Purines bearing diverse β -substituted ethyl or vinyl groups in position 6 were prepared by the conjugate addition of N-, O- and S-nucleophiles to 6-vinylpurines or 6-ethynylpurines. The scope of this methodology was systematically studied. The addition of amines, alcoholates and thiolates to 6-vinylpurines gave the corresponding 6-(2-aminoethyl)-, 6-(2-alk-

oxyethyl)- and 6-[2-(alkylsulfanyl)ethyl]purines. The addition of amines to 6-ethynylpurines gave 6-(2-aminovinyl)-purines, while the addition of alcoholates and thiolates gave 6-(2-dialkoxyethyl)- and 6-[2-bis(alkylsulfanyl)ethyl]purines. Introduction

Purine bases and nucleosides bearing C-substituents at position 6 are an important class of compounds possessing a broad spectrum of biological effects including cytostatic,^[1] antiviral^[2] and antimicrobial^[3] activity and receptor modulation.^[4] Purines bearing functionalized C-substituents are still quite rare and are, therefore, a subject of extensive study in our laboratory. Recently, we have reported the synthesis and cytostatic activity of 6-(hydroxymethyl),^[5] 6-(fluoromethyl)^[6] and 6-(difluoromethyl)purine^[7] bases and nucleosides, as well as the synthesis of (purin-6-yl)alanines^[8] and (purin-6-yl)phenylalanines.^[9] All these syntheses relied on cross-coupling reactions^[10] of 6-halopurines with functionalized organometallics and further functional group transformations (e.g. deoxyfluorination). We then became interested in the related 6-(2-substituted ethyl)purines that are not readily accessible via analogous cross-coupling reactions, since the corresponding β -substituted organometallics easily undergo β -elimination.^[11] Therefore, our method of choice was the conjugate addition of nucleophiles to 6-vinylpurines and 6-ethynylpurines.

Purine is an electron-withdrawing substituent and, thus, vinylpurines easily undergo conjugate additions. The very first example was described by Sasaki et al.,^[12] who used the addition of thiophenol to a 2-amino-6-vinylpurine nucleoside in the synthesis of a 2-amino-6-[2-(phenylsulfanyl)ethyl]purine nucleoside, which was incorporated into oligonucleotides and used as a precursor for the corresponding

6-vinylpurine, which formed stable cross-links in DNA duplexes by the conjugate addition of cytosine. Czernecki et al.^[13] reported a radical azidophenylselenylation of vinylpurine in the synthesis of a 6-[2-(acylamino)ethyl]purine nucleoside. Several examples of preparative conjugate additions to 6-vinylpurines were described by Gundersen et al.^[14] including the addition of MeOH and thiophenol under acidic conditions and NaOMe, PhSNa and several examples of C-nucleophiles under basic conditions. Later, analogous additions of the same nucleophiles were also reported^[15] for 2- and 8-vinylpurines. More recently, Zhang et al.^[16] reported the synthesis of 6-(2-aminoethyl)purine and two other related purine ribonucleosides by the conjugate addition of ammonia, aniline and NaOMe to protected 6-vinylpurine ribonucleosides, and the title compound was found to exhibit cytostatic activity and RNA binding. The only examples of additions to ethynylpurines are the conversion of 6-ethynyl-9-phenylpurine to 6-acetylpurine by treating^[17] with aqueous mercury sulfate and sulfuric acid and to 6-(2,2-dimethoxyethyl)purine by the reaction with NaOMe and analogous synthesis of 2-acetyladenosine by the reaction^[18] of 2-ethynyladenosine with Hg(OAc)₂ in aqueous AcOH. Thus, examples of these reactions are isolated and no systematic study has been performed to define the scope and limitation of this methodology. The goal of this work was to perform such a study and to prepare a large series of derivatives for biological activity screening.

Results and Discussion

Conjugate Additions to 6-Vinylpurines

We first studied conjugate additions to 9-benzyl-6-vinylpurine (**1**)^[14] and 6-vinyl-9-(tetrahydropyran-2-yl)purine (**2**), both of which are easily available^[14] from the corresponding 6-chloropurines by a Stille cross-coupling with vi-

nyl(tributyl)tin. A series of experiments with five secondary amines, three primary amines and ammonia was performed (Scheme 1, Table 1). In all cases, the reactions were performed at ambient temperature in either THF or EtOH, without any catalyst or additive, to give the series of 6-(2-substituted aminoethyl)purines **3a–3i** and **4a–4i** in moderate to good yields. The reactions in THF were slower (taking 1–3 d) but cleaner than the reactions in EtOH, especially in the case of 9-THP-protected purine **2**, where partial cleavage of the protecting group was observed in EtOH. An additional treatment of 6-[(methylamino)ethyl]purine **3h** with an excess of vinylpurine **1** gave dimer **3j**. The same compound also formed by allowing compound **3h** to stand for several days. Apparently, a partial elimination and subsequent addition of the intermediate vinylpurine to another molecule of **3h** must have occurred. With other related amines, this side reaction was not observed.

Scheme 1.

We then examined the addition of O- and S-nucleophiles (Scheme 2, Table 2). Reactions of vinylpurines **1** and **2** with pure alcohols were very sluggish. However, the correspond-

ing alkoxides (either added or generated in situ from an alcohol and sodium hydride) reacted better to give the 6-[2-(alkyloxy)ethyl]purines **5a–5c** and **6a–6c** within 1–2 d. On the other hand, the addition of thiolates and sodium hydrogen sulfide proceeded very smoothly to give the 6-[(alkyl)sulfany]ethyl purines **5d–5f** and **6d–6f** in very good yields within 2 h. In the addition of sodium methanethiolate, performed in a mixture of EtOH and H₂O (Entries 5 and 11), the S-nucleophile was much more reactive than the corresponding O-nucleophile, giving the desired S-adducts **5d** and **6d** in very good yields, accompanied by only trace amounts of **5b** and **6b** as by-products from the addition of sodium ethoxide.

Conjugate Addition to 6-Ethynylpurines

We have further studied analogous additions to 6-ethynylpurines **7** and **8**, which are easily available^[19] by the Sonogashira cross-coupling of the corresponding 6-chloropurines, followed by desilylation by methanolic ammonia. The conjugate addition of a series of secondary and primary amines to 6-ethynylpurines **7** and **8** were performed under analogous conditions as for 6-vinylpurines (Scheme 3, Table 3). Secondary amines reacted slowly but cleanly to give (*E*)-configured 9-benzylated enamines **9** in high yields (Entries 1–5) and 9-THP-substituted enamines **10** in somewhat lower yields, accompanied by partial cleavage of the THP group (Entries 10–14). On the other hand, the addition of primary amines gave mixtures of (*Z*)- and (*E*)-configured enamines **11** and **12** with the (*Z*) isomers usually prevailing. The mixtures were virtually inseparable, and the ratio depended on the solvent, clearly showing an equilibrium between the two isomers. Apparently, the equilibration proceeds by imine–enamine tautomerism. The addition of ammonia or aniline did not proceed within 7 d.

Analogously, we have studied the addition of O- and S-nucleophiles to ethynylpurines **7** and **8** (Scheme 4, Table 4).

The addition of sodium methoxide to **7** and **8** proceeded under the conditions previously described for 6-vinylpurines to give the dimethyl acetals **13a** and **14a** within 4 h in very good yields. The additions of 1,2-ethanedithiol in the presence of NaH proceeded analogously to give the dithioacetals **13b** and **14b** in high yields.

Reactivity of Acetals and Enamines

Having a practical methodology for the synthesis of enamines **9–12** and acetals **13** and **14** in hand, we became interested in the reactivity and further synthetic applicability of these species. We first attempted the hydrolysis of acetal **13a** to the corresponding aldehyde according to dif-

Scheme 3.

ferent literature procedures (Scheme 5). However, under strongly acidic conditions (i.e. stirring with aqueous hydrochloric acid or with a heterogeneous system of TFA in H₂O/chloroform^[20]), 9-benzyl-6-methylpurine (**15**) was unexpectedly isolated in 22% and 20% yield, respectively, as a product of the fragmentation of the acetal. The remainder of the product was a complex mixture of chromatographically immobile by-products. When stirring **13a** in a solution of 10% hydrochloric acid in THF,^[21] the 6-methylpurine **15** was obtained almost quantitatively in 92% yield as the only product. This unusual C–C bond cleavage is not pre-cedented in the literature, to the best of our knowledge. Exposure of **13a** to the Lewis acid KBF₄,^[22] or heating it to a reflux in dioxane/DMSO^[23] led to complex mixtures of products, indicating degradation. On the other hand, under mild conditions in AcOH buffer, no reaction occurred. Additionally, we have not succeeded in the hydrolysis of dithioacetal **13b**. Under mild conditions, with NaHSO₄ on silica gel,^[24] no reaction occurred. Exposure of **13b** to the iodine systems CeCl₃/NaI^[25] and AgNO₃/I₂^[26] yielded complex mixtures of products.

The reactivity of the enamines **9a** and **9e** was studied (Scheme 6). Although there are many reports of the hydrolysis of enamines, compounds **9a** and **9e** did not react when exposed to heterogeneous SiO₂/H₂O in THF,^[27] TFA in H₂O/CHCl₃ or strongly basic conditions.^[28] The enamines **9a** and **9e** were also extremely resistant to hydride re-

ductions and catalytic hydrogenations. The attempted reduction with NaBH₄^[29] and hydrogenations over Pd on CaCO₃^[30] or Wilkinson's catalyst^[31] did not proceed. On the other hand, catalytic hydrogenations with Pd/C^[32] or PtO₂^[33] catalysts proceeded very slowly to give the unexpected 9-benzyl-6-ethylpurine (**16**) as the only product in about 25% yield (the rest was unreacted starting compound). The

reaction of enamine **9a** with sodium methoxide was also unsuccessful, showing that the enamine double bond is not

reactive to another conjugate addition. The attempted alkylation^[34] of **9a** with benzyl chloride did not proceed either. Taken together, these experiments showed a very strange chemical behaviour of such “push-pull” enamines compared to classical enamines, which is due to the presence of extremely electron-withdrawing purine.

Deprotection of THP-Protected Purines

The whole series of THP-protected purines **4**, **6**, **10**, **12** and **14** was deprotected to give the corresponding 9*H*-purines. We first tried our standard methodology of acidic cation exchange resin (Dowex, H⁺ form) in EtOH,^[35] but the amines and enamines suffered from strong binding to the resin. Therefore, we hydrolyzed with 1 M hydrochloric acid in MeOH to give the whole series of 25 6-(2-substituted ethyl or vinyl)-9*H*-purines **17a–i**, **18a–f**, **19a** and **19b**, **20a–e** and **21f–h** mostly in very good yields (Scheme 7, Table 5).

Cytostatic Activity of the Title Compounds

All of the title substituted purines **3–6**, **9–14** and **17–21** were subjected to biological activity screening. In vitro cytostatic activity (inhibition of cell growth) was studied on the following cell cultures: mouse leukaemia L1210 cells (ATCC CCL 219), human promyelocytic leukaemia HL60 cells (ATCC CCL 240), human cervix carcinoma HeLaS3 cells (ATCC CCL 2.2) and human T lymphoblastoid CCRF-CEM cells (ATCC CCL 119). The results are summarized in Table 6. Out of the 76 tested compounds, only

11 derivatives exhibited a considerable cytostatic effect against leukaemia cell lines L1210, HL60 and CCRF-CEM, while none of them were active against solid tumour (HeLa) cells. All the active compounds contained hydrophobic substituents in position 6. The most active were purines containing bulky hydrophobic cyclohexylamino (compounds **3f**, **11f** and **12f**) or dibutylamino (compounds **4c** and **10c**) groups connected to position 6. Sulfur derivatives **5f** and **14b** also showed some activity but only against L1210 cells. Although the activity of these compounds is not extremely high and some of them are of limited stability, these data will contribute to the design of other cytostatic purines.

Conclusions

The conjugate addition of N-, O- and S-nucleophiles to 6-vinylpurines proceeded under ambient temperature without catalysis and could be applied to the synthesis of a large

series of 6-(2-substituted ethyl)purines. The addition of amines to 6-ethynylpurines gave enamines (one equiv. of the nucleophile was added), while the addition of alcoholates and thiolates gave acetals and dithioacetals (two equiv. of the nucleophile were added). These enamines and acetals did not show characteristic reactivity due to the presence of the strongly electron-withdrawing purine system. Some of the title compounds exerted cytostatic activity.

Experimental Section

Melting points were determined on a Kofler block and are uncorrected. Mass spectra were measured on a ZAB-EQ (VG Analytical) spectrometer. NMR spectra were recorded with Bruker Avance 500 (^1H at 500 MHz, ^{13}C at 125.8 MHz) and Bruker Avance 400 (^1H at 400 MHz, ^{13}C at 100.6 MHz) spectrometers. ^1H and ^{13}C NMR spectra were referenced to the signal of TMS or to the residual solvent signal. ^1H - ^{13}C HMBC experiments were performed for the complete assignment of all signals. Starting compounds **1**,^[14] **2**,^[36] **3**^[19] and **4**^[19] were prepared according to literature procedures. Cytostatic activity tests were performed according to literature procedure.^[1a]

General Method for the Nucleophilic Addition of Primary and Secondary Amines: The amine (25.6 mmol) was added to a solution of 6-ethynylpurine **7** or **8** (1.281 mmol) or 6-vinylpurine **1** or **2** in THF or EtOH (8 mL) at room temperature. The mixture was stirred at room temperature for the reaction time specified below for each compound. The resulting mixture was concentrated under reduced pressure, and the residue was purified by column chromatography (silica gel, ethyl acetate). Crude products were purified by crystallization from ethyl acetate/hexane.

General Method for the Nucleophilic Additions of Alcoholates and Thiolates

6-Ethynylpurine **7** or **8** (2.13 mmol) or 6-vinylpurine **1** or **2** (2.13 mmol) was stirred with the particular alcoholate or thiolate in a solvent at room temperature. After completion, the reaction mixture was diluted with H₂O (50 mL), washed with ethyl acetate (3 × 50 mL) and brine. The organic layer was dried with anhydrous MgSO₄, filtered and concentrated under reduced pressure. The residue was purified by column chromatography (silica gel, ethyl acetate).

9-Benzyl-6-[2-(methoxy)ethyl]purine (5a):^[14] The reaction was performed in MeOH (5 mL) with the addition of 1 M methanolic NaOMe (0.5 mL, 0.5 mmol), reaction time 2 d, yield 55%, colourless oil. ¹H NMR (400 MHz, CDCl₃): δ = 3.37 (s, 3 H, OCH₃), 3.49 (t, J_{vic} = 6.6 Hz, 2 H, CH₂-pur), 4.00 (t, J_{vic} = 6.6 Hz, 2 H, CH₂-O), 5.44 (s, 2 H, CH₂-Ph), 7.29–7.40 (m, 5 H, Ph), 8.01 (s, 1 H, 8-H), 8.94 (s, 1 H, 2-H) ppm. ¹³C NMR (100.6 MHz, CDCl₃): δ = 33.47 (CH₂-pur), 47.26 (CH₂-Ph), 58.68 (OCH₃), 70.47 (CH₂-O), 127.90 (CH-*o*-Ph), 128.60 (CH-*p*-Ph), 129.13 (CH-*m*-Ph), 133.03 (C-5), 135.11 (C-*i*-Ph), 143.71 (CH-8), 150.86 (C-4), 152.60 (CH-2), 159.88 (C-6) ppm. General Method for the Cleavage of the THP Protective Group

The THP-protected compound (0.793 mmol) was dissolved in a solution of HCl in MeOH (1 M, 12 mL). After being stirred at ambient temperature for 6 h, H₂O (2 mL) was added. The solution was neutralized with K₂CO₃ and, after being stirred for another 30 min, the mixture was filtered, and the solvents were evaporated. The residue was purified by silica gel column chromatography (chloroform/MeOH).

6-[2-(Piperidin-1-yl)ethyl]-9H-purine (17a): Yield 90%, white crystals, m.p. 109–115 °C. ¹H NMR (400 MHz, [D₆]DMSO): $\delta = 1.35$ (m, 2 H, CH₂-pip), 1.45 (p, $J = 4.9$ Hz, 4 H, CH₂-pip), 2.55 (br. t, $J = 4.9$ Hz, 4 H, CH₂N-pip), 2.78 (m, 2 H, CH₂-N), 3.21 (m, 2 H, CH₂-pur), 8.51 (s, 1 H, 8-H), 8.76 (s, 1 H, 2-H) ppm. ¹³C NMR (100.6 MHz, [D₆]DMSO): $\delta = 24.19$ (CH₂-pip), 25.70 (CH₂-pip), 30.67 (CH₂-pur), 53.88 (CH₂N-pip), 57.04 (CH₂-N), 129.34 (C-5),
