Fe^{II} Complexes: Complexation by tach-3-Mepyr and tach-6-Mepyr was studied in H_2O and solution reactions for all other chelators were run in MeOH. $FeCl_2$ (10 μL of 0.1 M aqueous) was added to tach-3-Mepyr (10 μL of 0.1 M aqueous) affording a bronze solution. Aqueous $FeCl_2$ (30 μL of 0.1 M) was added to tach-6-Mepyr (30 μL of 0.1 M) resulting in a red-brown solution. Each solution was brought to 1 mL with water producing solutions adequate for analysis. $FeCl_2$ (10 μL of 0.1 M methanolic solution) was added to tach-*x*-Mepyr or tach-6-MeOpyr (10 μL of 0.1 M methanolic solution) producing a bronze solution when *x* = 3, 4 or 5, a red-brown solution when *x* = 6 and a yellow solution for tach-6-MeOpyr. MeOH (980 μL) was added to the reactions producing solutions suitable for UV/Vis spectroscopic analysis.

Ni^{II} Complexes: Aqueous $NiCl_2$ (100 μL, 0.05 M) was added to aqueous tach-*x*-Mepyr or tach-6-MeOpyr, (100 μL of a 0.05 M solution) producing a clear pink solution with tach-*x*-Mepyr (*x* = 3, 4, 5), a clear yellow solution with tach-6-Mepyr, and a violet-white precipitate with tach-6-MeOpyr. Water (800 μL) was added to the reactions and the solutions were warmed (60 °C, 1 min) affording the appropriate pink, brown, and violet solutions for UV/Vis spectroscopic analysis.

Cu^{II} Complexes: All solution reactions for Cu^{II} complexes were run in water. $Cu(ClO_4)_2$ (60 μL of 0.05 M solution) was added to tach-*x*-Mepyr (*x* = 3, 4, 5) or tach-6-MeOpyr (120 μL of 0.025 M solution) producing a pale blue precipitate in all the reactions. Applying heat (50 °C, 30 s) and adding water (820 μL) produced bright blue solutions appropriate for analysis. Aqueous $Cu(ClO_4)_2$ (100 μL of 0.05 M solution) was added to aqueous tach-6-Mepyr (100 μL of 0.05 M solution) affording a pale blue precipitate. Water (800 μL) was added to the reaction producing a blue solution for UV/Vis spectroscopic analysis.

HPLC Studies: HPLC analyses of $[Fe(tach\text{-}3\text{-}Mepyr)]^{2+}$, $[Zn(tachpyr)]^{2+}$,[1] $[Zn(tach\text{-}6\text{-}Mepyr)]^{2+}$, $[Zn(tach\text{-}6\text{-}MeOpyr)]^{2+}$, $[Mn(tachpyr)]^{2+}$,[1] $[Mn(tach\text{-}6Mepyr)]^{2+}$ and $[Mn(tach\text{-}6MeOpyr)]^{2+}$ were conducted. Chromatograms in the gradient elution mode (RP-HPLC) were obtained with a Waters 600E/486/746 dual-pump system with UV detection at 254 nm. A Beckman Ultrasphere 4.6 × 25 cm RP-18 column was eluted with a gradient of 100% 0.05 M Et_3N·HOAc buffer (pH = 5.5) to 100% MeOH over 25 min. Chromatograms in the isocratic mode (RP-HPLC) were obtained on a Perkin–Elmer 250 dual-pump system with UV detection at 254 nm. A Beckman Ultrasphere 4.6 × 25 cm RP-18 column was eluted with 90% 0.05 M Et_3N·HOAc buffer (pH = 5.5) and 10% MeOH over 20 min. All complexes of tach-6-Mepyr and tach-6-MeOpyr, and also $[Mn(tachpyr)]^{2+}$, produced signals attributed to the free ligand and were therefore determined to be labile under gradient elution conditions. The complex $[Zn(tachpyr)]^{2+}$ was found inert as described previously,[1] and $[Fe(tach\text{-}3\text{-}Mepyr)]^{2+}$ showed a broad set of peaks indicative of imine formation previously observed for iron complexes of tach derivatives.[2,12] Under isocratic elution, the separation of $[Fe(tach\text{-}3\text{-}Mepyr)]^{2+}$ oxidation products improved sufficiently that the progressive transformations into higher imino species were observed.

Attempted Aqueous Reaction of tachpyr with Mg^{II} and Ca^{II}: These reactions were conducted in D_2O and analyzed by ^1H NMR spectroscopy; tachpyr (500 μL of 0.0241 M, 1.20 × 10^{-5} mol) was added to excess $MgBr_2$·$6H_2O$ (0.0180 g, 6.20 × 10^{-5} mol) or $CaCl_2$ (6.8 × 10^{-3} g, 6.1 × 10^{-5} mol); tachpyr remained unbound in both reactions.

X-ray Data Collection, Structure Solution and Refinement: See Tables 3 and 4) Single crystals of the various solvates of **1d**, **1e**, **3d**, **4e**, **5a**, and **5d′** were grown as described. The crystals were removed from the supernatant under a stream of N_2 and immediately covered with a layer of viscous hydrocarbon oil (Paratone N, Exxon). A suitable crystal was selected under the microscope, attached to a glass fiber, and immediately placed in the low-temperature nitrogen stream of the diffractometer. All data sets were collected using a Bruker SMART system, complete with 3-circle goniometer and CCD detector operating at –54 °C. The data sets were collected using a Cryojet low-temperature device from Oxford Instruments by employing graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Crystal decay was monitored by repeating the initial frames at the end of the data collection and analyzing the duplicate reflections. In all cases, no decay was observed. The crystal structures of all compounds were solved by direct methods, as included in the SHELX program package.[13] Absorption corrections were made with SADABS.[14] Missing atoms were located in subsequent difference Fourier maps and included in the refinement. The structures were refined by full-matrix least-squares refinement on F^2.

Hydrogen atoms were placed geometrically and refined using a riding model, including free rotation about C–C bonds for methyl groups. Thermal parameters for hydrogen atoms were refined with U_{iso} constrained at 1.2 (for non-methyl groups), and 1.5 (for methyl groups) times U_{eq} of the carrier C atom. All non-hydrogen atoms, with the exception of some disordered or restrained positions were refined anisotropically. The twist angles Φ were calculated by first determining the centroid in each of the triangles of the three cyclohexylamino nitrogen atoms [N(tach); designated as X1] and of the three ethylamino nitrogen atoms [N(en); designated as X2]. Then, the torsion angles N(tach)–X1–X2–N(en), each involving the two nitrogen atoms of the same chelate arm, were calculated and averaged. ORTEP drawings were made with SHELXTL[13] and ORTEP-3.[15,16] The ORTEP plots of **1d**·1/2H_2O·1/2MeOH and **1e** are available as Supporting Information. CIF files for the structural analyses of **1d**·1/2H_2O·1/2MeOH, **1e**, **3d′**·0.5Et_2O, **4e**, **5a**·2MeOH·0.5H_2O, and **5d′**·0.5H_2O·0.5MeOH have been deposited with the Cambridge Crystallographic Data Centre. CCDC-

Cytotoxicity Assays: MCF-7, a breast cancer cell line, was obtained from the ATCC and was grown in Dulbecco's Modified Eagle medium containing 10% fetal bovine serum in a humidified chamber containing 5% CO_2. 5×10^3 cells were plated in 96-well tissue culture dishes and allowed to attach overnight before test compounds were added. Six replicate cultures were used for each point. After 8, 24, 48 and 72 h (8 and 72 h in the case of tach-6-Mepyr), viability was assessed using an MTT assay, in which 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide was added to the medium and the formation of a reduced product assayed by measuring the optical density at 560/650 nm after 3 h. Color formation is proportional to viable cell number.[17] Assays of all compounds were repeated at least three times.

Indium(I) Hexafluoropnictates ($InPnF_6$; Pn = P, As, Sb)

Zoran Mazej*[a]

Keywords: Fluorides / Indium / Pnictides / Raman spectroscopy / Structure elucidation

The colourless compounds $InPnF_6$ (Pn = P, As, Sb), with In^I in a solely fluorine environment, were prepared by reacting In metal with PnF_5 (Pn = P) and displacement of the weaker Lewis acid BF_3 from $InBF_4$ by a stronger one, PnF_5 (Pn = As, Sb), in anhydrous hydrogen fluoride (aHF). The X-ray powder diffraction analyses show that $InPF_6$ crystallises in cubic unit cell with a = 8.07(2) Å, while $InAsF_6$ crystallises in a rhombohedral unit cell with a = 7.58(2) and c = 7.90(1) Å. The Raman spectra of $InPnF_6$ (Pn = P, As, Sb) confirm the formation of PnF_6^- salts. An attempt to prepare InF and In_2F_4 ($In^IIn^{III}F_4$) by reaction of CsF with $InSbF_6$ in aHF or by metathetical reaction of $InSbF_6$ with $CsInF_4$ in aHF, respectively, failed. Instead of InF and In_2F_4, respectively, a mixture of In and InF_3 was obtained.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The main oxidation state of group 13 elements (B, Al, Ga, In, Tl) is trivalent, although on going from lighter to heavier elements the univalent state becomes more stable. The occurrence of the latter is often described as an inert-pair effect.[1] In contrast to thallium, univalent indium compounds are not common. All thallium monohalides are well characterised, whereas only InCl, InBr and InI are known in the condensed phase.[2] Unstable InF has only been observed in the gas phase.[2–5] Furthermore, reports of complex fluorides with In^+ in a solely fluorine environment are also scarce.[6,7] One rare example is $InBF_4$, which has been prepared by reaction of elemental In with BF_3 in anhydrous hydrogen fluoride (aHF).[6] In the second case the authors erroneously claimed that they made $InBF_4$ for the first time.[7]

In the present work, two aims were followed: to prepare and characterise new ternary compounds with In^+ in a solely fluorine environment and to exploit the possibility of preparing indium(I) fluoride (InF) and a mixed-valence In^I/In^{III} fluoride ($In^IIn^{III}F_4$).

Discussion

Synthesis

The previously known BF_4^- salt of In^+ was prepared by the reaction of In metal with an excess of BF_3 in anhydrous hydrogen fluoride (aHF).[6] The same approach is not applicable to other Lewis acids (i.e., AsF_5, SbF_5) because they oxidize elemental In to In^{3+} to yield InF_3 (with AsF_5) or a mixture of $InF_3{\cdot}3SbF_5$[8] and $SbF_3{\cdot}nSbF_5$ (with SbF_5). For that reason, a different approach has to be used.

The displacement of the weaker Lewis acid BF_3 from $InBF_4$ by the stronger acid, AsF_5 or SbF_5, in the highly acidic solvent aHF, was successful. When a stoichiometric amount of Lewis acid (AsF_5, SbF_5) was added to a colourless solution of $InBF_4$ in aHF, a colourless precipitate formed immediately. Colourless $InAsF_6$ and $InSbF_6$ were obtained after decanting the liquid phase and removing the remaining traces of volatiles under vacuum at ambient temperature, see Equation (1).

$$InBF_4 + PnF_5 \xrightarrow[298\ K]{aHF} InPnF_6\ (Pn = As, Sb) + BF_3 \quad (1)$$

Use of an excess of AsF_5 or SbF_5 caused oxidation of In^+ to In^{3+} to give InF_3 or a mixture of $InF_3{\cdot}3SbF_5$/$SbF_3{\cdot}nSbF_5$, respectively. In the course of this study it was also found that $InAsF_6$, prepared by the reaction of $InBF_4$ with AsF_5 in aHF [Equation (1)], should be isolated immediately after its precipitation. When the reaction was left to proceed for a longer time, In^+ was slowly oxidized to In^{3+} to give $InAsF_6$ contaminated with InF_3. Its oxidation was complete in a few days and only InF_3 was recovered from the reaction mixture.

Compared with AsF_5 or SbF_5, PF_5 and BF_3 are weak Lewis acids (MF_x; x = 4 when M = B and x = 6 when M = P, As, Sb). A good measure of the strength of their Lewis acidity is the reaction enthalpy $\Delta H(MF_x + F^- = [MF_{x+1}]^-)$, i.e. fluoride ion affinity (FIA).[9] The main driving forces for the formation of $InPnF_6$ compounds [Equation (1)] are the difference in fluoride ion affinities (FIA) of BF_3 (347.7 kJ mol^{-1})[9] and PnF_5 (Pn = P: 397.1 kJ mol^{-1}; As =

443.1 kJ mol^{-1}; Sb = 503.3 kJ mol^{-1})[9] and the lattice energy differences between the starting $InBF_4$ and the resulting $InPnF_6$ salts. The lattice potential energies of $InMF_x$ salts have been estimated by Jenkins and Passmore et al. from a generalized volume-based Kapustinskii equation, see Equation (2).[10,11]

$$U_{POT}(InMF_x) = 2I\cdot[a\cdot V_m(InMF_x)^{-1/3} + \beta] \quad (2)$$

where a = 117.3 kJ mol^{-1} nm, β = 51.9 kJ mol^{-1} and the lattice ionic strength, I, is 1 for $InMF_x$ salts. Using values of $V_m(InMF_x) = V_{unit\ cell}/Z$ from the crystallographic data of $InBF_4$[6] and $InPnF_6$ (Pn = P, As), their lattice potential energies were estimated to be 616 kJ mol^{-1} ($InBF_4$) and about 566 kJ mol^{-1} ($InPF_6$, $InAsF_6$). The smaller lattice energy of $InAsF_6$ in comparison to $InBF_4$ is offset by a better fluoride ion acceptor ability of AsF_5 against BF_3, which makes the reaction $InBF_4 + AsF_5$ thermodynamically more favourable. In the contrast to AsF_5, the FIA of PF_5 is insufficient to compensate the poorer lattice energy of $InPF_6$ in comparison to $InBF_4$ and the reaction with the latter does not proceed.

As mentioned previously, In metal is oxidized to In^{3+} by the excess of AsF_5 or SbF_5 in aHF. However, the reaction between In metal and an excess of PF_5 in aHF proceeded in a different manner. Indium metal was slowly oxidized to In^+ to yield a colourless powder and cubic-shaped single crystals of $InPF_6$. Even after several days the reaction was not completed. During the isolation the powdery $InPF_6$ material turned grey and the smooth transparent surface of the crystals became rough and opaque.

The attempt to prepare In^I hexafluorobismuthate by the reaction of $InBF_4$ with BiF_5 in aHF failed. The yellowish solid isolated immediately after its precipitation was found to consist of InF_3 and $BiF_3\cdot nBiF_5$.[12]

Crystal Structures

Hexafluoropnictates ($MPnF_6$, Pn = As, Sb, Bi) of the heavier univalent metals (M = Tl, Rb, Cs) crystallise in a rhombohedral unit cell with the $KOsF_6$ structure type.[13] The only exceptions are hexafluorophosphates, which have cubic lattices at room temperature.[14] The expectation that PnF_6^- salts of In^+ should crystallise in a similar manner were confirmed by X-ray powder analyses.

The X-ray powder data of $InPF_6$, obtained at 298 K, were indexed with the Dicvol91 program[15] as a cubic unit cell (Table 1) with a = 8.07(2) Å and V = 524.9 Å^3. The isomorphic $CsPF_6$ has a cubic unit cell with a = 8.228(5) Å, V = 557(1) Å^3 and Z = 4.[14,16]

The X-ray powder pattern of $InAsF_6$ obtained at 298 K is very similar to that of $CsAsF_6$. The isostructurality of both compounds was confirmed after indexing the X-ray powder data of $InAsF_6$ in a rhombohedral unit cell (Table 2) with a = 7.58(2) Å, c = 7.90(1) Å and V = 393.3 Å^3. Isomorphic $CsAsF_6$ has a rhombohedral unit cell with a = 7.723(1) Å, c = 8.0503(10) Å, V = 415.8 Å^3 and Z = 3.[17]

In the case of $InSbF_6$ the obtained X-ray powder photographs showed no lines, thereby indicating that the isolated $InSbF_6$ was of very low crystallinity. This couldn't be improved even after recrystallisation of $InSbF_6$ from its saturated solution in aHF.

Vibrational Spectra

The Raman spectra of $InPnF_6$ (Pn = P, As, Sb) are shown in Figure 1 and given in Table 3. They are in agreement with the presence of regular PnF_6^- octahedra.

Attempted Synthesis of InF and $InInF_4$

Preparation of InF has previously been attempted by thermal decomposition of $InBF_4$ at 373 K.[6] On the basis of the results of X-ray powder analysis, it was claimed that the grey product contains, along with In metal, another phase which couldn't be identified. However, the X-ray

[a] Assignments are made for octahedral symmetry although in the solid state the actual symmetry could be lower.

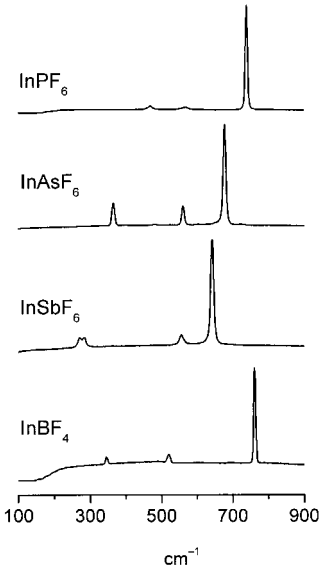

Figure 1. Raman spectra of indium(I) hexafluoropnictates and Raman spectrum of $InBF_4$ [761(100), 519(10), 346(10)].

powder diffraction pattern of this phase didn't match that of InF_3 nor could it be assigned to a high-ordered room-temperature form of TlF or to the NaCl structural type which is expected for InF.[6]

Our attempt to prepare InF slightly above the melting point of aHF (189.4 K) by reaction between $InSbF_6$ and CsF in aHF, expecting that the $CsSbF_6$ would precipitate and leave InF dissolved in aHF, failed. At this temperature all the insoluble solid was greyish. Colourless CsF reacted with $InSbF_6$ to form a mixture of colourless $CsSbF_6$ and InF_3 and finely powdered grey In metal.

Several phases have been isolated and characterised in the TlF/TlF_3 system (i.e., $Tl_2F_3 \equiv Tl^{I}_3\,Tl^{III}F_6$, $Tl_3F_5 \equiv Tl^{I}_2\,Tl^{III}F_5$, $TlF_2 \equiv Tl^{I}Tl^{III}F_4$, $Tl_3F_7 \equiv Tl^{I}Tl^{III}_2F_7$).[20,21] An attempt to prepare the indium analogue of TlF_2 (i.e., $InF_2 \equiv In^{I}In^{III}F_4$) by a metathetical reaction between $InSbF_6$ and $CsInF_4$ in aHF failed. Nothing happened at 243 K, and when the reaction mixture was brought to ambient temperature and left for one hour, a dark solid formed. This insoluble dark solid was separated from the colourless solution. The former consisted of a mixture of In and InF_3 still contaminated with $CsSbF_6$, while the colourless solid isolated from the decanted solution corresponded to $CsSbF_6$.

Experimental Section

CAUTION: Anhydrous HF and some of the fluorides below are highly toxic and must be handled using appropriate apparatus and protective gear.

Apparatus and Reagents: Volatile materials (PF_5, AsF_5, SbF_5, BF_3, aHF) were manipulated in an all-PTFE vacuum line equipped with PTFE valves. Non-volatile materials were manipulated in a dry box (M. Braun). The residual water in the atmosphere within the dry box never exceeded 1 ppm. The reactions were carried out in translucent fluorocarbon polymer (FEP, tetrafluoroethylene-hexafluoropropylene copolymer) reaction vessels (height 250–300 mm with inner diameter 15.5 mm and outer diameter 18.75 mm) equipped with PTFE body valves and PTFE-coated stirring bars. Reaction vessels made from two FEP tubes in a T-shape manner and equipped with PTFE body valves were used in some experiments. Each reaction vessel was pre-treated with F_2 (to about 1 bar) for several hours before use.

Pieces of In metal (Alfa Aesar, 99.99%) were treated with concentrated HCl prior to use to remove the oxide layer. BF_3 (Union Carbide Austria GmbH, 99.5%), CsF (Ventron, 99.9%) and InF_3 (Aldrich, 99.9) were used as supplied. Anhydrous HF (Praxair, 99.9%) was treated with K_2NiF_6 (Ozark-Mahoning, 99%) for several hours prior to use. PF_5, AsF_5, SbF_5 and BiF_5, were synthesised by pressure fluorination of phosphorus pentoxide (Aldrich, 99.99%), arsenic trioxide (Fluka, 99.5%), antimony trifluoride (Alfa Aesar, 99%) or bismuth trifluoride (ABCR, 99.5%), respectively, with elemental fluorine in a nickel reactor at 573 K.[22]

$InBF_4$ was synthesised from In metal and BF_3 in aHF as described.[6] $CsInF_4$ was prepared by annealing a stoichiometric mixture of CsF and InF_3.[23]

Instrumentation: Raman spectra were recorded with a Renishaw Raman Imaging Microscope System 1000, with He-Ne laser with wavelength 632.8 nm. X-ray powder diffraction photographs were obtained using the Debye–Scherrer technique with Ni-filtered Cu-K_α radiation. The positions of the lines were measured by visual inspection. Samples were loaded into 0.3-mm i.d. quartz capillaries in a dry-box, which were temporarily stoppered with halocarbonic grease and sealed outside in the H_2/O_2 flame.

Chemical Analyses: The amount of total fluoride ion was determined after total decomposition of the sample using a fluoride ion selective electrode.[24,25] The amount of indium was determined by complexometric titration with EDTA,[26] the amount of antimony by redox titration,[27] and the amount of AsF_6^- ion gravimetrically by precipitation with tetraphenylarsonium chloride.[28,29] The results of chemical analyses are given in mass percents.

Syntheses – General Procedure: Nonvolatile reactants were loaded into FEP reaction vessels in a glove box. Anhydrous hydrogen fluoride (aHF) and, when necessary, PF_5, AsF_5 or SbF_5 were con-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

densed onto the solid reactants at 77 K. The reaction vessels were brought to ambient temperature. The reaction mixtures were vigorously agitated and, after some time, the volatiles were pumped off. Isolated products were characterised by mass balance, chemical analysis, vibrational spectroscopy and/or X-ray powder diffraction analyses.

Reaction Between $InBF_4$ and PF_5 in aHF: Reaction mixture: 0.544 g (2.70 mmol) of $InBF_4$ and 0.340 g (2.70 mmol) of PF_5 in 2 mL aHF. After 2 d only a colourless clear solution was visible. An excess of PF_5 (ca. 1.00 g) was then added. The Raman spectrum of the isolated solid showed only bands which could be assigned to $InBF_4$ (Figure 1).

Synthesis of $InPF_6$: Reaction mixture: 0.340 g (2.96 mmol) of In metal and approximately 1.00 g of PF_5 in 4 mL of aHF. After 7 d pieces of In metal were still present. Cubic shaped crystals and a colourless powdered solid were observed beside unreacted In metal. After isolation the colourless powdered solid turned grey. Under microscopic observation it was found that single crystals also decomposed on the surface.

Synthesis of $InAsF_6$: Reaction mixture: 0.443 g (2.32 mmol) of $InBF_4$ and 0.480 g (2.44 mmol) of AsF_5 in 6 mL of aHF. A white precipitate formed immediately and the reaction was left to proceed for 10 min. To decrease the loss of $InAsF_6$ because of its solubility in aHF the reaction vessel was cooled to 243 K and, whilst cold, the solution was decanted to remove any possible traces of $InBF_4$. Yield of $InAsF_6$: 0.706 g (100% based on $InBF_4$). $InAsF_6$ (303.74): calcd. In 37.80, F 37.53, AsF_6 62.20; found In 37.6, F 37.1, AsF_6 62.5. X-ray powder diffraction analysis and Raman spectroscopy excluded the presence of $InBF_4$ or InF_3.

When the reaction mixture was left for a longer time the isolated product consisted of $InAsF_6$ and InF_3 (after 2 d) or only InF_3 (after 9 d).

When In metal or $InBF_4$ were treated with an excess of AsF_5 in aHF the final product consisted only of InF_3.

Synthesis of $InSbF_6$: Reaction mixture: 0.450 g (2.23 mmol) of $InBF_4$ and 0.398 g (2.23 mmol) of SbF_5 in 5 mL of aHF. A white precipitate formed immediately. After 1 d the volatiles were pumped off. Yield of $InSbF_6$: 0.794 g (100% based on $InBF_4$). $InSbF_6$ (350.56): calcd. In 32.75, F 32.52, Sb 34.73; found In 33.0, F 32.1, Sb 34.5.

The reaction between In metal or $InBF_4$ and an excess of SbF_5 in aHF yielded a mixture of $InF_3{\cdot}3SbF_5$[8] and $SbF_3{\cdot}nSbF_5$, as found by Raman spectroscopy. A detailed characterisation of the latter is beyond the scope of this study.

Reaction Between $InBF_4$ and BiF_5 in aHF: Reaction mixture: 0.569 g (2.82 mmol) of $InBF_4$ and 0.857 g (2.82 mmol) of BiF_5 in 10 mL of aHF. A white, very dense suspension was obtained. The liquid phase was decanted away and the remaining volatile components pumped off. The isolated solid was yellowish. The Raman spectrum [587 (100), 570 (sh), 535 (20), 493 (10), 231 (5) 125 (5)] indicated the formation of $BiF_3{\cdot}nBiF_5$.[12] A detailed characterisation of this adduct is beyond the scope of this study.

Attempt to Prepare InF: A mixture of $InSbF_6$ (0.84 mmol) and CsF (0.84 mmol) was loaded into the double T-shaped apparatus. After condensation of aHF onto the sample at 77 K, the reaction vessel was warmed slightly to the melting point of aHF (ca. 190 K). At that temperature the insoluble solid was greyish in aHF. The reaction vessel was allowed to reach room temperature and left for 0.5 h. The colourless liquid was decanted and aHF condensed back onto the insoluble solid. After repeating this procedure several times, the volatile materials were pumped off at ambient temperature. The X-ray powder diffraction pattern of the grey isolated solid showed lines that could be assigned to InF_3 still contaminated with $CsSbF_6$, while the Raman spectrum of the colourless solid isolated from the decanted solution corresponded to that of $CsSbF_6$.

Attempt to Prepare In_2F_4: A mixture of $InSbF_6$ (0.239, 0.68 mmol) and $CsInF_4$ (0.221 g, 0.68 mmol) was loaded into the double T-shaped apparatus. After condensation of aHF onto the sample at 77 K, the reaction vessel was warmed to 243 K. A clear solution was visible above the insoluble colourless solid. Since no visible change was observed after 1 h, the reaction vessel was brought to ambient temperature and left for 0.5 h. The colour of the insoluble solid turned to grey-black. The colourless liquid was decanted and aHF condensed back onto the insoluble solid. After repeating this procedure several times, the volatile materials were pumped off at ambient temperature. The X-ray powder diffraction pattern of the grey isolated solid showed lines which could be assigned to InF_3, while the Raman spectrum of the colourless solid isolated from the decanted solution corresponded to $CsSbF_6$.

Acknowledgments

The author gratefully acknowledges the Slovenian Research Agency (ARRS) for the financial support of the present study within the research program: P1-0045 Inorganic Chemistry and Technology. I am also grateful to Dr. Maja Ponikvar for the chemical analysis.

COVER PICTURE

The cover picture shows the concept of operating a homogeneous catalyst under continuous operation conditions: The recycling of molecular-weight-enlarged transition-metal complexes by suitable filtration methods and equipment in order to combine the advantages of both classical homogeneous and heterogeneous catalysis. Various aspects of molecular-weight enlargement and immobilization of catalysts, and recent developments, are reported in the Microreview by D. Vogt et al. on p. 4011 ff.

Continuous Homogeneous Catalysis

Christian Müller,[a] Marije G. Nijkamp,[a] and Dieter Vogt*[a]

Keywords: Homogeneous catalysis / Membrane reactor / Soluble support / Recycling / Immobilisation / Nanofiltration

This review article illustrates possible aspects for molecular-weight enlargement and immobilisation of transition-metal complexes that have been developed for bridging the gap between homogeneous and heterogeneous catalysis. The recycling of homogeneous catalysts can be performed using different types of supports, such as dendrimers, hyperbranched polymers, nanostructured materials or stabilized nanoparticles in combination with suitable filtration methods and equipments. Continuous homogeneous catalysis is ideally performed in a continuously operated membrane reactor. A general overview of molecular-weight enlargement along with selected examples and recent developments in continuous homogeneous catalysis is provided.

Introduction

The contribution of soluble transition-metal complexes as selective homogeneous catalysts for a number of chemical transformations under mild reaction conditions has increased significantly during the last decades. A number of important large-scale processes, such as the production of adiponitrile, α-olefins (SHOP process), acetic acid and acetic anhydride, and butanal are nowadays based on homogeneous catalysis.[1] A notorious drawback, however, is the tedious separation of the catalyst from the reaction products, a problem not encountered with typical heterogeneous catalysts and often accompanied by thermal strain on reactants and products. For large-scale industrial processes, individual solutions have been developed for catalyst separation and recovery in each case.

In most cases, the development of materials combining the advantages of classical homogeneous and heterogeneous catalysts has remained an elusive goal. However, molecular-weight enlargement and immobilisation of transition-metal complexes in combination with filtration methods offers the possibility to still operate the catalyst under homogeneous reaction conditions, hence maintaining the intrinsically high selectivity and activity, while avoiding mass-transfer limitations.[2] Furthermore, low energy consumption of the separation step and the potential for continuous homogeneous catalysis is provided. However, the synthesis of molecular-weight-enlarged catalyst systems is strongly related to the development of new membranes and reactors, which are compatible with homogeneous reaction conditions.

The Concept: Molecular-Weight Enlargement of Transition-Metal Complexes

A prerequisite for the application of filtration methods is a significant difference in molecular size of the catalyst, the reactants and products, as well as a suitable filtration unit. Different methods have been developed for the molecular-weight enlargement of transition-metal complexes in order to make them amenable to filtration methods. A general overview is given below, while specific examples will be given later on.

The first examples of the concept of binding catalytically active metal complexes to soluble supports were reported in the 1970s, when Rh-containing soluble polymers were successfully applied as hydrogenation catalysts.[3] Since then, functionalised soluble polystyrenes (**A**),[4] poly(ethylene glycol)s (**B**),[5] poly(methyl methacrylate)s (**C**),[6] poly(vinylpyrrolidine)s,[6] polyethylene oligomers,[6] poly(vinylchloride)s,[6] hyperbranched polymers[7] or polyelectrolytes (**D**)[8] have been applied as soluble polymeric supports for transition-metal complexes (Figure 1).[9]

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

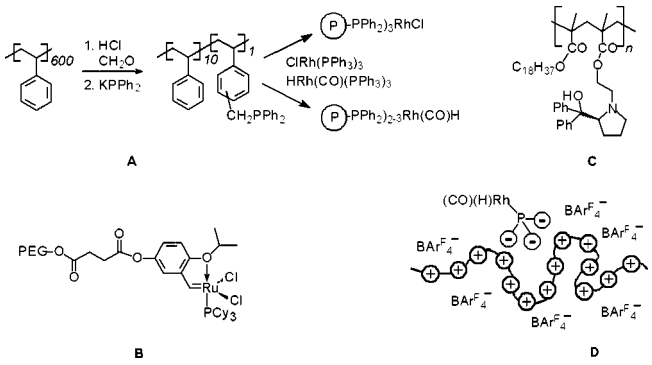

Figure 1. Functionalised polymeric supports.

Dendrimer-based systems are more defined soluble support structures. Most commonly, carbosilane (**1**), polyphenylene, poly(benzyl ether), DAB, PANAM (**2**) and PPI dendrimers have been applied for the immobilisation of transition-metal complexes.[10]

More recently, carbosilane dendrimers have been attached to polyhedral oligosilsesquioxane cages (POSS) (**3**).[11] In a different approach, this POSS cage has been used as the molecular-weight enlargement unit and directly linked to arylphosphane or aryl phosphite ligands (**4**).[12]

POSS-enlarged systems provide the unique properties of being rigid, three-dimensional and mostly kinetically and thermodynamically stable compounds whose size can easily be adjusted by the choice of the substituents attached to the silicon atoms.

In the above-mentioned examples, the transition-metal complexes, which are the catalytically active sites, are either covalently tethered to the support or through ionic interactions. A different approach is the stabilisation of catalytically active metal clusters on soluble supports, such as polyglycerols, polyamides or dendrimers (Figure 2). Metal atoms constituting nanoparticles can be generated in the presence of such a protecting agent, which forms a shell that prevents agglomeration of the particles into larger, and therefore less active, clusters. The protectors can be divided into two categories: those providing electrostatic and those providing steric stabilisation. Popular steric agents are polymers, poly(vinylpyrrolidone), cyclodextrins and dendrimers. Ionic surfactants protect nanoparticles by both electrostatic and steric mechanisms (Figure 2).

Membranes for Catalyst–Product Separations

Filtration processes can be classified into micro-, ultra-, nanofiltration and reversed osmosis, depending on the size of the particles that are retained by the membrane (Figure 3). In most cases ultra- or nanofiltration is used for catalyst separation and recycling.

An important parameter of a membrane is the molecular weight cut-off (MWCO), which is defined as the molecular weight at which 90% of the solutes are retained by the membrane. However, the pore size of many ultra- and nano-

Christian Müller was born in Germany in 1972. He studied Chemistry at the University of Bielefeld and the University of Michigan, Ann Arbor (USA). He received his Ph.D. under the supervision of Prof. Dr. P. Jutzi at the University of Bielefeld in 2000 and was awarded a fellowship of the Deutsche Forschungsgemeinschaft (DFG) to work with Prof. Dr. W. D. Jones at the University of Rochester, New York (USA). Afterwards he accepted a postdoctoral position in the group of Prof. Dr. P. W. N. M. van Leeuwen at the University of Amsterdam (The Netherlands). In February 2003 he joined the group of Prof. D. Vogt at Eindhoven University of Technology and was appointed Lecturer in 2004. His research interests are centred around the subjects "molecular weight enlarged systems for continuous homogeneous catalysis", "low-coordinate phosphorus ligands", "nanocatalysts" and "combinatorial approaches for ligand (catalyst) synthesis and testing".

Marije Nijkamp was born in 1973 in Paramaribo, Surinam. She finished her masters thesis in Inorganic Chemistry and Heterogeneous Catalysis at Utrecht University in 1998. In the same year she started her Ph.D. on Hydrogen Storage using physisorption, modified carbon nanofibres and related materials at Utrecht University with Prof. Dr. Krijn de Jong. In 2003 and 2004 she worked on a postdoctoral research project at Eindhoven University of Technology with Prof. Dr. Dieter Vogt where she investigated the use of polyglycerol- and polyamide-stabilized palladium colloids in continuous homogeneous catalysis. Currently she is employed by Engelhard De Meern B.V.

Dieter Vogt was born in Germany in 1962. He received his Ph.D. from the RWTH Aachen under the supervision of Prof. Dr. W. Keim in 1992 and continued with a Habilitation at the Institute of Industrial Chemistry and Petrochemistry of the RWTH Aachen. In 1999 he was appointed to full Professor of Inorganic Chemistry and Coordination Chemistry at the Eindhoven University of Technology, The Netherlands. Since 2001 he is chairman of the Schuit Institute of Catalysis and director of the Institute of Catalysis and Inorganic Chemistry. His main research interests are in the field of homogeneous catalysis. Ligand design for selectivity control in intermediate synthesis and fine chemicals, catalyst recycling, and new materials for application in catalysis, continuous miniplant operation, and kinetics of homogeneous catalytic processes, C1 building blocks, and renewable feed stocks are present research topics.

filtration membranes is greatly influenced by the reaction conditions, such as temperature and solvent, and should be taken into account.

As for the membrane material itself, basically two types of membranes are frequently used: organic (polymer) membranes and inorganic (ceramic) membranes. The most widely applied commercial organic membrane is the MPF series of Koch Int., which are basically silicon-derived membranes in the MWCO range of 400–700 Da (Figure 4, **a**).[13] Due to their polymeric nature, the MWCO is highly dependent on the solvent used.[14] Another common membrane is the STARMEM series from MET (polyimide-based), with MWCOs in the range of 200–400 Da.[15] Ceramic membranes are much less common, and published

results are only available for the tubular microporous silica membranes provided by ECN (Petten, The Netherlands).[16] These membranes have pore sizes between 0.5 and 0.8 nm and consist of several support layers of α- and γ- alumina, while the selective top layer at the outer wall of the tube is made of amorphous silica (Figure 4, **b**).[17]

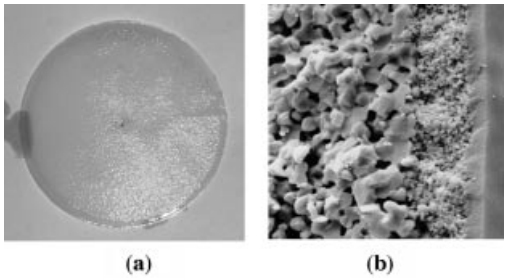

Figure 4. Organic (a) and ceramic (b) membranes.

Reactors for Continuous Homogeneous Catalysis

Decoupling of the residence times of the catalyst and the reactants by means of membrane technology provides the opportunity to control homogeneously catalysed processes by means of reaction engineering − an essential advantage largely restricted to heterogeneous catalysis to date. This is particularly desirable in the case of possible consecutive reactions, which can result in large amounts of undesired by-products. Such control of homogeneous catalysis would represent the break of a paradigm in fine chemicals production, where generally only batch processes are used nowadays.

For initial investigation of catalyst performance, a simple laboratory-scale dead-end ultrafiltration unit (Figure 5, a) with a commercially available flat membrane can be employed. Dead-end filtration means that the product flow is perpendicular to the surface of the membrane. This eventually is a disadvantage because concentration polarisation can occur. The dead-end filtration setup in Figure 5 was developed by us for applications at high pressures and used for the hydrovinylation of styrene (vide infra). In this reaction, ethylene was used as a solution in dichloromethane, prepared separately in a stainless-steel tank, while the second substrate (styrene), dissolved in dichloromethane, was pumped with a second HPLC pump into the reactor. The catalyst solution, on the other hand, was introduced via an HPLC injection valve. Products and unreacted compounds cross the membrane and leave the reactor on top.[18]

In a cross-flow filtration setup (Figure 5, **b**), the product flow is parallel to the membrane surface, which requires a separation unit next to the actual reactor and an additional pump to provide a rapid circulation across the membrane. A special type of cross-flow reactor has been developed in our laboratories to handle continuous gas/liquid reactions. The challenge in the reactor design was the combination of efficient gas/liquid mixing, liquid level control in the reactor, turbulent flow across the membrane and efficient gas/liquid separation to avoid gas contacting the membrane, which would lead to a shunt of gas. Ceramic membrane tubes (HITK) with higher temperature stability and much better solvent resistance are used.

Selected Examples of Continuous Homogeneous Catalysis

1) Polymer-Enlarged Homogeneous Catalysts

The use of homogeneous catalysts bound to soluble polymeric supports[19] in continuously operating membrane reactors was pioneered by Wandrey and co-workers as well as Kragl and Dreisbach. The catalyst consists of a soluble polymeric support − a copolymer of 2-hydroxyethyl methacrylate and octadecyl methacrylate − combined with α,α-

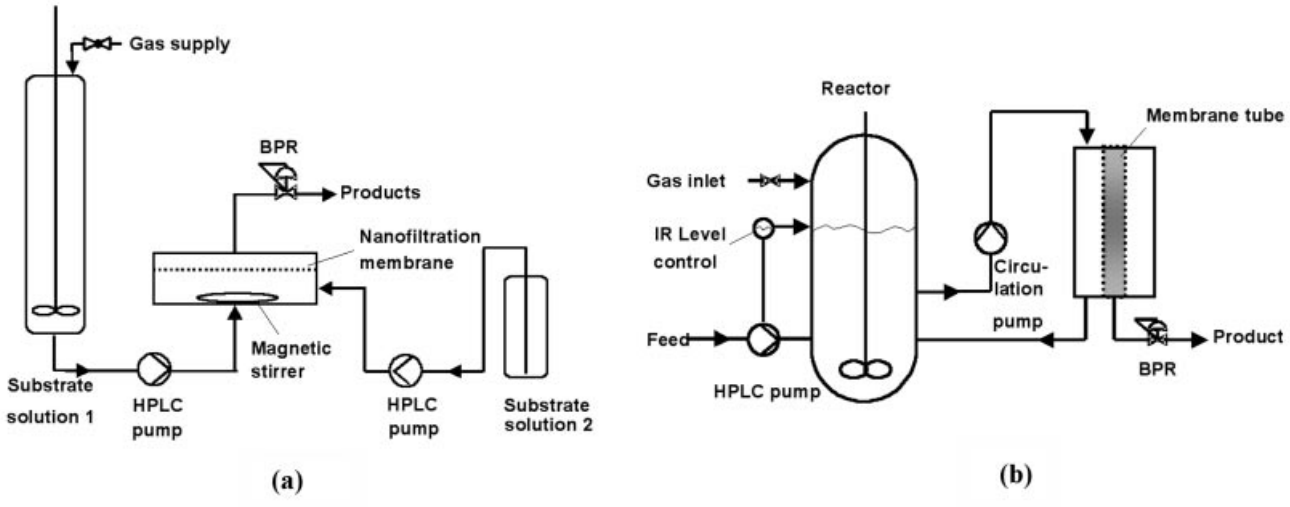

Figure 5. A dead-end filtration reactor (**a**) and cross-flow filtration reactor (**b**) described by Vogt et al.[18]

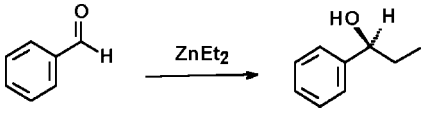
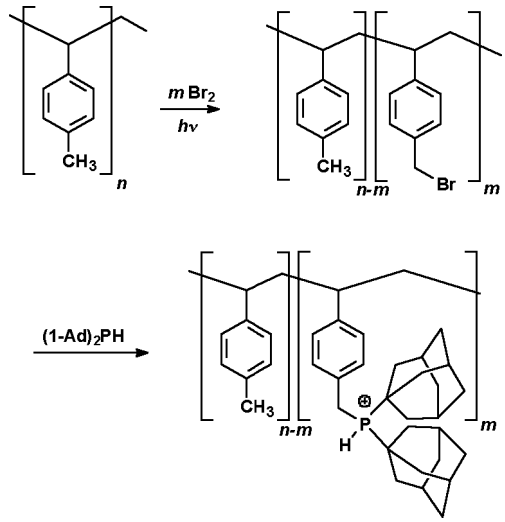
diphenyl-L-prolinol as the active organocatalytic site (see C), which was used for the enantioselective addition of diethylzinc to benzaldehyde [Equation (1)].



(1)

The reaction was carried out in a continuous way by using an ultrafiltration membrane (Hoechst-Nadir-UF-PA20). A retention of the polymeric support of more than 99.8% was observed. Even though the *ee* achieved with the molecular-weight-enlarged catalyst was lower (80%) than with the non-supported analogue (97%) the proof of principle to run the reaction in a continuous way was shown. Interestingly, the total turnover number (tTON) of the chiral organocatalyst under continuous conditions could be raised by a factor of 10, to 500. After seven days, no deactivation of the catalyst could be observed.[20]

Plenio et al. have used a polymer-enlarged catalyst formed from $(1\text{-Ad})_2$P-substituted poly(methylstyrene) (Scheme 1), a suitable palladium source {$[PdCl_2(PhCN)_2]$, $Pd(OAc)_2$, or $Pd(dba)_2$} and a base ($HNiPr_2$ or K_3PO_4).[21] This system was used to efficiently mediate carbon–carbon coupling reactions of the Suzuki, Sonagashira and Heck type for aryl bromides and aryl chlorides. Such catalysts were also studied in nanofiltration separation experiments. The linear 5000 Da polymer backbone [poly(*p*-methylstyrene)] is sufficiently large to be retained quantitatively by a PMDS nanofiltration membrane. The leaching of the catalyst into the product-containing permeate is very small (<0.05%). The catalyst was reused up to nine times by using the catalyst-containing retentate after filtration from the product. Further evidence for the recyclability of the catalyst was derived from the constant and high yields in the Sonogashira and Suzuki reactions and from the unchanged TOF. In the Heck reaction, the highly polar and aprotic solvents are detrimental to the integrity of the polymeric membranes. It is therefore impossible to draw conclusions on the suitability of using this catalyst in repeated Heck coupling reactions. A disadvantage of the system is the multistep synthesis of the polymer. The polymer is prepared by anionic polymerisation of *p*-methylstyrene and then treated with Br_2 to convert up to 18% of the CH_3 groups into CH_2Br. Subsequently, a phosphane group is loaded onto the polymer (Scheme 1) and the Pd catalyst is formed in situ. This multi-step synthesis makes such a polymer relatively expensive and therefore less suitable for industrial applications. Also, it should be noted that the catalyst was employed in a batch reaction and after completion of the reaction was recycled by nanofiltration. These experiments were not performed in a continuous manner.



Scheme 1. Preparation of a polymer-supported phosphonium salt.

2) Dendrimers as a Soluble Support

Dendrimers have attracted considerable attention since the pioneering work by Vögtle et al. on these systems.[22]

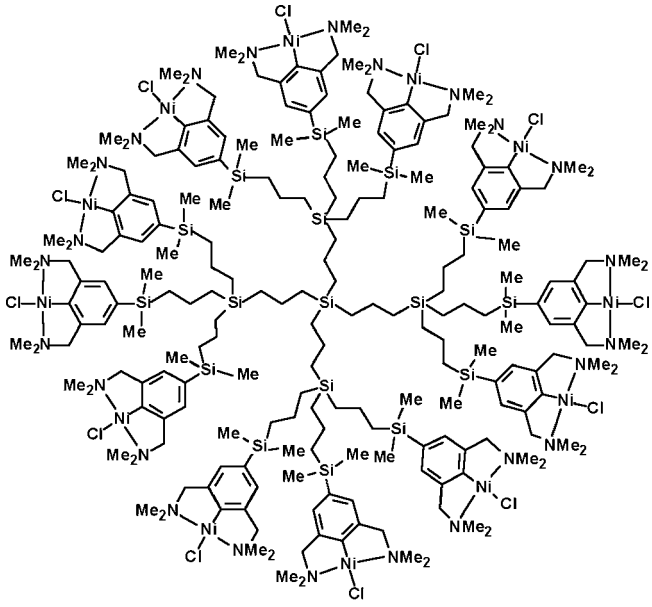
 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

While (perfectly branched) dendrimers provide a well-defined structure, their syntheses are usually tedious and expensive and, correspondingly, commercial applications of dendrimers are scarce. Dendrimers differ in the position of the catalytic site(s). Surface-functionalised dendrimers lead to catalysts that are sufficiently large to be retained by membranes. However, detailed studies on the macromolecular structure of dendrimers have revealed that they do not always adopt the ideal spherical structures their drawings suggest − amphiphilic dendrimers, in particular, have structures that are far from spherical.[23]

In principle, dendritic catalysts can show the kinetic behaviour and thus the activity and selectivity of a conventional homogeneous catalyst. The transition metals on the outer sphere are directly available for the substrate, which allows for reaction rates that are comparable with homogeneous systems. On the other hand, these periphery-functionalised systems contain multiple reaction sites and ligands, which results in extremely high local catalyst and ligand concentrations. For example, a second-generation carbosilane dendrimer functionalised with 36 terminal phosphanes results, theoretically, in local concentrations of 8 M of ligand and 4 M of catalyst. In reactions where excess ligand is required to stabilize the catalyst this local-concentration effect can indeed result in stable systems. However, several deactivation processes can operate by a bimetallic mechanism. Examples of these are ruthenium-catalysed metathesis,[24] palladium-catalysed reductive coupling of benzene and chlorobenzene[25] and reactions that involve radicals.[26]

A difficult problem in the use of dendrimers is leaching. Two forms of leaching are known: leaching of the dendritic catalyst through the membrane and metal leaching from the dendrimer into the solution and further leaching of the active metal through the membrane, usually in the form of small homogenized complexes. For industrial applications, the overall retention of the dendritic catalyst must be extremely good to keep a high activity in a continuous reactor for longer reaction times. The required retention obviously depends on the application, since processes for the bulk industry generally require more efficient catalyst recycling (higher TONs) than those for fine chemicals. Generally, a retention of at least 99.99% is required to obtain a catalyst system that remains in the reactor for a prolonged period of time, even for fine chemical production processes.

The groups of van Koten and van Leeuwen have reported G_0 and G_1 carbosilane dendrimers functionalised with up to 12 pincer NCN-nickel(II) groups (**5**).[27] These dendrimers were then applied as catalysts for the Kharasch addition of CX_3Y to alkenes [Equation (2)]. While being used in a continuous membrane reactor the compound showed decomposition, which has been ascribed to hydrolysis of the Si–O bond of the linker between the ligand and the carbosilane backbone. In a further modification of the system, the NCN ligands were attached directly to the carbosilane backbone of **5**.



5

While retentions of the molecular-weight-enlarged systems of up to 99.75% were observed, the formation of insoluble purple species occurred under continuous flow conditions. Addition of Bu_4NBr prevented catalyst precipitation but a fast decrease in conversion was detected: after 45 cycles, the activity of the catalyst dropped to almost zero, most likely due to the formation of inactive Ni^{III} species (Figure 6). Furthermore, the carbosilane support plays a pivotal role in the accessibility of the active sites: surface congestion can lead to the formation of mixed-valence Ni^{II}/Ni^{III} complexes on the dendrimer periphery that compete for reactions with substrate radicals.

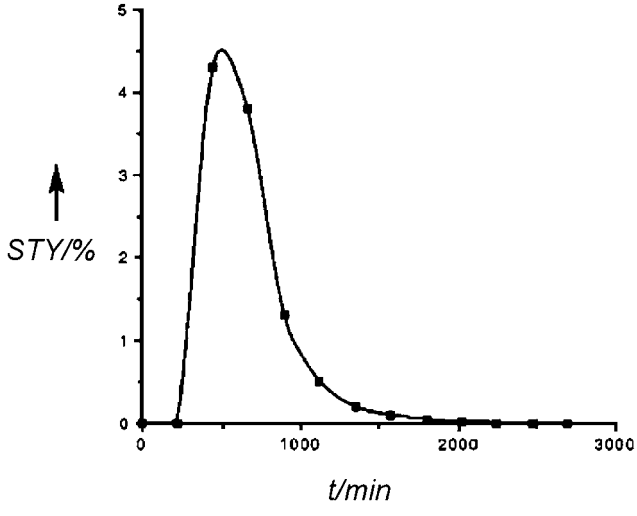


Figure 6. A continuous Kharasch addition (reprinted with permission from ref.[27d] Copyright 2000 American Chemical Society.

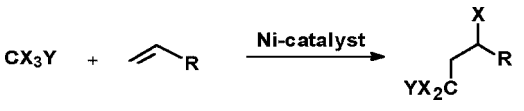
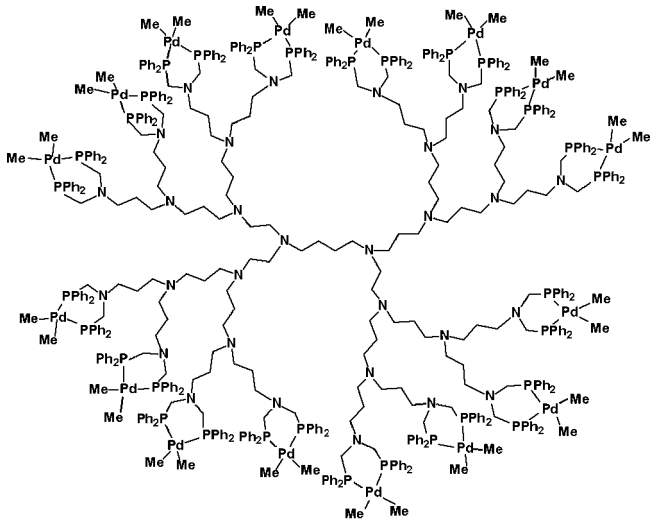


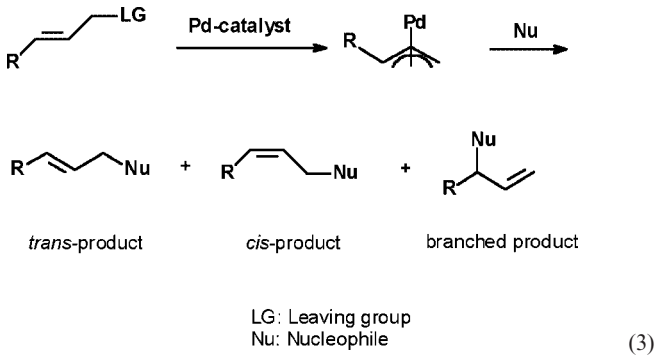
(2)

Commercially available fourth- and fifth-generation DAB dendrimers have been functionalised with diphenylphosphanyl groups at the periphery by Reetz and Kragl and their respective co-workers.



6

The corresponding Pd complexes (**6**) were used for the Pd-catalysed allylic amination to yield *N*-[3-phenyl-2-propenyl]morpholine in a continuously operating dead-end filtration [Equation (3)].

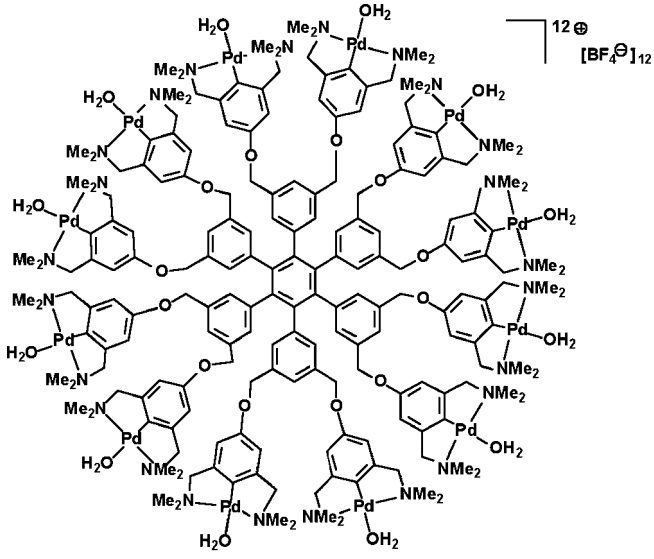


(3)

A conversion of 100% was obtained in the beginning but a 20% decrease was observed after 100 h, as well as palladium leaching of between 0.07 and 0.14% per residence time. The soluble support, on the other hand, was completely retained in the membrane reactor.[28] Several studies on the use of these types of palladium-functionalised dendrimers for allylic substitution reactions have all shown significant loss of activity during the reaction. In all cases, the leaching of the dendrimer through the membrane was much smaller than the observed loss in activity. These results suggest that the catalyst decomposes during the course of the reaction and leaches through the membrane as small soluble metal clusters.[28,29] The leaching gives rise to two problems, loss of expensive catalyst or active metal and contamination of the product with this metal. In some cases it can be economically acceptable to compensate for the loss in activity by addition of the active metal to the feed solution. However, the contamination of the product should be limited to an acceptable amount.

Van Koten et al. and ourselves have reported on shape-persistent multi-NCN-palladium and/or platinum complexes exhibiting one-, two- and three-dimensional geometries. These were subjected to nanofiltration experiments to investigate the influence of rigidity and geometry on the retention of these molecules by MPF membranes. A clear relationship between the dimensions calculated by molecular modelling and the retention rates of the synthesised complexes was observed. Furthermore, similar sized complexes with zero- and first-generation flexible dendrimers were compared and it was found that a high degree of rigidity in the backbone of the macromolecular complexes indeed leads to more efficient retention by the membrane.

In a later study, a very shape-persistent dendrimer, the dodecakis[NCN-Pd^{II}-aqua](BF$_4$)$_{12}$ complex **7** was synthesised and employed as a Lewis acid catalyst in the double Michael addition reaction between methyl vinyl ketone and ethyl α-cyanoacetate. The efficiency of the reaction was significantly enhanced, as the TON was increased by a factor of more than 40. After prolonged reaction times (>25 h) a small decrease in activity was observed, which can be completely ascribed to slow leaching of the catalyst. The retention of the reaction was 99.5%.[30]



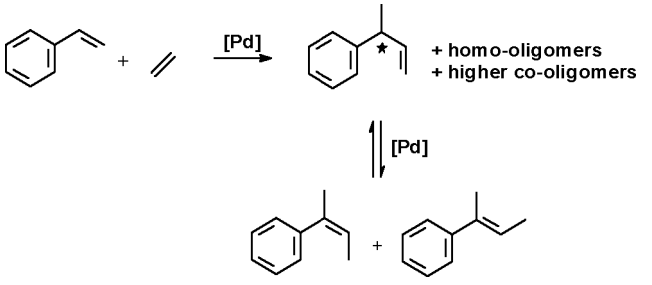
7

This shows that very shape-persistent dendrimers can be used in continuous homogeneous catalytic reactions. However, even under these optimised circumstances, the retention is still lower than desired (99.99%). Recycling of the catalyst by microporous filtration showed no significant loss of activity or selectivity during five consecutive runs. This is promising for use in a continuous process, but more experiments have still to be performed.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The above-mentioned examples describe catalytic reactions in which only liquid components participate in the chemical transformation. The situation becomes more complicated when one of the reactants is a gas. Typical reactors and membranes are not designed for use with certain organic solvents, high temperature and/or high pressure, and only a few examples of continuous catalytic gas/liquid reactions have been reported in the literature up to now. Therefore, C–H and C–C linkage reactions involving the consumption of one or more gases are usually performed in a batch-wise process with subsequent filtration through a membrane in order to separate the molecular-weight-enlarged catalyst from the product. In case of hydrogenation reactions, the saturation of the solvent with hydrogen is in most cases sufficient to run the reaction in a continuous way. However, the design of suitable reactors for applications under more drastic reaction conditions (e.g. elevated temperatures and pressures) is less obvious.

A pressure membrane reactor has been developed by us for the co-dimerisation of ethylene and styrene [the hydrovinylation reaction, Equation (4)] under continuous reaction conditions.



(4)

Molecular-weight-enlarged carbosilane dendrimers (such as **1**), functionalised with four or 12 P–O ligands on the periphery have been used as catalysts in this reaction. Interestingly, the reaction runs almost without any isomerisation of the products to a mixture of the (*E*)- and (*Z*)-isomers of 2-phenyl-2-butenes or formation of any side products, which are usually observed at high conversions. The maximum productivity was reached after an induction period of about nine hours, followed by a steady decrease of activity (Figure 7). However, catalyst deactivation was also observed (precipitation of palladium on the membrane).[18]

The core-functionalised dendritic dppf analogue **8** (dppf = diphenylphosphanylferrocene) was synthesised by van Leeuwen et al. While the corresponding rhodium complex could only be applied in a batch-wise hydroformylation reaction [the hydroformylation reaction is typically performed at elevated temperature (40–80 °C) as well as under a syngas pressure of 10–20 bar], the hydrogenation of dimethyl itaconate could be performed under continuous reaction conditions. Interestingly, no deactivation of the catalyst occurred during the catalytic experiment, which has often been observed in continuous palladium-catalysed reactions. The drop in conversion (77% after 35 exchanged reactor volumes) could fully be explained by the retention of the dendritic system (99.8%).[31]

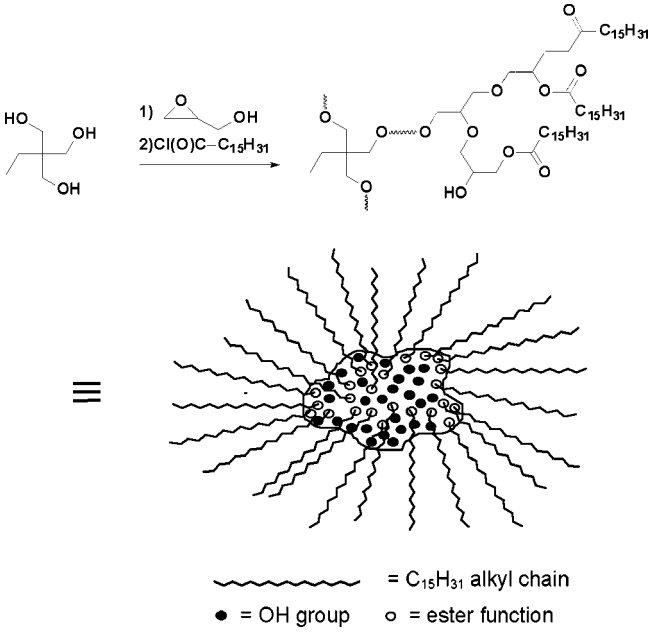
3) Nanocolloids: Metal Nanoclusters Stabilized in Dendrimers

Dendrimers can also be used as templates for the preparation of precise metal nanoclusters within their interior. Hydroxy-terminated poly(amido amine) dendrimers have been found to be particularly good for this purpose.[32] While high catalytic activity of metal clusters is well known, they tend to aggregate into larger and, therefore less-active, systems under catalytic conditions. Precise construction of nanocomposites in the cavities of dendrimers might lead to both cluster stability and full control over size and size distribution, while the dendrimer branches still allow substrate access to the catalytically active clusters. Additionally, dendrimers could enhance the solubility of the metal clusters, as they have good solubilities in a wide range of solvents. A water-soluble and stable G4-OH(Pd_{40}) dendrimer, for example, exhibits high activity for the hydrogenation of alkenes in water. It was reported to be sufficiently stable for recycling and reuse, although the actual data of such

experiments were not provided.[32a] The use of a dendrimer gives a more reproducible and more robust backbone than the use of polymers, but the preparation of a dendrimer is infinitely more time consuming and expensive, while the sizes of the palladium particles are similar those which are stabilized by branched polyglycerols and polyamides.

4) Metal Nanoparticles Stabilized with Hyperbranched Polyglycerols and Polyamides

Catalytically active metal nanoparticles can also be confined by utilizing the structure of easily accessible, compartmented amphiphilic (statistically branched) hyperbranched polymers. Recently, a one-step synthesis allowing a convenient access to hyperbranched polyglycerols of controlled, narrow molecular weight distributions was found.[33] Partial esterification of the OH groups with long-chain fatty acids yields amphiphilic molecules (Scheme 2; $M_w/M_n < 1.7$), which can function as nanocapsules for the incorporation of individual hydrophilic dye molecules as guests.[34]



Scheme 2. Schematic representation of the preparation and structure of a hyperbranched amphiphilic polyglycerol.

Solubilisation of metal salts by such well-defined polymers and subsequent reduction (H_2, CO or thermally) can yield stable solutions of metal colloid/polymer hybrids, while the metal-particle sizes (ranging from 1 to ≥20 nm) increase with increasing polymer molecular weight.[35] A large portion of the individual metal particles appears to be confined in a single branched macromolecule. Such metal nanoparticle/hyperbranched polymer hybrid materials display a remarkable catalytic activity and stability in cyclohexene hydrogenation as a model reaction.[36] A total of 7×10^4 turnover over 30 h and well-behaved kinetics were observed at 1 atm hydrogen pressure. Further investigations have shown these materials to be stable in small-scale ultrafiltration experiments.

In order to achieve a better membrane performance, a loop filtration module was employed rather than the commonly used dead-end filtration cell (Figure 5, b). In this way, much more reliable and reproducible data, also with a view to possible applications, were obtained. The use of tubular membranes enables a facile scale-up and membrane surface enlargement.

With polyglycerols of different molecular weights (M_n = 2000–20000 g mol^{-1}) as a scaffold, functionalised polymers with varying degrees of substitution can be prepared. Apart from palmitoyl moieties, other lipophilic groups (e.g. bulky adamantoyl moieties or aromatic residues) and other linking units (e.g. ether instead of ester functions) were investigated. Thus, hyperbranched polymers of low polydispersity and controlled, variable hydrophilic-hydrophobic balance were produced.

The polymeric molecule environment of the metal particles can control the approach of substrates to the metal particles and the reactivity of the metal surface atoms. Hydrogenation reactions employing substrates differing in polarity and steric bulk serve as initial simple model reactions. For instance, cyclohexene has been hydrogenated to cyclohexane and the reaction was performed in a continuous membrane reactor with good retentions observed (R = 99.8%).[37] Eventually, C–C coupling reactions, such as Heck, Suzuki and Stille reactions, will be particularly intriguing. Such reactions are important for the preparation of fine chemicals, and are employed, for example, for the production of pharmaceuticals and other biologically active substances.

Hyperbranched poly(ethylene imine) amides have been prepared by amidation of different carboxylic acid amide derivatives.[34,36,38,39] These poly(ethylene imine) amides proved more suited for structural investigations. The hyperbranched polyamine core binds metal precursors and consequently solubilises them in apolar organic solvents much more effectively than the polyether-polyol scaffold of polyglycerol, as expected. Silver nitrate (insoluble in toluene in the absence of the polymers) was found to be well suited as a model compound for structural investigations. For poly(ethylene imine) amides, the concept of solubilisation of a metal salt in a polymeric inverted unimolecular micelle, and formation of a metal particle in the micelle upon reduction, indeed proved to be applicable. Also, by contrast to unmodified poly(ethylene imine), the amphiphilic derivatives are not washed out by water.

Heck reactions have been studied with amphiphilic polyglycerol-stabilized colloids. Reaction conditions were studied extensively with respect to appropriate combinations of colloid stabilisation, solvent, substrates, base and temperature. Pivaloyl-modified polyglycerols were found to stabilize palladium colloids in dimethylacetamide effectively. With 4-bromoacetophenone and butylacrylate as substrates, potassium carbonate was found to be particularly suited as a base. The reaction solutions were filtered and the filtrates were found to contain small amounts of

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

palladium, as determined by ICP-AAS, and to be very active upon reuse for a further Heck reaction. This points towards smaller species than the original metal nanoparticles as the active species.

5) Continuous Homogeneous Catalysis in Supercritical Fluids

As an example of a continuous-flow approach to the separation of homogeneous catalysts, the use of supercritical fluids should be mentioned.[40] As a clear advantage, the catalyst always stays in its active state inside the reactor. Additionally, high throughputs can be obtained from relatively small-sized reactors. Webb and Cole-Hamilton have reported on the rhodium-catalysed hydroformylation of long-chain alkenes.[41] This process can be carried out as a continuous process using a supercritical fluid–ionic liquid biphasic system. The authors observed reaction rates that were comparable to those obtained in the commercially performed rhodium-catalysed hydroformylation of propene. Furthermore, very low rhodium leaching (0.012 ppm in the recovered product) was observed. The catalyst was formed in situ from [3-methyl-1-propylimidazolium][$Ph_2PC_6H_4SO_3$] and [$Rh(acac)(CO)_2$] in [3-methyl-1-octylimidazolium][bis-trifluoromethylsulfonyl amide], and supercritical CO_2 was used as the transport vector. The linear-to-branched ratio of the products could be improved from 3:1 to 40:1 by using a ligand based on the Xantphos backbone.[42] The major drawback of the system is that the overall pressure must be very high (200 bar) in order to extract the aldehyde from the ionic liquid in which it is soluble. However, the pressure can be reduced to 125 bar by omitting the ionic liquid and operating in such a way that the reaction product(s) is the solvent.[41b]

6) Continuous Homogeneous Catalysis Applying Zeolite Membranes

Molecular-weight enlargement of a homogeneous catalyst is not the only way to achieve a significant difference in molecular size of the catalyst, the reactants and products. Zeolite membranes, for example, have been developed by Turlan et al., with pore sizes in the 0.3 to 0.8 nm range.[43] For this work, silicalite was chosen with pores of 0.55 nm, well below the size of the homogeneous catalyst, but still able to permeate certain solvents and products.

The membranes were grown on the inner side of porous stainless-steel tubular supports.[44] Only separation experiments were carried out with model mixtures containing a Pd complex plus solvent and a possible reaction product. The reaction studied was the Heck reaction of 4-bromobenzonitrile with methyl acrylate. The chosen catalyst was [$Pd(\mu\text{-}Cl)(PPh_3)_2]_2(BF_4)_2$. This is a well-known Heck catalyst with a molecular diameter of 1.22 nm, which is considerably larger than the zeolite pores. The permeation rates were extremely low when DMA was used as a solvent, which suggests strong adsorption of the DMA in the zeolite pores, thus preventing permeation of catalyst and product. With the use of dichloromethane as solvent, complete catalyst retention was observed. Also, the permeation fluxes across the membrane were high. This shows the possibility to retain homogeneous catalysts of the right size behind very good membranes, without the need to molecularly enlarge their size. However, in order to truly evaluate these membranes, they have to be used in real continuous catalytic reactions and not to separate approximated reaction mixtures.

Conclusions

There is definitely not only one option for continuous homogeneous catalysis. Although many approaches exist to immobilize homogeneous catalysts, appropriate polymeric supports are not as readily available commercially. Furthermore, multi-step synthetic procedures are typically necessary to prepare the required ligand and the corresponding catalyst. Catalyst degradation and ligand oxidation have to be taken into account, especially when continuous processes are applied. Dendrimers have the advantage of high reproducibility and can be combined with a large variety of ligands and metals, which makes their catalytic scope very versatile. Also, they can be prepared with a very rigid backbone. In combination with a suitable filtration unit their retentions can be sufficiently high to be used in a broad range of utilisations. Similar to soluble polymeric supports, however, catalyst stability and their multistep synthesis is a major drawback and makes them relatively expensive and therefore less suitable for industrial applications. This also holds for the use of dendrimers as stabilizing agents for colloids.

Metal nanoparticles stabilized by polymers of different sizes and shapes can be more easily synthesised than dendrimers. They have proven their usefulness in hydrogenations and several types of C–C coupling reactions. The retentions are close to the desired amount for industrial purposes, so their future looks promising.

In general, both polymeric and ceramic membranes are used in these continuous processes and high retentions can be achieved with both options. The drawback of polymeric membranes is their solvent-sensitivity and their limited temperature resistance. Ceramic membranes can tolerate a wide range of solvents and higher temperatures, and the zeolite membranes are of special interest. Their very small pore diameters makes it possible to directly use some types of homogeneous catalyst without molecular-weight enlargement. Of course, such a small diameter also limits the possibilities for solvents and products, since they have to be able to penetrate the membrane.

The design of new membranes and reactors that are compatible with homogeneous reaction conditions is required to develop the fascinating area of continuous homogeneous catalysis to its full potential.

Reaction of [$Cp^xFe(\eta^5\text{-}P_5)$] {$Cp^x = \eta^5\text{-}C_5Me_5$ (**1a**), $\eta^5\text{-}C_5Me_4Et$ (**1b**)} with CuBr leads to the fullerene-like nanoballs [{$Cp^xFe(\eta^5{:}\eta^1{:}\eta^1{:}\eta^1{:}\eta^1\text{-}P_5)$}$_{12}${CuBr}$_{10}${$Cu_2Br_3$}$_5${Cu($CH_3CN$)$_2$}$_5$] {$Cp^x = \eta^5\text{-}C_5Me_5$ (**5a**), $\eta^5\text{-}C_5Me_4Et$ (**5b**)} comprising a cluster core of 90 non-carbon atoms. In contrast to previous results by variation of stoichiometry and concentration conditions, the formation of polymeric product was hindered, and exclusive formation of the spherical cage compound was achieved. The cluster **5b** possesses an inside diameter of 1.29 nm and an outside diameter of 2.37 nm. Definitive evidence for encapsulation of a [$Cp^xFe(\eta^5\text{-}P_5)$] unit (**1b**) within the inner cavity of the nanocluster **5b** is shown by X-ray crystallographic results.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Large spherical molecules and clusters are a fascinating field in contemporary chemistry. Established areas like the borane cages have recently been augmented by the discovery of low-valent aluminium and gallium metalloid clusters,[1] and within the growing area of giant clusters the chalcogeno-bridged copper and silver clusters[2] as well as the giant polyoxomolybdates establishing wheels and balls[3] are of the largest structurally characterised clusters so far. Among others an inorganic "superfullerene" $[Mo_{132}O_{372}(CH_3CO_2)_{30}(H_2O)_{72}]^{42-}$ has been reported reflecting a pentagonal-shaped symmetry.[4,5] Fullerene-like molecules based on carbon-free elements exist so far only in the solid state Zintl phases $Na_{172}In_{197}M_2$ (M = Ni, Pd, or Pt) with a C_{60}-like polyhedron of $In_{48}Na_{12}$ moieties, whereas an In_{74} fullerene-like unit with D_{3h} symmetry was found within $Na_{96}In_{97}M_2$.[6,7]

Within our efforts to study the coordination chemistry of naked P_n ligand complexes to form well-oriented supramolecular assemblies as well as one-dimensional (1D) and two-dimensional (2D) polymers, we used pentaphosphaferrocene **1a** as a starting material. Thus, the reaction of **1a** with Cu^I bromide and iodide led to the quantitative formation of 2D polymeric frameworks of **2a**,**b**.[8] However, when CuCl was used, the reaction yielded **3** as a linear 1D polymer in a maximum of about 50% yield.[8] As the soluble product of the latter reaction complex **4** was formed revealing a spherical fullerene-like molecule containing 90 non-carbon core atoms.[9] In continuation of these investigations the question arises whether it would be possible selectively to obtain such soluble nano-scaled spherical aggregates for the other Cu^I halides. We have now found that depending on the stoichiometry of the starting materials and the concentration conditions it is possible to obtain exclusively soluble spherical molecules of the formula [{$Cp^xFe(\eta^5{:}\eta^1{:}\eta^1{:}\eta^1{:}\eta^1\text{-}P_5)$}$_{12}${CuBr}$_{10}${$Cu_2Br_3$}$_5${Cu($CH_3CN$)$_2$}$_5$] {$Cp^x = \eta^5\text{-}C_5Me_5$ (**5a**), $\eta^5\text{-}C_5Me_4Et$ (**5b**)} by the reaction of **1a,b** with CuBr. This fullerene-like molecule possesses 90 non-carbon atoms. Furthermore, for the first time we have structural evidence of the existence of encapsulated molecules of **1b** in the ball of **5b**, results we are reporting herein.[10]

[$Cp^xFe(\eta^5\text{-}P_5)$] {$Cp^x = \eta^5\text{-}C_5Me_5$ (**1a**), $\eta^5\text{-}C_5Me_4Et$ (**1b**)} [$CuX\{Cp^*Fe(\eta^5{:}\eta^1{:}\eta^1\text{-}P_5)\}]_\infty$ (**2a**: X = Br, **2b**: X = I) [$CuCl\{Cp^*Fe(\eta^5{:}\eta^1\text{-}P_5)\}]_\infty$ (**3**)

$[\{Cp^*Fe(\eta^5{:}\eta^1{:}\eta^1{:}\eta^1{:}\eta^1\text{-}P_5)\}_{12}\{CuCl\}_{10}\{Cu_2Cl_3\}_5\{Cu(CH_3CN)_2\}_5]$ (**4**)

Results and Discussion

Complexes **5a,b** were obtained by the reaction of **1a,b** with CuBr in mixed solvents of CH_3CN and CH_2Cl_2 at ambient temperature. In comparison with the reactions leading to the 2D polymers **2a**,[8] the increase of the dilution (15 mmol/L to 7.5 mmol/L)[11] leads to the formation of the soluble products. However the polymer **2a** is still formed in yields up to 50%. With a more dilute solution (3.75 mmol/L) coupled with a stoichiometry of 2:1 CuBr/**1a**, as required for the composition of the spherical molecules of **5**, the formation of polymer was essentially negligible. Using the 2:1 stoichiometry without diluting the reaction mixture from 15 mmolar still resulted in formation of significant quantities of the polymer **2a**. Thus, the decisive criteria for the exclusive (polymer-free) formation of **5** are both the correct stoichiometry of 2:1 and a larger dilution of the reaction components ($\leq$ 3.75 mmol/L).

The black crystals of **5a**,**b** are stable under nitrogen and soluble in mixtures of CH_2Cl_2/CH_3CN. They exhibit broad ^{31}P NMR chemical shifts at about 66 and 68 ppm, respectively.

5b has been characterised by X-ray diffraction analysis.[12] The unit cell contains two crystallographically independent molecules of **5b** both lying on the mirror plane of the space group *Cm*. The molecular structure of **5b** is similar to the chlorine analog **4** (Figure 1).[9] All P atoms of the *cyclo*-P_5 ring of $[Cp^xFe(\eta^5\text{-}P_5)]$ coordinate to the copper atoms of CuBr, which are further coordinated by P atoms of other *cyclo*-P_5 rings, leading to the formation of six-membered P_4Cu_2 rings around the central *cyclo*-P_5 ring (Figure 1, a). The five- and six-membered ring alternation is similar to that seen in the fullerenes, with the difference that due to the distorted tetrahedral coordination sphere of the Cu^I ions, the six-membered rings are not planar and folded along the Cu···Cu axis (folding angle between 132.7 and 141.9°). The thus formed pseudo-hemispherical $[Cu_{10}Br_{10}\{Cp^xFe(\eta^5\text{-}P_5)\}_6]$ half-shells (Figure 1, a) are joined by five $[Cu_2Br_3]^-$ as well as by five $[Cu(CH_3CN)_2]^+$ units (Figure 1, b). Thus, ideal symmetry of the $[Cu_{25}Br_{25}(FeP_5)_{12}]$ core, consisting of 90 non-carbon atoms, is D_{5h} but the presence of ethyl groups at the cyclopentadienyl ligands reduces symmetry of the whole molecule to C_s or even C_1. All copper atoms have a tetrahedral P_3Br, P_2Br_2 or P_2N_2 environment. The Cu–Br bond lengths are 2.328(3)–2.379(3) Å (av. 2.351 Å) and 2.446(3)–2.472(4) Å (av. 2.462 Å) for terminal and bridging Br atoms, respectively. All *cyclo*-P_5 rings are nearly planar. The P–P distances, varying from 2.075(8) to 2.130(5) Å (av. 2.102 Å), are in good agreement with 2.088(3)–2.108(3) Å (av. 2.096 Å) found for the starting material **1b**.[13] The Cu–P bonds vary from 2.284(4) to 2.324(7) Å (av. 2.304 Å). This is also in good agreement with the values found in **4**

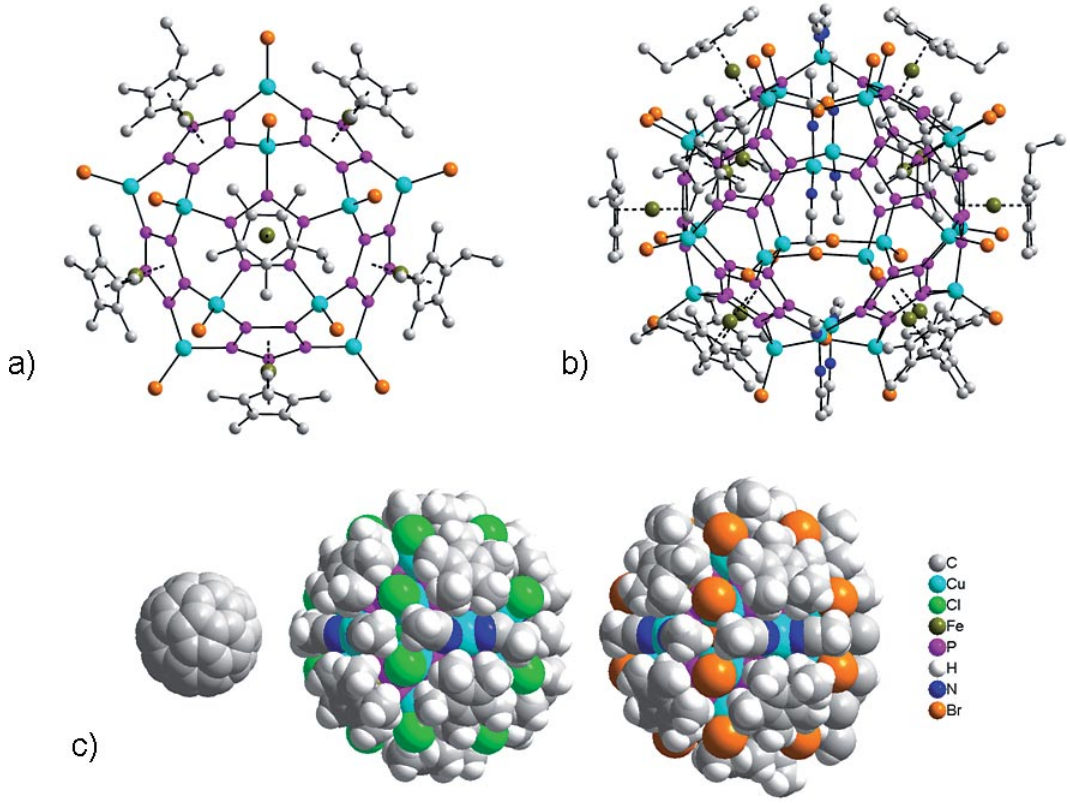

Figure 1. a) View of a half shell of a molecule of **5b**; b) Complete ball-and-stick structure of a molecule of **5b**; c) Size comparison of the spherical molecules of C_{60}, **4** and **5b** (space-filing model).

[2.294(6)–2.353(6) Å].[9] Due to the longer Cu–Br–Cu bridges [compare **4**: 2.294(6)–2.353(6) Å], which link the two half shells together, and the presence of Et groups at the Cp^x ligands the spherical body of **5b** is in comparison with **4** slightly larger and more elongated. It possesses an inside diameter of 12.9 Å (**4**: 12.2 Å) and an outside diameter of 21.4/23.7 Å (**4**: 21.4 Å), which is about three times larger than that of C_{60} (Figure 1, c).[14] Whereas for **4** we had only weak experimental data for the existence of an encapsulated [Cp*Fe(η^5-P_5)] (**1a**) moiety in every second ball, in **5b** we have much better structural data for the existence of an encapsulated molecule **1b** in each ball of **5b**, which is disordered in two directions with no special preference to the five-membered rings of the half-shells.

The results have shown that both stochiometry and dilution conditions are decisive for the exclusive formation of non-carbon containing nanoballs. Thus, while heterofullerenes are known containing only a few boron, nitrogen[15] and phosphorus atoms,[16] the complexes **4** and **5** exhibit a complete heteroatom composition and therefore represent a novel class of fullerene-like molecules.

Experimental Section

General Remarks: All manipulations were carried out under an atmosphere of dinitrogen using standard Schlenk techniques. All solvents were dried using standard procedures and distilled freshly before use. [$Cp^xFe(\eta^5$-$P_5)$] {Cp^x = η^5-C_5Me_5 (**1a**), η^5-C_5Me_4Et (**1b**)}[13] were prepared according to the literature.

[{$Cp^xFe(\eta^5$:η^1:η^1:η^1:η^1-$P_5)$}$_{12}${CuBr}$_{10}${Cu_2Br_3}$_5${$Cu(CH_3CN)_2$}$_5$] {Cp^x = η^5-C_5Me_5 (5a), η^5-C_5Me_4Et (5b)}: A solution of CuBr (21.5 mg, 0.15 mmol) in 5 mL of CH_3CN and 5 mL of CH_2Cl_2 was layered onto a solution of [$Cp^xFe(\eta^5$-$P_5)$] (**1a**: 26 mg, 0.075 mmol; **1b**: 27 mg, 0.075 mmol) in 10 mL of CH_2Cl_2 at room temperature. After complete diffusion of the phases (about one week), the solution was decanted into a fresh Schlenk tube and layered with 20 mL of hexane. This mixture was kept for two further weeks and black crystals of **5** were formed. The mother liquor was decanted and the obtained black crystals were dried under high vacuum. **5a**: 10 mg, 20% (based on **1a**); **5b**: 8 mg, 15% (based on **1b**).

5a: $^{31}P\{^1H\}$ NMR (162 MHz, CD_2Cl_2, 300 K): δ = 66 ppm (br., $\omega_{1/2}$ = 1000 Hz).

5b: $^{31}P\{^1H\}$ NMR (162 MHz, CD_2Cl_2, 300 K): δ = 68 ppm (br., $\omega_{1/2}$ = 850 Hz).

[10] Several intensive attempts to obtain soluble products with CuI failed.

[11] Concentrations discussed here refer to the overall concentrations of complexes **1**, as calculated using the total volume obtained after layering with the CuBr solutions.

[12] Since the single crystals of **5a** unfortunately proved to be very weakly diffracting, only the unit cell could be roughly determined at T = 100 K as a monoclinic unit cell with: a = 23.22(6) Å, b = 23.21(6) Å, c = 31.67(5) Å, β = 91.32(10), V = 17138 (105) Å^3. Crystal structure analysis of a single crystal of **5b** was carried out at 100 K on a Bruker SMART Apex CCD diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The data were corrected for absorption using the SADABS program.[17a] The structure was solved by direct methods and refined by full-matrix least-squares methods using SHELX-97 program set.[17b]

{(Cp^xFeP_5)⊂[$Cu_{25}Br_{25}(Cp^xFeP_5)_{12}(CH_3CN)_{10}$]}·0.5$CH_3CN$·2$CH_2Cl_2$ (Cp^x = η^5-C_5Me_4Et): $C_{166}H_{256.5}Br_{25}Cl_4Cu_{25}Fe_{13}N_{10.5}P_{65}$, M = 8866.47, crystal dimensions 0.30 × 0.25 × 0.08 mm^3, monoclinic, space group *C*m (No. 8), a = 37.4766(14) Å, b = 23.8734(9) Å, c = 37.3372(14) Å, β = 98.313(1)°, T = 100(1) K, Z = 4, V = 33054(2) Å^3, D_c = 1.782 Mg/m^3, μ(Mo-K_α) = 5.524 mm^{-1}. 82792 data measured to $2\theta_{max}$ = 56.04°, 68911 unique (R_{int} = 0.0562). 2726 parameters, wR_2 = 0.2315, R_1 = 0.1141 (all data), R_1 = 0.0877 [51811 with $I > 2\sigma(I)$].

There are two crystallographically independent molecules of **5b** in the unit cell both lying on mirror plane of the *Cm* space group. When all atoms of main molecules were localized the electron density ($\Delta\rho$) map contained a few peaks inside both of the spheres. Accurate analysis led us to a conclusion that each sphere contains a [$Cp^xFe(\eta^5$-$P_5)$] molecule located almost in the center. Each molecule is disordered over two positions with an opposite orientation and relative shift by 2.23–2.29 Å. Two positions of Cp^x ligand are overlapped. The iron and phosphorus atoms of disordered molecules were localized directly from the $\Delta\rho$ map and refined anisotropically with variable site occupancy factors. Then the positions of disordered Cp^x ligands were fitted from an idealized model to the largest $\Delta\rho$-peaks and included into refinement with fixed coordinates and U_{iso} = 0.04 Å^2. The final $\Delta\rho$ map contained one CH_3CN and four CH_2Cl_2 solvent molecules outside the ball-like structure. There were also some peaks probably corresponding to severely disordered CH_2Cl_2 molecules but several attempts to include them into refinement failed. Finally the structure was refined in anisotropic approximation for all non-hydrogen atoms except for carbon atoms of disordered [$Cp^xFe(\eta^5$-$P_5)$]

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

molecules inside the balls and two CH_2Cl_2 solvent molecules. Hydrogen atoms were refined geometrically. Site occupancy factors of disordered [$Cp^xFe(\eta^5\text{-}P_5)$] molecules were set as 0.70/0.30 and 0.60/0.40.

Multifunctional Dithiocarbamates as Ligands Towards the Rational Synthesis of Polymetallic Arrays: An Example Based on a Piperizine-Derived Dithiocarbamate Ligand

James D. E. T. Wilton-Ely,*[a] Dina Solanki,[a] and Graeme Hogarth*[a]

Keywords: Dithiocarbamates / Piperazine / Multimetallic arrays / Ruthenium complexes / Coordination chemistry

The zwitterionic piperazine-derived dithiocarbamate complex $[(dppm)_2Ru(S_2CNC_4H_8NCS_2)]$ has been prepared and utilised in the synthesis of multimetallic arrays incorporating a wide range of transition metal centres.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Dithiocarbamates are extremely versatile ligands which form complexes with all the transition metals, leading to the stabilisation of a wide range of oxidation states.[1] Since their complexes are easily prepared and manipulated, a wide range of applications have been developed in areas as diverse as materials science, medicine and agriculture. Given this versatility, their well-defined architecture and the bountiful metal-centred electrochemistry shown by these complexes,[2] it is surprising that they have found little use in the burgeoning area of supramolecular chemistry. Recently, however, Beer and co-workers have started to address this issue, preparing a range of exciting new supramolecular architectures based on multifunctional dithiocarbamate ligands, many of which show interesting structural-redox properties.[3] It is clear from this work that dithiocarbamates have the potential to be utilised to a far greater extent than found currently in the areas of supramolecular chemistry and materials science. With this in mind we have focused our initial efforts on the development of multidentate dithiocarbamate ligands for the synthesis of multimetallic arrays. Such arrays could be one, two or three-dimensional in nature, the dimensionality being easily controlled as a function of the properties of both the metal and ligand. We envisage that these materials will show novel physical properties in their own right and will be explored as precursors to the synthesis of well-defined nanoparticulates in a manner developed extensively by O'Brien and co-workers.[4]

Results and Discussion

A simple strategy for the synthesis of multimetallic wires is outlined below (Scheme 1). It centres on the use of a molecule containing two secondary amine centres. Such species react with CS_2 to afford a zwitterionic product,[5,6] whereby one of the amines acts as a nucleophile and the second as a base. Under the right conditions, only small amounts of the symmetrical double salt $[S_2CN(X)NCS_2][H_2N(X)NH_2]$ (X = spacer) are formed, which is a key advantage of this approach as this allows one end of the amine to be extended selectively by reaction with carbon disulfide. Reaction of the zwitterionic product, $[H_2NC_4H_8NCS_2]$, with a metal complex results in the formation of a new metal-amine compound, which in turn can react with further CS_2 to generate a new metal-containing dithiocarbamate ligand. In this manner multimetallic arrays can be constructed in a modular, step-wise fashion (Scheme 1). This approach, which is demonstrated by the reactions shown in Scheme 2, can be extended using tri- and tetradentate amines to incorporate further dimensionality.

As a proof of concept, we have used cheap and commercially available piperazine in order to demonstrate the ease and potential of such an approach. We have used the ruthenium(II) complex *cis*-$[RuCl_2(dppm)_2]$[7] to provide a *cis*-$Ru(dppm)_2$ moiety as the initial metal fragment. This choice was based on our observation that *cis*-$[RuCl_2(dppm)_2]$ reacts cleanly with a wide range of dithiocarbamate salts to afford the cations $[Ru(S_2CNR_2)(dppm)_2]^+$ in high yield. These complexes are easily characterised by a range of spectroscopic techniques, of which ^{31}P NMR spectroscopy proves particularly useful.

Addition of CS_2 to piperazine in water results in the formation of the zwitterion, $H_2NC_4H_8NCS_2$ (**1**), which is readily isolated (Scheme 2). Addition of one equivalent of *cis*-$[RuCl_2(dppm)_2]$ to this zwitterion, followed by an excess of $NaBF_4$ affords $[(dppm)_2Ru(S_2CNC_4H_8NH_2)][BF_4]_2$ (**2**) in high yield,[8] which is then converted into the new complex, $[(dppm)_2Ru(S_2CNC_4H_8NCS_2)]$ (**3**), upon sequential addition of two equivalents of base and CS_2. The latter is a

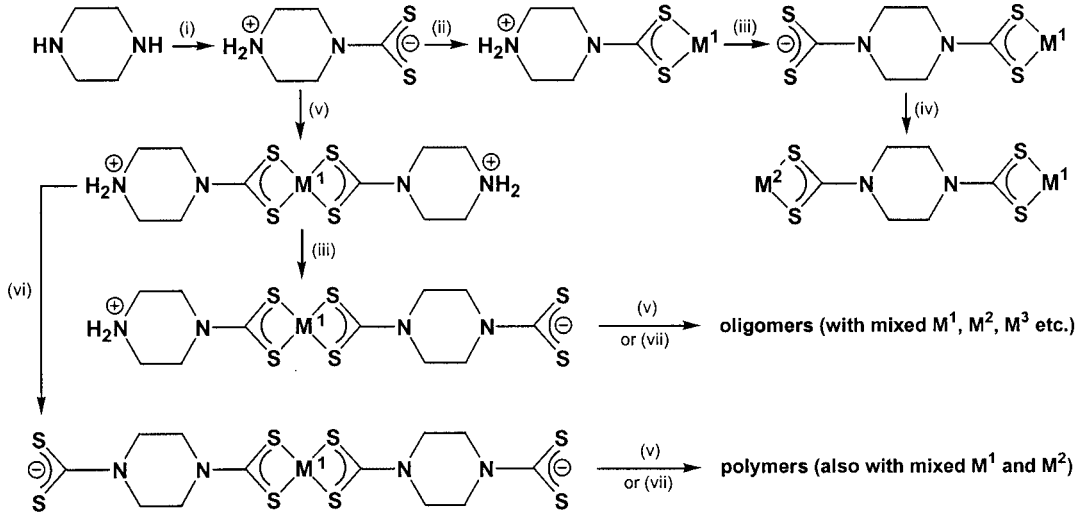
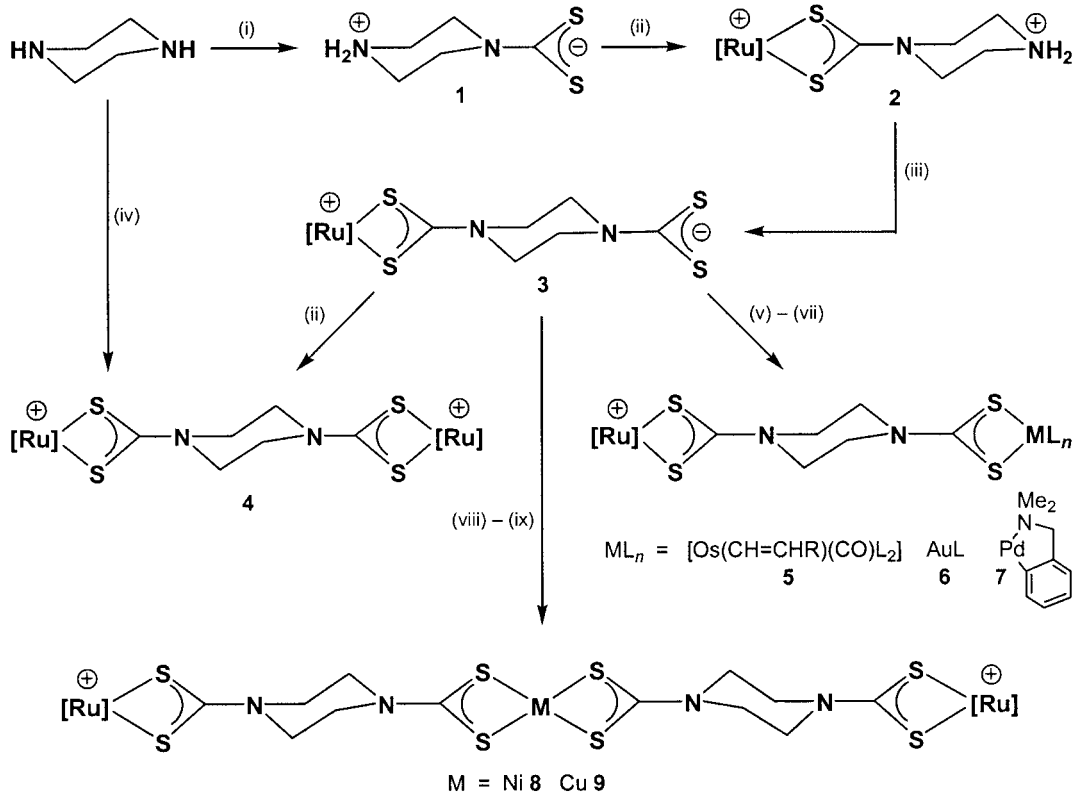


Scheme 1. (i) CS_2; (ii) M^1X; (iii) $2NEt_3$, CS_2; (iv) M^2X; (v) M^1X_2; (vi) $4NEt_3$, $2CS_2$; (vii) M^2X_2.



Scheme 2. [M] = $Ru(dppm)_2$;L = PPh_3; R = C_6H_4Me-4; (i) CS_2; (ii) *cis*-$[RuCl_2(dppm)_2]$, $2NaBF_4$; (iii) $2NEt_3$, CS_2; (iv) $2NEt_3$, $2CS_2$; 2*cis*-$[RuCl_2(dppm)_2]$; (v) $[Os(CH{=}CHR)Cl(CO)(BTD)L_2]$ (BTD = 2,1,3-benzothiadiazole); (vi) ClAuL; (vii) $[Pd(C_6H_4CH_2NMe_2)Cl]_2$; (viii) $Ni(OAc)_2$; (ix) $Cu(OAc)_2$.

key building block and can be considered to be a metallodithiocarbamate. In order to demonstrate its utility we treated this compound with a second equivalent of *cis*-$[RuCl_2(dppm)_2]$ to afford (after salt metathesis) the binuclear complex $[(dppm)_2Ru(S_2CNC_4H_8NCS_2)Ru(dppm)_2][BF_4]_2$ (**4**).[9] The same complex is also produced in a one-step reaction upon addition of $Na_2[S_2CNC_4H_8NCS_2]$ to two equivalents of *cis*-$[RuCl_2(dppm)_2]$ followed by salt metathesis. In order to confirm the bridging nature of the dithiocarbamate, a crystallographic study of **4** was performed (Figure 1).[10] The bridging dithiocarbamate mode found in **4** is rare but not unique; Shaver and co-workers having recently prepared a related diruthenium complex, $[Cp(PPh_3)Ru(S_2CNC_6H_4NCS_2)Ru(PPh_3)Cp]$, from the unusual reaction of two equivalents of $[CpRu(PPh_3)_2SH]$ with *para*-phenylenediisothiocyanate.[11] A dinuclear tin complex has

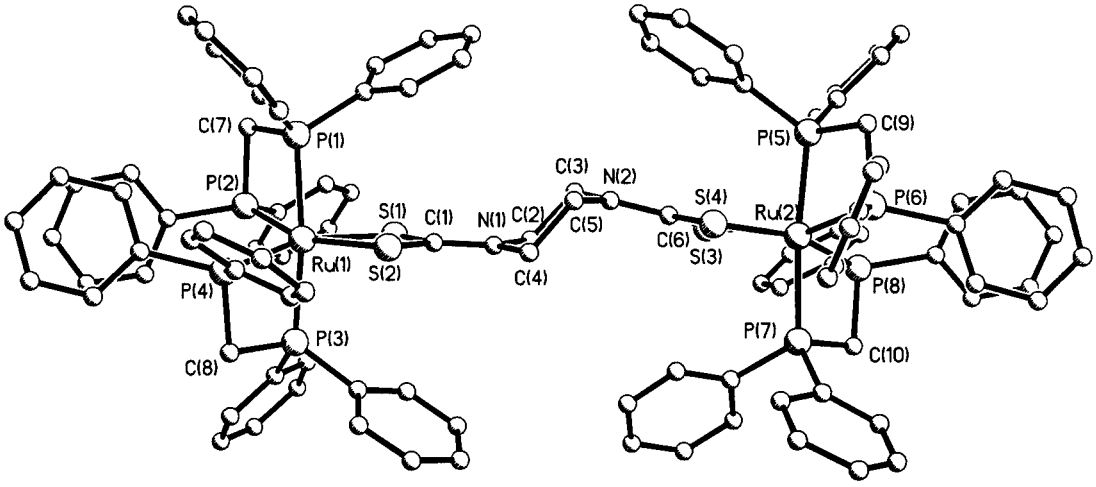


Figure 1. Structure of the cation in $[\{Ru(dppm)_2\}_2(S_2CNC_4H_8NCS_2)][BF_4]_2$ (**4**).

also been reported.[6a] Zwitterion **3** can be employed to prepare a wide range of dithiocarbamate-bridged binuclear metal complexes as we have illustrated with the formation of **5**–**7**,[9] in which osmium,[8] gold and palladium centres, respectively, are coordinated using suitable reagents.

In each of the cases described above, the added metal centre binds only a single dithiocarbamate ligand. Trimetallic units based on two bidentate dithiocarbamate ligands result from the addition of metals with two dithiocarbamate-binding sites. In order to illustrate this, we treated **3** with nickel and copper acetate to quantitatively afford $[\{(dppm)_2Ru(S_2CNC_4H_8NCS_2)\}_2M][BF_4]_2$ [M = Ni (**8**), Cu (**9**)] (Scheme 2).[9] These examples illustrate the ease of incorporation of diamagnetic and paramagnetic centres which show well-defined and understood redox properties into these arrays. We have extended this strategy to the formation of tetranuclear complexes upon coordination of zwitterion **3** to Fe^{III}, Co^{III} and La^{III} centres and are currently using methyl-substituted piperazines to prepare chiral materials. We have also begun work using 1,4,7-triazacyclononane and 1,4,8,11-tetraazacyclotetradecane (cyclam) as a building block to prepare multidentate dithiocarbamate ligands with the aim of preparing magnetic 2D sheet-like structures with large cavities.

Conclusions

The piperazine-based dithiocarbamate complexes reported here demonstrate how the construction of multimetallic arrays can be achieved in a controlled, stepwise manner. This approach has great potential for the fabrication of materials incorporating a wide range of metal centres whose properties (e. g., redox, CVD, host-guest chemistry) can be tailored.

Shape-Induced Enhanced Luminescent Properties of Red Phosphors: $Sr_2MgSi_2O_7:Eu^{3+}$ Nanotubes

Junxi Wan,[a] Zhenghua Wang,[a] Xiangying Chen,[a] Li Mu,[a] and Yitai Qian*[a]

Keywords: Nanotubes / Silicates / Hydrothermal synthesis / Photoluminescence

$Sr_2MgSi_2O_7:Eu^{3+}$ nanotubes with red phosphor luminescent properties were successfully synthesized via a low-temperature hydrothermal route in order to understand the underlying relationship between shape and luminescent properties. The one-dimensional shape results in an obvious improvement of color purity. From emission spectra, the relative intensity of $^5D_0\rightarrow{}^7F_2$ to $^5D_0\rightarrow{}^7F_1$ transitions in tubular phosphors is higher than that of bulk material. The better color purity results from the more distorted lattices and relatively lower crystal symmetry around Eu^{3+} ions, which ascribes to the large surface area due to synthesize it in the form of nanotubes. Furthermore, the as-synthesized tubular red phosphor has shorter fluorescent lifetime and blue-shift phenomenon in excitation spectra than that of the bulk counterpart. Based on these results, shape-induced luminescent properties improvement is proposed as an efficient way to obtain red phosphors with high color purity.

Introduction

Since decades, phosphors doped with rare earth ions have attracted great interest.[1–4] Among those rare earth ions, the Eu^{3+} ion as a red luminescent activator in many host materials[5–10] has been studied intensively. Major emissions are centered at 590 nm ($^5D_0\rightarrow{}^7F_1$) and 616 nm ($^5D_0\rightarrow{}^7F_2$), corresponding well to orange and red color, respectively. So, the relative intensities of $^5D_0\rightarrow{}^7F_2$ to $^5D_0\rightarrow{}^7F_1$ transitions in phosphors are important for their applications. In order to obtain red phosphors with high color purity, it is necessary to increase the relative intensity of $^5D_0\rightarrow{}^7F_2$ to $^5D_0\rightarrow{}^7F_1$ transitions. It is well known that the relative intensities of the $^5D_0\rightarrow{}^7F_2$ to $^5D_0\rightarrow{}^7F_1$ transitions strongly depend on the local symmetry of Eu^{3+} ions.[11–13] The peak at 616 nm is due to the forced electric dipole transition ($^5D_0\rightarrow{}^7F_2$), which is allowed on condition that the europium ion occupies a site without an inverse center. Its intensity is hypersensitive to crystal environments. A relatively strong $^5D_0\rightarrow{}^7F_2$ transition is associated with a relatively low local symmetry of Eu^{3+} ions. The better color purity might result from the more distorted lattices and relatively lower crystal symmetry. Consequently, a change of the crystal structure of host materials can produce a good red phosphor.[14] However, shape and size are now regarded as particularly important factors influencing the chemical and physical properties of the materials.[11–13,15–21] If materials were fabricated in the form of a one-dimensional nanostructure, they would be expected to be highly functionalized materials as a result of both shape-specific and quantum confinement effects, acting as optically functional host materials. Based on this viewpoint, a possible way to improve the performance of current phosphors is to synthesize them in the form of 1D nanostructures. Nanotubes possess especially large surface area and high surface energy owing to their inner and outer surfaces, which could lead to a high degree of disorder and correspondent lower symmetry of crystal field around Eu^{3+} ions.[16,17] This lower symmetry of the crystal field will result in a higher relative intensity of $^5D_0\rightarrow{}^7F_2$ to $^5D_0\rightarrow{}^7F_1$ transitions. Therefore, it is favorable to get red phosphors with high color purity while the host materials are fabricated in the form of nanotubes. Only few efforts have been made to test and apply this idea and to develop new red phosphors.

We have synthesized a tubular Eu^{3+}-doped $Sr_2MgSi_2O_7$ red phosphor via a hydrothermal route. The as-synthesized phosphor has better color purity, which illustrates the validity and practicability of the idea that shape influences the improvement of luminescent properties. To our best knowledge, this is the first report about hydrothermal synthesis of Eu^{3+}-doped $Sr_2MgSi_2O_7$ nanotubes.

Results and Discussion

The phase purity and phase structure of as-prepared samples were characterized by the X-ray powder diffraction (XRD) patterns, using a Philips X′pert X-ray diffractometer equipped with graphite-monochromatized Cu-

Kα radiation (λ = 1.54178 Å). Samples for XRD analysis were prepared by dispersing the as-synthesized phosphors into absolute ethanol, then spreading several drops of this suspension on a clear silicon wafer, and then letting the solvent evaporate slowly at room temperature. The transmission electron microscopy (TEM) images and corresponding selected area electron diffraction (SAED) pattern were performed with a Hitachi H-800 transmission electron microscope using an accelerating voltage of 200 kV. Photoluminescence (PL) spectra and luminescent decay curve were recorded on a Fluorolog-3-TAU fluorescence spectrophotometer with an Hg lamp at room temperature.

Figure 1 shows the XRD patterns of as-synthesized Eu^{3+}-doped $Sr_2MgSi_2O_7$ red phosphors. All the diffraction peaks can readily be indexed to a pure tetragonal structured $Sr_2MgSi_2O_7$ with cell constants of a = 7.993 Å, and c = 5.158 Å, which are in good agreement with the values in the literate (JCPDS card No. 75–1736, a = 7.996 Å, and c = 5.152 Å). No obvious impurity phase can be detected. Compared to the XRD patterns of bulk phosphor (Figure 1, a) and as-synthesized sample (Figure 1, b), the intensity of the XRD peaks from as-synthesized sample is weaker than that of the bulk phosphor. Some weak peaks in Figure 1 (b) are nearly invisible. The intensification of peaks from bulk phosphor would result in improved luminescent intensity due to the increase of crystallinity. Table 1 shows representative comparisons of half-width and relative intensities of the XRD peaks from bulk and as-prepared sample. In Table 1, only the eight strongest peaks of both XRD patterns are listed. The differences of the eight strongest peaks of both XRD patterns are sufficient to demonstrate the fine-structural differences in the bulk and as-prepared phosphors. The differences of relative intensities of the XRD peaks indicate that the as-synthesized sample has a tendency to grow only in one direction. The increase of half-width of XRD peaks from as-prepared sample indicates the nanometer-scale sizes of sample. These differences in XRD peaks would lead to enhanced luminescent properties of phosphors. These results are further evidenced by the following TEM images and luminescent spectra.

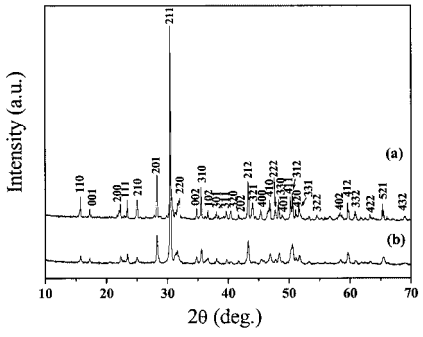

Figure 1. XRD patterns of the as-synthesized (a) bulk $Sr_2MgSi_2O_7$:Eu^{3+} and (b) $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes.

TEM analysis has provided further insight into the microstructural details of these nanotubes. As shown in Figure 2, all samples dispersed on to the TEM copper grids have uniform nanotube morphologies with open ends. The as-synthesized nanotubes have diameters of about 15 nm and lengths up to several hundreds of nanometer. Figure 2 (b) shows two $Sr_2MgSi_2O_7$ nanotubes (the white arrows shown) parallel to the electron beam, from which the hollow structure features can be clearly seen with an inner diameter of about 10 nm and an outer diameter of about 20 nm. The electron diffraction patterns (inset in Figure 2, b), taken from bundles of $Sr_2MgSi_2O_7$ nanotubes, indicate that the nanotubes are crystalline. This result is in agreement with that of XRD pattern.

Table 1. Comparisons of eight strongest peaks in XRD patterns from bulk $Sr_2MgSi_2O_7$:Eu^{3+} and $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes, respectively.

Indexing peaks	Bulk $Sr_2MgSi_2O_7$:Eu^{3+}		$Sr_2MgSi_2O_7$:Eu^{3+} nanotubes

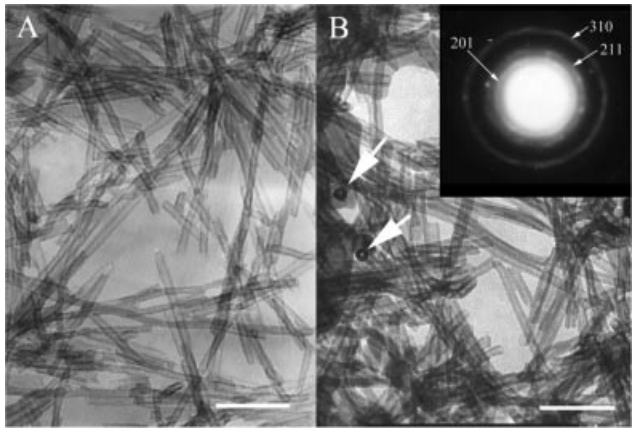

Figure 2. Representative TEM images and SAED pattern of synthesized samples; length of bar: 100 nm.

The excitation spectra of Eu^{3+}-doped $Sr_2MgSi_2O_7$ nanotubes and bulk phosphor for the emission at 616 nm are shown in Figure 3. The broad band on the excitation spectra is excitation from the ground state of the 4f shell to an Eu–O charge transfer state.[22] Moreover, the CTS (charge transfer state absorption) peak position of $Sr_2MgSi_2O_7$ nanotubes shows a blue-shift phenomenon compared with the bulk counterpart. The CTS peaks of the nanotubes and bulk phosphor center at 250 nm and 261 nm, respectively. A similar observation was reported in nanometer Y_2O_3:Eu phosphor.[19] The sharp absorption peaks on excitation

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

spectra is a characteristic of rare earth ions as a result of transitions within the 4f shell, which is shielded from environmental effects by the outer shell electrons.[23] Thus, these peaks position are consistent.

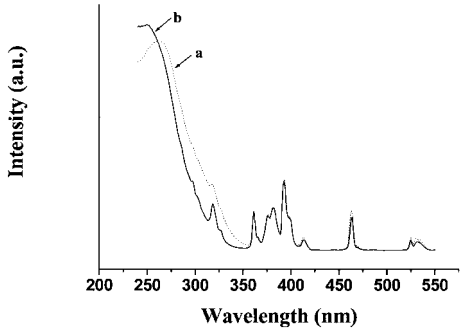

Figure 3. Excitation spectra of (a) bulk $Sr_2MgSi_2O_7$:Eu^{3+} phosphor, (b) $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes.

Figure 4 shows the emission spectra of as-synthesized Eu^{3+}-doped $Sr_2MgSi_2O_7$ nanotubes and bulk phosphor. Both of them consist of two main peaks centered at 590 nm and 616 nm, which come from the transitions of $^5D_0 \rightarrow {}^7F_1$ and $^5D_0 \rightarrow {}^7F_2$, respectively. The most intense emission is the $^5D_0 \rightarrow {}^7F_2$ transition located in 616 nm, corresponding to the red emission, in good accordance with the Judd–Ofelt theory.[24] Compared with the bulk phosphor, the luminescent properties of as-synthesized $Sr_2MgSi_2O_7$ nanotubes are obviously enhanced. The emission intensity of the $^5D_0 \rightarrow {}^7F_2$ transition is 3.2 times that of the $^5D_0 \rightarrow {}^7F_1$ transition. However, the ratio only is 1.7 for bulk phosphor. Only the emission peak located at 616 nm of $Sr_2MgSi_2O_7$ nanotubes has a remarkable enhancement than that of bulk phosphor. This phenomenon indicates that more Eu^{3+} occupy sites with relatively low local symmetry. These results prove the idea that red phosphors with high color purity can be obtained by changing the shape of host materials.

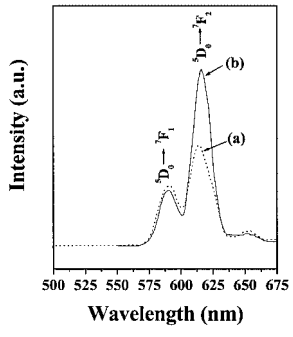

Figure 4. Emission spectra of (a) bulk $Sr_2MgSi_2O_7$:Eu^{3+} phosphor, (b) $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes.

The decay time of Eu^{3+} fluorescence of Eu^{3+}-doped $Sr_2MgSi_2O_7$ nanotubes and bulk phosphor were measured at room temperature. Figure 5 shows the results that the lifetime values are 1.2 ms of $Sr_2MgSi_2O_7$ nanotubes and 2.3 ms of bulk phosphor, respectively. Similar phenomena was observed in nanometer ZnS:Mn^{2+}[25] and Y_2O_3:Eu^{3+} phosphors.[26] The shorter lifetime value can be attributed to the fact that the $Sr_2MgSi_2O_7$ nanotubes have relatively more defects, which results from the increase of the surface/volume ratio in the nanotubes. The shorter decay time is beneficial to PDP (plasma display panel) applications. With further optimization, Eu^{3+}-doped $Sr_2ZnSi_2O_7$ may serve as good red phosphor candidates. Further research is underway.

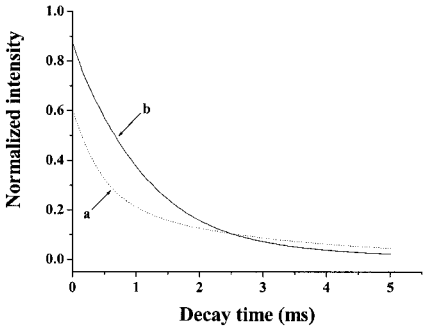

Figure 5. Normalized decay curve of (a) bulk $Sr_2MgSi_2O_7$:Eu^{3+} phosphor, (b) $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes.

Conclusions

In summary, we have successfully synthesized pure tetragonal phased $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes via a low-temperature hydrothermal route at 200 °C for 2 days. The resulting tubular red phosphor has a shorter decay time than that of the bulk counterpart. A close study of the excitation spectra points to a blue-shift phenomenon for the $Sr_2MgSi_2O_7$:Eu^{3+} nanotubes. The emission spectra show that the as-prepared tubular red phosphor has a better color purity than the bulk counterpart. The improvement of luminescent properties was analyzed and the influence of shape on luminescence was explored. Based on these results, shape-induced luminescent properties improvement is a simple and efficient way to obtain red phosphors with high color purity. This idea provides helpful guidance for the application of the $Sr_2MgSi_2O_7$:Eu^{3+} red phosphor. Furthermore, this strategy may also be applied to other rare earth ion-doped phosphors.

Experimental Section

All reagents were purchased from Shanghai Chemical Reagent Co. and used without further purification. Distilled water and absolute ethanol, degassed with N_2 for one hour, were used. In a typical procedure, 2 mmol of $Sr(NO_3)_2$, 1 mmol of $Mg(NO_3)_2 \cdot 6H_2O$, and 0.1 mmol of $EuCl_3$ were dissolved in a mixture of 5 mL of distilled water and 30 mL of absolute ethanol whilst stirring in a Teflon liner of 60 mL capacity. Then an aqueous solution of 2 mmol of $Na_2SiO_3 \cdot 9H_2O$ dissolved in 5 mL of distilled water was slowly added. After about 10 minutes, the aqueous solution of 1 g of NaOH dissolved in 5 mL of distilled water and 2 mL of 85% $N_2H_4 \cdot H_2O$ were added whilst stirring. Hydrazine hydrate was used to prevent reduction of Eu^{3+}. Finally, the mixture was degassed with N_2 for another one hour. Then, the liner was sealed in a stainless steel autoclave, first aged at 90 °C for 12 h, and then maintained at 220 °C for 2 days. After cooled to room temperature naturally,

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the resulting white solid products were filtered off, washed with distilled water and absolute ethanol for several times, respectively, and finally calcined in air at 800 °C for 6 h. For comparison, Eu^{3+}-doped $Sr_2MgSi_2O_7$ red phosphor was also prepared via solid-state reaction at 1300 °C for 3 h in air according to the literature.[27] The as-synthesized sample was finely ground to give a powder that was used for further characterization.

Electrochemical Deposition of $Ni(OH)_2$ and Fe-Doped $Ni(OH)_2$ Tubes

Shulei Chou,[a] Fangyi Cheng,[a] and Jun Chen*[a]

Keywords: Nickel hydroxide / Iron doping / Tubes / Electrochemical deposition / Template

Arrays of $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes were successfully prepared by electrochemical deposition in porous alumina membranes under ambient conditions. Extensive analysis of the tubes was carried out by X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM) and high-resolution transmission electron microscopy (HRTEM) equipped with energy dispersive spectroscopy (EDS), and X-ray photoelectron spectroscopy (XPS). The results show that the electrodeposition method yielded uniform $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes with inner diameters of 150–180 nm, wall thicknesses of 20–30 nm, and lengths of about 60 μm. This template-based electrochemical deposition method can be extended to the synthesis of other similar materials such as micro- or nanotubes, -wires, and -rods. Furthermore, the $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes may have promising applications in alkaline rechargeable batteries and electrocatalytic electrolysis for the production of hydrogen.

Introduction

A variety of 1D nanomaterials including nanotubes, nanorods, nanowires, and nanobelts have become a symbol of the new and fast-developing research area of nanoscience and nanotechnology.[1,2] As members of an important class of 1D nanomaterials, inorganic nanotubes[3–5] such as WS_2,[6] MoS_2,[7] BN,[8] Au,[9] Bi,[10] SiO_2,[11] VO_x,[12] and $NiCl_2$[13] have attracted much attention owing to their special properties. Substantial progress has been achieved in the synthesis of inorganic nanotubes by various methods. For example, the template synthesis,[14–16] in which a template membrane serves as a scaffold for other materials to be assembled with a morphology similar (or complementary) to that of the template pore, is a simple approach to the preparation of inorganic nanotubes such as Au,[9] Si,[17] MoS_2,[18] GaN,[19] and Bi_2O_3.[20]

Nickel hydroxide is the active material in the positive electrodes of alkaline rechargeable batteries such as nickel/cadmium (Ni/Cd), nickel/iron (Ni/Fe), nickel/metal hydride (Ni/MH), and nickel/zinc (Ni/Zn).[21] The capacities of these batteries are usually limited by the positive electrodes for reasons of proper recombination reactions and battery safety. It follows that increasing the energy density of the nickel hydroxide electrode is essential for raising the energy density of such batteries. To improve the characteristics of the nickel hydroxide electrode, much work has been focused on the development of spherical $Ni(OH)_2$ powder and related composite materials.[22–25] On one hand, spherical nickel hydroxide particles exhibit superior electrochemical behavior and higher proton diffusion coefficients.[26,27] On the other hand, the core of the spherical nickel hydroxide powder is still inactive at high-rate and high-temperature charge/discharge because of the diffusion barrier, which can be improved by using $Ni(OH)_2$ tubes.[28]

Electrolysis is an attractive process for hydrogen production from alkaline solutions when cheap solar power is available. A potentially more important application of Fe-doped $Ni(OH)_2$ tubes is their use as oxygen-evolving anodes for the electrolytic production of hydrogen. This is due to their low overpotential and stability in alkaline solution.[29] The tubelike Fe-doped $Ni(OH)_2$, which has a high specific surface area, could be very useful in hydrogen production in the future.

Electrochemical deposition, which is a convenient method to control the thickness of the deposited product, has already been used to prepare $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ thin films for a few years.[30–32] Four possible mechanisms of electrochemical deposition of $Ni(OH)_2$ from nickel nitrate solution have been proposed by MacArthur.[33] Furthermore, electrochemical deposition in Al_2O_3 templates has recently been used to prepare inorganic micro- or nanotubes of Au,[34] Co, Fe,[35] Ni,[36] Cu,[37] Pt,[38] CdS,[39] and TiO_2.[40] The process of electrochemical deposition of metal nanotubes under low-current-density conditions occurs by simultaneous deposition along the holes of the membranes.[41] However, to the best of our knowledge, the synthesis of metal hydroxide tubes or nanotubes by electrochemical deposition in templates is limited.

Here we report on the preparation of $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes by electrochemical deposition in the pores of alumina membranes. The results show that the wall

Tianjin 300071, P.R. China
E-mail: chenabc@nankai.edu.cn

thickness of the $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes is easily controlled by adjusting the reaction conditions. This method can be extended to the synthesis of other similar micro- or nanotubes, -wires, and -rods.

Results and Discussion

Figure 1 shows the XRD patterns of the α-$Ni(OH)_2$ (Figure 1a) and Fe-doped α-$Ni(OH)_2$ tubes (Figure 1b). The peaks in Figure 1a can be indexed as a hexagonal structure of α-$Ni(OH)_2$·$0.75H_2O$ with the lattice parameters a = 3.08 Å and c = 23.41 Å, which are in good agreement with the standard value (ICDD-JCPDS card 38–0715). The broadening of the peaks in the XRD pattern indicates that the product consists of nanocrystallites, in which amorphous particles may coexist. Figure 1b shows the XRD pattern of Fe-doped α-$Ni(OH)_2$ tubes. The 2θ value of each peak is in accordance with α-$Ni(OH)_2$·$0.75H_2O$ as shown in Figure 1a. However, the relative intensities of the peaks at 11.70° and 23.58° in Figure 1b are higher than those in Figure 1a. This might arise from the Fe-doping. That is, the incorporation of Fe in the Ni lattice sites of α-$Ni(OH)_2$ might have caused the intensity changes. Therefore, a further investigation by XPS was used to verify the existence and form of Fe present.

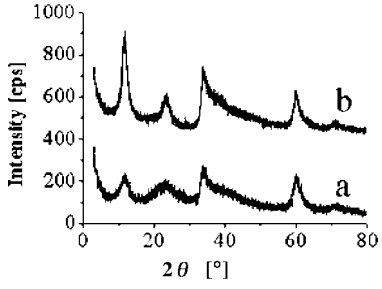

Figure 1. X-ray diffraction patterns of the α-$Ni(OH)_2$ tubes (a) and Fe-doped α-$Ni(OH)_2$ tubes (b).

Figure 2 shows the XPS spectra of the Fe-doped α-$Ni(OH)_2$ tubes. Figure 2a shows that the sample contains Fe, Ni and O. Figure 2b shows that a binding energy of 855.8 eV is assigned to Ni $2p_{3/2}$ in $Ni(OH)_2$. Figure 2c shows the Fe 2p spectrum of the tubes produced. The Fe-doped $Ni(OH)_2$ tubes contain only Fe^{III} because two binding energies of 725.3 eV and 711.1 eV were detected, which are assigned to Fe $2p_{1/2}$ and Fe $2p_{3/2}$ in Fe_2O_3, respectively.[42] Balasubramanian et al.[32] reported that cathodic codeposition of Fe^{II} with Ni^{II} led to the incorporation of Fe in the Ni lattice sites of α-$Ni(OH)_2$ and these Fe ions were present as Fe^{III}. Our XPS and XRD studies have confirmed this report and have shown that the Fe-doped $Ni(OH)_2$ tubes are Fe^{III}-doped α-$Ni(OH)_2$·$0.75H_2O$. The quantitative XPS study of Fe-doped $Ni(OH)_2$ tubes shows that the atomic ratio of Fe to Ni is 1:3.7. Since Corrigan's study shows that iron/nickel hydrous oxides with this atomic ratio are very useful in lowering the Tafel slope for catalyzing the oxygen evolution reaction,[29] we believe that the Fe^{III}-doped α-$Ni(OH)_2$·$0.75H_2O$ tubes have potential uses as electrocatalysts for alkaline electrolysis to produce hydrogen.

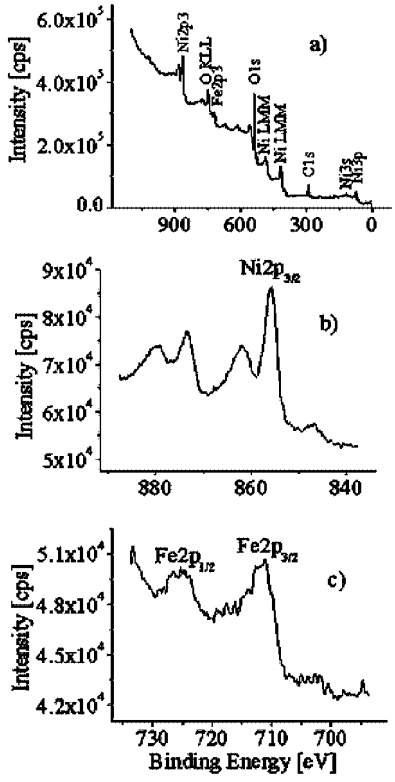

Figure 2. XPS spectra of Fe-doped $Ni(OH)_2$ tubes in the binding energy range of (a) 0–1100 eV, (b) 840–890 eV, and (c) 695–735 eV.

Figure 3 shows the SEM images of the $Ni(OH)_2$ (Figure 3a–c) and Fe-doped $Ni(OH)_2$ tubes (Figure 3d and e) at different magnifications. Figure 3a is an overall view of the $Ni(OH)_2$ tubes, which shows that bundles of standing or lying $Ni(OH)_2$ tubes were obtained. The length of the $Ni(OH)_2$ tube bundles is approximately 60 μm, which corresponds to the thickness of the template membrane employed in the synthetic process. In Figure 3a shorter and broken bundles can also be found, which may arise from the weakness of the tubes. Figure 3b shows that the $Ni(OH)_2$ tubes are arranged roughly parallel to one another with a smooth-surface alignment. This might be due to a remaining trace of the alumina matrix rather than any kind of self-organization. Figure 3c is the high-magnification SEM image of the bundle tips of the $Ni(OH)_2$ tubes which shows their open-ended character. The $Ni(OH)_2$ tubes are cylinders with a wall thickness of 20–30 nm. There is a distribution of diameters of the tubes around 200 nm because of the pore-diameter distribution of the template. Figure 3d and Figure 3e show the SEM images of Fe-doped $Ni(OH)_2$ tubes at different magnifications. Figure 3d shows a bundle of Fe-doped $Ni(OH)_2$ tubes, which is not as uniform as the $Ni(OH)_2$ tubes. Figure 3e, which is the enlargement of the square marked in Figure 3d, shows a clear view of the Fe-doped $Ni(OH)_2$ tubes with open-ended tips. It should be noted that when we removed Fe-doped $Ni(OH)_2$ tubes from the alumina membranes, almost all of them were broken.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Thus, the Fe-doped $Ni(OH)_2$ tubes are not as long as the $Ni(OH)_2$ tubes. This may be due to the Fe doping.

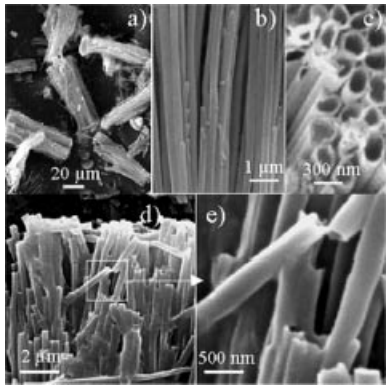

Figure 3. Typical SEM images of the $Ni(OH)_2$ (a, b, c) and Fe-doped $Ni(OH)_2$ tubes (d, e). $Ni(OH)_2$ tubes: (a) overall view, (b) walls of the tube bundles, and (c) tube bundle tips at high magnification. Fe-doped $Ni(OH)_2$ tubes: (d) low magnification and (e) enlargement of the square marked in (d).

To understand the structure in further detail, the $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes were inspected with TEM (Figure 4). Figure 4a shows the TEM image of the $Ni(OH)_2$ tubes at a lower magnification. In addition to the tubes there are some particles in the product. This phenomenon arises from the strong supersonic vibrations used in the sample preparation for TEM analysis, that is, some of the tubes were broken down into shorter ones and then into particles. Figure 4b shows a TEM image of an open-ended $Ni(OH)_2$ tube. The centers of the mesostructures are bright in contrast to their edges, confirming their hollow-tube nature. The inner diameters are about 150–160 nm, and the wall thickness is about 20–30 nm. Figure 4c shows the TEM image of the tube wall. It can be seen that the surface of the tube is smooth with an amorphous structure. This is consistent with the XRD analysis. Figure 4d shows that most of the Fe-doped $Ni(OH)_2$ tubes have similar wall thickness, and there is also an interesting branchlike structure which simply reflects the structure of alumina templates. That is, the template contains not only aligned pores but also some abnormal structures that look like branches. This phenomenon also means that, if we have the template, we can also prepare some complex tubular structures by this method. A view of the open-ended Fe-doped $Ni(OH)_2$ tubes is shown in Figure 4e, from which we can estimate that the tubes have an inner diameter of about 170–180 nm. EDS analysis in Figure 5 shows that the tubes in Figure 4e contain three elements, Fe, Ni, and O, and two other elements, Cu and C, which come from the carbon-coated copper grid. This is consistent with the XRD and XPS studies. The TEM image in Figure 4f shows that the Fe-doped $Ni(OH)_2$ tubes are needlelike structures with wall thicknesses of about 20–30 nm. The needlelike structure of Fe-doped $Ni(OH)_2$ tubes is weaker than the smooth-surface structure of $Ni(OH)_2$ tubes, so it might not be easy to prepare long bundles of Fe-doped $Ni(OH)_2$ tubes like the $Ni(OH)_2$ tubes under the same conditions.

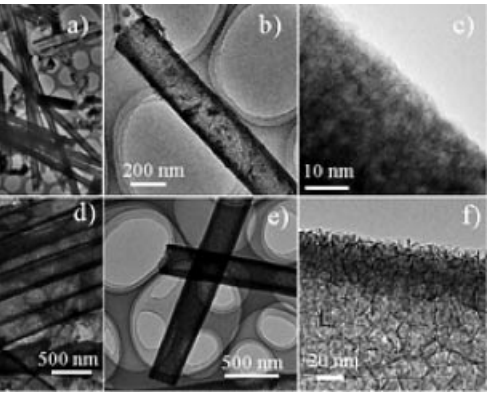

Figure 4. Representative TEM images of the $Ni(OH)_2$ (a, b, c) and Fe-doped $Ni(OH)_2$ tubes (d,e,f).

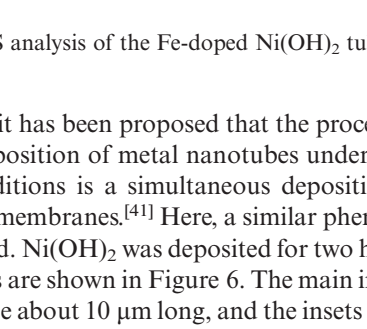

Figure 5. EDS analysis of the Fe-doped $Ni(OH)_2$ tubes taken from Figure 4e.

Recently, it has been proposed that the process of electrochemical deposition of metal nanotubes under low-current-density conditions is a simultaneous deposition along the holes of the membranes.[41] Here, a similar phenomenon was also observed. $Ni(OH)_2$ was deposited for two hours, and the TEM images are shown in Figure 6. The main image shows a $Ni(OH)_2$ tube about 10 μm long, and the insets (a, b, c and d) are the corresponding magnifications marked on the tube. The wall thickness of the $Ni(OH)_2$ tubes are different on the Au side of the membrane. It can be clearly seen from Figure 6 that the wall thickness decreases from Figure 6d to Figure 6a. This is especially evident as shown in Figure 6d where the

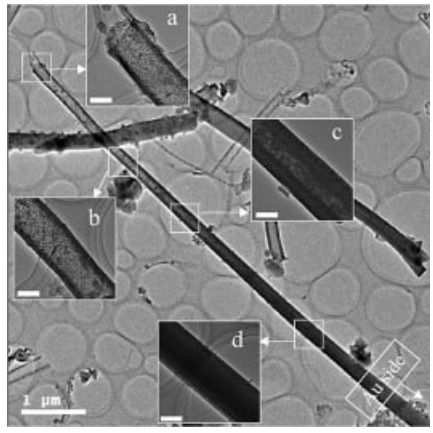

Figure 6. TEM images of $Ni(OH)_2$ deposited in the template for 2 h. The insets (a, b, c, and d) are the corresponding magnifications marked on the tube. Scale bars in the insets represent 100 nm.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tubes are already completely filled. Therefore, when we use electrochemical deposition in templates to prepare tubular semiconductors, attention must be paid to control the deposition time. Depositing for quite a long time such as 10 h leads to wire- or rodlike semiconductors. Figure 7 shows the TEM images of $Ni(OH)_2$ rods which were deposited for 10 h. Figure 7a shows several $Ni(OH)_2$ rods which are about 6 μm long and about 200 nm in outer diameter. Figure 7b shows the smooth-surface structure which is consistent with the structure of the $Ni(OH)_2$ tubes above.

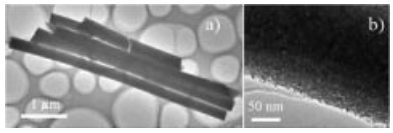

Figure 7. TEM images of the $Ni(OH)_2$ rods prepared by electrochemical deposition for 10 hours at low (a) and high (b) magnification.

Conclusions

Arrays of α-$Ni(OH)_2 \cdot 0.75H_2O$ and Fe^{III}-doped α-$Ni(OH)_2 \cdot 0.75H_2O$ tubes were prepared by electrochemical deposition in porous alumina membranes. The smooth-surface α-$Ni(OH)_2 \cdot 0.75H_2O$ tubes are more uniform and stronger than the needlelike Fe-doped α-$Ni(OH)_2 \cdot 0.75H_2O$ tubes. Nanostructures of tubes to wires or rods can be obtained by controlling the depositing conditions. It is obvious that this method of template-based electrochemical deposition can be extended for the synthesis of other similar materials such as micro- or nanotubes, -wires, and -rods.

Experimental Section

Electrochemical Deposition: A thin Au layer was evaporated onto one side of the pore walls of the alumina membranes (Whatman, Φ47 mm with 0.2-μm pores and 60 μm thickness), which was used as the working electrode for the electrochemical deposition. The Au-coated side of the alumina membrane was pasted on a Ni sheet with electric adhesive tape and the rest of the Ni tape was covered with insulated adhesive tape. The face and the side of the working electrode are schematically shown in Figure 8. The counter electrode was a nickel plate about 1.0 cm^2. The conditions for the electrochemical deposition of pure $Ni(OH)_2$ tubes and Fe-doped $Ni(OH)_2$ tubes are summarized in Table 1. Before the electrochemical deposition, the working electrode was submerged in the electrolyte, which was stirred by an electromagnetic blender, for 2 hours in order to make the electrolyte penetrate into the membranes. The electrochemical deposition was done in a plating bath under constant current and controlled temperature.

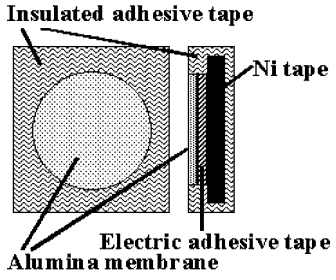

Figure 8. Schematic diagram showing the working electrode for electrochemical deposition of pure $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes.

Table 1. The electrochemical deposition conditions for preparing pure $Ni(OH)_2$ and Fe-doped $Ni(OH)_2$ tubes.

Tubes	Electrolyte composition	Temp. (°C)	Curr. dens. ($mA\,cm^{-2}$)	Time (min)
$Ni(OH)_2$	0.05 M $Ni(NO_3)_2 \cdot 6H_2O$	20	10	10
Fe-doped $Ni(OH)_2$	0.05 M $Ni(NO_3)_2 \cdot 6H_2O$	20	5	20
	0.001 M $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$			

Instrumental Analyses: The alumina membranes with the prepared samples were peeled off the Ni tape and immersed in 2 M NaOH for 4 h to remove the alumina template. After careful rinsing with deionized water, the samples were characterized using a combination of the following techniques: XRD, SEM, TEM and HRTEM equipped with EDS, and XPS.

XRD analysis was carried out with a Rigaku INT-2000 X-ray generator. The X-ray intensity was measured over a diffraction 2θ angle from 3° to 80° with a velocity of 0.02°/step and 2°/min. Specimens for SEM were collected on an electric adhesive tape and allowed to air-dry before the measurement. The electric adhesive tape with the sample was fixed to a piece of glass, which was attached to a SEM stub and then sputtered with a 2-nm layer of gold. Images were taken with a Philips XL-30 scanning electron microscope working at an accelerating voltage of 20 kV. Samples for TEM were put into an alcohol-water sonicator for about 5 min. Then the samples were collected on a carbon-coated copper grid and allowed to air-dry before the measurement. Images were obtained with a Philips Tecnai F20 TEM working at an accelerating voltage of 200 kV. EDS was performed in the microscope with use of a Kevex Super 8000 detector. The composition of the Fe-doped $Ni(OH)_2$ tubes was examined with an XPS (ESCA-3400, Shimadzu Electron) using monochromatic Mg–K_α radiation (1253.6 eV). The binding energy values were referenced to the carbon C 1*s* core peak at 284.7 eV.

A Theoretical Assessment of the Thermodynamic Preferences in the Cyclopalladation of Amines

Ramón Bosque*[a] and Feliu Maseras[b,c]

Keywords: Density functional calculations / Metallacycles / N ligands / Palladium

The factors affecting the cyclopalladation of amines are explored by a comparison of the energy differences between the cyclopalladated amine and the free ligand for a series of compounds. Four factors are considered: the substituents in the nitrogen atom (primary vs. tertiary amines), the hybridization (sp^2 or sp^3) of the metalated carbon atom, the number of members in the metallacycle ring (four, five, or six), and the presence of electron-donor or -acceptor groups. The trends that arise from these calculations, performed at the B3LYP level of theory, are compared with the experimental data available.

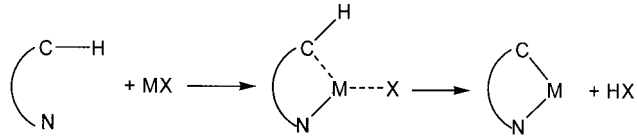
Introduction

The activation of C–H bonds is among the most important topics in organometallic chemistry. One of the ways that it can be achieved is by means of the so-called cyclometallation reaction, which can be defined as the formation of a bond between a transition metal and a carbon atom of one of its ligands, giving rise to a cycle that contains the metal atom (Scheme 1).[1] The most widely used metal is palladium, and to a lesser extent platinum, gold, manganese, rhodium, and ruthenium. As for the heteroatom E that attaches the ligand to the metal, most of the published work deals with N-donor systems, although there are examples with phosphorus, sulfur, oxygen, and arsenic. The mechanism of this reaction depends on the nature of the metallic atom; for example, cobalt(II) and palladium(II) react through an electrophilic pathway, while other late transition elements follow a nucleophilic pathway, which can also be regarded as an oxidative addition. On the other hand, early transition metals react via a multicentered pathway, which can be formally written as a nucleophilically assisted electrophilic reaction.[2]

There are many examples in the literature of the use of cyclometallated complexes in organic synthesis,[3] catalysis,[4] and medicine;[5] these substances can also be used as liquid crystals[6] or even as nanoscale devices.[7] Due to the importance of this cyclometallation reaction, a large amount of experimental work has been published, both presenting new features of the reaction and trying to elucidate which factors play a dominant role in its mechanism.[8,9] The work from Cope and Friedrich[8] regarding the cyclopalladation of N-donor ligands has achieved a seminal importance. These authors undertook the cyclopalladation of aromatic amines. By comparing the relative ease with which the reaction occurs, the authors postulated some empirical rules (the so-called Cope rules), that can be summarized as follows: (a) the stability of the cyclometallated species is greatest when the cycle has five members; (b) the reaction occurs more easily when the amine nitrogen is tertiary; (c) the mechanism is based on an electrophilic substitution. Although there are some exceptions in the literature,[10] these rules provide a useful guide for the rationalization of the products of the reaction in polyfunctional substracts. More recently, Ryabov[2] has reviewed the most important features of the mechanism based on kinetic measurements.



Scheme 1.

In contrast with the abundance of experimental results, the theoretical work published is scarce: although some articles about the reactivity of these species have appeared in the literature,[11] to the best of our knowledge the theoretical basis for the Cope rules has not been analyzed. In the bibliography there are several examples of theoretical studies of C–H activation;[12] however, none of them deals with cyclometallation reactions. The aim of this work is to start filling this void by presenting a first approach to the factors

influencing the mechanism of the cyclopalladation reaction from the thermodynamic point of view.

Results and Discussion

The cyclopalladation reaction is the most important example of cyclometallation that follows an electrophilic pathway.[2] It is also the most widely studied from an experimental point of view, beginning with the work of Cope and Friedrich that resulted in the empirical Cope rules.[8] In order to find the eventual thermodynamic basis for these rules, we have studied the variations in energy between the free amines and the cyclopalladated complexes (**1a**–**24a** and **1b**–**24b** respectively; Scheme 2). In the first stage, we performed the calculations on a series of aromatic amines (**1a**–**12a**). In order to discern the influence of the hybridization of the metalated carbon atom, we also studied a series of alkenylamines (**13a**–**18a**), as well as alkylamines (**19a**–**24a**). The role of the basicity of the nitrogen atom was evaluated by using either hydrogen or methyl as the substituent R^1 on nitrogen. On the other hand, modification of the number *n* of methylene groups allowed us to study the influence of the size of the metallacycle (from four to six members). In the case of five-membered rings derived from tertiary benzylamines, either acceptor or donor groups were added in order to evaluate their effect.

According to the proposed mechanism, the reaction takes place in two stages:[2] first, the palladium coordinates to the nitrogen atom, and then the electrophilic substitution of hydrogen occurs. Usually a dimeric compound, with halogen or acetate bridging ligands, depending on the starting palladium derivative, is obtained; subsequent treatment with a Lewis base affords the corresponding monomer (Scheme 3). It is worth noting that this ligand usually occupies a position *cis* to the metalated carbon; this is the so-called transphobia effect.[13] To simplify the calculations, we only considered the free ligand and the cyclometallated monomer with a phosphane ligand. As all the other species involved in the process are the same for all the reactions, the differences in energy between the metalated complexes and the corresponding free amines allowed us to define a simple scale of relative energies; the energy associated with the cyclopalladation of *N*,*N*-dimethylbenzylamine (**4a**), which features the formation of a five-membered metallacycle with an aromatic metalated carbon, a tertiary nitrogen, and with hydrogen as the only substituent in the remaining carbon atoms, was chosen as reference and assigned the value of 0 kcal mol^{-1}.

Geometry Optimizations

In order to obtain accurate values for the energies corresponding to the different species, the geometries of the free amines and the cyclometallated species were optimized without imposing any symmetry restriction. The most important geometric parameters for the amines that can give rise to four-membered metallacycles are listed in Table 1; the data for all the remaining ligands are included as Supporting Information. In these systems a possible problem of conformation arises from the free rotation around the single bonds. For this reason, several conformations were calculated for the different systems, and in each case only the most stable one was taken into account. In the case of the amines **11a**, **12a**, **17a**, and **18a**, which have larger chains,

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

a systematic search of conformers was performed at the semi-empirical AM1 level;[14] the most stable one for each ligand was then re-optimized at the DFT level.

Table 1. Selected optimized geometric parameters for the amines leading to four-membered metallacycles. Lengths are given in angstroms and angles in degrees.

	C1–C2	C2–N	C1–C2–N
1a	1.405	1.398	120.7
2a	1.413	1.394	121.3
13a	1.339	1.394	126.7
14a	1.330	1.431	122.7
19a	1.526	1.468	110.4
20a	1.529	1.464	113.5

The geometrical parameters corresponding to the cyclopalladated compounds are given in Table 2. The geometric distortions are apparent in the four-membered rings, with C(1)–Pd–N angles (see Scheme 2 for the atom numbering) of less than 70°, rather than the 90° that would correspond to a nonstressed, square-planar geometry. It is also worth mentioning the values of the C–N–Pd angles (87–92°, compared to a range of 105–110° for the five-membered rings and 114–120° for the six-membered metallacycles) and the C(2)–C(1)–Pd angles (93–99°, compared with 106–117° and 108–125° for the five- and six-membered rings); this angle is also smaller in the metallacycles that feature a metalated carbon atom with sp^3 hybridization.

The environment around the palladium atom changes as a function of the substituents in the nitrogen atom. Thus, in the tertiary amines the Pd–P and Pd–Cl distances are larger, while the palladium–carbon bonds are shorter than in the primary ones. On the other hand, the variation in the nitrogen–palladium bond-length also depends on the size of the metallacycle: the bonds in the five- and six-membered rings are much longer for the tertiary amines, while in the four-membered rings the observed trend is the opposite.

The variation in the size of the rings also modifies the environment of the palladium atom. The Pd–P and Pd–Cl distances increase upon incrementing the number of members of the ring. The palladium–carbon bond-length shows a less definite trend: for the non-aromatic sp^2 and sp^3 carbon atoms, the distance is smallest for the five-membered rings and largest for the six-membered systems, whereas for the aromatic derivatives the distance is smallest for the four-membered rings, while for the larger rings it depends also on the nature of the nitrogen atom. Finally, no clear trend arises for the variation of the palladium–nitrogen distances.

The changes of the hybridization of the carbon atom also result in some variations of the distances between the palladium atom and its neighbors. However, the only clear trend arises from the palladium–carbon bond length, which increases in the following order: d[Pd–C(sp^2), non aromatic] < d[Pd–C(sp^2), aromatic] < d[Pd–C(sp^3)]. As for the C(1)–Pd–N bite angle, this parameter is larger in nearly all cases for the C(sp^3) systems, as would be expected from the increment in the C(1)–C(2) distance that takes place upon changing the bond between these atoms from double to single; an exception is the six-membered ring with a tertiary nitrogen (**24b** vs. **12b** and **18b**): in this case the angle is nearly constant due to the flexibility of the aliphatic chain. The increment of the bite angle for the four- and five-membered metallacycles involves a decrease of the strain around the palladium atom due to the fact that it is smaller than

90° in all cases. The influence of the presence of donor or acceptor groups upon the environment of the palladium is small.

Factors Affecting the Cyclopalladation Reaction

In order to compare the factors that affect the stability of the palladacycles, the relative increment in energy corresponding to the metalation of the amines was calculated. We took into account the difference of energy between the cyclometallated species and the free amine, and the results were referenced to the formation of compound **4b** (five-membered ring with an aromatic metalated carbon, a tertiary nitrogen and without donor or acceptor groups bonded to the remaining carbon atoms), which was taken as 0.0 kcal mol^{-1}. The results are shown in Table 3.

Hybridization of the Metalated Carbon

The first factor that we took into account was the nature of the metalated carbon: C(sp^2, aromatic), C(sp^2, non-aromatic), or C(sp^3). Cope and Friedrich[8] worked only with benzylamine derivatives, and nearly all the published articles deal with the metalation of aromatic carbons; however, there are examples of the activation of C(sp^3)–H bonds in imines where there are aromatic carbons available.[15] This result is more remarkable considering that, in this case, the reaction yields a six-membered ring, while the activation of the C(sp^2)–H bond would yield a five-membered metallacycle, which is regarded as the most favored ring size. In this case, however, there are other factors that must be considered, especially the position of the C=N double bond: the systems in which this bond is included in the metallacycle (endocyclic) are formed more easily than those with the bond outside the metallacycle (exocyclic).[16] Minghetti and co-workers[17] have compared the aliphatic vs. aromatic C–H activation in the reaction of 6-substituted 2,2′-bipyridines with Na_2PdCl_4 in order to obtain five- or six-membered metallacycles. The reaction depends strongly on the substituent of the 2,2′-bipyridine, often in an unpredictable way. Dunina and co-workers[18] have studied the activation of C(sp^3)–H and C(sp^2)–H bonds in the reaction of *N*-methyl-α-*tert*-butylbenzylamine with palladium(II). In this secondary amine, weak palladating agents such as Li_2PdCl_4 favor the formation of C(sp^3)–Pd bonds, while under more drastic reaction conditions the C(sp^2)–H bond is activated. However, in the related tertiary amine *N*,*N*′-dimethyl-α-*tert*-butylbenzylamine only the palladation of the aromatic carbon is observed. There are other examples of four-[19] and five-membered[20] metallacycles with C(sp^3) metalated atoms, but they are prepared by oxidative addition and not by means of the cyclometallation reaction. A five-membered metallacycle with an aliphatic metalated carbon and a negative charge has also been postulated as an intermediate in the palladium-catalyzed internal phenylation of *N*,*N*-dialkylallylamines,[21] while an intermediate in the intramolecular Heck reaction of a pyrrolidine that features a five-membered aliphatic ring has recently been isolated and characterized.[22]

Finally, there are some examples of five-membered metallacycles where the metalated carbon has sp^2 hybridization although it is not aromatic,[23] and thus they are formally similar to our system **16b**. However, they are not prepared by the cyclopalladation reaction of the corresponding tertiary allylamine, but via the chloropalladation of substituted alkynes.

In view of this experimental evidence, we found it interesting to study the behavior of three different types of carbon center. The first of them was a phenyl, as in benzylamine (systems **1**–**12**), which represents the most usual case of aromatic carbons. The second one was a saturated alkyl (systems **19**–**24**), in line with the more recent results. We also introduced alkenyl in the comparison (systems **13**–**18**), with the idea that, if the energetics were similar, it could be a more computationally accessible model for a phenyl group. The relative energies from the calculations presented in Table 3 allow a series of comparisons between the behaviors of the three types of carbon hybridization. In order for the comparison to be fair, one must take a series of compounds where only the nature of the carbon changes and the rest of characteristics, that is, the substituents R^1 at nitrogen and the number, *n*, of carbons in the chain remain the same. A number of phenyl/alkenyl/alkyl series can be

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

defined following this concept, namely, **1/13/19**, **2/14/20**, **3/15/21**, **4/16/22**, **11/17/23**, and **12/18/24**. The corresponding relative energies are 14.1/13.1/4.9, 11.7/6.7/5.7, –3.3/–6.0/–4.3, 0.0/–2.5/–1.9, –3.2/–7.5/–1.1, and 0.4/–2.2/3.6 kcal mol^{-1}, respectively. It is worth noting that the first number of the series, corresponding to phenyl, is in no case the lowest (or the most negative). Thus, it can be concluded that the abundance of aromatic carbons in cyclopalladated compounds cannot be attributed to a thermodynamic preference because in no case is this the favored reaction. A second observation is that there is no special similarity between the first (phenyl) and the second (alkenyl) number of each series. Finally, concerning the particular numbers being presented, it can be seen that the larger differences (up to 10 kcal mol^{-1}) appear in the first two series (**1/13/19** and **2/14/20**), while for the other four groups the differences are 6 kcal mol^{-1} at most. This can be easily explained by the geometric strain of the four-membered rings in the first two sequences. The C–C–Pd angles are smaller than 100° in **1b**, **13b**, and **19b**, and this is more easily tolerated by sp^3 carbons than by their sp^2 counterparts.

Substituents on the Nitrogen Atom

The second factor considered was the variation in the nitrogen substituents. It is commonly assumed that M–N bonds are weaker in tertiary than in primary or secondary amines.[2] This effect is attributed, among other factors, to the steric hindrance of tertiary amines, as well as to the decrease in the outer-sphere solvation energy induced by N-alkylation;[24] however, it has been found that, in some cases, N-alkylation can stabilize coordination complexes in the gas phase.[25] Cope[8] was able to cyclometallate only tertiary amines, and nearly all the published work about the cyclopalladation of amines deals with tertiary nitrogen. Several explanations have been proposed for this fact: the greater coordinating ability of primary and secondary amines, which makes the subsequent C–H bond cleavage by the palladium atom via an electrophilic attack more difficult,[8] steric factors, which lead to a smaller internal entropy decrease in the cyclometallation of tertiary amines;[26] and, finally, the weaker bond between the palladium and the tertiary nitrogen atoms in the coordination intermediates, which facilitate the formation of unsaturated species that subsequently undergo Pd–C bond formation.[2] However, under carefully controlled experimental conditions, it is possible to prepare cyclopalladated compounds with primary[27] or secondary[27f,28] amines. Recently, the mechanism of the cyclometallation of primary amines has been investigated,[29] and it has been found that the choice of the solvent is critical in order to perform this reaction.

In our calculations we examined two limiting cases: primary amines, with two hydrogen substituents at nitrogen, and tertiary amines, with two methyl substituents. In this case, there are as many as nine primary/tertiary pairs of relative energies in Table 3 that can be compared. These are **1/2**, **3/4**, **11/12**, **13/14**, **15/16**, **17/18**, **19/20**, **21/22**, and **23/24**. The corresponding relative energies are 14.1/11.7, –3.3/0.0, –3.2/0.4, 13.1/6.7, –6.0/–2.5, –7.5/–2.2, 4.9/5.7, –4.3/–1.9, and –1.1/3.6 kcal mol^{-1}. In all but two pairs (**1/2** and **13/14**) the first number is smaller than the second, indicating that the reaction of primary amines is thermodynamically favored. The only two exceptions correspond to four-membered rings, which have their own characteristics associated with the large steric strain. Our calculations therefore indicate that cyclometallation tends to be favored when the nitrogen is primary; the energy differences between the metalation of primary and tertiary amines are between 2 and 5 kcal mol^{-1} for the five- and six-membered rings. The reasons for this can be electronic and/or steric; in this regard, the comparison of the Pd–N distances shows a shortening of the bond in the primary amines as compared to the tertiary ones. Also, we cannot rule out the presence of an interaction between the hydrogen of the primary amine and the chlorine atom. This interaction could lead to a stabilization of those metallacycles that feature primary nitrogen.

The experimental observation that the primary amines are so difficult to cyclopalladate is thus not due to a lack of thermodynamic stability of the product. In fact, it has been proposed from experimental data that an intermediate complex with two amines coordinated is too stable in this case, thus precluding the cyclometallation.[2] However, a definite answer can only be obtained after a thorough computational study of all the intermediates corresponding to the cyclopalladation reaction.

Size of the Metallacyle

The number of members in the formed metallacycle is considered to be a crucial factor in this reaction. In their original work, Cope and Friedrich tried the reaction of lithium tetrachloropalladate with *N*,*N*′-dimethylbenzylamine, *N*,*N*′-dimethyl-1-ethyl-2-phenylamine and *N*,*N*′-dimethyl-3-phenyl-1-propylamine in order to obtain five-, six-, and seven-membered rings, respectively, but they were successful only in the first case.[8] However, there are some recent examples of six-membered rings with primary benzyl-[10,30] and ferrocenylamines,[27e] and also with heterocycles.[31] Five- or six-membered rings can be obtained in the cyclopalladation of imines depending on the reaction conditions;[15,32] however, examples with six-membered metallacycles are less common than their five-membered counterparts.[1]

In order to test the importance of the ring size we performed calculations with four-, five-, and six-membered rings, both for primary and for tertiary amines (Table 3). In this case, we can form six series of relative energies corresponding to four/five/six-membered rings with identical settings for the other variables. The series are **1/3/11**, **2/4/12**, **13/15/17**, **14/16/18**, **19/21/23**, and **20/22/24**, and the corresponding relative energies are 14.1/–3.3/–3.2, 11.7/0.0/0.4, 13.1/–6.0/–7.5, 6.7/–2.5/–2.2, 4.9/–4.3/–1.1, and 5.7/–1.9/3.6 kcal mol^{-1}, respectively. As could be expected, the first number of the triad is always the highest, indicating that the formation of four-membered palladacycles is always the least thermodynamically favored, with differences larger than 10 kcal mol^{-1} in a number of cases. The reason for this

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

is the greater strain associated with four-membered rings, as can be seen in the comparison of the bond angles in the metallacycles (Table 2).

The comparison between five- and six-membered systems shows that the cyclopalladation is more favored for the former in nearly all the cases, with the only exception being the tertiary alkenylamines. Due to the lack of reaction between lithium tetrachloropalladate and *N*,*N*-dimethyl-1-ethyl-2-phenylamine,[8] it could be anticipated that the formation of six-membered rings would be less favored than in the five-membered systems. However, our calculations show that the difference in energy is small, mainly in the case of the aromatic amines, where it is smaller than 0.5 kcal mol^{-1}.

In order to ascertain the transferability of the results of these calculations, we analyzed the combined effect of the nature of the metalated atom and the size of the metallacycle on the 2-methylbenzylamine system depicted in Figure 1, which can produce the two different cyclometallation products shown. The calculation indicates that the isomer on the left-hand side, which features an aromatic metalated carbon atom and a five-membered metallacycle, is 5.9 kcal mol^{-1} more stable than the one on the right-hand side, which contains an aliphatic metalated carbon atom and a six-membered metallacycle. This compares well with the numbers in Table 3, where the reaction associated to an alkyl compound with a tertiary amine leading to a six-membered cyclometallated complex (**24a**) is 3.6 kcal mol^{-1} disfavored with respect to that of an aryl compound with a tertiary amine leading to a five-membered cyclometallated complex (**4a**). The minor difference between both energy differences can be easily explained by the presence of some sp^2 carbons in the six-membered ring of our test compound that are absent in model species **24b**.

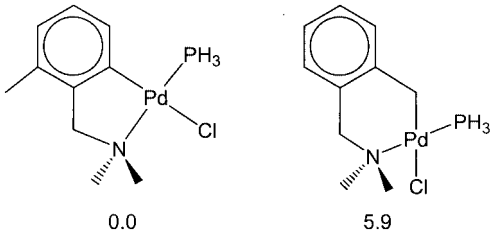

Figure 1. Relative energies [kcal mol^{-1}] of the two possible isomers that arise from the cyclopalladation of *N*,*N*-dimethyl(*o*-tolyl)methylamine.

We thus see that four-membered rings are indeed greatly disfavored from a thermodynamic point of view, and that five-membered rings are slightly more favored than six-membered rings. Therefore, it seems that the Cope rule concerning the size of the rings being formed can be explained by the thermodynamic stability of the product.

Electron-Donor or -Acceptor Groups in the Aromatic Ring

The last factor that was taken into account was the presence of electron-donor or -acceptor groups in the aryl ring. If the reaction has an electrophilic character, donors will favor it, while acceptors will render it more difficult. An example of this is the cyclopalladation of substituted azobenzenes, where the ring with electron-donating groups is preferentially metalated.[33] As for the tertiary benzylamines, Cope and Friedrich[8] metalated the 4-methoxy and 3,5-dimethoxy derivatives, with yields very similar to the unsubstituted tertiary amine, but were unsuccessful with the 4-NO_2 analog; this compound needs stronger palladating agents, such as palladium(II) acetate.[34] Kinetic measurements for the cyclometallation reaction of substituted *N*,*N*-dimethylbenzylamines[9a] or *N*-benzyltriamines[9d] show that there is a linear correlation between the logarithm of the rate constant and the Hammett parameter, σ_m, of the substituents, thus confirming that the reaction takes place through an electrophilic attack of the Pd^{II} center on the carbon atom.

In order to test the importance of the ring substituents we performed calculations on several substituted *N*,*N*′-dimethylbenzylamines of general formula 4-R-$C_6H_4CH_2N(CH_3)_2$, where R = -OCH_3 (**5a**), -NO_2 (**6a**), -Cl (**7a**), -CH_3 (**8a**), -CN (**9a**), and –OH (**10a**). They are depicted in Scheme 2. In addition to **5a** and **6a**, the cyclopalladated derivatives of **7a** and **8a** have been prepared previously,[9a] while, to the best of our knowledge, there are no examples of simple cyclopalladated derivatives of the hydroxy- and cyano-substituted tertiary benzylamines.

The relative energies corresponding to the cyclopalladation reactions, taking the unsubstituted tertiary benzylamine **4a** as reference, are shown in Table 3. There is not a perfect relationship between the electron-donor or -acceptor character of the R groups and the stability of the resulting palladacycles, but some trends are apparent. Acceptor groups, such as NO_2 (+1.8 kcal mol^{-1}) and CN (+1.5 kcal mol^{-1}), seem to render the metallacycles more unstable, whereas donor groups, such as OH (–5.4 kcal mol^{-1}), tend to stabilize the palladacycles, as would be expected from the electrophilic substitution mechanism indicated by the Cope rules. Donor groups making the reaction more difficult, as is the case with OCH_3 (+1.2 kcal mol^{-1}) and CH_3 (+0.4 kcal mol^{-1}), is somehow in disagreement with the rule, but can be attributed to their *meta* arrangement with respect to carbon C1. Finally, the chloro-substituted benzylamine **7a**, with a relative reaction energy of –5.6 kcal mol^{-1}, has a similar behavior to the electron donor OH. However, it has been reported that, at least in azobenzenes, a chloro substituent renders the substrate less reactive towards cyclopalladation than a hydrogen atom,[35] which would be in disagreement with this result.

It seems clear from these results that our simplified analysis fails to reproduce the experimental reactivity trends associated with the effect of electron-donor and electron-acceptor substituents. A subsequent study of the reaction mechanism could shed some light on the effect of these groups on the reaction kinetics.

Conclusions

A comparison of the relative energies of a series of amines and those of the corresponding cyclometallated

compounds allows a relatively simple computational evaluation of the correlation between the nature of the amine and the thermodynamic change involved in the cyclopalladation reaction. If these thermodynamic trends reproduced the experimental observations on the easiness of the reaction, this would be an efficient approach for the prediction of the likeliness of cyclometallation for a given compound and for the identification of the preferred product when more than one is possible. Unfortunately, our results indicate that this is not always the case.

The empirical rules proposed initially by Cope, and confirmed by a variety of experimental data afterwards, predict that cyclometallation is favored in the case of five-membered-ring products, tertiary amines, and in the presence of electron donors. Of these three rules, only the first of them, concerning the size of the rings, has an undisputable thermodynamic basis. Four-membered rings are strongly disfavored by the large steric strain, and products with five-membered rings are also preferred over their six-membered counterparts. The second rule, concerning the nature of the substituents at both the nitrogen and the carbon atoms, does not have a thermodynamic origin. It must therefore be associated to kinetics. The third rule, related to the nature of the substituents at the carbon atoms, seems to have a certain thermodynamic basis, but there are exceptions for some substituents, thus suggesting a significant kinetic contribution. The theoretical evaluation of kinetics requires a detailed knowledge of the reaction mechanism, with location of intermediates, transition states, and their associated energies. Further understanding of these empirical rules, as well as computational predictions on cyclometallation, will thus require the performance of a much more elaborate computational study.

Computational Details

All calculations were carried out with the Gaussian 98[36] package of programs at the B3LYP computational level.[37] The basis set was chosen as follows: an effective core potential was used to replace the 36 innermost electrons of Pd and the 10 innermost electrons of P and Cl; for these atoms, the LANL2DZ basis[38] was used, and in the case of phosphorus and chlorine, polarization functions were added. For carbon, hydrogen, oxygen, and nitrogen the 6-31G(d,p) basis including polarization functions[39] was used. Some conformational searches were carried out at the AM1 computational level[14] using the Spartan program.[40]

Synthesis and Characterisation of [Re(CO)$_3$(SS)(P)] Complexes: A [2+1] Concept for ^{99m}Tc- and ^{188}Re-Radiopharmaceutical Applications

Mattia Riondato,*[a] Davide Camporese,[a] David Martín,[b] Joan Suades,[b] Angel Alvarez-Larena,[c] and Ulderico Mazzi[a]

Keywords: Carbonyl ligands / P ligands / Rhenium / S ligands / Technetium

A new (SS)(P) coordination set based on the concurrent use of a dithiocarbamate and a functionalised phosphane is reported. The (SS)(P) fashion is achieved by applying the [2+1] mixed-ligand concept and makes it possible to obtain stable rhenium tricarbonyl complexes without employing tripodal bifunctional chelating agents (BFCAs). The coordination chemistry of the simple sodium *N*,*N*-dimethyldithiocarbamate and new functionalised phosphanes **L1**–**L3** [**L1** = $Ph_2PCH_2CH_2C(O)OCH_3$, **L2** = $Ph_2PCH_2CH_2C(O)NHCH_2C(O)OCH_3$, **L3** = $Ph_2PCH_2CH_2C(O)NHCH_2CH_2C(O)OCH_3$] was studied by reaction with the rhenium complex $[NEt_4]_2[fac\text{-}Re(CO_3)Br_3]$. The rhenium tricarbonyl core was found to be stabilised by the SS chelation of dithiocarbamate and by the P coordination of the phosphane. Two synthetic pathways leading to the complexes [*fac*-Re(CO)$_3$(L)(MDTC)] (L = **L1**, **L2**, **L3**; MDTC = *N*,*N*-dimethyldithiocarbamate) are described. The structural characterisation of the isolated complexes by spectroscopic methods is reported, including X-ray crystallographic analysis for rhenium complexes with ligands **L1** and **L3**. The homologous Tc-99m compounds with the same (SS)(P) coordination set were prepared at tracer level with the **L2** and **L3** ligands, and characterised by HPLC methods.

Introduction

The most important goal of radiopharmacy is the application of radiolabelled compounds in medicine for non-invasive diagnostic and therapeutic purposes. Technetium-99m is a γ-emitter with optimal characteristics that is widely employed in nuclear medicine for imaging and is readily available as pertechnetate from the ^{99}Mo/^{99m}Tc generator.[1] Rhenium-188 appears to be promising as a candidate for the treatment of neoplasia for its β^- emission and is available as perrhenate from a commercially available ^{188}W/^{188}Re generator, proposed by Oak Ridge National Laboratory (USA).[2]

For the development of site-directed diagnostic and therapeutic radiopharmaceuticals, a biomolecule (hormones, peptides) with high affinity for a receptor target should be labelled to deliver the radionuclide in a specific body region.[3] However, labelling a biomolecule might give an important alteration of its biological properties due to the link with transition metals such as Tc or Re. Hence, the most successfully employed procedure at present is the "bifunctional approach". This consists of a chelating system (bifunctional chelating agent, BFCA) that is able to stabilise and keep the metal far from the target molecule.[4]

In recent years, Tc and Re radiopharmaceutical chemistry with the cation *fac*-$[M(H_2O)_3(CO)_3]^+$ has been intensely stimulated by the fundamental contributions of Alberto, Schibli and Schubiger with the development of novel and simple methods for preparing the aqua ions *fac*-$[^{99m}Tc(H_2O)_3(CO)_3]^+$ and *fac*-$[^{188}Re(H_2O)_3(CO)_3]^+$.[5] The interest in the design of radiopharmaceuticals with carbonyl ligands results from their high thermodynamic stability, small size, kinetic inertia and in vivo stability.[6] Furthermore, the $[M(CO)_3]^+$ moiety allows the use of a wide range of ligand systems, therefore many different chelating sets have been tested.[7]

In this context, several research groups are currently looking for an "ideal building block" with an optimised in vitro and in vivo behaviour. In the last few years, these complexation studies have been principally focused on the development of tridentate BFCAs to obtain a tripodal mode of coordination (Scheme 1). Nevertheless, tricoordination can also be achieved by using a mixture of two ligands, one bidentate L_2 and one monodentate L_1 to produce an $[M(L_2)(L_1\text{-Biomol})(CO)_3]$ complex by means of a [2+1] mixed-ligand approach (Scheme 1).[8] A recent paper has reported the use of this "[2+1]" approach to prepare new *fac*-M(CO)$_3$ compounds for radiopharmaceutical use from a dithiocarbamate and a monodentate isocyanide ligand.[9]

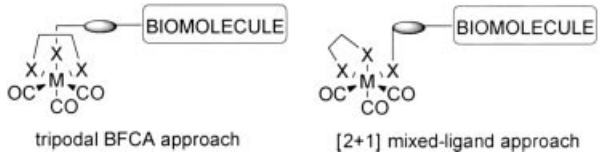

Scheme 1. Two different approaches for the stabilisation of a tricarbonylrhenium or -technetium core (M = Re/Tc).

Here, we report an investigation where we propose a suitable chelating system for the stabilisation of the *fac*-[M(CO)$_3$]$^+$ moiety by the [2+1] mixed-ligand approach, based on the simple *N*,*N*-dimethyldithiocarbamate (MDTC) as bidentate ligand and a functionalised phosphane as monodentate ligand. The phosphane acts as a bifunctional agent because it contains an anchor group that is useful for the conjugation with the biological vector, while MDTC acts as a co-ligand as it is able to neutralise and stabilise the metal system.

Phosphane ligands are well known for their capability to form very stable and inert bonds with organometallic fragments. Succinimidyl 3-diphenylphosphanylpropionate was selected as the BFCA because it can be simultaneously linked to a metal centre and to a biomolecule (Scheme 2).[10,11]

To evaluate the viability of this new [2+1] mixed-ligand approach we synthesised phosphane derivatives with aminoacid methyl esters following the above reaction. These ligands can simulate the presence of a conjugated targeting biomolecule and test the potential application of the new [2+1] mixed-ligand system in the presence of a biomolecule anchored to the monodentate ligand.

The coordination chemistry of the phosphane derivatives and sodium MDTC was studied by reaction with "cold" [NEt$_4$]$_2$[Re(CO$_3$)Br$_3$].[12] Rhenium complexes are structural models of technetium complexes due to the lanthanide contraction that ensures that the analogous complexes display very similar coordination parameters and physical properties.[13]

This study presents the syntheses and structural characterisation of three phosphane ligands and the [2+1] rhenium complexes obtained by combining the prepared phosphanes and sodium MDTC with the [Re(CO)$_3$]$^+$ moiety.

Results and Discussion

Synthesis of the Ligands

The synthesis and characterisation of the phosphane ester ligand **L1** has been reported previously.[14,15] We obtained the same compound using an alternative preparation starting from succinimidyl 3-diphenylphosphanylpropionate. The new functionalised phosphanes **L2** and **L3** were prepared by reaction of the same activated ester with the amino acid derivatives glycine methyl ester (**L2**) and β-alanine methyl ester (**L3**; Scheme 2) using modifications of the published procedures.[10,16] All these results are consistent with the ability of succinimidyl 3-diphenylphosphanylpropionate to act as a synthon for preparing phosphane-derivatised compounds. All ligands were obtained in good yields (70–75%) after purification by flash column chromatography as pale-yellow pure oils (air-sensitive compounds) and were characterised by NMR (^{1}H, ^{13}C, ^{31}P) and FT-IR spectroscopy and ESI mass spectrometry.

The collected data are consistent with the proposed structures and can be compared with the characterisation reported for similar ligands.[11,16] The ^{31}P NMR spectra of **L1**–**L3** show a sole singlet in the range δ = –13.9/–14.4 ppm characteristic of a ligand containing a diphenylphosphane group. The formation of the amide bond in **L2** and **L3** is evidenced by the IR spectra, which show a strong band near 1650 cm^{-1}, and by the proton signals of the amide group observed at δ = 6.12 (**L2**) and 6.03 ppm (**L3**) in the ^{1}H NMR spectra. The presence of a methyl ester group in **L1**–**L3** was evidenced in the IR spectra by a strong absorption between 1738–1752 cm^{-1} and by a singlet in the ^{1}H NMR spectra at around δ = 3.65 ppm. The ^{1}H and ^{13}C NMR

spectra display the signals of all organic groups involved in ligands **L1**–**L3**. Finally, the identities of **L1**–**L3** were confirmed by the positive ion ESI mass spectra, which display an intense signal assigned to the $[M + H]^+$ cation.

Complexation Studies

The great capability of phosphorus(III) to form stable complexes with transition metals in low oxidation states is well known, and coordination studies employing phosphanes with the Re^I tricarbonyl core have been carried out and reported in the literature.[17–20] Benak et al. have demonstrated that the reaction between $[Re(CO)_5Cl]$ and a diphenylphosphane ester affords the mononuclear tricarbonyl complexes *fac*-$[Re(CO)_3ClL_2]$ (L = phosphane) with the metal centre stabilised by the two phosphorus ligands.[18] Santos et al. have explored the coordination ability of tridentate hetero-functionalised diphenylphosphanes and obtained mainly PO or PN bicoordinated complexes.[19,20] In both cases tricoordination is generally not achieved, and the last position of the metal coordination sphere is occupied by a halogen. Furthermore, the formation of different isomers is often observed when bidentate ligands are employed.[21]

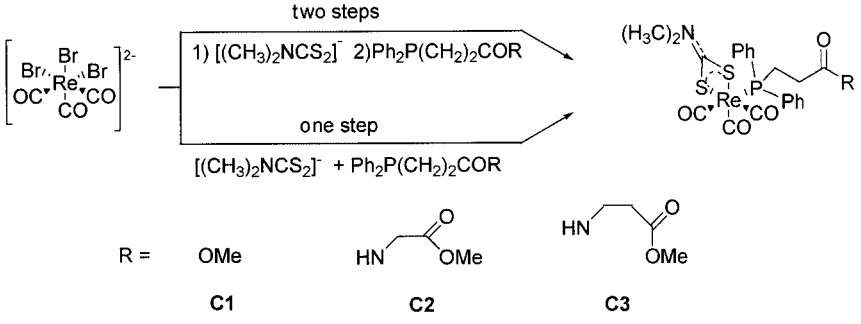
The use of sodium MDTC and diphenylphosphane in the [2+1] strategy has the potential advantage of producing monomeric and neutral tricoordinate complexes. Only one phosphane coordinates to rhenium in a monodentate fashion to produce minimal steric impact between the aliphatic chain and the metal sphere.

The rhenium(I) tricarbonyl complexes **C1**–**C3** were prepared in two different ways, as shown in Scheme 3. In the two-step pathway, or "indirect synthesis", complexes **C1**–**C3** were formed from an intermediate dithiocarbamate complex. This complex was synthesised in the first step by simple addition of sodium MDTC to a solution of the rhenium tricarbonyl precursor $[Re(CO)_3Br_3]^{2-}$ in methanol. The resulting product was not characterised; however, we suppose that a neutral soluble monomeric SS-bicoordinated species is formed, as reported by Gorshkov et al. for similar dithiocarbamates with the $[Re(CO)_3]^+$ moiety.[9] The simple substitution of a coordinated methanol by a monodentate phosphane ligand (**L1**–**L3**) blocks the coordination vacancy and leads to the target complexes (**C1**–**C3**) in good yields after purification by flash chromatography. The solid compounds are remarkably inert and stable to air and moisture, even in solution (organic solvents). No decomposition was observed after many weeks.

The presence of the *fac*-$[Re(CO)_3]$ fragment in complexes **C1**–**C3** was revealed by the three characteristic CO stretching bands (**C1**: 2016, 1921 and 1890 cm^{-1}) observed in the IR spectra.[18–21] This technique also supplies useful information about the coordination of the dithiocarbamate ligand, since a single, strong band at 1522–1526 cm^{-1} was observed, which was assigned to the C–N stretching of a symmetrical bidentate dithiocarbamate.[22] The C=O stretching vibrations of the ester and amide groups are similar to those of the free ligand, and were accorded to the exclusion of these groups from the participation in the metal sphere.

The ^{31}P NMR spectra of complexes **C1**–**C3** show the complete absence of the corresponding free ligand, and display a sole signal in the range δ = 5–8 ppm, thus confirming the absence of isomers. A significant downfield shift with respect to the resonance of the free ligands (δ = –14 to –16 ppm) was observed, in agreement with the formation of a phosphorus–metal bond. The coordination of the phosphane ligand is also evidenced by the ^{13}C NMR spectra, which show an important increase of the $^1J_{P,C}$ and $^2J_{P,C}$ couplings of the methylene groups with respect to the values observed in the free ligands. These data are in accordance with literature reports.[11,17,18] Furthermore, the simultaneous presence of MDTC and phosphane ligands with the rhenium tricarbonyl core is also consistent with the ^1H NMR, ^{13}C NMR and ESI-MS data, supporting the (SS)(P) coordination to the fragment *fac*-$[Re(CO)_3]^+$.

Single crystals of complexes **C1** and **C3** were obtained by recrystallisation and their structures were determined by X-ray methods. Perspective views of both molecules are displayed in Figures 1 and 2, respectively. Selected bond lengths and angles are collected in Table 1. The simultaneous coordination of the chelated dithiocarbamate and the phosphane to the *fac*-$[Re(CO)_3]^+$ fragment confirms the proposed structure and therefore the formation of the target [2+1] mixed-ligand rhenium tricarbonyl complexes. The coordination geometry around the metal atom can be described as a slightly distorted octahedron. The principal distortion comes from the bite angle of the chelated dithiocarbamate ligand, which forces the S–Re–S angles to be near 70°, a common value in other metal complexes with chelated dithiocarbamates.[23] The almost identical Re–S dis-



Scheme 3. Syntheses of the complexes **C1**–**C3** by the one-step and two-step approaches.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tances indicate that the dithiocarbamate ligand links to rhenium in a symmetrical bidentate mode in both complexes. The SCS plane of the dithiocarbamate is nearly coincident with the SReS plane, with S42–Re–S41 and S41–C43–S42 angles of 2.2(4)° and 4.7(5)° for **C1** and **C3**, respectively Consequently, the metal atom, the dithiocarbamate and the two carbonyl ligands *trans* to sulfurs lie in a slightly distorted plane. The third carbonyl and the Re–P bond are arranged almost perpendicular to this plane, and the Re–P distances for both **C1** and **C3** are in the range observed for other diphenylphosphanyl–metal complexes. It should be pointed out that the ester and amido groups of the functionalised phosphanes are located away from the metal atom. This result is relevant with regard to radiopharmaceutical applications since the amino acid fragment linked to the phosphane is not affected by the coordination to the metal. Another interesting point concerns the similar Re–C distances observed in the *fac*-Re(CO)$_3$ fragments despite the different electronic characteristics of the ligands located in the *trans* position (dithiocarbamate or phosphane). The Re–C distances of carbonyl ligands *trans* to phosphane are comparable with the carbonyls *trans* to dithiocarbamate both for **C3** and **C1**. This fact could be related to the capability of phosphane and dithiocarbamate ligands to form similar strong bonds with rhenium and to the observed experimental stability and kinetic inertia of the studied complexes.[22]

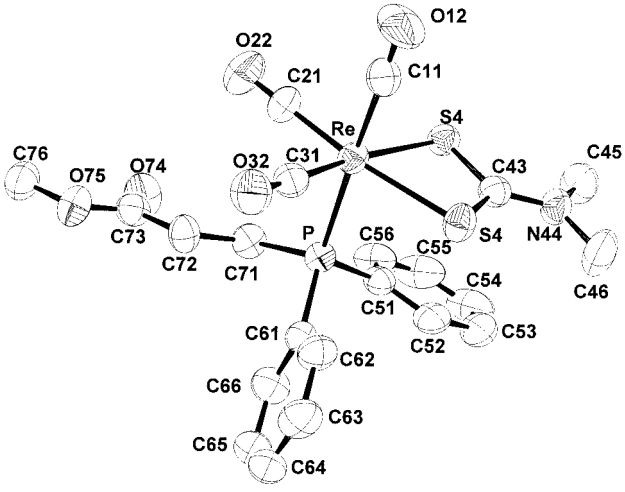


Figure 1. ORTEP diagram of **C1** showing 50% probability ellipsoids (hydrogen atoms omitted for clarity).

The one-step synthesis of complexes **C1**–**C3** by direct reaction between the rhenium precursor [Re(CO)$_3$Br$_3$]$^{2-}$ and an equimolecular mixture of dithiocarbamate and phosphane was studied in order to evaluate whether the characterised complexes are the main products by this pathway (Scheme 3). This reaction can be regarded as a test at macroscopic concentrations of the viability for future development of a [2+1] mixed-ligand kit for radiopharmaceutical applications.[24] Complexes **C1**–**C3** were obtained in good yields (68–75%) by this direct pathway and they display identical spectroscopic and analytical parameters to

the complexes synthesised by the two-step method. On comparing the two methods, the yields seem to be independent of the reaction path, but in the second case the product is obtained in a simple one-step reaction. In the reaction with a ligand mixture, the main product was still the tricoordinate monomeric neutral complex. The absence of significant quantities of phosphane complexes or dithiocarbamate complexes (or bidentate complexes in general) as by-products is a relevant result since it could be related to the peculiar thermodynamic stability of the tripodal (SS)(P) donor set for the metal tricarbonyl core.

Labelling Studies with ^{99m}Tc

The preparations of the homologous radioactive complexes were studied under no-carrier-added conditions by ligand substitution with the precursor *fac*-[^{99m}Tc(H$_2$O)$_3$(CO)$_3$]$^+$ and checked by HPLC analysis. The labile water ligands can easily be replaced by more stable and inert ligands. This reaction has been explored with DMTC[9] and phosphane ligands.[20,25,26]

R = $HNCH_2COOCH_3$ (**C4**), $HN(CH_2)_2COOCH_3$ (**C5**)

Scheme 4. Syntheses of the radio complexes **C4** and **C5** by the one-step approach.

We used the representative ligands **L2** and **L3** to simulate the presence of a biomolecule conjugated to the phosphorus atom of the phosphane (Scheme 4). The one-step synthesis was used to evaluate the (SS)(P) approach because it is the more attractive method for preparing radiopharmaceuticals. So, we added the dithiocarbamate and the phosphane ligand at the same time. The lipophilic character of diphenylphosphanes justified the use of ethanol to prepare the mixed-ligand solution. HPLC analysis showed that the addiction of the ligand mixture to the precursor *fac*-$[^{99m}Tc(H_2O)_3(CO)_3]^+$ led to the formation of a major compound in both cases. The retention times between the two ^{99m}Tc compounds (13.27 min for **C4** and 13.44 min for **C5**) and the analogous Re complexes (13.39 and 13.54 min for **C2** and **C3**, respectively) are almost identical (Figure 3). These results are consistent with the structure of the $Re(CO)_3$(SS)(P) coordination system for the radio complexes **C4** and **C5**.

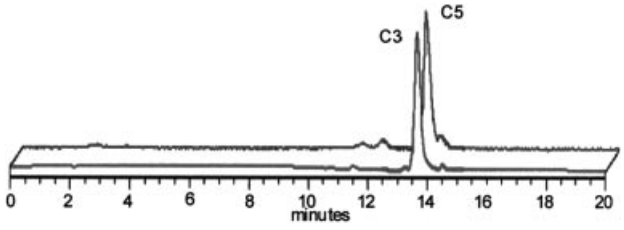

Figure 3. HPLC UV trace of the rhenium complex **C3** and γ-trace of the radioactive ^{99m}Tc complex **C5**.

The labelling reactions were also studied under different reaction conditions (pH temperature, reaction time, reagents' concentration and ratio) in order to obtain the optimised protocols. Reaction of a 4:1 mixture of MDTC and phosphane ligands at 80 °C for 60 min was found to give the best results in terms of yields.

To confirm the [2+1] coordination set, the precursor was reacted under the same conditions, but with only dithiocarbamate or with only phosphane ligands in the reaction mixture. The labelling mixtures were analysed by HPLC to determine the retention times of the products. DMTC reacts with the tricarbonyl radioactive moiety to give a unique peak at 14.21 min, while the reaction with the phosphane ligands gave two peaks at 10.98/11.57 min (**L2**) and 11.38/12.12 min (**L3**). These results support the formation of (SS)(P) coordination to $^{99m}Tc(CO)_3^+$ as the main product because these signals were observed as minor products in the reaction with the simultaneous addition of the dithiocarbamate and the phosphane ligand.

Conclusions

The coordinating chelating system (SS)(P) appears to be promising for a future medical application since complexes with the $[Re(CO)_3]^+$ moiety can easily be prepared in a one-step synthesis (useful in the design of a commercial kit), with good yields, and the synthesised products are very stable. The achieved tricoordination presented in this paper is very versatile and offers the possibility to link a wide range of target molecules to the monodentate phosphane. Furthermore, the chemistry of dithiocarbamates is well understood, and it is relatively easy to synthesise derivatives with different residues to modulate the hydro- or lipophilic characteristics of the desired complexes. Indeed, this [2+1] integrated approach with a symmetric bidentate chelating agent also avoids the formation of stereoisomers, which are often detected when using non-symmetric bidentate ligands or tridentate BFCA. The isomer formation influences the specific receptor binding because of the different metal–ligand orientation and may produce labelled species with different affinity for the same target, principally for small biomolecules.[27] From the perspective of developing a new drug, single and chemically stable products are essential for FDA approval.[8a]

Tc-99m labelling studies using the one-step method have confirmed the capability to produce (SS)(P) radio complexes. The next step will be to test the stability and kinetic inertia of the prepared compounds in order to evaluate their application for the formulation of new radiopharmaceuticals.

We conclude that the present [2+1] complex fashion could be a useful building block in the design and development of new target-specific ^{99m}Tc and $^{186/188}Re$ radiopharmaceuticals based on the tricarbonyl concept.

Experimental Section

Materials and Analytical Methods: All reactions were performed under nitrogen using standard Schlenk tube techniques. Solvents were degassed and tested for peroxides prior to use. All chemicals and solvents were reagent grade and were used without further purification. Infrared spectra were recorded with a Perkin–Elmer 1710 FT spectrometer as KBr pellets. The NMR spectra were recorded by the Servei de Ressonància Magnètica Nuclear de la Universitat Autònoma de Barcelona with a Bruker AM400 instrument. The ^{31}P chemical shifts are reported in ppm up-field from external 85% H_3PO_4. The ^1H and ^{13}C chemical shifts are expressed in ppm up-field from TMS.

Succinimidyl 3-diphenylphosphanylpropionate was provided by Argus Spechem S.a.s. (Prato, Italy) and the precursor $[NEt_4]_2[Re(CO_3)Br_3]$ was prepared by published procedures.[12] Microanalyses were performed at the Servei d'Anàlisi Química de la Universitat Autònoma de Barcelona. Electrospray ionisation mass spectra (ESI-MS) were obtained with an Applied Mariner System 5220 mass spectrometer (PerSeptive Biosystems Inc., Framingham, MA) in the positive-ion mode after dissolving the samples in acetonitrile (10^{-3} M).

The diffraction measurements were recorded by the X-ray Diffraction Service of the Universitat Autònoma de Barcelona.

Analytical thin-layer chromatography (TLC) was performed on Merck (Darmstadt, Germany) silica gel 60-F_{254} plates using the following elution systems: (a): *n*-hexane/EtOAc (3:2); (b): *n*-hexane/AcOEt (1:3); visualisation was accomplished by UV detection at 254 nm. Flash chromatography was carried out using silica gel 230–400 Mesh (Merck, Darmstadt, Germany) according to the method of Still.[28]

RP-HPLC analyses were performed on a Waters chromatography system (Waters, Milford, MA) controlled with a binary Waters 510 programmable gradient pump of the Department of Pharmaceutical Sciences, University of Padova. The analyses were monitored with a Waters 486 tunable absorbance detector set at 215 nm and a Bioscan-γ-detector B-FC 3200 (Milano, Italy). A Hamilton C18 reverse-phase column (10 μm, 250×4.6 mm, Alltech Italia, Sedriano, Milano) was used and the solvents were water with 0.1% trifluoroacetic acid (A) and acetonitrile with 0.05% trifluoroacetic acid (B). The HPLC gradient system started at 50% A/50% B, which was maintained for 5 min, rising to 100% B in 5 min with a linear gradient. It was maintained at a maximum of B for 8 min before returning to initial conditions in 2 min. The flow rate was 1 mL min^{-1}.

$Na^{99m}TcO_4$ was eluted from a commercial Drytec Sorin ^{99}Mo/^{99m}Tc Nycomed Amersham Sorin generator (Saluggia, Vercelli, Italy) using a 0.9% saline solution. The radioactive precursor *fac*-$[^{99m}Tc(H_2O)_3(CO)_3]^+$ was prepared with an IsoLink kit purchased from Mallinckrodt Med. B.V. (Pettern, Netherland).

All manipulations were carried out as approved for low-level radioactivity use.

Methyl 3-Diphenylphosphanylpropionate (L1): A solution of succinimidyl 3-diphenylphosphanylpropionate (1.41 mmol) in methanol (20 mL) was added dropwise to a stirred solution of (benzotriazol-1-yloxy)tripyrrolidinophosphonium hexafluorophosphate (PyBOP, 1.41 mmol) in the same solvent (20 mL). The mixture was left stirring for 6 h at room temperature, then the solvent was removed under vacuum. The oily residue containing product **L1** was purified by silica gel flash column chromatography (a) and concentrated to obtain a pale-yellow oil. Yield: 268 mg (70%). TLC (a): R_f = 0.8. HPLC: R_t = 14.63 min. FT-IR (KBr): $\tilde{\nu}$ = 1744 cm^{-1} (C=O, ester). ^{1}H NMR ($CDCl_3$): δ = 2.35–2.41 (m, 4 H, PCH_2CH_2), 3.64 (s, 3 H, OCH_3), 7.32–7.43 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$, except phenyl resonances): δ = 22.7 (d, $^1J_{C,P}$ = 12.5 Hz, P*C*H$_2$), 30.3 (d, $^2J_{C,P}$ = 19.2 Hz, PCH$_2$*C*H$_2$), 52.5 (s, OCH$_3$), 173.2 (d, $^3J_{C,P}$ = 15.3 Hz, *C*OOMe) ppm. ^{31}P NMR ($CDCl_3$): δ = –14.4 ppm. ESI-MS: *m*/*z* = 273 [M + H]$^+$.

Methyl [3-(Diphenylphosphanyl)propionylamino]acetate (L2): Triethylamine (2.39 mmol) was added to a suspension of glycine methyl ester hydrochloride (1.59 mmol) in anhydrous CH_2Cl_2 (50 mL). The solution was stirred for 30 min and then succinimidyl 3-(diphenylphosphanyl)propionate (1.59 mmol) was added. The mixture was stirred for 3 h and the solvent was then removed under vacuum. The oily crude containing product **L2** was purified by silica gel flash column chromatography (b) and concentrated to obtain a pale-yellow oil. Yield: 368 mg (70%). TLC (b): R_f = 0.8. HPLC: R_t = 9.90 min. FT-IR (KBr): $\tilde{\nu}$ = 1752 cm^{-1} (C=O, ester), 1654 (C=O, amide). ^{1}H NMR ($CDCl_3$): δ = 2.31–2.41 (m, 4 H, PCH_2CH_2), 3.72 (s, 3 H, OCH$_3$), 3.98 (d, $^3J_{CH,NH}$ = 6.3 Hz, 2 H, -NHCH_2), 6.12 (br., 1 H, NH), 7.30–7.45 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$, except phenyl resonances): δ = 23.3 (d, $^1J_{C,P}$ = 10.6 Hz, P*C*H$_2$), 32.5 (d, $^2J_{C,P}$ = 17.3 Hz, PCH$_2$*C*H$_2$), 41.5 (s, *C*H$_2$COOMe), 52.5 (s, OCH$_3$), 170.3 (s, *C*OOMe), 171.4 (d, $^3J_{C,P}$ = 13.4 Hz, *C*ONH) ppm. ^{31}P NMR ($CDCl_3$): δ = –13.9 ppm. ESI-MS: *m*/*z* = 330 [M + H]$^+$

Methyl [3-(Diphenylphosphanyl)propionylamino]propionate (L3): Triethylamine (2.68 mmol) was added to a suspension of β-alanine methyl ester hydrochloride (1.79 mmol) in anhydrous CH_2Cl_2 (50 mL). The resulting solution was stirred for 30 min and succinimidyl 3-(diphenylphosphanyl)propionate (1.79 mmol) was added. The mixture was stirred for 4 h and the solvent was then removed under vacuum. The oily crude residue containing product **L3** was purified by silica gel flash column chromatography (b) and concentrated to obtain a pale-yellow oil. Yield: 442 mg (72%). TLC (b): R_f = 0.75. HPLC: R_t = 9.98 min. FT-IR (KBr): $\tilde{\nu}$ = 1738 cm^{-1} (C=O, ester), 1652 (C=O, amide). ^{1}H NMR ($CDCl_3$): δ = 2.15–2.23 (m, 2 H, PCH_2), 2.32–2.35 (m, 2 H, PCH$_2$CH_2), 2.43 (t, ^3J = 6.3 Hz, 2 H, CH_2COOMe), 3.35–3.41 (dt, ^3J = 6.3, $^3J_{CH,NH}$ = 6.0 Hz, 2 H, -NHCH_2), 3.59 (s, 3 H, OCH$_3$), 6.03 (t, $^3J_{CH,NH}$ = 6.0 Hz, 1 H, NH), 7.22–7.36 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$, except phenyl resonances): δ = 23.1 (d, $^1J_{C,P}$ = 11.5 Hz, P*C*H$_2$), 32.4 (d, $^2J_{C,P}$ = 18.2 Hz, PCH$_2$*C*H$_2$), 33.5 (s, *C*H$_2$COOMe), 34.7 (s, HN*C*H$_2$), 51.5 (s, OCH$_3$), 171.9 (d, $^3J_{C,P}$ = 13.2 Hz, CONH), 172.1 (s, 1C, *C*OOMe) ppm. ^{31}P NMR ($CDCl_3$): δ = –14.3 ppm. ESI-MS: *m*/*z* = 344 [M + H]$^+$.

Synthesis of Rhenium Complexes. Two-Step Method: A solution of sodium *N*,*N*-dimethyldithiocarbamate (0.35 mmol) dissolved in methanol (20 mL) was added dropwise to a solution of rhenium tricarbonyl precursor $[NEt_4]_2[Re(CO_3)Br_3]$ (0.35 mmol) in the same solvent (20 mL). The obtained mixture was stirred for 30 min. A methanolic solution (20 mL) of phosphane ligand (0.35 mmol) was then added dropwise to the resulting pale yellow-green solution, and stirred for 90 min. The solvent was removed under vacuum and the oily residue containing the complex was purified by silica gel flash column chromatography (elution system a for **C1** and b for **C2** and **C3**). The solvents were then evaporated under vacuum. The obtained oil was taken up with 5 mL of Et_2O and then 50 mL of *n*-hexane was added to precipitate the product. The white powder was filtered off and dried under vacuum.

One-Step Method: A solution of *N*,*N*-dimethyldithiocarbamate (0.28 mmol) and phosphane ligand (0.28 mmol) dissolved in methanol (40 mL) was added dropwise to a solution of rhenium tricarbonyl precursor $[NEt_4]_2[Re(CO_3)Br_3]$ (0.28 mmol) in the same solvent (20 mL). The obtained mixture was stirred for 60 min and the solvent was removed under vacuum. The crude product containing the complex was purified by silica gel flash column chromatography (elution system a for **C1** and b for **C2** and **C3**). The solvents were evaporated under vacuum. The obtained oil was taken up with 5 mL of Et_2O and then 50 mL of *n*-hexane was added to precipitate the product. The white solid was filtered off and dried under vacuum.

[Re(CO)$_3$(L1)(*N*,*N*-dimethyldithiocarbamate)] (C1): Two-step method: Yield: 172 mg (76%). One-step method: Yield: 132 mg (73%). TLC (a): R_f = 0.4. HPLC: R_t = 14.94 min. FT-IR (KBr): $\tilde{\nu}$ = 2016 cm^{-1}, 1921, 1890 (C≡O), 1733 (C=O, ester), 1523 (C–N,

Synthesis of Technetium-99m Complexes. General Procedure: Technetium-99m labelling was performed by addiction of 15 μL of an ethanolic solution of *N*,*N*-dimethyldithiocarbamate (0.8 mM, 0.012 μmol) and phosphane ligand (0.2 mM, 0.003 μmol) to 85 μL of a freshly prepared solution of *fac*-[^{99m}Tc(H$_2$O)$_3$(CO)$_3$]$^+$ (15 MBq), pH 7.4. The mixture was incubated at 80 °C and stirred for 1 h. Analysis by HPLC equipped with a γ-radiometric detector showed a main peak for all experiments. Data are expressed as means of ±SD of three experiments.

Comparative *fac*-[^{99m}Tc(H$_2$O)$_3$(CO)$_3$]$^+$ labelling reactions with the only presence of *N*,*N*-dimethyldithiocarbamate or phosphane ligand were carried out under the same conditions and analysed by HPLC.

[^{99m}Tc(CO)$_3$(L2)(*N*,*N*-dimethyldithiocarbamate)] (C4): HPLC: R_t = 13.27 min. Labelling yield = 83 ± 1.7%. (HPLC: R_t [^{99m}Tc(CO)$_3$ with DMTC] = 14.29 min, R_t [^{99m}Tc(CO)$_3$ with L2] = 10.98 min, 11.57 min).

[^{99m}Tc(CO)$_3$(L3)(*N*,*N*-dimethyldithiocarbamate)] (C5): HPLC: R_t = 13.44 min. Labelling yield = 83 ± 1.7%. (HPLC: R_t [^{99m}Tc(CO)$_3$ with DMTC] = 14.29 min, R_t [^{99m}Tc(CO)$_3$ with L3] = 11.38 min, 12.12 min).

X-ray Crystallography: Colourless single crystals were obtained from methanol at –30 °C (**C1**) or by slow diffusion of *n*-hexane into a solution of the compound in ethyl acetate at room temperature (**C3**). Crystal data and selected information on data collection and structure determination are given in Table 2. Data were collected on a Bruker SMART CCD area-detector diffractometer at room temperature. Graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) was used. Lorentz-polarisation and absorption corrections were applied using Bruker SAINT and SADABS software. The structures were solved by direct methods and refined by full-matrix least-squares on F^2 for all unique measured data with weighting $w^{-1} = \sigma^2(F_o^2) + (aP)^2 + bP$, where $P = (F_o^2 + 2F_c^2)/3$.[29] Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included with riding model constraints and isotropic displace-

On the Borderline between *cis* and *trans* in Organometallic (Phosphane)platinum(II) Complexes

Dietrich Gudat,[a] Vimal K. Jain,[b] Axel Klein,*[c] Thilo Schurr,[c] and Stanislav Záliš[d]

Keywords: Density functional calculations / Isomers / NMR spectroscopy / Phosphane ligands / Platinum

The borderline between the *cis* and *trans* configurations in square-planar diarylplatinum(II) complexes with triethylphosphane ligands $[Pt(Ar)_2(PEt_3)_2]$ [Ar = 2,4,6-trimethylphenyl (mesityl), 2,6-dimethylphenyl, 2-methylphenyl, 3-methylphenyl, 4-methylphenyl and phenyl] has been investigated by a combination of multinuclear (^1H, ^{13}C, ^{31}P and ^{195}Pt) NMR spectroscopy, X-ray crystallography and quantum chemical (DFT) calculations. When formed under thermodynamic conditions, the complexes show a clear cut-off between *cis* (tolyl and phenyl complexes) and *trans* (2,6-xylyl and mesityl complexes). The *syn* and *anti* stereoisomers were identified for the 2-methylphenyl and 3-methylphenyl derivatives. Calculated data (structural isomers or NMR) are in excellent agreement with experimental findings.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The stability of the *cis* or *trans* conformation of square-planar complexes with a d^8 configuration is usually governed by an interplay of steric and electronic factors:[1,2] bulky ligands tend to avoid each other, and the presence of two of them usually leads to a *trans* configuration, whereas strong donor ligands prefer a *cis* orientation towards other strong ligands due to the *trans* influence. The latter should not be confused with the *trans* effect. The former is responsible for ground state-properties (structure, thermodynamic stability etc.), whereas the latter governs the behaviour in chemical reactions.[1] Both the *trans* influence and the *trans* effect are of high importance since both stability and formation reactions predetermine the occurrence of *cis* and *trans* configurations in such complexes, which is very often crucial for their applications. This is of enhanced importance for platinum(II) complexes, since in the series of d^8-configured transition metals like Rh^I, Ir^I, Ni^{II}, Pd^{II}, Pt^{II} and Au^{III} platinum(II) derivatives are markedly more resistant to isomerisation reactions than others.[1–3] The most prominent example of the different behaviour of two isomeric platinum(II) complexes is probably diamminedichloroplatinum $[PtCl_2(NH_3)_2]$: the *cis* derivative is an effective anti-cancer drug ("cisplatin") with sales of around 2 million € a year, whereas the *trans* derivative is inactive in that respect.[4–6]

Phosphane ligands have been explored in organoplatinum complexes for more than half a century.[2,7–9] Besides their numerous applications in organometallic catalysis, they have been found to be ideally suited for the determination of their configurations or configurational equilibria since the ^{31}P–^{195}Pt coupling constants are very sensitive to the *trans* and *cis* influence of further co-ligands.[10,11] Aryl ligands can be used to probe the subtle interplay of steric and electronic factors of the configuration since they are (i) strongly donating ligands; (ii) their electronic properties can be tuned by various substituents and the observed changes can be easily rationalised in terms of inductive or mesomeric influences; (iii) they can be easily introduced by established metathesis reactions;[9] (iv) their steric demand can be varied almost deliberately;[12] and (v) since their ring planes are usually oriented almost perpendicular with respect to the binding plane they allow discrimination of the two hemispheres above and below the binding plane, for example by unsymmetrical aryl ligands like 2-R,6-R′-C_6H_4 that give rise to further isomerism.[13]

We therefore decided to prepare a series of (triethylphosphane)platinum complexes $[Pt(Ar)_2(PEt_3)_2]$ [Ar = 2,4,6-trimethylphenyl (Mes), 2,6-dimethylphenyl (Xyl), 2-methylphenyl (2-Tol), 3-methylphenyl (3-Tol), 4-methylphenyl (4-Tol) and phenyl (Ph)] with various alkyl substitution patterns on the aryl ligands.

A similar study was undertaken by Rieger and coworkers some years ago[14] and some of the compounds (Ar = Ph, 2-Tol, 4-Tol) were reported in 1959 by Chatt and Shaw.[9] However, their preparation routes, involving me-

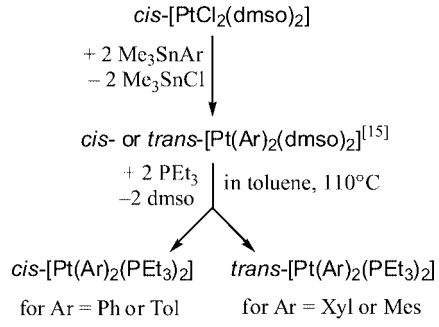
tathesis reactions between *cis*- or *trans*-[$PtCl_2(PEt_3)$] and an appropriate Grignard reagent, did not allow synthesis of the sterically highly crowded dimesityl or bis(2,6-xylyl) derivatives and often led to mixtures of isomers.[9,14] To prevent this we have chosen a different preparation route to ensure the thermodynamically controlled selective formation of only one isomer. To this end we applied ligand-exchange reactions at elevated temperatures using the DMSO precursor complexes [$Pt(Ar)_2(DMSO)_2$] to obtain isomerically pure compounds.

Results and Discussion

Preparation

The preparation of the complexes was performed as shown in Scheme 1 from the corresponding DMSO derivatives [$Pt(Ar)_2(DMSO)_2$][15] by ligand-exchange reactions at elevated temperatures (boiling toluene, see Exp. Sect.). With the exception of [$Pt(2\text{-Tol})_2(PEt_3)_2$], where ^1H and ^{31}P NMR spectra showed the presence of two isomers, we observed in all cases the formation of only one isomer in the crude reaction product as well as in the recrystallised products.



Scheme 1. Preparation of the platinum complexes [$Pt(Ar)_2(PEt_3)_2$].

NMR Spectroscopy

The thoroughly recrystallised complexes were submitted to multinuclear (^1H, ^{13}C, ^{31}P and ^{195}Pt) NMR studies. Selected data for the determination of the structure by NMR spectroscopy are summarised in Table 1 together with ADF/BP calculated data. Full NMR spectroscopic data can be found in the Experimental Section.

From the NMR spectroscopic data, especially from the $^1J_{Pt,P}$ and $^1J_{Pt,C(1)}$ coupling constants (Table 1), a clear line can be drawn between the Ph and Tol derivatives on one side and the Xyl and Mes derivatives on the other side. The $^1J_{Pt,P}$ coupling constants of the former are markedly smaller and the $^1J_{Pt,C(1)}$ couplings markedly larger than the values found for the more substituted derivatives. Both findings are indicative of shorter Pt–P and longer Pt–C(1) bonds, and thus the less substituted derivatives are assigned to have *cis* configurations whereas the more substituted ones are *trans*-configured. The calculated $^1J_{Pt,C}$ coupling constants are in excellent agreement with the experimental ones and clearly support the assignment of *cis* and *trans* configurations. Due to the simplification of the phosphane ligand (PMe_3 instead of PEt_3), the calculated $^1J_{Pt,P}$ coupling constants reflect the *cis*/*trans* variation only qualitatively.

Two sets of signals (ca. 2:1 ratio) were found for the 2-Tol derivative (Figure 1), both clearly showing a *cis* configuration. The two isomers correspond to species with a *syn* (C_S symmetry) and *anti* (C_2 symmetry) orientation of the two *ortho*-methyl groups (above and below the coordination plane), as has been reported previously for these systems[14] and related ditolyl complexes.[16,17] Detailed NMR experiments, including ^1H gsNOESY, ^1H,^{13}C HMQC and ^1H,^{195}Pt HMQC experiments, allowed the assignment of all signals to the two stereoisomers. Furthermore, the absence of exchange correlations in the ^1H NOESY spectra disclosed that the stereoisomers do not undergo any mutual exchange on a second time-scale, even in the presence of additional PEt_3. This stands in contrast to similar results

with the related DMSO complexes *cis*-[Pt(2-Tol)$_2$(DMSO)$_2$], where *syn*/*anti* isomerisation takes place presumably by a dissociative pathway.[15] Analogous stereoisomers were expected for the 3-Tol derivative. However, we found only one set of signals in the NMR spectra at ambient temperature (298 K). Recently, Hashemi and Rashidi have reported line-broadening on related bis(3-Tol) and bis(4-Tol) complexes, thus indicating fluxional behaviour.[16] We therefore performed quantum-chemical calculations on the energy barrier of *syn*/*anti* isomerisation of the 2-Tol and 3-Tol derivatives. The barrier calculated for [Pt(2-Tol)$_2$(PMe$_3$)$_2$] (111.7 kcal mol^{-1}) turns out to be much larger than for [Pt(3-Tol)$_2$(PMe$_3$)$_2$] (34.1 kcal mol^{-1}), which seems to be reasonable. However, both numbers indicate the occurrence of *syn* and *anti* isomers for 2-Tol as well as for 3-Tol. We therefore examined the 3-Tol derivative at low temperatures (223 and 193 K) and found two sets of signals in the ^{1}H, ^{13}C, ^{31}P and ^{195}Pt NMR spectra. Due to the rather small splitting of the corresponding signals of the two isomers (some signals are just broadened; see, for example, Tables 6 and 7) and signal ratios of approximately 1:1, we could not assign either the *syn* or *anti* isomers or calculate the energy difference. We also refrained from measuring exact coalescence temperatures since the two measurements (at 223 and 193 K) indicated already that different coalescence temperatures will be found for the various signals.

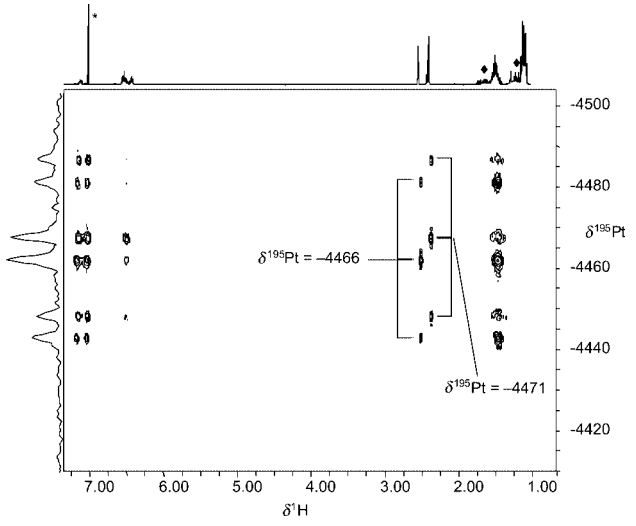

Figure 1. Magnitude-mode two-dimensional ^{1}H,^{195}Pt gs-HMQC spectrum (defocusing time 8.3 ms), showing various long-range correlations between the protons in the 2-Tol and PEt$_3$ groups and the metal atom, and the ^{1}H NMR spectrum (top projection; the solvent signal is denoted by * and the resonances of an impurity of OPEt$_3$ by ♦) of a mixture of the *syn* and *anti* stereoisomers of *cis*-[Pt(2-Tol)$_2$(PEt$_3$)$_2$]. The *F*1 projection (left) shows the ^{195}Pt signals of both isomers as interleaved triplets split by $^1J_{Pt,P}$.

Comparing the *syn*/*anti* ratios for the 2-Tol and 3-Tol derivatives we found a ratio of approx. 1:1 for 3-Tol, whereas for the 2-Tol derivative the ratio is about 2:1. This ratio is reversed (*syn*/*anti* = 1:2) in the precursor complex *cis*-[Pt(2-Tol)$_2$(DMSO)$_2$].[15] Since for the DMSO derivative we found isomerisation already at ambient temperature (NMR), we assume that the *syn* derivative of the DMSO precursor complex is more reactive than the *anti*, which is (thermodynamically) slightly more stable. It is also worthwhile mentioning that the PEt$_3$ complexes retain the *cis* or

trans configuration of their DMSO precursors. This is not trivial, since the DMSO precursor complexes may undergo facile isomerisation, which comprises not only *syn*/*anti* (vide supra) but also *cis*/*trans* isomerisation, for example during the formation of the *cis*-configured (diimine)platinum complexes *cis*-[Pt(Ar)$_2$($\widehat{NN}$)] ($\widehat{NN}$ = α-diimine; Ar = Mes or Xyl) from *trans*-configured DMSO precursor complexes.[18–20]

Crystal Structures

The crystal and molecular structures of [Pt(Ph)$_2$(PEt$_3$)$_2$], [Pt(3-Tol)$_2$(PEt$_3$)$_2$], [Pt(4-Tol)$_2$(PEt$_3$)$_2$], [Pt(Xyl)$_2$(PEt$_3$)$_2$] and [Pt(Mes)$_2$(PEt$_3$)$_2$] were determined from single-crystal XRD experiments. The structures of the *syn* and *anti* isomers of *cis*-[Pt(2-Tol)$_2$(PEt$_3$)$_2$] have been reported previously by Rieger et al.[14] The results of the structure determinations are summarised in Table 2, with bond lengths and angles given in Table 3. The first three compounds crystallise in monoclinic space groups, the Xyl derivative is found in triclinic $P\bar{1}$ and the Mes compound in orthorhombic $Pca2_1$. No significant intermolecular contacts were found in any of the crystal structures.

The molecular structures confirm the conclusions drawn from spectroscopic studies in solution: The Ph, 3-Tol and 4-Tol derivatives exhibit a *cis* conformation (Figure 2) as has been found before for the 2-Tol derivative.[14] The Xyl and Mes derivatives show a *trans* orientation of the two aryl groups (Figure 3), and the platinum atom lies on a centre of symmetry for Ar = Xyl. The 3-Tol derivative shows a *syn* orientation of the two methyl substituents. All structures show nearly perfect planar arrangements of ligands around the platinum atom, as can be seen from the sum of angles and the small CCPt/PPPt tilt angles (Table 3).

The bond lengths and angles around the platinum atom in the series of complexes nicely reflect the *trans* influence.[1] For instance, the Pt–P distances are slightly longer for the *cis*-configured compounds while the Pt–C distances are markedly shorter. The bond lengths and angles of the previously reported *syn* and *anti* isomers of *cis*-[Pt(2-Tol)$_2$(PEt$_3$)$_2$][14] fit nicely into our series. Interestingly, Osakada et al.[21] have recently reported the structure of the *trans*-

configured complex $[Pt(4\text{-}CF_3Ph)_2(PEt_3)_2]$, which they obtained by an oxidative addition/reductive elimination sequence using $[PtBr(PEt_3)_3]BF_4$ and the silanol 4-$CF_3PhSi(Me)_2OH$. The Pt–C bonds are markedly longer [2.089(8) Å] and the Pt–P bonds slightly shorter [2.287(3) Å] than what we found for the *cis*-4-Tol derivative.

The distances between the *ortho*-methyl groups and the platinum atoms in compounds Ar = Xyl or Mes range from 3.32 to 3.38 Å, with the upper value representing approximately the sum of the van der Waals radii of Pt and CH_3,[17] values which have also been found for the series of phosphane(2-Tol)platinum complexes reported by Rieger et al.[14] They are slightly lower for the (diimine)platinum complexes *cis*-$[Pt(Ar)_2(\widehat{NN})]$ ($\widehat{NN}$ = α-diimine; 3.2–3.3 Å),[19,20] probably caused by shorter Pt–C(1) bond lengths due to the weaker *trans* influence of the diimine ligands. The tilt angles between the aryl rings and the CCPtPP coordination plane range from 76 to 90° for the *cis* derivatives but are almost 90° for the two *trans*-configured analogues. Since 90° is the optimum value for steric reasons, this is remarkable. We have previously made a similar observation for related *cis*-configured (diimine)platinum complexes (angles around 70°) and have ascribed this effect to an optimisation of ligand-to-metal overlap in conjunction with a metal-mediated ligand-to-ligand interaction.[19] Such interactions seem to be absent for the *trans*-configured compounds.

Essential structural data marking the differences between *cis* and *trans* conformers are summarised in Table 4 together with DFT-calculated energies for possible isomers.

Table 4. Experimental and ADF/BP calculated structural data for complexes $[Pt(Ar)_2(PEt_3)_2]$.

	Exp. structure from single-crystal XRD	Lowest-energy structure[a]/ stabilisation energy [kcal mol^{-1}]

[a] Calculated data for $[Pt(Ar)_2(PMe_3)_2]$ model systems, stabilisation energy calculated as the energy difference between the highest and lowest bonding energies of the corresponding *cis* and *trans* isomers. [b] Data for *cis*-$[Pt(2\text{-}Tol)_2(PEt_3)_2]$ (*cis-syn*: monoclinic $P2_1/n$, *cis-anti*: monoclinic $P2_1/c$) from ref.[14]

The ADF/BP calculated ground-state molecular structures agree fully with the experimental structures The *syn* isomer was calculated to be slightly more stable (1 kcal mol^{-1}) for the *cis*-2-Tol complex, which is in agreement with the observed ratio of *syn*/*anti* stereoisomers of approximately 2:1 in solution (see NMR). The calculated difference in bond energy for the *syn* and *anti* isomers of the 3-Tol derivative is negligible, which fully agrees with the approximate 1:1 ratio found in the low-temperature NMR spectra. The fact that we found the *syn* form for the 3-Tol derivative in the crystal structure determination can thus not be ascribed to its higher stability; it might instead be due to a higher tendency to crystallise.

Conclusions

The combination of structural and spectroscopic data with quantum chemical calculations on diarylplatinum complexes with triethylphosphane ligands has revealed that the borderline between *cis*- and *trans*-configured ground-state geometries is crossed when two *ortho*-methyl groups are introduced on the aryl ligands. Under the applied preparation conditions (high-temperature ligand exchange using the $[Pt(Ar)_2(DMSO)_2]$ precursor complexes) we found the selective formation of either the *cis* (Ph or Tol) or *trans* (Xyl or Mes) isomers. In case of the 2-Tol and the 3-Tol derivatives, the formation of a mixture of the *syn* and *anti* stereoisomers was observed. Detailed NMR experiments allowed the structural assignment of the individual isomers and within these experiments we did not observe any isomerisation reaction. Therefore, we postulate that our chosen reaction conditions are appropriate to obtain the thermodynamically most stable forms. The results of quantum chemical calculations are in excellent agreement with the findings, even in predicting the relative energies of *syn* or *anti* stereoisomers with relatively small energy differences.

Experimental Section

General: The precursor complexes $[Pt(Ar)_2(DMSO)_2]$ (Ar = Ph, 2-Tol, 3-Tol, 4-Tol, 2,6-Xyl or Mes) were prepared according to literature methods.[15,18] Triethylphosphane was obtained from Aldrich. All reactions were carried out under argon in dry and distilled analytical-grade solvents. One-dimensional ^1H, $^{13}C\{^1H\}$, $^{31}P\{^1H\}$, and $^{195}Pt\{^1H\}$ NMR spectra were recorded with a Bruker DPX-300 NMR spectrometer (^1H: 300.13; ^{13}C: 75.47; ^{31}P: 121.49; ^{195}Pt: 64.52 MHz). Chemical shifts are relative to the internal chloroform peak at δ = 7.26 ppm for ^1H and δ = 77.0 ppm for ^{13}C, external 85% H_3PO_4 for ^{31}P and Na_2PtCl_6 in D_2O for ^{195}Pt. A 90° pulse was used in every case. NMR measurements for the assignment of the *syn* and *anti* conformations of $[Pt(2\text{-}Tol)_2(PEt_3)_2]$ were carried out with a Bruker DPX 400 spectrometer (^1H: 400.13 MHz; ^{195}Pt: 86.01 MHz; ^{13}C: 100.3 MHz) in $CDCl_3$ at 303(1) K; for $[Pt(3\text{-}Tol)_2(PEt_3)_2]$ these measurements were performed in CD_2Cl_2 at 223(5) or 193(5) K; chemical shifts were referenced to external TMS (^1H, ^{13}C) or K_2PtCl_6 (Ξ = 21.496784 MHz, ^{195}Pt). The assignment of ^{13}C and ^{195}Pt resonances was obtained from two-dimensional gradient selected (gs) $^1H,^{13}C$ HMQC and HMBC and $^1H,^{195}Pt$ HMQC spectra. Conformational assignments and the analysis of dynamic properties were derived from two-dimensional ^1H gs-NOESY NMR spectra using mixing times of between 500 and 750 ms. All 2D NMR spectra were obtained by using standard pulse sequences from the Bruker pulse program library.

Synthesis of the Complexes $[Pt(Ar)_2(PEt_3)_2]$: An excess of triethylphosphane (1 mmol) was added to a stirred toluene (20 mL) solution of $[Pt(Ar)_2(DMSO)_2]$ (Ar = Ph, 2-Tol, 3-Tol, 4-Tol, Xyl, Mes; typically 0.28 mmol). The mixture was stirred with refluxing for 24 h. The solvent, DMSO and the excess of PEt_3 were distilled off and the residue washed with cold pentane. The colourless products were dried in vacuo. Recrystallisation of the products from warm pentane gave colourless crystals. Yields and elemental analyses are given in Table 5, and full NMR spectroscopic data in Tables 6, 7 and 8.

Table 5. Yields and analytical data of complexes $[Pt(Ar)_2(PEt_3)_2]$.

Ar	Yield [mg]	Yield [%]	Calculated [%]	Found [%]

Crystallography: Single crystals of $[Pt(Ar)_2(PEt_3)_2]$ (Ar = Ph, 3-Tol, 4-Tol, 2,6-Xyl or Mes) were obtained by slow evaporation of the solvent from saturated solutions in CH_2Cl_2 or pentane. The X-ray data of these complexes were collected at 173(2) K with a Siemens P4 or P3 diffractometer, using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) and employing Wyckoff scans. The structures for Ar = Xyl or Mes were solved by direct methods; for all others the Patterson method was employed, in each case using the SHELXTL package,[22] while refinement was carried out with SHELXL97 employing full-matrix least-squares methods on F^2 with $F_o^2 \geq 2\sigma(F_o^2)$.[23] All non-hydrogen atoms were refined aniso-

tropically, including the disordered C atoms of the ethyl groups in the compounds Ar = 3-Tol or Mes. Hydrogen atoms were introduced using appropriate riding models. An empirical absorption correction was performed using ψ-scans. CCDC-266186 for $[Pt(Ph)_2(PEt_3)_2]$, -266187 for $[Pt(3\text{-}Tol)_2(PEt_3)_2]$, -266188 for $[Pt(4\text{-}Tol)_2(PEt_3)_2]$, -266189 for $[Pt(2,6\text{-}Xyl)_2(PEt_3)_2]$ and -266190 for $[Pt(Mes)_2(PEt_3)_2]$ contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Quantum Chemical Calculations: Ground-state electronic structure calculations were performed by density-functional theory (DFT) methods using the ADF2004.01 program package.[24] Nuclear spin-spin coupling constants were calculated with the CPL module[25] within ADF2004.01. The calculations were performed on the model systems $[Pt(Ar)_2(PMe_3)_2]$ due to the size of the $[Pt(Ar)_2(PEt_3)_2]$ complexes. Slater-type orbital (STO) basis sets of triple-ζ quality with one polarisation function (TZ2P)[24b] for Pt and two polarisation functions (TZP)[24b] for the remaining atoms were employed for geometry optimisation. The inner shells were represented by the frozen-core approximation (1s for C, 2p for P and 1s–4d for Pt were kept frozen). Core electrons were included for the calculation of NMR parameters, and here the quadruple-ζ with four polarisation functions (QZ4P)[24b] basis set was used for Pt. The calculations were carried out with the functional including Becke's gradient correction[26] to the local exchange expression in conjunction with Perdew's gradient correction[27] to the local correlation (BP86). The scalar relativistic (SR) zero-order regular approximation (ZORA) was used within this study. The energy barriers of *syn*/*anti* isomerisation within $[Pt(2\text{-}Tol)_2(PMe_3)_2]$ and $[Pt(3\text{-}Tol)_2(PMe_3)_2]$ model complexes were calculated as the lowest energy rotation barrier associated with the rotation of one 2-Tol or 3-Tol group, respectively.

Acknowledgments

Dr. M. Bader and Dr. M. Niemeyer (University of Stuttgart) are thanked for collecting single-crystal XRD data. Support for this work under the Indo-German bilateral program from the BMBF (Project No. IND 99/060) and the COST D14 action is also acknowledged. We are also grateful for a loan of K_2PtCl_4 by Johnson Matthey. S. Z. also acknowledges financial support by the Grant Agency of the Academy of Sciences of the Czech Republic (grant 1ET400400413).

Supramolecular Arrangement of C_{60} and Phenol into a Square Packing Arrangement of π-π Interacting and Hydrogen-Bonded Rods in C_{60}·5C_6H_5OH

Martin Schulz-Dobrick,[a] Martin Panthöfer,[a] and Martin Jansen*[a]

Keywords: Fullerenes / Supramolecular chemistry / Pi interactions / Hydrogen bonds

The supramolecular adduct C_{60}·5C_6H_5OH was obtained as single crystals by the slow hydrolysis of a solution of C_{60} in triphenylphosphite. The crystal structure was determined with atomic resolution by single-crystal X-ray diffraction [triclinic, space group $P\bar{1}$, a = 1003.52(14) pm, b = 1011.71(14) pm, c = 1264.17(17) pm, α = 88.566(2) °, β = 84.026(2) °, γ = 83.485(2) °, V = 1.2681(3) nm^3, Z = 1]. The overall structure can be described as a distorted square packing pattern of hydrogen-bonded and π-π interacting rods, $^1_\infty$[C_{60}(C_6H_5OH)$_4$]. The fullerene molecules are fully ordered and the C–C bond lengths exhibit remarkably small variations within the 6:6 and 6:5 subsets. The results are discussed in the context of an analysis of reliable crystal structure data for several different fullerene co-crystal compounds.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Fullerenes are promising candidates for the generation of novel materials due to their electron acceptor capabilities, and the interesting electronic and magnetic properties of chemically reduced fullerene species, e.g. A_3C_{60} (A = alkaline metal[1]), [Cr(C_7H_8)$_2$]C_{60},[2] TDAE-C_{60},[3] and the ability of fullerenes to form adducts with π-donors. A variety of supramolecular π-donor-fullerene arrangements have been crystallographically characterized, including donors like porphyrins[4,5], calixarenes,[6] tetrachalcogenefulvalenes[7] and various aromatic donors.[8,9] In order to provide a sufficiently strong interaction, the donor molecules should be able to complement the spherical shape of the fullerene species. This may be realized by large molecules exhibiting an intrinsic concave or even bowl-like shape, as well as by the supramolecular organization of small donor molecules into a network that gives rise to spherical voids of the appropriate size. The latter case was observed in the crystal structure of C_{60}·3HOC_6H_4OH,[10] where the hydroquinone molecules form a hydrogen-bonded network in which the fullerenes are encapsulated by bowl-shaped moieties. The primary motivation behind these efforts has been to study the electronic and structural response of the fullerenes to the supramolecular interactions. However, in many cases crystal structure analysis has been hampered by severe orientational and librational disorder of the fullerene sub-structure.

In this work, we present the synthesis and structural characterization of a supramolecular adduct of C_{60} and phenol, where the hydrogen-bonded arrangement of the phenol molecules is strong, yet at the same time flexible enough to give rise to strong π-π interactions and a full ordering of the C_{60} molecules, thus enabling an extraordinary accurate determination of the molecular structure of the fullerene moieties (Figure 1).

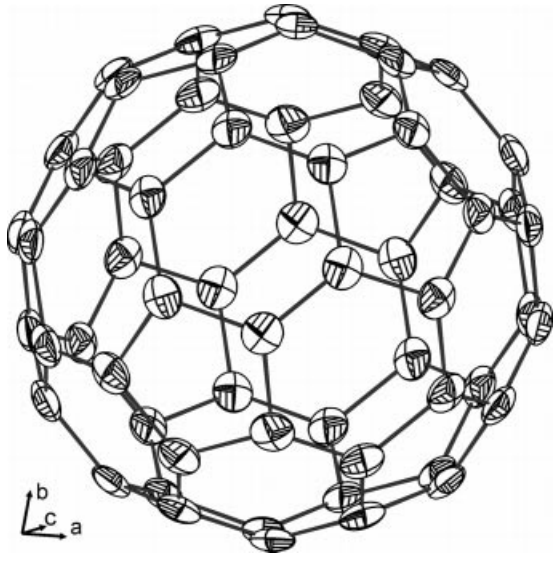

Figure 1. Molecular structure of the fullerene C_{60} moiety (probability density function corresponds to the 50% probability level).

Results and Discussion

The supramolecular adduct C_{60}·5C_6H_5OH was obtained as red, plate-shaped crystals by the slow hydrolysis (with

water vapor) of a solution of C_{60} in triphenylphosphite and the in-situ generation of phenol, which acts as a co-crystallization agent as well as a precipitation agent. This method (in-situ formation of the precipitation agent) has not been employed in the synthesis of fullerene co-crystals before. The majority of fullerene co-crystals, as reported in the literature, were obtained from solutions containing both the fullerene and the co-crystallization agent, either by the slow evaporation of the solvent or by vapor diffusion methods. It is particularly advantageous for precipitation to occur from a homogeneous solution by the slow chemical evolution of the co-crystallization agent, as in case of $C_{60}{\cdot}5C_6H_5OH$, as this allows crystal growth to proceed under low and almost constant super-saturation conditions, leading to well grown crystals of an appropriate size.

$C_{60}{\cdot}5C_6H_5OH$ crystallizes in the triclinic space group $P\bar{1}$ with one formula unit in the unit cell. The fullerene C_{60} molecule is located on a centre of symmetry (Wyckoff position 1*f,* ½ 0 ½). Despite the low crystallographic symmetry, the symmetry of the molecular structure of the C_{60} molecule is very close to I_h [rms = 0.48 pm^2, module molsym, Platon[11]]. While the C_{60} and two of the phenol molecules are fully ordered, orientational disorder is observed for the third phenol molecule, which is also located on a centre of symmetry (1*e,* ½ ½ 0). A TLS analysis of the ordered part of the molecular structure converges at convincing reliability factors (R_1 = 0.043, Platon) and points toward a slight rigid body librational motion of the fullerene molecule [$(\lambda/°)^2$ = (7.68, 7.04, 4.49)]. Corrections to the C–C bond lengths due to librational shortening ($\langle\Delta d$ = 0.28 pm$\rangle$) are of the same order of magnitude as the corresponding estimated standard deviations and were regarded negligible.

As a general feature, the intramolecular C–C bond lengths of the C_{60} molecule separate into a set of short 6:6 bonds and a set of long 6:5 bonds, exhibiting a remarkably sharp distribution, as measured by the total span ($d_{max.}$ – $d_{min.}$) and the standard deviation within each set (see Table 1 and the discussion below).

Each fullerene molecule is coordinated to four phenol molecules (see part a in Figure 2). The centre-to-centre distances are 660.5 pm (C_{60}–Phenol-0, 2×) and 673.8 pm (C_{60}–Phenol-1, 2×). The phenol molecules coordinate to different structural moieties, i.e. Phenol-0 to a hexagon [C(10), C(11), C(22), C(23), C(24), C(30)] and Phenol-1 to a pentagon [C(14), C(15), C(16), C(28), C(29)] with the closest phenol carbon to hexagon- and pentagon-plane approaches being 311(1) pm and 325(1) pm, respectively. The phenol and C_{60} rings have a virtual co-planar orientation [∠(Phenol-0 ···Hexagon) = 13.63(5) °, ∠(Phenol-1···Pentagon) = 8.95(5) °]. These distance values are shorter than the interlayer separation in graphite [d = 335.6(4) pm[12]], and lie in the range typically found in fullerene to arene π-π-interacting species (300 pm – 350 pm). Thus, π-π complex units, $[C_{60}(C_6H_5OH)_4]$, are present, and may be regarded as the basic building unit of this structure.

The hydroxyl groups of the phenol molecules are connected via almost linear, medium strength hydrogen bonds (d[O(100)-H(100)···O(110)] = 273.9(2) pm, ∠ = 174(2) °). Remarkably, these hydrogen-bonds do not appear between phenol molecules of the same complex unit, $[C_{60}(C_6H_5OH)_4]$, but in a pair wise manner with the phenol molecules of the neighboring complex units along the [100] and [$\bar{1}$00] directions. The Hydrogen-bonds between the complex units are the strongest intermolecular interactions present in this structure. The π-π complex units are connected via hydrogen-bonds to give $^1_\infty[C_{60}(C_6H_5OH)_4]$ rods along [100] (see part b of Figure 2). The overall structure is a distorted square packing of rods[13] in (100) plane. The remaining phenol molecules (Phenol-2) fill voids within the packing, which are located at a centre of symmetry.

Two symmetry equivalent Phenol-0 molecules, belonging to two different $^1_\infty[C_{60}(C_6H_5OH)_4]$ rods along the [011] diagonal

Table 1. Data for selected, reliable crystal structure analyses of C_{60} co-crystals, spans, statistical mean values, and standard deviations for the 6:6 and 6:5 sets of C–C bond lengths, and the results of thermal motion analyses of the structure models.

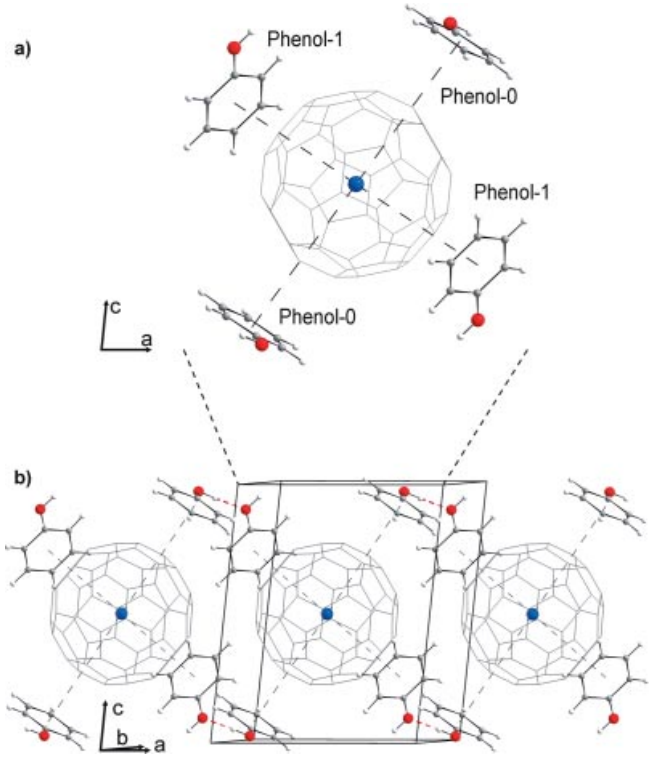

Figure 2. a) Coordination of C_{60} to four phenol molecules to give the supramolecular building unit $[C_{60}(C_6H_5OH)_4]$, and b) interconnection of these units via hydrogen bonds to give $^1_\infty[C_{60}(C_6H_5OH)_4]$ strands along [100]. Blue dots indicate the centers of gravity of the C_{60} molecules, and hydrogen bonds are emphasized in red.

of the square packing pattern, are found to be potential hydrogen-bond acceptors for different, but symmetry equivalent, orientations of the Phenol-2 molecules (d[O(120)···O(100)] = 275.9(3) pm, ∠ = 172(2) °). Thus, the orientational disorder of this particular phenol molecule is a consequence of the requirements of the supramolecular self assembly of the $^1_\infty[C_{60}(C_6H_5OH)_4]$ rods, and the comparably strong hydrogen-bond donor and acceptor capability of phenol.

The shortest intermolecular distances between fullerene molecules within this supramolecular arrangement, with d = 1003.5(1) pm, are observed along [100], i.e. the propagation direction of the $^1_\infty[C_{60}(C_6H_5OH)_4]$ rods, and are found to be significantly higher than those in pristine C_{60} (d = 992.8 pm[14]). While the fullerene-to-fullerene distances along [010] are only slightly higher [d = 1011.7(1) pm], the ones observed along [001] are significantly larger [d = 1264.2(2) pm]. This is due to the spatial requirements of the herring-bone like arrangement of the Phenol-0 and Phenol-1 molecules in the distorted square packing of the $^1_\infty[C_{60}(C_6H_5OH)_4]$ rods, and the occupation of the voids at symmetry site 1e by the orientationally disordered Phenol-2 molecules (Figure 3).

Despite the considerable effort made in determining reliable experimental values for the 6:6 and 6:5 bond lengths, reference data is still subject to review. For comparison, we have selected a set of reliable crystal structure analyses of fullerene co-crystals on the basis of the overall quality, span and standard deviation of the bond length distribution, and

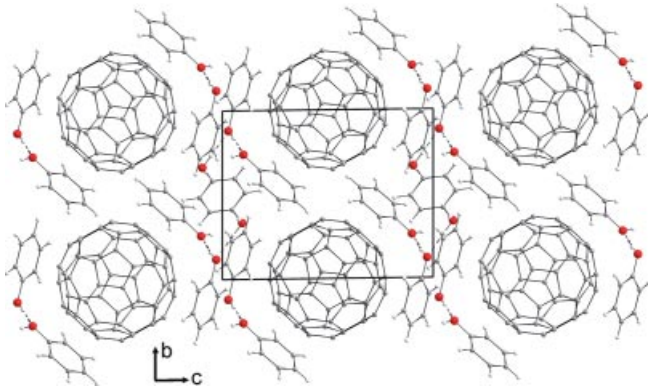

Figure 3. Distorted square packing of the $^1_\infty[C_{60}(C_6H_5OH)_4]$ strands in the (100) plane, the filling of the voids at 1e by further disordered phenol molecules is also shown.

the results of thermal motion analyses in context of the TLS formalism.[15] The data presented in Table 1 and Figure 4 include the overall statistical mean values of the corresponding bond sets within the range of the individual statistical standard deviations. From consideration of the span, as well as the standard deviation, of the reported 6:6 and 6:5 sets of bond lengths, the structure data in this work have to be regarded as the most precise.

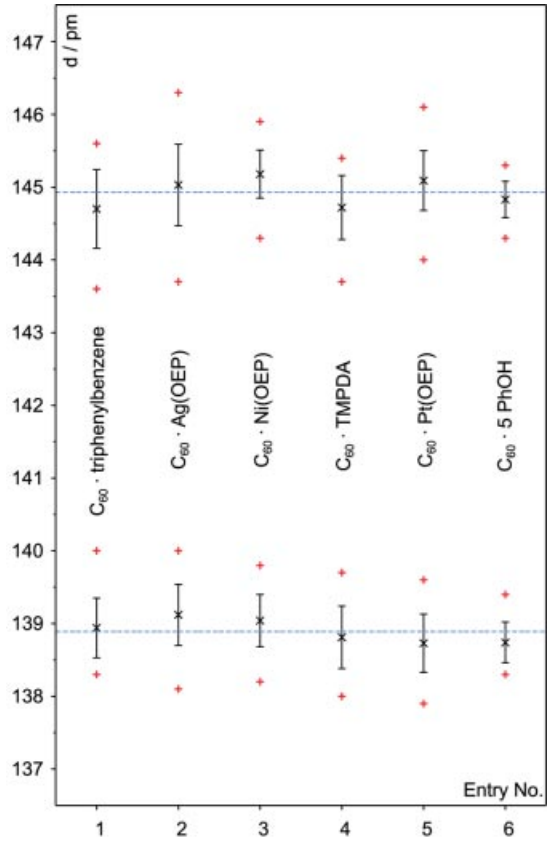

Figure 4. Spans (red), mean values and standard deviations (black) for the selected crystal structure data (Blue dashed lines correspond to the overall mean values of 138.9 pm and 144.9 pm; entry numbers correspond to the appearances of the compound in Table 1).

The kinds of interaction, e.g. pure π-π interactions, multipolar π interactions, and dipole–multipole interactions, and the strength of interaction differ between the various co-crystals. The strength of the overall interaction may be estimated by means of the mean square liberation amplitudes (λ_i, see Table 1). Surprisingly, the reported values do not differ significantly. There is no significant experimental evidence to indicate a change in the molecular structure of C_{60} upon alteration of the nature of a co-crystallization agent. Furthermore, the selected data are, despite the varying spans and standard-deviations, virtually identical and exhibit a significantly higher reliability than the data reported for pristine C_{60}.[14] The mean values are $\langle d_{6:6}\rangle$ = 138.9 pm and $\langle d_{6:5}\rangle$ = 144.9 pm.

Conclusions

Precipitation of $C_{60}{\cdot}5C_6H_5OH$ from a homogeneous solution of C_{60} in triphenylphosphite yields single crystals of high quality. The combination of hydrogen-bonding and π-π interactions leads to a distorted square packing of $^1_\infty[C_{60}(C_6H_5OH)_4]$ strands, in which the fullerene molecules are fully ordered. The 6:6- and 6:5-bond lengths were determined to be 138.74(28) pm and 144.83(25) pm, respectively. A careful analysis of selected, reliable structure data for C_{60}-co-crystals hints to i) no significant influence of the co-crystallization agent, and ii) $\langle d_{6:6}\rangle$ = 138.9 pm and $\langle d_{6:5}\rangle$ = 144.9 pm for the 6:6 and 6:5 bond lengths, respectively.

Experimental Section

Commercially available C_{60} (5 mg, 99.9%, MER Corporation, USA) was dissolved in triphenylphosphite (10 mL, >97% purity, Fluka). The violet solution was hydrolyzed slowly by exposure to water vapor under ambient conditions. During a period of ten days, the solution turned brown and then red, and plate-shaped crystals of $C_{60}{\cdot}5\ C_6H_5OH$ had formed. The crystals could be stored without any sign of decomposition in the mother liquid at 35 °C, which was necessary to prevent the crystallization of the phenol. Upon separation from the mother liquid, the crystals turned black within hours, this color change was accompanied by total loss of crystallinity.

A crystal suitable for X-ray diffraction was transferred into inert oil, picked with a loop and cooled rapidly to 100 K. Intensity data were collected on a SMART-APEX CCD X-ray diffractometer (Bruker) at 100 K with graphite-monochromated Mo-K_α radiation. A total of 1800 frames were collected with an exposure time of 30 s/frame. The reflection intensities were integrated using the SAINT[16] subprogram in the SMART[17] software package. Intensities were corrected for absorption effects by the application of a semi-empirical method (SADABS[18]). A total of 10841 reflections were measured, 5623 of which were independent, and 3584 of which had intensities greater than 2σ. The crystal structure was solved by direct methods and subsequent Fourier syntheses (SHELXS[19]). All non-hydrogen atoms were refined anisotropically (SHELXL[19]). Hydrogen atoms were located from the residual electron density map and refined individually with isotropic thermal parameters fixed to 1.2 and 1.5 times that of the equivalent isotropic displacement parameter of the carbon or oxygen atom to which it is bound. The disordered hydrogen atom, H(121), was fixed using the HFIX command.

In order to elucidate the nature of the disorder of the phenol-2 molecule, the structure was also solved and refined in space group $P1$. Two oxygen atoms at the 1,4 positions of the phenol-2 molecule (in $P\bar{1}$) were located in the residual electron density maps, and refined to a occupancy of ½, i.e. refined as an orientationally disordered phenol molecule, but not as a hydroquinone molecule. The

implementation of this disorder model, as well as the application of an inversion-twin law, enabled the refinement to converge to virtually the same residuals as the refinement of the structure model in space group $P\bar{1}$, but the model in *P*1suffered from strong pair wise correlation of positional and anisotropic displacement parameters for all the atoms, and exhibited esd values about four times higher for the C–C bond lengths than for the disordered structure model in $P\bar{1}$. Furthermore, no indications to the presence of a superstructure or modulation were observed. Thus, we conclude C_{60}·$5C_6H_5OH$ crystallizes in space group $P\bar{1}$ with phenol-2 being orientationally disordered, due to the structural boundary conditions set by the supramolecular motif. Further details of the structure analysis and selected bond lengths are given in Table 2 and Table 3.

CCDC-267147 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Raman spectra were recorded on individual single-crystals, which were protected by a thin layer of the mother liquid, with a microscope laser Raman system (Jobin–Yvon, LabRam) operating at an excitation wavelength of 784.7 nm at 20 mW. Bands corresponding exclusively to C_{60} were observed (270, 432, 492, 772, 1424, 1468 cm^{-1}). The deviations from the resonances of pristine C_{60}[20] are not larger than 3 cm^{-1}, which is expected for non-ionic molecular crystals.

Biomimetic Thiolate Alkylation with Zinc Pyrazolylbis(thioimidazolyl)borate Complexes

Mohamed M. Ibrahim,[a] Guosen He,[a] Jan Seebacher,[a] Boumahdi Benkmil,[a] and Heinrich Vahrenkamp*[a]

Keywords: Bioinorganic chemistry / Enzyme models / N,S ligands / Thiolates / Zinc

The NS_2ZnX coordination in thiolate-alkylating zinc enzymes is reproduced in (tripod)ZnX complexes with substituted pyrazolylbis(thioimidazolyl)borate tripod ligands. Intermediate (tripod)Zn nitrates and perchlorates are converted into (tripod)Zn thiolates, including the biologically relevant homocysteinate. Methylation with CH_3I converts these to (tripod)ZnI and the corresponding thioethers CH_3SR, including methionine. A kinetic investigation has shown the alkylations to be intramolecular S_N2 processes that take place at the zinc-bound thiolates. They are considerably faster for the $(NS_2)Zn$ thiolates than for the (N_2S)- and $(N_3)Zn$-thiolates with similar pyrazolylborate-derived tripod ligands, in agreement with Nature's choice of an NS_2 donor set for zinc.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

In two classes of zinc enzymes, a subgroup of the alcohol dehydrogenases and a subgroup of the thiolate alkylating enzymes, the zinc ion is in the unusual $(NS_2)ZnX$ coordination, with N representing histidine, S representing cysteinate, and X being the catalytic site.[1,2] Thus, as a complex the $(NS_2)ZnX$ unit is an uncharged molecular species, and the reacting substrates (alkoxides or thiolates) convert this into an anionic complex upon coordination to zinc. Obviously, this is of advantage for the reactions to be catalyzed (removal of a hydride from the α-carbon of the alkoxide or attack of the alkylating agent at the zinc-bound thiolate) due to the enhanced electron density at the substrates.

On the other hand, it is difficult to reproduce these bonding situations and chemical reactions in coordination compounds of zinc.[3] At present, alcohol dehydrogenase modeling has not gone beyond structural mimics, and thiolate alkylation has not yet been achieved for a thiolate bound to zinc in an anionic complex. Thiolate alkylation in other types of zinc complexes has, however, been performed in a number of cases. Thus, thiolates bound to ZnN_2O,[4,5] ZnN_2S,[5–7] $ZnNS_2$,[8] and ZnS_3 units[9] have been subjected to alkylations by our competitors in this field. The only anionic thiolate complex used for such reactions, $Zn(SPh)_4^{2-}$,[10] was found to dissociate prior to alkylation.

Our own contributions to this field have involved zinc thiolates with bidentate N_2[11] and tridentate N_2S ligands,[12] as well as the tris(pyrazolyl)borate as N_3 tripods.[13] During these studies it became obvious that the tripods of the pyrazolylborate type are the best substitutes for the biological ligand environment of zinc, as observed before,[14] due to their synthetic variability, which allows the encapsulation of the metal in a favorable way. It therefore seemed promising to us to use sulfur-containing pyrazolylborate ligands for studies of this kind, that is, to investigate the alkylation of **L**·Zn-SR complexes in which the ligands **L** are pyrazolylborate-derived tripods with N_2S, NS_2, and S_3 donor sets. A complete series of such ligands with substituted thioimidazolyl groups as sulfur donors is available now: after Reglinski's discovery of the tris(thioimidazolyl)borates,[15] Parkin[16] and ourselves[17] introduced the pyrazolylbis(thioimidazolyl)borates, and very recently we added the final member, the bis(pyrazolyl)(thioimidazolyl)borates.[18]

Following our introductory study on the alkylation of tris(pyrazolyl)boratozinc thiolates,[13] in the second part of the investigation we used the bis(pyrazolyl)(thioimidzolyl)-boratozinc thiolates.[19] The major, and unexpected, observation of this study was that the thiolate alkylations are slower than those of the tris(pyrazolyl)boratozinc thiolates, despite the increased electron density of the complexes. It remained to be demonstrated, however, that the trend continued for the (pyrazolyl)bis(thioimidazolyl)boratozinc thiolates. This is the subject of the present study, which is the third in the series. Work on part four, concerning the tris(thioimidazolyl)boratozinc thiolates, is in progress.

The zinc thiolate complexes of the present study, representing the $(NS_2)Zn$-SR ligand environment, are the closest structural models of the thiolate-alkylating zinc enzymes so far.[2,3] We chose $\mathbf{L^1}$ and $\mathbf{L^2}$ as the NS_2 ligands. The substitution pattern on their pyrazolyl and thioimidazolyl groups

[a] Institut für Anorganische und Analytische Chemie der Universität Freiburg,

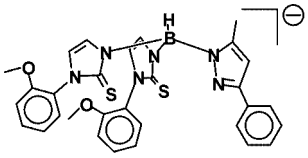
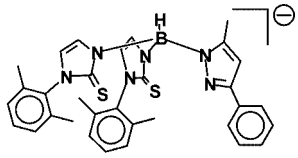
was meant to provide encapsulation of the zinc ion in a hydrophobic pocket. This was achieved for the pyrazolyl units in the usual way[14] by 3-phenyl-5-methyl substitution. The thioimidazolyl units bear *N*-phenyl groups with *ortho* substituents. This was found to be favorable for encapsulation as it induces the phenyl substituents that point away from the zinc centers to rotate such that their *ortho* positions get placed nearer to the metal.[20]



L¹



L²

Ligands L¹ and L²

L¹ has been described by us previously,[17] and **L²** was prepared by the same procedure from equimolar amounts of the thioimidazole and the pyrazole together with KBH_4 in boiling toluene. In order to purify **L²** it had to be subjected to column chromatography over silica gel. As a result of this the anionic ligand was protonated and isolated as the molecular species **HL²**. This is not unprecedented in the chemistry of the tris(pyrazolyl)borates.[21,22] We are, however, not aware of the existence of the protonated form of a pyrazolylborate-based heteroscorpionate like **HL²**. After isolating **HL²** it was straightforward to convert it into K**L²**, the standard form of all these tripod ligands, by treating it with KOH in methanol.

The identity of **HL²** was revealed by an X-ray structure determination (Figure 1). Compound **HL²** can be considered a zwitterion, with the positive charge on the protonated pyrazole nitrogen and the negative charge on boron. Although the pyrazole nitrogen is the only reasonable position for protonation, the NH hydrogen could not be located with certainty or refined freely. The geometry around the boron atom is close to ideally tetrahedral, and the B–N bond lengths are in the normal range for pyrazolylborates.[22] Unlike in the complexes of such ligands where the N and S donor atoms are locked in place by coordination to the metal, they seem to be locked in this free ligand by weak hydrogen bonds. One of these attaches one of the thioimidazole sulfur atoms to the oxygen atom of a co-crystallized methanol molecule, and the other links the pyrazole nitrogen atom with the other thioimidazole sulfur atom. This latter hydrogen bond serves as a reminder that the proton in question may actually be bound to sulfur rather than to nitrogen.

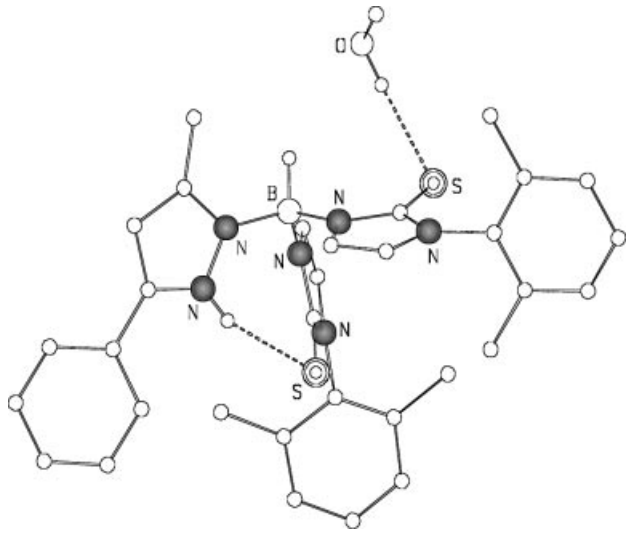


Figure 1. Molecular structure of **HL²**. Relevant distances [Å] and angles [°]: B–N 1.555, 1.534 and 1.550(4), C–S 1.677 and 1.695(3); N–B–N 108.1, 110.2, and 111.7(3); S···N 3.10; S···O 3.27.

Basic Complexes

While with the tris(pyrazolyl)borate ligands the starting point for all functional zinc complexes are the Zn–OH compounds,[14] these compounds have not been isolated yet with the pyrazolylbis(thioimidazolyl)borate ligands.[17] Instead, perchlorate and nitrate were found to be labile enough to be displaced from zinc by even weakly coordinating donors. Therefore, in addition to complexes **1a** and **1b** already described for ligand **L¹**,[17] the corresponding complexes **2a** and **2b** were prepared here for ligand **L²**. They resulted from the reaction of **HL²** with the zinc salts in methanol. It can be assumed that **2a** and **2b**, just like **1a** and **1b**,[17] contain the oxoanions attached to zinc through one of their oxygen atoms. As considerable amounts of complexes **1** and **2** are lost in the isolation process, further reactions with them were usually carried out by using them in situ.

When doing reactions with complexes **1** and **2**, or when trying to prepare further **L**Zn-X complexes by combining K**L** and ZnX_2, we observed many times, as before,[17] that these systems have a very high tendency to dismutate into ZnL_2 and ZnX_2. This is one of the reasons why the desired **L**Zn–OH complexes have evaded us so far and why the derivative chemistry with **L**Zn units is not nearly as rich as that of the tris(pyrazolyl)boratozinc units. For example, the attempted syntheses of **L²**Zn acetate from **HL²** and zinc acetate resulted in **3b**. The structure of **3b** (see Table 1 below and data deposited under CCDC-268609) complements those of other related ZnL_2 complexes.[16,17]

ZnL^1_2 ZnL^2_2

3a **3b**

On the other hand, halides coordinate readily to these **L**Zn units. Like other such **L**Zn halide complexes,[17] the iodides **4a** and **4b** were prepared here from the ligands and ZnI_2. They were fully characterized, including structure determinations for reference purposes, as they are one of the products of each of the alkylation reactions described below.

L^1Zn-I L^2Zn-I

4a **4b**

The structure of **4b** is shown in Figure 2, mainly for comparison with the structure of the free ligand in Figure 1. The tetrahedral coordination of zinc (bond angles 104–113°) and the Zn–N, Zn–S, and Zn–I bond lengths correspond to those reported for related **L**ZnI complexes.[17,23] One can say that in HL^2 the proton of the N–H···S hydrogen bond has the same role as the zinc ion in **4b** in fixing the orientation of the pyrazole and one thioimidazole of the ligand, but that in **4b** coordination to zinc overcomes the tendency of the second thioimidazole to point away from the center of the molecule. This comparison offers one explanation for the high tendency of formation of the ZnL_2 complexes, in which also only two donor units of the tripod are fixed, while the third is free and pointing away from the complex center.

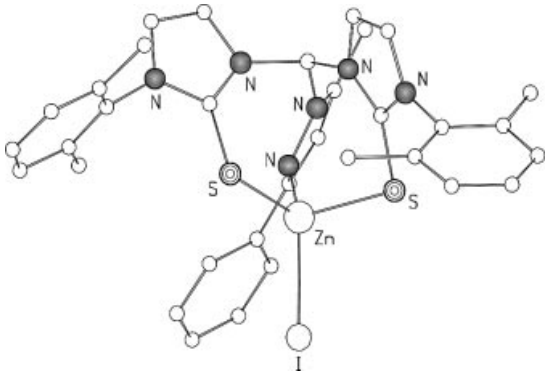

Figure 2. Molecular structure of L^2ZnI (**4b**). Relevant bond lengths [Å]: Zn–N 2.039(3), Zn–S 2.338 and 2.320(2), Zn–I 2.533(2).

Thiolates

While the preparation of (tripod)ZnSR complexes for the tris(pyrazolyl)borate[13] and bis(pyrazolyl)(thioimidazolyl)-borate tripods[18] is straightforward, in this case it required careful control of the reaction conditions. The high tendency of formation of the bis(ligand)complexes **3** and the oligomeric zinc bis(thiolates) prevented the isolation of most of the desired thiolate complexes with tripod L^2, and it allowed the isolation of the alkyl- and benzylthiolate complexes of tripod L^1 only when carefully controlling the reaction conditions. Only with the least electron-rich *p*-nitrothiophenolates was it easy to obtain the **L**ZnSR complexes.

Complexes **5a**–**c** and **6d** were prepared from the perchlorates **1b** and **2b** and the corresponding thiolates. Complex **5d** could be obtained in a one-pot synthesis from *p*-nitrothiophenol, $NaOCH_3$, $Zn(NO_3)_2{\cdot}6H_2O$, and KL^1. Likewise, the homocysteine derivative **5e**, which is the closest representation of the reactive intermediate in the synthesis of methionine from homocysteine by cobalamine-independent methionine synthase[2] reported so far, was prepared from *N*-acetylhomocysteine ethyl ester, NaOH, $Zn(NO_3)_2{\cdot}6H_2O$, and KL^1 in methanol. As mentioned above, **5a** and **5b** are very labile, dismutating in solution to $[Zn(SR)_2]_n$ and the ZnL_2 complex **3a**.

L^1Zn-SR L^2Zn-SR

5a-e **6d**

a: R = C_2H_5, **b**: R = $CH_2C_6H_5$, **c**: R = C_6H_5,

d: R = C_6H_4-p-NO_2, **e**: R = $CH_2CH_2CH(COOEt)NHAc$

The structures of the two most stable thiolate complexes (**5d** and **6d**) were determined. They are closely related, making it sufficient to display only the structure of **6d** in Figure 3. The coordination of zinc is severely distorted tetrahedral, with the largest angle (ca. 123°) being that between the pyrazole nitrogen and the thiolate sulfur and the smallest angle (ca. 101°) being that between the pyrazole nitrogen and one of the thioimidazolyl sulfurs. The Zn–N and Zn–S distances concerning the tripod ligand compare well with those in the other pyrazolylbis(thioimidazolyl)boratozinc complexes (this work and ref.[17]). The Zn–S (thiolate) bond lengths of 2.28 Å in both **5d** and **6d** are not much different

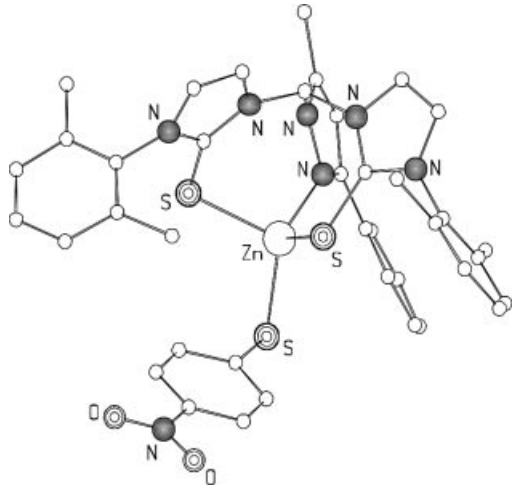

Figure 3. Molecular structure of the thiolate complex **6d**. Relevant bond lengths [Å]: Zn–S (tripod) 2.362(1) and 2.341(1), Zn–S (thiolate) 2.285(1), Zn–N 2.038(3).

from those in the related zinc *p*-nitrothiophenolate complexes of a tris(pyrazolyl)borate[13] and a bis(pyrazolyl)-(thioimidazolyl)borate ligand[19] [2.25 and 2.25 Å (av.) respectively]. A notable feature of the structure of **6d** is the orientation of one of the *o*-dimethylphenyl rings. As anticipated, it is rotated to such a degree that one of the methyl groups contributes to the encapsulation of the zinc ion in a similar way as the phenyl substituent on the pyrazole ring.

Methylation Reactions

As before for the N_3- and N_2S-ligated zinc thiolates,[13,19] all thiolate complexes **5** and **6** were subjected to methylation with methyl iodide in chloroform. In each case the reactions proceeded according to Equation (1) and, according, to ^{1}H NMR spectroscopy, they were quantitative. The solid reaction products **L**ZnI (**4a** and **4b**) were isolated, and the thioethers CH_3SR were identified by NMR spectroscopy; there were no other reaction products in the solutions.

$$\mathbf{L}ZnSR + CH_3I \rightarrow \mathbf{L}ZnI + CH_3SR \quad (1)$$

The ethyl and benzyl thiolates **5a** and **5b** reacted within minutes, whereas the phenyl and homocysteinyl thiolates **5c** and **5e** needed about an hour. Even the methylations of the *p*-nitrothiophenolates **5d** and **6d** came to completion within a few hours. This is in marked contrast to the reactions of the N_3- and N_2S-ligated zinc-*p*-nitrothiophenolates. Those of the tris(pyrazolyl)borates were found not to proceed at all at room temperature,[13] and those of the bis(pyrazolyl)-(thioimidazolyl)borates took weeks to come to completion. These observations lead to the rough estimate that the NS_2-ligated zinc thiolates react about two orders of magnitude faster than the N_3- and N_2S-ligated ones. Further work is needed to quantify this statement.

The popular alternative alkylating agent trimethylphosphate was also used here. We had found before that, under forcing conditions (i.e. in boiling DMSO), it does lead to methylation of neocuproinzinc bis(thiolates)[11] and of zinc thiolates bearing a tridentate N_2S ligand.[12] Yet, even under these forcing conditions, it reacted extremely slowly with the zinc thiolates bearing tripodal N_2S ligands.[19] This was now observed for complex **5d** too. In boiling DMSO it took three days to methylate about one third of the thiolate with $PO(OMe)_3$. While this is again about one to two orders of magnitude faster than the corresponding methylation of the complex ligated with a bis(pyrazolyl)(thioimidazolyl)borate,[19] it demonstrates again that zinc thiolate model complexes are not nearly as reactive as the thiolate-alkylating zinc enzymes, which employ such mild alkylating agents as methyl tetrahydrofolate.[2]

Kinetic data were obtained for the methylations of **5d** and **6d** with methyl iodide in $CDCl_3$ at 300 K. We found it convenient to record the intensity of the ^{1}H NMR signal of the SCH_3 group of the resulting *p*-nitrothioanisole during the kinetic runs. Complexes **5d** and **6d** were treated under pseudo-first-order conditions with a four- to tenfold excess of CH_3I. From the SCH_3 signal intensities, recorded for at least five $t_{½}$ intervals (see Figure 4), the pseudo-first-order rate constants were obtained according to $\ln(I_t - I_0) = \ln(I_\infty - I_0) - k_{obs} \times t$.

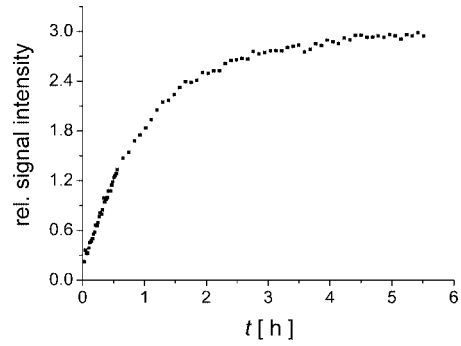

Figure 4. Intensities of the CH_3 ^{1}H NMR signals of $CH_3SC_6H_4$-*p*-NO_2 resulting from the reaction of **5d** with a sixfold excess of CH_3I.

The log plots for five different excess concentrations of CH_3I were linear with correlation coefficients greater than 0.995. The resulting k_{obs} values, plotted against the CH_3I concentrations (see Figure 5), define regression lines passing through the origin with correlation coefficients greater than 0.998. The second-order rate constants of the thiolate alkylations, taken from the slopes of these regression lines, are $8.5(1) \times 10^{-3}$ M^{-1} s^{-1} for **5d** and $1.5(1) \times 10^{-3}$ M^{-1} s^{-1} for **6d**.

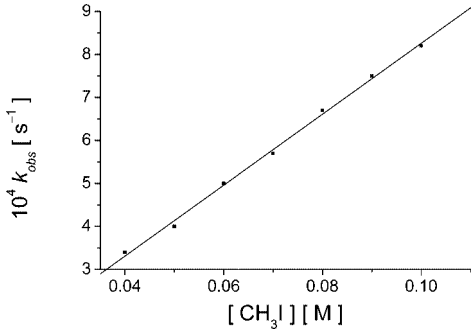

Figure 5. Plot of the pseudo-first-order rate constants against the CH_3I concentration for the methylation of **5d**.

Again, the clean second-order reactions support the statement that the alkylations occur at the zinc-bound thiolates, as proposed for the enzymes.[2,3] At present their rates can be compared only to one another, as comparable rates for other *p*-nitrothiophenolate complexes are not available. The fact that **5d** reacts faster than **6d** can be explained by electronic as well as steric effects: due to the *o*-methoxy substituents **5d** is slightly more electron-rich than **6d**, and the better encapsulation of the reactive center of **6d** (see discussion above) renders the latter less reactive. The fact that the thiolate complexes of this study are considerably more reactive than the previously studied ones with N_3[13] and N_2S tripods[19] certainly relates to the fact that sulfur donor ligands render the zinc ion, and hence the thiolate attached to it, more electron-rich.

Conclusions

The present study, the third in our series on thiolate alkylations of zinc complexes with pyrazolylborate-derived ligands, has yielded model complexes in which the (NS_2) ZnSR ligand environment of the zinc ion correctly reproduces that in the thiolate alkylating zinc enzymes like cobalamin-independent methionine synthase. The simple alkanethiolate complexes are labile, indicating that the electron-richness in these systems is reaching a borderline, comparable to the situation in the $Zn(SR)_4^{2-}$ species, among which the alkanethiolates have been inaccessible to date. Nevertheless, the homocysteinate complex could be prepared and methylated to yield methionine, which is the closest reproduction so far of the last step of enzymatic methionine synthesis.

The mechanistic investigation of the alkylation reactions has shown them to be second order and probably intramolecular again. They are significantly faster than the alkylations of the Zn-SR complexes with N_3 and N_2S tripod ligands, as expected due to their increased electron-richness. This relates well with Nature's choice of an NS_2 donor set for zinc in the thiolate-alkylating enzymes.

Nature, however, also uses a $Zn(SR)_4^{2-}$ system to dealkylate phosphate esters in the Ada repair protein.[24] Thus, model systems in the form of zinc complexes with an (S_3) Zn-SR composition are also a valuable subject of investigation. We are at present studying such a model system employing the tris(thioimidazolyl)boratozinc thiolates. The results of this study are to be published as the fourth part of our series on tripod-zinc thiolate complexes.

Experimental Section

General: For the general working and measuring procedures, see ref.[25] Ligand **L¹**,[17] 5-methyl-3-phenylpyrazole,[26] and *N*-(*o*-dimethylphenyl)thioimidazole[27] were prepared according to the published procedures. All other starting materials were commercially available. The methyl thioethers resulting from the methylations,[28–31] including *N*-acetylmethionine ethyl ester,[13] have been described and were identified by their ^{1}H NMR spectra, which are also reported in ref.[13]

A frequent problem with the elemental analyses of this kind of complexes is that the carbon values are outside the accepted range. When this was the case here, at least one additional analysis value (S or Zn) was determined.

Ligand HL²: a) HL²: A mixture of 5-methyl-3-phenylpyrazole (4.20 g, 26.5 mmol), *N*-(2,3-dimethylphenyl)-2-thioimidazole (5.42 g, 26.5 mmol), and KBH_4 (0.72 g, 13.3 mmol) was finely ground and heated to 100 °C in vacuo for 2 h. Then, 400 mL of freshly distilled toluene were added and the mixture refluxed at 160 °C in an oil bath for a week. The solvent was then removed in vacuo, the residue dissolved in dichloromethane, and filtered through celite. Chromatography through a 3 × 30 cm silica gel column with a gradient solvent system (dichloromethane/acetone, 200:0 → 200:4) yielded raw **HL²**. Repeating the chromatography yielded 5.32 g (69%) of **HL²** as a colorless powder, m.p. 194 °C. $C_{32}H_{33}BN_6S_2$ (576.60): calcd. C 66.78, H 5.60, N 14.60, S 11.14; found C 66.69, H 5.93, N 13.95, S 10.49. ^{1}H NMR ($CDCl_3$): δ = 2.25 [s, 6 H, Me(Ph)], 2.29 [s, 6 H, Me(Ph)], 2.92 [s, 3 H, Me(pz)], 6.78 [s, 1 H, H(pz)], 6.80 [d, J = 2.2 Hz, 2 H, H(im)], 7.20 [d, J = 2.2 Hz, 2 H, H(im)], 7.29 (m, 1 H, Ar), 7.33 (s, 3 H, Ar), 7.42 (m, 2 H, Ar), 7.64 (m, 3 H, Ar), 7.96 (m, 2 H, Ar) ppm.

b) KL²: 20 mL of a 0.1 M solution of KOH in methanol (2.00 mmol) was added dropwise to a solution of **HL²** (1.15 g, 2.00 mmol) in 20 mL of methanol. The solvent was removed in vacuo, the residue dissolved in dichloromethane, and the product precipitated by addition of petroleum ether (50–70 °C). Recrystallization from dichloromethane/heptane by slow evaporation yielded 0.71 g (58%) of **KL²** as a colorless powder, m.p. 240 °C (dec.). $C_{32}H_{32}BKN_6S_2$ (614.69): calcd. C 62.53, H 5.25, N 13.67, S 10.43; found C 62.75, H 5.42, N 13.28, S 10.14. ^{1}H NMR ($CDCl_3$): δ = 1.92 [s, 6 H, Me(Ph)], 1.96 [s, 6 H, Me(Ph)], 2.16 [s, 3 H, Me(pz)], 6.24 [s, 1 H, H(pz)], 6.43 [s, 2 H, H(im)], 6.47 [s, 2 H, H(im)], 6.98 (s, 1 H, Ar), 7.05 (m, 5 H, Ar), 7.30 (m, 2 H, Ar), 7.62 (m, 3 H, Ar) ppm.

Complex 2a: A solution of **HL²** (0.057 g, 0.10 mmol) in 20 mL of methanol was added with stirring to a solution of $Zn(NO_3)_2{\cdot}6H_2O$ (0.030 g, 0.10 mmol) in 20 mL of methanol. After stirring for 15 h the solvent was removed in vacuo and the residue dissolved in 20 mL of dichloromethane. After washing with water the dichloromethane solution was filtered through celite. The filtrate was then reduced to 5 mL in vacuo. Slow diffusion of *n*-pentane into the solution yielded 32 mg (46%) of **2a** as colorless crystals, m.p. 215 °C (dec.). $C_{32}H_{32}BN_7O_3S_2Zn$ (702.98): calcd. C 54.67, H 4.59, N 13.95, S 9.12; found C 54.98, H 4.49, N 13.36, S 8.73. ^{1}H NMR ($CDCl_3$): δ = 1.89 [s, 6 H, Me(Ph)], 1.93 [s, 6 H, Me(Ph)], 2.43 [s, 3 H, Me(pz)], 6.36 [s, 1 H, H(pz)], 6.77 [d, J = 2.1 Hz, 2 H, H(im)], 7.01 [d, J = 2.1 Hz, 2 H, H(im)], 7.04 (s, 2 H, Ar), 7.13–7.31 (m, 2 H, Ar), 7.45 (m, 6 H, Ar), 7.75 (s, 1 H, Ar) ppm.

Complex 2b: Prepared as **2a** from **HL²** (0.115 g, 0.20 mmol) in 50 mL of methanol and $Zn(ClO_4)_2{\cdot}6H_2O$ (0.074 g, 0.20 mmol) in 40 mL of methanol. Yield: 67 mg (45%) of **2a** as colorless crystals, m.p. 194 °C. $C_{32}H_{32}BClN_6O_4S_2Zn$ (740.43): calcd. C 51.91, H 4.36, N 11.35, S 8.66; found C 52.26, H 4.83, N 11.20, S 8.65. ^{1}H NMR ($CDCl_3$): δ = 1.70 [s, 3 H, Me(Ph)], 1.77 [s, 3 H, Me(Ph)], 1.83 [s, 3 H, Me(Ph)], 1.86 [s, 3 H, Me(Ph)], 2.45 [s, 3 H, Me(pz)], 6.59 [s, 1 H, H(pz)], 6.79 [s, br, 2 H, H(im)], 6.95 [s, br, 2 H, H(im)], 7.00 (s, 2 H, Ar), 7.10 (m, 4 H, Ar), 7.48 (m, 3 H, Ar), 7.87 (m, 2 H, Ar) ppm.

Complex 3b: This complex formed during an attempted synthesis of **L²Zn** acetate. It was prepared as **2a** from **HL²** (0.115 g, 0.20 mmol) and $Zn(OAc)_2{\cdot}6H_2O$ (0.044 g, 0.20 mmol). Workup yielded 144 mg (59%) of **3b** as colorless crystals, m.p. 210 °C (dec.). $C_{64}H_{64}B_2N_{12}S_4Zn$ (1216.6): calcd. C 63.19, H 5.30, N 13.82, S 10.54; found C 62.76, H 5.37, N 13.71, S 10.48. ^{1}H NMR ($CDCl_3$): δ = 1.60 [s, 3 H, Me(Ph)], 1.79 [s, 3 H, Me(Ph)], 1.83 [s, 3 H, Me(Ph)], 1.88 [s, 3 H, Me(Ph)], 2.66 [s, 3 H, Me(pz)], 6.28 [s, 1 H, H(pz)], 6.43 [d, J = 2.1 Hz, 2 H, H(im)], 6.49 [d, J = 2.1 Hz, 2 H, H(im)], 6.99 (s, 1 H, Ar), 7.02 (m, 2 H, Ar), 7.06 (s, 1 H, Ar), 7.17 (m, 3 H, Ar), 7.28 (m, 2 H, Ar), 7.84 (m, 2 H, Ar) ppm.

Complex 4a: A solution of **KL¹** (301 mg, 0.49 mmol) in 50 mL of methanol was slowly added dropwise, with stirring, to a solution of anhydrous ZnI_2 (155 mg, 0.49 mmol) in 30 mL of methanol. The resulting colorless precipitate was filtered off and the filtrate was reduced in vacuo to 20 mL to produce a precipitate of raw **4a**. Slow diffusion of toluene into a solution of raw **4a** in dichloromethane yielded 257 mg (69%) of **4a** as colorless crystals, m.p. 230 °C (dec.). $C_{30}H_{28}BIN_6O_2S_2Zn$ (771.83): calcd. C 46.69, H 3.66, N 10.89, S 8.31; found C 45.79, H 3.95, N 10.75, S 8.25. ^{1}H NMR ($CDCl_3$): δ = 2.49 [s, 3 H, Me(pz)], 3.85 (s, 6 H, OMe), 6.15 [s, 1 H, H(pz)], 6.91–7.95 [m, 17 H, H(im) + Ar] ppm.

Complex 4b: Prepared as **2a** from **HL²** (57 mg, 0.10 mmol) and anhydrous ZnI_2 (52 mg, 0.16 mmol). Yield: 37 mg (48%) of **4b** as colorless crystals, m.p. 240 °C (dec.). $C_{32}H_{32}BIN_6S_2Zn$ (767.88): calcd. C 50.05, H 4.20, N 10.94, S 8.35; found C 49.84, H 3.96, N 10.95, S 8.03. ^{1}H NMR ($CDCl_3$): δ = 1.93 [s, 6 H, Me(Ph)], 2.08 [s, 6 H, Me(Ph)], 2.40 [s, 3 H, Me(pz)], 6.32 [s, 1 H, H(pz)], 6.73 [d, J = 2.1 Hz, 2 H, H(im)], 7.01 [d, J = 2.1 Hz, 2 H, H(im)], 7.11 (m, 3 H, Ar), 7.19 (s, 2 H, Ar), 7.30 (m, 3 H, Ar), 7.40 (m, 3 H, Ar) ppm.

Complex 5a: A solution of 33 μL (28 mg, 0.45 mmol) of ethanethiol in 5 mL of methanol was deprotonated by addition of 1.8 mL (0.45 mmol) of a 0.25 M solution of $NaOCH_3$ in methanol. A solution of $Zn(ClO_4)_2{\cdot}6H_2O$ (112 mg, 0.30 mmol) in 15 mL of methanol and then a solution of **KL¹** (186 mg, 0.30 mmol) in 40 mL of methanol were added dropwise to this solution with stirring. After stirring for 4 d the volume of the solution was reduced to 15 mL in vacuo. Filtration yielded raw **5a**, which was dissolved in dichloromethane. Slow diffusion of *n*-hexane into this solution precipitated 126 mg (59%) of **5a** as a colorless powder, m.p. 215 °C (dec.). $C_{32}H_{33}BN_6O_2S_3Zn{\cdot}0.25CH_2Cl_2$ (706.05 + 21.23): calcd. C 53.26, H 4.64, N 11.56, S 13.23; found C 53.27, H 4.43, N 11.76, S 13.01. ^{1}H NMR ($CDCl_3$): δ = 1.32 [t, J = 7.4 Hz, 3 H, CH_3(SEt)], 2.48 [s, 3 H, Me(pz)], 2.54 [q, J = 7.4 Hz, 2 H, CH_2(SEt)], 3.71 (s, 6 H, OMe), 5.29 (s, 0.5 H, CH_2Cl_2), 6.31 [s, 1 H, H(pz)], 6.69–6.85 (m, 2 H, Ar), 6.91 [d, J = 2.0 Hz, 2 H, H(im)], 6.99 [d, J = 2.0 Hz, 2 H, H(im)], 7.02–7.05 (m, 4 H, Ar), 7.34 (m, 2 H, Ar), 7.36–7.58 (m, 3 H, Ar), 7.95 (d, J = 7.0 Hz, 2 H, Ar) ppm.

Complex 5b: Prepared as **5a** from 54 μL (56 mg, 0.45 mmol) of benzylmercaptan, $Zn(ClO_4)_2{\cdot}6H_2O$ (112 mg, 0.30 mmol), and **KL¹** (186 mg, 0.30 mmol). Yield: 128 mg (55%) of **5b** as a colorless powder, m.p. 190 °C (dec.). $C_{37}H_{35}BN_6O_2S_3Zn$ (768.12): calcd. C 57.86, H 4.59, N 10.94, S 12.52; found C 57.26, H 4.59, N 11.87, S 11.63. ^{1}H NMR ($CDCl_3$): δ = 2.36 [s, 3 H, Me(pz)], 3.62 (s, 6 H, OMe), 3.38 [s, 2 H, CH_2(Bz)], 6.31 [s, 1 H, H(pz)], 6.69–6.76 (m, 2 H, Ar), 6.90 [d, J = 2.2 Hz, 2 H, H(im)], 6.96 [d, J = 2.2 Hz, 2 H, H(im)], 7.01–7.05 (m, 4 H, Ar), 7.19 (m, 2 H, Ar), 7.30 (m, 2 H, Ar), 7.34 (m, 1 H, Ar), 7.39 (d, J = 1.8 Hz, 2 H, Ar), 7.52 (m, 3 H, Ar), 7.91 (d, J = 7.0 Hz, 2 H, Ar) ppm.

Complex 5c: A solution of thiophenol (45 mg, 0.41 mmol) in 15 mL of methanol was deprotonated by addition of a 0.25 M solution of $NaOCH_3$ in methanol (1.64 mL, 0.41 mmol). This solution was added dropwise with stirring to a solution of **1b** (306 mg, 0.41 mmol) in 40 mL of chloroform. After stirring for 12 h the solvent was removed in vacuo and the residue treated with 20 mL of dichloromethane. The dichloromethane extract was filtered and the filtrate evaporated to dryness. Recrystallization from dichloromethane/methanol (1:1) yielded 194 mg (63%) of **5c** as a colorless powder, m.p. 225 °C (dec.). $C_{36}H_{33}BN_6O_2S_3Zn$ (754.09): calcd. C 57.34, H 4.41, N 11.14, S 12.76; found C 56.87, H 4.36, N 10.85, S 12.63. ^{1}H NMR ($CDCl_3$): δ = 2.48 [s, 3 H, CH_3(pz)], 3.79 (s, 6 H, OMe), 6.34 [s, 1 H, H(pz)], 6.72 (m, 2 H, Ar), 6.82 [d, J = 2.0 Hz, 2 H, H(im)], 6.97 [d, J = 2.0 Hz, 2 H, H(im)], 7.22 (m, 2 H, Ar), 7.29 (m, 2 H, Ar), 7.36 (d, J = 1.8 Hz, 2 H, Ar), 7.39 (m, 1 H, Ar], 7.50–7.60 (m, 5 H, Ar), 7.92 (m, 2 H, Ar) ppm.

Complex 5d: A solution of *p*-nitrothiophenol (125 mg, 0.81 mmol) in 30 mL of methanol was treated with 5.0 mL of a 0.25 M solution of NaOH in methanol (1.25 mmol), thereby turning red. A solution of $Zn(ClO_4)_2{\cdot}6H_2O$ (240 mg, 0.81 mmol) in 15 mL of methanol was slowly added dropwise, with stirring, to the red solution, which turned yellow. Finally, a solution of **KL¹** (500 mg, 0.81 mmol) in 50 mL of methanol was slowly added with stirring, upon which a yellow precipitate formed. Filtration and drying in vacuo yielded 279 mg (43%) of **5d** as a yellow powder, m.p. 200 °C. $C_{36}H_{32}BN_7O_4S_3Zn$ (799.09): calcd. C 54.11, H 4.04, N 12.27, S 12.04; found C 54.68, H 4.24, N 12.60, S 10.75. ^{1}H NMR ($CDCl_3$): δ = 2.51 [s, 3 H, Me(pz)], 3.82 (s, 6 H, OMe), 6.31 [s, 1 H, H(pz)], 6.92 [d, J = 2.1 Hz, 2 H, H(im)], 7.01 [d, J = 2.1 Hz, 2 H, H(im)], 7.35 (m, 11 H, Ar), 7.55 (d, J = 8.8 Hz, 2 H, $C_6H_4NO_2$), 7.83 (m, 2 H, Ar), 8.11 (d, J = 8.8 Hz, 2 H, $C_6H_4NO_2$) ppm.

Complex 5e: Prepared as **5d** from *N*-acetylhomocysteine ethyl ester (168 mg, 0.82 mmol), NaOH (21.7 mg, 0.82 mmol), $Zn(NO_3)_2{\cdot}4H_2O$ (214 mg, 0.82 mmol), and **KL¹** (506 mg, 0.82 mmol). Yield: 390 mg (56%) of **5e** as a colorless powder, m.p. 200 °C (dec.). $C_{38}H_{42}BN_7O_5S_3Zn$ (849.19): calcd. C 53.75, H 4.98, N 11.55, S 11.33; found C 53.62, H 4.84, N 11.75, S 11.46. ^{1}H NMR ([D_6]DMSO): δ = 1.15 [t, J = 6.8 Hz, 3 H, CH_3(Et)], 1.69–1.93 (m, 2 H, CH_2), 1.85 [s, 3 H, CH_3(Ac)], 2.45 [s, 3 H, CH_3(pz)], 2.65–2.76 (m, 2 H, CH_2), 3.78 (s, 6 H, OMe), 4.07 [q, J = 6.8 Hz, 2 H, CH_2(Et)], 4.31 (m, 1 H, CH), 6.47 [s, 1 H, H(pz)], 6.75–7.66 [m, 15 H, H(im) + Ar], 7.91 (m, 2 H, Ar), 8.13 (m, 1 H, NH) ppm.

Complex 6d: A solution of *p*-nitrothiophenol (33 mg, 0.20 mmol) in 30 mL of methanol was deprotonated with 0.8 mL of a 0.25 M solution of NaOH in methanol (0.20 mmol). This solution was slowly added dropwise, with stirring, to a solution of **KL²** (123 mg, 0.20 mmol) in 50 mL of methanol. The resulting yellow precipitate was filtered off and dried in vacuo to yield 81 mg (51%) of **6d** as a yellow powder, m.p. 225 °C (dec.). $C_{38}H_{36}BN_7O_2S_3Zn$ (795.15): calcd. C 57.40, H 4.56, N 12.33, S 12.10; found C 57.41, H 4.68, N 12.37, S 11.98. ^{1}H NMR ($CDCl_3$): δ = 1.89 [s, 6 H, Me(Ph)], 2.07 [s, 6 H, Me(Ph)], 2.43 [s, 3 H, Me(pz)], 6.34 [s, 1 H, H(pz)], 6.75 [d, J = 2.1 Hz, 2 H, H(im)], 6.93 (d, J = 9.0 Hz, 2 H, $C_6H_4NO_2$), 7.02 [d, J = 2.1 Hz, 2 H, H(im)], 7.09 (s, 1 H, Ar), 7.13 (s, 1 H, Ar), 7.19 (m, 7 H, Ar), 7.36 (m, 2 H, Ar), 7.46 (d, J = 9.0 Hz, 2 H, $C_6H_4NO_2$) ppm.

Methylation Reactions: Methyl iodide was used as a 1 M solution in chloroform. Equimolar amounts (0.1–0.2 mmol) of methyl iodide and one of the complexes **5** or **6** were combined in 5 mL of chloroform (for **5e** DMSO was used as the solvent). Reactions were followed by ^{1}H NMR spectroscopy and were found to produce the resulting thioethers quantitatively. After 10 min (**5a**, **5b**), 2 h (**5c, 5e**), or 1 d (**5d**, **6d**) the solvent was removed in vacuo. The residue was washed with two 3-mL portions of diethyl ether and then dried in vacuo. The remaining solid was pure **4a** or **4b**, as seen from the ^{1}H NMR spectrum. Of the resulting thioethers, CH_3SEt was found in the condensate and the others in the diethyl ether extracts, which also contained part of the iodide complexes **4**.

Complex **5a** (44 mg, 0.062 mmol) gave 45 mg (94%) of **4a**.

Complex **5b** (48 mg, 0.062 mmol) gave 43 mg (89%) of **4a**.

Complex **5c** (87 mg, 0.12 mmol) gave 70 mg (79%) of **4a**.

Complex **5d** (88 mg, 0.11 mmol) gave 54 mg (64%) of **4a**.

Complex **5e** (5.1 mg, 006 mmol) gave 2.5 mg (55%) of **4a**.

Complex **6d** (72 mg, 0.09 mmol) gave 33 mg (48%) of **4b**.

Kinetic Measurements: The standard solutions of complexes **5d** and **6d** and of methyl iodide in $CDCl_3$ (99.8%) were kept in the dark. All reagents and the cavity of the NMR spectrometer were thermostatted to 300.0 K before the measurements. The reagents were combined immediately prior to the measurements. The intensities of the ^{1}H NMR resonance of the SCH_3 protons of the resulting *p*-nitrothioanisole were recorded automatically every 100 s and stored for digital data processing. Each kinetic run was repeated once, and the averaged data were used for the calculations.

The initial concentration of **5d** was adjusted to 0.010 M for all seven measurements, during which the concentrations of CH_3I were 0.040, 0.050, 0.060, 0.070, 0.080, 0.090, and 0.100 M. The resulting k_{obs} values for these concentrations were 3.4, 4.0, 5.0, 5.7, 6.7, 7.5, and 8.2×10^{-4} s^{-1}, respectively.

The initial concentration of **6d** was adjusted to 0.033 for all five measurements, during which the concentrations of CH_3I were 0.167, 0.209, 0.251, 0.293, and 0.335. The resulting k_{obs} values for these concentrations were 2.3, 2.9, 3.7, 4.2, and 4.9×10^{-4} s^{-1}, respectively.

Structure Determinations:[32] Crystals of **HL²**, **3b**, and **5d** were obtained by cooling saturated CH_2Cl_2/CH_3OH solutions, those of **4a** by diffusion of toluene into a CH_2Cl_2 solution, and those of **4b** and **6d** by cooling saturated CH_2Cl_2/*n*-pentane solutions. Diffraction data were recorded at room temp. with a Bruker Smart CCD diffractometer. Empirical absorption corrections (SADABS) were applied. The structures were solved by direct methods and refined anisotropically using the SHELX program suite.[33] Hydrogen atoms were included with fixed distances and isotropic temperature factors 1.2-times those of their attached atoms. Parameters were refined against F^2. Drawings were produced with SCHAKAL.[34] Table 1 lists the crystallographic details.

Classical 1,2,4-Triboracyclopentanes and Their Rearrangement into Nonclassical 2-Boryl-1,3-diboracyclobutanes: Intramolecular C–H Bond Activation by a B–B Moiety

David Scheschkewitz,[a] Peter Amseis,[a] Gertraud Geiseler,[a] Werner Massa,[a] Matthias Hofmann,[b] and Armin Berndt*[a]

Keywords: Ab initio computations / Boron heterocycles / Three-centre, two-electron bonds

1,2,4-Triboracyclopentanes **1a–c** in solution spontaneously transform into their nonclassical isomers **2a–c**. These have been characterised by NMR spectroscopy and X-ray structural analyses. Compounds **2a–c** are strongly distorted when compared with the five-membered ring of **1a**, the structure of which was determined for comparison. In addition, the pattern of the substituents at the boron centres in **2a**,**b** is different from that in **1a**,**b**. This can be rationalised on the basis of a rapid topomerisation in **2c** as determined by analysis of its temperature dependent ^{13}C NMR spectra. The environment of the boron centres B1 and B3 is exchanged by transforming the two 3c–2e bonds which both involve B1 into a B2–H and a B1–C 2c–2e bond. This leads to the 2-boryl-1,3-diboracyclobutane **4c** and formation of corresponding new 3c–2e bonds employing B3 gives the topomer of **2c**. The low barrier of this topomerisation reveals that **2a–c** may also be regarded as nonclassical isomers of the 2-boryl-1,3-diboracyclobutanes **4a–c**. Ab initio computations of models at the MP4SDTQ/6-311+G**// MP2/6-311+G** levels support this interpretation. In addition, they show that the transformation of **1u** to **2u** occurs by an intramolecular C–H bond activation process initiated by the B–B moiety. Derivatives of the type **1** and **2** described here represent the first examples of 1,2-diboron heterocycles which can be isolated as classical as well as nonclassical isomers.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Classical forms of unsubstituted 1,2-diboron heterocycles of type **I–III** (Scheme 1) have been computed to be considerably higher in energy than their nonclassical forms **IV–VI**.[1,2] This is due to the two-electron aromaticity of **IV** and homoaromaticity of **V** and **VI**, respectively. The electron deficiency at the boron atoms in **I–III** is reduced in **IV–VI** by formation of two three-centre, two-electron (3c–2e) bonds. Experimentally, derivatives are known for nonclassical **IV**[3] and **V**[2] as well as for classical **II**[4] and **III**.[5] While the boron atoms of all nonclassical species bear only weakly donating substituents, those of the experimentally known classical ones carry amino substituents which strongly reduce the electron deficiency at these boron atoms. As a consequence, isomerisation of the classical compounds **II** or **III** into nonclassical compounds of type **V** or **VI** has not been observed so far. Recently, 1,2,4-triboracyclopentanes with only weakly donating substituents at the boron atoms became accessible in their classical form **1**.[6]

In this paper we show that 1,2,4-triboracyclopentanes **1a–c** (Scheme 2) isomerise into nonclassical isomers **2a–c**. Ab initio computations at the MP2/6-311+G** level[7] for the prototypes **1u** and **2u** (Scheme 3) reveal that these transformations are intramolecular C–H bond activations by B–B moieties. However, **2a**,**b** are isomers of the products to be expected from these C–H bond activations in **1a**,**b**. This discrepancy can be rationalised by an additional rearrangement via **4a**,**b** (Scheme 4) which shows up in **2c** as a topomerisation via **4c**. Therefore, compounds of type **2** may be regarded equally well as nonclassical 1,2,4-triboracyclopentanes and as nonclassical 2-boryl-1,3-diboracyclobutanes.

Results and Discussion

Syntheses and NMR Characterisation

Details of the preparation of 1,2,4-triboracyclopentanes **1a**,**b**[6] and **1d**[6] are described in the experimental section. Compound **1d** does not react with duryllithium to yield **1c** which, finally, was synthesised by oxidation of its dianion $\mathbf{1c^{2-}}$. This can be obtained by addition of duryllithium to the borenate **3**.[6] In $CDCl_3$ solution, **1a**,**b** transform into their nonclassical isomers **2a**,**b** within four and nine days, respectively. Isomerisation of **1c** into **2c** requires only 2 h in diethyl ether. Interestingly, $CDCl_3$ solutions of the stereo-

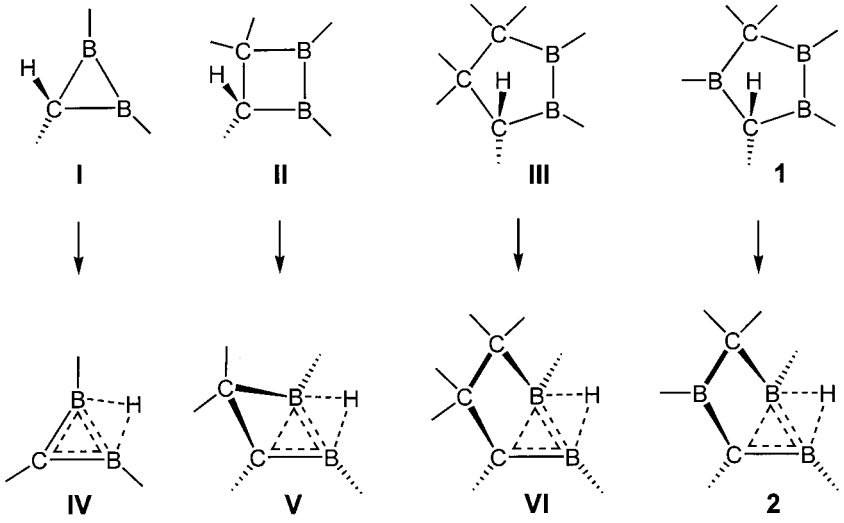
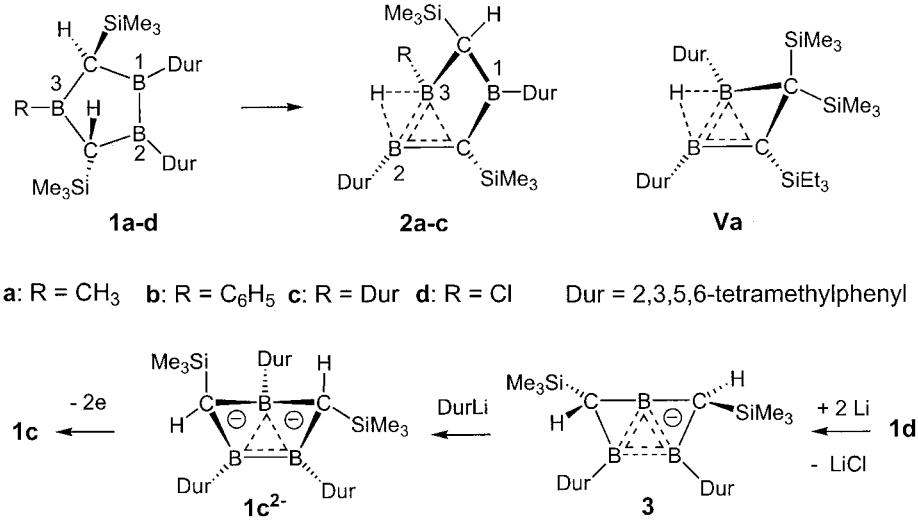


Scheme 1.



Scheme 2.

isomers of **1a**,**b** having the trimethylsilyl substituents in *cis* positions[8] do not show any isomerisation over a period of three months.

Compounds **2a–c** were characterised by ^{1}H, ^{13}C and ^{11}B NMR spectroscopy. The chemical shifts of the skeleton atoms of **2a**,**b** are in good agreement with those computed for **2u** at the IGLO/II/MP2/6-31+G* level and resemble those of **Va** (see Table 1).

Table 1. Selected NMR chemical shifts [ppm] of **2a**–**c**, **Va** (exp.) and **2u** (calcd. at IGLO/II/MP2/6-31+G*).

	2a	**2b**	**2c**	**2u**	**Va**

δ^{11}B B2[a]	48	42	ca. 47[b]	46.9	
δ^{11}B B1[a]	56	57	ca. 47[b]	48.5	48[d]
δ^{13}C C1[a]	74.6	70.7	105	72.6	68.2[e]
δ^{13}C C2[a]	27.6	26.8	24.8	16.6	32.1[f]

[a] Numbering as in Figures 1, 2, 3 and 4. [b] Broad signal. [c] B1. [d] B2. [e] C3. [f] C4.

These chemical shifts are characteristic for homoaromatic species containing a 3c–2e bond between one carbon and two boron atoms. Compounds **2a–c** are rare examples of homoaromatics having two-membered homobridges. The boron centres B1 of **2a**,**b**, which are not part of the 3c–2e bond, are considerably shielded (48, 42 ppm) compared with those of **1a**,**b** (88, 82 ppm). This can be explained mainly by the interactions of the formally empty p orbital at B1 with the 3c–2e bond between B2, B3 and C1 (see NBO analysis of **2u** in section "Ab initio computations").

The substitution patterns at the boron atoms of **2a**,**b** are different from those of the precursors **1a**,**b**. While the boron centres between two carbon atoms carry a methyl or phenyl group in **1a**,**b**, it is a duryl group in **2a**,**b**. The methyl and phenyl substituents are found at a boron atom *adjacent* to a boron atom in **2a**,**b**. This was demonstated for **2a**,**b** by the X-ray structure analyses discussed below and for **2a** in solution by a selectively ^{11}B-decoupled ^{13}C NMR spectrum.

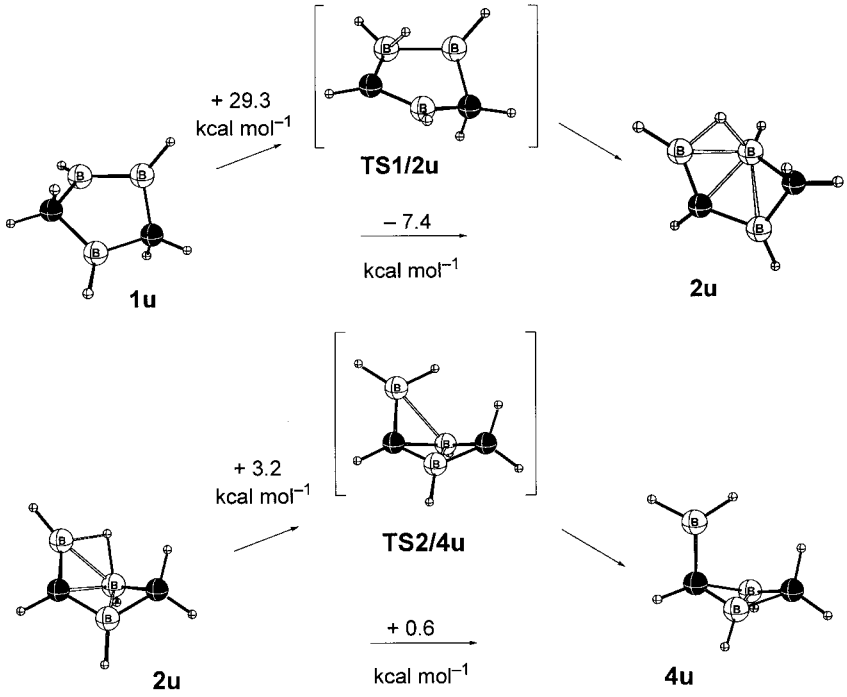
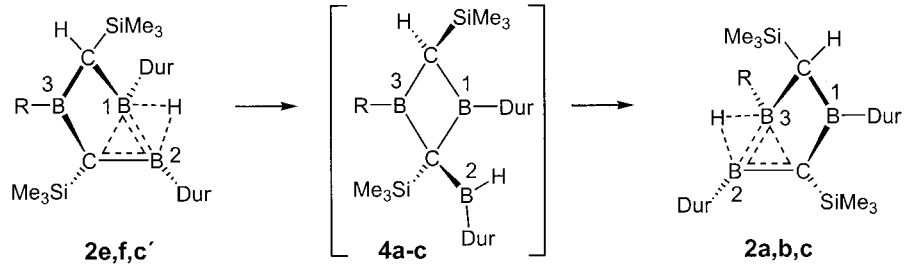


Scheme 3.



a,e: R = CH_3 **b,f**: R = C_6H_5 **c,c′**: R = Dur

Scheme 4.

Decoupling using the frequency corresponding to the chemical shift $\delta^{11}B = -2$ ppm strongly sharpens the ^{13}C NMR signal of the boron bound methyl group at 4.9 ppm. This indicates this methyl group to be bound to the pentacoordinate boron atom. Computations for **2u** (see below) clearly support the assignment of the most shielded boron atom to that of the highest coordination number.

The chemical shifts of the skeleton atoms of **2c** are distinctly different from those of **2a**,**b**. There is no sharp ^{11}B signal at about $\delta = 0$ for a pentacoordinate boron atom but only a broad shoulder at about 30 ppm of a very broad signal at about 47 ppm. The ^{13}C NMR spectrum of **2c** at ambient temperature shows signals for only two different kinds of duryl substituents and not for three as would be expected from its asymmetric structure which has been unambiguously deduced from the X-ray analysis described below. However, at –90 °C signals for three different duryl substituents can be observed which broaden at higher temperatures and show coalescence between –70 and –60 °C, respectively. From the chemical shift differences $\delta\nu$ of corresponding signals and their coalescence temperatures T_c, the following $\Delta G^{\#}$ values can be calculated using Equation (1): 9.2, 10.0, 9.7 and 10.0 kcal mol^{-1}.

$$\Delta G^{\#} = 4.57 \cdot T_c \cdot [9.97 + \log (T_c/\delta\nu)] \quad (1)$$

On average, a barrier of exchange of 9.7 kcal mol^{-1} can be obtained. We have assigned this barrier to the enantiomerisation of **2c′** to **2c** which arises through opening of the 3c–2e bonds in **2c′** to form the 2-boryl-1,3-diboracyclobutane **4c** and the corresponding new 3c–2e bonds employing the C1–B3 and B2–H bond. These transformations lead to **2c**, the enantiomer of planar-chiral **2c′**. The enantiomerisation of **2c** can be observed by NMR spectroscopy because it includes a topomerisation of two duryl substituents.

On the basis of the topomerisation of **2c′**, the unexpected pattern of substituents in **2a**,**b** can easily be explained by

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the corresponding process leading to isomerisation instead of topomerisation. Opening of both 3c–2e bonds in the primarily formed **2e**,**f** generates the classical 2-boryl-1,3-diboretanes **4a**,**b.** If the ring boron centre carrying the sterically less demanding substituent is employed in reforming the corresponding 3c–2e bonds, **2a**,**b** are obtained which are isomers of **2e**,**f**.

Crystal Structures

Figures 1, 2, 3 and 4 show the structures of **1a** and **2a–c** in the crystal. Characteristic distances and angles of **2a–c** and **1a** are compared with those computed for **2u** (Table 2).

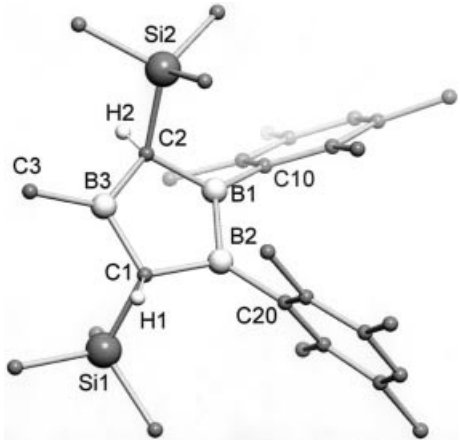


Figure 1. Structure of **1a** in the crystal. Most of the hydrogen atoms have been omitted for clarity. Selected bond lengths [pm] and angles [°] (completing Table 2): C1–B3 156.6(3), B3–C2 157.5(3), C2–B1 156.0(2), C1–Si1 189.8(2), B1–C10 158.0(2), C2–Si2 191.6(2), B2–C20 157.6(2); B1–C2–B3 107.6(1).

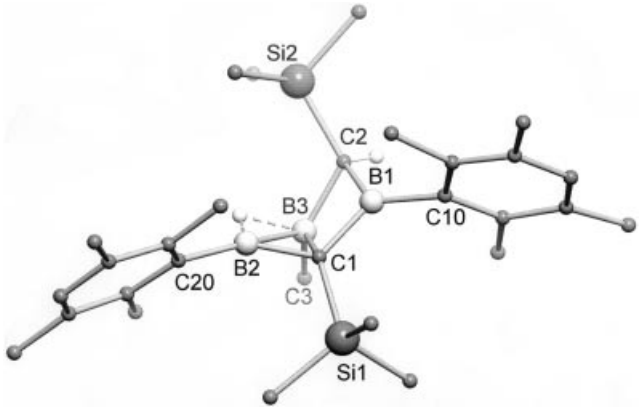

Figure 2. Structure of **2a** in the crystal. Most of the hydrogen atoms have been omitted for clarity. Selected bond lengths [pm] and angles [°] (completing Table 2): C1–B1 156.7(5), B1–C2 156.2(5), C2–B3 160.8(5), C1–Si1 188.3(3), B1–C10 159.0(5), C2–Si2 185.8(4), B3–C3 158.1(5), B2–C20 155.6(5); C1–B1–C2 106.6(3), B1–C2–B3 78.2(3).

The five-membered rings of **2a–c** are strongly distorted in comparison with that in **1a**. This can be demonstrated, inter alia, by the much shorter transannular C1···B3 distances in **2a–c** [178.0(5), 179.6(3) and 219.9(7) pm, respectively] compared with the shortest in **1a** [C2···B2 = 261.6(3) pm]. The bonding distances and angles of the C1B2B3 moiety of **2a**,**b** resemble those of the corresponding part of homoaromatic **Va**[3] (Table 2). Elongation of C1···B3 in **2a**,**b** relative to **Va** can be explained by weakening of the 3c–2e bond due to interaction with the formally empty orbital at B1 (see computations). For **2c**, the transannular B···C distance (219.9 pm) is about midway between those of **2a**,**b** and **1a**. In **2a** the C1,B1,B3 plane is folded towards the C1,B2,B3 and B1,C2,B3 planes by angles of 48 and 25°, respectively. In **2c** the corresponding angles are only 39 and 6°. Clearly, the sterically demanding duryl substituent at B3 in **2c** prevents the strong folding present in **2a,b** and **2u**, all of which lack a large substituent at the boron centre B3.

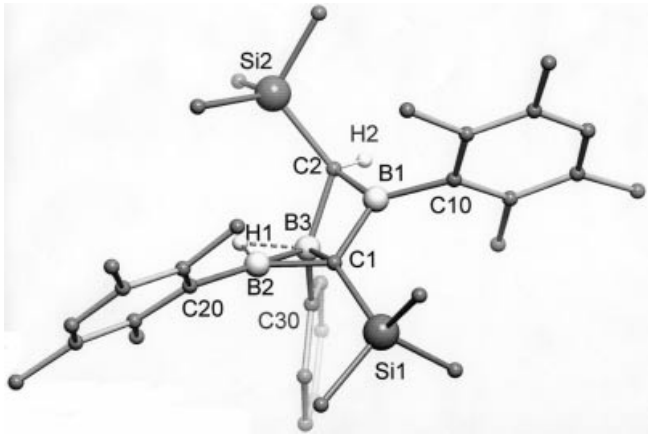

Figure 3. Structure of **2b** in the crystal. Most of the hydrogen atoms have been omitted for clarity. Selected bond lengths [pm] and angles [°] (completing Table 2): C1–B1 156.9(3), B1–C2 155.8(3), C2–B3 160.8(3), C1–Si1 189.3(2), B1–C10 157.9(3), C2–Si2 185.8(2), B3–C30 158.1(3), B2–C20 155.3(3); C1–B1–C2 107.9(2), B1–C2–B3 76.8(1).

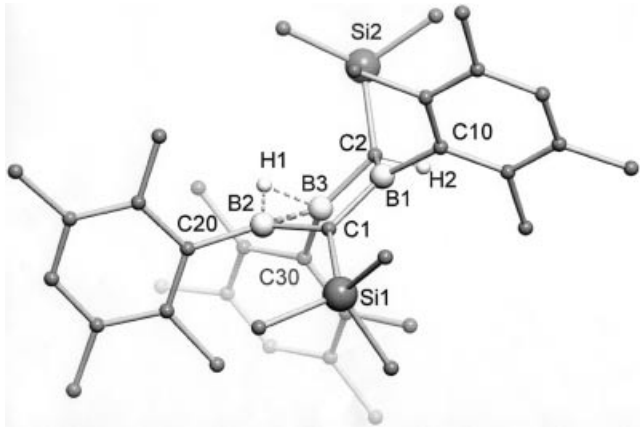

Figure 4. Structure of one of the two independent molecules **2c** in the crystal structure of **2c**·pentane. Most of the hydrogen atoms have been omitted for clarity. Selected bond lengths [pm] and angles [°] (completing Table 2): C1–B1 151.8(8), B1–C2 160.5(8), C2–B3 153.3(8), C1–Si1 189.2(6), B1–C10 159.3(7), C2–Si2 186.9(6), B3–C30 156.6(8), B2–C20 155.5(7); C1–B1–C2 109.7(4), B1–C2–B3 92.7(4).

Ab Initio Computations

Energies and geometries of model compounds **1u** and **2u** were computed at the MP2/6-311+G** level.[7] Bond lengths and angles obtained for **2u** are in good agreement (Table 2) with the corresponding data from the X-ray crystal structure determinations of **2a**,**b**. Chemical shifts computed at the IGLO/II/MP2/6-31+G* level for **2u** agree (Table 1) with the experimental data of **2a**,**b** but not with those of **2c**. This indicates the structure of **2c** to be different from those of **2a**,**b** in solution as well.

NBO analyses for **2u** reveal a 3c–2e bond between the neighbouring boron atoms and the formally tricoordinate carbon atom occupied by 1.84 electrons. The 0.26 electrons in the p orbital of the boron centre between carbon atoms indicate its interaction with the CB_2 3c–2e bond and explain the NMR shielding of the boron atom of the two-membered homo bridge. This interaction is essential for the stabilisation of **2u** relative to **1u** by 7.4 kcal mol^{-1}: the related nonclassical **VIu** with CH_2 instead of BH in the two-membered homo bridge is only 0.5 kcal mol^{-1} lower in energy than the classical C_s symmetric **IIIu**.[2,9]

The transition state **TS1/2u** for the transformation of **1u** into **2u** was computed to be 29.3 kcal mol^{-1} higher in energy than **1u**. **TS1/2u** has a short C–B distance (151.8 pm), a very long C–H (159.9 pm) distance as well as short (130.9 pm) and long (158.1 pm) B–H distances. According to an NBO analysis it contains a 3c–2e C–H–B bridge occupied by 1.79 electrons (29% at C, 24% at B and 37% at H). Only 4 and 7% of the two electrons are found in the p orbitals of the adjacent boron centres. This transition state thus describes the activation of a C–H bond by a neighbouring B–B moiety. The five-membered ring of the transition state is still considerably less distorted than that of the product **2u**.

Computations also revealed that classical **4u** is only 0.6 kcal mol^{-1} higher in energy than nonclassical **2u** and that the barrier for the **2u** → **4u** rearrangement via transition state **TS2/4u** is only 3.2 kcal mol^{-1}**.**

Compound **4u** is considerably stabilised by C–B hyperconjugation as revealed by an NBO analysis which showed the formally empty orbitals of the boron atoms to be occupied by 0.145 and 0.163 electrons at the boryl and ring boron centres, respectively. This stabilisation is certainly reduced by the substituents in **4a–c** and, as a result, the barrier from **2e**,**f**,**c′** to **2a**,**b**,**c** can be expected to be larger.

Conclusions

Classical and nonclassical 1,2,4-triboracyclopentanes **1a–c** and **2a–c** are the first representatives of 1,2-diboron heterocycles which can be isolated as classical as well as nonclassical isomers. Isomerisation of **1a**,**b** can be easily observed and computations for models reveal an intramolecular C–H bond activation by a B–B moiety as the mechanism for this process. Nonclassical 1,2,4-triboracyclopentanes **2a–c** are only slightly lower in energy than the corresponding classical 2-boryl-1,3-diboretanes **4a–c** which are considerably stabilised by C–B hyperconjugation, the general alternative to stabilisation by formation of 3c–2e bonds. Compounds of type **2** may therefore be regarded as nonclassical 2-boryl-1,3-diboracyclobutanes as well as nonclassical 1,2,4-triboracyclopentanes.

Experimental Section

General: Reactions were carried out under dry argon or nitrogen using standard Schlenk techniques. Solvents were dried, distilled and saturated with nitrogen. Glassware was dried with a heat gun under high vacuum. ^{1}H, ^{13}C NMR spectroscopy: Bruker DRX 200 and Bruker AC 500 instruments, ^{11}B NMR: Bruker DRX 200 instrument. The NMR references used were Me_4Si and BF_3·Et_2O. Melting points (uncorrected) were measured under argon.

4-Methyl-1,2-bis(2′,3′,5′,6′-tetramethylphenyl)-*trans*-3,5-bis(trimethylsilyl)-1,2,4-triboracyclopentane (1a): MeLi solution (Et_2O, 1.6 M, 4.20 mL) was added by syringe to a solution of **1d** (3.45 g, 6.8 mmol) in Et_2O (50 mL) at –78 °C. The solution was then allowed to reach –10 °C over 1 h with stirring. Stirring was then suspended to allow the salts to settle and the solution was decanted through a precooled reversed frit (–15 °C, about 4 cm diameter). All solvents were removed at –10 °C. The yellow residue consisted of spectroscopically pure **1a** which was used for subsequent reactions immediately after preparation. Yield: 3.31 g (99%) of deeply yellow **1a**, m.p. 105–106 °C (dec.) ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 6.88 (s, 2 H, Dur-H), 3.31 (s, 2 H, BCH), 2.12–1.98 (br., 24 H in total), 1.10 (s, 3 H, BCH_3), 0.03 (s, 18 H, $SiMe_3$) ppm. ^{13}C{^{11}B}NMR (125 MHz, $CDCl_3$, –10 °C): δ = 149.2 (s, *i*-C), 132.8, 131.5 (both s, *o*- and *m*-C), 130.0 (d, *p*-C), 66.4 [d, ^1J(C,H)

= 107 Hz, BCH], 20.5, 19.5 (both q, Dur-CH_3), 13.9 [br. q, ^1J(C,H) = 120 Hz, BCH_3], 2.8 (q, $SiMe_3$) ppm. ^{11}B NMR (96 MHz, $CDCl_3$, 25 °C): δ = 104 (2B), 88 (1B) ppm.

4-Phenyl-1,2-bis(2′,3′,5′,6′-tetramethylphenyl)-*trans*-3,5-bis(trimethylsilyl)-1,2,4-triboracyclopentane (1b): PhLi solution (cyclohexane/Et_2O, 1.85 M, 2.05 mL) was added to a solution of **1d** (1.91 g, 3.8 mmol) in Et_2O (50 mL) at –78 °C. The mixture was allowed to reach room temperature over 2 h and stirring was continued for 1 h at this temperature. The solvents were removed in vacuo and the residue was digested with pentane (50 mL). The salts were separated from the deep yellow solution by filtration with a reversed frit and washed with pentane (10 mL). The filtrates were reduced to dryness in vacuo yielding spectroscopically pure **1b**. Yield: 2.04 g (99%) of deep yellow **1b**, m.p. 99 °C (dec.). For spectroscopic data see ref.[6]

4-Chloro-1,2-bis(2′,3′,5′,6′-tetramethylphenyl)-*trans*-3,5-bis(trimethylsilyl)-1,2,4-triboracyclopentane (1d): $B(OMe)_3$ (9.15 g, 88.0 mmol, 10 mL) was added slowly by syringe to a suspension of dilithium-2,3-bis(2′,3′,5′,6′-tetramethylphenyl)-1,4-bis(trimethylsilyl)-2,3-diboratabuta-1,3-diene[6] (13.4 g, 21.5 mmol) in pentane (200 mL) at –78 °C. The mixture was allowed to reach room temperature during which time it gradually became yellow. Stirring was continued overnight and the solvents were then removed in vacuo. The viscous residue was thoroughly dried in vacuo for 2 h and was then digested with pentane (200 mL) and cooled again to –78 °C. After addition of BCl_3 (30 g, 256 mmol) with a syringe, the mixture was warmed to room temperature over 2 h and stirring was continued for 30 min at this temperature. All volatile materials were then removed in vacuo and the solid residue digested with pentane (200 mL). The salts were filtered through a reversed frit and washed with pentane (2×20 mL). The combined filtrates were reduced to dryness in vacuo and thoroughly dried thereafter. The deep yellow residue was of almost spectroscopic purity. Crystallisation from pentane (50 mL) at –30 °C yielded **1d** as yellow crystals. Yield: 8.17 g (75%) of bright-yellow **1d**, m.p. 134 °C (dec.). For spectroscopic data see ref.[6]

1-Methyl-2,4-bis(2′,3′,5′,6′-tetramethylphenyl)-3,5-bis(trimethylsilyl)-μ(1,2)-hydro-3-dehydro-1,2,4-triboracyclopentane (2a): A solution of freshly prepared **1a** (3.00 g, 6.17 mmol) in $CDCl_3$ (20 mL) was stored for 4 d at room temperature and the solution was monitored frequently by ^{1}H NMR spectroscopy. After completion of the reaction all volatile materials were removed in vacuo. The white residue consisted of essentially pure **2a** which could be crystallised at –30° from toluene. Yield: 2.97 g (99%) of white **2a**, m.p. 113 °C. ^{1}H NMR (500 MHz, $CDCl_3$, –40 °C): δ = 7.21, 6.99 (both s, 1 H each, Dur-H), 6.72 (br. s, 1 H, B–H–B), 2.49, 2.43, 2.37, 2.31, 2.28, 2.19 (all s, 24 H in total, Dur-CH_3), 1.10 (s, 1 H, CHSi), 0.66 (s, 3 H, BCH_3), 0.01, –0.26 (both s, 9 H each, $SiMe_3$) ppm. ^{13}C NMR (125 MHz, $CDCl_3$, –40 °C): δ = 146.7, 133.9 (each br. s, *i*-C), 140.0, 138.4, 134.0, 133.1, 133.05, 132.9, 132.8, 131.8 (each s, *o*- and *m*-C), 134.9, 129.6 (both d, *p*-C), 74.6 (s, B_2C), 27.6 [d, ^1J(C,H) = 116 Hz, B_2CH], 20.6, 20.5, 20.3, 20.1, 19.6, 19.3 (all q, Dur-CH_3), 4.9 [br. q, ^1J(C,H) = 117 Hz, BCH_3], 0.9, 0.2 (both q, $SiMe_3$) ppm. ^{11}B NMR (96 MHz, $CDCl_3$, 25 °C): δ = 56, 48, 0 (each 1B) ppm.

1-Phenyl-2,4-bis(2′,3′,5′,6′-tetramethylphenyl)-3,5-bis(trimethylsilyl)-μ(1,2)-hydro-3-dehydro-1,2,4-triboracyclopentane (2b): A solution of **1b** (5.67 g, 10.3 mmol) in $CDCl_3$ (25 mL) was stored for 9 d at room temperature and was monitored frequently by ^{1}H NMR spectroscopy. All volatile materials were then removed in vacuo and the residue was dissolved in a 1:1-mixture of Et_2O and pentane (30 mL). After four days at –30 °C **2b** precipitated as a white solid which was contaminated with approx. 5% of a product of unknown constitution. Yield: 1.97 g (35%) of white **2b**, m.p. 128 °C. ^{1}H NMR (500 MHz, $CDCl_3$, 25 °C): δ = 7.5 (br., BHB, located by ^{1}H/^{1}H COSY to d at 1.43), 7.5, 7.4 (br.s, 6 H in total, Ph–H and B–H–B), 7.17, 6.91 (both s, 1 H each, Dur-H), 2.61, 2.32, 2.28, 2.20, 2.2 (br.), 1.7 (br) (all s, 24 H in total, Dur-Me), 1.43 [d, ^3J(H,H) = 4.6 Hz, 1 H, CHSi, identified by a cross peak to δ^{13}C = 26.8 in a C,H correlated spectrum], 0.09, –0.12 (both s, 9 H each, $SiMe_3$) ppm. ^{1}H NMR (500 MHz, $CDCl_3$, –40 °C) 7.7–7.6 (br., 6 H in total, Ph–H and B–H–B), 7.24, 6.99 (both s, 1 H each, Dur-H), 2.65, 2.36, 2.31, 2.29, 2.28, 2.18, 2.02, 1.67 (all s, 3 H each, Dur-Me), 1.51 [d, ^3J(H,H) = 4.6 Hz, 1 H, CHSi], 0.09, –0.12 (both s, 9 H each, $SiMe_3$) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 25 °C): δ = 146.8 (br. s, *i*-C), 140.8, 139.8, 134.0, 133.5, 132.9, 132.5 (all s, Dur-*o*- and *m*-C), 136.7, 127.3 (both d, Ph-*o*- or *m*-C), 135.5, 130.0 (both d, Dur-*p*-C), 128.3 (d, Ph-*p*-C), 71.9 (br. s, B_2C), 26.8 [d, ^1J(C,H) = 113 Hz, B_2CH], 21.1, 20.3, 20.2, 20.0, 19.55, 19.50 (all q, Dur-CH_3), 1.6, 0.8 ppm (both q, $SiMe_3$), Ph-*i*-C and one Dur-*i*-C not observed. ^{13}C NMR (125 MHz, $CDCl_3$, –40 °C): δ = 146.5, 139.2 (both br., Dur-*i*-C′s), 141.0, 139.7, 133.9, 133.4, 133.0,. 132.9, 132.6, 132.3 (Dur-*o*- and *m*-C′s), 136.6, 127.2 (br., Ph-*o*- or *m*-C′s), 135.5, 129.7 (Dur-*p*-C′s), 133.1 (br., Ph-*i*-C), 128.2 (Ph-*p*-C), 70.7 (B_2C), 26.4 (B_2CH), 21.0, 20.6, 20.4, 20.3, 20.0, 19.9, 19.6, 19.5 (Dur-CH_3), 1.4, 0.6 ($SiMe_3$) ppm. ^{11}B NMR (160 MHz, $CDCl_3$, 25 °C): δ = 57, 42, –2 ppm (each 1B).

1,2,4-Tris(2′,3′,5′,6′-tetramethylphenyl)-3,5-bis(trimethylsilyl)-μ(1,2)-hydro-3-dehydro-1,2,4-triboracyclopentane (2c): A mixture of **1d** (5.5 g, 10.85 mmol) and lithium powder (0.25 g) in diethyl ether (70 mL) was stirred at room temperature and monitored frequently by ^{11}B NMR spectroscopy until the signals of **1d** were replaced by those of **3** at δ = 24 and 21 ppm (about 1 h). After cooling to –78 °C, duryllithium (1.53 g, 10.85 mmol) was added with stirring. Formation of the dianion of **1c** during warming to room temperature was indicated by the presence of a ^{11}B NMR signal at δ = –16 ppm. After disappearance of the signals of **3** and cooling to –78 °C, 2,3-dibromo-2,3-dimethylbutane (2.6 g, 10.85 mmol) was added and the mixture allowed to warm to room temperature with stirring for an additional 1 h. ^{11}B NMR signals at δ = 97 and 80 ppm unambiguously indicated the formation of **1c**. All volatile materials were removed in vacuo and the residue was dissolved in pentane (50 mL). The salts were separated by filtration with a reversed frit and washed further with pentane (10 mL). The filtrate was reduced to dryness in vacuo yielding yellow **2c** which could be crystallised at –30 °C from pentane**.** Yield: 6.2 g (84%) of yellow **2c**, m.p. 134 °C. ^{1}H NMR (500 MHz, CD_2Cl_2, 25 °C): δ = 7.87 (br., 1 H, BHB), 7.02, 6.98 (both s, 1H and 2 H, respectively, *p*-H), 2.30, 2.26, 2.20, 2.10, 1.95 (all s, 36 H in total, Dur-Me), 1.17 (d, ^1J = 6.2 Hz, 1 H, CHSi), 0.06, –0.15 (both s, 9 H each, $SiMe_3$) ppm. ^{13}C NMR (125 MHz, CD_2Cl_2, 25 °C): δ = 143.4 (br. s, *i*-C), 136.9, 133.9, 133.6, 133.4 (all s, Dur-*o*- and *m*-C), 132.6, 131.0 (all d, 1C and 2C, *p*-C), 102.3 (br. s, B_2C), 25.0 (br. B_2CH), 21.1, 19.9, 19.7, 19.6 (all q, Dur-CH_3), 1.6, 0.9 (both q, $SiMe_3$) ppm. ^{13}C NMR (125 MHz, CD_2Cl_2, –90 °C): δ = 149.0, 146.0, 142.3, 137.5, 136.0, 135.6, 135.0, 134.5, 133.3,. 132.5, 132.1, 131.6 (*o*- *m*- and *i*-C′s), 131.6, 130.1, 129.1 (*p*-C), 89.1 (B_2C), 21.6 (B_2CH), 22.2, 21.6, 21,4, 20.3, 20.2, 20.1, 19.1, 18.7, 18.1 (Dur-CH_3), –0.01, –0.21 ($SiMe_3$) ppm. ^{11}B NMR (96 MHz, $CDCl_3$, 25 °C): δ = ca. 47 (2B), ca. 30 ppm (1B).

X-ray Crystal Structure Analyses of 1a, 2a, 2b and 2c·pentane: Single crystals were grown from toluene/Et_2O at 0 °C for **2a** and pentane at –30 °C for **2b** and **2c**. Those of **1a** were obtained from diethyl ether at –30 °C. The crystals were investigated on imaging plate systems (IPDS Stoe) using graphite monochromated Mo-K_α radiation at 193 K. The space groups were determined from the

systematic absences and intensity statistics, no absorption corrections were applied. The structures were solved by direct methods and refined against all F^2 data using full-matrix least-squares and difference Fourier techniques [SHELX programmes[10,11]]. Most hydrogen atoms were kept riding in calculated positions with isotropic displacement factors taken as 1.2 times (1.5 times for CH_3) the U_{eq} value of the corresponding C atom. The hydrogen atoms at the central ring were located and refined with individual isotropic displacement factors. For all heavier atoms, anisotropic displacement parameters were used. The structure of **2c**·pentane showed two independent molecules and, in addition, two strongly vibrating or disordered pentane molecules in the asymmetric unit. The solvent molecules were refined with restraints in geometry and in the anisotropy of the displacement factors. Due to this problem and the weak data set [29% of reflections $> 4\sigma(F)$ only] the precision of the structural data is reduced. Details of the experimental and crystal data are summarised in Table 3. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-245202 (for **1a**), -245204 (for **2a**), -245203 (for **2b**) and -245205 (for **2c**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk]

Reactivity of the [η^2-Bis(*tert*-butylsulfonyl)acetylene](carbonyl)(η^5-cyclopentadienyl)cobalt Complex Towards Electron-Rich and -Poor Acetylenes

Avijit Goswami,[a] Tobias H. Staeb,[b] Frank Rominger,[b] Rolf Gleiter,[b] and Walter Siebert*[a]

Dedicated to Prof. Günter Helmchen on the occasion of his 65th birthday

Keywords: Alkynes / Cobalt / Cyclopentadienyl ligands / N ligands

The electron-rich aminoacetylenes Et_2NC_2R (**2a**–**c**, R = SPh, PPh_2, and Ph, respectively) react smoothly with [η^2-bis(*tert*-butylsulfonyl)acetylene](carbonyl)(η^5-cyclopentadienyl)cobalt (**1**) to form the donor–acceptor stabilized (η^4-cyclobutadiene)cobalt complexes **3a**–**c** in good yields. However, treatment of the electron-poor borylacetylenes **2d**–**f** with the cobalt complex **1** does not lead to the expected (η^4-cyclobutadiene)cobalt complexes. Analogously, the reaction of bis(1-phenylethynyl)sulfide (**2g**) with two equivalents of **1** gives rise to the sulfur-bridged bis[η^4-(cyclobutadiene)cobalt] complex **3g**. The new cobalt complexes were characterized by NMR spectroscopy, mass spectrometry, and by X-ray structure analysis for **3a**, which reveals almost equal C–C bond lengths within the cyclobutadiene ring.

Introduction

Di(carbonyl)(η^5-cyclopentadienyl)cobalt [$CpCo(CO)_2$] is a very convenient and efficient reagent for the di- and trimerization of alkynes.[1] The CpCo-supported oligomerization of unsymmetrical alkynes generally leads to isomers, which is one of the major disadvantages of that reaction. This might be overcome if oligomerization could be carried out in a stepwise fashion. Lee and Brintzinger[2] have been able to demonstrate by means of IR spectroscopy that, on irradiation of [$CpCo(CO)_2$] in the presence of diphenylacetylene, a new complex with only one CO ligand must be present. In order to contribute to the clarification of the mechanism of dimerization and trimerization of alkynes, Krebs et al.[3,4] reported the first generation of a mono(alkyne)cobalt complex by reacting the highly strained alkyne 3,3,6,6-tetramethyl-1-thiacycloheptyne[3] with [$CpCo(CO)_2$]. More recently, Gleiter et al.[5] have synthesized the mono(alkyne)cobalt complex **1** by the replacement of one of the carbonyl groups in di(carbonyl)(η^5-cyclopentadienyl) cobalt with bis(*tert*-butylsulfonyl)acetylene,[6] which was found to be a strong electrophile. In the course of their study, a large number of electron-rich, chalcogen-substituted acetylenes as well as alkyl- and aryl-substituted acetylenes were allowed to react with **1** to form a new class of stable (cyclobutadiene)cobalt complexes.[7] They found that the more electron-rich acetylenes react faster with **1** under mild conditions, whereas carbon-substituted acetylenes require heating to initiate the reactions. We have studied electron-poor borylacetylenes with respect to oligomerization and therefore tested the possibility whether electron-poor acetylenes can react with **1** under drastic conditions. Furthermore, we were interested to find out whether other heteroatom-substituted acetylenes (such as nitrogen and phosphorus) are also able to act in the same way as chalcogen-substituted alkynes. In this paper, we will address the scope and limitations of the replacement of the CO group in **1** by the triple bonds of the electron-rich and -poor acetylenes.

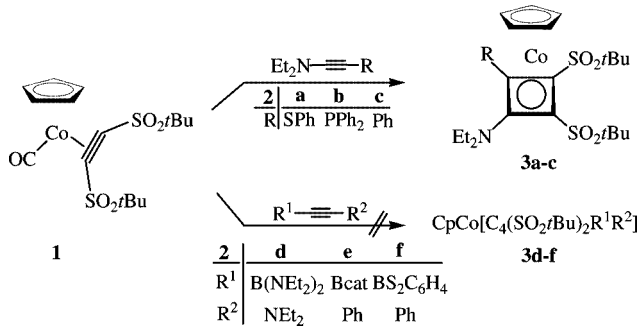
Results and Discussion

Treatment of Cobalt Complex 1 with Electron-Rich and -Poor Acetylenes

The reactions between the cobalt complex **1** and the electron-rich aminoacetylenes **2a**–**c** were carried out in toluene at room temperature to afford the (η^4-cyclobutadiene)cobalt complexes **3a**–**c**, respectively, in good yields (Scheme 1). On the other hand, reactions of the cobalt complex **1** with the "push-pull" 1-boryl-2-aminoacetylene **2d** as well as electron-poor borylacetylenes **2e** and **2f** in refluxing

 DOI: 10.1002/ejic.200500308

toluene were unsuccessful, and only the starting materials were recovered from the reaction mixtures. This indicates that electron-poor borylacetylenes have no tendency to react with the powerful electrophile **1**, even when applying drastic reaction conditions.



Scheme 1.

The cobalt complexes were isolated by column chromatography on silica gel and characterized by ^{1}H and ^{13}C NMR spectroscopy, mass spectrometry, and by X-ray structure analysis for **3a**. The ^{1}H NMR spectra of **3a**–**c** show two singlets in the region δ = 1.2–1.5 ppm for the *tert*-butyl groups in addition to the Cp resonance (δ = 5.0–5.3 ppm). In general, the characteristic feature of the ^{13}C NMR spectra is the chemical shift of the cyclobutadiene ring atoms, which have values of between δ = 75 and 85 ppm.[7a–7c] However, compounds **3a**,**b** exhibit low-field resonances (δ = 55–75 ppm) for the cyclobutadiene ring atoms. In the ^{13}C NMR spectra of **3a**–**c**, the signals for C_5H_5 (δ = 82–84 ppm) were detected along with the aryl carbon atoms (δ = 125.0–138.9 ppm). EI-MS data confirmed the formation of complexes **3a**–**c** by the appearance of the molecular-ion peaks with the expected isotopic pattern.

The molecular structure of the mononuclear (cyclobutadiene)cobalt complex **3a** is shown in Figure 1. In the solid-state, **3a** crystallizes with toluene. The conformation is highly influenced by the bulky *tert*-butylsulfonyl groups, which point away from the metal center, as does the phenyl group bound to the sulfur atom. This behavior allows an almost parallel orientation of the C_5 and C_4 rings. The space group ($P2_1/c$) of complex **3a** clearly indicates the presence of a racemic mixture.

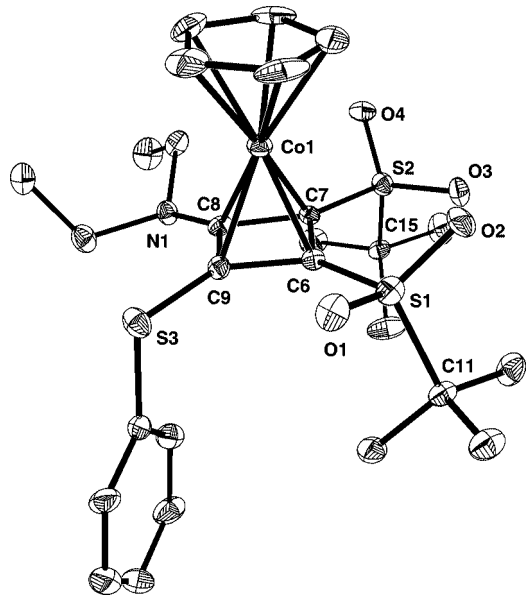


Figure 1. Molecular structure of **3a** in the solid state; hydrogen atoms have been omitted for the sake of clarity. Selected bond lengths [Å] and bond angles [°]: C6–S1 1.769(5), C7–S2 1.755(5), C6–C7 1.494(6), C7–C8 1.484(7), C8–C9 1.459(7), C6–C9 1.476(7), C8–N1 1.360(6), C9–S3 1.741(5); C9–C6–C7 88.8(4), C8–C7–C6 89.8(4), C9–C8–C7 89.9(4), C8–C9–C6 91.5(4).

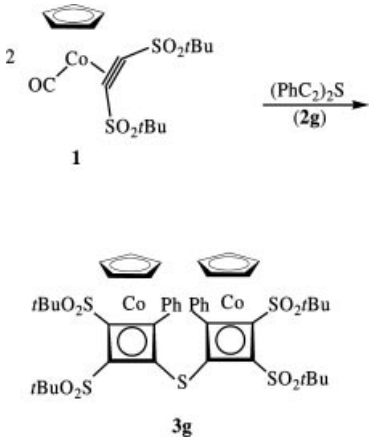

Scheme 2.

Sulfur-Bridged Dinuclear Cobalt Complex 3g

The sulfur-bridged bis[(η^4-cyclobutadiene)cobalt] complex **3g** was prepared in moderate yield by treating $(PhC_2)_2S$ (**2g**) with two equivalents of **1** (Scheme 2). No evidence for the mononuclear cobalt complex was found.

This reaction reveals an interesting route to a sulfur-bridged bis[(η^4-cyclobutadiene)cobalt] complex, which is important especially because the introduction of a heteroatom between two metal-stabilized cyclobutadiene rings is still difficult. The method used by Wadepohl et al.[8] leads to the mononuclear (η^4-cyclobutadiene)cobalt complex from the reaction of two equivalents of $(Me_3SiC_2)_2S$ with $[CpCo(CO)_2]$.

The brown oil **3g** was purified by column chromatography on silica gel and characterized by ^{1}H and ^{13}C NMR spectroscopy as well as by mass spectrometry. The ^{1}H NMR spectrum of **3g** shows the expected multiplets (δ = 6.9–7.1 ppm) for the aryl hydrogens in addition to two singlets (δ = 1.19 and 1.27 ppm) for the *tert*-butyl groups and the Cp resonance (δ = 5.01 ppm). In the ^{13}C NMR spectrum, the signals (δ = 58.6–75.2 ppm) for the cyclobutadiene ring are found along with the Cp resonance at δ = 83.5 ppm. The molecular-ion peak of **3g** was detected with the correct isotopic distribution in the mass spectrum.

Conclusions

We have shown that the electron-rich aminoacetylenes **2a**–**c** react smoothly (as do the chalcogen-substituted acetylenes) with complex **1** to form CpCo-stabilized η^4-cyclobutadiene complexes **3a**–**c**, respectively However, the CO group in the mono(alkyne)cobalt complex **1** cannot be replaced by the "push-pull" borylacetylene **2d** or by the electron-poor borylacetylenes **2e** and **2f**. This result may be explained by considering the electronic nature of complex **1**. The electron-poor bis(*tert*-butylsulfonyl)acetylene in **1** reduces the back bonding between the Co atom and the CO ligand, which means that CO is easily replaced by the electron-rich acetylenes **2a**–**c**; the electron-poor monoborylacetylenes **2d**–**f** have weaker donor capabilities and thus do not react with **1**. Interestingly, the sulfur-bridged bis[(η^4-cyclobutadiene)cobalt] complex **3g** can be prepared by treating complex **1** with $(PhC_2)_2S$ (**2g**). The cobalt complexes **3a**–**c** and **3g** are stable at room temperature and resistant to light, oxygen, and moisture.

Experimental Section

General: All reactions were performed under nitrogen using standard Schlenk techniques. Solvents were dried with the appropriate drying agents and distilled under nitrogen. Glassware was dried with a heat gun under high vacuum. ^{1}H, ^{11}B, and ^{13}C NMR: Bruker AC 200 spectrometer; ^{1}H and ^{13}C spectra were referenced to $(CH_3)_4Si$. IR spectra were recorded on a Bruker IFS 28 FT spectrometer. Mass spectra were obtained on a Finnigan MAT 8230 plus spectrometer using the EI technique. Elemental analyses were carried out by the Mikroanalytisches Laboratorium der Universität Heidelberg. Melting points (uncorrected) were obtained on a Büchi apparatus, using capillaries which were filled under nitrogen and sealed. Complex (**1**),[9] 2-(diethylamino)-1-phenylthioacetylene (**2a**),[10] 2-(diethylamino)-1-(diphenylphosphanyl)acetylene (**2b**),[11] 2-(diethylamino)-1-phenylacetylene (**2c**),[12] 1-(diethylamino)-2-bis(diethylaminoboryl)acetylene,[13] 1-catecholboryl-2-phenylacetylene,[12] 1-dithiocatecholboryl-2-phenylacetylene,[12] and $(PhC_2)_2S$ (**2g**)[14] were prepared according to literature procedures.

General Procedure for the Synthesis of 3a–c and 3g: The mono(alkyne)cobalt complex **1** was dissolved in 30 mL of toluene and the appropriate acetylene was added. The reaction mixture was stirred for 2 d at room temperature. After completion of the reaction, the solvent was removed to dryness and the crude product was purified by column chromatography on silica gel (THF/toluene, 2:1). Cobalt complex **3a** was recrystallized from a solution of toluene at –20 °C.

The Role of [η^2-Bis(*tert*-butylsulfonyl)acetylene](carbonyl)(η^5-cyclopentadienyl)cobalt(I) as an Intermediate in the Alkyne Dimerisation

Tobias H. Staeb,[a] Jorge Chávez,[a] Rolf Gleiter,*[a] and Bernhard Nuber[b]

Dedicated to Prof. Dr. Günter Helmchen on the occasion of his 65th birthday

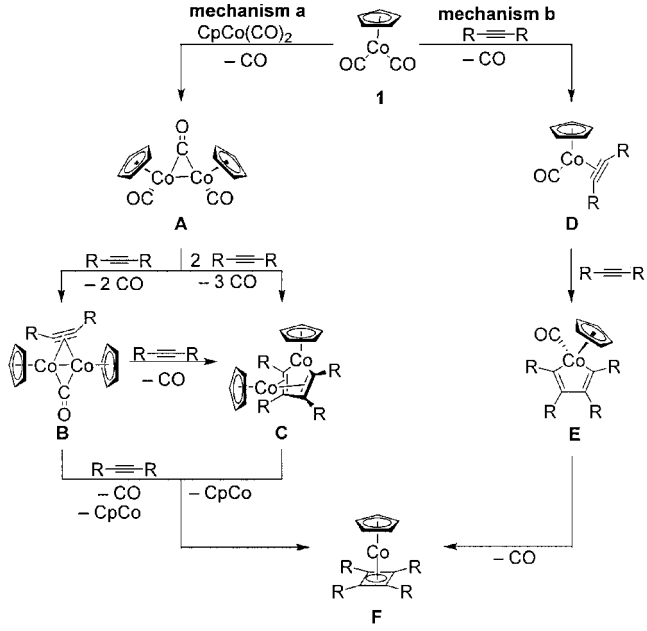
Keywords: Alkynes / Cobalt / Cyclobutadiene / Cyclopentadienyl ligands

Dicarbonyl(η^5-cyclopentadienyl)cobalt(I) (**1**) reacts with the electron-poor alkyne bis(*tert*-butylsulfonyl)acetylene to give the corresponding cyclobutadiene complex **6**, whereas the reaction of [$CpCo(CO)_2$] with dimethyl acetylenedicarboxylate yields the cyclopentadienone complex **7** under the same conditions. The cyclobutadiene complex **6** could not be obtained by the treatment of [η^2-bis(*tert*-butylsulfonyl)acetylene](carbonyl)(η^5-cyclopentadienyl)cobalt(I) [**3(H)**] with an excess of bis(*tert*-butylsulfonyl)acetylene. The same holds for the treatment of **3(H)** with dimethyl acetylenedicarboxylate and bis(catecholatoboryl)acetylene. With these results we assume that the monoalkyne complex **3(H)** is not an intermediate in the alkyne oligomerisation of electron-poor alkynes, as was shown for electron-rich ones.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The $CpCo^I$-mediated dimerisation of alkynes to cyclobutadiene (cbd) complexes is a well-known reaction.[1–4] There are two suggested mechanisms in the literature for the formation of these complexes, one by Brintzinger et al.[5,6] and the other based on work by Bergman, Vollhardt, Yamazaki and others.[6,7] Both mechanisms are shown in Scheme 1.

Brintzinger assumed that the reaction of two equivalents of dicarbonyl(η^5-cyclopentadienyl)cobalt(I) {[$CpCo(CO)_2$], **1**} leads to complex **A**, which can form complexes **B** and **C** by the reaction with alkynes (mechanism **a** in Scheme 1). These intermediates have been isolated and characterised.[6,8] The cyclobutadiene (cbd) complex **F** can arise from both precursors. The second mechanism (**b** in Scheme 1) involves intermediates with only one cobalt nucleus. Complex **1** yields a monoalkyne complex **D** by loss of one CO ligand and subsequent reaction with one equivalent of alkyne. Addition of another alkyne forms the cobaltol species **E**.[9] Dissociation of the second CO unit and subsequent reductive elimination gives the cbd complexes **F**. The second mechanism has also been investigated by theoretical means.[10–12] The first experimental evidence of a monoalkyne species **D** was provided by Brintzinger by means of IR spectroscopy.[5] Later, Krebs et al. were able to isolate the first monoalkyne complex **2** by reaction of 3,3,6,6-tetramethyl-1-thiacycloheptyne[13] with [$CpCo(CO)_2$] (Scheme 2).[14]



Scheme 1. Abridged version of mechanisms to rationalize the formation of cyclobutadiene CpCo complexes according to Brintzinger et al. (**a**) and based on the work by Bergman, Vollhardt, Yamazaki and others (**b**).

The second class of complexes of type **D** were synthesised in our laboratory by the reaction of bis(*tert*-butylsulfonyl)acetylene[15] with [$CpRCo(CO)_2$] derivatives.[16] The

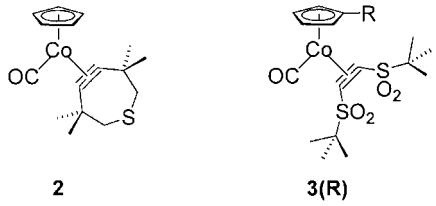
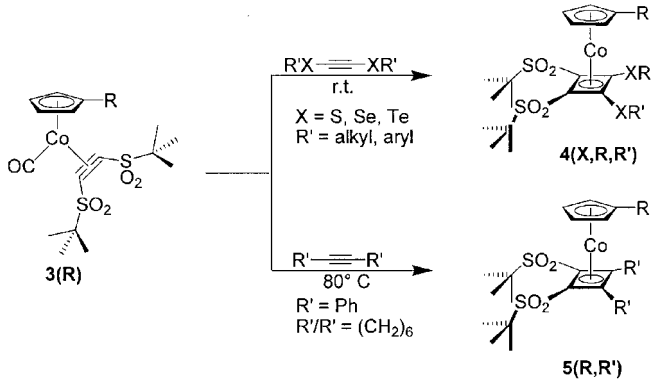


Scheme 2. Isolated monoalkyne Co^{I} complexes.

obtained complexes **3(R)** (Scheme 2) were treated with different alkynes to yield the corresponding cyclobutadiene complexes, as shown in Scheme 3.[17–19]

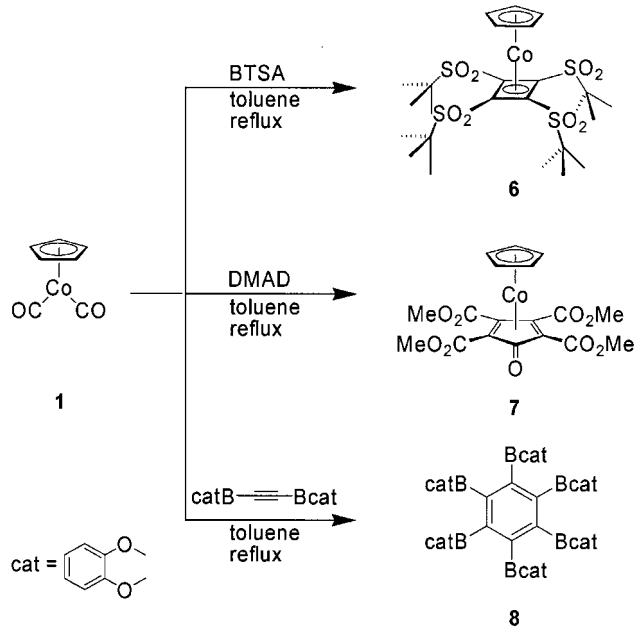


Scheme 3.

We showed that the electrophilic complexes **3(R)** react readily with electron-rich alkynes at room temperature to the corresponding cyclobutadiene complexes **4(X,R,R′)** in good yields. The reaction with alkynes that have no strong donor substituents, for example diphenylacetylene or cyclooctyne, needs higher temperatures to form the complexes **5(R,R′)**. These experiments provide strong evidence that the monoalkyne complexes **3(R)** are intermediates in the cyclobutadiene formation. In this paper we present the reactions of electron-poor alkynes with $[CpCo(CO)_2]$ and **3(H)**.

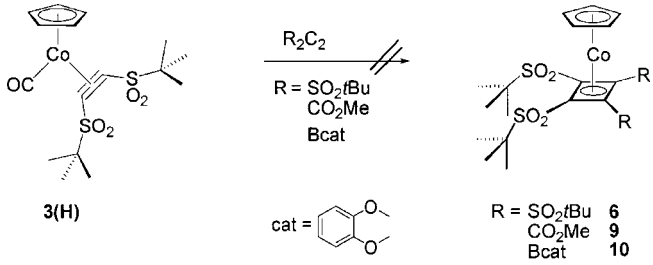
Results and Discussion

As electron-poor alkynes we chose bis(*tert*-butylsulfonyl)-acetylene (BTSA) and dimethyl acetylenedicarboxylate (DMAD). They react quite differently towards $[CpCo(CO)_2]$ in refluxing toluene. As shown in Scheme 4, BSTA forms the cbd complex **6** in 19% yield in refluxing toluene, whereas the reaction of **1** with an excess of DMAD gives the cyclopentadienone complex **7** (5% yield). A further electron-poor alkyne derivative, bis(catecholatoboryl)acetylene (BCBA),[20] yielded the hexakis-substituted benzene derivative **8** with **1**.[21]



Scheme 4.

Following our previous studies, we reacted the monoalkyne complex **3(H)** with BTSA, DMAD, and BCBA by heating **3(H)** and the corresponding alkynes in toluene. The anticipated products were not obtained (Scheme 5).



Scheme 5.

These results suggest that the nucleophilic monoalkyne complex **3(H)** is not an intermediate in the alkyne oligomerisation for electron-poor alkynes, as postulated in mechanism **b** (Scheme 1), and it seems more likely that this reaction has dinuclear Co^{I} intermediates, in analogy to the Brintzinger mechanism (cf. Scheme 1).[5,6]

Structural Investigations

In the case of **6** we were able to obtain single crystals which were investigated by X-ray techniques. Figure 1 shows the molecular structure of **6** (Table 1).

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

145	168	169	2.3
147			
145			
147			

Two opposite *tert*-butyl groups point away from the cyclopentadiene ring, whereas the other two groups point towards the Cp ring. This conformation reduces the steric strain and the overall dipole moment of the molecule arising from the sulfonyl groups. The two ring ligands are nearly parallel to each other (2.3° distortion). No bond alternation is found within the cyclobutadiene ring.

Conclusions

The products obtained from the reaction of [CpCo(CO)$_2$] and electron-poor alkynes are highly dependent on the electronic properties of the alkynes. The BTSA monoalkyne complex **3(H)** is not an intermediate in the cyclobutadiene formation with electron-poor alkynes, whereas it is with electron-rich ones.

Experimental Section

Starting Materials: Dicarbonyl(η^5-cyclopentadienyl)cobalt(I),[22] and bis(*tert*-butylsulfonyl)acetylene[11] were prepared according to literature methods. Dimethyl acetylenedicarboxylate (98%) was purchased from ACROS.

General Remarks: All melting points are uncorrected. Elemental analyses were carried out by the Mikroanalytisches Laboratorium der Universität Heidelberg. UV absorption data were recorded with a Hewlett–Packard 8452A spectrometer. IR spectra were recorded with a Bruker Vector 22. The NMR spectra were measured with a Bruker Avance 500 spectrometer (^{1}H NMR at 500 MHz and ^{13}C NMR at 125 MHz) using the solvent as internal standard (*δ*). FAB mass spectra refer to data from a Jeol JMS-700 instrument. *m*-Nitrobenzyl alcohol was used as the matrix for the FAB experiments. All reactions were carried out in dry glassware under argon in dry, oxygen-free solvents.

[η^4-Tetrakis-(*tert*-butylsulfonyl)cyclobutadiene](η^5-cyclopentadienyl)cobalt(I) (6): Dicarbonyl(η^5-cyclopentadienyl)cobalt(I) (200 mg, 1.1 mmol) and bis(*tert*-butylsulfonyl)acetylene (BTSA; 700 mg, 2.6 mmol) were dissolved in toluene (40 mL) and the mixture was stirred for 5 h at 120 °C. The product was purified by column chromatography (SiO_2, *n*-hexane/diethyl ether). Yield: 129 mg (19%) of a yellow solid (dec. 167 °C). ^{1}H NMR (500 MHz, $CDCl_3$): *δ* = 1.56 (s, 36 H, CH_3), 5.73 (s, 5 H, CH) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): *δ* = 25.3 [C(CH_3)$_3$], 65.2 [C(CH$_3$)$_3$], 82.2 (Cbd-C), 89.1 (Cp-C) ppm. MS (FAB+): *m*/*z* (%) = 679 [M + Na]$^+$, 656 [M$^+$], 583 [M – *t*BuO]$^+$. IR (KBr): $\tilde{\nu}$ = 2978, 2934, 1311, 1189, 1129 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log *ε*) = 254 nm (4.36), 304 (4.12), 334 (3.73), 352 (3.65), 388 (3.25). HRMS (FAB+): calcd. for $C_{25}H_{41}CoO_8S_4$ [M$^+$] 656.0989; found 656.1016; calcd. for $C_{25}H_{41}CoNaO_8S_4$ [M$^+$ + Na] 679.0896; found 679.0914. $C_{25}H_{41}CoO_8S_4$: calcd. C 59.77, H 8.13, S 11.00; found, C 59.65, H 8.08, S 10.98.

(η^5-Cyclopentadienyl)[η^4-2,3,4,5-tetrakis(methoxycarbonyl)cyclopentadienone]cobalt(I) (7): Dicarbonyl(η^5-cyclopentadienyl)cobalt(I) (2.0 mg, 11.0 mmol) and dimethyl acetylenedicarboxylate (DMAD; 700 mg, 2.6 mmol) were dissolved in toluene (40 mL) and the mixture was stirred for 5 h at 120 °C. The product was purified by column chromatography (SiO_2, *n*-hexane/diethyl ether and diethyl ether/methanol). Yield: 212 mg (5%) of a red solid (m.p. 112 °C). ^{1}H NMR (500 MHz, CH_3OD): *δ* = 3.82 and 3.85 (s, 6 H, CO_2CH_3), 5.41 (s, 5 H, Cp-CH) ppm. ^{13}C NMR (125 MHz, CH_3OD): *δ* = 53.5 (CO_2CH_3), 54.2 (CO_2CH_3), 72.0 (Cpd-C), 84.4 (Cpd-C), 88.2 (Cp-C), 156.1 (Cpd-CO), 165.5 (CO_2CH_3), 166.2 (CO_2CH_3) ppm. MS (FAB+): *m*/*z* (%) = 459 [M + Na]$^+$, 437 [M + H]$^+$, 436 [M$^+$]. IR (KBr): $\tilde{\nu}$ = 2955, 1733, 1634, 1447, 1234 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log *ε*) = 264 nm (4.03), 300 (4.01), 374 (3.49), 430 (2.97). HRMS (FAB+): calcd. for $C_{18}H_{18}CoO_9$ [M + H]$^+$ 437.0282; found 437.0256; calcd. for $C_{18}H_{17}O_9CoNa$ [M + Na]$^+$ 459.0102; found 459.0085.

X-ray Diffraction Analyses: The reflections of **6** were collected with a Syntex R3 diffractometer (Mo-K_α radiation, graphite monochromator). Intensities were corrected for Lorentz and polarisation effects, and an empirical absorption correction (psi-scans) was applied. The structure was solved by direct methods. The structural parameters of the non-hydrogen atoms were refined anisotropically according to a full-matrix least-squares technique (F^2). The hydrogen atoms were calculated according to stereochemical aspects. Structure solution and refinement were carried out with the SHELXTL-PLUS (5.10) software package.[23] ORTEP drawings were obtained using the ORTEP-3 program for Microsoft Windows® by Farrugia.[24] Table 2 contains the crystallographic data and details of the data collection and refinement procedure.
CCDC-269077 (for **6**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Keywords: 1-Nitroso-2-naphtholate ligand / 1,2-Naphthaquinone-2-imine ligand / Chelates / Rhenium complexes / Redox chemistry / CO_2 elimination

The halogeno complexes $(CO)_5ReX$ (**1a–c**) (X = Cl, Br, I) react with 1-nitroso-2-naphthol $C_{10}H_6N(O)OH$ (**2**) in refluxing CH_2Cl_2 to give the substitution product *cis*-$(CO)_4Re\{C_{10}H_6ON(O)\}$ (**3**) via HX and CO elimination in good yield. Compound **3** is coordinated to the Re centre by the bidentate chelate ligand via the N-atom of the nitroso and O-atom of the naphtholato groups. The same reaction in refluxing toluene, however, gave no HX elimination but instead, the *fac*-$(CO)_3XRe\{C_{10}H_6ON(H)\}$ (**4–6**) complexes are formed, which contain the rare, *N*,*O*-chelating ligand 1,2-naphthaquinone-2-imine. The nitroso function of **2** has been reduced to the imine function by an intermolecular redox process, which was confirmed by the detection of CO_2 generated during the reaction. The new compounds **3–6** have been characterised by their IR, ^1H and ^{13}C NMR, UV/Vis and mass spectra, as well as by X-ray structure analyses. The Re^I centres show a distorted octahedral coordination of the CO and X (in **4–6**) ligands and the almost planar aromatic (**3**) or quinoid (**4–6**) *N*,*O* chelating ligands.

(© Wiley-VCH Verlag GmbH & Co. KgaA, 69451 Weinheim, Germany, 2005)

Introduction

Metal complexes with *C*-nitroso ligands have attracted great attention for several reasons. The *C*-nitroso group is isoelectronic with dioxygen and like dioxygen can form adducts with metalloproteins[1–6] and metalloporphyrins.[6] Some metal complexes with *C*-nitroso compounds have also been proposed as reaction intermediates,[6–9] for example in the cytochrome-P450-dependent oxidative metabolism of amphetamines and other amino derivatives.[10]

Recently, we reported the synthesis of the dinuclear μ_2-(η^2-*NO*)-nitrosoaniline complexes of rhenium(I) of the type $[\{(CO)_3ReX\}_2ONC_6H_4NR_2]$ (X = Cl, Br, I; R = Me, Et).[11,12] The single crystals of all six compounds exhibit a pronounced linear dichroism. This surprising property may be due to the *C*-nitroso group which lies together with the planar phenyl- and NC_2-moieties (of NR_2) almost exactly within the symmetry plane of the dinuclear complexes.[11,12] Therefore, we tried to synthesise analogous complexes of $XRe(CO)_5$ (X = Cl, Br, I) with the sterically more demanding 1-nitroso-2-naphthol. Instead of the desired analogous dinuclear complexes mentioned above, we obtained new monomeric complexes of the type $[Re(CO)_3X\{C_{10}H_6ON(H)\}]$ (X = Cl, Br, I), whereby the nitroso group of the naphthol-derivative has been reduced to an imino-function by a CO-ligand, resulting in the new bidentate ligand 1,2-naphthaquinone-2-imine. Using milder reaction conditions we were also successful in isolating and characterising the intermediate product $[Re(CO)_4\{C_{10}H_6ON(O)\}]$, where the *C*-nitroso group remains intact.

Metal complexes which contain 1,2-naphthoquinone-monoimines are of interest because they are widely used for analytical purposes.[13,14] Metal complexes derived from 1,2-naphthoquinone-monoimines can also be employed as starting reagents in the synthesis of a wide variety of organic compounds.[15–17]

It is well known that nitro and nitroso compounds can be reduced to give products via the formation of imido intermediates. In 1975 Saarinen et al. published the X-ray structure of a copper complex with the 1-nitroso-2-naphthol ligand, which was followed by a report by Charalambous et al. in 1983.[18–20] Recently, Wong et al. prepared complexes with 1-nitroso-2-naphthol ligands and characterised a ruthenium complex as a by-product, where the nitroso group had been reduced to an imino function in very low yields.[21,22] N–O bond cleavage reactions of oximes have been recently documented by their oxidative addition reactions with suitable Re complexes to give the corresponding imine complexes.[23–25] Whereas Pombeiro et al.[23] report

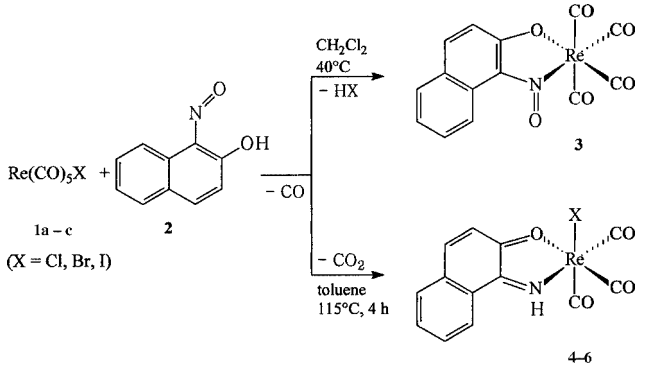
oxygen transfer only to the metal, Zubieta et al.[24] and Chakravorty et al.[25] observe its transfer to both metal and oxophilic co-ligands like phosphanes. In this work we present the first report on the formation of the 1,2-nitrosonaphtholato-*O*,*N* complex **3** which appears to be an intermediate in the reaction of $XRe(CO)_5$ (X = Cl, Br, I) with 1-nitroso-2-naphthol, because complexes **4**–**6** which are obtained by the same reaction in refluxing toluene, possess the 1,2-naphthochinone-2-imine-*N*,*O* ligand, which is generated by an intramolecular redox process.

Results and Discussion

The addition of one equivalent of 1-nitroso-2-naphthol to $XRe(CO)_5$ (X = Cl, Br, I) in CH_2Cl_2 or toluene followed by heating of this solution to 40 °C for 30 min leads to a colour change from yellow to orange. After 40 h, the orange product $[Re(CO)_4\{C_{10}H_6ON(O)\}]$ (**3**) was isolated by column chromatography (CH_2Cl_2, Scheme 1). When the same reaction was repeated in toluene with $XRe(CO)_5$ (X = Cl, Br, I) at 100 °C the colour changed initially to orange, then to green and finally to blue. After purifying the blue product by column chromatography (3 cm column, CH_2Cl_2), blue crystals of the compounds $[Re(CO)_3X\{C_{10}H_6ON(H)\}]$ (X = Cl, Br, I) (**4**–**6**) could be isolated. In compounds **4**–**6** no nitroso function was observed as it had been reduced to an imine function. Our first assumption that the overall redox reaction can only occur when a CO ligand is oxidised to CO_2 has been proven experimentally, as a white precipitate of $BaCO_3$ formed when the gas atmosphere in the reaction tube was connected with a solution of $Ba(OH)_2$ in H_2O (Scheme 1).



Scheme 1. Synthesis of **3**–**6**.

Compounds **3**–**6** are stable in air for some days, and are soluble in THF, acetone, $CHCl_3$, CH_2Cl_2 and even toluene, but nearly insoluble in nonpolar solvents like pentane or hexane. The orange (**3**) and blue solutions (**4**–**6**) can be stored in air for some days without decomposition. In the UV/Vis spectrum ($CHCl_3$) of **3** two broad absorptions at λ_1 = 260–315 nm and λ_2 = 360–440 nm due to ligand-to-metal CT bands ([NO–Re^I] and [O–Re^I]) are observed. For **4**–**6** two absorptions were also observed at lower frequencies in comparison to those observed for **3** at 380–395 and 570–670 nm (**4**), 380–420 and 570–670 nm (**5**), 450–500 and 590–690 nm (**6**) corresponding to [NH–Re^I] and [O–Re^I]. The position of these absorptions depends on the halogen and increases from X = Cl to X = I. In comparison with the corresponding electronic transition (π-π* NO) of the free ligand **2**, the absorption bands of the complexes **3**–**6** are shifted to lower frequencies.

The IR spectra (in CH_2Cl_2 and KBr) of the tetracarbonyl derivative **3** show four ν(CO)-absorptions at 2113 (A_1), 2017 (A_1), 2002 (B_2) and 1957 cm^{-1} (B_2) due to the pseudo-C_{2v} symmetry. The IR spectra of the facial tricarbonyl derivatives **4**–**6** in CH_2Cl_2 show three absorptions due to their lower symmetry (C_1) at 2031–2032 (*A*), 1923–1925 (*A*) and 1945–1951 cm^{-1} (*A*). The corresponding IR spectra (in KBr) show only two broad absorptions instead of the three observed in CH_2Cl_2 for compounds **4** and **5**. The NO group of **3** is found to absorb at 1380 cm^{-1}, indicating that the absorption of the NO bond of 1-nitroso-2-naphthol is shifted to lower wavenumbers on complexation. Depending on the halogen present, the ν(NH) absorptions of **4**–**6** are found at 3162 (**4**), 3175(**5**) and 3192 cm^{-1} (**6**).

The ^{1}H NMR spectrum of **3** shows three doublets for each proton at δ = 7.04, 7.82, 9.26 ppm and a triplet at δ = 7.49 ppm. The other three aromatic protons were only observed as a multiplet between 7.62–7.65 ppm. The ^{1}H NMR spectra of compounds **4**–**6** are very similar and display a double-doublet at δ = 7.05 (**4**), 7.10 (**5**) and 7.16 ppm (**6**). A further aromatic proton of **4**–**6** is detected at δ = 8.05 ppm, in addition to two multiplets at δ = 7.70–7.78 and 8.28–8.49 ppm. Only **5** shows an additional signal for the NH-group at δ = 14.47. All of the signals of **4**–**6** are generally shifted to a lower field in comparison to **3**.

In the ^{13}C NMR spectra of **3**–**6** the aromatic carbon atoms can be found between δ = 123.0–134.4 ppm, and the *N*-bonded carbon atom at δ = 156.3 (**3**), 160.1 (**4**), 166.4 (**5**) and 165.0 ppm (**6**). Compounds **4** and **6** show an additional signal for a quaternary carbon-atom at δ = 150.4 (**4**) and 148.0 ppm (**6**). The signals for the CO ligands and carbonyl groups appear between δ = 181.2–183.4 ppm. In comparison with the starting material **2**, all of the signals of complexes **4**–**6** are shifted to a lower field.

In the mass spectra (DEI-MS) of **3**–**6** the parent peaks are observed, as well as peaks corresponding to fragments resulting from the successive loss of up to three (**4**–**6**) and four CO ligands (**3**).

The stoichiometry and structures of complexes **3**–**6** were confirmed by X-ray structure analyses (Table 1).[26] In all cases, single crystals were obtained by the diffusion of pentane into solutions of **3**–**6** in $CHCl_3$. The molecular structures and selected bond lengths and angles are given in Figures 1, 2, 3 and 4.

All four compounds show the same distorted octahedral arrangement of the Re^I centre with O–Re–N angles between 73 and 75° [75.20 (**3**), 73.33 (**4**), 73.70 (**5**) and 73.07° (**6**)]. The O–Re–X and N–Re–X angles of **4**–**6** increase within the series **4** < **5** < **6** (84.65, 86.96 < 86.09, 87.40 < 88.20, 88.24°) depending on the size of the halogen atom. The Re–N bonds of **3** and **6** are approximately 2.115 Å and are significantly shorter than the corresponding Re–O bonds [2.155 (**3**) and 2.129 Å (**6**)]. However, in compounds **4** and **5**, the Re–O dis-

tem. In addition **4** and **5** have significantly shorter C–O bonds than **3**.

The N–O distance of the nitroso group in **3** is 1.246 Å, which is within the range of most metal complexes with *N*-bonded nitroso groups, for example in [Cu{η²-N(O)$C_{10}H_6O$}[PPh_3]$_2$] (1.287 Å)[17] and *cis*-[Ru{η²-N(O)$C_{10}H_6O$}$_2$($CO)_2$] (1.258 Å).[21] The dihedral angles N(1)–C(9)–C(4)–O(4) and N(1)–C(9)–C(8)–C(13) (for **4** and **5**) as well as N(1)–C(4)–C(9)–O(4) and N(1)–C(4)–C(5)–C(6) (for **6**) are less than 1.3°, which means that the quinone-imine in **4**–**6** is planar. In contrast to **4**–**6**, the 1-nitroso-naphthol ligand of **3** is slightly twisted out of the Re–O plane [N(2)–C(2)–C(1)–O(1) = 5.42°, N(2)–C(2)–C(3)–C(4) = 8.47°].

Experimental Section

All operations were carried out in an oxygen free atmosphere under Ar in dry and Ar-saturated solvents.[27] $Re(CO)_5X$ (X = Cl, Br, I) was prepared according to the literature procedure.[28] 1-Nitroso-2-naphthol was used as purchased from Alfa Aesar. NMR spectra were recorded with a Jeol EX 400 spectrometer (^{1}H: 399.78 MHz and ^{13}C: 100.54 MHz) and with a Jeol 270 spectrometer (^{1}H: 270.17 MHz, ^{13}C: 67.93 MHz) in [D_8]THF or CD_2Cl_2. Mass spectra were obtained with a Jeol Mstation JMS 700. IR and UV/Vis spectra were measured with a Perkin–Elmer Spectrum One FT-IR and a Perkin–Elmer UV Lambda 16 spectrometer, respectively. Elemental analyses were performed with a Heraeus Elementar Vario EL.

Tetracarbonyl-1-nitroso-naphtholato-*N*,*O*-rhenium(I) (3): Compounds **1b** (99.7 mg, 0.246 mmol) and **2** (46.9 mg, 0.271 mmol) were dissolved in CH_2Cl_2 (20 mL) and heated under reflux for 40 h, whereby the solution turned deep orange. The solvent was evaporated, and the orange residue was purified by column chromatography (CH_2Cl_2). The same product was obtained in similar yields when the appropriate quantities of **1a** or **1c** are used instead of **1b**. Yield: orange crystals (97.6 mg, 0.207 mmol, 72%), m.p. 184 °C (dec.). ^{1}H NMR (399.78 MHz, $CDCl_3$): δ = 7.04 (d, 1 H, ^3J = 9.40 Hz, $CH_{arom.}$), 7.49 (t, 1 H, ^3J = 7.86 Hz, $CH_{arom.}$), 7.62–7.65 (m, 2 H, $CH_{arom.}$), 7.82 (d, 1 H, ^3J = 9.40 Hz, $CH_{arom.}$), 9.26 (d, 1 H, ^3J = 8.35 Hz, $CH_{arom.}$) ppm. ^{13}C NMR (100.53 MHz, $CDCl_3$): δ = 123.0 ($CH_{arom.}$), 124.1 ($CH_{arom.}$), 125.0 ($CH_{arom.}$), 127.1 ($CH_{arom.}$), 128.0 ($CH_{arom.}$), 129.1 ($CH_{arom.}$), 133.4 ($CH_{arom.}$), 144.9 ($CH_{arom.}$), 156.3 ($C_{q,arom.}$), 183.4 ($C_{q,arom.}$), 190.9 ($C_{q,carbonyl}$) ppm. IR (KBr) : $\tilde{\nu}$ = 3121 (w), 3065 (w), 2962 (m), 2926 (m), 2854 (w), 2753 (w), 2687 (w), 2644 (w), 2584 (w), 2456 (w), 2421 (w), 2338 (w), 2114 (vs), 2017 (vs), 1994 (vs), 1958 (vs), 1820 (w), 1790 (w), 1726 (w), 1647 (m), 1619 (m), 1608 (s), 1599 (s), 1554 (s), 1517 (vs), 1482 (m), 1454 (w), 1422 (w), 1380 (s), 1357 (vs), 1323 (s), 1311 (s), 1266 (s), 1214 (s), 1139 (m), 1024 (m), 970 (w), 878 (w), 832 (w), 821 (s), 803 (m), 755 (s), 739 (m), 712 (w), 683 (w), 664 (m), 625 (s), 590 (w), 565 (m) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 2113 (vs), 2017 (vs), 2002 (vs), 1957 (vs) cm^{-1}. UV/Vis ($CHCl_3$) λ_{max} (log ε): 299 (13705), 323 (5836), 419 (13612) nm. $C_{14}H_6NO_5Re$ (470.40): calcd. C 35.63, H 1.50, N 2.97; found C 35.27, H 1.20, N 2.67. MS (DEI): *m*/*z* (%) = 470.7 (60) [M]$^+$, 442.8 (22) [M – CO]$^+$, 414.8 (7) [M – 2 CO]$^+$, 386.8 (35) [M – 3 CO]$^+$, 358.9 (100) [M – 4 CO]$^+$, 328.9 (47) [M – 4 CO, – NO]$^+$.

Synthesis of 4–6. General Procedure: $Re(CO)_5X$ (**1a**–**c**) and 1-nitroso-2-naphthol (**2**) were dissolved in toluene (20 mL) and heated to 115 °C for 4 h, whereby the solution turned deep blue. The solvent was evaporated, and the blue residue was purified by column chromatography (CH_2Cl_2, 3 cm column).

Tricarbonyl-chloro-(1-imino-*1H*-naphthalene-2-one)rhenium(I) (4): Complex **1a** (143 mg, 0.397 mmol) and **2** (68.4 mg, 0.397 mmol). Yield: blue crystals (104 mg, 0.225 mmol, 57%), m.p. 234 °C (dec.). ^{1}H NMR (270.16 MHz, [D_8]THF): δ = 7.05 (dd, 1 H, ^3J = 9.80, ^4J = 1.34 Hz, $CH_{arom.}$), 7.70–7.76 (m, 3 H, $CH_{arom.}$), 8.05 (d, 1 H, ^3J = 9.94 Hz, $CH_{arom.}$), 8.47–8.49 (m, 1 H, $CH_{arom.}$) ppm. ^{13}C NMR (67.94 MHz, [D_8]THF): δ = 125.4 ($CH_{arom.}$), 127.7 ($CH_{arom.}$), 128.7 ($CH_{arom.}$), 132.3 ($CH_{arom.}$), 132.3 ($CH_{arom.}$), 132.5 ($CH_{arom.}$), 134.2

New Polysulfur-Nitrogen Heterocycles by Thermolysis of 1,3λ⁴δ²,2,4-Benzodithiadiazines in the Hydrocarbon and Fluorocarbon Series

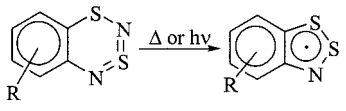
Vladimir V. Zhivonitko,[a,b] Alexander Yu. Makarov,[a] Irina Yu. Bagryanskaya,[a] Yuri V. Gatilov,[a] Makhmut M. Shakirov,[a] and Andrey V. Zibarev*[a,c]

Keywords: Fluorescence / Fluorine / Nitrogen heterocycles / Radicals / Sulfur heterocycles / Thermolysis

In contrast to thermolysis of 1,3λ⁴δ²,2,4-benzodithiadiazine (**1**) and its 5,6,7,8-tetrafluoro derivative **2** in dilute (10^{-3} M) hydrocarbon solutions, which leads to persistent 1,2,3-benzodithiazolyls in nearly quantitative yields, the thermolysis of **1** and **2** (the 6-6 bicyclic system) in concentrated (0.5 M) solutions at 150–170 °C results in complex mixtures of various polysulfur-nitrogen heterocycles, in particular differently fused 5-5-6, 5-6-7 and 5-6-6-6 polycyclic systems that were previously unknown. The products were isolated by column chromatography, and the structures of the 5-5-6 (**11**, **12**), 5-6-7 (**5**, **13**), and 5-6-6-6 (**6**, **14**, **15**) polycyclic systems, as well as the 6-7 (**4**) and 5-6 (**16**) bicyclic derivatives, confirmed by X-ray diffraction. The crystal packing of **6** and **11**–**16** is discussed with special emphasis on π-stacking interactions. The fluorescent properties of the 5-6-6-6 systems synthesized are reported. An alternative approach to the linear 5-6-6-6 system **15** based on self-condensation of an R–N=PPh_3 precursor (R = 4,5,6,7-tetrafluoro-1,2,3-benzodithiazol-2-yl) is described, and the free-radical character of this new reaction is proved.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Hyperelectronic (π- and σ-excessive) 1,3λ⁴δ²,2,4-benzodithiadiazine[1] and its carbocyclic substituted derivatives[2–5] (Scheme 1), including polyfluorinated versions, reveal some features of weak 12π-electron antiaromaticity[5–7] combined with moderate thermo- and photostability.[8–11] Mild thermolysis[8,9,11] or photolysis[10,11] of their dilute (10^{-3} M) hydrocarbon solutions results in persistent 1,2,3-benzodithiazolyls (Scheme 1), which are promising building blocks in the design and synthesis of organic molecular magnets and/or organic molecular conductors.[12,13] The key intermediates of this transformation are R–S–N: ↔ R–S≡N nitrenoids (R = 1,2,3-benzodithiazol-2-yl), which can be identified under matrix isolation conditions.[10]



Scheme 1.

The traditional synthetic approach to 1,2,3-benzodithiazolyls is the reduction of 1,2,3-benzodithiazolium chlorides (Herz salts). It should be emphasized that the thermolysis of 1,3λ⁴δ²,2,4-benzodithiadiazines affords 1,2,3-benzodithiazolyls for which the corresponding 1,2,3-benzodithiazoliums, for example fluoro-containing ones, are unknown.[8,9]

With dilute solutions of 1,3λ⁴δ²,2,4-benzodithiadiazines, the yields of radicals estimated by means of ESR measurements are nearly quantitative. It is therefore of obvious interest to investigate whether the thermolysis of 1,3λ⁴δ²,2,4-benzodithiadiazines can be a preparative approach to 1,2,3-benzodithiazolyls.

The present article deals with further investigation of the solution thermolysis of 1,3λ⁴δ²,2,4-benzodithiadiazines in both hydrocarbon and fluorocarbon series with special emphasis on concentrated solutions. It will be shown that under thermolysis conditions and in concentrated hydrocarbon solutions all the aforementioned species are seemingly involved in further transformations to give complex mixtures of products including several new and unusual polysulfur-nitrogen heterocyclic systems. Despite very low yields, the latter were isolated and unambiguously characterized by means of X-ray diffraction. Selected spectral properties of the new polysulfur-nitrogen heterocycles synthesized, including fluorescent properties, are also reported.

Results and Discussion

Thermal Transformations

Under argon, the thermolysis of 0.5 M solutions of 1,3λ⁴δ²,2,4-benzodithiadiazine (**1**) and its 5,6,7,8-tetra-

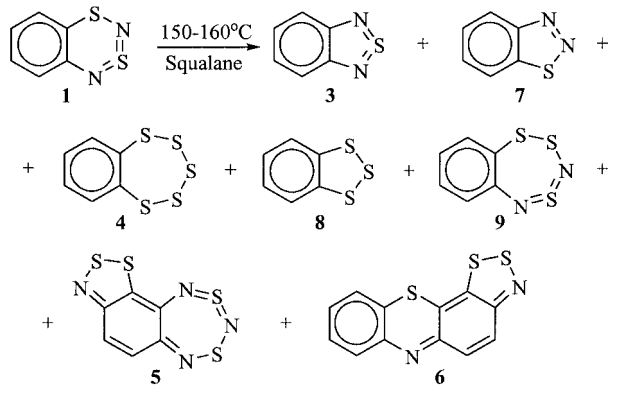
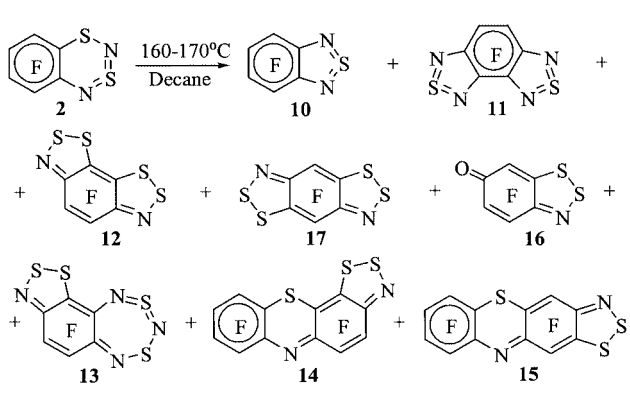
fluoro derivative **2** in hydrocarbons (squalane, decane) at 150–170 °C leads to complex mixtures of various polysulfur-nitrogen heterocycles, including previously unknown polycyclic systems (Schemes 2 and 3). In particular, the 6-6 bicyclic system of **1** and **2** transforms into differently fused 5-5-6, 5-6-7, and 5-6-6-6 polycyclic systems. The latter are identified for the first time. Thus, compound **1** affords 2,1,3-benzothiadiazole (**3**), benzopentathiepine (**4**), [1,2,3]dithiazolo[5,4-*g*][2λ^{4}δ^2,4,1,3,5]benzodithiatriazepine (**5**), and [1,2,3]dithiazolo[4,5-*c*]phenothiazine (**6**), which were isolated by column chromatography of the reaction mixtures; 1,2,3-benzothiadiazole (**7**), benzotrithiol (**8**), 1,2,4λ^{4}δ^2,3,5-benzotrithiadiazepine (**9**), and elemental sulfur were also identified in the reaction mixtures by GLC-MS and/or ^{1}H NMR techniques (Scheme 2), and NH_3 was detected in the gas phase.



Scheme 2.

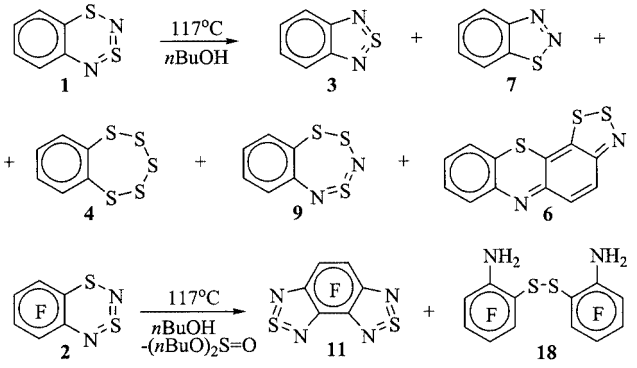


Scheme 3.

The thermolysis of compound **2** gives 4,5,6,7-tetrafluoro-2,1,3-benzothiadiazole (**10**), 7,8-difluorobenzo[1,2-*c*:3,4-*c*′]-bis[1,2,5]thiadiazole (**11**), 4,5-difluorobenzo[1,2-*d*:4,3-*d*′]-bis[1,2,3]dithiazole (**12**), 6,7-difluoro[1,2,3]dithiazolo-[5,4-*g*][2λ^{4}δ^2,4,1,3,5]benzodithiatriazepine (**13**), 4,5,7,8,9,10-hexafluoro[1,2,3]dithiazolo[4,5-*c*]phenothiazine (**14**), 4,6,7,8,9,11-hexafluoro[1,2,3]dithiazolo[5,4-*b*]phenothiazine (**15**), and 4,5,7-trifluoro-6-oxo-1,2,3-benzodithiazole (**16**), which were isolated by column chromatography (Scheme 3). Additionally, 4,8-difluorobenzo[1,2-*d*:4,5-*d*′]bis[1,2,3]dithiazole (**17**) was detected in the reaction mixture by ^{19}F NMR spectroscopy and GLC-MS (Scheme 3; the structure was assigned tentatively by comparison with isomeric **12**). In contrast to the thermolysis of **1**, evolution of acidic gases was observed.

In both cases the major isolated products are 2,1,3-benzothiadiazoles **3** and **10** (Schemes 2 and 3) as transformation of 12π-electron antiaromatic compounds **1** and **2** into 10π-electron aromatic derivatives **3** and **10** is thermodynamically attractive.

The thermal transformations of **1** also proceed in boiling 1-butanol (which does not react nucleophilically with either **1** or **2**) at 117 °C, i.e. at much lower temperature than in the hydrocarbons (Scheme 4). In this case only compound **6** was isolated from the reaction mixture, which also contained also small amounts of compounds **3**, **4**, **7**, **9** and elemental S according to the GLC-MS data.



Scheme 4.

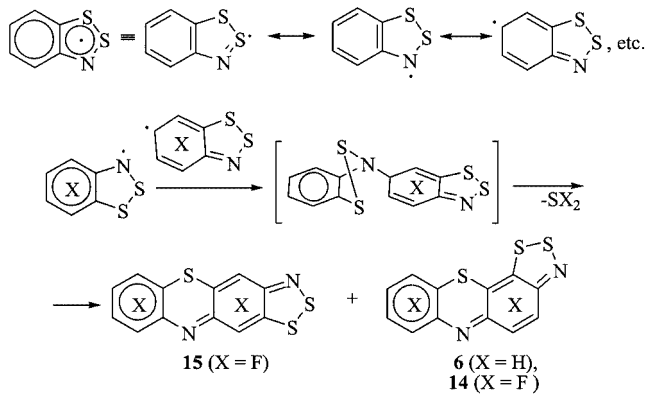
In the case of **2**, di-*n*-butyl sulfite and 2,2′-diamino-3,3′,4,4′,5,5′,6,6′-octafluorodiphenyl disulfide (**18**) were isolated as major products along with minor compound **11** (Scheme 4). Formation of $(n\text{BuO})_2\text{S=O}$ (not observed in the case of **1**) can be explained by an acid-catalyzed (traces of HF) dehydration of *n*BuOH, 1:1 addition of released H_2O to **2**,[14] and further reaction of the addition product with *n*BuOH. Compound **18** can also be considered to be a hydrolysis product (see ref.[3]). Thus, in this case acid-initiated hydrolysis seemingly dominates thermal transformations.

The structures of compounds **4**–**6** and **11**–**16** were confirmed by X-ray crystallography (see below).

Thus, the final products of the thermal transformations of 1,3λ^{4}δ^2,2,4-benzodithiadiazines appear to depend strongly upon the reaction conditions employed (this work and refs.[8,9,11]).

Formation of the same 5-6-7 and 5-6-6-6 polycyclic systems in both the hydrocarbon (**5**, **6**) and fluorocarbon (**13**, **14**) series indicates that the required carbocyclic substitution is not electrophilic or nucleophilic in character, as is typical of hydrocarbon and fluorocarbon aromatics, respectively. Rather, we are dealing with radical and nitrenoid processes − a conclusion which is in agreement with previous observations.[8–11] Thus, tetracyclic compounds **6**, **14**, and **15** can formally be considered the products of condensation of the corresponding 1,2,3-benzodithiazolyls accompanied by elimination of H_2S or SF_2 in the hydrocarbon and fluorocarbon series, respectively (Scheme 5).

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 5.

The formation of 2,1,3- (**3**, **10**) and 1,2,3-benzothiadiazoles (**7**) can be explained by oxidative imination of the S atoms of **1** and **2** by R–S–N: nitrenoids followed by splitting of the initial adducts (cf. the ability of $1,3\lambda^4\delta^2$,2,4-benzodithiadiazines to undergo oxidative imination with S^{II} and P^{III} derivatives).[4,15] Compound **7** is known to react with elemental sulfur to give benzopentathiepine **4**, which reversibly eliminates S to afford benzotrithiol **8**.[16] Compound **16** could be formed by reaction of 4,5,6,7-tetrafluoro-1,2,3-benzodithiazolyl with dioxygen.

Crystal and Molecular Structures

According to the X-ray diffraction data (Tables 2–4 and Figures 1, 2, and 3), the polysulfur-nitrogen heterocyclic molecules **6** and **11**–**16** are perfectly planar in the crystal. The standard deviations from the mean plane are 0.039, 0.014, 0.011, 0.023, 0.064, 0.064, and 0.018 Å for **6**, **11**, **12**, **13**, **14**, **15**, and **16**, respectively.

Generally, the crystal packing of **6** and **11**–**16** demonstrates numerous shortened contacts[17,18] between the heteroatoms of neighboring molecules, especially S···S (**4**, **12**, **13**, **16**), S···N (**6**, **11**–**13**), S···O (**16**), S···F (**12**–**16**), and F···F (**15**) contacts.

The crystal structures of **6**, **13**, and **15** reveal π-stacks with a slipped-parallel arrangement of the neighboring molecules. The molecules of **6** and **13** are arranged in a head-to-tail fashion, whilst those of **15** are packed in a head-to-head mode. The separation between the planes of π-stacked molecules is 3.67, 3.33–3.37, and 3.44 Å for **6**, **13**, and **15**, respectively (see Figures 4, 5, and 6, respectively), whereas their inclination varies from 0° for **15** to 2.8° for **6**. The crystal packing of **15** reveals shortened intermolecular F···F contacts of 2.74–2.79 Å.

In the crystal lattice of **12** (Figure 7), one of two crystallographically independent molecules is involved in S···π interactions (S···ring centroid distance: 3.46 Å) leading to columnar stacks, whilst another one is involved in π–π interactions that form dimeric pairs (interplanar separation: 3.51 Å). Both stacks and pairs are arranged in a head-to-tail fashion. For the hydrocarbon analog of **12**, a slipped π-stack structure with a head-to-head orientation of neighboring molecules is observed.[19]

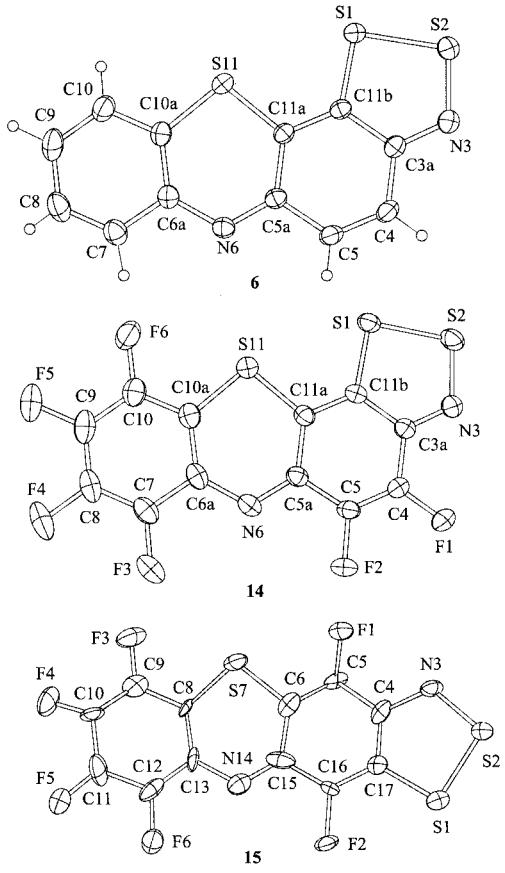


Figure 1. Molecular structures of **6**, **14**, and **15**. Selected bond lengths [Å] and bond angles [°]: **6**: C3a–N3 1.308(3), N3–S2 1.644(2), S2–S1 2.0934(9), S1–C11b 1.747(2), S11–C10a 1.752(2), S11–C11a 1.740(2), N6–C5a 1.312(3), C4–C5 1.342(3), C11a–C11b 1.365(3); C3a–N3–S2 116.0(2); N3–S2–S1 98.56(8), S2–S1–C11b 91.39(8). **14**: C3a–N3 1.303(4), N3–S2 1.627(3), S2–S1 2.0998(19), S1–C11b 1.747(3), S11–C10a 1.749(3), S11–C11a 1.749(3), N6–C5a 1.308(4), C4–C5 1.328(4), C11a–C11b 1.366(4); C3a–N3–S2 115.9(2), N3–S2–S1 98.57(11), S2–S1–C11b 91.50(11). **15** (averaged over four crystallographically independent molecules): C17–S1 1.73(2), S1–S2 2.114(7), S2–N3 1.66(2), N3–C4 1.32(2), N14–C13 1.42(2), N14–C15 1.27(2), S7–C8 1.766(7), S7–C6 1.73(2); C17–S1–S2 91.3(6), S1–S2–N3 97.9(6), S2–N3–C4 115.5(12), C13–N14–C15 119.4(12), C6–S7–C8 101.5(6).

The structure of **5**, a non-fluorinated analog of **13**, was reported earlier.[20] Previously, compound **5** was obtained in ca. 1% yield from an unsuccessful attempt to prepare the benzobis($1,3\lambda^4\delta^2$,2,4-dithiadiazine) system.[20] The crystal packing, with a π-stacked head-to-tail arrangement of neighboring molecules, features an interplanar separation of 3.39 Å that is closely reminiscent of that of **13** (Figure 5).

In contrast to **6**, the neighboring molecules in its fluorinated analog **14** are oriented in a head-to-head manner, whilst their enlarged offset leads to F···π interactions rather than normal π-stacking interactions (Figure 8). The dihedral angle between molecular planes is 6° and the F···π separation is 3.44–3.53 Å (Figure 8). As above, the different orientation of the molecules for **6** and **14** can be attributed to S···N interactions in the lattice of **6** (S···N contacts: 3.10 and 3.06 Å) and to S···F interactions in that of **14** (S···F contacts: 3.07 and 2.90 Å).

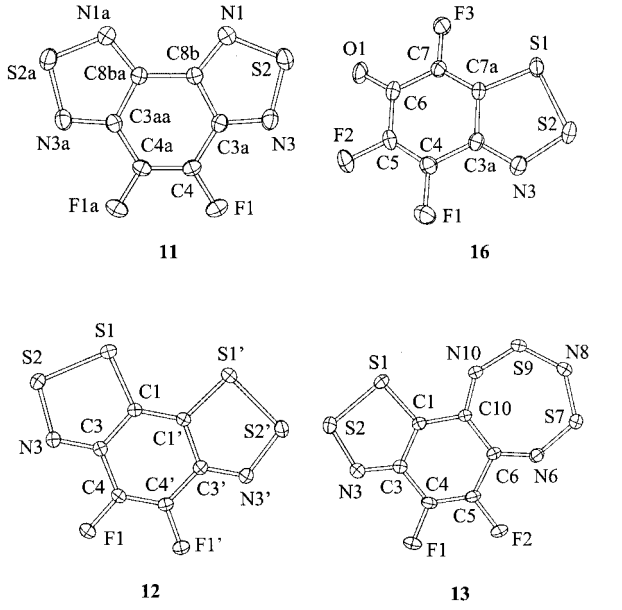

Figure 2. Molecular structures of **11**–**13** and **16**. Selected bond lengths [Å] and bond angles [°]: **11**: C3a–N3 1.330(2), N3–S2 1.628(2), S2–N1 1.625(2); C3a–N3–S2 106.0(1), N3–S2–N1 100.10(8), S2–N1–C8b 106.5(1). **12** (two crystallographically independent parts of molecule): C1–S1 1.743(2), 1.741(2), S1–S2 2.0944(9), 2.083(1), S2–N3 1.643(2), 1.645(2), C3–N3 1.310(3), 1.307(3); C1–S1–S2 91.04(8), 90.81(8), S1–S2–N3 99.10(8), 99.46(8), S2–N3–C3 115.2(2), 114.8(2). **13**: C6–N6 1.308(4), N6–S7 1.576(3), S7–N8 1.621(3), S9–N8 1.568(3), S9–N10 1.539(3), C10–N10 1.350(4), C1–S1 1.700(3), S1–S2 2.055(1), S2–N3 1.614(3), C3–N3 1.304(4); C6–N6–S7 137.0(2), N6–S7–N8 117.6(1), S7–N8–S9 130.3(2), N8–S9–N10 120.8(2), C10–N10–S9 135.6(2), C1–S1–S2 91.8(1), S1–S2–N3 99.0(1), S2–N3–C3 115.3(2). **16**: S1–S2 2.064(1), S2–N3 1.617(2), N3–C3a 1.314(3), S1–C7a 1.723(2), C6–O1 1.234(3); S1–S2–N3 99.19(8), S2–N3–C3a 115.7(2), S2–S1–C7a 92.07(9), S1–C7a–C3a 113.5(2), N3–C3a–C7a 119.6(2).

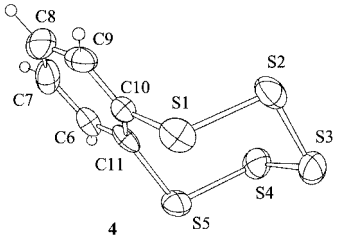

Figure 3. Molecular structure of **4**. Selected bond lengths [Å] and bond angles [°] (averaged over two crystallographically independent molecules): C10–S1 1.806(9), S1–S2 2.044(4), S2–S3 2.050(4), S3–S4 2.043(4), S4–S5 2.041(4), S5–C11 1.808(10); C11–C10–S1 123.2(8), C10–S1–S2 103.6(3), S1–S2–S3 104.1(1), S2–S3–S4 102.5(1), S3–S4–S5 104.3(2), S4–S5–C11 103.5(3), S5–C11–C10 122.7(7).

The crystal packing of **11** and **16** reveals a typical herringbone pattern. In contrast to **11**, columnar π-stacks and molecular layers are formed in the crystal structure of its non-fluorinated analog. Additionally, shortened S···N contacts give rise to a ribbon-like quasi-polymeric structure.[21]

For compound **4**, which was structurally defined previously[22] (see ref.[16] for derivatives), a new polymorph is observed. The hetero rings of two crystallographically independent molecules have the chair-twist-chair (TC) confor-

In the previously observed crystal lattice,[22] π-stacked dimers can be identified (separation of benzene rings: 3.41 Å) that are combined into stacks by S···π interactions (ring centroid···S atom distance: 3.48 Å). Overall, the stacks form a herringbone structure.[22]

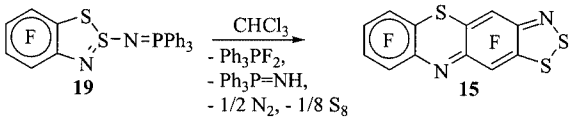
Selected Spectral Properties

For **1** and its carbocyclic substituted derivatives, the maxima of the weak ($\log \varepsilon \approx 2.4$–$2.8$) long-wavelength absorptions in the UV/Vis spectra are in the range of ca. 610–635 nm.[1–5] The 5-5-6 (**12** and its hydrocarbon analog[19]), 5-6-7 (**5**, **13**), and angular 5-6-6-6 (**6**, **14**) systems reveal strong ($\log \varepsilon \approx 3.9$–$4.2$) absorptions in about the same range of ca. 570–635 nm, whereas the linear 5-6-6-6 system **15** absorbs at shorter wavelengths (Table 1), with only a weak dependence of the corresponding π→π* transitions in extended polyheteroatom π-systems upon substitution of fluorine for hydrogen. Additionally, the 5-6-6-6 systems (**6**, **14**, **15**) demonstrate strong fluorescence in the range of ca. 660–680 nm (Table 1). The Stokes shifts are very different for angular (ca. 40–60 nm for **6**, **14**) and linear (ca. 140 nm for **15**) derivatives (Table 1). Taking into account the solubility of the discussed compounds in organic solvents, their thermal stability, and their stability towards moisture (in sharp contrast to starting 1,3λ^{4}δ^2,2,4-benzodithiadiazines),[3,14] it is possible to believe that the polysulfur-nitrogen heterocycles synthesized here can be considered as potential fluorescent dyes. Furthermore, the spectral properties of compound **15** are very similar to those of novel nondoping organic light-emitting diodes (OLEDs).[23]

Alternative Approaches to 5-6-6-6 Systems

Due to the potential of the 5-6-6-6 systems as fluorescent dyes, rational approaches to their preparation are of interest. These can probably be designed based on phenothiazine systems in both the hydrocarbon and fluorocarbon series.

Meanwhile, it was found that compound **15**, the most interesting in the context of OLEDs, can be obtained in moderate yield as the final product of a spontaneous transformation of R–N=PPh$_3$ (**19**; R = 4,5,6,7-tetrafluoro-1,2,3-benzodithiazol-2-yl) in $CHCl_3$ solution (Scheme 6). The ^{19}F and ^{31}P NMR spectra of the reaction mixture reveal formation of Ph_3PF_2 [$\delta_{^{19}F}$ = 121.9 ppm (d, $J_{F,P}$ = 660 Hz); $\delta_{^{31}P}$ = –54.5 ppm (t, $J_{P,F}$ = 660 Hz); cf. ref.[24]] and, tentatively, Ph_3P=N–H [$\delta_{^{31}P}$ = 22.0 (s); cf. ref.[25]] as by-products. At the same time, Ph_3P=S[26] and $(SN)_4$[27] are not observed in the ^{31}P and ^{14}N NMR spectra, respectively. The reaction is solvent-dependent and does not proceed, for example, in toluene.



Scheme 6.

We found by ESR spectroscopy that in $CHCl_3$ solution (but not in toluene) and at ambient temperature, compound **19** spontaneously produces 1,2,3-benzodithiazolyl (**20**; Scheme 7; see refs.[8,9] for the ESR spectrum), seemingly by reversible homolytic splitting of the exocyclic S–N bond. At the same time, the second product of such splitting − the

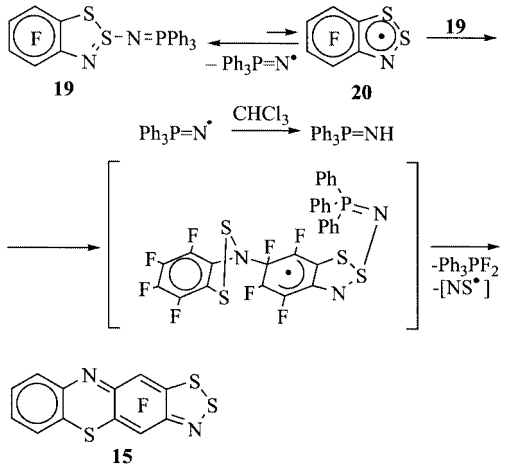
$Ph_3P{=}N^{\cdot}$ radical − was not observed, very likely due to fast decay by hydrogen abstraction from the $CHCl_3$ solvent. Thus, the equilibrium shown in Scheme 7 might be shifted towards radical **20** and an explanation of the self-condensation of **19** into **15** can be suggested, including the role of the $CHCl_3$ solvent (Scheme 7).



Scheme 7.

A postulated $SN^{\cdot}$ by-product (Scheme 7) is very unstable and undetectable by ESR spectroscopy in the condensed phase due to strong *g*-anisotropy (see ref.[28] and references therein).

Conclusions

In contrast to thermolysis in dilute solutions, which leads to persistent 1,2,3-benzodithiazolyls (which are promising building blocks in the design and synthesis of organic molecular magnets and/or organic molecular conductors) in nearly quantitative yields, the thermal transformations of 1,3λ^{4}δ^2,2,4-benzodithiadiazines **1** and **2** (the 6-6 bicyclic system) in concentrated solutions results in complex mixtures of various polysulfur-nitrogen heterocycles, in particular differently fused 5-5-6, 5-6-7, and 5-6-6-6 polycyclic systems that were previously unknown. Despite very low yields, the products were isolated and unambiguously identified by X-ray diffraction. The polycyclic π-functional molecules prepared engage in anisotropic intermolecular interactions in the solid state and are therefore of interest for materials science.[29] In both hydrocarbon and fluorocarbon series, the polycyclic systems synthesized demonstrate strong long-wavelength absorption and fluorescence and can be considered as potential fluorescent dyes. All the aforementioned properties motivate the elaboration of rational approaches to the discussed compounds, and this can be a direction for further investigations in this field. The transformation of the R–N=PPh_3 derivative **19** (R = 4,5,6,7-tetrafluoro-1,2,3-benzodithiazol-2-yl) into the 5-6-6-6 system **15**, which was discovered and explained in the present work, can be considered promising in this context.

Experimental Section

General: Compounds **1**[1] and **2**[2] were prepared by known methods. Their thermolysis was carried out under argon in absolute solvents, with stirring. The concentration of residual water in *n*BuOH was controlled by gas chromatography to be 0.02 M. The chromatographic separations of the products were performed with silica columns. The physical and analytical data for the compounds synthesized are listed in Tables 4 and 5. Compound **19**[15] was prepared in 60% yield by an improved procedure, the details of which will be given elsewhere.[30]

The ^{1}H, ^{13}C, ^{14}N, and ^{31}P NMR spectra were measured with a Bruker DRX-500 spectrometer at frequencies of 500.13, 125.76, 36.13, and 202.46 MHz, respectively, with TMS, NH_3 (liq.) and 85% H_3PO_4 as standards; the ^{19}F NMR spectra were recorded with a Bruker AC-200 machine at a frequency of 188.28 MHz with C_6F_6 as the standard; solutions in $CDCl_3$ were used unless otherwise indicated.

The high-resolution mass spectra (EI, 70 eV) were recorded with a Finnigan MAT MS-8200 instrument.

The UV/Vis spectra were recorded on Specord M40 and Hewlett–Packard 8453 spectrophotometers for solutions in $CHCl_3$. The fluorescent spectra were measured with a Kontron SFM-25 spectrofluorimeter for MeCN solutions.

The GLC-MS determinations were performed with a Hewlett–Packard G1800A GDC apparatus. The GC measurements were carried out with a Hewlett–Packard 5890 instrument.

The ESR measurements were carried out on a Bruker ESP-300 spectrometer (MW power: 265 mW; modulation frequency: 100 kHz; modulation amplitude: 0.005 mT) for a $CHCl_3$ solution of **19**. The spectral integration and simulation were performed with the Winsim 32 program.

Crystallographic Analysis: The single-crystal structure determinations (Tables 2, 3, and 4) were carried out on Bruker P4 (**4**–**6**, **11**–**14**, **16**) and Syntex $P2_1$ (**15**) diffractometers with graphite-monochromated Mo-K_α (λ = 0.71073 Å) and Cu-K_α (λ = 1.54178 Å) radiation, respectively. The structures were solved by direct methods by use of the SHELXS-97 program[31] and refined by the least-squares method in the full-matrix anisotropic (isotropic for H atoms) approximation by use of the SHELXL-97 program.[31] Hydrogen atoms were located geometrically. The structures obtained were analyzed for shortened contacts between non-bonded atoms with the PLATON program.[32,33]
For compounds **4** and **15**, available single crystals were very small (Tables 2 and 4) and reflections could only be measured to θ = 22.5° and θ = 57°, respectively. The structure of **15** was refined with AFIX and EADP restraints applied to selected geometrical and anisotropic parameters, respectively: the C_6F_4 moiety was restrained to be a right hexagon with all C–F bond distances of 1.35 Å, for each C–F bond of the molecule thermal parameters of the F atom were fixed at corresponding values of the C atom.
CCDC-268796 (for **4**), -268797 (for **6**), -268798 (for **11**), -268799 (for **12**), -268800 (for **13**), -268801 (for **14**), -268802 (for **15**), and -268803 (for **16**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. For **5**, the data obtained in this work are in full agreement with those published previously.[20]

Identification of Known Compounds: The isolated compounds **3**,[34] **5**,[20] **10**,[35] and **18**,[3] described previously, were identified by comparison of reported m.p.'s, unit cell (XRD) and spectral (^{1}H and

Table 4. Crystal data and structure refinement for compounds **15** and **16**.

Compound	**15**	**16**
Empirical formula	$C_{12}F_6N_2S_3$	$C_6F_3NOS_2$
Formula mass	382.32	223.19
Temperature [K]	296(2)	296(2)
Crystal system	monoclinic	monoclinic
Space group	*Cc*	$P2_1/n$
a [Å]	11.310(2)	5.1828(7)
b [Å]	11.311(2)	9.706(1)
c [Å]	39.884(8)	14.298(2)
β [°]	97.97(2)	95.85(1)
Volume [Å^3]	5052.7(18)	715.5(2)
Z	16	4
$D_{calcd.}$ [Mg m^{-3}]	2.010	2.072
Absorption coefficient [mm^{-1}]	6.119	0.749
Crystal size [mm^3]	0.13 × 0.13 × 0.03	0.80 × 0.20 × 0.08
θ range for data collection [°]	2.24–57.43	2.54–24.99
Index ranges	$0 \le h \le 12$	$-6 \le h \le 0$
	$0 \le k \le 12$	$0 \le k \le 11$
	$-43 \le l \le 43$	$-16 \le l \le 16$
Reflections collected	4151	1398
Independent reflections	3688 [$R_{(int)}$ = 0.1374]	1250 [$R_{(int)}$ = 0.0186]
Completeness to *θ* [%]	100.0	99.9
Absorption correction	empirical	empirical
Min. and max. transmission	0.46 and 0.82	0.87 and 0.98
Data/restraints/parameters	3688/38/544	1250/0/118
Goodness-of-fit on F^2	1.051	1.065
Final *R* indices [$I > 2\sigma(I)$]	R_1 = 0.0739, wR_2 = 0.1679	R_1 = 0.0329, wR_2 = 0.0939
R indices (all data)	R_1 = 0.1311, wR_2 = 0.2071	R_1 = 0.0387, wR_2 = 0.0980

Table 5. Characterization of compounds **5**, **6**, and **11**–**16**.

	M.p. [°C]	Formula	MS: M^+ (*m*/*z*) measured (calculated)
5	269–271	$C_6H_4N_4S_4$	257.9154 (257.9162)
6	206–208	$C_{12}H_6N_2S_3$	273.9724 (273.9693)
11	175–176[a]	$C_6F_2N_4S_2$	229.9542 (229.9533)
12	230–232[a]	$C_6F_2N_2S_4$	265.8918 (265.8912)
13	280–282[a]	$C_6F_2N_4S_4$	293.8972 (293.8974)
14	216–217	$C_{12}F_6N_2S_3$	381.9133 (381.9128)
15[b]	234–236	$C_{12}F_6N_2S_3$	381.9152 (381.9128)
16	210–212	$C_6F_3NOS_2$	222.9371 (222.9374)

[a] In a sealed capillary. [b] Correct elemental analyses for C, F, N, S.

20 °C, filtered and chromatographed. Elution with hexane gave 50 mg of a red oil consisting (GLC-MS, ^{1}H NMR) of compounds **9** (33%), **4** (31%), **8** (13%), **3** (3%), **7** (1.5%), elemental S (0.6%), and squalane (5%). Compound **4** (5 mg) was isolated by low-temperature crystallization from hexane as pale-yellow crystals (m.p. 55–56 °C). Elution with toluene gave 30 mg (10% yield) of compound **3**[34] as colorless crystals. Elution with 1:1 CH_2Cl_2/ethyl acetate followed by crystallization of the product from 10:1 hexane/toluene gave compound **6** (4 mg) as black crystals. The reaction precipitate was refluxed in toluene and the solution formed was chromatographed. Elution with toluene followed by recrystallization of the product from the same solvent gave compound **5** (2 mg) as black crystals. The gases evolved during the thermolysis were absorbed by dilute HCl. Photometrical analysis with Nessler's reagent revealed NH_3 in 3% yield.

Thermolysis of 5,6,7,8-Tetrafluoro-1,3λ^{4}δ^2,2,4-benzodithiadiazine (2) in Decane. Formation of Compounds 10–16: A solution of 0.96 g (4 mmol) of **2** in 8 mL of decane was stirred at 160–170 °C for 6 h, cooled to 20 °C, filtered and chromatographed (hexane). Compound **10**[35] (36 mg; 5%) was obtained as colorless crystals. The reaction precipitate was sublimed at 170 °C/2 mm and the sublimate chromatographed. Elution with toluene gave blue and red zones. Sublimation of the product from the blue zone at 110 °C/2 mm gave a mixture of **12**, **14**, and **17**. Compound **14** (6 mg) was obtained as black crystals by further chromatography of this mixture (1:1 hexane/toluene) followed by crystallization from hexane. Compound **12** (3 mg) was obtained as black crystals by crystallization of its mixture with isomeric **17** from 4:1 hexane/toluene. The mother liquor contained residual **12** (GLC-MS: *m*/*z* = 226 [M^+]; ^{19}F NMR: *δ* = 17.9 ppm) and **17** (GLC-MS: *m*/*z* = 226 [M^+]; ^{19}F NMR: *δ* = 40.7 ppm; the structure was assigned tentatively). Crystallization (toluene) of the non-volatile residue from sublimation gave **13** (3 mg) as black crystals. Sublimation of the product from the red zone at 120 °C/2 mm gave **15** (1 mg) as black crystals. Elution with 10:1 toluene/ethyl acetate gave **11** and **16**, which were purified by sublimation at 120 °C/2 mm. Compound **11** (12 mg) was obtained as colorless crystals and compound **16** (6 mg) as black crystals.

Thermolysis of Compound 1 in 1-Butanol. Formation of Compound 6: A solution of 0.17 g (1 mmol) of **1** in 1 mL of *n*BuOH was refluxed for 3.5 h, cooled to 20 °C and chromatographed. Elution with CH_2Cl_2 gave ca. 4 mg of a mixture (GLC-MS data) of compounds **3** (20%), **4** (traces), **7** (40%), **9** (20%), and elemental S (20%). Elution with 10:1 CH_2Cl_2/ethyl acetate gave compound **6**. The latter was repeatedly chromatographed under the same conditions and recrystallized from 10:1 hexane/toluene to give black crystals (1 mg).

Thermolysis of Compound 2 in 1-Butanol. Formation of Compounds 11 and 18: A solution of 0.48 g (2 mmol) of **2** in 2 mL of *n*BuOH was refluxed for 4 h, cooled to 20 °C, and chromatographed (hexane) to give ca. 0.17 g of di-*n*-butyl sulfite, compound **11**, and compound **18**. Compound **11** (4 mg) was obtained as colorless crystals

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

by sublimation at 120 °C/2 mm followed by recrystallyzation from hexane. Compound **18**[3] (54 mg) was obtained as yellow crystals by sublimation at 130 °C/2 mm followed by recrystallization from hexane.

Spontaneous Transformation of Compound 19 in Chloroform Solution. Formation of Compound 15: A solution of 0.10 g (0.2 mmol) of **19** in 0.5 mL of $CHCl_3$ was kept for 7 d at ambient temperature and then evaporated. The residue was chromatographed (benzene) to give compound **15** (12 mg, 30%) as black crystals.

According to the ESR measurements, the radical **20** appeared immediately upon dissolving precursor **19** and was detectable for a few days. For the ^{19}F and ^{31}P NMR measurements, the preparation was performed in $CDCl_3$ solution.

Acknowledgments

The authors are grateful to Dr. Vladimir V. Koval and Dr. Irina G. Irtegova for measurements of fluorescent and ESR spectra, respectively, to the Siberian Division of the Russian Academy of Sciences for access to instrumental facilities at the Collective Chemical Center of the Division, and to the Russian Foundation for Basic Research for access to the Cambridge Crystallographic Database (grant 02-07-90322) and the STN International databases via STN Center at the Institute of Organic Chemistry, Novosibirsk, Russia (grant 00-03-32721).

Synthesis, Structure and Photoluminescent Studies of Two Novel Layered Uranium Coordination Polymers Constructed from UO(OH) Polyhedra and Pyridinedicarboxylates

Yan-Zhen Zheng,[a] Ming-Liang Tong,*[a] and Xiao-Ming Chen[a]

Keywords: Carboxylate ligands / Coordination polymers / Photoluminescence / Uranium

Two new uranium coordination polymers have been obtained from the hydrothermal reaction of $(UO_2)(CH_3COO)_2{\cdot}2H_2O$ with 3,4-pyridinedicarboxylic acid (3,4-pydaH$_2$) or 2,4-pyridinedicarboxylic acid (2,4-pydaH$_2$). $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)_2(3,4\text{-pydaH})(3,4\text{-pyda})_{0.5}]_n$ (**1**) crystallizes in the orthorhombic space group *Pccn* with a = 18.168(2), b = 12.635(1), c = 16.149(1) Å, V = 3707.0(5) Å^3, and Z = 8. $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)(\mu_2\text{-}OH)(2,4\text{-pyda})(H_2O)_2]_n{\cdot}nH_2O$ (**2**) is in the orthorhombic space group *Pbcn* with a = 22.788(2), b = 7.1468(5), c = 21.627(1) Å, V = 3522.1(4) Å^3, and Z = 8. Complex **1** features a wave-like 2D layer that is constructed by connecting the 1D UO(OH) ribbons by the V-shaped 3,4-pyda or 3,4-pydaH ligands. Complex **2** is a rare hexameric species amongst uranium compounds and features a (4,4) planar "open-layer", which is constructed by the 4-connected hexameric UO(OH) polyhedra and the 2-connected 2,4-pyda ligands. The fluorescence emission (521 nm) of **2** is red-shifted by about 13 nm (emission) and about 40 nm (excitation) compared to that of **1**, and the lifetimes increase with the polymerization of UO(OH) polyhedra (145 μs for **1** compared to 24.4 μs for **2**).

Introduction

In the area of inorganic-organic hybrid materials, metal-organic coordination polymers built from nano-sized MO(OH) clusters and multi-functional carboxylates are of current interest driven partially by their intriguing molecular topologies and crystal packing motifs as well as the fact that they may be designed with a variety of functionalities in mind, such as photoelectronics, separation, magnetism, ion exchange, gas storage, and catalysis.[1–7] In addition to being robust and thermally stable, some possess photoluminescent properties, a feature that has contributed to the closed-shell d^{10} metal compounds, including 3d^{10} copper(I) and zinc(II), 4d^{10} silver(I) and cadmium(II), and 5d^{10} gold(I) and mercury(II) complexes, being widely investigated for new materials.[8–11] In fact, the highest valent actinide elements have similar 5d^{10} electrons in spite of the shielding of the outer 6s^{2}6p^6 electrons, therefore they are also good candidates for luminescent materials. However, the luminescent properties of solid-state actinide compounds are relatively less studied compared to other transition metal compounds.[12] Uranium is the most representative element of the actinides and therefore has been investigated most.[12–15] Several groups are endeavoring to obtain functional uranium oxide and oxyfluoride materials and have made much progress; so far, a wide range of uranyl phosphates, nitrates, perchlorates, sulfates, selenates, and iodates have been successfully synthesized and characterized.[12a,12b,13,14] These uranium compounds can be classified as "uranium-inorganic frameworks" (UIFs), in which the frameworks are merely constructed by the inorganic UO(F) polyhedra, and the role of the organic component is just charge-balancing and/or space-filling. In contrast, the term "uranium-organic frameworks" (UOFs) means that the uranium–organic connectivity is interrupted by a bridging organic spacer.[1c] Unlike UIFs, UOFs were hardly known before 2003, and were not rapidly developed until recently by O'Hare, Cahill, You, and Chen.[12c,12d,15] The emergence of UOFs is meaningful because diverse organic components can be incorporated, and therefore the construction and functionalities of this kind of uranium coordination polymer are getting more intriguing.[12c,12d,15]

The heterofunctional pyridinedicarboxlic acids are optimal ligands not only due to their "antenna effect",[16] which can occur through an energy transfer from the excited π orbitals of the pyridine ring to the uranium metal center,[12c,12d,16] but also due to their ability to incorporate the MO(OH) clusters into the metal–organic frameworks.[17] Our previous studies of 3d^{10} and 4d^{10} photoluminescent compounds revealed that the formation of MO(OH) cores can significantly increase the emission lifetime,[11] which is important for luminescent materials. We have now extended our research to 5d^{10} actinides to search for new photolumi-

nescent materials containing MO(OH) clusters, and report herein two novel layered UOFs constructed from UO(OH) polyhedra and pyridinedicarboxylates, namely $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)_2(3,4\text{-pydaH})(3,4\text{-pyda})_{0.5}]_n$ (**1**) and $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)(\mu_2\text{-}OH)(2,4\text{-pyda})(H_2O)_2]_n{\cdot}nH_2O$ (**2**).

Results and Discussion

Synthesis and Characterization

The hydrothermal method has been proved to be very effective for the synthesis of uranium coordination polymers.[12–15] It is well known that changing the hydrothermal conditions, such as the temperature, reaction time, pH value, and molar ratio of the reactants, can significantly influence the final reaction products. In previous explorations of the synthesis of metal-cluster-based coordination polymers containing mixed organic ligands under typical hydrothermal conditions (i.e. 120–180 °C and 2–7 days), we and others have found that pH 8–9 is most suitable for the formation of metal–hydroxy(oxy) clusters,[11,17] although uranium–hydroxy(oxy) species can be formed at a rather lower pH value of 3–4, which was used in the preparation of uranylhydroxy(oxy) clusters **1** and **2**.

Crystal Structures

X-ray structural analysis showed that compound **1** crystallizes in the orthorhombic space group *Pccn*. Each asymmetric unit in **1** contains three crystallographically unique uranyl ions, one μ_3-oxo (O_7), two μ_3-hydroxo groups (O_8, O_9), and one 3,4-pydaH, all of which lie on a general position, and one 3,4-pyda which lies across a twofold axis. Selected bond lengths and angles are listed in Table 1. Bond-valence sum (BVS) calculations with U–O and U–N bond-valence parameters taken from the literature[13a,18] confirm that the uranium centers are unambiguously U^{VI} with values of 6.10, 6.08, and 6.11 in **1**. Owing to the presence of the heavy uranium atoms, hydrogen atoms can hardly be located in the difference map, so we distinguished the μ_3-oxo and μ_3-hydroxo oxygen atoms by comparing the U–O bond lengths and U–O–U angles with corresponding ones of related compounds containing $(UO_2)_4(\mu_3\text{-}OH)_2$[13a–13c] and $(UO_2)_3(\mu_3\text{-}O)$[15c] cores as well as by BVS calculations on the oxygen atoms.[13a,14c,18] Each uranium center is bound to two axial oxides to form a uranyl unit $[UO_2]^{2+}$. The $U\text{–}O_{uranyl}$ bond lengths range between 1.75(1) and 1.79(1) Å, in good agreement with the reported average uranyl bond length of 1.758(4) Å.[13a] Each uranyl unit is coordinated to five equatorial oxides to form a $[UO_7]$ pentagonal bipyramid (Figure 1, a) with U–O(μ_3-oxo), U–O(μ_3-hydroxo), and U–O (carboxylate) bonds lengths of 2.21(1)–2.264(9), 2.39(1)–2.54(1), and 2.38(1)–2.46(1) Å, respectively, which are all in the normal range of U–O distances reported in the literature.[12–15] Interestingly, no pyridyl nitrogen atoms from the pyda and pydaH ligands are coordinated to the uranyl units in **1**, therefore the polymerization of the uranyl cations extends in the [100] direction by edge-sharing the adjacent pentagonal bipyramids to form infinite $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)_2]_n^{2n+}$ ribbons. The one-dimensional ribbons are connected by 3,4-pyda and 3,4-pydaH bridges into wave-like sheets with a dihedral angle of 77.8° between the U–O ribbons (Figure 1, b). The coordination mode of the 3,4-pyda ligands in **1** is different from those found in other coordination polymers containing 3,4-pyda ligands.[17a,17b]

Each crystallographically independent unit of **1** contains one $[(UO_2)_3(\mu_3\text{-}O)(\mu_3\text{-}OH)_2]^{2+}$, one $(3,4\text{-pydaH})^-$, and one half of $3,4\text{-pyda}^{2-}$. The proton on the pyridyl nitrogen could not be located from the difference map owing to the presence of the heavy uranium ion. However, the distances [N···O = 2.85(2)–3.00(2) Å] between the pyridyl nitrogen and three uranyl oxygen atoms indicate the presence of a trifurcated hydrogen-bonding interaction, which means that the pyridyl nitrogen should be protonated and the net charge of the $(pydaH)^-$ moiety can be assigned as –1 (Figure 1, c). Moreover, C5 can be distinguished from N1 by considering their hydrogen-bonding environment. The C···O distance between C5 and O3A is 3.10(2) Å, with a C–H···O angle of 173.5°, which suggests a typical C–H···O interaction.[19] However, the N2 and C11 atoms of another pyda ligand are not distinguishable because this pyda moiety lies on a twofold axis.

Compound **2** crystallizes in the orthorhombic space group *Pbcn*. Each asymmetric unit in **1** contains three crystallographically unique uranyl ions, one μ_3-oxo(O_1), one μ_2-hydroxo(O_2), one μ_3-hydroxo(O_3), one 2,4-pyda, and two aqua ligands, all of which lie on a general position (Figure 2, a). Selected bond lengths and angles are listed in Table 2. BVS calculations confirm that the uranium centers are U^{VI}, with values of 6.05, 6.05, and 6.03 in **2** for U(1), U(2), and U(3), respectively.[13a,18] There are two kinds of uranium pentagonal bipyramids in **2**, namely a $[UO_7]$ and a $[UO_6N]$ unit, with mean U=O, U–O(μ_3-oxo), U–O(hydroxo), U–O(carboxylate), U–O(aquo), and U–N(pyridyl) bonds lengths of 1.775(7), 2.213(7), 2.397(7), 2.464(8), 2.389(8), and 2.617(9) Å, respectively. All these distances are also within the normal range of U–O or U–N bonds.[12–15] In contrast to **1**, the pyridyl nitrogen atom and one 2-position carboxylate oxygen atom of each 2,4-pyda ligand chelate to a uranium atom, while the other carboxylate end bridges two uranyl units in a μ_2-carboxylato-*O*,*O*′ mode. This coordination mode has recently been found in the 3D coordination polymer $\alpha\text{-}[Cd_2(\mu_3\text{-}OH)_2(2,4\text{-pyda})]$.[17c] The pyridyl ring is efficiently driven by this chelating coordination mode to be coplanar with the uranyl pentagonal equatorial plane. Each hexameric uranyl cluster is surrounded by four 2,4-pyda ligands, which means that further polymerization of uranyl in the plane is inevitably interrupted. As shown in part b of Figure 2, the resulting open framework is a 2D (4,4) square grid by considering the hexameric uranyl clusters as the 4-connected nodes and the 2,4-pyda ligands as the connections between the 4-connected nodes. The lattice water molecules are situated be-

tween the wave-like coordination layers and form water···oxo [O···O: 2.89(1)–3.05(1) Å; O–H–O: 145(13)–174(16)°] and water···hydroxo [O···O: 2.68(1) Å; O–H–O: 164.6°] hydrogen-bonding interactions with the upper and lower layers, respectively. These may make some contributions to the bending of the hexameric U–O polyhedra, with an angle of 142.6°, and disturb the further equatorial polymerization in **2**. It should be noted that **2** is the first hexameric species of uranium(VI) compounds, although hexameric uranium(IV) compounds have been found.[13d,13e] As far as we know, the majority of U^{6+} phases prefer to adopt a structure that is based upon infinite sheets of poly-

It is interesting to compare the dimensions and densities of compounds **1** and **2** with other recently reported UOFs and UIFs. As listed in Table 3, the representative UOFs are mainly based on uranium carboxylate coordination polymers, including the zero-dimensional metallamacrocycles constructed with (2*R*,3*R*,4*S*,5*S*)-tetrahydrofuran-tetracarboxylic acid,[15d] the one-dimensional chains constructed with glutaric acid,[15a] isophthalic acid,[15a] or adipic acid,[15b] the two-dimensional layers constructed with 1-oxo-4-cyanopyridine,[12c] ethyl (*S*)-lactic acid,[12c] or 3,5-pyrazoledicarboxylic acid,[12d] and the three-dimensional networks constructed with succinic acid,[15a] adipic acid,[15b] or quinolinic acid.[15c,15e] If we sort the order as the density, **1** and **2** are the densest UOFs and are even denser than some UIFs. These results may be due to the following two facts. Firstly, these two compounds adopt a close-packing style *ABAB*... in order to fill the hollow space as much as possible, and secondly, the inorganic uranyl ions are highly polymerized with the O^{2-} or OH^{-} ions, which can enhance the density of the entire compounds. Although both zero-dimensional (0D) UOFs and UIFs have the lowest density, it is hard to determine the relationship between density and dimensions because there is no appropriate example (such as supramolecular isomers) in the reported UOFs and UIFs.

Luminescent Properties

The fluorescence spectra (Figure 3) of **1** and **2** were measured for crushed single-crystalline powder samples, which are were pure phases, as confirmed by an XRD study (Figure S1 in the Supporting Information). Interestingly, the well-known characteristic emission fine-structure of UO_2^{2+} is observed in **1,** featuring a main peak (λ = 521 nm) and three shoulder peaks (λ = 503, 542, and 568 nm), while the emission fine-structure of **2** is inconspicuous and only a broad peak is observed (λ = 534 nm). In contrast, the highest emission peak of **2** is red-shifted by 13 nm compared to **1**, and the peaks (λ = 362, 478 nm) in the excitation spectrum of **2** are all red-shifted by 40 nm relative to **1** (λ = 322, 438 nm). It should be noted that the fluorescence spectra of free 2,4-pydaH$_2$ and 3,4-pydaH$_2$ display very weak photoluminescent properties (Supporting Information, Figure S2). Despite the weak intensity of the free ligands, the wavelengths of the excitation peaks (λ = 364 nm in 3,4-pydaH$_2$ and 343 nm in 2,4-pydaH$_2$) resemble the peaks of **1** and **2**, which indicates that the aromatic ligands may contribute to the related absorption bands in the excitation spectra of **1** and **2**, therefore ligand-to-metal charge transfer (LMCT) may occur between the 5d orbital of U^{6+} and the chromophoric pyridine-containing ligands,[20] and the component of LMCT in the emission peak may contribute to the single peak nature of **2**,[20] in which the pyridine nitrogen atom coordinates directly to the U^{6+} center. It is noteworthy that the exited-state lifetime (ca. 145 μs) of **1** is about six times that (ca. 24.4 μs) of **2** (see Figure S3; data were fitted with a single exponential decay function). This result is consistent with the long lifetime nature of the actinide ions.[12] Several reasons may account for this difference. Firstly, the enhancement of the lifetime in **1** may be caused by the effect of infinite UO(OH) ribbons, which is consistent with our previous studies of 3d^{10} and 4d^{10} compounds[11] as well as an aqueous fluorescence study of uranyl hydrolysis.[21] Secondly, the chromophoric 2,4-pyda li-

gand, which is a strong π-donor ligand that coordinates directly to the uranyl in the equatorial plane, would correlate well with the low luminescence quantum yield.[12,20] Thirdly, the presence of the protonated pyridyl ring could enhance energy transfer from pyridinium to uranyl moieties in **1**.[12] Finally, the existence of the lattice water molecules could partially quench the excited state in **2**.[12,20]

Conclusions

Two new layered uranium–organic photoluminescent coordination polymers of 3,4- and 2,4-pyridinedicarboxylates, which contain infinite and finite UO(OH) polyhedra, respectively, have been hydrothermally synthesized and crystallographically characterized. This work reveals that

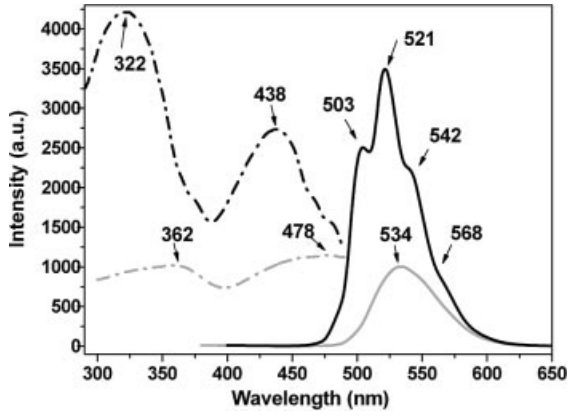

Figure 3. The emission spectra (solid line) and excitation spectra (dash-dot line) of **1** (black) and **2** (gray).

the multitopic ligand has an important effect on the structures of uranium–organic coordination polymers and the lifetimes evidently increase with the polymerization of the UO(OH) polyhedra.

Experimental Section

General Remarks: The reagents and solvents employed were commercially available and used as received without further purification. The C, H, and N microanalyses were carried out with an Elementar Vario-EL CHNS elemental analyzer. The FT-IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Bio-Rad FTS-7 spectrometer. X-ray powder diffraction (XRD) intensities for **1** and **2** were measured at 293 K on a Rigaku D/max-IIIA diffractometer (Cu-K_α, λ = 1.54056 Å). The crushed, single-crystalline powder samples were prepared by crushing the crystals and scanned from 4–65° with a step of 0.1° s^{-1}. Calculated patterns for **1** and **2** were generated with PowderCell 2.3. The emission/excitation spectra were recorded on an F-4500 fluorescence spectrophotometer and the lifetimes were measured on an Edinburgh FLS-920 spectrophotometer equipped with a continuous Xe-900 Xenon lamp or a μF900 microsecond flash lamp. Crushed single-crystalline powder samples of **1** and **2** and powder samples of the free ligands 2,4-pydaH$_2$ and 3,4-pydaH$_2$ were used for the photoluminescence measurements.

Synthesis: Complexes **1** and **2** were synthesized by heating a mixture of $(UO_2)(CH_3COO)_2 \cdot 2H_2O$ (0.203 g, 0.5 mmol), 3,4-pydaH$_2$ [or 2,4-pydaH$_2$ (0.083 g, 0.5 mmol)], and deionized water (9 mmol) in a molar ratio of 1:1:1000 in a 23-mL, Teflon-lined autoclave at

$D_{calcd.}$ [mg m^{-3}]	3.968	4.071
Absorption coefficient [mm^{-1}]	22.229	27.603
F(000)	3804	3712
Crystal size [mm]	0.10 × 0.08 × 0.02	0.08 × 0.08 × 0.02
θ range for data collection [°]	1.96 to 27.50	1.79 to 27.50
Limiting indices	$-21 \le h \le 23$, $-16 \le k \le 15$, $-17 \le l \le 20$	$-29 \le h \le 17$, $-9 \le k \le 9$, $-27 \le l \le 28$
Reflections collected/unique	20920/4238 [R_{int} = 0.0850]	19029/4002 [R_{int} = 0.0513]
Completeness	99.2% (θ_{max} = 27.50°)	98.9% (θ_{max} = 27.50°)
Absorption correction	Multi-scan (*SADABS*; Bruker, 2002)	Multi-scan (*SADABS*; Bruker, 2002)
Max. and min. transmission	0.6220 and 0.1790	0.6082 and 0.2162
Refinement method	Full-matrix least-squares on F^2	Full-matrix least-squares on F^2
Data/restraints/parameters	4238/342/271	4002/9/262
Goodness-of-fit on F^2	1.048	1.070
Final *R* indices [$I > 2\sigma(I)$]	R_1 = 0.0618, wR_2 = 0.1331[a]	R_1 = 0.0411, wR_2 = 0.1002[a]
R indices (all data)	R_1 = 0.0833, wR_2 = 0.1436[a]	R_1 = 0.0507, wR_2 = 0.1050[a]
Extinction coefficient	none	none
Largest diff. peak and hole [e Å^{-3}]	2.756 and –2.523	4.887 and –1.495

[a] $R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{1/2}$.

180 °C for 3 d. After slowly cooling down to room temperature within 12 h, yellow needle-like crystals of **1** (yield: 0.166 g, ca. 90% based on U) or yellow plate-like crystals of **2** (yield: 0.160 g, ca. 87% based on U) were filtered, washed with deionized water, and dried in the air.

1: $C_{10.5}H_8N_{1.5}O_{15}U_3$: calcd. C 11.37, H 0.73, N 1.89; found C 11.41, H 0.71, N 1.90. IR: $\tilde{\nu}$ = 911 cm^{-1} U=O; 1374, 1427, 1551, 1582 C=$C_{(py)}$ or C=$N_{(py)}$; 1643, 1680 C=O; 2881, 3000, 3058, 3077 C–H or N–H; 3438, 3547 cm^{-1} O–H.

2: $C_7H_{11}NO_{16}U_3$: calcd. C 7.79, H 1.03, N 1.30; found C 7.81, H 1.01, N 1.29. IR: $\tilde{\nu}$ = 930 cm^{-1} U=O; 1322, 1384, 1479, 1542 C=$C_{(py)}$ or C=$N_{(py)}$; 1596, 1635 C=O; 2850, 2916, 3067 C–H; 3424, 3535, 3623 cm^{-1} O–$H_{(H_2O)}$ (for details, see Figure S4 in the Supporting Information).

X-ray Crystallographic Study: Diffraction intensities of **1** and **2** were collected on a Bruker Apex CCD area-detector diffractometer (Mo-K_α, λ = 0.71073 Å). Absorption corrections were applied by using the multiscan program SADABS.[22] The structures were solved by direct methods and refined with a full-matrix least-squares technique with the SHELXTL program package.[23] Anisotropic thermal parameters were applied to all non-hydrogen atoms. The organic hydrogen atoms were generated geometrically (C–H = 0.96 Å), as were the hydroxy oxygen atoms (O–H = 0.85 Å); the aqua hydrogen atoms were located from difference maps. For **1**, the proton on the pyridyl nitrogen of (3,4-pydaH)$^-$ was added in a geometrically idealized position. The disordered atoms of N2 and C11 were treated as each having an occupation of 50%. The crystallographic data for **1** and **2** are listed in Table 4.

CCDC270938 (for **1**) and -270939 (for **2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Supporting Information Available: IR spectra, powder X-ray diffraction patterns, fluorescence spectra and lifetime spectra (with fitting results).

Acknowledgments

This work was supported by the NSFC (20131020 and 20471069), the FANEDD of China (200122), the Scientific and Technological Project of Guangdong Province (04205405), and Sun Yat-Sen University. Special thanks are offered to one of the reviewers who pointed out that compound **2** is the first hexameric species in U(VI) compounds. Z.-Y. Zheng thanks Prof. R. D. Rogers and Prof. Ling-Kang Liu for their help in collecting the references.

Vibrational Spectra of Eight-Coordinate Niobium and Tantalum Complexes with Peroxo Ligands: A Theoretical Simulation

Daisy Bayot,[a] Michel Devillers,[a] and Daniel Peeters*[b]

Keywords: Density functional calculations / IR spectroscopy / Niobium / Tantalum / Peroxo ligands / Raman spectroscopy

A theoretical interpretation of the experimental observations made by vibrational IR and Raman spectroscopy on eight-coordinate peroxo complexes of niobium(V) and tantalum(V) is carried out. The theoretical study, realised on stoichiometric models of general formula $[M(O_2)_4]^{3-}$, $[M(O_2)_3L_2]^{x-}$, *cis*- and *trans*-$[M(O_2)_2L_4]^{y-}$ and $[M(O_2)L_6]^{z-}$ (M = Nb^V or Ta^V), provides the normal modes of vibrations involving peroxo ligands, their corresponding calculated frequency and their activity in IR and/or Raman spectroscopy. The theoretical results from the model complexes are compared with experimental IR and Raman spectroscopic data.

Introduction

In the last decades, peroxo species of transition metals have attracted considerable attention because of their extended coordination chemistry as well as their role in several challenging domains. Peroxo species of d^0 transition metals, for example V^V, Ti^{IV}, Mo^{VI}, W^{VI} and Nb^V, are potential oxygen donors to organic substrates in the liquid phase.[1–5] They can act as stoichiometric oxidants or as catalysts in the presence of oxidizing agents, such as H_2O_2 or *t*BuOOH, that are used to regenerate the starting peroxo metal species in situ. Such peroxo complexes can oxidize some electrophilic species and a large variety of nucleophilic substrates, such as phosphanes, sulfides, alcohols, olefins, enolates, imines, amides, etc.[3]

A further interest in peroxo complexes results from the important role they play in biological systems. For example, peroxovanadium(V) complexes have been found to have anti-tumour and insulin mimetic activities, while others have been studied as functional models for the vanadium haloperoxidase enzymes.[6,7] Finally, because such peroxo-type coordination compounds are most of the time soluble in water, they are also of great interest as precursors for the preparation of oxide materials and, more particularly, multimetallic oxides involving highly polarizing d^0 transition metals like Ti^{IV}, Zr^{IV}, Nb^V or Ta^V, for which the availability of water-soluble compounds is very limited.[8–13] This "peroxo way" has recently been shown to be a valuable approach for the synthesis of mixed oxides containing niobium and/or tantalum from well-defined and pre-isolated complexes.[14,15]

The peroxo compounds of transition metals correspond either to homoleptic complexes or to heteroleptic ones. In the heteroleptic compounds, one to three coordinated peroxo groups are associated with one or more monodentate or polydentate ligands. The various ways in which a peroxo group is expected to coordinate to metals are illustrated in Figure 1, but the most common type, observed for d^0 transition metals, is the so-called side-bonded peroxo ligand, complexed in an η^2 mode.

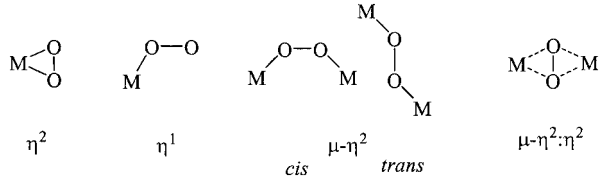

Figure 1. Coordination modes of peroxo groups to metal atoms.

The coordination polyhedra in heteroleptic peroxo compounds are fairly predictable. For the heavy group five elements niobium and tantalum, for example, coordination number 8 with dodecahedral geometry has invariably been observed. Several structural analyses of such heteroleptic complexes have been carried out, revealing the actual coordination spheres in each case.[14,16–21] However, most of the time no crystal structure could be obtained, and the determination of the metal environment in the complex is ambiguous. In that context, vibrational spectroscopy is still essential to characterise complexes containing coordinated peroxo groups. In the case of side-bonded peroxo ligands, two types of vibrational modes are expected: the peroxo stretch-

ing, ν(O–O), and the metal–peroxo stretching, ν[M(O_2)]. As far as niobium and tantalum compounds are concerned, the determination of the number of peroxo ligands present around the metal atom in heteroleptic complexes can be deduced from the number of ν(O–O) bands, occurring near 850 cm^{-1}, by using an empirical rule which states that the presence of two or three ν(O–O) bands in the IR spectrum indicates the formation of a diperoxo or triperoxo complex, respectively.[22] As far as homoleptic $[M(O_2)_4]^{3-}$ (M = Nb^V or Ta^V) complexes are concerned, one broad or two ν(O–O) bands are observed in the IR and two such bands in the Raman spectra.[23–26] A recent study reported the vibrational spectra of tetraperoxotantalate compounds with several different counterions, $(A^I)_3[Ta(O_2)_4]$ (A^I = K^+, Rb^+, Cs^+). The authors determined the different vibrational modes of the O–O and Ta–O stretching vibrations from the site-group analysis of the $[Ta(O_2)_4]^{3-}$ anion (site group symmetry D_{2d}).[26]

The present work deals with the theoretical simulation of the experimental observations made by vibrational IR and Raman spectroscopy on eight-coordinate peroxo complexes of niobium(v) and tantalum(v). This study will provide the normal modes of vibrations involving peroxo ligands, their corresponding frequency and their activity in IR and/or Raman spectroscopy and so constitute a guide to interpret experimental spectra. By validating the empirical rules mentioned so far for the interpretation of the vibrational spectra of eight-coordinate peroxo complexes, this work provides important tools to develop the coordination chemistry of such compounds.

Results and Discussion

Theoretical calculations were performed at the DFT level using various functionals for five stoichiometric models corresponding to tetra-, tri-, di- and monoperoxo species, of general formula $[M(O_2)_4]^{3-}$, $[M(O_2)_3L_2]^{x-}$, *cis*- and *trans*-$[M(O_2)_2L_4]^{y-}$ and $[M(O_2)L_6]^{z-}$, respectively. The metal, M, chosen for the simulation is niobium(v) and L corresponds to the oxygen atoms of oxalate, which mimics a coordinated atom from one or several mono- or polydentate ligand(s). More details about the methodologies used and the choices made for the computations are explicitly presented in the Computational Details section (Figure 2).

The symmetry obtained after geometry optimisation for the various compounds $[M(O_2)_4]^{3-}$, $[M(O_2)_3L_2]^{x-}$, *cis*- or *trans*-$[M(O_2)_2L_4]^{y-}$ and $[M(O_2)L_6]^{z-}$ is D_{2d}, C_s, C_{2v} or D_2 and C_1, respectively. For the diperoxo species, their relative stability is small and the results depend on the chosen methodology. As mentioned in the Computational Details section, the C_{2v} symmetry (*cis* configuration) is more stable at the Hartree–Fock level but the opposite is the case at the DFT level. More details about those structures are given in the Supporting Information. For each one, a normal mode analysis was realised at the harmonic level in order to obtain vibration frequencies and to identify the normal modes involving the peroxo functions.

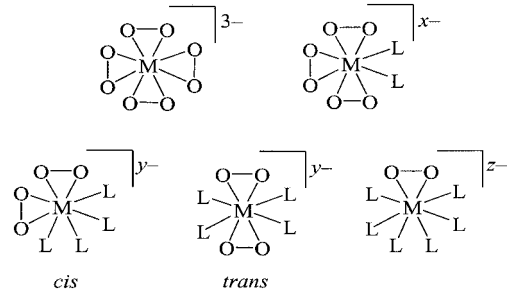

Figure 2. Schematic representation of model stoichiometries considered for the theoretical study (M = Nb^V and L = oxygen atom from an oxalate ligand).

The theoretical values were compared with those of corresponding complexes described in the literature for each of the tetra-, tri- and *cis*-diperoxo species studied. Because the experimental vibrational data of peroxotantalum(v) complexes are quite close to those of their niobium(v) equivalents, some of them are also taken into account in this study and compared to the calculated values. The stoichiometries of the selected representative Nb and Ta complexes are given in Table 1. As far as monoperoxo and *trans*-diperoxo species are concerned, no such compounds with an eight-fold coordination have been described so far in the literature. The IR data from complexes listed in Table 1 have already been reported,[14,16,17,22,27,28] while little information from Raman spectroscopy is available.

Table 1. Stoichiometries of the peroxo complexes of niobium(v) and tantalum(v) described in the literature and used in this work for comparison (ox = oxalate, *o*-phen = 1,10-phenanthroline, picO = picolinate *N*-oxide, tart = tartrate, edtaO_2 = ethylenediaminetetraacetate *N*,*N*′-dioxide).

calculated frequency (in cm^{-1}) and finally its frequency (in cm^{-1}) observed experimentally on the spectra.

In the tetraperoxometallate anion, the stretching vibrations of the peroxo groups, ν(O–O), belong to the A_1, B_2 and E modes. The first one is only Raman active and is due to the total symmetric vibration where all four peroxo groups vibrate in phase. The second one is only IR active, while the third one is active in IR as well as in Raman. These theoretical results are in agreement with the experimental IR and Raman spectra of complexes **1**–**3**, which each display two ν(O–O) bands beyond 800 cm^{-1} (see Table 2). Haeuseler et al. have observed only one ν(O–O) band in the IR spectrum of corresponding tantalum compounds with several counterions. This band was attributed to the ν(O–O) belonging to the E mode. As far as the metal–peroxo stretching ν[$M(O_2)$] vibrations are concerned, two modes occur and correspond to E and A_1 species; the first one is active in both techniques while the second one is only Raman active. These bands are observed near 550 and 530 cm^{-1}, respectively, in the experimental spectra of complexes **1**–**3** (see Table 2).

[a] The theoretical frequencies obtained at the B3LYP/6-31+G(d) level cannot be directly compared to the experimental ones but must be scaled by some empirical factor. [b] Doubly degenerate vibrational mode.

In the case of the heteroleptic tri- and *cis*-diperoxo complexes, the theoretical results confirmed the empirical rule which states that the presence of two or three ν(O–O) bands in the IR spectrum indicates the formation of a diperoxo or triperoxo complex, respectively.[22] Moreover, according to the theoretical results obtained, the same rule can be applied in the case of Raman spectroscopy.

The triperoxo species $[M(O_2)_3L_2]^{x-}$ shows three vibration modes which involve the O–O stretching and which are all active in both IR and Raman spectroscopy. This result is in agreement with the experimental spectra illustrated in Figure 3 in the case of $(gu)_2[Nb(O_2)_3(picO)]$ (**7**), which each display three ν(O–O) bands near 850 cm^{-1}. The additional bands occurring in the IR spectrum of compound **7** in that zone (871 and 811 cm^{-1}) are due to the bending vibration of the *N*-oxide group, δ(N–O), present in the picolinato ligand. The triperoxo complex also shows two ν[$M(O_2)$] vibrations which are both IR and Raman active, as confirmed by the experimental observations (see Figure 2). As illustrated in Table 3, the first ν[$M(O_2)$] mode implies the presence of two peroxo ligands, while the second one implies the presence of only one.

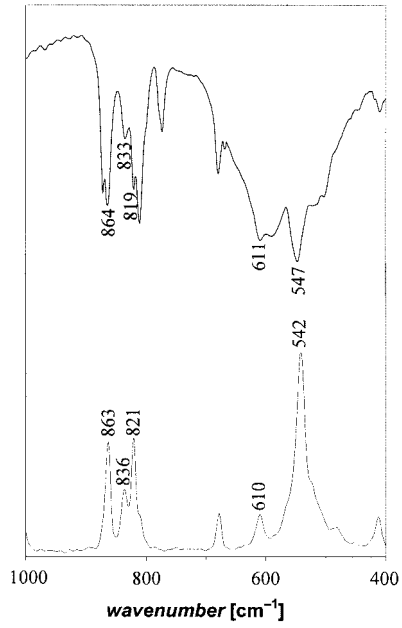

Figure 3. Experimental IR (top) and Raman (bottom) spectra of $(gu)_2[Nb(O_2)_3(picO)]$ (**7**).

As far as the *cis*-diperoxo species $[M(O_2)_2L_4]^{y-}$ is concerned, the theoretical calculations provide two ν(O–O) vibrations. As shown in Table 4, in the first mode, of B_1 symmetry, the peroxo ligands vibrate out of phase, while in the second one, of symmetry A_1, they vibrate in phase. The diperoxo complex also displays two ν[$M(O_2)$] vibrations, which are both active in IR and Raman spectroscopy. The theoretical results are in agreement with the experimental ones, which are illustrated in Figure 4 in the case of $(NH_4)_3[Nb(O_2)_2(ox)_2]$ (**9**).

As illustrated in Table 5, the *trans*-diperoxo model compound shows two peroxo stretching modes. The antisymmetric mode is active in both IR and Raman spectroscopy while the symmetric one is only Raman active. This species also displays four metal–peroxo stretching vibrations, ν[$M(O_2)$], which belong to the B_1, B_3, B_2 and A modes, respectively. Only the first and third ones show a fair ac-

tivity in IR spectroscopy, while the A mode is Raman active. No comparison can be made in this case with experimental data because such complexes have not been described in the literature so far.

Finally, in the case of the monoperoxo species $[M(O_2)L_6]^{z-}$, the results are quite simple because only one ν(O–O) mode and two ν[$M(O_2)$] vibrations − the symmetric and antisymmetric ones − are obtained (see Table 6). These three vibrational modes are all active in IR and Raman spectroscopy. Here also no comparison with the literature can be made because such compounds with an eightfold coordination are not yet known.

Conclusions

Theoretical interpretations of the experimental observations made by vibrational IR and Raman spectroscopy on eight-coordinate peroxo complexes of niobium(v) and tantalum(v) have been carried out. This study provides the normal modes of vibrations involving peroxo ligands, their corresponding calculated frequency and their activity in IR and/or Raman spectroscopy. This work thus validates the empirical rules mentioned so far for the interpretation of the vibrational spectra of eight-coordinate heteroleptic peroxo complexes, and provides important tools to develop the

coordination chemistry of peroxo species as it could be extended to equivalent complexes of other transition metals.

Experimental Section

General: The Nb^V and Ta^V complexes **1**–**3** and **9**–**12** (see Table 1) were prepared according to procedures described elsewhere.[14,16–18] The IR spectrum of compound **7** was recorded with an FTS-135 Bio-RAD spectrometer, using KBr pellets containing ca. 1 wt.-% of the powder. FT-Raman spectra of complexes **1**–**3**, **7** and **9**–**12** were recorded with a Bruker spectrometer (type RFS100/S) at a wavelength of 1064 nm. Measurements were carried out on powders sampled on an aluminium support.

Computational Details: Theoretical calculations were performed at the Hartree–Fock and DFT levels for five stoichiometric models corresponding to tetra-, tri-, di- and monoperoxo species, of general formula $[M(O_2)_4]^{3-}$, $[M(O_2)_3L_2]^{x-}$, *cis*- and *trans*-$[M(O_2)_2L_4]^{y-}$ and $[M(O_2)L_6]^{z-}$, respectively. The metal, M, chosen for the simulation is niobium(v) and L corresponds to the oxygen atoms of oxalate, which mimic a coordinated atom from one or several mono- or polydentate ligand(s). For the central metal atom, an effective core potential was used to represent all but the valence n*d* and (*n*+1)*s* and outer core n*s* and n*p* electrons. The latter were described with a double-zeta basis set, this combination being referred to as the LANL2DZ basis set. In order to check the functional dependence of the obtained results, the computations were completed using Becke's three-parameter hybrid functional (B3LYP), the Perdew 86 functional (P86) and finally the Perdew–Burke–Ernzerhof (PBE) hybrid functional. These anionic complexes require fairly good basis sets to obtain reliable results. In particular, polarisation functions are needed on the ligands to introduce enough flexibility into the wave function. The introduction of diffuse orbitals also improves the long-range spatial distribution required by the presence of negative charges. To check this point, we used two basis sets to represent the non-metal atoms, namely. the standard 6-31G(d) basis as starting point, completed afterwards by 6-31+G(d), which introduces diffuse functions on each atom. These basis sets are those available in the Gaussian series of programs.[29] Concerning the geometry optimisation, trial structures of the selected species were taken from available crystallographic data to yield the starting points for full optimisation. All structures were optimised without any symmetry constraints and the point group was deduced from the optimised geometries. A single minimum was obtained for all *n* values except when *n* equals two, where two minima appear. Within numerical precision, the symmetry deduced for the various compounds $[M(O_2)_4]^{3-}$, $[M(O_2)_3L_2]^{x-}$, *cis*- or *trans*-$[M(O_2)_2L_4]^{y-}$ and $[M(O_2)L_6]^{z-}$ is D_{2d}, C_s, C_{2v} or D_2 and C_1, respectively, regardless of the method or basis set being used. These structures are, of course, "gas-phase" structures that do not consider the nature of the counterion or the incidence of the solid-state environment. We report the relative stabilities obtained for the diperoxo species in Table 7. While B3LYP gives no significant energy difference between both structures, Hartree–Fock results give a C_{2v} symmetry (*cis* configuration) that is some 27 kJ mol^{-1} more stable than the D_2 symmetry (*trans* configuration). Finally, the P86 and PBE functional favour the D_2 structure slightly. A normal mode analysis was realised at the harmonic level for each obtained structure in order to obtain vibrational frequencies and to identify the normal modes involving the peroxo functions. At this level of methodology, the theoretical frequencies cannot be directly compared to the experimental ones but must be scaled by an empirical factor. As it is not useful to give all the results here, Table 8 gives an example of

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the wavenumbers obtained for $[M(O_2)_3L_2]^{3-}$ at all levels of methodology. They show that the numbers obtained at the B3LYP and P86 levels are close to the experimental values and that even though a slight improvement is obtained with the diffuse basis set, it is not really significant. Hartree–Fock results, as is well known, are overestimated by some 20%, but the PBE functional does not behave very well as it overestimates the frequencies by about 10%. As the best fit was obtained with the B3LYP and P86 functionals using the diffuse basis functions, the data referred to in the above discussion are those obtained at the B3LYP level. The optimised XYZ coordinates of the niobium complexes are given in the Supporting Information (see footnote on the first page of this article). The reported data contain the DFT/B3LYP level results obtained with a LANL2DZ pseudopotential for Nb and the 6-31+G(d) basis sets for C and O atoms.

Solvothermal Synthesis of Metastable γ-MnS Hollow Spheres and Control of Their Phase

Shuijin Lei,[a,b] Kaibin Tang,*[a,b] Qing Yang,[a,b] and Huagui Zheng[b]

Keywords: Manganese / Nanostructures / Semiconductors / Solvothermal synthesis

A solvothermal route has been developed to prepare metastable wurtzite-structure γ-MnS hollow spheres from anhydrous manganese chloride, sulfur powder, and potassium borohydride in ethylene glycol at 150–180 °C. The metastable γ-MnS and stable α-MnS were characterized by X-ray diffraction, X-ray photoelectron spectroscopy, field-emission scanning electronic microscopy, scanning electron microscopy, transmission electron microscopy, and photoluminescence. Experiments show that the reaction temperature, the solvent, and the concentration and reducibility of the reductant are the crucial factors affecting the phase of the product. A possible growth mechanism for the hollow sphere is proposed.

Introduction

In recent years, inorganic and inorganic–organic hybrid hollow spheres of nanometer or submicrometer size have attracted considerable attention because of their potential applications in a broad range of areas, such as delivery vehicles for the controlled release of various substances, for example drugs, cosmetics, dyes, and inks, and for the protection of biologically active macromolecules, artificial cells, catalysts, fillers, coatings, pigments, light-weight structural or low density materials, and waste removal owing to their low density, large specific area, mechanical and thermal stability, and surface permeability.[1–5] A variety of chemical and physicochemical approaches have been employed to prepare hollow spheres, for example polymer, oxide, glass, and ceramic materials, including nozzle systems to dispense individual liquid droplets of uniform size (e.g. spray drying or pyrolysis),[6] emulsion/phase separation techniques (usually associated with sol-gel processing),[7] emulsion/interfacial polymerization strategies,[8] and self-assembly routes.[9]

Manganese sulfide (MnS), is a VIIB–VIA dilute magnetic semiconductor with a wide gap [bandgap energy: E_g (T = 0) ≈ 3.7 eV],[10] which has potential applications in solar cells, as a window/buffer material, and in short-wavelength optoelectronic materials. MnS usually has three polymorphs:[11] α-MnS, with a rock-salt structure, and the metastable phases β-MnS, with a zincblende structure, and γ-MnS, with a wurtzite structure. During equilibrium growth techniques, MnS crystallizes in the stable α phase. Both of the latter phases are antiferromagnetic, with Néel temperatures of 152 K (β-phase) and 90 K (γ-phase), and are transformed irreversibly into stable α-MnS upon heating.[12–16]

In previous studies, MnS is usually prepared by the direct reaction of manganese (Mn) and sulfide in an evacuated tube at high temperatures (above 800 °C).[17] β- and γ-MnS bulk phases have been prepared in polycrystalline form by low temperature chemical synthesis or evaporation.[18,19] The direct synthesis of polycrystalline β- and γ-MnS has also been reported by gas source molecular-beam epitaxy (MBE).[13,14] Metastable MnS thin films, which consist of nanocrystallite domains with mixed cubic and hexagonal phases, have been prepared by adopting a chemical bath deposition (CBD) method,[20,21] and recently a solvothermal route has been used to grow stable α-MnS and rod-like metabstable β- and γ-MnS nanocrystallites.[22] α-MnS nanocrystallites have also been prepared by a colloidal synthesis route by the reaction of $MnCl_2$ and $S[Si(CH_3)_3]_2$ in trioctylphosphane oxide,[23] and α-MnS nanorods have been prepared by a hydrothermal method from the elements (manganese and sulfur powder).[24] However, to the best of our knowledge, the metastable γ-MnS hollow sphere structure has not been reported.

In this paper, metastable γ-MnS hollow spheres are prepared by a developed solvothermal reaction at 150–180 °C from anhydrous manganese chloride ($MnCl_2$), sulfur powder, and potassium borohydride (KBH_4) as the reactants and ethylene glycol (EG) as the solvent. The phase of the as-formed MnS crystallites is influenced by the solvent, the reaction temperature, and the concentration and reducibility of the reductant.

Results and Discussion

Figure 1 shows the XRD patterns of as-prepared MnS powders. The samples shown in parts a–d of Figure 1 were prepared in EG. The diffraction peaks in Figure 1a can be indexed as the hexagonal γ-MnS with lattice constants a = 3.981 and c = 6.423 Å, which are close to those reported for γ-MnS [Joint Committee on Powder Diffraction Standards (JCPDS), Powder Diffraction File No. 40-1289: a = 3.979 and c = 6.446 Å]. The average crystallite size of γ-MnS is about 30 nm, as calculated from the Debye–Scherrer formula. Figure 1 (parts b–d) are the XRD patterns of the samples in which α-MnS and γ-MnS are coexistent. The peak marked by an asterisk in part c of Figure 1 is derived from $MnCO_3$. In Figure 1 (e), the XRD pattern of the product synthesized in $N_2H_4{\cdot}H_2O$, can be indexed as the cubic α-MnS (RS) with a = 5.216 Å (JCPDS, Powder Diffraction File No. 06-0518: a = 5.224 Å). We found that α-MnS gradually becomes the dominant phase with an increase of the reaction temperature, the concentration, and reducibility of the reductant, or the complexing ability of the solvent.

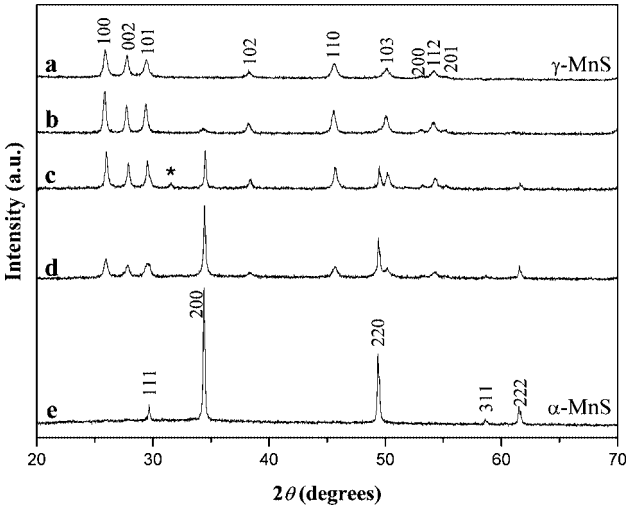

Figure 1. XRD patterns of the as-prepared MnS samples with different phase(s) synthesized: (a) in EG at 180 °C with a 3:5 molar ratio of S and KBH_4; (b) in EG at 240 °C with a 3:5 molar ratio of S and KBH_4; (c) in EG at 260 °C with a 3:10 molar ratio of S and KBH_4; (d) in EG at 260 °C with a 3:20 molar ratio of S and KBH_4; (e) in EA at 180 °C.

Figure 2 shows the XPS spectrum of as-synthesized γ-MnS. The binding energies of Mn $2p_{3/2}$ and S 2p were found to be 641.3 and 161.3 eV, respectively, which is consistent with the values reported in the literature.[25] There are also peaks for C reference and O impurity, due to the surface absorption of the samples exposed to air during processing of the samples. Direct elemental analysis for the composition of the sample was provided by ICP-AES, which gave an Mn/S molar ratio of 1:1.034. These results show that the product is stoichiometric.

Figure 3 (parts a and b) shows TEM images of the as-prepared γ-MnS, which reveal that the product consists of hollow spheres 300–500 nm in diameter; the wall thickness around the shell is about 50 nm. The strong contrast between the dark edges and pale centers is evidence of their hollow structures.[1d,2b,26,27] The direct observation of a broken sphere, as shown in Figure 3b, provides the most powerful proof of the hollow nature. The corresponding SAED pattern of the γ-MnS hollow sphere in Figure 3 (a) shows seven diffuse diffraction rings, which can be characterized as the (100), (002), (101), (102), (110), (103), and (112) planes from inner to outer (Figure 3, c) and further reveals the hexagonal γ-MnS polycrystals. The morphology of the sample synthesized in EG at 260 °C with a 3:10 molar ratio of S to KBH_4 was also examined. It consists of γ-MnS hollow spheres and α-MnS cubes. Figure 3 (d) presents the hollow and solid-sphere image of γ-MnS that was prepared using manganese chloride tetrahydrate ($MnCl_2{\cdot}4H_2O$) instead of anhydrous $MnCl_2$. The hollow spheres are clearly far fewer than the solid spheres. Figure 3 (e) gives the TEM image of α-MnS solid spheres prepared in EA at 180 °C. If the solvent is changed to EN, then α-MnS aggregates consisting of many micron-sized rods are obtained. Figure 3 (f) presents the TEM image of an individual rod aggregate. The corresponding ED pattern of a single rod (marked by an arrow) reveals that the as-prepared sample is well crystallized (see the inset).

Figure 4 shows the FE-SEM image of the γ-MnS broken hollow sphere. From this image, we can observe that the hollow sphere is structured with a lot of smaller particles, which are about 30–40 nm in size. Figure 4 (b) is the SEM image of γ-MnS hollow spheres and solid spheres. According to the difference of the hollow and solid sphere images, it can also be determined that the hollow spheres are in a very minor amount. The SEM photographs shown in Figures 4c and 4d are α-MnS solid sphere and α-MnS rod aggregates, respectively, which correspond to the samples of Figure 3 (parts e and f, respectively).

Figure 5 shows the room temperature PL spectra of the as-prepared γ-MnS hollow spheres (Figure 5, a) and α-MnS rod aggregates (Figure 5, b) with the same excitation wavelength of 365 nm (a filter with 500 nm wavelength was needed for γ-MnS). Figure 5 (a) exhibits a relatively strong and wide emission band peaking at about 720 nm (1.7 eV). In Figure 5 (b), an emission peaking at 435 nm (2.8 eV) can be observed, which is similar to the bandgap of the bulk counterpart.[23]

Table 1 summarizes the experiments and the effects of changing the solvent, the reaction temperature, and the concentration and reducibility of the reductant on the phase of the product.

From the results above, it can be seen that the optimum reaction temperature is 150–180 °C. When the reaction was performed in EG at 180 °C with a 3:5 molar ratio of S and KBH_4, γ-MnS hollow spheres were formed after five hours, whereas if the reaction temperature was reduced to 150 °C, then the reaction time had to be prolonged to 20 hours to produce pure γ-MnS. In this reaction system, KBH_4 is vital to prepare γ-MnS, and if the reaction temperature was increased above 200 °C, α-MnS appeared. In the range of 200–260 °C, the higher the temperature the greater the amount of α-MnS is present in the product. In this reaction

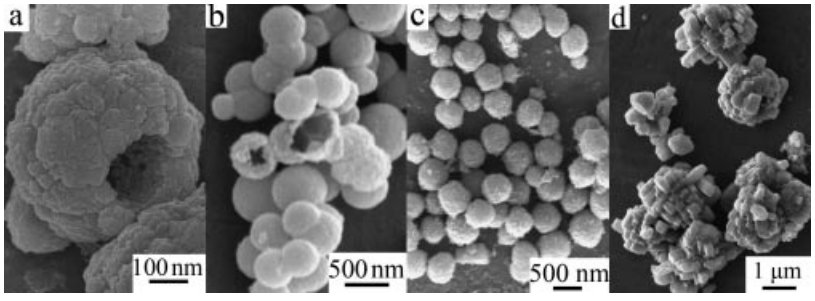

Figure 4. (a) FE-SEM image of γ-MnS broken hollow sphere and SEM images; (b) γ-MnS hollow spheres and solid spheres when $MnCl_2{\cdot}4H_2O$ was used as the reactant; (c) α-MnS solid spheres when EA was used as the solvent; (d) α-MnS rod aggregates when EN was used as the solvent.

system, the γ phase is readily obtained at low temperature and the α phase at high temperature as at higher reaction temperatures the metastable γ-MnS is transformed into stable α-MnS.

When the system was maintained at an appropriate reaction temperature above 200 °C, and the amount of KBH_4 was increased gradually, we also found that the content of α-MnS in the product increased. It must be pointed out

Table 1. Effects of the solvent, the reaction temperature, and the concentration and reducibility of the reductant on the phase of product.

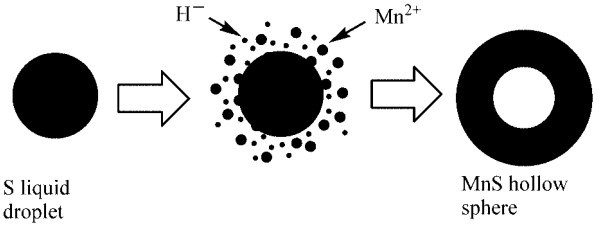
Reaction temperature [°C]	Solvent[a]	Molar ratio of $MnCl_2/KBH_4$ or the amount of $N_2H_4{\cdot}H_2O$	Reaction time [h]	Product[b]
150	EG	3:5	>20	γ-MnS
180	EG	3:5	>5	γ-MnS
220–240	EG	3:5	12	γ-MnS*, α-MnS
250–260	EG	3:10~15	12	γ-MnS, α-MnS
250–260	EG	3:20	12	γ-MnS, α-MnS*
180	EG	5 mL of $N_2H_4{\cdot}H_2O$	12	γ-MnS, α-MnS*
180	EG	10 mL of $N_2H_4{\cdot}H_2O$	12	α-MnS
180	EA	3:5	12	α-MnS
180	EN	3:5	12	α-MnS

[a] EG stands for ethylene glycol, EA for ethanol amine, and EN for ethylenediamine. [b] * indicates the dominant phase in the product.

that a large excess of KBH_4 (e.g. 10–20 mol) and a high reaction temperature (e.g. 240–260 °C) also resulted in the appearance of $MnCO_3$. If KBH_4 was replaced by the stronger reductant $N_2H_4{\cdot}H_2O$, α-MnS was obtained easily along with a small quantity of γ-MnS; an increase of the amount of $N_2H_4{\cdot}H_2O$ gave pure α-MnS. These results reveal that a stronger reductant and higher concentration are beneficial for the formation of α-MnS.

The influence of the solvent on the phase of the product was also studied. If EA and EN were used as the solvent, keeping the other conditions identical, the sample obtained was α-MnS. The amido groups in EA and EN, which have a strong N-chelation ability, form a relatively stable Mn^{2+} complex, which is favorable for the transformation to the stable form. $N_2H_4{\cdot}H_2O$ also has an amido group, so when it was used as the reductant α-MnS also formed.

Scheme 1 illustrates the possible mechanism for the formation of γ-MnS hollow spheres. In the detailed procedure, solid-state sulfur powder could be transformed into tiny spherical sulfur liquid droplets dispersed in the EG solvent to form a heterogeneous liquid–liquid two-phase mixture on account of the surface tension[28,29] at temperatures above the melting point of sulfur (120 °C at normal atmosphere) in the autoclave. Sulfur acts as the template for the fabrication of γ-MnS hollow spheres, as well as the sulfur source. Around the sulfur liquid droplets, BH_4^- and Mn^{2+} dissolved in EG react with them on the surface. BH_4^- can readily serve as a hydride and electron transfer agent,[30] which reduces elemental S to S^{2-} and forms MnS with Mn^{2+}. Experiments showed that elemental S can be reduced to S^{2-} by BH_4^- even in the absence of Mn^{2+} ions in this system, although Mn^{2+} ions could shift the redox reaction equilibrium to the forward reaction direction. The interface reaction results in the consumption of liquid sulfur droplets and the formation of γ-MnS hollow spheres. With the increase of the reaction temperature and the amount of KBH_4, α-MnS cubes were simultaneously obtained besides γ-MnS hollow spheres. The anisotropy of hexagonal γ-MnS should support the aggregation of the γ-MnS nanoparticles into spheres, while the formation of α-MnS cubes is maybe due to the growth character based on the cubic structure of α-MnS. In addition, compared with γ-MnS, α-MnS is high-temperature phase, and its nucleation velocity is smaller, so it is relatively difficult to be aggregated and tends to form bigger crystals.



Scheme 1. Schematic illustration of the possible growth mechanism for γ-MnS hollow spheres.

The crystallization water of the reactant evidently affects the morphology of the final product. When $MnCl_2{\cdot}4H_2O$ was used without prior dehydration, then γ-MnS solid spheres and a small number of hollow spheres were obtained, as shown in Figure 3 (c) and Figure 5 (a). In the presence of the crystallization water, the reaction was accelerated owing to hydrolysis of BH_4^- with the generation of hydrogen. This reaction even occurs very rapidly at room temperature. What's more, the higher the water temperature and the smaller the ratio of water to borohydride, the more rapid the hydrolysis.[31–34] In this system most of the sulfur probably reacts with BH_4^- and Mn^{2+} before the formation of the tiny liquid sulfur droplets.

$$4S_{(s)} + BH_4^- + 2H_2O \rightarrow BO_2^- + 4S^{2-} + 8H^+$$

$$S^{2-} + Mn^{2+} \rightarrow MnS$$

This causes the fabrication of the γ-MnS solid spheres. With an increase of temperature, the remaining sulfur forms the liquid droplets that act as the template for the formation of γ-MnS hollow spheres.

Sulfur is readily soluble in EA or EN therefore the liquid sulfur droplets can't form and hence the γ-MnS hollow spheres aren't obtained.

Conclusions

In summary, metastable γ-MnS submicrometer hollow spheres and α-MnS spheres have been successfully synthesized by a solvothermal method. The reaction temperature, the solvent, and the concentration and reducibility of the reductant strongly influence the phase(s) of the product. The photoluminescence of the γ-MnS hollow spheres and α-MnS rod aggregates has been investigated at room temperature using the same excitation line at 365 nm. A possible growth mechanism for the hollow structure has also

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

been tentatively proposed on the basis of the experimental results. A further exploration of the growth mechanism for the hollow structure, the control of the reaction kinetics, and the morphology of α-MnS are underway.

Experimental Section

All the chemical reagents were of analytical grade and were purchased from Shanghai Chemical Reagent Company and used without further purification. Anhydrous $MnCl_2$ was obtained by the dehydration of $MnCl_2·4H_2O$ with thionyl chloride as dehydrating agent.

Preparation of Metastable γ-MnS Hollow Spheres: Typically, a slight excess of anhydrous $MnCl_2$ (0.4 g) was dissolved in 20 mL of EG. Sulfur powder (0.096 g) and KBH_4 (0.27 g) with a 3:5 molar ratio, together with the above solution, were put into a 60-mL Teflon-lined autoclave, which was then filled with EG up to 85% of the total volume. The autoclave was sealed quickly and maintained at 150–180 °C for 5–24 h, and then cooled to room temperature naturally. The products were filtered off, washed with absolute ethanol and distilled water several times to remove impurities, and dried in vacuo at 60 °C for 4 h.

When 10 mL of 80% (wt.) hydrazine hydrate ($N_2H_4·H_2O$) solution was used instead of KBH_4, or the solvent EG was replaced by ethanol amine (EA) or ethylenediamine (EN), then α-MnS was obtained.

Sample Characterization: The X-ray powder diffraction (XRD) patterns were recorded on a Philips X'pert PRO SUPER diffractometer with Cu-K_α radiation (λ = 1.541874 Å). The X-ray photoelectron spectra (XPS) were recorded on a VGESCALAB MK II X-ray photoelectron spectrometer, using Mg-K_α radiation as the excitation source. Field-emission scanning electronic microscopy (FE-SEM) measurements were recorded with a field-emission microscope (JEOL, 7500B) operating at an acceleration voltage of 10 kV. The scanning electron microscopy (SEM) images were taken with an X-650 scanning electronic microanalyzer. The transmission electron microscopy (TEM) images and selected area electron diffraction (SAED) patterns were obtained with a Hitachi H-800 transmission electron microscope, using an accelerating voltage of 200 kV. Photoluminescence (PL) spectra of the sample were obtained on a Hitachi F-4500 fluorescence spectrophotometer at room temperature.

Synthesis and Luminescent Properties of Novel Europium(III) Heterocyclic β-Diketone Complexes with Lewis Bases: Structural Analysis Using the Sparkle/AM1 Model

Rani Pavithran,[a] M. L. P. Reddy,*[a] Severino A. Junior,[b] Ricardo O. Freire,[b] Gerd B. Rocha,[b] and Patricia P. Lima[b]

Keywords: Europium / Lewis bases / Luminescence / O ligands / Sparkle/AM1 model

Tris(β-diketonato)europium(III) complexes of general formula $[Eu(TPI)_3{\cdot}L]$, with chelating ligands such as 3-phenyl-4-(4-toluoyl)-5-isoxazolone (HTPI) and adduct-forming reagents [L = H_2O, tri-*n*-octylphosphane oxide (TOPO), triphenylphosphane oxide (TPhPO), 1,10-phenanthroline], have been synthesized and characterized by elemental analysis and FT-IR, ^1H NMR, and photoluminescence spectroscopy. The coordination geometries of the complexes were calculated using the Sparkle/AM1 (Sparkle model for the calculation of lanthanide complexes within the Austin model 1) model. The ligand–Eu^{3+} energy-transfer rates were calculated using a model of intramolecular energy transfer in lanthanide coordination complexes reported in the literature. The room-temperature PL spectra of the europium(III) complexes are composed of the typical Eu^{3+} red emission, assigned to transitions between the first excited state ($^5D_0$) and the multiplet ($^7F_{0-4}$). The results clearly show that the substitution of water molecules by TOPO leads to greatly enhanced quantum yields (i.e., 1.3 % vs. 49.5 %) and longer $^5D_0$ lifetimes (220 vs. 980 μs). This can be ascribed to a more efficient ligand-to-metal energy transfer and a less efficient nonradiative $^5D_0$ relaxation process. The theoretical quantum yields are in good agreement with the experimental quantum yields, which highlights that the present theoretical approach can be a powerful tool for the a priori design of highly luminescent lanthanide complexes.

Introduction

Eu^{III} complexes have been regarded as attractive for use in electroluminescent devices for light-emitting diodes,[1,2] phosphors,[3] contrast agents for medical magnetic resonance imaging,[4] luminescent probes for analytes,[5] and light-emitting sensors in fluoroimmunoassays[6] because of their red emissions. The characteristic emissions of Eu^{III} complexes mainly come from electric dipole transitions. Transition from the 4f inner shell of free Eu^{III} is forbidden because it does not correlate with the change of parity. However, transitions that are forbidden by odd parity become partially allowed by mixing 4f and 5d states through ligand-field effects of designed Eu^{III} complexes.[7] Unfortunately, the lanthanide ions are characterized by very low absorption coefficients ($\varepsilon < 1\ M^{-1}cm^{-1}$), which make direct excitation of the emitting levels impossible. Furthermore, coordination of solvent molecules to the lanthanide ions has dramatic effects on their excited state decay, because this decay is mainly governed by nonradiative processes. When solvents containing OH groups are coordinated to lanthanide ions, efficient nonradiative deactivations take place by vibronic coupling with the vibrational states of the OH oscillators.[8] A way to circumvent these difficulties is to use ligands bearing suitable chromophores that are capable of forming thermodynamically stable complexes with lanthanide ions. These ligands would play the antenna role, absorbing light and transferring excitation energy to the emitting ion. Additionally, when the Ln^{3+} cation is coordinatively unsaturated by the original ligands, an additional neutral ligand coordinates to the lanthanide center to form a highly coordinated complex, thereby excluding the coordination of solvent molecules. Recently, a large number of highly coordinated complexes of lanthanide tris(β-diketonates) containing several nitrogen ligands such as 1,10-phenanthroline, 2,2′-bipyridine, and 2,2′:6′,6′′-terpyridine have been reported.[9,10] The central Eu^{3+} ion coordinated with β-diketonato ligands gives stronger luminescence than that of the parent compounds, especially when β-diketonato ligands with aromatic or fluorinated substituents are present.[9] Phosphane oxide ligands in the europium(III) tris(β-diketonate) complex can produce a square-antiprismatic structure that promotes faster radiation rates and an increased quantum yield because of an increase in the $^5D_0$–$^7F_2$ emissions (electric dipole transitions), related to odd parity. Furthermore, increased quantum yields of the Eu^{3+} complexes can be expected because coordination of the

50670-901 Recife, PE, Brazil

phosphane oxide molecule prevents coordination of water or solvent molecule and lowers vibrations.[7] The above factors prompted us to utilize a novel heterocyclic β-diketone, namely 3-phenyl-4-(4-toluoyl)-5-isoxazolone, for the preparation of coordinatively saturated Eu^{III} tris(isoxazolonate) complexes with Lewis bases such as trioctylphosphane oxide, triphenylphosphane oxide, or 1,10-phenanthroline (Figure 1). The synthesized Eu^{3+} complexes have been characterized by various spectroscopic techniques and their photophysical properties investigated.

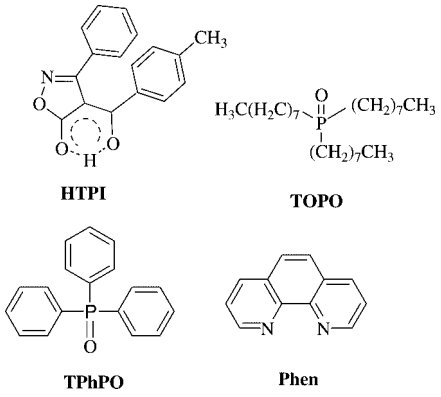

Figure 1. Structures of ligands used for the synthesis of Eu^{III} complexes.

Theoretical Approach

Sparkle Model Geometries

The ground-state geometries of all Eu^{III} complexes were calculated with the new version of the Sparkle/AM1 model[14] implemented in the MOPAC93r2 package.[15] The MOPAC keywords used in all Sparkle/AM1 calculations were: GNORM = 0.25, SCFCRT = 1.D-10 (in order to increase the SCF convergence criterion), and XYZ (the geometry optimizations were performed in Cartesian coordinates). Recently, Freire et al.[14] have improved the Sparkle model by presenting a much more accurate parameterization. This new parameterization, named Sparkle/AM1, yields an unsigned mean error for all interatomic distances between the Eu^{3+} ion and the ligand atoms of the first sphere of coordination for 96 different Eu^{3+} complexes of 0.09 Å, an improvement over the value of 0.28 Å for the second version SMLCII[16] and the value of 0.68 Å for the original version SMLC.[17]

INDO/S-CI Electronic Structures

For all calculated ground-state geometries, we predicted their singlet and triplet excited states using the intermediate neglect of differential overlap/spectroscopic configuration interaction (INDO/S-CIS) method[18,19] implemented in the ZINDO program.[20] We used a point charge of +3e to represent the trivalent europium ion. The CIS space was gradually increased until there were no further meaningful changes in the calculated transitions. In contrast, the energy levels of the Eu^{3+} metal ions were considered as being those of the free ion in the intermediate coupling scheme.[21] The INDO/S accuracy is about 1000 cm^{-1}.[18]

Energy-Transfer Rates

According to the theoretical model developed by Malta et al.,[22,23] the following expression was obtained for the ligand–lanthanide ion energy-transfer (ET) rate, W_{ET} [Equation (1)].

$$W_{ET} = W_{ET}^{mm} + W_{ET}^{em} \quad (1)$$

The first term, W_{ET}^{mm}, corresponds to the energy-transfer rate obtained from the multipolar mechanism and Equations (2) and (3)

$$W_{ET}^{mm} = W_{ET}^{mp} + W_{ET}^{dd} \quad (2)$$

$$\text{where } W_{ET}^{mp} = \frac{2\pi}{\eta}\frac{e^2 S_L}{(2J+1)G} F \sum_{\lambda} \gamma_{\lambda} \left\langle \alpha' J' \middle\| U^{(\lambda)} \middle\| \alpha J \right\rangle^2 \quad (3)$$

which correspond to the dipole–2^{λ} pole mechanism (λ = 2, 4, and 6), and Equation (4)

$$W_{ET}^{dd} = \frac{4\pi}{\eta}\frac{e^2 S_L}{(2J+1)G R_L^6} F \sum_{\lambda} \Omega_{\lambda}^{e,d} \left\langle \alpha' J' \middle\| U^{(\lambda)} \middle\| \alpha J \right\rangle^2 \quad (4)$$

corresponding to the dipole–dipole mechanism (λ = 2, 4, and 6).

The second term of Equation (1), W_{ET}^{em}, corresponds to the energy-transfer rate obtained from the exchange mechanism. This term is calculated from Equation (5)

$$W_{ET}^{em} = \frac{8\pi}{3\eta}\frac{e^2 (1-\sigma_0)^2}{(2J+1)R_L^4} F \left\langle \alpha' J' \middle\| S \middle\| \alpha J \right\rangle^2 \sum_m \left| \left\langle \phi \middle| \sum_k \mu_Z(k)\, s_m(k) \middle| \phi' \right\rangle \right|^2 \quad (5)$$

In the above equations, J represents the total angular momentum quantum number of the lanthanide ion, G is the degeneracy of the ligand initial state, a specifies a given 4f spectroscopic term, and S_L is the electric dipole strength associated with the $\varphi \rightarrow \varphi'$ transition in the ligand. The quantities are reduced matrix elements $U^{(\lambda)}$, and R_L is the distance from the lanthanide ion nucleus to the region of the ligand molecule in which the ligand donor (or acceptor) state is localized. In Equation (3), S is the total spin operator of the lanthanide ion, μ_z is the z component of the electric dipole operator and s_m (m = 0, ±1) is a spherical component of the spin operator, both for the ligand electrons, and σ_0 is a distance-dependent screening factor.

The quantities F and γ_{λ} are given by Equation (6)

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$$F = \frac{1}{\eta\gamma_L}\sqrt{\frac{\ln 2}{\pi}}\,exp\left[-\left(\frac{\Delta}{\eta\gamma_L}\right)^2 \ln 2\right] \quad (6)$$

where γ_L is the ligand-state band width at half-height and Δ is the difference between the donor and acceptor transition energies involved in the transfer process [Equation (7)].

$$\gamma_\lambda = (\lambda+1)\frac{\langle r^\lambda\rangle^2}{(R_L^{\lambda+2})^2}\langle 3\|C^{(\lambda)}\|3\rangle^2(1-\sigma_\lambda)^2 \quad (7)$$

where $\langle r^2\rangle$ is the radial expectation value of r^λ for 4f electrons, $\langle 3\|C^{(2)}\|3\rangle$ is a reduced matrix element of the Racah tensor operator $C^{(\lambda)}$,[24] and the σ_λ values are screening factors due to the 5s and 5p filled sub-shells of the lanthanide ion.

The selection rules that can be derived from the above equations are the following: $J + J' \geq \lambda \geq |J - J'|$, for the mechanisms expressed by Equations (1) and (2), and $\Delta J = 0, \pm 1$, for the exchange mechanism; in both cases $J' = J = 0$ is excluded. From the ligand side, the selection rules can be derived from the electric dipole strength, S_L, and the matrix element of the coupled operators μ_z and S_m in Equation (3). The theoretical procedures for using the above equations and the corresponding selection rules have been discussed in detail elsewhere.[25]

The numerical solution of the rate equations describing the kinetics of the 4f–4f luminescence was carried out according to this model.[23] These numerical solutions of the rate equations yield the time dependence of the energy level populations, which reach the steady-state regime after 10^{-6}–10^{-5} s. These steady-state populations were then used to calculate the emission quantum yield, which is given by Equation (8)

$$q = \frac{A_T\eta_2}{\phi\eta_1} \quad (8)$$

where the subscripts 1 and 2 indicate the ground state and the emitting level ($^5D_0$), respectively, in the complex, A_T is the sum of the coefficients of spontaneous emission for the $^5D_0 \rightarrow {}^7F_{0,1,2,4}$ transitions, and φ is the pumping rate.

The microanalyses of complexes **1**–**4** show that the Eu^{3+} ion has reacted with 3-phenyl-4-(4-toluoyl)-5-isoxazolone in a metal/ligand molar ratio of 1:3. The IR spectrum of complex **1** shows a broad absorption in the region 3000–3500 cm^{-1}, which indicates the presence of H_2O molecules in the complex. The existence of water molecules in lanthanide complexes with heterocyclic β-diketones such as 4-acyl-3-methyl-1-phenylpyrazolones is well documented.[26,27] The presence of water molecules was also noticed in the complexes **3** and **4**. The disappearance of the broad band in the region 3000–3500 cm^{-1} for complex **2**, which is associated with the coordinated water molecules in the neat complex **1**, suggests that water molecules have been displaced by the insertion of TOPO as a coordinating unit. The carbonyl stretching frequency of 3-phenyl-4-(4-toluoyl)-5-isoxazolone (1706 cm^{-1}) is shifted to lower wavenumbers in complexes **1**–**4** (1640 cm^{-1} in **1**, 1643 cm^{-1} in **2**, 1679 cm^{-1} in **3**, and 1639 cm^{-1} in **4**), thus indicating the involvement of the carbonyl oxygen atom in the complex formation with Eu^{3+}. Further, a shift in the P=O stretching frequency of the phosphane oxide molecules in complexes **2** (from 1143 to 1132 cm^{-1}) and **3** (from 1182 to 1155 cm^{-1}) shows the involvement of the phosphoryl oxygen atom in complex formation with Eu^{3+}. Vibration bands at 1608, 1574, 1476, 1445, and 1384 cm^{-1} in complex **4** are characteristic of 1,10-phenanthroline.

The ^1H NMR spectrum of complex **1** shows all expected signals for the 3-phenyl-4-(4-toluoyl)-5-isoxazolone protons. The integration of the bands is in accordance with the proposed formula. A clear indication of complex formation is given by the absence of the enolic OH peak of the free ligand HTPI. Signals for water protons were also noticed in the complex **1**, as evidenced from the IR spectroscopic data. The signals of the phenyl protons are shifted upfield upon coordination with the metal ion in the complex (from δ = 6.93–7.36 ppm in HTPI to δ = 4.99–6.57 ppm in **1**). The signal of the CH_3 group in the HTPI complex is also shifted upfield (from δ = 2.31 ppm in HTPI to δ = 2.13 ppm in **1**) upon coordination with Eu^{3+}.

Figures 2, 3, 4, and 5 show the optimized molecular structures of the Eu^{III} complexes **1**–**4**, respectively, obtained using the Sparkle/AM1 model. The Eu^{3+} ion in complexes **1**, **3**, and **4** is nine-coordinate and the coordination polyhedron can be approximately described as a tricapped trigonal prism. On the other hand, the Eu^{3+} ion in complex **2** is eight-coordinate and the coordination polyhedron can be described as a square antiprism. The spherical coordinates on the bonded oxygen atoms with respect to a coordinate system centered around the Eu^{3+} ion are given in Tables 1 and 2. These structural data are consistent with a very low symmetry of the chemical environment around the Eu^{3+} ion. An interesting point that is predicted by the present structure optimization is that the TOPO oxygen atoms are considerably closer to the Eu^{3+} ion than the H_2O oxygen atoms in the case of the hydrated compound **1**. Further, the two Eu–O bonds with TOPO ligands (2.32 and 2.33 Å) are shorter than the six Eu–O bonds with HTPI ligands (2.40–2.42 Å), as observed in the X-ray single-crystal structure (Eu–O bonds with TPhPO ligands: 2.31–2.32 Å; Eu–O bonds with hexafluoroacetylacetone ligand: 2.39–2.44 Å) of the complex tris-(hexafluoroacetylacetonato)europium(III) with phosphane oxide.[7] This clearly highlights that TOPO ligands interact more strongly with the Eu^{3+} ion in complex **2**. Similarly, the TPhPO oxygen atoms are also found to be closer to the Eu^{3+} ion than those of the water molecules in the hydrated complex. Another interesting phenomenon observed from the Sparkle/AM1 model prediction data for complex **4** is that the phenanthroline nitrogen atoms (Eu–N: 2.52 Å) are considerably further away from the Eu^{3+} ion than the HTPI oxygen atoms. This is again in good agreement with the recently reported X-ray single-crystal data

for the complex [Eu(HFNH)$_3$] with phenanthroline [Eu–N: 2.59 and 2.61 Å; Eu–O bonds with 4,4,5,5,6,6,6-heptafluoro-1-(2-naphthyl)hexane-1,3-dione (HFNH): 2.34–2.40 Å].[28]

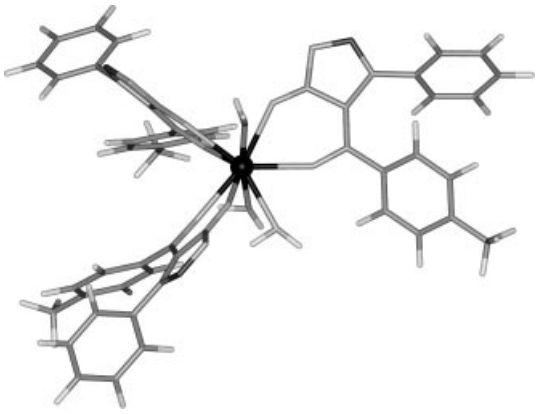

Figure 2. Optimized molecular structure of [Eu(TPI)$_3$·3H$_2$O] obtained from the Sparkle/AM1 model.

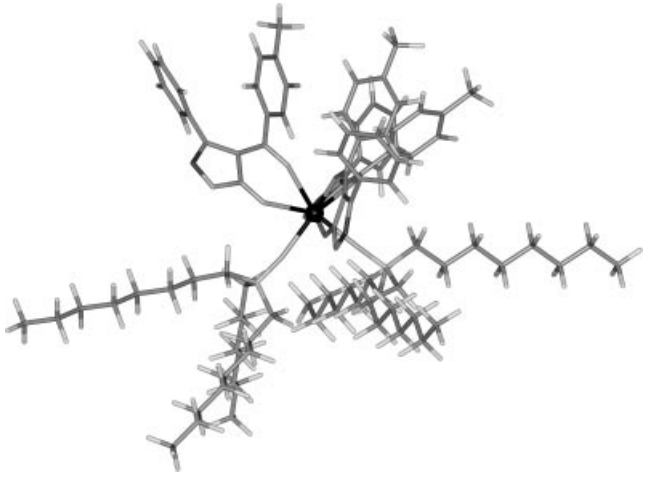

Figure 3. Optimized molecular structure of [Eu(TPI)$_3$·2TOPO] obtained from the Sparkle/AM1 model.

The excitation spectrum of the $^5D_0$ emission of Eu^{3+} in [Eu(TPI)$_3$·3H$_2$O] at 14 K is shown in Figure 6. It consists of two broad bands in the UV region, with maxima at 265, 325, and 387 nm, and 4f–4f excitation lines. The excitation spectrum suggests an efficient ligand-to-metal energy transfer, since the most intense feature is a broad band that corresponds to transitions populating ligand-centered excited states. The typical excitation spectrum of [Eu(TPI)$_3$·2TOPO] (**2**) at 300 K, depicted in Figure 7, exhibits a large, broad band between 270 and 400 nm, with a maximum around 294 nm, corresponding to ligand excitations. This strongly suggests an efficient sensitization process between the ligands and the metal ion, with the ligand unit acting as an antenna.

The room-temperature emission spectra of europium complexes **1**–**4** (in the solid state) are shown in Figures 8, 9, 10, and 11, respectively. Comparing the emission spectra of the complexes, a significant change in the profile and in the splitting of the $^5D_0 \rightarrow {}^7F_{0-4}$ transitions (essentially in the

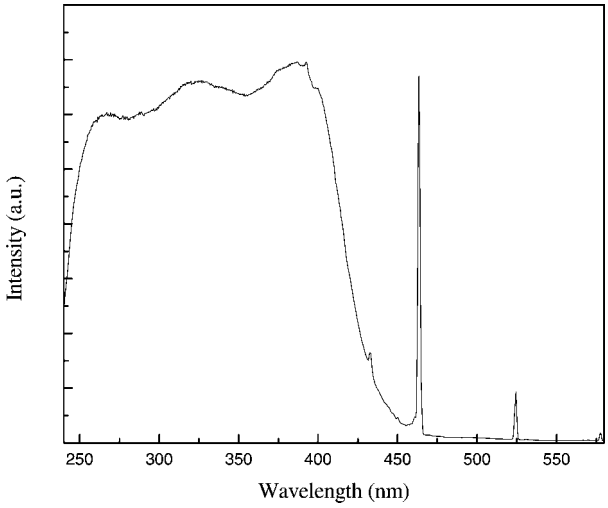

Figure 6. The excitation spectrum of $^5D_0$ emission (λ_{em} = 614 nm) of Eu^{3+} in $[Eu(TPI)_3{\cdot}3H_2O]$ (**1**) at 14 K.

$^5D_0 \rightarrow {}^7F_2$ lines) can be observed upon substitution of water molecules in **1** by Lewis bases such as TOPO, TPhPO, and Phen. The emission spectra of the complexes display characteristic sharp peaks in the 575–725 nm region associated with the $^5D_0 \rightarrow {}^7F_J$ transitions of the Eu^{3+} ion. The five expected Stark components of the $^5D_0 \rightarrow {}^7F_{0-4}$ transitions are well resolved and the hypersensitive $^5D_0 \rightarrow {}^7F_2$ transition is very intense, pointing to a highly polarizable chemical environment around the Eu^{3+} ion, and is responsible for the brilliant red emission color of these complexes.[29] The emission spectra of the complexes show only one peak for the $^5D_0 \rightarrow {}^7F_0$ transition, thus indicating the presence of a single chemical environment around the Eu^{3+} ion, and also show that the Eu^{3+} ion occupies a low symmetry site. Further, the emission band at 525 nm, corresponding to the emission from the lowest triplet state of the ligand, is not observed

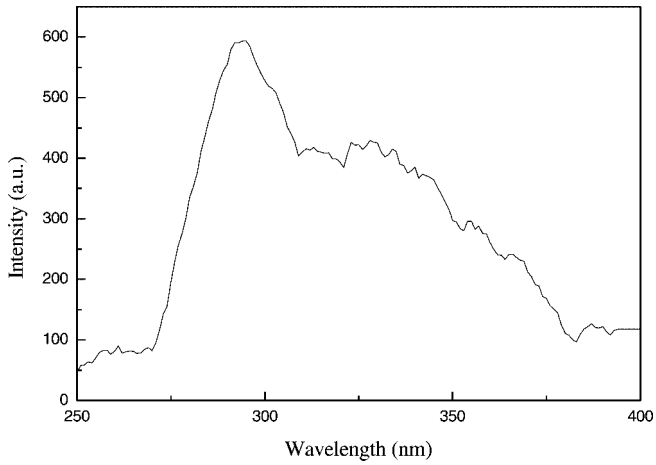

Figure 7. The excitation spectrum of $^5D_0$ emission (λ_{em} = 614 nm) of Eu^{3+} in $[Eu(TPI)_3{\cdot}2TOPO]$ (**2**) at 300 K.

in these Eu^{3+} complexes, thus indicating that energy transfer from the lowest triplet state of 4-toluoyl-5-isoxazolone to the Eu^{3+} ion is efficient.

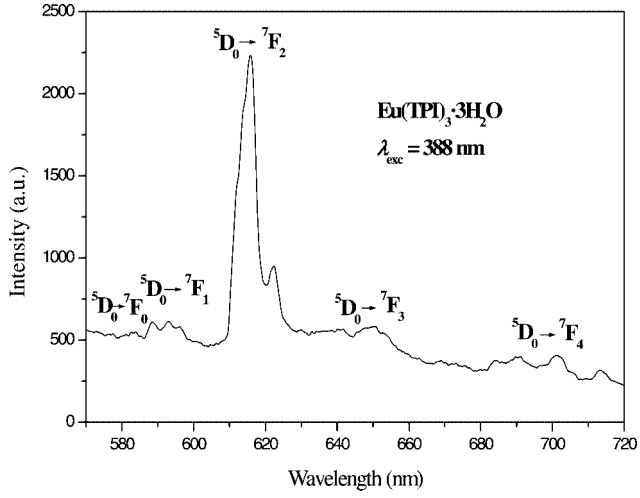

Figure 8. Room-temperature PL spectrum of compound **1** excited at 388 nm.

The experimental intensity parameters Ω_2 and Ω_4 were determined from the emission spectra (Figures 8–11) based on the $^5D_0 \rightarrow {}^7F_2$ and $^5D_0 \rightarrow {}^7F_4$ electronic transitions, respectively, and by expressing the emission intensity $I = \hbar\bar{\omega}A_{RAD}N$ in terms of the surface under the emission curve. Here $\hbar\bar{\omega}$ is the transition energy, A_{RAD} is the corresponding coefficient of spontaneous emission, and N is the population of the emitting level $^5D_0$. The magnetic dipole allowed $^5D_0 \rightarrow {}^7F_1$ transition was taken as the reference.[30,31] The A_{RAD} values are given by Equation (9)[32]

$$A_{RAD} = \frac{4e^2\omega^3}{3\eta c^3}\chi\sum_{\lambda}\Omega_\lambda\left\langle {}^7F_J\left\|U^{(\lambda)}\right\|{}^5D_0\right\rangle^2\frac{1}{2J+1} \quad (9)$$

where, λ = 2 and 4, χ is the Lorentz local field correction term that is given by $n(n^2 + 2)^2/9$, with a refraction index, n,

of 1.5, and $\langle {}^5D_0 \| U^{(2)} \| {}^7F_J \rangle^2$ are the squared reduced matrix elements whose values are 0.0032 and 0.0023 for $J = 2$ and 4, respectively.[21] Table 3 presents the values of Ω_2 and Ω_4 for complexes **1**–**4** at room temperature (300 K) and the values at 14 K for complex **1**. The high values of Ω_2 for complexes **1**–**3** might be interpreted as a consequence of the hypersensitive behavior of the $^5D_0 \rightarrow {}^7F_2$ transition,[33] suggesting that dynamic coupling mechanism is quite operative in these complexes.

Table 3. Experimental intensity parameters, radiative (A_{RAD}) and nonradiative decay rates (A_{NR}), experimental (q_{exp}) and theoretical emission quantum yields (q_{theo}), $^5D_0$ lifetime (τ), and quantum efficiency (ε) for complexes **1**–**4** at 300 K.

	Ω_2 ($\times 10^{-20}$) [cm^2]	Ω_4 ($\times 10^{-20}$) [cm^2]	A_{RAD} [s^{-1}]	A_{NR} [s^{-1}]	q_{exp} [%]	q_{theo} [%]	τ [ms]	ε [%]

4	6.02	6.99	335	1304	5.5	14.02	0.61	20

[a] Measured at 14 K.

By comparing the values of the Ω_2 parameter determined for the complexes at room temperature, it can be concluded that the polarizability is in the order [Eu(TPI)$_3$·Phen·H$_2$O] (**4**) < [Eu(TPI)$_3$·3H$_2$O] (**1**) < [Eu(TPI)$_3$·TPhPO·2H$_2$O] (**3**) and [Eu(TPI)$_3$·2TOPO] (**2**). As pointed out by Reisfeld and Jørgensen,[34] the intensity parameter Ω_2 can be correlated to the degree of covalency experienced by the lanthanide ion, greater values being obtained in more covalent surroundings (e.g., 1.2×10^{-20} cm^2 for LaF_3:Eu; 1×10^{-19} cm^2 for Y_2O_3:Eu). Therefore, the high value of Ω_2 obtained for complex **2** in the present investigations indicates that the covalent contribution is larger for the complex containing the TOPO ligand, which may be ascribed to stronger bonding. It can be argued that this is expected to increase the ligand–Eu^{3+} ion energy-transfer rate,[35] since a stronger bond causes the ligand–metal ion distances to be shorter, thus increasing electric-dipole interactions and wavefunction overlap.

The lifetime values (τ) of the $^5D_0$ level were determined from the luminescence decay profiles for the complexes at room temperature by fitting with a mono-exponential curve; they are listed in Table 3. The relatively shorter lifetimes obtained for complex **1** may be due to dominant nonradiative decay channels associated with vibronic coupling due to the presence of water molecules, as has been documented in many hydrated europium β-diketonate complexes.[25] A longer lifetime value has been observed for complex **2** as compared to complexes **3** and **4**. This may also be due to the presence of water molecules in complexes **3** and **4**.

The nonradiative rates, A_{NR}, can be obtained from the calculated A_{RAD} rates and the experimental decay rates by Equation (10).[35]

$$\tau^{-1} = A_T = A_{RAD} + A_{NR} \quad (10)$$

It is clear from Table 3 that complexes **1**, **3**, and **4**, which have water molecules in the coordination sphere, exhibit lower quantum efficiencies and lifetimes. This is due to the

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

presence of O–H oscillators in these systems, which effectively quench the luminescence of the Eu^{3+} ion. On the other hand, complex **2**, which does not contain any water molecule in its coordination sphere, as is also evident from the molecular structure analysis with the Sparkle/AM1 model, exhibits high quantum efficiency and lifetime values. The experimental and theoretical quantum yields of these complexes increase in the order **1** < **4** < **3** < **2**. The theoretical quantum yield of complex **2** is in good agreement with the experimental value. On the other hand, the degree of agreement between the theoretical and experimental quantum yields in the case of **1**, **3**, and **4** is not promising. This may be due to the fact that the model for quantum yield does not take into account the suppression by vibronic coupling with coordinated water molecules. Another factor contributing towards the error could be the phenomenon of nonradiative deactivation via a charge-transfer state involving the metal and the ligand.

The energy-transfer rates from the ligand triplet state T to the $^5D_1$ and $^5D_0$ levels and energy-transfer rates from the singlet state S to the $^5D_4$ level are presented in Table 4. We assumed a singlet→triplet intersystem crossing rate of 10^8 s^{-1}, a triplet state decay rate of 10^5 s^{-1}, and a nonradiative decay rate of 10^6 s^{-1}.[9] The theoretical energies of the singlet and triplet were used in the calculation of the energy-transfer rates. We considered an average of the three singlet and triplet excited states where the difference of the energy between the average values of the triplet states of the ^5D_J levels is smaller than 9.000 cm^{-1}. The average values of the singlet excited states were chosen because these values are closer to the values of the experimental singlet excited state of the complexes. The values for the theoretical triplet excited states were also chosen in the same way. An energy level diagram for the compound [$Eu(TPI)_3$·2TOPO] is shown in Figure 12. The symbols S_0, T, and S_1 shown in Figure 12 refer to the ground singlet, lowest energy triplet, and first excited singlet, respectively. The theoretical energies of the singlet and triplet were used in this diagram.

Table 4. Predicted values of intramolecular energy-transfer rates in compounds **1**–**4**. The back transfer rates were calculated by multiplying the direct transfer rates by the Boltzmann factor $e^{-|\Delta|/kT}$ at room temperature.

Compound	Levels	Transfer rate [s^{-1}]	Back transfer rate [s^{-1}]
1	$S_1 \rightarrow {}^5D_4$	1.386×10^5	1.924×10^{-5}
	$T \rightarrow {}^5D_1$	3.933×10^8	3.400×10^{-1}
	$T \rightarrow {}^5D_0$	8.353×10^7	9.757×10^{-6}
2	$S_1 \rightarrow {}^5D_4$	7.698×10^4	8.703×10^{-8}
	$T \rightarrow {}^5D_1$	1.703×10^8	4.121×10^{-4}
	$T \rightarrow {}^5D_0$	2.541×10^7	8.298×10^{-9}
3	$S_1 \rightarrow {}^5D_4$	4.311×10^4	7.148×10^{-9}
	$T \rightarrow {}^5D_1$	1.028×10^8	1.738×10^{-5}
	$T \rightarrow {}^5D_0$	1.306×10^7	2.982×10^{-10}
4	$S_1 \rightarrow {}^5D_4$	6.757×10^5	5.010×10^{-1}
	$T \rightarrow {}^5D_1$	1.169×10^8	7.086×10^{-5}
	$T \rightarrow {}^5D_0$	1.604×10^7	1.313×10^{-9}

According to the selection rules for the process of energy transfer, in the case of the ion Eu^{3+}, levels $^5D_2$, $^5L_6$, $^5G_6$, and $^5D_4$ are good candidates for the multipolar mechanism, while for the exchange mechanism a strong candidate is level $^5D_1$.[36] Therefore for the complexes in this work, the predominant process in the transfer of energy is the exchange mechanism. In accordance with Table 4, the values of the energy-transfer rate indicate that the energy transfer is predominant from the triplet state of the ligand to the $^5D_1$ and $^5D_0$ levels of the Eu^{3+} ion.

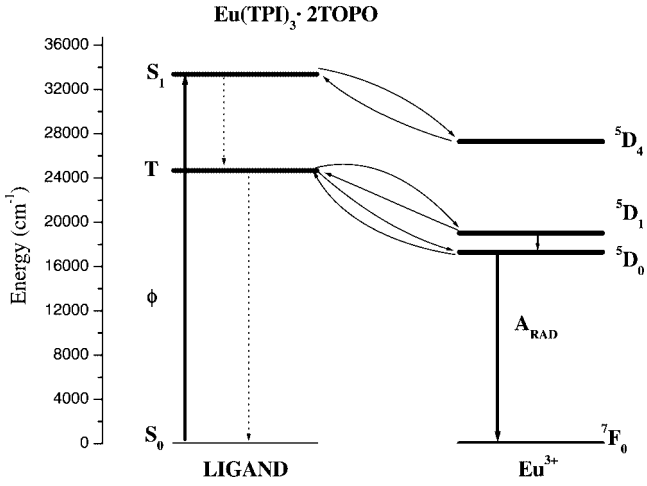

Figure 12. The energy level diagram of ligands and Eu^{3+} ion in [$Eu(TPI)_3$·2TOPO].

Conclusions

In the present study, various new 3-phenyl-4-(4-toluoyl)-5-isoxazolonate complexes of Eu^{3+} with Lewis bases such as tri-*n*-octylphosphane oxide, triphenylphosphane oxide, and 1,10-phenanthroline have been synthesized and characterized by various spectroscopic techniques. Their ground-state geometries have been calculated using the Sparkle/AM1 model. Experimental and theoretical results on ligand-field parameters, 4f–4f intensities, and intramolecular energy-transfer processes have been described. The photophysical properties of the above complexes have been determined and compared with the theoretical predictions.

The characteristic emission spectra of Eu^{3+} complexes **1**–**4** show a very high intensity for the hypersensitive $^5D_0 \rightarrow {}^7F_2$ transition, pointing to a highly polarizable chemical environment around the Eu^{3+} ion. The theoretically predicted values of intramolecular energy-transfer rates of complexes **1**–**4** clearly indicate that the energy transfer is predominant from the triplet state of the ligand to the $^5D_1$ and $^5D_0$ levels of the Eu^{3+} ion. Higher quantum yields (49.5%) and lifetime values (980 μs) are observed for complex **2** than for complexes **1**, **3**, and **4**, and this can be ascribed to a more efficient ligand-to-metal energy transfer and less efficient nonradiative $^5D_0$ relaxation process in the former case. This is also in accordance with the strong coordination between the oxygen atom of TOPO and the Eu^{3+} ion, as predicted by the Sparkle model. It is also important to point out that there is a good agreement between the experimental and the theoretical quantum yields, especially for complex **2**, thus

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

showing that the theoretical estimation of quantum yields can be a valuable tool for developing efficient light conversion molecular devices (LCMDs). The luminescent properties observed in the Eu–heterocyclic β-diketonate complexes indicate that 3-phenyl-4-aroyl-5-isoxazolones form a promising class of antenna molecules that can be employed in the design of new LCMDs.

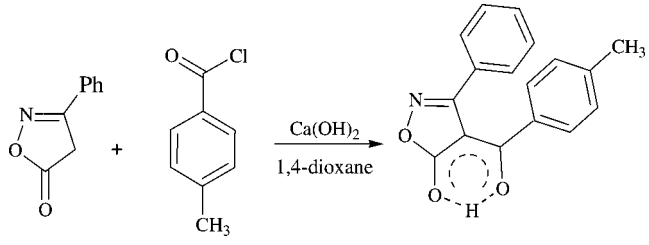
Experimental Section

Materials and Methods: The commercially available chemicals europium(III) nitrate hexahydrate, 99.9% (Acros Organics); 3-phenyl-5-isoxazolone, 98% (Aldrich), 4-toluoyl chloride, 98% (Aldrich), trioctylphosphane oxide, 99% (Aldrich), triphenylphosphane oxide, 98% (Aldrich), and 1,10-phenanthroline, 99.5% (Merck) were used without further purification. All the other chemicals used were of analytical reagent grade. C, H and N analyses were performed with a Perkin–Elmer Series 2 Elemental Analyser 2400. A Nicolet FT-IR 560 Magna Spectrometer (KBr, neat) was used to obtain IR spectroscopic data and a Bruker 300 MHz NMR spectrometer was used to obtain ^{1}H NMR spectra of the compounds in $CDCl_3$ or [D_6]acetone. Photoluminescence (PL) spectra were recorded with a Jobin Yvon Spex spectrometer (HR, 460) coupled to an R928 Hamamatsu photomultiplier. A Xe arc lamp (150 mW) coupled to a Jobin Yvon Spex monochromator (TRIAX 180) was used as the excitation source. All the spectra were corrected for the response of the detector. The lifetime measurements were taken using a pulsed Xe arc lamp (5 mJ/pulse, 3 ms bandwidth) coupled to a Kratos GM-252 monochromator and a Spex 1934 C phosphorimeter. The emission quantum yield, q_x, of the $^5D_0$ emission band of the Eu^{III} complexes, defined as the ratio between the number of photons emitted by the Eu^{3+} ion and the number of photons absorbed by the ligand, was determined from the following formula:

$$q_x = \left(\frac{1-r_{st}}{1-r_x}\right)\left(\frac{\Delta\Phi_x}{\Delta\Phi_{st}}\right)q_{st}$$

where r_{st} and r_x are the amounts of exciting radiation reflected by the standard phosphor and by the sample, respectively, and q_{st} is the quantum yield of the standard phosphor. The terms $\Delta\Phi_x$ and $\Delta\Phi_{st}$ give the integrated photon flux (photons per second) for the sample and the standard phosphor, respectively. A detailed description of this method has been presented elsewhere.[11,12]

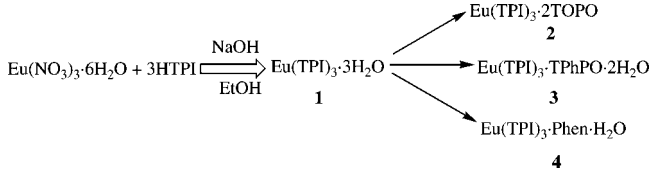
Synthesis of 3-Phenyl-4-(4-toluoyl)-5-isoxazolone (HTPI): A mixture of 3-phenyl-5-isoxazolone (3 g, 18 mmol), $Ca(OH)_2$ (2.7 g, 27 mmol), and dioxane (30 mL) was heated at 50 °C for 0.5 h. 4-Toluoyl chloride (2.88 g, 18 mmol) was then added dropwise and the mixture stirred for 6 h (Scheme 1). The crude product was filtered, dried, and recrystallized from ethyl acetate.[13] The synthesized 3-phenyl-4-(4-toluoyl)-5-isoxazolone was identified by elemental analyses and IR and ^{1}H NMR spectroscopic data.



Scheme 1.

HTPI: M.p. 145 °C. ^{1}H NMR: δ = 6.93–7.37 (m, 9 H, phenyl), 2.31 (3 H, methyl) ppm. The peak observed at δ = 4.08 ppm corresponds to the enolic OH group in the compound, which was found to undergo exchange on addition of D_2O, thus confirming the existence of this compound in the enolic form. The absence of a peak at δ = 3.8 ppm corresponding to the methylene proton at position 4 of the isoxazolone ring further confirms the existence of HTPI quantitatively in the enolic form. IR: $\tilde{\nu}$ = 2600, 1706, 1613, 1600, 830 cm^{-1}. $C_{17}H_{13}NO_3$ (279): calcd. C 73.12, H 4.66, N 5.02; found C 73.52, H 4.73, N 5.31.

[Eu(TPI)$_3$·3H$_2$O] (1): An aqueous solution of $Eu(NO_3)_3·6H_2O$ (0.5 mmol) was added to a solution of HTPI (1.5 mmol) in ethanol in the presence of NaOH (1.5 mmol). Precipitation took place immediately and the reaction mixture was stirred at room temperature for 10 h (Scheme 2). It was then filtered, washed with ethanol, water and then with ethanol, and dried and stored in a desiccator. $C_{51}H_{42}EuN_3O_{12}$ (1040.0): calcd. C 58.84, H 4.04, Eu 14.61, N 4.04; found C 58.63, H 4.27, Eu 14.59, N 4.4. IR (KBr): $\tilde{\nu}_{max}$ = 3300, 2919, 1640, 1606, 1441, 1387, 1189, 917, 771 cm^{-1}.



Scheme 2.

[Eu(TPI)$_3$·2TOPO] (2): An aqueous solution of $Eu(NO_3)_3·6H_2O$ (0.5 mmol) was added to a mixture of HTPI (1.5 mmol) and TOPO (1.0 mmol) in ethanol in the presence of NaOH (1.5 mmol). Precipitation took place immediately and the reaction mixture was stirred at room temperature for 10 h (Scheme 2). It was then filtered, washed with ethanol, water and then with ethanol, dried, and stored in a desiccator.$C_{99}H_{138}EuN_3O_{11}P_2$ (1759.3): calcd. C 67.53, H 7.84, Eu 8.64, N 2.39; found C 67.57, H 8.16, Eu 8.61, N 2.59. IR (KBr): $\tilde{\nu}_{max}$ = 2925, 2839, 1643, 1603, 1570, 1483, 1380, 1132, 909, 767 cm^{-1}.

[Eu(TPI)$_3$·TPhPO·2H$_2$O] (3): An aqueous solution of $Eu(NO_3)_3·6H_2O$ (0.25 mmol) was added to a mixture of HTPI (0.75 mmol) and TPhPO (0.5 mmol) in ethanol in the presence of NaOH (0.75 mmol). Precipitation took place immediately and the reaction mixture was stirred at room temperature for 10 h (Scheme 2). It was then filtered, washed with ethanol, water and then with ethanol, dried, and stored in a desiccator.$C_{69}H_{55}EuN_3PO_{12}$ (1300.3): calcd. C 63.67, H 4.23, Eu 11.68, N 3.23; found C 63.69, H 3.64, Eu 11.64, N 3.44. IR (KBr): $\tilde{\nu}_{max}$ = 3400, 2912, 2853, 1679, 1640, 1606, 1480, 1381, 1155, 910, 771 cm^{-1}.

[Eu(TPI)$_3$·Phen·H$_2$O] (4): An aqueous solution of $Eu(NO_3)_3·6H_2O$ (0.5 mmol) was added to a mixture of HTPI (1.5 mmol) and 1,10-phenanthroline (0.5 mmol) in ethanol in the presence of NaOH (1.5 mmol). Precipitation took place immediately and the reaction mixture was stirred at room temperature for 10 h (Scheme 2). It was then filtered, washed with ethanol, water and then with ethanol, dried, and stored in a desiccator. $C_{63}H_{46}EuN_5O_{10}$ (1184.2): calcd. C 63.84, H 3.88, Eu 12.83, N 5.91; found C 64.08, H 3.92, Eu 12.80, N 5.09. IR (KBr): $\tilde{\nu}_{max}$ = 3402, 2919, 1639, 1608, 1574, 1476, 1445, 1384, 1180, 916, 844, 766 cm^{-1}.

Direct Syntheses and Structural Novelty of Lanthanoid Aryloxides with Flexible Radial Arms

Marcus L. Cole,[a][‡] Glen B. Deacon,[a] Peter C. Junk,*[a,b] Kathryn M. Proctor,[b] Janet L. Scott,[b] and Christopher R. Strauss[b]

Keywords: Lanthanoids / Aryloxides / Benzyl group / π-Donors / Phenolates / X-ray crystal structures

Direct treatment of excess lanthanum, europium or ytterbium metal with 2,6-dibenzylphenol (HOdbp) at 150 °C afforded $[La_2(Odbp)_6]$, $[Eu_2(Odbp)_4]$ and $[Yb(Odbp)_2]_n$, respectively, in high yields. Alternatively, treatment of Yb metal with excess HOdbp gave an ytterbium(III) species $[Yb_2(Odbp)_6]$, similar to the lanthanum analogue. X-ray crystal structures were obtained for $[La_2(Odbp)_6]$, $[Eu_2(Odbp)_4]$ and $[Yb_2(Odbp)_6]$. $[La_2(Odbp)_6]$ and $[Yb_2(Odbp)_6]$ are pseudo-centrosymmetric dimers with two terminal and four bridging $Odbp^-$ ligands and $[Eu_2(Odbp)_4]$ crystallizes as a centrosymmetric dimer with further organization in a polymeric form through supramolecular interactions. All three structurally characterized compounds achieve coordination saturation by Ln–π-arene interactions.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Lanthanoid aryloxides are accessible by a wide array of synthetic routes and exhibit an enormous structural variety.[1] Use of bulky aryloxides has provided a range of exciting low-coordinate complexes for both Ln^{II} and Ln^{III} oxidation states.[1] Whilst most of these have additional neutral ligands, e.g. $[Ln(OAr)_3(THF)_n]$ (n = 1–3), (where OAr = 2,6-diphenylphenolate,[2] 2,6-diisopropylphenolate,[3] 3,5-dimethyl-2,6-diphenylphenolate,[4a] 3,5-di-*tert*-butyl-2,6-diphenylphenolate[4a] and 3,5-di-*tert*-butylphenolate[4b]), there has been increasing interest in homoleptic complexes, both neutral $[Ln(OAr)_n]$ (n = 2 or 3, where OAr = 2,6-diphenylphenolate[5] and 2,6-di-*tert*-butylphenolates[6]) and anionic $[Ln(OAr)_4]^-$ (where OAr = 2,6-diphenylphenolate[5a,7] 2,6-diisopropylphenolate,[8,9] 2,6-di-*tert*-butyl-4-methylphenolate[10]). Homoleptic complexes of the bulkiest aryloxides (OAr = $OC_6H_2tBu_2$-2,6-X-4, where X = H, Me) are normally coordinatively and sterically saturated with solely oxygen donors. However, less bulky phenolates, e.g. OAr = $OC_6H_3Ph_2$-2,6,[5,7] $OC_6H_3iPr_2$-2,6,[8,9] give rise to additional π-arene–Ln interactions ranging from η^1 to η^6. These can involve either the pendant groups as with $OC_6H_3Ph_2$-2,6[5,7] or the central arene as with $OC_6H_3iPr_2$-2,6.[8,9] Use of more flexible side arms presents opportunities for optimal π-arene–Ln coordination geometry provided that the interaction is strong enough to overcome the capacity of the aryl group to rotate away. We now report novel lanthanoid complexes obtained from the direct reactions of La, Eu or Yb metal with 2,6-dibenzylphenol (HOdbp) and find extensive π-arene–Ln interactions in the solid state. These are the first lanthanoid benzylphenolates to show such interactions, which do not appear to be exhibited by related calixarenes.[11]

Results and Discussion

Direct treatment of excess lanthanum, europium or ytterbium metal with 2,6-dibenzylphenol (HOdbp), in an evacuated Carius tube at 170 °C for 4 d, afforded crystalline material comprising $[Ln(Odbp)_n]_2$ [Ln = La, n = 3 (**1**); Ln = Eu, n = 2 (**2**)] or $[Yb(Odbp)_2]_n$ (**3**) [Equations (1) and (2)]. Initially, several drops of mercury were added to the reaction mixture to form a reactive lanthanoid amalgam. In previous related syntheses,[4,5] this was found to be essential for complete reaction. However, subsequently, it was found that the reactions occurred cleanly and in significant but lower yield without mercury for **1** and **2**, but not for **3** or **4**. In all cases crystals were obtained directly from the reaction tube. Low solubility in non-coordinating solvents (e.g. hexane and toluene) necessitated separation of crystalline products from excess metal by hand-picking under a microscope. In an attempt to improve the method of isolation, experiments were performed in the presence of excess ligand (rather than metal), followed by sublimation or washing out of the residual ligand from the product. In the cases of compounds **1** and **2**, this presented no apparent problems, but

 DOI: 10.1002/ejic.200500530

for Ln = Yb, a Yb^{III} species, $[Yb_2(Odbp)_6]$ (**4**), was obtained rather than the Yb^{II} compound **3**. This is not surprising since previously we have found that excess lanthanoid metal in redox transmetallation reactions,[12] as well as in direct Ln metal/phenol reactions,[5a] aids in formation of the lower oxidation state product. Excess metal acts as a reductant if any Ln^{III} species is formed for Ln = Yb. The formation of compound **4** rather than **3** contrasts with the chemistry of compound **2**, where the Eu^{II} species is obtained when either excess metal or ligand is used. The results are consistent with Eu having the most stable divalent state of the lanthanoids.

$$Ln_{(metal)} + 2n\,HOdbp \xrightarrow{170^{o}C} [Ln(Odbp)_n]_2 + n\,H_2$$

$$Yb_{(metal)} + 2n\,HOdbp \xrightarrow{170^{o}C} [Yb(Odbp)_2]_n + n\,H_2 \quad (2)$$

The infrared spectra of all compounds showed the absence of an OH stretching band at around 3560 cm^{-1} establishing complete deprotonation of the phenol. Furthermore, in the ^1H NMR spectrum (C_6D_6) of compounds **1** and **3**, there was no appreciable resonance at $\delta \approx 4.6$ ppm for the OH protons (however, products consistently showed small amounts of phenol detectable in the IR and NMR spectra perhaps arising from slight decomposition during measurement). Unfortunately, compounds **2** and **4** were too insoluble in C_6D_6 to afford reasonable ^1H NMR spectroscopic data. The low solubility of all compounds in the same solvent precluded recording of ^{13}C NMR spectra. The ^1H NMR spectra of compounds **1** and **3** had reasonably sharp peaks. The methylene resonances were slightly shifted in both compounds, from $\delta = 4.0$ ppm in the parent phenol, to $\delta = 3.78$ and 3.72 ppm in compounds **1** and **3**, respectively. Compounds **1**–**4** were all analytically pure based on lanthanoid analyses as determined by complexometric titrations. For compounds **1**, **2** and **4**, crystals suitable for X-ray crystal structure determination were obtained directly from the reaction tube, however, for compound **3** no such crystals resulted; nor could crystals be grown from non-coordinating solvents such as toluene or hexane due to insolubility. The aggregation of compound **3** is therefore unknown.

Compound **1** crystallizes in the triclinic space group $P\bar{1}$ with one whole dimer comprising the asymmetric unit. Aside from La–π-arene interactions (see below) each La center is four-coordinate, being bound by two terminal and two bridging phenolate ligands. The $La–O_{(bridging)}$ distances range from 2.402(4) to 2.565(5) Å, while the $La–O_{(terminal)}$ distances [range 2.172(6)–2.227(5) Å] are expectedly shorter than the former and comparable with those of mononuclear $[La(OC_6H_3Ph_2\text{-}2,6)_3]$,[5b] which exhibits solely terminal $OC_6H_3Ph_2$-2,6 ligands (though there are additional π-arene–Ln interactions). The La···La distance of 4.031(4) Å rules out any metal–metal interactions, being well in excess of the sum of the ionic radii of two four-coordinate La^{3+} ions.[13] Compared with monomeric $[La(OC_6H_3Ph_2\text{-}2,6)_3]$,[5b] the presence of the methylene linker in compound **1** allows for increased steric freedom about the metal center owing to the rotational ability about the $Ph–CH_2$ bond as well as the ability of the Ph group to swing away from the metal centres about the CH_2 linker. This creates more space about the La centers resulting in dimerisation, and a higher O-donor coordination number.

To compensate for the coordinatively unsaturated four-coordinate La center in compound **1**, the metal atom is also involved in La···π-arene interactions. This mode of interaction has been a common feature of other lanthanoid aryloxide chemistry that we have presented previously,[2,5,7] and the possibility arises due to the synthesis being performed in a donor-solvent-free manner. Thus, each La center interacts with an adjacent aromatic ring of an *O*-bridged ligand in an η^6-fashion through carbon atoms C(28) to C(33) for La(1) and C(8) to C(13) for La(2) (see Figure 1a). Therefore, the four-coordination about La (O only) expands to a formal coordination number of seven. If the centroid of the η^6-attachment is regarded as a coordination site, then the geometry about La is a distorted square pyramid with the arene ring seated at the apex (see Figure 1a). The La···C distances [for La(1) 3.057(8) to 3.277(8), for La(2) 3.043(8) to 3.300(8) Å] are all within the parameters defined for $[La(OC_6H_3Ph_2\text{-}2,6)_3]$[5b] (>3.5 Å is considered non-bonding for this compound) and similar to those in $[La_2(OC_6H_3iPr\text{-}2,6)_6]$[3b] (av. La···C 3.06 Å) where there are η^6-π-arene bridges. Thus, given there is only a small spread in La···C(π-arene) interactions for this compound, and there is no obvious cut-off in La···C distances, the interactions can only be regarded as η^6-binding. The π-arene bridges are from *O*-bridging ligands which thus bind in a $\mu\text{-}\eta^6\text{:}\eta^1\text{:}\eta^1$-manner and contrast the arrangement in $La(OC_6H_3Ph_2\text{-}2,6)_3$ where an arene arm from one terminal ligand binds in an η^6-fashion whilst a Ph from another binds η^3 to the metal atom.

Compound **4** is structurally similar to compound **1** in that it is also a dimer with Yb–π-arene interactions. Unfortunately, all attempts to determine a high-precision X-ray crystal structure were thwarted by consistent twinning of crystals. However, the low-precision structure leaves no doubt as to the connectivity of the compound, and the structure is similar to that of its La analogue **1**. One pertinent and clear feature of the structure is a reduction in coordination number about the metal center through reduced π-arene connectivity. In compound **3**, Yb(1) is bound in an η^3-manner, while Yb(2) is η^2-bound (Figure 2), lowered from $\eta^6\text{:}\eta^6$ in **1**. For Yb(1) there are three $Yb\cdots C_{arene}$ distances of 2.719(13), 2.997(12) and 3.174(13) Å, while there is a drastic increase (well outside error limits) to the next closest carbon atom on the same aromatic ring [Yb(1)–C(33) 3.610(12) Å], and for Yb(2) there are two $Yb\cdots C_{arene}$ distances of 2.837(12) and 2.894(12) Å, and the next closest approach is Yb(2)–C(10), 3.358(12) Å, thus defining a cut-off for potential bonding. These "bonding" distances compare well with previously established $Yb^{III}\cdots C$ bond lengths

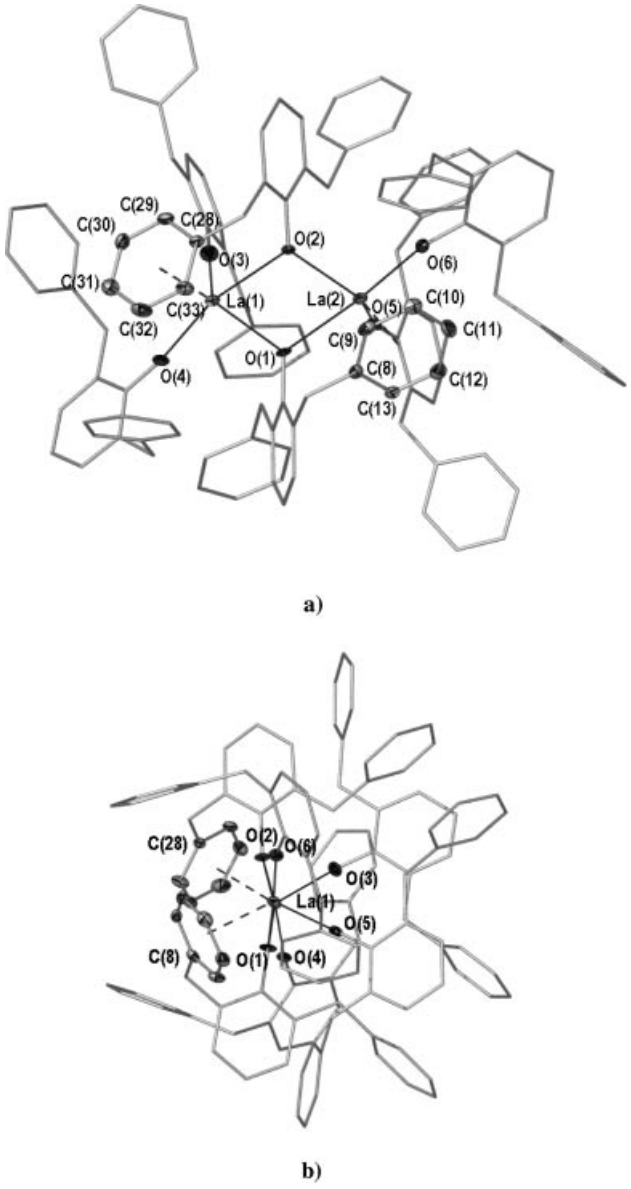

Figure 1. Molecular structure of [{La(μ-Odbp)(Odbp)$_2$}$_2$] (**1**) (40% thermal ellipsoids): all hydrogen atoms omitted for clarity and non-coordinating hydrocarbon groups depicted as wireframes. a) Normal to La_2O_2 fragment and b) along the La···La vector. Selected bond lengths [Å] and angles [°]: La(1)–O(1) 2.402(4), La(1)–O(2) 2.565(5), La(1)–O(3) 2.172(6), La(1)–O(4) 2.218(5), La(1)···C(28) 3.057(8), La(1)···C(29) 3.058(8), La(1)···C(30) 3.182(8), La(1)···C(31) 3.277(8), La(1)···C(32) 3.258(9), La(1)···C(33) 3.127(9), La(2)–O(1) 2.549(5), La(2)–O(2) 2.417(4), La(2)–O(5) 2.189(6), La(2)–O(6) 2.227(5), La(2)···C(8) 3.043(8), La(2)···C(9) 3.080(8), La(2)···C(10) 3.216(8), La(2)···C(11) 3.300(8), La(2)···C(12) 3.236(7), La(2)···C(13) 3.100(7); O1–La1–O2 69.90(16), O(1)–La(1)–O(3) 114.37(19), O(1)–La(1)–O(4) 95.18(17), O(2)–La(1)–O(3) 84.36(18), O(2)–La(1)–O(4) 165.07(16), O(3)–La(1)–O(4) 103.1(2), O(1)–La(2)–O(2) 69.94(16), O(1)–La(2)–O(5) 87.17(18), O(1)–La(2)–O(6) 174.38(16), O(2)–La(2)–O(5) 120.47(17), O(2)–La(2)–O(6) 104.52(17), O(5)–La(2)–O(6) 96.72(19).

in [Yb(OC$_6$H$_3$Ph$_2$-2,6)$_3$] and are consistent (after allowance for ionic radius differences) with the more extensive data for Yb^{II}···arene interactions.[2,5a,14] A consequence of this binding is that the capping aromatic ring does not sit flatly above the Ln center but is rather much more angled. Thus, in compound **1** the La–centroid–C_{ipso} angles are 85.0° and 84.3° for La(1) and La(2), while in compound **4** the corresponding angles are much more acute, at 72° and 69° for Yb(1) and Yb(2), respectively. The Yb–O(bridging) distances are asymmetric with two short [Yb(1)–O(1) 2.198(7) and Yb(2)–O(1) 2.209(8) Å] and two long [Yb(1)–O(2) 2.317(8) and Yb(2)–O(1) 2.378(7) Å] interactions, as is observed in compound **1**. In each case, the longer Ln–O bond is *cisoid* to a bonding phenyl group.

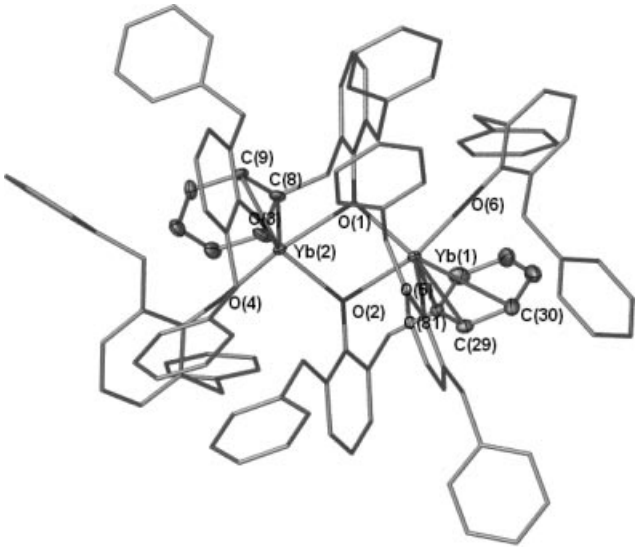

Figure 2. Molecular structure of [{Yb(μ-Odbp)(Odbp)$_2$}$_2$] (**4**) showing η^3-coordination to Yb(1) and η^2-coordination to Yb(2); all hydrogen atoms omitted for clarity. Selected bond lengths [Å] and angles [°]: Yb(1)–O(1) 2.198(7), Yb(1)–O(2) 2.317(8), Yb(1)–O(5) 2.031(9), Yb(1)–O(6) 2.055(10), Yb(2)–O(1) 2.378(7), Yb(2)–O(2) 2.209(8), Yb(2)–O(3) 2.056(8), Yb(2)–O(4)2.049(10), Yb(1)–C(28) 2.997(12), Yb(1)–C(29) 2.719(13), Yb(1)–C(30)3.174(13), Yb(2)–C(8) 2.894(12), Yb(2)–C(9) 2.837(12); O(1)–Yb(1)–O(2) 73.1(3), O(1)–Yb(1)–O(5) 121.3(3), O(1)–Yb(1)–O(6) 92.4(3), O(2)–Yb(1)–O(5) 89.2(3), O(2)–Yb(1)–O(6) 163.0(4), O(5)–Yb(1)–O(6) 106.2(4), O(1)–Yb(2)–O(2) 71.7(3), O(1)–Yb(2)–O(3) 90.5(3), O(1)–Yb(2)–O(4) 168.0(3), O(2)–Yb(2)–O(3) 120.6(3), O(2)–Yb(2)–O(4) 99.3(3), O(3)–Yb(2)–O(4) 101.0(4), Yb(1)–O(1)–Yb(2) 105.4(3), Yb(1)–O(2)–Yb(2) 107.1(3).

Compound **2** crystallizes in the triclinic space group $P\bar{1}$ with two unique half dimers in the asymmetric unit. Each unique europium(II) center is bound by oxygen atoms of a terminal and two bridging phenolate groups, thereby giving an oxygen donor coordination number about Eu^{II} of three. The Eu–O bond lengths (av. 2.46 Å for bridging and av. 2.29 Å for terminal) are unexceptional, being similar to Eu–O bridging and terminal distances of 2.48 (av.) and 2.361(3) Å, respectively, in [Eu(OC$_6$H$_3$Ph$_2$-2,6)$_2$]$_2$ where there are only one terminal and three bridging ligands.[5a] The longer Eu–$O_{terminal}$ distance in [Eu(OC$_6$H$_3$Ph$_2$-2,6)$_2$]$_2$ is consistent with a lower coordination number in compound **2**. Each dimer is structurally similar but with some significant differences, one being a discrete dimer and the other a polymer of dimers, involving extended nuclearity through inter- and intramolecular Eu–π-arene interactions (see below) that increase the coordination number of Eu

significantly. In the true dinuclear molecule the Eu centers are capped on two sides by an η^2- and an η^3-bound arene ring arising from one terminal and one bridging ligand (Figure 3a). In the other molecule, each Eu has one η^2-bound π-arene interaction with an arene group from *only* the bridging group of the dimer while an arene from the terminal groups (involved in π-interactions in the true dimer) swings away from the Eu atom with a closest Eu···C distance of 4.72(1) Å. This leaves a vacancy in the coordination sphere of Eu(2) which allows a further π-arene interaction between Eu(2) and (symmetry-generated) C(64)#1 of 3.136(16) Å [C(64) is the *p*-C atom of the central (phenolate) group of a terminal ligand rather than a radial group]. This forms a single-stranded polymer, where "dimers" are linked by Eu(2)···C(64)(arene) interactions (Figure 3b). This structure is drastically different from the stoichiometrically related $[Eu_2(OC_6H_3Ph_2\text{-}2,6)_4]$ which possesses a remarkable three bridging phenolate groups and one terminal phenolate ligand.

Conclusion

The direct reaction of lanthanoid metals (Ln = La, Eu, Yb) with 2,6-dibenzylphenol at 170°C provides the corresponding homoleptic lanthanoid phenolates in good yield. For Ln = Yb, use of either excess metal or excess phenol gives Yb^{II} or Yb^{III} complexes. All structures feature oxygen-bridged dimeric units with coordination saturation effected by intra- or intermolecular π-phenyl···Ln coordination.

Experimental Section

General: 2,6-Dibenzylphenol (HOdbp) was prepared by a literature method.[15] The lanthanoid metals used were purchased either from Strem chemicals, Tianjiao (Baotou, China), Rhône–Poulenc or Santoku, either as fine powders or as metal ingots, which were manually filed under an inert gas into metal powder for use in reactions. Toluene and hexane were dried with sodium/benzophenone and freeze-thaw-degassed prior to use. All manipulations were performed using conventional Schlenk or glovebox techniques under high-purity argon or dinitrogen in flame-dried glassware. Infrared spectra were recorded as Nujol mulls using sodium chloride plates with a Nicolet Nexus FTIR spectrophotometer. ^{1}H NMR spectra were recorded at 300.13 MHz using a Bruker BZH 300/52 spectrometer and chemical shifts were referenced to the residual ^{1}H resonances of the deuteriobenzene solvent employed. NMR and IR spectra of compounds **1** and **3** showed slight impurities of phenol due to decomposition of the rare earth phenolate compounds in the process of measurement. Compounds **2** and **4** had insufficient solubility in common non-coordinating solvents to obtain NMR spectra. Melting points were determined in sealed glass capillaries under dinitrogen. The metal analyses were adapted from the method described in a previous paper.[16]

$[La_2(Odbp)_6]$ (1). Method A: 2,6-Dibenzylphenol (0.60 g, 2.19 mmol) was treated directly with lanthanum metal (0.10 g, 0.73 mmol) in the presence of 2 drops of mercury and sealed under vacuum in a Carius tube. After 4 d of heating at 170 °C, a white crystalline material formed upon cooling. Unreacted ligand was removed by sublimation. Crystals suitable for XRD analysis were obtained. Yield: 0.58 g (82%). M.p. 184–187 °C. $C_{60}H_{51}LaO_3$ (958.92): calcd. La 14.48; found La 14.30. ^{1}H NMR (C_6D_6): δ = 3.78 (s, 12 H, CH_2), 6.67–6.70 (m, 3 H, ArH), 6.73–6.87 (m, 6 H, ArH), 6.88–7.12 (m, 30 H, ArH) ppm. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1589 m, 1452 s, 1262 s, 1191 m, 1081 s, 1029 m, 937 w, 859 m, 819 w, 754 s, 697 s, 559 w, 515 w.

$[La(Odbp)_3]_2$. Method B (Without Mercury): HOdbp (0.25 g, 0.91 mmol) was treated with excess lanthanum metal (0.10 g, 0.72 mmol) in an evacuated sealed glass Carius tube. The reaction mixture was heated at 250 °C for 5 d, forming a clear glassy solid upon cooling. Unreacted ligand was removed by a hexane wash. The product was identical to the compound **1** synthesised in the presence of mercury. Yield: 0.12 g (41%). M.p.183–187 °C. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1601 m, 1453 s, 1260 s, 1202 m, 1074 s, 1029 m, 950 w, 869 m, 820 w, 755 s, 698 s, 601 w, 515 w.

$[La(Odbp)_3]_2$. Method C (Excess Ligand): HOdbp (0.60 g, 2.18 mmol) and lanthanum metal (0.08 g, 0.55 mmol) were sealed under vacuum in the presence of 2 drops of mercury in a glass Carius tube. A white oil formed after heating at 210 °C for 2 d and all of the lanthanum metal was consumed. The remaining (excess) ligand was sublimed to one end of the tube (HOdbp sublimes at 240 °C). The product was identical with that obtained in Methods A and B above. Yield: 0.35 g (66%). M.p. 184–186 °C. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1594 m, 1456 s, 1259 s, 1200 m, 1072 s, 1029 m, 950 w, 865 m, 819 w, 755 s, 699 s, 600 w, 510 w.

$[Eu_2(Odbp)_4]$ (2). Method A: 2,6-Dibenzylphenol (0.53 g, 1.93 mmol) was treated directly with europium metal (0.15 g, 0.97 mmol) in the presence of 2 drops of mercury in an evacuated Carius tube. After 4 d of heating at 170 °C, an orange molten/crystalline material formed upon cooling. Unreacted excess ligand was removed by sublimation. Crystals suitable for XRD analysis were obtained. Yield: 0.56 g (83%). M.p. 198–200 °C. $C_{40}H_{34}EuO_2$ (698.63): calcd. Eu 22.81; found Eu 22.58. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1587 m, 1458 s, 1310 m, 1286 m, 1258 m, 1231 s, 1200 m, 1157 m, 1081 m, 1028 m, 933 w, 885 w, 854 m/w, 815 w, 748 s, 698 s, 601 w.

$[Eu(Odbp)_2]_2$ (2). Method B (Without Mercury): HOdbp (0.30 g, 1.09 mmol) was treated with excess europium metal (0.11 g, 0.72 mmol) in an evacuated glass Carius tube. The reaction was heated for 5 d at 250 °C, forming a glassy orange solid upon cooling. The residue was washed with hexane to remove any unreacted ligand. The product was identical to compound **2** from Method A. Yield: 0.19 g (49%). M.p. 197–200 °C. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1586 m, 1458 s, 1305 m, 1281 m, 1252 m, 1230 s, 1155 m, 1078 m, 1026 m, 971 w, 888 w, 850 m/w, 754 s, 696 s, 595 w.

$[Eu(Odbp)_2]_2$ (2). Method C (Excess Ligand): HOdbp (0.50 g, 1.82 mmol) and europium metal (0.09 g, 0.61 mmol) were sealed under vacuum in the presence of 2 drops of mercury in a glass Carius tube. An orange oil formed after heating at 210 °C overnight. All of the europium metal had reacted; the remaining excess ligand was sublimed to one end of the tube (HOdbp sublimes at 240°). The product was identical with that obtained from Methods A and B above. Yield: 0.32 g (77%). M.p. 197–200 °C. IR (Nujol): $\tilde{\nu}$ = 1600 m, 1453 s, 1347 m, 1286 m, 1231 m, 1200 m, 1150 m, 1075 m, 1026 m, 934 w, 885 w, 852 m/w, 755 s, 698 s, 590 w.

$[Yb(Odbp)_2]$ (3): 2,6-Dibenzylphenol (0.60 g, 2.19 mmol) was treated directly with excess ytterbium metal (0.40 g, 2.30 mmol) in the presence of 2 drops of mercury in a sealed, evacuated Carius tube. After 4 d of heating at 170 °C, a red glassy material formed upon cooling. Yield: 0.53 g (67%). M.p. 125–128 °C. $C_{40}H_{34}O_2Yb$ (719.75): calcd. Yb 23.99; found Yb 23.80. ^{1}H NMR (C_6D_6): δ =

3.72 (s, 8 H, CH_2), 6.72–6.77 (m, 2 H, ArH), 6.82–6.87 (m, 4 H, ArH), 6.89–7.13 (m, 20 H, ArH) ppm. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1601 m, 1456 s, 1363 s, 1230 s, 1074 w, 1028 w, 1006 w, 950 m, 923 m, 889 w, 830 w, 820 w, 794 w, 755 s, 698 s. Attempts to form this compound in the absence of mercury with heating up to 250 °C (2,6-dibenzylphenol slowly decomposes above 260 °C, so was not heated any further) resulted in the isolation of unreacted starting material.

$[Yb_2(Odbp)_6]$ (4): 2,6-Dibenzylphenol (0.30 g, 1.09 mmol) was treated directly with ytterbium metal (0.04 g, 0.23 mmol) in the presence of 2 drops of mercury. The reactants were sealed under vacuum in a glass Carius tube. After 2 d of heating at 150 °C, deep orange/red crystals were grown upon cooling. Unreacted ligand was removed by a hexane wash and the remaining material characterised. Yield: 0.18 g (78%). M.p. 78–80 °C. $C_{60}H_{51}O_3Yb$ (993.05): calcd. Yb 17.42; found 18.11. IR (Nujol, cm^{-1}): $\tilde{\nu}$ = 1601 m, 1459 s, 1365 s, 1230 s, 1074 w, 1029 w, 950 m, 923 m, 889 w, 829 w, 820 w, 794 w, 755 s, 698 s. Attempts to form this compound in the absence of mercury with heating up to 250 °C (2,6-dibenzylphenol slowly decomposes above 260 °C, so was not heated any further) resulted in the isolation of unreacted starting material.

X-ray Crystallography: Crystalline samples of compounds **1**, **2** and **4** were mounted on glass fibres in viscous paraffin oil at –150 °C (123 K). Crystal data were obtained using an Enraf–Nonius Kappa CCD. An empirical absorption correction (SORTAV)[17] was applied to all data. Structural solution and refinement were carried out using SHELXL-97[18] and SHELXS-97[19] utilising the graphical interface X-Seed.[20] Crystal data and refinement parameters for all complexes are compiled below.

$[La_2(Odbp)_6]$ (1): $C_{120}H_{102}La_2O_6$, M = 1917.84, 0.25 × 0.20 × 0.20 mm, triclinic, space group $P\bar{1}$ (No. 2), a = 13.4374(5), b = 13.9358(5), c = 26.7937(12) Å, α = 98.976(1), β = 95.312(2), γ = 108.065(4)°, V = 4658.3(3) Å^3, Z = 2, D_c = 1.367 g/cm^3, F_{000} = 1968, Nonius Kappa CCD, Mo-K_α radiation, λ = 0.71073 Å, T = 123(2) K, $2\theta_{max}$ = 56.5°, 53379 reflections collected, 21478 unique (R_{int} = 0.2204). Self-Assembly and Fluorescent Modification of Hydroxyapatite Nanoribbon Spherulites

Jinku Liu,[a] Qingsheng Wu,*[a] and Yaping Ding*[b]

Keywords: Fluorescence / Hydroxyapatite / Nanostructures / Self-assembly

Hydroxyapatite nanoribbon spherulites have been successfully synthesized, with the bioactive eggshell membrane as directing template and in the presence of ethylenediamine, in a one-step reaction under mild conditions. The spherulites are about 2.5 μm in diameter and the extended nanoribbon about 1.1 μm long. The spherulites were modified with fluorescein to obtain a fluorescent probe material with strong luminescence.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Assembly of nanocrystals to form ordered structures is of great interest in the area of materials science. The ability to synthesize uniformly assembled nanospheres with diameters ranging from nano- to microscale dimensions is especially desirable[1] as these structures can be used in therapeutic, storage, and catalytic fields[2,3] etc.[4] Ribbon-shaped nanomaterials or nanostructures have attracted a great deal of attention since the discovery of zinc oxide nanobelts in 2001 by Wang,[5] and the assembly of materials/structures is still an important objective. Up to now, the obtained inorganic nanobelts/nanoribbons mainly include oxides,[5–7] elementary substances,[8–10] sulfides,[11,12] etc.,[13–16] and no study has been reported on the formation of hydroxyapatite nanoribbons. On the other hand, although various spherical nano-/micromaterials have been reported, they are mainly solid[17–22] or hollow.[23–33]

In this paper, a novel assembly method for nanomaterials, which includes a bioactive eggshell membrane[34] template approach with the cooperative effect of ethylenediamine, is developed that gives hydroxyapatite nanoribbon spherulites in a single-step reaction at room temperature. The obtained spherulites can be modified with fluorescein to form spherical fluorescent probe materials with strong luminescence. The hydroxyapatite spherulites have attracted a good deal of attention as a delivery system because of their special physical and chemical properties, high surface-interaction properties, and their biocompatibility. Therefore, these nanoribbon spherulites have potential value in biology, medicine, and drug fields etc.

Results and Discussion

All the XRD diffraction patterns in Figure 1 can be readily indexed to a hydroxyapatite [$Ca_5(PO_4)_3(OH)$] phase, and there is an obvious indication of the crystal growth direction in the XRD pattern. The XRD analysis was repeated several times with similar results: the 002 diffraction looks rather sharp and intense, indicating a non-nanoscale and good crystallization at the 002 crystal face, while the other diffractions look broad, indicating a nanoscale and a poorer crystallization. According to the product's morphology and XRD results, the most likely growth direction of the nanoribbons is on the [002] crystal face.

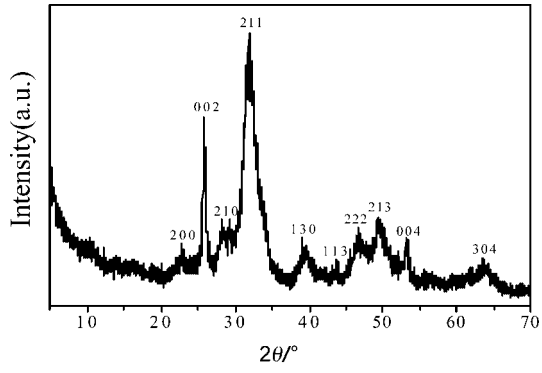

Figure 1. The XRD pattern of hydroxyapatite nanoribbon spherulites.

Figure 2 also shows a similar widening in the FT-IR absorption peaks. The ν_{P-O} vibration of the hydroxyapatite nanoribbon spherulites in Figure 2 (b) is at almost the same wavelength as that of hydroxyapatite bulk materials in Figure 2 (a) (1040 cm^{-1}), although it is obviously wider. This may be because the small-size effects and interface effects of nanomaterials change the ν_{P-O} vibration energy.

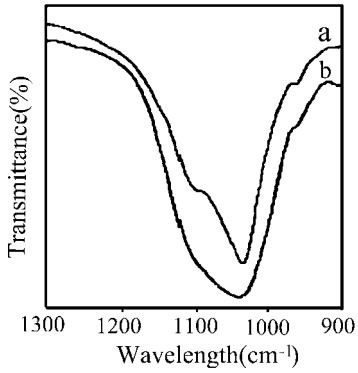

Figure 2. The FT-IR spectrum of products (a: bulk materials; b: spherulites).

The hydroxyapatite nanoribbon spherulites are different from hollow spherulites and solid spheres as the spherulites are in fact built from interlaced nanoribbons. Figure 3 (see part a) shows a typical TEM image of the products, which shows that they are spherulites with a diameter of about 2.5 μm. The high magnification TEM image in Figure 3 (part b) indicates that the spherulites consist of a large number of nanoribbons, the thickness and width of which are about 8 nm and 200 nm respectively; the length of the extended nanoribbons is about 1.1 μm. The electron diffraction (ED) lattice of a selected region suggests that the nanoribbons are single crystals (Figure 3, c). The obtained spherulites are porous structures composed of nanoribbons. They have a large surface area that contains a large number of hydroxy groups. With such a structure, they can easily combine with organic fluorescent compounds that contain carboxyl or hydroxy groups.

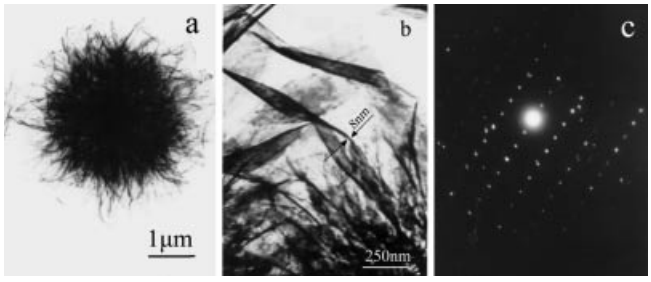

Figure 3. TEM and ED images of the products.

When irradiated with an electron beam, the hydroxyapatite nanoribbon spherulites change into a solid sphere. Figure 4 (a) shows the TEM image of a spherulite with a diameter of about 2.5 μm before irradiation. After irradiation with an electron beam for several seconds the product changes into a solid sphere with a diameter of 2.3 μm (Figure 4, b) consisting of melted hydroxyapatite. This can be explained by the fact that hydroxyapatite has a high chemical stability,[35] therefore decomposition cannot occur at the irradiation temperature of the electron beam[36] and it only melts.

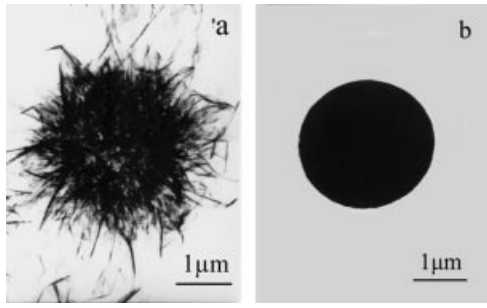

Figure 4. TEM images of the products (a: nanoribbon spherulite; b: solid sphere).

The growth processes of hydroxyapatite spherulites were determined by examining different stages of their formation. As shown in Figure 5a, nanoribbons with lengths ranging from 200 to 250 nm have formed after 0.5 h of aging, and they distributed randomly. After aging for 4 h, the products are approximately spherical with a diameter of 1.9 μm, as shown in part b of Figure 5, which suggests that the nanoribbons are not yet completely assembled and the spherulites are rather loose. When the aging time was further increased to 10 h, integrated spherical hydroxyapatite appeared, but the extended nanoribbons were still a little longer. They continued to become larger and more compact with time, and when the aging time reached two days, very compact spherulites had formed whose extended nanoribbons are shorter (200 nm; Figure 5, d). Even after aging for four days (further aging leads to the decomposition of the eggshell membrane), the final products were still hydroxyapatite nanoribbon spherulites similar to that in Figure 5, part d; no solid spherulite was obtained. These results indicate that shorter nanoribbons form at first, and then these assemble gradually to form many spherulite cores. Thereafter, the nanoribbons continue to assemble around the cores to form many large and compact spherulites.

The most suitable temperature for the formation of spherical hydroxyapatite is 37 °C, which is approximately physiological temperature. When the reaction was performed at a lower temperature (0 °C for 10 h) spherical hydroxyapatite also formed, as shown in Figure 6, but with a diameter of about 1.6 μm, far smaller than that at 37 °C. This may be explained by considering that the low temperature slows down diffusion of the ions and therefore assembly of the nanoribbons, and the eggshell membrane has lower activity at 0 °C than at physiological temperature, whichl weakens its inducing ability foro the formation of spherical hydroxyapatite.

The hydroxyapatite nanoribbons assemble into spherulites by an organic direction process.[22,23,37–39] This process is induced under the cooperative effect of the eggshell membrane and ethylenediamine. A TEM image in which the spherulites and the intermediate products exist simultaneously was taken during the experiment, as shown in Figure 7, from which a conjecture can be made that the spherulite cores marked with an arrow are assembled from a small

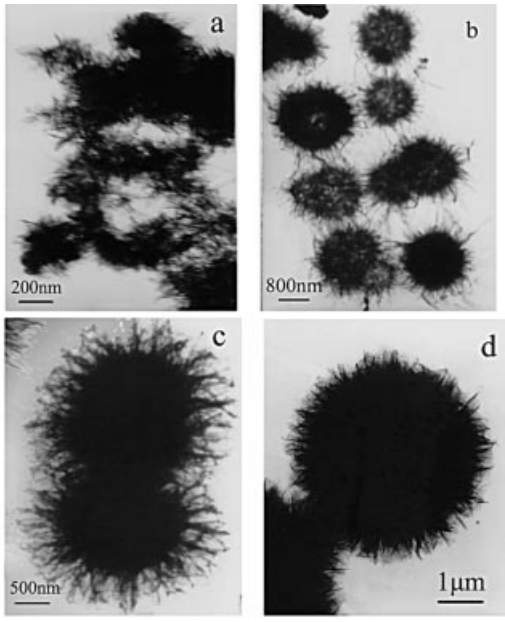

Figure 5. TEM images of the products [aging time: 1 h (a); 4 h (b); 10 h (c); 2 d (d)].

Figure 6. TEM pattern of the products obtained at 0 °C (aging for 10 h).

quantity of nanoribbons formed during the first step, and then these spherulite cores assemble into nanoribbon spherulites. Figure 8 shows a typical scanning electron microscopy (SEM) image of the eggshell membrane. The eggshell membrane is a microporous network with diameters of 1.5–10 μm, which is composed of interlaced protein fibers with an average diameter of about 2 μm. The eggshell membrane mainly contains collagens, glycoproteins, and proteoglycans. These macromolecules contain a large amount of amido, carboxy, and hydroxy groups, and have both hydrophilic and hydrophobic domains located at their ends.[40] The hydrophobic domains extend onto the surface of the crystal and block diffusion of the lattice ions to the crystal surface. The ethylenediamine acts as an additional template due to hydrogen-bonding effects between its NH_2 groups and the surface groups of the eggshell membrane such as COOH and NH_2. The products are obtained on either side of the eggshell membrane, which indicates that the products fall randomly from the template.

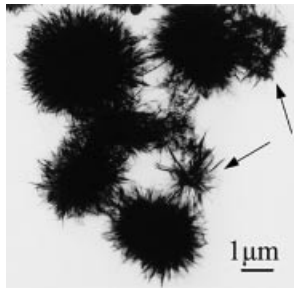

Figure 7. The SEM pattern of spherulites and intermediate products (after aging for 2 d).

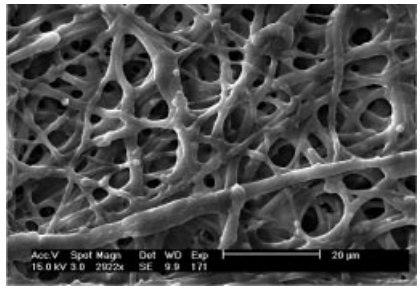

Figure 8. The SEM pattern of eggshell membrane.

As a template, the eggshell membrane has an effect in three aspects. Firstly, it can control the transport of ions due to its semi-permeable structure. Secondly, it not only can alone induce the formation of products, but can also interact with ethylenediamine through hydrogen bonds and consequently control the growth of products. Finally, the eggshell membrane offers a physical site in the hole channels of which the two kinds of ions meet, react, aggregate to form a crystal nucleus, and then grow under the control of the eggshell membrane and ethylenediamine to form the products. Moreover, it must be emphasized that the template used in this paper is not a simple flat structure. Rather, it is composed of macromolecules on the surface of curving hole channels of the eggshell membrane and ethylenediamine, which cooperatively form a spherical template and control the growth of hydroxyapatite nanoribbon spherulites. The nanoribbon spherulites can't be obtained in the absence of the eggshell membrane (Figure 9, a).

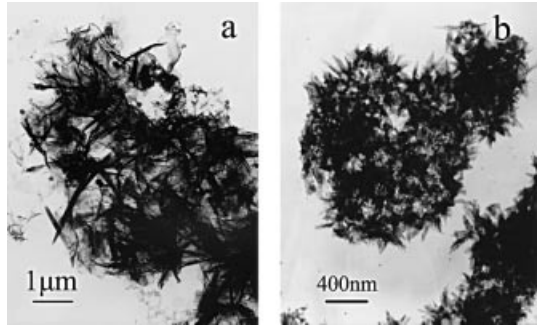

Figure 9. TEM images of the products (a: when the eggshell membrane is absent; b: when KOH was added to adjust the pH to 7.4).

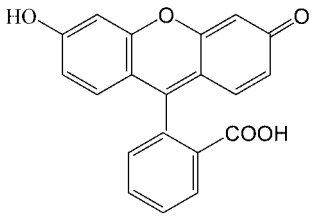
 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The organic base ethylenediamine is employed here to modulate the pH value to 7.4 and spherical products were obtained. When potassium hydroxide was used instead, the products were sparse flakes of hydroxyapatite about 300 nm long, as shown in part b of Figure 9. This indicates that the organic base plays an important role in the controllable assembly of spherical products. The morphological difference in the presence of inorganic and organic base is because, besides the adjusting pH value, ethylenediamine also acts as an accessorial template due to hydrogen-bonding effects between its NH_2 groups and the surface groups of the eggshell membrane such as COOH, NH_2.

The hydroxyapatite nanoribbon spherulites form as follows. First, the two reacting ions meet and react in the hole channels of the eggshell membrane. The formed $Ca_5(PO_4)_3$-OH molecules then aggregate to form a crystal nucleus, which grows under the cooperative control of the eggshell membrane and ethylenediamine on the surface of the eggshell membrane to form hydroxyapatite nanoribbon spherulites. The formed nanoribbon spherulites fall from the eggshell membrane into the solution due to the pressure of the diffused reaction ions, the newly formed products, gravity, and thermal motion.

The hydroxyapatite nanoribbon spherulites were treated with fluorescein, $C_{20}H_{12}O_5$, which is a fluorescent molecule whose structural formula is shown in Scheme 1. The TEM images of the resulting fluorescent probe materials (Figure 10, a) indicate that they are spherical with a diameter of about 2.1 μm, which is less than that of the unmodified products. This can be explained by supposing that the close combination of fluorescein and hydroxyapatite nanoribbon spherulites, mainly through two kinds of strong effects, reduces the diameter. As the hydroxyapatite nanoribbon spherulite is a porous structure composed of interlaced nanoribbons, one of these effect is likely to be hydrogen bonding between the hydroxy groups in the hydroxyapatite spherulite and the COOH, OH, and C=O groups of fluorescein. The other is the strong surface adsorption ability of hydroxyapatite spherulites to fluorescein molecules due to its large surface area. It is these two effects that combine the fluorescein and nanoribbon spherulite tightly. The TEM images show that the nanoribbons have almost disappeared, the surface is smooth, and there is appreciable darkness in the center, as indicated by the arrow in Figure 10 (b), which suggests that, instead of just adhering to the spherulite surface, fluorescein is embedded inside the spherulites.



Scheme 1. Structure of fluorescein.

The modified products were rinsed several times with ethanol to exclude the possibility that fluorescein just clings

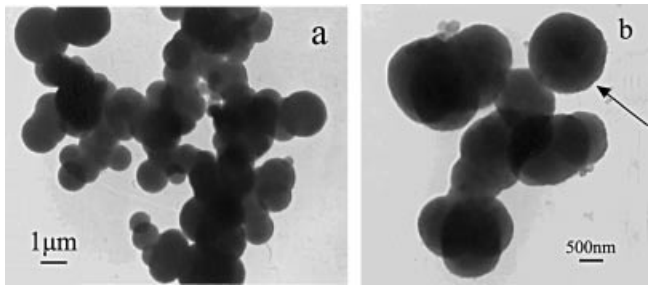


Figure 10. The TEM pattern of products modified with fluorescein.

to the surface of the fluorescent probe materials. The fluorescence spectra of unmodified and modified products indicate that nanoribbon spherulites are not photoluminescent, as shown in Figure 11 (c), whereas Figure 11 (b) shows that the luminescence of the modified products is very strong. At an excitation wavelength of 314 nm, the fluorescent probe materials emit green lighty of 514 nm (Figure 11, b), slightly different from the emission wavelength of the nanoribbon spherulites (511nm; Figure 11, a). This is because the interaction between the nanoribbons and fluorescein changes the ligand field of fluorescein and thus alters the electron distribution in the conjugated system of fluorescein molecules, which results in a change of the transition bandgaps of the electrons. Moreover, the XRD pattern of the modified product (Figure 12, a) shows that it is also a

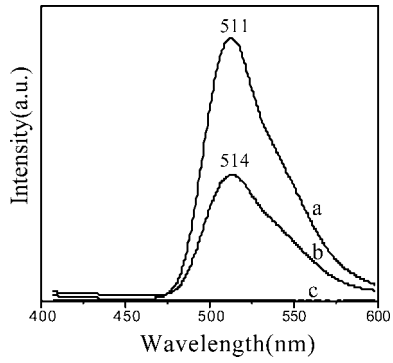

Figure 11. The fluorescence spectra of the products (a: fluorescein; b: fluorescent probe materials; c: nanoribbon spherulites. Excitation wavelength: 383 nm).

hydroxyapatite structure, which indicates that hydroxyapatite combines with the fluorescein through nonchemical bonds, such as hydrogen bonds.

Conclusion

Hydroxyapatite spherulites assembled from long nanoribbons have been synthesized in a one-step reaction at room temperature with a novel bioactive eggshell membrane as the template and in the presence of ethylenediamine. This porous spherulite can be transformed into a solid one by electron beam irradiation. It can also combine with some organic compounds through hydrogen bonding and surface adsorption effects. Based on these properties, a fluorescent probe material with hydroxyapatite nanoribbons spherulites as substrates has been successfully prepared, and it provides a novel idea for the application of assembling nanoribbon spherulites in medical, biological, and industrial fields.

Experimental Section

The eggshell membrane was taken from a fresh eggshell after removing the outer shell and washing with deionized water. It was then fastened in a container to separate it into two horizontal compartments into which 20 mL of 0.1 M $CaCl_2$ and 20 mL of 0.06 M KH_2PO_4 were added, respectively. Ethylenediamine was put in both sides of the membrane to modulate the pH value to 7.4. All reagents used were of analytical purity. Thereafter, the reaction container was kept at 37 °C for ten hours. The obtained products were separated in a centrifuge at 1500 rpm and washed with deionized water and alcohol several times, one after the other, until no Ca^{2+} and ethylenediamine could be detected. The washed products were collected and dried in a desiccator to give the final products.

A sample of the above products (0.5 g) was put in 50 mL of a 2% aqueous fluorescein solution, the system was vibrated ultrasonically for 20 min, and then separated. The precipitates were rinsed with ethanol to remove the excessive fluorescein until the ethanol solution showed no fluorescence by fluorescent spectroscopy. Then, the washed products were collected and dried in a desiccator to obtain the final modified products.

The morphologies of the products were observed by transmission electron microscopy (TEM). The crystal phase and structure of the products were determined by X-ray powder diffraction (XRD) using a Shimadzu XD-3A diffractometer with graphite-monochromated Cu-K_α radiation (50 kV, 100 mA). The optical properties of the products were studied by FT-IR spectroscopy and fluorescent spectroscopy (Perkin–Elmer LS-55).

Multiple Regulated Assembly, Crystal Structures and Magnetic Properties of Porous Coordination Polymers with Flexible Ligands

Chang-Yan Sun,[a] Xiang-Jun Zheng,[a] Song Gao,[b] Li-Cun Li,[c] and Lin-Pei Jin*[a]

Keywords: Cobalt / Coordination polymers / Magnetic properties / Nickel / Porous materials

Four novel coordination polymers of Ni^{II} and Co^{II} with flexible ligands, namely $[Ni(oba)(bpe)]_n \cdot nH_2O$ (**1**), $[Co(oba)(bpe)]_n$ (**2**), $[Ni_2(oba)_2(bpy)_2(H_2O)_2]_n \cdot n$bpy (**3**), and $[Co(oba)(bpy)_{1/2}]_n$ (**4**) [H_2oba = 4,4′-oxybis(benzoic acid), bpe = 1,2-bis(4-pyridyl)ethane, bpy = 4,4′-bipyridine] were synthesised by hydrothermal reactions and characterised by single-crystal X-ray diffraction, elemental analysis and IR spectroscopy. The Ni^{II} ions in complex **1** are linked by flexible oba and bpe ligands to form square-grid-like corrugated sheets. These sheets are interpenetrated with each other, resulting in the formation of a 3D porous network with lattice water molecules in the channels. The variable temperature X-ray diffraction analysis shows that the framework is stable up to 300 °C despite the complete removal of the lattice water molecules during the heat treatment. Complex **2** can be regarded as possessing a α-polonium-related topology. Triple interpenetration occurs to form a nonporous structure. In complex **3**, the oba and bpy ligands link Ni^{II} ions into 1D train-like boxes. These boxes are entangled, with the aid of hydrogen bonds, leading to the formation of a 3D porous supramolecular architecture. Free bpy ligands reside in the channels. The Co^{II} ions in complex **4** are linked by oba and bpy ligands to form a complicated 3D coordination polymer. The lattice water molecules in complex **1** and free bpy ligands in complex **3** can be regarded as templates that play an important role in the formation of the porous structures of complexes **1** and **3**. The magnetic properties of complexes **1**, **2**, and **4** have also been investigated.

Introduction

Porous coordination polymers are of current interest in the fields of supramolecular chemistry and crystal engineering not only because of the intriguing variety of architectures and topologies but also because of their potential applications in gas storage,[1] separation,[2] sensors[3] and catalysis.[4] The most commonly used synthetic strategy is to select appropriate ligands to bridge metal ions, with the aid of hydrogen bonds, metal–metal bonds, π-π stacking, van der Waals and electrostatic interactions, to form the desired extended network under mild conditions.[5] It is well-known that the topology of porous coordination polymers depends both on the coordination behaviour of the organic ligands and on the selection of the coordination geometry of the metal centres. Thus far, porous coordination polymers have centred on the assembly of linear rigid polycarboxylates, especially dicarboxylates,[6,7] and d-block metal ions, as these metal ions have low coordination numbers and are easily linked to form grid,[8] honeycomb,[9] brick-wall[10] and other geometries.[11] Long flexible ligands, because of their easy interpenetration, are seldom used in the construction of porous coordination polymers, although with ingenious design, interpenetrated networks can give novel topologies and useful properties.[12] More and more interest has focused on long flexible ligands recently, and how to avoid, or make use of, their interpenetration to construct porous coordination polymers is an interesting challenge. 4,4′-Oxybis(benzoic acid) (H_2oba) is the typical example of a long, V-shaped, flexible ligand. As far as we know, its coordination chemistry has been studied and several coordination polymers have been obtained.[13] Of these coordination polymers, only one complex, $[Zn_2(oba)_2(DMF)_2] \cdot 2DMF$, possesses a porous structure.[13f] In this complex, the DMF molecules act as guests, thus preventing interpenetrating. It is supposed that appropriate molecules may function as guests occupying the pores and consequently promote the formation of large pores,[14] and the introduction of ancillary ligands, such as the N-containing ligands 1,2-bis(4-pyridyl)ethane (bpe) and 4,4′-bipyridine (bpy), often has a significant effect on the formation and dimension of the resulting structures. With this idea in mind, we chose H_2oba as a bridging ligand to react with the d-block metal ions Ni^{II} and Co^{II}. The neutral ligands bpe and bpy were introduced into the M^{II}/oba system, and four novel coordination polymers, namely $[Ni(oba)(bpe)]_n \cdot nH_2O$ (**1**),

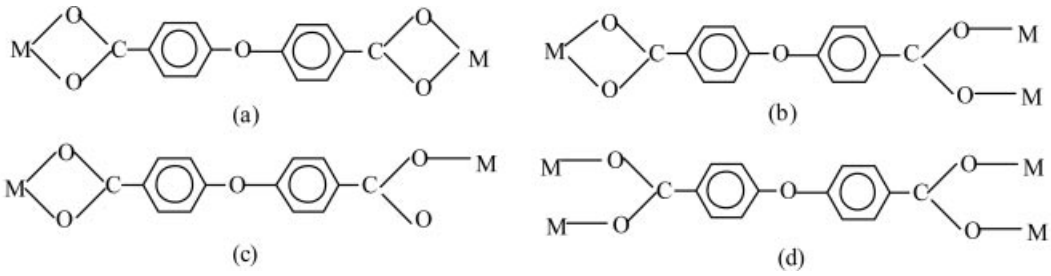

Scheme 1. The coordination modes of the oba ligands in complexes **1**–**4**.

$[Co(oba)(bpe)]_n$ (**2**), $[Ni_2(oba)_2(bpy)_2(H_2O)_2]_n \cdot n$bpy (**3**) and $[Co(oba)(bpy)_{1/2}]_n$ (**4**) were obtained. The details of their synthesis, structure and magnetic properties are reported below.

Results and Discussion

Description of the Structures

The oba ligands in complexes **1**–**4** are completely deprotonated and are significantly bent at the ether-oxygen sites [C–O–C = 115.9(3)–119.2(7)°]. They afford four kinds of coordination modes (see Scheme 1). All bpe ligands are in an *anti* conformation.

[Ni(oba)(bpe)]$_n$·nH$_2$O (1)

In the asymmetrical unit of complex **1**, there is one Ni^{II} ion, one oba ligand, one bpe ligand and one lattice water molecule. The Ni^{II} ion is located in a slightly distorted octahedral geometry and is coordinated to four oxygen atoms of two oba ligands and two nitrogen atoms of two bpe ligands, as shown in Figure 1. The average Ni–N bond length is 2.051 Å and the Ni–O bond lengths are in the range 2.010(2)–2.312(3) Å. The details are depicted in Table 1. Each oba ligand adopts a bis(chelating bidentate) mode, linking two Ni^{II} ions [see Scheme 1 (a)].

The Ni^{II} ions are linked by oba and bpe ligands into square-grid-like corrugated sheets with grid dimensions of about 13×13 Å^2 in the *bc* plane, as shown in Figure 2 (a) (based on the separation of the metal ions). It is noteworthy that all the metal ions in the layer of complex **1** are not coplanar, but are present in a stair-like fashion. These stair-like layers are interpenetrated with each other, resulting in the formation of the 3D network. Although interpenetration occurs in complex **1**, there are still channels in the 3D network [see Figure 2 (b)], and lattice water molecules are accommodated in the channels. Hydrogen bonds are formed between the lattice water molecules and the carboxylate groups {*d*[O(6)···O(2)i] = 3.005 Å (symmetry code i: *x* + 1, *y*, *z*), *d*[O(2)i···H(6B)] = 2.562 Å and *θ*[O(6)–H(6B)

···O(2)i] = 111.69°}, which enhances the stability of the open framework.

[Co(oba)(bpe)]$_n$ (2)

In complex **2**, one carboxylate group of an oba ligand adopts a chelating bidentate mode while the other adopts a bridging bidentate mode, which means that every oba ligand links three Co^{II} ions [see Scheme 1 (b)]. There is only one crystallographically unique Co^{II} centre, which is coordinated to four carboxylate oxygen atoms of three oba ligands and two nitrogen atoms of two bpe ligands (see Figure 3). The average Co–N bond length is 2.155 Å and the Co–O bond lengths are in the range 2.020(2)–2.232(2) Å. Thus, the Co^{II} centre displays a distorted octahedral geometry with one [CoO_4N_2] unit. Two such [CoO_4N_2] units are connected together by two carboxylate groups, leading to the formation of a binuclear secondary building unit (SBU) in which the Co···Co distance is 4.298 Å. The oba ligands link the SBUs into 2D layers with rhombus-shaped cavities of about 13 × 15 Å^2. Although this framework motif is common, the bent oba structure provides a new aspect in the cavity shape, and it has seldom been reported that this motif contains concertinaed corners.[15] These layers are pillared by bpe ligands with a Co–N coordination bond, resulting in the formation of a 3D net that can be regarded as possessing an α-polonium-related topology [see Figure 4 (a)]. There are large channels (13 × 15 Å^2) in the open sub-framework (named net), but triple interpenetration occurs, as shown in Figure 4 (b). The nodes of the second and third nets are located, equally spaced, along the rhombohedral diagonal of the first net, and each rhombic "window" has a rod from each of the adjacent two nets passing through it, giving a complicated nonporous structure.

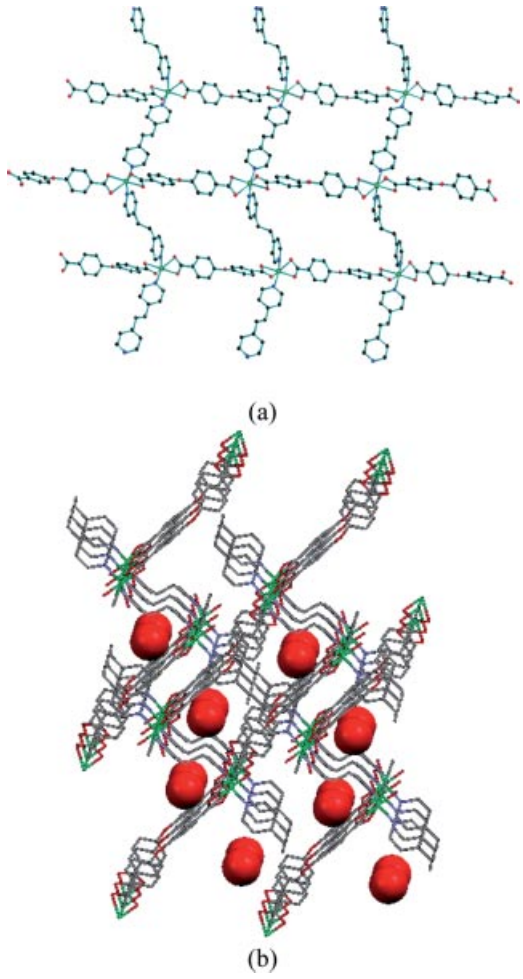

Figure 2. (a) Square-grid-like sheet of complex **1** in the *bc* plane. (b) The 3D porous network of complex **1,** with lattice water molecules in the channels, viewed along the *a* axis.

[Ni$_2$(oba)$_2$(bpy)$_2$(H$_2$O)$_2$]$_n$·nbpy (3)

There are two kinds of metal coordination environments in complex **3**, as shown in Figure 5. Ni(1) and Ni(2) are both six-coordinate and their coordination geometries can be described as distorted octahedral. Both Ni^{II} ions are coordinated to three oxygen atoms of two oba ligands, two nitrogen atoms of two bpy ligands and one oxygen atom of one water molecule. However, the corresponding bond lengths and bond angles are different. The Ni(1)–O bond lengths are in the range 1.992(4)–2.143(5) Å and the average value is 2.095 Å, while for Ni(2) the bond lengths range from 2.026(4) Å to 2.195(4) Å and the average value is 2.091 Å. The details are depicted in Table 2. In complex **3**, one carboxylate group of an oba ligand coordinates to a Ni^{II} ion in a monodentate mode while the other adopts a chelating-bidentate mode. Thus, every oba ligand links two Ni^{II} ions [see Scheme 1 (c)]. Ni(1) and Ni(2) are bridged by a bpy ligand with a distance of 11.129 Å, which can be regarded as a binuclear SBU. Such SBUs are linked together

by the oba ligands, resulting in 1D train-like boxes that contain free bpy ligands (see Figure 6). Each box is entangled with another two adjacent boxes. There are hydrogen bonds between the water molecules and the carboxylate groups {d[O(6)···O(2)] = 2.669 Å, d[O(2)···H(6A)] = 2.128 Å and θ[O(6)–H(6A)···O(2)] = 113.19°; d[O(12)···O(11)i] = 2.553 Å (symmetry code i: $x, y - 1, z$), d[O(11)i···H(12B)] = 2.027 Å and θ[O(12)–H(12B)···O(11)i] = 119.37°}, which leads to the formation of a 3D porous supramolecular architecture.

The Structure of [Co(oba)(bpy)$_{1/2}$]$_n$ (4)

The coordination environment of the Co^{II} ions in complex **4** is shown in Figure 7. The Co^{II} ion is five-coordinate, with four oxygen atoms from four oba ligands and one nitrogen atom from one bpy ligand. The coordination geometry of the Co^{II} ion can best be described as a distorted triangular bipyramid. The Co–N bond length is 2.084(3) Å and the Co–O bond lengths are in the range 1.976(3)–2.077(3) Å. Every oba ligand in complex **4** adopts a bis(bridging-bidentate) mode and links four Co^{II} ions [see Scheme 1 (d)]. The Co^{II} ions are bridged by the carboxylate groups of oba ligands into 1D chains along the c axis, in which the adjacent Co···Co distances are alternately 3.288 Å and 4.238 Å. These chains are further bridged by the bent oba ligands to produce 2D regular metal-organic layers. When viewed along the c axis, these 2D layers can be regarded as sine- and cosine-type curves intersecting at the zero points. The bpy ligands connect the Co^{II} ions in these 2D layers into a 3D structure.

Effect of the Metal Ions on the Molecular Structure

It is interesting that, although they are bound to the same ligands, Ni^{II} and Co^{II} give completely different pro-

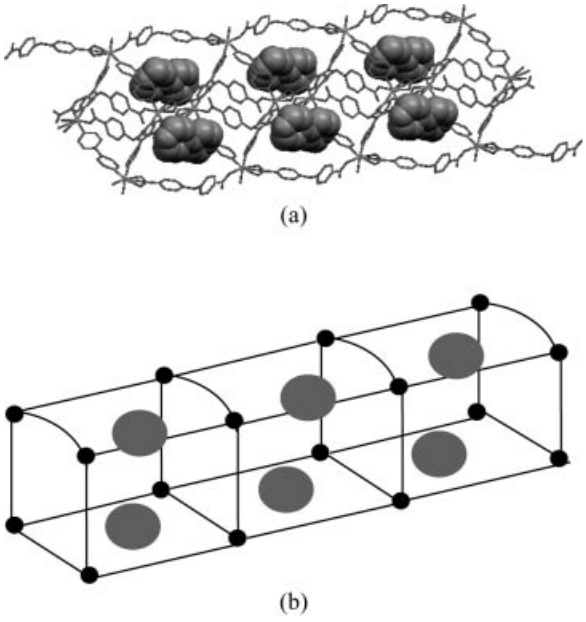

Figure 6. (a) The 1D train-like box in complex **3** (space-filling diagrams represent free bpy ligands). (b) A simplified representation of the 1D train-like box in complex **3** (nodes represent Ni^{II} ions and the balls represent free bpy ligands).

ducts, as shown in Scheme 2. We found from the structural analysis of complexes **1**–**4** that the two Ni^{II} complexes **1** and **3** possess a 3D open supramolecular architecture while the two Co^{II} complexes **2** and **4** have a 3D non-porous structure. Taking **1** and **2** as examples, the Ni^{II} and Co^{II} ions are both six-coordinate and in distorted octahedral geometries, but their coordination environments are different. In complex **1**, there are two oba ligands and two bpe ligands around each Ni^{II} ion, while in complex **2**, there are three oba ligands and two bpe ligands around each Co^{II} ion. More ligands are around each Co^{II} ion than each Ni^{II} ion. This is consistent with the fact that the radius of Co^{II} ion is larger than that of Ni^{II} ion. Furthermore, the coordination modes of the oba ligands in the two complexes are different. The oba ligands adopt a bis(chelating-bidentate) mode in complex **1** and a chelating-bridging mode in complex **2** (see parts a and b in Scheme 1), which results in the different structures of the corresponding complexes. Similar results are found for complexes **3** and **4**. This may also be attributed to the different size of the metal ions. Lower-dimensional nets are usually less likely to interpenetrate because there are more possible ways to maximize the packing efficiency.[16] So, after the stacking of 2D layers, complex **1** possesses 3D porous structure, while triple interpenetration occurs in complex **2**, as shown in Figure 6, to give a non-porous structure. A rational assembly of metal ions and flexible ligands is critical for the formation of a porous structure.

Effect of the Ligand on the Molecular Structure

Although the bpe and bpy ligands are both N-containing spacers, they are quite different. For example, bpe has *anti* and *gauche* conformations and is more flexible than bpy. When the bpe ligand is in the *anti* conformation, the distance between the two nitrogen atoms is larger than that of the bpy ligand, therefore *anti*-bpe is a longer spacer than bpy. When the bpe ligand is introduced into the M^{II}/H_2oba system, we obtain 2D square-grid-like sheets for Ni^{II} and a 3D α-polonium-related framework for Co^{II}, while with bpy we obtain 1D train-like boxes for the Ni^{II} complex and a complicated 3D framework for the Co^{II} complex. The oba ligands in the four complexes adopt four different coordination modes, as shown in Scheme 1, so for a special M^{II}/H_2oba system, the ancillary ligand has a significant effect on the formation and structure of the coordination polymers. In order to construct porous coordination polymers, it is a feasible method to introduce ancillary ligands.

Effect of Guest Molecules on the Molecular Structure

From the structural descriptions above, we know that lattice water molecules are accommodated in the channels of

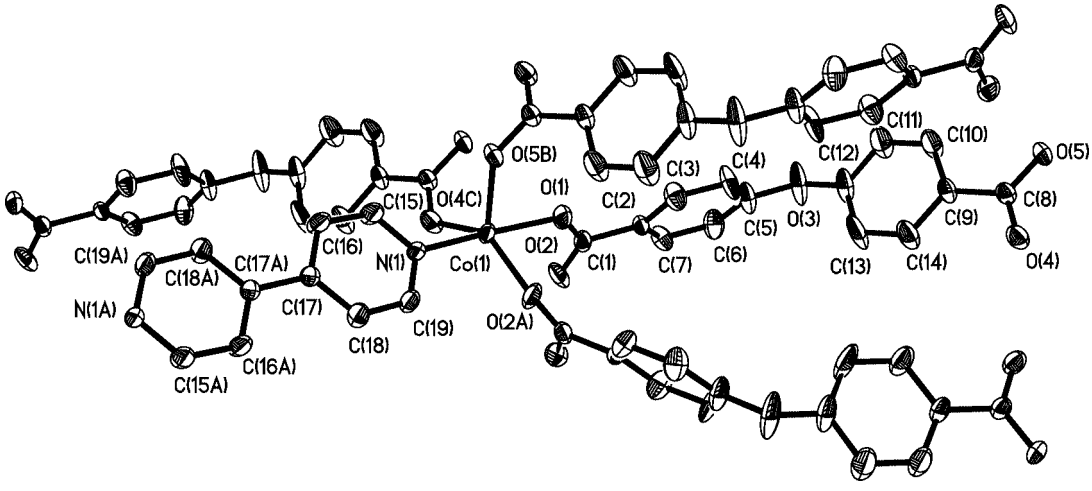

Figure 7. The coordination environment of the Co^{II} ion in complex **4** with 30% thermal ellipsoids. All hydrogen atoms have been omitted for clarity.

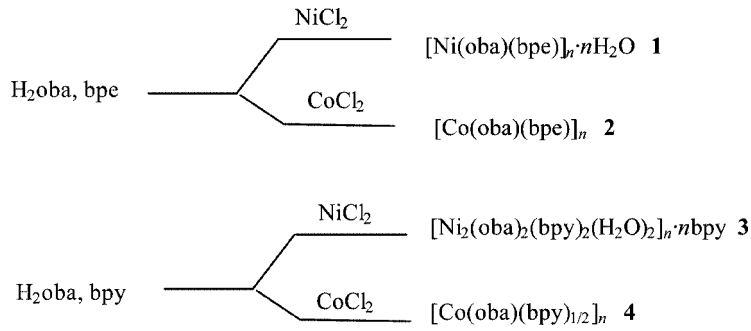

Scheme 2. Self-assembly of the coordination polymers.

complex **1** and free bpy ligands reside in the channels of complex **3**. The presence of lattice water molecules and free bpy ligands may be one of the more important factors for constructing the porous structures of complexes **1** and **3** as they occupy the pores and function as templates, thus preventing further interpenetration. This provides a valuable approach for constructing porous coordination polymers. If the potential pore walls are formed by the hydrophobic parts of ligand molecules, we can introduce hydrophobic molecules to function as guest molecules and occupy the pores through hydrophobic interactions with the ligands;[2b,14] on the other hand, if the potential pore walls are formed by the hydrophilic parts of ligand molecules, we can introduce hydrophilic molecules.[17] It can be expected that the presence of these guest molecules promotes the formation of large pores.

Thermal Stability Analysis of Complex 1

The thermal analysis of complex **1** is consistent with the crystallographic observations. The TG curve shows that the first weight loss of 3.7% from 75 °C to 290 °C corresponds to the loss of the lattice water molecules (calcd. 3.5%), leaving a framework of [Ni(oba)(bpe)]. This framework remains stable beyond 300 °C and it begins to decompose at 390 °C. This further decomposition finishes at 550 °C, leaving a powder of NiO. It is the interpenetrated nature of the structure that causes the higher thermal stability of complex **1**.

To further test the thermal stability of complex **1**, powder samples were examined by powder X-ray diffraction analysis. Corresponding to the TG analysis, powder XRD patterns were recorded at 20, 100, 300 and 450 °C (see Figure 8). It can be seen from Figure 8 that the XRD patterns at 100 °C and 300 °C are similar to that at room temperature, but not the same, indicating that the framework is able to survive. However, there are changes in the XRD patterns at 20, 100, and 300 °C, which are probably due to the contraction of the structure upon removal of the water molecules and the presence of the flexible ligands. At 450 °C, the XRD pattern changes completely, revealing the collapse of the framework, which is in accordance with the result of the thermogravimetric analysis.

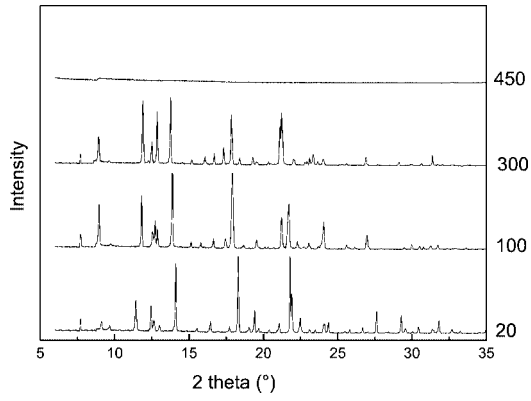

Figure 8. The powder X-ray diffraction patterns of complex **1** at different temperatures.

Magnetic Properties

Because the bridging ligands oba, bpe and bpy are quite long in complexes **1** and **3**, and thus the Ni···Ni distances are very long too, the magnetic interactions transferred by these ligands should be very weak. The magnetic properties of complexes **1** and **3** can be regarded as those of a single metal ion anisotropy. Here, we only give the magnetic property of complex **1** as an example.

Complex 1

The magnetic properties of complex **1** in the form of χ_M and μ_{eff} vs. T plots (χ_M is the molar magnetic susceptibility and μ_{eff} is the effective magnetic moment) are shown in Figure 9. Data were collected in the range 2–300 K in a magnetic field of 5 kOe. The μ_{eff} value for complex **1** is 3.15 μ_B at 300 K and it is practically constant in the temperature range analysed. It only starts to decrease at around 10 K, reaching a minimum value of 2.83 μ_B at 2 K, which should be mainly attributed to the zero-field splitting of Ni^{II} ions.

The experimental susceptibility data were fitted to the equation that considers only non-interacting $S = 1$ ions in the presence of a single ion anisotropy. The magnetic susceptibility is given in Equation (1).[18]

$$\chi_M = \frac{2Ng^2\beta^2}{3kT} \times \frac{2x^{-1} - 2\exp(-x)x^{-1} + \exp(-x)}{1 + 2\exp(-x)} \quad (1)$$

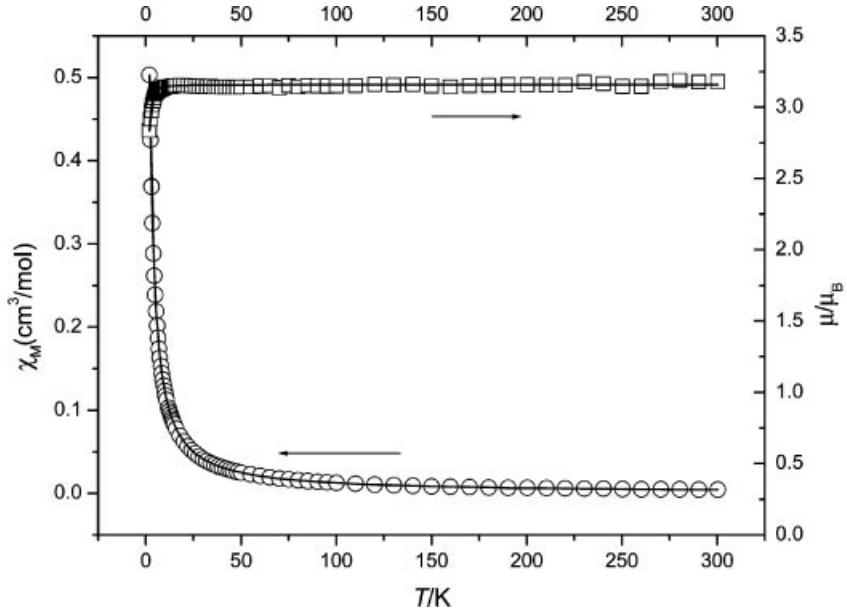

Figure 9. Plots of χ_M (○) and μ_{eff} (□) vs. T for complex **1**; the solid lines are theoretical fits based on Equation (1).

where $x = D/kT$. The best fit is given by the parameters $g = 2.23$, $D = 2.62\ cm^{-1}$, with an agreement factor, R, of 2.03×10^{-4} $\{R = \Sigma[(\chi_M)_{obs} - (\chi_M)_{calc}]^2/\Sigma[(\chi_M)_{calc}]^2\}$.

Complex 2

The magnetic susceptibility data of complex **2** in the form of $1/\chi_M$ and μ_{eff} vs. T plots are given in Figure 10. They were measured in the range 2–300 K in a magnetic field of 1 kOe. It can be seen that the μ_{eff} value decreases very gradually upon cooling and the μ_{eff} value at 300 K is 4.25 μ_B, which is larger than that expected for the spin-only case of Co^{II} (μ_{eff} = 3.87 μ_B), indicating an unquenched orbital contribution. The magnetic data above 30 K can be fitted to the Curie–Weiss law with $C = 2.268(5)\ cm^3\,mol^{-1}\,K$ and $\theta = -1.8$ K. The C value corresponds to $g = 2.20$ with $S = 3/2$. These results suggest a possible very weak antiferromagnetic coupling.

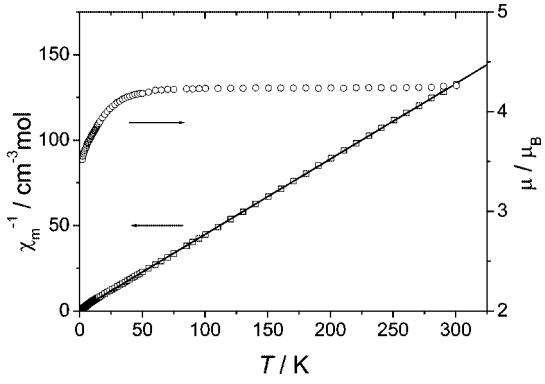

Figure 10. Plots of $1/\chi_M$ (□) and μ_{eff} (○) vs. T for complex **2**; the solid line is the theoretical fit based on the Curie–Weiss law.

Complex 4

Figure 11 shows the magnetic properties of complex **4** in the form of $1/\chi_M$ and μ_{eff} vs. T plots in the range 2–300 K measured at 1 kOe. It can be seen that the μ_{eff} value decreases very gradually upon cooling and the μ_{eff} value at 300 K is 4.71 μ_B, which is obviously larger than the expected spin-only value of 3.87 μ_B for a Co^{II} ion with S = 3/2, thus showing an unquenched orbital contribution. The magnetic data above 50 K can be fitted to the Curie–Weiss law with $C = 2.836(6)\ cm^3\,mol^{-1}\,K$ and $\theta = -7.3(1)$ K. The C value corresponds to $g = 2.46$ with $S = 3/2$. These results suggest a weak antiferromagnetic interaction.

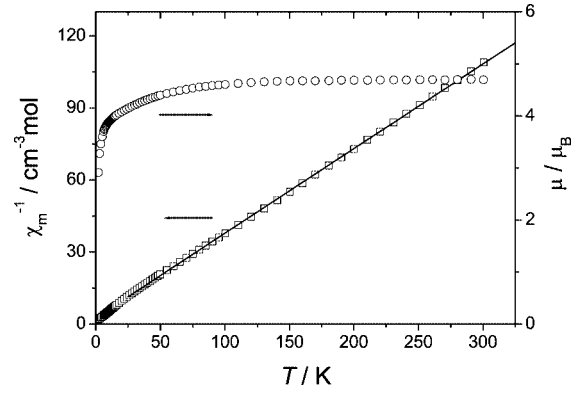

Figure 11. Plots of $1/\chi_m$ (□) and μ_{eff} (○) vs. T for complex **4**; the solid line is the best fit based on the Curie–Weiss law.

Conclusions

We have successfully obtained four novel coordination polymers of Ni^{II} and Co^{II}, namely $[Ni(oba)(bpe)]_n \cdot nH_2O$

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(**1**), $[Co(oba)(bpe)]_n$ (**2**), $[Ni_2(oba)_2(bpy)_2(H_2O)_2]_n \cdot n$bpy (**3**) and $[Co(oba)(bpy)_{1/2}]_n$ (**4**), with different dimensionalities. Comparing the structures of complexes **1** and **2**, and complexes **3** and **4**, it has been found that the different size of the metal ions has a significant effect on the formation and dimensions of the resulting structures. Furthermore, comparing the structures of complexes **1** and **3**, and complexes **2** and **4**, we can see that the neutral ancillary ligand is very important for the formation of coordination polymers. The presence of guest molecules can promote the formation of larger pores.

Experimental Section

General Remarks: All reagents were used as received without further purification. The C, H and N microanalyses were carried out with a Vario EL elemental analyzer. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. Thermogravimetric curves were measured on a Perkin–Elmer TGA-7 (USA) at a heating rate of 5 °C min^{-1} from room temperature to 600 °C under nitrogen. The magnetic susceptibilities were obtained on crystalline samples using a Quantum Design MPMS SQUID magnetometer. The experimental susceptibilities were corrected for the sample holder and the diamagnetism contributions estimated from Pascal's constants. The powder X-ray diffraction patterns were recorded on a Bruker AXS D8 ADVANCE diffractometer.

Synthesis of $[Ni(oba)(bpe)]_n \cdot nH_2O$ (1): A mixture of H_2oba (0.1 mmol), $NiCl_2 \cdot 6H_2O$ (0.1 mmol), bpe (0.1 mmol) and 5 mL of deionised water was placed in a Teflon-lined stainless vessel (25 mL) and 0.2 mL of a 0.65 M aqueous NaOH solution was added whilst stirring. The vessel was then sealed and heated to 180 °C for 72 h under autogenous pressure, and then cooled slowly to room temperature. Single crystals were obtained by filtration, washed with deionized water and ethanol, and dried in air. Yield: 0.042 g (81.2%) $C_{26}H_{22}NiN_2O_6$ (517.17): calcd. C 60.33, H 4.25, N 5.41; found C 60.44, H 3.91, N 5.53. IR data (KBr pellet): $\tilde{\nu}$ = 3449 cm^{-1} (m), 3063 (w), 2929 (w), 1616 (m), 1596 (s), 1534 (m), 1504 (m), 1417 (s), 1226 (m), 1165 (m), 1098 (w), 1071 (w), 1025 (w), 876 (m), 835 (w), 781 (m), 662 (w), 548 (w).

Synthesis of $[Co(oba)(bpe)]_n$ (2): The synthesis of complex **2** followed the same procedure as complex **1** except that the volume of aqueous NaOH solution added was 0.3 mL. Yield: 0.04 g (80.1%) $C_{26}H_{20}CoN_2O_5$ (499.37): calcd. C 62.48, H 4.00, N 5.61; found C 62.70, H 4.13, N. 5.50. IR data (KBr pellet): $\tilde{\nu}$ = 3445 cm^{-1} (m), 3058 (w), 2971 (w), 2928 (w), 1616 (m), 1596 (s), 1538 (m), 1503 (m), 1417 (s), 1227 (s), 1163 (m), 1094 (w), 1049 (w), 1025 (w), 875 (m), 836 (w), 781 (m), 662 (w), 546 (w).

Synthesis of $[Ni_2(oba)_2(bpy)_2(H_2O)_2]_n \cdot n$bpy (3): A mixture of H_2oba (0.1 mmol), $NiCl_2 \cdot 6H_2O$ (0.1 mmol), bpy (0.1 mmol) and 5 mL of deionised water was placed in a Teflon-lined stainless vessel (25 ml) and 0.2 mL of a 0.65 M aqueous NaOH solution was added whilst stirring. The vessel was then sealed and heated to 180 °C for 72 h under autogenous pressure, and then cooled slowly to room temperature. Single crystals were obtained by filtration, washed with deionized water and ethanol, and dried in air. Yield: 0.024 g (42.3%). $C_{58}H_{44}N_6Ni_2O_{12}$ (1134.4): calcd. C 61.35, H 3.88, N 7.40; found C 61.20, H 3.74, N 7.04. IR data (KBr pellet): $\tilde{\nu}$ = 3444 cm^{-1} (m), 1595 (s), 1540 (m), 1496 (w), 1420 (s), 1381 (s), 1300 (w), 1248 (m), 1232 (m), 1158 (w), 875 (w), 808 (w), 784 (w), 659 (w), 635 (w).

Synthesis of $[Co(oba)(bpy)_{1/2}]_n$ (4): The synthesis of complex **4** was similar to that of complex **3**. Yield: 0.027 g (68.7%) $C_{19}H_{12}CoNO_5$ (393.23): calcd. C 57.98, H 3.05, N 3.56; found C 57.95, H 3.03, N 4.01. IR data (KBr pellet): $\tilde{\nu}$ = 3436 cm^{-1} (w), 3063 (w), 2924 (w), 1594 (s), 1551 (m), 1499 (m), 1393(s), 1299 (w), 1240 (s), 1221 (m), 1159 (m), 1013 (w), 877 (m), 779 (m), 675 (w), 565 (w), 514 (w).

X-ray Crystallographic Study: Diffraction intensities for the four complexes were collected at 293 K on a Bruker SMART 1000 CCD diffractometer employing graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). A semi-empirical absorption correction was applied using the SADABS program.[19] The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXS 97 and SHELXL 97 programs, respectively.[20,21] Non-hydrogen atoms were refined anisotropically and hydrogen atoms were placed in geometrically calculated positions. The crystallographic data for complexes **1**–**4** are listed in Table 3, and selected bond lengths and angles are listed in Tables 1 and 2. CCDC-265220–265223 (for **1**–**4**, respectively) contain the supplementary crystallographic data for this paper. These data can be

Keywords: Cadmium / IR spectroscopy / Mercury / N,S ligands / Zinc

The pyrimidinethiolate complexes $^{3}_{\infty}$[Zn(S-2-$N_2C_4H_3$)$_2$], $^{2}_{\infty}$[Cd(S-2-$N_2C_4H_3$)$_2$] and [Hg(S-2-$N_2C_4H_3$)$_2$] have been prepared by reaction of MCl_2 (M = Zn, Cd, Hg) with 2 equiv. of Me_3SiS-2-$N_2C_4H_3$ in organic solvents, whilst [Cd(S-2-$N_2C_4H_3$)$_2$(tmeda)] was obtained by recrystallisation of $^{2}_{\infty}$[Cd(S-2-$N_2C_4H_3$)$_2$] in TMEDA at 40 °C. The structures of the complexes were determined by single-crystal X-ray crystallography, which shows that the different metal atoms each have different coordination environments. The zinc atom in $^{3}_{\infty}$[Zn(S-2-$N_2C_4H_3$)$_2$] exhibits a tetrahedral coordination with one sulfur and three nitrogen atoms from pyrimidinethiolate ligands, whereas the cadmium atoms in $^{2}_{\infty}$[Cd(S-2-$N_2C_4H_3$)$_2$] and [Cd(S-2-$N_2C_4H_3$)$_2$(tmeda)] are six-coordinate with either three sulfur and three nitrogen atoms or two sulfur and four nitrogen atoms. In contrast, the mercury atoms in [Hg(S-2-$N_2C_4H_3$)$_2$] display a distorted square-planar coordination to a pair of chelating $^{-}$S-2-$N_2C_4H_3$ ligands with additional weak Hg–S interactions to adjacent molecules. While known cadmium and zinc pyrimidinethiolate complexes consist of one-dimensional chains, $^{3}_{\infty}$[Zn(S-2-$N_2C_4H_3$)$_2$] and $^{2}_{\infty}$[Cd(S-2-$N_2C_4H_3$)$_2$] form either three- or two-dimensional polymeric networks of metal atoms.

Introduction

There has been considerable interest in the past in the synthesis and coordination properties of chalcogenolates, comprising an amine-based heterocyclic ring, towards group 12 transition metal elements. Heterocyclic thiols, like pyridinethiol or pyrimidinethiol, are some of the most versatile sulfur donor ligands as they can act as monodentate or chelating ligands in the neutral form or as monodentate, chelating and bridging ligands between two or three metal atoms when anionic to yield oligo- or polymeric species.[1,2] Several factors determine the degree of aggregation. [Cd(S-2-NC_5H_4)$_2$][3] and [Zn{S-4,6(CH_3)$_2$-2-N_2C_4H}$_2$],[4] for example, are polymeric, while the additional presence of pyridine in the case of the zinc complex leads to the isolation of the monomeric species [Zn{S-4,6(CH_3)$_2$-2-N_2C_4H}$_2$(NC_5H_5)].[5] Additional bonding of bulky groups near the donor atoms in cadmium complexes leads to a reduction of aggregation, as can be seen in [Cd{S-4,6(CH_3)$_2$-2-N_2C_4H}$_2$]$_6$,[6] which is hexanuclear, and the dimeric [Cd{S-3(CH_3)$_3$Si–NC_5H_4}$_2$]$_2$,[7] which contains the more bulky trimethylsilyl substituent close to the sulfur donor atom. However, [Cd(S-4-CH_3-6-CF_3-2-N_2C_4H)$_2$] is also found to consist of polymeric chains containing octahedrally *cis*-coordinated cadmium atoms.[8] Further influence on the aggregation behaviour also arises from the coordination chemistry of the different metal ions, with mercury preferring lower coordination numbers, as, for example, in [Hg(C_5H_4NS)$_2$][9] and [Hg{S-4,6-(CH_3)$_2$-2-N_2C_4H}$_2$].[10] As well as their rich structural chemistry, additional interest in these ligands also arises from their relationship to pyridine and pyrimidine bases and their nucleosides and nucleotides, which have important roles in living systems, with zinc being bonded to several enzymes and proteins, as well as the search for new antidotes to mercury poisoning.[10] Finally, their also exists a materials aspect to this chemistry as related complexes of cadmium with the general formula [Cd(E-2-NC_5H_6)$_2$]$_n$ (E = S,[11] Se[12]) have been found to be volatile CVD precursors for 12/16 semiconductors.

As a result of our general interest in structural studies of group 12 metal chalcogenide complexes,[13–17] we started studies on the ligand $^{-}$S-4-$N_2C_4H_3$, which has been reported to yield [M(S-2-$N_2C_4H_3$)$_2$] (M = Zn, Cd) in an electrochemical synthesis.[18] However, crystal structures have not been reported to date. Herein, the structures of [M(S-2-$N_2C_4H_3$)$_2$]$_n$ (M = Zn, Cd, Hg) are reported and the complexes synthesised by an organometallic approach.

Results and Discussion

The pyrimidinethiolate complexes $^{3}_{\infty}$[Zn(S-2-$N_2C_4H_3$)$_2$] (**1**), $^{2}_{\infty}$[Cd(S-2-$N_2C_4H_3$)$_2$] (**2**) and [Hg(S-2-$N_2C_4H_3$)$_2$] (**3**)

were prepared as crystalline precipitates by reaction of anhydrous MCl_2 (M = Zn, Cd, Hg) with 2 equiv. of $(CH_3)_3$-SiS-2-$N_2C_4H_3$ in organic solvents according to Scheme 1. Recrystallisation of **2** from TMEDA at room temperature yielded [Cd(S-2-$N_2C_4H_3)_2$(tmeda)] (**4**) nearly quantitatively along with some remaining **2**. Completion of this reaction was achieved by storing the suspension at 40 °C in a dry oven for one week.

Scheme 1.

Complex **1** crystallises in the orthorhombic space group $Pna2_1$. The zinc atoms in **1** are bridged in three dimensions by pyrimidinethiolate ligands to form an infinite network (Figure 1b). A view of a mononuclear fragment is given in Figure 1a, which shows a distorted tetrahedral coordination environment around the zinc atom formed by three nitrogen atoms [N(1), N(3) and N(4)] and one sulfur atom [S(1)]. These atoms belong to two differently coordinating $^-$S-2-$N_2C_4H_3$ ligands in either coordination mode **D** or **E** (Scheme 2). One of them, formed by C(1)–C(4), N(1), N(2) and S(1), bridges a neighbouring zinc atom through the sulfur atom and one nitrogen atom of the ligand, while the additional nitrogen atom N(2) is not involved in further coordination. The other pyrimidinethiolate ligand, consisting of C(5)–C(8), N(3), N(4) and S(2), bridges two adjacent zinc atoms through two of its nitrogen atoms [N(3) and N(4)] whilst the sulfur atom S(2) remains uncoordinated. Neither bridging mode has been observed before in related zinc and cadmium pyrimidinethiolate complexes, which usually comprise a bidentate chelating coordination mode of the ligands towards the metal atoms through a sulfur and a nitrogen atom, as found in [Zn{S-4,6$(CH_3)_2$-2-N_2C_4H}$_2$][4] or [Zn{S-4,6$(CH_3)_2$-2-N_2C_4H}$_2$$(NC_5H_5)$].[5] However, the Zn–N (205.3–209.8 pm) and Zn–S (234.4 pm) bond lengths in **1** are comparable to the related distances observed in theses complexes. The three-dimensional network in **1** is formed by helical chains of alternating zinc atoms and pyrimidinethiolate ligands in bridging mode **D** arranged along the crystallographic *c*-axis (2_1 symmetry) which are themselves further crosslinked through $^-$S-2-$N_2C_4H_3$ ligands in the coordination mode **E** (Figure 1b). This differs from known structures formed by pyrimidine- and pyridinethiolates with group 12 transition elements, such as [Cd(S-2-$NC_5H_4)_2$],[3] [Zn{S-4,6$(CH_3)_2$-2-N_2C_4H}$_2$],[4] [Cd(S-4-CH_3-6-CF_3-2-$N_2C_4H)_2$][8] and [$Hg(C_5H_4NS)_2$],[9] which all consist of chain structures.

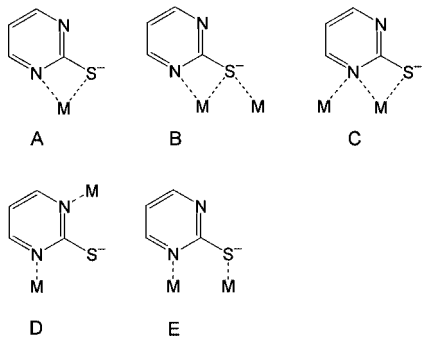

Scheme 2. Schematic drawing of the coordination modes of the pyrimidinethiolate ligand ($^{-}$S-2-$N_2C_4H_3$) found in **1**–**4**.

three sulfur [S(1), S(2) and S(2′)] and three nitrogen atoms [N(1)–N(3)]. Two pairs of sulfur and nitrogen atoms [S(2′), N(3) and S(1), N(1)] belong to two $^{-}$S-2-$N_2C_4H_3$ ligands that chelate the cadmium atom with bite angles of 59° and 61.6(1)° for N(3)–Cd(1)–S(2′) and N(1)–Cd(1)–S(1), respectively. These values are comparable to those found in the monomeric complex [Cd(S-2-$N_2C_4H_3)_2$(phen)].[18] However, further coordination of each of the pyrimidine-2-thiolate ligands is different, with one of the ligands coordinating additionally through the sulfur atom [S(2′)] to a neighbouring cadmium atom [Cd(1′)] to form an asymmetric μ_2-S-2-$N_2C_4H_3$ bridge and the other additionally binding through the free nitrogen atom [N(2′′)] to another neighbouring cadmium atom [Cd(1′′)]. Whilst the Cd–S bond of the pure chelating μ_2-S-2-$N_2C_4H_3$ ligand [Cd(1)–S(1): 261.2(2)] is comparable to that found in the monomeric complex [Cd(S-2-$N_2C_4H_3)_2$(phen)], the Cd–S bonds of the other pyrimidine-2-thiolate ligand, which acts as both a bidentate and a μ_2-bridging ligand, exhibit one shorter [Cd(1)–S(2): 260.3(2) pm] and one longer distance [Cd(1)–S(2′) 292.6(2) pm]. This effect of a weakening of the Cd–S chelating bond upon formation of additional μ_2-bridges has also been observed to a different extent in other complexes that contain heterocyclic thiolates as ligands, such as [Cd(S-2-$NC_5H_4)_2$],[3] [Cd{S-4,6-$(CH_3)_2$-2-N_2C_4H}$_2$]$_6$,[6] [Cd{S-3-$(CH_3)_3SiNC_5H_4$}$_2$]$_2$[7] and [Cd(S-4-CH_3-6-CF_3-2-$N_2C_4H)_2$].[8] The Cd–N bond lengths, which range from 233.3(5) to 248.0(6) pm, are also comparable to those found for the six-coordinate cadmium complexes mentioned above. In the crystal structure (Figure 2b), each cadmium atom is therefore linked to a total of three other cadmium atoms. One connection consists of two μ_2-S-2-$N_2C_4H_3$ bridges, each of which additionally chelates one of the two cadmium atoms, and the other two linkages are each formed by a single $^{-}$S-2-$N_2C_4H_3$ ligand in two inverted coordination forms. In one case the ligand chelates the central cadmium atom and acts as a monodentate ligand through the other nitrogen atom towards the neighbouring metal atom and in the other case the other way round. In this way **2** forms a distorted two-dimensional honeycomb network in the 011 plane which is in contrast to related structures in the literature which consist of one-dimensional polymeric structures.

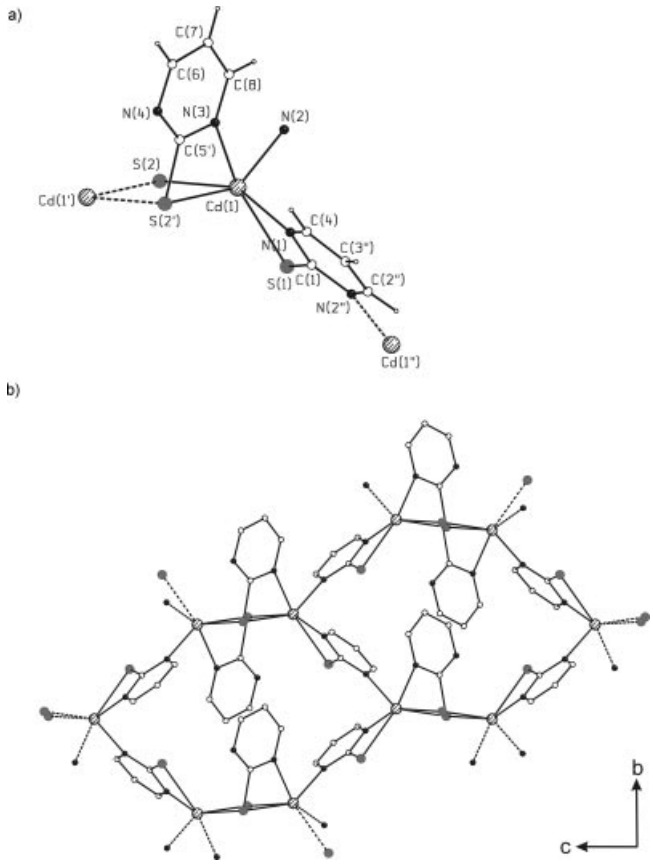

Figure 2. a) View of the coordination sphere of the cadmium atoms in [Cd(S-2-$N_2C_4H_3)_2$] (**2**). b) Section of the two-dimensional polymeric network in **2** viewed along *a*. Symmetry transformation for generation of equivalent atoms ^{I}: $-x$, $-y$, $-z + 1$; ^{II}: $-x$, $y + 1/2$, $-z + 3/2$; ^{III}: $-x$, $y - 1/2$, $-z + 3/2$. Selected bond lengths [pm] and angles [°]: Cd(1)–N(1) 248.0(6), Cd(1)–N(2) 240.2(5), Cd(1)–N(3) 233.3(5), Cd(1)–S(1) 261.2(2), Cd(1)–S(2) 260.3(2), Cd(1)–S(2′ 292.7(2); N(3)–Cd(1)–N(2) 90.4(2), N(3)–Cd(1)–N(1) 95.3(2), N(2)–Cd(1)–N(1) 113.3(2), N(3)–Cd(1)–S(2) 96.5(2), N(2)–Cd(1)–S(2) 91.9(1), N(1)–Cd(1)–S(2) 152.1(1), N(3)–Cd(1)–S(1) 156.5(1), N(2)–Cd(1)–S(1) 95.0(1), N(1)–Cd(1)–S(1) 61.6(1), S(2)–Cd(1)–S(1) 106.1(1), N(3)–Cd(1)–S(2)′ 59.0(1), N(2)–Cd(1)–S(2)′ 148.5(1), N(1)–Cd(1)–S(2)′ 79.4(1), S(2)–Cd(1)–S(2)′ 85.3(1), S(1)–Cd(1)–S(2)′ 115.9(1).

Complex **3** crystallises in the monoclinic space group $P2_1/n$ with two independent molecules **3a** and **3b**, which differ slightly in their geometry, in the asymmetric unit (Figure 3). In both molecules the mercury atoms are four-coordinate and are chelated by two $^{-}$S-2-$N_2C_4H_3$ ligands in a bidentate fashion through the sulfur atom and one nitrogen atom, with S–Hg–N bite angles ranging from 59.65° to 61.35° (coordination mode **A** in Scheme 2). Molecule **3a** [Hg(2), S(3), S(4), N(5)–N(8), C(9)–C(16)] (Figure 3a) exhibits an almost square-planar coordination of the mercury atom with a maximum deviation of 0.151(4) pm for S(4) from the molecular plane and a torsion angle along C(9)–S(3)–S(4)–C(13) of 176.9°. In molecule **3b** [Hg(1), S(1), S(2), N(1)–N(4), C(1)–C(8); (Figure 3b)], the pyrimidinethiolate ligands are twisted from this plane to give a torsion angle of 151.9° along C(1)–S(1)–S(2)–C(5). Mean Hg–S bond lengths of around 235.4 pm as well as mean Hg–N separa-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tions around 287.9 pm are comparable to those found in similar compounds like $[Hg(C_5H_4NS)_2]$[9] and $[Hg\{S\text{-}4,6\text{-}(CH_3)_2\text{-}2\text{-}N_2C_4H\}_2]$.[10] Additional weaker Hg–S separations with a mean value of 329.9 pm lead to the formation of one-dimensional chains for both forms of **3a** and **3b** (shown only for **3b** in Figure 3b). While the mercury thiopyridine structure also contains mercury(II) ions in a square-planar environment with a similar chain structure, the pyrimidinethiolate derivative exhibits five-coordinate metal atoms, which leads in the crystal structure to the formation of a helix-like polymer chain of the molecular units.

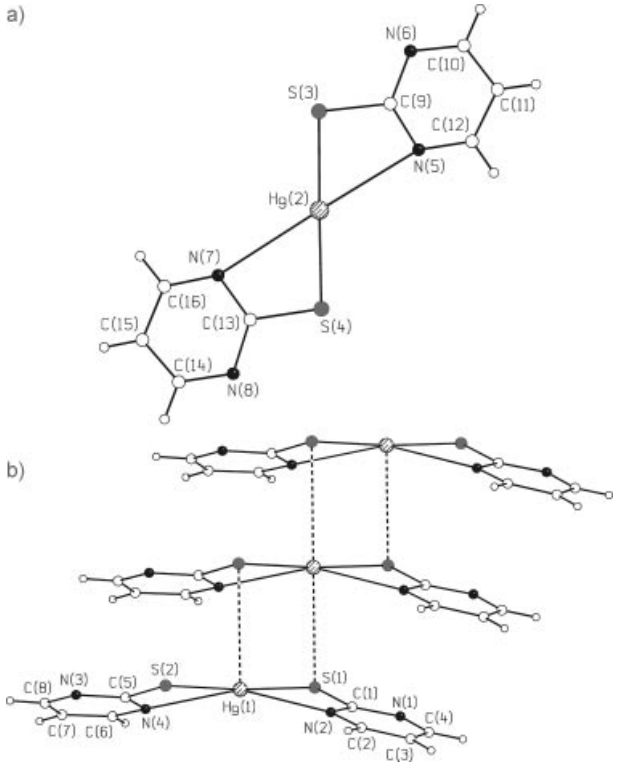

Figure 3. Molecular structures of the two independent molecules in $[Hg(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**3a**/**3b**) with a drawing of the chain structure formed by weak intermolecular Hg–S interactions (dotted lines). Selected bond lengths [pm] and angles [°]: Hg(1)–S(2) 235.0(2), Hg(1)–S(1) 236.0(2), Hg(1)–N(4) 290.7(7), Hg(1)–N(2) 281.5(6), Hg(2)–S(4) 234.9(2), Hg(2)–S(3) 235.5(2), Hg(2)–N(5) 286.0(6), Hg(2)–N(7) 293.5(6); S(2)–Hg(1)–S(1) 176.06(7), S(1)–Hg(1)–N(2) 61.4(1), S(2)–Hg(1)–N(4) 60.1(1), N(4)–Hg(1)–N(2) 157.1(1), S(4)–Hg(2)–S(3) 178.7(1), S(4)–Hg(2)–N(7) 59.7(1), S(3)–Hg(2)–N(5) 60.8(1), N(5)–Hg(2)–N(7) 177.3(1). Weak intermolecular Hg–S interactions [pm]: Hg(1)···S(1) 322.9, Hg(1)···S(2) 338.8, Hg(2)···S(3) 331.1, Hg(2)···S(4) 326.7.

Monomeric **4** crystallises in the monoclinic space group $P2_1/n$ (Figure 4) and exhibits a highly distorted octahedral coordination around the cadmium atom. The coordination sphere involves two nitrogen atoms [N(5) and N(6)] from the bidentate TMEDA ligand, and one sulfur atom [S(1) and S(2)] and one nitrogen atom [N(1) and N(3)] belonging to each of two pyrimidine-2-thiolate ligands. The bond lengths and bite angles of the three bidentate ligands are similar to those found in $[Cd(S\text{-}2\text{-}N_2C_4H_3)_2(phen)]$[18] and **2** as discussed above.

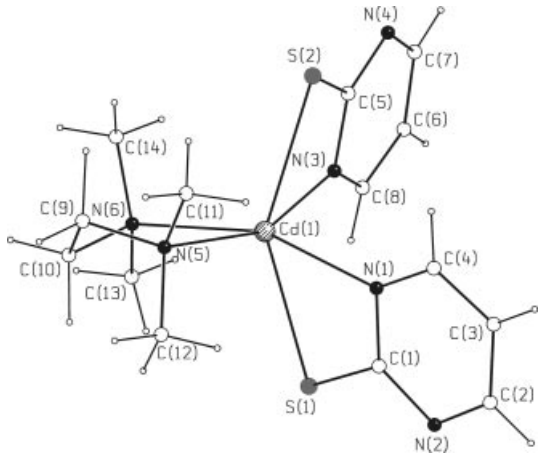

Figure 4. Molecular structure of $[Cd(S\text{-}2\text{-}N_2C_4H_3)_2(tmeda)]$ (**4**). Selected bond lengths [pm] and angles [°]: Cd(1)–N(6) 240.0(2), Cd(1)–N(5) 240.4(2), Cd(1)–N(1) 244.0(2), Cd(1)–N(3) 245.1(2), Cd(1)–S(1) 260.7(1), Cd(1)–S(2) 260.9(1); N(6)–Cd(1)–N(5) 76.1(1), N(6)–Cd(1)–N(1) 158.6(1), N(5)–Cd(1)–N(1) 91.5(1), N(6)–Cd(1)–N(3) 90.4(1), N(5)–Cd(1)–N(3) 158.9(1), N(1)–Cd(1)–N(3) 106.0(1), N(6)–Cd(1)–S(1) 102.3(1), N(5)–Cd(1)–S(1) 101.3(1), N(1)–Cd(1)–S(1) 62.7(1), N(3)–Cd(1)–S(1) 97.4(1), N(6)–Cd(1)–S(2) 103.7(1), N(5)–Cd(1)–S(2) 104.7(1), N(1)–Cd(1)–S(2) 96.2(1), N(3)–Cd(1)–S(2) 62.3(1), S(1)–Cd(1)–S(2) 146.8(1).

A comparison of the powder diffraction patterns of the crystalline precipitates of **1**–**4** with the calculated pattern of the crystals investigated by single-crystal X-ray analysis displays a good agreement, which proves, together with the elemental analysis, the purity of the compounds (Figure 5). Small deviations in intensity and reflection position at higher angles might be due to the fact that the powder measurements were done at room temperature in contrast to 190 K for the single-crystal measurement, and that needle-like crystals (e.g. **3**) preferably align in the capillary vertical to the beam.

The IR spectra of **1**–**3** (Figure 6) differ from that of the neutral thiol $HS\text{-}2\text{-}N_2C_4H_3$, in agreement with coordination of the monoanion $^-S\text{-}2\text{-}N_2C_4H_3$ to the metal atoms. Additionally, there are differences between the spectra of **1**–**3** due to the different coordination modes of the pyrimidinethiolate ligand towards the metal atoms. As IR data for complexes of monoanionic pyridine- and pyrimidinethiolate ligands are rare and have not been assigned in full detail, the discussion mostly refers to the spectra of the neutral thiol $HS\text{-}2\text{-}N_2C_4H_3$[19,20] and a study of several metal complexes of pyridinethiol.[21] In solution, pyrimidines and pyridines that are substituted at the 2- or 4-position by thiol groups can exist in two tautomeric forms **I** (thiol) and **II** (thione; Scheme 3).[22] In the solid state, 2-mercaptopyridine and 4-mercaptopyridine have been found to exist as H-bonded dimers of the thione form.[23,24] Similarly, it might be assumed that 2-mercaptopyrimidine also exists in the solid state as an H-bonded dimer, displayed in Scheme 3 as form **III**. Evidence for this in the IR spectrum of $HS\text{-}2\text{-}N_2C_4H_3$ is a broad band around 2633 cm^{-1}, which can be assigned to the stretching of the N–H bonds being strongly hydrogen-bonded in the solid state, and the three bands

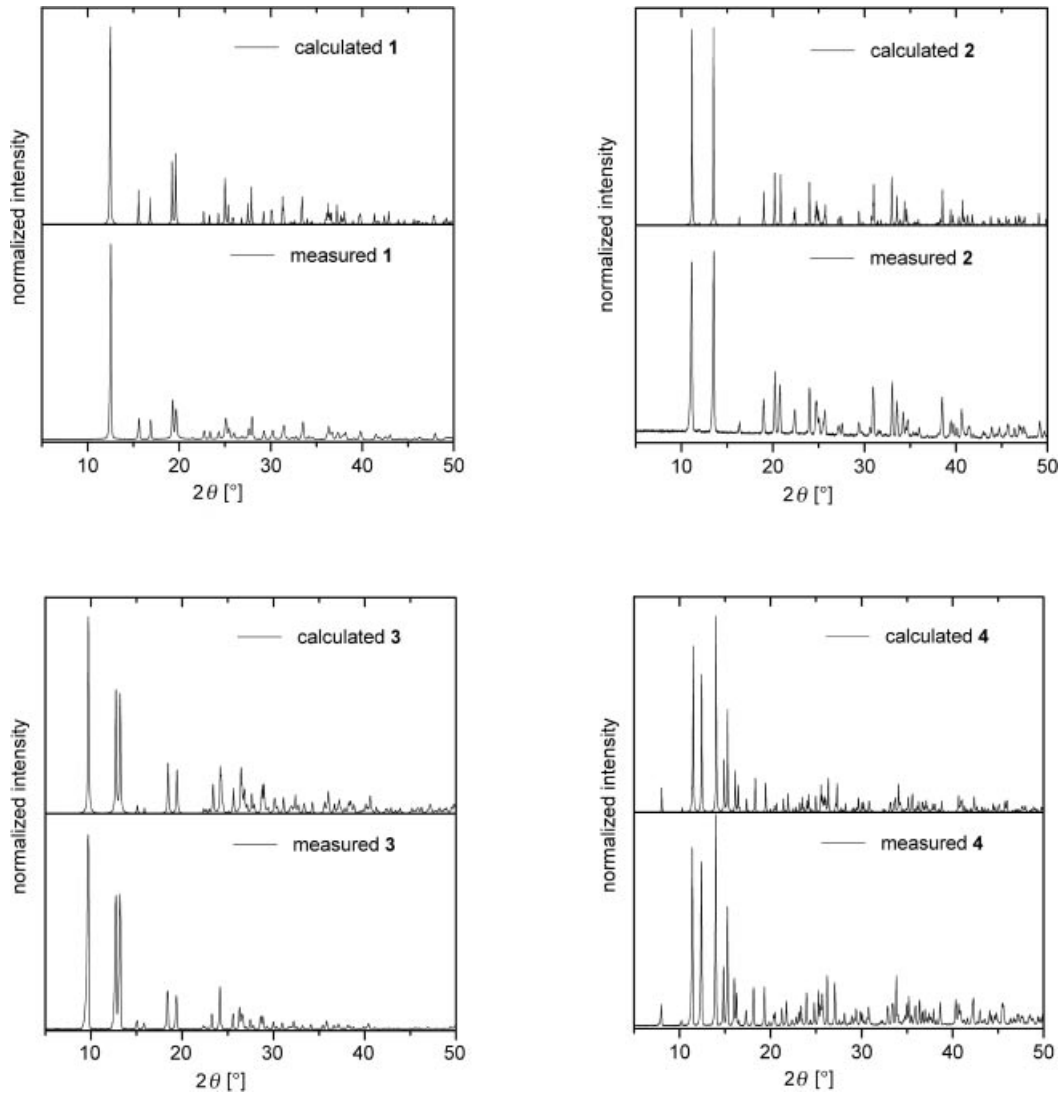

Figure 5. Calculated (top) and measured (bottom) powder XRD pattern of $[Zn(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**1**), $[Cd(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**2**), $[Hg(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**3**) and $[Cd(S\text{-}2\text{-}N_2C_4H_3)_2(tmeda)]$ (**4**).

near 2000 cm^{-1}, which can be assigned as a result of Fermi resonances and overtones of the ν(N–H) mode. Both these features are absent from the IR spectra of **1**–**3** because of the anionic character of the ligand. However, one can see the peaks that result from the C–H stretching vibrations of the aromatic pyrimidine rings between 3100 and 3000 cm^{-1}. The aromatic ring stretching vibrations (C=C and C=N), which fall in the region from 1600 to 1500 cm^{-1}, show a characteristic two-band structure with slightly shifted peak positions in **1**–**3**, especially when compared to the ligand spectrum. In the region further down to 1250 cm^{-1}, a strong and broad peak around 1370 cm^{-1}, which probably consists of several vibrations, is visible in all three group 12 metal pyrimidinethiolates rather than the three separate peaks at 1492, 1424 and 1333 cm^{-1} in the free thiol, which are assigned to ring stretching and C–H bending vibrations. This is followed by a pair of strong peaks (three peaks for **1**) at around 1200 cm^{-1}. These bands are interpreted as being due to C–H bending and C–S stretching vibrations in the neutral ligand. Interestingly, Kennedy et al. have found that extensive coupling within the ring system, as indicated, for example, by an ^{18}O study of 2-hydroxypyridine,[25] precludes the identification of any band definitively assigned to a C–S stretching vibration.[21] Two peaks in the spectrum of pyrimidinethiol at 1051 and 983 cm^{-1} have been assigned as ring breathing vibrations.[20] These are significantly altered in the spectra of the three metal complexes **1**–**3** of the anionic pyrimidine-2-thiolate ligand. A shift in the ring breathing mode in simple pyridine–metal complexes is used as a guide to metal coordination.[26] However, for metal complexes of 2-pyridinethiol and 4-pyridinethiol it has been found that changes in energy of these bands are indicative of a change in coordination but not informative concerning the mode of the coordination.[21] Further down, the neutral ligand displays two peaks at 793 and 751(sh) cm^{-1}, characteristic of a mono-substituted aromatic ring, which have been assigned to C–H bending and a combination of C–S stretching, C–H bending and ring deformation modes,

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

respectively. While one observes a similar group in **1**, consisting of a single peak at 810 cm^{-1} and a second peak at 750 cm^{-1} with a shoulder at 768 cm^{-1}, this second peak splits in **2** and **3** to give two well-separated peaks at either 767 and 746 cm^{-1} or 769 and 743 cm^{-1}, respectively. Four more peaks can be identified down to 300 cm^{-1} for HS-2-$N_2C_4H_3$, which are assigned to either ring deformation (625 cm^{-1}) and/or C–S bending and stretching modes (486, 472 cm^{-1} and 406 cm^{-1}). This area displays the most visible changes in the IR spectra for **1**–**3**, indicative of the different coordination modes of the anionic pyrimidinethiolate ligand towards the metal atoms. New bands arise in the spectra of **1**–**3** compared to the neutral ligand in the far-IR region below 300 cm^{-1}. For complexes of the type $[MX_2L_2]$ (M = Zn, Cd, Hg; X = Cl, Br and L = Py-2-SH, Py-4-SH), bands between 198 and 235 cm^{-1} have been assigned as M–L vibrational modes.[21] In pyridine complexes like $[Zn(py)_2X_2]$, M–Py vibrations have been assigned by the isotope technique in the region of 200 to 225 cm^{-1}.[27,26] Interestingly, **3** displays only one strong peak in this region at 254 cm^{-1}, probably due to the symmetric square-planar coordination environment of the metal atom, while the spectra of **1** and **2** contain several peaks.

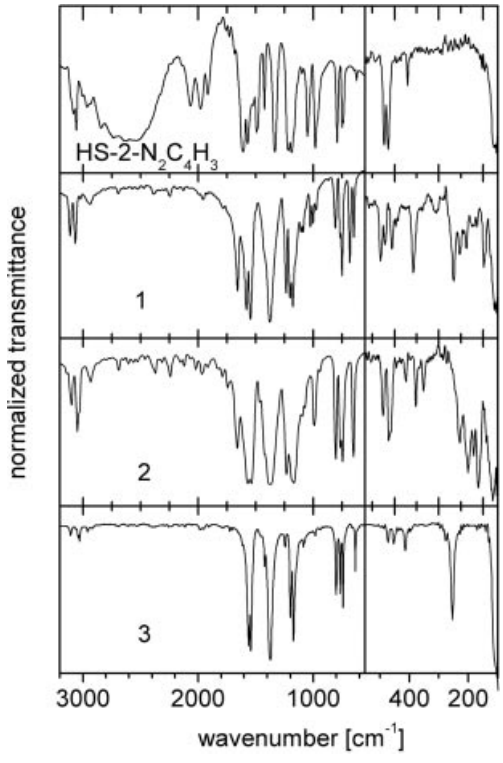

Figure 6. Comparison of the IR spectra of HS-2-$N_2C_4H_3$ (top), $[Zn(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**1**), $[Cd(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**2**) and $[Hg(S\text{-}2\text{-}N_2C_4H_3)_2]$ (**3**) measured as a CsI pellets.

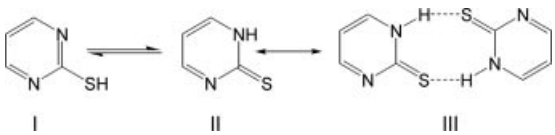

Scheme 3.

The UV/Vis spectra in the solid state display a shift in the absorption onset on going from **1** (450 nm) to **2** (430 nm) to **4** (395 nm) to **3** (366 nm) in such a way that the zinc complex **1** absorbs at higher wavelengths (lower energy) than the other complexes **2**, **3**, **4**. Apart from the spectrum of **1**, which shows a shoulder at 375 nm followed by a broad peak at 285 nm, and **4**, which displays a shoulder at 325 nm followed by a peak at 285 nm, the spectra of **1**–**4** are almost featureless.

The ^1H and ^{13}C NMR spectra of the complexes in dimethyl sulfoxide display similar peak patterns for the pyrimidinethiolate ligand to those observed for the precursor compound $(CH_3)_3S\text{-}2\text{-}N_2C_4H_3$, with only slightly shifted positions of the signals. In contrast to the situation found in the crystalline state, the equivalence of the two hydrogen and carbon atoms in the *meta* position indicates a symmetric coordination of the ligand in solution that is probably generated by a complex equilibrium with fast exchange between different coordination modes.

Experimental Section

Physical Measurements: ^1H and ^{13}C NMR spectra were recorded with a Bruker DPX Avance 300. ^{29}Si NMR spectra were measured with a Bruker Avance 400. UV/Vis absorption spectra of cluster molecules in solution were measured with a Varian Cary 500 spectrophotometer in quartz cuvettes. Solid-state reflection spectra were measured as micron-sized crystalline powders between quartz plates with a Labsphere integrating sphere. IR and FIR spectra were measured with a Perkin–Elmer Spectrum GX as CsI pellets in the region from 4000 to 30 cm^{-1}.

Synthesis: Standard Schlenk techniques were employed throughout the syntheses using a double-manifold vacuum line with high-purity dry nitrogen. The solvent diethyl ether was dried with sodium/benzophenone and distilled under nitrogen. Anhydrous DMF ($H_2O < 0.005\%$) and pyridine ($H_2O < 0.01$) obtained from Aldrich were degassed, freshly distilled and stored over molecular sieves under nitrogen. Anhydrous $ZnCl_2$, $CdCl_2$ and $HgCl_2$ were purchased from Aldrich. $(2\text{-}N_2C_4H_3)SSiMe_3$ was prepared according to a general procedure for silylthiopyrimidines.[28] Thus, $(2\text{-}N_2C_4H_3)SH$ [6 g (0.0535 mol)] was dissolved in a mixture of 130 mL of hexamethyldisilazane (HDMS) and 50 mL of dioxane and heated under reflux for 24 h. Excess HDMS and dioxane were removed by distillation and the remaining oil distilled under vacuum (1×10^{-3} mbar) to yield $(2\text{-}N_2C_4H_3)SSiMe_3$ as a yellow oily liquid (b.p. 70 °C). Yield: 8.93 g (90.6%). ^1H NMR (300 MHz, C_6D_6): $\delta = 0.52$ [s, $Si(CH_3)_3$, 9 H], 6.54 (t, $^3J_{H,H} = 4.9$ Hz, *para*-C*H*, 1 H), 8.18 (d, $^3J_{H,H} = 4.9$ Hz, *meta*-C*H*, 2 H) ppm. $^{13}C\{^1H\}$NMR (75 MHz, C_6D_6): $\delta = 1.4$ [s, $Si(CH_3)_3$], 117.1 (s, *meta*-*C*H), 157.3 (s, *para*-*C*H), 172.9 (s, *C*SSi) ppm. ^{29}Si NMR (79.5 MHz, C_6D_6): $\delta = 15.7$ [s, $Si(CH_3)_3$] ppm.

$[Zn(S\text{-}2\text{-}N_2C_4H_3)_2]$ (1): $ZnCl_2$ (0.14 g, 1.03 mmol) was dissolved in 20 mL of DMF. $(2\text{-}N_2C_4H_3)SSiMe_3$ (0.4 mL, 2.18 mmol) was then added at 0 °C and the resulting yellow solution slowly warmed to room temperature. After a short time, **1** started to precipitate as a pale-yellow crystalline powder. The crystallisation was completed by layering the reaction solution with diethyl ether by evaporation and condensation from a connected flask. Yield: 0.25 g (84.5%). $C_8H_6N_4S_2Zn$ (287.7): calcd. C 33.4, H 2.1, N 19.5, S 22.3; found C 33.5, H 2.4, N 19.5, S 21.5. Small but suitable crystals for single-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

crystal X-ray analysis were found in carefully layered DMF solutions of **1** with diethyl ether or directly in carefully warmed up reaction solutions. IR (CsI): $\tilde{\nu}$ = 3111 (m), 3066 (m), 3021 (w), 2940 (w, br), 2693 (w), 2389 (w), 2245 (w), 1956 (w, br), 1782 (w), 1657 (s), 1580 (vs), 1545 (vs), 1377 (vs, br), 1235 (s), 1202 (vs), 1178 (vs), 1106 (m), 1088 (m), 1025 (m), 1001 (m), 976 (w), 810 (m), 750 (s, sh), 684 (s), 648 (m), 498 (m), 483 (m), 459 (m), 446 (w), 386 (m), 250 (m), 230 (m), 207 (m), 187 (w, sh), 170 (w), 148 (m) cm^{-1}. UV/Vis (nujol): λ_{max} = 375 (sh), 285 (vbr) nm. ^1H NMR (300 MHz, $(CD_3)_2SO$]: δ = 6.9 (t, $^3J_{H,H}$ = 4.9 Hz, *para*-C*H*, 1 H), 8.3 (d, $^3J_{H,H}$ = 4.9 Hz, *meta*-C*H*, 2 H) ppm. $^{13}C\{^1H\}$ NMR [75 MHz, $(CD_3)_2SO$]: δ = 114.9 (s, *meta*-*C*H), 157.6 (s, *para*-*C*H), 182.6 (s, *C*SSi) ppm.

[Cd(S-2-$N_2C_4H_3$)$_2$] (2): $CdCl_2$ (0.4 g, 2.18 mmol) was dissolved in 55 mL of DMF. (2-$N_2C_4H_3$)$SSiMe_3$ (0.8 mL, 4.36 mmol) was then added at 0 °C and the resulting yellow solution warmed to room temperature. After a short time, **2** precipitated as a white crystalline powder. Yield: 0.53 g (73%). $C_8H_6CdN_4S_2$ (334.7): calcd. C 28.7, H 1.8, N 16.7, S 19.2; found C 28.8, H 1.9, N 16.1, S 19.2. Crystals suitable for single-crystal X-ray analysis were grown upon layering DMF/pyridine (1:1) solutions of **2** with diethyl ether. IR (CsI): $\tilde{\nu}$ = 3098 (m), 3048 (s), 2932 (w), 2688 (w), 2371 (w, sh), 2242 (w, sh), 1966 (w, b), 1789 (w), 1744 (w), 1659 (s), 1569 (vs), 1540 (vs), 1373 (vs, b), 1232 (vs), 1169 (vs, sh), 994 (s), 806 (s), 765 (s), 746 (s), 652(s), 488 (m), 465 (s), 412 (w), 378 (m), 352 (w), 229 (s), 201 (s), 182 (s), 167 (s) cm^{-1}. UV/Vis (nujol): λ_{max} = 350 (sh), 292 (vbr) nm. ^1H NMR (300 MHz, $(CD_3)_2SO$]: δ = 6.9 (t, $^3J_{H,H}$ = 4.9 Hz, *para*-C*H*, 1 H), 8.2 (d, $^3J_{H,H}$ = 4.9 Hz, *meta*-C*H*, 2 H) ppm. $^{13}C\{^1H\}$ NMR [75 MHz, $(CD_3)_2SO$]: δ = 114.6 (s, *meta*-*C*H), 157.3 (s, *para*-*C*H), 183.5 (s, *C*SSi) ppm.

[Hg(S-2-$N_2C_4H_3$)$_2$] (3): $HgCl_2$ (0.21 g, 0.78 mmol) was dissolved in 25 mL of acetonitrile. (2-$N_2C_4H_3$)$SSiMe_3$ (0.3 mL, 1.62 mmol) was then added at 0 °C which resulted immediately in the formation of a white and fluffy precipitate of **3**. After warming up to room temperature, **3** was filtered and washed twice with diethyl ether. Yield: 0.3 g (90.9%). $C_8H_6HgN_4S_2$ (422.9): calcd. C 22.7, H 1.4, N 13.3, S 15.2; found C 23.2, H 1.5, N 13.7, S 15.4. Crystals suitable for single-crystal X-ray analysis were grown by recrystallisation of ca. 30 mg of **3** from 10 mL of hot CH_3CN/DMF (10:2). IR (CsI): $\tilde{\nu}$ = 3108 (w), 3029 (w,sh), 2959 (w), 1726 (w), 1704 (w), 1560 (vs), 1542 (vs), 1423 (m), 1372 (vs), 1242 (w, sh), 1200 (s), 1173 (vs), 1087 (w, sh), 983 (w, sh), 803 (m), 769 (m), 743 (s), 635 (m), 473 (w), 454 (w), 414 (w), 279 (w), 254 (s) cm^{-1}. UV/Vis (nujol): λ_{max} = 280 (vbr) nm. ^1H NMR [300 MHz, $(CD_3)_2SO$]: δ = 7.2 (t, $^3J_{H,H}$ = 4.9 Hz, *para*-C*H*, 1 H), 8.5 (d, $^3J_{H,H}$ = 4.9 Hz, *meta*-C*H*, 2 H) ppm. $^{13}C\{^1H\}$ NMR [75 MHz, $(CD_3)_2SO$]: δ = 117.7 (s, *meta*-*C*H), 158.3 (s, *para*-*C*H), 176.5 (s, *C*SSi) ppm.

[Cd(S-2-$N_2C_4H_3$)$_2$(tmeda)] (4): Complex **1** (0.05 g, 0.15 mmol) was suspended in 15 mL of TMEDA for 2 min in an ultrasonic bath. Then, the flask was sealed with a Teflon screw tap and placed in a dry oven at 35 °C for one week to yield **4** as a white crystalline powder. Yield: 0.066 g (98%). $C_{14}H_{22}CdN_6S_2$ (450.9): calcd. C 37.3, H 4.9, N 18.6, S 14.2; found C 37.1, H 4.9, N 19.4, S 14.6. Crystals suitable for single-crystal X-ray analysis were grown by allowing the solution to stand at room temperature. IR (CsI): $\tilde{\nu}$ = 3097 (w), 3044 (w, sh), 2980 (m), 2956 (m), 2874 (m, br), 2847 (m), 2800 (m), 1730 (w), 1538 (vs), 1569 (vs), 1463 (s), 1426 (s), 1372 (vs), 1298 (m), 1239 (s), 1211 (s), 1181 (vs), 1134 (w), 1103 (w), 1068 (m), 1036 (m), 1019 (m), 983 (m), 953 (s), 791 (s, sh), 770 (s), 744 (s), 646 (m), 584 (w), 485 (m), 462 (s), 447 (w, sh), 433 (m), 401 (w), 377 (w, sh), 244 (w), 203 (s, sh), 181 (m, br), 171 (w, sh), 152 (m, sh), 142 (w), 135 (w) cm^{-1}. UV/Vis (nujol): λ_{max} = 325 (sh) 285 (br) nm. ^1H NMR [300 MHz, $(CD_3)_2SO$]: δ = 2.3 (s, N*C*H_3, 12 H), 2.5 (s, *C*H_2N, 4 H), 6.9 (t, $^3J_{H,H}$ = 4.9 Hz, *para*-C*H*, 1 H), 8.3 (d, $^3J_{H,H}$ = 4.9 Hz, *meta*-C*H*, 2 H) ppm. $^{13}C\{^1H\}$ NMR [75 MHz, $(CD_3)_2SO$]: δ = 47.0 (s, N*C*H_3), 57.1 (s, *C*H_2N), 114.8 (s, *meta*-*C*H), 157.5 (s, *para*-*C*H), 183.5 (s, *C*SSi) ppm.

Crystallography: Crystals suitable for single-crystal X-ray diffraction were taken directly from the reaction solution of the compound and then selected in perfluoroalkylether oil. Single-crystal X-ray diffraction data of **2**–**4** were collected using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) with a STOE IPDS

II (Imaging Plate Diffraction System) equipped with a Schneider rotating anode. Single-crystal X-ray diffraction data of **1** were collected using synchrotron radiation (λ = 0.80 Å) with a STOE IPDS II (Imaging Plate Diffraction System) at the ANKA synchrotron source in Karlsruhe. The structures were solved with the direct-methods program SHELXS[29] of the SHELXTL PC suite of programs, and were refined with the use of the full-matrix least-squares program SHELXL (Table 1).[29] Molecular diagrams were prepared using SCHAKAL 97[30] and DIAMOND.[31] All Cd, Zn, S, N and C atoms were refined with anisotropic displacement parameters whilst H atoms were calculated in fixed positions. CCDC-266974 (**1**), -266975 (**2**), -266976 (**3**) and -266977 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. X-ray powder diffraction patterns (XRD) were measured with a STOE STADI P diffractometer (Cu-$K_{\alpha 1}$ radiation, germanium monochromator, Debye–Scherrer geometry) in sealed glass capillaries. A theoretical powder diffraction pattern for **1** was calculated on the basis of the atom coordinates obtained from single-crystal X-ray analysis by using the program package STOE WinXPOW.[32]

Acknowledgments

This work was supported by the Deutsch–Israelisches Programm (DIP) and the Deutsche Forschungsgemeinschaft (centre for functional nanostructures CFN). A. E. is grateful to Prof. Dr. D. Fenske for helpful discussions and for providing excellent working conditions, E. Tröster for her invaluable assistance in the practical work, Dr. E. Matern for the measurement of the ^{29}Si NMR spectra and Dr. Dale Cave for careful revision of the manuscript.

Self-Assembly and Characterization of Grid-Type Copper(I), Silver(I), and Zinc(II) Complexes

Violetta Patroniak,*[a,b] Artur R. Stefankiewicz,[a,b] Jean-Marie Lehn,[b] and Maciej Kubicki[a]

Dedicated to Professor Bogdan Marciniec on the occasion of his 65th birthday

Keywords: Copper / Silver / Zinc / Supramolecular chemistry / Self-assembly

The reactions of ligand **L**, which comprises two bidentate binding units, with copper(I), silver(I), and zinc(II) lead to the self-assembly of the expected supramolecular architectures **1**–**3**, respectively, of the [2×2] grid type, containing four ions in tetrahedral coordination sites. The grid-type structures are assigned on the basis of the spectroscopic data in solution, and confirmed in the solid state in the case of complex **2** by X-ray crystallography.

Introduction

Metal-directed self-assembly is a powerful synthetic methodology for supramolecular architectures that may exhibit novel physical and chemical properties with potential applications in supramolecular engineering, nanotechnology, biomedical inorganic chemistry, biological catalysis, and in the area of sensors. A variety of architectural types are known, such as, for example, inorganic double,[1–5] triple,[4,5] and quadruple[6] helicates, rotaxanes,[7–9] clusters,[10–12] racks,[13] cages,[14–16] grids[17–28] etc., based on ligand design and on the application of suitable coordination geometries for the assembly process. Among them, there is an increasing interest in grid-shaped complexes based on ligands containing oligopyridine-type groups and various transition metal ions. These grids are thermodynamically most stable when metal ions of tetrahedral coordination geometry are combined with a planar ligand containing bidentate binding subunits.[17,18,29–40] The first [2×2] grid type was obtained with copper(I) ions,[17] and copper(I) grid complexes have recently attracted much attention because of their well-defined supramolecular architectures and their interesting properties, such as special optical,[35] magnetic,[36] and electrochemical features or the atypical geometry of the grid structure.[37] Silver(I) has also been used as an assembling ion and, thanks to the flexibility of its coordination sphere, has yielded sophisticated coordination architectures such as [3×3][29] and $[(2\times5)_2]$[6] multinuclear grids. Such compounds form supramolecular systems that self-assemble into monolayer or bilayer crystalline films, which are of potential interest for microelectronics and nanotechnology.[38–41] Zinc is one of the most abundant metals in the human body, and fluorescent imaging has been proven to be the most suitable technique for its monitoring in vivo.[42,43]

One aim of our studies has been to explore further the possibilities of the self-assembly of supramolecular structures, in particular multinuclear grids from N-heterocyclic ligands. In this paper, we describe the synthesis and structural characterization of some polynuclear metal complexes prepared from the tetradentate ligand **L**, which contains pyridine and pyrimidine nitrogen donor atoms. The investigation of the complexation of ligand **L** with metal ions of preferred tetrahedral coordination geometry, such as Cu^{I}, Ag^{I}, and Zn^{II}, has revealed that the ligand is adequately preorganised for the assembly of tetranuclear [2×2] grid type complexes.

Results and Discussion

Synthesis of Ligand L

Ligand **L** possesses two N,N bidentate binding subunits for the complexation of ions with tetrahedral coordination geometry. It contains heterocyclic pyrimidine and pyridine units and was synthesised as outlined in Scheme 1.

2-Methyl-6-(trimethylstannyl)pyridine was obtained from 2-bromo-6-methylpyridine by a halogen/lithium exchange protocol at low temperature in THF with *n*-butyllithium, followed by quenching the pyridyllithium interme-

diate with $ClSnMe_3$.[44,45] 4,6-Dichloro-2-phenylpyrimidine was prepared by treatment of $POCl_3$ with 2-phenylpyrimidine-4,6-diol.[46] The twofold Stille-type[47] coupling reaction of 2-methyl-6-(trimethylstannyl)pyridine with 4,6-dichloro-2-phenylpyrimidine in toluene using $[Pd(PPh_3)_4]$ as a catalyst furnished **L** in 54% yield after workup. The structure of ligand **L** was confirmed by NMR spectroscopy, FAB mass spectrometry, and elemental analysis. It was also structurally characterized by X-ray crystallography (Figure 1).

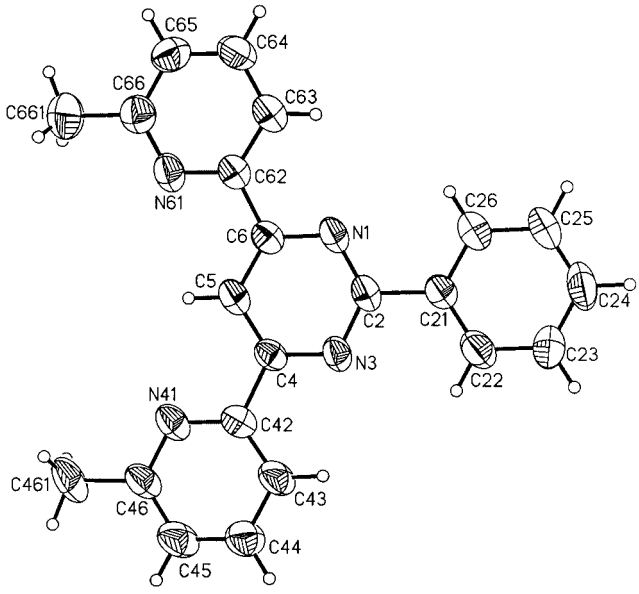

Figure 1. Anisotropic-ellipsoid representation of molecule **L** together with the numbering scheme. The ellipsoids are drawn at the 50% probability level; hydrogen atoms are represented by spheres of arbitrary radii.

Crystallographic Characterization of Ligand L

The crystal structure of the ligand molecule **L** shows that it is approximately planar (Figure 1). The four constituent rings are planar within the experimental error [maximum deviation from the least-squares plane is 0.012(3) Å], and the dihedral angles between their planes are small, up to 6.7(2)°. The mean values of aromatic C_{ar}–C_{ar} [1.373(9) Å], single C_{ar}–C_{ar} [1.489(6) Å], C_{ar}–C_{sp^3} [1.506(4) Å], and C_{ar}–N [1.340(4) Å] bond lengths are very close to typical values. The bond-angle pattern is also typical, with distortions from the ideal (120°) caused by the presence of heteroatoms and substituents. In the crystal structure, the principal intermolecular interaction is probably π-stacking between neighbouring molecules (approximately along the [610] direction); the mean distance between the π systems is 3.44 Å.

Synthesis and Characterization of the Complexes

Multitopic ligands with N,N-type donor sets allow the metal ion-directed assembly of coordination architectures. Thus, ligand **L** leads to the generation of the [2×2] grid architectures **1**–**3** with Cu^I, Ag^I, and Zn^{II}, respectively (Scheme 2).

The self-assembly of these complexes was achieved by reaction of **L** in acetonitrile, at room temperature, with tetrakis(acetonitrile)copper(I) hexafluorophosphate or the silver(I) and zinc(II) triflates. The complexation reactions were followed by ESI mass spectrometry and NMR spectroscopy.

The ^1H NMR spectra of the complexes show strongly shifted signals, as expected, and are strongly supportive of the grid-type structures. The signals of the symmetrically coordinated ligand in a single chemical and magnetic environment are in agreement with this type of structure. Interestingly, significant coordination-induced shifts of the signals are observed when the spectra of the complexes are compared to those of the uncomplexed ligand **L**.

ESI mass spectrometry is a highly sensitive and accurate analytical tool, which has been found to be particularly suitable for the identification of large metallosupramolecular architectures in solution, in which multiply charged ions are generated by sequential loss of counterions, resulting in characteristic isotopic patterns in the spectrum. The ESI-MS investigation of all complexes was performed with acetonitrile solutions at approximately 10^{-4} M. For example, the ESI mass spectrum of **2** shows peaks corresponding to multiply charged species at m/z = 785 (80%, $[AgL_2]^+$), 447 (100%, $[Ag_4L_4]^{4+}$), 339 (45%, $[L]^+$). These data confirm the presence of grid **2** in solution. The spectra of all the complexes include signals for $[ML_2]^{n+}$, $[M_4L_4]^{n+}$, and $[L]^+$, which means that significant dissociation of the grid complexes to mononuclear species and ligand molecules occurs in solution.

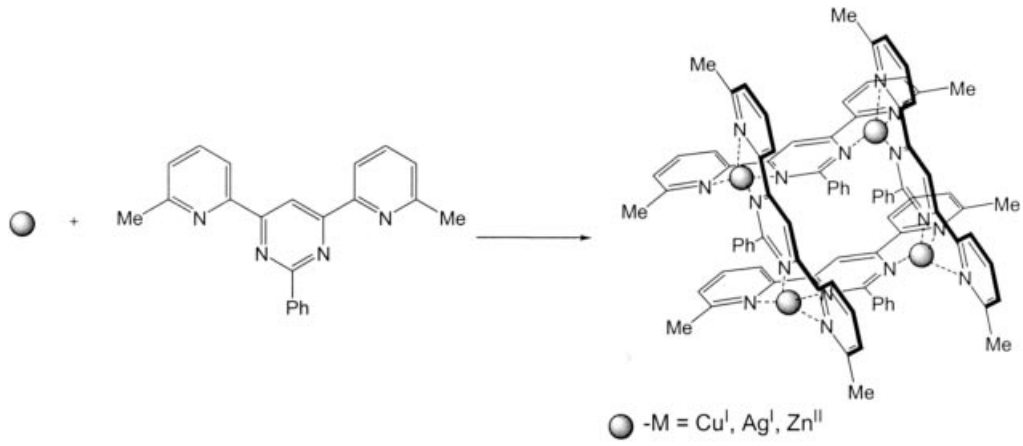

Scheme 2. Reaction scheme for the assembly of the [2×2] grid complexes **1**–**3**.

Solid-State Molecular Structure of Complex 2

Crystals of complex **2** were obtained by diffusion of diisopropyl ether into a solution of the complex in acetonitrile. The molecular structure of complex **2** was determined by X-ray crystallography at both 291 K and 100 K. It shows that it is of [2×2] grid-type (Figure 2), and is stable from 100 K to at least room temperature. We will discuss the low temperature structure here, but this discussion is equally valid for the structure determined at room temperature.

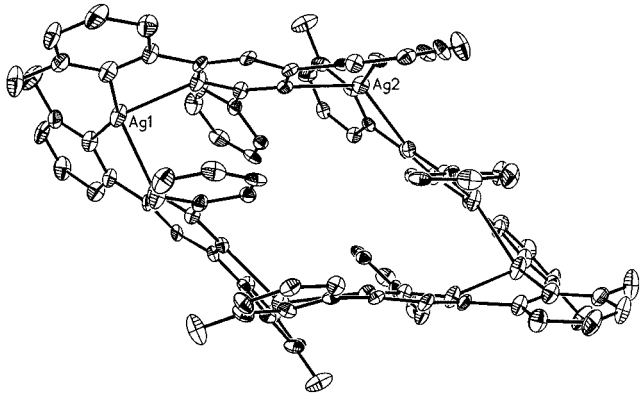

Figure 2. Anisotropic-ellipsoid representation of molecule **2** together with numbering scheme. The ellipsoids are drawn at the 50% probability level; hydrogen atoms are represented by spheres of arbitrary radii. The counterions, diisopropyl ether, and ligand molecules have been omitted for clarity.

The unit cell contains, besides the grid molecules, also the free ligand, counterion (triflate), and disordered solvent (diisopropyl ether) molecules. The grid is highly symmetrical: two independent silver ions, which lie on two different twofold axes, occupy the special positions of the space group *Ccca*. One of them occupies the Wyckoff position *e* (twofold axis along *x*), while the other occupies the Wyckoff position *f* (twofold axis along *y*). Thus, the symmetry-independent part of the grid contains two halves of silver ions and one ligand, and the rest is produced by symmetry operations. The free ligand molecule occupies yet another special position, that on the third twofold axis along the *z*-direction (atoms C2, C21, C24, and C5 lie at Wyckoff positions *g*).

Due to its symmetry, the grid is of rhombic shape and its size is within nanoscopic scale − the lengths of the diagonals are 1.18 and 1.92 nm. The formation of the grid causes significant changes in the shape of the ligand molecule. The free ligand molecule present in the crystal has a structure similar to that determined for **L**, with a maximum value of the dihedral angle between the least-squares of the aromatic planes of 9.9°. In contrast, the molecule in the complex is fairly folded. The dihedral angles between the planes of the central ring and terminal rings are 13.0°, 22.6°, and 40.0°, and the dihedral angles between the planes of the terminal rings are as large as 56.9°.

The Ag^{I} ions show distorted tetrahedral coordination, and the Ag···Ag distances are in the range 6.640–12.087 Å. The Ag–N distances can be divided into two classes: shorter [2.276(4) Å and 2.219(3) Å], to pyrimidine nitrogen atoms, and longer [2.449(5) Å and 2.471(5) Å], to pyridine nitrogen atoms. Selected bond lengths and angles are listed in Table 1.

planar, free ligand molecules lie between the grids, and interact with the aromatic rings by π-stacking interactions (the distance between the mean planes of the rings is about 3.4 Å). This intercalation occurs between two different grid fragments; an analogous intra-grid intercalation of the free ligand is observed, for example, in the copper(I) biphenanthroline grid structure.[33] There is additional free space in the crystal structure that is filled by disordered diisopropyl ether solvent molecules.

Conclusions

The novel ligand **L** containing two bidentate N,N-binding subunits has been prepared and its solid state conformational properties characterized by X-ray crystallography. The reaction of **L** with Cu^{I}, Ag^{I}, and Zn^{II} results in the clean and quantitative formation of [2×2] grid-type complexes, which were characterized in solution on the basis of ESI mass spectrometry and ^{1}H NMR spectroscopy. The molecular structure of the Ag^{I} complex **2** was also investigated by X-ray crystallography, which confirmed that it indeed has a [2×2] grid-type architecture, with each metal ion tetrahedrally coordinated by two N,N donors.

The present results detail a particularly facile and rapid synthetic protocol for the preparation of [2×2] grid-type coordination scaffolds with Cu^{I}, Ag^{II}, and Zn^{II}. Related ligands and coordination arrays may be envisioned for the generation of various metallosupramolecular architectures.

Experimental Section

General: CH_3CN was freshly distilled under argon over CaH_2. 2-Methyl-6-(trimethylstannyl)pyridine[44,45] and 4,6-dichloro-2-phenylpyrimidine[46] were prepared according to the literature. The metal salts were used without further purification as supplied by Aldrich. NMR spectroscopic data were recorded on a Varian Gemini 300 MHz spectrometer, and were calibrated against the residual protonated solvent signal ($CDCl_3$: δ = 7.24 ppm; CD_3CN: δ = 1.94 ppm) and are given in ppm. Mass spectra were determined by FAB^{+} using a ZAB-HF VG apparatus in a *m*-nitrobenzyl alcohol matrix and a Waters Micromass ZQ spectrometer in acetonitrile. The electronic absorption spectrum for ligand **L** in acetonitrile was measured on a Shimadzu UV 2401 PC spectrometer, with λ_{max} in nm and ε ($\times 10^4$) in $M^{-1}\,cm^{-1}$. The luminescence spectrum for ligand **L** in CH_3CN was recorded using a Perkin–Elmer MPF-3 spectrofluorimeter. Microanalyses were obtained using a Perkin–Elmer 2400 CHN microanalyzer. Melting points were recorded on an Electrothermal Digital melting point apparatus.

4,6-Bis(6-methylpyridin-2-yl)-2-phenylpyrimidine (L): 2-Methyl-6-(trimethylstannyl)pyridine (2.0 g, 8 mmol) and degassed toluene (25 mL) were added consecutively, by syringe, to a mixture of 4,6-dichloro-2-phenylpyrimidine (0.6258 g, 3 mmol), $[Pd(PPh_3)_4]$ (0.10 g, 0.9 mmol), and LiCl (0.68 g, 16 mmol) under argon. The reaction was refluxed and stirred at 120 °C for 24 h, and the toluene evaporated in a water bath under reduced pressure. The residue was then purified by column chromatography on alumina and eluted with dichloromethane/*n*-hexane (4:6); yield: 0.50 g (54%). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.27 (s, 1 H, H-5), 8.72 (t, *J* = 7.9 Hz, 1 H, H-4′′′), 8.50 (d, *J* = 7.6 Hz, 2 H, H-2′′′,6′′′), 7.79 (t, *J* = 7.6 Hz, 2 H, H-4′,4′′), 7.54 (m, *J* = 5.2 Hz, 4 H, H-3′,3′′,5′,5′′), 7.20 (t, *J* = 7.9 Hz, 2 H, H-3′′′,5′′′), 2.66 (s, CH_3) ppm. ^{13}C NMR (DEPT, 75 MHz, $CDCl_3$): δ = 164.4, 163.9, 158.4, 154.1, 138.0 (CH), 137.2 (CH), 130.6, 128.5 (CH), 128.4 (CH), 124.9 (CH), 119.0 (CH), 111.6 (CH), 24.6 (CH_3). FAB-MS: *m*/*z* (%) = 339.2 (100) [L + H]. UV/Vis (CH_3CN): λ = 233, 272.5, 281.5, 318 nm. Luminescence: $\lambda_{ex.}$ = 298 nm, $\lambda_{em.}$ = 356 nm. $C_{22}H_{18}N_4$ (338.4): calcd. C 78.08, H 5.36, N 16.56; found C 77.99, H 5.33, N 16.42. M.p. 170 °C.

Cu Complex 1: An equimolar mixture of $[Cu(CH_3CN)_4]PF_6$ (11.0 mg, 30 μmol) and ligand **L** (10.0 mg, 30 μmol) in MeCN (5 mL) was stirred at room temperature for 24 h. The solvent was then evaporated under reduced pressure to give a quantitative yield of **1** as a purple-violet powder. ^{1}H NMR (300 MHz, CD_3CN): δ = 9.16 (s, 1 H, H-5), 8.71 (t, 1 H, H-4′′′), 8.59 (d, 2 H, H-2′′′,6′′′), 8.01 (t, 2 H, H-4′,4′′), 7.55 (m, 4 H, H-3′,3′′,5′,5′′), 7.26 (t, 2 H, H-3′′′,5′′′), 2.68 (s, CH_3) ppm. ESI-MS: *m*/*z* = 739 $[CuL_2]^{+}$, 401 $[Cu_4L_4]^{4+}$, 339 $[L]^{+}$. $Cu_4(L)_4(PF_6)_4$ (2187.7): calcd. C 48.31, H 3.32, N 10.24; found C 49.01, H 3.33, N 9.98.

Ag Complex 2: A solution of ligand **L** (10.0 mg, 30 μmol) and $Ag(CF_3SO_3)$ (7.6 mg, 30 μmol) in MeCN (5 mL) was stirred at room temperature for 24 h. The white complex **2** was isolated in quantitative yield by evaporation of the solvent. ^1H NMR (300 MHz, $CDCl_3$): δ = 9.21 (s, 1 H, H-5), 8.73 (t, 1 H, H-4′′′), 8.55 (d, 2 H, H-2′′′,6′′′), 7.91 (t, 2 H, H-4′,4′′), 7.58 (m, 4 H, H-3′,3′′,5′,5′′), 7.45 (t, 2 H, H-3′′′,5′′′), 2.69 (s, CH_3) ppm. ESI-MS: *m*/*z* = 785 $[Ag\mathbf{L}_2]^+$, 447 $[Ag_4\mathbf{L}_4]^{4+}$, 339 $[\mathbf{L}]^+$. $Ag_4(\mathbf{L})_4(CF_3SO_3)_4 \cdot 2\mathbf{L} \cdot C_6H_{14}O$ (3160.4): calcd. C 53.97, H 3.89, N 10.64, S 4.06; found C 54.39, H 3.83, N 10.65, S 4.10.

Zn Complex 3: An equimolar mixture of $Zn(CF_3SO_3)_2$ (13.3 mg, 39 μmol) and ligand **L** (14.2 mg, 39 μmol) in MeCN (5 mL) was stirred at room temperature for 24 h. The solvent was evaporated under reduced pressure to yield a pale-green complex **3** in quantitative yield. ESI-MS: *m*/*z* = 889 $\{[Zn(\mathbf{L})_2](CF_3SO_3)\}^+$, 553 $\{[Zn_4(\mathbf{L})_4](CF_3SO_3)_4\}^{4+}$, 371 $[Zn(\mathbf{L})_2]^{2+}$, 339 $[\mathbf{L}]^+$, 254 $\{[Zn_4(\mathbf{L})_4](CF_3SO_3)\}^{7+}$. ^1H NMR (300 MHz, CD_3CN): δ = 9.32 (s, 1 H, H-5), 8.64 (t, 1 H, H-4′′′), 8.52 (d, 2 H, H-2′′′,6′′′), 7.99 (t, 2 H, H-4′,4′′), 7.83 (m, 4 H, H-3′,3′′,5′,5′′), 7.60 (t, 2 H, H-3′′′,5′′′), 2.75 (s, CH_3) ppm. $Zn_4(\mathbf{L})_4(CF_3SO_3)_8$ (2807.7): calcd. C 41.07, H 2.58, N 7.98, S 9.14; found C 41.12, H 2.49, N 7.77, S 9.28.

Crystal Structure Determination of Ligand and Complex 2: Diffraction data for **L** were collected at 291(1) K and for **2** at both 291(1) and 100(1) K by the ω-scan technique up to $2\theta = 60°$, on a KUMA-KM4CCD diffractometer[48] with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The temperature was controlled by an Oxford Instruments Cryosystems cooling device. The data were corrected for Lorentz-polarization effects,[49] as well as for absorption, with SORTAV.[50] Unit-cell parameters were determined by the least-squares fit of 2258 (**L**), 4514 (**2**-RT), and 3783 (**2**-LT) reflections of highest intensity, chosen from the whole experiment. The structures were solved with SHELXS97[51] and refined with the full-matrix least-squares procedure on F^2 by SHELXL97.[52] Scattering factors incorporated in SHELXL97 were used. All non-hydrogen atoms were refined anisotropically; hydrogen atoms were placed geometrically in idealized positions and refined as rigid groups, with U_{iso} of the hydrogen atoms set as 1.2 (1.3 for CH_2 and CH_3 groups) times U_{eq} of the appropriate carrier atom. Relevant crystal data are listed in Table 3, together with refinement details.

The Influence of the Neutral Coligand on the Spectroscopic Properties and Crystal Structures of Lithium Tri(*tert*-butyl)silylarsanides of the Type [(L)LiAs(H)Si*t*Bu$_3$] (L = DME, THF)

Matthias Westerhausen,*[a] Mathias Krofta,[b] Peter Mayer,[b] and Holger Piotrowski[b]

Keywords: Arsanes / Arsanides / Lithium / Lithiation / Pnicogens

The reaction of [(dme)LiAsH$_2$] with F$_3$CSO$_3$Si*t*Bu$_3$ yields tri(*tert*-butyl)silylarsane (**1**). The reaction of **1** with *n*-butyllithium in 1,2-dimethoxyethane gives [(dme)LiAs(H)Si*t*Bu$_3$]$_2$ (**2**), whereas the lithiation of **1** in THF leads to the formation of the one-dimensional polymer [(THF)LiAs(H)Si*t*Bu$_3$]$_\infty$ (**3**). The Li–As bond lengths of both of these compounds show a similar value of approximately 260 pm. However, the smaller coordination number of the lithium atom in **3** leads to a short Li–O distance of 190 pm, whereas in **2**, which has a tetracoordinate lithium atom, an average bond length of 199 pm is observed.

Introduction

Silylphosphanes and their lithiated derivatives have aroused the interest of many research groups over several decades[1–5] because these compounds are valuable synthons for a wide variety of novel compounds such as phosphaalkenes and phosphaalkynes.[6] However, the homologous silylated arsanes, as well as their lithium derivatives, have been investigated far less extensively, although the synthesis and the structure of DME complexes of LiAsH$_2$ have been published[7,8] and have led to a moderate development of arsanide chemistry. The huge preference for phosphorus chemistry stems from the NMR-sensitive ^{31}P nucleus, which allows a spectroscopic follow-up of reactions prior to isolation of new compounds. Furthermore, the comparable van der Waals radii of phosphorus (1.85 Å) and arsenic (1.9 Å) due to the contraction of the d-block elements suggest a similar chemical behaviour of homologous compounds, whereas nitrogen (1.55 Å) and antimony (2.2 Å) differ more drastically. In addition, the structures of silylated amines also show planar-coordinated and sp^2-hybridized nitrogen atoms, whereas the heavy pnicogen atoms in silylated phosphanes, arsanes and stibanes display a pyramidal environment and avoid hybridisation.[5]

After the first synthesis of [LiAs(SiMe$_3$)$_2$] by Becker and co-workers 25 years ago,[9] the crystal structures of the DME[10] and THF adducts[11] were reported. The growing interest in these compounds, for example as precursors for element III/V semiconductors, finally led to the publication of slightly modified and improved preparation procedures.[12,13] Modifications of the substitution pattern of tris(triorganylsilyl)arsanes were also investigated.[14] Whereas the reaction of E(SiMe$_3$)$_3$ with an alkyllithium yields [LiE(SiMe$_3$)$_2$] (E = P, As, Sb), the monosubstituted trimethylsilylated phosphanes undergo redistribution reactions with the formation of a mixture of LiPH$_2$, [LiP(H)SiMe$_3$] and [LiP(SiMe$_3$)$_2$].[15] In order to prevent these redistribution reactions larger groups such as Si*i*Pr$_3$ and Si*t*Bu$_3$ have to be employed, and even the bulkiness of the triisopropylsilyl substituents enforces an almost planar environment at the pnicogen atoms in E(Si*i*Pr$_3$)$_3$ (E = P, As, Sb).[16]

The synthesis of H$_2$AsSi*i*Pr$_3$ succeeded smoothly by the reaction of [(dme)LiAsH$_2$][7] with chlorotriisopropylsilane.[17] Metallation reactions led to the formation of triisopropylsilylarsanediides, which can be part of a cluster[18] or trapped between two metal fragments.[17] Monometallated triisopropylsilylarsanes have been published for the alkaline-earth metals;[19] however, there are no detailed investigations on the key compounds [(L)$_n$LiAs(H)SiR$_3$] with bulky trialkylsilyl substituents. There are only sporadic investigations on lithiated easily accessible primary arsanes, even though reports on [LiAs(H)R] were published as far back as 1964/65 (R = *t*Bu)[20] and 1977 (R = Ph).[21] The helical structure of [(THF)$_2$LiAs(H)Ph]$_\infty$ was determined more than two decades later.[22]

Results and Discussion

Synthesis and NMR Spectroscopy

Whereas the metallation of tri(*tert*-butyl)silylphosphane has already been reported,[23] there are no reports on the homologous arsane. The metathesis reaction of [(dme)LiAsH$_2$] with tBu$_3$SiO$_3$SCF$_3$ in DME yields tri(*tert*-butyl)silylarsane (**1**) and lithium trifluoromethanesulfonate in large quantities according to Equation (1). This primary arsane shows no tendency to undergo dismutation or redistribution reactions. The AsH$_2$ moiety is clearly detected by the symmetric and asymmetric stretching vibrations at 2100 and 2091 cm^{-1} in the IR spectrum.

$$(\text{dme})\text{LiAsH}_2 + \text{F}_3\text{C}-\overset{\overset{\text{O}}{\|}}{\underset{\underset{\text{O}}{\|}}{\text{S}}}-\text{OSi}t\text{Bu}_3 \xrightarrow[-\text{DME}]{-\text{LiO}_3\text{S-CF}_3} t\text{Bu}_3\text{Si-AsH}_2 \quad \mathbf{1} \qquad (1)$$

The stoichiometric metallation of H$_2$AsSitBu$_3$ with alkyllithium leads to the monolithiated arsanides according to Equation (2). The solvent determines which solvate is formed during the metallation reaction. These complexes are very sensitive to moisture and air.

$$\text{H}_2\text{As-Si}t\text{Bu}_3 + n\text{BuLi} \xrightarrow[-n\text{BuH}]{\text{L}} [(\text{L})\text{LiAs(H)Si}t\text{Bu}_3] \quad \text{L = DME (}\mathbf{2}\text{), THF (}\mathbf{3}\text{)} \qquad (2)$$

The deprotonation (lithiation) shifts the As–H stretching vibrations to lower energies. These frequencies, as well as the NMR parameters, are listed in Table 1. Several general trends can be deduced from the NMR spectroscopic parameters dependent on the pnicogen atom and the substitution of hydrogen by a lithium atom (higher negative charge on the pnicogen atom). The heavier pnicogen atom causes the E–H vibration to lie at lower wavenumbers and the ^{1}H NMR resonance at higher field. Furthermore, the ^{29}Si{^{1}H} NMR shift is observed at lower field for the arsenic derivatives. Similar trends are observed for the substitution of an H atom by a lithium atom: the trialkylsilylphosphanides and -arsanides show lower E–H stretching energies, a high-field shift of the proton in the NMR spectra, and a low-field shift for the silicon nuclei. The substitution of the triisopropylsilyl groups by the bulkier tri(*tert*-butyl)silyl substituents leads to larger δ values of the silicon nucleus.

Molecular Structures

The tetracoordinate pnicogen atoms in the lithium tri(*tert*-butyl)silylarsanides discussed above are bonded to a silicon, a hydrogen and two lithium atoms. The structure of the DME adduct is shown in Figure 1. The central structural motif is a four-membered Li$_2$As$_2$ cycle with an alkali metal in a distorted tetrahedral environment.

Table 1. Spectroscopic properties of H$_2$AsSitBu$_3$ (**1**) and the lithium tri(*tert*-butyl)silylarsanides of the type [(L)LiAs(H)SiR$_3$] [L = DME (**2**), THF (**3**)]. For comparison reasons the values of the homologous phosphorus derivatives H$_2$PSitBu$_3$ (**A**) and [(dme)LiP(H)SitBu$_3$]$_2$ (**B**) are also included.

	A	**B**	**1**	**2**	**3**

[a] $^1J_{P,H}$ = 185.6 Hz; $\delta_{^{31}P}$ = –263.8 ppm. [b] $^1J_{P,H}$ = 165.9 Hz; $\delta_{^{31}P}$ = –322.2 ppm.

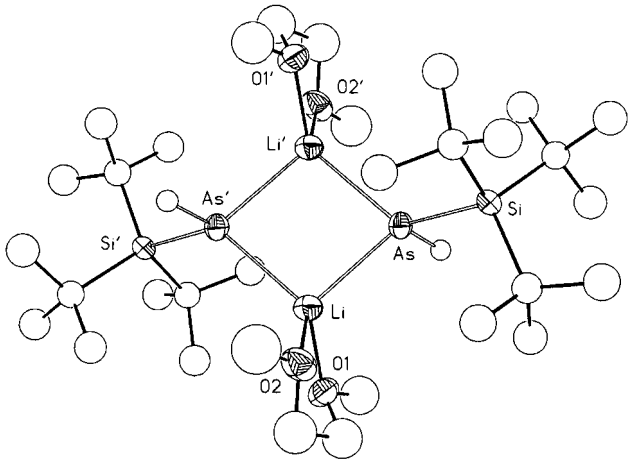

Figure 1. Molecular structure of **2**. The hydrogen atoms have been omitted for clarity, with the exception of the arsenic-bound H atom. Symmetry-related atoms (x, $-y$ + 1, $-z$ + 1) are marked with an apostrophe. Selected bond lengths [pm]: As–Li 260.9(3), As–Li′ 259.7(3), As–Si 231.49(5), As–H 154(2), Li–O1 201.0(4), Li–O2 197.2(4), Si–C1 194.6(2), Si–C5 194.9(2), Si–C9 195.3(2); angles [°]: Si–As–Li 122.61(8), Si–As–Li′ 123.90(8), Li–As–Li′ 85.2(1), Si–As–H 96(1), Li–As–H 111(1), Li′–As–H 120(1), As–Li–As′ 94.8(1).

The THF complex **3** crystallises as an infinite polymeric strand. Part of the chain is represented in Figure 2. Although the four-membered Li$_2$E$_2$ cycle (E = P, As), which can annelate into ladder-type structures, is the main structural feature, infinite chains of alternating lithium and pnicogen atoms have also been observed for [(dme)LiPH$_2$]$_\infty$[25,26] and [(THF)$_2$LiAs(H)Ph]$_\infty$.[22]

Selected structural parameters of the ether complexes of lithium tri(*tert*-butyl)silylarsanide are listed in Table 2 together with those of other phosphanides and arsanides of lithium. Bis(triisotriisopropylsilyl)phosphane[27] and tris(triisopropylsilyl)phosphane and -arsane[16] are included for comparison reasons as well. The anionic charge on the pnicogen atom leads to a shortening of the E–Si bond of approximately 6 pm due to an additional electrostatic attraction between the pnicogen and the silicon atoms. The Li–E distances are scattered widely between 247 and 262 pm for the phosphanides and between 258 and 273 pm for the arsanides. These values depend on the coordination

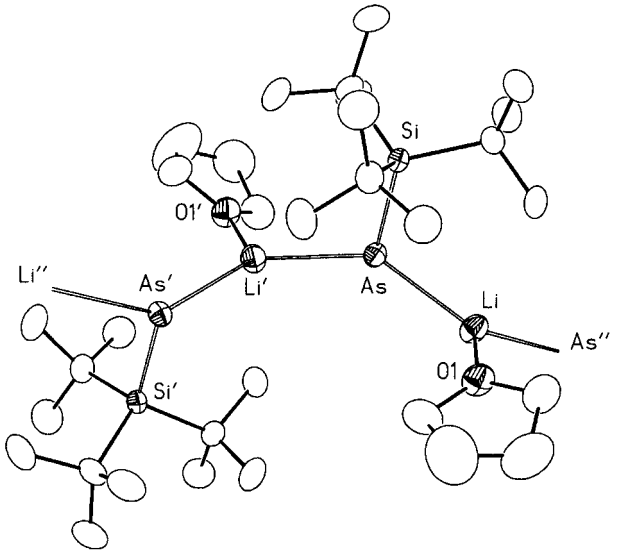

Figure 2. Structure model of **3**. All hydrogen atoms have been omitted for clarity. Symmetry-related atoms are marked with one (x + 1, y – 1/2, $–z$ + 1/2) or two apostrophes (x + 1, y + 1/2, $–z$ + 1/2). Selected bond lengths [pm]: As–Si 233.83(6), As–Li 258.1(4), As–Li′ 260.8(4), Li–O1 190.4(4), Si–C1 194.9(2), Si–C2 195.3(2), Si–C3 194.8(2); angles [°]: Si–As–Li 104.9(1), Si–As–Li′ 107.8(1), Li–As–Li′ 141.81(4), As–Li–As″ 128.4(1).

numbers of the alkali metal and the pnicogen atoms. Thus, the smallest Li–P bond lengths were observed for a phosphanide with a two-coordinate lithium atom and the shortest Li–As bonds were found for arsanides with three-coordinate alkali metals. Intramolecular steric repulsion leads to an enhancement of these bonds. The Li–O distances follow a similar pattern: triply coordinated lithium atoms show smaller distances, whereas a coordination number of four leads to an elongation of this bond. Furthermore, monodentate ethers display shorter Li–E bonds than the bidentate 1,2-dimethoxyethane ligand.

The smallest angle is observed at the alkali metal atom in four-membered Li_2E_2 ring systems. This fact is a consequence of repulsive forces between the large pnicogen atoms. If the four-membered cycle is opened to a one-dimensional strand, Li–E–Li′ angles of more than 140° are realized, whereas in polymeric $[(dme)LiPH_2]_\infty$ a nearly linear Li–P–Li′ fragment is found. A linear E–Li–E′ moiety is never found because additional agostic interactions enhance the coordination number, especially of the low-coordinate alkali metal atoms.

Summary

Lithiated primary arsanes do not undergo redistribution reactions if large trialkylsilyl groups are bonded at the arsenic atom. The bidentate 1,2-dimethoxyethane ligand leads to a dimeric molecule whereas the smaller and monodentate tetrahydrofuran molecule favours the crystallisation of a one-dimensional coordination polymer. These compounds are valuable synthons for arsenide-transfer reactions and further deprotonation reactions (formation of arsanedides).

Experimental Section

General: All experiments and manipulations were carried out under an atmosphere of argon. Reactions were performed by using standard Schlenk techniques and in dried and thoroughly deoxygenated solvents. $[(dme)LiAsH_2]$[7] as a DME solution and F_3CSO_3Si-tBu$_3$[24] were prepared according to a literature procedure. The NMR spectroscopic data were obtained at room temperature from [D$_6$]benzene solutions. For the IR spectra the crystalline compounds were dissolved in Nujol and measured between CsBr windows.

***t*Bu$_3$SiAsH$_2$ (1):** A solution of $[(dme)LiAsH_2]$ (80.0 mmol) in 100 mL of 1,2-dimethoxyethane was cooled to –50 °C. Then,

$F_3CSO_3SitBu_3$ (13.9 g, 40.0 mmol) dissolved in 25 mL of DME was added dropwise. After complete addition the reaction solution was heated to reflux for 5 h. Thereafter all volatile materials were removed in vacuo at room temp. and the residue redissolved in 100 mL of *n*-pentane. This solution was decanted from the precipitate. After removal of the solvent 8.84 g of tri(*tert*-butyl)silylarsane (**1**; 32.0 mmol, 80%) remained as a slightly yellow solid which was very sensitive towards moisture and air. M.p. 207 °C. ^1H NMR: δ = 1.10 ($SitBu_3$), 1.15 (AsH_2) ppm. $^{13}C\{^1H\}$ NMR: δ = 23.4 (SiC), 30.6 ($SiCMe_3$) ppm. $^{29}Si\{^1H\}$ NMR: δ = 31.20 ($SitBu_3$) ppm. IR: $\tilde{\nu}$ = 2292 cm^{-1} w, 2177 w, 2100 vs, 2091 vs, 1478 vs, 1441 w, 1423 w, 1390 vs, 1366 s, 1260 w, 1189 w, 1178 w, 1096 w, 1049 w, 1013 s, 956 m, 932 m, 913 w, 816 vs, 745 w, 695 vw, 648 m w, 624 s, 609 m, 587 m, 565 s, 495 vs, 450 s, 407 w, 378 w. $C_{12}H_{29}AsSi$ (276.37): calcd. C 52.15, H 10.58; found C 51.07, H 10.59.

[(dme)LiAs(H)Si*t*Bu$_3$] (2): Tri(*tert*-butyl)silylarsane (**1**; 0.42 g, 1.5 mmol) was dissolved in 10 mL of DME at –78 °C. Then, 1.5 mmol of *n*-butyllithium in hexane (0.6 ml of 2.5 M solution) was added dropwise. Whilst warming to room temp. the solution turned yellow. All volatile materials were removed at room temp. in vacuo and the residue was extracted with pentane. From this solution 0.44 g of **2** (0.6 mmol, 78%) precipitated at 0 °C in the shape of slightly blue prisms; decomp. above 135 °C. ^1H NMR: δ = –2.83 (LiAsH), 1.42 ($SitBu_3$), 3.11 (DME), 3.25 (DME) ppm. $^7Li\{^1H\}$ NMR: δ = 3.9 ppm. $^{13}C\{^1H\}$ NMR: δ = 24.1 (SiC), 32.2 ($SiCMe_3$), 58.5 (DME), 71.6 (DME) ppm. $^{29}Si\{^1H\}$ NMR: δ = 39.2 ($SitBu_3$) ppm. IR: $\tilde{\nu}$ = 2065 cm^{-1} vs, 1478 vs, 1444 m, 1407 vw, 1390 s, 1366 m, 1354 w, 1271 s, 1262 s, 1242 m, 1192 s, 1180 s, 1162 m, 1123 vs, 1107 vs, 1086 vs, 1046 s, 1032 s, 1014 vs, 956 w, 932 m, 869 s, 838 m, 814 vs, 644 m, 623 m, 592 s, 564 s, 539 m, 497 vs, 451 s, 410 m, 380 m, 354 w, 347 w, 343 w, 331 w, 325 w, 300 w. $C_{32}H_{76}As_2Li_2O_4Si_2$ (744.85): calcd. C 51.60, H 10.28; found C 51.03, H 10.28.

[(THF)LiAs(H)Si*t*Bu$_3$] (3): A 2.5 M solution of *n*-butyllithium in hexane (15 mL) was added dropwise to a solution of tri(*tert*-butyl)silylarsane (**1**; 0.58 g, 2.1 mmol) in 15 mL of THF at 0 °C. Whilst warming up to room temp. the solution turned greenish. Recrystallisation from benzene gave **3** (0.53 g, 1.5 mmol, 71%) as colourless prisms; decomp. above 127 °C. ^1H NMR: δ = –2.48 (LiAsH), 1.39 (THF), 1.47 ($SitBu_3$), 3.66 (THF) ppm. $^7Li\{^1H\}$ NMR: δ = 4.9 ppm. $^{13}C\{^1H\}$ NMR: δ = 23.9 (SiC), 25.2 (THF), 32.0 ($SiCMe_3$), 68.4 (THF) ppm. $^{29}Si\{^1H\}$ NMR: δ = 38.2 ($SitBu_3$) ppm. IR: $\tilde{\nu}$ = 2042 cm^{-1} s, 1495 w, 1477 s, 1444 m, 1388 m, 1381 s, 1359 m, 1354 m, 1316 w, 1293 vw, 1261 vw, 1246 vw, 1193 m, 1184 m, 1049 s, 1013 s, 973 m, 932 m, 917 m, 892 m, 817 vs, 729 s, 695 m, 673 w, 636 w, 621 m, 593 s, 563 s, 497 vs, 463 s, 454 s, 410 s, 393 s, 386 s, 348 m, 320 m, 308 m, 299 w. $C_{16}H_{36}AsLiOSi$ (354.40): calcd. C 54.22, H 10.24; found C 53.71, H 9.93.

Crystal Structure Determinations of 2 and 3: The data sets were collected on a STOE-IPDS diffractometer (operating at –73 °C) with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) using oil-coated, rapidly cooled single crystals.[34] Crystallographic parameters, details of data collection and refinement procedures are summarised in Table 3. The structures were solved by direct methods with the program SIR97[35] and refined with the software packages SHELXL-93 and SHELXL-97.[36] Neutral scattering factors were taken from Cromer and Mann[37] and for the hydrogen atoms from Stewart et al.[38] The hydrogen atoms were considered with a riding model under the restriction of ideal tetrahedral symmetry at the corresponding carbon atoms. The arsenic-bound H atoms were taken from the residual electron density maps and refined isotropically.

CCDC-269668 (for **2**) and -269669 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Aerosol-Assisted Chemical Vapor Deposition of NbS_2 and TaS_2 Thin Films from Pentakis(dimethylamido)metal Complexes and 2-Methylpropanethiol

Emily S. Peters,[a] Claire J. Carmalt,*[a] Ivan P. Parkin,[a] and Derek A. Tocher[a]

Keywords: Niobium disulfide / Tantalum sulfide / Thin film / Aerosol-assisted CVD

Thin films of NbS_2 and TaS_2 have been produced from $[M(NMe_2)_5]$ (M = Nb, Ta) and *t*BuSH by aerosol-assisted chemical vapor deposition on glass. Gold-colored, reflective films were obtained and deposition took place at 250–350 °C for NbS_2 and 225–450 °C for TaS_2 using dichloromethane or hexanes as solvent. The niobium and tantalum sulfide films were analyzed by Raman spectroscopy, scanning electron microscopy (SEM), X-ray powder diffraction, energy dispersive analysis of X-rays (EDAX) and X-ray photoelectron spectroscopy (XPS). In order to identify possible compounds present in the aerosol mist, the solution phase reaction of $[M(NMe_2)_5]$ and five equivalents of *t*BuSH in toluene at room temperature was carried out. Yellow crystals of the partially substituted tantalum thiolate $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ were isolated. The X-ray structure of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ has been determined.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

The layered transition-metal dichalcogenides, which include tantalum disulfide and niobium disulfide, exhibit a number of interesting properties as a result of their structure. Thus, the layered structure has resulted in transition-metal dichalcogenides having diverse applications, such as high-temperature lubricants, catalysts and also in photovoltaic cells.[1–3] Tantalum disulfide in particular has been tested for use in lithium ion batteries, while NbS_2 has been shown to be an effective humidity sensor, in addition to uses as a catalyst in hydrotreating petroleum cuts.[4–9] These applications require a high surface area for optimum performance suggesting that thin film formation would be favorable. However, there are only limited reports of thin film formation of either NbS_2 or TaS_2.[3,10–15]

Physical deposition of NbS_2 films has been achieved by dipping the substrate into a NbS_2 powder layer, lying at the interface between water and an organic solvent.[5,10] This produced films with the basal planes parallel to the substrate's surface. Chemical vapor deposition (CVD) from single-source precursors of the form $[NbCl_4(S_2R_2)_2][NbCl_6]$ [R = CH_3 or $CH(CH_3)_2$] produced mixed NbS_2/Nb_2O_5 films.[11] However, the films formed were very thin (≤1000 Å) due to insufficient volatility of the precursors. Niobium monosulfide (NbS) films were deposited by low-pressure CVD from the homoleptic niobium thiolate $[Nb(SC_6H_3Me_2\text{-}2,6)_5]$.[12] We have recently reported the formation of NbS_2 films by atmospheric pressure CVD from the reaction of $NbCl_5$ with a range of sulfur precursors.[13] It was found that reaction of $NbCl_5$ with sulfides $[S(SiMe_3)_2$ or $tBu_2S_2]$ produced a new 1T-NbS_2 polytype. Conversely, reaction of $NbCl_5$ with thiols [*t*BuSH or $HS(CH_2)_2SH$] produced the known 3R-NbS_2 polytype. Reports of TaS_2 films have been limited to physical deposition routes.[14,15]

To the best of our knowledge, this paper represents the first thin film growth of TaS_2 by CVD and a novel aerosol-assisted (AA)CVD route to MS_2 (M = Nb, Ta) from $[M(NMe_2)_5]$ and *t*BuSH. Different and unique morphologies of films can be obtained by AACVD due to the influence of the solvent on the deposition, which could potentially lead to improved properties. Furthermore, thin films can be deposited under AACVD conditions at low temperatures and require only minimal amounts of precursor (ca. 0.1 g). In this study, niobium and tantalum thiolates were generated in situ from the reaction of $[M(NMe_2)_5]$ and *t*BuSH in hexanes or dichloromethane. An aerosol of this reaction mixture was then passed over a heated glass substrate, which resulted in the deposition of thin films of niobium and tantalum sulfide. The synthesis and crystal structure of the tantalum thiolate precursor $[Ta(S\text{-}tBu)_2(NMe_2)_3]$, prepared from the solution phase reaction of $[Ta(NMe_2)_5]$ and *t*BuSH, is also reported. Previous reports of the reaction of transition-metal amides with thiols suggest that complete substitution of the amide ligands is not achieved.[16,17] For example, the reaction of $[Ta(NMe_2)_5]$ with an excess of 2,6-dimethylthiophenol resulted in the substitution of four thiolate ligands forming $[Ta(SC_6H_3Me_2\text{-}2,6)_4(NMe_2)]$.[17]

Results and Discussion

Aerosol-Assisted Chemical Vapor Deposition

Gold-colored, reflective films have been deposited on glass from the dual-source AACVD reaction of

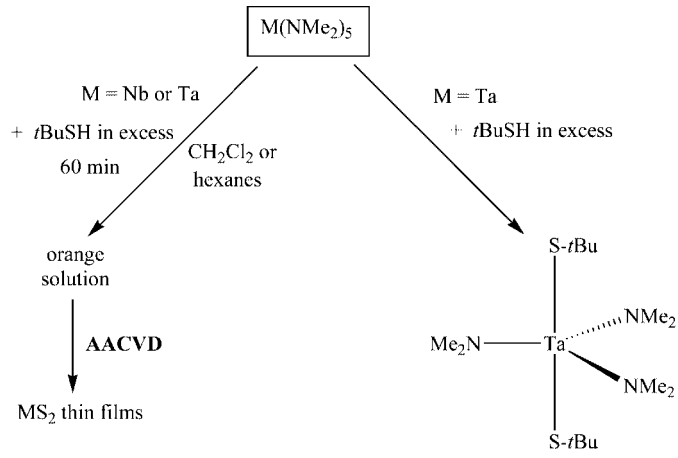

Scheme 1.

$[M(NMe_2)_5]$ (M = Nb, Ta) and *t*BuSH (Scheme 1). The reaction of $[M(NMe_2)_5]$ (M = Nb, Ta) and excess *t*BuSH in hexanes or dichloromethane was assumed to generate in situ the homoleptic metal thiolate, $[M(S\text{-}tBu)_5]$. However, solution phase studies (vida supra) indicate that this reaction could be incomplete and the bubbler would probably comprise of a mixture of $[M(S\text{-}tBu)_x(NMe_2)_{5-x}]$ (x = 0–5). Deposition was observed on both the top plate and the substrate due to larger particles formed by gas phase nucleation being unable to diffuse through the boundary layer at the substrate surface. However, the films deposited on the top plate correspond to those on the substrate but at a lower (50–75 °C) temperature (as measured). Niobium sulfide films were deposited between 250 and 350 °C and tantalum sulfide films were deposited between 225 and 450 °C (Table 1). The films deposited at the higher temperatures were localized towards the front of the substrate, which is an effect of fast film-growth kinetics. As the temperature was reduced complete substrate coverage was achieved. The gold color of the films is consistent with NbS_2 films grown by dual-source CVD routes at atmospheric pressure.[13] The films were adherent to the substrate, passing the Scotch Tape test. However, they were readily scratched by a brass or stainless steel stylus. The films remained unchanged after immersion in toluene, dichloromethane, THF, ether or acetonitrile for 1 month. The tantalum sulfide films were also unchanged by immersion in HCl for 1 month although the niobium sulfide films dissolved after one day. However, the niobium and tantalum sulfide films dissolved within minutes on immersion in HNO_3.

The reflectance and transmission spectra indicated that the gold-colored niobium sulfide films had good reflectance and minimal transmission (approx. 5%) in the region 400–1000 nm. The reflectance was fairly low in the visible region (approx. 15–20%) but increased to approx. 35% in the IR region. Four-point probe measurements suggest that the niobium sulfide films are metallic conductors at room temperature, as expected. Accurate readings could not be obtained as the films were scratched by the probe causing the reading to fluctuate. The tantalum sulfide films did not transmit at any wavelength and had a low reflectance (max. 15%).

Table 1. Deposition conditions and analysis of the films grown from the AACVD of $[M(NMe_2)_5]$ (M = Nb, Ta) and *t*BuSH.

Precursors	T [°C]	Solvent	EDXA
$Nb(NMe_2)_5$/*t*BuSH	350	dichloromethane	$NbS_{2.0}$
$Nb(NMe_2)_5$/*t*BuSH	300	dichloromethane	$NbS_{1.9}$
$Nb(NMe_2)_5$/*t*BuSH	250	dichloromethane	$NbS_{1.8}$
$Nb(NMe_2)_5$/*t*BuSH	300	hexanes	$NbS_{1.9}$
$Nb(NMe_2)_5$/*t*BuSH	250	hexanes	$NbS_{1.6}$
$Ta(NMe_2)_5$/*t*BuSH	450	dichloromethane	$TaS_{2.1}$
$Ta(NMe_2)_5$/*t*BuSH	350	dichloromethane	$TaS_{1.6}$
$Ta(NMe_2)_5$/*t*BuSH	450	hexanes	$TaS_{2.0}$
$Ta(NMe_2)_5$/*t*BuSH	400	hexanes	$TaS_{2.1}$
$Ta(NMe_2)_5$/*t*BuSH	350	hexanes	$TaS_{1.9}$
$Ta(NMe_2)_5$/*t*BuSH	300	hexanes	$TaS_{2.1}$
$Ta(NMe_2)_5$/*t*BuSH	250	hexanes	$TaS_{2.1}$
$Ta(NMe_2)_5$/*t*BuSH	225	hexanes	$TaS_{2.0}$

The niobium and tantalum sulfide films were characterized using a range of techniques. EDAX analysis shows the films are homogeneous and have a metal to sulfur ratio close to 1:2 over a number of spots (Table 2). The deviations from the MS_2 stoichiometry occurred primarily for the films deposited at lower temperatures, which were thinner meaning that a significant amount of the underlying glass was incorporated in the quantification. XPS of the niobium peaks in the NbS_2 films show that there is a single niobium environment with binding energies of 207.9 and 210.7 eV for $3d_{5/2}$ and $3d_{3/2}$, respectively. This matches well with the previously reported $3d_{5/2}$ value of 207.7 eV for bulk NbS_2.[19] However, ca. 2 atom-% nitrogen contamination was found by XPS in the films suggesting that complete reaction of the niobium amide with thiol to afford the homoleptic niobium thiolate had not occurred. Carbon and oxygen were found on the surface of the films by XPS, but these were removed by sputtering to leave the bulk of the film consisting of niobium and sulfur. The XPS of the tantalum in the TaS_2 films gave peaks at 23.5 and 25.4 eV corresponding to Ta $4f_{7/2}$ and $4f_{5/2}$ (Figure 1), which match well with published values for TaS_2 ($4f_{7/2}$, 23.8 eV; $4f_{5/2}$,

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

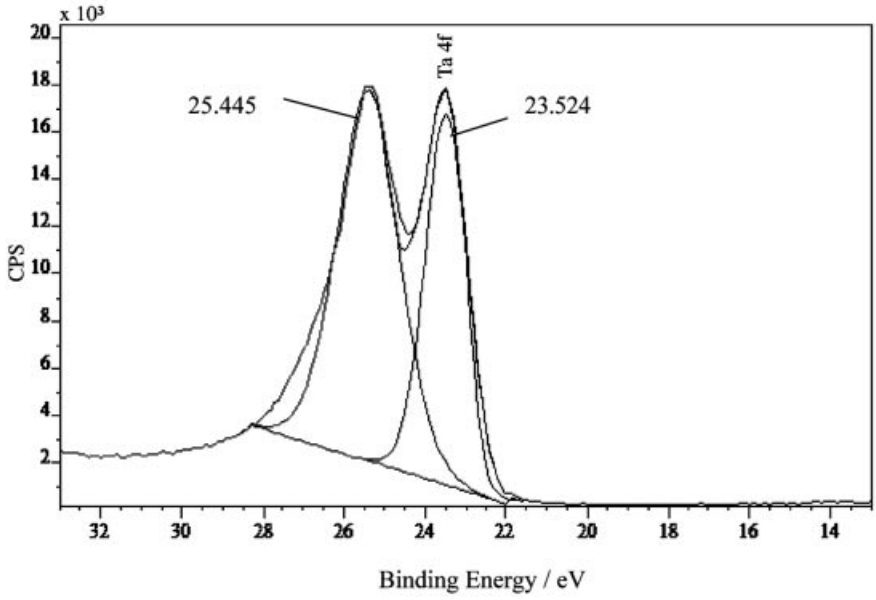

Figure 1. XPS of the Ta 4f peaks from a film deposited by AACVD from the in situ reaction of $[Ta(NMe_2)_5]$ and *t*BuSH at 450 °C.

25.7 eV).[20] Again, carbon and oxygen were found on the surface of the films by XPS but these were removed by sputtering to leave the bulk of the film comprised of tantalum and sulfur. The XPS of the TaS_2 films shows that there is also only one sulfur environment present with binding energies of 161.3 and 162.5 eV, corresponding to S $2p_{3/2}$ and $2p_{1/2}$, respectively.

All the films deposited were amorphous to X-rays even at the highest deposition temperatures. In comparison, NbS_2 films grown at 350–600 °C by atmospheric-pressure CVD from $NbCl_5$ and *t*BuSH were nanocrystalline; films deposited below 350 °C were amorphous.[13] The Raman pattern obtained for the NbS_2 films formed in this study (AACVD of $[Nb(NMe_2)_5]$/*t*BuSH) had a series of poorly separated peaks between 191 and 320 cm^{-1}, in addition to a peak at 543 cm^{-1} (Figure 2). The pattern is similar to that reported previously for 2H-NbS_2.[21] The Raman pattern obtained for the TaS_2 films had a large peak between 233 and 301 cm^{-1} and a second broad peak at 365 cm^{-1}. This Raman pattern does not correspond with any reported for TaS_2. However, the Raman pattern is similar to that obtained for 3R-NbS_2, suggesting that the 3R-TaS_2 polytype has been formed. Furthermore, Raman spectroscopy of the niobium and tantalum disulfide films indicated the absence of graphitic carbon in the films despite the use of a carbon-containing solvent being used to create the aerosol.

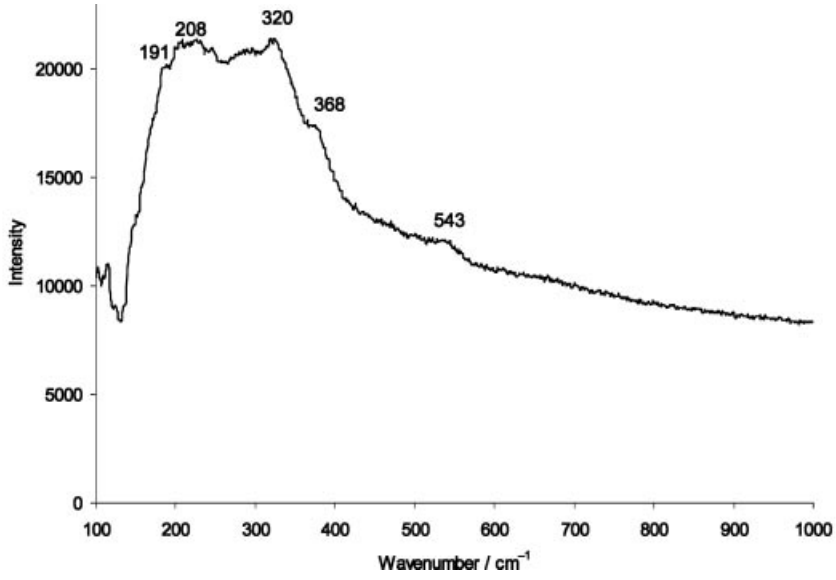

Figure 2. Raman pattern obtained for the film formed on glass from the AACVD reaction of $[Nb(NMe_2)_5]$ and *t*BuSH in dichloromethane at 300 °C.

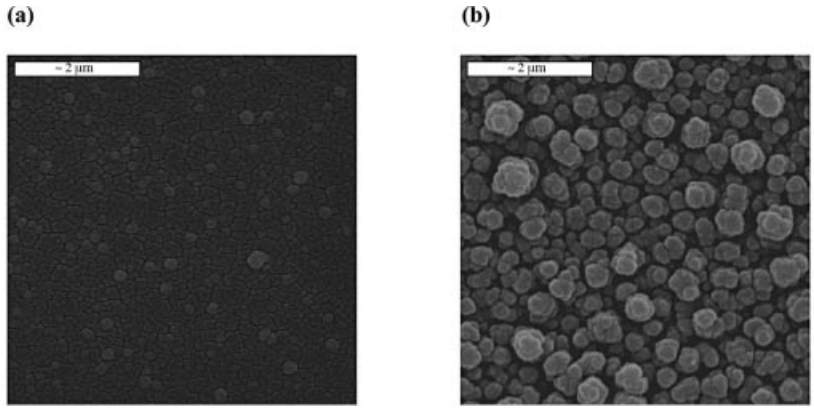

Figure 3. SEM images for films deposited by AACVD from the in situ reaction of $[Nb(NMe_2)_5]$ and *t*BuSH (**a**) in hexanes at 250 °C and (**b**) in dichloromethane at 350 °C.

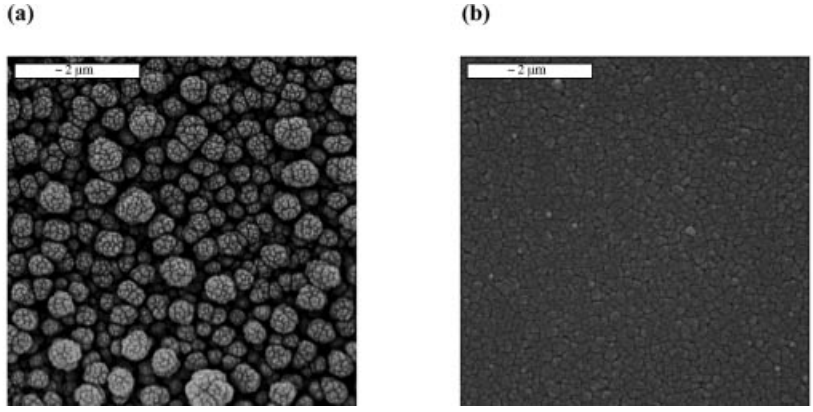

Figure 4. SEM images for films deposited by AACVD at 350 °C from the in situ reaction of $[Ta(NMe_2)_5]$ and *t*BuSH in (**a**) hexanes and (**b**) dichloromethane.

The film morphology was studied using SEM, which showed that the NbS_2 and TaS_2 films grew by an island growth-type mechanism. Individual clusters are clearly visible in the NbS_2 images with cluster size of 0.6 μm and 0.4 μm for films deposited from dichloromethane and hexanes, respectively (Figure 3). The NbS_2 films deposited from hexanes were more uniform than when dichloromethane was used as the solvent. However, the reverse was observed for TaS_2, with films deposited from dichloromethane being more uniform with clusters of 0.4 μm in diameter in comparison with those using hexanes, which had a diameter of 0.8 μm (Figure 4).

The successful formation of NbS_2 and TaS_2 thin films from the in situ AACVD reaction of $[M(NMe_2)_5]$ and *t*BuSH indicates that there is no need to prepare, isolate and purify a metal thiolate single-source precursor, such as $[M(S\text{-}tBu)_5]$. The use of excess *t*BuSH in the AACVD reactions resulted in little oxygen contamination and pre-treating the coater led to more adherent and uniform films. The mechanism for the deposition process was not investigated. However, the decomposition of $[Ti(S\text{-}tBu)_4]$ to TiS_2 has been described previously, and it is likely that the formation of MS_2 (M = Nb, Ta) films described herein would follow a similar mechanism.[22] Thus, the byproducts formed during the deposition of TiS_2 from $[Ti(S\text{-}tBu)_4]$ were principally isobutylene and *tert*-butyl thioalcohol, along with smaller amounts of isobutene, di-*tert*-butyl disulfide, H_2S and di-*tert*-butyl sulfide. The formation of these byproducts was thought to be the result of both β-hydrogen abstraction and a proton-transfer mechanism.[22] In the absence of a sulfur precursor, $[M(NMe_2)_5]$ produces amorphous metal carbonitride coatings.[23] Therefore, the decomposition of $[M(NMe_2)_5]$ can be considered to be the baseline in terms of the coating produced. The reaction of *t*BuSH with $[M(NMe_2)_5]$ results in facile elimination of Me_2NH either via gas phase or surface reactions, due to the presence of the acidic hydrogen in *tert*-butyl thiol. Notably the coatings produced from these reactions contained minimal nitrogen incorporation and even at low substrate temperatures formed MS_2 films with no MN_xC_y incorporation. We attribute this to the fact that the decomposition of $[M(NMe_2)_5]$ is slower than its reaction with *tert*-butyl thiol.

Synthesis

In order to gain an insight into compounds present in the aerosol mist of the AACVD reactions described above, the reaction of $[Ta(NMe_2)_5]$ with five equivalents of *t*BuSH was carried out in toluene at room temperature. An immediate color change from pale yellow to bright orange occurred. After work-up a dark orange oil resulted, which

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

produced large yellow crystals, on cooling a concentrated dichloromethane solution to –20 °C, in a 47% yield. $^1H/^{13}C$ NMR spectroscopic data obtained from solutions of these crystals were consistent with the formation of the neutral species $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ (Scheme 1). The structure of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ was confirmed by X-ray crystallography, the results of which are shown in Figure 5. Selected bond lengths and angles are detailed in Table 2. The structure of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ is monoclinic and crystallizes in the *C*2/*c* space group with the metal on a twofold axis. The tantalum centre in $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ adopts a distorted trigonal bipyramidal geometry with a S–Ta–S bond angle of 166°. Therefore, the two thiolate ligands take up axial positions, with the equatorial sites occupied by the three NMe_2 groups. The Ta–S bonds are 2.47 Å in length and are comparable to those in the reported tantalum thiolate $[Ta(S\text{–}2,6\text{-}Me_2C_6H_3)_4(NMe_2)]$ (2.39–2.43 Å).[17] Ta–N bonds lengths are in the range 1.94–1.97 Å and again compare well with those in $[Ta(S\text{-}2,6\text{-}Me_2C_6H_3)_4(NMe_2)]$ (1.92 Å). The formation of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ suggests that in the AACVD reaction a mixture of $[M(S\text{-}tBu)_x(NMe_2)_{5-x}]$ (x = 0–5) may be present. However, it is worth noting that a larger excess of thiol is present in the AACVD reaction and so the formation of the homoleptic metal thiolate is possible.

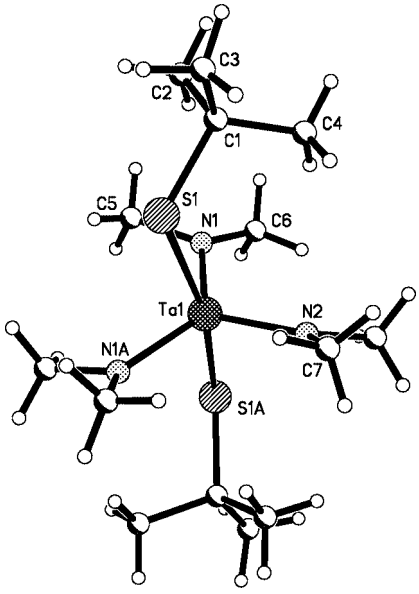

Figure 5. The molecular structure of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$.

Table 2. Selected bond lengths [Å] and angles [°] for $[Ta(S\text{-}tBu)_2(NMe_2)_3]$.

Ta(1)–N(2)	1.939(9)	Ta(1)–S(1)	2.4698(19)
Ta(1)–N(1)	1.968(7)		
N(2)–Ta(1)–N(1)	116.0(2)	N(1A)–Ta(1)–N(1)	128.1(4)
N(2)–Ta(1)–S(1)	96.88(5)	N(1A)–Ta(1)–S(1)	80.4(2)
N(1)–Ta(1)–S(1)	93.5(2)	S(1)–Ta(1)–S(1A)	166.24(10)

Further evidence for the formation of a mixture of complexes in the AACVD reaction was obtained from the reaction of $[Nb(NMe_2)_5]$ with five equivalents of *t*BuSH in toluene at room temperature. After work-up a red/brown oil resulted which was shown by ^1H and ^{13}C NMR to consist of a mixture of products. Thus, in the ^1H NMR of the red/brown oil a number of peaks were observed for each proton environment (*t*Bu, NMe_2) suggesting the formation of a mixture of products of the type $[Nb(S\text{-}tBu)_x(NMe_2)_{5-x}]$ (x = 0–5). The formation of $[Nb(S\text{-}tBu)_x(NMe_2)_{5-x}]$ is in agreement with previous reports of the reaction which suggest that complete substitution of the metal amide ligands by thiolate groups is not achieved.[16,17] Attempts to purify the red/brown oil by recrystallization and distillation were unsuccessful.

Conclusions

Thin films of NbS_2 and TaS_2 can be grown from $[M(NMe_2)_5]$ and *t*BuSH under AACVD conditions. This represents the first deposition of TaS_2 by CVD and the first AACVD formation of NbS_2 and TaS_2 films. Furthermore, the in situ reaction of $[M(NMe_2)_5]$ and *t*BuSH eliminates the need for the synthesis, isolation and purification of a single-source metal thiolate precursor. The solution phase reaction of $[Ta(NMe_2)_5]$ and *t*BuSH resulted in the isolation of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$, which has been structurally characterized. The formation of $[Ta(S\text{-}tBu)_2(NMe_2)_3]$ suggests that a mixture of species of the type $[M(S\text{-}tBu)_x(NMe_2)_{5-x}]$ may be present in the aerosol bubbler. However, due to the large excess of thiol present in the AACVD reactor, it is possible that the homoleptic metal thiolate forms in solution.

Experimental Section

Depositions were carried out under dinitrogen (99.99% from BOC). Precursors were placed in a round-bottomed glass bubbler and a mist was created using a PIFCO HEALTH ultrasonic humidifier (product no. 1077). The solvent mist was transported in a flow of cold nitrogen from the bubbler in an 8-mm gauge pipe to a mixing chamber and then to a horizontal bed, cold-wall reactor with a carbon-heating block containing two Whatman cartridge heaters. Aerosol droplet sizes were calculated to be 50–60 μm.[18] A top plate was suspended 0.5 cm above the glass substrate to ensure a laminar flow. Films were deposited on pieces of 150 mm × 47 mm × 4 mm SiCO-coated float glass (SiCO is a coating containing Si, O and C. It is an effective blocking layer that prevents diffusion of ions in the glass into the coating). The transition metal thiolate complex was generated in situ from the reaction of $[M(NMe_2)_5]$ with excess *t*BuSH (0.3 g $[M(NMe_2)_5]$, M = Ta (0.74 mmol), Nb (0.96 mmol), *t*BuSH 1.0 mL, 8.87 mmol) in solvent (80 mL). Pentakis(dimethylamido)tantalum $[Ta(NMe_2)_5]$ was supplied by Epichem Ltd. and used without further purification, $[Nb(NMe_2)_5]$ was prepared using literature procedures.[16] *t*BuSH was purchased from Aldrich, dried with molecular sieves and degassed. Excess thiol was used in order to minimize the risk of producing partially oxidized films. The reagents were left to react for 1 h prior to the start of each deposition. The *t*BuSH was placed in solvent (60 mL) and the coater was pre-treated with the thiol (1.0 mL) for 20 minutes prior to deposition. Depositions were carried out in either dichloromethane or hexanes at a flow rate of 1.0 $Lmin^{-1}$ over a range of substrate temperatures (225–450 °C).

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Dichloromethane was distilled from CaH_2 prior to use; hexanes and toluene were dried using sodium/benzophenone. The experiment was contained in a fume cupboard and the exhaust gases passed through three bleach bubblers. At the end of the deposition the bubbler line was closed and nitrogen was passed over the substrate. The glass substrate was cooled to ca. 60 °C before it was removed. The substrates were cut into ca. 4 cm × 1 cm strips for analysis by SEM, XPS, Raman and UV studies. 3 cm × 2 cm strips were used for X-ray diffraction. Film adherence to the glass was assessed using the Scotch tape test and by scratching the surface using brass and steel.

X-ray powder diffraction patterns were measured with a Siemens D5000 diffractometer using monochromated Cu-$K_{\alpha1}$ radiation (λ_1 = 1.5406 Å). The diffractometer used glancing incident radiation (1.5°). EDXA was obtained with a JOEL 35CF and SEM was obtained with a Hitachi S570 instrument using the KEVEX system. X-ray photoelectron spectra were recorded using a VG ESCALAB 220i XL instrument using focused (300 μm spot) monochromatic Al-K_α radiation at a pass energy of 20 eV. Scans were acquired with steps of 50 meV. A flood gun was used to control charging and the binding energies were referenced to an adventitious C 1s peak at 284.8 eV. Depth profile measurements were obtained by using argon beam sputtering. Reflectance and transmission spectra were recorded between 300 and 1200 nm by a Zeiss minature spectrometer. Reflectance measurements were standardized relative to a rhodium mirror and transmission relative to air. Raman spectra were acquired with a Renishaw Raman System 1000 using a helium-neon laser of wavelength 632.8 nm. The Raman system was calibrated against the emission lines of neon. NMR spectra were recorded with a Bruker AMX400 spectrometer at UCL, referenced to CD_2Cl_2, which was dried and degassed over molecular sieves prior to use. ^1H and ^{13}C chemical shifts are reported relative to $SiMe_4$ (δ, 0.00). Single-crystal X-ray data were collected with a Bruker SMART APEX CCD diffractometer.

AACVD Reaction of [Nb(NMe$_2$)$_5$] and *t*BuSH: *t*BuSH (1.0 mL, 8.87 mmol) was placed in 60 mL of solvent in the AACVD bubbler and used to pre-treat the reactor for 5 min before the addition of the niobium precursor. After pre-treating the reactor, [Nb(NMe$_2$)$_5$] (0.3 g, 0.96 mmol) in 15 mL of solvent was added to the bubbler. An orange solution formed immediately, and the mixture was reacted for 60 minutes before each deposition was started.

AACVD reaction of [Ta(NMe$_2$)$_5$] and *t*BuSH: The experimental procedure was the same as for the AACVD reaction of [Nb(NMe$_2$)$_5$] and *t*BuSH but [Ta(NMe$_2$)$_5$] (0.3 g, 0.74 mmol) was used in place of [Nb(NMe$_2$)$_5$].

Reaction of [Nb(NMe$_2$)$_5$] and *t*BuSH: 2-Methylpropanethiol (0.4 mL, 1.60 mmol) was added to a stirred solution of [Nb(NMe$_2$)$_5$] (0.2 g, 0.64 mmol) in toluene (30 mL). An immediate color change from pale orange to deep red occurred on addition of the thiol. Stirring was continued for 4 h and the solution was concentrated in vacuo to give a dark red/brown oil. ^1H NMR (CD_2Cl_2): δ = 1.2 [s, (CH_3)$_3$CS], 1.3 [s, (CH_3)$_3$CS], 1.4 [s, (CH_3)$_3$CS], 1.6 [s, (CH$_3$)$_3$CS*H*], 3.45 (s, N*Me*$_2$), 3.55 (s, N*Me*$_2$) ppm. $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 30.7 [(*C*H$_3$)$_3$CS], 31.7 [(*C*H$_3$)$_3$CS], 34.6 [(CH$_3$)$_3$CSH], 35.0 [(CH$_3$)$_3$*C*S], 35.7 [(*C*H$_3$)$_3$CS], 49.0 (s, N*Me*$_2$), 50.6 (s, N*Me*$_2$) ppm.

Synthesis of [Ta(S-*t*Bu)$_2$(NMe$_2$)$_3$]: 2-Methylpropanethiol (0.14 mL, 1.25 mmol) was added to a stirred solution of [Ta(NMe$_2$)$_5$] (0.1 g, 0.25 mmol) in toluene (20 mL). Stirring was continued for 16 h resulting in a dark orange solution. The solvent was removed in vacuo to give an orange-brown oil. This oil was redissolved in ca. 2 mL of hexanes and cooled to –20 °C. Large, rectangular, pale yellow crystals (0.06 g, 47%) suitable for X-ray analysis were formed. ^1H NMR (CD_2Cl_2): δ = 1.25 [s, 18 H, (CH_3)$_3$CS], 3.45 (s, 18 H, N*Me*$_2$) ppm. $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 36.0 [(*C*H$_3$)$_3$CS], 42.0 [(CH$_3$)$_3$*C*S], 47.3 (N*Me*$_2$) ppm. $C_{14}H_{36}N_3TaS_2$ (491): calcd. C 34.2, H 7.38, N 8.55; found C 34.1, H 7.5, N 8.1. M.p. 105 °C.

Caution: It should be noted that the AACVD reaction of [M(NMe$_2$)$_2$] (M = Nb, Ta) and *t*BuSH could conceivably produce H_2S. Care should be taken to conduct all experiments in a fume cupboard.

X-ray Crystallography: Crystals of [Ta(S-*t*Bu)$_2$(NMe$_2$)$_3$] were grown from hexanes at –20 °C. Yellow rectangular crystals 0.50 × 0.50 × 0.10 mm, M_r = 491.53, monoclinic, *C*2/*c*, *a* = 10.2460(14), *b* = 15.052(2), *c* = 13.2966(18) Å, β = 92.855(2)°, *V* = 2048.1(5) Å^3, ρ(calcd.) = 1.594 g cm^{-3}, *Z* = 4, Mo-K_α (λ = 0.71073 Å), 150 K, 7531 reflections measured, 2376 independent, μ(Mo-K_α) = 5.567 mm^{-1}, T_{max} –0.600, T_{min} = 0.1673, structure solved by direct methods (SHELXS) and refined on F^2 (SHELXL97), 98 parameters, all non-hydrogen atoms anisotropic, hydrogen atoms refined with riding model, R = 0.0578, wR_2 = 0.1376 (all data), R = 0.0551, wR_2 = 0.1353 [$I > 2\sigma(I)$], largest residual 3.6 e Å^3, close to the metal atom.

CCDC-256491 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

A Stable Trinuclear Zinc Cluster Assembled from a Thiazolylazo Dye and Zinc Acetate: Preparation, Structural Characterization and Spectroscopic Studies

Guoqi Zhang,[a] Shuangqing Wang,[a] Quan Gan,[a] Yongfang Zhang,[a] Guoqiang Yang,*[a] Jin Shi Ma,[a] and Huijun Xu[a]

Keywords: Azo compounds / Pi interactions / UV/Vis spectroscopy / Zinc

A thiazolylazo dye, 5-(diethylamino)-2-(2-thiazolylazo)phenol (H**L**), containing potential tridentate binding sites was synthesized in high yield and well characterized. In solution, the reaction of zinc acetate and the deprotonated ligand, $\mathbf{L}^-$, results in the instantaneous formation of the supramolecular trinuclear species $[Zn_3\mathbf{L}_2(OAc)_4]$ (**1**). UV/Vis and ^{1}H NMR spectroscopic titration experiments in solution confirmed that the ligand and zinc salt interact spontaneously with each other and produce exclusively the polymetallic complex with the metal-to-ligand ratio of 3:2. The crystal structures of both the ligand and coordination complex are reported in this paper. The aromatic part of H**L** is planar and, significantly, the intermolecular C–H···π hydrogen bonds and thiazo ring-S···π weak interactions observed here should be responsible for the orthorhombic space group $P2_12_12_1$. The structure of **1** reveals a linear trinuclear zinc cluster. The two $\mathbf{L}^-$ units are linked to three zinc atoms in an N_2O tridentate mode, and the four acetate anions are chelated to three metal centers as bridges to result in two pentacoordinate and one hexacoordinate zinc centers. The resulting bridging Zn1–Zn2–Zn1A array is linear by symmetry, with a nonbonding Zn···Zn distance of 3.390 Å and a Zn1···Zn2···Zn1A angle of 180.0°.

Introduction

Aromatic azo derivatives are widely used in the dyestuff industry, in analytical chemistry as acid-base, redox, and metallochromic indicators,[1,2] and also, more recently, in the field of optical data storage and nonlinear optics.[3,4] The structure of azo dyes has also attracted considerable attention over the years in view of their wide applicability as optical materials.[5,6] While numerous publications have focused on the industrial applications of azo dyes, the structural characterization and studies of the metal-chelating properties of substituted azo compounds remain sparse in the literature.[7–9]

Metal-chelating azo derivatives are considered to be some of the most promising optical materials.[8,9] Coordination of transition metals to aromatic azo dyes not only results in a rich variety of supramolecular structures, but also in a significant enhancement of their nonlinearity, both of which are potentially useful in a wide range of optical devices. Hence, it is greatly promising to develop new functionalized azo-metal chelates. Goswami and co-workers have systematically studied metal coordination compounds of one class of pyridine-containing phenylazo ligands.[10] Divalent transition metals such as Zn^{II}, Cd^{II}, Hg^{II}, Ni^{II}, Pd^{II}, and Pt^{II}, or trivalent metals like Cr^{III}, In^{III}, etc., have been widely used to coordinate to the azo ligands. Accordingly, mononuclear or binuclear metallized azo complexes were obtained depending on the different nature of the metal ions. Their crystal structures, reactivity, and optical properties have also been investigated in detail.[10]

Recently, we became interested in the investigation of a new class of azo derivative, namely 5-(diethylamino)-2-(2-thiazolylazo)phenol (H**L**), and its transition metal chelates (Scheme 1).[8] The azo compound H**L** has several coordination sites and displays versatile chelating properties toward transition metal ions. The spectroscopic properties and third-order nonlinearity of certain transition metal complexes of H**L** have been investigated very recently. These results showed that the third-order nonlinearity is remarkably enhanced and size-tunable in nanoparticles of a nickel(II) complex of H**L**.[8e]

Inspired by these interesting results on the nonlinearity and optical spectroscopic properties of this class of metallized thiazolylazo dyes as optical recording materials, we report here the synthetic procedure, solution properties, and structural characterization of the azo ligand H**L** and its zinc(II) complex. Both the ligand and complex display an ordered molecular arrangement in the solid state and significant intermolecular interactions are observed. The formation of the resultant trinuclear Zn^{II} cluster, as confirmed by both solution studies and X-ray diffraction analysis, is

Bridging multi-metallic coordination of $\mathbf{L}^-$

Scheme 1. The structure of the azo ligand and its bridging multimetallic binding mode.

the first example of an azo-based polymetallic cluster. Both compounds were characterized by microanalysis, TGA analysis, mass spectrometry, FT-IR, ^{1}H NMR, and UV/Vis spectroscopy, and single-crystal X-ray diffraction analysis.

Results and Discussion

Synthesis and Characterization

The thiazolylazo ligand **HL** was readily synthesized in high yield. The 2-aminothiazo precursor was diazotized with solid $NaNO_2$ in 85% phosphoric acid at 0–5 °C to give the diazonium salt, which was then added dropwise to the coupling component 3-diethylaminophenol in ethanol. After filtration, the azo dye was separated as a bright red solid. Block-like, deep-red crystals were obtained by slow evaporation of a MeOH/EtOH solution of the ligand. The azo dye is well soluble in common organic solvents like MeOH, EtOH, CH_2Cl_2, CH_3CN, THF, etc. It is a potentially tridentate N,N,O-donor ligand for transition metal complexes, with the thiazoimine-N, azo-N, and phenoxo-O atoms providing the coordination sites, which can lead to versatile coordination models with different metal ions. Accordingly, the reaction of **HL** with zinc acetate hydrate resulted in the quantitative separation of an unusual trinuclear complex **1**. This needle-like complex is dark-red and also has excellent solubility in CH_2Cl_2, $CHCl_3$, and THF, etc. The structures of both the ligand and trinuclear zinc complex were confirmed by mass spectrometry, ^{1}H NMR, IR, and UV/Vis spectroscopy, and elemental analysis. X-ray diffraction analysis unambiguously confirmed the solid-state structures of both compounds.

UV/Vis Titration with Zn^{2+}

The formation of the zinc complex in solution was monitored by a UV/Vis titration experiment. Figure 1 shows the changes in the absorption spectra of the azo ligand **HL** upon increasing the concentration of Zn^{2+} in methanol. The inset presents the plot of the absorbance at 540 nm as a function of the $[Zn^{2+}]/[\mathbf{HL}]$ ratio. In methanol, the absorption spectrum of the free ligand exhibits a band with a maximum at 500 nm characteristic of the π–π* transition. The absorbance of this band decreases and a new band appears at around 540 nm upon increasing the $[Zn^{2+}]/[\mathbf{HL}]$ ratio. An apparent isosbestic point appears at 512 nm, indicating the formation of a metal–ligand coordination compound. Furthermore, the inset shows a maximum at [metal]/[ligand] = 1.5, which indicates the formation of a 2:3 complex in solution.

X-ray Structural Analysis

An ORTEP view of **HL**, including the atomic numbering scheme, is shown in part a of Figure 2; selected bond lengths and angles are given in Table 1. The azo ligand crystallizes in the orthohombic space group $P2_12_12_1$ with the Flack parameter refined to be 0.28(6), indicating the ligand crystallizes as a racemic twin. Overall, the conjugated aromatic part of the azo molecule is planar (part b, Figure 2); the dihedral angle of the two ring planes is only 4.0°. Interestingly, in the crystal packing of **HL** (part c, Figure 2), both intermolecular C–H···π hydrogen bonding and weak thiazo ring-S···π interactions are observed. While C–H···π hydrogen bonding is prevalent and also one of the most important intermolecular forces in the crystal packing of multi-aromatic systems,[11] the thio···π weak interaction reported here is a new class of aromatic–aromatic interaction. It is well-known that the ability of the π-cloud of aromatic ring to interact with positively polarized atoms is not limited to C–H···π interactions,[12] and electron-deficient cations can interact with aromatic systems, even biological macromolecules. In contrast, an interaction between electron-rich donors and/or anions with aromatic π-clouds is usually unexpected. A few papers are devoted to theoretical and experimental studies on this interaction.[12] Hence, the observed interaction of an electron-rich thiazolyl S atom with a phenyl ring is reasonable, albeit unusual, on the basis of the similar reports.

The moderately strong C–H···π hydrogen bond has a separation of 3.082 Å for H···π-ring center and an angle of 146.3° for C–H···π-ring center,[13] while the weak S_{thiazo}···π interaction has a short separation of 3.569 Å and a dihedral angle of 64.7° between the phenol and thiazo ring planes, comparable to the common distances of strong π···π interactions.[14]

The neutral complex with a formula of $[Zn_3\mathbf{L}_2(OAc)_4]$ (**1**) was obtained by reaction of two equivalents of azo ligand with three equivalents of zinc(II) acetate hydrate in CH_2Cl_2/MeOH solution, according to the results of the UV/Vis titration. Complex **1** crystallizes in the monoclinic space group $P2_1/c$. Its ORTEP structure is shown in Figure 3, in which two deprotonated ligand molecules $\mathbf{L}^-$ are linked with three zinc atoms, and two of three zinc atoms (Zn1 and Zn1A) are located in the thiazolylazo chelate moieties in a five-coordinate ZnN_2O_3 environment, with a thi-

azo nitrogen, an azo nitrogen, a phenoxo oxygen, and two oxygens from two acetate ions. The μ-phenoxo oxygen atoms (O1 and O1A), together with four acetate oxygen atoms, coordinate further to Zn2 at the inversion center to form a ZnO_6 octahedral geometry. Four μ-acetato ligands bind to three zinc centers (bridging Zn1–Zn2 and Zn1A–Zn2) and saturate the coordination numbers of zinc atoms, meaning that the whole charge of the complex is neutral. Thus, the resulting bridging Zn1–Zn2–Zn1A array is linear by symmetry. The nonbonding Zn···Zn distance is 3.390 Å, with a Zn1···Zn2···Zn1A angle of 180.0°, which indicates a weak interaction between the three zinc centers. The Zn–O bond lengths are in the range of 1.946(2)–2.128(2) Å, and the Zn–N bond lengths are 2.094(3) Å and 2.162 Å, respectively (see Table 1), comparable to other known zinc complexes.[15–17]

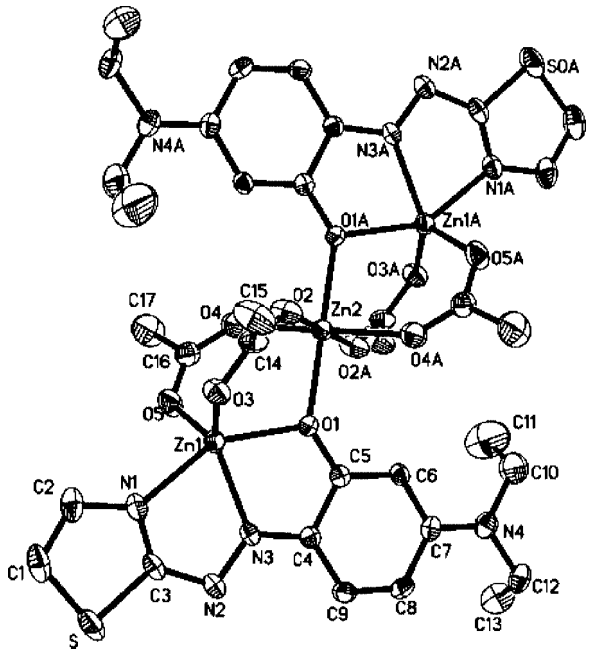

Figure 3. ORTEP structure (30% probability level) and atom-numbering scheme for trinuclear zinc cluster **1**. Hydrogen atoms have been omitted for clarity.

In addition, due to the good planarity and conjugation of the whole supramolecular complex, significant intermolecular π···π stacking interactions are observed in the crystal packing of **1** along the crystallographic *c* axis. (Figure 4) The aromatic planes of adjacent molecules are parallel, and the shortest C···C and C···N separations of π···π interactions are 3.426(4) Å and 3.455(4) Å, respectively, thus falling in the range of strong π···π interactions.[14] It is worth mentioning that the reported metal complexes based on azo ligands usually adopt mono- or binuclear structures,[10] therefore the trinuclear cluster structure depicted herein is surely the first example of an azo-based polynuclear Zn^{II} complex, although polynuclear cluster structures are not uncommon. Moreover, this observation may provide new references for designing other novel polynuclear metal complexes with special functional properties.

Spectroscopic Studies and Thermal Analysis

The infrared spectra (see Exp. Section) of ligand H**L** and complex **1** reveal the stretching vibration of the N=N band at 1431 and 1304 cm^{-1}. These values are indicative of the metal chelating behavior and are very similar to previous results.[10d] The thioazole ν(C=N) (1527 cm^{-1}) vibration appears as a very strong band which, upon complex formation, shifts to lower frequency (1501 cm^{-1}) with a reduction in its intensity.

The UV/Vis absorption spectra of both the free ligand H**L** and complex **1** were measured in various solvents. The π–π* transition band of H**L** is slightly solvent-dependent, the absorption maxima varied from 489 to 500 nm upon increasing the polarity of the solvent from ethyl acetate to methanol. (Table 2) The spectra of two forms of the conjugated base and protonated salt of H**L** show a pronounced bathochromic shift, relative to that of H**L** in methanol, which was attributed to the formation of conjugated species. In contrast, the UV/Vis spectra of complex **1** show a remarkable solvent effect (see Supporting Information). In methanol, the spectrum exhibits a single peak at around 530 nm, while in other solvents like ethyl acetate, chloroform, and toluene etc. this single band splits into two or three fine peaks between 400 and 600 nm, indicating that this complex is very sensitive to the solvent environment.

In contrast, some salicylideneimine ligands usually form mononuclear or binuclear metal complexes depending on the substituents or the reaction conditions.[17,18] As discussed previously, however, the [Zn(**L**$^-$)] unit readily assembles spontaneously to give the stable 2:3 complex in excellent yield. The ^{1}H NMR titration experiment confirmed the cooperative formation and stability of the unique trinuclear complex [Zn_3**L**$_2$(OAc)$_4$] in solution. (see Supporting Information) The ^{1}H NMR spectra of the reaction were monitored by varying the amount of zinc(II) in $CDCl_3$/CD_3OD (1:1), and the results clearly indicated that a single species, [Zn_3**L**$_2$(OAc)$_4$], was formed very cooperatively upon the addition of a 1.5-fold amount of zinc(II).

The crystalline solid of complex **1** is stable up to 220 °C. The TGA curve exhibits an important weight loss from ca. 220 °C to 324 °C, assigned to the removal of four bridging acetate ions, with a weight decrease of 24.08% (calcd. 24.14%). Further heating leads to the degradation of the compound, which might be attributed to the elimination of azo ligand moieties (see Supporting Information).

Conclusions

In summary, we have synthesized and characterized a thiazolylazo dye and its zinc(II) complex. X-ray structure analysis showed the interesting intermolecular interactions, i.e. C–H···π hydrogen bonds and thiazo ring-S···π weak interactions, present in the crystal of H**L**, which are believed to play a crucial role in stabilizing the crystalline solid. A stable 2:3 complex was confirmed both in solution and in the solid state by UV/Vis, ^{1}H NMR, and FT-IR spectroscopy, elemental analysis, TGA measurements, and X-ray crystal diffraction. Spectroscopic studies showed that the formation of the trinuclear complex is highly efficient. The trinuclear zinc cluster complex obtained here is significant for building supramolecular arrays with novel optical properties. Further, the formation of the trinuclear complex from a multidentate azo-based chelate is interesting for the study of coordination-driven molecular assembly by introduction of various metal ions (transition metal or lanthanide ions), and also opens up new pathways for the design of more complicated and polynuclear metallosupramolecules by changing the appropriate substituent groups (and/or binding sites) on the azo ligand.

Experimental Section

Materials and Synthesis: All reagents and solvents for syntheses and analyses were of analytical grade and were used as received. Solvents for spectral measurements were purchased as spectrophotometric grade. 2-Aminothiazole, 3-diethylaminopheno,l and zinc acetate hydrate were purchased from Aldrich and used without further purification.

Synthesis of 5-(Diethylamino)-2-(2-thiazolylazo)phenol (HL). Diazotization of 2-Aminothiazole: 2-Aminothiazole (1.0 g, 0.01 mol) was dissolved in 15 mL of 85% phosphoric acid. The solution was cooled to 0–5 °C in an ice-brine bath and maintained at this temperature. Solid sodium nitrite (0.75 g, 0.011 mol, 10% excess) was added to the solution over 30 min and stirring was continued for 3 h, keeping the temperature in the range of 0–5 °C. Urea (50 mg) was then added to destroy the excess nitrous acid.

Coupling with 3-(Diethylamino)phenol: 3-(Diethylamino)phenol (1.65 g, 0.01 mol) was dissolved in 25 mL of ethanol and the solution was cooled to 0–5 °C in an ice-brine bath. The above diazonium solution was added portionwise to the coupling component, and maintained at 0–5 °C for 3 h. Then, 30 mL of water was added, stirring was continued for another 3 h, and the solution was allowed to stand overnight while the temperature rose spontaneously to room temperature. After filtration, 1.09 g of crude dye was obtained (yield 39.4%). The crude dye was purified by column chromatography on neutral aluminum oxide using chloroform as eluent. Deep brown single crystals suitable for X-ray structure analysis were grown from a MeOH/EtOH solution of the azo dye. M.p.: 140–141 °C. MALDI-TOF-MS ($C_{13}H_{16}N_4OS$): *m*/*z* = 277 [M + 1]$^+$, 299 [M + Na]$^+$. FT-IR (KBr pellet): $\tilde{\nu}$ = 3410 cm^{-1}, 2972, 2361, 1636, 1527, 1474, 1431, 1336, 1272, 1181, 1137, 1008, 949, 807, 729, 683, 629. ^{1}H NMR ($CDCl_3$): δ = 1.26 (t, *J* = 7.14 Hz, 6 H), 3.47 (q, *J* = 7.14 Hz, 4 H), 6.15 (d, *J* = 2.61 Hz, 1 H), 6.44 (q, *J* = 9.30 Hz, 1 H), 7.16 (d, *J* = 3.33 Hz, 1 H), 7.53 (d, *J* = 9.30 Hz, 1 H), 7.78 (d, *J* = 3.33 Hz, 1 H), 13.36 (s, 1 H) ppm. $C_{13}H_{16}N_4OS$ (276.1): calcd. C 56.50, H 5.84, N 20.27, S 11.60; found C 56.11, H 5.70, N 20.26, S 11.72.

Synthesis of Complex 1: The 5-(diethylamino)-2-(2-thiazolylazo) phenol dye (55.2 mg, 0.2 mmol) was dissolved in 10 mL of dichloromethane and a 5 mL methanol solution of zinc acetate hydrate (65.9 mg, 0.3 mmol) was added. The solution was stirred at room temperature for 2 h, then allowed to stand at 5 °C for two weeks. During this period dark-red needle-like crystals appeared and were collected by filtration, washed with diethyl ether, and dried under vacuum. Yield: 51.8 mg (53.0%). MALDI-TOF-MS: *m*/*z* = 859.21 [M – 2OAc$^-$], 741.1 [M – 4OAc$^-$]. FT-IR (KBr pellet): $\tilde{\nu}$ = 2975 cm^{-1}, 2353, 1605, 1501, 1420, 1304, 1211, 1127, 1078, 1011, 949, 874, 826, 795, 665. ^{1}H NMR ($CDCl_3$): δ = 1.24 (t, *J* = 7.04 Hz, 12 H), 2.01 (s, 12 H), 3.50 (q, *J* = 7.08 Hz, 8 H), 6.10 (s, 2 H), 6.47 (q, *J* = 9.88 Hz, 2 H), 7.21 (d, *J* = 3.50 Hz, 2 H), 7.54 (d, *J* =

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

3.50 Hz, 2 H), 7.60 (d, J = 9.81 Hz, 2 H) ppm. $C_{34}H_{42}N_8O_{10}S_2Zn_3$ (978.0): calcd. C 41.54, H 4.31, N 11.40; found C 41.83, H 4.32, N 11.30.

Physical Measurements: Melting points were determined on a Yanaco MP-500 micro-melting point apparatus. MALDI-TOF MS measurements were carried out on a Bruker APEX II and KYKY-ZHP-5 spectrometer. FT-IR spectra were recorded on a BIO-RAD FT-165 IR spectrometer. Samples for C, H, N, and S analyses were dried under vacuum and the analysis were performed with a Carlo Erba-1106 elemental analyzer. Thermogravimetric analysis was performed with a Dupont 951 thermogravimetric analyzer under nitrogen atmosphere, with a heating rate of 10 °C min^{-1}. ^{1}H NMR spectra were measured with a Bruker dmx400 MHz NMR spectrometer at room temperature in $CDCl_3$ with tetramethylsilane as the internal reference. UV/Vis absorption spectra and solution titration measurement were obtained on a Hitachi UV-3010 absorption spectrophotometry. UV/Vis spectrophotometric titration experiments were carried out as follows: a solution of H**L** in MeOH (original concentration 1×10^{-5} M) was titrated directly in 10 mL volumetric flasks by successive addition of methanol solutions of zinc acetate hydrate. A concentrated $Zn(OAc)_2 \cdot H_2O$ (0.01 M) solution was added in 2 to 20-μL aliquots using a microliter syringe. The absorption spectra were obtained by monitoring the spectra between 350 and 750 nm after transfer of the solution to a 1-cm quartz cell. The total volume change during the titration was negligible; the titration process was readily repeatable.

X-ray Crystallography: Crystals suitable for X-ray diffraction studies were obtained by solvent evaporation at 5 °C. Accurate unit-cell parameters were determined by a least-squares fit of 2θ values, measured for 200 strong reflections, and intensity data sets were measured on Rigaku Raxis Rapid IP diffractometer with Mo-K_α radiation (λ = 0.71073 Å) at room temperature. The intensities were corrected for Lorentz and polarization effects, but no corrections for extinction were made. All structures were solved by direct methods. The non-hydrogen atoms were located in successive difference Fourier synthesis. The final refinement was performed by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The hydrogen atoms were added theoretically as riding on the concerned atoms. Crystallographic data and experimental details for structure analyses are summarized in Table 3. Selected bond lengths and angles data are listed in Table 1. CCDC-272172 (for H**L**) and -272173 (for **1**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

B-Substituted (Arene)ruthenacarborane–Sulfonium, –Thioether and –Mercaptan Complexes: Mild Single and Double Dealkylation and Structural Implications in the Antipodal Distance

José Giner Planas,[a] Clara Viñas,[a] Francesc Teixidor,*[a] Mark E. Light,[b] Michael B. Hursthouse,[b] and Helen R. Ogilvie[b]

Keywords: Antipodal effect / (Arene)ruthenacarboranes / Carboranes / Charge-compensated ligands / Dealkylation

Reactions of $[RuCl_2(\eta^6\text{-arene})]_2$ (arene = benzene, *p*-cymene) with *nido*-[7-R-10-L-7,8-$C_2B_9H_9$]$^-$ in THF at room temperature for 3 d give the (arene)ruthenacarborane complexes *closo*-[3-Ru(η^6-arene)-1-R-8-L-1,2-$C_2B_9H_9$]$^+$ {arene = benzene, R = H [L = Me_2S (**1a**), THT (**1b**), EtPhS (**1c**)], R = Me [L = Me_2S (**2a**)]; arene = *p*-cymene, R = H [L = Me_2S (**3a**)]} and mercaptan *closo*-[3-Ru(η^6-arene)-1-R-8-HS-1,2-$C_2B_9H_9$] [arene = benzene, R = H (**4**), Me (**5**); arene = *p*-cymene, R = H (**6**)] in yields of 20–40 % and 22–29 %, respectively. The asymmetric ligand *nido*-[9-Me_2S-7,8-$C_2B_9H_{10}$]$^-$ leads to the thioether complex *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**) in 34 % yield under the same reaction conditions. The crystal structure of **1a** is described and compared with those of **4** and **8**. The fully assigned ^{11}B NMR spectroscopic data for a whole series of ruthenacarboranes having *B*-substituted sulfonium, thioether and mercaptan groups are presented. These data show a relation between antipodal cluster atom distances (antipodal distance) and antipodal effect (AE) in the crystal structures of these complexes and for other families of heteroboranes such as *closo*-[$EB_{11}H_{11}$] and *closo*-[EB_9H_9].

Introduction

Metal complexes having the dicarbollide ligand *nido*-[7-R-8-R^1-7,8-$C_2B_9H_9$]$^{2-}$ constitute the most widely studied class of metallacarboranes since they were first reported by Hawthorne in the 1960s.[1] These dicarbollide ligands have planar binding faces and are isolobal and isoelectronic analogues of the cyclopentadienide ligand $[C_5H_5]^-$ (Cp), both behaving as 6-electron donors in transition metal complexes.[1,2] Introduction of substituents such as amines, ethers, sulfides and phosphanes etc. at the boron atoms reduces the cluster charge, thereby producing "charge-compensated" ligands such that a better comparison with the classical (Cp)metal complexes can be made.[3] In particular, sulfides are widely used as substituents in polyhedral *B*-substituted carboranes affording "charge-compensated" ligands of the type *nido*-[9- or 10-L-7,8-R$R^1$$C_2B_9H_8$]$^-$ (L = SR^2R^3).[4] Interestingly, whereas nearly 500 structures of icosahedral cages of the type *closo*-[3,1,2-MC_2B_9] have been determined by X-ray crystallography, only 33 of those contain a sulfur atom attached to a boron atom.[5] Of these, only 5 correspond to ruthenacarboranes all having a "charge-compensated" ligand, i.e. *closo*-[3-Ru(Cp*)-7-Me_2S-1-R-2-R^1-1,2-$C_2B_9H_8$] (R/R^1 = H/H, H/Ph, Ph/H),[3g] *closo*-[3-Ru(η^6-benzene)-7-Me_2S-1,2-$C_2B_9H_{10}$][6] and *closo*-[3-Ru-3-H-3,3-$(PPh_3)_2$-8-Me_2S-1,2-$C_2B_9H_{10}$].[3i] The latter type of (phosphane)ruthenacarborane complexes have proven to be very efficient catalysts in various types of olefin-related catalytic reactions surpassing, in some cases, the Cp-type complexes.[7] As part of our systematic work on monoanionic *o*-carboranes as alternatives to the cyclopentadienide ligand in transition metal complex catalysts,[7] we became interested in the synthesis of (arene)ruthenacarborane complexes. Here we report the syntheses and characterisation of the new symmetrically *B*-substituted (arene)ruthenacarborane–sulfonium complexes *closo*-[3-Ru(η^6-arene)-1-R-8-L-1,2-$C_2B_9H_9$]$^+$ {arene = benzene, R = H [L = Me_2S (**1a**), THT (**1b**), EtPhS (**1c**)], R = Me [L = Me_2S (**2a**)]; arene = *p*-cymene, R = H [L = Me_2S (**3a**)]} and of the unprecedented (arene)ruthenacarborane–mercaptan complexes *closo*-[3-Ru(η^6-arene)-1-R-8-HS-1,2-$C_2B_9H_9$] {arene = benzene, R = H (**4**), Me (**5**); arene = *p*-cymene, R = H (**6**)} and the asymmetric thioether complex *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**), formed by double and single dealkylation of the sulfonium groups in the starting *nido*-carboranes, respectively. A pathway for the dealkylation reaction is proposed. The structure for [**1a**]PF_6 is now reported and compared with those of complexes **4** and **8**

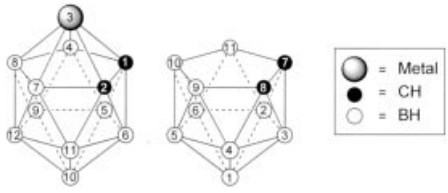
which were published in a preliminary communication.[8] We present here the fully assigned ^{11}B NMR spectroscopic data for a whole series of ruthenacarboranes having *B*-substituted sulfonium, thioether and mercaptan groups. The study reveals clear trends in the ^{11}B NMR spectra and the antipodal effect (AE)[9] which, to date, had only been related to NMR spectroscopic data. We have found that the AE can be clearly observed in the crystal structures for the new complexes and other previously reported heteroboranes of the type $EB_{11}H_{11}$ and EB_9H_9. We have adopted in this work the carborane numbering system shown in Scheme 1.



Scheme 1. Carborane numbering.

Results

1. Reactions of $[RuCl_2(\eta^6\text{-arene})]_2$ with Charge-Compensated Carboranes *nido*-[7-R-10-L-7,8-$C_2B_9H_9$]$^-$ and *nido*-[9-Me_2S-7,8-$C_2B_9H_{10}$]$^-$

According to protocols established in our group, *t*BuOK was employed as the base for in situ deprotonation of the neutral "charge-compensated" *o*-carboranes *nido*-[7-R-10-L-7,8-$C_2B_9H_{10}$] (R = H, L = Me_2S, THT, EtPhS; R = Me, L = Me_2S) (THT = tetrahydrothiophene) affording the potassium salt of the anionic "charge-compensated" *o*-carboranes *nido*-[7-R-10-L-7,8-$C_2B_9H_9$]$^-$.[10] Exclusive deprotonation of the bridge BHB proton is confirmed by disappearance of its resonance signal in the $^1H\{^{11}B\}$ NMR spectrum. The $^{11}B\{^1H\}$ NMR spectra show the typical highfield displacement of the antipodal boron B-1 signal after hydrogen bridge deprotonation (see Figure 1 for one example). Treatment of the *nido*-[7-R-10-L-7,8-$C_2B_9H_9$]$^-$ compounds with a suspension of the (arene)ruthenium complexes $[RuCl_2(\eta^6\text{-arene})]_2$ (arene = benzene, *p*-cymene) in THF at room temperature for 3 d afforded the new cationic ruthenacarborane complexes *closo*-[3-Ru(η^6-arene)-1-R-8-L-1,2-$C_2B_9H_9$]$^+$ Cl^- (**1**–**3**) as insoluble solids (Scheme 2). A Cl^- exchange reaction in **1**–**3** using PF_6^- afforded the readily soluble complexes *closo*-[3-Ru(η^6-arene)-1-R-8-L-1,2-$C_2B_9H_9$][PF_6] (**1a**–**c** and **3a**) in yields of 20–40% but only traces of **2a** were obtained. Detailed analysis of the remaining solution showed, in all cases, the presence of starting anionic "charge-compensated" *o*-carboranes *nido*-[7-R-10-L-7,8-$C_2B_9H_9$]$^-$ which could be recovered. In addition, we unexpectedly found that (mercaptan)ruthenacarborane complexes of the type *closo*-[3-Ru(η^6-arene)-1-R-8-HS-1,2-$C_2B_9H_9$] (**4**–**6**) were also formed in yields of 22–29% (Scheme 2). Although yields for the latter complexes were low, their formation is remarkable since they are the result of double dealkylation of all sulfonium salt derivatives under very mild conditions regardless of the nature of the substituents at the sulfur atom. Small amounts of sandwich complexes of the type *closo*-[3,3′-Ru-(8-L-1,2-$C_2B_9H_{10})_2$] were also detected in the reaction mixtures in some cases. Synthesis of the latter has been reported in a separate paper.[11] As an example, the sandwich complex *closo*-[3,3′-Ru-(8-Me_2S-1,2-$C_2B_9H_{10})_2$] was obtained in 8% yield after workup of the reaction mixture of *nido*-[10-Me_2S-7,8-$C_2B_9H_{10}$]$^-$ with (benzene)ruthenium dichloride. Fortunately, the latter type of sandwich complexes could, in most cases, be easily removed by column chromatography (see Exp. Sect.). The reactions shown in Scheme 2 have been conclusively established by spectroscopic (^{11}B, ^1H and ^{13}C NMR) and analytical characterisation of all compounds and crystallographic characterisation of [**1a**]PF_6 and **4**.

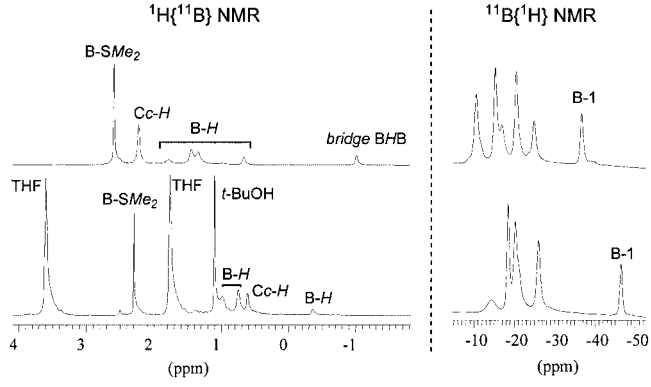


Figure 1. NMR monitoring for the deprotonation of *nido*-[10-Me_2S-7,8-$C_2B_9H_{11}$]: (top) NMR spectra before addition of *t*BuOK (1.0 M solution in THF); (bottom) after addition of 1 equiv. of *t*BuOK (>99% *nido*-K[10-Me_2S-7,8-$C_2B_9H_{10}$]).

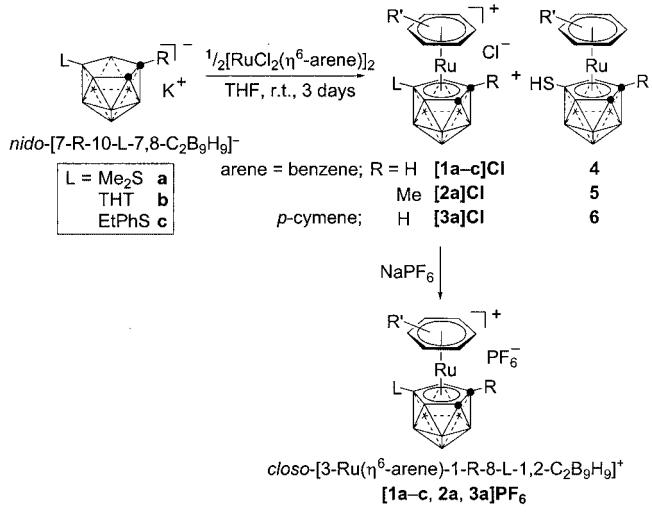
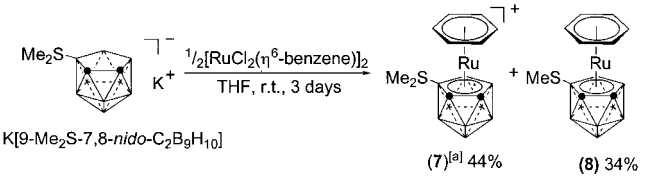


Scheme 2. Syntheses of new (arene)ruthenacarborane complexes.

Interestingly, the asymmetric isomer of **1a**, namely *closo*-[3-Ru(η^6-benzene)-7-Me_2S-1,2-$C_2B_9H_{10}$]$^+$ (**7**), has been previously reported in an analogous reaction of $[RuCl_2(\eta^6$-benzene)]$_2$ with the anionic *nido*-[9-Me_2S-7,8-$C_2B_9H_{10}$][Na] in

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

44% yield but no other species were reported to be formed.[6] Based on our present results, we have examined this reaction in more detail in order to determine whether C–S bond cleavage of Me_2S was also possible in this case. We found that the new soluble neutral complex *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**) is formed, in addition to the previously reported **7**, in 34% yield [Equation (1)]. Complex **8** has been identified by ^{11}B, ^1H and $^{13}C\{^1H\}$ NMR spectroscopy and structurally characterised by X-ray diffraction.



K[9-Me_2S-7,8-*nido*-$C_2B_9H_{10}$] (**7**)[a] 44% (**8**) 34%

2. Characterisation of the New Complexes

a. closo-[3-Ru(η^6-arene)-1-R-8-L-1,2-$C_2B_9H_9$]$^+$

The ^1H NMR spectra for all cationic complexes **1**–**3** (anion for all cationic complexes throughout the text is PF_6^-, unless otherwise noted) show diagnostic signals for coordinated (η^6-arene) fragments to Ru at δ = 6.62–6.82 ppm.[12] Signals for the cage C–H protons (C_c–H) appear as broad resonances at δ = 4.61–4.67 ppm for the unsubstituted carborane compounds (**1** and **3**) and at δ = 4.97 ppm for the methylcarborane complex **2a**, all data being consistent with those of other (arene)ruthenacarborane complexes.[6,13] The $^{13}C\{^1H\}$ NMR spectra for all complexes also show characteristic peaks for the benzene or *p*-cymene ligands, two cage-carbon vertices and the L groups (see Exp. Sect.). The $^{11}B\{^1H\}$ NMR spectra for all complexes are consistent with a *closo*-icosahedral geometry for the cage and are similar to those found for related metallacarborane species.[3i,11] The fully coupled ^{11}B NMR spectra of these complexes show a singlet for the L–B boron vertex whereas the rest of the boron atoms appear as doublets due to ^{11}B-^1H coupling. For example, complex **1a** displays six resonances in a 1:1:2:2:2:1 ratio in its ^{11}B NMR spectrum at δ = 7.1 (s, B-8), 1.9 (d, $^1J_{B,H}$ = 148 Hz, B-10), –6.9 (d, $^1J_{B,H}$ = 153 Hz, B-4,7), –9.8 (d, $^1J_{B,H}$ = 144 Hz, B-9,12), –17.5 (d, $^1J_{B,H}$ = 155.1 Hz, B-5,11), –22.0 (d, $^1J_{B,H}$ = 169 Hz, B-6) ppm. The assignments for each boron atom have been unequivocally determined by 2D $^{11}B\{^1H\}$-$^{11}B\{^1H\}$ COSY for all complexes. These data are consistent with C_s symmetry for the complexes as shown in Scheme 2. However, the symmetry is disrupted in complexes **1c** and **2a** due the presence of the compensating EtPhS group at B(8) and a methyl group at one of the carbon cage vertexes. Thus, the $^{11}B\{^1H\}$ NMR spectrum for **1c** displays seven resonances with relative intensities of 1:1:2:1:1:2:1. The asymmetry can also be observed in the $^{13}C\{^1H\}$ NMR spectrum which shows two different C_c–H resonances (two broad singlets at δ = 49.2 and 49.9 ppm). The asymmetry of **2a** results in all the B signals being inequivalent such that extensive overlap can be observed. In addition, all cationic complexes [**1**–**3**]PF_6 show typical septuplets in their ^{31}P NMR spectra at $\delta \approx$ –143 to –146 ppm, due to $^1J_{P,F}$ coupling (ca. 710 Hz).

b. closo-[3-Ru(η^6-arene)-1-R-8-HS-1,2-$C_2B_9H_9$]

The ^{11}B NMR spectrum for the neutral mercaptan derivative **4** closely resembles that of **1a** with an even larger downfield resonance for the B–SH vertex (δ = 14.3 ppm). The corresponding ^1H NMR spectrum shows a broad resonance at δ = 0.87 ppm which is consistent with an SH group, a situation similar to that found in the related (mercaptan)cobaltacarborane complex *closo*-[3-Co(Cp)-8-HS-1,2-$C_2B_9H_{10}$].[14] In addition, the ^1H and $^{13}C\{^1H\}$ NMR signals for the η^6-benzene moiety and the cage C_c–H for this complex appear at higher field than in the cationic complex **1** and are consistent with other neutral ruthenacarborane complexes.[13a] Complexes **5** and **6** exhibited very similar NMR characteristics to **4** so that their multinuclear NMR spectroscopic data were assigned accordingly.

c. closo-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$]

The resonance for the substituted B atom in the ^{11}B NMR spectrum is more shielded than in **4** (δ = 6.4 ppm) and, unlike the latter, a signal for an MeS fragment can be observed in the ^1H and $^{13}C\{^1H\}$ NMR spectra. These data are in agreement with cleavage of only one of the C–S bonds of the Me_2S moiety affording the new neutral thioether complex **8** as outlined in Equation (1). The asymmetry of the complex is also evident in the ^1H and $^{13}C\{^1H\}$ NMR spectra which display two resonances for the C_c–H atoms.

3. Crystal Structures

The structures for [**1a**]PF_6, **4** and **8** have been unequivocally established by X-ray crystallography (Figures 2, 3 and 4). The Exp. Sect. contains the crystal and data collection parameters for [**1a**]PF_6. Figure 2 clearly shows that the ruthenium atom in **1a** is sandwiched between the benzene and *nido*-[10-Me_2S-7,8-$C_2B_9H_{10}$]$^-$ ligands giving the cluster the expected *closo*-[3,1,2-MC_2B_9] geometry. The Ru–(C_2B_3 plane) and Ru–(C_6 plane) distances are 1.629 and 1.724 Å, respectively, and these values are similar to those of the dicarbollide-containing neutral complex *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$].[13c] Interestingly, the C_6 benzene ring and C_2B_3 plane angle is 1.59° in **1a** which is significantly smaller than that for the related complex *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] (4.1°).[13c] Notably the C1–C2 distance is 1.637(4) Å which is similar to that in other *closo* structures.[3] The B8–S1 distance of 1.899(2) Å is consistent with that in other *B*-substituted sulfonium salts.[15]

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

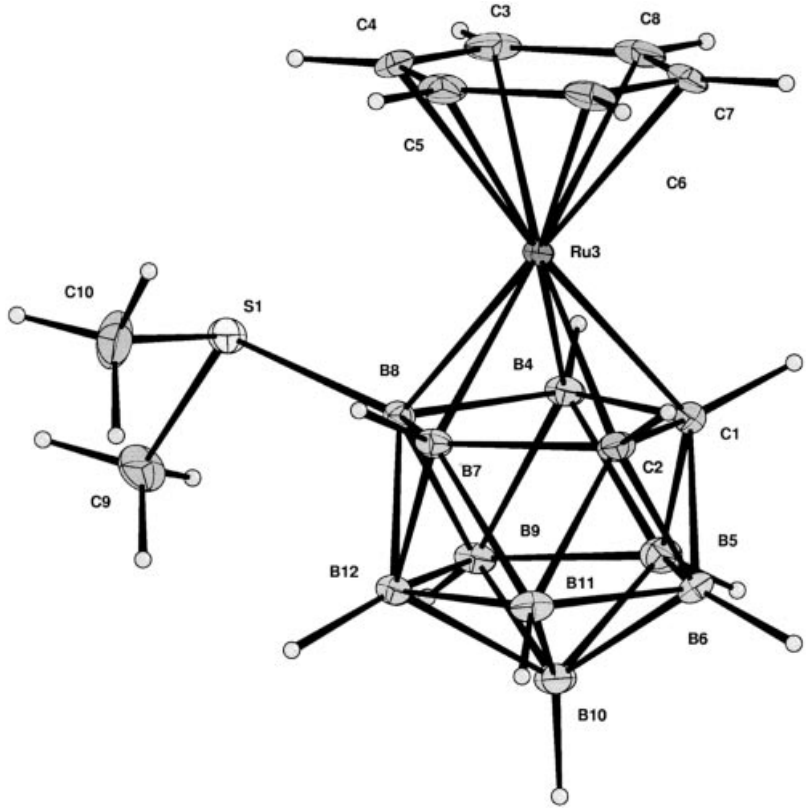

Figure 2. Molecular structure of [**1a**]PF_6 (thermal ellipsoids shown at the 50% probability level). The PF_6^- anion has been omitted for clarity. Selected interatomic distances [Å]: Ru3–C1 2.169(2), Ru3–C2 2.177(2), Ru3–B4 2.212(2), Ru3–B7 2.215(2), Ru3–B8 2.217(2), Ru3–C3 2.219(2), Ru3–C4 2.218(2), Ru3–C5 2.228(2), Ru3–C6 2.236(2), Ru3–C7 2.230(2), Ru3–C8 2.226(2), C1–C2 1.637(4), C2–B7 1.719(3), B7–B8 1.798(3), B4–B8 1.794(3), B8–S1 1.899(2).

The neutral complex **4** also displays a *closo*-[3,1,2-MC_2B_9] geometry for the cluster (Figure 3). The ruthenium atom is sandwiched between the benzene and *nido*-[10-HS-7,8-$C_2B_9H_{10}]^-$ ligands, thus supporting the structure for the complex in solution and confirming that double demethylation occurs from the starting charge-compensated ligand. The average Ru–(C_2B_3 plane) and Ru–(C_6 plane) distances are similar to those in **1a** (1.613 and 1.718 Å). The C_6 benzene ring and the C_2B_3 planes are nearly parallel, the dihedral angle of 2.74° is slightly larger than that for the sulfonium derivative **1a**. The C1–C2 distance is 1.644(4) Å and the B8–S1 bond [1.836(3) Å] is shorter than that of **1a** thereby being consistent with a thiol fragment attached to a boron atom.[16]

As can be seen in Figure 4, the structure of **8** exhibits a similar sandwich-type geometry with the ruthenium atom flanked both by the benzene ring and the C_2B_3 face of the *nido*-[9-MeS-7,8-$C_2B_9H_{10}]^-$ cage. The Ru–(C_2B_3 plane) and Ru–(C_6 plane) distances are 1.719 and 1.606 Å, respectively, the angle between planes of 3.68° is similar to that for the related complex *closo*-[3-Ru(η^6-benzene)-7-Me_2S-1,2-$C_2B_9H_{10}]^+$ (**7**) (4.4°).[6] The C1–C2 [1.627(3) Å] and B4–S1 distances [1.855(3) Å] are also consistent with the above data.

Discussion

1. Reactions of [$RuCl_2(\eta^6$-arene)]$_2$ with Charge-Compensated Carboranes *nido*-[7-R-10-L-7,8-$C_2B_9H_9]^-$ and *nido*-[9-Me_2S-7,8-$C_2B_9H_{10}]^-$

The yields of the new cationic (arene)ruthenacarborane complexes **1**–**3** (Scheme 2) and the reported **7**[6] [Equation (1)] are usually below 50% (Table 1). As demonstrated in this work, these low yields can be partially accounted for by the formation of the (mercaptan)ruthenacarborane complexes **4**–**6** in the case of the symmetric ligands *nido*-[7-R-10-L-7,8-$C_2B_9H_9]^-$ (*isomer-10*) or the thioether complex **8** for the related asymmetric ligand *nido*-[9-Me_2S-7,8-$C_2B_9H_{10}]^-$ (*isomer-9*). Since the starting (arene)ruthenium dichloride and *isomer-10* ligand were also detected during workup of the reactions, we initially thought that insolubility of the benzene(chloro)ruthenium dimer was responsible for the low yields of the complexes (Table 1, Entries 1–2 and 4–5). However, yields for the cationic complexes did not increase when using the more soluble chloro(*p*-cymene) ruthenium dimer (Table 1, Entry 3). Heating was avoided to minimise the formation of the unwanted sandwich complexes *closo*-[3,3′-Ru-(8-L-1,2-$C_2B_9H_{10})_2$] mentioned earlier.[11]

[a] Spectroscopically characterised (see Exp. Sect. for details).

Formation of complexes **4**–**6** is remarkable since they are the result of double dealkylation of any of the sulfonium derivatives at room temperature regardless of the nature of the groups attached to the sulfur atom. This was further confirmed by detection of MeCl (Entry 1 in Table 1), $Cl(CH_2)_4Cl$ (Entry 4) or PhCl and EtCl (Entry 5) during the formation of **4**. Elimination of the alkyl or aryl halides suggests that C–S bond cleavage takes place by means of nucleophilic addition of Cl^- to the organic fragments of the L groups. Similar yields for complexes **4**–**6**, regardless of the starting sulfonium salt derivative, indicate that neither the electronic nor the steric nature of the carbon substituents at the sulfur atom have an important role in the C–S bond cleavage. Although this type of C–S bond activation has been previously reported in thioethers coordinated to electron-withdrawing W or Pt centres, cleavage of only one C–S bond (single dealkylation) was observed in those cases.[17] Double demethylation has only been observed in polyhedral boranes having the charge-compensated Me_2S group but, in this case, a large excess of Li was needed as the reducing agent.[18] Two crucial questions then arise: (i) Does the C–S bond cleavage take place prior to or after coordination of Ru to the open face of the monoanionic carboranes and (ii) does Ru participate in the double C–S bond cleavage? In order to address these points, we first attempted the reaction of complex [**1a**]PF_6 with a Cl^- source such as $[Bu_4N]Cl$. The latter did not cleave any C–S bond. The only reaction observed was a single anion exchange reaction as shown in Equation (2). On the other hand, addition of an excess of the same Cl^- source during the reaction of $[RuCl_2(\eta^6\text{-benzene})]_2$ with *nido*-[10-Me_2S-7,8-$C_2B_9H_{10}]^-$ (Scheme 2) did not affect the ratio of species formed. These two observations are consistent with the cationic complexes not being intermediates of the dealkylation reaction, a fact which is further supported by in situ NMR spectroscopic studies of the formation of [**1a**]Cl and **4** (see Exp. Sect.). In fact, the (arene)ruthenacarborane complexes are so stable that they could be subjected to heating under reflux or photolysis for days without alteration. This clearly suggests that the Cl^- anion itself is not the nucleophile and that Ru must play some role in the cleavage reaction.

(2)

All the above data support the suggestion that cleavage of the C–S bond in the sulfonium fragments takes place prior to coordination of Ru to the open face of the cluster. Since addition of an external Cl^- source did not affect the dealkylation reaction, formation of alkyl halides could then only be explained by the occurrence of some type of nucleophilic addition of Cl^- bonded to Ru. Taking into account all experimental evidence, we propose the following pathway for the dealkylation reactions: thioether–*exo*-*nido*-carboranes could be formed first (Scheme 3, proposed intermediate **B**) with release of 1 equiv. of either an alkyl or aryl halide. In this way, only Cl^- anions attached to Ru are able to cleave the C–S bond by some type of sulfonium–Ru interaction like that proposed in **A**. The first stepwise single dealkylation is supported by the isolation and crystallographic characterisation of the neutral methyl thioether complex *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**). Observation of a resonance at δ = –4.27 ppm in the ^{1}H NMR spectrum during the double dealkylation reaction provides evidence for the participation of some type of B–H→Ru agostic interaction like that postulated in **B**.[19] We have previously reported a series of *exo*-cluster monothioether and monophosphanyl complexes having these types of B–H→M (M = Rh, Ru) agostic bonds (Scheme 4, **I** and **IVa**).[20] Carbon–sulfur bond cleavage in (thioether)Ru complexes, as could be the case in intermediate **B**, is known to happen by means of π-back-donation from the metal to the thioether C–S σ*-orbitals.[21] Thus, further dealkylation by C–S bond cleavage in the thioether **B** would follow liberation of a second equivalent of the halide and an *exo*-cluster *S*-bonded (thiolato)ruthenium intermediate like **C** could be formed (Scheme 3). Decoordination of the *S*-bonded thiolato complex **C** could then take place[22] thus forming the more stable (η^5-C_2B_3)ruthenacarborane complex which becomes protonated to give the mercaptan complex.

The stability of the thioether complex **8** towards further cleavage to the corresponding (mercaptan)ruthenacarborane derivative could be related to the different electronic nature of this isomer with regard to its symmetrical analogue. Calculation of Mulliken charges at the Hartree-Fock 3-21G level clearly confirms that charge distribution is affected by the position of C atoms in the C_2B_3 open face of the *nido*-[10-MeS-7,8-$C_2B_9H_9$]$^{2-}$ and *nido*-[9-MeS-7,8-$C_2B_9H_9$]$^{2-}$ carboranes as shown in Scheme 5. It is noteworthy that whereas both hydrogen atoms in the BH vertexes besides the BSMe group are negatively charged in *isomer-10* (both have hydridic B–H hydrogen atoms), those for the asymmetric *isomer-9* have different charges (a hydridic B–H and a protic C–H hydrogen atom). The necessary condition for B–H→M agostic interactions to take place is the existence of electron-enriched B–H bonds such as those in the open-face (C_2B_3) boron atoms of *nido*-C_2B_9 clusters.[20d] Therefore, existence of two hydridic B–H hydrogen atoms in the postulated *exo*-*nido* intermediate **B** (Scheme 3), which could interact indistinctly with Ru, might prevent fast isomerisation of **B** to the thioether and facilitate the second dealkylation to give the observed mercaptan complex **4** (Schemes 2 and 5 left). In the presence of only one hydridic hydrogen atom, the related *isomer-9* might isomerise faster from *exo*-*nido* to *closo* than its symmetrical analogue precluding the Ru from cleaving the second C–S bond (Scheme 5, right). Such isomerisation has been shown to take place in related Rh complexes of the type **IV** at room temperature in $CHCl_3$ solution (Scheme 3).[20d] Removal of the bridging H in the *nido*-carborane in **II** also favours the formation of the *closo* tautomer **III**.[23]

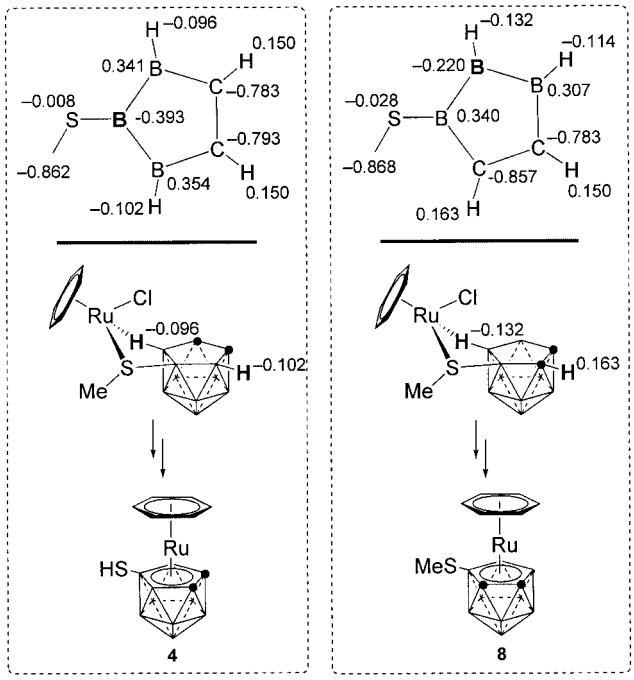
2. Trends in ^{11}B NMR Spectroscopy for the Ruthenacarboranes

All compounds reported in this paper exhibit a *closo*-[3,1,2-RuC_2B_9] geometry; thus, it is possible to compare the differences in the boron chemical shifts caused by the dif-



Scheme 5. Representation of the C_2B_3 faces of the *nido*-[10-MeS-7,8-$C_2B_9H_{10}]^{2-}$ (left) and *nido*-[9-MeS-7,8-$C_2B_9H_{10}]^{2-}$ ligands (right) and corresponding postulated *exo-nido* Ru species prior to the dealkylation reaction (below bold lines). Boron atoms in bold correspond to the B-8 vertex in the *closo*-ruthenacarborane complexes.

ferent substituents at the boron atoms. Cationic **1**–**3** and **7** as well as the neutral ruthenacarborane complexes **4**–**6** and **8** can be considered as resulting from substitution of a hydride ion in *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] by sulfonium and thioether or thiol fragments, respectively. Figure 5 shows a comparison of the neutral *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] which is taken as the reference, with substituted Me_2S and HS at B-8 (Table 2; Entries 1, 2 and 7).

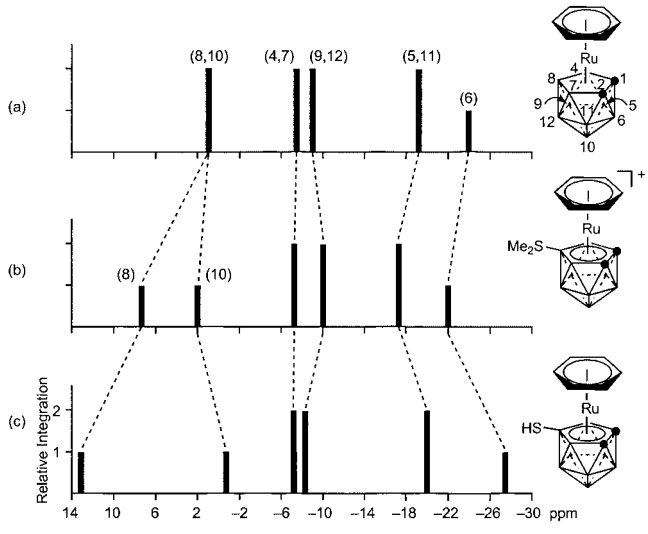


Figure 5. Representation of the $^{11}B\{^1H\}$ NMR spectra for complexes: (a) *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] (showing boron assignment); (b) [**1a**]PF_6; (c) **4**.

{Although the ruthenacarborane complex *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] has been previously reported,[13a] assignment of the cluster ^{11}B NMR spectroscopic data was not published; the present assignments were made by $^{11}B\{^1H\}$-$^{11}B\{^1H\}$ COSY spectrosopy ([D_6]acetone): δ = 1.3 (m, 2 B, B-8 and -10), –7.4 (d, $^1J_{B,H}$ = 117 Hz, 2 B, B-4 and -7), –8.7 (d, $^1J_{B,H}$ = 117 Hz, 2 B, B-9 and -12), –18.9 (d, $^1J_{B,H}$ = 152 Hz, 2 B, B-5 and -11) and –23.7 [d, $^1J_{B,H}$ = 176 Hz, 1 B, B-6] ppm.} The most apparent effect observed in Figure 5 is a large downfield displacement of chemical shifts for the substituted B-8 with respect to our reference complex, that of the HS derivative being larger than that of the Me_2S derivative. Whereas the signal for the Me_2S–B boron atom in **1a** is shifted downfield by about 7 ppm, that for the HS-B boron atom in **4** is displaced by 13 ppm. A second significant effect apparent from Figure 5 is the so-called antipodal effect (AE)[9] to the substituted boron atom (B-6). Whereas the chemical shift for the boron atom antipodal to Me_2S has moved downfield (Figure 5b), that of the boron atom antipodal to HS is displaced upfield (Figure 5c). These two main effects have good precedent.[9,18] As expected, smaller antipodal effects can also be observed in the asymmetric complexes *closo*-[3-Ru(η^6-benzene)-7-Me_2S-1,2-$C_2B_9H_{10}]^+$ (**7**) and *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**) due to the lack of a plane of symmetry crossing both the substituted and antipodal vertex[9] {compound/δ(B-5): *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$]/–18.9 ppm, **7**/–18.7 ppm,[6] **8**/–17.0 ppm}.

Other minor effects include a downfield/upfield butterfly effect (BE)[9] analogous to the AE in our system (signals for B-5, -10 and -11 have moved downfield with respect to the reference in the case of the Me_2S-substituted species **1a** but those for the HS analogue **4** are displaced upfield) and the neighbouring effect (NE)[9] which only affects B-9 and -12 in the Me_2S-substituted **1a**.

3. Crystal Structures and Antipodal Effect

The empirically observed AE has been previously explained through cooperation of atomic orbitals on antipodally interacting vertices.[9] It is noteworthy that although the AE has been extensively studied using calculations[24] and by comparing various series of compounds,[9] the comparison has always been related to the ^{11}B chemical shifts as the only experimental evidence. Surprisingly, even though such a hypothesis involves the transfer of part of the electrons between antipodal boron atoms and, therefore, through some type of interaction between atomic orbitals, no other experimental evidence has ever been obtained apart from NMR chemical shifts.

We were curious to see whether the AE obtained by NMR spectroscopy, for neutral and cationic ruthenacarboranes, has any influence on their X-ray structures. A comparison of the X-ray structures of the complexes *closo*-[3-Ru(η^6-benzene)-1,2-$C_2B_9H_{11}$] (the reference compound) with *closo*-[3-Ru(η^6-benzene)-8-Me_2S-1,2-$C_2B_9H_{10}]^+$ (**1a**) and *closo*-[3-Ru(η^6-benzene)-8-HS-1,2-$C_2B_9H_{10}$] (**4**)

[a] See Scheme 1 for numbering.

(Table 3, polyhedral type V) shows a significant shortening of the distance between the substituted B atom and its antipodal boron atom (A_d: antipodal distance) in the sulfonium salt derivative **1a** with respect to the reference complex (0.061 Å). A smaller shortening can be observed for the neutral complex **4** (0.023 Å). The same situation can be observed when comparing the structures of the related substituted polyhedral boranes *closo*-[1-L-$B_{12}H_{11}$]$^{z-}$ with the reference *closo*-[$B_{12}H_{12}$]$^{2-}$ molecule (Table 3, polyhedral type VII). In this case the shortening of A_d is slightly larger (0.093 Å) than in the related ruthenacarborane structures. In contrast, the shortening of A_d is hardly seen in the asymmetric *closo*-[3-Ru(η^6-benzene)-7-L-1,2-$C_2B_9H_{10}$]$^+$ (Table 3, polyhedral type VI) which is consistent with a smaller AE for these complexes as expected from the lack of symmetry.[9] It is remarkable that the shortening of the antipodal distance (A_d) is observed in those compounds having strong electron-attracting substituents attached to boron atoms. According to the accepted hypothesis,[9] such substituents are believed to decrease the electron density at the antipodal boron atom with the consequent downfield shift of the chemical shift of the signal of this boron atom. Although the magnitudes of both the downfield chemical shift and the shortening of A_d are quite small in our complexes, a relation between AE and the shortening of A_d can be clearly seen when analysing the X-ray structures for the polyhedral heteroboranes *closo*-$EB_{11}H_{11}$ and *closo*-EB_9H_9 (Table 4).[25] The latter complexes are known to exhibit AE of at least one order of magnitude larger than the examples in Table 3.[8] The data summarised in table 4 clearly show that the downfield AE and the shortening of A_d both follow the same order, E = $MeAl^{2-}$ < HB^{2-} < HC^- < HN, i.e. with decreasing electron density at the E vertex. The shortening of the antipodal distances A_d is really significant. The difference between the first compound in the *closo*-$EB_{11}H_{11}$ series ($MeAl^{2-}$) and the last (HC^-) is 0.637 Å (Table 4)! The shortening of A_d is clearly not driven by the charges on the clusters, since *closo*-[$MeAlB_{11}H_{11}$]$^{2-}$ and *closo*-[$B_{12}H_{12}$]$^{2-}$ already show a significant shortening. To the best of our knowledge, this correlation has not been previously observed.

Conclusion

In this study, we describe the formation of cationic ruthenacarborane complexes *closo*-[3-Ru(η^6-arene)-1-R-8-L-

1,2-$C_2B_9H_9]^+$ (L = Me_2S, THT, EtPhS) (**1**–**3**) and neutral mercaptan *closo*-[3-Ru(η^6-arene)-1-R-8-HS-1,2-$C_2B_9H_9$] (**4**–**6**) and *closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-$C_2B_9H_{10}$] (**8**). The neutral complexes are the result of double or single dealkylation of L groups in mono-anionic "charge-compensated" *o*-carborane derivatives at room temperature. Such facile C–S bond activations are unprecedented in polyhedral carborane chemistry and open a new route to mercaptan metallocarboranes. A pathway for the dealkylation reactions is proposed. The findings also show, for the first time, a relation between the empirical antipodal effect (AE) and the structural antipodal distance (A_d) in the crystal structures for the new complexes and other previously reported 12- and 10-vertex heteroboranes. We are currently working on an extension of this correlation to other *closo*-heteroboranes.

Experimental Section

General: All manipulations were carried out under N_2. Chemicals were prepared as follows: THF was distilled from Na/benzophenone; acetone was distilled from P_2O_5; *t*BuOK (95%, Aldrich or 1.0 M solution in THF) and $NaPF_6$ (98%, Aldrich) were used as received. The following were prepared by literature procedures: *nido*-[9-Me_2S-7,8-$C_2B_9H_{11}$],[4a] *nido*-[7-R-10-L-7,8-$C_2B_9H_{10}$] (R = H, L = Me_2S, THT, EtPhS; R = H, L = Me_2S)[4] and [$RuCl_2$(η^6-arene)]$_2$ (arene = benzene, *p*-cymene).[12] NMR spectra were acquired with a Bruker ARX 300 MHz spectrometer and referenced to the solvent (^{1}H, residual signals of [D_5]acetone, [D_2]acetonitrile or [D_7]THF; ^{13}C signals of [D_6]acetone or [D_3]acetonitrile),[26] BF_3·OEt_2 (^{11}B NMR) or PPh_3 (^{31}P NMR; a C_6D_6 solution in an internal sealed capillary, δ = –5.00 ppm). Chemical shifts are reported in ppm and coupling constants in Hz. Multiplet nomenclature is as follows: s, singlet; d, doublet; t, triplet; sept, septuplet; br., broad; m, multiplet. Chromatography was carried out using ACROS silica gel (0.035–0.070 mm, pore diameter ca. 6 nm). Microanalyses were conducted with a Carlo Erba EA1108 instrument. The mass spectra were recorded in the negative ion mode using a Bruker Biflex MALDI-TOF instrument [N_2 laser; λ_{exc} = 337 nm (0.5 ns pulses); voltage ion source 20.00 kV (Uis1) and 17.20 kV (Uis2)]. Photochemical reactions were performed in a quartz Schlenk vessel equipped with a magnetic bar and condenser. The unfiltered output of an in-house 76.8 W medium-pressure mercury lamp was used as a light source.

***closo*-[3-Ru(η^6-benzene)-8-Me_2S-1,2-$C_2B_9H_{10}$]$^+$ (1a) and *closo*-[3-Ru(η^6-benzene)-8-HS-1,2-$C_2B_9H_{10}$] (4). General Procedure:** A Schlenk flask was charged with *nido*-[10-Me_2S-7,8-$C_2B_9H_{11}$] (95.1 mg, 0.489 mmol), *t*BuOK (0.550 mL, 1.0 M) and THF (10 mL). The mixture was stirred at room temperature for 30 min giving a clear pale yellow solution. The flask was then charged with [$RuCl_2$(η^6-benzene)]$_2$ (122.4 mg, 0.245 mmol) and the resultant heterogeneous brown mixture was stirred at room temperature for 3 d. Workup for **1a** and **4** was as follows:

1a: A solid residue was separated from the supernatant orange solution and transferred into another Schlenk vessel for further isolation of **4** (vide infra). The solid residue remaining in the flask was dried by oil-pump vacuum to give **[1a]**Cl and KCl as a pale brown powder. Addition of an aqueous solution of $NaPF_6$ (176.7 mg, 1.052 mmol) to the heterogeneous brown mixture of **[1a]**Cl in ethanol (10 mL) resulted in the formation of a tan precipitate. After stirring for at room temperature for 1 h, the remaining ethanol was removed under reduced pressure and the resultant suspension was allowed to settle without stirring in the refrigerator for 1 h. The aqueous solution was separated by cannula and the residue was washed with H_2O (1 mL) and extracted with CH_2Cl_2 which was then evaporated and the residue dried by oil-pump vacuum to afford **[1a]**PF_6 as a tan powder (101.3 mg, 0.196 mmol, 40%). $C_{10}H_{22}B_9F_6PRuS$: calcd. C 23.20, H 4.28, S 6.19; found C 22.92, H 3.92, S 5.86. MALDI-TOF *m*/*z* (%) = 373.53 (100) [M], 311.46 (43) [M – Me_2S].

[1a]Cl: ^{1}H NMR ([D_3]acetonitrile): δ = 6.58 (s, 6 H, η^6-C_6H_6), 4.50 (br. s, 2 H, C_c-*H*), 2.45 (s, 6 H, Me_2S) ppm. ^{1}H{^{11}B} NMR ([D_3]acetonitrile; only signals due to B-H protons are given): δ = 2.92 (br. s, 2 H), 1.90–1.60 (m, 6 H) ppm. ^{11}B NMR ([D_3]acetonitrile): δ = 6.9 (s, 1 B, B-8), 1.7 (d, $^1J_{B,H}$ = 154 Hz, 1 B, B-10), –7.1 (d, $^1J_{B,H}$ = 150 Hz, 2 B, B-4 and -7), –10.0 (d, $^1J_{B,H}$ = 144 Hz, 2 B, B-9 and -12), –17.6 (d, $^1J_{B,H}$ = 162 Hz, 2 B, B-5 and -11), –22.0 (d, $^1J_{B,H}$ = 175, 1 B, B-6) ppm. ^{13}C{^{1}H} NMR ([D_3]acetonitrile): δ = 93.3 (s, η^6-benzene), 50.8 (br. s, C_c-H), 25.7 (s, Me_2S) ppm.

4: Concentration of the above-mentioned supernatant orange THF solution afforded a mixture of **4** and *closo*-[3,3′-Ru-(8-Me_2S-1,2-$C_2B_9H_{10}$)$_2$] as an orange residue. Chromatographic separation on silica gel using THF as the eluent afforded *closo*-[3,3′-Ru-(8-Me_2S-1,2-$C_2B_9H_{10}$)$_2$] (R_f = 0.63) as a yellow-orange solid (10.0 mg, 0.020 mmol, 8%) and **4** (R_f = 0.50) as a yellow solid after washing with cold CH_2Cl_2 (36.4 mg, 0.106 mmol, 22%). $C_8H_{17}B_9RuS$ (343.65): calcd. C 27.96, H 4.99, S 9.33; found C 28.09, H 4.74, S 8.39. ^{1}H NMR ([D_6]acetone): δ = 6.38 (s, 6 H, η^6-benzene), 4.31 (br. s, 2 H, C_c-*H*), 0.87 (br. m, 1 H, S*H*) ppm. ^{1}H{^{11}B} NMR ([D_6]acetone; only signals due to B-H protons are given): δ = 3.09 (br. s, 1 H), 2.91 (br. s, 2 H), 1.99 (br. s, 2 H), 1.53 (br. s, 2 H), 1.31 (br. s, 1 H) ppm. ^{11}B NMR ([D_6]acetone): δ = 14.3 (s, 1 B, B-8), –1.1 (d, $^1J_{B,H}$ = 140 Hz, 1 B, B-10), –6.9 (d, $^1J_{B,H}$ = 144 Hz, 2 B, B-4 and -7), –8.5 (d, $^1J_{B,H}$ = 160 Hz, 2 B, B-9 and -12), –20.0 [d, $^1J_{B,H}$ = 155 Hz, 2 B, B-5 and -11), –27.5 (d, $^1J_{B,H}$ = 170 Hz, 1B, B-6) ppm. ^{13}C{^{1}H} NMR ([D_6]acetone): δ = 92.1 (s, η^6-benzene), 46.2 (br. s, C_c-H) ppm.

The synthesis was repeated in a modified form to identify the volatile by-product MeCl. A Schlenk flask was charged with 10-Me_2S-7,8-*nido*-$C_2B_9H_{11}$ (294.0 mg, 1.513 mmol), *t*BuOK (1.65 mL, 1.0 M) and THF (20 mL). The mixture was stirred at room temperature for 30 min affording a clear pale-yellow solution. The flask was then charged with [$RuCl_2$(η^6-benzene)]$_2$ (369.9 mg, 0.740 mmol), closed with a rubber stopper and the resultant heterogeneous brown mixture was stirred at room temperature for 3 d. MeCl gas was detected using gas chromatography by comparing the retention time with that of an authentic sample. ^{1}H NMR identification was also carried out (see in situ NMR studies below).

***closo*-[3-Ru(η^6-benzene)-8-THT-1,2-$C_2B_9H_{10}$]$^+$ (1b) and 4:** The general procedure described above was applied using *nido*-[10-THT-7,8-$C_2B_9H_{11}$] (103.9 mg, 0.471 mmol), *t*BuOK (0.48 mL, 1.0 M),

MALDI-TOF: *m*/*z* (%) = 429.00 (100) [M], 363.97 (22) [M – Me$_2$S – 3 H]. ^1H NMR ([D$_6$]acetone): δ = 6.63 (d, $^2J_{H,H}$ = 6.6 Hz, 2 H, *m*- of *p*-cymene), 6.58 (d, $^2J_{H,H}$ = 6.6 Hz, 2 H, *o*- of *p*-cymene), 4.49 (br. s, 2 H, C_c-*H*), 3.11 (sept, $^3J_{H,H}$ = 6.8 Hz, 1 H, MeC$_6$H$_4$C*H*Me$_2$), 2.65 (s, 6 H, *Me*$_2$S), 2.53 (S, 3 H, *Me*C$_6$H$_4$CHMe$_2$), 1.38 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, MeC$_6$H$_4$CH*Me*$_2$) ppm. $^1H\{^{11}B\}$ NMR ([D$_6$]acetone; only signals due to B-H protons are given): δ = 3.38 (br. s, 1 H), 2.80–2.50 (br. s, 2 H), 1.86 (br. s, 2 H), 1.69 (br. s, 3 H) ppm. ^{11}B NMR ([D$_6$] acetone): δ = 7.2 (s, 1 B, B-8), 1.2 (d, $^1J_{B,H}$ = 144 Hz, 1 B, B-10), –5.7 (d, $^1J_{B,H}$ = 146 Hz, 2 B, B-4 and -7), –9.8 (d, $^1J_{B,H}$ = 142 Hz, 2 B, B-9 and -12), –17.6 (d, $^1J_{B,H}$ = 159 Hz, 2 B, B-5 and -11), –21.6 (d, $^1J_{B,H}$ = 195 Hz, 1 B, B-6) ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 116.0 (s, *C*CHMe$_2$), 106.8 (s, Me*C*), 92.5 (s, *o*- of *p*-cymene), 89.9 (s, *m*- of *p*-cymene), 49.5 (s, C_c-H), 31.7 (s, MeC$_6$H$_4$*C*HMe$_2$), 24.9 (s, *Me*$_2$S), 22.1 (s, *Me*C$_6$H$_4$CHMe$_2$), 18.2 (s, MeC$_6$H$_4$CH*Me*$_2$) ppm. $^{31}P\{^1H\}$ NMR ([D$_6$]acetone): δ = –145.6 (sept, $^1J_{P,F}$ = 708 Hz, PF$_6$) ppm.

6: ^1H NMR ([D$_6$]acetone): δ = 6.17 (d, $^2J_{H,H}$ = 6.5 Hz, 2 H, *m*- of *p*-cymene), 6.10 (d, $^2J_{H,H}$ = 6.5 Hz, 2 H, *o*- of *p*-cymene), 4.19 (br. s, 2 H, C_c-*H*), 3.02 (sept, $^3J_{H,H}$ = 7.2 Hz, 1 H, MeC$_6$H$_4$C*H*Me$_2$), 2.43 (s, 3 H, *Me*C), 1.35 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, MeC$_6$H$_4$CH*Me*$_2$) ppm. ^{11}B NMR ([D$_6$]acetone): δ = 13.6 (s, 1 B, B-8), –2.9 (d, $^1J_{B,H}$ = 143 Hz, 1 B, B-10), –7.7 (d, $^1J_{B,H}$ = 137 Hz, 4 B, B-4, -7, -9 and -12), –20.9 (d, $^1J_{B,H}$ = 154 Hz, 2 B, B-5 and -11), –27.9 (d, $^1J_{B,H}$ = 183 Hz, 1 B, B-6) ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 113.2 (s, *C*CHMe$_2$), 104.1 (s, Me*C*), 92.9 (s, *o*- of *p*-cymene), 89.7 (s, *m*- of *p*-cymene), 46.1 (s, C_c-H), 31.5 (s, MeC$_6$H$_4$*C*HMe$_2$), 22.1 (s, *Me*C$_6$H$_4$CHMe$_2$), 18.0 (s, MeC$_6$H$_4$CH*Me*$_2$) ppm.

***closo*-[3-Ru(η^6-benzene)-7-MeS-1,2-C$_2$B$_9$H$_{10}$] (8):** A Schlenk flask was charged with *t*BuOK (52.5 mg, 0.408 mmol), *nido*-[9-Me$_2$S-7,8-C$_2$B$_9$H$_{11}$] (64.9 mg, 0.334 mmol), THF (10 mL) and CH$_3$CN (1.0 mL). The mixture was stirred at room temperature for 30 min giving a clear pale yellow solution. The flask was then charged with [RuCl$_2$(η^6-benzene)]$_2$ (81.5 mg, 0.167 mmol) and the resultant heterogeneous brown mixture was stirred at room temperature for 3 d. The supernatant orange solution was filtered using a cannula and transferred into another Schlenk vessel. The remaining solid residue was washed with further THF (2×5 mL) and combined with the orange solution. The orange residue obtained after evaporation of the THF was then filtered through a short silica gel column using CH$_2$Cl$_2$ as eluent. Concentration of the eluate gave a yellow-orange solid which was washed with Et$_2$O (2×5 mL) to eliminate of the remaining 9-Me$_2$S-7,8-*nido*-C$_2$B$_9$H$_{11}$ and complex **8** was obtained as a yellow solid (40.8 mg, 0.114 mmol, 34%). $C_8H_{17}B_9RuS$ (343.65): calcd. C 30.22, H 5.35, S 8.96; found C 30.24, H 5.37, S 8.71. ^1H NMR ([D$_6$]acetone): δ = 6.34 (s, 6 H, η^6-benzene), 4.51 (br. s, 1 H, C_c-*H*), 4.30 (br. s, 1 H, C_c-*H*′), 1.87 ppm (s, 3 H, *Me*S). $^1H\{^{11}B\}$ NMR ([D$_6$]acetone; only signals due to B-H protons are given): δ = 3.22 (br. s, 1 H), 2.98 (br. s, 1 H), 2.49 (br. s, 1 H), 1.64 (br. s, 2 H), 1.38 (br. m, 3 H) ppm. ^{11}B NMR ([D$_6$]acetone): δ = 6.4 (s, 1 B, B-7), 4.91 (d, $^1J_{B,H}$ = 114 Hz; this resonance overlaps partially with the signal at δ = 6.36 ppm so that the coupling constant is an estimate, 1 B, B-8), 1.2 (d, $^1J_{B,H}$ = 127 Hz, 1 B, B-10), –6.6 (d, $^1J_{B,H}$ = 159 Hz, 2 B, B-4 and -12), –8.3 (d, $^1J_{B,H}$ = 171 Hz, 1 B, B-9), –17.0 (d, $^1J_{B,H}$ = 159 Hz, 1 B, B-5), –20.2 (d, $^1J_{B,H}$ = 169 Hz, 1 B, B-11), –22.1 (d, $^1J_{B,H}$ = 197 Hz, 1 B, B-6) ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]acetone): δ = 91.0 (s, η^6-benzene), 51.0 (br. s, C_c-H), 47.3 (br. s, C'_c-H), 14.7 (s, *Me*S) ppm.

Reaction of *closo*-[3-Ru(η^6-benzene)-8-Me$_2$S-1,2-C$_2$B$_9$H$_{10}$][PF$_6$] ([1a]PF$_6$) with [Bu$_4$N]Cl: A 5-mm NMR tube was charged with solid [**1a**]PF$_6$ (22.9 mg, 0.044 mmol), [Bu$_4$N]Cl (13.6 mg, 0.046 mmol) and [D$_6$]acetone (0.50 mL). A beige precipitate was observed after a few minutes and a remaining pale yellow solution. After 1 h, ^1H and ^{11}B NMR spectra showed no change in the chemical shifts for all species but the ratio of [**1a**]$^+$/[Bu$_4$N]$^+$ was found to be 1:2. Addition of D$_2$O (0.50 mL) was followed by dissolution of the precipitate and the ratio between the latter species was restored to 1:1. Whereas [**1a**]PF$_6$ and [Bu$_4$N]Cl are readily soluble in [D$_6$]acetone, [**1a**]Cl is only partially soluble. The NMR experiment can be explained by a simple anion exchange reaction as shown in Equation (2).

Reaction of [RuCl$_2$(η^6-benzene)]$_2$ with *nido*-[10-Me$_2$S-7,8-C$_2$B$_9$H$_{10}$][K]. In situ NMR Studies: An analogous procedure for the deprotonation of the carborane was applied: *nido*-[10-Me$_2$S-7,8-C$_2$B$_9$H$_{11}$] (10.7 mg, 0.055 mmol), [D$_8$]THF (0.50 mL) and a THF solution of *t*BuOK (0.07 mL, 1.0 M) were mixed. The clear solution rapidly turned light yellow. After 20 min, ^1H and ^{11}B NMR spectra showed 100% conversion of *nido*-[10-Me$_2$S-7,8-C$_2$B$_9$H$_{11}$] to *nido*-K[10-Me$_2$S-7,8-C$_2$B$_9$H$_{10}$] with concomitant formation of *t*BuOH. The solution was then transferred by syringe to another NMR tube containing [RuCl$_2$(η^6-benzene)]$_2$ (13.7 mg, 0.028 mmol) under N$_2$. NMR spectra of the heterogeneous mixture were frequently recorded over a period of 6 d. Due to low solubility of the ruthenacarborane [**1a**]Cl, no quantitative measure of concentration of the species was obtained. However, the experiment clearly showed a gradual and constant increase in **1a** and **4**, whereas *nido*-K[10-Me$_2$S-7,8-C$_2$B$_9$H$_{10}$] decreased. A small amount of reprotonation of the latter was observed, probably due to moisture in the solvent. MeCl (δ = 3.06 ppm) was also detected by ^1H NMR spectroscopy and a broad resonance at low field (δ = – 4.27 ppm) was observed during the experiment which could be due to a B–H→Ru agostic interaction. NMR spectroscopic data for *nido*-K[10-Me$_2$S-7,8-C$_2$B$_9$H$_{10}$]: ^1H NMR ([D$_8$]THF): δ = 2.37 (s, 6 H, *Me*$_2$S), 0.85 (br. s, 2 H, C_c-*H*) ppm. $^1H\{^{11}B\}$ NMR ([D$_6$]acetone; only signals due to B-H protons are given): δ = 1.59 (br. s, 1 H), 1.0–0.6 (m, 6 H), –0.16 (br. s, 1 H) ppm. ^{11}B NMR ([D$_8$]THF, 96 MHz): δ = –14.1 (br. s, 1 B, B-8), –18.2 (d, $^1J_{B,H}$ = 135 Hz, 3 B), –19.6 (d, $^1J_{B,H}$ = 135 Hz, 2 B), –25.4 (d, $^1J_{B,H}$ = 132 Hz, 2 B), –45.9 (d, $^1J_{B,H}$ = 134 Hz, 1 B, B-10) ppm.

Photolysis of *closo*-[3-Ru(η^6-arene)-8-Me$_2$S-1,2-C$_2$B$_9$H$_{10}$][PF$_6$]: An acetonitrile solution (8.0 mL) of the benzene complex [**1a**]PF$_6$ (36.4 mg, 0.070 mmol) or *p*-cymene complex [**3a**]PF$_6$ (40.7 mg, 0.071 mmol) was irradiated with stirring for 3–5 d. Evaporation of the solvent afforded unreacted starting material.

Calculation Details: The geometries for *nido*-[10- and 9-MeS-7,8-C$_2$B$_9$H$_{10}$]$^{2-}$ were obtained from the X-ray structures of *nido*-[10- and 9-Me$_2$S-7,8-C$_2$B$_9$H$_{11}$].[4c,28] Geometries were then optimised with AM1 semiempirical methods and a single-point UHF calculation at the 3-21G level using Hyperchem Release 7 for Windows (Hypercube Inc.). A summary of selected charges is outlined in Scheme 5.

Synthesis and Structure of Neutral and Cationic Gallium Complexes Incorporating Bis(oxazolinato) Ligands

Samuel Dagorne,*[a] Stéphane Bellemin-Laponnaz,*[b] Aline Maisse-François,[b] Marie-Noëlle Rager,[c] Lauriane Jugé,[c] and Richard Welter[d]

Keywords: Cations / Gallium / Lewis acids / N ligands

The bis(oxazolinato)dimethylgallium complexes [{BOX-Me_2}$GaMe_2$] (**2a**) and [{BOX-(*S*)-*i*Pr}$GaMe_2$] (**2b**) are easily obtained in nearly quantitative yield by a methane elimination reaction between $GaMe_3$ and the corresponding bis(oxazoline) ligands {BOX-Me_2}H (**1a**) and {BOX-(*S*)-*i*Pr}H (**1b**). Compound **2a** was also synthesized by a salt metathesis involving the formation of the dichloro complex [{BOX-Me_2}$GaCl_2$] by reaction of [(BOX-Me_2)Li] with $GaCl_3$, followed by its in situ methylation with MeMgBr. The neutral complexes **2a** and **2b** are rapidly ionized by $B(C_6F_5)_3$ to cations **3a**$^+$ and **3b**$^+$, respectively, which are either three-coordinate methylgallium cations or four-coordinate Ga solvent adducts, as their $MeB(C_6F_5)_3^-$ salts. These cationic species exhibit a limited stability and decompose in solution within several hours at room temperature. However, stable four-coordinate Ga-NMe_2Ph cations (**4a**$^+$ and **4b**$^+$) are isolated in good yield when these ionization reactions are performed in the presence of a Lewis base such as NMe_2Ph. Unlike that of $B(C_6F_5)_3$, the reaction of [{BOX-Me_2}$GaMe_2$] with $[Ph_3C][B(C_6F_5)_4]$ quantitatively affords an unusual bis(imine)-dimethylgallium cation {H_2C=C(OX-Me_2)$_2$}$GaMe_2^+$ (**5a**$^+$) in a reaction that proceeds via a hydride abstraction occurring at the Me group located at the back of the bis(oxazolinato) ligand chelated to the Ga center in **2a**. Overall, the reactivity and structural trends observed for the Ga derivatives are closely related to those of the Al analogs, with the Ga compounds being more stable.

Introduction

Cationic group 13 complexes have been the subject of several studies over the past few years since the enhanced Lewis acidity at the metal center, which is a result of its cationic charge, renders these species potentially interesting as Lewis acid catalysts.[1] As such, they have already found applications in isobutene,[2] ethylene,[3] alkene oxide,[4] and D,L-lactide[5] polymerization catalysis. In this regard, three- and four-coordinate cationic group 13 complexes of the general type $[(LX)MR]^+$ and $[(LX)M(R)(L)]^+$ (L labile), readily accessible by reaction of neutral precursors $[(LX)MR_2]$ with strong Lewis acids such as $[Ph_3C][B(C_6F_5)_4]$ and $B(C_6F_5)_3$, have appeared as appealing targets because they incorporate a cationic and low-coordinate metal center; accordingly, these cations behave like potent Lewis acids.[6,7] Thus far, most of the investigations in this area have concerned aluminum derivatives, where it has been found that the structure and the stability of the formed Al cations are greatly dependent upon the steric properties of the ancillary LX^- bidentate ligand and the nature of the counterion.[7] More specifically, the presence of an extremely bulky LX^- ligand and the use of an inert counterion $[B(C_6F_5)_4^-$ or $MeB(C_6F_5)_3^-]$ are required to obtain, in some cases, reasonably stable Al cations. However, the frequent poor stability of these highly reactive alkylaluminum species may limit the scope of their applications in catalysis.

Although much less studied than their Al counterparts, low-coordinate cationic alkylgallium complexes are expected to exhibit an increased stability as a result of the less polar character of the Ga–C vs. Al–C bond,[8] while still remaining reactive due to the presence of an electron-deficient metal center. Thus, cationic Ga derivatives may well represent a reasonable balance of reactivity and stability, which is a required feature for catalysis involving polar substrates and/or media.

We are interested in the design and synthesis of stable low-coordinate cationic group 13 complexes of the type $[(LX)MR]^+$ and $[(LX)M(R)(L)]^+$ for applications in catalysis. To this purpose, we have recently focused our attention toward the synthesis of $[(LX)AlR]^+$ and $[(LX)Al(R)(L)]^+$

cations bearing either an *N*,O-aminophenolate or an *N*,*N*-bis(oxazolinato) bidentate ligand (**A** and **B**, Scheme 1).[9,10] In particular, the use of a chiral C_2-symmetric *N*,*N*-bis(oxazolinato) ligand has provided access to chiral cationic alkylaluminum complexes, which are of potential interest in asymmetric catalysis.[10] However, the instability of the Al cations incorporating **B**, especially in catalytic conditions, prompted us toward the synthesis of the Ga analogs, which are expected to be more stable. Thus, as part of our continuous studies of cationic and chiral group 13 alkyl complexes, we here report the synthesis and structure of neutral and cationic bis(oxazolinato)methylgallium complexes.

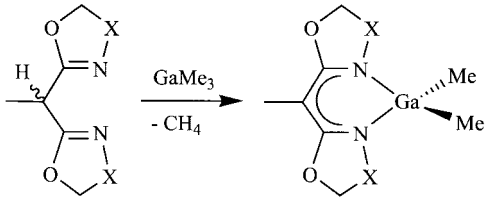
Scheme 1.

Results and Discussion

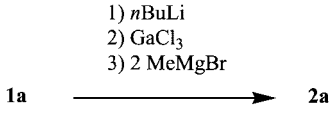
Bis(oxazolinato)dimethylgallium compounds were synthesized by the classical alkane elimination route involving a reaction between the appropriate bis(oxazoline) ligand and $GaMe_3$. This pathway was found to be the most straightforward and efficient method to access such compounds.

Thus, the reaction of the bis(oxazoline) ligands (BOX-Me_2)H (**1a**) and {BOX-(*S*)-*i*Pr}H (**1b**; Scheme 2) with an equimolar amount of $GaMe_3$ in pentane at –35 °C yields the bis(oxazolinato)dimethylgallium compounds [(BOX-Me_2)$GaMe_2$] (**2a**) and [{BOX-(*S*)-*i*Pr}$GaMe_2$] (**2b**; Scheme 2), respectively, which were isolated in nearly quantitative yields (>95% yield) as air-stable colorless solids. Alternatively, the achiral Ga derivative **2a** was also obtained by a salt metathesis pathway, although this approach was less efficient. Thus, the reaction of the bis(oxazolinato)lithium salt [(BOX-Me_2)Li], generated by deprotonation of bisoxazoline **1a** with *t*BuLi at –78 °C, with an equimolar amount of $GaCl_3$ (18 h, room temp.) yields [(BOX-Me_2)-$GaCl_2$], as observed by ^{1}H NMR spectroscopy. The in situ methylation of the dichlorogallium derivative with two equivalents of MeMgBr affords [(BOX-Me_2)$GaMe_2$] (**2a**) in moderate yield (48%).

The molecular structures of the Ga complexes **2a** and **2b** were determined by X-ray crystallography analysis, thus establishing their monomeric nature as well as the effective chelation of one bis(oxazolinato) ligand (Figures 1 and 2 and Table 1). As expected, both Ga species exhibit very similar structural features in the solid state and these will only discussed for the chiral derivative **2b**.



1a: X = CMe_2 **2a**: X = CMe_2
1b: X = (*S*)-CH*i*Pr **2b**: X = (*S*)-CH*i*Pr



Scheme 2.

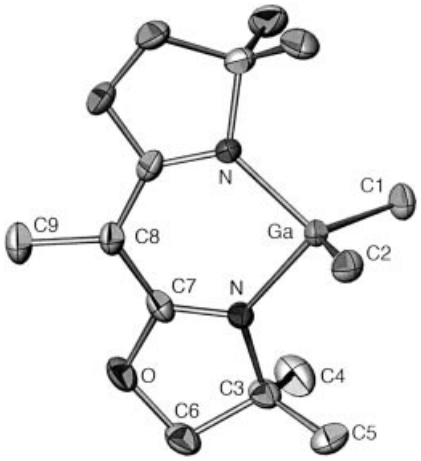


Figure 1. Molecular structure of complex **2a**. The H atoms have been omitted for clarity.

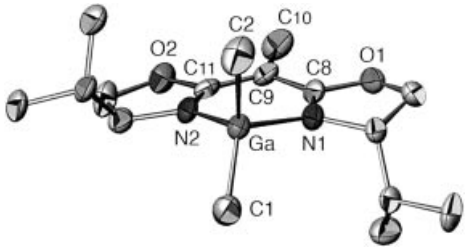

Figure 2. Molecular structure of chiral complex **2b**. The H atoms have been omitted for clarity. Selected torsion angles [°]: N(1)–C(8)–C(9)–C(11) = 5.8(15), Ga–N(2)–C(11)–C(10) = 3.2(4), Ga–N(2)–C(11)–C(9) = 2.5(11).

The Ga metal center in **2b** adopts a slightly distorted tetrahedral geometry with a chelate bite angle [N(1)–Ga–N(2) = 91.1(2)°] similar to that in the related β-diketiminatodimethylgallium complex [HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}-$GaMe_2$] [93.92(7)°], which also contains a six-membered C_3N_2Ga metallacycle.[11] The Ga–N and Ga–C bond lengths in **2b** [1.966(9) Å and 1.98(1) Å average, respectively] are similar to those observed in related {LX}$GaMe_2$

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Table 1. Selected bond lengths [Å] and angles [°] for **2a** and **2b**.

2a		**2b**	
Ga–N	1.9677(17)	Ga–N(1)	1.967(6)
Ga–C(1)	1.970(3)	Ga–N(2)	1.966(6)
Ga–C(2)	1.970(3)	Ga–C(1)	1.963(9)
N–C(7)	1.320(3)	Ga–C(2)	2.004(10)
C(7)–C(8)	1.395(3)	N(1)–C(8)	1.333(8)
		N(2)–C(11)	1.306(9)
		C(8)–C(9)	1.384(11)
		C(9)–C(11)	1.386(10)
N–Ga–N	91.33(10)	N(1)–Ga–N(2)	91.1(2)
N–Ga–C(2)	109.38(8)	C(1)–Ga–N(2)	111.8(4)
N–Ga–C(1)	111.85(8)	C(1)–Ga–N(1)	113.5(3)
C(1)–Ga–C(2)	119.47(14)	C(1)–Ga–C(2)	119.9(4)

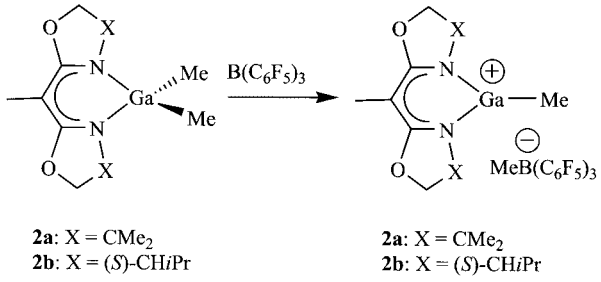
species such as [HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}$GaMe_2$],[11] [{PhC($NPh)_2$}$GaMe_2$],[12] and [{*t*BuC($NCy)_2$}$GaMe_2$].[13]

The six-membered C_3N_2Ga metallacycle in [{BOX-(*S*)-*i*Pr}$GaMe_2$] (**2b**) is nearly planar (C–C–Ga–N < 6°) with the carbon and nitrogen atoms adopting a trigonal-planar geometry (sum of angles ca. 360°). The planarity of the six-membered C_3N_2Ga backbone in **2b** contrasts with the folding of the C_3N_2Ga ring observed in [HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}$GaMe_2$], in which the Ga metal center lies significantly out of the C_3N_2 plane (0.76 Å). This structural difference presumably results from much weaker steric interactions between the Ga metal center and the chelating ligand in **2b** compared to [HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}-$GaMe_2$].[11] The C–C bond lengths within the C_3N_2 moiety [1.38(1) Å average] in **2b** are close to the C–C bond length in aromatic systems (1.395 Å), while the C–N bond lengths [1.32(1) Å average] lie between the C=N double-bond length in imines (1.28 Å) and the C(sp^2)–N single-bond length (1.47 Å). Altogether, these structural data are consistent with significant π-delocalization of the bis(oxazolinato) ligand backbone, resulting in a nearly C_2 symmetry for **2b** in the solid state. Similar structural features have been observed for the Al analogs.[10]

The NMR spectroscopic data for the Ga complexes **2a** and **2b** at room temperature are consistent with these species adopting overall C_{2v} and C_2 symmetry, respectively, in solution. These NMR spectroscopic data are therefore in agreement with the solid-state structures of **2a** and **2b** being retained in solution under the conditions studied here. For example, the ^{1}H NMR spectrum of **2b** (C_6D_6, room temp.) exhibits one Ga*Me*$_2$ resonance, one N-C*H* resonance and two Me-*i*Pr resonances, which is in agreement with a C_2-symmetric complex.

Reaction of Bis(oxazolinato)dimethylgallium Complexes 2a and 2b with $B(C_6F_5)_3$

Cationic alkylgallium complexes could be obtained by reaction of the neutral dimethylgallium derivatives with the strong Lewis acid $B(C_6F_5)_3$, which is known to readily abstract a methyl anion from the metal center of group 13 [{LX}MMe_2] species. Thus, the reaction of [{BOX}$GaMe_2$] (**2a**,**b**) with one equivalent of $B(C_6F_5)_3$ (C_6D_5Br, room temp., 10 min) results in the nearly quantitative formation of the cations [{BOX-Me_2}GaMe]$^+$ (**3a**$^+$) and [BOX-(*S*)-*i*Pr}GaMe]$^+$ (**3b**$^+$), respectively, as their $MeB(C_6F_5)_3^-$ salts, as observed by ^{1}H, ^{13}C, and ^{19}F NMR spectroscopy (Scheme 3). As expected, the Ga cations **3a**,**b**$^+$ are more stable than their Al counterparts; however, they slowly decompose at room temp. in C_6D_5Br ($t_{1/2} \approx 10$ h) to yield unidentified species, which precluded their isolation in a pure form. Initial attempts (by ^{1}H NMR) to observe cations **3a**,**b**$^+$ by carrying out the reaction on an NMR-tube scale in CD_2Cl_2 were unsuccessful, presumably due to fast decomposition of the desired cations in CD_2Cl_2.



Scheme 3.

The ^{1}H, ^{13}C and ^{19}F NMR spectroscopic data for the [**3a**,**b**][$MeB(C_6F_5)_3$] salt species are consistent with weak interactions between the cation and the anion down to –30 °C in C_6D_5Br solution. In particular, the *Me*$B(C_6F_5)_3^-$ resonance (δ = 0.97 ppm) in the ^{1}H NMR spectra of [**3a**,**b**]-[$MeB(C_6F_5)_3$] is characteristic of a free $MeB(C_6F_5)_3^-$ anion in solution at room temp. (Figure 3).[14] The NMR spectroscopic data for the Ga cations **3a**$^+$ and **3b**$^+$ are essentially unchanged between –30 °C and room temp. and agree with effective C_{2v}- and C_2-symmetric species for **3a**$^+$ and **3b**$^+$, respectively, under these conditions. For instance, as illustrated in Figure 3, the ^{1}H NMR spectrum of [**3a**][$MeB(C_6F_5)_3$] only exhibits four resonances for cation **3a**$^+$ (Ga*Me*$^+$, C*Me*$_2$, O-C*H*$_2$, and C*Me*), which is in agreement with a C_{2v}-symmetric complex. In addition, the Ga*Me*$^+$ resonance in **3a**$^+$ (δ = 0.40 ppm) is shifted dramatically downfield relative to the Ga*Me*$_2$ resonance of the neutral precursor **2a** (δ = –0.17 ppm) as a result of the cationic charge on Ga. Overall, on the basis of NMR spectroscopic data, the Ga cations **3a**,**b**$^+$ are most likely either three-coordinate "base-free" cationic species or four-coordinate cationic Ga solvent adducts (i.e. C_6D_5Br adducts) with a fast coordination/decoordination process on the NMR scale down to –30 °C. The latter proposal is based on the fact that a solid-state structure of a four-coordinate cationic Ga-ClPh adduct has been reported recently.[15]

The Lewis acidic Ga cation **3a**$^+$ reacts rapidly with an excess of propylene oxide (PO; 200 equiv., –20 °C, 5 min) to yield atactic oligomers with a broad polydispersity (40% conversion, M_n = 448, M_w/M_n = 2.38). A longer reaction time did not yield higher conversion, which strongly suggests a fast decomposition of cation **3a**$^+$ (within 5 min at –20 °C) to inactive species in the presence of excess PO.

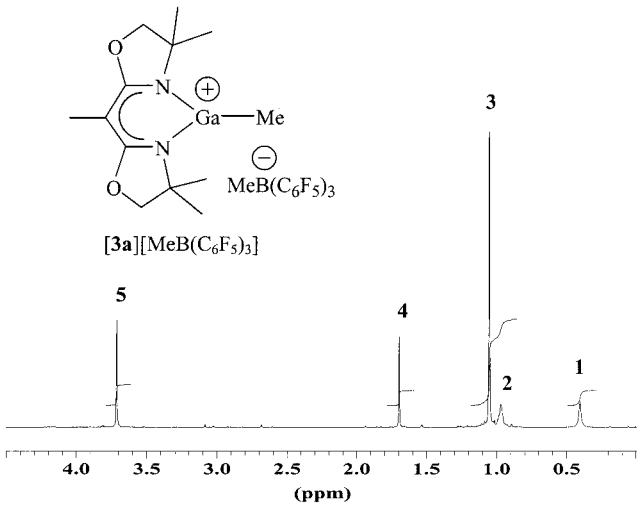

Figure 3. ^{1}H NMR spectrum of [**3a**][MeB(C_6F_5)$_3$] (C_6D_5Br, room temp.): δ = 0.40 (**1**, Ga*Me*), 0.97 (**2**, *Me*B), 1.05 (**3**, C*Me*$_2$), 1.70 (**4**, *Me*CCN), 3.71 (**5**, OCH_2) ppm.

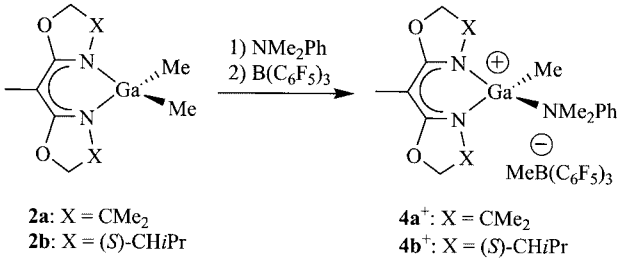
Synthesis and Structure of Four-Coordinate Methylgallium Cations (4a,b$^+$)

The lack of stability of cations **3a**,**b**$^+$ prompted us to generate them in the presence of a Lewis base such as NMe_2Ph, which is expected to trap the Ga cations to yield stable four-coordinate Ga–NMe_2Ph cationic adducts. Thus, the reaction of the bis(oxazolinato)dimethylgallium complexes (**2a**,**b**) with one equivalent of B(C_6F_5)$_3$ in the presence of one equivalent of NMe_2Ph (CH_2Cl_2, room temp., 10 min) yields the quantitative formation of the four-coordinate cations [{BOX-Me_2}Ga(Me)(NMe_2Ph)]$^+$ (**4a**$^+$) and [{BOX-(*S*)-*i*Pr}Ga(Me)(NMe_2Ph)]$^+$ (**4b**$^+$), respectively, as their MeB(C_6F_5)$_3^-$ salts (Scheme 4). The salt compounds [**4a**,**b**][MeB(C_6F_5)$_3$] are stable for days at room temperature in CH_2Cl_2 and could thus be isolated in a pure form as colorless solids in good yields. To the best of our knowledge, cation **4b**$^+$ in [**4b**][MeB(C_6F_5)$_3$] is the first example of a chiral cationic alkylgallium complex.



Scheme 4.

Compounds [**4a**,**b**][MeB(C_6F_5)$_3$] are dissociated species down to –30 °C in CD_2Cl_2 with weakly interacting **4a**,**b**$^+$ cations and MeB(C_6F_5)$_3^-$. The ^{1}H NMR spectra of the cationic NMe_2Ph adducts **4a**,**b**$^+$ both contain a Ga*Me*$^+$ resonance that is significantly downfield shifted as compared to the Ga*Me*$_2$ resonances in the neutral precursors **2a**,**b**, which is indicative of a cationic Ga center. Likewise, the ^{1}H and ^{13}C NMR resonances of **4a**,**b**$^+$ assigned to the coordinated NMe_2Ph are strongly downfield shifted relative to those in free NMe_2Ph, which is consistent with an effective coordination of NMe_2Ph to the Ga center. Overall, the NMR spectroscopic data at room temp. agree with effective C_{2v}- and C_2-symmetric solution structures for cations **4a** and **4b**$^+$, respectively, thereby indicating a fast face-exchange of NMe_2Ph on the NMR timescale. To probe this issue further, low temperature ^{1}H and ^{13}C NMR experiments were carried out to reach a slow NMe_2Ph exchange process. Thus, the NMR spectroscopic data for cations **4a**$^+$ and **4b**$^+$ recorded at –25 °C and –35 °C in CD_2Cl_2, respectively, exhibit an overall C_s symmetry for **4a**$^+$ and a C_1 symmetry for chiral **4b**$^+$. These data are consistent with a slow face-exchange of NMe_2Ph on the NMR timescale for both cations (see Exp. Sect.). For comparison, the labile coordination of NMe_2Ph to Ga observed here for **4a**,**b**$^+$ at room temperature contrasts with the nonlabile coordination of this amine to Al in the cationic Al analogs under identical conditions, which may reflect a more Lewis acidic cationic Al vs. Ga center.[10]

The Lewis acid character of the Ga–NMe_2Ph adduct **4a**$^+$ was also tested with PO. Like **3a**$^+$, cation **4a**$^+$ oligomerizes PO (200 equiv. of PO, room temp., 15 min) to afford low molecular weight oligomers in high conversion (85% conversion, M_n = 339, M_w/M_n = 1.25). The oligomerization process is clearly multimodal, as deducted from size exclusion chromatographic data, thus suggesting the presence of several active species.

Solid-State Structure of the Cationic Adduct 4a$^+$

While a few examples of X-ray characterized low-coordinate Al cations are known, solid-state structures of Ga analogs are rather scarce,[1,7a,16] and, to date, none of the type [{LX}Ga(R)(L)]$^+$ have been reported.

The molecular structure of the salt species [**4a**][MeB(C_6F_5)$_3$] was confirmed by X-ray crystallography analysis (Tables 2 and 3). It crystallizes as discrete **4a**$^+$ cations and MeB(C_6F_5)$_3^-$ anions, with no cation–anion interaction. As shown in Figure 4, cation **4a**$^+$ is an NMe_2Ph-stabilized four-coordinate methylgallium cation in which the Ga center adopts a distorted tetrahedral structure with a chelate bite angle N(1)–Ga–N(2) [96.98(7)°] similar to that in the neutral precursor **2a**. Unlike the nearly planar six-membered C_3N_2Ga metallacycle in complexes **2a**,**b**, that in **4a**$^+$ is significantly distorted from planarity, with the Ga center being displaced by 0.33(2) Å from the N(2)–C(6)–N(1)–C(9) average plane toward the coordinated NMe_2Ph. This distortion may well be to minimize steric interactions between the Ga-NMe_2Ph moiety and the bis(oxazolinato) ligand. The Ga–N bond lengths within the chelate-Ga entity [1.9018(19) and 1.9100(16) Å] are rather short as compared to those in **2a** [1.966(9) Å], due to the stronger ionic character of these bonds in **4a**$^+$ vs. **2a**, a result of the cationic charge, whereas the Ga–N_{amine} bond length [Ga–N(3) = 2.124(3) Å] is considerably longer and is comparable to those observed in neutral bulky gallium amine adducts such

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

as $[Me_3Ga(tBuNH_2)]$ [2.12(1) Å].[17] Due to the enhanced Lewis acidity of Ga in **4a**$^+$ vs. $[Me_3Ga(tBuNH_2)]$, a shorter Ga–N(3) bond length in **4a**$^+$ vs. $Me_3Ga(tBuNH_2)$ would be expected from an electronic point of view; this rather long Ga–N distance for **4a**$^+$ may be to minimize steric interactions between the aniline and the chelating ligand.

Table 2. Selected bond lengths [Å] and angles [°] for [**4a**][$MeB(C_6F_5)_3$] and [**5a**][$B(C_6F_5)_4$].

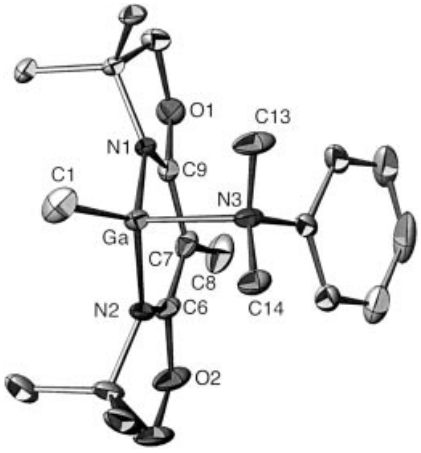

Figure 4. Molecular structure of the Ga cation **4a**$^+$. The H atoms have been omitted for clarity. Selected torsion angles [°]: N(2)–Ga–N(1)–C(9) = 13.54(14),; N(1)–Ga–N(2)–C(6) = 15.36(15), N(1)–C(9)–C(7)–C(6) = 13.0(3).

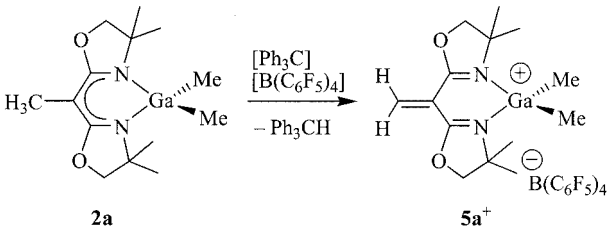
Reaction of [{BOX-Me_2}$GaMe_2$] (2a) with [Ph_3C][$B(C_6F_5)_4$]

As stated in the introduction, the trityl salt [Ph_3C][$B(C_6F_5)_4$] is the other landmark reagent, along with $B(C_6F_5)_3$, that is used to generate group-13 alkyl cations of the type [{LX}MMe]$^+$ from [{LX}MMe_2] by a Me^- abstraction at the metal center. We thus decided to study the reaction between [{BOX-Me_2}$GaMe_2$] (**2a**) and [Ph_3C][$B(C_6F_5)_4$].

The reaction of [{BOX-Me_2}$GaMe_2$] (**2a**) with one equivalent of [Ph_3C][$B(C_6F_5)_4$] (CH_2Cl_2, room temp., 10 min) yields the quantitative formation of the bis(imine)-dimethylgallium cation [{H_2C=C(OX-Me_2)$_2$}$GaMe_2$]$^+$ (**5a**$^+$) as a $B(C_6F_5)_4^-$ salt, along with one equivalent of Ph_3CH (Scheme 5). Thus, instead of abstracting a Me^- from the Ga center of **2a**, Ph_3C^+ abstracts a hydride from the Me group located at the back of the bis(oxazolinato) ligand in compound **2a** to afford cation **5a**$^+$. The outcome of this reaction confirms a reactivity already observed with the Al analog [{BOX-Me_2}$AlMe_2$], which has been found to yield a similar bis-imine cation when treated with [Ph_3C][$B(C_6F_5)_4$].[10] Nevertheless, the observed reactivity, i.e. a hydride abstraction at a group rather far away from the metal center, contrasts with the usual reactivity of Ph_3C^+ with alkyl metal complexes. Typically, hydride abstractions by Ph_3C^+ at such dialkyl species occur either at the C_α of the metal-bonded alkyl group or at the C_β, both of which, in any case, are in the vicinity of the metal center.[18]



Scheme 5.

The salt compound [**5a**][$B(C_6F_5)_4$], which is stable for days at room temp. in CH_2Cl_2, was obtained as an analytically pure colorless solid in good yield (see Exp. Sect.). Its molecular structure, as determined by X-ray crystallography, shows that [**5a**][$B(C_6F_5)_4$] crystallizes as **5a**$^+$ cations and $B(C_6F_5)_4^-$ anions with no cation–anion interaction in the solid state. The cationic species **5a**$^+$can be seen as a dimethylgallium cation in which the $GaMe_2^+$ moiety is chelated by the neutral bisoxaline H_2C=C(OX-Me_2)$_2$ (Figure 5). Accordingly, the bonding parameters within the C_3N_2 ligand backbone in **5a**$^+$ are consistent with a π-localized structure: the C(3)–N(1) and C(10)–N(2) bond lengths [1.285(3) and 1.282(3) Å] compare with the typical value for C(sp^2)=N double bonds (1.30 Å) while the C(8)–C(9) bond length [1.329(3) Å] is consistent with that of a C=C double

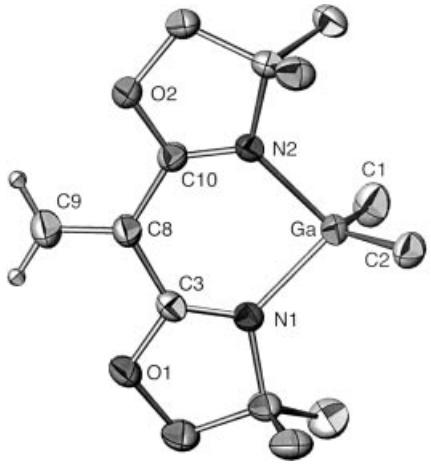


Figure 5. Molecular structure of the Ga cation **5a**$^+$. The H atoms have been omitted for clarity. Selected torsion angles [°]: N(1)–Ga–N(2)–C(10) = 12.53(19), N(2)–C(10)–C(8)–C(3) = 3.7(3), N(2)–C(10)–C(8)–C(9) = 3.0(3).

bond (1.337 Å). In addition, the Ga–N bond lengths in **5a**$^+$ [2.018(1) Å average] are comparable to those observed in neutral Ga imine complexes, e.g. in dimethyl-(*N*-methylsalicylaldiminato)gallium, Ga–N = 2.019 Å,[19] as expected for a bis-imine gallium complex such as **5a**$^+$. All other structural parameters are very similar to those in the neutral precursor **2a**.

As for the solution structure of **5a**$^+$, the NMR spectroscopic data agree with the solid-state structure being retained in solution and with no association between **5a**$^+$ and its counterion in CD_2Cl_2 solution at room temp. In particular, the ^1H and ^{13}C NMR spectra of **5a**$^+$ both contain one characteristic resonance at δ = 7.30 and 143.7 ppm, respectively, which can be assigned to the H_2C=C group of the chelating bis(oxazoline).

Summary and Conclusions

Bis(oxazolinato)dimethylgallium complexes of the type [{BOX}$GaMe_2$] (**2a**,**b**) can be obtained in high yield by reaction of $GaMe_3$ with the desired neutral bis(oxazoline) via methane elimination. These neutral dimethylgallium precursors react rapidly with $B(C_6F_5)_3$, via a Me^- abstraction, to yield the Ga cations **3a**,**b**$^+$, which are either three-coordinate methylgallium cations of the type [{BOX}GaMe]$^+$ or four-coordinate cationic Ga-solvent adducts. Although more stable than their Al counterparts, cations **3a**,**b**$^+$ decompose over the course of several hours to give unidentified species. The lack of stability of the [{BOX}GaMe]$^+$ methyl cations reported here contrasts with the stability of the three-coordinate Al cation [HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}AlMe]$^+$, which also incorporates a six-membered Al metallacycle. The greater steric crowding provided at the metal center by HC{C(Me)N(C_6H_3-2,6-*i*Pr_2)}$^-$ vs. {BOX-Me_2}$^-$ or {BOX-(*S*)-*i*Pr}$^-$ may be responsible for this difference of stability.

When the ionization of [{BOX}$GaMe_2$] (**2a**,**b**) with $B(C_6F_5)_3$ is performed in the presence of an external Lewis base such as NMe_2Ph, the corresponding four-coordinate cationic Ga adducts [{BOX}Ga(Me)(NMe_2Ph)]$^+$ (**4a**,**b**$^+$) are isolated in good yield, the cation **4b**$^+$ being of particular interest as a chiral cationic derivative. Finally, [{BOX-Me_2}$GaMe_2$] (**2a**) reacts with [Ph_3C][$B(C_6F_5)_4$] to yield an unusual cationic bis(imino)gallium adduct [{H_2C=C(OX-Me_2)$_2$}$GaMe_2$]$^+$ (**5a**$^+$) via a hydride abstraction at the back of the bis(oxazolinato) ligand.

Cations **3a**$^+$ and **4a**$^+$ were found to rapidly olygomerize PO at low temperature, thereby illustrating the Lewis acid character of these species. However, the broad polydispersity of the obtained oligomers suggests a poor stability of these species in catalytic conditions.

Further studies will focus on the synthesis and use of bulkier and chiral LX^- ligands for coordination to group 13 metals.

Experimental Section

General Procedures: All experiments were carried out under N_2 using standard Schlenk techniques or in an Mbraun Unilab glovebox. Toluene, pentane, and THF were distilled from Na/benzophenone and stored over activated molecular sieves (4 Å) in a glovebox prior to use. CH_2Cl_2 and CD_2Cl_2, were distilled from CaH_2 and stored over activated molecular sieves (4 Å) in a glovebox prior to use. C_6D_6 was degassed under an N_2 flow and stored over activated molecular sieves (4 Å) in a glovebox prior to use. $B(C_6F_5)_3$ was purchased from Strem Chemicals and was extracted with dry pentane prior to use. [Ph_3C][$B(C_6F_5)_4$] was purchased from Asahi Glass Europe and used as received. CD_2Cl_2, C_6D_6, and C_6D_5Br were purchased from Eurisotop. All other chemicals were purchased from Aldrich and were used as received. The bisoxazoline ligands **1a**,**b** were synthesized according to a literature procedure.[10] All NMR spectra were recorded at room temperature (unless otherwise indicated) on a Bruker Avance 300 MHz or 400 MHz spectrometer. ^1H and ^{13}C chemical shifts are reported relative to $SiMe_4$ and were determined by reference to the residual ^1H and ^{13}C solvent peaks. ^{11}B and ^{19}F chemical shifts are reported relative to $BF_3{\cdot}Et_2O$ in CD_2Cl_2 and $CFCl_3/CDCl_3$, respectively. SEC analysis was carried out on a system equipped with 4 PL Gel columns (250 mm length × 7.5 mm inner diameter) in series and with THF as solvent. A Shimadzu SPD10Avp UV detector coupled with a Shimadzu RID6A refractometer was employed. The apparatus was calibrated using a POE standard from Polymer Laboratories. Elemental analyses for [**4a**,**b**][$MeB(C_6F_5)_3$] and [**5a**][$B(C_6F_5)_4$] were performed by the Mikroanalytisches Labor Pascher, Remagen-Bandorf, Germany, while those for compounds **2a**,**b** were performed by the microanalysis laboratory of the Université Pierre et Marie Curie, Paris, France.

For the compounds listed below, the assignment of all ^1H and $^{13}C\{^1H\}$ NMR resonances was possible using DEPT experiments combined, when necessary, with HMQC experiments.

[{BOX-Me_2}$GaMe_2$] (2a) by Methane Elimination: In a glovebox, a pentane solution (3 mL) of $GaMe_3$ (285 mg, 2.48 mmol), previously cooled to –35 °C in a freezer, was slowly added with a Pasteur pipette to a pentane solution (7 mL) of bisoxazoline **1a** (557 mg, 2.48 mmol), also precooled to –35 °C. The resulting colorless solution was then allowed to warm to room temperature. Upon warming to room temperature, a slight bubbling was observed, as expected for methane formation. After stirring the solution for 2 h at room temperature, it was then evaporated to dryness under vacuum to yield pure **2a** as a colorless solid in nearly quantitative yield (785 mg, 98% yield). ^1H NMR (400 MHz, C_6D_6): δ = 0.03 (s, 6 H, Ga*Me*$_2$), 1.02 (s, 12 H, C*Me*$_2$), 2.26 (s, 3 H, *Me*CCN), 3.41 (s, 4 H, OC*H*$_2$) ppm. ^1H NMR (400 MHz, CD_2Cl_2): δ = –0.38 (s, 6 H, Ga*Me*$_2$), 1.29 (s, 12 H, C*Me*$_2$), 1.70 (s, 3 H, *Me*CCN), 3.95 (s, 4 H, OC*H*$_2$) ppm. ^1H NMR (400 MHz, C_6D_5Br): δ = –0.17 (s, 6 H, Ga*Me*$_2$), 1.11 (s, 12 H, CMe$_2$), 1.99 (s, 3 H, *Me*CCN), 3.64 (s, 4 H, OC*H*$_2$) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, C_6D_6): δ = –2.8 (Ga*Me*$_2$), 10.3 (*Me*CCN), 27.7 (C*Me*$_2$), 62.3 (Me*C*CN), 63.7 (*C*Me$_2$), 78.7 (O*C*H$_2$), 170.2 (O*C*N) ppm. $C_{14}H_{25}GaN_2O_2$ (323.08): calcd. C 52.05, H 7.80; found C 52.14, H 7.72.

[{BOX-Me_2}$GaMe_2$] (2a) by Salt Metathesis: On a nitrogen-filled vacuum line, *t*BuLi (0.550 mL of a 1.7 M pentane solution, 0.934 mmol) was added dropwise, from a syringe, to a THF solution (10 mL) of bisoxazoline **1a** (209 mg, 0.934 mmol) that had been cooled to –78 °C in an acetone/dry ice bath. Upon addition of *t*BuLi, the initial colorless solution turned bright yellow. After the addition, the resulting yellow solution was allowed to warm to room temperature and was stirred for 3 h. Evaporation of the volatiles under reduced pressure yielded a yellow sticky residue which was washed twice with cold pentane (2 × 10 mL cooled to –35 °C) to afford a colorless solid. In a glovebox, this solid was dissolved

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

in toluene (10 mL) in a small Schlenk flask and cooled to –35 °C in a freezer for 1 h. After this time, the cold colorless solution was taken out of the freezer and stirred vigorously. A toluene solution (5 mL) of $GaCl_3$ (164 mg, 0.934 mmol), also precooled to –35 °C, was then quickly added to this solution and the resulting mixture was allowed to warm to room temperature. Upon warming to room temperature, the initial solution turned into a colorless suspension (indicating the formation of LiCl), which was left stirring overnight at room temperature. The reaction mixture was then filtered through a glass frit and the resulting filtrate evaporated under vacuum to yield crude **2a** as a sticky colorless solid. Recrystallization of this crude product from a 1:1 Et_2O/pentane solution cooled to –35 °C afforded pure **2a** as colorless crystals (145 mg, 48% yield).

[{BOX-(*S*)-*i*Pr}$GaMe_2$] (2b): The chiral dimethylgallium compound **2b** was synthesized by methane elimination using the same procedure as for **2a**, using an equimolar amount of {BOX-(*S*)-*i*Pr}H (300 mg, 1.19 mmol) and $GaMe_3$ (136 mg, 1.19 mmol) to afford pure **2b** as a colorless solid in high yield (401 mg, 96% yield). ^{1}H NMR (300 MHz, C_6D_6): δ = 0.00 (s, 6 H, Ga*Me*$_2$), 0.49 (d, $^3J_{H,H}$ = 7.0 Hz, 6 H, *Me*-*i*Pr), 0.74 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, *Me*-*i*Pr), 1.91 (d of septet, $^3J_{H,H\ doublet}$ = 3.3, $^3J_{H,H\ septet}$ = 6.9 Hz, 2 H, C*H*-*i*Pr), 2.21 (s, 3 H, *Me*CCN), 3.56–3.66 (m, 4 H, OCH_2), 3.68–3.75 (m, 2 H, C*H*N) ppm. ^{1}H NMR (300 MHz, CD_2Cl_2): δ = –0.45 (s, 6 H, Ga*Me*$_2$), 0.80 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, *Me*-*i*Pr), 0.89 (d, $^3J_{H,H}$ = 7.0 Hz, 6 H, *Me*-*i*Pr), 1.68 (s, 3 H, *Me*CCN), 1.96 (d of septet, $^3J_{H,H\ doublet}$ = 3.4, $^3J_{H,H\ septet}$ = 6.9 Hz, 2 H, C*H*-*i*Pr), 3.96–4.01 (m, 2 H, C*H*N), 4.06–4.11 (dd, $^2J_{H,H}$ = 8.4, $^3J_{H,H}$ = 8.4 Hz, 2 H, OCH_2), 4.17–4.23 (dd, $^2J_{H,H}$ = 8.4, $^3J_{H,H}$ = 9.2 Hz, 2 H, OCH_2) ppm. ^{1}H NMR (300 MHz, C_6D_5Br): δ = –0.19 (s, 6 H, Ga*Me*$_2$), 0.66 (d, $^3J_{H,H}$ = 7.0 Hz, 6 H, *Me*-*i*Pr), 0.73 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, *Me*-*i*Pr), 1.90 (d of septet, $^3J_{H,H\ doublet}$ = 3.3, $^3J_{H,H\ septet}$ = 6.9 Hz, 2 H, C*H*-*i*Pr), 1.96 (s, 3 H, *Me*CCN), 3.84–3.92 (m, 6 H, OCH_2 and C*H*N) ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6): δ = –6.4 (Ga*Me*$_2$), 10.4 (*Me*CCN), 14.5 (*Me*-*i*Pr), 18.9 (*Me*-*i*Pr), 30.0 (*C*H-*i*Pr), 61.4 (Me*C*CN), 66.5 (*C*HN), 66.9 (O*C*H$_2$), 171.1 (O*C*N) ppm. $C_{16}H_{29}GaN_2O_2$ (351.14): calcd. C 54.73, H 8.32; found C 54.42, H 8.17.

[{BOX-Me_2}GaMe][MeB(C_6F_5)$_3$] ([3a][MeB(C_6F_5)$_3$]): In a glovebox, an equimolar amount of **2a** (30.0 mg, 0.093 mmol) and B(C_6F_5)$_3$ (47.5 mg, 0.093 mmol) were charged in a J-Young NMR tube and 0.75 mL of C_6D_5Br was added. The NMR tube was vigorously shaken to yield a colorless solution and a ^{1}H NMR spectrum was immediately recorded, showing the nearly quantitative formation of [**3a**][MeB(C_6F_5)$_3$] as a fully dissociated salt species, along with minor impurities. Due to the relatively poor stability of [**3a**][MeB(C_6F_5)$_3$], the ^{13}C{^{1}H} NMR spectrum was recorded at –25 °C to ensure good data. ^{1}H NMR (400 MHz, C_6D_5Br): δ = 0.40 (s,3 H, Ga*Me*), 0.97 (br. s, 3 H, *Me*B), 1.05 (s, 12 H, C*Me*$_2$), 1.70 (s, 3 H, *Me*CCN), 3.71 (s, 4 H, OCH_2) ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_5Br, 248 K): δ = –4.6 (Ga*Me*), 9.3 (*Me*CCN), 11.7 (br., *Me*B), 28.2 (C*Me*$_2$), 64.4 (*C*Me$_2$), 71.3 (Me*C*CN), 79.4 (O*C*H$_2$), 137.2 (dm, $^2J_{C,F}$ = 256 Hz, *o*- or *m*-C_6F_5), 137.9 (dm, $^2J_{C,F}$ = 243 Hz, *p*-C_6F_5), 148.8 (dm, $^2J_{C,F}$ = 237 Hz, *o*- or *m*-C_6F_5), 171.0 (O*C*N) ppm.

[{BOX-(*S*)-*i*Pr}GaMe][Me(BC_6F_5)$_3$] ([3b][MeB(C_6F_5)$_3$]): The chiral salt compound [**3b**][MeB(C_6F_5)$_3$] was generated on an NMR scale using the same procedure as that for [**3a**][MeB(C_6F_5)$_3$], with an equimolar amount of **2b** (15 mg, 0.043 mmol) and B(C_6F_5)$_3$ (21.9 mg, 0.043 mmol). ^{1}H NMR (400 MHz, C_6D_5Br, 298 K): δ = 0.36 (s,3 H, Ga*Me*), 0.57 (d, $^3J_{H,H}$ = 6.8 Hz, 6 H, Me-*i*Pr), 0.63 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, Me-*i*Pr), 0.97 (br. s, 3 H, *Me*B), 1.57 (d of septet, $^3J_{H,H\ doublet}$ = 3.1, $^3J_{H,H\ septet}$ = 6.6 Hz, 2 H, C*H*-*i*Pr), 1.74 (s, 3 H, *Me*CCN), 3.77–3.83 (m, 4 H, OCH_2), 3.90–3.95 (m, 2 H, NC*H*) ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_5Br, 248 K): δ = –4.1 (Ga*Me*), 9.9 (*Me*CCN), 11.7 (br., *Me*B), 15.2 (*Me*-*i*Pr), 18.7 (*Me*-*i*Pr), 33.1 (*C*H-*i*Pr), 65.9 (*C*HN), 69.7 (*C*H$_2$O), 71.9 (Me*C*CN), 137.2 (dm, $^2J_{C,F}$ = 256 Hz, *o*- or *m*-C_6F_5), 137.9 (dm, $^2J_{C,F}$ = 243 Hz, *p*-C_6F_5), 148.8 (dm, $^2J_{C,F}$ = 237 Hz, *o*- or *m*-C_6F_5), 172.3 (O*C*N) ppm.

[{BOX-Me_2}Ga(Me)(NMe_2Ph)][MeB(C_6F_5)$_3$] ([4a][MeB(C_6F_5)$_3$]): In a glovebox, the dimethylgallium derivative **2a** (200 mg, 0.619 mmol) was charged in a Schlenk flask and dissolved in CH_2Cl_2 (5 mL). NMe_2Ph (78.5 µL, 0.620 mmol) was then first added from a syringe to the colorless solution, followed by the addition of B(C_6F_5)$_3$ (317 mg, 0.619 mmol) all at once. The resulting mixture was stirred for 1 h at room temperature and, after this time, evaporated to dryness under vacuum to yield a colorless foamy residue. Trituration of this residue with cold pentane (precooled to –35 °C) caused the precipitation of a colorless solid, which, after passing the solution through a glass frit nd further drying in vacuo, was found to be the salt species [**4a**][MeB(C_6F_5)$_3$] in a pure form (479 mg, 81% yield). ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 0.39 (s, 3 H, Ga*Me*), 0.48 (*Me*B), 1.13 (br., 12 H, C*Me*$_2$), 1.73 (s, 3 H, *Me*CCN), 2.96 (s, 6 H, N*Me*$_2$Ph), 4.05 (br., 4 H, OCH_2), 7.00–7.41 (br., 5 H, NMe$_2$*Ph*) ppm. ^{1}H NMR (400 MHz, CD_2Cl_2, 253 K): δ = 0.36 (s, 3 H, Ga*Me*), 0.42 (*Me*B), 0.92 (s, 6 H, C*Me*$_2$), 1.11 (s, 6 H, C*Me*$_2$), 1.67 (s, 3 H, *Me*CCN), 2.93 (s, 6 H, N*Me*$_2$Ph), 3.81 (br. d, $^2J_{H,H}$ = 8.2 Hz, 2 H, OCH_2), 4.16 (br. d, $^2J_{H,H}$ = 8.2 Hz, 2 H, OCH_2), 7.20 (d, $^3J_{H,H}$ = 7.2 Hz, 2 H, NMe$_2$*Ph*), 7.33 (br., 1 H, NMe$_2$*Ph*), 7.44 (br., 2 H, NMe$_2$*Ph*) ppm. ^{13}C{^{1}H} NMR (100 MHz, CD_2Cl_2): δ = –10.2 (Ga*Me*), 8.3 (*Me*CCN), 9.1 (br., *Me*B), 26.8 (br., C*Me*$_2$), 45.2 (br., N*Me*$_2$Ph), 63.6 (*C*Me$_2$), 67.4 (Me*C*CN), 78.4 (O*C*H$_2$), 118.5 (br., NMe$_2$*Ph*), 129.0 (br., NMe$_2$*Ph*), 129.5 (NMe$_2$*Ph*), 136.7 (d, $^1J_{C,F}$ = 233 Hz, *m*-C_6F_5), 137.9 (d, $^1J_{C,F}$ = 238 Hz, *p*-C_6F_5), 148.6 (d, $^1J_{C,F}$ = 233 Hz, *o*-C_6F_5), 171.7 (O*C*N) ppm. ^{13}C{^{1}H} NMR (100 MHz, CD_2Cl_2, 263 K): δ = –10.7 (Ga*Me*), 8.1 (*Me*CCN), 9.4 (br., *Me*B), 23.8 (C*Me*$_2$), 27.6 (C*Me*$_2$), 45.8 (br., N*Me*$_2$Ph), 63.2 (*C*Me$_2$), 69.0 (Me*C*CN), 77.9 (O*C*H$_2$), 119.6 (*o*-*Ph*NMe$_2$), 127.2 (*p*-*Ph*NMe$_2$), 129.4 (*m*-*Ph*NMe$_2$), 136.7 (d, $^1J_{C,F}$ = 233 Hz, *m*-C_6F_5), 137.9 (d, $^1J_{C,F}$ = 238 Hz, *p*-C_6F_5), 145.1 (C_{ipso}-*Ph*NMe$_2$), 148.6 (d, $^1J_{C,F}$ = 233 Hz, *o*-C_6F_5), 171.2 (O*C*N) ppm. $C_{40}H_{36}BF_{15}GaN_3O_2$ (956.24): calcd. [{H$_2$C=C(OX-Me$_2$)$_2$}GaMe$_2$][B(C$_6$F$_5$)$_4$] ([5a][B(C$_6$F$_5$)$_4$]): In a glovebox, stoichiometric amounts of [{BOX-Me$_2$}GaMe$_2$] (50 mg, 0.155 mmol) and [Ph_3C][$B(C_6F_5)_4$] (143 mg, 0.155 mmol) were charged in a 25-mL round-bottomed flask and dissolved in CH_2Cl_2 (2 mL). While under vigorous stirring at room temperature, the initial bright-red solution turned pale yellow within seconds, indicating the total consumption of the trityl salt. The mixture was stirred for 1 h at room temperature, after which it was evaporated to dryness under vacuum. Addition of cold pentane (precooled to –35 °C) provoked the precipitation of a colorless solid. The mixture was then filtered through a glass frit and the obtained colorless residue washed three times with cold pentane to remove any remaining Ph_3CH. Further drying of the residue in vacuo afforded the salt species [**5a**][$B(C_6F_5)_4$] as an analytically pure colorless solid (136 mg, 88% yield). ^{1}H NMR (400 MHz, CD_2Cl_2): δ = –0.01 (s, 6 H, Ga*Me*$_2$), 1.53 (s, 12 H, C*Me*$_2$), 4.44 (s, 4 H, OC*H*$_2$), 7.30 (s, 2 H, C*H*$_2$=C) ppm. ^{13}C{^{1}H} NMR (100 MHz, CD_2Cl_2): δ = –4.3 (Ga*Me*$_2$), 26.8 (C*Me*$_2$), 69.3 (*C*Me$_2$), 80.6 (O*C*H$_2$), 118.4 (H$_2$C=*C*), 136.7 (dm, $^1J_{C,F}$ = 243 Hz, *C*$_6$F$_5$), 138.6 (dm, $^1J_{C,F}$ = 243 Hz, *C*$_6$F$_5$), 143.7 (H$_2$*C*=C), 148.5 (dm, $^1J_{C,F}$ = 239 Hz, *C*$_6$F$_5$), 162.6 (O*C*=N) ppm. $C_{38}H_{24}BF_{20}GaN_2O_2$ (1001.11): calcd. C 45.59, H 2.42; found C 45.95, H 2.37.

X-ray Structure Analysis of Complexes 2a,b, [4a][MeB(C$_6$F$_5$)$_3$] and [5a][B(C$_6$F$_5$)$_4$]: Single crystal of **2a**, **2b**, [**4a**][$MeB(C_6F_5)_3$], and [**5a**][$B(C_6F_5)_4$] were mounted on a Nonius Kappa-CCD area detector diffractometer (Mo-K_α radiation; λ = 0.71073 Å). The complete conditions of data collection (Denzo software)[20] and structure refinements are given in Table 3. The cell parameters were determined from reflections taken from one set of 10 frames (1.0° steps in phi angle), each at 20 s exposure. The structures were solved by direct methods (SHELXS97) and refined against F^2 using the SHELXL97 software.[21] The absorption was not corrected. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were generated according to stereochemistry and refined using a riding model in SHELXL97.

CCDC-273080 (for **2a**), -273081 (for **2b**), -273082 (for [**4a**][$MeB(C_6F_5)_3$]), and -273083 (for [**5a**][$MeB(C_6F_5)_3$]) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Hydride Route for the Palladium-Catalysed Cyclocarbonylation of Monoterpenes

Duc Hanh Nguyen,[a] Gábor Laurenczy,[b] Martine Urrutigoïty*[a] and Philippe Kalck*[a]

Keywords: Carbonylation / Hydrides / Palladium / Terpenes

This paper focuses on the mechanism by which a monoterpene undergoes a cyclocarbonylation reaction catalysed by a palladium complex. Evidence is provided, based on intermediate species observed under pressure or with various ligands, that the catalytic cycle follows a hydride route starting from $[Pd(H)(SnCl_3)L_2]$. The $[Pd(H)(SnCl_3)L_2]$ complexes (L = PPh_3 or PCy_3) have been observed for the first time by multinuclear NMR spectroscopy. Cationic hydride complexes or palladium(0) precursors show either no or poor reactivity. Studies related to model platinum complex chemistry have detected an acylplatinum species. Most of the observations have been done on the cyclocarbonylation of isopulegol, dihydromyrcenol or isolimonene into the corresponding lactones or cyclopentanones. The use of dihydromyrcene allowed us to observe the acylplatinum complex and the corresponding elusive acylpalladium species. The co-catalytic role of $SnCl_2$ is also demonstrated.

Introduction

Palladium chemistry is currently the workhorse of organic chemistry and is a versatile tool to perform carbon–carbon coupling.[1] When appropriate building blocks are introduced the substrate can follow a multistep functionalisation so that tandem reactions open the way for the preparation of rather sophisticated organic molecules.[2] A number of interesting compounds that show biological activity contain a lactone moiety.[3] During the last few years we have explored the introduction of a CO building block into an unsaturated substrate to obtain such a backbone in a one-pot synthesis.[4] We chose to follow an hemisynthetic way starting from an abundant and cheap raw material like monoterpenes. Thus, we functionalised isopulegol and dihydromyrcenol into the corresponding lactones,[4] and then extended this type of tandem reaction to the cyclocarbonylation of isolimonene, which produces a cyclopentanone.[5] All these reactions are an extension of the classical alkoxycarbonylation reaction by which a terminal alkene is carbonylated in the presence of an alcohol to provide an ester. Generally, this reaction is catalysed by a palladium complex containing a phosphane or a diphosphane ligand, and most often the $[PdCl_2L_2]$ precursor is introduced into the medium. These reactions are promoted by the addition of a Lewis acid such as $SnCl_2$. Two catalytic pathways have been considered, and are still proposed in the literature: the first one involves an alkoxycarbonylpalladium intermediate [Pd-COOR] to which the alkene coordinates and finally a *cis*-migration produces an alkylpalladium moiety containing the ester group,[6] whereas the second one starts from an intermediate palladium hydride species [Pd–H] which gives an alkylpalladium intermediate by successive coordination of the alkene and subsequent hydride transfer.[1,7] The copolymerisation of ethylene and carbon monoxide catalysed by the cationic $[Pd(diphos)]^{2+}$ complexes in the presence of methanol perfectly interconnects the two catalytic pathways[8] such that polymers with $-CH_2COOCH_3$ and $-CH_2CH_3$ terminal functions are produced in equal proportions. For the alkoxycarbonylation reaction of an alkene, Knifton has reported the $[PdCl_2(PPh_3)_2]/SnCl_2$ catalytic system, with which he detected the presence of a ν(Pd–H) stretching frequency.[7] In the literature, several papers deal with evidence that the palladium hydride pathway operates preferentially.[9,10] Particularly, in recent studies Heaton and co-workers have synthesised cationic Pd^{II} hydride complexes containing both a diphosphane ligand and a coordinated solvent molecule, $[Pd(H)(dtbpx)(MeOH)]^+$ [dtbpx = 1,2-$(CH_2P\mathit{t}Bu_2)_2C_6H_4$].[10] They demonstrated that this complex is an essential intermediate in the catalytic system for the formation of methyl propanoate by carbonylation of ethene in methanol.

The present study is concerned with spectroscopic evidence obtained for various $[Pd(H)(X)L_2]$ and $[Pd(H)L_3]^+$

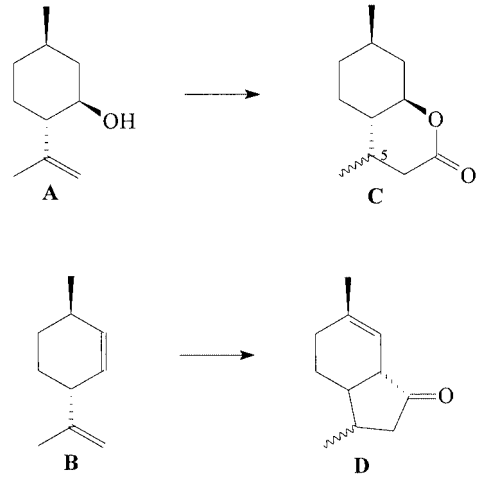
complexes under normal conditions or under CO pressure. We demonstrate that the essential active species in the cyclocarbonylation reaction is $[Pd(H)(SnCl_3)L_2]$.

Results and Discussion

Carbonylation of isopulegol **A** or isolimonene **B**, under a CO pressure of 40 bar, in the presence of $[PdCl_2L_2]/SnCl_2$ provides the lactone **C** or the cyclopentanone **D**, irrespective of whether the medium contains methanol or not (Scheme 1).[4,11,12]



Scheme 1. Cyclocarbonylation of isopulegol **A** and isolimonene **B**.

After catalysis, we never detected any alkoxycarbonylpalladium complex containing the isopulegyl moiety among the organometallic compounds. However, starting from isolimonene, small amounts of dehydro-**D** have previously been identified corresponding to a cyclopentenone resulting from the sacrificial formation of the palladium hydride species.[5,11,13]

During the present study, we carefully analysed the products resulting from the cyclocarbonylation of isopulegol by GC/MS and we identified small amounts of the unsaturated lactone dehydro-**C**, which leads to Equation (1). In order to gain direct evidence of the involvement of this catalytic hydride route, we prepared a series of neutral and cationic palladium hydride complexes, whose characterisation is described below.

Synthesis of $[Pd(H)(X)L_2]$ and $[Pd(H)(L_3)]^+$ Complexes

Complexes $[PdCl_2L_2]$ were prepared in high yields by addition of PPh_3, PCy_3 or the diphosphane dCypb [dCypb = bis(dicyclohexylphosphanyl)butane] to the complex $[PdCl_2(PhCN)_2]$ according to the published procedures.[12,14,15] Addition of ten equivalents of the silane $HSiPh_3$ to these dichloro-, PPh_3- or PCy_3-containing compounds gave the corresponding hydrido complexes $[Pd(H)(Cl)L_2]$ (L = PPh_3 **1**, PCy_3 **2**) in 40% yields after crystallisation.[16a] For the tricyclohexylphosphane ligand, better yields can be obtained when $[Pd(PCy_3)_2]$ is synthesised by reduction of $[PdCl_2(PCy_3)_2]$. Subsequent addition of one equivalent of anhydrous HCl in diethyl ether affords **2** in 80% yield as a crystalline material.[16b] We did not succeed in preparing [Pd(H)(Cl)(dCypb)] (**3**) by reduction of one chloro ligand in $[PdCl_2(dCypb)]$ by $HSiPh_3$, since in all experiments palladium black precipitated. As our attempts with other diphosphanes also resulted in the precipitation of abundant quantities of black materials, we suspect that this absence of stability is due to the *trans*-position of the incoming hydride ligand to a phosphorus atom. However, starting from $[Pd(PCy_3)_2]$ we succeeded in the exchange of ligand dCypb, and addition in an NMR tube at 183 K of one equivalent of HCl (in Et_2O solution) produced the corresponding hydride [Pd(H)(Cl)(dCypb)] (**3**), which shows a hydride signal at δ = –8.0 ppm (Table 1), a doublet of doublets due to the coupling with a phosphorus in the *trans*-position ($^2J_{^1H,^{31}P_{trans}}$ = 200 Hz) and another one in the *cis*-position ($^2J_{^1H,^{31}P_{cis}}$ = 10 Hz). However, we could not isolate the hydride in the solid state.

Addition of one equivalent of $SnCl_2$ to $[D_8]$THF solutions of **1** or **2** gives $[Pd(H)(SnCl_3)L_2]$ (L = PPh_3 **4**, PCy_3 **5**). As shown in Table 1, these two derivatives are characterised in their ^1H NMR spectra by a hydride signal at δ = –6.90 and –8.50 ppm, respectively, flanked by two satellites due to $^2J_{^1H,^{119}Sn}$ coupling (944 Hz and 1760 Hz, respectively). The ^1H-^{31}P coupling is too small to be detected. The coupling between ^1H and ^{119}Sn was confirmed by a 2D-HMQC sequence and is shown in Figure 1.

The ^{31}P NMR spectra show a broad singlet at δ = 33.80 ppm for **4** and a singlet at δ = 52.26 ppm for **5** flanked by the two satellites due to the coupling with ^{119}Sn ($^2J_{^{31}P,^{119}Sn}$ = 138 Hz). In these compounds, the two phosphane ligands are in mutual *trans* positions and the exchange of a Cl for an $SnCl_3$ ligand results in a decrease of nearly 6 ppm for the chemical shift of the hydride ligand

(6.22 ppm between **1** and **4** and 5.82 ppm between **2** and **5**), thus showing that the addition of $SnCl_2$ has a dramatic effect. Such a shift is certainly related to significant changes and decreases in the electron density at the H ligand and thus its hydride character. Recent studies on [Mo(H)(NO)(dmpe)$_2$] [dmpe = bis(dimethylphosphanyl)ethane] have shown that the hydridic character of the hydride ligand is largely influenced by the nitrosyl ligand in the *trans* position. As a consequence, this complex presents a high propensity to undergo hydride-transfer reactions.[17]

The ^{1}H NMR spectrum of complex **5** at 183 K shows the additional presence of a small amount of complex **2** (Figure 2). Increasing the temperature to 203 K leads to a large increase in the concentration of **2** due to decoordination of $SnCl_2$, complex **5** becoming the minor species. This observation does not mean that under the catalytic conditions (348–373 K, P_{CO} = 30–100 bar) only the chloro complex is operative. Indeed, the NMR spectra at room temperature (under inert atmosphere) still show the presence of **5** but a fluxional process occurs, as detected by the broadening of its hydride signal, whereas that of **2** remains sharp. We did not observe the possible intermediates, i.e. the *cis*-isomer of **5** or a pentacoordinate species arising from the coordination of $SnCl_2$ to **2**.

It is worth mentioning that addition of $SnCl_2$ to complex **3**, even at 183 K, does not result in the formation of the expected Pd-$SnCl_3$ species. The hydride signal of **3** disappears, and several unassigned signals are detected in the ^{31}P NMR spectrum. Decomposition into an orange material occurs rapidly. Table 1 lists all the NMR spectroscopic data for complexes **1**–**5**.

The synthesis of complexes containing the Pd(H)($SnBu_3$) core was attempted in order to introduce another Lewis acid into the coordination sphere of palladium. The synthetic procedure is to add $HSnBu_3$ directly to a palladium(0) species. In fact, [$Pd(PPh_3)_n$] (n = 2, 3, 4 in solution) reacts sluggishly, and at room temperature gives mainly the complex [Pd($SnBu_3$)$_2$(PPh_3)$_2$] ($\delta_{^{31}P}$ = 34.30 ppm, $^2J_{^{31}P,^{119}Sn}$ = 113 Hz). Nevertheless, a ν(Pd–H) absorption is detected at 2046 cm^{-1} in the IR spectrum, which belongs presumably to [Pd(H)($SnBu_3$)(PPh_3)$_2$]. The reaction proceeds cleanly with [$Pd(PCy_3)_2$], [Pd(diphos)(PCy_3)] [diphos = 1,2-bis(dicyclohexylphosphanyl)ethane (dCype)], 1,4-bis(dicyclohexylphosphanyl)butane or 1,6-bis(diphenylphosphanyl)hexane

(dpph) to give, according to ^{1}H and ^{31}P NMR analysis, $[Pd(H)(SnBu_3)(PCy_3)_2]$ (**6**), $[Pd(H)(SnBu_3)(dCype)]$ (**7**), $[Pd(H)(SnBu_3)(dCypb)]$ (**8**) or $[Pd(H)(SnBu_3)(dpph)]$ (**9**), respectively, in which the two hydrido and $SnBu_3$ ligands are in mutual *trans* (**6**) or *cis* (**7**–**9**) positions. Indeed, the hydride signal of **6** is at δ = –14.32 ppm due to the large *trans* influence of the $SnBu_3$ ligand. For **7**–**9**, the hydride signals are at δ = –2.67, –3.84 and –4.06 ppm, respectively. All NMR spectroscopic data are displayed in Table 2. Similarly, the platinum analogue $[Pt(H)(SnBu_3)(PPh_3)_2]$ (**10**) was prepared from $[Pt(PPh_3)_4]$. Here also addition of $HSnBu_3$ provides $[Pt(SnBu_3)_2(PPh_3)_2]$ directly, which was characterised by ^{31}P NMR spectroscopy ($\delta_{^{31}P}$ = 18.0 ppm). However, as already described in the literature[18] for the preparation of $[Pt(H)(SnMe_3)(PPh_3)_2]$, bubbling dihydrogen through the solution allows the isolation of **10**.

Comparison between the two $SnCl_3$ and $SnBu_3$ ligands shows immediately that the *trans* influence of the tributyltin ligand is significantly stronger than that of $SnCl_3$ and is rather similar to that of the chloro ligand. The hydridic character decreases significantly when $SnCl_2$ is introduced into the coordination sphere (the chemical shift is δ = –8.5 ppm for **5**, whereas it is δ = –14.32 ppm for **2** and δ = –14.53 ppm for **6**). When we consider complex **8**, in which the hydrido and $SnBu_3$ ligands are in mutual *cis* positions, the situation is more contrasted. Indeed, the hydride signal is found at δ = –3.84 ppm, i.e. roughly 10 ppm to lower field than in **6**. Provided the steric effects are ignored, the phosphorus atom P_A in the *trans* position to $SnBu_3$ [$\delta_{^{31}P}$ = 27.36 ppm (t, $J_{^{31}P,^{119}Sn}$ = 1402 Hz] receives more electron density from the metal centre than the second phosphorus atom P_B *trans* to the hydride [$\delta_{^{31}P}$ = 43.96 ppm (t, $^2J_{^{31}P,^1H}$ = 166 Hz], which is not significantly affected by the presence of the $SnBu_3$ in the *trans* position. In the paragraph devoted to catalysis, these electronic effects will be taken into account to explain the various catalytic activities observed.

Variable-temperature ^{1}H and ^{31}P NMR studies of complex **8** (Figure 3) show that a stereochemical non-rigidity phenomenon occurs, and the square-planar complex does not lose the $SnBu_3$ ligand. The ^{1}H NMR signal at room temperature is consistent with a hydride ligand coupled to two equivalent phosphorus atoms and to tin. A fast isomerisation process makes the P_A and P_B phosphorus atoms equivalent. A similar phenomenon has recently been reported for $[Pd(H)(SiR_3)(dCype)]$.[19] In addition, sophisticated ^{1}H-^{119}Sn{^{31}P} 2D-HMQC NMR experiments unambiguously show the ^{119}Sn chemical shift at δ = 7.50 ppm.

Some authors consider that the main role of adding $SnCl_2$ is to provide the $SnCl_3^-$ counterion, but this hypothesis has been essentially confirmed in platinum chemistry.[20] We prepared the cationic hydrido complexes $[Pd(H)L_3]^+$ in the presence of weakly coordinating anions such as CF_3COO^- **a**, BF_4^- **b**, and $TolSO_3^-$ **c**. Table 3 displays all the NMR spectroscopic data related to the complexes that were isolated and characterised by ^{1}H and ^{31}P NMR spectroscopy. They obey the general formula $[Pd(H)(PCy_3)L_2]^+$, except for $[Pd(H)(PCy_3)_2]^+$ (**11**), for which the hydride signal appears at δ = –18.8 ppm as a triplet with a small hydride–phosphorus coupling of 3.5 Hz, consistent with a 14-electron palladium complex having the two PCy_3 ligands in *trans* positions and the hydrogen atom *cis* to each phosphorus atom.[9i–9k,21] For the 16-electron complexes $[Pd(H)(PCy_3)L_2]^+$ {L_2 = dCype **12**, [1,2-bis(diphenylphosphanyl)ethane] (dppe) **13**, [1,3-bis(diphenylphosphanyl)propane] (dppp) **14**, [1,4-bis(diphenylphosphanyl)butane] (dppb) **15**, [1,1′-bis(diphenylphosphanyl)ferrocene] (dppf) **16**}, the nature of the counterion is almost insignificant. For instance, when L_2 = dppp, $\delta_{^1H}$ = –6.62 ppm with CF_3COO^- or –6.84 ppm with BF_4^-. Variation of L_2 (**13**–**16**) induces larger effects. For example, for **13a**, **14a**, **15a** and **16a** the shifts are δ = –5.58, –6.62, –6.12 and –7.87 ppm, respectively. The geometry is presumably square planar, with the PCy_3 ligand being *cis* to the hydride ligand. The

Catalytic Activity in Carbonylation of Isopulegol

The catalytic activity of $[Pd(H)(SnCl_3)(PPh_3)_2]$ {formed from $[Pd(H)(Cl)(PPh_3)_2]$ by addition of an excess of $SnCl_2$ in situ with a P/Pd ratio of 4} was examined in the cyclocarbonylation of isopulegol in toluene, exclusively with CO as a reactant (**A** giving **C** in Scheme 1). Conversion of the substrate is 100% within 16 h at 60 °C (see Table 4, run R1). One more experiment was carried out at the same pressure but at lower temperature (40 °C, run R2): the yield was 62%. The effect of the temperature appears to be prominent, since when the pressure was decreased from 30 bar to 20 bar and even 10 bar the yields were not affected (compare runs R1, R3 and R4 at 60 °C).

Table 4. Catalytic activity for cyclocarbonylation of isopulegol in the presence of $[Pd(H)(Cl)L_2/SnCl_2/L]$.

Test	t [h]	P_{CO} [bar]	T [°C]	Yield [%]	(5*R*)-C [%]	(5*S*)-C [%]	*de*[a] [%]

R5	68	10	50	68	45	23	22
R6[b]	16	10	60	100	78	22	56

[a] de = {R(%) – S(%)}/{R(%) + S(%)}. [b] dppb was used as ligand.

The two diastereomers of lactone **C** were obtained in a nearly 60:40 proportion (runs R1, R3 and R4). In fact, as noted by Knifton in his early studies, the promoting role of the $SnCl_2$ co-catalyst is essentially to increase the regioselectivity of the alkoxycarbonylation of the terminal alkene into the corresponding linear ester.[7] In the present case, the re-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

action with $[Pd(H)(Cl)(PPh_3)_2]$ is slower and less diastereoselective.[11] Increasing the electron density on palladium by substituting the PPh_3 ligands with PCy_3 results in the complete absence of reactivity under the same reaction conditions irrespective of whether the complex is prepared and isolated or generated in situ. Formation of $[Pd(H)(SnCl_3)(dppb)]$ from $[Pd(H)(Cl)(PPh_3)_2]$ (**1**), dppb and $SnCl_2$ leads to lower reaction rates but improved diastereomeric ratios (78:22). On the contrary, producing the cationic hydrido precursor **15a** by direct addition of CF_3COOH to $[Pd(PCy_3)(dppb)]$ gives a poor yield of **C** (17%). Similarly, $[Pd(H)(PCy_3)(dppf)]^+[CF_3COO]^-$ (**16a**) leads to a 21% yield. All the other prepared cationic complexes were examined in the carbonylation of isopulegol: the results are similarly deceiving.

Moreover, the effect of the introduction of $SnBu_3$ in the coordination sphere of palladium was analysed. In the presence of $[Pd(H)(SnBu_3)(PPh_3)_2]$, prepared in situ by addition of $HSnBu_3$ to $[Pd(PPh_3)_n]$, or *cis*-$[Pd(H)(SnBu_3)(dCypb)]$, the carbonylation reaction gives only traces of lactone. The important difference in the chemical shift − δ = –14.50 ppm for **6** and δ = –8.50 ppm for **5** − is presumably related to the significant differences in reactivity of the two complexes. Indeed, **6** presents a high hydridic character and its intrasphere nucleophilic attack of the olefin should be easy, this transfer producing the alkyl species, but the coordination of the olefin to the metal centre is presumably retarded. Moreover, we cannot exclude that in the subsequent step the CO migratory insertion could be disfavoured due to the steric hindrance of $SnBu_3$ and/or the electronic effects on palladium.

Mechanistic Proposal

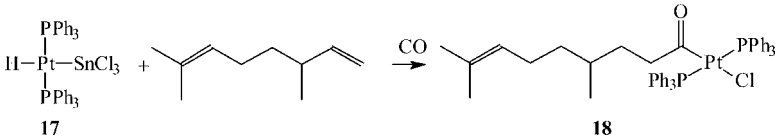
Characterisation of an Acylplatinum Species

Platinum complexes are often used to mimic the reactivity of palladium because they are less labile and they lead to more stable pentacoordinate species. The complex *trans*-$[Pt(H)(SnCl_3)(PPh_3)_2]$ (**17**) was therefore prepared from *cis*-$[PtCl_2(PPh_3)_2]$[22] and treated with dihydromyrcene at 100 °C under a CO pressure of 40 bar. Microcrystalline material precipitated at the end of the reaction. After separation and dissolution of the solid, analysis by multinuclear NMR showed that its structure corresponds to the square-planar acyl complex *trans*-$[PtCl\{C(O)CH_2CH_2CH(CH_3)CH_2CH_2CHC(CH_3)_2\}(PPh_3)_2]$ (**18**), as shown in Equation (2).

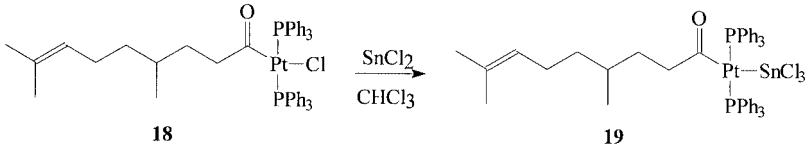
A signal with two satellites is observed in the ^{31}P NMR spectrum at δ = 23.18 ppm due to the coupling with ^{195}Pt ($^1J_{^{31}P,^{195}Pt}$ = 3186 Hz), and a triplet is observed for the ^{195}Pt signal at δ = –3933 ppm due to the coupling with two equivalent phosphorus atoms. Furthermore, in the ^{13}C NMR spectrum the acyl carbon atom appears as a triplet at δ = 219.45 ppm ($^2J_{^{31}P,^{13}C}$ = 6 Hz) flanked by satellites with $^1J_{^{195}Pt,^{13}C}$ = 458 Hz. A similarly high chemical shift value of δ = 243.9 ppm has been found for the C(O)Me carbon in the anionic acylplatinum(II) complex [Li][(η^2-Tp′)Pt(CO-Me)(Me)] [Tp′ = hydridotris(3,5-dimethylpyrazolyl)borate].[23]

Thus, under a CO atmosphere the platinum complex that separates from the medium as a solid contains the acyl moiety *trans* to the chloro atom. We supposed that, in fact, the formation of the $SnCl_3$ ligand is reversible, so we decided to add one equivalent of $SnCl_2$ to the acyl chloro complex. All the analyses show that we unambiguously produced the acylplatinum $SnCl_3$ complex *trans*-$[Pt(SnCl_3)\{C(O)CH_2CH_2CH(CH_3)CH_2CH_2CHC(CH_3)_2\}(PPh_3)_2]$ (**19**), as given by Equation (3).

The ^{31}P NMR spectrum of this complex shows that the two phosphane ligands are equivalent and give a signal, with two satellites, at δ = 18.95 ppm ($^1J_{^{195}Pt,^{31}P}$ = 3186 Hz). The ^{195}Pt NMR signal at δ = –4466 ppm is a triplet due to the coupling with the two equivalent phosphorus atoms. The ^{119}Sn NMR spectrum contains a signal at δ = 55.61 ppm (t) with a ^{31}P-^{119}Sn coupling constant of 296 Hz that we obtained from ^{31}P-^{119}Sn INEPTND and ^{31}P-^{119}Sn HMQC experiments. Finally, the ^{13}C NMR spectrum presents an acyl signal at δ = 224.80 ppm (t), with $^2J_{^{13}C,^{31}P}$ = 5 Hz, the $^2J_{^{13}C,^{195}Pt}$ coupling constant being difficult to determine due to the low signal-to-noise ratio.

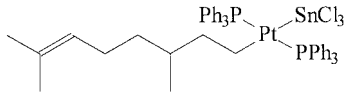


(2)



(3)

Observations by ^{1}H NMR carried out over a period of several days showed that the acyl complex **19** evolves toward the starting complex [Pt(H)($SnCl_3$)(PPh_3)$_2$] (**17**). Dihydromyrcene was also unambiguously detected. Thus, we can deduce that the equilibrium between these two complexes involves the intermediate alkyl species **20** shown in Figure 4. Indeed, decarbonylation of complex **19** would give **20**, which produces the pentacoordinate species [Pt(H)($SnCl_3$)(dihydromyrcene)(PPh_3)$_2$] by β-elimination. This latter complex would give **17** by loss of dihydromyrcene.



20

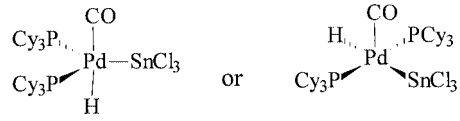
Figure 4. Alkylplatinum species **19** resulting from the addition of dihydromyrcene.

In situ Characterisation of Palladium Species under CO Pressure

Zudin and al.[24] have previously shown that the cationic hydridopalladium complex [Pd(H)(PPh_3)$_3$]$^+$[CF_3COO]$^-$, prepared in situ, reacts with CO to afford the dinuclear complex [Pd_2(μ-H)(μ-CO)(PPh_3)$_4$]$^+$[CF_3COO]$^-$ in which the hydrido and carbonyl ligands occupy the two bridging positions. A similar monocationic dinuclear complex has been prepared with the diphosphane ligand 1,3-bis[di(isopropyl)-phosphanyl]propane.[25] Moreover, Elsevier and Tóth started from the mononuclear neutral acyl complex [Pd(Cl)(COMe)(bdppp)] [bdppp is (2*S*,4*S*)-2,4-bis(diphenylphosphanyl)pentane] and observed that a methanolysis reaction occurs under a CO atmosphere to provide the elusive intermediate [Pd(H)(Cl)(bdppp)], which leads to a mixture of [$PdCl_2$(bdppp)] and [Pd_2(μ-H)(μ-CO)(bdppp)$_2$]$^+$-[Cl]$^-$.[26]

Introduction of $SnCl_2$ into the Palladium Hydride Coordination Sphere

[Pd(H)($SnCl_3$)(PCy_3)$_2$] (**5**), prepared in situ in an NMR tube by addition of one equivalent of $SnCl_2$ to [Pd(H)(Cl)(PCy_3)$_2$] (**2**), was pressurised with 3 bar ^{13}CO. The ^{1}H NMR spectra present a broad signal at δ = –8.70 ppm and even at 183 K no ^{1}H-^{31}P nor ^{1}H-^{119}Sn coupling constants could be determined due to an exchange phenomenon. However, the ^{13}C NMR spectra clearly reveal a triplet at δ = 232.4 ppm with a $^2J_{^{13}C,^{31}P}$ coupling constant of 3.7 Hz, the CO ligand thus being *cis* to two equivalent phosphorus atoms. The same spectra also show two satellites due to ^{13}C-^{119}Sn coupling (^2J = 144.6 Hz), such a value being in agreement with a mutual *cis* arrangement of the CO and $SnCl_3$ ligands. In the ^{31}P NMR spectrum, a signal is detected at δ = 50.80 ppm with two satellites due to a small coupling with ^{119}Sn (^2J = 148 Hz), consistent with the $SnCl_3$ ligand being *cis* with regard to the two equivalent phosphorus atoms. Thus, we can assign to this pentacoordinate species either the trigonal bipyramid geometry **21a** or the square-planar pyramid structure **21b** represented in Figure 5.

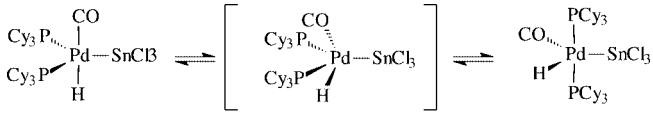


21a **21b**

Figure 5. Two possible geometries for the pentacoordinate species [Pd(H)($SnCl_3$)(CO)(PCy_3)$_2$] (**21a**) and **21b**.

The hydrido and carbonyl ligands in **21a** occupy the axial positions of the tbp geometry. Although such pentacoordinate hydrido species have already been proposed in the literature,[27] no such characterisation has been reported in palladium chemistry. However, it is worth mentioning that a palladium atom with five ligands in tbp or sp environments is known for [Pd(CH_2CMe_2-*o*-C_6H_4)-(PMe_3)$_2$(SO_2)],[28] or for a cationic palladium complex containing a triphosphane ligand and an imine ligand in the *o*-position of an aryl group.[29a]

Although we did not reach the slow exchange limit for complex **21a**, we suggest that a Berry pseudo-rotation mechanism occurs in solution which exchanges the axial and equatorial ligands. In this way the dynamic equilibrium shown in Figure 6 should occur. In this case, the second tbp isomer contains the CO and $SnCl_3$ ligands in mutual *cis* positions with regard to the two PCy_3 ligands (Figure 6).



21a **21a'**

Figure 6. Axial–equatorial ligand exchange in [Pd(H)($SnCl_3$)(CO)(PCy_3)$_2$] (**21a**).

In addition to these observations, we detected a weak signal in the ^{1}H NMR spectrum at δ = –14.5 ppm corresponding to a weak signal in the ^{13}C NMR spectrum at δ = 194.6 ppm. Such a value for the hydride ligand recalls the shift of [Pd(H)(Cl)(PCy_3)$_2$] (**2**) ($\delta_{^1H}$ = –14.32 ppm) and we suggest that these signals should correspond to the species [Pd(H)(CO)(Cl)(PCy_3)$_2$] (**22**) (**21**/**22** = 65:35). As we previously observed (see above) the equilibrium between [Pd(H)($SnCl_3$)(PCy_3)$_2$] (**5**) and [Pd(H)(Cl)(PCy_3)$_2$] (**2**) + $SnCl_2$, and since removing $SnCl_2$ from a pentacoordinate species is rather uncommon, we propose that the complex [Pd(H)(Cl)(CO)(PCy_3)$_2$] (**22**) results from the direct coordination of a CO ligand to the square-planar complex [Pd(H)(Cl)(PCy_3)$_2$] (**2**).

NMR Monitoring of the Reactivity of the Substrate with [Pd(H)($SnCl_3$)(PCy_3)$_2$] (5)

We carried out the same type of experiments, maintaining the same temperature and concentrations, but now four equivalents of dihydromyrcene were added and the ^{13}CO/^{12}CO pressure was increased to 10 bar. In less than one hour, still at 183 K, the main hydride peak at δ =

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

–8.7 ppm and the weak signal at δ = –14.5 ppm disappeared, presumably due to the formation of the corresponding alkyl species. In the ^{13}C NMR spectrum two CO signals were detected at δ = 232.6 ppm (complex **23**) and δ = 194.7 ppm (complex **24**) as two triplets with relative intensities of 70:30 and $^{2}J_{^{13}C,^{31}P}$ coupling constants of 4.5 and 3.2 Hz, respectively; this ratio was found to be 75:25 for the hydride signals of $[Pd(H)(SnCl_3)(PCy_3)_2]$ (**5**) and $[Pd(H)(Cl)(PCy_3)_2]$ (**2**) in the ^1H NMR spectrum. The proximity of the two chemical shifts and the coupling constants for **21a** and **23** led us to propose that we observe the pentacoordinate species in which CO is coordinated as shown in Figure 7. Similarly, we propose that **24**, with the chloro ligand, is characterised by the shift at δ = 194.7 ppm. Pentacoordinated platinum species have previously been described in which the coordination sphere contains the diphosphane dppe, CO, methyl and methoxy ligands.[29b]

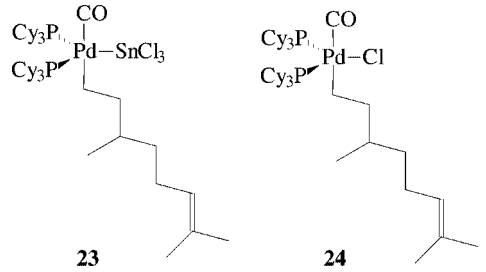


Figure 7. Representation of the two pentacoordinate acyl species **23** and **24** observed under CO pressure in HP/NMR spectroscopy.

The CO migratory insertion is presumably the rate-determining step, since at 183 K the coordination of the alkene followed by the hydride transfer are relatively fast steps. Such an observation parallels the reactivity of $[Pd(H)(SnCl_3)(PPh_3)_2]$ (**4**) in catalytic tests, since at 40 °C and 30 bar the conversion rate is near to 60% in 16 h, whereas at 60 °C and even at 10 bar the reaction reaches completion overnight (see Table 4).

Conclusions

In this paper, the identification of various neutral, cationic, square-planar and pentacoordinate (under CO pressure) hydridopalladium complexes has been described. It appears that the co-catalyst role of $SnCl_2$ is crucial because it produces an active palladium–$SnCl_3$ species. Preparation of $[Pd(H)(SnCl_3)(PPh_3)_2]$, as shown by multinuclear NMR spectroscopy, leads to an active complex which catalyses the alkoxycarbonylation reaction of an alkene efficiently. Thus, we propose a catalytic cycle exclusively based on the hydride route, with the two L phosphorus ligands in *trans* positions (Figure 8).

Recent studies reported by van Leeuwen and Heaton[30] are consistent with the coordination of methanol to explain the last step of the alcoholysis, provided the two phosphane

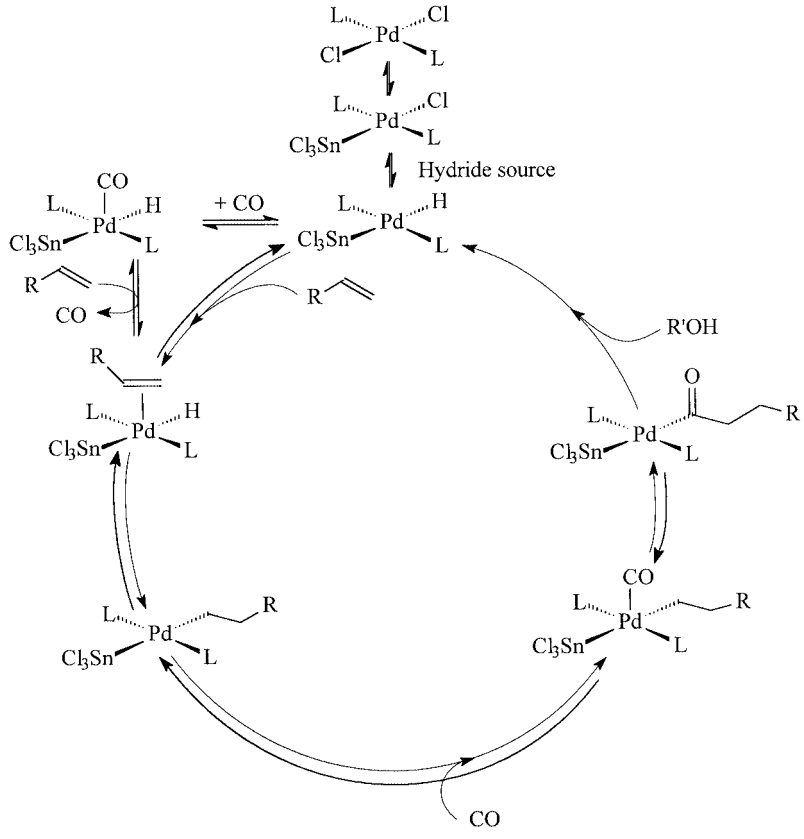

Figure 8. Proposed hydridopalladium route for alkoxycarbonylation reaction.

ligands are mutually *cis*. Our preliminary observations that isomerisation occurs for the monophosphane ligands prompted us to explore and investigate the final step of the catalytic reaction in the present system.

Experimental Section

General Considerations: All reactions and manipulations were carried out in dried and distilled solvents under argon using standard Schlenk techniques. All NMR measurements were performed on Bruker AM250, AMX400 or DRX400 spectrometers using 5-mm triple resonance inverse probes with a dedicated ^{31}P channel. All chemical shifts for ^{1}H and ^{13}C are relative to TMS using ^{1}H (residual) or ^{13}C chemical shifts of the solvent as a secondary standard. The chemical shifts were referenced to external H_3PO_4 (85%) for ^{31}P, $SnMe_4$ for ^{119}Sn and H_2PtCl_6 for ^{195}Pt. High-pressure NMR experiments in situ were carried out in special sapphire tubes with a diameter of 10 mm (for more details concerning the setup and procedure see ref.[31]). IR spectra were recorded on a Perkin–Elmer 1710 FT-IR spectrophotometer. Gas chromatography analyses were performed on a Perkin–Elmer instrument equipped with a DB-5GC column (30 m × 0.25 mm × 0.25 μm) and a flame ionisation detector. Mass spectrometric measurements were performed at the Service de Spectrométrie de Masse de l'Université Paul Sabatier on a NERMAG R 10-10 apparatus for organometallic compounds and on a Perkin–Elmer TURBO MASS instrument equipped with a DB-5MS 30 m × 0.25 mm × 0.25 μm column for organic products. Elemental analysis (C,H,O) was performed at the Ecole Nationale Supérieure des Ingénieurs en Arts Chimiques et Technologiques de Toulouse. Several compounds are unstable, so mass spectrometry or elemental analyses were not always possible.

All the chemical products were purchased from Aldrich Chemical Co., except for the following complexes, which were prepared by the methods reported in the literature: $[PdCl_2(PhCN)_2]$,[15] *cis*-$[PdCl_2(dppb)]$,[12,15] *cis*-$[PdCl_2(dCypb)]$,[12,15] *trans*-$[Pt(H)(SnBu_3)(PPh_3)_2]$ (**6**),[18] *cis*-$[PtCl_2(PPh_3)_2]$,[22] *trans*-$[Pt(H)(SnCl_3)(PPh_3)_2]$ (**17**),[22] *trans*-$[PdCl_2(PPh_3)_2]$,[14] *trans*-$[PdCl_2(PCy_3)_2]$,[12,32] $[Pd(PPh_3)_n]$,[14] $[Pd(PCy_3)_2]$.[32] ^{12}CO and ^{13}CO (99%) were purchased from Air Liquide.

Catalytic Tests: A mixture of triphenylphosphane (0.4 mmol) and tin(II) chloride (0.5 mmol) was introduced into a 150 mL stainless steel autoclave with magnetic stirring. A nitrogen-saturated mixture of palladium complex [chlorobis(triphenylphosphanyl)palladium(II) hydride or dichlorobis(triphenylphosphanyl)palladium (0.2 mmol)] and isopulegol (10 mmol) in toluene (10 mL) was introduced into the evacuated autoclave by aspiration. It was heated (40–60 °C) under pressure (10–30 bar) of carbon monoxide. After 16 h, the autoclave was cooled and then slowly depressurized. The obtained solution was analysed by gas chromatography.

Synthesis of $[Pd(H)(Cl)L_2]$ (L = PPh_3 1; PCy_3 2): A 100 mL benzene solution of $[PdCl_2L_2]$ (0.57 mmol) and $HSiPh_3$ (11.44 mmol) was heated at 70–80 °C for 2 h. The resultant red solution was concentrated to ca. 30 mL, and addition of hexane afforded a powder of *trans*-$[Pd(H)(Cl)L_2]$ which was dissolved in benzene and precipitated with hexane three times; the final product was white and was isolated in 40% yield.

Alternative Method for the Synthesis of 2: A pale-green solution of $[Pd(PCy_3)_2]$ (1 mmol) in 10 mL of toluene was slowly treated with one equivalent of 2 M HCl in diethyl ether solution at room temperature. The resultant pale-yellow solution was evaporated under reduced pressure. The obtained solid was washed three times with diethyl ether; the final product was pale yellow and was isolated in 80% yield.

$[Pd(H)(Cl)(PPh_3)_2]$ (1): IR: ν(Pd–H) = 2050 cm^{-1}. ^{1}H NMR (250 MHz, 293 K, $CDCl_3$): δ = –13.12 ppm. ^{31}P NMR (250 MHz, 293 K, $CDCl_3$): δ = 30.75 ppm.

$[Pd(H)(Cl)(PCy_3)_2]$ (2): IR: ν(Pd–H) = 2046 cm^{-1}. ^{1}H NMR (250 MHz, 293 K, $CDCl_3$): δ = –14.32 ppm. ^{31}P NMR (250 MHz, 293 K, $CDCl_3$): δ = 46.63 ppm.

Preparation of [Pd(H)(Cl)(dCypb)] (3): A solution of $[Pd(PCy_3)_2]$ (0.1 mmol) in 1 mL of $[D_8]$THF was treated with 0.1 mmol of 1,4-bis(dicyclohexylphosphanyl)butane at room temperature. After 1 h, one equivalent of HCl (in Et_2O solution) was added and the solution was stirred for 1 h at 183 K. Then, ^{1}H NMR spectra were recorded, and revealed the presence of [Pd(H)(Cl)(dCypb)] (**3**) along with small amounts of $[Pd(H)(Cl)(PCy_3)_2]$ (**2**) and traces of unidentified hydridopalladium complexes. ^{1}H NMR (400.13 MHz, 183 K): δ = –8.0 ppm ($^{2}J_{^{1}H,^{31}P}$ = 10 and 200 Hz). From the integration of the ^{1}H signals, the yield of **3** was estimated to be 40%.

Preparation of $[Pd(H)(SnCl_3)L_2]$ (L = PPh_3, 4; PCy_3, 5): A solution of $[Pd(H)(Cl)L_2]$ (0.1 mmol) in 1 mL of $[D_8]$THF was treated with one equivalent of anhydrous $SnCl_2$ at 183 K for 2 h, and the ^{1}H, ^{31}P and ^{119}Sn NMR spectra were recorded; the spectra indicated the presence of a mixture of $[Pd(H)(SnCl_3)L_2]$ and $[Pd(H)(Cl)L_2]$ with relative intensities **1/4** = 20:80 and **2/5** = 75:25.

$[Pd(H)(SnCl_3)(PPh_3)_2]$ (4): ^{1}H NMR (400.13 MHz, 183 K): δ = –6.90 ppm ($^{2}J_{^{1}H,^{119}Sn}$ = 944 Hz). $^{31}P\{^{1}H\}$ NMR (161.98 MHz, 183 K): δ = 33.80 ppm.

$[Pd(H)(SnCl_3)(PCy_3)_2]$ (5): ^{1}H NMR (400.13 MHz, 183 K): δ = –8.50 ppm. $^{31}P\{^{1}H\}$ NMR (161.98 MHz, 183 K): δ = 52.3 ppm ($^{2}J_{^{31}P,^{119}Sn}$ = 138.1 Hz). ^{1}H-^{119}Sn HMQC NMR (400.13 MHz, 149.21 MHz, 183 K): δ = 154 ppm ($^{2}J_{^{1}H,^{119}Sn}$ = 1760 Hz).

Synthesis of $[Pd(H)(SnBu_3)(dCypb)]$ (8): A solution of $[Pd(PCy_3)_2]$ (0.2 mmol) in 5 mL of toluene was treated with 0.2 mmol of 1,4-bis(dicyclohexylphosphanyl)butane at room temperature. After 1 h, one equivalent of tri(*n*-butyl)tin hydride was added and the solution was stirred for 1 h. Then, the solvent was removed under reduced pressure and the remaining solid with 75% yield was dissolved in C_7D_8 for characterisation by NMR spectroscopy. ^{1}H NMR (400.13 MHz, 213 K): δ = –3.84 ppm ($^{2}J_{^{1}H,^{31}P_{cis}}$ = 8.4, $^{2}J_{^{1}H,^{31}P_{trans}}$ = 165.9, $^{2}J_{^{1}H,^{119}Sn}$ = 110 Hz). ^{1}H-^{119}Sn {^{31}P} HMQC NMR (400.13 MHz, 149.22 MHz, 253 K): δ = 7.50 ppm. $^{31}P\{^{1}H\}$ NMR (161.99 MHz, 233 K): δ = 27.36 ppm ($^{31}P_A$, $^{2}J_{^{31}P_A,^{119}Sn}$ = 1402 Hz), 43.96 ($^{31}P_B$, $^{2}J_{^{31}P_B,^{119}Sn} < 20$ Hz).

Identification of Neutral and Cationic Complexes: A similar procedure to the preceding one was adopted. A solution of $[Pd(PCy_3)_2]$ (0.1 mmol) in 2 mL of $[D_8]$toluene was treated with 0.1 mmol of ligand L (L = dCype, dppe, dppp, dCypb, dppb, dpph, dppf) at room temperature. After 1 h, one equivalent of HX (HX = $HSnBu_3$, CF_3COOH, HBF_4, $TolSO_3H$) was added and the solution was stirred for 1 h. The solution was filtered and transferred to a 5-mm NMR tube for NMR measurements. Only the most relevant shifts are given below. In addition, after removal of the solvent, the resulting solids were tested in cyclocarbonylation reaction.

$[Pd(H)(SnBu_3)(PCy_3)_2]$ (6): ^{1}H NMR: δ = –14.5 ppm ($^{2}J_{^{1}H,^{31}P}$ = 5.5, ($^{2}J_{^{1}H,^{119}Sn}$ = 2494 Hz). ^{31}P NMR: δ = 48.30 ppm.

$[Pd(H)(SnBu_3)(dCype)]$ (7): ^{1}H NMR: δ = –2.67 ppm ($^{2}J_{^{1}H,^{119}Sn}$ = 310, $^{2}J_{^{1}H,^{31}P_{trans}}$ = 177 Hz). ^{31}P NMR: δ = 25.10 ppm, 45.20 ($^{2}J_{^{1}H,^{31}P_{trans}}$ = 200 Hz), 40.70.

[Pd(H)(SnBu$_3$)(dpph)] (9): ^{1}H NMR: δ = –4.01 ppm (exchange phenomena at room temperature).

[Pd(H)(PCy$_3$)(dCype)]$^+$(CF$_3$COO)$^-$ (12a): ^{1}H NMR: δ = –6.29 ppm ($^2J_{^1H,^{31}P}$ = 7, 13, 179 Hz). ^{31}P NMR: δ = 86.95, 65.43, 49.68 ppm ($^2J_{^{31}P,^{31}P}$ = 18, 311 and 18 Hz).

[Pd(H)(PCy$_3$)(dCype)]$^+$(BF$_4$)$^-$ (12b): ^{1}H NMR: δ = –6.15 ppm. (exchange phenomena at room temperature).

[Pd(H)(PCy$_3$)(dCype)]$^+$(TolSO$_3$)$^-$ (12c): ^{1}H NMR: δ = –6.12 ppm ($^2J_{^1H,^{31}P}$ = 9, 12 and 177 Hz).

[Pd(H)(PCy$_3$)(dppe)]$^+$(CF$_3$COO)$^-$ (13a): ^{1}H NMR: δ = –5.58 ppm ($^2J_{^1H,^{31}P}$ = 20, 196 Hz.

[Pd(H)(PCy$_3$)(dppp)]$^+$(CF$_3$COO)$^-$ (14a): ^{1}H NMR: δ = –6.62 ppm ($^2J_{^1H,^{31}P}$ = 28, 189 Hz). ^{31}P NMR: δ = 51.18, 9.16, 3.58 ppm $^2J_{^{31}P,^{31}P}$ = 306, 48 and 22 Hz).

[Pd(H)(PCy$_3$)(dppp)]$^+$(BF$_4$)$^-$ (14b): ^{1}H NMR: δ = –6.90 ppm ($^2J_{^1H,^{31}P}$ = 12, 75 Hz). ^{31}P NMR: δ = 49.87, 7.66, 3.97 ppm ($^2J_{^{31}P,^{31}P}$ = 315, 51 and 21 Hz).

[Pd(H)(PCy$_3$)(dppb)]$^+$(CF$_3$COO)$^-$ (15a): ^{1}H NMR: δ = –6.12 ppm ($^2J_{^1H,^{31}P}$ = 13, 185 Hz).

[Pd(H)(PCy$_3$)(dppf)]$^+$(CF$_3$COO)$^-$ (16a): ^{1}H NMR: δ = –7.87 ppm ($^2J_{^1H,^{31}P}$ = 10, 179 Hz). ^{31}P NMR: δ = 52.57, 24.94, 20.15 ppm ($^2J_{^{31}P,^{31}P}$ = 337, 27, 31 Hz). FAB$^+$/MS: *m*/*z* = 941.3; mode FAB$^-$/MS: *m*/*z* = 113.1.

Synthesis of [(CH$_3$)$_2$C=CH(CH$_2$)$_2$CH(CH$_3$)CH$_2$CH$_2$C(O)-PtCl(PPh$_3$)$_2$] (18): Complexes **18** and **19** were prepared according to the methods previously reported by Gómez et al.[27] A mixture of *trans*-[Pt(H)(Cl)(PPh$_3$)$_2$] (0.473 g, 0.5 mmol), PPh$_3$ (0.118 g, 0.45 mmol), dihydromyrcene (6.90 g, 50.0 mmol) and ethanol (25 mL) was charged in an autoclave. The autoclave was purged of air under reduced pressure and was then pressurised with 50 bar of CO, heated to 100 °C and stirred for 4 h. Then, the reactor was cooled to room temperature and depressurised. The resulting green solution was cooled to –30 °C to give **18** as a white solid, which was washed three times with cool ethanol, diethyl ether and finally dried under vacuo. Yield: 55%.

18: ^{31}P{^{1}H} NMR (161.98 MHz, CDCl$_3$, 298 K): δ = 23.2 ppm ($^2J_{^{31}P,^{195}Pt}$ = 3510.7 Hz). ^{195}Pt{^{1}H} NMR (85.68 MHz, CDCl$_3$, 298 K): δ = –3933 ppm. ^{13}C{^{1}H}bb+{^{31}P} NMR (100.63 MHz, CDCl$_3$, 298 K): δ = 219.4 ($^2J_{^{13}C,^{31}P}$ = 6, $^1J_{^{13}C,^{195}Pt}$ = 457.8 Hz), 135.4, 134.5, 131.3, 131.3, 130.8, 125.4, 57.1, 37.4, 32.1, 31.4, 26.2, 25.9, 19.5, 15.7 ppm.

Synthesis of [(CH$_3$)$_2$C=CH(CH$_2$)$_2$CH(CH$_3$)CH$_2$CH$_2$C(O)-Pt(SnCl$_3$)(PPh$_3$)$_2$] (19): A mixture of complex **18** (0.0922 g, 0.10 mmol), SnCl$_2$ (0.019 g, 0.1 mmol) and CHCl$_3$ (2 mL) was placed in a Schlenk tube and stirred for 15 min at room temperature. The solution was filtered and multinuclear NMR analysis was carried out. After removal of the solvent **19** was obtained as a yellow compound in 50% yield. ^{31}P-^{119}Pt HMQCND {^{1}H}bb NMR (161.98 MHz, 85.63 MHz, CDCl$_3$, 233 K) and ^{31}P{^{1}H} NMR (161.98 MHz, CDCl$_3$, 233 K): δ = 18.9 ppm ($^2J_{^{31}P,^{119}Sn}$ = 296 Hz). ^{31}P-^{119}Sn INEPTND {^{1}H}bb NMR: δ = 55.6 ppm. ^{31}P-^{195}Pt HMQCND {^{1}H}bb NMR, ^{195}Pt{^{1}H,^{31}P} NMR (85.68 MHz, CDCl$_3$, 233 K) and ^{31}P-^{195}Pt INEPTND {^{1}H}bb NMR: δ = –4466 ppm ($^1J_{^{195}Pt,^{31}P}$ = 3185.6 Hz). ^{13}C NMR: δ = 224.8, 135.1, 134.2, 132.5, 132.2, 129.9, 125.1, 37.3, 32.0, 30.5, 26.6, 25.7, 18.5, 15.1 ppm.

Observation of Mixtures of [Pd(H)(^{13}CO)(SnCl$_3$)(PCy$_3$)$_2$] (21) and [Pd(H)(^{13}CO)(Cl)(PCy$_3$)$_2$] (22): A solution of [Pd(H)(Cl)L$_2$] (0.1 mmol) in 2 mL of [D$_8$]THF was treated with one equivalent of anhydrous SnCl$_2$ at 183 K. After 2 h, this solution was transferred to a sapphire tube and the solution was charged with 3 bar of ^{13}CO at the same temperature. The ^{1}H, ^{31}P and ^{13}C spectra indicated the presence of [Pd(H)(^{13}CO)(SnCl$_3$)(PCy$_3$)$_2$] (**21**; 65%) and [Pd(H)(^{13}CO)(Cl)(PCy$_3$)$_2$] (**22**; 35%).

[Pd(H)(^{13}CO)(SnCl$_3$)(PCy$_3$)$_2$] (21): ^{1}H NMR: δ = –8.70 ppm. ^{31}P NMR: δ = 50.80 ppm ($^2J_{^{31}P,^{119}Sn}$ = 148 Hz). ^{13}C NMR: δ = 232.4 ppm (CO; $^2J_{^{13}C,^{31}P}$ = 3.7, $^2J_{^{13}C,^{119}Sn}$ = 144.6 Hz).

[Pd(H)(^{13}CO)(Cl)(PCy$_3$)$_2$] (22): ^{1}H NMR: δ = –14.50 ppm. ^{13}C NMR: δ = 194.6 ppm (CO).

Observation of Mixtures of [Pd(Alkyl)(CO)(SnCl$_3$)(PPh$_3$)$_2$] (23) and [Pd(Alkyl)(CO)(Cl)(PPh$_3$)$_2$] (24): A solution of [Pd(H)(Cl)L$_2$] (0.1 mmol) in 2 mL of [D$_8$]THF was treated with one equivalent of anhydrous SnCl$_2$ at 183 K. After 2 h, this solution was transferred to a sapphire tube and the solution was charged with four equivalents of dihydromyrcene and 3 bar of ^{13}CO at the same temperature. Multinuclear NMR analyses indicated the formation of a mixture of **23** and **24**, with a **23/24** ratio of 70:30. **23:** ^{13}C NMR: δ = 232.6 ppm ($^2J_{^{13}C,^{31}P}$ = 4.5 Hz). **24:** ^{13}C NMR: δ = 194.7 ppm ($^2J_{^{13}C,^{31}P}$ = 3.2 Hz).

Characterisation of Compound (5*R*)-C: MS: *m*/*z* (%) = 95(100), 81 (62), 96(41), 122 (30), 183 (18) [M + 1], 138 (7). ^{1}H NMR (250.13 MHz, CDCl$_3$): δ = 3.75 (ddd, *J* = 4.2, 10.5 and 10.5 Hz, 1 H, H1), 2.55 (dd, *J* = 6.8 and 18 Hz, 1 H, H4$_{ax}$), 1.96 (dd, *J* = 9.4 and 17.8 Hz, 1 H, H4$_{eq}$), 1.8 (m, 1 H, H10$_{eq}$), 1.84 (m, 1 H, H7$_{eq}$), 1.54 (m, 1 H, H8$_{ax}$), 1.45 (m, 1 H, H5), 1.34 (m, 1 H, H9), 1.10 (m, 1 H, H7$_{ax}$), 0.92 (m, 1 H, H8$_{eq}$), 0.82 (d, *J* = 6.2 Hz, 3 H, CH$_3$ 11), 0.80 (m, 1 H, H6), 0.77 (d, *J* = 6.5 Hz, 3 H, CH$_3$ 12) ppm. ^{13}C NMR (62.9 MHz, CDCl$_3$): δ = 171.3 (C3), 82.3 (C1), 44.6 (C6), 40.4 (C10), 38.0 (C4), 33.7 (C8), 31.7 (C5), 30.9 (C9), 27.7 (C7), 21.8 (C12), 19.0 (C11) ppm.

Characterisation of Compound (5*S*)-C: MS: *m*/*z* (%) = 96 (100), 81 (85), 122 (31), 183 (12) [M + 1], 138 (6). ^{1}H NMR (250.13 MHz, CDCl$_3$): δ = 4.13 (ddd, *J* = 4.3, 11, and 11 Hz, 1 H, H1), 2.69 (dd, *J* = 6.6 and 17.6 Hz, 1 H, H4$_{ax}$), 2.41 (dd, *J* = 2.8 and 17.6 Hz, 1 H, H4$_{eq}$), 2.13 (ddd, *J* = 1.6, 12, and 12 Hz, 1 H, H10$_{eq}$), 2.07 (m, 1 H, H5), 1.73 (m, 2 H, H8$_{ax}$ and H8$_{eq}$), 1.66 (m, 1 H, H7$_{eq}$), 1.60 (m, 1 H, H6), 1.48 (m, 1 H, H9), 1.27 (ddd, *J* = 3.5, 12.9, and 12.9 Hz, 1 H, H7$_{ax}$), 1.16 (ddd, *J* = 3.0, 12, and 12 Hz, 1 H, H10$_{ax}$), 1.00 (d, *J* = 7.2 Hz, 3 H, CH$_3$ 11), 0.97 (d, *J* = 6.6 Hz, 3 H, CH$_3$ 12). ^{13}C NMR (62.9 MHz, CDCl$_3$): δ = 171.2 (C3), 77.8 (C1), 41.7 (C6), 40.9 (C10), 38.9 (C4), 33.9 (C8), 30.8 (C9), 28.8 (C5), 27.2 (C7), 21.7 (C12), 14.7 (C11) ppm. C$_{11}$H$_{18}$O$_2$ (182.12): calcd. C 71.5, H 10, O 17.6; found C 71.8, H 9.8, O 18.3.

Characterisation of Dehydro-C: MS: *m*/*z* (%) = 181 (14) [M + 1], 138 (12), 123 (40), 109 (13), 95 (66), 81 (100), 67 (69), 55 (30), 41 (55), 29 (13).

COVER PICTURE

The cover picture shows the self-assembly of two selected terpy-type ligands by π-π stacking around the Zn^{2+} ion to form isolated "heterodimers" (top left with terpy and a bis-Schiff-base ligand), 2D layers (bottom right with a hydrazone bis-pyridine ligand and a bis-Schiff-base ligand) and a double helix (on the diagonal, with only bis-Schiff-base ligands). In addition a 1D stacked layer could be synthesized. Further details may be found in the article by M. Barboiu et al. on p. 4255ff.

Mechanism of Taurine: α-Ketoglutarate Dioxygenase (TauD) from *Escherichia coli*

J. Martin Bollinger Jr.,*[a,b] John C. Price,[a] Lee M. Hoffart,[a] Eric W. Barr,[a] and Carsten Krebs*[a,b]

Keywords: Bioinorganic chemistry / Metalloenzymes / Reaction intermediates / Oxygen activation / Iron

The iron(II)- and α-ketoglutarate-dependent dioxygenases comprise enzymes that catalyze a variety of important reactions in biology, including steps in the biosynthesis of collagen and antibiotics, the degradation of xenobiotics, the repair of alkylated DNA, and the sensing of oxygen and response to hypoxia. In these reactions, the reductive activation of oxygen is coupled to hydroxylation of the substrate and decarboxylation of the co-substrate, α-ketoglutarate. It is believed that a single, conserved mechanistic pathway for formation of a high-valent iron intermediate that attacks the substrate is operant in all members of this family. Application of a combination of rapid kinetic and spectroscopic techniques to the reaction of taurine/α-ketoglutarate dioxygenase (TauD), one member of this large enzyme family, has led to the detection of two reaction intermediates. The first intermediate, which is termed **J**, is a high-spin Fe^{IV}-oxo complex. Decay of **J** exhibits a large, normal C1 deuterium kinetic isotope effect, demonstrating that it is the species activating the C–H bond for hydroxylation. The second intermediate is an Fe^{II}-containing product(s) complex.

1. Introduction

The Fe^{II}- and α-ketoglutarate (αKG)-dependent dioxygenases are a large and functionally diverse family of enzymes that employ a structurally conserved, mononuclear, non-heme Fe^{II} center.[1–4] The Fe^{II} center is facially coordinated by three protein ligands, two histidines and one aspartate or glutamate.[5,6] These residues are organized in a His-Xxx-(Asp/Glu)-$(Xxx)_n$-His sequence motif.[3] The Fe^{II} center is used to activate dioxygen to effect (1) the decarboxylation of the co-substrate, αKG, and (2) a two-electron oxidation of the substrate. In most cases the substrate oxidation is a hydroxylation of an unactivated carbon atom, although other two-electron oxidations, such as desaturation and cyclization reactions, are effected by some family members.[3,4]

The αKG-dependent dioxygenases catalyze a wide variety of reactions with diverse biological functions, which have recently been summarized by Hausinger.[3] They catalyze reactions involved in the degradation of xenobiotics,[7] and the biosyntheses of connective tissue,[8,9] various antibiotics,[10–12] and a wide variety of plant secondary metabolites, including flavonoids, gibberellins, and alkaloids (see ref.[3] and references cited therein). In addition, the dysfunction of members of the αKG-dependent dioxygenase family has been implicated in the etiology of several disease states.[13]

Recently, several additional reactions of importance to human biochemistry have been found to be catalyzed by αKG-dependent dioxygenases. The first involves repair of alkylated DNA and RNA by the enzyme AlkB.[14,15] Studies on AlkB from *E. coli* have demonstrated that it can hydroxylate the N-linked carbon of alkyl groups on 1-alkyladenine and 3-alkylcytosine residues in DNA and RNA, leading to elimination of the potentially mutagenic substituent and repair of the base.[14–16] Eight putative homologues of AlkB have been identified in humans, but they are less well studied than *E. coli* AlkB.[14,17]

The second involves control of oxygen homeostasis by the transcription factor, hypoxia inducible factor (HIF).[18,19] When oxygen levels drop, an adaptive response is initiated by the HIF-mediated transcriptional activation of genes that, for example, direct synthesis of new blood vessels (angiogenesis) and production of red blood cells

(erythropoiesis) to combat hypoxia.[20] HIF activity is controlled by posttranslational hydroxylation of specific amino acid residues in its α-subunit. These reactions are catalyzed by two αKG-dependent dioxygenases. Because molecular oxygen is a co-substrate, the activities of the enzymes provide the mechanism by which oxygen levels are sensed by cells. The first enzyme is the HIF-specific prolyl-4-hydroxylase, which hydroxylates Pro564 of the HIFα-protein.[18,19] Hydroxylated HIFα forms a complex with the von Hippel-Lindau (VHL) tumor suppressor protein, is ubiquitinated, and consequently is subject to proteasomal degradation. The second enzyme catalyzes the hydroxylation of a specific asparagine, Asn803.[21,22] This enzyme has been termed FIH, *f*actor *i*nhibiting *H*IF. Hydroxylation of Asn803 prevents binding of HIFα to the transcriptional coactivator, p300, rendering it (HIFα) inactive. These processes play important roles in the pathophysiology of human diseases, including cancer, cardiovascular, and pulmonary diseases.[20,23] Manipulation of these processes is thus considered a promising strategy for drug design.[24,25]

The third process contributes to iron homeostasis by controlling the activity of the iron regulatory protein 2 (IRP2). It is known that IRP2 is posttranslationally modified, and that modified IRP2 is subject to ubiquitination and proteasomal degradation.[26,27] This process is remarkably similar to the constitutive degradation of the HIFα-protein in oxygen homeostasis. Current evidence suggests that the posttranslational modification of IRP2 is also carried out by a αKG-dependent dioxygenase.[28,29]

2. Mechanism

It is thought that the αKG-dependent dioxygenases use a conserved mechanistic pathway to activate O_2 and form a high-valent iron intermediate that attacks the substrate, leading to hydroxylation or a related two-electron oxidation.[3,4,30] The consensus mechanism for hydroxylation was first formulated by Hanauske-Abel and Günzler solely on the basis of theoretical considerations.[31] Nevertheless, it has thus far held up to the experimental and computational scrutiny of the enzymes and inorganic models of them that has since been carried out. A modified version of this mechanism, adapted for the specific case of the enzyme taurine/αKG dioxygenase (TauD) from *E. coli*, is shown in Scheme 1. The first step in the mechanism is binding of αKG in a chelating mode to the binary enzyme·Fe^{II} complex, a step that gives rise to a weak ($\varepsilon \approx 200\ M^{-1}\,cm^{-1}$) absorption feature in the visible regime (with a peak at 530 nm in TauD). Solomon and co-workers demonstrated for the enzyme clavaminate synthase by a combination of UV/Visible absorption, CD, and MCD spectroscopy and computational studies that this feature arises from a metal-to-ligand charge transfer (MLCT) transition involving the coordinated αKG ligand.[32] The iron site in the ternary enzyme·Fe^{II}·αKG complex is six-coordinate (6C), nearly octahedral, and in the high-spin configuration. The next step in the consensus mechanism is binding of substrate to the ternary enzyme·Fe^{II}·αKG complex.[33] Substrate binds in the vicinity of the Fe^{II} center, but not directly as a ligand, causing changes in the CD and MCD spectra that are indicative of conversion to a five-coordinate (5C) square-pyramidal Fe^{II} site.[32] Hausinger and co-workers have shown that, for TauD, binding of substrate results in a shift of the peak of the MLCT band from 530 nm to 520 nm.[34] Que and co-workers studied the ternary enzyme·Fe^{II}·αKG and quaternary enzyme·Fe^{II}·αKG·substrate complexes of TauD, as well as model complexes for them, by resonance Raman spectroscopy.[35] The bidentate binding mode of the co-sub-

Lee M. Hoffart (left) obtained his Bachelor of Science in Biochemistry, Genetics, and Mathematics in 2003 from Texas A&M University and joined the Department of Biochemistry and Molecular Biology at Penn State as a graduate student in 2003. He continues the work on the α-ketoglutarate dioxygenases under the supervision of Professors Bollinger and Krebs.

Eric W. Barr (second from left) obtained his Bachelor of Science degree in Biochemistry in 1998 from Temple University. He joined Professor Bollinger's group in 2001 as a research assistant and works on the mechanism of oxygen activation by the enzyme taurine/α-ketoglutarate dioxygenase.

John C. Price (middle) obtained his Bachelor of Arts in Chemistry in 2001 from Utah State University, where he worked under the supervision of Professor Lisa Berreau. He joined the Department of Biochemistry and Molecular Biology at Penn State as a graduate student in 2001. His thesis work, which he carries out under the supervision of Professors Bollinger and Krebs, is on the mechanism of oxygen activation by the enzyme taurine/α-ketoglutarate dioxygenase.

Carsten Krebs (second from right) received his Diploma in Chemistry in 1994 and his Ph.D. in Chemistry in 1997 from the Ruhr-University of Bochum, Germany, under the supervision of Professor Karl Wieghardt. In 1997 he joined the group of Professor Boi Hanh (Vincent) Huynh in the Department of Physics at Emory University, Atlanta. In 2002, he joined the Department of Biochemistry and Molecular Biology at the Pennsylvania State University as Assistant Professor. In 2004 he was appointed to the Department of Chemistry at Penn State. His research interest is the determination of the reaction mechanisms of iron-containing enzymes.

J. Martin Bollinger Jr. (right) received his Bachelor of Science degree in Chemistry from Penn State University in 1986 and his Ph.D. degree in Chemistry in 1993 from the Massachusetts Institute of Technology, where he worked under the direction of Professor JoAnne Stubbe. After an N.I.H. post-doctoral fellowship with Professor Christopher Walsh at Harvard Medical School, Professor Bollinger joined the department of Biochemistry and Molecular Biology at Penn State in 1995. He was promoted to Associate Professor in 2002 and appointed to the Department of Chemistry in 2004. His work focuses on enzyme reaction mechanisms, particularly those of iron-dependent oxygenases.

strate, αKG, has also been demonstrated by X-ray crystallographic studies of a number of αKG-dependent dioxygenases (see ref.[3] and references cited therein). The structures reveal that the carbonyl group of αKG binds *trans* to the protein carboxylate ligand, whereas the C1 carboxylate group of αKG binds opposite to one of the histidine residues. Interestingly, it can bind either *trans* to the histidine of the His-Xxx-Asp/Glu-motif, which is termed "in line" binding mode, or it can bind *trans* to the histidine more distant in sequence ("off line" binding mode).[3] There is X-ray crystallographic evidence for flexibility of αKG-binding in some of the enzymes. For example, in clavaminate synthase, αKG binds "in line" when the substrate analogue deoxyguanidinoproclavaminate is bound, and it binds "off line" when NO as an analogue of oxygen coordinates to the Fe center of the deoxyguanidinoproclavaminate complex.[36] Another example is the enzyme alkyl sulfatase, for which "in line" coordination of αKG to the Fe^{II} center is observed, whereas "off line" binding is observed when the Fe^{II} is substituted with Na^+.[37] In addition, αKG binding is stabilized by the ionic interaction of its C5 carboxylate group with an arginine or lysine residue.

The dissociation of the water ligand creates an open coordination site, and it is proposed that this is the site to which oxygen adds.[4,30] Indeed, it has been shown that binding of the substrate increases reactivity toward O_2 many-fold.[38,39] Thus, the enzymes have evolved what amounts to a conformational "trigger" for O_2 activation, which serves to favor the formation of reactive intermediates only in the presence of the target substrate, thereby minimizing the potentially inactivating self-oxidation reactions that have been demonstrated to occur in a number of the enzymes when the ternary enzyme·Fe^{II}·αKG complex reacts with O_2 in the absence of substrate.[40–42] Addition of oxygen to the coordinatively unsaturated Fe^{II} center of the quaternary complex yields intermediate **I**, in which the O_2 moiety is proposed to coordinate end-on to the Fe center. **I** is a $\{FeOO\}^8$ complex, and computational studies from the Solomon group suggest that it should be described as a Fe^{III}-superoxo species.[43] These calculations were calibrated by correlating experimental and computational data for the related $\{FeNO\}^7$ complexes,[43] which have been prepared by addition of NO to the Fe^{II} forms of a number of different mononuclear non-heme enzymes[44,45] and models thereof.[46,47] The postulated Fe^{III}-superoxo complex **I** is proposed to react by a nucleophilic attack of the uncoordinated O atom on C2 of αKG, thereby forming the bicyclic species, **II**. The next step in the proposed mechanism is decarboxylation of αKG and cleavage of the O–O bond to yield an Fe^{IV}-oxo, intermediate, **J**.[48] Alternative structures for the Fe^{IV}-oxo intermediate have been proposed. These include a mixed anhydride of carbonic and succinic acids, in which the O atom is inserted into the C1–C2 bond of αKG.[3] The products of decarboxylation of αKG are succinate and CO_2. Importantly, the mechanism predicts that one O atom of succinate should derive from O_2, and this has been verified for several of the enzymes by use of $^{18}O_2$ (see ref.[3] and references cited therein). In the next step, the Fe^{IV}-oxo intermediate is proposed to abstract a H atom from the substrate, yielding **IV**, which consists of a Fe^{III}–

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

OH complex and a substrate radical. Although **IV** has never been detected directly, evidence for the formation of a substrate radical was obtained by Begley and co-workers in their study of prolyl-4-hydroxylase (P4H) from *Paramecium bursaria Chlorella virus* 1.[49] P4H-directed oxidation of a peptide substrate containing 5-oxaproline was shown to result in conversion of the proline analogue to aspartate in a process that is likely to involve rearrangement of the expected substrate radical intermediate. In the normal catalytic processes, "oxygen rebound" of the Fe^{III}–OH complex of **IV** with the substrate radical generates the hydroxylated product and a Fe^{II} center. Thus, the mechanism also predicts that the O atom incorporated into the substrate should be derived from dioxygen, and this has also been verified by isotopic labeling experiments. Importantly, incorporation of ^{18}O from O_2 has been shown for some enzymes to be less than stoichiometric, suggesting that the O atom in **J** or **IV** (or both) may exchange with solvent (see ref.[3] and references cited therein). Alternatively, the oxo group may be protonated and a coordinated hydroxide ligand may become deprotonated and be incorporated into the product. This mechanism was named "ferryl-flip".[3] The hydroxide ligand required for this mechanism is not shown in Scheme 1, but coordination of a hydroxide ligand in addition to the ligands shown is entirely possible, especially considering that **J** and **IV** are depicted as having only five ligands.

Significant insight into the mechanism was also obtained from studies on inorganic model complexes.[4] Fe^{IV}-oxo complexes have been synthesized and characterized spectroscopically,[50–54] and oxygen activation by Fe^{II} centers coordinated by α-ketoacids has been investigated in detail.[35,55–59] These studies revealed that the α-ketoacid can bind as a monodentate or bindentate ligand, but only the latter exhibits the diagnostic MLCT band. Decarboxylation is accelerated by electron-withdrawing substituents on the α-ketoacid, consistent with the proposed nucleophilic attack of the superoxo species of **I** on the α-ketone carbonyl.[57]

Although the aforementioned studies provided support for the consensus mechanism, until very recently none of the proposed intermediates (enclosed in brackets in Scheme 1) had been directly detected for any enzyme in the family. In 2002, we selected one member of this enzyme family, TauD, which catalyzes hydroxylation of C1 of taurine (2-aminoethane-1-sulfonic acid) and other organosulfonates to initiate elimination of sulfite for sulfur acquisition,[60] for kinetic studies designed finally to reveal intermediates in this important reaction cycle. Several characteristics made it an ideal choice for such studies.[34] It is relatively small (32 kDa), soluble to high concentration, thermally stable, and readily obtained in large quantity by overexpression in *E. coli*.[34] In addition, its substrate, taurine, is chemically simple, making analogues with chemical or isotopic substitutions designed to perturb the reaction kinetics or mechanism synthetically accessible.

Investigation of the TauD reaction by rapid kinetic (stopped-flow and freeze-quench) and spectroscopic methods (UV/Visible, Mössbauer, EPR, resonance Raman, X-ray absorption) led to the detection of two intermediates in the catalytic cycle not previously detected for any member of the family. These studies are summarized in the following sections.

3. Detection of Two Intermediates in the TauD Reaction

The first evidence for the accumulation of two intermediates was obtained from stopped-flow absorption experiments.[61] Changes in the spectrum after mixing of the quaternary TauD·Fe^{II}·αKG·taurine complex with an oxygenated buffer solution (but not after a control mix with O_2-free buffer) were shown to be dominated by a positive feature at 318 nm, which reaches maximum intensity after approximately 20 ms (Figure 1, A), and a negative feature associated with loss of the chromophoric reactant complex, which develops fully only after the 318 nm feature has decayed (inset to Figure 1, A). These observations were rationalized by a minimal kinetic mechanism involving two accumulating intermediate states, the 318-nm absorbing first intermediate, **J**, which also absorbs into the visible regime to partially compensate for the loss of the absorption from the reactant complex, and a second species lacking both UV and visible absorption that accumulates prior to regeneration of the reactant complex. Rate constants of 1.5×10^5 M^{-1} s^{-1} for formation of **J**, 13 s^{-1} for decay of **J** to the second intermediate, and 2.5 s^{-1} for conversion of this intermediate back to the reactant quaternary complex were shown to accommodate the data well. Kinetic traces at 318 nm and 520 nm illustrate the three-step sequence clearly (Figure 1, B).

Although revealing their accumulation, the stopped-flow absorption experiments provided no clues as to the structures of the two intermediates, nor their positions within the catalytic cycle. Rapid freeze-quench (RFQ) Mössbauer spectroscopy provided the first such clues.[61] Mixing of the quaternary complex, which has a spectrum typical of a high-spin Fe^{II} species (Figure 1, C, top), with O_2-containing buffer results in a new Mössbauer absorption line at +0.75 mm/s (Figure 1, C). With increasing reaction time, the new peak was found to decay (Figure 1, D, filled circles) with the same time-dependence predicted for **J** (Figure 1, D, solid line), thereby establishing that the Mössbauer absorption at +0.75 mm/s is associated with **J**. Analysis of the experimental spectra revealed that **J** exhibits a quadrupole doublet (solid line shown above the spectrum of the 20-ms sample in Figure 1, D) with unusual parameters, an isomer shift (δ) of 0.31 mm/s and a quadrupole splitting parameter (ΔE_Q) of 0.88 mm/s. In general, the reduced isomer shift of **J** suggested that it is an oxidized species, but the value did not allow assignment of oxidation state, because it is higher than any of the isomer shifts reported for Fe^{IV} complexes[51,62–66] but also at the low extreme for high-spin Fe^{III}. Indeed, a trigonal bipyramidal high-spin Fe^{III} model complex reported by MacBeth et al. has the same isomer

(**A**) UV/Visible absorption spectroscopic changes recorded 20 ms (solid lines), 68 ms (dot-dashed lines), 210 ms (dotted lines), and 10 s (dashed lines) after equal-volume mixing at 5 °C of a solution of 2.4 mM TauD, 2.2 mM Fe^{II}, 10 mM αKG, and 10 mM taurine with O_2-saturated buffer. The inset is a magnification of the absorbance changes in the 500-nm region. (**B**) Absorbance kinetic traces at 318 nm (circles) and 520 nm (triangles). The solid lines are simulations according to the rate constants shown in Scheme 1. (**C**) 4.2-K/40-mT Mössbauer spectra of RFQ samples from the reaction of the TauD·Fe^{II}·αKG·taurine complex with O_2. The reaction times are shown. A simulation of the spectrum of **J** (δ = 0.31 mm/s, ΔE_Q = 0.88 mm/s) is shown as solid line. (**D**) Concentration of **J** determined from RFQ Mössbauer spectroscopy (circles) and a simulation according to Scheme 1 (solid line). All figures are adapted from Price et al.[61]

shift, 0.31 mm/s.[67] Exposure of samples containing high levels of **J** to γ-irradiation at 77 K (cryoreduction) monitored by EPR and Mössbauer spectroscopy was shown to convert it to one (or more) high-spin Fe^{III} complex, establishing the formal oxidation state of **J** as +IV.[61]

Decay of **J** is accompanied by an increase of the intensity of the high-energy line (at ≈ 2.7 mm/s) of the Mössbauer quadrupole doublet of the high-spin Fe^{II} species, demonstrating that the second intermediate contains Fe^{II}.[39]

4. Placement of the Intermediates within the Catalytic Cycle and Integration of the Kinetic and Chemical Mechanisms

The stopped-flow absorption and freeze-quench Mössbauer data by themselves established neither the identities nor the positions within the catalytic cycle of the two intermediates. The formal +IV oxidation state of **J** and +II state of the second intermediate suggested that the former occurs before taurine hydroxylation and the latter after, but the lack of good precedents for intermediates in the catalytic cycle precluded more definitive assignment by simple comparison of Mössbauer and optical properties. For example, it is possible to depict both **I** and **II** (in addition to **J**) with "resonance structures" having the Fe in the +IV oxidation state. Similarly, the second intermediate might be either a product(s) complex or the TauD·Fe^{II} binary complex awaiting rebinding of substrates. Additional kinetic experiments resolved these issues.

4.1 J is the Hydroxylating Intermediate

The position of **J** in the catalytic cycle was resolved by testing for substrate deuterium kinetic isotope effects (KIEs) on formation and decay of the intermediate. 1,1-$[^2H]_2$-taurine and the (control) unlabeled substrate were synthesized and used to prepare the reactant quaternary complex for reaction with O_2. A large normal KIE ($k_H/k_D \approx 37$) on decay of **J**, but no KIE on its formation, were observed. This result was shown both by stopped-flow absorption measurements (Figure 2, A) and by RFQ Mössbauer (Figure 2, B).[68] The result suggests that **J** is responsible for cleavage of the C1-$[^{1,2}H]$ bond, making the most likely identity of the complex the Fe^{IV}-oxo species in Scheme 1. This conclusion was subsequently confirmed by resonance Raman and X-ray absorption spectroscopic experiments (see below).

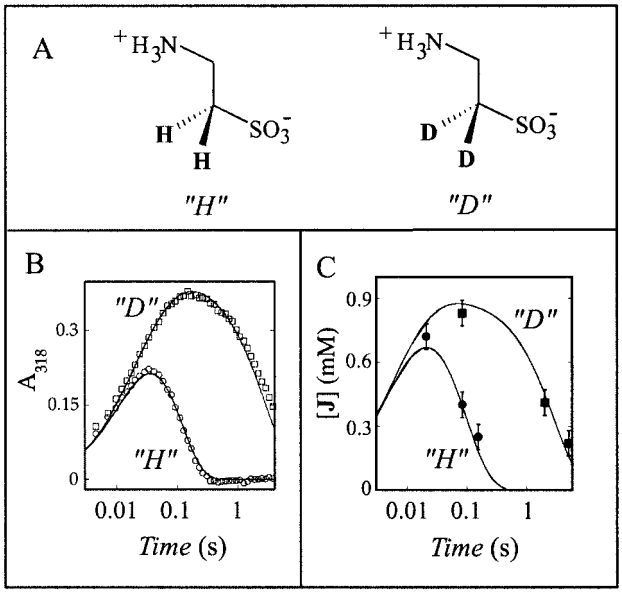

Figure 2. (**A**) Structures of 1,1-$[^1H]_2$-taurine and 1,1-$[^2H]_2$-taurine. Kinetics of **J** monitored by (**B**) stopped-flow absorption and (**C**) RFQ Mössbauer spectroscopy. The circles and squares represent the experimental data obtained using 1,1-$[^1H]_2$-taurine and 1,1-$[^2H]_2$-taurine, respectively. The solid lines are simulations for **J** according to the rate constants shown in Scheme 1. In **B**, a solution containing 2.0 mM TauD, 1.8 mM Fe^{II}, 17 mM αKG and 17 mM taurine was mixed with air-saturated buffer in a volume ratio of 2:5 at 5 °C. In **C**, a solution containing 4 mM TauD, 3.6 mM $^{57}Fe^{II}$, 10 mM αKG, and 10 mM taurine was mixed with an equal volume of O_2-saturated buffer at 5 °C. Adapted from Price et al.[68]

4.2 An Integrated Kinetic/Chemical Mechanism: Verification of its Predictions

The identity of **J** and the apparent failure of precursors to accumulate suggested that **J** forms rapidly after the initial slower addition of O_2 to the quaternary complex. The demonstration of a first-order dependence of the kinetics of formation of **J** on the concentration of O_2 proved this point[69] and allowed an upper limit to be established for the quantity of a precursor that can accumulate.[39] The demonstration by chemical quenched-flow experiments that loss of CO_2 from αKG correlates with formation of **J** established a second important prediction of the integrated mechanism and provided support for the structure assigned to **J**. The large C1 deuterium KIE on conversion of **J** to an Fe^{II} complex, again apparently without accumulation of intervening intermediates (e.g., **IV** in Scheme 1), indicates that the postulated "radical rebound" to the C1 radical is rapid compared to the preceding H atom abstraction. The implication that decay of **J** should be kinetically correlated with formation of product has been verified by chemical quenched-flow experiments quantifying sulfite released by the immediate product, 1-hydroxytaurine. All that remained was to establish the nature of the second intermediate and define the steps involved in its rate-limiting conversion back to the reactant quaternary complex.

4.3 Assignment of the Second Intermediate as a Product Complex

The initial transient-kinetic study on TauD had reported that binding of αKG to the TauD·Fe^{II} binary complex is relatively slow (2–6 s^{-1} at 4 °C) and, somewhat surprisingly for an association reaction, of kinetic order zero in αKG.[34] This report implicated a unimolecular step associated with formation of the TauD·Fe^{II}·αKG complex as the rate-limiting step and suggested that the second intermediate might be the binary complex. Resolution of the Mössbauer spectrum of the second intermediate showed that it is distinct from that of the TauD·Fe^{II} complex and also different from those of the TauD·Fe^{II}·αKG and TauD·Fe^{II}·αKG·taurine complexes.[39] Re-examination of αKG binding by stopped-flow absorption experiments monitoring development of the MLCT band at 530 nm showed that formation of the complex is remarkably complex, but much faster overall than the rate-limiting conversion of the second intermediate back to the reactant complex (Figure 3, A).[39] Taurine binding to the TauD·Fe^{II}·αKG complex is fast, but prior binding of taurine impedes binding of αKG (Figure 3, B), consistent with the preferred or obligatory order of substrate binding that has been seen in the reactions of other members of this family and providing a rationale for inhibition by taurine of both steady-state turnover and quaternary complex re-formation. The demonstration that formation of **J** upon mixing of TauD·Fe^{II} simultaneously with all three substrates is only slightly slower than upon mixing of the quaternary complex with O_2 (and much faster than the 2.5 ± 0.5 s^{-1} decay of the second intermediate) ruled out the possibility that steps involved in substrate binding contribute to the rate-limiting conversion of the second intermediate to the quaternary complex. This conclusion left only steps involved in product dissociation as candidates for the rate-limiting step and implied that the second intermediate is a product(s) complex. Support for these inferences came from examining the dependence of k_{cat} on solvent viscosity. With 1,1-[^{1}H]$_2$-taurine, the significant reduction of k_{cat} by increasing viscosity is consistent with rate-limiting diffusion of product from the active site. By contrast, with 1,1-[^{2}H]$_2$-taurine as substrate, the large KIE renders H atom abstraction rate-limiting, leading to a much less pronounced solvent-viscosity effect.[39]

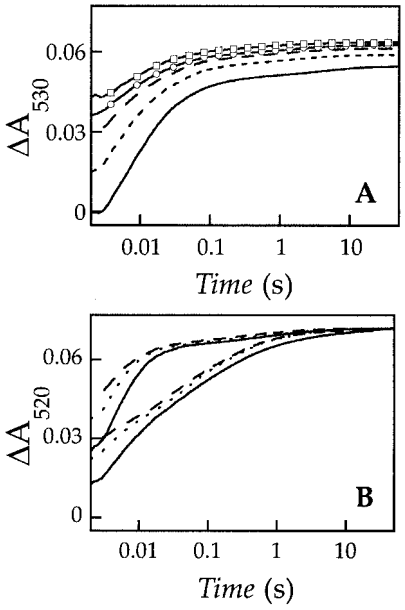

Figure 3. Absorbance-vs.-time traces monitoring binding of αKG in the absence (**A**) and presence (**B**) of taurine. In **A**, TauD containing 0.69 equivalents of Fe^{II} was mixed at 5 °C in the absence of O_2 with solutions of αKG to give final concentrations of 0.49 mM TauD and 1.5 mM (solid trace), 3 mM (dotted trace), 6 mM (dashed trace), 9 mM (solid trace with open circles), or 15 mM (solid trace with open squares) αKG. In **B**, both sets of traces are from experiments in which TauD containing 0.69 equivalents of Fe^{II} was mixed with a solution of αKG to give final concentrations of 0.49 mM TauD and 3 mM (solid traces), 6 mM (dotted traces), or 9 mM (dashed traces) αKG. For the lower three traces, taurine was present in the TauD·Fe^{II} solution such that [taurine] was 5 mM after mixing. In the upper three traces, taurine was present in the αKG solution, also giving 5 mM taurine after mixing. Adapted from Price et al.[39]

5. Structural Characterization of J

The results described in Sections 3 and 4 established that **J** contains a (formally) Fe^{IV} center and that it cleaves the C1–H bond of taurine to initiate its hydroxylation. In the consensus mechanism, the C1–H abstracting species is an Fe^{IV}-oxo species. Characterization of **J** by a variety of spectroscopic and computational methods described in the following sections demonstrated that **J** is indeed the long-pos-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tulated Fe^{IV}-oxo complex. Interestingly, the Fe center of **J** is in the high-spin ($S = 2$) configuration.

5.1 Mössbauer Spectroscopy

Mössbauer spectra of **J** recorded in varying external magnetic fields allowed for the determination of the spin state of the Fe center and the associated zero-field splitting (ZFS) parameters, D and E/D. The facts that **J** gives rise to a quadrupole doublet in a weak (40-mT) magnetic field but displays increasing magnetic splitting with increasing externally applied magnetic field is typical of paramagnetic complexes with (almost) axial integer-spin electronic ground states and $D > 0$. The 8-T spectrum of **J** exhibits six sharp lines with peak separations that reflect an effective magnetic field of about 24 T experienced by the ^{57}Fe nucleus, corresponding to an internal magnetic field of ca. 32 T oriented antiparallel to the externally applied 8-T field (Figure 4, A).[61] The magnitude of the internal magnetic field is much larger than those experimentally observed for the many low-spin ($S = 1$) heme and non-heme Fe^{IV}-oxo compounds,[50–52,62,70] suggesting that S of the Fe^{IV} site in **J** is larger than 1. To illustrate this point, a simulation of the spectrum of a low-spin ($S = 1$) non-heme Fe^{IV}-oxo complex is shown in part B of Figure 4 for comparison.[51] Analysis of the field-dependent spectra under the assumption that the Fe^{IV} site of **J** is in the high-spin ($S = 2$) configuration yielded $D = 10.5\ cm^{-1}$, $E/D = 0.03$, $g = (2.0, 2.0, 2.0)$ (fixed), $\delta = 0.31$ mm/s, $\Delta E_Q = -0.88$ mm/s, $\eta = 0$ (fixed), and $A/g_N\beta_N = (-18\ T, -18\ T,$ not determined).[71] Interestingly, these parameters are similar to those observed for the high-spin Fe^{IV} site of intermediate **X** from *E. coli* ribonucleotide reductase,[65] thereby corroborating the assignment of **J** as a high-spin Fe^{IV} species.

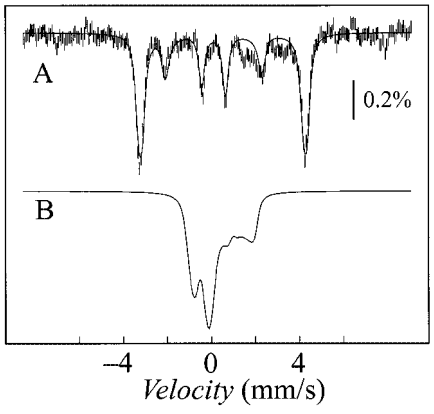

Figure 4. (**A**) 4.2-K/8-T Mössbauer reference spectrum of **J**. The solid line is a spin Hamiltonian simulation according to parameters given in the text. (**B**) Theoretical simulation of the spectrum of the low-spin Fe^{IV}-oxo complex reported by Rohde et al.: $S = 1$, $D = 29\ cm^{-1}$, $E/D = 0$, $g = (2.3, 2.3, 2.0)$, $\delta = 0.17$ mm/s, $\Delta E_Q = 1.24$ mm/s, $\eta = 0.5$, $A/g_N\beta_N = (-22.5, -18.2, -2.9)$ T.[51]

5.2 Resonance Raman Spectroscopy

The assignment of **J** as an Fe^{IV}-oxo complex was to this point based solely on chemical precedent and intuition. Resonance Raman experiments by Proshlyakov et al. provided the first direct evidence for the assignment.[72] One of the spectroscopic hallmarks of the Fe^{IV}-oxo unit is a vibrational frequency in the 800 cm^{-1} region which is downshifted by approximately 35 cm^{-1} for the ^{18}O isotopomer.[73] This downshift is close to the value predicted for a Fe–O diatomic harmonic oscillator. Proshlyakov et al.[72] succeeded in obtaining the stretching frequency of the Fe^{IV}-oxo unit of **J** by using continuous flow of reactants (quaternary complex and O_2) at low temperature (- 38 °C) to generate the intermediate and collecting at a distance from the mixer corresponding to a reaction time of 150 ms. This time was selected on the basis of absorption data recorded under the same experimental conditions, which suggested that the concentration of **J** would be at its maximum then. Resonance Raman difference spectra, which were obtained from the reaction carried out with either $^{16}O_2$ or $^{18}O_2$, revealed bands at 821 cm^{-1} ($^{16}O_2$) and 789 cm^{-1} ($^{18}O_2$). The energies of these bands are close to those observed in resonance Raman spectra of Fe^{IV}-oxo units found in heme enzymes and heme and non-heme model complexes.[51,73] Consequently, these features were attributed to the Fe=O stretching frequency.

In addition to the vibration of the Fe^{IV}-oxo unit, the authors observed a second O isotope-sensitive feature at 583 cm^{-1} ($^{16}O_2$) and 555 cm^{-1} ($^{18}O_2$). Because Fe^{IV}-oxo species do not exhibit a band in this region, the authors reasoned that it originates from a different intermediate. Interestingly, terminally coordinated Fe^{III}-superoxo oxyhemoglobins exhibit the Fe–O stretching frequency in this region, in addition to the O–O stretching frequency in the 1130 cm^{-1} region.[74] The authors did indeed observe a derivative band in the 1100 to 1160 cm^{-1} spectral region, but it overlaps with an intense solvent band, hence not allowing for its unambiguous assignment. This raises the possibility that the features at 583 (555) cm^{-1} may also emanate from a Fe^{III}-superoxo species, e.g. structure **I** of Scheme 1. Whereas this assignment is plausible, the vast quantities of protein required and the inflexibility of the apparatus necessitated by the extraordinary technical demands of the experiment prevented the crucial demonstration of the expected time-dependent decrease in the ratio of intensities of the 583/555 cm^{-1} band of the putative precursor and the 821/789 cm^{-1} band of **J**. If the lower energy feature does indeed arise from a precursor to **J**, the complex should be detectable by RFQ Mössbauer experiments carried out with similar reaction conditions, because it should have an integer-spin ground state, give rise to a quadrupole doublet at 4.2 K in a small externally applied magnetic field, and, therefore, be detectable even at relatively modest concentrations.

5.3 X-ray Absorption Spectroscopy

The second prominent characteristic of the Fe^{IV}-oxo group is a short (ca. 1.65 Å) Fe–O bond.[51,52,70,75–77] Because of the high reactivity of the Fe^{IV}-oxo unit, the bond

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

length generally cannot be determined using X-ray crystallography. The recent report of the first X-ray structure of a Fe^{IV}-oxo non-heme model complex is a remarkable exception.[51] For the case of **J**, the Fe–O distance was determined by X-ray absorption spectroscopy.[78] These experiments required that the Fe^{IV}-oxo complex be the predominant species in the sample. Accumulation of **J** to 80% of the Fe in the sample was made possible by the use of 1,1-$[^2H]_2$-taurine and the large deuterium KIE on decay of **J**.[68] X-ray absorption spectra of samples containing primarily **J** were shown to exhibit the hallmarks of a Fe^{IV}-oxo unit. First, the edge energy is significantly higher than that of the quaternary TauD·Fe^{II}·αKG·taurine complex, suggesting that **J** is in a high oxidation state. Second, the pre-edge feature caused by the 1s→3d transitions is intense, which is caused by the less centrosymmetric ligand environment of the Fe center imposed by the oxo ligand. Third, fitting of the EXAFS region of the spectra requires the assumption of a short, 1.62 Å, interaction between the Fe and one of its ligands. Importantly, the coordination number for this short interaction was found to range from 0.5 to 0.8, in agreement with the fraction of **J** in the sample determined independently by Mössbauer spectroscopy. On the basis of the extensive precedent, the 1.62 Å interaction was assigned to the Fe^{IV}-oxo unit.

5.4 Proposed Structure of J

The data indicate that **J** has an Fe^{IV}-oxo unit with the iron in high-spin configuration. To the best of our knowledge, the only other example of a high-spin Fe^{IV}-oxo unit is a dinuclear model complex.[79] Importantly, the large number of characterized mononuclear heme and non-heme Fe^{IV}-oxo species all have a low-spin (S = 1) Fe^{IV}-oxo group.[50–52,62,70] In a trigonal bipyramidal ligand field the d-orbitals split into two low-lying *e*-sets and one orbital high in energy (d_{z^2}). To evaluate the possibility that the four low-lying orbitals can accommodate four unpaired electrons, resulting in the experimentally observed S = 2 configuration, density functional calculations on the trigonal bipyramidal model of **J** shown in Figure 5 were conducted.[71] This model contains two imidazole ligands (one axial and one equatorial), two equatorial carboxylate ligands, and the axial oxo ligand. The three protein ligands derived from the $(His)_2$-$(Asp)_1$ triad are represented by the two imidazole ligands and one of the carboxylate ligands. They coordinate the Fe center facially. The second equatorial carboxylate ligand mimics one of the products of the reaction, succinate. The other product of the decarboxylation reaction, CO_2, has not been included in this model, although interactions of CO_2 with the Fe center have been reported. Coordination of CO_2, derived from hydrogencarbonate in the buffer, to the Fe^{II} center opposite to the more distant (in sequence) histidine has been detected by X-ray crystallography for deacetoxycephalosporin C synthase,[80] and by perturbation of the Fe^{III}-catecholate chromophore in TauD, which is obtained by the self-hydroxylation of tyrosine 73 followed by coordination of the catecholate to the iron.[40] Geometry optimization of the model of **J** does not result in significant structural changes and yields a lower energy for the S = 2 state, suggesting that the trigonal bipyramidal geometry is one way of rationalizing the high-spin state of the Fe^{IV} center of **J**.

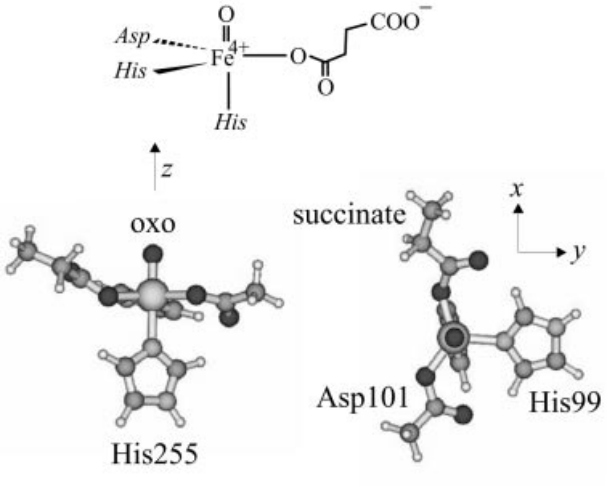

Figure 5. Structural model of intermediate **J** in TauD obtained by DFT calculations. Adapted from Krebs et al.[71]

As noted, the Mössbauer isomer shift of **J** is unusually high, approaching values observed for high-spin Fe^{III} complexes.[67] Because DFT methods can predict Mössbauer parameters with considerable accuracy,[81–84] the comparison of calculated and experimental parameters provides a means of validating structural models for reactive intermediates of unknown structure. Although the Mössbauer isomer shift of the trigonal bipyramidal model calculated by this approach (0.22 mm/s) is lower than the experimentally observed isomer shift of **J** (0.31 mm/s), the deviation is still within the uncertainty of the method (0.10 mm/s).[81] Although further calculations, in particular those taking into account the effect of the protein, are clearly warranted to more rigorously evaluate potential structures for **J**, the agreement between theory and experiment suggests that **J** may have a trigonal bipyramidal structure with an axial oxo ligand.

6. Conclusion and Outlook

Two intermediates detected in the reaction of the quaternary TauD·Fe^{II}·αKG·taurine complex with oxygen have been assigned by a combination of rapid kinetic and spectroscopic methods as a high-spin Fe^{IV}-oxo species, **J**, which abstracts H from C1 of taurine, and a product(s) complex, **V** in Scheme 1, that releases product in the rate-limiting step of the catalytic cycle. Other intermediates in the consensus mechanism are kinetically masked, and therefore do not accumulate. Current efforts are directed towards accumulation of these intermediate states for their spectroscopic characterization. For example, the resonance Raman spectroscopic studies by Proshlyakov et al. suggest that in-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

termediate **I** or **II** may accumulate when the reaction is carried out at low temperature (–35 °C).[72] Perturbation of the reaction kinetics by the use of substrate analogues, variant proteins, or both may also allow for accumulation and characterization of additional complexes in the cycle.

Homo- and Heteroduplex Complexes Containing Terpyridine-Type Ligands and Zn^{2+}

Florina Dumitru,[a,b] Eddy Petit,[a] Arie van der Lee,[a] and Mihail Barboiu*[a]

Keywords: Crystal engineering / N ligands / Supramolecular chemistry / Ternary complexes / Zinc

We describe a study of the equilibrium binding of Zn^{2+} to binary mixtures of tridentate terpy-type ligands **1**–**3**, which leads to the formation of a dynamic mixture of homo (**4**–**6**) and hetero (**7**–**9**) coordination compounds. We report the crystal structures of five such complexes (**4**, **5**, **7**–**9**) which assemble into complementary duplex compounds that further self-organize into double helical- or lamellar-type architectures in the solid state. The ligand exchange between homoduplex complexes in solution leads to the preferential formation of the heteroduplex complexes. As might be expected, these processes display a statistical distribution of homoduplex:heteroduplex:homoduplex complexes of 1:2:1 for the mixtures resulting from **4**:**6** and **5**:**6** ligands. However, complex **8** is preferred in a **4**:**5** mixture which presents a composition of 1:4:1 (amplification factor of about 33 %). The X-ray structural determinations of selected single crystals resulting from the stoichiometric mixtures of homoduplex complexes show unique heteroduplex superstructures **7**–**9** in the solid state. The present results present the solid-state structures of homo- and heterocomplexes resulting from terpyridine-type ligands **1**–**3** and Zn^{2+} metal ions. The heteroduplex Zn^{2+} complexes **7**–**9** are quantitatively crystallized in the solid state by statistical (**7**, **9**) and structural (**8**) driven selection in solution from a binary mixture of the terpyridine-type complexes and then trapped by crystallization in the solid state.

Introduction

Under biological and environmental conditions, multiligand-multimetal equilibria dominate homonuclear interactions and mixed- or higher-order complexes are formed.[1] Thus it becomes understandable why the mixed complexes have been studied extensively during the last four decades. The most simple of these species − the ternary (heteroduplex) complexes − consist of a metal ion and two different ligands. The driving forces leading to the formation of such complexes are statistical events, and non-covalent forces like charge and hydrophobic or π-π stacking interactions.[2]

The self-organization of metallosupramolecular entities may be directed by design and is based on the implementation of ligands containing specific molecular information stored in the arrangement of suitable binding sites and of metal ions reading out the structural information through the algorithm defined by their coordination geometry. The design of the ligand is crucial, and bipyridine, terpyridine, etc. derivatives have been extensively used.[3] The synthesis of such ligands is very challenging and other simple procedures are much sought-after as they may provide a more direct access to these systems by using or imine and hydrazone mimics, which are useful building blocks for the generation of grid-type, cage, helical architectures, etc.[4–7]

Coordination complexes based on terpyridine-type ligands **1** and octahedrally coordinated metal ions are of special interest as they reveal a range of interesting structural and physicochemical properties.[5] Other terpyridine-type (terpy) tridentate ligands like the bis-Schiff-base **2**[6] and the hydrazone bis-pyridine **3**[7] give easy synthetic access to similar systems (Scheme 1). Addition of Zn^{2+} to the binary mixture of terpy-type ligands **1**–**3** should cause the appropriate recruitment of two ligands in a pairwise mode and might be controlled by the coordination behavior and internal interactions between different aromatic moieties of these compounds. Specifically, it is of interest to investigate whether the coordination behavior of these systems on the addition of octahedral Zn^{2+} ions can be selectively expressed in the formation of ternary complexes.

We describe in this paper a study of the equilibrium binding of Zn^{2+} to binary mixtures of tridentate terpy-type ligands **1**–**3**, which leads to the formation of a dynamic mixture of homo- (**4**–**6**) and hetero- (**7**–**9**) coordination compounds. We report the crystal structures of five such complexes (**4**, **5**, **7**–**9**), which assemble into complementary duplex compounds that further self-organize into double helical- or lamellar-type architectures in the solid state.

Result and Discussions

Synthesis and Characterization of Ligands 2 and 3

Ligands **2** and **3** were synthesized in EtOH by condensation of one equivalent of 2,6-pyridinedicarboxaldehyde with two equivalents of aniline and of one equivalent of 2-pyridinecarboxaldehyde with one equivalent of hydrazinopyridine, respectively. The solutions of **2** and of **3** in $CDCl_3$ give sharp ^1H NMR spectra with a strong deshielding of the *meta* protons of the central pyridine (**2**) and of the iminopyridine (**3**) rings, consistent with the *transoid* conformation[8] of the –N=C–C=N– moiety. As expected, a strong deshielding is observed for the *meta* pyridine hydrogens, thus indicating a tight contact with the neighboring imine nitrogen atoms; this effect agrees with an unwrapped conformation of compounds **2** and **3**.

Two-Component Self-Assembly, Generation and Interconversion of the Zn^{2+} Complexes Formed by Ligands 1–3

The formation of homoduplex Zn^{2+} complexes from terpyridine-type ligands **1**–**3** has been studied in detail because it is a very common prototype for coordination self-assembly processes and because of the physicochemical properties and functions that such materials may possess.[2–9] One may consider the formation of these complexes to result from the "reading" of the steric and binding information of the ligands by the Zn^{2+} ions following their octahedral coordination geometry.

Of particular interest, both as a control of the ligand selection and due to the formation of novel mixed species, would be the generation of the heteroduplex complexes from two different terpy-type ligands **1**–**3** and Zn^{2+} ions. Considering that Zn^{2+} ions, which display hexacoordination geometry, bind two terpy units in a octahedral geometry, one might expect that the exchange of different terpy-type ligands in the metal coordination sphere would result in the interconversion of all possible combinations. The rate of such exchange depends on the coordination behavior and on the specific interactions between ligands, therefore it should be possible to form mixtures from which a ternary architecture[10] can be amplified by favorable attractive interactions, including stacking[11] or hydrophobic[12] interactions, between the ligands, while minimizing the ligand–solvent interactions.[8]

As a step towards this goal, we decided to investigate the formation and interconversion of the Zn^{2+} duplex complexes that may result from the binding of Zn^{2+} ions to stoichiometric ratios (1:1) of binary mixtures of ligands **1**–**3**. Such systems form by self-assembly under mild conditions and are readily amenable to solution studies by ^1H NMR spectroscopy and ESI mass spectrometry.

The ^1H NMR spectra of homoduplex complexes **4**–**6** (Scheme 1) consist of a series of sharp peaks, indicating high symmetry (Figure 1). The spectra can be interpreted as ligands **1**–**3** in one magnetic environment and show a deshielding of the protons of the pyridine moieties due to the Zn^{2+} ion complexation. Tridentate metal ion coordination converts the *transoid* form of the free ligand to the *cisoid* one, corresponding to a terpy-type complexation site. The proton signals of the phenyl moieties of complex **5** are overall strongly shielded ($\Delta\delta$ = 0.5 ppm) with respect to ligand **2**, thus suggesting strong intramolecular attractive π-π stacking interactions between the phenyl and central pyri-

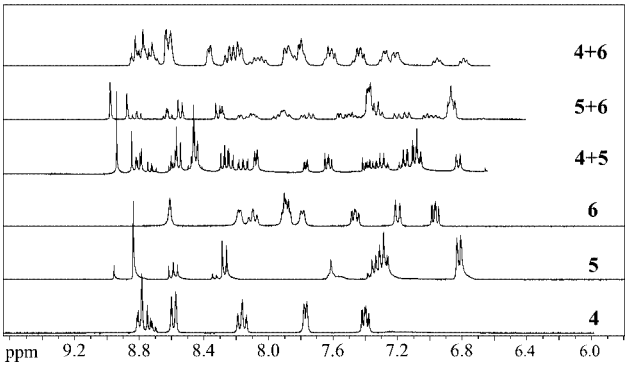

Figure 1. ^1H NMR spectra of the homoduplex complexes **4**–**6** in CD_3CN and of species resulting from the combination of stoichiometric binary mixtures of **4**:**5**, **5**:**6**, and **4**:**6** in a 1:1 molar ratio.

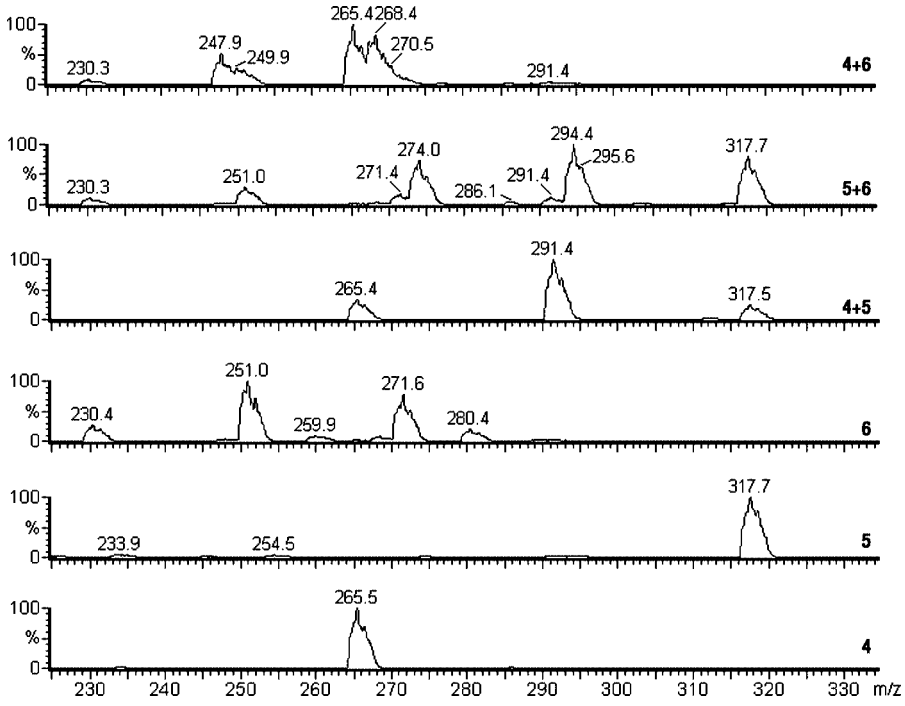

Figure 2. ESI mass spectra of the homoduplex complexes **4**–**6** in CH_3CN and of species resulting from the combination of stoichiometric binary mixtures of **4**:**5**, **5**:**6**, and **4**:**6** in a 1:1 molar ratio.

dine moiety. The ESI mass spectra of homoduplex Zn^{2+} complexes **4**–**6** show strong doubly charged molecular peaks at M/2 (**4**, **5**) or at (M + $n$$CH_3CN$)/2 ($n$ = 0–2, **6**; Figure 2).

The ligand exchange between Zn^{2+} complexes **4**–**6** was studied in the reaction of stoichiometric binary mixtures (**4**:**5**, **4**:**6**, **5**:**6**, 1:1, mol:mol) of homoduplex complexes. In all reactions the signals of symmetrical complexes as well as those of the cross-products were monitored by ^1H NMR spectroscopy (Figure 1) and ESI mass spectrometry (Figure 2). The same results were obtained by mixing two different ligands in a 1:1 ratio and by subsequently adding the stoichiometric amount of metal ions. The ^1H NMR spectra of the binary mixtures show three sets of sharp proton resonances and consist of the two initial homoduplex complexes together with the heteroduplex mixed species. We did not detect any N-exchange reaction between the bis-Schiff-base **2** and the hydrazone bis-pyridine **3** ligands; the core Zn^{2+}–ligand units, despite their kinetic lability, are thermodynamically very stable species in solution.

The ^1H NMR signals of heteroduplex complexes **7**–**9** show an overall shielding of the pyridine protons with respect to the homoduplex species, thereby suggesting an enhanced coordination power when two different ligands are coordinated. Moreover, the proton signals of the phenyl moieties of the heteroduplex complex **8** are overall strongly shielded ($\Delta\delta$ = 0.4 ppm) with respect to the homoduplex complex **5** (Figure 1). This suggests that intramolecular attractive π-π stacking interactions play an important role in the formation of the heteroduplex complexes **7**–**9**.

The ligand exchange was also monitored by ESI mass spectrometry; in all reactions, the mass spectra showed the preferential formation of the cross-products **7**–**9** after a rapid equilibration of the 1:1 solutions of the homoduplex complexes **4**–**6** (Figure 2). The composition of the binary mixtures was determined on the basis of the NMR signals of the imine, phenyl, and pyridine protons of the homo- and heteroduplex complexes **4**–**9**. As might be expected, these processes display a statistical distribution of homoduplex:heteroduplex:homoduplex complexes of 1:2:1 for the mixtures resulting from **4**:**6** and **5**:**6** ligands. However, complex **8** is preferred in a **4**:**5** mixture, which has a composition of 1:4:1. Considering the statistical distribution of 1:2:1 and the NMR detection limit error under the experimental conditions used is about 1%, the formation of **8** must display an amplification factor of about 33%.

Solid-State Structures of the Homoduplex (4, 5) and Heteroduplex (7–9) Zn^{2+} Complexes

The crystal structures of the complexes were determined from crystals obtained from acetonitrile/diisopropyl ether (**4**, **5**, **8**, **9**) and acetonitrile/benzene (**7**) solutions at room temperature. The molecular and the crystal packing structures are presented below. In all structures the Zn^{2+} ion is fully coordinated by two ligands and presents an octahedral coordination geometry. The average Zn^{2+}–$N_{Pyridine}$ Zn^{2+}–N_{imine}, and Zn^{2+}–$N_{hydrazone}$ distances are 2.07 or 2.20 (depending on the nature and the position of the pyridine moiety), 2.25, and 2.15 Å, respectively.

Surprisingly, only one crystal structure containing the $Zn(terpy)_2^{2+}$ [13a] duplex (with the peroxodisulfate counterion) was found in the Cambridge Structural Database (Feb-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ruary 2005).[13b] The unit cell of the new crystal structure of **4** was found to contain four homoduplex complexes together with eight triflate counterions. Each $Zn(terpy)_2^{2+}$ duplex has the two terpyridines arranged into two orthogonal planes (Figure 3a), associated by offset face-to-face (***off***)[5a] pyridine–pyridine interactions with average π-π stacking centroid–centroid distances of 3.90 Å.[12a] In the crystal lattice, the homoduplex cations of **4** pack in one direction into parallel layers that are alternatively stratified. In the adjacent layers, the terpyridine ligand planes on either side of the layer interface are rotated by 45° to each other (Figure 3b). The triflate anions and the cations are in van der Waals contact, thus disrupting the classical two-dimensional motif of "terpyridine embrace"[5a] and filling the interstices so that all available space is filled.

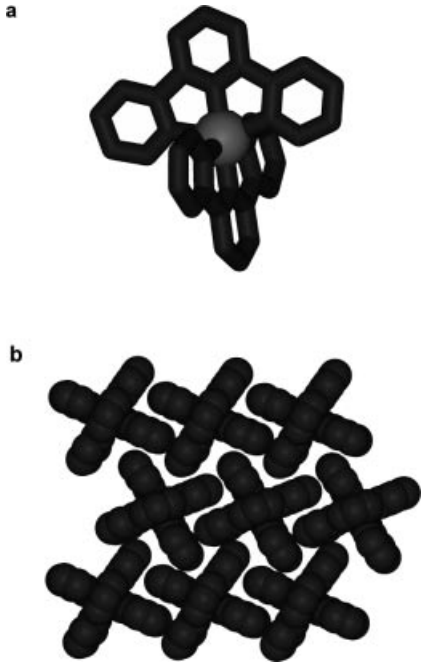

Figure 3. Crystal structure of the homoduplex complex **4**: a) side view in stick representation (the Zn^{2+} ion is shown as a gray sphere); b) space-filling representation of the crystal packing.

The unit cell of complex **5** was found to contain two homoduplex complexes together with four triflate counterions and four acetonitrile molecules. The two ligands of the duplex are arranged into two intertwined strands that are held together in double-helix form (0.5 turns per duplex) by the Zn^{2+} cation (Figure 4, a). As expected from the solution studies, the relative position of the duplex ligands allow an internal overlap between the phenyl moieties and the central pyridine moiety, with an average distance of 3.8 Å corresponding to a van der Waals contact. Each duplex of one helical sense is π-π stacked with two duplexes of the same helical sense (Figure 4, b). Each duplex present a tight contact with the two neighboring ones by stacking of the terminal phenyl moieties (average distance of 3.68 Å). This pattern generates infinite double helix stacks of units of one helical sense, with a helical pitch of about 15.3 Å. The crystal contains spontaneously resolved domains of alternate helicity. Accordingly, chiral double helical channels are generated in the solid state with an interior void of about 1.8 Å (considering a projection in a plane and taking into account the van der Waals radii of diagonally located N and C-H sites). The zinc ions are arranged into an approximately linear array that fits tightly into the central cavity of the double helical channel. The double helical entity is reminiscent of other terpyridine–Ag^+ complexes[5e] or of the double stranded dinuclear Ag^+ helicates[12b] described earlier.

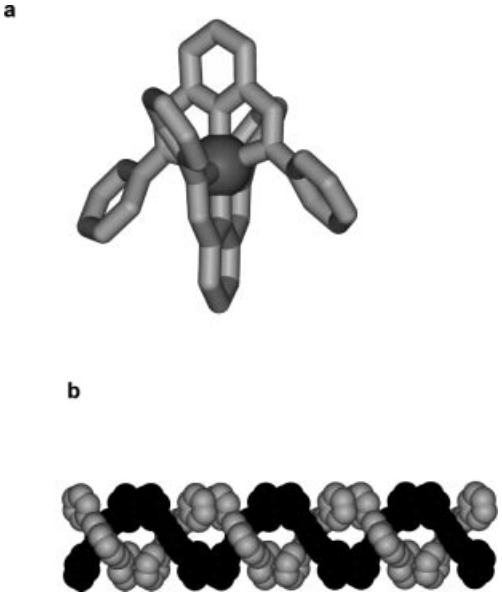

Figure 4. Crystal structure of the homoduplex complex **5**: a) side view in stick representation (the Zn^{2+} ion is shown as a gray sphere); b) space-filling representation of the crystal packing.

All attempts to crystallize complex **6** failed, and only tiny single crystals too small for X-ray analysis could be obtained from different solution-diffusion experiments.

Layering such solutions of stoichiometric binary mixtures (1:1, mol:mol) of homoduplex complexes **4**–**6** in acetonitrile with a non-solvent resulted in a unique set of crystals for each experiment. The X-ray structural determinations of selected single crystals resulting from these stoichiometric binary mixtures revealed that such complexes present unique heteroduplex superstructures **7**–**9** in the solid state. Redissolution of the crystals in CD_3CN results in regeneration of the reaction mixture prior to crystal growth. These features are similar to other dynamic processes operating in mixtures of coordination complexes from which a single member may be trapped by crystallization.[14]

The unit cell of complex **7** was found to contain four heteroduplex complexes together with eight triflate counterions and four benzene molecules. The two different ligands of the duplex are arranged into two orthogonal planes (Figure 5, a). Each duplex of **7** associates in the crystal lattice by terpyridine–terpyridine offset-face-to-face (***off***)[5a] interactions. They are restricted to one direction (average π-π stacking centroid–centroid distances of 3.75 Å), thus forming parallel layers that are alternatively stratified (Figure 5, b). Interactions in the other direction are disrupted, and the

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

hydrazone bis-pyridine ligands are not involved in pyridine–pyridine π-π stacking interactions (average centroid–centroid distances of 4.60 Å).

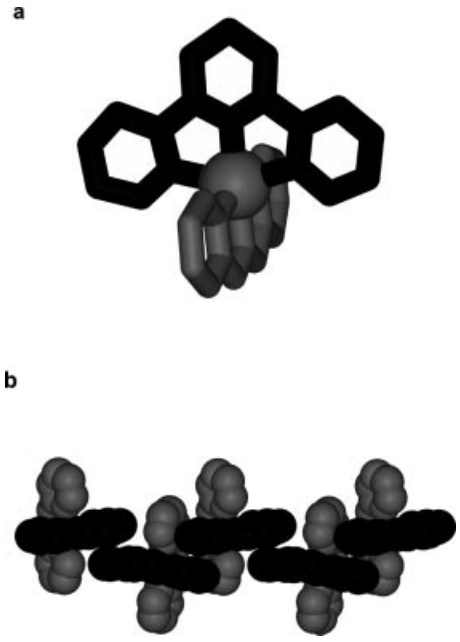

Figure 5. Crystal structure of the heteroduplex complex **7**: a) side view in stick representation (the Zn^{2+} ion is shown as a gray sphere); b) space-filling representation of the crystal packing.

The unit cell of complex **8** was found to contain four heteroduplex complexes together with eight triflate counterions and four acetonitrile molecules. The two different ligands of the duplex are arranged into two orthogonal planes (Figure 6, a). The relative flexibility of ligand **2** allows an internal overlap between the phenyl moieties and the central pyridine moiety of the terpyridine **1** with an average distance (3.98 Å) corresponding to a van der Waals contact. This is consistent with the NMR results and suggests that intramolecular attractive π-π stacking interactions play an important role in the preferential formation and amplification of the heteroduplex **8** from a stoichiometric mixture of **4** and **5**. Each heteroduplex of **8** associates two by two in the crystal lattice by terpyridine–terpyridine ***off*** interactions (average π-π stacking centroid–centroid distances of 3.75 Å), resulting in the formation of dimeric species that are alternatively stratified in the crystal lattice (Figure 6, b).

The unit cell of complex **9** was found to contain four heteroduplex complexes together with eight triflate counterions and four acetonitrile molecules. The two different ligands of the duplex are arranged into two orthogonal planes. The replacement of the central pyridine group by a hydrazone group in ligand **3** results in the disruption of the internal π-π stacking between the phenyl and pyridine moiety; in the heterocomplex **9** the phenyl substituents are perpendicularly twisted with the respect to the ligand **3** plane (Figure 7, a). In the crystal lattice, the heteroduplex cations of **9** associate by ***off*** interactions between the lateral pyridine moieties of ligand **3** (average π-π stacking centroid–centroid distances of 3.80 Å), forming parallel layers (Figure 7, b). In the other direction, each layer is alternatively stratified above another by stacking of the terminal phenyl moieties of the ligand **2**, such that each layer is in van der Waals contact (average distance of 4.05 Å).

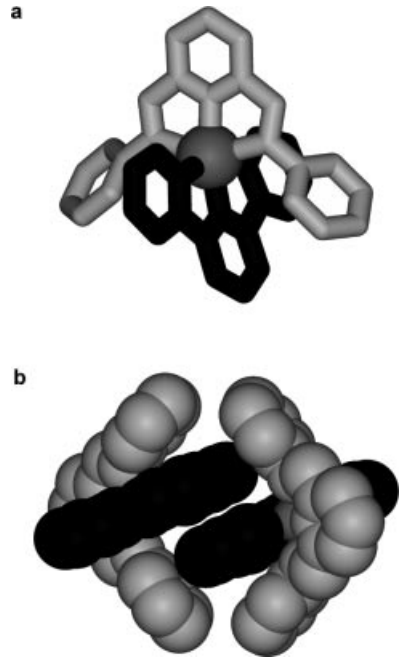

Figure 6. Crystal structure of the heteroduplex complex **8**: a) side view in stick representation (the Zn^{2+} ion is shown as a gray sphere); b) space-filling representation of the crystal packing.

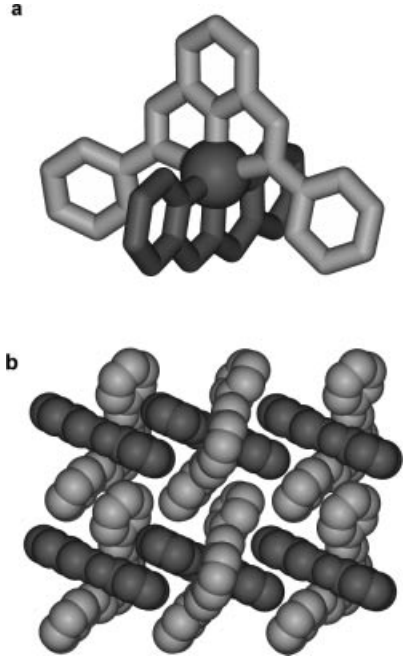

Figure 7. Crystal structure of the heteroduplex complex **9**: a) side view in stick representation (the Zn^{2+} ion is shown as a gray sphere); b) space-filling representation of the crystal packing.

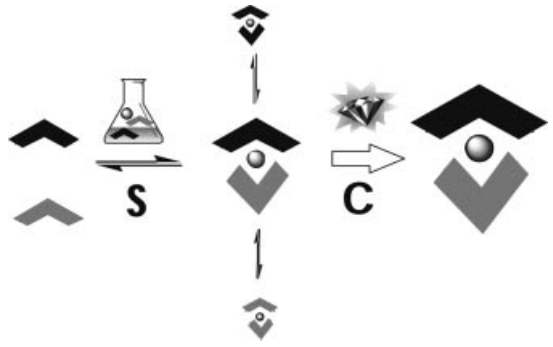
The X-ray crystallographic results allow the following conclusions to be made. In term of specific self-assembly, the homo- and heteroduplex Zn^{2+} complexes of the terpyri-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

dine-type ligands **1**–**3** self-organize in the solid state into 1D or 2D stacked layers (**4**, **7**, **9**), double-helix (**5**), or dimeric (**8**) architectures as a function of synergetic intra- and intermolecular π-π stacking interactions between different constitutional ligands. In terms of specific self-organization, the heteroduplex architectures **7**–**9** represent an attractive example of solid-state structures resulting from the synergistic effects of statistical (**7**, **9**) and structural-driven (**8**) binding of two different ligands by the Zn^{2+} metal ions.

Conclusions

This paper present the solid-state structures of homo- and heterocomplexes resulting from terpyridine-type ligands **1**–**3** and Zn^{2+} metal ions. The heteroduplex Zn^{2+} complexes **7**–**9** are quantitatively crystallized in the solid state by statistical (**7**, **9**) and structural (**8**) driven selection in solution from a binary mixture of the terpyridine-type complexes and are then trapped by crystallization in the solid state (Scheme 2).



Scheme 2. Statistical pre-amplification in solution (**S**) and solid-state selection process (**C**) of the heteroduplex complexes **7**–**9**.

The crystal structures and their packing present common features with many other similar architectures reported up to now.[5] However, their structural concept − octahedral Zn^{2+} coordination, positioning two ligands in an orthogonal position such that they further interact by π-π stacking in the crystal − allows us to obtain different 1D or 2D stacked layers (**4**, **7**, **9**), double-helix (**5**), or dimeric (**8**) architectures.

A further step toward such nanosystems could involve side-by side formation of "dynamic ligands" by correct selection of their specific components by reversible interconnections. We are currently extending this approach to such optical, magnetic, etc. dynamic combinatorial nanosystems.

Experimental Section

General Methods: 2,6-Pyridinedicarboxaldehyde, 2,2′:6′,2′′-terpyridine (**1**), 2-pyridinecarboxaldehyde, and 2-pyridylhydrazine were purchased from Aldrich and used as received. All other reagents were obtained from commercial suppliers and used without further purification. All organic solutions were routinely dried over sodium sulfate (Na_2SO_4).

^{1}H NMR, COSY, and ROESY spectra were recorded on an ARX 300 MHz Bruker spectrometer in $CDCl_3$ and CD_3CN, with the use of the residual solvent peak as reference. Mass spectrometric studies were performed in the positive-ion mode using a quadrupole mass spectrometer (Micromass, Platform 2+). Samples were dissolved in acetonitrile and were continuously introduced into the mass spectrometer at a flow rate of 10 mL min^{-1} with a Waters 616HPLC pump. The temperature (60 °C) and the extraction cone voltage (5–10 V) were usually set to avoid fragmentations. The numerotations used for the assignments of the ^{1}H NMR signals (according to the corresponding COSY and ROESY spectra) are given below.

Synthesis of Ligands and Complexes: The pyridine-based ligands **2**[6] and **3**[7] were prepared according to the procedures described in the literature. Their NMR, ESI-mass spectra, and elemental analyses are consistent with analytically pure compounds.

General Procedure for the Preparation of Zn^{II} Homoduplex Complexes 4–6: The reactions were performed typically on a 10-mg scale of ligand. The ligands **1–3** (0.035 mmol) and $Zn(CF_3SO_3)_2$ (0.0175 mmol) were dissolved in CD_3CN (1 mL), and stirred overnight at 60 °C.

$[Zn(1)_2](CF_3SO_3)_2$ (4): ^{1}HNMR (300 MHz, CD_3CN): δ = 8.81–8.78 (d, ^1J = 6.6 Hz, 4 H, H^b), 8.75–8.73 (t, ^2J = 6.6 Hz, 2 H, H^a), 8.60–8.57 (d, ^1J = 7.91 Hz, 4 H, H^4), 8.19-8.13 (td, ^2J = 7.91 Hz, 4 H, H^3), 7.78–7.76 (d, ^1J = 4.71 Hz, 4 H, H^1), 7.42–7.37 (td, ^2J = 5.28 Hz, 4 H, H^2) ppm. MS (ESI): *m*/*z* (%) = 265.5 (100) $[Zn(\mathbf{1})_2]^{2+}$.

$[Zn(2)_2](CF_3SO_3)_2$ (5): ^{1}HNMR (300 MHz, CD_3CN): δ = 8.81 (s, 4 H, H^1), 8.61–8.55 (t, ^2J = 8.1, J = 7.5 Hz, 2 H, H^a), 8.27–8.24 (d, ^1J = 7.8 Hz, 4 H, H^b), 7.36–7.26 (m, 12 H, H^{3+4}), 6.82–6.79 (d, ^1J = 3.6 Hz, 8 H, H^2) ppm. MS (ESI): *m*/*z* (%) = 317.7 (100) $[Zn(\mathbf{3})_2]^{2+}$.

$[Zn(3)_2](CF_3SO_3)_2$ (6): ^{1}HNMR (300 MHz, CD_3CN): δ = 8.61 (s, 2 H, H^5), 8.19–8.17 (d, ^1J = 4.52 Hz, 2 H, H^1), 8.12–8.07 (t, ^2J = 7.72 Hz, 2 H, H^3), 7.92-7.86 (m, 4 H, H^{8+4}), 7.80–7.78 (d, ^1J = 4.71 Hz, 2 H, H^{10}), 7.49–7.44 (td, ^2J = 5.27 Hz, 2 H, H^2), 7.21-7.19 (d, ^1J = 8.48 Hz, 2 H, H^7), 6.99–6.95 (td, ^1J = 4.53 Hz, 2 H, H^9) ppm. MS (ESI): *m*/*z* (%) = 230.4 (25) $[Zn(\mathbf{3})_2]^{2+}$, 251.0 (100) $[Zn(\mathbf{3})_2 + CH_3CN]^{2+}$, 259.9 (10) $[Zn(\mathbf{3})_2 + CH_3CN + H_2O]^{2+}$, 271.6 (75) $[Zn(\mathbf{3})_2 + 2\ CH_3CN]^{2+}$, 280.4 (20) $[Zn(\mathbf{3})_2 + 2\ CH_3CN + 2\ H_2O]^{2+}$.

tions (1:1, molar ratio) of homoduplex complexes **4**–**6** in CD_3CN were mixed and stirred overnight at 60 °C. Stoichiometric binary solutions (1:1, molar ratio) of binary mixtures of ligands **1**–**3** in CD_3CN were mixed with the stoichiometric amount of metal ions and stirred overnight at 60 °C. These solutions were monitored by ^{1}H NMR spectroscopy and ESI mass spectrometry.

X-ray Crystallographic Data for Complexes 4, 5, 7, 8, and 9: All X-ray diffraction data were collected on an Xcalibur-I diffractometer (Oxford Diffraction) with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) at the joint X-ray scattering service of the Institut Européen des Membranes and the Institut Charles Gerhardt of the Université de Montpellier II. All measurements were carried out at 173 K using ω-scans after having placed the crystals in oil. All structures were solved using SIR2002;[15a] refinements were carried out using CRYSTALS[15b] against $|F|$ on data having $I > 2\sigma(I)$; R-factors are based on these data. Hydrogen atoms were partly located from difference Fourier synthesis, partly placed based on geometrical arguments, and in general not refined. Non-hydrogen atoms were in general refined anisotropically, except where the data-to-parameter ratio did not allow us to do this. Details of the refinements and data collections can be found in Table 1.

CCDC-266698–266702 (for **4**, **5**, **7**, **8**, and **9**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Free and Metal-Coordinated (*N*-Isocyanimino)triphenylphosphorane: X-ray Structures and Selected Reactions

Heribert Stolzenberg,[a][‡] Bernd Weinberger,[a] Wolf Peter Fehlhammer,*[b,c] Frank G. Pühlhofer,[d][‡‡] and Robert Weiss[d][‡‡]

Keywords: Chromium / Isocyanide ligands / Isomerisation / Phosphoranes / Tungsten / Quantum chemical calculations

An improved procedure for the synthesis of (*N*-isocyanimino)-triphenylphosphorane, C≡N–N=PPh_3 (**3**), is described. The X-ray structure analysis reveals an unusually small N–N=P angle [115.2(2)°] and an N–N bond order of only about 1.5, which indicates considerable C≡N–N^-–P^+ participation and electronically more-isolated functional groups (CN, P=N) in the isocyanide than, for example, in the isomeric N≡C–N=PPh_3 (**4**) [C–N=P = 123.0(4)°, C–N bond order = 2.0]. In order to gain insight into the stereochemical consequences of metal coordination of **3**, an X-ray structural study of [Cr-$(CO)_5$C≡N–N=PPh_3] (**5**) was also undertaken. Surprisingly, the central bond lengths (C–N, N–N) and angles (C–N–N) remain practically unchanged with noticeable coordination effects occurring only at the periphery of **5**, with the N–N–P angle [112.3(2)°] further decreased by 15σ, the elongated (by 7σ) P–N bond, the somewhat shortened (by 4σ) P–C(Ph) bonds and even shorter C–H(Ph) bonds on the one side, and the well-known Cr–$C(O)_{trans}$ contraction on the other. Treatment of **5** or its tungsten derivative with anhydrous Brønstedt and Lewis acids such as CF_3COOH, HCl, COS, phosgene or, most efficiently, [$PdCl_2$(1,5-COD)] causes CN→NC isomerisation to give [$M(CO)_5$N≡C–N=PPh_3] [M = Cr (**6**), W (**7**)]. In solution, [$PdCl_2(CNNPh_3)_2$] and $Ph_3BCNNPPh_3$ (**8**) slowly isomerize even without additional acid to give both free and Pd-coordinated **4** and $Ph_3BNCNPPh_3$ (**9**), respectively. In the presence of catalytic amounts of [$PdCl_2$(1,5-COD)], **3** is converted into **4** and the dimer Ph_3PN–C(CN)=N–$NPPh_3$ (**10**) in an almost 1:1 ratio. The optimised geometries of the methyl derivatives of **3** and **4**, namely Me_3P=N–N≡C (**3c**) and Me_3P=N–C≡N (**4c**), are in excellent agreement with the experimental data; major differences between the isomers (P–N–N angle, N–N bond length) are explained by the higher electronegativity of the isocyano group as compared to the CN substituent, which, in turn, is a better π-acceptor). The reaction path of the isomerisation of **3** to **4** (**3c** to **4c**) has also been studied computationally and been found to proceed via an [(P)=N^A–N≡C^A(N^A–C^A)] cyclic transition state. The overall process is exothermic by 50 kcal mol^{-1}.

Introduction

Despite occasional reports for almost 100 years now, *N*-isocyanides, i.e. species with the structural element C≡N–N, still remain an exotic class of compounds. This holds particularly true of the parent molecule, isodiazomethane, C≡N–NH_2 (**1**).[1] Its mere naming as something which it is *not*, viz. diazomethane, reflects the uncertainties and difficulties connected with the discovery and understanding of this very labile substance.[2] Staudinger, in search of diisocyan, CN–NC, obviously was the first to get hold of **1**, and very remarkably assigned it the correct structure of an isocyanoamine.[3] Later, for more than 30 years, alternative constitutions were favoured, and it was not until 1968 that Müller et al. returned to Staudinger's formula.[2,4] In the mid-1970s, the first metal complexes of **1** were synthesised in our laboratory both from Müller's isodiazomethane solutions and, much more elegantly, from a stable, storable derivative, Wiberg's C≡N–N($SiMe_3$)$_2$ (**2**), by hydrolysis at the protecting metal.[5,6] The only disadvantage of **2** was its problematic accessibility, requiring many steps and costly low-temperature techniques. In 1980 we reported a novel precursor of **1** which is synthesised in a one-step procedure from cheap starting materials and actually proved to be a key substance in *N*-isocyanide chemistry.[7,8] In the following we present an improved preparation of C≡N–$NPPh_3$ (**3**), its X-ray structure in comparison with that of its pentacarbonylchromium complex, and its metal-catalysed CN/NC-isomerisation and dimerisation reactions. In addition, quantum chemical calculations have been carried out to get more insight into the electronic and structural properties of

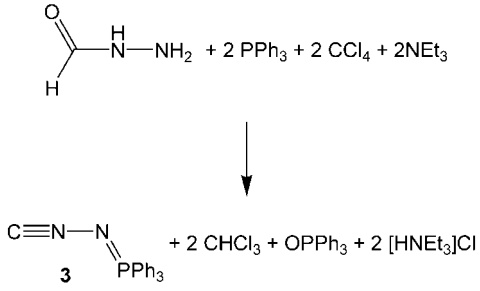
compounds **3** and **4** and the reaction path of their respective isomerisation.

Results

(*N*-Isocyanimino)triphenylphosphorane: Synthesis and X-ray Structure

The title compound was prepared by reaction of *N*-formyl hydrazine with two equivalents of Appel's three-component reagent, which serves two purposes, viz. dehydration of the formamido group and masking of the primary amine function [Equation (1)].[7]



(1)

Repetition of the procedure as published, however, turned out to be difficult, and in only a few cases could yields of the claimed order of magnitude be reached. As reasons presumably responsible for this problem we have identified an incomplete reaction and decomposition of the desired product during work-up (vide infra). Taking this into account, in the modified procedure refluxing of the reaction mixture is prolonged and immediately followed by basic hydrolysis (with aqueous Na_2CO_3) of the highly acidic phosphorus(v) intermediates (e.g. $Ph_3PCl^+Cl^-$) and separation of the organic layer (containing **3**) from the aqueous one (see Experimental Section).

Single crystals suitable for an X-ray structure analysis were grown by slowly cooling a solution of **3** in warm ethanol. The molecule shows the expected bent structure at the imino nitrogen N1 (Figure 1). Structural investigations of iminophosphoranes generally reveal a considerable flexibility of this nitrogen as regards its hybridisation. P=N–X angles ranging from 119° up to 137° indicate that this is primarily sp^2 with a tendency to higher *s* participation. The unusually small angle in **3** [115.2(2)°] conversely points to more *p*-character (i.e. some $C^-{\equiv}N^+{-}N^-{-}P^+Ph_3$ form), which causes the phosphorus and the isocyano nitrogen atoms to get as close as 2.494 Å which is actually the shortest nonbonding distance between non-hydrogen atoms in this crystal structure.

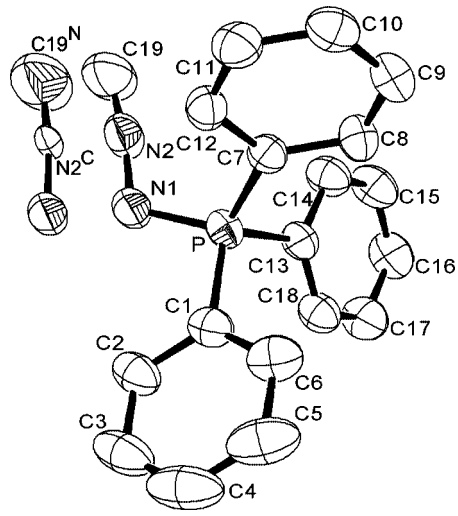


Figure 1. ORTEP drawing of the molecular structure of **3** (30% probability). The effect on the thermal ellipsoids of the functional group of a refinement cycle with interchanged scattering factors for C19 and N2 ("CN/NC test") is also shown. Both the abnormal blowing up of C19 (treated as an N atom) and the odd shrinkage of N2 (calculated as C) clearly exclude the cyanide form of **3**, as does the *R* value which increased by 0.34%. Selected bond lengths [Å] and angles [°]: P–N1 1.604(2), P–$C_{av.}$ 1.797, N2–N1 1.345(4), N2–C19 1.154(4); P–N1–N2 115.2(2), N1–N2–C19 173.4(3).

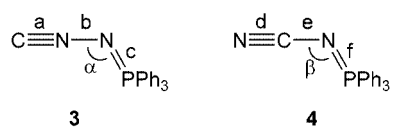
Interestingly, the corresponding P=N–C angle [123.0(4)°] in the isomeric cyanoiminophosphorane **4** (Scheme 1) is much wider, while the C≡N and P=N bond lengths are identical with those in **3** within one or two standard deviations.[9] Furthermore, the CN distances agree perfectly with the rated value for an ideal CN triple bond, and both PN bonds come very close to a true PN double bond (1.57 Å) as derived from experimental data.[10] Another major difference occurs in the remaining bonds, however. The N1–N2 bond distance in **3** [1.345(4) Å] lies halfway between an NN single (1.44 Å) and an NN double bond (1.24 Å), while the C–N(imine) bond in **4**, which is formally a single bond, is only slightly longer than a typical CN double bond (1.27 Å). The two functional groups (C≡N and P=N) are thus electronically more isolated in the isocyanide **3** than in the cyano isomer **4**, an observation which has been made many times in systems of the type C≡N(N≡C)–X=Y. A more realistic description of the bonding in **4** – although not in **3** (!) – might therefore make use of a further resonance formula such as **4a**.



Scheme 1. Schematic formulae with selected bonding parameters (bond lengths in Å): *a* = 1.154(5), *b* = 1.345(4), *c* = 1.604(2) Å, *α* = 115.2(2)°; *d* = 1.151(9), *e* = 1.301(7), *f* = 1.595(4) Å, *β* = 123.0(4)°.

Deviations from a tetrahedral configuration at the P atom in **3** are marginal. The phenyl rings show the well-known propeller-like arrangement with dihedral angles rel-

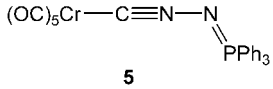
4a

ative to the P–N1–N2–C19 plane of 18.3° (Ph1), 69.8° (Ph2) and –69.6° (Ph3).

The intermolecular contacts (≤ 3.5 Å) were also calculated. With the exception of a weak N···H–C bridge between a phenyl hydrogen and N1, which also shows strong intramolecular interactions with two hydrogen atoms, none of the contacts lies substantially below the sum of the corresponding van der Waals radii.

X-ray Structure of Pentacarbonyl[(*N*-isocyanimino)-triphenylphosphorane]chromium (5): Stereochemical Consequences of Metal Coordination

Metal coordination of a stable isocyanide is routine, and C≡N–N=PPh_3 (**3**) is no exception. Preparation of the chromium complex **5** proceeds by substitution of THF in the photolytic intermediate [$Cr(CO)_5$THF];[7,8] suitable crystals for the X-ray study were obtained from dichloromethane.



5

Figure 2 presents the overall geometry as expected for the combination of the functional *N*-isocyanide ligand **3** and the metal complex fragment $Cr(CO)_5$, together with selected bonding parameters. The first point of interest is the stereochemistry of the $Cr(CO)_5$ entity, which reflects the ligand properties of the incoming group. While all of the CO ligands experience the donating capacity of a typical isocyanide ligand, it is the *trans*-CO ligand which has to take the lion's share of the electronic charge transported onto the metal. In the present case the result is particularly striking: the Cr–$(CO)_{trans}$ bond in **5** is shortened to 1.861(3) Å as compared, for example, to that in $Cr(CO)_6$ (1.918 Å) or those of $Cr(CO)_5$ adducts of several other functional isocyanides such as [$Cr(CO)_5CNCH_2C(Me)(CH_2NC)_2$] [1.882(2) Å],[11] [$Cr(CO)_5CNC{\equiv}N$] [1.913(4) Å],[12] [$Cr(CO)_5$-CNC(=O)Ph] [1.899(3) Å][13] and [$Cr(CO)_5CNC{\equiv}CPh$] [1.896(4) Å],[14] while the average Cr–$(CO)_{cis}$ distance in **5** only drops to 1.895 Å. A much less significant effect, yet one pointing in the same direction, is the corresponding lengthening of the C–O bonds, which again is more pronounced for $(C–O)_{trans}$ [1.140(4) Å] than for the averaged $(C–O)_{cis}$ (1.135 Å).

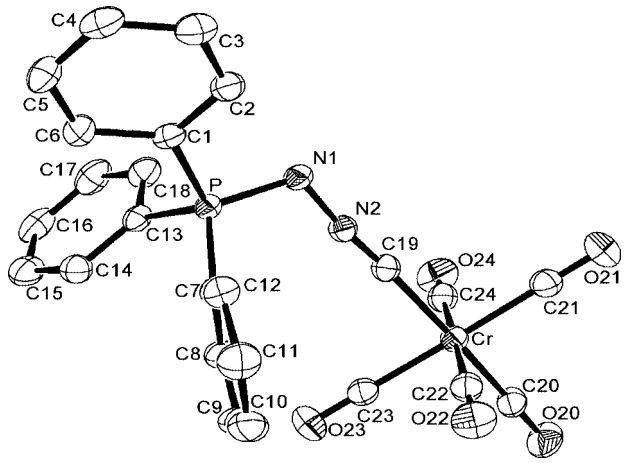


Figure 2. ORTEP drawing of the molecular structure of **5** (30% probability). The isocyanide nature of the ligand was ascertained by a "CN/NC test" (cf. caption of Figure 1), which resulted in unrealistic temperature factors and an increase of the *R* value by 0.66%. Selected bond lengths [Å] and angles [°]: P–N1 1.618(2), $P–C_{av.}$ 1.787, N2–N1 1.345(3), N2–C19 1.151(4), Cr–C19 2.031(3), Cr–$C20_{trans}$ 1.861(3), $(Cr–C_{cis})_{av.}$ 1.895, $(C20–O20)_{trans}$ 1.140(4), $(C–O)_{cis,av.}$ 1.135; P–N1–N2 112.3(2), N1–N2–C19 174.2(2), Cr–C19–N2 176.9(2).

The Cr–CN bond length is 2.031(3) Å, which fits well into the range of 2.00–2.05 Å determined so far for pentacarbonyl(*N*-isocyanide)chromium complexes. This is long in comparison with the corresponding values for [$Cr(CO)_5$(*C*-isocyanide)] complexes [*d*(Cr–CNC) < 2.00 Å] and clearly indicates a lower degree of π back-bonding.

Turning to the new ligand itself, which, according to what we know from the stereochemistry of the CrC_6 surrounding, is a markedly better donor than common *C*-isocyanides, we were surprised to find its central skeleton practically unchanged: the C≡N and N–N bond lengths are absolutely identical in **3** and **5**, and the 3σ deviation in the quasi-linearity of the C–N–N atomic sequence is insignificant; again, coordination effects are noticed only at the periphery of $CNNPPh_3$ [as they appeared – most distinctly – at the other end of the molecule, namely the remote *trans*-CO ligand (see above)]: the more acute N–N–P angle of 112.3(2)° [–2.9° (15σ)], which brings the P and N2 atoms even closer together, the slight elongation [by 0.014 Å (7σ)] of the P–N bond and, remarkably, the somewhat shortened P–C(Ph) bonds [–0.010 Å (4σ)]. All these data point to a considerable $Ph_3P^+–N^––N^+C[M^–]$ participation in the overall bonding in **5** by which extra electronic charge is transferred to $M(CO)_5$. Obviously, the N–N bond is not as insulating as inferred from a comparison with the nitrile **4** (**4a**) earlier on. These findings are perhaps best understood in terms of Gutmann's "pile up" and "spill over" effects accompanying Lewis acid–Lewis base interactions.[15]

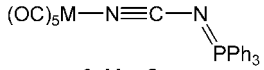
Selected Reactions

CN/NC Isomerisations of (N-Isocyanimino)-triphenylphosphorane Complexes

The action of aqueous trifluoroacetic acid on $CNNPPh_3$ coordinated to pentacarbonyl–group VI metal fragments

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

proceeds with hydrolysis of the (imino)N–P bond to give isodiazomethane complexes, occasionally in excellent yield (group VI metal = chromium).[7,8] A totally different reaction occurs, however, when $[Cr(CO)_5CNNPPh_3]$ (**5**) is treated with anhydrous acids: when allowed to stand for 1–2 days a solution of **5** in dichloromethane containing a few drops of CF_3COOH undergoes complete conversion of the isocyanide ligand into its nitrile isomer to form **6**.

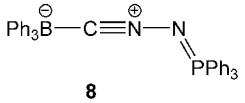


6: M = Cr
7: M = W

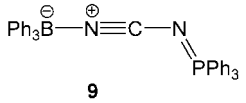
The same effect can be achieved by passing a stream of dry HCl through a solution of **5**. While protic acids seem not to prompt the corresponding tungsten complex to isomerize, Lewis acids like COS and $COCl_2$ are effective with both metal complexes. Even more sophisticated Lewis acids such as $[PdCl_2(1,5\text{-COD})]$ work if the reaction is carried out under a CO atmosphere. Thus, under 1 bar of CO **5** isomerizes quantitatively within 3–4 days, whereas in a rotating autoclave under a CO pressure of 10 bar the transformation is complete in 24 h. Without carbon monoxide, Pd metal separates slowly from the solution, which then turns deep green. Complexes **6** and **7** were adequately characterised by their analytical and IR spectroscopic data (see Experimental Section); the data of **6** are in full agreement with the data reported for the compound which has earlier been synthesised directly by photolysis of hexacarbonylchromium in the presence of $NCNPPh_3$.[16]

At palladium(II), **3** isomerizes without the need for any additional acid. After two weeks two strong new bands appear at 2230 and 2180 cm^{-1} in the IR spectrum of a solution of $[PdCl_2(CNNPPh_3)_2]$[8] in dichloromethane in place of the very weak original ν(CN) (2200 cm^{-1}). Of these, the absorption at 2180 cm^{-1} can unambiguously be assigned to the free $NCNPPh_3$, while the band at 2230 cm^{-1} fits into the range of palladium-coordinated nitrile species.

With equimolar amounts of triphenylboron, **3** forms an almost colourless crystalline adduct **8** which is air-stable and soluble in chlorinated hydrocarbons. In the IR spectrum, the weak CN stretch of the free ligand at 2067 cm^{-1} has been replaced by a new weak band at much higher wavenumbers (2230 cm^{-1}). As frequency shifts even of this order of magnitude are quite possible for isocyanide–BPh_3 adducts − for the corresponding (*N*-isocyanodialkylamine)triphenylboron species $Ph_3B–CN–NR_2$, $\Delta\nu(CN)$ $[\nu(CN)_{complex} - \nu(CN)_{free}]$ amounts to 135 cm^{-1}[17] − we can be sure that we are still dealing with the isocyanide isomer. In the end, this was unequivocally confirmed by its slow conversion in chloroform into **9**, which exhibits a very strong IR absorption at even higher wavenumbers (2280 cm^{-1}).



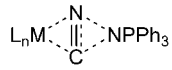
8



9

CN ⇌ NC isomerisations in both directions are by no means rare.[18] What is surprising here, though, is how spontaneously and smoothly they occur under the applied mild reaction conditions. It is true that these kinds of isomerisations are very common in cyanometal coordination polymers and are known to happen immediately by what has been termed a "flip-over" mechanism, however, the organic synthesis of nitriles by isomerisation of free *C*-isocyanides requires severe heating over a longer period.[19] Obviously, the involvement of at least one metal (or metalloid, e.g. $SiMe_3$[18,20]) is essential for the activation energy to be sufficiently small. Strangely enough, this is particularly born out by the functional *N*-isocyanide under consideration, which, as a free ligand, cannot be transformed into its isomer at all, either thermally, say by refluxing in THF or chloroform, or by protonation.

If we accept a synchronous mechanism with a "rotating" C≡N species between the fixed metal and $NPPh_3$ groups, or, which comes down to the same thing, a migration of these groups about a stationary C≡N, perhaps via some bicyclic transition state of the type **A**, it seems plausible that the addition of an acid (Brønsted or Lewis) to the imino nitrogen greatly enhances the (less pronounced) migration tendency of the iminophosphorane group (as $HN{=}PPh_3$). At any rate, in the absence of an acid the $[M(CO)_5CNNPPh_3]$ complexes do not show any sign of isomerisation even after standing for weeks in various solvents.



A

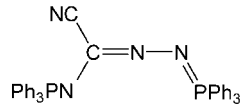
A closely related case of a CN → NC isomerisation to the one presented here is the rearrangement of a coordinated fulminate into an isomeric isocyanate ligand. This reaction occurred on attempted protonation of difulminatobis(triphenylphosphane)platinum to produce the then unknown isofulminic acid (C≡N–OH) stabilized in a complex.[21] Later, we studied the spontaneous isomerisation of $[W(C{\equiv}N–O)(CO)_5]^-$ and found it to be strongly solvent-dependent.[22]

Catalytic Isomerisation and Dimerisation of 3

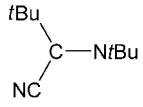
From the findings discussed above, it was obvious that we should study the possibility of a catalytic isomerisation of **3** with traces of a metal component. As such, $[PdCl_2(1,5\text{-COD})]$ was chosen and found to produce complete disappearance of the weak ν(CN) band at 2067 cm^{-1} within 20 h at ambient temperature. What appeared, however, were two absorptions at 2180 and 2220 cm^{-1} instead of the only one expected. Work-up finally resulted in two products: the isomeric (*N*-cyanoimino)triphenylphosphorane (**4**), which has already been synthesised by Appel and co-workers and was identified on the basis of its elementary analysis, its melting point and its IR data,[23,24] and a second pale -yellow compound **10**, which was recrystallised from dichloromethane/diethyl ether and showed the same analytical composition but double the molecular mass. The IR spectrum with a

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

weak to medium intensity band at 2200 cm^{-1} [ν(C≡N)], a ν(C=N) absorption at 1520 cm^{-1} and two ν(P=N) features at 1110 [ν(P=N–N)] and 1300 cm^{-1} [ν(P=N–C)], as well as the ^{31}P NMR spectrum, which contains two singlets at δ = 24 and 11 ppm, are in perfect agreement with the suggested structure for **10**.



10



11

A catalytic dimerisation of isocyanides has so far only been reported in one case, that of *tert*-butyl isocyanide with trace amounts of BF_3 to give **11**.[25] On the other hand, there are numerous examples of stoichiometric C-C couplings of *C*-bonded species in the ligand spheres of metal complexes,[26] with Lippard's reductive dimerisation of *tert*-butyl isocyanide ligands in $[Mo(CNtBu)_6I]I$ to give **B** being among the first.[27] Still, for the case at hand it seems most plausible to assume a mechanism **C** in analogy to that of the well-known metal-catalysed α-additions to isocyanides (or isocyanide insertions), which proceed via a primary nucleophilic attack at the metal-bonded isocyano carbon.[28] Actually, all the necessary "instruments" are there: thus, we have shown that *N*-isocyanides are prone to nucleophilic attack even in less activating metal complexes,[8,29] **3** carries a strong nucleophile in the form of the imino nitrogen, and N–N cleavage is a common occurrence in *N*-isocyanide chemistry.[17,30,31]

C

Computational Section

Quantum chemical calculations were performed to gain a detailed insight into the electronic and structural properties of the compounds **3** and **4**. To simplify the problem, the phenyl substituents in **3** and **4** were replaced by methyl groups, and the geometries of the resulting compounds **3c** and **4c** were optimised at the B3LYP/6-311+G** level of theory. ZPEs were determined at the same level. The frequencies were also analysed at this level to confirm that the optimised geometries correspond to minima (NIMAG = 0) or first-order transition states (NIMAG = 1). A transition-state search was performed using the QST3 method. NBO analyses were performed at the above-mentioned level of theory. All computations were run using the Gaussian98W suite of programs and NBO 3.1, as implemented in G98W.[32]

Discussion

Table 1 contains selected stereochemical parameters of compounds **3**, **3c**, **4** and **4c**. In general, the differences between the bond lengths and angles of the phenyl-substituted systems **3** and **4**, as obtained from X-ray analyses, and the data computed for the corresponding methyl species (**3c** and **4c**) are minor and easily explained by the exchange at P1 of phenyl for methyl (cf. Figure 3 and Table 1). Thus, the elongation of the P1–N1 bonds in **3c** and **4c** is clearly a consequence of the decreased electron-acceptor capacity of the trimethylphosphonio moiety. Other points of interest are the deviations between **3c** and **4c** (**3** and **4**, respectively), especially those of the P1–N1–X angles (**3**, **3c**: X = NC; **4**, **4c**: X = CN).

Table 1. Comparison of the experimental bonding parameters of **3** and **4** with those obtained from geometry optimisation (B3LYP/6-311+G**) (**3c**, **4c**).

Bond length [Å]	**3**	**3c** (*Cs*)	**4**	**4c** (*Cs*)
P1–N1	1.604	1.620	1.595	1.600
N1–N2	1.345	1.342		
N1–C1			1.301	1.318
C1–N2	1.154	1.176	1.151	1.167
Bond angle [°]				
P1–N1–N2	115.2	114.5		
P1–N1–C1			123.0	121.8

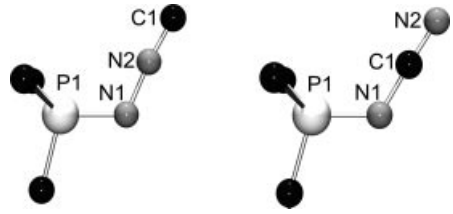

Figure 3. Representative structural elements in **3** (**3c**) (left) and **4** (**4c**) (right).

The exchange of N2 by the less electronegative C1 in **3c** (to give **4c**) changes the electronic nature of N1. NBO analyses assume N1 in both compounds to carry a lone pair of *p*-character oriented perpendicular to the symmetry plane of **3c** and **4c**. This results in an overall hybridisation of sp^2 for the remaining three substituents of N1 in this plane: the PMe_3 group, the second lone pair and the -NC (**3c**) or -CN (**4c**) group. The specific breakdown of the overall sp^2 hybridisation into the contributions of N1 to each bond results in the data listed in Table 2. The most noticeable changes are obviously caused by very different hybridisations of the lone pair and the bond to the (iso)cyano group, whereas the hybridisation of the N1–P1 bond remains nearly unchanged. The former can easily be explained by Bent's rule:[33] electronegative substituents force the central atom (N1) to increase the *p*-character of the corresponding bond. The isocyano substituent in **3c** is clearly more electronegative than the cyano function in **4c**, which results in the very different orbital hybridisations of N1 in the two N1–X bonds (Table 2). As a result, the P1–N1–N2

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

angle in **3c** is smaller than the P1–N1–C1 angle in **4c**. In **3c**, both bonds (P1–N1 and N1–N2) have contributions from N1 hybridisations with *p* coefficients close to 3.0, hence the P1–N1–N2 angle is expected to be way below 120° (computed: 114.5°). In **4c**, the average hybridisation of the respective two bonds is $sp^{2.1}$ (cf. Table 2), which should give rise to an angle of about 120° (computed: 122°). These values are in excellent agreement with the corresponding X-ray data of the phenyl derivatives **3** (115°) and **4** (123°; Table 1).

Table 2. Orbital hybridisation of N1 based on NBO analyses (B3LYP/6-311+G**).

	3c (X = NC)	**4c** (X = CN)
N1–PMe_3	$sp^{2.8}$	$sp^{2.5}$
N1–X	$sp^{2.9}$	$sp^{1.7}$
Lone pair (in plane)	$sp^{1.1}$	$sp^{1.9}$

As described above, the N1–N2 bond in **3** lies halfway between an N-N single and an N-N double bond, whereas the N1–C1 bond in **4** is much closer to a C-N double bond. The same observations are made in the case of the computed structures **3c** and **4c**, and can again be explained on the basis of NBO analyses: both lone pairs of N1 interact with the two mutually perpendicular π*-orbitals of the C1–N2 bond. Since the π-bonds between C1 and N2 are polarized towards the nitrogen atom, the π*-orbitals have larger coefficients at C1, and hence the cyano group in **4c** is a much better π-acceptor than the isocyano function in **3c**. The respective donor–acceptor interactions were computed at the B3LYP/6-311+G** level resulting to be about 63 kcal mol^{-1} for **4c** and 33 kcal mol^{-1} for **3c**. The experimentally observed pronounced multiple-bond character of the N1–CN bond in **4** is thus confirmed computationally.

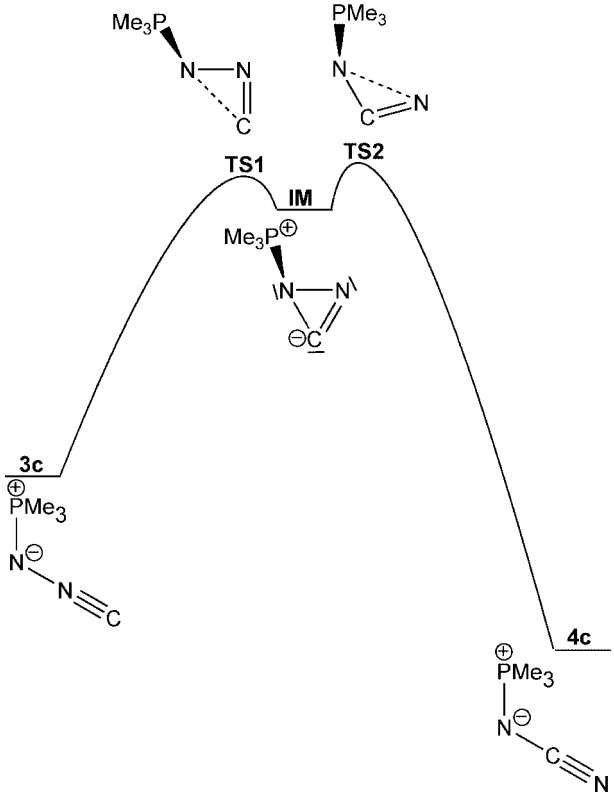

Figure 4. Reaction profile of the isomerisation of **3c** to **4c** at the B3LYP/6-311+G** level (including uncorrected ZPE at the same level).

Finally, the reaction path of the isomerisation of **3** to **4** (**3c** to **4c**) was studied computationally using the QST3 method as implemented in Gaussian98W. The reaction profile is shown qualitatively in Figure 4, quantitative details are given in Table 3, and geometric parameters of TS1, TS2 and IM are given in Figure 5 (see also Supporting Information).

Table 3. Relative energies of the species in Figure 3 (B3LYP/6-311+G** incl. uncorrected ZPE).

	Relative energy [kcal mol^{-1}]
3c	+50.3
TS1	+81.7
IM	+79.8
TS2	+82.1
4c	±0.0

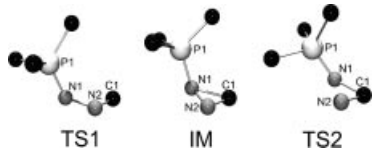

Figure 5. Geometrical data of TS1, IM and TS2 (bond lengths in Å). TS1: P1–N1 1.631, N1–N2 1.556, N1–C1 2.018, N2–C1 1.215; N1–N2–C1 92.7°. IM: P1–N1 1.646, N1–N2 1.613, N1–C1 1.681, N2–C1 1.234; N1–N2–C1 71.0°, N1–C1–N2 65.1°. TS2: P1–N1 1.629, N1–N2 1.861, N1–C1 1.597, N2–C1 1.215; N1–C1–N2 81.7°.

As shown in Figure 4, the reaction proceeds with formation of a new σ-bond between the $2p_z$ lone pair at N1 and the terminal carbon atom, via the transition state TS1 (E_a = 31.4 kcal mol^{-1}), to the cyclic intermediate IM. The latter reacts with cleavage of the N–N bond via TS2 (E_a = 2.3 kcal mol^{-1}) to the rearrangement product **4c**. The overall process is exothermic by 50.3 kcal mol^{-1} (cf. Table 3).

The experimentally observed lowering of the activation energy for the isomerisation by addition of Lewis acids can also be explained on this basis: the formation of donor–acceptor complexes between the intermediate IM and Lewis acids stabilizes the former by decreasing the repulsive interactions of lone pairs (see Figures 4 and 5).

Experimental Section

General Remarks: All experiments were performed under argon in dry, argon-saturated solvents. The (*N*-isocyanimino)triphenylphosphorane metal complexes [$M(CO)_5CNNPPh_3$] [M = Cr (**5**), W] and [$PdCl_2(CNNPPh_3)_2$] were prepared according to literature procedures.[7,8] IR spectra were recorded on a Perkin–Elmer 621 or a Beckman IR 12 spectrometer. NMR spectra (^{31}P) were recorded on a Jeol JNM-PS-100. Mass spectra were recorded on a Varian CH-5 (excitation energy 70 eV). Microanalyses (C,H,N) were obtained with a Heraeus CHN Rapid-Elementanalysator. Molecular

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

weights were determined in CH_2Cl_2 solution using a Knauer Dampfdruck Osmometer, and melting or decomposition points were determined with a Büchi Model 510 melting point apparatus and are uncorrected.

Preparation of (*N*-Isocyanimino)triphenylposphorane (3). Revised Procedure: CH_2Cl_2 (600 mL), PPh_3 (157.4 g, 0.6 mol), NEt_3 (freshly distilled from KOH; 50.6 g, 0.5 mol) and formylhydrazine (dried in high-vacuum at 45 °C; 15.3 g, 0.25 mol) were placed in a reaction flask which had been dried with a heat-gun under high-vacuum. The slurry was then heated to 50–60 °C, and CCl_4 (77.0 g, 0.5 mol) was added dropwise over a period of about 30 min. The mixture was kept at 50–60 °C for at least 5–6 h. After cooling to room temp., 250 mL of a saturated aqueous Na_2CO_3 solution was added, the layers were separated, and the aqueous layer was washed with two 50-mL portions of CH_2Cl_2. The combined organic phases were dried with Na_2SO_4 and filtered. After evaporation of the solvent, the residue was dried under high vacuum, pulverised, stirred in 200 mL of ethanol/water (1:1.5) and collected on a frit. Recrystallisation from hot ethanol yielded 30.2 g (40%) of an orange-brown crystalline material (m.p. 159–160 °C, dec.). IR (KBr): $\tilde{\nu}$ = 2067 cm^{-1} w [ν(CN)]; 1117 s, 1099 sh [ν(PN)]. $C_{19}H_{15}N_2P$ (302.32): calcd. C 75.49, H 5.00, N 9.27; found C 75.69, H 4.99, N 9.40.

CN/NC-Isomerisation of Pentacarbonyl[(*N*-isocyanimino)triphenylphosphorane]chromium (5) with Protic Acids and COS: A few drops (8–10) of CF_3COOH were added, with stirring, to a solution of $[Cr(CO)_5CNNPPh_3]$ (**5**; 1.48 g, 3.0 mmol) in dry CH_2Cl_2 (25 mL). After standing for 48 h at room temp. the volatile components were removed under high vacuum and the residue was dissolved in a small amount of CH_2Cl_2 and chromatographed on silica gel in *n*-hexane (3.5 × 20 cm column) with a CH_2Cl_2/*n*-hexane (3.5:1) eluent. Slow evaporation of the bright yellow phase resulted in the cyano isomer **6** as yellow to green crystals.

Similar results were obtained by (a) passing a rapid stream of dry HCl through the above solution for a few seconds and keeping it at room temp. for 14 h, and (b) by treating a solution of $[Cr(CO)_5CNNPPh_3]$ (1.48 g, 3.0 mmol) in THF (30 mL) with an excess of COS at 45 °C for 24 h and applying the same work-up procedure to the reaction mixtures. The yields (non-optimised) varied between 30 and 70% (see also below).

CN/NC-Isomerisation of Pentacarbonyl[(*N*-isocyanimino)triphenylphosphorane]chromium (5) with $[PdCl_2(1,5\text{-COD})]$. Preparation of Pentacarbonyl[(*N*-cyanimino)triphenylphosphorane]chromium (6): (a) $[Cr(CO)_5CNNPPh_3]$ (**5**; 990 mg, 2 mmol) and $[PdCl_2(1,5\text{-COD})]$ (290 mg, 1 mmol) were dissolved in 90 mL of toluene/CH_2Cl_2 (2:1) under a CO atmosphere and stirred for one week at room temp. Every two days the CO atmosphere was renewed. After evaporation of the solvent, the residue was extracted with diethyl ether. The extract was filtered and concentrated, and the product **6** crystallised on cooling to about –35 °C as yellow-green crystals. Yield: 60%.

(b) A mixture of **5** (1.98 g, 4.0 mmol) and $[PdCl_2(1,5\text{-COD})]$ (580 mg, 2.0 mmol) in 60 mL of toluene/CH_2Cl_2 (2:1) was placed in a 500-mL rotation autoclave and reacted under a CO pressure of 10 atm for 2 d. The work-up procedure was the same as in (a) and yielded 1.4 g (71%) of yellow-green crystalline **6**, m.p. 107 °C (dec.; ref.[16] 102–106 °C). IR (KBr): $\tilde{\nu}$ = 2240 cm^{-1} s [ν(NC)]; 2065 s, 1920 vs, 1870 sh [ν(CO)]; 1260 s, br. [ν(PN)]. $C_{24}H_{15}CrN_2O_5P$ (494.4): calcd. C 58.31, H 3.06, N 5.67; found C 58.49, H 3.07, N 5.55.

CN/NC-Isomerisation of Pentacarbonyl[(*N*-isocyanimino)triphenylphosphorane]tungsten. Preparation of 7: $COCl_2$ (30 mL of a 0.1 M solution in THF) was added to a solution of $[W(CO)_5CNNPPh_3]$ (940 mg, 1.5 mmol) in 30 mL of CH_2Cl_2. After stirring for 2 h at room temp., the solvent was removed in vacuo and the raw product was dissolved in a few millilitres of CH_2Cl_2. Cooling to about –35 °C gave 432 mg (48%) of **7** as yellow-green crystals, m.p. 125 °C (dec.). IR (KBr): $\tilde{\nu}$ = 2230 cm^{-1} s [ν(NC)]; 2060 m, 1905 vs, br., 1870 sh [ν(CO)]; 1280 s, br. [ν(PN)]. $C_{24}H_{15}N_2O_5PW$ (626.22): calcd. C 46.03, H 2.41, N 4.47; found C 45.89, H 2.39, N 4.62.

CN/NC-Isomerisation of (*N*-Isocyanimino)triphenylphosphorane at BPh_3

Preparation of [(*N*-Isocyanimino)triphenylphosphorane]triphenylborane (8): A solution of $CNNPPh_3$ (**3**; 906 mg, 3.0 mmol) in 35 mL of CH_2Cl_2 was added dropwise to a solution of BPh_3 (730 mg, 3.0 mmol) in 30 mL of CH_2Cl_2 at 0 °C. After stirring for 1.5 h at 0 °C the product was precipitated with petroleum ether and stored overnight at –18 °C to give **8** (1.2 g, 74%) as off-white crystals, m.p. 153 °C (dec.). IR (KBr): $\tilde{\nu}$ = 2225 cm^{-1} w [ν(CN)]; 1190 sh, 1150 sh, 1120 vs, br. [ν(PN)]. $C_{37}H_{30}BN_2P$ (544.5): calcd. C 81.63, H 5.55, N 5.15; found C 81.63, H 5.87, N 4.88. Compound **8** is thermally stable in the solid state and can be kept under nitrogen at room temp.

CN/NC Isomerisation of [(*N*-Isocyanimino)triphenylphosphorane]triphenylborane. Preparation of [(*N*-Cyanimino)triphenylphosphorane]-triphenylborane (9): A solution of **8** (1.09 g, 2.0 mmol) in 10 mL of $CHCl_3$ was stored for 2 weeks at room temp. After evaporation of the solvent the crude material was treated with ethanol. The insoluble white powder (**9**) was filtered off and dried in high vacuum. Yield: ca. 600 mg (55%). IR (KBr): $\tilde{\nu}$ = 2280 cm^{-1} vs, 2085 sh [ν(NC)]; 1350 s, 1320 sh [ν(PN)]. $C_{37}H_{30}BN_2P$ (544.5): calcd. C 81.63, H 5.55, N 5.15; found C 80.03, H 5.80, N 5.14.

Catalytic Isomerisation and Dimerisation of (*N*-Isocyanimino)triphenylphosphorane (3). Preparation of (*N*-Cyanimino)triphenylphosphorane (4) and $(CNNPPh_3)_2$ (10): A catalytic amount of $[PdCl_2(1,5\text{-COD})]$ (29 mg, 0.1 mmol) was added, with stirring, to a solution of $CNNPPh_3$ (**3**; 3.25 g, 10.75 mmol) in 40 mL of CH_2Cl_2. Stirring was continued for 20 h at room temp., after which time the solvent was removed in vacuo and the residue stirred in 30 mL of ethanol for 1 h. The insoluble yellow product was filtered off and recrystallised from CH_2Cl_2/Et_2O to give 1.6 g (50%) of pure **10**, m.p. 221 °C (dec.). IR (KBr): $\tilde{\nu}$ = 2220 cm^{-1} w [ν(NC)]; 1300 s, br., 1275 sh, 1130 sh, 1110 s, br. [ν(PN)]; 1540 s, 1480 w, 1140 s, 1040 sh, 1030 s. $C_{38}H_{30}N_4P_2$ (604.60): calcd. C 75.49, H 5.00, N 9.27, P 10.25; found C 75.81, H 5.05, N 9.21, P 10.14. Mol. mass calibrated against PPh_3: 616.

The brown ethanolic solution was evaporated to dryness and the solid residue was dissolved in 10 mL of warm CH_2Cl_2. Compound **4** (1.45 g, 45%) separated in the form of a light-brown powder at 0 °C, m.p. 188 °C (dec.). [ref.[23,24] 192–196 °C (dec.)]. IR (KBr): $\tilde{\nu}$ = 2180 cm^{-1} vs [ν(NC)]; 1270 s, br. [ν(PN)]. $C_{19}H_{15}N_2P$ (302.3): calcd. C 75.49, H 5.00, N 9.27; found C 74.73, H 5.07, N 9.18.

X-ray Structure Determinations: Single crystals of **3** were obtained by slowly cooling a warm ethanol solution of **3**; those of **5** were grown from dichloromethane. Crystallographic data of **3** and **5** were collected on a Philips PW1100 diffractometer in the ω–2θ scan mode using Ag-K_α radiation (λ = 0.5596 Å) and a graphite monochromator (Table 4). The phase problem in **3** was solved by direct methods, and that of **5** by applying the heavy atom approach. Neither absorption nor extinction corrections were carried out. In both cases, all hydrogen positions could be obtained from ΔF syntheses yet were not included in the final cycles of refinement. All calculations were carried out using the program system SHELX-76[34] with scattering factors for neutral atoms taken from the literature.[35] The molecular plots were produced with the ORTEP program.[36]

(Salen)nickel-Catalysed Epoxidations in the Homogeneous and Heterogeneous Phase: The Implications of Oxygen on the Efficiency and Product Selectivity

Rita Ferreira,[a][‡] Hermenegildo García,[b] Baltazar de Castro,[a] and Cristina Freire*[a]

Keywords: Alkenes / Epoxidation / Heterogeneous catalysis / N,O ligands / Nickel / Zeolites

The catalytic activity of several nickel(II) complexes with salen-type ligands and their zeolite-immobilised analogues is assessed in the epoxidation of *trans*-β-methylstyrene by NaOCl, in the absence and in the presence of oxygen. The complexes were immobilised in zeolites X and Y using the "ship-in-a-bottle" procedure, and the resulting materials were characterised by chemical analysis, XPS and IR, and UV/Vis diffuse reflectance spectroscopy. The loading and the distribution of the complexes in the materials were found to be dependent on the ligand. All (salen)nickel complexes proved to be active in the homogeneous and heterogeneous epoxidation of *trans*-β-methylstyrene by NaOCl. The immobilised complexes gave lower conversions and their catalytic activity is dependent on the loading and distribution of the complexes within the zeolites. In both homogeneous and heterogeneous systems, the alkene conversion is influenced by oxygen. Removing oxygen from the reaction media results in lower alkene conversion but higher epoxide selectivity. Based on these results, two competitive mechanisms are proposed for the epoxidation reaction, one implying the formation of free radicals and other involving the binding of the substrate to a (oxo)metal intermediate.

Introduction

The use of transition metal complexes as catalysts for the epoxidation of alkenes has been a subject of interest in the past few decades due to the increasing use of epoxides in agro- and pharmacological chemistry.[1] A large number of publications concern the use of the (salen)Mn complexes developed by Katsuki and Jacobsen as highly enantioselective catalysts in the epoxidation of alkenes.[2–4] In these studies, oxidants such as *tert*-butyl hydroperoxide and iodosylbenzene are often employed, although lately the use of environmentally more friendly oxidants such as H_2O_2 and NaOCl has been pursued.

Although (salen)nickel(II) complexes have not been as widely investigated as their manganese analogues, earlier studies by Burrows and co-workers, and later by Kureshy, proved that nickel complexes with cyclam and salen ligands are also active catalysts in the epoxidation of alkenes.[5–10]

The immobilisation of transition metal complexes in solid supports has intrinsic practical advantages, namely the heterogenised catalysts are easy to handle and can be reused.[11,12] Transition metal complexes can be immobilised in several supports such as zeolites,[13] activated carbon[14] and pillared clays.[15] Recently, we demonstrated that (salen)-manganese complexes immobilised in carbon and pillared clays can be used as heterogeneous catalysts in epoxidation reactions without significant loss in their catalytic activity upon re-use.[16–18]

The immobilisation and employment of (salen)nickel complexes in heterogeneous catalysis has not been extensively explored. Some examples include the use of (salen)-Ni-type complexes in faujasites for the oxidation of phenol with H_2O_2[19] and for the epoxidation of cyclohexene and 1-hexene by NaOCl.[20,21] A more recent study concerned the use of [Ni(salen)] immobilised in several solid supports as a catalyst for hydrogenation reactions.[22]

This paper exploits the use of (salen)Ni^{II} complexes as homogeneous catalysts and, after immobilisation in zeolites X and Y, as heterogeneous catalysts in the epoxidation of *trans*-β-methylstyrene by NaOCl. Zeolites X and Y have a crystalline faujasite-type structure composed of small pores (diameter 7 Å), which access internal cavities with a diameter of 13 Å. This topology originates two special properties: (i) zeolites can act as molecular sieves, and (ii) they can be hosts by accommodating and restricting molecules inside the cavities. When considering the potential use of zeolites as supports for catalysts, the above characteristics can result in very important features such as reactant/product size-and-shape selectivity and the possibility to host metal complexes that have proved to be good catalysts in solution. Nevertheless, it is noteworthy that the catalyst performance

can be affected by the immobilisation in a solid material with its own physical and chemical properties.

Four different (salen)Ni^{II} complexes (Scheme 1) were encapsulated in both zeolites X and Y using the "ship-in-a-bottle" procedure[23] accomplished by the "flexible ligand" approach. This two-step synthesis consists of (i) the introduction of Ni^{II} cations by ion exchange and (ii) solvent-free diffusion of the ligands, followed by complexation with the nickel ions. The four (salen)nickel(II) complexes meet the requirements needed for this method of immobilisation because their ligands have a suitable size to diffuse through the pores and reach the cavities containing the metal ions.

4	[Ni(3-MeOsalen)]	H	CH_3O	CH_2CH_2

Scheme 1. Structure of (salen)nickel(II) complexes.

The catalytic activity of the materials was then tested in the epoxidation of *trans*-β-methylstyrene by NaOCl and compared with the results obtained for the complexes in the homogeneous phase. In order to understand the effect of molecular oxygen, a possible co-oxidant, all the reactions were performed in the presence and in the absence of oxygen. These experiments have enabled us to obtain insights into the mechanism of the alkene epoxidation by nickel complexes.

Results and Discussion

Materials Characterisation

The ship-in-a-bottle synthesis resulted in an efficient loading of the nickel complexes inside the zeolites. The loading of the complexes and their distribution within the material was deduced from the nickel content determined by bulk chemical analysis and from XPS. Table 1 presents the nickel content of the materials (wt.-% Ni) obtained by chemical bulk analysis and the Ni/Si ratio obtained by chemical analysis and by XPS.

Table 1. Nickel content (% weight) obtained by chemical analysis (CA) and Ni/Si ratios obtained by chemical analysis (CA) and XPS for the immobilised (salen)nickel(II)complexes.

Catalyst	wt.-% Ni (CA)	Ni/Si CA	Ni/Si XPS
[Ni(salen)]@X	1.0	0.040	0.176
[Ni(salhd)]@X	1.9	0.053	0.142
[Ni(α,α′-Me_2salen)]@X	1.0	0.033	0.196
[Ni(3-MeOsalen)]@X	1.8	0.050	0.161
[Ni(salen)]@Y	1.0	0.019	0.101
[Ni(salhd)]@Y	1.3	0.055	0.074
[Ni(α,α′-Me_2salen)]@ Y	0.4	0.011	0.117
[Ni(3-MeOsalen)]@Y	1.5	0.031	0.074

The results in Table 1 show that the amount of complex and its distribution within the solids differs with the size of the complex and with the zeolite type. Loadings between 0.4 and 1.8 wt.-% Ni were obtained, but generally zeolite X presents a slightly higher complex content than zeolite Y. This is explained by the higher number of exchangeable cations present in the parent NaX (Na/Si = 0.7) when compared with NaY (Na/Si = 0.4), which results in a higher number of Ni^{II} cations in the cavities and, consequently, a higher complex loading.

In both zeolites X and Y, the complexes [Ni(3-MeOsalen)] and [Ni(salhd)] have a higher content inside the zeolites. Also, the distribution of the complexes depends on the ligand type. All the complexes show a higher Ni/Si ratio by XPS than by chemical analysis, pointing to a preferential location of the complexes in the outer layers. This difference is more significant for [Ni(salen)] and [Ni(α,α′-Me_2salen)], suggesting that these complexes occupy more the surface layers while [Ni(3-MeOsalen)] and [Ni(salhd)] are more uniformly distributed.

The preferential location in the outer layers could be due to diffusion of the complexes out of the inner cavities, probably during the extraction step.

The IR spectra of the solids were recorded and compared with the IR spectra of the corresponding free complexes. Figures 1a and 1b show the IR spectra of [Ni(salen)]@X and [Ni(salen)]@Y, respectively, in the region 2000–1000 cm^{-1}. For comparison, the spectra of the parent materials, NiX, NiY, and of [Ni(salen)] are also included. All the materials present intense bands in this region due to zeolite lattice vibrations (1200–1000 cm^{-1}) and a large band centred at 1620 cm^{-1} attributed to adsorbed water.[24]

The characteristic bands of the complex are observed in the region between 1600 and 1200 cm^{-1}, where the zeolites do not absorb, and represent the ν(C=N), ν(C=C), ν(C–C) and ν(C–O) vibrations. The frequencies of these vibrations are practically coincident with those of the complexes, thus providing evidence for their presence inside the zeolites without significant interaction with the matrixes.

The encapsulation of the complexes was also confirmed by UV/Vis diffuse reflectance. Figures 2a and b display typical UV/Vis diffuse reflectance spectra of [Ni(salen)]@X and [Ni(salen)]@Y, respectively. The spectra of the corresponding original materials, NiX and NiY, and of [Ni(salen)] are included for comparison.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

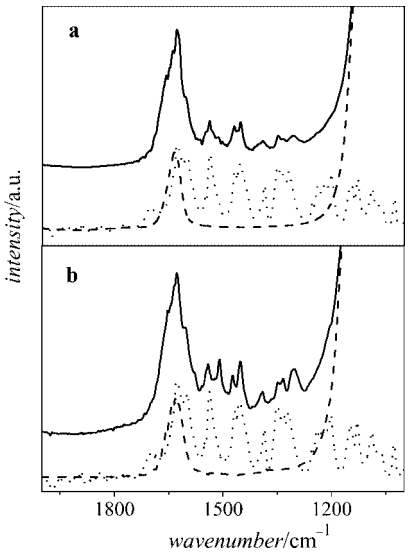

Figure 1. a) IR spectra of [Ni(salen)]@X (solid line), [Ni(salen)] free complex (dotted line) and the parent NiX (dashed line), and b) IR spectra of [Ni(salen)]@Y (solid line), [Ni(salen)] free complex (dotted line) and the parent NiY (dashed line).

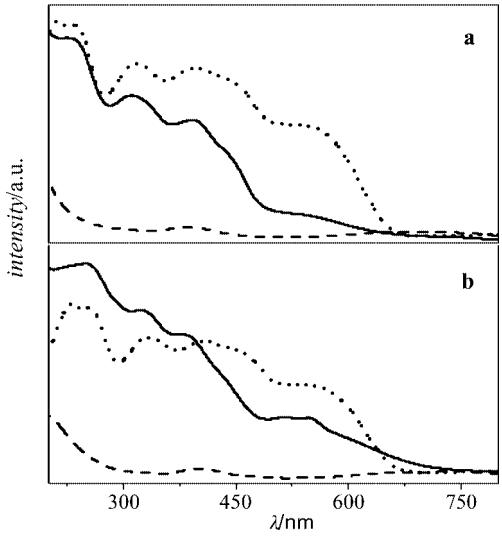

Figure 2. a) UV/Vis solid-state diffuse reflectance spectra of [Ni(salen)]@X (solid line), [Ni(salen)] (dotted line) and NiX (dashed line), and b) UV/Vis solid-state diffuse reflectance spectra of [Ni(salen)]@Y (solid line), [Ni(salen)] (dotted line) and NiY (dashed line).

All the materials exhibit bands in the range λ = 300–700 nm. The bands with $\lambda_{max} < 450$ nm were attributed to charge-transfer bands. Characteristic d-d bands appear at 510–560 nm in the spectra of the free complexes as well as in the spectra of the zeolite-immobilised complexes. However, the materials show slight shifts of the transition bands in relation to the free complexes, thus suggesting some degree of distortion around the metal centre, probably induced by the immobilisation.

Homogeneous Catalysis

The catalytic activity of the four (salen)nickel(II) complexes was first studied in the homogeneous phase (substrate/catalyst ratio = 0.025:1, in dichloromethane) with NaOCl as oxidant. The experiments were run in the presence and in the absence of oxygen. Figure 3 shows the alkene conversion as a function of the reaction time for the epoxidation of *trans*-β-methylstyrene catalysed by [Ni(salen)], [Ni(salhd)], [Ni(α,α′-Me$_2$salen)] and [Ni(3-MeOsalen)] in the presence of oxygen. It is clear from this figure that all complexes are active catalysts in the reaction. The conversion follows a sigmoid curve with an induction period of about 1 h, and reaches maximum conversion after 10 h. The presence of an induction period suggests that the oxidant efficiency is limited.[25]

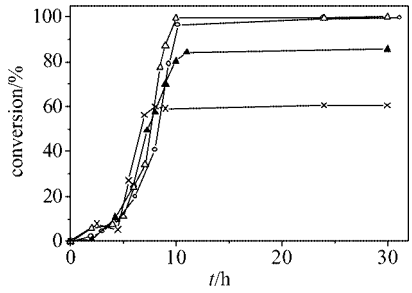

Figure 3. Conversion vs. time plot of the epoxidation of *trans*-β-methylstyrene with NaOCl catalysed by [Ni(salen)] (Δ), [Ni(salhd)] (○), [Ni(α,α′-Me$_2$salen)] (▲) and [Ni(3-MeOsalen)] (×) in the presence of oxygen.

Figure 4 shows the alkene conversion as a function of the reaction time obtained in the epoxidation of *trans*-β-methylstyrene catalysed by [Ni(salen)], [Ni(salhd)], [Ni(α,α′-Me$_2$salen)] and [Ni(3-MeOsalen)], in the absence of oxygen. All the complexes are also active in the absence of oxygen and the evolution with time pursues a similar pattern as observed in the presence of oxygen: a sigmoidal curve with an induction period, although the reaction is slower and the time needed to reach the maximum conversion is about 20 h. The induction period is higher in this case, and dependent on the complex. Table 2 summarises the results obtained after 24 h for the reactions catalysed by the nickel(II) complexes in the homogeneous phase under aerobic or anaerobic conditions.

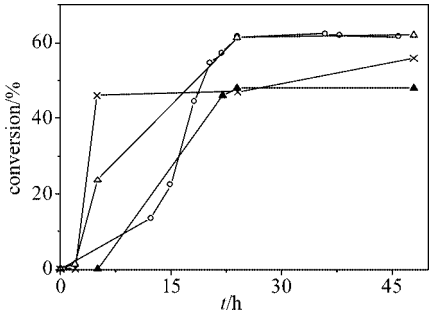

Figure 4. Conversion vs. time plot of the epoxidation of *trans*-β-methylstyrene with NaOCl catalysed by [Ni(salen)] (Δ), [Ni(salhd)] (○), [Ni(α,α′-Me$_2$salen)] (▲) and [Ni(3-MeOsalen)] (×) in the absence of oxygen.

Alkene conversions of between 61 and 100% were obtained in the presence of oxygen and between 47 and 65%

[a] Solvent: CH_2Cl_2; alkene/catalyst ratio = 1.0:0.025; results after 24 h. [b] Oxygen is present as in normal atmosphere (1 atm). For the conditions in the absence of oxygen, see Exp. Sect. [c] Conversion (as disappearance of alkene) determined by GC using *n*-decane as internal standard. [d] Obtained as 100% *trans*-epoxide.

in its absence; epoxide was the major product but benzaldehyde and other products were also obtained.[26]

In the presence of oxygen, the reactions catalysed by [Ni(salen)] and [Ni(salhd)] show the highest conversion, reaching almost 100%. The introduction of two methyl groups at the α-imine carbon atom in [Ni(α,α′-Me_2salen)] decreases the conversion but does not affect the epoxide selectivity. The effect of an electron-donor group in the third position of the aldehyde fragment is more significant: the methoxy group in [Ni(3-MeOsalen)] decreases the conversion significantly (61%), although the epoxide selectivity is not affected. No significant changes were observed when the aliphatic imine bridge was substituted by a cyclohexyl bridge, as in [Ni(salhd)]. In general, the selectivity of the products does not seem to be dependent on the ligand: [Ni(α,α′-Me_2salen)] shows the highest value for the epoxide selectivity (58%) whereas [Ni(3-MeOsalen)] has the lowest value (52%).

For the reactions in the absence of oxygen, the alkene conversion is lower when compared with reactions under aerobic conditions (Table 2), but the complexes [Ni(salen)] and [Ni(salhd)] still present the highest values (62 and 65%, respectively) followed by [Ni(α,α′-Me_2salen)] (48%) and finally [Ni(3-MeOsalen)] (47%). On the other hand, the epoxide selectivity increases for all complexes except for the [Ni(3-MeOsalen)]-catalysed reaction. As observed for the reactions in the presence of oxygen, the highest epoxide selectivity was obtained for [Ni(α,α′-Me_2salen)], whereas [Ni(3-MeOsalen)] shows the lowest value. The dependency of the epoxide selectivity on the ligand is noteworthy, and is more significant when oxygen is absent.

Overall, the alkene conversion is higher and the reaction faster in the presence of oxygen, although the epoxide selectivity is higher in the absence of oxygen.

Reaction Mechanism

Salen-type complexes have been used in epoxidation reactions owing to their special coordination environment, which, like porphyrins, provides a square-planar geometry around the metal atom that allows reactants and/or oxidant to access the active centre. Although the oxidation mechanism through which the metal complexes act in an oxidation reaction is not completely understood, it is known that the reaction selectivity depends on how the oxygen atom is transferred to the alkene. A rebound mechanism involving the formation of a (oxo)metal intermediate and alkyl radicals has been proposed for Cytochrome P450, a (porphyrin)iron compound.[27] Recently, it has been proved that these short-lived radicals are mainly free in solution rather than being bound to the (oxo)metal species.[28]

The involvement of an (oxo)metal species of high oxidation state (M^{n+}=O; n = 3, 4 or 5) has also been proved for (salen)manganese- and -chromium-catalysed epoxidations.[29] In the case of the (salen)nickel-catalysed epoxidations, the formation of an (oxo)metal intermediate is consistent with the dependency of the alkene conversion with the ligand type, although, as suggested by Burrows and coworkers, another intermediate with a radical character can also be formed, namely Ni^{III}–O$^{\cdot}$. This species can instigate the formation of free radicals that compete in the oxidation of the substrate and, therefore, result in reactions with low epoxide selectivity (Scheme 2, mechanism A).[6,9] Alternatively, the alkene can bind to the (oxo)metal intermediate and different paths can then follow (Scheme 2, mechanism B).[30] In the case of epoxidations catalysed by (cyclam) nickel complexes, two main pathways have been suggested for the subsequent steps: (1) a concerted mechanism in which the substrate–(oxo)metal intermediate suffers a heterolytic cleavage leading to the desired epoxide, and (2) a stepwise pathway implying the formation of a carbocation or a carbon radical, which forms the product by homolytic cleavage. The heterolytic cleavage is known to afford high yields of epoxide, while the other preferably performs allylic oxidations;[31] both are summarised in Scheme 2.

On the basis of the catalytic results obtained in the absence and presence of oxygen, the formation of free radicals (mechanism A) cannot be excluded. Free radicals can capture oxygen and consequently enhance the reaction rate and alkene conversion;[32,33] therefore, a free-radical mechanism would explain the higher rates and alkene conversions observed for the reactions run under oxygen. On the other hand, the dissimilarity in product selectivity obtained with different complexes in the absence of oxygen points to the involvement of a substrate–(oxo)metal intermediate (mechanism B), which, through a concerted or a stepwise

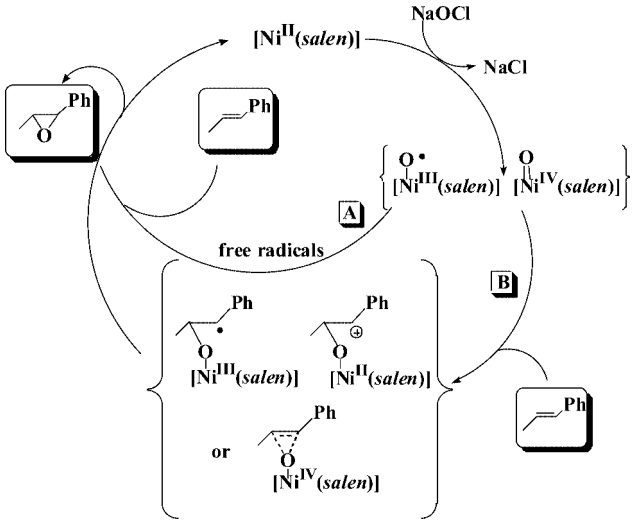

Scheme 2. Proposed mechanism for the *trans*-β-methylstyrene epoxidation by NaOCl with (salen)nickel(II) complexes.

mechanism, allows a good proximity of the substrate to the ligand. Also, as the carbon radical formed in the stepwise pathway in mechanism B is expected to be very sensitive to the presence of O_2, resulting in highly oxidised products (such as benzaldehyde), this mechanism could explain the lower epoxide selectivity observed in the reactions run in the presence of oxygen.

The substantially lower epoxide selectivity obtained with the complex that bears electron-donor substituents, [Ni(3-MeOsalen)], in the absence of oxygen is noteworthy. Studies on the epoxidation of alkenes by (salen)chromium complexes have shown that complexes bearing methoxy groups in the *ortho*-position to the hydroxy group of the salicylaldehyde moiety are easily destroyed by the oxidant.[34]

In this context, our results support the occurrence of two competitive mechanisms (Scheme 2): a mechanism where the (oxo)metal species originates free radicals that, in the presence of oxygen, cause higher and faster alkene conversions but indistinguishable epoxide selectivity (mechanism A), and a mechanism involving binding of the substrate to the (oxo)metal intermediate that, through a concerted or a stepwise pathway, results in lower conversions, but higher epoxide selectivity (mechanism B).

Mechanism A is favoured in the presence of oxygen, while mechanism B is favoured in its absence.

Heterogeneous Catalysis

To study the catalytic activity of the immobilised nickel(II) complexes, the epoxidation of *trans*-β-methylstyrene by NaOCl was carried out using the prepared materials as heterogeneous catalysts. The reactions were run under the same conditions as described for the homogeneous phase, using an amount of zeolite corresponding to the same substrate/catalyst ratio (1:0.025) in dichloromethane (see Exp. Sect.). As in the homogeneous phase, the reactions were performed in the presence and in the absence of oxygen.

Table 3 summarises the results obtained in the heterogeneous phase using the nickel complexes immobilised in zeolites X and Y, in the presence of oxygen.

Table 3. Results obtained for the heterogeneous catalysis in the presence of oxygen.[a]

[Ni(salen)]@Y	30	34 (10)	16 (5)	50 (15)
[Ni(salhd)]@Y	44	48 (21)	23 (10)	28 (12)
[Ni(α,α′-Me_2salen)]@Y	62	45 (28)	22 (14)	33 (20)
[Ni(3-MeOsalen)]@Y	19	25 (5)	60 (11)	15 (3)

[a] Solvent: CH_2Cl_2; alkene/catalyst ratio = 1.0:0.025; results after 48 h. [b] Conversion (as disappearance of alkene) determined by GC using *n*-decane as internal standard. [c] Obtained as 100% *trans*-epoxide.

The reaction time increased significantly and thus the results in Table 3 refer to values obtained after 48 h. The results show that all the immobilised complexes are active in the epoxidation of the alkene, but the catalytic activity is lower than in the homogeneous reactions. The reactions catalysed by zeolites with [Ni(α,α′-Me_2salen)], which reached conversions close to those obtained in the homogeneous phase, are excluded from this conclusion. In fact, the maximum conversion (88%) among the heterogeneous catalysts was observed for [Ni(α,α′-Me_2salen)]@X, together with the highest epoxide selectivity.

Lower conversions and longer reactions times are usually observed on going from solution to immobilised catalysts due to the diffusion constraints imposed by the pore network.[18] Although the solid support can constitute a protective environment around the metal atom, the physical restrictions imposed by the zeolite can make the access of reactants to the metal centre more difficult and, as a result, the activity decreases.

In this case, a correlation between the catalytic activity of the complexes and their distribution within the solids confirms the effect of diffusion constraints: the complexes localised in the outer layers of the zeolites (see above), which therefore can be more easily accessed by the reactants, give higher catalytic activities.

Surprisingly, the epoxide selectivity was lower in all the heterogeneous reactions than in the homogeneous phase, resulting in higher benzaldehyde selectivity. The chemical microenvironment imposed by the zeolites could be the cause of this result. Epoxide ring opening in acidic media forms benzaldehyde, thus the acid character of the zeolites contributes to the lowering of the epoxide selectivity. Again, the zeolites that bear complexes closer to the surface, such as [Ni(α,α′-Me_2salen)]@X and [Ni(α,α′-Me_2salen)]@Y, are less affected by the zeolite characteristics and present nearly the same epoxide selectivity as in the homogeneous phase.

The effect of the zeolites' acidity in the reaction selectivity can be noted by comparing the epoxide selectivity ob-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tained for a complex immobilised in zeolite X with the same complex immobilised in zeolite Y (Table 3). Apart from the other factors already discussed in this paper, the complexes in zeolite X have a higher epoxide selectivity than the complexes in Y, a zeolite with more acidic sites.

The activity of the immobilised catalysts was also evaluated in the absence of oxygen and the results are collected in Table 4. As observed for the homogeneous phase, the absence of oxygen results in lower conversions and higher epoxide selectivity, except for [Ni(3-MeOsalen)], which registers an increase in the conversion when compared with the reaction run under oxygen. Once more, as observed for the homogeneous system, this is the complex with the lowest epoxide selectivity, due to its fast decomposition in the reaction media.

Table 4. Results obtained for the heterogeneous catalysis in the absence of oxygen.[a]

Catalyst	Conv. [%][b]	Selectivity [%] (Yield [%])		
		Epoxide[c]	Benzaldehyde	Others
[Ni(salen)]@X	62	60 (37)	13 (8)	28 (17)
[Ni(salhd)]@X	13	41 (5)	7 (1)	52 (7)
[Ni(α,α′-Me_2salen)]@X	62	59 (37)	12 (7)	29 (18)
[Ni(3-MeOsalen)]@X	39	46 (18)	14 (5)	40 (16)
[Ni(salen)]@Y	48	60 (29)	18 (9)	22 (11)
[Ni(salhd)]@Y	43	59 (25)	14 (6)	27 (12)
[Ni(α,α′-Me_2salen)]@Y	64	64 (41)	16(10)	20 (13)
[Ni(3-MeOsalen)]@Y	32	38 (12)	31 (10)	31 (10)

[a] Solvent: CH_2Cl_2; alkene/catalyst ratio = 1.0:0.025; results after 48 h. [b] Conversion (as disappearance of alkene) determined by GC using *n*-decane as internal standard. [c] Obtained as 100% *trans*-epoxide.

The catalytic activity in the heterogeneous phase follows the same pattern as the homogeneous-phase reactions, hence we propose that the conclusions concerning the reaction mechanism drawn for the homogeneous system can be extended to the heterogeneous counterpart. In this context, the two mechanisms presented above are also competing in the heterogeneous reaction: a mechanism involving the formation of free radicals and a mechanism occurring through a substrate–(oxo)metal intermediate.

Re-Use of Heterogeneous Catalysts

The possibility to re-use [Ni(3-MeOsalen)]@X and [Ni(3-MeOsalen)]@Y was evaluated in the subsequent way: after the first run, the catalysts were filtered from the solution, washed with copious amounts of dichloromethane, dried and re-used according to the general procedure described for the heterogeneous reactions. The results of the re-utilisation and the relation with the first use are illustrated in Figure 5.

For [Ni(3-MeOsalen)]@X, the conversion is similar to that obtained in the first use (19%), but the epoxide selectivity shows a significant increase from 22% to 53%. In the case of [Ni(3-MeOsalen)]@Y, an increase in both conversion (from 19 to 30%) and epoxide selectivity (from 25 to 46%) was observed.

The immobilised catalysts show similar conversions in their re-use compared to their first utilisation: the conversion is equal or even higher than in the first use and there is an increase in the epoxide selectivity. These positive results can be attributed to a change in the overall chemical environment around the complex. In the first use the materials are in contact with NaOCl and a chemical modification from acidic to more basic environment might have occurred. This effect is more significantly reflected in the reactions catalysed by the zeolite with higher initial acidity (zeolite Y). Also, a possible migration of the complex to the outer surface layers of the zeolites cannot be excluded; this decreases the diffusion constraints and therefore favours an increase in conversion.

However, as [Ni(3-MeOsalen)] suffers decomposition in both homogeneous and heterogeneous media, additional experiments should be performed to reach safer conclusions about the catalysts' re-utilisation.

Conclusions

All the (salen)nickel(II) complexes are active catalysts in the epoxidation of *trans*-β-methylstyrene by NaOCl in homogeneous media, both in the presence and in the ab-

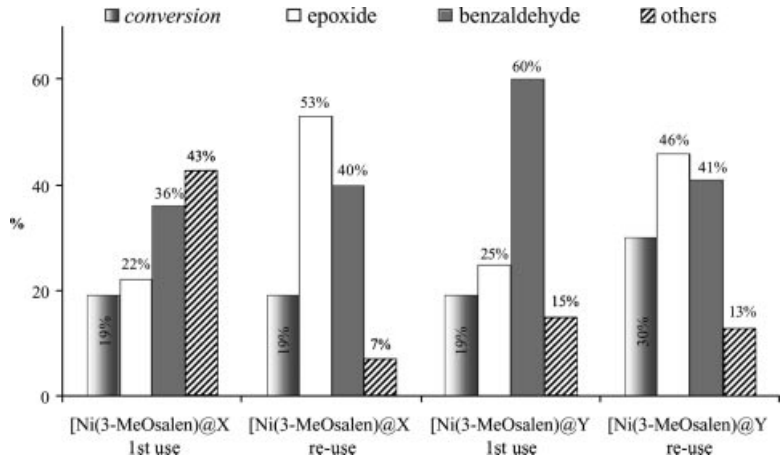

Figure 5. Conversion and selectivity obtained in the first use and in the re-use of [Ni(3-MeOsalen)]@X and of [Ni(3-MeOsalen)]@Y in the epoxidation of *trans*-β-methylstyrene by NaOCl.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

sence of oxygen. Conversions of up to 100% and epoxide selectivity of around 54% are obtained in the presence of oxygen. However, in the absence of oxygen, the reaction is slower, with lower conversions but with higher epoxide selectivity.

These results lead to a proposal of two simultaneous mechanisms for this reaction: a mechanism implying the formation of free radicals, which is favoured in the presence of oxygen, in competition with a mechanism where the substrate binds to an (oxo)metal intermediate. The first would lead to higher alkene conversions but lower and indistinguishable epoxide selectivity, while the other would result in higher epoxide selectivity dependent on the ligand, but lower conversions.

The immobilisation of the four nickel complexes in zeolites X and Y results in materials with different loading and distribution of the complexes. Complexes [Ni(salhd)] and [Ni(3-MeOsalen)] have higher loadings than [Ni(α,α′-Me_2-salen)] and [Ni(salen)]. The former are also more uniformly distributed than the latter, which are preferentially localised in the surface layers of the zeolites.

All the materials are active catalysts in the epoxidation of *trans*-β-methylstyrene by NaOCl, both in the presence of oxygen and in its absence, but the conversions are lower than in the homogeneous phase. The zeolites bearing the metal complexes closer to the surface give higher conversions than those having higher loadings, but a more uniform distribution of the complexes. These results can be explained by the physical restrictions imposed by the zeolite pore network, which makes the access of the reactants to the metal centre more difficult, resulting in lower activities. Furthermore, the zeolite chemical environment, namely its acidic character, influences the selectivity of the reaction. Nevertheless, the zeolites can constitute an important protective environment around the ligand and an opportunity to improve the catalyst life, i.e., by catalyst re-utilisation.

Experimental Section

Reagents and Solvents: The solvents used in the preparation of the complexes were of reagent grade and were used as received. Dichloromethane used in the epoxidation reactions was HPLC grade. An aqueous solution of NaOCl (available chlorine 10–13%, Aldrich) was used as oxidant. Salicylaldehyde, 2-hydroxy-3-methoxybenzaldehyde, 2′-hydroxyacetophenone and the diamines 1,2-cyclohexanediamine (as *cis*/*trans* mixture) and ethylenediamine were purchased from Aldrich. The substrate *trans*-β-methylstyrene was also purchased from Aldrich and *n*-decane was obtained from Fluka. Nickel acetate, nickel nitrate pentahydrate and sodium hydrogen phosphate were obtained from Merck. All reagents were used with no further purification, except the diamines, which were distilled prior to use. The GC standard epoxide was prepared by epoxidation of *trans*-β-methylstyrene with *m*-chloroperbenzoic acid (*m*-CPBA) at 4 °C and stored at that temperature. The phase-transfer catalyst benzyltributylammonium bromide was obtained from Fluka. The zeolites in their sodium form, NaY and NaX, were kindly provided by Grace GmbH (Germany) and were calcinated at 600 °C under oxygen before use.

Instrumentation: Silicon, aluminium, sodium and nickel contents were determined by Kingston Analytical Services (UK) by ICP-AES. The samples were previously treated by fusion with $LiBO_2$ and the mixture dissolved in nitric acid. Surface chemical analysis of the materials was performed by X-ray photoelectron spectroscopy at the Centro de Materiais da Universidade do Porto (Portugal) in a VG Scientific ESCALAB 200A spectrometer, using Mg-K_α radiation (1253.6 eV). Electronic spectra were recorded with a Shimadzu UV/3101PC spectrophotometer equipped with a $BaSO_4$ sphere and using the same salt as reference. FTIR spectra were recorded from KBr pellets of the materials or complexes with a JASCO FT/IR-460 Plus spectrometer. GC analysis was carried out with a Varian 3400 CX equipped with a fused silica Chrompack capillary column (30 m × 0.53 mm) and a TCD detector. The column temperature was programmed from 60 °C (3 min) to 170 °C, at a rate of 5 °C min^{-1}, and the injection temperature was 200 °C.

General Procedure for the Synthesis of Nickel Complexes: The ligands H_2salen, H_2(salhd), H_2(α,α′-Me_2salen) and H_2(3-MeOsalen) and the respective nickel(II) complexes *N*,*N*′-bis(salicylidene)-1,2-diamine, [Ni(salen)] (**1**), *N*,*N*′-bis(salicylidene)-1,2-cyclohexenediamine, [Ni(salhd)] (**2**), *N*,*N*′-bis(α-methylsalicylidene)-1,2-diamine [Ni(α,α′-Me_2salen)] (**3**) and *N*,*N*′-bis(3-methoxysalicylidene)-1,2-diamine, [Ni(3-MeOsalen)] (**4**) (Scheme 1) were prepared and fully characterised in refs.[35,36] according to standard procedures.[37]

General Procedure for the Preparation of the Immobilised Catalysts: The preparation of the immobilised (salen)nickel complexes followed the "ship-in-a-bottle" procedure[23] using the "flexible ligand" method. In a typical preparation, a suspension of calcinated NaY or NaX (10 g) in an aqueous solution containing $Ni(NO_3)_2$ (6 mmol) was heated at 70–80 °C for 24 h. The solid was then filtered and dried at 120 °C under vacuum, and the ion-exchanged zeolite (2 g; NiY or NiX) was mixed with the corresponding ligand (metal/ligand molar ratio = 1:2) and heated to 130–150 °C for 2 h. A change in the colour of the material from pale green (characteristic of hexahydrated Ni^{II}) to orange-brown [typical of (salen)Ni^{II} complexes] confirmed complex formation. The solids were then purified by solid-liquid Soxhlet extraction with appropriate solvents (dichloromethane or ethanol) to remove unreacted ligands and surface-bound complexes. The materials were denoted as [Ni(salen)]@X, [Ni(salhd)]@X, [Ni(α,α′-Me_2salen)]@X [Ni(3-MeOsalen)]@X, [Ni(salen)]@Y, [Ni(salhd)]@Y, [Ni(α,α′-Me_2salen)]@Y and [Ni(3-MeOsalen)]@Y.

General Procedure for the Epoxidation Reactions: In a typical experiment, a solution of the oxidant (5 mL) buffered to pH = 11 (with a solution of Na_2HPO_4) was stirred at room temperature in a solution of dichloromethane (5 mL) enriched with *trans*-β-methylstyrene (2 mmol), the nickel catalyst (0.05 mmol) (substrate/catalyst = 1:0.025) and benzyltributylammonium bromide (0.06 mmol), used as phase-transfer agent. A similar procedure was employed for the heterogeneous reactions using an amount of material corresponding to a substrate/nickel complex ratio of 1:0.025. In this case the catalysts were first activated at 120 °C for 2 h just before use and no phase-transfer agent was employed. The reactions were run at room temperature with continuous magnetic stirring and were followed by GC using *n*-decane as internal standard. For the reactions carried out in the absence of oxygen, the solvent was first deoxygenated with argon for some minutes in a Schlenk tube, and the reaction was run under argon.

One-Dimensional Oxalato-Bridged Metal(II) Complexes with 4-Amino-1,2,4-triazole as Apical Ligand

Urko García-Couceiro,[a] Oscar Castillo,*[a] Antonio Luque,*[a] Juan P. García-Terán,[a] Garikoitz Beobide,[a] and Pascual Román[a]

Keywords: Chain structures / Oxalato bridging ligand / Triazole / X-ray diffraction / Structure–magnetism relationships

The synthesis, chemical characterization, thermal behavior and magnetic properties of six new one-dimensional oxalato-bridged metal(II) complexes of formula $[M(\mu\text{-ox})(4atr)_2]_n$ [M^{II} = Cu (**1**), Ni (**2**), Co (**3**), Zn (**4**), Fe(**5**)] and $[Cd(\mu\text{-ox})(4atr)_2(H_2O)]_n$ (**6**) (ox = oxalato dianion, 4atr = 4-amino-1,2,4-triazole) are reported. The crystal structures of **1** and **6** have been solved by single-crystal X-ray diffraction, whereas the remaining compounds have been studied by means of X-ray powder diffraction methods. Compounds **1**–**5** are isomorphous and crystallize in the triclinic space group $P\bar{1}$ with unit cell parameters for **1** of a = 5.538(1) Å, b = 7.663(1) Å, c = 7.711(2) Å, α = 62.21(1)°, β = 73.91(1)°, γ = 86.11(1)°, and Z = 1. The crystal structures are comprised of one-dimensional linear chains in which the *trans*-$[M(4atr)_2]^{2+}$ units are sequentially bridged by bis(bidentate) oxalato ligands, resulting in an octahedral O_4N_2 donor set. Cryomagnetic susceptibility measurements show the occurrence of antiferromagnetic intrachain interactions for **2**, **3**, and **5**, whereas compound **1** exhibits a weak ferromagnetic coupling in agreement with the out-of-plane exchange pathway involved. The magnetic behavior of **1** and **2** is analyzed and discussed in the light of the available magneto-structural data for analogous systems. Cd^{II} complex crystallizes in the monoclinic space group $C2/c$ with unit cell parameters of a = 16.128(2) Å, b = 6.757(1) Å, c = 11.580(2) Å, β = 104.46(1)°, and Z = 4. Its crystal structure contains one-dimensional chains in which metal centers are heptacoodinated to four oxygen atoms from two symmetry-related bis(bidentate) oxalato bridges, two endocyclic nitrogen atoms of *trans*-coordinated triazole ligands and one water molecule, to give a $CdO_4O_wN_2$ pentagonal-bipyramidal geometry. Thermoanalytical and variable-temperature X-ray powder diffraction analyzes show that compound **6** undergoes a reversible dehydration–hydration process in which the anhydrous residue crystallizes with a different crystal lattice retaining the dimensionality of the oxalato–metal framework.

Introduction

In recent years the area of inorganic crystal engineering[1] has become one of intense research activity due to the growing need for novel solid-state architectures with potential applications as functional materials in fields such as catalysis, conductivity, zeolitic behavior and magnetism.[2] The judicious choice of the metal ion, a well understanding of the coordination preferences of the bridging entities, and a careful selection of the terminal ligands are key steps for the rational design of metal-organic coordination polymers with novel topologies and specific chemical and physical properties.[3] In this context, the oxalato dianion, essentially as bridging ligand, has appeared as a very appealing tecton in constructing a great diversity of homo- and heterometallic compounds with interesting physical properties (magnetic, electric, or optical).[4] The prevalence of its rigid bis(chelating) bridging mode provides a degree of predictability with regard to the structural motifs, and architectures reported for oxalato coordination networks range from discrete oligonuclear species to high dimensionality (one-, two-, and three-dimensional) systems.[5] The formation of these structures largely depends on the shape of the templating counterions and/or the features of the auxiliary ligands used to complete the metal coordination sphere.

Without being exhaustive, 2D honeycomb-layered structures of general formula $[M^{II}M^{III}(ox)_3]^-$ (M^{II} = V, Cr, Mn, Fe, Co, Ni, Cu, Zn; M^{III} = V, Cr, Fe) are obtained with voluminous cations such as $[XR_4]^+$ (X = N, P; R = phenyl, *n*-propyl, *n*-butyl, *n*-pentyl), decamethylferrocenium, and tetrathiafulvalene derivatives.[6] The use of tris(chelated) transition-metal diimine complexes $[M(L)_3]^{m+}$ (L = 2,2-bipyridine or phenanthroline, m = 2, 3) leads to helical 3D networks of formula $[M^{II}_2(ox)_3]^{2-}$, $[M^{II}M^{III}(ox)_3]^-$, and $[M^{I}M^{III}(ox)_3]^{2-}$ where cation and anion exhibit inverted chirality.[7] Discrete species are obtained by using polydentate N- and/or O-donor ligands that block most of the coordination sites around the metal center which precludes the formation of extended polymeric oxalato–metal systems of higher di-

mensionality.[8] Interestingly, in a series of previous papers, we have demonstrated that zigzag or linear one-dimensional complexes of formula $[M(\mu\text{-ox})(L)_x]_n$ (M^{II} = Cu, Ni, Co) can be obtained by utilizing aromatic pyridyl moieties as monodentate terminal/axial ligands, which permits the polymerization process of the oxalato–metal framework.[9–11] This work aims (a) to develop standard synthesis routes (nature of reactants and synthetic conditions) to achieve a straight-forward design of one-dimensional oxalato–metal frameworks, (b) to study the influence of the structural features of these compounds on the magnetic interactions transmitted through the oxalato ligand, (c) to analyze the role of the terminal ligands in the type and magnitude of the crystalline interactions (essentially, hydrogen bonds and other non-covalent interactions between the aromatic systems of the pyridine rings), which ensure the cohesiveness of the crystal structure, and finally (d) to obtain analogous 1D systems with biological molecules such as nucleobases and other N-containing rings as terminal ligands. Indeed, our synthesis efforts have recently been successful with the isolation of a new family of 1D oxalato-bridged complexes in which the pyridinic bases are replaced by nucleobases such as purine and adenine, which behave as N-monodentate ligands.[12]

As a continuation of our research program concerning the use of structure-directing N-containing ligands in the synthesis of 1D oxalato network structures, herein we report the synthesis, crystal structures, and the magnetic behavior of a new family of complexes of formula $[M(\mu\text{-ox})(4atr)_2]_n$, where M = Cu^{II}, Ni^{II}, Co^{II}, Fe^{II}, Zn^{II}, and $[Cd(\mu\text{-ox})(4atr)_2(H_2O)]_n$ with the 4-amino-1,2,4-triazole ligand (4atr) acting as apical ligand with a quite unusual monodentate coordination mode. The use of the 1,2,4-triazole moiety as a part of ligand systems has gained considerable attention in recent years mainly because of the fact that it represents a hybrid of pyrazole and imidazole with regard to the arrangement of its heteroatoms, thus promising a rich and versatile coordination chemistry.[13]

Results and Discussion

$[M(\mu\text{-ox})(4atr)_2]$ [M = Cu (1), Ni (2), Co (3), Zn (4), Fe (5)]

Compounds **1**–**5** are isomorphous and crystallize in the triclinic space group $P\bar{1}$. Crystal parameters and details of the final refinements are summarized in Tables 1 and 2. Compounds **2**–**5** crystallize as poor-quality specimens, and therefore X-ray powder diffraction methods have been performed to obtain structural information (for Supporting Information see footnote on the first page of this article). The observed, calculated and difference X-ray powder diffraction patterns of compound **2** are shown in Figure 1. The

XRPD pattern of **5** shows preferred orientation effects and it has only allowed a structureless pattern matching analysis giving a centric triclinic unit cell with a = 5.685(1) Å, b = 7.773(1) Å, c = 8.110(1) Å, α = 61.27(2)°, β = 72.16(2)°, γ = 87.29(1)°, and V = 297.0(1) Å^3.

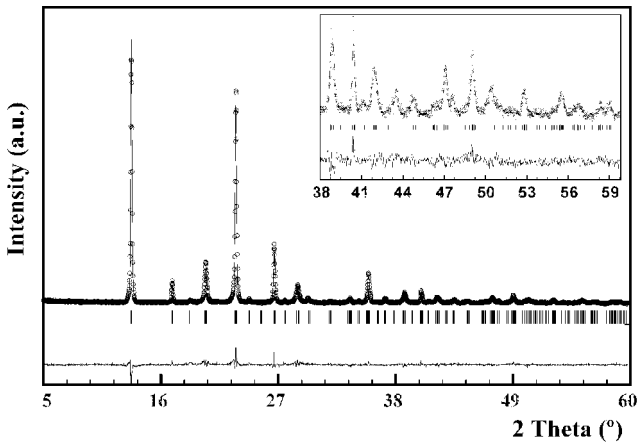

Figure 1. Final Rietveld plot for compound **2**. The observed data are shown by the dots, the calculated pattern by the solid line, and the lower trace corresponds to the difference between observed and calculated patterns.

The crystal structures of **1**–**4** are built up of *trans*-$[M(4atr)_2]^{2+}$ units joined sequentially by centrosymmetric bis(bidentate) oxalato ligands to form polymeric linear chains running parallel to the *a*-axis. The separation of the M^{II} atoms along the chains varies from 5.386(1) Å (**2**) to 5.538(1) Å (**1**). The metal atoms, located on crystallographic inversion centers, are coordinated to four oxygen atoms of two bridging oxalato ligands, and two endocyclic nitrogen atoms from two crystallograhically related 4atr molecules, resulting in octahedral MO_4N_2 donor sets. A perspective view of the polymeric chain of **1** is given in Figure 2, whereas selected bond lengths and angles are gathered in Table 3.

Table 3. Selected bond lengths [Å] and angles [°] for $[M(\mu\text{-ox})(4atr)_2]_n$ [M = Cu (**1**), Ni (**2**), Co (**3**) and Zn (**4**)].

Symmetry code: (a) $-x$, $-y$, $2-z$

The most striking difference between the polymeric chains is the expected tetragonal Jahn–Teller elongation of the copper(II) octahedron in **1**, with two *trans* axial bond lengths [Cu–O2: 2.307(3) Å] substantially longer than the equatorial ones (ca. 2.00 Å). The difference of the Cu–O bond lengths (0.31 Å) involving the bis(bidentate) oxalato ligand is similar to those observed in other six-coordinate copper(II) complexes based on asymmetrically coordinated oxalato bridges.[14–16] The atoms involved in the four short bonds (O1, O1a, N11, N11a) define the equatorial plane of the MO_4N_2 chromophore that forms a dihedral angle of 83.5° with the oxalato bridging ligand.

Compounds **2**, **3** and **4** exhibit a rather typical octahedral metal(II) coordination with $M–O_{ox}$ bond lengths similar to those found in other oxalato-bridged metal(II) complexes (Ni: 1.960–2.152 Å; Co: 2.051–2.212 Å; Zn: 2.011–2.271 Å) registered in the Cambridge Structural Database (CSD, March 2005 release).[17] The triazole ligand is coordinated to the metal atom through the endocyclic N11 atom of the pentagonal ring[18] and it is perpendicular to the oxalato–metal framework (ca. 89°). The rings are arranged along the growing axis of the polymeric chain owing to an intra-

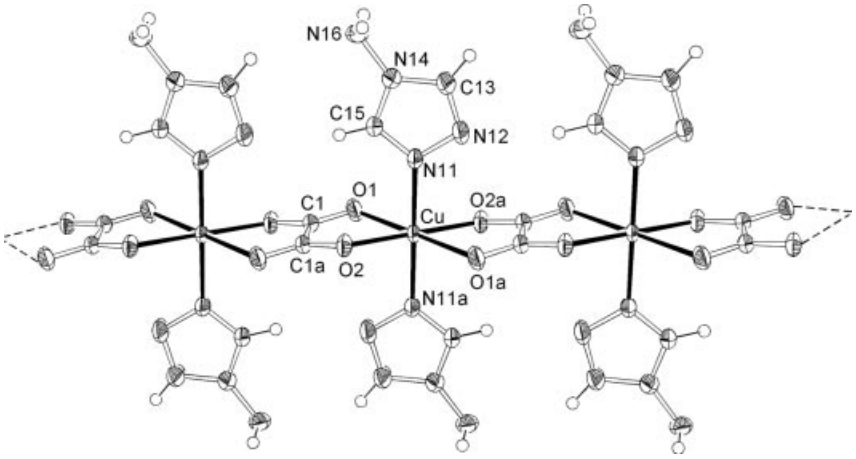

Figure 2. Perspective drawing of the polymeric chain of **1**. Thermal ellipsoids are drawn at the 50% probability level. Symmetry code: (a) $-x$, $-y$, $2-z$.

molecular C–H···N hydrogen bond that is established between two consecutive 4atr ligands of the same side of the chain [C15···N12: 3.381(5) Å, C15–H15···N12: 166° for compound **1**]. The hydrogen atoms of the exocyclic amino group of the apical ligands are projected forward to the outside of the chains which allows their involvement in an extended network of N–H···O_{ox} hydrogen bonds with the oxalato oxygen atoms belonging to adjacent chains which sustains the supramolecular 3D structure of the complexes (Figure 3). The hydrogen-bonded chains are related by crystallographic inversion centers with a chain···chain distance coincident with the *c* parameter of the unit cell [from 7.711(2) Å for **1** to 8.002(1) Å for **4**]. Crystal building of these compounds can be alternatively described as a pillar-layered structure based on sheets of neutral oxalato–metal chains along the *ab* plane and triazole ligands perpendicularly inserted in the interlamellar region. Each organic molecule serves as pillar to link adjacent inorganic sheets. It is directly bound to a metal center of a sheet and its hydrogen-bonding donor is attached to the adjacent one supporting the cohesiveness of the layered structure.

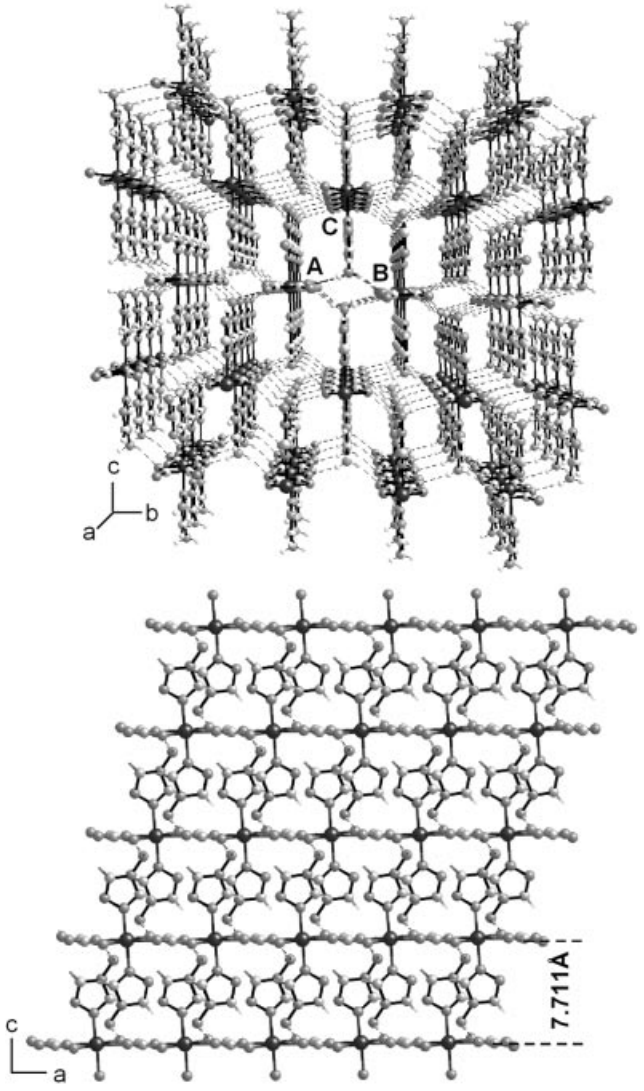

Figure 3. Views of the crystal packing of compound **1** showing the hydrogen bonds (dashed lines) and the layered structure. Intrachain distances [Å]: A···B = 7.663(1) (*b* parameter of the unit cell); A···C = 7.711(2) (*c* parameter).

The thermal degradation of compounds **1**–**5**, deduced from their TG and DTA curves in synthetic air (see Supporting Information), clearly indicates that the overall supramolecular three-dimensional architecture of all compounds is quite stable. The metal-organic framework of **1** retains its rigidity and stability up to 200 °C after which three exothermic processes take place to give copper(II) oxide as a final black powdery product above 500 °C. The three-dimensional cohesiveness of the remaining crystal structures is more robust and they undergo a first exothermic degradation process with an on-set temperature of approximately 325 °C for **2**, 310 °C for **3**, 250 °C for **4**, and 255 °C for **5**. In all the cases, the thermal degradation is completed above 500 °C to yield the metal(II) oxide (**2** and **4**) or M_2O_3 (**3** and **5**) as final products.

The temperature dependence of the $\chi_M T$ product (χ_M is the magnetic susceptibility per copper atom) and the variation of the inverse susceptibility (χ_M^{-1}) for compound **1** are shown in Figure 4. The $\chi_M T$ values increase continuously, upon cooling, from 0.418 cm^3 mol^{-1} K at room temperature up to a value of 0.920 cm^3 mol^{-1} K at 2.0 K. Above 15 K, thermal variation of χ_M^{-1} is well described by the Curie–Weiss law with a θ value of +4.12 K. That is indicative of the predominance of ferromagnetic interactions between the metal centers. The magnetic data were successfully fitted by a numerical expression proposed for uniform copper(II) chains with ferromagnetic[19] intrachain interactions derived through the Hamiltonian $H = -J\Sigma S_i S_{i+1}$. The best-fitted values were $J = +2.18\ cm^{-1}$, $g = 2.16$ and $R = 2.0 \times 10^{-5}$. The agreement factor R is defined as $\Sigma_i[(\chi_M T)_{obsd.}(i) - (\chi_M T)_{calcd.}(i)]^2/\Sigma_i[(\chi_M T)_{obsd.}(i)]^2$.

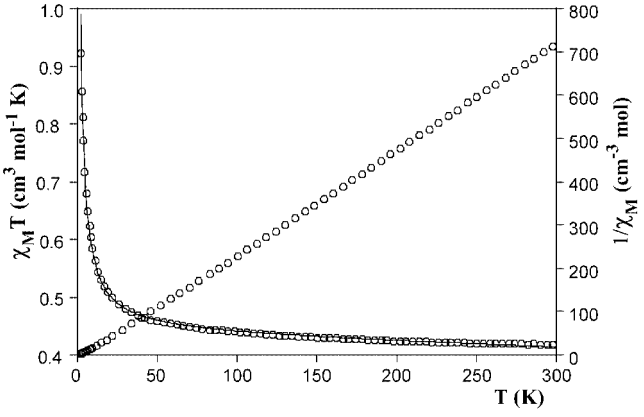

Figure 4. Thermal dependence plots of $\chi_M T$ and $1/\chi_M$ for compound **1**. (−) best theoretical fit (see text).

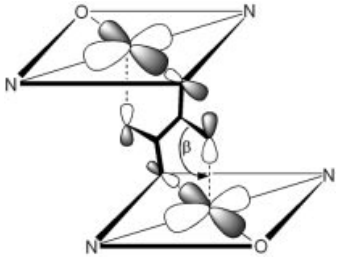
For oxalato-bridged Cu^{II} complexes it has been found[9–12,20] that the value and type of the magnetic coupling is essentially governed by the magnitude of the overlap between the symmetry-adapted highest occupied molecular orbitals (HOMOs, σ symmetry) of the oxalato ligand and the metal-centered magnetic orbitals (mainly, a $d_{x^2-y^2}$-type

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

orbital in square-pyramidal or tetragonally elongated octahedral geometries) which are defined by the short equatorial (or basal) copper–ligand bonds. The strongest antiferromagnetic coupling (values of J ranging from –260 to –400 cm^{-1})[12,20,21] result when the oxalato bridge is symmetrically coordinated with two short bonds to each copper(II) center in such a way that it is coplanar with the singly occupied molecular orbitals (SOMOs) of the copper atoms. But when one copper–bridge distance is long (i.e., oxalato bridge is asymmetrically coordinated), the two metal-centered magnetic orbitals are parallel to each other and perpendicular to the bridging ligand (Scheme 1), the interaction between the d magnetic orbitals through the oxalato ligand is poor, and a weak anti- or ferromagnetic (when the overlap is zero, accidental orthogonality)[9–11,14,20,22–25] coupling results, as occurs in **1**.



Scheme 1.

The magnetostructural data which are listed in Table 4 correspond to copper(II) complexes with an out-of-plane exchange pathway (perpendicular orbital arrangement). It shows that the value of the bond angle C–O–Cu involving the apical oxalate oxygen atom (β) is the main structural factor governing the nature of the magnetic interaction for the perpendicular topology between the oxalato and the copper(II) magnetic plane represented in Scheme 1. Compounds with $\beta \leq 109.5°$ show ferromagnetic interactions, whereas for $\beta > 109.5°$ the magnetic coupling between copper(II) ions is antiferromagnetic. This angle seems to be related to the overlap between the two metal-centered SOMOs and as a consequence to the sign of the magnetic exchange for the perpendicular topology. This magnetostructural result could be used to anticipate the magnetic interaction for new structurally characterized compounds based on oxalato-bridged copper(II) frameworks. For example, the two-dimensional $[Cu_3(\mu\text{-ox})_3(\mu\text{-bpy})_2(bpy)]_n$ polymer consists of sheets in which oxalato–copper(II) chains are crosslinked by bridging bidentate 4,4′-bypyridine ligands. The magnetic measurements show the occurrence of weak ferromagnetic interactions ($J = +0.6\ cm^{-1}$) transmitted through two asymmetrically coordinated oxalato bridges with $\beta < 108.3°$.[26]

Figure 5 shows the magnetic behavior of compounds **2**, **3** and **5**. The thermal dependence of the molar magnetic susceptibility, χ_M, of compound **2** shows a maximum at 44 K which is characteristic of antiferromagnetic interactions between the nickel(II) centers. The magnetic data of compound **2** were fitted by numerical expressions proposed for $S = 1$ chains with uniform antiferromagnetic interactions.[27] The results of the best fits were $J = -23.7\ cm^{-1}$, $g = 2.10$, $\rho = 0.010$ and $R = 4.0 \times 10^{-5}$. The percentage of paramagnetic impurities per mol of nickel atom is ρ (assuming that the molecular weight of the impurity is the same as that of the investigated compound). Previous magnetostructural studies of dinuclear oxalato-bridged Ni^{II} complexes have revealed that the magnitude of the exchange coupling constant is strongly dependent on the nature of the donor atoms in the peripheral ligands: the less electronegative they are, the greater the antiferromagnetic coupling is. This effect is more marked when the less electronegative donor atoms are coplanar with the bridging oxalato ligand.[9,28] The observed J value for compound **2** ($-23.7\ cm^{-1}$) compares well with that reported for the

1D-[Ni(μ–ox)(4apy)$_2$]$_n$ (4apy = 4-aminopyridine) (J = –24.4 cm^{-1})[9] that also shows a *trans*-NiO_4N_2 chromophore, but it is somewhat lower than those reported for other one-dimensional complexes with a *cis*-NiO_4N_2 environment (J varies between –26.8 and –31.3 cm^{-1}).[9,11]

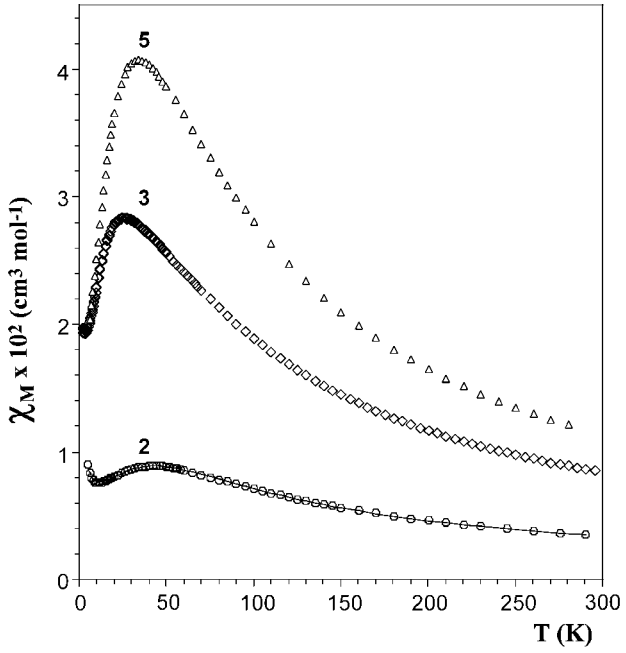

Figure 5. Thermal dependence plots of χ_M for the nickel(II) (**2**), cobalt(II) (**3**), and iron(II) (**5**) compounds; (–) best theoretical fit for **2** (see text).

The molar magnetic susceptibility (χ_M) values of compounds **3** and **5** increase when the temperature decreases, reaching a maximum at approximately 26 (**3**) and 35 K (**5**), with values of 2.83×10^{-2} for **3** and 4.07×10^{-2} cm^3 mol^{-1} for **5**, and then decreases very quickly. The $\chi_M T$ curves exhibit a continuous decrease upon cooling. This behavior suggests the presence of a moderate antiferromagnetic coupling between the magnetic centers through the bridging oxalato ligand. The experimental effective magnetic moments at room temperature of 5.00 (**3**) and 5.64 μ_B (**5**) are larger than the spin-only values of 3.87 μ_B for an uncoupled high-spin cobalt(II) ion (S = 3/2) and 4.90 μ_B for a high spin Fe^{II} center (S = 2). This behavior is typical of cobalt(II) and iron(II) ions in distorted octahedral geometries and a large orbital contribution to the magnetic moment should be considered.[9,11,24,29]

The quantitative analysis of the magnetic properties for systems involving ions with a significant orbital contribution is a difficult task. All our attempts to reproduce the experimental data of the compounds **3** and **5** by using the classical spin Heissenberg chain model[30] with S = 3/2 (Co) and S = 2 (Fe) or by fitting the low-temperature data (for **3**) as collections of Ising chains S = 1/2 effective spins with antiferromagnetic interactions were unsuccessful.[9,31,32] However, it is necessary to note that the magnetism curves and the χ_{max} and T_{max} values for complexes **3** and **5** are similar to those reported for polynuclear oxalato-bridged metal(II) complexes containing these paramagnetic centers with J values up to –25 cm^{-1} (Co)[8a,32] and –10 cm^{-1} (Fe).[32a,33] There are no known examples where the oxalate ion mediates a ferromagnetic interaction.

[Cd(μ-ox)(4atr)$_2$(H$_2$O)]$_n$ (6)

Crystal parameters and refinement results for compound **6** are summarized in Table 5. Its crystal structure consists of zigzag polymeric chains in which the Cd^{II} centers are sequentially bridged by bis(bidentate) oxalato ligands. The intrachain Cd···Cd distance across the oxalato bridge is 6.068(1) Å with a Cd···Cd···Cd angle between three consecutive atoms of 145(1)°. A detailed picture of a one-dimensional fragment is shown in Figure 6. Values of selected bond lengths and angles are reported in Table 6. The distorted pentagonal-bipyramidal coordination about each Cd^{II} center is completed by a water molecule [Cd–O3w: 2.431(9) Å] in the equatorial plane and the N11 endocyclic nitrogen atoms of two triazole ligands [2.321(6) Å] in the apical positions with an N11–Cd–N11a angle of 168.4(4)°, to give a $CdO_4O_wN_2$ donor set with a twofold axis along the Cd–O3w bond. The centrosymmetric oxalato bridge is coordinated with two similar Cd–O distances [Cd–O1: 2.331(6) Å, Cd–O2: 2.422(6) Å]. These values are typical of Cd^{II} complexes based on bis(bidentate) oxalato ligands.[34] The bite angle O1–Cd–O2 [70.1(2)°] is similar to those reported for oxalato-bridged cadmium(II) complexes with a pentagonal-bipyramidal coordination (range from 66 to 71°), but it is lower than the octahedral ones (72–74°).[17] The two symmetry-related oxalato ligands around the metal

The polymeric chains grow along the *c*-axis of the unit cell, and each coordinated water molecule forms two hydrogen bonds, related by a twofold axis, with the O2 oxygen atom from two consecutive oxalato bridges belonging to a neighboring chain with an interchain Cd···Cd distance of 6.757(1) Å (*b* parameter). These O_w–H_w···O_{ox} interactions give rise to sheets, which are spreading out along the crystallographic *bc* plane (Figure 7). The triazole rings are pointing in a direction almost perpendicular to the layers (in the inter-lamellar region) and crosslink adjacent sheets by means of the N–H···O_{ox} hydrogen bonds involving the exocyclic amino group and the oxalato oxygen atoms belonging to two adjacent chains with Cd···Cd and chain···chain distances of 8.813 and 8.064 Å, respectively.

The analysis of the crystal packing clearly shows that the coordinated water molecules are located in unobstructed microchannels along the *c*-axis. This arrangement is able to facilitate the reversible transport of the water molecules along the channels and allows an understanding of why the dehydration temperature of the compound **6** falls within the lower range of values reported for the loss of coordinated water molecules.[35] Thermogravimetric curves (TG/DTA) of compound **6** are portraited in Figure 8. The release of

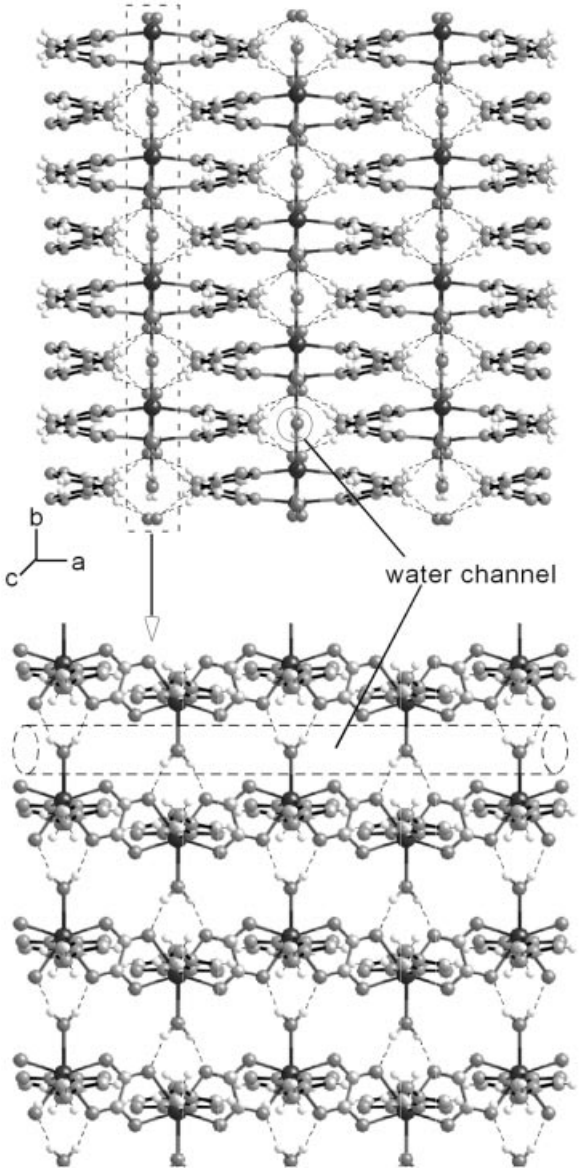

Figure 7. Crystal packing of compound **6** (hydrogen bonds are indicated by dashed lines).

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the water molecule is an endothermic process that starts at 90 °C and is completed by about 110 °C (DTA peak: 100 °C; weight loss: exp. 4.70%, calcd. 4.66%). The anhydrous compound **7** is stable up to 290 °C and then it undergoes three successive exothermic processes (DTA peaks: 310, 380 and 515 °C) leading to CdO above 520 °C, with a total weight loss of 67.60% (calcd. 66.79%).

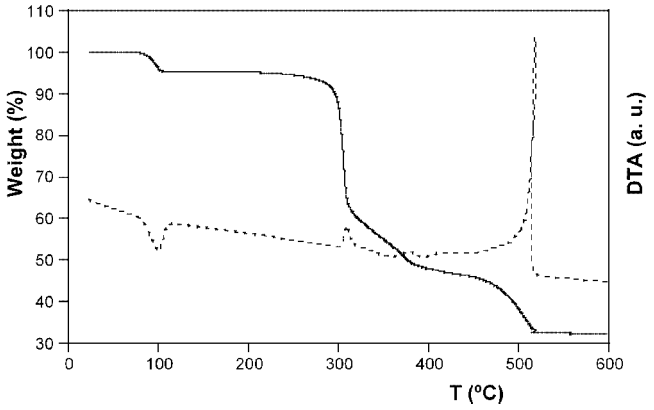

Figure 8. Thermogavimetric curves (TG/DTA) of compound **6** from room temperature to 600 °C.

Although crystal shape and size seem to be initially retained during the loss of the coordinating water molecule, single crystals of **6** lose gradually luster and become effectively a polycrystalline powder, precluding the in-situ structure determination from single-crystal diffraction techniques. Nevertheless, variable-temperature X-ray powder diffraction measurements (XRPD) revealed that the sample remains crystalline (Figure 9). The XRPD profile at 135 °C of **7** is not only substantially different than that obtained for the original compound, but also shows marked differences with the ones of the above-described compounds **1**–**5** (Figure 10). In a first approach, the powder pattern of **7** has been indexed in the orthorhombic space group *Pnmn* with unit cell parameters of a = 5.915(2) Å, b = 7.408(4) Å, c = 14.210(2) Å. These values are comparable to those found for the one-dimensional $[Mn(\mu\text{-ox})(4atr)_2]_n$ compound[36] except for a significant elongation of the crystallographic parameter a.

The Mn^{II} complex contains linear one-dimensional chains similar to those described for the triclinic compounds **1**–**4** where the M···M distance across the oxalato bridge also coincides with the repeat distance of the a-axis [5.599(1) Å for Mn]. The subtle difference between the Mn^{II} crystal structure and those of the above described compounds is the greater parallel displacement of the neighboring chains of the Mn^{II} compound. The hydrogen-bonded polymeric chains are related through a symmetry center in compounds **1**–**5**, whereas they are related through twofold axes in the Mn^{II} complex in such a way that the observed value of 5.915(2) Å for the fully anhydrous compound might be the Cd···Cd intrachain distance, and it is within the range found for other oxalato-bridged Cd^{II} complexes (5.827–6.213 Å).[17] Therefore, the Mn complex and the dehydrated Cd^{II} compound seem to be isostructural and it is

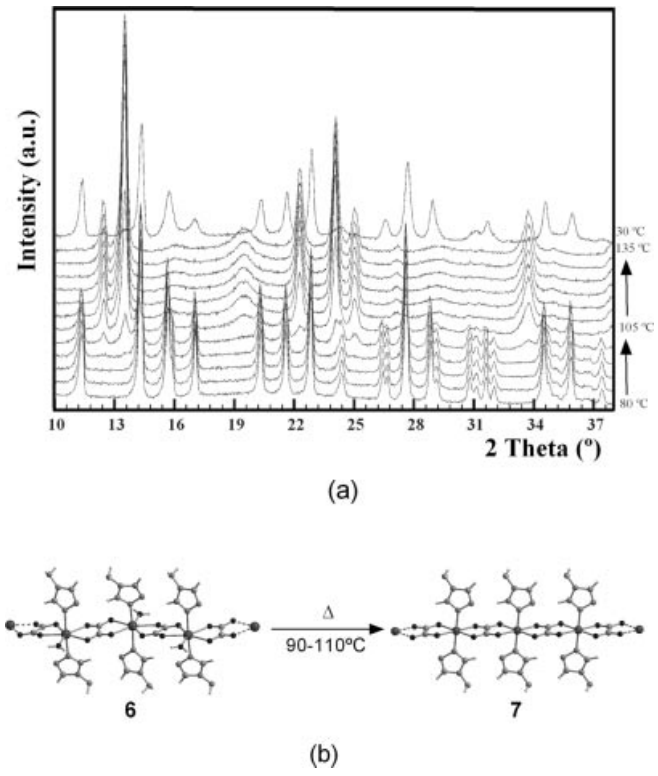

Figure 9. (a) Variable-temperature XRPD patterns of compound **6**. The last one was performed at room temperature 12 h after cooling. (b) Drawing of the polymeric chains of compounds **6** and the tentative structure of the anhydrous one (**7**) above 110 °C.

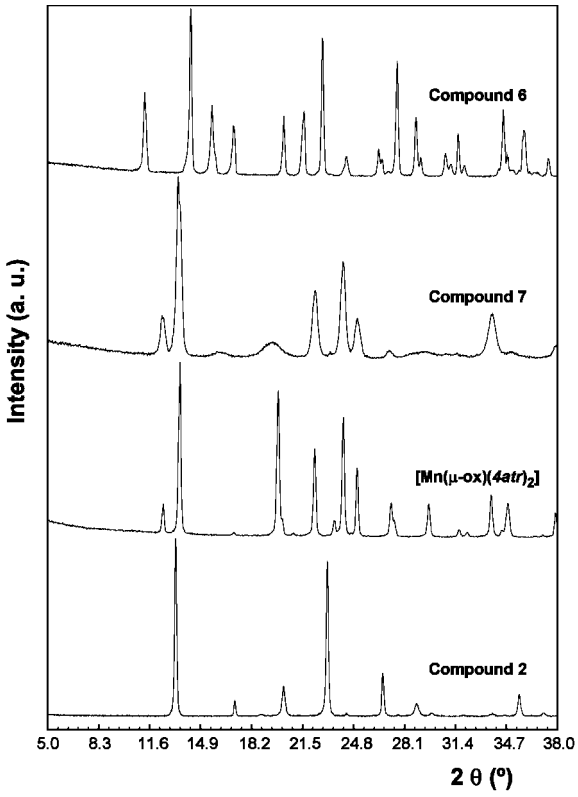

Figure 10. Diffraction patterns for compounds **2**, **6**, **7** and the analogous $[Mn(\mu\text{-ox})(4atr)_2]_n$.

likely that the loss of the coordinated water molecule provides an octahedral coordination environment around the Cd^{II} atoms with a slight distortion of the oxalato–metal framework, but the initial overall 1D structure of the polymeric chain is retained without a drastic structural rearrangement (Figure 9b). In addition, thermogravimetric and X-ray powder crystallographic analyses indicate that the dehydration process is reversible. Upon exposure of **7** to air at room temperature for 12 h, it changed back to the initial aqua form, and the crystallinity was again retained. The system does not suffer any noticeable fatigue after repeating several **6** ↔ **7** cycles. It deserves to note that the references in the literature concerning the reversible loss of coordinated water molecules with no loss of crystallinity are scarce.[37] Usually, the residue is poorly crystalline (even amorphous) or its anhydrous crystal lattice shows a substantial rearrangement of the structural units that precludes the reversibility of the process.

Conclusions

Complexes **1**–**6** are examples of crystal engeneering, because we show how the 4-amino-1,2,4-triazole can be used as terminal ligand towards oxalato–metal frameworks to afford one-dimensional architectures, as previously thought. The analysis of structural and magnetic data of compound **1** and another related oxalato-bridged copper(II) complexes with an out-of-plane exchange pathway clearly evidences the influence of the C–O–Cu angle on the type of the magnetic coupling. This trend would provide a useful tool to predict the behavior of new magnetic compounds. The Cd complex is one of the few examples that shows a reversible release of coordination water molecules, the anhydrous compound remains crystalline but with a different phase.

Experimental Section

Reagents: All chemicals were of reagent grade and were used as commercially obtained. Standard literature procedures were used to prepare the starting materials Co(ox)·$2H_2O$, Ni(ox)·$2H_2O$, K_2[Cu(ox)$_2$]·$2H_2O$ and Cd(ox)·$3H_2O$.[38]

Physical Measurements: Elemental analyses (C, H, N) were performed with a Perkin–Elmer 2400 microanalytical analyser. Metal content was determined by absorption spectrometry. The purity and homogeneity of the polycrystalline samples of **1**–**6** used for physical measurements were checked by IR spectroscopy, elemental analysis, and X-ray powder diffraction methods.[39] The IR spectra (KBr pellets) were recorded with a Nicolet 740 FT-IR spectrometer in the 4000–400 cm^{-1} spectral region. Magnetic measurements were performed on polycrystalline samples of the complexes taken from the same uniform batches used for the structural determinations with a Quantum Design SQUID susceptometer covering the temperature range 2.0–300 K at a magnetic field of 1000 G. The susceptibility data were corrected for the diamagnetism estimated from Pascal's tables,[40] the temperature-independent paramagnetism and the magnetization of the sample holder. Thermal analyses (TG/DTA) were performed with a TA Instruments SDT 2960 thermal analyser in synthetic air (79% N_2/21% O_2) with a heating rate of 5 °C min^{-1}. A prismatic blue crystal of **1** (0.15 × 0.06 × 0.06 mm) and a prismatic colorless crystal of **6** (0.10 × 0.10 × 0.06 mm) were selected for the structural analysis. Diffraction data were collected at 293(2) K with Enraf–Nonius CAD4 automatic four-circle (**1**) and Oxford Diffraction Xcalibur (**6**) diffractometers with graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å). Unit-cell parameters and orientation matrix of **1** were determined by least-squares treatment of the setting angles of 25 reflections on the range $4° < \theta < 13°$. Indexation and unit-cell refinement of **6** were based on all observed reflections from 10 frames collected with an oscillation range of 1°/frame and an exposure time of 3 min/frame. The data reduction was done with the XCAD[41] and CrysAlis RED[42] programs for compounds **1** and **6**, respectively. Both structures were solved by direct methods using the SIR92 program[43] and refined by full-matrix least squares on F^2 including all reflections (SHELXL93).[44] All calculations were performed using the WINGX crystallographic software package.[45] The final geometrical calculations and the graphical manipulations were carried out with the PARST95[46] and PLATON[47] programs. The X-ray powder diffraction (XRPD) patterns of compounds **2**–**5** were collected with a Phillips X'PERT powder diffractometer with Cu-K_α radiation over the range $5° < 2\theta < 60°$ with a fixed-time counting of 6–25 s at 25 °C. Indexation of the diffraction profiles of compounds **2**–**5** was made by means of the FULLPROF program (pattern-matching analysis)[48] on the basis of the space group and the cell parameters found for compound **1**. The atomic coordinates of **1** have been used as starting values for a least-squares refinement based on fitting the calculated and observed intensity profiles of an XRPD pattern of compounds **2**–**4**. Crystallographic data for compounds **1**–**4** and **6** have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-269268 (**1**), -282657 (**2**), -282658 (**3**), -282659 (**4**), and -269269 (**6**). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk]. Thermodiffractometry measurements of the Cd^{II} compound **6** were run under ambient atmosphere in the range $9° < 2\theta < 38°$ with a step size of 0.03° and an acquisition time of 2.5 s per step. The compound was heated to 80 °C with a heating rate of 10 °C min^{-1} and after that diagrams were collected every 5 °C with a heating rate of 1 °C min^{-1} up to 140 °C. Finally, the sample was allowed to cool for 12 h and a new diffraction profile was collected at 30 °C.

Synthesis of [Cu(μ-ox)(4atr)$_2$]$_n$ (1): Single crystals of **1** were grown by layering a methanol solution of 4-amino-1,2,4-triazole (0.200 g, 2.5 mmol) onto an aqueous solution of K_2[Cu(ox)$_2$]·$2H_2O$ (0.175 g, 0.5 mmol) and K_2ox·H_2O (0.061 g, 0.33 mmol). After allowing the solution to stand for 2 weeks, the crystals were isolated in 80% yield by filtration. They were washed with cold water and diethyl ether, and dried in air. $C_6H_8CuN_8O_4$ (319.74): calcd. C 22.54, H 2.52, N 35.05, Cu 19.87; found C 22.48, H 2.52, N 34.99, Cu 19.82. Main IR features (KBr pellet): $\tilde{\nu}$ = 3295 s, 3175 s for ν(N–H); 3115 s for ν(C–H); 1655 vs. for $\nu_{as}(CO_2)$; 1615 s for $\delta(NH_2)$; 1540 m, 1465 m for ν_{as}(C=N); 1360 m, 1310 s for $\nu_s(CO_2)$; 1220 m, 1200 m, 1075 s for δ_{ip}(C–H); 1035 m, 1015 m for ν_s(CO); 970 m for δ_{ring}; 890 m, 850 w δ_{op}(C–H); 800 s for $\delta(CO_2)$; 690 w, 625 s for τ_{ring}; 500 m, 415 m for ν(M–O, M–N) cm^{-1}.

Synthesis of [Ni(μ-ox)(4atr)$_2$]$_n$ (2): An aqueous solution (10 mL) of 4-amino-1,2,4-triazole (0.168 g, 2.00 mmol) was added dropwise to an aqueous solution (30 mL) containing Ni(ox)·$2H_2O$ (0.080 g, 0.44 mmol) and K_2ox·H_2O (0.442 g, 2.4 mmol). Immediately, a green precipitate corresponding to compound **2** appeared. Yield 90%. $C_6H_8N_8NiO_4$ (314.87): calcd. C 22.89, H 2.56, N 35.59, Ni

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

18.64; found C 22.92, H 2.55, N 35.55, Ni 18.62. Main IR features (KBr pellet): $\tilde{\nu}$ = 3305 m, 3215 m for ν(N–H); 3105 m for ν(C–H); 1655 sh for $\nu_{as}(CO_2)$; 1615 vs for $\delta(NH_2)$; 1535 w, 1470 w for ν_{as}(C=N); 1360 m, 1315 m for $\nu_s(CO_2)$; 1230 m, 1205 m, 1070 m for δ_{ip}(C–H); 1020 m for ν_s(CO); 970 m for δ_{ring}; 890 w, 855 w δ_{op}(C–H); 800 m for $\delta(CO_2)$; 685 w, 620 m for τ_{ring}; 490 m, 420 m for ν(M–O, M–N) cm^{-1}.

Synthesis of $[Co(\mu\text{-ox})(4atr)_2]_n$ (3): The preparation of **3** is analogous to that described for **2** but using $Co(ox)\cdot 2H_2O$ (0.080 g, 0.44 mmol), $K_2ox\cdot H_2O$ (0.737 g, 4.00 mmol) and 4-amino-1,2,4-triazole (0.168 g, 2.0 mmol). A pink polycrystalline powder of **3** was obtained almost immediately. Yield 90%. $C_6H_8CoN_8O_4$ (315.11): calcd. C 22.87, H 2.56, Co 18.70, N 35.56; found C 22.88, H 2.56, Co 18.68, N 35.60. Main IR features (KBr pellet): $\tilde{\nu}$ = 3295 m, 3215 m for ν(N–H); 3105 m for ν(C–H); 1655 sh for $\nu_{as}(CO_2)$; 1615 vs for $\delta(NH_2)$; 1535 m, 1465 w for ν_{as}(C=N); 1365 m, 1320 m for $\nu_s(CO_2)$; 1220 m, 1205 m, 1075 m for δ_{ip}(C–H); 1010 w for ν_s(CO); 965 m for δ_{ring}; 895 m, 855 w δ_{op}(C–H); 800 m for $\delta(CO_2)$; 680 w, 625 m for τ_{ring}; 495 m, 415 m for ν(M–O, M–N) cm^{-1}.

Synthesis of $[Zn(\mu\text{-ox})(4atr)_2]_n$ (4): 10 mL of a water solution containing $H_2C_2O_4\cdot 2H_2O$ (0.034 g, 0.2 mmol) was added dropwise to an aqueous solution (25 mL) of 4-amino-1,2,4-triazole (0.069 g, 1.00 mmol) and $ZnCl_2$ (0.054 g, 0.40 mmol). Immediately, a white polycrystalline powder of **4** appeared. The precipitate was separated from the mother liquor and it was washed with cold water and diethyl ether, and dried in air. Yield 90%. $C_6H_8N_8O_4Zn$ (321.57): calcd. C 22.41, H 2.51, N 34.85, Zn 20.33; found C 22.43, H 2.52, N 34.82, Zn 20.35. Main IR features (KBr pellet): $\tilde{\nu}$ = 3295 s, 3210 s for ν(N–H); 3100 s for ν(C–H); 1655 sh for $\nu_{as}(CO_2)$; 1615 vs for $\delta(NH_2)$; 1540 m, 1465 m for ν_{as}(C=N); 1370 m, 1320 s for $\nu_s(CO_2)$; 1220 m, 1205 m, 1075 m for δ_{ip}(C–H); 1015 m for ν_s(CO); 970 m for δ_{ring}; 895 m, 850 w for δ_{op}(C–H); 800 s for $\delta(CO_2)$; 685 w, 625 s for τ_{ring}; 500 m, 410 m for ν(M–O, M–N) cm^{-1}.

Synthesis of $[Fe(\mu\text{-ox})(4atr)_2]_n$ (5): Orange polycrystalline samples of compound **5** were prepared as **4** but using $FeSO_4\cdot 7H_2O$ (0.064 g, 0.2 mmol). Yield 90%. $C_6H_8FeN_8O_4$ (312.02): calcd. C 23.09, H 2.58, N 35.91, Fe 17.90; found C 23.05, H 2.57, N 35.95, Fe 17.96. Main IR features (KBr pellet): $\tilde{\nu}$ = 3340 m, 3300 m, 3215 m for ν(N–H); 3110 m for ν(C–H); 1620 vs for $\delta(NH_2)$; 1530 m, 1460 w for ν_{as}(C=N); 1360 w, 1325 m for $\nu_s(CO_2)$; 1215 m, 1200 m, 1075 m for δ_{ip}(C–H); 1005 m for ν_s(CO); 960 m for δ_{ring}; 885 w, 860 w δ_{op}(C–H); 800 m for $\delta(CO_2)$; 680 w, 620 m for τ_{ring}; 495 m, 410 m for ν(M–O, M–N) cm^{-1}.

Synthesis of $[Cd(\mu\text{-ox})(4atr)_2(H_2O)]_2$ (6): Prismatic colorless crystals appropriate for the X-ray diffraction were obtained using an analogous method to that described for **2** but using $Cd(ox)\cdot 3H_2O$ (0.072 g, 0.28 mmol), $K_2(ox)\cdot H_2O$ (1.182 g, 5.0 mmol) and 4atr (0.087 g, 1.0 mmol). Yield 60%. $C_6H_{10}CdN_8O_5$ (386.62): calcd. C 18.64, H 2.61, Cd 29.08, N 28.98; found C 18.59, H 2.60, Cd 29.10, N 29.01. Main IR features (KBr pellet): $\tilde{\nu}$ = 3435 s for ν(O–H); 3330 s, 3275 m, 3225 m for ν(N–H); 3130 m, 3105 m for ν(C–H); 1680 m, 1630 sh for $\nu_{as}(CO_2)$; 1610 vs. for $\delta(NH_2)$; 1530 m, 1460 w for ν_{as}(C=N); 1385 w, 1315 m for $\nu_s(CO_2)$; 1200 m, 1070 m for δ_{ip}(C–H); 1005 m, 990 sh for ν_s(CO); 960 w for δ_{ring}; 880 m for δ_{op}(C–H); 790 m for $\delta(CO_2)$; 685 w, 620 m for τ_{ring}; 505 w, 420 w for ν(M–O, M–N) cm^{-1}.

Generation and Reactions of Overcrowded Diaryldilithiostannane and Diaryldipotassiostannane

Tomoyuki Tajima,[a] Nobuhiro Takeda,[a] Takahiro Sasamori,[a] and Norihiro Tokitoh*[a]

Keywords: Group 14 elements / Tin / Anions / Lithium / Potassium / Solid-state structures

Exhaustive reduction of an overcrowded dibromostannane bearing two bulky aromatic substituents, Tbt(Dip)$SnBr_2$ {Tbt = 2,4,6-tris[bis(trimethylsilyl)methyl]phenyl; Dip = 2,6-diisopropylphenyl}, with an excess amount of lithium naphthalenide in THF at –78 °C gave the corresponding dilithiostannane, Tbt(Dip)$SnLi_2$, the generation of which was confirmed by trapping experiments with some electrophiles together with ^{119}Sn and ^{7}Li NMR spectroscopy. The diaryldilithiostannane was found to be stable in solution under an inert gas below –25 °C. The potassium analogue, Tbt(Dip)-SnK_2, was also generated by the reduction of the dibromostannane in THF at –78 °C by the use of KC_8 as a reductant. The reactions of dilithiostannane and dipotassiostannane obtained with *o*-dibromobenzene did not give a stannacyclopropabenzene derivative but an unexpected cyclization product, a stannacyclobutabenzene derivative, in contrast to the reactions of the corresponding dilithiosilane and dilithiogermane, Tbt(Dip)ELi_2 (E = Si, Ge), with *o*-dibromobenzene leading to the formation of the corresponding metallacyclopropabenzenes as stable crystalline compounds. A preliminary result of the synthesis of a tin–tellurium double-bond compound from the dilithiostannane is also presented.

Introduction

One of the most important classes of organometallic compounds is probably that of organolithium compounds, which are now recognized as very powerful synthetic tools in organic chemistry. Among them, the chemistry of lithium compounds of heavier group 14 elements has attracted considerable interest in recent years,[1] and some dilithiosilane and dilithiogermane derivatives have been structurally characterized and successfully applied to the construction of novel bondings and/or structures of heavier group 14 elements.[2] By contrast, there are very few reports on tin dianion species. Saito and his co-workers have recently reported the spectroscopic observation of a stannole dianion.[3] Although Schmidt et al. have proposed the formation of $(C_6H_5)_2SnLi_2$ in the reaction of $(C_6H_5)_2SnCl_2$ with 4 molar amounts of Li,[4,5] the yields of the trapping reactions are not high and the generation of dilithiodiphenylstannane was not evidenced by ^{119}Sn and ^{7}Li NMR spectroscopy. More recently, Egorov et al. reported the ^{119}Sn and ^{13}C NMR studies of Et_2SnLi_2 and $(C_6H_5)_2SnLi_2$.[6] The chemistry of tin-dianion species has recently gained more and more attention.

Meanwhile, the study of three-membered ring compounds containing a heavier group 14 element is one of the most fascinating research areas in main group element chemistry.[7,8] Recently, we have also succeeded in the synthesis and isolation of the first stable sila-[9] and germacyclopropabenzenes,[10] **2a** and **2b**, by reactions of the corresponding overcrowded dilithiosilane **1a**[11] and dilithiogermane **1b**[2g,10] with *o*-dibromobenzene, respectively. Although there have been many reports on the syntheses and characterization of Si- and Ge-containing three-membered ring compounds, investigations of their tin analogues, stannacyclopropanes and stannacyclopropenes,[8] are quite rare. To the best of our knowledge, only one report has so far appeared on the synthesis of stannacyclopropenes.[8c]

In this article, we report the generation of overcrowded, diaryl-substituted dilithiostannane and dipotassiostannane together with their attempted applications to the synthesis of a hitherto unknown stannacyclopropabenzene **2c** and a tin–tellurium double-bond compound,[12] stannanetellone (Scheme 1).

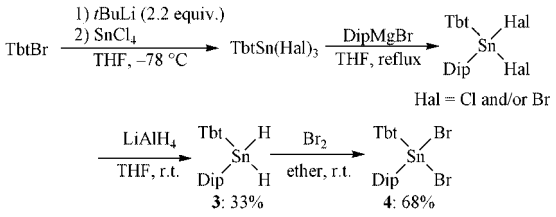
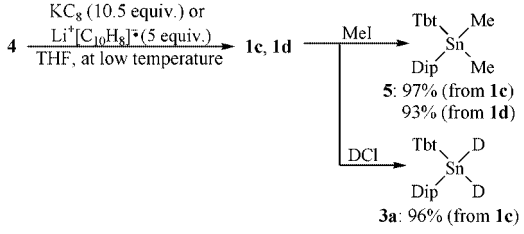
Results and Discussion

Dibromostannane **4** was prepared by a method similar to that for the synthesis of Tbt(Mes)$SnBr_2$,[13] as shown in Scheme 2. Tbt-substituted trihalostannane was synthesized by the reaction of $SnCl_4$ with TbtLi. Tbt- and Dip-substituted stannane, Tbt(Dip)SnH_2 (**3**), was prepared by the nucleophilic displacement reaction of the Tbt-substituted trihalostannane using DipMgBr, followed by reduction with $LiAlH_4$. Bromination reaction of **3** using Br_2 in ether afforded the corresponding dibromostannane **4**.



Scheme 2. Synthesis of dibromostannane **4**.

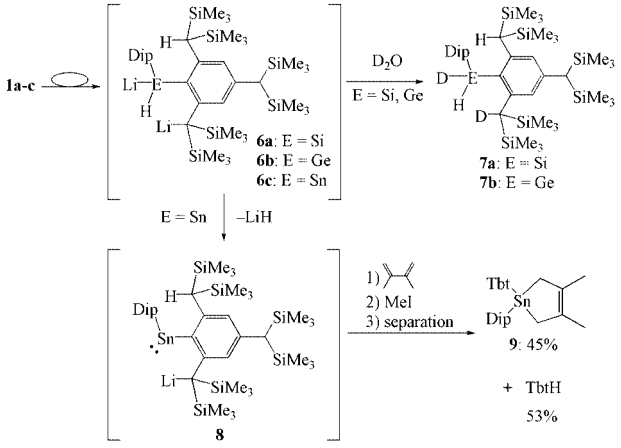
Tbt(Dip)$SnLi_2$ (**1c**) was generated by the exhaustive reduction of the overcrowded diaryldibromostannane **4** with an excess amount of lithium naphthalenide (5 equiv.) in dry THF at –78 °C under argon. The reaction mixture was stirred at the same temperature for 1 h, and then treated with an excess amount of MeI to afford Tbt(Dip)$SnMe_2$ (**5**) in 96% yield. The addition of DCl to the solution of **1c** at –78 °C resulted in the formation of Tbt(Dip)SnD_2 (**3a**) in 96% yield (D content: 93%) (Scheme 3). The formation of **3a** and **5** in the trapping experiments in high yields is most likely interpreted in terms of the almost quantitative generation of dilithiostannane **1c** as a stable compound in THF at –78 °C.



Scheme 3. Generation of overcrowded dilithiostannane **1c** and dipotassiostannane **1d**.

The ^{119}Sn NMR spectrum of **1c** in THF at –80 °C showed a broad signal at δ = –362.2 ppm, which is observed at a much higher field than that of Tbt(Dip)$SnBr_2$ (**4**: δ = –162.0 ppm in THF at –80 °C).[14] In the ^{7}Li NMR spectrum, only one singlet signal was observed at δ = 0.6 ppm, suggesting the rapid exchange of lithium cations between **1c** and LiBr. After the NMR sample was left at room temperature for a few days, the remeasurement of the ^{119}Sn NMR spectrum was performed. The ^{119}Sn NMR signal of **1c** disappeared and a new signal appeared at 1856.8 ppm, the chemical shift of which is close to those of stannylene species reported so far.[16]

Meanwhile, we have already succeeded in the generation of dilithiosilane **1a**[11] and dilithiogermane **1b**[2g,10] bearing Tbt and Dip groups on the silicon and germanium atoms, respectively. The thermal stability of **1a** and **1b** in THF solutions has been investigated by the trapping experiments using D_2O, which revealed that dilithiosilane **1a** was stable below –78 °C and dilithiogermane **1b** was stable below –25 °C. When the solutions of **1a** and **1b** were warmed above these temperatures, they underwent intramolecular proton abstraction from one of the *o*-$CH(SiMe_3)_2$ units of the Tbt group to give the corresponding lithium migration products **6a** and **6b**, respectively (Scheme 4).[10,11] Treatment of the intermediates such as **6a** and **6b** with D_2O afforded **7a** and **7b**, respectively. Similarly, thermal stability of **1c** was studied by the trapping reactions using MeI at various temperatures. The isolated yields of **5** in these reactions were 97% at –78 °C, 97% at –25 °C, and 45% at 0 °C, suggesting that dilithiostannane **1c** could be stable at least below –25 °C.



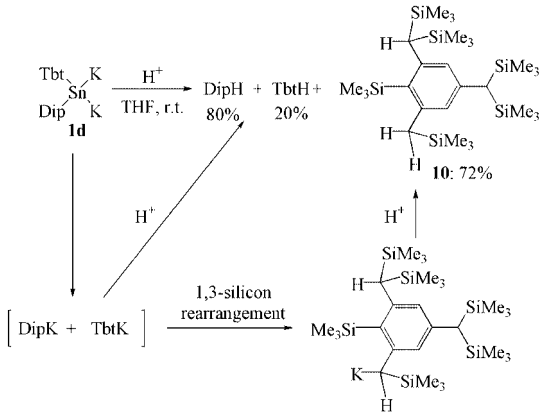
Scheme 4. Stability of **1a**, **1b**, and **1c**.

Trapping reactions of the decomposed compound from **1c** were performed. Treatment of the THF solution of **1c** with 2,3-dimethyl-1,3-butadiene at room temperature followed by the addition of MeI afforded TbtH and **9** (Scheme 4). The trapping experiment and the ^{119}Sn NMR studies suggest that dilithiostannane **1c** is initially formed and then it undergoes an intramolecular lithium migration reaction giving a lithium-migrated compound **6c** as in the case of **6a** and **6b**. However, the stability of **6c** is considered to be different from that of **6a** and **6b**. The formation of **9** strongly indicates that stannylene **8** is generated from **6c** by the elimination of LiH.

The reduction of **4** was alternatively performed with KC_8 in THF at –110 °C to give the corresponding dipotassiostannane **1d**, the generation of which was confirmed by the trapping experiment with MeI, giving **5** in 93% yield (Scheme 3). Dianion species **1d** was unstable at higher temperatures, and its purple solution in THF rapidly turned yellow at room temperature within a few minutes. The addition of H_2O to the yellow solution resulted in the formation of TbtH, DipH, and **10**[17] (Scheme 5). As this 1,3-silicon rearrangement product **10** was reportedly obtained from TbtLi above –30 °C in THF,[20] these results strongly suggest the initial formation of TbtK and DipK at low tem-

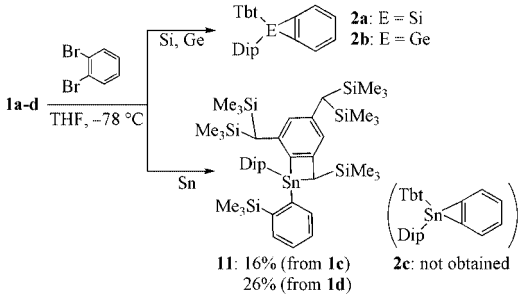
 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

perature in this reaction. Although we attempted the reactions of **4** with other reductants (Li, K, *t*BuLi, and *n*BuLi), the generation of the corresponding dianion species (**1c** or **1d**) was not confirmed.



Scheme 5. Stability of **1d**.

With the evidence for the formation of dilithiostannane **1c** and dipotassiostannane **1d** in hand, we next attempted the synthesis of stannacyclopropabenzene **2c** by the method similar to those for the syntheses of **2a**[9] and **2b**.[10] However, the reactions of **1c** or **1d** with *o*-dibromobenzene gave an unexpected cyclic compound **11** as stable colorless crystals (16% yield from **1c** and 26% yield from **1d**) instead of the expected product **2c** (Scheme 6). The structure of the cyclic product **11** was satisfactorily confirmed by mass spectrometry, elemental analysis, and NMR spectroscopy, and the molecular structure of **11** was finally determined by X-ray crystallographic analysis. In Figure 1 the ORTEP drawing of stannacyclobutabenzene **11** is shown.[18] The deformation from the normal sp^2 configuration is larger on the C1 atom than the C6 atom, as judged by the bond angles of Sn1–C1–C6 [92.6(3)°] and C1–C6–C7 [114.4(4)°]. Additionally, the bond lengths of Sn1–C1 [2.144(4) Å] and C7–C6 [1.522(6) Å] are slightly shorter than those reported for stannabutabenzene [Sn1–C1 2.185(5) Å, C7–C6 1.588(8) Å].[18] All carbon–carbon bond lengths in the central benzene ring of **11** are almost equal.



Scheme 6. Reaction of **1a**–**d** with *o*-dibromobenzene.

Although the detailed formation mechanism for **11** is not clear at present, compound **13** might be formed as an initial intermediate by the mechanism similar to those in the reactions of **1a** and **1b**; thus, the dilithiostannane **1c** or dipotassiostannane **1d** reacts with *o*-dibromobenzene to give

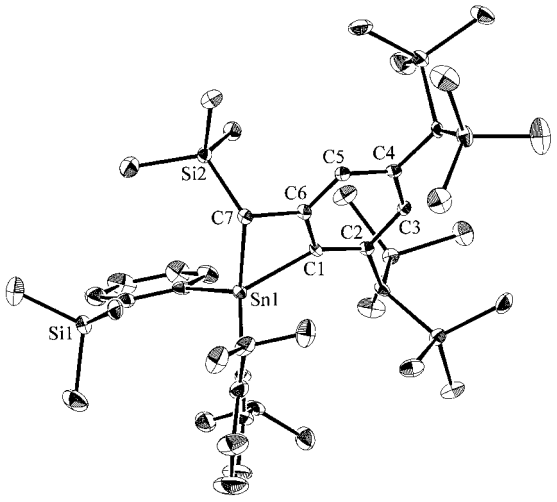


Figure 1. ORTEP drawing of **11** (50% probability). Hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Sn1–C1 2.144(4), Sn1–C7 2.205(4), C7–C6 1.522(6), C1–C2 1.398(6), C2–C3 1.397(6), C3–C4 1.411(6), C4–C5 1.402(6), C5–C6 1.379(6), C6–C1 1.407(6), C1–Sn1–C7 67.62(16), Sn1–C7–C6 87.2(3), C1–C6–C7 114.4(4), Sn1–C1–C6 92.6(3), C1–C2–C3 117.8(4), C2–C3–C4 122.5(4), C3–C4–C5 118.0(4), C4–C5–C6 120.3(4), C5–C6–C1 121.0(4), C6–C1–C2 120.3(4).

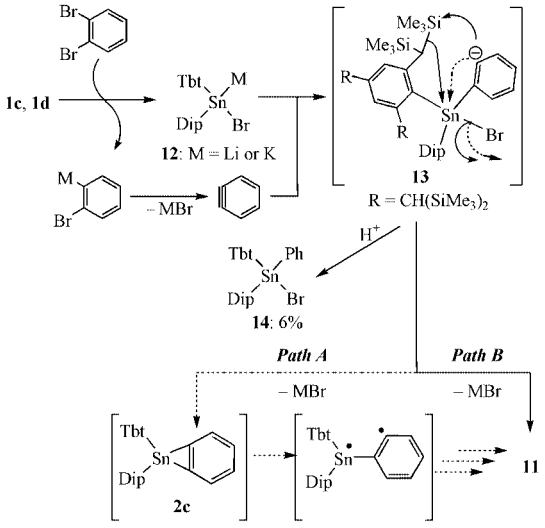
Tbt(Dip)SnMBr (M = Li, K) (**12**) and 1-bromo-2-metallabenzene by the M–Br exchange reaction, and then the resulting **12** adds to benzyne generated from 1-bromo-2-metallabenzene to afford the *o*-stannylated phenyl anion **13**. The intermediacy of **13** in these reactions is strongly supported by the fact that a small amount of Tbt(Dip)SnBr(Ph) (**14**; 6%) was obtained along with **11** (7%) when the reaction mixture was quenched by the addition of water after stirring for 3 h.

For the transformation of the anionic intermediate **13** into the final product **11**, we propose here two possible mechanisms as shown in Scheme 7. In the first mechanism, the intramolecular cyclization of **13** may give stannacyclopropabenzene **2c**, and the subsequent ring-opening reaction of the three-membered ring in **2c** results in the formation of cyclic compound **11** along with the 1,6-migration of a trimethylsilyl group (path A).[19] The other is the direct nucleophilic attack of the anionic center of **13** toward one of the trimethylsilyl groups followed by the ring-closure reaction giving **11** (path B).

In our previous works, there was no evidence of the formation of silicon or germanium analogues of the anionic intermediate **13** under any conditions for the reactions of dilithiosilane or dilithiogermane with *o*-dibromobenzene. In fact, these anionic species were not detected by quenching reactions using D_2O.[9,10] These results suggest that these anionic species of silicon and germanium readily undergo intramolecular cyclization reactions giving metallacyclopropabenzenes, **2a** and **2b**. Thus, the different results among the reactions of **1a**, **1b**, **1c**, and **1d** with *o*-dibromobenzene are most likely interpreted in terms of much lower reactivity of **13** in the intramolecular cyclization to give **2c** than that of the silicon and/or germanium analogues or instability of the strained stannacyclopropene ring of **2c**.

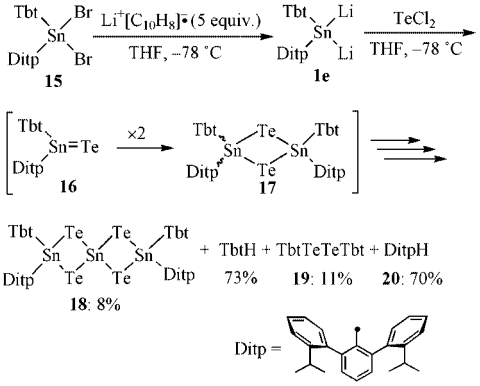
 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 7. Possible formation mechanism for **11**.

On the other hand, it is well known that dilithiosilanes and dilithiogermanes are useful for the preparation of double-bond compounds of heavier group 14 elements.[2] Recently, we reported the synthesis of silanetellone and germanetellone by the reactions of overcrowded dilithiometallanes **1a** and **1b** with tellurium(II) dichloride, respectively.[2g,20] Taking these results into account, the dilithiostannane should be a good precursor for the synthesis of a tin–tellurium double-bond compound **16**.[12] We reported that tin–chalcogen double-bond compounds having Tbt and 2,4,6-triisopropylphenyl (Tip) groups on the tin atom easily underwent self-dimerization, giving 1,3,2,4-dichalcogenastannetanes at room temperature.[13] In order to stabilize a stannanethione and stannanesellone effectively, it was necessary to use a combination of extremely bulky ligands such as 2,2′′-diisopropylphenyl-*m*-terphenyl-2′-yl (Ditp) and the Tbt group.[21] Therefore, we tried the synthesis of stannanetellone having Tbt and Ditp groups.

Interestingly, treatment of a THF solution of Tbt(Ditp)-$SnLi_2$ (**1e**)[22] with tellurium(II) dichloride[23] at –78 °C afforded a unique cyclic compound **18** (8%) along with TbtTeTeTbt (**19**; 11%), DitpH (**20**; 70%), and TbtH (73%), (Scheme 8). Orange crystals of **18** are stable under air for at least several weeks. The ^{119}Sn NMR signals of the cyclic compound, spirobi(ditelluradistannetane) **18**, were observed at δ = –149, –384, and –387 ppm in C_6D_6. The ^{125}Te NMR chemical shift of **18** was observed at δ = 762.9, 765.0, 766.0, and 771.3 ppm in C_6D_6. The molecular structure of **18** was finally determined by X-ray crystallographic analysis (Figure 2). Both ditelluradistannetane rings were found to be nearly planar (the sums of interior bond angles are about 359.99° and 359.91°, respectively). The three tin atoms are situated in a linear alignment (angle of Sn2–Sn1–Sn3: 179.9°). All Sn–Te bond lengths [2.7445(13)–2.7661(13)] Å are in the range reported for 1,3,2,4-ditelluradistannetanes, $[(Dis)_2SnTe]_2$ [Dis = –$CH(SiMe_3)_2$] [2.756(1) and 2.771(1) Å][24a] and $(tBu_2SnTe)_2$ [2.754(1) and 2.758(1) Å].[24b]



Scheme 8. Reaction of **1e** with tellurium(II) dichloride.

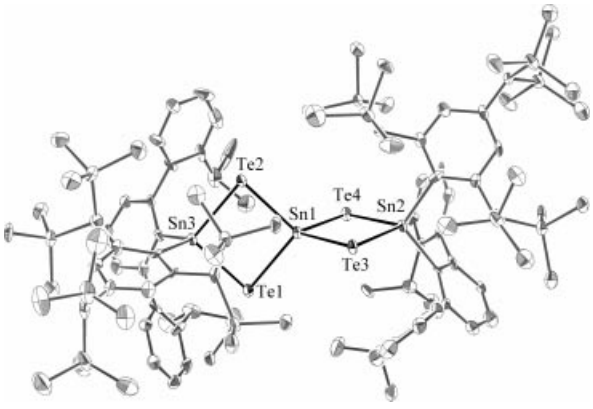


Figure 2. ORTEP drawing of **18**·1.5(toluene) (50% probability). Hydrogen atoms and solvated toluene molecules are omitted for clarity. Tbt and Ditp groups are described with gray lines for clarity. Selected bond lengths [Å] and angles [°]: Sn1–Te1 2.7445(13), Sn1–Te4 2.7526(13), Sn1–Te3 2.7536(13), Sn1–Te2 2.7574(13), Sn2–Te3 2.7577(13), Sn2–Te4 2.7657(13), Te1–Sn3 2.7661(13), Te2–Sn3 2.7627(13), Te4–Sn1–Te3 94.95(4), Te1–Sn1–Te2 95.03(4), Te3–Sn2–Te4 94.56(4), Sn1–Te1–Sn3 85.36(4), Sn1–Te2–Sn3 85.18(4), Te2–Sn3–Te1 94.42(4), Sn1–Te3–Sn2 85.27(4), Sn1–Te4–Sn2 85.13(4).

Although the formation mechanism of **18** is not clear at present, the formation of **18** can be explained in terms of a mechanism similar to the case of the formation of a spirobi(dithiasiletane) in the reaction of a silylene with S_8 through the corresponding silanethione and silanethione dimer.[25] Based on this report, the self-dimerization of stannanetellone **16**, which is generated in the reaction of dilithiostannane **1e** with tellurium(II) dichloride, afforded stannanetellone dimer **17** and the subsequent reactions of **17** result in the formation of cyclic compound **18**. The formation of **18** indicates that some amount of stannanetellone **16** might be generated in the reaction of **1e** with tellurium(II) dichloride; however, on the other hand, it suggests that stannanetellones are much less stable and much more difficult to isolate than the silicon and germanium analogues such as silanetellones and germanetellones and the lighter chalcogen analogues (e.g., stannanethiones and stannanesellones), because of the longer Sn–Te bonds and larger energy gaps between σ- and π-bond energies than those of the lighter element(s) analogues. In order to isolate a stable stannane-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tellone, it is necessary to introduce a much more crowded combination of the protection groups than that in Tbt(Ditp)Sn=Te.

Conclusions

By taking advantage of a bulky substituent, Tbt group, we succeeded in the generation of diaryldimetallastannanes **1c**, **1d**, and **1e** by the exhaustive reduction of overcrowded diaryldibromostannanes **4** and **15**. We found that the reactions of **1c** and **1d** with *o*-dibromobenzene resulted in the formation of an unexpected compound **11** instead of the expected stannacyclopropabenzene **2c**. The reaction of **1e** with tellurium(II) dichloride afforded a novel cyclic compound **18**. As **1c** and **1d** were found to have enough stability in solution at low temperature, further investigation of their synthetic application toward a variety of tin-containing new chemical species is currently in progress.

Experimental Section

General: All experiments were performed under argon unless otherwise noted. THF was dried by standard methods and freshly distilled prior to use. ^{1}H NMR (300 MHz), ^{13}C NMR (75 MHz), ^{119}Sn NMR (111 MHz), and ^{125}Te NMR (94 MHz) spectra were measured in $CDCl_3$ or C_6D_6 with a JEOL JNM AL-300 spectrometer. ^{1}H and ^{13}C NMR chemical shifts were recorded in ppm relative to tetramethylsilane (δ = 0 ppm) and were referenced internally with respect to the residual proton impurity ($CHCl_3$: δ = 7.26 ppm, benzene: δ = 7.15 ppm) and the ^{13}C resonance of the solvent ($CDCl_3$: δ = 77.2 ppm, [D_6]benzene: δ = 128.0 ppm), respectively. ^{119}Sn NMR chemical shifts were referenced with tetramethylstannane (δ = 0 ppm) as an external standard. ^{125}Te NMR chemical shifts were referenced with diphenylditelluride (δ = 450 ppm) as an external standard. Fast atom bombardment (FAB) mass spectrometric data were obtained with a JEOL JMS-700 spectrometer. Mass spectrometric data (EI) were obtained with a Shimadzu QP-5000. Preparative gel permeation liquid chromatography (GPLC) was performed with an LC-918 apparatus (Japan Analytical Industry Co., Ltd.) equipped with JAIGEL 1H and 2H columns (eluent: $CHCl_3$ or toluene). Preparative thin-layer chromatography (PTLC) was performed with Merck Kieselgel 60 PF254. All melting points were determined with a Yanaco micro melting point apparatus and are uncorrected. IR spectra were measured at room temperature with a JASCO FT/IR-460 plus. Elemental analyses were carried out at the Microanalytical Laboratory of the Institute for Chemical Research, Kyoto University. 1-Bromo-2,4,6-tris[bis(trimethylsilyl)-methyl]benzene (TbtBr),[26] 1-bromo-2,6-diisopropylbenzene (DipBr),[27] and 2′-iodo-2,2′′-diisopropyl-1,1′:3′1′′-terphenyl (DitpI)[21] were prepared according to reported procedures.

Tbt(Dip)SnH$_2$ (3): *t*BuLi (2.30 N solution in pentane, 35.2 mL, 81.0 mmol) was added to a solution of TbtBr (22.5 g, 35.6 mmol) in THF (380 mL) at –78 °C. After the reaction mixture was stirred at the same temperature for 30 min, $SnCl_4$ (5.0 mL, 42.7 mmol) and LiCl (34.4 g, 0.81 mol) were added at –78 °C. The mixture was warmed to room temperature, and then the solvents were evaporated. After removal of the insoluble inorganic salts by filtration through Celite®, the reaction mixture was concentrated to give colorless crystals. Recrystallization from CH_3CN/$CHCl_3$ afforded a mixture of TbtSn(Hal)$_3$ (Hal = Cl and/or Br) (16.4 g). A THF solution (50 mL) of DipMgBr (5.78 g, 21.8 mmol), which was prepared by the reaction of Mg (602 mg, 24.8 mmol) and DipBr (5.25 g, 21.8 mmol), was added to a THF solution (100 mL) of the mixture of TbtSn$Cl_{3-n}Br_n$ (n = 0–3) (10.1 g) at room temperature. After the solution was stirred under reflux conditions for 16 h, the reaction mixture was cooled to room temperature. $LiAlH_4$ (6.00 g, 19.5 mmol) was added to the reaction mixture at 0 °C and then the mixture was stirred for 5 h. After quenching by an ice-cold 15% NaOH solution (100 mL) and the subsequent filtration to remove the insoluble inorganic salts, the organic layer was extracted. After extraction with hexane (50 mL), the organic layers were combined, washed with H_2O, and then dried with Na_2SO_4. After the removal of the solvent, the mixture was purified by column chromatography (SiO_2/hexane) to afford Tbt(Dip)SnH_2 (**3**) as colorless crystals. Yield: 4.0 g (33%). M.p. 155.5 °C (dec.). $C_{39}H_{78}Si_6Sn$ (834.26): calcd. C 56.15, H 9.42; found C 56.06, H 9.51. FAB-MS: *m*/*z* calcd. for $C_{39}H_{78}Si_6{}^{120}Sn$ 834 [M$^+$], found 834 [M$^+$]. ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.30 (s, 9 H, $SiMe_3$), 0.32 (s, 36 H, $SiMe_3$), 0.35 (s, 9 H, $SiMe_3$), 1.34 (d, $^3J_{HH}$ = 5.5 Hz, 6 H, CH_3), 1.51 (d, $^3J_{HH}$ = 5.5 Hz, 6 H, CH_3), 1.61 (s, 1 H, *p*-BnH for Tbt), 2.15 (br. s, 1 H, *o*-BnH for Tbt), 2.45 (br. s, 1 H, *o*-BnH for Tbt), 2.91 (sept, $^3J_{HH}$ = 5.5 Hz, 2 H, BnH for Dip), 6.38 (s, $^1J_{^{117}SnH}$ = 1769.4, $^1J_{^{119}SnH}$ = 1855.2 Hz, 2 H, SnH_2), 6.73 (br. s, 1 H, *m*-PhH for Tbt), 6.87 (br. s, 1 H, *m*-PhH for Tbt), 7.14–7.50 (m, 3 H, *m*- and *p*-PhH for Dip) ppm. ^{13}C NMR (75 MHz, C_6D_6, 25 °C): δ = 0.6 (q), 1.0 (q), 1.2 (q), 25.1 (q), 30.6 (d), 33.3 (d), 37.5 (d × 2), 122.1 (d), 123.1 (d), 127.0 (d), 130.1 (d), 135.6 (s), 140.1 (s), 143.9 (s), 151.74 (s), 151.83 (s), 155.4 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, C_6D_6, 25 °C): δ = –345.6 ppm. IR (KBr): $\tilde{\nu}$ = 1863.9 [ν(Sn–H)] cm^{-1}.

Tbt(Dip)SnBr$_2$ (4): A solution of **3** (3.70 g, 4.43 mmol) and Br_2 (0.50 mL, 9.76 mmol) in Et_2O (130 mL) was stirred at room temperature for 2 h. The solution was washed with an aqueous solution of NaOH and then with a saturated aqueous solution of NaCl. The organic layer was dried with Na_2SO_4. After the removal of the solvent, the residue was recrystallized from $CHCl_3$ and EtOH to afford **4** as colorless crystals. Yield: 2.98 g (68%). M.p. 188.4–192.5 °C. $C_{39}H_{76}Br_2Si_6Sn$ (992.05): calcd. C 47.22, H 7.72; found C 47.24, H 7.82. FAB-MS: *m*/*z* calcd. for $C_{39}H_{76}{}^{79}Br_2Si_6{}^{120}Sn$ 992 [M$^+$], found 992 [M$^+$]. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.03 (s, 36 H, $SiMe_3$), 0.05 (s, 18 H, $SiMe_3$), 1.16 (s, 1 H, *p*-BnH for Tbt), 1.33 (d, $^3J_{HH}$ = 6.6 Hz, 12 H, CH_3), 2.13 (br. s, 1 H, *o*-BnH for Tbt), 2.43 (br. s, 1 H, *o*-BnH for Tbt), 3.36 (sept, $^3J_{HH}$ = 6.6 Hz, 2 H, BnH for Dip), 6.37 (br. s, 1 H, *m*-PhH for Tbt), 6.47 (br. s, 1 H, *m*-PhH for Tbt), 7.20–7.42 (m, 3 H, *m*- and *p*-PhH for Dip) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 25 °C): δ = 1.2 (q), 1.8 (q), 2.0 (q), 26.4 (q), 31.1 (d), 31.8 (d), 37.4 (d × 2), 123.6 (d), 125.4 (d), 128.4 (d), 131.6 (d), 133.7 (s), 137.5 (s), 143.8 (s), 146.7 (s), 151.0 (s), 154.5 (s) ppm. ^{119}Sn NMR (111 MHz, $CDCl_3$, 25 °C): δ = –171.0 ppm.

Generation of Tbt(Dip)SnM$_2$ (M = Li, K) and Preparation of Tbt(Dip)SnMe$_2$ (5). Method A (M = Li): Lithium naphthalenide (2.33 N solution in THF, 0.14 mL, 0.33 mmol, 5 molar amounts) was added to a THF solution (1.0 mL) of **4** (62.4 mg, 62.9 μmol) at –78 °C. The reaction mixture was stirred at the same temperature for 1 h, and then an excess amount of MeI (0.1 mL, 1.6 mmol) was added to the reaction mixture. After the removal of the solvent, the residue was extracted with hexane several times. Insoluble inorganic salts were removed by filtration through Celite®. The residue was subjected to GPLC ($CHCl_3$) followed by PTLC (hexane) to afford **5** as colorless crystals. Yield: 52.7 mg (97%). **Method B (M = K):** KC_8 (98.0 mg, 0.72 mmol) was added to a THF solution (1.0 mL) of **4** (68.0 mg, 68.5 μmol) at –110 °C. The reaction mixture was stirred vigorously at the same temperature for 1 h, and

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

then an excess of MeI (0.1 mL, 1.6 mmol) was added to the mixture. A similar workup procedure mentioned above afforded **5** as colorless crystals. Yield: 63.5 mg (93%). M.p. 167.9–174.3 °C. $C_{41}H_{82}Si_6Sn$ (862.31): calcd. C 57.11, H 9.58; found C 56.96, H 9.59. FAB-MS: *m*/*z* calcd. for $C_{41}H_{82}Si_6{}^{120}Sn$ 863 [M$^+$], found 863 [M$^+$]. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = –0.05 (s, 18 H, $SiMe_3$), –0.01 (s, 18 H, $SiMe_3$), 0.02 (s, 18 H, $SiMe_3$), 0.64 (s, $^2J_{HSn}$ = 48.3 Hz, 6 H, SnMe), 1.23 (d, $^3J_{HH}$ = 5.5 Hz, 12 H, CH_3), 1.31 (s, 1 H, *p*-BnH for Tbt), 1.68 (br. s, 1 H, *o*-BnH for Tbt), 1.84 (br. s, 1 H, *o*-BnH for Tbt), 2.99 (sept, $^3J_{HH}$ = 5.5 Hz, 2 H, BnH for Dip), 6.25 (br. s, 1 H, *m*-PhH for Tbt), 6.38 (br. s, 1 H, *m*-PhH for Tbt), 7.18–7.40 (m, 3 H, *m*- and *p*-PhH for Dip) ppm. ^{13}C NMR (75 MHz, C_6D_6, 25 °C): δ = 0.9 (q), 1.2 (q), 1.5 (q), 3.7 (q), 26.0 (q), 30.0 (d), 30.7 (d), 30.9 (d), 36.5 (d), 122.1 (d), 123.1 (d), 127.0 (d), 128.9 (d), 131.8 (s), 137.2 (s), 143.0 (s), 143.9 (s), 151.3 (s), 155.4 (s) ppm. ^{119}Sn NMR (111 MHz, $CDCl_3$, 25 °C): δ = –126.4 ppm.

Generation of Tbt(Dip)SnLi$_2$ and the Trapping Reaction with DCl: Lithium naphthalenide (1.26 N solution in THF, 0.22 mL, 0.28 mmol, 5 molar amounts) was added to a THF solution (1.0 mL) of **4** (58.6 mg, 59.1 μmol) at –78 °C. The reaction mixture was stirred at the same temperature for 1 h. After stirring for 30 min, DCl (1.0 N solution in Et_2O, 75 μL) was added to the reaction mixture. After the removal of the solvent, the mixture was extracted with hexane several times. The extracts were combined, filtered through Celite®, and the solvents evaporated. The residue was subjected to GPLC (toluene) to give Tbt(Dip)SnD_2 (**3a**) as colorless crystals. Yield: 47.5 mg [96% (deuterium content: 93%)]. M.p. 154.8 °C (dec.). High-resolution FAB-MS: *m*/*z* calcd. for $C_{39}H_{76}D_2Si_6{}^{120}Sn$ 836.3865 [M$^+$], found 836.3894 [M$^+$]. ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.30 (s, 9 H, $SiMe_3$), 0.32 (s, 36 H, $SiMe_3$), 0.35 (s, 9 H, $SiMe_3$), 1.34 (d, $^3J_{HH}$ = 5.5 Hz, 6 H, CH_3), 1.51 (d, $^3J_{HH}$ = 5.5 Hz, 6 H, CH_3), 1.61 (s, 1 H, *p*-BnH for Tbt), 2.15 (br. s, 1 H, *o*-BnH for Tbt), 2.45 (br. s, 1 H, *o*-BnH for Tbt), 2.91 (sept, $^3J_{HH}$ = 5.5 Hz, 2 H, BnH for Dip), 6.73 (br. s, 1 H, *m*-PhH for Tbt), 6.87 (br. s, 1 H, *m*-PhH for Tbt), 7.14–7.50 (m, 3 H, *m*- and *p*-PhH for Dip) ppm. ^{13}C NMR (75 MHz, C_6D_6, 25 °C): δ = 0.6 (q), 1.0 (q), 1.2 (q), 25.1 (q), 30.6 (d), 33.3 (d), 37.5 (d × 2), 122.1 (d), 123.1 (d), 127.0 (d), 130.1 (d), 135.6 (s), 140.1 (s), 143.9 (s), 151.74 (s), 151.83 (s), 155.4 (s) ppm. ^{119}Sn NMR (111 MHz, C_6D_6, 25 °C): δ = –346.8 (quint, $^1J_{SnD}$ = 280.7 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 1317.1 [ν(Sn–D)] cm^{-1}.

Generation of Tbt(Dip)SnLi$_2$ (1c) and the Trapping Reaction of the Decomposed Compounds with 2,3-Dimethyl-1,3-butadiene and MeI: Lithium naphthalenide (1.03 N solution in THF, 0.25 mL, 0.26 mmol, 5 molar amounts) was added to a THF solution (1.0 mL) of **4** (50.2 mg, 50.0 μmol) at –78 °C. The reaction mixture was stirred at the same temperature for 1 h. After additional stirring at room temperature for 30 min, 2,3-dimethyl-1,3-butadiene (0.1 mL, 82.0 μmol) was added. After stirring for 30 min, an excess of MeI (0.1 mL, 1.6 mmol) was added to the reaction mixture. After the removal of the solvent, hexane was added to the residue. Insoluble inorganic salts were removed by filtration through Celite® and the filtrate was concentrated. The residue was subjected to GPLC ($CHCl_3$) followed by PTLC (hexane) to give TbtH (14.7 mg, 53%) and **9** (20.4 mg, 45%). M.p. 164.2–166.4 °C. FAB-MS: *m*/*z* calcd. for $C_{45}H_{87}Si_6{}^{120}Sn$ 915 [M + H]$^+$, found 915 [M + H]$^+$. High-resolution FAB-MS: *m*/*z* calcd. for $C_{45}H_{87}Si_6{}^{120}Sn$ 915.4445 [M + H]$^+$, found 915.4456 [M + H]$^+$. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = –0.05 (br. s, 18 H, $SiMe_3$), –0.24 (br. s, 18 H, $SiMe_3$), 0.03 (s, 18 H, $SiMe_3$), 1.19 (d, $^3J_{HH}$ = 6.6 Hz, 9 H, CH_3 for Dip), 1.19 (br. s, 1 H, *p*-BnH for Tbt), 1.28 (d, $^3J_{HH}$ = 6.6 Hz, 3 H, CH_3 for Dip), 1.68 (s, 1 H, *o*-BnH for Tbt), 1.74 (br. s, 6 H, CH_3), 1.79 (s, 1 H, *o*-BnH for Tbt), 2.09 (d, ^2J = 17.0 Hz, 2 H, CH_2), 2.14 (d, ^4J = 17.0 Hz, 2 H, CH_2), 3.02 (sept, $^3J_{HH}$ = 6.6 Hz, 1 H, BnH for Dip), 3.12 (sept, $^3J_{HH}$ = 6.6 Hz, 1 H, BnH for Dip), 6.27 (br. s, 1 H, *m*-PhH for Tbt), 6.41 (s, 1 H, *m*-PhH for Tbt), 7.12 (d, $^3J_{HH}$ = 7.5 Hz, 2 H, *m*-PhH for Dip), 7.23 (t, $^3J_{HH}$ = 7.5 Hz, 1 H, *p*-PhH for Dip) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 25 °C): δ = 0.8 (q), 1.1 (q), 1.3 (q), 21.4 (q), 24.9 (q), 25.8 (q), 30.1 (d), 31.1 (d), 31.5 (d × 2), 32.6 (t), 37.9 (d), 122.0 (d), 123.1 (d), 124.6 (d), 128.9 (d), 131.7 (s), 137.7 (s), 141.2 (s), 142.9 (s), 145.7 (s), 151.2 (s), 154.7 (s) ppm. ^{119}Sn NMR (111 MHz, $CDCl_3$, 25 °C): δ = –110.2 ppm.

Generation of Tbt(Dip)SnK$_2$ and the Trapping Reaction of the Decomposed Compounds with H$_2$O at Room Temperature: KC_8 (129 mg, 0.95 mmol) was added to a THF solution (1.5 mL) of **4** (101 mg, 0.10 mmol) at –110 °C. The reaction mixture was stirred vigorously at the same temperature for 1 h, and then warmed to room temperature. After additional stirring at the same temperature for 1 h, the reaction mixture was exposed to air. After the removal of the solvent, the mixture was extracted with hexane several times. Insoluble inorganic salts were removed by filtration through Celite® and the filtrate was concentrated. The residue was subjected to GPLC ($CHCl_3$) followed by PTLC (hexane) to give TbtH (12.1 mg, 20%), **10** (39.7 mg, 72%), and DipH (14.1 mg, 80%).[17]

Stannacyclobutabenzene (11). Method A: Lithium naphthalenide (1.56 N solution in THF, 0.67 mL, 5 molar amounts) was added to a THF solution (5.0 mL) of **4** (205 mg, 0.21 mmol) at –78 °C. After stirring at the same temperature for 1 h, *o*-dibromobenzene (25 μL, 0.21 mmol) was added to the reaction mixture. The solution was slowly warmed to room temperature over 10 h. After the removal of the solvent, hexane was added to the residue. Insoluble inorganic salts were removed by filtration through Celite® and the filtrate was concentrated. The residue was subjected to GPLC ($CHCl_3$) followed by PTLC (hexane) to give **11** as colorless crystals. Yield: 30.1 mg (16%). **Method B:** KC_8 (150 mg, 1.11 mmol) was added to a THF solution (3.0 mL) of Tbt(Dip)$SnBr_2$ (**4**) (170 mg, 0.17 mmol) at –78 °C. After stirring at the same temperature for 1 h, *o*-dibromobenzene (25 μL, 0.21 mmol) was added to the reaction mixture. The solution was slowly warmed to room temperature over 10 h, and **11** was separated and purified by a procedure similar to that described above. Yield: 40.1 mg (26%). M.p. 99.4 °C (dec.). $C_{45}H_{80}Si_6Sn$ (908.34): calcd. C 59.50, H 8.88; found C 59.53, H 8.63. FAB-MS: *m*/*z* calcd. for $C_{45}H_{80}Si_6{}^{120}Sn$ 908 [M$^+$], found 908 [M$^+$]. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = –0.26 (s, 9 H, $SiMe_3$), –0.16 (s, 9 H, $SiMe_3$), 0.02 (s, 9 H, $SiMe_3$), 0.04 (s, 9 H, $SiMe_3$), 0.15 (s, 9 H, $SiMe_3$), 0.17 (s, 9 H, $SiMe_3$), 0.86 (br. s, 6 H, Me), 1.24 (br. s, 6 H, Me), 1.34 (s, 1 H, BnH), 1.57 (s, 1 H, BnH), 2.94 (s, $^2J_{HSn}$ = 64 Hz, 1 H, BnH), 3.29 (br. s, 2 H, BnH for Dip), 6.39 (br. s, 1 H, *m*-PhH for Tbt), 6.45 (s, 1 H, *m*-PhH for Tbt), 7.07 (d, $^3J_{HH}$ = 7.2 Hz, 2 H, *m*-PhH for Dip), 7.20–7.27 (m, 2 H, PhH), 7.30 (t, $^3J_{HH}$ = 7.2 Hz, 1 H, *p*-PhH for Dip), 7.60 (dd, $^3J_{HH}$ = 7.2, $^4J_{HH}$ = 2.1 Hz, 1 H, PhH), 7.93 (dd, $^3J_{HH}$ = 7.2, $^4J_{HH}$ = 2.1 Hz, 1 H, PhH) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 50 °C): δ = 0.2 (q), 0.39 (q), 0.44 (q), 0.5 (q), 0.6(q), 1.1 (q), 24.9 (br. q), 30.2 (d), 30.4 (d), 37.1 (d), 39.7 (d), 121.8 (br. d), 123.2 (d), 123.4 (d), 127.5 (d), 128.0 (d), 129.5 (d), 135.8 (d), 138.0 (d), 143.9 (s), 145.0 (s), 145.1 (s), 147.5 (s), 147.7 (s), 154.6 (s), 155.0 (s), 155.8 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, $CDCl_3$, 25 °C): δ = –83.4 ppm.

Tbt(Dip)Sn(Ph)Br (14): Lithium naphthalenide (1.30 N solution in THF, 1.87 mL, 5 molar amounts) was added to a THF solution (10 mL) of **4** (479 mg, 0.48 mmol) at –78 °C. After stirring at the same temperature for 1 h, *o*-dibromobenzene (65 μL, 0.54 mmol)

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

was added to the reaction mixture. The solution was stirred for 3 h, and then the mixture was separated by the procedure similar to that described above to afford **11** (29.0 mg, 7%) and **14** (29.6 mg, 6%). M.p. 155.8 °C (dec.). FAB-MS: *m*/*z* calcd. for $C_{45}H_{81}{}^{79}BrSi_6{}^{120}Sn$ 988 [M$^+$], found 988 [M$^+$]. High-resolution FAB-MS: *m*/*z* calcd. for $C_{45}H_{81}{}^{79}BrSi_6{}^{120}Sn$ 988.3159 [M$^+$], found 988.3193 [M$^+$]. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = –0.16 (s, 27 H, $SiMe_3$), –0.13 (s, 9 H, $SiMe_3$), –0.07 (s, 9 H, $SiMe_3$), –0.06 (s, 9 H, $SiMe_3$), 0.83 (d, $^3J_{HH}$ = 6.3 Hz, 6 H, Me), 1.20 (d, $^3J_{HH}$ = 6.3 Hz, 6 H, Me), 1.23 (s, 1 H, *p*-BnH for Tbt), 1.97 (br. s, 1 H, *o*-BnH for Tbt), 2.02 (br. s, 1 H, *o*-BnH for Tbt), 3.18 (sept, $^3J_{HH}$ = 6.3 Hz, 2 H, BnH for Dip), 6.24 (br. s, 1 H, *m*-PhH for Tbt), 6.36 (br. s, 1 H, *m*-PhH for Tbt), 7.05–7.13 (m, 2 H, PhH), 7.20–7.28 (m, 4 H, PhH), 7.59–7.82 (m, 2 H, PhH) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 25 °C): δ = 0.8 (q), 1.0 (q), 1.7 (q), 1.9 (q), 24.3 (q), 27.2 (q), 30.5 (d), 31.1 (d), 31.5 (d), 36.8 (d), 122.9 (d), 124.6 (d), 127.2 (d), 128.3 (d), 129.2 (d), 130.3 (d), 136.5 (d), 138.4 (s), 140.2 (s), 144.9 (s), 147.0 (s), 151.2 (s), 154.6 (s), 155.2 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, $CDCl_3$, 25 °C): δ = –102.2 ppm.

Synthesis of Tbt(Ditp)SnH$_2$: A THF solution (20 mL) of $TbtSn(Hal)_3$ (2.31 g) was added to a THF solution of DitpLi, prepared from DitpI (1.49 g, 3.37 mmol) and *t*BuLi (2.32 M in pentane, 3.2 mL, 7.41 mmol) at –78 °C in THF (20 mL), at –78 °C, and then the mixture was stirred at room temperature for 2 h. After the removal of the solvent, hexane was added to the residue. Insoluble inorganic salts were removed by filtration through Celite®. The filtrate was concentrated and subjected to GPLC ($CHCl_3$) to afford a mixture containing $Tbt(Ditp)Sn(Hal)_2$ (1.48 g) as colorless crystals. $LiAlH_4$ (734 mg, 19.3 mmol) was added to a THF solution (50 mL) of the mixture containing $Tbt(Ditp)Sn(Hal)_2$ (1.28 g) at 0 °C. The mixture was stirred at room temperature for 3 h. After quenching by an ice-cold 15% NaOH solution (30 mL) and subsequent filtration to remove the insoluble inorganic salts, the organic layer was extracted. After extraction with hexane (50 mL), the organic layers were combined, and washed with H_2O, and then dried with Na_2SO_4. After removal of the solvents, the mixture was purified by column chromatography (SiO_2/benzene) to afford $Tbt(Ditp)SnH_2$ as colorless crystals. Yield 962 mg (29%). M.p. 155.5 °C (dec.). FAB-MS: *m*/*z* calcd. for $C_{51}H_{87}Si_6{}^{118}Sn$ 985 [M + H]$^+$, found 985 [M + H]$^+$. ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.09 (s, 36 H, $SiMe_3$), 0.20 (s, 18 H, $SiMe_3$), 0.95 (d, $^3J_{HH}$ = 5.1 Hz, 6 H, Me), 1.40 (d, $^3J_{HH}$ = 5.1 Hz, 6 H, Me), 1.43 (s, 1 H, *p*-BnH for Tbt), 1.71 (br. s, 1 H, *o*-BnH for Tbt), 1.85 (br. s, 1 H, *o*-BnH for Tbt), 3.01 (sept, $^3J_{HH}$ = 5.1 Hz, 2 H, BnH for Ditp), 5.66 (s, $^1J_{^{117}SnH}$ = 1768.6, $^1J_{^{119}SnH}$ = 1851.7 Hz, 2 H, SnH), 6.41 (br. s, 1 H, *m*-PhH for Tbt), 6.53 (br. s, 1 H, *m*-PhH for Tbt), 7.09–7.26 (m, 9 H, ArH for Ditp), 7.52 (d, $^3J_{HH}$ = 6.6 Hz, 2 H, ArH for Ditp) ppm. ^{13}C NMR (75 MHz, C_6D_6, 25 °C): δ = 1.1 (q), 1.7 (q), 22.4 (q), 24.8 (q), 30.2 (d), 30.4 (d), 32.4 (d × 2), 122.5 (d), 125.4 (d), 125.7 (d), 126.2 (d), 128.9 (d), 129.4 (d), 129.7 (d), 135.3 (d), 139.0 (s), 141.2 (s), 143.2 (s), 143.7 (s) 147.2 (s), 149.8 (s), 151.2 (s) 151.3 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, C_6D_6, 25 °C): δ = –342.9 ppm. IR (KBr): $\tilde{\nu}$ = 1841.7 [ν(Sn–H)] cm^{-1}.

Synthesis of Tbt(Ditp)SnBr$_2$ (15): A solution of $Tbt(Ditp)SnH_2$ (734 mg, 0.74 mmol) and Br_2 (0.21 mL, 0.84 mmol) in Et_2O (40 mL) was stirred at room temperature for 30 min. The solution was washed with a saturated aqueous solution of Na_2SO_3 and then with a saturated aqueous solution of NaCl. The organic layer was dried with Na_2SO_4. After the removal of the solvent, the residue was recrystallized from $CHCl_3$ and EtOH to afford **15** as colorless crystals. Yield: 621 mg (73%). M.p. 278.5–279.6 °C. $C_{51}H_{84}Br_2Si_6Sn$ (1144.24): calcd. C 53.53, H 7.40; found C 53.52, H 7.46. FAB-MS: *m*/*z* calcd. for $C_{51}H_{84}{}^{79}Br_2Si_6{}^{120}Sn$ 1144 [M$^+$], found 1144 [M$^+$]. ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.19 (br. s, 36 H, $SiMe_3$), 0.21 (br. s, 18 H, $SiMe_3$), 1.03 (d, $^3J_{HH}$ = 6.3 Hz, 6 H, Me), 1.39 (d, $^3J_{HH}$ = 6.3 Hz, 6 H, Me), 1.51 (br. s, 1 H, *p*-BnH for Tbt), 1.80 (br. s, 1 H, *o*-BnH for Tbt), 2.82 (br. s, 1 H, *o*-BnH for Tbt), 2.96 (sept, $^3J_{HH}$ = 6.3 Hz, 2 H, BnH for Ditp), 6.37–6.75 (m, 2 H, *m*-PhH for Tbt), 7.01–7.35 (m, 9 H, ArH for Ditp), 7.45 (d, $^3J_{HH}$ = 7.2 Hz, 2 H, ArH for Ditp) ppm. ^{13}C NMR (75 MHz, C_6D_6, 25 °C): δ = 0.6 (q), 1.9 (q), 2.4 (q), 2.6 (q), 23.2 (q), 25.2 (q), 30.0 (d), 31.1 (d), 32.8 (d), 33.1 (d), 123.4 (d), 123.9 (d), 126.3 (d), 126.9 (d), 128.8 (d), 129.4 (d), 129.7 (d), 135.3 (d), 141.1 (s × 2), 142.9 (s), 146.1 (s), 146.4 (s) 147.7 (s), 148.8 (s), 153.5 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, $CDCl_3$, 25 °C): δ = –192.5 ppm.

Generation of Tbt(Ditp)SnLi$_2$ and Preparation of Tbt(Ditp)SnMe$_2$: Lithium naphthalenide (1.30 N solution in THF, 0.15 mL, 0.20 mmol, 5 molar amounts) was added to a THF solution (1.0 mL) of **15** (45.6 mg, 39.8 μmol) at –78 °C. The reaction mixture was stirred at the same temperature for 1 h, and then MeI (0.1 mL, 1.6 mmol) was added to the reaction mixture. After the removal of the solvent, hexane was added to the residue. Insoluble inorganic salts were removed by filtration through Celite®. The filtrate was concentrated and subjected to GPLC ($CHCl_3$) followed by PTLC (hexane) to afford $Tbt(Ditp)SnMe_2$ as colorless crystals. Yield: 38.1 mg (93%). M.p. 265.3–265.7 °C. $C_{53}H_{90}Si_6Sn$ (1014.50): calcd. C 62.75, H 8.94; found C 62.67, H 9.05. High-resolution FAB-MS: *m*/*z* calcd. for $C_{53}H_{90}Si_6{}^{120}Sn$ 1014.4680 [M$^+$], found 1014.4697 [M$^+$]. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = –0.45 (s, $^2J_{HSn}$ = 51.0 Hz, 6 H, SnMe), –0.04 (br. s, 36 H, $SiMe_3$), –0.09 (s, 18 H, $SiMe_3$), 1.04 (d, $^3J_{HH}$ = 6.6 Hz, 6 H, Me), 1.15 (d, $^3J_{HH}$ = 6.6 Hz, 6 H, Me), 1.27 (s, 1 H, *p*-BnH for Tbt), 1.32 (br. s, 2 H, *o*-BnH for Tbt), 2.71 (sept, $^3J_{HH}$ = 6.6 Hz, 2 H, BnH for Ditp), 6.25 (br. s, 1 H, *m*-PhH for Tbt), 6.40 (br. s, 1 H, *m*-PhH for Tbt), 6.98 (t, $^3J_{HH}$ = 7.2 Hz, 1 H, PhH for Ditp), 7.13 (d, $^3J_{HH}$ = 7.2 Hz, 2 H, PhH for Ditp), 7.21–7.39 (m, 8 H, PhH for Ditp) ppm. ^{13}C NMR (75 MHz, $CDCl_3$, 25 °C): δ = –0.4 (q, $^1J_{^{117}SnC}$ = 339.6, $^1J_{^{119}SnC}$ = 346.0 Hz), 1.0 (q), 1.9 (q), 2.2 (q), 22.8 (q), 24.9 (q), 29.2 (d × 2), 29.8 (d), 31.1 (d), 121.9 (d), 122.5 (d), 125.4 (d), 125.8 (d), 126.8 (d), 127.7 (d), 128.9 (d), 130.0 (d, $^3J_{SnC}$ = 37.7 Hz), 140.1 (s), 142.3 (s), 143.1 (s), 143.7 (s), 147.3 (s), 148.2 (s), 150.3 (s), 150.7 (s) ppm. ^{119}Sn{^{1}H} NMR (111 MHz, $CDCl_3$, 25 °C): δ = –114.9 ppm.

Reaction of Tbt(Ditp)SnLi$_2$ (1e) with Tellurium(II) Dichloride: Lithium naphthalenide (1.24 N solution in THF, 0.38 mL, 0.47 mmol, 5 molar amounts) was added to a THF solution (1.0 mL) of **15** (108 mg, 94.0 μmol) at –78 °C. After stirring at the same temperature for 1 h, tellurium(II) dichloride (20.2 mg, 101 μmol) was added to the reaction mixture. The solution was slowly warmed to room temperature over 10 h. After the removal of the solvent, hexane was added to the residue. Insoluble inorganic salts were removed by filtration through Celite® and the solvents evaporated. The residue was subjected to GPLC (toluene) to give TbtH (37.8 mg, 73%), **18** (19.6 mg, 8%), **19** (20.2 mg, 11%), and **20** (20.6 mg, 70%). **18:** Orange crystals. NMR Measurement of Tbt(Dip)SnLi$_2$ (1c): Lithium naphthalenide (1.33 N THF solution, 0.38 mL, 0.51 mmol) was added to a THF solution (0.5 mL) of **4** (99.2 mg, 0.1 mmol) at –78 °C in a 5-mm NMR glass tube. After it was sealed and the reaction mixture kept at –78 °C for 30 min, the ^{119}Sn NMR of this solution was measured at –80 °C.

X-ray Crystallography: Single crystals of **11** and **18**·1.5(toluene) were grown by the slow concentration of their saturated solutions in acetone and toluene, respectively, at room temperature. The sample preparation consisted of coating the crystal with hydrocarbon oil, mounting it on a glass fiber, and placing it under a cold stream of N_2 on the diffractometer. The intensity data of **11** and **18**·1.5(toluene) were collected with a Rigaku/MSC Mercury CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71071 Å) to $2\theta_{max}$ = 50° at 103 K (Table 1). All structures were solved by Patterson methods (DIRDIF)[28] and refined by full-matrix least-squares procedures on F^2 for all reflections (SHELXL-97).[29] All hydrogen atoms except for 0.5(toluene) of **18**·1.5(toluene) were placed using AFIX instructions; hydrogen atoms of 0.5(toluene) were not placed. All the other atoms were refined anisotropically. In the case of **18**·1.5(toluene), the over-

lapped and disordered toluene molecules were restrained to be identical to each other using DFIX, SADI, SAME, and SIMU instructions. The *ipso*-carbon atom of the Ditp group was restrained using ISOR instruction. The residual electron densities of **18**·1.5(toluene) that are larger than 1.0 can be assigned to the heavy elements (Si, Sn, and Te atoms) of a minor disordered molecule (about 2%). However, the peaks for the carbon atoms of the disordered molecule could not be found. CCDC-265559 (**11**) and -276174 [**18**·1.5(toluene)] contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

[14] It is well known that ^{119}Sn NMR chemical shifts of halostannanes are extremely sensitive towards solvent influence, concentration, and sometimes temperature. However, such a drastic change was not observed in the case of **4** (δ = –166.0 to –165.6 ppm: 0.11 to 2.8×10^{-2} M THF solution at 25 °C; δ = –162.0 ppm: 0.11 M THF solution at –80 °C). Dibromostannane **4** is considered to exist as a monomer in solution, probably because bulky Tbt and Dip groups prevent the intermolecular coordination of the halogen atoms to the tin atom constructing halogen-bridged structures.[15]

Keywords: Luminescence / N ligands / Sensors / Zinc

The synthesis, protonation behaviour and Zn^{2+} coordination chemistry of a new photoactive polyamine exhibiting "off-on-off" fluorescence is presented. Addition of Zn^{2+} reduces the width of the fluorescence window, which is centred around physiological pH, and sharply enhances the emission intensity.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The concept of pH windows leading to "off-on-off" fluorescence was discussed by A. P. de Silva and co-workers a few years ago.[1] Their basic idea consisted of the connection of an amine to a fluorophoric anthracene unit on one side and to a pyridine moiety on the other. At acidic pH values the amino and the pyridine groups are protonated and a photoinduced electron transfer (PET) occurs from the π-π* excited state of the anthracene to the protonated pyridinium unit, leading to quenching of the fluorescence. However, at high pH values, where the amino group is not protonated, PET alternatively takes place from the amine lone pair to the same excited state of the fluorophore, yielding the same inhibitory effect on the fluorescence. Between these two pH values, there is a pH window where PET does not take place and fluorescence emission is observed. Based on this idea, A. P. de Silva et al. have developed several related "off-on-off" fluorescent systems combining anthracene, pyridine and amino groups.[2,3] On the same lines, S. A. de Silva et al. have reported a system containing two pyridine units and one anthracene fluorophore, all of them connected to a tertiary nitrogen through methylenic groups, that is able to display on-off-on behaviour in the presence of Zn^{2+} in methanol/water.[4] Fabbrizzi et al.[5] have also reported a related tweezer that has anthracene and a two-amine, two-pyridine system which displays off-on-off fluorescent behaviour in water/acetonitrile both when free and when coordinated to Zn^{2+}. More recently, S. A. de Silva has shown the influence of sodium and protons on the on-off-on behaviour of a system built up by a 15-membered crown ether, anthracene and anabasine in methanol. The on state is only achieved when the system is monoprotonated in the presence of Na^+.[6]

In this paper, we present a tweezer system that works in water and exhibits an optimised pH window. With this purpose, we have prepared a compound consisting of a triamine chain functionalised at both of its termini with 4-picolyl units and at its central nitrogen with a methylnaphthyl fragment (L, Scheme 1). The binding of metal ions like

Zn^{2+} to the polyamine chain can give rise to metal complexes that are able to present fluorescence pH windows with improved "off-on-off" performance and a narrower pH range. In addition, Zn^{2+} is a very interesting metal ion from a biochemical point of view due to its presence in the active site of many hydrolytic enzymes and its involvement in processes that take place in the central nervous system.[7–13] Thus, the ability to sense Zn^{2+} at physiological pH is an attractive goal. As the characteristics of the system reported here make it a promising candidate in this respect, we have explored this possibility.

Results and Discussion

Synthesis

L was synthesised in a four-step procedure (Scheme 2) that includes: i) protection of N^1-(2-aminoethyl)ethane-1,2-diamine with phthalate groups to avoid the alkylation of the secondary amino groups,[14] ii) alkylation of the central nitrogen by nucleophilic attack with (bromomethyl)naphthalene,[12–16] iii) deprotection of the phthalate groups with hydrazine in ethanol to give the free alkylated polyamine, which precipitated as its hydrochloride salt, and iv) condensation of the polyamine with 4-pyridinecarbaldehyde in a 1:2 ratio to obtain the imine of L, which was reduced in situ with $NaBH_4$. Finally, L was precipitated as its hydrochloride salt by addition of aqueous HCl to an ethanolic solution of L.

Protonation Behaviour

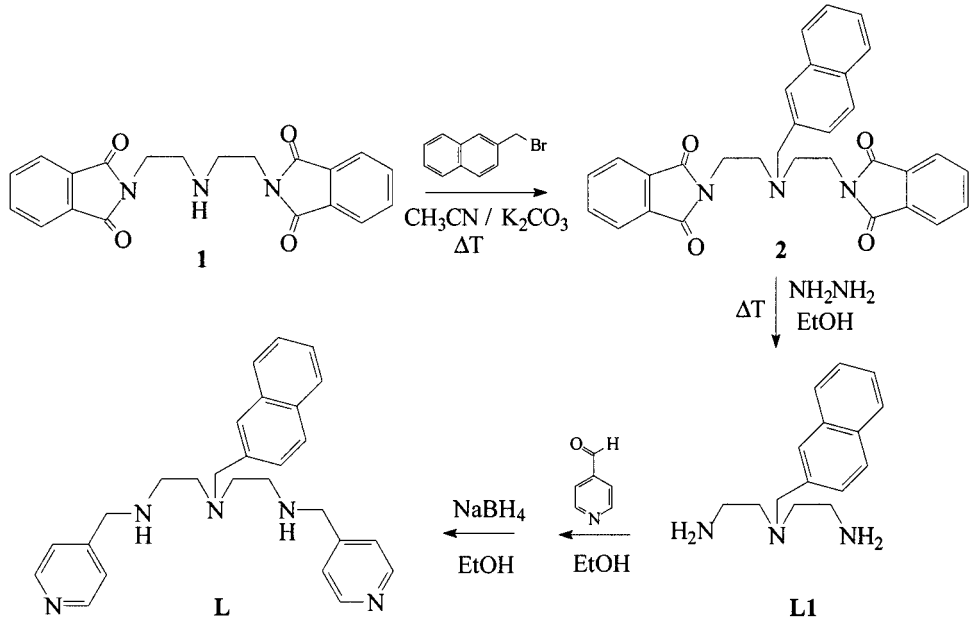
The protonation constants of tweezer L at 298.1 ± 0.1 K in 0.15 M NaCl by pH-metric titration, determined using the program HYPERQUAD,[17] are shown in Table 1. There are several points of interest to be noted. First, the number of protonation constants found (five) indicates that all the protonable groups in the compound undergo protonation in the pH range of study. As discussed below, the first two protonation processes, which mainly affect the secondary amino groups, are rather low in comparison with saturated triamines like 1,4,7-triazaheptane (dien)[18] or with respect to analogous polyamines functionalised with benzene rings at both of their termini instead of pyridine.[19] This detrimental effect on the basicity can be ascribed to the electron-withdrawing characteristics of pyridine, which cause the adjacent nitrogen atoms to be less negatively charged. On the other hand, it is well-known that tertiary nitrogen atoms are less basic in water than secondary ones due to solvation effects.[20] Therefore, the presence of the methylnaphthyl group at the central nitrogen also contributes to the low overall basicity displayed by L.

Table 1. Protonation constants of L determined in 0.15 M NaCl at 298.1 ± 0.1 K.

Reaction	pK_a
$H^+ + L \rightleftharpoons [HL]^+$	8.33(1)[a]
$[HL]^+ + H^+ \rightleftharpoons [H_2L]^{2+}$	7.06(1)
$[H_2L]^{2+} + H^+ \rightleftharpoons [H_3L]^{3+}$	4.41(1)
$[H_3L]^{3+} + H^+ \rightleftharpoons [H_4L]^{4+}$	3.37(1)
$[H_4L]^{4+} + H^+ \rightleftharpoons [H_5L]^{5+}$	2.14(1)
log β	25.31

[a] Values in parentheses are standard deviations in the last significant figure.

The pH-dependent absorption spectra of compound L are presented in Figure 1A. The two contributions from the pyridine and naphthalene chromophores can easily be detected: the pyridine shows an absorption band at around



Scheme 2. Synthetic pathway to L.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

255 nm whose intensity increases upon protonation, whereas the naphthalene contribution is pH independent and appears as a maximum at approximately 275 nm. Observation of Figure 1A shows that there is little broadening (or extended tail) of the naphthalene absorption (above 300 nm). This presumably suggests little formation (but not absence) of a pre-formed charge-transfer complex (CT complex, also commonly know as an electron donor–acceptor complex),[21] which would result from the interaction between the electron-donating moiety (pyridine) and the electron-accepting species (naphthalene).

Fluorescence emission spectra as a function of pH are shown part B of Figure 1. As mentioned above, protonation of the pyridine units leads to an increase of the absorption intensity. Since there are five basic centres in L, all of them − the two secondary amino groups, the tertiary one at the centre of the chain and both pyridine nitrogens − will be protonated in H_5L^{5+}. The spectroscopic data suggest that both pyridine units are also protonated in H_4L^{4+}, and that even in H_3L^{3+} the proton should still interact with the pyridine units as no significant decrease in the absorption maximum is observed for the three more protonated species. The ^{1}H NMR spectroscopic data also support this average protonation sequence, since the greatest downfield shifts of the pyridine protons Py2 and particularly Py3 (see Scheme 1 for the labelling; $\Delta\delta$ = 0.1 and 0.5 ppm, respectively) occur from pH 6.0 to 4.0, corresponding to the protonation of H_2L^{2+} to give H_3L^{3+} (see Figure S1A in the Supporting Information).

However, the most remarkable aspect to note in the emission spectra of compound L (Figure 1, B) is the additional band at longer emitting wavelengths. In fact, this emission exhibits the well-known characteristics of an exciplex as it is broad, structureless and red-shifted. The existence of a double exponential law (see below) is compatible with the existence of a "monomer" species (naphthalene emission) in equilibrium with an exciplex-like structure involving the naphthalene and one of the pyridine units. This is likely to be the case, because in a similar previously studied compound we found the coexistence of the emission of a monomer and an excimer formed by two naphthalenes.[22] In that case the macrocyclic structure studied also possessed pyridine units, yet the maximum emission wavelength occurred at 400 nm. This is in contrast with the 443 nm maximum found with the present system. It also excludes intermolecular interactions as the origin of this band. Moreover, since there is no formal difference between a relaxed CT excited state of an electron donor–acceptor complex and an exciplex, it is not easy sometimes to distinguish between the two.[21] However, in systems where CT contributions are reported, the presence of CT band leads to a visible colour of the solutions in contrast with colourless solutions where CT is absent,[21] which is reflected by the appearance of a tail at longer wavelengths. In the present case no such band is observed. Moreover, it can be seen that the absorption tail does not display a significant change with the pH, which clearly points to a lower contribution of a CT state.

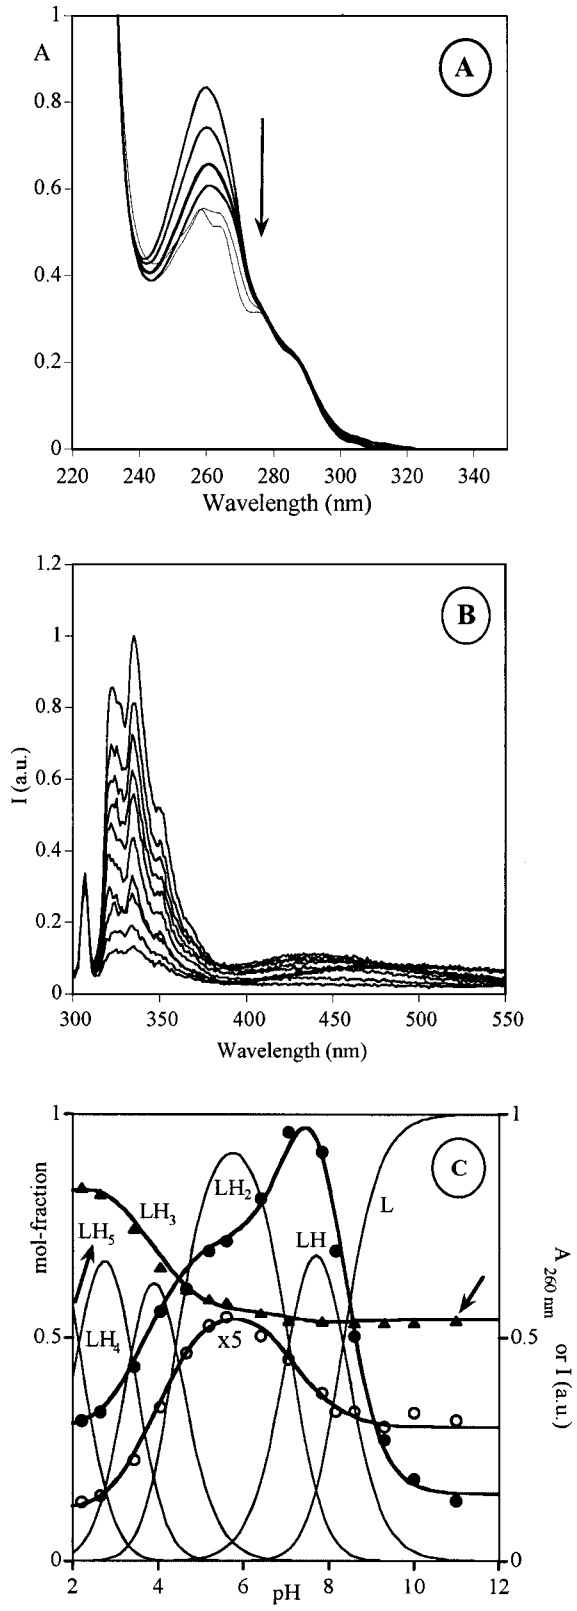


Figure 1. Absorption (A) and emission spectra (B) as function of pH of L (λ_{exc} = 280 nm at pH 2.20, 3.45, 4.05, 4.65, 6.40 and 11.0. [L] = 2.50×10^{-5} M; [NaCl] = 0.15 M). Fluorescence emission and absorption titration curves of L: emission [λ_{exc} = 280 nm, λ_{em} = 335 nm (●) and λ_{em} = 443 nm (○); absorption λ_{abs} = 260 nm (▲)] [L] = 2.5×10^{-5} M, superimposed on the respective mol-fraction distribution of the different species present in solution.

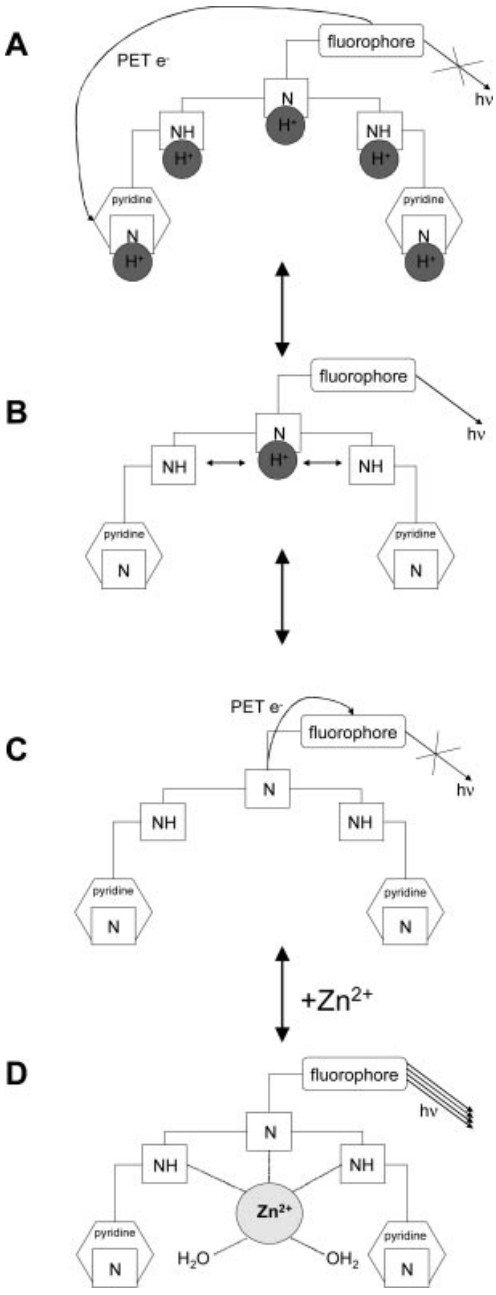
 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The possibility of formation of a charge-transfer excited state, as observed, for instance, in dendrimers functionalised at the periphery with naphthylsulfonamide units,[23] between the excited naphthalene and the amine units could potentially explain the emission of this structureless long-emission band. However, this is not likely to explain the present situation, since a similar band is not observed with analogous compounds containing a single naphthalene unit and an amine chain.[24,25] In fact, macrocyclic structures possessing a single naphthalene unit and polyaminic chains (with different sizes) have been shown to display only the naphthalene monomer emission.[24] Based on the considerations above, we therefore felt confident enough to attribute the long-wavelength emission band as being due to an exciplex-type species.

Inspection of part C of Figure 1 shows that the decrease in the absorption (deprotonation of the pyridines) and the increase in the fluorescence emission occur simultaneously. This result can be ascribed to an electron transfer quenching from the excited naphthalene to the protonated pyridine rings.[1–6] On the other hand, the sharp decrease of fluorescence observed at higher pH values can be explained by the well-established quenching by electron transfer from the lone pairs of the amines to the naphthalene fluorophore.[24] It is interesting to note that although a higher fluorescence emission intensity should, in principle, be expected for the H_2L^{2+}species, the most emissive species is HL^+. One plausible explanation could be that the two protons in H_2L^{2+}, due to their mutual repulsion, should be principally located at the two terminal nitrogens.[20,26] Therefore, the central nitrogen will be free at this stage for the quenching of the neighbouring excited naphthalene. However, the proton in HL^+ will be more shared between the secondary and the tertiary nitrogens due to the absence of charge–charge repulsion. The ^{1}H NMR spectroscopic data support this explanation. First, although the signal of the proton labelled as Pyb, which is placed in the α-position with respect to the secondary amino groups,[9] shifts downfield throughout all the pH range, it experiences its greatest downfield shift in the pH range 9–7, where the first two protonations occur ($\Delta\delta$ = 0.3 ppm). This supports the involvement of the secondary amino groups in such protonation steps. On the other hand, the ^{1}H signal of Nb also undergoes a slight downfield shift ($\Delta\delta$ = 0.12 ppm) on going from pH 9.0 to 7.5, corresponding to the first protonation step, which suggests that the first proton binding L is also shared by the tertiary nitrogen atom.

The off-on-off behaviour of L is depicted in Scheme 3. This "off-on-off" behaviour of the fluorescence emission of compound L, however, presents some disadvantages as the fluorescence emission quantum yields are very low and the pH width of the window is very large. A much better performance can be achieved with the Zn^{II} complexes of compound L (see below).

The speciation studies for the system Zn^{2+}-L carried out by pH-metric titration at 298.1 ± 0.1 K show a very simple model in which three species of stoichiometries $[ZnL]^{2+}$, $[ZnL(OH)]^+$ and $[ZnL(OH)]_2$ are formed. The stability constants for these species are collected in Table 2 and the distribution of the species with pH is shown in Figure 2.



Scheme 3. Representation of the changes in fluorescence of L with pH and upon addition of Zn^{2+}. A) Fully protonated L. B) Monoprotonated L; the proton is shared to some extent between the three nitrogens of the chain. C) Deprotonated L. D) Emission of the $[ZnL]^{2+}$ complex.

The most noticeable observation is the low stability displayed by these complexes. The stability constant of the $[ZnL]^{2+}$ complex is clearly lower than that presented by the open-chain polyamine 1,4,7-triazaheptane (log K = 8.8)[18] or that of a related ligand with both of its terminal nitrogens functionalised with naphthylmethyl groups (log K =

Species	log K[a]
$Zn^{2+} + L \leftrightharpoons [ZnL]^{2+}$	4.72(1)
$Zn^{2+} + L + H_2O \leftrightharpoons [ZnL(OH)]^{+} + H^{+}$	–4.22(2)
$Zn^{2+} + L + 2H_2O \leftrightharpoons [ZnL(OH)_2] + 2H^{+}$	–12.89(1)
$[ZnL]^{2+} + H_2O \leftrightharpoons [ZnL(OH)_2]^{+} + H^{+}$	–8.94
$[ZnL(OH)]^{+} + H_2O \leftrightharpoons [ZnL(OH)_2] + H^{+}$	–8.66(1)

[a] Values in parentheses are standard deviations in the last significant figure.

8.25).[27] This low stability can be ascribed to the electron-withdrawing characteristics of the pyridine rings and to the poor σ-donor character of the central tertiary nitrogens. This low constant leads to a ready hydroxylation of two water molecules that would serve to complete the coordination sphere of the metal ion. In fact, the pH range of formation of the dihydroxylated species overlaps that of the monohydroxylated and of the neutral species. This low stability also means that, as might be expected, the pyridine rings do not participate in the coordination of the Zn^{2+} ion.

The pH-dependent absorption and emission spectra of compound L in the presence of equimolar amounts of Zn^{2+} are shown in Figure 2. A comparison of the absorption spectra in the absence and presence of metal does not show any significant difference. However, the fluorescence emission exhibits a much higher intensity, and the shape of the fluorescence emission titration curve presents a much narrower pH-dependent fluorescence window (Figure 2, C). The mol-fraction distribution of the various species in solution are also represented superimposed on the fluorescence emission titration curve in part C of Figure 2. Inspection of this figure shows the background emission from the free ligand up to pH 6.0, and for more basic pH values an emission whose shape and position can be attributed to the $[ZnL]^{2+}$ species. In this species the metal is bonded to the polyamine chain, thus preventing the PET from occurring (see Scheme 3).

No interaction of the metal with the pyridine units is observed. This is confirmed by the lack of changes in the absorption spectra and absence of fluorescence quenching, which is expected when Zn^{2+} is bonded to pyridine units. The ^1H NMR signals of Py2 and Py3 in the system Zn^{2+}-L do not experience any shift with respect to the free ligand from pH 2.0 to 6.0, thus supporting this point (see Figure S2).

At higher pH values the formation of hydroxo species leads to a quenching effect, as reported previously,[28] which explains the bell shape of the titration curve. One of the most remarkable aspects is the great increase in the intensity of the fluorescence emission when Zn^{2+} is complexed to L (see Figure 3), which exceeds the maximum intensity of the free ligand 10-fold.

The fluorescence decays of ligand L were obtained at the shorter and longer wavelength bands at different pH values. The data resulting from the best fitting, obtained with global or independent analysis of the decays (Table 3) show

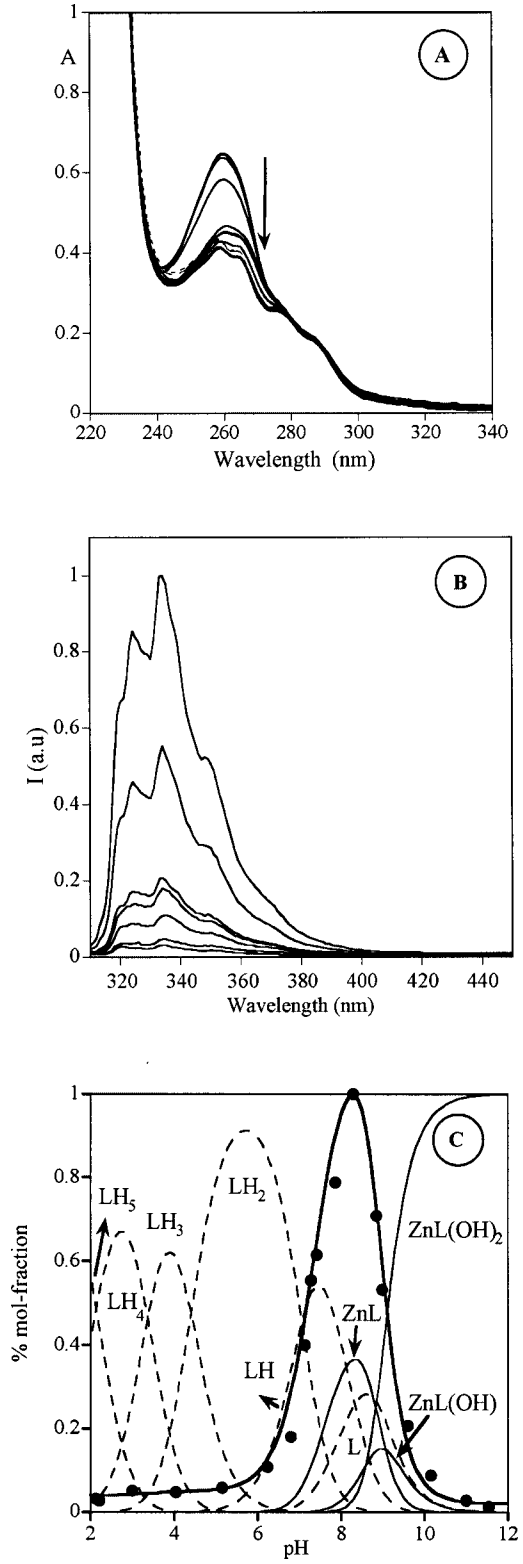

Figure 2. Absorption (A) and emission spectra (B) of the complex ZnL as a function of pH. (λ_{exc} = 280 nm, [ZnL] = 2.50×10^{-5} M, [NaCl] = 0.15 M). Fluorescence emission titration curve of the complex ZnL (C) (λ_{exc} = 280 nm, λ_{em} = 335 nm (●), [ZnL] = 2.50×10^{-5} M, [NaCl] = 0.15 M) superimposed on the respective mol-fraction distribution of the different species present in solution.

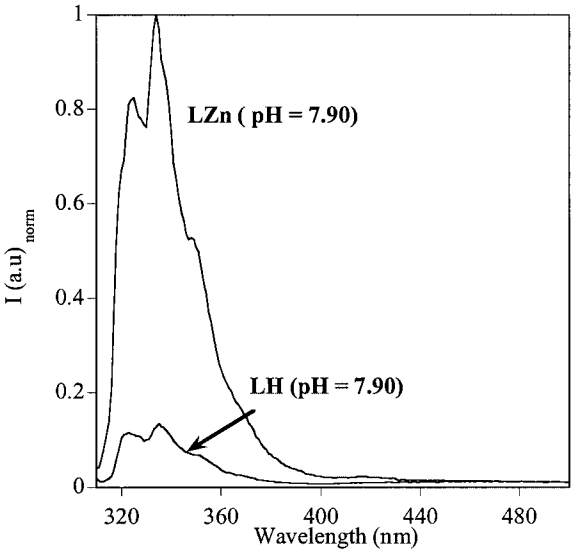

Figure 3. Comparison between the fluorescence of free L and its Zn^{2+} complex at pH 7.9.

that the decays are properly fitted with double-exponential laws, according to:

$$I_\lambda(t) = a_{i1}e^{-t/\tau_1} + a_{i2}e^{-t/\tau_2}$$

where $i = 1$ for $\lambda_{em} = 335$ nm and $i = 2$ for $\lambda_{em} = 450$ nm.

According to Table 3, the shorter-lifetime component remains approximately constant with the pH (with an averaged value of ca. 3.4 ns) and the longer-lifetime component increases up to pH 7.0–8.0, decreasing thereafter. As reported in Figure 1, the emission at pH values above 8.0 is due to the deprotonated HL and L species. In this situation the lone electron pairs of the deprotonated amines are able to effectively quench the emission of compound L.[29] This is revealed both by the decrease in the lifetime of this component as well as by the decrease of the total fluorescence emission, as shown in Figure 1, B. Analysis of the lifetime data points to another important observation: the absence of a rise-time (negative pre-exponential) is associated with the shorter lifetime at $\lambda_{em} = 450$ nm. The lack of a rise-time (see below) might indicate that this new emission band should, presumably, possess some (small) CT degree; with improved time-resolution (ours is presently limited to 150 ps) it could be the case that a faster component, with a rising component, is present. However, with our current time resolution we were unable to visualize such a component. Based on our present data, this again presumably indicates that the 443 nm (maxima) emissive species (exciplex) results from a small CT degree contribution. In fact, exciplex formation due to CT interactions can involve excited- and ground-state molecules and be the driving force for its formation. However, based on our current data, we believe that we have a complex (presumably with some ground-state contribution) with CT character.

However, even if the formation of the exciplex-type species (emission at 443 nm) does not show a strong dependence on the exciting light, it is clearly dependent on the pH of the medium. This can be viewed by the observation of the ratio of the emission at 335 nm vs. 443 nm, where it can be seen that this attains two maxima at pH 2.0 and pH 8.0.

In summary, the analysis of the fluorescence data (steady-state and time-resolved) suggest that the 443 nm emitting species can be interpreted as a charge-transfer complex A^-D^+ which is stabilised by electron transfer form the donor (pyridine unit) to the acceptor (naphthalene) that is not totally unstable in its ground-state. In fact, it is unlikely, based on the arguments discussed above, that this equilibrium is only formed once the excited state is formed, but rather that it is already present (to some degree) in the ground state. Therefore, the off-on-off system is mainly due to the pH of the media and less to the action of light, contrary to other related systems previously studied by our groups.[25]

Table 3. Fluorescence decay times and pre-exponential factors (τ_i and a_{ij}) for compound L in water as a function of pH. The data were obtained with excitation at 290 nm and emission at 335 nm and 440 nm. Also presented are the chi-squared values for a better judgment of the quality of the fits.

pH	λ_{em}	τ_1	τ_2	a_{i1}	a_{i2}	χ^2	Type of analysis[a]

Off-On-Off Behaviour

According to the data reported in Figure 2 (C), Zn^{2+} can be detected by the fluorescence emission intensity of its complex with tweezer L, in a very narrow pH window centred at around pH 8.0. In order to characterise the narrowness of the bell shape titration curve, it is useful to measure the width at half of the maximum of the fluorescence intensity. In the present system it is 1.9 pH units. This value compares with a value of about 3 for the system previously reported by A. P. de Silva.[1] Another aspect concerns the central pH value of the window, which is pH 8.2 in our system and about 6.5 in the one previously described by de Silva.

Different to previously reported systems, our system presents the advantage of being soluble and therefore operative in aqueous 0.15 M NaCl solutions. This ionic strength is close to that found in biological fluids.

Experimental Section

The synthesis of **1** was carried out as described previously.[12]

3-Naphthylmethyl-1,5-Diphthalimido-3-azapentane (2):[15,16] 1,5-Diphthalimido-3-azapentane (**1**; 10.1 g, 36.2 mmol), 2-(bromomethyl)naphthalene (10.0 g, 45.2 mmol) and K_2CO_3 (6.4 g, 45.2 mmol) were dissolved in 200 mL of CH_3CN and the mixture was refluxed for 24 h under nitrogen. After filtration, the solvent was removed under reduced pressure. The resulting residue was mixed with 50 mL of water and extracted with dichloromethane (3 × 50 mL). The organic phase was dried with anhydrous sodium sulfate and the solvent was evaporated to yield a light-yellow oil. The oil was taken up in EtOH and precipitated as a solid, which was filtered to give **2**. Yield: 6.85 (38%).^{1}H NMR ($CDCl_3$): δ = 2.87 (t, J = 6 Hz, 4 H), 3.79 (t, J = 6 Hz, 4 H), 3.80 (s, 2 H), 7.16 (d, J = 8 Hz, 1 H), 7.20 (d, J = 8 Hz, 1 H), 7.23–7.36 (m, 2 H), 7.45–7.48 (m, 1 H), 7.51 (s, 1 H), 7.58–7.61 (m, 1 H), 7.62–7.69 (m, 8 H) ppm. ^{13}C NMR (D_2O): δ = 36.2, 52.2, 58.8, 123.3, 125.7, 126.1, 127.5, 127.9, 128.0, 128.0, 132.7, 132.9, 133.5, 134.0, 136.8, 168.5 ppm.

4-(2-Napthylmethyl)-1,4,7-triazaheptane Tris(hydrochloride) (L1·3HCl): Compound **2** (6.9 g, 13.6 mmol) and hydrazine monohydrate (13.6 g 272 mmol) were dissolved in 400 mL of EtOH and the mixture was refluxed for 1 d under nitrogen. The precipitate was removed by filtration and the solvent was evaporated until the sample was dry. The resulting residue was dissolved in 300 mL of $CHCl_3$ and the solution was stirred for 12 h under nitrogen. The solution was vacuum evaporated to dryness to give the crude product. This product was dissolved in EtOH and was precipitated with aqueous HCl to obtain L as its hydrochloride salt (1.98 g, 42%). M.p. 223–224 °C. ^{1}H NMR (D_2O): δ = 3.30–3.34 (m, 4 H), 3.35–3.42 (m, 4 H), 4.43 (s, 2 H), 7.49 (d, J = 8 Hz, 1 H), 7.51–7.57 (m, 2 H), 7.89–797 (m, 4 H) ppm. ^{13}C NMR (D_2O): δ = 34.8, 50.1, 59.0, 127.4, 127.6, 127.7, 128.0, 128.2, 128.5, 129.8, 131.3, 133.2, 133.7 ppm. $C_{15}H_{24}Cl_3N_3$ (352.8): calcd. C 51.5, H 6.9, N 11.9; found C 50.9, H 7.0, N 11.8.

1,7-Bis(4-methylpyridine)-4-(2-napthylmethyl)-1,4,7-triazaheptane Pentahydrochloride (L·5HCl): 4-Pyridinecarbaldehyde (1.28 g, 11.9 mmol) dissolved in 100 mL of EtOH was added to a solution of L1 (1.30 g, 5.96 mmol) in EtOH. $NaBH_4$ (0.56 g, 15 mmol) was then added portionwise. The mixture was stirred for 2 h at room temperature and the solvent was then vacuum evaporated to dryness. The residue was treated with 50 mL of water and extracted with CH_2Cl_2 (3 × 40 mL). The organic phase was dried with anhydrous sodium sulfate and the solvent evaporated to dryness. The resulting oil was dissolved in EtOH and L was precipitated as its pentahydrochloride salt with aqueous HCl (1.55 g, 43%). M.p. 177–178 °C. ^{1}H NMR (D_2O): δ = 2.95 (t, J = 6 Hz, 4 H), 3.15 (t, J = 6 Hz, 4 H), 3.73 (s, 2 H), 4.16 (s, 4 H), 7.33–7.40 (m, 4 H), 7.60–7.63 (m, 3 H), 7.70 (d, J = 7 Hz, 4 H), 8.52 (d, J = 7 Hz, 4 H) ppm. ^{13}C NMR (D_2O): δ = 45.1, 49.4, 50.4, 59.3, 127.9, 128.1, 128.3, 129.3, 129.5, 133.0, 133.2, 133.5, 142.1, 151.3 ppm. $C_{27}H_{40}Cl_5N_5O_2$ (644.1): calcd. C 50.5, H 6.3, N 10.9; found C 50.6, H 6.4, N 10.8.

Emf Measurements: The potentiometric titrations were carried out at 298.1 ± 0.1 K with 0.15 M NaCl as the supporting electrolyte. The experimental procedure (burette, potentiometer, cell, stirrer, microcomputer, etc.) has been fully described elsewhere.[30] The acquisition of the emf data was performed with the computer program PASAT.[31] The reference electrode was an Ag/AgCl electrode in saturated KCl solution. The glass electrode was calibrated as a hydrogen-ion concentration probe by titration of previously standardised amounts of HCl with CO_2-free NaOH solutions and the equivalent point determined by Gran's method,[32] which gives the standard potential, $E°'$, and the ionic product of water [pK_w = 13.73(1)].

The computer program HYPERQUAD was used to calculate the protonation and stability constants.[30] The pH range investigated was 2.5–11.0 and the concentration of the metal ions and of the ligand ranged from 1×10^{-3} to 5×10^{-3} M with M:L molar ratios varying from 2:1 to 1:2 The different titration curves for each system (at least two) were treated either as a single set or as separate curves without significant variations in the values of the stability constants. Finally, the sets of data were merged together and treated simultaneously to give the final stability constants.

Spectrophotometric and Spectrofluorimetric Measurements: Absorption spectra were recorded on a Shimadzu UV-2501PC spectrophotometer and fluorescence emission on a Horiba–Jobin–Yvon SPEX Fluorolog 3.22 spectrofluorimeter at 25 °C. HCl and NaOH were used to adjust the pH values, which were measured on a Metrohm 713 pH meter. All measurements were made in 0.15 M NaCl.

Fluorescence decays were measured using a home-built TCSPC apparatus with an N_2-filled IBH 5000 coaxial flashlamp as excitation source, Jobin–Yvon monochromators, Philips XP2020Q photomultiplier, and Canberra instruments TAC and MCA. Alternate measurements (1000 c.p.c.) of the pulse profile at 285 nm and the sample emission were performed until $1–2 \times 10^4$ counts at the maximum were reached.[33] The fluorescence decays were analysed using the modulating functions method of Striker with automatic correction for the photomultiplier "wavelength shift".[34]

Supporting Information: As supporting information we include plots of the variations with pH of the ^{1}H NMR chemical shifts of protons labelled as py2, py3 (Figure S1A), Nb and pyb (Figure S1B). Figure S2 plots the variations with pH of the chemical shifts of protons py2 and py3 in the absence and presence of Zn^{2+}.

An Approach Towards Functional Dendrimers Based on the Hydroboration Reaction and Spontaneous Boron–Nitrogen Bond Formation

Monika C. Haberecht,[a] Michael Bolte,[a] Hans-Wolfram Lerner,[a] and Matthias Wagner*[a]

Keywords: Boranes / Dendrimers / Hydroboration / N ligands

The reaction of 1,4-bis- or 1,3,5-tris(bromoboryl)benzenes **4** and **6**, respectively, with 2 or 3 equiv. of 4,4′-bis(but-3′′-enyl)-2,2′-bipyridyl (**2**) leads to the corresponding 2,2′-bipyridylboronium cations **5** and **7** in almost quantitative yield. Using the monocation $[(MeC_6H_4)B(Br)\{4,4'$-bis(but-3′′-enyl)-2,2′-bipyridyl$\}]^+$ (**3Br**) as a model system, it is shown that the olefinic side-chains of such compounds are readily transformed into alkyldibromoborane functionalities by hydroboration with $HBBr_2$. Subsequent addition of 4,4′-dimethyl-2,2′-bipyridyl leads to the formation of a branched system of three 2,2′-bipyridylboronium cations (**9Br**). The species **5** and **7** can be regarded as generation zero (G_0) 2,2′-bipyridylboronium dendrimers, and the hydroboration/B–N adduct formation sequence offers a convenient route for the assembly of higher generations.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Dendrimers are macromolecules with well-defined molecular architectures derived from a central atom or core with multiple branches. They are gaining great attention due to their potential applications in, for example, biology, catalysis and materials science. Apart from purely organic dendrimers, metallodendrimers[1–3] and heteroatom-based dendrimers[4–6] represent an important area of research. In 1994, Puddephatt reported organometallic dendrimers featuring (2,2′-bipyridyl)Pt^{IV} chelates in every generation.[7,8] Since then, numerous dendrimers incorporating (polypyridyl)metal complexes have been synthesised, mainly with the aim of studying photoinduced energy transfer and multielectron redox processes.[9]

Research in our group focuses on the chemistry of main group chelates of the 2,2′-bipyridyl (bipy) ligand, particularly on 2,2′-bipyridylboronium cations **A** (Figure 1), which are relatives of the organic electron acceptor Diquat (**B**; Figure 1) and thus behave as reversible two-electron redox systems.[10–15]

Cations **A** form spontaneously and under very mild conditions upon treatment of haloboranes XBR_2 (X = Cl, Br) with 2,2′-bipyridyl. For example, starting from 1,1′,3,3′-tetrakis(bromoboryl)ferrocene, the ferrocene derivative **C** (Figure 1) bearing four redox-active 2,2′-bipyridylboronium units has been synthesised in almost quantitative yield.[16] Compound **C**, which possesses an unusual deep-purple colour due to charge-transfer interactions between the ferrocene backbone and its Diquat-like substituents,[15] acts as a fully reversible nine-electron redox system in DMF solution.[16] In an attempt to generate larger aggregates, we initially employed 1,1′-diborylated ferrocenes and bridging 2,2′-bipyridyl derivatives (e.g. quaterpyridine) with the hope of obtaining polymeric materials. However, macrocyclic dimers (e.g. **D**; Figure 1) always formed as the sole reaction products irrespective of the experimental conditions applied.[17] In our second approach, we tried to link ferrocene-1,1′-diylbis(2,2′-bipyridylboronium) cations via their boron atoms by introducing oxygen bridges between them. In contrast to our expectations, no polymeric species were formed but *ansa*-bridged complexes **E** (Figure 1) were obtained as the result of an intramolecular reaction.[12]

We therefore developed a new concept for the preparation of macromolecules containing larger numbers of 2,2′-bipyridylboronium cations and thus possessing the potential to act as electron storage media. Our synthetic methodology is based on a two-reaction sequence using a spontaneous B–N adduct formation in combination with a hydroboration reaction (Scheme 1).

To start, multiply borylated core units are required. Ferrocene and benzene are particularly well-suited candidates since they can easily be borylated up to four (ferrocene)[18] or up to three times (benzene).[19] In the present study, *p*-(dibromoboryl)toluene together with 1,4-bis- and 1,3,5-tris-(dibromoboryl)benzene will be employed. The other building blocks are 4,4′-bis(but-3′′-enyl)-2,2′-bipyridyl (**2**) and dibromoborane, $HBBr_2$, which may either be purchased as its dimethyl sulfide adduct or prepared in situ from tribromoborane and triethylsilane[20,21] in dichloromethane solution. In order to build the desired macromolecules, we will follow a divergent reaction sequence (Scheme 1): First, the

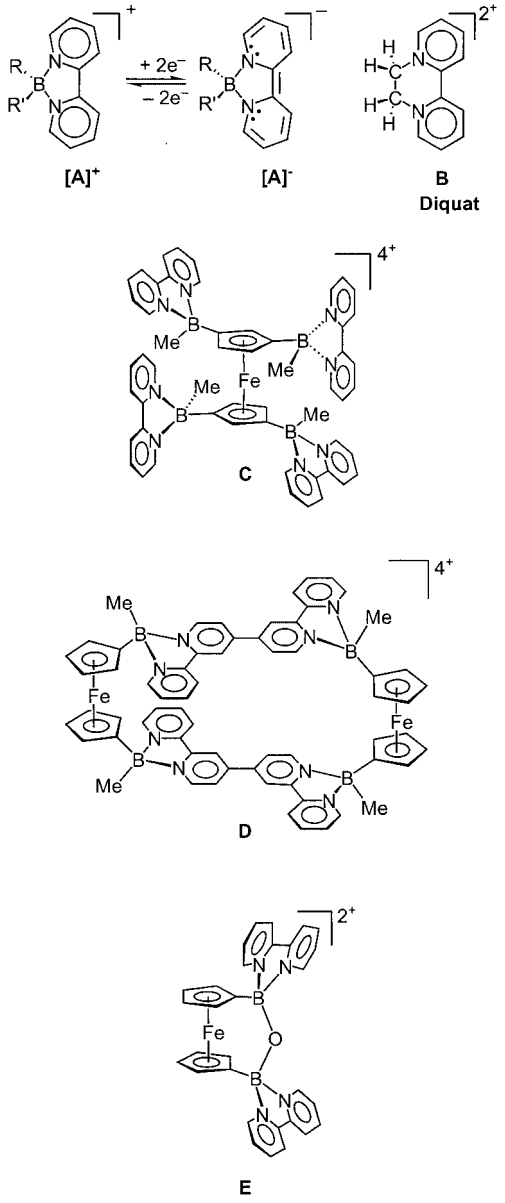

Figure 1. 2,2′-Bipyridylboronium cation (**A**), Diquat (**B**), ferrocene **C** bearing four 2,2′-bipyridylboronium substituents, macrocyclic dinuclear ferrocene complex **D**, and *ansa*-ferrocene **E**.

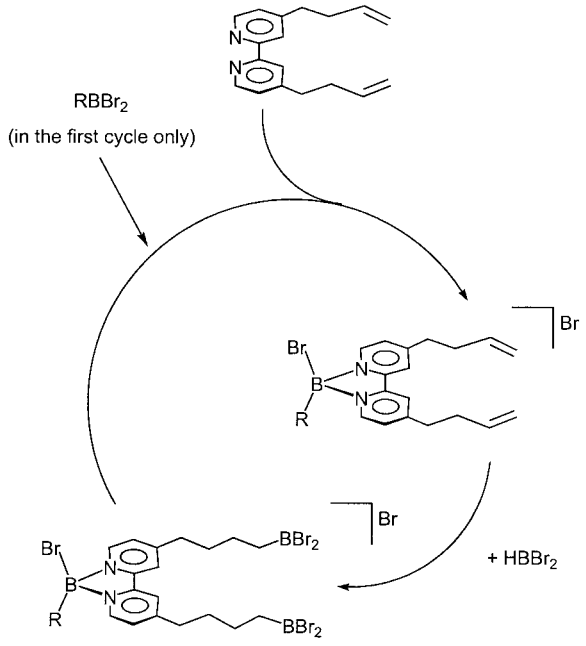
core unit is treated with the appropriate amount of substituted 2,2′-bipyridyl to prepare the zeroth generation (G_0) of the dendrimer. Second, the G_0 2,2′-bipyridylboronium cation is hydroborated with $HBBr_2$ at its peripheral olefin substituents to generate a molecule bearing alkyldibromoborane side-chains. In the third step, addition of the functionalised 2,2′-bipyridyl gives access to the G_1 dendrimer. The reaction cycle may then be repeated to attach further 2,2′-bipyridylboronium cations and to obtain higher generation dendrimers. The purpose of this paper is (i) to present an optimised procedure for the hydroboration of bipyridylboronium cations with olefinic side-chains, (ii) to prove that up to three bipyridylboronium substituents can be grouped around a benzene ring such that it qualifies as a core unit



Scheme 1. Concept for the synthesis of branched 2,2′-bipyridylboronium cations by hydroboration with dibromoborane.

for further dendrimer syntheses, and (iii) to describe our first results regarding the synthesis of G_1 dendrimers.

Results and Discussion

Syntheses

Treatment of *p*-(dibromoboryl)toluene (**1Br**)[19] with tetramethylstannane or diethyl ether gives *p*-[bromo(methyl)boryl]toluene (**1Me**) and *p*-[bromo(ethoxy)boryl]toluene (**1OEt**), respectively (Scheme 2). Addition of **1Br**, **1Me** or **1OEt** to the 2,2′-bipyridyl derivative **2**[22] in toluene or dichloromethane at ambient temperature leads to the formation of **3Br**, **3Me** and **3OEt**, respectively, in excellent yields. Compound **3Br**, bearing a bromo substituent at the boron atom, closely mimics the reaction intermediates encountered during the hydroboration/adduct formation cycle (cf. Scheme 1). However, B–Br bonds are prone to hydrolysis and it was therefore desirable to have also the moisture-stable methyl derivative **3Me** at hand. The ethoxy-2,2′-bipyridylboronium cation **3OEt** is described here because it gave crystals suitable for X-ray crystal structure analysis. Most importantly, the bromo substituent of **3Br** can be replaced by a methoxy group (**3OMe**; Scheme 2) when **3Br** is dissolved in dry methanol in the presence of stoichiometric amounts of triethylamine. This reaction proceeds cleanly and quantitatively, and thus offers a convenient way to transform the primary products of future dendrimer syntheses into air- and moisture-stable materials.

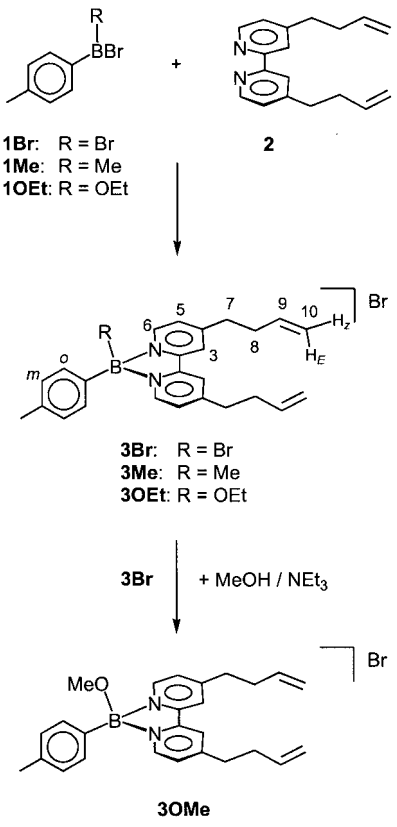
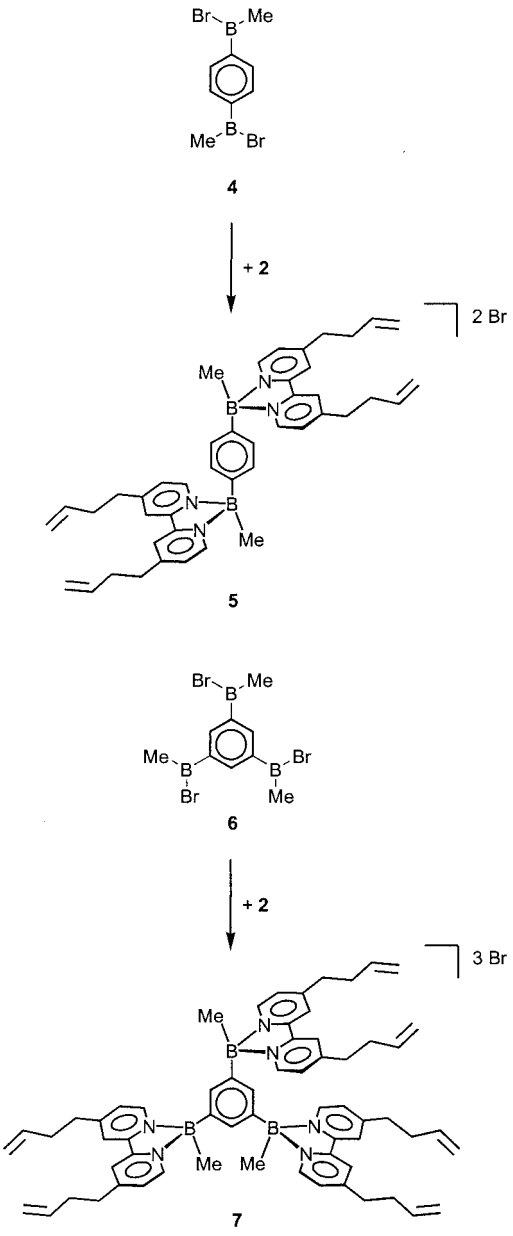


Scheme 2. Synthesis of the 2,2′-bipyridylboronium bromides **3Br**, **3Me**, **3OEt** and **3OMe**.



Scheme 3. Synthesis of the bis- and tris(2,2′-bipyridylboronium) bromides **5** and **7**.

The bromo(methyl)boryl-substituted benzenes **4** and **6**, which are accessible from $SnMe_4$ and 1,4-bis(dibromoboryl)benzene or 1,3,5-tris(dibromoboryl)benzene,[19] respectively, in a way similar to the synthesis of **1Me**, readily react with ligand **2** in dichloromethane to form the di- and trications **5** and **7**, respectively (Scheme 3). For purification, the reaction products were precipitated from their dichloromethane solutions by the addition of hexane.

The crucial hydroboration step was carried out using the bromo-substituted monocation **3Br**, since it is the least complex system available but nevertheless contains all the functional groups of a growing dendrimer according to Scheme 1. At the beginning we relied on $HBBr_2{\cdot}SMe_2$ as the hydroboration reagent, but it soon turned out that the in situ generation of $HBBr_2$ from equimolar amounts of triethylsilane and boron tribromide[20,21] gives better results. In the optimised procedure, a mixture of **3Br** and triethylsilane in dichloromethane is added dropwise at –78 °C to a solution of tribromoborane in the same solvent. The reaction is usually complete after warming to ambient temperature. Note that 3 equiv. of BBr_3 are required since 1 equiv. coordinates the bromide counterion of **3Br** to form tetrabromoborate $[BBr_4]^-$. As expected, the hydroboration of **3Br** is not fully regioselective such that isomers $\mathbf{8^t}$ (t = terminal) and $\mathbf{8^i}$ (i = internal) with a BBr_2 substituent attached to C-10 and C-9, respectively, are obtained [approx. ratio (^{1}H NMR spectroscopy): $\mathbf{8^t/8^i}$ = 4:1; see below] (Scheme 4). In order to increase the regioselectivity, we extended our studies to a derivative of **3Br** bearing methyl groups at both its C-9 atoms. In this case, however, C-9 becomes a chiral atom after hydroboration and a mixture of diastereomers is obtained.

Apart from the regioselectivity problem, the crude product **8** is sufficiently pure for further reaction with 2,2′-bipyridyls. A sample of **8** was thus treated with 4,4′-dimethyl-2,2′-bipyridyl in dichloromethane and subsequently with methanol/triethylamine to synthesise the G_1 trication **9OMe**. Attempts to isolate the regioisomers of **9OMe** by reversed-phase HPLC failed since a satisfactory separation could not be achieved.

As already mentioned above, tetrabromoborate is created as a new counterion in the hydroboration reaction. This causes additional problems, since $[BBr_4]^-$ reacts stoichio-

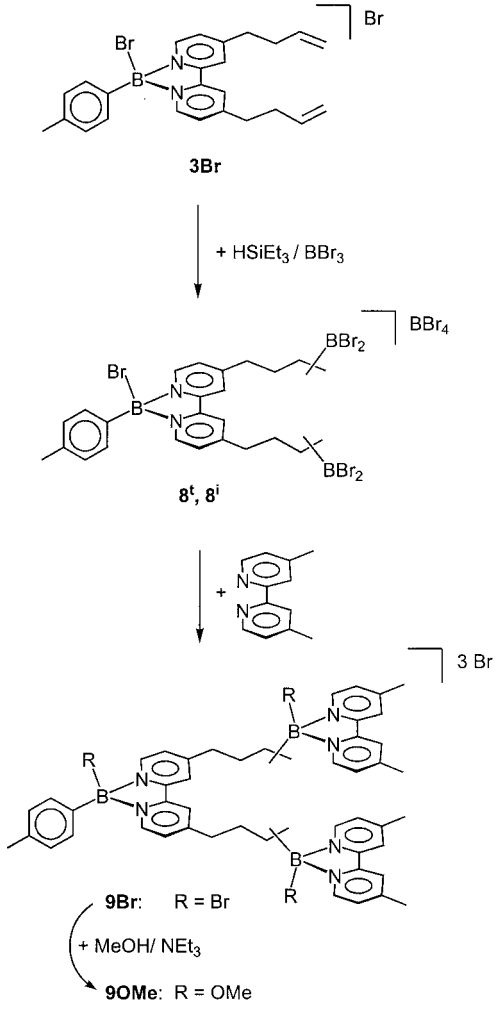

Scheme 4. Hydroboration of **3Br**, subsequent formation of the branched cation **9Br**, and transformation of **9Br** into the moisture-stable derivative **9OMe**.

metrically with 2,2′-bipyridyl similar to the alkyldibromoborane side-chains of **8**. As a consequence, the preparation of the first generation dendrimer **9Br** requires 3 rather than 2 equiv. of the ligand to achieve quantitative conversion. In our search for more suitable counterions, we finally found that $[B(C_6F_5)_4]^-$ is not affected by BBr_3/$HSiEt_3$, which makes it the counterion of choice for further dendrimer syntheses.

NMR Spectroscopy

The ^{11}B NMR shifts of the 2,2′-bipyridylboronium cations appear in the range between δ = 9.8 (**3OMe**) and 6.5 ppm (**3Br**, **7**), thus indicating the presence of tetracoordinate boron nuclei.[23] Very similar ^1H NMR spectra are observed for the monocations **3Br**, **3Me**, **3OEt** and **3OMe**. In all these compounds, the position of the H-3 resonance is strongly dependent on the nature of the counterion and the choice of solvent [cf. **3Me**: δ(H-3) = 10.31 (Br^-/$CDCl_3$), 8.87 (Br^-/CD_3OD), 7.16 ($[B(C_6H_5)_4]^-$/$CDCl_3$), 8.88 ppm ($[PF_6]^-$/$CDCl_3$)]. This effect may therefore be attributed to the formation of contact ion pairs, an interpretation also supported by the structure of **3OEt** in the solid state in which the two C-3–H-3 vectors act as "chelating hydrogen-bond donors" towards the bromide ion (corresponding H···Br contacts in the range between 2.80 and 3.00 Å (Figure 2; for the theoretical treatment of a related system, see ref.[24]). Hydroboration of **3Br** leads to the disappearance of the signals for the olefinic protons [δ(H-9) = 5.81, δ(H-10_E) = 5.05, δ(H-10_Z) = 4.99 ppm] and carbon atoms [δ(C-9) = 135.6, δ(C-10) = 117.1 ppm] and the appearance of new signals in the aliphatic region of the spectrum [**8^t**: δ(H-9) = 1.80, δ(H-10) = 1.71 ppm; δ(C9) = 26.4, δ(C-10) = 36.2 ppm]. Moreover, the ^{11}B NMR spectrum of **8** now reveals two resonances possessing chemical shift values typical of four- and three-coordinate boron nuclei [δ(Bbipy) = 6.5, δ(BBr_2) = 57.3 ppm; integral ratio ≈ 1:2]. Upon addition of 2 equiv. of 4,4′-dimethyl-2,2′-bipyridyl to **8**, the signal at δ = 57.3 ppm disappears and an extremely broad signal occurs at δ ≈ 7 ppm, which clearly shows that all former BBr_2 groups are now tetracoordinate.[23] There are three possible regioisomers of **9OMe**, containing between two and three different kinds of 2,2′-bipyridyl fragments. As a consequence, both the ^1H and the ^{13}C NMR spectra of **9OMe** are poorly resolved and very complex. It is therefore not possible to assign resonances to individual atoms

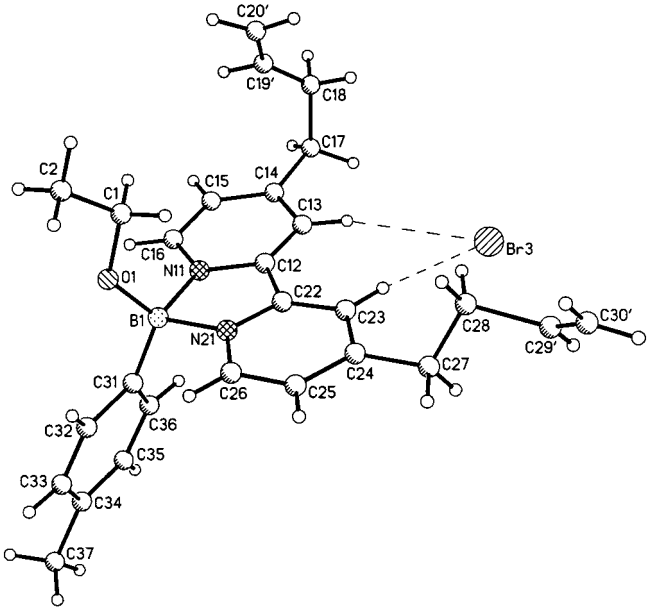

Figure 2. Ball-and-stick model of **3OEt** in the solid state. For clarity, only one of the three crystallographically independent molecules within the asymmetric unit is shown. Selected bond lengths [Å], angles [°] and torsion angles [°]: B(1)–O(1) 1.416(12), B(1)–C(31) 1.539(16), B(1)–N(11) 1.635(13), B(1)–N(21) 1.666(11), N(11)–C(12) 1.369(10), C(12)–C(22) 1.473(11), N(21)–C(22) 1.334(11); O(1)–B(1)–C(31) 114.7(8), O(1)–B(1)–N(11) 111.2(9), O(1)–B(1)–N(21) 110.2(7), C(31)–B(1)–N(11) 114.6(8), C(31)–B(1)–N(21) 111.9(8), N(11)–B(1)–N(21) 92.0(6), C(1)–O(1)–B(1) 123.1(8), C(12)–N(11)–B(1) 115.0(6), C(22)–N(21)–B(1) 113.9(7), N(11)–C(12)–C(22) 108.1(7), N(21)–C(22)–C(12) 110.8(7), C(13)–C(12)–C(22) 129.7(8), C(12)–C(22)–C(23) 127.1(8); N(11)–C(12)–C(22)–N(21) –3.4(12).

in this case. However, the proposed molecular structure of **9OMe** was clearly proven by mass spectrometry.

Mass Spectrometry

Low resolution electrospray mass spectra (ESI) in the positive-ion mode were recorded for the G_0 compounds **3Me**, **3OMe**, **3OEt**, **5** and **7**. The spectra of the 2,2′-bipyridylboronium salts **3Me**, **3OMe**, **3OEt** reveal exclusively peaks of the free monocations [**3Me** – Br]$^+$, [**3OMe** – Br]$^+$, and [**3OEt** – Br]$^+$ at *m*/*z* values of 381, 397 and 411, respectively. A similar result was obtained for the diborylated species **5**, which gave rise to only one peak assignable to the free dication [**5** – 2 Br]$^{2+}$ (*m*/*z* = 328). In the case of the trisubstituted benzene derivative **7**, two peaks with an integral ratio of 100 (*m*/*z* = 512):95 (*m*/*z* = 315) appear in the mass spectrum, which correspond to the di- and trications [**7** – 2 Br]$^{2+}$ and [**7** – 3 Br]$^{3+}$. An ESI mass spectrum was also recorded for **9OMe**. Again, the most intense peaks (*m*/*z* = 465, 284) by far may be assigned to the cations [**9OMe** – 2 Br]$^{2+}$ and [**9OMe** – 3 Br]$^{3+}$.

X-ray Crystallography

Single crystals of **3OEt** (triclinic, space group $P\bar{1}$) grew slowly from an oily sample at room temperature. There are three crystallographically independent molecules in the asymmetric unit. Since their structure parameters are equal within experimental error, the data of only one of the three molecules are discussed here. As already deduced from the NMR spectra, the compound contains a tetracoordinate boron centre chelated by a 2,2′-bipyridyl ligand [B(1)–N(11) = 1.635(13) Å, B(1)–N(21) = 1.666(11) Å; N(11)–B(1)–N(21) = 92.0(6)°]. Chelation of the small boron atom leads to a slight distortion of the 2,2′-bipyridyl moiety such that the angles C(13)–C(12)–C(22) and C(12)–C(22)–C(23) on the outer frame of the aromatic system are stretched to values of 129.7(8)° and 127.1(8)°, respectively. The terminal atoms C(19′), C(20′), C(29′) and C(30′) of the butenyl chains are disordered. Although a model with two different conformations has been employed, the anisotropic displacement parameters of C(19′) and C(20′) are still rather large.

Conclusions

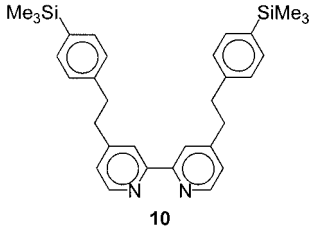
This paper reports a novel strategy for the generation of dendritic macromolecules consisting of redox-active 2,2′-bipyridylboronium cations. 1,4-Di- and 1,3,5-triborylated benzenes are chosen as core units and a hydroboration/B–N adduct formation sequence is suggested for the assembly of the individual branches.

To prove the suitability of the benzene core unit, we first synthesised the air- and moisture-stable benzene derivatives **5** and **7** bearing two and three 4,4′-bis(but-3′′-enyl)-2,2′-bipyridylboronium substituents in their 1,4- and 1,3,5-positions. The reactions proceed cleanly and quantitatively, which leads to the conclusion that there is sufficient space along the periphery of a benzene ring to attach up to three branching subunits. Compounds **5** and **7** may therefore be regarded as generation zero (G_0) dendrimers.

In order to optimise the hydroboration reaction, the monocation **3Br**, derived from *p*-(dibromoboryl)toluene (**1Br**) and 4,4′-bis(but-3′′-enyl)-2,2′-bipyridyl (**2**), was employed as a model system. Quantitative conversion of both its olefinic side-chains into alkyldibromoboryl substituents was achieved under mild conditions with BBr_3/$HSiEt_3$ as hydroborating reagent. The regioselectivity of the hydroboration reaction is high (ratio of terminal vs. internal hydroboration ≈ 4:1). Introduction of methyl groups into the β-positions of the terminal alkenes eliminates the regioselectivity problem (NMR spectroscopic control) but leads to an inseparable mixture of diastereomers after hydroboration.

Apart from the fact that **8** was found to be a mixture of isomers **8**$^{\mathbf{t}}$ and **8**$^{\mathbf{i}}$, the sample obtained was sufficiently pure for further derivatisation with 4,4′-dimethyl-2,2′-bipyridyl. This reaction requires 3 rather than 2 equiv. of bipyridyl ligand; the third equivalent is consumed by the $[BBr_4]^-$ counterion of **8**. Bromo-substituted 2,2′-bipyridylboronium cations are sensitive towards hydrolysis, therefore **9Br** was transformed into the air- and moisture-stable derivative **9OMe** by treatment with methanol/triethylamine. The successful synthesis of **9OMe** was proven by ESI mass spectrometry.

Overall, the general synthetic concept outlined in this paper has successfully passed its first evaluation. However, the following modifications are required: (1) Despite numerous efforts, we have not been able to separate the different regioisomers of **9OMe** by HPLC or GPC techniques. Apart from the fact that the solubilities, polarities etc. of these isomers are obviously similar, the alkyl(bipyridyl)boronium cations within the dendrimer branches appear to be less stable than the aryl(bipyridyl)boronium cations formed with the core unit. We therefore decided to abandon the hydroboration step in future syntheses and to look for an alternative reaction that leads to more stable aryl(bipyridyl)-boronium ions and does not suffer from any regioselectivity problems. All these requirements are met by the system (trimethylsilyl)arene/BBr_3, which gives aryldibromoboranes and bromotrimethylsilane (in fact, this reaction has already been employed for the synthesis of our di- and triborylated core units[19]). Since we already have the 2,2′-bipyridyl derivative **10** (Figure 3) at our disposal,[22] there should be no major problem on switching from the hydroboration reaction to the Si/B exchange protocol. (2) During the hydro-



10

boration step, a $[BBr_4]^-$ ion is created, which is reactive towards 2,2′-bipyridyls. Since the perfluorated tetraphenylborate anion $[B(C_6F_5)_4]^-$ turned out to be inert under the reaction conditions applied, it is advantageous to replace the Br^- ion by $[B(C_6F_5)_4]^-$ in future syntheses {e.g. by treatment with $Tl[B(C_6F_5)_4]$ or $Ag[B(C_6F_5)_4]$}.

Experimental Section

General Remarks: All reactions were carried out under oxygen-free argon or nitrogen using standard Schlenk techniques. Solvents were distilled under argon from sodium/benzophenone (toluene, *n*-hexane, *n*-pentane, triethylamine, methanol) or passed through a 4 Å molecular sieves column (CH_2Cl_2, $CHCl_3$) prior to use; the syntheses of *p*-(dibromoboryl)toluene (**1Br**),[19] 1,4-bis(dibromoboryl)benzene,[19] 1,3,5-tris(dibromoboryl)benzene[19] and 4,4′-bis(but-3′′-enyl)-2,2′-bipyridyl (**2**)[22] have been described elsewhere. NMR spectra were recorded with Bruker AMX 250, DPX 250 or Avance 400 spectrometers. Chemical shifts are referenced to residual solvent peaks (^1H, $^{13}C\{^1H\}$); ^{11}B NMR chemical shifts are reported relative to external $BF_3{\cdot}Et_2O$. Low resolution electrospray mass spectra (ESI) were recorded in the positive-ion mode with a Fisons VG Platform II spectrometer.

1Me: Tetramethylstannane (4.699 g, 26.27 mmol) was added dropwise, at ambient temperature, to **1Br** (6.543 g, 25.00 mmol) in *n*-pentane (15 mL), and the mixture was stirred for 5 h. After the solvent had been evaporated, the residue was kept at 50 °C in vacuo for 3 h. Subsequent vacuum distillation gave pure **1Me** as a colourless liquid. Yield: 3.498 g (70%). ^1H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 7.99 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, H-Ar$_o$), 7.25 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, H-Ar$_m$), 2.39 (s, 3 H, CH_3-Ar), 1.49 (s, 3 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 70.5 ($h_{1/2}$ = 250 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 146.8 (C-Ar$_p$), 138.0 (C-Ar$_o$), 129.0 (C-Ar$_m$), 22.1 (CH_3-Ar) ppm; C-Ar$_i$, CH_3B not observed.

1OEt: Diethyl ether (1.495 g, 20.17 mmol) was added with a syringe to **1Br** (5.235 g, 20.00 mmol) in toluene (40 mL). After the solution had been stirred at room temperature for 5 d, the solvent was evaporated to give **1OEt** as an off-white oil, which was used without further purification. Yield: 3.993 g (88%). ^1H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 8.16 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar), 7.13 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar), 4.18 (q, $^3J_{H,H}$ = 7.1 Hz, 2 H, OCH_2), 2.16 (s, 3 H, CH_3-Ar), 1.13 (t, $^3J_{H,H}$ = 7.1 Hz, 3 H, OCH_2CH_3) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 38.4 ($h_{1/2}$ = 200 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 137.9, 135.9, 128.9 (C-Ar), 66.0 (OCH_2), 21.4 (CH_3-Ar), 16.1 (OCH_2CH_3) ppm; C-Ar$_i$ not observed.

3Br: A solution of **1Br** (0.393 g, 1.50 mmol) in toluene (2.5 mL) was added dropwise to a solution of **2** (0.397 g, 1.50 mmol) in toluene (5 mL). The reaction mixture immediately turned yellow and **3Br** precipitated as a yellow oil. This oil was isolated, washed with *n*-hexane and dried in vacuo to give the pure product as a yellow foam. Yield: 0.602 g (76%). ^1H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 10.25 (br., 2 H, H-3), 8.45 (d, $^3J_{H,H}$ = 6.0 Hz, 2 H, H-6), 7.76 (dd, $^3J_{H,H}$ = 6.0, $^4J_{H,H}$ = 1.4 Hz, 2 H, H-5), 7.15 (d, $^3J_{H,H}$ = 8.3 Hz, 2 H, H-Ar$_o$), 7.09 (d, $^3J_{H,H}$ = 8.3 Hz, 2 H, H-Ar$_m$), 5.81 (ddt, $^3J_{H,H}$ = 17.1, 10.3, 6.6 Hz, 2 H, H-9), 5.05 (d, $^3J_{H,H}$ = 17.1 Hz, 2 H, H-10$_E$), 4.99 (d, $^3J_{H,H}$ = 10.3 Hz, 2 H, H-10$_Z$), 3.20 (t, $^3J_{H,H}$ = 7.4 Hz, 4 H, H-7), 2.67 (m, 4 H, H-8), 2.27 (s, 3 H, CH_3-Ar) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 6.5 ($h_{1/2}$ = 400 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 164.7 (C-4), 144.6 (C-2), 142.3 (C-6), 140.0 (C-Ar$_p$), 135.6 (C-9), 132.2 (C-Ar$_o$), 129.4 (C-Ar$_m$), 129.0 (C-5), 126.8 (C-3), 117.1 (C-10), 35.3 (C-7), 33.1 (C-8), 21.2 (CH_3-Ar) ppm; C-Ar$_i$ not observed.

3Me: A solution of **1Me** (0.591 g, 3.00 mmol) in dichloromethane (5 mL) was added dropwise, at ambient temperature, to **2** (0.793 g, 3.00 mmol) in dichloromethane (10 mL). The solvent volume was reduced to approximately 5 mL and *n*-hexane added dropwise, whereupon **3Me** precipitated as a pale-yellow oil. Yield: 1.211 g (88%). ^1H NMR (400.1 MHz, $CDCl_3$, 25 °C): δ = 10.31 (br., 2 H, H-3), 8.22 (d, $^3J_{H,H}$ = 5.9 Hz, 2 H, H-6), 7.59 (dd, $^3J_{H,H}$ = 5.9, $^4J_{H,H}$ = 1.4 Hz, 2 H, H-5), 7.06 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar$_m$), 6.91 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar$_o$), 5.85 (ddt, $^3J_{H,H}$ = 17.1, 10.3, 6.7 Hz, 2 H, H-9), 5.07 (d, $^3J_{H,H}$ = 17.1 Hz, 2 H, H-10$_E$), 5.01 (d, $^3J_{H,H}$ = 10.3 Hz, 2 H, H-10$_Z$), 3.20 (t, $^3J_{H,H}$ = 7.5 Hz, 4 H, H-7), 2.69 (m, 4 H, H-8), 2.27 (s, 3 H, CH_3-Ar), 0.61 (s, 3 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 7.5 ($h_{1/2}$ = 350 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 161.5 (C-4), 145.1 (C-2), 141.3 (C-6), 138.1 (C-Ar$_p$), 135.7 (C-9), 131.1 (C-Ar$_o$), 129.0 (C-Ar$_m$), 128.3 (C-5), 125.3 (C-3), 116.5 (C-10), 34.8 (C-7), 33.2 (C-8), 20.9 (CH_3-Ar), 6.9 (CH_3B) ppm; C-Ar$_i$ not observed. ESI-MS: *m*/*z* (%) = 381 (100) [M^+ – Br]. $C_{26}H_{30}BBrN_2$ (461.25): calcd. C 67.70, H 6.56, N 6.07; found C 67.11, H 6.51, N 5.91.

3OEt: Compound **2** (2.247 g, 8.50 mmol) was dissolved in toluene (20 mL) and a solution of **1OEt** (1.929 g, 8.50 mmol) in toluene (20 mL) was added dropwise at ambient temperature, whereupon the reaction mixture became cloudy and the product precipitated as a red-brown oil. The solvent was decanted and the oil washed with *n*-hexane. Yield: 3.645 g (87%). ^1H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 10.18 (br., 2 H, H-3), 8.27 (d, $^3J_{H,H}$ = 5.8 Hz, 2 H, H-6), 7.67 (dd, $^3J_{H,H}$ = 5.8, $^4J_{H,H}$ = 1.4 Hz, 2 H, H-5), 7.00 (m, 4 H, H-Ar), 5.81 (ddt, $^3J_{H,H}$ = 17.2, 10.3, 6.8 Hz, 2 H, H-9), 5.02 (d, $^3J_{H,H}$ = 17.2 Hz, 2 H, H-10$_E$), 4.96 (d, $^3J_{H,H}$ = 10.3 Hz, 2 H, H-10$_Z$), 3.17 (t, $^3J_{H,H}$ = 7.6 Hz, 4 H, H-7), 2.92 (q, $^3J_{H,H}$ = 6.9 Hz, 2 H, OCH_2), 2.65 (m, 4 H, H-8), 2.23 (s, 3 H, CH_3-Ar), 1.06 (t, $^3J_{H,H}$ = 6.9 Hz, 3 H, OCH_2CH_3) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 9.1 ($h_{1/2}$ = 350 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 163.6 (C-4), 145.2 (C-2), 141.7 (C-6), 138.7 (C-Ar$_p$), 135.7 (C-9), 131.0 (C-Ar$_o$), 129.0 (C-Ar$_m$), 128.5 (C-5), 126.0 (C-3), 116.8 (C-10), 58.2 (OCH_2), 35.1 (C-7), 33.3 (C-8), 21.2 (CH_3-Ar), 17.4 (OCH_2CH_3) ppm; C-Ar$_i$ not observed. ESI-MS: *m*/*z* (%) = 411 (100) [M^+ – Br]. $C_{27}H_{32}BBrN_2O$ (491.27): calcd. C 66.01, H 6.57, N 5.70; found C 65.74, H 6.47, N 5.59.

3OMe: Compound **3Br** (0.789 g, 1.50 mmol) was dissolved in dry methanol (5 mL), treated with dry triethylamine (0.152 g, 1.50 mmol) from a syringe and the resulting reaction mixture was stirred at ambient temperature for 2 h. The solvent was evaporated and the residue dissolved in dichloromethane (5 mL). Addition of a few drops of *n*-hexane made the product precipitate as a light brown oil, which was isolated by decantation and washed with a mixture of dichloromethane and *n*-hexane. Yield: 0.635 g (89%). ^1H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 10.18 (br., 2 H, H-3), 8.26 (d, $^3J_{H,H}$ = 5.8 Hz, 2 H, H-6), 7.67 (dd, $^3J_{H,H}$ = 5.8, $^4J_{H,H}$ = 1.5 Hz, 2 H, H-5), 7.02 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, H-Ar$_m$), 6.97 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, H-Ar$_o$), 5.81 (ddt, $^3J_{H,H}$ = 17.1, 10.4, 6.9 Hz, 2 H, H-9), 5.03 (d, $^3J_{H,H}$ = 17.1 Hz, 2 H, H-10$_E$), 4.97 (d, $^3J_{H,H}$ = 10.4 Hz, 2 H, H-10$_Z$), 3.18 (t, $^3J_{H,H}$ = 7.5 Hz, 4 H, H-7), 2.86 (s, 3 H, OCH_3), 2.66 (m, 4 H, H-8), 2.23 (s, 3 H, CH_3-Ar) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 9.8 ($h_{1/2}$ = 400 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 163.7 (C-4), 145.2 (C-2), 141.7 (C-6), 138.8 (C-Ar$_p$), 135.7 (C-9), 131.0 (C-Ar$_o$), 129.0 (C-Ar$_m$), 128.6 (C-5), 126.0 (C-3), 116.8 (C-10), 50.4 (OCH_3), 35.1 (C-

7), 33.2 (C-8), 21.2 (CH_3-Ar) ppm; C-Ar_i not observed. ESI-MS: *m/z* (%) = 397 (100) [M^+ – Br]. $C_{26}H_{30}BBrN_2O$ (477.25): calcd. C 65.43, H 6.34, N 5.87; found C 64.80, H 6.33, N 5.62.

4: 1,4-Bis(dibromoboryl)benzene (2.295 g, 5.50 mmol) was dissolved in chloroform (15 mL) and tetramethylstannane (1.967 g, 11.00 mmol) was added dropwise at ambient temperature. The reaction mixture was stirred overnight, the solvent was evaporated, bromotrimethylstannane removed at 50 °C in vacuo, and the residue vacuum-sublimed to give pure **4** as a colourless solid. Yield: 0.854 g (54%). ^{1}H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 8.14 (s, 4 H, H-Ar), 1.55 (s, 6 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$): δ = 72.3 ($h_{1/2}$ = 400 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 135.5 (C-Ar) ppm; C-Ar_i, CH_3B not observed.

5: A solution of **4** (0.431 g, 1.50 mmol) in dichloromethane (5 mL) was added dropwise, at ambient temperature, to **2** (0.793 g, 3.00 mmol) in dichloromethane (10 mL). After the addition was complete, the solvent volume was reduced to approximately 5 mL and *n*-hexane added dropwise, which made **5** precipitate as a pale-yellow oil. Yield: 1.084 g (89%). ^{1}H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 9.88 (br., 4 H, H-3), 8.31 (d, $^3J_{H,H}$ = 5.9 Hz, 4 H, H-6), 7.76 (dd, $^3J_{H,H}$ = 5.9, $^4J_{H,H}$ = 1.4 Hz, 4 H, H-5), 6.89 (s, 4 H, H-Ar), 5.81 (ddt, $^3J_{H,H}$ = 17.0, 10.3, 6.6 Hz, 4 H, H-9), 5.04 (d, $^3J_{H,H}$ = 17.0 Hz, 4 H, H-10$_E$), 4.98 (d, $^3J_{H,H}$ = 10.3 Hz, 4 H, H-10$_Z$), 3.15 (t, $^3J_{H,H}$ = 7.5 Hz, 8 H, H-7), 2.63 (m, 8 H, H-8), 0.58 (s, 6 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 7.7 ($h_{1/2}$ = 580 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 161.8 (C-4), 145.2 (C-2), 141.4 (C-6), 135.9 (C-9), 131.5 (C-Ar), 128.6 (C-5), 125.5 (C-3), 116.9 (C-10), 35.1 (C-7), 33.4 (C-8) ppm; C-Ar_i, CH_3B not observed. ESI-MS: *m/z* (%) = 328 (100) [M^{2+} – 2 Br]. $C_{44}H_{50}B_2Br_2N_4$ (816.34): calcd. C 64.74, H 6.17, N 6.86; found C 64.29, H 6.07, N 6.66.

6: Preparation and purification was achieved as described for **4**. 1,3,5-Tris(dibromoboryl)benzene (2.348 g, 4.00 mmol), tetramethylstannane (2.217 g, 12.40 mmol), chloroform (20 mL). Yield: 0.674 g (43%). ^{1}H NMR (250.1 MHz, $CDCl_3$, 25 °C): δ = 9.02 (s, 3 H, H-Ar), 1.34 (s, 9 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, $CDCl_3$, 25 °C): δ = 72.0 ($h_{1/2}$ = 350 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 149.0 (C-Ar) ppm; C-Ar_i, CH_3B not observed.

7: Compound **6** (0.863 g, 2.20 mmol) was dissolved in dichloromethane (10 mL) and added dropwise to a solution of **2** (1.718 g, 6.50 mmol) in dichloromethane (20 mL). The reaction mixture became yellow. After the addition was complete, *n*-hexane was added, which made **7** precipitate as a yellow oil. Yield: 2.086 g (80%). ^{1}H NMR (400.1 MHz, $CDCl_3$, 25 °C): δ = 8.89 (br., 6 H, H-3), 8.81 (d, $^3J_{H,H}$ = 5.9 Hz, 6 H, H-6), 8.13 (dd, $^3J_{H,H}$ = 5.9, $^4J_{H,H}$ = 1.3 Hz, 6 H, H-5), 6.62 (s, 3 H, H-Ar), 5.80 (ddt, $^3J_{H,H}$ = 17.1, 10.4, 6.6 Hz, 6 H, H-9), 5.05 (d, $^3J_{H,H}$ = 17.1 Hz, 6 H, H-10$_E$), 5.01 (d, $^3J_{H,H}$ = 10.4 Hz, 6 H, H-10$_Z$), 3.07 (m, 12 H, H-7), 2.56 (m, 12 H, H-8), 0.45 (s, 9 H, CH_3B) ppm. ^{11}B NMR (128.4 MHz, CD_3OD, 25 °C): δ = 6.5 ($h_{1/2}$ = 600 Hz) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$, 25 °C): δ = 160.4 (C-4), 144.5 (C-2), 143.9 (C-6), 135.6 (C-9), 134.3 (C-Ar), 129.8 (C-5), 123.2 (C-3), 117.0 (C-10), 35.2 (C-7), 33.6 (C-8), 7.6 (CH_3B) ppm; C-Ar_i not observed. ESI-MS: *m/z* (%) = 512 (100) [M^{2+} – 2 Br], 315 (95) [M^{3+} – 3 Br]. $C_{63}H_{72}B_3Br_3N_6$ (1185.45): calcd. C 63.83, H 6.12, N 7.09; found C 63.39, H 6.08, N 6.85.

8: An intensely yellow solution of **3Br** (0.395 g, 0.75 mmol) and Et_3SiH (0.262 g, 2.25 mmol) in dichloromethane (5 mL) was added dropwise at –78 °C to BBr_3 (0.564 g, 2.25 mmol) in dichloromethane (5 mL) and the mixture then warmed to room temperature. Addition of *n*-hexane (5 mL) made **8** precipitate as a pale-yellow oil, which was isolated and vacuum-dried to give a colourless foam. According to the NMR spectra the conversion was quantitative. Major isomer **8^t**: ^{1}H NMR (400.1 MHz, CD_2Cl_2, 25 °C): δ = 8.87 (s, 2 H, H-3), 8.60 (d, $^3J_{H,H}$ = 6.0 Hz, 2 H, H-6), 7.86 (dd, $^3J_{H,H}$ = 6.0, $^4J_{H,H}$ = 1.4 Hz, 2 H, H-5), 7.27 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar$_o$), 7.17 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, H-Ar$_m$), 3.15 (t, $^3J_{H,H}$ = 7.6 Hz, 4 H, H-7), 2.32 (s, 3 H, CH_3-Ar), 1.94 (m, 4 H, H-8), 1.80 (m, 4 H, H-9), 1.71 (m, 4 H, H-10) ppm. ^{11}B NMR (126.8 MHz, CD_2Cl_2, 25 °C): δ = 57.3 (BBr_2, $h_{1/2}$ = 530 Hz), 6.5 (Bbipy, $h_{1/2}$ = 650 Hz), –24.1 ($[BBr_4]^-$, $h_{1/2}$ = 260 Hz) ppm. ^{13}C NMR (100.6 MHz, CD_2Cl_2, 25 °C): δ = 165.5 (C-4), 144.6 (C-2), 143.7 (C-6), 140.5 (C-Ar$_p$), 132.9 (C-Ar$_o$), 130.0 (C-5), 129.7 (C-Ar$_m$), 124.4 (C-3), 36.5 (C-7), 36.2 (C-10), 31.8 (C-8), 26.4 (C-9), 21.4 (CH_3-Ar) ppm; C-Ar_i not observed.

9OMe: Compound **8** (0.840 g, 0.75 mmol) was dissolved in dichloromethane (5 mL) and a solution of 4,4′-dimethyl-2,2′-bipyridyl (0.415 g, 2.25 mmol) in dichloromethane (5 mL) added dropwise with stirring. Upon addition, the solution adopted an intense yellow colour. After the reaction mixture had been stirred at ambient temperature for 2 h, the solvent was evaporated and the solid residue redissolved in methanol (5 mL). Et_3N (0.227 g, 2.25 mmol) was added with a syringe, the reaction mixture was stirred for 2 h, and the volatiles were removed in vacuo. All attempts to isolate **9OMe** from the solid residue obtained applying reversed-phase HPLC techniques [stationary phase: ReproSil-Pur C18-AQ (10 μm, 250 × 20 mm); eluent: methanol or methanol/acetonitrile] failed. However, ESI mass spectrometry proved the presence of **9OMe** in the crude product. ESI-MS: *m/z* = 284 [M^{3+} – 3 Br], 465 [M^{2+} – 2 Br].

Crystal Structure Determination: $C_{27}H_{32}BBrN_2O$, M = 491.27, triclinic, space group $P\bar{1}$, a = 13.154(2), b = 14.371(2), c = 23.377(5) Å, α = 87.329(15)°, β = 87.113(15)°, γ = 63.314(12)°, V = 3941.9(12) Å^3, Z = 6, D_c = 1.242 Mg m^{-3}, F(000) = 1536, Mo-K_α radiation (λ = 0.71073 Å), T = 173(2) K; crystal size 0.24 × 0.23 × 0.16 mm, ω-scan mode, measurement range ($-16 \le h \le 15$, $-17 \le k \le 17$, $-28 \le l \le 26$, $3.58 \le \theta \le 25.92$), 15100 independent reflections, μ = 1.584 mm^{-1}. The structure was solved by direct methods[25] and full-matrix least-squares refinement was carried out against F^2 using the SHELXL-97 program,[26] 905 parameters, R_1 = 0.1833 (all data), wR_2 = 0.2230 (all data), max./min. residual electron density +0.580/–0.512 e Å^{-3}. CCDC-271402 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Metal Binding Within a Peptide-Based Nucleobase Stack with Tuneable Double-Strand Topology

Andrea Küsel,[a] Jinhua Zhang,[a] Miguel Alvariño Gil,[b] A. Claudia Stückl,[b] Wolfram Meyer-Klaucke,[c] Franc Meyer,*[b] and Ulf Diederichsen*[a]

Keywords: EXAFS spectroscopy / Molecular recognition / Nucleic acids / Peptides / Protein models

Peptide nucleic acid (PNA) oligomers with linear topology are synthesised with histidines at the central positions in order to provide metal-ion coordination sites within the water shielded and non-polar environment of a nucleobase stack that emerges upon duplex formation. Variation of the linker length used for attachment of the nucleobases to the regular peptide backbone allows for fine tuning of the distances and coordination environment at the metal binding site. The effect of zinc and copper incorporation into the modified alanyl-PNA scaffolds on duplex stability was probed by temperature-dependent UV spectroscopy, and additional insight was gained from EPR spectroscopy and EXAFS. Whenever four histidines (two per oligomer strand) are available, addition of Zn^{2+} significantly enhances double-strand stability, thus supporting coordination of Zn^{2+} by the histidine-N and incorporation of the metal ion within the base stack. In contrast to Zn^{2+}, however, Cu^{2+} ions do not induce double-strand formation of an alanyl/norvalyl-PNA oligomer, as confirmed by EPR and EXAFS, which reveal a mixed $\{N_2O_x\}$ donor environment. While metal-ion binding to histidine-modified alanyl-PNA oligomers (and homologues) is apparently feasible, a proper matching of the binding-site geometry and the stereoelectronic requirements of the specific metal ion are essential in order to mediate double-strand formation. This might offer new options for alternative pairing schemes in alanyl-PNA chemistry in which metal coordination substitutes the common base-pair H-bonding pattern, and for metal-dependent regulation of alanyl-PNA duplex formation.

Introduction

Artificial DNA, in which one or multiple nucleosides is replaced by so-called "ligandosides" capable of metal-ion binding, is receiving increasing attention.[1–3] Inter alia, metal-mediated base pairing is exploited in order to increase the thermal stability of the DNA duplex, to extend the genetic alphabet for DNA-based information storage, or to develop novel nanostructured metal-containing architectures with interesting physical properties.[4] Peptide nucleic acids (PNAs) are synthetic analogues of nucleic acids with a non-natural polyamide backbone, most commonly based on *N*-(2-aminoethyl)glycine.[5] Their particularly attractive properties comprise self-recognition, high chemical and biological stability, and strong binding to target DNA or RNA sequences. Recently, some high affinity metal-binding sites such as porphyrins,[6] bipyridines[7,8] or chelating amines[9–11] and organometallic moieties[12] have been appended to PNA, and these metal complex/PNA conjugates have been probed in the context of sequence-specific DNA/RNA cleavage and detection,[6,8,13] DNA-templated catalysis,[10] and for the development of new antisense drugs.[14] In most of these systems the ligand site for metal binding is attached to one end of the PNA strand, but it has also been shown that metal incorporation in the middle of complementary *N*-(2-aminoethyl)glycine PNA strands that have been modified by bipyridine is indeed feasible and leads to preservation of the helical duplex structure.[7]

In the present contribution we probe hitherto unexplored metal incorporation into alanyl peptide nucleic acids (alanyl-PNA). Alanyl-PNA is structurally based on a regular peptide composed of alanyl amino acids with alternating configuration and nucleobases covalently linked to methylene side-chains.[15–17] Double strands are formed by two complementary alanyl-PNA strands based on base-pair recognition, stacking and solvation. The duplexes need to adopt a linear double-strand topology since the distance between consecutive side-chains in an extended peptide is close to the ideal base-pair stacking distance. The resulting alanyl-PNA double strand with linear topology is well defined regarding nucleobase orientation and distances and it is limited with respect to conformational freedom. Further-

more, chromophores incorporated within the nucleobase stack are known to be significantly shielded from aqueous solution.[18]

Coordination of metal ions within the nucleobase stack is especially interesting, since the non-polar environment inside the base stack should have unique consequences for the stability and geometry of metal coordination. The alanyl-PNA framework offers the particular advantage of being able to use natural amino acids such as histidine as biomimetic metal binding sites at different positions of the strand. Metal ions in such a metalloenzyme-inspired water-shielded environment might be useful for, inter alia, catalytic applications, while the alanyl-PNA backbone and nucleobases offer additional possibilities for specific substrate recognition via hydrogen-bonding interactions. This investigation might also be of interest to establish specific metal-mediated recognition next to hydrogen bonding in double-strand interactions. Finally, homologation of the side-chains in alanyl-PNA might allow for fine tuning of the distances and geometries of the metal binding sites or even the possibility to introduce dinuclear metal arrays.

Here, various alanyl-PNAs and side-chain homologous oligomers with central histidine metal binding sites are presented and investigated with respect to their ability to stabilize double-strand formation mediated by metal ions. It should be noted that in the absence of high-affinity ligands the amide groups in the PNA backbone and the nucleobases may act as competing binding sites for metal ion complexation,[19] and various spectroscopic and analytical tools are thus required in order to clearly characterise metal incorporation into the modified PNA duplexes.

Results and Discussion

Double-strand formation of an alanyl-PNA hexamer based on Watson–Crick pairing of six G-C base pairs is

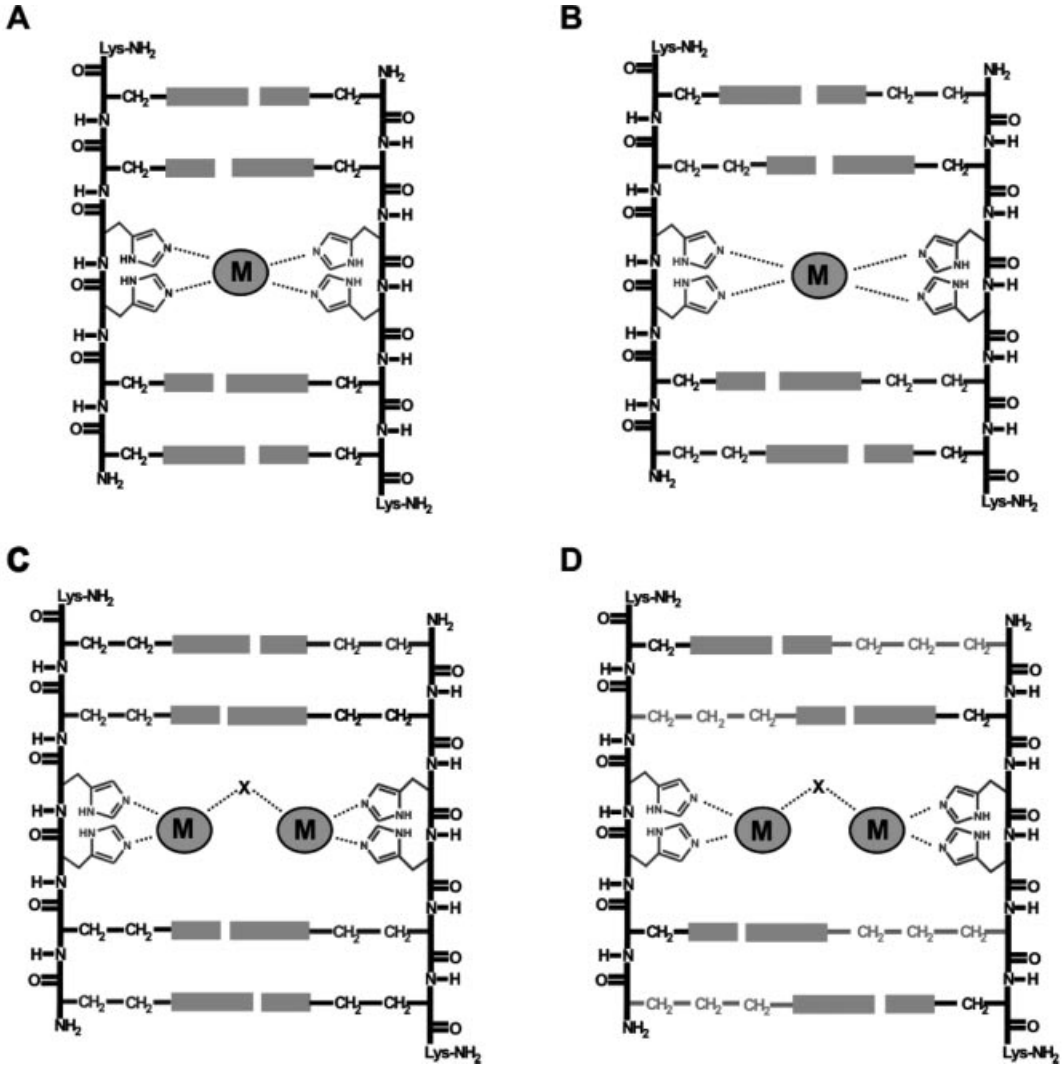

Figure 1. Idealized representation of double strands with a linear topology based on a peptide backbone with alternating amino acid configuration, four G-C base pairs and central histidines as metal ion coordination sites. Alanyl-peptide nucleic acids (alanyl-PNAs) should allow for coordination of one metal ion (**A**) as should alanyl/homoalanyl mixed PNAs (**B**). The distance of histidine coordination sites in homoalanyl-PNA might allow incorporation of two metal ions (**C**); the metal binding geometry in mixed alanyl/norvalyl-PNAs should be comparable (**D**). X might be a small bridging ligand such as HO^-, Cl^- or AcO^-.

known to be quite stable (T_m = 58 °C).[16] Therefore, it was likely that an exchange of the central two G-C base pairs for histidine side-chains would retain the ability for duplex formation. In alanyl-PNA and mixed alanyl/homoalanyl-PNA double strands with four central histidines, coordination of one metal ion can be expected based on a backbone distance of about 14–15 Å (Figure , A and B). The backbone distance is extended to about 16.5 Å by further side-chain homologation, possibly allowing for two metal coordination sites. Therefore, homoalanyl-PNA and alanyl/norvalyl-PNA with central histidines were prepared (Figure 1, C and D).

Alanyl-PNA oligomers **1**–**3** as well as the side-chain homologous alanyl/homoalanyl-PNAs **4**–**6**, homoalanyl-PNAs **7** and **8** and alanyl/norvalyl-PNA oligomers **9** and **10** (Table 1) were prepared by manual solid-phase peptide synthesis based on a Boc strategy.[20] The respective nucleobase-substituted amino acids were assembled on an MBHA polystyrene support using HATU as the coupling reagent. The oligomers were purified by HPLC and characterised by mass spectrometry.

Double-strand formation was investigated by temperature-dependent UV spectroscopy. This method relies on a sigmoidal increase of UV absorption with higher temperatures caused by a cooperative destacking of the nucleobases. It was adapted from oligonucleotide chemistry and has been used successfully for the characterisation of PNA double strands.

Alanyl-PNA Oligomers

In the alanyl-PNA series enantiomeric oligomers provide tridentate G-C Watson–Crick pairing, as has been shown for an equimolar mixture of hexamers **1** and ***ent*-1** (T_m = 58 °C).[16] In contrast, nucleo amino acids with a different configuration form the less stable G-C reverse Watson–Crick base pair (self pairing of **1**: T_m = 42 °C).[16] Therefore, the enantiomeric oligomers **2** and ***ent*-2** were prepared, both of which feature two histidines in central positions. Watson–Crick self-pairing as well as equimolar pairing of enantiomers **2** and ***ent*-2** turned out not to be stable enough for detection of double-strand formation. Nevertheless, in the presence of Zn^{2+} ions UV melting curves clearly indicate self-pairing of **2** and pairing of enantiomeric oligomers **2** and ***ent*-2**, both with a stability of about 15 °C (Figure 2, A). Zinc ions obviously interact with the respective oligomers in order to overcome the low double-strand stability.

In the absence of zinc, however, the non-coordinating histidines seem to suppress double-strand formation, presumably because of charge repulsion of the protonated side-chains at physiological pH; one should note that double-strand formation with considerable stability is known for G-C alanyl-PNA tetramers.[16]

Oligomer **3**, which features a histidine next to a glycine in the central position, was synthesised with the intention to test oligomers with lower potential for zinc coordination. Interestingly, self-pairing was now provided with a stability of T_m = 13 °C and it was not possible to increase this stability by zinc addition. First of all, this is an argument for the charge repulsion of neighbouring histidines hampering formation of double strands in the case of oligomer **2**. Furthermore, the lack of double-strand stabilisation upon addition of zinc to oligomer **3** is in agreement with two histidines not being sufficient for incorporation of zinc. Coordination at the nucleobases can be excluded as a reason for the stabilisation of double strands formed by oligomers **2** and ***ent*-2**, which only occurs in the presence of zinc ions. This result was confirmed by homochiral Watson–Crick pairing of oligomers **2** and **3** providing a potential zinc binding centre of three histidines: in agreement with the more stable pairing mode and possible charge repulsion of neighbouring histidines, the double strand **2** + **3** without zinc ions was formed only with slightly higher stability (T_m = 15 °C) than self-pairing of oligomer **3**, whereas addition of zinc had no effect on the overall stability (T_m = 14 °C).

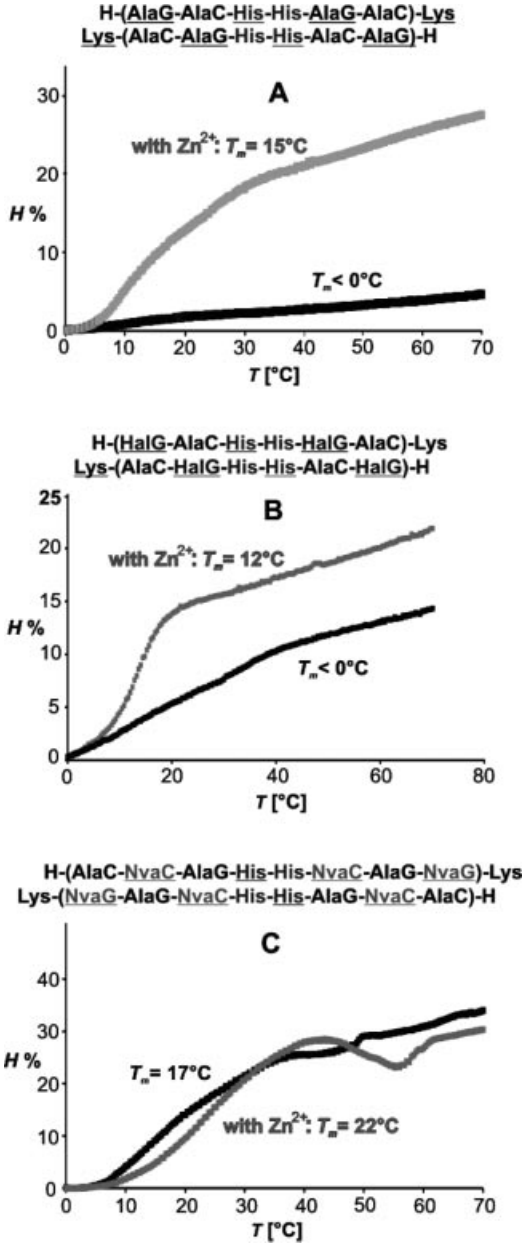

Figure 2. UV melting curves of alanyl-PNA (**2**) in phosphate buffer (A) and of alanyl/homoalanyl-PNA (**5**; B) as well as alanyl/norvalyl-PNA (**10**; C) in HEPES buffer in the absence (dark curves) or presence (light curves) of Zn^{2+}.

Mixed Alanyl/Homoalanyl-PNA Oligomers

Peptide nucleic acid double strands composed of alternating alanyl and homoalanyl nucleo amino acids provide a backbone distance that is about 1 Å larger than alanyl-PNA duplexes. This should significantly influence metal coordination by the central histidines. Furthermore, in the mixed alanyl/homoalanyl-PNA series the more stable Watson–Crick G-C base pairs are formed with self-pairing homodimers.[20] A stability of T_m = 52 °C was found for the homodimer of hexamer **4**. Like in alanyl-PNA, the exchange of the central G-C base pairs for four histidines in the double strand of oligomer **5** prevents double-strand formation. Addition of zinc ions to oligomer **5** leads to stabilisation (T_m = 17 °C) of the same order of magnitude as observed for the respective alanyl-PNA **2**.

Since a possible application of the metal/PNA conjugates will be the catalysis of, inter alia, phosphodiester hydrolysis, the double-strand stabilities were also investigated in HEPES buffer instead of the more common phosphate buffer in order to evaluate the effect of the medium. In HEPES buffer double-strand formation of oligomer **5** was again not observed and zinc ions turned out to be essential for stabilisation (T_m = 12 °C; Figure 2, B). However, the change from phosphate to HEPES buffer resulted in a 5 °C decrease of stability.

With the aim of providing double strands with a higher overall stability, the mixed alanyl/homoalanyl-PNA oligomer **6**, which features six nucleo amino acids and two central histidines, was prepared. The low double-strand stability of the homodimer **6** (T_m = 13 °C) resembles the effect of four non-coordinating histidines in the central region, as mentioned already in the alanyl-PNA series. Addition of zinc ions leads to a significant increase in stability (T_m = 25 °C) even in HEPES buffer, which makes this system a promising candidate for further studies.

Homoalanyl-PNA and Mixed Alanyl/Norvalyl-PNA Oligomers

Both homoalanyl-PNA as well as mixed alanyl/norvalyl-PNA double strands provide a distance between the peptide

backbones that is determined by the base-pair size extended by overall four methylene units (Figure 1, C and D). This might open the possibility for coordination of two zinc ions within the centre of a linear PNA double strand. In the homoalanyl-PNA series, double-strand formation with nucleobases having the same configuration (homochiral base pairing) leads to the more stable G-C Watson–Crick pairing.[20] The double strand of homoalanyl-PNA enantiomers **7** and ***ent*-7** with six G-C base pairs provides a stability of T_m = 32 °C. The drop of stability compared to the alanyl and alanyl/homoalanyl-PNAs **1** and **4** is caused by higher side-chain flexibility and lower stacking contributions.[20] As a consequence, double-strand formation of homoalanyl-PNA **8** was not observed since it would only be based on four poorly stacked reverse Watson–Crick G-C base pairs with four histidine amino acids in the centre. Considering the poor situation for self-pairing, it is even more remarkable that addition of zinc ions to oligomer **8** induced duplex formation with a similar order of stability as observed for alanyl/homoalanyl oligomer **5** (T_m = 15 °C in phosphate and T_m = 8 °C in HEPES buffer).

The stabilities of the G-C Watson–Crick pairing homoalanyl-PNA hexamer double strand **7** + ***ent*-7** (T_m = 32 °C) and the respective alanyl/norvalyl-PNA duplex **9** + ***ent*-9** (T_m = 16 °C) are quite different despite a similar overall double-strand geometry.[20] The lower degree of side-chain preorganisation in the case of the norvalyl amino acids seems to be responsible for this effect. In analogy to oligomer **6**, the alanyl/norvalyl-PNA oligomers **10** and ***ent*-10**, with six nucleo amino acids and two central histidines, were prepared for the investigation of zinc binding. Reverse Watson–Crick pairing was provided with a stability of T_m = 17 °C in the absence of zinc, whereas the stability of the mixture of enantiomers **10** and ***ent*-10** forming the more stable Watson–Crick base pairs was even higher at T_m = 22 °C. The larger backbone distance in alanyl/norvalyl-PNA provides reduced charge interaction for opposed central histidines. In contrast to oligomers **2** and **5**, this allows for stable duplex formation without zinc binding. For both alanyl/norvalyl-PNA oligomers **10** and **10** + ***ent*-10** the addition of zinc leads to a significant increase in double-strand stability of 5 or 6 °C, respectively.

In order to provide additional information on the metal ion binding potential of oligomer **10**, this particular system was studied in more detail by spectroscopic methods in solution. Since Zn^{2+} is spectroscopically silent, Cu^{2+} was used instead. It should be noted, though, that according to the temperature-dependent UV spectra, double-strand formation was not induced by the addition of copper salts to oligomer **10** (data not shown).

EPR spectroscopy was used as a qualitative probe to verify the binding of Cu^{2+} by PNA **10**. Part a of Figure 3 shows the X-band EPR spectra of a solution of Cu^{2+} only (top) and of a solution of oligomer **10** with 1 equiv. of Cu^{2+} (bottom) in HEPES-buffered water/glycerine (3:1). A much smaller value for $A_z(^{63,65}Cu)$ in the presence of oligomer **10** is clearly discernible, thus confirming coordination of Cu^{2+}. Both the g_z and A_z values are within the range expected

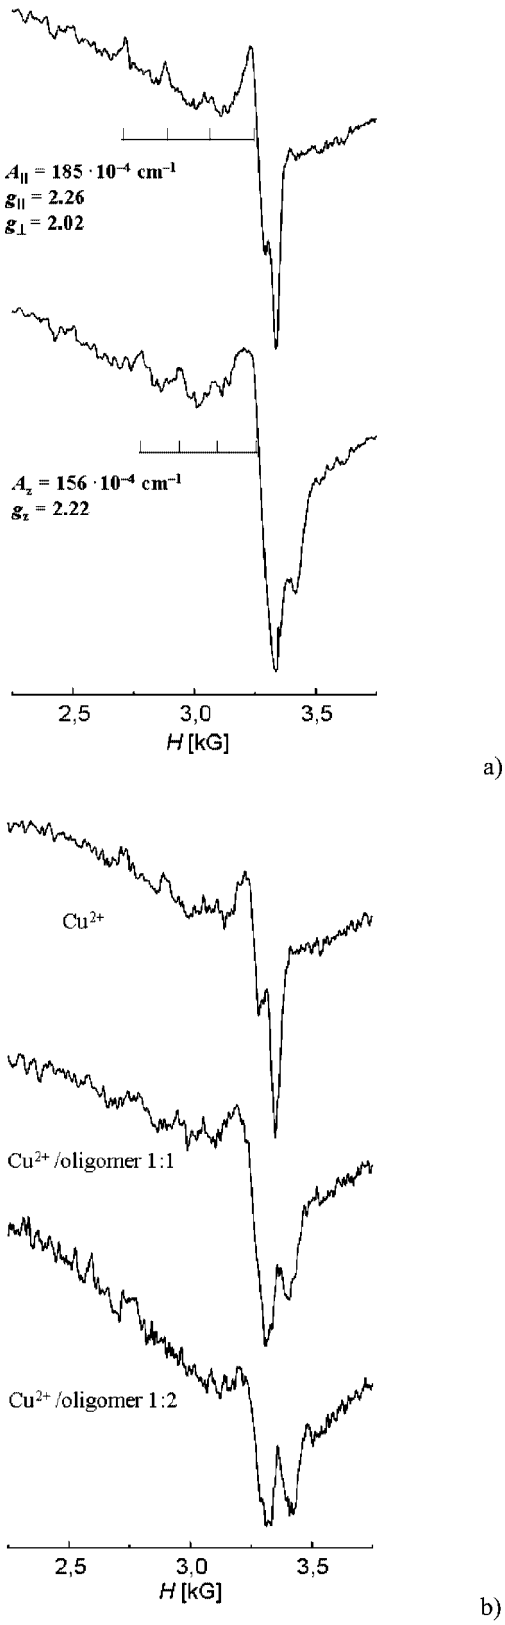

Figure 3. a) EPR spectra of Cu^{2+} in the absence or presence of **10**: H_2O/glycerin (3:1), HEPES pH 7, 150 K; only Cu^{2+} (top) or Cu^{2+}/**10** (1:1, bottom). b) EPR spectra of Cu^{2+} in the absence or presence of **10**: H_2O, HEPES pH 7.4, 150 K; only Cu^{2+} (top), Cu^{2+}/**10** (1:1, middle) or Cu^{2+}/**10** (1:2, bottom).

for some mixed $\{N_xO_y\}$ ligation,[21] but no ^{14}N hyperfine coupling could be detected and no satisfactory simulation of the data could be achieved because of, inter alia, a relatively low signal-to-noise ratio.[22] In addition, the spectra in water at different ratios of Cu^{2+} to PNA **10** (Figure 3, b) indicated the possible presence of several species, leaving the EPR confirmation of metal ion binding by oligomer **10** only a qualitative one.

Cu^{2+} coordination by the histidine N-atoms of PNA **10** was further substantiated by X-ray absorption spectroscopy conducted on a frozen sample of oligomer **10**/Cu^{2+}. X-ray absorption spectroscopy allows the element-specific characterisation of metal environments and thus yields information about the type and distances of coordinating ligands. Ligands with a rather linear arrangement of the backscattering atoms lead to special features in the spectrum due to multiple scattering of the photoelectron wave that is created upon absorption of photons with energies larger than the edge energy. Here, a flat plateau at $k \approx 4.5$ Å^{-1} indicates the presence of imidazole groups coordinating the metal ion. This was further supported by the Fourier transform of the spectrum. The intense contribution at about 4 Å arises from scattering events at the remote atoms of the imidazole rings. Their intensity was increased due to the multiple scattering events including the metal coordinating nitrogen atom. The first coordination shell has a typical distance of about 2.0 Å and its high intensity indicates a homogeneous coordination by light atoms (C/N or O).

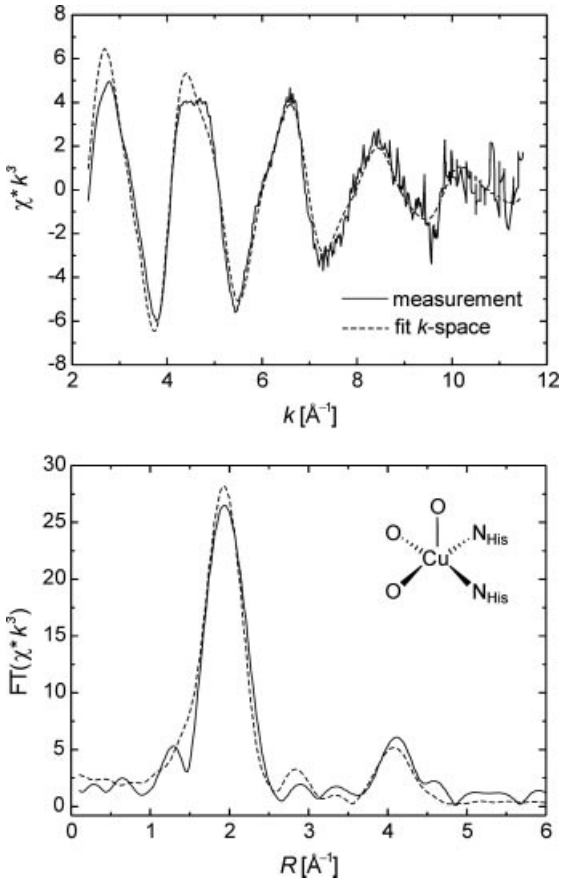

Figure 4. EXAFS and corresponding Fourier transform for the PNA **10**/Cu^{2+} complex (black). The best fit to the data is shown in dashed lines and represents coordination by two imidazole groups and three oxygen atoms.

With this in mind, different combinations of O and imidazole ligands were modelled to the data. The final model given in Figure 4 comprises two imidazole groups and three oxygen ligands at a distance of 1.98 Å. In order to keep the number of free parameters as low as possible the distances for these ligands as well as their Debye–Waller factors ($2\sigma^2 = 0.021$ Å^2) were constrained. Thus, the measurement is not resembled in all details, but any over-interpretation of data is prevented. Typical errors for the coordination number are in the range of 20%, whereas the distances have an error of less than 1% for the first coordination sphere.

Conclusions

A series of alanyl-, homoalanyl- and norvalyl-PNA hexamers or octamers has been prepared in which two central nucleobase-substituted amino acids are replaced by histidines. While the incorporation of histidine residues is shown to drastically lower the tendency for self-pairing compared to the parent PNAs, double-strand formation is still observed for properly chosen systems that provide at least six G-C pairs framing the central histidines (such as in **6**, **10** or **10**/***ent*-10**). As soon as four histidines (two per oligomer strand) are placed at the centre of PNA double strands, addition of Zn^{2+} significantly enhances the duplex stability, thus supporting the coordination of Zn^{2+} by the histidine-N and incorporation of the metal ion within the base stack (Figure 5). Metal ion binding to the histidine-N of the modified alanyl/norvalyl-PNA oligomers is further supported by ESR and EXAFS spectroscopy on the corresponding Cu^{2+} hybrid of **10**. In contrast to Zn^{2+}, however, Cu^{2+} ions do not induce double-strand formation, in accordance with the mixed $\{N_2O_x\}$ donor environment that was deduced from EPR and EXAFS experiments (Figure 5). One might speculate that the different geometric preferences of Zn^{2+} and Cu^{2+} upon binding to four histidine-N (tetrahedral for Zn^{2+}, square planar for Cu^{2+}) give rise to these different effects. It should be noted that for modified DNA it has also been observed that duplex formation is mediated by only specific metal ions.[3]

The present findings thus confirm the anticipated metal ion binding capabilities of histidine-modified alanyl-PNA oligomers (and homologues), i.e. metal binding to conjugates of alanyl-PNA and natural amino acids. However, proper organisation of the metal binding site is essential in order to match the stereoelectronic requirements of the specific metal ion upon double-strand formation. This might offer new options for alternative pairing schemes in alanyl-PNA chemistry in which metal coordination substitutes the common base-pair H-bonding pattern, and for metal-dependent regulation of alanyl-PNA duplex formation.

Experimental Section

General Remarks: All reagents were of analytical grade and used as supplied. Solvents were of the highest grade available. Synthesis and analytical data of *N*-Boc-AlaG-OH, *N*-Boc-AlaC(*Z*)-OH, *N*-Boc-HalG-OH, *N*-Boc-HalC(*Z*)-OH, *N*-Boc-NvaG-OH and *N*-Boc-NvaC(*Z*)-OH were performed as described previously.[20] (*S*)-*N*-Boc-His(Bom)-OH and (*R*)-*N*-Boc-His(Bom)-OH were purchased from Bachem.

ESI mass spectra were recorded with a TSQ 700 Finnigan spectrometer and high resolution mass spectra with a Bruker Apex IV FT-ICR MS instrument. HPLC was done on a Pharmacia Äkta Basic using YMC-Pack ODS, RP-C18 with a linear gradient of A (0.1% TFA in water) to B (0.1% TFA in acetonitrile/water, 9:1). Oligomers were purified using 250 × 20 mm, 5 μm, 120 Å for preparative and 250 × 4.6 mm, 5 μm, 120 Å columns for analytical samples. UV melting curves were measured with a Perkin–Elmer UV/Vis Lambda 10 with a Peltier temperature programmer PTP 1 or a Jasco V-550 UV/Vis spectrometer equipped with a Jasco ETC-505S/ETC-505T temperature controller. The oligomer concentration was determined by taking the extinction coefficient at 80 °C as being the sum of the extinction coefficients of all nucleo amino acids.[20] Complex formation was achieved by heating to 85 °C, followed by slow cooling over a period of three hours to 0 °C and equilibration for at least three hours at 0 °C. EPR spectra were measured on a Bruker ELEXSYS E500 spectrometer, equipped with a digital temperature control system ER 4131 VT using nitrogen as coolant. All spectra at 150 K were recorded at about 9.4 GHz microwave frequency, 5–9 G field modulation amplitude, 100 kHz field modulation frequency, and around 10 mW microwave power. Glycerine was added to some of the samples to improve their freezing behaviour. To induce complex formation, the same procedure was used as in the case of UV/Vis spectroscopy immediately before recording the spectra.

General Method for Solid-Phase Peptide Synthesis (SPPS) of the Oligomers: Oligomerisation was performed as a solid-phase peptide synthesis on a 4-methylbenzhydrylamine (MBHA)-polystyrene resin loaded with (*S*)-*N*-*tert*-butoxycarbonyl-lysine(2-Cl-Z)-OH (0.43 mmol/g) or (*R*)-*N*-Boc-lysine(*Z*)-OH (0.57 mmol/g) in a small column. For each step, 5 equiv. of *N*-Boc-protected amino acid was used and activated by 4.5 equiv. of *N*-(7-azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HATU) and 5 equiv. of 1-hydroxy-7-azabenzotriazol (HOAt) in DMF (600–1000 μL). After 3 min, 10 equiv. of *N*,*N*-diisopropylethylamine was added.

After swelling the resin for 1 h in CH_2Cl_2, the following strategy was repeated for every amino acid unit: 1) Deprotection: The resin was washed with TFA/*m*-cresol (95:5, 2 mL) and then treated with TFA/*m*-cresol (95:5, 2 mL) for 5 min. 2) Washing: CH_2Cl_2/DMF (1:1; 5 × 2 mL) followed by pyridine (2 × 2 mL). 3) Coupling: The reaction column was gently moved for 30–90 min with the coupling reagents (30 min for natural amino acids, 45 min for cytosine-containing amino acids, 90 min double coupling for guanine-containing amino acids). 4) Washing: CH_2Cl_2/DMF (1:1; 5 × 2 mL), DMF/piperidine (9:1; 5 × 2 mL), CH_2Cl_2/DMF (1:1; 5 × 2 mL). 5) Capping: 2 × 5 min with Ac_2O/NEt_3/DMF (1:1:8; 2 mL). 6) Washing: CH_2Cl_2/DMF (1:1; 5 × 2 mL), DMF/piperidine (9:1; 5 × 2 mL), CH_2Cl_2/DMF (1:1, 5 × 2 mL). Finally, the resin was washed with MeOH and dried for 3 h over KOH. Cleavage from the solid support was carried out within 2 h using trifluoromethanesulfonic acid/*m*-cresol/TFA (1:1:8; 2 mL). The dark brown solution was concentrated to 300 μL and the peptide nucleic acids were precipitated with diethyl ether (10–20 mL) as a white solid. The PNA was separated using a centrifuge, followed by purification with HPLC (RP-C18).

H-(AlaG-AlaC-His-His-AlaG-AlaC)-Lys-NH_2 (2): HPLC (gradient: 5–30% B in 30 min): t_R = 11.54 min. ESI-MS: *m*/*z* = 1220.7 $[M + H]^+$, 611.2 $[M + 2H]^{2+}$. HRMS: calcd. for $C_{48}H_{61}N_{29}O_{11}$ $[M + 2H]^{2+}$ 610.76254; found 610.76220.

EXAFS Measurements: An X-ray absorption spectrum at the Cu-*K* edge for oligomer **10** was recorded in fluorescence mode at the EMBL beamline D2 (DESY, Hamburg, Germany) equipped with a Si(111) double crystal monochromator, a focusing mirror and a 13 element Ge solid-state fluorescence detector (Canberra). The Cu-peptide solution was filled into plastic sample holders covered with polyimide windows, frozen in liquid nitrogen, and kept at 30 K during the experiment. Harmonic rejection was achieved by a focusing mirror with a cut-off energy of 21 keV and a monochromator detuning to 70% of peak intensity. A dead-time correction was applied. Saturation was not observed because the dead-time was always below 20%. The energy axis of each scan was calibrated by using the Bragg reflections of a static Si(220) crystal in back reflection geometry.[23] Averaging of 12 scans and data reduction was performed with the EXPROG software package (C. Hermes and H. F. Nolting, EMBL, Hamburg) using $E_{0,Cu}$ = 8979 eV. The EXAFS spectrum was analysed with EXCURV98.[24]

[22] The sample solution was prepared from 14.2 μL of 10^{-3} M $Cu(ClO_4)_2$ in H_2O/HEPES and a stoichiometric amount of the investigated oligomer. The low concentrations led to significant problems with regard to the signal-to-noise ratio. In addition, aging of the samples could be observed during repeated measurements as well as a slight temperature dependence of the peak intensities in the range from 8 to 180 K (spectra were recorded using the helium temperature control system ER4112HV; not depicted). The latter finding could be a hint of an increased mobility quenching within the glassy samples at lower temperatures (see also: M. F. Ottaviani, F. Montalti, N. Turro, D. A. Tomalia, *J. Phys. Chem. B* **1997**, *101*, 158–166.). A dependence on the pH values of the actual solution is to be expected but was not tested due to the small amount of sample.

Anions of 1,3,5-Benzenetricarboxylic and Heptanedioic Acids Serving as Bridges between Dimolybdenum(V) Metal–Metal Bonded Units: Preparation and Structural Characterization of Dinuclear and Tetranuclear Complexes

Barbara Modec,*[a] and Jurij V. Brenčič[a]

Keywords: Molybdenum / Carboxylato complexes / 1,3,5-Benzenetricarboxylate / Heptanedioate

$(PyH)_5[MoOCl_4(H_2O)]_3Cl_2$ and $(PyH)[MoOBr_4]$ reacted with the anions of 1,3,5-benzenetricarboxylic acid ($btcH_3$) and heptanedioic acid ($hdaH_2$) to afford a series of novel carboxylato complexes based on the $\{Mo_2O_4\}^{2+}$ structural core: $(PyH)_4[Mo_2O_4Cl_4(\mu_2\text{-}btcH_2)]Cl$ (**1**), $(PyH)_4[Mo_2O_4Br_4(\mu_2\text{-}btcH_2)]Br$ (**2**), $[(Mo_2O_4Py_3)_2(\mu_3\text{-}btcH)_2]\cdot 6Py$ (**3**), $(PyH)_6[(Mo_2O_4Cl_4)_2(\mu_4\text{-}hda)]\cdot 2CH_3CN$ (**4**), and $(PyH)_{10}[(Mo_2O_4Cl_4)_2(\mu_4\text{-}hda)][MoOCl_5]Cl_2$ (**5**) {Py = pyridine, C_5H_5N; PyH^+ = pyridinium cation, $C_5H_5NH^+$; $btcH_2^-$ = $(HOOC)_2C_6H_3COO^-$; $btcH^{2-}$ = $(HOOC)C_6H_3(COO)_2^{2-}$ and hda^{2-} = $^-OOC(CH_2)_5COO^-$}. A pair of isostructral compounds **1** and **2** contains dinuclear anions $[Mo_2O_4X_4(\mu_2\text{-}btcH_2)]^{3-}$ (X = Cl, Br) in which the $btcH_2^-$ ligand is bonded to the $\{Mo_2O_4\}^{2+}$ core via one carboxylate group in a *syn-syn* bidentate bridging manner. In **3**, two $btcH^{2-}$ ligands link two $\{Mo_2O_4\}^{2+}$ cores into a loop-like structure. Each $btcH^{2-}$ ligand is coordinated via two carboxylate groups, with one in the *syn-syn* bidentate bridging manner and with another in a monodentate manner. The linkage of two dinuclear subunits was also realized in $[(Mo_2O_4Cl_4)_2(\mu_4\text{-}hda)]^{6-}$, the anion in **4** and **5**, where both carboxylate groups of the hda^{2-} ligand bind in the *syn-syn* bidentate-bridging manner to $\{Mo_2O_4\}^{2+}$ cores. The title compounds were characterized by X-ray crystallography and infrared spectroscopy.

Introduction

The use of labile metal cations and polyfunctional organic molecules in the assembly of supramolecular arrays has emerged as an area of great interest.[1] In this context, di- and tricarboxylates constitute one of the most commonly employed classes of organic ligands.[2] The anions of 1,3,5-benzenetricarboxylic acid with three symmetrically arranged carboxylate groups form rigid, planar linkers.[3] By contrast, the ligands derived from dicarboxylic acids such as heptanedioic acid possess flexibility, an advantageous property in certain cases.[4] The metal cations such as Cu^{II}, Cd^{II}, Zn^{II}, Co^{II}, and Ni^{II} often do not impose a strong preference for a given geometry, leading to the lack of predictability over the stoichiometry and the structure of the product. On the contrary when dimolybdenum(II) precursors were used, both the number of coordinative sites and their locations could be suitably chosen in order to produce in combination with organic linkers a variety of supramolecular complexes.[5] Our quest has been the preparation of complexes containing a dinuclear $\{Mo_2O_4\}^{2+}$ structural core (Scheme 1). The core consists of two metal atoms, each with a strongly bound terminal oxygen atom, and a pair of bridging oxygen atoms. A single metal–metal bond between molybdenum atoms with a typical separation of 2.5–2.6 Å contributes to the cohesion of the unit.[6] Its six sites open for further coordination are not equivalent: the two which are in *trans* positions relative to the terminal oxo groups are subject to their labilizing *trans* influence and consequently bonding of the ligands at these sites is weaker when compared to the four equatorial sites. Various supramolecular complexes, encompassing discrete species[7] and infinite 1D or 2D arrays[8–10] could be prepared by combining the reactive $\{Mo_2O_4\}^{2+}$ precursors and multidentate ligands. Unfortunately, the control over the reaction outcome cannot be gained solely by tuning the ligand-to-molybdenum ratio. When the amount of the ligand was small, a necessary condition for the formation of polymeric phases, the metal centres attained the coordination saturation through the self-assembly of $\{Mo_2O_4\}^{2+}$ cores, enabled by the ability of oxo groups to participate in μ_3- and μ_4-bridging interactions.[7a] The latter process is the reason for the scarcity of polymeric $\{Mo_2O_4\}^{2+}$ complexes with multidentate ligands. The literature reports on only three structurally characterized $\{Mo_2O_4\}^{2+}$ species of this type: an oxalate-bridged $[Mo_2O_4(\mu_2\text{-}C_2O_4)Cl_2]_n^{2n-}$, a phosphate-bridged $[Mo_2O_4(C_2O_4)_2(\mu_2\text{-}H_2PO_4)]_n^{3n-}$, both with an infinite chain structure, and a phosphate-bridged $[Mo_2O_4(PO_4)(HPO_4)]_n^{3n-}$ with an infinite layer structure.[8–10] No preferential binding pattern of multidentate ligands over the six coordination sites of the $\{Mo_2O_4\}^{2+}$ core could be dis-

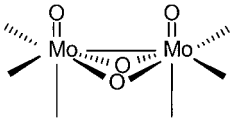
cerned. A normally favoured, chelating coordination of the ligand was observed only in $[Mo_2O_4(\mu_2\text{-}C_2O_4)Cl_2]_n^{2n-}$. We were interested to see how different multidentate ligands, in particular the carboxylate-based ligands with a well-known tendency towards the chelating coordination, coordinate to the $\{Mo_2O_4\}^{2+}$ core. Herein we report the preparation and the structural characterization of a novel anionic tetranuclear heptanedioato complex, $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$, and three 1,3,5-benzenetricarboxylato complexes: anionic dinuclear $[Mo_2O_4X_4(\mu_2\text{-btcH}_2)]^{3-}$ (X = Cl, Br) and a neutral tetranuclear $[(Mo_2O_4Py_3)_2(\mu_3\text{-btcH})_2]$.



Scheme 1. The $\{Mo_2O_4\}^{2+}$ structural core.

Results and Discussion

Solid State Structures

The structures of $(PyH)_4[Mo_2O_4Cl_4(\mu_2\text{-btcH}_2)]Cl$ (**1**) and $(PyH)_4[Mo_2O_4Br_4(\mu_2\text{-btcH}_2)]Br$ (**2**) will be discussed concurrently because of their structural similarity. A dinuclear anion $[Mo_2O_4X_4(\mu_2\text{-btcH}_2)]^{3-}$, depicted in Figure 1a, occu-

pies a general position within the unit cell of the monoclinic space group $P2_1/n$. Associated with each dinuclear anion are four protonated pyridine molecules and one halide counteranion. Geometric parameters of the basic $\{Mo_2O_4\}^{2+}$ core are very similar to those determined in related compounds:[6] (i) a short distance between molybdenum atoms, 2.5962(4) Å for **1** and 2.5856(3) Å for **2**, typical for a single metal–metal bond; and (ii) a buckled $Mo(\mu_2\text{-}O)_2$-Mo ring with the metal atoms above and the bridging oxygen atoms below the mean plane. The dihedral angle between the two $Mo(\mu_2\text{-}O)_2$ planes, 159.85(5)° for **1** and 159.37(4)° for **2**, is greater than the angles observed for $\{Mo_2O_4\}^{2+}$ compounds without the third bridging ligand. A distorted octahedral coordination of each metal centre of the $\{Mo_2O_4\}^{2+}$ core is completed by a pair of halides and an oxygen from the carboxylate group. An exhaustive list of bond lengths is given in Table 1. The carboxylato ligand, the anion of 1,3,5-benzenetricarboxylic acid with two non-ionized carboxylic groups, is coordinated to the metal centres of the $\{Mo_2O_4\}^{2+}$ core, as will be shown presently, in the usual manner, i.e., through both oxygen atoms of the carboxylate group to a pair of molybdenum atoms. This type of carboxylate coordination will be denoted throughout this paper as a *syn-syn* bidentate bridging mode.[11] The carboxylate group thereby serves as a third bridge between a pair of molybdenum atoms. Taking into account that the carboxylate group occupies a pair of *trans* positions relative to Mo=O bonds and is, therefore, subject to their well-documented *trans* influence, the molybdenum-to-carboxylate oxygen bond lengths are relatively short, 2.269(2) and 2.281(2) Å for **1** and 2.270(2) and 2.292(2) Å for **2**. It has been observed that the extent to which the *trans* influence is expressed within a certain species differs from one case to another.[12] Table 2 lists some $\{Mo_2O_4\}^{2+}$ complexes with different carboxylates. In all, the carboxylato ligand occupies a pair of *trans* positions within the $\{Mo_2O_4\}^{2+}$ unit. It can be seen that the Mo–O distances span a wide range and that they can exceed 2.40 Å. The carboxylate group in all listed complexes in Table 2 is invariably almost coplanar with the plane defined by a pair of molybdenyl groups. The same observation pertains to the coordinated carboxylate moiety in the anions of **1** and **2**, whereas the benzene ring of the $btcH_2^-$ ligand with both carboxylic groups is slightly rotated away (Figure 1b). The protonated carboxylate groups and pyridinium cations, which can act as donors of hydrogen bonds, are matched with the halide counteranions and the doubly-bridging oxygen atoms as the acceptors. The hydrogen bonding interactions between the carboxylic groups and halide counteranions result in infinite chains that propagate along the [10–1] unit cell direction (Figure 1c). The corresponding O(7)···X and O(9)···X distances are 2.920(3) and 2.938(3) Å for **1** and 3.084(3) and 3.093(2) Å for **2**. The halide counteranion also forms hydrogen bonds to three protonated pyridine molecules with the N···X distances ranging from 3.112(3) to 3.291(3) Å for **1** and from 3.240(3) to 3.415(3) Å for **2**. Protonated pyridine

molecules are engaged in another type of interaction. These occur with both doubly bridging oxo groups of the $\{Mo_2O_4\}^{2+}$ core. Their lengths are 2.711(4)–2.802(4) Å for **1** and 2.708(3)–2.844(3) Å for **2**.[16]

The structure of **3** consists of neutral, tetranuclear molecules with the $[(Mo_2O_4Py_3)_2(\mu_3\text{-btcH})_2]$ composition and pyridine solvent molecules. Two $\{Mo_2O_4\}^{2+}$ moieties are linked by two carboxylato ligands to form a tetranuclear molecule (Figure 2a). Both carboxylato ligands, each with a nonionized carboxylic group and two deprotonated ones, are bound in the same way: with one carboxylate group in the usual *syn-syn* bidentate bridging mode to a pair of metal atoms of the $\{Mo_2O_4\}^{2+}$ unit in the asymmetric manner [2.209(2) vs. 2.343(2) and 2.233(2) vs. 2.325(2) Å] and with the other carboxylate group in a monodentate manner to molybdenum from the other dinuclear unit (Figure 2b) with bond lengths of 2.068(2) and 2.070(2) Å. The asymmetric carboxylate coordination finds precedence in several other complexes (see Table 2). No adequate explanation could be provided in either case.[12] The $\{Mo_2O_4\}^{2+}$ core with the *syn-syn* bidentately bridging carboxylato ligand resembles the anions of **1** and **2**. The carboxylate group is coplanar

with the plane of two molybdenyl groups, while the remaining part of the ligand is rotated away from this plane. The misalignment of the two planes is smaller in complex **3** than in the anions of **1** and **2**, as shown by the values of the corresponding dihedral angles, 5.42(7) and 8.99(7)° for **3** vs. 17.79(6) for **1** and 20.80(5)° for **2**. The participation of $btcH^{2-}$ ligands in **3** in a monodentate coordination via another carboxylate group may well be responsible for such a conformation of the ligand. Each $btcH^{2-}$ ligand thus connects three molybdenum atoms: a pair of metal atoms from one $\{Mo_2O_4\}^{2+}$ unit is connected via a long bridge with molybdenum from another dinuclear unit. The separations between the molybdenum atoms are in the range 8.1894(9)–11.0690(4) Å. The geometric parameters of the $\{Mo_2O_4\}^{2+}$ moieties are: (i) separations between molybdenum atoms of 2.5410(3) and 2.5326(3) Å; and (ii) fold angles of 160.4(1) and 160.1(1)°. A distorted octahedral environment of molybdenum atoms in **3** is completed by pyridine ligands. The rather short length of the metal–metal bonds in **3** may be explained in terms of the high content of pyridine ligands whose nature is electron-donating. As a rule, longer metal–metal bonds occur in complexes with the electron-withdrawing ligands such as chloro or bromo ligands. Although the entire tetranuclear molecule of **3** is the crystallographic asymmetric unit, it comes very close to having C_2 symmetry with the C_2 axis going through the centre of the loop delineated by Mo(1), a $btcH^{2-}$ ligand, Mo(3) and another $btcH^{2-}$ ligand. As far as the bonding pattern in the distorted octahedral environment of each molybdenum atom is concerned, the pairwise equivalences demanded by the C_2 symmetry are very closely approximated. An exhaustive list of bond lengths is given in Table 3. The nonionized carboxylic group of each $btcH^{2-}$ ligand is engaged in hydrogen bonding interaction with a pyridine solvent molecule. The corresponding O···N distances are 2.646(4) and 2.657(4) Å.

The ionic structure of **4** consists of tetranuclear anions with the $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$ composition (Figure 3), protonated pyridine molecules as countercations and solvent molecules of acetonitrile. The linkage of two basic $\{Mo_2O_4\}^{2+}$ cores to produce a tetranuclear structure is achieved via a quadridentate hda^{2-} ligand whose two carboxylate groups occupy *trans* positions within both $\{Mo_2O_4\}^{2+}$ cores. Each carboxylate group of the hda^{2-} ligand is coordinated in the *syn-syn* bidentate bridging manner and serves as a third bridge between a pair of metal–metal bonded atoms whose separation, 2.5824(3) Å, falls in the normally observed range. The hda^{2-} ligand thus connects four molybdenum atoms: two pairs are connected via a long bridge consisting of the whole hda^{2-} ligand. The resulting separations between the molybdenum atoms from different dinuclear subunits are in the 8.9043(4)–11.6186(4) Å range. The molybdenum-to-carboxylate bond lengths, subject to the labilizing *trans* influence of the Mo=O bonds, reveal an asymmetric bonding pattern, 2.274(2) vs. 2.320(2) Å. The tetranuclear anion has a twofold rotation symmetry. The anion sits with the central carbon atom of the alkyl chain on a special position within the *C*2/*c* space group, on a twofold rotation axis. The pattern of hydrogen bonds in **4** is typical for anionic $\{Mo_2O_4\}^{2+}$ complexes with protonated pyridine molecules as the countercations: each doubly-bridging oxygen from the $\{Mo_2O_4\}^{2+}$ core is linked to a pyridinium cation. The corresponding N···O distances are 2.710(3) and 2.732(3) Å. The remaining two pyridinium cations participate in another type of hydrogen bonding interaction: each forms a relatively short hydrogen bond with one of the four coordinated chloro ligands, N(2)···Cl(21) = 3.071(3) Å, leading to a nonequivalence of the molybdenum-to-chlorine bond lengths. As expected, the respective bond length is longer than the others. A list of bond lengths is given in Table 4.

In spite of the wide use of 1,3,5-benzenetricarboxylate anions in coordination chemistry, the literature reports on only one molybdenum(v) complex with this ligand, a cyclic $[Mo_{12}S_{12}O_{12}(OH)_{12}(\mu_6\text{-btc})]^{3-}$ anion.[17] The dodecanuclear complex consists of six $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$ moieties arranged around the central btc^{3-} anion which is coordinated with each of its carboxylate groups in the *syn-syn* bidentate bridging manner. The btc^{3-} anion serves on the whole as a μ_6-ligand with the molybdenum-to-carboxylate oxygen bond lengths in the 2.350(10)–2.425(10) Å range. The ability of inorganic rings with the general formula $[Mo_nO_nS_n(OH)_n]$ (n = 8, 10, 12) to encapsulate in their centres organic templates was further exploited in the preparation of $[Mo_{12}S_{12}O_{12}(OH)_{12}(\mu_6\text{-hda})]^{2-}$, the only structurally characterized molybdenum(v) heptanedioato complex prior to this study.[18] Each carboxylate group of the ligand is coordinated to three molybdenum atoms as follows: one oxygen atom is bonded to the metal atom of the $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$ moiety, while the other oxygen binds to the other metal atom of the same dinuclear core and also to molybdenum from the neighbouring dinuclear core. The heptanedioate thus serves as a μ_6-ligand with the molybdenum-to-carboxylate oxygen bond lengths in the 2.341(12)–2.440(9) Å range. Both ring structures are essentially planar. The most apparent difference between them is the shape of

the ring: a perfect cycle for the btc^{3-} complex and an oval ring for the hda^{2-} complex.

Although the carboxylate group is known to coordinate in several different ways,[11] a survey of molybdenum(V) carboxylate complexes reveals that a number of possible coordination modes reduces to only two: (i) a monodentate terminal mode; and (ii) a *syn-syn* bidentate bridging mode. Speaking in terms of distances, the carboxylato ligand spans in the latter case distances between metal atoms as short as 2.5–2.6 Å and at the other extreme, as long as 3.850 Å as exemplified by $[Mo_4O_6(\mu_2\text{-}OOCCH_3)_6Cl_2]$.[19] It is pertinent to note that in no instance was a chelating coordination of carboxylate encountered among molybdenum(V) complexes. The X-ray structures of two thiobenzoato complexes, $[Mo_2O_2S_2(OSCC_6H_5)_2Py_2]$ and $[Mo_2O_2S_2(OSCC_6H_5)_2(4\text{-MePy})_2]$ (4-MePy = 4-methylpyridine), demonstrate that thio derivatives of carboxylato ligands are capable of chelating coordination.[20] The same binding scheme emerges upon inspection of the rare di- and tricarboxylato molybdenum(V) complexes. In addition to the above-described coordination modes, only two new ones are displayed: (i) the coordination of each carboxylate group of the hda^{2-} ligand to three metal atoms in $[Mo_{12}S_{12}O_{12}(OH)_{12}(\mu_6\text{-hda})]^{2-}$;[18] and (ii) the chelating coordination of malonate ions in $[\{Mo_2O_4(mal)_2\}_2(\mu_4\text{-mal})]^{6-}$ via two oxygen atoms, each belonging to a different carboxylate group.[15] The binding modes adopted by the $btcH_2^-$, $btcH^{2-}$, and hda^{2-} ligands in the title complexes add further validity to the observed binding scheme of carboxylato ligands in complexes with molybdenum(V).

In contrast to numerous oligonuclear complexes obtained upon the self-assembly of $\{Mo_2O_4\}^{2+}$ cores,[6] species where two or more dinuclear subunits are linked covalently solely by multidentate ligands are extremely rare. Apart from the three polymeric species, already mentioned in the introduction, that leaves to the best of our knowledge two tetranuclear anions, $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$[21] and $[\{Mo_2O_4(mal)_2\}_2(\mu_4\text{-mal})]^{6-}$,[15] where the linkage is achieved via quadridentate oxalate and malonate, respectively. Their structural analogy to $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$, the anion in **4**, is obvious: pairs of dinuclear subunits are linked covalently by dicarboxylates, differing in the number of carbon atoms between the carboxylate groups. It is to be noted that a class of related $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$ species also reveals tetranuclear anions of this type, $[\{Mo_2O_2S_2(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$[22] and $[\{Mo_2O_2S_2(\eta^2\text{-}SO_4)_2\}_2(\mu_4\text{-}SO_4)]^{6-}$.[23] The X-ray structure analysis of $[\{Mo_2O_4(\eta^2\text{-}$

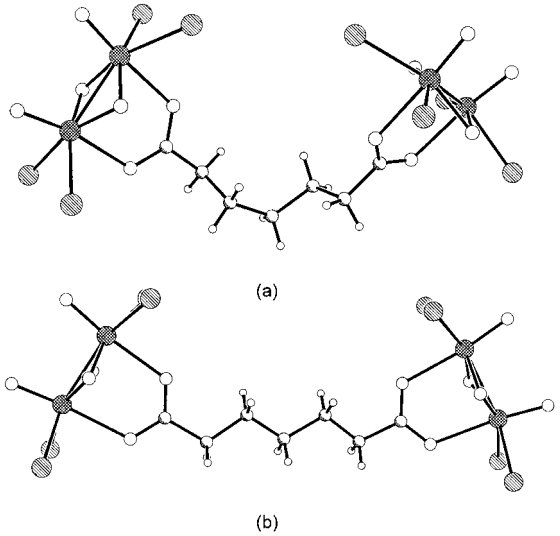

Figure 4. Two different conformations of the $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$ anion as found in **4** (a) and **5** (b).

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ revealed the μ_4-oxalate in a complete staggered conformation, whereas the μ_4-oxalate in $[\{Mo_2O_2S_2(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ adopted the usual planar form. With dicarboxylates that contain alkyl chains, the existence of complexes with different chain conformations in the solid state seems very likely. The $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$ anion, found in **4** and **5**, presents such a case. The alkyl chain in the anion of **5** is straighter than in **4** (Figure 4). Consequently, the separations between molybdenum atoms from the two $\{Mo_2O_4\}^{2+}$ moieties in **5** are larger than in **4**. The $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$ anions in **4** and **5** also differ in the mutual orientations of the metal–metal bond vectors. Unfortunately, the low-quality X-ray data of **5** does not allow any further discussion of its structural parameters. The linkage of two dinuclear subunits with the agency of $btcH^{2-}$ ligands in $[(Mo_2O_4Py_3)_2(\mu_3\text{-}btcH)_2]$ (**3**) finds no precedence.

Infrared Spectroscopy

The positions of asymmetric and symmetric ν(COO) vibrations can be used to diagnose the carboxylate binding mode: large Δ values, defined as $\nu_{asym}(COO) - \nu_{sym}(COO)$, are observed for the monodentate binding mode, while *syn-syn* bidentate bridging carboxylates display Δ values which are close to those observed for ionic compounds.[24] Accordingly, the bands at 1538 and 1410 cm^{-1} in the spectrum of **4** can be attributed to $\nu_{asym}(COO)$ and $\nu_{sym}(COO)$, respectively. The calculated Δ value, 128 cm^{-1}, is in line with the *syn-syn* bidentate bridging coordination. With at least two carboxylate groups of the 1,3,5-benzenetricarboxylate anions in **1**, **2**, and **3** engaged in different binding modes, no unambiguous assignations can be made. The spectra of **1** and **2** are very similar to each other. An absorption band at 1718 cm^{-1} for **1** and bands at 1722 and 1708 cm^{-1} for **2** are indicative of nonionized carboxylic groups in the $btcH_2^-$ ligand. The region of asymmetric and symmetric ν(COO) vibrations displays a number of strong bands, at 1618, 1554, 1539, 1433, and 1365 cm^{-1} for **1** and at 1617, 1537, 1435, and 1365 cm^{-1} for **2**. The spectrum of **3**, with all carboxylate groups distinctly different, displays a band at 1711 cm^{-1} which is associated with the C=O stretching vibration of the carboxylic group and several bands in the region of asymmetric [at 1649, 1607, and 1545 cm^{-1}] and symmetric ν(COO) vibrations [at 1449 and 1406 cm^{-1}]. For comparison, several bands were also observed for $[Cd_{1.5}(btc)(bpe)(H_2O)_2]\cdot H_2O$ [bpe = 1,2-bis(4-pyridyl)ethane] where two carboxylate groups are bound in a chelating manner and the third one is bound monodentately.[3d] Δ values of 122 and 255 cm^{-1} were calculated from their positions.

Synthetic Considerations

The composition of the heptanedioato complex $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$, the anion in **4** and **5**, is as anticipated. Acetonitrile was used as a solvent for its low coordinating ability towards molybdenum(v) and since both, the molybdenum(v) starting material and the tetrabutylammonium heptanedioate, display a good acetonitrile solubility. The substitution of the labile aqua and halo ligands in acetonitrile usually does not proceed beyond the formation of the $\{Mo_2O_4\}^{2+}$ core and so species with a high content of unsubstituted halo ligands can be isolated.[12] The carboxylate groups of the heptanedioate coordinated to two $\{Mo_2O_4\}^{2+}$ cores, resulting in a tetranuclear anion $[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]^{6-}$. The successful isolation of $(PyH)_6[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]\cdot 2CH_3CN$ (**4**) required a substantial reduction of the volume of the reaction mixture. When too much solvent was removed, a product with a different composition, $(PyH)_{10}[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})][MoOCl_5]Cl_2$ (**5**), crystallized from the concentrate. The composition of **5** is intriguing for two reasons. Although a sufficient amount of the hda^{2-} ligand was used, its coordination to molybdenum(v) was not quantitative. The identity of the uncomplexed species turned out to be $[MoOCl_5]^{2-}$, giving evidence for the transformation of $[MoOCl_4(H_2O)]^-$ into $[MoOCl_5]^{2-}$.

The compositions of the 1,3,5-benzenetricarboxylato complexes, the $[Mo_2O_4X_4(\mu_2\text{-}btcH_2)]^{3-}$ anions, and the neutral $[(Mo_2O_4Py_3)_2(\mu_3\text{-}btcH)_2]$, didn't meet expectations. Although fully neutralized salt of 1,3,5-benzenetricarboxylic acid was used in the case of **1** and **2**, the protonation of two carboxylate groups by pyridinium cations, introduced into the reaction mixture via the molybdenum(v) starting materials, prevented their ligation to two more $\{Mo_2O_4\}^{2+}$ units. The only carboxylate group of the 1,3,5-benzentricarboxylate capable of coordination attached to the $\{Mo_2O_4\}^{2+}$ core in the usual manner. Because of the greater lability of bromo vs. chloro ligands, the crystallization of **2** was not as straightforward as that of **1**, it took longer and the yield was significantly smaller. An important role for the solvent was observed. When methanol or ethanol was used in place of acetonitrile, the coordination of alcohol and alkoxide to the $\{Mo_2O_4\}^{2+}$ core took place first, followed by the assembly of two $\{Mo_2O_4\}^{2+}$ units into a tetranuclear $\{Mo_4O_4(\mu_3\text{-}O)_2(\mu_2\text{-}O)_2(\mu_2\text{-}OR)_2\}^{2+}$ core. The composition of the final products as $(PyH)_2[Mo_4O_8(OR)_2(ROH)_2X_4]$ (R = Me, Et; X = Cl, Br) was established on the basis of their infrared spectra.[25–26] Carrying out the reaction between (PyH)[$MoOBr_4$] and 1,3,5-benzenetricarboxylic acid in pyridine, a solvent with a strong coordinating ability, at 115 °C resulted in the coordination of both ligands and a neutral complex $[(Mo_2O_4Py_3)_2(\mu_3\text{-}btcH)_2]$ (**3**) was isolated. By using the oxobromomolybdate(v) starting material, the number of labile sites in the molybdenum(v) coordination sphere was increased. The $btcH^{2-}$ ligand with two carboxylate groups is capable of coordination to two $\{Mo_2O_4\}^{2+}$ cores, yet in $[(Mo_2O_4Py_3)_2(\mu_3\text{-}btcH)_2]$ (**3**) the coordination of both in the *syn-syn* bidentate bridging manner was not realized. Namely, one carboxylate group coordinated monodentately. The large amount of the ligand used explains the formation of a discrete species.

Conclusions

A series of 1,3,5-benzenetricarboxylato and heptanedioato molybdenum(v) complexes based on the $\{Mo_2O_4\}^{2+}$

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

structural core was prepared. The carboxylate group usually binds to a pair of metal atoms of the $\{Mo_2O_4\}^{2+}$ core in the *syn-syn* bidentate bridging manner. Coordination of two carboxylate groups of either 1,3,5-benzenetricarboxylate or heptanedioate results in the formation of tetranuclear clusters.

Experimental Section

General Remarks: All manipulations and procedures were conducted in air. Chemicals were purchased from Aldrich and used as received. $(PyH)_5[MoOCl_4(H_2O)]_3Cl_2$ and $(PyH)[MoOBr_4]$ were prepared as reported.[26–27] The solvothermal reactions were carried out in sealed glass tubes under autogenous pressure. The IR spectra were measured on solid samples as Nujol or poly(chlorotrifluoroethylene) mulls using a Perkin–Elmer 2000 series FT-IR spectrometer. Elemental analyses were performed by the Chemistry Department service at the University of Ljubljana.

Preparation of the Acetonitrile Solution of $(n\mathrm{Bu_4N})_3$btc: 1,3,5-benzenetricarboxylic acid (2.1 g, 0.010 mol) was dissolved in methanol (35 mL), followed by the addition of a methanol solution (1.0 M) of $n\mathrm{Bu_4NOH}$ (30 mL, 0.030 mol). Methanol was removed by careful pumping on the vacuum line. Acetonitrile was added (20 mL) to the oily residue. Each gram of the resulting solution contained 0.315 mmol of $(n\mathrm{Bu_4N})_3$btc.

Preparation of the Acetonitrile Solution of $(n\mathrm{Bu_4N})_2$hda: Heptanedioic acid (w = 0.98, 1.429 g, 8.74 mmol) was dissolved in methanol (10 mL) followed by the addition of a methanol solution (1.0 M) of $n\mathrm{Bu_4NOH}$ (17.5 mL, 17.5 mmol). Methanol was removed by careful pumping on the vacuum line. Acetonitrile (30 mL) was added to the oily residue. Each gram of the resulting solution contained 0.355 mmol of $(n\mathrm{Bu_4N})_2$hda.

$(PyH)_4[Mo_2O_4Cl_4(\mu_2\text{-btcH}_2)]Cl$ (1): $(PyH)_5[MoOCl_4(H_2O)]_3Cl_2$ (450 mg, 1.05 mmol of Mo) was dissolved in acetonitrile (20 mL). A weighted amount of the acetonitrile solution of $(n\mathrm{Bu_4N})_3$btc (0.647 mmol) was added dropwise with constant stirring. The reaction mixture was left to stand at 8 °C in the refrigerator. The orange, block-shaped crystals of **1** that formed after three days were collected by filtration and washed with the hexanes. Yield: 53% (269 mg). $C_{29}H_{29}Cl_5Mo_2N_4O_{10}$ (962.7): calcd. C 36.18, H 3.04, N 5.82; found C 36.44, H 3.27, N 6.11. IR: $\tilde{\nu}$ = 3228 (w), 3156 (w), 3134 (w), 3090 (w), 3059 (w), 1718 (vvs), 1635 (s), 1618 (vs), 1554 (s), 1539 (vs), 1488 (vvs), 1458 (w), 1433 (vs), 1365 (vs), 1245 (m), 1201 (s), 1183 (vvs), 1163 (vs), 1108 (w), 1097 (w), 1048 (w), 1000 (w), 957 (vvs), 940 (s), 893 (w), 766 (s), 750 (vvs), 694 (m), 678 (vs), 665 (vvs), 649 (vvs), 606 (vvs), 513 (s), 488 (s), 428 (m), 397 (m), 384 (s), 373 (vs), 330 (vvs), 310 (s), 299 (vvs), 292 (vvs), 272 (vs) cm^{-1}.

$(PyH)_4[Mo_2O_4Br_4(\mu_2\text{-btcH}_2)]Br$ (2): $(PyH)[MoOBr_4]$ (540 mg, 1.06 mmol) was dissolved in acetonitrile (20 mL). A weighted amount of the acetonitrile solution of $(n\mathrm{Bu_4N})_3$btc (0.647 mmol) was added dropwise with constant stirring. The volume of the reaction mixture was reduced on the following day to ca. one half by pumping on the vacuum line. The solution was allowed to stand at ambient conditions. The orange, block-shaped crystals of **2** which formed after six days were collected by filtration and washed with the hexanes. Yield: 19% (119 mg). $C_{29}H_{29}Br_5Mo_2N_4O_{10}$ (1185.0): calcd. C 29.40, H 2.47, N 4.73; found C 29.23, H 2.52, N 4.70. IR: $\tilde{\nu}$ = 3219 (w), 3132 (w), 3057 (w), 1722 (vvs), 1708 (s), 1636 (m), 1617 (s), 1537 (s), 1487 (vvs), 1435 (s), 1365 (s), 1246 (w), 1201 (w), 1173 (vs), 1162 (vs), 1107 (w), 1058 (w), 1049 (w), 1026 (w), 1001 (w), 958 (vvs), 941 (s), 893 (w), 748 (vvs), 721 (w), 697 (m), 677 (vvs), 664 (vs), 635 (w), 605 (s), 510 (m), 477 (m), 424 (w), 397 (w), 379 (m), 357 (s), 325 (m), 264 (m), 252 (m) cm^{-1}.

$[(Mo_2O_4Py_3)_2(\mu_3\text{-btcH})_2]\cdot 6Py$ (3): A glass tube was charged with $(PyH)[MoOBr_4]$ (120 mg, 0.235 mmol), 1,3,5-benzenetricarboxylic acid (220 mg, 1.05 mmol) and pyridine (4 mL). The tube was sealed and heated for 90 h in an electric oven maintained at 115 °C. After cooling to room temperature, the reaction mixture consisted of a clear, orange solution and colourless, crystalline material. Red, block-shaped crystals of **3** which formed after one month were separated manually from the colourless phase. Yield: 55% (61 mg). Note: The crystals lost interstitial solvent and turned powdery immediately upon removal from the mother liquor. IR: $\tilde{\nu}$ = 3112 (w), 3078 (w), 1958 (w), 1711 (m), 1649 (vs), 1633 (m), 1607 (vs), 1573 (w), 1545 (s), 1486 (m), 1449 (vs), 1436 (m), 1406 (m), 1319 (s), 1291 (s), 1271 (vs), 1234 (m), 1218 (vs), 1161 (m), 1102 (w), 1071 (s), 1046 (s), 1016 (m), 1007 (m), 966 (vvs), 942 (vs), 758 (vvs), 742 (vvs), 718 (vs), 694 (s), 641 (m), 626 (m), 570 (s), 524 (w), 474 (w), 452 (m), 436 (m), 410 (w), 371 (m), 317 (s), 277 (s), 256 (w) cm^{-1}.

$(PyH)_6[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})]\cdot 2CH_3CN$ (4): $(PyH)_5[MoOCl_4(H_2O)]_3Cl_2$ (450 mg, 1.05 mmol of Mo) was dissolved in acetonitrile (20 mL). A weighted amount of the acetonitrile solution of $(n\mathrm{Bu_4N})_2$hda (0.65 mmol) was added dropwise with constant stirring. The solution was concentrated on the following day on the vacuum line to ca. one half of the initial volume. The resulting solution was left to stand at ambient conditions overnight. The yellow, plate-shaped crystals of **4** were collected by filtration and washed with the hexanes. Yield: 26% (105 mg). $C_{41}H_{52}Cl_8Mo_4N_8O_{12}$ (1516.3): calcd. C 32.48, H 3.46, N 7.39; found C 32.42, H 3.53, N 7.12. IR: $\tilde{\nu}$ = 3223 (w), 3160 (w), 3130 (w), 2249 (m), 1634 (m), 1612 (s), 1538 (vvs), 1486 (vvs), 1410 (vs), 1273 (w), 1250 (m), 1202 (m), 1163 (m), 1048 (m), 1024 (m), 1002 (m), 960 (vvs), 938 (vvs), 879 (w), 758 (vvs), 740 (vvs), 708 (vvs), 682 (vvs), 663 (w), 639 (w), 604 (s), 517 (m), 483 (m), 448 (w), 398 (w), 379 (s), 292 (vvs), 262 (vs) cm^{-1}.

$(PyH)_{10}[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})][MoOCl_5]Cl_2$ (5): The same procedure was used as for **4**, only the initial solution was concentrated to ca. 2 mL and left to stand at ambient conditions. Large, yellow-orange, block-like crystals of **5** deposited from the solution overnight. Yield: 11% (51 mg). ***Note:*** The crystals decompose in air.

X-ray Crystallographic Study: Crystals were mounted on the tip of a glass fibre with a small amount of silicon grease and transferred to a goniometer head. Data were collected with a Nonius Kappa CCD diffractometer. Data reduction and integration were performed with the software package DENZO-SMN.[28] Averaging of the symmetry-equivalent reflections largely compensated for the absorption effects. For all compounds, the coordinates of some or all of the non-hydrogen atoms were found via direct methods using the structure solution program SHELXS.[29] The positions of the remaining non-hydrogen atoms were located by use of a combination of least-squares refinement and difference Fourier maps in the SHELXL-97 program. The carboxylic hydrogen atoms in **1** and **2**, located in the final stages of refinement from the difference Fourier maps, were refined with isotropic displacement parameters. The remaining hydrogen atoms were added in calculated positions. Although the R_1 and wR_2 residuals for the least-squares refinement of **5** are large (R_1 almost 10%), its composition, determined to be $(PyH)_{10}[(Mo_2O_4Cl_4)_2(\mu_4\text{-hda})][MoOCl_5]Cl_2$, is unquestionable. Unfortunately, repeated attempts to obtain crystals with better diffraction data have not been successful. Therefore, we only report some basic crystal data (triclinic, space group $P1$, a = 9.9381(2), b = 14.3948(2), c = 15.5022(3) Å, α = 69.9388(8), β = 86.5969(7), γ = 89.1332(7)°, V = 2079.44(6) $Å^3$, Z = 1, T = 150(2) K, 29834 mea-

The Redox Chemistry of (N^1-[3-(2-aminoethylimino)-1,1-dimethylbutyl]ethane-1,2-diamine)nickel(II) Perchlorate, $Ni^{II}L^1(ClO_4)_2$, in Aqueous Solutions – A Pulse Radiolytic and an Electrochemical Study

Yael Albo,[a] Eric Maimon,*[a,b] Israel Zilbermann,[a,b] Magal Saphier,[a,b] Haim Cohen,[a,c] and Dan Meyerstein*[a,c]

Keywords: Nickel complexes / Pulse radiolysis / Electrochemistry

The ligand (N^1-[3-(2-aminoethylimino)-1,1-dimethylbutyl]-ethane-1,2-diamine), L^1, induces a high ligand field on the central Ni^{II} ion. Thus it is relatively easy to oxidize $(Ni^{II}L^1)^{2+}$. However, the kinetic stability of the $Ni^{III}L^1$ complexes is considerably lower than that of their analogous macrocyclic complexes. This difference in stabilities is attributed to the less rigid ligand framework, which facilitates the oxidation of ligand.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

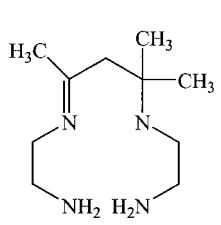
Introduction

The thermodynamic and kinetic stabilization of uncommon oxidation states of transition metal ions has been studied extensively. It has been suggested that for tetraaza aliphatic ligands a macrocyclic ligand frame sets the condition for the acceptance of high oxidation states,[1–3] which are not achievable in the case of the open tetraamine analogues. As a result there is not much information regarding the redox properties of transition metal complexes with open tetraamine ligands in aqueous solutions. Thus, there is an interest in expanding the knowledge of the ability of such ligands to stabilize uncommon oxidation states of transition metal ions. Herein the redox properties of the linear tetraamine Ni complex $Ni^{II}L^1(ClO_4)_2$ are investigated in aqueous solutions, and are compared to those of the tetraaza macrocyclic analogue $Ni^{II}L^2(ClO_4)_2$.

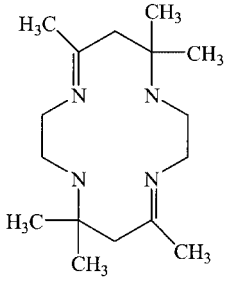
Results and Discussion

Characterization of $NiL^1(ClO_4)_2$

The complex was characterized by X-ray diffraction and by UV/Vis spectrophotometry. Spectral data of the complex at pH = 6.0 are summarized in Table 1. Spectral data of the $NiL^2(ClO_4)_2$ are included in the Table for comparison. It is interesting to note that the d-d bands of both complexes have the same λ_{max}, i.e. the two ligands impose the same ligand field on the central nickel ion. The electronic configuration of both complexes is low spin, i.e. the ligands impose a strong ligand field.



L^1



L^2

Table 1. UV/Vis spectrophotometric data for the $Ni^{II}L^1(ClO_4)_2$ and $Ni^{II}L^2(ClO_4)_2$ complexes.

	λ_{max} [nm]	ε [$M^{-1}cm^{-1}$]
$Ni^{II}L^1(ClO_4)_2$	436	70
	268	2000
	208	15000
$Ni^{II}L^2(ClO_4)_2$[18]	436	104
	238	7900
	213	17000

Crystal Structure

The ORTEP view of $[NiL^1(ClO_4)_2]$ is provided in Figure 1 and relevant geometric details are listed in Table 2. The complex is isolated as its perchlorate salt, and the Ni^{II} ion has a typical square-planar coordination geometry, as the bond angles N^1–Ni–N^4 and N^1–Ni–N^3 are 91.7° and 176°, respectively. The two perchlorate counterions are above and below the coordination plane, beyond bonding

distance. There is a hydrogen bonding interaction between the perchlorate counterions and the amines' hydrogen atoms of two neighboring complexes. These intermolecular interactions stabilize the structure of the complex. The Ni–N^3_{imine} bond length, 1.899 Å, is slightly shorter than the Ni–N^2_{amine} bond length. This is probably due to some back donation to the π system. The relative Ni–N bond lengths are clearly also affected by the N–H···O–Cl hydrogen bonds between the perchlorate anions and the N^1, N^2 and N^4 amines. The same effect was observed for the analogous macrocyclic complexes.[4]

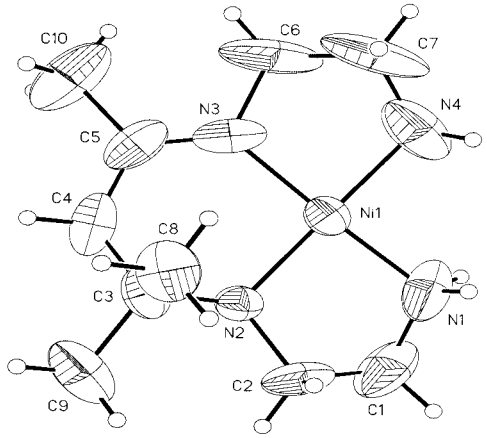

Figure 1. ORTEP view of $[NiL^1(ClO_4)_2]$, with displacement.

Table 2. Bond lengths [Å] and angles [°].

Ni(1)–N(1)	1.875(7)
Ni(1)–N(3)	1.899(8)
Ni(1)–N(2)	1.911(5)
Ni(1)–N(4)	1.910(7)
N(1)–Ni(1)–N(3)	176.6(4)
N(1)–Ni(1)–N(2)	87.6(3)
N(3)–Ni(1)–N(2)	95.0(3)
N(1)–Ni(1)–N(4)	91.7(4)
N(3)–Ni(1)–N(4)	85.7(4)
N(2)–Ni(1)–N(4)	179.3(4)

The small ellipsoids and the high order of the crystallographic structure indicate that only the R chiralic isomer was obtained, and not a racemic mixture of the two possible isomers.

Electrochemistry

A cyclic voltammetric study of $(NiL^1)^{2+}$ in aqueous solutions containing perchlorate and/ or sulfate ions was performed. The complex displays a quasi-reversible wave in the cyclic voltamogramm associated with the $Ni^{III/II}$ redox process. The redox potential of the couple in 0.1 M $NaClO_4$ is cathodically shifted by 250 mV relative to its tetraaza macrocyclic analogue,[5] $(NiL^2)^{2+}$, thus displaying a better ability of the open ligand frame to thermodynamically stabilize the trivalent state. This observation is probably due to contributions of the following factors:

a) The macrocyclic ligand contains two iminic bonds and is thus a softer base.

b) The macrocyclic complex has less hydrogen bonds with the solvent, i.e. is more hydrophobic.[6–9]

c) The open ligand is less rigid and thus has a better ability to satisfy the electronic and stereochemical demands of the central metal ion.

The redox potential in neutral solutions containing only $NaClO_4$ (0.1 M) is 950 mV vs. SCE. The complex is thermodynamically stabilized by sulfate ions (Figure 2), due to ligation of the anion to the complex $(NiL^1)^{3+}$. From the dependence of the redox potential on $[SO_4^{2-}]$ the slope of the plot of E vs. $\log[SO_4^{2-}]$ is 57 mV, thus it is concluded that the complex formed is $Ni^{III}L^1(SO_4)^+$ with an apparent stability constant $K_{app} = [(NiL^1SO_4)^+]/[(NiL^1)^{3+}][SO_4^{2-}] = 490 \pm 50\ M^{-1}$. This equilibrium constant was determined at pH = 6.0, as the divalent complex is unstable at lower pH values in sulfate containing solutions. The equilibrium constant for the macrocyclic complex $K = [\{NiL^2(SO_4)_2\}^-]/[(NiL^2)^{3+}][SO_4^{2-}]^2 > 10^5\ M^{-2}$ was obtained at pH = 1.2.[5] The lower value of the apparent equilibrium constant of the open complex probably stems from the higher pH value at which it was determined, as the equilibrium constant is pH dependent, as shown by the following relations:

$$NiL^1(H_2O)^{3+} \rightleftharpoons NiL^1OH^{2+}_{(aq)} + H^+_{(aq)}$$

$$K_1 = \frac{[(NiL^1OH)^{2+}][H^+]}{[(NiL^1)^{3+}]}$$

$$(NiL^1)^{3+}_{(aq)} + SO_4^{2-}{}_{(aq)} \rightleftharpoons NiLSO_4^+{}_{(aq)}$$

$$K_2 = \frac{[(NiL^1SO_4)^+]}{[(NiL^1)^{3+}][SO_4^{2-}]}$$

Combining the two equations:

$$K_2 = \frac{[(NiL^1SO_4)^+]K_1}{[SO_4^{2-}][(NiL^1OH)^{2+}][H^+]}$$

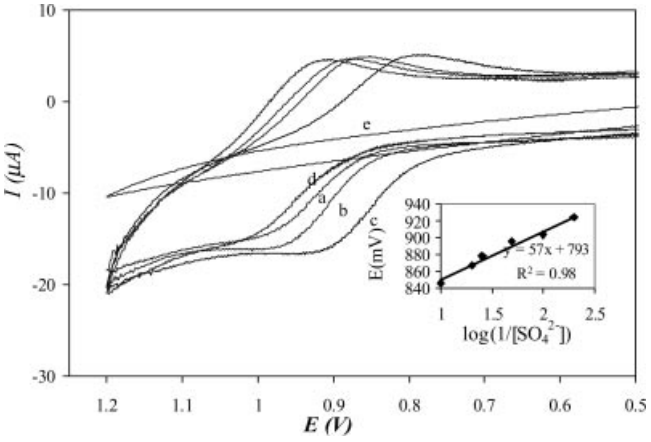

Figure 2. Cyclic voltammograms of the couple $Ni^{III/II}L^1$ in sulfate-containing solutions. Conditions: working electrode glassy carbon, reference SCE, scan rate 150 mV/s, ionic strength regulated with $NaClO_4$: $1 \cdot 10^{-3}$ M $Ni^{II}L^1$(a–d), 0.005 M Na_2SO_4 (a), 0.01 M Na_2SO_4 (b), 0.04 M Na_2SO_4 (c), 0.15 M $NaClO_4$ (d), 0.1 M Na_2SO_4 (e), pH = 6, I = 0.15.

The observation that two sulfate ions ligate to the macrocyclic complex, in comparison to the open complex, to

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

which only one sulfate ion ligates might be attributed to the fact that the less rigid open ligand enables a tetragonal bipyramid conformation which is not possible for the macrocyclic complex.

Pulse Radiolysis Studies

The redox properties of the complex were further investigated using the pulse radiolysis technique. N_2O-saturated solutions in the presence and absence of bromide ions were irradiated.

Oxidation of the Complex by Hydroxyl Radicals

When N_2O-saturated solutions containing $(2–25)\cdot10^{-5}$ M $Ni^{II}L^1(ClO_4)_2$ are irradiated three consecutive reactions are observed. The rate of the formation of the first trivalent transient obeys a pseudo-first order rate law, Figure 3. From the linear dependence of the observed rate on $[(Ni^{II}L^1)^{2+}]$, a rate constant of $(5.0\pm1.0)\cdot10^9$ $M^{-1}s^{-1}$ is determined. The trivalent complex is obtained via:[10]

$$H_2O \xrightarrow{e,\gamma} e^-_{aq}(2.65), H^{\cdot}(0.60), {}^{\cdot}OH(2.65), H_2(0.45), H_2O_2(0.75)$$

where the values in parentheses give the relative yields of the primary products, number of molecules formed per 100 eV absorbed in the solution.

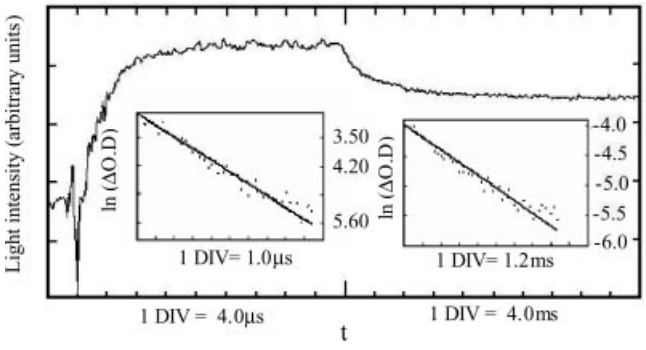

Figure 3. The formation and isomerization kinetics of $Ni^{III}L^1$. Conditions: $5.0\cdot10^{-5}$ M $(Ni^{II}L^1)^{2+}$, pH = 3.8, λ = 525 nm, N_2O-satd., pulse intensity 8.1 Gy.

$$e^-_{aq} + N_2O + H_2O \rightarrow N_2 + {}^{\cdot}OH + OH^- \quad (1)$$
$$k_1 = 8.7\cdot10^9\ M^{-1}s^{-1}[11]$$

$$Ni^{II}L^1 + {}^{\cdot}OH \rightarrow Ni^{III}L^1{}_{aq} + OH^- \quad (2)$$
$$k_2 = 5.0\cdot10^9\ M^{-1}s^{-1}$$

(The rate of the analogous reaction for the macrocyclic complex is $9\cdot10^9$ $M^{-1}s^{-1}$.[12]) The second reaction, which obeys a first order rate law with a rate which is independent of the complex concentration, causes a significant change in the spectrum of the $Ni^{III}L^1{}_{aq}$ complex (Figure 4). This reaction is attributed to the isomerization of the complex from a pentacoordinated geometry to an octahedral geometry in analogy[12] to the observations for $Ni^{III}L^2{}_{(aq)}$.

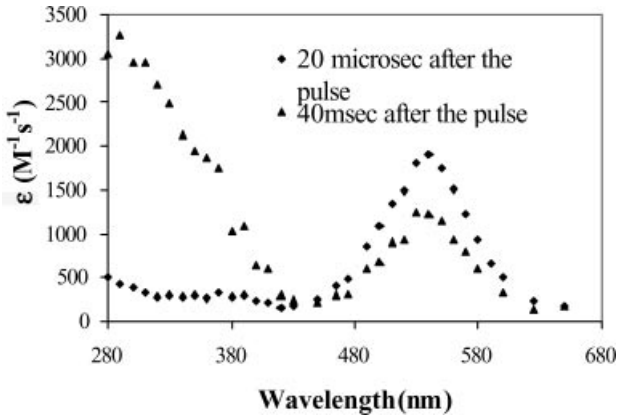

Figure 4. Spectra of $Ni^{III}L^1$ and $(Ni^{III}L^1)_R$. Conditions: $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, pH = 4.0 N_2O-satd., pulse intensity: 7.2 Gy.

The absorbance of the product of reaction (3), $(Ni^{III}L^1)_R$, depends on the pH value (Figure 5). The results indicate a pK_a of 4.3 ± 0.2 for the complex formed after the first reaction, reaction (2). It is suggested that this pK_a is due to equilibrium (4). The pK_a value for the complex with the macrocyclic ligand is lower (3.4).[12] The strong absorption band of $Ni^{III}L^1(OH)^{2+}$ at 540 nm is attributed to a d-d transition in the highly unsymmetrical $Ni^{III}L^1(OH)^{2+}$ complex. It is thus found that the basic complex $Ni^{III}L^1(OH)^{2+}$ does not isomerize. Again this finding is analogous to that reported earlier for $Ni^{III}L^2(OH)^{2+}$.[12]

$$Ni^{III}L^1\ aq \rightarrow (Ni^{III}L^1aq)_R \quad (3)$$
$$k_3 = 190\ s^{-1}$$

$$(Ni^{III}L^1)_{aq}{}^{3+} \rightleftharpoons Ni^{III}L(OH)^{2+} + H_3O^+ \quad (4)$$

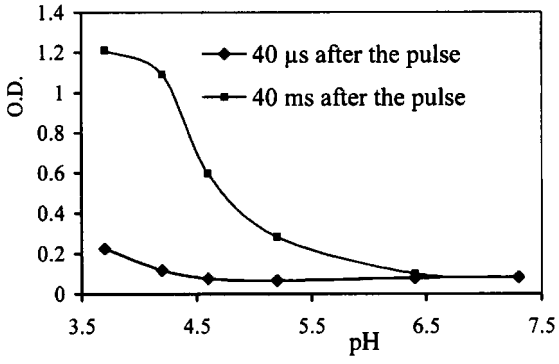

Figure 5. Optical densities of transient as a function of the pH value. Conditions: $2.5\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, λ = 300 nm, N_2O-satd., pulse intensity 32 Gy.

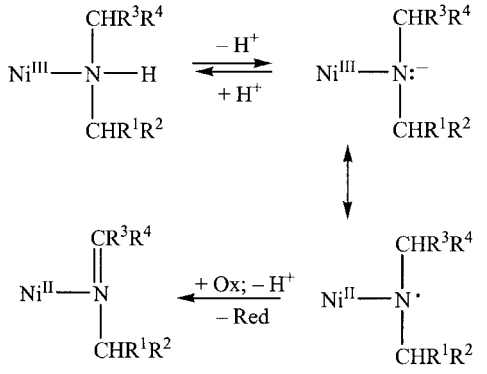
Clearly the formation of the red Ni^{III} transient in this study is not due to the macrocyclic effect and not to the favorable preorientation of the donor atoms in the 14-membered tetraaza macrocyclic ligand as proposed in the literature.[13]

The third reaction occurs on a time scale of seconds, obeys a second order rate law and is base catalyzed. This reaction results in the disappearance of the spectrum of the in-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

termediate and is attributed to the decomposition of the trivalent complex. It is proposed that the decomposition mechanism is as described in reaction (5).



(5)

A linear dependence of the observed second-order rate constant on [OH^-] is observed, but the slope is 0.25 (Figure 6), i.e. considerably smaller than a slope of 1 which is expected according to this mechanism. This discrepancy is attributed to the pK_a of the tervalent complex, reaction (4) and probably to another pK_a i.e. to the formation of $Ni^{III}L^1(OH)_2^+$. Alternatively there is another decomposition mechanism, which does not require the loss of a proton.

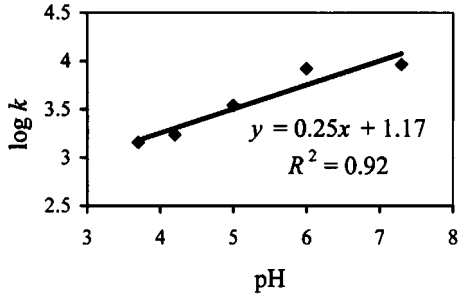


Figure 6. Decomposition rate constant as a function of the pH value. Conditions: $2.5\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, N_2O-satd., pulse intensity: 7.2 Gy.

The oxidation mechanism by the hydroxyl radicals and the mechanism of decomposition of the trivalent complex and its products are similar to those of its macrocyclic analogue.[12] However the oxidation product of $(Ni^{II}L^1)^{2+}$ is less stable.

Oxidation of the Complex by $Br_2^{\cdot-}$ Ion Radicals

As hydroxyl radicals might, at least partially, react also via hydrogen abstraction from the organic ligands it was decided to use also $Br_2^{\cdot-}$ as an oxidizing agent [$E^0(Br_2^{\cdot-}/2Br^-)$ = +1.63 V vs. N.H.E[11]]. N_2O-saturated solutions containing 0.01–0.1 M NaBr, $(0.1–2.0)\cdot10^{-4}$ M $Ni^{II}L^1(ClO_4)_2$ were irradiated. The first reaction observed obeys a first order rate law, with a rate proportional to $[(Ni^{II}L^1)^{2+}]$. The spectrum of the transient formed in this reaction differs considerably from that of $(Ni^{III}L^1)^{3+}$, Figure 7 and 4, and therefore it is proposed that $Ni^{III}LBr^{2+}$ is formed in this reaction, see (8).

$$^{\cdot}OH + Br^- \rightleftharpoons OHBr^{\cdot-} \quad (6)$$

$$OHBr^{\cdot-} + Br^- + H^+ \rightarrow Br_2^{\cdot-} + H_2O \quad (7)$$

$k > 10^9$ M^{-1}s^{-1} at pH $\leq$ 9.5

$$(Ni^{II}L^1)^{2+} + Br_2^{\cdot-} \rightarrow (Ni^{III}L\text{–}Br)_{aq}^{2+} + Br^- \quad (8)$$

$k = (7.5\pm2.0)\cdot10^9$ M^{-1}s^{-1}

(The rate of the analogous reaction for the macrocyclic complex is $2.5\cdot10^9$ M^{-1}s^{-1}.[12])

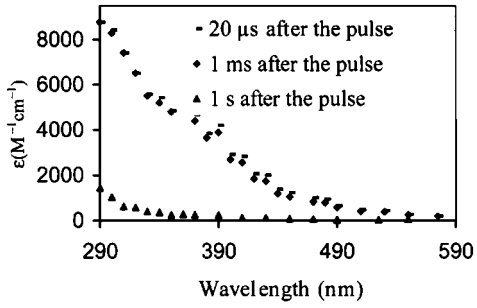

Figure 7. Spectra at different times after the pulse in the bromide-containing system. Conditions: $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, 0.1 M NaBr (for the micro- and milliseconds time scales), 0.01 M NaBr (1 second after the pulse), pH = 3.8, N_2O-satd., pulse intensity 8.2 Gy.

The second reaction observed also obeys a first order rate law and its rate is proportional to [Br^-], Figure 8; the large intercept suggests that this is an equilibrium process, see (9).

$$(Ni^{III}L^1Br)^{2+}_{(aq)} + Br^- \rightleftharpoons Ni^{III}L^1Br_2^+ \quad (9)$$

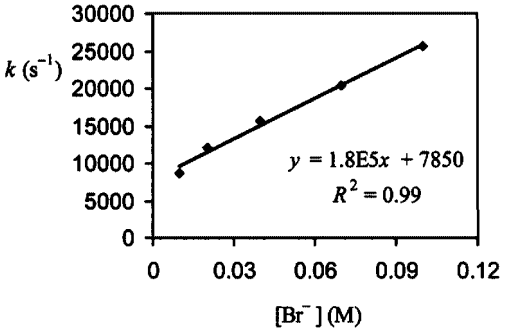

Figure 8. Observed rate as a function of [Br^-]. Conditions: $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, (0.01–0.1) M NaBr, pH = 3.8, ionic strength of 0.1 M adjusted by $NaClO_4$, N_2O-satd., pulse intensity 7.1 Gy, λ = 500 nm.

The spectrum of the product of the transient formed in reaction (9) is very similar to that formed in reaction (8), Figure 7. This is reasonable as the major band observed is clearly due to a LMCT transition. The slight shift to the blue is attributed to the lowering of the redox potential of the $Ni^{III/II}$ couple by the binding of a second bromide. From the slope and intercept in Figure 8 one obtains $k_9 = (1.8\pm0.2)\cdot10^5$ M^{-1}s^{-1} and $K_9 = 23\pm10$ M^{-1}.

The oxidation mechanism by the $Br_2^{\cdot-}$ ion radicals of the macrocyclic complex is different. In this case only one bromide ion ligates as an axial ligand, and the number of reac-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tions occurring and the reaction rate constants are pH-dependent.[12]

The decomposition reaction of $Ni^{III}L^1Br_2^+$ obeys a second order rate law, with a rate independent on the divalent complex concentration and weakly dependent on pH and bromide concentration [k = $9.9\cdot10^5$ $M^{-1}s^{-1}$, $2\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, 0.01 M NaBr, pH = 3.8; k = $9.8\cdot10^5$ $M^{-1}s^{-1}$, $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, 0.01 M NaBr, pH = 3.8; k = $3.6\cdot10^6$ $M^{-1}s^{-1}$, $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, 0.1 M NaBr, pH = 3.8; k = $1.7\cdot10^4$ $M^{-1}s^{-1}$, $1\cdot10^{-4}$ M $(Ni^{II}L^1)^{2+}$, 0.01 M NaBr, pH = 7.0]:

$$2\ Ni^{III}L^1Br_2^{+} \longrightarrow \begin{cases} 2\ (Ni^{II}L^1)^{2+} + Br_2 + 2\ Br^- \ (Br^- + BrO^-) \\ (Ni^{II}L^1)^{2+} + Ni^{II}L_{-2H}^{2+} + 4\ Br^- + H^+ \end{cases} \quad (10)$$

The mechanism of decomposition of the trivalent macrocyclic complexes in the presence of bromide differs considerably. Comparison of the decomposition reaction shows that the rate of decomposition in the case of the open ligand is slightly higher at acidic pH values, and is much higher in neutral solutions than that of the analogous macrocyclic complex. The dependence of the rate on the bromide concentration is smaller in the case of the open ligand frame, both in acidic and neutral solutions. For the open ligand the decomposition reaction is second order in the whole pH range, while it is first order in neutral solution in the macrocyclic system. The difference in the kinetic stabilities of the two complexes is attributed to the less rigid frame of the open ligand. The formation of $Ni^{II}L_{-2H}^{2+}$ requires the formation of a C–N double bond, i.e. a significant change in geometry, which is facilitated by the less rigid open ligand.[14] This conclusion is in agreement with the observation that the stabilities of the isomers of Ni^{III}(5,7,7,12,14,14-hexamethyl-1,4,8,11-tetraaazacyclotetradecane) differ considerably.[15]

Concluding Remarks

In conclusion it was found that the less rigid open ligand has a better ability to adjust itself to the structure of each valence, and as such it thermodynamically stabilizes the trivalent state better than its macrocyclic analogue, although the oxidation product is less kinetically stable.

Experimental Section

Materials: All the chemicals used were of AR grade and were used without further treatment. All solutions were prepared with deionized water, which was further purified by passing through a Millipore Milli-Q water purification system, the final resistance being above 10 MΩ

Synthesis of $NiL^1(ClO_4)_2$: 0.2 mol $Ni(ClO_4)_2\cdot6H_2O$ and 0.4 mol of ethylenediamine were added to an excess of acetone (as the solvent). The solution was stirred and heated under reflux for 4 days. The first crude orange crystals formed were filtered and washed in methanol. Single crystals suitable for X-ray diffraction were obtained from recrystalization in methanol.

The tetrachlorozincate salt of this complex was synthesized by Curtis and House using a different procedure.[16]

Electrochemical Measurements: Electrochemical studies were carried out using an EG&G Princeton Applied Research potentiostat/galvanostat, Model 263, operated by a Research Electrochemistry software EG&G PARC, using a three electrode assembly consisting of a glassy carbon electrode (A = 0.07 cm^2), a Pt wire auxiliary electrode and a SCE as the reference electrode. The solutions were purged with argon.

Pulse Radiolysis: The solutions were handled by the syringe technique. Deaeration was performed by bubbling N_2O through the solutions.

The experiments were carried out at the linear electron accelerator facility of the Hebrew University of Jerusalem; 0.5–1.5 μs, 5 MeV and 200 mA pulses were used. The dose per pulse was in the range of 7–32 Gy/pulse. The experimental setup and the techniques used for evaluating the results have been described elsewhere in detail.[17]

X-ray Structure Determination: The data were collected on a Bruker SMART system with 1 K CCD detector. Mo-$K\alpha$ radiation was used with a graphite monochromator. The data were reduced using SAINT, absorption corrections were performed using SADABS, and then solved with SHELXL and refined using SHELXL. The non-hydrogen atoms were located from the difference map and refined anisotropically. The hydrogen atoms were located from the difference map and then allowed to refine using a riding model. An ORTEP view of the molecules is provided in Figure 1, and geometry details are listed in Table 2.

***C*rystal and Structure Refinement Data:** Crystal data $[NiL^1(ClO_4)_2]$: $C_{10}H_{24}Cl_2N_4NiO_8$ (457.92), monoclinic, space group $P21/c$, a = 10.3442(17), b = 12.540(2), c = 14.381(2) Å, $\alpha = \gamma$ = 90°, β = 101.795(5)°, V = 1826.1(5) $Å^3$, D_c (Z = 4) = 1.658 g/cm^3, crystal size $0.97\times0.77\times0.41$ mm^3, hkl range –8 to 13, –16 to 16, –19 to 19, N = 14613, N_{ind} = 4538 (R_{int} = 0.0412), residuals $R_1(F)$ 0.0674, wR_2 = 0.2067, GoF(all) = 1.307, Dr (min./max.) = 0.964/–0.664 $e\cdot A^3$.

CCDC-238587 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Center via www.cccdc.cam.ac.uk/data_request/cif.

Acknowledgments

We thank Dr. Janice Rubin-Preminger for her X-ray structure determination. This study was supported in part by a grant from the Budgeting and Planning Committee of the Council of Higher Education and the Israel Atomic Energy Commission. D. M. wishes to express his thanks to Mrs. Irene Evens for her ongoing interest and support.

Ruthenium Complexes Containing Chiral N-Donor Ligands as Catalysts in Acetophenone Hydrogen Transfer – New Amino Effect on Enantioselectivity

Montserrat Gómez,*[a] Susanna Jansat,[a] Guillermo Muller,[a] Gabriel Aullón,[a] and Miguel Angel Maestro[b]

Keywords: Ruthenium / Chiral N-donors / Asymmetric catalysis / NMR spectroscopy / Density functional calculations

New *p*-cymene ruthenium species containing chiral amino alcohols (**1**–**3**), primary (**4**–**7**) and secondary (**8**, **9**) amino-oxazolines, were tested as catalysts in the hydrogen transfer of acetophenone, using 2-propanol as the hydrogen source. A remarkable effect on the enantioselectivity, but also on the activity, was observed depending on the amino-type oxazoline, Ru/**8** and Ru/**9** being low active and nonselective catalytic systems, in contrast to their primary counterpart Ru/**5**. Complexes containing amino-oxazolines (**10**–**12**) were prepared and fully characterized, both in solution and in solid state. The X-ray structure was determined for (S_{Ru},R_C)-**10**. The diastereomeric ratios observed for complexes **10** and **11** were determined by ^{1}H NMR and confirmed by means of structural modeling (semi-empirical PM3(tm) level). DFT theoretical calculations for the transition states involved in the hydrogen transfer process proved the important differences in their relative populations, which could justify the enantioselectivity divergences observed between primary and secondary amino-oxazoline ruthenium systems.

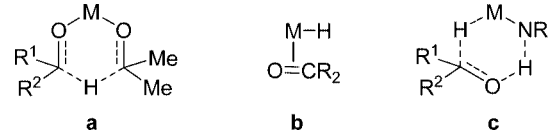
Introduction

Chiral hydrogen transfer of prochiral ketones catalyzed by transition metals has emerged as a convenient methodology to give enantiomerically pure secondary alcohols, based on the simplicity of the process and the safety of the reagents.[1]

From a mechanistic point of view, three alternatives have been proposed for metal-catalyzed hydrogen transfer of ketones (Scheme 1): i) direct transfer of a hydrogen atom of the alcohol to the carbonyl carbon through a concerted process involving a six-membered cyclic transition state (**a**), a mechanism accepted for Al-catalyzed Meerwein-Ponndorf-Verley reductions and generally for main group elements;[2] ii) stepwise mechanism through the formation of a hydride metal intermediate and the migratory insertion of a C=O into a M–H bond (**b**), a mechanism suggested for rhodium(I) and ruthenium free-arene systems;[3] and iii) a concerted mechanism where a proton and a hydride are simultaneously transferred to the unsaturated substrate (**c**), a mechanism proposed by Noyori for the Ru arene derivatives.[4]



Scheme 1. Key species involved in the three main mechanisms [concerted (**a**) and (**c**), and stepwise (**b**)] of metal-catalyzed hydrogen transfer (spectator ligands on the metal have been omitted for clarity).

The efficient catalytic system described by Noyori and co-workers, Ru/TsDPEN (TsDPEN=*N*-(*p*-tolylsulfonyl)-1,2-diphenylethylendiamine), suggests the requirement of amino groups in order to achieve high activities.[4,5] Other related works showed similar trends.[6] In order to understand the reaction pathway, theoretical studies have been reported on the basis of the ruthenium complex structures and their reactivity, for systems containing primary and secondary amines.[7] These systems are in agreement with a metal–ligand bifunctional mechanism.

We previously tested *p*-cymene ruthenium systems containing chiral bis(oxazolines) as catalysts in the acetophenone reduction processes, in particular in hydrogenation transfer.[8] Moderated enantiomeric excesses were obtained (*ee* up to 38%), and the best chiral auxiliaries were found among those containing two carbon spacers between both oxazoline fragments. As stated above, the presence of NH_2 or NH groups in the auxiliaries is fundamental for catalytic reactivity.[4b] For that reason, and following our research with oxazoline ligands,[9] we proposed to use primary (**4**–**7**)

and secondary (**8**–**9**) amino-oxazolines in order to improve the results previously obtained (Figure 1). The amino alcohol precursors of the corresponding oxazolines were also tested (**1**–**3**). In order to rationalize the catalytic results found, a structural study of ruthenium complexes was carried out, both in solution (by means of NMR spectroscopy) and in solid state (by means of X-ray diffraction). The diastereomeric distributions observed in solution were confirmed by structural modeling (PM3(tm) level). In addition, a theoretical study (DFT level) was also carried out concerning the relative energies of the corresponding transition states responsible for the hydrogen transfer from catalytic species to the prochiral ketone.

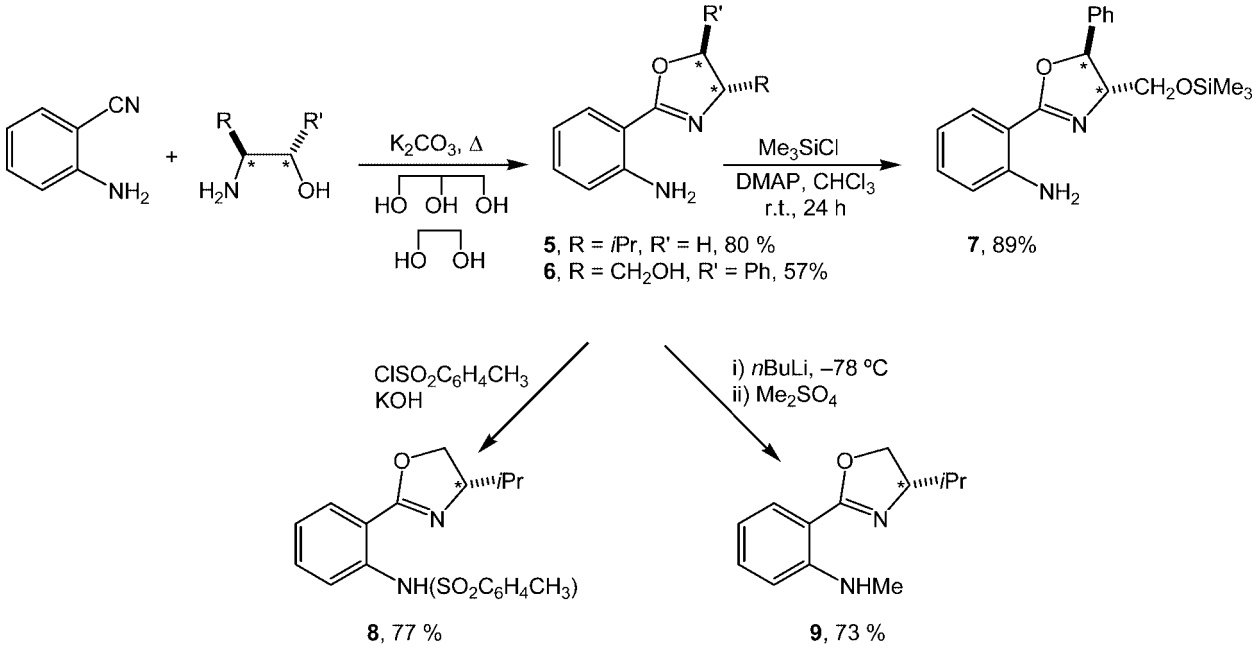
Results and Discussion

Synthesis of Chiral Amino-Oxazoline Ligands

The optically pure amino-oxazolines **4** and **5** recently reported in the literature were prepared in one and three steps, respectively.[10] The standard Zn-catalyzed condensation of anthranilonitrile with the appropriated amino alcohol, followed for the synthesis of **4**,[10b] gave low yields for **5** and **6** (less than 30% after three days of reaction). But better results were obtained when the cyclization process took place under basic conditions in a mixture of glycerol and ethylenglycol in a one-step process (Scheme 2),[11] in contrast to the three-step synthetic route from isatoic anhydride.[10c] The one-pot synthesis gave a mixture of the expected oxazoline and the corresponding amide (oxazoline/amide 85:15 for **5** and 1:1 for **6**), which were separated by aqueous extractions (the oxazoline remains in the organic phase). The pure amide derived from L-valinol can be transformed to the corresponding oxazoline **5** by substitution of the hydroxyl group with *p*-tolylsulfonyl chloride and cyclization under basic conditions (0.5 M NaOH, in H_2O/MeOH 1:1) at room temperature for two days. The oxazoline **7** was easily obtained by silylation of **6** with $SiClMe_3$ in excellent yield. The secondary amine ligands, **8** and **9**, were obtained in two different synthetic ways. Ligand **8** was prepared from the primary amino-oxazoline **5** following the procedure described previously in the literature.[12] But analogous methodology using methyl iodide in place of *p*-toluenesulfonyl chloride failed to give **9**, which was isolated in good yield



Scheme 2. Synthesis of primary (**5**–**7**) and secondary (**8**–**9**) chiral amino-oxazolines.

in two steps, reacting dimethyl sulfate with the lithium derivative of **5** (Scheme 2).

Ruthenium Complexes

The cationic complexes **10**, **11** and **12**, of general formula [RuCl(*p*-cymene)(κ²-*N,N*-L)]Cl (where L = **4**, **5** and **8**, respectively) were synthesized from the dimeric *p*-cymene precursor and the appropriated amino-oxazoline (Scheme 3). Complexes **10** and **11** were obtained as a mixture of two diastereomers, since the ruthenium chiral center formed upon coordination of optically pure oxazoline ligand: (S_{Ru},R_C)- + (R_{Ru},R_C)-**10** and (S_{Ru},S_C)- + (R_{Ru},S_C)-**11**, as observed for analogous arene Ru complexes containing pyridino-oxazolines.[13] In solution, complex **12** shows at least three isomers, probably due to the N stereocenter. The complexes were fully characterized both in solid state and solution.

12, R = *i*Pr, R" = *p*-tolylsulfonyl

Scheme 3. Synthesis of ruthenium complexes (**10**–**12**) containing amino-oxazolines (**4**, **5**, **8**).

Single crystals of **10** were obtained by slow diffusion of hexane over a chloroform/dichloromethane solution of the complex (Figure 2). Selected bond lengths and angles are listed in Table 1. The absolute configuration of the ruthenium stereocenter is S_{Ru} [according to the priority sequence η⁶-arene > Cl > N_{ox}(1) > N_{amino}(2)].[14] The complex adopts a distorted three-legged "piano stool" geometry. The ruthenium atom is η⁶-coordinated to the *p*-cymene unit (calculated distance between the planar arene group and metal is 1.66 Å), and the other three positions are occupied by the two nitrogen (from the bidentated ligand) and chlorine atoms. The bond distances and angles are quite similar to those for the known analogous ruthenium complexes.[15] It is interesting to note the short intramolecular nonbonded distances of one amino hydrogen atom (H1B) with the oxazoline nitrogen and chlorine atoms: N_{amino}(1)–H(1B)···Cl(1) = 2.62 Å and N_{amino}(1)–H(1B)···N_{ox}(2) = 2.79 Å, shorter than the expected van der Waals separations (3.0 Å),[16] and consistent with hydrogen bonds.[17,18] These distances are significantly shorter than for H(1A): N_{amino}(1)–H(1A)···Cl(1) = 2.85 Å and N_{amino}(1)–H(1A)···N_{ox}(2) = 3.30 Å (the hydrogen positions were calculated, not found in the difference Fourier map). It is also significant that the nitrogen–axial hydrogen distance (N–H(1B) = 0.862 Å) is shorter than the nitrogen–equatorial hydrogen one (N–H(1A) = 0.869 Å), as observed for other related compounds.[5b]

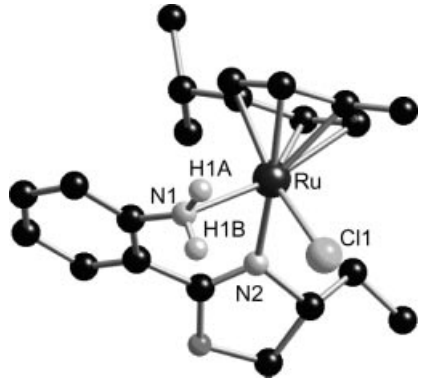

Figure 2. Molecular structure and atom labeling scheme for the cation of (S_{Ru},R_C)-**10**. Hydrogen atoms, except H1A, H1B, and the chloride contra-anion have been omitted for clarity.

Table 1. Selected bond lengths [Å] and angles [°] for (S_{Ru},R_C)-**10** (with esd's in parentheses).

N(2)–Ru(1)–Cl(1)	83.2(2)
N(1)–Ru(1)–Cl(1)	83.7(2)

Conductivity measurements in acetonitrile for complexes **10** and **11** show the existence of 1:1 electrolytes in solution (about 50 $\Omega^{-1}cm^2mol^{-1}$).[19] The highest peak of positive FAB mass spectra corresponds to the cation [RuCl(*p*-cymene)L]⁺ (L = **4** for **10**; L = **5** for **11**).

^{1}H NMR spectra for both ruthenium complexes indicate the existence of two isomers in about 5:1 and 2:1 ratios for **10** and **11**, respectively. For complex **10** many signals appeared overlapped and consequently a complete assignment for both isomers was not possible, in contrast to complex **11** (see Experimental section for NMR spectroscopic data). The N_{amino}-coordination of the oxazoline ligand in **11** is proven by the different chemical shifts of the two N–H protons, for each isomer, analogously to Ru arene complexes containing amino alcohols.[20] The difference between both chemical shifts (more than 5 ppm) stands out, due to the intramolecular hydrogen bond between one N–H and the

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

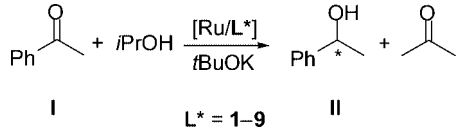
chlorine atom coordinated to the metal (see above, X-ray discussion). As mentioned above, the diastereomers are due to the two chiral centers, the oxazoline carbon stereocenter (*R* or *S* for **4** or **5**, respectively), and the Ru atom. These isomers are exchanged at a low rate in solution, because no isomeric composition change was observed in the noncoordinating solvent ($CDCl_3$) in the temperature range studied (223–298 K). When a 2-propanol solution of **11** was treated at 60 °C for three hours, slight changes in the diastereomeric composition were detected (ratio of both isomers about 2.5:1).

The ^{1}H NMR spectrum for **12** shows the existence of at least three isomers in a ratio of about 4:1:1 at room temperature. A complete assignment could be done only for the major isomer. At lower temperatures (temperature range studied: 298–233 K), the signals corresponding to the minor isomers became larger and the relative ratio could not be determined. Upon coordination of the amino nitrogen atom (NHR, R = *p*tolylsulfonyl) to the ruthenium, a new stereocenter is formed, which could be the factor responsible for the presence of more isomers: (S_{Ru},S_C,R_N)-**12**, (S_{Ru},S_C,S_N)-**12**, (R_{Ru},S_C,R_N)-**12**, and (R_{Ru},S_C,S_N)-**12**.

In order to evaluate the relative isomer stability for complexes **10** and **11**, semi-empirical optimizations [PM3(tm) level] were carried out for both isomers of each complex.[21] The energy difference between the two diastereomers is 1.029 and 0.685 kcal mol^{-1} for **10** and **11**, respectively, the most stable isomers being (R_{Ru},R_C)-**10** and (S_{Ru},S_C)-**11**. The Boltzmann species distribution (about 6:1 and 3:1 for **10** and **11**, respectively, at 298 K) is in good accordance with the ratio observed in the ^{1}H NMR spectra (see above). For both cases, the most stable diastereomer corresponds to the configuration at the Ru atom, that leads to the oxazoline substituent at the stereocenter pointing away from the arene group. To prove the steric hindrance between *p*-cymene and the remaining ligands, the rotation effect around the Ru-arene axis has been considered for both diastereomers. In Figure 3, calculated formation enthalpies versus the dihedral angle defined by C(methyl of *p*-cymene)–*p*-cymene ring–ruthenium–chlorine are plotted for both isomers of each complex **10** and **11**. For the epimer in which the ethyl or isopropyl oxazoline group points toward the arene [(S_{Ru},R_C)-**10** and (R_{Ru},S_C)-**11**, respectively], higher energy intermediates are observed than for the other isomer [(R_{Ru},R_C)-**10** and (S_{Ru},S_C)-**11**, respectively]. In addition, these hills show higher energy for (R_{Ru},S_C)-**11** than for (S_{Ru},R_C)-**10**, due to the more important steric hindrance of the isopropyl than the ethyl group.

Ru-Catalyzed Enantioselective Hydrogen Transfer of Acetophenone

The Ru/amino alcohol (**1**–**3**) and Ru/amino-oxazoline (**4**–**9**) catalytic systems were tested in the asymmetric transfer hydrogenation of acetophenone (**I**), using 2-propanol as the hydrogen source under basic conditions (Scheme 4).[22] The catalytic results are summarized in Table 2. The catalyses were performed with in situ prepared catalyst precursor, [Ru_2Cl_4(*p*-cymene)$_2$], and the corresponding chiral ligand, in a Ru/**L*** ratio 1:2. In the absence of *t*BuOK, Ru/**L*** systems were inactive. Conversions of acetophenone (**I**) and enantiomeric excesses of 1-phenylethanol (**II**) were monitored during the catalytic reaction by GC.



Scheme 4. Hydrogen transfer of acetophenone (**I**) catalyzed by Ru/**L*** systems (**L*** = **1**–**9**).

Concerning the catalytic behavior of Ru/amino alcohols (entries 1–5), the β-monosubstituted amino alcohols, **1** and **2**, are more active than the α,β-disubstituted one, **3** (entries

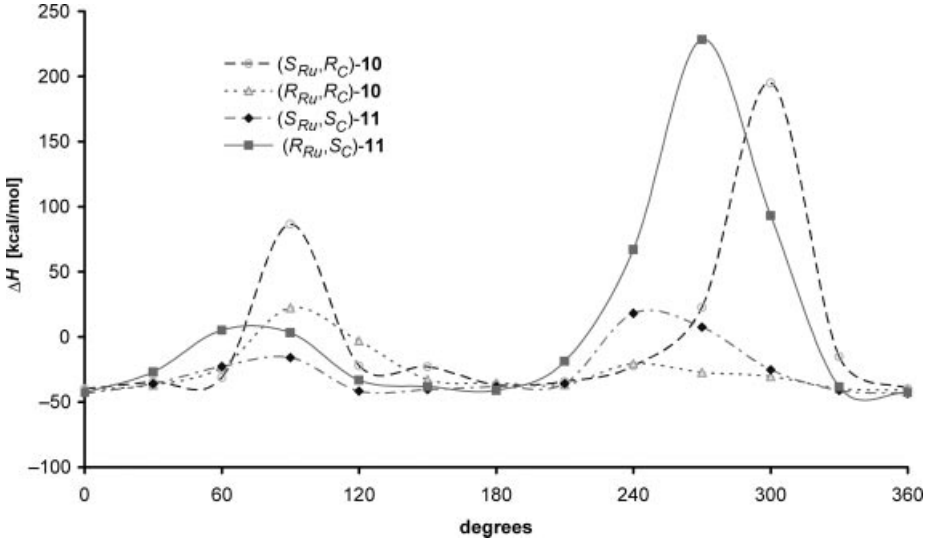


Figure 3. Plot of calculated enthalpies (kcal mol^{-1}) vs dihedral angle "C(methyl of *p*-cymene)–*p*-cymene ring–ruthenium–chlorine" [°] for complexes **10** and **11**.

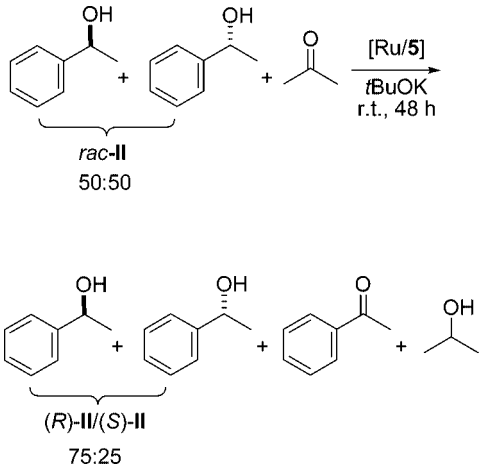
[a] Results from duplicated experiments. Ru/**L***/*t*BuOK 1:2:3. See Scheme 4. [b] Conversions based on the substrate **I** and enantiomeric excesses (absolute configuration in parenthesis) determined by GC. [c] Reaction monitored up to 120 h, being conversion and enantioselectivity constants.

1 and 2 vs 4 and 5), in contrast to the results observed with α,β-dialkyl-substituted amino alcohols.[20] In our case the introduction of a second alcohol function leads to a dramatic activity decrease, but with an asymmetric induction similar to ligand **2** (entries 2 and 5). The selectivity of Ru/**1** and Ru/**2** systems is independent of the acetophenone/ruthenium ratio (entries 2 and 3). When the ruthenium-to-ligand ratio was 1:1, the catalytic behavior did not change, proving that the catalytic species are active without the ligand excess in the reaction medium that was observed previously for other ligands.[23]

Amino-oxazolines **4** and **5** are less active but more selective than the corresponding amino alcohols **1** and **2** (entries 6 and 7 vs 1 and 2, respectively). Also, oxazoline **6** is more selective than **3** (entry 11 vs 5), and, in turn, the silyl oxazoline **7** is more active than **6** (entry 12 vs 10 and 11), the Ru/**7** system being the most active oxazoline catalyst tested. These results indicate a "poison" effect of the alcohol group, both for the amino alcohol **3** and the oxazoline derivative **6**. In addition, we observe that the catalytic activity and selectivity are highly influenced by the substitution degree of the oxazoline heterocycle (**7**, α,β-disubstituted oxazoline, is more active and affords better enantiomeric excesses than **4** and **5**, β-monosubstituted oxazolines), as reported for α,β-dialkyl-substituted amino alcohols.[20]

We note that only the Ru/**5** catalytic system leads to an increase of enantiomeric excess (up to 79%) at long reaction times, together with a conversion decrease (entries 8 and 9). This proves the reversibility of the transfer hydrogenation, as stated by Noyori.[4a,24] In order to verify this kinetic resolution, the dehydrogenative oxidation of *rac*-**II** with acetone was carried out under similar conditions as those described above for the direct process (Scheme 5). After 48 h at room temperature, 46% of acetophenone was formed, achieving an enantiomeric excess for 1-phenylethanol up to 50% (*S*); then (*R*)-**II** dehydrogenates faster than the (*S*)-**II** enantiomer.



Scheme 5. Dehydrogenative oxidation of *rac*-**II** catalyzed by the Ru/**5** system.

Secondary amino-oxazolines, *N*-(*p*-tolylsulfonyl)- and *N*-methyl-amino-oxazoline (**8** and **9**, respectively), were somewhat less active than the analogous primary amino-oxazoline **5** (entries 14 and 17 vs 8), and what is more significant, they did not induce asymmetry (entries 13–17). Then a primary amine moiety and not a secondary amine function in the ligand appears essential for the enantioselectivity. This is something that has not been observed before and is only mentioned for indanol amino alcohol derivatives.[6c]

Theoretical Calculations

Assuming that the Ru-catalyzed hydrogen transfer process involves a concerted transfer of both proton and hydride, a six-membered transition state may be responsible for the ketone reduction by means of a double hydrogen transfer from Ru–H and N–H bonds towards the prochiral substrate, as postulated by Noyori.[7a,25] This concerted

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

mechanism for Ru complexes containing bidentated N-donor ligands, in particular oxazolinyl (N_{ox})-amino(NHR) ligands, is represented in Figure 4.

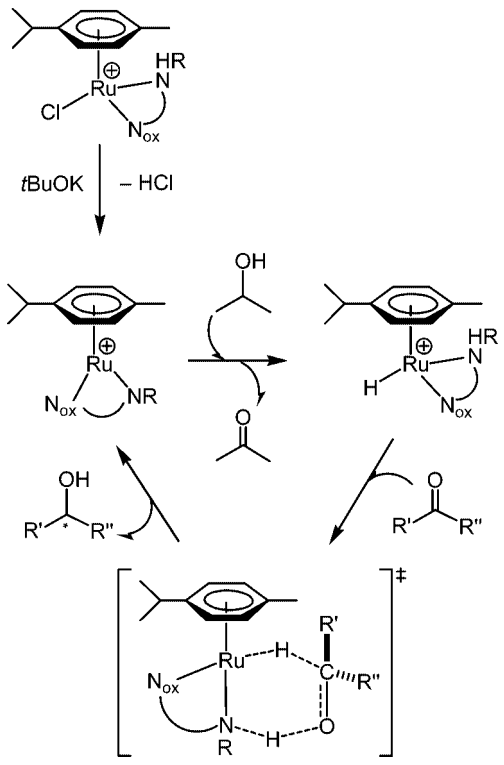


Figure 4. Catalytic cycle for Ru-catalyzed hydrogen transfer of ketones through a concerted mechanism.

For prochiral substrates, like the acetophenone, the enantiomeric enhancement of the chiral alcohol formed depends on the way that the ketone enantioface approaches the metal–hydride intermediate (see transition states depicted in Figure 5). In order to understand the enantioselectivity differences observed with our catalytic systems containing substituted (NHR for ligands **8** and **9**) and nonsubstituted (NH_2 for **4**–**7**) amino groups, theoretical calculations at DFT level were carried out for the corresponding transition states (see below). In the hydride model structure **13** (Figure 5), the substituent on the oxazoline stereocenter is a methyl group with *S* absolute configuration. The energy difference between both optimized diastereomers was 0.59 kcal mol^{-1} (Boltzmann distribution, 73:27), the S_{Ru} being the most stable isomer, where the oxazoline substituent at the stereocenter points away from the arene group, analogously to the related prepared chloro complexes **10** and **11** (see above).

The calculated transition states are labeled as **TS**-R_{II}-**13** or **TS**-S_{II}-**13** depending on the 1-phenylethanol enantiomer afforded (Figure 5). Their relative stability of four transition states are determined by an equilibrium between weak hydrogen interactions of the type C–H···Ar. Our calculations show that the two most stable states produce the *R* alcohol (relative energies are 0.0 and +1.2 kcal mol^{-1}), whereas the relative *S* alcohol states are higher in energy (+1.6 and +2.5 kcal mol^{-1}). Concerning the transition states related to the **13** hydride species, the Boltzmann distribution (298 K) for their four transition states leads to a calculated enantiomeric excess for the secondary alcohol **II** of about 40% in the *R* isomer (Figure 6), in agreement with the catalytic results obtained with the analogous amino-oxazolines con-

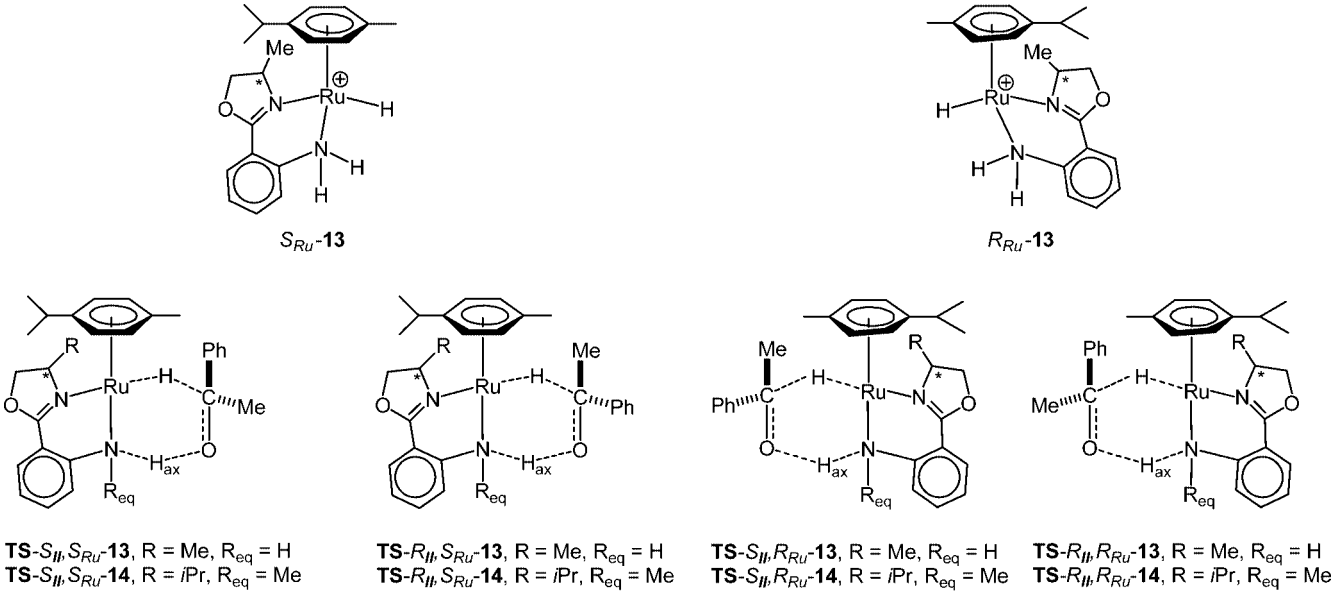

Figure 5. Optimized hydride species **13** (S_{Ru}-**13** and R_{Ru}-**13**) and the transition states involved in the hydrogenation of acetophenone used in the DFT study.

taining an ethyl and isopropyl instead of the methyl group (ligands **4** and **5**).

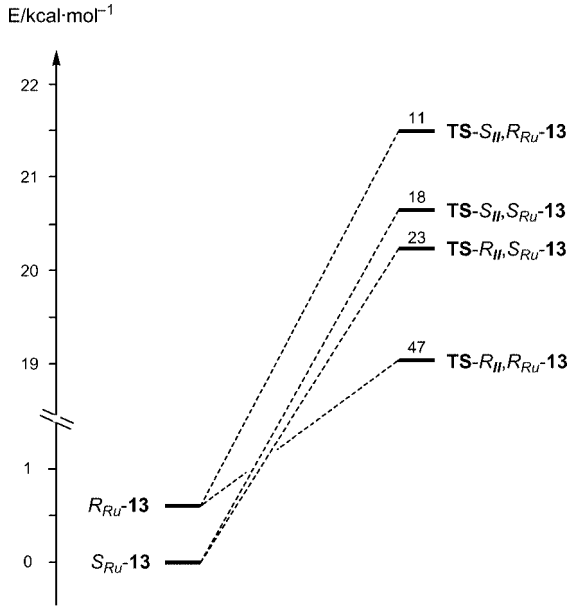

Figure 6. Energy profile for minima of compound model **13**, and their generated transition states (Figure 5) for the reaction with acetophenone, depending on the relative orientation of prochiral ketone. Relative populations of transition states are shown according to the Boltzmann distribution at 298 K.

The good correlation observed between experimental and calculated data for the Ru systems containing primary amino ligands led us to calculate the relative population of the transition states involved with Ru species containing secondary amino-oxazoline **9** (transition states labeled as **14** in Figure 5). For these states, only the two axial related species were taken into account because of the topological arrangement for hydrogen transfer to the prochiral ketone in the transition state (Figure 5). As depicted in Figure 7, the isomers **TS**-S_{Ru}-**14** are less stable than the other two, possibly due to steric repulsions, having an energy higher than 10 kcal mol^{-1} and higher than the related **TS**-R_{Ru}-**14**. For this reason they do not play any role in our catalytic system (Figure 8). Consequently, only the lowest transition states, **TS**-R_{II},R_{Ru}-**14** and **TS**-S_{II},R_{Ru}-**14**, participate in the hydrogenation reaction and the small energy gap between the two forms is responsible for a decrease of enantiomeric excess (calculated *ee* = 26%). In contrast, in the related transition states of **13**, the largest populations corresponded to the transition states loading to the *R* enantiomers, explaining the selectivity trends observed for Ru catalytic systems containing primary and secondary amino-oxazolines (see Catalytic section).

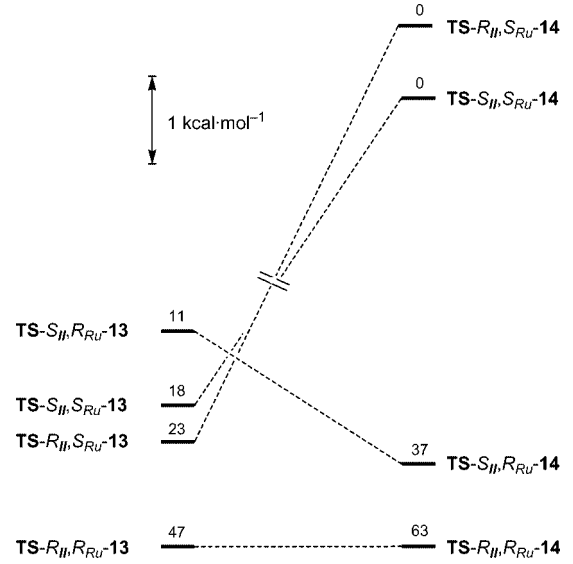

Figure 7. Relative stabilities of Ru transition states involved in the acetophenone hydrogen transfer containing primary (**13**) and secondary (**14**) oxazolinyl-amines. Relative populations are shown as Figure 5 and zero level is taken from the **TS**-R_{II},R_{Ru} isomer.

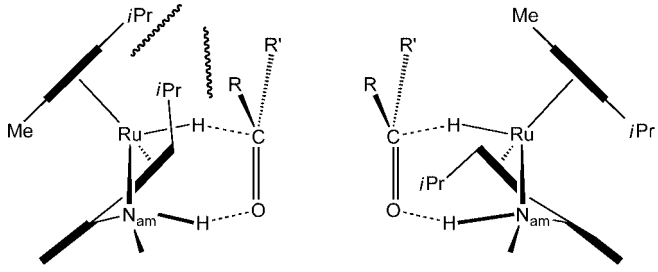

Figure 8. Schematic representation of the transition states **TS-14**. The steric repulsions between hydrocarbon groups for **TS**-S_{Ru}-**14** (left) are missing in analogous **TS**-R_{Ru}-**14** (right).

Conclusions

We used modular chiral N-donor ligands in order to study the fine effects on the transfer hydrogenation of acetophenone catalyzed by Ru arene systems. An important influence on selectivity was found to depend on the nature of the amino group: secondary amino ligands (**8**–**9**) do not induce enantioselectivity, in contrast to their analogous primary derivative (**5**). In order to rationalize these results, a structural and mechanistic study was proposed. The synthesis and full characterization of complexes containing primary (**10** and **11**) and secondary (**12**) oxazolinyl-amino ligands was carried out. The NMR spectroscopic data show the presence of isomers due to the new sterocenters (Ru and also N for **12**) generated upon coordination of the ligands (**4**, **5**, and **8**) to the metal. The relative populations found by modeling structures (PM3(tm) level) are in agreement with the diastereomeric ratios observed by NMR spectroscopy. The enantioselectivity loss observed for secondary amines relative to the analogous primary ligands can be justified by the theoretical data obtained (DFT studies) for the transition states proposed for the arene ruthenium systems involved in the hydrogen transfer of prochiral ketones.

Experimental Section

General Remarks: All compounds were prepared under purified nitrogen using standard Schlenk and vacuum-line techniques. The solvents were purified by standard procedures and distilled under nitrogen.[26] (*R*)-(+)-2-Aminobutanol (Fluka), L-valinol (Aldrich), and [RuCl(*p*-cymene)(μ-Cl)]$_2$ (Aldrich) were used without previous purification. Ligand **4**[10b] was prepared as described previously. NMR spectra were recorded with Varian XL-500 (^{1}H, standard $SiMe_4$), Varian Gemini (^{1}H, 200 MHz; ^{13}C, 50 MHz; standard $SiMe_4$), Bruker DRX 250 (^{13}C, 62.9 MHz, standard $SiMe_4$), and Mercury 400 (^{1}H, 400 MHz; ^{13}C, 100 MHz, standard $SiMe_4$) spectrometers, using $CDCl_3$ as solvent, unless stated otherwise. Chemical shifts were reported downfield from standards. IR spectra were recorded with a Nicolet 520 FTIR spectrometer. FAB mass chromatograms were obtained on a Fisons V6-Quattro instrument. The GC analyses were performed on a Hewlett–Packard 5890 Series II gas chromatograph (50 m Ultra 2 capillary column) with a FID detector. Enantiomeric excesses were determined by GC on a FS-cyclodex-β-I/P column. Optical rotations were measured on a Perkin–Elmer 241MC spectropolarimeter. Conductivities were obtained on a Radiometer CDM3 conductimeter. Elemental analyses were carried out by the *Serveis Cientifico-Tècnics de la Universitat de Barcelona* in an Eager 1108 microanalyzer.

(+)-(4′*S*)-2-(4′-Isopropyl-3′,4′-dihydrooxazol-2′-yl)aniline (5): L-Valinol (0.743 g, 7.20 mmol), 2-aminobenzonitrile (0.500 g, 4.23 mmol), and potassium carbonate (0.054 g, 0.39 mmol) were successively introduced in a Schlenk, followed by a solution of glycerol (5 mL) in dry ethylene glycol (9 mL). The resulting mixture was brought to 105 °C under nitrogen. The disappearance of the nitrile was followed by thin-layer chromatography (hexane/ethyl acetate, 3:1). After 24 h, the reaction was complete. Two new spots appeared on the thin layer, which were further identified as the amide for the high R_f and the oxazoline for the low R_f one (15:85 respectively, determined by GC analysis). The mixture was cooled to room temperature and then poured over crushed ice. The resulting white solid was filtered, dissolved in dichloromethane and, after several extractions with water, the organic phases were dried with anhydrous Na_2SO_4. Solvent elimination under low pressure gave the product as a white solid. Yield: 0.860 g (80%). IR (KBr): $\tilde{\nu}$ = 3395 (N–H), 3261 (N–H), 1640 (C=N), 1255 (C–O) cm^{-1}. ^{1}H NMR (250 MHz, $CDCl_3$; multiplicity, coupling constants in Hz, and relative integration in parentheses): 7.67 (pdd, 8.8, 1.6, 1 H), 7.19 (pt, 7.4, 1 H), 6.69 (m, 2 H), 6.13 (br. s, 2 H), 4.32 (ppd, 8.6, 7, 1 H), 4.11 (m, 1 H), 4.00 (t, 7.3, 1 H), 1.81 (m, 1 H), 1.03 (d, 6.8, 3 H), 0.93 (d, 6.8, 3 H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): 163.4 (C), 148.5 (C), 131.8 (C), 129.5 (CH), 115.9 (CH), 115.5 (CH), 109.1 (CH), 72.9 (CH), 68.7 (CH_2), 33.2 (CH), 19.1 (CH_3), 18.6 (CH_3) ppm. $C_{12}H_{16}N_2O$ (204): calcd. C 70.58, H 7.84, N 13.72; found C 70.29, H 8.02, N 13.74. MS (FAB positive) *m*/*z* 204 ([M]$^+$). Melting point: 103 °C. $[\alpha]_D^{25}$ (1×10^{-3} M, $CHCl_3$) = +19.8.

(+)-(3′*S*,4′*S*)-2-(3′-Phenyl-4′-hydroxymethyl-3′,4′-dihydrooxazol-2′-yl)aniline (6): (1*S*,2*S*)-2-Amino-1-phenyl-1,3-propanediol (1.201 g, 7.20 mmol), 2-aminobenzonitrile (0.500 g, 4.23 mmol), and potassium carbonate (0.054 g, 0.39 mmol) were successively introduced in a Schlenk, followed by a solution of glycerol (5 mL) in dry ethylene glycol (9 mL). The resulting mixture was brought to 105 °C under nitrogen. The disappearance of the nitrile was followed by thin-layer chromatography (hexane/ethyl acetate, 3:1). The reaction was complete after 36 h. Two new spots appeared on the thin layer, which were further identified as the amide for the high R_f and the oxazoline for the low R_f one (1:1 respectively, determined by GC analysis). The mixture was cooled to room temperature and washed with a saturated aqueous solution of NH_4Cl and extracted with dichloromethane (3 × 15 mL). The organic extracts were dried with anhydrous Na_2SO_4. Solvent elimination under low pressure gave the product as a yellow oil. Yield: 0.640 g (57%). IR (NaCl): $\tilde{\nu}$ = 3466 (N–H), 3415 (O–H), 3309 (N–H), 1633 (C=N), 1261 (C–O) cm^{-1}. ^{1}H NMR (200 MHz, $CDCl_3$; multiplicity, coupling constants in Hz, and relative integration in parentheses): 7.81 (dd, 7.9, 0.6, 1 H), 7.24 (m, 3 H), 6.70 (m, 5 H), 6.07 (br. s, 2 H), 4.39 (d, 7, 1 H), 4.26 (pq, 3.6, 1 H), 3.94 (pdd, 11.5, 3.7, 1 H), 3.74 (dd, 11.2, 4.0, 1 H), 2.61 (br. s, 1 H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): 164.8 (C), 148.6 (C), 140.8 (C), 132.4 (CH), 129.9 (CH), 128.8 (CH), 128.2 (CH), 125.6 (CH), 116.4 (CH), 115.9 (CH), 108.8 (C), 80.9 (CH), 64.1 (CH_2) ppm. MS (FAB positive) *m*/*z* 267 ([M – H]$^+$). $[\alpha]_D^{25}$ (1×10^{-3} M, $CHCl_3$) = +59.3.

(+)-(3′*S*,4′*S*)-2-(3′-Phenyl-4′-trimethylsilyloxymethyl-3′,4′-dihydrooxazol-2′-yl)aniline (7): Compound **6** (0.330 g, 1.23 mmol), imidazole (0.175 g, 2.58 mmol), DMAP (6.6 mg, 5.3×10^{-2} mmol), and $SiClMe_3$ (0.132 g, 1.22 mmol) were successively introduced in a Schlenk. The solids were dissolved in 50 mL of freshly distilled chloroform, and the resulting mixture was stirred for 24 h at room temperature. The evolution of the reaction was followed by thin-layer chromatography (hexane/ethyl acetate, 2:1). When the reaction was over, the organic phase was treated successively with 10 mL of saturated aqueous solution of sodium hydrogenocarbonate and 10 mL of a saturated aqueous solution of brine, and the organic extracts were then dried with anhydrous Na_2SO_4. After solvent evaporation, the resulting oil was purified by column chromatography on silica using a mixture of hexane/ethyl acetate (2:1) as eluent. The product was obtained as a white solid. Yield: 0.372 g (89%). IR (KBr): $\tilde{\nu}$ = 3408 (N–H), 3276 (N–H), 1635 (C=N), 1261 (C–O) cm^{-1}. ^{1}H NMR (200 MHz, $CDCl_3$; multiplicity, coupling constants in Hz, and relative integration in parentheses): 7.67 (pdd, 7.9, 1.5, 2 H), 7.16 (m, 4 H), 6.58 (d, 8.6, 2 H), 6.54 (pt, 7.6, 1 H), 5.97 (br. s, 2 H), 5.29 (d, 6.0, 1 H), 4.15 (m, 1 H), 3.83 (dd, 10.4, 4.2, 1 H), 3.55 (pdd, 10.1, 7.3, 1 H), –0.02 (s, 9 H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): 164.2 (C), 148.8 (C), 141.5 (C), 132.2 (CH), 129.8 (CH), 128.6 (CH), 127.9 (CH), 125.0 (CH), 116.0 (CH), 115.6 (CH), 108.9 (C), 81.6 (CH), 77.2 (CH), 64.9 (CH_2), 0.1 (CH_3) ppm. $C_{19}H_{25}N_2O_2Si$ (341.5): calcd. C 67.03, H 7.05, N 8.23; found C 67.69, H 7.11, N 8.30. MS (FAB positive) *m*/*z* 340 ([M]$^+$). Melting point: 153 °C. $[\alpha]_D^{25}$ (1×10^{-3} M, $CHCl_3$) = +30.7.

(+)-(4′*S*)-2-(4′-Isopropyl-3′,4′-dihydrooxazol-2′-yl)-*N*-(*p*-tolylsulfonyl)aniline (8): Stirring a solution of **5** (0.100 g, 0.49 mmol) and *p*-tolylsulfonyl chloride (0.160 g, 0.84 mmol) in dichloromethane with an aqueous solution of KOH (0.049 g, 0.89 mmol) for 8 h gave a white solid, which was filtered off and purified by column chromatography on silica using hexane/ethyl acetate (5:1) as eluent. Yield: 0.134 g (77%). IR (KBr): $\tilde{\nu}$ = 3389 (N–H), 1637 (C=N), 1341 (S=O), 1163 (S=O) cm^{-1}. ^{1}H NMR (200 MHz, $CDCl_3$; multiplicity, coupling constants in Hz, and relative integration in parentheses): 12.54 (br. s, 1 H), 7.66 (d, 8.2, 2 H), 7.62 (m, 2 H), 7.26 (ptd, 7.8, 1.4, 2 H), 6.91 (ptd, 7.9, 1.0, 1 H), 4.28 (dd, 8.6, 7.4, 1 H), 4.06 (m, 1 H), 3.98 (m, 1 H), 2.26 (s, 3 H), 1.73 (m, 1 H), 0.98 (d, 6.6, 3 H), 0.88 (d, 6.6, 3 H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): 164.8 (C), 142.5 (C), 137.8 (C), 135.4 (C), 132.3 (CH), 129.4 (CH), 129.1 (CH), 127.1 (CH), 122.1 (CH), 117.6 (CH), 72.3 (CH), 69.5 (CH_2), 33.1 (CH), 18.8 (CH_3), 18.6 (CH_3) ppm. $C_{19}H_{22}N_2O_2S$ (342): calcd. C 63.68, H 6.14, N 7.81; found C 63.78, H 6.53, N 7.60. MS (FAB positive) *m*/*z* 340 ([M]$^+$). Melting point : 129 °C. $[\alpha]_D^{25}$ (1×10^{-3} M, $CHCl_3$) = +82.1.

(4′*S*)-2-(4′-Isopropyl-3′,4′-dihydrooxazol-2′-yl)-*N*-(methyl)aniline (9): Compound **5** (0.150 g, 0.73 mmol) was dissolved in 10 mL of

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

THF. The resulting mixture was cooled to –78 °C under nitrogen. After 30 min, *n*BuLi (0.55 mL, 0.88 mmol) was introduced in the Schlenk, followed by a solution of Me_2SO_4 (0.111 g, 0.88 mmol) in THF (3 mL). The resulting mixture was warmed to room temperature. The reaction was complete after 18 h. Two new spots appeared on the thin layer, which were further identified as the product for the high R_f and the oxazoline **5** for the low R_f one (70:30 respectively, determined by GC analysis). The mixture was dissolved in dichloromethane and after several extractions with an aqueous saturated solution of NH_4Cl and water, the organic phases were dried with anhydrous Na_2SO_4. The resulting oil was purified by column chromatography on silica using hexane/ethyl acetate (20:1) as eluent. Solvent elimination under low pressure gave the product as a yellow oil. Yield: 0.116 g (73%). IR (KBr) = 3265 (N–H), 3171 (N–H), 2959 (C–H), 1636 (C=N), 1253 (C–O) cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$; multiplicity, coupling constants in Hz, and relative integration in parentheses): 8.31 (br. s, 1 H), 7.63 (dd, 7.9, 1.8, 1 H), 7.23 (m, 1 H), 6.53 (m, 2 H), 4.21 (dd, 8.4, 7.0, 1 H), 4.03 (m, 1 H), 3.90 (q, 7.0, 1 H), 2.85 (d, 4.8, 3 H), 1.69 (m, 1 H), 0.94 (d, 6.6, 3 H), 0.84 (d, 6.6, 3 H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): 163.6 (C), 149.8 (C), 132.2 (CH), 129.6 (CH), 113.9 (CH), 109.6 (CH), 108.3 (C), 72.8 (CH), 68.3 (CH_2), 33.1 (CH), 29.4 (CH_3), 19.0 (CH_3), 18.5 (CH_3) ppm. Ruthenium-Catalyzed Hydrogen Transfer of Acetophenone: The precursor ($[Ru(p\text{-cymene})Cl(\mu\text{-}Cl)]_2$, 1.8 mg, 3×10^{-3} mmol) and ligand (12×10^{-3} mmol) were dissolved in a solution (2 mL, 0.012 M) of *t*BuOK in 2-propanol at room temperature for 30 min. Then a solution of acetophenone in 2-propanol (2 mL, 0.06 M) was added. The reaction was performed at room temperature under nitrogen, monitored by GC. When the Ru/substrate ratio was 1:100, the precursor (1.8 mg, 3×10^{-3} mmol) and ligand (12×10^{-3} mmol) were dissolved in a solution of *t*BuOK in 2-propanol (10 mL, 0.012 M) at room temperature for 30 min. Then a solution of acetophenone in 2-propanol (10 mL, 0.06 M) was added. The reaction was performed at room temperature under nitrogen, monitored by GC.

Ruthenium-Catalyzed Dehydrogenation of *rac*-1-Phenylethanol: The precursor (1.8 mg of $[Ru(p\text{-cymene})Cl(\mu\text{-}Cl)]_2$, 3×10^{-3} mmol) and ligand **5** (25 mg, 12×10^{-3} mmol) were dissolved in a solution of *t*BuOK in 2-propanol (2 mL, 0.012 M) at room temperature for 30 min. Then an equimolar solution of *rac*-1-phenylethanol and acetone in 2-propanol (2 mL, 0.06 M) was added. The reaction was performed at room temperature under nitrogen, monitored by GC.

X-ray Crystallographic Study: An orange block of **10** was selected and mounted on a Bruker SMART CCD area detector single-crystal diffractometer with graphite monochromatized Mo-K_α radiation (λ = 0.71073 Å) operating at room temperature. Crystal data are summarized in Table 3.

Table 3. Crystal data for (S_{Ru},R_C)-**10**.

	(S_{Ru},R_C)-**10**
Empirical formula	$C_{23}H_{29}Cl_8N_2ORu$
Molecular mass	734.15
Crystal size [mm]	$0.39\times0.09\times0.08$
Temperature [K]	298(2)
Crystal system	orthorhombic
Space group	$P2_12_12_1$
a (Å)	8.881(1)
b (Å)	18.102(2)
c (Å)	20.231(2)
V [Å^3]	3252.6(5)
Z	4
Density (calculated) [Mg m^{-3}]	1.499
Absorption coefficient [mm^{-1}]	1.158
θ range for data collection [°]	1.51–26.37
Reflections collected ($I \geq 2\sigma(I)$)	19013
Independent reflections	6599
Final R indices [$I > 2\sigma(I)$][a]	R_1 = 0.0643
Final wR_2 indices (all data)[a]	wR_2 = 0.1547
Gof on F^2	1.018
Abs. structure parameter[b]	0.05(8)
Largest diff. peak and hole [e Å^{-3}]	0.565 and –0.481

[a] $R_1 = \Sigma||F_o| - |F_c|| / \Sigma|F_o|$ and $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2] / \Sigma[w(F_o^2)^2]\}^{1/2}$. [b] H. D. Flack, *Acta Crystallogr. Sect. A* **1983**, *39*, 876.

Preliminary unit cell constants were calculated with a set of 45 narrow-frame (0.3° in ω) scans. A total of 1271 frames of data were collected using the phi–omega scan method. The first 50 frames were recollected at the end of data collection to monitor for decay. The crystal used for the diffraction study showed no decomposition during data collection. Absorption corrections were applied by using the SADABS program[27] (maximum and minimum transmission coefficients 0.9130 and 0.6608). The structure was solved by direct methods using the SHELXS-97 computer program[28] for crystal structure determination and refined by full-matrix least-squares method on F^2, with the SHELXL-97 computer program.[29] 6599 reflections were included in the refinement and no restraints were applied to the 310 parameters. Hydrogen atoms were included in calculated positions and refined in riding mode. The weighting scheme employed was $w = [\sigma^2(F_o^2 + (0.0997P)^2 + 0.4457P]$ and $P = (|F_o|^2 + 2|F_c|^2)/3$.

CCDC-274550 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Computational Details: Calculations were carried out using the GAUSSIAN98 package.[30] The hybrid density function method known as B3LYP was applied.[31] Relativistic effective core potentials (ECP) from the Stuttgart–Dresden group were used to represent the innermost electrons of the ruthenium atoms.[32] The basis set for the main group elements was split-valence and included a polarization function in all atoms (abbreviated as SVP).[33] The geometries for the minima **13** and **14** were fully optimized in all the isomers. The search for transition states failed, and in an attempt to evaluate their relative stability we decided to make a partial optimization, which was performed by keeping the distances of the Ru···H···C fragment fixed at 1.75 and 1.38 Å, respectively.[7] Some changes in these parameters were introduced without major changes in the relative stability of each family of compounds.

Acknowledgments

The authors thank Prof. Santiago Álvarez for constructive discussions. The authors also wish to thank the Ministerio de Educación y Ciencia (CTQ2004-01546/BQU and 2002-04033/BQU) and the Generalitat de Catalunya for financial support. The installation of the SMART CCD Single-Crystal Diffractometer at the University of A Coruña was supported by the Xunta de Galicia (XUGA INFRA-97).

Mechanisms of Concurrent Hydride Migration Processes in a Triruthenium Cluster Capped by a Phenylphosphinidene (PPh) Ligand

Antony J. Deeming*[a] Caroline S. Forth,[a] Md. Iqbal Hyder,[b] Shariff E. Kabir,*[b] Ebbe Nordlander*[c] Fiona Rodgers[a] and Bettina Ullmann[c]

Keywords: Ruthenium / Clusters / Hydrides / Dynamic mobility / Kinetics

Two methods were used to synthesise $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) (dppm = $Ph_2PCH_2PPh_2$), the subject of this paper. Treatment of $[Ru_3(CO)_{10}(\mu\text{-}dppm)]$ (**1**) with phenylphosphane in refluxing THF gave both $[Ru_3(\mu\text{-}H)(\mu\text{-}PHPh)(CO)_8(\mu\text{-}dppm)]$ (**2**) and $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**). Cluster **2** converts to **3** in refluxing THF. Alternatively the phenylphosphinidene cluster $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ (**4**), prepared by the reported method of treating $[Ru_3(CO)_{12}]$ with phenylphosphane, reacts with dppm to produce cluster **3**. The single-crystal X-ray structures of **2** and **3** are reported. Hydride mobility in $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) was analysed by variable-temperature ^1H and $^{31}P\{^1H\}$ NMR methods. The variations in the spectra with temperature could not be interpreted by a single process, several of which were explored and which gave inadequately matching computed and experimental spectra. However, the spectra were successfully analysed by two concurrent processes, both involving the migration of hydride ligands between Ru–Ru edges. The faster process leads to the exchange of the nonequivalent phosphorus nuclei but not hydride exchange, whereas the hydrides are also exchanged in the slower process. Both processes require hydride ligand migration from one Ru–Ru edge to a vacant one. The hydride ligand bridging the same pair of ruthenium atoms as the dppm ligand is the slower to migrate.

Introduction

Hydride migration between edge-bridging, face-bridging and terminal sites in transition-metal clusters has been commonly observed.[1] It is possible to probe these migrations by NMR coalescence and other classical methods if the hydride ligands are inequivalent, by changes in the appearance of coupling patterns to the metal centres if there is a spin-active metal nucleus, or by exchanges in sites within another ligand that result from hydride migration. The phosphinidene-capped cluster $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$[2–4] (**4**) presumably has mobile hydride ligands which can undergo degenerate migrations from either of the two occupied edges to the vacant one. To the best of our knowledge this has never been demonstrated although in related clusters, such as $[Os_3(\mu\text{-}H)_2(\mu_3\text{-}S)(CO)_9]$, this type of process has been investigated.[5] By introducing phosphane ligands into $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ (**4**), the hydrides may become inequivalent and distinguishable hydride migrations of different rate might occur. The hydride ligands will preferentially occupy some sites rather than others, in particular the bridging sites between the most electron-rich metal centres. Migration of hydrides out of electron-rich sites into electron-poor sites is likely to be slow.

In this paper we will describe in detail the fluxional behaviour of the cluster $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) which has C_1 symmetry. There are inequivalent hydrides and three inequivalent ^{31}P nuclei so that NMR analysis of the fluxional behaviour is straightforward.

Results and Discussion

Synthesis and Characterisation of Compounds

We used two different methods to synthesise compound **3** from $[Ru_3(CO)_{12}]$ as shown in Scheme 1. The introduction of the diphosphane (dppm) ligand first followed by treatment of $[Ru_3(CO)_{10}(dppm)]$ (**1**)[6] with Ph_2PH in refluxing THF, gave both $[Ru_3(\mu\text{-}H)(\mu\text{-}PHPh)(CO)_8(\mu\text{-}dppm)]$ (**2**) and $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**), which were easily separated and characterised. There was no improvement in the reaction of **1** with $PhPH_2$ when Me_3NO was employed to remove CO ligands by oxidation. Thermal treatment of **2** in refluxing THF leads to **3**, and presumably this is the route by which **3** is formed as shown in Scheme 1.

Alternatively, the PPh ligand may be introduced in the first step to form $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ **4** from Ph_2PH and $[Ru_3(CO)_{12}]$ by known methods.[2–4] Cluster **4** may then

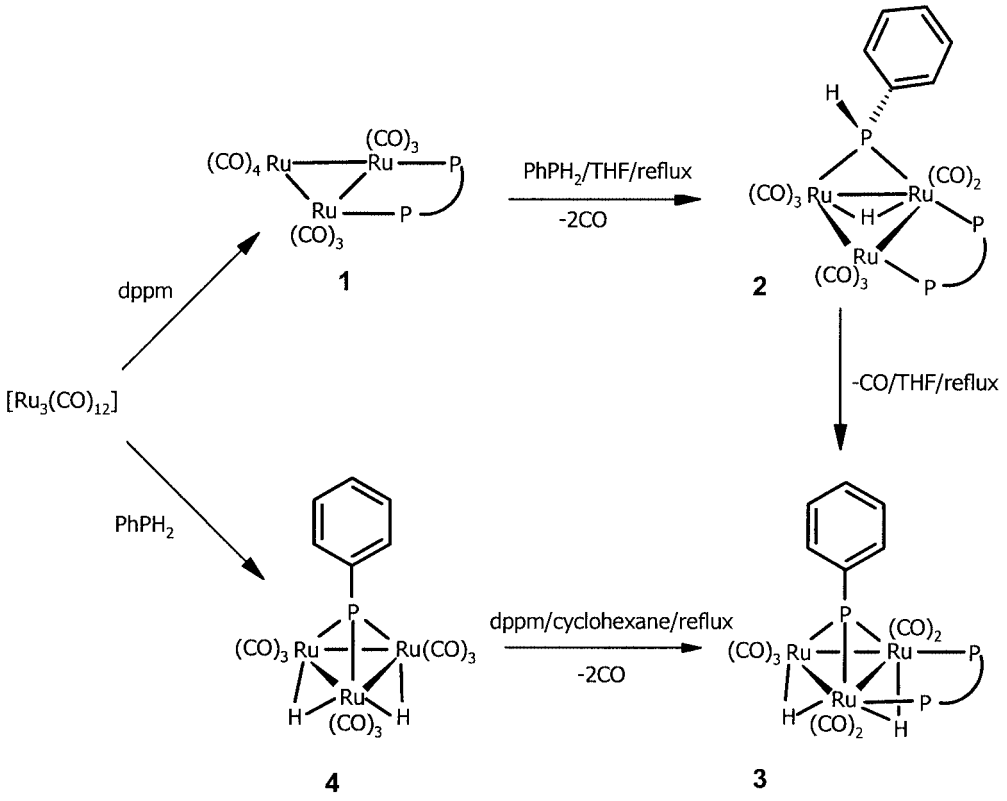

Scheme 1.

be substituted by dppm. This substitution was attempted unsuccessfully by preparing MeCN derivatives of the type $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_{9-x}(MeCN)_x]$ (x = 1 or 2), followed by treatment of these in situ with dppm. Likewise a photochemical procedure (UV) for the reaction of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ (**4**) with dppm was attempted. Neither of these methods gave much product. However, direct thermal treatment of **4** with dppm leads to the two products: $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) and a minor yellow band which gave $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(\mu\text{-}dppm)]$. The latter complex readily looses CO to form **3**, and we have been unable to characterise it fully. We believe it contains a monodentate dppm ligand. This was indicateded by its IR spectrum around 2000 cm^{-1}, which is very closely similar to that of monodentate phosphane derivatives such as $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(PMe_2Ph)]$.[7,8]

Characterisation of Compound 2

The single-crystal XRD structure of cluster **2** is shown in Figure 1. Crystal data are in Table 1 and some selected geometric data are in Table 2. The framework of the compound corresponds to that of $[Ru_3(\mu\text{-}H)(\mu\text{-}PHPh)(CO)_{10}]$ with the H and the PHPh ligands spanning the same Ru–Ru edge.[2] The hydride ligand was located from diffraction data. The dppm ligand, however, bridges one of the other two Ru–Ru edges, unlike the structure of $[Os_3(\mu\text{-}H)_2(CO)_8(\mu\text{-}dppm)]$ in which the three bridging ligands are at the same Os–Os edge.[9] The structure of **2** is essentially as expected for this arrangement of ligands but there are some bond lengths worth noting. Atom Ru(3) is the most heavily substituted by P-donors but is associated with the shorter Ru–P bonds. For the PHPh ligand, Ru(3)–P(1) [2.3069(12) Å] is shorter than Ru(1)–P(1) [2.3490(12) Å] and for dppm, Ru(3)–P(2) [2.2998(11) Å] is shorter than Ru(2)–P(3) [2.3245(12) Å]. If, as one would expect, Ru(3) is the most electron-rich centre, the bond lengths could be explained by greater π donation by that atom to the phosphorus ligands. One should also note that Ru–CO distances *trans* to the μ-PHPh ligand are long and Ru–CO distances *trans* to μ-H are short with respect to the other related distances in this molecule. The bridging dppm has negligible impact on the length of the Ru–Ru bond compared to the unbridged edge; 2.8494(10) Å compared with 2.8509(8) Å.

In the light of this structure, there are some problems in accounting for the ^1H NMR spectra. The IR and mass spectra are completely consistent with the solid-state structure but the NMR spectrum seems to indicate higher symmetry than that in the crystal. The hydride appears as a 1:2:1 triplet at δ = –16.30 ppm and the CH_2 hydrogen atoms appear as a single triplet at δ = 4.26 ppm. Neither of these observations are predicted from the XRD structure. The spectra at –50 °C as well as at 27 °C show these features so we believe the compound is non-fluxional. The CH_2 triplet must be due to accidental isochronicity and the observed triplet for the hydride signal is probably due to similar coupling to the two non-equivalent ^{31}P nuclei at Ru(3)

which are not resolved, together perhaps with virtual coupling effects.

Characterisation of $[Ru_3(\mu\text{-H})_2(\mu_3\text{-PPh})(CO)_7(\mu\text{-dppm})]$ (3)

The single-crystal XRD structure of cluster **3** is shown in Figure 2 and some selected geometric data are listed in Table 3. The structure is based on that known for $[Ru_3(\mu\text{-H})_2(\mu_3\text{-PPh})(CO)_9]$.[2] The dppm ligand bridges in equatorial sites at Ru(1) and Ru(2) with all three P nuclei on the same side of the Ru_3 plane. The hydride ligands are located on the Ru(1)–Ru(2) and Ru(1)–Ru(3) edges consistent with these bonds being longer than Ru(2)–Ru(3). ^{1}H NMR spectroscopic data at 233 K and $^{31}P\{^1H\}$ NMR spectroscopic data at 213 K show all three ^{31}P nuclei are in different environments and that the hydrides are non-equivalent. The P nuclei of the dppm ligand both lie equatorially (*cis* to the PPh ligand) and it is the hydride locations that make the dppm unsymmetrical.

Analysis of VT ^{1}H and $^{31}P\{^1H\}$ NMR spectra for $[Ru_3(\mu\text{-H})_2(\mu_3\text{-PPh})(CO)_7(\mu\text{-dppm})]$ (3)

Figure 3 shows that the $^{31}P\{^1H\}$ NMR spectrum for $[Ru_3(\mu\text{-H})_2(\mu_3\text{-PPh})(CO)_7(\mu\text{-dppm})]$ (**3**) at 213 K contains a double doublet at δ = 277.75 for the phosphinidene ligand and two doublets of doublets at δ = 25.20 and 27.70 ppm for the inequivalent dppm phosphorus nuclei. Changes oc-

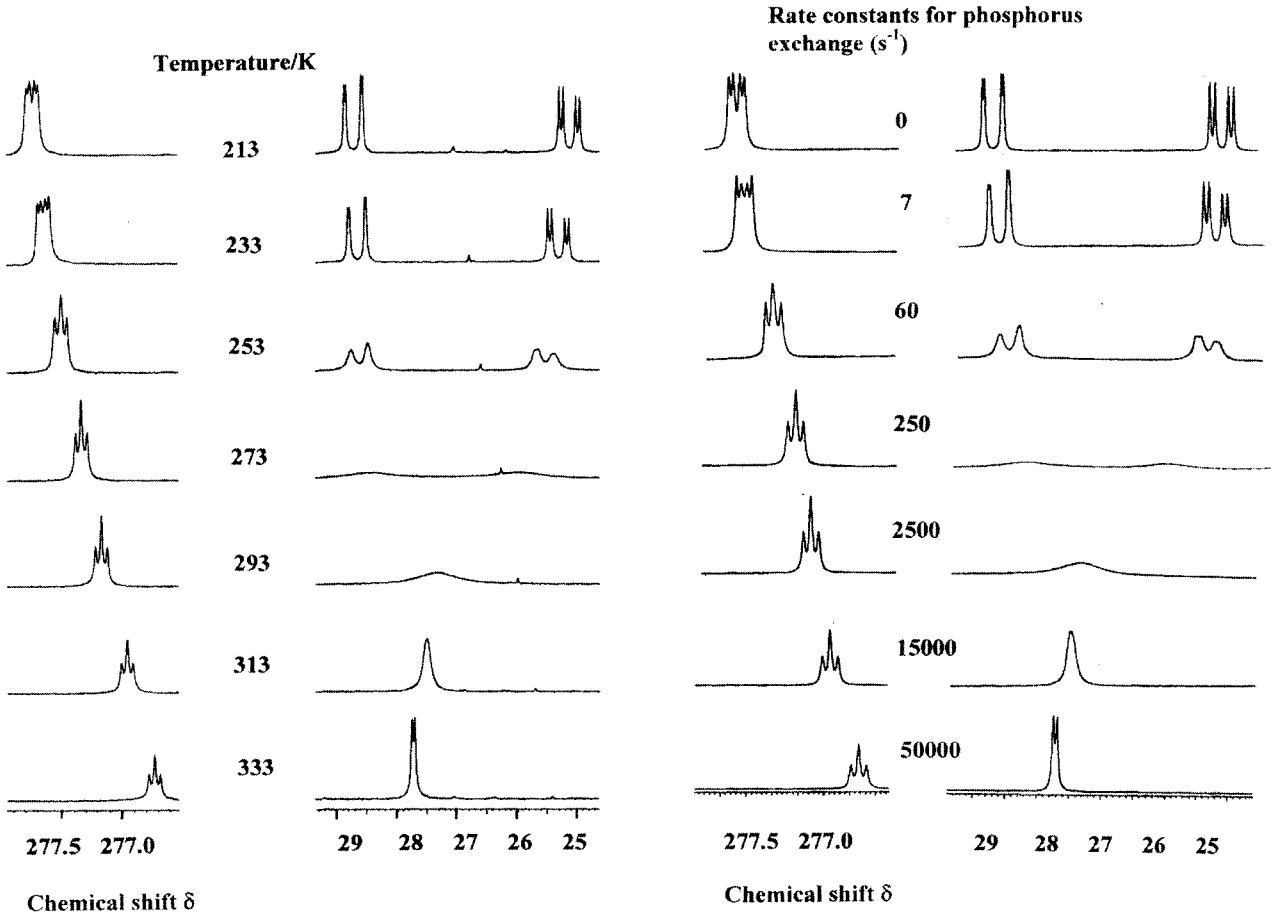

Figure 3. Spectra on left: observed 202.5 MHz $^{31}P\{^1H\}$ NMR spectra of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) in $CDCl_3$ recorded at the various temperatures given. Spectra on right: corresponding $^{31}P\{^1H\}$ NMR spectra of **3** simulated using gNMR at the given rate constants for phosphorus–phosphorus exchange.

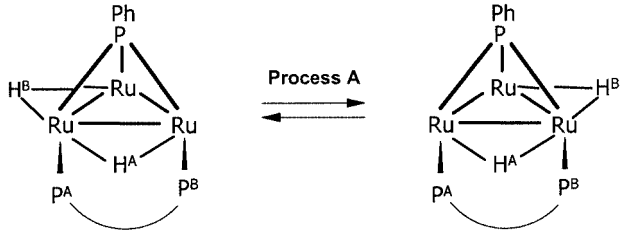
cur as the temperature is raised. The dppm signals broaden and coalesce at about 260 K forming a doublet at 333 K. The phosphinidene converts from a double doublet to a 1:2:1 triplet over the same temperature range. These observations are consistent with the exchange of the phosphorus atoms of the dppm resulting from hydride mobility. This was confirmed by a accurate simulation of the $^{31}P\{^1H\}$ NMR spectra (using gNMR[10]) also shown in Figure 3 which gives the rates used to simulate the spectra. It was also necessary to change the chemical shifts somewhat with temperature to produce an accurate simulation. The simplest intramolecular process to account for the observations is shown in Scheme 2.



Scheme 2.

Process A does not lead to hydride exchange. This wastested by recording the hydride spectrum over a temperature range (Figure 4). The ^1H NMR spectrum for the hydrides of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ at 333 K is a single doublet (with an indication of a small triplet pattern at each branch of the doublet). The crystal structure indicates that the hydrides should be non-equivalent, and at 233 K the hydride spectrum appears as a complex multiplet (at least 10 peaks resolved) (see Figure 4). We were able to model this multiplet satisfactorilly by two overlapping multiplets for the non-equivalent hydride ligands at δ = –18.450 and –18.466 ppm, and the NMR shifts and coupling constants used in these simulations are given in Table 4. By using the data in Table 4 we obtained good agreement between observed and calculated spectra at the low-temperature limit (233 K for ^1H and 213 K for ^{31}P). The overlap of hydride signals made it difficult to follow coalescence. We attempted to simulate the spectra on the basis of various exchange processes. Figure 4 shows spectra predicted by process A in Scheme 2. Clearly the hydrides are not exchanging so two overlapping multiplets are found even at the highest rates. Hydride exchange is required to give the observed high-temperature spectra. Figure 4 show the spec-

tra expected on the basis of the exchange of hydride nuclei alone without any other exchange occurring. A single resonance is obtained but very different from that observed. We also simulated spectra on the basis of process B shown in Scheme 3. The central configuration with a plane of symmetry is not detectably populated at any time and is not observed in the low-temperature spectra. Hence we cannot descriminate process B from one in which there is synchro-

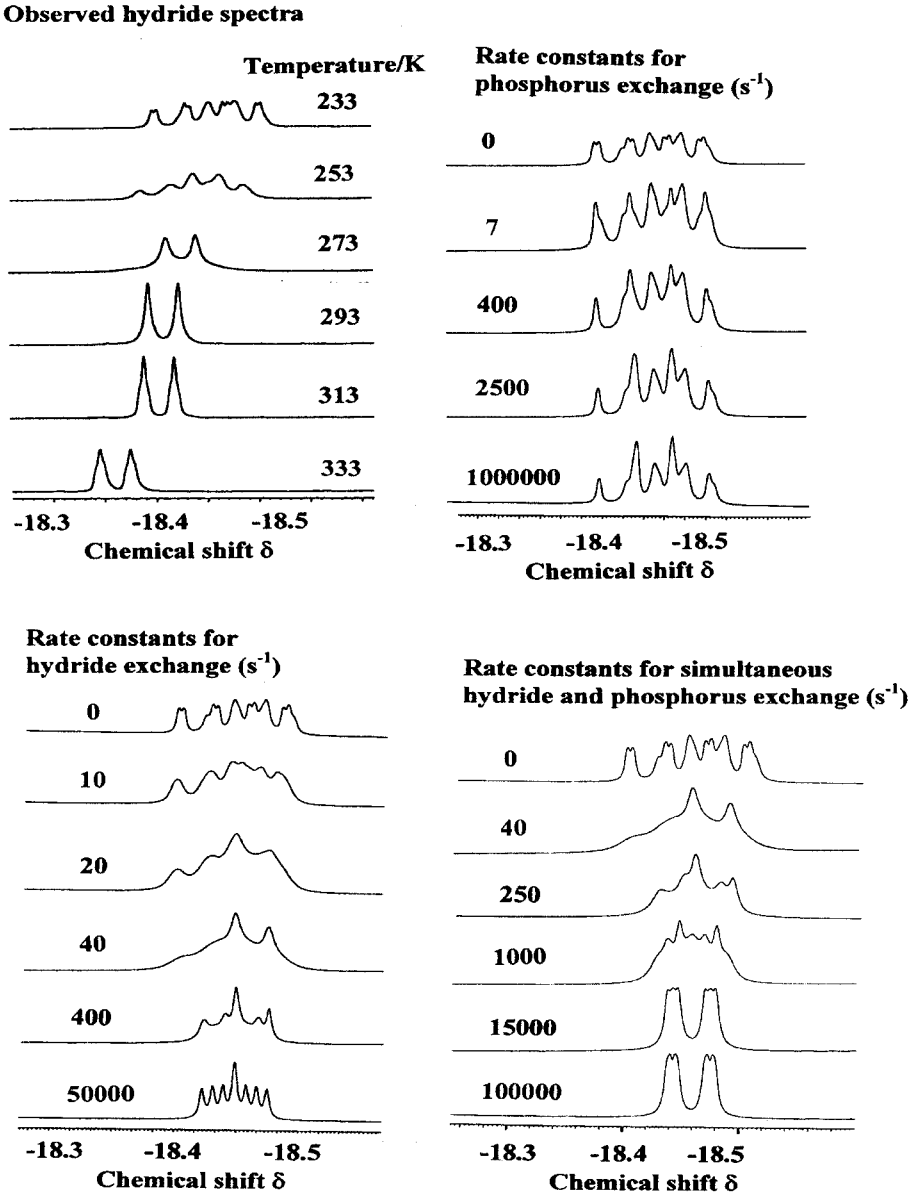

Figure 4. Top left: observed 500 MHz ^{1}H NMR spectra of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) in $CDCl_3$ in the hydride region recorded at various temperatures. Top right: Corresponding spectra of **3** simulated on the basis of exchange of the phosphorus nuclei of the dppm ligand without simultaneous exchange of the hydride ligands. Bottom left: corresponding spectra of **3** simulated on the basis of hydride exchange alone. Bottom right: corresponding spectra of **3** simulated on the basis of exchange of the hydride nuclei and exchange of the phosphorus nuclei both with the rate constants given.

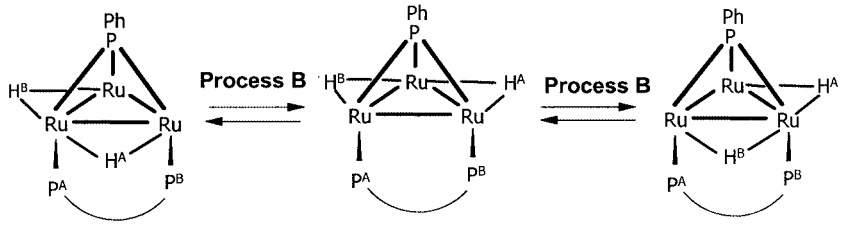

Scheme 3.

nous motion of both hydrides without the intermediate shown in Scheme 3. In this case there would be a transition state with a mirror plane.

In process B (or the modified single-step process described above) there is simultaneous exchange of H^A with H^B and of P^A with P^B, and Figure 4 shows the predicted outcome, again different to observed spectra. Process B does not lead to total exchange because, for example, H^A does not become equally correlated to P^A and to P^B. We have found that it is necessary to apply both processes A and B with different rates to obtain satisfactory correspondence of observed with calculated spectra. Figure 5 shows an excellent match, except that there is some observed drift of chemical shift with temperature which is not accounted for by exchange processes. It is surprising that there is such good correspondence, and we believe that this is because the H^A and H^B signals change chemical shifts in a similar way with changing temperature. A graphical presentation of these rate data is given in Figure 6. Note that the rates of process A obtained from a deconvolution of the two processes observed in the hydride spectra are closely similar to those obtained from the $^{31}P\{^1H\}$ spectra. Process B is about 5 times slower than process A and activation data for process **A** are $\Delta G^{\ddagger}$ = (52.2 ± 3.7) kJ·mol^{-1}, $\Delta H^{\ddagger}$ = (57.1 ± 3.7) kJ·mol^{-1}, $\Delta S^{\ddagger}$ = (16.7 ± 13.7) J·K^{-1}·mol^{-1} while those for process B are $\Delta G^{\ddagger}$ = (56.1 ± 3.0) kJ·mol^{-1}, $\Delta H^{\ddagger}$ = (60.0 ± 3.0) kJ·mol^{-1}, $\Delta S^{\ddagger}$ = (12.9 ± 9.6) J·K^{-1}·mol^{-1} The rate of migration of H^A from the most electron-rich site between the dppm-substituted Ru atoms is slower than migration of H^B which is in a less electron-rich site. However, the difference is very small, largely enthalpic and only represents a difference in $\Delta H^{\ddagger}$ of 2.9 kJ·mol^{-1}. A combination

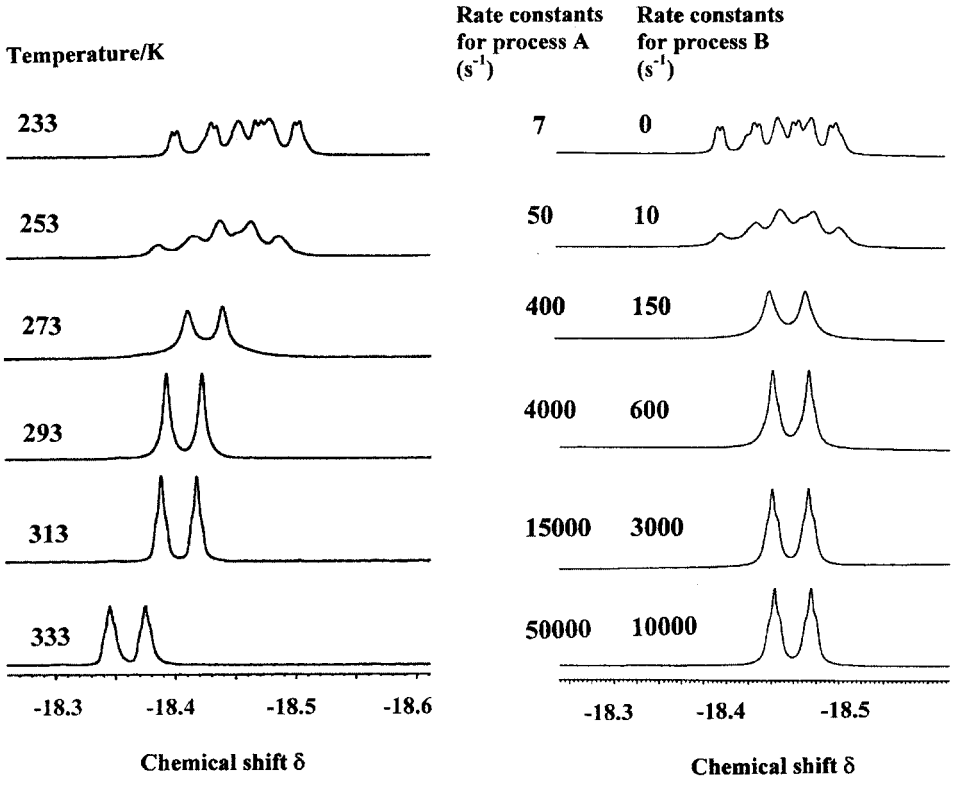

Figure 5. Left: observed 500 MHz ^1H NMR spectra of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) in $CDCl_3$ solution in the hydride region recorded at various temperatures. Scheme 4.

of processes A and B can be represented by Scheme 4. In the cycle each hydride jumps in turn and progresses through the three edges of the metal triangle.

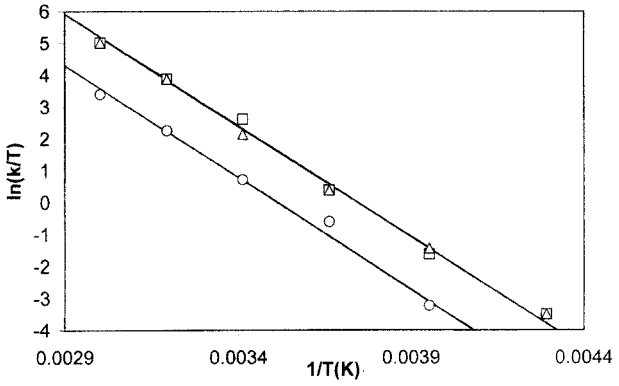

Figure 6. Graph of ln(k/T) for the processes **A** and **B** against (1/T)/K^{-1} for cluster [Ru_3(μ-H)$_2$(μ$_3$-PPh)(CO)$_7$(μ-dppm)] (**3**) in $CDCl_3$ solution. The rate of process **A** were obtained from the exchange of P nuclei observed in the $^{31}P\{^1H\}$ NMR spectrum (points Δ) and from ^1H NMR spectroscopic data (points □). Rates of process **B** were also obtained from ^1H NMR spectroscopic data (points ○).

Experimental Section

The compound [$Ru_3(CO)_{10}$(μ-dppm)] (**1**) was prepared according to the known method.[6] Infrared spectra were recorded with a Shimadzu FTIR 8101 spectrophotometer. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded with a Bruker DPX400 or DRX500 spectrometer.

Reaction of [$Ru_3(CO)_{10}$(μ-dppm)] (1) with $PPhH_2$: A 10% hexane solution of PH_2Ph (0.70 cm^3, 0.636 mmol) was added to a THF solution (35 cm^3) of **1** (0.205 g, 0.212 mmol) in a three-necked round-bottom flask. The reaction mixture was then refluxed for 6 h. The solvent was removed under reduced pressure and the residue was chromatographed by TLC on silica gel. Elution with cyclohexane/CH_2Cl_2 (7:3, v/v) developed two major and several very minor bands. The fastest moving band afforded unreacted **1** (0.005 g) and [Ru_3(μ-H)(μ-PHPh)(CO)$_8$(μ-dppm)] **2** (0.015 g, 7%) after fractional crystallization from hexane/CH_2Cl_2 at –15 °C.

Characterization of 2: $C_{39}H_{29}O_8P_3Ru_3$: calcd. C 45.84, H 2.87; found C 45.79, H 2.95. IR (νCO, CH_2Cl_2): $\tilde{\nu}$ = 2062 s, 2016 m, 1995 vs, 1950 m cm^{-1}. ^1H NMR ($CDCl_3$, 25 °C): δ = 4.26 (t, J = 10.8 Hz, 2 H), 7.35 (m, 26 H), –16.30 (t, J = 28.4 Hz, 1 H). FAB MS showed the parent molcular ion: m/z 1022. The second band yielded [Ru_3(μ-H)$_2$(μ$_3$-PPh)(CO)$_7$(μ-dppm)] (**3**) (0.042 g, 20%) as yellow crystals from hexane/CH_2Cl_2 at room temperature. $C_{38}H_{29}O_7P_3Ru_3$ calcd. C 45.92, H 2.95; found C 45.99, H 2.72. IR (νCO, CH_2Cl_2): $\tilde{\nu}$ = 2054 s, 2031 s, 1994 vs, 1985 sh, 1940 w cm^{-1}. FAB MS showed the parent molecular ion: m/z 994. The minor bands were too small for complete characterization.

Reaction of 1 with $PPhH_2$ in Presence of Me_3NO: To a dichloromethane solution (35 cm^3) of **1** (0.105 g, 0.109 mmol) was added a 10% hexane solution of $PPhH_2$ (0.24 cm^3, 0.218 mmol) followed by a dichloromethane solution (25 cm^3) of Me_3NO (0.017 g, 0.226 mmol). The reaction mixture was stirred at room temperature for 30 min. The solution was filtered through a short silica column, and the volatiles were removed under reduced pressure. Chromatographic separation as above developed one major and several minor bands. The major band gave unreacted **1** (0.010 g) and **2** (0.012 g, 11%) after fractional crystallization from hexane/CH_2Cl_2 at –4 °C. The minor bands were not completely characterized.

Conversion of 2 into 3: A THF solution of **2** (0.012 g, 0.012 mmol) was heated to reflux for 3 h. Removal of solvent under reduced pressure and chromatographic separation of the residue as above afforded **3** (0.007 g, 51%) as yellow crystals.

Synthesis of [Ru_3(μ-H)$_2$(μ$_3$-PPh)(CO)$_9$]: This cluster was prepared by a method modified from that in the literature. The cluster

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$[Ru_3(CO)_{12}]$ (0.252 g) was treated with equimolar PH_2Ph in cyclohexane at 60 °C for 45 min and then at 80 °C for 60 min. The product was separated by TLC on silica to give the product as yellow crystals (0.134 g, 51%) which were characterised by IR, MS, ^1H and ^{31}P NMR and by elemental analysis.

Synthesis of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ from $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$: A standard procedure of preparing an acetonitrile derivative prior to substitution by phosphane was unsuccessful. Thus treatment of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ with $Me_3NO{\cdot}2H_2O$ in dichloromethane and acetonitrile did not form significant amounts of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_{9-x}(MeCN)_x]$, where $x = 1$ or 2. Treatment of the solution formed in this way with tertiary phosphanes did not give simple substitution products. Likewise visible photolysis of dichloromethane solutions of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ in the presence of dppm at room temperature did not lead to any significant reaction. However, direct thermal reaction of $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_9]$ (0.0419 g) with dppm (0.0391 g) in refluxing cyclohexane (50 cm^3) under dinitrogen lead to the yellow solution becoming deep orange after 50 min. IR spectrsocopy indicated that most of the starting material had been consumed. Removal of the solvent under reduced pressure and separation of the residue by TLC [silica; eluent, petroleum ether (b. p. 40–60 °C)/dichloromethane, 3:1 by volume)] gave several bands. The major yellow band yielded $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_7(\mu\text{-}dppm)]$ (**3**) as yellow crystals (0.020 g, 32%), whereas a minor yellow band gave $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(\mu\text{-}dppm)]$ as a yellow solid (0.010 g, 16%). The latter compound has a similar IR spectrum [2072 w, 2047 m, 2038 vs, 2000 s, 1992 m cm^{-1} in cyclohexane] to monophosphane derivatives such as $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(PMe_2Ph)]$[8] [2072 m, 2038 vs, 2003 m, 1989 m, 1973 cm^{-1} in cyclohexane], $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(PH_2Ph)]$[2] [2077 m, 2048 s, 2041 s, 2009 s, 2001 m, 1993 m, 1978 w cm^{-1} in cyclohexane] and $[Ru_3(\mu\text{-}H)_2(\mu_3\text{-}PPh)(CO)_8(PMePh_2)]$.[9] Therefore, we believe the dppm is monodentate but we have not characterised the compound further.

X-Ray Crystal Structure Determinations for Compounds 2 and 3: Single crystals of compounds **2** and **3** were mounted on glass fibers and all geometric and intensity data were obtained with a Bruker SMART APEX CCD diffractometer using graphite-monochromated Mo-K_α radiation ($\lambda = 0.71073$ Å) at 150(2) K (compound **2**) and 293(2) K (compound **3**). Data reduction and integration was carried out with SAINT+ and absorption corrections were applied using the programme SADABS.[11,12] Structures were solved by Patterson synthesis for compound **2** or direct methods for compound **3** and developed using alternating cycles of least-squares refinement and difference-Fourier synthesis. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms, except those bonded to ruthenium, were placed in calculated positions and their thermal parameters linked to those of the atoms to which they were attached (riding model). Hydrogen atoms bridging the ruthenium atoms were located and their positions refined using fixed isotropic thermal parameters. The SHELXTL PLUS V6.10 program package was used for structure solution and refinement.[13] General details: data collection method, ω rotation with narrow frames; absorption correction, semi-empirical from equivalents; refinement method, full-matrix least-squares on F^2.

CCDC-243253 (for **2**) and -243253 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Synthesis and Electrochemical and Spectroscopic Properties of Molybdenum Complexes Bearing 5-Alkoxythiophene or -bithiophene Groups

António M. Fonseca,*[a] Maria Manuela M. Raposo,[a] Ana M. R. C. Sousa,[a] Gilbert Kirsch,[b] and Marc Beley[c]

Keywords: Sulfur heterocycles / Molybdenum / N ligands / Conjugated systems

trans-[MoF{NN=CH(5′-R-thienyl)}(dppe)$_2$][BF_4] (R = OMe and OEt) and *trans*-[MoF{NN=CH(5′-R-2,2′-bithienyl)}-(dppe)$_2$][BF_4] (R = OMe, OEt and O*i*Pr) were synthesised in good yields by treating 5-alkoxy-2-formylthiophenes and 5′-alkoxy-5-formyl-2,2′-bithiophenes, respectively, with the hydrazido(2–) complex *trans*-[MoF(NNH_2)(dppe)$_2$][BF_4]. The electrochemical, spectroscopic and solvatochromic properties of these compounds were studied. These results suggest that efficient π-conjugated systems are obtained due to the low-energy charge-transfer between the metal atom and the heterocyclic moieties.

Introduction

There is considerable interest in the synthesis of new organic and organometallic materials with large second-order optical nonlinearities because of their potential applications in telecommunications, optical computing, optical storage and optical information processing.[1–3]

Structural, redox and photophysical properties can easily be tuned in organometallic compounds. Consequently, they have been explored in the design of materials for nonlinear optical (NLO) applications.[4,5] In this case, for a molecule to be of interest it must present an excited state of similar energy to the ground state, as well as a dipolar moment that is quite different in the ground and excited states.[6,7] These requirements are satisfied in asymmetric conjugated complexes containing electron-acceptor and electron-donor groups connected by a conjugated π system.[8,9] For example, metal complexes based on nitrosylmolybdenum and -tungsten moieties stabilised by tris(3,5-dimethylpyrazolyl)-borate and attached to phenolato or anilido groups are strongly polarised and may therefore be able to act as electron termini of dipolar complexes having second-order NLO properties.[7] Thiophene and bithiophene chromophores exhibit greater β second-order polarisabilities compared to those of biphenyls or stilbenes.[10] Transition metal complexes of the general type *trans*-[MX(NNR)(dppe)$_2$]$^+$ [M = Mo or W; X = halide; dppe = 1,2-bis(diphenylphosphanyl)ethane; R = heterocyclic group] are particularly attractive because the conjugated structure, including the central metal atom and the square-planar {M(dppe)$_2$} assembly, is robust.[11,12]

In this paper we wish to report the synthesis and the electrochemical, spectroscopic and solvatochromic properties of the new electron-donor–π-acceptor systems *trans*-[MoF{NN=CH(thienyl-5′-alkoxy)}(dppe)$_2$][BF_4] **6** and **8** (alkoxy = OMe and OEt, respectively) and *trans*-[MoF{NN=CH(bithienyl-5′-alkoxy)}(dppe)$_2$][BF_4] **7**, **9** and **10** (alkoxy = OMe, OEt and O*i*Pr, respectively). As far as we know, the synthesis and the characterisation of molybdenum complexes bearing 2-alkoxythienyl groups and 2-alkoxybithienyl groups has not been reported previously.

Results and Discussion

Synthesis

As part of our ongoing effort to develop chromophores for nonlinear optical applications,[13–16] we synthesised several donor–acceptor 5,5′-disubstituted 2,2′-bithiophenes[13] by functionalisation of the corresponding 5-alkoxybithiophenes.[17] We have recently reported the synthesis of the 5′-alkoxy-5-formyl-2,2′-bithiophene derivatives **2**, **4** and **5** (alkoxy = OMe, OEt and O*i*Pr, respectively), which made these compounds available in reasonable amounts.[13] Indeed, we were able to use these compounds successfully as substrates for the synthesis of the molybdenum complexes. The versatile method to form carbon–nitrogen bonds involves the initial conversion of *trans*-[Mo(N_2)$_2$-

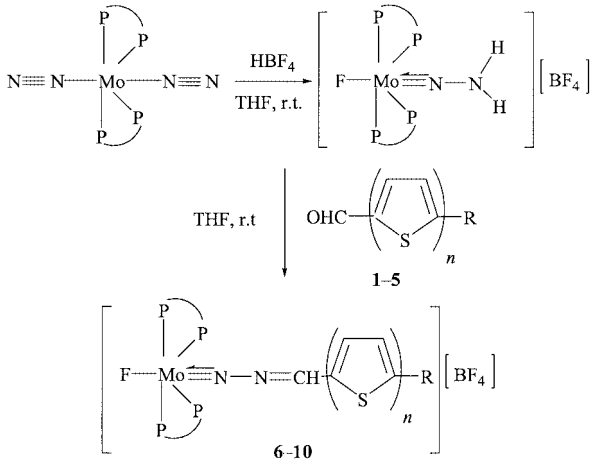
$(dppe)_2$] into the hydrazido(2–) complex *trans*-$[MoF(NNH_2)(dppe)_2][BF_4]$, which then undergoes an electrophilic attack at the terminal nitrogen atom. It can therefore be used as a key intermediate in the preparation of organonitrogen complexes by subsequent reactions with organic carbonyl compounds.[18] Condensation with 5-alkoxy-2-formylthiophene [alkoxy = OMe (**1**) or OEt (**3**)] or 5′-alkoxy-5-formyl-2,2′-bithiophene [alkoxy = OMe (**2**), OEt (**4**) or O*i*Pr (**5**)] gave the molybdenum complexes **6**–**10** bearing the alkoxythiophenic or alkoxybithiophenic group, respectively, in good yields (65–78%; Scheme 1).



R	*n*	Thiophenic or bithiophenic group	Complex	Yield [%]
OMe	1	**1**	**6**	73
OMe	2	**2**	**7**	77
OEt	1	**3**	**8**	67
OEt	2	**4**	**9**	78
O*i*Pr	2	**5**	**10**	65

Scheme 1.

The structures of these complexes were confirmed by the usual spectroscopic methods. Each diazenido [hydrazido-(–2)] complex shows a characteristic band in the 1515–1550 cm^{-1} region of its FTIR spectrum that can be assigned to ν(C=N).[19] Their *trans* stereochemistry was confirmed by the $^{31}P\{^1H\}$NMR spectra, which show a single resonance.

Electrochemistry

Electrochemical data for compounds **1**–**5** are summarised in Table 1. Cyclic voltammetry shows an irreversible single-electron oxidation process (E_{pa}) which can be attributed to the formation of the radical cation of the heterocyclic part. As the HOMO levels in the heterocyclic part increase with the donor effect of the alkoxy groups along the series OMe < OEt < O*i*Pr, the ease of oxidation increases gradually. The oxidation processes of the bithienyl groups are systematically shifted to less positive potentials than those of the thienyl groups. This fact can be explained by the stabilisation of the cation radical due to its higher delocalisation on the bithienyl moiety. At low potentials (< –2 V vs. fc/fc^+) these compounds exhibit one irreversible single-electron process ($-E_{pr}$), which generates a radical anion. The electron goes into a π*-antibonding orbital of the heterocycle. This electron injection occurs at more negative potentials as the alkoxy group is an electron donor and its delocalisation on the heterocyclic part is difficult.

Electrochemical data for complexes **6**–**10** are collected in Table 2. A typical cyclic voltammogram of *trans*-$[MoF\{NN{=}CH(5'\text{-OEt-}2,2'\text{-bithienyl})\}(dppe)_2][BF_4]$ (**9**) in DMF/0.1 M $[Bu_4N][BF_4]$ at a vitreous carbon electrode is shown in Figure 1. The molybdenum complexes show three single-electron oxidation processes. The first ($E_{a1/2}$) and second processes (E_{pa1}) are reversible and irreversible, respectively, and correspond to the Mo^{IV}/Mo^{V} and Mo^{V}/Mo^{VI} waves. Controlled potential coulometry of the first oxidation step confirms a single-electron process. The resulting solution displays a cyclic voltammetric profile that resembles the original one. The parent complex *trans*-$[MoF(NNH_2)(dppe)_2][BF_4]$ has only one irreversible wave at 0.34 V vs. fc^+/fc. A comparison of the values obtained for **6**–**10** with that of the parent complex shows that the donor effect of the alkoxy substituent stabilises Mo^{V} completely and Mo^{VI} partially. However, the oxidation potentials of compounds **7** and **9**, which have a bithiophenic link, are slightly higher (40 mV) than those of **6** and **8,** which bear a thiophenic link. This fact can be explained by metal-to-heterocycle π*-orbital back-donation via the hydrazido ligand. This back-donation increases in the case of a bithiophenic link, which contributes to the stabilisation of the metal-centred HOMO orbital. In both cases this suggests a

π-conjugated system between the metal acceptor group and the alkoxythiophene and -bithiophene moieties. In complexes **6**–**10** the oxidation potentials (E_{pa2}) of the heterocyclic parts are not significantly modified in comparison with those of the corresponding compounds **1**–**5**. The reduction of the complexes occurs in a quasi-reversible one-electron process ($-E_{c1/2}$, ΔE_p = 200 mV). For **7**, **9** and **10**, with a bithiophenic linker, the reduction potentials are shifted to higher values than for **6** and **8**. The corresponding stabilisation of the LUMO (π*) ligand orbital does not correspond to an electron-donor effect of this link, but to a better delocalisation of the injected electron into the ligand on the bithiophene moiety via the imino bridge.

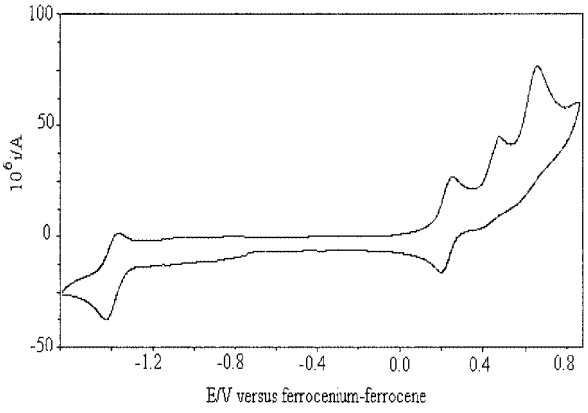

Figure 1. Cyclic voltammogram of *trans*-[MoF{NN=CH(5′-OEt-2,2′-bithienyl)}(dppe)$_2$][BF_4] (**9**) in DMF/0.1 M $[Bu_4N][BF_4]$ at a vitreous carbon electrode (area = 0.049 cm^2). Scan rate: 100 mV s^{-1}; concentration of complex: 2.3 mM.

UV/Vis and Solvatochromic Studies

The UV/Vis spectroscopic data for heterocycles **1**–**5** are presented in Table 1. The electronic absorption spectra show an absorption band in the near-UV region due to the π–π* transitions in the heterocyclic parts. The bithienyl groups show red-shifted absorption maxima relative to the thienyl groups. This is due to better delocalisation of the excited electron in the π*-orbital, which causes its stabilisation. Moreover, the position of these bands is influenced by the donor effect of the alkoxy group, which lowers the energy gap.

The UV/Vis spectroscopic data for complexes **6**–**10** are summarised in Table 2. The parent complex *trans*-[MoF(NNH_2)(dppe)$_2$][BF_4] shows a broad band at around 275 nm corresponding to a transition in the dppe ligand. Complexes **6**–**10**, which bear heterocyclic groups, show an absorption band in the visible region because the molybdenum part lowers the energies of the transition in the heterocycle. For example, the absorption maximum of **1**, which appears at 310 nm, is red-shifted to 469 nm for complex **6**. The intramolecular charge-transfer process, which originates in the Mo part and is propagated through the π-conjugated spacer ligand [hydrazido(2–)], gives rise to a considerable bathochromic shift of the alkoxythiophenic and -bithiophenic transitions (Figure 2). For these complexes, the alkoxy group effect and the better delocalisation in the bithienyl groups induce modifications of their electronic spectra similar to those described for compounds **1**–**5**. The influence of the incorporation of thiophene moieties in push-pull compounds on the charge-transfer properties has been described previously.[20]

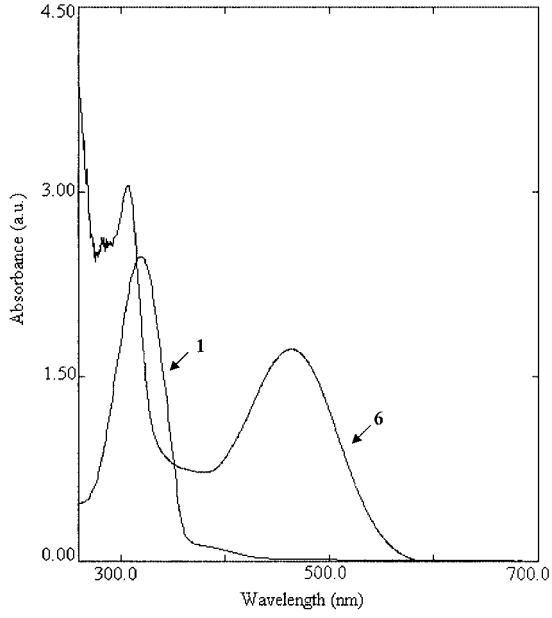

Figure 2. UV/Vis spectra of 2-formyl-5-methoxythiophene (**1**) and *trans*-[MoF{NN=CH(5′-methoxythienyl)}(dppe)$_2$][BF_4] (**6**) in acetonitrile, demonstrating the effect of the Mo part on the absorption maxima between 300 and 700 nm.

Table 3. Solvatochromic data (λ_{max} [nm] and $\tilde{\nu}_0$ [cm^{-1}] of the charge-transfer band) for complexes **6**–**10** in selected solvents in comparison with the π* values of Kamlet and Taft.[24]

Complex	Solvent (π*) THF (0.58) λ_{max}, $\tilde{\nu}_0$	Acetone (0.71) λ_{max}, $\tilde{\nu}_0$	Acetonitrile (0.75) λ_{max}, $\tilde{\nu}_0$	CH_2Cl_2 (0.82) λ_{max}, $\tilde{\nu}_0$	DMSO (0.88) λ_{max}, $\tilde{\nu}_0$
6	466, 21459	468, 21413	469, 21322	471, 21231	474, 21097
7	479, 20877	481, 20790	482, 20747	485, 20619	488, 20492
8	479, 20877	482, 20747	484, 20661	487, 20534	490, 20408
9	493, 20284	495, 20202	497, 20121	501, 19960	505, 19802
10	491, 20366	494, 20243	496, 20161	499, 20040	502, 19920

In general, the stronger the donor and/or acceptor group, the smaller the energy difference between the ground and excited states and the longer the wavelength of the absorption. According to Zyss,[21] the increase in the β-values characteristic of the NLO effects is accompanied by an increase of λ_{max} in the UV/Vis spectra.

Solvatochromism is easily quantified by UV/Vis spectroscopy and is particularly suitable for the empirical determination of the polarity of a solvent[22,23] on a molecular-microscopic level. To evaluate the intermolecular forces between the solvents and the solute molecules we recorded absorption spectra of all complexes in five polar solvents of different solvation character (Table 3). Due to the insolubility of complexes **6**–**10** in apolar solvents the solvatochromic study of these compounds was only performed in polar solvents such as tetrahydrofuran, acetone, acetonitrile, dichloromethane and dimethyl sulfoxide. The electronic excitations are governed by a positive solvatochromism with increasing solvent polarity, indicating dipole changes within the ground excited state.

Good correlation with the π* parameters defined by Kamlet and Taft[24] was obtained. Table 4 summarises the results of the linear regression analyses of absorption maxima for complexes **6**–**10**. The most important values of the linear relationship between absorption maxima and π* are the correlation coefficient, *r*, and the slope, *s*, which describes the extent of solvatochromism from π* = 0.58 (tetrahydrofuran) to π* = 1.00 (DMSO). As shown in Table 4, the greatest value for *s* is found for complex **9**. The change in dipole moment on electronic excitation is shown to be oriented parallel to the transition dipole and is, moreover, constant over the whole charge-transfer band.

Table 4. Correlation of the UV/Vis absorption maxima of complexes **6**–**10** and the solvent parameter π*.[a]

Conclusions

We have described the synthesis and characterisation of molybdenum complexes connected via a hydrazido(2–) bridge to alkoxythiophenic or alkoxybithiophenic groups. Their electrochemical, spectroscopic and solvatochromic behaviours exhibit an intramolecular charge-transfer effect. These new complexes are promising candidates for developing novel NLO materials.

Experimental Section

General: All reactions were carried out under nitrogen or argon using standard Schlenk techniques. Solvents were freshly distilled from appropriate drying agents under dinitrogen. The syntheses of 5′-alkoxy-5-formyl-2,2′-bithiophenes[13] and complexes *trans*-$[Mo(N_2)(dppe)_2]$ and *trans*-$[MoF(NNH_2)(dppe)_2]$[17] have already been described. The NMR spectra were obtained with a Varian Unity Plus Spectrometer at 300 MHz using the solvent peak as internal reference. Infrared spectra were recorded with a Perkin–Elmer 1600 FTIR spectrophotometer. UV/Vis absorption spectra were obtained with a Shimadzu UV/2501PC spectrophotometer. High-resolution mass spectra (HRMS) were obtained with a GV AutoSpec spectrometer with *m*-nitrobenzyl alcohol (NBA) as matrix. Elemental analyses were performed with a Leco CHNS-932 analyser. Voltammetric measurements were performed with a potentiostat/galvanostat (AUTOLAB /PSTAT 12 with low current module ECD from ECO-CHEMIE) and the data processed with the General Purpose Electrochemical System software package (ECO-CHEMIE). Three-electrode two-compartment cells equipped with vitreous carbon-disc working electrodes, a platinum-wire secondary electrode and a silver-wire pseudo-reference electrode were employed for cyclic voltammetric measurements. The ferrocenium-ferrocene redox couple was used as a secondary internal reference. The concentrations of the compounds were typically 1–2 mM, and 0.2 M $[Bu_4N][BF_4]$ was used as the supporting electrolyte in *N*,*N*-dimethylformamide solvent. The potential was measured with respect to ferrocinium/ferrocene as an internal standard. Controlled-potential electrolyses were carried out in an H-type cell with a vitreous carbon working electrode as described previously.[12]

General Procedure for the Preparation of Complexes 6–10: The complex *trans*-$[MoF(NNH_2)(dppe)_2][BF_4]$ (0.2 g, 0.19 mmol) was dis-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

solved in THF (20 mL) at room temperature. Formyl ligands **1**–**5** (0.40 mmol) were added in excess to the solution, which was stirred for 28 h. The volume of the solution was then reduced to about 5 mL and the precipitates were filtered off. These solids were dissolved in CH_2Cl_2 and filtered through a pad of Celite. The solutions were concentrated to dryness and the solids obtained washed with cold THF (3×5 mL), then Et_2O (2×3 mL), and dried in vacuo to give complexes **6**–**10** as coloured solids. In all cases, the solids thus obtained were crystallised from CH_2Cl_2/Et_2O.

A Facile and Controllable Synthesis of γ-Al_2O_3 Nanostructures without a Surfactant

Bo Tang*[a] Jiechao Ge,[a] Linhai Zhuo,[a] Guangli Wang,[a] Jinye Niu,[a] Zhiqiang Shi,[a] and Yubin Dong[a]

Keywords: γ-Alumina / Materials science / Nanostructures / Solvothermal synthesis

Boehmite [AlOOH] nanoneedles, nanorods, and nanotubes were successfully synthesized by a facile sol-hydrothermal method without using any surfactant. Calcination of the corresponding boehmite nanostructures at 700 °C gave the corresponding γ-Al_2O_3 nanoneedles, nanorods, and nanotubes. The resulting products were characterized by XRD, TEM, HRTEM, and FT-IR spectroscopy. We found that the conditions used to produce the sol and the pH value of the hydrothermal process have important effects on the nucleation and growth of nanostructured materials.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

Developing a controllable synthesis process is always one of the most important goals of materials scientists. Because of their application in adsorbents, catalysts, and catalyst supports, the synthesis of alumina nanostructured materials, especially one-dimensional (1D) nanostructures, has received considerable interest due to their novel properties, such as high elastic modulus, thermal and chemical stability, and optical characteristics.[1] However, the synthesis of these nanostructures is still a challenge owing to their extremely small size and their anisotropy. The control of nucleation and growth of nanostructured materials is therefore becoming crucial.

So far, materials scientists have succeeded in preparing various morphologies of boehmite [AlOOH] and Al_2O_3, such as nanowires,[2] nanotubes,[3] nanobelts,[2a] nanofibers,[4] nanorods,[5] and whiskers[6] by different methods. The hydrothermal synthesis of fibrillar boehmite was originally studied by Bugosh[7] and further developed by a number of researchers.[8] In particular, a surfactant-assisted hydrothermal method has been developed to synthesize 1D boehmite and γ-Al_2O_3 nanostructures in recent years.[9] However, the preparation of semiconducting oxide nanobelts,[10] MnO_2 nanowires,[11] TiO_2 nanotubes,[12] $La(OH)_3$ nanorods,[13] $Cd(OH)_2$ nanowires,[14] and CeO_2 nanowires[15] has shown that a 1D nanostructure can be prepared under properly controlled conditions, even without the presence of surfactants. This means that the formation of a 1D nanostructure is thermodynamically preferable for many substances under certain conditions. Herein, we report a facile and controllable sol-hydrothermal method for direct growth of three kinds of nanostructures of as-prepared boehmite and γ-Al_2O_3. The salient feature of this procedure is the convenient control of the morphologies, as the nucleation process of boehmite is easily tuned by the manner of adding the starting materials while the growth of the formed nucleus is adjusted by the pH value of the hydrothermal system. The subsequent calcinations do not change the shape of the synthesized boehmite, and therefore γ-Al_2O_3 with different morphologies of nanoneedles, nanorods, and nanotubes were obtained. This route is simple and controllable.

Results and Discussion

The crystalline phases were identified by X-ray diffraction (XRD). Representative XRD patterns of as-prepared and calcined samples are shown in Figure 1, parts A and B, respectively. All the diffraction peaks in Figure 1 (A) can be perfectly indexed to the data available in the JCPDS21-1307 powder diffraction file, thus indicating that all the samples contain only a boehmite crystalline phase. However, the samples prepared under different conditions exhibit XRD traces that differ from each other in relative peak intensities. We assumed that the relative intensities of the peaks are related to the changes in boehmite crystallization, which affects the degree of preferred orientation and, as a result, a change in the crystalline order of a sample could result in the change of the corresponding peak intensity if the crystal is perfect. The as-prepared samples were calcined at 700 °C, as previously reported.[16] The XRD patterns of the products are shown in Figure 1 (B), in which all the diffraction peaks can be indexed to the γ-Al_2O_3 phase (JCPDS29-63). The XRD patterns indicate that the nanostructures obtained by our methods consist of pure phases. Similarly, the relative intensities of the peaks corresponding to different

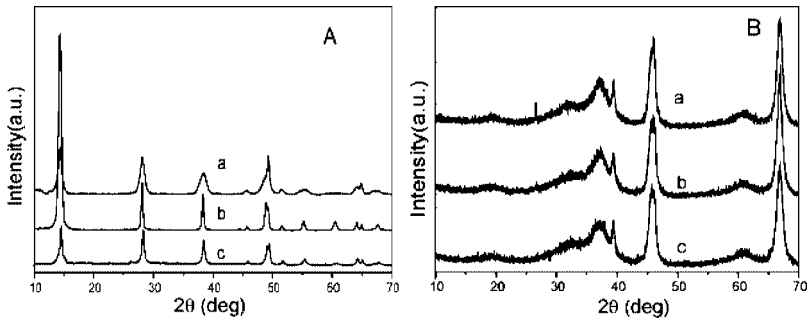

Figure 1. X-ray diffraction patterns for (A) as-prepared samples and (B) calcined samples: (a) nanoneedles, (b) nanorods, (c) nanotubes.

crystallizations of γ-Al_2O_3 are quite different, indicating that the degrees of crystallinity are different for the different nanostructures.

The morphologies and structures of the products were examined by transmission electron microscopy (TEM). As shown in Figure 2, three as-prepared products obtained by different synthetic routes display quite different morphologies, although the calcined samples exhibit almost the same morphologies as their precursors. Figure 2 (A, B) shows a needlelike shape and similar sizes, with a width of about 6 nm and a length of around 50 nm. It should be noted that when ammonia was added at room temperature during step (2), the morphology of the boehmite precursor of sample 2 changed from a needlelike shape to rodlike (Figure 2, C). These nanorods are straight, with uniform diameters of about 40 nm and lengths up to 800 nm. The cross-sectional dimensions of the calcined nanorods (sample 2) are slightly wider than the precursor (Figure 2, D). A representative HRTEM image of a nanorod (Figure 2, G) shows clear fringes, indicating that these nanorods are perfectly crystalline. Figure 2 (E) shows TEM images of the as-prepared boehmite nanotubes (precursor of sample 3). The nanotubes are typically about 40–60 nm in length with an outer diameter of around 5 nm. For the γ-Al_2O_3 nanotubes (sample 3) obtained by calcination of an as-prepared boehmite precursor (Figure 2, F), the outer diameter of the nanotubes is about 5–6 nm and the inner diameter is around 3–4 nm. The obtained nanotubes are thus characterized by their small inner diameter and thin inorganic wall, in contrast to other metal oxide nanotubes reported to date. An HRTEM image and the selected-area electron diffraction (SAED) pattern of the as-prepared nanotube are shown in Figure 2 (H), which reveals that the product is highly crystalline. According to the above XRD results, the boehmite nanostructures are converted into γ-Al_2O_3 nanostructures after calcination. It is well known that γ-Al_2O_3 is most commonly used as a high-temperature catalyst support and as a membrane due to its high surface area and mesoporous properties.[17] Therefore, the obtained γ-alumina nanostructures are expected to exhibit excellent catalytic properties.

In our synthetic system, there are three main reactions:

$$Al^{3+} + 3\,NH_3{\cdot}H_2O \rightarrow Al(OH)_3 + 3\,NH_4^+ \quad (1)$$

$$Al(OH)_3 \rightarrow AlOOH + H_2O \quad (2)$$

$$2\,AlOOH \rightarrow Al_2O_3 + H_2O \quad (3)$$

The formation of boehmite nanostructures indicates that nucleation and growth are well controlled. The manner of adding the precipitator and the pH value of the hydrothermal system play important roles in controlling the nucleation and growth of the boehmite nanostructures. In the first reaction, different conditions can lead to different morphologies of the crystal nucleus. At low temperatures, the particles form a smaller crystal nucleus faster, whereas at

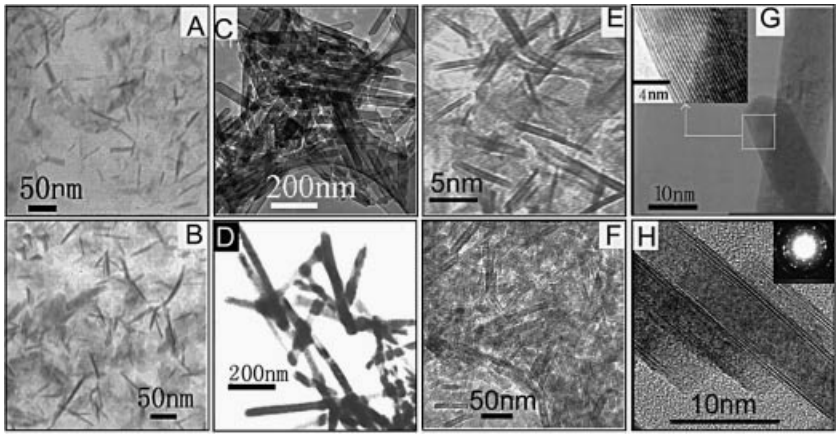

Figure 2. TEM images of the boehmite [AlOOH] samples (A, C, and E) and the corresponding γ-Al_2O_3 samples (B, D, and F): (A, B) nanoneedles, (C, D) nanorods, (E, F) nanotubes; (G) HRTEM images of γ-Al_2O_3 nanorods; (H) HRTEM images of AlOOH nanotubes.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

high temperatures the reverse is the case. We suppose that more homogeneous boehmite nanostructures are formed finally in the hydrothermal process by reaction (2). In the hydrothermal system with a pH value of around 6–7, boehmite possesses a cubic crystal structure exhibiting anisotropic growth, which makes it have the tendency to grow along a certain direction quickly. Finally, the bigger crystal nucleus forms rod-like structures whereas the smaller crystal nucleus forms needle-like structures. For the formation of nanotubes, the pH values in reactions (1) and (2) are thought to be crucial. These crystal nuclei obtained in a basic environment have different morphologies for samples 1 and 2. In reaction (2), it is reasonable to suggest that *n*-butylamine acts as a structure-directing-template in the formation of nanotubes owing to its amphiphilic nature. As reported previously,[9d] these different nuclei may grow into platelet-like ones, then curve into tubes. In reaction (3), the γ-alumina is formed upon dehydration of the boehmite after calcination at 700 °C. The internal water is lost in this process (from AlOOH to Al_2O_3), while the morphologies are maintained.

Figure 3 show the characteristic IR absorption spectra for three kinds of samples in the wavenumber range from 400 to 1000 cm^{-1}, which is the characteristic region for nano-Al_2O_3 powders.[18] Although the IR spectra of all samples exhibit double peaks, they have distinct differences. Comparing the spectra of samples 1–3, for instance, it can be seen that the characteristic infrared absorption peaks of the nanoneedles, nanotubes, and nanorods are at 750.32, 608.62, and 744.87 cm^{-1}, respectively, and are blue-shifted with a decrease in sample size. In accordance with the literature,[19] however, the changes in the infrared absorption spectra of nanomaterials may actually be due to different vibrations.

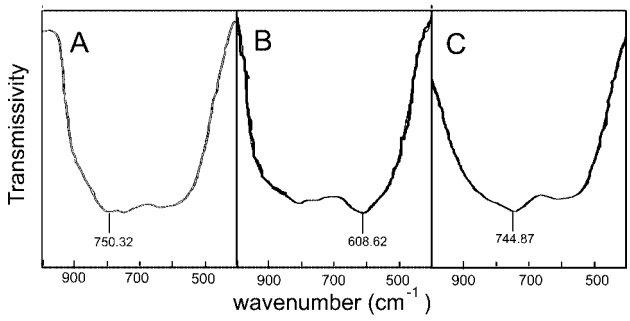

Figure 3. IR absorption spectra for three kinds of samples (A: nanoneedles; B: nanorods; C: nanotubes).

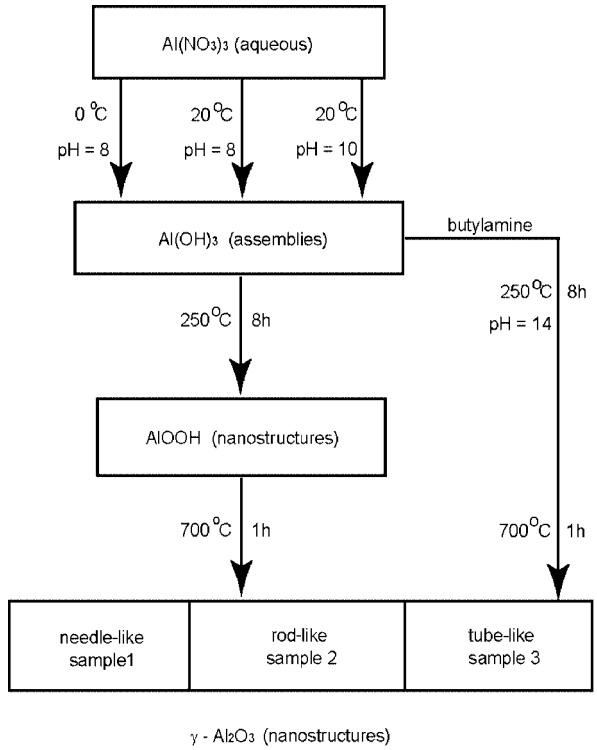
Conclusions

In summary, a facile and controllable hydrothermal synthesis method has been developed to synthesize three kinds of γ-Al_2O_3 nanomaterials without using any surfactant. These samples of nanoneedles, nanorods, and nanotubes exhibit relatively homogeneous sizes and regular morphologies, are were characterized by XRD, TEM, HRTEM, and FT IR spectroscopy.

Experimental Section

Synthesis: In a typical synthesis process there are four main steps: (1) 0.002 mol of $Al(NO_3)_3 \cdot 9H_2O$ was dissolved in 20 mL of distilled water; (2) 60 mL of 0.3 M $NH_3 \cdot H_2O$ was added to the above solution at 0 °C with vigorous stirring until the pH was around 8. This produced a transparent sol of $Al(OH)_3$. The mixture was centrifuged and washed until the pH was 6–7; (3) the obtained precipitate was redispersed in 16 mL of distilled water and then transferred into a 20-mL, Teflon-lined, stainless steel autoclave, which was sealed and maintained at 250 °C for 8 h. The resultant gels were vacuum-filtered in a Buchner funnel and washed with distilled water. The white product was dried at 60 °C for 4 h; (4) part of the product was heated at a heating rate of 3 °C min^{-1} up to 700 °C for 1 h to get sample 1 (nanoneedles). For the preparation of sample 2 (nanorods), the procedure was similar to that of sample 1 except that the ammonia was added quickly to the aqueous $Al(NO_3)_3$ solution at room temperature in step (2). To obtain sample 3 (nanotubes), the pH values of the neutral hydrothermal system and the transparent sol of $Al(OH)_3$ were adjusted to 14, with *n*-butylamine, and 10, with ammonia, respectively. The other steps were the same as for sample 1. This controllable synthetic route is shown in Scheme 1.



Scheme 1. Synthesis route of the γ-Al_2O_3 nanostructures.

Sample Characterization: The XRD patterns were recorded on a rigaku Dmax-rB X-ray diffractometer using Cu-K_α radiation (λ = 1.54178 Å) at a scanning rate of 0.02° s^{-1} in the 2θ range 10–70°. Transmission electron microscopy (TEM) analysis was conducted on a model Hitachi H-800 TEM with an accelerating voltage of 200 kV. The electron diffraction (ED) patterns and high-resolution transmission electron microscopy (HRTEM) images were recorded on a JEOL-2010 TEM at an acceleration voltage of 200 kV. FT IR spectra of the samples were recorded with a Tensor 27 (Bruker) FTIR spectrometer. Specimens for the measurements were prepared by mixing 2 mg of the sample with 100 mg of KBr and press-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ing the mixture into pellets. The spectra were acquired in a wavenumber range between 400 and 1000 at 2 cm^{-1} resolution and averaged over 30 scans.

Cationic Silver Coordination Compounds of Polydentate Ligands: Supramolecular Structures of $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ and $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ {$Pz^{bp2}Py$ = 2-[3,5-Bis(4-butoxyphenyl)pyrazol-1-yl]pyridine}

M. Luz Gallego,[a] Mercedes Cano,*[a] José A. Campo,[a] José V. Heras,[a] Elena Pinilla,[a,b] M. Rosario Torres,[b] Pilar Cornago,[c] and Rosa M. Claramunt*[c]

Keywords: N ligands / NMR spectroscopy / Silver / Supramolecular chemistry

The new silver complexes $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$, $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$, $[Ag(Pz^{bp}Py)_2(OSO_2CF_3)]$, $[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ and $[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ (**5**–**9**) have been obtained by reaction of $Ag(OSO_2CF_3)$ with the corresponding polydentate ligand 2-[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp2}Py$, **1**), 2-[3-(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp}Py$, **2**), 2,4,6-tris[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp2}Tz$, **3**) and 2,4,6-tris[3-(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp}Tz$, **4**), respectively. The coordination effects induced on the ^1H, ^{13}C and ^{15}N NMR chemical shifts of the complexes in solution and in the solid state have been quantified, with the ^{15}N NMR spectra being used as a tool to establish the coordination site. All complexes are consistent with an *N*,*N*′-chelating coordination at each silver centre involving nitrogen atoms from pyrazole and pyridine groups for **5** and **7** or from pyrazole and triazine groups for **8** and **9**. An additional Ag···OSO_2CF_3 interaction completes the environment around the silver atom, giving rise to a five-coordination or a three-coordination for complexes **5** and **7** and **8** and **9**, respectively. The X-ray structures of **5** and **6** confirm the presence of the *N*,*N*′-chelating coordination of the $Pz^{bp2}Py$ ligands and the coordinative participation of the CF_3SO_3 counterion in the metal environment. The Ag···η^2-arene bonds between neighbouring units in **6** are responsible for the dimers containing four-coordinate silver atoms. At a supramolecular level, Ag···O, C–H···O or C–H···F interactions generate a 2D network in both compounds.

Introduction

Cationic silver(I) coordination compounds containing N-donor ligands have extensively been described as producing supramolecular arrays of different dimensionality in the solid, this fact being related with the coordinative versatility of the silver atom to adopt several coordination numbers and with the variety of N-donor ligands and counterions.[1,2]

In previous papers we began to study the molecular assemblies produced by silver or gold coordination to substituted pyrazole ligands (HPz^{R2}). The cationic coordination compounds containing monodentate HPz^{R2} ligands [HPz^{R2} = 3,5-bis(butoxyphenyl)pyrazole (HPz^{bp2}), 3,5-dimethyl-4-nitropyrazole (HPz^{NO_2})] were bonded to their respective counterions, NO_3^-, BF_4^- or $CF_3SO_3^-$, giving rise to 1D, 2D and 3D networks through hydrogen-bonding interactions between the counterion and the cationic fragment. Hydrogen bonds involving the H-atom of the pyrazole ligand and some other non-classical hydrogen-bonding interactions were responsible for the networks of different dimensionality.[3–5]

On this basis, we thought that related polydentate ligands based on the pyridine or triazine cores and pyrazole groups as substituents (in which the NH is absent) should be candidates for supramolecular arrays of metallic complexes centred on coordinative bonds or coordinative interactions. There are several examples described in the literature of supramolecular networks based on a silver centre and different types of N-donor ligands.[1,6]

We present here our studies of new silver complexes containing the polydentate ligands 2-[3,5-bis(4-butoxyphenyl)-pyrazol-1-yl]pyridine ($Pz^{bp2}Py$, **1**), 2-[3-(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp}Py$, **2**), 2,4,6-tris[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp2}Tz$, **3**) and 2,4,6-tris[3-(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp}Tz$, **4**; Scheme 1). The silver compounds **5**–**9** were obtained by treatment of $Ag(OSO_2CF_3)$ with the respective polydentate ligand. These new complexes exhibit variable environments around the metal centre in which the nitrogen atoms of the

polydentate PzPy and PzTz units and the oxygen atoms from the counterion $CF_3SO_3^-$ are involved. In particular, an additional Ag···η^2-arene interaction is also established for **6** (Scheme 2). The structures of the complexes are supported by multinuclear magnetic resonance studies and, in the cases of **5** and **6**, by X-ray crystallography. Formation of one- and multidimensional networks through the interconnection of metallic centres by the inorganic $CF_3SO_3^-$ anion, as well as coordinative Ag···O and Ag···η^2-arene and other non-coordinative C–H···F, C–H···O, or π···π interactions, will be discussed.

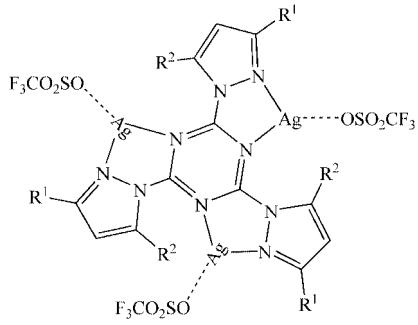
Results and Discussion

Syntheses of Ligands and Silver(I) Complexes

The synthesis of 2-[3-(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp}Py$, **2**) and 2,4,6-tris[3-(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp}Tz$, **4**) was achieved by reaction of the sodium salt of 3-(4-butoxyphenyl)propane-1,3-dione with hydrazinopyridine and the sodium salt of 3-(4-butoxyphenyl)pyrazole with 2,4,6-trichlorotriazine, respectively, by similar procedures to those of the related compounds 2-[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp2}Py$, **1**) and 2,4,6-tris[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp2}Tz$, **3**) previously described by us.[4,7]

Silver complexes **5**–**9** were obtained by combining the inorganic salt $Ag(OSO_2CF_3)$ with ligands **1**–**4** in different stoichiometries, giving rise to monometallic $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (**5**) and $[Ag(Pz^{bp}Py)_2(OSO_2CF_3)]$ (**7**) (from 1:2), dimetallic $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ (**6**) (from 1:1) or trimetallic $[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ (**8**) and $[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ (**9**) (from 3:1) complexes. Scheme 2 shows the molecular characteristics of the three types of compounds. A more detailed description of trimetallic complexes **8** and **9** is given in Scheme 3.



$[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ **8** $R^1 = R^2 = C_6H_4OC_4H_9$

$[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ **9** $R^1 = C_6H_4OC_4H_9$; $R^2 = H$

Scheme 3. Schematic representation of trimetallic compounds **8** and **9**.

The IR spectra of the new complexes **5**–**9** were recorded in KBr in the 4000–400 cm^{-1} range. For comparative purposes, the IR spectra of the free ligands were also obtained. The new complexes exhibit the characteristic bands of the ligands, slightly modified by coordination. Compounds **5** and **6** were also characterised by X-ray diffraction and show Ag–O distances of 2.704(8) and 2.325(6) Å, respectively, as will be described below. The former one could be considered to be a coordinative Ag···O interaction[1c,1f,1g,1i,1l,1m,6a,8] or even an Ag–O bond, as has been reported by some authors,[1h,1m,9] whereas the latter is clearly characteristic of an Ag–O bond.[1i,1k,10] The IR spectra of **5** and **6** show absorption frequencies at 1273 and

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

1288 cm^{-1}, respectively, assigned to $\nu_{as}(SO_3)$.[11] Thus, the $\nu_{as}(SO_3)$ values for related compounds are tentatively used to differentiate between interactions and/or covalent bonds. Following these results, the $\nu_{as}(SO_3)$ absorption at 1290 cm^{-1} in **8** suggests a strong Ag···O interaction. The related complex **9** exhibits a broad band centred at 1253 cm^{-1}, characteristic of the ligand, which could mask the $\nu_{as}(SO_3)$ absorption.

Multinuclear Magnetic Resonance Spectroscopy

The ^1H NMR spectroscopic data of the ligands and their complexes are gathered in Tables 1 and 2.

The ^1H NMR spectra of $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (**5**) and $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ (**6**) show all the expected resonances of the $Pz^{bp2}Py$ units. In both cases, as expected, an inequivalence of the substituents at the 3- and 5-positions of the pyrazole ring is observed, in agreement with the lack of symmetry. This fact is reflected by the presence of two sets of signals for the OCH_2 groups and the aromatic H_o and H_m protons of the substituents. In solution, the two $Pz^{bp2}Py$ ligands appear to be equivalent in both complexes, as deduced from the unique signals observed for the H4 proton and the pyridine protons. The signals of the latter ones are shifted downfield in relation to the free ligand (specially noted in **6**), except the H3′ signal, which is shifted upfield by about 0.5 ppm. In contrast, the environment of the aromatic C_6H_4 protons is not significantly modified, thus indicating that metal–arene interactions do not exist in solution.[2e,2f,12]

When comparing the ^1H NMR spectra of $[Ag(Pz^{bp}Py)_2(OSO_2CF_3)]$ (**7**) with that of **5**, very close chemical shifts are observed for the signals of the pyridine protons H5′ and H6′, whereas for the signals of H3′ and H4′ the shift upon complexation is larger in complex **5**.

Complexes $[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ (**8**) and $[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ (**9**) present analogous ^1H NMR spectra, the only differences coming from the pyrazole moieties. This fact suggests similar three-coordinate silver environments by considering the chelating complexation through the nitrogen atoms of the pyrazole and triazine rings (N-Pz and N-Tz) and the Ag···OSO_2CF_3 interaction proposed above from their IR spectra. Complex **8** exhibits two different types of signals for the aromatic protons H_o and H_m, the first set is broad and the second one shows sharp multiplets. An analogous behaviour is found for the 4-butoxyphenyl substituent in complex **9**. The broadness of the signals in both complexes can be explained on the basis

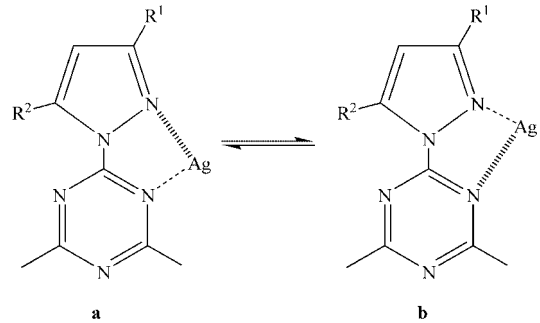
of a hypothetical equilibrium between two forms (**a** and **b**), as represented in Scheme 4. These forms should present an asymmetric metal environment produced by a closer approach to one of the two different coordinated nitrogen atoms (N-Tz or N-Pz). In this way, the environment of the R^2 substituent at the 5-position should not be appreciably modified when moving from **a** to **b**, therefore it gives rise to well-defined signals. In contrast, the R^1 substituent at the 3-position will be strongly affected by this equilibrium; this causes a broadening of its signals. Dynamic experiments were undertaken, but unfortunately they proved to be inconclusive. A similar explanation was provided for a related case in a previous paper.[4]



$R^1 = R^2 = C_6H_4OC_4H_9$ **8**
$R^1 = C_6H_4OC_4H_9$; R^2 = H **9**

Scheme 4. Hypothetical equilibrium in solution for **8** and **9**.

Table 3 shows the ^{15}N NMR chemical shifts of ligands **1**–**4** in $CDCl_3$ solution. Those corresponding to complexes **5**–**9** were recorded in solution and/or the solid state, where no fluxional processes would occur. We have already demonstrated that ^{15}N NMR spectroscopy is the most useful tool for establishing the coordination site, as the increase in the nitrogen shielding on metal complexation reflects the changes in the paramagnetic shielding term.[4,13]

In complexes **5** and **7**, it is clear that both the pyridine N1′ and the pyrazole N2 bind to the metal atom as the

Table 3. ^{15}N NMR chemical shifts (δ in ppm).[a] The silver coordination effects on the chemical shifts [$\Delta\delta(^{15}N) = \delta(^{15}N)$complex – $\delta(^{15}N)$ ligand] are given in brackets.

chemical shifts of their signals move upfield with respect to the free ligands **1** and **2** [$\Delta\delta(^{15}N) = \delta(^{15}N)$complex – $\delta(^{15}N)$ ligand]. In the solid state, the asymmetry of the PzPy units binding the silver cation in the crystal accounts for the two signals observed for each nitrogen. The X-ray structure of **5**, which will described below, supports the above suggestion.

When dealing with the data for **8** and **9** in comparison with those for **3** and **4**, the coordination effects [$\Delta\delta(^{15}N)$] on the triazine N atoms and the pyrazole N2 atom are also negative (Table 3). However, for **5** and **7** the $\Delta\delta$ value for N-Py is higher than that for N-Pz, while the opposite is observed for **8** and **9**. These results agree with a higher crowding of the N-Tz than that of the N-Py.

The ^{15}N NMR spectra of **8** in solution show a higher coordination shift for the N2 of the pyrazole than that for the nitrogen atoms of the triazine, which could be related to the greater strength of the Ag–N bond with the pyrazole. This result is in agreement with the proposed asymmetric silver environment for the complexes.

On the other hand, the chemical shift value of N1 of the pyrazole in all complexes is not significantly affected by the metal coordination, as expected due to the absence of its participation in coordination to the metal atom.

The ^{13}C NMR spectroscopic data for all complexes in solution and the solid state (Table 4 and Table S1 in the Supporting Information) are also in agreement with the proposed structures. The chemical shifts have been analysed relative to those of the corresponding ligands and the main conclusions are: (a) the chemical shifts of the carbon signals of the 4-butoxyphenyl chains are not shifted upon coordination, (b) a downfield coordination shift of the C4 signal of around +3.5 ppm occurs, (c) the downfield shift of the pyridine carbon signals follows the order C4′ (+2.5 ppm) > C6′ ≈ C5′ (+2.0 ppm) > C3′ (+0.6 ppm), with the C2′ signal showing an upfield shift of 2.5 ppm, (d) an upfield coor-

dination shift of the signals of the three equivalent triazine carbon atoms takes place.

The ^{13}C NMR spectra in solution show the equivalence of the pyrazole groups, as well as the inequivalence of their substituents, as already deduced by ^{1}H NMR spectroscopy. In the case of $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (**5**), the ^{13}C CPMAS NMR spectroscopic data indicate that both $Pz^{bp2}Py$ ligands are inequivalent as well as the two 4-butoxyphenyl groups of each ligand, as has also been established by X-ray crystallography. The splitting of the signals observed in all compounds in the solid state can also be attributed to packing effects.

The above results establish a bidentate coordination involving the N-Pz/N-Py in complexes **5** and **7** or N-Pz/N-Tz in **8** and **9**. A new coordinative position around the silver should be occupied by the oxygen atom from the triflate CF_3SO_3 groups, giving rise to five-coordinate species containing two PyPz ligands for **5** and **7**, while three-coordination is proposed for **8** and **9**.

In the search for additional structural information, the X-ray structures of **5** and **6** were solved, and the results are described in the following section.

Crystal and Molecular Structures of 5 and 6

Compounds **5** and **6** crystallised from dichloromethane solutions. Table 5 provides a selected list of bond lengths and angles.

As depicted in Figure 1, the silver centre in **5** is four-coordinate with the nitrogen atoms of two $Pz^{bp2}Py$ ligands in a distorted tetrahedral environment. This is reflected in the dihedral angle formed by the AgN1N3 and AgN4N5 planes of 124.8(2)°. The Ag–N bond lengths fall in the range of 2.28–2.50 Å found for related compounds.[1b,1h,1k,6e,6f,14] The mean Ag–N distance involving the N-Py atoms [2.318(8) Å] is shorter than that of the N-Pz atoms [2.467(8) Å]. The largest distortion from tetrahedral geometry is given by the N–Ag–N bite angle [N1–Ag–N3: 70.9(3)°; N6–Ag–N4: 69.7(3)°] associated with the chelating ligands.

Table 5. Selected bond lengths [Å] and angles [°] for **5** and **6**.

	5

Ag–C25C26[b]	2.598(1)	N1–Ag–C25C26[b]	104.9(2)

[a] $-x + 1, -y + 1, -z + 1$. [b] C25C26 means the centroid of the C25–C26 bond.

The C_6H_4 group at the 3-position in one molecule of **5** is almost parallel to the C_6H_4 group at the 5-position of the other molecule [dihedral angle of 4.2(3)°], and the remaining aryl rings are orthogonal between them [86.7(2)°] with the butoxy chains in an opposite and almost symmetrical disposition. The four chains produce a crowding in one corner of the metal environment. As a consequence, the silver centre has a deprotected position that allows the approach of an oxygen atom of the triflate group. The Ag···O5 distance of 2.704(8) Å is smaller than the sum of the van der Waals radii of 2.84 Å.[14b] Similar values have been attributed to metal–oxygen bonds.[1h,1m,9] Therefore, the distance observed for **5** can be considered a "strong" coordinative interaction, giving rise to a distorted trigonal bipyramidal geometry around the metal atom.

Because of the usually found three-coordination around the silver centre, we thought that the coordination of the triflate group could be assessed by using a ratio of $Pz^{bp2}Py$ ligand/$Ag(OSO_2CF_3)$ = 1.

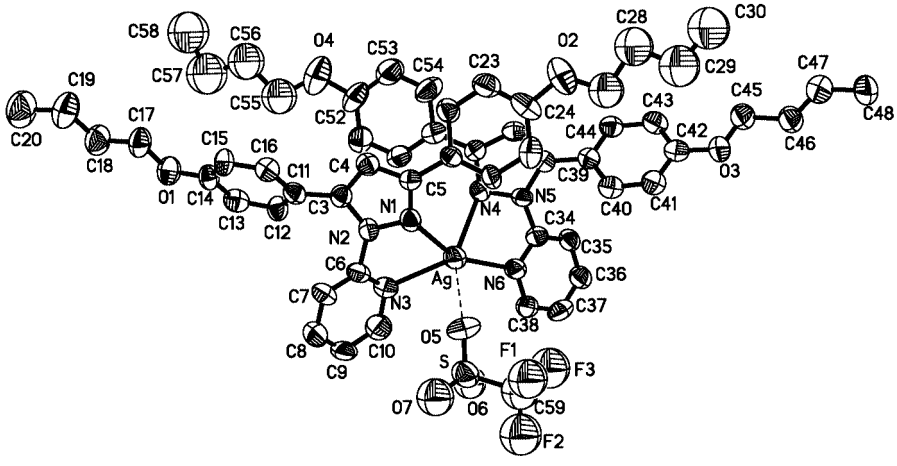

Figure 1. ORTEP plot of **5** with ellipsoids at 40% probability, showing the $Pz^{bp2}Py$ coordination and the Ag···O intermolecular bonds. Hydrogen atoms and the labelling of some atoms have been omitted for clarity.

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

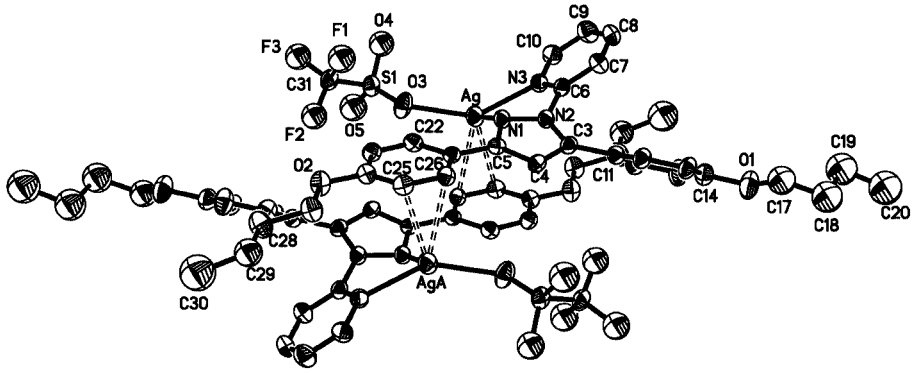

Figure 2. ORTEP plot of **6** with ellipsoids at 35% probability level, showing the dimeric unit formed by Ag···arene interactions. Hydrogen atoms and the labelling of some atoms have been omitted for clarity.

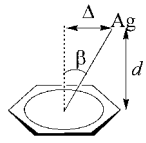
The molecular structure of **6** is shown in Figure 2 and corresponds to a dimeric entity produced by Ag···π(aryl ring) interactions between two molecules that are symmetrically related by an inversion centre. The coordination geometry around each silver atom in **6** is quite different from that in **5**. Thus, the metal atom in **6** adopts the usual three-coordination with the silver cation being trigonally coordinated by the two nitrogen atoms of the bidentate $Pz^{bp2}Py$ ligand and an oxygen atom from the triflate anion. The Ag–N1 and Ag–N5 distances of 2.584(6) and 2.307(6) Å, respectively, are almost equivalent to those found in **5**. The metal atom deviates 0.741(1) Å from the plane defined by the three coordinated atoms (N1, N3, O), this deviation being produced by the proximity of an aryl group from the second molecule, to which the silver atom is also coordinated by an Ag···π bond,[15] thus generating a distorted tetrahedral environment. The short Ag–C distances [mean value of 2.668(7) Å] are in the range found in other compounds containing η^2-Ag···π arene interactions (2.40–2.75 Å).[9,16] The contacts of the silver atom with the other aromatic carbon atom are greater than 3 Å [the shortest is Ag–C24 ($-x + 1$, $-y + 1$, $-z + 1$) with 3.22(3) Å], consisting of an asymmetric coordination of the silver atom with the two carbon atoms of the benzene ring. The separation of each silver atom from the mean plane of its coordinated aryl group of 2.567(5) Å lies in the range inherent to the bonding of an arene ligand.[16a] In addition, the positional parameters β and Δ (where Δ and β measure the deviation from the centroid axis;[16a] see Scheme 5) of the silver centre of 30.9° and 1.54 Å, respectively, are in agreement with the range of other structures showing an η^2-coordination of the arene.[16a] All the above arguments allow us unequivocally to establish the presence of a dimerisation through an η^2-Ag···π arene bond.



Scheme 5. Δ and β parameters for Ag···arene interactions.[16a]

In the crystal structures of **5** and **6** shown in Figures 3–6, the triflate anion intervenes in the organisation around the $[Ag(Pz^{bp2}Py)_2O]$ and $[Ag(Pz^{bp2}Py)O]$ units, either coordinating or forming a covalent bond with the metal atom in **5** and **6**, respectively. Such an anion is also employed to expand the supramolecular environment with one of the remaining oxygen atoms interacting with the silver centre or carbon atoms of neighbouring units. Thus, the coordination of the anion in **6**, or strong interaction in **5**, can be considered as the first stage of the supramolecular organi-

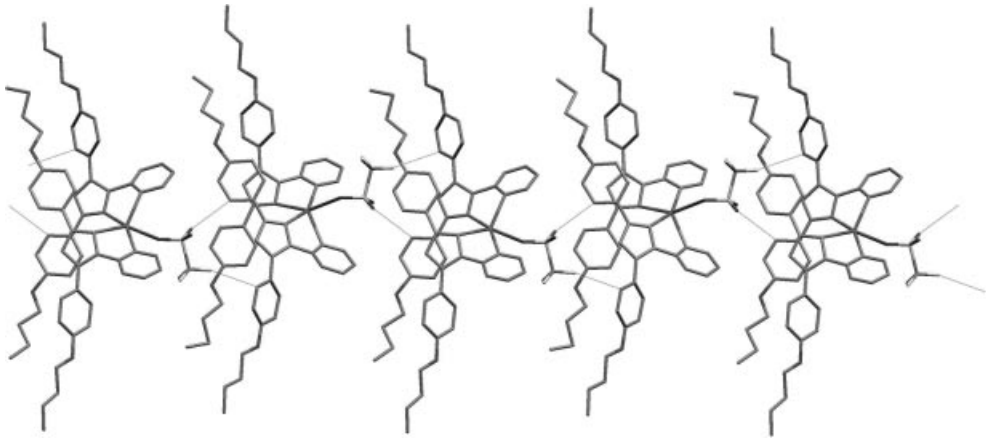


Figure 3. View of the strand along the *b* axis in **5**, showing the Ag···O, C–H···O and C–H···F contacts.

sation, while the next one is consistent with the assembly of $[Ag(Pz^{bp2}Py)_2O]$ and $[Ag(Pz^{bp2}Py)O]$ units, which can be described as follows:

i) The oxygen atoms of the triflate, which are not involved in a direct bond or interaction with the silver atom, are bonded to a pair of adjacent molecules by Ag···O or C–H···O/F interactions, thus generating strands. In **5**, the strands are defined along the *b* axis by the C22···O7 [$-x$ + ½ + 1, y – ½, $-z$ + ½: 3.24(2) Å] and C16···F2 [$-x$ + ½ + 1, y – ½, $-z$ + ½: 3.04(2) Å] interactions (Figure 3). In **6**, the overall arrangement consists of a double strand along the *b* axis in which two triflate anions act as bridging groups of each neighbouring dimer [Ag1···O5 ($-x$ + 1, $-y$ + 2, $-z$ + 1): 2.84(1) Å; Ag1···O4 ($-x$ + 1, $-y$ + 2, $-z$ + 1): 3.32(1) Å; see Figure 4). In addition to related C–H···O interactions [C10···O5 ($-x$ + 1, $-y$ + 2, $-z$ + 1): 3.24(2) Å;

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

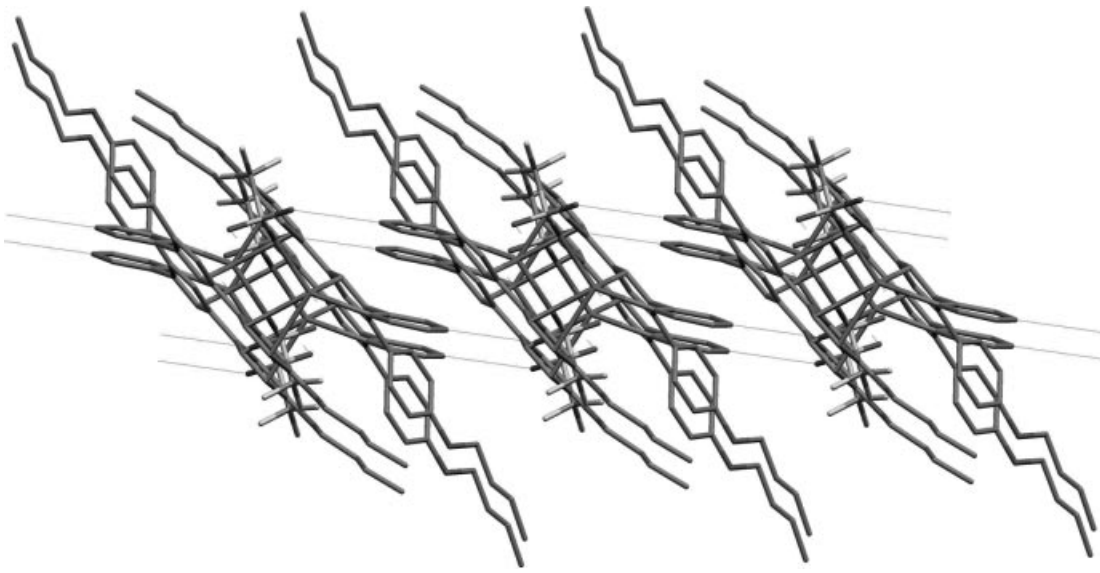

Figure 6. View of a layer parallel to the (001) plane of the 2D network of **6**.

C25···O4 (x, y – 1, z): 3.18(2) Å], the strands are mainly determined by a direct Ag···O bond. The triflate tecton in both **5** and **6** is responsible for the 1D arrangement.
ii) New non-conventional hydrogen-bonding interactions involving the CF_3 groups of the triflate group in **5** or bifurcated C–H···O interactions in **6** extend the supramolecular arrangements into a 2D network. Thus, the C–H···F interactions between the chains in **5** [C58···F3 (x + ½, $-y$ + ½ + 1, z – ½): 3.25(3) Å], where the F atoms proceed from alternating and symmetrically disposed bridging triflate groups along the c axis of the chain, give rise to layers which lie parallel to the (101) plane (Figure 5). In **6**, the same oxygen atom implicated in the strand interacts with the pyridine group of an adjacent strand [C8···O4 ($-x$, y + 2, $-z$ + 1): 3.31(1) Å], thereby extending these interactions through the (001) plane (Figure 6).

Concluding Remarks

Silver(I) coordination complexes containing $Pz^{bp2}Py$ (**1**), $Pz^{bp}Py$ (**2**), $TPz^{bp2}Tz$ (**3**) and $TPz^{bp}Tz$ (**4**) polydentate ligands have been obtained. An *N*,*N*′-bidentate coordination has been established in $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (**5**) and $[Ag(Pz^{bp}Py)_2(OSO_2CF_3)]$ (**7**), which involves the N-Pz/N-Py sites, and implicates the N-Pz/N-Tz ones in $[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ (**8**) and $[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ (**9**). A new coordinative position is occupied by the oxygen atom from the triflate groups, giving rise to five-coordinate species containing two PzPy ligands for **5** and **7**, while three-coordination is proposed for **8** and **9**.

The compound $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ (**6**), which contains Ag/$Pz^{bp2}Py$ in a 1:1 stoichiometric ratio, exhibits the expected metal environment determined by the *N*,*N*′-bidentate $Pz^{bp2}Py$ ligand and the oxygen atom of the triflate group. However, in this case, this environment is expanded through an M–π olefinic bond to give rise to dimeric units.

From the comparative study of the structures of **5** and **6**, several features can be established as determining factors of the supramolecular arrays: i) The structural role of the triflate anion takes place by coordination or strong interaction of the silver centre to an oxygen atom (Ag···O); ii) the coordination of the anion to the $[Ag(Pz^{bp2}Py)_2]^+$ units in **5** is less favoured than in **6** due to the crowding around the metal centre, which prevents the additional Ag···π interaction that is responsible for the dimer in **6**; iii) double or single strands are built on the basis of hydrogen-bonding interactions.

Experimental Section

Materials and Instrumentation: All commercial reagents were used as supplied. 3-(4-Butoxyphenyl)pyrazole (HPz^{bp}), 2-[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp2}Py$, **1**) and 2,4,6-tris[3,5-bis(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp2}Tz$, **3**) were prepared according to the literature.[4,7,17] Commercial solvents were dried prior to use. Elemental analyses for C, H, N, S were carried out by the Microanalytical Service of the Complutense University. IR spectra were recorded with an FTIR Nicolet Magna-550 spectrophotometer with samples as KBr pellets in the 4000–400 cm^{-1} region. The exact mass of **4** was determined by high resolution mass spectrometry at 70 eV using the electron impact mode with a VG AutoSpec spectrometer.

NMR Parameters: Spectra were recorded at 298 K with a Bruker DRX 400 spectrometer (400.13 MHz for ^1H; 100.62 MHz for ^{13}C; 40.56 MHz for ^{15}N NMR), except for compound **6**, where only the ^1H NMR spectrum was registered with a Bruker AC 200 spectrometer. Chemical shifts (δ in ppm) are given relative to internal solvents [$CDCl_3$ (δ = 7.26 ppm), CD_2Cl_2 (δ = 5.32 ppm) and $(CD_3)_2CO$ (δ = 2.05 ppm) for ^1H NMR; $^{13}CDCl_3$ (δ = 77.0 ppm), CD_2Cl_2 (δ = 54.0 ppm) and $(CD_3)_2CO$ (δ = 29.9 and 206.7 ppm) for ^{13}C NMR; external nitromethane (δ = 0.0 ppm) for ^{15}N NMR]. Coupling constants (J in Hz) are accurate to ±0.2 Hz for ^1H and ^{13}C. ^2D inverse proton detected heteronuclear shift correlation spectra, ^1H-^{13}C gs-HMQC, ^1H-^{13}C gs-HMBC, ^1H-^{15}N gs-HMBC and ^1H-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

^{15}N gs-HMQC were recorded with the standard pulse sequences.[18] Solid-state ^{13}C (100.73 MHz) and ^{15}N (40.60 MHz) CPMAS NMR spectra were recorded with a Bruker WB-400 spectrometer at 300 K using a 4-mm DVT probehead. Samples were carefully packed in 4-mm diameter cylindrical zirconia rotors with Kel-F end-caps. Operating conditions involved 3.2-μs, 90° ^{1}H pulses and a decoupling field strength of 78.1 kHz with the TPPM sequence. ^{13}C NMR spectra were originally referenced to a glycine sample and then the chemical shifts were recalculated relative to $SiMe_4$ [for the carbonyl atom: δ(glycine) = 176.1 ppm], and ^{15}N spectra to $^{15}NH_4Cl$ and then converted to the nitromethane scale using the relationship $\delta(^{15}N)MeNO_2 = \delta(^{15}N)NH_4Cl - 338.1$ ppm. The typical acquisition parameters for ^{13}C CPMAS were: spectral width: 40 kHz; recycle delay: 5 s; acquisition time: 30 ms; contact time: 2 ms; accumulation number: 900–2200; spin rate: 12 kHz. In order to distinguish protonated and unprotonated carbon atoms, the NQS (non-quaternary suppression) experiment by conventional cross-polarisation was recorded; before the acquisition, the decoupler was switched off for a very short time of 25 μs.[18] Those for ^{15}N CPMAS were: spectral width: 40 kHz; recycle delay: 5 s; acquisition time: 35 ms; contact time: 6 ms; accumulation number: 80000–115000; and spin rate: 6 kHz.

Synthesis of 2-[3-(4-Butoxyphenyl)pyrazol-1-yl]pyridine ($Pz^{bp}Py$, 2): A solution of 4-butoxyacetophenone (1.81 g, 9.42 mmol) in ethyl formate (1.16 mL, 14.13 mmol) and toluene (15 mL) was added to a slurry of anhydrous sodium methoxide (0.51 g, 9.42 mmol) in toluene (50 mL). A clear solution was obtained, which became a slurry after 5 min. The solid was isolated by filtration after 2 h at room temperature and washed with hexane. The solid obtained (0.36 g, 1.48 mmol) was dissolved in 96% ethanol (10 mL), and then treated with hydrochloric acid (ca. 2.5 mL, spec. grav. 1.18). 2-Hydrazinopyridine (0.65 g, 5.92 mmol) dissolved in the minimum amount of 96% ethanol was added to this solution. The mixture was refluxed for 3 h, and then the solvent was evaporated to about half the original volume and the resulting solution kept in a refrigerator at 4 °C. Pale-yellow needles were obtained after 2 d, which were filtered off and washed with hexane. Yield: 0.30 g (69%). M.p. 79 °C. $C_{18}H_{19}N_3O$ (293.37): calcd. C 73.70, H 6.53, N 14.32; found C 73.61, H 6.45, N 14.25. IR (KBr): $\tilde{\nu}$ = 1616 and 1580 cm^{-1} ν(C=N).

Synthesis of 2,4,6-Tris[3-(4-butoxyphenyl)pyrazol-1-yl]-1,3,5-triazine ($TPz^{bp}Tz$, 4): NaH (95%, 63.9 mg, 2.53 mmol) was added to a solution of HPz^{bp} (438.5 mg, 2.03 mmol) in freshly distilled dry THF (30 mL) under argon. After 1.5 h at 90 °C, the solution was allowed to cool, and 2,4,6-trichlorotriazine (cyanuric chloride, 126.1 mg, 0.677 mmol) was added. The solution was heated at 90 °C for 11.5 h and at 60 °C for 15 h. The solvent was evaporated and the residue chromatographed on 60-F_{254} silica gel with chloroform/acetonitrile (92:8) as eluent. R_f = 0.35. Yield: 122 mg (25%). M.p. 197–199 °C. Exact mass calcd. for $C_{42}H_{45}N_9O_3$: 723.3645; found 723.5. IR (KBr): $\tilde{\nu}$ = 1612 cm^{-1} ν(C=N).

Synthesis of $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (5): $Ag(OSO_2CF_3)$ (45 mg, 0.17 mmol) was added under nitrogen to a solution of $Pz^{bp2}Py$ (**1**; 153 mg, 0.34 mmol) in dry THF (40 mL). After 24 h of stirring, the solution was filtered through a plug of Celite. Then, the solvent was removed in vacuo and 10 mL of dichloromethane was added. The solution was again filtered through a plug of Celite and concentrated. A colourless solid was isolated after addition of hexane at 4 °C. The product was crystallised from a solution of dichloromethane and hexane at 4 °C. Yield: 111 mg (38%). $C_{57}H_{62}AgF_3N_6O_7S$ (1140.1): calcd. C 60.05, H 5.48, N 7.37, S 2.81; found C 59.65, H 5.34, N 7.34, S 2.78. IR (KBr): $\tilde{\nu}$ = 1612 and 1573 cm^{-1} ν(C=N), 1273 $\nu_{as}(SO_3)$, 1028 $\nu_s(SO_3)$.

Synthesis of $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ (6): This compound was prepared in a similar way to **5**, from $Ag(OSO_2CF_3)$ (35 mg, 0.14 mmol) and $Pz^{bp2}Py$ (**1**; 60 mg, 0.14 mmol). The product was crystallised from a solution of dichloromethane at 4 °C. Yield: 38 mg (40%). $C_{58}H_{62}Ag_2F_6N_6O_{10}S_2$ (1397.0): calcd. C 49.87, H 4.47, N 6.02, S 4.59; found C 49.82, H 4.57, N 5.93, S 4.56. IR (KBr): $\tilde{\nu}$ = 1605 and 1572 cm^{-1} ν(C=N), 1288 $\nu_{as}(SO_3)$, 1027 $\nu_s(SO_3)$.

Synthesis of $[Ag(Pz^{bp}Py)_2(OSO_2CF_3)]$ (7): The compound was prepared in a similar way to **5**, from $Ag(OSO_2CF_3)$ (87 mg, 0.34 mmol) and $Pz^{bp}Py$ (**2**; 200 mg, 0.68 mmol). The product was recrystallised from dichloromethane/hexane at 4 °C. Yield: 109 mg (38%). $C_{37}H_{38}AgF_3N_6O_5S$ (843.7): calcd. C 52.68, H 4.54, N 9.96, S 3.80; found C 52.49, H 4.47, N 9.95, S 3.81. IR (KBr): $\tilde{\nu}$ = 1608 and 1578 cm^{-1} ν(C=N), 1249 $\nu_{as}(SO_3)$, 1031 $\nu_s(SO_3)$.

Synthesis of $[Ag_3(TPz^{bp2}Tz)(OSO_2CF_3)_3]$ (8): $Ag(OSO_2CF_3)$ (33.7 mg, 0.13 mmol) was added to a solution of $TPz^{bp2}Tz$ (50.6 mg, 0.04 mmol) in 30 mL of dry THF. After 24 h of stirring, the solution was filtered through a plug of Celite. The solvent was then evaporated to about 5 mL, and pentane (10 mL) was added. The yellow solid formed was filtered off, washed with small portions of pentane and dried in vacuo. Yield: 40 mg (48%). $C_{75}H_{81}Ag_3F_9N_9O_{15}S_3$ (1939.3): calcd. C 46.45, H 4.21, N 6.50; found C 46.49, H 4.36, N 6.49. IR (KBr): $\tilde{\nu}$ = 1610 cm^{-1} ν(C=N), 1253 $\nu_{as}(SO_3)$, 1027 $\nu_s(SO_3)$.

Synthesis of $[Ag_3(TPz^{bp}Tz)(OSO_2CF_3)_3]$ (9): The compound was prepared as described for **8**, from $TPz^{bp}Tz$ (31.4 mg, 0.04 mmol) and $Ag(OSO_2CF_3)$ (33.3 mg, 0.13 mmol). Yield: 41.2 mg (63%). $C_{45}H_{45}Ag_3F_9N_9O_{12}S_3$ (1494.7): calcd. C 36.16, H 3.03, N 8.43; found C 36.34, H 3.41, N 8.38. IR (KBr): $\tilde{\nu}$ = 1610 cm^{-1} ν(C=N), 1253 $\nu_{as}(SO_3)$, 1027 $\nu_s(SO_3)$.

X-ray Structure Determinations: Colourless thin plate or prismatic single crystals of $[Ag(Pz^{bp2}Py)_2(OSO_2CF_3)]$ (**5**) and $[Ag_2(Pz^{bp2}Py)_2(OSO_2CF_3)_2]$ (**6**), respectively, were grown from dichloromethane solutions. Data collection was carried out at room temperature with a Bruker Smart CCD diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) operating at 50 kV and 20 mA. In all cases, data were collected over a hemisphere of the reciprocal space by combination of three exposure sets. Each exposure covered 0.3° in ω. The cell parameters were determined and refined by a least-squares fit of all reflections collected. The first 50 frames were recollected at the end of the data collection to monitor crystal decay; no appreciable decay was observed. A summary of the fundamental crystal and refinement data is given in Table 6. The structures were solved by direct methods and refined by full-matrix least squares on F^2.[19] Anisotropic parameters were used in the last cycles of refinement for all non-hydrogen atoms, with some exceptions. Thus, some carbon atoms of the butoxy chains, the fluorine and only two oxygen atoms of the triflate group were refined isotropically. The third oxygen atom of the triflate group, which interacts with the silver atom, was refined anisotropically. Some of these atoms were refined with geometrical restraints and variable common carbon–carbon and carbon–oxygen distances. Hydrogen atoms were included in calculated positions, and refined as riding on their respective carbon atoms with thermal parameters related to the bonded atoms. Hydrogen atoms were analysed with SHELXS-97 and PARST97.[20] The largest residual peaks in the final difference map were 1.173 and 1.266 e Å^{-3} for **5** and **6**, respectively, in the vicinity of the fluorine atoms. CCDC-266326 (**5**) and -266327 (**6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of

Early and Late Transition Metal Complexes Stabilised by Imidazopyridazine-Substituted Bisamido Ligands

Torsten Irrgang*[a] and Rhett Kempe*[a,b]

Keywords: Amido ligands / Imidazo[1,5-*b*]pyridazines / N ligands / Chromium / Iridium / Rhodium / Titanium / Zirconium

The preparation of a series of new imidazo[1,5-*b*]pyridazine-substituted diamines (**5**) is reported. They can be synthesised by the nucleophilic ring transformation of 2-amino-5-methyl-1,3,4-oxadiazolium halogenides (**1**) with diaminoalkanes followed by condensation reactions with 1,3-diketones. After deprotonation they were then used as bisamido ligands. These ligands stabilise early and late transition metal complexes as five-membered chelates. The reaction with selected group 4 metals (titanium and zirconium) leads via amine elimination to unusual dark blue and purple mononuclear amido complexes. Deprotonation of the bisamido ligands using BuLi and further reaction with group 6 metals like chromium results in a dinuclear octahedral Cr^{III} complex, where the different coordinated metal centres are bridged by two of the amido N atoms. The double deprotonation of **5** followed by reaction with the group 9 metals rhodium and iridium led to dinuclear complexes in a *trans* binding mode. The X-ray structures of one of the novel bisamido ligands (protonated) and all complexes are reported and discussed.

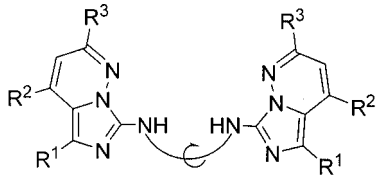
Introduction

Amido metal chemistry[1] has attracted much attention recently.[2] The amido ligands used to accomplish this chemistry are obtained mainly from the smooth and selective formation of Si–N bonds via salt elimination or from palladium catalysed aryl amination, which is highly efficient for forming C–N bonds.[3] Both systems have certain limitations e.g. the instability of the Si–N bond and the catalyst cost of the amination reactions. Thus we became interested in an amine synthesis protocol, which allows the synthesis of stable amido ligand precursors and the introduction of a large variety of substitution patterns. A further advantage is the classical bench top chemistry used to carry out the amine syntheses. In this paper synthesis of imidazo[1,5-*b*]-pyridazine-substituted diamines (Scheme 1) and the application of these amines as amido ligands to stabilise early and late transition metals, is reported.



Scheme 1. Imidazo[1,5-*b*]pyridazine-substituted diamines ($R^{1–3}$ aryl or alkyl substituents).

Results and Discussion

Synthesis of the Ligand Precursors – Synthesis of the Diamines

2-Amino-5-methyl-1,3,4-oxadiazolium halogenides[4] **1** (Scheme 2) react with a large variety of primary and secondary amines to afford 2-amino-substituted 1-acetylamino-imidazoles via ring transformation.[5] Thus, the reaction with diaminoalkanes should give rise to *N*,*N*′-bis(1-acetylamino-4-alkyl/aryl-imidazol-2-yl)-1,ω-diaminoalkanes **2a**–**c** (Scheme 2).

In the course of the ring transformation one equiv. of the amine acts as a nucleophile, attacking the amine-substituted carbon atom of the oxadiazolium halide with HBr being eliminated. An excess of the amines is used to trap the HBr. Furthermore, water is eliminated and a new bond between the exocyclic N atom and the exocyclic C atom of the carbonyl group is formed. These ring transformations are extremely exothermic. Variation of the diamines and the oxadiazolium halogenides (substituent R^1) allows the formation of, for instance, **2a**–**c** (Scheme 2). Reaction of **2** with HCl in ethanol produces **3a**–**d** (deacetylation) and neutralisation with aqueous NaOH leads to **4a**–**c**.

The reactions of 1-amino-4-arylimidazoles[6] with diketones afford imidazo[1,5-*b*]pyridazines,[7] a class of substances with a very interesting potential as a suitable non-nucleoside inhibitor of HIV-1 (RT).[8] Analogously, **4** reacts

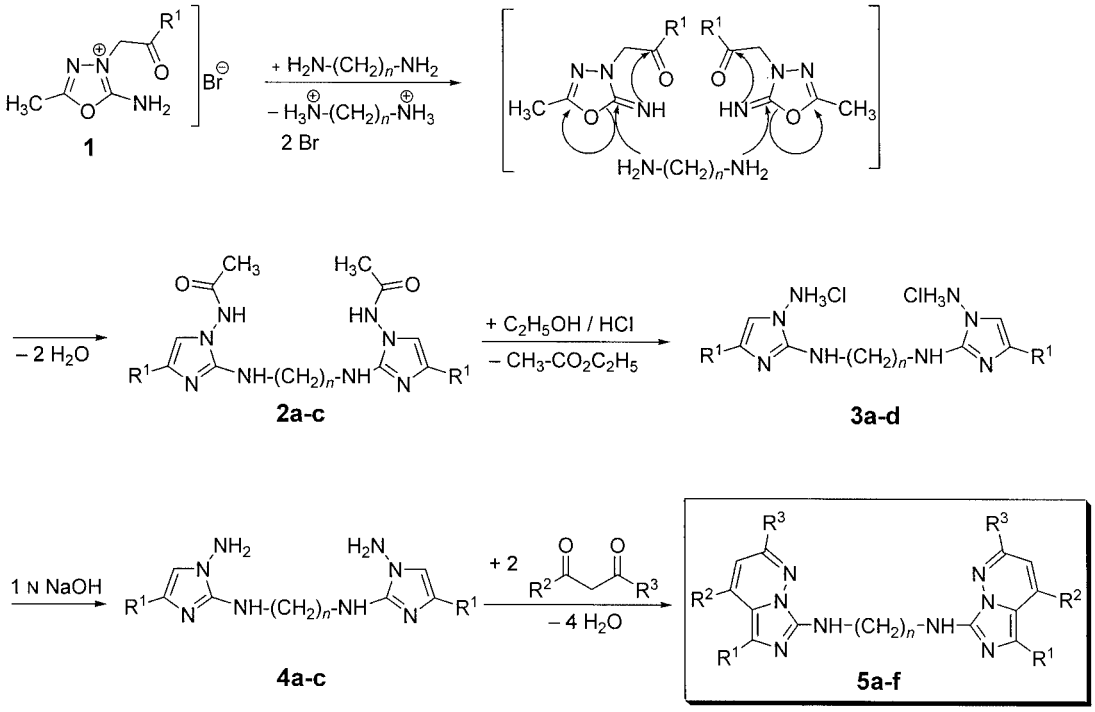

Scheme 2. Ring transformation with diaminoalkanes [n = 2: R^1 = –$C(CH_3)_3$ (**2a/3a/4a**), R^1 = C_6H_5 (**2b/3b/4b**); n = 3: R^1 = C_6H_5 (**2c/3c/4c**), R^1 = C_6H_4-$p$$CH_3$ (**3d**)] and synthesis of **5a**–**f** [n = 2: $R^1/R^2/R^3$ = –$C(CH_3)_3/CH_3/CH_3$ (**5a**), $R^1/R^2/R^3$ = -$C(CH_3)_3/C_6H_5/CH_3$ (**5b**), $R^1/R^2/R^3$ = $C_6H_5/CH_3/CH_3$ (**5c**); n = 3: $R^1/R^2/R^3$ = $C_6H_5/CH_3/CH_3$ (**5d**), $R^1/R^2/R^3$ = $C_6H_5/C_6H_5/CH_3$ (**5e**), $R^1/R^2/R^3$ = C_6H_4-$p$$CH_3/CH_3/CH_3$ (**5f**)].

with acetylacetone and/or benzoylacetone and diaminoalkyl-bridged imidazo[1,5-*b*]pyridazines **5a**–**f** (Scheme 2) are formed. The reactions with benzoylacetone lead to 2-methyl-4-phenyl-imidazopyridazines selectively, which means the methyl group is found in the 2- and the phenyl group in the 4-position. The reason for this might be the higher reactivity of the acetyl group towards the amine function of **4**. A methyl group in the 4-position is characterised by a doublet (^{1}H NMR signal) as well as the H atom in the 3-position. The splitting is about 3 Hz (both signals) and is caused by ^4J coupling due to the short C–C distances of the C–C double bond of the six-membered ring.

Substituents in the 2-(R^3), 4-(R^2) and 5-(R^1)-positions are easily modified with the synthetic protocol described above. Thus, the electronic properties, the steric demand and the solubility behaviour of the corresponding amido ligands can easily be fine-tuned. Compounds **5a**–**f** are obtained as orange to red crystalline materials in good yields after recrystallisation from ethanol water mixtures. X-ray crystal structure analysis was performed to determine the molecular structure (Figure 1) of **5a**. Experimental details are summarised in Table 1. The significantly shorter N1–C2 (1.30 Å) and C3–C4 (1.35 Å) bonds indicate the localisation of the double bonds of the six-membered pyridazine rings in **5a**. The ^{1}H NMR spectroscopic data of **5a**–**f** confirms this observation. The dihedral angles between the two-imidazopyridazine planes are 93.5° in **5a**. The deviations from planes are 0.0078 Å and 0.0071 Å. Both 7-substituted amido N atoms are in the plane with the imidazopyridazines. The deviations of the N1 and N5 atoms, out of the imidazopyridazine planes, are 0.0135 Å and 0.0097 Å, respectively. Complex **5a** is predicted to form inter- or intramolecular H bonds because it contains potential proton donor and acceptor functionalities. An intramolecular hydrogen bond[9] N5–HN5···N2 (with a HN5···N2 distance of 2.40 Å) forces **5a** into a transoid arrangement.

Complex Syntheses and Structures

Compounds **5** as well as the deprotonated versions have six different donor functions to coordinate transition metals. Thus, a range of binding modes depending on the nature of the transition metal as well its oxidation state, are expected. Possible binding modes of double deprotonated **5** are shown in Scheme 3.

A cisoid/transoid orientation concerning the diamido unit can be considered as well as the formation of four- or five-membered chelates. Thus, the binding modes A (*cis*55), B (*cis*44), C (*cis*45), D (*trans*45), E (*trans*55) and F (*trans*44) are expected (*cis* = cisoid, *trans* = transoid, 4 = four-membered and 5 = five-membered chelates). Coordination chemical studies were performed with **5a**. Group 4 metal complexes are efficiently accessible via amine elimination reactions,[2,10] especially since the availability of a variety of amido and mixed amido chloro starting material complexes.[11] The reaction of **5a** with one equiv. of bis(dimethylamido)titanium dichloride gave rise to **6** as a dark blue-purple crystalline material (Scheme 4). Due to the good solubility of **5a** in nonpolar solvents the reaction was accomplished in ether. We wondered about the dark blue to purple colour since titanium amides are usually red coloured and thus put the colour change down to the deprotonation of the ligand. The reaction of **5a** with tetrakis(di-

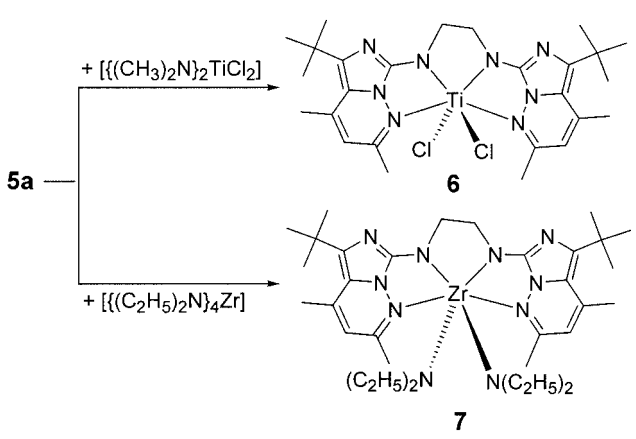
ethylamido)zirconium, during which **7** is formed as a crystalline purple material in high yield (Scheme 4) goes along with such a colour change, and supports this hypothesis since zirconium amides are usually colourless. The UV/Vis spectra of **5a**, **6** and **7** are shown in Figure 2. The optical spectra were recorded in C_6H_6 using the same concentrations for all compounds. The ligand shows a significant lower absorption (abs < 0.2) over a plateau with a major peak at 511.0 nm. The longer UV absorption wavelengths of the complexes **6** (626.0 nm) and **7** (572.3 nm, 553.9 nm) were consistent with the observed colour of **6** and **7** in the solid states and in solutions with different solvents. These absorption wavelengths indicate transitions between d levels of the metal ions. The shorter UV absorption wavelengths of **6** (422.0 nm) and **7** (520.0 nm, 347.6 nm) are attributed to electron transitions between the metal ion and ligand or within the ligand.[12] The NMR spectra of **6** and **7** show a single signal set of deprotonated **5a** and thus were indicative of the formation of mononuclear complexes.



Scheme 4. Synthesis of **6** and **7** via amine elimination.

An X-ray crystal structure analysis of **6** and **7** was performed. Experimental details are summarised in Table 1. The molecular structures of **6** and **7** are shown in Figure 3 and Figure 4, respectively. Both compounds are best described as octahedrally coordinated and adopt the *cis*55 binding mode. The $M–N_{pyridazine}$ bond lengths in **6** (2.313 Å, 2.307 Å) and **7** (2.562 Å) are significantly longer than the $M–N_{amido}$ bond lengths (**6** = 1.973 Å, 1.991 Å; **7** = 2.184 Å), which indicates localised bonding modes for the five-membered chelates of both complexes . The $N_{amido}–Ti–N_{pyridazine}$ angle of the five-membered chelate (mean = 74.8°) is 6.3° larger and the $N_{amido}–Ti–N_{amido}$ (75.57°) is 4.8° larger than the corresponding angle in **7**. The Cl–Ti–Cl angle of the two chloro ligands and the N–Zr–N angles of the two diethylamido ligands are 138° and 123°, respectively. Considering the ideal angles in an octahedral scenario, 90° or 180° for these additional ligands, the smaller titanium seems closer to a *trans* arrangement and the larger zirconium closer to a *cis* arrangement. The dihedral angles

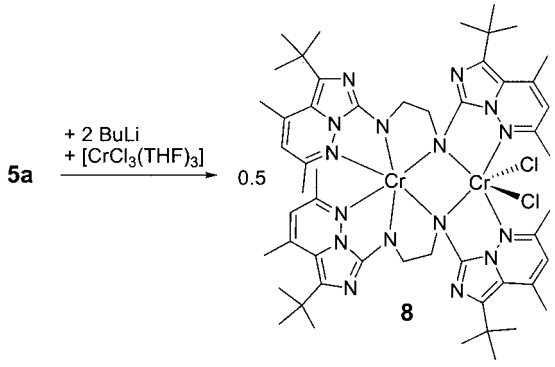
Group 6 metal amides do not eliminate as efficiently as group 4 metals and the variety of possible starting materials is much smaller. Thus the opportunities of salt metathesis reactions to synthesise chromium complexes were explored. The double lithiation of **5a** at –70 °C and the reaction of this mixture with $[CrCl_3(THF)_3]$ (THF = tetrahydrofuran) led to the crystalline material of the paramagnetic chromium complex **8** (Scheme 5). Due to the paramagnetic nature of this compound, structural characterisation by NMR spectroscopic methods was not of much help.

The molecular structure was explored by X-ray analysis. Experimental details are summarised in Table 2. The molecular structure of **8** is shown in Figure 5, and includes selected bond lengths and angles. Compound **8** is a dinuclear dichloro chromium(III) complex. Both chromium atoms adopt an octahedral coordination, as preferred by Cr^{III}



Scheme 5. Synthesis of **8**.

complexes,[13] bridged by two of the amido N atoms (Scheme 6). Cr^{III}, d^3, is the most stable and important state and octahedral complexes must have three unpaired electrons irrespective of the strength of the ligand field, giving a sort of half-filled shell stability. The magnetic moment of **8** is μ_{eff} = 4.28 μ_B. The chromium–chromium distance of 3.110 Å does not indicate a direct metal–metal interaction.

The Cl–Cr–Cl angle is 94° and fits well the octahedral coordination. Both chloro ligands are in the plane with the almost square-planar four-membered ring of Cr2, N13, Cr1 and N4 (deviation from plane 0.0072 Å) (Scheme 6). The bond lengths observed between N13–Cr1(Cr2) and N4–Cr1(Cr2) reflect a delocalised bonding mode. The lengths of the $Cr–N_{pyridazine}$ bonds are almost 0.20 Å longer than the $Cr–N_{amido}$ bonds. This difference indicates a localised bonding mode. The flexible coordination mode of the bis(imidazopyridazine) ligands allows a coordinative saturation of the metal centres, leaving two amido N atoms for bridging of two chromium(III) atoms.

Group 9 metal amides such as the late metal amido complexes are rarely described in general.[14] The mismatch of

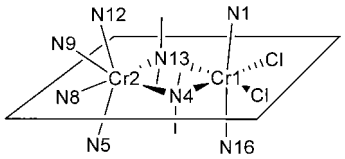
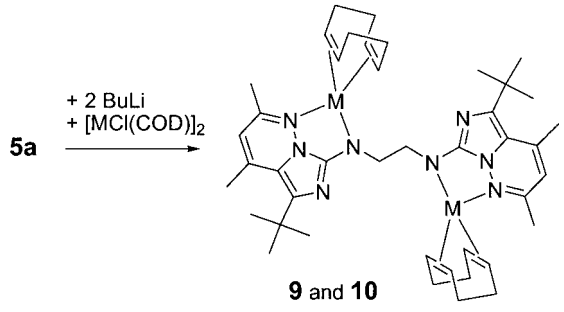


Scheme 6. Coordination sphere of **8**.

the rather hard amido ligands and the soft nature of the late transition metals might be one of the reasons for this shortage.[15] The most studied amido compounds of iridium and rhodium are dinuclear complexes containing the chelating and bridging ligands[16] and mononuclear complexes with chelating bifunctional ligands.[17] Dinuclear amido iridium[18] and rhodium[19] complexes with simple amides ($RR'N^-$ and RHN^-), as well as the very reactive mononuclear compounds[20] with these amides, have been scarcely studied. The double deprotonation of **5a** (using BuLi) followed by the reaction with $[IrCl(COD)]_2$ or $[RhCl(COD)]_2$ (COD = 1,5-cyclooctadiene) led to the group 9 metal amides **9** and **10** (Scheme 7). The ^1H and ^{13}C NMR spectroscopic data of **9** and **10** are similar, taking into consideration the fact that characteristic ligand signals are slightly



Scheme 7. Synthesis of **9** (M = Ir) and **10** (M = Rh).

different. Thus, only the spectra of **9** are discussed. Its ^1H NMR spectra exhibit a single signal and a doublet for the methyl groups and single signals at 1.5 ppm for the *tert*-butyl group and 3.8 ppm for the bridging CH_2. Furthermore, the H atom in the 3-position is characterised by a doublet as well as the methyl group in the 4-position. The splitting is about 1 Hz (both signals) and is caused by ^4J coupling. The coordinated COD ligand on the metal centre gives two broad signals for the CH and two broad multiplies for the CH_2 group. Thus, **9** and **10** possess symmetry

in solution and only signals for half of the complexes are observed. The molecular structures (solid state) of **9** and **10** are shown in Figure 6 and Figure 7, respectively. Experimental details are summarised in Table 2.

In **9** and **10** deprotonated **5a** binds two metal centres accomplishing the *trans*55 binding mode. These dinuclear complexes are better described as mononuclear complexes with chelating bifunctional ligands in which only the ligands over an alkyl bridge are connected. Compounds **9** and **10** are not isostructural in the solid state.

Conclusions

The results of the present work allow several conclusions to be drawn. The alkyl-bridged imidazopyridazine-substituted bisamines can be synthesised by nucleophilic ring transformation followed by condensation reactions from nonexpensive starting materials in good yields, in large variety and in high purity. The deprotonated diamines can act as bisamido ligands. These ligands bind early and late transition metals as a five-membered chelate. Group 4 metal complexes are accessible via amine elimination and group 6 and 9 metal complexes via salt elimination reactions. In summary, we introduced a novel amido ligand system.

Experimental Section

General Procedures: All reactions and manipulations with air-sensitive compounds were performed under dry argon, using standard Schlenk and glove box techniques. Non-halogenated solvents were distilled from sodium benzophenone ketyl and halogenated solvents from P_2O_5. Deuterated solvents were obtained from Cambridge Isotope Laboratories and were degassed, dried and distilled prior to use. $[Ti(NMe_2)_2Cl_2]$ was prepared according a literature method.[11] All chemicals were purchased from commercial vendors and used without further purification. NMR spectra were obtained using either a Bruker ARX 250 or Bruker ARX 400 spectrometer. Chemical shifts are reported in ppm relative to the deuterated solvent. X-ray crystal structure analyses were performed by using a STOE-IPDS I or II equipped with an Oxford Cryostream low-temperature unit. Structure solution and refinement were accomplished using SIR97,[21] SHELXL-97[22] and WinGX.[23] Crystallographic details are summarised in Table 1 and Table 2. CCDC-267047 (for **5a**), -267042 (for **6**), -267044 (for **7**), -267043 (for **8**), -267046 (for **9**) and -267045 (for **10**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. Elemental analyses were carried out by the Vario elementar EL *III* or Leco CHNS-932 elemental analyser. Melting points were carried out in sealed capillaries, with a Büchi 535 apparatus or Stuart SMP3 apparatus. UV spectroscopic studies were carried out with a Varian CARY 3. The magnetic moment was determined with a magnetic susceptibility balance Sherwood Mark 1 MSB at room temperature.

Synthesis of Ligands and Ligand Precursors

***N*,*N*′-Bis(1-acetylamino-4-*tert*-butylimidazol-2-yl)ethylenediamine Hydrate (2a):** Ethylenediamine (0.48 mL, 0.43 g, 7.19 mmol) was added to 2-amino-5-methyl-3-(2-oxo-3,3-dimethylbutyl)-1,3,4-oxadiazolium bromide (2.00 g, 7.19 mmol) whilst stirring. The mixture was stirred for 1 min on a hot plate (250 °C) and was then allowed to reach room temperature. Water (20 mL) was added to the reaction mixture and colourless crystals formed after some hours. The product was recrystallised from ethanol/water (1:1 ratio). Yield 0.74 g (44%), m.p.146 °C. $C_{20}H_{34}N_8O_2{\cdot}2.5H_2O$ (463.53): calcd. C 51.82, H 8.84, N 24.17; found C 51.96, H 7.84, N 24.46. ^{1}H NMR ([D$_6$]DMSO): δ = 10.73 (sbs, 1 H, NH, acetylamino), 6.46 (s, 1 H, H-5, imidazole), 6.19 (br. s, 1 H, *NH*–CH_2), 3.57 (s, 2 H, CH_2), 2.18 (s, 3 H, CH_3), 1.38 [s, 9 H, –C*(CH$_3$)$_3$*] ppm. ^{13}C NMR ([D$_6$]-DMSO): δ = 169.21 (C=O), 148.35 (C-2, imidazole), 143.14 (C-4, imidazole), 108.67 (C-5, imidazole), 42.61 (CH_2), 31.52 [–*C*(CH_3)$_3$], 29.91 [–C*(CH$_3$)$_3$*], 21.15 (CH_3) ppm.

***N*,*N*′-Bis(1-acetylamino-4-phenylimidazol-2-yl)ethylenediamine (2b):** 2-Amino-5-methyl-3-phenacyl-1,3,4-oxadiazolium bromide (2.00 g, 6.72 mmol) and ethylenediamine (0.44 mL, 0.40 g, 6.72 mmol) were stirred for 1 min on a hot plate (250 °C) and then allowed to reach room temperature. After cooling to room temperature water was added. The resulting solid was recrystallised from ethanol. Yield 0.65 g (42%), m.p. 160 °C. $C_{24}H_{26}N_8O_2$ (458.48). ^{1}H NMR ([D$_6$]-DMSO): δ = 10.71 (s, 1 H, NH, acetylamino); 7.69–7.67 (d, 2 H, H$_o$, C_6H_5); 7.32–7.27 (t, 2 H, H$_m$, C_6H_5); 7.15–7.10 (t, 1 H, H$_p$, C_6H_5); 7.12 (s, 1 H, H-5, imidazole); 6.11 (br. s, 1 H, *NH*–CH_2); 3.49 (br. s, 2 H, *CH_2*–NH); 1.95 (s, 3 H, CH_3) ppm. ^{13}C NMR ([D$_6$]DMSO): δ = 168.78 (C=O); 149.25 (C-2, imidazole); 134.81 (C-1′, C_6H_5); 133.38 (C-4, imidazole); 128.11, 123.65 (C$_{o,m}$, C_6H_5); 125.48 (C$_p$, C_6H_5); 111.93 (C-5, imidazole); 42.34 (*CH_2*–NH); 20.64 (CH_3) ppm.

***N*,*N*′-Bis(1-acetylamino-4-phenylimidazol-2-yl)-1,3-diaminopropane Monohydrate (2c):** 1,3-Diaminopropane (0.56 mL, 0.50 g, 6.71 mmol) was added dropwise to 2-amino-5-methyl-3-phenacyl-1,3,4-oxadiazolium bromide (2.00 g, 6.71 mmol) and the reaction mixture was stirred for 1 min on a hot plate (250 °C). After cooling to room temperature water was added. The resulting solid was recrystallised from ethanol and a colourless product was obtained. Yield 0.57 g (34%), m.p. 179 °C. $C_{25}H_{28}N_8O_2{\cdot}H_2O$ (490.50): calcd. C 61.21, H 6.17, N 22.85; found C 61.55, H 5.85, N 22.85. ^{1}H NMR ([D$_6$]DMSO): δ = 10.98 (br. s, 1 H, NH, acetylamino), 7.93–7.92 (d, 2 H, H$_o$, C_6H_5), 7.57–7.53 (q, 2 H, H$_m$, C_6H_5), 7.40–7.38 (d, 1 H, H$_p$, C_6H_5), 7.36 (s, 1 H, H-5, imidazole), 6.32–6.29 (t, 1 H, *NH*–CH_2), 3.59–3.55 (q, 2 H, *CH_2*–NH), 2.20 (s, 3 H, CH_3), 2.15–2.09 (m, 1 H, *0,5CH_2*–CH_2–NH) ppm. ^{13}C NMR ([D$_6$]-DMSO): δ = 169.25 (C=O), 149.84 (C-2, imidazole), 135.29 (C-1′, C_6H_5), 133.86 (C-4, imidazole), 128.60, 124.08 (C$_{o,m}$, C_6H_5), 125.90 (C$_p$, C_6H_5), 112.27 (C-5, imidazole), 40.27 (CH_2–NH), 29.86 (*CH_2*–CH_2–NH), 21.15 (CH_3) ppm.

***N*,*N*′-Bis(1-amino-4-*tert*-butylimidazol-2-yl)ethylenediamine Dihydrochloride Dihydrate (3a):** Concentrated aqueous HCl (1.5 mL) was slowly added to a stirred suspension of *N*,*N*′-bis(1-acetylamino-4-*tert*-butylimidazol-2-yl)ethylenediamine hydrate (1.50 g, 3.24 mmol) in ethanol (20 mL). The mixture was heated for 1.5 h under reflux. The solvent was removed and colourless crystals were obtained and recrystallised from ethanol. Yield 1.40 g (98%), m.p. 230 °C. $C_{16}H_{30}N_8{\cdot}2HCl{\cdot}2H_2O$ (443.37): calcd. C 43.34, H 8.18, N 25.27; found C 42.98, H 7.81, N 25.02. ^{1}H NMR ([D$_6$]-DMSO): δ = 12.82 (s, 1 H, HCl), 8.01 (s, 1 H, NH), 6.76 (s, 1 H, H-5, imidazole), 6.15 (br. s, 2 H, NH_2), 3.89–3.88 (t, 2 H, CH_2), 1.44 [s, 9 H, –C*(CH$_3$)$_3$*] ppm. ^{13}C NMR ([D$_6$]DMSO): δ = 146.76 (C-2, imidazole), 133.62 (C-4, imidazole), 112.66 (C-5, imidazole), 42.44 (CH_2), 30.72 [–*C*(CH_3)$_3$], 29.04 [–C*(CH$_3$)$_3$*] ppm.

Complex Synthesis

Preparation of 6: A solution of bis(dimethylamino)titanium dichloride (0.22 g, 1.08 mmol) in diethyl ether (20 mL) was slowly added to a stirred orange solution of *N*,*N*′-bis(2,4-dimethyl-5-*tert*-butylimidazo[1,5-*b*]pyridazin-7-yl)ethylenediamine (0.50 g, 1.08 mmol) in diethyl ether (30 mL) and the reaction mixture turned into a dark violet colour. After stirring for 16 h the solvent was removed under vacuum. The residue was washed with 5 mL of hexane. The violet product was dried in vacuo. A concentrated solution of diethyl ether at –30 °C gave X-ray diffraction quality crystals. Yield 0.58 g (92%). $C_{26}H_{36}Cl_2N_8Ti$ (579.38): calcd. C 53.90, H 6.26, N 19.34; found C 54.43, H 6.48, N 19.66. ^{1}H NMR ([D_8]THF): δ = 6.25–6.24 (d, 1 H, $^4J_{H,H}$ = 1 Hz, H-3, imidazopyridazine); 4.99 (s, 2 H, *CH₂*–CH_2); 2.77 (s, 6 H, 2×CH_3); 1.56[s, 9 H, -C*(CH₃)₃*] ppm. ^{13}C NMR ([D_8]THF): δ = 153.46 (C-7, imidazopyridazine); 147.75(C-2, imidazopyridazine); 142.57, 142.03 (C-4, C-4a, imidazopyridazine); 124.46(C-5, imidazopyridazine); 109.86 (C-3, imidazopyridazine); 57.23 (*CH₂*–CH_2); 34.08 [–*C*$(CH_3)_3$]; 31.70 [–C*(CH₃)₃*]; 22.41 (*CH₃*–C-2); 20.63 (*CH₃*–C-4) ppm.

Preparation of 7: Tetrakis(diethylamino)zirconium (0.20 mL, 0.21 g, 0.54 mmol) was slowly added, via a syringe, to a stirred orange solution of *N*,*N*′-bis(2,4-dimethyl-5-*tert*-butylimidazo[1,5-*b*]-pyridazin-7-yl)ethylenediamine (0.25 g, 0.54 mmol) in diethyl ether (25 mL). The resulting dark violet reaction mixture was stirred for 3.5 h at room temperature. The solution was concentrated to 10 mL. After cooling to –78 °C dark violet crystals were obtained. The solution was decanted, concentrated and at –30 °C more crystalline product was obtained. The crystals were collected and dried under vacuum. Yield 0.27 g (73%), m.p. 236 °C. $C_{34}H_{56}N_{10}Zr$ (696.08): calcd. C 58.66, H 8.11, N 20.12; found C 57.41, H 8.01, N 19.74. ^{1}H NMR ([D_8]THF): δ = 5.77–5.76 (d, 1 H, $^4J_{H,H}$ = 1 Hz, H-3, imidazopyridazine), 4.14 (s, 2 H, *CH₂*–CH_2), 3.07–2.99 [q, 4 H, –*N*–(*CH₂*–CH_3)$_2$], 2.57–2.56 (d, 3 H, $^4J_{H,H}$ = 1 Hz, CH_3–C-4), 2.48(s, 3 H, CH_3–C-2), 1.47 [s, 9 H, –C*(CH₃)₃*], 0.57–0.51 [t, 6 H, (*CH₃*–CH_2)$_2$–*N*–] ppm. ^{13}C NMR ([D_8]THF): δ = 153.23 (C-7, imidazopyridazine), 149.02(C-2, imidazopyridazine), 143.70 (C-4, imidazopyridazine), 141.50 (C-4a, imidazopyridazine), 117.12 (C-5, imidazopyridazine), 107.60 (C-3, imidazopyridazine), 52.47

(CH_2–CH_2), 43.24 [–N–(CH_2–CH_3)$_2$], 33.82 [–C(CH_3)$_3$], 31.97 [–C$(CH_3)_3$], 22.45 (CH_3–C-4), 20.83 (CH_3–C-2), 14.29 (CH_3–CH_2)$_2$–N–) ppm.

Preparation of 8: *n*BuLi (1.21 mL, 3.02 mmol, 2.5 M in hexane) was slowly added to a stirred solution of *N*,*N*′-bis(2,4-dimethyl-5-*tert*-butylimidazo[1,5-*b*]pyridazin-7-yl)ethylenediamine (0.70 g, 1.51 mmol) in THF (10 mL) at –60 °C. After complete addition, the dark blue mixture was stirred for 1.5 h at –60 °C and warmed to –40 °C. At this temperature a suspension of [$CrCl_3$(THF)$_3$] (0.57 g, 1.51 mmol) in THF (10 mL) was added. The resulting dark green reaction mixture was stirred for 30 min at –40 °C and warmed to room temperature and stirred for a further 24 h. The solution was concentrated to ¼ of its volume and 30 mL of diethyl ether was added. The mixture was filtered, the residue washed with 10 mL of diethyl ether and 10 mL of hexane. The combined filtrates were concentrated to 15 mL. By cooling to –30 °C a dark green/blue crystalline product was obtained. Yield 0.57 g (69%), m.p. 307 °C. $C_{52}H_{72}Cl_2Cr_2N_{16}$ (1096.10): calcd.C 56.98, H 6.62, N 20.45; found C 57.42, H 7.11, N 20.02. μ_{eff} = 4.28 μ_B.

Preparation of 9: A solution of *N*,*N*′-bis(2,4-dimethyl-5-*tert*-butylimidazo[1,5-*b*]pyridazin-7-yl)ethylenediamine (0.70 g, 1.51 mmol) in THF (20 mL) was cooled to –78 °C. *n*BuLi (1.88 mL, 3.02 mmol, 1.6 M in hexane) was slowly added to this stirred solution via a syringe. The resulting dark blue reaction mixture was stirred for 30 min at –78 °C and then warmed to room temperature. After stirring for 30 min a solution of chloro-1,5-cyclooctadieneiridium(I) dimer (1.01 g, 1.51 mmol) in THF (30 mL) was added at 0 °C. The resulting dark green reaction mixture was stirred for 18 h at room temperature. The solution was concentrated to ¼ of its volume and 30 mL of dichloromethane was added. The mixture was filtered and the filtrate concentrated to dryness under vacuum. The resulting residue was recrystallised from toluene and dark green crystals were collected at –30 °C. Yield 1.34 g (84%), $C_{42}H_{60}Ir_2N_8$ (1061.38): calcd. C 47.52, H 5.70, N 10.56; found C 48.02, H 5.82, N10.83. ^{1}H NMR (CD_2Cl_2): δ = 5.62–5.61 (d, 1 H, $^4J_{H,H}$ = 1 Hz, H-3, imidazopyridazine), 4.51 (br. s, 2 H, 2×CH, COD), 4.32 (br. s, 2 H, 2×CH, COD), 3.80 (s, 2 H, CH_2–N), 2.58–2.57 (d, 3 H, $^4J_{H,H}$ = 1 Hz, CH_3–C-4), 2.36 (s, 3 H, CH_3–C-2), 2.24–2.11 (m, 4 H, 2×CH_2, COD), 1.77–1.66 (m, 4 H, 2×CH_2, COD), 1.48 [s, 9 H, C(CH_3)$_3$] ppm. ^{13}C NMR (CD_2Cl_2): δ = 159.88 (C-7, imidazopyridazine), 155.07 (C-2, imidazopyridazine), 149.71 (C-4, imidazopyridazine), 139.98 (C-4a, imidazopyridazine), 119.34 (C-5, imidazopyridazine), 108.56 (C-3, imidazopyridazine), 62.09 (2×CH, COD), 51.21 (2×CH, COD), 47.55 (CH_2–N), 34.98 [C(CH_3)$_3$], 31.71 [C$(CH_3)_3$], 31.64 (2×CH_2, COD), 30.64 (2×CH_2, COD), 23.10 (CH_3–C-2), 20.35 (CH_3–C-4) ppm.

Preparation of 10: A solution of *N*,*N*′-bis(2,4-dimethyl-5-*tert*-butylimidazo[1,5-*b*]pyridazin-7-yl)ethylenediamine (0.50 g, 1.08 mmol) in THF (10 mL) was cooled to –78 °C. *n*BuLi (0.86 mL, 2.16 mmol, 2.5 M in hexane) was slowly added to this stirred solution via a syringe. The resulting dark blue reaction mixture was stirred for 30 min at –78 °C and then warmed to room temperature. After stirring for 30 min a suspension of chloro-1,5-cyclooctadienerhodium(I) dimer (0.54 g, 1.08 mmol) in THF (20 mL) was added. The resulting dark green reaction mixture was stirred for 18 h at room temperature. The solution was concentrated to ⅓ of its volume and 30 mL of diethyl ether was added. The mixture was filtered and the precipitate was washed twice with 10 mL of diethyl ether. The combined filtrates were concentrated to dryness under vacuum. Crystals of **10** were grown from toluene at –30 °C. Yield 0.51 g (54%), m.p. 275 °C. $C_{42}H_{60}N_8Rh_2$ (882.78): calcd. C 57.14, H 6.85, N 12.69; found C 57.62, H 7.21, N 12.27. ^{1}H NMR (CD_2Cl_2): δ = 5.46 (s, 1 H, H-3, imidazopyridazine); 4.60 (br. s, 4 H, 4×CH, COD); 3.30 (s, 2 H, CH_2–N); 2.50 (s, 3 H, CH_3–C-4); 2.39–2.35 (m, 4 H, 2×CH_2, COD); 2.15 (s, 3 H, CH_3–C-2); 1.89–1.83 (m, 4 H, 2×CH_2, COD); 1.43 [s, 9 H, C(CH_3)$_3$] ppm. ^{13}C NMR (CD_2Cl_2): δ = 156.50 (C-7, imidazopyridazine); 152.47 (C-2, imidazopyridazine); 146.50 (C-4, imidazopyridazine); 138.74 (C-4a, imidazopyridazine); 116.98 (C-5, imidazopyridazine); 106.55 (C-3, imidazopyridazine); 77.24, 77.13, 69.62, 69.53 (4×CH, COD); 46.58 (CH_2–N); 33.46 [C(CH_3)$_3$]; 31.35 [C$(CH_3)_3$]; 30.21 (2×CH_2, COD); 29.74 (2×CH_2, COD); 22.01 (CH_3–C-2); 19.00 (CH_3–C-4) ppm.

Acknowledgments

We thank Anke Spannenberg, Wolfgang Saak and Wolfgang Milius for their support in the X-ray laboratories and Dominikus Huttner for his assistance in obtaining the UV/Vis data. Financial support from the Fonds der Chemischen Industrie is gratefully acknowledged.

Mössbauer Investigation of Peroxo Species in the Iron(III)–EDTA–H_2O_2 System

Virender K. Sharma,[a] Petra Á. Szilágyi,[b] Zoltán Homonnay,*[b] Ernő Kuzmann,[c] and Attila Vértes[b,c]

Keywords: Chelates / EDTA / Iron / Mössbauer spectroscopy / Peroxo ligands

The reaction of a diiron(III)–EDTA complex with H_2O_2 in alkaline medium is studied by Mössbauer spectroscopy in conjunction with the rapid-freeze/quench technique in order to identify possible intermediate species during the formation and decomposition of the purple $(EDTA)Fe^{III}(\eta^2\text{-}O_2)^{3-}$ complex ion. Starting from the six-coordinate $[Fe^{III}EDTA]^-$ species at acidic pH, it is demonstrated that mononuclear complexes formed at a pH of about 1 are convert into the diiron(III)–EDTA complex $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]^{4-}$ upon raising the pH to around 10.4. H_2O_2 reacts with the diiron(III) complex to give peroxide/hydroperoxide related adducts. Initially, the reaction tears apart the dimers to form a peroxo adduct, namely the seven-coordinate mononuclear $[(EDTA)Fe^{III}(\eta^2\text{-}O_2)]^{3-}$, which is stable only at very high pH. The decomposition of this peroxo adduct gives two new species, which are reported for the first time. The Mössbauer parameters of these species suggest a six-coordinate μ-peroxodiiron(III) complex $[(EDTA)Fe^{III}\text{-}(OO)\text{-}Fe^{III}(EDTA)]^{4-}$ and a seven-coordinate μ-hydroxo-μ-peroxodiiron(III) complex $[(EDTA)Fe^{III}\text{-}(OO)(OH)\text{-}Fe^{III}(EDTA)]^{5-}$. A badly resolved, extremely broad component is observed in the Mössbauer spectra during the conversion of the monomer to dimeric peroxo species, which may be attributed to the short-lived $[(EDTA)Fe^{III}\text{-}OO]^{3-}$ or $[(EDTA)Fe^{III}\text{-}OOH]^{2-}$ intermediate species.

Introduction

There has been increasing interest in the reactivity of the iron(III)–ethylenediaminetetraacetate (Fe^{III}-EDTA) system because of its importance in inorganic chemistry, biochemistry, and industrial chemistry.[1] One of the most important reactions is the formation of the purple peroxoiron complex $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$ in the reaction between $[Fe^{III}\text{-}(EDTA)]^-$ and hydrogen peroxide (H_2O_2)[1,2] as peroxoiron species play an important role in the oxygen activation and transfer reactions mediated by heme and nonheme iron proteins.[3,4] The characterization of a peroxoiron intermediate has been performed spectroscopically in methane monooxygenase and ribonucleotide reductase.[4,5] Peroxoiron complexes have also been shown to catalyze the polymerization of styrene and organic substrates.[6,7] The formation of a peroxoiron complex in the decomposition of hydrogen peroxide by Fe^{III} in aqueous solution is relevant in the chemistry of natural waters and atmospheric water droplets,[8–10] and the presence of a peroxo complex in Fenton-like ($Fe^{II} + H_2O_2$) and photo-Fenton ($Fe^{II} + H_2O_2 + UV$) reactions has been suggested.[11]

Recently, we have studied the kinetics of the formation of the purple complex, $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$ by the reaction of $[Fe^{III}(EDTA)H_2O]^-$ with hydrogen peroxide by using a stopped-flow technique.[2] The rate law for the formation of the complex was found to be $d[\{Fe^{III}(EDTA)(\eta^2\text{-}O_2)\}^{3-}]/dt = k[\{Fe^{III}(EDTA)H_2O\}^-][H_2O_2]$, where the observed second-order rate constant, k, decreases with an increase in pH and appears to be related to the deprotonation of $[Fe^{III}(EDTA)H_2O]^-$ [Equation (1)].

$$[Fe^{III}(EDTA)H_2O]^- \overset{K_1}{\leftrightarrows} [Fe^{III}(EDTA)OH]^{2-} + H^+ \qquad pK_1 = 7.58^{[12]} \qquad (1)$$

Brausam and van Eldik[1] have performed a detailed study on the reaction between $[Fe^{III}(EDTA)(H_2O)]^-$ and hydrogen peroxide. The reaction consists of two steps, in which the second step is independent of the hydrogen peroxide concentration. The first involves the reversible end-on coordination of H_2O_2 to give an intermediate, $[Fe^{III}(EDTA)\text{-}OOH]^{2-}$, which undergoes an intramolecular rearrangement to give the high-spin Fe^{III} side-on bound peroxo complex $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$.

The kinetic measurements in the work of Brausam and van Eldik[1] and in our study were conducted using a total Fe^{III} concentration of $\leq 1 \times 10^{-3}$. Under these conditions,

the Fe^{III}–EDTA complex exists predominantly in the monomeric form (>90%). However, at concentrations higher than 1×10^{-3} M of the complex, the formation of a dimer occurs[12–15] [Equations (2) and (3)].

$$2\,[Fe^{III}(EDTA)OH]^{2-} \overset{K_2}{\leftrightarrows} [(EDTA)Fe^{III}\text{–}O\text{–}Fe^{III}(EDTA)]^{4-} + H_2O \qquad (2)$$

$$pK_2 = -2.95$$

$$2\,[Fe^{III}(EDTA)H_2O]^{-} \overset{K_3}{\leftrightarrows} [(EDTA)Fe^{III}\text{–}O\text{–}Fe^{III}(EDTA)]^{4-} + 2\,H^+ + H_2O \qquad (3)$$

$$pK_3 = 12.21$$

The overall equilibrium (3) represents the combination of Equations (1) and (2).

The spectral studies of the Fe^{III}–EDTA system at various pH's indicated that the concentration of the dimer species depends on the pH and the concentration of the complex.[12–17] The maximum concentration of the dimer is obtained at pH $\geq$ pK_1.

In recent years, there has been tremendous interest in diiron complexes due to their role in biological systems.[3,4,18] For example, several metalloproteins contain a carboxylate-bridged diiron center, which performs a variety of functions.[19,20] This has prompted many workers to develop small molecule synthetic model compounds for nonheme, dinuclear iron-based metalloproteins.[19–22] Studies of such compounds with hydrogen peroxide help us to understand the function of an enzyme that catalyzes an important chemical transformation. Moreover, characterizing the peroxodiiron(III) intermediates in the reactions will eventually enhance our understanding in the biological environment.[19,23]

In the present work, we have selected diiron(III)–EDTA {i.e., $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]^{4-}$} as a simple compound to study the formation of peroxo-bridged complexes in the reaction with hydrogen peroxide at a pH of around 10.4. Mössbauer spectroscopy in conjunction with the rapid-freeze/quench technique was used to characterize the formation of the Fe^{III}–peroxo species formed during the reaction. The results demonstrate the conversion of the diiron(III)–EDTA complex into a purple Fe^{III}–peroxo species. In addition to the formation of the already characterized monomeric species $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$, another two peroxodiiron(III) species are reported for the first time.

Results and Discussion

Initially, the Mössbauer spectrum of 0.05 M $Fe(NO_3)_3$ at a pH of around 1.0 was measured as a simple reproduction of literature data[24] (Figure 1, a). The spectrum shows a slightly broadened, relaxational line shape, which is in agreement with the expected slow paramagnetic relaxation of monomeric Fe^{3+} ($3d^5$) species at this concentration. Addition of a stoichiometric excess of EDTA to the 0.05 M $Fe(NO_3)_3$ stock solution resulted in the formation of iron–EDTA species, as shown in Figure 1 (b). A well-developed sextet shows up, with some broadening, with a typical relaxation spectrum in the middle. Our spectrum is similar to those published by other authors who have studied the aqueous Fe^{III}–EDTA system in frozen solutions by Mössbauer spectroscopy.[25–27] The spectrum obviously indicates two different species, so it was evaluated as a superposition of a relaxational component for the central part (Species **A1**) using the Blume–Tjon two-state relaxation model implemented in MossWinn 3.0,[28] and a Lorentzian sextet (Species **A2**). The parameters are given in Table 1. Both components indicate that the relaxation rate of the Fe^{3+} spins decreases as an effect of the complexing agent. More importantly, it also shows that association of the Fe species does not take place, the significance of which at high pH will be seen later. Our observation, and the spectrum of the Fe–EDTA system (Figure 1, b) itself, are very similar to the spectrum found by Morup and Knudsen[29] for frozen aqueous solution of $FeCl_3$ containing $[Fe(H_2O)_6]^{3+}$ and $[Fe(H_2O)_5Cl]^{2+}$ species in about a 1:1 proportion.

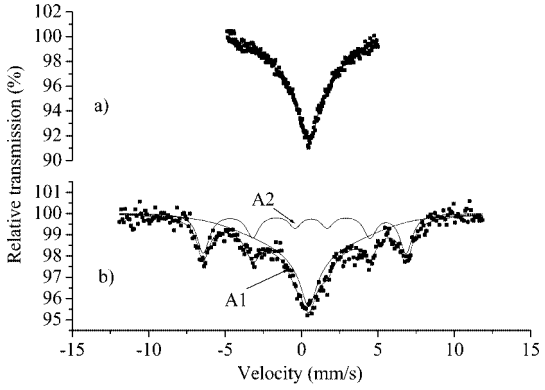

Figure 1. Mössbauer spectra of a frozen solution of 0.05 M $[Fe^{III}(EDTA)]^-$ at a pH of about 1 prepared with nitric acid (a) and after addition of EDTA in stoichiometric excess (b).

The structure of these monomeric species may be considered to be very close to that of $[Fe^{III}(EDTA)(H_2O)]^-$, which is present in solid $Na[Fe^{III}(EDTA)(H_2O)]\cdot 2H_2O$ (**S**). In this solid, the first water molecule is directly coordinated to the Fe^{3+} center, while the other two are crystal water molecules. We have measured the Mössbauer spectrum of solid $Na[Fe^{III}(EDTA)(H_2O)]\cdot 2H_2O$ at 80 K under the same conditions as the frozen solution samples so that direct comparison becomes possible. The well-known amplitude asymmetry of the doublet was observed, which is the result of the differing Larmor precession time of the m_I = 1/2 to 1/2 and m_I = 1/2 to 3/2 nuclear transitions (m_I is the magnetic quantum number) of the ^{57}Fe nucleus. Thus, the slight relaxational broadening of the doublet lines representing these two transitions is not the same under the same conditions. This phenomenon is often called the Blume effect.[30,31] The observed Mössbauer parameters (i.e., the

Table 1. Mössbauer parameters of various Fe^{III}–EDTA species observed at 80 K. δ: isomer shift; Δ: quadrupole splitting; 2ε: quadrupole shift (in case of magnetic splitting); B: internal magnetic field. The uncertainties of the parameters are estimated on the basis of the errors of individual fits of those spectra in which the abundance of that particular species was larger than 10%.

Species	Description	pH	Coord. number	δ [mm s^{-1}]	Δ or 2ε* [mm s^{-1}]	B [T]
S	$[Fe(EDTA)(H_2O)]^-$ in solid $Na[Fe(EDTA)(H_2O)]\cdot 2H_2O$		7	0.57(1)	0.66(1)	≈0
A1	$[Fe(EDTA–H)(H_2O)]$	≈1.0	6	0.48(11)	+0.16(45)*	30(6)
A2	$[Fe(EDTA)]^-$	≈1.0	6	0.43(2)	–0.44(5)*	41.2(2)
B	$[(EDTA)Fe\text{-}O\text{-}Fe(EDTA)]^{4-}$	≈10.4	6	0.455(5)	1.60(5)	0
F	$[(EDTA)Fe(\eta^2\text{-}O_2)]^{3-}$	≈10.4	7	0.62(4)	+0.53(5)*	51.1(5)
D	$[(EDTA)Fe\text{-}(OO)(OH)\text{-}Fe(EDTA)]^{5-}$	≈10.4	7	0.57(1)	0.40(3)	0
E	$[(EDTA)Fe\text{-}(OO)\text{-}Fe(EDTA)]^{4-}$	≈10.4	6	0.47(3)	0.85(4)	0

high isomer shift) given in Table 1 are consistent with sevenfold coordination of Fe^{3+} in the solid species **S**.[32] Note that the solubility limit of $Na[Fe^{III}(EDTA)(H_2O)]\cdot 2H_2O$ did not allow us to perform experiments in aqueous solution, in which magnetic relaxation would be absent, because, even in the solid, the average distance between Fe^{3+} ions is not small enough to speed up spin relaxation, so no magnetic field is observed.

There is an apparent contradiction between the isomer shifts observed for solid $Na[Fe^{III}(EDTA)(H_2O)]\cdot 2H_2O$ (**S**) and the aqueous Fe^{III}–EDTA complexes (**A1** and **A2**) at a pH of around 1.0 (Table 1). This is not surprising because one of the carboxylic groups is very likely to become protonated in highly acidic solution, which results in dechelation of this carboxylic group from the coordinative bond and results in sixfold coordination of the central Fe^{3+}. Such species have been observed by Spijkerman et al.[33] in the solid $Fe^{III}(EDTA\text{-}H)(H_2O)$ with Mössbauer parameters δ = 0.45(5) mm s^{-1} and Δ = 0.42(5) mm s^{-1} at 78 K. It is reasonable to assume that due to a protolytic equilibrium (which means acid-catalyzed exchange of a water molecule and a carboxylate group at one of the six coordination sites of the central Fe^{3+} ion), one of the two subspectra in our Mössbauer spectrum represents $[Fe^{III}(EDTA\text{-}H)(H_2O)]$, while the other can be assigned to $[Fe^{III}(EDTA)]^-$, both of which contain sixfold coordinated Fe^{3+}, in agreement with the observed isomer shifts. Since both the magnetic field and the relaxation time are expected to increase with increasing electron donation to the Fe 3*d* orbitals, we can tentatively assign the structure $[Fe^{III}(EDTA\text{-}H)(H_2O)]$ to species **A1** and $[Fe^{III}(EDTA)]^-$ to species **A2**, although the quadrupole splitting for species **A1** observed by us is smaller than that in ref.[33] Note that the quadrupole shift of **A2** may not be directly related to quadrupole splitting data obtained from Lorentzian fits of nonmagnetic species because the relative orientation of the electric field gradient and the magnetic field is not known. We note here that Kanamori et al.[34] have found hexacoordinate Fe^{III}–EDTA species in solution only at even lower pH (in 1–2 M HCl) using Raman spectroscopy, while at pH 1.2 they identified heptacoordinate species. The presence of chloride vs. nitrate anions (the latter in our case) may have some significance in this discrepancy.

As a next step, measurements on the Fe^{III}–EDTA system were conducted in alkaline medium. The pH of the 0.05 M Fe^{III}–EDTA solution was raised to about 10.4, which resulted in precipitation of some hydrous iron(III) oxide, as checked by a Mössbauer run. (This precipitation is most probably due to kinetic effects, and has also been observed by other authors.[35]) The solution was filtered and the filtrate was frozen to record the Mössbauer spectrum (Figure 2, a). The expected species present in alkaline solution is $[Fe^{III}(EDTA)OH]^{2-}$ [Equation (1)]. However, the Mössbauer spectrum of the frozen solution showed no sign of any magnetic splitting (in agreement with the observation of Kachanova et al.[26]) due to very fast spin-spin relaxation. The doublet of Figure 2 (a) can therefore be assigned to a dimer species. The Mössbauer parameters of the doublet were found to be δ = 0.44(2) mm s^{-1} and Δ = 1.6(1) mm s^{-1} (Table 1). Marton et al.[16] have assigned this doublet to an oxo-bridged species $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}\text{-}(EDTA)]^{4-}$ (**B**), which implies a coordination number of 7 for both Fe^{3+} centers. If this assignment is correct, the simple rule that an increasing coordination number results in increasing isomer shift, which seems to work for momoneric species,[32] would not work when going from monomer to dimer [Equation (2)]. This isomer shift implies sixfold coordination, which would be in agreement with the suggestion of Kanamori et al.,[34] who claim that one carboxylate on each Fe center is dechelated. On the other hand, the driving force for dechelation could be a tendency to gain a more symmetrical (closer to octahedral) and therefore energetically favorable structure for the ligand sphere of iron, which would certainly result in a low quadrupole splitting. In contrast, a large quadrupole splitting is observed, which is not characteristic for Fe^{3+} (although not uncommon for μ-oxo dimers[36]), and shows a highly distorted electronic structure. It has been proposed that the [Fe-O-Fe] moiety has a closely linear structure,[14,15] and now it is logical to assume that this linearity is, at least partially, enforced by the bulky and spatially highly restricted EDTA ligand, and that even after the dechelation of one carboxylate arm, it still remains severely distorted, causing a high quadrupole splitting in the Mössbauer spectrum. The stability of the Fe–O–Fe bridge seems to overcompensate the destabilization of the ligand sphere of iron caused by distortion. Thus, there seem to be more arguments in favor of the sixfold coordination of iron in the dimeric species **B**. Our reasoning is strongly supported by the single crystal XRD study of Ozarowski et al.[37] on $Na_4[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]\cdot 3H_2O$, who

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

found sixfold coordination with one dechelated carboxylate group for each EDTA ligand. Our results thus show that this coordination number is preserved in high pH aqueous solutions. On the other hand, it is interesting to note that Schugar et al.[35] have reported Mössbauer data on solid $Na_4[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]\cdot 12H_2O$, for which the isomer shift (0.44 mm s^{-1} at 77 K) matches our observation for dissolved $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]^{4-}$ perfectly, although the quadrupole splitting is somewhat larger at 1.94 mm s^{-1}. This is an indication of different distortions of the ligand sphere of Fe^{3+} in the solid crystal and in the alkaline aqueous solution.

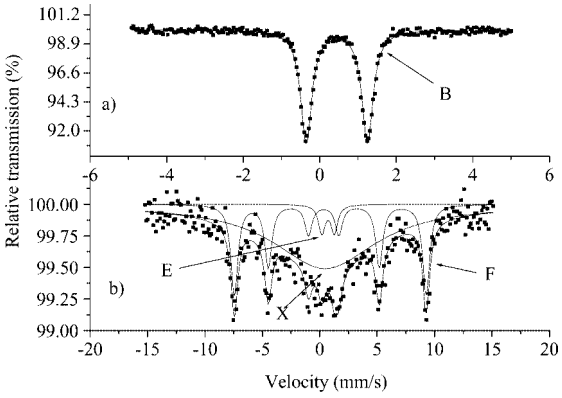

Figure 2. The Mössbauer spectrum of a frozen solution of the Fe^{III}–EDTA system at a pH of about 10.4 (a) and the spectrum after addition of excess H_2O_2 (b).

A very interesting example of the structure of the $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]^{4-}$ moiety in solids has been presented by Gomez-Romero et al.,[38] who reported results on the heterobimetallic complex $[Cu^{II}(en)_2]_2[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]\cdot 2H_2O$ and also found six-coordinate iron, although the dechelated fourth carboxylate arm of EDTA is coordinated in this complex to the neighboring Cu center according to XRD analysis.

It should be pointed out that the Mössbauer parameters of monomeric $[Fe^{III}(EDTA)(OH)]^{2-}$ are not known because dissociation of the dimers at high pH would become significant in a low concentration range where recording a Mössbauer spectrum is not feasible even with ^{57}Fe-enriched material.

Finally, the Mössbauer study of the reaction of iron(III)–EDTA with H_2O_2 was conducted in alkaline medium. Addition of H_2O_2 to the Fe^{III}–EDTA system at a pH of around 10.4 gave a purple coloration of the solution, which has been attributed to the formation of an $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$ species (**F**) by several spectroscopic techniques.[39–41] The Mössbauer spectrum of the purple species shows a sextet (Figure 2, b), thus indicating that the dimer species (**B**) is converted into a monomer (**F**) by hydrogen peroxide. This is due to the side-on coordination of the peroxide ion, which saturates the coordination environment of the Fe center and steric hindrance does not allow the coordination of another Fe. The observed large isomer shift (Table 1) is consistent with an increased coordination number of the iron centers. Brausam and van Eldik[1] have suggested that iron is seven-coordinate in this complex, which means dechelation of one carboxylate arm (pentadentate EDTA), although they cited theoretical calculations in the literature that were in favor of sixfold coordination.[40] XAS measurements on peroxoiron(III) complexes with pentadentate N-donor ligands by Koehntop et al.[42] were not always conclusive either regarding the exact coordination number of iron (side-on or end-on bonding of O_2^{2-}). Our Mössbauer data support minimum sevenfold coordination on the basis of the large isomer shift. Horner et al.,[41] who prepared $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$ in a very pure form in solution, also found a large isomer shift but these authors did not discuss possible implications for the coordination number. A comparison with the six-coordinate $[Fe^{III}(EDTA\text{-}H)(H_2O)]$ (**A1**) and $[Fe^{III}(EDTA)]^-$ (**A2**) shows that the increase in the Fe 3*d* (spin-)density as a result of the "7th ligand" in the coordination sphere of Fe^{3+} appears to be enough to further raise the magnetic field to 50.4 T. It is also remarkable that the quadrupole shifts for the monomeric $[Fe^{III}(EDTA)]^-$ (**A2**) and monomeric $[Fe^{III}(EDTA)(\eta^2\text{-}O_2)]^{3-}$ (**F**) have opposite signs (Table 1). The exact interpretation of this observation would be difficult but the substantial difference in the symmetry of the two systems makes it quite reasonable.

In addition to species **F**, two other species, **E** and **X**, were also observed (Figure 2, b). A small doublet for species **E** co-exists with the sextet (species **F**), with an isomer shift of $\delta = 0.46$ mm s^{-1} (see Figure 2, b). This component was found to be formed from the sextet component. Doublet **E** has no magnetic splitting, therefore it was assigned to a dimer species (Table 1). It is worth mentioning that peroxodiiron(III) coordination compounds with other ligands have very similar Mössbauer parameters.[36] Species **X** shows-up with extreme line broadening, which is most probably due to relaxation.

The fate of the purple solution was studied in a separate experiment. In this experimental set-up, Fe^{III}–EDTA and H_2O_2 solutions were mixed in the dark and the Mössbauer spectrum of the frozen purple solution was recorded (Figure 3, a). We have observed many times in our experiments that light influences the rate of the reactions in the Fe–EDTA–H_2O_2 system. This effect is not unknown, but is rather unexplored in detail. We deliberately used this phenomenon to slow down or speed up reactions but we do not attempt in this work to give an explanation for this photochemical effect. The formation of species **F**, **E**, and **X** occurred similar to the observations made in the previous experiment (Figure 2, b). The frozen solution was then allowed to melt for 5 min at room temperature in the dark and a Mössbauer spectrum was recorded again after freezing of the solution (Figure 3, b). The fraction of doublet **E** increased slightly at the expense of **X**. Species **X** is thus an intermediate in the conversion of species **F** to **E**. After further aging at room temperature for 10 min under daylight conditions, an abrupt change in the Mössbauer spectra was observed. Species **F**, **E**, and **X** all disappeared, and a new species having a doublet with an isomer shift, δ, of 0.57 (**D**) formed in addition to the already known oxo-bridged species $[(EDTA)Fe^{III}\text{-}O\text{-}Fe^{III}(EDTA)]^{4-}$ (**B**; Figure 3, c).

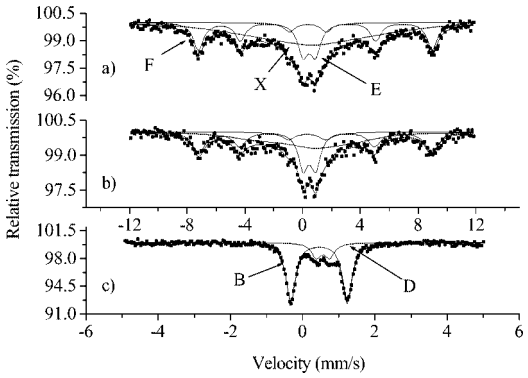

Figure 3.Mössbauer spectra of the Fe^{III}–EDTA–H_2O_2 system at a pH of about 10.4: a) initial state, b) after 5 min aging at room temperature (room temp.) in the dark, and c) after a further 10 min aging at room temp. in daylight.

The formation of species **B** from species **D** was confirmed by conducting the reaction between Fe^{III}–EDTA and H_2O_2 at room temperature in daylight, where formation and decay of the purple species is fast. The Mössbauer spectra of the reaction are given in Figure 4. Species **X** and **E** were not observed. This further suggests the intermediate nature of these species. The initial spectra show traces of the sextet of species **F** together with doublets of species **B** and **D** (Figure 4, a). Species **D** decays quickly to the original Fe^{III}–EDTA species **B** (Figure 4, b and c). It is noteworthy that the color of the solution belonging to the Mössbauer spectrum of Figure 4 (b) is still purple. Since **B** has a yellow color, species **D** should be responsible for the characteristic purple color of this solution. It is tentatively assumed (since it has been observed only together with the purple species **F**) that species **E** also has a purple color as a consequence of the presence of the peroxo moiety.

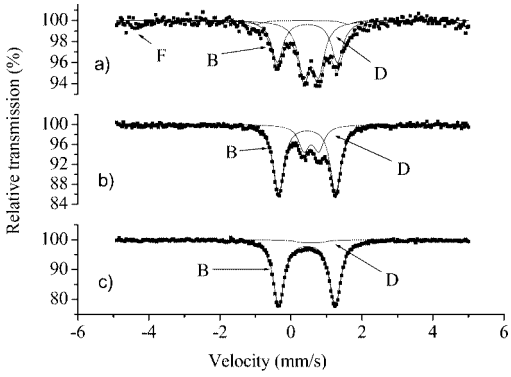

Figure 4. Evolution of Fe-bearing species in the Fe^{III}–EDTA–H_2O_2 system at a pH of about 10.4 in daylight: initial state (a), after 4 min aging at room temp. (b), and after 10 min aging at room temp. (c).

To further understand the conversions of species in the purple solution, another study was conducted at low temperature in darkness in order to slow down the reactions. The Fe^{III}–EDTA and H_2O_2 were mixed in an ice bath (ca. 0 °C) and the spectra were recorded after aging the mixture in consecutive three-minute steps (Figure 5). All agings were carried out at around 0 °C. A slow evolution of the various species from **B** to **F** (and **X**) to **E** at low temperature was observed. The formation and decomposition of species **X** is pronounced (Figure 5, c and d). Since species **X** shows up together with **F** and/or **E**, it is reconfirmed now that it should represent a very short-lived (to account for the extremely large line broadening) transitional state between **F** and **E**. We should note here that in the spectra c and d of Figure 5 and b of Figure 2, the assignment of the very small doublets (3–4%) to species E is rather tentative due to statistical insignificance; this doublet is fully developed only in the spectra in Figure 5 (e) and Figure 3 (a and b).

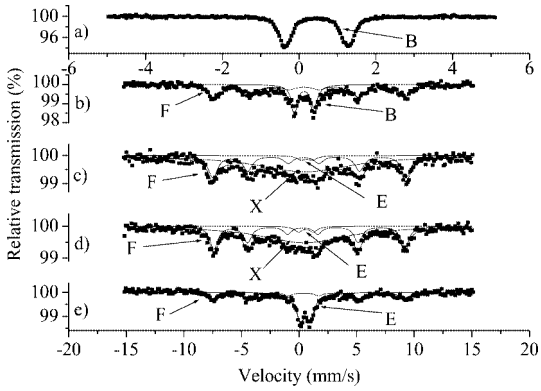

Figure 5. Evolution of Fe-bearing species in the Fe^{III}–EDTA–H_2O_2 system at a pH of about 10.4 (initial value before adding H_2O_2) at around 0 °C: a) before addition of H_2O_2, b) immediately after addition of H_2O_2, c) after 3 min aging at 0 °C, d) after an additional 3 min of aging at 0 °C, and e) after a second additional 3 min of aging at 0 °C.

The formation and the decomposition of species **F** may be summarized as shown in Schemes 1 and 2, respectively. In Scheme 1, the dimer species **B** is converted into the monomeric species **F** upon the addition of hydrogen peroxide. The decay of the monomer **F** to dimer **E** (Scheme 2) takes place through intermediate **X** (structure not shown).

The observation of species **X** is probably the consequence of an equilibrium giving a short-lived monomeric [(EDTA)-Fe^{III}-OO]$^{3-}$ species or its protonated form [(EDTA)Fe^{III}-OOH]$^{2-}$ (with end-on coordination of O_2^{2-} to iron). Only the much more stable dimer (**E**) clearly shows up in the Mössbauer spectra. The isomer shift of species **E** is practically the same as that of species **B** and formally corresponds to a sixfold coordinated monomeric species. This indicates that the dechelation of one carboxylate arm at each iron center occurs here, similar to the species **B**. At the same time, since the peroxo bridge allows larger separation of the Fe^{III}–EDTA moieties as compared to the case of a regular oxo bridge, the repulsion between the two pentadentate EDTAs and, inherently, their spatial distortion is smaller, which results in only half of the quadrupole splitting found for species **B**. It is noteworthy that in this picture, the isomer shift does not differ for a μ-oxo and a μ-peroxo species as the difference in the donicity of the oxo and peroxo oxygens (as a sixth ligand around the Fe^{3+} center) is probably not substantial.

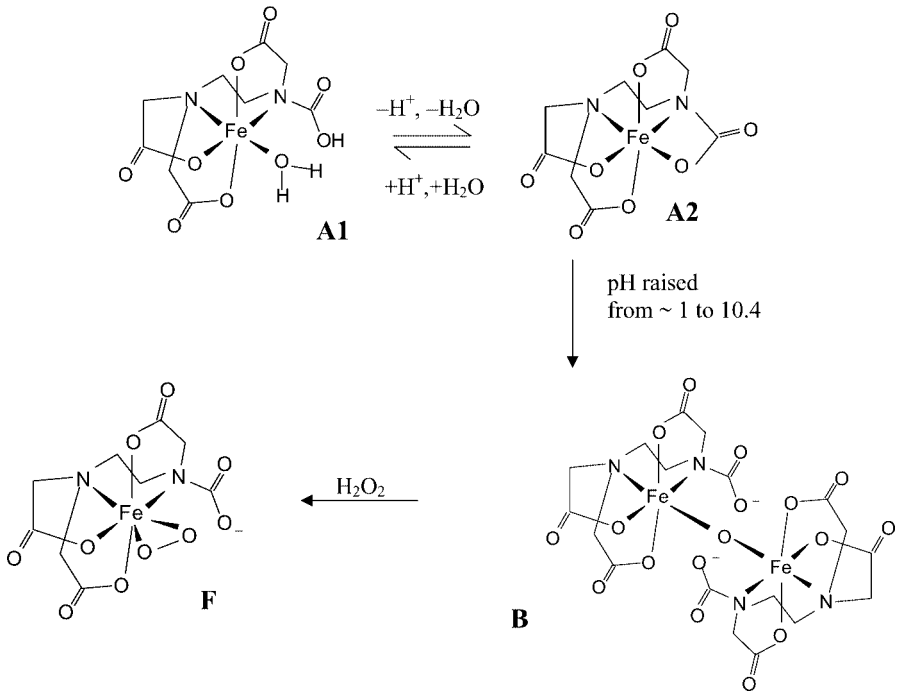
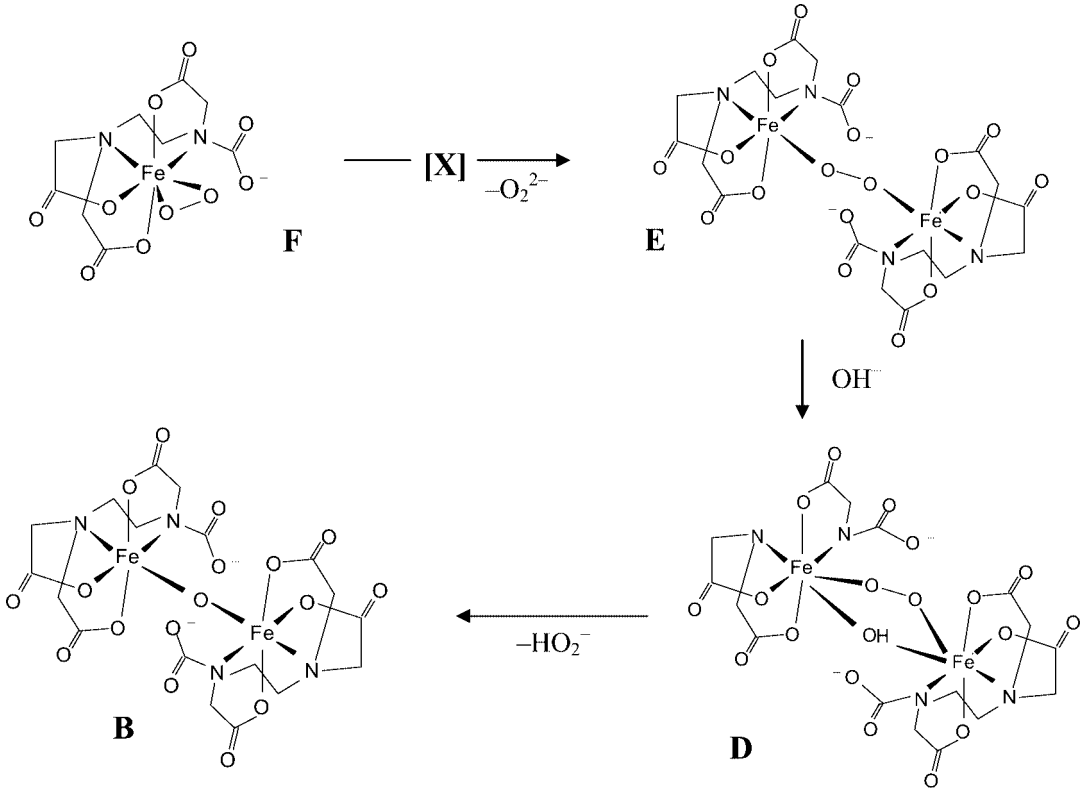


Scheme 1.



Scheme 2.

The driving force for the transformation of monomeric species **F** to dimeric species **E** could be the loss of H_2O_2 due to its decomposition. The decomposition of H_2O_2 results in an increase in the pH since H_2O_2 is more acidic then H_2O. Therefore, further decomposition of species **E** may occur through the addition an OH^- ion to form a doubly bridged species **D**. Doubly and triply bridged binuclear complexes of Fe^{III} with nonequivalent bridging ligands are known, for example (μ-carboxylato)(μ-oxo)diiron(III)-type compounds.[43] We are not aware of any reports of (μ-hy-

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

droxo)(μ-peroxo)diiron(III) complexes, which may be due to their low stability, as found here. The isomer shift of species **D** is significantly higher than that of species **E**, which is in agreement with the increased coordination number (7). The decrease of the quadrupole splitting cannot be fully understood in this simple picture.

At this stage, decomposition (further loss) of H_2O_2 and the concomitant rise in pH logically drives us back to species **B**.

We have to mention here that the proposed structures for species **E** and **D**, which should be very logical, may not be the ultimate choice. For example, partial protonation of the peroxo bridge may occur, which would result in the species $[(EDTA)Fe^{III}\text{-}HOO\text{-}Fe^{III}(EDTA)]^{2-}$. However, such a species contains nonequivalent iron centers, and thus two doublets are always expected to be a pair in the Mössbauer spectrum. This is not observed. It is assumed that the position of the proton is not averaged out between the two oxygens on the Mössbauer timescale, and that the Mössbauer parameters of the two nonequivalent irons would be significantly different. Thus, since species **D** is a peroxo-type dimeric species, the increase of the isomer shift upon going from species **E** to **D** can be considered as a strong argument to support the formation of the double bridge.

Experimental Section

A stock solution of $Fe(NO_3)_3$ (0.05 M) was prepared by dissolving metallic iron (enriched in ^{57}Fe to ca. 90%) in nitric acid. The final pH of this stock solution was about 1.0. The Mössbauer measurements were performed by mixing the iron(III) solution (500 μL, 0.05 M) with solid EDTA. The amount of EDTA in the mixture was in excess and the final molar ratio of EDTA to Fe^{III} was 1.3:1. The pH of the solution, measured with a digital pH meter (Radelkis), was adjusted by adding KOH (0.5 M). At alkaline pH, some precipitate was observed in the Fe^{III}–EDTA solution. This precipitate were filtered off through a 5-μm filter. The filtrate was diluted with distilled water to achieve 1.0 mL total volume. No further precipitation of the solution was observed.

The reaction of Fe^{III}–EDTA with hydrogen peroxide was studied by adding H_2O_2 (50 μL, 30%) to the solution. The concentration of H_2O_2 in the final solution was in large excess. The resultant deep-purple solution was quenched immediately drop-by-drop on a pre-cooled metal slab almost completely immersed in liquid nitrogen. The freezing of the total volume (15–20 droplets) lasted for about half a minute. Vértes[24] has shown previously that this quenching technique (cooling speed ca. 30 °C s^{-1}) preserves the structure of the solution, and therefore the species existing in the liquid state can be studied. The frozen droplets were collected in a sample holder and placed into a bath-type cryostat filled with liquid nitrogen.

The frozen samples were measured by a conventional constant acceleration type Mössbauer spectrometer (Ranger). The spectrum evaluations were carried out with the assumption of a Lorentzian line-shape, unless otherwise stated, using MossWinn 3.0.[28] All isomer shifts are given relative to α-Fe at room temperature.

Structural Trends in Divalent Benzil Bis(thiosemicarbazone) Complexes

David G. Calatayud,[a] Elena López-Torres,[a] M. Antonia Mendiola,*[a] César J. Pastor,[b] and Jesús R. Procopio[c]

Keywords: Copper / N ligands / S ligands / Thiosemicarbazone complexes / Zinc

Redox-related changes in the biological properties of copper bis(thiosemicarbazones) are induced by the backbone of the ligand. To get information about how these changes depend on the structural parameters, three X-ray structures of complexes with different behaviour of the benzil bis(thiosemicarbazone) ligand have been determined. These include two almost planar copper(II) complexes with different grades of deprotonation in the ligand and a Zn^{II} complex in which the ligand acts as a monoanion and a nitrate group is bonded to the metal ion in a square-based pyramid. The changes in the backbone bond lengths agree with the variation in the ionic radius and with the grade of electronic charge delocalisation in the chelate rings; these have consequences for the coordination sphere, allowing the metal to fit slightly better into the ligand cavity, which in turn may affect the complex stability and the redox potential.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The increasing interest in thiosemicarbazones (TSCs) that has arisen in the last decades is related to their wide range of biological properties, for example as antiviral, antibacterial and anticancer agents.[1–4] These biological activities are often attributed to their chelating ability with metal ions. Copper complexes of bis(thiosemicarbazones) have been investigated for use as anti-cancer chemotherapeutic agents[5,6] and as superoxide dismutase-like radical scavengers.[7] It is, however, their use as delivery agents for radioactive copper in new copper-based radiopharmaceuticals and the hypoxic selectivity of certain copper bis(thiosemicarbazonate) complexes that has created much recent interest.[8–20] The biological characteristics of copper bis(thiosemicarbazonate) complexes derived from 1,2-diones are dependent on the nature of the "backbone" substituents in the ligand. The most detailed studies of these structure–activity relationship have been carried out in connection with hypoxia imaging.[14,15,21] These studies correlated hypoxic cell selectivity with the reduction potential, electronic structure and chemical behaviour and found that all of these properties are extraordinarily sensitive to the alkyl groups attached to the diimine backbone of the ligand. The trapping in a hypoxic cell is believed to occur by reduction of the copper(II) complex by intracellular reducing agents to give stable protonated Cu^{I} species, which are trapped inside the cell.[22] The structure–activity relationships of copper bis(thiosemicarbazone) radiopharmaceuticals derived from 1,2-diones show a correlation between the reduction potential for the Cu^{II}/Cu^{I} couple and the hypoxic cell selectivity.[14,23] The hypoxia-selective radiopharmaceutical [Cu(ATSM)] [ATSM = biacetyl bis(4-methylthiosemicarbazone)], for example, undergoes a reversible reduction at $E_{1/2}$ = –0.620 V in DMF at a glassy carbon working electrode. On the other hand, some zinc thiosemicarbazone complexes that have been shown to be active as anti-tumour agents are as cytotoxic as cisplatin and are also effective against cisplatin-resistant cell lines.[24] Recently, fluorescence studies and the cellular distribution of zinc bis(thiosemicarbazone) complexes have been reported.[25]

Since relatively superficial modifications induce remarkable changes in redox and biological properties, it is natural to enquire whether they might also significantly affect the core structural parameters of the complexes and, if so, whether this might be related to their biological behaviour. The aim of this work is to get information about the importance of the changes induced by the modification of the backbone of benzil bis(thiosemicarbazone) (LH_6) in some complexes. In particular, for copper(II) complexes these changes affect the redox properties and therefore their potential activity as hypoxia-selective radiopharmaceuticals. We report the X-ray structures of two copper complexes derived from LH_6 (Figure 1) whose reduction potential values are –0.550 and –0.520 V,[26] close to those of [Cu(ATSM)], a related zinc complex, as well as the structure of a nickel complex for comparison.[27] We also discuss structural variations as a function of the ligand behaviour and/or the metal ion.

Results

All complexes were synthesised as described previously, except complex **2**, which was isolated from the mother liquor of the synthesis of a previously published complex.[26] Their analytical and spectroscopic properties are consistent with those reported previously.[26,28] Complex **2** presents a 1:1 ligand:copper molar ratio and has a nitrate group as a counterion.

In complex **1**, which was prepared from copper(II) chloride, benzil bis(thiosemicarbazone) acts as a dianion, while in complexes **2** and **3**, which were synthesised from copper and zinc nitrate, respectively, it has lost only a hydrazinic hydrogen atom and therefore acts as a monoanion. However, the nitrate ion contained in **2** and **3** shows a different behaviour: it is outside of the coordination sphere in the first complex but is bonded to the zinc atom in complex **3**.

The crystal structures of all complexes consist of discrete molecules where the ligand is tetradentate through the imine nitrogen and the sulfur atoms by changing the *trans* disposition of the thiosemicarbazone moieties in the free ligand to *cis* to form an N_2S_2 chelate, as has been observed in other complexes.[27]

The crystal structure of **1** consists of discrete molecules of [$CuLH_4$]. A perspective view of the complex, together with the atom-labelling scheme, is given in Figure 2 (the thermal ellipsoids are shown at 50% probability) and selected bond lengths and angles are given in Tables 1 and 2, respectively. The crystallographic data of the complex confirm the geometry proposed from spectroscopic data[26] and the cell parameters are close to those reported previously.[29] The copper(II) ion is tetracoordinate in a planar disposition. The coordination sphere of the copper atom is formed by two sulfurs and two imine nitrogens, as expected for this ligand.[30,31] The environment of the copper ion is planar, with a distance from the copper ion to the basal plane of 0.1219 Å. The phenyl rings C(5)–C(10) and C(11)–C(16) form dihedral angles of 81.9° and 81.0°, respectively, with respect to the basal plane. The molecules are held together in the crystal packing through an extended network of intermolecular hydrogen bonds involving the amino groups and the hydrazinic nitrogen atoms (see Figure 3 and Table 3).

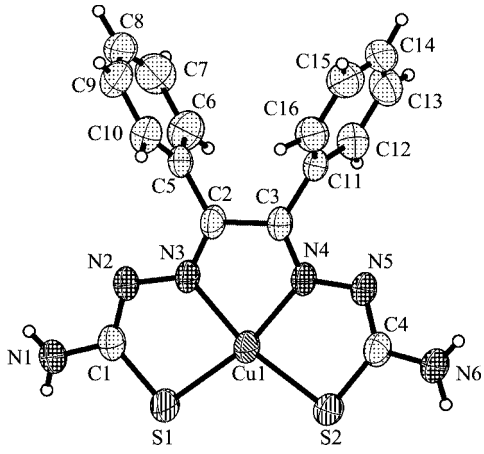

Figure 2. XSHELL view of [$CuLH_4$] (**1**).

The structure determination of [$CuLH_5$]NO_3 (**2**; Figure 4 with the thermal ellipsoids shown at 50% probability. See also Tables 1 and 2) shows a similar disposition for the copper ion as in complex **1**, but with a nitrate group acting as a counterion, although a weak interaction with the copper ion is also observed [*d*(Cu–O) = 2.46 Å]. The bis(thiosemicarbazone) acts as an N_2S_2 chelate ligand around the metal ion, giving a quasi-planar geometry for the copper with a deviation of 0.2084 Å from the basal plane. The main difference is the unusual asymmetric behaviour of the thiosemi-

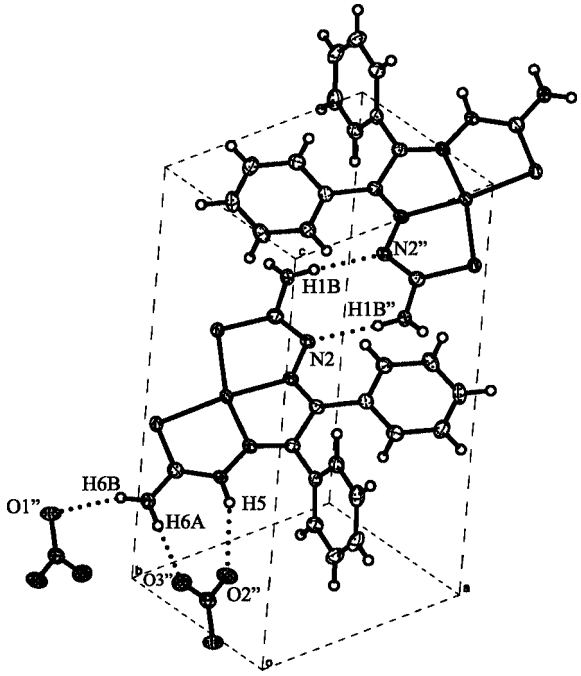

Figure 5. Plot of complex $[CuLH_5]NO_3$ (**2**) showing the hydrogen bonds.

the crystal structure of the complex (Figure 6 with the thermal ellipsoids shown at 50% probability. See also Tables 1 and 2). The benzil bis(thiosemicarbazone) acts as a monodeprotonated N_2S_2 ligand in a pseudo-planar disposition. The coordination sphere of the zinc atom is completed by an oxygen atom provided by the nitrate group to give a distorted square-based pyramidal geometry for the metal ion, as proposed from the spectroscopic data.[28] The value of the parameter, τ, defined by Addison et al.,[30] is 0.08 (τ = 0.0 for a regular square-based pyramid). The zinc atom is displaced by 0.439 Å out of the basal plane toward the oxygen atom at the apex of the pyramid. The phenyl rings C(5)–C(10) and C(11)–C(16) form dihedral angles of 63.6° and 57.0°, respectively, with respect to the basal plane. The molecules are bonded through hydrogen bonds between the amine and the nitrate groups (Figure 7, Table 3).

Discussion

The overall impression from the bonds and angles around the copper atoms (Tables 1 and 2) is that the ligand cavity is too small to accommodate the copper(II) ideally. The N–Cu–N bond angles are only 81.06° and 79.87° and the sulfur ends of the ligand arms are pushed outward well beyond the natural position that would be adopted by the planar ligand with 120° bond angles. For comparison, the Ni^{II} complex with the same ligand shows a much better fit[27] as a result of the smaller ionic radius of nickel, with Ni–N and Ni–S distances of 1.86 and 2.157 Å, respectively, compared to 1.976 Å (N) and 2.235 Å (S) and 1.987 Å (N) and 2.24 Å (S) for complexes **1** and **2**, respectively. All the angles at the nickel centre are significantly closer to the 90° preferred at the square-planar metal centre. Thus, the average N–Cu–N angle in our complexes is 80.45°, whereas for the nickel complex it is 83.32°. Similarly, the S–M–S angles are 108.7° for copper but only 101.68° for nickel, while the N–M–S angles are 85.21° for the copper complexes and 87.62° for the nickel complex.

Although the ligand appears somewhat strained in the copper complexes, it has been shown that the ligand can open up even further to accommodate Cd^{II} in its neutral form, while still maintaining an essentially planar structure.[28] As a result of the larger ionic radius of the zinc (giving two Zn–N distances of 2.1407 and 2.1290 Å and two Zn–S distances of 2.3143 and 2.3695 Å), all the angles are significantly far from 90°. Thus, the N–Zn–N angle is 73.46°, the S–Zn–S angle is 115.57° and the N–Zn–S angles are 81.93° and 81.37°. For comparison with the copper and nickel complexes, these data agree with the variation in the ionic radius for these ions even though the grade of deprotonation of the benzil bis(thiosemicarbazone) changes.

The backbone C(2)–C(3) distances in the complexes, except for the nickel complex, are larger than in the free ligand, ranging from 1.475 to 1.491 Å, in accordance with the metal ratio variations. The C(2)–N(3) distances range from 1.285 to 1.308 Å, and are consistent with a bond order greater than 1.5 but less than 2. The C(3)–N(4) bonds in

the non-deprotonated thiosemicarbazone branch are closer to a full double bond than in the deprotonated one. The N(2)–N(3) distances, which range from 1.351 to 1.371 Å, are consistent with a bond order less than 1.5 but greater than 1. The N(2)–C(1) distances are larger than the C(2)–N(3) distances, but are still greater than 1, and the N(5)–C(4) distances are larger than before, but shorter than in the free ligand. The C(1)–S(1) distances in the deprotonated thiosemicarbazone branch are much larger than in the non-deprotonated one [C(4)–S(2)] and are consistent with a bond order close to 1. The largest difference (0.084 Å) appears between the free ligand (1.667 Å) and complex **2** (1.751 Å). The C(1)–N(1) distances range from 1.328 to 1.338 Å and the C(4)–N(6) distances from 1.314 to 1.319 Å; they are intermediate between the C–N and N–CS distances. These data confirm there is extensive conjugation within the ligand that is greater in the deprotonated thiosemicarbazone branch.

The study of the electrochemical behaviour of the copper complexes was carried out in the range from +1 to –1.5 V.[26] In the positive range (+1 to 0 V), a quasi-reversible Cu^{III}/Cu^{II} oxidation process can be observed. Cyclic scanning between 0 and –1.5 V permits the study of the copper-centred reduction processes and the ligand reductions; the values of the potential for the Cu^{II}/Cu^{I} reduction processes are related to the biological activity. The cyclic voltammogram of complex **1** in the latter range shows a peak at –0.520 V in the cathodic scan, which can be attributed to the Cu^{II}/Cu^{I} reduction. Under the same conditions, the cyclic voltammogram of complex **2** shows waves at –0.600 V and –0.500 V associated with a quasi-reversible Cu^{II}/Cu^{I} process.

It appears that a relationship exists between the backbone C(2)–C(3) bond length and the categorisation according to reduction potential, and, in turn, with the biological behaviour, although any relationship between these structural parameters and biological function remains speculative. Thus, complex **1**, with a longer C(2)–C(3) bond than complex **2**, has a lower reduction potential (harder to reduce). As was mentioned in the introduction, the hypoxia selectivity (HSI) is related to the electrochemical behaviour, and those complexes with an HIS greater than 0.4 have a low redox reduction potential (<0.58 V).[14] Therefore, some hypoxic selectivity of complex **1**, which has a reduction potential of –0.550 V vs. Ag/AgCl, could be expected.

The ease of deformation away from planarity could be connected to the redox potential and other aspects of the redox behaviour because distorting ions towards tetrahedral favours the copper reduction and decreases the stability of the copper(II) complex. Complex **2** shows a slightly larger distance to the plane formed by the ligand than complex **1**, which agrees with the values of the reduction potential.[26] The grade of the deviation from planarity can be determined from the least-squares displacement of the ligand atoms from the mean plane of the complex. Figure 8 shows the displacement of the ligand atoms from the least-squares plane for the complexes. Both copper and nickel complexes are closer to planarity than the zinc complex. Complexes **1** and **4**, which show the same behaviour of the ligand, show a similar pattern, although in the nickel complex both sulfur atoms show identical deviation with respect to the least-squares plane, which agrees with the minimum degree of deviation from planarity in this complex, probably due to the better fit of the nickel atom. Moreover, the deviation from planarity of complexes **2** and **3** shows the same pattern, namely two distances for the sulfur and the imine nitrogen atoms, which agrees with the asymmetry in the ligand and the tetragonal deformation in the metal environment. Additional information can be gained from the torsion angles: the value of the N(3)–C(2)–C(3)–N(4) torsion angle is less than 2° for the complexes, except for the zinc complex, where it is 4.1°.

The presence of terminal nitrogen atoms gives rise to intermolecular N–H–N hydrogen bonds, which lead to extended architectures in all complexes. The intermolecular contact distances are listed in Table 3. Complex **1** shows intermolecular interactions between the terminal amine group and the deprotonated secondary amine, as was shown in complex **4**, although N–H–S hydrogen bonds do

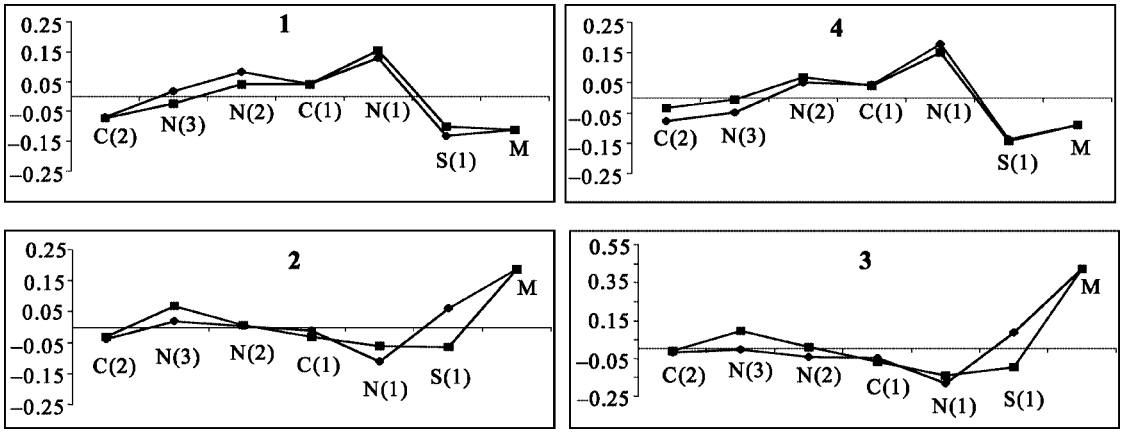

Figure 8. Displacement of atoms [Å] from least-squares plane defined by C(1), C(2), C(3), C(4), N(1), N(2), N(3), N(4), N(5), N(6), S(1), S(2) and M.

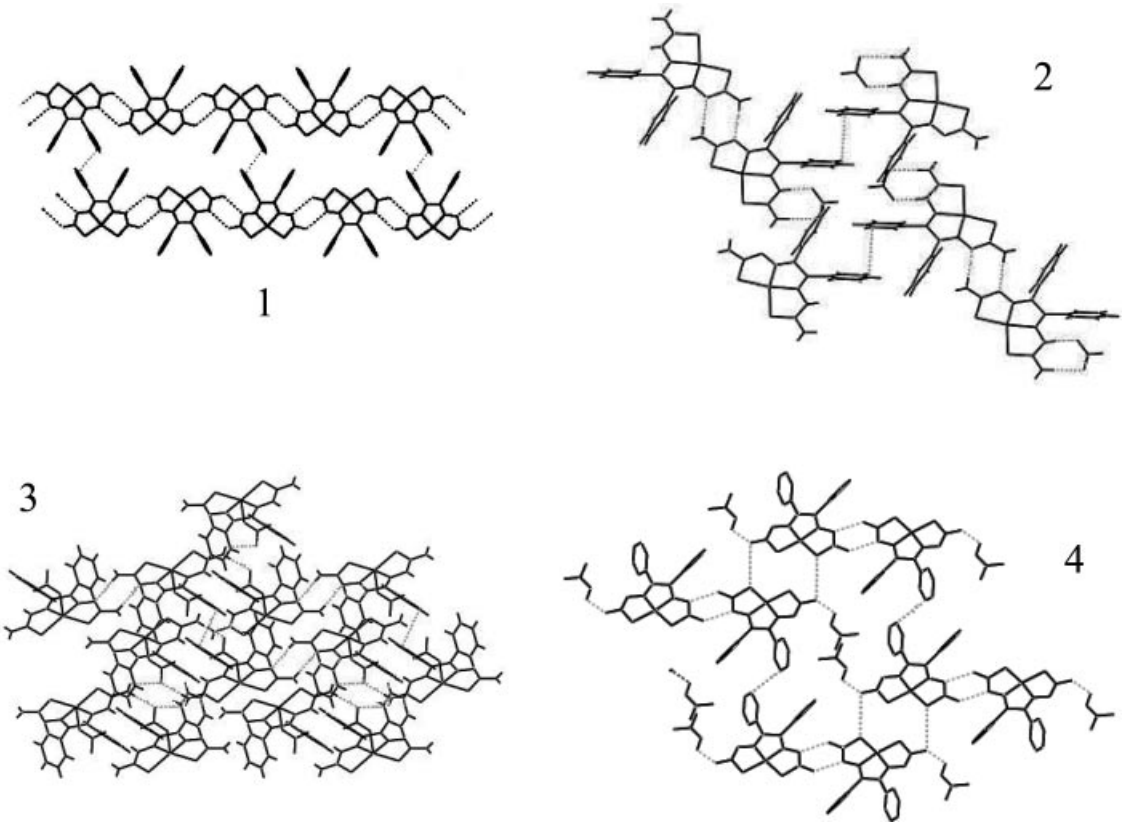

Figure 9. N–H–N hydrogen bonds and π–π interactions in the complexes.

not appear in the free ligand or in complex **4**.[27] Complex **1** is formed by flat ribbons that are linked through π–π interactions between the phenyl rings, which are at 3.644 Å (Figure 9). In complexes **2** and **3**, the molecules are linked to form couples by paired N(1)–H(1B)–N(2) hydrogen bonds, and these couples are linked by π–π interactions between the phenyl rings at 3.459 and 3.401 Å, respectively. They also contain hydrogen bonds to the nitrate ions, although in a different way: Complex **2** contains interactions between two oxygen atoms and both primary and secondary amine groups from the neutral thiosemicarbazone branch, whereas in complex **3** the nitrate group interacts also with NH and NH_2 groups, but belonging to two different chains, instead of to the same thiosemicarbazone arm (Figure 9). Complex **4** shows an intermolecular structure similar to those of complex **2**, but with hydrogen bonds with the DMF molecule. Couples are linked by π–π interactions with a distance of 3.376 Å.

Conclusions

The copper complexes are inherently planar and the zinc complex shows a distorted square-based pyramidal geometry with the nitrate group in the apical position, as proposed from the spectroscopic data. The bond length and angles for the complexes agree with the variable grade of deprotonation in the ligand and the requirements of the metal ion. The complexes present a variable grade of distortion from planarity although they all present intermolecular interactions, especially pairs of N(1)–H(1B)–N(2) hydrogen bonds and π–π interactions between the phenyl rings. Complex **1** shows the smallest deviation with respect to the planar nickel complex **4**. The presence of a hydrazinic hydrogen and a nitrate group in complexes **2** and **3** changes the intermolecular interactions, which increases the deviation from planarity, as reflected in the reduction potential of complex **2**. We have established the relationship between the distorted geometry and the reduction potential of copper complexes. In complex **1**, this parameter is close to those of copper bis(thiosemicarbazones) with hypoxic selectivity, therefore some activity could be expected.

Experimental Section

Physical Measurements: Microanalyses were carried out with a Perkin–Elmer 2400 II CHNS/O Elemental Analyser. IR spectra in the 4000–400 cm^{-1} range were recorded as KBr pellets on a Jasco FT/IR-410 spectrophotometer. FAB mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzyl alcohol (*m*-NBA) as the matrix. Conductivity data were measured for freshly prepared DMF solutions (ca. 10^{-3} M) at 25 °C with a Metrohm Herisau model E-518 instrument.

Synthesis: Thiosemicarbazide (Fluka), benzil (Aldrich), copper(II) nitrate trihydrate (Merck), copper(II) chloride dihydrate (Aldrich) and zinc(II) nitrate hexahydrate (Fluka) were used as received.

Benzil Bis(thiosemicarbazone) (LH_6): This compound was prepared following the procedure reported previously.[37] FAB-MS (*m*-NBA):

m/z (%) = 357 (25) $[M + 1]^+$. IR (KBr): $\tilde{\nu}$ = 3420, 3386, 3342, 3330, 3210, 3151 (NH); 1608 (NH_2); 1581 (C=N); 848 (CS) cm^{-1}.

[$CuLH_4$] (1):[26] A solution of copper(II) chloride dihydrate (120 mg, 0.70 mmol) in methanol (20 mL) was added to a suspension of LH_6 (500 mg, 1.40 mmol) in methanol (20 mL). The mixture was stirred for 48 h at room temperature. The reddish solid formed was filtered off, washed with methanol and dried in vacuo (yield: 65 mg, 22%). FAB-MS (*m*-NBA): *m/z* (%) = 418 (30) $[M + 1]^+$. IR (KBr): $\tilde{\nu}$ = 3343, 3271, 3102 (NH) + (NH_2); 1626, 1600, 1569 (C=N) + (NH_2); 1467, 1427 thioamide II; 836 thioamide IV; 449 (Cu–N); 428 (Cu–S) cm^{-1}. Recrystallisation from DMSO gave reddish crystals suitable for X-ray analysis.

[$CuLH_5$]NO_3 (2): A solution of copper(II) nitrate trihydrate (360 mg, 1.49 mmol) in methanol (20 mL) was added to a suspension of LH_6 (500 mg, 1.40 mmol) in methanol (20 mL). The mixture was stirred for 19 h at room temperature. The brown solid formed was filtered off, washed with methanol and dried in vacuo.[26] A black solid (**2**) was isolated from the mother liquor. $C_{16}H_{15}CuN_7S_2O_3$ (480.55): calcd. C 39.95, H 3.12, N 20.39, S 13.31; found C 39.63, H 2.98, N 20.77, S 13.02. FAB-MS (*m*-NBA): *m/z* (%) = 418 (50) $[M - NO_3]^+$. IR (KBr): $\tilde{\nu}$ = 3443, 3408, 3274, 3097 (NH) + (NH_2); 1663, 1628, 1604 (C=N) + (NH_2); 1554, 1534, 1490, 1444 thioamide II; 778 thioamide IV; 475 (Cu–N); 428 (Cu–S) cm^{-1}. Λ_M = 86 $\Omega^{-1}cm^2mol^{-1}$. Black crystals suitable for X-ray analysis were obtained from the mother liquor after a week in the freezer.

[$ZnLH_5NO_3$] (3):[28] A solution of zinc(II) nitrate hexahydrate (520 mg, 1.75 mmol) in ethanol (10 mL) was added to a suspension of LH_6 (500 mg, 1.40 mmol) in ethanol (40 mL). The mixture was stirred under reflux for 4 h. The yellow-orange solid was filtered off, washed with ethanol and dried in vacuo (yield: 305 mg, 45%). FAB-MS (*m*-NBA): *m/z* (%) = 419 (100) $[M - NO_3]^+$. IR (KBr): $\tilde{\nu}$ = 3440, 3268, 3111 (NH); 3421, 3169 $\nu(NH_2)$; 1629, 1576 (C=N); 1615 (NH_2); 1439 thioamide II; 816 thioamide IV; 447 (Zn–N); 341 (Zn–S) cm^{-1}. Λ_M = 51 $\Omega^{-1}cm^2mol^{-1}$. Yellow crystals suitable for X-ray analysis were obtained by recrystallisation from methanol.

[$NiLH_4$] (4): This compound was prepared following the procedure previously described.[27]

Crystallography: Single crystals of complexes **1** and **3** were obtained by recrystallisation from DMSO and methanol, respectively, and crystals of **2** were isolated from the mother liquor of the reaction. Crystals of the compounds were mounted on a glass fibre and transferred to a Bruker SMART 6 K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. Rotating Anode generator (Cu-K_α radiation, λ = 1.54178 Å) equipped with Goebel mirrors at settings of 50 kV and 110 mA. X-ray data were collected with a combination of six runs at different φ and 2θ angles for 3600 frames. The substantial redundancy in data allows empirical absorption corrections (SADABS)[32] to be applied using multiple measurements of symmetry-equivalent reflections (ratio of minimum to maximum apparent transmission: 0.578995 for complex **1**, 0.514195 for complex **2** and 0.722376 for complex **3**). The unit cell parameters were obtained by full-matrix least-squares refinements of 4562 reflections for complex **1**, 4593 reflections for complex **2** and 4356 reflections for complex **3**. Crystallographic details are reported in Table 4. The raw intensity data frames were integrated with the SAINT[33] program, which was also used to apply corrections for Lorentz and polarisation effects.

The software package SHELXTL[34] version 6.10 was used for space group determination, structure solution and refinement. The structures were solved by direct methods (SHELXS-97),[35] completed with difference Fourier syntheses, and refined with full-matrix least-squares using SHELXL-97[36] by minimizing $\omega(F_o^2 - F_c^2)^2$. Weighted *R* factors (R_w) and all goodness-of-fit (*S*) values are based on F^2; conventional *R* factors (*R*) are based on *F*. All non-hydrogen atoms were refined with anisotropic displacement parameters. All scattering factors and anomalous dispersions factors are contained in the SHELXTL 6.10 program library. The high quality of the data set allowed all hydrogen atoms to be located by difference maps and refined isotropically in all complexes.
CCDC-258838 (for **1**), -258839 (for **2**) and -258840 (for **3**) contain the supplementary crystallographic data for this paper. These data

Influence of Na Content on the Chemical Stability of Nanometric Layered Na_xRhO_2 ($0.7 \leq x \leq 1.0$)

Aúrea Varela,[a] Marina Parras,[a] and José M. González-Calbet*[a]

Keywords: Na_xRhO_2 nanoparticles / Layered oxides / High resolution electron microscopy

A new Na_xRhO_2 solid solution composed of nanometric particles of the α-$NaFeO_2$ structural type has been stabilised in the $0.7 \leq x \leq 1$ range. Its rhombohedral structure is built from close packed layers of edge-sharing [RhO_6] octahedra separated by intercalant layers consisting of octahedrally coordinated Na. Electron microscopy shows that compositional variations are indeed accommodated by means of stacking faults leading to a local change in the Na oxygen environment. Samples are air-sensitive, and the aged materials partially decompose, segregating sodium carbonate.

Introduction

AMO_2 layered oxides (A: alkaline, M: transition metal) have been widely studied because of their interesting physical properties.[1–5] Among them, Na_xCoO_2 has attracted particular interest due to the large thermoelectric power of the metallic conductor $NaCo_2O_4$[6–7] and the recent discovery of superconductivity near 4 K in hydrated $Na_{0.3}CoO_2{\cdot}1.3H_2O$.[8,9]

The structures of various Na_xCoO_2 phases have been reported. All of them are based on the stacking of CoO_2 layers, consisting of edge-sharing CoO_6 octahedra. The Na atoms form layers between the CoO_2 layers. $NaCoO_2$ (x = 1) crystallises in the α-$NaFeO_2$ structure.[10] This rock-salt type structure is built from a cubic stacking of oxygen layers (*ABCABC*) with Co and Na occupying the octahedral sites of alternating layers.[11] A decrease in the Na content changes the Na coordination from octahedral to trigonal prism, leading to the stabilisation of different structures.[10] Moreover, a recent electron diffraction study of various Na_xCoO_2 ($0.15 < x < 0.75$) compositions has shown the existence of several ordered distributions of the Na vacancies that lead to a wide range of superstructures of the basic hexagonal cell depending on the x value.[12]

The discovery of superconductivity in the cobalt oxyhydrate $Na_{0.3}CoO_2{\cdot}1.3H_2O$[8,9] spread the interest in this system. From a structural point of view, the oxyhydrate phases are formed by CoO_2 layers stacked together with one layer of Na^+ ions and two layers of water molecules. The insulating layers, which alternate with the CoO_2 layers, play the dual role of spacing provider and redox controller. In addition to this superconducting phase, a series of hydrated phases have been stabilised for the same Na/Co ratio, the H_2O content ranging from $Na_{0.3}CoO_2{\cdot}1.4H_2O$ to $Na_{0.3}CoO_2$.[13] In this work, Foo et al. studied the influence of Na and H_2O contents on the structural and physical properties of these compounds.

Much less attention has been devoted to 4d or 5d metal oxides. Among them, the ruthenium oxides have probably been the most studied because they exhibit a rich variety of magnetic and electrical properties.[14,15] Recently the structural characterisation of the new layered oxide $NaRuO_2$ and and oxyhydrate $Na_{0.22}RuO_2{\cdot}0.45H_2O$ have been reported but no superconducting behaviour has been observed in the hydrated phase.[16]

Rhodium oxides have also been studied recently, and a new sodium rhodate, $NaRh_2O_4$, has been stabilised under high pressure.[17] This compound crystallises in the $CaFe_2O_4$ structure, which is a 3-D structure comprising a network of edge-sharing RhO_6 octahedra. In addition to this 3-D material, layered $NaRhO_2$ has been reported by K. Hobbie et al.[18] The structural refinement carried out on a single crystal shows this compound to be isostructural to α-$NaFeO_2$. However, unlike the aforementioned Na_xCoO_2 system, where compositional variations have been extensively studied, only $NaRhO_2$ is known in the Na_xRhO_2 series. The present work is devoted to the systematic investigation of the compositional variations of the Na_xRhO_2 system and its structural and microstructural characterisation.

Results and Discussion

Chemical and Structural Characterisation

The Na:Rh cationic ratio, determined as described in the experimental section, is shown in Table 1. The Na content depends on both the time of the thermal treatment and the

container used. Our results indicate that Na loss is favoured by long thermal times and by the use of Al_2O_3 crucibles.

Table 1. Preparation conditions of the Na_xRhO_2 samples.

Label	Crucible	Annealing time [h]	Chemical composition[a]
PT-24	Pt	24	$NaRhO_2$
PT-48	Pt	48	$Na_{0.85}RhO_2$
AL-24	Al_2O_3	24	$Na_{0.7}RhO_2$
AL-48	Al_2O_3	48	phase mixture[b]

[a] The estimated error in cationic composition is around 2%. [b] Hydrated and non-hydrated $NaRhO_2$ phases.

Na_xRhO_2 ($1 \geq x \geq 0.7$) samples were characterised by means of XRD. The pattern corresponding to $NaRhO_2$ (PT-24) is shown in Figure 1a. All maxima can be indexed on the basis of a rhombohedral unit cell (R-3m) of parameters a = 3.0903(1) and c = 15.5400(6) Å. The pattern has been refined by the Rietveld method by taking as the starting model the structural data of the isostructural α-$NaFeO_2$. The graphic result of this refinement can be seen in Figure 1a. Table 2 lists the refined structural parameters and selected interatomic distances are shown in Table 3. The crystallographic data obtained are in agreement with those previously reported for a $NaRhO_2$ single crystal.[18]

The XRD pattern corresponding to $Na_{0.85}RhO_2$ (PT-48), Figure 1b, is very similar to that of stoichiometric $NaRhO_2$. The only visible difference is that (00l) reflections are shifted toward lower 2θ values, indicating a slight increase in the c-axis length. Actually, the obtained cell parameters correspond to a = 3.0867(6), c = 15.5785(5) Å. The structure was refined in the R-3m space group, by using the $NaRhO_2$ structure model with a reduced Na content of 0.85 per unit formula, according to cationic analysis. The graphic result of this refinement is shown in Figure 1b, while Figure 2 depicts the crystal-structure view of $Na_{0.85}RhO_2$. As it can be observed, the structural features of stoichiometric $NaRhO_2$ are maintained. The rhombohedral structure is formed by close-packed layers of edge-sharing [RhO_6] octahedra perpendicular to the c-axis separated by intercalant Na layers, Na also being octahedrally

Rh–Na	3.145	3.145	3.171

coordinated to the oxygen atoms. The refined structural parameters and some selected interatomic distances are listed in Table 2 and Table 3, respectively.

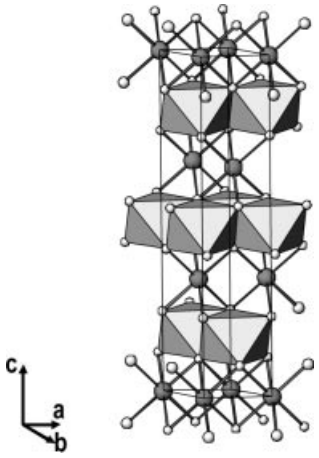

Figure 2. Crystal structure of $Na_{0.85}RhO_2$. Grey dots correspond to sodium and small dots to oxygen atoms.

It is well known that XRD is not the most powerful technique to study structural effects of light atoms such as oxygen or sodium. However, the refinement was stable, and it was possible to refine the Na fractional occupancy. The obtained value, corresponding to a Na content of 0.86 atoms per unit formula, nicely agrees with the cationic analysis. Moreover, the lack of extra maxima in the XRD patterns indicates a random distribution of the Na vacancies through the intercalant layers. The metal-oxygen distances correspond to 2.069(2) and 2.358(3) Å for Rh–O and Na–O, respectively, both comparable with their typical values.[17,18]

According to these results, the decrease in the Na concentration from $NaRhO_2$ occurs only with minor structural changes. The *c* parameter increases, indicating a slight increase in the thickness of the intercalant Na layers. Furthermore, a small shrinkage of the *a*-axis is also observed. The shrinking of the RhO_2 layers is probably due to the partial oxidation of Rh(III) to Rh(IV), which occurs in order to ensure charge neutralisation when Na ions are removed.

The above features are more pronounced in $Na_{0.7}RhO_2$ (AL-24), which also presents the structural characteristics of stoichiometric $NaRhO_2$. The corresponding structure has also been refined by the Rietveld method (Figure 1c), and the refined lattice parameters, a = 3.0750(2), c = 15.766(1) Å (see Table 2), show again the expansion of the *c*-axis as well as the contraction of the *a*-axis when Na content decreases. As a consequence, (101) and (006) reflections overlap, and only one diffraction maximum is observed (see inset of Figure 1). These structural features are also reflected in the corresponding interionic distances. Actually, as it can be seen in Table 3, the Na–Rh distance increases from 3.14 for $NaRhO_2$ to 3.17 Å for $Na_{0.7}RhO_2$. In addition, the Rh–O distance decreases from 2.058(2) to 2.0269(5) Å, because of the smaller size of Rh^{IV} ($r_{Rh^{IV}}$ = 0.60; $r_{Rh^{III}}$ = 0.65 Å in an octahedral environment[19]).

Similar behaviour has been previously observed in the Na_xCoO_2 system.[13] The *c*-axis is increased from 10.82 Å, for the stoichiometric $NaCoO_2$ (x = 0), to 11.23 Å for x = 0.3. A series of hydrated phases has recently been reported for this Na content.[8,20,21] The lower hydrate, $Na_{0.3}CoO_2{\cdot}0.6H_2O$, has a *c*-parameter of 13.8 Å that corresponds to an expansion of 1.3 Å per intercalant layer as compared to $Na_{0.3}CoO_2$. The H_2O molecules are found in the same plane as the Na atoms, unlike the model proposed for superconducting $Na_{0.3}CoO_2{\cdot}1.4H_2O$[8] in which the *c*-parameter is increased to 19.6 Å. This value corresponds to an expansion of 2.8 Å per intercalant layer, and, in this case, Na ions and H_2O molecules are not located in the same plane.

In Na_xRhO_2, the *c*-axis value increases from 15.540 for x = 1 to 15.766 Å for x = 0.7. This small expansion seems to indicate that, up to x = 0.7, the Na^+ ions lost into the intercalant layers are not replaced by H_2O molecules. However, to fully discard this possibility a thermogravimetric analysis of the above samples has been performed.

The weight change of PT-24, PT-48 and AL-24 samples, when heated at 0.2 °C/min in flowing O_2 in a thermogravimetric analyser (TGA), is presented in Figure 3. No substantial weight loss occurs over the temperature range of 30 to 300 °C. Actually, if we consider that the observed weight loss (close to 0.2%) corresponds to H_2O molecules, a content of only 0.02 water molecules per unit formula should be obtained. These results seem to indicate that down to 0.7-mol Na content, H_2O molecules are not introduced into the layer space, at least not in a significant amount.

A different result is obtained when the sample is treated at 800 °C for 48 h in alumina crucibles (AL-48). The corresponding XRD pattern is shown in Figure 4a. The main peaks of this pattern can be also indexed on the basis of the above-described rhombohedral unit cell with lattice parameters close to a = 3.09, c = 15.7 Å; however, extra maxima of very low intensity are also visible (marked in the figure with asterisks). This sample is air-sensitive, and, after 24 h in air, the intensities of the extra maxima increase (Figure 4b). This fact has also been reported for the isostructural $NaRuO_2$.[12] Actually, this compound is also air-sensitive, and, after one night in air, an oxyhydrate is formed with the stoichiometry $Na_{0.22}RuO_2{\cdot}0.45H_2O$. Therefore, the extra peaks of Figure 4 could correspond to a new $Na_xRhO_2{\cdot}yH_2O$ hydrate. In fact, all these maxima can be indexed on the basis of a rhombohedral unit cell of parameters a = 3.02, c = 20.46 Å. The high value of the *c*-axis should be a consequence of the intercalation of some H_2O molecules. Unfortunately, this oxyhydrate phase has

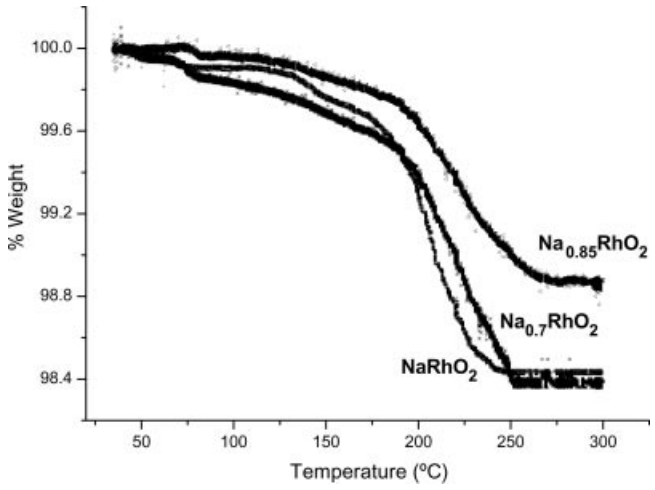

Figure 3. Thermogravimetric curves of Na_xRhO_2 samples ($1 \leq x \leq 0.7$). Experiments were carried out in O_2 for a ~100 mg specimen with a heating rate of 0.2 °C/min.

not been isolated up to now. Finally, it is worth recalling that this hydration process is highly reversible, and, after 1 hour at 800 °C in air, the non-hydrated phase is already stabilised (see Figure 4c).

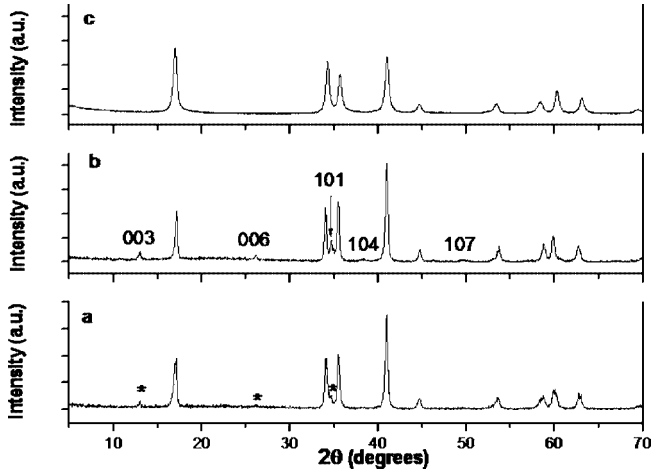

Figure 4. Experimental powder XRD patterns corresponding to (a) sample AL-48; (b) sample AL-48 after being aged 24 h in air and (c) the previous sample heated for 1 h at 800 °C in air.

As described above, the Na content of the samples varies, depending on the preparation conditions, from 1.0 to 0.7 mol per unit formula. Recently, Zandbergen et al.[12] have studied the Na_xCoO_2 system by electron diffraction. They have shown the existence of an extensive series of superstructures of the basic $NaCoO_2$ structure originating from different ordered distributions of the Na vacancies. In order to study the influence of the Na content in the microstructure of the Na–Rh–O system, a study by selected area electron diffraction (SAED) and high resolution electron microscopy (HREM) has been carried out.

Figure 5a corresponds to the SAED pattern of stoichiometric $NaRhO_2$ (PT-24) along the [010] zone axis. All the observed crystals show the same pattern. The local composition, analysed by energy-dispersive X-ray spectroscopy (EDS), nicely agrees with the experimental composition. All the spots appearing in the pattern can be indexed on the basis of the rhombohedral unit cell with parameters $a \approx 3.8$, $c \approx 15.6$ Å, which are in agreement with the XRD results. Moreover, the lack of streaking along the c^* axis is evidence of an ordered situation as confirmed by HREM. The HREM image along [010] (Figure 5b) shows a fully ordered material with interplanar distances of 2.7 and 15.6 Å, corresponding to d_{100} and d_{001}, respectively. The optical Fourier transform (inset in the figure) shows features similar to the experimental SAED pattern in Figure 5a. An enlargement of the image is depicted in Figure 5c. The observed differences can be associated to the atomic configuration shown in the structural model projection depicted in Figure 5c. The brightest dots are attributed to Rh atoms forming the ABCABC stacking sequence, which corresponds to the 3R structure. The dots of intermediate intensity correspond to the lighter Na and O atoms. The calculated image for $\Delta t = 7$ nm, $\Delta f = -60$ nm, shown in the inset, nicely fits the experimental data. All observed crystals have the same features, and no stacking faults are observed.

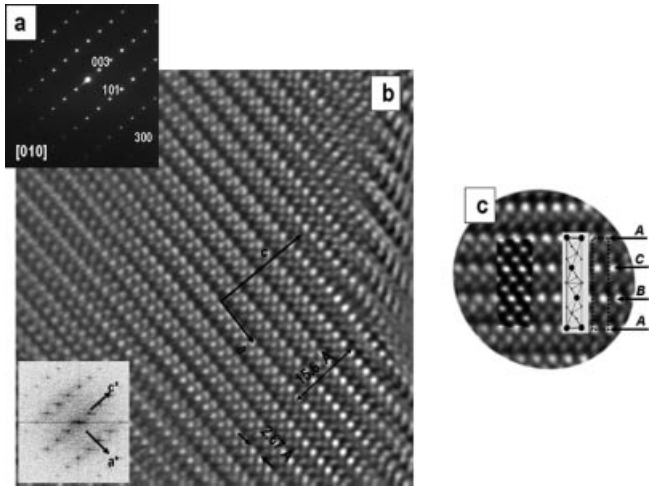

Figure 5. (a) SAED pattern corresponding to $NaRhO_2$ along [010]. (b) Corresponding HREM image. The Optical Fourier Transform and the calculated image are shown in the insets. (c) Enlargement of the above image. The unit cell shows the ...*ACB*... stacking sequence characteristic of the $NaRhO_2$ structure. The calculated image is shown in the inset. Big dots correspond to Rh, grey dots to Na and small black dots to oxygen atoms.

It is worth recalling that, under electron beam irradiation, crystals are unstable. Actually, Figure 6a and b shows the SAED pattern and the corresponding HREM, along [010], of a $NaRhO_2$ crystal after an extended period of electron beam illumination. Radical changes were observed and the microstructure was altered in such a way that some kind of disorder appeared, as evidenced by the presence of streaking along the c^*-axis (see Figure 6a). The corresponding HREM shows the presence of stacking faults along the crystal. These faults locally change the stacking of the 3R-$NaRhO_2$ phase by the incorporation of one A-layer in the ABC cubic sequence, giving rise to a local change in the

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Na sites from octahedral to trigonal prismatic. The electron damage is more important for thinner crystals. For this reason, in order to obtain images such as the ones in Figure 5, low exposure times should be used and crystals that are not too thin must be chosen.

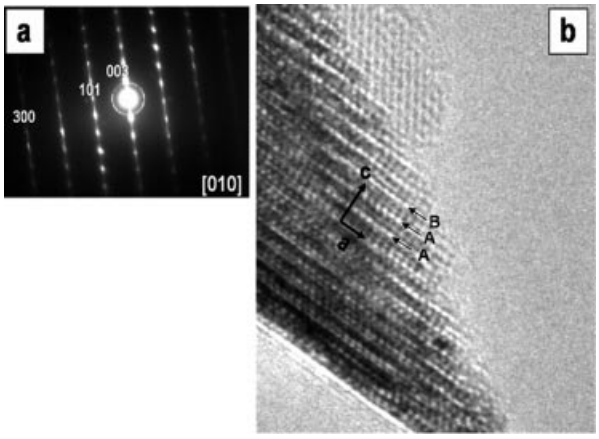

Figure 6. (a) SAED pattern corresponding to $NaRhO_2$ along [010] after electron beam irradiation. Streaking along the *c*-axis is apparent. (b) Corresponding HREM image showing stacking faults.

TEM characterisation of Na_xRhO_2 samples reveals a disordered stacking sequence apparent in the SAED pattern (Figure 7a) as diffuse streaking along the *c** axis, as well as in the corresponding image (Figure 7b) as planar defects. Note that the same disordered microstructure of Na-deficient materials is observed for stoichiometric $NaRhO_2$ under long beam time exposure. It seems that the electron beam favours the diffusion of Na out of the irradiated area, generating local Na-deficient areas with a disordered microstructure.

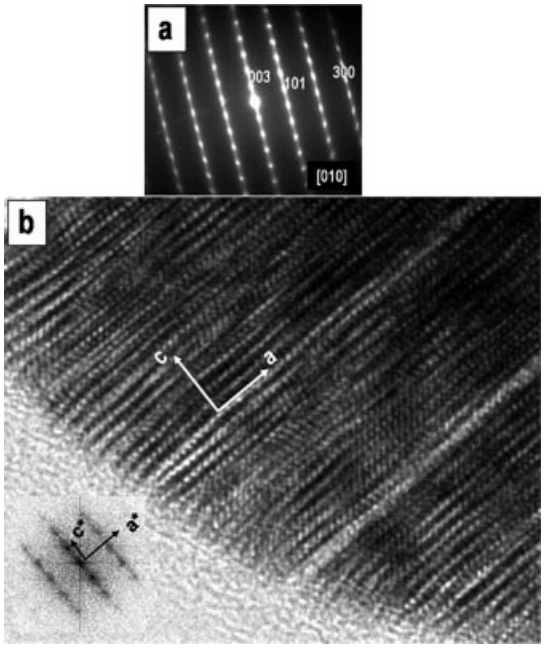

Figure 7. (a) SAED pattern corresponding to Na_xRhO_2 along [010]. (b) Corresponding HREM image.

Morphological Characterisation

In order to study the dependence of the morphology of the Na_xRhO_2 samples ($0.7 \leq x \leq 1$) on the duration of the thermal treatment and the crucibles used, a SEM characterisation was performed. Figure 8a–d shows SEM micrographs of the Na_xRhO_2 samples heated for 24 (24-PT) and 48 h (48-PT) in Pt (a, b), and for 24 (24-AL) and 48 h (48-AL) in Al_2O_3 (c,d) containers. All samples exhibit a similar platelike morphology with a quite homogeneous size distribution (100–200 nm). These small particles form agglomerates of around 1–2 μm. The powders obtained exhibit a partially sintered microstructure due to a certain degree of particle coarsening and sintering. All of the studied samples show analogous features. This fact seems to indicate that neither the thermal treatment nor the container used plays an important role in the morphology and crystallinity of the samples.

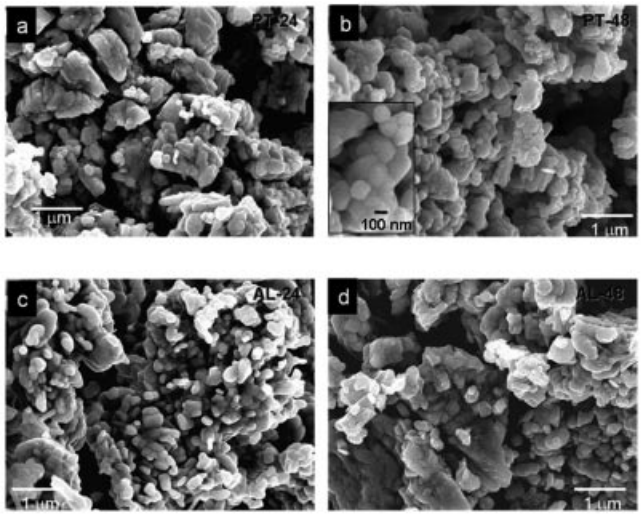

Figure 8. SEM micrographs of the Na_xRhO_2 samples heated at 800 °C, 24 and 48 h in Pt (a, b) and 24 and 48 h in Al_2O_3 (c,d) containers. Sintered microstructure of the nanoparticles can be observed in the enlargement of (b).

In addition to the morphology, SEM characterisation has evidenced an important common feature of these samples. Although the samples are carefully stored in a dry box, their morphology markedly changes with the aging time. Figure 9 corresponds to the $NaRhO_2$ sample (PT-24) 15 (a) and 30 (b) days after being prepared. It is clearly visible that, besides the platelike particles characteristic of $NaRhO_2$, needlelike particles (2–3 μm) appear to some extent. Both the amount as well as the particle size of these needles gradually increases with the aging time. In fact, these particles grow up to around 6 μm after 30 days, whereas the size of the platelike particles remains constant. The EDS analysis carried out on the needles indicates the presence of C and Na, but no Rh is detected. It follows that these particles should correspond to a minor phase of sodium carbonate segregated when the material is aged. At this stage, we have studied these samples by XRD. The XRD patterns of the aged samples are not different from a

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

freshly prepared sample. Neither extra maxima nor intensity changes of the maxima are detected. This result, corroborated by electron diffraction, suggests that the segregated sodium carbonate is a noncrystalline phase. The decomposition process progresses over time and, after several months, it is visible in the XRD patterns by the appearance of broadened diffraction maxima corresponding to a hydrated and poorly crystalline sample. The other Na_xRhO_2 (x = 0.85, 0.7) samples undergo the same aging process.

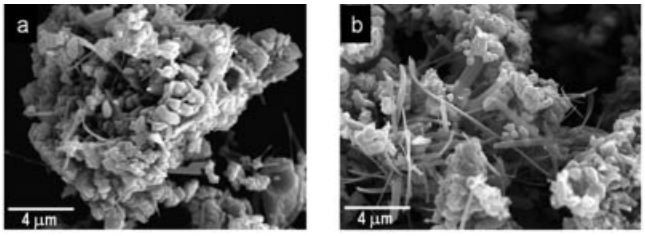

Figure 9. SEM micrographs of $NaRhO_2$ (PT-24): (a) 15 and (b) 30 days after preparation.

Concluding Remarks

On the basis of the XRD results, it can be concluded that a Na_xRhO_2 solid solution with the α-$NaFeO_2$ structure is stable in the $0.7 \leq x \leq 1$ compositional range. The relative disposition of the CoO_6 sheets is kept, and therefore no significant modifications in the Na environment are observed. In fact, in this compositional range, the main structural features of stoichiometric $NaRhO_2$ are maintained, and only a variation of the lattice parameters is observed. Finally, whereas no water is incorporated in the $0.7 \leq x \leq 1$ range, a hydrated phase appears for $x < 0.7$, which has not been isolated to date.

According to SAED and HREM results, variations in the amount of Na in Na_xRhO_2 are not totally randomly distributed throughout the crystal as indicated by XRD. In fact, the decrease in Na content gives rise to a local change in the stacking sequence of the RhO_2 sheets, leading to Na in a trigonal prism environment. However, no long-range order was attained, and no new ordered phases were stabilised in the compositional range studied. In this respect, the situation is different from the Na_xCoO_2 system,[12] where several structures have been stabilised as a function of the Na content. In this way, we would like to emphasize that, in spite of the presence of a significant Na vacancy concentration, none of the prepared samples show Na ion conductivity.

Finally, the morphological characterisation shows that all freshly prepared samples are composed of nanometric particles (100–200 nm) with the same platelike shape. In addition, all Na_xRhO_2 ($0.7 \leq x \leq 1$) samples are air-sensitive: the aging process leads to a final stage in which deliquescence takes place, and the sample decomposes, segregating sodium carbonate.

Experimental Section

Samples were prepared as polycrystalline powders by the solid state reaction of Na_2CO_3 and Rh_2O_3 in a 1:1 ratio with heating at 800 °C in flowing oxygen. It is well known that, during the synthesis process, Na can be lost because of the high volatility of Na_2O. Therefore, in order to obtain materials with various Na:Rh ratios, different annealing times as well as different crucibles were used.

The Na:Rh cationic ratio was determined on pellet samples by microprobe analysis with a JSEM-8600 scanning electron microscope working at an acceleration voltage of 10 KV. In addition, the local composition was analysed by EDS with an INCA analyser system attached to a JEOL 3000 FEG electron microscope.

To determine the precise water content of the samples, a thermal study was carried out with a high-sensitivity thermobalance (CAHN D-200) by heating in oxygen a specimen of around 80 mg up to 300 °C at a rate of 0.2 °C/min. This electrobalance allows the detection of weight variations within $\pm 5 \times 10^{-3}$ mg in a sample of about 100 mg.

Powder X-ray diffraction (XRD) patterns were collected using Cu-K_α radiation (λ = 1.5418 Å) at room temperature with a PHILIPS X′PERT diffractometer equipped with a graphite monochromator. Diffraction data were analysed by the Rietveld method,[22] using the Fullprof program.[23]

The samples were characterised by SAED and HREM with a JEOL 3000 FEG electron microscope fitted with a double-tilting goniometer stage (±22°, ±22°). Simulated HREM images were calculated by the multislice method using the MacTempas software package. The morphological study was carried out with a JSM-6330F FEG scanning electron microscope working at 10 kV.

Tuning pGa with Chelating Agents Related to (*o*-Hydroxybenzyl)iminodiacetic Acid

Olivier Jarjayes*[a] Florent Mortini,[a] Amaury du Moulinet d'Hardemare,[a] Christian Philouze,[a] and Guy Serratrice[a]

Keywords: Carboxylate ligands / Gallium / N ligands / Potentiometry / Stability constants

Gallium complexes with R-(*o*-hydroxybenzyl)iminodiacetate ligands (**Lx**) have been synthesized and their thermodynamic constants determined in aqueous solution by potentiometric titration. These quantitative results were also confirmed by ^{1}H and ^{19}F NMR spectroscopy. An X-ray study of Ga**L3** (R = NO_2) showed that the gallium(III) ion is hexacoordinate with two H_2O molecules in *cis* positions. The ability of the ligands to chelate Ga^{III} was evaluated at physiological pH and ionic strength from the pGa values. Among the different ligands studied, **L6** (R = OMe) has a pGa value two orders of magnitude higher than that of the complex between Ga and the blood serum protein transferrin.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

The design and synthesis of new chelating agents for effective coordination of Ga^{III} has received an important and increasing interest in the past decade. This is in part because of promising potential applications of ^{67}Ga and ^{68}Ga complexes as diagnostic radiopharmaceuticals.[1–4] In order to be considered as radiopharmaceuticals, these metal complexes must be stable with respect to demetalation by the blood serum protein transferrin and they must have a conditional stability constant greater than that of Ga–transferrin.[5] Moreover, the presence on the ligand of a second functional group that is not involved in the metal chelating process leads to a bifunctional chelator[6] and allows covalent linkage to targeting biomolecules such as antibodies, small proteins, or synthetic macromolecules. These conjugates are considered as in vivo metal carriers. Concerning the metal bonding unit, a large number of chelators have been synthesized and studied,[6] including groups such as catechols, hydroxamates, hydroxypyridinones, or aminophosphonates. Among them, aminocarboxylate groups presenting a high affinity towards Ga^{III} have been widely used to build polydentate ligands based on EDTA and DTPA backbones. However, ligands possessing both aminocarboxylate and phenolic sub-units have been studied to a lesser extent, even though they present the highest stability constants towards Ga^{III} [for HBED, i.e. *N*,*N*′-bis(2-hydroxybenzyl)ethylenediamine-*N*,*N*′-diacetic acid, $\log \beta_{110} = 37.7$].[7] The introduction of a conjugation group for the attachment to a biomolecule is rather difficult when several phenolic rings are present.[8,9] For this reason, we have reported the synthesis of bifunctional chelating agents based on phenol. This synthesis compares favorably in terms of simplicity and step saving with other bifunctional structures based on DTPA or DOTA. Moreover, a wide number of chemical functions can be made available in the *para* position of the phenol.

In this present work, we report the stability constants of the gallium complexes in aqueous solution with R-(*o*-hydroxybenzyl)iminodiacetate ligands (**Lx**; Figure 1) to determine if these systems are good candidates for radiopharmaceutical applications. These studies were performed by combining potentiometry and NMR (^{1}H and ^{19}F) spectroscopy. Solid-state characterizations were also performed for **L6** (R = OMe) and the complex Ga**L3** (R = NO_2).

Results and Discussion

Synthesis of the Ligands and Complexes

The **Lx** ligands are easily accessible from the appropriate *para*-substituted phenols and diethyl iminodiacetate in a solvent-less Mannich reaction, followed by the hydrolysis of the diethyl ester functions with hydrochloric acid. More details concerning the ligands' synthetic procedure have been described elsewhere.[10]

Solid-State Structure of the Ligand L6 and Complex GaL3

Crystals of **L6** (R = OMe) suitable for X-ray structure determination were obtained from an aqueous solution (10^{-2} M, pH 2.8) stored at room temperature. Details of the data collections are summarized in Table 4. The unit cell of **L6** is depicted in Figure 2 and the structural representation of **L6** is given in Figure 3.

The unit cell is shown down the *a* axis and displays two molecules, one of which is linked to three molecules of neighboring cells through hydrogen bonds (O5–H4···O5* = 1.22 Å, O3–H3···O3* = 1.21 Å, O1–H1···O2* = 1.95 Å). This representation explains the zwitterionic state of **L6**, since two hydrogens atoms (H3 and H4) of the molecule are shared with two molecules from adjacent unit cells. There is also a hydrogen bond between the hydrogen H1 of the phenol and the oxygen O2* of the carboxylic function. All of these intermolecular hydrogen bonds provide the stability of the crystal. In addition, three intramolecular hydrogen bonds are observed (N1–H2···O2 = 2.18 Å, N1–H2···O4 = 2.23 Å, N1–H2···O1 = 2.56 Å; see Figure 2). They realise the cohesion of the internal structure of the molecule, and might propitiously orientate the donor atoms for complexation.

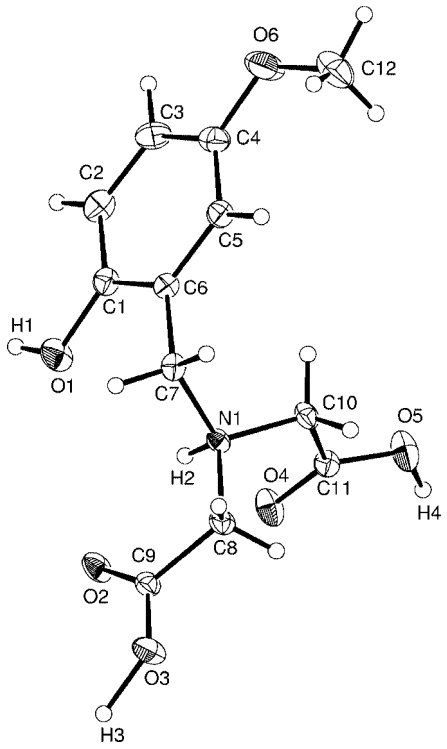

Figure 3. Structural representation of **L6**.

Among the different Ga**Lx** complexes, only Ga**L3** gave suitable crystals for an X-ray structural study. The ORTEP diagram of Ga**L3** (R = NO_2) is depicted in Figure 4, with selected bond lengths and angles listed in Table 1.

The gallium ion is located in a slightly distorted octahedral coordination environment formed by the deprotonated phenolic oxygen, two carboxylate oxygen atoms, the tertiary nitrogen atom, and two H_2O molecules coordinated in *cis* positions. The bond lengths of Ga to the tertiary amino

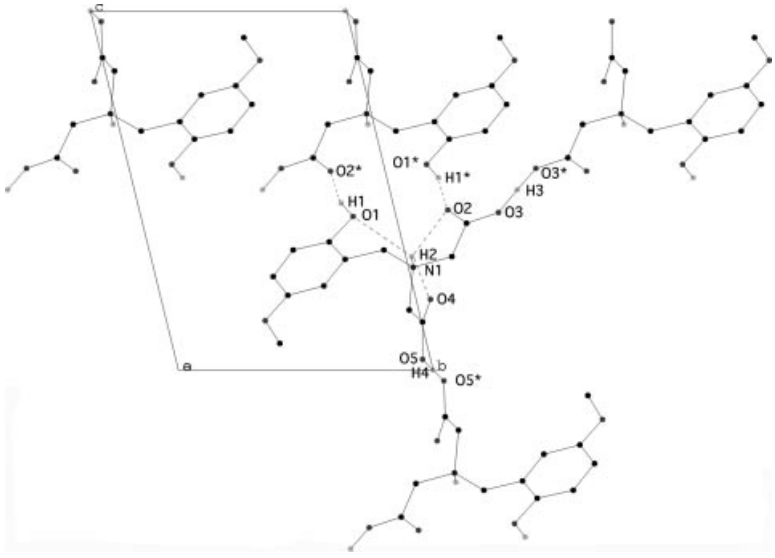

Figure 2. Unit cell representation down the *a* axis. This representation explains the zwitterionic state of **L6** as it can be seen that two protons of the molecule are shared with two molecules from adjacent unit cells (most of the hydrogen atoms have been omitted for clarity).

nitrogen atom and to the carboxlate oxygen atoms presented in Table 1 are consistent with those observed in complexes obtained with other carboxylate ligands.[11,12] The gallium–phenolate bond length (1.884 Å) compares well with such bonds in other similar complexes,[13] but is significantly shorter than that found for the bridging phenolate in [Ga_2(HXTA)] [1.999 Å and 2.078 Å;[14] HXTA = *N*,*N*′-(2-hydroxy-5-methyl-1,3-xylene)bis(*N*-methoxycarbonylglycine].[15] The N(1)–Ga–OOC angles have the largest deviation from 90°, probably caused by the steric constraints of the five-membered chelate rings.

Ligand Deprotonation Constants

The deprotonation constants, K_{an}, of the ligands (as hydrochloride salts) investigated in this work were studied by potentiometric titrations. Analysis of the titration curve (part a of Figure 5, as an example) by the program SUPERQUAD[16] yielded the pK_{an} values defined by Equations (1) and (2) and reported in Table 2.

$$LH_n \rightleftharpoons LH_{n-1} + H^+ \quad (1)$$

$$K_{an} = [LH_{n-1}][H^+]/[LH_n] \quad (2)$$

For each ligand, three pK_a values out of the four possible ones were determined, corresponding to one carboxylic acid group, the ammonium group, and the phenolic hydroxyl group. The pK_a value of the other carboxylic acid was inferred to be significantly lower than 2, since if we tried to include this pK_a in the fit, this constant was discarded by the program. The pK_a values for the different **Lx** ligands are close to those given (see Table 2) for the ligand HBIDA [*N*-(2-hydroxybenzyl)iminodiacetic acid],[17,18] which has a similar structure.

From a general point of view, it should be noted that the substituent in the *para* position of the phenol plays an important part in its acidity. For example, the presence of an electron-withdrawing group for **L2** (R = CHO) and **L3** (R = NO_2) increases the phenol acidity (pK_{a1} = 10.35 and 10.05, respectively, instead of 11.7 for HBIDA). In the same way, the phenolate basicity of **L1** (R = Me) is slightly higher

Table 2. Deprotonation constants of the ligands **Lx**.

pK_{an}[a]	L1	L2	L3	L4	L5	L6	HBIDA[b]
pK_{a1}	12.1(1)[c]	10.35(2)	10.05(5) 10.22[e]	12.2(1)[c]	12.3[d]	12.5[g]	11.7
pK_{a2}	8.30(1) 8.0[f]	6.65(6)	6.20(4) 6.18[e]	8.05(9)	7.60(7) 7.5[d]	7.92(5)	8.07
pK_{a3}	2.3(1)[c]	2.1(1)[c]	2.4[c]	1.9[f]	1.8[d]	1.9[f]	2.34

[a] All values were determined at 25 °C and I = 0.1 M. Values in parentheses are standard deviations in the last significant digit. [b] *N*-(2-Hydroxybenzyl)iminodiacetic acid.[17] [c] Estimated value since the true uncertainty in these pK_a values is greater than the standard deviation obtained from the least-squares fitting of the potentiometric data. [d] Determined by ^{19}F NMR spectroscopy. [e] Ref.[18] [f] Determined by ^{1}H NMR spectroscopy. [g] Determined by UV/Vis spectroscopy.

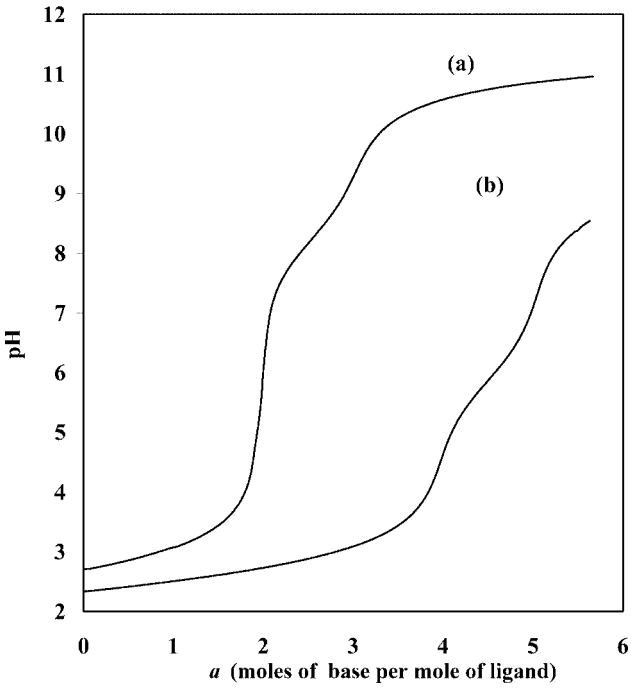

Figure 5. Potentiometric titration curves for (a) 1 mM ligand **L1** and (b) **L1** + Ga^{3+} (1:1, 1 mM). a = mols of base added per mol of ligand. All solutions were at 25 °C and I = 0.1 M ($NaNO_3$). The data were refined with the program SUPERQUAD (σ_{fit} = 3.5–4.5).

than that of HBIDA; this effect is due to the presence of the methyl group, which increases the electronic density on the phenolic ring. The effect of these groups also has an influence on the ammonium acidity, which is more acidic for ligands **L2** and **L3** (pK_{a2} values of 6.65 and 6.21, respectively). On the other hand, for ligands **L1** and **L4**, which bear low inductive groups (R = Me and CH_2OH, respectively), or with an electron-donating group (R = OMe, **L6**), the ammonium always has a pK_a value larger than 8.

Since low pK_a values are difficult to determine by potentiometric titration, some of the deprotonation constants of **L4** and **L6** were also calculated by ^1H NMR spectroscopy from the titration curves of δ vs. pH under the same conditions of ionic strength as used for the potentiometric study (Table 3). The K_{an} values were obtained from the chemical shift.[19] The resonances of the methylene protons of the benzylic and acetic (CH_2COO) positions (singlets) become more shielded upon addition of base ($\Delta\delta$ = 0.8 ppm in all the cases for pH ranging from 0.5 to 12) while the deprotonations only produce a small chemical shift (around 0.1 ppm) of the three aromatic protons. These observations make it clear that these protons are sensitive to the protonation state of the amine and one of the two carboxylic functions. In the same way, ^{19}F NMR spectroscopy can be considered as an excellent tool for the pK_a determination for **L5** because three constants out of the four can be determined. The fourth deprotonation produces a marked change in the ^{19}F chemical shift ($\Delta\delta$ = 6 ppm). This increased shielding of the fluorine ring substituent indicates a net increase of negative charge on the aromatic ring in this process. This observation is consistent with the loss of the phenolic proton, which cannot be determined by ^1H NMR spectroscopy. It is also very interesting to notice that the fluorine atom is a much more sensitive probe than ^1H, since a carboxylic function located in a ^9J position can affect the fluorine chemical shift. The agreement between the values from various experimental techniques is reasonable, and the dissociation constants correlate well with the data reported for HBIDA (see Table 2).

Table 3. Stability constants and pGa values.

Constants[a]	L1	L2	L3	L4	L5	L6	HBIDA[b]
$\log \beta_{110}^{FeLx}$	23.5	20.5	20.1	22.5	22.4	25.3	21.40
$\log \beta_{110}^{GaLx}$	22.1	19.4	19.1	21.1	21.4	25.2	21.55

[a] All values were determined at 25 °C and I = 0.1 M ($NaNO_3$). [b] Ref.[17] [c] K_{OH}^{1} = [Ga**Lx**(OH)][H^+]/[Ga**Lx**]for the equilibrium Ga**Lx** + H_2O ⇌ Ga**Lx**(OH) + H^+. [d] Determined by ^1H NMR titration. [e] Determined by ^{19}F NMR titration. [f] K_{OH}^{2} = [Ga**Lx**$(OH)_2$][H^+]/[Ga**Lx**(OH)] for the equilibrium Ga**Lx**(OH) + H_2O ⇌ Ga**Lx**$(OH)_2$ + H^+. [g] Calculated for [**Lx**]$_{tot}$ = 10^{-5} M and [Ga]$_{tot}$ = 10^{-6} M at pH 7.4.

Stability Constants of the Gallium Complexes

It was not possible to determine the stability constants β_{110}^{GaLx} of the complexes by potentiometric titration since the formation of the complexes is complete at low pH values (Figure 5b). The titration curves for a 1:1 ratio of Ga^{III} and ligand (Figure 5b as an example) exhibit two breaks at a = 4 and a = 5, where a is equal to the number of mols of base added per mol of ligand. This indicates the formation of the hydroxo complexes [Ga**Lx**(OH)] and [Ga**Lx**$(OH)_2$] at relatively low pH values. Analysis of the titration curves with the program SUPERQUAD[16] yielded the K_{OH}^{n} (n = 1 or 2) constants expressed by Equation (3).

$$K_{OH}^{n} = [Ga\mathbf{Lx}(OH)_n][H^+]/[Ga\mathbf{Lx}(OH)_{n-1}] \quad (3)$$

The K_{OH}^{n} values are given in Table 3, and can also be determined by ^1H NMR spectroscopy for Ga**L1**. In the case of Ga**L5**, ^{19}F NMR spectroscopy was used to determine the two hydrolysis constants, as shown in Figure 6, revealing two important chemical shift jumps ($\Delta\delta$ = 0.75 and 1.2 ppm) as a function of pH.

The obtained values are in good agreement with the potentiometric titrations. It should be noted that higher pK_{OH}^{1} values have been obtained for Ga**L5** and Ga**L6** in relation with the higher basicity of the phenolate group as it increases the electronic density on the metal ion. The stability constants β_{110}^{GaLx} were determined in acidic medium[19] (pH 2.01) by metal–metal competition, using the absorbance of Fe**Lx** as a spectral probe. In these experiments, exchange of Ga^{III} with Fe^{III} was allowed to occur [Equations (4) and (5)].

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

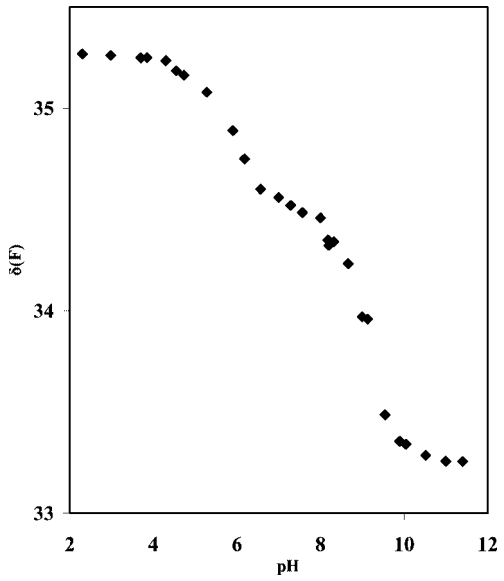

Figure 6. Dependence of the ^{19}F chemical shift (vs. C_6F_6) of Ga**L5** on the addition of NaOH [measured in an H_2O/D_2O (80:20) medium at 25 °C and I = 0.1 M $NaNO_3$].

$$Fe\mathbf{Lx} + Ga^{III} \rightleftharpoons Ga\mathbf{Lx} + Fe^{III} \quad (4)$$

$$K = \frac{[Ga\mathbf{Lx}][Fe^{III}]}{[Fe\mathbf{Lx}][Ga^{III}]} = \frac{\beta_{110}^{Ga\mathbf{Lx}}}{\beta_{110}^{Fe\mathbf{Lx}}} \quad (5)$$

The amount of uncomplexed **Lx** was assumed to be negligible.

Knowledge of the formation constants of Fe**Lx** complexes, along with mass balance, absorbance, and pH measurements, is necessary to calculate the formation constants of Ga**Lx**. Beforehand, the stability constants of Fe**Lx** ($\beta_{110}^{Fe\mathbf{Lx}}$) were determined by competition experiments against HEDTA[17] over the pH range 2–2.5. The following equation corresponds to the equilibrium [charges omitted for clarity, Equation (6)].

$$Fe\mathbf{Lx} + HEDTA \rightleftharpoons FeHEDTA + \mathbf{Lx} \quad (6)$$

where HEDTA is (hydroxyethyl)ethylenediaminetriacetic acid [Equation (7)].

$$K' = \frac{[\mathbf{Lx}][FeHEDTA]}{[Fe\mathbf{Lx}][HEDTA]} = \frac{\beta_{110}^{FeHEDTA}}{\beta_{110}^{Fe\mathbf{Lx}}} \quad (7)$$

The concentrations of Fe**Lx** complexes were calculated from the absorbances between 486 and 578 nm (depending on the ligand **Lx**), where Fe**Lx** is the only absorbing species. The concentration of the other species was calculated from mass balance equations and pH, using the usual α Ringbom coefficient.[21] With the known formation constant of Fe^{III}-HEDTA ($\log \beta_{110}^{FeHEDTA}$ = 19.8), and the deprotonation constants of HEDTA (pK_{a1} = 9.81, pK_{a2} = 5.37, and pK_{a3} = 2.6),[18] the values of $\beta_{110}^{Fe\mathbf{Lx}}$ and $\beta_{110}^{Ga\mathbf{Lx}}$ were calculated from Equations (6) and (7), respectively, and are reported in Table 3. They span over the range 19.1–25.3 and are consistent with the one obtained for the HBIDA ligand taken as the reference (no electronic effect).[17]

As we can observe, the stability of the complexes (Fe^{III} or Ga^{III}) increases with the basicity of the phenolate, i.e. with its greater electron donor ability. Ligands with an electron-withdrawing substituent (the more acidic) lead to complexes with a gallium stability constant lower than that of Ga-transferrin ($\log K$ = 19.8),[22] whereas ligands with electron-donating substituents (R = OMe, Me) give $\beta_{110}^{Ga\mathbf{Lx}}$ values up to five times higher than the complex Ga-transferrin. The distribution curves shown in Figure 7 for the 1:1 Ga^{III}:**L1** system provide a typical picture of the successive complexes formed as a function of pH. Ga**L1** is dominant in the pH range 2–4.5, while the first hydroxo complex [Ga-**L1**(OH)] is the major species at physiological pH. pK^1_{OH} values can also be related to the basicity of the phenolate group: this increases the electronic density on the metal ion and decreases its affinity towards coordinated water molecules, so the highest pK^1_{OH} values are obtained for Ga**L5** and Ga**L6**.

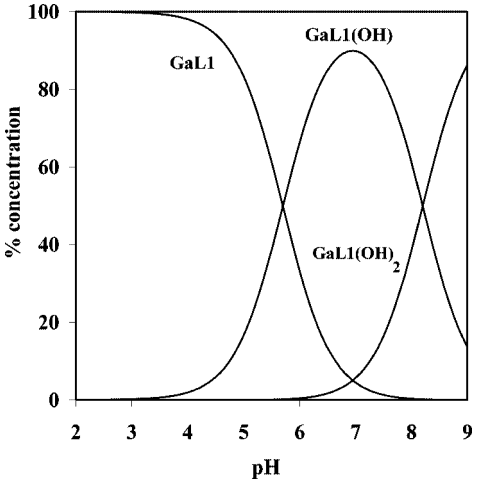

Figure 7. Distribution curves for the system Ga^{III}–**L1** as a function of pH. [Ga^{3+}] = 1 mM and [**L1**] = 10 mM.

Since the ligands are weak acids, proton competition occurs depending on their pK_a and the pH. The pGa (–log [Ga^{3+}]) is thus a better measure of the relative complexation efficiency of the ligands under given conditions of pH, Ga, and **Lx** concentrations: the larger the pGa values, the more effective the ligand. The pGa values for pH 7.4 ([Ga^{3+}] = 10^{-6} M, [**Lx**] = 10^{-5} M) are collected in Table 3. They have also been calculated for pH values over the range 2–8 and reported as the plot pGa = f(pH) presented in Figure 8. In this pH range, the uncertainty in the high pK_a values does not affect the calculations of the pGa values.

Except for **L6**, it is important to note a similar efficiency in the complexation of Ga^{III} by the various aminophenolate ligands. pGa values have small variations whenever **Lx** bears electron-withdrawing substituents (R = CHO, R = NO_2) or an electron-donating group (R = Me). These ligands' complexing abilities are thus similar to Ga-EDTA (pGa = 20.0)[22] and Ga-DTPA (pGa = 20.2)[22] but with a lower denticity. pGa vs. pH curves indicate that **L6** is the best complexing agent of this family over the whole pH range

 © 2005 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

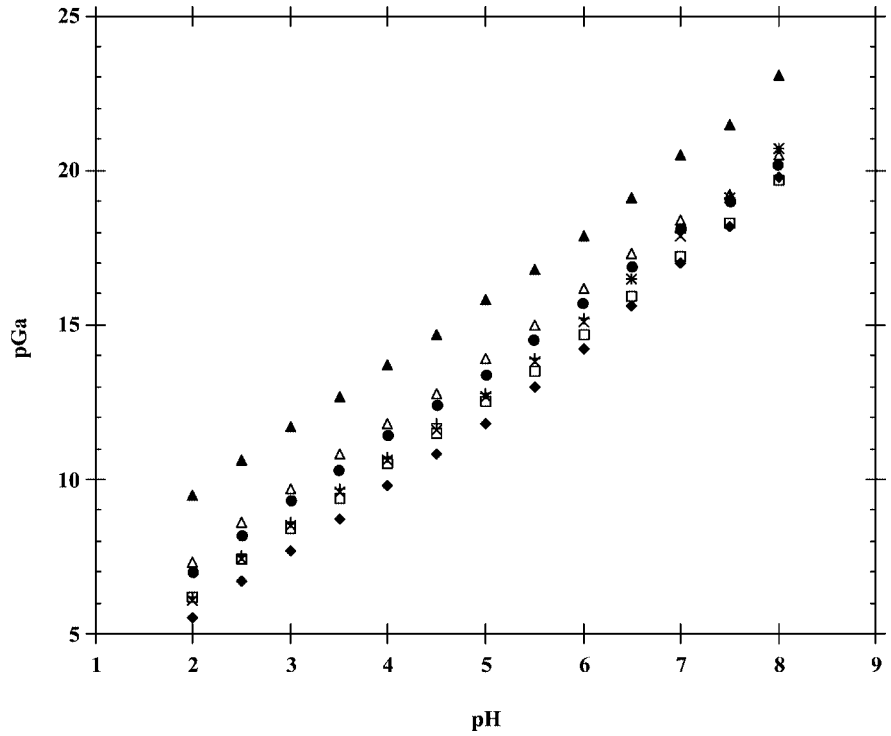

Figure 8. Plot of pGa (–log [Ga^{3+}]) vs. pH. pGa was calculated for [**Lx**] = 10^{-5} M and [Ga^{3+}] = 10^{-6} M. For HBIDA, the deprotonation constants and the complexation constants β_{110} were taken from ref.[20] (× **L1**, ● **L2**, Δ **L3**, ♦ **L4**, □ **L5**, ▲ **L6**, + HBIDA).

(pGa = 21.5 at pH 7.4). This good affinity is due to an increased basicity of the phenolate with a methoxy group in the *para* position. Indeed, according to Pearson's principle of hard and soft acids and bases (HSAB),[23] a very basic negative oxygen donor has a high affinity for a hard metal ion such as Ga^{III}. Except for **L6**, and as could be expected from theory, acidic ligands (those bearing electron-withdrawing substituents) have the best complexing ability at low pH. So, **L6** is a good Ga^{III} chelator compared to the Ga-transferrin (pGa = 19.7)[22] system (around two orders of magnitude difference). Ga**L6** may thus be resistant to demetalation in vivo, and radiopharmaceutical applications are possible in this context.

Conclusions

This work has shown that the R-(*o*-hydroxybenzyl)iminodiacetate ligands (obtained in only two steps) with a potential conjugating group in the *para* position to the phenol and a rather low denticity are strong chelators for Ga^{III}. For the Ga**L3** (R = NO_2) complex in the solid state, the Ga^{III} ion is hexacoordinate with two water molecules in *cis* positions. The protonation constants of the ligands and the hydoxo complexes' formation constants were measured by different techniques and gave consistent data. Considering the pGa values, Ga**L6** (R = OMe) appears to be a promising candidate for use in radioimaging since the stability constant of Ga-transferrin is two orders of magnitude lower. Studies with $^{67/68}$Ga radiolabeling are now in progress in order to confirm the kinetic inertness of these bifunctional chelating systems against common decomplexation pathways.

Experimental Section

General Remarks: ^{1}H NMR spectra were recorded on a Bruker AC 200 spectrometer. Chemical shifts are reported in ppm from internal sodium 3-(trimethylsilyl)propane-1-sulfonate. ^{19}F NMR spectra were recorded on a Varian U400 with chemical shifts in ppm relative to an external C_6F_6 reference in $CDCl_3$ (δ = –163 ppm relative to $CFCl_3$). The pH was adjusted with small additions of concentrated HCl or NaOH solutions (prepared in D_2O). The pK_a values were measured in pure D_2O and the pD was obtained from the pH meter readings by adding 0.4 units.[24] For the dissociation constants in D_2O and H_2O, the relationship pK_D = 1.018 pK_H + 0.43 was used.[25] Measurements were made in a H_2O/D_2O medium (80:20 v/v) and in this case no correction for isotopic or solvents effects was needed. Analyses were performed by the Service Central d'Analyse (CNRS Solaize). All chemicals were obtained from Acros or Aldrich and were used without further purification.

Synthesis of GaL3: 10 mL of an aqueous solution of NaOH (2 mmol) was added to a solution of **L3** (165 mg, 0.5 mmol) in water (10 mL). The gallium nitrate salt in H_2O (0.5 mmol in 10 mL) was then added to this homogeneous solution and the pH adjusted to 3–4. After stirring for 30 min, half of the solvent was slowly removed under reduced pressure. Slow concentration of the filtrate over a period of one week yielded suitable crystals for X-ray diffraction studies. Yield: 164 mg (81%). $C_{11}H_{15}GaN_2O_{10}$: calcd. C 32.62, H 3.73, Ga 17.22, N 6.92; found C 32.82, H 3.59, Ga 16.95, N 6.85. ^{1}H NMR (DMSO): δ = 3.16–3.38 (dd, J = 21 Hz, 4 H, H_{ac}), 3.95 (s, 2 H, H_{benz}), 6.65–6.67 (d, J = 6 Hz, 1 H, H_{ar}), 7.95–8.05 (m, 2 H, H_{ar}) ppm.

Potentiometric Titrations: All the measurements were made at 25 °C and the solutions were prepared with deionized water that had been distilled twice. The ionic strength was fixed at I = 0.1 M with $NaNO_3$ (PROLABO puriss). The potentiometric titrations were performed using an automatic titrator system, DMS 716 Titrino (Metrohm), equipped with a combined glass electrode (Metrohm, filled with saturated NaCl solution) and connected to an IBM Aptiva microcomputer. The electrodes were calibrated to read pH according to the classical method[26] (from titration of 0.01 M $HClO_4$ with 0.025 M NaOH). The ligands and their gallium(III) complexes (ca. 0.001 M) were titrated with standardized 0.025 M sodium hydroxide. Argon was bubbled through the solutions to exclude CO_2 and O_2. Aqueous sodium hydroxide (0.1 M NaOH) was prepared from 1 M commercial NaOH solution (Prolabo) and was standardized against hydrogen phthalate solution. The titration data (120 points collected over the pH range 2.5–10.5 for the ligand solutions and 100 points collected over the pH range 2.5–10 for the Ga^{III}–ligand solution) were refined with the nonlinear least-squares refinement program SUPERQUAD[16] to determine the deprotonation constants (σ_{fit} in the range 3.5–4.5). The pK_{an} values were calculated from the cumulative constants determined with the above program. The uncertainties in the pK_{an} values correspond to the standard deviations (1σ) in the cumulative constants.

Spectrophotometric Experiments: UV/Vis absorption spectra were recorded with a Perkin–Elmer Lambda 2 spectrometer using 1-cm path-length quartz cells and connected to a microcomputer; the acquisition was made with the UV Winlab software (Perkin–Elmer). The temperature was maintained at 25 °C with a Perkin–Elmer PTP.1 variable temperature unit. The pH measurements were made with a 713 Metrohm digital pH meter equipped with a microelectrode. The ionic strength was fixed at I = 0.1 M with $NaNO_3$.

X-ray Crystallographic Data Collection and Refinement of the Structures: The main crystallographic features, the strategy used for the crystal structure determination, and its results are gathered in Table 4. Data collection was performed at room temperature. The U_{iso} of the H atoms was fixed to 1.2 U_{eq} of the C atom to which they are bound. All the structures were solved by direct methods (SIR92).[27]

CCDC-201447 (for **L6**) and -201562 (for Ga**L3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Formation of 3-Sulfanylcoumarins by $SnPh_3OH$-Promoted Cyclization of 3-Aryl-2-Sulfanylpropenoic Acids

Pedro Álvarez-Boo,[a] José S. Casas,[b] María D. Couce,[a] Vanesa Fernández-Moreira,[a] Eduardo Freijanes,[a] Emilia García-Martínez,[a] José Sordo,*[b] and Ezequiel Vázquez-López[a]

Keywords: Tin / Triphenyltin complexes / 3-(2-hydroxyphenyl)-2-sulfanylpropenoic acids / 3-sulfanylcoumarin / X-ray diffraction

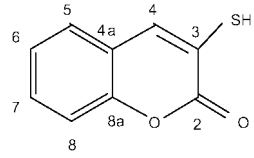
Reaction of $SnPh_3OH$ with 3-(2-hydroxyphenyl)sulfanylpropenoic acid [H_2(*o*-hpspa)] yielded [$SnPh_3$(SC)], where SC is deprotonated 3-sulfanylcoumarin (3-sulfanyl-2H-1-benzopyran-2-one, HSC), by a cyclization process. Similarly, when 3-(2-hydroxy-5-bromophenyl)- and 3-(2-hydroxy-3,5-dibromophenyl)-2-sulfanylpropenoic acids were treated with the same tin hydroxide, the cyclization resulted in [$SnPh_3$(BrSC)] and [$SnPh_3$(Br_2SC)], where BrSC and Br_2SC are the new ligands formed from the deprotonation of 3-sulfanyl-6-bromocoumarin and 3-sulfanyl-6,8-dibromocoumarin, respectively. The new compounds were characterized by elemental analysis, multinuclear NMR (^{1}H, ^{13}C and ^{119}Sn) and vibrational spectroscopy, and mass spectrometry. Single-crystal X-ray structures of these complexes all showed that the tin atom is surrounded by three phenyl C atoms and the S and O atoms of the bidentate ligand in a distorted trigonal-bipyramidal environment.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2005)

Introduction

In previous work,[1] treatment of 3-(phenyl)-2-sulfanylpropenoic acid (H_2pspa) with $SnPh_3OH$ in the presence of diisopropylamine afforded the compound [Q][$SnPh_3$(pspa)] (Q = diisopropylammonium), which showed antibacterial activity against *Staphylococcus aureus* and, although minor, against *Escherichia coli*. In an effort to synthesize a more soluble product with similar activity we have now prepared the 3-(2-hydroxyphenyl)-2-sulfanylpropenoic acid [H_2(*o*-hpspa)]. However, reaction of this compound with $SnPh_3OH$ yielded the unexpected complex [$SnPh_3$(SC)], where SC is deprotonated 3-sulfanylcoumarin. Formation of the same product in the absence of diisopropylamine showed that the amine played no role in the reaction.

Coumarin (1,2-benzopyrone, Scheme 1) is a natural product present in plants with widespread use in foodstuffs and cosmetic products. Furthermore, this substance is used in medicine as an anticoagulant. Coumarin derivatives (in particular those substituted at positions 3 or 4 of the pyrone cycle), have bacteriostatic and rodenticide applications.[2–4]



Scheme 1.

The synthesis of 3-sulfanylcoumarin had been previously carried out by Shi et al.[5] by reacting 5-(*o*-hydroxybenzylidene)rhodanine with hydrazine hydrate in EtOH at 80 °C. In this paper, we describe the formation of tin(IV) complexes containing this deprotonated species as well as its 6-

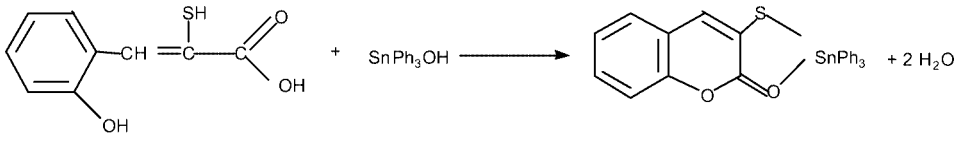

Scheme 3.

bromo- and 6,8-dibromo derivatives which resulted from the cyclization of 2-sulfanylpropenoic acids (Scheme 2), together with their structural study by means of X-ray diffraction and characterisation by vibrational and NMR spectroscopy. We chose Br-substituted derivatives in an effort to examine the influence of relatively bulky and electronegative atoms in the aromatic moiety of the acids on the cyclization process.

Results and Discussion

Synthesis of [$SnPh_3$(L)] (L = SC, BrSC, Br_2SC)

The reaction of the complex formation is shown in Scheme 3.

In the Experimental Section we describe the reactions carried out with excess $SnPh_3OH$. Besides these conditions, the reaction was also explored in a 1:1 mol ratio of reactants in the presence and absence of diisopropylamine in EtOH solution. In all cases, the solid isolated was determined to be the same sulfanylcoumarin derivative.

The reactions of $H_2(Br_2$-*o*-hpspa) with $Zn(OAc)_2$, $Cd(OAc)_2$, $Pb(OAc)_2$ and SnR_2O (R = Me, Et, Bu, Ph) were also explored. In all cases, the solids isolated have stoichiometries corresponding to the 3-aryl-2-sulfanylpropenoic acid derivatives. For example, the reaction of $H_2(Br_2$-*o*-hpspa) with $SnMe_2O$ afforded a solid with the analytical data C 26.4, H 1.9, S 6.3%; [$SnMe_2(Br_2$-*o*-hpspa)] requires C 26.4, H 2.0, S 6.4%, while [$SnMe_2(SC)_2$] requires C 29.3, H 1.5, S 7.8%. Further work to elucidate the role of the metal in the cyclization process is in progress. In order to explore the behaviour of [$SnPh_3$(SC)] in acidic medium, $HOOCCF_{3(aq.)}$ was used as a proton source; no formation of free sulfanylcoumarin was detected.

Crystal Structures

[$SnPh_3$(SC)]

Tin Coordination Sphere

Figure 1 shows the structure of the compound and the numbering scheme, and Table 1 lists the significant bond lengths and angles. The tin atom is coordinated to three phenyl C atoms and to the S and O donor atoms of the SC ligand, which results a distorted trigonal-bipyramidal environment in which O(1) and C(11) are apical. The equatorial C atoms are closer to Sn than the apical carbon, as expected in this type of polyhedron; i.e. for the apical C atom: Sn–C(11) = 2.154(3) Å, for the equatorial C atoms: Sn–C(21) = 2.137(3), Sn–C(31) = 2.131(3) Å – all three are within the range of 2.12–2.18 Å reported for other triphenyltin compounds.[6] On the other hand, the Sn–S bond length [2.4691(10) Å] is slightly greater than the sum of the covalent radii of tin and sulphur atoms (2.42 Å),[7] but within the range reported for triphenyltin thiolates (2.405–2.481 Å).[6,8–10] The most remarkable bond length around the tin atom is the long (even for an apical position) Sn–O distance [2.589(2) Å], which is greater than the sum of their covalent radii (2.13 Å),[7] though smaller than the sum of their van der Waals radii (3.70 Å)[7] and in the range that has confidently been reported to indicate Sn–O bonding.[11] This long bond length denotes a weak interaction between these atoms and is in line with the short C–O distance of 1.215(4) Å, indicating that the C=O bond is only slightly altered upon coordination [*d*(C=O) = 1.20 Å].[7]

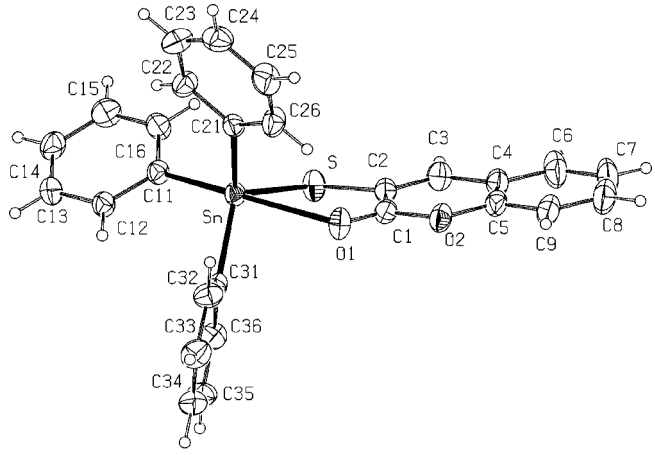

Figure 1. Displacement ellipsoid plot for [$SnPh_3$(SC)] with the atom numbering scheme. Ellipsoids at 30% probability.

The bond angles around the metal atom are indicative of the distortion from the regular trigonal-bipyramidal geometry. Thus, for instance, C(11)–Sn–S = 95.36(9)°, C(31)–Sn–C(11) = 105.09(12)° and C(21)–Sn–C(11) = 105.23(12)° (instead of 90°); C(31)–Sn–C(21) = 113.77(13)°, C(31)–Sn–S = 115.41(9)° and C(21)–Sn–S = 118.47(9)° (instead of 120°). The bond angles involving the two donor atoms of the sulfanylcoumarin ligand have values quite different from that expected for a regular polyhedron, namely: C(31)–Sn–O(11) = 78.01(10)°, C(21)–Sn–O(11) = 83.50(11)° and, specially, S–Sn–O(1) = 73.08(6)°, which are considerably narrower than the theoretical 90° angle because of the bite of the SC ligand. Nevertheless, according to Addison's τ-criterion,[12] (τ = 0.83) we can state that the coordination polyhedron is much closer to a trigonal bipyramid (τ = 1) than to a square pyramid (τ = 0).

The general features of the tin kernel are similar to those found in triphenyltin sulfanylcarboxylates,[1] in which an

C(21)–Sn–O(1)	83.50(11)	83.74(12)	80.5(2)
C(11)–Sn–O(1)	168.04(11)	161.95(11)	167.0(2)
S–Sn–O(1)	73.08(6)	70.73(6)	72.77(12)
C(2)–S–Sn	105.87(13)	108.49(12)	107.4(2)
C(1)–O(1)–Sn	116.7(2)	113.3(2)	115.7(5)

SCCO donor fragment is also present; the main difference lies in the Sn–O bond length, which is longer in this case.

The SC Ligand

The C–C (1.44–1.46 Å) and C–O [1.354(4), 1.382(4) Å] bond lengths are as expected for a single bond between sp^2 carbon atoms, except for the C(12)–C(13) [1.345(5) Å] and C(1)–O(1) [1.215(4) Å] lengths which indicate some double bond character.

[SnPh$_3$(BrSC)]·EtOH and [SnPh$_3$(Br$_2$SC)]

The type of coordination and the bond lengths involving the tin atom are similar to those discussed above for [$SnPh_3$(SC)]. As seen in Table 1, the bond lengths around the metal atom are almost identical in all three compounds. The only noticeable difference in the metrical data of these complexes is the Sn–O bond length. Even though the Sn–O bond lengths are quite different [2.589(2), 2.784(3) and 2.666(5) Å], we can conclude that the presence of one or two Br atoms on the phenyl ring of the SC ligand does not induce any significant change in the molecular structure of the complex.

Spectroscopic Studies

The vibrational patterns of the complexes have been analysed in light of their structural study by X-ray diffraction. Thus, the position of ν(C=O) is consistent with the weak Sn–O bond, which is close to that found in inclusion complexes[13] in which a coumarin ligand is hydrogen-bonded via this group. The band at 360 cm^{-1}, present in both IR and Raman spectra and attributable to ν(Sn–S), is consistent with the coordination via the S atom, and ν_{asym}(Sn–C) and ν_{sym}(Sn–C) vibrations are located at positions typical of a non-planar SnC_3 framework.[1,14]

The ^{1}H NMR spectra agree with the evolution associated with the cyclization and deprotonation processes. For instance, carboxylic acid signal found in the spectra of the parent sulfanylpropenoic acids (between 13 and 11 ppm) is absent in the spectra of the tin derivatives due to cyclization. In addition, no signal attributable to the SH proton is observed in the spectra of any of these complexes. The ^{13}C NMR spectra for these complexes are consistent with those for other 3-substituted, 6-bromo-3-substituted or 6,8-dibromo-3-substituted coumarins.[15]

The ^{119}Sn NMR spectra show a singlet at about –101 ppm. This value for the chemical shift falls in the range proposed for a tetra-coordinated tin centre,[16,17] which seems to indicate the loss of the five-coordinate nature upon dissolution. This signal slightly shifts upfield as the temperature increases from 230 to 330 K, but no splitting occurs.

Experimental Section

Methods and Materials: Triphenyltin(IV) hydroxide, rhodanine and diisopropylamine (Aldrich-Chemie) were used as supplied. Elemental analyses were performed with a Carlo Erba 1108 apparatus. Melting points were determined using a GallenKamp MFB-595 apparatus. The IR spectra were recorded on a Bruker IFS 66v FT-IR spectrometer, and the Raman spectra were recorded with the same spectrometer using an FRA-106 accessory. NMR spectra were recorded at room temperature in $CDCl_3$. ^{1}H and ^{13}C NMR spectra were obtained with a Bruker AMX300 spectrometer operating at 300.14 and 75.48 MHz, respectively (referenced to $SiMe_4$). ^{119}Sn NMR spectra were recorded with a Bruker AMX500 apparatus operating at 186.50 MHz (referenced to $SnMe_4$). Downfield shifts were taken to be positive. Mass spectra were recorded with a Kratos MS50TC spectrometer connected to a DS90 data system and operating under EI (70 eV, 250 °C) and FAB conditions (Xe, 8 eV) using as liquid matrix 3-nitrobenzyl alcohol. Crystallographic data were recorded at room temperature on a Bruker CCD Smart apparatus using Mo-K_α radiation (λ = 0.71073 Å). An absorption correction was made by means of the SADABS program,[18] and the structure solution was carried out using the SHELXS-97 program.[19a] Least-squares full-matrix refinements on F^2 were performed using the program SHELXL97.[19a] Reflection data for [$SnPh_3$(BrSC)] were corrected for the diffuse scattering as a result of disordered ethanol molecules by means of the program SQUEEZE,[19b] and the illustrations were obtained with the PLATON package.[19c] Crystal data, details of data collections and refinements are given in Table 2. The molecular structures of the complexes are depicted in Figure 1 and Figures S1 and S2 (Supporting Information) and show ellipsoids at 30% probability level. CCDC reference numbers 265333–265335 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Synthesis of the Compounds: 3-Aryl-2-sulfanylpropenoic acids were prepared[20] by condensation of the appropriate benzaldehyde with rhodanine, subsequent hydrolysis in NaOH (1 M) and subsequent acidification with aqueous HCl (1 M).

H_2(*o*-hpspa): From 2-hydroxybenzaldehyde (2.50 g, 10 mmol) as starting material. Colour: yellow. Yield: 1.14 g, 58%. Mp: 140 °C.
