesized[6,7] and tested in olefin polymerization.[6a,7c] We have observed[7c] that, in such cases, dendrimers are more than mere supports of active sites and may significantly modify activities and molecular weights. Less attention has been paid to dendrimers, such as those reported here, that are metallated at their core or focal-point with cyclopentadienyl complexes.[8] However, the ability of dendritic shells to encapsulate functional core moieties and to create specific site-isolated nanoenvironments,[9] a concept taken from biological systems, has already been exploited in catalysis using a variety of metal complexes.[9,10]

In the present report, we describe the syntheses of titanium and zirconium metallocenes bearing one or two first generation carbosilane dendritic wedges, together with their behavior in ethylene polymerization using MAO as a cocatalyst.

Results and Discussion

The new dendritic titano- and zirconocenes were synthesized following the pathway depicted in Scheme 1. The reactions described below fulfil two conditions in order to warrant pure final products: high yields in every step and at least one step involving enough differences in solubility between the target compound and by-products. These conditions are required since the separation of by-products accumulated in these multistep preparations is complicated by

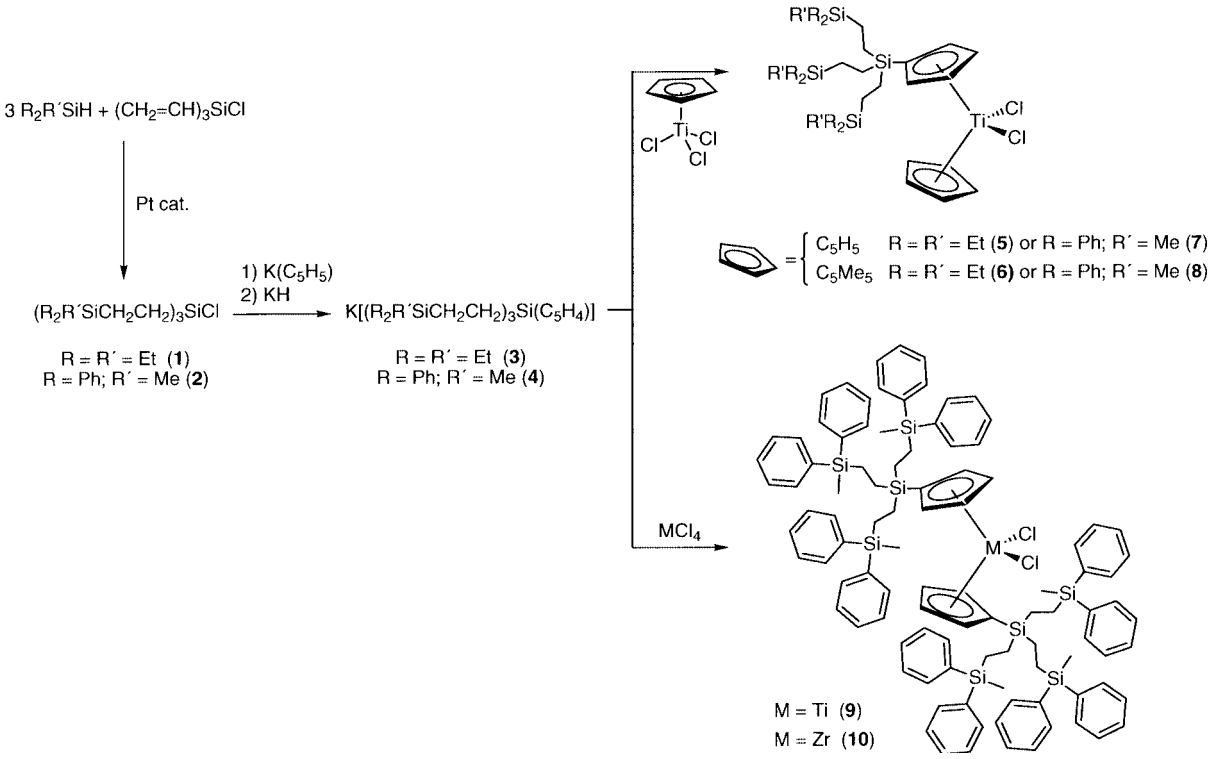

Scheme 1

the high solubility and oily nature of these dendritic compounds.

The chlorosilanes $(R_2R'SiCH_2CH_2)_3SiCl$ [R = R′ = Et (**1**); R = Ph, R′ = Me (**2**)] were obtained from a solvent-free reaction in which chlorotrivinylsilane was hydrosilylated with an excess of the corresponding silane $R_2R'SiH$, using hydrogen hexachloroplatinate(IV) as a catalyst (Scheme 1). Only the formation of β-silylated compounds was observed. Silane **1** was obtained as a colorless oil after removal of volatiles in vacuo, whereas compound **2** was recrystallized from pentane at −30 °C as an off-white solid. The dendronized cyclopentadienides **3** and **4** were synthesized as their potassium salts by reaction of **1** or **2** with $K(C_5H_5)$ in THF and subsequent treatment of the cyclopentadienes with KH. Compound **3** separated from pentane at −30 °C as an oily pale yellow product whereas **4** was precipitated from hexane at room temperature as a white solid.

The mixed-ring titanocenes **5**−**8** were prepared by reaction of **3** or **4** and one equiv. of $[(C_5H_5)TiCl_3]$ or $[(C_5Me_5)TiCl_3]$. The symmetrically substituted metallocenes **9** (Ti) and **10** (Zr) were obtained from the reaction of **4** and $TiCl_4$ or $[ZrCl_4]\cdot 2THF$ in a 2:1 ratio. The reactions were carried out in THF and products were initially isolated as oils. Complexes **5**−**8** crystallized after workup whereas all attempts to crystallize **9** and **10** failed. Compounds **5**−**10** are rather stable to air and the analytical and spectroscopic data are in agreement with their proposed structure (see Exp. Sect.).

Among electrochemical methods, cyclic voltammetry has been widely used to study the influence of substituents on the electronic density at the metal center of complexes.[11,12] Cyclic voltammograms of metallocene derivatives **5**−**10** were recorded in THF solution. Each complex shows a quasi-reversible electrode process due to a one-electron reduction of the titano- and zirconocene derivatives at the potentials summarized in Table 1 vs. the ferricinium/ferrocene couple. The potential of the reference complex $[(C_5H_5)_2TiCl_2]$ is within the narrow range in which potentials of C_5H_5 complexes **5**, **7**, and **9** are observed (1.34−1.40 V). The same is true for $[(C_5H_5)(C_5Me_5)TiCl_2]$ and the range of C_5Me_5 compounds **6** and **8** (1.64−1.66 V), and for $[(C_5H_5)_2ZrCl_2]$ and **10**. These data can be interpreted in the sense that dendritic silane substituents have a minor influence on the electron-donating properties of the cyclopentadienyl ring and therefore on the electronic density of the metal center. Similar results have been obtained for the $SiMe_3$-substituted complexes $[(C_5H_4SiMe_3)_2TiCl_2]$ and $[(C_5H_3(SiMe_3)_2]_2TiCl_2]$, whose potentials are not shifted from those observed for $[(C_5H_5)_2TiCl_2]$.[13] It has been pointed out that steric hindrance between cyclopentadienyl substituents, when they are placed at the hinge positions of titanocene dichlorides, decreases the dihedral angle (φ) formed by the ring planes. This change results in LUMO orbitals of lower energy, and therefore in the observation of a decreased absolute value of the reduction potential.[12] The absence of a significant shift in the potential values of the dendritic titanocenes **5**−**9** (and for **10**) compared to their non-dendritic counterparts {$[(C_5H_5)_2MCl_2]$ or $[(C_5H_5)(C_5Me_5)TiCl_2]$} is compatible with a dynamic model in which the rotating Cp ligands are preferentially accommodated in conformations in which the intramolecular

steric strain is relieved; obviously these conformations are those with the dendritic wedges occupying the lateral positions of the molecule. However, the rotation of the Cp rings is far from being fully stopped in solution, as demonstrated by the fact that only two types of cyclopentadienyl protons are observed in the ^{1}H NMR spectrum of **9** even at −90 °C.

Upon activation with an excess of methylaluminoxane (MAO), complexes **5**−**10** catalyze the polymerization of ethylene. These results are summarized in Table 2 and details of the polymerization procedure are given in the Exp. Sect. As a reference, polymerization with $[(C_5H_5)_2MCl_2]$ (M = Ti, Zr) and $[(C_5H_5)(C_5Me_5)TiCl_2]$ was also carried out under the same conditions. Every dendritic catalyst displayed a lower activity than its reference complex.

For the titanium series, we can establish the following order of activity according to the type of cyclopentadienyl ligands: $(C_5H_5)_2$ > $(C_5H_4R)(C_5H_5)$ >> $(C_5H_4R)_2$ ≈ $(C_5H_5)(C_5Me_5)$ >> $(C_5H_4R)(C_5Me_5)$, where each >> corresponds to an activity reduction of one order of magnitude. What it is remarkable in these data is that replacement of a $C_5H_5^-$ ligand by a dendritic cyclopentadienide in **5** and **7** only causes a moderate decrease in activity (from 4320 in $[(C_5H_5)_2TiCl_2]$ to 2064 and 1728 kg/mol·h, respectively). Steric hindrance might cause the later decrease and an argument for this hypothesis is based on the CV results (see above) that show slight electronic density differences between their metal centers. The lower activity of bis-dendritic Cp system **9** might be interpretable in steric terms assuming that interaction between both dendritic wedges restricts the conformations in which they are kept far away from the metal center. In the case of zirconium, much less appreciable effects might be expected because of the bigger size of the metal center. In fact, the activity of the bis-dendritic Zr complex **10** is similar to that of $[(C_5H_5)_2ZrCl_2]$ with a decrease (from 8016 to 5472 kg/mol·h) far away from the one order of magnitude decrease observed for the analogous pair of titanium complexes. This result seems to contradict the data reported by Alt and Köppl in a recent review on the polymerization activity of ethylene with metallocenes. For complex $[(C_5H_4SiMe_2Ph)_2ZrCl_2]$ the activity found was less than 10% that of $[(C_5H_5)_2ZrCl_2]$.[1f] However, in this case an interaction of the aromatic end group of the substituent with the Lewis-acid center of the catalyst could be responsible for such an effect because of the additional stabilization of the active site. In the above discussion, it has been assumed that the concentration of active centers is the same for all the compared catalysts (and ideally equal to the precursor concentration). This is a general obstacle in the discussion of results in polymerization with metallocene/MAO catalysts.[14,15] In any case, the practical question is that dendritic wedges can be used as cyclopentadienyl substituents without hindering the closest metal environment to such an extent that the polymerization process is prevented.

The polyethylene samples generated with complexes **5**, **7**, **9**, and **10** were analyzed by gel-permeation chromatography (GPC). The molecular weights of the polymers obtained with dendritic systems are near to 400×10^3, a normal region for metallocenes, although the titanium dendrimers **5**−**9** gave polymers somewhat larger than those produced with $[(C_5H_5)_2TiCl_2]$/MAO. More remarkable are the molecular weight distributions of the samples obtained from the titanium complexes: the polydispersity values increase with the number of dendritic substituents on the catalyst precursor (from 1.86 for non-dendritic to 5.81 for bis-dend-

ritic). As shown in Figure 1, these values reflect the appearance of bimodal molecular weight distributions, especially for polymer yielded by the bis-dendritic system **9**. In contrast, the zirconium complex **10** produces polyethylene of low polydispersity. Bimodal distributions may result for several reasons, such as a multistate catalyst with slow interconversion of states,[16] or the presence of traces of impurities (for example, unsubstituted metal complexes).

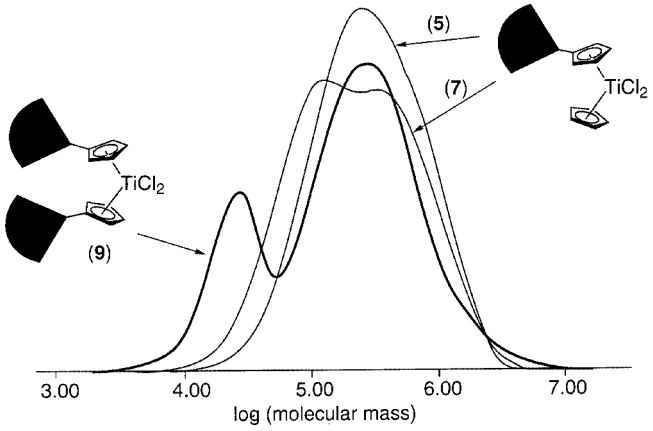

Figure 1. Molecular weight distributions for polyethylene samples obtained from **5**, **7**, and **9**/MAO catalytic systems

Conclusion

In this paper, we have modified the metal environment in titanium and zirconium metallocenes by the incorporation of first-generation carbosilane dendritic wedges into Cp ligands. An effect of such a modification in ethylene polymerization is the observed correlation between polyethylene polydispersities and the number of dendritic wedges in the titanium catalysts. Bimodal molecular weight distributions have been observed for several of the reported complexes, especially for the bis-dendritic titanocene **9**. On the other hand, the activity decreases caused by the bulky substituents are moderate, especially for zirconium complex **10**, suggesting that the metal centers remain quite accessible. In contrast to other bulky substituents, the long range of their space-filling properties is a distinctive feature of dendritic wedges (Figure 2) that may be truly useful for polymer stereocontrol. Work on the effects of growing dendritic generations on the polymerization of α-olefins is under way in our laboratory.

Experimental Section

Reagents and General Techniques: All operations were performed under an argon atmosphere using Schlenk or dry box techniques. Solvents were dried and distilled under argon as described elsewhere.[17] Unless otherwise stated, reagents were obtained from commercial sources and used as received. MAO was obtained in toluene solution 1.5 M from Witco. $K(C_5H_5)$ was prepared from freshly distilled cyclopentadiene and KH in THF. [$M(C_5H_5)_2Cl_2$] (M = Ti, Zr),[18] [$Ti(C_5H_5)(C_5Me_5)Cl_2$],[19] [$Ti(C_5H_5)Cl_3$],[20] and [$Ti(C_5Me_5)Cl_3$][21] were prepared according to reported procedures. ^1H, ^{13}C, and ^{29}Si NMR spectra were recorded on Varian Unity 300 or 500 Plus spectrometers. Chemical shifts (δ, ppm) are relative to $SiMe_4$ and were measured by internal referencing to the deuterated solvent (^{13}C and residual ^1H resonances), or by the substitution method from the ^{29}Si resonance of $SiMe_4$. C, H and N analyses were performed in a Heraeus CHN-O-Rapid microanalyzer by the Microanalytical Services of the Universidad de Alcalá. Cyclic voltammograms were obtained with an AMEL 553 Potentiostat, an AMEL 567 Wave Generator, and a three-platinum-electrode cell. [Bu_4N][PF_6] (0.2 M in THF) was used as supporting electrolyte and potentials were zeroed to the ferricinium/ferrocene couple used as internal reference.

Synthesis of ($Et_3SiCH_2CH_2)_3SiCl$ (1): A mixture of trivinylchlorosilane (2.0 mL, 13 mmol), an excess of Et_3SiH (8.2 mL, 52 mmol), and a hydrosilylation Pt catalyst (4 drops of a 2×10^{-3} M solution of H_2PtCl_6 in 2-propanol) was stirred for 24 h at 70 °C. After completion of the reaction (^1H NMR monitoring) the volatiles were removed under vacuum to give **1** (5.7 g, 89%) as a colorless oil. The sample was not analytically pure but was suitable for further preparations. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.91 (t, 27 H, CH_3CH_2), 0.70 and 0.46 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.50 (quart, 18 H, CH_3CH_2) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.4 (CH_3CH_2), 7.0 [$Si(CH_2)_2Si$], 2.8 (CH_3CH_2), 2.5 [$Si(CH_2)_2Si$] ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 35.2 (*Si*Cl), 8.5 (Et_3Si) ppm.

Synthesis of ($Ph_2MeSiCH_2CH_2)_3SiCl$ (2): This compound was prepared by the procedure described above for **1** from trivinylchlorosilane (1.9 mL, 12.5 mmol) and Ph_2MeSiH (10 mL, 50 mmol). After completion of the reaction, pentane (50 mL) was added to the solution and then cooled at −30 °C overnight. Sometimes an oil, instead of a solid, separated from the solution. In that case, the mixture was shaken vigorously, cooled again to −30 °C for several hours, and the process repeated until precipitation of a white solid. The mixture was filtered and the solid dried in vacuo and characterized as **2**. Further crops of **2** were collected from the pentane solution by repeated (2−3 times) concentration and crystallization, giving an overall yield of 7.0 g (76%). $C_{45}H_{51}ClSi_4$ (739.7): calcd. C 73.07, H 6.95; found C 72.68, H 7.17. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.45 (m, 12 H, C_6H_5), 7.31 (m, 18 H, C_6H_5), 0.91 and 0.73 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.51 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 136.5 (C_{ipso}, C_6H_5), 134.4 (C_{meta}, C_6H_5), 129.2 (C_{para}, C_6H_5), 127.8 (C_{ortho}, C_6H_5), 7.2 and 5.7 [$Si(CH_2)_2Si$], −5.0

(CH_3) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 35.8 (*Si*Cl), −5.5 (Ph_2MeSi) ppm.

Synthesis of K[(Et$_3$SiCH$_2$CH$_2$)$_3$Si(C$_5$H$_4$)] (3): This compound was prepared by the same procedure described below for **4** from potassium cyclopentadienide (0.58 g, 6.0 mmol), **1** (3.0 g, 6.0 mmol) and KH (0.24 g, 6.0 mmol). However, its high solubility in hexane prevented its crystallization. Compound **3** was obtained as a pale yellow oil by evaporation of the final solution in vacuo to dryness (2.8 g, 85% yield). ^1H NMR (300 MHz, C_6D_6, 25 °C): δ = 6.07 and 6.04 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 1.20 (t, 27 H, CH_3CH_2), 1.06 and 0.68 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.79 (quart, 18 H, CH_3CH_2) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, C_6D_6, 25 °C): δ = 114.2 and 109.3 (C_5H_4), 8.2 (CH_3CH_2), 7.8 and 5.9 [$Si(CH_2)_2Si$], 3.5 (CH_3CH_2) ppm; C_{ipso} of C_5H_4 not found.

Synthesis of K[(Ph$_2$MeSiCH$_2$CH$_2$)$_3$Si(C$_5$H$_4$)] (4): Potassium cyclopentadienide (0.42 g, 4.0 mmol) was added to a solution of **2** (3.0 g, 4.0 mmol) in THF (50 mL). The mixture was stirred for 24 h at room temperature. Then the mixture was treated with solid KH (0.16 g, 4.0 mmol) and stirred until evolution of H_2 ceased. After addition of hexane (10 mL), the mixture was filtered off and the solution was concentrated (up to ca. 5 mL). Hexane (100 mL) was added again to the metastable solution, and the stirring continued until precipitation of **4** as a white solid. The precipitate was filtered, washed with hexane and dried in vacuo (2.3 g, 72%). ^1H NMR (300 MHz, C_6D_6, 25 °C): δ = 7.67 (m, 12 H, C_6H_5), 7.22 (m, 18 H, C_6H_5), 5.85 and 5.71 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 1.15 and 0.85 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.71 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, C_6D_6, 25 °C): δ = 137.8 (C_{ipso}, C_6H_5), 135.1 (C_{meta}, C_6H_5), 129.5 (C_{para}, C_6H_5), 128.3 (C_{ortho}, C_6H_5), 114.2 (C_5H_4), 109.1 (C_5H_4), 7.7 and 5.9 [$Si(CH_2)_2Si$], −4.51 (CH_3) ppm; C_{ipso} of C_5H_4 not found.

Synthesis of [{(Et$_3$SiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}(C$_5$H$_5$)TiCl$_2$] (5): [$(C_5H_5)TiCl_3$] (0.50 g, 2.3 mmol) was added to a solution of the substituted potassium cyclopentadienide **3** (1.30 g, 2.3 mmol) in THF (20 mL). The mixture was stirred at room temperature for 4 h. After filtration, the THF solution was evaporated in vacuo to dryness. The crude red oil was dissolved in the minimum amount of pentane and **5** was crystallized as a red solid (0.97 g, 61%) at −30 °C. $C_{34}H_{66}Cl_2Si_4Ti$ (706.0): calcd. C 57.84, H 9.42; found C 57.54, H 9.48. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 6.83 and 6.60 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 6.51 (s, 5 H, C_5H_5), 0.90 (t, 27 H, CH_3CH_2), 0.70 and 0.42 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.50 (quart, 18 H, CH_3CH_2) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 132.3 (C_{ipso}, C_5H_4), 128.6 (C_5H_4), 121.6 (C_5H_4), 120.0 (C_5H_5), 7.5 (CH_3CH_2), 4.6 and 3.6 [$Si(CH_2)_2Si$], 2.8 (CH_3CH_2) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 8.3 (Et_3Si), 0.0 (*Si*C_5H_4) ppm.

Synthesis of [{(Et$_3$SiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}(C$_5$Me$_5$)TiCl$_2$] (6): This complex was prepared by the same procedure described for **5**, starting from [$(C_5Me_5)TiCl_3$] (0.49 g, 1.7 mmol) and **3** (0.95 g, 1.7 mmol) in THF (20 mL). Due to its high solubility in pentane, compound **6** was obtained as a dark red oil (1.0 g, 78%) by removal of the solvent in vacuo. Crystals grew inside the oily samples when stored at room temperature for several days. Unfortunately, they were not suitable for X-ray diffraction studies. $C_{39}H_{76}Cl_2Si_4Ti$ (776.2): calcd. C 60.35, H 9.87; found C 60.60, H 10.09. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 6.40 and 6.07 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 2.02 (s, 15 H, C_5Me_5), 0.88 (t, 27 H, CH_3CH_2), 0.76 and 0.43 (A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$), 0.47 (quart, 18 H, CH_3CH_2) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 136.0 (C_{ipso}, C_5H_4), 129.4 (C_5Me_5), 128.7 and 117.3 (C_5H_4), 13.5 (C_5Me_5), 7.5 (CH_3CH_2), 4.3 and 3.5 [$Si(CH_2)_2Si$], 2.8 (CH_3CH_2) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 8.3 (Et_3Si), −0.6 (*Si*C_5H_4) ppm.

Synthesis of [{(Ph$_2$MeSiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}(C$_5$H$_5$)TiCl$_2$] (7): This complex was prepared by the same procedure described for **5**, from [$(C_5H_5)TiCl_3$] (0.13 g, 0.62 mmol) and **4** (0.50 g, 0.62 mmol) in THF (20 mL). Due to its high solubility in pentane, compound **7** was obtained by removal of the solvent in vacuo as a dark red oil, which solidified after several weeks at room temperature (0.48 g, 81%). $C_{55}H_{60}Cl_2Si_4Ti$ (952.2): calcd. C 69.38, H 6.35; found C 69.22, H 6.63. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.53 (m, 12 H, C_6H_5), 7.40 (m, 18 H, C_6H_5), 6.63 and 6.51 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 6.29 (s, 5 H, C_5H_5), 0.91 and 0.81 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.53 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 136.8 (C_{ipso}, C_6H_5), 134.5 (C_{meta}, C_6H_5), 130.5 (C_{ipso}, C_5H_4), 129.1 (C_{para}, C_6H_5), 128.5 (C_5H_4), 127.8 (C_{ortho}, C_6H_5), 121.7 (C_5H_4), 119.9 (C_5H_5), 6.5 and 4.5 [$Si(CH_2)_2Si$], −5.1 (CH_3) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 0.7 (*Si*C_5H_4), −5.7 (Ph_2MeSi) ppm.

Synthesis of [{(Ph$_2$MeSiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}(C$_5$Me$_5$)TiCl$_2$] (8): This complex was prepared by the same procedure described for **5**, from [$(C_5Me_5)TiCl_3$] (0.18 g, 0.62 mmol) and **4** (0.50 g, 0.62 mmol) in THF (20 mL). Due to its high solubility in pentane, compound **8** was obtained, after removal of the solvent in vacuo, as a dark red oil, which solidified after several weeks at room temperature (0.54 g, 86%). $C_{60}H_{70}Cl_2Si_4Ti$ (1022.4): calcd. C 70.49, H 6.90; found C 70.31, H 6.99. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.40 (m, 12 H, C_6H_5), 7.25 (m, 18 H, C_6H_5), 6.26 and 6.00 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 1.95 (s, 15 H, C_5Me_5), 0.88 and 0.81 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.48 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 137.4 (C_{ipso}, C_6H_5), 134.6 (C_{meta}, C_6H_5), 129.54 (C_5Me_5), 129.48 (C_{ipso}, C_5H_4), 129.0 (C_{para}, C_6H_5), 128.8 (C_5H_4), 127.7 (C_{ortho}, C_6H_5), 117.2 (C_5H_4), 13.5 (C_5Me_5), 6.4 and 4.5 [$Si(CH_2)_2Si$], −5.01 (CH_3) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 0.2 (*Si*C_5H_4), −5.8 (Ph_2MeSi) ppm.

Synthesis of [{(Ph$_2$MeSiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}$_2$TiCl$_2$] (9): [$TiCl_4$] (68 mL, 0.62 mmol) was added via syringe to a solution of **4** (1.00 g, 1.24 mmol) in toluene (25 mL). The solution was stirred overnight at room temperature. After filtration of the KCl precipitate, the solution was evaporated in vacuo to dryness yielding **9** (0.94 g, 92%) as a dark red oil. $C_{100}H_{110}Cl_2Si_8Ti$ (1655.5): calcd. C 72.55, H 6.70; found C 72.61, H 6.79. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.40 (m, 12 H, C_6H_5), 7.25 (m, 18 H, C_6H_5), 6.39 and 6.17 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 0.85 and 0.75 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.49 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 136.9 (C_{ipso}, C_6H_5), 134.4 (C_{meta}, C_6H_5), 129.1 (C_{para}, C_6H_5), 131.5 (C_{ipso}, C_5H_4), 128.5 (C_5H_4), 127.8 (C_{ortho}, C_6H_5), 120.2 (C_5H_4), 6.6 and 4.7 [$Si(CH_2)_2Si$], −5.0 (CH_3) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 0.6 (*Si*C_5H_4), −5.7 (Ph_2MeSi) ppm.

Synthesis of [{(Ph$_2$MeSiCH$_2$CH$_2$)$_3$SiC$_5$H$_4$}$_2$ZrCl$_2$] (10): This complex was obtained as a colorless oil (0.49 g, 94%) by the same procedure described for **9** from $ZrCl_4$·2THF (0.12 g, 0.31 mmol) and **4** (0.50 g, 0.62 mmol) in toluene (25 mL). $C_{100}H_{110}Cl_2Si_8Zr$ (1698.8):

calcd. C 70.70, H 6.53; found C 70.53, H 6.62. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 7.42 (m, 12 H, C_6H_5), 7.26 (m, 18 H, C_6H_5), 6.28 and 6.14 (AA′ and BB′ parts of an AA′BB′ spin system, 4 H, C_5H_4), 0.85 and 0.74 [A and B parts of an A_2B_2 spin system, 12 H, $Si(CH_2)_2Si$], 0.49 (s, 9 H, CH_3) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$, 25 °C): δ = 136.9 (C_{ipso}, C_6H_5), 134.4 (C_{meta}, C_6H_5), 129.1 (C_{para}, C_6H_5), 127.7 (C_{ortho}, C_6H_5), 125.3 (C_5H_4), 124.3 (C_{ipso}, C_5H_4), 116.3 (C_5H_4), 6.5 and 4.6 [$Si(CH_2)_2Si$], −5.0 (CH_3) ppm. $^{29}Si\{^1H\}$ NMR (500 MHz, $CDCl_3$, 25 °C): δ = 0.0 (SiC_5H_4), −5.7 (Ph_2MeSi) ppm.

Ethylene Polymerization: A 250 mL flask charged with toluene (50 mL) and equipped with a magnetic stirrer was evacuated four times and refilled with pre-dried ethylene gas. Keeping the flask pressurized with ethylene (1 bar) and stirred at room temperature, a toluene solution of methylaluminoxane (MAO, 0.83 mL, 1.5 M) was syringed through a septum. After 5 min, a toluene solution of the catalyst (0.50 mL, 2.5 mM) was injected into the flask with simultaneous starting of a stopwatch. The polymerization was quenched 10 min later by closing the ethylene feed, release of the overpressure and addition of acidified methanol (4% v/v HCl). The mixture was stirred for 6 h and the polymer was filtered, washed with copious amounts of methanol, and dried in an oven to constant weight. Molecular weights were determined by gel-permeation chromatography (GPC).

Copper-Mediated Oxygenolysis of Flavonols via Endoperoxide and Dioxetan Intermediates; Synthesis and Oxygenation of $[Cu^{II}(Phen)_2(Fla)]ClO_4$ and $[Cu^{II}(L)(Fla)_2]$ [FlaH = Flavonol; L = 1,10-Phenanthroline (Phen), 2,2′-Bipyridine (Bpy), *N*,*N*,*N*′,*N*′-Tetramethylethylenediamine (TMEDA)] Complexes

Keywords: Enzyme models / Copper / Peroxides / Kinetics

$[Cu(phen)_2(fla)]ClO_4$ was prepared by treating $[Cu(CH_3CN)_4]$-ClO_4 with flavonol (flaH) in the presence of 1,10-phenanthroline (phen) as a co-ligand. Its oxygenation in DMF (or CH_3CN) solution at elevated temperature gave the (*O*-benzoylsalicylato)copper(II) complex $[Cu(phen)_2(O\text{-bs})]ClO_4$ (bs = benzoylsalicylato) and carbon monoxide via an endoperoxide intermediate. Crystallographic characterisation of $[Cu(phen)_2(O\text{-bs})]ClO_4$ as the CH_2Cl_2 solvate [triclinic, space group $P\bar{1}$, a = 10.499(3) Å, b = 12.556(4) Å, c = 17.094(5) Å, α = 72.69(2), β = 89.35(2), γ = 69.19(2)°, V = 1999.7(10) Å^3, Z = 2, $R1$ = 0.0962] shows that the molecule has a distorted trigonal-bipyramidal structure (τ = 0.96). The oxygenolysis was monitored by spectrophotometry, and the pseudo-first-order rate constant k'_{phen} was found to be $(2.47 \pm 0.11) \times 10^{-4}$ s^{-1} at 120 °C. Complexes of $[Cu(L)(4'R\text{-fla})_2]$ (L = phen, bpy, TMEDA; R = H, OCH_3, CH_3, Cl) were also prepared by treating the complexes $Cu(4'R\text{-fla})_2$ with nitrogen-containing co-ligands. Their oxygenation resulted in the corresponding complexes $Cu(L)(2HOpg)_2$ (2HOpg =2-hydroxyphenylglyoxylate) derived by spontaneous hydrolysis of $Cu(L)(bpg)_2$ (bpg = 2-benzoatophenylglyoxylate). The (phenylglyoxylato)-copper complexes were probably formed via 1,2-dioxetan intermediates, since the oxygenation of $Cu(phen)(fla)_2$ showed chemiluminescence with bands at 506, 546, and 578 nm in the emission spectrum due to the decomposition of a 1,2-dioxetan species. Labelling experiments with an $^{18}O_2/^{16}O_2$ mixture (1:3) showed the incorporation of both ^{18}O atoms of $^{18}O_2$ into the flavonolate ligand. The kinetics of the oxygenolysis of $Cu(L)(fla)_2$ gave rate constants according to the rate law $-d[Cu(L)(4'R\text{-fla})_2]/dt = k[Cu(L)(4'R\text{-fla})_2][O_2]$: k/m^{-1} s^{-1} = $(9.50 \pm 0.60) \times 10^{-2}$ (L = phen), $(2.40 \pm 0.10) \times 10^{-2}$ (L = bpy), $(2.00 \pm 0.10) \times 10^{-2}$ (L = TMEDA) m^{-1} s^{-1} at 353.16 K. The oxygenolysis of the complexes $Cu(phen)(4'R\text{-fla})_2$ fits a Hammett linear free energy relationship and an increase of the electron density on the copper ion makes the oxygenation reaction faster.

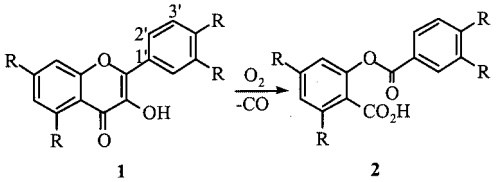
Introduction

Flavonols are widely distributed in vascular plants,[1,2] and flavonoids form active constituents of a number of herbal and traditional medicines.[3] Flavonols are readily degraded by microorganisms, especially by fungi such as *Aspergillus* or *Pullularia* species.[4] Flavonol 2,4-dioxygenase (quercetinase), which catalyses the oxidative degradation of flavonols (**1**) to a depside (phenolic carboxylic acid esters, **2**) with concomitant evolution of carbon monoxide [Equation (1)], was purified from culture filtrate of *Aspergillus niger*.[4b]



1 **2** (1)

This reaction is rather exceptional as it involves the oxygenolytic cleavage of two carbon−carbon bonds. Carbon monoxide forming enzymes are rare. To date, three prokaryotic dioxygenases are known that catalyse a dioxygenolytic release of CO in a manner analogous to that of fungal quer-

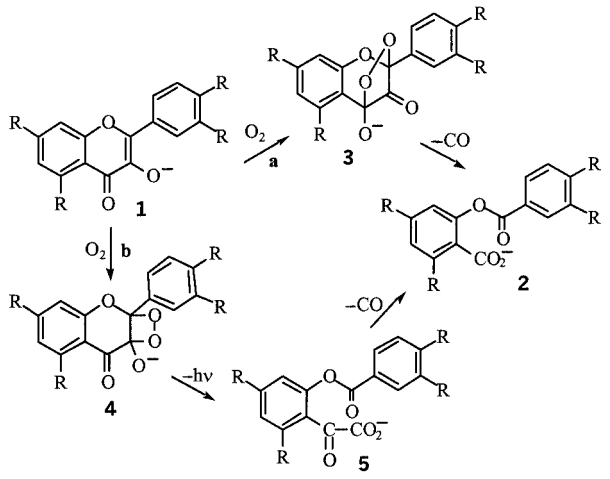
cetinase, these being 3-hydroxyquinaldin-4(1*H*)-one 2,4-dioxygenase, 3-hydroxyquinolin-4(1*H*)-one 2,4-dioxygenase,[5] and 1,2-dihydroxy-5-(methylthio)pent-1-en-3-one anion 1,3-dioxygenase.[6] These prokaryotic enzymes were claimed not to contain any metal ion or organic cofactor[5b] and thus differ fundamentally from the copper-containing flavonol 2,4-dioxygenase. However, it was reported recently, that the 1,2-dihydroxy-5-(methylthio)pent-1-en-3-one anion 1,3-dioxygenase is a Ni-containing enzyme.[6c]

For the oxidative cleavage reaction of the heterocycle in flavonols, two pathways have been proposed (Scheme 1),[7] the first via an endoperoxide **3** (route a) and the other via a 1,2-dioxetan **4** (route b).



Scheme 1

Since flavonol 2,4-dioxygenase is a copper-containing metalloenzyme, metal complexes of copper[8,9] and cobalt[10] have been used in model reactions. Autoxidation reactions of potassium[11] and zinc flavonolates[12] have also resulted in enzyme-like products, and some efforts have been made to elucidate the mechanism of the reaction. From our earlier results obtained both with redox and non-redox metal-containing systems, the conclusion could be drawn that the oxygenolysis of the flavonolate ion in aprotic solvents takes place via an endoperoxide intermediate.[9e−9h,11,12]

Flavonol 2,4-dioxygenase has been claimed to contain nonblue type 2 Cu^{II} ions at its active site.[4b] Recent crystal structure determination of quercetin 2,3-dioxygenase from *Aspergillus japonicus* reveal that it forms homodimers. The mononuclear type 2 copper centre displays two distinct geometries: a distorted tetrahedral coordination, formed by three histidine residues and one water molecule, and a distorted trigonal-bipyramidal environment, which additionally comprises a glutamate.[4i] In this paper we report details for the synthesis and characterisation of $[Cu(phen)_2(fla)]ClO_4$ (**6**) and $[Cu(L)(4'R\text{-}fla)_2]$ [L = phen (**7**), bpy (**8**), TMEDA (**9**); R = H (a), OCH_3 (**7b**), CH_3 (**7c**), Cl (**7d**)] complexes, which are models for the enzyme−substrate (ES) complex. Spectrophotometric and kinetic studies aimed at elucidating the mechanism of the stoichiometric oxygenation of the two systems are also reported on.

Results and Discussion

Synthesis and Characterisation of the Complex $[Cu(phen)_2(fla)]ClO_4$

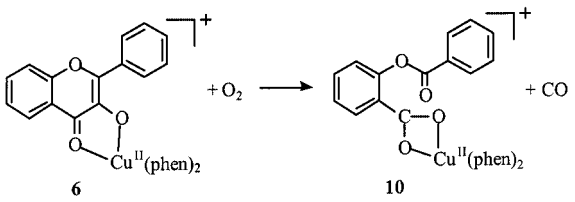
Complex $[Cu(phen)_2(fla)]ClO_4$ was isolated as a green solid by the reaction of $[Cu(CH_3CN)_4]ClO_4$, flavonol (**1**) and 1,10-phenanthroline monohydrate at room temperature in acetonitrile under dioxygen. Its IR spectrum shows the principal band corresponding to the coordinated flavonolate at 1581 cm^{-1}. The decrease of approximately 20 cm^{-1} of the ν(CO) band compared to that of free flavonol [ν(CO): 1602 cm^{-1}] is due to chelation and formation of a stable five-membered ring.[13] The absorption bands at 1082 and 626 cm^{-1} can be assigned to the perchlorate anion. A very strong band at 1608 cm^{-1} [ν(C=N)] is due to the coordinated 1,10-phenanthroline. The electronic spectrum of the complex in the charge transfer region exhibits a band of the coordinated flavonolate ligand at 419 nm. The band at 702 nm is associated with the d−d transition of Cu^{II}. Room-temperature magnetic measurements yielded a value of μ_B = 1.92, consistent with a copper(II) ion.

Synthesis and Characterisation of $Cu(L)(4'R\text{-}fla)_2$

$Cu(4'R\text{-}fla)_2$ (R = H, CH_3, OCH_3, Cl) complexes reacted with 1,10-phenanthroline at room temperature in acetonitrile under argon to give the corresponding complexes $Cu(phen)(4'R\text{-}fla)_2$ in fairly good yields. Similarly, in the presence of TMEDA or bpy co-ligands $Cu(TMEDA)(fla)_2$ or $Cu(bpy)(fla)_2$ was obtained. Satisfactory elemental analyses were obtained for all of the new complexes. Compounds $Cu(L)(fla)_2$ have very similar IR and electronic spectra. The IR spectrum shows the principal bands corresponding to the coordinated flavonolate in the 1560−1580 cm^{-1} region. Decreases of approximately 40 cm^{-1} of the ν(CO) bands compared to that of the 4′-substituted flavonols [ν(CO): ca. 1605 cm^{-1}] are due to chelation and formation of a stable five-membered ring.[13] In the case of complexes with 2,2′-bipyridine and 1,10-phenanthroline, a strong band in the 1590−1600 cm^{-1} region is seen due to the coordinated nitrogen donor ligands ν(C=N). The π−π* transitions in the 420−435 nm region arise from the coordinated flavonolate ligands.

Oxygenation of $[Cu(phen)_2(fla)]ClO_4$

Treatment of $[Cu(phen)_2(fla)]ClO_4$ with dioxygen in DMF or CH_3CN solution at elevated temperature led to the corresponding (*O*-benzoylsalicylato)copper complex $[Cu(phen)_2(O\text{-}bs)]ClO_4$ (**10**) and carbon monoxide contaminated with a small amount of CO_2 [Equation (2)]. The formation of **10** from **6** required dioxygen, which was measured by volumetry (no apparent dioxygen uptake was observed, because the absorption of dioxygen and the liberation of CO compensate each other).



6 10 (2)

The oxygenation of **6** was monitored by UV/Vis spectroscopy. The time course of the variation of $[Cu(phen)_2(fla)]ClO_4$ (**6**) in DMF solution at 120 °C is shown in Figure 1. Plots of $\log[Cu(phen)_2(fla)]ClO_4$ vs. time show a linear dependence under pseudo-first-order conditions[14] (constant dioxygen pressure), in agreement with a rate equation of first-order dependence with respect to the complex **6**. The pseudo-first-order rate constant k' was found to be $(2.47 \pm 0.11) \times 10^{-4}$ s^{-1} at 120 °C. This value is very close to that found for the oxygenation of $[Cu(idpaH)(fla)]ClO_4$ [idpaH = 3,3′-iminobis(*N*,*N*-dimethylpropylamine)] in DMF [$k'_{120\ °C} = (1.45 \pm 0.06) \times 10^{-4}$ s^{-1})].[9g]

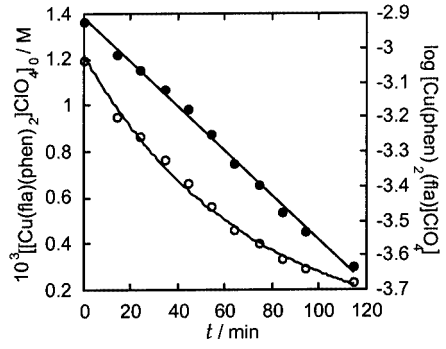


Figure 1. Time course for the oxygenation of $[Cu(phen)_2(fla)]ClO_4$ in DMF (o) and plot of $\log[\{Cu(phen)_2(fla)]ClO_4\}]$ (•) vs. reaction time for the oxygenation of $[Cu(phen)_2(fla)]ClO_4$ ($[\{Cu(phen)_2(fla)]ClO_4\}]_0 = 1.35 \times 10^{-3}$ M, $[O_2] = 6.1 \times 10^{-3}$ M, 120 °C)

Characterisation of $[Cu(phen)_2(O\text{-bs})]ClO_4$

The complex $[Cu(phen)_2(O\text{-bs})]ClO_4$ can also be prepared by the reaction of $[Cu(CH_3CN)_4]ClO_4$, *O*-benzoylsalicylic acid and 1,10-phenanthroline monohydrate at room temperature in acetonitrile under dioxygen. Its IR spectrum shows bands corresponding to the coordinated *O*-benzoylsalicylate at 1741 [ν(CO), indicating that the carbonyl group of the benzoyl group is not coordinated], 1572 and 1388 [$\nu(CO_2)$] cm^{-1}. The difference between the asymmetric and symmetric stretching frequencies of the carboxylato group [$\Delta\tilde{\nu} = \nu_{as}(CO_2) - \nu_s(CO_2)$] is 184 cm^{-1}, rendering these to a monodentate carboxylate bonding mode. Absorption bands at 1068 and 635 cm^{-1} are associated with the perchlorate anion. In the UV/Vis spectrum the d−d transition may be assigned to the 694 nm absorption and the ligand-to-metal charge transfer at 271 and 294 nm. The magnetic moment of $\mu_B = 2.06$ is in agreement with a d^9 Cu^{II} ion without magnetic interactions.

X-ray Crystal Structure of $[Cu(phen)_2(O\text{-bs})]ClO_4$

The molecular structure and atom numbering scheme for $[Cu(phen)_2(O\text{-bs})]ClO_4$ is shown in Figure 2, and selected bond lengths and angles are listed in Table 1. The copper ion has a slightly distorted trigonal-bipyramidal geometry with $\tau = 0.96$.[9g] Two nitrogen atoms of the 1,10-phenanthroline ligands [Cu(1)−N(1) 2.176(5), Cu(1)−N(3) 2.074(5) Å] and one oxygen atom of the *O*-benzoylsalicylate ligand [Cu(1)−O(1) 1.993 Å] occupy basal positions. The two other nitrogen atoms of the phenanthroline ligands [Cu(1)−N(2) 1.992(5) and Cu(1)−N(4) 1.987(5)] are in apical positions. The Cu−N distances in the basal plane are longer than those in apical positions.

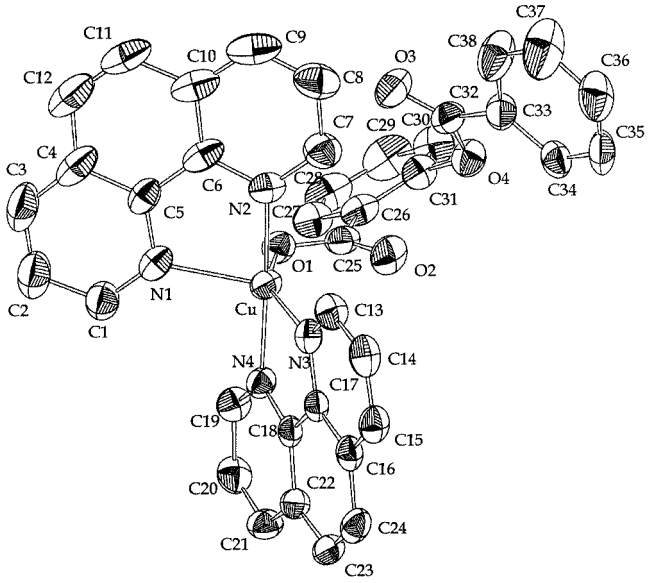

Figure 2. Molecular structure of $[Cu(phen)_2(O\text{-bs})]ClO_4\ 1.5CH_2Cl_2$

Table 1. Selected bond lengths [Å] and angles [°] for $[Cu(phen)_2(O\text{-bs})]ClO_4 \cdot 1.5CH_2Cl_2$

Cu(1)−N(4)	1.987(5)	Cu(1)−N(3)	2.074(5)

Oxygenation of the Complexes $Cu(L)(4'R\text{-fla})_2$

Treatment of the complexes $Cu(L)(4'R\text{-fla})_2$ (L = bpy, phen, TMEDA; R = H, CH_3, OCH_3, Cl) with dioxygen in DMF or CH_3CN solution at elevated temperature led to the corresponding (2-hydroxyphenylglyoxylato)copper complexes $Cu(L)(2HOpg)_2$ and 4-substituted benzoic acids [Equation (3)]. According to gas-volumetric and GC measurements, the stoichiometry of the oxygenation reactions

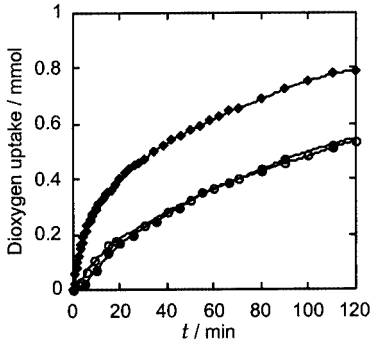

Figure 3. Time course for the oxygenation of the complexes Cu(L)-(fla)$_2$ (**7**−**9**) (L = phen (◆), bpy (●), TMEDA (○); [Cu(L)(fla)$_2$]$_0$ = 0.4 mmol in 50 mL of DMF, [O_2] = 6.91 × 10^{-3} M, 80 °C)

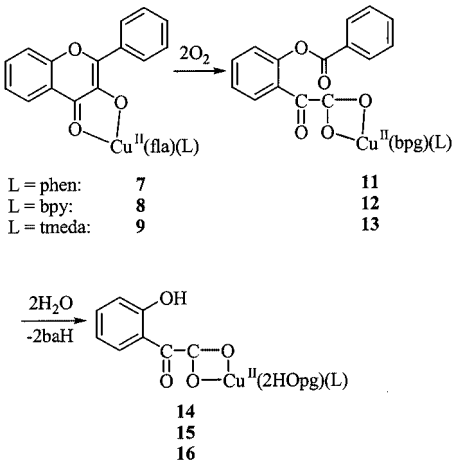
corresponds to Equation (3). Figure 3 shows typical dioxygen uptakes vs. time curves for the complexes [Cu(L)(fla)$_2$] (L = bpy, phen, TMEDA). No other oxidation products could be detected.



(3)

The GC and GC-MS analyses of the reaction mixture obtained by the oxygenation of Cu(phen)(fla)$_2$, after treatment with dilute HCl solution (10%) and ethereal diazomethane, show the presence of methyl benzoate {136 (23) [M^+], 105 (100), 77 (87)}, coumaronedione {148 (3) [M^+], 120 (100), 92 (59), 64 (22), 63 (14)}, and methyl 2-hydroxyphenylglyoxylate {180 (7) [M^+], 121 (100), 93 (11), 65 (11)}. In the case of complex Cu(phen)(fla)$_2$, during the oxygenation reaction chemiluminescence was observed, which is crucial evidence for the decomposition of a 1,2-dioxetan[15] intermediate to carbonyl compounds. Figure 4 shows the electron spectrum of the emitted light (λ = 506, 546, 578 nm). Compound Cu(phen)(2HOpg)$_2$ does not seem to be involved in the chemiluminescence process since its fluorescence spectrum in DMF excited by 430 nm shows bands at 480 and 535 nm with a shoulder at 557 nm (Figure 5), which does not match the spectrum of the emitted light of the chemiluminescence process. It seems likely that the real emitter is Cu(phen)(bpg)$_2$ (**11**), which could not be isolated due to its extreme sensitivity toward hydrolysis.

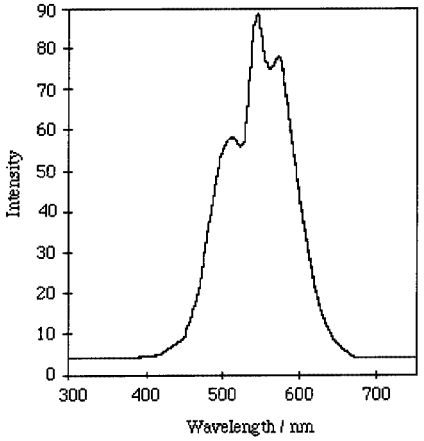


Figure 4. Electron spectrum of the emitted light during the oxygenation of Cu(phen)(fla)$_2$ in DMF

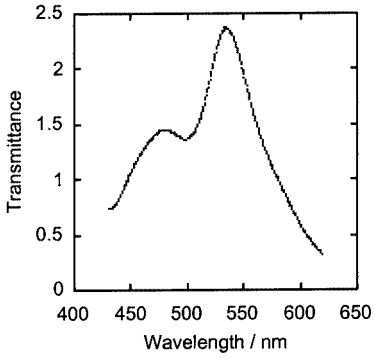

Figure 5. Fluorescence spectrum of Cu(phen)(2HOpg)$_2$ in DMF

Characterisation of the Complexes Cu(L)(2HOpg)$_2$ (L = phen, bpy, TMEDA)

Satisfactory elemental analyses were obtained for the three new (2-hydroxyphenylglyoxylato)copper complexes, namely Cu(phen)(2HOpg)$_2$ (**14**), Cu(bpy)(2HOpg)$_2$ (**15**), and Cu(TMEDA)(2HOpg)$_2$ (**16**). The IR spectrum shows the presence of the coordinated α-oxocarboxylato ligand {ca. 1616 [ν(CO)], ca. 1575, ca. 1375 [ν(CO_2)] cm^{-1}, respectively}.

Kinetic Measurements

The kinetics of the oxygenation of Cu(phen)(fla)$_2$ were monitored by electron spectroscopy at 432 nm. Experimental conditions are summarised in Table S1 (Supporting Information). To determine the rate dependence on the two reactants, oxygenation runs were performed at various initial Cu(phen)(fla)$_2$ concentrations and different dioxygen pressures. A simple rate law for the reaction between Cu-(phen)(fla)$_2$ and O_2 is as shown in Equation (4).

$$-d[Cu(phen)(fla)_2]/dt = d[Cu(phen)(2HOpg)_2]/dt = k_{phen}[Cu(phen)(fla)_2]^m[O_2]^n \quad (4)$$

Under pseudo-first-order conditions (constant dioxygen concentration) for the oxygenation of **7** a typical time course and first-order plot are shown in Figure 6; the reaction remained first-order in **7** during the whole time in which the experiment was monitored (81% conversion, 0.6 h). The first-order dependence on the reaction rate on **7** could also be confirmed by plotting the initial reaction rate $-d[Cu(phen)(fla)_2]/dt$ vs. initial substrate concentration. The straight line obtained [as shown in Figure S1 (Supporting Information)] validates the first-order dependence in $Cu(phen)(fla)_2$ with the pseudo-first-order rate constant $k'_{phen} = 6.86 \times 10^{-4}\ s^{-1}$ and a correlation coefficient of 99.5%.

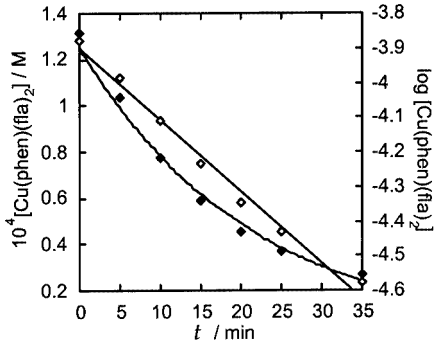

Figure 6. Time course for the oxygenation of $Cu(phen)(fla)_2$ in DMF (◆) and plot of $\log[Cu(phen)(fla)_2]$ (□) vs. reaction time for the oxygenation of $Cu(phen)(fla)_2$

Experiments made at different dioxygen pressures show that p_{O2} appreciably influences the rate of the reaction. Kinetic measurements of the reaction rate indicate a first-order dependence with respect to the dioxygen concentration. Plots of k'_{phen} vs. $[O_2]$ for the above experiments give a straight line with $k_{phen} = 0.10\ M^{-1}\ s^{-1}$ and a correlation coefficient of 99.1% (Figure 7). On the basis of the results above, it can be concluded that the reaction follows the rate law of Equation (4) with $m = n = 1$, from which a mean value of the kinetic constant k_{phen} of $(9.50 \pm 0.60) \times 10^{-2}\ M^{-1}\ s^{-1}$ at 353.16 K can be obtained. In the case of the oxygenation of $Cu(bpy)(fla)_2$ and $Cu(TMEDA)(fla)_2$ the mean values of the kinetic constants at 353.16 K were found to be $k_{bpy} = (2.40 \pm 0.10) \times 10^{-2}\ M^{-1}\ s^{-1}$ and $k_{TMEDA} = (2.00 \pm 0.10) \times 10^{-2}\ M^{-1}\ s^{-1}$.

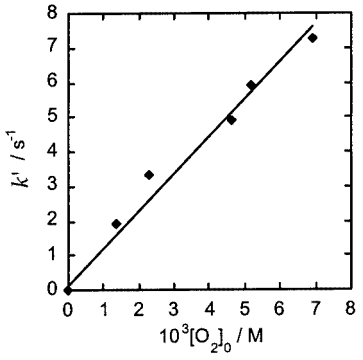

Figure 7. Plot of pseudo-first-order rate constant k' vs. O_2 pressure

The activation parameters for the oxygenation reactions were determined from the temperature dependence of the kinetic constant k_{phen} in the temperature range of 348.16−363.16 K. From the straight line in the Eyring plot [Figure S2 (Supporting Information)], with a correlation coefficient of 99.7% the activation parameters $\Delta H^{\ddagger} = 79 \pm 16\ kJ\ mol^{-1}$ and $\Delta S^{\ddagger} = -40 \pm 44\ J\ mol^{-1}\ K^{-1}$ were calculated at 353.16 K.

Reaction rates on the oxygenation of the 4′-substituted complexes $Cu(phen)(4'R\text{-}fla)_2$ under identical conditions were also determined (with various electron-withdrawing or releasing substituents R) in order to find out electronic effects on the reaction rate. The Hammett plot obtained is shown in Figure 8. Electron-releasing substituents enhanced the reaction rate, and the reaction constant ρ_{phen} was found to be −1.03 (R = 98.3%).

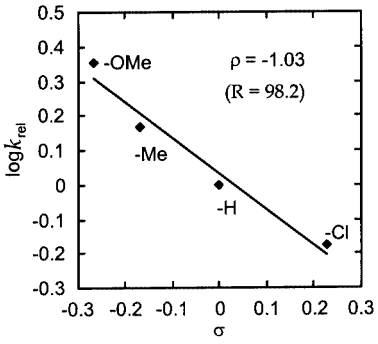

Figure 8. Hammett plot for the oxygenation of $Cu(phen)(4'R\text{-}fla)_2$ complexes

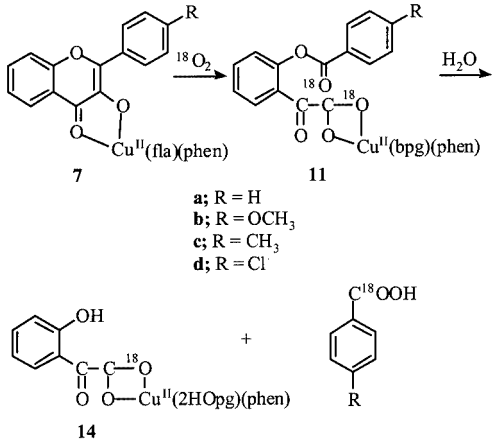
$^{18}O_2$ Labelling Experiments

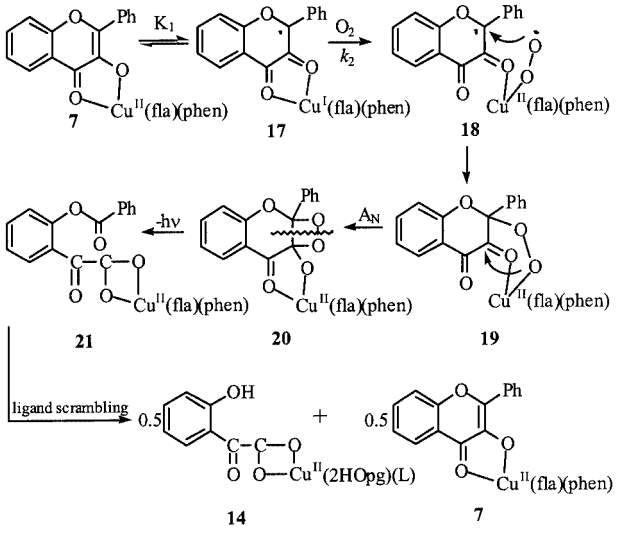
Oxygenation of $Cu(phen)_2(fla)$ was also carried out with a mixture of $^{16}O_2$ and $^{18}O_2$ (3:1) in acetonitrile. After stirring the reactants at 25 °C for 48 h, the unchanged starting material was filtered off (ca. 50%), and the green solution was concentrated to dryness, giving a mixture of $Cu(phen)(^{16}O\text{-}bpg)_2$ and $Cu(phen)(^{18}O\text{-}bpg)_2$ {IR (Nujol): 1685 [$\nu(C^{18}O)$], 1716 [$\nu(C^{16}O)$] cm^{-1}}, $Cu(phen)(^{18}O\text{-}2HOpg)_2$ and $Cu(phen)(^{16}O\text{-}2HOpg)_2$, respectively. The GLC-MS analysis of the residue, after treatment with ethereal diazomethane, showed the presence of ^{16}O- and ^{18}O-containing methyl benzoate: *m/z* (%) = 136 (23) [M^+], 105 (100), 77 (87); 138 (8) [$M^+ + 2$], 181 (9), 107 (26), 105 (100), 77 (87); methyl 2-methoxyphenylglyoxylate: *m/z* (%) = 194 (32) [M^+], 179 (22), 135 (100), 120 (29), 105 (15), 92 (15); 196 (12) [$M^+ + 2$], 181 (9), 135 (100), 120 (29), 105 (15), 92 (28); methyl 2-hydroxyphenylglyoxylate: *m/z* (%) = 180 (7) [M^+], 121 (100), 93 (17), 65 (23); 182 (2.2) [$M^+ + 2$], 121 (100), 93 (17), 65 (23); and coumaronedione: *m/z* (%) = 148 (4.3) [M^+], 120 (100), 92 (69), 64 (27), 63 (30); 138 (8) [$M^+ + 2$], 107 (26), 105 (100), 77 (87); in the appropriate ratio. On the bases of the above results it can be said that both ^{18}O atoms of $^{18}O_2$ are incorporated into the primary oxygenated product 2-benzoatophenylglyoxylic acid from molecular oxygen (Scheme 2).



Scheme 2

All experimental data reported in the previous sections can be used for the interpretation of the mechanism of copper-assisted oxygenolysis of coordinated flavonolate to *O*-benzoylsalicylate or 2-benzoatophenylglyoxylate. Flavonolate as a chelating ligand forms stable complexes with copper ions. In most cases they are stable toward dioxygen in the solid form or even in solution at ambient conditions. At elevated temperatures the oxygenolysis proceeds reasonably rapidly. Recently, we have found that copper(II) flavonolate complexes with simple N-containing tridentate ligands reacted with dioxygen to the corresponding enzyme-like (*O*-benzoylsalicylato)copper complexes and CO. On the basis of kinetic measurements of the reaction of the complexes above with dioxygen, a mechanism was proposed to proceed via an endoperoxide intermediate according to route a in Scheme 1.[9g,9h] Treatment of the (flavonolato)copper complex $[Cu(phen)_2(fla)]ClO_4$ with dioxygen in DMF or CH_3CN solution at elevated temperature leads also to an (*O*-benzoylsalicylato)copper complex $[Cu(phen)_2(O\text{-}bs)]ClO_4$ and carbon monoxide, indicating that the mechanism of this reaction is the same as that proposed for copper-containing model systems investigated earlier by us.

Recently, we have published that the oxygenolysis of $Cu(fla)_2$ in DMF resulted in the $Cu(O\text{-}bs)_2$ complex and CO.[9e] We found that this reaction proceeded in a bimolecular step via an endoperoxide intermediate (Scheme 1, route a), and the kinetic constant k_{obs} was found to be $9.90 \pm 0.80 \times 10^{-3}$ mol^{-1} dm^3 s^{-1} at 90 °C.[9e] This value is much smaller than that obtained for the oxygenolysis for $Cu(phen)(fla)_2$ ($21.3 \pm 1.8 \times 10^{-2}$ mol^{-1} dm^3 s^{-1} at 90 °C). This difference in the reaction rates indicates that there are two different pathways for the above reactions. The formation of (oxocarboxylato)copper(II) complexes **14**−**16** in the oxygenation of the complexes $Cu(L)(fla)_2$ (L = phen, bpy, TMEDA) also suggest that the oxidative cleavage reaction of the coordinated flavonolate ligand can only proceed via a 1,2-dioxetan intermediate, which, upon the usual decomposition and hydrolysis of the ester linkage, leads to the corresponding (oxocarboxylato)copper complexes **14**−**16**. The $^{18}O_2$ labelling experiments on the oxygenation of $Cu(phen)(fla)_2$ revealed that both ^{18}O atoms of the $^{18}O_2$ molecule are incorporated into the substrate. A reaction mechanism that nicely fits the chemical, photochemical, spectroscopic, labelling, kinetic, and thermodynamic data is shown in Scheme 3.



Scheme 3

The second-order overall rate expression for the oxygenation of the flavonolato complexes **7** supports the proposal that in a fast pre-equilibrium the copper(II) flavonolate complex **7** undergoes intramolecular electron transfer from the ligand fla^- to Cu^{II}, resulting in the copper(I) flavonoxy radical complex **17**. The equilibrium is largely shifted to the left (K_1 is rather small). In **17** there are two redox-active centres, the radical ligand and the copper(I) ion. The biradical dioxygen may react at both sites; in an oxidative addition to the copper ion [leading to a (superoxo)copper(II) complex **18**], or in a radical-radical reaction with the flavonoxy ligand. We believe that the former is the rate-determining step. The Hammett relationship shows that higher electron density at the copper ion enhances the rate of the reaction. This is consistent with an electrophilic attack of dioxygen at the copper(I) centre.

The reaction constant of the oxygenation reaction is almost the same ($\rho_{phen} = -1.03$, $R = 98.2\%$) as that found for the oxygenation of copper(I) chloride in pyridine ($\rho = -1.24$).[16] The crucial evidence for a bimolecular reaction step is the negative $\Delta S^{\ddagger}$ value (−40.3 J mol^{-1} K^{-1}). The (superoxo)copper(II) complex **18** is possibly then transformed in a fast consecutive coupling reaction to **19**, which reacts by an intramolecular nucleophilic addition on C3 to give the 1,2-dioxetan **20**. The main difference between the two types of mechanistic routes can be explained by this step. The nucleophilic attack of the bound peroxide could also take place on the 4-C=O group as well giving rise to an endoperoxide intermediate, but in that case the higher electron density on the 4-C=O carbon atom compared to that on the 3-C=O carbon atom renders this pathway unlikely. The 1,2-dioxetan **20** is then believed to decompose in a fast step to the (oxocarboxylato)copper complex **21**. Ow-

ing to a ligand scrambling reaction, the starting copper flavonolate complex **7** and the product (2-hydroxyphenylglyoxylato)copper complex **14** are formed by hydrolysis of the ester linkage in complex **11**. In order to prove the formation of 1,2-dioxetan during the oxygenolysis the chemiluminescence of the reaction was tested. In the emission spectrum bands at 506, 546, and 578 nm were found, which were assigned to the decomposition of the 1,2-dioxetan species.[15] Light emission is a result of the transition of the exited complex **21** to its ground state. Assuming steady-state conditions for species **17** the rate according to Equation (5) can be deduced, which after some simplification ($k_2[O_2] << k_1 + k_{-1}$ and [Cu] means the total copper concentration) is in good agreement with an overall second-order dependence according the experimental data obtained in the kinetic measurements.

$$-\frac{d[Cu]}{dt} = \frac{k_1 k_2 [Cu][O_2]}{k_1 + k_{-1} + k_2[O_2]} = \frac{k_1 k_2 [Cu][O_2]}{k_1 + k_{-1}} = k_{obs}[Cu][O_2] \quad (5)$$

Conclusion

From the results obtained the conclusion may be drawn that the oxidative ring-cleavage reaction of the flavonolate ligand coordinated to the copper ion may take place by two different reaction routes, namely through an endoperoxide or a 1,2-dioxetan intermediate. We believe that the coordination mode and the ligand environment around the metal centre, and the Lewis acidity of the copper ion influence the mechanism of this unusual reaction. Both complexes $Cu(phen)(fla)_2$ and $[Cu(phen)_2(fla)]ClO_4$ are sterically very crowded so that the discrimination of the intramolecular nucleophilic peroxide group between the 4-C=O and 3-C=O carbon atoms seems to be governed by the different electron densities on the carbon atoms, which is influenced by changing the ligand environment. Further work is in progress to better understand the reasons and factors affecting the selectivity between this two types of C−C cleavage reactions.

Experimental Section

General Remarks: Solvents used for the reactions were purified using literature methods[17] and stored under argon. Flavonol,[18] 4′-methoxyflavonol,[18] 4′-methylflavonol,[19] 4′-chloroflavonol,[19] O-benzoylsalicylic acid,[20] $Cu(OCH_3)_2$,[21] $[Cu(CH_3CN)_4]ClO_4$,[22] and $Cu(fla)_2$ [9b] were prepared using literature methods. The ligands 1,10-phenanthroline, 2,2′-bipyridine, and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (Aldrich) were used as provided.

CAUTION: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of material should be prepared, and these should be handled with great care.

Preparation of $[Cu(phen)_2(fla)]ClO_4$ (6): $[Cu(CH_3CN)_4]ClO_4$ (0.328 g, 1 mmol) was dissolved in acetonitrile (60 mL), and flavonol (0.238 g, 1 mmol) and 1,10-phen·H_2O (0.396 g, 2 mmol) were added and stirred under argon for 1 h, and then under dioxygen (0.1 MPa) for 2 h. A green solid formed, which was filtered, washed with acetonitrile, and dried under vacuum (0.66 g, 87%). The product was recrystallised from acetonitrile. M.p. 195 °C. IR (KBr): $\tilde{\nu}$ = 1608 (vs, C−N), 1581 (vs, C−O), 1511, 1493, 1416, 1207, 1141, 1082 (vs, ClO_4), 845, 756, 719, 626 cm^{-1} (vs, ClO_4). UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 229 (67608), 269 (69183), 419 (8318), 702 nm (51). μ_B = 1.92. $C_{39}H_{25}ClCuN_4O_7$ (760.7): calcd. C 61.58, H 3.31, N 7.36; found C 61.04, H 3.16, N 7.18.

Preparation of $Cu(phen)(fla)_2$ (7a): To a solution of $Cu(fla)_2$ (0.538 g, 1 mmol) in acetonitrile (35 mL) was added 1,10-phen·H_2O (0.198 g, 1 mmol) and the reaction mixture stirred under argon for 4 h. A green precipitate formed, which was filtered off, washed with ether, and dried under vacuum (0.65 g, 90%). M.p. 236 °C. IR (KBr): $\tilde{\nu}$ = 3059 vw, 3044 vw, 1595 vs, 1564 vs, 1508 s, 1485 m, 1465 m, 1408 vs, 1350 m, 1310 s, 1221 vs, 1187 m, 1144 m, 1109 m, 1077 m, 1033 m, 995 w, 913 m, 859 s, 774 s, 747 s, 735 m, 721 w, 698 s, 571 m, 533 m, 499 m cm^{-1}. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 265 (64125), 432 nm (63658). μ_B = 1.98. $C_{42}H_{26}CuN_2O_6$ (718.2): calcd. C 70.24, H 3.64, N 3.90; found C 69.88, H 3.48, N 3.98.

$Cu(phen)(4'OCH_3\text{-}fla)_2$ (7b): Yield 0.66 g (85%). M.p. 200 °C. IR (KBr): $\tilde{\nu}$ = 3052 vw, 2924 vw, 2823 w, 1591 vs, 1568 vs, 1542 s, 1491 s, 1416 vs, 1355 m, 1305 s, 1249 vs, 1216 vs, 1181 s, 1116 s, 1046 s, 1003 m, 923 m, 852 s, 761 s, 742 s, 691 m, 642 m, 578 m, 529 m cm^{-1}. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 271 (70018), 434 (67844) nm. μ_B = 2.01. $C_{44}H_{30}CuN_2O_8$ (778.3): calcd. C 67.90, H 3.38, N 3.82; found C 67.29, H 3.48, N 3.98.

$Cu(phen)(4'CH_3\text{-}fla)_2$ (7c): Yield 0.62 g (83%). M.p. 197 °C. IR (KBr): $\tilde{\nu}$ = 3030 vw, 2895 vw, 2841 wv, 1590 vs, 1576 vs, 1495 vs, 1476 s, 1412 vs, 1353 m, 1312 s, 1217 vs, 1189 s, 1147 m, 1112 s, 1050 w, 1029 w, 1001 m, 916 s, 861 s, 834 s, 766 s, 738 s, 689 m, 663 w, 638 m, 514 s cm^{-1}. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 271 (80041), 429 (63062) nm. μ_B = 1.86. $C_{44}H_{30}CuN_2O_6$ (746.3): calcd. C 70.81, H 4.05, N 3.75; found C 69.84, H 3.89, N 3.88.

$Cu(phen)(4'Cl\text{-}fla)_2$ (7d): Yield 0.59 g (75%). M.p. 238 °C. IR (KBr): $\tilde{\nu}$ = 3048 vw, 1595 vs, 1568 vs, 1510 m, 1483 vs, 1410 vs, 1355 m, 1316 s, 1219 vs, 1149 m, 1109 s, 1093 m, 1022 m, 1003 m, 916 s, 849 s, 758 s, 736 s, 691 w, 661 w, 616 m, 551 w, 505 m. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 271 (73578), 424 (60173) nm. μ_B = 1.81. $C_{42}H_{28}Cl_2CuN_2O_6$ (788.1): calcd. C 64.01, H 3.67, N 3.56; found C 63.68, H 3.89, N 3.66.

$Cu(bpy)(fla)_2$ (8): Yield 0.22 g (40%). M.p 280 °C. IR (KBr): $\tilde{\nu}$ = 3023 vw, 1588 vs, 1578 vs, 1513 m, 1484 m, 1465 s, 1438 m, 1405 vs, 1348 m, 1305 vs, 1239 vs, 1142 w, 1117 w, 1078 m, 1057 vw, 1032 m, 997 w, 913 m, 857 vw, 765 vs, 742 w, 719 w, 703 s, 671 m, 591 vw, 532 m, 507 s cm^{-1}. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 273 (67640), 431 (58829) nm. μ_B = 1.89. $C_{40}H_{26}CuN_2O_6$ (694.2): calcd. C 69.21, H 3.77, N 4.04; found C 68.79, H 3.92, N 4.11.

$Cu(TMEDA)(fla)_2$ (9): Yield 0.43 g (65%). M.p. 160 °C (dec.). IR (KBr): $\tilde{\nu}$ = 3055 vw, 2999 vw, 2873 vw, 2827 vw, 1573 vs, 1524 m, 1473 s, 1440 m, 1427 vs, 1352 m, 1318 vs, 1298 w, 1256 w, 1226 vs, 1188 w, 1150 w, 1124 w, 1086 m, 1061 vw, 1037 w, 973 w, 937 vw, 918 m, 863 vw, 822 m, 783 s, 751 vs, 749 vw, 724 w, 705 s, 692 vw, 674 m, 612 vw, 537 m, 501 s cm^{-1}. UV/Vis (DMF): λ_{max}(ε/L mol^{-1} cm^{-1}) = 272 (51368), 430 (59979), 674 (380) nm. μ_B = 1.91. $C_{36}H_{34}CuN_2O_6$ (654.2): calcd. C 66.09, H 5.24, N 4.28; found C 65.79, H 4.95, N 4.21.

Preparation of [Cu(phen)$_2$(*O*-bs)]ClO$_4$ (10): [Cu(CH$_3$CN)$_4$]ClO$_4$ (0.328 g, 1 mmol) was dissolved in acetonitrile (30 mL), then *O*-benzoylsalicylic acid (0.242 g, 1 mmol) and 1,10-phen·H$_2$O (0.360 g, 2 mmol) were added and the reaction mixture was stirred under argon for 1 h and then under dioxygen (0.1 MPa) for 4 h. A blue crystalline solid formed, which was filtered, washed with acetonitrile, and dried under vacuum (0.69 g, 90%). Recrystallisation of the product from dichloromethane gave blue crystals. The dichloromethane solution produced crystals suitable for X-ray analysis upon standing at room temperature for a few days. M.p. 262 °C. IR (KBr): $\tilde{\nu}$ = 741 (vs, C−O), 1600 (vs, C−N), 1572 (vs, CO$_2$), 1420, 1388 (vs, CO$_2$), 1253, 1200, 1143, 1094, 1068 (vs, ClO$_4$), 841, 800, 731, 719, 635 (vs, ClO$_4$) cm^{-1}. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 271 (52481), 294 (17783), 331 (2042), 694 (115) nm. μ_B = 2.06. $C_{38}H_{25}ClCuN_4O_8$ (764.6): calcd. C 59.70, H 3.29, N 7.33; found C 58.62, H 2.98, N 7.21. The complex was also prepared by stirring (0.76 g, 1 mmol) Cu(fla)(phen)$_2$]ClO$_4$ in acetonitrile (30 mL) at room temperature under dioxygen (0.1 MPa) for 25 h (0.61 g, 80%).

Oxygenation of Cu(L)(fla)$_2$ (7a−d, 8−9): In a typical experiment, [Cu(phen)(fla)$_2$] (**7a**) (0.57 g, 0.8 mmol) in DMF (50 cm^3) was treated with dioxygen (0.1 MPa) until dioxygen uptake ceased at 80 °C. The dioxygen uptake was measured by a gas-volumetric method. The GC-MS analyses of the reaction mixture, after treatment with dilute HCl solution (10%) and ethereal diazomethane showed the presence of methyl benzoate: *m*/*z* (%) = 136 (23) [M$^+$], 105 (100), 77 (87); coumaronedione: *m*/*z* (%) = 148 (3) [M$^+$], 120 (100), 92 (59), 64 (22), 63 (14); and methyl 2-hydroxyphenylglyoxylate: *m*/*z* (%) = 180 (7) [M$^+$], 121 (100), 93 (11), 65 (11). Addition of excess Et$_2$O resulted in the deposition of [Cu(phen)(2HOpg)$_2$] (**14**) as a green microcrystalline solid: Yield 0.20 g (43%). M.p. 204 °C (dec.). IR (KBr): $\tilde{\nu}$ = 3037 w, 1616 vs, 1575 vs, 1516 s, 1462 m, 1423 s, 1375 m, 1346 m, 1326 m, 1265 w, 1213 vs, 1158 s, 1110 m, 1039 vw, 908 w, 858 vs, 785 s, 752 m, 733 s, 688 m, 629 w, 575 m. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 273 (42213), 398 (5262) nm. μ_B = 1.91. $C_{28}H_{18}CuN_2O_8$ (574.0): calcd. C 58.59, H 3.16, N 4.88; found C 57.89, H 3.33, N 5.12.

Cu(bpy)(2HOpg)$_2$ (15): Yield 0.18 g (41%). M.p. 176 °C. IR (KBr): $\tilde{\nu}$ = 3057 w, 1618 vs, 1577 vs, 1550 s, 1516 s, 1496 s, 1448 m, 1428 s, 1387 m, 1352 w, 1326 m, 1258 w, 1217 vs, 1156 s, 1041 w, 770 vs, 668 m, 629 w, 573 m. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 268 (29960), 305 (46121) nm. μ_B = 1.94. $C_{26}H_{18}CuN_2O_8$ (550.0): calcd. C 56.78, H 3.30, N 5.09, found C 56.49, H 3.16, N 5.12.

Cu(TMEDA)(2HOpg)$_2$ (16): Yield 0.12 g (30%). M.p 195 °C (dec.). IR (KBr): $\tilde{\nu}$ = 3126 vw, 3084 vw, 3068 vw, 3045 vw, 2871 vw, 2827 vw, 1616 vs, 1571 vs, 1519 s, 1478 w, 1465 w, 1445 s, 1421 s, 1407 m, 1362 m, 1320 m, 1258 m, 1207 s, 1147 s, 1084 vw, 1062 w, 1035 m, 990 w, 913 w, 861 m, 845 w, 769 s, 758 s, 745 s, 735 m, 720 m, 671 m, 558 m. UV/Vis (DMF): λ_{max} (ε/L mol^{-1} cm^{-1}) = 266 (14207), 302 (19828), 349 (7650) nm. μ_B = 1.91. $C_{22}H_{26}CuN_2O_8$ (510.0): calcd. C 51.81, H 5.14, N 5.49; found C 52.23, H 4.95, N 5.57.

X-ray Data Collection: Crystal data for [Cu(*O*-bs)(phen)$_2$]ClO$_4$·1.5 CH$_2$Cl$_2$: crystal dimensions 0.20 × 0.25 × 0.30 mm, triclinic, space group $P\bar{1}$, a = 10.499(3) Å, b = 12.556(4) Å, c = 17.094(5) Å, α = 72.69(2), β = 89.35(2), γ = 69.19(2)°, V = 1999.7(10) Å^3, Z = 2, $\rho_{calcd.}$ = 1.481 g·cm^{-3}, 2 Θ_{max} = 48.0°, radiation Mo-K_α (λ = 0.71073 Å), ω-scan, T = 200 K. Of the 6861 measured reflections, 6160 were independent, and 4838 observed for $I > 2\sigma(I)$. Lorentz and polarisation factors and experimental absorption correction (ψ scan, μ = 0.870 mm^{-1}). Data were collected with a Siemens (Nicolet Syntex) R3m/V diffractometer and the structure was solved by direct methods and refined by full-matrix least-squares techniques against F^2 (SHELXL-93,[23] SHELXS-86[24]), hydrogen atoms located geometrically, R_1 = 0.0962, ωR_2 = 0.2614 (all data) for 540 parameters, min/max residual electron density = −0.642/1.448 e Å^{-3}. CCDC-179746 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Physical Measurements: Electronic spectra were recorded with a Shimadzu UV-160 (Carl Zeiss) spectrometer, infrared spectra with a Specord IR-75 (Carl Zeiss) spectrometer. Magnetic susceptibilities were determined at room temperature with a Bruker B-E 10B8 magnetic balance. GC analyses were performed with an HP 5830A gas chromatograph equipped with a flame ionization detector and a CP SIL8CB column. GC-MS measurements were recorded with an HP 5890 II, 5971 GC/MSD at 75 eV.

Kinetic Measurements: Reactions of copper flavonolate complexes with O$_2$ were performed in DMF solutions. In a typical experiment Cu^{II}(phen)(fla)$_2$ was dissolved under argon in a thermostatically controlled reaction vessel with an inlet for taking samples with a syringe, and connected to a mercury manometer to maintain a constant pressure. The solution was then heated to the appropriate temperature, a sample was taken by syringe, and the initial concentration of Cu^{II}(phen)(fla)$_2$ was determined by UV/Vis spectroscopy measuring the absorbance of the reaction mixture at 432 nm (63 658) {λ_{max} of a typical band of Cu^{II}(phen)(fla)$_2$}. The argon was then replaced by dioxygen, and the consumption of Cu^{II}(phen)(fla)$_2$ was analysed periodically (ca. every 10 min). Experimental conditions are summarised in Table 1. The temperature was determined with an accuracy of ±0.5 °C and the pressure of dioxygen with an accuracy of ±0.5%. The O$_2$ concentration was calculated from literature data,[25] taking into account the partial pressure of DMF[26] and assuming the validity of Dalton's law.

Supporting Information: Kinetic data and diagrams for the oxygenations are available (see also footnote on the first page of this article).

Synthesis and Properties of Donor/Acceptor-Substituted Metal-Capped Twofold-Sila-Bridged Cyclobutadieno Superphanes

Rolf Jens Schaller,[a] Gebhard Haberhauer,[a] Rolf Gleiter,*[a] and Frank Rominger[a]

Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Donor-acceptor systems / Phanes / Cyclic voltammetry / Electron transfer / Cobalt

The synthesis of the tetrasilasuperphanes **10**–**18** can be achieved from 1,1,3,3-tetramethyl-1,3-disilacyclonona-4,8-diyne (**7**), 1,1,2,2-tetramethyl-1,2-disilacyclonona-3,8-diyne (**8**) or 1,1,4,4-tetramethyl-1,4-disilacyclodeca-5,9-diyne (**9**) by heating with [RCpCoL$_2$] [R = H, Si(CH$_3$)$_3$, (CH$_3$)$_5$, CO$_2$CH$_3$; L$_2$ = COD, (CO)$_2$, (C$_2$H$_4$)$_2$]. The reaction of **7** with [RCpCo(CO)$_2$] [R = H, CH$_3$, Si(CH$_3$)$_3$, (CH$_3$)$_5$] produces the tricyclic cobalt-stabilized cyclobutadienediynes **20**–**23**, whereas reaction with [R′CpCo(L$_2$)] [R′ = H, (CH$_3$)$_5$, CO$_2$CH$_3$; L$_2$ = COD, (CO)$_2$] leads to the donor/acceptor superphanes **24**–**31**. X-ray investigations on the superphanes **10**, **13**–**15** and **18** reveal distances between the two cyclobutadiene units in the range of 2.65 Å and 3.79 Å. Investigations by means of cyclic voltammetry of the superphanes **10**–**18** show a dependence of the oxidation potentials on the nature of the bridges. A comparison between the first oxidation potentials of **10/28**, **24/29**, and **26/31** gives evidence for a partial charge delocalization over both CpCoCbd fragments of the superphanes.

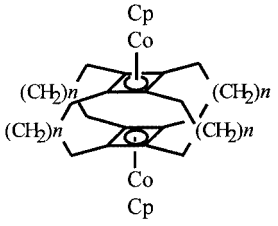
Introduction

Rigid metallorganic species with two or more metal centers are often used as model systems for generating intervalence compounds. Attractive examples are biferrocene[1–3] and related species as well as metal-capped cyclophanes with benzene[4] or cyclobutadiene rings[5] as π-systems. For such intervalence compounds Robin and Day suggested a classification scheme 35 years ago[6] which is based on the extent of electron transfer between the metal fragments. According to this classification the charge can either be localized (class I), fully delocalized (class III) or partly delocalized (class II). The latter two classes deserve special interest because the delocalization promises new properties of the radical cations as compared to the localized species. Those systems on the interface of class II and class III with a relatively low barrier to intramolecular electron transfer have been called "almost delocalized" and are currently of considerable interest.[7]

Our recent studies of a series of superphanes with two[5] or four[8] cobalt centers revealed that for larger bridges between the metal fragments (**2**, **3**) the mixed valent monocations are valence trapped with very weak interactions between the metal centers.



n = 1, 2, 3
1 2 3

For **1** we found strong interactions between the molecular halves which suggested classifying this system as an "almost delocalized" intervalence compound.[9] This finding encouraged us to synthesize related superphanes with smaller bridges between the metal fragments. In this paper we report on the synthesis, structural and electrochemical properties of CpCo-capped cyclobutadieno superphanes derived from **A**, **B** or **C**.

Results and Discussion

Synthesis

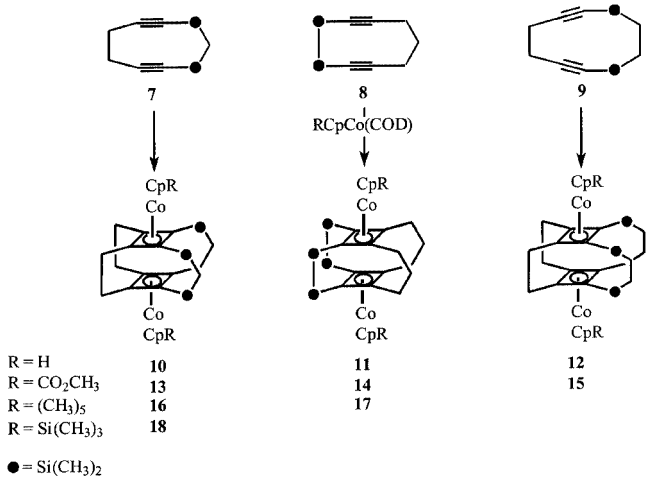
Our studies on the reactivity of cyclic diynes with (η^5-cyclopentadienyl)cobalt complexes at 150 °C revealed two major products:[5] the intramolecular tricyclic system **5** and the intermolecular product **6** (Scheme 1).

If one side of the two alkyne units in **4** is tethered by an ethano or tetramethyldisilano bridge only superphanes **6** are obtained.[10] To prepare the target systems **A**−**C** we used 1,1,3,3-tetramethyl-1,3-disilacyclonona-4,8-diyne (**7**),[11] 1,1,2,2-tetramethyl-1,2-disilacyclonona-3,8-diyne (**8**)[11] and 1,1,4,4-tetramethyl-1,4-disilacyclodeca-5,9-diyne (**9**)[11] as starting materials (Scheme 2).

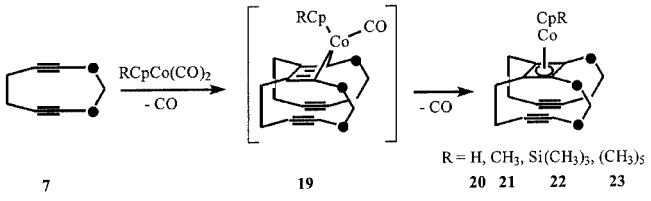
Heating these alkynes with [RCpCo(COD)] [R = H, $Si(CH_3)_3$, $(CH_3)_5$, CO_2CH_3] at 150 °C in cyclooctane afforded the superphanes **10**−**18** in yields between 10% and 68%. Especially noteworthy are the high yields (>60%) of **10**, **12**, **13** and **18**.

Donor/Acceptor Superphanes

In view of the mechanism of the formation of the superphanes[5] shown in Scheme 2 it was of interest to try and isolate some reaction intermediates. When we heated the diyne **7** with various substituted (η^5-cyclopentadienyl)(dicarbonyl)cobalt complexes (Scheme 3) at 100 °C[10] instead of 150 °C we were able to isolate the intermediates **20**−**23**. In all cases the bulky silyl groups are found adjacent to each other.[5,12] We ascribe this observation to the intermediate metallacycle[13] **19** in which the bulky groups are pointing away from each other. The yields of **20**−**23** vary between 20% and 30%.



Scheme 2



Scheme 3

In the case of **23** we were able to isolate single crystals which confirm the assigned stereochemistry (Figure 1). The two triple bonds are nearly parallel to each other with an intermolecular distance of 4.7 Å on the ethano-tethered side and 5.3 Å on the other side.

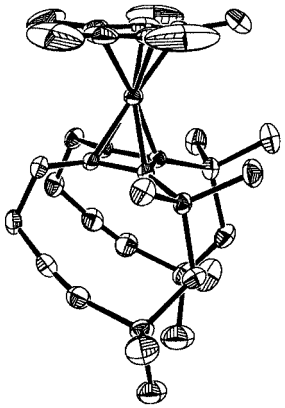


Figure 1. Molecular structure of **23** (ORTEP drawing, 50% probability ellipsoids); the hydrogen atoms have been omitted for clarity

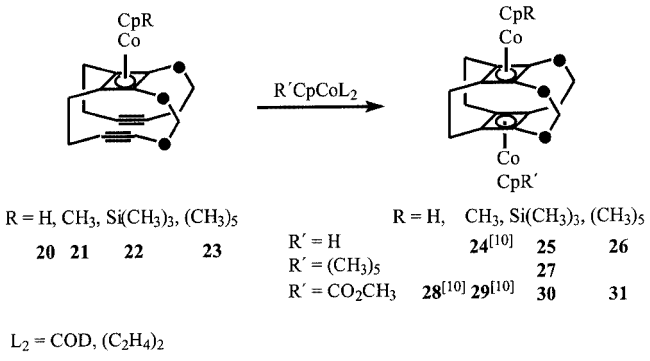
Having in our hands the intermediates **20**−**23** prompted us to synthesize the donor- and acceptor-substituted superphanes **24**−**31** (Scheme 4) in order to compare their electronic properties with those of **10**−**18**.



Scheme 4

The species **24**−**31** were obtained in a straightforward way by heating **20**−**23** with [R′CpCoL$_2$] [L$_2$ = COD, (C$_2$H$_4$)$_2$] [R′ = H, (CH$_3$)$_5$, CO$_2$CH$_3$] in cyclooctane. The yields of **24**−**31** vary from 24% up to 97%.

Structural Studies on the Superphanes

We were able to grow single crystals of **10**, **13**−**15** and **18** which allowed us to study the molecular structures of these species in the solid state. In Figure 2 we compare the molecular structures of **13**−**15** as examples.

In this series the tilting of the planes of the cyclobutadiene rings varies considerably. To demonstrate this we have listed the intramolecular distance at the short-bridged (*c*) and the long-bridged side (*d*) of the two cyclobutadiene units as well as the interplanar angle γ in Table 1. The disilano and propano bridges in **14** provide approximately the same intramolecular distance giving rise to a small value for γ (6.2°) and almost equal lengths for *c* and *d* (Table 1). For **10**, **13** and **18** the differences between *c* and *d* amount to ca. 0.7 Å and the interplanar angle γ varies between 24° and 25°. The deviation is largest for **15** with about 1.1 Å difference between *c* and *d* and a γ value of 41°.

The average distances between the ligands and the cobalt atom (*a*, *b*) are close to those found for other (η^5-cyclopentadienyl)(cyclobutadiene)cobalt complexes.[14−19]

Cyclovoltammetric Investigations

To probe the interactions between the [RCpCoCbd] units in **10**−**18** we carried out cyclic voltammetry studies (CV).[20] As reference we used the oxidation potentials of **1** and **32**.[21] The latter species serves as a model for systems

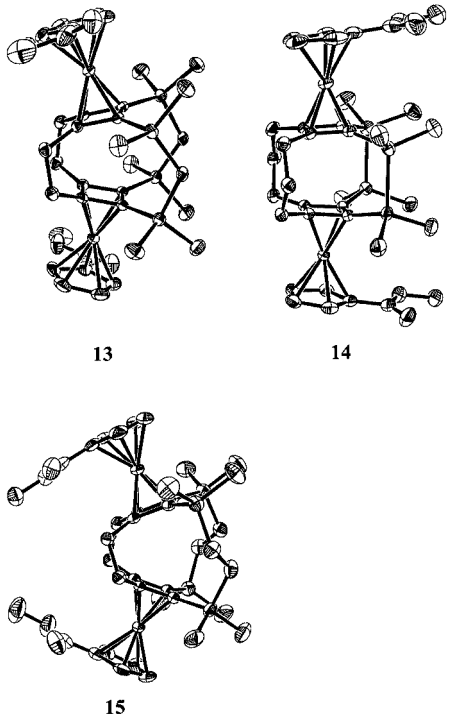


Figure 2. Molecular structures of **13**−**15** (ORTEP drawing 50% probability ellipsoids); the hydrogen atoms have been omitted for clarity

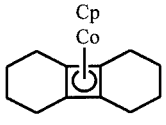
that are not influenced by the interaction of a second CpCo(Cbd) unit.



32

Compound **32** shows only one oxidation potential (Table 2) whereas for **1** two oxidation steps are observed. The one at $E^1_{1/2}$ = 656 mV was found to be reversible, whereas the second one at E^{ox}_{2p} = 1101 mV is irreversible.[9,21] The observed half-wave potentials for the reversible redox steps ($E^1_{1/2}$ and $E^2_{1/2}$) and the oxidation peak potentials for the irreversible steps (E^{ox}_{1p} and E^{ox}_{2p}) of **10**−**18** are compiled in Table 2.

We found that the differences $\Delta E = E^2_{1/2} - E^1_{1/2}$ are, with the exception of **12** and **16**, close to that found for **1**. As anticipated the oxidation potentials are highest for **13**−**15**

Table 1. Average distances [Å] between the metal and the C(Cp) atoms (*a*) and the C(Cbd) atoms (*b*), respectively, the distances between the cyclobutadiene rings on the short-bridged side (*c*) and opposite (*d*) as well as the average angle (γ) [°] between the planes of both cyclobutadiene units of **10**, **13**−**15** and **18**

due to the electron-withdrawing effect of the methoxycarbonyl group. The difference between ΔE correlates approximately with the average distance [$(c + d)/2$] of the cyclobutadiene moieties: it is largest for **11** and smallest for **15**. To probe any transannular interactions between the molecular halves we carried out further cyclovoltammetric studies on the donor/acceptor superphanes **24** and **26**−**31**. The measured half wave potentials ($E^1_{1/2}$ and $E^2_{1/2}$) or the oxidation peak potentials (E^{ox}_{1p} and E^{ox}_{2p}) are compared in Table 3.

Table 3. Half wave potentials ($E^1_{1/2}$ and $E^2_{1/2}$) or oxidation peak potentials (E^{ox}_{1p} and E^{ox}_{2p}) of **24** and **26**−**31**; the values are given in mV vs. Ag/AgCl[a]

[a] Solvent: CH_2Cl_2, 0.1 M of NBu_4PF_6. [b] Irreversible oxidation.

We noticed that the first oxidation step is reversible with the exception of the superphanes containing the $(CH_3)_5Cp$ ligand (**26**, **27** and **31**). The second oxidation step was found to be irreversible in most cases, possibly indicating an electrochemical-chemical-electrochemical (ECE) mechanism.

A comparison between the first oxidation potentials of **10** (857 mV), **24** (851 mV) and **26** (737 mV) as well as **28** (941 mV), **30** (916 mV), **29** (899 mV) and **31** (803 mV) shows a decrease of the first oxidation step in both series. This was anticipated since the donor character of one Cp ring increases in both series.[22] This finding suggests that the first electron is removed from the RCpCo fragment where R is either CH_3, $Si(CH_3)_3$ or $(CH_3)_5$. The assumption that the electrochemical oxidation removes the first electron from the donor-substituted unit allows us to probe the intramolecular interaction in the radical cation. A comparison of the first oxidation potentials of the pairs **10/28**, **24/29** and **26/31** shows in all three cases that the methoxycarbonyl substituent causes a shift of the first oxidation potential to higher values: $E^1_{1/2}$(**10**) − $E^1_{1/2}$(**28**) = −84 mV, $E^1_{1/2}$(**24**) − $E^1_{1/2}$(**29**) = −48 mV and E^{ox}_{1p}(**26**) − E^{ox}_{1p}(**31**) = −66 mV. Due to the irreversibility the values obtained for **26** and **31**, their differences have to be taken with a grain of salt. This increase of the oxidation potential is indicative of the delocalization of the positive charge between the two π-fragments of the cyclophanes. These results demonstrate the same tendency as for the carbocyclic systems.

Conclusion

The use of cyclic diynes with a short bridge on one side enabled us to synthesize and characterize the superphanes **10**−**18** and **24**−**31**. Structural investigations reveal that the two planes of the cyclobutadiene rings deviate from being parallel due to the different lengths of the bridges. The CV data indicate that the intramolecular distance of the cyclobutadiene rings affects the potential difference between the first two oxidation potentials. The comparison between the pairs of donor/acceptor superphanes **10/28**, **24/29** and **26/31** shows a clear substituent effect of the distant ester group on the electron-rich part of the molecule. This result corroborates the model of charge delocalization for the superphanes investigated.

Experimental Section

General: All melting points are uncorrected. The NMR spectra were measured with a Bruker WH 300 or Avance 500 spectrometer (^{1}H NMR at 200, 300 or 500 MHz and ^{13}C NMR at 50, 75 or 125 MHz) using the solvent as internal standard (δ). The mass spectra refer to data from a JEOL JMS-700 instrument. IR spectra were recorded with a Bruker Vector 22 FT-IR-spectrometer. UV/Vis absorption data were recorded using a Hewlett Packard HP 8452A Diode Array-spectrometer. Elemental analysis: Microanalytical laboratory of the University of Heidelberg. All reactions were carried out under an argon atmosphere using dried and oxygen-free solvents.

X-ray Crystallography and Structure Solution: Data were collected on a Siemens CCD-diffractometer at 200 K. Relevant crystal and data collection parameters are given in Table 4. The structures were solved by direct methods and refined against F^2 with a full-matrix least-square algorithm by using SHELXTL-97[23] software. An empirical absorption correction was applied by using SADABS,[24] based on the Laue symmetry of the reciprocal space.

chemically reversible systems are an average of the observed anodic and cathodic peak potentials, whereas the E_{1p}^{ox} and E_{2p}^{ox} values for chemically irreversible systems are the absolute values of the anodic peak potential. A supporting electrolyte concentration of 0.1 M of NBu_4PF_6 was employed unless otherwise noted. The working electrode for cyclic voltammetry was a glassy carbon disk GC disk of 3 mm diameter. The potential of the ferrocene/ferrocenyl system was set with an error of 5 mV at 721 mV vs. SCE at a scan rate of 100 mVs^{-1} and of 200 mVs^{-1}.

1,1,2,2-Tetramethyl-1,2-disilacyclonona-3,8-diyne (8): 1,6-Heptadiyne (0.46 g, 5.0 mmol) was dissolved in 50 mL of THF. At −20 °C a butyllithium solution (1.6 M in hexane; 7.5 mL, 12.0 mmol) was added and the mixture was stirred for 30 minutes at this temperature. After warming the mixture to room temperature it was cooled again (−20 °C) and 1,2-dichloro-1,1,2,2-tetramethyldisilane (0.94 g, 5.0 mmol) dissolved in 25 mL of THF was added over two hours. While stirring for a further hour the reaction mixture reached room temperature. After removal of the solvent the crude product was purified by column chromatography (silica gel/CCl_4) to give 0.10 g (10.0%) of colorless crystals; m.p. 49 °C. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.40 (m, 4 H, CH_2), 1.85 (m, 2 H, CH_2), 0.21 [s, 12 H, $Si(CH_3)_2$] ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 114.8 [$Si(CH_3)_2$], 88.1 ($C_{\equiv}$), 28.4 (CH_2), 21.2 (CH_2), −2.4 (CH_2) ppm. HRMS (positive EI) calcd. for $C_{11}H_{18}Si_2$ ([M]$^+$): 206.0947; found 206.0959 (+1.2 mmu). IR (KBr): $\tilde{\nu}$ = 2955 cm^{-1}, 2896, 2157, 1428, 1320, 1244. UV/Vis (CH_2Cl_2) (log ε): λ_{max} = 226 nm (3.88). $C_{11}H_{18}Si_2$ (206.4): calcd. C 64.00, H 8.79; found C 63.89, H 8.81.

Superphane 10: A solution of 1,1,3,3-tetramethyl-1,3-disilacyclonona-4,8-diyne (**7**) (93 mg, 0.45 mmol) and [CpCo(COD)] (130 mg, 0.55 mmol) in 8 mL of cyclooctane was heated to 150 °C. The reaction progress was checked by TLC and after 8 hours the reaction mixture was allowed to cool to room temperature. After removal of the solvent the crude product was purified by column chromatography (silica gel/CCl_4) to give 104 mg (70.0%) of yellow crystals; m.p. > 250 °C. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 4.70 (s, 10 H, CpH), 2.25−2.00 (m, 8 H, CH_2), 0.09 [s, 24 H, $Si(CH_3)_2$], −0.19 (m, 4 H, $SiCH_2$) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 90.1 (C_{Cbd}), 77.9 (CH), 64.4 (C_{Cbd}), 24.5 (CH_2), 7.0 ($SiCH_2$), 3.0 [$Si(CH_3)_2$], 0.0 [$Si(CH_3)_2$] ppm. HRMS (positive EI) calcd. for $C_{32}H_{46}Co_2Si_4$ ([M]$^+$): 660.1340; found 660.1340 (±0.0 mmu). IR (KBr): $\tilde{\nu}$ = 2949 cm^{-1}, 2848, 1624, 1478, 1407, 1248. UV/Vis (CH_2Cl_2) (log ε): λ_{max} = 224 nm (4.62), 294 (4.64), 336 (3.59), 392 (3.08). $C_{32}H_{46}Co_2Si_4$ (660.9): calcd. C 58.15, H 7.02; found C 58.29, H 7.15.

Superphane 11: A solution of 1,1,2,2-tetramethyl-1,2-disilacyclonona-3,8-diyne (**8**) (93 mg, 0.45 mmol) and [CpCo(COD)] (130 mg, 0.55 mmol) in 8 mL of cyclooctane was heated to 150 °C. The reaction progress was checked by TLC and after 8 hours the reaction mixture was allowed to cool to room temperature. After removal of the solvent the crude product was purified by column

chromatography (alumina III/petroleum ether) to give 16 mg (11.0%) of yellow crystals; m.p. > 250 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.68 (s, 10 H, CpH), 2.13−1.26 (m, 12 H, CH_2), 0.21 (s, 12 H, $SiCH_3$), 0.12 (s, 12 H, $SiCH_3$) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 93.0 (C_{Cbd}), 78.2 (CH), 65.3 (C_{Cbd}), 28.4 (CH_2), 26.9 (CH_2), −1.5 [$Si(CH_3)_2$], −1.7 [$Si(CH_3)_2$] ppm. HRMS (FAB+) calcd. for $C_{32}H_{46}Co_2Si_4$ ([M]$^+$): 660.1340; found 660.1306 (−3.6 mmu). IR (KBr): $\tilde{\nu}$ = 3095 cm^{-1}, 2941, 2900, 1631, 1245. UV/Vis (CH_2Cl_2) (log ε): λ_{max} = 234 nm (4.53), 300 (4.49), 404 (3.04). $C_{32}H_{46}Co_2Si_4$ (660.9): calcd. C 58.15, H 7.02; found C 58.54, H 7.33.

Superphane 12: A solution of 1,1,4,4-tetramethyl-1,4-disilacyclodeca-5,9-diyne (**9**) (100 mg, 0.45 mmol) and [CpCo(COD)] (130 mg, 0.55 mmol) in 8 mL of cyclooctane was heated to 150 °C. The reaction progress was checked by TLC and after 8 hours the reaction mixture was allowed to cool to room temperature. After removal of the solvent the crude product was purified by column chromatography (silica gel/CCl_4) to give 94 mg (61.0%) of yellow crystals; m.p. > 250 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.60 (s, 10 H, CpH), 2.36−1.94 (m, 8 H, CH_2), 0.45 (s, 8 H, $SiCH_2$), 0.00 [s, 12 H, $Si(CH_3)_2$], −0.08 [s, 12 H, $Si(CH_3)_2$] ppm. ^{13}C NMR (50 MHz, $CDCl_3$): δ = 90.5 (C_{Cbd}), 79.0 (CH), 64.3 (C_{Cbd}), 26.7 (CH_2), 8.6 ($SiCH_2$), 0.1 [$Si(CH_3)_2$], −0.4 [$Si(CH_3)_2$] ppm. HRMS (positive EI) calcd. for $C_{34}H_{50}Co_2Si_4$ ([M]$^+$): 688.1654; found 688.1659 (+0.5 mmu). IR (KBr): $\tilde{\nu}$ = 2943 cm^{-1}, 2898, 1624, 1473, 1408, 1246. UV/Vis (CH_2Cl_2) (log ε): λ_{max} = 224 nm (4.62), 284 (4.66), 322 (3.70), 394 (3.23). $C_{34}H_{50}Co_2Si_4$ (689.0): calcd. C 59.27, H 7.31; found C 59.41, H 7.42.

Superphane 13: A solution of 1,1,3,3-tetramethyl-1,3-disilacyclonona-4,8-diyne (**7**) (93 mg, 0.45 mmol) and [H_3CO_2CCpCo(COD)] (160 mg, 0.55 mmol) in 8 mL of cyclooctane was heated to 150 °C. The reaction progress was checked by TLC and after 12 hours the reaction mixture was allowed to cool to room temperature. After removal of the solvent the crude product was purified by column chromatography (silica gel/CH_2Cl_2, petroleum ether/diethyl ether 5:1) to give 116 mg (66.0%) of yellow crystals; m.p. > 250 °C. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 5.26 (pseudo t., 4 H, CpH), 4.90 (pseudo t., 4 H, CpH), 3.72 (s, 6 H, OCH_3), 2.10−1.93 (m, 8 H, CH_2), 0.08 [s, 24 H, $Si(CH_3)_2$], −0.20 (m, 4 H, $SiCH_2$) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 168.0 (CO), 92.0 (C_{Cp}), 83.5 (C_{Cbd}), 81.3 (CH), 80.2 (CH), 67.3 (C_{Cbd}), 50.9 (OCH_3), 23.4 (CH_2), 6.8 ($SiCH_2$), 2.8 [$Si(CH_3)_2$], −0.3 [$Si(CH_3)_2$] ppm. HRMS (FAB+) calcd. for $C_{36}H_{50}Co_2O_4Si_4$ ([M]$^+$): 776.1450; found 776.1411 (−3.9 mmu). IR (KBr): $\tilde{\nu}$ = 2951 cm^{-1}, 1710, 1464, 1281, 1247. C−Cl and Si−Cl Activation by *P,N*-Chelated Pt^{II} Complexes

Frank Stöhr,[a] Dietmar Sturmayr,[a] Guido Kickelbick,[a] and Ulrich Schubert*[a]

Keywords: Platinum / Silicon / Hemilabile ligands / Oxidative addition / Halogen compounds

The complex [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$PtMe_2$ reacts with chlorinated hydrocarbons such as CCl_4, $CHCl_3$, CH_2Cl_2, and CH_3Cl by oxidative addition of the C–Cl bond. In the reaction with CCl_4, the complexes [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]-Pt(Me)Cl, [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$Pt(Me)_3Cl$, and [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$Pt(CCl{=}CH_2)Cl$ are obtained. The analogous *P,P*-chelated complex [(κ²-*P,P*)-$Ph_2CH_2CH_2PPh_2$]-$PtMe_2$ does not react under the same conditions. Reaction of [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$PtMe_2$ with $ClSiMe_2Ph$ results in the formation of $Ph_2Me_4Si_2$ along with [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]Pt(Me)Cl and [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$Pt(Me)_3Cl$.

Introduction

The oxidative addition of organic halides to several complexes of the type (*N,N*-chelate)$PtMe_2$ to form Pt^{IV} derivatives has been described. While bromides and iodides react readily, simple alkyl chlorides were not employed since they react poorly.[1] The reason is probably the carbon−halogen bond strength, which increases in the sequence C−I (56 kcal·mol^{-1} for CH_3I), C−Br (70 kcal·mol^{-1}), C−Cl (84 kcal·mol^{-1}), and C−F (109 kcal·mol^{-1}). While the *thermal* reaction of chlorocarbons is not straightforward, Zelewsky et al. reported *photochemical* oxidative additions of chlorinated hydrocarbons to Pt^{II} complexes with hemilabile C,N ligands.[2]

In previous studies on the oxidative addition of organosilanes to Pt^{II} complexes, we found that the reactivity the complexes is strongly enhanced by hemilabile *P,N*-chelating ligands.[3,4] In this paper, we report that this is also true for reactions with chlorocarbons. The presence of the hemilabile ligands allows the *thermal* reactions of chloromethane derivatives with Pt^{II} complexes.

Results and Discussion

Reaction of (P∩N)$PtMe_2$ with CCl_4

When CCl_4 was added to a solution of [(κ²-*P,N*)-$Ph_2PCH_2CH_2NMe_2$]$PtMe_2$ (**1**) (the chelating ligand $Ph_2PCH_2CH_2NMe_2$ is abbreviated as P∩N) in C_6D_6 at room temperature, a colorless precipitate was immediately formed. The reaction was complete within 2 min. In contrast, no reaction occurred with the bis(phosphane) complexes [(κ²-*P,P*)-$Ph_2PCH_2CH_2PPh_2$]$PtMe_2$ or $(PhMe_2P)_2$-$PtMe_2$.

The course of the reaction was monitored by ^{31}P, ^{1}H, and ^{195}Pt NMR spectroscopy. Three new sets of signals are observed in the ^{31}P and ^{195}Pt NMR spectra, with characteristic coupling constants (Table 1).

Table 1. ^{31}P and ^{195}Pt NMR spectra of complexes **2**−**4** (in [D_6]acetone; δ in ppm, *J* in Hz)

Complex	δ(^{195}Pt)	$^{1}J_{PtP}$	δ(^{31}P)
2	−4243	4678	27.29
3	−3905	4363	25.5
4	−2976	1213	9.33

The precipitate was spectroscopically characterized as (P∩N)Pt(Me)Cl (**2**) and independently synthesized by reaction of (P∩N)$PtMe_2$ with HCl or from (norbornadiene)Pt(Me)Cl and $Ph_2PCH_2CH_2NMe_2$, as described for [(κ²-*P,P*)-$Ph_2PCH_2CH_2CH_2PPh_2$]Pt(Me)Cl.[5] Complex **2** was only sparingly soluble in benzene, and therefore part of the formed **2** precipitated from the reaction solution.

After separation of **2** and addition of petroleum ether to the clear solution, the additional complex **3** crystallized. Compound **3** was identified by an X-ray crystal structure analysis as (P∩N)Pt($CCl{=}CH_2$)Cl (Figure 1 and Table 2). The vinylic protons in the ^{1}H NMR spectrum of isolated **3** have chemical shifts and $^{3}J_{PtH}$ coupling constants similar to those reported in the literature.[6,7] $^{4}J_{PH}$ and geminal $^{2}J_{H,H}$ were not observed.

In **3**, Pt^{II} has the typical square-planar coordination. The Pt−P(1) distance of 220.19(8) pm and the Pt−N(16) distance of 218.1(2) pm are in the same range as observed for (silyl)Pt^{II} complexes with such ligands.[4] The chloro ligand is located *trans* to the phosphorus atom; the Pt−Cl(1) distance of 236.64(8) pm is typical for this arrangement.[8] The only other related structure is a methyl-substituted complex (PTFA)$Pt(CH_3)Cl$ [PTFA: (η⁵-cyclopentadienyl)(η⁵-4-*endo*-

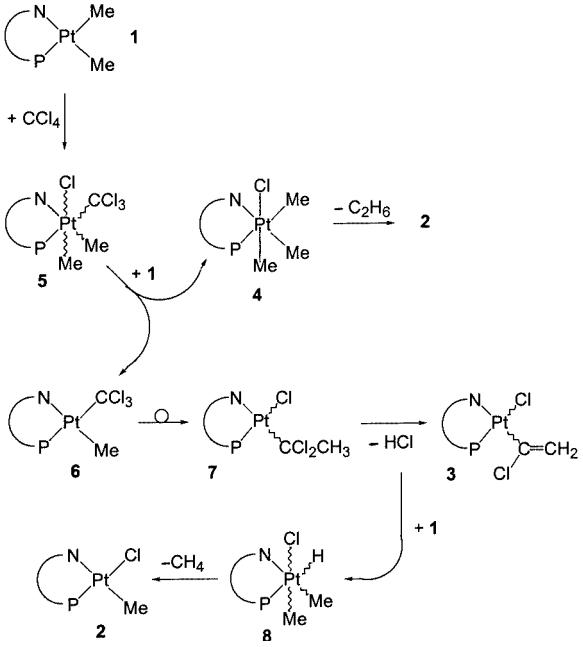
dimethylamino-3-diphenylphosphanyl-4,5,6,7-tetrahydro-1*H*-indenyl)iron].[9] A chlorovinyl-substituted bis(phosphane)Pt^{II} complex $(Me_2PhP)_2Pt(CCl{=}CH_2)_2$ was reported in the literature with a Pt−C bond length of 205.3(5) pm.[10] In comparison, the Pt−C bond length in **3** is rather short [Pt−C(19), 200.2(3) pm]. However, the accuracy of the bond lengths in the chlorovinyl ligand of **3** is rather low because the Cl and C positions are disordered. The position Cl(2) (Figure 1) has an occupation of 70% Cl and 30% C, and that of C(20) vice versa.

The ^{1}H NMR spectrum of the original reaction solution shows four Pt−CH_3 signals with characteristic $^2J_{PtH}$ and $^3J_{PH}$ coupling constants. One of them is assigned to the PtMe group of complex **2**. Since **3** contains no methyl ligands, the remaining three signals with equal intensity must belong to a single complex. This complex is spectroscopically identified as (P∩N)$Pt(Me)_3Cl$ (**4**) by comparison with an authentic sample of **4** obtained by another route (see below). An X-ray structure analysis of **4** was performed.

The postulated sequence of reactions starting with **1** and CCl_4 is shown in Scheme 1.

CCl_4 probably attacks (P∩N)$PtMe_2$ (**1**) by oxidative addition of one C−Cl bond in the first step of the reaction. Kuyper reported the oxidative addition of CCl_4 to (bpy)$PtMe_2$ yielding the stable product (bpy)$Pt(Me)_2Cl(CCl_3)$.[11] In contrast, we did not observe the corresponding Pt^{IV} complex **5**. It can therefore be assumed that subsequent reductive elimination to Pt^{II} complexes is fast. It appears that the hemilabile (P∩N)-chelate ligand facilitates both the oxidative addition and the reductive elimination from the Pt complex. There are three possibilities of reductive elimination from complex **5**: (i) Elimination of Me−CCl_3 to give complex **2**. This possibility can be excluded because there is no NMR spectroscopic evidence for $MeCCl_3$. (ii) Elimination of MeCl to give complex **6**. (iii) Elimination of ethane. There is no experimental evidence for the formation of ethane.



Scheme 1

A bis(phosphane) complex analogous to **6**, $[(\kappa^2\text{-}P,P')\text{-}Ph_2PCH_2CH_2PPh_2]Pt(CCl_3)Me$, was reported to rearrange by a CCl_2 shift, followed by the elimination of HCl.[12] The same mechanism leads to the formation of **7** and the isolated vinylidene complex **3**. The eliminated HCl can react with the starting complex **1** to give complex **8**, followed by the elimination of methane to give complex **2**. The latter reaction sequence was confirmed by the reaction of (P∩N)$PtMe_2$ (**1**) with a solution of HCl in diethyl ether, which resulted in the formation of **2**.

Complex **1** does not react with the methyl chloride eliminated in the second step under the conditions at which the reaction with CCl_4 was performed (room temperature) to form the observed product **4** (**4** is only formed at elevated temperatures, see below). We therefore propose a methyl transfer reaction between complexes **1** and **5** to give **4** and **6**. The elimination of ethane from **4** can be assumed as another source of complex **2** in the reaction scheme above. This was proven by another experiment described below.

Due to the different donor/acceptor properties of the two Lewis basic centers of the (P∩N) ligand, the reactions described above are highly selective, and no isomers of the complexes **2**−**4** were observed.

When the deuterated complex (P∩N)$Pt(CD_3)_2$ is used for the reaction with CCl_4, the ^{31}P NMR spectrum is unchanged. The Pt−CH_3 signals of complexes **2** and **4** and the $=CH_2$ signals of complex **3** are not detected in the ^{1}H

NMR spectrum. The ^2H NMR spectrum shows three $Pt-CD_3$ signals of equal intensity for the deuterated complex **4**, and one $Pt-CD_3$ signal for deuterated **2**. There is one additional peak at $\delta = 0.11$ ppm in the ^1H NMR spectrum. This may belong to deuterated ethane, proving the formation of **2** from **4** by reductive elimination. Only one $=CD_2$ signal of the deuterated form of **3** is detected. The experiment was repeated in C_6H_6 since the second peak may be hidden by the broad signal of the solvent C_6D_6. However, no further peak is detected. The lack of the second $=CD_2$ signal may be due to exchange effects.[13]

Reaction of $(P^{\frown}N)PtMe_2$ with $CHCl_3$

$(P^{\frown}N)PtMe_2$ was much more reactive towards CCl_4 than towards $CHCl_3$. While the reaction with CCl_4 was complete within 2 min at room temperature, no reaction was observed with $CHCl_3$ after 1 d under the same conditions. However, $(P^{\frown}N)Pt(Me)Cl$ (**2**) crystallized from a $CHCl_3$/petroleum ether solution of $(P^{\frown}N)PtMe_2$ after several weeks. For a reasonable reaction rate, it was necessary to heat the mixture to 60 °C. At this temperature, the reaction was complete in about 10 h.

Three new signals are observed in the ^{31}P NMR spectrum when a mixture of $(P^{\frown}N)PtMe_2$ and $CHCl_3$ in a 1:2 ratio was heated in C_6D_6. Comparison of the spectra with those of the products obtained in the reaction of $(P^{\frown}N)PtMe_2$ with CCl_4 shows that complexes **2** and **4** are also formed in the reaction with $CHCl_3$. The concentrations of **2** and **4** increase simultaneously, while the concentration of **1** decreases. The new complex **9** with a large $^1J_{PtP}$ coupling constant, indicating a chlorine atom *trans* to the phosphorus atom, is detected in small quantities only after a reaction time of about 6 h. No Pt−Me resonances are observed in the ^1H NMR spectrum, other than those of complexes **4** and **2**. According to the reaction mechanism shown in Scheme 1, complex **9** could be $(P^{\frown}N)Pt(Cl)(CH=CH_2)$. There are signals between $\delta = 5$ and 6 ppm in the ^1H NMR spectrum, which may arise from the vinyl group of **9**. The signals are very weak probably due to the H−H, H−P, and H−Pt coupling, and unequivocal identification is therefore not possible. We were not able to separate **9** from the reaction mixture.

When $(P^{\frown}N)Pt(CD_3)_2$ is treated with $CHCl_3$, no $Pt-CH_3$ signals are observed in the ^1H NMR spectrum, and the ^2H NMR spectrum shows a signal for deuterated **2** and three signals of equal intensity for deuterated **4**.

Reaction of $(P^{\frown}N)PtMe_2$ with CH_2Cl_2

The reactivity of CH_2Cl_2 was lower than that of $CHCl_3$. At 60 °C in C_6D_6, **2** and **4** were formed after a few days, along with decomposition products, which were not identified, and a black precipitate. In contrast to the reaction with CCl_4 and $CHCl_3$, no other P-containing platinum complex is observed by ^{31}P NMR spectroscopy.

The sequence of reactivity of the halogenated hydrocarbons, i.e. $CCl_4 > CHCl_3 > CH_2Cl_2$, is related to the C−Cl bond strength in these compounds (CCl_4 −248 kJ·mol^{-1}, $CHCl_3$ −280 kJ·mol^{-1}, CH_2Cl_2 −304 kJ·mol^{-1}, CH_3Cl −328 kJ·mol^{-1}).

Reaction of $(P^{\frown}N)PtMe_2$ with CH_3Cl

CH_3Cl does not fit into the sequence as it reacted with $(P^{\frown}N)PtMe_2$ in a hot C_6D_6 solution to form complex **4** and traces of **2**. The reaction was complete within 12 h. The amount of **2** increased on further heating, indicating reductive elimination of ethane from **4**. At room temperature no reaction occurred after 1 h (see above). Again, the analogous *P,P*-chelated complex $(dppe)PtMe_2$ did not react with CH_3Cl at 60 °C in C_6D_6 after 24 h.

Complex **4** was structurally characterized and has a distorted octahedral geometry (Figure 2 and Table 3). The asymmetric unit contains only half of the molecule with Pt, C(20), C(21), C(8) N(10), and P(1) in a crystallographic mirror plane. Therefore, the positions of Cl and C(22A) are disordered and hence have a mixed occupancy. The C(9) atom of the ethylene bridge is also disordered. The Pt−C distances of the equatorial methyl substituents [Pt−C(20):

206.3(10) pm; Pt−C(21): 208.2(9) pm] are in the same range as for corresponding Pt^{II} complexes with a P−N-chelating ligand.[14] Due to the disorder of the axial positions, an average distance of only 240.9(3) pm was found.

In order to estimate the Pt−Cl and Pt−C distances, in spite of the disorder of the axial ligands, an ab initio calculation was performed. The phenyl and methyl groups of the chelate ligand were substituted by hydrogen to reduce calculation time. The geometry optimization of this simplified molecule **4b** resulted a Pt−C(22) distance of 208.3 pm and a Pt−Cl distance of 252.8 pm. Additional bond lengths and angles are given in Table 2. Most bond lengths and angles are in good agreement with the measured values of complex **4**. The calculated bond lengths are typical for hexacoordinated Pt compounds and are in agreement with those found in an iodotrimethylplatinum(IV) complex.[15]

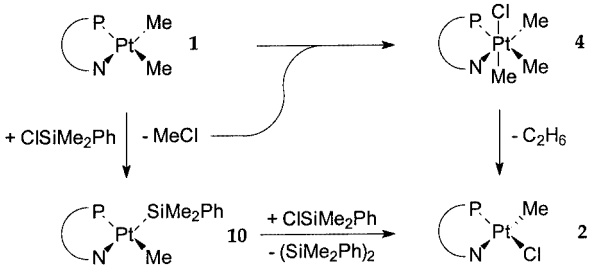
Elimination of Ethane from (P⌒N)Pt(Me)$_3$Cl (4) on Heating

A sample of the isolated complex **4** was dissolved in [D_8]toluene and heated in an NMR tube. At 60 °C, formation of **2** was detected in the ^{1}H and ^{31}P NMR spectra, but the reaction rate was quite low. Therefore, the temperature was increased to 90 °C, at which temperature the reaction was complete in about 12 h. At this temperature the two Pt−CH_3 signals of **4** at δ = 0.59 and 1.92 ppm are extremely broad, while the third Pt−CH_3 signal of **4** at δ = 1.49 ppm remains unchanged. Comparison of the Pt−CH_3 resonances of **4** with that of complexes **1**, **2**, and a $(PhMe_2P)_2PtMe_3Cl$ isomer[16] analogous to **4**, allows for the assignment of the Pt−Me signal at δ = 0.59 ppm to the methyl group *trans* to Cl, the signal at δ = 1.92 ppm to the methyl group *trans* to the nitrogen atom, and the signal at δ = 1.49 ppm to the methyl group *trans* to the phosphorus atom. The broadening of the two methyl resonances appears to be related to the start of the reductive elimination of ethane, i.e. ethane is probably formed from the methyl groups *trans* to the nitrogen atom and *trans* to the chlorine atom. The formation of ethane was proven by mass spectrometry.

(P⌒N)Pt(CD_3)$_2$ was analogously treated to check whether the addition of CH_3Cl is stereospecific. However, no difference is seen in the ^{31}P NMR spectra compared with those of the experiments with (P⌒N)PtMe_2. The ^{1}H NMR spectrum shows three Pt−CH_3 signals of **4** with equal intensities. Instead of three singlets with satellites, there are three doublets of doublets with satellites. The additional line splitting may be due to an H−D coupling, or due to the different chemical shifts of the structural isomers. Corresponding signals, also with equal intensity, are seen in the ^{2}H NMR spectrum, indicating a statistical distribution of the added CH_3 group to the three possible positions of complex **4**. An intermolecular exchange reaction, or rearrangement via a five-coordinate complex with an intermediate and the reversible opening of the (P⌒N)-chelate ligand may be responsible for the scrambling reaction. Thermolysis of (P⌒N)Pt(CD_3)$_2$(Me)Cl results in the formation of both C_2H_6 and $C_2H_3D_3$, as found by mass spectrometry.

Reaction of (P⌒N)PtMe$_2$ with ClSiMe$_2$Ph

(P⌒N)PtMe_2 not only exhibited a strongly increased reactivity towards C−Cl bonds in comparison with related (P⌒P)PtMe_2 complexes, but was also able to activate the stronger Si−Cl bond of $ClSiMe_2Ph$. When a solution of (P⌒N)PtMe_2 was heated in C_6D_6 with a stoichiometric amount of $ClSiMe_2Ph$, the disilane $Ph_2Me_4Si_2$ was the only silicon-containing product. Complexes **4** and **2** were formed in this reaction in a ratio of about 1:4. The amount of **2** increased after complete conversion of the chlorosilane, indicating a reductive elimination of ethane from **4**, forming **2**. The products were identified by spectroscopic comparison with independently prepared samples. A possible reaction mechanism is shown in Scheme 2. Although the intermediate complex **10** was not observed, this mechanism appears plausible because the formation of both **4** and **10** would correspond to the formation of complexes **4**−**5** in the reaction of **1** with CCl_4 (Scheme 1). A rearrangement similar to **6** → **7** is obviously less favored than the substitution of the second methyl ligand.



Scheme 2

Conclusions

The reactivity of Pt^{II} complexes with the chelating P⌒N ligands towards chlorinated hydrocarbons and chlorinated silanes is greatly enhanced relative to the corresponding chelating bis(phosphane) complexes. This reactivity enhancement may have two reasons: (i) The nitrogen donor group of the P⌒N ligands can be reversibly de-coordinated, i.e. the ligand is hemilabile. In comparison, the de-coordination of a phosphorus donor center chelating bis(phosphane) complexes is much more difficult. Hemilabile ligands are known to promote both oxidative addition and reductive elimination reactions. (ii) Due to the different donor/acceptor properties of the two Lewis basic centers in the P⌒N ligands, the electronic difference *trans* to the nitrogen atom is different to that *trans* to the phosphorus atom, i.e. the bond strengths of the *trans* ligands are greatly influenced.

Experimental Section

General: All reactions were performed under dried argon. All reagents were of best commercial grade. The complexes (P⌒N)PtMe_2,

$(P^{\frown}P)PtMe_2$, and $(PhMe_2P)_2PtMe_2$ were prepared as previously described.[4] Solids were used without further purification, liquids were dried with molecular sieves (4 Å) for 24 h and argon-saturated by freeze-pump-thaw. NMR spectra were recorded with a Bruker DPX 300 Avance spectrometer (^1H and ^{29}Si NMR spectroscopy, TMS as an external standard. ^{31}P NMR spectroscopy, 85% H_3PO_4 as an external standard; ^{195}Pt NMR spectroscopy, Na_2PtCl_6 in D_2O as an external standard). ^{29}Si NMR spectra were recorded with an INEPT pulse sequence.

Computational Details: The geometry optimization of the equilibrium geometry of **4b** was carried out using the B3LYP version of DFT, which is comprised of Becke's hybrid three-parameter exchange functional,[17] and the correlation functional of Lee, Yang, and Parr.[18] The structure was characterized as minima by computing the Hessian matrices. The ab initio calculation was performed with the Gaussian98 program package.[19] From the available ECP basis sets in Gaussian98, the SDD basis set was used for platinum and the 6-311++G(d) basis set for all the other atoms.

General Procedure for the Reaction of Pt Complexes with Halogenated Compounds: All reactions were performed under argon in NMR or Schlenk tubes. The reaction vessels were flame-dried and argon-saturated before addition of the Pt complex. After addition of the solvent and the liquid halogenated compound, the vessel was closed and put into a thermostatically controlled oil bath or into the thermostatically controlled NMR spectrometer immediately. Experiments with silanes were performed in an NMR Teflon liner.

Reaction of $(P^{\frown}N)PtMe_2$ with CCl_4 in C_6D_6: CCl_4 (11.4 μL, 0.12 mmol) was added to a solution of **1** (28.7 mg, 0.06 mmol) in 0.7 mL of C_6D_6. A colorless solid precipitated immediately. It was separated by decanting the liquid phase and washed twice with cold benzene. The NMR spectra were identical with that of an independently prepared sample of **2** (see below). The supernatant solution was decanted and analyzed by NMR spectroscopy. ^1H NMR (C_6D_6, 27 °C): δ = 0.61 (d, $^3J_{PH}$ = 7.7, $^2J_{PtH}$ = 71 Hz, Pt−CH_3, **4**), 1.39 (d, $^3J_{PH}$ = 3.0, $^2J_{PtH}$ = 75 Hz, Pt−CH_3, **2**), 1.61 (d, $^3J_{PH}$ = 8.1, $^2J_{PtH}$ = 57 Hz, Pt−CH_3, **4**), 1.89 (s, $^3J_{PtH}$ = 13.8 Hz, NMe_2, **4**), 2.03 (d, $^3J_{PH}$ = 7.0, $^2J_{PtH}$ = 73 Hz, Pt−CH_3, **4**), 2.56 (s, $^3J_{PtH}$ = 13 Hz, NMe_2, **3**), 2.64 (s, $^3J_{PtH}$ = 11 Hz, NMe_2, **2**), 2.69 (s, $^3J_{PtH}$ = 10 Hz, NMe_2, **4**), 5.04 (s, $^3J_{PtH}$ = 34 Hz, *cis* =CH, **3**), 6.18 (s, $^3J_{PtH}$ = 89 Hz, *trans* =CH, **3**) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 27 °C): δ = 8.11 (s, $^1J_{PtP}$ = 1185 Hz, **4**), 24.43 (s, $^1J_{PtP}$ = 4375 Hz, **3**), 26.45 (s, $^1J_{PtP}$ = 4677 Hz, **2**) ppm. $^{195}Pt\{^1H\}$ NMR (C_6D_6, 27°C): δ = −4243 (d, $^1J_{PtP}$ = 4678 Hz, **2**), −3905 (d, $^1J_{PtP}$ = 4363 Hz, **3**), −2976 (d, $^1J_{PtP}$ = 1213 Hz, **4**) ppm. After the addition of some petroleum ether (boiling range 30−50°C)) to the decanted reaction solution, crystals of **3** suitable for a crystal structure analysis were formed within a few days. **3**: ^1H NMR ([D_6]acetone, 27 °C): δ = 2.65−2.85 (m, 4 H, CH_2), 2.87 (s, $^3J_{PtH}$ = 14 Hz, 6 H, NCH_3), 4.39 (s, $^3J_{PtH}$ = 36 Hz, 1 H, *cis* =CH), 5.43 (s, $^3J_{PtH}$ = 90 Hz, 1 H, *trans* =CH), 7.50−7.95 (m, 10 H, C_{arom}) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 27 °C): δ = 24.33 (s, 4376 Hz) ppm. $^{31}P\{^1H\}$ NMR ([D_6]-acetone, 27°C): δ = 25.5 (s, $^1J_{PtP}$ = 4369 Hz) ppm.

Synthesis of $(P^{\frown}N)Pt(Cl)Me$ (2) by Reaction of $(P^{\frown}N)PtMe_2$ with HCl: A solution of HCl (0.1 mL, 0.10 mmol) in diethyl ether was added to a solution of $(P^{\frown}N)PtMe_2$ (23.9 mg, 0.05 mmol) in 0.7 mL of C_6D_6. The volatile compounds were then removed from the solution, and $(P^{\frown}N)Pt(Me)Cl$ (**2**) remained as a colorless powder in a quantitative yield. ^1H NMR ($CDCl_3$, 27 °C): δ = 0.63 (d, $^3J_{PH}$ = 2.8, $^2J_{PtH}$ = 73 Hz, Pt−CH_3, **2**), 2.3−2.7 (m, CH_2CH_2), 2.87 (s, $^3J_{PtH}$ = 11 Hz, NMe_2), 7.4−7.8 (m, PPh_2) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 27 °C): δ = 27.28 (s, $^1J_{PtP}$ = 4700 Hz) ppm. $C_{17}H_{23}ClNPPt$ (475.4): calcd. C 40.61, H 4.70, N 2.56; found C 41.39, H 4.70, N 2.56.

Synthesis of $(P^{\frown}N)Pt(Cl)Me$ (2) by Reaction of (nbd)PtMeCl[5] with $P^{\frown}N$: A solution of [2-(diphenylphosphanyl)ethyl]dimethylamine ($P^{\frown}N$)[20] (282 mg, 1.09 mmol) in 10 mL of CH_2Cl_2 was added slowly to a solution of (nbd)Pt(Me)Cl (365 mg, 1.08 mmol) in 40 mL of CH_2Cl_2. After the mixture was stirred for 1 h, the colorless product was filtered and washed with benzene (3 × 5 mL) and pentane (3 × 5 mL). Yield 543 mg (85%).

Reaction of $(P^{\frown}N)Pt(CD_3)_2$ with CCl_4 in C_6D_6: CCl_4 (8.7 μL, 0.09 mmol) was added to a solution of $(P^{\frown}N)Pt(CD_3)_2$ (22 mg, 0.045 mmol) in 0.7 mL of C_6D_6. ^1H NMR (C_6D_6, 27 °C): δ = 1.83 (s, $^3J_{PtH}$ = 14.3 Hz, NMe_2, **4**), 2.59 (s, $^3J_{PtH}$ = 13 Hz, NMe_2, **3**), 2.64 (s, $^3J_{PtH}$ = 10.7 Hz, NMe_2, **2**), 2.69 (s, $^3J_{PtH}$ = 9.6 Hz, NMe_2, **4**) ppm. $^2H\{^1H\}$ NMR (C_6D_6, 27 °C): δ = 0.43 (s, $^2J_{PtD}$ = 10.1 Hz, Pt−CD_3, **4**), 1.18 (s, $^2J_{PtD}$ = 10.0 Hz, Pt−CD_3, **2**), 1.40 (s, $^2J_{PtD}$ = 7.5 Hz, Pt−CD_3, **4**), 1.83 (s, $^2J_{PtD}$ = 10.9 Hz, Pt−CD_3, **4**), 4.89 (s, =CD_2, **3**) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 27 °C): δ = 8.67 (s, $^1J_{PtP}$ = 1180 Hz, **4**), 24.72 (s, $^1J_{PtP}$ = 4381 Hz, **3**), 26.89 (s, $^1J_{PtP}$ = 4679 Hz, **2**) ppm.

Reaction of $(P^{\frown}N)PtMe_2$ with $CHCl_3$ in C_6D_6: $CHCl_3$ (7.8 μL, 0.095 mmol) was added to a solution of **1** (23 mg, 0.05 mmol) in 0.7 mL of C_6D_6. After addition, the sample was heated to 60 °C. ^1H NMR (C_6D_6, 60 °C): δ = 0.59 (d, $^3J_{PH}$ = 7.7, $^2J_{PtH}$ = 71.0 Hz, Pt−CH_3, **4**), 1.34 (d, $^3J_{PH}$ = 3.5, $^2J_{PtH}$ = 75.1 Hz, Pt−CH_3, **2**), 1.53 (d, $^3J_{PH}$ = 8.3, $^2J_{PtH}$ = 58.0 Hz, Pt−CH_3, **4**), 1.91 (s, $^3J_{PtH}$ = 14.1 Hz, NCH_3, **4**), 1.94 (d, $^3J_{PH}$ = 6.9, $^2J_{PtH}$ = 73.1 Hz, Pt−CH_3, **4**), 2.60 (s, $^3J_{PtH}$ = 12.6 Hz, NCH_3, **9**), 2.64 (s, $^3J_{PtH}$ = 11.5 Hz, NMe_2, **2**), 2.70 (s, $^3J_{PtH}$ = 9.3 Hz, NMe_2, **4**) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 60 °C): δ = 7.57 (s, $^1J_{PtP}$ = 1175 Hz, **4**), 26.15 (s, $^1J_{PtP}$ = 4657 Hz, **2**), 27.95 (s, $^1J_{PtP}$ = 4559 Hz, **9**) ppm.

Reaction of $(P^{\frown}N)Pt(CD_3)_2$ with $CHCl_3$ in C_6D_6: $CHCl_3$ (19.5 μL, 0.24 mmol) was added to a solution of **1** (58.6 mg, 0.12 mmol) in 0.7 mL of C_6D_6. The sample was then heated to 60 °C. ^1H NMR (C_6D_6, 60 °C): δ = 1.93 (s, $^3J_{PtH}$ = 13.9 Hz, NCH_3, **4**), 2.59 (s, $^3J_{PtH}$ = 12.4 Hz, NCH_3, **9**), 2.64 (s, $^3J_{PtH}$ = 11.8 Hz, NMe_2, **2**), 2.72 (s, $^3J_{PtH}$ = 9.2 Hz, NMe_2, **4**). $^2H\{^1H\}$ NMR (C_6D_6, 60 °C): 0.45 (s, $^2J_{PtD}$ = 10.4 Hz, Pt−CD_3, **4**), 1.26 (s, $^2J_{PtD}$ = 10.0 Hz, Pt−CD_3, **2**), 1.48 (s, $^2J_{PtD}$ = 7.5 Hz, Pt−CD_3, **4**), 1.86 (s, $^2J_{PtD}$ = 11.0 Hz, Pt−CD_3, **4**) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 60 °C): δ = 7.93 (s, $^1J_{PtP}$ = 1180 Hz, **4**), 26.63 (s, $^1J_{PtP}$ = 4679 Hz, **2**), 28.41 (s, $^1J_{PtP}$ = 4562 Hz, **9**) ppm.

Reaction of $(P^{\frown}N)PtMe_2$ with CH_2Cl_2 in C_6D_6: CH_2Cl_2 (29.4 μL, 0.445 mmol) was added to a solution of **1** (21.5 mg, 0.045 mmol) in 0.7 mL of C_6D_6. After addition, the sample was heated to 60 °C. $^{31}P\{^1H\}$ NMR (C_6D_6, 60 °C): δ = 7.33 (s, $^1J_{PtP}$ = 1167 Hz, **4**), 26.60 (s, $^1J_{PtP}$ = 4681 Hz, **2**) ppm.

Formation of $(P^{\frown}N)Pt(Me)_3Cl$ (4) by Reaction of $(P^{\frown}N)PtMe_2$ with CH_3Cl in C_6D_6: A gentle stream of methyl chloride was bubbled through a solution of **1** (108 mg, 0.22 mmol) in 2 mL of C_6D_6. After 1 h, the ^1H NMR spectrum showed an intensive CH_3Cl signal at δ = 2.48 ppm, but no formation of new complexes. The CH_3Cl saturated solution was then heated to 60 °C and a finely divided colorless solid precipitated. After 12 h, the conversion into **4** was approximately 95%. After 24 h, conversion was complete and only traces of **1** were observed. Crystallization from a saturated benzene solution yielded pure **4** as colorless crystals, some of them suitable for a X-ray structure analysis. ^1H NMR (C_6D_6, 60 °C): δ = 0.59 (d, $^3J_{PH}$ = 7.7, $^2J_{PtH}$ = 70.8 Hz, Pt−CH_3), 1.51 (d, $^3J_{PH}$ = 8.2, $^2J_{PtH}$ = 57.6 Hz, Pt−CH_3), 1.89 (s, $^3J_{PtH}$ = 14.1 Hz, NCH_3), 1.93

(d, $^2J_{PtH}$ = 7.2, $^3J_{PH}$ = 73.1 Hz, Pt−CH_3), 2.70 (s, $^3J_{PtH}$ = 9.4 Hz, NCH_3) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 60 °C): δ = 8.01 (s, $^1J_{PtP}$ = 1166 Hz) ppm. $C_{19}H_{29}ClNPPt$ (525.9): found C 42.82, H 5.48, N 2.63; found C 42.81, H 5.37, N 2.65.

Reaction of (P⌒N)Pt(CD$_3$)$_2$ with CH$_3$Cl in C$_6$D$_6$: A gentle stream of methyl chloride was bubbled through a solution of (P⌒N)Pt$(CD_3)_2$ (27.5 mg, 0.056 mmol) in 0.6 mL of C_6D_6. The CH_3Cl-saturated solution was heated to 60 °C for 24 h. The conversion was complete yielding (P⌒N)Pt$[(CH_3)/(CD_3)]_3Cl$, with a statistical distribution of the added CH_3 group. (P⌒N)Pt$(CH_3)(CD_3)_2Cl$: ^1H NMR (C_6D_6, 60 °C): δ = 0.59 (dd, *J* = 1.0, $^3J_{PH}$ = 7.7, $^2J_{PtH}$ = 71.0 Hz, Pt−CH_3), 1.49 (dd, *J* = 1.1, $^3J_{PH}$ = 8.1, $^2J_{PtH}$ = 57.0 Hz, Pt−CH_3), 1.92 (dd, *J* = 1.0, $^3J_{PH}$ = 7.0, $^2J_{PtH}$ = 72.6 Hz, Pt−CH_3) ppm. ^2H NMR (C_6D_6, 27 °C): δ = 0.45 ($^3J_{PD}$ = 1.1, $^2J_{PtD}$ = 10.7 Hz, Pt−CD_3), 1.36 ($^3J_{PD}$ = 1.7, $^2J_{PtD}$ = 6.9 Hz, Pt−CD_3), 1.84 ($^3J_{PD}$ = 1., $^2J_{PtD}$ = 10.8 Hz, Pt−CD_3) ppm. $^{31}P\{^1H\}$ NMR (C_6D_6 60 °C): δ = 8.01 (s, $^1J_{PtP}$ = 1161 Hz) ppm.

Reaction of (P⌒N)PtMe$_2$ with ClSiMe$_2$Ph in C$_6$D$_6$: $ClSiMe_2Ph$ (26 μL, 0.156 mmol) was added to a solution of (P⌒N)$PtMe_2$ (37.5 mg, 0.078 mmol) in 0.5 mL of C_6D_6 in a Teflon liner. The sample was then heated to 60 °C. Because of the Teflon liner, the resolution of the ^1H NMR spectrum was very low, and resolution of the Pt complexes was not possible. ^1H NMR (C_6D_6, 60 °C): δ = 0.39 [s, $(SiMe_2Ph)_2$] ppm. $^{29}Si\{^1H\}$ NMR (C_6D_6, 60 °C): δ = −21.45 ppm. $^{31}P\{^1H\}$ NMR (C_6D_6, 60 °C): δ = 7.87 (s, $^1J_{PtP}$ = 1168 Hz, **4**), 26.24 (s, $^1J_{PtP}$ = 4665 Hz, **2**) ppm.

X-ray Structure Analyses: Crystal data and experimental details are given in Table 4. The X-ray data were collected at 294 K with a Siemens SMART CCD area detector diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), a nominal crystal-to-detector distance of 4.40 cm and 0.3° ω-scans frames. Corrections for Lorentz polarization, and an empirical absorption correction with the program SADABS were applied. The structures were solved by direct methods (SHELXS-86) and refined by the full-matrix least-squares method based on F^2 (SHELXL-93). All non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were included in idealized positions. CCDC-174589 (**3**) and -174590 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Molecular Recognition of Anions by a Novel Organocobalt Receptor: Oxyanion versus Halide Selectivity in Water

Mike Robitzer,[a] Claude Sirlin,*[a] Nathalie Kyritsakas,[b] and Michel Pfeffer*[a]

Keywords: Host-Guest Systems / Cobalt / N,C ligand / Anions / Allosterism

The dissolution of $[Co\{2,6\text{-}(Me_2NCH_2)_2C_6H_3\}(\eta^5\text{-}C_5H_5)(H_2O)]PF_6$ (**1a**) in dry methanol or dry acetonitrile affords compounds **1b** and **1c**, respectively, in which the water ligand of **1a** has been substituted by MeOH or by CH_3CN. The crystal structure analysis of **1b** established that a strong intramolecular interaction exists between the methanolic proton and the NMe_2 group that was interacting with H_2O in **1a**. For **1c** no interaction could be found between the Co-bound acetonitrile ligand and this NMe_2 as it has changed its position in order to be as far away from the cobalt atom as possible. Whereas no reaction takes place between **1a** and an excess of sodium iodide in water or in methanol, in acetone I^- easily substitutes the water ligand of **1a** to afford high yields of the neutral compound **3**. Here also ^1H NMR spectroscopic data are in favour of a structure with no interaction between the NMe_2 and the iodide ligand as in **1c**. Protonation of the free NMe_2 unit of **1a** by adding increasing amounts of HPF_6 in water leads to the synthesis of **4a**. The p*K*a of **1a** in D_2O was found to be 6.1. Treating **1a** with acidic buffered water solutions (pH = 5.5) leads to the in situ formation of **4a**. From these solutions, association constants were determined for Cl^-, Br^-, I^-, AcO^-, $H_2PO_4^-$ and NO_3^-. Significant selectivity in water for AcO^- and $H_2PO_4^-$ vs. halide anions has been established.

Introduction

The molecular recognition of anions[1−3] emerged with the discovery of a multiprotonated hollow, called katapinate,[4] which was the first host for a chloride ion. Crystal structure determinations established that the anion is indeed encapsulated within the macrobicyclic cavity of the host molecule.[5] Important results were reported when chloride and azide were selectively complexed in water by tetraprotonated macrotricyclic[6,7] and hexaprotonated macrobicyclic[8] molecules, respectively. In all these examples the anions were found to have formed hydrogen-bonding interactions with the protonated ammonium derivatives. It was therefore thought that complexation of anions should also be feasible with metallic cations located in related cavities.[9,10] A macrobicyclic biscopper cryptate complex was thus synthesised which was shown by potentiometric studies to display the expected interactions between the bis-metallic centres and a chloride anion. Another related compound containing one copper atom only displayed a chloride anion interacting with the Cu centre and the ammonium moieties of the ligand.[11] Until then only very rare examples derived from organometallic compounds had been reported to exhibit a related behaviour.[12−14]

We have recently described the synthesis and the preliminary behaviour of a simple organocobalt compound[15] which was built with the well-known mono-anionic pincer ligand extensively studied by van Koten et al.[16,17] In our compound, however, the N,C,N ligand is only coordinated to the cobalt centre in a bidentate fashion as one N atom does not interact directly with the metal. In fact we found that these organometallic species are interesting Brønsted acid receptors as a series of such acids were indeed coordinated to the (N,C,N)metal moiety without any hydrolysis of the Co−C bond being observed. It thus appeared that in these species the anions associated with the acids were interacting both with a metal cation *and* an ammonium unit as in the anion hosts mentioned above. We thus embarked on a project aimed at defining both the mechanism of the acid complexation by our cobalt complex and the thermodynamic data associated with the protonation of the amine unit that is not directly bound to Co in **1a**. This study allowed us to determine the association constants between the organocobalt host and various anions and to compare their selectivity with related known systems.

Results and Discussion

The key compound of this study is the aquo derivative **1a** in which an intramolecular hydrogen bond between one

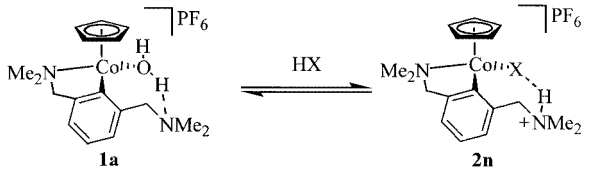
of the aquo protons and the noncoordinated nitrogen atom of the pincer ligand was established. The reaction of **1a** with acids affords the complexes **2a**−**e**, which display a related intramolecular H-bond between the dimethylammonium unit and the X atoms (see Scheme 1). These intramolecular H-bonds in both **1a** and **2a**−**e** contribute to the stability of the complexes by forming pseudo seven-membered organometallic rings.

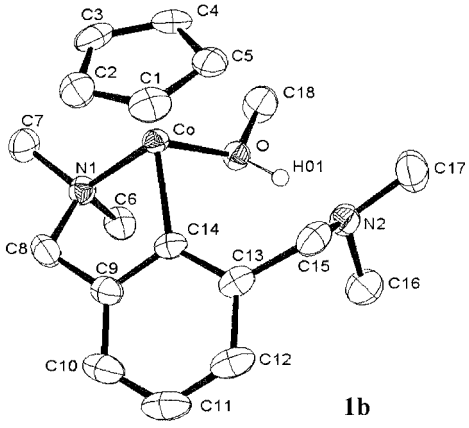


1a **2n**

Scheme 1. Complexation of HX by **1a** affords **2a**−**e** [**a** (X = F), **b** (X = Cl), **c** (X = Br), **d** (X = I), **e** (X = OAc)]

This stabilisation seems to play a key role for the coordination of the anion to the cobalt centre as, when treating **1a** *in water* with excess (up to 10^3 equivalents) of NaI, for instance, no complexation of the iodide was observed. Changing water for methanol in order to increase the solubility of **1a**, with the same excess of sodium iodide, did not lead to the coordination of I^- to cobalt. However, following this reaction by UV/Vis spectroscopy, we noticed the presence of new absorption bands at λ = 459, 560 and 675 nm vs. one band only for **1a** in water at λ_{max} = 465 nm. The ^{1}H NMR spectrum of **1a** in CD_3OD displays only slight modifications of the chemical shifts of the various signals of **1a** as compared to the same spectrum in [D_6]acetone. Single crystals of **1b** were obtained from a methanol/hexane solution of **1a**. The molecular structure of **1b** was determined by means of an X-ray diffraction study on one of these crystals (Figure 1 and Table 1). It was at once apparent that, in **1b**, a molecule of methanol has substituted the water molecule in **1a**. Importantly, a strong intramolecular OH···N bond is also found between the coordinated methanol and the free NMe_2 unit. The ^{1}H NMR spectrum of **1b** in [D_6]acetone containing traces of water showed the spectrum of **1a**, confirming that the coordination of methanol is easily reversed even by small amounts of water.

In dry CD_3CN, **1a** displays a ^{1}H NMR spectrum which allows the identification of both unmodified **1a** and a new species **1c** in ratios depending on the concentration of **1a**. The ^{1}H NMR spectrum of **1c** shows the presence of one singlet for the NMe_2 group not interacting with the cobalt centre at δ = 2.30 ppm, together with the expected two singlets for the diastereotopic Co-bound NMe_2 unit. These features suggest that **1c** is a derivative of **1a** in which the water molecule has been substituted by a MeCN ligand. The X-ray diffraction study of a single crystal of **1c** (Figure 1 and Table 1) confirmed that **1c** is a MeCN adduct of **1a**. The conformation of the five-membered cyclometallated ring of the pincer ligand is very similar to that found for this ligand in **1a**. The only difference between **1a** and **1c** is a different orientation of the second NMe_2 group with respect to Co: it is now as far away from the acetonitrile ligand as possible, this being achieved by a rotation of ca. 90° around the C_{13}−C_{15} vector.



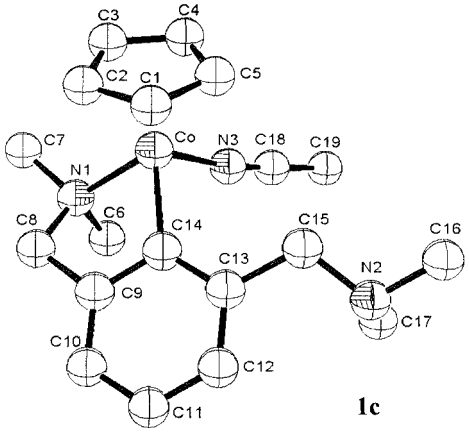


Figure 1. ORTEP representation of the cationic parts of **1b** and **1c**

As NaI is not soluble in CD_3CN we added one equivalent of NBu_4I to a solution of **1a** in order to check whether I^- can substitute the MeCN ligand in **1c**. We noticed no such complexation unless we increased the concentration of I^-: when adding more than 10 equivalents of NBu_4I a new species **3** was observed together with **1a** and **1c** (**3**:**1a**:**1c** = 0.07:0.16:0.77 with 12 equiv. of NBu_4I). The ^{1}H NMR spectroscopic data of **3** show significant high-field shifts for all the protons of the pincer ligand. Moreover the $\Delta\delta$ of the NMe_2 group bound to Co drops to 0.5 ppm as compared to its value in **1a**, **1b**, and **1c** (2.15, 2.11 and 1.47 ppm respectively). In the latter three compounds displaying these rather important $\Delta\delta$ values, the molecular structure shows a similar ring puckering of the five-membered cobaltacyclic ring, whereby one of the N−Me bonds eclipses either the Co−O or the Co···NCMe bond. The $\Delta\delta$ value found for **3** militates in favour of a staggered conformation in which the NMe_2 has now rotated around the C_8−N_1 vector by ca. 60° as shown in Figure 2. This latter feature is probably due to steric interactions between the bulky I^- ligand and the N−Me bond.

Table 1. Selected bond lengths and angles in complexes **1b** and **1c**

Bond lengths [Å]		Compound **1b**	Angles [°]

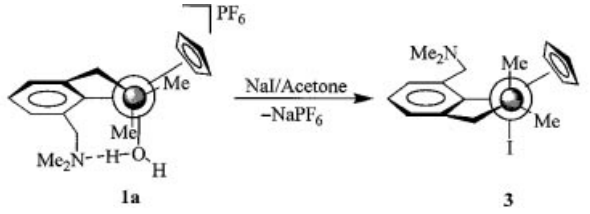

Figure 2. Newman representation of **3** around the Co−N_1 bond

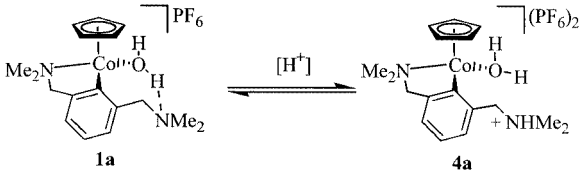
This latter experiment showed unambiguously that iodide can indeed be coordinated to cobalt by displacement of the water *provided that the reaction is run in a non-protic solvent*. Indeed, the synthesis of **3** can be better achieved in acetone as, in this poorly coordinating solvent, **3** is obtained in almost quantitative yields. It is most likely that coordination of I^- takes place from an acetone solvate derivative **1d** akin to **1c** in which MeCN is substituted by acetone, knowing that cobalt has a much higher affinity for I^- than for acetone. We assume that in this solvent, **1a** might well be in equilibrium with the hypothetical acetone adduct **1d**, although the concentration of this latter species is far too low to be detected by ^{1}H NMR spectroscopy.

We have seen that the "CpCo(pincer)" moiety could be a host for HX, as HF, HCl, HBr, HI or HOAc could substitute the water ligand when an excess of one of these Brønsted acids is added to solutions of **1a** in methanol.[15] From the results discussed above, it appears that the coordination of the X^- anions to Co is probably only possible once the NMe_2 unit of the pincer ligand not coordinated to cobalt in **1a** has been protonated by HX. We have indeed checked that a solution of **1a** and 10^3 equiv. of NaCl in water leads to the formation of **2b** only when decreasing the pH of the solution by addition of HPF_6.

We have also studied the protonation of **1a** in D_2O as a function of [H^+]. In this respect we have run the ^{1}H NMR spectra of several solutions of **1a** in D_2O to which various amounts of HPF_6 had been added. The correlation between the chemical shifts of certain protons of **1a** and the pH of the solutions allowed the determination of the pK_a of the species **4a**. The equilibrium between **1a** and **4a** (Scheme 2) must be fast on the ^{1}H NMR time scale, as only one signal is observed for the two species. Most of the signals of **1a** experience a decrease of chemical shifts upon lowering the pH of the D_2O solutions. However, the signal of one proton of a CH_2 group (at δ = 3.89 ppm) displays a behaviour that is worthy of further discussion. At pH 8.0 the intensity of this doublet starts to decrease, it then gradually becomes broader as the pH drops and finally disappears when the pH is in the range 6.5 to 7.0. Surprisingly, at pH 4.05 it reappears as a doublet but at a very different chemical shift (δ = 5.02 ppm). During this process the chemical shift of the second CH associated to the previous one does not change (δ = 4.59 vs. 4.57 ppm). One explanation for this dynamic behaviour could be that the reversible protonation of the NMe_2 unit induces the cleavage of the OH···NMe_2 bond in **1a** and rotation around the C_{13}−C_{15} vector as in **1c**. Since the chemical shifts of the two protons of the CH_2 group resonate at very different chemical shifts in the two exchanging position it is reasonable to observe a broadening of the high-field shifted proton as it is known that the broadness of any given signal that is exchanging with another one is proportional to the square of the difference of the chemical shifts of both signals.[18] At pH < 4.5 the protonation of the NMe_2 close to this CH_2 is complete and thus exchange of the CH_2 group is no longer possible.



Scheme 2. Equilibrium between **1a** and **4a**

At pH ≥ 8.5 the NMe_2 interacting with H_2O is a broad singlet because this species is rapidly exchanging the two diastereotopic methyl groups by a fast coordination-decoordination of the N atom to the O−H group. We found good evidence for this while studying the behaviour of **1a** in [D_6]acetone. At room temperature the signal of the "free" NMe_2 group is a broad singlet at δ = 2.20 ppm, but when the temperature is lowered (< −20 °C) the diastereotopic nature of this NMe_2 group is recovered, the difference

in chemical shift between the two methyls being more than 0.6 ppm. At lower pH (4.05) the NMe_2, which until then is a broad singlet, appears as two broad signals, showing that the NMe_2 group is indeed completely protonated: the N atom can no longer invert its configuration and hence the exchange process is not detectable anymore. The pK_a value of **4a** in D_2O follows from the results reported in Figure 3, leading to a value of 6.1 ± 0.1.

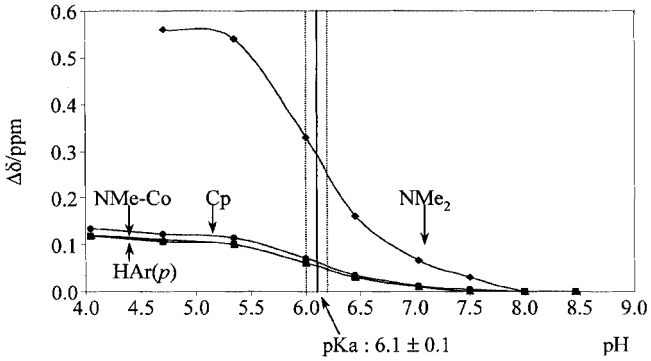


Figure 3. Variation of Δδ for significant signals as a function of pH

Association Constant Determinations

As we have seen that **1a** becomes a good host for anions at slightly acidic pH, we looked for the best buffer solutions to determine the thermodynamic data for the various complexations of anions by our system. We have thus chosen MES (2-[*N*-morpholino]ethanesulfonic acid) which leads to a pH of 5.5 in water. The K_{ass} values were obtained by following the addition of various amounts of anions (as their NH_4^+ or NEt_3H^+ derivatives)[19] to a buffered solution of **1a** by standard UV/Vis spectroscopy; the spectra of **4a** and **2b**−**d** are shown in Figure 4.

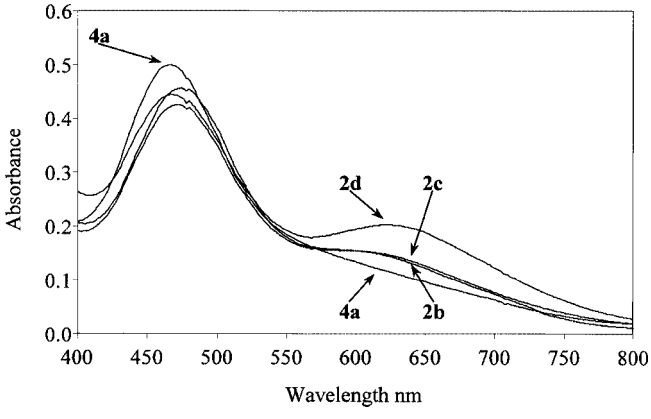

Figure 4. Superposition of UV/Vis of **4a** and **2b**−**d**

As the concentrations of the species **2b**−**d** are proportional to the absorption around 620−650 nm we used this modification to determine the association constants according to Equation (1). These constants are given in Table 2.

The constant for the fluoride anion could not be measured by any of these techniques because this anion reacts with the buffer leading to the formation of an uncharacterised insoluble material.

Table 2. log K_{ass} for compounds **2b**−**g** in various solvents

Entry	Anion	Complexes	log K_{ass} in water pH = 5.5[b]	log K_{ass} in M/W[a] pH = 5.4[b]	log K_{ass} in methanol pH = 6.4[c]
1	Cl^-	**2b**	1.8[d] [e]	3.9[e]	3.4[e]
2	Br^-	**2c**	1.5[d,e]	3.1[e]	2.7[e]
3	I^-	**2d**	1.7[d,e]	3.2[e]	2.9[e]
4	CH_3COO^-	**2e**	3.0[e]	1.7[e]	1.9[e]
5	$H_2PO_4^-$	**2f**	3.1[e]	ns[f]	ns[f]
6	NO_3^-	**2g**	1.0[e]	1.4[e]	1.5[e]

[a] M/W = methanol/water (95:5). [b] MES. [c] MOPS. [d] UV/Vis. [e] ^{1}H NMR spectroscopy. [f] Not soluble.

$$\mathbf{4a} + NR_3HX \underset{MES,\ D_2O}{\overset{K_{ass}}{\rightleftharpoons}} \mathbf{2b\text{-}g} + D_2O + NR_3 \qquad (1)$$

$$K_{ass} = \frac{[\mathbf{2b\text{-}g}]}{[\mathbf{4a}][X^-]}$$

R = Et X = Cl, Br
R = H X = I, OAc, H_2PO_4, NO_3

This technique could not be applied to oxygen-containing anions such as acetate, nitrate or dihydrogenophosphate because the UV/Vis spectra of the complexes obtained by trapping of these latter ions do not display significant differences with the aquo derivative **4a**.

We checked that the K_{ass} obtained by analysis of the ^{1}H NMR spectra for the halide anions afforded results in line with those obtained by the UV/Vis technique. An example of the spectra obtained for different concentrations of iodide is shown in Figure 5 and 6, in which the chemical shift of the Cp ring in both **4a** and **2d** is represented. A related study was then performed for the $CH_3CO_2^-$, NO_3^- and $H_2PO_4^-$ anions, which led to the results reported in Table 2.

In order to be able to compare these data with related values for different anion hosts reported in the literature, we also determined these K_{ass} values in pure CD_3OD and

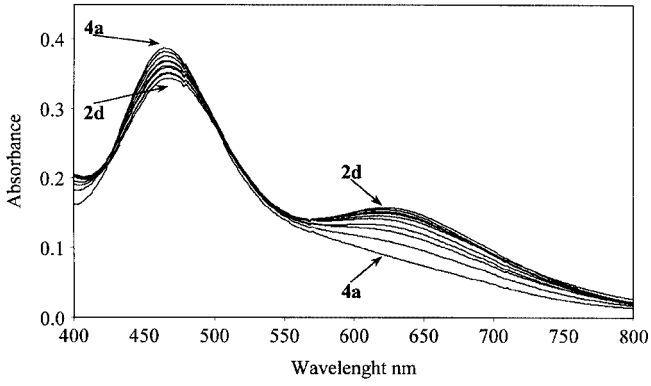

Figure 5. Evolution of the UV/Vis spectra of **4a** with increasing amounts of NH_4I (10, 20, 30, 40, 50, 60, 80 and 100 equiv.)

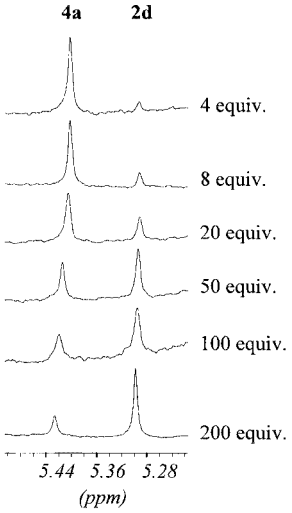

Figure 6. Evolution of the ^{1}H NMR spectra of **4a** with increasing amounts of NH_4I

in a 95:5 mixture of CD_3OD and D_2O. The relative concentration of **1a** and **1b**, as anticipated, is dependent on the amount of water present. In dry CD_3OD ($HDO/D_2O <$ 0.03%) the ratio of **1a** to **1b** is 5:95, whereas in CD_3OD/D_2O (95:5) this ratio is 40:60. These data are another illustration of a much stronger complexation of water to cobalt as opposed to methanol. In order to determine the pK_a of **1b** in pure CD_3OD and in CD_3OD/D_2O (95:5), we used the same procedure as described above for **1a** in D_2O. Addition of DPF_6 in CD_3OD resulted in a duplication of most of the signals of **1a** and **1b** in the ^{1}H NMR spectrum. We believe that the explanation for this phenomenon is due to the occurrence of four species, namely **1a**, **1b**, **4a** and **4b** (**4b** is the N-protonated derivative of **1b**). Particularly diagnostic of the existence of **4a** and **4b** are the presence of two pairs of CH_2 signals at chemical shifts analogous to those observed for **4a** in D_2O (see above).

As MES is poorly soluble in pure methanol, we decided to use MOPS (3-[*N*-morpholino]propanesulfonic acid) whose pH is slightly higher than that of MES (6.4 vs. 5.5). Solutions of **1a** in both solvents display the same ^{1}H NMR spectra, i.e. the Cp ring appears as three resonances. We believe that three different species should exist in these solutions, i.e. **1a**, **1b** and a compound in which the sulfonic group of the buffers has been trapped by the cobalt receptor. This compound is found in very low yield (< 5%) and it is always present in methanol solution whatever the concentration of the anions. A likely explanation for the occurrence of this species in methanol is based upon a different solvation of the sulfonic group, which is more solvated in water than in methanol. The occurrence of **1a** and **1b** in these solutions must be due to a very small degree of protonation of the nitrogen atom of either **1a** or **1b** by the buffer protons. However, despite the fact that it is not visible in the ^{1}H NMR spectrum, a small amount of the protonated form must exist to enable the trapping of the anions to take place. The presence of large quantities of buffer must be therefore be a strong enough driving force for the anion complexation to occur. The K_{ass} in this case was determined using a slightly different equation [Equation (2)] than above:

$$\mathbf{1a} + \mathbf{1b} + NR_3HX \underset{\text{i or ii}}{\overset{K_{ass}}{\rightleftharpoons}} \mathbf{2b\text{-}g} + D_2O + CD_3OD + NR_3$$

$$K_{ass} = \frac{[\mathbf{2b\text{-}g}]}{([\mathbf{1a}]+[\mathbf{1b}])[X^-]}$$

R = Et X = Cl, Br
R = H X = I, OAc, H_2PO_4, NO_3
i : MES, MeOD:D_2O (95:5)
ii : MOPS, MeOD

(2)

Several interesting comments can be made with respect to the K_{ass} values obtained in water or in methanol. There is an obvious important difference between the K_{ass} values measured for the halides and those obtained for the oxyanions. Whereas these values are much higher on going from water to methanol for the halides, the opposite is found for the oxyanions (see below). Schmidtchen has found a similar trend for the halide series when changing water for methanol.[20] However, in marked contrast to our results the complexation of the halide was somehow parallel to their sizes, iodide being by far the best complexed species. In our case K_{ass} for chloride is ca. five times higher than that for iodide. Our receptor is a competitive Cl^- host in methanol as compared to those reported elsewhere.[6,20] It is, however, important to note that the previously reported receptors were usually built from several ammonium units, whereas in our case this result was obtained by interaction of the Cl^- with Co^+ and one NH^+ moiety only. Our organocobalt receptor displays an interesting behaviour with respect to the oxyanions such as acetate and dihydrogenophosphate, since the stability of **2e**−**f** is higher than that of **2b**−**d** by at least one order of magnitude. The only previous data in water concerning these two anions are those of Schmidtchen who reported values of 1.86 and 2.1, respectively.[20] Upon comparing the selectivity of our receptor for oxyanions vs. chloride with that of other hosts (cf. Table 3) it appeared that the organocobalt complex is 10 times more selective than the better such hosts in water.

Table 3. Selectivity of hosts for oxyanions vs chloride

Entry	NO_3^-	CH_3COO^-	$H_2PO_4^-$	Receptors
1	0.2	15	20	**4a**
2	0.6	0.2[a]	−	Bis-Tren[8]
3	−	1.5	2.5	Macrotricyclic quaternary ammonium salt[20]

[a] $HCOO^-$ value.

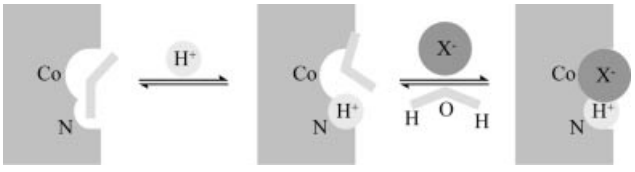
Our result is without precedent in the literature. The only known examples of a better complexation of the oxyanions have been found for non-protic solvents such as CH_3CN, DMSO and $CHCl_3$.[21−24]

As the respective hydration free energies of the chloride and the acetate anions are similar [$\Delta G_H(Cl^-) = -365$ kJ·mol^{-1}, $\Delta G_H(AcO^-) = -340$ kJ·mol^{-1}][3] the better acetate vs. chloride complexation can be rationalized

by means of both a stronger coordination of an oxygen-containing anion to a cobalt(III) center and a stronger hydrogen bond between an NH^+ and an oxygen atom. In the case of the dihydrogenophosphate, a rather strong hydration energy has been reported [$\Delta G_H(H_2PO_4^-) = -465$ kJ·mol^{-1}].[3] Thus the arguments given above cannot be sufficient to explain the stronger complexation of this anion vs. halides. We suggest that in this case the H_2PO_4 anion coordinated to the outer surface of the organocobalt receptor is partially solvated by several water molecules, thus contributing to the somehow surprising selectivity disclosed for this substrate.

Conclusion

Our organocobalt compound can be a genuine host for anion in water or in methanol provided that a source of protons is present in the solution. We have observed that a too-acidic medium can cause decomposition of the complex. This anion host is therefore most efficient in solutions whose pH is slightly acidic through the presence of a buffer. When no source of protons is present the aquo ligand cannot be displaced by any anions. This behaviour is reminiscent of an allosteric behaviour[25−27] of our molecule, as the bonding of the anion to the cobalt receptor is somehow modulated by prior protonation at another part of the molecule. This behaviour is represented schematically in Scheme 3.



Scheme 3. Representation of the allosteric phenomenon

Further work in line with this property, as well as modification of the cobalt complexes, is being actively pursued.

Experimental Section

General Remarks: All chemicals used [NEt_3·$(HF)_3$, NEt_3·HCl, NEt_3·HBr, NH_4I, NH_4OAc, NH_4NO_3 and $NH_4H_2PO_4$] were of analytical grade and dried under vacuum before use. Buffer solutions were prepared from 3-[*N*-morpholino]propanesulfonic acid (MOPS, hemisodium salt) or 2-[*N*-morpholino]ethanesulfonic acid (MES, 2 equivalents of hemisodium salt and 3 equivalents of acid). In water the pH of the thus obtained solutions is 7.1 and 5.5, respectively, whereas in methanol the pH is 6.4 and 5.4, respectively.

UV/Vis experiments were carried out in distilled water or in spectrophotometer UV-fluo methyl alcohol quality (Carlo Erba). Absorption spectra were recorded on a Uvikon XL spectrometer. pH was determined using a PHN78 (Tacussel electronique) with an ECS electrode.^{1}H NMR spectra were recorded at 300.13 MHz and $^{13}C\{^1H\}$ NMR spectra at 75.47 MHz on a Bruker FT instrument (AV-300). Chemical shifts (δ) and coupling constants (*J*) are expressed in ppm and Hz, respectively, and referenced to external TMS. The starting materiel $[CpCo(NCN)H_2O]^+$·PF_6^- (**1a**) was prepared according to a published method.[15] Elemental analyses were performed by the Service Central d′Analyse de l′Institut de Chimie (Strasbourg). Association constants were determined from a Scatchard plot [2n/X = f(2n)]. The respective concentrations of **4a** and **2n** in water or **1a**, **1b** and **2n** in methanol or methanol/water were determined by ^{1}H NMR integrations or UV/Vis Δabs variations. Reproducibility of multiple experiments afforded in general the same values for a determined anion within a 10% variation. All the selected values have an R^2 value greater than 0.90 and errors were estimated to be between 5 and 10%.

[Co{2,6-(Me_2NCH_2)$_2$$C_6H_3$}(η^5-$C_5H_5$)($H_2O$)]$PF_6$ (1a): ^{1}H NMR spectra of **1a** (5×10^{-4} M) in D_2O at pH 8.5: δ = 7.30 (d, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 7.21 (t, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 7.14 (d, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 5.26 (s, 5 H, C_5H_5), 4.59 and 3.87 (AB spin system, $^2J_{H\text{-}H}$ = 12.4, 2 H, CH_2N), 4.23 and 3.63 (AB spin system, $^2J_{H\text{-}H}$ = 14.0, 2 H, CH_2N-Co), 3.33 and 1.26 (2s, 6 H, Co-NMe_2), 2.31 (br. s, 6 H, NMe_2).

[Co{2,6-(Me_2NCH_2)$_2$$C_6H_3$}(η^5-$C_5H_5$)(MeOH)]$PF_6$ (1b): *n*-Hexane (80 mL) was slowly added to a solution of **1a** (0.240 g, 0.5 mmol) in CH_3OH (20 mL) and the solution was cooled to 0 °C for two days. This afforded **1b** as brown crystals, which were collected by filtration, washed with hexane and dried in vacuo (quantitative yield). ^{1}H NMR (CD_3OD): δ = 7.24 (d, $^3J_{H\text{-}H}$ = 7.2, 1 H, Ar), 7.16 (t, $^3J_{H\text{-}H}$ = 7.2, 1 H, Ar), 7.07 (d, $^3J_{H\text{-}H}$ = 7.2, 1 H, Ar), 5.37 (s, 5 H, C_5H_5), 4.50 and 3.63 (AB spin system, $^2J_{H\text{-}H}$ = 12.4, 2 H, CH_2N), 4.29 and 3.57 (AB spin system, $^2J_{H\text{-}H}$ = 14.0, 2 H, H_2N-Co), 3.40 and 1.29 (2s, 6 H, Co-NMe_2), 2.26 (br. s, 6 H, NMe_2) ppm. $^{13}C\{^1H\}$ NMR (CD_3OD): δ = 152.8, 148.0, 131.2, 126.2 and 12.7 (C_6H_3), 85.9 (C_5H_5), 77.7 (CH_2N-Co), 68.2 (CH_2N), 59.1 and 49.2 (Co-NMe_2), 30.7 (NMe_2). $C_{18}H_{28}CoF_6N_2OP$ (492.33): calcd. C 43.91, H 5.73, N 5.69; found C 44.03, H 5.73, N 5.62.

[Co{2,6-(Me_2NCH_2)$_2$$C_6H_3$}(η^5-$C_5H_5$)($NCCH_3$)]$PF_6$ (1c): Et_2O (80 mL) was slowly added to a solution of **1a** (0.240 g, 0.5 mmol) in CH_3CN (20 mL) and this solution was cooled to 0 °C for two days. This afforded **1c** as red crystals, which were washed with hexane and dried in vacuo (quantitative yield). ^{1}H NMR (CD_3CN): δ = 7.33 (m, 1 H, Ar), 7.09 (t, $^3J_{H\text{-}H}$ = 7.3, 1 H, Ar), 6.96 (m, 1 H, Ar), 5.38 (s, 5 H, C_5H_5), 4.12 and 3.47 (AB spin system, $^2J_{H\text{-}H}$ = 14.0, 2 H, CH_2N), 3.81 and 3.33 (AB spin system, $^2J_{H\text{-}H}$ = 13.0, 2 H, CH_2N-Co), 3.14 and 1.67 (2s, 6 H, Co-NMe_2), 2.30 (br. s, 6 H, NMe_2) ppm. $^{13}C\{^1H\}$ NMR (CD_3CN): δ = 153.2, 150.5, 150.2, 129.5, 125.7, 122.7 (C_6H_3), 135.4 (N*C*CH$_3$), 88.3 (C_5H_5), 76.7 (CH_2N-Co), 65.9 (CH_2N), 59.0 and 52.7 (Co-NMe_2), 45.7 (NMe_2), 1.1 (NC*C*H3) ppm. $C_{19}H_{27}CoF_6N_3P$ (501.34): calcd. C 45.52, H 5.43, N 8.38; found C 45.54, H 5.41, N 8.30.

[CoI{2,6-(Me_2NCH_2)$_2$$C_6H_3$}(η^5-$C_5H_5$)] (3): NaI (0.750 g, 5.0 mmol) was added to a solution of **1a** (0.240 g, 0.5 mmol) in acetone (10 mL). The colour of the solution turned from purple to green in 5 minutes. After removal of insoluble material by filtration, the product was precipitated by addition of *n*-hexane. Yield: 2.21 g (75%). ^{1}H NMR ([D$_6$]acetone): δ = 7.13 (d, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 6.71 (t, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 6.66 (d, $^3J_{H\text{-}H}$ = 7.1, 1 H, Ar), 5.22 (s, 5 H, C_5H_5), 4.18 and 3.42 (AB spin system, $^2J_{H\text{-}H}$ = 12.2, 2 H, CH_2N), 3.74 and 3.18 (AB spin system, $^2J_{H\text{-}H}$ = 13.0, 2 H, H_2N-Co), 3.00 and 2.53 (2s, 6 H, Co-NMe_2), 2.22 (s, 6 H, NMe_2).

[Co{2-(Me_2NCH_2)-6-($Me_2ND^+CH_2$)C_6H_3}(η^5-C_5H_5)(D_2O)]$(PF_6)_2$ (4a): HPF_6 (pH 2.2 in D_2O) was added to a solution of **1a** (5×10^{-4} M) in D_2O, leading to a pH of ca. 4.0. ^{1}H NMR (D_2O): δ = 7.39 (d, $^3J_{H\text{-}H}$ = 7.2, 1 H, Ar), 7.32 (t, $^3J_{H\text{-}H}$ = 7.2, 1 H, Ar), 7.18

X-ray Crystallographic Study: Single crystals suitable for X-ray diffraction analysis were obtained as described above. Data were collected on a Nonius KappaCCD diffractometer, using Mo-K_α graphite-monochromated radiation (λ = 0.7107 Å), and ω scans. Absorption corrections were partially included in the data reduction procedure. The structures were solved by direct methods and refined against |F|. Hydrogen atoms were introduced in structure factor calculations as fixed contributors by their computed coordinates [d(C-H) = 0.95 Å, B(H) = 1.3*Beqv Å^2 of the attached carbon atom] except for the OH protons of **1a**, which were located in difference Fourier maps. The absolute structures were determined by refinement of Flack's x parameter. For all computations, the Nonius OpenMoLeN package[28] was used. Further experimental details are given in Table 4.

Phosphacarborane Chemistry: The Synthesis of the Parent Phosphadicarbaboranes *nido*-7,8,9-$PC_2B_8H_{11}$ and [*nido*-7,8,9-$PC_2B_8H_{10}$]$^-$, and Their 10-Cl Derivatives − Analogs of the Cyclopentadienide Anion

Keywords: Ab initio calculations / Boranes / Clusters / Phosphorus

The reaction of the carborane *nido*-5,6-$C_2B_8H_{12}$ (**1**) with PCl_3 in dichloromethane in the presence of a "proton sponge" [PS = 1,8-bis(dimethylamino)naphthalene], followed by hydrolysis of the reaction mixture, resulted in the isolation of the eleven-vertex *nido*-phosphadicarbaboranes 7,8,9-$PC_2B_8H_{11}$ (**2**) and 10-Cl-7,8,9-$PC_2B_8H_{10}$ (**10-Cl-2**), depending on the ratio of the reactants. Both of these compounds can be deprotonated by PS to give the *nido* anions [7,8,9-$PC_2B_8H_{10}$]$^-$ (**2**$^-$) and [10-Cl-7,8,9-$PC_2B_8H_9$]$^-$ (**10-Cl-2**$^-$). The molecular geometries of all compounds were optimized by ab initio methods at a correlated level of theory [RMP2(fc)] using the 6-31G* basis set and their correctness was assessed by a comparison of the experimental ^{11}B NMR chemical shifts with those calculated by the GIAO-SCF/II//RMP2(fc)/6-31G* method. Moreover, the structure of **10-Cl-2**$^-$ was determined by an X-ray diffraction analysis. The anionic compounds **2**$^-$ and **10-Cl-2**$^-$ are analogs of the Cp (Cp = η^5-$C_5H_5^-$) anion.

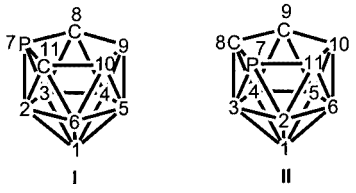
Introduction

There is current interest in the synthesis and chemistry of phosphacarboranes since the presence of P as a B-cluster constituent gives borane clusters carborane character. The cluster P atom in these species contributes three electrons and three orbitals into the cluster bonding, as does a carborane CH group, while the remaining two electrons reside in the exopolyhedral P sp^3 orbital.[1] Recent efforts are dominated by successful attempts at the isolation of phosphacarborane analogues of tricarbollides (11-vertex *nido*-tricarbaboranes).[2] In this field of chemistry, one of our groups has recently reported preliminary results on the synthesis of the *nido*-phosphadicarbaboranes 7,8,11-$PC_2B_8H_{11}$ and [7,8,11-$PC_2B_8H_{10}$]$^-$ based on the reaction between [6,9-$C_2B_8H_{10}$]$^{2-}$ and PCl_3.[3] The first species is an analog of the neutral tricarbollide 7,8,9-$C_3B_8H_{12}$ and the second anion is analogous to [7,8,9-$C_3B_8H_{11}$]$^-$.[4] Both anions, [7,8,11-$PC_2B_8H_{10}$]$^-$ and [7,8,9-$C_3B_8H_{11}$]$^-$ are also regarded[2] as perfect Cp analogs as they are monoanionic and contain an open pentagonal face which can donate five electrons for the η^5-type coordination to metal ions. As shown in structures **I** and **II**, the presence of the P vertex in the open pentagonal face of an eleven-vertex phosphadicarbaborane anion with the general formula [$PC_2B_8H_{10}$]$^-$ allows for two possible configurations of open-face heteroatoms in adjacent positions. While Cp analogs of configuration **I** are known,[3] those of structure **II** have not yet been reported. Although Sneddon et al. have prepared neutral compounds 7-R-7,8,9-$PC_2B_8H_{10}$ (R = Me and Ph)[5] adopting configuration **II**, these cannot be regarded as Cp analogs as they are not monoanionic. We report here a simple and efficient method for the synthesis of the missing Cp analogs of structure **II**, specifically the preparation of the neutral compound 7,8,9-$PC_2B_8H_{11}$ and the anionic [7,8,9-$PC_2B_8H_{10}$]$^-$, and their 10-Cl derivatives.



Results and Discussion

Syntheses

As shown in Scheme 1 [path *i)*] (C = CH, vertices of individual polyhedra denote BH groups), treatment of *nido*-

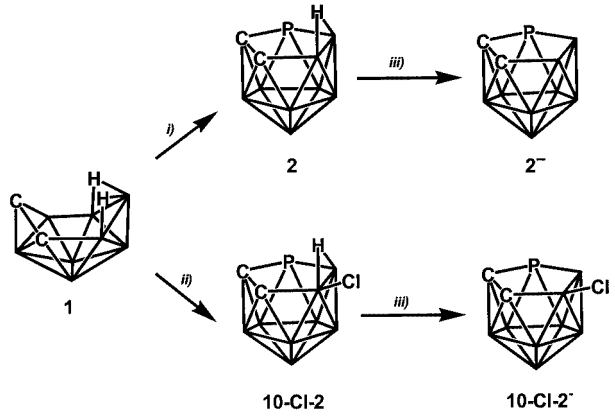
5,6-$C_2B_8H_{12}$ (**1**)[6] with excess PCl_3 in the presence of a proton sponge [PS = 1,8-bis(dimethylamino)naphthalene] (molar ratio **1**/PS = 1:1.5) in CH_2Cl_2, at room temperature for 48 h, followed by hydrolysis and chromatographic purification of the products, resulted in the isolation of the 11-vertex phosphadicarbaborane *nido*-7,8,9-$PC_2B_8H_{11}$ (**2**) in a yield of 38% (based on **1**). One of the chromatographic fractions contained the dicarbaborane *closo*-1,2-$C_2B_8H_{10}$, which justifies the overall stoichiometry as in Equation (1); otherwise the formation of **2** could not be explained [Equation (1)].



Scheme 1

$$2\,C_2B_8H_{12}\,(\mathbf{1}) + PCl_3 + 3\,PS \rightarrow PC_2B_8H_{11}\,(\mathbf{2}) + C_2B_8H_{10} + 3\,PSH^+Cl^- \quad (1)$$

We assume that 1 equiv. of **1** is oxidized to give *closo*-1,2-$C_2B_8H_{10}$ under the formation of transient $[PHCl_2]$ [Equation (2)] which then reacts with **1** according to Equation (3) to produce the phoshacarborane **2**.

$$C_2B_8H_{12} + PCl_3 + PS \rightarrow C_2B_8H_{10} + [PHCl_2] + PSH^+Cl \quad (2)$$

$$C_2B_8H_{12} + [PHCl_2] + 2\,PS \rightarrow PC_2B_8H_{11} + 2\,PSH^+Cl^- \quad (3)$$

In contrast to the reaction according to Equation (1), the same reaction of **1** with an excess of PCl_3, but using a different **1**/PS ratio (1:2) [Scheme 1, path *ii)*], leads to the formation of the 10-Cl-substituted derivative 10-Cl-*nido*-7,8,9-$PC_2B_8H_{10}$ (**10-Cl-2**) as a predominant product (yield 30%).

$$C_2B_8H_{12}\,(\mathbf{1}) + PCl_3 + 2\,PS \rightarrow PC_2B_8H_{10}Cl\,(\mathbf{10\text{-}Cl\text{-}2}) + 2\,PSH^+Cl^- \quad (4)$$

From the mechanistic viewpoint, reactions according to Equations (1) and (4) are consistent with the insertion of the P vertex into the area identified by the C(6), B(7), B(8), and B(9) vertices in structure **1** (see Scheme 1). Interestingly, in the reaction corresponding to Equation (4), the Cl substituent enters a position not adjacent to the P vertex, as observed earlier in the case of the $P_2C_2B_7H_8Cl$ derivatives.[7] Both **2** and **10-Cl-2** can easily be deprotonated by reactions with stoichiometric amounts of PS in CH_2Cl_2 to give the crystalline salts PSH^+ [*nido*-7,8,9-$PC_2B_8H_{10}$]$^-$ (compound $PSH^+\mathbf{2}^-$) and PSH^+ [10-Cl-*nido*-7,8,9-$PC_2B_8H_9$]$^-$ (compound $PSH^+\mathbf{10\text{-}Cl\text{-}2}^-$) upon careful addition of pentane onto the surface of the solution. The deprotonation reaction thus generates a bare pentagonal face, a favorable feature for employing these anions as Cp analogs for metal complexation.

NMR Spectroscopic Studies

The asymmetrical structure with a contiguous P−C−C string in the open face of an 11-vertex framework (see Scheme 1) is in agreement with the NMR-spectroscopic data of all the compounds described above. The ^{11}B NMR spectra of all the isolated compounds consist of eight different resonances with some incidental overlaps. All of them are doublets, except that the spectra of the substituted compounds **10-Cl-2** and **10-Cl-2**$^-$ contain one B(10) singlet, the resonances being shifted downfield ($\Delta\delta$ = 11.4 and 11.8 ppm, respectively) in comparison to the unsubstituted counterparts. It is also obvious that the ^{11}B NMR signals of the anionic compounds **2**$^-$ and **10-Cl-2**$^-$ are all shifted upfield ($\Delta\delta$ = 11.2 and 11.0 ppm, respectively) in comparison to those of the neutral compounds **2** and **10-Cl-2**. Graphical comparisons of the ^{11}B NMR shifts of **2**, **10-Cl-2**, and the isostructural tricarbaboranes *nido*-7,8,9-$C_3B_8H_{12}$ (compound **3**)[4] are given in Figure 1 (bottom part) together with similar comparisons for the corresponding anionic species **2**$^-$, **10-Cl-2**$^-$, and [*nido*-7,8,9-$C_3B_8H_{11}$]$^-$ (**3**$^-$)[4] (top diagrams).

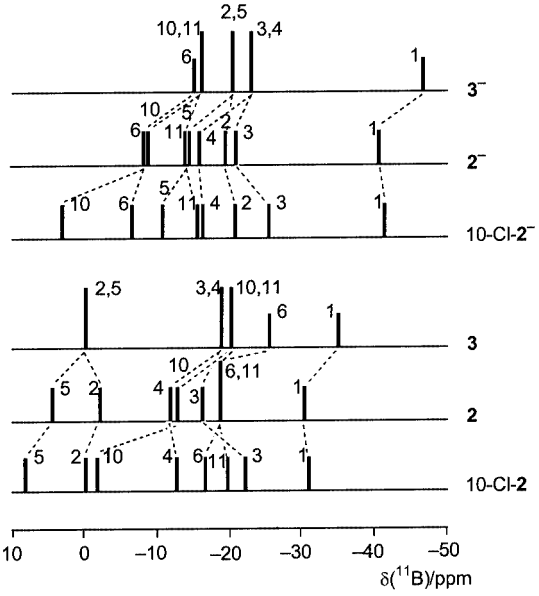


Figure 1. Stick representation and intercomparison of the $\delta(^{11}B)$ chemical shifts for neutral *nido* compounds 7,8,9-$PC_2B_8H_{11}$ (**2**), 10-Cl-7,8,9-$PC_2B_8H_{10}$ (**10-Cl-2**), and 7,8,9-$C_3B_8H_{12}$ (**3**) (bottom diagrams) and their anionic counterparts [7,8,9-$PC_2B_8H_{10}$]$^-$ (**2**$^-$), [10-Cl-7,8,9-$PC_2B_8H_9$]$^-$ (**10-Cl-2**$^-$), and [7,8,9-$C_3B_8H_{11}$]$^-$ (**3**$^-$) (top diagrams)

Figure 1 clearly shows that the δ(^{11}B) data of individual isostructural couples **2/3** and **2**$^-$**/3**$^-$ are very similar (spectrum span δ = 36.4/35.5 and 35.2/31.9 ppm, respectively), but all signals of the P compounds are shifted downfield by an increment of Δδ ≈ 5 ppm. Similar deshielding effects are also observed in the corresponding ^{1}H NMR spectra. These straightforward NMR similarities between tricarbaboranes and the corresponding phosphadicarbaborane counterparts reflect the isolobal relationship between CH and bare P vertices, which is that each contribute three electrons to the cluster bonding scheme. The characteristic feature of the ^{1}H NMR spectra of all compounds isolated is the presence of one CH(9) singlet and one CH(8) doublet ($^2J_{PH}$ coupling). The spectra of the neutral compounds **2** and **10-Cl-2** contain a typical broad, high-field μH(10,11) resonance at δ = −2.48 and −1.12 ppm, respectively. The ^{31}P NMR spectra of all compounds show one singlet and the ^{13}C NMR spectra display one doublet ($^1J_{P-C}$ splitting) and one broader singlet (with fine multiplet $^1J_{CB}$ splitting) due to C(8) and C(9) resonances, respectively. As in the ^{11}B NMR spectra, there are similar upfield shifts of both CH(9) (Δδ = 1.58 [9.3] and 1.79 [9.8] ppm) and CH(8) (Δδ = 1.75 [27.7] and 1.82 [28.9] ppm) resonances, in the corresponding ^{1}H and ^{13}C (data in square brackets) NMR spectra of anions **2**$^-$ and **10-Cl-2**$^-$, with respect to those of the neutral **2** and **10-Cl-2**. This effect is copied in the ^{31}P NMR spectra in which the singlet resonances of the anionic species **2**$^-$ and **10-Cl-2**$^-$ again exhibit shielding (Δδ = 33.1 and 27.7 ppm) with respect to those of the neutral compounds **2** and **10-Cl-2**. As shown in Figure 2, there is a linear correlation between δ(^{13}C) and δ(^{1}H) shifts for CH(8) (line A) and CH(9) (line B) cluster units which can be useful for further NMR-spectroscopic considerations in the fields of carborane and heterocarborane chemistry.

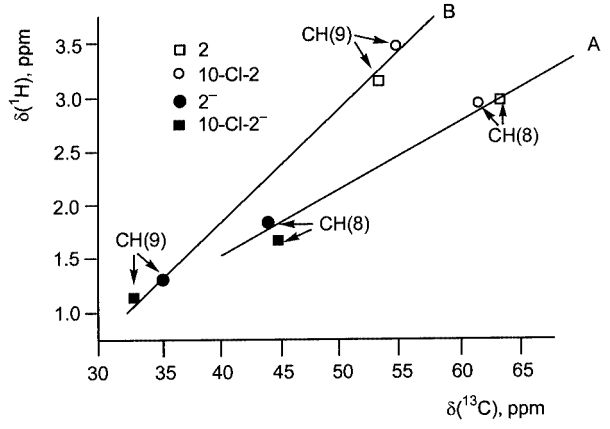

Figure 2. Plot of δ(^{1}H) versus δ(^{13}C) chemical shifts for CH(8) (line A) and CH(9) (line B) cluster units for the *nido*-phosphadicarbaboranes 7,8,9-$PC_2B_8H_{11}$ (**2**), 10-Cl-7,8,9-$PC_2B_8H_{10}$ (**10-Cl-2**), [7,8,9-$PC_2B_8H_{10}$]$^-$ (**2**$^-$), and [10-Cl-7,8,9-$PC_2B_8H_9$]$^-$ (**10-Cl-2**$^-$)

Geometry Optimization

Gimarc's topological stabilization rule[8] suggests that elements with higher electronegativity than boron, such as e.g. C and P, occupy cluster sites of the highest electronegativity of a parent boron hydride from which a corresponding isostructural heteroborane is formally derived. Indeed, the contiguous P−C−C string substitutes the analogous B−B−B string of the hypothetical [*nido*-$B_{11}H_{11}$]$^{4-}$ in its open pentagonal belt [RMP2(fc)/6-31G* natural population analysis (NPA) charge is −0.334, in contrast to −0.170 attributed to the B_5 girdle capped by B(1)].[7] The experimental NMR spectra indicate a total lack of symmetry in all compounds and, consequently, their geometries were fully optimized (see Figure 3) without any symmetry constraints beginning at the SCF level with 3-21G and 6-31G* basis sets. Frequency calculations confirmed the structures to be minima on the corresponding 6-31G* potential energy hypersurfaces. The final level of optimization was second-order Møller−Plesset perturbation theory in frozen core approximation (fc). These geometries were used for GIAO-SCF/II//RMP2(fc)/6-31G* (level of NMR theory// geometry) calculations of the ^{11}B and ^{13}C NMR shifts. Comparisons of these shifts with experimental values are in satisfactory agreement [see Exp. Sect., maximum differences for δ(^{11}B) fall within the range of 5 ppm with the exception of B(4) in **2** (δ = 7 ppm), δ(^{13}C) calculations performed slightly worse but these usually show strong dependence on the theory and basis set used[9]] and thus provide evidence for believing that the RMP2(fc)/6-31G* internal coordinates can be deemed as good representations of the molecular geometries of **2** and **10-Cl-2** and of the anionic species **2**$^-$ and **10-Cl-2**$^-$ in their solutions. The calculated geometries are depicted in Figure 3 and Table 1 offers salient computed geometrical parameters. Apparently, the presence of the P vertex is a principal source of the distortion from a regular "icosahedral-like" shape. The carbon atoms contribute to such a deformation to a lesser extent.

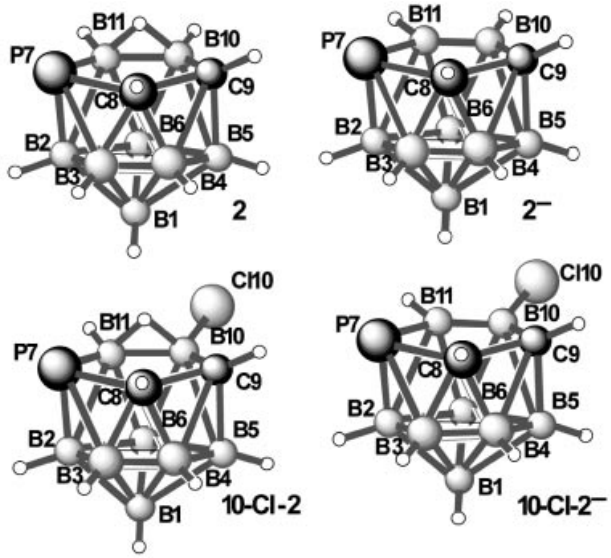

Figure 3. RMP2(fc)/6-31G*-optimized structures of the phosphadicarbaboranes 7,8,9-$PC_2B_8H_{11}$ (**2**), 10-Cl-7,8,9-$PC_2B_8H_{10}$ (**10-Cl-2**), [7,8,9-$PC_2B_8H_{10}$]$^-$ (**2**$^-$), and [10-Cl-7,8,9-$PC_2B_8H_9$]$^-$ (**10-Cl-2**$^-$)

[a] For atomic numbering, see Figure 3. [b] Lower pentagon.

The most remarkable features of the computed molecular structures of these systems are the considerable deformations of the open pentagonal belts. For instance, the C(8)−P(7)−B(11) angles for **2** and **10-Cl-2** are 91.5 and 91.4°, respectively. Such deviations from a regular pentagonal angle of 108° are by far the largest noticed so far in the family of heteroboranes that contain a third-row element.[7,10] In the case of the corresponding anions, **2$^-$** and **10-Cl-2$^-$**, these angles are opened by ca. 3.5° with respect to **2** and **10-Cl-2**, but still deviate substantially from 108°. On the other hand, such a pronounced narrowing in **2** and **10-Cl-2** is likely to be compensated by opening of the P(7)−C(8)−C(9) angles when compared with their smaller values for both anions. Moreover, these pentagons are not planar, as exemplified by some dihedral angles in Table 1, although such a nonplanarity is less marked in the neutral species. As found in other phosphaboranes,[7,11] the Cl-substitution brings about only marginal effects in the molecular cage geometry relative to an unsubstituted compound (see Table 1). The P−C, P−B, C−C, and B−B nearest-neighbor separations in the open pentagonal belts resemble those determined for the four $P_2C_2B_7H_9$ isomers and their Cl derivatives[7], at the same level of theory [e.g. *r*(C−C), retain their aliphatic single-bond character, which is also revealed by their Wiberg bond indices (WBI, natural atomic bond orders) calculated for **2** and **2$^-$**: 0.962 (0.833) and 0.946 (0.817), respectively]. Whereas the WBI for the remaining four linkages of the open pentagonal face of **2$^-$** span a narrow interval of <0.773, 0.866> (<0.688, 0.823>), the presence of the hydrogen bond in **2** considerably decreases electron delocalization in the open pentagonal face {WBI for *r*[B(10)−B(11)] = 0.457 (0.619)}.

X-ray Diffraction Studies

The structure of PSH^+**10-Cl-2$^-$** was determined unambiguously by an X-ray diffraction analysis (for selected crystallographic parameters see Tables 2 and 3). As seen from Figure 4, the structure of the anionic part **10-Cl-2$^-$** is consistent with all NMR-spectroscopic data and compares well with the calculated RMP2(fc)/6-31G* geometrical parameters. The computed and experimental structural parameters in Tables 1 and 2, respectively, are generally in good agreement. The cage P−C, P−B, C−C and C−B, B−B distances in the open pentagonal face are 1.866(4), 1.939(4), 1.517(4) and 1.596(5), 1.723(4) Å, respectively, similar to those found crystallographically for the diphosphadicarbaboranes $P_2C_2B_7H_9$, the other cluster C−B and P−B, B−B, and B−Cl separations fall within usual limits.[7] The structure determination also confirms the asymmetrical arrangement of the C and P heteroatoms within a distorted open pentagonal face. As also exhibited in the calculated structure, the distortion is due to relatively long P−B and P−C separations as demonstrated, e.g., by the torsion angle B(11)−P−C(8′)−C(9′) −13.3(2)°. Also the C(8′)−P−B(11) angle shows at 94.92(14)°, a remarkable deviation from the ideal 108° in a regular pentagon. We were even able to localize the bridging N−H−N hydrogen in the cationic (PSH^+) part of the molecule, which is closer to one of the nitrogen atoms by 0.7454(3) Å than to the other.

Conclusions

The neutral compound 7,8,9-$PC_2B_8H_{11}$ (**2**) and its chlorinated derivative **10-Cl-2** can now easily be prepared by phosphorus insertion from the readily available 5,6-$C_2B_8H_{12}$ (**1**) dicarbaborane.[6] We have demonstrated that the constitution of **2** is analogous to that of the neutral tricarbollide 7,8,9-$C_2B_8H_{12}$ (**3**) as the bare P vertex is isolobal with the cage CH group. The bridging hydrogen atom in **2** can be removed by deprotonation to generate anion **2$^-$**. This anion is analogous to the Cp anion as it is monoanionic, contains a bare pentagonal face and would then be capable of donating five electrons for η^5-type complexation of suitable metal centers. This is also justified by similar electron densities in the linkages forming the PCCBB pentagon in terms of the Wiberg and natural bond orders. Indeed, recent experiments in our laboratories[12] point to facile formation of the isomeric (cyclopentadienyl)-ferraphosphadicarbaboranes of general formula $CpFePC_2B_8H_{10}$, analogues of ferrocene and the earlier reported[2] ferratricarbollides. Apart from extending metal complexation reactions of **2$^-$**, we are also exploring various

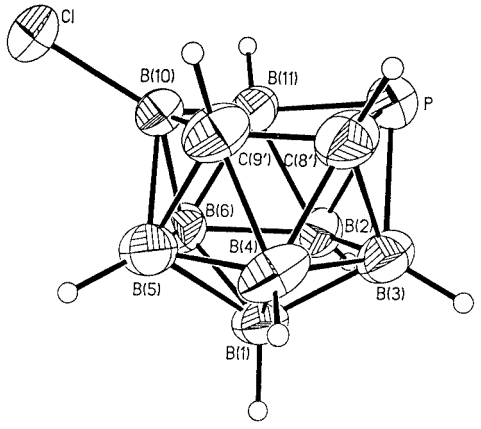

Figure 4. ORTEP representation of the crystallographically determined molecular structure of the $[10\text{-Cl-}nido\text{-}7,8,9\text{-}PC_2B_8H_9]^-$ (**10-Cl-2**$^-$) anion

isomerization and substitution reactions of the phosphadicarbaborane species outlined in this paper. Moreover, phosphorus insertion reactions with other borane and carborane compounds are also being studied with the aim of generating new types of chemically versatile heteroborane cages.

Experimental Section

General Procedures: All reactions were carried out with the use of standard vacuum or inert-gas techniques as described by Shriver,[13] although some operations, such as column LC, were carried out in air. The starting carborane **1** was prepared according to the literature.[6] Dichloromethane and hexane (both from Fluka) were dried with CaH_2 and freshly distilled before use. Other chemicals were reagent- or analytical grade and were used as purchased. Column chromatography was carried out using silica gel (Aldrich, 130−270 mesh) as the stationary phase. The purity of individual chromatographic fractions was checked by analytical TLC on Silufol (silica gel on aluminum foil; detection by diiodine vapor, followed by 2% aqueous $AgNO_3$ spray). Melting points were measured in sealed capillaries under argon and are uncorrected. Low-resolution mass spectra were obtained using a Finnigan MAT MAGNUM ion trap quadrupole mass spectrometer equipped with a heated inlet option, as developed by Spectronex AG, Basel, Switzerland (70 eV, EI ionisation). Proton (^1H) and boron (^{11}B), and phosphorus (^{31}P) NMR spectroscopy was performed at 11.75 and 5.88 Tesla with Varian XL-500, and ARX 250 instruments and the ^{13}C NMR spectra were measured with a Bruker DRX 500 spectrometer, equipped for heteronuclear $^{13}C\{^1H,^{11}B\}$ triple-resonance experiments. The [^{11}B-^{11}B]-COSY[14] and ^1H-{^{11}B(selective)}[15] NMR experiments were essentially as described in other related papers from our laboratories.[16] Chemical shifts are given in ppm to high frequency (low field) of Ξ = 32.083971 MHz (nominally $F_3B{\cdot}OEt_2$ in $CDCl_3$) for ^{11}B (quoted ±0.5 ppm), Ξ = 25.144 MHz ($SiMe_4$) for ^{13}C (quoted ±0.5 ppm), Ξ = 40.4805 MHz (H_3PO_3) for ^{31}P (quoted ±0.5 ppm), and Ξ = 100 MHz ($SiMe_4$) for ^1H (quoted ±0.05 ppm), Ξ being defined as in ref.[17] Solvent resonances were used as internal secondary standards. Coupling constants $^1J(^{11}B$-$^1H)$ are taken from resolution-enhanced ^{11}B spectra with digital resolution ±8 Hz and are given in Hz. The ^{11}B and ^1H NMR spectra of all phosphacarborane compounds discussed in this work can easily be assigned using two-dimensional [^{11}B-^{11}B]-COSY spectroscopy[14] combined with $^1H\{^{11}B$(selective)$\}$[15] measurements. Moreover, all $^1H\{^{11}B\}$ resonances of individual BH and CH vertices adjacent to the cluster P vertex are spit into doublets due to $^2J_{PH}$ coupling, which helps all cluster resonances to be assigned. IR spectra were obtained with an EU 9512 Pye−Unicam Fourier transform spectrometer.

***nido*-7,8,9-$PC_2B_8H_{11}$ (2):** A solution of compound **1** (5.0 g, 40.2 mmol) in CH_2Cl_2 (50 mL) was cooled to 0 °C and treated with PS (10.0 g, 46.7 mmol) whilst stirring for 15 min. To this solution, PCl_3 (3.5 mL, 40.4 mmol) was added dropwise over a period of 15 min and the mixture was then stirred for 24 h at ambient temperature. The mixture was then cooled again to 0 °C and decomposed carefully with water (50 mL) whilst stirring. The CH_2Cl_2 layer was separated, the solvent evaporated and the residual materials were separated by chromatography on a silica gel column (30 × 2.5 cm) to collect a pure fraction of R_f = 0.22 which was identified by NMR spectroscopy as **2** (2.42 g, 39%). Crystallization of an analytical sample of **2** by slow concentration of a pentane solution. R_f (hexane) = 0.22; m.p. 260 °C. ^{11}B NMR ($CDCl_3$, ppm): δ = 5.7 (d, $^1J_{B-H}$ = 162 Hz, 1 B, B^5), 2.2 (d, $^1J_{B-H}$ = 158 Hz, 1 B, B^2), −12.8 (d, 1 B, B^4), −13.6 (d, $^1J_{B-\mu H}$ = 42 Hz, 1 B, B^{10}), −17.2 (d, 1 B, B^3), ca. −18.0 (d, 1 B, B^6), −18.3 (d, 1 B, B^{11}), −30.9 (d, $^1J_{B-H}$ = 158 Hz, 1 B, B^1), all theoretical [^{11}B-^{11}B]-COSY cross-peaks observed. ^{11}B NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 9.5 (B^5), 7.0 (B^2), −11.1 (B^4), −13.9 (B^{10}), −14.2 (B^3), −17.0 (B^6), −17.5 (B^{11}), −30.2 (B^1). $^1H\{^{11}B\}$ NMR ($CDCl_3$, ppm): δ = 3.22 (s, 1 H, H^9), 3.02 (d, $^2J_{P-H}$ = 17 Hz, 1 H, H^8),. 2.96 (s, 1 H, H^5), 2.68 (d, $^2J_{P-H}$ = 23 Hz, 1 H, H^2), 2.35 (d, $^2J_{P-H}$ = 23 Hz, 1 H, H^3), 2.34 (s, 1 H, H^4),. 2.29 (s, 1 H, H^{10}), 1.88 (s, 1 H, H^1), 1.73 (s, 1 H, H^{11}), 1.72 (s, 1 H, H^6), −2.73 (q, $^2J_{H-H}$ = 12 Hz, 1 H, $\mu H^{10,11}$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, ppm): δ =

63.3 (d, $^1J_{P-C}$ = 72 Hz, 1 C, C^8), 53.4 (s, 1 C, C^9). ^{13}C NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 58.3 (C^8), 44.8 (C^9). $^{31}P\{^1H\}$ NMR ($CDCl_3$, ppm): δ = −60.1 (s, 1 P, P^7). IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2926 (C−H), 2576 (B−H). MS (70 eV, EI): *m*/*z* (%) = 154 (9) $[M]^+$, 150 (100) $[M - 4\ H]^+$; elemental analysis: calcd. (%) for $C_2H_{11}B_8P$ (152.64): B 56.71, found B 55.11.

10-Cl-*nido*-7,8,9-$PC_2B_8H_{10}$ (10-Cl-2): To a solution of **1** (2.00 g, 16.1 mmol) in CH_2Cl_2 (40 mL) was added PS (7.00 g, 32.7 mmol), followed by dropwise addition of PCl_3 (5 mL, 57.7 mmol) whilst stirring and cooling to 0 °C. The mixture was then stirred at ambient temperature for 24 h and carefully treated with water (50 mL) at 0 °C and the CH_2Cl_2 layer was concentrated to dryness. The residual solid was then separated by LC on a silica gel column (2.5 × 35 cm) using hexane as a mobile phase to collect three pure fractions of R_f (hexane) = 0.22, 0.13, and 0.07 which were concentrated to dryness and identified by ^{11}B NMR spectroscopy as **2** (130 mg, 5%), 1,2-$C_2B_8H_{10}$ (125 mg, 6%), and **10-Cl-2** (910 mg, 30%), respectively. Crystallization of **10-Cl-2** by slow concentration of a pentane solution gave an analytically pure sample. R_f (hexane) = 0.07; m.p. 150 °C. ^{11}B NMR ($CDCl_3$, ppm): δ = 7.8 (d, $^1J_{B-H}$ = 165 Hz, 1 B, B^5), −0.4 (d, $^1J_{B-H}$ = 154 Hz, 1 B, B^2), −2.2 (s, 1B, B^{10}), −13.1 (d, $^1J_{B-\mu H}$ = 177 Hz, 1 B, B^4), −16.9 (d, $^1J_{B-H}$ = 154 Hz, 1 B, B^6), ca. −19.9 (d, $^1J_{B-H}$ = 158 Hz, 1 B, B^{11}), −22.8 (d, $^1J_{B-H}$ = 173 Hz, 1 B, B^3), −31.2 (d, $^1J_{B-H}$ = 154 Hz, 1 B, B^1), all theoretical [^{11}B-^{11}B]-COSY cross-peaks observed. ^{11}B NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 11.4 (B^5), 4.9 (B^2), −2.0 (B^{10}), −11.7 (B^4), −15.5 (B^6), −18.5 (B^3), −18.8 (B^{11}), −30.7 (B^1). $^1H\{^{11}B\}$ NMR ($CDCl_3$, ppm): δ = 3.48 (s, 1 H, H^9), 3.35 (s, 1 H, H^5), 2.96 (d, $^2J_{P-H}$ = 28 Hz, 1 H, H^8), 2.61 (d, $^2J_{P-H}$ = 21 Hz, 1 H, H^2), 2.39 (s, 1 H, H^4), 2.20 (d, $^2J_{P-H}$ = 14 Hz, 1 H, H^3), 1.98 (s, 1 H, H^6), 1.85 (d, $^2J_{P-H}$ = 55 Hz, 1 H, H^{11}), 1.80 (s, 1 H, H^1), −1.12 (q, $^2J_{H-H}$ = 9 Hz, 1 H, $\mu H^{10,11}$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, ppm): δ = 61.5 (d, $^1J_{P-C}$ = 72 Hz, 1 C, C^8), 54.6 (q, $^1J_{C-B} \approx$ 33 Hz, 1 C, C^9). ^{13}C NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 56.1 (C^8), 47.6 (C^9). $^{31}P\{^1H\}$ NMR ($CDCl_3$, ppm): δ = −67.7 (s, 1 P, P^7). IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2932 (C−H), 2581 (B−H). MS (70 eV, EI), *m*/*z* (%) = 189 (5) $[M]^+$, 185 (100) $[M - 4\ H]^+$. $C_2H_{10}B_8ClP$ (187.13): calcd. B 46.26; found B 45.12.

PSH$^+$[*nido*-7,8,9-$PC_2B_8H_{10}$]$^-$ (PSH$^+$2$^-$): To a solution of **2** (129 mg, 0.85 mmol) in CH_2Cl_2 (10 mL) was added PS (193 mg, 0.9 mmol) whilst stirring and cooling to 0 °C. Onto the surface of the solution, a layer of hexane (20 mL) was carefully added and the mixture was left to crystallize for 48 h. The colorless crystals were then isolated by filtration, washed with hexane, and vacuum-dried at room temperature to give PSH$^+$**2**$^-$ (290 mg, 93%). Crystallization of an analytical sample was achieved by diffusion of pentane vapors into a CH_2Cl_2 solution. R_f (CH_2Cl_2) = 0.1; m.p. 230 °C. ^{11}B NMR ($CDCl_3$, ppm): δ = −8.0 (d, 1 B, B^6), −8.3 (d, 1 B, B^{10}), −13.6 (d, 1 B, B^{11}), −14.4 (d, $^1J_{B-H} \approx$ 150 Hz, 1 B, B^{10}), −15.5 (d, $^1J_{B-H} \approx$ 165 Hz, 1 B, B^4), −19.0 (d, $^1J_{B-H}$ = 143 Hz, 1 B, B^2), −20.9 (d, $^1J_{B-H}$ = 158 Hz, 1 B, B^3), −41.1 (d, $^1J_{B-H}$ = 142 Hz, 1 B, B^1), all theoretical [^{11}B-^{11}B]-COSY cross-peaks observed. ^{11}B NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = −3.7 (B^6), −10.4 (B^{10}), −13.8 (B^5), −14.4 (B^{11}), −14.7 (B^4), −17.5 (B^2), −19.6 (B^3), −42.7 (B^1). $^1H\{^{11}B\}$ NMR ($CDCl_3$, ppm): δ = 2.16 (d, $^2J_{P-H}$ = 10 Hz, 1 H, H^3), 2.15 (s, 1 H, H^6), 2.13 (s, 1 H, H^4), 2.03 (s, 1 H, H^9), 1.81 (s, 1 H, H^5), 1.80 (s, 1 H, H^{10}), 1.46 (d, $^2J_{P-H}$ = 30 Hz, 1 H, H^8), 1.18 (d, $^2J_{P-H}$ = 40 Hz, 1 H, H^{11}), 1.18 (d, $^2J_{P-H}$ = 20 Hz, 1 H, H^2), 1.02 (s, 1 H, H^1). $^{13}C\{^{11}B,^1H\}$ NMR (CD_3CN, ppm): δ = 44.1 (s, 1 C, C^9), 35.4 (d, $^1J_{C-P}$ = 55 Hz, 1 C, C^8). $^{13}C\{^{11}B\}$ NMR (CD_3CN, ppm): δ = 44.1 (d, $^1J_{C-H}$ = 162 Hz, 1 C, C^9), 35.4 (dd, $^1J_{C-H}$ = 169, $^1J_{C-P} \approx$ 60 Hz, 1 C, C^8). ^{13}C NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 38.2 (C^9), 28.6 (C^8). $^{31}P\{^1H\}$ NMR (CD_3CN, ppm): δ = −91.0 (s, 1 P, P^7). PSH$^+$[10-Cl-*nido*-7,8,9-$PC_2B_8H_9$]$^-$ (PSH$^+$10-Cl-2$^-$): To a solution of **10-Cl-2** (200 mg, 1.1 mmol) in hexane (20 mL), a solution of PS (300 mg, 1.4 mmol) in hexane was added whilst stirring and cooling to 0 °C. The colorless crystals that deposited were filtered, washed with hexane, and vacuum dried at room temperature to give PSH$^+$**10-Cl-2**$^-$ (390 mg, 91%). Crystallization of an analytical sample by diffusion of pentane vapors into a CH_2Cl_2 solution. R_f (CH_2Cl_2) = 0.04; m.p. 155 °C. ^{11}B NMR (CD_3CN, ppm): δ = 3.0 (s, 1 B, B^{10}), −7.3 (d, $^1J_{B-H}$ = 138 Hz, 1B, B^6), −11.8 (d, $^1J_{B-H}$ = 147 Hz, 1B, B^5), −16.4 (d, 1B, B^{11}),−17.2 (d, $^1J_{B-H} \approx$ 165 Hz, 1 B, B^4), −20.8 (d, $^1J_{B-H}$ = 142 Hz, 1 B, B^2), −25.6 (d, $^1J_{B-H}$ = 154 Hz, 1 B, B^3), −42.2 (d, $^1J_{B-H}$ = 139 Hz, 1 B, B^1), all theoretical [^{11}B-^{11}B]-COSY cross-peaks observed. ^{11}B NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 3.0 (B^{10}), −2.3 (B^6), −10.3 (B^5), −15.8 (B^{11}), −16.1 (B^4), −18.8 (B^2), −22.8 (B^3), −43.2 (B^1). $^1H\{^{11}B\}$ NMR (CD_3CN, ppm): δ = 1.91 (s, 1 H, H^6), 1.84 (s, 1 H, H^4), 1.69 (s, 1 H, H^9), 1.64 (s, 1 H, H^5), 1.54 (d, $^2J_{P-H}$ = 32 Hz, 1 H, H^{11}), 1.80 (s, 1 H, H^{10}), 1.14 (d, $^2J_{P-H}$ = 32 Hz, 1 H, H^8), 0.78 (d, $^2J_{P-H}$ = 40 Hz, 1 H, H^2), 0.60 (d, $^2J_{P-H}$ = 20 Hz, 1 H, H^3), 0.44 (s, 1 H, H^1). $^{13}C\{^{11}B,^1H\}$ NMR (CD_3CN, ppm): δ = 44.8 (s, 1 C, C^9), 33.0 (d, $^1J_{C-P}$ = 56 Hz, 1 C, C^8). $^{13}C\{^{11}B\}$ NMR (CD_3CN, ppm): δ = 44.8 (d, $^1J_{C-H}$ = 163 Hz, 1 C, C^9), 33.0 (dd, $^1J_{C-H}$ = 170, $^1J_{C-P}$ = 56 Hz, 1 C, C^8). ^{13}C NMR [calcd., GIAO-SCF/II/RMP2(fc)/6-31G*, ppm]: δ = 40.0 (C^9), 26.0 (C^8). $^{31}P\{^1H\}$ NMR (CD_3CN, ppm): δ = −91.0 (s, 1 P, P^7). IR (KBr, cm^{-1}): $\tilde{\nu}$ = 2579 (B−H). $C_{16}H_{28}B_8ClN_2P$ (401.44): calcd. B 21.56; found B 19.90.

X-ray Crystallography: A colorless crystal of PSH$^+$**10-Cl-2**$^-$ of dimensions 0.30 × 0.21 × 0.18 mm was sealed into a glass capillary under argon and measured with a Siemens P4 four-circle diffractometer at 293(2) K with Mo-K_α radiation (graphite monochromator). The crystallographic details are summarized in Table 3 and selected interatomic distances are listed in Table 2. The structure was solved by the direct methods and refined by a full-matrix least-squares procedure based on F^2 (SHELXLTL V.5.1: G. M. Sheldrick, program package SHELXTL, Göttingen). The absorption was neglected. Hydrogen atoms were localized on a difference Fourier map and refined isotropically. The final difference map had no peaks of chemical significance. Scattering factors were those implemented in the SHELXLTL V.5.1 programs. CCDC-175954 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Details: Geometry optimizations and frequency calculations employed standard ab initio methods incorporated[18] in the Gaussian94 suite of programs[19] and were performed with the Power Challenge XL computer of the Supercomputing Center of the Charles University in Prague. This program package also enabled us to compute both the Wiberg bond indices (WBI),[20] overlap-weighted natural atomic orbital (NAO) bond orders[21] and the chemical shifts, the latter being calculated at an SCF level using the GIAO (gauge-invariant atomic orbital) method and employing a II Huzinaga basis set[22] well-proven for the calculations of shielding tensors.[23]

Synthesis, Structure, and Molecular Orbital Calculations of (Pyrazolato)vanadium(III) Complexes − Understanding η^2-Pyrazolato Ligand Coordination on d^2 Metal Centers

Karl R. Gust,[a] John E. Knox,[a] Mary Jane Heeg,[a] H. Bernhard Schlegel,[a] and Charles H. Winter*[a]

Keywords: Vanadium / Pyrazolato ligands / Ab initio calculations / N ligands / Coordination modes

Treatment of trichlorotris(tetrahydrofuran)vanadium(III) with (3,5-di-*tert*-butylpyrazolato)potassium (1, 2, or 3 equiv.) in tetrahydrofuran afforded V(*t*Bu$_2$Pz)Cl$_2$(THF)$_2$ (48%), V(*t*Bu$_2$Pz)$_2$Cl(THF)$_2$ (67%), and V(*t*Bu$_2$Pz)$_3$(THF) (77%), respectively, as purple crystalline solids. The X-ray crystal structures of V(*t*Bu$_2$Pz)Cl$_2$(THF)$_2$, V(*t*Bu$_2$Pz)$_2$Cl(THF)$_2$, and V(*t*Bu$_2$Pz)$_3$(THF) reveal six- and seven-coordinate vanadium centers with η^2-pyrazolato ligands. Molecular orbital calculations were carried out to understand the electronic nature of pyrazolato coordination to transition metal centers containing d electrons. It is demonstrated that η^2-pyrazolato ligand coordination occurs through interaction of filled symmetric and antisymmetric combinations of the nitrogen lone pairs with empty d_z^2 and d_{yz} orbitals. The complexes described herein are the first examples of η^2-pyrazolato ligand coordination to a d^2 metal center.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Pyrazolato ligand coordination has been extensively investigated among complexes of the main-group, d-block, and lanthanide metals.[1−6] Structurally documented coordination modes in mid to late d-block metals have been restricted to η^1-bonding to a single metal ion,[1] μ-η^1:η^1-bonding between two metal centers,[1] and our recent report of η^5-bonding in a ruthenium complex.[7] Prior to 1997, only one example of η^2-pyrazolato coordination to a d-block metal had been reported.[3] Since 1997, we have reported many examples of η^2-pyrazolato ligand coordination among d^0 group-4 and -5 complexes.[4,5]

Until recently, η^2-pyrazolato ligand coordination in d-block metals was limited to systems with empty d shells.[1,3−5] In our original report of titanium complexes containing η^2-pyrazolato ligands,[4] molecular orbital calculations demonstrated that the η^2-coordination occurs through interaction of symmetric and antisymmetric combinations of the nitrogen lone pairs with empty d orbitals on titanium. A significant open question relates to the occurrence of η^2-pyrazolato ligands among d-block metal complexes with partially filled d shells, where repulsions between the filled d orbitals and pyrazolato nitrogen atoms might destabilize η^2-pyrazolato coordination in favor of other coordination modes. In this vein, Mösch-Zanetti has reported the synthesis and structure of tris(3,5-di-*tert*-butylpyrazolato)titanium(III) and several other (pyrazolato)titanium(III) complexes, and found η^2-coordination of the pyrazolato ligands in these d^1 systems.[8] In addition, we have recently described the synthesis, structure, and bonding of tris(3,5-di-*tert*-butylpyrazolato)chromium(III) and -iron(III).[9] These d^3 and d^5 complexes contain η^2-pyrazolato ligands, and suggest that many transition metal complexes with partially filled d shells may be able to support η^2-pyrazolato ligands. As part of our general studies, we sought to explore pyrazolato ligand coordination to d^2 metal centers.

Herein, we report the synthesis, structure, and characterization of a series of vanadium(III) complexes that exhibit η^2-pyrazolato ligand coordination. Molecular orbital calculations performed on a model vanadium(III) complex demonstrate that η^2-pyrazolato ligand coordination is preferred over η^1-coordination by 4.1 kcal/mol. The η^2-coordination occurs through overlap of symmetric and antisymmetric combinations of the nitrogen lone pairs with empty d orbitals on the vanadium(III) centers. These complexes are the first examples of η^2-pyrazolato ligand coordination to a d^2 metal center.

Results and Discussion

Synthesis of New Complexes

Treatment of trichlorotris(tetrahydrofuran)vanadium(III) with 1, 2, or 3 equiv. of (3,5-di-*tert*-butylpyrazolato)potas-

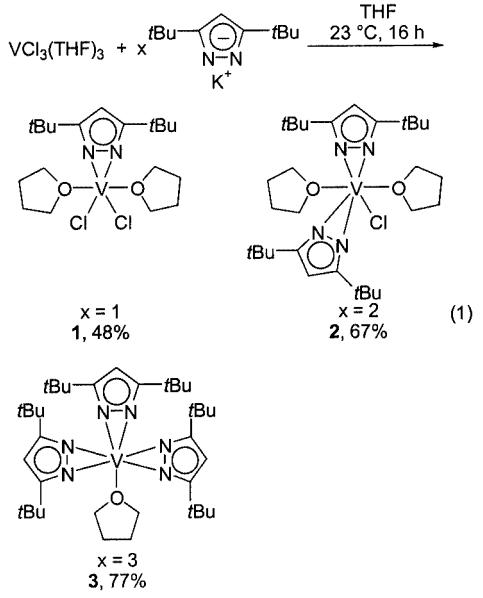
sium afforded dichloro(3,5-di-*tert*-butylpyrazolato)bis-(tetrahydrofuran)vanadium(III) (**1**), chlorobis(3,5-di-*tert*-butylpyrazolato)bis(tetrahydrofuran)vanadium(III) (**2**), and tris(3,5-di-*tert*-butylpyrazolato)tetrahydrofuranvanadium(III) (**3**), respectively, as purple crystalline solids (Scheme 1). Compounds **1**−**3** are air-sensitive in solution and in the solid state, but are thermally stable indefinitely at ambient temperature under argon. The structures of **1**−**3** were assigned by ^{1}H NMR spectroscopy, IR spectroscopy, microanalysis, and by X-ray structure determinations (vide infra). Complexes **1**−**3** are paramagnetic, and exhibited broad resonances in the ^{1}H NMR spectra. Magnetic moments (μ_{eff}) of **1**−**3** were also determined and ranged between 2.60 and 2.82 BM. These values are close to the spin-only magnetic moment expected for the two unpaired electrons of a vanadium(III) center (μ_s = 2.83 BM).[10] EPR spectra were not recorded, since even-electron systems generally do not give useful spectra.[11]



Scheme 1

X-ray Crystal Structures of 1−3

The X-ray crystal structures of **1**−**3** were determined to establish the geometry about the metal center and the bonding modes of the pyrazolato ligands. Experimental crystallographic data are summarized in Table 4, selected bond lengths and angles are given and perspective views are presented for **1** (Figure 1, Table 1), **2** (Figure 2, Table 2), and **3** (Figure 3, Table 3).

Complex **1** contains one η^2-pyrazolato, two chloride, and two tetrahydrofuran ligands. The coordination sphere about the vanadium atom possesses approximate trigonal-bipyramidal geometry, if the center of the nitrogen−nitrogen bond in the 3,5-di-*tert*-butylpyrazolato ligand is considered as a monodentate donor. The tetrahydrofuran ligands comprise the axial substituents, with an oxygen−vanadium−oxygen angle of 177.88(13)°. The

ging from 90.03(8) to 91.14(8)°. The vanadium−chlorine bond length is 2.2655(9) Å. The pyrazolato ligand displays symmetric η^2-coordination with a vanadium−nitrogen bond length of 2.021(3) Å. The nitrogen−nitrogen distance [1.356(5) Å] and the bite angle [39.19(13)°] of the pyrazolato ligand in **1** are similar to the corresponding values found in η^2-pyrazolato complexes of the early transition metals.[5]

Complex **2** contains two η^2-pyrazolato, one chloride, and two tetrahydrofuran ligands. The coordination sphere about the vanadium atom possesses approximate trigonal bipyramidal geometry, if the centers of the nitrogen−nitrogen bonds in both 3,5-di-*tert*-butylpyrazolato ligands are considered to be monodentate donors. The tetrahydrofuran ligands comprise the axial ligands, with an oxygen−vanadium−oxygen angle of 174.49(13)°. The vanadium−oxygen distances are 2.112(3) and 2.118(3) Å. The chlorine atom lies in the equatorial plane, with chlorine−vanadium−oxygen angles of 93.40(9) and 91.94(11)°. The vanadium−chlorine bond length of 2.3338(14) Å is longer than the vanadium−chlorine bond length in **1**, due to the coordination number of seven in **2** compared to six in **1**. The two pyrazolato ligands are approximately coplanar and lie in the equatorial plane. The nitrogen−vanadium−oxygen angles range from 85.28(13) to 92.03(14)°. The pyrazolato ligands exhibit η^2-coordination to the vanadium atom, with vanadium−nitrogen bond lengths ranging from 2.014(4) to 2.106(4) Å. The longer vanadium−nitrogen bond lengths [to N(1) and N(3)] are farthest from the chlorine atom, and are the result of steric crowding between the *tert*-butyl groups containing C(4) and C(15). The nitrogen−nitrogen bond lengths [1.354(4) and 1.367(4) Å] and bite angles [38.20(12) and 38.68(12)°] of the pyrazolato ligands in **2** are similar to the corresponding values found in η^2-pyrazolato complexes of the early transition metals.[5]

Complex **3** contains three η^2-pyrazolato and one tetrahydrofuran ligands. The coordination sphere about the vanadium atom possesses a pseudo-tetrahedral geometry, if the centers of the nitrogen−nitrogen bonds in the 3,5-di-*tert*-butylpyrazolato ligands are considered as monodentate donors. The vanadium−nitrogen bond lengths range from 2.035(2) to 2.102(2) Å. The pyrazolato ligand containing N(1) and N(2) exhibits symmetric η^2-bonding to the vanadium atom within 5σ. However, the pyrazolato ligands containing N(3)−N(6) show a slight (0.062−0.066 Å) asymmetry in the vanadium−nitrogen bond lengths. In the pyra-

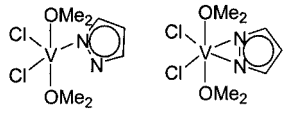
zolato ligand containing N(3) and N(4), the slightly longer bond to N(3) can be rationalized as arising through steric repulsion between the *tert*-butyl group containing C(15) and the tetrahydrofuran ligand. Similarly, the pyrazolato ligand containing N(5) and N(6) shows a slightly longer bond from the vanadium atom to N(6) due to steric crowding between the *tert*-butyl groups containing C(19) and C(30). This steric crowding causes these two pyrazolato ligands to be canted with respect to each other, as opposed to the coplanar pyrazolato ligands observed in **2**. The vanadium−oxygen bond length is 2.1289(17) Å. This value is similar to the related bond lengths in seven-coordinate **2**. The nitrogen−nitrogen bond lengths range from 1.368(3) to 1.382(2) Å. The pyrazolato bite angles range from 38.56(8) to 39.44(7)°. These values are similar to those found in **1**, **2**, and other complexes containing η^2-pyrazolato ligands.[5]

Molecular Orbital Calculations

To understand the nature of the pyrazolato ligand bonding to vanadium(III), ab initio calculations were performed using the Gaussian suite of programs.[12] The simplified models used in this study are the η^1- and η^2-pyrazolato complexes **4** and **5**. A previous study of ours has shown that a simplified model (pyrazolato)titanium(IV) complex does not significantly change the electronic distribution relative to homoleptic pyrazolato complexes.[4] Model complexes **4** and **5** optimized using the B3LYP/6−311G* level of theory.[13] The bond lengths and angles associated with the pyrazolato ligand in the optimized structure of **5** are in good agreement with the X-ray crystal structures of **1**−**3** [V−N(calcd) = 2.040, 2.042 Å versus V−N (X-ray) = 2.014−2.106 Å; N−N(calcd) = 1.350 Å versus N−N(X-ray) = 1.354−1.382 Å; N−N−V(calcd) = 70.86° versus N−N−V(X-ray) 67.0−74.3°]. Complex **5** is calculated to be 4.09 kcal/mol more stable than the η^1 complex **4**.



4 **5**

Natural population analysis[14] shows that the charges on the pyrazolato ligands are −0.556 in **4** and −0.561 in **5**. These values can be compared to charges of −0.32 for (η^2-Me_2pz)$TiCl_3$[4] and −0.75 in (η^2-pz)$YCl_2(NH_3)_2$[15a] that have been previously reported by our group. Natural bond order analysis[14] indicates that there is very little interaction between the occupied vanadium d orbitals and the unoccupied pyrazolato ligand orbitals. A more significant stabilization occurred by the symmetric and antisymmetric occupied nitrogen lone pair orbitals interacting with empty vanadium d orbitals. The fragment orbitals involved are shown in Figure 4. The symmetric combination of the nitrogen lone pair combines with the empty d_z^2 vanadium orbital and appropriate in-plane orbitals based on the carbon and chlorine atoms. The antisymmetric combination of the nitrogen lone pairs interacts with an antisymmetric combination of vanadium−chlorine σ* orbitals. These vanadium−chlorine orbitals consist primarily of the metal d_{yz} orbital and a smaller, antibonding contribution from a chlorine p orbital.

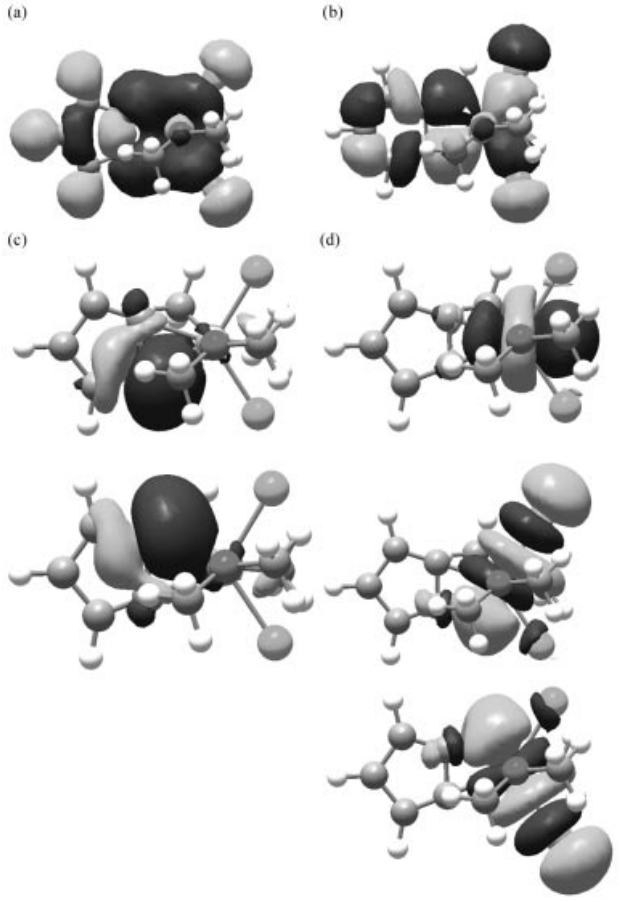


Figure 4. Calculated molecular orbitals of **5**: (a) symmetric combination of the nitrogen lone pairs that interact with the empty d_{z^2} fragment; (b) antisymmetric combination of the nitrogen lone pairs that interact with the empty d_{yz} fragment; (c) pyrazolato nitrogen atom lone pair fragments that add together to form symmetric and antisymmetric combinations; (d) empty d_{z^2} and d_{yz} fragments that interact with the symmetric and antisymmetric combinations of the pyrazolato nitrogen atom lone pair fragments

Additionally, there is some mixing between the HOMO π orbital on the pyrazolato fragment and an occupied d_{xz} orbital, but the NBO analysis indicates that this does not stabilize the complex significantly. Thus, the most important orbital contributions to the bonding between the pyrazolato ligand and the vanadium center are the symmetric and antisymmetric combinations of the nitrogen lone pairs interacting with the unoccupied vanadium d_{z^2} and d_{yz} orbitals.

Discussion

The central discovery highlighted herein is the η^2-pyrazolato ligands bonded to the d^2 vanadium(III) centers in **1**−**3**. These are the first examples of η^2-pyrazolato ligand coordination to a metal center with a d^2 electronic configuration. In addition, **1**−**3** constitute rare examples of η^2-pyrazolato ligand coordination to d-block metal centers with partially filled d shells.[8,9] There has been one previous report of a (pyrazolato)vanadium complex, [(Tp*i*Pr^{2}V(O)(μ-OH)(μ-Pz*i*Pr^2)V(O)(μ-OH)(μ-Pz*i*Pr^2)V(O)Tp*i*Pr^2)], which was obtained by partial hydrolysis of a vanadium(IV) hydrotris(3,5-diisopropyl-1-pyrazolyl)borate complex.[16] The 3,5-diisopropylpyrazolato ligands in this complex bridge between two vanadium(IV) ions with the well-documented μ-η^1:η^1-coordination mode. There have been 70 tris(pyrazolyl)borate complexes of vanadium whose structures are listed in the Cambridge Crystallographic Database (version 5.22; October 2001).[17] These complexes contain μ-η^1:η^1-pyrazolato ligands bridged between boron(III) and vanadium ions in various oxidation states. Traditional wisdom[1] holds that the lone pairs of electrons on each nitrogen atom within a pyrazolato ligand are pointed in geometrically inappropriate directions to allow η^2-coordination to a small metal ion such as vanadium(III), and the μ-η^1:η^1 coordination mode is therefore favored. Instead, our theoretical studies[4,14] demonstrate that η^2-pyrazolato ligand coordination occurs through overlap of symmetric and antisymmetric combinations of the nitrogen-based lone pairs with empty d orbitals on the metal center. Recent reports of η^2-pyrazolato ligands among main-group metal and d^0, d^1, d^3, and d^5 transition metal complexes,[2−5,8,9] together with the present work, suggest that this previously rare coordination mode may be generally accessible among the transition metals. In particular, most of the known η^2-pyrazolato complexes contain the bulky 3,5-di-*tert*-butylpyrazolato ligand. Molecular orbital calculations described above demonstrate that η^2-pyrazolato ligand coordination is thermodynamically preferred over η^1 coordination, even in the absence of steric effects. However, very bulky pyrazolato ligands or extremely bulky ancillary ligands may be required to destabilize the μ-η^1:η^1 coordination mode and make η^2-pyrazolato ligands feasible.

There is an analogy between **1**−**3** and related vanadium(III) complexes containing other bidentate, monoanionic donor ligands.[18−21] In particular, vanadium(III) complexes containing amidinate or formamidinate ligands are highly relevant, since these ligands are bidentate nitrogen donors that are similar to η^2-pyrazolato ligands. The complexes V(RNCR′NR)$_3$ (R = *p*-tol, R′ = H;[18] R = C_6H_{11}, R′ = CH_3[19]) contain six-coordinate metal centers with distorted D_3 geometries. Unlike seven-coordinate **3**, which contains a coordinated tetrahydrofuran molecule in addition to the η^2-pyrazolato ligands, V(RNCR′NR)$_3$ did not crystallize with coordinated tetrahydrofuran. The smaller bite angle of the η^2-pyrazolato ligands (38−40°), compared to the related values for V(RNCR′NR)$_3$ (63−64°), make the vanadium(III) center in **3** more accessible sterically and allows tetrahydrofuran coordination. The benzamidinate complex VCl[N(SiMe$_3$)CPhN(SiMe$_3$)]$_2$ is related structurally to **2**.[20] However, **2** contains two tetrahydrofuran ligands, while VCl[N(SiMe$_3$)CPhN(SiMe$_3$)]$_2$ does not contain any neutral donor ligands. Again, tetrahydrofuran coordination in **2** occurs due to the more open coordination sphere, compared to VCl[N(SiMe$_3$)CPhN(SiMe$_3$)]$_2$.

Experimental Section

General Considerations: All reactions were performed under argon using either glovebox or Schlenk line techniques. Toluene was distilled from sodium, tetrahydrofuran was distilled from sodium benzophenone ketyl, and hexane was distilled from P_2O_5. Trichlorotris(tetrahydrofuran)vanadium(III) was purchased from Aldrich Chemicals, Inc. (3,5-Di-*tert*-butylpyrazolato)potassium was prepared by a literature procedure.[22] ^1H and $^{13}C\{^1H\}$ NMR were obtained at 300 or 75 MHz in [D_6]benzene. IR spectra were obtained using Nujol as the medium. Elemental analyses were performed by Midwest Microlab, Indianapolis, IN. Melting points were obtained with a Haake−Buchler HBI digital melting point apparatus and are uncorrected. Magnetic susceptibility measurements were determined using a Johnson−Matthey magnetic susceptibility balance.

Preparation of Dichloro(3,5-di-*tert*-butylpyrazolato)bis(tetrahydrofuran)vanadium(III) (1): A 100-mL Schlenk flask was charged with trichlorotris(tetrahydrofuran)vanadium(III) (0.856 g, 2.29 mmol), (3,5-di-*tert*-butylpyrazolato)potassium (0.502 g, 2.29 mmol), and tetrahydrofuran (50 mL). The resultant purple solution was stirred for 16 h. The solvent was then removed under reduced pressure to yield a purple solid. This solid was extracted with hexane (50 mL), and the resultant solution was filtered through a 2-cm pad of Celite on a coarse glass frit. The filtrate was concentrated to a volume of about 20 mL, and was then placed in a −20 °C freezer for 36 h. Decanting of the solvent, followed by vacuum drying for 1 h, afforded **1** as purple crystals (0.49 g, 48%), m.p. 115 °C (dec). IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1589 (w), 1563 (w), 1250 (s), 1030 (s), 862 (w), 795 (m). ^1H NMR (C_6D_6, 22 °C, ppm): δ = 2.86 (broad, C_4H_8O), 1.49 [broad, $C(CH_3)_3$]. μ_{eff} = 2.82 BM. $C_{19}H_{35}Cl_2N_2O_2V$ (445.3): calcd. C 51.24, H 7.92, N 6.29; found C 51.27, H 8.12, N 6.26.

Preparation of Chlorobis(3,5-di-*tert*-butylpyrazolato)bis(tetrahydrofuran)vanadium(III) (2): In a fashion similar to the preparation of **1**, trichlorotris(tetrahydrofuran)vanadium(III) (1.189 g, 3.18 mmol) was treated with (3,5-di-*tert*-butylpyrazolato)potassium (1.388 g, 6.36 mmol) to afford **2** as purple crystals (1.26 g, 67%), m.p. 117 °C. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1515 (m), 1498 (m), 1415 (m), 1361 (s), 1312 (w), 1251 (s), 1234 (s), 1208 (w), 1171 (w), 1030 (s), 919 (w), 874 (s), 792 (s), 725 (m), 712 (m). ^1H NMR (C_6D_6, 22 °C, ppm): δ = 1.63 [broad, C_4H_8O and $C(CH_3)_3$]. μ_{eff} = 2.60 BM. $C_{30}H_{65}N_6OV$ (1589.2): calcd. C 61.16, H 9.24, N 9.51; found C 61.42, H 9.27, N 9.36.

Preparation of Tris(3,5-di-*tert*-butylpyrazolato)tetrahydrofuranvanadium(III) (3): In a fashion similar to the preparation of **1**, trichlorotris(tetrahydrofuran)vanadium(III) (0.804 g, 2.15 mmol) was treated with (3,5-di-*tert*-butylpyrazolato)potassium (1.500 g, 6.87 mmol) to afford **3** as purple crystals (1.11 g, 77%), m.p. 149 °C dec. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1567 (w), 1515 (m), 1310 (w), 1251 (s), 1278 (m), 1202 (w), 1017 (m), 874 (w), 783 (m), 715 (m). ^1H NMR (C_6D_6, 22 °C, ppm): δ = 4.80 (broad, C_4H_8O), 2.26 [broad, $C(CH_3)_3$]. μ_{eff} = 2.71 BM. $C_{37}H_{65}N_6OV$ (660.9): calcd. C 67.24, H 9.91, N 12.72; found C 67.36, H 10.01, N 12.73.

X-ray Crystallography for 1−3: The crystalline samples were mounted in thin-walled glass capillaries under nitrogen. All crystallographic data were collected at room temperature with a Siemens/Bruker automated P4/CCD diffractometer with monochromated Mo radiation. 1650 frames were collected at 10 s/frame and integrated with the manufacturer's SMART and SAINT software. Absorption corrections were applied with Sheldrick's SADABS program and the structure was solved and refined using the programs of SHELX-97. The molecules crystallize as neutral complexes. Hydrogen atoms were calculated and assigned to ride on the carbon atoms to which they are bound. CCDC-178824 (**1**), -178825 (**2**), and -178826 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]. Complex **1** crystallized as purple rods in *C*2/*c* with *Z* = 4. The vanadium atoms occupy a crystallographic twofold axis. Atoms C9 and C10 in the coordinated THF were assigned alternate partial positions to model the disorder. Complex **2** crystallized as purple rods in *P*4(2)/*n* with *Z* = 8. All atoms in the vanadium complex occupied general positions, but there is an indeterminate solvent region near the twofold axis. Any placement and refinement of atoms in this solvent region becomes unreasonable. There was no evidence for any solvate inclusion in the C,H,N microanalysis. The coordinated THF exhibits typically large thermal parameters. Complex **3** crystallized as purple rectangles in $P2_1/c$ with *Z* = 4. All atoms occupy general positions. Partially occu-

Homoscorpionate Ligands Based on 3-(Cyclobutyl)pyrazole and 3-(Cyclopentyl)pyrazole

Arnold L. Rheingold,[a] Glen P. A. Yap,[b] Lev N. Zakharov,[a] and Swiatoslaw Trofimenko*[a]

Keywords: Scorpionates / Cobalt / Borates / N ligands

The novel scorpionate ligands hydrotris[3-(cyclobutyl)pyrazol-1-yl]borate (Tp^{Cbu}), hydrotris[3-(cyclopentyl)pyrazol-1-yl]borate (Tp^{Cpe}), tetrakis[3-(cyclobutyl)pyrazol-1-yl]borate (pz^oTp^{Cbu}), tetrakis[3-(cyclopentyl)pyrazol-1-yl]borate (pz^oTp^{Cpe}), have been synthesized, converted into a variety of homo- and heteroleptic complexes, and studied by NMR spectroscopy. The complexes $Tl[Tp^{Cbu}]$ (**1**), $Tl[Tp^{Cpe}]$ (**2**), $Co[Tp^{Cbu}]_2$ (**3**), $Co[Tp^{Cpe*}]_2$ (**4**), $Co[Tp^{Cpe}][Tp]$ (**5**), $Co[pz^oTp^{Cbu}]_2$ (**6**), and $Co[pz^oTp^{Cpe}]_2$ (**7**) have been structurally characterized by X-ray crystallography. The coordination behavior of Tp^{Cpe} is similar to that of Tp^{Cy} or Tp^{iPr} in producing stable tetrahedral $Tp^{Cpe}MX$ complexes, but octahedral homoleptic complexes only with ligand rearrangement, yielding $M[Tp^{Cpe*}]_2$. By contrast, Tp^{Cbu} is unusual in forming both tetrahedral $Tp^{Cbu}MX$, and homoleptic $M[Tp^{Cbu}]_2$ complexes, without rearrangement. The complex **6** is tetrahedral in solution but octahedral in the crystal, while complex **7** is tetrahedral in solution and in the crystal.

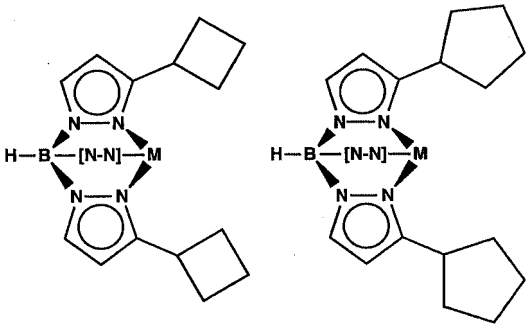
Introduction

Among the many known homoscorpionate [tris(pyrazolyl)borate] ligands of the type Tp^R,[1] where the R substituent is in the 3-position, there are only two in which R is a cycloalkyl group. One is Tp^{Cpr},[2,3] where R is cyclopropyl, and the other Tp^{Cy},[4–7] where R is cyclohexyl. Their coordinative behavior is strikingly different. Tp^{Cpr} coordinates very much like the parent Tp ligand, forming octahedral $M[Tp^{Cpr}]_2$ complexes with great ease, as does its tetrakis analog, pz^oTp^{Cpr} {= $[B(pz^{Cpr})_4]^-$} and, conversely, it is very reluctant to form stable tetrahedral species $M[Tp^{Cpr}]X$. By contrast, Tp^{Cy} readily forms stable tetrahedral complexes $M[Tp^{Cy}]X$, and its $M[Tp^{Cy}]_2$ complexes are not octahedral but tetrahedral, containing κ^2-Tp^{Cy} ligands. It is only through thermally induced rearrangement, which converts one 3-(cyclohexyl)pyrazolyl arm to 5-(cyclohexyl)pyrazolyl, that octahedral complexes are obtained.[7] We decided to study the coordination chemistry of scorpionates with 3-R = cycloalkyl substituents intermediate in size between cyclopropyl and cyclohexyl, in order to determine where the transition from one type of behavior to the other occurs.

That the variations in the size and geometry of 3-R substituents have a pronounced effect on the coordination chemistry, and on the catalytic effectiveness of specific Tp^R metal complexes, has been conclusively demonstrated in the studies, where a series of Tp^R copper(I) complexes was used in achieving carbene transfer, and C-bond activation. Thus, in the cyclopropanation reaction by way of carbene transfer from ethyl diazoacetate to styrene and to other olefins, the by far most active ligand was Tp^{Ms} (Ms = mesityl).[8] On the other hand, in the rather similar cyclopropenation of acetylenes, catalysts derived from Tp^{Ms} gave only mediocre results, but catalysts based on Tp^{Cy} were stellar performers.[9]

We have, therefore, synthesized Tp^R ligands where R was 3-cyclobutyl (= Tp^{Cbu}) or 3-cyclopentyl (= Tp^{Cpe}), as well as their tetrakis analogs pz^oTp^{Cbu} and pz^oTp^{Cpe}, and have examined their coordination chemistry in high-spot fashion.



$M[Tp^{Cbu}]$ $M[Tp^{Cpe}]$

-(N-N)- is the third, hidden, 3-cycloalkylpyrazolyl ring

Results and Discussion

The two new pyrazoles, 3-(cyclobutyl)pyrazole and 3-(cyclopentyl)pyrazole, were synthesized by way of formylating cyclobutyl methyl ketone, and cyclopentyl methyl ketone, respectively, and treatment of the resulting dicarbonyl intermediates with hydrazine. Reaction of these pyrazoles with KBH_4 produced the respective ligands, characterized as their Tl derivatives, Tl[Tp^{Cbu}] (**1**) and Tl[Tp^{Cpe}] (**2**). Comparing the cone and wedge angles of the structurally

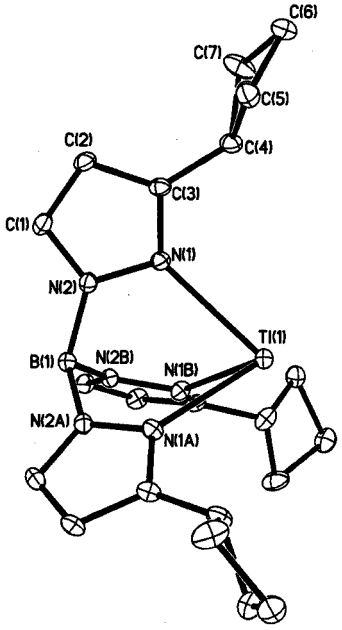

Figure 1. ORTEP plot of the structure of Tl[Tp^{Cbu}] (**1**); selected bond length [Å] and angle [°]: Tl−N(1) 2.562(2); N(1)−Tl−N(1A) 75.20(7)

characterized compounds **1** and **2** (Figure 1 and 2), which were 234 and 253°, respectively,[11] with those of Tl[Tp^{Cpr}] (223°) and Tl[Tp^{Cy}] (281°), one can see that the cone angle of **1** is still relatively close to Tl[Tp^{Cpr}], in differing by only 11°, but the cone angle of **2** is roughly midway between those of Tl[Tp^{Cpr}] and Tl[Tp^{Cy}]. One could expect, therefore, at first approximation, the ligand [Tp^{Cbu}] to be somewhat similar in terms of its coordination behavior to [Tp^{Cpr}], while [Tp^{Cpe}] might resemble [Tp^{Cy}]. The average Tl−N bond lengths of **1** and **2** were both 2.562 Å, although in the case of **1** all lengths were exactly equal, while in **2** they ranged from 2.530 to 2.607 Å. The respective N−Tl−N angles averaged 75.2 and 75.5°, again being all identical in the case of **1**, but ranging from 72.3 to 77.3° in the case of **2**. Both, the Tl−N bond lengths and N−Tl−N bond angles fall right into the middle range of known Tl[Tp^R] complexes.[12]

The cyclopropyl group in Tp^{Cpr} compounds has the angle between its 2- and 3-C atoms very close to the theoretical 60°.[2,3] The cyclopropyl ring is thus very constrained, as compared to an isopropyl (or cyclohexyl) group, the two methylene groups being pinned back and offering little in terms of steric hindrance. Hence, the coordination behavior

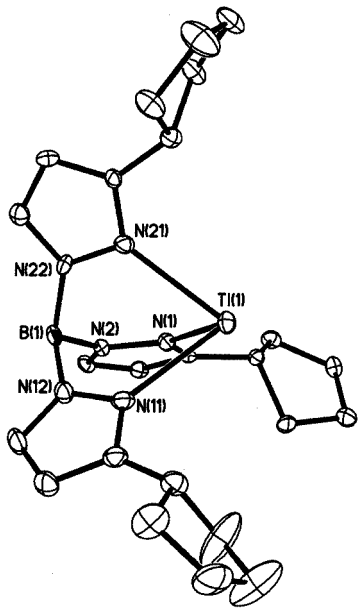

Figure 2. ORTEP plot of the structure of Tl[Tp^{Cpe}] (**2**); selected bond lengths [Å] and angles [°]: Tl−N(1) 2.530(10), Tl−N(11) 2.607(10), Tl−N(21) 2.59(9); N(1)−Tl−N(11) 77.3(3), N(1)−Tl−N(21) 76.7(3), N(1)−Tl−N(11) 72.6(3)

of Tp^{Cpr} resembles that of the parent Tp or of Tp^{Me}. Going to the less tight angle between the 2- and 4-C atoms in the cyclobutyl group, which was 86.4° in Co[Tp^{Cbu}]$_2$ (**3**) and 86.7° in Co[pz^oTp^{Cbu}]$_2$ (**6**) for the cyclobutyl groups in the equatorial belt, such small contraction of the angle is perhaps necessary in order to accommodate there the six cyclobutyl groups. The angle was 96° for the cyclobutyl groups in **6** on the uncoordinated pyrazolyl ring. Clearly, one would expect an increase in steric hindrance in Tp^{Cbu}, as compared to Tp^{Cpr}. A further increase in steric hindrance is anticipated in the case of Tp^{Cpe}, where the angle between the 2- and 5-C atoms of a planar cyclopentyl group would be 108°, and thus almost equal to the tetrahedral angle of 109° present in isopropyl or cyclohexyl groups. In the Co[Tp^{Cpe*}]$_2$ complex **4** the angle in the inner cyclopentyl groups was 101°, while it was 103° in the cyclopentyl group on the rearranged pz^{Cpe} arm. This increased loosening of the 2- and 5-methylene groups would make the cyclopentyl substituent even closer, in terms of steric effects, to a cyclohexyl or isopropyl group.

The Tp^{Cbu} ligand was found to form isolable tetrahedral M[Tp^{Cbu}]X complexes, differing in this respect from Tp^{Cpr}, where such complexes with transition metals were spontaneously converted into octahedral homoleptic species, M[Tp^{Cpr}]$_2$.[3] At the same time homoleptic complexes M[Tp^{Cbu}]$_2$ could also be prepared. In the case of the paramagnetic Co[Tp^{Cbu}]$_2$ (**3**) its NMR spectrum was extremely sharp and indicated all pz^{Cbu} arms to be identical, which meant that no rearrangement of the ligands to Tp^{Cbu*} had taken place. The structure of **3** was determined by X-ray crystallography, and showed the molecule to be of D_{3d} symmetry (Figure 3). There appeared to be no problem of accommodating the six cyclobutyl groups in the equatorial

belt of the molecule. The N−Co distances averaged 2.142 Å, and this is very close to the values found in $Co[Tp]_2$ (2.129 Å),[13] $Co[Tp^*]_2$ (2.143 Å),[14] and to the N−Co distances of the Tp^{Cpr} component in $Co[Tp^{Cpr}][Tp^{Ph}]$, where the N−Co distances average 2.121 Å for Tp^{Cpr}, and 2.223 Å for Tp^{Ph}.[3]

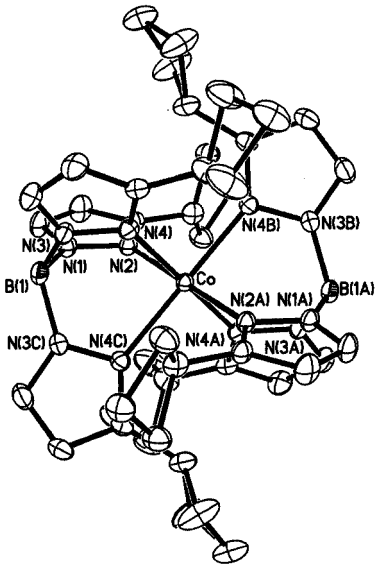

Figure 3. ORTEP plot of the structure of $Co[Tp^{Cbu}]_2$ (**3**); selected bond lengths [Å] and angle [°]: Co−N(2) 2.139(5), Co−N(4) 2.143(4); N(2)−Co−N(4) 88.7(1)

As an example of heteroleptic complexes, $Co[Tp^{Cbu}][Tp]$ was synthesized by the reaction of $Co[Tp^{Cbu}]Cl$ with Tl[Tp]. The NMR of this complex was very sharp and indicative of C_{3v} symmetry for the molecule, with each proton readily identifiable, even to the point of separating the *cis*- and *trans*-protons of the cyclobutyl ring. We assumed that the protons nearer to the metal center would exhibit the larger chemical shift.[15]

The ligand $[Tp^{Cpe}]^-$ readily formed tetrahedral $Co[Tp^{Cpe}]X$ complexes, which were stable, yet reactive enough to serve as precursors to a variety of heteroleptic compounds of the type $Co[Tp^{Cpe}][Tp^R]$, as discussed further on.

The homoleptic complex $Co[Tp^{Cpe}]_2$ was prepared readily from $Tl[Tp^{Cpe}]$ and $Co(ClO_4)_2$. It was purple in solution, but wine-red in the solid state. Heating in hydrocarbon solvents, such as toluene or xylene produced a purple solution, suggestive of tetrahedral coordination, and on concentration the wine-red solid was recovered unchanged. However, when $Co[Tp^{Cpe}]_2$ was refluxed briefly in benzonitrile, the purple color changed to amber, and layering of the solution with heptane resulted in the formation of bright yellow crystals, m.p. 286−288 °C. This color is typical of octahedral cobalt homoscorpionates, and so the crystals were assumed to be $Co[Tp^{Cpe*}]_2$ (**4**). Heating of $Co[Tp^{Cpe}]_2$ in a melting point tube, resulted in a purple melt at 142−144 °C, resolidification with a color change to amber at around 166−168 °C, and melting of that solid at around 280 °C. That this, indeed, involved rearrangement of $Co[Tp^{Cpe}]_2$ to **4**, containing one 5-(cyclopentyl)pyrazolyl group per ligand, was suggested by the proton NMR spectrum. It was rather complicated, as each proton of the two 3-(cyclopentyl) rings was unique [*cis* and *trans*, inner and outer protons with respect to the C_2 axis, plus the tertiary one for a total of nine peaks for the two 3-(cyclopentyl) rings], the 5-(cyclopentyl) ring had four pairs of 2,5- and 3,4-protons, plus the tertiary one for a total of five peaks. In addition, there were the pyrazolyl protons (three 4-H, two 5-H, and one 3-H), for a total of 19 peaks. Nevertheless, they all could be assigned, on the basis of the protons closer to the cobalt center exhibiting the greater shifts.[15] The four 2,5-protons of the 3-(cyclopentyl) rings were well separated in the $\delta = -32$ to -49 ppm range, while those of the 3,4-protons were closely bunched together in the $\delta = -14$ to -15 ppm area. Such thermal rearrangements [Equation (1)] have been observed before as, for instance, in converting $Co[Tp^{Np}]_2$ to $Co[Tp^{Np*}]_2$,[16] or $Co[Tp^{Cy}]_2$ to $Co[Tp^{Cy*}]_2$.[7]

$$M[HB(3\text{-}Rpz)_3]_2 \rightarrow M[HB(3\text{-}Rpz)_2(5\text{-}Rpz)]_2 \quad (1)$$

The rearranged structure of **4** was confirmed by X-ray crystallography. In this structure (Figure 4) the two pyrazolyl arms with the 5-(cyclopentyl) group are *trans* to each other, and their Co−N bond lengths are 2.11 Å, while those with the 3-(cyclopentyl) group have Co−N bond lengths of 2.16 Å, thus being significantly longer (see Table 1).

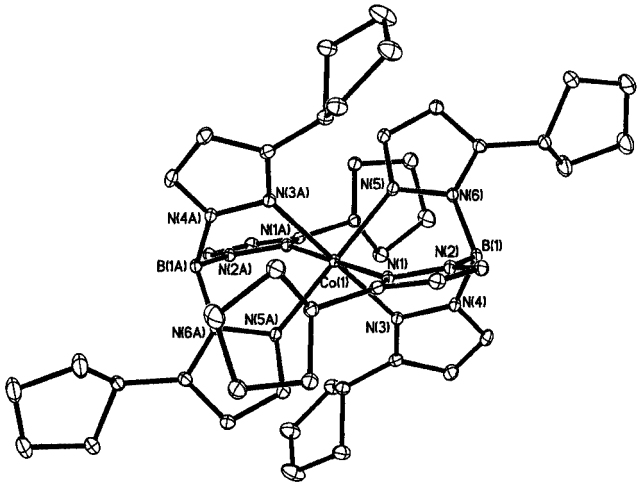

Figure 4. ORTEP plot of the structure of $Co[Tp^{Cpe*}]_2$ (**4**); selected bond lengths [Å] and angles [°]: Co−N(5) 2.1154(14), Co−N(3) 2.1576(13), Co−N(1) 2.11619(13); N(5)−Co−N(3) 88.18(5), N(5)−Co−N(1) 87.21(5), N(1)−Co−N(3) 84.44(5)

A series of heteroleptic complexes $Co[Tp^{Cpe}][Tp^R]$ was also prepared, to check how large an R group in 3-position of the Tp^R ligand can still be accommodated in such complexes without causing rearrangement of $[Tp^{Cpe}]$ to $[Tp^{Cpe*}]$, or altering the octahedral structure. Three such compounds were prepared: $Co[Tp^{Cpe}][Tp]$ (**5**), $Co[Tp^{Cpe}][Tp^*]$ and $Co[Tp^{Cpe}][Tp^{Cpr}]$. In each of them, the octahedral structure was maintained without rearrangement of the Tp^{Cpe} ligand, as was clearly indicated by the NMR spectra of these paramagnetic complexes. All the

[a] Values taken from the two 3-cyclopentylpyrazolyl arms per ligand. [b] Values taken from the two 3-isopropylpyrazolyl arms per ligand. [c] Values taken from the two 4-bromo-3-isopropylpylpyrazolyl arms per ligand. [d] $Tp^{Me,mt3}$ = hydrotris(3-methyl-4,5-propylenepyrazol-1-yl)borate. [e] $Tp^{3Bo,7Me}$ = hydrotris(7-methylindazol-1-yl)borate. [f] $Tp^{a*,3Me}$ = hydrotris(3-methyl-2*H*-benz[*g*]indazol-2-yl)borate.

spectra were extremely sharp, as is the case with octahedral cobalt(II) bis(homoscorpionates), and showed each proton to be in a specific environment, with assignments based on the previously established ranges for the chemical shifts of the pyrazolyl ring protons, and protons of pyrazolyl substituents in the various positions. The structure of **5** was determined by X-ray crystallography (Figure 5). It was of C_{3v} symmetry, and contained slightly longer Co−N bonds for the Tp^{Cpe} ligand than for Tp (2.168 versus 2.129 Å).

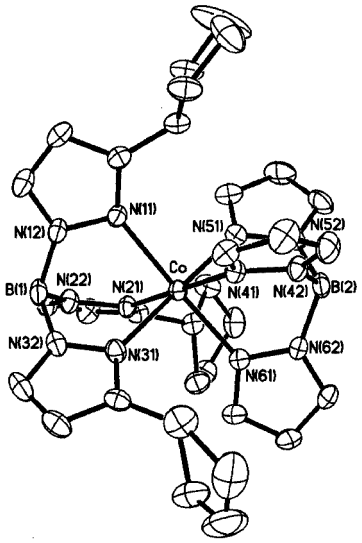

Figure 5. ORTEP plot of the structure of $Co[Tp^{Cpe}][Tp]$ (**5**); selected bond lengths [Å] and angles [°]: Co−N(11) 2.173(3), Co−N(21) 2.167(3), Co−N(31) 2.165(4), Co−N(41) 2.132(3), Co−N(51) 2.130(4), Co−N(61) 2.126(4); N(11)−Co−N(21) 87.4(1), N(11)−Co−N(31) 87.5(1), N(31)−Co−N(21) 87.3(1), N(41)−Co−N(51) 85.7(1), N(41)−Co−N(61) 84.7(1), N(51)−Co−N(61) 85.2(1)

When the reaction of KBH_4 with 3-(cyclobutyl)pyrazole or 3-(cyclopentyl)pyrazole was carried out without solvent, and long reaction times were employed, the tetrakis ligands $[B(pz^{Cbu})_4]^-$ (= pz^oTp^{Cbu}) and $[B(pz^{Cpe})_4]^-$ (= pz^oTp^{Cpe}) were obtained and were converted into their thallium derivatives, $Tl[pz^oTp^{Cbu}]$ and $Tl[pz^oTp^{Cpe}]$. While $Tl[pz^oTp^{Cbu}]$ could be isolated in crystalline form and characterized, $Tl[pz^oTp^{Cpe}]$ was very difficult to crystallize and, for this reason, the crude K salt was used to prepare $[pz^oTp^{Cpe}]$ complexes. The coordination chemistry of the two new ligands fitted neatly between that of pz^oTp^{Cpr} and pz^oTp^{Cy}. Whereas pz^oTp^{Cpr}, just like the parent pzTp,[17] coordinated only in a κ^3-fashion, forming with first-row transition metals octahedral complexes $M[Tp^{Cpr}]_2$, in which the three-coordinated and one uncoordinated pz^{Cpr} arms did not exchange, giving rise to NMR signals for each pyrazolyl arm in 3:1 ratio, the ligand pz^oTp^{Cy} coordinated only in a κ^2-fashion, yielding tetrahedral complexes, as was also the case with the ligand pz^oTp^{iPr}.[10] This distinction between octahedral and tetrahedral complexes is most apparent in the $Co[pz^oTp^R]_2$ species, where the octahedral complexes are yellow, while the tetrahedral ones are deep purple.

The solid complex $Co[pz^oTp^{Cbu}]_2$ (**6**) was yellow, but when in solution, be it in chloroform at room temperature or in boiling toluene, the color changed to deep purple, indicating dissociation of one of the pz^{Cbu} arms per ligand, and formation of a dynamic tetrahedral structure. Upon crystallization of the complex from the purple solution, the resulting crystals were again bright yellow, indicative of octahedral coordination. The NMR of this compound was quite different from that of $Co[pz^oTp^{Cpr}]_2$ in which the signals corresponding to the three-coordinated and one uncoordinated pyrazolyl arms per ligand were sharp and well separated, consistent with a lack of exchange between the coordinated and uncoordinated pyrazolyl arms. The NMR spectrum of **6**, by contrast, contained broad peaks at positions averaging the peaks of the two-coordinated and two uncoordinated pyrazolyl arms per ligand. Nevertheless, the structure determination of **6** (Figure 6) confirmed the octahedral nature of the complex in the crystal, with each ligand being κ^3-coordinated, and the fourth pz^{Cbu} arm remaining free.

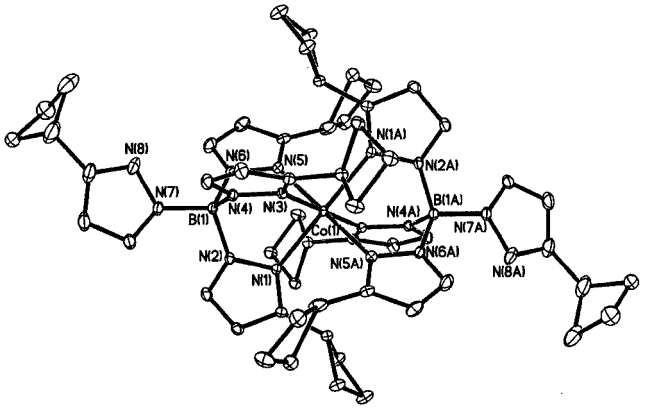

Figure 6. ORTEP plot of the structure of $Co[pz^oTp^{Cbu}]_2$ (**6**); selected bond lengths [Å] and angles [°]: Co−N(1) 2.1317(18), Co−N(3) 2.0923(18), Co−N(5) 2.1469(18), N(1)−Co−N(3) 88.33(7), N(1)−Co−N(5) 88.14(7), N(5)−Co−N(3) 88.41(7)

The $[pz^oTp^{Cpe}]$ ligand also formed a 2:1 cobalt complex, $Co[pz^oTp^{Cpe}]_2$ (**7**), which was purple in solution, and remained purple on concentration suggestive of a tetrahedral structure throughout, with κ^2-coordination of each ligand. It is similar, in this regard, to the ligands $[pz^oTp^{iPr}]$ and $[pz^oTp^{Cy}]$. The NMR spectrum of **7** showed broad peaks, indicative of exchange of all four pyrazolyl arms at room temperature. In the crystal (Figure 7) the complex also exhibited a tetrahedral structure, similar to that found in the case of $Co[pz^oTp^{Cy}]_2$ and $Co[pz^oTp^{iPr}]_2$. The Co−N distances for the coordinated pz^{Cpe} arms averaged 1.997 Å, and were thus considerably shorter than the values of 2.158 Å found in **4** or 2.168 Å encountered in **5**, implying a lesser degree of congestion in the tetrahedral structure.

The steric hindrance imposed on Tp^R ligands by the R substituents in 3-position manifests itself in the slight, but persistent, M−N bond lengthening in their octahedral homo- and heteroleptic complexes. In Table 1 we have collected Co−N bond length data from structurally determined $Co[Tp^R]_2$ and $Co[Tp^R][Tp^{R'}]$ complexes. As can be seen there, the parent Tp ligand is indeed, and expectedly, the least hindered, while the ligand Tp^{Cbu} resembles Tp*, in terms of steric hindrance, as expressed in terms of Co−N bond lengths. The Tp^{Cpe} ligand appears closest in its Co−N bond length values to Tp^{iPr}, which is also in consonance with its observed coordination chemistry.

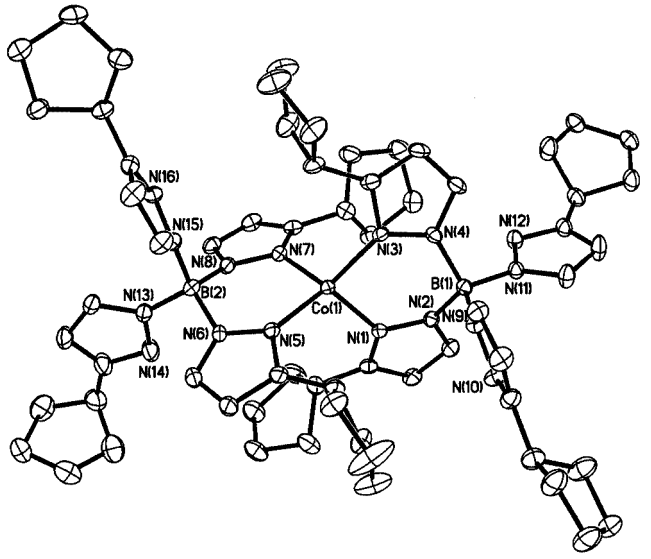

Figure 7. ORTEP plot of the structure of $Co[pz^oTp^{Cpe}]_2$ (**7**); selected bond lengths [Å] and angles [°]: Co−N(1) 1.991(3), Co−N(3) 1.986(3), Co−N(5) 1.985(3), Co−N(7) 1.984(3); N(1)−Co−N(3) 96.79(13), N(1)−Co−N(5) 115.56(13), N(5)−Co−N(3) 125.76(15), N(1)−Co−N(7) 109.01(14), N(3)−Co−N(7) 112.82(13)

We also compared the propensity for dynamic exchange of the coordinated and uncoordinated pyrazolyl arms in a series of $[pz^oTp^R]$ ligands by examining the NMR spectra for the 4- and 5-protons in a series of diamagnetic zinc complexes $Zn[pz^oTp^R]_2$, where R was methyl, cyclopropyl, cyclobutyl, cyclopentyl and cyclohexyl. For the complexes where R was methyl or cyclopropyl, there were only two very sharp peaks for the 4- and 5-protons, implying very rapid exchange of all the pyrazolyl arms. When R was cyclobutyl, there were still only two peaks present, but they ceased to be sharp, with one of them being more of a hump than a peak and the other significantly broadened. The broadest peak was the one for 5-H, as was the C-5 peak in the ^{13}C NMR spectrum of this compound. When R was cyclopentyl, there were already four peaks for the 4- and 5-protons, although they could not be discerned as doublets, implying still a small degree of exchange. In the case where R was cyclohexyl, the four peaks were narrow and sharp with their doublets clearly resolved. These comparisons indicate that the ligand $[pz^oTp^{Cbu}]$ exhibits a hybrid type of behavior which, in turn, implies that the energy difference in solution between the tetrahedral and octahedral forms is quite small.

Conclusion

In summary, we have prepared and characterized new Tp^{Cbu} and Tp^{Cpe} ligands and their tetrakis analogs, [pz^oTp^{Cbu}] and [pz^oTp^{Cpe}], establishing the main features of their coordination chemistry. The ligands Tp^{Cpe} and [pz^oTp^{Cpe}] act very much like the more hindered analogs Tp^{Cy} and [pz^oTp^{Cy}]. However, the Tp^{Cbu} and [pz^oTp^{Cbu}] ligands are, in some ways, special. Tp^{Cbu} is a Tp^R ligand with the largest cycloalkyl group which still permits the formation of homoleptic $Co[Tp^R]_2$ complexes without rearrangement of the ligand to Tp^R*, while [pz^oTp^{Cbu}] exhibits a very facile conversion from octahedral to tetrahedral when going into solution. Being relatively unhindered, this tetrahedral form of [pz^oTp^{Cbu}] might interact/coordinate with some small molecules and, perhaps, exhibit interesting catalytic properties. We are planning to investigate these aspects in the future.

Experimental Section

General: All chemicals were of the highest commercial reagent grade and were used as received. Cyclobutyl methyl ketone and cyclopentylmagnesium chloride were purchased from Aldrich. Elemental analyses were done by Microanalysis, Inc., Wilmington, DE. Infrared spectra were obtained as Nujol mulls of KBr pellets with a Perkin−Elmer 1625 FTIR infrared spectrophotometer, using 16 scans. Proton NMR spectra were obtained with a Nicolet NT360WB spectrometer. The compounds were studied with typical conditions of 16 K data points, a sweep width of 3000−4000 Hz, 90° pulse angles, and a recycle time of 4−5 s.

3-(Cyclobutyl)pyrazole: This compound was prepared by formylation of cyclobutyl methyl ketone (125 g 1.27 mol) with methyl formate, and anhydrous sodium methoxide, followed by the reaction with hydrazine, as has been done in the synthesis of 3-isopropylpyrazole.[10] The product, b.p. 123 °C/1.7 Torr, was obtained in 98 g (63%) yield. ^{1}NMR: δ = 7.49 (d, J = 2.0 Hz, 1 H, 5-H), 6.12 (d, J = 2.0 Hz, 1 H, 4-H), 3.59 (quint, 1 H, tertiary H), 2.14 (m, 2 H, cyclobutyl), 2.20 (quint of d, 2 H, cyclobutyl), 2.1−1.8 (m, 4 H, cyclobutyl) ppm. ^{13}C NMR: δ = 18.8 (unique methylene), 29.6 (2 methylenes), 32.5 (tertiary C), 102.0 (C-4), 135 (C-5), 151.6 (C-3) ppm. $C_7H_{10}N_2$ (122.09): calcd. C 68.9, H 8.20, N 23.0; found C 68.8, H 8.29, N 22.8.

3-(Cyclopentyl)pyrazole: Cyclopentyl methyl ketone was prepared by adding 1.20 mol of cyclopentylmagnesium chloride to a solution of 1.35 mol of acetic anhydride in 1 L of THF. After completion of the addition and another hour of stirring, saturated aqueous ammonium chloride was added, and the two layers were separated. The upper layer was passed through alumina, and the filtrate was stripped and distilled in vacuo, saving the cut with b.p. 163−165 °C. The yield was 56 g (41%). 3-(Cyclopentyl)pyrazole was prepared from the above cyclopentyl methyl ketone, methyl formate, and anhydrous sodium methoxide, followed by the reaction with hydrazine as has been done in the case of 3-isopropylpyrazole.[10] The redistilled pyrazole, b.p. 145−150 °C/5.8 Torr, was obtained in 26 g (42%) yield. ^{1}H NMR: δ = 12.4 (br., 1 H, NH), 7.47 (d, J = 2.0, 1 H, 5-H), 6.06 (d, J = 2.0, 1 H, 4-H), 3.14 (quint, 1 H, tertiary H), 2.07 (m, 2 H, cyclopentyl), 1.5−1.9 (m, 6 H, cyclopentyl) ppm. ^{13}C NMR: δ = 15.1, 33.2, 37.5 (tertiary C), 101.6 (C-4), 135.0 (C-5), 151.4 (C-3) ppm. $C_8H_{12}N_2$ (136.10): calcd. C 70.6, H 8.82, N 20.6; found C 70.6, H 8.94, N 20.6%.

Thallium Hydrotris[3-(cyclobutyl)pyrazol-1-yl]borate, Tl[Tp^{Cbu}] (1): A mixture of 96 g (0.79 mol) of 3-(cyclobutyl)pyrazole and 11.6 g (0.215 mol) of KBH_4 was stirred and refluxed in 200 mL of 4-methylanisole. Hydrogen evolution was steady, and the theoretical amount was evolved within 4 h. The solvent was distilled off under vacuum, and the residue was boiled with 300 mL of heptane, and the solution was filtered hot. The crude K[Tp^{Cbu}] had a B−H band at $\tilde{\nu}$ = 2383 cm^{-1}. The compound was converted into Tl[Tp^{Cbu}] in standard fashion, and this product was obtained in 58 g (48%) overall yield. M.p. 132−134 °C. IR: $\tilde{\nu}$ = 2428 (B−H) cm^{-1}. ^{1}H NMR: δ = 7.54 (d, J = 2.0, 3 H, 5-H), 6.05 (d, J = 2.0, 3 H, 4-H), 3.65 (quint, 3 H, tertiary H), 2.33 (m, 6 H, cyclobutyl), 2.16 (m, 6 H, cyclobutyl), 1.99 (m, 3 H, cyclobutyl), 1.86 (m, 3 H, cyclobutyl) ppm; the BH signal of intensity 1 is visible by integration in the δ = 3.6−5.2 ppm region. ^{13}C NMR: δ = 18.9 (Cbu C-3), 30.0 (Cbu C-2,4), 33.9 (Cbu C-1), 101.6 (C-4), 135.9 (C-5), 157.8 (C-3) ppm. $C_{21}H_{28}BN_6Tl$ (579.67): calcd. C 43.5, H 4.84, N 14.5; found C 43.6, H 4.98, N 14.3.

Thallium Hydrotris[3-(cyclopentyl)pyrazol-1-yl]borate, Tl[Tp^{Cpe}] (2): This compound was prepared as above from 50 g (0.37 mol) of 3-(cyclopentyl)pyrazole and 5.6 g (0.10 mol) of KBH_4 in 75 mL of 4-methylanisole. The residue, after removal of the solvent in vacuo, was converted into Tl[Tp^{Cpe}], which was obtained in 30 g (47%) overall yield. IR: $\tilde{\nu}$ = 2438 (B−H) cm^{-1}. ^{1}H NMR: δ = 7.51 (3 H, 5-H), 5.98 (3 H, 4-H), 3.21 (3 H, quint, Cpe 1-H), 2.07 (6 H, Cpe), 1.75 (m, 6 H, Cpe), 1.64 (m, 12 H, Cpe) ppm; the BH (1 H) signal is visible by integration in the δ = 3.6−5.2 ppm region. ^{13}C NMR: δ = 25.4, 34.1, 38.9 (Cpe, C-1), 101.1 (C-4), 135.8 (C-5), 157.9 (C-3) ppm. $C_{24}H_{34}BN_6Tl$ (621.75): calcd. C 46.4, H 5.48, N 13.5; found C 46.3, H 5.56, N 13.4.

Co[Tp^{Cbu}]Cl: A solution of Tl[Tp^{Cbu}] (1.2 g, 2.0 mmol) in 50 mL of dichloromethane was stirred vigorously with a large excess of anhydrous $CoCl_2$. After 2 h, the blue slurry was filtered through a pad of Celite, and the filtrate was concentrated, yielding a blue solid in 0.64 g (68%) yield. It was obtained after recrystallization from a toluene/heptane mixture as dark blue crystals, m.p. 148−150 °C. IR: $\tilde{\nu}$ = 2504 (B−H) cm^{-1}. $C_{21}H_{28}BClCoN_6$ (469.46): calcd. C 53.6, H 5.96, N 17.9; found C 54.0; H 6.14, N 17.7.

Co[Tp^{Cpe}]Cl: This compound was synthesized in the same way as Co[Tp^{Cbu}]Cl, and was obtained in 63% yield as dark blue crystals, m.p. 161−163 °C. IR: $\tilde{\nu}$ = 2478 (B−H) cm^{-1}. $C_{24}H_{34}BClCoN_6$ (505.49): calcd. C 56.3, H 6.64, N 16.4; found C 56.4, H 6.83, N 16.3.

Zn[Tp^{Cpe}]NCS: The compound was prepared by stirring vigorously in dichloromethane Tl[Tp^{Cpe}] with a large excess of zinc perchlorate and potassium thiocyanate (1:4 mol ratio) in a minimum amount of water. After 2 h, the organic layer was separated, passed through alumina, and the solvents were evaporated, yielding the product in 64% yield. M.p. 160−162 °C. IR: $\tilde{\nu}$ = 2496 (B−H), 2063 (NCS) cm^{-1}. ^{1}H NMR: δ = 7.54 (3 H, 5-H), 6.03 (d, 3 H, 4-H), 3.24 (3 H, quint, Cp 1-H), 2.13 (m, 6 H, Cpe), 1.77 (m, 12 H, Cpe), 1.58 (m, 6 H, Cpe) ppm. $C_{35}H_{34}BN_7SZn$ (660.63): calcd. C 55.6, H 6.30, N 18.2; found C 55.7, H 6.41, N 18.0.

Co[Tp^{Cbu}]$_2$ (3): To a stirred solution of Tl[Tp^{Cbu}] (1.2 g, 2.0 mmol) in 50 mL of THF was added dropwise a concentrated aqueous solution of 0.26 g (1 mmol) of $Co(ClO_4)_2 \cdot (H_2O)_6$ followed, after 1 h, by 200 mL of water and 100 mL of chloroform. The layers were separated, and the chloroform layer was passed through a shallow

bed of alumina, and the solvents were evaporated, yielding 0.67 g (83%) of yellow Co[Tp^{Cbu}]$_2$, which was purified by recrystallization from xylene. M.p. 254−256 °C. IR: $\tilde{\nu}$ = 2439, 2467 cm^{-1}. ^{1}H NMR: δ = 97 (1 H, BH), 74.0 (3 H, 5-H), 48.9 (3 H, 4-H), −12.0 (6 H, 3′-H), −26.1 and 26.7 (6 H each, *cis* and *trans* 2′-H), −92.5 (3 H, 1′-H) ppm. $C_{42}H_{56}B_2CoN_{12}$ (809.50): calcd. C 62.3, H 6.92, N 20.8; found C 62.5, H 7.14, N 20.6.

Co[Tp^{Cpe*}]$_2$ (4): The complex Co[Tp^{Cpe}]$_2$ was prepared as above, but using Tl[Tp^{Cpe}] instead of Tl[Tp^{Cbu}], and it was obtained in 76% yield, as a pale purplish-red solid. It melted to a purple melt at 142−144 °C, then the melt resolidified with a color change to amber at around 166−168 °C, melting again at around 280 °C. Boiling of a sample of the product in benzonitrile resulted in an amber solution, after passing through a deep purple stage. Overlayering this solution with heptane resulted, on standing, in the formation of bright yellow needles, m.p. 286−288 °C. NMR: δ = 84.9 (2 H, 5-H of 3-Cpe), 59.2 (1 H, 4-H of 5-Cpe), 49.5 (2 H, 4-H of 3-Cpe), 38.6 (1 H, tertiary H of 5-Cpe), 24.8 (2 H, *trans*-2,4-H of 5-Cpe), 16.9 (2 H, *cis*-2,4-H of 5-Cpe), 13.5 (2 H, *trans*-3,4-H of 5-Cpe), 9.12 (2 H, *cis*-3,4-H of 5-Cpe), −14.104 (2 H, 3,4-H of 3-Cpe), −14.7 (2 H, 3,4-H of 3-Cpe), −14.7 (2 H, 3,4-H of 3-Cpe) −15.0 (2 H, 3,4-H of 3-Cpe), −31.9 (2 H, *trans*-2,5-H of 3-Cpe), −36.3 (2 H, *trans*-2,5-H of 3-Cpe), −40.9 (2 H, *cis*-2,5-H of 3-Cpe, −46.8 (2 H, *cis*-2,5-H of 3-Cpe), −94 (1 H, 3-H), −108 (2 H, tertiary H of 3-Cpe) ppm. $C_{48}H_{68}B_2CoN_{12}$ (893.69): calcd. C 64.5, H 7.61, N 18.8; found C 65.1, H 7.80, N 19.0.

Zn[Tp^{Cbu}]$_2$: M.p. 186−188 °C. IR: $\tilde{\nu}$ = 2466, 2438 (B−H) cm^{-1}. ^{1}H NMR: δ = 7.57 (d, *J* = 2.0, 3 H, 5-H), 6.16 (d, *J* = 2.0, 3 H, 4-H), 2.73 (quint, 3 H, tertiary H), 1.81 (m, 6 H, cyclobutyl), 1.62 (m, 6 H, cyclobutyl), 1.57 (m, 6 H, cyclobutyl) ppm; the BH (1 H) signal can be discerned by integration in the δ = 3.5−5.0 ppm range. ^{13}C NMR: δ = 18.1 (C-3′), 30.1 (C-2′), 32.9 (C-1′), 102.1 (C-4), 135.9 (C-5), 159.3 (C-3) ppm. $C_{42}H_{56}B_2N_{12}Zn$ (815.55): calcd. C 61.8, H 6.87, N 20.6; found C 62.0, H 7.01, N 20.5.

Zn[Tp^{Cpe}]$_2$: M.p. 182−184 °C. ^{1}H NMR: δ = 7.31 (d, 3 H, 5-H), 6.06 (d, 3 H, 4-H), 2.60 (3 H, quint, Cpe 1-H), 1.63 (m, 12 H, Cpe), 1.47 (m, 12 H, Cpe) ppm. ^{13}C NMR: δ = 25.3, 33.8, 38.9, 102.0, 137.5, 161.0 ppm. $C_{48}H_{68}B_2N_{12}Zn$ (899.61): calcd. C 64.1, H 7.56, N 18.7; found C 64.2, H 7.69, N 18.5.

Preparation of Heteroleptic Co[Tp^R][$Tp^{R'}$] Complexes. A: One method to synthesize octahedral cobalt complexes containing two different Tp^R ligands was to stir equimolar amounts of Co[Tp^R]Cl (R = Cbu, Cpe) and Tl[$Tp^{R'}$] (R′ = H, Me, cyclopropyl) in dichloromethane until the disappearance of the characteristic blue color of Co[Tp^R]Cl. This took from a few minutes to several hours, depending on the steric hindrance of $Tp^{R'}$. The slurry was then filtered through a bed of Celite to remove TlCl, and the filtrate was chromatographed on alumina, collecting the yellow band. Concentration of the eluate yielded the crude product, which was recrystallized from toluene or xylene. **B:** An alternative way was to stir Tl[Tp^R] in dichloromethane with a large excess of anhydrous $CoCl_2$, to filter the blue slurry after 4 h, and without isolation of Co[Tp^R]Cl, adding an equimolar amount of the appropriate Tl[$Tp^{R'}$] salt. When the color of the slurry changed from blue to yellowish, the slurry was filtered to remove TlCl, the filtrate was chromatographed on alumina, and concentration of the eluate yielded the crude Co[Tp^R][$Tp^{R'}$] complex, which was purified by recrystallization. The unoptimized yields in these reactions ranged from 55 to 82%.

Co[Tp^{Cbu}][Tp]: This complex was prepared by method A, was obtained in 82% yield, and recrystallized from toluene. M.p. 267−268 °C. IR: $\tilde{\nu}$ = 2469, 2445 (B−H) cm^{-1}. ^{1}H NMR: δ = 114.2 and 111.8 (1 H each, BH), 90.4 and 82.5 (3 H each, 5-H), 44.8 and 41.5 (3 H each, 4-H), −14.5 and − 15.0 (3 H each, *cis*- and *trans*-3′-H), −31.5 and −35.4 (6 H each, *cis*- and *trans*-2′-H), −102.1 (3 H, 1′-H), −124.3 (3 H, 3-H) ppm. $C_{30}H_{38}B_2CoN_{12}$ (646.97): calcd. C 55.6, H 5.87, N 26.0; found C 55.5, H 6.01, N 25.7.

Co[Tp^{Cpe}][Tp] (5): This complex was prepared by method A and was obtained in 77% yield. M.p. 278−280 °C. IR: $\tilde{\nu}$ = 2473, 2440 (B−H) cm^{-1}. ^{1}H NMR: δ = 118.5 and 115.7 (1 H each, BH and BH′), 92.9 and 93.4 (3 H each, 5-H and 5′-H), 45.3 and 42.0 (3 H each, 4-H and 4′-H), −13.6 and − 14.5 (6 H each, Cp 3-H, *cis* and *trans*), −35.5 (6 H, Cp 2-H, *trans*) −45.6 (6 H, Cp 2-H, *cis*), −106.3 (3 H, Cp 1-H), −131.7 (3 H, 3-H) ppm. $C_{33}H_{44}B_2N_{12}$ (689.40): calcd. C 57.5, H 6.39, N 24.4; found 57.8, H 6.48, N 24.1.

Co[Tp^{Cpe}][Tp*]: This complex was prepared by method B and was obtained in 69% yield. M.p. 282−284 °C. IR: $\tilde{\nu}$ = 2515, 1475, 2443 (B−H) cm^{-1}. ^{1}H NMR: δ = 105.5 (2 H, BH and BH′), 77.6 (3 H, 5-H), 48.1 and 44.8 (3 H each, 4-H and 4′-H), 42.9 (9 H, 5-Me), −12.3 and −12.9 (6 H each, Cp 3-H, *cis* and *trans*), −31.5 (6 H, Cp 2-H, *trans*), −38.4 (6 H, Cp 2-H, *cis*), −75.7 (9 H, 3-Me), −113.6 (3 H, Cp 1-H) ppm. $C_{39}H_{56}B_2CoN_{12}$ (773.06): calcd. C 60.5, H 7.24, N 21.7; found C 60.4, H 7.31, N 21.6.

Co[Tp^{Cpe}][Tp^{Cpr}]: This complex was prepared by method B and was obtained in 55% yield. M.p. 247−248 °C. IR: $\tilde{\nu}$ = 2438, 2473 (B−H) cm^{-1}. ^{1}H NMR: δ = 99.6 and 97.2 (1 H each, BH and BH′), 76.0 and 69.4 (3 H each, 5-H and 5′-H), 47.6 and 45.4 (3 H each, 4-H and 4′-H), −11.2 (12 H, Cpr 3-H), −23.8 (3 H, Cpr 2-H, *trans*), −25.6 (6 H, Cpr 2-H, *cis*), −28.9 (6 H, Cpr 2-H, *trans*) −32.4 (6 H Cpe 2-H, *cis*), −97.3 and −100.0 (3 H each, Cpr and Cpe 1-H) ppm. $C_{42}H_{56}B_2CoN_{12}$ (809.09): calcd. C 56.6, H 6.92, N 20.8; found C 56.5, H 7.04, N 20.7.

Preparation of the [pz^oTp^{Cbu}] and [pz^oTp^{Cpe}] Ligands: These ligands were prepared by heating with stirring the appropriate pyrazole and KBH_4 in a 5:1 mol ratio, bringing the oil-bath temperature slowly up to 250−270 °C, and maintaining this temperature under a gentle nitrogen stream for 24 h. After some cooling, the excess pyrazoles were distilled off in vacuo, and the residues were refluxed for 1 h in heptane, cooled and filtered, yielding the crude K salts K[pz^oTp^{Cbu}] and K[pz^oTp^{Cpe}], respectively. Samples of each were converted into the Tl salts, Tl[pz^oTp^{Cbu}] and Tl[pz^oTp^{Cpe}]. However, only Tl[pz^oTp^{Cbu}] could be recrystallized, as the resinous Tl[pz^oTp^{Cpe}] resisted all attempts at crystallization. For this reason, the crude K[pz^oTp^{Cpe}] salt was employed for preparing M[pz^oTp^{Cpe}] complexes.

Tl[pz^oTp^{Cbu}]: It was recrystallized from octane. M.p. 129−132 °C. ^{1}H NMR: δ = 7.41 (d, *J* = 2 Hz, 1 H, 5-H), 6.15 (d, *J* = 2 Hz, 1 H, 4-H), 3.65 (quint, 1 H, tertiary H), 2.34 (m, 2 H, Cbu), 2.18 (m, 2 H, Cbu), 1.8−2.1 (m, 2 H, Cbu) ppm. ^{13}C NMR: δ = 18.8 (Cbu C-3), 29.7 (Cbu C-2), 33.9 (Cbu C-1), 102.7 (C-4), 136.0 (C-5), 158.9 (C-3) ppm. $C_{28}H_{36}BN_8Tl$ (699.55): calcd. C 48.1, H 5.15, N 16.0; found C 48.2, H 5.23, N 15.8.

Co[pz^oTp^{Cbu}]$_2$ (6): This complex was prepared from Tl[pz^oTp^{Cbu}] and $Co[ClO_4]_2{\cdot}(H_2O)_6$. It turns gradually deep purple above 150 °C, and melts at around 250 °C. ^{1}H NMR: δ = 63.9 (1 H), 34.8 (1 H), −5.0 (1 H), − 5.6 (1 H), −14.8 (16 H), −57 (1 H) ppm. $C_{56}H_{72}B_2CoN_{16}$ (1049.85): calcd. C 64.1, H 6.86, N 21.4; found C 63.9, H 6.92, N 21.2.

Co[pz^oTp^{Cpe}]$_2$ (7): This complex was prepared from Tl[pz^oTp^{Cpe}] and $Co[ClO_4]_2{\cdot}(H_2O)_6$. M.p. 251−253 °C. ^{1}H NMR: very broad

X-ray Crystal Structure Determinations: Diffraction intensity data were collected with Siemens P4 (**1**−**3**, **5**) and Bruker Smart Apex CCD (**4**, **6**, **7**) diffractometers. Crystal, data collection, and refinement parameters are given in Table 2. The systematic absences in the diffraction data of **1**−**3**, **5**−**7** structures are uniquely consistent with the reported space groups. The space group for **4** has been chosen by intensity statistics. The structures were solved by direct methods (**1**−**6**) and the Patterson function (**7**), completed by subsequent Fourier syntheses and refined by full-matrix, least-squares procedures on reflection intensities (F^2). SADABS absorption corrections were applied to the data of **1**, **3**−**6** and DIFABS[22] corrections to the data of **2** (T_{min} = 0.48, T_{max} = 1.00) and **7** (T_{min} = 0.28, T_{max} = 1.00).[23] All non-hydrogen atoms were refined with anisotropic displacement coefficients, and hydrogen atoms were treated as idealized contributions. In the structure of **6**, two C_4 rings are disordered in two positions with occupation multiplicity μ = 0.60, 0.40 and 0.59, 0.41, respectively. All software and sources scattering factors are contained in the SHELXTL (5.10) program package (G. Sheldrick, Bruker XRD, Madison, WI). CCDC-178940 (**1**), -178941 (**2**), -178942 (**3**), -178943 (**4**), -178944 (**5**), -178945 (**6**) and -178946. (**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

[23] Confronted with a difficult correction for absorption, a prudent crystallographer will sample the output of the many programs at his disposal, and then select the one that does the job best. In the realm of empirical and semi-empirical correction schemes, many programs have been written, some old and some new. Each analyzes the data in a somewhat different way, and each can produce different results. While DIFABS may be one of the older methods, it is, on occasion, the one that performs best, and because its routines are well known and some newer routines are undocumented "black boxes," its idiosyncrasies are also well known. We are unaware that anyone has declared DIFABS ineffective or fatally flawed, and until such time, it is a useful procedure that we intend to keep using.

Europium(II) Complexes With Benzo-18-Crown-6[‡]

Przemysław Starynowicz,*[a] Krystyna Bukietyńska,[a] Stanisław Gołąb,[b] Witold Ryba-Romanowski,[b] and Jerzy Sokolnicki[a]

Keywords: Europium / Lanthanides / Crown compounds / X-ray diffraction / Luminescence

Two compounds of Eu^{II} with benzo-18-crown-6, triaqua(benzo-18-crown-6)europium(II) diperchlorate (**1**) and triaqua(benzo-18-crown-6)europium(II) perchlorate hydrate benzo-18-crown-6 solvate (**2**), were synthesized by electrochemical reduction. The coordination environment of the metal cation in both cases contains six O atoms of the crown ligand and three water molecules. The first complex display strong blue luminescence with a maximum at 425 nm. The excitation spectra do not show any significant energy transfer from the benzo rings to europium.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Crown ethers have attracted much attention owing to their specific and selective coordination of metal ions. Encapsulation of the metal by the ligand provides at least partial protection from the influence of other reagents that may be present in the system. Therefore crown ethers seem to be a promising class of ligands that may stabilize otherwise unstable entities such as divalent lanthanides. Compounds of divalent lanthanides (mainly Eu^{2+}) with crown ethers have therefore attracted much attention; the present state of the investigations on such complexes was excellently reviewed by Adachi et al.[1] The interest in these compounds arises both due to the luminescent properties of the Eu^{2+} cation in the macrocyclic coordination environment and by the ability of the ligand to stabilize the divalent oxidation state of the lanthanide. The encapsulation effected by the crown ethers leads to an increase of the luminescence quantum yield in comparison with noncyclic polyethers. The other interesting feature of the discussed complexes is their ability to shift the reduction potential of the Eu^{III}/Eu^{II} couple towards more positive values,[2] which may eventually open a way to the application of these compounds or their derivatives as redox-sensitive shift agents in MRI tomography. It is therefore important and very interesting to collect information about the structures and properties of macrocyclic complexes of Eu^{II} both in solution and in the solid state. In previous work[3] we have described the structure of bis(benzo-15-crown-5)europium(II) diperchlorate. This work, which is a continuation of our investigations on the structure and spectroscopy of Eu^{II} complexes with crown ethers in the solid state, deals with two other complexes: triaqua(benzo-18-crown-6)europium(II) diperchlorate (**1**) and triaqua(benzo-18-crown-6)europium(II) perchlorate hydrate benzo-18-crown-6 solvate (**2**).

Results and Discussion

Structures

Crystals of **1** are composed of complex trisaqua(benzo-18-crown-6)europium(II) cations and perchlorate anions, and they are isomorphic with the analogous compound of Sr.[4] Crystals of **2**, apart from the same constituents as in **1**, also contain other, uncoordinated, benzo-18-crown-6 molecules and water of crystallization. The coordination environment of europium is essentially the same in both crystals and consists of three water molecules and six oxygen atoms from the macrocycle ring. The coordination figure in either case is rather irregular. The roughly equatorial positions are occupied by the crown oxygen atoms, whereas two water molecules (OW2 and OW3) are located in axial positions on one side of the equatorial plane, and the third water molecule (OW1) is located in an axial position at the opposite side. A similar coordination geometry is also typical for nine-coordinate compounds of Ln^{III} with 18-crown-6 derivatives, for example triiodo(dibenzo-18-crown-6)samarium,[5] trichloro(18-crown-6)lanthanum(III),[6] and numerous dichloro(18-crown-6)lanthanide(III) solvates (e.g. water or an alcohol)[6–10] or chloro(18-crown-6)lanthanide(III) disolvates.[6,9,11–13] The Eu–O distances, presented

Table 1. The Eu−O distances (Å) for **1** and **2**

1		2	
Eu−OW1	2.584(3)	Eu−OW2	2.576(3)
Eu−OW2	2.592(3)	Eu−OW1	2.584(3)
Eu−OW3	2.596(3)	Eu−OW3	2.624(3)
Eu−O(4)	2.660(3)	Eu−O(3)	2.633(3)
Eu−O(2)	2.671(3)	Eu−O(2)	2.651(3)
Eu−O(3)	2.682(3)	Eu−O(5)	2.656(3)
Eu−O(6)	2.693(3)	Eu−O(6)	2.663(3)
Eu−O(5)	2.695(3)	Eu−O(4)	2.698(3)
Eu−O(1)	2.741(3)	Eu−O(1)	2.757(3)

in Table 1, are rather long in comparison with other Eu^{II}−O bond lengths. Their average values are the following: $Eu-O_{crown}$ = 2.690(29) Å for **1** and 2.676(45) Å for **2**, $Eu-O_{water}$ = 2.591(7) Å for **I** and 2.595(26) Å for **2**. These quantities compare well with the relevant values for the isomorphic Sr compound: $Sr-O_{crown}$ = 2.683(22) Å, and $Sr-O_{water}$ = 2.568(14) Å.[4] On the other hand it is interesting to see the difference between the analogous Eu^{II} and Eu^{III} complexes. For chlorodiaqua(18-crown-6)europium(III) cations[6,9] the overall mean $Eu-O_{crown}$ distance is 2.536(50) Å, and the $Eu-O_{water}$ distance is 2.424(35) Å. The differences between the values for our Eu^{II} compounds and the Eu^{III} complexes quoted above are in good agreement with the difference between the ionic radii of Eu^{2+} and Eu^{3+} for nine-coordinate compounds (0.18 Å).[14] It is noteworthy that in all the discussed complexes the water molecules are closer to the metal ion than the crown oxygen atoms. The cavity in the unligated crown molecule in **2** remains empty, although OW3 and the uncoordinated OW4 water molecule approach it somewhat (OW3 forms a hydrogen bond with O42, and OW4 interacts in the same way with O43). The coordination of Eu in **1** is shown in Figure 1, and a fragment of **2** is shown in Figure 2. Both crystals are held together by hydrogen bond networks, and electrostatic and Van der Waals interactions.

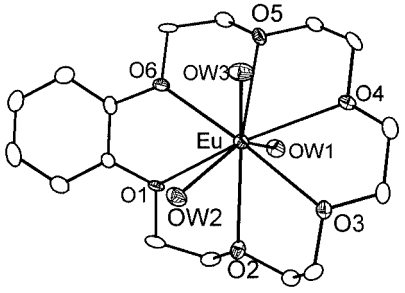

Figure 1. A view of the complex cation in **1**, together with labelling of the metal first coordination sphere

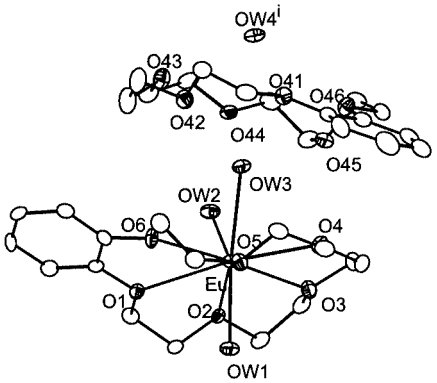

Figure 2. A view of a fragment of **2**; the labels are rendered for Eu and O atoms only for the sake of clarity; [i] represents the symmetry operation $-1/2 + x$, $1/2 - y$, $-1/2 + z$

Spectroscopy of 1

The compound displays bright blue luminescence with a maximum at 425 nm (23520 cm^{-1}) at room temperature, and at 430 nm (23260 cm^{-1}) at 77 K (see Figure 3). These values are similar to those reported for bis(benzo-15-crown-5)europium(II) diperchlorate[3] (422 and 426.5 nm, respectively) and remarkably different from the emission maximum observed for the complex formed from $EuCl_2$ and benzo-18-crown-6 in methanol (447 nm[1,15]). This difference may be due to several factors, such as: a) coordination of methanol instead of water, b) the possible coordination of Cl^-, and c) a different coordination number of the metal cation. The discrepancy between the present compound and the quoted complex in solution is manifested even more strikingly in the luminescence lifetimes of both systems. The luminescence lifetime of the $EuCl_2$/benzo-18-crown-6/methanol system was reported to be 0.028 μs. For the present compound the decay curves were measured at 293 and 77 K. At room temperature the decay is bi-exponential, with τ_1 = 8.34(6) μs and τ_2 = 137(11) μs; the decay equation may be expressed as: $I = I_0 \cdot \{0.890(3)\exp[-t/8.34(6)] + 0.110(3)\exp[-t/137(11)]\}$ the e.s.d.'s are given in parentheses. At 77 K the decay is a single exponential with a lifetime of 8.01(2) μs. The second, long lived component that appears at room temperature may be due to partial decomposition of the complex brought about by the laser flashes, and, accordingly, can be disregarded. The observed disparity between the τ values for the crystal and the solu-

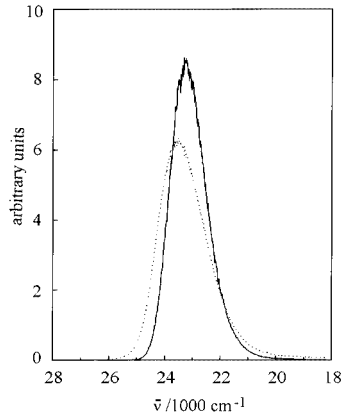

Figure 3. The emission spectrum of **1** at room temperature (dotted line) and at 77 K (solid line)

tion may be caused by several factors. We can safely eliminate the role of OH oscillators in the Eu first-coordination sphere, as they are present in both cases. Therefore the probable reasons for the discussed discrepancy are: a) internal rotations of the macrocycle ring, and b) the exchange dynamics of methanol molecules and possibly chloride anions. Finally, it is noteworthy that the luminescence lifetime for the present compound is an order of magnitude greater than that reported for the benzo-15-crown-5 complex (0.59 μs at 77 K).[3]

The excitation spectrum may be divided into two parts: one, larger, between 275 and 408 nm (24500−38900 cm^{-1}), and the other, smaller, between 230 and 275 nm (38900−43500 cm^{-1}). In the first part three maxima are discernible, at 392 nm (25510 cm^{-1}), 352 nm (28410 cm^{-1}) and 309 nm (32360 cm^{-1}). In the other part only one maximum can be identified at 248 nm (40320 cm^{-1}). The difference in wavenumbers between these and the lowest lying excited (emitting) level are 2250, 5150, 9100 and 17060 cm^{-1}, respectively. Using the simple approach of Johnson and Sandoe[16] we can interpret the first three maxima as being dominated mostly by $4f^6(^7F)5d$ states, whereas the last one, lying 17060 cm^{-1} above the emitting level, should include mainly the $4f^6(^5D)5d$ states, as the respective difference parallels that between the energies of the ^7F_J and ^5D_J levels in Eu^{3+}.

The excitation spectrum of **1**, juxtaposed with the absorption spectrum of the free ligand (Figure 4) shows no evidence for energy transfer from the benzo rings to the metal ion (the so called "antenna effect"), as no correspondence between the peaks in both spectra can be noticed.

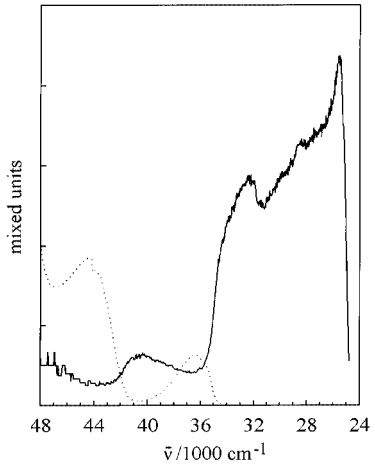

Figure 4. The excitation spectrum of **1** at 77 K (solid line), and the absorption spectrum of benzo-18-crown-6 in water/methanol solution (dotted line)

Conclusion

Two new complexes of Eu^{II} with benzo-18-crown-6 have been obtained in the crystalline state. In both complexes the metal ion is nine-coordinate and the coordination environment is composed of six O atoms belonging to the crown ligand and three water molecules. The spectroscopic properties are similar to those previously reported for a benzo-15-crown-5/Eu^{II} complex, with the exception of the luminescence lifetime, which is an order of magnitude larger in the present case. Both the emission maximum and luminescence lifetime are different from the analogous quantities reported for the $EuCl_2$/benzo-18-crown-6 complex in methanol solution.

Experimental Section

Preparation: a) Compound **1** was obtained by dissolving 0.5 g of Eu_2O_3 in $HClO_4$, evaporating the resulting solution until the evolution of white fumes, cooling down the resulting perchlorate, dissolving it in a 1:2 water/methanol mixture, and then adding 1 g of benzo-18-crown-6. The resulting solution was placed in the cathode compartment of an H-shaped electrolyzer with a sintered glass diaphragm and a pool Hg cathode. A dilute water/methanol (1:2) solution of $HClO_4$ was the anolyte. The reduction was performed at −1.2 V with respect to the saturated calomel electrode, and with a stream of N_2 passing slowly above the reduced solution. Colourless crystals of **1** formed after 1−2 days. The compound is unstable in air and begins to darken after ca. 10−15 min. $C_{16}H_{30}Cl_2EuO_{17}$ (717.26) calcd. C 26.8, H 4.2, Eu 21.2; found C 26.4, H 4.0, Eu 20.3. Compound **2** was the result of an unsuccessful attempt to prepare an acetate salt of the crown complex. The preparation was started from europium acetate, obtained by dissolving 0.5 g of Eu_2O_3 in concentrated acetic acid. The acetate was then dissolved in the water/methanol mixture and a few drops of moderately dilute $HClO_4$ were added to increase the solution conductivity. The synthesis continued similarly as in the case of **1**. The crystals of **2** were also colourless and unstable in air.

X-ray Crystallographic Study: Appropriate crystals were cut from larger ones and mounted on a Kuma KM4 diffractometer equipped with a CCD counter. The collected data were corrected for polarization, Lorentz and absorption effects; the latter were calculated from the crystal habits captured from photo scans. The positions of Eu were found from Patterson maps, and the rest of the non-H atoms from difference Fourier maps. The positions of the C-bonded hydrogen atoms were calculated geometrically. No attempt was made to localize the O-bonded H atoms The refinement was full-matrix with all non-H atoms anisotropic. The temperature factors of the H-atoms were constrained to 1.2 times the factors of the relevant C atoms. A peak with height of 2.0 e·$Å^{-3}$ (see Table 2) located 2.8 Å away from Eu and placed between OW2 and OW3, that appeared on the final residual difference Fourier map of **2**, was unrefinable, and therefore was not included in the model. The programs used were SHELXS-97[17] for the solution, SHELXL-97[18] for the refinement, and DIAMOND[19] for the molecular graphics. The data collection and refinement details are presented in Table 2.

Spectroscopy: The spectroscopic investigations for **1** only will be presented here. The luminescence and excitation spectra were taken on an SCL Aminco 500 spectrofluorimeter. The luminescence was excited with a lamp source with wavelength of 330 nm, and the excitation spectra were recorded for the emission at 425 nm. The luminescence decay curves were detected on a device equipped with a Hamamatsu photomultiplier and a Tektronix TDS-3052 digital oscilloscope. The sample was excited with the third harmonic of a neodymium laser (355 nm), and the registered output signal had

Electrochemical Synthesis of Cobalt Complexes with 4-Methyl-*N*-(2-pyridylmethyl)benzenesulfonamide (HL) − Crystal Structures of HL, $[Co^{II}L_2]$ and $[Co^{III}L_2L^o]$ [L^o = {$HNC(CH_3)$}$_2C(CN)$]

Keywords: Cobalt / Electrochemistry / N ligands / X-ray crystal structures

Electrochemical oxidation of cobalt in a solution of 4-methyl-*N*-(2-pyridylmethyl)benzenesulfonamide (HL, **1**) in acetonitrile afforded the compounds $[Co^{II}L_2]$ (**2**) or $[Co^{III}L_2L^o]$ (**3**). When 2,2′-bipyridine (bipy) or 1,10-phenanthroline (phen) was added to the electrolytic phase, $[Co^{II}L_2bipy]$ (**4**) and $[Co^{II}L_2phen]$ (**5**) were obtained. The crystal structures of HL (**1**), $[Co^{II}L_2]$ (**2**) and $[Co^{III}L_2L^o]$ (**3**) were determined by X-ray diffraction techniques. The compound $[Co^{II}L_2]$ is mononuclear and has a distorted tetrahedral $[CoN_4]$ geometry, with each amide ligand acting as an anionic ($N_{amide}N_{py}$) bidentate ligand. In the monomeric complex $[Co^{III}L_2L^o]$ the cobalt atom is in a distorted octahedral $[CoN_6]$ environment defined by the amide and pyridyl nitrogen atoms of two L^- anionic ligands and the two nitrogen atoms of the NH groups of a new anionic ligand L^o, which is formed by trimerisation of three acetonitrile molecules in the electrolytic cell. The electronic, IR and FAB spectra of the compounds are discussed.

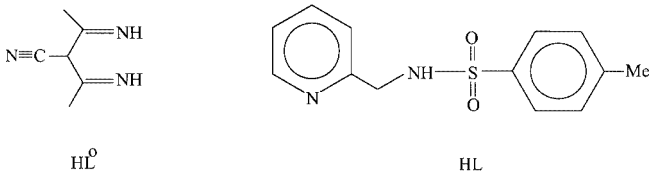
Introduction

Electrochemical procedures have been widely used for the synthesis of metal complexes, especially when the ligands have weakly acidic organic donor groups. It is well known that metal complex formation by substitution of the amide proton by a metal ion is not an easy process.[1] However, the presence of an additional donor atom in the molecule allows the formation of a stable five- or six-membered chelate ring with the metal ion[2] and this situation may facilitate the complexation process. In addition, the presence of a tosyl group in the amide increases the acidity of the amide hydrogen atom, making the formation of the anionic ligand easier.[3]

The work described here is a continuation of our previous studies on metal complexes with ligands containing a pyridyl ring and a tosylamide group.[4] This paper describes the preparation of the ligand [4-methyl-*N*-(2-pyridylmethyl)benzenesulfonamide] (HL, **1**) (Scheme 1), and the cobalt complexes $[Co^{II}L_2]$ (**2**), $[Co^{II}L_2L']$ [where L′ is 2,2′-bipyridine (bipy) (**4**), 1,10-phenanthroline (phen) (**5**) and $[Co^{III}L_2L^o]$ (**3**), where L^o (Scheme 1) represents the anionic form of an additional ligand formed during the electrochemical process by trimerisation of three molecules of acetonitrile.



Scheme 1

Results and Discussion

The ligand [4-methyl-*N*-(2-pyridylmethyl)benzenesulfonamide] (HL) was prepared by a standard procedure, by treatment of 2-(aminomethyl)pyridine with *p*-toluenesulfonyl chloride in the presence of base. An interesting feature of the ^1H NMR spectrum of the ligand is the signal at δ = 11.6 ppm for the NH proton in $CDCl_3$; for simple sulfonamides of the form RSO_2NH-Ar this resonance normally appears at $\delta \approx 7$ ppm. The observed difference was probably due to the presence in solution of an intramolecular hydrogen bonding interaction between the NH group and the pyridine nitrogen atom. The same explanation can also be put forward to explain the very lowfield resonance of the OH proton in the case of the salicylaldimines.

Molecular Structure of the Ligand HL (1)

The molecular structure of [HL] is shown in Figure 1, together with the adopted atomic numbering scheme. Selected bond lengths and angles are given in Table 1.

The bond lengths and bond angles of the phenyl and pyridine rings are similar to those found in other pyridylbenzenesulfonamide ligands.[5−9] The C(6)−N(2) and S(1)−N(2) distances [1.447(7) and 1.603(5) Å] are very close to those observed in *N*-(*p*-tolylsulfonyl)benzylamine [1.475(3) and 1.619(2) Å].[10]

The phenyl and pyridine rings are almost flat, with the maximum deviation of any atom from the best least-squares planes being 0.010(5) and 0.011(4) Å, respectively. The carbon atom C(20) and the sulfur atom S(1) lie approximately in the plane of the phenyl ring to which they are bound [deviation of 0.022(10) Å for C(20) and 0.019(7) Å for S(1)]. Atom C(6) is also out of the plane of the pyridine ring to which it is bound [0.102(10) Å]. The interplanar angle between the phenyl and pyridine rings is 55.7°.

The crystal structure is completed by half a water molecule, which is associated with the ligand molecules through intermolecular hydrogen bonds. Hydrogen bonds exist between the pyridine nitrogen atoms of two ligand molecules and the oxygen atom of the water molecule. In addition, the oxygen atom of the water molecule is involved in a hydrogen bond with the amide nitrogen atoms of two other neighbouring ligands. Therefore, infinite hydrogen bonded chains of ligand and water molecules are formed in this system (Table 2).

Table 2. Hydrogen bonds in the ligand

Cobalt Complexes

The cobalt complex $[Co^{II}L_2]$ and its adducts with 2,2′-bipyridine (bipy) and 1,10-phenanthroline (phen) − $[Co^{II}L_2(bipy)]$ and $[Co^{II}L_2(phen)]$, respectively − were prepared in good yield by the simple one-step electrochemical method described below. In all cases, the product formed was separated by filtration as a crystalline product. In addition, all of the compounds were air-stable and moderately soluble in organic solvents such as ethanol or chloroform.

The values of the electrochemical efficiency, defined as the amount of metal dissolved per Faraday of charge, were all close to 0.5 mol·F^{-1}, irrespective of the presence or absence of additional ligands. This fact, in conjunction with the evolution of hydrogen at the cathode, is compatible with the following mechanism:

Cathode: $2\ HL + 2\ e^- \longrightarrow 2\ L^- + H_2$

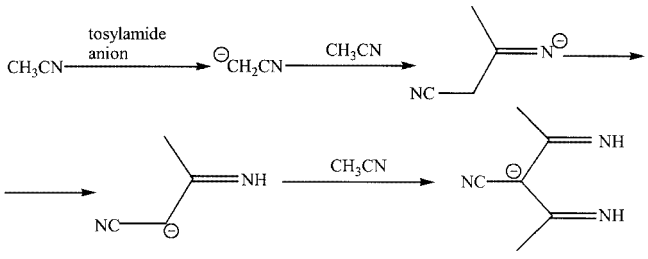
Anode: $Co + 2\ L^- \longrightarrow [Co^{II}L_2] + 2\ e^-$

or, when an additional neutral ligand (L′ = bipy or phen) is added:

Anode: $Co + 2\ L^- + L' \longrightarrow [Co^{II}L_2L'] + 2\ e^-$

When the electrochemical oxidation of cobalt metal in an acetonitrile solution of the amide ligand was carried out at a much higher voltage than in the previous case, the compound $[Co^{III}L_2L^{\circ}]$ was formed. In this compound, besides the deprotonated amide ligands, a new ligand, formed by trimerisation of three acetonitrile molecules, appears in the coordination sphere of the metal ion.

The trimerisation of acetonitrile can be viewed as the result of a tandem reaction catalysed by the nucleophilic attack of a tosylamide anion, formed during the electrochemical reaction, on an acetonitrile molecule, as shown in Scheme 2.



Scheme 2

It is most probable that these reactions occur in the coordination sphere of the metal ion, given the fact that they do not occur in its absence. The occurrence of this process may

be ascribed to the increased sensitivity of the acetonitrile molecule to nucleophilic attack as a result of coordination to the metal ion. This reaction can be considered as the intramolecular version of the Thorpe−Ziegler reaction.

The CH_3CN trimerisation process is not without precedent. It has previously been observed when MMe_3 (M = Al, Ga or In) was boiled for 24−72 h at 60−65 °C in acetonitrile in the presence of cesium halides ($X = F^-$, Cl^-, Br^-) to give $[CH_3M\{HNC(CH_3)\}_2C(CN)]$.[11,12]

Molecular Structure of $[Co^{II}L_2]$ (2)

The molecular structure of $[Co^{II}L_2]$ is shown in Figure 2, along with the adopted atomic numbering scheme. Selected bond lengths and angles are listed in Table 3. The structure of the complex consists of mononuclear units in which a tetracoordinated cobalt atom is bound to both nitrogen atoms of two bidentate monoanionic ligands in a distorted tetrahedral arrangement. Two different Co−N bond lengths are observed: the bonds involving amide nitrogen atoms [1.926(4), 1.946(4) Å] are significantly shorter than those involving pyridine nitrogen atoms [2.028(4), 2.040(4) Å]. These values are similar to those found in other cobalt compounds containing both anionic and neutral nitrogen donor atoms, such as in the tetrahedral complex [2-tosylamino(2′-pyridyl)anilinato]cobalt(II) [Co−N_{amide}, 1.959(13) Å][13] or in the cobalt(II) complex with the ligand obtained by the reaction between 2-(2-aminophenyl)pyridine with *p*-toluenesulfonyl chloride[3] [Co−N_{amide} 1.960(2), 1.967(2) Å; Co−$N_{pyridine}$ 2.041(2), 2.043(2) Å]. The tetrahedral environment of the cobalt atom is distorted due to the small bite required by N−Co−N = 81.37(16)−82.08(16)°, which also results in secondary deviation of the other perinuclear angles from the ideal values of 109°. Each five-membered chelate ring lies in a plane with the maximum deviation of any atom from this plane being 0.0004 and 0.0165 Å. The two planes are nearly perpendicular, with a dihedral angle of 82.11°. In each ligand the phenyl and pyridine rings are planar.

Molecular Structure of $[Co^{III}L_2L^o]$ (3)

The molecular structure of $[Co^{III}L_2L^o]$ is shown in Figure 3, together with the adopted atomic numbering scheme. The main bond lengths and angles are given in Table 4. The structure consists of monomer $[Co^{III}L_2L^o]$ units. The cobalt atom is in a $[CoN_6]$ environment produced by two amide and two pyridine nitrogen atoms of two bidentate monoanionic tosylamide ligands and two nitrogen atoms of the ligand L^o, formed by the trimerisation of three molecules of the acetonitrile used as the solvent in the electrochemical cell. Both amide nitrogen atoms are in a *trans* disposition.

The $Co-N_{amide}$ and $Co-N_{py}$ bond lengths have similar values. The average $Co-N_{py}$ bond length (1.957(5) Å) is longer than those found in other octahedral cobalt(III) complexes with pyridine nitrogen donor ligands, such as 1.882(5) Å in $[Co^{III}L^1]^+$ {HL^1 = 3,11-bis(methoxycarbonyl)-7-methyl-3,7,11,17-tetraazabicyclo[11.3.1]heptadeca-1(17),13,15-triene}[14] and 1.884(3) Å in $[Co^{III}L^3]$ [HL^3 = 3,7,11-tris(carboxymethyl)-3,7,11,17-tetraazabicyclo-[11.3.1]heptadeca-1(17),13,15-triene][14] or 1.911(3) and 1.915(3) Å in $[Co^{III}(dpkH)_2](MeO)(MeOH)$ [dpkh = bis(2-pyridyl) ketone hydrate],[15] but is only slightly longer than 1.934(2) Å found in the complex $[Co^{III}L(OH)](ClO_4)_2$ [L = 2,6-bis(1′,3′-diamino-2′-methylprop-2′-yl)pyridine].[16] The $Co-N_{amide}$ bond length, with an average value of 1.959(5) Å, is similar to those found in other cobalt(III) amide complexes, such as 1.97(2) Å in [Co(2-amino-4-imino-2-methylpentane)$_2$(methazolamidate)$(NH_3)](NO_3)_2$.[17]

Bond lengths and angles within the framework of the pyridinesulfonamide ligand fall within the range found for other related metal complexes with similar ligands.[9,18]

The Co−N bond lengths from the ligand L^o are equal [Co−N(5) = 1.892(7) and Co−N(6) = 1.891(6) Å] and similar to those found in other hexacoordinated cobalt complexes with ligands possessing the same chemical skeleton: 1.995(5) Å in [Co(*R*-ala)-(1,5*R*,7*R*,11-Me_4-2,3,2-tet)-Br_2·$3H_2O$[19] or 2.009(5) Å in *cis*-$[Co^{III}L^2Cl_2]Cl$, in which L^2 stands for (5*RS*,7*SR*)-dimethyl-1,4,8,11-tetraazacyclooctatetradecane.[20] The bond angles have normal values for a six-membered chelate ring and are 88.8°. The bond lengths N−C and C−C in the new ligand L^o are essentially identical to those found in the other complexes with this ligand.[11,12] The N(5)−C(27) [1.275(10) Å] and N(6)−C(29) [1.276(9) Å] bond lengths are in agreement with the value of 1.30 Å proposed for a C=N double bond,[21] and the C(32)−N(7) bond length of 1.155(6) Å is shorter than for C=N but not as short as for a C≡N triple bond.[22] The C−C bonds in the chelate ring and the C(31)−C(32) bond are shorter [1.386(11)−1.432(11) Å] than the other C−C bonds [1.498(10)−1.522(10) Å]. The C(31)−C(32)−N(7) angle is very close to the theoretical value for a linear disposition [176.9(5)°].

The crystal packing is such that the molecules and the Co−C(9)−C(8)−N(7) units of adjacent complex molecules appear to form chains parallel to the *b* axis. The distance from the N(7) atom of a given molecule to the Co atom of the neighbouring molecule is 4.615(5) Å.

Spectroscopic Studies

The IR spectra of the complexes are in accordance with the X-ray data discussed above. The ligand HL shows a broad band at around 3095 cm^{-1}, attributable to ν(N−H). This band is absent in the IR spectra of the complexes, a fact in agreement with the deprotonation of the N−H amide bond during the electrosynthesis. The stretching band of the pyridine ring, observed between 1600 and 1400 cm^{-1} and the ring deformation bands, which appear at about 600 and 400 cm^{-1}, are shifted to higher frequencies in the complexes. This behaviour has been proposed as evidence for the coordination of the pyridine nitrogen atom to the metal ion,[23] as confirmed by the structural data. In addition, the spectrum of the $[Co^{III}L_2L^o]$ complex also shows a sharp band at 3350 cm^{-1}, assigned to ν(N−H), as well as another band at 2190 cm^{-1} due to ν(C≡N) of the new ligand L^o.

The IR spectra of the mixed complexes containing 2,2′-bipyridine or 1,10-phenanthroline as additional ligands show the bands characteristic of these coordinated ligands[24,25] (bipy: ca. 770 and 720 cm^{-1}; phen: ca. 1520, 847 and 722 cm^{-1}).

The diffuse reflectance spectrum of $[Co^{II}L_2]$ in the NIR/Vis region shows two multicomponent bands, one at 7600, 8900 and 11200 cm^{-1} [assigned to $^4A_2 \rightarrow {}^4T_1(F)$ (ν_2)] and the other at 17100, 19455 and 20790 cm^{-1} [due to $^4A_2 \rightarrow {}^4T_1(F)$ (ν_3)], both of which are consistent with a distorted tetrahedral environment for the metal ion.[26] The $^4A_2 \rightarrow {}^4T_1$ (P) (ν_1) transition was not observed, but its position at ca. 5300 cm^{-1} was calculated by the method described by Lever. The presence of three closely spaced transitions in the spectrum of $[Co^{II}L_2]$ arises due to distortion from the regular tetrahedral symmetry, a situation resulting from the inequivalence of the pyridyl and sulfonamide donor atoms and the restrictive bite angle of the chelating ligands. At room temperature this complex has a magnetic moment of 4.0 B.M., which is well within the range expected for tetrahedral cobalt(II) compounds.

The solid-state electronic spectra of the mixed complexes $[Co^{II}L_2L']$ between 20000 and 5000 cm^{-1} are all very similar, but differ from those found for the $[Co^{II}L_2]$ and $[Co^{III}L_2L^o]$ complexes. The former complexes gave rise to three bands in the regions 7400−9500, 14600−15150 and 21800−23000 cm^{-1}, assigned to $^4T_{1g}(F) \rightarrow {}^4T_{2g}$ (ν_1), $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ (ν_2) and $^3T_{1g}(F) \rightarrow {}^4T_{2g}(\nu_3)$ transitions, respectively, in a distorted octahedral field.[26] The magnetic moments of these complexes at room temperature are in the

range 4.60−4.80 B.M., and these values are on the low side of the range expected for octahedral cobalt(II) complexes, probably as a result of a reduced orbital contribution. The magnetic moment of the $[Co^{III}L_2L^o]$ complex shows that this compound is diamagnetic and which is consistent with a low-spin d^6 octahedral complex. The solid-state electronic spectrum shows two bands at 15200 and 21800 cm^{-1}, as would be expected for low-spin six-coordinated cobalt(III) complexes. The first band has been attributed to a $^1A_{1g} \rightarrow {}^1T_{1g}$ transition and the other band to a $^1A_{1g} \rightarrow {}^1T_{2g}$ transition.[26]

In the FAB mass spectra of $[Co^{II}L_2]$, $[Co^{III}L_2L^o]$, $[Co^{II}L_2bipy]$ and $[Co^{II}L_2phen]$, the molecular ion peaks are observed at m/z = 582, 703, 737 and 762, respectively, together with corresponding peaks at m/z = 426, 442, 476 and 500 formed by loss of one tosyl ligand from each complex. A peak is also observed at m/z = 580 in the spectrum of $[Co^{III}L_2L^o]$, and this corresponds to a fragment formed by loss of the ligand L^o.

Experimental Section

Materials and Instrumentation: Cobalt (Aldrich Chemie) was used as plates (ca. 2 × 2 cm). All other reagents, including 1,10-phenanthroline and 2,2′-bipyridine, were used as supplied. The C,H,N,S analyses of the compounds were performed with a Carlo−Erba EA 1108 microanalyzer. IR spectra were recorded as KBr mulls with a Bruker IFS-66V spectrophotometer. The ^1H NMR spectrum of the ligand was recorded with a Bruker AMX 300 MHz spectrometer, with $[D_6]$DMSO as solvent. The chemical shifts were recorded against TMS as an internal standard. FAB mass spectra were recorded with an Autospec-Micromass instrument, with 3-nitrobenzyl alcohol (3-NBA) as the matrix. Solid-state electronic spectra were recorded with a Shimadzu UV 3101 PC apparatus. Magnetic measurements were obtained with a DMS VSM 1160 instrument.

Synthesis of the Ligand HL (1): The ligand HL was prepared from equimolar amounts of 2-aminomethylpyridine (1.00 mL, 10.1 mmol) and tosyl chloride (1.93 g, 10.1 mmol) in dichloromethane (40 mL). Aqueous NaOH (10%) was added to the mixture until pH = 8 was reached, and a white product was obtained.[27] The solid was filtered off and dried in vacuo. Yield 78%. The purity of the product was assessed by microanalysis, IR and ^1H NMR spectroscopy. Crystals suitable for X-ray structure determination were obtained by crystallisation from dichloromethane. IR (KBr): $\tilde{\nu}$ = 3094 [ν(N−H)], 1598−1385 [ν(C=C, C=N)$_{py}$], 1328 [$\nu_{as}(SO_2)$], 1164 [$\nu_s(SO_2)$] cm^{-1}. ^1H NMR ($[D_6]$DMSO): δ = 11.6 (s, 1 H, N−H$_{tosyl}$), 8.5 (d, 1 H, 2-H$_{py}$), 2.1 (s, 3 H, Me$_{tosyl}$) ppm. $C_{13}H_{15}N_2O_{2.5}S$ (271.3): calcd. H 5.58, C 57.55, N 10.33, S 11.79; found H 5.38, C 57.52, N 10.10, S 12.22.

Preparation of the Complexes (General Procedure): The complexes were formed by an electrochemical procedure.[28] This method allows the preparation of different products simply by changing the conditions of the electrochemical reaction. The cell consisted of two electrodes submerged in a solution of the tosylated ligand and a small amount of tetraethylammonium perchlorate (ca. 15−20 mg) as a current carrier in acetonitrile. The cathode was a platinum wire and the anode a plate of the appropriate metal. For the synthesis of mixed complexes, the corresponding coligand − 1,10-phenanthroline or 2,2′-bipyridine − was also added to the solution. Applied voltages of 9−15 V allowed sufficient current flow for smooth dissolution of the metal. In all cases the electrochemical synthesis was carried out at room temperature. The cell can be summarised as Pt(−)/CH_3CN + HL/M(+).

Preparation of $[Co^{II}L_2]$ (2): Electrolysis of an acetonitrile solution containing HL (0.2932 g, 1.12 mmol) and a small amount of tetraethylammonium perchlorate (ca. 25 mg) at 10 mA and 9 V for 3 h dissolved 32 mg of cobalt (E_f = 0.49 mol·F^{-1}). At the end of the experiment, a purple solution had been obtained and was allowed to stand for a few days. Purple crystals suitable for X-ray diffraction formed, and these were collected and dried in vacuo. The compound was characterised as $[Co^{II}L_2]$. IR (KBr): $\tilde{\nu}$ = 1611−1439 [ν(C=C, C=N)$_{py}$], 1275 [$\nu_{as}(SO_2)$], 1147 [$\nu_s(SO_2)$] cm^{-1}. $C_{26}H_{26}CoN_4O_4S_2$ (581.5): calcd. H 4.51, C, 53.70, N 9.63, S 11.01; found H 4.47, C 53.52, N 9.62, S 9.76.

Preparation of $[Co^{III}L_2L^o]$ (3): Electrolysis of an acetonitrile solution containing HL (0.1947 g, 0.7432 mmol) and a small amount of tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 20.8 V for 2 h dissolved 20 mg of cobalt (E_f = 0.46 mol·F^{-1}). At the end of the experiment a brown solution had formed, with brown crystals at the bottom of the vessel. These crystals were filtered off and dried in vacuo and were suitable for X-ray crystallography. The compound was characterised as $[Co^{III}L_2L^o]$. IR (KBr): $\tilde{\nu}$ = 3354 [ν(NH)], 2189 [ν(C≡N)], 1604−1396 [ν(C=C, C=N)$_{py}$], 1280 [$\nu_{as}(SO_2)$], 1134 [$\nu_s(SO_2)$] cm^{-1}. $C_{32}H_{34}CoN_7O_4S_2$ (703.7): calcd. H 4.87, C 54.62, N 13.93, S 9.09; found H 4.88, C 54.45, N 13.41, S 9.75.

Preparation of $[Co^{II}L_2(bipy)]$ (4): Electrolysis of an acetonitrile solution containing HL (0.1947 g, 0.7432 mmol), 2,2′-bipyridine (0.0584 g, 0.3715 mmol) and a small amount of tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 20.3 V for 2 h dissolved 22 mg of cobalt (E_f = 0.51 mol·F^{-1}). At the end of the experiment a brown solid had formed, and this was filtered off, washed with acetonitrile and dried in vacuo. The compound was characterised as $[Co^{II}L_2(bipy)]$. IR (KBr): $\tilde{\nu}$ = 1628−1492 [ν(C=C, C=N)$_{py}$], 1283 [$\nu_{as}(SO_2)$], 1159 [$\nu_s(SO_2)$] cm^{-1}. $C_{36}H_{34}CoN_6O_4S_2$ (737.7): calcd. H 4.61, C 58.60, N 11.39, S 8.68; found H 4.57, C 59.39, N 12.07, S 7.92.

Preparation of $[Co^{II}L_2(phen)]$ (5): Electrolysis of an acetonitrile solution containing HL (0.1947 g, 0.7432 mmol) and a small amount of tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 24.6 V for 2 h dissolved 23 mg of cobalt (E_f = 0.53 mol·F^{-1}). At the end of the experiment a dark brown solid had formed, and this was filtered off, washed with acetonitrile and ether, and dried in vacuo. The compound was characterised as $[Co^{II}L_2(phen)]$. IR (KBr): $\tilde{\nu}$ = 1628−1429 [ν(C=C, C=N)$_{py}$], 1281 [$\nu_{as}(SO_2)$], 1160 [$\nu_s(SO_2)$] cm^{-1}. $C_{38}H_{34}CoN_6O_4S_2$ (761.8): calcd. H 4.46, C 59.90, N 11.03, S 8.40; found H 4.79, C 59.37, N 11.00, S 8.28.

Crystal Structure Determination: Crystals of HL (**1**) and $[Co^{III}L_2L^o]$ (**3**) were mounted on glass fibres and used for data collection with an Enraf Nonius CAD4 diffractometer, while a Siemens SMART CCD area detector diffractometer was used in the case of $[Co^{II}L_2]$ (**2**). Mo-K_α radiation (λ = 0.71073 Å, graphite monochromator) was used for the collection of the intensity data by a 2θ/ω-scan technique. Decomposition of the crystals did not occur during data collection. Corrections were applied for Lorentz and polarisation effects and for absorption.[29] The structures were solved by direct methods; missing atoms were located in the difference Fourier maps and included in subsequent refinement cycles. The structures were refined by full-matrix, least-squares refinement on F^2, with anisotropic displacement parameters used for all non-

hydrogen atoms except those of the methyl group [C(20)] of the ligand HL, which were located in their calculated positions (C−H 0.96 Å). In all cases, hydrogen atoms were included by using a riding model with C−H distances of 0.93−0.97 Å and fixed isotropic thermal parameters. The weighting scheme of the form $\omega = 1/\sigma^2(F)$ was introduced, and the refinement proceeded smoothly to convergence with a maximum delta/σ of 0.001. The absolute configuration was determined for **3**.[30] The crystallographic programs used for the structure solutions and refinement were from SHELX97.[31] Atomic scattering factors and anomalous dispersion corrections for all atoms were taken from International Tables for X-ray Crystallography.[32] The crystal data and summary of data collection and structure refinement for these compounds are given in Table 5. Selected bond lengths and angles for **1**, **2** and **3** are given in Tables 1, 3 and 4. ORTEP3[33] drawings of the molecules with the numbering schemes used are shown in Figures 1−3. CCDC-171729 (**1**), -171730 (**2**) and -171731 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Structures of Complexes of Thallium(I) and Functionalized Benzoate Ligands with Pronounced Stereoactivity of the Lone Pair of Electrons and Metal−Phenyl π-Bonding

Olof Kristiansson[a]

Keywords: Thallium(I) / Stereoactive inert pair / Thallophilic interaction / Coordination polymer / Metal−phenyl π-bonding

Four complexes between thallium(I) and functionalized benzoate ligands, namely salicylate, *p*-aminosalicylate, 3,4-dimethoxybenzoate and 3,5-dimethoxybenzoate have been prepared and their structures determined by X-ray diffraction. They are all based on dimeric, centrosymmetric $Tl_2(RCOO)_2$ units with μ_2-bridging carboxylic groups resulting in Tl···Tl separations of 4.2–4.4 Å. These dimeric units are further linked to form infinite coordination polymers. In *catena*-[bis(μ_3-salicylato)dithallium(I)] (**1**) and *catena*-[bis(μ_3-4-aminosalicylato)dithallium(I)] (**2**) are adjacent units are held together by secondary Tl–O(hydroxy) interactions resulting in a crystal organization which can be described as stair-like, infinite one-dimensional polymers. In *catena*-[μ_4-(3,4-dimethoxybenzoato)thallium(I)] (**3**) bridges each carboxylic group four thallium(I) cations resulting in infinite two-dimensional, puckered sheets. Finally, in *catena*-[μ_3-(3,5-dimethoxybenzoato)thallium(I)] (**4**) each carboxylic unit acts as a μ_3-bridging ligand to give nearly planar, infinite double-stranded arrays of Tl^+ cations. Another characteristic structural motif is the tendency of the thallium ion to only use less than one hemisphere to coordinate ligands. This "half-nakedness" is due to the stereochemically active inert pair ($6s^2$), which thus plays a prominent role in controlling the structures of these compounds. The Tl^+ cations are in approximate pyramidal geometries, with four or five oxygen donor atoms in the basal plane and the stereoactive lone pair occupying the apex position of the pyramid. There are, on the naked side of the metal ions, relatively large spaces in non-polar environments provided by neighboring phenyl groups. The distances between the planes of the phenyl rings and the Tl^+ cation are in the range 3.3–3.5 Å, indicating that Tl^+–phenyl η^6-interactions are important in the crystal organization.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The Tl^+ ion is nonspherical, with its inert pair ($6s^2$) partially hybridized leading to the formation of a local dipole that may strongly affect cation···ligand interactions. This "inert-pair effect" has, in a general way, been explained by Pitzer[1] and by Pykko and Desclaux[2] as a relativistic effect causing the outer s electrons to be more strongly attracted to the nucleus than normally expected. In p-block cations with an ns^2 np^0 electronic configuration, lone pairs of electrons may thus play a prominent role in controlling the structures and chemical behavior. In inorganic salts, the lone pair is manifested by a distortion of regular coordination geometries by a substantial elongation of certain bonds, as exemplified in, for example, TlF,[3] $Tl[CuAsO_4]$, $Tl[CuPO_4]$[4] or $TlZn(PO_3)_3$.[5] In several organometallic compounds, the stereoactive lone pair is manifested by a "half-naked" cation, with ligands only coordinating one hemisphere, as observed in the crystal structures of complexes between Tl^+ and tris(pyrazolyl)borate, where the lone pair occupies the fourth position of a tetrahedron bis(pyrazolyl)phosphinate,[6] with an obvious gap in the coordination sphere due to the lone pair, and also in [HB(3-*p*-tolylpyrazolyl)$_3$Tl].[7] In (malonohydroxamato)Tl, a square-pyramidal geometry of Tl^+ is observed, with the lone pair oriented in the axial direction.[8] In addition, in several organometallic thallium compounds the stereoactivity of the inert pair is apparent.[9]

There is a paucity of data on complexes between thallium(I) and arylcarboxylate ligands in the literature, the only known example being *catena*-[bis(μ_3-2-hydroxybenzoato)dithallium(I)].[10] In this paper we wish to present the crystal structures of four complexes between thallium(I) and functionalized benzoate ligands, namely salicylate (**1**), 4-aminosalicylate (**2**), 3,4-dimethoxybenzoate (**3**) and 3,5-dimethoxybenzoate (**4**) (Scheme 1). These ligands present a limited range of steric and electronic properties and are therefore useful for establishing basic patterns in thallium(I)−benzoate interactions. In following papers, we wish to extent these investigations to systems where steric requirements of the ligands impose restrictions on the thallium coordination geometries and also attempt the use of

the inert lone pair as a Lewis base for the construction of extended solids.

Results and Discussion

catena-[Bis(μ$_3$-salicylato)dithallium(I)] (1) − Crystal Structure

The crystal structure is based on dimeric units as depicted in Figure 1. The carboxylate groups act as μ$_2$-bridging ligands. One oxygen atom is bound to two thallium ions and the other to one thallium ion. The doubly coordinated O1 bridges thallium ions unsymmetrically with Tl−O distances of 2.601(11) and 2.751(11) Å and a Tl−O−Tl angle of 103.8(4)°. The O1^i−Tl1−O1 and O1−Tl1−O2 angles equal 76.2(4) and 48.4(3)°, respectively. The singly coordinated O2 has a Tl−O distance of 2.778(11) Å. This geometry results in a Tl···Tl separation of 4.213(1) Å. Each Tl^+ ion is coordinated on one side to three oxygen atoms of two carboxylic groups and, at a longer distance, to one O3 atom of adjacent units. The other side is, however, completely "naked" due to the inert pair (6s^2) in an sp-hybridized orbital producing an electronic bulge on this side. Each Tl^+ cation is therefore in a distorted square-pyramidal geometry, with the four oxygen atoms in the basal plane and the stereoactive lone pair occupying the apex position of the pyramid (Figure 2). The Tl^+ ion is situated 1.64 Å from the least-squares plane defined by the oxygen atoms. There is, on the "naked" side of the metal ion, a relatively large space in a hydrophobic environment provided by two neighboring phenyl groups. The distance between the planes of the phenyl rings and the Tl^+ cation is 3.29 Å. This value is similar to that of 3.27 Å in [Tl(PhNNNPh)]$_2$ and 3.33 Å in [Tl(TolNNNNNTol)]$_2$[11] or to that in a complex between Tl^+ and Lasalocid A, an ionophore containing a salicylic group, where a distance of 3.22 Å is observed.[12] These values fall essentially within the range of van der Waals distances [the sum of the ionic radius of Tl^+ (1.47 Å)[13] and the van der Waals radius of the aromatic ring (1.77 Å)[14]], which is 3.24 Å, thus indicating Tl^+−phenyl η^6-interactions. The aromatic ring is nearly perpendicular (87.1°) to the vector joining the Tl^+ cation and the centroid of the phenyl group.

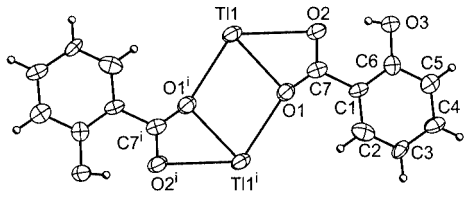

Figure 1. Molecular structure and atom numbering scheme for bis(salicylato)dithallium(I) (**1**); the displacement ellipsoids are drawn at the 50% probability level for non-H atoms; symmetry code: i: $-x$, $2-y$, $2-z$

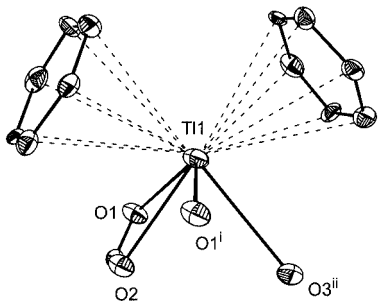

Figure 2. The coordination of the Tl^+ ion in **1** showing the stereoactivity of the lone pair; the geometry of the Tl^+ cation can be described as a distorted square-based pyramid, with the stereoactive lone pair occupying the apex position in a hydrophobic environment; the centroids of the phenyl rings are situated 3.29 Å from the Tl^+ cation; the displacement ellipsoids are drawn at the 50% probability level; bond lengths [Å]: Tl1−O1 2.601, Tl1−O2 2.778, Tl1−O1^i 2.751, Tl1−O3^{ii} 2.798; symmetry codes i: $-x$, $2-y$, $2-z$; ii: $x-1$, y, z

The $Tl_2(COO)_2$ unit is virtually planar with a mean deviation from the least-squares plane of 0.0128 Å. The phenyl rings form an angle of 11.1° with this plane, resulting in an average deviation from the plane defined by all atoms of the $Tl_2(C_7H_5O_3)_2$ molecule of 0.125 Å. The $Tl_2(COO)_2$ units are stacked into piles along the *c* axis. The units are tilted 47.9° versus the *c* axis giving a parallel displacement of 5.77 Å with a perpendicular distance of 3.23 Å between successive units. The displacement of successive planes makes aromatic π-interactions unfeasible in the crystal organization. Adjacent units are held together by secondary Tl−O3 interactions [*d*(Tl−O3) = 2.978(11) Å], resulting in stair-like, infinite one-dimensional polymers as schematically depicted in Figure 3. The packing in the unit cell is shown in Figure 4.

catena-[Bis(μ$_3$-*ortho*-aminosalicylato)dithallium(I)] (2) − Crystal Structure

The molecular structure of bis(2-aminosalicylato)dithallium(I) (**2**) is shown in Figure 5. In this case the carboxylate groups act also as μ$_2$-bridging ligands with one oxygen atom unsymmetrically bridging two thallium ions [*d*(Tl−O) = 2.614(12) and 2.713(11) Å] and the other one to one thallium ion [*d*(Tl−O) = 2.879(12) Å] which results in a Tl−Tl separation of 4.253(1) Å. The Tl^+ ion is in a distorted square-pyramidal geometry, with the four oxygen atoms in the basal plane and the stereoactive lone pair oc-

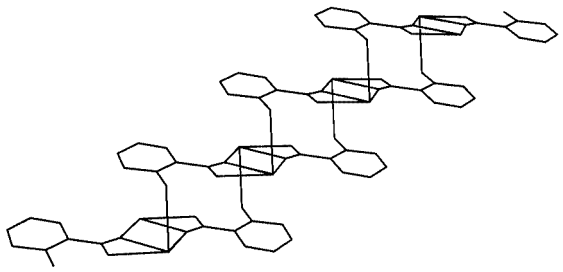

Figure 3. Schematic drawing of the crystal organization of **1**; each $Tl_2(C_6H_5OHCOO)_2$ unit is linked to adjacent units via two secondary Tl−O(hydroxy) interactions [*d*(Tl−O) = 2.97(1) Å]; successive units are parallel displaced by 5.77 Å producing a stair-like, infinite one-dimensional polymer

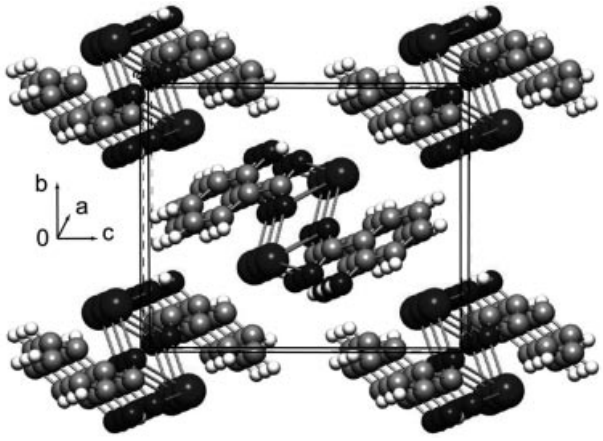

Figure 4. The unit cell content of **1** viewed along the crystallographic *a* axis

cupying the apex position of the pyramid, in a hydrophobic environment provided by two neighboring phenyl groups. The distance between the planes of the phenyl rings and the Tl^+ cation are 3.31 and 3.68 Å with angles of 87.2 and 62.7° between the aromatic plane and the vector joining the Tl^+ cation and the centroid of the phenyl group. In addition to the strong intramolecular hydrogen bond between O3 and O2 [*d*(O···O) = 2.53(2) Å] are also weak hydrogen bonds formed between the amino protons and O2 atoms of adjacent units [*d*(N···O) = 3.02(2) and 3.15(2) Å].

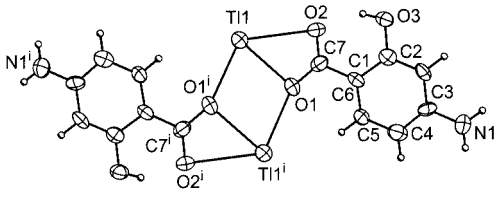

Figure 5. Molecular structure and atom numbering scheme for bis(2-aminosalicylate)dithallium(I) (**2**); the displacement ellipsoids are drawn at the 50% probability level for non-H atoms; symmetry code: i: $-x$, $2-y$, $2-z$

The crystal organization shows large similarities with that of compound **1**. The $Tl_2(COO)_2$ unit is slightly twisted with a mean deviation from the least-square plane of 0. 123 Å. The phenyl rings form an angle of 16.0° with this plane, resulting in an average deviation from the plane defined by all atoms of the $Tl_2(C_7H_5O_3)_2$ moiety of 0.217 Å. The $Tl_2(COO)_2$ units are stacked into piles along the *c* axis. The units are tilted 45.1° versus the *c* axis giving a parallel displacement of 6.00 Å. Adjacent units are held together by secondary Tl−O3 interactions [*d*(Tl−O3) = 2.923(11) Å]. The overall crystal organization can be described as stair-like, infinite one-dimensional polymers as depicted in Figure 3. The crystal structures of compounds **1** and **2** show certain similarities with that of a previous determination of *catena*-[bis(μ_3-2-hydroxybenzoato)dithallium(I)].[11] The dimeric unit in this compound shows a Tl−Tl separation of 4.129 Å and successive units are linked via Tl−O(hydroxy) interactions [*d*(Tl−O) = 2.727 Å] to give infinite polymers similar to those in Figure 3.

catena-[(3,4-Dimethoxybenzoato)thallium(I)] (3) − Crystal Structure

The crystal structure is based on dimeric $Tl_2(C_7H_6NO_3)_2$ units as shown in Figure 6. Each dimeric unit is extensively cross-linked to adjacent units to form an infinite two-dimensional network as schematically shown in Figure 7**.** One

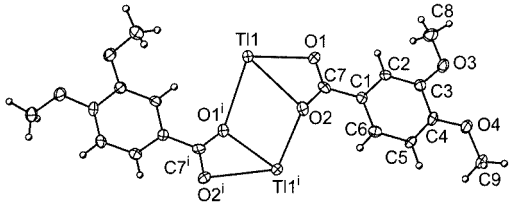

Figure 6. Molecular structure and atom numbering scheme for *catena*-[(3,4-dimethoxybenzoato)dithallium(I)] (**3**); the displacement ellipsoids are drawn at the 50% probability level for non-H atoms; symmetry code: i: $-x$, $-0.5+y$, $0.5-x$

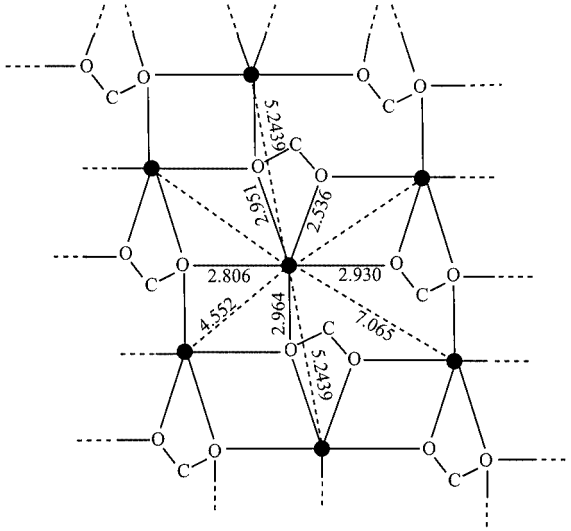

Figure 7. Schematic drawing of the crystal organization of **3**, which consists of infinite two-dimensional, puckered sheets of Tl^+ cations, linked by μ_4-bridging carboxylate groups

oxygen atom the carboxylate group is bound to three thallium ions and the other one to two thallium ions, with each carboxylate group acting as a μ_4-bridging ligand. The doubly coordinated oxygen atom O1 bridges two thallium ions unsymmetrically with Tl−O distances of 2.536(6) and 2.930(6) Å, while the triply coordinated O2 has a Tl−O distances of 2.806(7), 2.951(6) and 2.964(7) Å. As a result of this geometry each Tl^+ cation is surrounded by three other cations at comparatively short distances, two at 4.4111(8) Å and one at 4.552(1), and three cations at significantly longer distances, two at 5.244(1) and one at 7.065(1) Å. Each Tl^+ ion is coordinated on one side to five oxygen atoms of four carboxylic groups. In this case the other side is also completely naked due to the stereoactive lone pair. The geometry of the Tl^+ cation may be described as a distorted pyramid, with the five oxygen atoms in the basal plane and the stereoactive lone pair occupying the apex position of the pyramid, with the Tl^+ ion being situated 1.16 Å from the least-squares plane defined by the oxygen atoms. The phenyl rings form an angle of 46.0° with the Tl_2O_2 plane, resulting in an average deviation from the plane defined by all atoms of the $Tl_2(C_9H_9O_4)_2$ moiety of 0.692 Å. The crystal organization is shown in Figure 8. The infinite layers of Tl^+ cations extend perpendicular to the *a* axis, alternating with hydrophobic areas. The relatively large empty spaces, in hydrophobic environments, around one side of the Tl^+ cations are clearly seen.

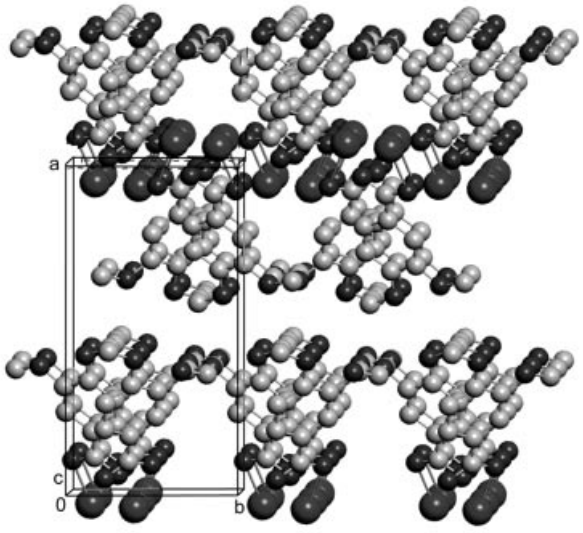

Figure 8. View parallel to the *c* axis of the packing of **3** in the unit cell; hydrogen atoms are omitted for clarity

catena-[(3,5-Dimethoxybenzoato)thallium(I)] (4) − Crystal Structure

The crystal structure is based on dimeric $Tl_2(C_9H_9O_4)_2$ units as shown in Figure 9. The Tl_2O_4 moiety is virtually planar, with a mean atomic displacement from the least-squares plane of 0.019 Å. This plane forms an angle of 7.5°

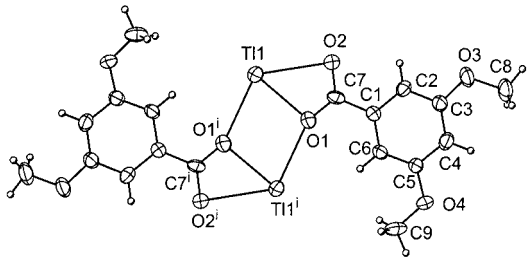

Figure 9. Molecular structure and atom numbering scheme for *catena*-[(3,5-dimethoxybenzoato)dithallium(I)] (**4**); the displacement ellipsoids are drawn at the 50% probability level for non-H atoms; symmetry code: i: $-x$, $1-y$, $-x$

with the aromatic planes which results in an average deviation from planarity for the entire $Tl_2(C_9H_9O_4)_2$ unit of 0.075 Å. The two Tl^+ ions are unsymmetrically bridged by the carboxylic oxygen atoms O1 and O1^i with Tl−O distances of 2.530(5) and 2.710(5) Å, respectively, and a Tl−O−Tl angle of 105.3(2) Å. The O2−Tl1 distance is 2.785(4) Å. This geometry results in a Tl−Tl separation of 4.1669(8) Å. Each Tl^+ ion is coordinated on one side to four oxygen atoms of three carboxylate groups. In this case the other side is also completely "naked" due to the inert pair ($6s^2$). The Tl^+ cation is therefore in a distorted square-pyramidal geometry, with the four oxygen atoms in the basal plane and the stereoactive lone pair occupying the apex position of the pyramid.

The dimeric $Tl_2(C_9H_9O_4)_2$ units are further linked to infinite one-dimensional chains as depicted in Figure 10. Each carboxylic unit acts as a μ_3-bridging ligand since the O2 oxygen atom links an adjacent unit with an O2−Tl1 distance of 2.720(6) Å. The result is a double-stranded, infinite linear one-dimensional polymeric array of Tl^+ cations with an average deviation from the plane defined by all Tl^+ cations within the chain of 0.014 Å. The chain forms an angle of 34.4° with the plane of the $Tl_2(C_9H_9O_4)_2$ unit. The closest separations between the Tl^+ cations within the chain are 4.1669(8) (within the basic unit), 4.2637(7) and 6.3813(9) Å (Figure 11). The chains run parallel to the *b* axis and the distance between adjacent chains is 5.55 Å. This arrangement results in the lamellar structure shown in Figure 12.

Figure 10. Conclusions

The four complexes structurally determined in the present study, as well as (*o*-hydroxybenzoato)thallium(I) previously determined, are all based on centrosymmetric dimeric $Tl_2(RCOO)_2$ units. Geometrical parameters of this structural motif are summarized in Table 1. The carboxylate groups act as μ_2-bridging ligands within the unit. One oxygen atom is bound to two thallium ions and the other one to one thallium ion. The doubly coordinated oxygen atom bridges the thallium ions unsymmetrically with average Tl−O distances of 2.59(6) and 2.77(9) Å for the five thallium(I) benzoate compound so far structurally characterized. The singly coordinated oxygen atom has an average Tl−O distance of 2.79(6) Å. This geometry results in a Tl−Tl separation of 4.24(11) Å.

Another characteristic structural motif is the tendency of the thallium ion to only use less than one hemisphere to coordinate ligands. This "half-nakedness" is due to the stereochemically active inert pair ($6s^2$) in an sp-hybridized orbital producing an electronic bulge on one side. This lone pair of electrons thus plays a prominent role in controlling the structures of these compounds. The Tl^+ cations are therefore in pyramidal geometries, with four or five oxygen donor atoms in the basal plane and the stereoactive lone pair occupying the apex position of the pyramid. There are, on the "naked" side of the metal ions, relatively large spaces in a nonpolar environment provided by neighboring phenyl groups, with the nearest carbon atoms situated 3.2−3.4 Å from the Tl^+ ion. The aromatic rings are nearly perpendicular to the vector joining the Tl^+ cation and the centroid of the phenyl group, suggesting that Tl^+−phenyl η^6-interactions are of a certain importance for the crystal organization. Several other examples of structures with Tl^I−arene interactions have been presented, with comparable distances, as discussed by Janiak in his comprehensive review

[f] Angle between the plane defined by the Tl1, Tl1^i, O1 and O2^i atoms and the plane defined by the benzoate ligands. [g] The fraction of the total cell volume occupied by atoms as determined by the Platon software.[19]

of thallium(I) chemistry.[15] The Tl−Tl distances observed in the present study, both within and between dimers, suggest a possible Tl···Tl metallophilic interaction, similar to the well-established aurophilic attraction.[16] Recent ab initio calculations on thallocene dimers suggests energy minima with Tl···Tl distances slightly under 4 Å and interaction strengths of the order of 10 kJ/mol.[17] This attractive interaction is due to dispersion mechanisms and can only be reproduced by ab initio calculations including explicit electron-electron correlation.

Despite the structural similarities, a large variation in crystal organization is observed. In *catena*-[bis(μ_3-salicylato)thallium(I)] (**1**), *catena*-[bis(μ_3-4-aminosalicylato)thallium(I)] (**2**) and *catena*-[bis(μ_3-2-hydroxybenzoato)thallium(I)][10] are adjacent units are held together by secondary Tl−O(hydroxy) interactions, with an average Tl−O distance of 2.96(3) Å, resulting in a crystal organizations which can be described as stair-like, infinite one-dimensional polymers as depicted in Figure 3. In *catena*-[μ_3-(3,4-dimethoxybenzoato)thallium(I)] (**3**), each carboxylic group acts as a μ_4-bridging ligand resulting in infinite two-dimensional, puckered sheets. Finally, in *catena*-[μ_3-(3,5-dimethoxybenzoato)thallium(I)] (**4**) bridges each carboxylic unit three Tl^+ cations to form double-stranded, nearly planar, infinite array of Tl^+ cations, resulting in the lamellar structure shown in Figure 12. The ligands used in this study present a rather limited range of steric and electronic properties and are therefore useful for establishing basic patterns in thallium(I)−benzoate interactions. In following papers, we wish to extent these investigations where steric requirements of the ligands impose restrictions on the thallium coordination geometries and also attempt the use of the inert lone pair as a Lewis base for the construction of extended solids.

Experimental Section

Materials and Methods: Chemicals were purchased from Aldrich Chemicals and used without further purification. IR spectra were recorded with a Perkin−Elmer 1720 X FT-IR spectrometer in the 4000−400-cm^{-1} region with 2 cm^{-1} resolution both as KBr pellets and as pure powders between NaCl windows.

Preparation: All compounds were prepared by adding 5.0 mM Tl_2CO_3 to 100 mL of H_2O and 10.0 mM salicylic acid, 4-aminosalicylic acid, 3,4-dimethoxybenzoic acid or 3,5-dimethoxybenzoic acid, respectively. The solutions were allowed to boil for 2 h while stirring which in all cases yielded clear solutions. The solutions were slowly concentrated which yielded crystals of X-ray quality. The crystals chosen for X-ray analysis and the bulk material were identical as shown by superimposable IR spectra. Total yield > 90%.

Single Crystal X-ray Crystallography: Single crystal diffraction data were collected at 298 K with a Bruker SMART platform equipped with a CCD area detector and a graphite monochromator using Mo-K_α radiation. Cell parameters were refined using 985, 955, 1488 and 1400 reflections for **1**, **2**, **3** and **4**, respectively. A hemisphere of data (1291 frames) was collected for each structure using the ω-scan method (0.3° frame width) with 40 s exposure time. The crystal−detector distance was 4.77 cm. The first 50 frames were re-measured at the end of the data collection to monitor instrument and crystal stability. Intensity decay was negligible for all compounds. Data reduction and empirical absorption correction were performed using the program packages Bruker SAINT and SADABS, respectively.[18] The structures were solved by the direct methods in SHELXTL and refined using full-matrix least-squares on F^2. Non-H atoms were treated anisotropically. Carbon-H atoms were generated in ideal positions riding on their respective carbon atom. Oxygen-H and nitrogen-H atoms were localized on difference Fourier maps but their distances were constrained to 0.82 and 0.86 Å, respectively. Crystal and experimental data are summarized in Table 2. CCDC-174558 (**1**), -174556 (**2**), -174555 (**3**) and -174557 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The Synthesis and Structure of Bis- and Tris(amino)-Functionalised Cyclopentadienylyttrium Derivatives

Marco M. Corradi,[a] Margaret A. D. McGowan,[a] Patrick C. McGowan,*[a] and Mark Thornton-Pett[a]

Keywords: N ligands / Cyclopentadienyl ligands / Yttrium

The reaction of YCl_3 with 2 or 3 equiv. of $NaC_5H_4CH([CH_2]_2)_2NMe$ in toluene affords $[\{Y[\eta\text{-}C_5H_4CH([CH_2]_2)_2NMe]_2(\mu\text{-}Cl)\}_2]$ (**1**) and $[Y\{\eta\text{-}C_5H_4CH([CH_2]_2)_2NMe\}_3]$ (**2**), respectively, in high yield; the three amino-functionalised cyclopentadienyl units of **2** are fluxional at room temperature, giving us a rare example of stabilisation of an yttrium centre without the use of extraneous ligands.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Amino-functionalised cyclopentadienyl derivatives have been used to great effect in complexes of the d-block elements.[1,2] As part of our ongoing studies investigating the early transition metal systems for metal−dihydrogen bonding we decided, given previous successes, to concentrate on the (*N*-methylpiperid-4-yl)cyclopentadienyl ligand.[3−6] In this paper we present a number of new yttrium chloride complexes, one of which shows particularly interesting fluxional properties and provides a rare example of stabilisation of a cyclopentadienyl centre without the use of extraneous ligands.

Results and Discussion

As part of our ongoing work concerning the formation of new bis(cyclopentadienyl)yttrium hydride derivatives we report the synthesis and structure of $[\{Y[\eta\text{-}C_5H_4CH([CH_2]_2)_2NMe]_2(\mu\text{-}Cl)\}_2]$ (**1**) and $[Y\{\eta\text{-}C_5H_4CH([CH_2]_2)_2NMe\}_3]$ (**2**); the latter derivative is an intriguing fluxional tris(cyclopentadienyl) compound and provides the first example of a homoleptic base-stabilised tris(cyclopentadienyl)yttrium complex. The reaction of YCl_3 with 2 equiv. of $NaC_5H_4CH([CH_2]_2)_2NMe$ in THF at 45 °C afforded **1** in high yield (71%) (Scheme 1) which was characterised by ^1H, $^{13}C\{^1H\}$, and ^1H-^{13}C correlation NMR spectroscopy. The reaction of YCl_3 with 3 equiv. of $NaC_5H_4CH([CH_2]_2)_2NMe$ in THF at 50 °C similarly afforded **2** in high yield (85%) which was also formed when the reaction was carried out in toluene.

Crystallisation of **1** from a concentrated toluene solution at −30 °C afforded colourless prisms. The molecular structure, determined from a single-crystal X-ray diffraction study, revealed **1** to be dimeric with an inversion centre at the intersection of the Y(1)−Y(1′) and Cl(1)−Cl(1′) vectors and a *metallocene dichloride type* ligand geometry about the Y atoms (Figure 1) while the *N*-methylpiperid-4-yl moieties, in chair conformation, point to opposite sides of the *metallocene* geometry to minimise steric crowding. A similar bonding arrangement has been previously reported for $[\{Y(\eta\text{-}C_5H_4SiMe_3)_2(\mu\text{-}Cl)\}_2]$,[7,8] $[\{Y(\eta\text{-}C_5H_4[C_6H_9\text{-}2\text{-}i\text{Pr}\text{-}5\text{-}Me])_2(\mu\text{-}Cl)\}_2]$,[9] $[\{Y(\eta\text{-}C_5H_5)_2(\mu\text{-}Cl)\}_2]$,[10] and $[\{Y(\eta\text{-}C_5H_4PPh_2)_2(\mu\text{-}Cl)\}_2]$.[11] The Y(1)−Cl(1) and Y(1)−Cl(1′) bond lengths of 2.6850(7) and 2.6984(7) Å are similar to other reported chloro-bridged dimeric bis(cyclopentadienyl)-yttrium derivatives. The average cyclopentadienyl ring C−C bond lengths and angles are unexceptional [1.412(4) Å, 108.0(3)°].

Despite the relatively high coordination number, monomeric tris(cyclopentadienyl)Ln complexes are coordinatively unsaturated. In the absence of solvents, these molecules form oligomeric structures in the solid state.[12,13] With the addition of donor ligands or coordinating solvents molecules of the type $LnCp_3L$ can be formed, e.g., $[Y(\eta\text{-}C_5H_5)_3(THF)]$[14] and $[Y(\eta\text{-}C_5H_5)_2(\eta\text{-}C_5H_4CH_2CH_2OMe)]$.[15] Crystallisation of the extremely air- and moisture-sensitive compound **2** from a concentrated toluene solution at −30 °C afforded pale yellow prisms. The molecular structure was determined from a single-crystal X-ray diffraction study (Figure 2). The ligand geometry about the Y atom is slightly distorted from trigonal-planar, with

the angles between the centroids of the cyclopentadienyl substituents, M−Y(1)−M, of ca. 116−118°.

Two of the *N*-methylpiperid-4-yl rings adopt a chair conformation and point away from the metal centre [Cp^A and

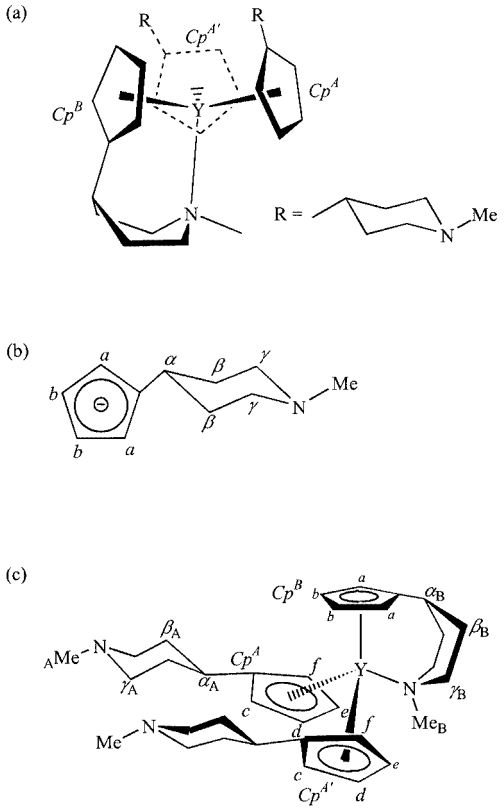

Figure 3. (a) Ligand geometry about the yttrium centre of **2**; (b) $C_5H_4CH([CH_2]_2)_2NMe$ ligand; (c) molecular structure of **2** at −60 °C

$Cp^{A'}$, see (a) in Figure 3], whereas the third *N*-methylpiperid-4-yl ring (Cp^B) is bound to the metal centre through the d_{z^2} metal orbital.[16] A similar bonding arrangement has been previously reported for [2-(dimethylamino)ethyl]cyclopentadienyl derivatives $[Ln(\eta\text{-}C_5H_4CH_2CH_2NMe_2)_3]$ (Ln = La, Nd).[17] The boat confomation of the Cp^B ring confirms the bound nature of the N moiety. The Y(1)−N(19) bond length of 2.6954(19) Å is somewhat longer than the distance of 2.501(4) Å reported for $[Y(\eta\text{-}C_5Me_5)(\eta\text{-}C_5H_4CHC_6H_4CH_2NMe_2)Cl]$[18] and **2** could be viewed as a strained 10-coordinate compound. The Y−C(Cp) bond lengths are similar to previously reported tris(cyclopentadienyl)Y derivatives.[12,14,15] The average cyclopentadienyl ring C−C bond lengths and angles are unexceptional [1.409(3) Å, 108.0(2)°].

Compound **2** was initially characterised by ^1H NMR spectroscopy; the room-temperature ^1H NMR spectrum (300.13 MHz, C_7D_8) displayed broad resonance signals, which sharpened upon warming to 80 °C to give the time-averaged ^1H NMR spectrum typical for the $C_5H_4CH([CH_2]_2)_2NMe$ ligand [see (b) in Figure 3]. Compound **2** was characterised at this elevated temperature by

^1H, $^{13}C\{^1H\}$, and ^1H-^{13}C correlation NMR spectroscopy. Cooling of **2** from room temperature to −60 °C afforded multiple resonance signals in the ^1H NMR spectrum, indicating the formation of a static structure with one of the pendant arms bound to the yttrium centre [see (c) in Figure 3]. This structural arrangement was also investigated by low-temperature $^{13}C\{^1H\}$, DEPT-135, INEPT (Figure 4), and ^1H-^{13}C correlation NMR spectroscopy. The $^{13}C\{^1H\}$ NMR resonance assignments for the *N*-methylpiperid-4-yl function at both 80 and −60 °C are summarised in Table 1.

The $^{13}C\{^1H\}$ NMR spectrum of **2** at −60 °C in the *N*-methylpiperid-4-yl region (δ ≈ 20−60 ppm) displays 9 distinct resonances due to slow structural isomer interconversion on the NMR time-scale. Two resonance signals are observed for the γ-CH_2 environment at δ = 56.5 and 53.1 ppm in the approximate ratio 2:1. Warming sees a gradual broadening and coalescence at ca. 20 °C eventually giving rise to one ^{13}C resonance at δ = 55.6 ppm. Two ^{13}C resonances are also observed for the Me environments (δ = 46.9 and 50.8 ppm coalescing at ca. 20 °C and giving one resonance at 50 °C at δ = 47.2 ppm) and the α-CH environment (δ = 25.1 and 36.7 ppm coalescing at ca. 30 °C giving one resonance at δ = 34.0 ppm). The β-CH_2 environments give rise at −60 °C, however, to three distinct resonances (δ = 25.0, 34.2, and 34.9 ppm), indicating a further decrease in the symmetry of the molecular fragment, due to close approach of the *N*-methylpiperid-4-yl arms at the β-position. A similar phenomenon has been previously observed in the

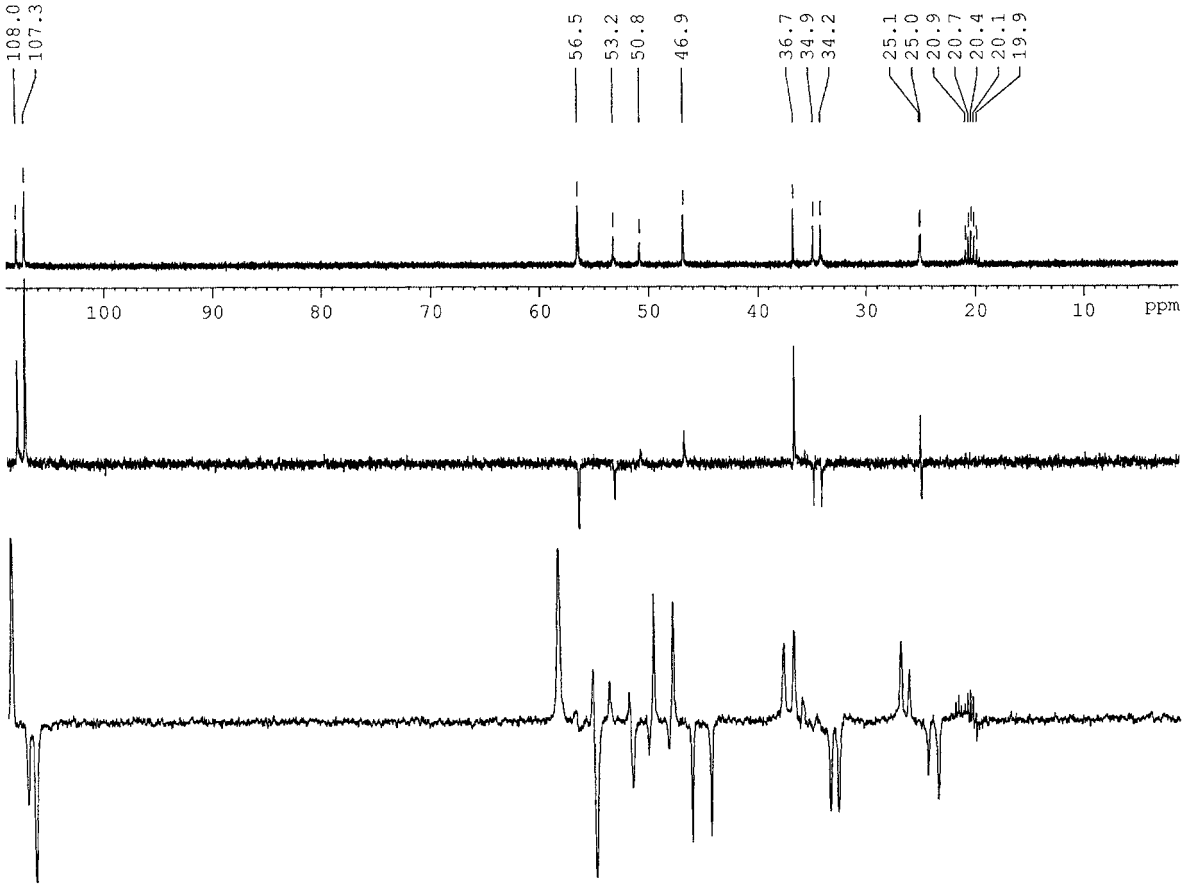

Figure 4. (a) $^{13}C\{^1H\}$, (b) DEPT 135, and (c) INEPT NMR spectra of **2** at −60 °C

Table 1. $^{13}C\{^1H\}$ NMR resonance assignments for the *N*-methylpiperid-4-yl function

Compound	Assignment			
	β-CH_2	α-CH	Me	γ-CH_2
$NaC_5H_4CH([CH_2]_2)_2NMe$ (C_4D_8O, room temp.)	36.7	38.4	47.4	58.3
1 (C_4D_8O, room temp.)	34.5	36.8	47.0	57.1
2 (C_7D_8, 80 °C)	32.0	34.0	47.2	55.6
2 (C_7D_8, −60 °C)	25.0 (β_B), 34.2 (β_A), 34.9 (β_A)	25.1 (α_B), 36.7 (α_A)	46.9 (Me_A), 50.8 (Me_B)	53.2 (γ_B), 56.5 (γ_A)

cyclohexyl derivative [Fe(η-C_5H_2-1,2,4-{$CH([CH_2]_2)_2$-CH_2}$_3$)$_2$].[19] The ^{1}H NMR spectrum of **1** at room temperature exhibits resonances typical for the $C_5H_4CH([CH_2]_2)_2NMe$ ligand. Comparison of the $^{13}C\{^1H\}$ resonance values of **2** with those of **1** at both −60 and 80 °C (Table 1) provides evidence for non-coordination of the *N*-methylpiperid-4-yl side arm to the Y^{3+} centre. Compound **1** was found to be only sparingly soluble in toluene, petroleum ether, and dichloromethane solvents. The ^{1}H and $^{13}C\{^1H\}$ NMR spectral assignments, obtained in C_4D_8O with resulting cleavage of the bridging Y−Cl bonds,[20] are thus of the THF adduct Y{η-$C_5H_4CH([CH_2]_2)_2$-NMe}$_2$Cl(THF).

In conclusion the following features of **1** and **2** are noteworthy. (*i*) The presence of the pendant arm functionality on **1** provides a Lewis base for protonation in close proximity to the metal centre. (*ii*) Compound **2** also reveals the potential advantage of the strained *N*-methylpiperid-4-yl-functionalised cyclopentadienyl ligand in the stabilisation and reaction of related yttrium hydride derivatives as it may point towards, yet only weakly bind to, the Y^{3+} metal centre. (*iii*) Compound **2** is the first example of a homoleptic base-stabilised tris(cyclopentadienyl)yttrium derivative.

Experimental Section

[{Y[η-$C_5H_4CH([CH_2]_2)_2NMe]_2(μ-Cl)$}$_2$] (1): To a Schlenk tube charged with a slurry of YCl_3 (0.61 g, 3.1 mmol) in THF (80 mL) was added a THF slurry (60 mL) of $NaC_5H_4CH([CH_2]_2)_2NMe$ (1.15 g, 6.2 mmol) at room temperature. The reaction mixture was warmed to 45 °C and stirred for 12 h to afford an off-white slurry. The THF was removed in vacuo and the resulting beige solid extracted with toluene (2 × 50 mL). The extracts were combined and the solvents were removed in vacuo to afford **1** as a white solid (0.99 g, 1.10 mmol, 71%). $C_{44}H_{64}Cl_2N_4Y_2$ (897.7): calcd. C 58.87, H 7.19, N 6.24; found C 55.0, H 7.2, N 3.7 (after many attempts, this was the best microanalysis found). ^{1}H NMR (300.13 MHz, C_4D_8O, room temp.): δ = 1.48 (m, 2 H, γ), 1.69 (br. s, THF), 1.87 (m, 4 H, β), 2.16 (s, 3 H, Me), 2.49 (tt, $J_{H,H}$ = 3.68, 11.76 Hz, 1 H, α), 2.76 (m, 2 H, γ), 3.53 (br. s, THF), 5.91 (br. s, 4 H, Cp) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, C_4D_8O, room temp.): δ = 34.5 (β, $^1J_{CH}$ = 129 Hz), 36.8 (α, $^1J_{CH}$ = 131 Hz), 47.0 (Me, $^1J_{CH}$ = 132 Hz), 57.1 (γ, $^1J_{CH}$ = 132 Hz), 110.1 (Cp, $^1J_{CH}$ = 167 Hz), 110.2 (Cp, $^1J_{CH}$ = 167 Hz) ppm.

[Y{η-$C_5H_4CH([CH_2]_2)_2NMe$}$_3$] (2): To a Schlenk tube charged with a slurry of YCl_3 (0.99 g, 5.1 mmol) in THF (80 mL) was added a THF slurry (50 mL) of $NaC_5H_4CH([CH_2]_2)_2NMe$ (2.80 g, 15.2 mmol) dropwise at room temperature. An immediate colour change of white to pale yellow was observed. The reaction mixture was warmed to 50 °C and stirred for 12 h to afford a brown slurry. The THF was removed in vacuo and the resulting sticky brown solid extracted with toluene (3 × 30 mL). The toluene was removed in vacuo to afford **2** as a white solid (2.48 g, 4.3 mmol, 85%). $C_{33}H_{48}N_3Y$ (575.7): calcd. C 68.9, H 8.3, N 7.3; found C 68.45, H 8.2, N 6.9. ^{1}H NMR (300.13 MHz, C_7D_8, room temp.): δ = 1.98 (br. s, 6 H, β, γ), 2.21 (br. s, 3 H, Me), 2.82 (br. s, 1 H, α), 2.90 (br. s, 2 H, γ), 6.01 (br. s, 4 H, Cp) ppm; (300.13 MHz, C_7D_8, 80 °C): δ = 1.77 (m, 4 H, β), 1.90 (m, 2 H, γ), 2.15 (s, 3 H, Me), 2.56 (m, 1 H, α), 2.80 (m, 2 H, γ), 5.79 (m, 2 H, Cp), 5.82 (m, 2 H, Cp) ppm; (300.13 MHz, C_7D_8, −60 °C): δ = 1.27 (br. s, γ_B), 1.29 (br. s, β_B), 1.79 (s, Me_B, β_B), 1.84 (m, β_A), 1.95 (m, γ_A), 2.04 (m, β_A), 2.09 (m, β_A), 2.28 (s, Me_A), 2.49 (br. s, γ_B), 2.73 (br. s, α_A, α_B), 2.95 (bt, γ_A), 5.47 (s, Cp), 5.50 (s, Cp), 5.87 (s, Cp), 5.95 (s, Cp), 6.03 (s, Cp), 6.18 (s, Cp) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, C_7D_8, −60 °C): δ = 25.0 (β_B, $^1J_{CH}$ = 130 Hz), 25.1 (α_B, $^1J_{CH}$ = 132 Hz), 34.2 (β_A, $^1J_{CH}$ = 127 Hz), 34.9 (β_A, $^1J_{CH}$ = 128 Hz), 36.7 (α_A, $^1J_{CH}$ = 135 Hz), 46.9 (Me_A, $^1J_{CH}$ = 132 Hz), 50.8 (Me_B, $^1J_{CH}$ = 137 Hz), 53.2 (γ_B, $^1J_{CH}$ = 139 Hz), 56.5 (γ_A, $^1J_{CH}$ = 132 Hz), 107.3 (Cp, $^1J_{CH}$ = 167 Hz), 108.0 (Cp, $^1J_{CH}$ = 167 Hz), 110.8 (Cp, $^1J_{CH}$ = 166 Hz), 111.6 (Cp, $^1J_{CH}$ = 164 Hz), 112.4 (Cp, $^1J_{CH}$ = 166 Hz) ppm; (75.47 MHz, C_7D_8, 80 °C): δ = 32.0 (β), 34.0 (α), 47.2 (Me), 55.6 (γ), 109.2 ($Cp_{a,b}$), 111.4 ($Cp_{a,b}$) 129.6 (Cp-C) ppm.

X-ray Structure Determination for 1 and 2

Crystal Data for [{Y[η-$C_5H_4CH([CH_2]_2)_2NMe]_2(μ-Cl)$}$_2$]·$C_7H_8$ (1·C_7H_8): Crystallographic measurements were made with a Nonius Kappa CCD area diffractometer using (Mo-K_α) radiation, λ = 0.71073 Å. The structure was solved by direct methods and refined on F^2 by the full-matrix least-squares procedure. T = 150(2) K. Specimen 0.53 × 0.46 × 0.22 mm, $C_{51}H_{72}Cl_2N_4Y_2$, M = 989.85, monoclinic, spacegroup $P2_1/c$, a = 16.1070(3), b = 21.8000(3), c = 7.02100(10) Å, β = 97.6950(10)°, V = 2443.10(7) Å^3, $D_{calcd.}$ = 1.346 Mg/m^3, Z = 2. For reflections with 0.998° ≤ θ ≤ 27.48°, $R(F)$ = 0.0442 for 4810 observed reflections [$I > 2\sigma(I)$] and $wR(F^2)$ = 0.1389 for 5576 independent reflections [R(int) = 0.0571]. A molecule of toluene was found which showed a symmetry-related disorder over 2 sites, which was modelled using a rigid body refinement.

Crystal Data for [Y{η-$C_5H_4CH([CH_2]_2)_2NMe$}$_3$] (2): Crystallographic measurements were made with a Nonius Kappa CCD area diffractometer using (Mo-K_α) radiation, λ = 0.71073 Å. The structure was solved by direct methods and refined on F^2 by the full-matrix least-squares procedure. T = 150(2) K. Specimen 0.36 × 0.28 × 0.22 mm, $C_{33}H_{48}N_3Y$, M = 575.65, monoclinic, spacegroup $C2/c$, a = 36.9061(6), b = 12.5796(2), c = 13.2611(2) Å, β = 108.9720(10)°, V = 5822.21(16) Å^3, $D_{calcd.}$ = 1.313 Mg/m^3, Z = 8. For reflections with 1.72° ≤ θ ≤ 26°, $R(F)$ = 0.0332 for 4803 observed reflections [$I > 2\sigma(I)$] and $wR(F^2)$ = 0.085 for 5701 independent reflections [R(int) = 0.0445].

A Unique Dinuclear Cu^{II} Compound with Two Phase Transitions Clearly Visible from Thermal and Magnetic Behaviour; Synthesis, Magnetism and X-ray Structures at Three Temperatures of Bis(di-2-pyridylamine)bis-(μ-hydroxo)bis(μ-perchlorato-*O*,*O*)dicopper(II)

Keywords: Copper / Bridging ligands / Magnetic properties / Phase transitions / X-ray structure

A new compound, $[Cu(dpyam)(OH)]_2(ClO_4)_2$ (dpyam = di-2-pyridylamine) is studied in detail and characterised by magnetic susceptibility and heat capacity measurements. This unique compound exhibits two phase transitions at 192 and 116 K. To obtain more insight into the origin of this transition, X-ray crystal structures at 3 different temperatures, below (**1A**, 110 K), between (**1B**, 150 K) and above (**1C**, 200 K) the transitions are measured. The structure consists of a dinuclear Cu^{II} unit with two bridging hydroxo groups and with two ligands bound to each copper atom via N, while the axial sites are occupied by oxygen atoms of bridging perchlorate anions, providing a distorted tetragonal environment with a Cu–Cu distance which varies from 2.9328(6) to 2.9633(6) Å, and a Cu–O–Cu angle which varies from 99.00(9) to 100.53(9)°. In all three structures, the $Cu_2O_2L_2$ unit does not change significantly. The only changes involve the position of the perchlorate anions and their H bonds with the bridging OH groups. These anions have slightly different positions at different temperatures and appear to be the major origin of the crystallographic phase-transitions. Fitting the magnetic susceptibility measurements revealed a singlet-triplet separation (J) of -37.2 cm^{-1} (antiferromagnetic), in the temperature ranges 275–190 K and 115–50 K. In the range 190–115 K a best fit, albeit inaccurate, of 29.3 cm^{-1} for J (ferromagnetic) is found. A small magnetic hysteresis of 0.5 K has been observed in the phase transition at 116 K. The heat capacity measurements have confirmed the transitions and the excess entropy (ΔS) and enthalpy (ΔH) have been calculated as 4.9 and 2.0 J K^{-1} mol^{-1} for ΔS (for 192.3 K and 116.4 K, respectively), and 0.96 and 0.25 kJ mol^{-1} for ΔH (for 192.3 K and 116.4 K, respectively).

Introduction

In the past decades a lot of work has been devoted to the magnetic and structural characterisation of square-planar dinuclear copper(II) complexes, formulated as $[LCu(OH)_2CuL]X(H_2O)_n$, where L = a didentate ligand and X = a variety of mono- and divalent anions.[1] Detailed analysis results in the linear correlation between the Cu−O−Cu angle and the singlet-triplet exchange parameter J established by Hodgson and Hatfield,[2] and is proposed as $J = -74.53 + 7270$ cm^{-1} (where is the Cu−O−Cu angle).[1b,2]

From this correlation it has been concluded that when the Cu−O−Cu angle is larger than 97.55°, i.e. in cases where the Cu_2L_2 chromophore is almost coplanar, the overall magnetic behaviour is antiferromagnetic, and for smaller values, a ferromagnetic coupling is observed. At a Cu−O−Cu angle of 97.55°, the singlet-triplet splitting energy would be zero.[2]

These earlier studies have also revealed that the nature of exchange coupling and the geometry of the copper environment is strongly influenced by the nature of the terminal ligands and the coordination of counterions and solvent molecules.[3] Copper(II) compounds with the ligand 2,2′-bipyridine have been investigated extensively, and it is postulated that they exhibit ferromagnetic interactions,[1b] where as for dpyam complexes (dpyam = di-2-pyridylamine), only three systems have been prepared and structurally characterised, both spectroscopically and magnetically, and indicated an antiferromagnetic interaction.[4]

In the literature many dinuclear dihydroxo-bridged copper(II) compounds containing other terminal ligands with ClO_4^- as a counteranion were characterised.[3a,5] Three copper environments are commonly observed: rhombic coplanar, CuN_2O_2;[5a,5f] square-based pyramidal, CuN_2O_2X;[5c−5e,5g] and elongated rhombic octahedral, $CuN_2O_2X_2$.[3a,5b,5h]

In order to investigate the magnetic and structural correlation in the H bond donor cases, such as the dpyam system, the compound $[Cu(dpyam)(OH)_2Cu(dpyam)](ClO_4)_2$ has been synthesized and characterised.

By monitoring the temperature behaviour with respect to the magnetic properties, an abrupt change in the magnetism was noted at about 192 and about 116 K. Such an abrupt change is usually associated with a crystallographic phase transition. Reports on an abrupt variation in the magnetic interaction in coupled Cu^{II} systems are, however, very rare. In fact only a few reports on that phenomenon involving Cu^{II}, and which are fully magnetically and crystallographically investigated, are available.[6] $[[Cu(petdien)]_2(CO_3)](ClO_4)_2$ (petdien = *N*,*N*,*N*′,*N*′′,*N*"-pentaethyldiethylenetriamine)[6b] has a phase transition at 212−202 K, $[Cu(CH_3\text{-nso})NCS]$ {CH_3-nso = 2-[2-(dimethylamino)-ethylthio]ethanolato}[6a] has an abrupt phase transition at 240 and 180 K, while $[Cu(btaO)_2(MeOH)]_n$ [6c] (btaOH = 1-hydroxybenzotriazole) has a phase transition at 6.4 and 4.4 K. In this paper, $[Cu(dpyam)(OH)]_2(ClO_4)_2]$ is studied in detail and characterised by magnetic susceptibility and heat capacity measurements. The X-ray crystal structures at three different temperatures, above, between, and below the transitions are also studied in order to obtain an insight into the crystallographic changes of the compound.

Results and Discussion

Description of the Crystal Structures of $[Cu(dpyam)(OH)]_2(ClO_4)_2$ at 110 K (1A), 150 K (1B) and 200 K (1C)

According to the magnetic observations and heat capacity measurements (vide infra), two phase transitions are present, i.e. at about 192 and about 116 K. Therefore, it was decided to obtain the X-ray structures in all three temperature ranges. The X-ray data were collected at 110 K (structure **1A**), at 150 K (structure **1B**) and at 200 K (structure **1C**), all from the same single crystal. The structures of **1A** to **1C** all consist of a dinuclear $[Cu_2(OH)_2(dpyam)_2]^{2+}$ cation and two weakly coordinating, bridging ClO_4^- anions. The geometry of the cation is a distorted elongated octahedral with two bridging OH^- anions, two terminal bis-(chelating) dpyam ligands as equatorial ligands, and two weak axial $O_{(ClO4)}$ interactions.

The unit cell of **1A** contains two chemically identical, but crystallographically independent dinuclear units. The unit cell of **1B** contains two dinuclear units related to each other by an inversion centre. The unit cell of **1C** contains one dinuclear unit located on a crystallographic inversion centre. Atomic displacement plots, together with the numbering scheme of the three compounds are shown in Figure 1, Figure 2 and Figure 3, for structures **1A**, **1B** and **1C**, respectively, with selected distances and angles in Table 1.

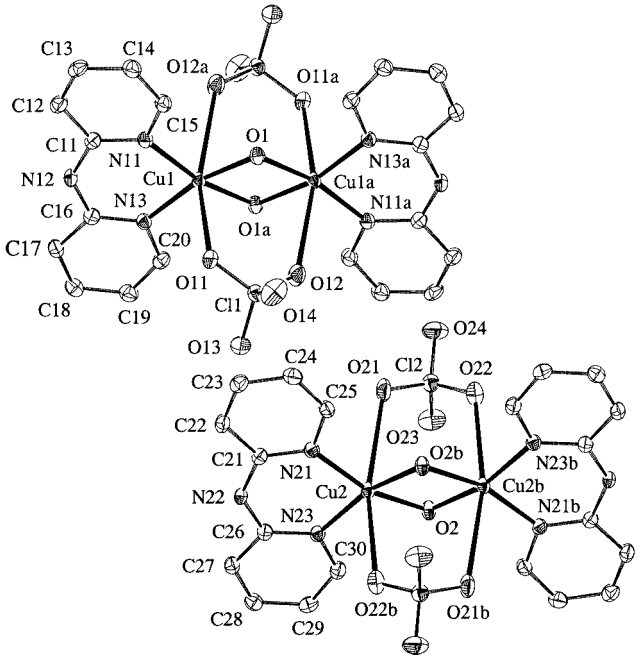

Figure 1. Atomic displacement plot (50% probability) of structure **1A** (110 K); both crystallographic dinuclear units are shown; atoms with suffix "a" are generated by symmetry operation $-x$, $-y$, $1-z$; atoms with suffix "b" are generated by symmetry operation $-x$, $1-y$, $-z$; hydrogen atoms are omitted for clarity

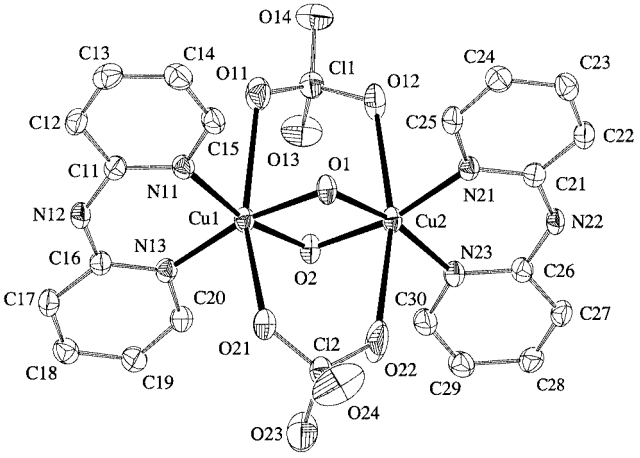

Figure 2. Atomic displacement plot (50% probability) of structure **1B** (150 K); hydrogen atoms are omitted for clarity

As seen from Table 1, the geometry of the $[Cu_2(OH)_2(dpyam)_2]^{2+}$ cation is basically the same in all three structures. Each copper atom has a distorted elongated octahedral geometry with two oxygen atoms of the bridging hydroxo groups and two nitrogen atoms of the dpyam ligand forming the basal plane; both axial sites of each copper atom are occupied by oxygen atoms of perchlorate anions at long (semi-coordinating) distances ($Cu-O_{(ClO4)}$ distances vary from 2.70 to 2.95 Å). The Cu−N distances vary from 1.975 to 2.004 Å, while the

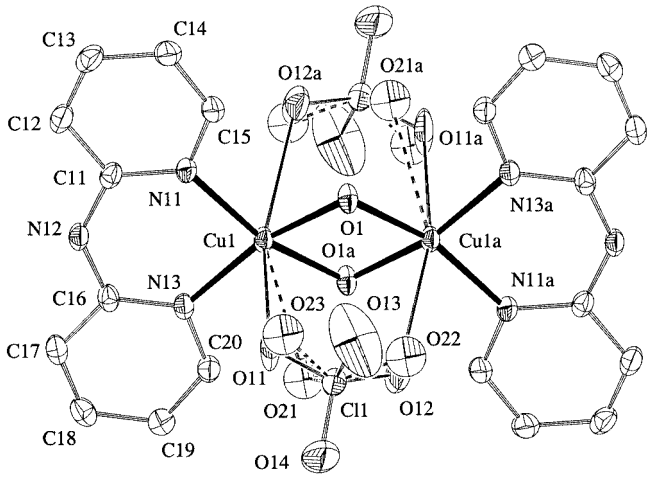

Figure 3. Atomic displacement plot (30% probability) of structure **1C** (200 K); atoms with suffix "a" are generated by symmetry operation $1 - x$, $1 - y$, $1 - z$; hydrogen atoms are omitted for clarity

$Cu-O_{(OH)}$ distances vary from 1.916 to 1.937 Å. These values are in accordance with earlier observations made for Cu^{II} dinuclear hydroxo-bridged compounds.[4,11b] The Cu−Cu distances in the three structures and the Cu−O−Cu angles are almost the same in all 3 structures with values of 2.933 and 2.963 Å for **1A**; 2.948 Å for **1B** and 2.941 Å for **1C**; and with Cu−O−Cu angles of 99.00 and 100.53° for **1A**; 99.76 and 99.54° for **1B**; and 99.53° for **1C**.

However, the main differences in the three structures are the orientation and distances of the perchlorate anions with respect to the CuN_2O_2 plane, as detailed below.

Due to the abrupt change in symmetry, the three structures are different with respect to the orientation of the perchlorate anion. This is shown in Figure 4, where the "canting" (tilting) of the perchlorate anions is projected in each case.

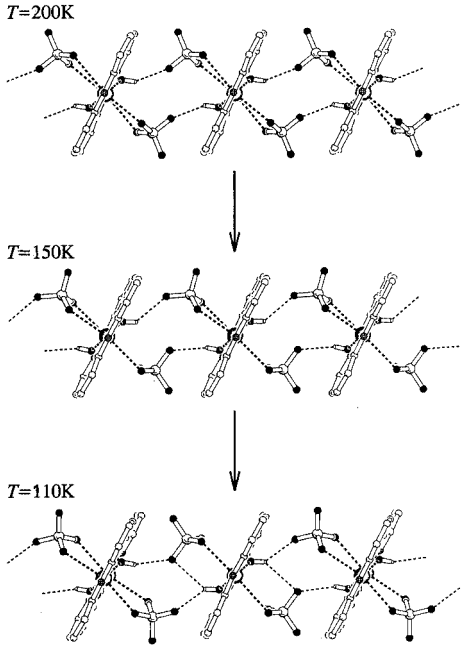

Figure 4. Plot showing the perchlorate orientations and the hydrogen bonds; projections are along the Cu···Cu axis

At 200 K (structure **1C**), the perchlorate is disordered along the Cl1−O14 axis and has to be refined in two positions. The ClO_4^- ions are centrosymmetrically located with respect to the $Cu(OH)_2Cu$ core. At 150 K (structure **1B**), this centrosymmetric arrangement is broken, and both ClO_4^- anions take their own position. In structure **1A** (110 K), after the second abrupt transition, the ClO_4^- anions are once again centrosymmetrically arranged around the dinuclear copper core, albeit that the unit cell now contains two different centrosymmetric units.

Since the planar CuO_2N_2 unit does not display significant differences (dihedral angles in the $Cu_2N_4O_2$ planes vary from 16 to 20°), the phase transitions must originate from

[a] Bifurcated hydrogen bond; the sum of the angles involving H(2) is 359(4)°.

the tilting of the perchlorate anions, and their effect on the H bonds.

The lattice structures are stabilised by stacking between the pyridine groups, and by moderate to weak hydrogen bonding between the hydroxo atom and an oxygen atom of the perchlorate anion [D···A distances vary from 2.844(8) to 2.959(3) Å] and between the amine nitrogen atom and an oxygen atom of the perchlorate anion [distances vary from 2.902(3) to 2.951(3) Å]. Details of the hydrogen bonds are given in Table 2.

Spectroscopy

The most relevant features of the IR spectra are those involving the presence of hydroxo bridges and the perchlorate counteranion. The presence of the $Cu(OH)_2Cu$ unit is supported by the occurrence of a weak, but sharp peak of medium intensity at 3550 cm^{-1} (bridging OH stretching). The ν_3 mode of the ClO_4^- anion appears as a strong absorption, split into three broad components at about 1100, 1046 and 1015 cm^{-1}, consistent with its didentate and relatively long Cu−O bonding distance of 2.72 Å.[5h,7]

The electronic reflectance spectra of **1** measured as a powder at room temp. shows a broad band at 15430 cm^{-1} consistent with the distorted elongated octahedral geometry.[8] No spectroscopic data were recorded at low temperature.

EPR and Magnetic Properties

The X-band polycrystalline powder EPR spectra of this compound, up to 800 mT at 77 K, exhibits a typical triplet spectrum with four features at 150, 325, 590, 690 and 755 mT. The spectrum is qualitatively similar to that reported for other coupled copper(II) pairs with $D > h\nu$.[5c,9] The feature at 325 mT is most certainly from a mononuclear Cu^{II} impurity, which is often present in dinuclear species, and the weak absorption at low field (150 mT) comes from the $\Delta M_s = \pm 2$ transition. The presence of the other peaks at high field values is as expected for cases in which the value of the axial zero-field splitting parameter D is larger than the incident quantum (about 0.3 cm^{-1}). Although it is not the intention of this paper to perform a detailed EPR study, including variable frequencies, to determine the parameters D and E, an approximate analysis[10] yields a D value of about 0.5 cm^{-1}.

In a frozen solution (DMF/MeOH, 1:1), only a mononuclear $S = 1/2$ signal is observed with a $g_\perp$ value of 2.04, a $g_{//}$ of 2.28 and an $A_{//}$ value of about 15.8 mT, indicating that the compound dissociates in this solution.

The temperature dependence of the molar magnetic susceptibility χ_m^{-1} of **1** down to 5 K, measured on a powder sample, is shown in Figure 5. At 275 K, χ_M is equal to 2.87 $\times 10^{-3}$ cm^3 mol^{-1}, which is very close to what is expected for two noninteracting copper(II) ions ($g = 2$). When cooled to 50 K, χ_M slowly increases to 11.14 $\times 10^{-3}$ cm^3 mol^{-1}. The absence of any maximum indicates, at best, weakly antiferromagnetically coupled copper(II) ions within the dinuclear units. However, two discontinuities are observed at 192 K and 116 K. The magnetic data therefore point at the presence of two phase changes that are likely to have a consequence for the magnetic behaviour of compound **1**. The susceptibility increases at 192 K and decreases again at 116 K, but in an asymmetric manner, the decrease at 116 K being larger than the increase at 192 K. This indicates that a difference in g value cannot be the origin of these changes. Most likely, the interaction between the two copper ions changes quite drastically. Below 50 K χ_M increases more sharply, to reach 0.113 cm^3 mol^{-1} at 5 K. In the same range, the effective magnetic moment of **1** remains almost

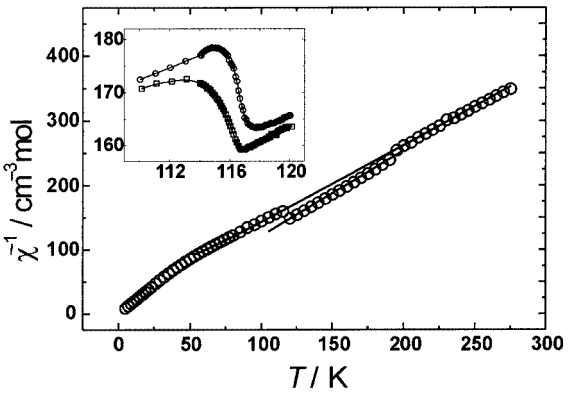

Figure 5. A plot of temperature dependence of χ_m^{-1} vs. T for compound **1**; the full lines correspond to fits of the different temperature ranges (see text); insert: variation of χ_M^{-1} in the 110−120 K temperature range on cooling (○) and warming (□)

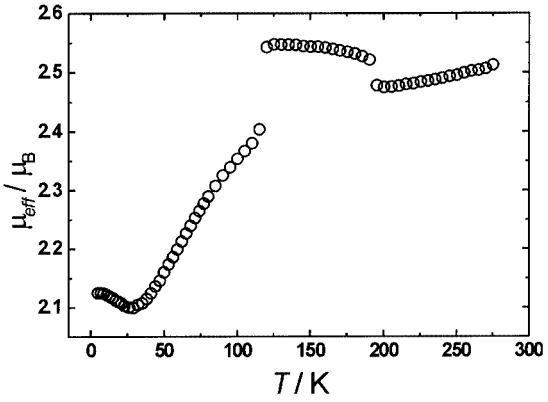

Figure 6. A plot of temperature dependence of μ_{eff} vs. T for compound **1**

constant at a value of 2.12 μ_B (Figure 6). This low-temperature behaviour cannot be attributed to a paramagnetic impurity, and is not understood yet, and therefore omitted from the present analysis. Full analysis would also require X-ray structures below 50 K. Subsequently, the fitting procedure was performed from 275 to 50 K (vide infra). The magnetic data above 50 K, and above and below the two discontinuities, can be reproduced (see Figure 5), with the theoretical expression of the magnetic susceptibility of a copper(II) pair given in the following equation, where J is the singlet-triplet energy gap (a positive or negative J value corresponds to a ferromagnetic or antiferromagnetic interaction, respectively) and the other parameters have their usual meaning.[1b]

$$\chi_M = \frac{2N_A\beta^2g^2}{k_BT}\left[3+\exp\left(\frac{-J}{k_BT}\right)\right]^{-1}$$

The minimisation of $R = \Sigma\,(\chi_M^{calcd.} - \chi_M^{obs.})^2/\Sigma(\chi_M^{obs})^2$ led to $J = -37.2$ cm^{-1} and $g = 2.09$, with $R = 3.37 \times 10^{-3}$. Applying the same expression to the data between the two discontinuities, yields $J = 29$ cm^{-1} and $g = 2.0$ with $R = 5.1 \times 10^{-3}$. Although the exact value of J may not be precisely defined because of the small number of data points fitted, a change in the sign of J is clearly observed. Indeed, the effective magnetic moment of **1** in that temperature range increases, whereas it decreases in the other fitted regions, also indicating a change in the sign of the exchange interaction. Such a drastic change of the magnetic interaction in a polynuclear compound upon a crystallographic phase transition is unprecedented. Sletten et al.[6b] have observed a change of 7 cm^{-1} in the strength of the antiferromagnetic interaction in $\{[Cu(petdien)]_2(CO_3)\}(ClO_4)_2$, but the perchlorate anions are not coordinated and the two copper ions are bridged by a carbonato anion. In that case, the change in the S-T energy gap has been related to a subtle change of the character of the magnetic orbital.

Here, the present phase transitions must mainly result from changes in the perchlorate anion orientation with respect to the $Cu_2(dpym)_2$ plane. Considering the Hatfield−Hodgson relationship[2] between J and the Cu−O−Cu angle for bis(μ-dihydroxo)copper dimers, the expected value for the S-T energy gap in **1** would range from −148 to −157 cm^{-1}. Such a discrepancy from the measured value was already observed in two of the rarely studied bis(μ-dihydroxo)copper dinuclear compounds having perchlorate anions coordinated, or semi-coordinated via two oxygen atoms.[11] It is thought[11a] that the perchlorate coordination greatly, but indirectly, affects the exchange interaction, and hence in two possible ways. The electronic perturbation due the additional coordination can affect the superexchange mechanism through the hydroxo oxygen atom, by altering the electron density available to it.

Alternatively, the very small changes in the Cu geometries (deviations from planarity) may be the origin.[11c,11d] None of these origins can be excluded in **1**. The abrupt change in behaviour from the ordering and change in orientation of the perchlorate anions only proves the strong influence of their coordination on the magnetic interaction. What is clear in this case is that the magnetic properties cannot be explained on the basis of Cu−Cu distances and Cu−OH−Cu angles alone.

The two ranges of temperature showing discontinuities were reinvestigated by cooling and heating at a much lower rate. A small hysteresis of 0.5 K is detected at the low-temperature transition, with $T^{\downarrow} = 116.2$ K and $T^{\uparrow} = 116.6$ K (see insert in Figure 5), which is in good agreement with the calorimetric measurements (see separate section). However, the step at high temperature occurs at $T = 5$ K on cooling and heating, which differs from the calorimetric measurements in which a hysteresis of 2 K was detected.

Heat Capacity Measurements

To understand more of these two phase transitions, calorimetric analyses have been performed on **1**. The sample was first rapidly cooled down to 250 K, measurements were then carried out on cooling to 85 K and warming back to 240 K. The temperature dependence of the molar heat ca-

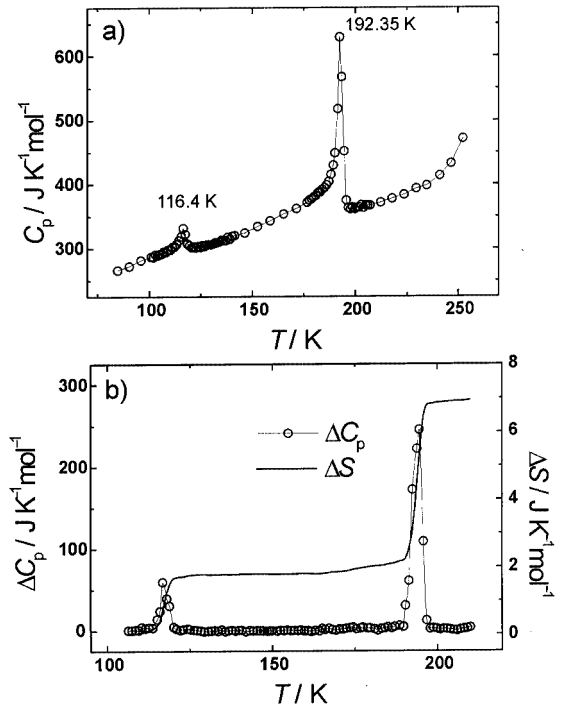

Figure 7. Temperature dependence of a) the heat capacity of compound **1** in the cooling mode and b) the excess heat capacity (empty circles) and the derived entropy gain (full line) in the warming mode

pacity of **1** in the cooling mode is shown in Figure 7a. Two thermal anomalies are found at 192.3 ($T_{c1}^{\downarrow}$) and 116.4 K ($T_{c2}^{\downarrow}$), and the same is observed in the warming mode at 116.8 ($T_{c2}^{\uparrow}$) and 194.4 K ($T_{c1}^{\uparrow}$). These values are in good agreement with the steps observed in the magnetic properties. The presence of hysteresis in the phase change at high temperature is also confirmed, with $T_{c1}^{\uparrow}$ and $T_{c1}^{\downarrow}$ differing by 2 K. The presence of hysteresis in the high-temperature transition, where no hysteresis could be detected by magnetic measurements, may indicate that the magnetic change does not occur while the structural phase transition takes place, but just after it has occurred. Since the hysteresis is so small, the magnetic change then appears at the same temperature on cooling and warming. The enthalpy gain ΔH and the entropy gain ΔS, associated with the excess heat capacities ΔC_p, were determined by integration of ΔC_p with respect to T and ln$T$, respectively, both in the cooling and warming mode. The temperature dependence of ΔC_p and the excess entropy in the warming mode are shown in Figure 7b. The ultimate value at high temperatures corresponds to $\Delta S = (6.9 \pm 0.7)$ J K^{-1} mol^{-1}, while the excess enthalpy was found to be $\Delta H = (1.2 \pm 0.1)$ kJ mol^{-1}. Similar calorimetric values were found in the cooling mode, the only marked difference being the temperatures. This confirms the reversibility of the phase changes in compound **1**. Large errors are due to the ambiguity in the determination of normal heat capacity curves, which were done by fitting the experimental data above, below and between the C_p anomalies, to a polynomial function. Since the two C_p anomalies are well separated, an approximation of the excess entropy and enthalpy associated with the two transitions is possible, e.g. $\Delta S(T_{c1}) = 4.9$ J K^{-1} mol^{-1}/$\Delta H(T_{c1}) = 0.96$ kJ mol^{-1} and $\Delta S(T_{c2}) = 2.0$ J K^{-1} mol^{-1}/ $\Delta H(T_{c2}) = 0.25$ kJ mol^{-1}. The entropy variation ΔS is usually[12] written as $\Delta S = \Delta S_{el} + \Delta S_{vib,intra} + \Delta S_{vib,inter}$.

In the present case, there is almost no variation in the metal−ligand bond lengths, and the intramolecular geometry is not modified, as shown by the very similar Cu−O−Cu angles. Therefore, $\Delta S_{vib,intra}$ is negligible. The observed change in magnetic interaction may result in a small contribution of the electronic entropy ΔS_{el}, while the dominant term is probably the lattice term $\Delta S_{vib,inter}$. The high-temperature transition entropy is approximated, within the error, in terms of Rln 2 (5.76), which agrees with an order-disorder phenomenon occurring between two positions. This is indeed in agreement with the structural data at 200 and 150 K. On the other hand, the phase change between the 150 and 110 K structures only involves changes in the crystal lattice. This is in agreement with the amount of entropy gain measured at T_{c2}, which can reasonably arise from lattice vibrations.

Conclusions

The results described above have shown a unique double phase transition for a dinuclear hydroxo-bridged Cu^{II} compound. X-ray structures were measured at three different temperatures (below, between and above the two phase transitions), and it can be concluded that the main reason for the crystallographic phase transition must originate from the abrupt change in the positions (canting or tilting) of the perchlorate anions, and therefore influencing the Cu−O$_{(ClO4)}$ bonds and Cu geometries. The abrupt change in behaviour from the ordering and change in orientation of the perchlorate anions confirms the influence of their coordination on the magnetic interaction.

More insight in the exact mechanism of the transition from more studies using other examples would be desirable. In fact, it is likely that such phase transitions, involving the movements of (semi)coordinated anions do occur, since many coordination compounds are studied only at one temperature and in many cases no magnetic susceptibility measurements are performed.

Experimental Section

General: All reagents were commercial-grade materials and were used without further purification. C,H,Cu,N determinations were performed by the Microanalytical Service of Science and Technological Research Equipment Centre, Chulalongkorn University. Infrared spectra were taken with a Biorad FTS-7/PC FTIR spectrophotometer as KBr pellets in the 4000−450 cm^{-1} region. Solid-state (diffuse reflectance) electronic spectra were recorded as polycrystalline samples with a Perkin−Elmer Lambda 2S spectrophotometer over the range 8000−18000 cm^{-1}. X-band EPR spectra were recorded on polycrystalline samples with a Jeol RE2X electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard.

Magnetic susceptibility measurements (5−275 K) were carried out using a Quantum Design MPMS-5 5T SQUID magnetometer (measurements carried out at 0.1 and 1 T). Data were corrected for magnetisation of the sample holder and for diamagnetic contributions, which were estimated from Pascal constants. Heat-capacity measurements were carried out using the heat-capacity option of a Quantum Design PPMS model 6000. A few crystals (total mass = 2.3 mg) were mounted onto the sample platform of the heat capacity puck with a little Apiezon N grease, which was previously measured as an addendum (puck + grease). The heat-capacity option uses a relaxation technique, fitting the whole thermal response to a heating period followed by a cooling period with a model that accounts for both thermal relaxation from the sample platform to the bath and the relaxation between the platform and the sample.

Synthesis of the Title Compound: Solid sodium carbonate (0.052 g, 0.5 mmol) was slowly added under continuous stirring to an aqueous solution (60 mL) containing copper(II) perchlorate hexahydrate (0.370 g, 1.0 mmol) and di-2-pyridylamine (0.171 g, 1.0 mmol). The greenish-blue solution was allowed to concentrate at room temperature. After several days, purple-blue rod-shaped crystals were formed. They were filtered off, washed with the mother liquor and air-dried. Yield: ca. 0.32 g (45%). $C_{20}H_{20}Cl_2Cu_2N_6O_{10}$ (702.4): calcd. C 34.0, H 2.6, Cu 17.8, N 11.8; found C 34.2, H 2.9, Cu 18.1, N 12.0. ***Caution:*** Perchlorate salts are potentially explosive, caution is advised and handling of only small quantities is recommended.

X-ray Data Collection and Structure Determination: A crystal was mounted on top of a glass fibre (using the inert-oil technique) and transferred to a cold nitrogen stream of a Nonius Kappa-CCD diffractometer for data collection at 200, 150 and 110 K (rotating anode, graphite-monochromated Mo-K_α radiation, λ = 0.71073 Å). The unit-cell parameters were checked for the presence of higher lattice symmetry.[13c] No absorption correction was applied. The structure was solved by automated direct methods (SHELXS-86).[13a] Refinement on F^2 was carried out by full-matrix least-squares techniques (SHELXL-97).[13b] For the structure determination of **1C**, a two-site disorder model was adopted for the ClO_4^- ion. The occupancy of the major component was refined to 0.811(5). Mild distance restraints and a common displacement parameter were applied to the minor component. Anisotropic displacement parameters were used for all non-hydrogen atoms, except for those belonging to the minor disorder component. Hydroxo hydrogen atoms were located on a difference Fourier map and their positions were refined. All other hydrogen atoms were introduced at calculated positions and included in the refinement riding on their carrier atoms. Geometrical calculations, including the ORTEP illustrations were performed with the PLATON package.[13c] Crystallographic details are tabulated in Table 3. CCDC-173825, -173824 and CCDC-173823 for structures **1A**, **1B** and **1C** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Oxa-aza Crown Ethers as Ligands for Mixed-Ligand Cisplatin Derivatives and Dinuclear Platinum Anticancer Drugs

Bart A. J. Jansen,[a] Peter Wielaard,[a] Hans den Dulk,[b] Jaap Brouwer,[b] and Jan Reedijk*[a]

Keywords: Anticancer drugs / Platinum / DNA binding / Crown ethers / A2780 human ovarian cancer

In the search for novel platinum anticancer drugs, cisplatin derivatives and dinuclear platinum complexes containing oxa-aza crown ether and oxa-diaza crown ether ligands have been prepared. The cisplatin derivatives *cis*-[$PtCl_2(NH_3)$(1,4,7,10,13-pentaoxa-16-azacyclooctadecane-*N*)] (**AO18**) and *cis*-[$PtCl_2(NH_3)$(1,4,7,10-tetraoxa-13-azacyclopentadecane-*N*)] (**AO15**), and the dinuclear cationic platinum complexes [{*trans*-$PtCl(NH_3)_2$}$_2$(μ-1,4,10,13-tetraoxa-7,16-diazacyclooctadecane-*N*,*N*′)]$(NO_3)_2$ (**DAO18**) and [{*trans*-$PtCl(NH_3)_2$}$_2$(μ-1,4,10-trioxa-7,13-diazacyclopentadecane-*N*,*N*′)]$(NO_3)_2$ (**DAO15**) were investigated for their cytotoxic properties, cellular uptake and intracellular DNA binding in A2780 human ovarian cancer. The cisplatin derivative **AO15** shows the highest cytotoxic activity, whereas the cationic dinuclear complexes **DAO18** and **DAO15** display a disappointing lack of biological activity at concentrations up to 100 μM. In the intracallular DNA platination experiments, the fifteen-membered rings were found to have a threefold higher intracellular DNA binding compared to their 1eight-membered analogues for the neutral cisplatin derivatives as well as for the cationic dinuclear complexes. The crown ether complex with the most effective binding to DNA, **AO15**, also shows the highest cytotoxicity against A2780 cancer cells. It is remarkable that, although **AO15** binds more effectively to DNA than cisplatin, its cytotoxic effect is much lower.

Introduction

The success of the anticancer drug cisplatin [*cis*-$PtCl_2(NH_3)_2$] has inspired the search for new platinum complexes with anticancer properties.[1−3] In the current paper, new platinum complexes based on aza crown ethers are described for their cytotoxic properties and binding to intracellular DNA. Binding to DNA is assumed to be a major mechanism of action,[4] leading to the death of cancer cells in platinum anticancer therapy.[5]

Although crown ethers are not known to possess medicinal properties themselves, they may improve drug uptake and transport properties.[6,7] Crown ethers are known to form cationic complexes with alkali metal ions and tertiary amines.[8] The special complexing properties of crown ethers have led to applications in drug delivery systems[9,10] and as targeting functionalities incorporated in drug derivatives and DNA-binding agents.[11−18] It was shown in DNA-binding studies that the positive charge of cation−crown ether complexes increases the affinity of crown ether linked compounds with the polyanionic phosphate backbone of DNA.[11,19] Thus, crown ether derivatized drugs may gain an increased interaction with DNA by the formation of cationic complexes with ions that are abundant in cells, such as sodium (5−15 mM) or potassium (140 mM).[20]

The groups of Keppler[21] and Sohn[22] have reported complexes where a crown ether is linked to a platinum atom through a functionalized bipyridine ligand. The bipyridine−crown ether compounds are biologically active and overcome cisplatin resistance. Sohn[22] also prepared carboplatin analogues of theses complexes by replacing the chloride leaving groups with 1,1-cyclobutanedicarboxylate. Similar to carboplatin, these complexes have a significantly lower cytotoxicity than the corresponding cisplatin (chloride) derivatives, probably due to their lower reactivity. A dinuclear platinum complex with a polycarboxylato crown ether as a bridging ligand has been reported by Fruhauf and Zeller.[23,24] The crown ether acts as a leaving group, releasing aquated species of cisplatin. The complex shows remarkable activity and DNA-binding properties in sensitive ovarian tumor cells as well as cisplatin-resistant cell lines.

In the platinum−crown ether complexes described above, the platinum atom is linked through a spacer or to pendant coordinating groups. In the current chapter, two types of platinum complexes are presented (Scheme 1), where the

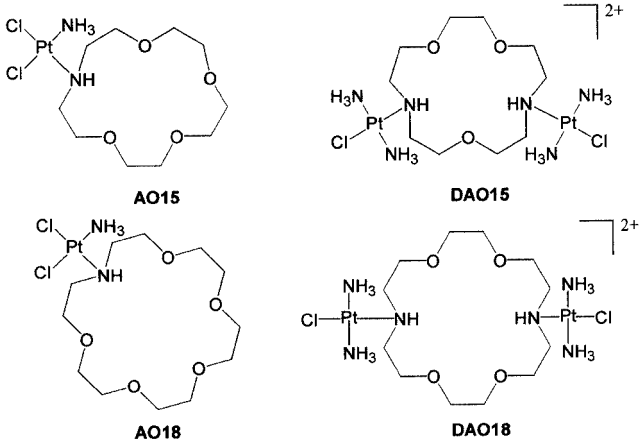
platinum atom is directly coordinated to the nitrogen atom in an aza crown ether. The first type comprise mixed-amine cisplatin derivatives of the general formula *cis*-$[PtCl_2(NH_3)(L)]$, where L are azacrown ethers. The second type are cationic dinuclear *trans* complexes using diaza crown ethers as linkers, similar to the anticancer active cationic dinuclear *trans*-(diaminoalkyl)platinum complexes as developed by Farrell.[25–28] The cytotoxic properties of the complexes are investigated, and the results are related to the efficiency of DNA binding in A2780 human ovarian cancer cells.



Scheme 1. Oxa-aza crown ether cisplatin derivatives **AO18** and **AO15** and the cationic oxa-diaza crown ether dinuclear platinum complexes **DAO18** and **DAO15**

Results and Discussion

Synthesis

Both cisplatin derivatives[29,30] and dinuclear oxa-aza crown ether platinum complexes[25] could be prepared employing standard synthesis methods.

The reactions of $Ph_4P[Pt(NH_3)Cl_3]$ with the appropriate oxa-aza crown ether produced the asymmetric cisplatin derivatives **AO18** and **AO15**. Yields after recrystallization from methanol were found to be 15% and 39%, respectively. The ^{195}Pt NMR shifts of **AO18** and **AO15** are at $\delta = -2222$ and -2231 ppm, respectively, both in the typical range for $PtCl_2N_2$ complexes.[31]

The dinuclear complexes **DAO18** and **DAO15** were obtained in 24% and 51% yield from the reaction of silver nitrate activated *trans*-$PtCl_2(NH_3)_2$ with the appropriate diamine linker. The oxa-diaza crown ether complexes have the platinum atom coordinated to a secondary amine group. The ^{195}Pt NMR chemical shifts of **DAO18** ($\delta = -2408$ ppm) and **DAO15** ($\delta = -2424$ ppm) are somewhat higher than those of related alkyldiamine complexes where the platinum atom coordinates to primary amines ($\delta \approx -2385$ ppm).[25,32]

The formation of all four platinum complexes is quantitative, as can be monitored by ^{195}Pt NMR, the final yields are relatively low. The solubility properties of the crown ether complexes resulted in losses in the purification steps. Elemental analysis results are not completely satisfactory for all complexes, apparently the samples still include some impurities that were not removed even with repeated recrystallization. Possibly, the impurities are related to degraded crown ether moieties, although these were not apparent from the ^1H NMR spectroscopic data. The ^{195}Pt NMR spectra showed only a single signal even after overnight measurements. The inclusion of considerable amounts of highly active platinum species like cisplatin, that could influence the outcome of the cytotoxicity assays, can be ruled out on basis of these data.

Cytotoxicity Assays

All complexes were tested for cytotoxicity by determination of the IC_{50} values in the human ovarian cancer cell line A2780 and the cisplatin-resistant A2780cisR line. Cytotoxicity results are summarized in Table 1. In the A2780 cell line, the neutral cisplatin derivative **AO15** is the most active oxa-aza crown ether platinum complex, followed by **AO18**. Interestingly, in a recently published series of crown ether analogues of actinomycin D, the 15-crown-5 derivatives were also found to be biologically more active than the 18-crown-6 compounds.[18] The dinuclear diazacrown ether complexes show a disappointing lack of cytotoxic effect. In the cisplatin-resistant cell line, all oxa-aza crown ether complexes failed to induce a cytotoxic effect at concentrations as high as 100 μM. When compared with the established platinum anticancer drug cisplatin, none of the oxa-aza crown ether complexes appears to be a potential anticancer drug.

Table 1. Cytotoxicity results in human ovarian cancer A2780 and the cisplatin-resistant derivative A2780cisR

Compound	IC_{50} (μM)	
	A2780	A2780cisR
cisplatin	0.37	2.4
AO18	66	> 100
AO15	21	> 100
DAO18	> 100	> 100
DAO15	> 100	> 100

Intracellular DNA Platination

A2780 cells were incubated for 1 h at drug concentrations of 200 μM. After the DNA was extracted from the cells, the drug-to-base pair ratio (r_b) was determined by UV and FAAS. The results are presented in Figure 1.

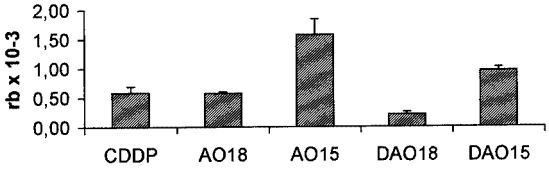


Figure 1. DNA binding (r_b = drug-to-basepair ratio) of cisplatin and aza crown ether platinum complexes in A2780 cells after a 1 h incubation at 200 μM

For both the mononuclear and dinuclear complexes, the 15-crown-5 derivatives show a higher binding to DNA than the corresponding 18-crown-6 compounds. The complex with the highest biological activity of the oxa-aza crown ether complexes studied, **AO15**, also shows the highest binding to DNA in the A2780 cells. The difference in lipophilicity may play an important role here, as it influences the permeation of the cell membrane. Interestingly, a comparable result was found for a series of crown ether derivatized phenoxazone drugs,[18] were the fifteen-membered compounds were also more effective in biological activity and intracellular DNA binding than the eighteen-membered derivatives.

It is remarkable that although **AO15** binds more effectively to DNA than cisplatin, its IC_{50} is much higher. Apparently, not only the amount of DNA damage is important for the cytotoxic effect, but also the type of molecule that binds DNA.

For the dinuclear cationic complexes, the fifteen-membered ring compound **DAO15** performs better in intracellular DNA binding than the eighteen-membered ring compound **DAO18**. Both show a reduced DNA binding compared to the corresponding neutral cisplatin derivatives. **DAO18** binds even less than cisplatin. This is remarkable, because in several cell studies related cationic polynuclear platinum complexes with alkyldiamine linkers were shown to have a much higher affinity for DNA than cisplatin.[28,33−35] Active uptake mechanisms,[32] that are thought to transport cationic polynuclear platinum complexes into cells, may not facilitate the transport of the crown ether compounds.

Conclusion

For both neutral cisplatin derivatives and the cationic dinuclear complexes, the fifteen-membered rings were found to have an increased binding to intracellular DNA compared to their eighteen-membered counterparts. The complex with the highest affinity for DNA, **AO15**, also showed the highest cytotoxicity of the series against A2780 cancer cells. Although **AO15** was found to bind more effectively to intracellular DNA than cisplatin, its cytotoxicity was found to be significantly lower. The effectivity of DNA binding appears not to be the determining factor for cytotoxicity. Apparently, the crown ether moiety plays a role here, but its interactions with for instance DNA repair systems would require further study.

Due to charge interactions, most cationic polynuclear platinum complexes show a significantly higher affinity for DNA than neutral platinum complexes, like cisplatin.[28,33−35] Surprisingly, the cationic dinuclear complexes with oxa-diaza crown ethers exhibit a lower DNA binding in the A2780 cells than cisplatin and its mono-aza crown ether derivatives. Although the efficiency of transport by diffusion probably depends on the lipophilicity of the linker, it has also been suggested that, due to their resemblance of natural polyamines like spermine and spermidine, cationic dinuclear complexes are taken up through active transport mechanisms.[34,35] The present results suggest that the linear shape of the linker is important for these molecules to enter the cell.

Experimental Section

General: Oxa-aza crownethers and oxa-diaza crown ethers were either a gift from Dr. L. G. A. van de Water (Leiden Institute of Chemistry), or obtained from Acros Chemicals, the Netherlands. K_2PtCl_4 was obtained as a loan from Johnson-Matthey. The complex $Ph_4P[PtCl_3(NH_3)]$ was prepared from *cis*-$[PtCl_2(NH_3)_2]$ using literature procedures.[29,30] Solvents and other chemicals were obtained from Acros and Aldrich. NMR spectra were recorded with a Bruker DPX 300 spectrometer with a 5-mm multi-nucleus probe. ^1H NMR spectra were determined with respect to external TMS. ^{195}Pt spectra were calibrated using K_2PtCl_4 as an external reference at $\delta = -1614$ ppm. Reaction mixtures could be monitored using ^{195}Pt NMR by adding 10% of a deuterated solvent (D_2O or $CDCl_3$) for the locking signal. C, H and N analyses were performed with a Perkin−Elmer 240B microanalyzer. Platinum concentrations were determined by using graphite-oven flameless atomic absorption spectroscopy (FAAS), based on a previously published method.[28] Measurements were carried out with a Perkin−Elmer 3100 AAS apparatus, equipped with a platinum hollow cathode lamp and an AS-60 graphite-oven autosampler. For each determination, 20 μL of sample was injected. The used furnace program was: drying 120 °C/90 s, ashing 1300 °C/60s, 20 °C/15s, atomization and measurement 2650 °C/5s, purging 2600 °C/5 s. The furnace was purged with argon gas.

Synthesis

***cis*-[$PtCl_2(NH_3)$(1,4,7,10,13-pentaoxa-16-azacyclooctadecane-*N*)] (AO18):** To a solution of 102 mg (0.155 mmol) of $Ph_4P[Pt(NH_3)Cl_3]$ in 5 mL of methanol a solution of 40 mg (0.152 mmol) of aza-18-crown-6 (1,4,7,10,13-pentaoxa-16-azacyclooctadecane) in 5 mL of methanol was added. The mixture was stirred for 48 h at room temperature. The intensity of the yellow/orange color of the solution gradually decreased. After 48 h, the volume was reduced to 5 mL by rotary evaporation and the mixture was allowed to stand overnight at −20 °C. A yellow precipitate was formed. The product was filtered off, washed with diethyl ether and dried in air. A second crop was obtained by reducing the volume further by rotary evaporation. The solution was allowed to stand overnight at −20 °C. The product was recrystallized from a minimum amount of methanol. Yield: 13 mg (15%). ^1H NMR (MeOD): $\delta = 2.5$ (m, 2 H), 2.83 (m, 2 H), 3.5 (m, 18 H), 3.78 (m, 2 H), 5.09 (m, 2 H), 5.23 (s, br, 1 H) ppm. ^{195}Pt NMR (MeOD): $\delta = -2222$ ppm. $C_{12}H_{28}Cl_2N_2O_5Pt$ (546.3): calcd. C 26.38, H 5.17, N 5.13; found C 25.37, H 5.28, N 5.04.

***cis*-[$PtCl_2(NH_3)$(1,4,7,10-tetraoxa-13-azacyclopentadecane-*N*)] (AO15):** Complex **AO15** was prepared according to the procedure as described for **AO18**, with 33.3 mg (0.15 mmol) of aza-15-crown-5 (1,4,7,10-tetraoxa-13-azacyclopentadecane). Yield: 29 mg (39%). ^1H NMR (D_2O): $\delta = 2.70$ (m, 2 H), 3.25 (m, 2 H), 3.70 (m, 16 H), 4.00 (br, 1 H), 5.10 (br, NH) ppm. ^{195}Pt NMR (D_2O): $\delta = -2231$ ppm. $C_{10}H_{24}Cl_2N_2O_4Pt$ (502.3): calcd. C 23.91, H 4.82, N 5.58; found C 23.70, H 4.56, N 5.77.

[{*trans*-$PtCl(NH_3)_2$}$_2$(μ-1,4,10,13-tetraoxa-7,16-diazacyclooctadecane-*N*,*N*′)]$(NO_3)_2$ (DAO18): To a solution of 302 mg (1.0 mmol) of *trans*-$[PtCl_2(NH_3)_2]$ in 5 mL of DMF a solution of 162 mg (0.95

mmol) of $AgNO_3$ in 5 mL of DMF was added. The solution was stirred in the dark overnight at room temperature. The precipitated AgCl was filtered off and a solution of 98 mg (0.37 mmol) of 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane (diaza-18-crown-6) in 5 mL of DMF was added to the yellow filtrate. The solution was stirred for 72 h at 40 °C. Subsequently, diethyl ether (400 mL) was added to the solution and an off-white precipitate appeared immediately. The solution was allowed to stand overnight at 4 °C and the precipitate was filtered off. The product was suspended in methanol and stirred for 1 h at 40 °C. Insoluble material was filtered off. Diethyl ether (400 mL) was added to the filtrate, a white precipitate appeared immediately. The mixture was allowed to stand overnight at 4 °C. The white product was filtered off, washed with diethyl ether and dried under vacuum. Yield: 81 mg (24%). ^{1}H NMR (D_2O): δ = 3.06 (m, 6 H), 3.70 (m, 8 H), 3.94 (m, 8 H), 4.20 (m, 2 H), 5.1 (s, br, 2 H), 4.75 (m, 2 H) ppm. ^{195}Pt NMR (D_2O): δ = −2408 ppm. $C_{12}H_{38}Cl_2N_8O_{10}Pt_2$ (915.5): calcd. C 15.74, H 4.18, N 12.24; found C 15.57, H 4.44, N 11.95.

[{*trans*-PtCl(NH$_3$)$_2$}$_2$(μ-1,4,10-trioxa-7,13-diazacyclopentadecane-*N*,*N*′)](NO$_3$)$_2$ (DAO15): The complex was prepared according to the procedure for **DAO18**, using 66.8 mg (0.31 mmol) of 1,4,10-trioxa-7,13-diazacyclopentadecane (diaza-15-crown-5) as the linker. Yield: 136 mg (51%). ^{1}H NMR (D_2O): δ = 3.15 (m, 12 H), 3.8 (m, 4 H), 4.2 (br, 2 H), 4.4 (m, 4 H) ppm. ^{195}Pt NMR (D_2O): δ = −2424 ppm. $C_{10}H_{34}Cl_2N_8O_9Pt_2$ (895.5): calcd. C 13.78, H 3.93, N 12.86; found C 14.40, H 3.86, N 12.90.

Cytotoxic Studies: A2780 and A2780cisR human ovarium cell lines were a gift from Dr. J. M. Perez (Universidad Autónoma de Madrid, Spain). The cell lines were grown as monolayers in Dulbecco's modified Eagle's Medium (DMEM) supplemented with 10% fetal calf serum (Gibco, Paisley, Scotland), penicillin (100 units/ml: Duchefa, Netherlands) and streptomycin (100 μg/ml: Duchefa, Netherlands) in a humidified 6% CO_2, 94% air atmosphere. Cells were passed after trypsinization when the plates were 80−90% full. Growth inhibition by the platinum compounds was determined using an MTT-based assay.

Intracellular DNA Binding Studies: For the uptake/DNA binding experiment, A2780 cells were grown in 6-cm plates with 4 mL of DMEM medium, until a concentration of approximately 1×10^7 cells was reached. At this point, the medium was replaced by 4 mL of serum-free DMEM medium, as the binding of platinum complexes to proteins in the serum might influence the uptake efficiencies. Fresh stock solutions of the platinum complexes were added to a concentration of 200 μM. Each experiment was performed in duplicate. After 1 h of incubation (37 °C, 6% CO_2, dark), the medium was removed and the cells were washed twice with 1 mL of PBS (0.1 M phosphate buffer in 0.15 M NaCl). The cells were then trypsinized and centrifuged at 1000 G for 10 min. At this point, the cell pellets may be stored at −20 °C for future use. DNA was isolated from the cells by using the following procedure. Cell pellets were suspended in 300 μL of buffer (10 mM tris, pH = 8, 150 mM NaCl, 10 mM edta). 5 μL of proteinase K solution was added and mixed well with the cells. Finally, 50 μL of 10% SDS was added and the resulting mixture was heated at 50−55 °C for 1.5 h. The solutions were transferred to 2-mL Eppendorf Phaselock tubes, and extracted with 300 μL of chloroform/phenol/amyl alcohol (24:25:1), and subsequently with 300 μL of chloroform/amyl alcohol (24:1). DNA was precipitated by adding 600 μL of isopropyl alcohol to the water layer. The DNA pellet was washed once with cold 70% ethyl alcohol, and then dissolved in 1 mL of milli-Q water. The DNA concentration was determined by measuring the UV absorption at 260 nm. From this absorption, the concentration of base pairs was calculated, using an average molar extinction coefficient per base pair of ε_{260} = 16800 $M^{-1}cm^{-1}$. The platinum concentration was measured by FAAS. From the platinum concentration, the actual drug concentration was derived. Combining FAAS and UV results, the drug molecules per base pair ratio (r_b) was calculated.

Acknowledgments

The authors are indebted to the EU for a grant as Host Institute in the EU programme Human Capital and Mobility. Also support and sponsorship by COST Actions D8/0007/97 and D20/0003/00 is kindly acknowledged. The authors wish to thank Johnson & Matthey (Reading, UK) for their generous loan of K_2PtCl_4. Cucurbituril as a New Macrocyclic Ligand for Complexation of Lanthanide Cations in Aqueous Solutions

Denis G. Samsonenko,[a] Janusz Lipkowski,[b] Olga A. Gerasko,[a] Alexander V. Virovets,[a] Maxim N. Sokolov,[a] Vladimir P. Fedin,*[a] Javier G. Platas,[c] Rita Hernandez-Molina,[d] and Alfredo Mederos[d]

Dedicated to Professor F. A. Kuznetsov on the occasion of his 70th birthday

Keywords: Lanthanides / Solid-state structures / Supramolecular chemistry / Aqua complexes / Cucurbituril

(Aqua)lanthanide complexes with cucurbituril {[Gd(NO_3)(H_2O)$_4$]($C_{36}H_{36}N_{24}O_{12}$)}(NO_3)$_2$·7H_2O (**1**), {[Gd(NO_3)(C_2H_5OH)(H_2O)$_3$]($C_{36}H_{36}N_{24}O_{12}$)}(NO_3)$_2$·5.5H_2O (**2**), {[Ho(NO_3)(H_2O)$_4$]($C_{36}H_{36}N_{24}O_{12}$)}(NO_3)$_2$·7H_2O (**3**), {[Yb(NO_3)(H_2O)$_4$]($C_{36}H_{36}N_{24}O_{12}$)}(NO_3)$_2$·6H_2O (**4**), {[La(H_2O)$_6$(SO_4)]($C_{36}H_{36}N_{24}O_{12}$)}(NO_3)·12H_2O (**5**), {[Gd(H_2O)$_4$]$_2$($C_{36}H_{36}N_{24}O_{12}$)$_3$}Br_6·45H_2O (**6**), and {[Ce(H_2O)$_5$]$_2$($C_{36}H_{36}N_{24}O_{12}$)$_2$}Br_6·26H_2O (**7**) were obtained in high yield by reaction of cucurbituril with aqueous solutions of lanthanide(III) species. The crystal structures of the compounds show a packing of 1:1, 2:2, and 2:3 in the (cucurbituril)lanthanide complexes in which cucurbituril plays a bidentate ligand role, and water molecules of the (aqua)lanthanide complexes form hydrogen bonds with carbonyl groups of the cucurbituril molecule. The guest water molecule is situated in the cucurbituril molecule cavity of **2** and **5**. The crystal structure of **6** is a packing of three-deck sandwiches, built from alternating cucurbituril molecules and Gd(H_2O)$_4^{3+}$ ions. The largest distance between outermost oxygen atoms in the sandwiches is 30.04 Å.

Introduction

Lanthanide(III) species exhibit rich and unique spectroscopic and magnetic properties, and rare-earth compounds are used for numerous applications, as relaxation agents in nuclear magnetic resonance imaging,[1] as luminescent probes in biology and medicine,[2] or as catalysts for the cleavage of RNA and DNA.[3]

In aqueous solution, large f-element ions form high-coordination number aqua complexes with various, often unique, coordination environments. The extremely high rates of exchange of ligands at f-element centers make the isolation of their coordination complexes difficult, particularly from aqueous solutions. A successful method of overcoming this kinetic instability is to increase the thermodynamic stability of the complexes by exploring the chelate and macrocyclic effects.[4]

There is a considerable body of information concerning macrocyclic ligand complexes of the lanthanides, where a metal atom is coordinated in a multidentate manner with nitrogen- or oxygen-donor ligands: crown ethers, calixarenes, etc.[5,6] The coordination selectivity exhibited by these ligands towards rare-earth cations has been widely investigated, in particular because of its role in processes of separation of f-elements in acidic aqueous solution, which is an important step in strategies for management and storage of high-level radioactive waste and clean-up of decommissioned nuclear facilities.[7]

However, the scope of neutral macrocyclic ligand systems studied for f-elements is limited, as the complexation with most of them occurs in organic solvents and not in aqueous solutions, where water acts as a very strong competitor. Introduction of the sulfonate group in the *para* position to the phenolic group of calixarenes made it possible to prepare (calixarene)lanthanide complexes in aqueous solution, but the metal ion coordinates to the ligand through the sulfonate functionalities, and in no case was evidence obtained

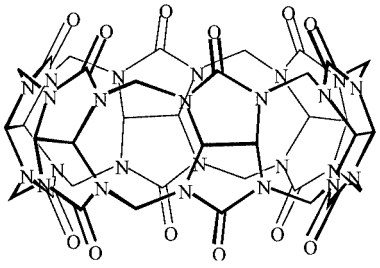
for a multidentate mode of lanthanide complexation by the calixarene involving the phenolic oxygen atoms.[6a−6d]

In the present work, we report the synthesis and crystallization of lanthanide (La, Ce, Gd, Ho, Yb) complexes in aqueous media with the macrocyclic ligand cucurbituril. Using lanthanide nitrates or bromides, the following compounds were obtained: {[Gd(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·7H$_2$O (**1**), {[Gd(NO$_3$)(C$_2$H$_5$OH)(H$_2$O)$_3$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·5.5H$_2$O (**2**), {[Ho(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·7H$_2$O (**3**), {[Yb(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·6H$_2$O (**4**), {[La(H$_2$O)$_6$(SO$_4$)](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)·12H$_2$O (**5**), {[Gd(H$_2$O)$_4$]$_2$(C$_{36}$H$_{36}$N$_{24}$O$_{12}$)$_3$}Br$_6$·45H$_2$O (**6**), and {[Ce(H$_2$O)$_5$]$_2$(C$_{36}$H$_{36}$N$_{24}$O$_{12}$)$_2$}Br$_6$·26H$_2$O (**7**) and characterized by single-crystal X-ray analysis.

Results and Discussion

Cucurbituril (C$_{36}$H$_{36}$N$_{24}$O$_{12}$) is a barrel-shaped macrocyclic cavitand with an internal cavity having a ca. 5.5 Å diameter and two identical carbonyl-fringed portals on each side.[8] Each portal of this molecule has six carbonyl oxygen atoms located in a plane which can interact with metal cations in such a way that cucurbituril behaves like a macrocyclic ligand. These portal atoms have a higher electric charge compared with crown ether oxygen atoms and consequently stronger interactions between carbonyl groups and positively charged ions take place.[9] Its easy synthesis, rigid structure, and chemical and thermal stability make cucurbituril very attractive for complexation of cations in aqueous solution.



Scheme 1. Cucurbituril

A number of adducts of cucurbituril and s-metals (Na^+, K^+, Rb^+, Cs^+, Ca^{2+}) have been prepared with their quite unique structures and reactivities.[10] Due to the strong interactions of carbonyl oxygen donor atoms with cations, stable complexes are formed, and the metal ions and their coordinated water molecules cover each portal of cucurbituril like a "lid" on a "barrel". Also aliphatic and aromatic ammonium ions show a high affinity toward cucurbituril to form host−guest complexes.[11]

We have recently shown that the macrocyclic cavitand cucurbituril is by its geometry almost ideally suited for design of supramolecular adducts with triangular cluster aqua ions $[M_3Q_4(H_2O)_9]^{4+}$ (M = Mo, W; Q = S, Se), as well as their heterometal cuboidal derivatives.[12] Six water molecules, coordinated to the cluster core, form hydrogen bonds with the six carbonyl oxygen atoms of cucurbituril leading to the formation of nanosized molecules with the ratio of cluster/cucurbituril of 1:1 or 2:1. In the latter case the cavity in the cavitand molecule is effectively closed by cluster "lids" and small molecules or ions can be trapped inside. We have also shown that cucurbituril molecules are associated with (aqua)indium and -aluminum cations by hydrogen bonds with the portal oxygen atoms and also coordinate to the cluster water molecules.[13] An attractive point here is that, since cucurbituril usually belongs to the second coordination sphere, the aqua complexes will be much less perturbed by the adduct formation with cucurbituril than by introducing other ligands in the first coordination sphere. This enhances the relevance of the structural information obtained from cucurbituril adducts to the hydrolytic species actually present in solution. However, as we found in the present study cucurbituril can coordinate directly to Ln^{3+}.

The synthesis of the compounds **1**−**7** is straightforward. They were obtained by reaction of cucurbituril with aqueous solutions of lanthanide(III) species. Cucurbituril is not soluble in water, but it is well soluble in hot saturated aqueous solutions of Ln^{III} salts. Within a week or even overnight well-shaped colorless crystals suitable for X−ray studies separate in high yields. When taken out of the mother liquor, the crystals of compounds **6** and **7** lose water of crystallization and crystallinity. This fact explains the difference between the analytically deduced formulae and the stoichiometry found by X-ray analysis, performed at a low temperature with crystals sealed inside quartz capillaries.

The gadolinium complex **1** was obtained from solutions containing gadolinium nitrate and cucurbituril. The elemental analysis gives the formula {[Gd(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·7H$_2$O (**1**). The crystals suitable for the X-ray experiment were obtained by diffusion of ethanol into the solution used to prepare **1**, and have the composition {[Gd(NO$_3$)(C$_2$H$_5$OH)(H$_2$O)$_3$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·5.5H$_2$O (**2**).

The crystal structure of compound **2** shows a 1:1 packing of (cucurbituril)gadolinium complexes in which cucurbituril plays the role of the bidentate ligand (Figure 1). One guest water molecule is situated inside the cucurbituril molecule cavity. In addition to the two oxygen atoms of the two cucurbituril carbonyl groups, the gadolinium cation has one ethanol molecule, one bidentate nitrate and three aqua ligands in its coordination environment. The coordination number of gadolinium is eight and its coordination polyhedron is a distorted triangulated dodecahedron in which the nitrate anion occupies the shortest edge.

Isostructural complexes of holmium, {[Ho(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·7H$_2$O (**3**), and ytterbium, {[Yb(NO$_3$)(H$_2$O)$_4$](C$_{36}$H$_{36}$N$_{24}$O$_{12}$)}(NO$_3$)$_2$·6H$_2$O (**4**), were obtained under the same conditions, but in contrast to the gadolinium complex **2**, holmium and ytterbium cations have no ethanol molecules in their coordination environment (Figure 2). The space vacated by ethanol is occupied with water molecules forming hydrogen bonds with one another and the carbonyl groups of the cucurbituril molecule.

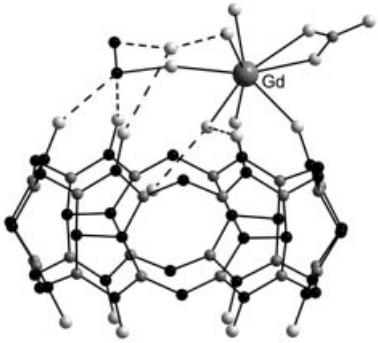


Figure 1. Structure of $\{[Gd(H_2O)_3(C_2H_5OH)(NO_3)](1/2\text{-}H_2O\subset C_{36}H_{36}N_{24}O_{12})\}^{2+}$ complex in **2**; dashed lines show hydrogen bonds

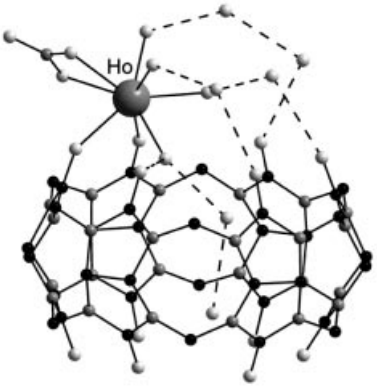

Figure 2. Structure of $\{[Ho(H_2O)_4(NO_3)](H_2O\subset C_{36}H_{36}N_{24}O_{12})\}^{2+}$ complex in **3**; dashed lines show hydrogen bonds

The crystal packing of compound **3** is shown in Figure 3. The cationic complexes form polar, i.e. having a preferential direction, hydrogen-bonded chains running along the *c* axis and the centers of the supermolecules form a body-centered motif. The chains are shifted from each other by one-half of a crystallographic translation along the axis of their expansion. The space between the polar chains is filled with solvate water molecules and nitrate anions. The ytterbium compound **4** has the same crystal structure, but complex **3** has one more solvate water molecule.

The comparison of calculated and experimental X-ray powder diffraction data for compounds **1** and **3** shows that complex **1** is isostructural with **3** (see figure in the Supporting Information).

Another example of 1:1 stoichiometry is given by an adduct with hexaaqualanthanum(III) sulfate, $\{[La(H_2O)_6(SO_4)](C_{36}H_{36}N_{24}O_{12})\}(NO_3)\cdot 12H_2O$ (**5**). It was isolated from an aqueous solution containing lanthanum nitrate, copper(II) sulfate and cucurbituril. The crystal structure of compound **5** is a packing of supermolecules, which consist of a cucurbituril molecule capped by a cationic (aqua)lanthanum complex on one side (Figure 4). Cucurbituril is bound to the lanthanum cation via two carbonyl groups and the coordination polyhedron of La^{3+}

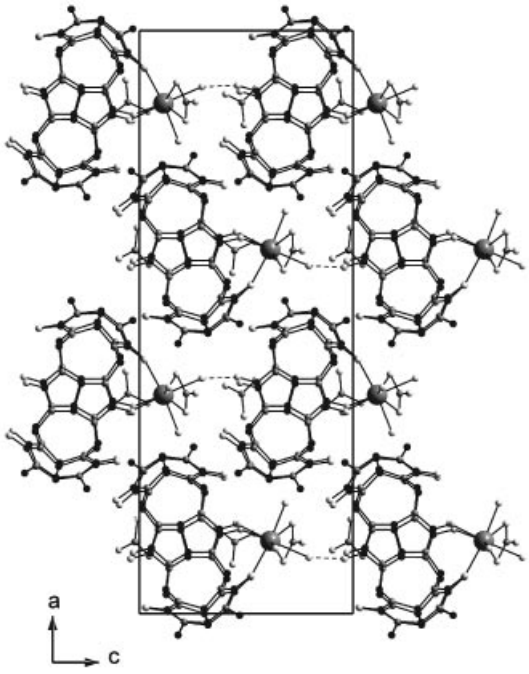

Figure 3. Crystal packing in **3** (projection on the *ac* plane); solvate water molecules and nitrate anions are omitted for clarity

(CN = 9, mono-capped square antiprism) is completed by six water molecules and one monodentate sulfate anion. The sulfate is disordered over two orientations around the S(1)−O(1S) bond with relative weights of 0.60 and 0.40 for O(2S1), O(3S1), O(4S1) and O(2S2), O(3S2), O(4S2), respectively. Three aqua ligands participate in hydrogen bonding with four carbonyl groups and another one does the same with a guest water molecule disordered over two positions (Figure 4). There is one water molecule in the open portal of the cucurbituril molecule, which is hydrogen-bound with the guest water molecule.

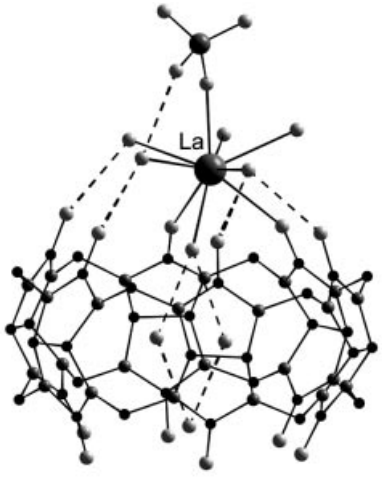

Figure 4. Structure of $\{[La(H_2O)_6(SO_4)](2H_2O\subset C_{36}H_{36}N_{24}O_{12})\}^{2+}$ complex in **5**; dashed lines show hydrogen bonds

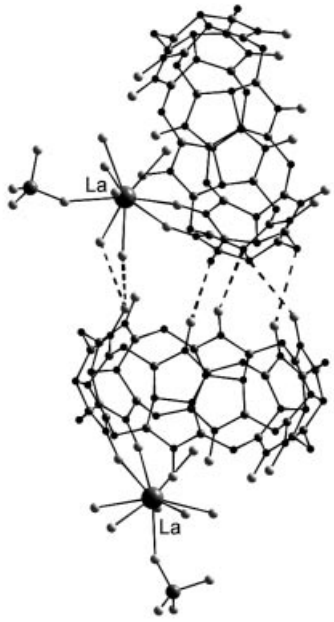

Figure 5. Two supermolecules in **5**; dashed lines show hydrogen bonds

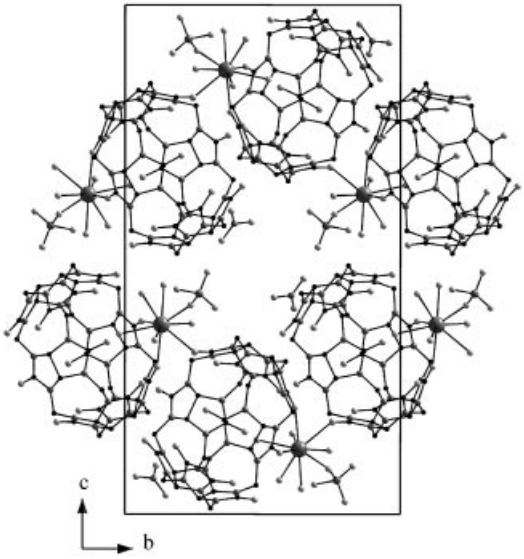

Figure 6. Crystal packing in **5** (projection on the *bc* plane); solvate water molecules and nitrate anions are omitted for clarity

Two neighboring supermolecules form hydrogen bonds between carbonyl groups of one supermolecule and aqua ligands (mean O···O distance: 2.861 Å) and the C−H groups (mean O···C distance: 3.050 Å) of another one (Figure 5). The supermolecules are stacked in columns shifted by one half of a crystallographic translation with regards to each other. The columns form corrugated layers parallel to the *ab* plane (Figure 6). There are channels between the layers filled with water of crystallization and nitrate anions. All the moieties of **5** are involved in a complicated network of hydrogen bonds.

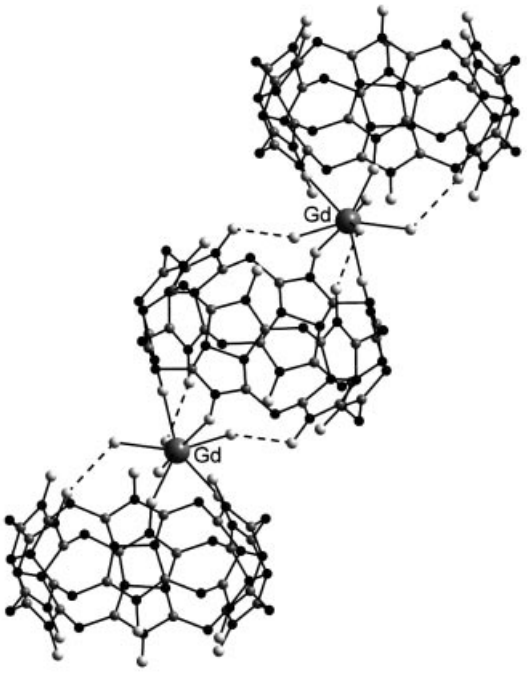

Figure 7. Three-deck sandwich $\{(C_{36}H_{36}N_{24}O_{12})[Gd(H_2O)_4](C_{36}H_{36}N_{24}O_{12})[Gd(H_2O)_4](C_{36}H_{36}N_{24}O_{12})\}^{6+}$ complex in **6**; dashed lines show hydrogen bonds

Compound **6**, $\{[Gd(H_2O)_4]_2(C_{36}H_{36}N_{24}O_{12})_3\}Br_6 \cdot 45H_2O$, was obtained from an aqueous solution containing gadolinium bromide and cucurbituril. The crystal structure of **6** reveals a packing of nanosized three-deck sandwiches, $\{(C_{36}H_{36}N_{24}O_{12})[Gd(H_2O)_4](C_{36}H_{36}N_{24}O_{12})[Gd(H_2O)_4](C_{36}H_{36}N_{24}O_{12})\}^{6+}$ (Figure 7), built from alternating cucurbituril molecules and Gd^{3+} cations. The shape of the sandwich complex can be approximated by an oblique cylinder with van der Waals dimensions about 15 × 28 Å. The largest distance between the oxygen atoms from the opposite sides is 30.04 Å.

Each Gd^{3+} is octacoordinated by two bidentate cucurbituril molecules, the mean Gd−O distance being 2.375 Å, and by four aqua ligands with a mean Gd−O distance of 2.397 Å. The coordination polyhedron of gadolinium is a slightly distorted square antiprism.

Crystal packing of sandwich complexes in **6** is shown in Figure 8. The centers of sandwiches coincide with centers of inversion in a body-centered motif (crystallographic position *2b* (1/2, 0, 0; 0, 1/2, 1/2) of $P2_1/n$ space group). The complexes are arranged in pillars oriented along the *a* axis. In each pillar, the sandwiches stack parallel to each other, being related by crystallographic translation. Each pillar has four other pillars as neighbors, oriented with respect to the former at angles of ca. 90°. The pillars are shifted by one-half of a crystallographic translation along the axis of their expansion and leaving quadrangular channels between them. The channels are filled with disordered solvate water molecules and bromide anions.

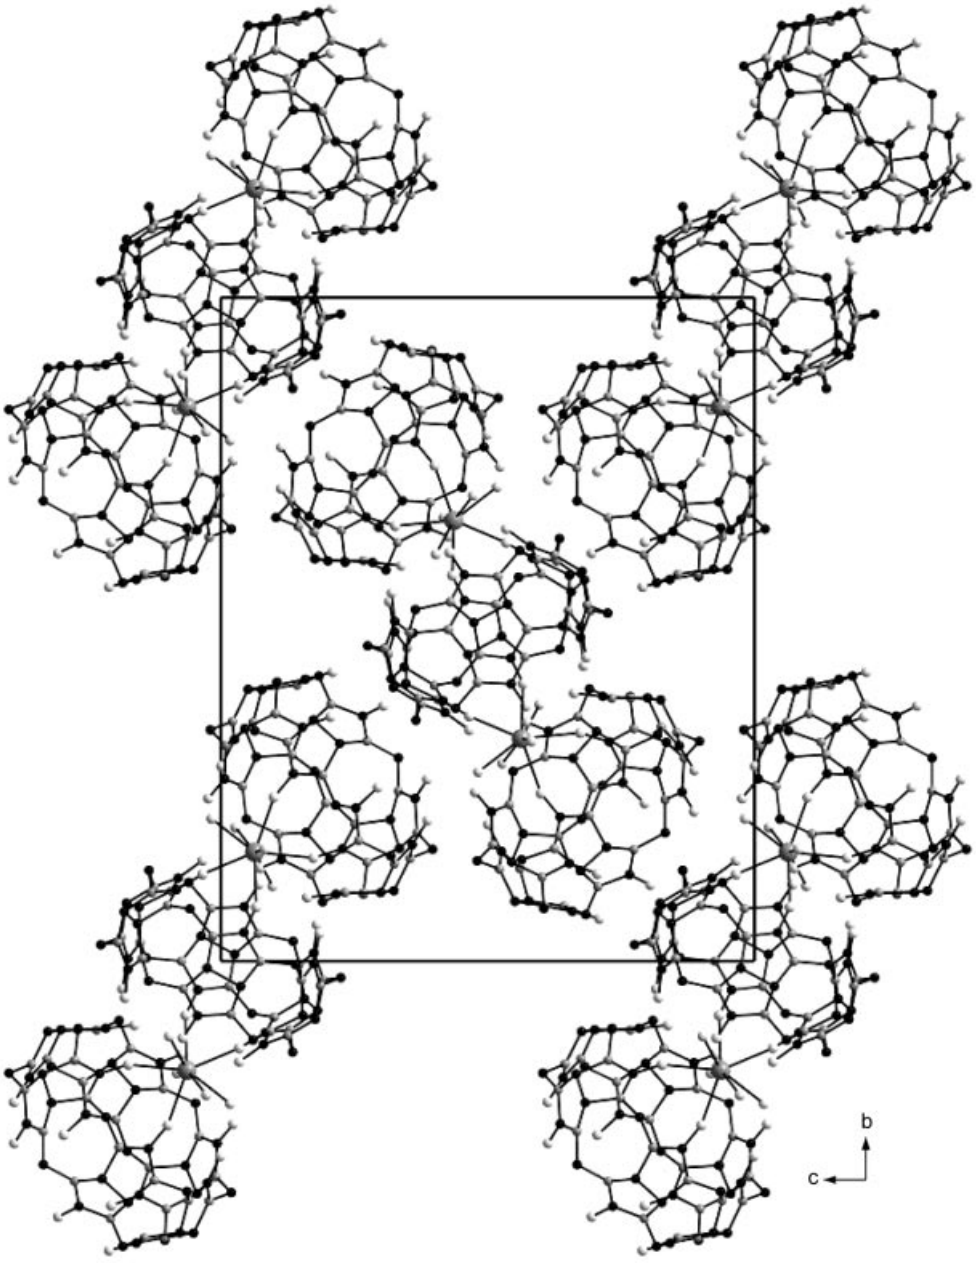

Figure 8. Crystal packing in **6** (projection on the *bc* plane); solvate water molecules and bromide anions are omitted for clarity

As a whole, the structure of **6** can be described as two interpenetrating networks, one of them being built of sandwich complexes and another representing a complicated network of hydrogen bonds formed by solvate water molecules and bromide anions.

Calculations carried out with the KPACK[14] program showed the sandwich complexes occupy 46.0% of the cell volume. The water molecules and bromide anions occupy another 18.0%. The packing coefficient in **6** is thus 0.64. Water molecules coat the sandwiches forming a bulky network of hydrogen bonds.

Another sandwich compound is a 2:2 (cucurbituril)cerium(III) complex, $\{[Ce(H_2O)_5]_2(C_{36}H_{36}N_{24}O_{12})_2\}Br_6 \cdot 26H_2O$ (**7**), crystallized from an aqueous solution containing cerium bromide and cucurbituril. The crystal structure of **7** represents a packing of supermolecules built from two cucurbituril molecules and two (aqua)cerium(III) ions sandwiched between them (Figure 9). Nonacoordinated Ce^{3+} has four oxygen atoms of cucurbituril carbonyl groups and five aqua ligands in its coordination environment. Two of the five aqua ligands of each cerium cation are disordered over two positions.

The trigonal crystal packing of sandwich complexes in **7** is shown in Figure 10. Large triangular channels with a van der Waals diameter of about 4.3 Å are filled with disordered water molecules and bromide anions.

To summarize, the cases when cucurbituril directly coordinates to a metal center, seem to be limited by

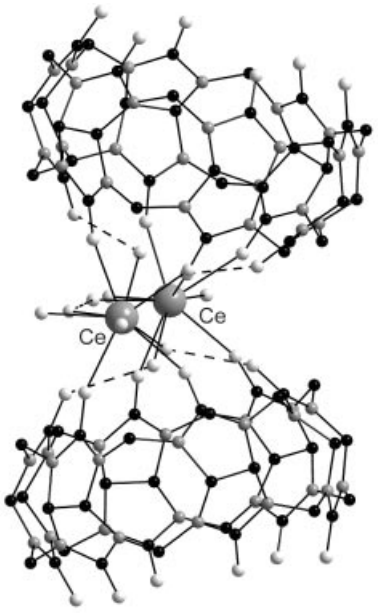

Figure 9. Structure of $\{[Ce(H_2O)_5]_2(C_{36}H_{36}N_{24}O_{12})_2\}^{6+}$ complex in **7**; dashed lines show hydrogen bonds

alkali,[10a−10c] alkali earth[10d,10e] and rare earth metal cations (groups 1−3). These are the most electropositive metals, forming hard and large (e.g., ionic radius of Na^+ 0.97 Å, Ca^{2+} 1.03 Å, Gd^{3+} 0.94 Å, Lu^{3+} 0.86 Å[12i]) ions, whose bonding to ligands can be accounted for in terms of electrostatic (ion−dipole) interactions. Only under these conditions can cucurbituril, being a weak donor, but possessing polar C=O groups, compete with other ligands for the first coordination sphere. Transition metals (and metals of group 13) form smaller ions (In^{3+} 0.76 Å, Al^{3+} 0.50 Å, Ni^{2+} 0.67 Å[12i]) which prefer covalent bonding. The higher charge and smaller size of the metal cation enhance the acidity of the coordinated water in the aqua-coordinated ions, so that, e.g., $[Al(H_2O)_6]^{3+}$ and $[In(H_2O)_6]^{3+}$ are by 4−5 orders of magnitude more acidic than any $[Ln(H_2O)_n]^{3+}$, (n = 8, 9).[15] This acidity allows for the formation of strong hydrogen bonds between the polar C=O groups of cucurbituril and the coordinated water molecules, thus increasing the energy gain of keeping cucurbituril in the second coordination sphere instead of substituting it for coordinated water.

Experimental Section

General: The lanthanide nitrates and bromides were of commercial quality and used without further purification. Cucurbituril was synthesized by published procedures.[8] Elemental analyses were carried out in the Laboratory of Microanalysis, Institute of Organic Chemistry SB RAS, Novosibirsk. The IR spectra were recorded on KBr pellets with an IFS-85 spectrometer (Bruker). X-ray powder patterns were recorded with a Philips APD diffractometer (Cu-K_α radiation).

X-ray Structure Determination: A summary of the crystallographic data, data collection and refinement parameters for compounds **2**−**7** is given in Table 1. For **2**, **4** and **5**, data were reduced in the usual way and absorption correction from ψ-scans was applied using the HELENA[16] program. For crystals **3**, **6** and **7**, data reduction and cell refinement were carried out using the Denzo,[17] Scalepak[17] and maXus[18] packages. The structures were solved by direct methods using SIR97[19] (for **2**) and SHELXS-97[20] (for **3**−**7**) programs and refined anisotropically for non-hydrogen atoms (except for some disordered atoms) by full-matrix least squares on F_o^2 using the SHELXL-97[20] program. In the case of **3**, **4** and **7** a racemic merohedral twinning was found with the twinning law of {−1, 0, 0, 0, −1, 0, 0, 0, −1} and relative component weights of 0.66(1)/0.34(1) for **3**, 0.53(5)/0.47(5) for **4** and 0.45(2)/0.55(2) for **7**. The hydrogen atoms of cucurbituril molecules were refined in the rigid-body approximation. The positions of hydrogen atoms of the coordinated water molecules in the structure of **2** were calculated using the CALC-OH[21] program. In the case of **7** only 15 bromide ions out of a total of 18 per unit cell could be found, but the chemical analysis confirmed the formula with 18 Br^-. Figures showing the coordination environment of lanthanide cations and tables with selected bond lengths and valence angles for compounds **2**−**7** are given in the Supporting Information. CCDC-177555 (**2**), -177556 (**3**), -177557 (**4**), -177558 (**5**), -177559 (**6**) and -177560 (**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses

$\{[Gd(NO_3)(H_2O)_4](C_{36}H_{36}N_{24}O_{12})\}(NO_3)_2\cdot 7H_2O$ (1): In a solution of $Gd(NO_3)_3\cdot 5H_2O$ (0.24 g, 0.54 mmol) in water (5 mL), cucurbituril (0.025 g, 0.021 mmol) was dissolved after heating for 15 min on a hot plate. The solution was filtered and the filtrate was left in an open beaker for 1 d. Colorless crystals of **1** were separated and dried on a filter paper. Yield: 0.028 g (86%). IR (KBr): $\tilde{\nu}$ = 634 (m), 676 (m), 757 (m), 801 (s), 966 (s), 1149 (s), 1191 (s), 1235 (s), 1326 (s), 1381 (s), 1487 (s), 1735 (s), 3362 cm^{-1} (s). μ_{eff} (298 K) = 7.81 μ_B. $C_{36}H_{58}GdN_{27}O_{32}$ (1538.27): calcd. C 28.11, H 3.80, N 24.58; found C 28.57, H 3.81, N 24.56. Crystals of $\{[Gd(NO_3)(C_2H_5OH)(H_2O)_3](C_{36}H_{36}N_{24}O_{12})\}(NO_3)_2\cdot 5.5H_2O$ (**2**) for X-ray experiments were obtained by diffusion of ethanol into an aqueous solution of **1**.

$\{[Ho(NO_3)(H_2O)_4](C_{36}H_{36}N_{24}O_{12})\}(NO_3)_2\cdot 7H_2O$ (3): In a solution of $Ho(NO_3)_3\cdot 5H_2O$ (0.23 g, 0.52 mmol) in water (5 mL), cucurbituril (0.022 g, 0.019 mmol) was dissolved after heating for 10 min on a hot plate. The solution was left in an open beaker for 1 d. Pale crystals of **3** were separated and dried on a filter paper. Yield: 0.022 g (76%). $C_{36}H_{58}HoN_{27}O_{32}$ (1545.95): calcd. C 27.97, H 3.78, N 24.46; found C 27.81, H 3.35, N 24.10.

$\{[Yb(NO_3)(H_2O)_4](C_{36}H_{36}N_{24}O_{12})\}(NO_3)_2\cdot 6H_2O$ (4): In a solution of $Yb(NO_3)_3\cdot 5H_2O$ (0.21 g, 0.47 mmol) in water (5 mL), cucurbituril (0.021 g, 0.018 mmol) was dissolved after heating for 10 min on a hot plate. The solution was left in an open beaker for 1 d. Colorless crystals of **4** were separated and dried on a filter paper. Yield: 0.020 g (73%). $C_{36}H_{56}N_{27}O_{31}Yb$ (1536.04): calcd. C 28.15, H 3.67, N 24.62; found C 28.13, H 3.70, N 24.51.

$\{[La(H_2O)_6(SO_4)](C_{36}H_{36}N_{24}O_{12})\}(NO_3)\cdot 12H_2O$ (5): In a solution of $La(NO_3)_3\cdot 5H_2O$ (0.13 g, 0.31 mmol) and $CuSO_4\cdot 5H_2O$ (0.18 g, 0.72 mmol) in water (10 mL), cucurbituril (0.030 g, 0.026 mmol) was dissolved after heating for 15 min on a hot plate. The solution was left in an open beaker for about 7 d. Colorless crystals of **5** were separated and dried on a filter paper. Yield: 0.027 g (68%).

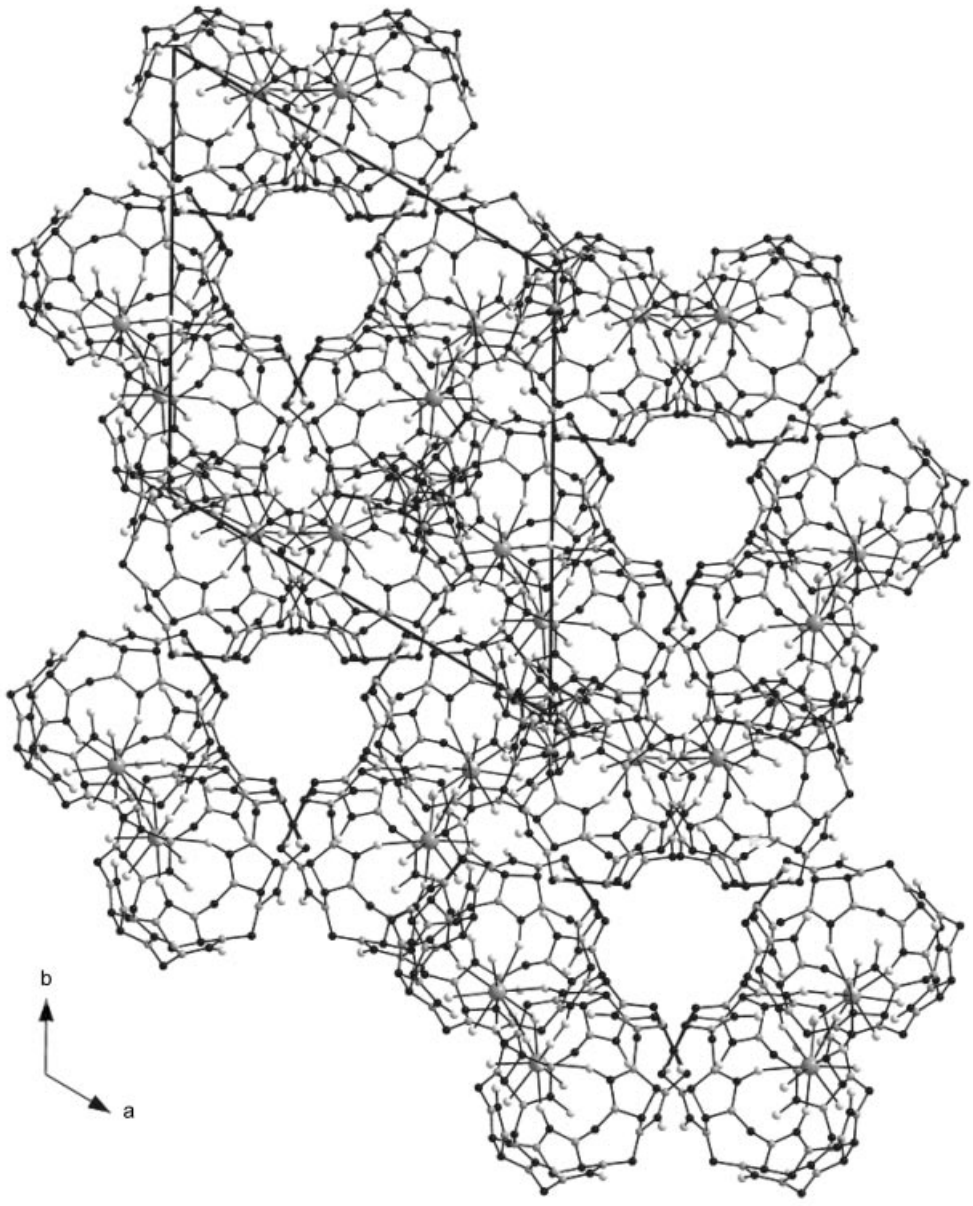

Figure 10. Crystal packing in **7** (projection on the *ab* plane); solvate water molecules and bromide anions are omitted for clarity

$C_{36}H_{72}LaN_{25}O_{37}S$ (1618.09): calcd. C 26.72, H 4.49, N 21.64, S 1.98; found C 27.01, H 4.56, N 21.78, S 2.02.

{[Gd(H$_2$O)$_4$]$_2$(C$_{36}$H$_{36}$N$_{24}$O$_{12}$)$_3$}Br$_6$·45H$_2$O (6): In a solution of $GdBr_3$ (0.15 g, 0.38 mmol) in water (13 mL), cucurbituril (0.052 g, 0.044 mmol) was dissolved after heating for 15 min on a hot plate. The solution was left in an open beaker for about 7 d. Colorless crystals of **6** were separated and dried on a filter paper. Yield: 0.050 g (77%). $C_{108}H_{180}Br_6Gd_2N_{72}O_{72}$ ({[Gd(H$_2$O)$_4$]$_2$-(C$_{36}$H$_{36}$N$_{24}$O$_{12}$)$_3$}Br$_6$·28H$_2$O) (4432.98): calcd. C 29.26, H 4.06, Br 10.81, N 22.75; found C 29.00, H 3.87, Br 10.86, N 23.25.

{[Ce(H$_2$O)$_5$]$_2$(C$_{36}$H$_{36}$N$_{24}$O$_{12}$)$_2$}Br$_6$·26H$_2$O (7): In a solution of $CeBr_3$ (0.11 g, 0.30 mmol) in water (5 mL), cucurbituril (0.022 g, 0.020 mmol) was dissolved after heating for 15 min on a hot plate. The solution was left in an open beaker for about 7 d. Colorless crystals of **7** were separated and dried on a filter paper. Yield: 0.020 g (63%). $C_{72}H_{144}Br_6Ce_2N_{48}O_{60}$ (3401.88): calcd. C 25.42, H 4.27, N 19.76; Br 14.09. found C 25.25, H 4.34, N 19.46, Br 14.29.

Acknowledgments

The First Crystal and Molecular Structure of a *syn*-Acetato-Bridged Dinuclear Cyclometallated Complex [Pd{2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$}-(μ-OAc)]$_2$

Alberto Fernández,*[a] Digna Vázquez-García,[a] Jesús J. Fernández,[a] Margarita López-Torres,[a] Antonio Suárez,[a] Samuel Castro-Juiz,[a] and José M. Vila*[b]

Keywords: C-H activation / Cyclometallation / P ligands / Schiff bases / Palladium

Treatment of the Schiff base ligands 2,3,4-$(MeO)_3C_6H_2C(H)=NR$ (R = CH_2CH_2OH, **1**; R = Me, **17**; R = Et, **18**; R = Pr, **19**; R = *t*Bu, **20**) with palladium(II) acetate in toluene gave the dinuclear cyclometallated complexes [Pd{2,3,4-$(MeO)_3C_6HC(H)=NR$}(μ-O_2CMe)]$_2$ (R = CH_2CH_2OH, **2**; R = Me, **21**; R = Et, **22**; R = Pr, **23**; R = *t*Bu, **24**), with the ligand bonded to the palladium atom through the imine nitrogen and the C6 carbon atoms. The ^1H and $^{13}C\{^1H\}$ NMR spectra of the complexes showed the presence of the *anti* and *syn* isomers in solution. The *anti*/*syn* ratio varies with the solvent and the nature of the imine nitrogen substituent R. Complex **24** with the bulky *t*Bu group showed a 28:1 ratio in chloroform whilst the less bulky substituted complexes showed lower ratios. The X-ray crystal structure of the *syn* isomer of complex **2** is described. Reaction of the acetato-bridged complex **2** with PPh_3 gave the mononuclear complex **4**, in a bridge-splitting reaction. Reaction of **2** with the diphosphanes dppm, dppp and dppb in a 1:1 molar ratio gave the dinuclear cyclometallated complexes **5**, **6** and **7**, respectively. Treatment of **2** with an aqueous solution of sodium chloride gave the chloro-bridged complex **3**. Treatment of the cyclometallated chloro-bridged complex **3** with PPh_3 in acetone yielded the mononuclear complex **8**, and reaction of **3** with silver triflate gave the cyclometallated complex **9**, with the palladium atom bonded to four different atoms C, N, O and P. Treatment of **3** with the tertiary diphosphanes dppp, dppb and dppf, in a 1:1 molar ratio gave the dinuclear complexes **10**, **11** and **12**, respectively, with terminal chloride ligands. However, reaction of **3** with the small "bite" diphosphane dppm gave **13**, with a bridging chloride ligand. Reaction of **11** with silver triflate in acetone gave the new dinuclear complex **14**, with the Schiff base ligand as [C,N,O] terdentate. Reaction of **3** with the diphosphane dppe in a 1:2 molar ratio, and silver perchlorate, gave the mononuclear complex **15**. Treatment of **3** with the triphosphane bis(2-diphenylphosphanylethyl)phenylphosphane in a 1:2 molar ratio, followed by treatment with sodium perchlorate, gave **16**, in which the palladium atom was bonded to the triphosphane through the three phosphorus atoms. The X-ray crystal structures of complexes **8**, **9**, **15** and **16** are also reported.

Introduction

Cyclometallated compounds have attracted much attention in recent years and abundant reports concerning them have appeared.[1−7] They are important not only because they show numerous applications in organic and organometallic synthesis[8] and in biologically active compounds,[9,10] among others, but also due to the new structural features they promote.[11,12] Lately, we have been interested in the study of Schiff base cyclometallated complexes prepared by direct reaction of the ligand with palladium(II) acetate, which gives dimeric acetato-bridged complexes with the characteristic open-book geometry;[13,14] these species are good starting materials for a great number of cyclometallated derivatives. Two different dispositions are possible for such compounds: the *syn* isomer with overall C_s symmetry, and the *anti* isomer with overall C_2 symmetry. The latter is by far the most common, and the known crystal structures of dinuclear acetato-bridged complexes correspond to the *anti* isomer.[10,15−27] We therefore sought to isolate and characterise the *syn* isomer in a pure form by modifying the steric requirements of the substituent at the imine nitrogen atom, i.e., substituents with small or negligible steric hindrance, which should allow the nitrogen atoms to lie above each other in the *syn* form without repulsions arising from the N-R groups, and in the present paper we report the crystal and molecular structure of a dinuclear acetato-bridged cyclometallated complex **2**, which, to the best of our knowledge, is the first example of a *syn* isomer. Compound **2** was obtained as an equilibrium mixture of the *anti* and *syn* isomers, and the features involved in the

equilibrium are also described. As we have observed before in related compounds with terdentate [C, N, X] (X = N, O, S] ligands,[28−31] the reactivity of the acetate dimeric compounds, and of their chloro-bridged derivatives, is fairly extensive, especially when they react with mono-, di- and triphosphanes, and herein we also report this chemistry, as well as the synthesis of [C, N, O] derivatives with Pd−O bond formation via halide abstraction by a silver(I) salt. The crystal structures of the cyclometallated compounds **8**, **9**, **15** and **16** are also given.

Results and Discussion

For the convenience of the reader the compounds and reactions are shown in Schemes 1, 2 and 3. The compounds described in this paper were characterised by elemental analysis (C, H, N), IR spectroscopy and by ^{1}H, ^{31}P{^{1}H} and, in part, ^{13}C{^{1}H} NMR spectroscopy and FAB mass spectrometry (data in the Exp. Sect.).

Reaction of the Schiff base ligand 2,3,4-$(MeO)_3C_6H_2C(H)=NCH_2CH_2OH$ (**1**) with palladium(II) acetate (Scheme 1) gave the dinuclear acetato-bridged complex $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_2CH_2OH\}(\mu\text{-}O_2CMe)]_2$ (**2**) as an orange air-stable solid which was fully characterised. *Syn* and *anti* isomers are possible for the folded arrangement of the acetato-bridged dimers: the *anti* isomer with C_2 symmetry and the *syn* isomer with C_s symmetry

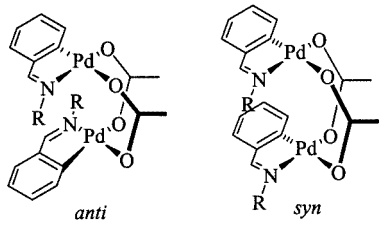

Figure 1. Isomers of compound **2**

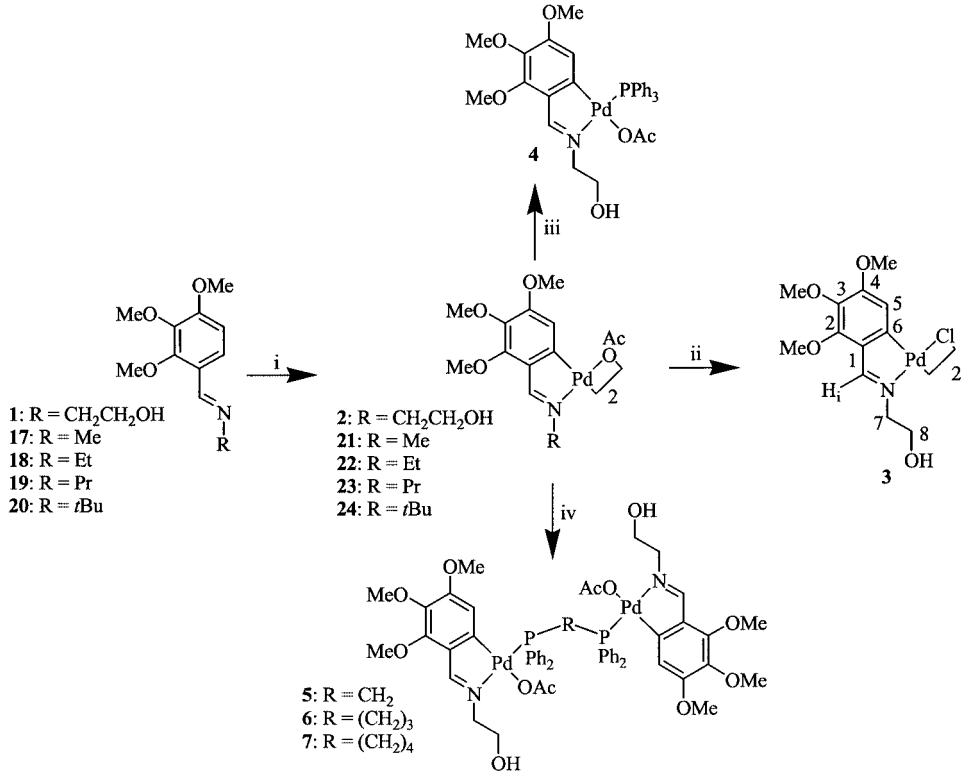
(see Figure 1), with the *anti* disposition being by far the most frequent.[14]

If both isomers are present in the final product two resonances would be expected for the *H*C=N and aromatic protons and three for the *Me*COO protons in the ^{1}H NMR spectrum: one for the *anti* isomer and two for the *syn* isomer. Thus, the ^{1}H NMR spectrum of **2** shows two sets of signals, one for each isomer. The resonance corresponding to the HC=N proton appears as a singlet (δ = 7.57 and 7.81 ppm, for the *anti* and *syn* isomers, respectively) shifted to lower frequency due to the coordination of the imine group to the palladium atom through the lone pair of the nitrogen atom.[32] The H^5 resonance also appears as a singlet, confirming metallation of the C6 carbon. The ^{1}H NMR spectrum shows the signal of the *Me*COO protons as a singlet at δ = 2.07 ppm, for the *anti* isomer, and as two singlets at δ = 2.25 and 2.02 ppm for the *syn* isomer. The IR spectrum of **2** shows the ν(C=N) stretch at 1604 cm^{-1}, shifted



Scheme 1. (i) $Pd(ACO)_2$, (toluene), (ii) NaCl (acetone/water), (iii) PPh_3 (acetone), (iv) dppm, dppp or dppb (acetone, 1:1 molar ratio)

to lower wavenumbers (relative to the free ligand) due to N-coordination of the imine.[33,34] The IR spectrum also shows strong bands assigned to the symmetric and asymmetric ν(COO) vibrations, in agreement with bridging acetate ligands[35] (see Exp. Sect.). The ν(O−H) stretch appears at 3384 cm^{-1}, close to its position in the spectrum of the free ligand, in agreement with a noncoordinated hydroxyl group. From the integration of the peaks corresponding to both isomers in the ^1H NMR spectrum we concluded that the *anti*/*syn* ratio is ca. 5:1

The $^{13}C\{^1H\}$ NMR spectrum showed the presence of signals corresponding to both isomers, with the C=N, C6 and C1 resonances shifted toward higher frequency, thus confirming that metallation had occurred.[28] The mass FAB spectrum of **2** shows a cluster of peaks, centred at 808 amu, which correspond to $[M]^+$. The isotopic pattern is in good agreement with the expected dinuclear structure.

The synthesis of complex **2** was performed under different reaction conditions: toluene at 60 °C, chloroform at room temperature and boiling methanol. Irrespective of the method used the *anti*/*syn* ratio is ca. 5:1 in all cases, which seems to be the equilibrium ratio. Although we cannot ascertain completely that the solid state of **2** contains only crystals of the *syn* form, the ^1H NMR spectrum of the solid, freshly dissolved in $CDCl_3$, also shows the presence of both isomers in the resulting solution in a 5:1 ratio, and the relative amount of isomers does not vary perceptively with temperature: heating a chloroform solution does not change the ^1H NMR spectrum of **2**, nor its concentration. However, the solvent in which the spectra were recorded does have a noticeable effect on the isomer ratio. Thus, the ^1H NMR spectrum in $[D_3]$acetonitrile shows an *anti*/*syn* ratio of 3:1 and a solution in $[D_6]$acetone a ratio of ca. 4:1, whereas dissolution in $[D_6]$DMSO causes partial decomposition of the compound. Nevertheless, the ^1H NMR spectrum recorded after removal of $[D_6]$acetone from the NMR tube and dissolution of the product in $CDCl_3$, again shows the initial 5:1 ratio. Therefore, it seems that solubility factors could account for such an equilibrium. Furthermore, we also considered that steric factors should be regarded, i.e., the bulkiness of the -N−R group could also influence the *anti*/*syn* ratio. It is known that most of the acetato-bridged dimer complexes for which the existence of *syn* and *anti* isomers has been reported are phenylimidazole derivatives. The imidazole ligand, after [C,N] coordination to the palladium atom, adopts a *quasi* planar disposition,[36−39] and we therefore suppose that the small steric repulsion between the imidazole rings in the *syn* disposition should favour this geometry. However, Schiff base ligands with more or less bulky substituents at the imine nitrogen should favour a *trans* disposition in order to avoid the steric hindrance. In complex **2**, the CH_2CH_2OH moiety allows a *cis* disposition of the ligands. To confirm this we prepared analogues to **1**, ligands **17**−**20**, which, upon reaction with palladium(II) acetate in toluene (Scheme 1), gave the acetato-bridged complexes $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NR\}(\mu\text{-}O_2CMe)]_2$, (**21**, R = Me; **22**, R = Et; **23**, R = Pr; **24**, R = *t*Bu). The resonances for the *anti* and *syn* isomers were ascribed accordingly (see Exp. Sect.).

The integration of the signals corresponding to both isomers showed that the *anti*/*syn* ratio is ca. 7.5:1 for complexes **21**, **22** and **23** in $CDCl_3$, whereas in $[D_6]$acetone a 5:1 ratio is observed (cf. compound **2**), and for complex **24**, with the bulky *t*Bu moiety bonded to the imine nitrogen a value of 28:1 is found.

Molecular Structure of $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_2CH_2OH\}(\mu\text{-}OAc)]_2$ (2)

Suitable crystals were grown by slowly evaporating a chloroform/*n*-hexane solution of the complex. The molecular structure is illustrated in Figure 2. Crystal data are given in Table 1 and selected bond lengths and angles with estimated standard deviations are shown in Table 2.

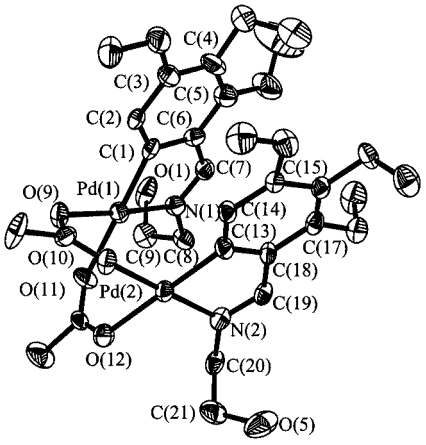


Figure 2. Molecular structure of $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_2CH_2OH\}(\mu\text{-}OAc)]_2$ (**2**), with labelling scheme; hydrogen atoms have been omitted for clarity

The structure consists of dimeric molecules at van der Waals distances. The molecular structure corresponds to the *syn* isomer, with the cyclometallated moieties in an open-book disposition and two acetate ligands bridging the palladium atoms. Although a large number of crystal structures of dinuclear acetato-bridged cyclometallated complexes have been reported, to the best of our knowledge this is the first example of a *syn* disposition of the metallated ligands.

The Pd(1)−Pd(2) bond length of 2.8514(13) Å is similar to values reported for related complexes [13] and can be regarded as nonbonding. Each palladium atom is bonded in a slightly distorted square-planar geometry to four atoms: a carbon atom of the phenyl ring and the imine nitrogen atom of the Schiff base ligand, and two oxygen atoms of the bridging acetate ligands.

The sum of the angles around the palladium atoms is approximately 360°. The angles between adjacent atoms in the coordination sphere are close to the expected value of 90°, with the most noticeable distortions corresponding to the C(1)−Pd(1)−N(1) and C(13)−Pd(2)−N(2) angles [81.9(4) and 82.1(4)°, respectively] due to chelation. The

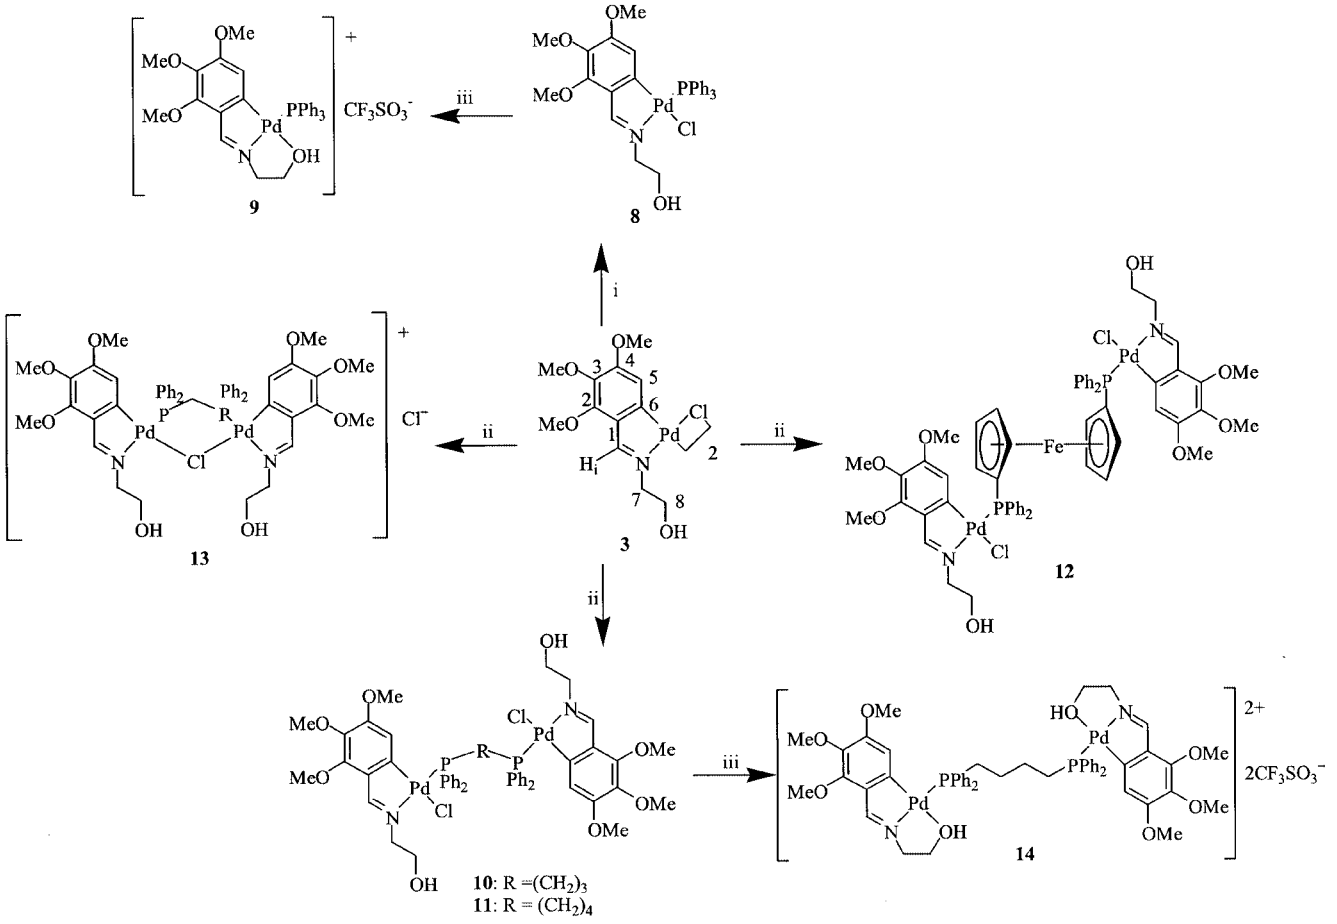
Pd(1)−C(1) and Pd(2)−C(13) bond lengths of 1.973(11) and 1.963(10) Å, respectively, are somewhat shorter than the values predicted from their covalent radii[40] but similar to values found earlier.[13,14] However, the Pd(1)−N(1) and Pd(2)−N(2) bond lengths of 2.018(9) and 2.012(9) Å, respectively, are in agreement with the value based on the sum of the covalent radii for nitrogen and palladium,[40] and are similar to values reported previously.[13,14] The differing Pd(1)−O(9) and Pd(1)−O(11) [2.084(7) and 2.131(7) Å, respectively] and Pd(2)−O(10) and Pd(2)−O(11) [2.064(8) and 2.130(8) Å, respectively] bond lengths reflect the higher *trans* influence of the aryl carbon as compared to the imine nitrogen atom.

As a result of the palladium atoms being bridged by two mutually *cis* μ-acetate ligands the metallated Schiff bases are forced to lie above one another in the dimeric molecules. This leads to inter-ligand repulsions and results in the coordination planes of the palladium atoms (planes 1 and 2) being tilted at an angle of 25.0°. The disposition of the chelating C,N ligands is not completely eclipsed, probably as a consequence of these repulsions. This is shown by the dihedral angles C(1)−Pd(1)−Pd(2)−C(13), N(1)−Pd(1)−Pd(2)−N(2), O(9)−Pd(1)−Pd(2)−O(10) and O(11)−Pd(1)−Pd(2)-0(12) of 17.3(5), 17.6(4), 15.3(3) and 14.0(3)°, respectively. No intra- or intermolecular O−H···O−H bonding is observed.

Reactivity of the Acetato-Bridged Complex 2

The reaction of **2** with aqueous sodium chloride gave the chloro-bridged complex [Pd{2,3,4-$(MeO)_3C_6HC(H)$=NCH_2CH_2OH}(μ-Cl)]$_2$ (**3**; Scheme 2), which was fully characterised (see Exp. Sect.). The IR spectrum of this complex shows the absence of the ν(COO) bands. The ^{1}H NMR spectra of **3** shows the HC=N and H^5 resonances at δ = 8.08 and 7.51 ppm, respectively.

Reaction of **2** with PPh_3 gave the complex [Pd{2,3,4-$(MeO)_3C_6HC(H)$=NCH_2CH_2OH}$(O_2CMe)(PPh_3)$] (**4**) as an air-stable solid which was fully characterised (see Exp. Sect.). The IR spectrum of **4** shows strong bands at 1290 and 1570 cm^{-1} assigned to the symmetric and asymmetric ν(COO) vibrations, respectively, in agreement with those expected for monocoordinate acetate ligands.[35] The IR spectrum also shows the νC=N stretch at 1613 cm^{-1}. This absorption is shifted to lower wavenumbers relative to the free ligand due to N-coordination of the imine;[32] the ν(O−H) band at 3400 cm^{-1} (3402 cm^{-1} in the free ligand) is as ex-



Scheme 2. (i) PPh_3 (acetone), (ii) dppm, dppp, dppb or dppf (acetone, 1:1 molar ratio), (iii) $AgCF_3SO_3$ (acetone)

pected for a noncoordinated OH group. The ^1H NMR spectrum shows the *H*C=N and H^5 resonances coupled to the phosphorus nucleus [δ = 8.31 ($J_{P,H}$ = 7.8) and δ = 5.70 ($J_{P,H}$ = 5.8 Hz), respectively], and the C(4)−O*C*H_3 resonance shifted towards lower frequency by ca. 0.8 ppm, relative to complex **2**, due to the shielding effects of the phosphane phenyl ring;[41] in the $^{31}P\{^1H\}$ spectrum the resonance of the coordinated phosphane appears as a singlet at δ = 40.8 ppm. These findings are in agreement with a phosphorus *trans* to nitrogen arrangement, as we and others have observed earlier, which seems to be the more common arrangement for the entering phosphane.[41−46] The novel term *transphobia* has been introduced by J. Vicente et al. to describe the restricted coordination of mutually *trans* phosphanes and phenyl carbon atoms.[44,45]

The FAB-mass spectrum shows peaks centred at 666 and 608 amu assigned to the $[MH]^+$ and $[M - OAc]^+$ fragments, respectively.

Reaction of complex **2** with $Ph_2PCH_2PPh_2$ (dppm), $Ph_2P(CH_2)_3PPh_2$ (dppp) or $Ph_2P(CH_2)_4PPh_2$ (dppb), in a 1:1 complex-to-phosphane molar ratio gave the dinuclear cyclometallated complexes [{Pd[2,3,4-$(MeO)_3C_6HC(H)$=NCH_2CH_2OH](O_2CMe)}$_2$(μ-$Ph_2P(CH_2)_nPPh_2$)] (**5**, *n* = 1; **6**, *n* = 3; **7**, *n* = 4). The IR spectra of these complexes are in agreement with monocoordinate acetate ligands and with noncoordinated hydroxyl groups (vide supra). The ^1H NMR spectra show the coupling of the *H*C=N and the H^5 resonances to the phosphorus nucleus, and in the $^{31}P\{^1H\}$ NMR spectra the resonance of the phosphorus nuclei appears as a singlet at ca. δ = 31 ppm in accordance with the centrosymmetric nature of the complexes. We tentatively propose this structure in accordance with the conductivity data for **5**, **6** and **7**, which show them to be nonelectrolytes.

Reaction of the cyclometallated chloro-bridged complex **3** with PPh_3 in acetone yielded the mononuclear complex [Pd{2,3,4-$(MeO)_3C_6HC(H)$=NCH_2CH_2OH}(Cl)(PPh_3)] (**8**) which was fully characterised (see Exp. Sect.). The IR and NMR spectra of **8** are similar to those for complex **4**; the most noticeable difference in the IR spectra is the absence of the ν(COO) bands.

The ^1H NMR spectrum shows doublets assigned to the *H*C=N and H^5 protons coupled to the ^{31}P nucleus [δ = 8.38 ppm ($J_{P,H}$ = 8.3) and δ = 5.74 ppm ($J_{P,H}$ = 6.3 Hz), respectively], and the $^{31}P\{^1H\}$ NMR spectrum shows a singlet resonance at δ = 40.3 ppm. The mass FAB spectrum shows peaks centred at 606 amu corresponding to the $[M - Cl]^+$ fragment.

Treatment of **3** with the tertiary diphosphanes $Ph_2P(CH_2)_3PPh_2$ (dppp), $Ph_2P(CH_2)_4PPh_2$ (dppb) and $Ph_2PC_5H_4FeC_5H_4PPh_2$ (dppf) in a 1:1 molar ratio gave the dinuclear complexes [{Pd[2,3,4-$(MeO)_3C_6HC(H)$=NCH_2CH_2OH](Cl)}$_2${μ-$Ph_2P(CH_2)_nPPh_2$}], (**10**, *n* = 3; **11**,

n = 4), and the trinuclear compound [{Pd[2,3,4-$(MeO)_3$-$C_6HC(H)=NCH_2CH_2OH$](Cl)}$_2${μ-$Ph_2PC_5H_4FeC_5H_4$-PPh_2}] (**12**), respectively. The IR and NMR spectra of these complexes show similar features to those described for the spectra of compound **8** suggesting a similar disposition around the palladium atoms. The $^{31}P\{^1H\}$ NMR spectrum shows a singlet resonance for the phosphorus nuclei indicating the symmetric nature of the complexes. Conductivity measurements in dry acetonitrile showed the complexes to be molecular nonelectrolytes.

However, when complex **3** was reacted with $Ph_2PCH_2PPh_2$ (dppm) the dinuclear complex [{Pd[2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$]}$_2$(μ-Cl)(μ-$Ph_2PCH_2$-$PPh_2$)][Cl] (**13**) was obtained (see Exp. Sect.). The ^1H NMR spectrum also shows coupling of the *H*C=N and H^5 protons to the phosphorus nucleus and the $^{31}P\{^1H\}$ NMR spectra shows a singlet resonance. The specific molar conductivity in dry acetonitrile (175.1 ohm^{-1} cm^2 mol^{-1}) is in agreement with the value expected for a 1:1 electrolyte.[47] This behaviour is in contrast to that observed for compound **5**, where a 1:1 electrolyte formulation with both palladium atoms bridged by the diphosphane and by one acetate ligand would be possible. However, the low conductivity values preclude this formulation for **5**.

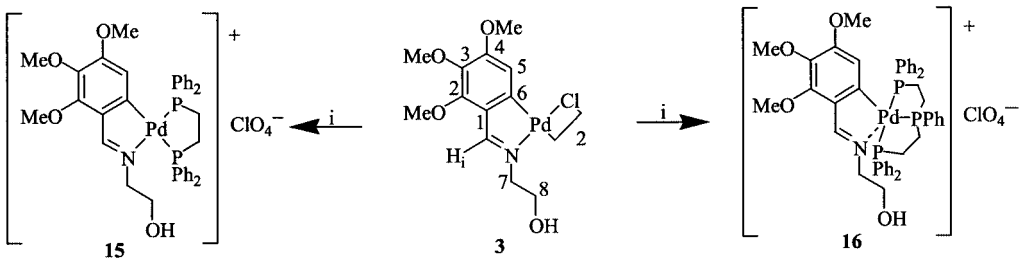
In order to promote coordination of the hydroxyl oxygen, thus giving a coordinated [C,N,O] ligand, we treated the cyclometallated complexes **8** and **11** with silver triflate to remove the chloride moiety. Thus, treatment of **8** with silver triflate gave the complex [Pd{2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$}$(PPh_3)$][$CF_3SO_3$] (**9**) and an AgCl precipitate. The IR spectrum shows a band assigned to the ν(O−H) vibration at 3245 cm^{-1} shifted to lower wavenumber (3402 and 3365 cm^{-1} in the spectra of the free ligand and compound **8**, respectively) due to Pd−O bond formation.[48] The most noteworthy differences in the ^1H NMR spectrum of **9** from that of **8** are in the lowfield shift of the -O*H* hydroxyl proton resonance which appears as a triplet at δ = 7.02 ppm ($J_{H,H}$ = 5.6 Hz), (for complex **8** a broad resonance at ca. δ = 3.2 ppm was assigned to O*H*) and the resolution of the CH_2CH_2OH signals, which appear as a multiplet in the spectrum of **8** at δ = 4.03 ppm and as two broad resonances at δ = 4.13 and 3.89 ppm for **9**.

In the $^{13}C\{^1H\}$ NMR spectrum the resonances assigned to the CH_2CH_2OH carbon atoms appear at δ = 67.7 and 56.8 ppm shifted to high and low frequency, respectively, relative to compound **8** (δ = 62.9 and 61.8 ppm in the spectrum of **8**). We have observed a similar behaviour in the $^{13}C\{^1H\}$ NMR spectra of cyclometallated complexes derived from the Schiff base ligand 2-$ClC_6H_4C(H)=NCH_2CH_2NMe_2$ with formation of a new Pd−NMe_2 bond after treatment with a silver(I) salt.[29] Conductivity measurements carried out in dry acetonitrile gave a value for the molar conductivity of 116.2 ohm^{-1} cm^2 mol^{-1}, characteristic of 1:1 electrolytes.[47]

Similarly, when compound **11** was treated with silver triflate in acetone the new dinuclear complex [{Pd[2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$]}$_2${μ-$Ph_2P(CH_2)_4PPh_2$}]-[$CF_3SO_3$]$_2$ (**14**) was obtained with the Schiff base ligand as [C,N,O] terdentate. The IR spectrum of this complex shows a broad band due to the ν(O−H) stretch centred at ca. 3250 cm^{-1}. The ^1H NMR spectrum shows similar features to those observed for the spectrum of **9**. Similarly, the $^{13}C\{^1H\}$ NMR spectrum shows the signals assigned to the methylene carbon atoms at δ = 66.3 and 57.5 ppm. Conductivity measurements carried out in dry acetonitrile showed the complex to be a 1:2 electrolyte.

Reaction of complex **3** with the diphosphane $Ph_2P(CH_2)_2PPh_2$ (dppe) in a 1:2 molar ratio, followed by treatment with sodium perchlorate, gave the mononuclear complex [Pd{2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$}-{$PPh_2(CH_2)_2PPh_2$-*P,P*}][$ClO_4$] (**15**; Scheme 3) as an air-stable solid which was fully characterised (see Exp. Sect.). The ^1H NMR spectrum shows the signal corresponding to H^5 at δ = 5.93 ppm, coupled to both phosphorus atoms ($J_{H,P}$ = 8.8, 5.8 Hz). However, the *H*C=N resonance only shows coupling to the ^{31}P nucleus *trans* to nitrogen (δ = 8.50 ppm; $J_{H,P}$ = 8.3 Hz). The $^{31}P\{^1H\}$ NMR spectrum shows two doublets for the two nonequivalent phosphorus nuclei (δ = 61.0, 43.0 ppm; $J_{P,P}$ = 25.4 Hz). The resonance at lower frequency was assigned to the phosphorus nucleus *trans* to the phenyl carbon atom in accordance with the higher *trans* influence of the latter with respect to the C=N nitrogen atom.[49] The $^{13}C\{^1H\}$ spectrum shows coupling of the C6 resonance to the two phosphorus nuclei (δ = 156.0 ppm; $J_{P,C}$ = 12.0, 5.6 Hz). Conductivity measurements were in accordance with a 1:1 electrolyte formulation.

Treatment of **3** with the triphosphane bis(2-diphenylphosphanylethyl)phenylphosphane in a 1:2 molar ratio, followed by treatment with sodium perchlorate, gave [Pd{2,3,4-$(MeO)_3C_6HC(H)=NCH_2CH_2OH$}{$(PPh_2CH_2$-$CH_2)_2$PPh-*P,P,P*}][$ClO_4$] (**16**; Scheme 3). The phosphorus resonances in the $^{31}P\{^1H\}$ NMR spectrum of **16** are shifted downfield from their values in the free phosphane sug-



Scheme 3. (i) 1: dppe or triphos (acetone, 1:2 molar ratio), 2: $NaClO_4$

gesting coordination of the three phosphorus atoms to the metal centre. A triplet resonance at δ = 86.0 ppm was assigned to the central ^{31}P nucleus *trans* to the phenyl carbon atom, and a doublet at δ = 44.5 was assigned to the two equivalent mutually *trans* phosphorus nuclei. This latter signal appears at lower frequency due to the higher *trans* influence of the phosphane ligand.[49] The resonance of the proton in the *ortho* position to the metallated carbon atom appears as a doublet of triplets showing coupling to the central ^{31}P atom ($J_{P,H}$ = 8.8 Hz) and to the terminal phosphorus atoms ($J_{P,H}$ = 2.4 Hz). The shift of the ν(C=N) stretching vibration to lower wavenumber in the IR spectrum and the upfield shift of the HC=N proton resonance in the ^1H NMR spectra indicate the existence of a palladium-nitrogen interaction in solution. These results strongly agree with those previously obtained by us in related pentacoordinate palladium(II) species,[12] and although the proposed structure in Scheme 3 seems slightly different from the solid state structure (Figure 6), we suggest the former as the probable solution disposition; for a thorough discussion regarding this issue see ref.[12] The C=N signal in the $^{13}C\{^1H\}$ NMR spectrum at δ = 167.3 ppm coupled to the central phosphorus ($J_{P,C}$ = 5.7 Hz) is also indicative of a Pd-N interaction. Molar conductivity measurements showed that complex **16** is a 1:1 electrolyte. The FAB-mass spectrum shows a set of peaks centred at 979 and 877 amu assigned to the $[M]^+$ and the $[M - ClO_4]^+$ fragments, respectively.

Molecular Structure of Complexes 8, 9, 15 and 16

Suitable crystals were grown by slowly evaporating chloroform solutions of the complexes. Crystal data are given in Table 1 and selected bond lengths and angles with estimated standard deviations are shown in Table 3.

[Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}(Cl)(PPh$_3$)] (8)

The crystal structure of this complex (Figure 3) consists of discrete molecules separated by van der Waals distances. The palladium atom is bonded in a slightly distorted square-planar geometry to the C(1) carbon atom of the phenyl ring, to the imine N(1) atom of the Schiff base ligand, to the Cl(1) atom and to the P(1) phosphorus atom of the triphenylphosphane ligand. The angles between adjacent atoms in the coordination sphere of palladium are close to the expected value of 90° with the most noticeable distortions corresponding to the bite angle C(1)−Pd(1)−N(1) of 82.8(2)°. The sum of the angles about palladium is approximately 360°.

The geometry around palladium is planar [mean deviation from the least-square plane Pd(1), C(1), N(1), P(1), Cl(1), (plane 1), of 0.960 Å] and approximately co-planar with the metallated ring [Pd(1), C(1), C(6), C(7), N(1), mean deviation 0.0166 Å (plane 2)] and with the phenyl ring [plane 3, mean deviation of 0.0031 Å] (angles between planes are: plane 1:2, 6.0°; plane 1:3, 10.1°; 2:3, 5.0°). All bond lengths and angles are normal. The OH group, hydrogen H(1) and the Cl(1) atom are bonded by intramolecular H-bonding [O(1)−H(1)···Cl(1): 3.079(6) Å, 173.8°].

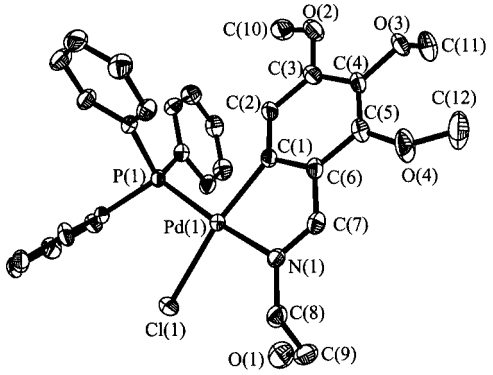

Figure 3. Molecular structure of complex [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}(Cl)(PPh$_3$)] (**8**), with labelling scheme; hydrogen atoms have been omitted for clarity

[Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}(PPh$_3$)][CF$_3$SO$_3$] (9)

The crystal structure of this complex (Figure 4) contains one $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_2CH_2OH\}(PPh_3)]^+$ cation and one $CF_3SO_3^-$ anion per asymmetric unit.

The palladium atom is bonded in a slightly distorted square-planar geometry to the C(1) carbon atom of the phenyl ring, the imine N(1) nitrogen atom, the O(1) oxygen atom and to the phosphorus atom of the triphenylphos-

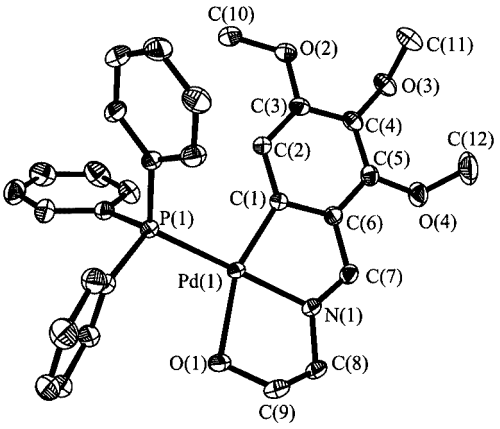

Figure 4. Perspective view of the cation of complex [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}(PPh$_3$)][CF$_3$SO$_3$] (**9**), with labelling scheme; hydrogen atoms have been omitted for clarity

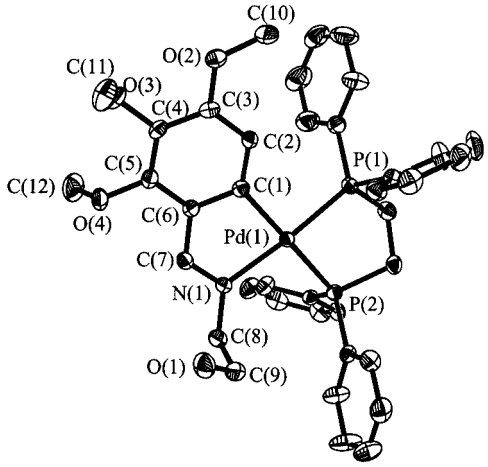

Figure 5. Perspective view of the cation of complex [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{PPh$_2$(CH$_2$)$_2$PPh$_2$-*P,P*}][ClO$_4$] (**15**), with labelling scheme; hydrogen atoms have been omitted for clarity

phane ligand P(1). The angles between adjacent atoms in the coordination sphere of palladium are close to the expected value of 90°, with the most noticeable distortions corresponding to the C(1)−Pd(1)−N(1) and N(1)−Pd(1)−O(1) angles of 81.31(7)° and 78.46(6)°, respectively. The sum of the angles about palladium is approximately 360°.

The cation of **9** forms hydrogen bonds with the CF_3SO_3 anion [O(1)−H(1)···O(2s): 3.783(3) Å, 165(4)°].

The most noticeable differences between the structures of complexes **8** and **9** correspond to a shortening of the Pd−C and Pd−N bond lengths [2.061(5) and 2.093(4) Å, respectively, for complex **8** vs. 1.997(2) and 2.028(2) Å, also respectively, for complex **9**] and the greater C(1)−Pd(1)−P(1) angle [92.60(15)° for complex **8**; 99.85(5)° for complex **9**]. The latter is probably due to the steric repulsion between the large chlorine Cl(1) atom in complex **8**, as opposed to the smaller O(1) oxygen atom in complex **9**, and the bulky PPh_3 ligand. In complex **9**, the small "bite" of the NCH_2CH_2OH chelate [shown by the N(1)−Pd(1)−O(1) bond angle of 77.46(6)°], which forces the O(1) hydroxyl oxygen and the phosphorus P(1) atoms apart, also reduces repulsion.

[Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{PPh$_2$-(CH$_2$)$_2$PPh$_2$-P,P}][ClO$_4$] (15)

The crystal structure of this complex (Figure 5) contains one [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{PPh$_2$-(CH$_2$)$_2$PPh$_2$-*P,P*}]$^+$ cation and one ClO_4^- anion per asymmetric unit. The palladium atom is bonded to four atoms: the adjacent C(1) carbon atom and the N(1) nitrogen of the Schiff base ligand **1**, and the phosphorus atoms P(1) and P(2) of the dppe ligand. The different *trans* influences of the C(1) carbon atom and the N(1) nitrogen atom are reflected in the somewhat enlarged Pd(1)−P(2) bond length of 2.3335(1) Å [Pd(1)−P(1): 2.256(1) Å]. These distances are in agreement with values previously reported.[28,48,50] Hydrogen bonding between the O−H(1) hydroxyl hydrogen and O(3s) oxygen atom of the perchlorate anion was found [O(1)−H(1)···O(3s): 3.021(6) Å, 156(11)°].

Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{(PPh$_2$-CH$_2$CH$_2$)$_2$PPh-P,P,P}][ClO$_4$] (16)

The crystal structure of this complex (Figure 6) contains one [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{(PPh$_2$-CH$_2$CH$_2$)$_2$PPh-*P,P,P*}]$^+$ cation and one ClO_4^- anion per asymmetric unit. The palladium atom is bonded to the C(1) carbon atom of the metallated ring and to the three phosphorus atoms P(1), P(2) and P(3), of the triphos ligand. A fifth interaction with the imine nitrogen completes the coordination sphere about the palladium atom.

The Pd(1)−N(1) distance of 2.480(3) Å is somewhat longer than the values of 2.338(3) Å, reported recently by us in a similar complex with a triphos ligand[51] and 2.23(2)

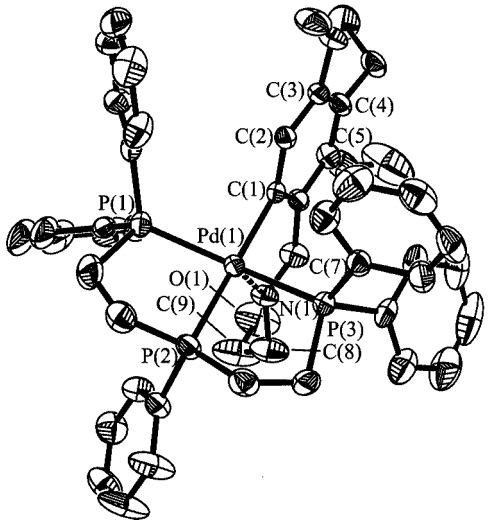

Figure 6. Perspective view of the cation of complex [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{(PPh$_2$CH$_2$CH$_2$)$_2$PPh-*P,P,P*}]-[ClO$_4$] (**16**), with labelling scheme; hydrogen atoms have been omitted for clarity

Å found in an authentic pentacoordinate palladium(II) complex.[52] However, the Pd−N bond length is shorter than the weak interactions in the range 2.576(4)−2.805(5) found in other five-coordinate complexes of palladium.[44,53−58] The coordination around the palladium atom may be viewed as a trigonal bipyramid, with the Pd(1), N(1), P(1) and P(3) atoms in the equatorial plane (r.m.s. for the mean plane; 0.0158 Å); the metallated carbon atom and the central phosphorus atom are at the apical positions. However, the trigonal bipyramidal geometry is severely distorted as shown by the N(1)−Pd(1)−P(1) and N(1)−Pd(1)−P(3) bond angles of 113.81(9) and 91.61(9)°, respectively, which differ considerably from the ideal value of 120°. Nevertheless, the bond angle values at palladium preclude the geometry from being considered as square pyramidal.

The Pd(1)−C(1) bond length of 2.064(4) Å is similar to values reported for related five-coordinate complexes.[12,51] The Pd(1)−P(1), Pd(1)−P(2) and Pd(1)−P(3) bond lengths of 2.2893(12), 2.2773(11) and 2.3243(12) Å, respectively, are also similar to those found in related Pd^{II} complexes.[12,51]

Hydrogen bonding between the O−H(4) hydroxyl hydrogen and the O(7) oxygen atom of the disordered perchlorate anion was found [O(1)−H(4)···O(7a): 2.692(3) Å, 167.3(4)°; O(1)−H(4)···O(7b): 2.990(3) Å, 140.7(4)°].

Experimental Section

General Remarks: Solvents were purified by standard methods.[59] Chemicals were reagent grade. The phosphanes PPh_3, $Ph_2PCH_2PPh_2$ (dppm), $Ph_2P(CH_2)_2PPh_2$ (dppe), $Ph_2P(CH_2)_3PPh_2$ (dppp), $Ph_2P(CH_2)_4PPh_2$ (dppb), $Ph_2PC_5H_4FeC_5H_4PPh_2$ (dppf) and $(Ph_2PCH_2CH_2)_2PPh$ (triphos), were purchased from Aldrich. Microanalyses were carried out using a Carlo Erba Elemental Analyser, Model 1108. IR spectra were recorded as Nujol mulls or polythene discs on a Perkin−Elmer 1330 or on a Mattson spectrophotometer. NMR spectra were obtained as $CDCl_3$ solutions. They are referenced to $SiMe_4$ (^1H, $^{13}C\{^1H\}$) or 85% H_3PO_4 ($^{31}P\{^1H\}$) and were recorded on a Bruker AC-200F spectrometer. All chemical shifts are reported downfield from these standards. The FAB mass spectra were recorded using a VG Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix.

CAUTION: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of these materials should be prepared and handled with great caution.

Preparation of 2,3,4-$(MeO)_3C_6H_2C(H)=NCH_2CH_2OH$ (1): 2,3,4-$(MeO)_3C_6H_2COH$ (3.21 g, 16.38 mmol) and $NH_2CH_2CH_2OH$ (1.01 g, 16.45 mmol) were added to 50 cm^3 of dry chloroform. The mixture was heated under reflux in a Dean−Stark apparatus for 4 h. After cooling to room temperature, the solvent was evaporated to give a yellow oil. Yield: 3.52 g (90%). IR (nujol mull): ν(O−H) = 3402m; ν(C=N) = 1642s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 3.71, 3.68, 3.67 (s, 9 H, OMe), 3.54 (br. s, 2 H, -CH_2), 4.01 (br. s, 2 H, -CH_2), 6.50 (d, $J_{H5,H6}$ = 8.8 Hz,1 H, H^5), 7.47 (d, 1 H, H^6), 8.36 (s, 1 H, H_i) ppm. $^{13}C\{^1H\}$ NMR (50.28 MHz, $CDCl_3$): δ = 61.8, 60.8, 55.9 (O*C*H_3), 63.5, 62.3 (C8, C9), 107.7 (C5), 122.1 (C6), 122.4 (C1), 141.7 (C3), 155.9, 153.8 (C2, C4), 158.6 (C=N) ppm. FAB-MS: *m/z* = 240 $[MH]^+$.

The Schiff base ligands **19** and **20** were prepared similarly.

2,3,4-$(MeO)_3C_6H_2C(H)=NCH_2CH_2CH_3$ (19): Yield: 3.50 g (90%). IR (nujol mull): ν(C=N) = 1638s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 0.90 (t, $J_{H,H}$ = 7.3 Hz, 3 H, $NCH_2CH_2CH_3$), 1.67 (m, 2 H, $NCH_2CH_2CH_3$), 3.51 (t, $J_{H,H}$ = 7.3 Hz, 2 H, NCH_2CH_2), 3.83, 3.88 (s, 9 H, OMe), 6.67 (d, $J_{H5,H6}$ = 8.8 Hz,1 H, H^5), 7.64 (d, 1 H, H^6), 8.47 (s, 1 H, H_i) ppm.

2,3,4-$(MeO)_3C_6H_2C(H)=NC(CH_3)_3$ (20): Yield: 3.91 g (95%). IR (nujol mull): ν(C=N) = 1636s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 1.15 [s, 9 H, $NC(CH_3)_3$], 3.73, 3.79 (s, 9 H, OMe), 6.56 (d, $J_{H5,H6}$ = 8.8 Hz, 1 H, H^5), 7.56 (d, 1 H, H^6), 8.42 (s, 1 H, H_i) ppm.

Preparation of 2,3,4-$(MeO)_3C_6H_2C(H)=NCH_3$ (17): A pressure tube containing 2,3,4-$(MeO)_3C_6H_2COH$ (3.21 g, 16.38 mmol) and 40 cm^3 of dry chloroform was cooled to −20 °C and an excess of NH_2Me (1.53 g, 49.14 mmol; 200% excess), also cooled to −20 °C, was added. The tube was sealed and heated to 80 °C for 24 h. After cooling to room temperature, the solvent and the unreacted NH_2Me were removed under vacuum to give a yellow oil. Yield: 3.26 g (95%). IR (nujol mull): ν(C=N) = 1644s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 3.50 (s, 3 H, N−CH_3), 3.87, 3.88, 3.92 (s, 9 H, OMe), 6.71 (d, $J_{H5,H6}$ = 8.8 Hz, 1 H, H^5), 7.63 (d, 1 H, H^6), 8.52 (s, 1 H, H_i) ppm.

Ligand **18** was prepared similarly.

2,3,4-$(MeO)_3C_6H_2C(H)=NCH_2CH_3$ (18): Yield: 3.51 g (96%). IR (nujol mull): ν(C=N) = 1638s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 1.04 (t, 3 H, NCH_2CH_3), 3.37 (q, $J_{H,H}$ = 7.3 Hz, 2 H, NCH_2CH_3), 3.59, 3.60, 3.66 (s, 9 H, OMe), 6.44 (d, $J_{H5,H6}$ = 8.8 Hz, 1 H, H^5), 7.43 (d, 1 H, H^6), 8.29 (s, 1 H, H_i) ppm.

Preparation of $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_2CH_2OH\}(\mu\text{-}O_2CMe)]_2$ (2): A pressure tube was charged with 2,3,4-$(MeO)_3C_6H_2C(H)=NCH_2CH_2OH$ (**1**) (0.219 g, 0.92 mmol), palladium(II) acetate (0.206 g, 0.92 mmol) and 20 cm^3 of dry toluene was then sealed under argon. The mixture was heated for 24 h at 60 °C. After cooling to room temp. the solution was filtered through celite to remove the black palladium formed. The solvent was then removed under vacuum to give a brown oil, which was chromatographed on a column packed with silica gel. Elution with dichloromethane/ethanol (92:8) afforded the final product as a yellow oil after solvent removal. Yield: 0.30 g (40%). M.p. 111.3 °C. $C_{28}H_{38}N_2O_{12}Pd_2$ (807.4): calcd. C 41.6, H 4.7, N 3.5; found C 40.9, H 4.8, N 3.6. IR (polythene disc): ν(O−H) = 3384m cm^{-1}; ν(C=N) = 1604sh, m cm^{-1}; ν_{as}(COO) = 1563s cm^{-1}; ν_s(COO) = 1421s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$), *anti* isomer: δ = 2.07 (s, 3 H, OAc), 3.73, 3.80, 3.84 (s, 9 H, OMe), 2.23 (br. s, 2 H, -CH_2), 6.22 (s, 1 H, H^5), 7.57 (s, 1 H, H_i); *syn* isomer: δ = 2.25, 2.02 (s, 3 H, OAc), 3.20 (br. s, 1 H, OH), 3.68, 3.71, 3.82 (s, 9 H, OMe), 6.00 (s, 1 H, H^5), 7.81 (s, 1 H, H_i) ppm. $^{13}C\{^1H\}$ NMR (50.28 MHz, $CDCl_3$), *anti* isomer: δ = 24.4 (*C*H_3COO), 61.7, 61.3, 55.9 (O*C*H_3), 61.6 (C8, C9), 110.2 (C5), 130.7 (C1), 137.9 (C6), 154.4, 151.3, 151.0 (C2, C3, C4), 170.6 (C=N), 181.5 (CH_3*C*OO) ppm; *syn* isomer: δ = 24.4, 24.1 (*C*H_3COO), 61.6, 60.6, 55.5 (O*C*H_3), 110.6 (C5), 130.3 (C1), 137.3 (C6), 154.1, 151.3, 150.9 (C2, C3, C4), 171.2 (C=N), 182.2, 180.9 (CH_3*C*OO) ppm. FAB-MS: *m/z* = 808 $[M]^+$, 659 $[M - OAc - CH_2CH_2OH]^+$, 404 $[M - OAc - L - Pd]^+$, 344 $[M - 2OAc - L - Pd]^+$.

Compounds **21**, **22**, **23** and **24** were prepared similarly and isolated as yellow solids.

$[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=NCH_3\}(\mu\text{-}O_2CMe)]_2$ (21): Yield: 0.39 g (50%). M.p. 120.3 °C. $C_{26}H_{34}N_2O_{10}Pd_2$ (747.4): calcd. C

FAB-MS: *m/z* = 742 [M − ClO_4]$^+$. Specific molar conductivity: Λ_m = 142.8 $ohm^{-1}{\cdot}cm^2{\cdot}mol^{-1}$ (in acetonitrile).

Compound **16** was obtained following a similar procedure as a yellow, air stable, solid.

[Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=NCH$_2$CH$_2$OH}{(PPh$_2$CH$_2$CH$_2$)$_2$-PPh-*P,P,P*}][ClO$_4$] (16): Yield: 7.8 mg (59%). $C_{46}H_{49}ClNO_8P_3Pd$ (978.7): calcd. C 56.4, H 5.0, N 1.4; found C 56.9, H 4.6, N 1.5. IR (nujol mull): ν(O−H) = 3501m cm^{-1}; ν(C=N) = 1614s cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 2.80 [s, 3 H, C(4)−OMe], 3.71, 3.88 (s, 6 H, OMe), 2.82, 3.36 (br. s, 4 H, -CH_2), 5.25 (dd, $J_{P,H}$ = 8.8, 2.4 Hz, 1 H, H^5), 8.40 (s, 1 H, H_i) ppm. $^{13}C\{^1H\}$ NMR (50.28 MHz, $CDCl_3$): δ = 167.3 (d, $J_{P,C}$ = 5.7 Hz, C=N), 163.3, 161.1, 154.1 (C2, C3, C4), 154.0 (m, C6), 116.3 (m, C5), 62.8, 61.6

(C8, C9), 62.1, 60.9, 54.8 (OCH_3); $P(CH_2)_2P$: δ = 32.3, 25.9 (m) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $CDCl_3$): δ = 44.5 (d, $J_{P,P}$ = 26.3), 86.0 (t) ppm. FAB-MS: *m/z* = 979 $[M]^+$, 877 $[M - ClO_4]^+$. Specific molar conductivity,: Λ_m = 125.9 ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

X-ray Crystallographic Study: Three-dimensional, room temperature X-ray data were collected on a Siemens Smart CCD diffractometer by the ω scan method using graphite-monochromated Mo-K_α radiation. All the measured reflections were corrected for Lorentz and polarisation effects and for absorption by semi-empirical methods based on symmetry equivalent and repeated reflections. The structures were solved by direct methods and refined by full-matrix least-squares on F^2. Hydrogen atoms were included in calculated positions (except the -O*H* hydrogens which were located in a difference Fourier map) and refined in a riding mode. The O(6), O(7) and O(8) oxygen atoms of the perchlorate counterion in complex **16** were found to be disordered over two positions (with occupancies of approximately 50%). The refinement was carried out taking into account both components. Refinement converged at a final R = 0.0776, 0.0460, 0.0294, 0.0412 and 0.0466 (for complexes **2**, **8**, **9**, **15** and **16**, respectively, observed data, F) and wR_2 = 0.1690, 0.1992, 0.0776, 0.1137 and 0.0829 (for complexes **2**, **8**, **9**, **15** and **16**, respectively, unique data, F^2), with allowance for the thermal anisotropy of all non-hydrogen atoms. The structure solution and refinement were carried out using the program package SHELX-97.[60]

CCDC-178027 (**2**), -178028 (**8**), -178029 (**9**), -178030 (**15**) and -178031 (**16**) contain the supplementary crystallographic data for this paper. New Mixed-Ligand Re^V Complexes with Bis(2-mercaptoethyl) Sulfide and Functionalized Thioimidazolyl Ligands

Elisa Palma,[a] João D. G. Correia,[a] Ângela Domingos,[a] and Isabel Santos*[a]

Keywords: S ligands / Rhenium / Peptides / N ligands

The preparation of the mixed-ligand Re^V complexes [Re(O)(κ^3-SSS)(κ^1-Simz)] (**1**), [Re(O)(κ^3-SSS)(κ^1-Simz)]·HCl (**2**) and [Re(O)(κ^3-SSS)(κ^1-SimzCOGlyGly)] (**3**) are described. These [3+1] type compounds are stabilized by tridentate bis(2-mercaptoethyl) sulfide (HSSSH) and by monodentate functionalized thioimidazolyl ligands. Complexes **1**, **2** and **3** were fully characterized by IR and ^{1}H NMR spectroscopy, and by X-ray diffraction analysis in the case of **1** and **2**. In complexes **1** and **2** the Re atom is five-coordinate, presenting a distorted square pyramidal coordination geometry. Based on the angular structural parameter, τ, this distortion lies towards a trigonal bipyramidal geometry (τ = 0.40, **1**; τ = 0.46, **2**).

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The development of mixed-ligand complexes of Re and Tc, of the so-called [3+1] type, has been thoroughly investigated for labeling biomolecules, namely CNS receptor ligands. For this purpose different tridentate ligands and mono thiol co-ligands have been used.[1−7] This approach can be considered to be greatly advantageous since the combination of different ligands has allowed the synthesis of complexes with a wide variety of chemical and biochemical properties. However, in spite of this versatility they show a remarkable *in vivo* reactivity against nucleophiles, namely SH-group containing compounds like glutathione. This instability arises not only from ligand-exchange reactions between the co-ligand and nucleophiles, but also from the presence of a vacant coordination site trans to the oxo group.[3,6] Both processes depend on the nature and the concentration of the tridentate and monodentate ligands. In order to overcome this problem we studied the chemistry of Re and Tc using the well-known tridentate ligand bis(2-mercaptoethyl) sulfide (HSSSH) and functionalized thioimidazolyl molecules as co-ligands. This type of co-ligands can coordinate through the nitrogen and sulfur atoms. This bidentate coordination mode could provide complexes with higher stability against substitution.[3,6] The functionalized thioimidazolyl molecules will also allow the labelling of small peptides with $[^{99m}Tc(O)]^{3+}$. In this paper, we report on the synthesis and characterization of the mixed-ligand Re^V complexes, stabilized with these co-ligands, including one bearing a dipeptide (GlyGly): [Re(O)(κ^3-SSS)(κ^1-Simz)] (**1**), [Re(O)(κ^3-SSS)(κ^1-Simz)]·HCl (**2**) and [Re(O)(κ^3-SSS)(κ^1-SimzCOGlyGly)] (**3**).

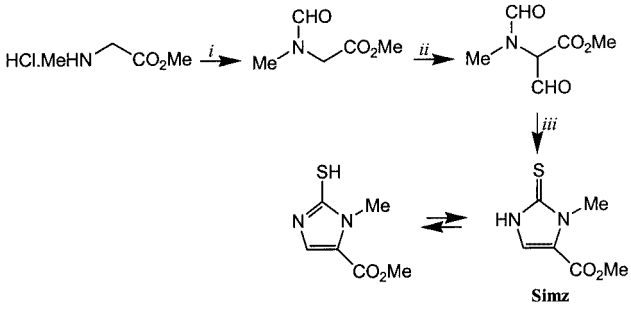
Results and Discussion

Synthesis and Characterization of the Simz, SimzCOOH and SimzCOGlyGly Co-Ligands

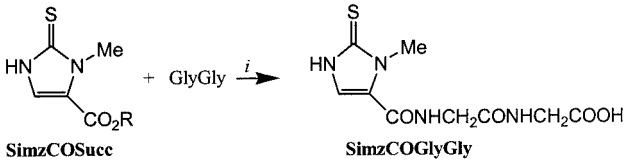
Methyl (2-mercapto-3-methylimidazol-4-yl)methanoate (**Simz**) was obtained, in a fair yield (68%), by a slight modification of a previously reported method.[9] The synthetic pathway for its preparation involves the formation of *N*-formyl and *C*-formyl intermediates, followed by ring formation with KSCN (Scheme 1).



Scheme 1. Synthesis of the **Simz** co-ligand; (*i*) NEt_3, HCOOH, THF, reflux; (*ii*) $NaOCH_3$, CH_3OCHO, room temperature; (*iii*) HCl, KSCN, 65−70° C

2-(Mercapto-3-methylimidazol-4-yl)methanoic acid (**SImzCOOH**) was isolated as a white precipitate in an almost quantitative yield (97%) by classical hydrolysis of the **Simz** ester under basic conditions, followed by acidification of the reaction solution. The compound glycylglycine (2-

mercapto-3-methylimidazol-4-yl)methanamide (**SimzCOGlyGly**) was obtained by reacting [(2-mercapto-3-methylimidazol-4-yl)methyloxy]succinimide (**SimzCOSucc**)[10,11] with Glycylglycine (**GlyGly**) (Scheme 2). For the coupling reaction to proceed, it is necessary of the presence of a deprotonating agent such as triethylamine. The compound **SimzCOGlyGly** is poorly soluble in most organic solvents, and is readily soluble in aqueous alkaline solutions only (pH ≈ 12).



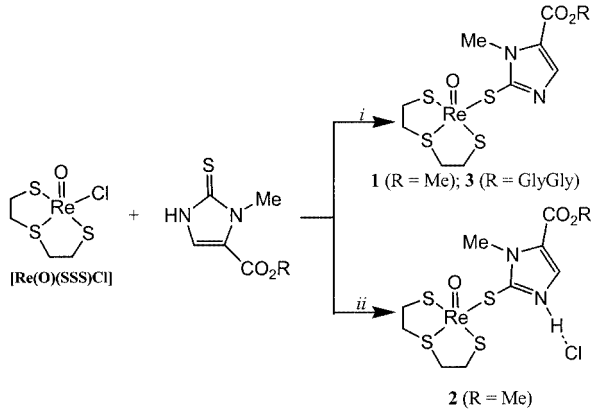
Scheme 2. Synthesis of **SimzCOGlyGly**; R = *N*-succinimido; (*i*) NEt_3, THF, DMF, H_2O, room temperature

The most important features in the IR spectra of **Simz** and derivatives is the existence of strong bands in the 1630−1765 cm^{-1} range, and medium intensity bands in the 735−760 cm^{-1} range, which are assigned to the ν(C=O) and ν(C=S) stretching vibrations, respectively.

The ^1H NMR spectra of **Simz**, **SimzCOOH** and **SimzCOSucc** in CD_3OD present one singlet at δ = 3.81, 3.81 and 3.78 ppm, respectively, assigned to the methyl group attached to one of the nitrogen atoms of the thioimidazolyl ring. **Simz** presents another singlet at δ = 3.83 ppm, which is assigned to the methyl group of the ester. In all spectra, one resonance assigned to the methylenic proton of the ring system can also be observed (**Simz**: δ = 7.61 ppm; **SimzCOOH**: δ = 7.57 ppm; **SimzCOsucc**: δ = 8.05 ppm). The NH proton of the thioimidazolyl ring is also observed when $CDCl_3$, CD_3CN or $[(CD_3)_2SO]$ is used as solvent. For instance, in the case of the **Simz** ligand, that signal appears as a broad singlet at δ = 12.08 ppm in $CDCl_3$ and at δ = 10.28 ppm in CD_3CN. In the IR spectrum, the (glygly)-functionalized thioimidazolyl ligand (**SimzCOGlyGly**) presents two strong bands at 1630 cm^{-1} and 1715 cm^{-1}, assigned to the ν(C=O) stretching vibrations of the amide functionalities and of the free carboxylic acid of the dipeptide. A characteristic medium band at 760 cm^{-1} also appears, which is assigned to the $\tilde{\nu}$(C=S) stretching vibration. The ^1H NMR spectrum in $[(CD_3)_2SO]$ of this ligand compares well with the above mentioned thioimidazolyl derivatives: a singlet at δ = 3.66 ppm assigned to the methyl group, a singlet at δ = 7.58 ppm assigned to the methylenic proton of the ring, and a broad singlet at δ = 12.55 ppm assigned to the NH group of the ring. The signals corresponding to the dipeptide are also clearly observed: two sets of doublets at δ = 3.75 and 3.83 ppm are assigned to the CH_2 groups, and two sets of triplets at δ = 8.23 and 8.60 ppm are assigned to the protons of the amide.

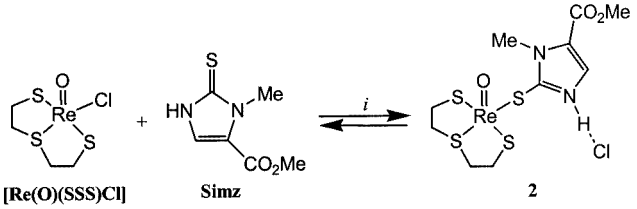
Synthesis and Characterization of the Complexes

Reactions of **Simz** and **SimzCOGlyGly** with the (chloro)oxorhenium(V) complex [ReO(SSS)Cl],[8] under different conditions, afforded the mixed-ligand complexes [Re(O)(κ³-SSS)(κ¹-Simz)] (**1**), [Re(O)(κ³-SSS)(κ¹-Simz)]·HCl (**2**) and [Re(O)(κ³-SSS)(κ¹-SimzCOGlyGly)] (**3**) (Scheme 3).



Scheme 3. Synthesis of complexes **1**, **2** and **3**; (*i*) NEt_3, CH_2Cl_2 (**1**), CH_3CN (**3**), reflux; (*ii*) CH_3CN, reflux

The neutral oxo complex **1** was obtained in a 68% yield, after appropriate workup, by refluxing [Re(O)(SSS)Cl] with **Simz** in CH_2Cl_2, with NEt_3 as the deprotonating agent. In this complex, the monodentate thioimidazolyl co-ligand is mononegative. When the reaction is run in CH_3CN, and in the absence of a base, the ^1H NMR spectrum of the product obtained, after workup, indicates a mixture of three species. Two of these species are unambiguously identified as [Re(O)(SSS)Cl] and free functionalized thioimidazolyl. The third species presented an ^1H NMR spectrum that is consistent with the presence of one tridentate SSS and one neutral **Simz** ligand (^1H NMR (δ, CD_3CN): 10.43 (1 H, s, br., NH), 7.84 (1 H, s, CH), 4.10−4.05 (2 H, m, CH_2), 3.88 (3 H, s, CH_3), 3.85 (3 H, s, CH_3), 3.13 (2 H, m, CH_2)). Recrystallization of the crude product of this reaction, from CH_3CN/hexane, led to the formation of violet crystals and to the precipitation of a blue solid. The blue solid was identified by ^1H NMR spectroscopy as [Re(O)(SSS)Cl]. The X-ray diffraction analysis of the violet crystals allowed the formulation of complex **2**, where the Simz is not deprotonated and is neutral. These crystals, after being washed with CH_3CN to remove any [Re(O)(SSS)Cl] present, were analyzed by NMR spectroscopy. The spectrum was identical to the one observed for the crude product. This result can only be explained by assuming that in solution **2** dissociates as indicated in Scheme 4.



Scheme 4. (*i*) CH_3CN

The neutral oxo complex **3** was obtained in a 60% yield by refluxing [ReO(SSS)Cl] and **SimzCOGlyGly** in dry

CH_3CN in the presence of NEt_3. Complex **1** is soluble in chlorinated solvents and insoluble in methanol and water. Complex **3**, which bears a GlyGly moiety, is soluble in methanol, relatively soluble in water and insoluble in chlorinated solvents. Both complexes **1** and **3** are air- and moisture-stable.

Complexes **1**, **2** and **3** present strong bands in the IR spectra at 970 cm^{-1}, which are assigned to the ν(Re=O) stretching vibrations. This value compares well with those found in other compounds of the [3+1] type, previously described (930−980 cm^{-1}).[7] Strong bands at 1715, 1725, and at 1535 cm^{-1}/1645 cm^{-1} are assigned to the ν(C=O) stretching vibrations of complexes **1**, **2** and **3**, respectively.

In the ^1H NMR spectra of **1** and **3**, four sets of multiplets appear, which are assigned to the methylenic protons of the tridentate ligand HSSSH; most of these signals are shifted upfield relative to those of the corresponding free ligand. For complex **2**, the identification of all methylenic protons of the tridentate ligand was not possible since two of the resonances are superimposable with those of [ReO(SSS)Cl], which is also present due to the equilibrium depicted in Scheme 4.

The chemical shifts corresponding to the monodentate ligand of the complexes **1** (δ = 7.73, 3.85 and 3.82 ppm) and **2** (δ = 10.43, 7.84, 3.88 and 3.85 ppm) in CD_3CN are shifted downfield relative to those of the free ligand (δ = 10.28, 7.45, 3.78 and 3.73 ppm) in the same solvent. The same holds true for complex **3** in CD_3OD (**3**: δ = 7.76, 4.05, 3.94 and 3.89 ppm; **SimzCOGlyGly**: δ = 7.51, 4.00, 3.88 and 3.79).

Crystal Structures of [Re(O)(κ³-SSS)(κ¹-Simz)] (1) and [Re(O)(κ³-SSS)(κ¹-Simz)]·HCl (2): Suitable crystals for X-ray structural analysis were obtained for complexes **1** and **2**. ORTEP views are shown in Figure 1 and Figure 2, and selected bond lengths and angles for both complexes are presented in Table 1.

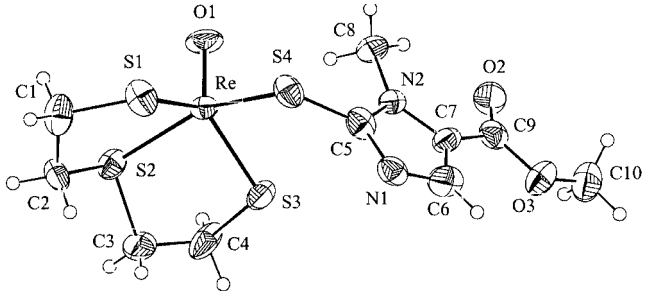


Figure 1. ORTEP drawing of complex **1** with the atom numbering scheme; thermal ellipsoids are drawn at the 40% probability level. Hydrogen atoms were introduced in calculated positions.

Complex **2** is monocationic with a chloride atom as the counterion, while complex **1** is neutral. In both compounds the coordination geometry around the five-coordinate Re^v atom is best described as distorted square-pyramidal, with the axial Re−O(1) bond length significantly shorter than the Re−L(basal) distances. The Re=O(1) bond lengths in **1** [1.683(8) Å] and **2** [1.673(5) Å] are comparable, and are in the range (1.67−1.70 Å) so far observed for this type of

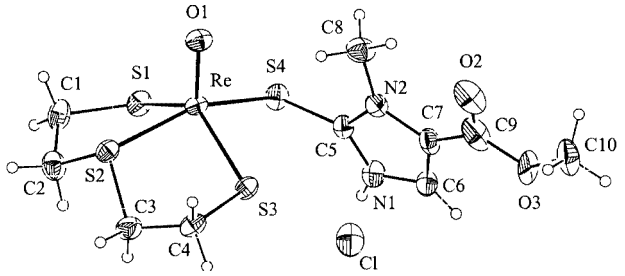

Figure 2. ORTEP drawing of complex **2** with the atom numbering scheme; thermal ellipsoids are drawn at the 30% probability level. Hydrogen atoms were introduced in calculated positions.

Table 1. Selected bond lengths (Å) and Angles (°) for [Re(O)(κ³-SSS)(κ¹-Simz)] (**1**), and [Re(O)(κ³-SSS)(κ¹-Simz)]·HCl (**2**)

	1	2
Re−O(1)	1.683(8)	1.673(5)
Re−S(1)	2.285(3)	2.290(2)
Re−S(2)	2.367(3)	2.364(2)
Re−S(3)	2.285(3)	2.282(2)
Re−S(4)	2.327(3)	2.345(2)
S(4)−C(5)	1.745(13)	1.734(7)
O(1)−Re−S(1)	114.5(3)	116.6(2)
O(1)−Re−S(2)	100.6(3)	99.3(2)
O(1)−Re−S(3)	115.1(3)	115.4(2)
O(1)−Re−S(4)	105.3(3)	105.1(2)
S(1)−Re−S(3)	130.35(14)	127.86(7)
S(3)−Re−S(4)	87.64(12)	88.29(7)
S(1)−Re−S(4)	82.38(12)	81.15(7)
S(3)−Re−S(2)	84.25(11)	84.44(7)
S(1)−Re−S(2)	84.18(11)	84.76(7)
S(4)−Re−S(2)	154.00(11)	155.29(7)
Re−S(4)−C(5)	110.7(4)	110.1(2)

3+1 compounds.[1−6,12−16] The C−S bond lengths [1.745(13) Å (**1**), 1.734(7) Å (**2**)] are comparable and are similar to those found previously,[17] which range from 1.68 to 1.73 Å. Additionally, provided that the values found for the best least-square planes through the atoms S(1)−S(2)−S(3)−S(4) (RMSD = 0.218 Å for **1**, RMSD = 0.253 Å for **2**) show significant deviations from planarity, we conclude that these atoms in both structures do not define a basal plane. The chloride ion is hydrogen bonded to N(1) and the distance between them [3.023(8) Å] allows for the presence of a hydrogen atom [N(1)−H(1): 0.86 Å, H(1)···Cl: 2.18 Å]. The angle N(1)−H(1)−Cl is 166.7°, which can be considered to be linear. Relative to the coordination positions, in both complexes (**1** and **2**), only one of the axial positions is occupied by the oxo group. The equatorial positions are defined by sulfur atoms, three from the tridentate and dianionic ligand $(SSS)^{2-}$, and a thione sulfur atom belonging to the monodentate thioimidazolyl co-ligand.

The Re−S(4) bond lengths in **1** [2.327(3) Å] and **2** [2.345(2) Å] are comparable and typical of a monothiolate. The Re−S bonds within the tridentate ligand in **1** [2.285(3), 2.367(3) and 2.285(3) Å] and **2** [2.290(2), 2.364(2) and 2.282(2) Å] compare with the values found for the same

type of bond in complexes of the 3+1 type, stabilized by SSS chelates.[1,18]

The five-membered rings, formed by the atoms Re, S(1), C(1), C(2) and S(2) are in the twisted form in both complexes. Relative to the plane [Re−S(1)−S(2)], C(1) is 0.53 and 0.50 Å above the plane for **1** and **2**, respectively, and C(2) is −0.25 and −0.21 Å below the plane for **1** and **2**, respectively.

The five-membered rings, formed by the atoms Re, S(2), C(3), C(4) and S(3) are in the twisted form in both complexes. Relative to the plane [Re−S(2)−S(3)], C(3) and C(4) are equally far from the plane by 0.37 Å in complex **1,** and in **2** are 0.30 and −0.39 Å above and below the plane, respectively.

In terms of the trigonality index, τ, the values are 0.40 and 0.46 for **1** and **2**, respectively (τ = 0 for a regular square pyramid, τ = 1 for a regular trigonal bipyramid).[19] According to the results in this work and those obtained earlier for complexes with a SSS/S donor atom set,[1,18] the τ values remain between 0.253−0.473. This means that the majority of structures in this study may be classified as intermediate between the square pyramidal and trigonal bipyramidal limiting geometries, but in agreement with the structural index parameter (τ) adopted, all of the structures are described as distorted square pyramidal rather than distorted trigonal bipyramidal. The major distortions from the regular square pyramidal geometry arise from the chelate bite angles of the tridentate ligand (see Table 2).

We also note that one of the reasons that the thioimidazolyl co-ligand acts as a monodentate ligand may be due to the existence of a wide angle [Re−S(4)−C(5): 110.7(4)° (for **1**) and 110.1(2)° (for **2**)] that prevents N(1) from coordinating to the metal.

Concluding Remarks

Using the tridentate bis(2-mercaptoethyl) sulfide ligand and functionalized thioimidazolyl co−ligands, it was possible to isolate and characterize oxorhenium(V) complexes of the [3+1] type. The complexes are stable in solution when the monodentate thioimidazolyl co-ligands are monoanionic. The functionalization of the thioimidazolyl with a dipeptide leads to a water soluble complex, which is promising for biomedical applications.

Experimental Section

General Procedures: All chemicals were of reagent grade. Solvents were dried and distilled prior to use, according to described procedures. Methyl (2-mercapto-3-methylimidazol-4-yl) methanoate (**Simz**) was prepared by a modification of a reported method and [Re(O)(SSS)Cl] as described in the literature.[8,9] The reactions were run in air unless otherwise indicated. ^{1}H NMR spectra were recorded on a Varian Unit 300 MHz spectrometer. ^{1}H chemical shifts were referenced to the residual solvent resonance relative to tetramethylsilane. The NMR samples were prepared in $CDCl_3$, CD_3OD, $[(CD_3)_2SO]$ and CD_3CN. Infrared spectra were recorded in the range 4000−200 cm^{-1} on a Perkin−Elmer 577 spectrometer with KBr pellets. Elemental analyses were performed on a Perkin−Elmer automatic analyser.

Methyl (2-Mercapto-3-methylimidazol-4-yl)methanoate (Simz). i. Methyl *N*-Formylsarcosinate: Triethylamine (48 mL, 0.344 mol) and formic acid (4.8 mL, 0.127 mol) were added to a solution of sarcosine methyl ester hydrochloride (16.0 g, 0.115 mol) in THF (30 mL). The suspension was stirred at 125° C overnight, cooled to room temperature, filtered, and the obtained solid rinsed with THF. The filtrate was collected and the solvent evaporated to dryness. The obtained yellow oil was dissolved in water (20 mL) and a solution of NaOH (1 N) was added dropwise until pH = 7. After extracting with CH_2Cl_2 (3 × 20 mL), the solution was dried over magnesium sulfate, filtered and concentrated to dryness. A white solid was obtained. Yield: 8.53 g (57%). ^{1}H NMR (δ, $CDCl_3$) two rotamers: 2.62 (s, 3 H, NCH_3), 2.77 (s, 3 H, NCH_3), 3.46 (s, 2 H, CH_2), 3.49 (s, 2 H, CH_2), 3.79 (s, 1 H, OCH_3), 3.82 (s, 1 H, OCH_3), 7.76 (s, 1 H, CHO), 7.83 (s, 1 H, CHO).

ii. Methyl (2-Mercapto-3-methylimidazol-4-yl)methanoate (Simz): A solution of methyl *N*-formylsarcosinate (8.52 g, 65.0 mmol) in methyl formate (14 mL, 0.227 mol) was added dropwise to a solution of sodium methoxide (4.11 g, 76.1 mmol) in distilled THF (40 mL), at 10-15° C. The resulting mixture was stirred overnight at room temperature. The solvent was removed under vacuum and the residue diluted with 150 mL MeOH/H_2O (1:1). The solution was treated with activated carbon, filtered and cooled in ice. Hydrochloric acid (12 N, 13 mL) and a solution of potassium thiocyanate (7.92 g, 81.5 mmol) in a minimum amount of water were added, and the resulting solution heated at 65°-70° C for 24 hours. The precipitate formed was removed by filtration, and the solvent was evaporated to dryness affording a white solid that corresponds to the pure product. Yield: 7.57 g (68%). ^{1}H NMR ($CDCl_3$): δ = 3.84 (s, 3 H, CH_3), 3.87 (s, 3 H, CH_3), 7.42 (s, 1 H, CH), 12.08 (br. s, 1 H, NH) ppm. ^{1}H NMR (CD_3OD): δ = 3.81 (s, 3 H, CH_3), 3.83 (s, 3 H, CH_3), 7.61 (s, 1 H, CH) ppm. ^{1}H NMR (CD_3CN): δ = 3.73 (s, 3 H, CH_3), 3.78 (s, 3 H, CH_3), 7.45 (s, 1 H, CH), 10.28 (br. s, 1 H, NH) ppm. IR (KBr): $\tilde{\nu}$ = 1715 cm^{-1} (vs, C=O), 755 cm^{-1} (m, C=S).

(2-Mercapto-3-methylimidazol-4-yl)methanoic Acid (SImzCOOH): Methyl (2-mercapto-3-methylimidazol-4-yl)methanoate (Simz) (6.00 g, 34.8 mmol) was dissolved in a NaOH solution (50 mL, 2.1 M). After 3 hours at room temperature, whilst stirring, HCl (3 N) was added dropwise until pH = 1−2. A white solid precipitated that was collected by filtration, washed with water and dried. Yield: 5.33 g (97%). ^{1}H NMR (CD_3OD): δ = 3.81 (s, 3 H, CH_3), 7.57 (s, 1 H, CH) ppm. IR (KBr): $\tilde{\nu}$ = 1670 cm^{-1} (vs, C=O), 755 cm^{-1} (m, C=S). $C_5H_6N_2O_2S$ (158.2): calcd. C 37.97, H 3.82, N 17.71, S 20.27; found C 38.13, H 4.11, N 17.55, S 20.52.

[(2-Mercapto-3-methylimidazol-4-yl)methyloxy]succinimide (SimzCOSucc): *N*-hydroxysuccinimide (0.71 g; 6.2 mmol) was added to a suspension of SimzCOOH (0.89 g; 5.6 mmol) in CH_2Cl_2 (15 mL) in an ice bath, and the mixture was stirred for 15 minutes. On addition of *N*-(3-dimethylaminopropyl)-*N*′-ethylcarbodiimidehydrochloride (1.19 g; 6.2 mmol) and after stirring for 63 hours, the reaction was complete. The solvent was evaporated to dryness, and the urea formed and the excess *N*-hydroxysuccinimide were removed by washing the residue with water. The compound was then vacuum-dried for several hours and used without further purification. Yield: 1.35 g (95%). ^{1}H NMR (CD_3OD): δ = 2.88 (s, 4 H, C_2H_2), 3.78 (s, 3 H, CH_3), 8.05 (s, 1 H, CH) ppm. ^{1}H NMR [$(CD_3)_3SO$]: δ = 2.86 (s, 4 H, C_2H_2), 3.66 (s, 3 H, CH_3), 8.34 (s, 1 H, CH), 13.21 (br. s, 1 H, NH) ppm. IR (KBr): $\tilde{\nu}$ = 1725 cm^{-1}, 1765 cm^{-1} (vs, C=O), 735 cm^{-1} (m, C=S). $C_9H_9N_3O_4S{\cdot}H_2O$ (273.3): calcd. C 39.56, H 4.06, N 15.38, S 11.73; found C 40.02, H 3.92, N 15.52, S 12.03.

Glycylglycine (2-Mercapto-3-methylimidazol-4-yl)methanamide (SimzCOGlyGly): A mixture of glycylglycine (0.25 g; 1.9 mmol) and triethylamine (0.30 mL, 2.2 mmol) in THF/H_2O 3:4 (7 mL) was added dropwise, at room temperature, to a stirred solution of SimzCOSucc (0.25 g; 0.97 mmol) in THF/DMF 1:1 (4 mL). After 20 hours, whilst stirring at room temperature, the solvent was evaporated to dryness and the white solid obtained was washed with water. Yield: 0.053 g (20%). ^{1}H NMR (CD_3OD): δ = 3.79 (s, 3 H, CH_3), 3.88 (s, 2 H, CH_2), 4.00 (s, 2 H, CH_2), 7.51 (s, 1 H, CH). ^{1}H NMR [$(CD_3)_2SO$]: δ = 3.66 (s, 3 H, CH_3), 3.75 (d, 2 H, CH_2), 3.83 (d, 2 H, CH_2), 7.58 (s, 1 H, CH), 8.23 (t, 1 H, NH), 8.60 (t, 1 H, NH), 12.55 (br. s, 1 H, NH) ppm. IR (KBr): $\tilde{\nu}$ = 3060 cm^{-1}, 3220 cm^{-1}, 3320 cm^{-1}(m, N−H), 1630 cm^{-1}, 1715 cm^{-1} (vs, C=O), 760 cm^{-1} (m, C=S). $C_9H_{12}N_4O_4S$ (272.3): calcd. C 39.70, H 4.44, N 20.58, S 11.77; found C 38.97, H 4.32, N 20.01, S 11.18.

[Re(O)(κ^3-SSS)(κ^1-Simz)] (1): A solution of **Simz** (0.071 g; 0.41 mmol) and triethylamine (68 μL, 0.49 mmol) in dichloromethane (2 mL) was added dropwise, at room temperature, to a stirred solution of [Re(O)Cl(SSS)] (0.080 g; 0.21 mmol) in the same solvent (9 mL). After several minutes the color of the solution turned brown. The mixture was refluxed under a nitrogen atmosphere for 4 hours. A brown solid was obtained after evaporation of the solvent and washing with methanol. Brown crystals suitable for X-ray diffraction analysis were obtained by slow diffusion of hexane to a solution of the complex in chloroform. Yield: 0.072 g (67%). ^{1}H NMR (CD_3CN): δ = 2.28−2.18 (m, 2 H, CH_2), 3.14−3.04 (m, 2 H, CH_2), 3.82 (s, 3 H, CH_3), 3.85 (s, 3 H, CH_3), 4.07−4.02 (m, 2 H, CH_2), 4.24−4.18 (m, 2 H, CH_2), 7.73 (s, 1 H, CH) ppm. IR (KBr): $\tilde{\nu}$ = 1715 cm^{-1}, (vs, C=O), 970 cm^{-1} (s, Re=O), 740 cm^{-1}, 760 cm^{-1}, 770 cm^{-1}. $C_{10}H_{15}N_2O_3S_4Re{\cdot}3CHCl_3$ (883.8): calcd. C 17.67, H 2.05, N 3.17 S 14.51; found C 17.52 H 1.98, N 3.08, S 14.02.

[Re(O)(κ^3-SSS)(κ^1-Simz)]·HCl (2): A suspension of Simz (0.022 g, 0.13 mmol) in CH_3CN (2 mL) was added dropwise, at room temperature, to a blue solution of [Re(O)Cl(SSS)] (0.050 g, 0.13 mmol) in the same solvent (9 mL). The violet mixture was refluxed under a nitrogen atmosphere for 4 hours. The solvent was evaporated, the crude product was washed with CH_3CN and, after drying under vacuum, analyzed by ^{1}H NMR spectroscopy. The NMR spectrum indicates a mixture of three species, two of them identified as **Simz** and [Re(O)Cl(SSS)]. Recrystallization of the crude solid from CH_3CN/hexane led to violet crystals, which were formulated as complex **2** by X-ray diffraction analysis. IR (KBr): $\tilde{\nu}$ = 1725 cm^{-1} (vs, C=O), 965 cm^{-1}(s, Re=O), 750 cm^{-1}, 760 cm^{-1}.

[Re(O)(κ^3-SSS)(κ^1-SimzCOGlyGly)] (3): A mixture of **SimzCOGlyGly** (0.029 g, 0.11 mmol) and triethylamine (18 μL, 0.13 mmol) in acetonitrile (2 mL) and a few drops of dry dimethylformamide was added dropwise, at room temperature, to a stirred solution of [Re(O)Cl(SSS)] (0.050 g, 0.13 mmol) in acetonitrile (9 mL). After several minutes the color of the solution turned brown. The reaction mixture was refluxed under a nitrogen atmosphere overnight and the solvent evaporated to dryness. The residue obtained was extracted with methanol and a brown solid was obtained after evaporation of the solvent. This compound was then washed with acetonitrile and further purified by recrystallization from methanol/dichloromethane. Yield: 0.044 g (64%). ^{1}H NMR (CD_3OD): δ = 2.32−2.22 (m, 2 H, CH_2), 3.13−3.03 (m, 2 H, CH_2), 3.89 (s, 3 H, CH_3), 3.94 (s, 2 H, CH_2), 4.05 (s, 2 H, CH_2), 4.13−4.08 (m, 2 H, CH_2), 4.26−4.20 (m, 2 H, CH_2), 7.76 (s, 1 H, CH) ppm. IR (KBr): $\tilde{\nu}$ = 1645 cm^{-1}, 1535 cm^{-1} (vs, C=O), 970 cm^{-1} (s, Re=O). $C_{13}H_{19}N_4O_5S_4Re{\cdot}2CH_2Cl_2$ (795.6): calcd. C 22.64, H 2.91, N 7.04, S 16.12; found C 22.69, H 2.64, N 7.32, S 16.35.

X-ray Crystallographic Analysis: A brown crystal of **1** was obtained by recrystallization from $CHCl_3$/hexane, and a violet crystal of **2** was obtained from CH_3CN/hexane. Both were mounted in thin-walled glass capillaries. Data were collected at room temperature on an Enraf−Nonius CAD-4 diffractometer with graphite-monochromatized Mo-K_α radiation, using a ω-20 scan mode. The crystallographic data for both complexes are summarized in Table 2. Unit cell dimensions were obtained by least-squares refinement of the setting angles of 25 reflections with $14.85<2\theta<27.28°$ for **1** and $15.30<2\theta<26.87°$ for **2**. Data were corrected for Lorentz and polarization effects, for linear decay (for **1**) and for absorption by empirical corrections based on ψ scans.[20] The heavy atom positions were located by Patterson methods using SHELXS-86.[21] The remaining atoms were located by successive different Fourier maps and refined by least-squares refinements on F^2 using SHELXL-93.[22] One $CHCl_3$ molecule of crystallization was also located in the Fourier difference map for **1**. In **2**, the atoms O(2), C(3) and C(10) are disordered over two positions rotated about the C(7)−C(9) bond, which refined with site occupancy factors of 0.69 and 0.31, respectively (in the interests of clarity only one site is shown in Figure 2). In the residual electron density of **2**, the highest peak was assumed to be an oxygen atom of a water molecule, which presents a high thermal motion. All the non-hydrogen atoms were refined with anisotropic thermal motion parameters and the contribution of the hydrogen atoms was included in calculated positions, (except the hydrogens of the water molecule in **2**). The drawings were made with ORTEP-3 and the calculations were performed on a DEC α 3000 computer.[23] CCDC-178292 (**1**) and CCDC-178293 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Late Transition Metal Complexes of the Heterofunctional Phosphane *o*-$Ph_2PNHC_6H_4P(S)Ph_2$

Stephen M. Aucott,[a] Alexandra M. Z. Slawin,[a] and J. Derek Woollins*[a]

Keywords: Phosphorus−sulfur ligands / Monodentate complexes / Chelate complexes

The difunctional ligand *o*-$Ph_2PNHC_6H_4P(S)Ph_2$ (PS) has been prepared by treatment of the lithium amide salt of 2-(diphenylthiophosphanyl)aniline {2-$[Ph_2P(S)]C_6H_4NH_2$} with Ph_2PCl. The new ligand was oxidised to give the mixed chalcogen species $Ph_2P(E)NHC_6H_4P(S)Ph_2$, by treatment with H_2O_2 (where E = O) or aerial oxidation by recrystallisation from MeOH, and by reaction with Se_8 (where E = Se) in warm toluene. The complexes [M(Cl)(η^3-C_3H_5)(PS)] (M = Pt or Pd), *cis*-[$PtCl_2$(PS)(PMe_2Ph)], [(AuCl)(PS)], *cis*-[$MCl_2(PS)_2$] (M = Pt or Pd), *cis*-[$PtMe_2(PS)_2$] and *trans*-[PtMeCl$(PS)_2$] have been synthesised by reaction of either [Pt(μ-Cl)(μ-η^2:η^1-C_3H_5)]$_4$, [Pd(μ-Cl)(η^3-C_3H_5)]$_2$, [{PtCl(μ-Cl)(PMe_2Ph)}$_2$], [AuCl(tht)] (tht = tetrahydrothiophene), [$PdCl_2$(cod)] or [PtX_2(cod)] (X = Me or Cl; cod = cycloocta-1,5-diene) with (PS). In all these complexes the ligand (PS) is monodentate *P*-bound. Chloride abstraction from [M(Cl)(η^3-C_3H_5)(PS)] (M = Pt or Pd), *cis*-[$PtCl_2$(PS)(PMe_2Ph)], *cis*-[$PtCl_2(PS)_2$] and *trans*-[PtMeCl$(PS)_2$], using Ag[ClO_4], gave the monocationic [M(η^3-C_3H_5)(PS)][ClO_4] (M = Pt or Pd), *cis*-[PtCl(PS)(PMe_2Ph)][ClO_4], *trans*-[PtMe$(PS)_2$][ClO_4] or dicationic [$Pt(PS)_2$][ClO_4]$_2$ compounds in which the ligand (PS) is κ^2-*P*,*S*-bound. All compounds described here have been characterised by a combination of $^{31}P\{^1H\}$ and ^1H NMR spectroscopy, microanalyses, FAB mass spectrometry and IR spectroscopy. The molecular structures of [AuCl($Ph_2PNHC_6H_4P$-$(S)Ph_2$-*P*)] in which there is an intramolecular hydrogen-bonding interaction between the amine proton and the sulfur atom of the thiophosphoryl group and *trans*-[$Pt(Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*)$_2$][ClO_4]$_2$·CH_2Cl_2·$2H_2O$ in which the perchlorate counterions are associated by hydrogen-bonding interactions to the amine protons of the κ^2-*P*,*S* ligands have been determined by single-crystal X-ray diffraction.

Introduction

There are numerous examples in the literature of ligands containing both phosphorus and sulfur donor atoms. Meek and co-workers described the preparation of [*o*-(methylthio)phenyl]diphenylphosphane[1] − a ligand with an aromatic backbone which chelates to form five-membered C_2PSM rings.[1,2] Rigo and Bressan prepared a series of P−S donor ligands ($Ph_2PCH_2CH_2SR$) (R = Me, Et and Ph) by the addition of the appropriate chloro derivative $RS(CH_2)_2Cl$ to sodium diphenylphosphide in liquid ammonia.[3] The methylene-bridged ligand Ph_2PCH_2SMe was found to exhibit both monodentate *P*-bound and bidentate bridging coordination modes.[4,5] Other phosphane−thioether-based ligands have also been explored[6−9] as have phosphane−thiolate,[10−13] phosphane−thioformamide,[14] phosphane−thiophene,[15−17] phosphane−sulfoxide,[18] phosphane−sulfide[19−21] and phosphane−aminophosphane−sulfide ligands including $Ph_2PNHP(S)Ph_2$,[22] $Ph_2PNPhP(S)Ph_2$,[23] in addition to the methylene-, ethylene-, and −$[CH_2]_3$−backboned bis(phosphane−monosulfides) $Ph_2PCH_2P(S)Ph_2$,[24,25] $Ph_2PCH_2CH_2P(S)Ph_2$,[25] and $Ph_2PCH_2CH_2CH_2P(S)Ph_2$,[26] respectively. A logical extension to investigations into the reactivity of $Ph_2PNHC_6H_4PPh_2$ [27,28] is the chemistry of the monochalcogens $Ph_2P(E)NHC_6H_4PPh_2$ or $Ph_2PNHC_6H_4P(E)Ph_2$ (E = O, S or Se). We anticipated that these molecules would exhibit a variety of coordination modes, notably as monodentate phosphorus donors and as bidentate phosphorus−chalcogen donor ligands resulting in the formation of seven-membered metallacycles. The nitrogen atom presents a further site to be explored if deprotonation is possible. To further understand the chemistry of these molecules we have synthesised $Ph_2PNHC_6H_4P(S)Ph_2$ and investigated its reactivity towards Au^I, Pt^{II}, and Pd^{II}. In addition, we have prepared the mixed chalcogen compounds $Ph_2P(O)NHC_6H_4P(S)Ph_2$ and $Ph_2P(Se)NHC_6H_4P(S)Ph_2$.

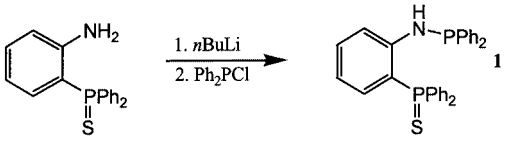
Results and Discussion

Preparation and Characterisation of $Ph_2PNHC_6H_4P(S)Ph_2$

Treatment of 2-[diphenyl(thio)phosphanyl]aniline with *n*BuLi, at −78 °C in diethyl ether, followed by reaction with Ph_2PCl, gave **1** in good to excellent yields (71−85%) [Equation (1)].



(1)

Attempted preparation of the oxo and seleno analogues $Ph_2PNHC_6H_4P(E)Ph_2$ (E = O, Se) under the same conditions resulted in re-isolation of the $Ph_2P(O)C_6H_4NH_2$ starting material and the formation of a complex mixture, respectively. Since the synthesis of the oxo and seleno ligands by the addition of Ph_2PCl to the lithium salt of the appropriate aniline proved unsuccessful, an alternative synthesis was sought. A second possible route to monochalcogen compounds of $Ph_2PNHC_6H_4PPh_2$ is by selective oxidation. This route has been applied to the synthesis of $Ph_2PNHP(E)Ph_2$ (E = O, S and Se).[22,29] A series of experiments involving the reaction of $Ph_2PNHC_6H_4PPh_2$ [27] with a slightly less than stoichiometric quantity of the appropriate chalcogen or aqueous H_2O_2 in various solvent systems at 0 °C gave poor results. These reactions usually resulted in the precipitation of the dichalcogen compounds $Ph_2P(E)NHC_6H_4P(E)Ph_2$,[28] while lesser amounts of starting material and both mixed P^{III},P^{V} species $Ph_2P(E)NHC_6H_4PPh_2$ and $Ph_2PNHC_6H_4P(E)Ph_2$ remain in solution. Separation of these mixtures was not attempted. $Ph_2PNHC_6H_4P(S)Ph_2$ (**1**) was isolated as a colourless solid and displays similar solubilities and the same sensitivity to air or light as $Ph_2PNHC_6H_4PPh_2$. The $^{31}P\{^1H\}$ NMR spectrum (in $CDCl_3$) of **1** displays two single resonances at $\delta(P_A) = 28.2$ ppm and $\delta(P_X) = 39.6$ ppm {the starting material 2-[diphenyl(thio)phosphanyl]aniline has $\delta(P) = 39.6$ ppm} for the $-NHPPh_2$ and $-P(S)Ph_2$ groups, respectively; the $^4J(^{31}P_A\text{-}^{31}P_X)$ coupling was not resolved. The ^1H NMR spectrum (in $CDCl_3$) showed the amine proton as a doublet at $\delta(H) = 5.68$ ppm [$^2J(^{31}P\text{-}^1H) = 9$ Hz]. From the IR spectrum we can identify ν(N−H), ν(P−N) and ν(P=S) at $\tilde{\nu} = 3223$, 896 and 634 cm^{-1}, respectively. Microanalytical data were within specified limits and the positive-ion FAB mass spectrum gave the expected parent-ion peak at $m/z = 494$ with appropriate isotope distribution and fragmentation patterns.

Synthesis of $Ph_2P(E)NHC_6H_4P(S)Ph_2$

The syntheses of the mixed chalcogen species are straightforward (Scheme 1). The mixed sulfur,oxygen species $Ph_2P(O)NHC_6H_4P(S)Ph_2$ (**2**) is prepared in 90% yield by the dropwise addition of aqueous hydrogen peroxide to a THF solution of **1**. The sulfur,oxygen species **2** was also isolated after recrystallisation in air of **1** from MeOH (59%) Warming **1** with a stoichiometric amount of elemental selenium in toluene at 60 °C followed by filtration of the warm solution, concentration and storage at below 0 °C gives the mixed S,Se species $Ph_2P(Se)NHC_6H_4P(S)Ph_2$ (**3**) in good yield (85%). Synthesis and characterisation of the disulfide has been reported elsewhere.[28] The mixed chalcogen species **2** and **3** are air- and moisture-tolerant colourless solids and in common with **1** display two sharp single resonances in their $^{31}P\{^1H\}$ NMR spectra (Table 1) with no observable $^4J(^{31}P_A\text{-}^{31}P_X)$ couplings in addition to amine proton resonances as broad doublets at $\delta(H) = 8.66$ ppm [$^2J(^{31}P\text{-}^1H) = 10$ Hz] (**2**) and $\delta(H) = 8.34$ ppm [$^2J(^{31}P\text{-}^1H) = 8$ Hz] (**3**). The infrared spectra of compounds **1** and **2** are consistent with the proposed structures and show bands attributable to ν(P=O) at $\tilde{\nu} = 1212$ cm^{-1} (**2**) and ν(P=Se) at $\tilde{\nu} = 548$ cm^{-1} (**3**) as well as the anticipated ν(N−H), ν(P−N) and ν(P=S) bands (see Exp. Sect.).

Monodentate Coordination Chemistry of $Ph_2PNHC_6H_4P(S)Ph_2$

Treatment of suspensions of the di- and tetranuclear species $[Pd(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)]_2$ and $[Pt(\mu\text{-}Cl)(\mu\text{-}\eta^2\text{:}\eta^1\text{-}C_3H_5)]_4$ (in toluene and THF, respectively) with **1**, results in bridge cleavage to give the mononuclear complexes $[MCl(\eta^3\text{-}C_3H_5)(Ph_2PNHC_6H_4P(S)Ph_2\text{-}P)]$ [where M = Pd (**4**) (83%) or Pt (**5**) (88%)] (Scheme 1). The $^{31}P\{^1H\}$ NMR ($CDCl_3$) spectra of **4** and **5** show the $-NHPPh_2$ resonances at $\delta(P) = 55.3$ (**4**) and 51.0 ppm [$^1J(^{195}Pt\text{-}^{31}P)$ 4946 Hz] (**5**) and the pendent $-P(S)Ph_2$ group resonances at $\delta(P) = 39.8$ (**4**) and 39.9 ppm (**5**) which are similar to that of the "free" ligand. The unsymmetrical mixed-ligand complex *cis*-$[PtCl_2\{Ph_2PNHC_6H_4P(S)Ph_2\text{-}P\}(PMe_2Ph)]$ (**6**) was prepared by chloride bridge cleavage of the platinum(II) dimer $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$ with **1** in CH_2Cl_2 (Scheme 1). The $^{31}P\{^1H\}$ NMR ($CDCl_3$) spectrum of **6** reveals a small phosphorus-phosphorus coupling constant (18 Hz), indicative of a structure with a *cis* arrangement of monodentate phosphane ligands. Two of the three unique phosphorus environments display large Pt-P couplings $\delta(P) = -16.3$ ppm [$^1J(^{195}Pt\text{-}^{31}P) = 3436$ Hz] assigned to the PMe_2Ph group and $\delta(P) = 32.6$ ppm [$^1J(^{195}Pt\text{-}^{31}P) = 4100$ Hz] to the $-NHPPh_2$ group of **1**. Furthermore, the chemical shift of the pendent $-P(S)Ph_2$ group [$\delta(P) = 39.4$ ppm] is similar to that observed for **1** and displays no platinum satellites indicating no interaction of the $-P(S)Ph_2$ moiety with the platinum centre. Evidence in support of the structural assignment of **6** is found in the IR spectrum showing two distinct ν(Pt−Cl) stretches at $\tilde{\nu} = 317$ and 291 cm^{-1} consistent with *cis*-$PtCl_2$ geometry. The reaction between $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$ and **1** was found to be somewhat sensitive to the reaction conditions as out of a total of five subsequent preparations of **6**, twice we found the isolated material to consist of an approximate 1:1 mixture of *cis* and *trans* isomers. Examination of the $^{31}P\{^1H\}$ NMR spectrum (in $CDCl_3$) of the isolated product showed the resonances of **6** and additional lines which display a large $^2J(^{31}P\text{-}^{31}P)$ coupling constant of 535 Hz indicative of a structure with a *trans* arrangement of phosphane ligands. As expected, two of the three distinct phosphorus environments display $^1J(^{195}Pt\text{-}^{31}P)$ couplings that are characteristically smaller than those previously observed for the *cis* isomer **6**. The doublet centred at $\delta(P) = -6.9$ ppm [$^1J(^{195}Pt\text{-}^{31}P) = 2531$ Hz] is assigned to the coordinated PMe_2Ph group and the doublet at $\delta(P) = 46.1$ ppm [$^1J(^{195}Pt\text{-}^{31}P) = 2715$ Hz]

to the coordinated $-NHPPh_2$ group of **1**. The single resonance at δ(P) = 41.5 ppm is assigned to the pendent $-P(S)Ph_2$ group and, although at slightly higher frequency than those observed for either **1** or **6**, remains uncoordinated, as indicated by the absence of platinum satellites. A number of literature studies have focused upon the solution *cis*/*trans* isomerism of platinum complexes of the type $[PtX_2(PR_3)_2]$ (where X = Cl, Br, or I and R = alkyl or aryl groups) and showed, in the main, that the kinetic *cis* isomer was rapidly converted into the thermodynamic *trans* isomer by the addition of a catalytic amount of PR_3.[29−32] We found that the addition of a small quantity (ca. 3−5 mg) of **1** to a dichloromethane solution of the *cis*/*trans* mixture resulted in isomerisation of the *trans* species to give pure *cis* isomer **6** (by $^{31}P\{^1H\}$ NMR). We have previously employed this technique to convert *trans*-$[PtCl_2(HL)(PMe_2Ph)]$ to *cis*-$[PtCl_2(HL)(PMe_2Ph)]$ [where HL = $Ph_2PNHP(O)Ph_2$].[33] In the absence of added **1** the composition of a CD_2Cl_2 solution of the *cis*/*trans* mixture remained unchanged after storage for up to six weeks at ambient temperature. Preparation of the pure *trans* isomer was not pursued. Compound **1** reacts cleanly with [AuCl(tht)] in CH_2Cl_2 by displacement of the tht molecule to give $[AuCl\{Ph_2PNHC_6H_4P(S)Ph_2\text{-}P\}]$ (**7**) (Scheme 1) as a colourless solid in 83% yield. The complex is slightly sensitive to light when in solution and a grey solid was deposited, presumably gold metal, after only moderate exposure. The ^{31}P NMR spectrum (in $CDCl_3$) shows two single lines at δ(P) = 40.1 and 58.2 ppm assigned to the $-P(S)Ph_2$ group and the gold-coordinated $-NHPPh_2$ group, respectively. Upon coordination, the signal of the phosphorus(III) centre

is shifted to higher frequency by 30 ppm relative to the that of the "free" ligand. The IR spectrum (KBr) of **7** shows that the ν(N−H) band at $\tilde{\nu}$ = 3109 cm^{-1} has undergone a large shift to lower frequency compared to that of **1** [ν(N−H) at $\tilde{\nu}$ = 3223 cm^{-1}] which suggests that the amine proton may be involved in intra/intermolecular hydrogen bonding. Crystals of X-ray quality were grown by layering a CH_2Cl_2 solution of **7** with diethyl ether. The crystal structure of [AuCl{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}] (**7**) along with selected bond lengths and angles (Table 1) is shown in Figure 1 and reveals an intramolecular hydrogen-bonding interaction between the S(2) atom and the amine hydrogen atom H(1n) of N(1) [H(1n)···S(2) 2.36 Å, S(2)···N(1) 3.25 Å, N(1)−H(1n)···S(2) 158°], corroborating the IR evidence. The molecule has a near planar P(2)−C(2)−C(1)−N(1)−P(1) backbone [maximum deviation from the mean plane 0.1 Å for P(1)]. The P(1)−Au(1)−Cl(1) angle is approximately linear [177.40(7)°] and is "*anti*" with respect to the amine proton H(1n) which appears to be a consequence of the previously discussed hydrogen-bonding interaction. The addition of 2 equiv. of **1** to a CH_2Cl_2 solution of [$PdCl_2$(cod)] gave a pale-yellow precipitate after only 5 min of stirring. The product, characterised as *cis*-[$PdCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**8**), was recovered in near quantitative yield (97%). The extreme insolubility of this material in all common organic solvents prevented measurement of its $^{31}P\{^1H\}$, ^1H NMR and mass spectra. Structural and geometrical assignments therefore, are based solely on microanalytical and IR data, the former was in excellent agreement with the proposed formulation, the latter showing two bands at $\tilde{\nu}$ = 318 and 298 cm^{-1} for ν(Pd−Cl), consistent with *cis*-$PdCl_2$ geometry. The ν(NH) stretch at $\tilde{\nu}$ = 3106 cm^{-1} like that of [AuCl{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}] (**7**) occurs at a much lower frequency than in the "free" ligand [ν(NH) at $\tilde{\nu}$ = 3223 cm^{-1}]. This suggests that the amine protons of *cis*-[$PdCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**8**) are involved in hydrogen-bonding interactions similar to those observed in complex **7**, which may account for the insolubility of **8**. In contrast, the preparation of the platinum analogue *cis*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**9**) under the same reaction conditions gave a pale-yellow solution that showed no sign of precipitation even after prolonged stirring. The product was precipitated by the addition of diethyl ether and isolated after recrystallisation from CH_2Cl_2/diethyl ether as a colourless solid in 88% yield (Scheme 1). Once dry, **9** displayed limited solubility in $CHCl_3$ but was readily soluble in CH_2Cl_2. The $^{31}P\{^1H\}$ NMR spectrum (in CD_2Cl_2) of *cis*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] showed two distinct phosphorus environments at δ(P) = 37.6 ppm [$^1J(^{195}Pt\text{-}^{31}P)$ = 4103] and δ(P) = 40.6 ppm, corresponding to the coordinated phosphorus(III) centres and the "dangling" phosphorus(V) moieties, respectively. The large $^1J(^{195}Pt\text{-}^{31}P_A)$ coupling constant of 4103 Hz is in good agreement with a *cis* disposition of ligands (i.e. P *trans* to Cl). In addition, no platinum satellites were observed for the uncoordinated phosphorus(V) groups, also, the chemical shift of the pendent $-P(S)Ph_2$ group is similar to that found in **1** [δ(P) = 39.6 ppm] implying no interaction with the metal centre. The $^{31}P\{^1H\}$ NMR spectrum of **9** also showed that the isolated product (from three separate syntheses) was consistently contaminated with an impurity (ca. 4−5%) observed as two singlets at δ(P) = 40.2 and 40.8 ppm thought to be *trans*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$]; positive assignment of the impurity resonances to the appropriate phosphorus(III) and -(V) centres is impossible as no obvious platinum satellites were observed for either peak. Further evidence in support of the neutral nonchelating *cis* structure comes from the IR spectrum (KBr) which shows two ν(Pt−Cl) stretches at $\tilde{\nu}$ = 311 and 290 cm^{-1}, consistent with a *cis*-$PtCl_2$ geometry. The 2:1 molar ratio reaction of **1** with a CH_2Cl_2 solution of [PtClMe(cod)] results in the deposition of a colourless solid and near-quantitative recovery (98%) of the surprisingly insoluble complex *trans*-[PtClMe{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**10**). As for **8**, the insolubility of **10** in common organic solvents prevents measurement of its NMR or mass spectra, hence only infrared and microanalytical data are available. Elemental analysis confirms that the isolated material has been correctly formulated as [PtMeCl{$Ph_2PNHC_6H_4P(S)Ph_2$}$_2$]. The assignment of *trans* geometry to complex **10** is based purely upon the product obtained, **15**, using **10** as starting material (see below). Reaction of 2 equiv. of **1** with [$PtMe_2$(cod)] in CH_2Cl_2 produces an off-white powder, characterised as the dimethyl derivative *cis*-[$PtMe_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**11**), as is evident from the $^{31}P\{^1H\}$ NMR spectrum (in $CDCl_3$) where the much smaller $^1J(^{195}Pt\text{-}^{31}P)$ coupling constant of 2059 Hz is concordant with *cis* (P *trans* to CH_3) geometry. The coordinated $-NHPPh_2$ and "dangling" $-P(S)Ph_2$ group resonances occur at δ(P) = 55.3 and 39.6 ppm, respectively. The ^1H NMR ($CDCl_3$) spectrum displays the amine protons as a broad multiplet at δ(H) = 8.1 ppm and the $PtMe_2$ moiety at δ(H) = 0.20 ppm as a double doublet, flanked by ^{195}Pt satellites [$^2J(^{195}Pt\text{-}^1H)$ = 72 Hz]. In all of the above complexes (**4**−**11**) the IR spectra (KBr) provide additional evidence of coordination through P only showing strong ν(P=S) absorption at $\tilde{\nu} \approx$ 632−634 cm^{-1} ["free" ligand ν(P=S) at $\tilde{\nu}$ = 634 cm^{-1}] which is characteristic of no interaction between the $-P(S)Ph_2$ group and the metal centre.

Bidentate Coordination Chemistry of $Ph_2PNHC_6H_4P(S)Ph_2$

We have previously reported that chelation of the potentially bidentate mixed P^{III},P^V P,O ligand $Ph_2PNHP(O)Ph_2$[34] the P,N ligand Ph_2PNHpy,[35] and the unsymmetric P,P′ ligand $Ph_2PNHC_6H_4PPh_2$[27] can be induced by the use of halide abstractors such as $Ag[BF_4]$ and $Ag[ClO_4]$ in CH_2Cl_2. This preparative technique has been extended with good results to bring about the chelation of monodentate $Ph_2PNHC_6H_4P(S)Ph_2$ (**1**) resulting in the formation of cationic species containing seven-membered P−N−C−C−P−S−M rings. Smooth conversion of the neutral (allyl)Pd^{II} (**4**) and -Pt^{II} (**5**) complexes to the cationic "ring-closed" complexes [Pd(η^3-C_3H_5){$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*}][ClO_4] (**12**) and [Pt(η^3-C_3H_5)-

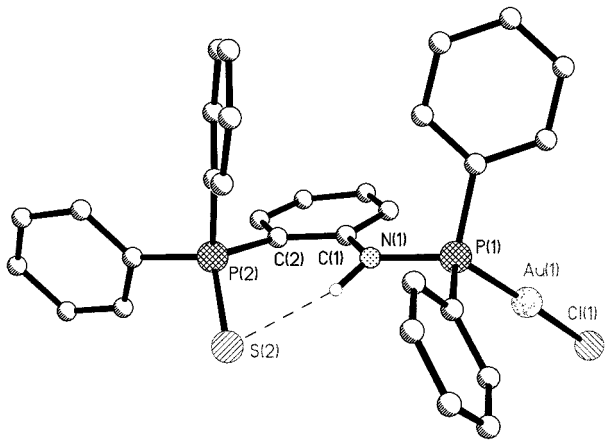

Figure 1. Crystal structure of [AuCl($Ph_2PNHC_6H_4P(S)Ph_2$-*P*)] (**7**)

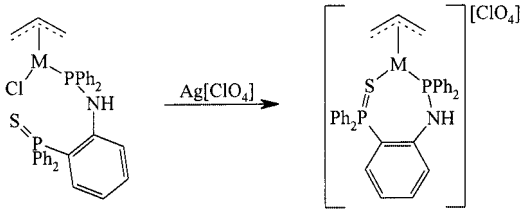
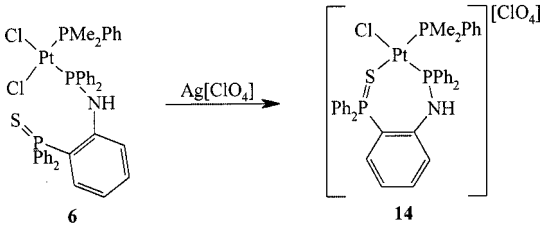
{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*}][ClO_4] (**13**) [Equation (2)] was achieved by the addition of a small excess of Ag[ClO_4] to CH_2Cl_2 solutions of **3** and **4**.

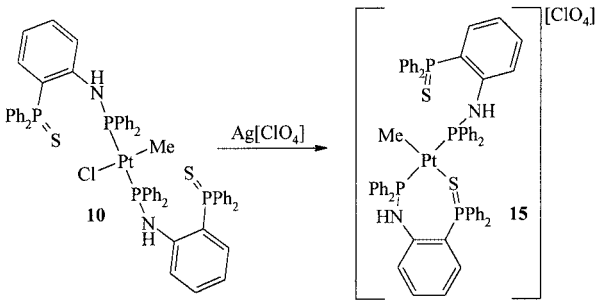


(2)

The products **12** and **13** were isolated in excellent yields (92 and 95%, respectively) as cream-coloured solids. The $^{31}P\{^1H\}$ NMR spectra for complexes **12** and **13** are of the AX type and show two sharp doublets at δ(P^{III}) = 69.5 ppm and δ(P^V) = 46.4 ppm for **12** and δ(P^{III}) = 58.3 ppm and δ(P^V) = 45.6 ppm for **13** which occur at higher frequency than their monodentate *P*-bound parent compounds. Indicative of chelating ligand behaviour are the small $^2J(P^{III}\text{-}P^V)$ couplings of 16 (**12**) and 13 Hz (**13**), the corresponding platinum satellites for compound **13** are particularly diagnostic and show a large $^1J(^{195}Pt\text{-}P^{III})$ coupling of 4720 Hz and a much smaller $^2J(^{195}Pt\text{-}P^V)$ coupling of 123 Hz. The complexes *cis*-[PtCl{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*}(PMe_2Ph)][ClO_4] (**14**) and *trans*-[PtMe{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*}][ClO_4] (**15**) were prepared from *cis*-[$PtCl_2$\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}(PMe_2Ph)] (**6**) and *trans*-[PtMeCl{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (**10**) in an identical manner to complexes **12** and **13** [Equations (3) and (4), respectively).



(3)



(4)

Both compounds were precipitated by the addition of diethyl ether and isolated as cream-coloured or colourless solids in 95 (**14**) and 82% (**15**) yields and are readily soluble in CH_2Cl_2 and MeOH but less so in $CHCl_3$. The $^{31}P\{^1H\}$ NMR spectrum of **14** reveals a small $^2J(^{31}P\text{-}^{31}P)$ coupling of 15 Hz, confirming that *cis* geometry was retained upon chelation. The low-frequency double doublet at δ(P) = −4.4 ppm [$^1J(^{195}Pt\text{-}^{31}P)$ = 3390 Hz] is assigned to the PMe_2Ph ligand and displays two P-P couplings, the previously mentioned $^2J(^{31}P\text{-}^{31}P)$ *cis* coupling and a $^3J(^{31}P\text{-}^{31}P)$ *trans* coupling of 9 Hz. The −$NHPPh_2$ group P resonance appears as a doublet at δ(P) = 40.5 ppm [$^1J(^{195}Pt\text{-}^{31}P)$ = 3821 Hz] and displays only the *cis* $^2J(^{31}P\text{-}^{31}P)$ coupling. The high-frequency resonance at δ(P) = 43.6 ppm appears as a doublet and is assigned to the coordinated −$P(S)Ph_2$ group by virtue of the small $^2J(^{195}Pt\text{-}^{31}P)$ coupling of 47 Hz. The $^{31}P\{^1H\}$ NMR spectrum (in CD_2Cl_2) of **15** shows four unique phosphorus environments. The first resonance at δ(P) = 43.1 ppm, assigned to the pendant −$P(S)Ph_2$ group, appears as a singlet with no platinum satellites which is consistent with noncoordinating behaviour. The double doublet resonance at δ(P) = 44.7 ppm, assigned to the coordinated −$P(S)Ph_2$ group of the chelating ligand, shows two distinct $^3J(^{31}P\text{-}^{31}P)$ couplings of 3 and 11 Hz in addition to platinum satellites with a small $^2J(^{195}Pt\text{-}^{31}P)$ coupling of 70 Hz. The doublet at δ(P) = 59.2 ppm, assigned to the −$NHPPh_2$ group of the nonchelating ligand, is coupled to the coordinated P^V centre [$^3J(^{31}P\text{-}^{31}P)$ = 11 Hz] and displays a small $^1J(^{195}Pt\text{-}^{31}P)$ coupling of 3192 Hz which is characteristic of mutual *trans* phosphane geometry. The high-frequency resonance at δ(P) = 64.4 ppm is assigned to the −$NHPPh_2$ group of the chelating ligand as chelation has previously been observed to cause a shift to higher frequency in both the P^{III} and P^V centres, cf. the conversions of [$MCl(\eta^3\text{-}C_3H_5)$\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}] [where M = Pd (**4**) or Pt (**5**)] to [$M(\eta^3\text{-}C_3H_5)$\{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*\}][ClO_4] [where M = Pd (**12**) or Pt (**13**)]. The phosphorus atom of this group is *cis*-coupled to the coordinated −$P(S)Ph_2$ group as suggested by the small $^3J(^{31}P\text{-}^{31}P)$ *cis* coupling of 3 Hz. The $^1J(^{195}Pt\text{-}^{31}P)$ coupling of 3225 Hz is also consistent with *trans* geometry as is the absence of any typically small (ca. 2000 Hz) phosphorus *trans* to methyl couplings. Contrary to expectation there is no resolvable *trans* $^2J(^{31}P\text{-}^{31}P)$ coupling, which we would expect to be of the order of ca. 500 Hz in magnitude. ($^{31}P\text{-}^{31}P$) COSY ex-

periments and re-recording of the spectrum at higher field do not shed any light on this anomaly. It is also worth noting the absence of $^2J(^{31}P\text{-}^{31}P)$ *trans* coupling between the two coordinated chemically inequivalent $-NHPPh_2$ groups. The ^1H NMR spectrum of **15** (in CD_2Cl_2) is consistent with the proposed structure and shows two multiplets at δ(H) = 8.62 ppm [$^3J(^{195}Pt\text{-}^1H)$ = 34 Hz] and δ(H) = 5.78 ppm [$^3J(^{195}Pt\text{-}^1H)$ = 54 Hz], assigned to the *P*-bound and the κ^2-*P*,*S*-bound ligand amine protons, respectively, with platinum satellites. The expected Pt−Me proton resonance appears as a broad pseudotriplet at δ(H) = −0.20 ppm with typical $^2J(^{195}Pt\text{-}^1H)$ and $^3J(^{31}P\text{-}^1H)$ couplings of 76 and 15 Hz, respectively. The IR spectrum is diagnostic and shows two ν(N−H) bands at $\tilde{\nu}$ = 3190 and 3144 cm^{-1} and two ν(P=S) bands at $\tilde{\nu}$ = 632 and 622 cm^{-1}, corresponding to pendant and coordinated $-P(S)Ph_2$ groups, respectively. In addition, the ν(P−N) band at $\tilde{\nu}$ = 916 cm^{-1} shows a prominent shoulder at $\tilde{\nu}$ = 925 cm^{-1} which is also compatible with two ligand environments. Treatment of *cis*-[$PtCl_2$\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}$_2$] (**9**) with 2 equiv. of $Ag[ClO_4]$ in CH_2Cl_2 resulted in abstraction of both chloride ligands and the formation of the dicationic bis(chelate) species *cis*-[Pt\{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*\}$_2$][ClO_4]$_2$ (**16**) isolated as an off-white microcrystalline solid in 88% yield. The isolated product, despite repeated recrystallisation, was consistently contaminated with an impurity (ca. 5%), observed as two triplets in the $^{31}P\{^1H\}$ NMR spectrum at δ(P) = 42.9 and 55.3 ppm [$^1J(^{195}Pt\text{-}^{31}P)$ = 2596 Hz], which was thought to be the *trans* isomer of **16**, formed from the suspected *trans*-[$PtCl_2$\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}$_2$] impurity in **9**. The complex is readily soluble in CH_2Cl_2 and MeOH but sparingly so in $CHCl_3$. The ^{31}P NMR spectrum (in CD_2Cl_2) of the platinum complex **16** shows two sets of resonances at δ(P) = 48.8 ppm [$^1J(^{195}Pt\text{-}^{31}P_X)$ = 3649 Hz] and δ(P) = 45.3 ppm [$^2J(^{195}Pt\text{-}^{31}P_A)$ = 38 Hz], corresponding to the coordinated phosphorus(III) and phosphorus(V) groups, respectively. Once again, chelation results in a shift of signals in both phosphorus environments to higher frequency relative to those of the neutral species *cis*-[$PtCl_2$\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}$_2$] (**9**) [$\delta(P^{III})$ = 37.6 ppm and $\delta(P^V)$ = 40.6ppm]. The $^1J(^{195}Pt\text{-}^{31}P^{III})$ coupling is decreased by over 450 Hz to 3649 Hz relative to that of **9** but is still consistent with the proposed *cis* geometry. Further evidence of ligand chelation is the now apparent small $J(^{31}P_A\text{-}^{31}P_X)$ coupling constant of 5 Hz. It is unclear whether the observed $J(^{31}P_A\text{-}^{31}P_X)$ coupling of 5 Hz is *cis* or *trans* in origin or a combination of both as the $^{31}P\{^1H\}$ NMR spectra of *cis*-[PtCl\{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*\}(PMe_2Ph)][ClO_4] (**14**) (see above), which has a single PtP_2C_2SN ring, and, as such, no *trans*-P−Pt−S−P grouping, contain no such coupling. However, the $^{31}P\{^1H\}$ NMR spectra of *trans*-[PtMe\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*\}\{$Ph_2PNHC_6H_4P(S)Ph_2$-*k*^{2}-*P*,*S*\}][ClO_4] (**15**) shows two distinct *cis* $^3J(^{31}P_A\text{-}^{31}P_X)$ couplings (see above). The IR spectrum supports the bis(chelate) structure, most notably by the observed shift to lower wavenumber of the ν(P=S) band [623 cm^{-1} vs. 634 cm^{-1} found in **9**] which is a trend also observed in all of the previously described k^2-*P*,*S* chelate complexes (**12**−**15**). An attempt to grow crystals of *cis*-[Pt\{$Ph_2PNHC_6H_4P(S)Ph_2$-*k*^{2}-*P*,*S*\}$_2$][ClO_4]$_2$ (**16**), suitable for X-ray crystallographic analysis by layering a CH_2Cl_2 solution with diethyl ether, resulted in crystallisation of the *trans* isomer. A $^{31}P\{^1H\}$ NMR study of CD_2Cl_2 and CD_2Cl_2/Et_2O solutions of **16** over a six week period showed that the *cis*/*trans* ratio of the compound, i.e. 95:5, remained constant and allowed us to discount the occurrence of slow *cis*-to-*trans* isomerism. The structure of *trans*-**16** (Figure 2) along with its core geometry (Figure 3) are displayed with selected bond lengths and angles (Table 2). The crystal structure of *trans*-[Pt\{$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-

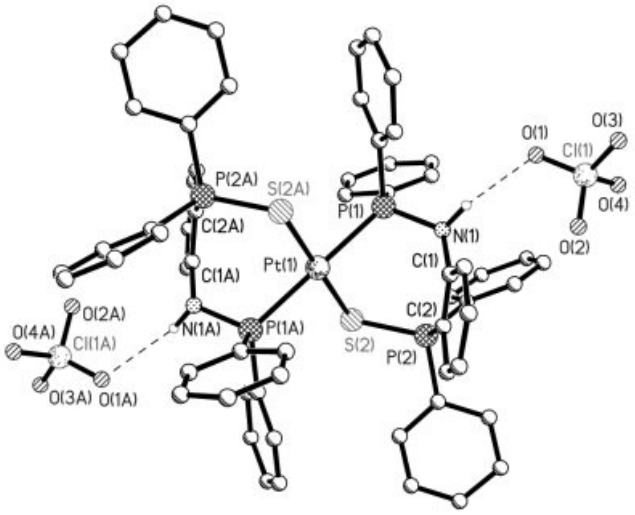


Figure 2. Crystal structure of *trans*-[Pt\{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*,*S*\}$_2$][ClO_4]$_2$·CH_2Cl_2·$2H_2O$; the CH_2Cl_2 and water molecules are omitted for clarity

$P,S\}_2][ClO_4]_2$ reveals that the molecule possesses a crystallographic centre of symmetry through the platinum atom and that one CH_2Cl_2 and two H_2O molecules (not shown for clarity) per molecule of complex are present. Near-perfect square-planar geometry at the metal centre is evident, presumably because of the lack of strain imposed at the platinum centre by the seven-membered rings. The two seven-membered PtP_2C_2NS metallacycles adopt a conformation best described as pseudo-boat form. Each ring consists of three distinct planes of atoms, [P(1), N(1), S(2), P(2)], [P(2)−C(2)−C(1)−N(1)] and [P(1)−Pt(1)−S(2)]. The angle between [P(1), N(1), S(2), P(2)] and [P(2)−C(2)−C(1)−N(1)] is approximately 119° whilst that between [P(1), N(1), S(2), P(2)] and [P(1)−Pt(1)−S(2)] is 56°. The dicationic nature of the complex is highlighted by the presence of two disordered $[ClO_4]^-$ counterions which are involved in hydrogen-bonding interactions with the two amine protons [H(1n)···O(2) 2.27(7) Å, O(1)···N(1) 3.03(1) Å, N(1)−H(1n)···O(1) 134(7)°]. Reaction of the near insoluble palladium complex **8** with $Ag[ClO_4]$ in a CH_2Cl_2/MeOH solvent mixture gave, after removal of the deposited AgCl and precipitation of the product with diethyl ether, a yellow solid. Examination of this material by $^{31}P\{^1H\}$ NMR (in CD_2Cl_2) showed that multiple products had been formed. No further attempt was made to prepare *cis*-$[Pd\{Ph_2PNHC_6H_4P(S)Ph_2$-$k^2$-$P,S\}_2][ClO_4]_2$.

Anionic Bidentate Coordination Chemistry of $Ph_2PNHC_6H_4P(S)Ph_2$

Previous work has demonstrated that metal complexes constructed using ligands bearing phosphanylamine groups can be easily deprotonated using a relatively mild base, e.g. Et_3N or the metal alkoxide *t*BuOK, to afford neutral chelate ring metallacycles.[29,30] Upon reaction of complexes **8** and **9** with *t*BuOK in MeOH a rapid change in colour is observed. Bright-yellow and bright-orange solids were isolated from the platinum and palladium reactions, respectively. Although the positive-ion FAB MS data gave promising results, i.e. showed isotope profiles at m/z = 1091/2 for palladium and 1180 for platinum corresponding to $[M\{Ph_2PNC_6H_4P(S)Ph_2$-κ^2-$P,S\}_2]^+$, supporting evidence was poor. In particular, $^{31}P\{^1H\}$ NMR evidence showed that multiple products had been formed. Attempts to isolate single products from the mixtures were not successful. Substitution of *t*BuOK for the milder base Et_3N failed as no reaction was observed even at reflux in MeOH.

Conclusion

We have shown that the mixed P^{III},P^V ligand $Ph_2PNHC_6H_4P(S)Ph_2$ (**1**) can be prepared by treating the lithium amide salt of $Ph_2P(S)C_6H_4NH_2$ with Ph_2PCl and that this ligand has the potential to ligate in a number of bonding modes. Apart from behaving as a typical unidentate *P*-bonded ligand, participation of the P=S function can be induced by removal from a metal complex of a chloride ligand using a halide abstractor. Further studies are currently in progress into additional coordination modes of this ligand.

Experimental Section

General: Unless otherwise stated, manipulations were performed under oxygen-free dinitrogen using predried solvents and standard Schlenk techniques. 2-[Diphenyl(thio)phosphanyl]aniline was prepared by the addition of a stoichiometric quantity of elemental sulfur to a toluene solution of 2-(diphenylphosphanyl)aniline. The complexes $[Pd(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)]_2$,[36] $[Pt(\mu\text{-}Cl)(\mu\text{-}\eta^2\text{:}\eta^1\text{-}C_3H_5)]_4$,[37] $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$,[38] [MX(Y)(cod)] (M = Pt or Pd; X, Y = Me, Cl, Br or I; cod = cycloocta-1,5-diene),[39−32] or $[AuCl(tht)]$[33] (tht = tetrahydrothiophene) were prepared according to literature procedures. *n*BuLi (Lancaster) was titrated against diphenylacetic acid just prior to use. Aqueous H_2O_2 (30% w/w, Fluka) and $Ag[ClO_4]$ (99% purity, Aldrich) were obtained commercially and used without further purification. Infrared spectra were recorded as KBr pellets in the range 4000−220 cm^{-1} with a Perkin−Elmer system 2000 Fourier transform spectrometer, ^1H NMR spectra (250 or 270 MHz) either with a Bruker AC250 FT or a JEOL GSX270 spectrometer with δ referenced to external $SiMe_4$ and $^{31}P\{^1H\}$ NMR spectra (36.2, 101.3 or 109.4 MHz) either with a JEOL FX90Q, a Bruker AC250 FT, or a JEOL GSX270 spectrometer with δ referenced to external H_3PO_4. Microanalyses were performed by the St Andrews University School of Chemistry Service. Precious metal salts were provided on loan by Johnson Matthey plc.

$Ph_2PNHC_6H_4P(S)Ph_2$ (1): A solution of 2.43 M *n*BuLi (4.0 mL, 9.72 mmol) in hexane was added dropwise over a period of 10 min to a cooled (−78 °C cardice/acetone), stirred suspension of 2-[diphenyl(thio)phosphanyl]aniline (3.00 g, 9.70 mmol) in dry, degassed diethyl ether (200 mL). The mixture was stirred at −78 °C for 1 h, warmed to room temperature and stirred for a further 3 h giving a white suspension in a dark orange solution. The reaction mixture was cooled once more to −78 °C (cardice/acetone) and neat chlorodiphenylphosphane (1.75 mL, 2.15 g, 9.74 mmol) was added dropwise over 5 min. The white suspension in a pale yellow solution was stirred at −78 °C for 30 min, warmed to room temperature, stirred for 3 h and then stripped of solvent in vacuo. The pale brown oily solid was then triturated with dry MeOH (30 mL) at 0 °C for 10 min. The colourless solid was collected by suction filtration, washed with ice-cold MeOH (2 × 10 mL) and dried overnight in vacuo. Yield: 4.07 g, 85%. ^1H NMR ($CDCl_3$): δ = 7.75−7.66 (m, 4 H, aromatics), 7.56−7.16 (m, 18 H, aromatics), 6.71−6.59 (m, 2 H, aromatics), 5.68 [br. d, $^2J(^{31}P\text{-}^1H)$ = 9 Hz, 1 H, NH] ppm. FAB^+ MS: m/z = 494 $[M]^+$. Selected IR data (KBr): $\tilde{\nu}$ = 3223 [br, ν(N−H)], 896 [vs, ν(P−N)], 634 [vs, ν(P=S)] cm^{-1}.

$Ph_2P(O)NHC_6H_4P(S)Ph_2$ (2). Method A: To a stirred THF (25 mL) solution of **1** (0.480 g, 0.973 mmol) was added aqueous hydrogen peroxide (30% w/w, 0.2 mL, 1.76 mmol) dropwise over a 10 min period. The mixture was stirred for 10 min, then concentrated to dryness, giving an off-white oily residue. The residue was taken up in CH_2Cl_2 and dried with anhydrous $MgSO_4$. Filtration to remove the drying agent, followed by concentration of the filtrate to dryness, and recrystallisation from a minimum of hot toluene gave **2** as a colourless crystalline solid. The product was collected by suction filtration, washed with toluene (2 × 5 mL) and dried in vacuo. Yield: 0.445 g, 90%. ^1H NMR ($CDCl_3$): δ = 8.66 [br. d, $^2J(^{31}P\text{-}^1H)$ = 10 Hz, 1 H, NH], 7.78−7.69 (m, 4 H, aromatics), 7.57−7.24 (m, 18 H, aromatics), 6.77−6.79 (m, 2 H, aromatics)

ppm. FAB^+ MS: *m*/*z* = 510 $[M]^+$. Selected IR data (KBr): $\tilde{\nu}$ = 3117 [w,ν(N−H)], 1212 [s, ν(P=O)], 924 [s, ν(P−N)], 632 [vs, ν(P=S)] cm^{-1}. **Method B:** $Ph_2PNHC_6H_4P(S)Ph_4$ (**1**) (0.536 g, 1.086 mmol) was dissolved in boiling MeOH (30 mL) and the hot solution was first cooled to room temperature and then stored at 4 °C overnight to give **2** as a colourless powder, which was collected by suction filtration, washed with ice-cold MeOH (2 × 10 mL), and dried overnight in vacuo. Yield: 0.324 g, 59%. $^{31}P\{^1H\}$ NMR ($CDCl_3$) and microanalytical data are similar to those of the material generated by Method A.

$Ph_2P(Se)NHC_6H_4P(S)Ph_2$ (3): Elemental selenium (0.085 g, 1.076 mmol) and **1** (0.534 g, 1.072 mmol) were stirred in warm (60 °C) toluene (20 mL) for 30 min. The solution was filtered through Celite while still warm to remove a trace amount of unchanged selenium. The Celite was washed with warm (60 °C) toluene (2 × 10 mL). The filtrate and washings were combined and reduced in volume to ca. 15 mL, and the resulting colourless solid was collected by suction filtration, washed with toluene (2 × 5 mL) and ice-cold diethyl ether (2 × 5 mL), and dried in vacuo. Yield: 0.524 g, 85%. ^1H NMR ($CDCl_3$): δ = 8.34 [br. d, $^2J(^{31}P\text{-}^1H)$ = 8 Hz, 1 H, NH], 7.79−7.68 (m, 4 H, aromatics), 7.63−7.24 (m, 18 H, aromatics), 6.85 (m, 1 H, aromatic), 6.77−6.67 (m, 1 H, aromatic) ppm. FAB^+ MS: *m*/*z* = 573 $[M]^+$. Selected IR data (KBr): $\tilde{\nu}$ = 3098 [s, ν(N−H)], 925 [vs, ν(P−N)], 631 [s, ν(P=S)], 548 [vs, ν(P=Se)] cm^{-1}.

[PdCl(η³-C_3H_5){$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}] (4): To a stirred toluene (15 mL) suspension of [Pd(μ-Cl)(η³-C_3H_5)]$_2$ (0.115 g, 0.316 mmol) was added in one portion solid **1** (0.312 g, 0.632 mmol). The mixture was stirred for 3 h to give a light, cream-coloured precipitate. The solvent volume was reduced in vacuo to ca. 5 mL and light petroleum ether (40−60 °C) (20 mL) was added to further precipitate the product, which was collected by suction filtration, washed with light petroleum ether (40−60 °C) (2 × 15 mL), and dried in vacuo. Yield: 0.354 g, 83%. ^1H NMR ($CDCl_3$): δ = 8.02 (s, 1 H, NH), 7.81−7.24 (m, 22 H, aromatics), 6.82−6.73 (m, 2 H, aromatic), 5.36 (m, 1 H, allyl), 4.64 (m, 1 H, allyl), 3.59 (m, 1 H, allyl), 3.04 (m, 1 H, allyl), 2.39 (m, 1 H, allyl) ppm. FAB^+ MS: *m*/*z* = 676 $[M]^+$, 641 $[M - Cl]^+$, 600 $[M - Cl - C_3H_5]^{2+}$. Selected IR data (KBr): $\tilde{\nu}$ = 3144 [br, ν(N−H)], 912 [m, ν(P−N)], 632 [m, ν(P=S)] cm^{-1}.

[PtCl(η³-C_3H_5){$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}] (5): To a stirred THF (20 mL) suspension of [Pt(μ-Cl)(μ-η²:η¹-C_3H_5)]$_4$ (0.153 g, 0.141 mmol) was added in one portion solid **1** (0.280 g, 0.568 mmol). The mixture was stirred for 6 h to give a dirty yellow solution that was filtered through a Celite plug to remove a small quantity of dark insoluble material. The resulting very pale yellow solution was reduced in vacuo to ca. 4−5 mL, and light petroleum ether (40−60 °C) (25 mL) was added to precipitate the product as a cream-coloured powder, which was collected by suction filtration, washed with light petroleum ether (40−60 °C) (2 × 10 mL), and dried in vacuo. Yield: 0.379 g, 88%. ^1H NMR ($CDCl_3$): δ = 8.07 [s, $^3J(^{195}Pt\text{-}^1H)$ = 47 Hz, 1 H, NH], 7.80−7.19 (m, 22 H, aromatics), 6.78−6.71 (m, 2 H, aromatic), 4.76 (m, 1 H, allyl), 4.28 (m, 1 H, allyl), 2.92 (m, 2 H, allyl) 1.87 [m, $^3J(^{195}Pt\text{-}^1H)$ = 78 Hz, 1 H, allyl] ppm. FAB^+ MS: *m*/*z* = 765 $[M]^+$, 730 $[M - Cl]^+$, 689 $[M - Cl - C_3H_5]^{2+}$. Selected IR data (KBr): $\tilde{\nu}$ = 3142 [br, ν(N−H)], 912 [s, ν(P−N)], 634 [s, ν(P=S)], 298 [w, ν(Pt−Cl)] cm^{-1}.

***cis*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}(PMe_2Ph)] (6):** To a stirred CH_2Cl_2 (25 mL) solution of [{PtCl(μ-Cl)(PMe_2Ph)}$_2$] (0.126 g, 0.156 mmol) was added dropwise over 10 min a CH_2Cl_2 (20 mL) solution of **1** (0.154 g, 0.312 mmol). The resulting pale yellow solution was stirred for 30 min and then concentrated under reduced pressure to ca. 1−2 mL, and addition of petroleum ether (60−80 °C) precipitated an off-white solid. The product was collected by suction filtration, washed with petroleum ether (60−80 °C) (3 × 10 mL) and dried in vacuo. Yield: 0.246 g, 88%. ^1H NMR ($CDCl_3$): δ = 8.47 (m, 1 H, NH), 7.90 (m, 1 H, aromatic), 7.83 (m, 22 H, aromatics), 6.82−6.68 (m, 2 H, aromatics) and 1.46 [d, $^2J(^{31}P\text{-}^1H)$ = 11, $^3J(^{195}Pt\text{-}^1H)$ = 35 Hz, 6 H, PMe] ppm. FAB^+ MS: *m*/*z* = 898 $[M]^+$, 862 $[M - Cl]^+$, 827 $[M - 2\ Cl]^{2+}$. Selected IR data (KBr): $\tilde{\nu}$ = 3143 [w, ν(N−H)], 912 [s, ν(P−N)], 634 [m, ν(P=S)], 317 (w) + 291 (w) [ν(PtCl)] cm^{-1}.

[AuCl{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}] (7): To a stirred solution of [AuCl(tht)] (0.045 g, 0.140 mmol) in CH_2Cl_2 (4 mL) was added **1** (0.070 g, 0.142 mmol) as a solid in one portion. The mixture was stirred for 1 h and filtered through a Celite plug to remove a small amount of grey insoluble material. Diethyl ether (35 mL) was added slowly until a white solid precipitated. The product was collected by suction filtration, washed with diethyl ether (2 × 10 mL), and dried in vacuo. Yield: 0.085 g, 83%. ^1H NMR ($CDCl_3$): δ = 8.00 [br. d, $^2J(^{31}P\text{-}^1H)$ = 3 Hz, 1 H, NH], 7.71−7.29 (m, 21 H, aromatics), 7.14 (m, 1 H, aromatic), 6.95 (m, 1 H, aromatic) and 6.71 (m, 1 H, aromatic) ppm. FAB^+ MS: *m*/*z* = 726 $[M]^+$, 691/692 $[M - Cl]^+$. Selected IR data (KBr): $\tilde{\nu}$ = 3109 [m, ν(N−H)], 927 [m, ν(P−N)], 632 [s, ν(P=S)], 339 [w, ν(Au−Cl)] cm^{-1}.

***cis*-[$PdCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (8):** To a stirred solution of [$PdCl_2$(cod)] (0.078 g, 0.273 mmol) in CH_2Cl_2 (2.5 mL) was added **1** (0.273 g, 0.553 mmol) as a solid in one portion. The resulting clear pale yellow solution was stirred for 10 min, and the pale yellow precipitate was collected by suction filtration, washed with CH_2Cl_2 (2 × 2 mL) and diethyl ether (3 × 10 mL), and dried in vacuo. Yield: 0.309 g, 97%. Selected IR data (KBr): $\tilde{\nu}$ = 3108 [br, ν(N−H)], 919 [vs, ν(P−N)], 632 [vs, ν(P=S)], 318 (w) + 298 (w) [ν(Pd−Cl)] cm^{-1}.

***cis*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (9):** This compound was prepared in the same way as **8** using [$PtCl_2$(cod)] (0.051 g, 0.136 mmol) in CH_2Cl_2 (2.5 mL) and **1** (0.138 g, 0.280 mmol). The resulting clear pale yellow solution was stirred for 2 h, and the product was precipitated by slow addition of diethyl ether (15 mL). The crude product was immediately redissolved in CH_2Cl_2 (5 mL) and reprecipitated by slow addition of diethyl ether (30 mL), washed with ice-cold CH_2Cl_2/diethyl ether (1:1) (4 mL) and diethyl ether (3 × 10 mL). The resulting white solid was collected by suction filtration and dried in vacuo. Yield: 0.150 g, 88%. ^1H NMR (CD_2Cl_2): δ = 7.90 [br. d, $^2J(^{31}P\text{-}^1H)$ = 7 Hz, 2 H, NH], 7.76−7.08 (m, 44 H, aromatics) and 6.71−6.58 (m, 4 H, aromatics) ppm. FAB^+ MS: *m*/*z* = 1217/8 $[M - Cl]^+$, 1182 $[M - 2\ Cl]^{2+}$. Selected IR data (KBr): $\tilde{\nu}$ = 3125 [m, ν(N−H)], 920 [s, ν(P−N)], 634 [s, ν(P=S)], 311 (w) + 290 (w) [ν(Pt−Cl)] cm^{-1}. The product was consistently contaminated with an impurity (ca. 4−5%) observed as two singlets in the $^{31}P\{^1H\}$ NMR at δ(P) = 40.2 and 40.8 ppm, thought to be *trans*-[$PtCl_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$].

***trans*-[PtClMe{$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (10):** This was prepared in the same way as **8** using [PtClMe(cod)] (0.093 g, 0.263 mmol) in CH_2Cl_2 (4 mL) and **1** (0.270 g, 0.547 mmol). The white solid was collected by suction filtration, washed with CH_2Cl_2 (2 × 2 mL) and diethyl ether (3 × 10 mL) and dried in vacuo. Yield: 0.318 g, 98%. Selected IR data (KBr): $\tilde{\nu}$ = 3128 [br, ν(N−H)], 911 [vs, ν(P−N)], 633 [vs, ν(P=S)], 288 [w, ν(Pt−Cl)] cm^{-1}.

***cis*-[$PtMe_2${$Ph_2PNHC_6H_4P(S)Ph_2$-*P*}$_2$] (11):** This was prepared in the same way as **8** using [$PtMe_2$(cod)] (0.070 g, 0.210 mmol) in toluene (4 mL) and **1** (0.210 g, 0.43 mmol). The resulting clear pale

yellow solution was stirred for 2 h resulting in the deposition of a light precipitate. Petroleum ether (60−80 °C) (30 mL) was added with stirring to further precipitate the product. The off-white solid was collected by suction filtration, washed with petroleum ether (60−80 °C) (3 × 10 mL), and dried in vacuo. Yield: 0.215 g, 84%. ^{1}H NMR ($CDCl_3$): δ = 8.10 (m, 2 H, NH), 7.86−6.59 (m, 48 H, aromatics) and 0.20 [dd, $^2J(^{195}Pt\text{-}^1H)$ = 72 Hz, 6 H, PtMe] ppm. FAB$^+$ MS: *m*/*z* = 1235 [M + Na]$^+$, 1212 [M]$^+$ and 1196 [M − Me]$^+$. Selected IR data (KBr): $\tilde{\nu}$ = 3168 [br, ν(N−H)], 902 [s, ν(P−N)], 634 [s, ν(P=S)] cm^{-1}.

[Pd(η^3-C_3H_5){$Ph_2PNHC_6H_4P(S)Ph_2$-κ^2-*P*,*S*}][ClO_4] (12): To a stirred CH_2Cl_2 (15 mL) solution of **4** (0.171 g, 0.253 mmol) was added Ag[ClO_4] (0.055 g, 0.265 mmol) as a solid in one portion. The resulting mixture was stirred in the dark for 17 h and then filtered through Celite to remove the AgCl. The pale yellow filtrate was concentrated in vacuo to ca. 5−6 mL and upon addition of diethyl ether (25 mL) deposited a cream-coloured solid. The solid was collected by suction filtration, washed with diethyl ether (3 × 10 mL), and dried in vacuo. Yield: 0.172 g, 92%. ^{1}H NMR ($CDCl_3$): δ = 7.93−6.97 (m, 23 H, aromatics), 6.66 (m, 1 H, aromatics), 5.61 (m, 1 H, allyl), 5.21 [br. d, $^2J(^{31}P\text{-}^1H)$ = 11 Hz, 1 H, NH], 4.76 (m, 1 H, allyl), 3.76 (m, 1 H, allyl), 3.56 (m, 1 H, allyl), 2.87 [br. d, $J(^1H\text{-}^1H)$ = 13 Hz, 1 H, allyl] ppm. FAB$^+$ MS: *m*/*z* = 641 [M − ClO_4]$^+$, 600 [M − ClO_4 − C_3H_5]$^{2+}$. itate. The cream-coloured microcrystalline product was collected by suction filtration, washed with diethyl ether (2 × 10 mL)and dried in vacuo. Yield: 0.194 g, 88%. ^1H NMR (CD_2Cl_2): δ = 7.96−7.85 (m, 8 H, aromatics), 7.69−6.88 (m, 36 H, aromatics) and 6.72−6.59 (m, 6 H, aromatics and NH) ppm. FAB$^+$ MS: *m*/*z* = 1281/1282 $[M - ClO_4]^+$ and 1182 $[M - 2\ ClO_4]^{2+}$. Selected IR data (KBr): $\tilde{\nu}$ = 3164 [br, ν(N−H)], 1099 [vs (br), ν(ClO_4)], 927 [m, ν(P−N)], 623 [s, ν(P=S)] cm^{-1}. The product was consistently contaminated with an impurity (ca. 5%) observed as two triplets in the $^{31}P\{^1H\}$ NMR spectrum at δ(P) = 42.9 and 55.3 ppm [$^1J(^{195}Pt-^{31}P)$ = 2596 Hz] thought to be *trans*-$[Pt\{Ph_2PNHC_6H_4P(S)Ph_2\text{-}P,S\}_2][ClO_4]_2$.

The $^{31}P\{^1H\}$ spectroscopic and microanalytical data for all new compounds are compiled in Tables 3 and 4, respectively.

X-ray Crystallography: X-ray diffraction measurements were made with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) using a Siemens SMART diffractometer, intensity data were collected using 0.3° or 0.15° width ω steps accumulating area detector frames spanning a hemisphere of reciprocal space for all structures (data were integrated using the SAINT program) and for the Rigaku AFC7S data collections by ω scans over a single quadrant of reciprocal space. All data were corrected for Lorentz, polarisation and long-term intensity fluctuations. Absorption effects were corrected on the basis of multiple equivalent reflections (SADABS) or by semi-empirical methods.[44] Structures were solved by direct methods and refined by full-matrix least squares against F^2 (SHELXTL). All hydrogen atoms (except those on the water molecules of complex **16**, which we have not included in the refinement) were assigned isotropic displacement parameters and were constrained to idealised geometries. All calculations were made with SHELXTL.[44] $C_{30}H_{25}AuClNP_2S$ (**7**), *M* = 725.9, monoclinic, space group *C*2/*c*, *a* = 18.2461(2), *b* = 9.3531(2), *c* = 33.2678(3) Å, β = 92.23(1)°, *V* = 5673.1(1) Å^3, *T* = 293 K, *Z* = 8, μ(Mo-K_α) = 5.487 mm^{-1}, 16863 reflections measured, 6645 unique (R_{int} = 0.0475), observed independent reflections 4353, final *R*1[$I > 2\sigma(I)$] = 0.0459. $C_{60}H_{50}N_2P_4PtS_2[ClO_4]_2[CH_2Cl_2][H_2O]_2$ (**16**), *M* = 1502.0, monoclinic, space group $P2_1/n$, *a* = 12.4175(4), *b* = 20.5319(7), *c* = 13.8955(5) Å, β = 99.38(1)°, *V* = 5673.1(1) Å^3, *T* = 293 K, *Z* = 2, μ(Mo-K_α) = 2.364 mm^{-1}, 21230 reflections measured, 8178 unique (R_{int} = 0.0430), observed independent reflections 5041, final *R*1[$I > 2\sigma(I)$] = 0.0487. Synthesis, Reactivity and Molecular Structures of Bis(diphenylphosphanyl)methane-Bridged Heterobimetallic Iron−Platinum Isocyanide Complexes: Breaking and Formation of Metal−Metal Bonds

Michael Knorr,*[a] Isabelle Jourdain,[a] Grégorio Crini,[a] Katja Frank,[b] Hermann Sachdev,[b] and Carsten Strohmann[c]

Keywords: Heterobimetallics / Isocyanide ligands / Metal−metal interactions / Iron / Platinum

When $[(OC)_3Fe(\mu\text{-}CO)(\mu\text{-}dppm)PtCl_2]$ (**1**) is allowed to react with stoichiometric amounts of various isocyanides, cleavage of the metal–metal bond occurs, yielding the heterodinuclear isocyanide complexes $[(OC)_4Fe\{\mu\text{-}dppm\}Pt(Cl)_2(CNR)]$ (**2a**: R = 2,6-xylyl; **2b**: R = *o*-anisyl; **2c**: R = benzyl; **2d**: R = cyclohexyl; **2e**: R = tosylmethyl). Reduction of **2a**–**2e** by $NaBH_4$ in the presence of PPh_3 affords the isocyanide-bridged complexes $[(OC)_3Fe(\mu\text{-}C{=}N\text{–}R)(\mu\text{-}dppm)Pt(PPh_3)]$ (**3a**: R = 2,6-xylyl; **3b**: R = *o*-anisyl; **3c**: R = benzyl; **3d**: R = cyclohexyl; **3e**: R = tosylmethyl). Metathesis of **2a**–**2d** with NaI rapidly results in the formation of $[(OC)_4Fe\{\mu\text{-}dppm\}PtI_2(CNR)]$ (**4a**–**4d**), which is slowly transformed under extrusion of CO giving $[(OC)_2IFe\{\mu\text{-}dppm\}(\mu\text{-}CO)PtI(CNR)]$ (**6a**: R = 2,6-xylyl; **6b**: R = *o*-anisyl; **6c**: R = benzyl; **6d**: R = cyclohexyl), bearing an iodine ligand at the iron center. Due to this intramolecular iodide migration from Pt to Fe, an Fe^I d^7 fragment interacts with a Pt^I d^9 fragment through a covalent bond. Alternatively, **6a**–**6d** are obtained by stoichiometric treatment of $[(CO)_3Fe(\mu\text{-}I)(\mu\text{-}dppm)PtI]$ (**5**) with CNR. Single-crystal X-ray diffraction studies are performed on **2d**, **2e** and **3c** as well as on **6d**. In the solid state, the two metal centers of **2e** remain in close contact (3.862 Å), whereas in the case of **2d** they are separated by 6.573 Å after cleavage of the metal–metal bond by CNR.

Introduction

The continuing interest in the preparation and reactivity of heterometallic complexes results from the possibility to investigate (i) cooperativity effects between the different metal centers, (ii) metallosite selectivity on reaction with substrate molecules, and comparison with the reactivity of related monometallic complexes and (iii) possible correlations between unusual bonding modes of coordinated ligands and their activation.[1−10] As part of our studies on the coordination and activation of isocyanide ligands on heterodimetallics,[11−16] we have recently shown that heterodinuclear isocyanide-bridged complexes $[(OC)_3Fe(\mu\text{-}C{=}N{-}R)(\mu\text{-}dppm)Pt(PPh_3)]$ with aromatic substituents R (R = 2,6-xylyl, *o*-anisyl, *p*-anisyl; *p*-$C_6H_4NH_2$) can be obtained by treatment of $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-}dppm)Pt(H)(PPh_3)]$ with CNR.[15] Alternatively, some bis(diphenylphosphanyl)amine-bridged complexes $[(OC)_3Fe(\mu\text{-}C{=}N{-}R)(\mu\text{-}dppa)Pt(PPh_3)]$ were prepared by selective substitution of the bridging carbonyl ligand of $[(OC)_3Fe(\mu\text{-}C{=}O)(\mu\text{-}dppa)Pt(PPh_3)]$ by CNR.[13]

In contrast to the well-established μ-CNR bonding mode for homodimetallic systems,[17,18] this bonding mode is extremely rare for heterometallic systems,[19] therefore, we are interested in developing synthetic methods for [M(μ-C=N−R)M′] complexes. Here, we report on the reactivity of $[(CO)_3Fe(\mu\text{-}CO)(\mu\text{-}dppm)PtCl_2]$ (**1**) towards various isocyanides, intramolecular redox reactions due to migration of iodo ligands between two adjacent metal centers, and present the molecular structures of several Fe−Pt compounds ligated by terminal or bridging CNR ligands.

Results and Discussion

Reactivity of 1 towards Isocyanides

Since it is easy to substitute the bridging carbonyl ligand of $[(OC)_3Fe(\mu\text{-}C{=}O)(\mu\text{-}dppa)Pt(PPh_3)]$ by CNR (see above), it seemed promising to prepare $[(CO)_3Fe\{\mu\text{-}CNR\}(\mu\text{-}dppm)PtCl_2]$ using Shaw's compound $[(CO)_3Fe\{\mu\text{-}CO\}(\mu\text{-}dppm)PtCl_2]$ (**1**) as the starting material.[20] For the latter compound, the presence of a semi-bridging carbonyl ligand has been established both in solution and in the solid

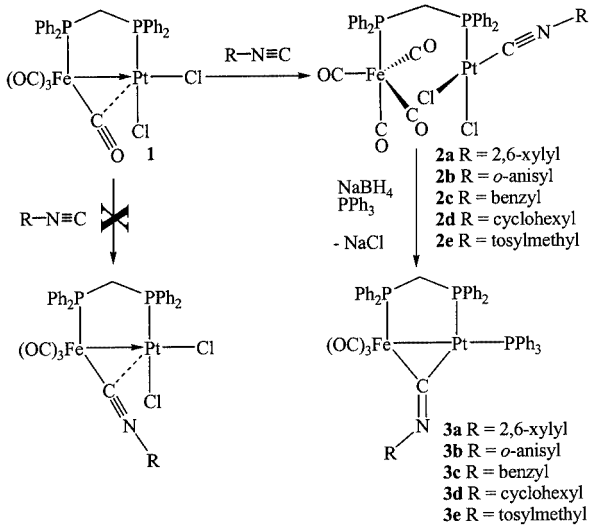
state. Instead of the anticipated CO substitution reaction, instantaneous opening of the dative iron→platinum bond occurred at ambient temperature on addition of stoichiometric amounts of RNC to a CH_2Cl_2 solution of **1**. The resulting complexes $[(OC)_4Fe\{\mu\text{-dppm}\}Pt(Cl)_2(CNR)]$ (**2a**: R = 2,6-xylyl; **2b**: R = *o*-anisyl; **2c**: R = benzyl; **2d**: R = cyclohexyl; **2e**: R = tosylmethyl) (Scheme 1) were isolated in high yields as yellow solids, which can be handled in air without significant decomposition. They show poor solubility in hexane or Et_2O, but are very soluble in THF or dichloromethane.



Scheme 1

The IR spectrum of **2a** indicates the breaking of the Fe−Pt bond**.** The pattern and position of the four ν(CO) stretching modes at 2051, 1978, 1942 and 1936 cm^{-1} in the IR spectrum is very similar to that of $[(OC)_4Fe(\eta^1\text{-dppm})]$.[21] The ν(C≡N) vibration at 2199 cm^{-1} is assigned to the terminally bound isocyanide ligand on Pt. Due to the absence of a metal−metal bond, the $^2J_{P,P}$ coupling of the two doublets found at δ = 64.5 (P_{Fe}) and 2.9 ppm (P_{Pt}) in the $^{31}P\{^1H\}$ NMR spectrum, is reduced to 26 Hz compared with 51 Hz reported for **1**. The data of all other derivatives are very similar and are listed in Table 1. The $^{195}Pt\{^1H\}$ NMR spectra of **2a**, **2b** and **2e** give rise to broadened doublets at δ ≈ −2400 ppm, whose $^3J_{Pt,P}$ coupling is not resolved. This is in contrast to the sharp resolved $^{31}P\{^1H\}$ NMR spectra that exhibit a $^3J_{Pt,P}$ coupling of ca. 90 Hz, in addition to an averaged $^1J_{Pt,P}$ coupling of 3300 Hz. The cleavage of the Fe−Pt bond of **2d** and **2e** was further corroborated by an X-ray diffraction study.

Crystal Structures of $[(OC)_4Fe\{\mu\text{-dppm}\}PtCl_2(CNCH_2SO_2C_6H_4Me)]\cdot 0.5CH_2Cl_2$ (2e) and $[(OC)_4Fe\{\mu\text{-dppm}\}PtCl_2(CNC_6H_{11})]$ (2d)

Suitable crystals of **2e**·$0.5CH_2Cl_2$ were grown from CH_2Cl_2/Et_2O. The molecular structure is shown in Figure 1 with selected bond lengths and angles. The cleavage of the metal−metal bond by the isocyanide ligand is shown by the separation of 3.862 Å between the iron center and the platinum center. The angle P(2)−C(17)−P(1) of 121.7(3)° is larger than in the case of $(CO)_3Fe\{\mu\text{-C=N-benzyl}\}(\mu\text{-dppm})Pt(PPh_3)]$ (**3c**), for which a P−C−P angle of 112.8(2)° is found (see below). The coordination sphere around Pt is square-planar, the root mean square deviation from the plane defined by Cl(1), Cl(2), P(2), C(30) and Pt is quite small (0.045 Å). The two chlorine atoms are in a *cis* arrangement [Cl(1)−Pt−Cl(2) = 90.64(10)°], the angles P(2)−Pt−Cl(1) and P(2)−Pt−Cl(2) are 84.93(8)° and 175.53(7)°, respectively. The two Pt−Cl bond lengths of 2.331(2) Å and 2.350(2) Å are very similar. The Pt−P(2) and Fe−P(1) distances of 2.253(2) Å and 2.256 Å are comparable to those found in **3c**. The Pt−C(30)−N−C(31) array of the terminally bound isocyanide ligand {*d*[C(30)]−N = 1.164(11) Å}, having angles of 178.2(7)° and 173.7(9)°, is almost linear. The geometry around the iron center can be described as a weakly deformed trigonal bipyramid, in which the angle C(2)−Fe−P(1) [171.7(4)°] of

the axial ligands deviates slightly from the ideal value. The angles of the equatorial carbonyl ligands deviate considerably from the ideal value of 120°; C(1)−Fe−C(4) and C(1)−Fe−C(3) are 139.0(4) and 109.6(4)°, respectively.

Surprisingly, despite the similarity of the spectroscopic data recorded in solution, the mutual arrangement of the two metal fragments of **2d** in the crystalline state is very different from that of **2e**. Although the geometry and ligand arrangement of each individual moiety remains unaltered (square-planar around Pt and trigonal-bipyramidal around Fe), the two metal centers are far apart from each other (6.573 Å) after cleavage of the metal−metal bond by cyclohexyl isocyanide (see Figure 2). The angle P(2)−C(17)−P(1) [130.1(2)°] is still larger than in the case of **2e**, for which a P−C−P angle of 121.7(3)° is found. Compared with **2e**, the distances Fe−P(1) and Pt−P(2) [2.2565(14) and 2.2540(13) Å, respectively] of **2d** remain almost identical. However, all interligand angles on the iron fragment are now much closer to the values expected for an ideal trigonal-bipyramidal polyhedron. Notably the angles between the equatorial carbonyl ligands C(1), C(2) and C(4) are 123.1(2), 119.8(2) and 117.1(3)°, which are much closer to 120°. Furthermore, the angle P(1)−Fe−C(3) [178.2(2)°] is much closer to 180° than the angle 171.7(4)° found for derivative **2e**.

A very similar important separation of the two dppm-spanned metal fragments has recently been encountered, after cleavage of the dative metal−metal bond of [MeCp-$(OC)_2$Mn(μ-CO)(μ-dppm)PdCl_2] by isocyanides.[22] In the case of [(η^5)-MeCp$(OC)_2$Mn(μ-dppm)Pd(CNxylyl)Cl_2], an X-ray diffraction study determined a separation of 6.31 Å between the square-planar palladium center and the three-legged piano-stool MeCp$(OC)_2$MnP fragment.

These findings outline the flexibility and the rotational degrees of freedom along the M−P−C−P−M′ chains. At present we cannot state whether the different arrangements of **2d** and **2e** are only due to *packing effects* in the crystalline state, or whether the different *electronic behavior* of the CNR ligands may account for this phenomenon. The C_6H_{11} group is known as electron-releasing, whereas the CH_2SO_2*p*-tolyl group should somewhat lower the electron density on Pt by the enhanced propensity of tosylmethyl isocyanide to act as a π-accepting ligand.[14] In the latter case, the proximity of the two adjacent metal centers and the widening of the angle C(1)−Fe−C(4) to 139.0(4)°, may tentatively be interpreted as *incipient dative metallic interaction* between the iron and platinum fragment. [The closest contacts between Pt and C(4) and C(1) are 3.499 Å and 3.819 Å, respectively.] Examples of heterodimetallic complexes with dative Fe→Pt bonds such as [$(OC)_3$Fe(μ-CO)(μ-dppm)PtBr_2] and [$(CO)_3$Fe(μ-I)(μ-dppm)PtI] (**5**) exhibit metal−metal separations of 2.647(4) and 2.523(4) Å, respectively.[20] For the cyclopentadienethiolato compound [$(C_5H_4S)_2$FePdPPh_3], which possesses a weak dative Fe→Pd interaction, a value of 2.878(1) Å has been reported.[23] A separation of 3.784 Å, which is quite close to that of **2e**, has been determined for the dppm-spanned complex [Cp(PPh_3)Ru(μ-dppm)(μ-Cl)PtCl_2].[24] However, in the

latter case a bridging chloro ligand additionally links the two moieties. Of course, further molecular structures of derivatives of **2** ligated by strongly π-accepting CNR ligands are necessary to corroborate (or exclude) this hypothesis.

Reduction of 2a−2e Yielding μ-Isocyanide Complexes

Due to the paucity of heterometallic M(μ-C=N−R)M′ systems, it is desirable to develop facile preparative routes to deepen the knowledge on the structural features and reactivity pattern of this class of compounds. We found that apart from the two strategies mentioned in the introduction, Fe(μ-C=N−R)Pt systems are also accessible using **2a−2e** as precursors. When **2a−2b** were reduced by $NaBH_4$ in the presence of 1 equiv. of PPh_3 using a CH_2Cl_2/MeOH mixture as the solvent, the recently described μ-isocyanide complexes $[(CO)_3Fe(\mu\text{-}C{=}N\text{-aryl})(\mu\text{-dppm})Pt(PPh_3)]$ **3a−3b** were isolated after workup in ca. 60% yield. In an analogous manner, the stable complexes **3c−3e**, possessing μ-CNR bridges with aliphatic groups R, have been obtained in moderate yields as yellow-orange solids. The ^{31}P and ^{195}Pt NMR spectroscopic data, which have already been discussed in detail,[15] are listed in Table 1. A comparison of the ν(C=N) vibration in the IR spectra reveals that the position of this absorption can roughly be correlated with the donor/acceptor properties of the group R. Thus, the CH_2SO_2*p*-tolyl substituent, which is the best π-acceptor in this series, gives rise to a ν(C=N) vibration at 1648 cm^{-1}. For R = xylyl and *o*-anisyl a ν(C=N) vibration at 1667 and 1668 cm^{-1}, respectively, has been reported,[15] and for the benzyl derivative a ν(C=N) vibration appears at 1679 cm^{-1}. Finally, in the case of **3d** with a strongly electron-donating C_6H_{11} group, this stretching mode is shifted to 1689 cm^{-1}.

Crystal Structure of $[(CO)_3Fe\{\mu\text{-}C{=}N\text{-}Bz\}(\mu\text{-dppm})Pt(PPh_3)]\cdot 0.5CH_2Cl_2$ (3c)

The molecular structure of the benzyl derivative is depicted in Figure 3 with selected bond lengths and angles. The Fe−Pt distance of 2.5575(10) Å confirms the existence of a metal−metal bond and is almost identical to those of $[(CO)_3Fe(\mu\text{-}C{=}N{-}R)(\mu\text{-dppm})Pt(PPh_3)]$ and $[(CO)_3Fe(\mu\text{-}C{=}O)(\mu\text{-dppm})Pt(PPh_3)]$ [2.579(4) Å].[21] On the whole, there are many parallels in the overall structure, therefore only the most salient structural features of **3c** will be mentioned. The bridging isocyanide ligand is again symmetrically ligated between the two metal centers, the Fe−C(1) and Pt−C(1) distances are 2.040(5) and 1.984(5) Å, respectively. The angle defined by the two planes Fe−P(1)−P(2)−Pt and Fe−C(1)−Pt is 6.02°. The length of the C(1)=N double bond [1.234(6) Å] compares with that of other dimetallic isocyanide-bridged systems. Distances of 1.239(7) and 1.23(3) Å have been reported for $[Ni_2(\mu\text{-dppm})_2\{\mu\text{-}C{=}NMe\}(CNMe)_2]$ and for $[Pd_2(\mu\text{-dppm})_2\{\mu\text{-}C{=}NMe\}(CNMe)_2][PF_6]_2$.[25,26] The C(1)−N−C(2) bending of 122.0(4)° is even more accentuated than in the above-mentioned homodimetallic Ni−Ni [129.9(6)°] and Pd−Pd systems [131.0(2)°], and parallels that of $[Fe_2(\mu\text{-}C{=}NEt)_3(CNEt)_6]$ [123.1(1)°].[27] Due to the bending of the organic

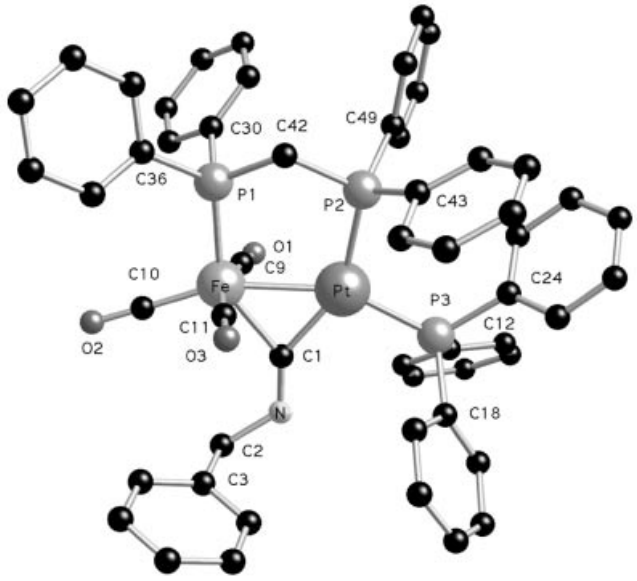

Figure 3. View of the crystal structure of **3c** showing the atom numbering scheme; selected bond lengths [Å] and angles [°]: Fe−Pt 2.5577(10), Fe−P(1) 2.240(2), Pt−P(2) 2.3087(13), Pt−P(3) 2.2632(13), Pt−C(1) 1.984(5), Fe−C(1) 2.040(5), Fe−C(9) 1.788(5), Fe−C(10) 1.762(5), Fe−C(11) 1.786(5), C(1)−N 1.234(6), C(2)−N 1.470(6), C(10)−O(2) 1.150(6), C(10)−O(2) 1.150(6), C(11)−O(3) 1.152(6), P(1)−C(42) 1.854(9), P(2)−C(42) 1.859(5); C(1)−N(1)−C(2) 122.0(4), Pt−C(1)−Fe 78.9(2), Fe−Pt−C(1) 51.51(14), C(1)−Fe−Pt 49.58(12), C(1)−Fe−P(1) 144.08(13), C(1)−Pt−P(2) 148.99(14), C(1)−Pt−P(3) 102.70(14), C(1)−Fe−C(9) 82.1(2), C(1)−Fe−C(10) 110.2(2), C(1)−Fe−C(11) 83.1(2), N−C(1)−Fe 140.0(3), N−C(1)−Pt 140.9(4), P(1)−Fe−Pt 93.63(8), P(2)−Pt−P(3) 107.17(5), Fe−Pt−P(3) 154.18(4), P(1)−C(42)−P(2) 112.8(2)

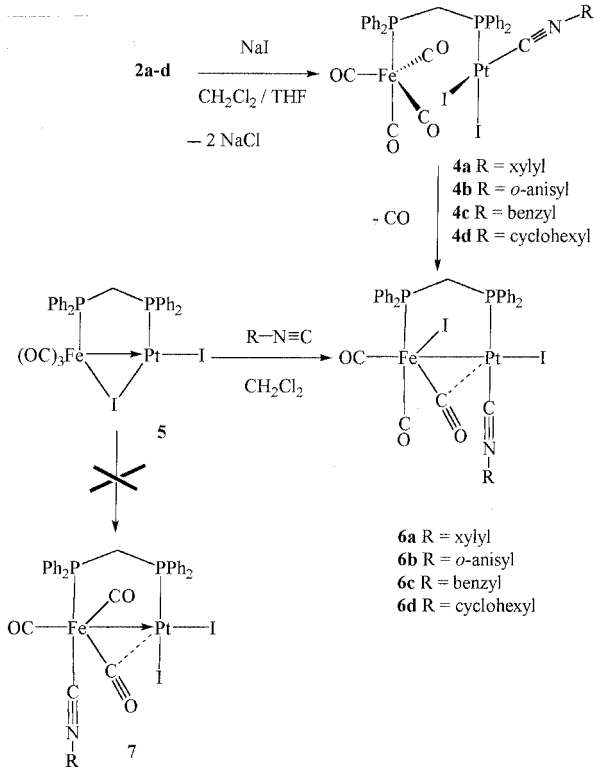
group R of the isocyanide bridge, two isomeric forms, with orientation towards Pt or Fe, are conceivable a priori. From Figure 3 it can be seen that from a steric point of view, an orientation of the benzyl group towards the carbonyliron fragment is imposed in order to avoid repulsion with the bulky PPh_3 ligand.

Iodide Migration from Pt to Fe

With the objective of obtaining additional information on the parameters influencing the structural features of **2,** we tried to prepare the iodo derivatives $[(OC)_4Fe(\mu\text{-dppm})PtI_2(CNR)]$ (**4**) in a metathesis reaction by addition of an excess of NaI to a CH_2Cl_2/THF solution of **2a−2d** according Scheme 2. Surprisingly, **4a** could not be isolated in a pure form. Instead, after 8 h at ambient temperature, and subsequent workup, red-brown crystals were isolated in a 60% yield. The spectroscopic data and elemental analysis were consistent with the formation of the heterodimetallic complex $[(OC)_2FeI(\mu\text{-dppm})(\mu\text{-CO})PtI(Xylyl\text{-}CN)]$ (**6a**). Compound **6a** can be described as a dinuclear complex, in which the Fe^I d^7 fragment interacts with the Pt^I d^9 fragment through a covalent Fe−Pt bond. This description, implying the formal oxidation of Fe and reduction of Pt, satisfies an 18-e configuration for Fe and a 16-e configuration for Pt. Mechanistically, this reaction can be rationalized as the migration of a *Pt*-bound iodide ligand to Fe,

initiated by the extrusion of a carbonyl ligand (due to the bigger diameter of iodide compared with a chloride ligand). Although an intermolecular ligand transfer cannot be excluded unambiguously, an intramolecular migration seems more probable. This hypothesis is corroborated by the observation that isolated **4c** or **4d** are converted within ca. 8 h quantitatively to **6c**, **6d** after dissolution in CH_2Cl_2. Halide transfer reactions are not unusual in heterodimetallic chemistry.[28−33] For example, the reaction of *cis*-[Pt(DMSO)$_2$Cl$_2$] with [CpRh(CO)(Ph$_2$Ppy)] yielded (via some intermediates) the $Rh^{II}-Pt^{I}$ compound [CpRhCl(μ-Ph$_2$Ppy)Pt(CO)Cl] by mutual CO/chloride exchange.[28]



Scheme 2

Spectroscopic Data

^{31}P NMR spectroscopic monitoring of the metathesis reaction of **2b** in a $CDCl_3$/acetone solution revealed the formation of a new species whose chemical shifts [δ = 66.5 (P_{Fe}) and −1.0 (P_{Pt})] and coupling constants ($^2J_{P,P}$ = 28, $^1J_{P,Pt}$ = 3168, $^3J_{P,Pt}$ = 73 Hz) are very similar to those of **2b**, indicating the formation of **4b** as an intermediate. In the course of several hours, a new AX pattern due to **6b** emerged. It consists of two doublets at δ = 49.1 ppm ($^{2+3}J_{P,P}$ = 75 Hz), assigned to the *Fe*-bound phosphorus nucleus, and at δ = 6.4 ppm for the *Pt*-bound phosphorus nucleus. All resonance signals are flanked by ^{195}Pt satellites, the Pt−P couplings are 152 and 3159 Hz. After 7 h, **4b** was completely converted to **6b**. The IR spectrum of **4b** (recorded in CH_2Cl_2) exhibits 4 vibrations due to the Fe(CO)$_4$ fragment, whose positions are, as expected, very close to that of **2b**. However, the ν(C≡N) absorption at 2093 cm^{-1} shifts to a lower frequency by 11 cm^{-1}, relative to the chloro precursor **2b**. The IR spectrum of **6b** exhibits two terminal ν(CO) stretching modes at 2013 and 1947 cm^{-1}, a vibration due to a semi-bridging carbonyl ligand is found at 1840 cm^{-1}. The strong absorption at 2189 cm^{-1} is assigned to the ν(CN) stretching mode of the terminally bound isocyanide ligand on Pt.

We were further interested in examining the reactivity of the iodide-bridged complex **5** towards the addition of stoichiometric amounts of isocyanide. This reaction could also a priori lead to **6** by the coordination of CNR on Pt and the formation of a terminal iron−iodine bond. Alternatively, the formation of an isomeric complex of type **7**, bearing a terminal CNR ligand on a formally Fe^0 center and two iodine ligands on a Pt^{II} center (the two metal atoms connected by a dative metal−metal bond), could be envisaged. However, performing this experiment in dichloromethane at ambient temperature with xylyl-, benzyl- or cyclohexyl isocyanide exclusively afforded **6a**−**6d**, with excellent yields.

It is interesting to compare this reactivity pattern of **5** towards the CNR donor ligand, with the results of Shaw's group who used PPh_3. In the latter case, the iodide bridge between the two metal atoms remained intact and the formation of [(CO)$_3$Fe(μ-I)(μ-dppm)Pt(PPh$_3$)I] was observed.[20]

Crystal Structure of [(OC)$_2$FeI(μ-CO)(μ-dppm)PtI-(CNC$_6$H$_{11}$)]·CH$_2$Cl$_2$ (6d)

Suitable red-violet crystals were obtained by slow diffusion of heptane into a saturated dichloromethane solution of **6d**. The molecular structure of the cyclohexyl derivative, including the atom numbering scheme is shown in Figure 4 with selected bond lengths and angles. The iron and platinum moieties are linked by a dppm bridge giving a five-membered Fe−P−C−P−Pt ring. The Fe−Pt distance of 2.6981(8) Å confirms the existence of a metal−metal bond, and is close to that of [(OC)$_3$Fe{Si(OMe)$_3$}(μ-dppa)Pt(H)(PPh$_3$)] [2.670(2) Å],[15] but appreciably longer than that of **3c**. The Pt−C(3) distance of 2.250(5) Å and the angles Fe−C(3)−O(3) [158.5(4)°] and Pt−C(3)−O(3) [118.6(3)°] indicate the presence of a semi-bridging carbonyl ligand, as suggested by the IR spectra. The Fe atom is located in a distorted octahedral environment due to the semi-bridging C(3)O(3) group [C(2)−Fe−I(1) 114.7(2)°, C(2)−Fe−C(3) 104.1(2)°]; the P(1) and I(1) atoms are in a mutual *cis* arrangement [I(1)−Fe−P(1) 87.42(4)°], whereas the remaining coordination sites are occupied by the Pt atom and three carbonyl groups. The square-planar geometry around Pt [neglecting the weak Pt−C(3) interaction] is achieved by bonding with Fe, P(2), C(29) and I(2). The latter I atom is *cis* to P(2) [I(2)−Pt−P(2) 90.50(4)°] and *trans* to the Fe−Pt bond [I(2)−Pt−Fe 168.95(2)°], forming a torsion angle I(1)−Fe−Pt−I(2) of 15.44°.

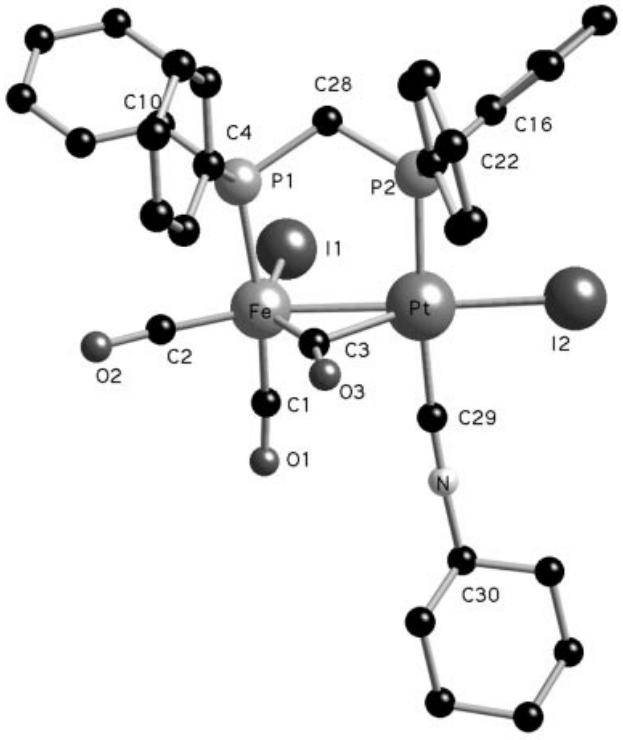


Figure 4. View of the crystal structure of **6d** showing the atom numbering scheme; selected bond lengths [Å] and angles [°]: Fe−Pt 2.6981(8), Fe−I(1) 2.660(5), Fe−P(1) 2.2712(13), Pt−P(2) 2.2891(12), Pt−I(2) 2.6553(6), Pt−C(29) 1.980(5), Pt−C(3) 2.250(5), Fe−C(1) 1.813(6), Fe−C(2) 1.755(6), Fe−C(3) 1.800(4), C(29)−N 1.146(6), C(1)−O(1) 1.130(7), C(2)−O(2) 1.157(7), C(3)−O(3) 1.174(6), P(1)−C(28) 1.822(5), P(2)−C(28) 1.832(4); N−C(29)−Pt 175.6(5), C(29)−N−C(30) 177.4(6), Pt−C(3)−Fe 82.7(2), Fe−Pt−C(29) 93.59(14), I(1)−Fe−Pt 85.40(3), I(2)−Pt−Fe 168.95(2), I(1)−Fe−P(1) 87.42(4), I(2)−Pt−P(2) 90.50(4), C(29)−Pt−P(2) 174.74(13), C(29)−Pt−Fe 93.59(14), C(1)−Fe−C(2) 87.4(2), C(1)−Fe−C(3) 94.2(2), C(2)−Fe−C(3) 104.1(2), O(3)−C(3)−Fe 158.5(4), O(3)−C(3)−Pt 118.6(3), P(1)−Fe−Pt 96.63(4), Fe−Pt−P(2) 91.44(4), P(1)−C(28)−P(2) 111.5(2)

Conclusion

These investigations have shown that **1** is a very useful precursor for the synthesis of heterodimetallic complexes ligated by aliphatic and aromatic isocyanide ligands in a terminal or bridging bonding mode. This study has shown that complexes **2**, resulting from the rupture of the dative Fe→Pt bond of **1**, possess diverging conformations in the crystalline state, depending on the nature of R of the CNR ligand. By varying (i) the steric and electronic properties of R, (ii) the spanning diphosphane ligand and (iii) the substitution of the two *Pt*-bound chloro ligands by other ligands, future studies may elucidate the origin of the different conformations of the Fe−P−C−P−Pt arrays encountered for **2d**, **2e**. Furthermore, the iodo complexes [$(OC)_2$FeI(μ-dppm)(μ-CO)PtI(RCN)] (**6**), obtained by intramolecular halide transfer, seem to be promising starting materials for reactivity studies towards unsaturated small molecules, for the transformation of the reactive CN triple bond to other organic functional groups, such as aminocarbenes, as well as for C−C coupling reactions.[17,34−38]

Experimental Section

General: All reactions were performed in Schlenk-tube flasks under purified nitrogen. Solvents were dried and distilled under nitrogen before use, toluene and hexane from sodium, dichloromethane from P_4O_{10}. Nitrogen was passed through BASF R3-11 catalyst and molecular sieve columns to remove residual oxygen and water. IR spectra were recorded with a Nicolet Nexus 470 spectrometer. Elemental C, H, N analyses were performed with a Leco Elemental Analyser CHN 900. The ^{1}H, ^{31}P{^{1}H}, and ^{13}C{^{1}H} NMR spectra were recorded at 200.13, 81.01 and 50.32 MHz, respectively, with a Bruker ACP 200 instrument and a Bruker Avance 300 MHz (300.13 and 121.49 MHz for ^{1}H and ^{31}P, respectively). ^{31}P chemical shifts were referenced to 85% H_3PO_4 in H_2O, with downfield shifts reported as positive. ^{195}Pt chemical shifts were measured with a Bruker ACP 200 instrument (42.95 MHz) and externally referenced to K_2PtCl_4 in water, with downfield chemical shifts reported as positive. NMR spectra were recorded in pure $CDCl_3$, unless otherwise stated. The presence and amount of CH_2Cl_2 retained in **2a**−**2c**, **2e**, **3c**, **3e** and **6** were determined from the ^{1}H NMR spectra. The reactions were generally monitored by IR spectroscopy in the ν(CO) region. The isocyanides were obtained from Aldrich and Fluka and were used as received.

Preparation of [$(OC)_4$Fe(μ-dppm)$PtCl_2$(CNR)] (2): To a suspension of **1** (409 mg, 0.5 mmol) in CH_2Cl_2) (10 mL), the equivalent amount of CNR was added (over 5 min) in several portions as a solid, or dropwise via a syringe in the case of liquid isocyanides. The resulting clear yellow solution was stirred for a further 10 min, then the solvent was removed affording yellow **2**, in quantitative yields, in sufficient purity for further reactions. If required, **2** can be recrystallized in a refrigerator from a saturated CH_2Cl_2 solution layered with Et_2O or hexane.

2a: Yield: 474 mg. IR (CH_2Cl_2): $\tilde{\nu}$ = 2199 (s) ν(C≡N); 2051 (s), 1978 (m), 1942 (vs), 1936 (sh) ν(CO). ^{1}H NMR: δ = 1.93 (s, 6 H, xylyl−CH_3), 4.52 (t, 2 H, CH_2, $^3J_{P,H}$ = 11.0 Hz), 6.94−7.92 (m, 23 H, phenyl). $C_{58}H_{31}Cl_2FeNO_4P_2Pt{\cdot}CH_2Cl_2$ (949.45 + 84.93): calcd. 2d: Yield: 463 mg. IR (CH_2Cl_2): $\tilde{\nu}$ = 2205 (s) ν(C≡N); 2050 (s), 1971 (m), 1938 (vs), 1928 (sh) ν(CO). ^{1}H NMR: δ = 3.73 (s, 3 H, OCH_3), 4.53 (t, 2 H, CH_2, $^2J_{P,H}$ = 12.0 Hz), 6.54−7.98 (m, 24 H, phenyl). $C_{36}H_{33}Cl_2FeNO_4P_2Pt$ (927.44): calcd. C 46.62, H 3.59, N 1.51; found C 46.23, H 3.22, N 1.40.

2e: Yield: 506 mg. IR (CH_2Cl_2): $\tilde{\nu}$ = 2223 (s) ν(C≡N); 2052 (s), 1978 (m), 1943 (vs), 1932 (sh) ν(CO). ^{1}H NMR: δ = 2.35 (s, 3 H, CH_3), 3.99 (s, 2 H, NCH_2), 4.40 (t, 2 H, CH_2, $^2J_{P,H}$ = 11.2 Hz), 7.21−7.73 (m, 24 H, phenyl). $C_{38}H_{31}Cl_2FeNO_6P_2PtS{\cdot}0.5\ CH_2Cl_2$

(1013.53 + 42.47): calcd. C 44.13, H 3.06, N 1.33; found C 44.89, H 3.40, N 1.32.

Preparation of [(OC)$_3$Fe(μ-C=N−R)(μ-dppm)Pt(PPh$_3$)] (3): A solution of an excess of $NaBH_4$ (106 mg, 2.8 mmol) in MeOH (5 mL) was added dropwise to a solution of **2** (0.5 mmol) and PPh_3 (131 mg, 0.5 mmol) in CH_2Cl_2 (15 mL). The orange solution was stirred for 1 h, and the solvents were then removed under reduced pressure. Extraction with CH_2Cl_2 afforded **3** as yellow-orange solids in moderate yields (50−60%). Analytically pure **3** was obtained by recrystallization in a refrigerator from a saturated CH_2Cl_2 solution, layered with Et_2O or hexane.

3c: Yield: 282 mg, 52%. IR (CH_2Cl_2): $\tilde{\nu}$ = 1992 (m), 1924 (vs) ν(CO); 1679 (m, br.) ν(C=N). ^{1}H NMR: δ = 3.75 (dt, 2 H, CH_2, $^2J_{P,H}$ = 1.5, 10.0, $^3J_{Pt,H}$ = 39.8 Hz), 4.90 (s, br., 2 H, NCH_2), 6.82−7.55 (m, 40 H, phenyl). $C_{54}H_{44}FeNO_3P_3Pt$·0.5 CH_2Cl_2 (1098.80 + 42.47): calcd. C 57.36, H 3.97, N 1.23; found C 57.34, H 3.94, N 1.27.

3d: Yield: 305 mg, 56%. IR (CH_2Cl_2): $\tilde{\nu}$ = 1988 (m), 1921 (vs) ν(CO); 1689 (m, br.) ν(C=N). ^{1}H NMR: δ = 0.82−1.84 (m, 11 H, C_6H_{11}), 3.71 (t, 2 H, CH_2, $^2J_{P,H}$ = 10.0, $^3J_{Pt,H}$ = 40.0 Hz), 6.89−7.74 (m, 35 H, phenyl). $C_{53}H_{48}FeNO_3P_3Pt$ (1090.82): calcd. C 58.36, H 4.43, N 1.28; found C 58.58, H 4.68, N 1.28.

3e: Yield: 300 mg, 51%. IR (CH_2Cl_2): $\tilde{\nu}$ = 1996 (m), 1928 (vs) ν(CO); 1648 (m, br.) ν(C=N). ^{1}H NMR: δ = 2.17 (s, 2 H, CH_3), 3.75 (t, 2 H, CH_2, $^2J_{P,H}$ =10.0, $^3J_{Pt,H}$ = 40.3 Hz), 4.88 (s, br., 2 H, NCH_2), 6.89−7.55 (m, 40 H, phenyl). $C_{55}H_{46}FeNO_5P_3PtS$·1.5 CH_2Cl_2 (1176.93 + 127.39): calcd. C 52.03, H 3.79, N 1.07; found C 52.04, H 3.98, N 1.26.

Preparation of [(OC)$_2$FeI(μ-dppm)(μ-CO)PtI(CNR)] (6). Method A: NaI, in a 5-fold excess, was added to a solution of **2** (0.2 mmol) in a mixture of THF/CH_2Cl_2 (50:50, 10 mL). The initially orange-yellow solution gradually changed to red-violet. After 8 h, all volatiles were removed under reduced pressure. The residue was redissolved in CH_2Cl_2, NaI and NaCl were filtered off, and the solution concentrated to ca. 5 mL. After layering with heptane, **6** was obtained in the form of air-stable red-violet crystals in yields varying between 50 and 60%. When the reaction was stopped after ca. 1 h by removing all volatiles, the intermediates [(OC)$_4$Fe(μ-dppm)PtI$_2$(CNR)] (**4**) (contaminated by small quantities of **6**) could be isolated after extraction with CH_2Cl_2, as yellow-orange solids. Selected spectroscopic data for **4c**: IR (ATR): $\tilde{\nu}$ = 2224 (m) ν(C≡N); 2048 (s), 1970 (m), 1940 (vs), 1926 (vs) ν(CO). ^{1}H NMR: δ = 4.71 (t, 2 H, CH_2, $^2J_{P,H}$ = 11.0 Hz), 4.21 (s, 2 H, NCH_2), 6.99−7.57 (m, 25 H, phenyl). **4d**: IR (ATR): $\tilde{\nu}$ = 2217 (m) ν(C≡N); 2047 (s), 1968 (m), 1940 (vs), 1927 (vs) ν(CO). **Method B:** An equimolar amount of CNR was added to a solution of **5** (543 mg, 0.5 mmol) in CH_2Cl_2 (15 mL). The red-violet solution was stirred for 15 min after which all volatiles were removed under reduced pressure affording almost quantitatively pure **6**. If required, **6** can be recrystallized in a refrigerator from a saturated CH_2Cl_2 solution, layered with heptane.

6a: Yield: 134 mg, 61%. IR (ATR): $\tilde{\nu}$ = 2183 (s) ν(C≡N); 2011 (vs), 1946 (vs), 1844 (m) ν(CO). ^{1}H NMR: δ = 2.50 (s, 6 H, xylyl−CH_3), 4.55 (t, 2 H, CH_2, $^3J_{P,H}$ = 12.0 Hz), 6.95−7.86 (m, 23 H, phenyl). $C_{37}H_{31}FeI_2NO_3P_2Pt$·$CH_2Cl_2$ (1104.34 + 84.93): calcd. C 38.38, H 2.80, N 1.18; found C 38.53, H 2.70, N 1.17.

6b: Yield: 128 mg, 58%. IR (ATR): $\tilde{\nu}$ = 2188 (s) ν(C≡N); 2012 (vs), 1947 (vs), 1840 (m) ν(CO). ^{1}H NMR: δ = 3.85 (s, 3 H, OCH_3), 4.64 (t, 2 H, CH_2, $^3J_{P,H}$ = 12.0 Hz), 6.64−7.95 (m, 24 H, phenyl). $C_{36}H_{29}FeI_2NO_5P_2Pt$·$CH_2Cl_2$ (1105.87 + 84.93): calcd. C 37.31, H 2.62, N 1.18; found C 37.82, H 3.02, N 1.20.

6c: Yield: 133 mg, 61%. IR (ATR): $\tilde{\nu}$ = 2224 (s) ν(C≡N); 2015 (vs), 1944 (vs), 1837 (m) ν(CO). ^{1}H NMR: δ = 4.57 (m, not resolved, 2 H, CH_2), 5.07 (s, 2 H, NCH_2), 7.08−7.95 (m, 25 H, phenyl). $C_{36}H_{29}FeI_2NO_3P_2Pt$·$CH_2Cl_2$ (1090.32 + 84.93): calcd. C 37.81, H 2.66, N 1.19; found C 37.94, H 3.04, N 1.25.

6d: Yield: 121 mg, 56%. IR (ATR): $\tilde{\nu}$ = 2213 (s) ν(C≡N); 2008 (vs), 1952 (vs), 1851 (m) ν(CO). ^{1}H NMR: δ = 1.33−2.10 (m, 11 H, C_6H_{11}), 4.57 (t, 2 H, CH_2, $^3J_{P,H}$ = 11.5 Hz), 7.06−7.87 (m, 20 H, phenyl). $C_{36}H_{33}FeI_2NO_3P_2Pt$·$CH_2Cl_2$ (1082.35 + 84.93): calcd. C 37.04, H 3.02, N 1.20; found C 37.54, H 3.42, N 1.28.

Collection of the X-ray Data and Structure Determination: Data were collected with a Siemens Stoe AED2 four-circle diffractometer (**3c**) or a Siemens Stoe IPDS (**2d**, **2e**, **6d**) using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The final unit cell parameters were obtained by least squares on the setting angles for 20 reflections with 2Θ = 20−23°. Data were corrected by semi-empirical methods for the absorption correction, using Ψ scans. SHELXS-97 and SHELXL-97 computer programs were used.[39] CCDC-179020 to -179023 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Crystal Structure Determination of 2d: Collection of crystallographic data: intensity data were collected using the Ω/2Θ scan mode at 173 K. $C_{36}H_{33}Cl_2FeNO_4P_2Pt$ (927.41): yellow crystals with approximate dimensions 0.4 × 0.3 × 0.2 mm, triclinic, space group $P\bar{1}$; a = 9.713(2), b = 11.393(3), c = 17.435(6) Å, α = 79.91(4), β = 86.45(3), γ = 70.11(13)°, V = 1786.3(8) Å^3, Z = 2, $\rho_{calcd.}$ = 1.724 g cm^{-3}, $F(000)$ = 912; 7273 independent reflections in the scan range 4.74° < 2θ < 54°, of which 6567 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 424 parameters; $R1 = \Sigma|F_o - F_c|/\Sigma|F_o|$ = 0.0330 [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2}$ = 0.0896 (all data), GoF = 1.052; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries, except for H(1) and H(2), which were refined isotropically. Highest residual electron density 1.764 e·Å^{-3}.

Crystal Structure Determination of 2e: Collection of crystallographic data: intensity data were collected at 293 K. $C_{38.5}H_{32}Cl_3FeNO_6P_2PtS$ (1055.94): yellow crystals with approximate dimensions 0.2 × 0.3 × 0.4 mm, triclinic, space group $P\bar{1}$; a = 11.178(2), b = 11.245(2), c = 19.578(3) Å, α = 85.392(11), β = 80.148(11), γ = 63.417(10)°, V = 2168.2(5) Å^3, Z = 2, $\rho_{calcd.}$ = 1.617 g cm^{-3}, $F(000)$ = 1038; 6487 independent reflections in the scan range 4.2° < 2θ < 48.5°, of which 6086 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 488 parameters; $R1 = \Sigma|F_o - F_c|/\Sigma|F_o|$ = 0.0628 [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2}$ = 0.1615 (all data), GoF = 1.091; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 2.278 e·Å^{-3}.

Crystal Structure Determination of 3c: Collection of crystallographic data: intensity data were collected at 293 K. $C_{54.5}H_{45}ClFeNO_3P_3Pt$ (1141.21): orange crystals with approximate dimensions 0.2 × 0.3 × 0.35 mm, triclinic, space group $P\bar{1}$; a = 11.713(2), b = 12.779(3), c = 18.798(4) Å, α = 107.03(3), β = 92.26(3), γ = 113.18(3)°, V = 2434(9) Å^3, Z = 2, $\rho_{calcd.}$ = 1.557 g cm^{-3}, $F(000)$ = 1138; 8562 independent reflections in the scan

range $3.62° < 2\theta < 50.0°$, of which 7871 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 594 parameters; $R1 = \Sigma|F_o - F_c|/\Sigma|F_o| = 0.0323$ [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2} = 0.0861$ (all data), $GoF = 1.009$; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 1.452 e·Å^{-3}.

Crystal Structure Determination of 6d: Collection of crystallographic data: intensity data were collected at 173 K. $C_{36}H_{35}Cl_2FeI_2NO_3P_2Pt$ (1167.23): red violet crystals with approximate dimensions 0.3 × 0.2 × 0.2 mm, monoclinic, space group $P2_1/c$; $a = 15.236(3)$, $b = 11.781(2)$, $b = 22.430(5)$ Å, $\beta = 98.17(3)°$, $V = 3985.4(14)$ Å^3, $Z = 4$, $\rho_{calcd.} = 1.945$ g cm^{-3}, $F(000) = 2224$; 6815 independent reflections in the scan range $4.38° < 2\theta < 50.0°$, of which 5560 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 433 parameters; $R1 = \Sigma|F_o - F_c|/\Sigma|F_o| = 0.0289$ [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2} = 0.0642$ (all data), $GoF = 0.931$; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 0.994 e·Å^{-3}.

Keywords: Cobalt / Peroxides / Radicals / Radiation chemistry

The long-lived transient complexes (2,3,9,10-tetramethyl-1,4,8,11-tetraazacyclo-tetradeca-1,3,8,10-tetraene)(H_2O)-Co^{III}–OOR^{2+}, [(tim)(H_2O)Co^{III}–O_2R]$^{2+}$ (R = CH_2OH, CH_2CN, CCl_3) were prepared from the reaction of [Co^{II}(tim)(H_2O)$_2$]$^{2+}$ with the corresponding peroxyl radicals, applying radiation chemistry techniques. The resultant transient complexes, which are relatively stable (lifetime of days), were subsequently treated with methylperoxyl ($CH_3O_2^{\cdot}$) radicals to form [Co^{III}(tim)(H_2O)$_2$]$^{3+}$ and formaldehyde. The results point out that the $CH_3O_2^{\cdot}$ radicals rapidly oxidize MOOR peroxides.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Peroxyl radicals are key intermediates in a large variety of oxidation processes that include, amongst others, catalytic oxidations by peroxides, which proceed via radical mechanisms[1] (for example processes which involve the Fenton reaction[2]), catalytic oxidations by dioxygen,[3] and radical processes, involving organic radicals, in oxygenated solutions.[4] Of special importance here are deleterious radical processes in biological systems.[5] It is therefore not surprising that the properties of peroxyl radicals have been studied by many research teams and summarized in several comprehensive reviews.[6]

Surprisingly enough the kinetics and reaction mechanisms of peroxyl radicals with different types of peroxides have not been studied — no rates of such reactions are reported in the compilation of the rates of reaction of peroxyl radicals.[4] This is surprising as peroxides are formed in many of the reactions of peroxyl radicals and might therefore participate in the processes studied and thus affect the nature of the final products in a variety of catalytic oxidations and biological processes. Of special importance are systems where one of the reactants is a transition metal peroxo complex, as intermediates of this type are formed in most catalytic — including enzymatic — processes.[1–3]

Recently, while studying the properties of the relatively long lived peroxide [L^1(H_2O)$Co^{III}-OOCH_3$]$^{2+}$ (L^1 = tim = 2,3,9,10-tetramethyl-1,4,8,11-tetraazacyclotetradeca-1,3,8,10-tetraene) it was noted that the $CH_3OO^{\cdot}$ radical reacts with it via reaction (1):[7]

$$[L^1(H_2O)Co^{III}-OOCH_3]^{2+} + CH_3OO^{\cdot} \rightarrow [L^1Co^{II}(H_2O)_2]^{2+} + CH_2O + CH_3OH + O_2 \quad (1)$$

$k = 1.5 \times 10^9$ M^{-1}s^{-1} [7]

i.e. via a mechanism which yields the same products as one of the possible mechanisms for the decomposition of $CH_3OOOOCH_3$,[8] and thus results in the same products as the dimerization of the peroxyl radical. However, the formation of the dimer $CH_3OOOOCH_3$ in this reaction seems unlikely. It is therefore of interest to note that the same products would also be expected if the peroxyl radical acts as a reducing agent towards the [L^1(H_2O)$Co^{III}-OOCH_3$]$^{2+}$ peroxide. {The CH_3OO^+ formed will decompose in aqueous solutions, maybe synchronously, into dioxygen and methanol and the [L^1(H_2O)$Co^{II}-OOCH_3$]$^+$ into [L^1Co^{II}(H_2O)$_2$]$^{2+}$ and CH_3OOH which yields CH_2O}. In principle, the same products will also be formed if the peroxyl radicals oxidize the [L^1(H_2O)$Co^{III}-OOCH_3$]$^{2+}$ peroxide forming [L^1(H_2O)$Co^{IV}-OOCH_3$]$^{3+}$ and CH_3OO^-. {[L^1(H_2O)-

$Co^{IV}-OOCH_3]^{3+}$ has then to decompose into $[L^1Co^{II}(H_2O)_2]^{2+} + CH_3^+ + O_2$ in order to form the observed products.} However, as L^1 stabilizes low-valent complexes due to the four imine ligating groups, the formation of a Co^{IV} transient complex seems unlikely. However, the results of this study point out that the peroxyl radicals oxidize the peroxide bound to the central cation.

The reaction of the peroxyl radical with $[L^1(H_2O)Co^{III}-OOCH_3]^{2+}$ is extremely fast,[7] even faster than the dimerization reaction of the radical ($CH_3OO^{\cdot} + CH_3OO^{\cdot}$ = products, $k = 4 \times 10^8$ M^{-1}s^{-1}).[9] This observation is of special interest as the reactions of peroxyl radicals with many transition metal complexes yield transient complexes of the type $L_mM^{n+1}-OOR$,[5b] and complexes of this type are also formed in a variety of biological and catalytic processes involving oxidation by peroxides or dioxygen.[1−3] Recent reports suggest that these transient complexes are relatively stable in some systems.[10] In some cases for transient complexes of the type $L_mM^{n+1}-OOH$ the reversible, pH dependent, switching of the hydro-peroxide complex and the peroxide complex has been demonstrated.[11] Reactions of the $L_mM^{n+1}-OOR$ complexes with peroxyls are therefore mechanistically of similar importance to the reaction of high-valent iron-oxenes with peroxides.[12]

It therefore seemed of crucial importance to study the mechanisms and rates of reactions of a variety of peroxyl radicals with a variety of peroxides in order to elucidate the detailed mechanisms of these reactions and the factors that affect them and their rates. For the present study radiation chemistry techniques were chosen.[13,14] In order to obtain a better understanding of the mechanisms of the reactions studied it was decided to prepare relatively stable $[L(H_2O)Co^{III}-OOR]^{2+}$ ($R \neq CH_3$) complexes and react them with $CH_3O_2^{\cdot}$ radicals. Such a study was expected to yield different final products depending on whether the $CH_3O_2^{\cdot}$ radical reacted as an oxidizing or as a reducing agent. The results demonstrate that the complexes with R = CH_2OH, CH_2CN, CCl_3 are indeed stable enough.

Results

Formation of the Transients $[(tim)(H_2O)Co^{III}-OOR]$

The following solutions were irradiated by a short electron pulse from the linear accelerator. *MeOH/CH₃CN system:* 70% N_2O and 30% O_2 saturated solutions containing 0.3 M MeOH or CH_3CN and $[Co(tim)(H_2O)_2]^{2+}$ $(0.5-2.0) \times 10^{-4}$ M at pH = 3.0.

CCl_4 system: 70% Helium or Argon and 30% O_2 saturated solutions containing 0.1% CCl_4, 10% 2-propanol and $[Co(tim)(H_2O)_2]^{2+}$ $(0.5-2.0) \times 10^{-4}$ M at pH = 3.0.

Under these conditions more than 90% of the primary radicals are converted into the desired $^{\cdot}OOR$ (R = CH_2OH, CH_2CN, CCl_3) radicals during the pulse (see Exp. Sect.). In all the systems studied a formation reaction was observed after conversion of the initially formed radicals into the peroxyl radicals. A typical reaction is shown in Figure 1. The formation of the transients obey pseudo first order rate laws, under conditions of excess $[Co(tim)(H_2O)_2]^{2+}$, and the observed rates are proportional to the initial $[Co(tim)(H_2O)_2]^{2+}$ concentration (see Figure 2). The rates are independent of the concentration of all other components of the solution, pH, pulse intensity and wavelength of observation. The kinetics of the formation of the transient complexes indicate that they are produced from a reaction between $[Co(tim)(H_2O)_2]^{2+}$ and the specific peroxyl radical formed by the radiation, as in the reaction of $[Co(tim)(H_2O)_2]^{2+}$with methylperoxyl radicals.[7] Thus it is proposed that the reaction observed is:

$$[Co(tim)(H_2O)_2]^{2+} + RO_2^{\cdot} \rightarrow [(tim)(H_2O)Co^{III}-OOR]^{2+} \quad (2)$$

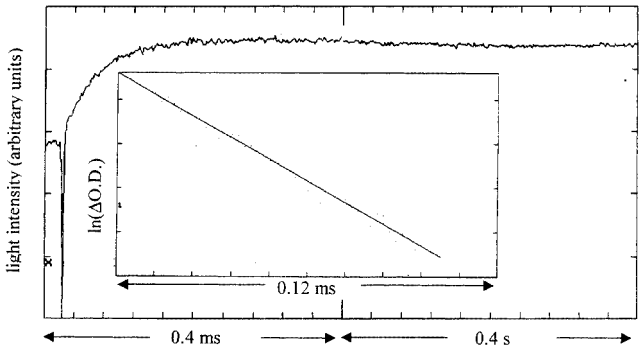

Figure 1. Increase of the absorption (at 314 nm) due to the formation of $[(tim)(H_2O)Co^{III}-OOCH_2CN]^{2+}$ in the presence of oxygen (30% O_2, 70% N_2O) and first order plot (insert); conditions: 0.3 M CH_3CN, 5×10^{-5} M $[Co(tim)(H_2O)_2]^{2+}$

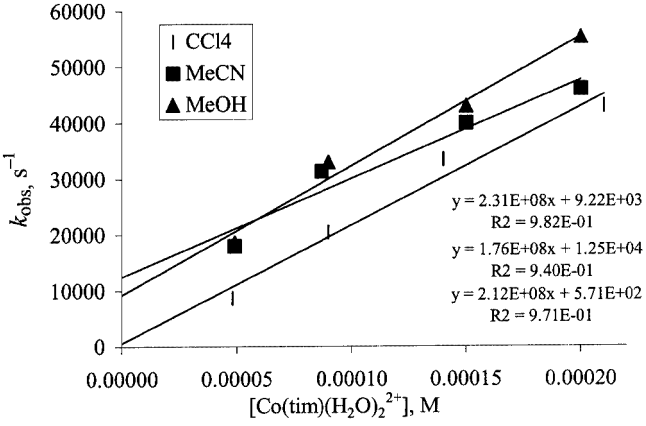

Figure 2. Dependence of k_{obs} for the transients formation on $[Co(tim)(H_2O)_2]^{2+}$

The derived second order rate constants, i.e. the specific rate constants of the cobalt peroxo complex formation, are calculated as $(1.8-2.3) \times 10^8$ M^{-1}s^{-1}, in good agreement with the value measured for the formation of the methylperoxo complex,[7] see Table 1.

Table 1. Formation rate constants of the complexes $[(tim)(H_2O)Co^{III}-OOR]$

CH_2CN	1.8
CCl_3	2.1
CH_3	1.8 [7]

Decomposition of the Transients $[(tim)(H_2O)Co^{III}-OOR]$

The transient complexes are relatively long lived. The transient complexes absorb in the UV region similar to $[(tim)(H_2O)Co^{III}-O_2CH_3]^{2+}$,[7] and they do not absorb around 520 nm where the absorption spectrum of $[Co(tim)(H_2O)_2]^{2+}$ has a maximum. The complex with R = CH_2CN is the longest lived one — it decomposes within about eight days — followed by R = CH_2OH, decomposing within 2.5 days, and R = CCl_3, decomposing within 1.5 days under the experimental conditions. Figure 3 shows a typical decomposition sequence. In comparison to these $[(tim)(H_2O)Co^{III}-O_2CH_3]^{2+}$ has a half life time of only approximately ten minutes at pH = 3.0 under the experimental conditions.[7] The final product of the decomposition in all cases is $[(tim)Co(H_2O)_2]^{3+}$ as verified by comparison of its spectrum with the spectra obtained after several days (see Figure 3).

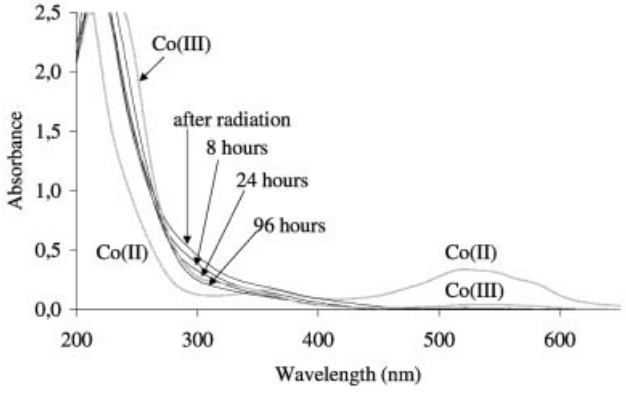

Figure 3. Decomposition sequence of the transient $[tim(H_2O)Co^{III}-OOR]$ (R = CH_2OH) over a period of four days after irradiation of an aqueous solution (70% N_2O and 30% O_2 saturated) containing $[Co(tim)(H_2O)_2]^{2+}$ (9.6×10^{-5} M) and CH_3OH (0.3 M) for 45 min in a ^{60}Co γ-source

Reaction of the Transients $[(tim)(H_2O)Co^{III}-OOR]$ (R = CH_2CN, CH_2OH) with the $^{\cdot}OOCH_3$ Radical

As the resulting peroxo complexes proved to be so stable, although experiments to purify them by ion exchange failed, these complexes were considered ideal candidates to investigate their reaction with a different peroxyl radical (reaction 3).

$$[(tim)(H_2O)Co^{III}-OOR]^{2+} + R'O_2^{\cdot} \rightarrow \text{products} \quad (3)$$

Initially, the simplest peroxyl radical, methylperoxyl, was chosen as we had previously investigated its reaction with the $[Co(tim)(H_2O)_2]^{2+}$ complex.[7] For these experiments the solutions were irradiated twice: during the first irradiation the relatively stable peroxo cobalt complex was formed and in the second irradiation the methylperoxyl radical was formed in the presence of the long-lived metal peroxy complex. The reaction of the peroxo cobalt complex with the methylperoxyl radical was monitored by recording UV/Vis spectra and measuring the amount of formaldehyde produced in the systems.

Solutions prepared as above to yield the peroxo cobalt complexes, for two different cobalt complex concentrations for each system (7.5×10^{-5} and 9.6×10^{-5} M for R = CH_2CN and 9.7×10^{-5} and 1.2×10^{-4} M for R = CH_2OH), were irradiated in the ^{60}Co γ-source for 35 and 45 minutes for R = CH_2CN and 40 and 55 minutes for R = CH_2OH. These times were calculated to yield a slight excess of the peroxyl radical over the $[(tim)Co(H_2O)_2]^{2+}$ complex and thus a radiation dose sufficient to convert all the $[(tim)Co(H_2O)_2]^{2+}$ complex into the specific peroxo cobalt complex, as verified by the absence of the specific absorbance of $[(tim)Co(H_2O)_2]^{2+}$ at 520 nm. The yield of the peroxo cobalt complex was calculated accordingly by the disappearance of the absorbance at 520 nm. Before the second radiation two thirds (8 mL) of the derived solution had N_2O bubbled through it; DMSO was then added to achieve a final concentration of 1 M, and distilled water saturated with O_2 added to give a final volume of 12 mL and a final concentration of 30% dioxygen and 70% N_2O. These solutions were then irradiated in the ^{60}Co γ-source by an additional dose producing $CH_3O_2^{\cdot}$ radicals so that

Table 2. Formaldehyde produced during the reaction of the complexes $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ with the methylperoxyl radical

R	$[(tim)Co(H_2O)_2{}^{2+}]_{init}$ M	$[(tim)(H_2O)Co^{III}-OOR]$[a] M	$[H_2CO]$ M
CH_2CN	7.5×10^{-5}	5.0×10^{-5}	5.1×10^{-5}
CH_2CN	9.6×10^{-5}	6.4×10^{-5}	5.9×10^{-5}
CH_2OH	9.7×10^{-5}	6.1×10^{-5}	5.8×10^{-5}[b]
CH_2OH	1.2×10^{-4}	8.2×10^{-5}	7.4×10^{-5} [b]

[a] Approximately 2/3 of the derived concentration after the first irradiation as measured by the disappearance of the UV/Vis band due to $[(tim)Co(H_2O)_2]^{2+}$. [b] These values were corrected for those derived in blank solutions.

$[CH_3O_2^{\cdot}] = 1.1[(tim)(H_2O)Co^{III}-OOR^{2+}]$. The UV/Vis spectra of these solutions were recorded. The spectra demonstrated that the $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ complexes were consumed during the second irradiation and transformed into $[Co^{III}(tim)(H_2O)_2]^{3+}$; no $[Co^{II}(tim)(H_2O)_2]^{2+}$ was formed during the second irradiation.

The yields of formaldehyde found in the two systems after the second irradiations are tabulated in Table 2. It should be noted that no formaldehyde was produced for R = CH_2CN after the first irradiation, i.e. during the formation of the $[(tim)(H_2O)Co^{III}-OOCH_2CN]^{2+}$ complex. For R = CH_2OH a slight amount of formaldehyde, similar to a blank solution containing only methanol, was produced after the first irradiation, probably due to the reaction of $^{\cdot}O_2CH_2OH$ radicals with each other.

Discussion

Formation of the Transients $[(tim)(H_2O)Co^{III}-OOR]^{2+}$

The rate constants of the reactions of $[Co(tim)(H_2O)_2]^{2+}$ with the peroxyl radicals $^{\cdot}OOR$ (R = CH_2OH, CH_2CN, CCl_3) to form $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ obtained in this work, $k = (1.8-2.3) \times 10^8$ M^{-1}s^{-1} agree well with the value of $k = (1.8 \pm 0.3) \times 10^8$ M^{-1}s^{-1} reported earlier for R = CH_3 [7] (see Table 1). These rates are in agreement with the known rates of ligand exchange of cobalt(II) in such complexes,[15] and indicate that the rate-determining step in these reactions is the ligand exchange, in agreement with reports for a variety of radical reactions with transition metal complexes.[15b]

The very long lifetime of the $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ transient complexes suggests that k_{-2} is very low, otherwise the transient complexes would decompose much faster via 2 $RO_2^{\cdot} \rightarrow$ products or via $RO_2^{\cdot}$ + $[(tim)(H_2O)Co^{III}-OOR]^{2+}$.

$$[Co(tim)(H_2O)_2]^{2+} + RO_2^{\cdot} \underset{k_{-2}}{\rightleftharpoons} [(tim)(H_2O)Co^{III}-OOR]^{2+} \quad (2)$$

The lifetimes of the transient complexes are relatively long, in the range of days at pH = 3.0 under the experimental conditions. As the transient complexes are strong oxidizing agents, such long lifetimes suggest that reactions of transients of this type with different substrates might play a crucial role both in catalytic systems and in deleterious biological processes.

Reaction of the Transients $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ (R = CH_2CN, CH_2OH) with the $^{\cdot}OOCH_3$ Radical

The reaction of $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ (R = CH_2CN, CH_2OH) with $^{\cdot}OOCH_3$ radicals was followed and shown to produce formaldehyde and $[Co^{III}(tim)(H_2O)_2]^{3+}$ in all cases. The amount of formaldehyde produced is equal to the concentration of the peroxometal complex reacted with the methylperoxyl radical.

The observation that all the transient complexes $[(tim)(H_2O)Co^{III}-OOR]^{2+}$ decomposed during the second irradiation suggests that under the experimental conditions the rate of reaction (4) is relatively fast, competing with reaction (5).

$$[(tim)(H_2O)Co^{III}-OOR]^{2+} + CH_3O_2^{\cdot} \rightarrow \text{products} \quad (4)$$

$$2CH_3O_2^{\cdot} \rightarrow \text{products} \ (k_5 = 4 \times 10^8 \text{ M}^{-1}\text{s}^{-1}) \quad (5)$$

From the dose rate of the ^{60}Co source and k_5 one can calculate (see Exp. Sect.) that $k_4 \geq 2 \times 10^5$ M^{-1}s^{-1}.

The fact that CH_2O is quantitatively formed in reaction (4), and no CH_2O is formed when the solutions are irradiated without the addition of DMSO, proves that the $CH_3O_2^{\cdot}$ radicals react as an oxidizing agent in this reaction. As the redox potential of the $CH_3O_2^{\cdot}$ radicals, 0.77 V vs. NHE,[8] is probably too low to oxidize the central Co^{III} cation, it is proposed that the reaction observed is:

$$[(tim)(H_2O)Co^{III}-OOR]^{2+} + CH_3O_2^{\cdot} \rightarrow [(tim)(H_2O)Co^{III}-OOR]^{3+} + CH_3O_2^{-} \quad (6)$$

followed by

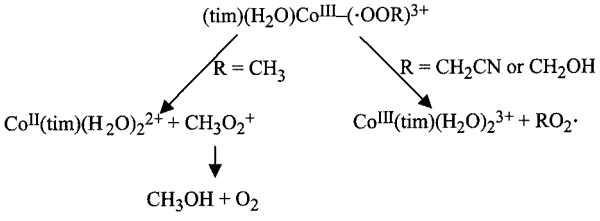
$$CH_3O_2^{-} + H_3O^{+}/H_2O \rightarrow CH_3OOH + H_2O/OH^{-} \quad (7)$$

$$CH_3OOH \rightarrow CH_2O + H_2O \quad (8)$$

and as the other final product is $[Co^{III}(tim)(H_2O)_2]^{3+}$ by

$$[(tim)(H_2O)Co^{III}-(^{\cdot}OOR)]^{3+} \rightarrow [Co^{III}(tim)(H_2O)_2]^{3+} + {}^{\cdot}OOR \rightarrow \text{products} \quad (9)$$

It is of interest to note that the final product of reaction (1), which is analogous to reaction (6), is $[Co^{III}(tim)(H_2O)_2]^{2+}$ and not $[Co^{II}(tim)(H_2O)_2]^{3+}$. If reaction (1) proceeds via an analogous mechanism to reaction (6) one has to conclude that the mechanism of decomposition of the transient complexes $[(tim)(H_2O)Co^{III}-(^{\cdot}OOR)]^{3+}$ depends on the redox potentials of the $ROO^{+}/ROO^{\cdot}$ couples. Electron-withdrawing substituents such as -CN and -OH are expected to shift this potential anodically and therefore these transient complexes decompose via the right pathway in the scheme whereas the transient with R = CH_3 decomposes via the left pathway.



In order to verify this hypothesis other stable complexes of the type $[(L)(H_2O)Co^{III}-OOR]$ have to be found where R is an electron-donating substituent.

Concluding Remarks

The results obtained in this study suggest that transient complexes of the type $L_mM^{n+1}-OOR$ might be relatively stable, at least for $M^{n+1} = Co^{III}$, even in aqueous solutions.

The results demonstrate that $RO_2^{\cdot}$ radicals react by fast reactions with complexes of the type $L_mM^{n+1}-OOR$. It is suggested that these reactions proceed via $R'O_2^{\cdot} + LM^{n+1}-(^{-}OOR) \rightarrow R'O_2^{-} + LM^{n+1}-(^{\cdot}OOR)$.

These reactions might be of crucial importance in a variety of catalytic and biological processes.

Experimental Section

Materials: All solutions were prepared from A.R. grade chemicals and from distilled water further purified by passing through a Milli Q Millipore setup, final resistivity >10 MΩ/cm.

$[Co(tim)Cl_2]PF_6$ was prepared according to literature methods[16] and characterized by NMR spectroscopy and UV/Vis spectrophotometry. Solutions of $[Co(tim)Cl_2]^+$ at pH = 2 were reduced by the introduction of the Adams catalyst, PtO_2, and bubbling dihydrogen for ca. 1 h. The spectrum of $[Co(tim)(H_2O)_2]^{2+}$ thus obtained is identical to that reported in the literature.[16]

Techniques: Solutions were handled by syringe techniques. pH values were measured with a Hanna HI 9017 pH meter and adjusted with $HClO_4$ and/or NaOH.

Irradiations: Pulse-radiolysis experiments were carried out with the Varian 7715 linear electron accelerator of the Hebrew University of Jerusalem. The pulse duration was 0.1−1.5 μs with a 200 mA current of 5 MeV electrons. The dose per pulse was 3−30 Gray. Irradiations were carried out in a 4 cm spectrosil optical cell, the analyzing light passing three times through the cell. A 150-W Xenon arc provided the analyzing light. The experimental setup was identical to that described earlier in detail.[17a]

For dosimetry, an N_2O-saturated solution containing 1×10^{-3} M KSCN was used. The yield of $(SCN)_2^{\cdot-}$ was measured by using $\varepsilon_{475} = 7600\ M^{-1}cm^{-1}$ and the dose per pulse was calculated assuming $G(SCN)_2^{\cdot-} = 6.0$[17] (the G value is defined as the number of molecules of each product/100 eV radiation absorbed by the solution) and an optical path of 12.3 cm. The dose per pulse was set so that the initial radical concentration was 2−20 μM. The value of the molar extinction coefficients calculated from the dosimetry measurements carry an error limit of 15% due to the scatter of the pulse intensity and uncertainties in G values.

A ^{60}Co source, Noratom, with a dose rate of 4 Gray/min was used for low dose-rate experiments and product analysis.

Simulation of k_4: The rate constant was estimated with the help of the Pro-K global analysis/simulation software by Applied Photophysics. The γ-source irradiation was mimicked by formally adding a reaction forming the radicals at the appropriate rate over the course of the reaction.

Production of Radicals: The radiolysis of water in dilute aqueous solutions can be summarized by:[17]

$$H_2O \xrightarrow{e^-,\gamma} e^-aq\ (2.65),\ \ldots \quad (10)$$

$$\ldots\ OH^{\cdot}\ (2.65),\ H^{\cdot}\ (0.60),\ H_2\ (0.45),\ H_2O_2\ (0.75)$$

(G value in parentheses). In concentrated solutions, the yields of the primary radicals are somewhat higher and those of H_2O_2 and H_2 are somewhat lower.[17]

In neutral N_2O-saturated solutions ($[N_2O] = 0.022$ M) the hydrated electron is converted into the hydroxyl radical via:

$$e^-aq + N_2O \xrightarrow{H_2O} N_2 + OH^- + {}^{\cdot}OH \quad (11)$$

$$k_{11} = 8.7 \cdot 10^9\ M^{-1}\ s^{-1}\ [18]$$

In acidic solutions the reaction of e^-_{aq} with H^+, which produces $H^{\cdot}$ atoms, becomes important:

$$e^-_{aq} + H^+ \rightarrow H^{\cdot}\ (k_{12} = 2.2 \times 10^{10}\ M^{-1}s^{-1}) \quad (12)\ [18]$$

however at pH > 3 the contribution of $H^{\cdot}$ atoms to the total radical yield is less than 10%.

Methyl radicals were prepared by the reaction of $^{\cdot}OH$ radicals with $(CH_3)_2SO$:

$$(CH_3)_2SO + {}^{\cdot}OH \rightarrow (CH_3)_2{}^{\cdot}S(O)OH \quad (k_{13} = 7.0 \times 10^9\ M^{-1}s^{-1}) \quad (13)[19]$$

$$(CH_3)_2{}^{\cdot}S(O)OH \rightarrow {}^{\cdot}CH_3 + CH_3S(O)OH \quad (k_{14} = 1.5 \times 10^7\ M^{-1}s^{-1}) \quad (14)[19]$$

$^{\cdot}CH_2OH$ and $^{\cdot}CH_2CN$ radicals were formed by hydrogen abstraction:

$$CH_3OH + {}^{\cdot}OH \rightarrow {}^{\cdot}CH_2OH + H_2O \quad (k_{15} = 9.7 \times 10^8\ M^{-1}s^{-1}) \quad (15)\ [18]$$

$$CH_3OH + {}^{\cdot}H \rightarrow {}^{\cdot}CH_2OH + H_2 \quad (k_{16} = 2.6 \times 10^6\ M^{-1}s^{-1}) \quad (16)\ [18]$$

$$CH_3CN + {}^{\cdot}OH \rightarrow {}^{\cdot}CH_2CN + H_2O \quad (k_{17} = 2.2 \times 10^7\ M^{-1}s^{-1}) \quad (17)\ [20a]$$

$$CH_3CN + {}^{\cdot}H \rightarrow {}^{\cdot}CH_2CN + H_2\ (k_{18} = 3.6 \times 10^6\ M^{-1}s^{-1}) \quad (18)\ [20b]$$

$^{\cdot}CCl_3$ radicals were prepared from solutions containing 2-propanol and CCl_4 via the reactions below (these reactions were performed in solutions containing argon or helium instead of N_2O):

$$CCl_4 + e^-_{aq} \rightarrow {}^{\cdot}CCl_3 + Cl^-\ (k_{19} = 1.3 \times 10^{10}\ M^{-1}s^{-1}) \quad (19)\ [21]$$

$$(CH_3)_2CHOH + {}^{\cdot}OH/{}^{\cdot}H \rightarrow {}^{\cdot}C(CH_3)_2OH + H_2O/H_2 \quad (k_{20} = 1.9 \times 10^9/7.4 \times 10^7\ M^{-1}s^{-1}) \quad (20)\ [18]$$

$$^{\cdot}C(CH_3)_2OH + CCl_4 \rightarrow CH_3COCH_3 + {}^{\cdot}CCl_3 + Cl^- + H^+ \quad (k_{21} = 1 \times 10^8\ M^{-1}s^{-1}) \quad (21)\ [22]$$

For experiments performed in this work the N_2O or Ar/He saturated solutions were mixed with identical O_2 saturated solutions in the ratio 70:30 prior to irradiation. Under these conditions the $^{\cdot}R$ radicals react with dioxygen to form the desired peroxyl radicals:

$$^{\cdot}R + O_2 \rightarrow RO_2^{\cdot} \quad (22)$$

These reactions are very fast and approach the diffusion controlled limit, e.g.: $k_{22} = 4.7 \times 10^9\ M^{-1}s^{-1}$ for $R = CH_3^{\cdot}$.[4,23]

Product Analysis: UV/Vis spectra were recorded on a Hewlett-Packard 8452A diode array spectrophotometer.

Analysis of formaldehyde was performed according to a literature procedure.[24] Formaldehyde reacts with a reagent containing 0.05 M acetylacetone, 1 M ammonium acetate and 0.033 M acetic acid, to form a yellow complex. The concentration of formaldehyde was determined colorimetrically at the wavelength of maximum absorption (412 nm).

Acknowledgments

This study was supported in part by grants from the Israel Science Foundation and from the Budgeting and Planning Committee of The Council of Higher Education and the Israel Atomic Energy Commission. D. M. wishes to express his thanks to Mrs. Irene Evens for her ongoing interest and support.

Selective Self-Assembly of a Sequential Bipyridine–Bipyrazine Ligand Strand into a Double-Stranded Cu^{I} Helicate

Julien Mathieu,[a] Alain Marsura,*[a] Nouzha Bouhmaida,[b] and Noureddine Ghermani[c]

Keywords: Helicates / Self-assembly / Copper / NMR spectroscopy / N ligands

In this paper new aspects on the self-assembly processes of didentate coordinating ligands leading to a double-stranded helicate are described. It was reported, that directionality in the self-recognition of Cu^{I} ions could be driven by factors relating to the electronic configuration of heterocycles in carefully designed heterotopic ligands. If the sequential bipyrazine–bipyridine ligand strand **4** reacts with 1 equiv. of Cu^{I} the dimetallic complex $[Cu_2(\mathbf{L4})_2][PF_6]_2$ is formed in a cooperative process. In this coordination compound the two strands are oriented in opposite directions (HT) as illustrated by the X-ray structure of $[Cu_2(\mathbf{L4})_2][PF_6]_2$.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

In recent years, intensive research on self-assembling processes has been derived. Among numerous structures published in the literature[1] the spontaneous formation of double-stranded or more complex organometallic helical complexes was extensively studied. The formation of a helicate depends on the nature of the metal and ligands, and sometimes on additional information introduced by appropriate templating.[2]

Some years ago, papers dealt with the self-assembly of a class of directional ligands, which led to saturated double-stranded heterotopic helicates with Cu^{I} [3] or Pd^{II}.[4] In the latter case the two strands selectively adopt a head-to-tail arrangement which leads to a C_2-symmetrically saturated heterotopic double-stranded helicate, with each Pd^{II} lying in a distorted five-coordinated environment, produced by the coordination of one bipyridine and one terpyridine subunit in each strand. In the former case introduction of bulky substituents in the basic quaterpyridine by Constable and co-workers[5,5a] was shown to induce a distinction between head-to-head (HH) and head-to-tail (HT) conformers leading to the exclusive formation of an (HH) C_2-symmetrical double-stranded Cu^{I} helicate in solution and in the solid state. In a previous study, Albrecht and Fröhlich synthesized a sequential ligand which contains one catecholate and one aminophenolate unit, in which the ability of the two nucleophilic sites to control the metal-directed self-assembly of chelates was reported.[6]

The aim of this work was to pursue the research to resolve unknown features on the Cu^{I} complexing behavior, concerning saturated heterotopic ligands, which here provide an original example, since they may be separated into one didentate "bipyridine" segment and one didentate "bipyrazine" segment upon complexation to metal ions. This means that only the same number of four inner nitrogen atoms could be engaged in the coordination with Cu^{I} to form a helicate, which is a coordination complex and not a chelate. Thus, a potentially induced directionality cannot come from outside modifications on the strand as reported for quaterpyridine examples[5] or from different nucleophilic centers as in the case of catecholate vs. aminophenolate,[6] but probably from the different electronic configuration of the bipyrazine nucleus[7] vs. bipyridine.

Results and Discussion

Because of a poor reproducibility of reactions leading to the rather difficult functionalization of 6,6′-dimethyl-2,2′-bipyrazine (**1**) into the 6-(hydroxymethyl)-6′-methyl-2,2′-bipyrazine (**3**), our concern was first to improve the synthesis of **4**. Using an unusual reagent like the tetrachloro-diphenylglycouril (Scheme 1) in the radical chlorination limiting step, we selectively obtained the 6-(chloromethyl)-6′-methyl-2,2′-bipyrazine in good yield (58%). our previously reported synthesis[7a] the changes in the synthetic pathway led to a better yield (70%) of **4**. An equimolar amount of $[Cu(CH_3CN)_4][PF_6]$ added to **4** in anhydrous CH_3CN spontaneously led to a deep-red solution which confirmed the occurrence of the Cu^I coordination process. A thin layer chromatographic control showed that the ligand was totally consumed in the reaction. The crude material was recrystallized by slow diffusion of ether through an acetonitrile solution of the copper complex giving deep-red crystals that were stable in air.

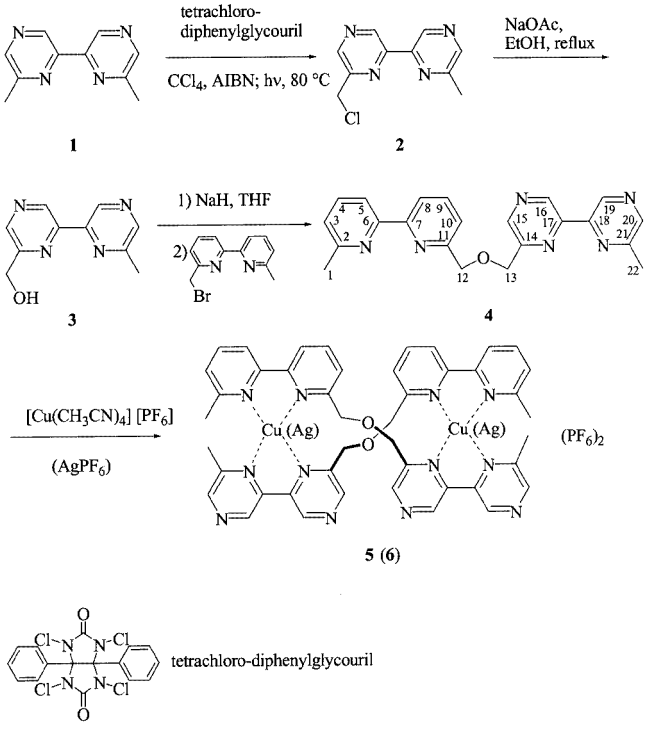

Scheme 1

The ligand **4** (or **L4**) spontaneously forms the desired $[L_2Cu_2][PF_6]_2$ dinuclear double-stranded helical structure (see Exp. Sect.) as indicated by X-ray diffraction in the solid state. This structure persists in the dissolved state as established by various spectroscopic techniques (UV/Vis, ^1H NMR, ^{13}C NMR, and ES MS). An UV/Vis spectrophotometric titration of the ligand **4** by $[Cu(CH_3CN)_4][PF_6]$ in CH_3CN solution (see B in Figure 1) exhibits a clear isosbestic point indicating that a single species was formed and the appearance of an MLCT at 450 nm indicates the effective coordination of the Cu^I atoms. The titration plots (see A in Figure 1) assess that this species has a composition of ca. 1 Cu atom for 1 equiv. of **4** in agreement with the stoichiometry expected for the dihelicate $[Cu_2(\mathbf{L4})_2]^{2+}$.[8] The formation of the dinuclear helicate proceeds with a positive cooperativity as indicated by the increasing values of the calculated binding constants $\log\beta_{metal-ligand}$:[9] $\log\beta_{11} = 5.93$·for $[Cu(\mathbf{L4})]^+$; $\log\beta_{12} = 9.35$·for $[Cu(\mathbf{L4})_2]^+$; $\log\beta_{22} = 15.29$·for $[Cu_2(\mathbf{L4})_2]^{2+}$. This means that the formation of the final helicate is highly favored. In addition, preliminary results with other metal ions like Ag^I giving the $[Ag_2(\mathbf{L4})_2]$ complex **6** (Figure 2) show that the double-stranded

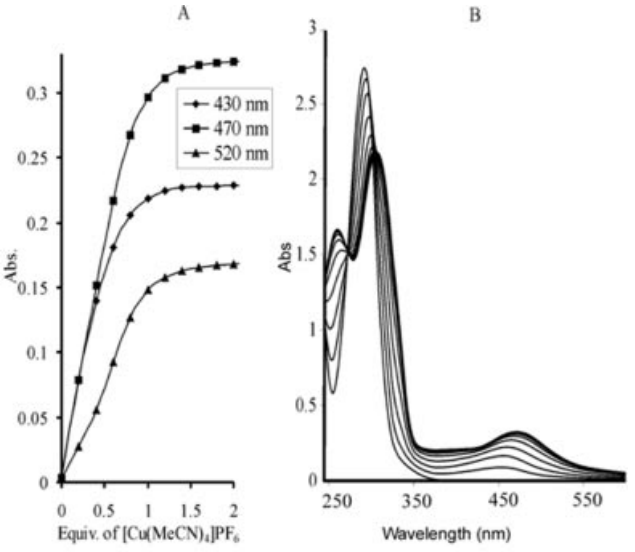

Figure 1. Spectrophotometric titration of the ligand **4** with $[Cu(MeCN)_4]PF_6$ (0.2−2.0 equiv.) in MeCN: A) plots of absorbance vs. added salt at three wavelengths and B) UV/Vis absorption spectra

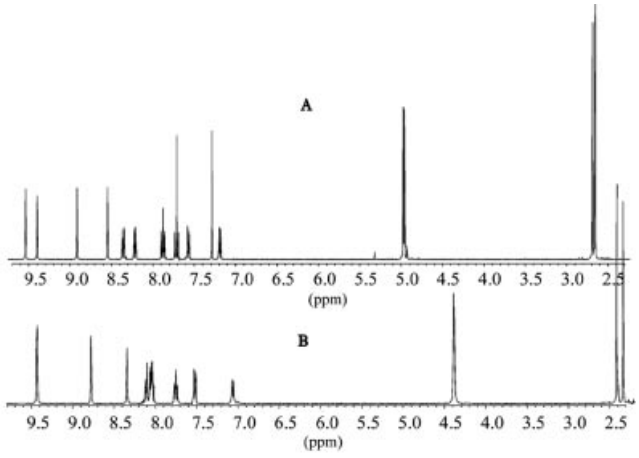

Figure 2. ^1H NMR spectra (400 MHz) of the free ligand **4** (A) and $[Ag_2(\mathbf{L4})_2][PF_6]_2$ in CD_3CN (B)

helix formation with **4** is probably a more extended phenomenon.

As previously established by Lehn and co-workers,[10] the ^1H NMR spectra of ligand **4** and its Cu^I complex (Figure 3) show the splitting of the enantiotopic methylene protons of the oxopropylene bridges in **4** (A_2 spin systems) to diastereotopic protons and doublets (AB spin systems) in the copper complex, on lowering the temperature. Methylene protons are also very useful for the estimation of the dynamic interconversion between dinuclear right-handed (*P*) and left-handed (*M*) enantiomeric helicates.[11] An investigation of the helical interconversion of complex **5** in a CD_3CN solution was realized using variable-temperature ^1H NMR experiments with analysis of the lateral methylene proton pattern between $\delta = 4.2$ and 3.4 ppm (Figure 3). The free energy for the (*P*)/(*M*) interconversion in solution was estimated by the Eyring equation as $\Delta G^{\ddagger} = 66.9$ kJ·mol^{-1}, this value is close to those found for analogous copper helicates.[12]

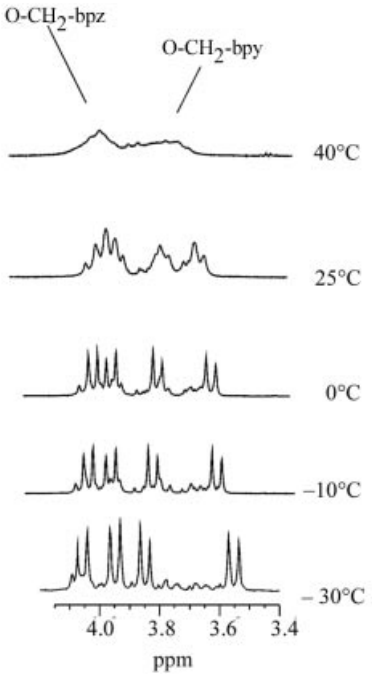

Figure 3. Variable-temperature ^{1}H NMR spectra of $[Cu_2(\mathbf{L4})_2][PF_6]_2$ in CD_3CN; selected region of methylene proton signals; each group of methylene protons is split into two distinct AB systems

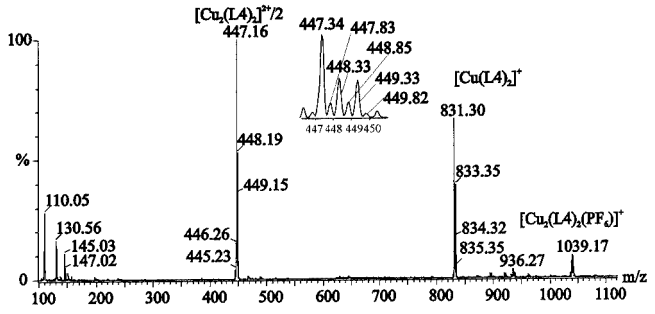

Figure 4. ES mass spectrum of the dinuclear double-stranded helical complex $[Cu_2(\mathbf{L4})_2][PF_6]_2$ (**5**) in acetonitrile

Finally, ES mass spectra (Figure 4) of **5** led to the observation of the $[Cu_2(\mathbf{L4})_2]^{2+}$ doubly charged ion (m/z = 447 a.m.u.) and the $[Cu_2(\mathbf{L4})_2(PF_6^-)]^+$ singly charged ion (m/z = 1040 a.m.u.). The isotopic distribution of the m/z = 447 ion shows peaks separated by 0.5 Da which is only compatible with a doubly charged species and the formation of the double-stranded helicate.[13] Similar results were obtained with the silver complex **6**. ES mass spectra exhibit the $[Ag_2(\mathbf{L4})_2]^{2+}$ doubly charged ion (m/z = 491 a.m.u.) and the $[Ag_2(\mathbf{L4})_2(PF_6^-)]^+$ singly charged ion (m/z = 1128 a.m.u.) with an isotopic distribution of the m/z = 491 ion showing peaks separated by 1.0 Da compatible with a doubly charged species.

X-ray diffraction analysis of a single crystal of the salt of the copper complex shows the presence of a double-stranded head-to-tail heterotopic helicate (Figure 5) which could be obtained by slow diffusion of diethyl ether into an acetonitrile solution containing **L4** and $[Cu(CH_3CN)_4][PF_6]$ in a 1:1 molar ratio. This structure represents the first example of such a helicate, having a strong directionality in self-assembly without external steric induction. The compound crystallizes in the triclinic $P\bar{1}$ space group with two dinuclear Cu^I complexes (a and b) and four PF_6^- disordered counterions in the asymmetric unit. Figure 5 depicts an ORTEP[14] view of the Cu^I complex structures displaying left- and right-handed helices. The Cu−Cu distances are 6.45 and 6.20 Å in the a and b complexes, respectively. The angle between the two corresponding Cu−Cu axes is 21°. Each Cu^I cation is in a distorted tetrahedral coordination and is attached to two pairs of N atoms belonging to one bipyridine and one bipyrazine molecule, respectively. All Cu−N bond lengths are equal to 2 Å within a narrow deviation interval (caption of Figure 5). The N−Cu−N angle values range from 80 to 135°, the most distorted helicate complex being the b one. All the bond lengths and angles are in good agreement with those obtained for (4,4′-bipyrimidine)- and (2,2′-bipyrazine)copper complexes.[15] In the present study, bipyrazine and bipyridine molecules are not ideally planar, the corresponding torsion angle between the two connected rings varies by up to 10° in order to accommodate the copper coordination on one hand and the outer interactions on the other. However, in each dinuclear complex, the bipyridine molecule mean planes are almost parallel. This is not true for the bipyrazine molecules which are attracted to each other in both the a and b complexes enhancing the metal tetrahedron distortions. Such an attraction of heterocycle molecules has been reported in our pre-

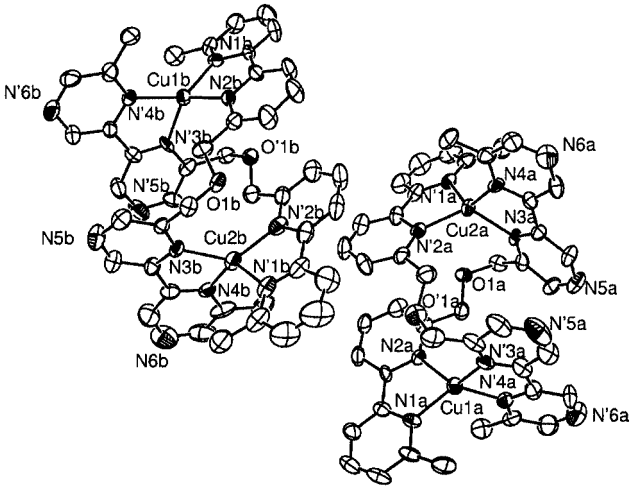

Figure 5. Structure (ORTEP view) of the two helicates in the asymmetric unit; the hexafluorophosphate anions and hydrogen atoms have been omitted for clarity; selected distances [Å] and angles [°]: Cu1a−N′3a 1.99 (1), Cu2a−N′2a 2.00(1), Cu1a−N1a 2.01(1), Cu2a−N3a 2.02(1), Cu1a−N2a 2.04(1), Cu2a−N4a 2.03(1), Cu1a−N′4a 2.06(1), Cu2a−N′1a 2.03(1), N′3a−Cu1a−N2a 123.7(5), N′2a−Cu2a−N3a 123.2(5), N1a−Cu1a−N′4a 124.7(5), N4a−Cu2a−N′1a 127.9(5), N′3a−Cu1a−N′4a 82.6(6), N3a−Cu2a−N4a 81.8(5), N1a−Cu1a−N2a 81.6(5), N′2a−Cu2a−N′1a 82.6(5); Cu1b−N′3b 2.01(1), Cu2b−N′2b 2.01(1), Cu1b−N1b 2.00(1), Cu2b−N3b 2.05(1), Cu1b−N2b 2.03(1), Cu2b−N4b 2.04(1), Cu1b−N′4b 2.01(1), Cu2b−N′1b 2.03(1), N′4b−Cu1b−N1b 134.6(5), N′1b−Cu2b−N4b 122.8(5), N′3b−Cu1b−N′4b 81.2(5), N3b−Cu2b−N4b 80.9(5), N2b−Cu1b−N1b 82.0(5), N′2b−Cu2b−N′1b 80.7(6), N2b−Cu1b−N′3b 120.8(5), N′2b−Cu2b−N3b 129.6(5)

vious work.[15] The crystal packing (see CCDC supplementary material) shows how the disordered PF_6^- counterions are distributed in the interstices.

In addition to the high atomic thermal vibration (room-temperature data in this study), the PF_6^- anion disorder probably breaks down a symmetry operation (center of inversion) which can hypothetically relate the two heterotopic helicates of the asymmetric unit. Furthermore, PF_6^- anions interact with the dinuclear complexes as revealed by the close F···H contacts ranging from 2.3 to 2.6 Å. Therefore, in the solid state, the PF_6^- counterion found close to the two bipyrazine heterocycles, belonging to the same helicate, can explain the non-parallelism of the corresponding molecular mean planes. The other counterions are found approximately in the same plane as the bipyridine molecule of one complex and are connected to the methyl group attached to the bipyrazine heterocycle of the second helicate.

Conclusions

In contrast to other helicates previously described, a directional selective double-stranded head-to-tail spontaneous assembly has been obtained from a heterotopic ligand without the help of external hindered factors, stereochemical requirements or the electronic nature of a chelating center[6] belonging to the coordination preference of the metal ions. In the asymmetric unit Cu−N bond lengths (2 Å) of the same distance were found whatever the nature of the biheterocycle involved in the coordination with the copper atom. The PF_6 disorder in the solid state induces a geometrical distinction of two double-stranded dinuclear complexes in the asymmetric unit. Furthermore, particular interactions between the PF_6 counteranions and biheterocycle protons of the ligand **4** through F−H hydrogen bonds were observed. In this study, it was reported that a careful design of the ligands can lead to a new class of helicates, which appear to be driven in their assembling process by the electronic configuration of the biheterocyclic units. Previous results of the experimental electron density,[7] which clearly pointed to the greater non-aromatic character of the 2,2′-bipyrazine compared to other diazines or monoazines, corroborate this hypothesis. Further work is in progress to analyze the general character of these results with other sequential heterotopic ligands.[16]

Experimental Section

General Remarks: ^1H and ^{13}C NMR spectra were recorded with a Bruker DRX 400 spectrometer. UV/Vis spectra were recorded with a UVmC^2 Safas spectrometer. Mass spectra (ES) were taken with a Micromass Platform spectrometer. Elemental analyses were obtained with a Perkin−Elmer 240C CHN-O-S analyzer. The solvents were purified by standard methods.

6-Chloromethyl-6′-methyl-2,2′-bipyrazine (2): To a solution of 6,6′-dimethyl-2,2′-bipyrazine (1 g, 5.38 mmol) in CCl_4 (100 mL) under Ar, tetrachloro-diphenylglycouril {1,3,4,6-tetrachloro-3a,6a-diphenyltetrahydroimidazo[4,5-*d*]imidazole-2,5(1*H*,3*H*)-dione} (1 g, 2.32 mmol) and AIBN were added. The mixture was refluxed and irradiated by a tungsten lamp (100 W) for 24 h. The resulting precipitate was filtered, washed with CH_2Cl_2, and the solvent was removed in vacuo. The crude product was purified by chromatography on silica gel (elution: CH_2Cl_2/Et_2O, 95:5) to give two fractions. Fraction 1: **2:** Yield 683 mg (58%). ^1H NMR ($CDCl_3$, 25 °C): δ = 9.54 (s, 1 H), 9.38 (s, 1 H), 8.81 (s, 1 H), 8.53 (s, 1 H), 4.78 (s, 2 H), 2.66 (s, 3 H) ppm. ^{13}C NMR ($CDCl_3$, 25 °C): δ = 153.1, 151.0, 148.5, 147.7, 145.2, 144.4, 143.1, 142.4, 43.9, 21.6 ppm. Fraction 2: **6,6′-Bis(chloromethyl)-2,2′-bipyrazine:** Yield 257 mg (19%). ^1H NMR ($CDCl_3$, 25 °C): δ = 9.57 (s, 2 H), 8.84 (s, 2 H), 4.80 (s, 4 H) ppm. ^{13}C NMR ($CDCl_3$, 25 °C): δ = 151.1, 147.8, 144.8, 142.6, 43.8 ppm.

6-(Hydroxymethyl)-6′-methyl-2,2′-bipyrazine (3): To a solution of **2** (477 mg, 2.16 mmol) in anhydrous EtOH (20 mL), NaOAc (1.77 g, 21.60 mmol) was added. The mixture was refluxed for 24 h. The resulting precipitate was filtered and the solvent was removed in vacuo. The crude product was purified by chromatography on silica gel (elution: CH_2Cl_2/MeOH, 95:5) to give two fractions. Fraction 1: **3:** Yield 250 mg (57%). ^1H NMR ($CDCl_3$, 25 °C): δ = 9.50 (s, 1 H), 9.36 (s, 1 H), 8.73 (s, 1 H), 8.52 (s, 1 H) 4.95 (d, *J* = 4.2 Hz, 2 H), 3.66 (s, 1 H), 2.67 (s, 3 H) ppm. ^{13}C NMR ($CDCl_3$, 25 °C): δ = 153.9, 153.3, 148.1, 148.0, 145.0, 143.0, 141.8, 140.0, 63.0, 21.6 ppm. Fraction 2: **6-(Acetoxymethyl)-6′-methyl-2,2′-bipyrazine:** Yield 102 mg (19%). ^1H NMR ($CDCl_3$, 25 °C): δ = 9.50 (s, 1 H), 9.34 (s, 1 H), 8.68 (s, 1 H), 8.51 (s, 1 H), 5.34 (s, 2 H), 2.64 (s, 3 H), 2.19 (s, 3 H) ppm, ^{13}C NMR ($CDCl_3$, 25 °C): δ = 170.3, 153.0, 150.1, 148.5, 147.8, 145.0, 143.4, 142.3, 140.2, 64.6, 21.5, 20.7 ppm.

6-Methyl-6′-[(6′-methyl-2,2′-bipyridin-6-yl)methoxymethyl]-2,2′-bipyrazine (4): To NaH (54 mg, 2.24 mmol) in anhydrous THF (5 mL) under Ar at 0 °C **3** (268 mg, 1.32 mmol) in THF (10 mL) was added. The mixture was stirred at 0 °C for 1 h. 6-(Bromomethyl)-6′-methyl-2,2′-bipyridine (348 mg, 1.32 mmol) in THF (10 mL) was then added, and the mixture was allowed to warm to room temp. The mixture was stirred at 40 °C for 24 h. After cooling to room temp., H_2O (10 mL) was added to the mixture and the phases were separated. The aqueous layer was extracted with CH_2Cl_2 (3×30 mL). The combined organic phases were dried with $MgSO_4$, and the solvent was removed in vacuo. The crude product was purified by chromatography on alumina gel (elution: CH_2Cl_2) to give a white powder. Yield 353 mg (70%); m.p 142 °C. ^1H NMR ($CDCl_3$, 25 °C): δ = 9.52 (s, 1 H, bpz), 9.39 (s, 1 H, bpz), 8.90 (s, 1 H, bpz), 8.53 (s, 1 H, bpy), 8.35 (d, $^3J_{8,9}$ = 7.8 Hz, 1 H, bpy), 8.20 (d, $^3J_{5,4}$ = 7.8 Hz, 1 H, bpy), 7.86 (t, $^3J_{9,10}$ = 7.8 Hz, 1 H, bpy), 7.70 (t, $^3J_{4,3}$ = 7.8 Hz, 1 H, bpy), 7.55 (d, $^3J_{10,9}$ = 7.6 Hz, 1 H, bpy), 7.17 (d, $^3J_{3,4}$ = 7.6 Hz, 1 H, bpy), 4.96 (s, 2 H), 4.94 (s, 2 H), 2.67 (s, 3 H), 2.64 (s, 3 H) ppm. ^{13}C NMR ($CDCl_3$, 25 °C): δ = 157.9 (C^{21}), 157.1 (C^{14}), 155.9 (C^{18}), 155.3 (C^{17}), 153.0 (C^2), 152.5 (C^{11}), 148.3 (C^6), 148.1 (C^7), 145.0 (C^{19}), 143.7 (C^{20}), 142.0 (C^{15}), 140.2 (C^{16}), 137.5 (C^9), 137.0 (C^4), 123.2 (C^3), 121.2 (C^{10}), 120.0 (C^8), 118.2 (C^5), 74.2 (C^{13}), 71.8 (C^{12}), 24.6 (C^1), 21.6 (C^{22}) ppm. UV/Vis (CH_3CN): λ_{max} (ε)$_{max}$ = 292 nm (27339). $C_{22}H_{20}N_6O$ (384.4): calcd. C 68.72, H 5.24, N 21.86; found C 68.64, H 5.22, N 21.73.

$[Cu_2(L4)_2][PF_6]_2$ (5): $[Cu(CH_3CN)_4][PF_6]$ (194 mg, 0.52 mmol) was added to the ligand **4** (200 mg, 0.52 mmol) in anhydrous CH_3CN (50 mL) solution under Ar. The mixture was stirred at room temp. and spontaneously led to a deep-red solution. After evaporation of the solvent, the solid residue was crystallized by slow diffusion of diethyl ether into an acetonitrile solution, which gave deep-red crystals. ^1H NMR (CD_3CN, −30 °C): δ = 9.68 (s, 4 H, bpz), 8.91 (s, 2 H, bpz), 8.34−8.32 (m, 4 H, 2 H-bpz, 2 H-bpy), 8.19−7.96 (m, 6 H, bpy), 7.57 (d, $^3J_{10,9}$ = 7.5 Hz, 2 H, bpy), 7.01 (d, $^3J_{3,4}$ = 7.4 Hz, 2 H. 1 H-bpy and 1 H-bpy′), 4.09−3.54 (m, 8 H, 4 CH_2), 2.42 (s, 3 H, CH_3), 2.26 (s, 3 H, CH_3), 2.15 (t, ^2J = 8.8 Hz; CH_3), 2.05 (s, 3 H,CH_3)

ppm. ^{13}C NMR (CD_3CN, −30 °C): δ = 158.4 (q), 154.8 (q), 152.4 (2 q), 150.6 (2 q), 149.3 (2 q), 149.0 (C^{19}), 145.5 (C^{20}), 143.6 (C^{15}), 142.0 (C^{16}), 139.9 (C^9), 139.6 (C^4), 127.0 (C^3), 126.1 (C^{10}), 122.5 (C^8), 120.5 (C^5), 71.7 (C^{13}), 68.4 (C^{12}), 24.1 (C^1), 21.5 (C^{22}) ppm. ^{13}C CPMAS NMR (75 MHz, 7 kHz, 20 °C): δ = 156.0 (q), 149.0 (q), 142.0 (C^{15}, C^{16}), 139.0 (C^9, C^4), 128.0 (C^3, C^{10}), 122.0−120.0 (C^8, C^5), 70.0 (C^{13}, C^{12}), 25.0 (C^1), 22.0 (C^{22}) ppm. UV/Vis (CH_3CN): λ_{max} $(\varepsilon)_{max}$ = 306 nm (21680). ES MS: *m*/*z* (%) = 1040.2 (20) $[Cu_2(\mathbf{L4})_2(PF_6^-)]^+$, 831.3 (90) $[Cu_2(\mathbf{L4})]^+$, 447.3 (100) $[Cu_2(\mathbf{L4})_2]^{2+}$/2. $C_{44}H_{40}Cu_2F_{12}N_{12}O_2P_2$ (1185.9): calcd. C 44.56, H 3.40, N 14.17; found C 44.52, H 3.37, N 13.95.

$[Ag_2(L4)_2][PF_6]_2$ (6): $AgPF_6$ (65.84 mg, 0.26 mmol) was added to the ligand **4** (100 mg, 0.26 mmol) in anhydrous CH_3CN (20 mL) solution under Ar. The mixture was stirred at room temp. and after evaporation of the solvent, the solid residue was crystallized by slow diffusion of diethyl ether into an acetonitrile solution, which gave white crystals. ^{1}H NMR (CD_3CN, 25 °C): δ = 9.43 (s, 1 H, bpz), 9.42 (s, 1 H, bpz), 8.77 (s, 1 H, bpz), 8.34 (s, 1 H, bpz), 8.11 (m, 3 H, bpy), 7.75 (t, ^3J = 7.8 Hz, 1 H, bpy), 7.52 (d, ^3J = 7.8 Hz, 1 H, bpy), 7.06 (d, ^3J = 7.6 Hz, 1 H, bpy), 4.39 (s, 2 H, CH_2), 4.38 (s, 2 H, CH_2), 2.41 (s, 3 H, CH_3), 2.33 (s, 3 H, CH_3) ppm. ^{13}C NMR (CD_3CN, 25 °C): δ = 158.8 (q), 156.0 (q), 154.8 (q), 151.3 (q), 150.8 (q), 147.9, 145.7, 143.6, 141.7, 140.2, 140.0 (CH bpy), 126.1, 124.6, 122.5, 120.8 (CH bpz), 74.0 (CH_2 bpz), 70.5 (CH_2 bpy), 26.2 (CH_3 bpz), 22.4 (CH_3 bpy) ppm. UV/Vis (CH_3CN): λ_{max} $(\varepsilon)_{max}$ = 298 nm (25379). ES MS: *m*/*z* (%) = 1128.9 (10) $[Ag_2(\mathbf{L4})_2(PF_6^-)]^+$, 491.2 (100) $[Ag_2(\mathbf{L4})_2]^{2+}$/2.

X-ray Structural Analysis of $[Cu(C_{22}H_{20}N_6O)]_2[PF_6]_2$: The crystal structure of $[Cu(C_{22}H_{20}N_6O)]_2[PF_6]_2$, $\rho_{calcd.}$ = 1.61 Mg·m^{-3}, μ(Mo-K_α) = 1.036 mm^{-1}, was determined from a single-crystal X-ray diffraction experiment. The deep-red crystals obtained are plate-like and very fragile. A crystalline fragment sample was mounted on an Enraf−Nonius CAD-4F diffractometer. Several attempts were made because of the diffraction-limited power of the samples. Therefore, data collection was performed at room temp. on a large crystal fragment (approximately 0.5 × 0.9 × 0.2 mm) with Mo-K_α X-ray radiation (λ = 0.71073 Å). $[Cu(\mathbf{L4})]_2[PF_6]_2$ crystallizes in the triclinic $P\bar{1}$ space group, Z = 4 (two dinuclear complexes in the asymmetric unit). The unit cell parameters were obtained by least-squares fit to setting angles of 25 reflections in the range 12° < 2θ < 26°. The cell parameters are a = 13.912(2), b = 19.903(4), c = 20.062(3) Å, α = 97.67(2), β = 105.49(1), γ = 109.89(2)°, V = 4877.2(17) Å^3. The ω-2θ scan mode was used to record the diffracted intensities. Three standard reflections (−5 −1 2), (−5 0 0) and (−3 1 −1) were monitored every 2 h in order to control the intensity decay, which is not significant. 25304 reflections were collected up to $2\theta_{max}$ = 55.9°. Lorentz polarization corrections and data reduction was performed by using the WINGX package[17] for CAD4-collected intensities. The structure was solved by direct methods by using the SIR92 program.[18] Due to a large amount of weak intensities, only 22843 observed reflections were taken into account in order to refine the structure by full-matrix least squares based on $|F^2|$ by using the SHELX97[19] program. Thermal displacements of non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included at their idealized positions but not refined. Three of the four PF_6^- counterions in the asymmetric unit are disordered. Two atomic positions were assigned to one phosphorus and 16 fluorine atoms, respectively. The site occupancy factors of these disordered atomic positions were refined. During the last cycles of refinement, an empirical absorption correction was applied (T_{min} = 0.040, T_{max} = 0.441) using the DIFABS program in the WINGX package.[17] The final statistical factors are $R1$(all observed data) = 0.319, $wR2$ = 0.387 for 22843 data and 1495 parameters, $R1$ [$I > 2\sigma(I)$] = 0.127 for 6758 data with $I > 2\sigma(I)$. The weak ratio N_{obs}/N_{par} is assigned to the high disorder of the PF_6^- counterions in the solid state. The final residual densities in the unit cell are +0.85 and −0.80 e·Å^{-3}. CCDC-176336 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +b 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

[8] The behavior of the titration curve at 520 nm could indicate the presence (at ca. 0.5 equiv. of Cu^I) of traces of another species. Knowing that both (HH) and (HT) conformers belong to the same C_2 point group, the collected NMR data in solution cannot distinguish between the two possibilities. Nevertheless, the ^{107}Ag NMR spectrum of complex **6** (not shown) exhibits a single resonance, indicating the same environment for silver atoms in the helicate. This situation is in agreement with an (HT) orientation of the sequential ligand **4** in solution.

Chiral 2,3-Dihydro-1*H*-1,3,2-diazaboroles

Lothar Weber,*[a] Andreas Rausch,[a] Henning B. Wartig,[a] Hans-Georg Stammler,[a] and Beate Neumann[a]

Keywords: Boron / Chirality / Diazaboroles / Heterocycles / Crystal structure

A series of differently substituted chiral 2,3-dihydro-1*H*-1,3,2-diazaboroles has been prepared by various methods. 2-Bromo-1-*tert*-butyl-3-[(*S*)-1-phenylethyl]-2,3-dihydro-1*H*-1,3,2-diazaborole (**3a**), 2-bromo-1,3-di[(*S*)-1-phenylethyl]-2,3-dihydro-1*H*-1,3,2-diazaborole (**3b**) and 2-bromo-1,3-di[(*S*)-1-cyclohexylethyl]-2,3-dihydro-1*H*-1,3,2-diazaborole (**3c**) were formed from the reaction of the corresponding 1,4-diazabutadienes and boron tribromide and the subsequent reduction of the resulting borolium salts [R^1N^a = CH–CH=$N^b(R^2)BBr_2$]Br(N^a–*B*) [**2a**: R^1 = *t*Bu, R^2 = CH(Me)Ph; **2b**: R^1 = R^2 = CH(Me)Ph; **2c**: R^1 = R^2 = CH(Me)(*c*C_6H_{11})] with sodium amalgam. Treatment of (*S*)-**3a** with $LiAlH_4$ or methyllithium afforded 1-*tert*-butyl-2-hydro-3-[(*S*)-1-phenylethyl]-2,3-dihydro-1*H*-1,3,2-diazaborole [(*S*)-**6**] and 1-*tert*-butyl-2-methyl-3-[(*S*)-1-phenylethyl]-2,3-dihydro-1*H*-1,3,2-diazaborole [(*S*)-**7**], respectively. Aminolysis of the BBr bond of (*S*)-**3a** by *tert*-butylamine or (*S*)-1-phenylethylamine gave the corresponding 2-*tert*-butylamino- and 2-[1-phenylethylamino]-2,3-dihydro-1*H*-1,3,2-diazaboroles (*S*)-**8** and (*S,S*)-**9**, respectively. Similarly, (*S,S*)-**3b** and (*S,S*)-**3c** were reacted with *tert*-butylamine to furnish the 2-*tert*-butylamino-2,3-dihydro-1*H*-1,3,2-diazaborole derivatives (*S,S*)-**11** and (*S,S*)-**12**, respectively. The 2-trimethylstannyl-2,3-dihydro-1*H*-1,3,2-diazaboroles (*S,S*)-**10** and (*S,S*)-**14** were accessible from **3b** or **3c** and trimethylstannyllithium. The transformation of achiral 2-bromo-1,3-di-*tert*-butyl-2,3-dihydro-1*H*-1,3,2-diazaborole into the chiral (*S*)-2-[1-phenylethylamino]- and (*S*)-2-[1-cyclohexyl-ethylamino] derivatives (*S*)-**15** and (*S*)-**16** was effected by aminolysis with enantiomerically pure (*S*)-1-phenylethylamine or (*S*)-1-cyclohexylethylamine. The novel compounds were characterized by ^1H, ^{11}B, ^{13}C, and ^{119}Sn NMR spectroscopy as well as mass spectrometry and determination of the optical rotation. The molecular structure of compound **3c** was confirmed by X-ray structural analysis.

Introduction

The synthesis of the first 2,3-dihydro-1*H*-1,3,2-diazaboroles **I** dates back to the early 1970s,[1,2] and since then a series of contributions concerning the synthesis, structure, and bonding of such heterocycles has been published.[3–6]

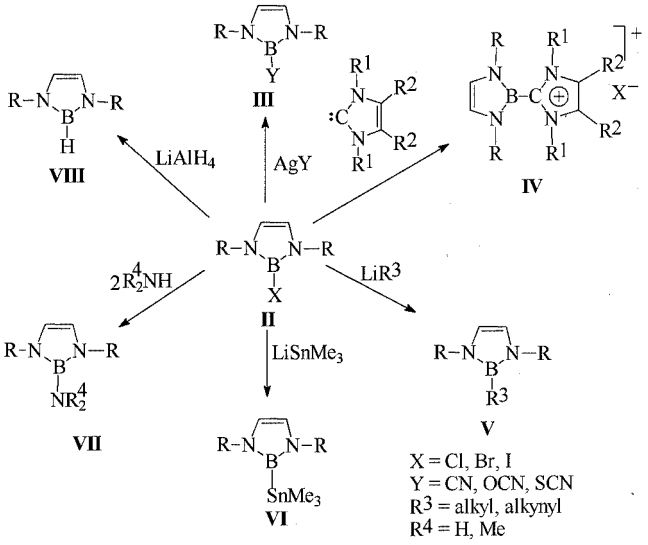
Recently, we started a program investigating the synthesis of 2-halo-2,3-dihydro-1*H*-1,3,2-diazaboroles **II** as starting materials for further chemical transformations.[7,8] Treatment of **II** with organolithium compounds,[9] $LiSnMe_3$,[9] $LiAlH_4$,[9] imidazol-2-ylidenes,[7] amines[10] and silver salts[8] afforded a series of novel 1,3,2-diazaboroles **III**–**VIII** (Scheme 1).



Scheme 1. Chemical transformations of **II**

Terminal as well as internal alkynes are inserted regioselectively into the B–Sn bond of **VI** in a reaction catalyzed by low-valent Pd species (Scheme 2).[11]

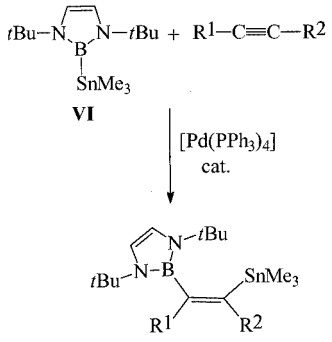
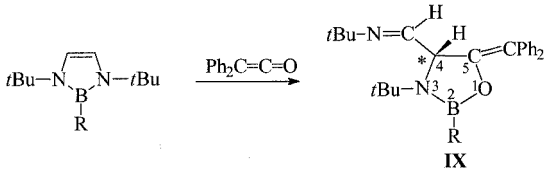
E-mail: lothar.weber@uni-bielefeld.de



Scheme 2. Insertion of alkynes into the B−Sn bond of **VI**

Moreover, it was demonstrated that 1,3,2-diazaboroles are smoothly converted into 1,3,2-oxazaborolidines **IX** upon reaction with an equimolar amount of diphenylketene (Scheme 3).[12]



Scheme 3. Conversion of 2,3-dihydro-1*H*-diazaboroles into 1,3,2-oxazaborolidines by treatment with diphenylketene

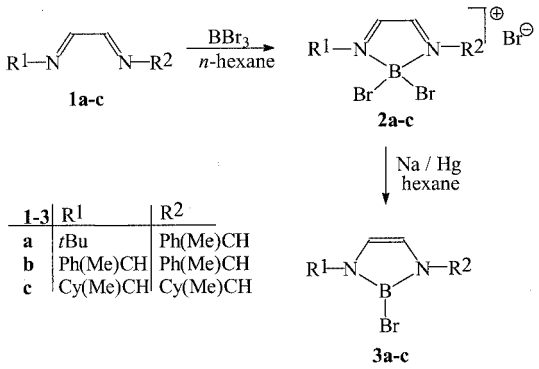
Here a stereogenic center was created at C(4), and it was challenging to elaborate conditions that would allow the stereoselective synthesis of these compounds.

Results and Discussion

The intention of the work described herein is to provide efficient syntheses of chiral 2,3-dihydro-1*H*-1,3,2-diazaboroles as the required precursors for such transformations. The most obvious way to introduce chirality into 1,3,2-diazaboroles is the use of chiral substituents at the heteroatoms of the ring. This target may be achieved by the employment of chiral 1,4-diazabutadienes as starting materials. The latter are available from the condensation of glyoxal and chiral primary amines such as (*S*)-1-phenylethylamine or (*S*)-1-cyclohexylethylamine. The combined condensation of glyoxal with *tert*-butylamine and (*S*)-phenylethylamine in a molar ratio of 4:7:1 leads to the formation of a 3:1 mixture of 1,4-di-*tert*-butyl-1,4-diazabutadiene and Ph(Me)CHN=CH−CH=N*t*Bu (**1a**). The former product is easily removed in vacuo at ambient temperature. The residue of crude **1a** was purified by distillation to give a light yellow oil (43% yield). This compound is thermolabile and has to be stored at −30 °C. According to NMR spectroscopic data **1a** is a 1:2 mixture of two isomers.

The diazabutadienes (*S*,*S*)-Ph(Me)CHN=CH−CH=NCH(Me)Ph (**1b**)[13] and (*S*,*S*)-*c*-C_6H_{11}(Me)CHN=CH−CH=N−CH(Me)(*c*-C_6H_{11}) (**1c**) were prepared from an aqueous glyoxal solution and the respective amines in a molar ratio of 1:2. Compound **1c** was isolated as colorless crystals in 82% yield, whereas **1b** was obtained as a colorless oil as described previously.

Combination of equimolar amounts of **1a** and BBr_3 in hexane at 20 °C led to the precipitation of the orange borolium salt **2a**. Its moisture sensitivity and low volatility precluded reliable elemental analyses and useful mass spectra. The reduction of compound **2a** with sodium amalgam in hexane afforded 1,3,2-diazaborole **3a** as a yellow oil in 66% yield after distillation (Scheme 4).



Scheme 4. Preparation of 1,3,2-diazaboroles **3a**−**c** (Cy = cyclohexyl)

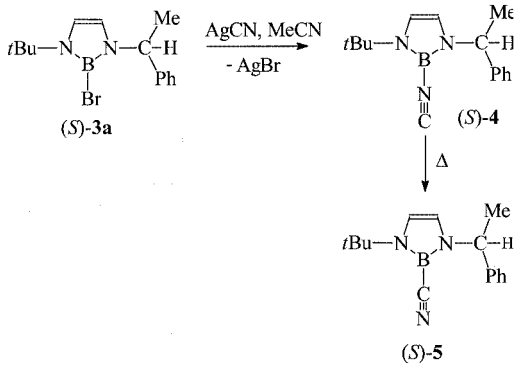
Neat **3a** decomposes to a brown oil after 24 h at 20 °C, therefore it is recommended to store the reaction mixture and to isolate the compound only prior to use.

The preparation of the yellow borolium salt **2b** was achieved by reaction of diazabutadiene (**1b**) and boron tribromide under similar conditions. Sodium amalgam reduction of **2b** over a period of two days led to a 32% yield of crude oily **3b**. Like **3a**, compound **3b** should only be isolated immediately before subsequent transformations.

In contrast to this, the reduction of analogously prepared orange moisture-sensitive **2c** with sodium amalgam led to the formation of colorless crystalline **3c** (60.5%), which separated upon concentrating the hexane reaction solution. Further purification of the thermostable product was achieved by sublimation at 80 °C and 5×10^{-6} bar.

In the $^{11}B\{^1H\}$ NMR spectra the 2-bromo-1,3,2-diazaboroles **3a**−**c** show singlets at δ = 17.3 (**3a**), 19.0 (**3b**) and 18.2 ppm (**3c**), which are very similar to the ^{11}B resonance in *t*BuN^{a}CH=CHN^b(*t*Bu)BBr(N^a−*B*) (δ = 16.2 ppm).[7] The ^1H and ^{13}C NMR resonances of the CH=CH building block (δ_H = 6.13−6.41 ppm and δ_C = 111.9−114.9 ppm are also very similar to the corresponding data for *t*BuN^a-CH=CHN^b(*t*Bu)BBr (δ_H = 6.27 ppm, δ_C = 113.6 ppm).

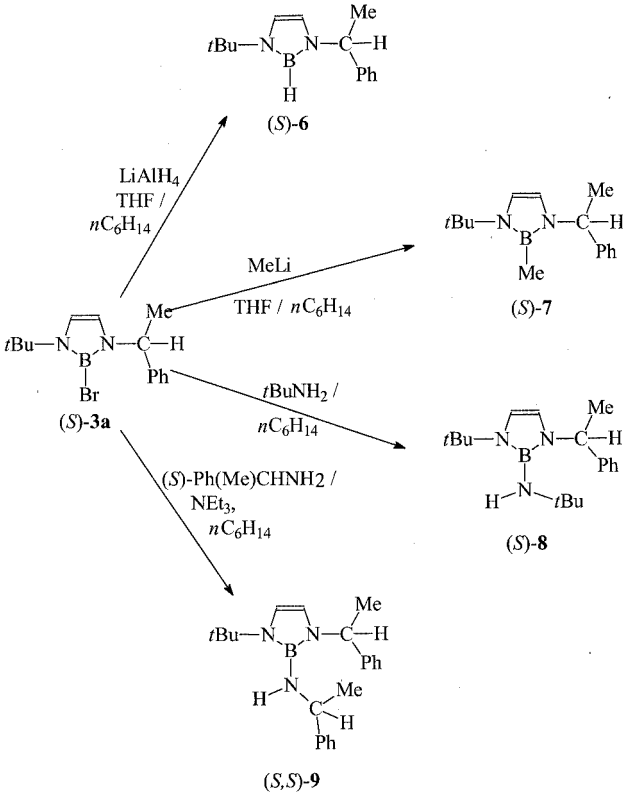
A series of chiral 1,3,2-diazaboroles were derived from **3a** by nucleophilic substitution at the boron center. Reaction of **3a** with silver cyanide in acetonitrile for 1 h furnished a liquid mixture of 2-isocyano-1,3,2-diazaborole (**4**) and 2-cyano-1,3,2-diazaborole (**5**) (Scheme 5)



Scheme 5. Reaction of (*S*)-**3a** with AgCN

The presence of both isomers was confirmed by the ^{1}H, ^{13}C NMR and IR spectra of a freshly prepared sample. Particularly informative is the IR spectrum where sharp bands at $\tilde{\nu}$ = 2113 and 2206 cm^{-1} are attributed to the ν(CN) vibrations of the isocyano function in **4** and the cyano group in **5**, respectively. Storing the product mixture at −30 °C for two weeks or vacuum distillation at 200 °C led to the complete disappearance of the band at 2113 cm^{-1}. After the rearrangement **4** → **5** the pure cyano derivative was obtained as a colorless solid (57% yield). In contrast to precursor **3a**, compound **5** is stable at room temperature. A similar rearrangement was not observed during the preparation of *t*BuN^{a}−CH=CH−N^{b}(*t*Bu)BCN(*N^{a}*−*B*) from the corresponding 2-bromo-1,3,2-diazaborole and AgCN. To the best of our knowledge stable boryl isocyanides are still undocumented. The $^{11}B\{^{1}H\}$ NMR spectrum of **5** is characterized by a singlet at δ = 11.6 ppm. In the ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra the HC=CH unit gives rise to two doublets at δ = 6.25 and 6.40 ppm ($^{3}J_{H,H}$ = 2.3 Hz) and two singlets at δ = 114.8 and 116.1 ppm, respectively. In *t*BuN^{a}−CH=CH−N^{b}(*t*Bu)BCN(*N^{a}*−*B*) the corresponding resonances were observed at δ_B = 12.0 ppm (s), δ_H = 6.14 ppm (s) and δ_C = 114.6 ppm (s).

Reduction of (*S*)-**3a** with lithium aluminium hydride in a THF/hexane mixture (Scheme 6) afforded the 2-hydro-1,3,2-diazaborole (*S*)-**6** as a yellow oil (95%). Purification by vacuum distillation to give (*S*)-**6** as a colorless liquid was accompanied by considerable loss of product (47%). At room temperature decomposition of a pure sample to a brown oil was complete within 24 h. In the IR spectrum a strong band at $\tilde{\nu}$ = 2621 cm^{-1} is due to the ^{11}B-H stretching mode. In the proton-coupled ^{11}B NMR spectrum ($CDCl_3$ solution) compound (*S*)-**6** exhibits a doublet at δ = 19.4 ppm ($^{1}J_{B,H}$ = 146 Hz). These values compare well with the result given for *t*BuN^{a}CH=CH−N^{b}(*t*Bu)BH(*N^{a}*−*B*) [δ_B = 18.9 ppm (d, $^{1}J_{B,H}$ = 149 Hz)].[9] In contrast to the latter compound, where the boron-ligated hydrogen atom appears in the ^{1}H NMR spectrum as a quadruplet resonance (δ = 4.78 ppm, $^{1}J_{B,H}$ = 150 Hz) no such signal was detected in the ^{1}H NMR spectrum of (*S*)-**6**.



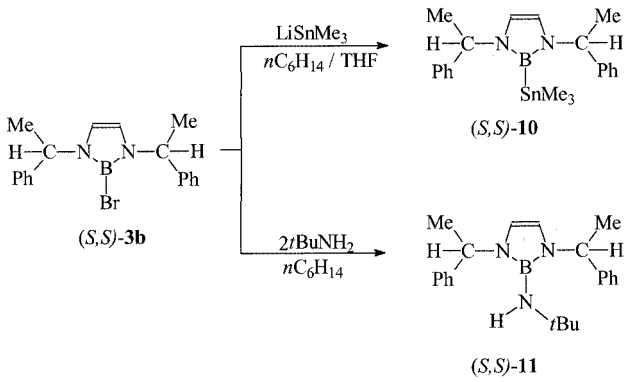
Scheme 6. Reaction of (*S*)-**3a** with $LiAlH_4$, MeLi, *t*$BuNH_2$ and (*S*)-Ph(Me)CH−NH_2

The reaction of 2-bromo-1,3,2-diazaborole (*S*)-**3a** with methyllithium in a mixture of hexane and THF (Scheme 6) cleanly afforded (*S*)-**7** as a colorless oil after distillation at 200 °C and 10^{-5} bar (51%). The $^{11}B\{^{1}H\}$ NMR spectrum of (*S*)-**7** shows a singlet at δ = 26.2 ppm, which is identical with that of *t*BuN^{a}CH=CHN^{b}(*t*Bu)BCH$_3$(*N^{a}*−*B*).[3] The CH=CH unit appears as two doublets at δ = 6.32 and 6.48 ppm ($^{3}J_{H,H}$ = 2.5 Hz) in the ^{1}H NMR spectrum and two singlets at δ = 111.1 and 113.5 ppm in the $^{13}C\{^{1}H\}$ NMR spectrum of the compound.

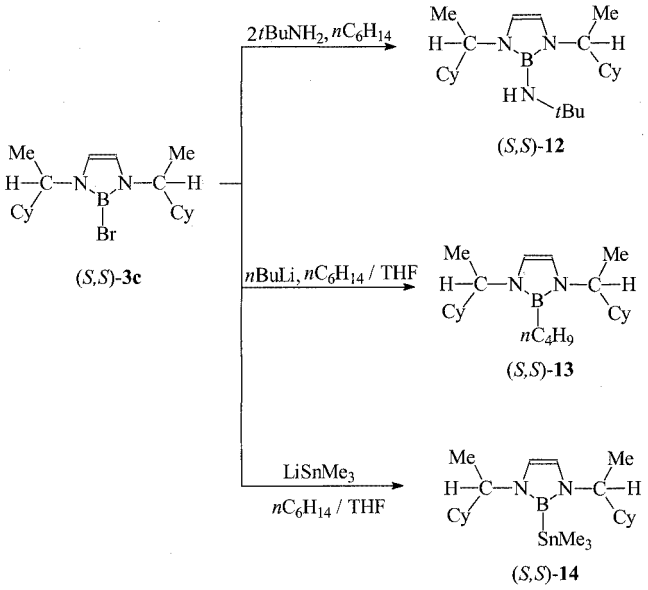
To increase the steric demand of chiral 1,3,2-diazaboroles we introduced bulky amino substituents at the boron atom of the ring. Reaction of (*S*)-**3a** with an excess of *tert*-butylamine in hexane gave (*S*)-**8** (Scheme 6), which was isolated as a yellow oil by vacuum distillation (300 °C, 10^{-5} bar, 74%). Compound (*S*,*S*-**9**) resulted from the treatment of (*S*)-**3a** with an equimolar amount of (*S*)-1-phenylethylamine in the presence of triethylamine. The heterocycle was isolated as a colorless liquid in 48% yield by vacuum distillation. The ^{11}B NMR signals of (*S*)-**8** (δ = 22.3 ppm) and (*S*,*S*)-**9** (δ = 21.6 ppm) are similar to those of the amino-functionalized 1,3,2-diazaboroles *t*BuN^{a}CH=CHN^{b}(*t*Bu)BN(H)*t*Bu(N^{a}−B) (δ = 22.9 ppm) and *t*BuN^{a}-CH=CHN^{b}(*t*Bu)BNH(2,6-$Me_2C_6H_3$)(*N^{a}*−*B*) (δ = 21.6 ppm).[10]

It was also intended to convert the chiral 1,3,2-diazaborole (*S*,*S*)-**3b** into more stable and sterically more congested

derivatives. A hexane solution of (*S*,*S*)-**3b** was combined with a solution of a slight excess of $LiSnMe_3$ in THF at room temperature, whereupon the stannylated heterocycle (*S*,*S*)-**10** was generated. Analytically pure colorless (*S*,*S*)-**10** was obtained by crystallizing the crude material from toluene (67% yield). (Scheme 7)



Scheme 7. Conversion of (*S*,*S*-**3b**) into (*S*,*S*-**10**) and (*S*,*S*-**11**)



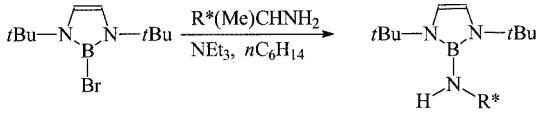
Scheme 8. Synthesis of (*S*,*S*)-**12**, (*S*,*S*)-**13** and (*S*,*S*)-**14** from (*S*,*S*)-**3c**

Compound **10** can be stored at room temperature under an inert atmosphere without discernible decomposition. The singlet at δ = 28.2 ppm in the $^{11}B\{^1H\}$ NMR spectrum is accompanied by ^{119}Sn satellites ($^1J_{Sn,B}$ = 994 Hz). Similarly, the $^{119}Sn\{^1H\}$ NMR spectrum of **10** features a quadruplet at δ = 150.0 ppm ($^1J_{Sn,B}$ = 994 Hz). The $^{11}B\{^1H\}$ NMR spectrum of 2,6-$Me_2C_6H_3N^aCH{=}CHN^b$(2,6-$Me_2C_6H_3$)$BSnMe_3$(*N*^{a}−*B*) is characterized by a singlet at δ = 28.2 ppm with ^{119}Sn satellites ($^1J_{Sn,B}$ = 960 Hz). The $^{119}Sn\{^1H\}$ NMR resonance of this molecule appears as a quadruplet at δ = 146 ppm with $^1J_{Sn,B}$ = 960 Hz.

The stable amino-functionalized 1,3,2-diazaborole (*S*,*S*)-**11** was isolated as a yellow liquid from the reaction of **3b** with a twofold equimolar amount of *tert*-butylamine in hexane at 20 °C (50%). Similarly, the colorless liquid diazaborole (*S*,*S*)-**12** was synthesized from (*S*,*S*)-**3c** and *tert*-butylamine (58% after distillation at 300 °C, 4 × 10^{-6} bar; Scheme 8). Preparation of the 2-butyl-1,3,2-diazaborole (*S*,*S*)-**13** was accomplished by reaction of **3c** with an excess of *n*-butyllithium in a hexane/THF mixture at −15 to 20 °C. Pure colorless oily **13** was obtained by distillation (250 °C, 5 × 10^{-6} bar, 47%).

Analogously to the preparation of (*S*,*S*)-**10** the stannylated diazaborole (*S*,*S*)-**14** was synthesized as a colorless liquid from **3c** and $LiSnMe_3$ in a THF/hexane mixture (58% yield).

A different approach to chiral 1,3,2-diazaboroles was based upon the reaction of achiral *t*$BuN^aCH{=}CHN^b$(*t*Bu)BBr(*N*^{a}−*B*) with the chiral auxiliaries (*S*)-Ph(Me)$CHNH_2$ and (*S*)-Cy(Me)$CHNH_2$ in the presence of triethylamine (Scheme 9). Heterocycle **15** was isolated as a pale yellow oil in 74% yield by distillation (200 °C, 10^{-5} bar). The same holds for **16**, which was isolated as a colorless oil after distillation (150 °C, 2 × 10^{-6} bar, 72%). The $^{11}B\{^1H\}$ spectra of the 2-amino-1,3,2-diazaboroles (*S*,*S*)-**11** [δ = 22.5 (s)], (*S*,*S*)-**12** [δ = 22.1 (s)], (*S*)-**15** [δ = 22.3 (s)] and (*S*)-**16** [δ = 22.0 (s)] resemble those of **8** and **9** and do not show any marked influence of the substituent at the nitrogen atom.



Scheme 9. Preparation of (*S*)-**15** and (*S*)-**16**

X-ray Structural Analysis of (*S*,*S*)-3c

The molecular structure of (*S*,*S*)-**3c** (Figure 1) features a planar 1,3,2-diazaborole ring with two nearly orthogonally oriented 1-cyclohexylethyl substituents at the nitrogen atoms. A C_2 axis bisects the molecule along the B(1)−Br(1) vector. The bond length B(1)−Br(1) [1.930(2) Å] is close to the sum of the covalent radii of boron (0.81 Å) and bromine (1.14)[14] and compares well with the B−Br distances in [(2,4,6-$Me_3C_6H_2$)(Br)B]$_2$ [1.928(4) and 1.932(4) Å].[15] B−Br bond lengths involving sp^2-hybridized boron atoms range from 1.87(1) Å in [*i*$Pr_3P{=}N^a{-}B^a$(Br)N^b-(=P*i*Pr$_3$)B^bBr_2]Br(*N*^{a}−*B*^{b})[16] or 1.902(5) Å in 2,6-$Mes_2C_6H_3BBr_2$ (Mes = 2,4,6-$Me_3C_6H_2$)[17] to 2.00(1) Å in the triborane [(Me_2N)(Br)B]$_2$$BNMe_2$.[18] Atomic distances and valence angles within the diazaborole ring are in good agreement with the corresponding data for (2,6-$Me_2C_6H_3$)$N^a{-}CH{=}CH{-}N^b$(2,6-$Me_2C_6H_3$)BI(*N*^{a}−*B*).[18] In (*S*,*S*)-**3c** the B−N bond length [1.417(1) Å] indicates multiple bond character. In a series of diazaboroles the B−N bond lengths range from 1.407(5) to 1.450(2) Å. The atomic distance C(1)−C(1A) [1.350(3) Å] and the

N−C(sp^2) bond length [1.403(2) Å] also indicate multiple bonding. For the N(sp^2)−C(sp^3) single bond N(1)−C(2) a length of 1.471(2) Å was determined. The endocyclic angles in (*S*)-**3c** — N(1)−B(1)−N(1A) [107.7(1)°] B(1)−N(1)−C(1) [106.6(1)°], and N(1)−C(1)−C(1A) [109.5(1)°] — are similar to those in 2,6-$Me_2C_6H_3N^aCH$=CHN^b(2,6-$Me_2C_6H_3$)BI(*N*^{a}−*B*) [106.9(4)°, 107.5(3)°, and 109.1(2)°, respectively].[8] This also applies to the exocyclic angle N(1)−B(1)−Br(1) [126.1(1)°] in (*S*)-**3c** and the N(1)−B(1)−I(1) angle [126.6(2)°] in 2,6-$Me_2C_6H_3N^a$−CH=CHN^b(2,6-$Me_2C_6H_3$)BI(*N*^{a}−*B*).

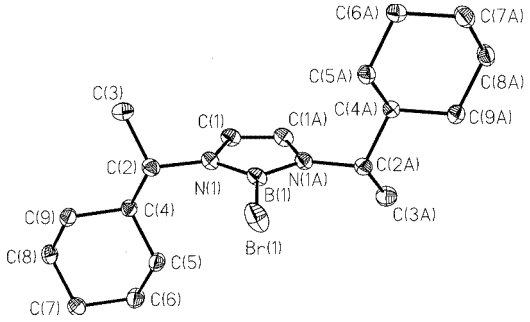


Figure 1. Molecular structure of (*S*,*S*)-**3c** in the crystal; selected bond lengths [Å] and bond angles [°]: B(1)−Br(1) 1.930(2), B(1)−N(1) 1.417(1), N(1)−C(1) 1.403(2), N(1)−C(2) 1.471(2), C(1)−C(1A) 1.350(3); N(1)−B(1)−N(1A) 107.7(1), Br(1)−B(1)−N(1) 126.1(1), B(1)−N(1)−C(1) 106.6(1), B(1)−N(1)−C(2) 131.0(1), N(1)−C(1)−C(1A) 109.5(1); B(1)−N(1)−C(2)−C(3) 124.3, B(1)−N(1)−C(2)−C(4) −110.0

Experimental Section

General: All manipulations were performed under dry argon. Solvents were rigorously dried with an appropriate drying agent and freshly distilled before use. The following compounds were prepared as described in the literature: (*S*,*S*)-Ph(Me)CHN=CH−CH=NCH(Me)Ph (**1b**),[13] *t*BuN^aCH=CHN^b(*t*Bu)BBr(*N*^{a}−*B*).[7]

An aqueous glyoxal solution (40%) of *tert*-butylamine, boron tribromide, silver cyanide, trimethyltin chloride, *n*-butyllithium, methyllithium, triethylamine, (*S*)-1-phenylethylamine and (*S*)-1-cyclohexylethylamine were purchased commercially. IR spectra Bruker FTIR Vector 22, Bruker FTIR IFS66. ^{1}H, ^{11}B, ^{13}C NMR spectra: Bruker AC 100 (^{1}H, 100.13 MHz, ^{11}B (32.13 MHz); Bruker Avance DRX 500 (^{1}H, 500.13 MHz, ^{11}B, 160.46 MHz, ^{13}C, 125.75 MHz); references: $SiMe_4$ (^{1}H, ^{13}C), BF_3·OEt_2 (^{11}B). Mass spectra EI (70 eV), CI (NH_3): Autospec sector-field mass spectrometer (Micromass). Optical rotations were measured with a Jasco DIP-360 in CH_2Cl_2 solution [c = 0.01 g·mL^{-1}, d = 1 dm].

Preparation of the 1,4-Diazabutadienes. (*S*)-*t*BuN=CH−CH=N−CH(Me)Ph (1a): Solutions of (*S*)-1-phenylethylamine (28.8 g, 0.24 mol) in hexane (200 mL) and *tert*-butylamine (121.7 g, 1.90 mol) in hexane (200 mL) were simultaneously added dropwise to a well-stirred chilled mixture of an aqueous solution of glyoxal 114.3 mL (114.2 mL, 1.0 mol, 0 °C) and 400 mL of hexane. Then stirring was continued at room temp. for 30 min. The liquid content of the flask separated into two phases. The aqueous phase was extracted with hexane (30 mL) and then discarded. The combined hexane phases were dried (Na_2SO_4) and then freed from solvent. The remaining yellow oil was kept at 5 × 10^{-6} bar and 20 °C to remove *t*BuN=CH−CH=N*t*Bu (49.0 g crude **1a**). The brown oily residue (10.0 g) was distilled at (5 × 10^{-6} bar, and 70 °C) to give 4.5 g (43%) of **1a** as a light-yellow liquid. This purification step could not be scaled up because of serious loss of product. IR (film): $\tilde{\nu}$ = 3062 cm^{-1} w, 3029 m, 2981 s, 2864 s, 1629 s [ν(C=N)], 1493 m, 1451 m, 1361 s, 1213 s, 759 s, 699 s. ^{1}H NMR ($CDCl_3$): δ = 1.21 and 1.23 (2s, 9 H, *t*Bu), 1.55 and 1.56 (2d, $^3J_{H,H}$ = 6.4, 6.8 Hz, 3 H, CH_3), 4.48 [q, $^3J_{H,H}$ = 6.8 Hz, 1 H, C*H*Me], 7.23−7.33 (m, 5 H, *H*−Ph), 7.92−8.02 (m, 2 H, N=CH) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 23.9 (s, CH*C*H$_3$), 29.27 and 29.34 [2s, C(*C*H$_3$)], 58.2 and 58.3 [2s, *C*(CH$_3$)$_3$], 69.66 and 69.71 (2s, *C*HCH$_3$), 126.6, 126.7, 127.2, 128.5, 128.6, 143.6, 143.7 (7s, *C*−Ph), 157.0, 157.8, 160.7, 161.5 (4s, H*C*=N) ppm. MS/EI: *m*/*z* (%) = 216 (6) [M$^+$], 201 (36) [M$^+$ − CH_3], 159 (33) [M$^+$ − *t*Bu], 145 (100) [M$^+$ − CH_3 − CH_2=CMe_2]. [α]$_D^{24}$ = −97. $C_{14}H_{20}N_2$ (216.33): calcd. C 77.73, H 9.32, N 12.95; found C 77.40, H 9.56, N 12.86.

(*S*,*S*)-Cy(Me)CH−N=CH−CH=N−CH(Me)Cy (1c): A solution of (*S*)-1-cyclohexylethylamine (17.8 g, 140 mmol) in 80 mL of hexane was added during 30 min to a vigorously stirred mixture of 8 mL of aqueous glyoxal (70 mmol) and 50 mL of hexane. Both phases were separated and the aqueous layer was extracted with 50 mL of hexane. The combined organic phases were dried twice with Na_2SO_4. Solvent was removed in vacuo to afford 16.1 g (82%) of **1c** as colorless crystals. ^{1}H NMR ($CDCl_3$): δ = 0.85 (m, 2 H, Cy), 0.93 (m, 2 H, Cy), 1.15 (m, 8 H, Cy), 1.23 (m, 4 H, Cy), 1.42 (m, 2 H, Cy), 1.63 (m, 4 H, Cy), 1.75 (m, 6 H, CH_3), 2.97 (q, $^3J_{H,H}$ = 6.6 Hz, 2 H, C*H*CH$_3$), 7.85 (s, 2 H, N=CH) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 19.6 (s, CH_3), 26.2, 26.3, 26.5, 29.5, 29.8, 43.4 (6s, Cy), 71.6 (s, *C*HCH$_3$), 160.2 (s, CH=N) ppm. MS/EI: *m*/*z* (%) = 276 (7) [M$^+$], 193 (100) [M$^+$ − Cy]. [α]$_D^{24}$ = +34. $C_{18}H_{32}N_2$ (276.47): calcd. C 78.20, H 11.67, N 10.13; found C 77.40, H 11.94, N 10.30.

Preparation of the 2,3-Dihydro-1*H*-1,3,2-diazaboroles. (*S*)-*t*BuN^a-CH=CHN^b {CH(Ph)Me}BBr(*N*^{a}−*B*) (3a): A solution of 1,4-diazabutadiene **1a** (3.3 g, 15.3 mmol) in 50 mL of hexane and a solution of boron tribromide (3.85 g, 15.5 mmol) in 50 mL of hexane were added dropwise and simultaneously at 20 °C to a volume of 100 mL of hexane. The resulting orange slurry was stirred for another 30 min and filtered. The filter cake was washed with pentane (50 mL) and dried at 5 × 10^{-3} bar. The borolium salt (*S*)-*t*BuN^a=CH−CH=N^b {CH(Ph)Me}BBr$_2$]Br(*N*^{a}−*B*) **2a** was obtained as an orange powder (6.4 g, 90%). ^{1}H NMR ($CDCl_3$): δ = 1.75 (s, 9 H, *t*Bu), 2.02 (d, $^3J_{H,H}$ = 6.9 Hz, 3 H, CHC*H*$_3$), 5.35 (q, $^3J_{H,H}$ = 6.9 Hz, 1 H, C*H*CH$_3$), 7.40 (m, 3 H, Ph), 7.57 (m, 2 H, Ph), 8.40 (d, $^3J_{H,H}$ = 7.9 Hz, 1 H, *C*H=N−CH), 8.68 (d, $^3J_{H,H}$ = 7.9 Hz, 1 H, *C*H=N*t*Bu) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = −1.2 (s) ppm. Compound **2a** (11.5 g, 24.6 mmol) was added to a mixture of sodium amalgam (from 2.5 g, 108 mmol Na and 240 g Hg) and hexane (200 mL) and vigorously stirred for two days. The yellow hexane solution was then decanted and the solvent evaporated. The remaining brown oil was distilled by means of a hot air gun to afford **3a** as a yellow oil (5.1 g, 66%). As pure diazaborole **3a** decomposes markedly at ambient temp. within one day, it is recommended to store the compound in the hexane solution over sodium amalgam and to use the freshly isolated material. IR (film): $\tilde{\nu}$ = 3030 cm^{-1} m, 2985 s, 2873 s, 1603 w, 1495 m, 1450 s, 1147 m, 962 m, 755 m, 700 s, 610 m. ^{1}H NMR ($CDCl_3$): δ = 1.51 (s, 9 H, *t*Bu), 1.66 (d, $^3J_{H,H}$ = 7.1 Hz, 3 H, CH_3), 5.19 (q, $^3J_{H,H}$ = 7.1 Hz, 1 H, C*H*CH$_3$), 6.19 (d, $^3J_{H,H}$ = 2.4 Hz, 1 H, *H*C=NCHMe), 6.41 (d, $^3J_{H,H}$ = 2.4 Hz, 1 H, *H*C=N*t*Bu), 7.26 (m, 3 H, Ph), 7.3 (m, 2 H,

Ph) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 21.4 (s, CH*C*H_3), 31.2 [s, C(*C*H_3)$_3$], 52.8 [s, *C*(CH$_3$)$_3$], 58.3 (s, *C*HCH$_3$), 111.9 (s, H*C*=NCHMe), 114.9 (s, H*C*=N*t*Bu), 126.5, 126.8, 128.3, 144.0 (4s, Ph) ppm. $^{11}B\{^1H\}$ NMR ($CDCl_3$): δ = 17.3 s ppm. MS/EI: *m*/*z* (%) = 308 (6) [M^+ with ^{81}Br], 306 (7). [M^+ with ^{79}Br]. $[\alpha]_D^{24}$ = −104. $C_{14}H_{20}BBrN_2$ (307.04): calcd. C 54.77, H 6.57, N 9.12; found C 55.40, H 6.89, N 8.62.

(*S*,*S*)-Me(Ph)HCN^a−CH=CH−N^b\|CH(Ph)Me\|BBr(*N*^{a}−*B*) (3b): A solution of (*S*,*S*)−Me(Ph)HC−N=CH−CH=N−CH(Ph)Me (**1b**) (7.04 g, 27.0 mmol) in 50 mL of hexane and a solution of BBr_3 (6.67 g, 27.0 mmol) in 50 mL of hexane were added slowly at 20 °C to 300 mL of hexane, whereupon a yellow precipitate separated. Stirring was continued for two days. The mixture was then filtered, the filter cake was washed with hexane (50 mL) and then dried in vacuo. Yield: 11.2 g (81.4%) [(*S*,*S*)−Me(Ph)HC−N^a=CH−CH=N^b−CH(Ph)MeBBr$_2$]Br(*N*^{a}−*B*) (**2b**).

A slurry of **2b** (8.0 g, 18.4 mmol) and sodium amalgam (from 230 g Hg and 2.4 g Na) in 200 mL of hexane was stirred vigorously for two days. The yellow organic phase was decanted and the solvents evaporated to dryness to afford 2.1 g (32%) of crude **3b**. The marked thermolability of this compound thwarted reliable elemental analyses. As in the case of **3a** it is recommended to store the reaction mixture and to isolate the required amount of compound prior to use. ^1H NMR (C_6D_6): δ = 1.38 (d, $^3J_{H,H}$ = 7.1 Hz, 6 H, CH$_3$), 5.13 (q, $^3J_{H,H}$ = 7.1 Hz, 2 H, C*H*CH$_3$), 6.13 (s, 2 H, CH=N), 7.01−7.17 (m, 10 H, Ph) ppm. $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 21.5 (s, CH*C*H$_3$), 53.9 (s, *C*HCH$_3$), 114.6 (s, CH=N), 126.7, 127.1, 128.5, 144.3 (4s, Ph). $^{11}B\{^1H\}$ NMR (C_6D_6): δ = 19.0 (s) ppm.

(*S*,*S*)-Me(Cy)HC−N^{a}CH=CH−N^b\|CH(Cy)Me\|BBr(*N*^{a}−*B*) (3c): A solution of 1,4-diazabutadiene **1c** (8.0 g, 29.0 mmol) in 100 mL of hexane and a solution of BBr_3 (7.52 g, 30.0 mmol) in 100 mL of hexane were added simultaneously at 0 °C to 100 mL of hexane. The resulting slurry was allowed to stir for 1 h at 20 °C and was then filtered. The filter cake was washed with 100 mL of pentane and dried in vacuo. The borolium salt (*S*,*S*)-[Me(Cy)CH−N^a=CH−CH=N^b{CH(Cy)Me}BBr$_2$]Br(*N*^{a}−*Br*) (**2c**) was obtained as an orange solid (14.5 g, 93%). ^1H NMR (C_6D_6): δ = 0.69−2.00 (m, 22 H, C_6H_{11}), 1.41 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, CH$_3$), 3.76 (m, 2 H, C*H*CH$_3$), 9.12 (s, 2 H, HC=CH) ppm. $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 18.4 (s, CH$_3$), 26.2, 26.3 (2s, 3,5-*C*−Cy), 29.0, 31.5 (2s, 2,6-*C*−Cy), 42.2 (s, 1-*C*−Cy), 60.9 (s, *C*HCH$_3$), 146.7 (s, HC=CH) ppm. $^{11}B\{^1H\}$ NMR (C_6D_6): δ = 0.6 (s, BBr_2), −23.8 (s, BBr_4^-) ppm.

Solid borolium salt **2c** (9.5 g, 18.0 mmol) was combined with sodium amalgam [from Na (1.3 g, 55.0 mmol) and 130 g of Hg]. After the addition of 200 mL of hexane the resulting slurry was stirred at room temp. for three days. The yellow hexane phase was decanted and concentrated to ca 10 mL, whereby crystalline colorless **3c** precipitated (4.0 g, 60.5%). The purity of the sample was satisfactory for most chemical transformations. Analytically pure **3c** was obtained by sublimation at 80 °C and 5 × 10^{-6} bar. ^1H NMR ($CDCl_3$): δ = 0.79−1.81 (m, 22 H, C_6H_{11}), 1.25 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, CH$_3$), 3.46 (m, 2 H, C*H*CH$_3$), 6.17 (s, 2 H, HC=CH) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 19.6 (s, CH$_3$), 26.15, 26.22 (2s, 3,5-*C*−Cy), 26.3 (s, 4-*C*−Cy), 29.9, 30.3 (2s, 2,6-*C*−Cy), 44.1 (s, 1-*C*−Cy), 55.6 (s, *C*HCH$_3$), 113.5 (s, HC=CH) ppm. $^{11}B\{^1H\}$ NMR: δ = 18.2 (s) ppm. MS/CI (toluene): *m*/*z* (%) = 367 (9) [MH^+]. $[\alpha]_D^{24}$ = −29. $C_{18}H_{32}BBrN_2$ (367.18): calcd. C 58.88, H 8.78, N 7.63; found C 58.44, H 9.17, N 7.48.

(*S*)-*t*BuN^{a}CH=CHN^b\|CH(Ph)Me\|B−NC(*N*^{a}−*B*) (4) and (*S*)-*t*BuN^{a}CH=CHN^b\|CH(Ph)Me\|BCN(*N*^{a}−*B*) (5): A solution of **3a** (0.65 g, 2.1 mmol) in 5 mL of acetonitrile was added to a slurry of silver cyanide (0.3 g, 2.2 mmol) in hexane (70 mL) and the mixture was stirred for 1 h. The supernatant yellow solution was decanted, and the residue was extracted with pentane (2 × 20 mL). The combined organic phases were evaporated to dryness to afford a mixture of isocyanide **4** and cyanide **5** as a yellow oil (0.41 g). This mixture was dissolved in hexane (30 mL) and stored at −30 °C for two weeks. The solvent was then removed and the solid brown residue was distilled by means of a hot air gun (200 °C, 5 × 10^{-3} bar) to give 0.3 g (57%) of the 2-cyano derivative **5** as a colorless solid. IR (KBr): $\tilde{\nu}$ = 2976 cm^{-1} (s), 2206 w [ν(C≡N)], 1455 s, 1414 m, 1372 w, 1336 w, 1259 w, 1228 m, 1156 m, 704 s, 647 m. ^1H NMR ($CDCl_3$): δ = 1.49 (s, 9 H, *t*Bu), 1.74 (d, $^3J_{H,H}$ = 7.1 Hz, 3 H, CH$_3$), 5.19 (q, $^3J_{H,H}$ = 7.1 Hz, 1 H, C*H*CH$_3$), 6.25 (d, $^3J_{H,H}$ = 2.3 Hz, 1 H, =C*H*−NCH), 6.40 (d, $^3J_{H,H}$ = 2.3 Hz, 1 H, =C*H*N*t*Bu), 7.27 (m, 3 H, Ph), 7.31 (m, 2 H, Ph) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 22.1 (s, CH*C*H$_3$), 31.6 [s, C(*C*H$_3$)$_3$], 53.6 [s, *C*(CH$_3$)$_3$], 55.1 (s, *C*HCH$_3$), 114.8 (s, =*C*NCH), 116.1 (s, =*C*N*t*Bu), 126.3 (s, C≡N), 126.4, 127.3, 128.5, 143.4 (4s, Ph) ppm. $^{11}B\{^1H\}$ NMR ($CDCl_3$): δ = 11.6 (s) ppm. MS/EI: *m*/*z* (%) = 253 (40) [M^+], 252 (10) [M^+ with ^{10}B]. $[\alpha]_D^{24}$ = −140. $C_{15}H_{20}BN_3$ (253.16): calcd. C 71.17, H 7.96, N 16.60; found C 71.16, H 7.93, N 16.41.

4: IR (KBr): $\tilde{\nu}$ = 2113 cm^{-1} w [ν(B−N≡C)]. ^1H NMR ($CDCl_3$): δ = 1.51 (s, 9 H, *t*Bu), 1.78 (d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH$_3$), 5.10 (q, $^3J_{H,H}$ = 7.0 Hz, 1 H, C*H*CH$_3$), 6.22 (d, $^3J_{H,H}$ = 2.3 Hz, 1 H, =C*H*NCH), 6.37 (d, $^3J_{H,H}$ = 2.3 Hz, 1 H, =C*H*N*t*Bu) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 22.5 (s, CH$_3$), 31.6 [s, C(*C*H$_3$)$_3$], 53.7 [s, *C*(CH$_3$)$_3$], 55.7 (s, *C*HCH$_3$], 114.7 (s, =*C*N*t*Bu), 116.0 (s, =*C*N−CH), 126.3, 127.2, 128.4, 143.3 (4s, Ph).

(*S*)-*t*BuN^{a}CH=CHN^b\|CH(Ph)Me\|BH(*N*^{a}−*B*) (6): At 0 °C a quantity of $LiAlH_4$ (0.05 g, 1.3 mmol) was added to a slurry of **3a** (0.4 g, 1.3 mmol) in a mixture of 20 mL of hexane and 5 mL of THF. After a few minutes of stirring the reaction mixture became clear. It was then filtered, and the filtrate was evaporated to dryness. The residue was triturated with pentane (6 mL), and filtered again. Removal of pentane afforded 0.28 g (95%) of crude **6** as a yellow oil. Distillation with a hot air gun at 150 °C and 2 × 10^{-5} bar afforded pure **6** as a colorless liquid (0.14 g, 47%). This product is temperature-sensitive at room temp.; decomposition to a brown oil was complete after 24 h (NMR control). IR (film): $\tilde{\nu}$ = 3086 m, 3063 m, 3027 m, 2973 s, 2868 s, 2621 s [ν(BH)], 1603 m, 1494 m, 1151 m, 920 m, 753 m, 664 s. ^1H NMR ($CDCl_3$): δ = 1.44 (s, 9 H, *t*Bu), 1.71 (d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH$_3$), 4.88 (q, $^3J_{H,H}$ = 7.0 Hz, 1 H, C*H*CH$_3$), 6.15 (d, $^3J_{H,H}$ = 2.0 Hz, 1 H, =C*H*NCH), 6.40 (d, $^3J_{H,H}$ = 2.0 Hz, 1 H, =C*H*N*t*Bu), 7.27 (m, 3 H, Ph), 7.30 (m, 2 H, Ph) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 24.0 (s, CH$_3$), 31.8 [s, C(*C*H$_3$)$_3$], 51.5 [s, *C*(CH$_3$)$_3$], 56.5 (s, *C*HCH$_3$), 114.4 (s, =*C*NCH), 116.2 (s, =*C*N*t*Bu), 126.1, 126.7, 128.3, 146.1 (4s, Ph) ppm. ^{11}B NMR ($CDCl_3$): δ = 19.4 (d, $^1J_{B,H}$ = 146 Hz) ppm. MS/EI: *m*/*z* (%) = 228 (7) [M^+], 213 (7) [$M^+ - CH_3$]. $[\alpha]_D^{24}$ = +94. $C_{14}H_{21}BN_2$ (228.15): calcd. C 73.70, H 9.28, N 12.28; found C 73.44, H 9.39, N 12.21.

(*S*)-*t*BuN^{a}CH=CHN^b\|CH(Ph)Me\|BCH$_3$(*N*^{a}−*B*) (7): A sample of **3a** (0.57 g, 1.8 mmol) was suspended in a mixture of hexane (40 mL) and THF (2.5 mL). An ethereal solution of methyllithium was then added (2 mL, 1.6 M), and the resulting mixture was stirred at 20 °C for two days. The volatile components were removed in vacuo, and the residue was extracted twice with 2.5 mL of hexane.

After filtration it was evaporated to dryness to give crude **7** (0.4 g, 92%) as a red oil. Purification was achieved by hot air distillation (200 °C, 1.5×10^{-5} bar) to yield 0.23 g (51%) of **7** as a colorless liquid. IR (film): $\tilde{\nu}$ = 3027 s, 2972 s, 1602 m, 1401 s, 1253 s, 1152 m, 1029 m, 758 m, 700 s, 665 m. ^{1}H NMR ($CDCl_3$): δ = 0.75 (s, 3 H, BCH_3), 1.56 (s, 9 H, *t*Bu), 1.80 (d, $^3J_{H,H}$ = 7.1 Hz, 3 H, $CHCH_3$), 5.12 (q, $^3J_{H,H}$ = 7.1 Hz, 1 H, $CHCH_3$), 6.32 (d, $^3J_{H,H}$ = 2.5 Hz, 1 H, =C*H*−NCH), 6.48 (d, $^3J_{H,H}$ = 2.5 Hz, 1 H, =C*H*N*t*Bu), 7.34 (m, 3 H, Ph), 7.41 (m, 2 H, Ph) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.2 ($CHCH_3$), 31.6 [s, $C(CH_3)_3$], 52.4 [s, $C(CH_3)_3$], 55.7 (s, $CHCH_3$), 111.1 (s, =*C*HNCH), 113.5 (s, =*C*HN*t*Bu), 126.2, 126.3, 128.4, 145.7, (4 s, Ph) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 26.2 (s) ppm. MS/EI: *m*/*z* (%) = 242 (75) [M^+], 241 (19) [M^+ with ^{10}B], 227 (54) [$M^+ - CH_3$]. $[\alpha]_D^{24}$ = −111. $C_{15}H_{23}BN$ (242.17): calcd. C 73.06, H 10.07, N 12.17; found C 73.28, H 9.85, N 12.19.

(*S*)-*t*BuN^{a}CH=CHN^b[CH(Ph)Me]BNH*t*Bu(*N^a*−*B*) (8): *tert*-Butylamine (1 mL, 0.66 g, 9.0 mmol) was added at room temp. to a well stirred slurry of **3a** (1.3 g, 4.2 mmol) in hexane (10 mL). A colorless precipitate was formed immediately. After filtration the filtrate was freed from solvent to yield 1.17 g of a brown oil, which was subsequently purified by distillation with a hot air gun (300 °C, 10^{-5} bar). Compound **8** was obtained as a yellow oil (yield 0.93 g, 74%). IR (film): $\tilde{\nu}$ = 3443 cm^{-1} w [ν(NH)], 3061 m, 3027 m, 2986 s, 2865 s, 1602 w, 1494 s, 1135 m, 1028 m, 817 m, 789 m, 753 m, 699 s, 647 m. ^{1}H NMR ($CDCl_3$): δ = 1.28 (s, 9 H, NH*t*Bu), 1.47 (s, 9 H, =CHN−*t*Bu), 1.69 (d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3), 5.22 (q, $^3J_{H,H}$ = 7.0 Hz, 1 H, $CHCH_3$), 5.93 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, =C*H*−NCH), 6.24 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, =C*H*−N*t*Bu), 7.21 (m, 1 H, Ph), 7.29 (m, 4 H, Ph) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 21.9 (s, CH_3), 31.6 [s, $NC(CH_3)_3$], 33.6 [s, $NHC(CH_3)_3$], 49.2 [s, $NHC(CH_3)_3$], 51.8 [s, =CH−N$C(CH_3)_3$], 52.2 (s, $CHCH_3$), 109.6 (s, =H*C*N−CH), 113.0 (s, =*C*HN*t*Bu), 126.1, 126.4, 128.3, 144.0 (4s, Ph) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 22.3 (s) ppm. $[\alpha]_D^{24}$ = −125. $C_{18}H_{30}BN_3$ (299.27): calcd. C 72.24, H 10.10, N 14.04; found C 71.91, H 10.20, N 13.87.

(*S*,*S*)−*t*BuN^a−CH=CHN^b−[CH(Ph)Me]BNH[CH(Ph)Me]-(*N^a*−*B*) (9): Triethylamine (0.12 g, 1.2 mmol) was added to a slurry of (*S*)-**3a** (0.38 g, 1.2 mmol) in hexane (15 mL) at ambient temp. followed by the addition of (*S*)-1-phenylethylamine (0.16 g, 1.3 mmol). The reaction mixture spontaneously turned cloudy with separation of a colorless precipitate. The mixture was stirred for 15 min and then filtered. The filtrate was evaporated to dryness to yield (*S*,*S*)-**9** as a red-brown oil (yield 0.38 g, 92%). Distillation of the product (hot air gun, 150 °C, 2×10^{-6} bar) gave 0.2 g (48%) of **9** as a colorless liquid. IR (film): $\tilde{\nu}$ = 3463 cm^{-1} w [ν(NH)], 3061 m, 3026 m, 2961 s, 2865 s, 1601 w, 1478 w, 1332 s, 1137 m, 1028 m, 908 w, 758 m, 700 s, 636 m. ^{1}H NMR ($CDCl_3$): δ = 1.24 (d, $^3J_{H,H}$ = 6.9 Hz, 3 H, BNHCC*H*$_3$), 1.33 (d, $^3J_{H,H}$ = 6.7 Hz, = HC−NCHC*H*$_3$), 1.46 (s, 9 H, *t*Bu), 2.27 (d, $^3J_{H,H}$ = 8.8 Hz, 1 H, *NH*), 4.37 [m, 1 H, N(H)C*H*CH_3], 4.72 (q, $^3J_{H,H}$ = 7.0 Hz, 1 H, CH=NC*H*CH_3), 5.86 (d, $^3J_{H,H}$ = 2.6 Hz, 1 H, =C*H*NCH), 6.13 (d, $^3J_{H,H}$ = 2.6 Hz, 1 H, =C*H*N*t*Bu), 7.20 (m, 4 H, Ph), 7.34 (m, 6 H, Ph) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.1 (s, CNCH*C*H_3), 28.2 (s, HNCH*C*H_3), 31.1 [s, $C(CH_3)_3$], 51.5 [s, $C(CH_3)_3$], 51.9 (s, $CHCH_3$), 52.0 (s, $CHCH_3$), 109.2 (s, =*C*HNCH), 111.9 (s, =*C*HN*t*Bu), 125.3, 125.9, 126.1, 126.15, 128.1, 128.2, 146.5, 148.8 (8s, Ph) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 21.6 (s) ppm. MS/EI: *m*/*z* (%) = 347 (37) [M^+], 346 (9) [M^+ with ^{10}B]. $[\alpha]_D^{24}$ = −99. $C_{22}H_{30}BN_3$ (347.31): calcd. C 76.08, H 8.71, N 12.10; found C 76.10, H 8.77, N 11.86.

(*S*)-Me(Ph)CH−N^a−CH=CH−N^b[CH(Ph)Me]BSnMe$_3$(*N^a*−*B*) (10): Trimethyltin chloride (1.68 g, 8.45 mmol) was added to a slurry of lithium sand (0.13 g, 18.6 mmol) in THF (80 mL) and stirred at 20 °C until a green solution was formed (ca. 2 h). A solution of **3b** (1.31 g, 5.6 mmol) in hexane (30 mL) was then added dropwise to this mixture and stirring was continued for another 2 h. The volatile components were removed in vacuo and the residue was extracted with pentane (3 × 10 mL). The filtrate was evaporated to dryness. Recrystallization of the residue from toluene gave 1.66 g (67%) of **10** as colorless crystals. ^{1}H NMR (C_6D_6): δ = 0.22 (t, $^2J_{Sn,H}$ = 47.3 Hz, 9 H, $SnMe_3$), 1.51 (d, $^3J_{H,H}$ = 7.1 Hz, 6 H, $CHCH_3$), 5.15 (q, $^3J_{H,H}$ = 7.1 Hz, 2 H, $CHCH_3$), 6.38 (s, 2 H, HC=CH), 7.01 (t, $^3J_{H,H}$ = 7.3 Hz, 2 H, *p*-H−Ph), 7.09 (m, 4 H, Ph), 7.16 (m, 4 H, Ph) ppm. ^{13}C{^{1}H} NMR (C_6D_6): δ = −9.4 [t, $^1J_{Sn,C}$ = 298.9 Hz, $Sn(CH_3)_3$], 23.0 (s, $CHCH_3$), 55.9 (s, $CHCH_3$), 116.4 (s, HC=CH), 126.5, 126.7, 128.6, 145.5 (4s, Ph) ppm. ^{11}B{^{1}H} NMR (C_6D_6): δ = 28.2 (t, $^1J_{Sn,B}$ = 994 Hz). ^{119}Sn{^{1}H} NMR (C_6D_6): δ = −150.0 (q, $^1J_{Sn,B}$ = 994 Hz) ppm. MS/EI: *m*/*z* (%) = 440 (2) [M^+]. $[\alpha]_D^{24}$ = −119. $C_{21}H_{29}BN_2Sn$ (439.00): calcd. C 56.62, H 6.58, N 6.28; found C 57.46, H 6.66, N 6.38.

(*S*,*S*)-Me(Ph)CH−N^a−CH=CH−N^b[CH(Ph)Me]B(NH*t*Bu)-(*N^a*−*B*) (11): A slurry of **3b** (1.80 g, 5.0 mmol) in hexane (50 mL) was treated with *tert*-butylamine (0.74 g, 1.1 mL, 10 mmol) and stirred for 5 min at room temperature. The mixture was then filtered. The filtrate was evaporated to dryness to give a red oil (1.75 g), which was distilled at 200 °C (hot air gun) and 2×10^{-6} bar to afford **11** as a pale yellow liquid (0.86 g, 50%). IR (film): $\tilde{\nu}$ = 3414 cm^{-1} w [ν(NH)], 3060 m, 3026 m, 2969 s, 2871 m, 1946 w, 1602 m, 1493 s, 1243 m, 1167 m, 1027 m, 757 m, 699 s. ^{1}H NMR ($CDCl_3$): δ = 1.15 (s, 9 H, *t*Bu), 1.70 (d, $^3J_{H,H}$ = 7.0 Hz, 6 H, CH_3), 5.04 (q, $^3J_{H,H}$ = 7.0 Hz, 2 H, $CHCH_3$), 6.12 (s, 2 H, CH=CH), 7.30 (m, 4 H, Ph), 7.34 (m, 6 H, Ph) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.4 (s, CH_3), 33.2 [s, $C(CH_3)_3$], 49.1 [s, $C(CH_3)_3$], 111.9 (s, H*C*=*C*H), 126.1, 126.4, 128.2, 145.7, (4s, Ph) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 22.5 (s) ppm. $[\alpha]_D^{24}$ = −165. $C_{22}H_{30}BN_3$ (347.31): calcd. C 76.08, H 8.71, N 12.10; found C 75.90, H 8.93, N 11.66.

(*S*,*S*)-Me(Cy)CHN^a−CH=CH−N^b[CH(Cy)Me]BN(H)*t*Bu (12): A solution of **3c** (0.70 g, 1.9 mmol) in hexane (25 mL) was treated at 20 °C with *tert*-butylamine (0.29 g, 4.0 mmol). After stirring for 10 min this mixture was filtered, and the filtrate was evaporated to dryness. The residual yellow oil was distilled by means of a hot air gun (300 °C, 4×10^{-6} bar) to afford 0.40 g (58%) of **12** as a colorless oil. IR (film): $\tilde{\nu}$ = 3419 cm^{-1} w [ν(NH)], 2923 s, 2843 s, 2658 w, 1446 s, 1229 s, 890 s, 657 s. ^{1}H NMR ($CDCl_3$): δ = 0.87−1.80 (m, 22 H, C_6H_{11}), 1.20 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, $CHCH_3$), 1.21 (s, 9 H, *t*Bu), 3.25 (m, 2 H, $CHCH_3$), 5.95 (s, 2 H, HC=CH) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.7 (s, $CHCH_3$), 26.4 (s, 3,5-*C*−Cy), 26.5 (s, 4-*C*−Cy), 30.4, 30.8 (2s, 2,6-*C*−Cy), 31.6 [s, $C(CH_3)_3$], 33.6 [s, $C(CH_3)_3$], 44.5 (s, 1-*C*−Cy), 54.4 (s, $CHCH_3$), 110.6 (s, HC=CH) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 22.1 (s) ppm. MS/CI (NH_3): *m*/*z* (%) = 360 (87) [MH^+], 359 (100) [MH^+ with ^{10}B and M^+ with ^{11}B], 358 (22) [M^+, ^{10}B]. $[\alpha]_D^{24}$ = −55. $C_{22}H_{42}BN_3$ (359.41): calcd. C 73.52, H 11.78, N 11.69; found C 73.23, H 12.06, N 11.40.

(*S*,*S*)−Me(Cy)CHN^a−CH=CH−N^b[CH(Cy)Me]B−*n*C$_4$H$_9$(*N^a*-*B*) (13): A hexane solution of *n*-butyllithium (12%, 2.0 g, 3.8 mmol) was added dropwise at −15 °C to a solution of **3c** (0.76 g, 2.1 mmol) in a mixture of 50 mL of hexane and 10 mL of THF. After stirring for one day at 20 °C the solvent and volatile components were removed in vacuo. The residue was extracted with 30 mL of pentane. Removal of solvent gave a yellow oil (0.75 g) which was

distilled at 250 °C and 5×10^{-6} bar to give 0.32 g (47%) of **13** as a colorless oil. ^{1}H NMR (C_6D_6): δ = 0.80−1.70 (m, 31 H, C_6H_{11} and C_4H_9), 1.24 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, CHCH_3), 3.37 (m, 2 H, CHCH$_3$), 6.19 (s, 2 H, HC=CH) ppm. ^{13}C{^{1}H} NMR (C_6D_6): δ = 14.4 (s, CH_2CH_3), 20.9 (s, CHCH$_3$), 26.5 (s, CH_2CH_3), 26.7 (s, 3,5-C−Cy), 26.8 (s, 4-C−Cy), 30.3 (s, $CH_2CH_2CH_3$), 30.7, 30.9 (2s, 2,6-C−Cy), 44.5 (s, 1-C−Cy), 55.6 (s, CHCH$_3$), 112.4 (s, HC=CH) ppm. ^{11}B{^{1}H} NMR (C_6D_6): δ = 26.4 (s) ppm. MS/EI: *m*/*z* (%) = 344 (50) [M$^+$, ^{11}B], 343 (14) [M$^+$, ^{10}B], 262 (20) [M$^+$ − C_6H_{10}], 261 (100) [M$^+$ − C_6H_{11}]. $[\alpha]_D^{24}$ = −18. $C_{22}H_{41}BN_2$ (344.39): calcd. C 76.73, H 12.00, N 8.13; found C 76.47, H 12.12, N 7.88.

(*S*,*S*)-Me(Cy)CHN^a−CH=CH−N^b\|CH(Cy)Me\|BSnMe$_3$(*N*^{a}−*B*) (14): Lithium sand (0.14 g, 20 mmol) was added to a solution of trimethyltin chloride (0.77 g, 3.9 mmol) in 40 mL of THF and the slurry was stirred at ambient temp. with sonification. The resulting mixture was combined with a solution of (*S*,*S*)-**3c** (1.45 g, 3.95 mmol) in hexane (20 mL). Stirring was continued for 1 h. The mixture was then evaporated to dryness, and 30 mL of hexane was added to the residue. It was filtered, and the filtrate was freed from solvent to give crude (*S*,*S*)-**14** as a cloudy yellow oil (1.7 g). Distillation (250 °C, 1×10^{-5} bar) gave 1.02 g (58%) of pure (*S*,*S*)-**14** as colorless liquid. IR (film): $\tilde{\nu}$ = 2979 cm^{-1} m, 2924 s, 2853 s, 2651 w, 2348 w, 1643 s, 1449 s, 1398 s, 1225 m [δ(SnMe$_3$)], 891 w, 764 s, [(SnMe$_3$)], 513 s. ^{1}H NMR (C_6D_6): δ = 0.4 (s, $^2J_{Sn,H}$ = 45.2 Hz, 9 H, SnMe$_3$), 0.78−1.74 (m, 22 H, C_6H_{11}), 1.22 (d, $^3J_{H,H}$ = 6.3 Hz, 6 H, CHCH_3), 3.49 (m, 2 H, CHCH$_3$), 6.37 (s, $^4J_{Sn,H}$ = 12.6 Hz, 2 H, CH=CH) ppm. ^{13}C{^{1}H} NMR (C_6D_6): δ = −9.7 (s, $^1J_{Sn,C}$ = 269 Hz, $SnCH_3$), 20.9 (s, CHCH$_3$), 26.6 (s, 4-C−Cy), 26.6, 26.7 (2s, 3,5-C−Cy), 30.68/31.72 (2s, 2,6-C−Cy), 44.7 (s, 1-C−Cy), 58.4 (s, CHCH$_3$), 115.4 (s, $^3J_{Sn,C}$ = 37.9 Hz, HC=CH) ppm. ^{11}B{^{1}H} NMR (C_6D_6): δ = 30.8 (s, $^1J_{Sn,B}$ = 986 Hz) ppm. ^{119}Sn{^{1}H} NMR (C_6D_6): δ = −149.1 (q, $^1J_{Sn,B}$ = 986 Hz) ppm. MS/CI (NH_3): *m*/*z* = 453 (100) [M$^+$ + H]. $[\alpha]_D^{24}$ = −44. $C_{21}H_{41}BN_2Sn$ (451.08): calcd. C 55.92, H 9.16, N 6.21; found C 56.11, H 9.05, N 6.21.

(*S*)-*t*BuN^a−CH=CH−N^b(*t*Bu)B−N(H)CH(Ph)Me(*N*^{a}−*B*) (15): Equimolar amounts of 1,3,2-diazaborole *t*BuN^{a}CH=CHN^b(*t*Bu)BBr(*N*^{a}−*B*) (2.33 g, 9.0 mmol) and triethylamine (1.25 mL, 9.0 mmol) were dissolved in hexane (70 mL). At room temperature (*S*)-1-phenylethylamine (1.1 g, 9.0 mmol) was then added. After 15 min of stirring the mixture was filtered, and the filtrate was freed from solvent and volatile components to afford a cloudy oil (2.27 g). Pure compound **14** (2.02 g, 74%) was obtained as a pale yellow oil by distillation (200 °C, hot air gun, 10^{-5} bar). IR (film): $\tilde{\nu}$ = 3443 cm^{-1} w [ν(NH)], 2971 s, 2930 m, 2862 m, 1601 s, 1395 s, 1365 s, 1233 s, 1133 m, 1021 w, 821 w, 699 m, 631 m. ^{1}H NMR (C_6D_6): δ = 1.31 (s, 18 H, *t*Bu), 1.47 (d, $^3J_{H,H}$ = 6.7 Hz, 3 H, CHCH_3), 1.90 (d, $^3J_{H,H}$ = 11.3 Hz, 1 H, NH), 4.64 (m, 1 H, CHCH$_3$), 6.19 (s, 2 H, CH=CH), 7.01 (m, 1 H, *p*-*H*−Ph), 7.18 (m, 2 H, *m*-*H*−Ph), 7.36 (d, $^3J_{H,H}$ = 7.2 Hz, 2 H, *o*-*H*−Ph) ppm. ^{13}C{^{1}H} NMR (C_6D_6): δ = 26.4 (s, CHCH$_3$), 31.8 [s, C(CH$_3$)$_3$], 51.9 [s, C(CH$_3$)$_3$], 54.6 (s, CHCH$_3$), 111.3 (s, HC=CH), 126.3, 128.6, 148.3 (3s, Ph) ppm. ^{11}B{^{1}H} NMR (C_6D_6): δ = 22.3 (s) ppm. MS/CI (NH_3): *m*/*z* (%) = 300 (100) [MH$^+$], 299 (45) [M$^+$]. $[\alpha]_D^{24}$ = −29. $C_{18}H_{30}BN_3$ (299.27): calcd. C 72.24, H 10.10, N 10.04; found C 71.88, H 10.18, N 13.85.

(*S*)-*t*BuN^a−CH=CH−N^b(*t*Bu)BN(H)CH(Cy)Me(*N*^{a}−*B*) (16): Analogously 1.1 g of crude **16** were prepared from *t*BuN^{a}CH=CHN^b(*t*Bu)BBr(*N*^{a}−*B*) (0.93 g, 3.6 mmol), triethylamine (0.37 g, 5.0 mmol) and (*S*)-1-cyclohexylethylamine (0.46 g, 3.6 mmol). Purification to afford a colorless oil (0.23 g, 72%) was achieved by vacuum distillation (150 °C, hot air gun, 2×10^{-6} bar). IR (film): $\tilde{\nu}$ = 3450 cm^{-1} w [ν(NH)], 2925 s, 2853 m, 1396 s, 1365 s, 1233 s, 1133 m, 821 w, 625 m. ^{1}H NMR ($CDCl_3$): δ = 0.85−1.84 (m, 11 H, C_6H_{11}), 1.04 (d, $^3J_{H,H}$ = 6.6 Hz, 3 H, CHCH_3), 1.40 (s, 18 H, *t*Bu), 3.29 (m, 1 H, CHCH$_3$), 6.06 (s, 2 H, HC=CH) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 21.5 (s, CHCH$_3$), 26.6, 26.7 (2s, 3,5-C−Cy), 28.6 (s, 4-C−Cy), 30.1 (s, 2,6-C−Cy), 31.4 [s, C(CH$_3$)], 46.5 (s, 1-C−Cy), 51.7 [s, C(CH$_3$)$_3$], 110.0 (s, CH=CH) ppm. ^{11}B{^{1}H} NMR ($CDCl_3$): δ = 22.0 (s) ppm. MS/EI: *m*/*z* (%) = 305 (62) [M$^+$]. $[\alpha]_D^{24}$ = −6. $C_{18}H_{36}BN_3$ (305.32): calcd. C 70.81, H 11.89, N 13.76; found C 70.75, H 12.04, N 13.73.

X-ray Structural Analysis of (*S*,*S*)-3c: Colorless single crystals were grown from *n*-hexane; 0.27 × 0.24 × 0.15 mm, T = 100 K; Nonius Kappa CCD Mo-K_α (graphite monochromator, λ = 0.71073 Å) empirical formula $C_{18}H_{30}BBrN_2$, tetragonal space group $P4_12_12$; unit cell dimensions: $a = b$ = 10.8870(1), c = 16.0510(1) Å; V = 1902.47(3) Å^3, $d_{calcd.}$ = 1.275 g·cm^{-3}, Z = 4; μ = 2.16 mm^{-1}; range for data collection: 2.9 < θ < 30.0°; index ranges −15 < h < 15, −10 < k < 10, −22 < l < 22; reflection collected 56253; unique reflections 2761 (R_{int} = 0.049); parameters 102; absorption correction multi-scan, min/max transmission 0.738/0.593: Program used: SHELXL-97; structure refinement: full-matrix least-squares on F^2, wR_{F^2} = 0.064 (all data) R_F = 0.024, wR_F = 0.063 based on 2651 unique reflections with $I > 2\sigma(I)$, GOOF (F^2) = 1.057, maximum residual electron density 0.561 e Å^{-3}; hydrogen atoms treated as riding group.

CCDC-180671 [(*S*,*S*)-**3c**] contains the supplementary crystallographic data for this paper. Unprecedented Formation of Dinuclear Macrocyclic Complexes by Insertion of 2,3,5,6-Tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4-Tcnq) into a C−H Bond and Subsequent Coordination to Metal Atoms

Yasuhiro Yamamoto,*[a] Hitoshi Settu,[a] Kazunori Nishiyama,[a] Katsuaki Kuge,[b] and Kazuyuki Tatsumi[b]

Keywords: Cyclopentadienyl ligands / Rhodium / Iridium / Lithium / Macrocyclic ligands

The complexes [Cp*RhCl{PPh[C_6H_3-2,6-$(MeO)_2$](C_6H_3-2-O-6-OMe)-*P,O*}] (**1a**) and [Cp*MCl{PPh_2(C_6H_3-2-O-6-MeO)-*P,O*}] (**1b**: M = Rh; **3b**: M = Ir) with P,O chelating coordination react readily with lithium 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane [Li(F_4-tcnq)] to form the dimeric complexes **2a**, **2b** and **4b** by substitution of the H atom adjacent to the metal-O bond with F_4-tcnq and coordination through the nitrogen atom of a cyano group to another metal. The X-ray crystal structure of **2a** is described. Reaction of **1b** with F_4-tcne proceeds by an insertion into the C–H bond adjacent to the Rh–O bond.

Introduction

Aromatic phosphanes bearing the two methoxy groups at the *ortho* positions have extreme nucleophilicity and large cone angles.[1,2] Previously we reported that one of the *ortho*-methoxy groups in (2,6-dimethoxyphenyl)diphenylphosphane and bis(2,6-dimethoxyphenyl)phenylphosphane were demethylated upon treatment with bis[dichloro(η^6-arene)ruthenium(II)] or bis[dichloro(η^5-pentamethylcyclopentadienyl)rhodium(III) (or iridium(III))] to give ruthenium(II),[3,4] rhodium(III)[5] and iridium(III)[6] complexes with P,O chelating phosphane ligands, as shown in Scheme 1. The rhodium and iridium complexes (**1a**: M = Rh, R = C_6H_3-2,6-$(MeO)_2$; **1b**: M = Rh, R = Ph; **3b**: M = Ir, R = Ph) reacted with mono- or disubstituted alkyne in the presence of KPF_6 or $NaPF_6$ to give novel six- or seven-membered metallacycles arising from a single or double insertion of alkyne into the Rh−O or P−C bond.[7−9] When complexes **1b** and **3b** were treated with electron-deficient olefins such as tetracyanoethylene (tcne) or 7,7,8,8-tetracyano-*p*-quinodimethane (tcnq), the olefin inserted into weakly activated C−H bond on the phenyl ring of the phosphane ligand (Scheme 1).[10,11]

A similar insertion of an electron-deficient olefin into the C−H bond has been documented for 2-furanyl- and 2-thienylplatinum complexes.[12] We also reported that the reaction of [Cp*IrCl{PPh_2(C_6H_3-2-*O*-6-MeO)}] (**3b**) with Li(tcnq) afforded the green charge-transfer complex [Cp*Ir{PPh_2(C_6H_3-2-*O*-6-MeO)}(tcnq)].[11]

During our research on interactions of the aforementioned complexes with lithium 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane [Li(F_4-tcnq)], we found that the F_4-tcnq molecule underwent a substitution reaction at the position adjacent to the M−O bond and coordination to another metal atom of a cyano group, forming a dinuclear macrocyclic complex. This type of compounds provides a new entry into the family of inorganic macrocycles.

Results and Discussion

When compound **1a** was treated with Li(F_4-tcnq) at room temperature (Scheme 2), the orange yellow complex **2a** was formed. Its FAB mass spectrum shows peaks at *m*/*z* = 1761 (26.5%) and *m*/*z* = 881 (100%). The former is the molecular peak with a mass corresponding to a dimer [Cp*Rh{PPh[C_6H_2-2,6-$(MeO)_2$](C_6H_3-2-O-6-MeO)-*P,O*}-(F_4-tcnq)]$_2$ (mol. wt. = 1761.3). The base peak of the spectrum corresponds to half of the molecular peak value ([M/2] = 880.6). This result suggested that **2a** has a dimeric structure. The electronic spectrum shows a strong absorption band at 332 nm (Figure 1a). The IR spectrum has absorptions at 2194 and 2164 cm^{-1} due to a C-N triple bond. The ^1H NMR spectrum shows broad resonances at δ = 1.59, 3.20 and 3.46 ppm, the former being assignable to Cp*

protons and the others to methoxy protons, indicating that the molecule has a symmetric structure.

The detailed structure was confirmed by X-ray analysis (Figure 2 and Table 1). The molecule constructs of a macrocyclic structure with two Cp*Rh{PPh[C_6H_3-2,6-$(MeO)_2$](C_6H_2-2-*O*-6-MeO)-*P*,*O*} moieties connected by two F_4-tcnq molecules. Each F_4-tcnq molecule has undergone the aromatization of a quinone ring to a benzene one by the substitution of an H atom adjacent to an ether-O coordination, and one of the C-N triple bonds is coordinated to another Rh center. The dihedral angles between the benzene rings bearing F atoms (C35-C36-C37-C38-C39-

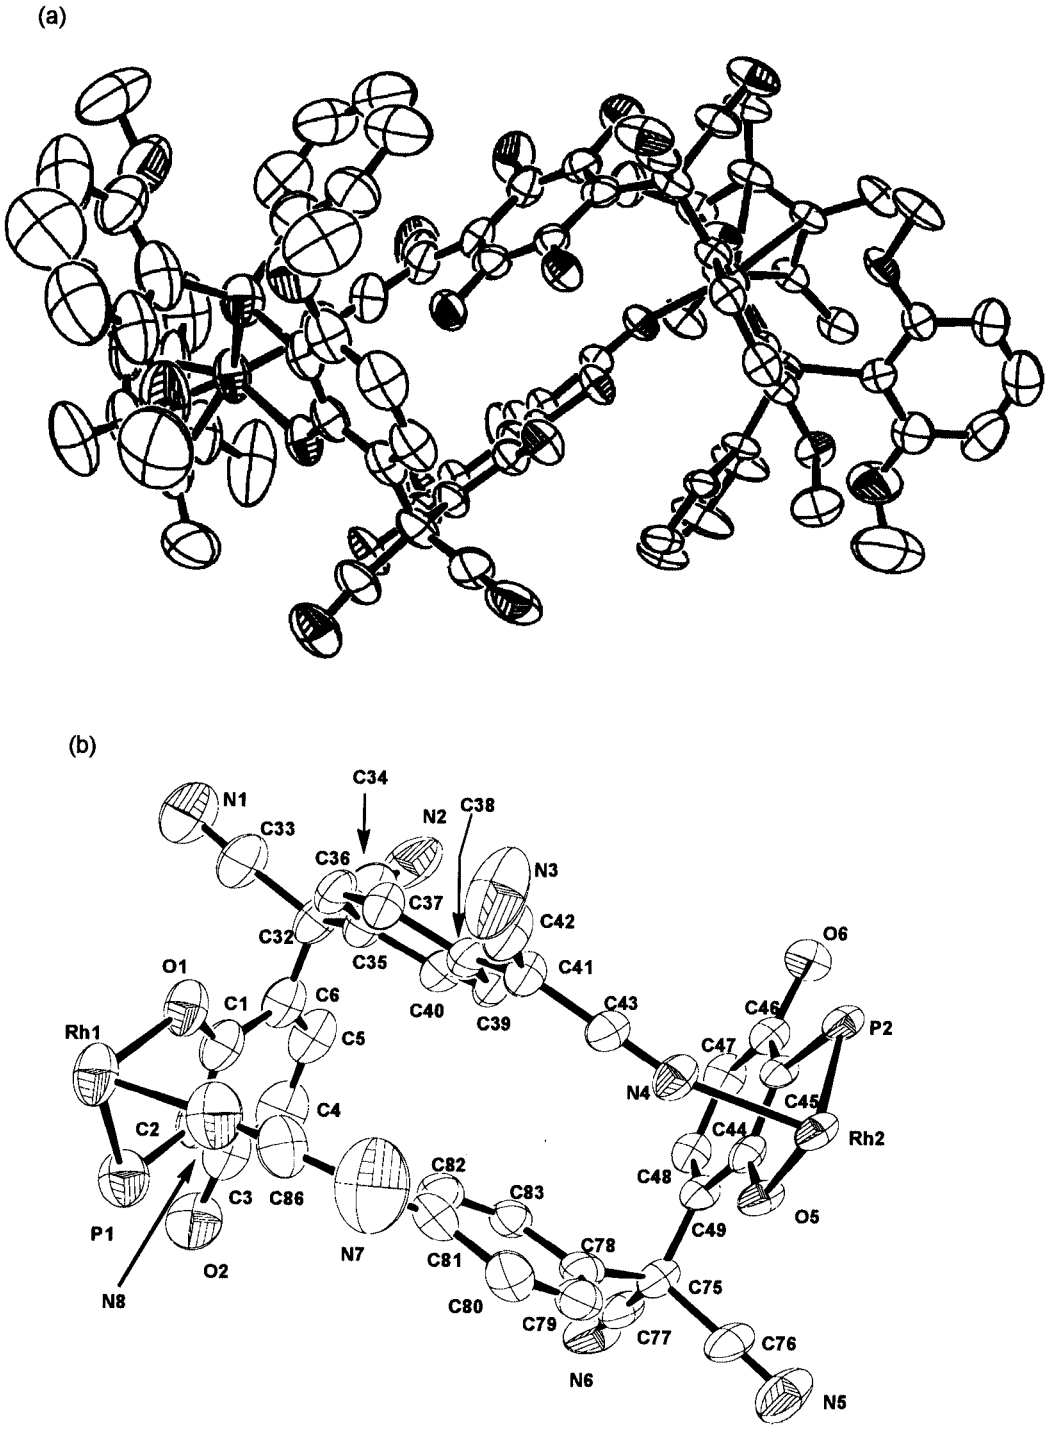

Figure 2. (a) Molecular structure of **2a**; the C84 and C85 atoms sit behind the N7 atom; displacement ellipsoids are shown at the 30% probability level; (b) framework for a core of **2a**; the Cp*, PF_6 anions, F and some other atoms have been omitted for clarity

C40 and C78-C79-C80-C81-C82-C83) and the six-membered rings (C1-C2-C3-C4-C5-C6 and C44-C45-C46-C47-C48-C49) containing the P,O coordination are nearly perpendicular in the range 81−99°. The dihedral angles between two opposite benzene rings are 142.5° and 20.1°, respectively, forming a distorted-rectangular cavity with the dimensions of about 3.5 × 7.0 Å.

The average angles around the C41 and C84 atoms are 120.0°, compared to the more normal bond angles of 109.4° and 109.5° around the C32 and C75 atoms, respectively. These data suggest that the C41 and C84 atoms are sp^2 hybridized. The average C−C and C≡N bond lengths in the inner C-C≡N groups containing the C32 and C75 atoms are 1.49 and 1.13 Å, respectively, and are therefore

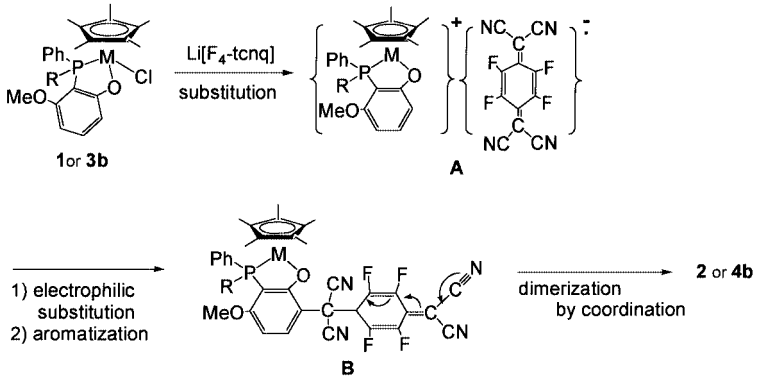


Scheme 3

similar to normal C-C single and C-N triple bonds. However, the average C−C bond length of 1.39 Å in the C-C≡N groups containing the C81 and C84 atoms is shorter by 0.1 Å than that in the inner C-C≡N groups, falling in the region of a C-C double bond, and the N7−C85 bond length of 1.16 Å is slightly long than those in the inner C-C≡N groups. These bond lengths suggest the presence of electron delocalization through the N3−C42−C41−C43−N4 and N7−C85−C84−C86−N8 bonds. The average Rh−P and Rh−O bond lengths are 2.323 Å and 2.080 Å, respectively [those found in the parent complex **1a** are 2.323(2) Å and 2.050(5) Å].[9] The average Rh−N bond length of 2.077 Å is normal for a Rh−N bond.

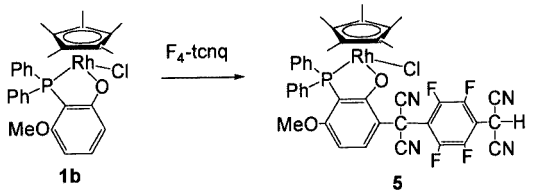
A similar reaction occurred for **1b** to give the dimeric complex **2b** as yellow crystals, which showed an electronic spectrum very similar to that of **2a** (Figure 1b).

The iridium complex **3b** reacts readily with Li(F_4-tcnq) to generate a brown complex **4b**, which has a molecular peak of m/z = 1819, corresponding to a binuclear complex. The IR spectrum of **4b** has absorptions at 2218 and 2170 cm^{-1} due to C-N triple bonds and at 1640 cm^{-1} due to C-N or C-C double bonds. The UV/Vis spectrum shows a sharp absorption band at 330 nm and has a similar pattern to those of **2a** and **2b** (Figure 1c). These results suggested that **4b** has a macrocyclic structure similar to **2**.

Previously, we have reported that a similar reaction of **3b** with Li(tcnq) affords the green charge-transfer complex [Cp*Ir{PPh_2(C_6H_3-2-O-6-MeO)-*P*,*O*}(tcnq)] (a tcnq analogy of intermediate A in Scheme 3) without generating the corresponding dinuclear complex.[11] The difference in electrophilicity between F_4-tcnq and tcnq is assumed to be the driving force leading to the formation of the dinuclear complex.

This reaction consists of the initial formation of a charge-transfer complex A, followed by an electrophilic substitution of a F_4-tcnq radical to the carbon atom adjacent to the ether-O atom, forming an intermediate species B. In the reaction with Li(tcnq), a tcnq analog of the charge transfer complex A was isolated. In the case of Li(F_4-tcnq), the reaction proceeds further and completes by aromatization of the quinone ring and coordination to the metal atom of another molecule to generate the dimeric complex **2** or **4** (Scheme 3).

Finally, the reaction of **1b** with F_4-tcnq led to insertion of F_4-tcnq into a C−H bond adjacent to the ether-O rhodium bond to generate the mononuclear complex **5**



Scheme 4

(Scheme 4). This type of insertion has already been reported.[10,11]

Experimental Section

All reactions were carried out under a nitrogen atmosphere. Dichloromethane was distilled from over CaH_2 and diethyl ether was distilled from over $LiAlH_4$. The pentamethylcyclopentadienyl complexes of rhodium and iridium [Cp*MCl{PPh_2(C_6H_3-2-O-6-MeO)-*P*,*O*}] (**1b**: M = Rh;[5] **3b**: M = Ir[6]) and [Cp*RhCl{$PPh(C_6H_3$-2,6-$(MeO)_2$](C_6H_3-2-O-6-MeO)-*P*,*O*}}][5] (**1a**) were prepared according to literature procedures. Lithium 2,3,5,6-tetracyanotetrafluoroquinodimethane [Li(F_4-tcnq)] was prepared by modification of a literature method.[13] The infrared and electronic absorption spectra were measured on FT/IR-5300 and U-best 30 instruments, respectively. The ^1H NMR spectra were measured on a Bruker AC250 instrument at 250 MHz, and $^{31}P\{^1H\}$ NMR spectra were measured at 101 MHz using 85% H_3PO_4 as an external reference. Elementary analyses were preformed by the Analytical Center, School of Pharmaceutical Science, Toho University.

Reaction of 1a with Li(F_4-tcnq): Li(F_4-tcnq) (33.8 mg, 0.123 mmol) was added at room temperature to a solution of **1a** (65 mg, 0.101 mmol) in CH_2Cl_2 (20 mL). After 5 h, the solvent was removed. The residue was washed with diethyl ether and recrystallized from CH_2Cl_2 and diethyl ether, giving **2a** as an orange solid (13.2 mg, 14.8%). FAB MS: *m*/*z* (%) = 1761 (26) $[M]^+$, 881 $[M/2]^+$. IR (Nujol): $\tilde{\nu}$ = 2194, 2164 (C≡N), 1647 (C=N) cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} = 400 (sh), 331 nm. ^1H NMR ($CDCl_3$): δ = 1.59 (br. s, Cp*, 30 H), 3.20 (s, MeO, 3 H), 3.45 (s, MeO, 3 H), 5.27 (s, CH_2Cl_2), 6.9−7.9 (m, Ph, 11 H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 69.5 (s) ppm. $C_{86}H_{68}F_8N_8O_8P_2Rh_2 \cdot CH_2Cl_2$ (1864.2): calcd. C 56.60, H 3.82, N 6.07; found C 56.32, H 4.01, N 5.92.

Reaction of 1b with Li(F_4-tcnq): According to the above-mentioned procedure, the binuclear macrocycle **2b** (yellow, 40.5 mg, 38.0%) was obtained from **1b** (75.5 mg, 0.130 mmol) and Li(F_4-tcnq) (37.0 mg, 0.131 mmol). FAB MS: *m*/*z* (%) = 1641 $[M]^+$. IR (Nujol): $\tilde{\nu}$ = 2202, 2156 (C≡N), 1643 (C=N) cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} = 410 (sh), 330 nm. $C_{82}H_{60}F_8N_8O_4P_2Rh_2$ (1641.5): calcd. C 60.01, H 3.68, N 6.82; found C 59.31, H 3.80, N 6.74.

Reaction of 1b with F_4-tcnq: A mixture of **1b** (71.7 mg, 0.123 mmol) and F-tcnq (34.7 mg, 0.126 mol) was stirred in CH_2Cl_2 (15 mL) at room temperature. After 5 h, the solvent was removed in vacuo. The residue was washed with diethyl ether and recrystallized from CH_2Cl_2 and diethyl ether to afford reddish brown crystals of **5** (38.4 mg, 36.3%). FAB MS: *m*/*z* = 857 $[M]^+$. IR (Nujol): $\tilde{\nu}$ = 2156 (C≡N) cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} = 333, 260 nm. $C_{41}H_{31}ClN_4O_2F_4PRh$ (857.0): calcd. C 57.46, H 3.65, N 6.54; found C 57.18, H 3.85, N 6.44.

Reaction of 3b with Li(F_4-tcnq): According to the above-mentioned procedure, the iridium macrocycle **4b** (yellow, 39.1 mg, 40.2%) was obtained from **3b** (71.6 mg, 0.107 mmol) and Li(F_4-tcnq) (31.03 mg, 0.111 mmol). IR (Nujol): $\tilde{\nu}$ = 2189, 2137 (C≡N), 1641 (C=N) cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} = 410(h), 330 nm. $C_{82}H_{60}F_8Ir_2N_8O_4P_2$ (1819.8): calcd. C 54.12, H 3.32, N 6.15; found C 52.10, H 3.44, N 5.91.

X-ray Crystallography: Complex **2a** was recrystallized from CH_2Cl_2/diethyl ether. A crystal was mounted at the top of a quartz fiber using perfluoro(polyoxopropylene ethyl ether), which was set on a MSC/ADSC Quantum CCD/Rigaku AFC8(ultraX 18) diffractometer. The measurement was made using Mo-K_α radiation at 0 °C under a cold nitrogen stream. Four preliminary data frames were measured at 0.5° increments of ω, in order to assess the crystal quality, and preliminary unit cell parameters were calculated. The cell parameters were refined using all the reflections measured in the range $2.8° < 2\theta < 40°$. The intensity images were measured at 0.5° intervals of ω for a duration of 20 s. The frame data were integrated using the d*TREK program package, and the data sets were corrected for absorption with the REQAB program. The crystal parameters along with data collection are summarized in Table 2. The data were corrected for Lorentz and polarization effects. Atomic scattering factors were taken from Cromer and Waber with the usual tabulation.[14] Anomalous dispersion effects were included in F_c;[15] the values of Δf′ and Δf″ were those of Creagh and McAuley.[16] All calculations were performed using the teXsan crystallographic software package.[17] The structure was solved by direct methods (SIR92). The positions of all non-hydrogen atoms were refined with anisotropic thermal parameters by using full-matrix least-squares methods. All hydrogen atoms were calculated at the ideal positions with a C−H distance of 0.97 Å.

Serendipity and Rational Design of One-Dimensional Doubly Stranded Chains with Nanometric Cavities Based on Ag^I Coordination Chemistry

Lamia Mimassi,[a] Carine Guyard-Duhayon,[a] Laurence Raehm,[a] and Hani Amouri*[a]

Keywords: Coordination chemistry / Polymers / Silver / Self-assembly / Supramolecular chemistry

Spontaneous and cooperative self-assembly processes allowed the preparation of two complexes $\{[AgL^1_2][X]\}_n$ [X = CF_3SO_3, (**3a**); X = BF_4, (**3b**)] in quantitative yields, identified as 1-D doubly stranded chains. The X-ray molecular structures of **3a,b** are reported. Complexes **3a,b** are isostructural and crystallize in the triclinic unit cell. The structures of **3a** and **3b** show the formation of a one-dimensional coordination polymer exhibiting as an outstanding feature the presence of infinite chained metallomacrocycles with nanometric cavities. Interestingly, NMR spectroscopy and electrospray mass spectrometry suggest that the identified elemental sub-unit $[AgL^1_2]^+$ is the key building block which self-assembles to provide the inorganic polymers **3a,b**. The effect of weakly coordinating counteranions and the assembling ligand L^1 on the supermolecule design are presented and discussed.

Introduction

The design of mono- and double-stranded chains is a great challenge for supramolecular chemists.[1] These supramolecular architectures are aesthetically appealing and exhibit potential applications as molecular wires,[2] electrical conductors,[3] molecular magnets,[4] in host-guest chemistry[5] and in catalysis.[6] Particular interest has been devoted to the construction of helical chains. For instance, polymetallic double helices have been elegantly self-assembled from poly-2,2′-bipyridine ligand strands with ether linkages and tetrahedral Ag^I ions.[7] More recently, efforts have been directed to the preparation of infinite coordination helices. Such infinite chains have been reported by Jung and co-workers,[8] von Zelewsky and co-workers,[9] Ciani and co-workers[10] and Erxleben[10] using tectonic bridging ligands[11] and taking advantage of the tetrahedral nature of Ag^I ions. Although this process sounds relatively straightforward, the rational design of these materials is complicated by the uncertain coordination propensity of the metal ion, which is influenced by such factors as the counteranion,[12] the solvent and the ligand geometry. Thus, controlling these elements is at the heart of controlling supramolecular coordination chemistry.

Pursuing our research in the area of supramolecular chemistry, in particular the design of metallomacrocyles, metallocryptands, and metallocryptates as anion hosts,[13] we extended our investigations to the construction of 1-D chains with appropriate cavities that would host anionic guests. In this work we report novel and rare infinite doubly stranded chains with a propeller arrangement around each metal center, using the tectonic ligand L^1 (Scheme 1) and Ag^I ions. Initially this assembly was discovered by serendipity, as are most assemblies in the area of supramolecular chemistry, but later it was rationally reproduced with $AgCF_3SO_3$ (**1a**) and $AgBF_4$ (**1b**).

Results and Discussion

Self-Assembly of the Doubly Stranded Chain Complexes $\{[AgL^1_2][X]\}_n$ [X = CF_3SO_3, (3a); X = BF_4, (3b)]

To demonstrate the viability of our strategy we prepared the bidentate ligand 1,3-bis(benzimidazol-1-ylmethyl)-2,5-dimethoxy-4,6-dimethylbenzene (L^1, **2a**). It was synthesized by allowing the corresponding bis(chloromethyl) derivative to react with two equivalents of benzimidazole in the presence of K_2CO_3 in CH_3CN (overall yield: 90%). Its spectroscopic data are consistent with the proposed structure.

Significantly, treatment of $AgCF_3SO_3$ (**1a**) with two equivalents of L^1 in CH_3CN/CH_2Cl_2 solution gave a white precipitate after five minutes of stirring. The reaction was allowed to proceed for several hours without any further change being observed. The white precipitate was isolated in quantitative yield and identified as 1-D doubly stranded chains of $\{[AgL^1_2][CF_3SO_3]\}_n$ (**3a**). Complex **3a** was found to be soluble in polar solvents such as methanol, acetonitrile and dimethyl sulfoxide, hence the ^1H NMR spectrum was recorded in CD_3CN (Figure 1). The ^1H and ^{13}C NMR spectroscopic data are consistent with the proposed formulae and show that the coordinated ligand L^1 displays a sym-

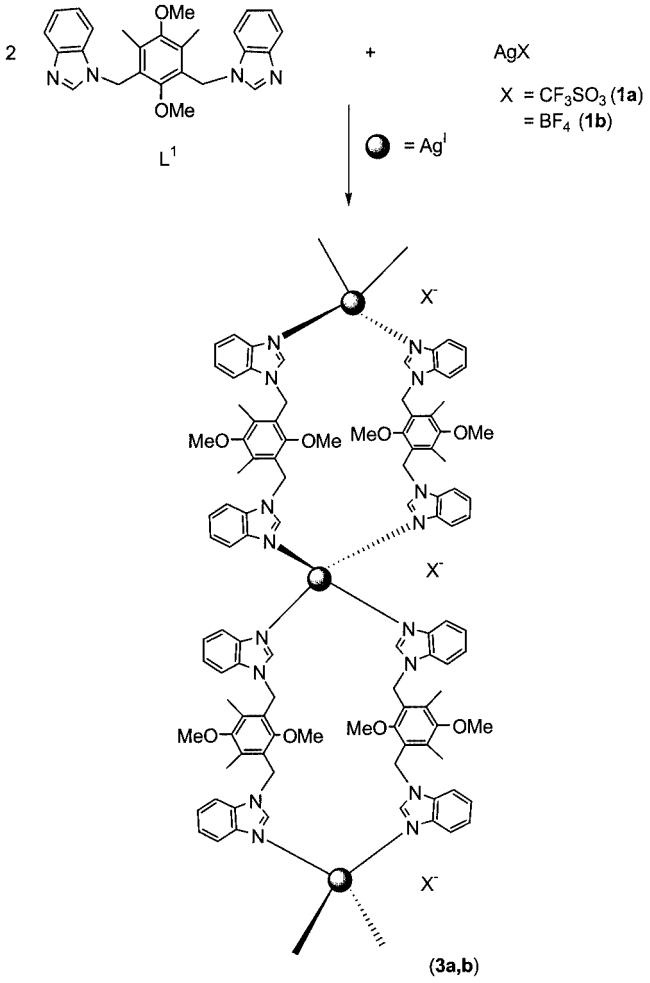

Scheme 1. General synthetic strategy for 1-D chains (**3a,b**)

metric pattern close to that of the free ligand L^1. Most remarkably, the resonances ascribed to the protons of the benzimidazole group appear at δ = 7.92 (s, 2 H), 7.71 (m, 4 Hz, 4 H), 7.55 (m, 4 H) and 7.29 ppm (m, 8 H) (see Figure 1). The NMR symmetry is probably due to the fragmentation of the polymer and formation of oligomeric species during the dissolution process. The electrospray (ES) mass spectrum shows a peak at m/z = 961.19 which corresponds to the formation of $[Ag(L^1)_2]^+$ species in solution. This suggests that the $[Ag(L^1)_2]^+$ sub-unit is the key building block which leads to the formation of the doubly stranded chains $\{[AgL^1_2][CF_3SO_3]\}_n$ (**3a**) through self-assembly. Variable temperature ^{1}H NMR spectra recorded for **3a** in CD_3CN show no signal broadening, suggesting that the exchange phenomenon may be fast on the NMR time scale. It is worth noting that von Zelewsky and co-workers have reported that a polymeric double-helix silver complex breaks down in solution to produce circular helicates or oligomers which are in rapid dynamic equilibrium.[9]

Suitable crystals of **3a** were obtained by slow evaporation of Et_2O into a CH_3CN solution. The complex crystallizes in the triclinic unit cell space group $P\bar{1}$. Crystallographic data for **3a** are shown in Table 1. Selected bond lengths and angles are shown in Table 2. The structure shows that complex **3a** consists of one-dimensional doubly stranded chains (Figure 2a). Four L^1 ligands wrap around the Ag^I ion to give a tetrahedral coordination geometry and are disposed in a propeller arrangement with a dihedral angle θ of 80.3°. Each ligand L^1 connects another Ag^I center through the other benzimidazole arm generating a 1D-doubly stranded chain. Further we note the presence of a center of symmetry lying half way between two parallel phenyl rings within the double stranded chain (Figure 2b). Interestingly, the phenyl rings of two close doubly stranded chains show an offset π-stacking phenomenon, with a plane-to-plane

distance of 3.8 Å. This weak π-interaction is observed throughout the infinite chain and only between alternate metallomacrocycles (Figure 2c).[14] In a well-documented paper, Janiak reported on π-π stacking in metal complexes with aromatic ligands. He showed that strong interactions exist when plane-to plane-distances are around 3.3 Å. These interactions are weaker when the distance is above 3.6 Å with 3.8 Å being approximately the maximum for which π-π interactions are accepted.[14d] It is clear that the two L^1 ligands and the two Ag^I centers describe a 25-membered ring with a nanometric cavity where both extremities are capped by the silver centers (Figure 2b). The average Ag−Ag distance in **3a** is 12.7 Å (1.27 nm), while the average distance between the two phenyl rings is 8.4 Å (0.84 nm). Perhaps due to the steric hindrance presented by the internal methoxy groups, all the $CF_3SO_3^-$ anions are located outside the metallomacrocyclic cavity and in between two doubly stranded chains (Figure 2c). The average Ag−Ag distance between two close doubly stranded chains is 11.3 Å. Taken together, this is a rare one-dimensional structure for Ag^I ions connected by benzimidazole ligands. Related complexes of this family are often obtained as classical mono-helix or doubly stranded helical chains.[8−10]

It is interesting to speculate as to the extent to which this π-π stacking interaction is responsible for the self-assembly and stability of these doubly stranded chains. In this context we note that Lehn and co-workers have elegantly shown that a pre-organized helical conformation of discrete encoded oligoheterocyclic strand can be envisaged through π-π interactions between parallel aromatic heterocycles of neighboring molecules.[15a] Furthermore, Stoddart and co-workers have beautifully shown that an infinite two-dimensional polymeric supramolecular network is generated as a result of extended π-π stacking interactions.[15b]

We then examined the role of the anion on the formation of this one-dimensional chain. Thus we repeated the above experiment but using $AgBF_4$ (**1b**) instead of $AgCF_3SO_3$ (**1a**). A white precipitate was similarly obtained in quantitative yield and was identified as 1D-doubly stranded chains of $\{[AgL^1_2][BF_4]\}_n$ (**3b**) analogous to **3a**. The spectroscopic data were identical to those obtained for **3a**. To confirm the solid-state structure of **3b** an X-ray structural determination was carried out on a single crystal of **3b**. Although complete refinement could not be achieved due to the small size of the crystals, we were able to obtain valuable information about complex **3b**.

The structure shows indeed that **3b** consists of doubly stranded chains, and that the BF_4 anions are located outside the metallomacrocyles and in between the two doubly stranded chains. The average Ag−Ag distance in **3b** is 12.3 Å (1.23 nm), while the average distance between the two phenyl rings is 8.5 Å (0.85 nm). The Ag−Ag distance between two close doubly stranded chains is 12.1 Å (1.21 nm). These results are similar to those obtained for **3a** and they show that the size of the weakly coordinating counterion does not affect the overall structure.

It is noteworthy, however, that it has been reported recently that treatment of $AgCF_3SO_3$ or $Cu(ClO_4)_2$ with the analogous bidentate ligands L^2 and L^3 possessing two benzimidazole arms in the 1,3- and 1,4-positions of a phenyl ring, respectively, afforded the binuclear boxes M_2L_3 and M'_2L_4 (M = Ag, M′ = Cu) in which an anion guest is encapsulated.[16] Our results contrast sharply with those reported and this is no doubt related to the steric factors displayed by our ligand L^1.

Conclusion

In conclusion, using the tetrahedral coordination chemistry of Ag^I ions and the tectonic ligand L^1, we have reported a rational synthetic strategy for the formation of rare doubly stranded chains (**3a,b**). The cavity size in these 1D-chains is of nanometric size and we expect that it can be modulated, depending on the bridging di-benzimidazole ligands used. These surprising results address once again the important role of assembling tectonic ligands, metal and ligand geometries, coordination sites, π-π interactions and steric effects which determine the final structure of the supramolecular species obtained. Thus, ligand tailoring is at the heart of the art and science of inorganic supramolecular construction.

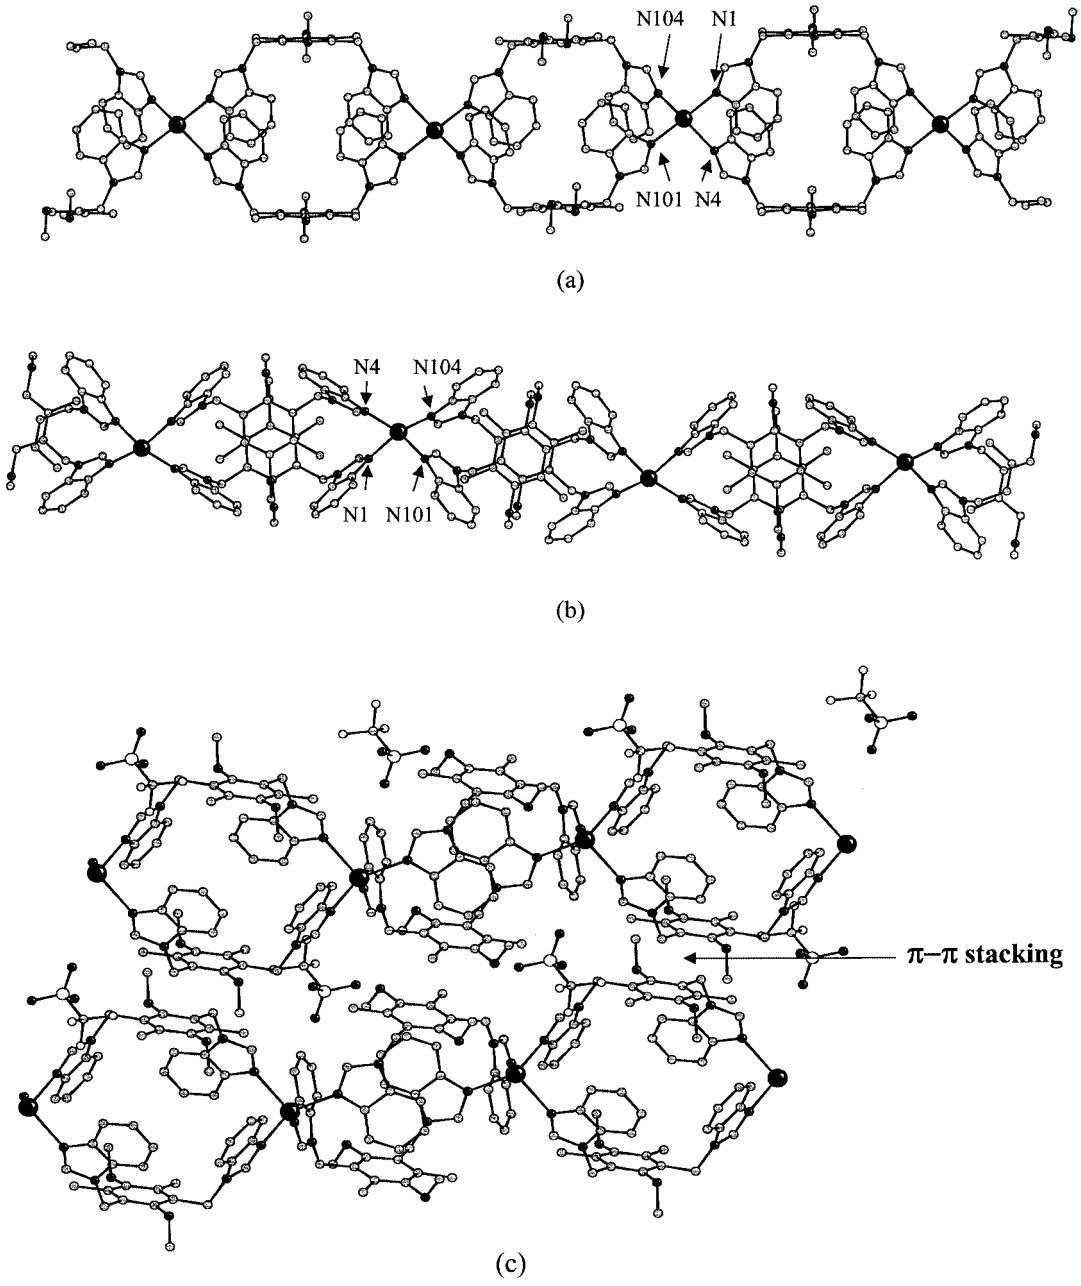

Figure 2. a) Crystallographic structure of the cationic part of the doubly stranded infinite chains **3a** perpendicular to the *b* axis with atom numbering system; hydrogens have been omitted for clarity; b) crystallographic structure of the cationic part of **3a** showing the two coplanar phenyl rings within each metallomacrocyle of the infinite chain; note the alternate arrangement of the metallomacrocycles; c) view of the infinite 1D-chain of $\{[AgL_2][CF_3SO_3]\}_n$ (**3a**) showing the triflate anions lying in between two doubly stranded chains as well as the offset π-π stacking phenomenon between the phenyl rings of two neighboring doubly stranded chains

Further investigations are ongoing on this and related 1-D and 2-D supramolecular assemblies with the aim of obtaining selective hosts for a variety of anionic guests.

Experimental Section

All experimental manipulations were carried out under argon using Schlenk tube techniques.

Synthesis of L[1]: This bidentate ligand was prepared by addition of 1,3-di(chloromethyl)-2,5-dimethoxy-4,6-dimethylbenzene (1.09 g, 4.41 mmol) in CH_3CN to benzimidazole (0.98 g, 8.3 mmol) in the presence of K_2CO_3 (1.14 g, 8.24 mmol). The reaction was stirred for 30 minutes before being refluxed for 12 hours. The resulting precipitate was filtered and extracted with $CHCl_3$. After being washed with distilled water the organic phase was isolated before being dried over $MgSO_4$. The solvent was removed on a rotary evaporator to yield an off-white microcrystalline solid. Yield: 1.58 g (90%). $C_{26}H_{26}N_4O_2{\cdot}H_2O$ (444): calcd. C 70.27, H 6.30, N 12.61; found C 70.64, H 6.10, N 12.57. ^{1}H NMR (400 MHz, [D$_6$]DMSO): δ = 8.10 (s, 2 H, =CH), 7.63 (d, 2 H, =CH), 7.47 (d, 2 H, =CH), 7.16 (m, 4 H, H-aromatic), 5.49 (s, 4 H, -CH_2-), 3.70 (s, 3 H, MeO), 3.50 (s, 3 H, MeO), 2.12 (s, 6 H, CH_3).

Synthesis of 3a: A solution of L^1 (**2a**) (438 mg, 1.02 mmol) in $CHCl_3$ (10 mL) was added to a solution of $AgCF_3SO_3$ (**1a**; 126 mg, 0.5 mmol) in CH_3CN (10 mL). After 5 minutes stirring, a white precipitate was formed. The reaction was allowed to proceed for several hours without any further changes. The precipitate was filtered and washed several times with CH_2Cl_2 then dried under vacuum. Yield: 550 mg (quantitative). ^1H NMR (400 MHz, [D$_6$]DMSO): δ = 8.25 (s, 2 H, =CH), 7.74 (dd, 4 H, H-aromatic), 7.58 (dd, 4 H, H-aromatic), 7.23 (m, 8 H, H-aromatic), 5.56 (s, 8 H, -CH$_2$-N), 3.70 (s, 6 H, -OCH$_3$), 3.53 (s, 6 H, -OCH$_3$), 2.16 (s, 12 H, -CH$_3$) ppm. ^{13}C NMR (100.62 MHz, [D$_6$]DMSO): δ = 154.4, 153.8, 144.5, 142.4, 133.5, 133.1, 125.9, 123.3, 122.6, 119.5, 111.2, 63.5, 60.2, 41.3, 12.5 ppm. ^{19}F NMR (376.49 MHz, [D$_6$]DMSO): δ = −78.18 (s, free CF_3SO_3) ppm. IR (KBr): $\tilde{\nu}$=1267 s (ν_{C-F}) cm^{-1}.

Synthesis of 3b: Compound **3b** was prepared in a similar way to **3a** but using $AgBF_4$ instead of $AgCF_3SO_3$. It was obtained quantitatively. $C_{52}H_{52}AgBF_4N_8O_4$ (1047.8): calcd. C 59.61, H 5.00, N 10.70; found C 59.38, H 5.01, N 11.60. ^1H NMR (400 MHz, [D$_6$]DMSO): δ = 8.26 (s, 2 H, =CH), 7.76 (dd, 4 H, H-arom.), 7.62 (dd, 4 H, H-arom.), 7.26 (m, 8 H, H-arom.), 5.57 (s, 8 H, -CH$_2$-N), 3.69 (s, 6 H, -OCH$_3$), 3.55 (s, 6 H, -OCH$_3$), 2.17 (s, 12 H, -CH$_3$) ppm. ^{13}C NMR (100.62 MHz, [D$_6$]DMSO): δ = 154.5, 153.8, 144.6, 142.1, 133.4, 133.2, 125.8, 123.5, 122.8, 119.5, 111.3, 63.5, 60.2, 41.3, 12.5 ppm. ^{19}F NMR (376.49 MHz, [D$_6$]DMSO): δ = −148.70 (s, free BF_4) ppm. IR (KBr): $\tilde{\nu}$ = 1068 s (ν_{B-F}) cm^{-1}.

X-ray Structure Determination: A colorless needle-shaped crystal of **3a** was mounted on a glass fiber. All measurements were made on a Enraf−Nonius Mach-3 diffractometer, Mo-K_α radiation (λ = 0.71069 Å), collection range 2θ = 2−50°. The Ψ-scan curve of **3a** was flat, hence no absorption correction was applied. The structure was determined by direct methods and subsequent difference-Fourier syntheses, and refined by full-matrix least-squares on *F* using the programs of the PC version of CRYSTALS. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located on a difference-Fourier map and their coordinates were refined with an overall isotropic thermal parameter.

CCDC-166133 (**3a**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Zinc Complexes of a Helical 22-mer Peptide with Two Histidine Donors[‡]

Michael Gelinsky[a] and Heinrich Vahrenkamp*[a]

Dedicated to Professor Karl Wieghardt on the occasion of his 60th birthday

Keywords: Zinc / Peptides / Bioinorganic chemistry / Enzyme mimics

A new 22-mer model peptide **P22** was designed for maximal α-helicity in nonpolar media, synthesized by solid-phase methods, and isolated in an analytically pure state. It contains histidine at positions 10 and 14 representing the *i*, *i* + 4 motif which is typical for metal ion binding. Treatment with zinc halides yielded the uncharged molecular complexes (**P22**)$ZnCl_2$ and (**P22**)ZnI_2 which are the first metal complexes of medium-sized peptides to be isolated in an analytically pure state and identified by mass spectrometry. The helicity of both the free peptide and its complexes was confirmed by IR and CD spectroscopy as well as by molecular mechanics calculations. This has allowed us to propose a molecular structure which shows that the complexes are viable models for zinc-binding sections in zinc finger proteins.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Of the two functions of zinc in biology — structural and catalytic[2] — the latter has found much more attention in the literature even though the structural function may be the more important. It is essential for many enzymes,[3] and the ubiquity of zinc finger motifs[4] is underlined by the fact that about 1% of the human genome seem to encode zinc finger proteins.[5]

The classical zinc finger sequence is X_3-Cys-X_{2-4}-Cys-X_{12}-His-X_3-His-X_4 with X being any amino acid.[6] Its most well preserved feature is the location of two histidines in the *i* and *i* + 4 positions on a helical peptide chain. This has been found in the two X-ray structure determinations of zinc finger fragments,[7] and confirmed by chemical modifications of truncated zinc finger peptides.[8]

Based on this information the methods of chemical peptide synthesis were applied to the design of some medium-sized peptides containing pairs of cysteine and/or histidine residues at appriopriately spaced positions on the peptide chain.[9] It was found that such peptides form stable zinc complexes when the donor residues are placed at the *i* and *i* + 4 positions.[9−17] In some cases the addition of zinc and other metal ions enhanced the helicity of these peptides.[10−12,15] This proves the metal binding by the two His or Cys donors, which in the *i* and *i* + 4 positions on the α-helix point in the same direction. So far the identification of such metal-peptide complexes has rested only on spectroscopic methods, and none of them has been isolated in a pure state or subjected to mass spectrometry.

Our own contributions to the chemistry of zinc-peptide complexes[1] have focused so far on small peptides, as exemplified by the role of structural zinc in bis(cysteinyl) protein sequences[18] or in β-turn motifs,[19] and the parameterization of the donor qualities of histidine and cysteine in peptides toward zinc.[20] In continuation of this we have now turned to the complexation of zinc by histidine and cysteine donors which are constituents of helical peptides. This calls for the synthesis of medium-sized peptides and the use of amino acids which favor helix formation. This paper reports our first results in this area in the form of the preparation, isolation in the pure state, and the full characterization of a zinc complex of a 22-mer peptide with histidine in the *i* and *i* + 4 positions.

Results and Discussion

In order to enable the isolation and full characterization of both the peptide and its zinc complexes a strategy was chosen which differs from that in the previous investigations. The peptide was chosen to be hydrophobic and to contain no donor functions other than two histidine constituents. This should allow us to work in non-aqueous media and facilitate isolations. For the same reason both termini of the peptide were derivatized: the N-terminus was chosen to be *N*-acetyl glycine as the simplest terminator of a capping box,[21] and the C-terminus was protected as the

amide. Only amino acids that are predominantly hydrophobic were considered, and among these those with the highest tendency for helix formation. This limited the choice of the amino acids for the peptide backbone to alanine, leucine, methionine and phenylalanine, which hold the top positions in the various rankings of helix formation propensity.[22−25]

The length of the peptide was chosen to be above the minimum length for helix formation (16−18)[26] but below the maximum length for clean chromatographic separation (25−30). It was decided to use a 22-mer peptide with histidine at positions 10 and 14. The amino acid sequence was optimized with the AGADIR algorithm[27] for a maximum degree of α-helicity. Among 100 randomly chosen sequences made up from the four amino acids the computation selected the one given below in the peptide **P22** as the best choice, with a computed helicity of 88%.

NAc-Gly-Phe-Leu-Met-Ala-Phe-Leu-Met-Ala-His-Phe-Leu-Met-His-Phe-Leu-Met-Ala-Phe-Leu-Met-Ala-NH_2

P22

P22 was prepared on a solid-phase synthesizer using Fmoc-protected amino acids and purified by reversed-phase HPLC. Its purity was confirmed by elemental analysis, and its identity was verified by an ESI mass spectrum which reproduced the calculated isotope pattern for $C_{128}H_{187}N_{27}O_{23}S_5$. As expected, **P22** was found to have a very low solubility in water but to be quite soluble in acetonitrile and THF. This was the first indication of the helical structure of **P22**, based on the experience that hydrophobic oligopeptides which are not helical (i.e. which don't have their hydrogen bonds in their interior) have a very low solubility in these solvents.[28]

Further support for the helical nature of **P22** was obtained by FTIR and CD spectroscopy. The intense amide-I band in the IR spectrum was observed at 1654 cm^{-1} in THF solution and at 1658 cm^{-1} in a KBr matrix, as expected for α-helices.[29] The CD spectra of **P22** and its $ZnCl_2$ complex are shown in Figure 1. The CD spectrum in acetonitrile displays a molar ellipticity Θ at 222 nm of −497000 deg·cm^2·$dmol^{-1}$. This converts to an average ellipticity per peptide function (n = 21) of −24000 deg·cm^2·$dmol^{-1}$. According to the equation

helicity [%] = $100 \cdot \Theta_{222}/[-39500 \cdot (1 - 2.57/n)]$[30]

the helicity of **P22** is thus 69%. Considering that five of the 22 amino acids in **P22** are phenylalanine, which at 222 nm has a positive ellipticity, it can be concluded that the 69% value is a lower limit and the actual helicity is considerably higher. This is confirmed by the CD spectrum in 2,2,2-trifluoroethanol, a solvent which strongly favors the formation of α-helices.[31] In this solvent the Θ_{222} value of **P22** is even slightly lower than in acetonitrile, i.e. the helicity of **P22** cannot be raised, supporting the notion that **P22** is nearly perfectly helical even in the absence of 2,2,2-trifluoroethanol.[32]

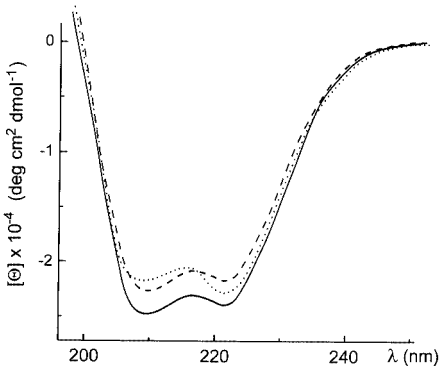

Figure 1. CD spectra of **P22** in acetonitrile (solid line) and in 2,2,2-trifluoroethanol (dashed line) and of **P22**·$ZnCl_2$ (**1**) in acetonitrile (dotted line); concentrations 0.4−0.5 mM

The NMR spectroscopic data of **P22** were not as informative as expected. As is typical for α-helical peptides,[33] the ^{1}H NMR resonances of the amide protons are spread over a range of several ppm, and the resonances of the mobile side-chains are sharper than those of the α-CH and amide groups in the peptide backbone. Unfortunately the side-chain interactions, which are very diagnostic for α-helical peptides,[34] could not be extracted from NOESY and ROESY spectra, even when taken at 500 MHz, as neither intensive NOE effects with a positive nor those with a negative phase occurred. For the same reason the resonances for the individual amino acids (alanine, phenylalanine, leucine and methionine occur 4 or 5 times each) could not be assigned. The failure to obtain structural information from NMR spectroscopic data, albeit not unprecedented for medium-sized peptides or their zinc complexes,[16,35] is a drawback of this work. It calls for a more detailed NMR study which is beyond the scope of this investigation.

As isolated by HPLC, peptide **P22** contained about five equivalents of trifluoroacetic acid. In order to remove these before the reaction with zinc salts, **P22** was treated with gaseous ammonia in THF solution. Filtration and prolonged pumping left **P22** in a water-, acid- and base-free form. In this form **P22** as an uncharged hydrophobic molecule is soluble only in nonpolar media. As such it is a chelating organic bis-nitrogen ligand, and in terms of zinc coordination chemistry it is well suited to form molecular L·ZnX_2 complexes. In contrast, we have experienced repeatedly that small bis-histidine peptides form insoluble coordination polymers with ionic zinc species such as $Zn(ClO_4)_2$.[36] For this reason we reacted **P22** with zinc salts which are themselves molecular in nonpolar media, i.e. the zinc halides.

Treatment of THF solutions of **P22** with equimolar amounts of anhydrous $ZnCl_2$ or ZnI_2 resulted in clear solutions of complexes **1** and **2**, respectively. After workup both complexes were isolated as yellow or brown powders which are analytically pure. Both **1** and **2** are quite soluble in nonpolar solvents but insoluble in water. Many attempts to obtain them as X-ray quality crystals were unsuccessful.

(**P22**)$ZnCl_2$ (**P22**)ZnI_2

1 **2**

The fact that **1** and **2** are molecular entities and not constituents of equilibrium mixtures containing **P22**, Zn^{2+} and Hal^- is not only evident from their insolubility in water, but could also be proved by their ESI mass spectra taken from acetonitrile solutions (see Exp. Sect.), which show the complex constituents but neither the free peptide nor the free zinc halide. The conservation of the peptide structure in the complexes is indicated by the amide-I IR bands which, for both **1** and **2**, are observed at 1655 cm^{-1}, i.e. almost at the same position as that of the free peptide. The CD spectra, displaying the 222 nm maxima with about the same intensities as that of free **P22** (see Figure 1), lead to the same conclusion.

The attachment of the $ZnHal_2$ units to the peptide could clearly be identified by ^1H NMR spectroscopy. While most of the proton resonances remained in place both after deprotonation with ammonia and after addition of the zinc halide (which means that the helical secondary structure is not affected), significant shifts of the histidine imidazole CH resonances were observed. Table 1 lists the four imidazole CH signals for the three states of the peptide. They were assigned by H,H-COSY NMR spectra taken in CD_3CN. Under these conditions the NH resonances could not be observed. Upon deprotonation all four CH signals move to higher field, the successive zinc complexation moves two of them further up but the two others down again. The shifts for the protonation of the uncharged peptide are larger than those for zinc binding. Altogether the NMR spectroscopic data are the clearest indication for the attachment of the $ZnHal_2$ units to both imidazole side chains of the histidine constituents in the 10 and 14 positions. In the absence of X-ray structure data they also provide the main basis for a structural assignment of the complexes.

Table 1. ^1H NMR spectroscopic data for the imidazole CH protons in Peptide **P22**

	CH^2	$CH^{2'}$	CH^4	$CH^{4'}$
protonated	8.02	8.45	7.14	7.21
deprotonated	7.64	7.89	6.58	6.70
$ZnCl_2$ complex	7.85	7.86	6.51	6.77
ZnI_2 complex	7.83	7.86	6.49	6.75

Conclusions

The approach and outcome of this work represent a conceptual difference from previous work on medium-sized peptides and their metal complexes. Both the peptide **P22** and its zinc complexes were designed to be nonpolar molecular entities. This has not only simplified their synthesis and isolation but also made them susceptible to the rules of molecular zinc chemistry. This means that **1** and **2** could be predicted to be stable and inert toward dissociation and that the chelate ligand **P22** and the halide ligands would be an ideal combination for a tetrahedral ZnN_2Hal_2 coordination. The accumulated evidence supports these predictions.

As expected and designed, the peptide **P22** was found to exist in the α-helical form. The usual criteria applied to this − solubility, IR and CD spectra − have confirmed it both for the free peptide and for its complexes with $ZnCl_2$ and ZnI_2. Although NMR spectroscopy has failed to assist in the structural assignment of the peptide, it has shown unambiguously that the $ZnHal_2$ units are attached to the two imidazole side chains of the histidines. As these are placed in the 10 and 14 positions of the peptide they are located one above the other and are separated by one turn of the helix. The identity of both the peptide and its zinc complexes was certified by mass spectra. To the best of our knowledge this is the first time that metal complexes of a medium-sized peptide have been isolated in an analytically pure form and fully characterized.

The available data allowed us to assign the peptide and complex structures with confidence by molecular modelling software. This was done by applying the force field method MM+ of the HYPERCHEM program package.[37] Figure 2 shows the energy-minimized structures of the uncharged peptide and its $ZnCl_2$ complex. It is obvious that only minimal conformational changes are necessary to convert the peptide to the complex. Thus the aims of this investigation − the design of a highly helical peptide with two preorganized binding sites for zinc − have been achieved.

Experimental Section

General: All manipulations were performed under an inert gas atmosphere. Starting materials were obtained commercially. IR: Bruker IFS-25 FTIR. NMR: Varian Unity 300 and Bruker Avance DPX 500. CD: Jobin-Yvon CD6. MS: Finnigan TSQ 700. Peptide synthesis: Milligan 9050 Synthesizer, PAL-PEG-PS resin, Fmoc protected L-amino acids, coupling reagent TBTU, for further details see ref.[38] Chromatography: Waters Model 4000, Waters DeltaPak C18 PrepPak reversed phase column. The figure was produced with SCHAKAL.[39]

Peptide P22: This peptide was prepared to order by the Merrifield method at the Institut für Biologie II of Freiburg University. The details of preparation and workup corresponded to the published procedures.[38] The raw product was dissolved in acetonitrile and purified by HPLC using a gradient of acetonitrile/water (75:25 → 100:0) containing 0.1% of HTFA. Retention time: 35 min. After freeze-drying 194 mg (28%) of **P22**·4.8HTFA were obtained as a colorless powder, m.p. 135 °C (dec.) whose HTFA content was determined by potentiometric titration.[16] $C_{128}H_{187}N_{27}O_{23}S_5$·$4.8C_2HF_3O_2$ (2632.38 + 547.31): calcd. C 51.98, H 6.08, N 11.89; found C 51.88, H 6.08, N 11.69. ESI-MS: correct isotope pattern for M^+ from 2630.3 to 2637.3. IR (KBr): $\tilde{\nu}$ = 3299s, 2959w, 2922w, 1658vs, 1543s, 1454w, 1203m (CF), 1174m, 833w, 800w, 701w, 628w cm^{-1}. ^1H NMR (signal ranges) in CD_3CN: δ = 0.74−2.80 (95 H, aliphatic protons), 2.80−3.40 (14 H, β-protons of Phe and His), 3.71 (t, 2 H, CH_2-Gly), 3.78−4.37 (21 H, α-protons), 7.13−7.33 (25 H, Phe-aromatic), 7.20−8.68 (26 H, NH and imidazole-CH).

Complex 1: Ammonia was bubbled for 3 min through a solution of **P22**·4.8HTFA (25 mg, 7.77 μmol) in 15 mL of dry THF. After pumping to remove excessive NH_3 and to reduce the volume to 10 mL, the mixture was filtered through a fine-porosity frit. A 0.01 M solution of anhydrous $ZnCl_2$ in THF (0.78 mL, 7.8 μmol) was then added. Slow evaporation of the solvent left a yellow oil. This was treated several times with a few millilitres of water to remove the remaining ammonia and ammonium salts. After prolonged pumping 21 mg (96%) of **1** remained as a pale yellow powder, m.p. 142 °C (dec.). $C_{128}H_{187}Cl_2N_{27}O_{23}S_5Zn$ (2768.68): calcd. C 54.53, H 6.81, N 13.66, Zn 2.36; found C 54.65, H 6.89, N 12.12, Zn 1.94. ESI-MS: *m*/*z* = 2733 (11) [M − Cl], 2698 (13) [M − 2Cl], 1349 (7) [M − 2Cl]$^{2+}$. IR (KBr): $\tilde{\nu}$ = 3300m, br, 2958w, 2924w, 1655vs, 1541s, 1453w, 1297w, 1129w, 802w, 700w cm^{-1}. ^1H NMR (CD_3CN): identical to **P22** except for the data in Table 1.

Complex 2: Prepared in a similar manner to complex **1** from 25 mg (7.77 μmol) of **P22**·4.8 HTFA and 0.78 mL (7.8 μmol) of a 0.01 M ZnI_2 solution. Yield 22 mg (96%), light brown powder, m.p. 179 °C (dec.). $C_{128}H_{187}I_2N_{27}O_{23}S_5Zn$ (2951.58): calcd. C 52.09, H 6.39, N 11.81, Zn 2.22; found C 49.58, H 6.29, N 11.72, Zn 2.66. ESI-MS: *m*/*z* = 2825 (59) [M − I], 2698 (20) [M − 2I], 1349 (45) [M − 2I]$^{2+}$. IR (KBr): $\tilde{\nu}$ = 3301m, br, 2957w, 2922w, 1655vs, 1540s, 1453w, 1296w, 1114w, 700w cm^{-1}.

Keywords: Perovskite structure / Neutron diffraction / Magnetic properties / Antiferromagnetic ordering / Cobalt

Ba_2CoBO_6 (B = Mo, W) perovskites have been prepared in polycrystalline form by thermal treatment, in air, of previously decomposed citrate precursors. These materials have been characterized by X-ray (XRD) and neutron powder diffraction (NPD) data and magnetization measurements. At room temperature, the crystal structure is cubic, space group $Fm\bar{3}m$, with a = 8.08623(3) and 8.10799(3) Å for the Mo and W compounds, respectively. The crystal contains alternating CoO_6 and $Mo(W)O_6$ octahedra, with an almost negligible anti-site disordering. The low temperature antiferromagnetic ordering has been followed from sequential neutron diffraction data. Peaks of magnetic origin appear at the NPD patterns below temperatures of T_N = 27 K and T_N = 19 K for the Mo and W compounds, respectively. The magnetic structures are both defined by a propagation vector k = (1/2, 1/2, 1/2). They can be described as an array of ferromagnetic layers of Co moments, perpendicular to the [111] directions, coupled antiferromagnetically. The refined magnitude of the Co^{2+} magnetic moments suggests a high-spin electronic configuration (S = 3/2); covalence effects account for the slight reduction in the low-temperature ordered moments, although this effect is minimized for the W compound. Structural and magnetic features are discussed in relation to the chemical nature of the species present in the solids.

Introduction

The description of colossal magnetoresistance (CMR) properties in perovskite-related materials has triggered a revival of interest in transition metal oxides in an effort to optimize the observed CMR properties and to understand the involved mechanisms. CMR materials undergo a large change in electrical resistance in response to an external magnetic field. In these compounds, the applied field tends to align the local spins and hence leads to a rapid drop of the measured resistivity by suppressing spin fluctuations and enhancing electronic transfer. CMR was first reported in $LaMnO_3$ perovskite derivatives; further research demonstrated that it is also present in a range of compounds, most of them exhibiting ferromagnetic and semimetallic characteristics simultaneously.[1,2] It is well established now that the ferromagnetic Curie temperature of mixed-valence manganites (based upon $LaMnO_3$) cannot be increased above 400 K by any chemical substitution. Materials with a substantially higher T_c must be developed to operate in a useful temperature range around room temperature.

Recently, the double perovskite Sr_2FeMoO_6 has been proposed as a half-metallic ferromagnet and an alternative to perovskite manganites.[3−7] Further studies on other double perovskites seem to indicate that the occurrence of MR properties is a common feature in some of them. The A = Ca, Ba analogues of the A_2FeMoO_6 family were also found to exhibit semimetallic and ferromagnetic properties.[8,9] Furthermore, Sr_2FeReO_6 has[10] an electronic structure similar to that of Sr_2FeMoO_6: these results have expanded the options for optimizing CMR properties for specific technological applications, searching in other members of the wide family of perovskites of composition $A_2B'B''O_6$ (A: alkaline earth metal; B′, B″: transition metals).

We have become interested in revisiting other transition metal double perovskites, prepared in the Sixties and forgotten for more than 30 years. We have chosen the Co derivatives in the series A_2CoBO_6 (A = Ba, Sr; B = Mo, W). Recently, we described CMR properties in conveniently reduced $Sr_2CoMoO_{6-\delta}$;[11] we have now focused our attention on the Ba derivatives. There is very little literature concerning these phases. Ba_2CoBO_6 (B = Mo, W) perovskites were first studied in the sixties.[12−15] The crystal structure of the Mo phase was described as cubic (with a = 4.043 Å) assuming a random distribution of Co and Mo cations. The W compound was also reported to be cubic, with a = 8.098 Å, exhibiting an ordered $(NH_4)_3FeF_6$ crystal structure. There are a few studies on their magnetic properties;[16−18] Ba_2CoWO_6 was reported to be an antiferromagnet with T_N = 17 K.[16] Its magnetic structure was also studied by

[a] Instituto de Ciencia de Materiales de Madrid, C.S.I.C., Cantoblanco, 28049 Madrid, Spain
[b] Institut Laue-Langevin, B. P. 156, 38042 Grenoble Cedex 9, France

neutron diffraction at 4.2 K,[19] and described as ferromagnetic [111] Co layers coupled antiparallel to adjacent Co layers. There are no reports on the magnetic structure of the Mo compound.

In the present work we describe the synthesis of Ba_2CoBO_6 (B = Mo, W), prepared by soft chemistry procedures, and the results of a neutron diffraction (NPD) study on well-crystallized samples. The crystal structure has been revisited; we report complete structural data for these perovskites. The magnetic data suggest the presence of an unquenched orbital contribution to the effective magnetic moment. Low temperature NPD data allowed us to probe the microscopic origin of the antiferromagnetic ordering, and the evolution of the ordered Co^{2+} magnetic moments.

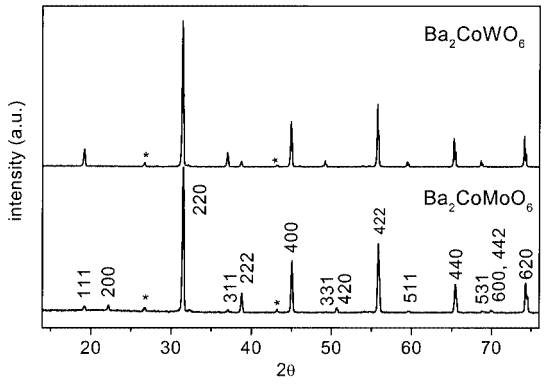

Figure 1. XRD patterns for Ba_2CoBO_6 (B = Mo, W), indexed in a cubic unit cell with $a = 2a_0$, $a_0 \approx 4$ Å; the asterisks indicate the main reflections of the $BaBO_4$ impurity phases

Results

The perovskites Ba_2CoBO_6 (B = Mo, W) were obtained as well crystallized powders; the XRD diagrams are shown in Figure 1. The patterns are characteristic of perovskite structures, showing superstructure peaks (with odd indices) corresponding to the Co/B (B = Mo, W) ordering. The superstructure peaks are more intense in the W compound, due to the higher difference in scattering power with respect to Co. Minor amounts of $BaBO_4$ (B = Mo, W) were detected from both XRD and NPD data; the main reflections of the impurities are indicated with a star in Figure 1.

Magnetic Data

The magnetic susceptibility vs. temperature data for Ba_2CoBO_6 (B = Mo, W) are displayed in Figure 2. The susceptibility exhibits, in both cases, a low temperature maximum, at $T_N = 20$ K and 17 K for B = Mo, W, respectively.

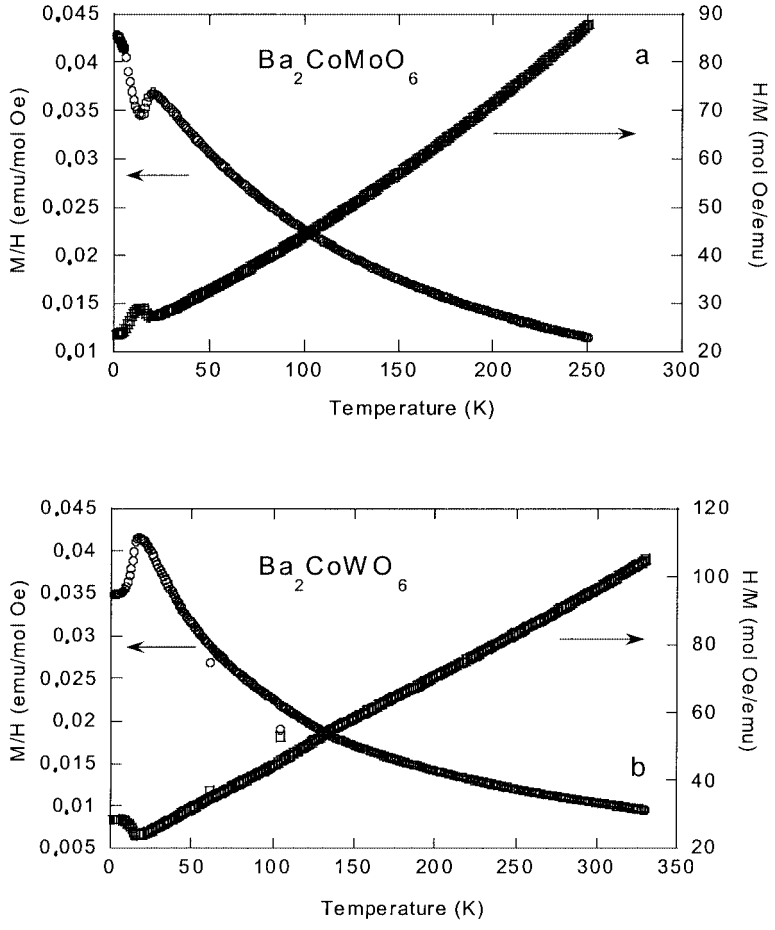

Figure 2. Thermal evolution of the magnetic susceptibility (left axes) and the reciprocal susceptibility (right axes) for (a) Ba_2CoMoO_6 and (b) Ba_2CoWO_6

These maxima correspond to the transition from the high-temperature paramagnetic state to a low-temperature antiferromagnetically ordered phase. A similar Néel temperature (17 K) has been reported for the B = W compound.[17] The reciprocal susceptibility data above T_N (right axes of Figure 2) show a slight curvature, probably due to crystal field effects or a progressive change in the population of the low-spin vs. high-spin electronic configurations for Co cations. A tentative Curie−Weiss fit above 100 K gives paramagnetic moments of 5.24 μ_B/f.u. (f.u. = formula unit) and 5.58 μ_B/f.u. for B = Mo and W, respectively. These values are much larger than expected for spin only Co^{2+}/Mo^{6+} (in any spin configuration for Co^{2+}). This point will be discussed in detail later. The Weiss temperatures of −47.1 K and −75.2 K for B = Mo, W, respectively, confirm the presence of antiferromagnetic interactions in the paramagnetic region. The magnetization vs. field data displayed in Figure 3 are also characteristic of antiferromagnetically ordered systems. The field evolution of the magnetization at 5 K is perfectly linear, excluding the presence of any weak ferromagnetic effect.

Structural Refinement

The structural refinement from room temp. high resolution NPD data was performed in the $Fm\bar{3}m$ space group (No. 225), $Z = 4$, with unit-cell parameters related to a_0 (ideal cubic perovskite, $a_0 \approx 4$ Å) as $a = b = c = 2a_0$. The Ba atoms were located at *8c* positions, Co at *4a*, Mo or W at *4b* sites, and oxygen atoms at *24e* positions. Minor impurities of $BaBO_4$ (B = Mo, W) were included in the refinement as second phases, defined in the space group $I4_1/a$. From the scale factors, the amount of impurity phase is 4.5% and 5.2% for Mo and W, respectively. An excellent fit was obtained for this model, as shown in Figure 4. In the final refinement, the possibility of anti-site disordering was checked by assuming that some Co atoms could occupy Mo or W sites, and vice versa: the refinement of the inversion degree led to less than 1% of anti-site disordering. The oxygen stoichiometry was also checked by refining its occupancy factors; no deficiency was detected within the standard deviations. The most important structural parameters of the crystallographic

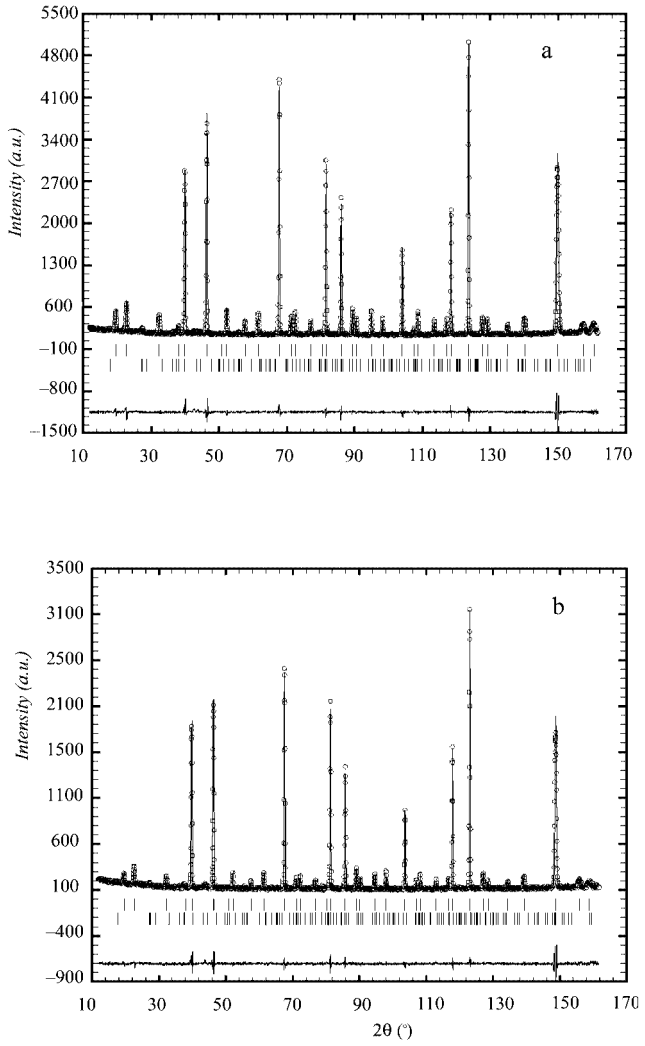

Figure 4. Observed (crosses), calculated (full line) and difference (bottom) high resolution NPD Rietveld profiles for Ba_2CoBO_6 at 295 K for (a) B = Mo, (b) B = W; the second series of tick marks correspond to the Bragg reflections of the $BaBO_4$ impurity phase

structure at room temp. and the discrepancy factors after the refinements are listed in Table 1. The main interatomic distances and angles are included in Table 2. A view of the crystal structure is shown in Figure 5.

The cubic unit cell of Ba_2CoWO_6 is slightly larger than that of Ba_2CoMoO_6, as expected for the larger ionic radius of W^{6+} (0.60 Å) versus Mo^{6+} (0.59 Å) in octahedral coordination.[20] It is interesting to note the significant expansion of the Co−O interatomic distances (Table 2) from the Mo compound [Co−O: 2.114(1) Å] to the W perovskite [Co−O: 2.129(1) Å]. This expansion of Co−O bond lengths is a result of the competing interactions of Co−O and B−O (B = Mo, W) bonds through common oxygens; the higher electronegativity of W than Mo accounts for a more covalent (or less ionic) W−O bond and a weakening of the Co−O chemical bonding in Ba_2CoWO_6.

Magnetic Structure

The magnetic structure of Ba_2CoMoO_6 and its thermal evolution was analyzed by considering a set of NPD patterns collected in the range $2 < T < 72$ K with $\lambda = 2.42$ Å. On decreasing the temperature below 27 K, new reflections appear at positions forbidden for the Bragg reflections in the space group $Fm\bar{3}m$. These new peaks correspond to magnetic satellites defined by the propagation vector $k = (1/2, 1/2, 1/2)$. An antiferromagnetic structure was modeled with magnetic moments at the Co positions; after the full refinement of the profile, including the magnetic moment

Table 1. Unit cell, positional and thermal parameters for Ba_2CoBO_6 (B = Mo, W) in the cubic $Fm\bar{3}m$ space group, from NPD data at 295 K

	B = Mo	B = W
$a = b = c$ (Å)	8.08623(3)	8.10799(3)

magnitude, a discrepancy factor R_{mag} of 10.6% was reached for the 2 K diagram, collected with a longer counting time. The determination of the orientation of the moments is not possible in a cubic structure from powder data. We supposed that the moments are lying along the [001] direction. The magnetic structure is stable from 2 K to T_N, as demonstrated in a sequential refinement in all the available temperature range. The thermal evolution of the magnetic moments at the Co positions and the lattice parameter are shown in Figure 6 and 7. The good agreement between the observed and calculated pattern at $T = 2$ K is illustrated in Figure 8a. For Ba_2CoWoO_6, the magnetic reflections appear at temperatures below $T_N = 19$ K; these reflections can be indexed with the same propagation vector $k = (1/2, 1/2, 1/2)$. After the refinement of the antiferromagnetic structure, a discrepancy factor of $R_{mag} = 13.6\%$ was obtained. The evolution of the magnetic moments and a unit-cell parameter with temperature are displayed in Figure 6b and 7b; the goodness of the fit at 2 K, including the magnetic structure, is depicted in Figure 8b. A view of the magnetic structure for both materials is shown in Figure 9. It consists of ferromagnetic layers of Co moments, perpendicular to the [111] directions, coupled antiferromagnetically. This magnetic structure compares well with that determined by Cox et al. for Ba_2CoWO_6.[19]

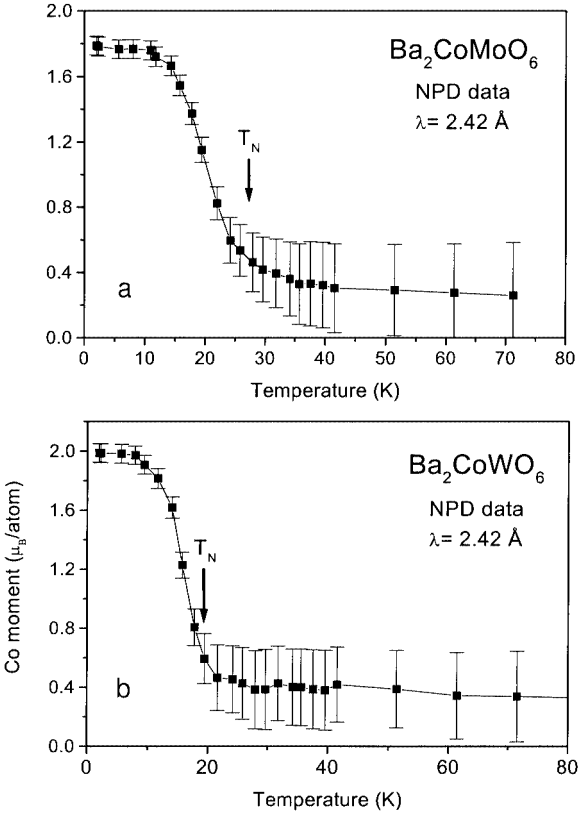

Figure 6. Thermal variation of the ordered Co magnetic moment for the antiferromagnetic structure of Ba_2CoBO_6: (a) B = Mo (b) B = W

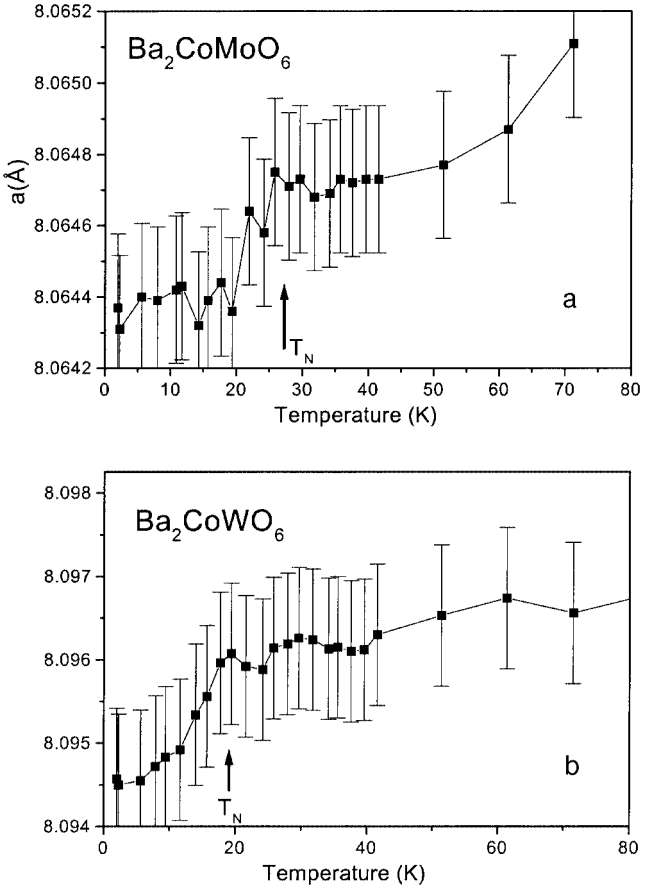

Figure 7. Thermal variation of the a unit-cell parameter for Ba_2CoBO_6: (a) B = Mo (b) B = W

Discussion

Ba_2CoMoO_6 and Ba_2CoWO_6 adopt the well-known $(NH_4)_3FeF_6$ structure, corresponding to a perfect 1:1 B-site ordering, due to the large differences in charge existing between Co^{2+} and $Mo(W)^{6+}$ cations. The refinement of a possible inversion or anti-site disordering confirms an almost complete ordering degree between both cations. A bond valence calculation[21] from the observed bond lengths can give some insight into the actual oxidation states of the different cations present in the crystal structures. In Ba_2CoMoO_6, the calculated valences for Ba, Co and Mo are 2.57, 1.93 and 5.61, respectively; in Ba_2CoWO_6 the calculated valences for Ba, Co and W are 2.51, 1.85 and 5.85, respectively. In both compounds the Ba cations seem to be significantly overbonded, exhibiting valences much higher than the expected 2+ value. In fact, the observed Ba−O distances are much shorter (Table 2) than expected from the sum of the ionic radii (2.95 Å). It seems that the much more covalent network determined by CoO_6 octahedra and BO_6 octahedra (B = Mo, W) mainly determines the size of the unit cell; the low degree of freedom of this cubic crystallographic structure constrains the Ba−O bond lengths outside of the

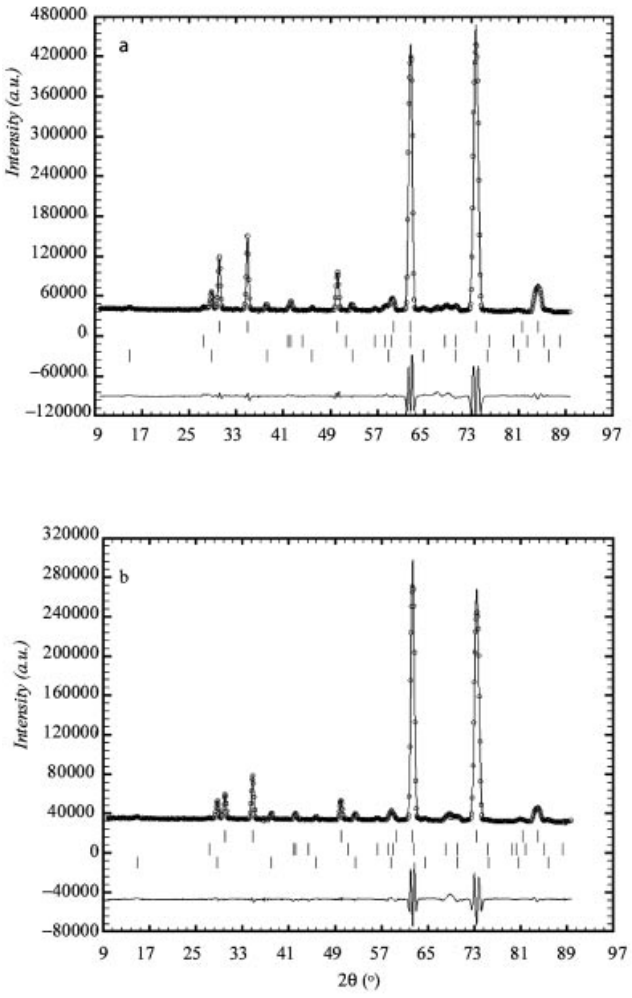

Figure 8. Observed (solid circles), calculated (solid line) and difference (bottom line) NPD patterns collected at 2 K with λ = 2.42 Å; the two series of tick marks correspond to the crystallographic and magnetic Bragg reflections: (a) Ba_2CoMoO_6 (b) Ba_2CoWO_6

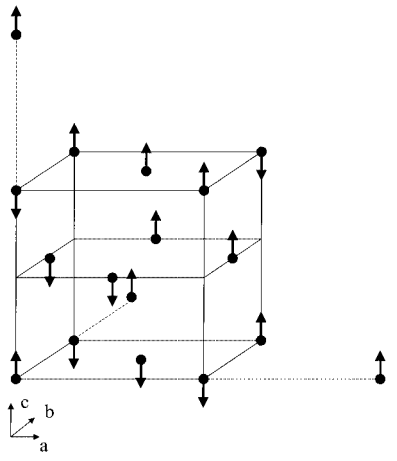

Figure 9. A sketch of the magnetic structure for k = (1/2, 1/2, 1/2); for the sake of clarity, the figure shows the chemical cell ($a \approx 8$ Å) and a part of three adjacent cells

optimal values. This is not an isolated behavior; in many other double perovskites, the Ba−O bond lengths exhibit values within a wide range: for instance, the Ba−O distances range from 2. 85 Å for Ba_2NiWO_6 to 2.96 Å for Ba_2CdWO_6. The valences for Co and Mo(W), although slightly lower than expected, suggest the divalent and hexavalent oxidation states for both cations, respectively.

In relation to the electronic configurations of the B cations, the comparison with Sr_2FeMoO_6 (prepared under reducing conditions and showing half-metallic and ferromagnetic properties) is enlightening: although the actual electronic configurations $Fe^{3+}(3d^5)$-$Mo^{5+}(4d^1)$ vs. $Fe^{2+}(3d^6)$-$Mo^{6+}(4d^0)$ have been considered as possible, the average valence for Fe has been found to be intermediate between high-spin configuration values of Fe^{2+} and Fe^{3+} from Mössbauer spectroscopy studies.[22] The case of $Ba_2Co(Mo,W)O_6$ is rather different: from the chemical point of view, the preparation in air suggests a hexavalent oxidation state for Mo cations, with the Co cations being divalent. From this chemical point of view, the electronic configuration $Co^{2+}(3d^7)$-$Mo(W)^{6+}(4d^0)$ seems to be more probable than $Co^{3+}(3d^6)$-$Mo(W)^{5+}(4d^1)$, although a slight degree of dynamic electron transfer between Co and Mo cations should not be excluded in view of the bond valence results.

To account for the results from the magnetic susceptibility data, the electronic configuration $Co^{2+}(3d^7)$-$Mo^{6+}(4d^0)$ requires a completely unquenched orbital contribution for the high-spin Co^{2+} cation, which would explain the large effective moment obtained in the paramagnetic region, well above T_N, of 5.24 μ_B/f.u. and 5.58 μ_B/f.u for B = Mo, W. Recently, Primo-Martín et al.[23] studied the $Sr_3CoSb_2O_9$ double perovskite, with an effective moment of 5.39 μ_B and also proposed a high-spin Co^{2+} configuration with a completely unquenched orbital contribution ($^4T_{1g}$ term). This is not an isolated observation; many Co^{2+} compounds show effective moments between 3.87 μ_B (spin only) and 5.20 μ_B (spin plus completely unquenched orbital contribution);[24,25] some examples are CoF_2 (μ_{eff} = 5.15 μ_B) or CoO (μ_{eff} = 5.1 μ_B).

In relation to the ordered magnetic moment obtained for Co cations from the refinement of the magnetic structure at 2 K, it seems to saturate at a value close to 2 μ_B, for both compounds with B = Mo, W. Again, this suggests a high spin configuration for the Co^{2+} cations ($t_{2g}^5\ e_g^2$, S = 3/2) as a low-spin configuration would imply S = 1/2. The reduction of the saturation moment with respect to the expected value of 3 μ_B is believed to be due to covalence effects. In fact, the ordered moment is slightly higher for the W compound (Figure 6): this is related to the increase in Co−O atomic distances (as commented above) and a decrease of the orbital overlapping and covalence effects.

Finally, the thermal evolution of the unit cell parameters (Figure 7) seems to indicate a contraction of the unit-cell size at the onset of the antiferromagnetic ordering for both compounds; this effect suggests the possibility of a magneto-elastic coupling, which has not been described before for antiferromagnetic double perovskites. This effect is not common in magnetic oxides, unless the magnetic transition is associated with an electronic fluctuation which is responsible for the change in bonding strength between the metallic element and oxygen; a paradigmatic example is

that of the $RNiO_3$ perovskites,[26] where the AFM transition is coupled with a metal-insulator transition and a dramatic contraction in unit-cell volume is observed upon electron delocalization. The present magneto-volume effect suggests a subtle change in the electron localization concomitant with the AFM transition in the Ba_2CoBO_6 double perovskites.

Conclusions

The study of the crystallographic structure of the double perovskites Ba_2CoMoO_6 and Ba_2CoWO_6 from neutron powder diffraction data allowed us to determine subtle structural features relating the Co−O bond lengths and ordered magnetic moments with the chemical environment in the crystals; the larger electronegativity for W in front of Mo accounts for a more ionic, weaker Co−O bond with a larger magnetic moment for Co in Ba_2CoWO_6. These compounds experience a low-temperature antiferromagnetic ordering characterized by an isotropic propagation vector k = (1/2, 1/2, 1/2), giving rise to antiferromagnetic couplings between each Co moment and the six nearest neighbors. It seems clear that the Co ions adopt a divalent oxidation state, in a high-spin configuration. A completely unquenched orbital contribution for the Co^{2+} cation is necessary to account for the large effective moment obtained in the paramagnetic region A magneto-elastic effect observed at the onset of the antiferromagnetic ordering is unusual in completely localized oxides, suggesting a certain degree of electron itinerancy in these compounds.

Experimental Section

Ba_2CoBO_6 (B = Mo, W) perovskites were prepared as black (B = Mo) or brown (B = W) polycrystalline powders from citrate precursors obtained by soft chemistry procedures. Stoichiometric amounts of analytical grade $Ba(NO_3)_2$, $Co(NO_3)_2{\cdot}6H_2O$, $(NH_4)_6Mo_7O_{24}{\cdot}4H_2O$ or $H_{26}N_6O_{41}W_{12}{\cdot}18H_2O$ were dissolved in citric acid. The citrate + nitrate solutions were slowly evaporated, leading to organic resins containing a random distribution of the involved cations at an atomic level. These resins were first dried at 120 °C and then slowly decomposed at temperatures up to 600 °C. All the organic materials and nitrates were eliminated in a subsequent treatment at 800 °C in air, for 2 hours. This treatment gave rise to highly reactive precursor materials. Afterwards, the resulting black or brown powders were treated at 1100 °C in air for 12 hours.

The initial characterization of the products was carried out by laboratory X-ray diffraction (XRD) (Cu-K_α, λ = 1.5406 Å). Neutron powder diffraction (NPD) diagrams were collected at the Institut Laue-Langevin (ILL) in Grenoble (France). The crystallographic structures were refined from the high resolution NPD patterns, acquired at room temperature at the D2B diffractometer with λ = 1.594 Å. For the determination of the magnetic structures and the study of their thermal variation, a series of NPD patterns were obtained at the D20 high-flux diffractometer (ILL, Grenoble) with a wavelength of 2.42 Å, in the temperature range from 2 to 72 K for B = Mo and 2 to 99 K for B = W. The refinements of both crystal and magnetic structures were performed by the Rietveld method, using the FULLPROF refinement program.[27] A pseudo-Voigt function was chosen to generate the line shape of the diffraction peaks. The coherent scattering lengths for Ba, Co, Mo, W and O were 5.07, 2.49, 6.72, 4.86 and 5.803 fm, respectively. The magnetic form factor considered for the Co^{2+} cation was determined with the coefficients taken from the International Tables of Crystallography. The *dc* magnetic susceptibility was measured with a commercial SQUID magnetometer on powdered samples, in the temperature range 1.5 to 250 K (B = Mo) and 330 K (B = W).

New Group 4 Metallocene and Niobocene Complexes Containing Phosphane-Functionalized *ansa*-Ligands

Antonio Antiñolo,[a] Rafael Fernández-Galán,[a] Irache Orive,[a] Antonio Otero,*[a] and Sanjiv Prashar[b]

Keywords: Metallocenes / Niobium / Phosphane ligands / Homogeneous catalysis / Insertion

The asymmetric *ansa*-ligand precursors $Me_2Si(C_5Me_4H)(C_5H_4R)$ [R = $CH_2CH_2PPh_2$ (**1**), PPh_2 (**2**)] and their lithium derivatives $Li_2\{Me_2Si(C_5Me_4)(C_5H_3R)\}$ [R = $CH_2CH_2PPh_2$ (**3**), PPh_2 (**4**)] have been prepared. The group 4 metal *ansa* complexes $[M\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3R)\}Cl_2]$ [M = Ti, R = $CH_2CH_2PPh_2$ (**5**), PPh_2 (**6**); M = Zr, R = $CH_2CH_2PPh_2$ (**7**), PPh_2 (**8**); M = Hf, R = $CH_2CH_2PPh_2$ (**9**), PPh_2 (**10**)] were obtained by the reaction of $[TiCl_4(THF)_2]$ or MCl_4 (M = Zr or Hf) and the corresponding lithiated *ansa* derivative. The reaction of complexes **7** and **8** with two equivalents of MgMeCl led to the formation of the alkyl complexes $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3R)\}Me_2]$ [R = $CH_2CH_2PPh_2$ (**11**), PPh_2 (**12**)]. Methyl abstraction from **11** and **12** with $B(C_5F_6)_3$ gave the cationic species $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3R)\}Me]^+$ [R = $CH_2CH_2PPh_2$ (**13**), PPh_2 (**14**)]. The insertion reaction of the isocyanide reagent $CNC_6H_3Me_2$-2,6 into the Zr–Me bond of complex **12** giving the corresponding η^2-iminoacyl compound $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}\{\eta^2\text{-}MeC{=}N(C_6H_3Me_2\text{-}2,6)\}(Me)]$ (**15**) is described. The *ansa*-niobocene imide $[Nb(=N\mathit{t}Bu)\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl]$ (**16**) and the niobocene imide complexes $[Nb(=N\mathit{t}Bu)(\eta^5\text{-}C_5H_4PPh_2)_2Cl]$ (**17**) were synthesised by the reaction of $[Nb(=N\mathit{t}Bu)Cl_3(py)_2]$ with $Li_2\{Me_2Si(C_5Me_4)(C_5H_3PPh_2)\}$ (**4**) or two equivalents of $Li(C_5H_4PPh_2)$, respectively. Preliminary results for the catalytic activity of **7** and **8** in the polymerization of ethylene are presented.

Introduction

The use of *ansa*-cyclopentadienyl ligands has received wide attention in the chemistry of group 4 metals,[1] due mainly to their ability to impart to their complexes a selective degree of catalytic activity.[2] Recent studies have demonstrated that the incorporation of an *ansa* bridge may have a profound influence on the chemistry of the metallocene system.[3]

In 1996 we reported the first *ansa*-niobocene complexes, in which both cyclopentadienyl rings are bound only in an η^5 mode to niobium,[4] and since then several complexes of this type have been described.[5]

Furthermore the use of substituted *ansa*-cyclopentadienyl ligands in the synthesis of group 4 metal complexes and their importance in catalysis is receiving special attention,[6] but there are only a few examples for group 5.[3b,5d,6–8] Some examples of asymmetric *ansa*-zirconocene complexes have been described,[8–10] although the vast majority contain indenyl or fluorenyl systems.[11]

Chiral group 4 *ansa*-metallocene complexes are important stereoselective olefin polymerization catalysts, and have also been used as catalysts or reagents in stereoselective olefin and imine hydrogenation, Diels–Alder reactions, and cyclopolymerization.[12] We are investigating the stereoselective synthesis of *ansa*-metallocene complexes and the application of these compounds as catalysts. For example, we recently developed a general synthesis of some $SiMe_2$-bridged asymmetric *ansa*-zirconocene complexes[8,9] and this series of highly active C_1 symmetric olefin polymerization catalysts polymerize propylene with a high level of stereospecificity.[9] Our research in this area is now focused on the elucidation of the mechanism of olefin polymerization as well as on the use of new types of metallocene complexes in stereoselective catalysis.

The role of cyclopentadienyl ligands with attached tertiary phosphane groups in the chemistry of metallocene complexes has been well documented.[13] In the chemistry of group 4 elements several examples of this type of complex have been described. These include $[Ti(\eta\text{-}C_5H_4CH_2CH_2PPh_2)_2Cl_2]$[14] and $[Zr(\eta\text{-}C_5H_4CMe_2\text{-}PPh_2)_2X_2]$ (X = Cl, Me).[15] Special interest in this chemistry has been placed in the ability of the phosphane moiety to join two different metallic centres[16] and to stabilize cat-

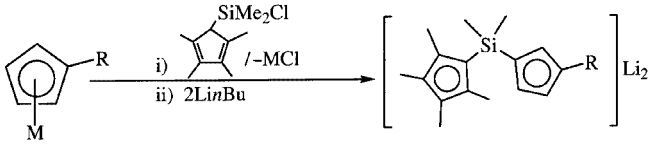
ionic species by intramolecular bonding to the metal centre.[15] However, despite the large number of related complexes reported there has been only one publication on the use of phosphane-substituted cyclopentadienyl ligands in the chemistry of the group 5 elements, in which the synthesis and reactivity of the tantalum complex, [Ta(η-C_5Me_5)(η-$C_5H_4PPh_2$)Cl_2] is described.[17] To the best of our knowledge the incorporation of such precursors in *ansa*-metallocene systems has not been reported previously.

As an extension of our previous work related to *ansa*-metallocene complexes of zirconium and niobium[4,5d,8,9] we now report the synthesis and characterization of the first phosphane-substituted *ansa*-cyclopentadienyl ligands and their incorporation in new metallocene complexes of the group 4 and 5 elements.

Results and Discussion

We have previously reported the synthesis of asymmetrically substituted cyclopentadienyl *ansa* ligands such as $Me_2Si(C_5Me_4H)(C_5H_4R)$ (R = H, Me, Et, *i*Pr, *t*Bu, $SiMe_3$)[8,9] and using the same methodology the *ansa* ligands $Me_2Si(C_5Me_4H)(C_5H_4CH_2CH_2PPh_2)$ (**1**) and $Me_2Si(C_5Me_4H)(C_5H_4PPh_2)$ (**2**) and their lithium derivatives $Li_2\{Me_2Si(C_5Me_4)(C_5H_3CH_2CH_2PPh_2)\}$ (**3**) and $Li_2\{Me_2Si(C_5Me_4)(C_5H_3PPh_2)\}$ (**4**) were prepared [Equation (1)].



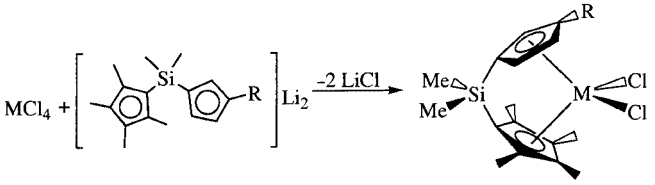
R = $CH_2CH_2PPh_2$ or PPh_2; M = K or Li

R = $CH_2CH_2PPh_2$ (**3**) Yield 96%
R = PPh_2 (**4**) Yield 93%

(1)

The possibility of various isomers for the *ansa* ligands **1** and **2** was confirmed by ^{1}H NMR spectroscopy. In addition **1** and **2** were characterised by electron impact mass spectrometry (see Exp. Sect.).

The reaction of the di-lithium derivatives of the phosphane-substituted *ansa* ligands **3** and **4** with $[TiCl_4(THF)_2]$ gave the *ansa*-titanocene(IV) complexes [Ti{Me_2Si(η^5-C_5Me_4)(η^5-$C_5H_3CH_2CH_2PPh_2$)}Cl_2] (**5**) and [Ti{Me_2Si(η^5-C_5Me_4)(η^5-$C_5H_3PPh_2$)}Cl_2] (**6**) [see Equation (2)].



M = Ti; R = $CH_2CH_2PPh_2$ (**5**) Yield 64%; PPh_2 (**6**) Yield 58%
M = Zr; R = $CH_2CH_2PPh_2$ (**7**) Yield 52%; PPh_2 (**8**) Yield 55%
M = Hf; R = $CH_2CH_2PPh_2$ (**9**) Yield 61%; PPh_2 (**10**) Yield 59%

(2)

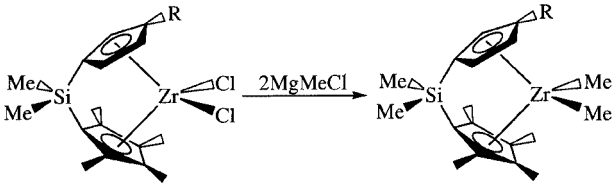
Complexes **5** and **6** were isolated as crystalline solids and characterised spectroscopically. Their ^{1}H NMR spectra show the lack of symmetry in these chiral C_1 symmetric complexes. Observed signals were assigned to the four inequivalent methyl groups attached to one of the cyclopentadienyl rings, the two distinct methyl groups of the $SiMe_2$ bridge and the three protons of the functionalized cyclopentadienyl moiety (see Exp. Sect.). In addition, in the ^{1}H NMR spectrum of **5** the expected signals for the alkyl chain and phenyl groups were observed. The ^{31}P NMR spectrum of **5** and **6** gave unique signals at δ = −42.8 and δ = −44.0 ppm, respectively indicating that the phosphorus atom is not interacting directly with the metal centre.[13b]

The *ansa*-metallocene complexes [M{Me_2Si(η^5-C_5Me_4)(η^5-C_5H_3R)}Cl_2] [M = Zr, R = $CH_2CH_2PPh_2$ (**7**), PPh_2 (**8**); M = Hf, R = $CH_2CH_2PPh_2$ (**9**), PPh_2 (**10**)] were prepared by the reaction of **3** or **4** with $ZrCl_4$ or $HfCl_4$ [see Equation (2)].

The ^{1}H NMR spectra for **7**−**10** concurred with those recorded for their titanocene analogues **5** and **6** (see Exp. Sect.). Complexes **5**−**10** represent, to the best of our knowledge, the first examples of group 4 *ansa*-metallocene complexes containing phosphane-substituted cyclopentadienyl moieties.

Compounds **7** and **8** were tested as catalysts in the polymerization of ethylene. The experiments were conducted at 25 °C and 1.5 bar with a zirconocene/MAO ratio of 1:500. Compared with [Zr(η^5-$C_5H_5)_2Cl_2$] [5000 kg polymer (mol Zr·h)$^{-1}$], complex **8** has a somewhat lower catalytic activity [3110 kg polymer (mol Zr·h)$^{-1}$]. Complex **7** was found to be a very poor catalyst [600 kg polymer (mol Zr·h)$^{-1}$]. The interaction of MAO with the phosphane group and the consequent steric effects exerted by the bulky Ph_2P-MAO unit may be responsible for the low catalytic activities observed.

The alkylzirconocene derivatives [Zr{Me_2Si(η^5-C_5Me_4)(η^5-C_5H_3R)}Me_2] [R = $CH_2CH_2PPh_2$ (**11**), PPh_2 (**12**)] were prepared by the reaction of two equivalents of the Grignard reagent MgMeCl with the corresponding *ansa*-metallocene dichloride complex **5** or **6**, respectively [see Equation (3)].



R = $CH_2CH_2PPh_2$ (**11**) Yield 81%
R = PPh_2 (**12**) Yield 80%

(3)

Compounds **11** and **12** were characterised by spectroscopic methods (see Exp. Sect.). ^{1}H NMR spectroscopy showed the expected signals for the C_1 symmetric complexes **11** and **12**. For the metal-bonded methyl groups two singlets at δ = −0.48 and −0.35 ppm were observed for **11**. In **12** these signals overlap to give one peak at δ = −0.49 ppm. However, the ^{13}C NMR spectrum of **12** gave the ex-

pected two distinct signals for the metal-bonded methyl groups. The ^{31}P NMR spectrum of **11** and **12** showed no significant changes with respect to their parent compounds **7** and **8** and therefore it can be proposed that there is no alteration in the coordination mode of the phosphorous atom.

The reaction of **11** and **12** with one molar equivalent of $B(C_6F_5)_3$ gave the cationic species $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3R)\}Me]^+$ [R = $CH_2CH_2PPh_2$ (**13**), PPh_2 (**14**)] with $MeB(C_6F_5)_3$ as the counteranion. The borane reagent reacts preferentially at the more nucleophilic methyl group rather than the phosphane substituent. Complexes **13** and **14** were characterised by ^{1}H, ^{11}B and ^{31}P NMR spectroscopy. The ^{1}H NMR spectra of **13** and **14** revealed the disappearance of one methyl peak and a shifting of the remaining peaks. In addition the Me-B proton resonance was observed as a broad signal at $\delta = 0.31$ ppm.

Initially there exists two possibilities for the methyl abstraction of **11** and **12**. The borane derivative can interact with either the methyl group positioned below or that orientated away from the phosphane substituent of the cyclopentadienyl moiety. ^{1}H NMR spectroscopy revealed in all cases the presence of only one compound and it appears likely on the grounds of steric effects that this corresponds to the product of the alkyl abstraction at the less hindered metal-methyl group. Nevertheless we cannot rule out the rapid exchange of coordination positions between the metal-methyl and boron-coordinated methyl groups; for a similar C_s symmetric *ansa*-system, $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_4)\}Me]^+$,[9] however, such a phenomenon was not observed. An extensive study into the behaviour of alkyl-zirconocene borate ion pairs has been published recently.[18]

^{31}P NMR spectroscopy revealed that the phosphane groups in **13** and **14** behave in different ways. For **13** a signal at $\delta = -4.3$ ppm (compared with $\delta = -40.0$ ppm for the parent compound **11**) was observed in the ^{31}P NMR spectrum. This is indicative of a change in the coordination mode of the phosphorous atom.[13b] This shift can be explained by the fact that the abstraction of a methyl group by $B(C_6F_5)_3$ creates a vacant coordination site at the metal centre which is occupied by the phosphorous atom of the pendant phosphane ligand (see Figure 1). However, in **14** the geometric restrictions of the phosphane group which is directly attached to the cyclopentadienyl moiety inhibit its coordination to the metal centre in the cationic species and thus ^{31}P NMR spectroscopy gives a signal at $\delta = -41.4$ ppm similar to that observed for the parent complex **12** (see Figure 2).

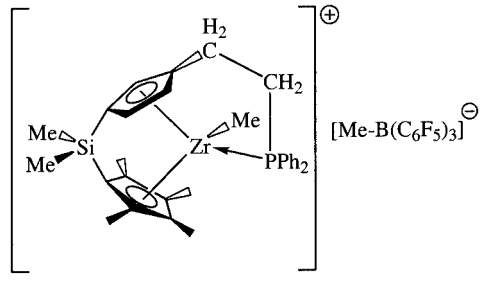


Figure 1. Proposed structure for $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3CH_2CH_2PPh_2)\}Me][MeB(C_6F_5)_3]$ (**13**)

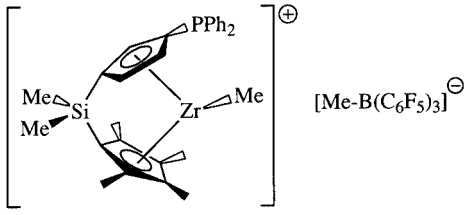

Figure 2. Proposed structure for $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Me][MeB(C_6F_5)_3]$ (**14**)

The reaction of the isocyanide reagent $CNC_6H_3Me_2$-2,6 with **12** has also been studied [Equation (4)]. The product of the insertion reaction $[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}\{\eta^2\text{-}MeC{=}N(C_6H_3Me_2\text{-}2,6)\}(Me)]$ (**15**) was characterised by ^{1}H, ^{13}C and ^{31}P NMR spectroscopy.

15
Yield 60%

The migratory insertion of alkyl groups towards isocyanide ligands allows the introduction of iminoacyl groups, which are present in different coordination modes. In fact, for high-valent oxophilic early transition metals, the iminoacyl group typically adopts an η^2-coordination mode through both the nitrogen and carbon atoms.[19] Similarly, an η^2-coordination mode is proposed for the iminoacyl ligand in **15** on the basis of IR and ^{13}C NMR spectroscopy, which show the characteristic ν(C=N) stretching vibration at 1584 cm^{-1} and the iminoacyl quaternary carbon atom signal at $\delta = 246.8$ ppm, respectively.

The ^{1}H NMR spectrum of **15**, in addition to the expected signals for the *ansa*-metallocene protons, gave signals for the metal-bonded methyl group at $\delta = 0.28$ ppm and for the iminoacyl methyl group at $\delta = 2.19$ ppm. The chemical shift observed for the only signal in the ^{31}P NMR spectrum ($\delta = -43.5$ ppm) showed that the chemical properties of the phosphorous atom remained unaltered with respect to the parent complex.

In **12** the two methyl groups are not equivalent and the insertion of the isocyanide probably occurs preferentially into one of the metal-methyl bonds. This was confirmed by NMR spectroscopy, which showed the presence of only one of the possible isomers. For steric reasons we propose that the insertion takes place at the metal-methyl group that is

orientated away from the bulky phosphane moiety (Figure 3).

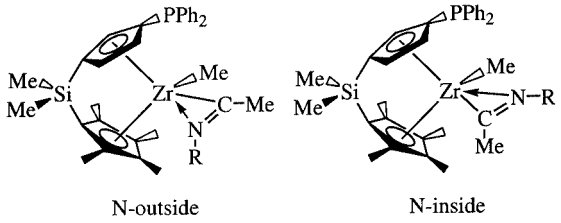

Figure 3. Two possible conformations for the metal-iminoacyl complex **15**

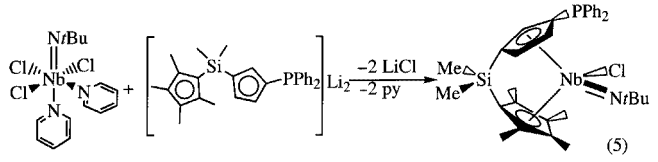
In addition the iminoacyl group can position itself in two distinct conformations, the "proximal" or "N-outside" and the "distal" or "N-inside" configurations (see Figure 3). ^{1}H and ^{13}C NMR spectroscopic data indicated the presence of only one of the two possible conformations. Although it has been demonstrated that the N-outside isomer is the resulting initial kinetic iminoacyl product of the insertion reaction, most group 4 metal derivatives show the structure of the N-inside isomer which results from thermodynamic control.[20] For **15** the isolated product was observed not to evolve over time and, in addition, the NOE experiment showed a negligible effect between the metal-methyl and iminoacyl-methyl groups. Therefore we propose that **15** is the product resulting from thermodynamic control and adopts the N-inside conformation.

A second insertion into the remaining methyl group was not observed even when stoichiometries greater than 1:1 were tested.

The use of phosphane-substituted cyclopentadienyl ligands in the chemistry of group 5 elements has been restricted to one reference concerning the tantalum complex $[Ta(\eta\text{-}C_5Me_5)(\eta\text{-}C_5H_4PPh_2)Cl_2]$ and its reactivity.[17] To the best of our knowledge there have been no reports of this type of compounds in the chemistry of niobium.

By the reaction of the lithium derivative $Li_2\{Me_2Si(C_5Me_4)(C_5H_3PPh_2)\}$ (**4**) with $[Nb(=N\textit{t}Bu)Cl_3(py)_2]$ we have also prepared the *ansa*-phosphane niobocene imido complex $[Nb(=N\textit{t}Bu)\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl]$ (**16**) [Equation (5)]. The complex $[Nb(=N\textit{t}Bu)(\eta^5\text{-}C_5H_4PPh_2)_2Cl]$ (**17**), was prepared in a similar manner by reaction of two equivalents of $Li(C_5H_4PPh_2)$ with $[Nb(=N\textit{t}Bu)Cl_3(py)_2]$.



16
Yield 63%

By comparison with our previous work in imidoniobocene chemistry[5d,8,21] we can assume that the imido group acts as a four-electron donor. Complexes **16** and **17** can therefore be considered as "20-electron" complexes. However the two excess electrons are most probably located in a ligand-based orbital as has previously been reported for similar compounds.[22]

Both **16** and **17** were characterised spectroscopically. The ^{1}H NMR spectrum of **16** showed the lack of symmetry in this chiral complex. The four methyl groups attached to the cyclopentadienyl ring are inequivalent as are the methyl groups of the $SiMe_2$ bridge. In addition signals were observed for the alkyl-imido and phenyl groups and the three protons of the phosphane-substituted cyclopentadienyl moiety (see Exp. Sect.). In the case of **17** an ABCD system was observed in the ^{1}H NMR spectrum due to the inequivalency of the cyclopentadienyl ring protons, although a plane of symmetry makes the two cyclopentadienyl rings equivalent, thus giving four multiplets for the eight ring protons. The expected signals for the alkyl-imido and phenyl groups were also observed (see Exp. Sect.).

Complex **16** has the possibility to form two isomers depending on the position of the phosphane group, which can either be orientated towards or away from the imido group (see Figure 4). ^{1}H NMR spectroscopy revealed that only one isomer was present. For other alkyl-substituted *ansa*-niobium complexes this same phenomenon was observed,[8] and all the molecular structures reported for related complexes revealed that the substituent was situated pointing away from the bulky imido group. It is logical to assume the same is true for **16** and therefore the proposed structure (a) is that illustrated in Figure 4.

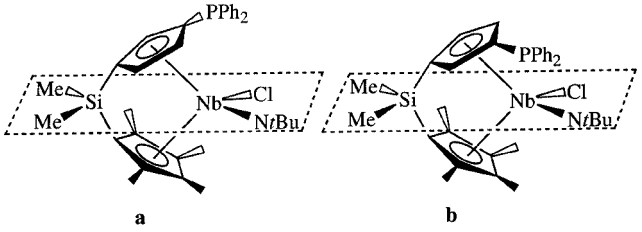


Figure 4. Possible isomers for $[Nb(=N\textit{t}Bu)\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl]$ (**16**)

In conclusion we have reported the synthesis of new phosphane-containing *ansa*-cyclopentadienyl ligands and their lithium derivatives. We have prepared the first phosphane-substituted *ansa*-metallocene complexes with group 4 and group 5 elements. The catalytic activity of the zirconocene complexes has been tested in olefin polymerization and discussed as a function of the phosphane group attached to the cyclopentadienyl ring. The reactivity of some of these compounds has been described.

Experimental Section

General Remarks: All reactions were performed using standard Schlenk-tube techniques under an atmosphere of dry nitrogen. Solvents were distilled from appropriate drying agents and degassed before use. $K(C_5H_4CH_2CH_2PPh_2)$,[23] $Li(C_5H_4PPh_2)$[24] and $[Nb(=N\textit{t}Bu)Cl_3(py)_2]$[25] were prepared as described earlier. $[TiCl_4(THF)_2]$, $ZrCl_4$, $HfCl_4$, $Me_2Si(C_5Me_4H)Cl$, MgMeCl, $B(C_6F_5)_3$ and (2,6-dimethylphenyl)isocyanide were purchased from

Aldrich and used directly. IR spectra were recorded on a Perkin−Elmer PE 883 IR spectrophotometer. ^{1}H and ^{13}C spectra were recorded on Varian FT-300 and Varian Gemini FT-200 spectrometers and referenced to the residual deuterated solvent. Microanalyses were carried out with a Perkin−Elmer 2400 micro analyzer. Mass spectroscopic analyses were performed on a Hewlett−Packard 5988A (*m*/*z* = 50−1000) instrument (electron impact).

Preparation of $Me_2Si(C_5Me_4H)(C_5H_4CH_2CH_2PPh_2)$ (1): $Me_2Si(C_5Me_4H)Cl$ (1.36 g, 6.32 mmol) in THF (50 mL) was added to a solution of $K(C_5H_4CH_2CH_2PPh_2)$ (2.00 g, 6.32 mmol) in THF (50 mL) at −78 °C. The reaction mixture was allowed to warm to room temperature and stirred for 18 h. Solvent was removed in vacuo and hexane (150 mL) was added to the resulting orange oil. The mixture was filtered and solvent removed from the filtrate under reduced pressure to yield the title compound as a yellow oil (2.78 g, 96%). ^{1}H NMR (200 MHz, C_6D_6, 25 °C) (for the predominant isomer, 60%): δ = 0.10 (s, 6 H, Si*Me*$_2$), 1.75 and 1.85 (2s, each 6 H, C_5Me_4), 2.20−2.60 and 3.00−3.30 (2m, each 2 H, -CH_2CH_2-), 2.80 and 3.47 (2m, each 1 H, *H*C$_5$), 6.35, 6.37 and 6.56 (3m, each 1 H, C_5H_3), 7.00−7.60 (m, 10, P*Ph*$_2$) ppm. EI-MS: *m*/*z* (%) = 456 (25) [M$^+$], 335 (30) [M$^+$ − C_5Me_4H], 179 (100) [M$^+$ − $C_5H_4CH_2CH_2PPh_2$], 123(65) [M$^+$ − C_5Me_4H − $CH_2CH_2PPh_2$].

Preparation of $Me_2Si(C_5Me_4H)(C_5H_4PPh_2)$ (2): The synthesis of **2** was carried out in an identical manner to **1**. $Me_2Si(C_5Me_4H)Cl$ (1.10 g, 5.12 mmol) and $Li(C_5H_4PPh_2)$ (1.31 g, 5.12 mmol). Yield 2.05 g, 94%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C) (for the predominant isomer, 60%): δ = 0.05 (s, 6 H, Si*Me*$_2$), 1.70 and 1.80 (2s, each 6 H, C_5Me_4), 3.05 and 3.35 (2m, each 1 H, *H*C$_5$), 6.28, 6.32 and 6.52 (3m, each 1 H, C_5H_3), 7.00−7.60 (m, 10, P*Ph*$_2$) ppm. EI-MS: *m*/*z* (%) = 428 (20) [M$^+$], 307 (25) [M$^+$ − C_5Me_4H], 179 (100) [M$^+$ − $C_5H_4PPh_2$], 123(70) [M$^+$ − C_5Me_4H − PPh_2].

Preparation of $Li_2\{Me_2Si(C_5Me_4)(C_5H_3CH_2CH_2PPh_2)\}$ (3): *n*BuLi (1.6 M in hexane) (7.6 mL, 12.18 mmol) was added via syringe to a solution of **1** (2.78 g, 6.09 mmol) in Et_2O (75 mL) at −78 °C. The mixture was allowed to warm to 10 °C and stirred for 15 h. Solvent was removed in vacuo to give a white solid which was washed with hexane (2 × 50 mL) and dried under vacuum to yield a white solid of the title complex (2.74 g, 96%). $C_{30}H_{35}Li_2PSi$ (468.5): calcd. C 76.90, H 7.53; found C 76.62, H 7.43.

Preparation of $Li_2\{Me_2Si(C_5Me_4)(C_5H_3PPh_2)\}$ (4): The synthesis of **4** was carried out in an identical manner to **3** from **2** (2.19 g, 5.11 mmol) and *n*BuLi (1.6 M in hexane) (6.39 mL, 10.22 mmol). Yield 2.09 g, 93%. $C_{28}H_{31}Li_2PSi$ (440.5): calcd. C 76.35, H 7.09; found C 76.19, H 7.00.

Preparation of $[Ti\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3CH_2CH_2PPh_2)\}Cl_2]$ (5): Compound **3** (1.50 g, 3.20 mmol) in THF (50 mL) was added to a solution of $[TiCl_4(THF)_2]$ (1.07 g, 0.64 mmol) in THF (50 mL). The resulting dark red solution was stirred for 18 h. Solvent was removed in vacuo and toluene (75 mL) was added. The suspension was filtered and the filtrate was concentrated (10 mL) and cooled (−30 °C) to yield the title complex as a red crystalline solid (1.17 g, 64%). ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = −0.01 and 0.34 (2s, each 3 H, Si*Me*$_2$), 1.45, 1.60, 2.07 and 2.09 (4s, each 3 H, C_5Me_4), 2.04−2.61 and 2.98−3.35 (2m, each 2 H, -CH_2CH_2-), 4.88, 5.31 and 6.93 (3m, each 1 H, C_5H_3), 7.06−7.12, 7.32−7.55 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.7, −0.6 (Si*Me*$_2$), 12.1, 12.2, 14.5, 14.7 (C_5Me_4), 27.0 (d, $^1J_{C,P}$ = 19.7 Hz), 28.6 (d, $^2J_{C,P}$ = 13.8 Hz) (-*C*H_2CH_2-), 110.0, 110.7, 112.6 125.0, 126.10 (*C*$_5$H$_3$), 128.0−141.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −42.8 ppm. $C_{30}H_{35}Cl_2PSiTi$ (573.5): calcd. C 62.84, H 6.15; found C 62.56, H 6.09.

The syntheses of **6**−**10** were carried out in an identical manner to **5**.

$[Ti\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl_2]$ (6): From $[TiCl_4(THF)_2]$ (1.18 g, 0.89 mmol) and **4** (1.56 g, 3.54 mmol). Yield 1.12 g, 58%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.08 and 0.16 (2s, each 3 H, Si*Me*$_2$), 1.39, 1.54, 1.96 and 2.04 (4s, each 3 H, C_5Me_4), 5.34, 5.45 and 6.32 (3m, each 1 H, C_5H_3), 7.37−7.74 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −1.1, −0.2 (Si*Me*$_2$), 11.3, 12.9, 13.6, 13.9 (C_5Me_4), 110.4, 112.6, 117.4, 118.4 (d, $^1J_{C,P}$ = 32.4 Hz), 125.6 (*C*$_5$H$_3$), 128.0−138.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −42.2 ppm. $C_{28}H_{31}Cl_2PSiTi$ (545.4): calcd. C 61.66, H 5.73; found C 61.47, H 5.66.

$[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3CH_2CH_2PPh_2)\}Cl_2]$ (7): From $ZrCl_4$ (0.99 g, 4.27 mmol) and **3** (2.00 g, 4.27 mmol). Yield 1.37 g, 52%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.33 and 0.37 (2s, each 3 H, Si*Me*$_2$), 1.58, 1.69, 1.98 and 1.99 (4s, each 3 H, C_5Me_4), 2.28−2.57 and 2.95−3.26 (2m, each 2 H, -CH_2CH_2-), 5.04, 5.37 and 6.72 (3m, each 1 H, C_5H_3), 7.01−7.10, 7.43−7.53 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.7, −0.6 (Si*Me*$_2$), 12.3, 12.4, 14.8, 15.0 (C_5Me_4), 27.0 (d, $^1J_{C,P}$ = 19.8 Hz), 28.6 (d, $^2J_{C,P}$ = 13.5 Hz) (-*C*H_2CH_2-), 112.3, 113.1, 125.0, 125.1, 126.1 (*C*$_5$H$_3$), 128.0−141.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −39.5 ppm. $C_{30}H_{35}Cl_2PSiZr$ (616.8): calcd. C 58.42, H 5.72; found C 58.33, H 5.68.

$[Zr\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl_2]$ (8): From $ZrCl_4$ (0.80 g, 3.41 mmol) and **4** (1.50 g, 3.41 mmol). Yield 1.12 g, 55%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.18 and 0.30 (2s, each 3 H, Si*Me*$_2$), 1.56, 1.64, 1.95 and 2.00 (4s, each 3 H, C_5Me_4), 5.54 (2 H), 6.75 (1 H) (m, C_5H_3), 6.97−7.13, 7.38−7.73 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −1.0, −0.7 (Si*Me*$_2$), 12.4, 12.5, 14.8, 15.0 (C_5Me_4), 110.7, 114.4, 116.5, 120.4, 125.4 (d, $^1J_{C,P}$ = 33.6 Hz) (*C*$_5$H$_3$), 128.0−138.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −43.8 ppm. $C_{28}H_{31}Cl_2PSiZr$ (588.7): calcd. C 57.12, H 5.31; found C 56.99, H 5.25.

$[Hf\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3CH_2CH_2PPh_2)\}Cl_2]$ (9): From $HfCl_4$ (1.08 g, 3.37 mmol) and **3** (1.58 g, 3.37 mmol). Yield 1.45 g, 61%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.31 and 0.35 (2s, each 3 H, Si*Me*$_2$), 1.63, 1.75, 1.99 and 2.00 (4s, each 3 H, C_5Me_4), 2.24−2.59 and 2.98−3.24 (2m, each 2 H, -CH_2CH_2-), 4.98, 5.31 and 6.62 (3m, each 1 H, C_5H_3), 7.01−7.10, 7.40−7.51 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.7, −0.6 (Si*Me*$_2$), 12.1, 12.2, 14.5, 14.7 (C_5Me_4), 27.0 (d, $^1J_{C,P}$ = 19.7 Hz), 28.6 (d, $^2J_{C,P}$ = 13.8 Hz) (−*C*H_2CH_2-), 110.0, 110.7, 112.61 125.0, 126.1 (*C*$_5$H$_3$), 128.0−141.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −39.8 ppm. $C_{30}H_{35}Cl_2HfPSi$ (704.1): calcd. C 51.18, H 5.01; found C 50.91, H 4.90.

$[Hf\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl_2]$ (10): From $HfCl_4$ (1.10 g, 3.43 mmol) and **4** (1.51 g, 3.43 mmol). Yield 1.37 g, 59%. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.20 and 0.32 (2s, each 3 H, Si*Me*$_2$), 1.65, 1.73, 1.99, 2.05 (4s, each 3 H, C_5Me_4), 5.52, 5.54 and 6.72 (3m, each 1 H, C_5H_3), 6.99−7.14, 7.37−7.71 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −1.0, −0.7 (Si*Me*$_2$), 12.2, 12.3, 14.5, 14.7 (C_5Me_4), 112.1, 114.3, 116.5, 120.1, 125.4 (d, $^1J_{C,P}$ = 33.6 Hz) (*C*$_5$H$_3$), 128.0−138.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz,

C_6D_6, 25 °C): δ = −41.0 ppm. $C_{28}H_{31}Cl_2HfPSi$ (676.0): calcd. C 49.75, H 4.62; found C 49.63, H 4.55.

Preparation of [Zr{Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$CH$_2$CH$_2$PPh$_2$)}Me$_2$] (11): A 3 M solution of MgMeCl in THF (0.43 mL, 1.30 mmol) was added to a stirred solution of **7** (0.40 g, 0.65 mmol) in THF (50 mL) at −78 °C. The solution was allowed to warm to room temperature and stirred for 4 h. Solvent was removed in vacuo and the remaining solid extracted with hexane (30 mL). A white crystalline solid was obtained by concentrating (5 mL) and cooling (−30 °C) the solution (0.30 g, 81%). ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = −0.48 and −0.35 (2s, each 3 H, Zr-C*H*$_3$), 0.34 and 0.37 (2s, each 3 H, Si*Me*$_2$), 1.54, 1.65, 1.91 and 1.92 (4s, each 3 H, C$_5$*Me*$_4$), 2.38−3.05 (m, 4 H, -C*H*$_2$C*H*$_2$-), 5.05, 5.28 and 6.58 (3m, each 1 H, C$_5$*H*$_3$), 7.01−7.14, 7.42−7.52 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.3, 1.4 (Si*Me*$_2$), 11.6, 11.7, 14.3, 14.5 (C$_5$*Me*$_4$), 26.9 (d, $^1J_{C,P}$ = 19.6 Hz), 30.5 (d, $^2J_{C,P}$ = 8.6 Hz) (−*C*H$_2$*C*H$_2$-), 31.4, 35.2 (Zr-*C*H$_3$), 111.4, 112.2, 125.0, 125.1, 126.1 (*C*$_5$H$_3$), 128.0−140.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −40.0 ppm. $C_{32}H_{41}PSiZr$ (576.0): calcd. C 66.73, H 7.18; found C 66.51, H 7.12.

Preparation of [Zr{Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$PPh$_2$)}Me$_2$] (12): The synthesis of **12** was carried out in an identical manner to that of **11**, with a 3 M solution of MgMeCl in THF (0.51 mL, 1.52 mmol) and **8** (0.45 g, 0.76 mmol). Yield 0.34 g, 80%. ^{1}H NMR (200 MHz, C_6D_6): δ = −0.49 (s, 6 H, Zr-C*H*$_3$), 0.26 and 0.37 (2s, each 3 H, Si*Me*$_2$), 1.56, 1.63, 1.89 and 1.97 (4s, each 3 H, C$_5$*Me*$_4$), 5.47, 5.57 and 6.74 (3m, each 1 H, C$_5$*H*$_3$), 7.07−7.17, 7.52−7.74 (m, 10 H, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.7, 0.1 (Si*Me*$_2$), 11.6, 11.7, 14.4, 14.5 (C$_5$*Me*$_4$), 37.3, 37.7 (Zr-*C*H$_3$), 110.4, 115.6, 116.5, 125.5, 127.4 (*C*$_5$H$_3$), 128.0−140.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −44.1 ppm. $C_{30}H_{37}PSiZr$ (547.9): calcd. C 65.76, H 6.81; found C 65.49, H 6.71.

Preparation of [Zr{Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$CH$_2$CH$_2$PPh$_2$)}Me][MeB(C$_6$F$_5$)] (13): A solution of B(C$_6$F$_5$)$_3$ (0.25 g, 0.49 mmol) in toluene (25 mL) was added to a stirred solution of **11** (0.28 g, 0.49 mmol) in toluene (25 mL) at −78 °C. The mixture was allowed to warm to room temperature and stirred for 30 min. Solvent was removed in vacuo to give the title complex as an orange oil. ^{1}H NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = −0.11 (s, 3 H, Zr-C*H*$_3$), 0.31 (br, 3 H, B-C*H*$_3$), 0.50 and 1.17 (2s, each 3 H, Si*Me*$_2$), 1.29, 1.34, 1.40 and 1.96 (4s, each 3 H, C$_5$*Me*$_4$), 2.20−2.80 (m, 4 H, -C*H*$_2$C*H*$_2$-), 4.84, 5.01 and 6.58 (3m, each 1 H, C$_5$*H*$_3$), 7.01−7.42 (m, 10 H, P*Ph*$_2$) ppm. ^{11}B{^{1}H} NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = 15 ppm. ^{31}P{^{1}H} NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = −4.29 ppm.

Preparation of [Zr{Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$PPh$_2$)}Me][MeB(C$_6$F$_5$)] (14): The synthesis of **14** was carried out in an identical manner to that of **13**, from B(C$_6$F$_5$)$_3$ (0.25 g, 0.49 mmol) and **12** (0.27 g, 0.49 mmol). ^{1}H NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = −0.49 (s, 3 H, Zr-C*H*$_3$), 0.18 and 0.30 (2s, each 3 H, Si*Me*$_2$), 0.31 (br, 3 H, B-C*H*$_3$), 1.56, 1.63, 1.89 and 1.97 (4s, each 3 H, C$_5$*Me*$_4$), 4.98, 5.64 and 6.22 (3m, each 1 H, C$_5$*H*$_3$), 7.01−7.34 (m, 10 H, P*Ph*$_2$) ppm. ^{11}B{^{1}H} NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = 15 ppm. ^{31}P{^{1}H} NMR (300 MHz, [D$_8$]toluene, 25 °C): δ = −44.6 ppm.

Preparation of [Zr{Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$PPh$_2$)}{η^2-MeC=N(C$_6$H$_3$Me$_2$-2,6)}(Me)] (15): (2,6-dimethylphenyl)isocyanide (0.12 g, 0.91 mmol) and **12** (0.50 g, 0.91 mmol) were dissolved in THF (100 mL). The resulting orange solution was stirred at room temperature for 18 h. Solvent was removed in vacuo and the remaining solid extracted with toluene (30 mL). An orange solid was obtained by concentrating (5 mL) and cooling (−30 °C) the solution (0.37 g, 60%). IR (Nujol): ν$_{C=N}$ 1584 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.25 (s, 3 H, Zr-C*H*$_3$), 0.36 and 0.58 (2s, each 3 H, Si*Me*$_2$), 1.28 and 1.50 (2s, each 3 H, C$_6$H$_3$*Me*$_2$), 1.75, 1.82, 1.90 and 1.95 (4s, each 3 H, C$_5$*Me*$_4$), 2.19 (s, 3 H, C-C*H*$_3$ iminoacyl) 5.54, 5.65 and 5.88 (3m, each 1 H, C$_5$*H*$_3$), 6.82−7.07, 7.32−7.53 (m, P*Ph*$_2$ and C$_6$*H*$_3$Me$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −0.7, 0.1 (Si*Me*$_2$), 11.6, 11.7, 14.4, 14.5 (C$_5$*Me*$_4$), 19.8 (C*C*H$_3$ iminoacyl), 25.8 (Zr-*C*H$_3$), 110.7, 113.4, 120.9, 125.5, 127.4 (*C*$_5$H$_3$), 128.0−140.0 (various signals assigned to P*Ph*$_2$, *C*$_6$H$_3$Me$_2$, and *C*$_5$Me$_4$), 246.8 (*C*CH$_3$ iminoacyl) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −43.5 ppm. $C_{39}H_{46}NPSiZr$ (679.1): calcd. C 68.98, H 6.83, N 2.06; found C 68.75, H 6.77, N 2.00.

Preparation of [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$Me$_4$)(η^5-C$_5$H$_3$PPh$_2$)}Cl] (16): THF (50 mL) was added to a solid mixture of [Nb(=N*t*Bu)Cl$_3$(py)$_2$] (0.78 g, 1.82 mmol) and **4** (0.80 g, 1.82 mmol). The resulting brown solution was stirred for 12 h. Solvent was removed in vacuo and hexane added (75 mL) to the resulting solid. The mixture was filtered and the filtrate concentrated (10 mL) and cooled to −30 °C. The resulting yellow solid that precipitated from the solution was isolated by filtration (0.67 g, 63%). IR (Nujol): ν$_{Nb=N}$ = 1255 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.10 and 0.45 (2s, each 3 H, Si*Me*$_2$), 0.87 (s, 9 H, C*Me*$_3$), 1.65, 1.71, 2.03 and 2.25 (4s, each 3 H, C$_5$*Me*$_4$), 5.61, 6.27 and 6.42 (3m, each 1 H, C$_5$*H*$_3$), 6.91−7.80 (m, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −1.5, −0.8 (Si*Me*$_2$), 12.6, 13.3, 13.4, 16.4 (C$_5$*Me*$_4$), 31.2 (C*Me*$_3$), 71.3 (*C*Me$_3$), 102.0, 104.7, 114.5, 114.9, 115.0 (*C*$_5$H$_3$), 128.0−135.0 (various signals assigned to P*Ph*$_2$ and *C*$_5$Me$_4$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = −43.49 ppm. $C_{32}H_{40}ClNNbPSi$ (626.1): calcd. C 61.39, H 6.44, N 2.24; found C 61.17, H 6.36, N 2.25.

Preparation of [Nb(=N*t*Bu)(η^5-C$_5$H$_4$PPh$_2$)$_2$Cl] (17): The synthesis of **17** was carried out in an identical manner to **16**, from [Nb(=N*t*Bu)Cl$_3$(py)$_2$] (0.50 g, 1.16 mmol) and Li(C$_5$H$_4$PPh$_2$) (0.60 g, 2.34 mmol). Yield 0.58 g, 72%. IR (Nujol): ν$_{Nb=N}$ = 1240 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 0.96 (s, 9 H, C*Me*$_3$), 5.89, 6.05, 6.12 and 6.18 (4m, each 2 H, 2 × C$_5$*H*$_4$), 6.91−7.50 (10 H) (m, P*Ph*$_2$) ppm. ^{13}C{^{1}H} NMR (300 MHz, C_6D_6, 25 °C): δ = 29.9 (C*Me*$_3$), 70.6 (*C*Me$_3$), 111.8, 112.7, 120.6, 120.7 124.7 (*C*$_5$H$_4$), 128.0−134 (various signals assigned to P*Ph*$_2$) ppm. ^{31}P{^{1}H} NMR (300 MHz, C_6D_6, 25 °C). δ = −40.10 ppm. $C_{38}H_{37}ClNNbP_2$ (698.0): calcd. C 65.39, H 5.34, N 2.01; found C 65.17, H 5.23, N 1.99.

Polymerization Experiments: The *ansa*-zirconocene catalyst (**7** or **8**; 6 μmol), MAO (10% in toluene) (3000 μmol) and toluene (150 mL) were mixed together in a Schlenk tube. The N_2 pressure inside the Schlenk tube was reduced by applying vacuum. An ethylene pressure of 1.5 bar was then applied to the Schlenk tube and stirring of the mixture commenced. After exactly 30 min, stirring was halted and the ethylene pressure was released. Excess MAO was then destroyed by adding a mixture of methanol/HCl (90:10) cautiously. The polymer formed was isolated by filtration, washed with ethanol and dried under vacuum at 60 °C for 12 h.

Acknowledgments

We gratefully acknowledge financial support from the Dirección General de Enseñanza Superior e Investigación Científica, Spain (Grants. No. PB 98-0159-C02-01-02 and No. BQU2000-0463) and

funding for S. P. from the FEDER project 1FD97-1375. We would also like to thank Dr. M. Laguna for providing mass spectrometry data.

Palladium and Platinum Units Grafted on the Periphery of Carbosilane Dendrimers

Mónica Benito,[a] Oriol Rossell,*[a] Miquel Seco,[a] Guillermo Muller,[a] Juan I. Ordinas,[a] Mercè Font-Bardia,[b] and Xavier Solans[b]

Keywords: Dendrimers / Alkynes / Homogeneous catalysis / Palladium / Platinum

The reaction of a series of phosphanyl-terminated carbosilane dendrimers with palladium and platinum complexes was carried out. The new metallodendrimers containing $PdCl(\eta^3\text{-}2\text{-}MeC_3H_4)$ and $PtCl_2$ or $Pt(C{\equiv}CPh)_2$ as peripheral groups were characterized by ^1H, ^{13}C, ^{29}Si, ^{31}P, and ^{195}Pt NMR spectroscopy, and, in some cases, by mass spectrometry. The $PtCl_2$-containing species of the second-generation carbosilane dendrimer displays only one of the two possible stereoisomers. By comparison with the ^{31}P NMR spectra of the model compounds *cis*-$[PtCl_2(PPh_2CH_2SiMe_3)_2]$ (**4**) and *cis*-$[PtCl_2\{Me_2Si(CH_2PPh_2)_2\}]$ (**5**), it was deduced that the $PtCl_2$ units are bound on the surface of the dendrimer through two phosphorus atoms belonging to the same branch. The palladium dendrimers were tested as catalysts in the hydrovinylation of styrene, and their activity was compared with that of the model catalyst $[PdCl(\eta^3\text{-}2\text{-}MeC_3H_4)(PPh_2CH_2SiMe_3)]$. The crystal structures of **4**, **5**, and $[Pt(C{\equiv}CPh)_2\{Me_2Si(CH_2PPh_2)_2\}]$ (**6**) were solved by X-ray diffraction analysis.

Introduction

There is currently an interest in the synthesis of dendrimers and in the development of their chemistry.[1] Carbosilane dendrimers have been widely used in recent years because they are very stable, both kinetically and thermodynamically.[2] Moreover, peripheral groups, such as Si−Cl offer the opportunity of introducing other functions through the appropriate chemistry; such as the synthesis of carbosilane dendrimers containing diphenylphosphane-terminated groups.[3] Recently, we used these species as "dendrimer ligands" to coordinate a number of metal units (e.g., AuCl).[4] These units reacted, in turn, with metal anions to give dendrimers decorated on the surface by transition metal clusters.[5] We now report an extension of our previous efforts to graft palladium and platinum fragments on the periphery of the dendrimers and the study of the reactivity of such types of species, including the use of palladium compounds as catalytic precursors in the hydrovinylation of styrene.

Results and Discussion

The carbosilane dendrimers chosen for this study are listed in Scheme 1. They display different numbers of terminal phosphanyl groups on the surface (**1** and **2**), and the surface congestion on **3** is lower due to the presence of $CH_2-CH_2-SiMe_2$ spacers in the arms. The dendrimers were obtained by a repetitive stepwise synthetic route of hydrosilylation of the vinylic end groups of the dendrimer with chlorosilanes followed by alkenylation with vinylmagnesium chloride.[3] Next, reaction with the tetramethylethylenediamine complex of [(diphenylphosphanyl)methyl]lithium permitted the incorporation of terminal CH_2PPh_2 groups.

Platinum Dendrimers

Generally, the functionalization of the peripheral *P*-branched dendrimers with transition metals is simply achieved by taking advantage of the complexation ability of these species.[6] For example, they have been treated with complexes such as [Rh(acac)(COD)][7] or $[Pd(\mu\text{-}Cl)(\eta^3\text{-}2\text{-}MeC_3H_4)]_2$.[8] Several reports describe peripheral platinum-containing dendrimers, but only one example shows platinum centers bonded to phosphorus atoms.[7]

In this paper we have functionalized the surface of our *P*-branched dendrimers with platinum by reaction with [$PtCl_2$(COD)]. We also synthesised the model compounds $[PtCl_2(PPh_2CH_2SiMe_3)_2]$ (**4**) and $[PtCl_2\{Me_2Si(CH_2PPh_2)_2\}]$ (**5**). Compound **4** was synthesised from $PPh_2CH_2SiMe_3$ (2 equiv.) and [$PtCl_2$(COD)] (1 equiv.), and **5** from [$PtCl_2$(COD)] (1 equiv.) and $Me_2Si(CH_2PPh_2)_2$ (1 equiv) (Scheme 2). Details of spectroscopy data of these compounds are given in the Exp. Sect.

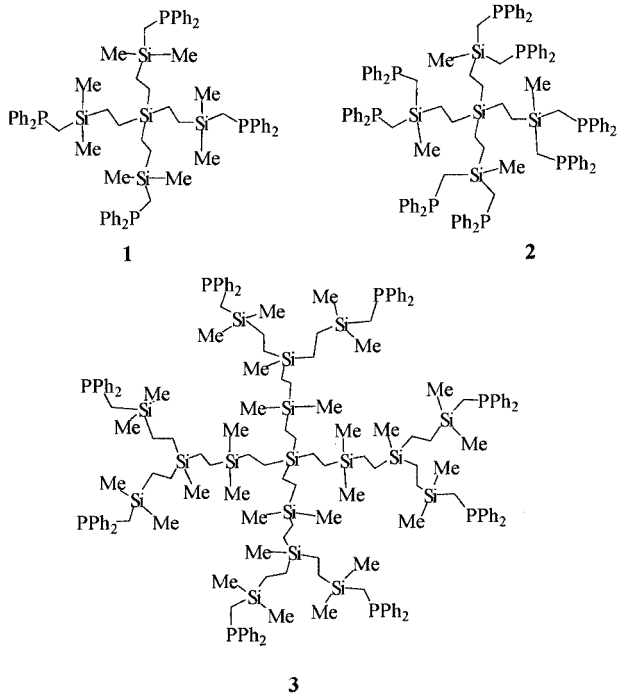
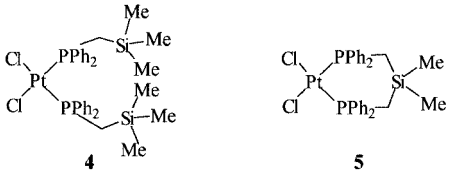


Scheme 1



Scheme 2

X-ray Crystal Structures of 4 and 5

A view of the compound *cis*-[$PtCl_2(PPh_2CH_2SiMe_3)_2$] (**4**) appears in Figure 1, and selected bond lengths and angles are given in Table 1. The platinum atom has a planar coordination with the slight tetrahedral distortion frequently observed for d^8 metal ions with bulky ligands.

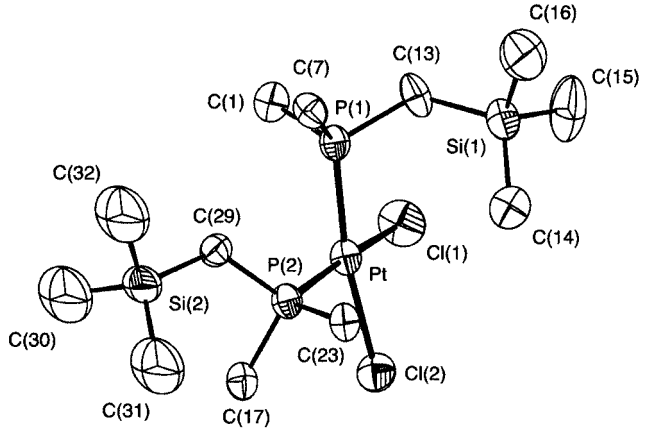


Figure 1. ORTEP drawing of the molecular structure and numbering scheme of **4**

Table 1. Selected bond lengths [Å] and angles [°] for **4**

Pt−P(1)	2.2401(9)	P(2)−C(29)	1.813(3)
Pt−P(2)	2.2545(8)	Si(1)−C(13)	1.892(4)
Pt−Cl(1)	2.3563(8)	Si(2)−C(29)	1.901(3)
Pt−Cl(2)	2.3506(9)	P(1)−C(13)	1.825(3)
P(1)−Pt−P(2)	100.90(3)	P(2)−C(29)−Si(2)	126.43(17)
P(1)−Pt−Cl(2)	169.85(3)	C(17)−P(2)−Pt	110.46(11)
P(2)−Pt−Cl(2)	87.89(3)	C(23)−P(2)−Pt	111.47(10)
P(1)−Pt−Cl(1)	84.92(3)	Cl(2)−Pt−Cl(1)	86.70(3)
P(2)−Pt−Cl(1)	172.88(3)	C(7)−P(1)−Pt	120.23(11)
C(13)−P(1)−Pt	112.61(14)	C(1)−P(1)−Pt	112.43(12)
C(29)−P(2)−Pt	118.06(10)		

The phosphane ligands adopt a *cis* configuration, in spite of the known fact that the bulky phosphane favors the formation of *trans* isomers to minimize ligand interactions. The Pt−Cl bond lengths are in the expected range, and the Pt−P distances are not elongated to any significant extent. The angles around the platinum atom are in the range 84.92(3)° [P(1)−Pt−Cl(1)] to 100.90(3)° [P(1)−Pt−P(2)]. The latter is intermediate between that found for [$PtCl_2(PPh_3)_2$] (97.8°)[9] and [$PtCl_2(PCy_3)_2$] (107.6°).[10] There is a steric tension between C(31) and the phenyl group C(17), which implies an increase in the Si(2)−C(29)−P(2) angle to 126.4°.

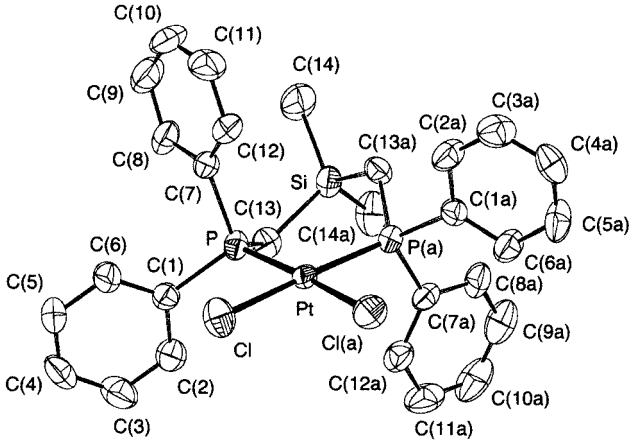

Figure 2. View of the molecular structure of **5** together with the atomic numbering scheme

The molecular structure of **5** is shown in Figure 2. Selected bond lengths and angles are listed in Table 2. Com-

Table 2. Selected bond lengths [Å] and angles [°] for **5**

Pt−P(1)	2.2456(16)	Si(1)−C(14)	1.845(7)
Pt−Cl(1)	2.3440(17)	Si(1)−C(13)	1.872(7)
P(1)−C(1)	1.822(6)	P(1)−C(13)	1.806(7)
P(1)−C(7)	1.810(6)		
P(1)−Pt−Cl(1)	88.59(7)	P(1)−Pt−Cl(1′)	175.98(6)
Cl(1)−Pt−Cl(1′)	87.40(10)	C(14′)−Si−C(13)	105.9(4)
C(14′)−Si−C(14)	109.3(6)	C(13)−Si−C(13′)	107.5(4)
C(14)−Si−C(13)	114.3(4)	C(13)−P−Pt	115.5(2)
C(7)−P−C(1)	105.4(3)	C(7)−P−Pt	113.9(2)
P−C(13)−Si	118.1(4)	C(1)−P−Pt	114.9(2)
P−Pt−P′	95.43(8)		

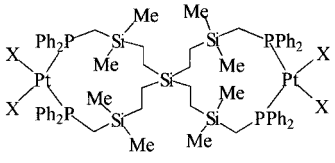
plex **5** contains a four-coordinate distorted square-planar platinum center, with the chlorine ligands displaced by −0.0052(1) Å (Cl) and 0.0052(1) Å [Cl(a)] from the Pt−P−P(a) plane. The ligand PP is bound in a bidentate fashion.

It should be noted that the ligand 2,2-dimethyl-1,3-bis(diphenylphosphanyl)-2-silapropane is an analogue of dppp, although the substitution of the CH_2 unit for $SiMe_2$ in the backbone not only increases complex solubility but also provides an excellent NMR spectroscopic handle. The Pt−P distances compare well with values reported in the compound $[PtCl_2(dppp)]$.[11] The shorter Pt−P bond lengths also suggest that a stronger bond than normal results from the chelate ring formation.

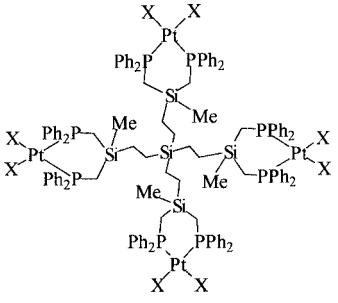
The six-membered chelate ring comprising Pt−P−C−Si−C−P adopts a twisted boat conformation, as found, for example, in $[Ni(NO_3)_2\{Ph_2PCH_2Si(CH_3)_2CH_2PPh_2\}]$.[12] It is noteworthy that the equivalent chelate ring in $[CoBr_2\{Me_2Si(CH_2PPh_2)_2\}]$[13] adopts a chair conformation, presumably due to the tetrahedral metal center. The chelate bite angle in **5** is 95.43(8)° (P1−Pt−P1′), somewhat shorter than that found for **4** and for the tetrahedral metal compounds $[CdCl_2(PP)]$,[14] $[CoCl_2(PP)]$,[13] and $[HgI_2(PP)]$[15] [PP = $Me_2Si(CH_2PPh_2)_2$].

Synthesis

Dendrimers **1** and **2** reacted with $[PtCl_2(COD)]$ in CH_2Cl_2 at room temperature to give, after COD displacement, the soluble, yellow, platinum-containing dendrimers **1a** and **2a**, respectively, within a few minutes (Scheme 3).



1a

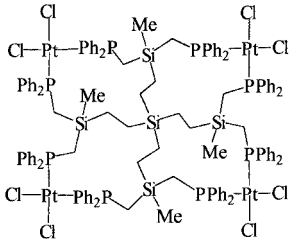


2a X= Cl
2b X= C≡CPh
2c X= $Co_2(CO)_6(C_2Ph)$

Scheme 3

The unique signal in the ^{31}P NMR spectra of their solutions clearly indicate that no mixture of compounds was formed, and reveal the complexation of platinum by the presence of platinum satellites (J_{Pt-P} = 3686 Hz for **1a** and 3558 Hz for **2a**). Two silicon signals are observed for both compounds, namely δ = 8.98 ppm (Si_0) and δ = 4.04 ppm (Si_1) ($CDCl_3$) for **1a**, and δ = 9.54 ppm (Si_0) and δ = 0.49 ppm (Si_1) ($[D_6]$DMSO) for **2a**. The ^{195}Pt NMR spectra showed a triplet at δ = −4320 ppm for **1a** and at δ = −4482 ppm for **2a** indicating the equivalence of the platinum atoms.

It is worth noting that the $PtCl_2$ units can be bound on the surface of the dendrimer through two P atoms belonging to the same branch, or alternatively, to different branches. Accordingly, **2a** can exhibit another stereoisomer, **2a′** (Scheme 4). A third possibility would be the simultaneous interaction of the platinum fragment with two molecules of dendrimer. However, in this case, the solubility of the resulting polymer species would probably be very low.



2a'

Scheme 4

As mentioned earlier, the unique resonance in the ^{31}P NMR spectrum indicates that only one isomer is formed. In order to assign it to **2a** or **2a′**, model compounds **4** and **5** are useful. Thus, for **4**, the angle P−Pt−P is 100.9° and J_{P-Pt} = 3673 Hz (δ = 4.2 ppm), while for **5**, the P−Pt−P angle is 95.43° and J_{P-Pt} = 3560 Hz (δ = 3.48 ppm). Although both values are close, we tentatively propose that the stereoisomer formed is **2a** (J_{P-Pt} = 3558 Hz; δ = 3.23 ppm), based on these data.

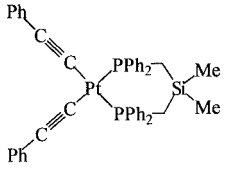
The FAB mass spectrum of **1a** contains two ion peaks at 1665.0 (calcd. 1666) and 815.0 (calcd. 815.4) corresponding to $[M - Cl]^+$ and $[M - 2\ Cl]^{2+}$, respectively. For **2a**, ion peaks at 1450, 954, and 707 were assigned to fragments $[M - 2\ Cl]^{2+}$, $[M - 3\ Cl]^{3+}$, and $[M - 4\ Cl]^{4+}$, respectively.

In contrast with the reported results for **1a** and **2a**, the ^{31}P NMR spectrum of the reaction of **3** with $[PtCl_2(COD)]$ to afford **3a**, shows, along with a sharp signal at δ = 4.4 ppm (t, J_{P-Pt} = 3683 Hz), another broad resonance at δ = 3.7 ppm (J_{P-Pt} = 3545 Hz). This spectrum indicates the presence of a mixture of stereoisomers, which was confirmed by the ^{195}Pt NMR spectrum. However, attempts to separate these isomers were unsuccessful. Electrospray spectrometry showed peaks corresponding to $[M - n\ Cl]^{n+}$ (n = 2, 3, 4, 6).

Following the same methodology for **1a**, **2a**, and **3a**, novel organometallic dendrimers containing platinum acetylide units were prepared. This class of derivatives has been actively investigated in the design of polymeric transition-metal complexes containing σ-bonded acetylide units because of their potential use in catalytic processes and as

precursors to cluster-containing dendrimers.[16] Two examples of organometallic dendrimers with a backbone composed of platinum acetylide units have been recently reported.[17]

We grafted $Pt(C{\equiv}CPh)_2$ fragments onto the surface of dendrimers **1** and **2** by treating them with $[Pt(C{\equiv}CPh)_2(COD)]$. According to the methodology followed in this paper, the model compound **6** was firstly synthesised from $Me_2Si(CH_2PPh_2)_2$ and $[Pt(C{\equiv}CPh)_2(COD)]$. (Scheme 5).



6

Scheme 5

The $^{195}Pt\{^1H\}$ NMR spectrum of **6** shows a resonance at $\delta = -3813$ ppm ($J_{P-Pt} = 2266$ Hz) and the ^1H NMR spectrum reveales the coupling of the CH_2 protons of the CH_2P fragment with the P and Pt nucleus ($J_{H-P} = 11.2$ Hz and $^3J_{H-Pt} = 32.95$ Hz). In accordance with its structure, the C_α acetylene carbon resonances appear in the $^{13}C\{^1H\}$ NMR spectrum at $\delta = 104.9$ ppm as a first-order doublet of doublets ($^2J_{C\alpha-Pcis} = 20.1$ Hz; $^2J_{C\alpha-Ptrans} = 150.2$ Hz), while the C_β signal is found at $\delta = 109.67$ ppm as the typical A part of a second-order AXX′ system [$^3J_{C\beta-Pcis} + {}^3J_{C\beta-Ptrans} = 35.5$ Hz)]. These values are very close to those reported by Forniés et al. in a series of *cis*-bis(alkynyl)platinum complexes.[18]

Crystal Structure of 6

The molecular structure of **6** was determined by X-ray structure analysis (Figure 3). Selected bond lengths and angles are collected in Table 3. Compound **6** is a nearly square-planar 16e$^-$ platinum complex formed by a diphosphane ligand and two mutually *cis*-oriented acetylide groups. The six atoms that form the chelate ring adopt a boat conformation with no appreciable twist distortion compared with that of **5**. The Pt−C and Pt−P distances are within the range of values quoted in the literature for *cis*-acetylide complexes. Bond lengths and angles in the two independent acetylide ligands are normal and the Pt−C≡C−C systems do not deviate significantly from linearity (see Table 3).[18,19]

The reaction of **2** with the platinum acetylide complex in a 1:4 molar ratio gave **2b** in a high yield. The analytical and spectroscopic (IR and ^1H, ^{13}C, ^{31}P, ^{29}Si, ^{195}Pt NMR) data are in agreement with the formula proposed for the new complex. The most remarkable feature of the IR spectrum is the presence of an absorption at 2117 cm^{-1} attributed to the $\nu_{C\equiv C}$ stretching vibration, which is considerably shifted to lower wavenumbers compared to that of the σ-alkynyl precursor. The C_α alkynyl carbon resonance in the $^{13}C\{^1H\}$ NMR spectrum appears at $\delta = 104.4$ ppm ($^2J_{C\alpha-Pcis} = 20.0$ Hz; $^2J_{C\alpha-Ptrans} = 150.3$ Hz); that of C_β appears at $\delta = 109.97$ ppm [$^3J_{C\beta-Pcis} + {}^3J_{C\beta-Ptrans} = 32.0$ Hz)]. The ^{195}Pt NMR spectrum shows a triplet with a coupling constant ($J_{Pt-P} = 2255$ Hz), very similar to that found for **6**, which, along with the NMR spectroscopic data discussed above, confirms the proposed structure for **2b**.

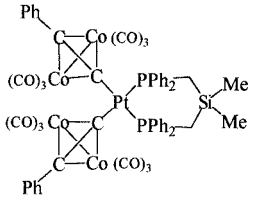
As expected, the attachment of the acetylide group increased its solubility considerably compared with that of **2a**. In contrast, the reaction of the platinum acetylide compound with **1** gave a mixture of species. These species were not analyzed because of their complexity. It seems that the bite angle P−Pt−P displayed in **1**, as compared with **2**, is higher than that required for the complexation of the $Pt(C{\equiv}CPh)_2$ fragment.

Reaction with $Co_2(CO)_8$

Alkyne systems easily react with $Co_2(CO)_8$ to afford $C_2[Co(CO)_3]_2$ tetrahedrane clusters that can be used as a part of the backbone dendritic connectivity or as peripheral groups. This is a facile method for the introduction of mul-

tiple metal clusters, but it has found little use in metallodendrimer chemistry,[20] although it is well known in the area of heterometallic stars.[21]

This strategy was thus applied to our dendrimers, in an attempt to form multiple $\{C_2Co_2(CO)_6\}$ cluster sites. A previous reaction between the model compound **6** and $Co_2(CO)_8$ gave $[Pt\{C_2PhCo_2(CO)_6\}_2\{Me_2Si(CH_2PPh_2)_2\}]$ (**7**) (Scheme 6), the spectroscopic data of which are listed in the Exp. Sect., thus permitting optimization of the reaction conditions.



7

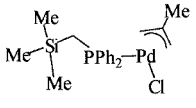
Scheme 6

Compound **2b** was treated in dichloromethane at room temperature with the octacarbonyldicobalt compound, and the new species **2c** was obtained in moderate yields after 2 h.

The incorporation of the carbonylmetal units was confirmed by the appearance of strong absorptions in the IR spectrum at 2081, 2060, and 2016 cm^{-1}, typical of $[Co_2(CO)_6(RCCR)]$ clusters. Strong evidence of cluster formation could not be inferred from the ^{13}C NMR spectrum, given the poor solubility of **2c**. A single signal at $\delta = 210$ ppm was assigned to the carbonyl carbon atoms. In the ^1H NMR spectrum the broad signal at $\delta = 1.65$ ppm is in agreement with the diastereotopic and therefore nonequivalent nature of the CH_2−P protons. This fact was observed analogously in the spectra of **2a** and **2b**. The ^{31}P NMR spectrum shows only one signal at $\delta = 12.6$ ppm flanked by platinum satellites. The $Co_2(CO)_6$ coordination caused an increase of the coupling constant J_{P-Pt} from 2254 Hz of **2b** to 3496 Hz. We are currently extending the chemical and structural aspects of these novel high-nuclearity species.

Palladium Dendrimers

Before the synthesis of the Pd-containing dendrimers, we prepared the model compound $[PdCl(\eta^3\text{-}2\text{-}MeC_3H_4)(PPh_2CH_2SiMe_3)]$ (**8**) by treating $[Pd(\mu\text{-}Cl)(\eta^3\text{-}2\text{-}MeC_3H_4)]_2$ with $PPh_2CH_2SiMe_3$ (Scheme 7).

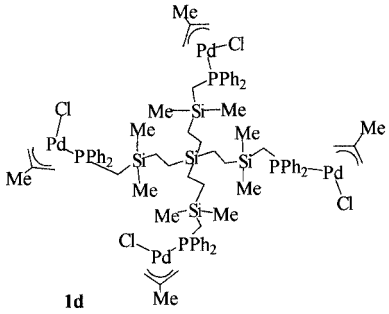


8

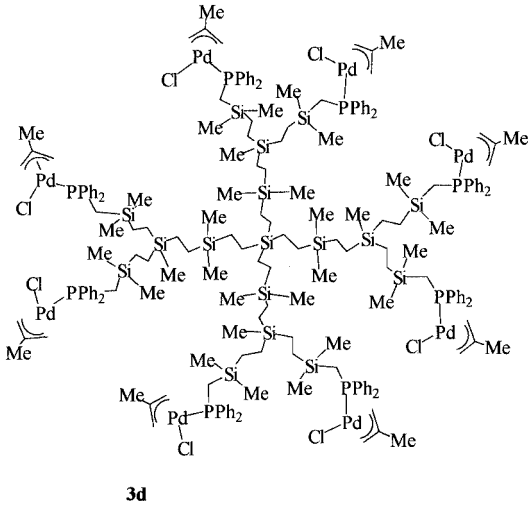
Scheme 7

The ^{31}P NMR spectrum of **8** shows only one signal at $\delta = 17.8$ ppm and the ^{29}Si NMR spectrum, another one at $\delta = 0.8$ ppm. The ^1H and ^{13}C NMR spectra evidence the presence of the allyl and the dendrimer ligands.

The grafting of the palladium fragments $Pd(\eta^3\text{-}2\text{-}MeC_3H_4)Cl$ on the surface of our dendrimers was achieved in good yields by treating **1** and **3** with the dinuclear allyl complex $[Pd(\mu\text{-}Cl)(\eta^3\text{-}2\text{-}MeC_3H_4)]_2$ in THF at room temperature (Scheme 8).



1d



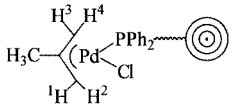
3d

Scheme 8

The synthesis of the new palladodendrimers **1d** and **3d** was monitored by ^{31}P NMR spectroscopy. In both cases, the complete disappearance of the signal at $\delta = -23$ ppm along with the emergence of a new one at $\delta \approx 17$ ppm confirmed that the reaction occurred quantitatively. The yellow compounds obtained were pure within the limits of the NMR spectroscopic detection. They were soluble in the most common organic solvents, and were characterized by elemental analyses, ^1H, ^{13}C, ^{31}P, and ^{29}Si NMR, as well as by fast atom bombardment (FAB) or electrospray mass spectrometry.

The ^1H NMR spectra for **1d** and **3d** showed the resonances for the methyl, methylene, and ethylene protons with chemical shifts in the corresponding regions of the spectrum in the expected integrated ratio. The coordination of the palladium fragment to the dendrimer gives rise to the coupling of the H^1 and H^2 with the phosphorus nucleus

($^3J_{H-P}$ = 6.5 and 10 Hz) and the high-field shifts of the H^3 and H^4 resonances (Scheme 9).

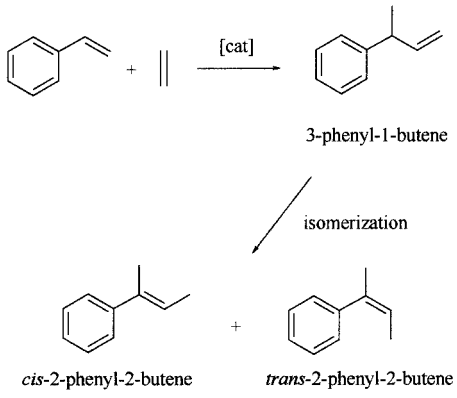


Scheme 9

The ^{13}C NMR spectra confirmed the presence of the above-mentioned groups. The ^{29}Si NMR spectra display clearly separated signals (two for **1d** and four for **3d**) for the different types of silicon atoms in the molecules. These signals can be easily assigned on the basis of the chemical shifts and the peak intensities. The presence of only one signal in the ^{31}P NMR spectra indicates that no mixture of products is formed in the reaction.A solution of sodium chloride in THF was added to the samples **1d** and **3d** in order to improve the peak resolution in mass spectrometry. Thus, FABMS showed the $[M - Cl]^+$ peak at m/z = 1923.6 for **1d** (calcd. 1920.5), and the MS/ES, the peak $[M - 3\{Pd(2\text{-}CH_3\text{-}C_3H_4)Cl\} - 3\ Cl]^{3+}$ at m/z = 1272.2 for **3d** (calcd. 1273.1) in accordance with the proposed formula. Other fragments were also assigned (see Exp. Sect.).

Catalytic Studies

One of the main applications of dendrimers is in catalysis. The well-defined structure and the possibility of attaching a large number of active sites makes them especially interesting for catalyst immobilization and catalyst recycling.[22] Recently, some palladium-containing carbosilane dendrimers have been used as catalysts in allylic alkylation reactions[8] and in the selective hydrovinylation of styrene performed in a continuous flow membrane reactor.[23] Here, the palladium dendrimers **1d** and **3d** were tested as catalysts in the hydrovinylation of styrene (Scheme 10), and their activity was compared with that of the mononuclear model complex $[PdCl(\eta^3\text{-}2\text{-}MeC_3H_4)(PPh_2CH_2SiMe_3)]$ (**8**). Interestingly, hydrovinylation of styrene produced 3-phenyl-1-butene as a main product, this process being a model reaction for the synthesis of compounds with pharmacological activity.



Scheme 10

The fact that **8**, **1d**, and **3d** have an $RCH_2Si(CH_3)_2\text{-}CH_2PPh_2$ moiety in common permits the evaluation of the steric effects caused only by changes in the dendrimeric structure.

It is well known that active catalysts in hydrovinylation reactions are cationic species, so we synthesised the cationic species of our dendrimers in situ by adding $Ag[BF_4]$ to their dichloromethane solutions and removing the silver chloride by filtration. Otherwise, the cationic complexes stabilized with CH_3CN ligands were isolated as solids and their activity compared with that exhibited by the species prepared in situ. In order to differentiate between the two types of species, we will refer to the cationic dendrimers obtained in situ as **1d**$^+$, **3d**$^+$, and **8**$^+$, and the salts stabilized with CH_3CN as **1d***, **3d***, and **8***.

The catalytic data obtained in the hydrovinylation of styrene using the described compounds are shown in Table 4.

Table 4. Hydrovinylation of styrene by palladium compounds

Entry[a]	Precursor	T [°C]	t [h]	Conversion[b]	Selectivity[c]	TOF/h[d]
1	**8**$^+$	15	2	94.2	80.3	465

[a] Initial ethylene pressure, 15 bar; solvent: CH_2Cl_2; ratio styrene/Pd 1000:1. [b] Conversion of starting styrene. [c] Selectivity:% of 3-phenyl-1-butene respect to the total amount of arylbutenes formed. [d] TOF/h calculated as the total amount of arylbutenes formed. [e] In THF.

As can be seen from Table 4, activity is lower for the cationic dendritic precursors **1d**$^+$ (or **1d***) and **3d**$^+$ (or **3d***), compared with the mononuclear precursor **8**. The same effect was observed by Vogt and van Koten in similar hemilabile PO-stabilized dendritic precursors.[24] Probably, the dendrimers block some of the space that olefins can use in their approach to the palladium atoms, the active sites. However, it is remarkable that the activity of the biggest system **3d** is higher or similar to that of **1d** (Entries 5 and 6) in spite of the fact that the first shows 8 PPh_2 groups in comparison with the 4 PPh_2 ligands displayed by the second. This interesting effect can be explained by the fact that **3d** has one methyl group over the neighboring Si while bulkier ligands are attached to the neighboring Si in **1d**. This can be seen by comparing Entries 2, 5, 6, with 7, 10, 13. Moreover, Table 4 shows that the catalysts obtained in situ in dichloromethane are better than those previously isolated, due to the ineffective coordinating ability of the

solvent. When a solvent of greater coordination ability, like THF, was used, an impressive decrease in activity was observed (Entries 10 and 11). Formation of oligomers or higher co-oligomers is not significant. In conclusion, it is clear from our data that the catalytic activity is affected by "surface congestion".

The isomerization of the chiral product 3-phenyl-1-butene to achiral (*E*) and (*Z*) internal olefins (Scheme 10) is related to the conversion of the process. Thus, at high conversions the consecutive isomerization reaction becomes important and consequently an increase of the internal olefins is obtained (Table 4). It is well known that the isomerization occurs through the previous coordination of the 3-phenyl-1-butene to the catalyst. Thus, the coordination ability of other molecules present in the reaction media determines the selectivity. Obviously, in our case, the solvent can compete with the 3-phenyl-1-butene. For example, Entries 1−3 and 8 indicate that the presence of stoichiometric amounts of acetonitrile competes successfully with 3-phenyl-1-butene and avoids its attachment to the catalyst, thus improving the selectivity of the process. In conclusion, in order to improve the selectivity of the process, a major goal would be to find a ligand or a hemilabile bidentate ligand with a coordinating ability towards the metallic system intermediate between styrene and 3-phenyl-1-butene.

From Table 4 we can observe in all cases a decrease of the activity in increasing the reaction times, as a consequence of the deactivation of the catalytic species. This effect is more important for the dendrimers. The deactivation of the catalyst is clearly observed when runs at different reaction times are compared − Entries 4 and 5 or 12 and 13. This is evidenced by a decrease in the TOF number upon increasing the reaction time, in the significant range of conversions. The model compound **8** showed higher stability, but shorter reaction times − Entries 2 and 3. Our preliminary results showed similar loss of activity of **1d** and **3d** precursors. Interestingly, no precipitation of palladium black was observed before total conversion. In order to obtain more conclusive results about the relative stability of these dendritic systems as a function of their size we would need to test the activity of catalyst based on higher generations.

In summary, the dendrimers studied in this paper are active for the hydrovinylation of styrene, but their activity is lower than that shown by the mononuclear model **8** and other related palladium complexes containing different phosphane ligands.[25] However, polynuclear complexes **1d** and **3d** are more active compared with other dendritic catalysts containing 8 and 12 terminal bidentate PO coordinating atoms on the surface.[24] Moreover, the good selectivity of our dendrimers towards 3-phenyl-1-butene is remarkable.

Experimental Section

General: All reactions were carried out under dry nitrogen using standard Schlenk techniques. Solvents were distilled from sodium/benzophenone ketyl (THF and Et_2O), $CaCl_2$ and stored over molecular sieves (acetone) or dried with $CaCl_2$ and distilled from CaH_2 (CH_2Cl_2) under N_2 prior to use. Elemental analyses (C, H) were performed at the Servicio de Microanálisis del Centro de Investigación y Desarrollo del Consejo Superior de Investigaciones Científicas (CSIC). ^1H, $^{13}C\{^1H\}$, $^{29}Si\{^1H\}$, $^{31}P\{^1H\}$, and $^{195}Pt\{^1H\}$ NMR spectra were recorded at 25 °C with a Bruker 250 spectrometer. Chemical shifts are reported in ppm relative to external standards ($SiMe_4$ for ^1H, ^{13}C and ^{29}Si, 85% H_3PO_4 for ^{31}P and H_2PtCl_6 for ^{195}Pt) and coupling constants are given in Hz. Infrared spectra were recorded with FT-IR 520 Nicolet or Impact 400 Nicolet spectrometers in the 4000−400 cm^{-1} range as KBr pellets. MS (FAB and ES) spectra were recorded with a Fisons VGQuattro spectrometer using NBA (3-nitrobenzyl alcohol) as a matrix for FAB spectra. MALDI-TOF spectra were recorded with a Voyager DE-RP (Perspective Biosystems) spectrometer using DHB (2,5-dihydrobenzoic acid) as a matrix. The starting materials $Me_2Si(CH_2PPh_2)_2$,[26] $[Pd(\mu\text{-}Cl)(\eta^3\text{-}2\text{-}Me\text{-}C_3H_4)]_2$,[27] $[PtCl_2(COD)]$,[28] and $[Pt(C{\equiv}CPh)_2(COD)]$[29] were prepared according to published procedures. Other reagents were purchased from commercial suppliers and used as received.

Synthesis of Diphenyl[(trimethylsilyl)methyl]phosphane ($PPh_2CH_2SiMe_3$): This phosphane, described in the literature,[30] was synthesised by a different method here. To a suspension of the Grignard reagent (slight excess) of (chloromethyl)trimethylsilane, prepared from 1.77 g (14.4 mmol) of (chloromethyl)trimethylsilane and 0.45 g (18.5 mmol) of magnesium in THF (50 mL), was slowly added chlorodiphenylphosphane (2.95 g, 13.4 mmol); the resulting mixture was stirred at room temperature for 30 min and hydrolysed with an aqueous solution of NH_4Cl (10%). The organic layer was washed twice with water and dried with Na_2SO_4. Concentration of this solution to dryness gave the desired phosphane as a colorless oil (2.92 g, yield 80%). ^1H NMR (250 MHz, $CDCl_3$, 25 °C): δ = −0.25 (s, 9 H, CH_3), 1.34 (s, 2 H, CH_2), 7.28−7.34 (m, 6 H, C_6H_5), 7.45−7.50 (m, 4 H, C_6H_5) ppm. ^{31}P NMR (101.26 MHz, $CDCl_3$, 25 °C): δ = −22.05 (s) ppm. ^{29}Si NMR (49.66 MHz, $CDCl_3$, 25 °C): δ = 1.26 (d, J = 14.7 Hz) ppm. ^{13}C NMR (75.4 MHz, $CDCl_3$, 25 °C): δ = −0.2 (d, J = 4.7 Hz, CH_3), 14.6 (d, J = 29.0 Hz, CH_2), 128.1−141.2 (m, C_6H_5) ppm.

Synthesis of $[PtCl_2(Me_3SiCH_2PPh_2)_2]$ (4): $[PtCl_2(COD)]$ (0.08 g, 0.21 mmol) was dissolved in CH_2Cl_2 (10 mL) and a solution of $PPh_2CH_2Si(Me_2)CH_2PPh_2$ (0.12 g, 0.43 mmol) in CH_2Cl_2 (10 mL) was added. The solution was stirred overnight and then concentrated to dryness. The solid was recrystallized from CH_2Cl_2/Et_2O and dried under vacuum. Yield: 172 mg, 50%. ^1H NMR (250 MHz, $CDCl_3$, 25 °C): δ = −0.18 (s, 18 H, CH_3), 1.72 (d, $^2J_{H-P}$ = 15.7, $^3J_{H-Pt}$ = 32 Hz, 4 H, CH_2P), 7.24−7.57 (m, 20 H, C_6H_5) ppm. $^{13}C\{^1H\}$ NMR (62.86 MHz, $CDCl_3$, 25 °C): δ = 0.9 (s, CH_3), 18.3 (m, CH_2P), 128.1−133.2 (m, C_6H_5) ppm. $^{29}Si\{^1H\}$ NMR (49.66 Hz, $CDCl_3$, 25 °C): δ = 0.11 ppm. $^{31}P\{^1H\}$ NMR (101.26 MHz, $CDCl_3$, 25 °C): δ = 4.2 (s, $^1J_{P-Pt}$ = 3673.2 Hz) ppm. $^{195}Pt\{^1H\}$ NMR (53.54 MHz, $CDCl_3$, 25 °C): δ = −4318.0 (t) ppm. $ESMS^+$ (CH_2Cl_2): m/z = 775.7 $[M - Cl]^+$. $MSFAB^+$ (THF): m/z = 810.2 $[M]^+$, 775.3 $[M - Cl]^+$. $C_{32}H_{42}Cl_2P_2PtSi_2$ (810.80): calcd. C 47.36, H 5.22; found C 48.26, H 5.43.

Synthesis of $[PtCl_2\{Me_2Si(CH_2PPh_2)_2\}]$ (5): Experimental conditions and workup were identical to those for the preparation of **4**. Yield: 218 mg, 90%. ^1H NMR (250 MHz, CD_2Cl_2, 25 °C): δ = −0.34 (s, 6 H, CH_3), 1.77 (d, 4 H, $^2J_{P-H}$ = 12.3, $^3J_{H-Pt}$ = 62.3 Hz, CH_2P), 7.4−7.8 (m, 20 H, C_6H_5) ppm. $^{13}C\{^1H\}$ NMR (62.86 MHz, CD_2Cl_2, 25 °C): δ = −0.1 (t, $^3J_{C-P}$ = 3.4 Hz, CH_3), 12.2 (m, CH_2P), 128.2−133.5 (m, C_6H_5) ppm. $^{29}Si\{^1H\}$ NMR (49.66 MHz, CD_2Cl_2, 25 °C): δ = −0.96 ppm. $^{31}P\{^1H\}$ NMR (101.26 MHz, CD_2Cl_2, 25 °C): δ = 3.5 (s, $^1J_{P-Pt}$ = 3559.8 Hz,

PPh_2) ppm. $^{195}Pt\{^1H\}$ NMR (53.54 MHz, CD_2Cl_2, 25 °C): δ = −4491.7 (t) ppm. MSFAB$^+$ (CH_2Cl_2): *m/z* = 687.2 [M − Cl]$^+$. $C_{28}H_{30}Cl_2P_2PtSi$ (722.58): calcd. C 46.54, H 4.19; found C 45.60, H 4.23.

Synthesis of 1a: Experimental conditions and workup were identical to those for the preparation of **4**. Yield: 145 mg, 71%. ^1H NMR (250 MHz, $CDCl_3$, 25 °C): δ = −0.06 (br. s, 24 H, CH_3), 0.75−1.44 (br. s, 16 H, CH_2), 1.92 (d, $^2J_{H-P}$ = 15.8 Hz, 8 H, CH_2P), 7.00−7.70 (m, 40 H, C_6H_5) ppm. $^{13}C\{^1H\}$ NMR (62.86 MHz, $CDCl_3$, 25 °C): δ = −0.6 (s, C^1H_3), 4.7 (s, $-CH_2-$), 10.3 (s, $-CH_2-$), 16.2 (m, CH_2P), 127.7−132.4, (m, C_6H_5) ppm. $^{29}Si\{^1H\}$ NMR (49.66 MHz, $CDCl_3$, 25 °C): δ = 4.04 (s, Si_1), 8.98 (s, Si_0) ppm. $^{31}P\{^1H\}$ NMR (101.26 MHz, $CDCl_3$, 25 °C): δ = 4.4 (s, $^1J_{P-Pt}$ = 3686.4 Hz, PPh_2) ppm. $^{195}Pt\{^1H\}$ NMR (53.54 MHz, $CDCl_3$, 25 °C): δ = −4322.0 (t) ppm. ESMS$^+$ (THF): *m/z* = 1665.0 [M − Cl]$^+$, 815.0 [M − 2 Cl]$^{2+}$. $C_{68}H_{88}Cl_4P_4Pt_2Si_5$ (1701.77): calcd. C 47.99, H 5.21; found C 47.70, H 5.27.

Synthesis of 2a: Experimental conditions and workup were identical to those for the preparation of **4** Yield: 170 mg, 50%. ^1H NMR (250 MHz, [D$_6$]DMSO, 25 °C): δ = −(0.64−0.52) (s, 12 H + 16 H, $-CH_3$; $-CH_2-$), 1.66−1.93 (m, 16 H, CH_2P); 7.30−7.76 (m, 40 H, C_6H_5) ppm. $^{13}C\{^1H\}$ NMR (62.86 MHz, [D$_6$]DMSO, 25 °C): δ = −2.8 (s, CH_3-), 0.6 (s, $-CH_2-$), 7.6 (s, $-CH_2-$), 10.2 (m, CH_2P), 128.3−133.8 (m, C_6H_5) ppm. $^{29}Si\{^1H\}$ NMR (49.66 MHz, [D$_6$]DMSO, 25 °C): δ = 0.49 (s, Si_1), 9.54 (s, Si_0) ppm. $^{31}P\{^1H\}$ NMR (101.26 MHz, [D$_6$]DMSO, 25 °C): δ = 4.1 (s, $^1J_{P-Pt}$ = 3558.4 Hz, PPh_2) ppm. $^{195}Pt\{^1H\}$ NMR (53.54 Hz, [D$_6$]DMSO, 25 °C): δ = −4482.0 (s). to ± 0.5 °C. The internal temperature was monitored by means of a thermocouple. Internal temperature and pressure as a function of time were registered with a Linseis L-200 Recorder. Gas chromatography was run using an HP 5890 series two chromatograph.

Hydrovinylation Reactions

a) 1d$^+$, 3d$^+$, and 8$^+$ as Catalysts: A mixture of 4.0×10^{-5} mol of the neutral palladium complex, **1d**, **3d**, or **8**, $AgBF_4$ (in a 1:4, 1:8, and 1:1 molar ratio, respectively) and styrene (0.04 mol) in 10 mL of freshly distilled CH_2Cl_2 was stirred for 5 min in the dark under nitrogen. After filtering off the AgCl formed, the solution was placed in a thermostatically controlled autoclave, which had previously been purged with successive applications of vacuum and argon. The autoclave was then pressurized with ethylene to 15 bar. After the desired time, the autoclave was slowly depressurized and 10% HCl (10 mL) was added. The mixture was stirred for 10 min in order to quench the catalyst. The CH_2Cl_2 layer was decanted and dried with Na_2SO_4. The quantitative distribution of products fractions was determined by GC analysis.

b) 1d*, 3d*, and 8* as Catalysts: A solution of 4.0×10^{-5} mol of the cationic palladium complexes, **1***, **3***, or **8***, and styrene (0.0400 mol) in freshly distilled CH_2Cl_2 (10 mL) was prepared under an inert gas. The solution was transferred via syringe under argon into the autoclave, which had previously been purged with successive applications of vacuum and argon. Ethylene was admitted until the initial pressure of 15 bar was reached. The workup procedure was as already described.

X-ray Structure Determination of 4, 5 and 6: Block crystals of compounds **4** and **5** were selected and mounted on a MAR345 diffractometer with image plate detector. A crystal of **6** was mounted on an Enraf−Nonius CAD4 four-circle diffractometer. Crystallographic and experimental details of both compounds are summarized in Table 5. Data were collected at room temperature. Intensities were corrected for Lorentz and polarization effects in the usual manner. The structures were solved by Direct Methods, using SHELXS computer program and refined by full-matrix least-squares methods with SHELX97 computer program.[31] The function minimized was $\Sigma w||F_o|^2 - |F_c|^2|^2$, where $w = [\sigma^2(I) + (0.0774 P)^2]^{-1}$, and $P = (|F_o|^2 + 2|F_c|^2)/3$; f, f' and f'' were taken from International Tables of X-ray Crystallography .[32] All H atoms were computed and refined with an overall isotropic temperature factor equal to 1.2 times the equivalent isotropic temperature factor of the atoms, which were linked using a riding model. The supplementary crystallographic data for this paper can be found in publications CCDC-181768 (**4**), -181770 (**5**), and -181769 (**6**.) These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

A One-Dimensional Manganese(II) Coordination Polymer Derived from Zerovalent Manganese and 1-Hydroxybenzotriazole − Synthesis, Characterization, Crystal Structure and Magnetic Properties

Giannis S. Papaefstathiou,[a] Ramon Vicente,[b] Catherine P. Raptopoulou,[c] Aris Terzis,[c] Albert Escuer,*[b] and Spyros P. Perlepes*[a]

Keywords: Coordination polymers / Nitrogen heterocycles / Magnetic properties / Manganese / X-ray crystal structure

The reaction of zerovalent manganese with 1-hydroxybenzotriazole, btaOH, and NH_4SCN in DMF in the presence of dioxygen allows isolation of the one-dimensional coordination polymer $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**). X-ray diffraction analysis reveals that the chain is best described as $[Mn_2(btaO)_2(NCS)_2(DMF)_6]$ dimers linked by $Mn(NCS)_2(DMF)_2$ bridges. Molar magnetic susceptibility measurements of **3** in the 5–300 K range indicate weak antiferromagnetic coupling between the Mn^{II} atoms within the dinuclear subunits of the chain.

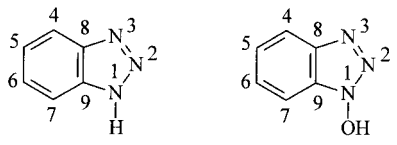
Introduction

Over the last twenty years, we[1] and others[2] have been exploring the coordination chemistry of benzotriazole (btaH, Scheme 1) and its derivatives. The first reason for this is the anticorrosion properties of btaH and benzene ring-substituted benzotriazoles toward certain metals, particularly copper and its alloys.[3] The second reason is the observation that reactions between metal β-diketonates or carboxylates and btaH or its ring-substituted (with non-donor groups) derivatives lead to incomplete replacement of β-diketonato or carboxylato ligands by the deprotonated benzotriazoles and the formation of large heteroleptic 3d-metal cages with unique structural motifs and exciting magnetic properties.[1a,2b,2c] Thus, benzotriazolato ligands are amongst the most important in the field of high-nuclearity transition metal chemistry.



btaH btaOH

Scheme 1

More recently,[4,5] our efforts have turned towards the use of benzotriazoles, substituted on the azole ring with donor groups, to see how incorporation of this ligand type might affect the structures and physical properties of the products. The first ligand employed was 1-hydroxybenzotriazole (btaOH, Scheme 1). The synthetic investigation of the $[Cu_2(O_2CMe)_4(H_2O)_2]$/btaOH reaction system in MeOH resulted in the isolation of the three-dimensional (3D), diamond-like polymeric complex $[Cu(btaO)_2(MeOH)]_n$ (**1**), which is a soft magnet exhibiting two critical temperatures at 6.4 and 4.4 K.[4] Reaction of $[Ni(NO_3)_2]\cdot 6H_2O$ with btaOH in DMF/aqueous NH_3 has recently yielded the trinuclear complex $[Ni_3(btaO)_6(NH_3)_6]$ (**2**).[5]

In the present work, reactions of btaOH with zero-valent manganese were investigated. Zero-valent transition metals as starting materials are a good source for the construction of unusual polymeric and/or discrete metal complexes, which exhibit interesting magnetic properties and cannot be synthesised starting from conventional metal salts.[6] The subject of the present paper is the 1D coordination polymer $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**) which is the product of the reaction between Mn^0, btaOH and NH_4SCN in DMF under aerobic conditions.

Transition metal coordination polymers are of considerable interest as magnetic, electronic and photooptical materials.[7] Compounds with fascinating topologies and intricate interweaving of multiple networks have been discovered. Restricting further discussion to magnetic coordination polymers, we should mention that these molecular compounds may contain the same metal ion, two kinds of spin carriers (either two different metal ions or a metal ion and an organic radical) and, in a very limited number of cases,

[a] Department of Chemistry, University of Patras, 265 00 Patras, Greece
[b] Departament de Química Inorgànica, Universitat de Barcelona, Diagonal 647, 08028 Barcelona, Spain

three spin carriers. The attainment of magnetic ordering generally requires[8] the organisation of transition metal centres into 3D networks. However, to better interpret magnetic properties of 3D coordination polymers, reduced dimensionalities (i.e. 1D and 2D) are preferred to develop the necessary theoretical models.[9,10] In this context, 1D magnetic systems are being thoroughly investigated from both experimental and theoretical viewpoints.[11]

Results and Discussion

Synthesis

The preparation of complex **3** can be achieved by the reaction of zero-valent manganese with btaOH and NH_4SCN in DMF under reflux in air for 2 h. This preparation is summarised in Equation (1).

$$3n\text{Mn} + 2n\text{btaOH} + 4n\text{NH}_4\text{SCN} + 8n\text{DMF} + 3/2n\text{O}_2 \xrightarrow[\text{reflux}]{\text{DMF}} [\text{Mn}_3(\text{btaO})_2(\text{NCS})_4(\text{DMF})_8]_n + 4n\text{NH}_3 + 3n\text{H}_2\text{O} \quad (1)$$

3

In this reaction dioxygen is reduced to give H_2O and Mn is oxidized to Mn^{II}. The same product can be isolated from the 2:1:1, 1:1:1, 1:2:2, 1:2:3, 1:3:4, 1:4:4, 1:3:5, 1:4:5 and 1:5:5 Mn/btaOH/NH_4SCN reaction systems in DMF. When btaOH and/or SCN^- are in excess the reaction proceeds faster (in less than 2 h) giving the same product in almost the same yield, while, when the quantities of btaOH and/or SCN^- are less than the stoichiometric ones, the reaction proceeds more slowly and we do not observe complete dissolution of the Mn powder.

IR Spectra

The IR spectrum of **3** exhibits the ν(CN), ν(CS) and δ(NCS) modes at 2078, 787 and 478 cm^{-1}, respectively; these frequencies are typical of terminal isothiocyanato groups.[12] The presence of coordinated DMF in **3** is manifested by a strong band at 1650 cm^{-1} and a medium intensity band at 1496 cm^{-1}, assigned to ν(C=O) and ν(C−N), respectively.[13] The spectra of the sodium and potassium salts of 1-hydroxybenzotriazole (btaONa, btaOK) exhibit bands at 1178 and 1102 cm^{-1}, associated with the ν(N=N) and ν(N−N) vibrational modes, respectively.[4] These bands are shifted to 1213 and 1128 cm^{-1}, respectively, in the spectrum of the complex; these shifts to higher frequencies are compatible with N(3) (Scheme 1) being the N-donor atom of $btaO^-$.[1b] The band assignable to the N−O stretching vibration appears at 1224 cm^{-1} in the IR spectrum of btaOK.[5] This band is shifted to 1155 cm^{-1} in the spectrum of **3** due to the coordination of the oxygen atom to the metal.[4]

X-ray Crystal Structure

A labelled ORTEP[14] drawing of the structure is shown in Figure 1. Selected distances and angles are listed in Table 1. The asymmetric unit of the one-dimensional (1D) polymer consists of three independent Mn^{II} atoms, Mn(2), Mn(1) and Mn(3). If we name the Mn(2), Mn(1) and Mn(3) ions as A, B and C, respectively, then a satisfactory way to describe this structure is to consider it as a chain of the alternating dimers CC and AA, which are connected via the Mn(1) ion (B) (Figure 2). Each dinuclear subunit (AA or CC) consists of two Mn^{II} atoms which are bridged by two μ_2-O atoms of two symmetry-related $btaO^-$ ligands, forming a planar four-membered ring (Mn_2O_2), in the centre

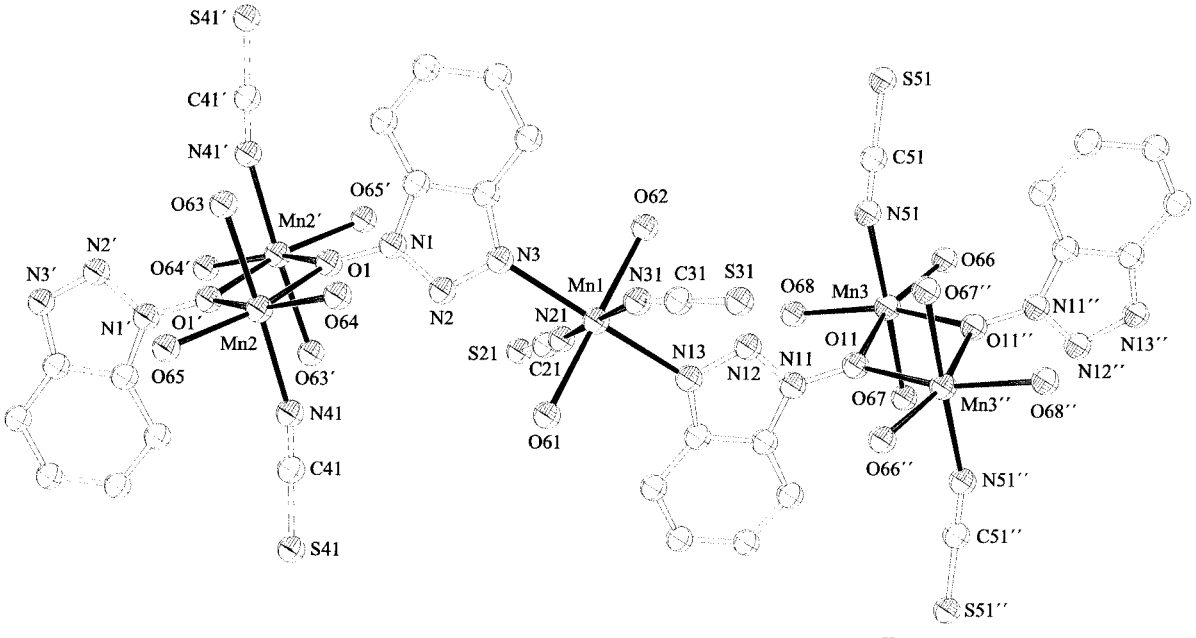

Figure 1. ORTEP plot of $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**) at the 30% probability level; five Mn^{II} atoms are shown; all the carbon and nitrogen atoms of the DMF molecules, as well as all H atoms, have been omitted for clarity; the symbols ′ and ′′ denote atoms related by symmetry (see Table 1)

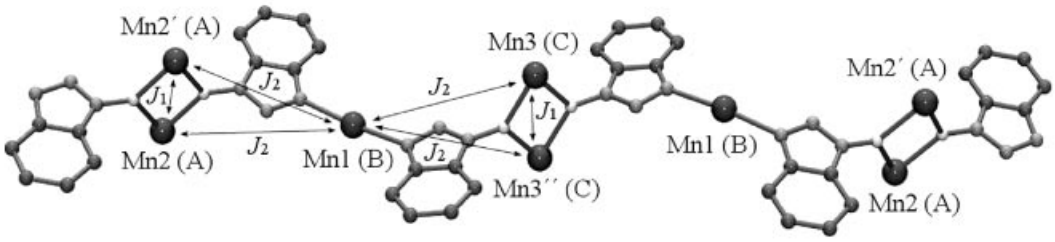

Figure 2. Ball and stick drawing of $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**), where the ...AA-B-CC-B-AA... view of the chain is emphasized; only the Mn^{II} atoms and the bridging $btaO^-$ ligands have been drawn; the magnetic exchange pathways between the metal ions are also shown

Table 1. Selected bond lengths (Å) and angles (°) for $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**); symmetry transformations used to generate equivalent atoms: (′): $-x+2, -y, -z+1$; (′′): $-x+1, -y+1, -z$

of which there is an inversion centre. The Mn···Mn distances are 3.588(1) and 3.570(1) Å for the AA [Mn(2)···Mn(2′)] and CC [Mn(3)···Mn(3′′)] subunits, respectively. The octahedral coordination at each Mn^{II} atom, which is part of a dinuclear subunit, is completed by three oxygen atoms of three DMF molecules at *fac* positions and one nitrogen atom of a linear, terminal SCN^- anion. Thus, the empirical formula of each dinuclear subunit is $Mn_2(btaO)_2(NCS)_2(DMF)_6$. The two dinuclear subunits AA and CC are connected via a mononuclear subunit containing the Mn(1) (B) ion, through the nitrogen atom at the 3-position of the 1-hydroxybenzotriazolato(−1) ligands. The octahedral coordination at Mn(1) is completed by the oxygen atoms [O(61), O(62)] of two *trans* DMF molecules and the nitrogen atoms [N(21), N(31)] of two *trans* isothiocyanato ligands. The Mn···Mn distances between the isolated Mn(1) ion (B) and the Mn^{II} atoms of the dinuclear subunits (AA and CC) are 6.687(1) and 6.875(1) Å for the Mn(1)···Mn(2) and Mn(1)···Mn(2′) pairs, and 6.601(1) and 6.965(1) Å for the Mn(1)···Mn(3) and Mn(1)···Mn(3′′) pairs, respectively.

The $Mn-N_{isothiocyanato}$ bond lengths are in the range 2.155(6)−2.218(6) Å; this range is typical for octahedral manganese(II) complexes containing terminal isothiocyanato ligands.[15a] The SCN^- ions are not perfectly linear, the N−C−S bond angles being in the range 176.5(7)−179.0(6)°. The terminal isothiocyanate anions involving N(31), N(41) and N(51) as donor atoms are coordinated in a slightly bent fashion, as indicated by the Mn−N≡C angles [157.7(5)−164.6(5)°]; the fourth SCN^- ion is coordinated in an almost linear fashion [Mn(1)−N(21)−C(21) = 176.8(6)°]. The average $Mn(1,2,3)-O_{DMF}$ bond length is 2.194(5) Å, as in other high-spin octahedral manganese(II) complexes with O-donors.[15b] The Mn(2)−O(1)−Mn(2′) and Mn(3)−O(11)−Mn(3′′) angles are 109.6(1) and 109.3(1)°, respectively. The angles around the Mn^{II} atoms show that the $Mn(1)N_4O_2$, $Mn(2)NO_5$ and $Mn(3)NO_5$ coordination octahedra are distorted, with the Mn(1) polyhedron being less distorted.

Complex **3** joins a small family of structurally characterised, neutral, 1D coordination polymers containing six-coordinate Mn^{II} sites; representative examples have been described previously.[16−18] This compound also extends to three the number of structurally characterised coordination complexes of any metal with $btaO^-$ ion as ligand; the other two examples are complexes **1** and **2**.

Magnetic Properties

Complex **3** shows a $\chi_M T$ value of 12.98 $cm^3 \cdot K \cdot mol^{-1}$ at room temperature for each Mn_3 unit, which is slightly lower than the expected value for three isolated Mn^{II} centres.

Upon cooling, $\chi_M T$ decreases continuously down to 6.07 $cm^3 \cdot K \cdot mol^{-1}$ at 5 K, indicating an overall antiferromagnetic coupling. The molar susceptibility χ_M increases continuously upon decreasing the temperature. The EPR spectrum at room temperature (Figure 3) consists of an isotropic signal (ΔH_{pp} = 210 G) centred at g = 2.01, and one weak half-field signal centred at g = 3.97 (ΔH_{pp} = 180 G), which arises from the dipolar interaction in the Mn_2O_2 rings, in which the average Mn···Mn distance is only 3.579(1) Å.

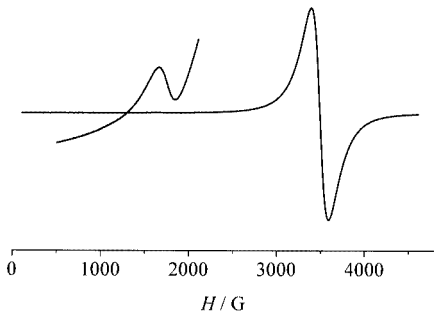

Figure 3. Room-temperature X-band EPR spectrum of a powdered sample of complex $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**), showing an isotropic signal centred at g = 2.01 and a weak half-field signal centred at g = 3.97

From the structural data we can assume that the magnetic interactions between the isolated Mn(1) ion (B) and the four surrounding Mn(2) (A), Mn(2′) (A), Mn(3) (C) and Mn(3′′) (C) ions are the same, and that the magnetic interactions within the Mn(2), Mn(2′) [AA] and Mn(3), Mn(3′′) [CC] dinuclear subunits are also equal because the Mn−O−Mn bond angles differ by only 0.3°. Thus we can describe the chain as an alternating system with a J_1-$(J_2)_2$-$(J_2)_2$-J_1 interaction sequence, where J_1 describes the magnetic interaction between the Mn^{II} atoms within each dinuclear subunit and J_2 describes the magnetic interaction between the central Mn(1) ion and each one of the Mn^{II} atoms of the neighbouring dinuclear subunits (Figure 2).

Analytical expressions to calculate the interaction parameters for systems of this kind are not available, but a simplified analysis of this system can be done assuming that the value of the J_2 coupling parameter is close to zero. This assumption is fully justified on the basis of the large distances (6.601−6.965 Å) between Mn(1) and Mn(2,2′,3,3′′) ions bridged by a four-atom ligand, and the reported magnetic properties of complex **1**,[20] which shows a very weak coupling for a similar bridge. Additionally, in **3**, the quasi-orthogonal arrangement of the Mn_2O_2 plane with respect to the $btaO^-$ plane reduces the possibility of any coupling between the isolated Mn(1) atom and each of the Mn^{II} atoms of the dinuclear subunits. Assuming that J_2 = 0, compound **3**, which is a one-dimensional system from the structural viewpoint, may be adequately described from the magnetic viewpoint as an ordered sequence of dinuclear units and isolated Mn^{II} paramagnetic centres.

The molar susceptibility for this system can be treated as the sum of two contributions: a contribution from one dimeric entity for which the Hamiltonian $H = -J_1 S_1 \cdot S_2$ can be applied,[19] and a second Curie-law contribution corresponding to one isolated isotropic Mn^{II} atom. The analytical expression used to fit the experimental data was therefore the conventional equation for a pair of interacting S = 5/2 centres plus a constant S = 5/2 Curie contribution with g = 2.00. The best-fit parameters for the dimeric unit were J_1 = −2.45(4) cm^{-1} and g = 2.024(4), with $R = 2.2 \times 10^{-4}$ [agreement factor $R = \Sigma(\chi_M^{calc} - \chi_M^{obs})^2/(\chi_M^{obs})^2$]. The fit is in very good agreement with the experimental data, confirming the validity of the J_2 = 0 approach. Figure 4 shows the best-fit plot, together with the isolated contributions of the single Mn(1) atoms (a typical exponential Curie−Weiss plot) and the dimeric Mn(2), Mn(2′) and Mn(3), Mn(3′′) subunits, for which the plot exhibits a susceptibility maximum at 10 K. It has recently been pointed out that a weak antiferromagnetic coupling should be expected between O-bridged Mn^{II} atoms when the Mn−O−Mn bond angles are large.[20] The low J value in **3** is in good agreement with the low J values (−1 to −5 cm^{-1}) found for other RO^- bridges between Mn^{II} atoms with Mn−O−Mn bond angles larger than 105°.[21]

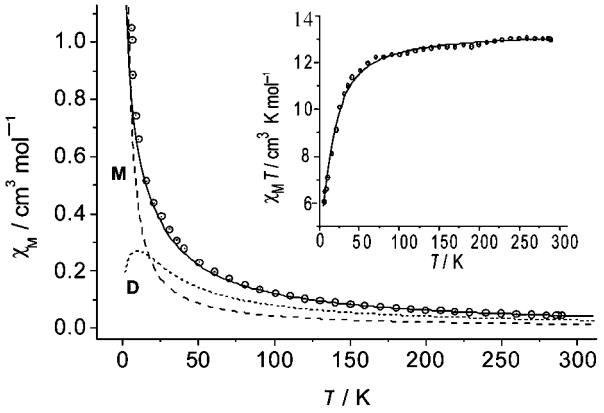

Figure 4. Susceptibility plot versus temperature for $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (**3**); dot-centred circles correspond to the experimental data and the solid line is the best fit, the solid line can be considered the addition of a antiferromagnetically coupled dinuclear subunit (plot D) and one isolated Mn^{II} atom (plot M); inset: the $\chi_M T$ versus T plot is presented showing the best overall fit

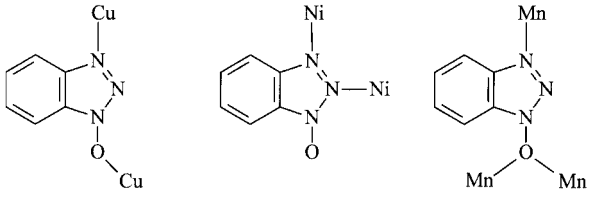
Conclusions

The initial use of btaOH in manganese chemistry has provided access to an 1D manganese(II) complex with interesting structural and magnetic characteristics. The use of zero-valent Mn has also fulfilled its promise as a source of unusual products. Compound **3** is the third structurally characterised coordination complex of any metal containing $btaO^-$ ions as ligands, the other two complexes being **1** and **2**. The ligand adopts completely different coordination modes in the three complexes (Scheme 2). Al-



Scheme 2

though the outcome of the reaction system described by Equation (1) was unpredictable, the btaO$^-$ ion in **3** exhibits a novel μ_3-coordination mode binding through N(3) to an Mn^{II} atom and bridging two other Mn^{II} atoms through the deprotonated oxygen. The 1-hydroxybenzotriazolate ligand is also present[22] in the organometallic compounds $[Os_3(\mu\text{-}H)(CO)_{10}(btaO)]$, $[Os_3(CO)_{10}(btaO)(C{=}NHnPr)]$ and $[Os_3(CO)_{10}(btaO)(C{=}NHCH_2Ph)]$, where it adopts the μ_2-coordination mode observed in the Ni^{II} complex **2**. The flexibility of btaO$^-$ observed in the structures of **1**, **2**, **3** and some new complexes (recently isolated by us) makes this ion a versatile new ligand for a variety of objectives, including variable denticity levels, high-nuclearity cluster formation, linking of clusters into 1D, 2D and 3D polymeric arrays, 3d-4f mixed-metal chemistry and ferromagnetic exchange interactions.

As far as the magnetic properties of **3** are concerned, the system can be described as a summation of antiferromagnetically coupled dinuclear subunits and isolated mononuclear subunits.

Experimental Section

Physical Methods: Elemental analyses (C, H N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer. Magnetic susceptibility measurements were carried out on a polycrystalline sample of **3** with a DSM8 pendulum-type susceptometer working in the range 5−300 K at magnetic fields of approximately 1 T. Diamagnetic corrections were estimated from Pascal tables. EPR spectra were recorded on a Bruker ES200 spectrometer at X-band frequency. Infrared spectra (4400−450 cm^{-1}) were recorded from KBr pellets on a Perkin−Elmer PC 16 FTIR spectrometer.

Preparation of $[Mn_3(btaO)_2(NCS)_4(DMF)_8]_n$ (3): Solid btaOH (0.08 g, 0.6 mmol) and NH_4SCN (0.09 g, 1.2 mmol) were dissolved with stirring in DMF (25 cm^3). Manganese powder (0.05 g, 0.9 mmol) was then added and the mixture was refluxed for approximately 2 h until all the powder had disappeared and the solution had turned yellow. The yellow solution was cooled and layered with Et_2O (50 cm^3). Yellow, X-ray quality crystals of the product formed over a period of three weeks. The needles were collected by filtration, washed with Et_2O and dried in air. Yield 0.28 g, 74%. $C_{40}H_{64}Mn_3N_{18}O_{10}S_4$ (1250.2): calcd. C 38.43, H 5.16, N 20.16; found C 38.40, H 5.10, N 20.18.

Crystal Structure Determination and Refinement of the Structure: A crystal of **3** with approximate dimensions of 0.10 × 0.10 × 0.50 mm was mounted in a capillary filled with drops of mother liquor. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo-K_α radiation. Complete crystal data and parameters for data collection and refinement are listed in Table 2. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a θ-2θ scan with a scan speed of 2°·min^{-1} and a scan range of 2° plus $\alpha_1\alpha_2$ separation. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz polarisation corrections were applied using the Crystal Logic software package.

Residuals [e Å^{-3}]	0.909/−0.606

[a] $R1 = \Sigma||F_0| - |F_c||/\Sigma|F_0|$. [b] $wR2 = \{\Sigma[w(F_0^2 - F_c^2)^2]/\Sigma[w(F_0^2)^2]\}^{1/2}$.

The structure was solved by direct methods using SHELXS-86[23a] and refined by full-matrix least-squares techniques on F^2 with SHELXL-93.[23b] All hydrogen atoms [except those on C(66), C(69), C(77) and C(78), which were introduced at calculated positions as riding on their parent atoms] were located by difference maps and refined isotropically. All non-hydrogen atoms were refined anisotropically.

CCDC-179198 contains the supplementary crystallographic data for this paper. Synthesis, Stereochemistry and Molecular Structures of Chiral-at-Metal (Cycloheptatrienyl)molybdenum Complexes Containing the Diphosphane Prophos[‡]

Henri Brunner,*[a] Jürgen Klankermayer,[a] and Manfred Zabel[a][‡]

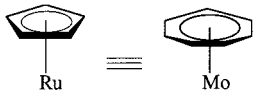
Keywords: Chirality / Molybdenum / Half-sandwich complexes / Configuration determination

The synthesis of a series of 18-electron chiral-at-metal (cycloheptatrienyl)molybdenum complexes [(η^7-C_7H_7)Mo(prophos)X] [prophos = (*R*)-1,2-bis(diphenylphosphanyl)propane; X = $NCMeBF_4$, Cl, I, CN, H, Me] is reported, which consist of diastereomers differing only in the metal configuration. Diastereomer enrichments have been achieved and the configurational stability of the compounds [(η^7-C_7H_7)Mo(prophos)X] has been studied and compared with the isoelectronic ruthenium complexes [(η^5-C_5H_5)Ru(prophos)X]. The stereochemistry of the substitution reactions has been investigated, and X-ray analysis and NMR spectroscopy were used to determine the absolute configuration of the complexes.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Cyclopentadienyl (η^5-C_5H_5) and benzene (η^6-C_6H_6) are among the most common ligands encountered in organotransition metal chemistry. Although transition metal complexes of the cycloheptatrienyl ligand η^7-C_7H_7 have been known for more than four decades, the chemistry of this ligand has not been studied much in comparison.[1] Until now, there is only one example of a chiral-at-metal cycloheptatrienyl complex.[2]

Whereas the neutral η^5-C_5H_5 ligand contributes 5 electrons to a metal centre, the (η^7-C_7H_7) ligand is a 7-electron ligand. As Ru has two electrons more than Mo, the isoelectronic fragments (η^5-C_5H_5)Ru and (η^7-C_7H_7)Mo should be intimately related (Scheme 1). The similarity of their chemistry will be corroborated in the present paper and in subsequent publications.[3,4]



Scheme 1

Three-legged "piano stool" complexes [(η^n-C_nH_n)MLL′L′′] are prominent examples of chiral-at-metal compounds.[5–7] Frequently, in these complexes the metal atom is the unique centre of chirality, with the compounds forming racemates. If one of the ligands is enantiomerically pure, a pair of diastereomers arises, differing only in the metal configuration. Usually, such diastereomers can be distinguished on the basis of their NMR spectra. Therefore, the diastereomer ratio and enrichment can be determined by the integration of suitable signals.

In solution some of the chiral-at-metal complexes are configurationally stable even at higher temperatures, whereas others are labile with respect to the metal configuration. Mostly, changes in the metal configuration are initiated by ligand dissociation, which converts an 18-electron species into an unsaturated 16-electron intermediate. Theoretical studies claim that for a series of isoelectronic 16-electron fragments [(η^n-C_nH_n)M(CO)$_2$] the ring size of the polyenyl ligand and the location of the metal in the periodic table have a distinct influence on the barrier of the pyramidal inversion at the metal centre.[8,9] The calculations showed that [(η^5-C_5H_5)Mn(CO)$_2$] and [(η^6-C_6H_6)Cr(CO)$_2$] have a pyramidal ground state and high inversion barriers. Interestingly, the situation changes upon going to either [(η^4-C_4H_4)Fe(CO)$_2$] or [(η^7-C_7H_7)V(CO)$_2$]. In both cases extremely shallow, only weakly pyramidal minima were found. As a consequence, [(η^5-C_5H_5)RuLL′L′′] and [(η^7-C_7H_7)MoLL′L′′] complexes should differ in their configurational stability, provided the change in the metal configuration includes a ligand dissociation.

In the present paper we compare the stereochemistry of the ruthenium complexes [(η^5-C_5H_5)Ru(prophos)X], studied by Consiglio et al.,[10] with the corresponding molybdenum compounds [(η^7-C_7H_7)Mo(prophos)X] (X = $NCMeBF_4$, Cl, I, CN, H, Me) (Scheme 2).[11]

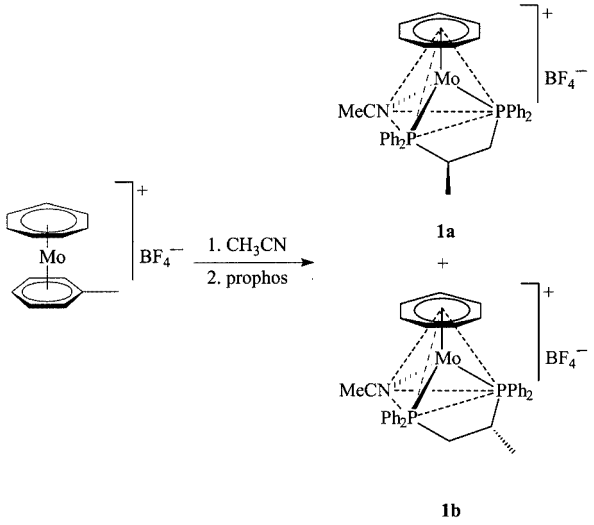
Results and Discussion

1. Synthesis and Characterisation of Complexes 1a/1b

Reaction of the reactive complex $[(\eta^7\text{-}C_7H_7)Mo(\eta^6\text{-}C_6H_5CH_3)]BF_4$ [12] with the chiral diphosphane (*R*)-1,2-bis(diphenylphosphanyl)propane, (*R*)-prophos,[13] in CH_3CN resulted in the formation of a diastereomeric mixture $[(\eta^7\text{-}C_7H_7)Mo(prophos)(NCMe)]BF_4$ **1a/1b** (Scheme 3). The ratio of diastereomers could be determined by ^1H NMR spectroscopy as **1a/1b** = 93:7 in [D_6]acetone. It remained unchanged after 1 d in acetone solution. In the major diastereomer **1a**, the $\eta^7\text{-}C_7H_7$ signal was shifted to lower field compared to that of the minor diastereomer **1b**. Besides the C_7H_7 and the phenyl resonances, the ^1H NMR spectra of both diastereomers showed three signals due to the CH_2 and CH protons and a signal due to the methyl group of the diphosphane ligand, characterised by the expected coupling constants. The $^{31}P\{^1H\}$ NMR spectrum of the major diastereomer **1a** consisted of two doublets at δ = 71.7 and 56.1 ppm. The resonances of the minor diastereomer **1b** were shifted to δ = 76.1 and 62.7 ppm.



Scheme 3

Consiglio et al. had reported that in compounds of the type $[(\eta^5\text{-}C_5H_5)Ru(prophos)X]$ the major diastereomers having an (S_{Ru},R_C) configuration exhibited differences in the ^{31}P chemical shifts of the two phosphorus atoms P_A and P_B which were always larger than those of $P_{A'}$ and $P_{B'}$ of the (R_{Ru},R_C) diastereomers. Furthermore, the chemical shifts of the (R_{Ru},R_C) diastereomers usually fell between those of the (S_{Ru},R_C) diastereomers.[11] In keeping with such an empirical correlation, the absolute configuration of **1a/1b** was assigned on the basis of the ^{31}P chemical shifts of the molybdenum complexes **2**, **4**−**6** shown in Table 1. The absolute configurations of **2** and **4** are known from their X-ray structure determinations (see below), and those of **5** and **6** from NOE spectroscopy (see below). All 5 diastereomer pairs exhibit the same ^{31}P NMR pattern. Since the ^{31}P chemical shifts of the $P_{A'}$ and $P_{B'}$ signals of the minor (R_{Mo},R_C) diastereomers of **2b**, **4b**, **5b** and **6b** are larger than than those of P_A and P_B of the major (S_{Mo},R_C) diastereomers **2a**, **4a**, **5a** and **6a**, we assign an (R_{Mo},R_C) configuration to **1b** and an (S_{Mo},R_C) configuration to **1a**.

Table 1. ^{31}P chemical shifts for the two phosphorus atoms in the molybdenum complexes **1**, **2**, **4**, **5**, **6**

Complex (solvent)	P_A [ppm]	$P_{A'}$ [ppm]	P_B [ppm]	$P_{B'}$ [ppm]
1 ([D_6]acetone)	71.7	76.1	56.1	62.7
2 (C_6D_6)	65.5	65.8	51.1	56.1
4 (C_6D_6)	69.7	74.3	53.9	61.8
5 (C_6D_6)	81.1	86.3	64.1	68.3
6 (C_6D_6)	77.6	77.4	60.0	64.0

The CH_3CN ligand in $[(\eta^7\text{-}C_7H_7)Mo(prophos)(NCMe)]BF_4$ (**1**) proved to be substitutionally labile. It could be replaced by CD_3CN (20 equiv.) in a solution of **1** in [D_6]acetone at room temperature [Equation (1)].

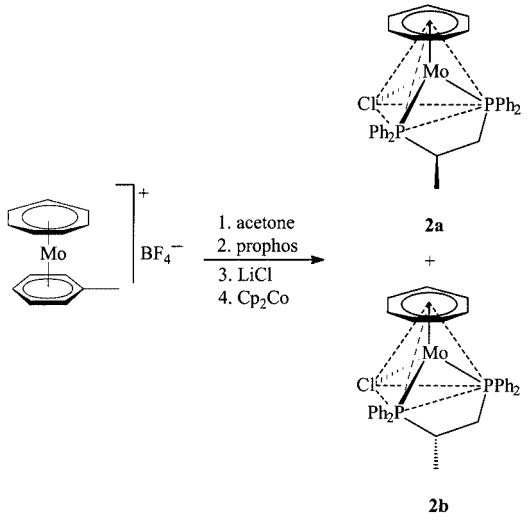
$$[(\eta^7\text{-}C_7H_7)Mo(prophos)(CH_3CN)]BF_4 + CD_3CN \rightarrow [(\eta^7\text{-}C_7H_7)Mo(prophos)(CD_3CN)]BF_4 + CH_3CN \quad (1)$$

The kinetics of this process was studied by ^1H NMR spectroscopy and analysed for pseudo-first-order conditions. The first-order rate constant obtained was $1.86 \cdot 10^{-3}$ min^{-1} at 21.8 °C (half-life 373 min). During the exchange no significant change in the diastereomeric ratio was observed. In comparison to the related ruthenium complex $[(\eta^5\text{-}C_5H_5)Ru(ppfa)(NCMe)]PF_6$ {ppfa = 2-[1-(dimethylamino)ethyl]-1-(diphenylphosphanyl)ferrocene}, the CH_3CN exchange in **1** was considerably slower.[14]

2. Synthesis and Characterisation of Complexes 2a/2b

Treatment of $[(\eta^7\text{-}C_7H_7)Mo(\eta^6\text{-}C_6H_5CH_3)]BF_4$ in acetone with 1 equiv. of (*R*)-prophos caused displacement of the $(\eta^6\text{-}C_6H_5CH_3)$ ligand. Reaction with an excess of anhydrous LiCl afforded the 17-electron cation $[(\eta^7\text{-}C_7H_7)Mo(prophos)Cl]^+$. The synthesis of the neutral 18-electron diastereomers $[(\eta^7\text{-}C_7H_7)Mo(prophos)Cl]$ (**2a/2b**) from the radical cation in $[(\eta^7\text{-}C_7H_7)Mo(prophos)Cl]BF_4$ was achieved by reduction with $CoCp_2$ in toluene (Scheme 4).[15−17] The complexes **2a/2b** initially failed to give satisfactory NMR spectra, probably due to trace oxidation. However, good NMR spectroscopic data for **2a/2b** were obtained on addition of a small quantity of $CoCp_2$ to the sample.[18] The diastereomer ratio could be determined

by ^{1}H NMR spectroscopy as **2a/2b** = 82:18 in C_6D_6. It remained unchanged after 1 d in benzene solution. In the major diastereomer **2a**, the η^7-C_7H_7 signal was shifted to



Scheme 4

lower field compared to that of the minor diastereomer **2b**.

Consiglio et al. had found in their studies, that the chiral-at-metal complex [(η^5-C_5H_5)Ru(prophos)Cl] was configurationally stable at room temperature and even did not epimerise in benzene at 80 °C.[19] In contrast, the analogous molybdenum complex [(η^7-C_7H_7)Mo(prophos)Cl] (**2**) epimerised at higher temperatures at the metal centre with no apparent decomposition. Thus, an 82:18 mixture of **2a/2b** changed to 90:10 after 18 h and to 93:7 after 42 h at 60 °C in C_6D_6. This result confirms the theoretical studies[8,9] that had predicted a lower barrier of the pyramidal inversion for (η^7-C_7H_7)MoLL systems compared to (η^5-C_5H_5)RuLL systems.

3. Molecular Structure of Diastereomer 2a

To determine the absolute configuration of the major diastereomer [(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) by X-ray analysis, single crystals were grown in CH_2Cl_2/hexane from a 93:7 mixture of **2a/2b**. The molecular structure of **2a** is depicted in Figure 1 and selected structural parameters are listed in Table 2.

The η^7-C_7H_7 ring occupies three *fac* positions of an octahedral metal environment, which is completed by the chelate phosphane group and a terminal chlorine atom. The absolute configuration of the metal centre is (S_{Mo}) in agreement with the ligand priority sequence[20,21] η^7-C_7H_7 > Cl > P1(CH_3) > P2. Thus, the thermodynamically more stable diastereomer **2a** has (S_{Mo},R_C) configuration.

The cycloheptatrienyl ring is almost planar. The molybdenum atom lies 1.612 Å apart from the least-squares plane through the carbocyclic ring. The two Mo−P bond lengths are slightly different from each other. The sequence of the angles around the molybdenum atom is P1−Mo1−P2 < P1−Mo1−Cl1 < P2−Mo1−Cl1, with the chlorine ligand displaced towards P1.

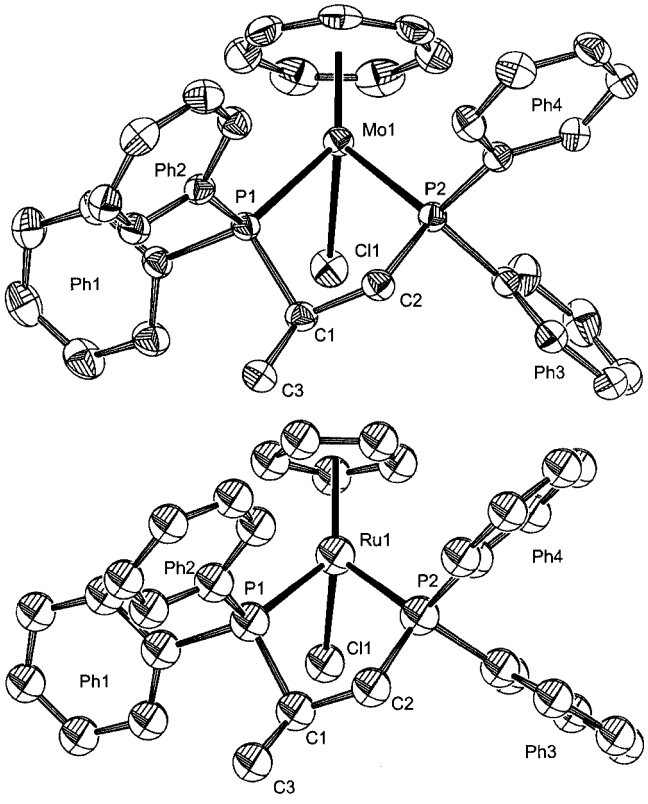


Figure 1. Molecular structures of (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) (top) and (S_{Ru},R_C)-[(η^5-C_5H_5)Ru(prophos)Cl][20] (bottom); hydrogen atoms have been omitted for clarity

As compound (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) resembles the complex (S_{Ru},R_C)-[(η^5-C_5H_5)Ru(prophos)Cl],[19] it was interesting to compare their molecular structures (Figure 1). The similarity is striking. In both complexes even the phenyl rings (except Ph4) of the prophos ligand are orientated in the same way. As a consequence of the smaller polyenyl ligand, the bond C(g)−Ru (1.851 Å) in [(η^5-C_5H_5)Ru(prophos)Cl] is longer than the bond C(g)−Mo (1.612 Å) in **2a** [C(g) = ring centroid]. Due to the different metal radii, the M−P bonds are about 0.2 Å shorter in the ruthenium complex.

The Mo(prophos) metallacycle in [(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) has λ conformation allowing an equatorial disposition of the methyl group C3 of the (*R*)-prophos ligand. The two carbon atoms C1 and C2 of the five-membered ring are both on the same side of the P1−Mo1−P2 plane, a frequently found conformation (distorted envelope conformation).[22] The Ru(prophos) metallacycle in [(η^5-C_5H_5)Ru(prophos)Cl] also has λ conformation with a torsion angle P2−C2−C1−P1 of −43.77°, which is smaller than the analogous angle in **2a** of −53.21° (Figure 2).

4. Synthesis and Characterization of Complexes 3a/b and 4a/b

Reaction of [(η^7-C_7H_7)Mo(prophos)(NCMe)]BF_4 (**1**) with an excess of NaI in acetone afforded the 18-electron complex [(η^7-C_7H_7)Mo(prophos)I] (**3**) (Scheme 5). The dia-

Table 2. Selected bond lengths [Å] and angles [°] for compounds [(η^n-C_nH_n)M(prophos)X]: [(η^5-C_5H_5)Ru(prophos)Cl],[19] [(η^7-C_7H_7)Mo(prophos)Cl] (**2a**), -[(η^7-C_7H_7)Mo(prophos)I] (**3a**) and [(η^7-C_7H_7)Mo(prophos)CN] (**4a**)

[a] C(g) indicates the centre of the polyenyl ligand.

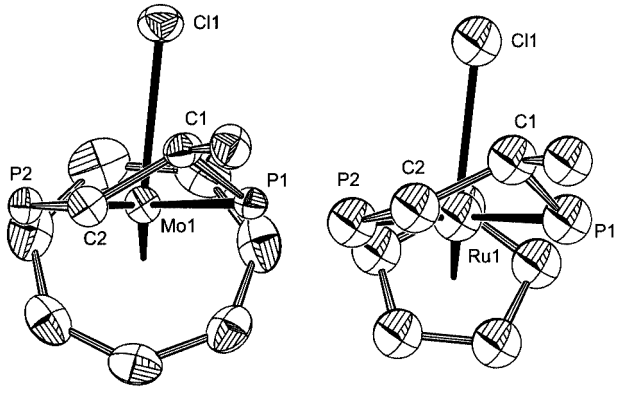

Figure 2. (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) (left) and (S_{Ru},R_C)-[(η^5-C_5H_5)Ru(prophos)Cl] (right); view along the plane P1−M−P2 that is normal to the plane of the drawing, showing the λ conformation of the M(prophos) ring and the equatorial arrangement of the methyl group of prophos

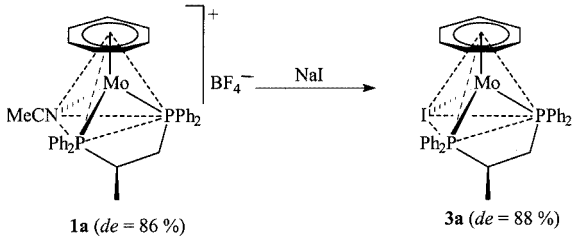
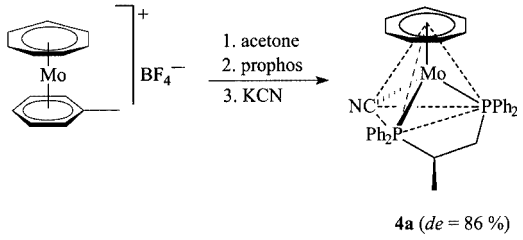
stereomer ratio could be determined by ^{1}H NMR spectroscopy as **3a/3b** = 94:6 in C_6D_6. It remained unchanged after 1 d in benzene solution. By fractional crystallisation it was possible to increase the diastereomer ratio to 98:2. After 3 h at 70 °C in benzene solution, the diastereomer ratio changed to 94:6. Thus, analogous to complex **2**, compound [(η^7-C_7H_7)Mo(prophos)I] (**3**) epimerised at higher temperatures in solution. Interestingly, the variation of the halogen had no considerable influence on the equilibrium ratio.



Scheme 5

The cyano complex [(η^7-C_7H_7)Mo(prophos)(CN)] (**4a/4b**) was obtained from the reaction of [(η^7-C_7H_7)Mo(prophos)($OCMe_2$)]BF_4 with KCN in acetone/methanol (Scheme 6). It was isolated as a red solid after purification by column chromatography. The diastereomer ratio could be determined by ^{1}H NMR spectroscopy as **4a/4b** = 93:7 in $CDCl_3$. This ratio remained unchanged after 1 d in $CDCl_3$ solution.



Scheme 6

5. Molecular Structures of Complexes 3a and 4a

Single crystals of [(η^7-C_7H_7)Mo(prophos)I] (**3a**) were grown at room temp. from toluene/pentane using a **3a/3b** = 98:2 mixture. An ORTEP view of **3a** is shown in Figure 3. The structure determination confirmed the (R_C) configuration of the stereogenic carbon centre. The configuration of the molybdenum centre was specified as (R_{Mo}) using the priority sequence I > η^7-C_7H_7 > P1(CH_3) > P2.

There is a change in the priority sequence of the ligands in **3a** and **2a**. Thus, (R_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)I] (**3a**) and (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)Cl] (**2a**) have opposite descriptors for the chiral metal atoms, although they have the same relative configuration (Figure 1 and Figure 3). The structural parameters of **3a** are very similar to those of **2a** except for the Mo−Hal part (Table 2). The cycloheptatrienyl ligand in **3a** is roughly planar with slightly different C−C [range 1.398(5)−1.417(4) Å] and Mo−C bond lengths, a consequence of the asymmetry of the coordination around the metal centre.

To determine the absolute configuration of the major diastereomer [(η^7-C_7H_7)Mo(prophos)CN] (**4a**) by X-ray analysis, single crystals were grown in $CHCl_3$/pentane from a

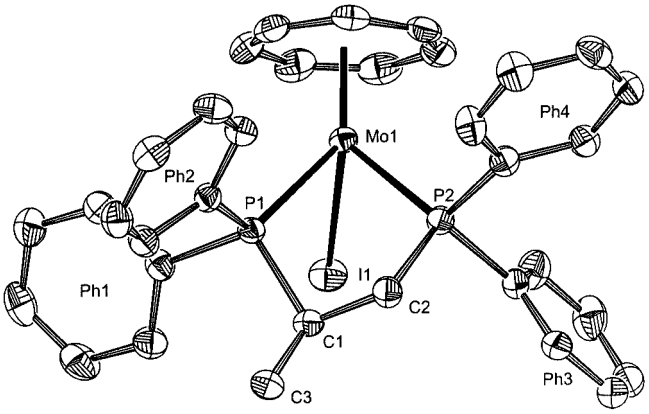


Figure 3. Molecular structure of (R_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)I] (**3a**) (hydrogen atoms omitted for clarity)

93:7 mixture of **4a/4b**. The molecular structure of **4a** is shown in Figure 4. It has an (S_{Mo},R_C) configuration which relates it to the relative configuration of **2a** and **3a**.

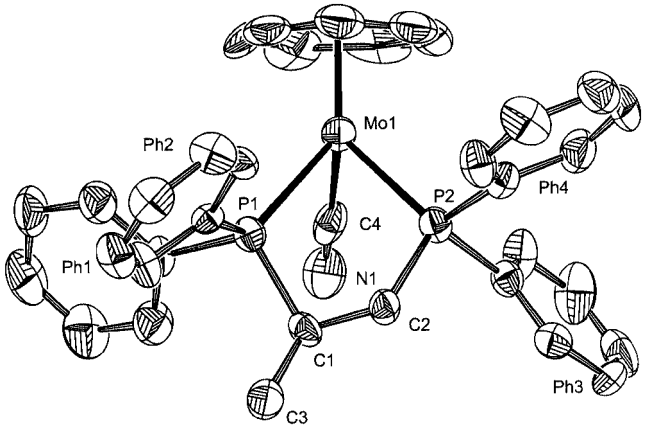

Figure 4. Molecular structure of (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)CN] (**4a**) (hydrogen atoms omitted for clarity)

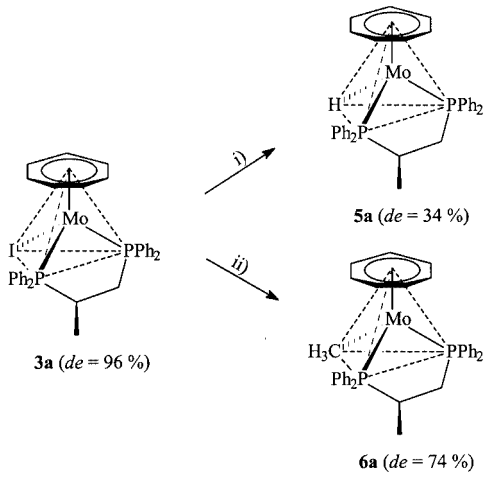
6. Formation of the Complexes 5a/b and 6a/b

Starting from [(η^7-C_7H_7)Mo(prophos)I] with a diastereomer ratio of **3a/3b** = 98:2 the reduction with sodium dihydrobis(2-methoxyethoxy)aluminate gave the hydrido compound [(η^7-C_7H_7)Mo(prophos)H] (**5a/5b**) (Scheme 7). The diastereomer ratio of the product could be determined by ^{1}H NMR spectroscopy as **5a/5b** = 67:33 in C_6D_6. The same ratio was obtained starting from [(η^7-C_7H_7)Mo(prophos)Cl] with a diastereomer ratio of **2a/2b** = 82:18. These results indicate that the metal centre in [(η^7-C_7H_7)Mo(prophos)H] **5a/5b** is configurationally labile. Obviously, the 67:33 mixture is the equilibrium ratio for **5a/5b**.

Complex [(η^7-C_7H_7)Mo(prophos)Me] (**6a/6b**) was prepared by reaction of [(η^7-C_7H_7)Mo(prophos)I] with MeLi in THF at 30 °C. The diastereomer ratio of the product could be determined as **6a**:**6b** = 87:13 in C_6D_6. This ratio remained unchanged after 1 d at 21 °C in solution. At higher temperatures decomposition occurred. By contrast,



Scheme 7. i) $Na[AlH_2(OCH_2CH_2OCH_3)_2]$ in toluene; ii) MeLi in THF

reaction of [(η^5-C_5H_5)Ru(prophos)Cl] at room temperature in toluene with an ether solution of CH_3MgBr stereospecifically had given the corresponding methyl derivative [(η^5-C_5H_5)Ru(prophos)Me] and reaction of [(η^5-C_5H_5)Ru(prophos)Cl] with methanolic CH_3ONa leading to the hydride [(η^5-C_5H_5)Ru(prophos)H] took place with retention of configuration at the ruthenium atom.[23]

As it was not possible to obtain single crystals of **5** and **6** for an X-ray analysis, the stereochemical assignment of **5** and **6** was accomplished by NOE experiments.[11] The thermodynamically more stable diastereomers were the (S_{Mo},R_C) epimers **5a** and **6a**. The determination of the absolute configuration at the chiral molybdenum atom was based on the NOEs between R (**5a**, R = H; **6a**, R = Me) and the hydrogen atom H_g bound to the chiral carbon atom of the diphosphane. The assignment of the *ortho* proton resonances for the four phenyl groups was made by inspection of their NOEs with R, H_g, H_c, H_t and the Me group of the diphosphane ligand. These NOEs supported an equatorial disposition of the methyl group in **5a** and **6a** with a λ conformation of the Mo(prophos) metallacycle (Figure 5).

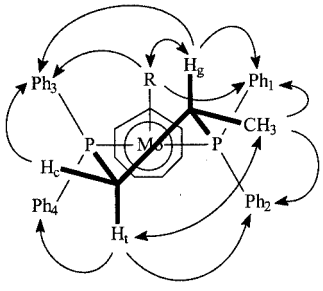


Figure 5. Schematic view of the prophos ligand in (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)H] (**5a**) (R = H) and (S_{Mo},R_C)-[(η^7-C_7H_7)Mo(prophos)Me] (**6a**) (R = Me) projected onto the C_7H_7 ring; some selected NOEs are shown

Conclusions

The new (η^7-C_7H_7)Mo complexes described in this paper are isolobal with the corresponding (η^5-C_5H_5)Ru complexes investigated by Consiglio et al.[10,19,23] Whereas [(η^7-C_7H_7)Mo(prophos)Cl] undergoes epimerization in solution at temperatures around 60 °C, [(η^5-C_5H_5)Ru(prophos)Cl] is configurationally stable at this temperature. In contrast to the analogous ruthenium complexes, the formation of [(η^7-C_7H_7)Mo(prophos)H] and [(η^7-C_7H_7)Mo(prophos)Me] was not stereospecific. Thus, our investigations demonstrate that the new (η^7-C_7H_7)Mo complexes are configurationally more labile at the metal centre than their (η^5-C_5H_5)Ru counterparts.

Experimental Section

General Remarks: All manipulations were carried out under dry nitrogen using standard Schlenk techniques. Most of the commercially available reagents were used without further purification. Solvents were dried by standard methods and distilled prior to use. Melting points (not corrected): Büchi SMP 20. IR spectra: BioRad FT-IR (KBr pellets). Mass spectra: Finnigan Mat 311 A, Finnigan Mat 95 and ThermoQuest TSQ 7000. Optical rotations: Perkin−Elmer 241 polarimeter at room temperature. ^{1}H NMR spectra: Bruker ARX 400 spectrometer (400 MHz). ^{31}P NMR spectra: Bruker ARX 400 spectrometer (162 MHz). Elemental analyses: Heraeus Elementar Vario El III. The diphosphane (*R*)-prophos[13] and the complex [(η^7-C_7H_7)Mo(η^6-$C_6H_5CH_3$)]BF_4 [12] were prepared according to the literature.

[(η^7-C_7H_7)Mo(prophos)(NCMe)]BF_4 (1): A solution of [(η^7-C_7H_7)Mo(η^6-$C_6H_5CH_3$)]BF_4 (0.190 g, 0.47 mmol) was refluxed in CH_3CN for 1 h. The red solution was cooled to 0 °C, treated with prophos (0.185 g, 0.45 mmol) and refluxed for 3 h. The resulting solution was filtered and the volume was reduced to ca. 5 mL. Addition of diethyl ether precipitated **1** as a pink solid. Yield 298 mg (91%). M.p. 209 °C. IR (KBr): $\tilde{\nu}$ = 3060 w, 2990 w, 2970 w, 1490 m, 1440 s, 1070 s, 830 m, 750 m, 710 m cm^{-1}. ^{1}H NMR (400 MHz, [D$_6$]acetone; signal of the minor diastereomer in parentheses): δ = 7.73−7.13 (m, 20 H, Ph-*H*), 5.09 (4.88) (dd, J_{HP} = 2.2 Hz, J_{HP} = 2.1 Hz, 7 H, η^7-C_7H_7), 2.99 (dddd, J_{HP} = 48.9, $^2J_{H,H}$ = 14.9 Hz, J_{HP} = 12.6, $^3J_{H,H}$ = 4.3 Hz, 1 H, CH_AH$_B$), 2.15 (m, 1 H, C*H*CH$_3$), 1.87 (dddd, $^2J_{H,H}$ = 14.9, $^3J_{H,H}$ = 14.9 Hz, J_{HP} = 6.4 Hz, J_{HP} = 2.5 Hz, 1 H, CH$_A$*H*$_B$), 1.63 (dd, J_{HP} = 1.6 Hz, J_{HP} = 1.6 Hz, 3 H, NCC*H*$_3$), 0.97 (ddd, J_{HP} = 10.4, $^3J_{H,H}$ = 6.6 Hz, J_{HP} = 1.2 Hz, 3 H, CHC*H*$_3$) ppm. ^{31}P{^{1}H} NMR (162 MHz, [D$_6$]acetone; signal of the minor diastereomer in parentheses): δ = 71.7 (76.1) (d, J_{PP} = 23.7 Hz), 56.1 (62.7) (d) ppm. MS (FAB-MS): *m*/*z* (%) = 642 (15) [cation], 601 (100) [cation − NCMe]. [α]$_D$ = +10, [α]$_{578}$ = −20, [α]$_{546}$ = −170, [α]$_{436}$ = −600 (*c* = 0.16, acetone). $C_{36}H_{36}BF_4MoNP_2$ (727.38): calcd. C 59.45, H 4.99, N 1.93; found C 58.42, H 4.97, N 1.94.

[(η^7-C_7H_7)Mo(prophos)Cl] (2): A solution of [(η^7-C_7H_7)Mo(η^6-$C_6H_5CH_3$)]BF_4 (0.150 g, 0.41 mmol) and prophos (0.170 g, 0.41 mmol) was stirred in acetone for 20 h. Then the solution was treated with LiCl (0.250 g, 5.9 mmol) and stirred for 20 h. The solvent was removed and the residue was washed with toluene and dried; 0.180 g of the green solid was suspended in toluene and treated with Cp_2Co (0.047 g, 0.25 mmol). The mixture was stirred at 35 °C. After 3 h, the solution was filtered and the solvent was removed. Recrystallisation of the crude product from CH_2Cl_2/hexane gave **2** as a green solid. Yield 80 mg (30%). M.p. > 250 °C. IR (KBr): $\tilde{\nu}$ = 3060 w, 2990 w, 2970 w, 1490 m, 1440 s, 1100 m, 820 m, 740 m, 690 m cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 8.01−7.90 (m, 2 H, Ph-*H*), 7.65−7.47 (m, 2 H, Ph-*H*), 7.37−6.92 (m, 16 H, Ph-*H*), 4.86 (4.79) (dd, J_{HP} = 1.9 Hz, J_{HP} = 1.9 Hz, 7 H, η^7-C_7H_7), 2.62 (m, 1 H, C*H*CH$_3$), 2.09 (dddd, J_{HP} = 46.7, $^2J_{H,H}$ = 14.7 Hz, J_{HP} = 10.9, $^3J_{H,H}$ = 5.2 Hz, 1 H, CH_AH$_B$), 1.38 (dddd, $^2J_{H,H}$ = 14.7, $^3J_{H,H}$ = 14.5 Hz, J_{HP} = 6.4 Hz, J_{HP} = 2.5 Hz, 1 H, CH$_A$*H*$_B$), 0.62 (0.76) (ddd, J_{HP} = 9.4, $^3J_{H,H}$ = 6.8 Hz, J_{HP} = 1.1 Hz, 3 H, CHC*H*$_3$) ppm. ^{31}P{^{1}H} NMR (162 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 65.5 (65.8) (d, J_{PP} = 16.0 Hz), 51.1 (56.1) (d) ppm. MS (FD-MS, CH_2Cl_2): *m*/*z* (%) = 636 (100) [M$^+$]. [α]$_D$ = −860, [α]$_{578}$ = −890, [α]$_{546}$ = −660 (*c* = 0.12, CH_2Cl_2). $C_{34}H_{33}ClMoP_2$ (634.98): calcd. C 64.31, H 5.24; found C 63.87, H 5.35.

[(η^7-C_7H_7)Mo(prophos)I] (3): Compound **1** (0.235 g, 0.32 mmol) in 30 mL of acetone was treated with NaI (0.200 g, 1.33 mmol). The reaction mixture was stirred for 20 h at room temp. and 3 h at 40 °C. The solvent was then removed and the residue was extracted with toluene (60 mL). The solution was filtered and reduced in volume. Addition of pentane gave green needles of **3**, which were dried in vacuo. Yield 181 mg (78%). M.p. > 250 °C. IR (KBr): $\tilde{\nu}$ = 3048 w, 2978 w, 2923 w, 2869 w, 1482 m, 1434 s, 1093 m, 814 s, 742 s, 696 s, 518 s cm^{-1}. ^{1}H NMR (400 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 7.97−7.90 (m, 2 H, Ph-*H*), 7.63−7.57 (m, 2 H, Ph-*H*), 7.48−7.42 (m, 2 H, Ph-*H*), 7.33−7.21 (m, 5 H, Ph-*H*), 7.20−7.02 (m, 9 H, Ph-*H*), 4.88 (4.82) (dd, J_{HP} = 1.9 Hz, J_{HP} = 1.9 Hz, 7 H, η^7-C_7H_7), 2.99 (m, 1 H, C*H*CH$_3$), 2.23 (dddd, J_{HP} = 46.4, $^2J_{H,H}$ = 14.7 Hz, J_{HP} = 10.7, $^3J_{H,H}$ = 5.5 Hz, 1 H, CH_AH$_B$), 1.32 (dddd, $^2J_{H,H}$ = 14.7, $^3J_{H,H}$ = 14.5 Hz, J_{HP} = 5.2 Hz, J_{HP} = 4.9 Hz, 1 H, CH$_A$*H*$_B$), 0.65 (0.97) (ddd, J_{HP} = 9.6, $^3J_{H,H}$ = 6.8 Hz, J_{HP} = 1.4 Hz, 3 H, CHC*H*$_3$) ppm. MS (FD-MS, CH_2Cl_2): *m*/*z* (%) = 728 (100) [M$^+$]. [α]$_D$ = −750, [α]$_{578}$ = −790, [α]$_{546}$ = −670, [α]$_{436}$ = −1500 (*c* = 0.16, CH_2Cl_2). $C_{34}H_{33}IMoP_2$ (726.43): calcd. C 56.22, H 4.58; found C 55.84, H 4.70.

[(η^7-C_7H_7)Mo(prophos)CN] (4): A solution of [(η^7-C_7H_7)Mo(η^6-$C_6H_5CH_3$)]BF_4 (0.364 g, 1.00 mmol) and prophos (0.412 g, 1.00 mmol) in 40 mL of acetone was refluxed for 18 h. The solution was reduced in volume to 10 mL and methanol (30 mL) was added. The resulting solution was treated with KCN and stirred for 30 min at 50 °C. The solvent was removed and the residue was extracted with CH_2Cl_2 (20 mL). The mixture was filtered through a plug of Al_2O_3 and the solvents were evaporated to dryness. The resulting solid was dissolved in CH_2Cl_2 and transferred to an Al_2O_3/hexane chromatography column cooled to 10 °C. Elution with acetone/hexane gave a red band, which was collected and the solvents were evaporated to dryness. Crystallisation of the crude product from $CHCl_3$/pentane gave **4** as red plates. Yield 199 mg (32%). M.p. > 250 °C. IR (KBr): $\tilde{\nu}$ = 3050 w, 2980 w, 2920 w, 2860 w, 2070 s, 1440 s, 1100 m, 820 m, 740 m, 690 m cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$; signal of the minor diastereomer in parentheses): δ = 7.83−6.95 (m, 20 H, Ph-*H*), 4.70 (4.54) (dd, J_{HP} = 2.2 Hz, J_{HP} = 2.2 Hz, 7 H, η^7-C_7H_7), 2.68−2.54 (m, 1 H, C*H*CH$_3$), 2.40 (dddd, J_{HP} = 48.1, $^2J_{H,H}$ = 14.7 Hz, J_{HP} = 11.7, $^3J_{H,H}$ = 5.1 Hz, 1 H, CH_AH$_B$), 1.52 (dddd, $^2J_{H,H}$ = 14.7, $^3J_{H,H}$ = 14.5 Hz, J_{HP} = 6.4 Hz, J_{HP} = 4.3 Hz, 1 H, CH$_A$*H*$_B$), 0.84 (0.75) (ddd, J_{HP} = 8.8, $^3J_{H,H}$ = 7.8 Hz, J_{HP} = 1.3 Hz, 3 H, CHC*H*$_3$) ppm. ^{31}P{^{1}H} NMR (162 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 69.7 (74.3) (d, J_{PP} = 26.7 Hz), 53.9 (61.8) (d) ppm. MS (FD-MS, CH_2Cl_2): *m*/*z* (%) = 627 (100) [M$^+$]. $C_{35}H_{33}MoNP_2$ (625.54): calcd. C 67.20, H 5.32, N 2.24; found C 66.12, H 5.95, N 1.84.

[(η⁷-C_7H_7)Mo(prophos)H] (5): Compound [(η⁷-C_7H_7)Mo(prophos)I] (**3**) (60.0 mg, 0.83 μmol) was dissolved in 15 mL of toluene. To this solution was added RedAl© (80 μL of a 70% solution in toluene) at −20 °C. The mixture was stirred for 16 h at room temp. and then for 10 h at 30 °C. After cooling to 0 °C, water (0.1 mL) was added and the solvent was removed. The residue was extracted with toluene (5 mL). The mixture was filtered and the solvents were evaporated to dryness. Yield 32 mg (68%). ^{1}H NMR (400 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 8.07−6.90 (m, 20 H, Ph-*H*), 4.78 (4.72) (ddd, J_{HP} = 1.9 Hz, J_{HP} = 1.9 Hz, $J_{H,H}$ = 1.3 Hz, 7 H, η⁷-C_7H_7), 2.11 (dddd, J_{HP} = 50.1, $^2J_{H,H}$ = 13.7 Hz, J_{HP} = 10.0, $^3J_{H,H}$ = 4.4 Hz, 1 H, CH_AH$_B$), 2.03−1.87 (m, 1 H, C*H*CH$_3$), 1.60 (dddd, $^3J_{H,H}$ = 13.8, $^2J_{H,H}$ = 13.7 Hz, J_{HP} = 6.7 Hz, J_{HP} = 3.1 Hz, 1 H, CH$_A$$H_B$), 0.72 (0.66) (dd, J_{HP} = 9.4, $^3J_{H,H}$ = 6.8 Hz, 3 H, CHCH_3), −4.07 (−3.58) (dd, J_{HP} = 59.1 Hz, J_{HP} = 41.7 Hz, 1 H, Mo-*H*) ppm. ^{31}P{^{1}H} NMR (162 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 81.1 (86.3) (d, J_{PP} = 25.2 Hz), 64.1 (68.3) (d).

[(η⁷-C_7H_7)Mo(prophos)Me] (6): Methyllithium (0.8 mL of a 1.6 M solution in diethyl ether) was added to [(η⁷-C_7H_7)Mo(prophos)I] (**3**) (60.0 mg, 83 μmol) in THF (16 mL) at −78 °C. The solution was warmed to 0 °C and stirred for 3 h at this temperature. After 30 min at room temp., the solvent was removed. The residue was filtered through a plug of Celite® and the solvents were evaporated. The resulting solid was dissolved in hexane and transferred to a cooled Al_2O_3/hexane chromatography column maintained at −78 °C. Elution with hexane gave a red band, which was collected and the solvents were evaporated to dryness. Yield 49 mg (78%). ^{1}H NMR (400 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 7.79−6.94 (m, 20 H, Ph-*H*), 4.67 (4.66) (dd, J_{HP} = 1.9 Hz, J_{HP} = 1.9 Hz, 7 H, η⁷-C_7H_7), 2.28 (dddd, J_{HP} = 48.0, $^2J_{H,H}$ = 14.5 Hz, J_{HP} = 10.9, $^3J_{H,H}$ = 4.8 Hz, 1 H, CH_AH$_B$), 2.04−1.89 (m, 1 H, C*H*CH$_3$), 1.56 (dddd, $^3J_{H,H}$ = 14.7, $^2J_{H,H}$ = 14.5 Hz, J_{HP} = 6.0 Hz, J_{HP} = 3.3 Hz, 1 H, CH$_A$$H_B$), 0.66 (0.88) (ddd, J_{HP} = 9.0, $^3J_{H,H}$ = 6.7 Hz, J_{HP} = 1.0 Hz, 3 H, CHCH_3), −0.66 (−0.42) (dd, J_{HP} = 8.6 Hz, J_{HP} = 6.8 Hz, 3 H, CH_3) ppm. ^{31}P{^{1}H} NMR (162 MHz, C_6D_6; signal of the minor diastereomer in parentheses): δ = 77.6 (77.4) (d, J_{PP} = 17.2 Hz), 60.0 (64.0) (d).

Acetonitrile Exchange Kinetics with 1 in [D$_6$]Acetone: The CH_3CN exchange in **1** was studied by monitoring the decrease in intensity of the ^{1}H NMR signal of the coordinated [CH_3CN]$_c$ (at δ = 1.63 ppm) and the increase of the free [CH_3CN]$_f$ (at δ = 2.05 ppm) after injection of CD_3CN. After adjusting to the selected temperature, the deuterated acetonitrile was added and spectra were taken at regular intervals. The time dependence of the mol fraction x = [CH_3CN]$_c$/([CH_3CN]$_c$ + [CH_3CN]$_f$), obtained by integration of the corresponding signals, was fitted to Equation (2),[14,24] in which x_0 and x_∞ are the values of x at t = 0 and ∞, and k is the observed first-order rate constant for the exchange.

$$x = x_\infty + (x_0 - x_\infty)\exp[-kt/(1 - x_\infty)] \quad (2)$$

Polynuclear Mn^{II} Complexes with Chloroacetate Bridge − Syntheses, Structure, and Magnetic Properties

Gema Fernández,[a] Montserrat Corbella,*[a] José Mahía,[b] and Miguel A. Maestro[b]

Keywords: Manganese / Crystal structures / Magnetic properties / EPR spectroscopy / Bridging ligands

Three new polynuclear Mn^{II} complexes with chloroacetate bridges were obtained and characterized by X-ray diffraction: $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**), $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**), and $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**). The Mn···Mn distance for **1** (3.624 Å) is smaller than for **2** (4.613 Å) and **3** (4.530 Å); this is in agreement with the number of carboxylate bridges. The three compounds show a weak antiferromagnetic coupling. The J values are –3.82 cm^{-1} for **1**, –0.85 cm^{-1} for **3**, and no coupling was observed for **2**. Each compound showed a characteristic EPR spectrum at 4 K. Simulation of these spectra could be obtained with D = –0.16 cm^{-1} and E = –0.015 cm^{-1} for compound **1**, and D = –0.045 cm^{-1} and E = –0.004 cm^{-1} for compound **2**.

Introduction

Manganese is found in several metalloproteins. Usually, the manganese ion binds the protein through the carboxylate groups of aspartate or glutamate. In coordination chemistry, this sort of ligand is often found bridging two metal ions, which helps polymerization. This fact is also observed in biological systems, where the reaction centers have between 1 and 4 Mn ions.

The Mn^{II} ion usually plays a structural and/or hydrolytic role; however, it is also found in the reduced form in manganese redox enzymes. There are some dinuclear Mn−carboxylate active sites, e.g. catalase,[1] aminopeptidase,[2] arginase.[3] Recently, it has been shown that one pyrophosphatase needs 3 Mn^{II} ions for catalytic activity.[4] Further, interest in Mn^{II}−carboxylate chemistry has arisen due to the fact that the spectroscopic properties of Mn^{II} have been used as a probe for the sites that normally bind other metal ions. Understanding the structural and magnetic properties of different Mn^{II}−carboxylate complexes will therefore be useful in gaining insight into the structural details of the active site(s) that may influence the chemical mechanisms of catalysis.

Some dinuclear complexes with carboxylate bridges are reported in the literature, with $[Mn_2(\mu\text{-}H_2O)(\mu\text{-}RCOO)_2]^{2+}$,[5−7] $[Mn_2(\mu\text{-}OH)(\mu\text{-}RCOO)_2]^{+}$,[8,9] and $[Mn_2(\mu\text{-}OR)(\mu\text{-}RCOO)_2]^{+}$ cores.[10−14] There are also some dinuclear compounds which only have carboxylate bridges, e.g. three,[9,15−18] two,[19−29] or one.[30,31]

On the other hand, the number of trinuclear Mn^{II} complexes with bridging carboxylate groups is limited.[32−37] Finally, the number of one-dimensional Mn^{II} polymers is increasing,[28,29,39−44] but very few have two carboxylate bridges.[19,45−47]

In this paper we report the isolation and characterization of three new Mn^{II} compounds, with the same carboxylate ligand, $ClCH_2COO^-$. The nuclearity of these compounds differs; $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**) is trinuclear, $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**) is dinuclear, and $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**) is a one-dimensional compound. The structural characterization of these compounds was achieved by X-ray diffraction, and both their magnetic behavior and their EPR spectra were studied.

Results and Discussion

Syntheses

In a previous paper we studied the reactivity of $Mn(RCOO)_2{\cdot}nH_2O$ (R = 2-ClC_6H_4, 3-ClC_6H_4, and 4-ClC_6H_4) with 2,2′-bipyridine.[19] Mn^{II}/bpy ratios of 1:$^2/_3$ and 1:1 were considered, but each carboxylate had a preferred nuclearity (trinuclear complex or chain). In the present work we studied the analogous reaction of $Mn(ClCH_2COO)_2{\cdot}2H_2O$ with various bidentate amines, 2,2′-bipyridine, and 1,10-phenanthroline. Independent of the Mn^{II}/amine ratio, two different compounds were found for the same carboxylate. The 2,2′-bipyridine ligand gave a trinuclear complex $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**), while the 1,10-phenanthroline ligand gave a chain $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**).

In the synthesis of the dinuclear compound $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**), a 1:2:1 ratio of Mn^{II}/phen/ClO_4^- was considered. Attempts to obtain the analogous compound with bpy led to the formation of the more stable mononuclear compound $[Mn(bpy)_3](ClO_4)_2$.

Crystal Structures

$[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (1)

The structure of compound **1** is depicted in Figure 1; selected bond lengths and angles are collected in Table 1; **1** consists of a linear array of three Mn^{II} ions with an Mn(2)−Mn(1)−Mn(2_2) angle of 179.98°. Each Mn(2)···Mn(1) pair is separated by 3.624 Å, a similar distance to that reported for the analogous complex with acetate bridges $[Mn_3(\mu\text{-}CH_3COO)_6(bpy)_2]$ (3.614 Å).[32] For the complex with benzoate ligands $[Mn_3(\mu\text{-}PhCOO)_6(bpy)_2]$,[34] this distance is a bit shorter (3.588 Å). Mn(1) is located on a crystallographic inversion center, and it is bridged to both Mn(2) by three chloroacetate ligands. Two of these ligands coordinate through the two oxygen atoms ($\mu_{1,3}$-$ClCH_2COO$), while the third carboxylate group coordinates through just one oxygen atom ($\mu_{1,1}$-$ClCH_2COO$). In this case, the other oxygen atom chelates through a weak bond the terminal Mn(2) ion. This unusual coordination mode of the carboxylate group provokes a great distortion around Mn(2). The two $\mu_{1,3}$-carboxylate groups are similar, with greater $Mn(1)-O_{carb}$ distances (av. 2.174 Å) than $Mn(2)-O_{carb}$ distances (av. 2.095 Å). The same is observed for the $\mu_{1,1}$-carboxylate, the $Mn(1)-O_{bridge}$ distance is 2.217 Å, while the $Mn(2)-O_{bridge}$ distance is 2.151 Å. For the acetate complex,[32] these distances are very similar (2.201 and 2.155 Å), however, for the benzoate complex,[34] the $Mn_{central}-O_{bridge}$ distance is 2.239 Å, while the $Mn_{terminal}-O_{bridge}$ distance is 2.286 Å. A similar difference is found for the Mn(2)−O(5)−Mn(1) angle. This angle is 112.12° for complex **1**, 112.2° for the acetate complex, and 104.94° for the benzoate complex. Another important difference between complexes with aliphatic and aromatic carboxylate groups is the $Mn_{terminal}-O_{terminal}$ distance. For the $\mu_{1,1}$-carboxylate, this distance is 2.611 Å with $ClCH_2COO^-$, 2.605 Å with CH_3COO^-; however, this distance is shorter with $PhCOO^-$ (2.274 Å) and quite similar to the $Mn_{terminal}-O_{bridge}$ distance. Therefore, the carboxylate is important for the localization or delocalization of the π-system−COO^-. The benzoate favors delocalization, while the aliphatic carboxylate, with or without a chloro substituent, favors the asymmetry of the $-COO^-$ group.

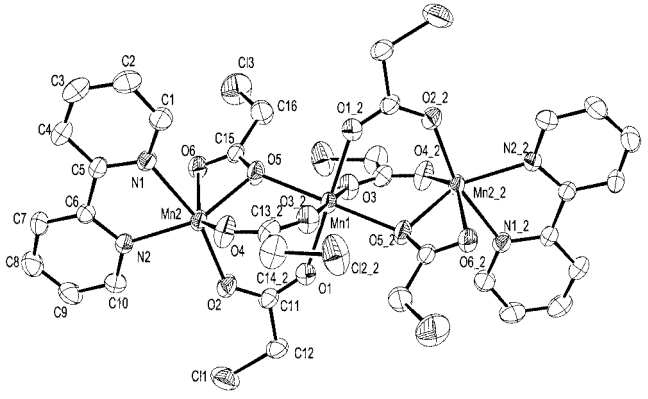

Figure 1. ORTEP drawing of complex **1**

The six-coordination of Mn(2) is completed by a 2,2′-bipyridine ligand. The acute angles O(5)−Mn(2)−O(6) (53.81°) and N(1)−Mn(2)−N(2) (73.19°) and the difference between the bond lengths Mn(2)−N and Mn(2)−O lead to

[a] Symmetry codes: a: $-x + 2, -y + 1, -z + 1$.

The manganese ions are bridged by two chloroacetate ligands, in a *syn-anti* fashion. Six-coordination on each manganese ion is completed by two chelating 1,10-phenanthroline groups. The interatomic Mn···Mn distance of 4.613 Å is a bit longer than Mn···Mn distances found in analogous complexes with only two bridging *syn-anti* carboxylates; $[Mn_2(\mu\text{-}CH_3COO)_2(bpy)_4](ClO_4)_2$ (4.583 Å),[20] $[Mn_2(\mu\text{-}PhCOO)_2(bpy)_4](ClO_4)_2$ (4.509 Å).[19] When a third bridging ligand is present, e.g. another carboxylate,[9,16−18] aqua,[5−7] hydroxo,[8,9] or phenoxo[10−13] group, the Mn···Mn distance becomes smaller (4.03−3.35 Å).

The Mn−O distances are 2.129 Å ($Mn-O_{anti}$) and 2.151 Å ($Mn-O_{syn}$), which are shorter than the Mn−N distances (2.271−2.327 Å). Moreover, the N(1)−Mn(1)−N(2) angle (72.4°) and N(3)−Mn(1)−N(4) angle (73.6°) are far from 90°, due to the restricted geometry of the phenanthroline ligands. Both factors contribute to the distortion of the octahedral geometry around the manganese ions.

For this compound, $d(Mn-O_{anti}) < d(Mn-O_{syn})$, while for the acetate[20] and the benzoate[19] complexes $d(Mn-O_{anti}) > d(Mn-O_{syn})$.

$[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (3)

The structure consists of an infinite zigzag chain, as shown in Figure 3. Selected bond lengths and angles are presented in Table 3. The manganese atoms in the chain are bridged by two chloroacetate ligands coordinated in a *syn-anti* fashion. The six-coordination of each metal center is completed by one phenanthroline ligand. Surprisingly, the interatomic Mn···Mn distance (4.530 Å) is shorter than the distance found for complex **2** (4.613 Å). Both compounds have the same bridging ligands, and the same terminal amine. The Mn···Mn distance for $[Mn(\mu\text{-}3\text{-}ClC_6H_4COO)_2(bpy)]_n$,[19] where the carboxylate bridge is also coordinated in a *syn-anti* fashion, is 4.515 Å. However, for $[Mn_2(\mu\text{-phth})(phen)_4]_n(ClO_4)_{2n}$ (phth= isophthalate),[47] where both manganese ions are bridged by two carboxylate groups coordinated in a *syn-syn* mode, the Mn···Mn distance is longer (4.86 and 4.66 Å).

[a] Symmetry codes: a: $-x + 2, y, -z + 3/2$; b: $-x + 2, -y, -z + 1$; c: $x, -y, z + 1/2$.

There are two equivalent Mn−N distances (2.306 Å), and the Mn−O distance is slightly shorter for the carboxylate oxygen atom *trans* to the phenanthroline nitrogen atom [$d(Mn-O_{transN}) = 2.134$ Å] than for the two carboxylate oxygen atoms *trans* to each other [$d(Mn-O_{transO}) = 2.183$ Å]. The O_{transN} are O_{syn}, while the O_{transO} atoms are O_{anti}, therefore $d(Mn-O_{anti}) > d(Mn-O_{syn})$. This is observed for the analogous chain $[Mn(\mu\text{-}3\text{-}ClC_6H_4COO)_2(bpy)]_n$,[19] but differs from the behavior shown by compound **2**. Moreover, the Mn−O distances are longer for the one-dimensional compound **3** than for the dinuclear complex **2**. The N−Mn−N angle (71.88°) is similar to the values found for the same amine group in compound **2**. Thus, the geometry around each manganese atom is distorted octahedral.

The chain runs parallel to the *c* axis, of the *C*2/*c* space group, in a helix-type conformation, and the phenanthroline ligands are stacked, with a phen···phen distance of 7.491 Å. The smallest interchain metal separation is 9.598 Å.

Magnetic Properties

Magnetic susceptibility data were recorded for the three complexes, from room temperature to 4 K. The $\chi_M T$ vs. T plots for compounds **1**−**3** are shown in Figure 4. For the dinuclear complex **2**, the $\chi_M T$ value is ca. 8.8 $cm^3mol^{-1}K$ in the range room temperature to 18 K. This value is very close to that expected for two uncoupled Mn^{II} ions. The decrease in $\chi_M T$ below this temperature may be a result of the antiferromagnetic interactions (intra- or intermolecular), or of the ZFS (Zero Field Splitting), which is usually small for Mn^{II} ions.

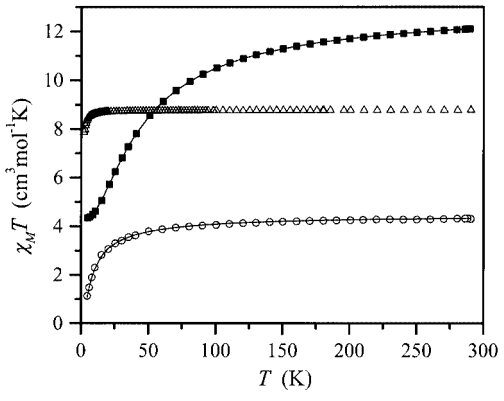

Figure 4. $\chi_M T$ vs. T plot for $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**) (■), $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**) (Δ), and $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**) (O); the solid line is the best fit to the experimental data

For the trinuclear complex **1**, $\chi_M T$ decreases from 12.10 $cm^3mol^{-1}K$ at 290 K to 4.34 $cm^3mol^{-1}K$ at 4.8 K. The $\chi_M T$ value at room temperature, is smaller than the expected value for three uncoupled Mn^{II} ions (13.125 $cm^3mol^{-1}K$). This is indicative of an antiferromagnetic coupling, as confirmed by the decrease in $\chi_M T$ when T decreases. At low temperature, the $\chi_M T$ value is indicative of an $S = 5/2$ spin state.

Taking into account the structure of this compound, the spin Hamiltonian considered would be $\boldsymbol{H}_S = -J(\boldsymbol{S}_1\cdot\boldsymbol{S}_2+\boldsymbol{S}_2\cdot\boldsymbol{S}_1) - J'(\boldsymbol{S}_2\cdot\boldsymbol{S}_2)$. However, the magnetic interaction between the terminal manganese ions ($Mn_2\cdots Mn_2$) in a linear complex is negligible ($J' \approx 0$),[19,32] and only the $Mn_1\cdots Mn_2$ interaction (J) is considered. The best fit corresponds to $J = -3.82$ cm^{-1}, $g = 2.01$ and $R = 1.9\ 10^{-7}$.

For the one-dimensional compound **3**, $\chi_M T$ values decrease monotonically from 4.18 $cm^3mol^{-1}K$ at 298 K to 1.10 $cm^3mol^{-1}K$ at 5 K. The magnetic susceptibility data were analyzed by the analytical expression derived by Fisher[48] for an infinite chain of classical spins based on the Hamiltonian $\boldsymbol{H} = -J\Sigma\boldsymbol{S}_i\cdot\boldsymbol{S}_{i+1}$, for local spin values of $S = 5/2$. The best fit corresponds to $J = -0.89$ cm^{-1}, $g = 2.01$ and $R = 2.6\ 10^{-4}$.

The three compounds reported here have the same bridging ligands, through which the magnetic interaction arises. In spite of this fact, a certain difference in the coupling constant could be appreciated. The trinuclear complex **1** presents a major Mn···Mn interaction. It differs from the other two compounds in the coordination mode of the bridge; there are two $ClCH_2COO$ ligands coordinated in a *syn-syn* fashion, and a third carboxylate ligand, $\mu_{1,1}$-$ClCH_2COO$, which provides a new interaction pathway, through only one oxygen atom. Unfortunately, the number of compounds described in the literature with this kind of structure it is limited,[32−36] and to the best of our knowledge, a magnetic study was reported for only three of them.[32,33,35] The compound $[Mn_3(\mu\text{-}AcO)_6(BiC_6H_4$-

[a] Mn_t = Mn terminal; O_b = O_1 of the $\mu_{1,1}$-carboxylate; Mn_c = Mn central; O_t = the other O of the $\mu_{1,1}$-carboxylate; α = $Mn_tO_bMn_c$ angle. [b] With the same Hamiltonian and J_{13} = 0; *: this work. [c] pybim = *N*-[2-(2-pyridylmethyleneamino)phenyl]pyridine-2-carboxamide. [d] BiPhMe = 2-[methoxy(1-methyl-1*H*-imidazol-2-yl)phenylmethyl]-1-methyl-1*H*-imidazole. [e] d_{anti} = $d(Mn-O_{anti})$; d_{syn} = $d(Mn-O_{syn})$; α = $O_{anti}MnO_{syn}$ angle; β = $MnO_{syn}C$ angle; γ = $MnO_{anti}C$ angle. [f] tpa = tris(2-pyridylmethyl)amine.

$Me)_2]$[33] presents different isomeric forms with different Mn−O distances; in general $d(Mn_t-O_b) \approx d(Mn_c-O_b)$. For **1**, $[Mn_3(\mu\text{-}AcO)_6(pybim)_2]$[35] and $[Mn_3(\mu\text{-}AcO)_6(bpy)_2]$[32] (Table 4), $d(Mn_t-O_b) < d(Mn_c-O_b)$ and is markedly different from $d(Mn_t-O_t)$. The magnetic interaction for all of these compounds is of the same order. Normally, a carboxylate group that is coordinated in a *syn-syn* fashion gives a moderate antiferromagnetic coupling.

Compounds **2** and **3** have the same kind of bridge, two $ClCH_2COO$ groups coordinated in a *syn-anti* fashion; however, while the one-dimensional compound shows a certain antiferromagnetic interaction, in the dinuclear complex this interaction is practically zero. The magnetic interaction through a *syn-anti* carboxylate bridge should be very sensitive to small structural changes. Figure 5 shows a schematic representation of the relative orientations of two magnetic orbitals for these compounds. The Mn···Mn interaction could be affected by several factors: the Mn−O distance, the $O_{anti}-Mn-O_{syn}$ angle (α), the $Mn-O_{syn}-C$ angle (β), the $Mn-O_{anti}-C$ angle (γ) and also by the non-planarity of the bridge (τ). Small changes in these parameters could change the overlap through the carboxylate group. Table 4 shows some structural parameters for these compounds in comparison with analogous compounds described in the literature. For the one-dimensional compound **3**, a major difference between d_{anti} and d_{syn} can be observed, probably due to the fact that *trans* to O_{anti} there is another O_{anti} of the chain. The same trend could be observed in the analogous compound with $3\text{-}ClC_6H_4COO$,[19] but the angle around O_{syn} is large, and a greater antiferromagnetic interaction was found.

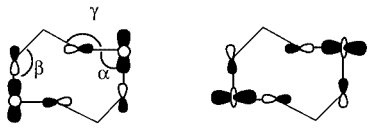

Figure 5. Relative orientation of two manganese(II) magnetic orbitals and their interaction through the carboxylate bridges with a *syn-anti* conformation in the $[Mn_2(\mu\text{-}ClCH_2COO)_2]^{2+}$ core (dinuclear compound **2** and one-dimensional compound **3**)

Compounds **2** and **3** have similar α angles, but they show some differences in the β and γ angles. The dinuclear compound presents a set of larger angles (α, β, γ) than the chain, in spite of the fact that the O−C−O angles are similar. For the dinuclear complex **2**, where d_{syn} is similar to d_{anti}, the angles around O_{syn} (β) and O_{anti} (γ) are also similar, while for $[Mn_2(\mu\text{-}PhCOO)_2(bpy)_4]^{2+}$ [19] β > γ, and for $[Mn_2(\mu\text{-}AcO)_2(tpa)_2]^{2+}$ [22] β is only slightly greater than γ, and d_{anti} and d_{syn} are markedly different. Both compounds show an antiferromagnetic interaction, in contrast to that found in compound **2** where no magnetic coupling is observed. The major asymmetry could contribute to a major overlap through the bridge.

EPR Spectra

The three compounds studied here show weak Mn···Mn interactions, so even at low temperatures several spin states may be populated. This may lead to many possible transitions, and thus to a complicated EPR spectrum.[30] At room temperature all the complexes show a broad signal centered at $g \approx 2$. However, at 4 K, the spectrum of each compound is quite different (Figure 6, solid line).

The spectrum at room temperature for the trinuclear complex (compound **1**) presents a broad signal (ΔH_{pp} = 1055 G) centered at $g \approx 2$. The intensity of this signal decreases with temperature. At 60 K, the shape of the spectrum is the same as the shape of the spectrum at room temperature. Variable-temperature EPR spectra are shown in Figure 7. At 17 K, the spectrum shows a new intense and broad band at $g \approx 3.3$, and another less intense feature at $g \approx 8$, which is already present at 40 K. At 4 K, the spectrum becomes complicated; the signal at $g \approx 2$ almost disappears, while many signals at high field and the more intense signals at low field ($g \approx 6.7$ and $g \approx 4$) remain. This spectrum is similar to that reported for the acetate[32] and chlorobenzoate[19] analogues. Considering the J value of

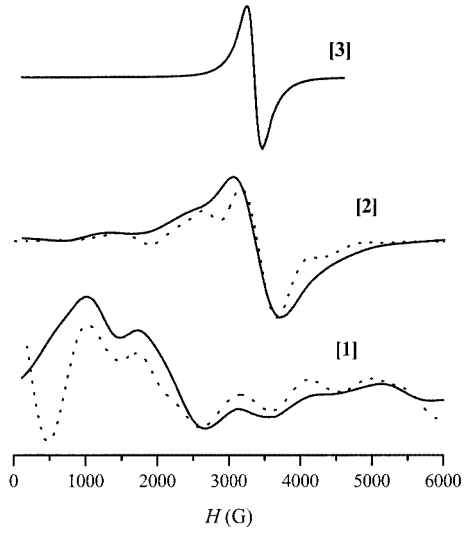

Figure 6. Comparative X-band EPR spectra of a microcrystalline sample at 4 K of complexes $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**), $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**), and $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**) (solid line); simulated spectra of complexes **2** and **1** (dashed line)

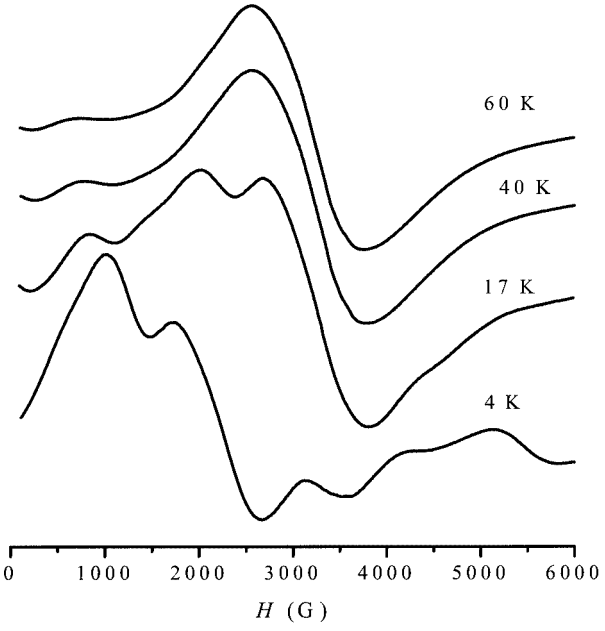

Figure 7. Variable-temperature X-band EPR spectra of $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**)

-3.82 cm^{-1}, at 4 K only the ground state ($S_T = 5/2$) may be populated. For the simulation of the experimental spectrum only the ground state was considered, and therefore, the possible transitions between the ground state and the excited states were not considered for the simulation. In spite of this approach, a quite good simulation has been obtained with $D = -0.16$ cm^{-1}, $E = -0.015$ cm^{-1}, $g_x = 2.20$, $g_y = 1.98$, $g_z = 1.95$ and a bandwidth of 270 G. (Figure 6, dashed line).

The EPR spectra at different temperatures for the dinuclear complex (compound **2**) show a broad signal centered at $g \approx 2$. Variable-temperature EPR spectra are shown in

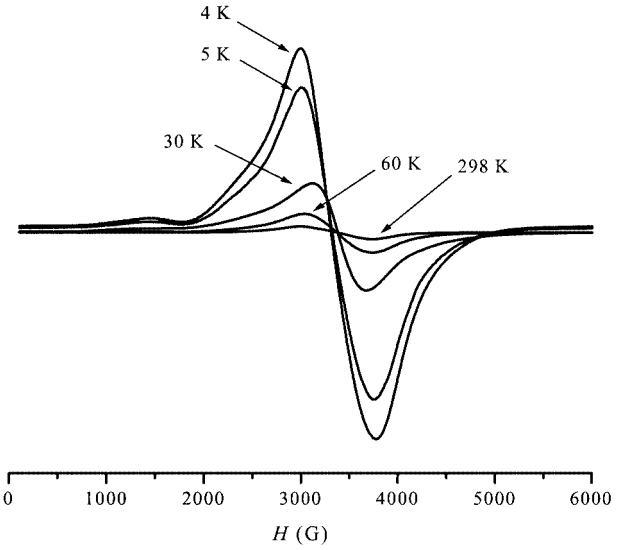

Figure 8. Variable-temperature X-band EPR spectra of $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (**2**)

Figure 8. The intensity of the signal increases when the temperature decreases. At 4 K, the broad signal centered at $g \approx 2$, with a $\Delta H_{pp} = 650$ G, is flanked by one feature at $g \approx 2.8$ and another at $g \approx 5.2$. Considering the fact that the Mn···Mn interaction is negligible, the spectrum can be considered to be that of an isolated Mn^{2+} ion. A good simulation could be obtained with $D = -0.045$ cm^{-1}, $E = -0.004$ cm^{-1}, and an isotropic $g = 2.06$ (Figure 6, dashed line). For the simulation of the spectrum, a bandwidth of 200 G was considered. With a bandwidth of 300 G a superimposable spectrum could be obtained. The variation in the intensity of the spectrum with temperature is due to the ZFS. For both simulations (for compounds **1** and **2**), a spin state of $S = 5/2$ was considered. For compound **2**, with no coupling between the Mn^{2+} ions, the ZFS parameters correspond to each Mn center of the dinuclear complex. The distortion around the metal ion is small, and the D and E values are also small. For compound **1**, the spin state of $S = 5/2$ is as a result of the Mn···Mn interaction in the trinuclear complex. This system shows a central Mn^{2+} ion, with a regular octahedral geometry, and two terminal Mn^{2+} ions with a greatly distorted geometry. The ZFS parameters include the single-ion ZFS for each manganese center, and the ZFS arising from spin-coupling. In this case, the values for D and E are greater than for the dinuclear complex where the distortion is smaller.

The spectrum of the chain (complex **3**) presents a single band centered at $g \approx 2$ at room temperature, with a peak-to-peak line width of 147 G. The broadness of the band increases at 4 K ($\Delta H_{pp} = 220$ G), and no change in position is observed (Figure 6). This behavior was also observed for the similar compound $[Mn(\mu\text{-}3\text{-}ClC_6H_4COO)_2(bpy)]_n$.[19]

Conclusion

With the same carboxylate bridging (chloroacetate) it was possible to obtain complexes of different nuclearity; dinuc-

lear, trinuclear and one-dimensional compounds. There are two factors that influence these results: the bidentate blocking ligand (phenanthroline or bipyridine), and the presence of perchlorate anions in the solution. The trinuclear complex was only obtained with the less rigid ligand, bipyridine, and surprisingly, it was not possible to obtain the ionic dinuclear complex with this amine. With the phenanthroline ligand, a neutral one-dimensional compound and the ionic dinuclear compound were obtained. The trinuclear complex **1** shows two *syn-syn* $ClCH_2COO$ bridges and one $\mu_{1,1}$-$ClCH_2COO$ bridge; this kind of bridge was also found in the arginase.[3] The observed Mn···Mn distance for **1** (3.624 Å) is slightly greater than for the arginase (3.3 Å), and very close to the Mn···Mn distance of the manganese-substituted ribonucleotide reductase (ca. 3.6 Å).[49] On the other hand, the dinuclear complex **2** and the one-dimensional compound **3** show greater values for the Mn···Mn distances (ca. 4.6 Å).

The magnetic measurement showed an antiferromagnetic Mn···Mn interaction. This antiferromagnetism is very small due to the presence of only carboxylate bridges, and the *J* value depends on the number and the coordination mode of the carboxylate bridges: $|J|_{trinuclear} > |J|_{chain} > |J|_{dinuclear}$. For compound **2**, with $J \approx 0$, the set of *d*(Mn−O), α, β, γ, and τ can probably give a small overlap through the bridge, then $J_{AF} \approx J_F$.

It is possible to differentiate the trinuclear complex **1** from the other two complexes **2** and **3** from their EPR spectrum at 4 K. The simulation of the EPR spectrum at this temperature for both compounds **1** and **2** give a *E*/*D* ratio of ca. 0.09. However, for the trinuclear complex **1**, the ZFS parameters *D* and *E* are bigger than for the dinuclear complex **2**.

Experimental Section

Syntheses: All manipulations were performed under aerobic conditions. Reagent grade solvents were used without further purification and organic reagents were used as received. $Mn(ClCH_2COO)_2{\cdot}2H_2O$ was synthesized by the reaction of $MnCO_3$ and $ClCH_2COOH$ in hot water. After several hours, the solution was filtered and the solvent was removed by evaporation giving a pale pink precipitate of the desired product. Yield ca. 70%. $C_4H_8Cl_2MnO_6$ (277.95): calcd. C 17.28, H 2.90; found C 17.5, H 2.9. ***Caution:*** Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of material should be prepared, and it should be handled with caution.

$[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (1): This compound was synthesized by adding an ethanolic solution of 2,2′-bipyridine (0.18 g, 1.2 mmol) to a solution of $Mn(ClCH_2COO)_2{\cdot}2H_2O$ (0.50 g, 1.8 mmol) in EtOH (30 mL) and H_2O (1 mL). The resulting mixture was left undisturbed at room temperature for several days. Yellow crystals suitable for X-ray determination were formed. Yield 0.36 g (ca. 58%). $C_{32}H_{28}Cl_6Mn_3N_4O_{12}$ (1038.11): calcd. C 37.02, H 2.72, N 5.40; found C 37.5, H 2.8, N 5.5. IR (cm^{-1}): $\tilde{\nu}$ = 1631 (vs), 1446 (m), 1407 (s), 1249 (m), 1242 (m), 795 (m), 769 (m).

$[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2$ (2): $Mn(ClCH_2COO)_2{\cdot}2H_2O$ (0.42 g, 1.5 mmol) and sodium perchlorate monohydrate (0.21 g, 1.5 mmol) were mixed in $EtOH/CH_2Cl_2$ (1:1, 50 mL). 1,10-Phenanthroline (0.54 g, 3.0 mmol), dissolved in the same solvent mixture, was then added to the solution, which immediately turned yellow. The solution was left undisturbed in a refrigerator for several days. Yellow crystals, stable only at low temperatures, were formed. Yield 0.73 g (ca. 80%). $C_{52}H_{36}Cl_4Mn_2N_8O_{12}$ (1216.58): calcd. C 51.34, H 2.98, N 9.21; found C 50.6, H 3.1, N 9.0 . IR (cm^{-1}): $\tilde{\nu}$ = 1650 (vs), 1624 (vs), 1520 (s), 1430 (vs), 1150 (vs), 1130 (vs), 1095 (vs), 854 (vs), 736 (vs), 643 (s).

$[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (3): This compound was synthesized by mixing ethanolic solutions (total volume: 60 mL) of $Mn(ClCH_2COO)_2{\cdot}2H_2O$ (0.50 g, 1.8 mmol) and 1,10-phenanthroline (0.32 g, 1.8 mmol). The pale yellow precipitate formed was filtered and washed in ether. Recrystallization from $EtOH/H_2O$ (9:1) yielded pale yellow crystals suitable for X-ray determination. Yield 0.64 g (ca. 84%). $C_{16}H_{12}Cl_2MnN_2O_4$ (422.12): calcd. C 45.53, H 2.87, Cl 16.80, N 6.64; found C 44.9, H 2.8, Cl 16.5, N 6.5. IR (cm^{-1}): $\tilde{\nu}$ = 1657 (vs), 1614 (vs), 1524 (m), 1413 (s), 1250 (m), 848 (m), 775 (m), 735 (m), 700 (m).

Spectral and Magnetic Measurements: Infrared spectra (4000−400 cm^{-1}) were recorded from KBr pellets with a Perkin−Elmer 380-B spectrophotometer. Magnetic susceptibility measurements were carried out using a Faraday-type magnetometer (MANICS DSM8) equipped with an Oxford CF 1200 S helium continuous-flow cryostat working in the temperature range 4−300 K. Diamagnetic corrections were estimated from Pascal Tables. The agreement factor considered to fit the experimental data to the corresponding equation is defined as $R = \Sigma(Y_i^{exp} - Y_i^{cal})^2/\Sigma(Y_i^{exp})^2$. The best fit corresponds to the minimum value of *R*. EPR spectra were recorded at X-band (9.4 GHz) frequencies using a Bruker ESP-300E spectrometer, from room temperature to 4 K.

EPR Simulation: A program written by H. Weihe[50] was used to simulate powder EPR spectra. The simulation was performed by generating the energy matrix for each orientation of the molecule relative to the magnetic field. The resonance condition for each transition was then found by successive diagonalizations and iterations of the energy matrix, and the relative intensities were calculated from the eigenvectors multiplied by the appropriate Boltzmann factor at 4 K. Summation of all the transitions over the whole space, where each transition is represented by a differentiated Gaussian curve, gives the simulated spectrum. The spin Hamiltonian used for the simulation include the ZFS parameters *D* and *E*.

Crystallographic Data Collection and Refinement: Suitable single crystals of $[Mn_3(\mu\text{-}ClCH_2COO)_6(bpy)_2]$ (**1**, needle, yellow, dimensions 0.50 × 0.10 × 0.10 mm), $[Mn_2(\mu\text{-}ClCH_2COO)_2(phen)_4](ClO_4)_2{\cdot}2CH_2Cl_2$ (**2**, prism, yellow, dimensions 0.50 × 0.30 × 0.25 mm) and $[Mn(\mu\text{-}ClCH_2COO)_2(phen)]_n$ (**3**, prism, yellow, dimensions 0.50 × 0.30 × 0.20 mm) were used for the structure determination. X-ray data were collected using a Bruker SMART CCD area detector single-crystal diffractometer, with graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å), using the -ω scan method. A total of 1271 frames of intensity data were collected for each compound. The first 50 frames were recollected at the end of data collection to monitor for decay. The integration process yielded a total of 6812 reflections for **1**, 8061 for **2**, and 4543 for **3**, of which 4855 [*R*(int) = 0.0287], 5123 [*R*(int) = 0.0195], and 2059 [*R*(int) = 0.0191], respectively, were independent. Absorption corrections were applied using the SADABS[51] program (maximum and minimum transmission coefficients, 0.875 and 0.548 for **1**; 0.814 and 0.674 for **2**; and 0.765 and 0.602 for **3**). The structures were solved using the Bruker SHELXTL-PC[52] software by direct

[a] $R1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $wR2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$.

methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were included in calculated positions and refined in the riding mode. The Cl(2) atom in compound **1** was refined in two different positions with partial occupation factors of 0.63 and 0.37. For **1**, convergence was reached at a final $R1 = 0.0593$ [for $I > 2\sigma(I)$], $wR2 = 0.1689$ [for all data], 269 parameters, with allowance for the thermal anisotropy for all non-hydrogen atoms. The weighting scheme employed was $w = [\sigma^2(F_o^2) + (0.1032 \cdot P)^2]$, $P = (|F_o|^2 + 2|F_c|^2)/3$; and the goodness of fit on F^2 was 1.001 for all observed reflections. For **2**, convergence was reached at a final $R1 = 0.0650$ [for $I > 2\sigma(I)$], $wR2 = 0.2125$ [for all data], 379 parameters, with allowance for the thermal anisotropy for all non-hydrogen atoms. The weighting scheme employed was $w = [\sigma^2(F_o^2) + (0.1377 \cdot P)^2 + (0.9991 \cdot P)]$, $P = (|F_o|^2 + 2|F_c|^2)/3$; and the goodness of fit on F^2 was 1.043 for all observed reflections. For **3**, convergence was reached at a final $R1 = 0.0375$ [for $I > 2\sigma(I)$], $wR2 = 0.1027$ [for all data], 114 parameters, with allowance for the thermal anisotropy for all non-hydrogen atoms. The weighting scheme employed was $w = [\sigma^2(F_o^2) + (0.0562 \cdot P)^2 + (1.2574 \cdot P)]$, $P = (|F_o|^2 + 2|F_c|^2)/3$; and the goodness of fit on F^2 was 1.065 for all observed reflections. Crystal data and details on the data collection and refinement are summarized in Table 5. CCDC-156272 for **1**, -156273 for **2**, and -156274 for **3** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Mixed Chloride/Azide Complexes of Arsenic and Antimony

Thomas M. Klapötke,*[a] Heinrich Nöth,[a][‡] Thomas Schütt,[a] and Max Suter[a][‡]

Keywords: Azides / Antimony / Arsenic / Lewis acids / Lewis bases / Density functional calculations

The Lewis acid base complexes $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2 pyridine were prepared. The products formed were characterised by Raman, IR and NMR spectroscopy. Density functional theory (B3LYP) was applied to calculate structural and vibrational data. Vibrational assignments of the normal modes for the isolated compounds were made on the basis of their vibrational spectra in comparison with computational results. The molecular structures of both complexes were determined by X-ray diffraction. The bonding situation of these Lewis acid base complexes is discussed on the basis of NBO analyses, which were performed, on the crystallographic data.

Introduction

Mixed halogen compounds of arsenic and antimony are known few in number. A compound does exist in the +5 oxidation state with the empirical formula $AsCl_2F_3$, which has an ionic structure with the composition $[AsCl_4][AsF_6]$ in the solid state.[1] This salt is a synthon for the preparation of chlorofluoroarsoranes. The mixed chlorofluoroarsorane $AsCl_4F$ was synthesised by vacuum thermolysis of $[AsCl_4][AsF_6]$.[2] $AsCl_2F_3$ [3] and $AsClF_4$ [4] were formed by intermolecular ligand exchange in the gas phase at 173 K. These compounds are extremely unstable due to dismutation under halogen exchange in the respective halides.[5] $AsCl_2F_3$ is the only structurally characterised mixed halogen compound of arsenic. The gas-phase structure of $AsCl_2F_3$ has been determined experimentally by electron diffraction.[5]

$AsCl_2Br$ and $AsClBr_2$ are the only reported mixed halogen compounds of arsenic in the +3 oxidation state. Müller et al. reported on the vibrational spectroscopic investigations of these mixed bromochloroarsanes.[6,7] The isolation of these compounds as pure substances was not possible due to fast dismutation into the respective trihalides.[6,8]

Mixed halogen/azide compounds in the +3 oxidation state are only reported for phosphorus. Dillon et al. characterised PX_2N_3 and $PX(N_3)_2$ (X = Cl, Br) by ^{31}P NMR spectroscopy.[9] The corresponding fluoro compound (PF_2N_3) could be synthesised by the reaction of PF_2X (X = I, Br) with MN_3 (M = Na, Li)[10] or PF_2Cl with NaN_3.[11]

$SbCl_4N_3$ is the only ternary synthesised[12] and structurally characterised antimony(V) azide species. X-ray diffraction revealed that this compound shows a dimeric structure in the solid state.[13]

Recently, we reported on the first structurally characterised ternary halogen/azide compound of antimony, $SbCl(N_3)_2$.[14] In this paper we report about the synthesis, the spectroscopic properties, the crystal structures and NBO (Natural Bond Orbital) analyses of the first mixed halide pseudohalide arsenic(III) species as its pyridine adduct, $AsCl(N_3)_2$·pyridine, as well as the monoazido-substituted antimony(III) species as its pyridine adduct, $SbCl_2N_3$·2pyridine.

Results and Discussion

Syntheses and Properties

The synthesis and characterisation of mixed halogen azide compounds of arsenic and antimony in the +3 oxidation state proved to be very difficult. On the one hand the compounds tend to dismutate easily,[6,8] on the other hand there is no suitable means of characterising such compounds. Neither the ^{75}As nor the ^{121}Sb nuclei can be detected by NMR spectroscopy in the +3 oxidation state due to the large quadrupole moment of these nuclei.[15]

Reactions of MF_3 (M = As, Sb) with stoichiometric amounts of AgN_3, NaN_3 or $TMS-N_3$ seemed to be especially suited for the synthesis of mixed halogen azide species of arsenic and antimony. These reactions were monitored by ^{14}N and ^{19}F NMR spectroscopy. It was shown, that in the ^{14}N NMR spectra resonances occurred, which could be assigned to covalently bound azide species. The ^{19}F NMR spectra, however, showed resonances, which could be assigned to AsF_3 and SbF_3. It thus follows that intermediary formed mixed fluoride/azide species dismutate easily into the trifluorides and triazides, respectively.

[‡] X-ray structure determination

Raman spectroscopy also shows that the reactions of MX_3 (M = As, Sb; X = Br, I) with AgN_3, NaN_3 or $TMS-N_3$ dismutate in the respective trihalides and triazides.

Reactions of arsenic(III) and antimony(III) chloride with $TMS-N_3$ yielded the expected compounds. Admittedly, the compounds could only be crystallised as Lewis acid base adducts with pyridine. The compounds were synthesised according to Equations (1) and (2).

$$AsCl_3 + 2\ TMS\text{-}N_3 + py \xrightarrow{CH_2Cl_2} AsCl(N_3)_2 \cdot py + 2\ TMS\text{-}Cl \quad (1)$$

$$SbCl_3 + TMS\text{-}N_3 + 2\,py \xrightarrow{CH_2Cl_2} SbCl_2N_3 \cdot 2py + TMS\text{-}Cl \quad (2)$$

NMR Properties

$AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine have been characterised by ^1H, ^{13}C and ^{14}N NMR spectroscopy. The most useful method for the characterisation of covalently bonded azides is undoubtedly ^{14}N NMR spectroscopy. For covalently bound azide species three well-resolved resonances can be found in the ^{14}N NMR spectra and assignment of the individual resonances to N_α, N_β and N_γ (connectivity: $M-N_\alpha-N_\beta-N_\gamma$) was made on the basis of arguments given in the literature.[16−18] The N_β atom of $AsCl(N_3)_2$·pyridine shows a very sharp resonance at δ = −139 ppm, the N_γ atom at δ = −181 ppm and the N_α atom a very broad resonance at δ = −269 ppm; $SbCl_2N_3$·2pyridine shows the analogous resonances at δ = −143 (N_β), −172 (N_γ) and −275 ppm (N_α). In addition to these resonances, the spectra show resonances at δ = −164 ppm [$AsCl(N_3)_2$·pyridine] and δ = −157 ppm ($SbCl_2N_3$·2pyridine). These resonances can be assigned to the nitrogen atoms of the pyridine rings. The resonances are shifted significantly towards higher field compared to free pyridine (pyridine: δ = −64 ppm).[19] Not only do the compounds form stable adducts in the solid state but also in solution. The ^1H and ^{13}C NMR spectra show the expected resonances for pyridine (see Exp. Sect.).

Vibrational Spectra

Table 1 summarises selected computed and experimentally observed IR and Raman frequencies for $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine. The recorded vibrational data agree well enough with our theoretical calculations (B3LYP) to allow assignment. It should be kept in mind that the computations were carried out for single, isolated (gas-phase) molecules. There may well be significant differences between gas-phase and solid-state spectra.

The measured IR and Raman spectra clearly show the presence of azide ligands bonded covalently to arsenic or antimony, as demonstrated by the simultaneous appearance of the antisymmetric (ca. 2100 cm^{-1}) and the symmetric (1250 cm^{-1}) azide stretching mode in both spectra (IR and Raman) and the presence of strong As−N and Sb−N stretching bands at ca. 386 cm^{-1} up to 452 cm^{-1} again in the IR and the Raman spectra. Based on our calculations the deformation vibration of the azide group should be split into four signals due to "in phase" and "out of phase" coupling of the "in plane" (637−670 cm^{-1}) and "out of plane" (567−595 cm^{-1}) deformation. The δN_3 "in phase" vibration appears at higher frequencies compared to the δN_3 "out of phase" vibration.

The symmetric Sb−Cl stretching vibration of $SbCl_2N_3$·2pyridine shows a signal at 326 cm^{-1} in the Raman spectrum and the antisymmetric stretching vibration shows a signal at 285 cm^{-1}. Both vibration modes are therefore shifted significantly to lower frequencies compared to the symmetric and antisymmetric Sb−Cl stretching modes of the parent $SbCl_3$ (ν_{as}: Sb−Cl 381 cm^{-1}; ν_s: Sb−Cl 359 cm^{-1}).[20] The Sb−Cl stretching modes of $SbCl(N_3)_2$ appear at 347 cm^{-1}.[14] These signals are less shifted towards

[a] In parentheses: IR intensity [in km mol^{-1}]. [b] In parentheses: rel. Raman intensity. [c] The distinction "*in/out of phase*" is not applicable for $SbCl_2N_3$·2pyridine. [d] The distinction "*symmetric/antisymmetric*" is not applicable for $SbCl_2N_3$·2pyridine. [e] All calculated frequencies are unscaled.

lower frequencies. Therefore, the Sb−Cl bond lengths should decrease in the following order: $SbCl_2N_3$·2pyridine > $SbCl(N_3)_2$ > $SbCl_3$. Increasing Sb−Cl bond lengths should cause decreasing Sb−Cl stretching modes towards lower frequencies. A similar shift of the As−Cl stretching mode could be observed for $AsCl(N_3)_2$·pyridine in the Raman spectrum. The As−Cl stretching mode shows a band at 287 cm^{-1} and is therefore significantly shifted to lower frequencies, by about 120 cm^{-1}, compared to the symmetric and antisymmetric As−Cl stretching modes of the parent $AsCl_3$ [20] For this, the As−Cl bond lengths should be longer compared with the parent, $AsCl_3$. This presumption could be verified by X-ray determination in both cases [see crystal structure of $AsCl(N_3)_2$·pyridine].

The covalent donor−acceptor properties of $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine can be obtained by signals assigned to the As− and Sb−N_{py} stretching and deformation vibrations. $AsCl(N_3)_2$·pyridine shows a band at 216 cm^{-1} assigned to the As−N_{py} stretching mode. The deformation mode appears at 139 cm^{-1}; $SbCl_2N_3$·2pyridine shows the analogous stretching mode at 166 cm^{-1} and the analogous deformation mode at 108 cm^{-1} in the Raman spectrum.

Crystal Structure of $AsCl(N_3)_2$·pyridine

$AsCl(N_3)_2$·pyridine crystallises in the triclinic space group $P\bar{1}$ with two molecules in the unit cell (Figure 1). The crystallographic data and refinement details for this compound are summarised in the Exp. Sect. The experimentally observed and calculated bond lengths and bond angles are compiled in Table 2.

The arsenic atom is surrounded in a Ψ-trigonal-bipyramidal fashion by three nitrogen atoms and one chlorine atom. Both azide ligands (N2−N3−N3 and N4−N5−N6) are in an equatorial position. The axial positions are occupied by the coordinating pyridine molecule and the chlorine atom. The free lone pair of the arsenic atom occupies, in accordance with the predictions of the VSEPR model,[21] the third equatorial position, due to the fact that the lone pair requires more space compared to the pyridine molecule and the chlorine atom. The experimentally observed and calculated (B3LYP) bonding parameters agree with this predicted Ψ-trigonal-bipyramidal arrangement of the ligands (Table 2).

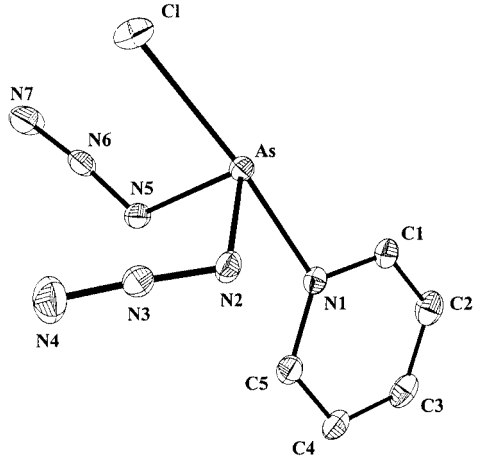

Figure 1. Molecular structure of $AsCl(N_3)_2$·pyridine (hydrogen atoms are omitted for clarity); the thermal ellipsoids represent a 25% probability

N(3)−N(4)	1.138(4)	1.140
N(5)−N(6)	1.185(4)	1.235
N(6)−N(7)	1.149(4)	1.140
N(1)−As−N(2)	84.1(1)	79.9
N(1)−As−N(5)	85.9(1)	79.9
Cl−As−N(2)	91.35(8)	97.2
Cl−As−N(5)	91.56(9)	97.2
N(2)−As−N(5)	94.9(1)	99.8
Cl−As−N(1)	174.51(6)	175.4
As−N(2)−N(3)	117.6(2)	119.7
As−N(5)−N(6)	118.0(2)	119.7
N(2)−N(3)−N(4)	175.7(3)	175.0
N(5)−N(6-N(7)	174.2(3)	175.0

The molecule does not show any special symmetry within the crystal. The calculations at the B3LYP level of theory predict an ideal C_s symmetry for this molecule in the gas phase. The predicted mirror plane can also almost be found in the crystal structure. The shape of this molecule agrees very well with the shape of the Lewis acid base adduct $AsCl_3$·NMe_3.[22]

The calculated bonding parameters of the azide ligands are in good agreement with the experimentally observed As−N and N−N bond lengths as well as with the As−N−N and N−N−N bond angles (Table 2). The molecule shows a relatively long bond between the arsenic and chlorine atom [2.4848(9) Å], whereas the coordinative bond between the arsenic atom and the nitrogen molecule of the pyridine ring is very short [As−N1 2.158(3) Å]. The strong coordination of the very strong Lewis base pyridine at the arsenic centre weakens the As−Cl bond. This lengthens the As−Cl bond, which is significantly longer than it is in the cationic species $AsCl_4^+$ [2.042(3)−2.0545(9) Å][1,23] or binary $AsCl_3$ [2.17(2) Å].[24]

The calculations show a coordinative bond (2.459 Å) between the arsenic atom and the nitrogen atom of the pyridine ring, which is weaker in the gas phase compared to the solid state [2.158(3) Å]. Due to the weaker interaction between the Lewis acid $AsCl(N_3)_2$ and the Lewis base in the gas phase, the calculated As−Cl bond shows a normal bond length (2.296 Å).

It should be noted, that structures of such weakly bound systems may differ considerably between the gas phase and the solid state.[25,26]

Crystal Structure of $SbCl_2N_3$·2pyridine

$SbCl_2N_3$·2pyridine crystallises in the orthorhombic space group *Pbca* with eight molecules in the unit cell and the lattice parameters a = 6.5566(5), b = 13.635(1) and c = 30.901(2) (Figure 2). The experimentally observed and calculated (B3LYP) bond parameters are summarized in Table 3.

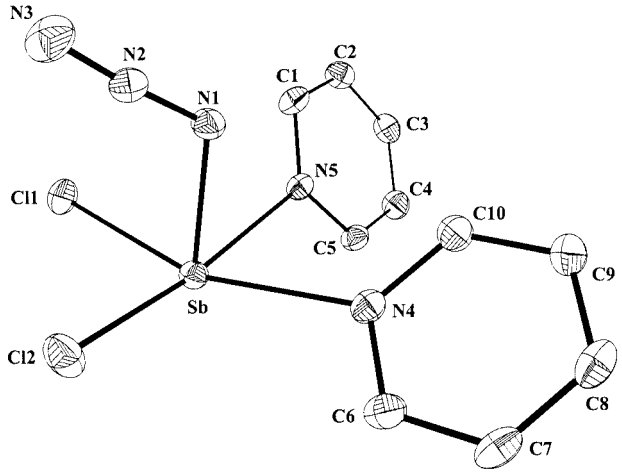

Figure 2. Molecular structure of $SbCl_2N_3$·2pyridine (hydrogen atoms are omitted for clarity); the thermal ellipsoids represent a 25% probability

The crystal structure reveals that $SbCl_2N_3$·2pyridine forms isolated molecules without intermolecular contacts, in which the antimony atom is surrounded, in an Ψ-octahedral or square-pyramidal fashion by three nitrogen atoms, two chlorine atoms and a free lone pair. The pyridine molecules and the chlorine atoms occupy the edges of an almost ideal planar plane. The N1 atom of the azide ligand occupies the top of the square pyramid. The experimentally observed and calculated bond parameters prove that the arrangement of the ligands is Ψ-octahedral (ca. 90°, Table 3).

The structural parameters obtained for the azide unit compares well with the calculated parameters. The Sb−N1 bond that is 2.084(2) Å, along with the N−N bond lengths within the azide unit, are in agreement with Sb−N and N−N bond lengths of other antimony azide compounds.[13,27−30]

The average Sb−Cl bond lengths are 2.5174 Å. Compared to the Sb−Cl bond lengths of $SbCl_3$ (2.36 Å)[31] these bond lengths are noticeably longer. Similar Sb−Cl bond lengths could only be observed in the bridging $Sb_2Cl_8^{2-}$ anions[32,33] or the Lewis acid base adduct $SbCl_3$·NH_2Ph[34] (2.52 Å).

The average Sb−N bond lengths between the antimony atom and the nitrogen atom of the coordinating pyridine molecule are 2.429 Å, leading to a relatively weak coordination of the pyridine molecules.

NBO Analyses

The molecular adduct complexes of arsenic and antimony trihalides or pseudohalides with pyridine are typical Lewis acid−base complexes. One of the major characteristics of these adducts is the total charge transfer q_{ct} between the donor molecule (pyridine) and the acceptor molecules [$AsCl(N_3)_2$ and $SbCl_2N_3$]. To obtain further insight into the donor−acceptor interaction we carried out NBO analyses on the data of the crystal structures of the two complexes.[35,36]

The NBO analyses of the adduct complexes $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine show fairly polarised molecules. Table 4 summarises the NPA (Natural Population Analysis) partial charges and the total amount of transferred charge in both adducts.

Table 4. NPA partial charges (e) for $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine

	$AsCl(N_3)_2$·pyridine	$SbCl_2N_3$·2 pyridine
M (M = As, Sb)	1.35	1.46
Cl[a]	−0.55	−0.56
N_{Py}[b]	−0.53	−0.53
N_α[c]	−0.68	−0.75
N_β[c]	0.24	0.24
N_γ[c]	−0.07	−0.09
q_{ct}	0.20	0.27

[a] Average of two chlorine atoms in $SbCl_2N_3$·2pyridine. [b] Average of two nitrogen atoms of the pyridine rings in $SbCl_2N_3$·2pyridine. [c] Average of the equivalent azide nitrogen atoms in $AsCl(N_3)_2$·pyridine.

The total amount for the charge transfer q_{ct} in these donor−acceptor complexes from the pyridine molecules to the Lewis acids [$AsCl(N_3)_2$ and $SbCl_2N_3$] was found to be 0.20 electrons for $AsCl(N_3)_2$·pyridine and 0.27 electrons for $SbCl_2N_3$·2pyridine. This result is in good agreement with the concept of +I and −I effects.

In $SbCl_2N_3$·2pyridine 0.13 electrons are transferred from one pyridine molecule and 0.14 electrons are transferred from the other pyridine molecule to the antimony centre. Therefore, the donor−acceptor interaction of $SbCl_2N_3$·2pyridine is much weaker than in $AsCl(N_3)_2$·pyridine. This is in good agreement with the experimentally obtained $As-N_{py}$ and $Sb-N_{py}$ bond lengths. The $As-N_{py}$ bond is extremely short [2.158(3) Å] and leads to a very strong interaction between the pyridine molecule and the $AsCl(N_3)_2$ unit. The average $Sb-N_{Py}$ bond lengths are noticeably longer (2.429 Å), pointing to a weaker interaction.

In addition, the NBO analyses at the B3LYP level of theory show that within the azide units, the charge distribution is fairly polarised. The N_α atoms of the azide unit have an average charge of −0.72 electron, the N_β atoms have an average charge of +0.24 electrons and the terminal N_γ atoms 0.08 electrons (connectivity: $M-N_\alpha-N_\beta-N_\gamma$).

Conclusion

Mixed chloride/azide compounds of arsenic and antimony in the +3 oxidation state could be synthesised. $AsCl(N_3)_2$ and $SbCl_2N_3$ were crystallised as pyridine adducts.

These adducts were characterised by Raman, IR and multinuclear NMR spectroscopy. The structures and normal modes were calculated at the B3LYP level of theory, and compared with experimentally observed data. The agreement between theory and experiment is good. The vibrational spectra of $AsCl(N_3)_2$·pyridine and $SbCl_2N_3$·2pyridine show bands, which can be assigned to the stretching vibrations as well as the deformation vibrations of the $M-N_{py}$ bonds (M = As, Sb).

Both adducts have been characterised by ^{14}N NMR spectroscopy. The ^{14}N NMR spectra show, in addition to three signals which can be assigned to the three different nitrogen atoms of the azide units, signals which can be assigned to the nitrogen atoms of the coordinated pyridine molecules. These resonances are significantly shifted compared to free pyridine.

Adduct structures which represent true minima structures (*NIMAG* = 0) were found for both adducts. The agreement between the calculated and experimentally observed bonding parameters is exceedingly good. The central atoms in $AsCl(N_3)_2$·pyridine are surrounded in a Ψ-trigonal-bipyramidal fashion, those in $SbCl_2N_3$·2pyridine are Ψ-octahedral.

On the basis of the experimentally observed atom coordinates, NBO analyses (B3LYP) have been performed to obtain more insight into the bonding situation of those weakly bonded Lewis acid base adducts. In $AsCl(N_3)_2$·pyridine 0.20 electrons are transferred from the pyridine molecule to $AsCl(N_3)_2$ and in $SbCl_2N_3$·2pyridine 0.27 electrons of both pyridine molecules are transferred to $SbCl_2N_3$. The average interaction of each pyridine molecule is much weaker than that of $AsCl(N_3)_2$·pyridine. This result is reflected in the experimentally observed $M-N_{py}$ bond lengths.

Experimental Section

General Remarks: ***CAUTION:*** Arsenic and antimony azide compounds are toxic and potentially explosive! They may explode violently under various conditions and should be handled only in small amounts with extreme care. The use of safety equipment like leather gloves, leather coat and face-shield is strongly recommended. $AsCl_3$[37] was prepared by literature methods and freshly distilled prior to use. Commercially available $SbCl_3$ (Fluka) was sublimed twice prior to use. Pyridine (Aldrich) and $(CH_3)_3SiN_3$ (Aldrich) were used as received. CH_2Cl_2 was dried by standard methods and freshly distilled prior to use. All the compounds reported here are moisture sensitive. Consequently, all manipulations were carried out under dinitrogen using Schlenk-techniques. NMR: Jeol EX 400, ^1H (400.0 MHz), ^{13}C (100.0 MHz): chemical shifts refer to δ(TMS) = 0.00 ppm; ^{14}N (28.6 MHz): shifts refer to CH_3NO_2. IR: Nicolet 520 FT-IR (KBr pellets). Raman: Perkin−Elmer FTIR-2000 spectrometer (Nd-Yag Laser: 1064 nm).

[Arsenic(iii) Diazide·Chloride]−Pyridine: $(CH_3)_3SiN_3$ (0.53 mL, 4.0 mmol) was added to a solution of $AsCl_3$ (0.17 mL, 2.0 mmol) in 25 mL of CH_2Cl_2 at 25 °C. After 1 h of stirring at room temperature, pyridine (0.32 mL, 4.00 mmol) was added. The solvent and the resulting $(CH_3)_3SiCl$ were removed in a dynamic vacuum. After recrystallisation from CH_2Cl_2 at −25 °C, colourless crystals were obtained. Yield 0.39 g (71%). IR (KBr): $\tilde{\nu}$ = 3066 (m), 2113 (vs, $\nu_{as}N_3$), 1635 (w), 1600 (s), 1537 (s), 1486 (s), 1447 (vs), 1339 (m), 1257 (vs, ν_sN_3), 1158 (m), 1065 (s), 1036 (s), 1008 (s), 946 (m), 755 (s), 670 (sh, δN_3), 637 (s, δN_3), 567 (m, δN_3), 431 (m, νAsN) cm^{-1}. Raman (66 scans, 150 mW, 180°, 20 °C): $\tilde{\nu}$ = 3073 (3), 2118 (2.5, $\nu_{as}N_3$), 2085 (1.5, $\nu_{as}N_3$), 1606 (1), 1575 (1), 1268 (1, ν_sN_3), 1258 (0.5, ν_sN_3), 1038 (3), 1013 (4), 670 (1.5, δN_3), 647 (1, δN_3), 452 (10, νAsN), 433 (1, νAsN), 287 (2, νAsCl), 265 (2.5, δAsN), 216 (2, νAsN_{py}), 180 (3), 139 (1.5, δAsN_{py}) cm^{-1}. ^1H NMR (CD_2Cl_2, 25 °C): δ = 6.33 (m, 2-H), 7.12 (m, 3-H), 8.22 (d, 1-H) ppm. ^{13}C NMR (CD_2Cl_2, 25 °C): δ = 124.0 (s, C-2), 127.7 (m, C-3), 141.1 (d, C-1) ppm. ^{14}N NMR (CH_2Cl_2, 25 °C): δ = −139 (s, N_β), −164 (s, N_{py}), −181 (s, N_γ), −269 (s, N_α) ppm.

[Antimony(iii) Azide Dichloride]−2Pyridine (2): $(CH_3)_3SiN_3$ (0.26 mL, 2.0 mmol) was added to a solution of $SbCl_3$ (0.456 g, 2.0 mmol) in 25 mL of CH_2Cl_2 at 25 °C. After 1 h of stirring at room temperature, pyridine (0.32 mL, 4.00 mmol) was added. The solvent and the resulting $(CH_3)_3SiCl$ were removed in a dynamic vacuum. After recrystallisation from CH_2Cl_2 at −25 °C, colourless crystals were obtained. Yield 0.52 g (66%). IR (KBr): $\tilde{\nu}$ = 3063 (m), 2136 (m, $\nu_{as}N_3$), 2079 (vs, $\nu_{as}N_3$), 1634 (s), 1608 (s), 1538 (s), 1485 (s), 1389 (w), 1331 (m), 1251 (s, ν_sN_3), 1179 (s, 1054 (s), 1004 (s), 936 (m), 750 (s), 648 (w, δN_3), 594 (s, δN_3), 509 (m) cm^{-1}. Raman (196 scans, 150 mW, 180°, 20 °C): $\tilde{\nu}$ = 3075 (3.5), 2091 (0.5,

$\nu_{as}N_3$), 1602 (2), 1572 (1.5), 1210 (2, ν_sN_3), 1035 (5), 1014 (5), 650 (1.5, δN_3), 386 (2, νSbN), 326 (10, νSbCl), 285 (9, νSbCl), 241 (4, δSbN), 166 (1.5, νSbN_{py}), 108 (3, δSbN_{py}) cm^{-1}. ^1H NMR (CD_2Cl_2, 25 °C): δ = 6.52 (m, 2-H), 7.42 (m, 3-H), 8.32 (d, 1-H) ppm. ^{13}C NMR (CD_2Cl_2, 25 °C): δ = 124.9 (s, C-2), 126.7 (m, C-3), 143.2 (d, C-1) ppm. ^{14}N NMR (CH_2Cl_2, 25 °C): δ = −143 (s, N_β), −157 (s, N_{py}), −172 (s, N_γ), −275 (s, N_α) ppm.

These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Methods: The structures and vibrational data for the reported compounds were calculated using the density functional theory with the program package Gaussian 98.[40] The calculations were carried out at the electron-correlated B3LYP level of theory[41] which includes a mixture of Hartree−Fock exchange with DFT exchange correlation. For C, H, N and Cl a standard 6-31G(d,p) double-zeta basis set was used and for As and Sb a quasi-relativistic pseudopotential (As: ECP28MWB; Sb: ECP46MWB)[42] and a (5s5p1d)/[3s3p1d]-DZ+P basis set.[43] Becke's 3-parameter functional, where the nonlocal correlation is provided by the LYP expression (Lee, Yang, Parr correlation functional), was used which is implemented in Gaussian 98.[40]

Acknowledgments

We are indebted to and thank Dr. M.-J. Crawford for stimulating ideas to start this research. Financial support of this work by the University of Munich and the Fonds der Chemischen Industrie is gratefully acknowledged.

COVER PICTURE

The cover picture shows the [2×2] grid, $[Cu^{1}_{4}(2+2)_{2}]^{4+}$, of four copper(I) ions and two (2+2) Schiff-base macrocycles, which self-assembles when copper(I) ions are used to template the reaction of 3,6-diformylpyridazine with 1,3-diaminopropane. In each case the two parallel strands of the [2×2] grid are linked together in a single (2+2) Schiff-base macrocycle, and the two macrocycles approach each other at right angles to give rise to the perpendicular strands of the grid structure. Thus, the copper(I) ions have distorted tetrahedral geometries, with each macrocycle providing a bidentate donor set at right angles to that supplied by the other macrocycle. Details are discussed in the Microreview by S. Brooker on p. 2535 ff. The cover image was generated by M. Crawford (University of Otago) with Strata Studio Pro (Strata).

Some Copper and Cobalt Complexes of Schiff-Base Macrocycles Containing Pyridazine Head Units[‡]

Sally Brooker[a]

Keywords: N ligands / Schiff bases / Macrocyclic ligands / Electrochemistry / Magnetic properties

The Schiff-base macrocycle L14, formed by the [2+2] condensation of 3,6-diformylpyridazine and 1,3-diaminopropane, has facilitated the preparation of the first extensive family of pyridazine-bridged macrocyclic complexes. The structural, magnetic and electrochemical behaviour of these complexes is of considerable interest. This microreview provides an overview of prior relevant studies and then describes some of the recent copper and cobalt chemistry of the macrocyclic ligand L14.

1. Scope

This microreview covers some aspects of the recent introduction of a new head unit, 3,6-diformylpyridazine (Figure 1), into Schiff-base macrocyclic chemistry,[1,2] focussing on the interesting copper and cobalt chemistry that it has generated to date.[3−11] The reader is referred to earlier reviews on Schiff-base macrocycles for excellent introductions to this general area and in-depth reviews of Schiff-base macrocycles incorporating pyridine- and phenol-based head units (e.g. $L2^{2-}$, Figure 2).[12−17] Recently, an overview of

Sally Brooker was born in Waikari, North Canterbury, New Zealand and educated at Hawarden Area School (1970−1982). She then studied at the University of Canterbury (NZ) and obtained her BSc(Hons) with first class honours in Chemistry in 1986, followed by her PhD with Dr Vickie McKee (now Professor and Head of Inorganic Chemistry at Loughborough University, UK) in 1989. After postdoctoral research, 1990−1991, at Georg-August-Universität Göttingen (Germany) with Professor George M. Sheldrick, she took up a Lectureship at the University of Otago (NZ) where she is now an Associate Professor (Reader). She has taken two periods of sabbatical leave, the first as an Alexander von Humboldt Fellow in Professor Karl Wieghardt's laboratory (MPI für Strahlenchemie) and the second as a Visiting Professor at Queens University of Belfast with Professor Jane Nelson followed by time on a Royal Society of Chemistry Journals Grant with Professors Mike D. Ward and Jon McCleverty and Dr John C. Jeffery at the University of Bristol. Sally was recently awarded the Easterfield Medal by the Royal Society of Chemistry and New Zealand Institute of Chemistry. Her research interests concern the design, synthesis and full characterisation of, primarily paramagnetic, di- and polymetallic complexes of communicating transition metal ions with new polydentate and macrocyclic ligands (http://neon.otago.ac.nz/chemistry/research/sab/sab-res.htm).

MICROREVIEWS: This feature introduces the readers to the author's research through a concise overview of the selected topic. Reference to important work from others in the field is included.

those which incorporate thiophenolate-based head units has been published (e.g. $L3^{2-}$, Figure 2),[18] and macrobicycles, or cryptands, have been comprehensively reviewed.[19]

2. Background

2.1 Acyclic Pyridazine and Phthalazine Ligands

Aromatic nitrogen heterocycles such as diazines have been extensively and effectively employed as bridging ligands.[20] In keeping with this, pyridazine- and phthalazine-based acyclic ligands and their complexes are numerous and well-known. The earliest studies relevant to our work are those by Blake and co-workers[21–24] and Lever and co-workers,[25,26] concerning structural and magnetic studies of acyclic pyridazine- and phthalazine-bridged dimetallic complexes of first row transition metal ions. Since the 1980's Thompson and co-workers have been the key players in the development of, in particular, magnetostructural data on pyridazine- and phthalazine-bridged acyclic dicopper(II) complexes.[27–75]

However, of all the acyclic studies reported in the literature, the paper that most caught our attention was one by Bremard and co-workers, in 1991, in which the observation of antiferromagnetic coupling in the dicopper(II) complex of the acyclic dioxime ligand H_2L1 derived from 3,6-diformylpyridazine was reported (Figure 1).[76] As coordination chemists with a strong background in Schiff-base ligand chemistry, the possibility of incorporating the interesting pyridazine bridging unit into Schiff-base macrocycles, using 3,6-diformylpyridazine as a head unit (see Section 3), was a natural extension of the chemistry reported by Bremard and co-workers. Before focussing on studies of pyridazine- and phthalazine-containing macrocycles, a short overview is presented of the — more numerous — copper and cobalt complexes of acyclic pyridazine- and phthalazine-containing ligands.

2.1.1 Copper Complexes of Acyclic Pyridazine and Phthalazine Ligands

There are many reports of copper complexes containing a Cu–N(pyridazine moiety) bond (SciFinder Scholar[77] indicates that there are 943 such complexes in 218 papers, as of 12.2.02). Many of these complexes have been structurally characterised, as a search of the Cambridge Crystallographic Database[78] (CSD version 5.22 October 2001) shows: there are 130 entries for crystallographically characterised copper complexes containing a Cu–N(pyridazine moiety) bond. Of these, other than the structures of our pyridazine-bridged copper complexes (only three of which are in the CSD[78] version 5.22 October 2001 as the others were published after this version was released),[3,6,7] there are 93 entries which contain copper ions bridged by a pyridazine or phthalazine moiety: the majority of these structures are of di- or polycopper(II) complexes (69 entries), with a smaller number of di- or polycopper(I) complexes (26 entries), and no examples of mixed-valent complexes other than one of ours[6] (Table 1). Narrowing the field still further, relatively few of these complexes contain copper ions doubly or triply bridged by pyridazine or phthalazine, with only seven dicopper(II) examples (none of these involve triple pyridazine or phthalazine bridges) and 17 di- or polycopper(I) compounds (Table 1).

Studies on acyclic pyridazine- and phthalazine-bridged dicopper(II) complexes have clearly shown that these moieties are capable of mediating moderate to strong antiferromagnetic coupling, although it should be remembered that, with only one structurally characterised exception,[76] hydroxide, halide, azide, alkoxide, nitrate or sulfate exogenous bridges are always present in addition to the diazine bridge(s) in these acyclic copper complexes.[30–34,36–39,41,42,44,45,47,48,50,52,53,57,60–62,67,68,70–73,79,80] Another point to note in this regard is that on coordination of two metal ions these acyclic ligands form either two five-membered chelate rings (as in the case of complexes of H_2L1) or two six-membered chelate rings, and this affects the planarity of the ligand in the complex, the number and type of exogenous bridging groups bound to the copper atoms, and hence the magnetic properties of the complexes.

As expected, the bridging π-acceptor pyridazine moiety has been shown to be able to stabilise copper ions in the +1 oxidation state, with Cu^I/Cu^{II} couples commonly observed at positive potentials relative to SCE,[37,39,42,44–46,60–62,73] with very few exceptions.[41] Generally pyridazine- and phthalazine-bridged dicopper complexes undergo a single — albeit sometimes quite broad — two-electron process $Cu_2^{II} \rightleftarrows Cu_2^{I}$.[37,42,44,45,60–62,73] There are very few examples of two well-separated one-electron waves being observed,[39,46,81] which is in stark contrast to the dicopper(II) complexes of related phenolate ligands,

[a] Macrocyclic-pyridazine bridging (our work). [b] Valence sum calculations indicate that the average oxidation state of copper is +1 in this mixed metal complex. [c] The only pyridazine- or phthalazine-bridged mixed-valent copper complex of any kind reported to date.

such as $L2^{2-}$ (Figure 2), in which this is commonly observed (albeit at negative potentials vs. SCE).[82] Consistent with these observations, there are some examples of di- and polycopper(I) complexes of bridging pyridazine and phthalazine acyclic ligands which have been isolated and fully characterised (including single crystal X-ray structure determination, Table 1), but, prior to our work, no example of a pyridazine- or phthalazine-bridged copper(I)/copper(II) mixed-valent complex.

2.1.2 Cobalt Complexes of Acyclic Pyridazine and Phthalazine Ligands

Whilst less common than copper pyridazine and phthalazine complexes, there are still numerous reports of cobalt complexes containing a Co−N(pyridazine moiety) bond (SciFinder Scholar[77] indicates that there are 192 such complexes, with a variety of oxidation states of cobalt, in 77 papers, as of 12.2.02). Of these, those concerned with cobalt(II) complexes are of some relevance to the studies described herein,[21,24,26,35,40,48,49,83−89] with those di- or polycobalt(II) complexes in which pyridazine[21,24,40,84,85] or phthalazine[21,24,26,35,49,89] bridging is observed being of most relevance. Focussing in on these pyridazine- or phthalazine-bridged cobalt(II) complexes: (a) for all cases in which magnetic data are reported the cobalt(II) ions are in the high-spin state and are only weakly antiferromagnetically coupled;[21,24,26,40,49,84] (b) only two of the complexes contain macrocyclic ligands and neither of these complexes are fully characterised;[88,89] (c) whilst aerobic oxidation leads to the production of dicobalt(III) complexes in some cases,[28] no electrochemical studies have been reported, other than a brief mention of the interesting fact that a macrocyclic dicobalt complex with double phthalazine bridges catalyses the four-electron reduction of O_2 in alkaline solutions when absorbed onto graphite.[89,90]

Very few such complexes have been structurally characterised, as a search of the Cambridge Crystallographic Database[78] (CSD version 5.22 October 2001) shows. There

are still — other than our own cobalt pyridazine complexes[4,5,8,9,11] — only four other crystallographically characterised cobalt complexes containing a Co−N(pyridazine moiety) bond.[49,83,91,92] The first structurally characterised example was a red-brown high-spin phthalazine-bridged dicobalt(II) complex $[Co_2^{II}\{1,4\text{-bis}[(6\text{-methylpyridine-2-carboxaldimino})\text{amino}]\text{phthalazine}\}Cl](H_2O)_4Cl_3$ [av. Co−N(phthalazine ligand) 2.151(5) Å].[49] Haupt and co-workers then reported two structurally characterised complexes, a dicobalt(I) complex $[Co_2^{I}\{\mu_2\text{-benzo}[c]\text{cinnoline-}N,N'\}\text{-bis}(\eta^5\text{-cyclopentadienyl})\text{trimethylphosphane}]$,[91] and a monocobalt(0) complex, $[Co^{0}\{\eta^2\text{-benzo}[c]\text{cinnoline-}N,N'\}\text{tris(trimethylphosphane)}]$.[92] Finally, an orange high-spin monocobalt(II) complex $[Co^{II}(\text{pyridazine})_4(NCS)_2]$ was reported in 1998 [Co−N(NCS) 2.057(2), av. Co−N(monodentate pyridazine) 2.204(2) Å].[83]

2.2 Macrocyclic Pyridazine and Phthalazine Ligands

Prior to our studies,[1−11] very little pyridazine- or phthalazine-based macrocyclic chemistry had been reported in the literature, despite an isolated but interesting example described early on by Rosen.[93] This 1971 publication described one of the earliest macrocycles to completely encircle *two* metal ions (following on from the independent breakthroughs in 1970 by Robson and co-workers[94] and by Busch and co-workers[95] in encircling two metal ions with a macrocycle), in this case two nickel(II) ions.[93] The macrocycle synthesis is reminiscent of the Curtis macrocycles,[96] being prepared from 1,4-dihydrazinophthalazine (expensive but commercially available as the dihydrochloride salt) and 2,2-dimethoxypropane in the presence of an acid and the metal salt. It was, quite reasonably, proposed that the phthalazine groups of L4 (Figure 3) bridge the nickel ions, but this was not confirmed by a single crystal X-ray structure determination.

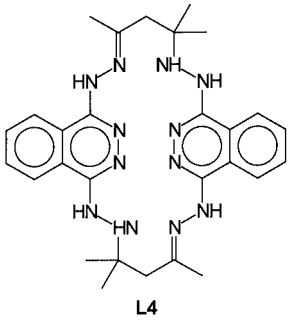

Figure 3. Phthalazine-containing macrocyclic ligand L4

A dicobalt complex of the Rosen phthalazine-containing macrocycle L4 is also mentioned in the literature, in the context that it catalyses the four-electron reduction of O_2 in alkaline solutions when absorbed onto graphite.[89][90] No synthetic detail or further characterisation information was provided for this complex.

There is one further isolated case of a phthalazine-containing macrocycle, H_2L5 (Figure 4), being prepared. In this case it is proposed by Okur that the macrocyclic cavity only incorporates a single metal ion (paramagnetic Co^{II} or diamagnetic Ni^{II}); again no structural information is available for either of these complexes.[88]

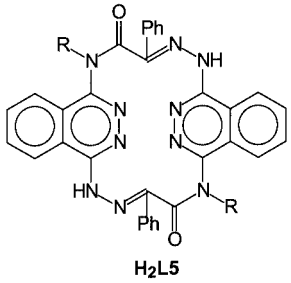

Figure 4. Phthalazine-containing macrocyclic ligand H_2L5

In addition to their extensive studies of complexes of acyclic pyridazine- and phthalazine- containing ligands (Section 2.1), Thompson and co-workers have also prepared a range of pyridazine- and phthalazine-containing macrocyclic thioether ligands, by reacting commercially available 3,6-dichloropyridazine (affordable) and 1,4-dichlorophthalazine (relatively expensive) with appropriate dithiolate reagents (e.g. L6 to H_2L12, Figure 5).[55,56,59,64−66]

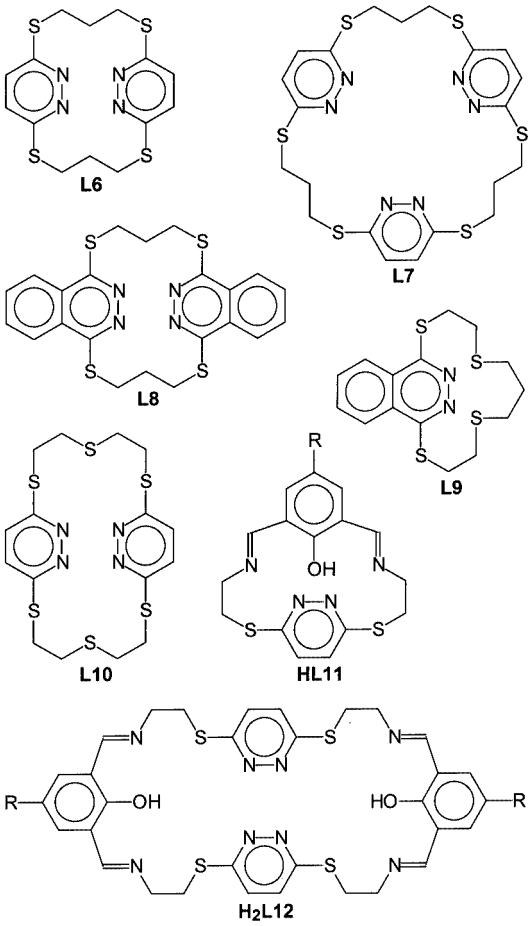

Figure 5. A selection of thioether pyridazine- and phthalazine-containing macrocycles

Initially both [2+2] and [3+3] thioether macrocycles were obtained from the reaction of 3,6-dichloropyridazine and 1,3-propanedithiol (L6 and L7, Figure 5): these macrocycles were separated from one another readily on the basis of solubility.[56] Other dithiols employed in the cyclisation with 3,6-dichloropyridazine included 3,7-dithianonane-1,9-dithiol,[55] 2,2′-thiodiethanethiol (L10, Figure 5),[64,65] and 1,4,7,10-tetrathiadecane.[65] Some [2+2] phthalazine analogues were prepared by reaction of 1,4-dichlorophthalazine with 1,3-propanedithiol (L8, Figure 5), 3,7-dithianonane-1,9-dithiol (L9, Figure 5) or 2,2′-thiodiethanethiol.[65] A series of copper(II), copper(I) and silver(I) complexes were characterised,[55,56,64,65] including an example of a mixed-valent copper(I)/copper(II) complex [Cu_2(L10)Br_3], which was not structurally characterised, but which was proposed to have a polymeric structure with the copper(II) ion bound within the macrocycle and the copper(I) ion, involved in bridging the macrocyclic rings, bound in an exocyclic manner.[64] In none of these complexes did the pyridazine rings bridge the metal ions.

The next development was the preparation of a "two armed pyridazine diamine", 3,6-bis[(2-aminoethyl)thio]pyridazine, from 3,6-dichloropyridazine, in 87% yield, which opened up the possibility of using metal ions to template the formation of Schiff base macrocycles.[66] Copper(II) template ions were employed in the reactions of this diamine with 2,6-diformyl-4-methylphenol or with 2,6-diformyl-4-*tert*-butylphenol (e.g. HL11 and H_2L12, Figure 5) and this resulted in a range of mono-, di- and tetranuclear copper complexes,[59,66] including examples of mixed valent copper(II)/copper(I) complexes.[66] However, once again, pyridazine bridging is not a feature of these complexes.[59,66] Rather, they contain phenolate bridge(s) so they are actually more closely related to the dicopper complexes of phenolate-containing macrocycles such as $L2^{2-}$ (Figure 2).[82]

More recently, Lehn and co-workers have reported a pyridazine-containing cryptand ligand, L13 (Figure 6), that can accommodate two sodium ions which are believed to be triply bridged by the pyridazine moieties, although no details are provided.[97]

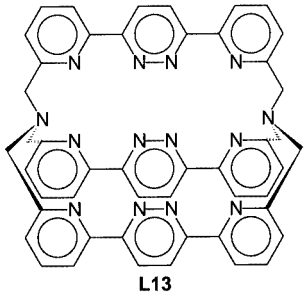

Figure 6. Pyridazine-containing cryptand ligand L13

To summarise, despite the construction of some pyridazine- and phthalazine-containing macrocycles,[55,56,59,64−66,88−90,93,97] in only three isolated cases was bridging of the incorporated metal ions by these moieties proposed (for L4 and L13, Figure 3 and 6 respectively).[89,90,93,97] Therefore we set out to carefully design and construct pyridazine-containing macrocycles in which bridging by this 1,2-diazine moiety was facilitated, and to subsequently thoroughly examine the resulting families of complexes to determine whether or not special features had resulted from incorporating this interesting diazine bridging unit into a macrocyclic framework.

3. Macrocycles Built from 3,6-Diformylpyridazine

3,6-Diformylpyridazine was targeted (Section 2.1, Figure 1) as a suitable macrocycle precursor to achieve the initial aim of producing a family of macrocycles capable of binding two metal ions and providing two pyridazine bridges. Initially this dialdehyde was prepared from 3,6-bis(hydroxymethyl)furan by the four-step method reported by Bremard and co-workers [Figure 7, steps (i)−(iv)],[76] modifying the final step from the reported Swern oxidation to an MnO_2 oxidation[98] in order to readily isolate the dialdehyde.[2] However this route[99,100] was less than satisfactory because: (a) the starting material, whilst not particularly expensive, was not cheap, (b) step (ii) was found to be unreliable, and (c) it was found that an extra step was necessary [step (iii) was replaced with steps (v) and (vi)] making it a five-step synthesis.[2] Hence a more convenient synthesis was sought. Wiley[101] has described a three step synthesis [Figure 7, steps (1)−(3)], starting from cheap starting materials, and this was found to be a good alternative route to 3,6-diformylpyridazine. The first two steps are reported as moderately large scale reactions which is advantageous, whilst the third and final step, being an ozonolysis reaction, must be done on a small scale for safety reasons.[2,101]

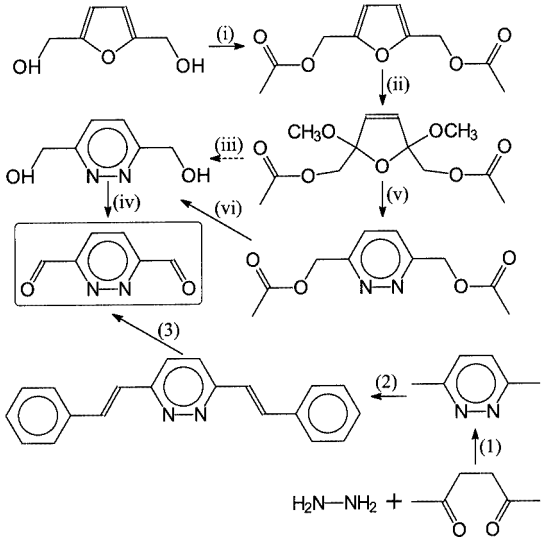

Figure 7. Syntheses of 3,6-diformylpyridazine from 2,5-bis(hydroxymethyl)furan [steps (i)−(v)] or from acetonylacetone and hydrazine hydrate [steps (1)−(3)]; reagents and conditions: (i) acetic anhydride/pyridine; (ii) Br_2/CH_3OH; (iii) 1% acetic acid/CH_3OH/$H_2NNH_2{\cdot}H_2O$; (iv) activated Amberlite IRA400 resin/CH_3OH; (v) oxalyl chloride/dmso or MnO_2/dioxane; (1) Pd/C-benzene; (2) $ZnCl_2$; (3) O_3/MeOH

With a good synthesis of 3,6-diformylpyridazine in hand, attention turned to preparing Schiff-base macrocyclic, and related acyclic, ligands and complexes from them. Whilst the condensation of this dialdehyde head unit is being explored with a wide range of amines,[11] this microreview will focus entirely on the results obtained using 1,3-diaminopropane.

3.1. Macrocycles L14 and L14′ from 3,6-Diformylpyridazine and 1,3-Diaminopropane

Models indicated that a [2+2] condensation of 1,3-diaminopropane with 3,6-diformylpyridazine would produce a macrocycle which would bind two first row transition metal ions well. Hence this was the diamine used initially, and the resulting [2+2] and [4+4] macrocycles, L14 and L14′ (Figure 8), are the focus of this section.

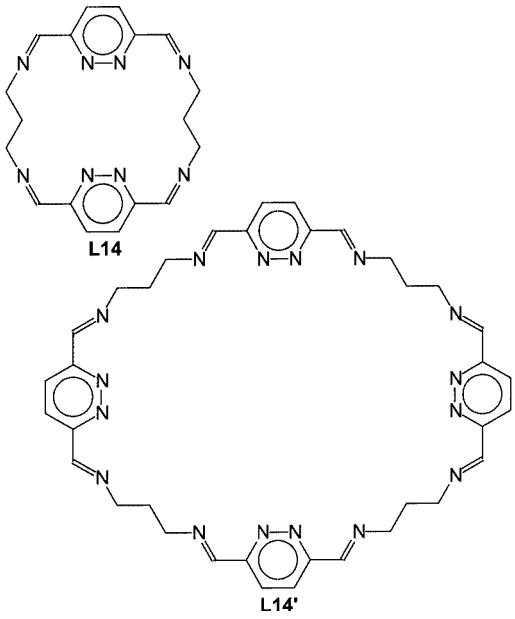

Figure 8. Pyridazine-containing [2+2] and [4+4] Schiff-base macrocycles L14 and L14′

It is relevant to note that many interesting complexes have been prepared from the [2+2] macrocycles formed by condensing 1,3-diaminopropane with either 2,6-diformylphenols[82,102] or 2,6-diformylthiophenols[18] (the $L2^{2-}$ and $L3^{2-}$ families of macrocycles, Figure 2). There are clearly both similarities and differences between phenolate and pyridazine moieties. Features they share include the well-established ability to bridge metal ions and to mediate magnetic exchange. However, they are also very different in that phenolate has a negative charge whilst pyridazine is neutral and is a π-acceptor ligand. Another key difference is that phenolate provides a one-atom bridge whereas pyridazine provides a two-atom bridge. These differences are significant and should impact on the properties of the complexes, in particular on the magnetic and redox chemistry, hence the interest in incorporating bridging pyridazines into Schiff base macrocycles for the first time.

Success came with a lead(II) templated cyclisation reaction of 3,6-diformylpyridazine and 1,3-diaminopropane, the results of which were published as a communication in 1994.[1] An unexpected [4+4] cyclisation occurred (confirmed by single crystal X-ray structural analysis, Figure 9) producing what was at the time only the second example of a [4+4] Schiff-base macrocycle.[103,104] Subsequently it was found that, depending on the reaction stoichiometry, one could produce either the [4+4] or the [2+2] macrocycle, as $[Pb_2L14'](ClO_4)_4$ or $[Pb_2L14](ClO_4)_4$ respectively, in good yields (Figure 8).[2] This ability to control the ring size of the product macrocycle by stoichiometry alone is unique to the best of our knowledge.

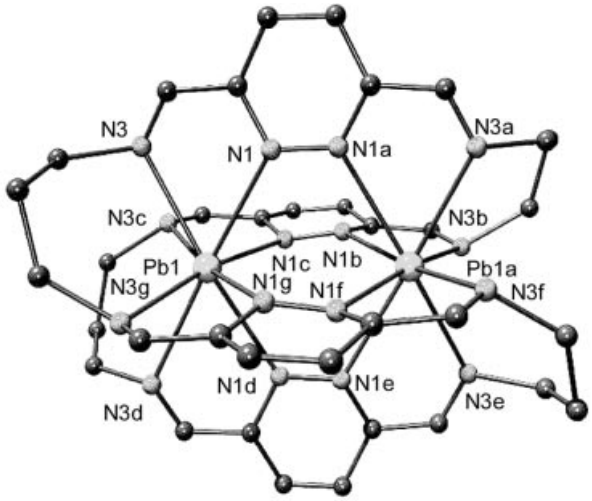

Figure 9. Perspective view of the cation of $[Pb_2L14']^{4+}$

Transmetallation reactions, starting from either $[Pb_2L14'](ClO_4)_4$ or $[Pb_2L14](ClO_4)_4$, allowed the preparation of the first row transition metal complexes of interest. Alternatively, these complexes could, in principle, have been prepared by using the transition metal ions as template ions, but in practice this was unsuccessful for most of the metal ions studied, including copper(II) and cobalt(II) ions. One of the key exceptions to this generalisation is that copper(I) ions could be used as template ions for the formation of L14 (see below).

Usually, for reasons of ease of synthesis of clean samples, $[Pb_2L14'](ClO_4)_4$ was the preferred precursor complex for the transmetallation reactions. The use of this precursor complex immediately raised the question as to whether the transition metal complexes would be of the [4+4] macrocycle L14′ or of the [2+2] macrocycle L14. The answer to this question is that, to date, all of the products obtained have been of the [2+2] macrocycle L14.[11] Hence the [4+4] Schiff-base macrocycle L14′ rearranges during the transmetallation reaction to form the [2+2] macrocycles L14, in contrast to the first known example of a [4+4] Schiff-base macrocycle in which the reverse was believed to be occurring (the [4+4] macrocycle was proposed to form from two [2+2] macrocycles coming together).[104] Interestingly, this substantial ring-size change from L14′ to L14 occurs suc-

cessfully even when inserting transition metal ions which cannot be used to template the macrocycle formation from 3,6-diformylpyridazine and 1,3-diaminopropane. Relatively minor changes to the size of Schiff-base macrocycles can occur during transmetallation reactions by the nucleophilic addition of solvent alcohol[105] to the imine bond(s) or by intramolecular attack of an alcohol[106] or amine[107] moiety on the imine bond(s), but a change in the actual number of head and lateral units making up the macrocyclic framework, such as is occurring here, is very uncommon.[104][108]

The metal ions incorporated into L14 to date include manganese, iron, cobalt, nickel, copper and zinc: here we will focus on the results obtained with copper and cobalt.

3.1.1 Copper Complexes of the L14 Schiff-Base Macrocycle

Direct reactions, employing copper(II) as a template ion for the cyclisation, were unsuccessful, presumably due to the tendency of the copper(II) ions to participate to some extent in redox chemistry in the presence of the ligand components.[3,7] Rather, the transmetallation route from $[Pb_2L14'](ClO_4)_4$ was followed and this yielded single crystals of an emerald green complex, $[Cu^{II}_2L14(CH_3CN)_4](ClO_4)_4$, in good yield.[3,7] The single crystal structure determination (Figure 10) shows that the macrocycle conformation is somewhat bent, with an angle of 29.67(7) ° between the planes of the two pyridazine rings. The copper(II) ions are square pyramidal with a weak interaction to a perchlorate ion in the otherwise vacant sixth site of the distorted octahedron. As expected (Section 2.1.1), strong antiferromagnetic coupling was observed between the doubly pyridazine-bridged copper(II) ions, with $-2J = 482\ cm^{-1}$. This value is similar to the $-2J$ values of 536 cm^{-1} and 489 cm^{-1} obtained for the only two closely related acyclic complexes known: orange-red $[Cu^{II}_2(HL1)_2(H_2O)_2(ClO_4)_2]$ and olive-green $[Cu^{II}(DHPH)_2(H_2O)_2](ClO_4)_2$ (where DHPH = 1,4-dihydrazinophthalazine), in which the copper(II) ions are doubly bridged by pyridazine[76] and phthalazine[57] moieties, respectively, and there are no other bridging moieties present.

Electrochemical experiments revealed the presence of two well-separated reversible one electron processes at positive potentials vs. SCE, which correspond to $Cu^{II}_2 \rightleftarrows Cu^{II}Cu^{I} \rightleftarrows Cu^{I}_2$. This result contrasts with the previous studies on acyclic pyridazine complexes in which the norm was the observation of a single two-electron process of varying reversibility (Section 2.1.1). The observation of two well-separated reversible processes is more reminiscent of the analogous doubly phenolate-bridged dicopper(II) macrocyclic complexes (e.g. $L2^{2-}$, Figure 2), however, in that case, the processes occur at negative potentials (Section 2.1.1), in contrast to the positive potentials observed in the case of dicopper(II) complexes of the pyridazine macrocycle L14. These redox properties opened up a unique opportunity to access not only the mixed valent copper(I)/copper(II) complex but also the dicopper(I) complex.

As a first attempt to prepare the dicopper(I) complex a transmetallation reaction was carried out with

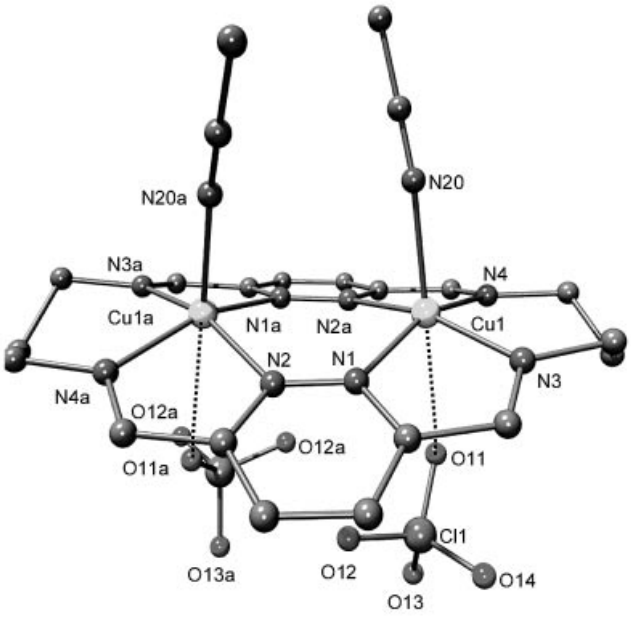

Figure 10. Perspective view of the cation of $[Cu^{II}_2L14(CH_3CN)_2(ClO_4)_2]^{2+}$

$[Cu^{I}(CH_3CN)_4](PF_6)$ in acetonitrile under argon. For ease of workup, vapour diffusion of diethyl ether into the resulting red-brown solution was carried out in air. This resulted in the isolation of red-brown single crystals of the mixed valent complex, $[Cu^{I}Cu^{II}L14(CH_3CN)_2](ClO_4)_2(PF_6)$, in 41% yield, due to the in situ air oxidation of the dicopper(I) complex, which was presumably the initial product of the transmetallation reaction.[6] A structure determination carried out on one of these crystals at low temperature clearly showed that this is a valence-localised compound: longer bond lengths are observed to the copper(I) atom and it is further out of the N_4 plane (Figure 11; Cu1 0.72 Å out-of-plane, Cu2 0.26 Å out-of-plane). The observation of a four-line EPR spectrum is consistent with this

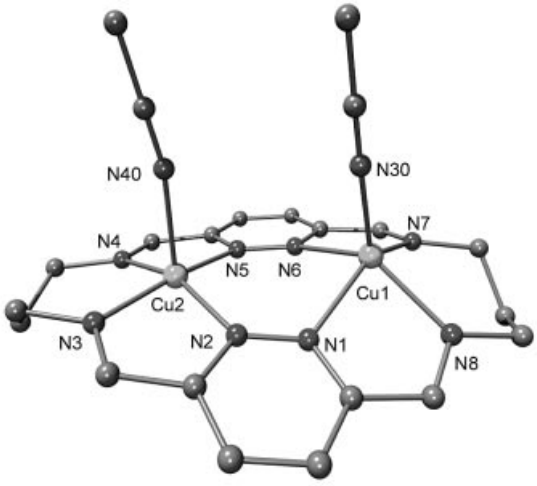

Figure 11. Perspective view of the cation of $[Cu^{I}Cu^{II}L14(CH_3CN)_2]^{3+}$

assignment.[7] It is also interesting to note that this is a relatively rare example of five coordinate copper(I).[109]

The use of copper(I) ions as template ions seemed an improbable route to clean L14 macrocycle formation given the preference of copper(I) for a tetrahedral (not square-based) geometry and the demands of L14 macrocycle formation. However, this experiment was attempted because related acyclic ligands have, in this laboratory[11] and elsewhere,[110] given grid complexes with tetrahedral copper(I) ions. Therefore an interesting and unusual result was possible, providing the propylene lateral units were capable of linking up the pyridazine head units which would be expected to be held perpendicular to one another by the copper(I) template ions. Fortunately this was the case, and brown single crystals of $[Cu^{I}_{4}(L14)_2](PF_6)_4$ were formed, in 61% yield, on diffusing diethyl ether vapour into the acetonitrile reaction solution, in air. The complex does have a grid structure, where each of the two parallel strands are linked together in a single macrocycle, and the two macrocycles approach each other at right angles to give rise to the perpendicular strands of the grid structure (Figure 12).[6] Thus the copper(I) atoms have distorted tetrahedral geometries, with each macrocycle providing a bidentate donor set at right angles to that supplied by the other macrocycle.

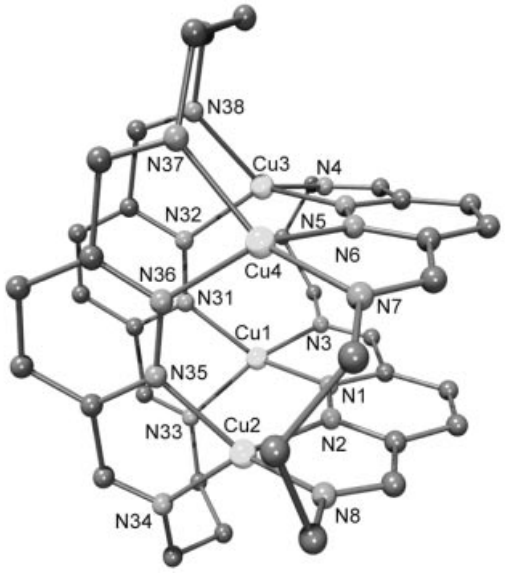

Figure 12. Perspective view of the cation of $[Cu^{I}_{4}(L14)_2]^{4+}$

In noncoordinating solvents, for example nitromethane and acetone, this tetracopper complex is stable in air. However, there is evidence, from both NMR spectroscopy and cyclic voltammetry, that when this complex is dissolved in coordinating solvents, such as acetonitrile, that it is then in equilibrium with an open form that looks like the dicopper(II) and mixed valent forms (Figure 10, 11 and 13).[7] In this "open" form (Figure 13) it is expected to be air sensitive, as it has already been observed that the transmetallation of the lead complex with copper(I), on air workup, yielded the mixed valent complex $[Cu^{I}Cu^{II}L14(CH_3CN)_2](ClO_4)_2(PF_6)$. Therefore, in order to improve the 61% yield one should presumably carry out the template synthesis completely under argon or in a noncoordinating solvent (but not acetone,[96] or nitromethane which makes explosive mixtures with amines). More importantly though, the presence of this equilibrium mixture in acetonitrile solution provides an easy route to cleanly isolate the dicopper(I) complex.

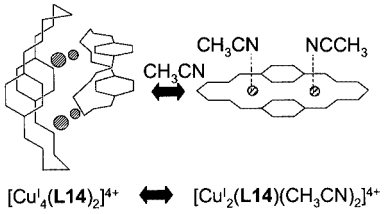

Figure 13. Proposed equilibrium formed between $[Cu^{I}_{4}(L14)_2]^{4+}$ and $[Cu^{I}_{2}L14(CH_3CN)_2]^{2+}$ in acetonitrile solution; reprinted from *Coord. Chem. Rev.* **2001**, *216–217*, 3–30, S. Brooker *et al.*, Doubly pyridazine-bridged macrocyclic complexes of copper in +1, +2 and mixed valent oxidation states, with permission from Elsevier Science

The reaction of $[Cu^{I}_{4}(L14)_2](PF_6)_4$ in acetonitrile with two equivalents of PPh_3 yields brown single crystals of $[Cu^{I}_{2}L14(PPh_3)_2](PF_6)_2$ in 51% yield.[7] PPh_3 was used in order to provide a donor that was better able to stabilise copper(I) than acetonitrile.[111–113] As expected, the steric bulk of the triphenylphosphane groups leads to the observation of a trans arrangement of the two PPh_3 groups relative to the macrocycle plane (Figure 14).[7] The five-coordinate copper(I) atoms are even further displaced from the N_4 plane [0.822(1) Å] than in the previous complexes. Despite the unusual five coordination of the copper(I) atoms the Cu–PPh_3 bond length [2.2239(8) Å] is at the lower end of

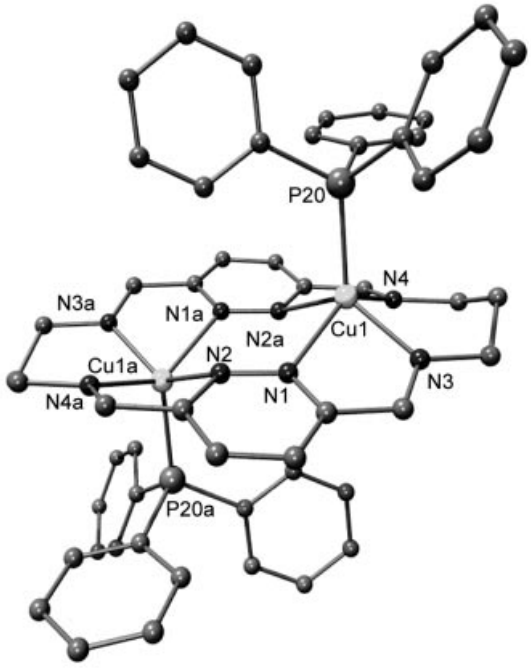

Figure 14. Perspective view of the cation of $[Cu^{I}_{2}L14(PPh_3)_2]^{2+}$

the range observed for the four copper(I) pyridazine phosphane complexes which have been structurally characterised to date, all of which contain copper(I) atoms in a distorted tetrahedral geometry [two monocopper(I) complexes $Cu^{I}-PPh_3$ 2.244−2.293 Å;[111,112] one singly pyridazine-bridged dicopper(I) complex with double bis(diphenylphosphanyl)methane bridging $Cu^{I}-P$ 2.23−2.29 Å;[113] one triply-pyridazine-bridged dicopper(I) complex $Cu^{I}-PPh_3$ 2.217 and 2.208 Å;[111]].

An expected difference between these doubly pyridazine-bridged macrocyclic complexes and those of the doubly phenolate-bridged macrocyclic complexes of $L2^{2-}$ was the metal ion separation (Section 3.1, Figure 2). The Cu···Cu separation in the dicopper(II) complexes of $L2^{2-}$ is typically 3.06−3.22 Å[82] whereas in the dicopper(II) complexes of L14 it is 3.805(3) Å in $[Cu_2^{II}L14(CH_3CN)_4](ClO_4)_4$ [3] and 3.888(3) Å in $[Cu_2^{II}L14(H_2O)_2](ClO_4)_4$.[7] The impact of the two-atom pyridazine bridge, as opposed to the one-atom phenolate bridge, is therefore clear. These Cu···Cu separations can also be usefully compared with the six acyclic structurally characterised doubly pyridazine- or phthalazine-bridged copper(II) complexes (Table 1). In three out of the six entries only double pyridazine/phthalazine bridging is present and the Cu···Cu separations are somewhat shorter than those observed in the macrocyclic complexes, at 3.760 Å (VIVHOX)[76] and 3.729 Å (PAGWOJ);[57] no detailed information is available for VIVHOZ.[76] In the other three entries an additional one-atom exogenous bridge is present (chloride or nitrate) and this results in a significant shortening of the Cu···Cu separation, to 3.269−3.406 Å.[51,79,114]

In the mixed-valent complexes the $Cu^{I}\cdots Cu^{II}$ separations are 3.8986(9) Å in $[Cu^{I}Cu^{II}L14(NCS)_4Cu^{I}]$[7] and 3.9599(4) Å in $[Cu^{I}Cu^{II}L14(CH_3CN)_2](ClO_4)_2(PF_6)$.[6] The Cu···Cu separation is a large 4.4316(12) Å for the dicopper(I) triphenylphosphane complex $[Cu_2^{I}L14(PPh_3)_2](PF_6)_2$, due primarily to the fact that the copper ions are displaced from the macrocyclic plane in opposite directions.[7] Double pyridazine or phthalazine bridging of copper(I) ions (Table 1) by acyclic ligands usually results in Cu···Cu separations in the range 2.970−3.679 Å, with a mean value of 3.261 Å which is significantly lower than the 4.4316(12) Å observed here.

Interestingly the shortest Cu···Cu separations observed in this series of macrocyclic pyridazine-bridged copper complexes are found in the tetracopper(I) complex $[Cu_4^{I}(L14)_2](PF_6)_4$, in which only one pyridazine bridge, not two, is observed between neighbouring copper atoms. In this case the nearest copper(I) atoms are separated by just 3.711(3)−3.738(3) Å.[6] The other eight entries of singly pyridazine- or phthalazine-bridged copper(I) complexes (Table 1) have shorter Cu···Cu separations, in the range 3.438−3.688 Å,[110,113,115−118] with the exception of FEDBIZ in which the separation is even shorter (2.788 Å).[119] The structure of the $[Cu_4^{I}(dppn)_4]^{4+}$ complex [dppn = 3,6-bis(2′-pyridyl)pyridazine], described by Youinou and co-workers,[110] is particularly closely related to that of $[Cu_4^{I}(L14)_2](PF_6)_4$ so the difference in Cu···Cu separations [3.566(1) and 3.582(1) Å vs. 3.711(3)−3.738(3) Å] is presumably due to the restrictions imposed by the macrocyclic nature of the two coordinated L14 ligands as opposed to the relative freedom of the four coordinated acyclic ligands in that study.

3.1.2 Cobalt Complexes of the L14 Schiff-Base Macrocycle

Direct reactions, employing cobalt(II) as a template ion for the cyclisation, were unsuccessful.[9] Instead, the transmetallation route was followed and this gave single crystals of a deep red complex, $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$, in good yield.[4] This dicobalt(II) complex was prepared in air so clearly it does not react spontaneously with oxygen, unlike the cobalt complexes of the large unsymmetrical phenolate macrocycles described by Okawa and co-workers which must be prepared carefully under an inert atmosphere.[120] In this sense, $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ is more similar to the dicobalt(II) complexes of the phenolate macrocycle $L2^{2-}$, $[Co_2^{II}L2X_2]\cdot yCH_3OH$ (where X = Cl^- and y = 2; or X = Br^- and y = 1), which are air stable even in solution.[121]

The deep red colour indicates that $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ is a low-spin cobalt(II) complex and a careful analysis of the parameters obtained from the low temperature single crystal structure analysis (Figure 15)[4] was consistent with this prediction. For example, the average Co−N(macrocycle) bond length is 1.983(4) Å, which strongly indicates that the cobalt(II) ion is low spin as the bond lengths are typically ca. 0.15 Å shorter for low-spin complexes than they are for high-spin complexes (Section 2.1.2).[9,120] The cobalt ions are in distorted octahedral environments and the macrocycle adopts a remarkably flat conformation. Detailed magnetic studies have subsequently confirmed the low-spin state of this complex at the temperature of the X-ray data collection.[9]

This complex, $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$, was the first pyridazine-bridged cobalt complex[21,24,40,84] established to

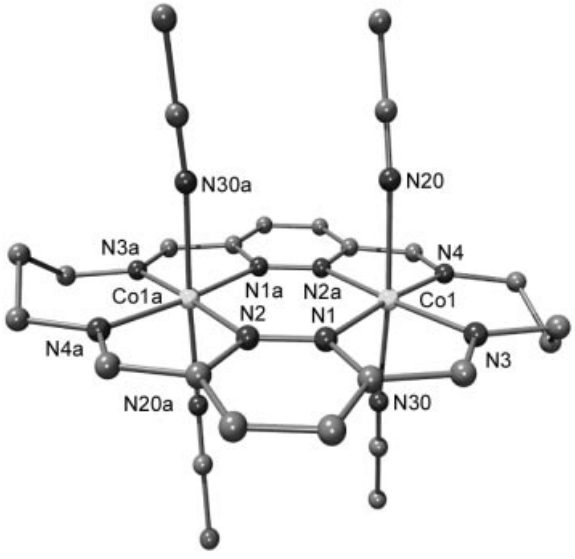

Figure 15. Perspective view of the cation of $[Co_2^{II}L14(CH_3CN)_4]^{4+}$

be low spin (Section 2.1.2). This implies that building the pyridazine moiety into a macrocyclic ligand has resulted in a unique and rather special environment for the encircled cobalt ions. Four reversible one-electron processes are a feature of the electrochemistry of this complex,[4] however, the magnetic properties have been the focus of attention to date. Given that the macrocycle encircles the two cobalt ions, providing each with a planar N_4 donor set, this leaves two axial sites on each cobalt ion available to be occupied by exogenous ligands. In the $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ complex the axial sites are occupied by solvent acetonitrile molecules. The next question was therefore: can the spin state be tuned by altering the group occupying the axial sites?

The first clue to the answer of this question was provided by the observation that on adding water to the deep red residues left on the glassware used to make $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ (i.e. washing up), an orange solution, indicative of high spin cobalt(II), was obtained. When this was repeated and optimised in a scientific manner it was found that the recrystallisation of $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ from 9% water (by volume) in acetonitrile by vapour diffusion of diethyl ether, yielded orange single crystals of the tetra-aquo adduct $[Co_2^{II}L14(H_2O)_4](ClO_4)_4$.[9] The low temperature crystal structure determination reveals a very similar overall structure (Figure 16) to that of the tetra-acetonitrile adduct, however the bond lengths are, as expected for this high-spin complex, significantly longer [av. $Co-N_{macro}$ 2.104(4) Å] than those in the low-spin tetra-acetonitrile adduct [av. $Co-N_{macro}$ 1.992(4) Å] and the bond angles are somewhat more distorted from those expected for an octahedron [tetra-aquo adduct 76.6−110.6°; vs. tetra-acetonitrile adduct 80.8−103.7°].[9]

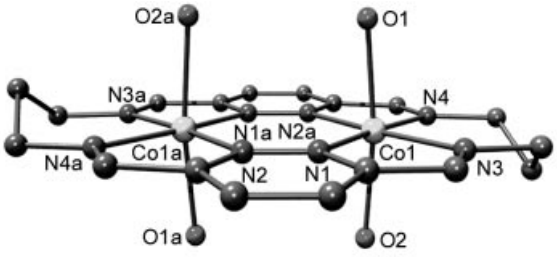

Figure 16. Perspective view of the cation of $[Co_2^{II}L14(H_2O)_4]^{4+}$

Sodium thiocyanate is often found to be useful when exogenous ligands are required in macrocyclic chemistry so this was the next reagent used in attempts to vary the nature of the axial ligands. In this case dark red-black single crystals of $[Co_2^{II}L14(NCS)_2(SCN)_2]$ formed when acetonitrile solutions of $[Co_2^{II}L14(CH_3CN)_4](ClO_4)_4$ and NaSCN were slowly diffused together. The colour indicated that the complex was low spin.[5] The low temperature single crystal structure determination revealed the same very flat macrocycle conformation seen in the previous two structures, and once again the presence of octahedral cobalt ions (Figure 17). Of note in this structure is that each cobalt ion has one N-bound and one S-bound thiocyanate ion, the latter being a first for cobalt(II). The bond lengths are consistent with the low spin configuration [av. $Co-N_{macro}$ 1.951(3) Å], and the angles at cobalt approach 90° more closely [86.8−92.8°] than they do in the high-spin complexes. The magnetic behaviour of this complex is even more interesting than the previous two complexes as it turns out that it is

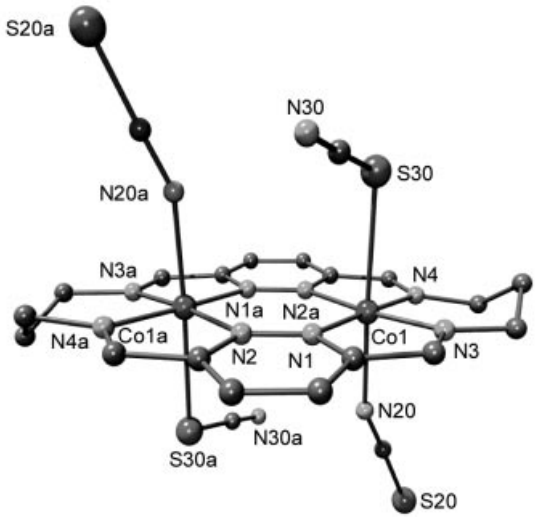

Figure 17. Perspective view of $[Co_2^{II}L14(NCS)_2(SCN)_2]$

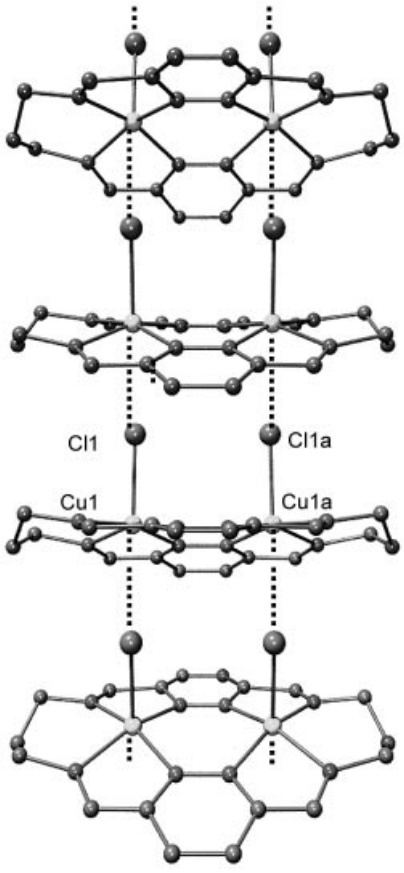

Figure 18. Perspective view of the cation of $[Cu_2^{II}L14(Cl)_2]^{2+}$

the first cobalt complex to exhibit both exchange coupling and spin-crossover effects.

Further variations have been made to the groups occupying the axial sites.[9] Attempts, unsuccessful to date, have also been made to insert bridging ligands in these sites in order to stack these complexes,[9] as has been seen before in the case of the "ladder" complex observed for copper(II), $[Cu_2^{II}L14Cl_2]_\infty^{2+}$ (Figure 18).[7]

4. Conclusions and Outlook

The incorporation of 3,6-diformylpyridazine into Schiff-base macrocycles has resulted in a novel coordination chemistry and a rich structural diversity. The first examples of complexes in which Schiff-base macrocyclic pyridazine bridging of encapsulated metal ions is observed have been isolated and fully characterised. A rare example of a [4+4] macrocycle, L14′, has been prepared and structurally characterised as a dilead(II) complex: in all cases transmetallation of this complex with first row transition metal ions has resulted in ring-size alteration to form complexes of the [2+2] macrocycle L14. Both $[M_2\{2+2\}]^{x+}$ and $[M_4\{2+2\}_2]^{y+}$ complexes have been formed and both flat and folded macrocycle conformations have been observed. Coordination numbers for metal ions encapsulated in either the [2+2] or [4+4] macrocycle range from 4−8 (examples of seven coordination are not discussed here[2]).

A rich and reversible electrochemistry is a feature of these complexes of L14. The macrocyclic framework has led to increased stability of the redox products over that generally observed for related acyclic complexes. This also led to the isolation of the first mixed-valent pyridazine-bridged complex (of copper), due to significant stabilisation of the mixed-valent oxidation state, in marked contrast to the acyclic analogues.

Exciting magnetochemistry is a feature of the cobalt(II) complexes. Incorporation of the bridging pyridazine moiety into this macrocyclic framework has resulted in the first examples of low-spin and spin-crossover cobalt(II) for pyridazine-bridged complexes of any type.

Many new and interesting avenues remain to be explored. These include the condensation of 3,6-diformylpyridazine with other mono-, di- and triamines.[11] For example, the reaction of this head unit with tris(2-aminoethyl)amine (tren) has provided ready access to a new cryptand and the coordination chemistry of this cryptand, and the amine analogue, is well underway.[8,10,11] The incorporation of related heterocycles into macrocyclic frameworks,[11] and the design and synthesis of polydentate acyclic ligands for use in extending and developing the grid-like behaviour observed in some of the macrocyclic complexes described above (e.g. Figure 12)[6,7] are other areas of considerable and ongoing interest to us.[11]

Acknowledgments

I am extremely grateful to the following research students and assistants, postdoctoral and research fellows, and collaborators who have "made things happen": Dr. Robert J. Kelly (research assistant and PhD student), Dr. Paul G. Plieger (PhD student), Janna D. Ewing [BSc(Hons) student], Dr. Duncan J. de Geest, Dr. Dietmar K. Kennepohl, Dr. David S. Larsen (organic synthesis advice), Dr. Eckhard Bill (EPR, MPI für Strahlenchemie), Dr. Eberhard Bothe (electrochemistry, MPI für Strahlenchemie), Dr. Boujemaa Moubaraki (magnetism, Monash University), Professor Keith S. Murray (magnetism, Monash University) and Professor Jane Nelson (pyridazine cryptates, Queens University of Belfast). This research program gained momentum thanks in large part to a small grant from the Public Good Science Fund (Foundation for Research, Science and Technology, NZ) in 1993 which meant I could employ RJK (research assistant) full time for seven months. Support from a variety of grants from the University of Otago has been vital throughout, and we are very fortunate that we currently have a three year grant from the Marsden Fund (Royal Society of New Zealand).

Symmetric and Asymmetric Coupling of Pyridylpyrimidine for the Synthesis of Polynucleating Ligands

Matthew I. J. Polson,[a] John A. Lotoski,[a] K. Olof Johansson,[a] Nicholas J. Taylor,[a] Garry S. Hanan,*[a] Bernold Hasenknopf,[b] René Thouvenot,*[b] Frédérique Loiseau,[c] Rosalba Passalaqua,[c] and Sebastiano Campagna*[c]

Keywords: Heterocycles / Ruthenium / N ligands / Radical reactions / Addition reactions

A convenient synthetic approach to build up new polynucleating ligands is presented. Symmetric and asymmetric pyridylpyrimidine dimers are produced by radical anion coupling and nucleophilic addition, respectively. A diruthenium complex of the asymmetric ligand was synthesised and characterised by cyclic voltammetry, luminescence and ^{99}Ru NMR spectroscopy.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Oligo(azaheterocyclic) compounds are highly regarded by coordination chemists for their use in building up large polymetallic complexes.[1,2] This appreciation stems from their stability in a wide range of reaction conditions and their ability to form stable complexes with most transition metal ions. They are synthesised in a variety of ways: ring-forming reactions (e.g., Kröhnke synthesis), ring-coupling reactions (e.g., Stille reaction), or a combination of the two. However, these reactions have the drawback of usually requiring substituted heterocycles in order to bring two moieties together. We report herein on a rapid and convenient synthesis of isomeric oligo(azaheterocyclic) ligands for incorporation into metallodendrimers starting from unsubstituted heterocycles. In addition, the diruthenium complex of one dinucleating ligand has been prepared and fully characterised.

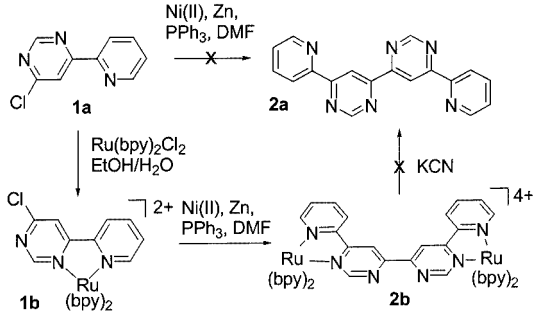
Results and Discussion

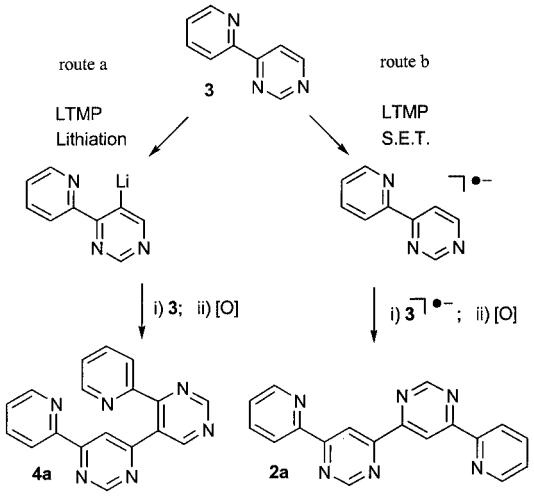
We previously demonstrated that an Ni-catalysed coupling reaction could be used to increase the metal ion content in metallodendrimers and proposed a general method to create new binding sites in metal complexes (Scheme 1).[3,4] Although dimetallic complex **2b** was readily synthesised by an Ni-catalysed coupling of monometallic complex **1b**, metal-free ligand **2a** was required to fully interpret the electrochemical and spectroscopic properties of its complexes.



Scheme 1. The attempted synthesis of ligand **2a**

Our initial attempt to synthesise **2a** by the nickel-catalysed coupling of **1a** failed to afford significant quantities of **2a** (Scheme 1), presumably due to the sequestering of the nickel catalyst by the free chelating site in **1a** or to its deactivation toward coupling as was previously shown for carbonylmetal compounds of chlorophenanthrolines.[5] In another attempt, dimetallic complex **2b** could not be demetallated using CN^-. Thus, a synthesis of **2a** without transition metals was required, and direct lithiation/addition appeared to be the best route.

Direct metallation of azaheterocycles is usually aided by directing metallation groups (DMGs),[6,7] such as those used for aromatic hydrocarbons.[8,9] The functional group serves to direct the lithiation either electronically or by coordination. However, there are a few reported cases of direct lithiation of unsubstituted electron-deficient heterocycles.[10,11] Pyrimidine can be lithiated directly in the 4-position using lithium 2,2,6,6-tetramethylpiperidide (LTMP), and its addition to pyrimidine gives 4,4′-bipyrimidine (bpym) in modest yield.[11] This suggested that lithiation of 4-(2-pyridyl)pyrimidine (**3**)[12] in the 6-position, followed by addition to another ligand **3**, would give **2a**. However, as the pyridine in **3** could also serve as a DMG,[13] an asymmetric coupling reaction could also occur (Scheme 2, route a).



Scheme 2. Synthetic routes to symmetric ligand **2a** and asymmetric ligand **4a** using LTMP with **3**

Direct lithiation/addition routes were attempted as outlined in Scheme 2 and Table 1. Thus, **3** was treated with LTMP at −78 °C in an effort to lithiate the 6-position, followed by its addition to **3**. Subsequent warming and air oxidation afforded the symmetric dimer **2a** and the asymmetric dimer **4a** in 16% and 22% yield, respectively (Table 1, Entry 1).

LTMP and **3** were recombined at −78 °C in order to verify the positions of lithiation and their relative ratios (Table 1).[14] The lithio intermediates were trapped by the addition of TMSCl at timed intervals after LTMP addition (Entries 2−4). The expected 6-lithio species was not formed in any appreciable amount after the first minute, instead only the 5-TMS adduct formed. After 5 min, **2a** had formed, even though no 6-TMS adduct could be trapped. This suggested that some other route may be operative as heterocyclic carbanions are usually trapped by TMSCl when competing with addition reactions to other heterocycles.[15] After 10 min, **4a** was formed by the addition of the 5-lithio species to the 6-position of **3**. The phenylation of **3** in the 6-position in 32% yield confirmed the site of addition (Entry 5). Interestingly, lithium diisopropylamide (LDA, Entry 6) gave only a minute quantity of **4a** via the 5-lithio species, with no sign of **2a**. LDA was previously shown to dimerize 2,2′-bipyridine and give its 3,6′-coupled dimer.[16,17]

Table 1. Lithiation/addition and radical anion coupling reactions for **3**

Entry	Ligand[a]	Alkali	Product[b]	Yield (%)
1	TMP	*n*BuLi	**2a**	16
			4a	22
2[c]	TMP	*n*BuLi	**2a**	0
			5-TMS-py-pm	30
3[d]	TMP	*n*BuLi	**2a**	11
			5-TMS-py-pm	58
4[e]	TMP	*n*BuLi	**2a**	17
			5-TMS-py-pm	28
			4a	10
5	−	PhLi	6-Ph-4-py-pm	32
6	−	LDA	**4a**	< 5
7[f]	−	$Na_{(s)}$	**2a**	95[g]
8[h]	TMP	*n* BuLi	**2a**	10
		+ $CuCl_2$	**4a**	22

[a] TMP = 2,2,6,6-tetramethylpiperidine. [b] 5-TMS-py-pm = 4-(2-pyridyl)-5-(trimethylsilyl)pyrimidine, 6-Ph-4-py-pm = 6-phenyl-4-(2-pyridyl)pyrimidine. [c] The reaction was quenched after 1 min with excess trimethylsilyl chloride. [d] The reaction was quenched after 5 min with excess trimethylsilyl chloride. [e] The reaction was quenched after 10 min with excess trimethylsilyl chloride. [f] No oxidation occurred with air. The residue was dissolved in acetone and an excess of $KMnO_4$ was added. The solution was stirred for 1 h before usual workup. [g] Based on recovered **3**, 40% conversion. [h] Reaction conducted in THF.[11]

As pyridine is well known to dimerize by way of its radical anion upon treatment with alkali metals[18,19] and LDA,[20] a radical pathway for the formation of **2a** with LTMP was still possible, especially considering the lower reduction potential of pyrimidine compared to pyridine.[21] A radical anion mechanism was indeed supported by the reduction of **3** with sodium (Entry 7), which afforded **2a** in 95% yield based on recovered **3**, with no sign of **4a** (Scheme 2b). Increasing the amount of sodium and the reaction time had no effect on the ratio **2a**/**3**.

The addition of a catalytic amount of the known radical quencher $CuCl_2$[11] to the reaction mixture (Entry 8, Table 1) resulted in a decrease in the yield of **2a**, but not its complete elimination. Increasing the amount of $CuCl_2$ leads to a lower yield of both isomers. Thus, we propose that the reaction in Entry 1 is a balance between a single electron transfer mechanism resulting in **2a** and an *ortho*-directed metallation at the pyrimidine 5-position followed by attack at the 6-position of the second ligand **3**, giving **4a** after oxidation. In the case of the reaction with Na(s), the lower reduction potential of the pyrimidine ring affords a direct route to homocoupled ligands through radical anion coupling.

Asymmetric ligands such as **4a** are generally more difficult to obtain than their symmetric counterparts,[16,17] but they can give valuable information on the interaction between metals in different binding sites. We therefore analysed the structure of **4a** and prepared its diruthenium complex. In this case, the steric hindrance about the C−C bond

joining the two pyrimidine rings may preclude metal−metal interaction in its dimetallic complex. An X-ray crystal structure determination allowed the bond connectivity in **4a** to be verified and the steric hindrance at both coordination sites to be compared. Thus, the bond between the two pyrimidine rings in **4a** (C13 to C9) is unequivocally assigned by X-ray crystallography (Figure 1).[22] The dihedral angle of 38.1° between the two pyrimidine rings clearly demonstrates the steric congestion about this bond. This is also seen in the 38.2° dihedral angle to the adjacent pyridine ring (C14 to C19), compared to the 2.7° dihedral angle at the other less encumbered pyridine ring (C1 to C7). The bond lengths and angles in **4a** are consistent with other pyridine- and pyrimidine-containing ligands.[23,24]

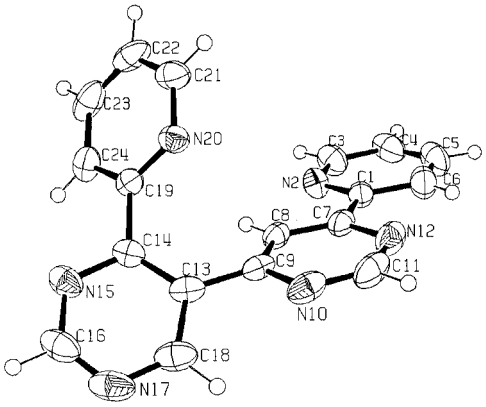


Figure 1. The crystal structure of **4a**

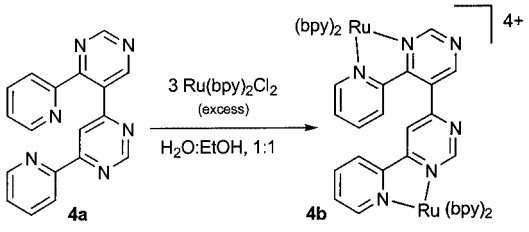
Diruthenium complex **4b** was readily prepared in 52% yield by allowing an excess (3 equiv.) of $Ru(bpy)_2Cl_2$ to react with **4a** in refluxing ethanol (Scheme 3). The complex was purified by chromatography on silica gel using a MeCN/water/KNO_3 (sat. aq.) (5:4:1) solution as eluent followed by anion exchange to its PF_6 salt. ^1H and ^{13}C NMR spectroscopic and mass spectrometric analyses confirm the dinuclear nature of **4b**. Cyclic and differential pulse voltammograms of **4b** in acetonitrile vs. SCE (in V, anodic and cathodic peak separation in mV) showed a single oxidation process which is assigned to two simultaneous, metal-based, one-electron oxidation processes [+1.40 V (100 mV)] and two reversible one-electron reduction processes [−0.70 V (62 mV), −1.00 V (63 mV)], which are assigned to successive one-electron reductions of the coordinated bridging ligand **4a**. No other reversible reductions were found out to −2.00 V. The coincidence of the two metal-centred oxidation processes indicates that the two metal centres are only weakly interacting with one another, as expected since the two chelating sites in **4b** cannot lie co-planar to afford orbital overlap (cf. Figure 1). The ligand-based reduction potentials are considerably less negative than bpy-centred reductions in $Ru(bpy)_3^{2+}$ (−1.28 V)[25] due to the electron-deficient nature of the pyrimidine rings.

The absorption and photophysical properties of **4b** are also in line with those of other dinuclear (polypyridine)Ru^{II} complexes containing relatively easy-to-reduce bridging ligands.[25] The electronic absorption spectrum of **4b** in acetonitrile shows the same general profile, with ligand-based absorptions predominating in the UV region: λ_{max} (ε [$M^{-1}cm^{-1}$]) = 247 (44,400), 286 nm (114,300)] and spin-allowed MLCT bands in the visible region: λ_{max} (ε [$M^{-1}cm^{-1}$]) = 429 (17,000), 518 nm (14,300)]. Complex **4b** is luminescent at room temperature, emitting at 784 nm with a lifetime of 34 ns. At 77 K, the emission shifts to shorter wavelength, 695 nm, and its lifetime extends to 126 ns.

Complex **4b** was further characterised using ^{99}Ru NMR.[26] At 343 K, the ^{99}Ru NMR spectrum of an acetonitrile solution of **4b** presents two baseline-resolved resonances of equal intensity at δ = 4660 and 4677 ppm (Figure 2). This agrees with the two inequivalent Ru sites in **4b**. The line width at half height ($W_{1/2}$), similar for both resonances (ca. 100 Hz, i.e. 4 ppm), is hardly larger than for the highly symmetrical analogue $Ru(bpy)_3^{2+}$ (65 Hz in CD_3CN at 22 °C).[27] This reflects the fact that the local symmetry at each Ru site is relatively higher than expected from the low symmetry of the whole complex **4b**. Attribution of the two signals to the ruthenium ions is virtually impossible, as there is no general correlation with other experimental data. It is nevertheless noteworthy that the very subtle differences of the two binding sites of asymmetric ligand **4a** are clearly reflected in different chemical shifts for the ruthenium atom. The observed difference in chemical shift between the two Ru nuclei (17 ppm) is very small when compared to the huge chemical shift range of ^{99}Ru (ca. 18,000 ppm) as well as to the various "medium" effects, such as the dependence of the ruthenium chemical shift on temperature, solvent and concentration. This confirms the



Scheme 3. Synthesis of diruthenium complex **4b**

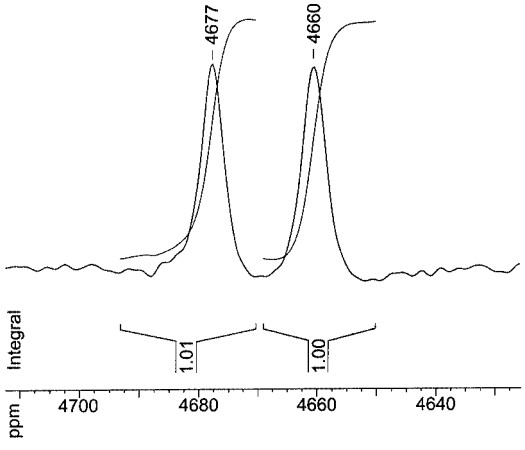


Figure 2. ^{99}Ru NMR of complex **4b** in acetonitrile at 343 K

high potential of ^{99}Ru NMR to characterise polynuclear ruthenium complexes.[27] We are currently working on other (azaheterocycle)di- and -triruthenium complexes and making use of ^{99}Ru NMR to probe ruthenium-containing dendrimers.

Conclusion

The combination of **3** and LTMP gives both radical anion coupling and lithiation/addition reactions, which were found to produce symmetric and asymmetric ligands **2a** and **4a**, respectively. Controlled radical anion coupling of the electron-deficient pyrimidine ring of **3** using Na has allowed a facile entry into the synthesis of trinucleating ligand **2a**. Thus, the judicious choice of reaction conditions is an easy way to produce different multinucleating ligands for coordination chemistry from unsubstituted azaheterocycles.

The diruthenium complex of asymmetric ligand **4a** has been fully characterised, including its ^{99}Ru NMR. It is noteworthy that although electrochemical studies could not clearly distinguish between the two metal centres in **4b**, this was readily accomplished using ^{99}Ru NMR. We are investigating methods to increase the overall yield of this reaction and to expand this approach to poly(azaheterocyclic) ligands.[28]

[14] BuLi (1.6 M in hexane, 200 μL, 0.32 mmol) and ligand (0.32 mmol) were added to 5 mL of THF at −78 °C and stirred for 15 min before being warmed to room temp. over 30 min. The solution was then returned to −78 °C and **3** (100 mg, 0.64 mmol) was dissolved in THF (5 mL) and added to the lithium solution by cannula. After stirring for 1 h at −78 °C, the solution was rapidly warmed to room temp. and quenched with ethanol (5 mL) and triethylamine (400 μL). Air was bubbled through the solution for 1 h. The solution was concentrated to dryness, dissolved in dichloromethane (20 mL) and extracted with water (2 × 20 mL). NMR was used to determine ratio of products to remaining starting material. The residue was then sublimed to remove the starting material (< 80 °C) and to collect the products (90−160 °C).

[26] The ^{99}Ru NMR spectra have been recorded with a Bruker DRX 500 spectrometer tuned at 23.142 MHz and equipped with a 10-mm broad-band probehead. Complex **4b** (30 mg) was dissolved in acetonitrile (3 mL). The spectra were recorded without lock and the chemical shifts were referenced with respect to a saturated aqueous solution of $K_4Ru(CN)_6$ (δ = 0 ppm at 300 K). A preliminary spectrum obtained at 300 K showed a broad signal ($W_{1/2}$ ≈ 400 Hz, 16 ppm) at δ ≈ 4580 ppm with two distinct maxima. Raising the temperature to 343 K, in order to increase the relaxation time of the quadrupolar ^{99}Ru nucleus, resulted in a clean separation of the two resonances. In addition, there is a strong deshielding by nearly 100 ppm, with respect to the 300 K resonance. The spectrum in Figure 2 required a total of 4 × 10^6 scans with an acquisition time of 16 ms, a pre-acquisition delay of 11.4 μs and a spectral width of 62 kHz. Exponential multiplication with a line-broadening factor of 10 Hz was applied prior to Fourier transformation.

Chiral Supramolecular Assemblies Derived from the Insertion of a Segmental Ligand into a Copper-Tyrosine Framework

Jiabao Weng,[a,b] Maochun Hong,*[a] Qian Shi,[a] Rong Cao,[a] and Albert S. C. Chan[c]

Keywords: Amino acids / Copper / Self-assembly / Polymers

The use of a predisposed 4,4-bipyridine segmental ligand in copper-tyrosine chiral complex self-assembly processes allows the preparation of a new type of complex $\{[Cu_2(tyrosine)_2(4,4\text{-bipyridine})\cdot 2H_2O]\cdot 2ClO_4\}_n$, which results in the fine tuning of network structure and stereo conformation.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

The construction of metal-organic molecular coordination frameworks by metal coordination-directed self-assembly processes has become an area of intense research in recent years.[1−4] The network structures and properties of these coordination supramolecules can be fine-tuned by a systematic change of the organic linking ligands.[5−7] However, the study of metal-amino acid chiral supramolecular assemblies is less popular and the synthesis of these assemblies with a mixture of organic ligands is a significant challenge.

Among the natural amino acids, phenylalanine with hydroxyl group(s) plays an important role in biological systems.[8] Tyrosine has also been known to be located at the active sites of a series of metal proteins and to act as an important part in the protein factors.[9−13] On the other hand, copper is a bioelement and an active site in several metalloenzymes and proteins.[14] The blue copper proteins have received considerable interest because of their unusual spectral and structural properties. The geometry around copper in blue proteins is intermediate between tetrahedral and square planar and several model systems have been developed to study the molecular structure with the electronic group state of those complexes.[15−17] Hence, copper-amino acid complexes, especially aromatic amino acid ones, are of great interest, not only due to their importance in biological systems but also because of their remarkable properties derived from stacking, hydrogen bonding, and metal-aromatic ring interactions.[18] In the course of our studies on this structure-function relationship, we report here the synthesis and crystal structures of two copper(II) coordination polymers with tyrosine as ligand $[Cu(Tyr)_2]_n$ (**1**) and $\{[Cu_2(Tyr)_2(4,4\text{-bipy})\cdot 2H_2O]\cdot 2ClO_4\}_n$ (**2**) (Tyr = tyrosine; 4,4-bipy = 4,4-bipyridine), where 4,4-bipy acts as an inserting component that has a subtle effect on the structural characteristics of the copper-tyrosine complex by self-assembled control. The synthesis and the structures of the polymers provide a new insight into understanding the mode of action of copper(II)-tyrosine complexes and are important not only for coordination chemistry but also for biochemistry.

Complex **1** was obtained by slow evaporation of solutions prepared by mixing tyrosine and Cu^{II} perchlorate in methanol/water with a metal-to-ligand molar ratio of 1:1. Figure 1 shows the crystal structure of the biologically relevant complex **1** formed between Cu^{II} and tyrosine. The geometry around the Cu^{II} ion can be described as square pyramidal. Two tyrosine molecules chelate the Cu^{II} ion through the nitrogen and oxygen atoms forming two five-membered rings with the Cu^{II} ion located in the center of the N_2O_2 square plane. There are two kinds of coordination modes of tyrosine molecule in complex **1**: chelating, which leaves one oxygen atom of the carboxyl group free, and exobidentate bridging, with a μ-carboxyl group linking adjacent Cu^{II} ions through the oxygen atom at the vertex of the square pyramid giving rise to a one-dimensional right-handed chiral chain structure generated by a 2_1 operation (Figure 2). The angles between the axial Cu−O bond and the four equatorial bonds in the square plane lie in the range of 85.3−95.7°. All Cu−N and Cu−O bond lengths are normal (1.92 Å to 2.00 Å) except for the axial Cu−O bond (2.36 Å). The phenyl-bound hydroxyl group of the bridging tyrosine hydrogen-bonds with that of the non-bridging tyrosine and the free oxygen atom of the carboxyl

group, which connects the adjacent chiral chains to form a three-dimensional supramolecular assembly.

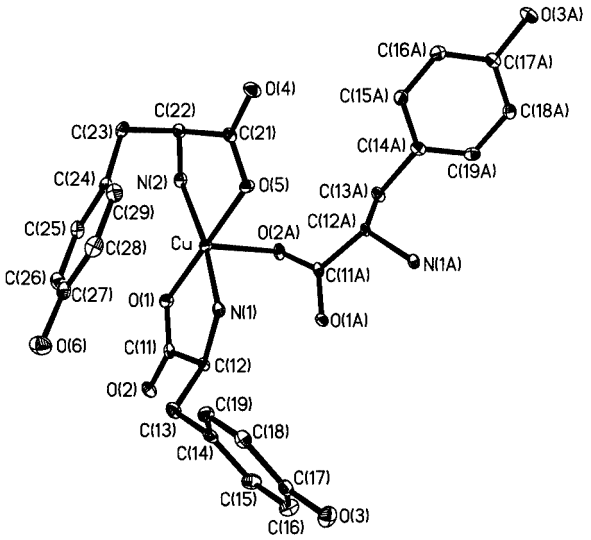

Figure 1. Coordination environment of **1**; the asymmetric unit is shown with ellipsoids at 30% probability; hydrogen atoms have been omitted for clarity

In order to insert an organic ligand into the chiral chains of the copper(II)-tyrosine assembly, 4,4-bipy was added to the reaction mixture of copper(II) and tyrosine; complex **2** was obtained. The structural subunit of complex **2** contains two copper ions(Figure 3), each of which is coordinated to one tyrosine molecule, one water molecule of crystallization and one 4,4-bipy molecule. The coordination geometry of Cu^{II} in **2** is also square pyramidal: the oxygen atom of the water molecule lies at the vertex of the square pyramid and four donor atoms — a nitrogen atom from 4,4-bipy, an oxy-

gen atom from the μ-carboxyl group and the chelated N and O atoms — form the N_2O_2 square plane. The angles between the bond of the axial oxygen with Cu^{II} and the equatorial bonds ranges from 87.6 to 97.3°, while the bond lengths are similar to those in complex **1**. Similar to complex **1**, the tyrosine in complex **2** coordinates to Cu^{II} ion in a bidentate fashion through N and O donor atoms and a μ-carboxyl group links adjacent Cu^{II} ions (Figure 4). The adjacent subunits are related by a 2_1 operation to form an infinite chiral chain structure similar to complex **1**. The N(1) and O(1) atoms in complex **1** are replaced by a nitrogen atom from 4,4-bipy and an oxygen atom from the bridging carboxyl group in complex **2**, respectively, and the 4,4-bipy ligand bridges the adjacent chiral Cu-Tyr chains to form the extended two-dimensional plane. These 2-D sheets are stacked through hydrogen bonding between the ClO_4^- counterion and the free phenol hydroxyl groups and between the counterion and crystal water. Although both chiral chain structures in **1** and **2** are similar topologically, the Cu−Cu−Cu angle and the distance between adjacent Cu atoms in the same chain are different, as shown in Figure 2 and Figure 4 (76.0° and 4.93 Å in **1**, 141.6° and 5.35 Å in **2**) due to the different coordination position of the oxygen atom of the bridging carboxyl of tyrosine (it is axial in complex **1** and equatorial in complex **2**). We believe that the presence of the 4,4-bipy ligand in **2** is responsible for the subtle tuning of the chiral chain structure, forming a square-planar geometry in the self-assembly process with amino acids.[15,19] The Cu^{II} ion acts as a kind of Lewis acid[20] and can therefore bind Lewis bases, such as the oxygen atom of the bridging carboxyl group in complex **1** and a water molecule of crystallization in complex **2**, in its free axial coordination site.

In conclusion, the use of a 4,4-bipy segmental ligand in Cu-Tyr complex self-assembly processes allows the preparation of a new type of complex $\{[Cu_2(Tyr)_2(4,4\text{-bipy})\cdot 2H_2O]\cdot 2ClO_4\}_n$. This modification of the ligand environment has a considerable effect on the solid-state structure

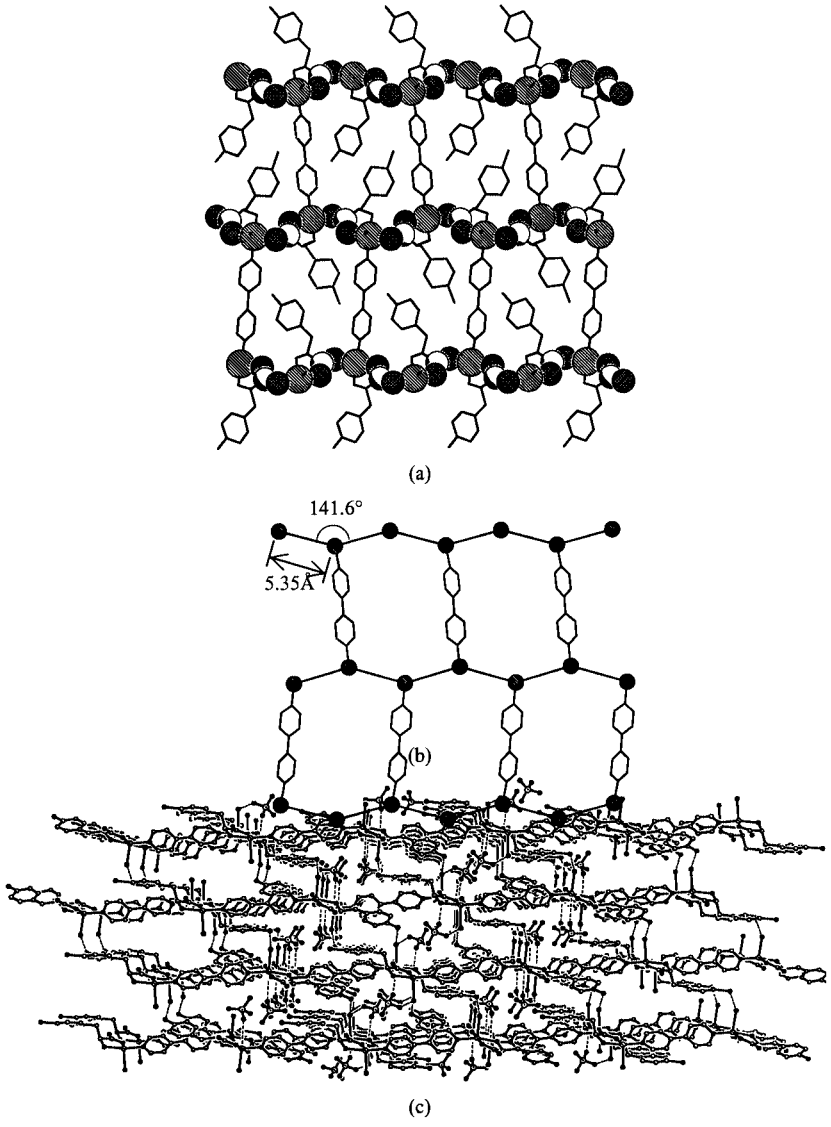

Figure 4. (a) perspective view of the 2-D sheet of **2**; the Cu^{II} and bridging carboxyl are represented by larger circles; (b) 2-D network connectivity in **2**; the filled circles represent the $Cu(Tyr)\cdot H_2O$ unit; (c) stacking of 2-D sheets of **2**

of Cu-Tyr complexes, thus leading to the fine tuning of the structural and stereo conformation.

Experimental Section

Synthesis of $[Cu(Tyr)_2]_n$ (1): A 1.0 M aqueous solution of NaOH was carefully added dropwise to a suspension of L-tyrosine (181 mg, 1.0 mmol) in 10 mL water, with vigorous stirring, until ligand dissolved. The solution was then mixed with a solution of copper perchlorate (576 mg, 1.0 mmol) in 10 mL methanol. The reaction mixture was stirred overnight to give a blue solution, which was then filtered. Blue needle-shaped crystals of $[Cu(Tyr)_2]_n$ (**1**) suitable for X-ray diffraction analysis were obtained after several days' evaporation at room temperature. Yield: 136 mg (64% for tyrosine). $C_{18}H_{20}CuN_2O_6$ (423.9): calcd. C 50.96, H 4.75, N 6.61; found C 50.47, H 4.66, N 6.82.

Synthesis of $\{[Cu_2(Tyr)_2(4,4\text{-bipy})\cdot 2H_2O]\cdot 2ClO_4\}_n$ (2): This complex was synthesized as for complex **1**. 4,4-Bipyridine (156 mg, 1.0 mmol) was added after the overnight reaction step and the mixture was stirred for another 4 h. Single crystals of complex **2** suitable for X-ray diffraction analysis were obtained by evaporation of the filtered mixture at room temperature after two weeks. Yield: 190 mg (43% for tyrosine). $C_{23}H_{32}Cl_2Cu_2N_4O_{16}$ (818.5): calcd. C 38.24, H 3.67, N 6.37; found C 38.86, H 3.68, N 6.62.

X-ray crystallography: The intensity data were collected on a Bruker CCD diffractometer with graphite-monochromated Mo-K_α radiation ($\lambda = 0.71073$ Å) at room temperature. All of the calculations were performed on an HP computer by using the SHELXTL-PL version 5.10 package. The structures were solved by direct methods and refined by full-matrix least-squares (Table 1).[21]

Crystal Data for 1: Blue needle, dimensions 0.25 × 0.20 × 0.10 mm, $C_{18}H_{20}CuN_2O_6$, M_r = 423.90, orthorhombic, space group $P2_12_12_1$; a = 6.0753(12) Å, b = 12.948(3) Å, c = 22.037(4) Å, V = 1733.4(6) Å^3; $\rho_{calc.}$ = 1.624 g/cm^3, Z = 4; $F(000)$ = 876; μ(Mo-K_α) = 1.300 mm^{-1}; 2340 reflections collected, 2340 reflections observed ($|F_0| \geq 2\sigma|F_0|$); R_1 = 0.0397; wR_2 = 0.1004.

Tetraamidosulfurane and its Decomposition Products — an ab initio MO Study[‡]

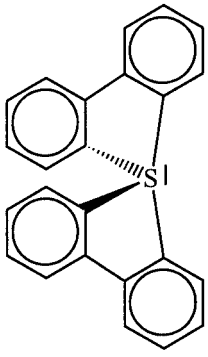
Ralf Steudel,*[a] Yana Steudel,[a] and Dieter Lentz[b]

Keywords: Sulfur / Hypervalent compounds / Reaction mechanisms / Ab initio calculations

Ab initio MO calculations at the G3(MP2) level of theory show that sulfur tetraamide $S(NH_2)_4$ is a local minimum energy structure but thermodynamically unstable with respect to both sulfur diamide $S(NH_2)_2$ plus hydrazine and sulfurimidediamide $S(NH)(NH_2)_2$ plus ammonia. The activation enthalpy of the latter reaction is 63 kJ·mol^{-1} at 298 K.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

The hypercoordinate compounds of sulfur — also termed as hypervalent — have attracted much attention owing to their unusual bonding situation with formal violation of the octet rule. In particular, sulfur hexafluoride has been investigated theoretically many times. It is now generally accepted that the covalent bonds in this species can be understood on the basis of multi-center interactions of the 3s and 3p atomic orbitals of sulfur with the 2p orbitals of the fluorine atoms, while the high-energy sulfur 3d valence orbitals play a minor role and, to a first approximation, can be neglected, although d and f functions serve as polarization functions in the basis sets used.[1] Compounds of this type are, however, thermodynamically stable only with highly electronegative substituents. The same holds for sulfuranes of the type SX_4, of which many derivatives have been prepared. Examples are SF_4,[2] $SClF_3$,[3] SCl_2F_2,[3] SCl_3F[3] and a large number of tetraoxosulfuranes with bidentate ligands.[4] Tetrachlorosulfurane (SCl_4) is thermodynamically unstable with respect to SCl_2 and Cl_2.[2] Therefore, SCl_4 is still unknown and the same holds for SMe_4,[5] $S(SH)_4$ [6] and SH_4.[7] However, in favorable cases, sulfuranes with substituents of low electronegativity can be prepared, as the successful synthesis of bis(2,2′-biphenylylene)sulfurane has demonstrated.[8]



If there is a high enough barrier for the decomposition of SX_4 to the corresponding sulfane (SX_2) and X_2 the molecule SX_4 should be accessible experimentally even if unstable in a thermodynamic sense.

The missing sulfuranes with four identical first-row atoms attached to sulfur are the tetraamidosulfurane $S(NH_2)_4$ and substituted organic derivatives thereof. The electronegativity of nitrogen is slightly higher than that of chlorine on the scales published by Allred[9] and by Allen[10] and should sufficiently stabilize such a structure. Therefore, we have explored for the first time the structure and stability of $S(NH_2)_4$ which represents one of the most basic structures in the very rich chemistry of sulfur-nitrogen compounds.[11] In this context we have also studied the related imidodiamide $S(NH)(NH_2)_2$ and the diamide $S(NH_2)_2$, which are both hypothetical compounds but probable decomposition products of $S(NH_2)_4$. So far, only the sulfurdiamide has been studied by theoretical methods: Leroy et al. reported calculations at the MP2(full)/6-31G(d,p) level of theory resulting in a C_{2v} symmetry for $S(NH_2)_2$, although they did not publish any geometrical details.[12] Kontopoulos and Sigalas[13] optimized the geometry of $S(NH_2)_2$

[‡] Sulfur compounds, 224. Part 223: R. Steudel, K. Hassenberg, J. Pickardt, E. Grigiotto, P. Zanello, *Organometallics* **2002**, *21*, 2604−2608.

at the MP2/3-21+G(d,p) level and reported two bond lengths and three bond angles but neither the molecular symmetry nor any torsion angles were published. It seems that the latter authors either assumed or obtained the molecular symmetry C_{2v} but the exact geometry remains unknown since two conformations of this symmetry are possible (see below). Partly and fully organyl-substituted derivatives of **1** are known.[11]

Calculations

Standard ab initio MO calculations were performed using the Gaussian 98[14] series of programs. The energies of various equilibrium structures and transition states were examined at the G3(MP2) level of theory.[15] In brief, the G3(MP2) method is a composite procedure which provides an accurate approximation to the high level of theory at QCISD(T)/GTMP2LARGE//MP2(full)/6-31G(d), with the incorporation of zero-point energy [calculated from HF/6-31G(d) vibrational wavenumbers, scaled by 0.8929] and higher level corrections. This level of theory is usually accurate to within 6 kJ·mol^{-1} of experimental values.[15] A charge density analysis, at the MP2(full)/6-31G* level, was performed using the natural bond orbital (NBO) approach.[16] Unless otherwise noted, all relative energies reported in this publication are given as $\Delta H°_{298}$ and correspond to the G3(MP2) level, while structural parameters were obtained at the MP2(full)/6-31G* level. The harmonic vibrational wavenumbers of $S(NH_2)_2$, $S(NH)(NH_2)_2$ and $S(NH_2)_4$ were calculated at the same level.

Results and Discussion

The structures of $S(NH_2)_2$, $S(NH)(NH_2)_2$ and $S(NH_2)_4$ are shown in Figure 1; selected geometrical parameters are given in Table 1. At the global minimum the diamide has C_{2v} symmetry (**1**), although two rotational isomers **2** (C_s) and **3** (C_{2v}) also exist. While **1** and **2** are almost degenerate ($\Delta H°_{298}$ = 1 kJ·mol^{-1}), isomer **3** is less stable than **1** by 9 kJ·mol^{-1} (Table 2), probably as the result of the repulsion between the nitrogen lone pairs which are directed towards each other. In all three conformers the nitrogen lone pairs are orthogonal to the sulfur 3p lone pair, which is expected to occupy the HOMO of these molecules. In the most stable isomer **1** the NBO atomic charges on sulfur, nitrogen and hydrogen are +0.61, −1.03 and +0.36, respectively. The geometrical parameters all have normal values.

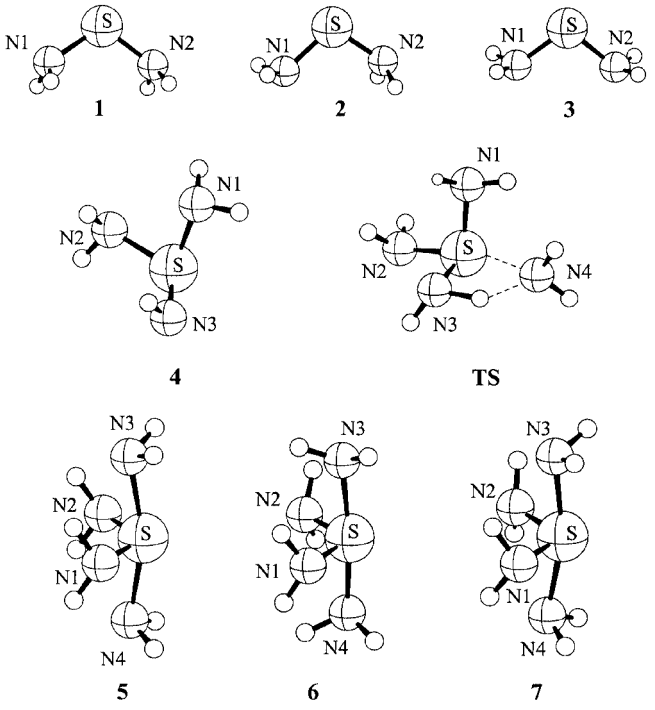

Figure 1. Structures of various rotamers of $S(NH_2)_2$ (**1**−**3**) and $S(NH_2)_4$ (**5**−**7**) as well as structure as $S(NH)(NH_2)_2$ (**4**) and of the transition state **TS** for the formation of **4** from **5**, calculated at the MP2(full)/6-31G* level

The imidodiamide **4** has no symmetry at all (C_1). The S=N bond length of 155.0 pm is considerably shorter than the two formal S−N single bonds of length 173.4 and 174.5 pm. The orientation of the two amido groups seems to be influenced by weak N−H···N hydrogen bonds between N1 and a hydrogen on N2 (250.2 pm) and between N2 and a

Table 2. Relative energies and enthalpies (kJ·mol^{-1}) of $S(NH_2)_2$ and $S(NH_2)_4$; the absolute energies of **1** and **5** are −509.47982 and −621.15958 hartree, respectively

G3(MP2)	ΔE_0°	ΔH°_{298}	ΔG°_{298}
$S(NH_2)_2$ **1**	0	0	0
$S(NH_2)_2$ **2**	1	1	1
$S(NH_2)_2$ **3**	8	9	8
$S(NH_2)_4$ **5**	0	0	0
$S(NH_2)_4$ **6**	12	12	11
$S(NH_2)_4$ **7**	14	15	13

hydrogen on N1 (249.4 pm); the N···H bond lengths given in parentheses are slightly shorter than the sum of the van der Waals radii (270 pm). The NBO atomic charges are +1.52 on sulfur, −1.14 on the amido nitrogens and −1.22 on the imido nitrogen. The four amido hydrogen atoms (+0.40) are slightly more positive than the imido hydrogen (+0.36). Salts containing the anion $S(NR)_3^{2-}$ — formally the substituted dianion of **4** — have been prepared recently.[17]

The tetraamide exists as three conformers: the most stable one is of C_{2v} symmetry (**5**) while the other two are of C_s symmetry (**6** and **7**). Their structures are in agreement with the expectations from VSEPR theory placing the lone pair at sulfur in an equatorial position of the trigonal bipyramids. The two axial substituents are bent towards the equatorial ones with $N_{ax}-S-N_{ax}$ bond angles of 162.7° (**5**), 165.4° (**7**) and 171.1° (**6**). The most symmetrical structure **5** seems to be stabilized by four N···H hydrogen bonds of length 215.8 pm between the axial nitrogens and the hydrogen atoms of the equatorial amido groups. However, since these bridges are bent by 94.4° and not aligned with the axes of the lone pair orbitals on the nitrogen atoms the hydrogen bonds will be weak. Interestingly, the two equatorial amido groups together with the sulfur atom have the same conformation as the most stable conformer of $S(NH_2)_2$ **1**. There are no indications for hydrogen bonds in rotational isomer **6**; however, four short N···H contacts of 216 pm (two) and 227 pm (two) can be recognized in **7**. However, for these interactions the same geometrical restrictions hold true as mentioned above in the case of isomer **5**. The absolute and relative energies of the di- and tetraamides are given in Table 2.

Table 3. Reaction energies and enthalpies (kJ·mol^{-1}) for the decomposition of $S(NH_2)_4$ **5**. The absolute energies of **TS**, $S(NH)(NH_2)_2$, N_2H_4 and NH_3 are −621.13591, −564.72321, −111.69962, and −56.47014 hartree, respectively

G3(MP2):	ΔE_0°	ΔH°_{298}	ΔG°_{298}
$S(NH_2)_4 \rightarrow S(NH_2)_2$ **1** + N_2H_4	−52	−48	−102
$S(NH_2)_4 \rightarrow$ **TS**	62	63	62
$S(NH_2)_4 \rightarrow S(NH)(NH_2)_2 + NH_3$	−87	−83	−134

The data presented in Table 3 demonstrate that tetraamidosulfurane is thermodynamically unstable with respect to a decomposition both to the diamide plus hydrazine and to the imidodiamide plus ammonia. The latter reaction is clearly favored with a reaction enthalpy of −83 kJ·mol^{-1} compared to only −48 kJ·mol^{-1} for the hydrazine extrusion.

The transition state (**TS**) for the ammonia elimination has been located; its structure is shown in Figure 1. The reaction begins with a transformation of **5** into **7**. Then, one of the axial S−N bonds increases from 191.3 pm in the sulfurane **7** to 243.9 pm in **TS** while one hydrogen atom of an equatorial amido group forms a bridge to the leaving axial NH_2 group with N···H distances of 117.2 (to N3) and 145.6 pm (to N4). The angle N3−H−N4 is 133.6°. Thus, the formation of NH_3 can clearly be recognized in the structure of **TS**, which is of C_1 symmetry. Simultaneously, the other axial S−N bond decreases in length from 191.3 pm in **7** to 172.3 pm in **TS**. The activation enthalpy at 298 K with respect to the most stable conformer **5** is 63 kJ·mol^{-1}. Thus, it is surprising that $S(NH_2)_4$ has not been prepared yet.

Unexpectedly, the decomposition of **5** to hydrazine and sulfurdiamide is also strongly exothermic despite the weak N−N bond in hydrazine. Despite numerous attempts, at various levels of theory, we did not succeed in locating a transition state for this reaction on the potential energy hypersurface. Instead, the formation of ammonia was always the preferred reaction. If the NH distances were kept con-

stant to suppress the NH_3 formation the only transition states found were those for the pyramidal inversion at the nitrogen atoms. Furthermore, the transition states for the decomposition of SF_4, SCl_4 and $S(SMe)_4$ were used to design the starting geometries for the wanted transition state,but these attempts also failed.

The thermodynamic instability of $S(NH_2)_4$ may be explained by the weakness of the two axial S−N bonds, which can be estimated from their rather long bond lengths (191.4 pm in **5**) compared to those of the equatorial bonds (169.8 pm) and to the S−N bonds in $S(NH_2)_2$ (169.6 pm in **1**). The gain in entropy also favors the two decomposition reactions.

To support future preparative work on these compounds the knowledge of the fundamental harmonic vibrational modes may be helpful. These data are given in Table 4.

Facile C−S Bond Activation of Levamisole Hydrochloride on a Triruthenium Cluster Core

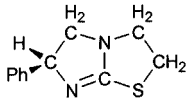
Javier A. Cabeza,*[a] Ignacio del Río,[a] Santiago García-Granda,[b] Víctor Riera,[a] and M. Gabriela Sánchez-Vega[c]

Keywords: Ruthenium / Metal clusters / Levamisole / S ligands / C−S bond activation

The reaction of $[Ru_3(CO)_{12}]$ with levamisole hydrochloride ([Hlvms]Cl) leads to $[Ru_3(\mu\text{-}Cl)(\mu\text{-}\eta^2\text{-}C_{11}H_{13}N_2S\text{-}C,S)(CO)_9]$ (**1**). This complex contains a new ligand that arises from an unprecedented oxidative addition of an S–C bond of protonated levamisole to a metal atom, and is the first example of a non-mononuclear complex derivative of levamisole. The mechanism of this reaction has been partially elucidated by studying the reaction of $[Ru_3(MeCN)_2(CO)_{10}]$ with [Hlvms]Cl and $[Ru_3(\mu\text{-}Cl)(CO)_{10}]^-$ with [Hlvms][BF_4]. It is concluded that upon treatment with levamisole hydrochloride, $[Ru_3(CO)_{12}]$ is attacked by the chloride anion to give $[Ru_3(\mu\text{-}Cl)(CO)_{10}]^-$; a subsequent coupling of this cluster anion with the $[Hlvms]^+$ cation leads to an uncharacterized neutral derivative which has an intact [Hlvms] group attached to a ruthenium atom through the sulfur atom. This neutral derivative readily undergoes an S–C bond activation process to give compound **1**. (© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002)

Introduction

Levamisole (lvms), (−)-2,3,5,6-tetrahydro-6-phenylimidazo[2,1-*b*]thiazole, and levamisole hydrochloride ([Hlvms]Cl) are well-known anthelmintic drugs with immunomodulatory[1] and anticancer[2] activities.



levamisole

From the point of view of coordination chemistry, levamisole is an attractive ligand because (a) it possesses three heteroatoms liable to attach metal atoms, (b) it has several C-heteroatom bonds that can be activated or modified by reaction with metal complexes, and (c) due to the presence of a stereogenic carbon atom, it may lead to optically active metal-containing products.

Very few inorganic derivatives of levamisole have been reported so far, the only examples being the complexes $[MCl_2(lvms)_2]$ (M = Co,[3] Ni,[3] Pd,[4] Cu,[3] Zn[3]), [Pd(η^2-amino acidato)$(lvms)_2$]Cl[4] and [PtCl(en)(lvms)]Cl.[5] Interestingly, the zinc complex $[ZnCl_2(lvms)_2]$ is less toxic and has a higher immunomodulating activity than uncomplexed levamisole.[3] In all these coordination compounds, levamisole behaves as a monodentate ligand which binds the metal through the N^7 atom. It is noteworthy that no complexes derived from levamisole hydrochloride and no complexes of nuclearity higher than one derived from any form of levamisole have been reported previously.

The molecular activation of C−S bonds by metal cluster complexes is currently receiving a great deal of attention in relation to hydrodesulfurization processes.[6] In particular, the use of transition metal carbonyl clusters as models for catalyst surfaces is based on the cluster-surface analogy proposed by Muetterties,[7] in which the cluster is viewed as a small fragment of the surface. Although it is realized that the metal atoms of molecular clusters are chemically very different from those of bulk metals, it is believed that the coordination of molecules to clusters and surfaces is similar because they are essentially localized phenomena.[6]

We now report the reactions of some triruthenium carbonyl cluster complexes with levamisole and levamisole hydrochloride, in which a facile C−S bond activation process has been recognized as a key reaction step.

Results and Discussion

The reactions of $[Ru_3(CO)_{12}]$ and $[Ru_3(MeCN)_2(CO)_{10}]$ with levamisole at different temperatures (10−80 °C) led to mixtures of many compounds which could not be satisfact-

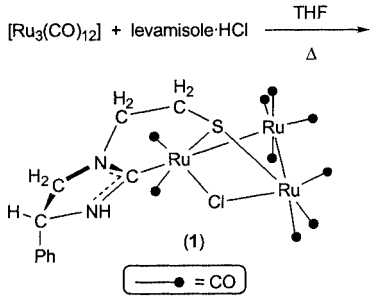
orily separated and identified. However, levamisole hydrochloride reacted smoothly with $[Ru_3(CO)_{12}]$ in THF at reflux temperature to give $[Ru_3(\mu\text{-}Cl)(\mu\text{-}\eta^2\text{-}C_{11}H_{13}N_2S\text{-}C,S)(CO)_9]$ (**1**) in high yield (Scheme 1).



Scheme 1. Synthesis of compound **1**

An X-ray diffraction study on $\mathbf{1}\cdot C_6H_6$ (Figure 1, Table 1) revealed that this compound is a 50-electron cluster with an open edge which is doubly bridged by the chloride ligand and by the sulfur atom of a 1-ethylenethiolate-3,4,5-trihydro-4-phenylimidazol-2-yl ligand. The C^2 atom of the imidazole ring is also attached to one of the ruthenium atoms of the open edge. The original N-*H* proton and the original chirality of levamisole hydrochloride are maintained in compound **1**.

Interestingly, the new organic ligand of complex **1** arises from an unprecedented oxidative addition of an S−C bond of protonated levamisole to a metal atom. Complex **1** is also the first example of a non-mononuclear derivative of levamisole.

In an attempt to shed light on the reaction pathway that leads to compound **1** from $[Ru_3(CO)_{12}]$, we treated the activated complex $[Ru_3(MeCN)_2(CO)_{10}]$[8] with levamisole hydrochloride in dichloromethane, expecting the observation of intermediates that are stable at room temperature. The anionic complex $[Ru_3(\mu\text{-}Cl)(CO)_{10}]^-$ was observed immediately by IR spectroscopy.[9] A spot TLC analysis of the solution also indicated the presence of small amounts of **1**, $[Ru_3(CO)_{12}]$ and a yellow compound that decomposed on the TLC plate after a couple of minutes. Heating this solution to reflux temperature led to compound **1** as the major product. In a subsequent experiment, we treated $[Ru_3(\mu\text{-}Cl)(CO)_{10}]^-$ (formed in situ from $[Ru_3(CO)_{12}]$ and [PPN]Cl)[9] with $[Hlvms][BF_4]$ (made from levamisole and $[HOEt_2][BF_4]$). Again, a mixture of $[Ru_3(CO)_{12}]$, the unknown yellow product and compound **1** was observed *at room temperature*. Unfortunately, all attempts to isolate the yellow compound were unsuccessful, since chromatographic supports promoted its transformation into complex **1**.

Ru(1)−Cl(1)	2.506(1)	Ru(3)−S(1)−C(3)	107.9(2)
Ru(1)−C(1)	2.084(6)	Ru(1)−C(1)−N(1)	121.8(5)
Ru(3)−S(1)	2.411(1)	Ru(1)−C(1)−N(2)	130.3(5)
Ru(3)−Cl(1)	2.493(1)	S(1)−C(3)−C(2)	111.1(5)
S(1)−C(3)	1.826(6)	N(2)−C(2)−C(3)	112.1(6)
N(1)−C(1)	1.351(8)	C(1)−N(2)−C(2)	126.8(5)
N(1)−C(5)	1.460(7)	N(1)−C(1)−N(2)	107.8(5)
N(2)−C(1)	1.304(8)	C(1)−N(1)−C(5)	113.5(5)
N(2)−C(2)	1.464(9)	N(1)−C(5)−C(4)	101.6(5)
N(2)−C(4)	1.463(7)	C(1)−N(2)−C(4)	114.2(5)
C(2)−C(3)	1.49(1)	N(2)−C(2)−C(3)	112.1(6)
C(4)−C(5)	1.53(1)	N(2)−C(4)−C(5)	102.3(5)

The above data suggest that upon treatment with levamisole hydrochloride, $[Ru_3(CO)_{12}]$ is attacked by the chloride anion to give $[Ru_3(\mu\text{-}Cl)(CO)_{10}]^-$. A subsequent coupling of this anion with the $[Hlvms]^+$ cation would lead to a neutral derivative which probably has an intact [Hlvms] group attached to a ruthenium atom through the sulfur atom, but which readily undergoes an S−C bond activation process to give compound **1**. The low solubility of levamisole hydrochloride in THF at room temperature made it necessary to carry out the reaction at reflux temperature and this prevented the observation of intermediates.

Metal cluster-mediated S−C bond activation processes have often been achieved when working with organic sulfur-containing compounds at elevated temperatures.[6] However, such processes have never been observed at room temperature in ruthenium cluster chemistry.[10−14] For comparison purposes, it should be noted that the reaction of $[Ru_3(CO)_{12}]$ with thiophene proceeds via C−S bond cleavage to yield the sulfur-free ferrole-type complex $[Ru_2(\mu\text{-}C_4H_4)(CO)_6]$ and the tetranuclear cluster $[Ru_4(\mu_3\text{-}S)(\mu\text{-}C_4H_4)(CO)_{11}]$.[10] Analogous products were obtained from the reactions with 2-methylthiophene.[10] In the reaction of $[Ru_3(CO)_{12}]$ with benzothiophene, the insertion of a metal atom into the less hindered C−S bond occurs to give the ruthenium analogs of benzoferrole and benzothiaferrole, in addition to the desulfurized ruthenaindenyl complex $[Ru_3(\mu_3\text{-}C_8H_6)(CO)_6]$.[11] Similarly, regiospecific insertion into the less hindered C−S bond occurs in the reaction of $[Ru_3(CO)_{12}]$ with 2,2′-bithiophene, which leads to $[Ru_2(\mu\text{-}C_8H_6S)(CO)_6]$.[12] The sulfide derivatives $[Ru_3(\mu_3\text{-}S)(CO)_{10}]$, $[Ru_3(\mu_3\text{-}S)(\mu\text{-}H)_2(CO)_9]$ and $[Ru_4(\mu_4\text{-}S)(CO)_{11}]$ have been

prepared from $[Ru_3(CO)_{12}]$ and thiophenol.[13] The reaction of $[Ru_3(CO)_{12}]$ with 2-(diphenylphosphanyl)thiophenol gives the phenyl derivative $[Ru_3(\mu_3\text{-}S)(\mu\text{-}C_6H_5)(\mu\text{-}PPh_2)(PPh_3)(CO)_6]$, in which both C−S and C−P bonds have been activated.[14]

Further studies on the synthesis of levamisole-derived metal complexes are underway.

Concluding Remarks

From the above results, the following conclusions can be drawn:

(a) The synthesis of the first non-mononuclear metal complex derivative of levamisole is described (compound **1**). Only a few inorganic derivatives of levamisole have been reported previously,[3−5] some of which have important biological activity as immunomodulatory drugs.[3]

(b) Compound **1** is the first metal complex derivative of levamisole hydrochloride. The chirality of the free ligand is maintained in the metal complex.

(c) Compound **1** arises from a facile S−C bond activation process which opens the thiazolic ring. Such a process is unprecedented for levamisole and its derivatives.

(d) Chemical evidence has been presented that sheds light on the mechanism of the formation of compound **1** from $[Ru_3(CO)_{12}]$ and levamisole hydrochloride. It reveals that the S−C bond activation process also takes place at room temperature. The activation of S−C bonds by ruthenium clusters has never been observed previously at room temperature.

Experimental Section

General Remarks: Solvents were dried over sodium diphenyl ketyl (THF, hydrocarbons) and distilled under nitrogen prior to use. The reactions were carried out under nitrogen, using Schlenk-vacuum line techniques, and were routinely monitored by solution IR spectroscopy (carbonyl stretching region). IR: Perkin−Elmer Paragon 1000 FT. NMR: Bruker DPX-300, room temperature, $SiMe_4$ as internal standard. Microanalyses were obtained from the University of Oviedo Analytical Service. FAB-MS were obtained from the University of Santiago de Compostela Mass Spectroscopic Service; data given refer to the most abundant molecular ion isotopomer.

Compound 1: A mixture of $[Ru_3(CO)_{12}]$ (100 mg, 0.158 mmol) and levamisole hydrochloride (42 mg, 0.173 mmol) in THF (25 mL) was stirred at reflux temperature for 40 min. After cooling down to room temperature, the insoluble excess of levamisole hydrochloride was filtered off. Concentration to ca. 5 mL and addition of hexane (15 mL) led to precipitation of compound **1** as an orange solid (105 mg, 93%). $C_{20}H_{13}ClN_2O_9Ru_3S$ (796.09): calcd. C 30.18, H 1.65, N 3.52; found C 30.26, H 1.71, N 3.42. FAB-MS: *m/z* = 797 [M^+]. IR (CH_2Cl_2): ν(CO) = 2085 (m), 2048 (s), 2003 (vs), 1993 (sh), 1948 (w) cm^{-1}. ^1H NMR (CD_2Cl_2): δ = 7.6−7.2 (m, 5 H), 6.44 (br. s, 1 H), 5.05 (m, 1 H), 4.4−2.9 (m, 6 H) ppm.

X-ray Crystallographic Study: A single crystal of **1**·C_6H_6 was measured on a Nonius CAD4 diffractometer, equipped with a graphite crystal monochromator, using the ω-2θ scan technique with a variable scan rate and a maximum scan time of 60 s per reflection (Table 2). 2648 Friedel pairs were measured. An empirical absorption correction was applied using XABS2,[15] maximum and minimum transmission factors 0.683 and 0.571. Lorentz and polarization corrections were applied and data reduced to F_0^2 values. The structure was solved by Patterson interpretation using DIRDIF-96.[16] Isotropic and full-matrix anisotropic least-squares refinements were carried out using SHELXL-97.[17] All non H-atoms were refined anisotropically. Hydrogen atom positions were geometrically calculated and refined riding on their parent atoms, except for the N-*H* proton, which was observed and freely refined. The molecular plot was made with the EUCLID program package.[18] The WINGX program system[19] was used throughout the structure determination.

Fullerene and Carborane in One Coordination Sphere: Synthesis and Structure of a Mixed η^2-C_{60} and σ-Carboranyl Complex of Iridium

Alexander V. Usatov,*[a] Ekaterina V. Martynova,[a] Fedor M. Dolgushin,[a] Alexander S. Peregudov,[a] Mikhail Yu. Antipin,[a] and Yurii N. Novikov[a]

Keywords: Fullerenes / Boranes / Iridium / Complexes / X-ray analysis

The first representative of metal complexes containing two different polyhedral clusters (namely, a fullerene and a carborane) as ligands in the same coordination sphere of the metal atom, [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (**II**), was synthesized in the reaction of C_{60} with the metallacyclic carboranyliridium dihydride complex [Ir(H)$_2$(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(PPh_3)(L)] (L = CO or PPh_3) by reflux in toluene in the presence of 2 equiv. of *t*BuNC. The compound obtained was characterized by analytical and spectroscopic (UV, IR, ^{1}H and ^{31}P NMR) data. The molecular structure of complex **II** was determined by single-crystal X-ray diffraction analysis, which showed that the most interesting structural feature of **II** is the distortion of the iridacyclopropane moiety due to the strong *trans* influence of the B-σ-carboranyl fragment.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2002

Most of the currently obtained metal complexes of fullerenes are known to possess η^2-coordination due to both electron-acceptor properties and the weakly conjugated polyene character of the fullerene molecule. However, all the complexes known to date exhibit a "symmetrical" η^2-coordination, where the metal atom is equidistant from the carbon atoms of the double bond because of the *trans* arrangement of either identical ligands or ligands having similar *trans* influence with respect to these carbon atoms.[1,2] With the ligands substantially different in there *trans* influence, one would, however, expect the formation of metal complexes of fullerene with "nonsymmetric" or slip-distorted η^2-coordination. The aim of this work was to attempt the synthesis of the first representatives of slip-distorted metal η^2-complexes of fullerene.

The initial metal complexes were *cis*-dihydridoiridium complexes [Ir(H)$_2$(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(PPh_3)(L)] (**Ia**, L = PPh_3; **Ib**, L = CO) chelated to the B-σ-carboranylphosphane fragment recently obtained by us.[3] Reductive elimination of a dihydrogen molecule from these complexes can result in an unsaturated Ir^+ intermediate capable of forming corresponding adducts with the electron-acceptor fullerene molecule. In addition, the bulky B-σ-carboranyl fragment should occupy a *trans* position with respect to the fullerene ligand that has a much stronger *trans* influence compared to phosphane.

We found that dihydrides chosen by us do not react with fullerene upon heating in toluene or chlorobenzene. This seems to be due to their unusual thermal stability, since these compounds do not undergo reductive elimination of dihydrogen, even upon heating in toluene or decane. It is well known that the presence of electron-acceptor ligands in the coordination sphere of a metal atom promotes the reductive elimination. To this end, we used the *t*BuNC ligand that combines the strong π-acceptor and σ-donor properties and can stabilize the complexes of transition metals both in low and high oxidation states. Such stabilisation is of great importance both for the reductive elimination and, especially, for the coordination of the intermediate metal complex to the electron-accepting fullerene molecule in the next stage of reaction. Indeed, in the presence of 2 equiv. of *t*BuNC, the dihydrido complexes **Ia** or **Ib** react smoothly with fullerene C_{60} in refluxing toluene by replacement of the triphenylphosphane or carbonyl ligand, respectively, by isocyanide with elimination of an H_2 molecule. The novel (η^2-C_{60})Ir complex containing the B-σ-carboranyl group incorporated into the chelate metallacycle, viz. [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (**II**), was obtained in a high yield as shown in Scheme 1.

The complex obtained was characterized by elemental analysis as well as UV, IR, and ^{1}H and ^{31}P{^{1}H} NMR spectroscopy. Since the molecule contains no other chromophore groups, the UV/Vis spectrum of **II** is typical for η^2-complexes of C_{60} fullerene with transition metals[4,5] exhibiting characteristic bands at 258, 329, 400, 453, and 717 nm. The IR spectrum contains stretching vibration bands of the B−H bonds of the carborane moiety (at 2576 cm^{-1}), the C−C bonds of the fullerene cage (at 1432 and 1184 cm^{-1}),

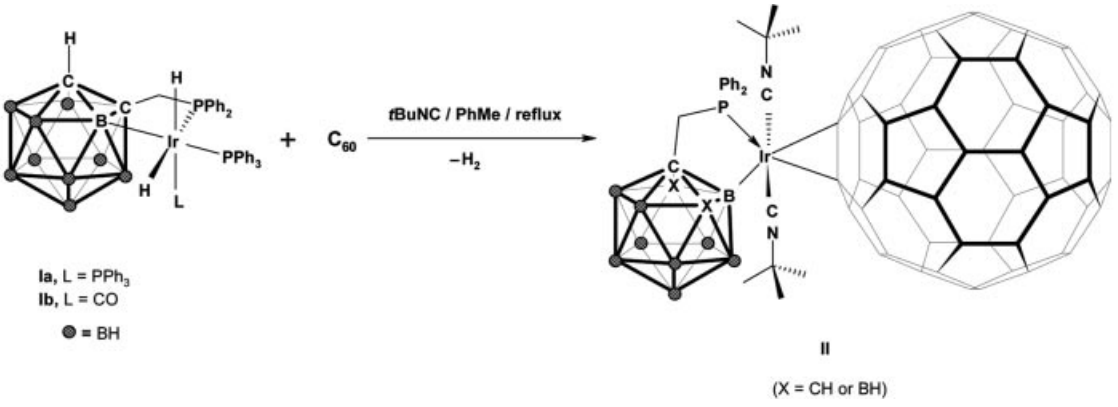

Scheme 1

and one strong, narrow absorption band of the isocyanide ligands [ν(NC)] at 2168 cm^{-1} corresponding to their mutual *trans* positions (*cis* arrangement of the ligands would require two IR-active stretching vibration bands) that completely determines the arrangement of all the ligands around the metal atom. The $^{31}P\{^1H\}$ NMR spectrum exhibits a singlet at δ_P = 37.8 ppm, which points to the existence of only one isomer with η^2-coordination of the fullerene fragment at the 1−2 bond. Otherwise (coordination at the 1−9 bond), we would observe the formation of two geometric isomers (for discussion, see, for example, refs.[5,6]). As in the initial dihydride complexes **Ia** and **Ib**, the molecular chirality of the carborane polyhedron is responsible for inequivalence of two *tert*-butyl isocyanide ligands, which manifests itself as two singlets from protons of the corresponding *tert*-butyl groups in the ^1H NMR spectrum. Similarly, protons of the methylene group in the five-membered metallacycle are inequivalent and their signals appear as an ABX system with the coupling constants ^2J(HH) = 16.2 Hz and ^2J(HP) = 6.6 and 9.6 Hz. These results are consistent with the proposed structure of compound **II** when taken together.

The molecular structure of this complex, determined by single-crystal X-ray diffraction, is presented in Figure 1. Selected bond lengths and bond angles are listed in Table 1. There are four solvate toluene molecules for each of the complex molecules in the crystal of the **II**·$4C_6H_5Me$ solvate whose crystal packing is characterized by the absence of specific interactions. All intermolecular distances correspond to the conventional van der Waals contacts. The carborane moiety involved in the five-membered metallacycle Ir(1)P(1)C(61)C(01)B(3) is bound to the iridium atom by a σ-bond through the boron atom in position 3(6) [Ir(1)−B(3) 2.101(5) Å]. The metallacycle adopts a flattened envelope conformation, with the P(1) atom deviating by 0.43 Å from the plane of the other four atoms in the cycle. A feature of the carborane ligand in complex **II** is disordering of the boron and carbon atoms in positions 2 and 4 of the carborane polyhedron (these positions are equally occupied and are denoted X2 and X4 in Figure 1). The disordering observed originates from the molecular chirality of the carborane moiety and points to the coexistence of both enantiomers in the crystal, differing in the mutual arrangement of these boron and carbon atoms with respect to the plane passing through the P(1), B(3), C(1), and C(2) atoms.

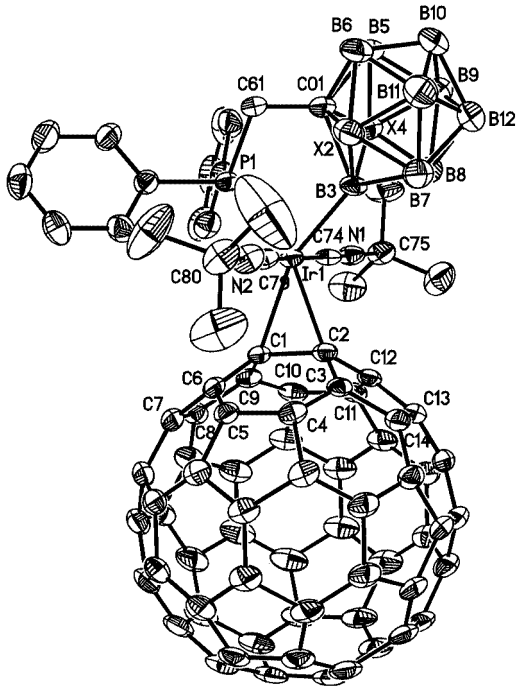

Figure 1. Molecular structure of **II** with numbering of key atoms (see text); hydrogen atoms are not shown

The iridium atom in **II** is coordinated to fullerene at the 6:6 bond C(1)−C(2), which is typical for η^2 complexes of fullerene with transition metals. As a result, the C(1)−C(2) coordination bond is appreciably lengthened as compared to the 6:6 bonds that are not involved in the coordination [cf. 1.525(6) and 1.394 Å, respectively) and is also very close to the corresponding bond length in the fullerene complex (η^2-C_{60})Ir(CO)Cl(PPh_3)$_2$ (**III**) (1.53 Å).[7] Distortion of the fullerene cage due to its coordination to the transition metal atom is also typical of this type of complex.[7,8] An important structural feature of complex **II** is strong distortion of the metallacyclopropane fragment C(1)−Ir(1)−C(2) due to

Table 1. Selected geometrical parameters for **II**

Bond lengths [Å]			
Ir(1)−C(1)	2.228(4)	C(01)−X(2)	1.656(8)

Ir(1)−C(74)	1.979(5)	C(1)−C(9)	1.454(6)
P(1)−C(61)	1.852(5)	C(2)−C(3)	1.477(6)
C(01)−C(61)	1.511(7)	C(2)−C(12)	1.482(6)
Bond angles [°]			
C(79)−Ir(1)−C(74)	172.3(2)	C(61)−P(1)−Ir(1)	109.0(2)
B(3)−Ir(1)−P(1)	84.5(2)	C(61)−C(01)−B(3)	112.9(4)
C(2)−Ir(1)−C(1)	40.6(2)	C(01)−B(3)−Ir(1)	116.8(3)
B(3)−Ir(1)−C(1)	158.0(2)	C(2)−C(1)−Ir(1)	67.4(2)
C(2)−Ir(1)−P(1)	157.9(1)	C(1)−C(2)−Ir(1)	72.0(2)

appreciable lengthening of the Ir(1)−C(1) bond compared to the Ir(1)−C(2) bond [2.228(4) vs. 2.162(4) Å, respectively] because of the strong *trans* influence of the other polyhedral ligand, i.e. the B-σ-carboranyl fragment. It should be mentioned that in the case of the symmetric ligand environment (e.g., in **III)** these bonds have the same length (2.19 Å).[7]

Thus, complex **II** is not only the first representative of metal complexes characterized by the simultaneous presence of two different polyhedral ligands in the coordination sphere of the metal atom, but also the first example of exohedral metallofullerenes with distorted η^2-coordination of fullerene to the transition metal atom. This can be both theoretically and practically valuable because of the possibility for selective insertion of various unsaturated substrates into the longer (and, correspondingly, more reactive) Ir−C bond.

Experimental Section

General: All experiments were carried out under dry, oxygen-free argon in deoxygenated solutions. IR spectra were obtained with a Specord M80 spectrometer. ^{1}H NMR spectra (400.3 MHz) and ^{31}P{^{1}H} NMR spectra (160.02 MHz) were recorded with a Bruker AMX-400 spectrometer relative to residual signals of the solvent (internal standard) and 85% H_3PO_4 (external standard), respectively.

Synthesis of [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B,P*)(*t*BuNC)$_2$] (II): To a solution of C_{60} (0.0654 g, 0.09 mmol) in toluene (50 mL), dihydride complex **Ia** (0.0954 g, 0.09 mmol) and *t*BuNC (22 μL, 0.198 mmol) were added while stirring and the reaction mixture was refluxed for 3 h. After cooling, the reaction mixture was filtered, concentrated to 5 mL, and diluted with pentane. The precipitate formed was filtered off, washed successively with methanol and pentane, and dried in vacuo at 60°C to give 95.9 mg (70.5%) of complex **II** as 1:1 solvate with toluene. $C_{85}H_{40}B_{10}N_2PIr\cdot C_7H_8$ (1512.7): calcd. C 73.05, H 3.20, B 7.15; found C 72.53, H 3.34, B 7.15. UV/Vis (THF): λ = 258, 329, 400 (sh), 453, 717 nm. IR (KBr disc), $\tilde{\nu}$ = 2576 (BH), 2168 (NC) cm^{-1}. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 37.8 ppm. ^{1}H NMR ($CDCl_3$): δ = 1.22 (s, 9 H, *t*Bu), 1.24 (s, 9 H, *t*Bu), 2.35 (s, 3 H, Ph*CH*$_3$), 3.31 [dd, ^2J(HP) = 6.5, ^2J(HH) = 16.0 Hz, 1 H, CH_2], 3.60 (s, 1 H, CH^{carb}), 4.07 [dd, ^2J(HP) = 9.8, ^2J(HH) = 16.0 Hz, 1 H, CH_2], 7.17 (m, 3 H, *Ph*CH_3), 7.24 (m, 2 H, *Ph*CH_3), 7.44 (m, 6 H, Ph), 7.84 (m, 6 H, Ph) ppm.

X-ray Structure Determination of II: Single crystals of **II**·4$C_6H_5CH_3$ were grown from a toluene solution of complex **II** at room temperature. The crystals were triclinic with the space group $P\bar{1}$, a = 15.317(8), b = 16.751(8), c = 19.317(10) Å, α = 88.10(3), β = 72.48(3), γ = 60.87(2)°, V = 4090(3) Å^3, Z = 2, $d_{calcd.}$ = 1.453 g/cm^3, μ(Mo-K_α) = 17.09 cm^{-1}. The intensities of 14417 independent reflections (R_{int} = 0.0687) were measured at 193(2) K with a Syntex $P2_1$ diffractometer (graphite-monochromated Mo-K_α radiation, λ = 0.71073 Å, ω-scan technique, θ ≤ 25°). The structure was solved by the direct methods and refined by the full-matrix least-squares method against F^2 in the anisotropic (isotropic for H atoms) approximation. All hydrogen atoms of the carborane cage were located from the electron density difference synthesis, while the other H atoms were placed geometrically and included in the refinement using the rigid motion model. The refinement converged to wR_2 = 0.1253 and GOF = 1.068 for all independent reflections [R_1 = 0.0446 was calculated against F for 13363 observed reflections with $I > 2\sigma(I)$]; the number of refined parameters was 1184. All calculations were performed using the SHELXTL-97 software[9] with an IBM PC/AT. CCDC-185865 contains the supplementary crystallographic data for this paper. Iridium-Catalysed Allylic Substitution: Stereochemical Aspects and Isolation of Ir^{III} Complexes Related to the Catalytic Cycle

Björn Bartels,[a] Cristina García-Yebra,[a] Frank Rominger,[a] and Günter Helmchen*[a]

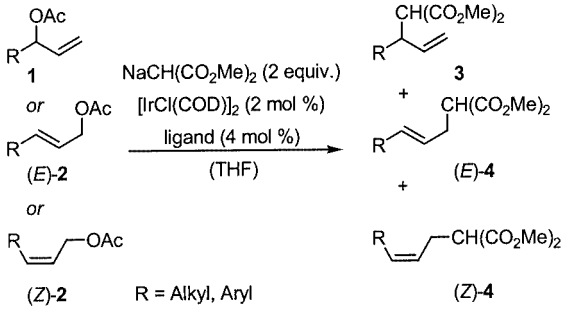
Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Iridium / Allyl complexes / NMR spectroscopy / Allylic substitution / Asymmetric catalysis

Ir-catalysed allylic alkylations of enantiomerically enriched monosubstituted allylic acetates proceed with up to 87% retention of configuration using $P(OPh)_3$ as ligand. High regio- and enantioselectivity of up to 86% *ee* in asymmetric allylic alkylations of achiral or racemic substrates is achieved with monodentate phosphorus amidites as ligands. Lithium *N*-tosylbenzylamide was identified as a suitable nucleophile for allylic aminations. Of particular importance is the use of lithium chloride as an additive, generally leading to increased enantioselectivities. Two (π-allyl)Ir^{III} complexes were characterised by X-ray crystal structure analysis and spectroscopic data.

Introduction

Asymmetric transition-metal-catalysed allylic substitution is a useful reaction in organic synthesis.[1] The selectivity of this reaction is a function of many factors, for example the metal ion, ligands, nucleophile and substituents of the allyl system. Over the last few years, work has been directed at finding catalysts that favour the formation of branched, chiral products **3** in the substitution of monosubstituted allylic substrates **1** and (*E*)-**2** (Scheme 1). With palladium complexes this is so far only possible for special cases.[2] With Mo- or W-based catalysts, branched products are generally preferred, with higher levels of both regio- and enantioselectivity reported for substrates with R = aryl.[3] It is assumed that in these cases the reactions proceed via π-allyl complexes, which can isomerize[3d] via π−σ−π rearrangement or related processes in such a way that memory of the chiral sense of the stereogenic centre in the branched substrate **1** is lost during the reaction.



Scheme 1. General scheme for the Ir^{I}-catalysed allylic alkylation of monosubstituted allylic acetates

Substitutions catalysed by Rh, Fe or Ru complexes differ from the above as they generally proceed for branched substrates **1** with a high degree of conservation of enantiomeric excess (*cee*). It has been proposed that these reactions proceed via σ-allyl or π-allyl complexes, which isomerize slowly.[4] As a consequence, from enantiomerically enriched substrates **1**, even with achiral ligands enantiomerically enriched products **3** are obtained via reactions proceeding with double inversion.

Not many examples of Ir^{I}-catalysed allylic substitutions have been published so far. In the last few years, it has been shown that catalysts prepared by combining $[IrCl(COD)]_2$ with a strong π-acceptor ligand — for example triphenylphosphite — in situ give rise to excellent regioselectivities in favour of the branched product **3** for both aryl- and alkyl-substituted allylic substrates.[5] In 1997, we described the first enantioselective Ir^{I}-catalysed allylic alkylations of aryl-allyl acetates (*E*)-**2**, which gave high levels of regio- and enantioselectivity in favour of product **3** when the bidentate phosphinooxazoline **L1** (Figure 1) was used as the chiral ligand.[6] Better results were later achieved with monodentate chiral strong π-acceptor ligands.[7] Thus, branched products **3** are obtained in Ir^{I}-catalysed allylic alkylations of both monoaryl- and monoalkylallyl acetates, (*rac*)-**1** and (*E*)-**2**, with ligands such as phosphites and phosphorus amidites [(*R*)-**L2**]. It was also found that Ir^{I}-catalysed allylic alkylations of enantiomerically enriched acetates **1** with achiral ligands occurred with a noticeable "memory effect", i.e. partial conservation of the enantiomeric purity of the starting substrates. For example, a sample of (*R*)-**1** with 91% *ee* furnished (*R*)-**3** with 51% *ee* [R = $(CH_2)_2Ph$].[7a]

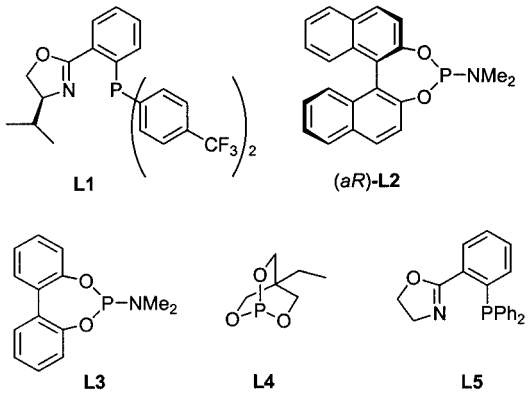

Figure 1. Ligands used in Ir^{I}-catalysed substitutions

This observation led us to consider the formation of π- as well as (σ-allyl)Ir^{III} complexes as intermediates, which undergo slow isomerization.[4d,8]

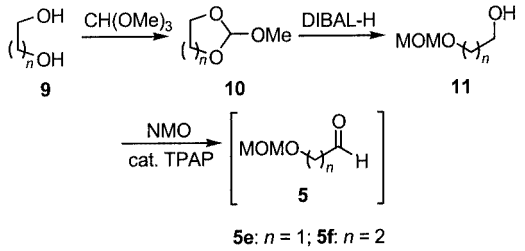
Herein we present a full account of our studies concerning the various factors affecting the course of the Ir^{I}-catalysed allylic alkylation and amination as well as the isolation and full characterization of Ir^{III} complexes related to the proposed intermediate species, in order to contribute to the elucidation of the still unclear mechanisms of these processes.

Results and Discussion

Synthesis of Allylic Substrates

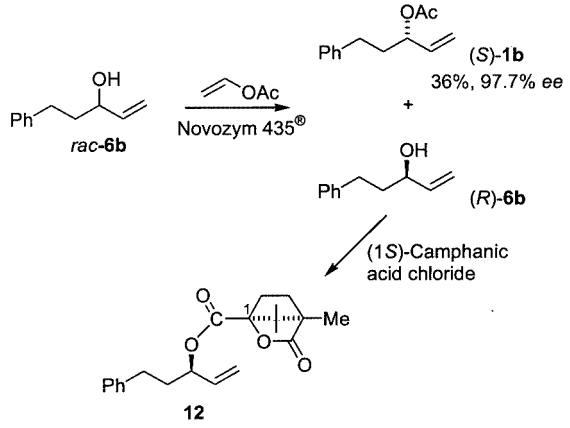
The branched substrates **1** were prepared by reaction of aldehydes **5** with vinylmagnesium bromide and esterification of the resulting alcohols **6**. The linear substrates (*E*)-**2** were obtained by Wittig−Horner−Emmons olefination to give the (*E*)-α,β-unsaturated ester **7** which, after reduction to alcohols **8** and esterification, gave the acetates (*E*)-**2** (Scheme 2).

Substrates **1e**,**f** and (*E*)-**2f** were prepared in a similar way; the requisite aldehydes[9] were not commercially available and were prepared according to the procedure described in Scheme 3, involving formation of the orthoester **10** by reaction of diol **9** with trimethyl orthoformate, reduction of the orthoester with DIBAL-H[10] and, finally, oxidation of the resulting alcohol **11** with NMO/TPAP.[11]



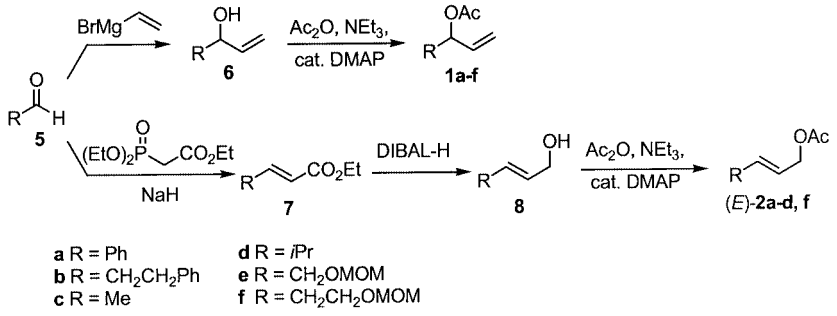
Scheme 3. Synthesis of aldehydes **5**; TPAP: (nPr_4N)[RuO_4]; MOM: methoxymethyl; DMAP: 4-dimethylaminopyridine; NMO: *N*-methylmorpholine *N*-oxide

Enantiomerically pure substrates **1a−c** were prepared either by esterification of commercially available enantiomerically pure alcohols (**6a** and **6c**) or by enzyme (Novozym 435®) catalysed kinetic resolution of *rac*-**6b** with vinyl acetate (**1b**) (Scheme 4).[12] The absolute configuration of (*R*)-**6b** was confirmed by X-ray crystal analysis of the corresponding ester **12** of (1*S*)-camphanic acid (Figure 2).



Scheme 4. Kinetic resolution of the alcohol **6b** by enzyme-catalysed esterification and confirmation of the absolute configuration of the products

Substrates (*Z*)-**2** were prepared as described in Scheme 5. (*Z*)-**2e** was obtained from the commercially available (*Z*)-2-buten-1,4-diol (**13**) via reaction with trimethyl orthoformate, reduction of the resulting orthoester **14**, and subsequent esterification.[10] The synthesis of the homologous alkene (*Z*)-**2f** was performed starting from 3-butyn-1-ol (**16**)



Scheme 2. Synthesis of substrates **1** and (*E*)-**2**; DIBAL-H: Diisobutylaluminium hydride; DMAP: 4-dimethylaminopyridine

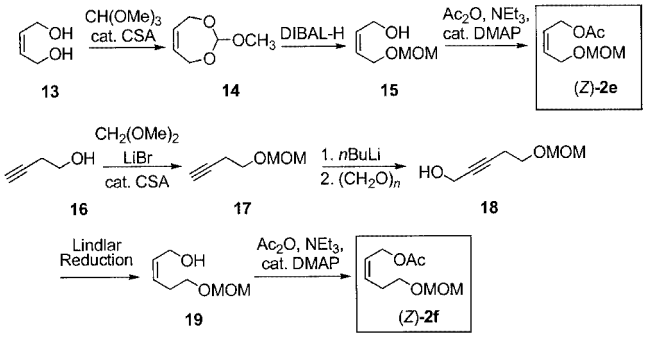

Scheme 5. Synthesis of substrates (*Z*)-**2e** and (*Z*)-**2f** (CSA: camphorsulfonic acid)

which, after a three-step sequence, afforded the (*Z*)-alkene **19**, which was then esterified to give acetate (*Z*)-**2f**.[13]

Factors Affecting the Rate and Regioselectivity of Ir^I-Catalysed Allylic Alkylation

Allylic alkylations of aryl- and alkyl-substituted allyl acetates **1** and (*E*)-**2** catalysed by $[IrCl(COD)]_2$ and combinations of this complex with PPh_3 or the strong π-acceptor ligand $P(OPh)_3$ were initially investigated. The results are summarized in Table 1.

Concerning the rate of the reaction, the allylic alkylation of linear substrate (*E*)-**2a** was slightly slower than that of the isomeric branched substrate **1a** when $[IrCl(COD)]_2$ without additional ligand was used as catalyst (Table 1, entries 2 and 5). Differences in reaction rates between branched and linear substrates have been observed for the Rh^I-catalysed reaction and they have been attributed to a S_N2' mechanism operating in the oxidative addition step.[4d]

While the combination of $[IrCl(COD)]_2$ with PPh_3 led to slow reactions and low degrees of regioselectivity (entries 6, 9 and 13), the π-acceptor ligand $P(OPh)_3$ gave rise to the shortest reaction times along with optimal yields and regioselectivities in favour of the branched product **3** (entries 1, 4, 7 and 11).[5a][5b] Furthermore, a 1:1 ratio of $P(OPh)_3$ and

14	**1b**	$P(OPh)_3$	2:1	25	18	90	95:5

[a] All reactions were carried out in THF on a 0.5 mmol scale (0.125 M) with 2 equiv. of $NaCH(CO_2Me)_2$ and 2 mol % of $[IrCl(COD)]_2$. [b] Isolated yields are given. [c] Determined by GC/MS.

Ir^I gave the best results (compare entries 7 and 14). In this respect, it is significant that only one complex is formed by reaction of $[IrCl(COD)]_2$ with two equivalents ($L/Ir^I = 1:1$) of $P(OPh)_3$ (^{31}P NMR: $\delta = 86.77$ ppm),[14] while an excess of ligand gives rise to the formation of additional species.[5b]

It is also remarkable that while the regioselectivities obtained from the reaction of the branched substrates are generally high, the linear substrates give rise to lower degrees of regioselectivity, with PPh_3 showing a particularly strong "memory effect" (entries 6 and 10).

It has been reported that the geometry of the double bond of the linear substrates is also a factor determining the regioselectivity of Ir^I-catalysed allylic substitutions.[15] Using substrates **1e**, **1f** and **2f** (Scheme 1), the dependence on the geometry of the double bond in combination with the influence of σ-acceptor substituents in the substrate was studied. The results (Table 2) clearly show that the allylic alkylations of (*Z*)-**2e** and (*Z*)-**2f** preferentially yield (*Z*)-**4e** and (*Z*)-**4f** as products, respectively. It is also remarkable that the (*Z*)-substrates react distinctly faster than the (*E*)-substrates. Furthermore, it is apparent from Table 1 and 2 that regioselectivity (**3**:**4**) is a function of the substituent at the allylic moiety, giving rise to the order Ph > $(CH_2)_2$Ph > $(CH_2)_2$OMOM > CH_2OMOM, reflecting the ability of the substituent to stabilize a positive charge.

Some of the results described above contribute to the understanding of the mechanism of the Ir^I-catalysed allylic alkylation. Generally, the following steps are to be considered: a) oxidative addition of the substrate to the metal centre and formation of π- and/or σ-allyl complexes, b) isomerization of the intermediates via π–σ–π rearrangement or similar processes, and c) attack of a nucleophile (Scheme 6). If π-allyl complexes are the product determining intermediates, it is expected that cationic character favours attack at the substituted allylic terminus. It is, therefore, clear that the rate and regioselectivity of the nucleo-

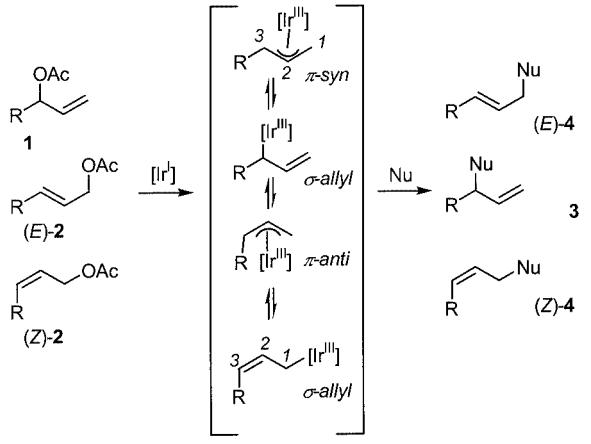


Scheme 6. Ir^I-catalysed allylic substitution of substrates **1** and **2** via σ- and π-allyl intermediates

philic attack would be higher with π-acceptor ligands such as $P(OPh)_3$ and olefins (such as COD) than with σ-donor ligands such as PPh_3.[16] It has been argued that nucleophilic attack on analogous Rh^{III} complexes is determined by the location of the acceptor ligand in the *trans* position to the higher substituted allyl terminus.[17] This argument neglects the fact that due to the strong *trans* influence of both an allyl and a phosphorus-based ligand, these ligands strongly prefer a mutual *cis* disposition. Furthermore, there is no marked influence of the steric bulk of the phosphorus ligand on the regioselectivity.[5b]

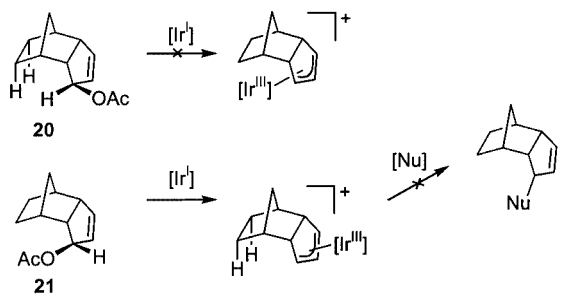
The fact that no (*Z*)-products were obtained from (*E*)-substrates while these are the major products in the allylic alkylation of (*Z*)-substrates is highly significant and is also found in the reaction catalysed by Fe complexes.[4b] As (*E*)-substrates would form *syn* π-allyl intermediates and (*Z*)-substrates *anti* π-allyl intermediates, these results clearly show that the *syn*-*anti* isomerization between these species is a slow process (Scheme 6). Considering a generally close analogy of Ir^I- and Rh^I-catalysed allylic substitutions, it is of interest to note that reactions of isolated *anti* (π-allyl)Rh^{III} complexes with carbon nucleophiles occur at the less substituted terminus of the allylic moiety, giving rise exclusively to the formation of (*Z*)-olefin complexes.[18] On the other hand, there are no facts which would rule out a reaction course via σ-complexes.

Steric Course of the Substitution and Memory Effects

It has already been reported that Rh^I- and Ir^I-catalysed allylic substitutions show a noticeable "memory effect",[4d,7a,19] i.e. enantiomerically enriched branched substrates **1** yield substitution products with retention of configuration and partial conservation of enantiomeric purity. Rather than aiming at high degrees of conservation we were interested in finding conditions that would maximally erode enantiomeric purity in order to achieve asymmetric induction via dynamic kinetic resolution. To this end, the influence of reaction conditions, such as concentration of the nucleophile, temperature, influence of additives and ligand, were studied in allylic alkylations of enantiomerically enriched acetates **1** using $[IrCl(COD)]_2$ combined in situ with achiral ligands $P(OPh)_3$ and **L3**−**L5** as catalysts. The results are summarized in Table 3.

The results allow the following conclusions: (a) phosphorus amidite **L3** gives rise to maximal erosion of enantiomeric purity (entries 7 and 8); (b) the highest degree of conservation of enantiomeric purity is induced by $[IrCl(COD)]_2$ without additional ligand (entry 11); (c) surprisingly, there is almost no influence of the concentration of the nucleophile (cf. entries 1 and 2). It was expected that an increase would lead to a higher degree of conservation of enantiomeric purity because of acceleration of the nucleophilic attack relative to isomerization of allyl complexes; (d) halide ions are known to accelerate the isomerization of allyl complexes via σ-allyl complexes.[20] Indeed, addition of LiCl induces an enhanced degree of racemisation (entries 5, 6 and 8), (e) finally, increase of the reaction temperature also favours racemisation (entry 6).

Concerning the steric course of the process, it was of interest to establish whether the Ir^I-catalysed reactions proceed with double inversion or retention. To this end, reactions with substrates **20** and **21** were investigated (Scheme 7).[21] These substrates do not allow a double inversion process because in **20** oxidative addition to Ir^I and in **21** nucleophilic attack at the (allyl)Ir^{III} intermediate are both prevented by steric hindrance. Indeed, no reaction occurred under reaction conditions typical for allylic alkylations.[22] Control experiments showed that under the same conditions the reaction of $NaCH(CO_2Me)_2$ with cyclopentenyl acetate proceeds to completion. These results demonstrate that the Ir^I-catalysed allylic alkylation proceeds via a double inversion process.



Scheme 7. Ir^I-catalysed allylic substitutions

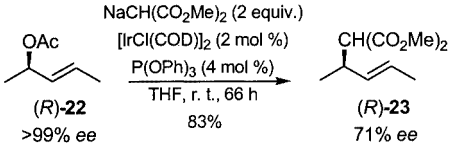
12	**1a**	94 (*R*)	$P(OPh)_3$	3	0.250	–	98	95:5	56 (*S*)	60
13	**1c**	99.8 (*R*)	$P(OPh)_3$	3	0.250	–	91	95:5	85 (*R*)	85

[a] All reactions were carried out in THF at a 0.5 mmol scale (0.125 M) with 2 mol % $[IrCl(COD)]_2$ and 4 mol % ligand, at room temperature. [b] Determined by HPLC (entries 1−12) or GC (entry 13). [c] Retention or *cee* (conservation of enantiomeric excess) is defined as [*ee*(product)/*ee*(substrate)]×100. [d] Ratio substrate/nucleophile 1:1. [e] Temperature: 50 °C.

To gain further insight, the alkylation of the symmetrically substituted acetate **22** was studied (Scheme 8).[7a] In this reaction enantiomerically pure (*R*)-**22** gave the product (*R*)-**23** with 71% *ee*.



Scheme 8. Allylic substitution using a substrate with a potentially symmetric (π-allyl)Ir^{III} intermediate

This result rules out the intermediacy of a symmetric (π-allyl)Ir^{III} complex or a fast dynamic equilibrium between isomeric complexes, as is typical in palladium chemistry. Possible intermediates (Figure 3) are a σ-complex **A**, formed by direct oxidative addition with inversion, or a corresponding π-complex **B** with a nonsymmetric ligand sphere. A third type of intermediate conceivable is a *nondynamic* (σ+π)-allyl complex **C** formed by S_N2' attack of an Ir^I species. Complexes of this type have been proposed for Rh^I-catalysed allylic substitutions which proceed with almost complete conservation of enantiomeric purity.[4d] In principle, proposals **B** and **C** are identical as they are simply different ways of describing a nonsymmetric π-allyl complex. Assessing such intermediates is fairly straightforward

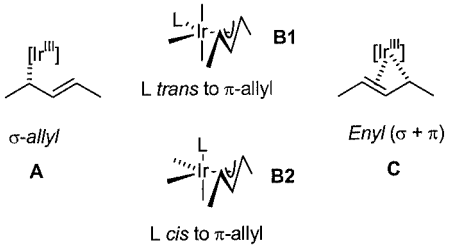


Figure 3. Possible intermediates in the allylic substitution of acetate (*R*)-**22**

for tetracoordinate planar Pd complexes.[23] However, for octahedral Ir^{III} or Rh^{III} complexes the *trans* disposition of an allyl and a phosphorus ligand, i.e. **B1**, is destabilised by their strong *trans* influence.[24] A complex **B2** with *cis* disposition of these ligands is expected to be more stable. Rescue of the argument, i.e. control of the substitution via the trans effect operating in **B1**, would require further assumption of a dynamic system with strong *kinetic* preference for attack of a nucleophile at the *trans* complex **B1**.

Also conceivable is a reaction via a (π-allyl)metal complex with *syn-anti* configuration of the allyl ligand. According to precedents in Pd-catalysed allylic substitutions, such a complex might react preferentially at the terminus carrying the *anti* substituent.[25] In view of the results for the Ir^I-catalysed allylic substitution of monosubstituted (*Z*)-substrates (vide infra), i.e. preferential formation of linear product, this possibility appears unlikely.[15]

Asymmetric Catalysis

The results in Table 3 show that isomerization among the various intermediate species is fastest with phosphorus amidites as ligands and, therefore, these appeared particularly suited for asymmetric Ir^I-catalysed allylic substitutions. In preliminary experiments we found that branched substrates yield higher degrees of enantio- as well as regioselectivity than linear substrates. Accordingly, reactions with branched substrates were studied preferentially. Using (*R*)-**L2** as the chiral ligand, the dependence of the enantioselectivity on the reaction conditions and substrate structure were investigated. These results are displayed in Table 4.

The ratio of ligand to iridium is an important parameter. In analogy to the earlier finding (Table 1), a 1:1 ratio was optimal (compare entries 2−4). In view of the previous discussion concerning allylic intermediates it is significant that a decrease of temperature leads to a lowering of enantioselectivity (cf. entries 2, 5 and 6). This is probably caused by a slow isomerization of intermediary allyl complexes. A further aspect to take into account is the influence of the

[a] Nucleophiles were prepared by treatment of $CH_2(CO_2Me)_2$ with base over a period of 30 min at room temperature in THF. [b] One equivalent (relative to substrate) of additive was added before the nucleophile. [c] Isolated yields. [d] Determined by GC/MS. [e] Determined by HPLC. [f] Not determined. [g] The nucleophile was generated by addition of *n*BuLi at −78 °C and keeping the reaction mixture at room temperature for 30 min. [h] The nucleophile was generated by reacting the base with dimethyl malonate in THF for 30 min at reflux temperature. [i] BSA = *N*,*O*-bis(trimethylsilyl)acetamide; KOAc (catalytic quantity) was added to start the reaction.

leaving group on rate, regio- and enantioselectivity (cf. entries 2, 7−9). Substrates with better leaving groups than acetate give rise to very low selectivities. As of now, the best results are obtained with acetates. Of the solvents used, tetrahydrofuran was found to be the most suitable (entries 2, 10−12).

Variation of the cation (entries 13−17) did not lead to an improvement of the enantioselectivity. This was surprising because an improvement had been achieved previously with zinc derivatives in a closely related reaction.[7b] In contrast, addition of *anhydrous* lithium bromide or lithium chloride resulted in an improved regio- and enantioselectivity (up to 86% *ee*) (entries 20−22).

Using the reaction conditions optimized for **1b**, allylic substitutions with a set of systematically varied substrates were investigated (Table 5). In every case addition of LiCl led to markedly improved enantioselectivities; this is probably due to an acceleration of the isomerization of the intermediary allyl complexes. A most surprising result was the low enantioselectivity obtained with the phenyl derivative **1a**. It is quite clear that further progress in this area will depend on establishing conditions for further enhanced rates of isomerization of allylic intermediates.

Ir^I-Catalysed Allylic Amination

Ir^I-Catalysed allylic aminations have so far only been described for amines as nucleophiles.[15] These reactions require polar solvents and/or high concentration and relatively high temperature. We have now found that lithium *N*-tosylbenzyl amide, already successfully employed in Rh^I-catalysed allylic aminations,[19a,26] reacts under the conditions typical for malonates (Scheme 9). Some preliminary results obtained in allylic aminations of both branched and linear substrates with this nucleophile are presented here (Table 6). With triphenylphosphite as ligand, only moderate yields and regioselectivities were obtained in the amination of substrate **1b** (entry 1). With the chiral phosphorus amidite (*R*)-**L2** as ligand (entries 2−3) yield (up to 97%) and regioselectivity (up to 99:1) were improved for the branched

[a] The reaction was carried out on a 0.5 mmol scale in THF (0.1 M) (18 h, room temp.), with 2 equiv. of $LiN(CH_2Ph)Ts$, 2 mol % $[IrCl(COD)]_2$ and 4 mol % ligand. [b] Determined by HPLC.

Characterization of Ir^I and Ir^{III} Complexes Related to the Catalytic Cycle

Both Ir^I- and σ- or (π-allyl)Ir^{III} complexes are expected to participate in the catalytic process. Therefore, the isolation and structural characterization of such complexes is of great interest. We have prepared a variety of these compounds by stoichiometric reactions of the type comprising the catalytic cycle.

A Chiral Ir^I Complex Containing a Chiral Phosphorus Amidite

Reaction of ligand **L** with complex $[IrCl(COD)]_2$ proceeds with cleavage of the chloride bridges to give monomeric complexes of the type [IrCl(COD)L].[27] Thus, with the chiral ligand (*R*)-**L2**, the complex [IrCl(COD){(*R*)-**L2**}] (**29**) was prepared and fully characterised by NMR spectroscopy and X-ray diffraction. The crystal structure of **29** together with a selection of bond lengths is shown in Figure 4.

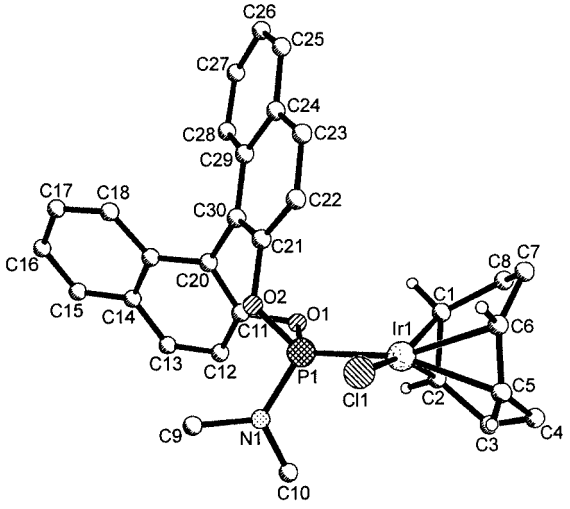

Figure 4. X-ray structure of complex **29**; selected bond lengths (Å): Ir(1)−C(1) 2.114(6), Ir(1)−C(2) 2.118(6), Ir(1)−C(5) 2.222(5), Ir(1)−C(6) 2.222(5), Ir(1)−P(1) 2.2363(13), Ir(1)−Cl(1) 2.358(1), C(1)−C(2) 1.434(8), C(5)−C(6) 1.371(8)

As expected, the coordinated double bond [C(1)-C(2)] *trans* to the chloro ligand is noticeably longer than that [C(5)-C(6)] *trans* to the phosphorus due to the greater *trans* influence of the phosphorus ligand, which is translated into a weakening of the Ir−C(5,6) bonds and a stronger C(5)-C(6) double bond character.

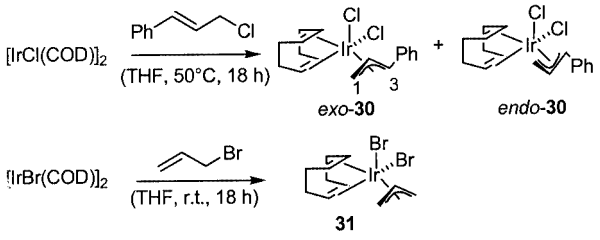
Preparation of (π-Allyl)Ir^{III} Complexes

Oxidative addition is a necessary step in the catalytic process. Therefore, we attempted to generate the corresponding (allyl)Ir^{III} intermediates by direct reaction of al-

lyl acetates with the Ir^I precursors $[IrCl(COD)]_2$ or complexes [IrCl(COD)(L)]. Surprisingly, despite long reaction times and a large excess of the allyl acetate, the expected oxidative addition reaction, which proceeds readily in palladium chemistry,[1c] did not take place here.

We observed that addition of the nucleophile $NaCH(CO_2Me)_2$ to a solution of the catalyst generally produced a change of colour from pale orange to pale yellow. This seemed to indicate that the true catalyst is produced by reaction with the nucleophile. Accordingly, the stoichiometric reaction of $[IrCl(COD)P(OPh)_3]$,[14] formed by treatment of $[IrCl(COD)]_2$ with triphenylphosphite (1:2), with $NaCH(CO_2Me)_2$ (1 equiv.) was explored. The $^{31}P\{^1H\}$ NMR spectrum of the mixture, recorded in $[D_8]$THF after one hour at room temperature, showed a singlet (δ = 86.3 ppm), corresponding to the initial complex, and two sets of doublets of which one (δ = 124.5 and 81.4 ppm, $^3J_{P,P}$ = 74 Hz) was identified as belonging to the previously reported orthometallation product $[Ir\{\eta^2\text{-}(P,C)\text{-}P(OC_6H_4)(OPh)_2\}(COD)\{P(OPh)_3\}]$.[14] The second set of doublets (δ = 104.3 and 85.1 ppm, $^3J_{P,P}$ = 43 Hz) indicates coordination of two equivalents of ligand per metal centre. Attempts to isolate and characterise this complex were unsuccessful.

Next, the oxidative addition of allyl halides to $[IrCl(COD)]_2$ was studied. The reaction of (*E*)-cinnamyl chloride with $[IrCl(COD)]_2$ and allyl bromide with $[IrBr(COD)]_2$ gave complexes **30** and **31**, respectively, in up to 80% yield (Scheme 10).[28] In the presence of phosphorus-derived ligands such as $P(OPh)_3$ or $P(C_6F_5)_3$ the same compounds were formed, which demonstrates the very strong coordination of COD. Complexes **30** and **31** were fully characterised by spectroscopic methods and X-ray diffraction.



Scheme 10. Oxidative addition of allyl halides to Ir^I complexes

X-ray Crystal Structures of (π-Allyl)Ir^{III} Complexes 30 and 31

Complexes **30** and **31** gave yellow single crystals from dichloromethane/diethyl ether solutions.

The crystal of complex **30** (Figure 5) contains a ca. 1:1 mixture of *endo* and *exo* isomers.[29] As a consequence, the structural data of the allyl moieties are of low precision. The configuration of the complex is as expected on the basis of *trans* influences of the ligands. The *syn* configuration of the allyl ligands is typical for aryl-allyl ligands.

The allyl ligand of complex **31** was found to be in the *exo* disposition. The Ir(1)−C(10) bond [2.321(8) Å] is longer than the Ir(1)−C(12) bond [2.176(8) Å] due to the *trans* influence of the COD double bond C(1)−C(2) (Figure 6). Concerning the bond lengths within the allyl moiety, it is remarkable that the C(10)−C(11) bond [1.36(1) Å] is considerably shorter than the C(11)−C(12) bond [1.46(1) Å], i.e. the allyl ligand is highly unsymmetrical and distorted towards a σ-complex.

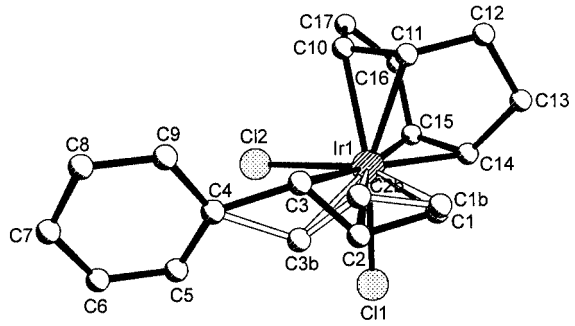


Figure 5. Crystal structure of complex **30**; selected bond lengths (Å) with estimated standard deviations: Ir(1)−C(1)/C(1B) 2.11(3)/2.31(5), Ir(1)−C(2)/C(2B) 2.24(2)/2.31(2), Ir(1)−C(3)/C(3B) 2.45(1)/2.48(1), C(1)−C(2) = 1.44(1), C(1B)−C(2B) 1.44(2), C(2)−C(3) 1.35(1), C(2B)−C(3B) 1.34(2)

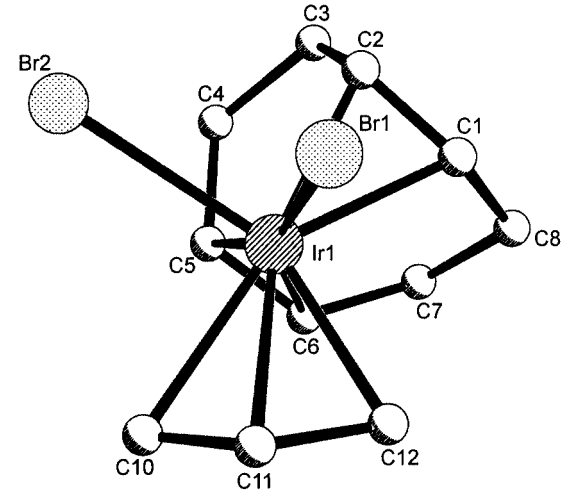

Figure 6. Crystal structure of complex **31**; selected bond lengths (Å) with estimated standard deviations: Ir(1)−C(10) 2.321(8), Ir(1)−C(11) 2.241(9), Ir(1)−C(12) 2.176(8), C(10)−C(11) 1.36(1), C(11)−C(12) 1.46(1), C(1)−C(2) 1.39(1), C(3)−C(4) 1.53(1), C(5)−C(6) 1.38(1), C(7)−C(8) 1.53(1)

Asymmetry in π-allyl systems as a consequence of either an asymmetric set of ligands or an asymmetric substitution pattern of the allyl group is quite common for Ir[30] or Mo[31] complexes and distinctly more pronounced than in Pd complexes.[32] For example, Fryzuk et al. have found a situation similar to that of **30** for the (π-allyl)Ir^{III} complexes $[Ir(\eta^3\text{-}CH_2CHCHMe)(H)\{N(SiMe_2CH_2PPh_2)_2\}]$ and $[Ir(\eta^3\text{-}CH_2CHCHCN)(H)\{N(SiMe_2CH_2PPh_2)_2\}]$, which display σ-character for the substituted allylic carbon and double bond character for the $CHCH_2$ moiety. The authors describe this situation as a $\sigma\text{-}\pi^2$-type allyl ligand.[30d] Many additional examples of such ligands have been

reported.[8e,30b−30d,31] Obviously, the previously discussed "enyl (σ+π)" species proposed as intermediates in Rh^{I}-catalysed allylic substitutions (cf. Scheme 8) belong to this type.[4d]

NMR Spectroscopic Study of (π-Allyl)Ir^{III} Complexes

(π-Allyl)Ir^{III} complexes generally show slow isomerisation compared to π-allyl complexes of the first and second row late transition metals such as Ni, Pd, Fe, Ru and Co.[8,30] In contrast, complexes **30** and **31** display broad peaks in their ^{1}H NMR spectra at room temperature, indicating that dynamic processes are taking place.

The ^{1}H and ^{13}C{^{1}H} NMR spectra of **30** at temperatures in the range −60 to −40 °C show a 2:1 ratio of two species which, on the basis of the proton coupling constants, are the *syn*-π-allyl complexes found in the crystal structure (cf. Scheme 10). The ^{1}H NMR spectrum of **30** at 50 °C shows one set of signals as a consequence of fast equilibration; coalescence was found at ca. 0 °C.

For both isomers of complex **30**, the resonances of the allylic protons appear in the range δ = 4−6.5 ppm (^{1}H NMR spectrum at −60 °C). The *syn*-configuration of the allyl ligand is apparent from the values of the coupling constant ($^3J_{2,3}$ = 14 Hz) for both isomers, indicating the *anti*-disposition of 3-H (for numbering see Scheme 10). An unusual feature is a marked downfield shift of 3-H for the minor (δ = 6.33 ppm) relative to the major isomer (δ = 4.93 ppm).

The ^{13}C{^{1}H} NMR spectroscopic data (recorded at −60 °C) were analysed with the help of HMQC and HMBC experiments. Resonances at δ = 40.9 and 42.6 ppm for the methylene carbon atoms (C-1) of the major and minor isomer, respectively, are characteristic of the CH_2 group of (π-allyl)Ir^{III} systems; σ-bound allylic CH_2 groups typically appear in the range δ = 0−25 ppm. Resonances at δ = 110.6 and 102.2 ppm for C-2 of the major and minor isomer, respectively, are also in the range typical for π systems; σ systems display values greater than δ = 130 ppm. The resonances for the substituted carbon (-*C*HPh) appear at δ = 111 and 123 ppm for the major and minor isomers, respectively. The latter value is unusually low compared to other (η^3-$CH_2CHCHPh$)Ir^{III} or (η^3-$CH_2CHCHPh$)Pd complexes.[8d,33]

The rate of interconversion of the isomers of **30** was determined as follows. By recording ^{1}H-^{1}H EXSY spectra at varied mixing times (t_m) at −40 °C, the magnetisation transfer between chosen atoms present in both isomers, denoted as **A** (minor isomer) and **B**, was measured (Figure 7).[34] From the 2D NMR spectra a correlation between the allylic protons in the isomers was chosen to perform the calculations. Applying Equation (1) (I_{ii}, I_{ij} integral values of diagonal and cross-peaks, respectively, X_i molar fraction)[35] to the data summarised in Table 7 a value of k = 4 Hz at −40 °C was determined for the rate constant.

The ^{1}H and ^{13}C{^{1}H} NMR spectra of complex **31** measured at −60 °C show two isomeric species in a 9:1 ratio; these are probably the *endo* and *exo* isomers in analogy to

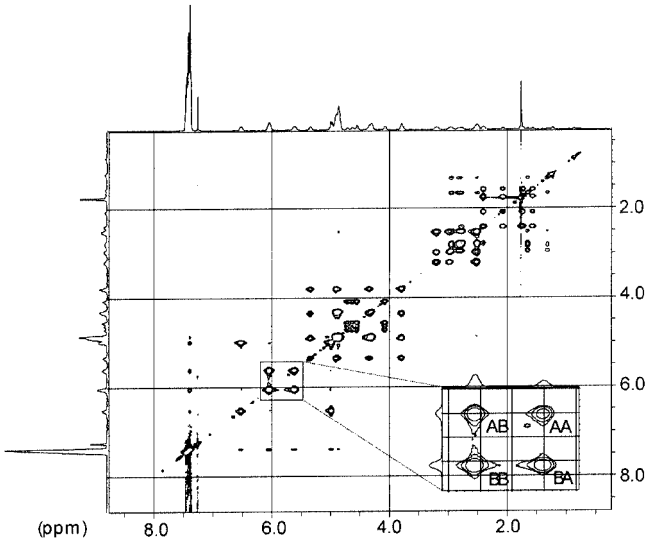

Figure 7. ^{1}H,^{1}H EXSY spectrum of complex **30** recorded at −40 °C ($CDCl_3$, 500.13 MHz); cross peaks chosen for the calculations are enlarged; A and B denote the minor and major isomer, respectively

Table 7. ^{1}H,^{1}H EXSY data for the determination of the isomerisation rate constant k [a]

t_m [ms]	X_A [b]	X_B [b]	I_{AA}	I_{BB}	I_{AB}	I_{BA}	r	k [s^{-1}]
25	0.43	0.57	1.00	1.77	0.065	0.069	23.74	3.37
50	0.42	0.58	1.00	1.88	0.150	0.147	10.32	3.89
100	0.41	0.59	1.00	2.08	0.309	0.302	5.16	3.92

[a] Measured at −40 °C in $CDCl_3$. [b] The molar fraction X_i is given by the formula $X_A = \sqrt{I_{AA}} / \left(\sqrt{I_{AA}} + \sqrt{I_{BB}}\right)$

complex **30**. Coalescence was found at ca. 50 °C. The ^{1}H NMR resonances are found in the expected range. In the ^{13}C{^{1}H} NMR spectrum (−60 °C), one of the CH_2 groups shows resonances in the expected range (δ = 44.6 and 44.9 ppm) while the other appears at unusually low field (δ = 79.7 and 89.6 ppm), for the major and minor isomer, respectively. The latter values are very unusual for (π-allyl)Ir^{III} complexes,[8a−8d,30c,36] although values at similarly low field are known for (π-allyl)Pd complexes.[33] Similar to complex **30**, the resonances of C-2 appear at fairly low field, δ = 114.5 and 107.9 ppm for the minor and major isomer, respectively.

$$k = \frac{1}{t_m} \cdot \ln\frac{r+1}{r-1} \qquad r = \frac{4X_A X_B \cdot \left(I_{AA} + I_{BB}\right)}{\left(I_{AB} + I_{BA}\right) - \left(X_A - X_B\right)^2} \tag{1}$$

Activity of Complex 30 in Stoichiometric Reactions with Nucleophiles and in Catalysis

The low-temperature stoichiometric reaction of complex **30** with dimethyl 2-sodiomalonate as nucleophile in the presence of chiral ligand (*R*)-**L2** was investigated. The ^{1}H and ^{31}P NMR spectra of the reaction mixture, recorded at −60 °C, show fast formation of the branched substitution

product **3a** and the complex {IrCl(COD)[(*R*)-**L2**]} (**29**) in a 1:1 ratio. After workup compound **29** was isolated in 32% yield and **3a** in 64% yield. A GC and HPLC investigation revealed that **3a** had been formed with 99% regioselectivity and 0% *ee*. The lack of enantioselectivity shows that nucleophilic attack at the allyl ligand is faster than coordination of the chiral ligand by displacement of a COD double bond.

Complexes **30** and **31** were found to possess catalytic activity. For example, allylic alkylations of substrates **1** and (*E*)-**2** with $NaCH(CO_2Me)_2$ gave very similar results with catalyst **30**/(*R*)-**L2** (4 mol %) and catalyst $[IrCl(COD)]_2$/(*R*)-**L2** (see Table 8). In agreement with the results obtained in the stoichiometric reaction described above, small amounts of racemic **3a** (HPLC) were formed in allylic alkylations of substrates **1b** and (*E*)-**2b** upon catalysis with **30**/(*R*)-**L2** as a consequence of attack of the nucleophile at the allyl ligand present in complex **30**. In this reaction, complex **29** is also formed, which acts as the catalyst of the process.

Table 8. Allylic alkylations of substrates **1** and (*E*)-**2** catalysed by mixtures of **30** and **L2** or [IrCl(COD)**L2**] (**29**)[a]

Entry	Substrate	Catalyst[b]	Time [h]	Yield [%] **3** and **4**	Ratio **3**:**4**	*ee* [%] of **3** (config.)[c]
1	**1a**	**30/L2** [1:1]	18	85	98:2	9 (*S*)
2	**1a**	[IrCl(COD)**L2**]	3	98	92:8	8 (*S*)
3	(*E*)-**2a**	**30/L2** [1:1]	18	38	95:5	34 (*R*)
4	(*E*)-**2a**	[IrCl(COD)**L2**]	3	99	98:2	37 (*R*)
5[d]	**1b**	**30/L2** [1:1]	3	80	99:1	67 (*R*)
6	**1b**	[IrCl(COD)**L2**]	3	92	98:2	69 (*R*)
7[d]	(*E*)-**2b**	**30/L2** [1:1]	18	12	50:50	40 (*R*)
8	(*E*)-**2b**	[IrCl(COD)**L2**]	3	54	95:5	43 (*R*)

All the reactions were performed at 25 °C in THF with 0.5 mmol of allyl substrate [0.125 M], 1 mmol of $NaCH(CO_2Me)_2$ and 4 mol % of [Ir]. [b] When catalyst [IrCl(COD)**L2**] was used, this was formed in situ by reaction of $[IrCl(COD)]_2$ (2 mol %) with (*R*)-**L2** (4 mol %). [c] Determined by HPLC. [d] Small quantities of **3a** were also formed.

Conclusions

Our results demonstrate that it is possible to achieve modest to high levels of enantioselectivity in Ir^I-catalysed asymmetric alkylations of monoalkylallyl acetates. Presently it is necessary to use racemic, branched allylic derivatives as substrates. Further progress will probably be achieved on the basis of more detailed mechanistic investigations. In particular, further investigations of the structure and dynamic properties of (allyl)Ir^{III} complexes are required.

Experimental Section

General: All reactions were carried out using dry solvents under an argon atmosphere. TLC: Macherey & Nagel Polygram Sil G/UV precoated sheets, treatment with I_2 or aqueous $KMnO_4$ solution for visualization of spots. Column chromatography: Fluka silica gel, grade 60 (0.04−0.063 mm). ^1H, ^{13}C and ^{31}P NMR spectra were recorded on Bruker DRX 200, DRX 300 or DRX 500 instruments. ^1H NMR chemical shifts are relative to residual non-deuterated solvent in $CDCl_3$ (δ = 7.26 ppm) or CD_2Cl_2 (δ = 5.32 ppm). ^{13}C NMR shifts are given relative to the solvents $CDCl_3$ (δ = 77.0 ppm) and CD_2Cl_2 (δ = 53.8 ppm) and ^{31}P NMR shifts are relative to 85% H_3PO_4 (δ = 0.00 ppm). MS: JEOL, JMS-700. FAB: JEOL, JMS-700; matrix: 4-nitrobenzyl alcohol (NBA) or 4-nitrophenyl octyl ether (NPOE). Optical rotation: Perkin−Elmer P 241. GC: Hewlett Packard HP 5890 with Chiraldex γ-CD TA column (30 m × 0.25 mm). GC/MS: Hewlett Packard HP 5890/7972 instrument with a HP 5 column (crosslinked methylsilicon, 25 m × 0.2 mm, helium). HPLC: Hewlett Packard HP 1090 with DAICEL Chiralcel ODH column (25 cm × 0.46 cm) in combination with DAICEL Chiralcel ODH precolumn (5 cm × 0.46 cm). Elemental analyses: Microanalytical laboratory of the Organisch-Chemisches Institut, Universität Heidelberg. The compounds (*aR*)-**L2**,[37] **L5**[38] and $[IrCl(COD)]_2$,[39] were prepared according to published procedures. The allylic esters were prepared by reaction of the corresponding alcohols with acetic anhydride [**1a**,[40] **1b**,[41] **1c**,[42] **1d**,[43] (*E*)-**2a**,[40] (*E*)-**2b**,[44] (*E*)-**2c**,[42]], methyl chloroformate (**25b**)[45] or diethyl chlorophosphate (**26b**). Compounds **3a**,[40] **3c**,[4d,42] **6b**,[12a] **7b**−**8b**,[46] **8d**,[47] **7a**,[48] **7c**−**7f**,[48] **20**−**21**,[21a] and **23**[4d] have been described and characterised previously. The enantiomerically pure allylic acetates (*S*)-**1b**,[12a] (*R*)-**1b**,[12a,49] and **22**[50] were obtained by enzyme-catalysed partial esterification of the corresponding racemic alcohols. Compounds **14** and **15**,[10] and **18**[13] were prepared according to previously published methods. 1-(*S*)-Phenylpropen-2-ol [(*S*)-**6a**], (*R*)-buten-2-ol [(*R*)-**6c**], tetra(*n*-propyl)ammonium perruthenate (TPAP), $[P(NMe_2)_3]$ and **L4** are commercially available.

General Procedure I. Acetylation of the Alcohols: A solution of the alcohol (10 mmol), DMAP (12 mg, 0.10 mmol) and NEt_3 (4.2 mL, 30 mmol) in CH_2Cl_2 (10 mL) was cooled to 0 °C. Freshly distilled Ac_2O (1.9 mL, 20 mmol) was added dropwise and the mixture was stirred for 18 h at room temperature. Water (20 mL) was then added and the aqueous layer extracted with CH_2Cl_2 (3 × 5 mL). The combined organic layers were washed with satd. NH_4Cl solution (20 mL), dried (Na_2SO_4) and concentrated in vacuo. Products were purified by flash chromatography.

1-Methoxymethoxymethylallyl Acetate (1e): Crude **1e** was prepared according to general procedure I from alcohol **6e** (740 mg, 5.6 mmol) and was purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 8:1). Yield: 58% (570 mg). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.10 (s, 3 H, $COCH_3$), 3.36 (s, 3 H, CH_3OCH_2), 3.63−3.67 [m, 2 H, $CH_2CH(OAc)$], 4.63 (s, 2 H, OCH_2O), 5.26 [ddd, $^2J_{H,H}$ = 1.1, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 10.7 Hz, 1 H, *syn*-(=CH_2)], 5.34 [ddd, $^2J_{H,H}$ = 1.1, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 17.3 Hz, 1 H, *anti*-(=CH_2)], 5.44−5.48 [m, 1 H, CH(OAc)], 5.83 (ddd, $^3J_{H,H}$ = 6.3, $^3J_{H,H}$ = 10.7, $^3J_{H,H}$ = 17.3 Hz, 1 H, =CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 20.9 ($COCH_3$), 55.1 (CH_3OCH_2), 68.4 [CH_2CH(OAc)], 73.0 [CH(OAc)], 96.2 (OCH_2O), 117.9 (=CH_2), 133.0 (=CH), 170.0 (C=O) ppm. MS (CI, isobutane): *m*/*z* (%) = 175 (10) [M^+ + 1], 143 (90) [M^+ − OCH_3], 113 (100) [M^+ − OMOM]. HRMS (EI) for $C_7H_{11}O_3$ [M^+ − OCH_3]: calcd. 143.0708; found 143.0685.

1-(2-Methoxymethoxyethyl)allyl Acetate (1f): Crude **1f** was prepared according to general procedure I from alcohol **6f** (1.5 g, 10.3 mmol) and purified by flash chromatography (silica gel, petroleum ether/ethyl acetate 6:1). Yield: 86% (1.7 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.85−1.99 [m, 2 H, CH_2CH(OAc)], 2.07 (s, 3 H, CH_3CO), 3.35 (s, 3 H, CH_3OCH_2), 3.56 (t, $^3J_{H,H}$ = 6.4 Hz, 2 H, MOMOCH_2), 4.60 (s, 2 H,

CH_3OCH_2), 5.19 [ddd, $^2J_{H,H}$ = 1.1, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 10.5 Hz, 1 H, *syn*−(=CH_2)], 5.27 [ddd, $^2J_{H,H}$ = 1.1, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 17.2 Hz, 1 H, *anti*−(=CH_2)], 5.80 (ddd, $^3J_{H,H}$ = 6.5, $^3J_{H,H}$ = 10.5, $^3J_{H,H}$ = 17.2 Hz, 1 H, =CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 21.0 (COCH_3), 34.1 [CH_2CH(OAc)], 55.0 (CH_3OCH_2), 63.4 (MOMOCH_2), 71.8 [CH(OAc)], 96.3 ($CH_3OCH_2OCH_2$), 116.7 (=CH_2), 136.0 (=CH), 170.0 (C=O) ppm. $C_9H_{16}O_4$ (188.22): calcd. C 57.43, H 8.57; found C 57.23, H 8.58.

5-Phenylpent-2-enyl Acetate [(*E*)-2b]: Crude **2b** was prepared according to general procedure I from alcohol **8b** (6.0 g, 37.0 mmol) and purified by flash chromatography (silica gel, petroleum ether/ethyl acetate 97:3). Yield: 83% (6.3 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.08 (s, 3 H, $COCH_3$), 2.41 (dt, $^3J_{H,H}$ = 6.7, $^3J_{H,H}$ = 8.1 Hz, 2 H, $PhCH_2CH_2$), 2.74 (br. t, $^3J_{H,H}$ = 7.4 Hz, 2 H, $PhCH_2$), 4.54 (dd, $^4J_{H,H}$ = 0.9, $^3J_{H,H}$ = 6.4 Hz, 2 H, CH_2OAc), 5.58−5.89 (m, 2 H, =CH), 7.19−7.34 (m, 5 H, Ph) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 20.8 (COCH_3), 33.9 (CH_2), 35.2 (CH_2), 64.1 (CH_2OAc), 124.4 (=$CHCH_2OAc$), 126.1 (Ph), 128.2 (Ph), 128.3 (Ph), 135.2 (CH=$CHCH_2OAc$), 141.4 (Ph), 170.6 (C=O) ppm. $C_{13}H_{16}O_2$ (204.27): calcd. C 76.44, H 7.90; found C 76.26, H 7.85.

4-Methylpent-2-enyl Acetate [(*E*)-2d]: Crude **2d** was prepared according to general procedure I from alcohol **8d** (4.6 g, 46.5 mmol) and purified by flash chromatography (silica gel, petroleum ether/diethyl ether 95:5). Yield: 89% (5.9 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.00 (d, $^3J_{H,H}$ = 7.0 Hz, 6 H, CH_3), 2.06 (s, 3 H, $COCH_3$), 2.31 [br. sext., $^3J_{H,H}$ = 7.0 Hz, 1 H, $CH(CH_3)_2$], 4.50 (d, $^3J_{H,H}$ = 6.6 Hz, 2 H, CH_2OAc), 5.50 (ddt, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 15.5 Hz, 1 H, =$CHCH_2OAc$), 5.74 (ddt, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 6.2, $^3J_{H,H}$ = 15.5 Hz, 1 H, CH=$CHCH_2OAc$) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 21.0 (COCH_3), 22.0 (two CH_3), 30.7 [$CH(CH_3)_2$], 65.4 (CH_2OAc), 120.9 ($CHCH_2OAc$), 143.2 (CH=$CHCH_2OAc$), 170.9 (C=O) ppm. $C_8H_{14}O_2$ (142.20): calcd. C 67.57, H 9.92; found C 67.69, H 10.07.

(*E*)-5-Methoxymethoxypent-2-enyl Acetate [(*E*)-2f]: Crude (*E*)-**2f** was prepared according to general procedure I from alcohol **8f** (1.2 g, 8.2 mmol) and purified by flash column chromatography (silica gel, petroleum ether/diethyl ether 5:1). Colourless oil. Yield: 97% (1.5 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.06 (s, 3 H, $COCH_3$), 2.37 (dt, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 12.1 Hz, 2 H, MOMOCH_2CH_2), 3.35 (s, 3 H, CH_3O), 3.58 (t, $^3J_{H,H}$ = 6.6 Hz, 2 H, $MOMOCH_2$), 4.51 (dd, $^4J_{H,H}$ = 1.1, $^3J_{H,H}$ = 6.2 Hz, 2 H, CH_2OAc), 4.62 (s, 2 H, CH_3OCH_2), 5.61−5.72 (m, 1 H, CH), 5.74−5.85 (m, 1 H, CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 20.8 (COCH_3), 32.5 ($MOMOCH_2CH_2$), 55.0 (CH_3O), 64.8 (MOMOCH_2 or CH_2OAc), 66.6 (MOMOCH_2 or CH_2OAc), 96.2 (CH_3OCH_2), 125.7 (CH), 132.2 (CH), 170.6 (C=O) ppm. $C_9H_{16}O_4$ (188.22): calcd. C 57.43, H 8.57; found C 57.21, H 8.56.

(*Z*)-4-Methoxymethoxybut-2-enyl Acetate [(*Z*)-2e]: Crude (*Z*)-**2e** was prepared from alcohol **15** (6.8 g, 51.8 mmol) according to general procedure I and purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 6:1). Colourless oil. Yield: 69% (6.2 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.03 (s, 3 H, CH_3CO), 3.30 (s, 3 H, OCH_3), 4.14 (d, $^3J_{H,H}$ = 5.7 Hz, 2 H, MOMOCH_2), 4.60 (s, 2 H, CH_3OCH_2), 4.63 (d, $^3J_{H,H}$ = 6.0 Hz, 2 H, CH_2OAc), 5.62−5.80 (m, 2 H, =CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 20.7 (CH_3CO), 55.2 (OCH_3), 60.1 (CH_2OAc), 62.6 (MOMOCH_2), 95.6 (CH_3OCH_2), 126.7, 130.2 (=CH), 170.7 (C=O) ppm. MS (EI): *m*/*z* (%) = 174 (1) [M^+], 129 (8) [$M^+ - CH_2OCH_3$], 99 (6) [$M^+ - CH_2OCH_3 - CH_2O$], 85 (32) [$M^+ - CH_2OCH_3 - CO_2$], 45 (100) [$CH_2OCH_3^+$]. HRMS (EI) - for $C_6H_9O_3$ [$M^+ - CH_2OCH_3$]: calcd. 129.0552; found 129.0557.

(*Z*)-5-Methoxymethoxypent-2-enyl Acetate [(*Z*)-2f]: Crude (*Z*)-**2f** was prepared from alcohol **19** (5.0 g, 34.2 mmol) according to general procedure I and purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 9:1). Colourless oil. Yield: 77% (4.9 g). ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.03 (s, 3 H, CH_3CO), 2.38 (dt, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 6.6 Hz, 2 H, MOMOCH_2CH_2), 3.32 (s, 3 H, OCH_3), 3.53 (t, $^3J_{H,H}$ = 6.6 Hz, 2 H, MOMOCH_2), 4.58 (s, 2 H, CH_3OCH_2), 4.60 (d, $^3J_{H,H}$ = 5.6 Hz, 2 H, CH_2OAc), 5.52−5.76 (m, 2 H, =CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 20.9 (CH_3CO), 28.1 (MOMOCH_2CH_2), 55.1 (OCH_3), 60.2 (CH_2OAc), 66.8 (MOMOCH_2), 96.3 (CH_3OCH_2), 125.4, 131.1 (=CH), 170.8 (C=O) ppm. $C_9H_{16}O_4$ (188.22): calcd. C 57.43, H 8.57; found C 57.27, H 8.72.

General Procedure II. Ir^I-Catalysed Allylic Alkylation: A solution of $[IrCl(COD)]_2$ (6.7 mg, 0.01 mmol) in THF (2 mL) was treated with substrate (0.5 mmol) and then ligand (0.02 mmol). The resulting solution was stirred for 5 min. If the reaction was run with additive, this was added now (0.5 mmol) and the solution stirred for a further 5 min. After that, a freshly prepared solution of dimethyl 2-sodiomalonate, prepared by suspending sodium hydride (24 mg, 1.0 mmol) in THF (2 mL) and dropwise addition of dimethyl malonate (115 μL, 1.0 mmol), was added. The mixture was stirred under the stated reaction conditions, then water (4 mL) was added and the mixture extracted with diethyl ether (3 × 5 mL). The combined organic layers were washed with a satd. NH_4Cl solution (10 mL), dried (Na_2SO_4) and concentrated in vacuo. The crude product was purified by flash column chromatography to give substitution products **3** and **4** as colourless oils.

2-(1-Phenethylallyl) Dimethylmalonate (3b): Compound **3b** was obtained by allylic alkylation of substrate **1b** (535 mg, 2.6 mmol) according to general procedure II [ligand: $P(OPh)_3$, reaction time: 3 h, room temperature]. After purification (silica gel, petroleum ether/ethyl acetate 97:3), a 95:5 mixture of **3b** and **4b** was obtained. Yield: 91% (650 mg). $[\alpha]_D^{20}$ = 11.4 (*c* = 0.63, $CHCl_3$) for **3b** with 93% *ee* (*R*). HPLC: DAICEL Chiralcel ODH column, length: 25 cm + 5 cm precolumn, flow: 0.5 mL·min^{-1}, eluent: *n*-hexane/*i*PrOH (99.5:0.5); **3b**: t_R(*R*) = 32.2 min, t_R(*S*) = 34.3 min; (*E*)-**4b**: t_R = 49.6 min. ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.57−1.88 (m, 2 H, $PhCH_2CH_2$), 2.46−2.77 (m, 2 H, $PhCH_2$), 2.84 (dddd, $^4J_{H,H}$ = 3.7, $^3J_{H,H}$ = 9.0, $^3J_{H,H}$ = 9.5, $^3J_{H,H}$ = 9.3 Hz, 1 H, $CHCH$=CH_2), 3.44 [d, $^3J_{H,H}$ = 9.0 Hz, 1 H, $CH(CO_2CH_3)_2$], 3.69 (s, 3 H, OCH_3), 3.71 (s, 3 H, OCH_3), 5.11−5.20 (m, 2 H, =CH_2), 5.73 (ddd, $^3J_{H,H}$ = 9.3, $^3J_{H,H}$ = 10.7, $^3J_{H,H}$ = 16.6 Hz, 1 H, CH=CH_2), 7.13−7.31 (m, 5 H, Ph) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 33.2 ($PhCH_2CH_2$), 33.9 ($PhCH_2$), 43.7 ($CHCH$=CH_2), 52.1 (CH_3), 52.2 (CH_3), 56.7 [$CH(CO_2CH_3)_2$], 117.9 (=CH_2), 125.8 (Ph), 128.2 (Ph), 128.3 (Ph), 137.6 (CH=CH_2), 141.6 (Ph), 168.3 (C=O), 168.5 (C=O) ppm. $C_{16}H_{20}O_4$ (276.33): calcd. C 69.55, H 7.30; found C 69.34, H 7.33.

2-(1-Isopropylallyl) Dimethylmalonate (3d): Ester **3d** was prepared by allylic alkylation of substrate **1d** (850 mg, 6.0 mmol) according to general procedure II [ligand: $P(OPh)_3$, reaction time: 5 days, room temperature]. After purification by flash chromatography (silica gel, petroleum ether/ethyl acetate 98:2), a 93:7 mixture of **3d** and **4d** was obtained. Yield: 69% (890 mg). $[\alpha]_D^{20}$ = 0.07 (*c* = 0.54, $CHCl_3$) for **3d** with 66% *ee* (*R*). GC: Chiraldex γ-CD TA column, length: 30 m, 100 kPa helium, 50→100 °C at 1 °C·min^{-1}, then 20 min at 100 °C; **3d**: t_R(*R*) = 44.8 min, t_R(*S*) = 46.3 min; (*E*)-**4d**: t_R = 56.7 min. ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 0.82

(d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3), 0.89 (d, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3), 1.71 [dqq, $^3J_{H,H}$ = 5.2, $^3J_{H,H}$ = 7.0, $^3J_{H,H}$ = 7.0 Hz, 1 H, C*H*(CH_3)$_2$], 2.64 (ddd, $^3J_{H,H}$ = 5.2, $^3J_{H,H}$ = 9.6, $^3J_{H,H}$ = 9.9 Hz, 1 H, C*H*CH=CH_2), 3.56 [d, $^3J_{H,H}$ = 9.6 Hz, 1 H, C*H*(CO_2CH_3)$_2$], 3.67 (s, 3 H, OCH_3), 3.71 (s, 3 H, OCH_3), 5.05 [dd, $^2J_{H,H}$ = 1.8, $^3J_{H,H}$ = 16.9 Hz, 1 H, *anti*-(=CH_2)], 5.10 [dd, $^2J_{H,H}$ = 1.8, $^3J_{H,H}$ = 10.1 Hz, 1 H, *syn*-(=CH_2)], 5.67 (ddd, $^3J_{H,H}$ = 9.9, $^3J_{H,H}$ = 10.1, $^3J_{H,H}$ = 16.9 Hz, 1 H, C*H*=CH_2) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 17.5 (CH_3), 21.2 (CH_3), 29.0 [*C*H(CH_3)$_2$], 50.3 (*C*HCH=CH_2), 52.2 (OCH_3), 52.4 (OCH_3), 54.9 [*C*H(CO_2CH_3)$_2$], 118.6 (=CH_2), 134.8 (*C*H=CH_2), 168.7 (C=O), 169.0 (C=O) ppm. $C_{11}H_{18}O_4$ (214.26): calcd. C 61.66, H 8.47; found C 61.47, H 8.43.

2-[1-Methoxymethoxymethylallyl] Dimethylmalonate (3e): Ester **3e** was obtained by allylic alkylation of substrate **1e** (43 mg, 0.25 mmol) according to general procedure II [ligand: $P(OPh)_3$, reaction time: 18 h, room temperature]. After purification by flash chromatography (silica gel, petroleum ether/ethyl acetate 9:1), a 77:23 mixture of **3e** and **4e** was obtained. Yield: 91% (56 mg). $[\alpha]_D^{24}$ = 23.3 (*c* = 0.69, $CHCl_3$) for **3e** with 78% *ee* (*R*). GC: Chiraldex γ-CD TA column, length: 30 m, 100 kPa helium, 50→100 °C at 10 °C·min^{-1}, then 60 min at 100 °C; **3e**: t_R(*R*) = 54.1 min, t_R(*S*) = 55.8 min; (*E*)-**4e**: t_R = 63.5 min. ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 3.06−3.23 [m, 1 H, C*H*(CH=CH_2)] 3.32 (s, 3 H, C*H*$_3$OCH$_2$), 3.59 (d, $^3J_{H,H}$ = 6.3 Hz, 1 H, MOMOC*H*$_2$), 3.61 (d, $^3J_{H,H}$ = 5.5 Hz, 1 H, MOMOC*H*$_2$), 3.68 [d, $^3J_{H,H}$ = 8.1 Hz, 1 H, C*H*(CO_2Me)$_2$], 3.70 (s, 3 H, Me), 3.73 (s, 3 H, Me), 4.57 (s, 2 H, CH_3OCH_2), 5.11−5.21 (m, 2 H, =CH_2), 5.84 (ddd, $^3J_{H,H}$ = 8.8, $^3J_{H,H}$ = 10.3, $^3J_{H,H}$ = 17.3 Hz, 1 H, =CH) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 43.8 [*C*H(CH=CH_2)], 52.3 (Me), 52.5 (Me), 53.1 [*C*H(CO_2Me)$_2$], 55.3 (*C*H$_3$OCH$_2$), 68.4 (MOMO*C*H$_2$), 96.5 (CH_3OCH_2), 118.2 (=CH_2), 135.3 (=CH), 166.9 (C=O), 168.7 (C=O) ppm. $C_{11}H_{18}O_6$ (246.26): calcd. C 53.65, H 7.37; found C 53.37, H 7.23.

2-[1-(2-Methoxymethoxyethyl)allyl] Dimethylmalonate (3f): Ester **3f** was obtained by allylic alkylation of substrate **1f** (94 mg, 0.5 mmol) according to general procedure II [ligand: $P(OPh)_3$, reaction time: 18 h, room temperature]. After purification by flash chromatography (silica gel, petroleum ether/ethyl acetate 9:1), a 93:7 mixture of **3f** and **4f** was obtained. Yield: 94% (122 mg). $[\alpha]_D^{24}$ = −1.4 (*c* = 0.76, $CHCl_3$) for **3f** with 70% *ee* (*R*). HPLC: DAICEL Chiralcel ODH column, length: 25 cm + 5 cm precolumn, flow: 0.5 mL·min^{-1}, eluent: *n*-hexane/*i*PrOH (95:5); **3f**: t_R(*R*) = 23.2 min, t_R(*S*) = 24.6 min; (*E*)-**4f**: t_R = 28.9 min. ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.54−1.66 (m, 1 H, MOMOCH$_2$C*H*$_2$), 1.76−1.87 (m, 1 H, MOMOCH$_2$C*H*$_2$), 2.94−2.97 [m, 1 H, C*H*(CH=CH_2)], 3.45 [d, $^3J_{H,H}$ = 8.4 Hz, 1 H, C*H*(CO_2Me)$_2$], 3.39−3.58 (m, 2 H, MOMOC*H*$_2$), 3.70 (s, 3 H, Me), 3.75 (s, 3 H, Me), 4.56−4.61 (m, 2 H, =CH_2), 5.69 (ddd, $^3J_{H,H}$ = 9.6, $^3J_{H,H}$ = 9.6, $^3J_{H,H}$ = 16.9 Hz, 1 H, =CH), 3.34 (s, 3 H, C*H*$_3$OCH$_2$) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 32.1 (MOMOCH$_2$*C*H$_2$), 41.1 [*C*H(CH=CH_2)], 52.4 (Me), 52.6 (Me), 55.2 (*C*H$_3$OCH$_2$), 56.6 [*C*H(CO_2Me)$_2$], 65.1 (MOMO*C*H$_2$), 96.4 (CH_3OCH_2), 118.0 (=CH_2), 137.3 (=CH), 168.4 (C=O), 168.6 (C=O) ppm. $C_{12}H_{20}O_6$ (260.29): calcd. C 55.37, H 7.74; found C 55.28, H 7.63.

(*Z*)-[2-(4-Methoxymethoxybut-2-enyl)] Dimethylmalonate [(*Z*)-4e]: Ester (*Z*)-**4e** was obtained by allylic alkylation of substrate (*Z*)-**2e** (87 mg, 0.5 mmol) according to general procedure II [ligand: $P(OPh)_3$, reaction time: 4 h, room temperature]. After purification by flash chromatography (silica gel, petroleum ether/ethyl acetate 9:1) an 8:92 mixture of (*E*)-**4e** and (*Z*)-**4e** was obtained. Yield: 65% (80 mg). GC/MS (*Z*)-**4e**: t_R = 12.79 min; (*E*)-**4e**: t_R = 12.85 min. **(*Z*)-4:** ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.65 [dd, $^3J_{H,H}$ = 7.4, $^3J_{H,H}$ = 7.4 Hz, 2 H, C*H*$_2$CH(CO_2Me)$_2$], 3.34 (s, 3 H, C*H*$_3$OCH$_2$), 3.40 [t, $^3J_{H,H}$ = 7.4 Hz, 1 H, C*H*(CO_2Me)$_2$], 3.70 (s, 6 H, CO_2CH_3), 4.11 (d, $^3J_{H,H}$ = 6.2 Hz, 2 H, MOMOC*H*$_2$), 4.59 (s, 2 H, CH_3OCH_2), 5.40−5.72 (m, 2 H, C*H*=C*H*) ppm. $^{13}C\{^1H\}$ NMR (50.32 MHz, $CDCl_3$, 25 °C): δ = 26.4 [*C*H$_2$CH(CO_2Me)$_2$], 51.3 [*C*H(CO_2Me)$_2$], 52.5 (CO_2CH_3), 55.1 (*C*H$_3$OCH$_2$), 62.6 (MOMO*C*H$_2$), 95.7 (CH_3OCH_2), 128.2 (=CH), 129.0 (=CH), 169.1 (2s, C=O) ppm. HRMS (EI) for $C_{10}H_{15}O_5$ [M^+ − OCH_3]: calcd. 215.0919; found 215.0892.

(*Z*)-[2-(5-Methoxymethoxypent-2-enyl)] Dimethylmalonate [(*Z*)-4f]. Ester (*Z*)-**4f** was obtained by allylic alkylation of substrate (*Z*)-**2f** (752 mg, 4.0 mmol) according to the general method II [ligand: $P(OPh)_3$, reaction time: 4 h, room temperature]. After purification (silica gel, petroleum ether/ethyl acetate 9:1), a 6:1 mixture of (*Z*)-**4f** and **3f** was obtained. Yield: 80% (830 mg). GC/MS (*Z*)-**4f**: t_R = 13.33 min. ^1H NMR (200.13 MHz, $CDCl_3$, 25 °C): δ = 2.31 (dt, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 6.6 Hz, 2 H, MOMOCH$_2$C*H*$_2$), 2.61 [dd, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 6.6 Hz, 2 H, C*H*$_2$CH(CO_2Me)$_2$], 3.29 (s, 3 H, C*H*$_3$OCH$_2$), 3.32−3.39 [m, 1 H, C*H*(CO_2Me)$_2$], 3.48 (t, $^3J_{H,H}$ = 6.6 Hz, 2 H, MOMOC*H*$_2$), 3.68 (s, 6 H, CH_3), 4.56 (s, 2 H, CH_3OCH_2), 5.27−5.53 (m, 2 H, C*H*=C*H*) ppm. $^{13}C\{^1H\}$ NMR (50.32 MHz, $CDCl_3$, 25 °C): δ = 26.7 [*C*H$_2$CH(CO_2Me)$_2$], 27.7 (MOMOCH$_2$*C*H$_2$), 51.5 [*C*H(CO_2Me)$_2$], 52.3 (CH_3), 56.4 (*C*H$_3$OCH$_2$), 66.9 (MOMO*C*H$_2$), 96.2 (CH_3OCH_2), 126.5 (=CH), 129.1 (=CH), 169.2 (C=O) ppm. $C_{12}H_{20}O_6$ (260.29): calcd. C 55.37, H 7.74; found C 55.22, H 7.85.

1-Methoxymethoxybut-3-en-2-ol (6e): This compound was prepared via intermediates (see Schemes 2 and 3) that were not fully characterised.

11e: A solution of 2-methoxy-1,3-dioxolane (**10e**) (30.0 g, 0.288 mol) in 250 mL of dichloromethane was cooled to −70 °C. Then, a pre-cooled (−70 °C) solution of DIBAL-H in hexane (346 mL, 0.346 mol) was added dropwise and the reaction mixture was stirred for 90 min at −70 °C. Thereafter, the temperature was allowed to rise slowly to 0 °C and water (20 mL) was added. The resulting precipitate was dissolved by addition of aqueous NaOH (20%, 300 mL) and the resulting solution was extracted with dichloromethane (4 × 50 mL). The combined organic layers were washed with satd. NaCl solution (2 × 80 mL), dried (Na_2SO_4) and concentrated in vacuo to give an oil which was distilled [65 °C (10 Torr)] to give **11e**. Yield: 51% (15.2 g).[51] ^1H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.44 (s, 1 H, OH), 3.38 (s, 3 H, C*H*$_3$OCH$_2$), 3.67 (m, 2 H, C*H*$_2$OH or MOMOC*H*$_2$), 3.73 (m, 2 H, C*H*$_2$OH or MOMOC*H*$_2$), 4.66 (s, 2 H, CH_3OCH_2) ppm. $^{13}C\{^1H\}$ NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 55.1 (*C*H$_3$OCH$_2$), 61.9, 70.1 (*C*H$_2$OH and MOMO*C*H$_2$), 96.3 (CH_3OCH_2) ppm.

6e: A mixture of **11e** (4.00 g, 37.7 mmol), NMO (6.63 g, 56.6 mmol), activated molecular sieves (4 Å) (18.86 g) and dichloromethane (75 mL) was cooled to 0 °C, then TPAP (0.132 g, 0.38 mmol) was added slowly and the mixture stirred for 30 min. After stirring for a further 2 h at room temperature the mixture was filtered through a short silica column. The filtrate containing the aldehyde **5e**,[52] was concentrated in vacuo and the residue was used immediately for the next step.

A solution of aldehyde **5e** (8 mL, 37.7 mmol) in THF (50 mL) was added dropwise to a pre-cooled (0 °C) solution of vinylmagnesium bromide in THF (1.0 M, 41.5 mL, 41.5 mmol). The resulting mixture was stirred for 1 h at 0 °C and 18 h at room temperature. Then,

water (ca. 50 mL) was added dropwise and the resulting precipitate was dissolved by addition of 2 N HCl. The solution was extracted with diethyl ether (4 × 20 mL) and the combined organic layers were washed with brine (30 mL), dried (Na_2SO_4) and concentrated in vacuo to give a yellow oil which was subjected to flash column chromatography (silica gel, petroleum ether/ethyl acetate 1:1). Yield: 10% (500 mg over 2 steps). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.85 (s, 1 H, OH), 3.39 (s, 3 H, CH_3O), 3.47 [dd, $^3J_{H,H}$ = 7.4, $^2J_{H,H}$ = 10.6 Hz, 1 H, CH_2CH(OH)], 3.67 (dd, $^3J_{H,H}$ = 3.2, $^2J_{H,H}$ = 10.6 Hz, 1 H, CH_2CH(OH)], 4.29−4.34 [m, 1 H, CH(OH)], 4.67 (s, 2 H, CH_3OCH_2), 5.22 [d, $^3J_{H,H}$ = 10.6 Hz, 1 H, *syn*−(=CH_2)], 5.29 (d, $^3J_{H,H}$ = 17.3 Hz, 1 H, *anti*−(=CH_2)], 5.86 (ddd, $^3J_{H,H}$ = 5.5, $^3J_{H,H}$ = 10.6, $^3J_{H,H}$ = 17.3 Hz, 1 H, =CH) ppm. ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 55.3 (CH_3O), 71.4 [CH(OH)], 72.5 [CH_2CH(OH)], 96.8 [CH_3OCH_2)], 116.3 (=CH), 136.4 (=CH_2) ppm. MS (CI, isobutane): *m*/*z* (%) = 133 (15) [M^+ + 1].

5-Methoxymethoxypent-1-en-3-ol (6f): This compound was prepared via intermediates (see Schemes 2 and 3) that were not fully characterised.

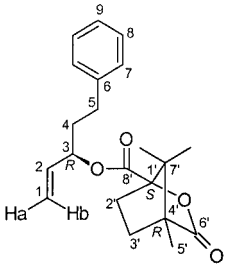
10f: Trimethyl orthoformate (151 mL, 1.38 mol) was dropwise added to a stirred solution of diol **9f** (50.0 mL, 0.69 mol) and camphorsulfonic acid monohydrate (1.73 g, 6.91 mmol) in dichloromethane (300 mL), and the mixture was stirred for 20 h at room temperature. The solvent was then removed under reduced pressure and the residue distilled to give **10f** (b.p. 148−152 °C) as a colourless oil.[53] Yield: 45% (37.02 g). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.71−1.73 (m, 2 H, CH_2CH$_2$O), 3.36 (s, 3 H, CH_3O), 3.74−3.77 (m, 2 H, CH_2CH_2O), 4.13−4.15 (m, 2 H, CH_2CH_2O), 5.18 [s, 1 H, CH(OCH$_3$)] ppm. ^{13}C{^{1}H} NMR (75.48 MHz, $CDCl_3$, 25 °C): δ = 24.7 (CH_2CH_2O), 52.5 (CH_3), 61.7 (CH_2CH_2O), 110.2 (OCHO) ppm

11f: Treatment of **10f** (15 g, 0.127 mol) with DIBAL-H (153 mL, 1 M in hexane, 0.153 mol) in 200 mL dichloromethane, according to the procedure described above for **11e**, gave crude monoester **11f**, which was purified by distillation (85−87 °C, 10 Torr) as a colourless oil.[54] Yield: 40% (6.16 g). ^{1}H NMR (200.13 MHz, $CDCl_3$, 25 °C): δ = 1.83 (tt, $^3J_{H,H}$ = 6.0, $^3J_{H,H}$ = 6.0 Hz, 2 H, CH_2CH$_2$OH), 2.41 (s, 1 H, OH), 3.34 (s, 3 H, CH_3O), 3.70 (t, $^3J_{H,H}$ = 6.0 Hz, 2 H, MOMOCH_2 or CH_2OH), 3.74 (t, $^3J_{H,H}$ = 5.9 Hz, 2 H, MOMOCH_2 or CH_2OH), 4.60 (s, 2 H, OCH_2O) ppm. ^{13}C{^{1}H} NMR (50.32 MHz, $CDCl_3$, 25 °C): δ = 32.1 (CH_2CH_2OH), 55.2 (CH_3O), 61.0, 66.1 (CH_2OH and MOMOCH$_2$), 96.4 (OCH$_2$O) ppm

6f: Monoester **11f** (4.9 g, 41.37 mmol) was transformed into aldehyde **5f** and this reacted in situ with vinylmagnesium bromide (1 M in THF, 45.8 mmol), by following an analogous procedure to the one described above for the preparation of **6e**.[55] After purification by flash column chromatography (silica gel, petroleum ether/ethyl acetate 2:1) **6f** was obtained as an oil. Yield: 29% over 2 steps (17.5 g). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.74−1.91 [m, 2 H, CH_2CH(OH)], 2.32 (s, 1 H, OH), 3.37 (s, 3 H, CH_3O), 3.60−3.80 (m, 2 H, MOMOCH_2), 4.31−4.36 [m, 1 H, CH(OH)], 4.62 (s, 2 H, CH_3OCH_2), 5.13 [ddd, $^2J_{H,H}$ = 1.4, $^4J_{H,H}$ = 1.4, $^3J_{H,H}$ = 10.5 Hz, 1 H, *syn*-(=CH_2)], 5.28 [ddd, $^2J_{H,H}$ = 1.4, $^4J_{H,H}$ = 1.4, $^3J_{H,H}$ = 17.2 Hz, 1 H, *anti*-(=CH_2)], 5.89 (ddd, $^3J_{H,H}$ = 5.6, $^3J_{H,H}$ = 10.5, $^3J_{H,H}$ = 17.2 Hz, 1 H, =CH) ppm. ^{13}C{^{1}H} NMR ($CDCl_3$, 75.47 MHz, 25 °C): δ = 36.3 [CH_2CH(OH)], 55.4 (CH_3O), 65.5 (MOMOCH$_2$), 71.6 [CH(OH)], 96.5 (CH_3OCH_2), 114.6 (=CH_2), 140.5 (=CH) ppm. MS (CI, isobutane): *m*/*z* (%) = 147 (100) [M^+ + 1], 129 (40) [M^+ + 1 − H_2O].

(*E*)-5-Methoxymethoxypent-2-en-1-ol (8f): A solution of ester **7f** (2.7 g, 14.4 mmol) in diethyl ether (50 mL) was cooled to −70 °C and DIBAL-H (31.6 mL of 1.0 M solution in hexane, 31.6 mmol) was slowly added via a dropping funnel. After stirring for 3.5 h at −70 °C, water (10 mL) was added dropwise and the solution was allowed to warm to room temperature. Additional water (10 mL) was added and the resulting precipitate was dissolved with 2 N HCl solution (ca. 90 mL). The mixture was extracted with diethyl ether (4 × 20 mL), the combined organic layers washed (2 × 30 mL satd. NH_4Cl solution), dried (Na_2SO_4) and concentrated in vacuo to give a colourless oil which was subjected to flash column chromatography (silica gel, diethyl ether/petroleum ether) to give **8f** with >95% purity (GC/MS). Yield: 66% (1.4 g, 9.5 mmol). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.56 (s, 1 H, OH), 2.31−2.42 (m, 2 H, MOMOCH_2CH_2), 3.36 (s, 3 H, CH_3O), 3.59 (t, $^3J_{H,H}$ = 6.6 Hz, 2 H, MOMOCH_2), 4.02−4.13 (m, 2 H, CH_2OH), 4.63 (s, 2 H, CH_3OCH_2), 5.71−5.77 (m, 2 H, =CH) ppm. ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 32.6 (MOMOCH_2CH_2), 55.2 (CH_3O), 63.7, 67.1 (CH_2OH and MOMOCH$_2$), 96.4 (CH_3OCH_2), 129.3, 131.1 (both =CH) ppm. MS (EI): *m*/*z* (%) = 145 (1) [M^+ − H], 129 (1) [M^+ − OH], 115 (10) [M^+ − OCH_3], 45 (100) [$H_3COCH_2^+$]. HRMS (EI) for $C_8H_{14}O_2$ [M^+ − (O=CH_2)]: calcd. 116.0837; found 116.0837.

(*R*)-5-Phenyl-1-penten-3-yl (1*S*,4*R*)-4,7,7-Trimethyl-3-oxo-2-oxabicyclo[2.2.1]heptane-1-carboxylate (12): (*R*)-5-phenyl-1-penten-3-ol [(*R*)-**6b**)] (0.50 g, 3.1 mmol) (prepared by enzyme-catalysed kinetic resolution of *rac*-**6b**)[12a] followed by 864 μL (6.2 mmol) of triethylamine were added dropwise to a cooled (0 °C) solution of (1*S*)-camphanic acid chloride (671 mg, 3.1 mmol) in anhydrous dichloromethane (10 mL). The solution was stirred at room temperature for 18 h and left to stand for 7 days. Colourless crystals precipitated from the mixture, were filtered off and washed with diethyl ether. The combined filtrates were concentrated in vacuo to give crude **12**. Crystals suitable for X-ray diffraction were obtained by recrystallization from ethyl acetate. Yield: 84% (890 mg). M. p. 55−58 °C.



12

^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 0.98 (s, 3 H, 7′-CH_3), 1.07 (s, 3 H, 7′-CH_3), 1.12 (s, 3 H, 5′-H), 1.71 (ddd, $^3J_{3'a,2'a}$ = 4.4, $^2J_{3'a,3'b}$ = 9.6, $^3J_{3'a,2'b}$ = 13.6 Hz, 1 H, 3′-Ha), 1.87−2.15 (m, 4 H, 4-H, 3′-Hb, 2′-Ha), 2.44 (ddd, $^3J_{2'b,3'b}$ = 4.4, $^2J_{2'b,2'a}$ = 10.7, $^3J_{2'b,3'a}$ = 13.6 Hz, 1 H, 2′-Hb), 2.67 (ddd, $^3J_{5,4a}$ = 3.3, $^3J_{5,3}$ = 6.6, $^3J_{5,4b}$ = 9.6 Hz, 2 H, 5-H), 5.25 (ddd, $^2J_{1a,1b}$ = 1.1, $^4J_{1a,3}$ = 1.1, $^3J_{1a,2}$ = 10.5 Hz, 1 H, 1-Ha), 5.32 (ddd, $^2J_{1b,1a}$ = 1.1, $^4J_{1b,3}$ = 1.1, $^3J_{1b,2}$ = 17.1 Hz, 1 H, 1-Hb), 5.36−5.45 (m, 1 H, 3-H), 5.83 (ddd, $^3J_{2,3}$ = 6.6, $^3J_{2,1a}$ = 10.5, $^3J_{2,1b}$ = 17.1 Hz, 1 H, 2-H), 7.13−7.32 (m, 5 H, *arom.* H) ppm. ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 9.66 (C-5′), 16.80 (7′-CH_3), 28.95 (C-3′), 30.73 (C-4′), 31.31 (C-5), 35.75 (C-4), 54.19, 54.82 (C-4′ and C-7′), 75.82 (C-3), 91.05 (C-1′), 118.16 (C-2), 126.11 (C-9), 128.32, 128.49 (C-7 and C-8), 135.51 (C-1), 140.87 (C-6), 166.81 (C-8′), 178.21 (C-6′) ppm. (*Z*)-5-Methoxymethoxypent-2-en-1-ol (19): A mixture of Lindlar catalyst (1.2 g), quinoline (0.33 mL, 357 mg, 2.77 mmol), alcohol **18** (5.9 g, 40.1 mmol) and methanol (340 mL) was stirred under a H_2 atmosphere for 15 hours at room temperature. The catalyst was removed by filtration through celite and the brown filtrate was concentrated in vacuo. The residue was purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 2:1) to afford a colourless oil. Yield: 69% (4.1 g). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 2.32 (ddt, $^4J_{H,H}$ = 1.5, $^3J_{H,H}$ = 6.2, $^3J_{H,H}$ = 6.2 Hz, 2 H, MOMOCH$_2$CH_2), 2.68 (br. s, 1 H, OH), 3.29 (s, 3 H, OCH_3), 3.50 (t, $^3J_{H,H}$ = 6.2 Hz, 2 H, MOMOCH_2), 4.09 (d, $^3J_{H,H}$ = 6.6 Hz, 2 H, CH_2OH), 4.55 (s, 2 H, CH_3OCH_2), 5.46−5.57 (m, 1 H, =CH), 5.62−5.77 (m, 1 H, =CH) ppm. ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 27.8 (MOMOCH$_2$CH_2), 55.1 (OCH_3), 57.8 (CH_2OH), 66.5 (MOMOCH_2), 96.2 (CH_3OCH_2), 128.8, 130.9 (= CH) ppm.

5-Phenyl-1-penten-3-yl Diethylphosphonate (26b): A solution of alcohol **6b** (2.0 g, 12.3 mmol) in THF (40 mL) was cooled to −78 °C and *n*BuLi (13 mL, 1.6 M in hexane, 20.9 mmol) was added slowly with a syringe. After stirring for 30 min at −78 °C, diethyl chlorophosphate (5.35 mL, 6.36 g, 36.9 mmol) was added. The mixture was stirred for 18 h, while the temperature was allowed to slowly rise from −78 °C to 25 °C. Then, water (40 mL) was added and the mixture was extracted with diethyl ether (3 × 20 mL). The combined organic layers were washed with satd. NaCl solution (50 mL), dried (Na_2SO_4) and concentrated in vacuo. The crude product was purified by flash column chromatography (silica gel, petroleum ether/ethyl acetate 2:1) to give **26b** as a yellow oil. Yield: 64% (2.3 g). ^{1}H NMR (300.13 MHz, $CDCl_3$, 25 °C): δ = 1.32 (t, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3), 1.33 (t, $^3J_{H,H}$ = 7.0 Hz, 3 H, CH_3), 1.87−2.14 (m, 2 H, CH_2CH), 2.65−2.74 (m, 2 H, PhCH_2), 4.10 (br. q, $^3J_{H,H}$ = 6.6 Hz, 4 H, OCH_2), 4.74−4.85 [m, 1 H, CHO-P(O)(OEt)$_2$], 5.25 (d, $^3J_{H,H}$ = 10.3 Hz, 1 H, =CH_2), 5.34 (d, $^3J_{H,H}$ = 17.3 Hz, 1 H, =CH_2), 5.88 (ddd, $^3J_{H,H}$ = 6.6, $^3J_{H,H}$ = 10.3, $^3J_{H,H}$ = 17.3 Hz, 1 H, =CH), 7.15−7.35 (m, 5 H, Ph) ppm. ^{13}C{^{1}H} NMR (75.47 MHz, $CDCl_3$, 25 °C): δ = 16.1 (2 CH_3), 31.0 (CH_2CHOR), 37.5 (PhCH_2), 63.7 (2 OCH_2), 79.2 (CHOR), 117.5 (=CH_2), 126.0 (Ph), 128.4 (Ph), 128.4 (Ph), 136.7 (=CH), 141.3 (Ph) ppm. ^{31}P NMR (121.49 MHz, $CDCl_3$, 25 °C): δ = −1.40 ppm. HRMS (FAB) for $C_{14}H_{24}O_4P$ [M^+ + 1]: calcd. 299.1412; found 299.1440.

***N*-Benzyl-4-methyl-*N*-(1-phenethylallyl) Benzenesulfonamide (27b):** An LHMDS solution (4.0 mL, 1.0 M in THF, 4.0 mmol) was added to a solution of *N*-tosylbenzylamine (1.1 g, 4.2 mmol) in THF (12 mL). The mixture was stirred for 30 min at room temperature and then added to a substrate/catalyst solution prepared as follows: $[IrCl(COD)]_2$ (26.8 mg, 0.04 mmol) was dissolved in THF (4 mL) and substrate **1b** (2.0 mmol) and then triphenylphosphite (21.7 μL, 0.08 mmol) were added. The reaction mixture was stirred for 18 h at room temperature and then, treated with water (20 mL) and extracted with diethyl ether (3 × 20 mL). The combined organic layers were washed with satd. $NaHCO_3$ (1 × 50 mL) and satd. NaCl solutions (1 × 50 mL) and dried over Na_2SO_4. After removal of the solvent in vacuo a yellow oil was obtained which was subjected to flash column chromatography (silica gel, petroleum ether/ethyl acetate 97:3) to give a 79:21 mixture of **27b** and **28b**. Yield: 47% (382 mg), colourless oil. $[\alpha]_D^{24}$ = 7.55 (*c* = 0.58, $CHCl_3$) for **27b** with 11% *ee* (*S*). HPLC: DAICEL Chiralcel ODH column, length: 25 cm + 5 cm precolumn, flow: 0.5 mL min^{-1}, eluent: *n*-hexane/*i*PrOH (95:5); **27b**: t_R(*S*) = 23.8 min, t_R(*R*) = 27.9 min; (*E*)-**28b**: t_R = 38.2 min.
