Keywords: Iron / Phosphane ligands / Enynes / Rearrangement

The preparation and characterisation of iron(II) complexes bearing unsymmetrically 1,4-disubstituted η^3 -butenyne ligands, *cis*-[Fe(C(C $\equiv$ CR)=C(H)R')(dmpe)₂][PF₆] (e.g. R = *t*Bu, R' = Ph **2e**; R = Ph, R' = *t*Bu **2e'**) are reported. The complexes were obtained as a mixture by protonation and rearrangement of the bis(acetylide)iron(II) complex *trans*-Fe(C(CPh)(CC*t*Bu)(dmpe)₂. The complexes **2e** and **2e'** were separated

by crystallisation and were both characterised crystallographically. In addition, a number of complexes with symmetrically 1,4-disubstituted butenyne ligands *cis*-[Fe(C(C $\equiv$ CR)=C(H)R)(dmpe)₂][PF₆] (R = *p*-C₆H₄-OMe **2a**; *p*-C₆H₄-Me **2b**, C₆H₃-3,5-(CF₃)₂ **2c**; 1-adamantyl **2d**) were synthesised by protonation and rearrangement of the corresponding bis(acetylide)iron(II) complexes.

Introduction

Transition-metal butenyne complexes have been identified as key intermediates in the metal-catalysed head-to-head couplings of alkynes leading to *E/Z*-1,4-disubstituted 1-buten-3-yne^[1–5] and *E/Z*-1,4-disubstituted butatrienes.^[6] Such compounds are of interest as building blocks in organic synthesis and as components of biologically active molecules.^[7] The majority of alkyne dimerisation studies have focused on the homo-dimerisation of terminal alkynes; there has been relatively little attention to the cross-coupling of two *different* terminal alkynes.^[8] The regioselective and stereoselective catalytic synthesis of unsymmetrically 1,4-disubstituted butenyne from alkyne mixtures could be utilised for the synthesis of more complex organic molecules.^[3,9] In a manner similar to the homodimerisation of alkynes, metal-catalysed cross-coupling reactions could involve the intermediacy of unsymmetrically 1,4-disubstituted butenyne metal complexes

When used as a ligand, the but-1-en-3-yn-2-yl moiety can coordinate in either an η^3 - or η^1 -mode, depending on the co-ligands and metal centre, and the η^1 -coordination mode of butenyne ligands has been implicated as an important intermediate preceding σ -bond metathesis with alkynes during the metal mediated coupling of alkynes.^[10] Butenyne complexes have been studied for a range of transition metals including iron,^[11–14] ruthenium,^[2,5,10,15–18] osmium,^[19] and platinum.^[20] Various methods have been established for the synthesis of butenyne complexes, including the addition of 1,4-disubstituted-1,3-diynes to metal hydride complexes,^[2,15,21] and the addition of terminal acetylenes to either metal hydrides,^[2,13,22,23] metal acetylides,^[1,17,24] or metal alkenyl complexes.^[22] Other methods of synthesis include the insertion of a coordinated acetylide into a metal–vinylidene bond.^[2,6,12,24,25]

We have previously reported^[12,18] the synthesis of symmetrical butenyne-iron(II) and -ruthenium complexes, [M(C(C $\equiv$ CR)=C(H)R)(P₄)]⁺ {M = Fe, P₄ = 2 $\times$ dmpe [1,2-bis(dimethylphosphanyl)ethane]; M = Ru, P₄ = 4 $\times$ PMe₃} by the acidification of the corresponding bis(acetylide)-iron(II) and -ruthenium(II) complexes. The bis(acetylide) complexes were protonated at an acetylenic β -carbon to form vinylideneacetylide complexes, which rearrange with coupling of the acetylide and vinylidene ligands to form the butenyne complexes.

As an extension of this work, we report the synthesis and characterisation of a number of iron(II) complexes bearing both symmetrically and unsymmetrically substituted butenyne ligands.

Results and Discussion

Synthesis of Bis(acetylide) Complexes

The reaction of terminal acetylenes with *cis*-FeH₂(dmpe)₂ in MeOH is known^[12] to yield bis(acetylide)iron(II) com-

plexes (Scheme 1). This method has been used to prepare a number of iron(II) complexes **1a–d** of the form *trans*-Fe(C≡CR)₂(dmpe)₂ incorporating a variety of aryl- and alkyl-substituted acetylenes.

Scheme 1.

The NMR spectra of the resultant complexes are unremarkable, with the *trans* configuration of the ligands confirmed by the presence of a single resonance in the ³¹P{¹H} NMR spectrum. Crystals suitable for X-ray structure determination were grown by recrystallisation from benzene (**1a**) or toluene (**1b**, **1c**) (Figure 1); selected bond lengths [Å] and angles [°] are shown in Table 1.

Figure 1. Molecular projection of the complexes *trans*-Fe(C≡C-C₆H₄-4-OMe)₂(dmpe)₂ (**1a**, left), *trans*-Fe(C≡C-C₆H₄-4-Me)₂(dmpe)₂ (**1b**, centre) and *trans*-Fe(C≡C-C₆H₃-3,5-(CF₃)₂)₂(dmpe)₂ (**1c**, right). Thermal ellipsoids are shown at the 50% probability levels, selected hydrogen atoms have been removed for clarity.

Crystallographically, the complexes **1a–1c** are highly symmetrical, with the asymmetric unit consisting of one half of each molecule. The structural analysis confirms the expected octahedral geometry with the two acetylide groups being disposed in a mutually *trans* fashion. The seven atoms forming the central core of the complexes (C–C≡C–Fe–C≡C–C) are essentially colinear with the acetylide groups orthogonal to the plane containing the iron and four phosphorus atoms. Comparison of the bond lengths with the

known bis(acetylide)iron(II) complex *trans*-[Fe(C≡CPh)₂-(dmpe)₂]^[26] shows that there is very little variation between the structures, with the Fe–C, C≡C and C–C bonds being essentially indistinguishable between complexes.

The bis(acetylide) complexes *trans*-[Fe(C≡CPh)-(C≡C*t*Bu)(dmpe)₂] (**1e**), *trans*-[Fe(C≡CC₆H₄-4-CH₃)-(C≡C*t*Bu)(dmpe)₂] (**1f**) and *trans*-[Fe(C≡CPh)(C≡CSi(CH₃)₃)(dmpe)₂] (**1g**) were synthesised as described previously from *trans*-Fe(CH₃)Cl(dmpe)₂ in a two-step sequence (Scheme 2).^[27]

Scheme 2.

Rearrangement to Butenynes

The addition of trifluoroacetic acid to **1a–d** in THF, followed by anion exchange and recrystallisation from ethanol led to the isolation of the complexes *cis*-[Fe(C-(C≡CR)=CHR)(dmpe)₂][PF₆] (**2a–d**) in good yield. The synthesis of complexes bearing unsymmetrically substituted butenynyl ligands was undertaken from the known^[27] bis(acetylide) complexes *trans*-[Fe(C≡CPh)(C≡C*t*Bu)(dmpe)₂] (**1e**), *trans*-[Fe(C≡CC₆H₄-4-CH₃)(C≡C*t*Bu)(dmpe)₂] (**1f**) and *trans*-[Fe(C≡CPh)(C≡CSi(CH₃)₃)(dmpe)₂] (**1g**). Addition of either trifluoroacetic acid or ammonium hexafluorophosphate to solutions of **1e–g** gave mixtures of the two possible regioisomeric complexes **2e/e'–2g/g'** (Scheme 3).

The relative yields of the two possible regioisomers of **2e/e'–2g/g'** were determined by NMR spectroscopy and depended on the nature of the acetylide ligands, and in the case of **2g/g'**, on the temperature at which the reaction was performed (Table 2).

Scheme 3. Preparation of butenynyl-iron(II) complexes **2a–g**. Reagents: i) CF₃COOH, KPF₆ (**2a–2d**, **2f/f'**). ii) NH₄PF₆ (**2e/e'**, **2g/g'**).

Table 2. Yields of non-symmetric butenynyl-iron(II) complexes from bis(acetylide)iron(II) complexes.

Acetylide complex	Butenynyl complex	Relative yield [%] ^[a]	Temp. [°C]

1g	2g/2g'	10:90	10
1g	2g/2g'	23:77	65

[a] Average of two preparations. [b] At the limit of detection.

Attempts to prepare complexes incorporating a trimethylsilyl group met with limited success. The first step in butenyne formation is generally taken to be protonation at one of the acetylide β -carbon atoms to yield a mixed vinylidene/acetylide complex,^[12,28] and this is followed by coupling of the two carbon-based ligands. Protonation of the β -carbon of the trimethylsilylacetylide ligand in *trans*-[Fe(C $\equiv$ CC₆H₅)(C $\equiv$ CSi(CH₃)₃)(dmpe)₂] (**1h**) resulted in the cleavage of the trimethylsilyl group to give *cis*-[Fe(C(C $\equiv$ CC₆H₅)=CH₂)(dmpe)₂][PF₆] (**2g'**), while protonation

at the phenylacetylide ligand resulted in retention of the trimethylsilyl group and the formation of *cis*-[Fe(C(C $\equiv$ CSi(CH₃)₃)=C(H)C₆H₅)(dmpe)₂][PF₆] (**2g**) (Scheme 4).

Scheme 4.

The lability of carbon–silicon bonds is well established, and, although the cleavage of trimethylsilyl groups from trimethylsilylacetylide complexes to form the parent acetylide complexes has been reported to be particularly difficult in some cases,^[29] the use of ammonium hexafluorophosphate appears to allow the isolation of vinylidene complexes bearing the C=CH₂ moiety in good yields.^[30] The desilylation of **2g'** occurs early in the reaction to yield the deprotected vinylidene complex, which then undergoes ligand coupling to give the final product.

As has previously been noted for iron butenyne complexes of this type,^[12,14] the butenynyliron(II) complexes generally exhibit four sharp eight-line multiplets in the ³¹P{¹H} NMR spectrum ranging from δ = 49 ppm to 65 ppm, with the observed splittings due to either *cis* (–19 to –50 Hz) or *trans* (150 Hz to 170 Hz) phosphorus–phosphorus coupling. Second-order coupling effects arise in the ³¹P{¹H} NMR spectrum of **2e** and **2e'** due to the close proximity of the chemical shifts. Assignment of the ³¹P{¹H} NMR spectra of these complexes was achieved by crude extraction of coupling constants from each species by the use of ³¹P-COSY NMR spectroscopy. The coupling constants and chemical shifts were then refined by the use of an iterative ³¹P{¹H}-NMR simulation program. The simulated spectra for each complex were obtained separately (see parts a and b in Figure 2), combined (Figure 2, c), and compared with the experimental data (Figure 2, d). The appearance of unique phosphorus resonances is entirely consistent with the structures revealed by the X-ray crystal structure analysis (vide infra).

The reaction of *trans*-[Fe(C $\equiv$ CC₆H₅)(C $\equiv$ C*t*Bu)(dmpe)₂] (**1e**) with NH₄PF₆ at –10 °C occurred at such a rate that it could be followed by ³¹P{¹H} and ¹H NMR spectroscopy. During the course of the reaction, two intermediates were

Figure 2. (a) Simulated $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **2f**. (b) Simulated spectrum of **2f'**. (c) Combined simulated spectra. (d) Experimental spectrum [162 MHz, $(\text{CD}_3)_2\text{CO}$].

observed in the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum, with broad singlet resonances appearing at $\delta = 56.8$ ppm and 56.7 ppm (in the ratio 45:55 respectively). Evidence allowing assignment of these intermediates as vinylidene species was provided by the ^1H NMR spectrum, with the appearance of resonances corresponding to vinyl protons at $\delta = 4.91$ and 5.79 ppm. Both (acetylide)vinylidene-iron(II) complexes then slowly rearranged at room temperature to the two butenynyl-iron(II) complexes **2e** and **2e'**. The proportions of the (acetylide)vinylidene-iron(II) intermediates mirrored the final distribution of butenynyl regioisomers. Clearly then, **1e** can be protonated at the β -carbon of both acetylide ligands, with little preference for the site of protonation in this case.

In the case of **2f/f'**, there is a clear preference for protonation at the β -carbon of the 4-methoxyphenylacetylide ligand. As there are essentially no steric differences between **1e** and **1f**, this stark difference in reactivity is likely the result of the high electron-donating ability of the methoxy substituent on the aryl ring in **1f** increasing the susceptibility of the acetylenic β -carbon to electrophilic attack (Scheme 5) and stabilising the resulting cation.

Suitable crystals of **2a**, **2b**, **2e** and **2e'** were subjected to X-ray crystallographic analysis. ORTEP^[31] diagrams of the crystal structures are shown in Figure 3, while selected bond lengths and bond angles are shown in Table 3.

The $\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2$ ligands in **2b** show considerable disorder, which required the use of two sites for each of these atoms. The iron atom and the atoms of the $\text{C}_{18}\text{H}_{15}$ ligand have full occupancy. The major isomer has P1 linked to P2 and P3 to P4; whereas the minor isomer has P91 (near P1) linked to P92 (near P4) and P93 (near P3) linked to P94 (near P2). As the various sites frequently overlap, restraints were imposed on P–C and C–C bonded distances and on C–P–C and P–C–C angles for the minor isomer. Isotropic displacement parameters were used for the minor sites. The

P(3)–Fe–C(3)	97.56(5)	93.0(1)	94.5(2)	90.6(2)

relative occupancies of the two isomers were refined. Similarly, **2e** is disordered, with two sites associated with two ligand orientations resolved for atom C18 and C20, with occupancies of the components refining to 0.4 and 0.6. The model C17 and C19 ellipsoids are large; however the atoms could not be successfully modelled with multiple sites.

The iron centre exhibits a distorted octahedral coordination sphere, in which the butenyne fragment binds in a trihapto fashion to the metal centre. A similar arrangement has been reported previously for the related complex *cis*-[FeC(C≡CC₆H₅)=C(H)C₆H₅(dmpe)₂]BPh₄.^[14] The bond lengths of the complexes show subtle changes in the binding of the butenyne fragment between the four butenyne-iron(II) complexes; notably the Fe(1)–C1 bond length for **2e** [2.344(8) Å] is significantly longer than for **2a** and **2e'** [2.269(2) and 2.260(7) Å, respectively]. The analogous bond lengths in **2c** and *cis*-[FeC(C≡CC₆H₅)=C(H)C₆H₅(dmpe)₂]-PF₆ [2.300(4) and 2.309(8) Å, respectively] are midway between these two extremes. Additionally, the C(1)–C(2) bond is shortened in **2e** [1.212(10) Å] compared to **2a**, **2b** and **2e'** [1.253(2), 1.237(5) and 1.234(8) Å, respectively]. Noteworthy changes in bond angles include an increase in the C(1)–C(2)–C(3) angle of **2e** [152.9(8)°] relative to the other complexes [*e.g.*, 149.6(7)° for **2e'**] and reductions in the C(1)–Fe–C(3) [70.7(3)° (**2e**) vs. 71.9(3)° (**2e'**)] and C(2)–C(1)–R angles [143.4(8)° (**2e**) vs. 151.4(7)° (**2e'**)]. The crystallographic results suggest that the alkyne group in *cis*-[FeC(C≡C*t*Bu)=C(H)C₆H₅(dmpe)₂]PF₆ (**2e**) is less strongly bound to the metal centre than in the other complexes studied. The interaction of the sterically demanding *tert*-butyl substituent with the methyl groups of the *cis* phosphane ligand almost certainly accounts for this observation.

Conclusions

Butenyne-iron(II) complexes of the general formula *cis*-[FeC(C≡CR)=C(H)R'(dmpe)₂]PF₆ (R = R', **2a–d**; R ≠ R', **2e/e'–g/g'**) have been prepared by the reaction of bis(acetylide)iron(II) complexes under mildly acidic conditions. The use of unsymmetrically substituted bis(acetylide)-iron(II) complexes results in a mixture of products in which both possible regioisomeric butenyne products are formed. In the rearrangement of arylacetylides, the major product is that derived from the more stable vinylidene intermediate. X-ray structure analysis of a pair of regioisomeric butenyne-iron(II) complexes show that the ligand binds in an η³-manner, with some significant differences in the bond lengths and angles.

Experimental Section

General: All syntheses and manipulations involving air-sensitive compounds were performed under an inert atmosphere in a nitrogen-filled box or by using standard Schlenk techniques. All solvents used with air-sensitive compounds were either distilled under nitrogen or degassed using three to five freeze-pump-thaw cycles.

Phenylacetylene, (trimethylsilyl)acetylene, 4-ethynyltoluene and (*tert*-butyl)acetylene were obtained from Aldrich and degassed prior to use. 1,2-Bis(dimethylphosphanyl)ethane (dmpe) was obtained from Strem and used as supplied. (4-Methoxyphenyl)acetylene,^[32] (1-adamantyl)acetylene,^[33] and *cis*-FeH₂(dmpe)₂^[34] were prepared according to literature methods. The unsymmetrical bis(acetylide) complexes *trans*-[Fe(C≡C*t*Bu)(C≡CC₆H₅)(dmpe)₂] (**1e**), *trans*-[Fe(C≡C*t*Bu)(C≡CC₆H₄OCH₃)(dmpe)₂] (**1f**) and *trans*-[Fe(C≡CPh)(C≡CSi(CH₃)₃)(dmpe)₂] (**1g**) were prepared as described previously.^[27]

NMR spectra were recorded on a Bruker AMX or DRX 400 spectrometer at 300 K unless otherwise stated, fitted either with a broadband or multinuclear probe tuned to 100.61, 400.13 and 162.00 MHz for ¹³C, ¹H and ³¹P nuclei, respectively. Chemical shifts (δ) are reported in ppm. ¹³C and ¹H NMR spectra were referenced to residual solvent resonances whilst ³¹P NMR spectra were referenced to external, neat, trimethyl phosphite taken to be 140.85 ppm at 300 K. Infrared spectra were recorded on a Perkin–Elmer 1600 Series FTIR. Electrospray mass spectra were recorded on a Finnigan LCQ mass spectrometer by direct infusion of a methanol or THF solution of the complexes into the source. Chemical ionisation (CI) mass spectra of organic compounds were recorded on a Hewlett–Packard 5989 A mass spectrometer “engine” using CH₄ as the ionization gas. Liquid secondary ion mass spectra (LSIMS) were recorded at the Central Science Laboratory, University of Tasmania, on a Kratos Concept ISQ mass spectrometer using a *m*-nitrobenzyl alcohol matrix.

Preparation of Bis(acetylide)iron(II) Complexes:^[35] An excess of the appropriate acetylene was added to a solution of FeH₂(dmpe)₂ in methanol (3 mL). The mixture was stirred at room temperature for 17 h, before the resultant precipitate was isolated by filtration, washed with methanol and dried.

cis-[Fe(η³-C{C≡CSi(CH₃)₃}=C(H)C₆H₅)(dmpe)₂][PF₆] (2g) and cis-[Fe(η³-C{C≡CC₆H₅}=CH₂)(dmpe)₂][PF₆] (2g'): Ammonium hexafluorophosphate (6.0 mg, 0.037 mmol) was added to an acetone solution (0.5 mL) of *trans*-[Fe(C≡CPh)(C≡CSi(CH₃)₃)(dmpe)₂] (1g) (19.5 mg, 0.035 mmol). The solution was heated at 65 °C for 1.5 h during which time it changed colour from green to orange to red. The solvent was removed and the brown residue recrystallised from ethanol to give a red/brown crystalline solid containing 23% *cis*-[Fe(η³-C{C≡CSi(CH₃)₃}=C(H)C₆H₅)(dmpe)₂][PF₆] (**2g**) and 77% *cis*-[Fe(η³-C{C≡CC₆H₅}=CH₂)(dmpe)₂][PF₆] (**2g'**); yield 24 mg (92%).

cis-[Fe(η³-C{C≡CSi(CH₃)₃}=CHC₆H₅)(dmpe)₂][PF₆] (2g): ³¹P{¹H} NMR ([D₆]acetone): δ = 54.2 (ddd, ²J_{P1P2} = 37, ²J_{P1P3} = 44, ²J_{P1P4} = 14 Hz, 1 P, P1), 57.0 (ddd, ²J_{P2P3} = 161, ²J_{P2P4} = 40 Hz, 1 P, P2), 62.1 (ddd, ²J_{P3P4} = 46 Hz, 1 P, P3), 64.9 (ddd, 1 P, P4) ppm. ¹H{³¹P} NMR ([D₆]acetone): δ = 0.46 (s, 3 H, PCH₃), 0.57 (s, 3 H, PCH₃), 1.34 (s, 3 H, PCH₃), 1.36 (s, 3 H, PCH₃), 1.52 (s, 3 H, PCH₃), 1.60–1.77 (m, 4 H, PCH₂), 1.81 (s, 3 H, PCH₃), 1.95–2.20 (m, 4 H, PCH₂), 2.01 (s, 3 H, PCH₃), 2.28 (s, 3 H, PCH₃), 6.82 (s, 1 H, =CH), 7.21 (m, 1 H, ArH), 7.36–7.39 (m, 2 H, ArH), 7.79 (m, 2 H, ArH) ppm. ¹³C{¹H, ³¹P} NMR ([D₆]acetone): δ = 1.6 (SiCH₃), 9.3 (PCH₃), 10.0 (PCH₃), 15.8 (PCH₃), 18.3 (PCH₃), 19.7 (PCH₃), 20.1 (PCH₃), 20.3 (PCH₃), 27.1 (PCH₂), 29.0 (PCH₂), 29.4 (PCH₃), 33.2 (PCH₂), 33.6 (PCH₂), 55.7 (Si-C≡C), 103.6 (Si-C≡C), 126.5 (ArCH), 127.2 (ArCH), 129.3 (ArCH), 130.0 (ArC), 134.1 (=CH), 155.5 (FeC) ppm.

cis-[Fe(η³-C{C≡CC₆H₅}=CH₂)(dmpe)₂][PF₆] (2g'): ³¹P{¹H} NMR ([D₆]acetone): δ = (AA'BC) 48.20 (ddd, ²J_{P1P2} = 40, ²J_{P1P3} = 29, ²J_{P1P4} = 21 Hz, 1 P, P1), 54.29 (ddd, ²J_{P2P3} = 161, ²J_{P2P4} = 37 Hz, 1 P, P2), 62.08 (ddd, ²J_{P3P4} = 49 Hz, 1 P, P3), 63.17 (ddd, 1 P, P4) ppm. ¹H{³¹P} NMR ([D₆]acetone): δ = 0.95 (s, PCH₃), 1.09 (s, 3 H, PCH₃), 1.38 (s, 3 H, PCH₃), 1.39 (s, 3 H, PCH₃), 1.47 (s, 3 H, PCH₃), 1.48 (s, 3 H, PCH₃), 1.60–1.77 (m, 4 H, PCH₂), 1.66 (s, 3 H, PCH₃), 1.93 (s, 3 H, PCH₃), 1.95–2.20 (m, 4 H, PCH₂), 6.23 (s, 1 H, =CHH), 6.79 (s, 1 H, =CHH), 7.42–7.46 (m, 5 H, ArH) ppm. Selected ¹H NMR ([D₆]acetone): δ = 6.23 (p, ³J_{PH} = 2.0 Hz, =CHH), 6.79 (p, ³J_{PH} = 3.0 Hz, =CHH) ppm. ¹³C{¹H, ³¹P} NMR ([D₆]acetone): δ = 9.1 (PCH₃), 9.7 (PCH₃), 16.0 (PCH₃), 17.9 (PCH₃), 19.7 (PCH₃), 20.0 (PCH₃), 20.2 (PCH₃), 21.1 (PCH₃), 27.4 (PCH₂), 28.7 (PCH₂), 32.6 (PCH₂), 33.7 (PCH₂), 50.6 (PhC≡C), 82.6 (PhC≡C), 119.5 (=CH₂), 129.4 (ArCH), 130.1 (ArCH), 130.6 (ArCH), 139.5 (ArC), 166.1 (FeC) ppm.

CCDC-768332 to 768336 (see Table 4) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Table 4. Crystallographic and structure refinement data for **1a**, **1b**, **1c**, **2a**, **2b**, **2e** and **2e'**.
