

## COVER PICTURE

The cover picture shows the enantiomers of the *exo* (front) and *endo* (back) isoxazolidines obtained from the box-catalysed 1,3-dipolar cycloaddition between 3-acryloyl-1,3-oxazolidin-2-one and diphenylnitron. The last and unknown *exo* isomer was selectively obtained (*de* = 80 %; *ee* = 99 %) for the first time by using the appropriate disubstituted box and Ni<sup>II</sup> as asymmetric catalyst, and its absolute configuration is reported in the article by G. Desimoni et al. on p. 1020ff. The view over the cross yards of the Old University of Pavia is the backdrop for the schematic representation of the four possible stereoisomers selectively obtained by using box-based asymmetric catalysts.
