THE PRIMARY STRUCTURE OF PROTEIN S3 FROM THE SMALL RIBOSOMAL SUBUNIT OF ESCHERICHIA COLI

Dieter BRAUER and Roswitha RÖMING

Max-Planck-Institut für Molekulare Genetik, Abt. Wittmann, D-1000 Berlin-Dahlem, Germany

Received 29 August 1979

1. Introduction

Protein S3 from the small Escherichia coli ribosomal subunit is involved in several ribosomal functions such as f-Met—tRNA_f^{Met} binding [1], and it is part of one binding site of dihydrostreptomycin [2]. Using immunoelectron microscopy it has been shown that there are two binding sites on the surface of the 30 S subunit for specific antibodies raised against S3 (reviewed in [3,4]). This finding is consistent with results from low-angle X-ray scattering [5] and from hydrodynamic studies [6,7] which show that protein S3 has an elongated shape.

Protein S3 has been found to be associated with an RNA region comprising about 900 nucleotides at the 5'-end of 16 S RNA [8] and can be crosslinked with ribosomal proteins S2, S4 and S10 [9,10]. This paper describes the complete primary structure of protein S3.

2. Materials and methods

Protein S3 was isolated from E. coli strain K as in [11] and was provided by Dr H. G. Wittmann. The primary structure was determined by combined enzymic and chemical digestions.

2.1. Enzymic digestions

Trypsin, treated with 1-chloro-4-phenyl-3-tosylamidobutan-2-one (Merck, Darmstadt) was used for enzymic cleavage of the intact protein both with and without reversible modification of the protein by protecting the ϵ -amino groups of the lysine residues with ETPA (exo-cis-3,6-endoxo- Δ^4 -tetrahydrophthalic anhydride) or after irreversibly modifying the arginine residues with 1,2-cyclohexanedione [12,13]. All tryptic cleavages were performed at pH 8 for 4 h at 37°C.

Digestion with thermolysin (Serva, Heidelberg) was carried out at pH 8 for 90 min at 50°C, and with Staphylococcus aureus protease from Miles Biochemicals (Frankfurt/Main) in 0.05% ammonium acetate buffer (pH 4) for 48 h at 37°C [14].

2.2. Chemical digestion

Specific cleavage of the protein at its tryptophanyl bonds was achieved by treatment with BNPS-skatole (2-(2-nitrophenylsulfonyl)-3-methyl-3'-bromidolenin) [15] for 40 h at room temperature.

2.3. Isolation of peptides and amino acid analyses

Peptides were separated either by gel filtration on Sephadex G-50 and G-75 (superfine; 170×1 , 140×1 cm) in 10% acetic acid [14] or on a microcolumn of Dowex M71 (0.3 × 10 cm) at 55°C using pyridine formate gradients [14,16]. The fractions were analysed either photometrically at 280 nm or by spotting aliquots of every second fraction onto cellulose plates, with subsequent ascending chromatography. If further separation procedures were necessary, the methods of preparative chromatography, electrophoresis or the fingerprint technique on cellulose thin-layer plates [14] were used. These latter proce-

dures, especially the fingerprint technique, were only used when sequencing according to the new sensitive double-coupling method [17] was performed. All amino acid analyses were carried out with a Durrum D-500 analyser. For estimating the cysteine content the protein was oxidized with performic acid before acid hydrolysis. The presence of tryptophan was tested by spraying the fingerprint plates with p-aminobenzaldehyde [18] and by the photometric method [19] carried out by Dr P. Woolley.

2.4. Sequencing methods

Both automated and manual techniques were used for the determination of amino acid sequences.

- (a) Automatic Edman degradation [20] of intact protein was performed in an improved Beckman sequenator [21] for the N-terminal sequence [22].
- (b) Manual Edman degradation was combined with dansylation of the free N-terminal amino acid residue after each degradation step [23]. Aspartic acid, glutamic acid and their corresponding amides were determined by converting the released 2-anilino-5-thiazolinone derivatives to their corresponding phenylthiohydantoin derivatives. These were identified by ascending chromatography [22]. Ambiguities in the identification of dansylated amino acids were resolved by liberation of the free amino acids from their 2-anilino-5-thiazolinones or phenylthiohydantoin derivatives by hydrolysis and amino acid analysis.
- (c) Manual Edman-type degradation was performed using the double-coupling method with 4-N,N-dimethylaminoazobenzene-4'-isothiocyanate/phenylisothiocyanate [17]. Nearly all peptides were sequenced by both manual methods.

3. Results and discussion

The primary structure of protein S3 could be established by various digestions producing the required overlapping peptides. The N-terminal region of the protein was determined by automatic Edmandegradation in an improved Beckman sequenator [22]. As shown in fig.1 the most important cleavages in the sequence analyses of protein S3 were the

tryptic digestion (supplemented by ETPA-modification of lysine residues), digestion with Staphylococcus aureus protease and chemical cleavage with BNPSskatole. The tryptic peptides were separated by either ion-exchange chromatography or gel-filtration followed in both cases by the fingerprint technique. The peptides obtained by SP-cleavage and from BNPSskatole treatment were separated by gel filtration on Sephadex G-50 (SP) and Sephadex G-75 (skatole). Nearly all peptides isolated were sequenced with both manual methods. The long peptides (BNPS, CHD and some SP peptides) were sequenced manually as far as possible, and analyses were completed by treating with other enzymes and separation by the fingerprint technique. Application of carboxypeptidase B resulted in a nearly equimolar amount of Lys and Arg in C-terminal analyses. Combination of all the results (which will be detailed elsewhere) led to the complete primary structure determination of \$3 as shown in fig.1.

The protein consists of 232 amino acid residues with the following amino acid composition:

Asp₉, Asn₇, Thr₁₁, Ser₉, Glu₁₆, Gln₉, Pro₁₀, Gly₁₉, Ala₂₄, Val₂₂, Met₄, Ile₁₈, Leu₁₃, Tyr₄, Phe₅, His₄, Lys₂₃, Arg₂₁ and Trp₄.

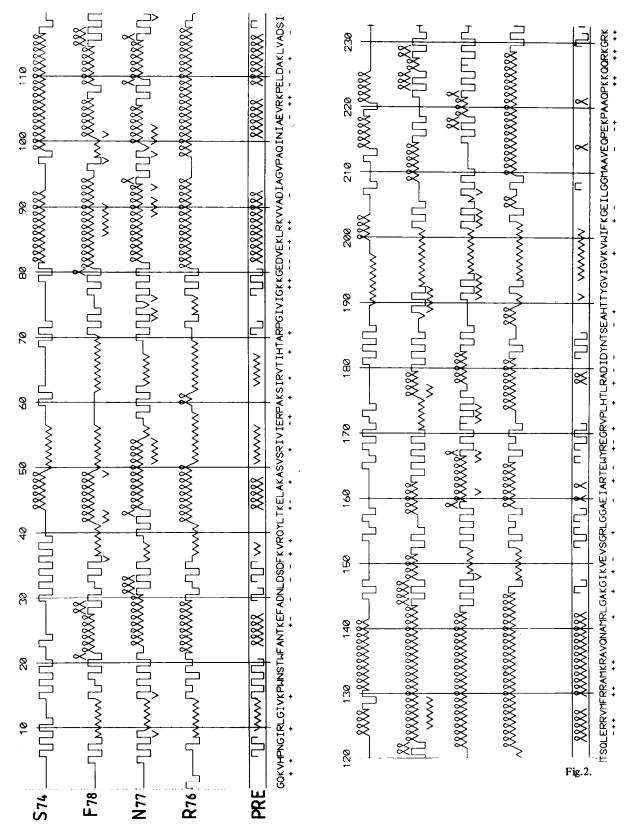

This composition leads to mol. wt 25 852, which is in excellent agreement with that determined by hydrodynamic methods, namely 25 800 (± 500) [7].

Our sequence analysis gave no hint of the presence of modified amino acids, e.g., no unusual spots were observed by different manual degradation methods and no unusual peaks were observed during the amino acid analysis. The presented primary structure of S3 corresponds to the longer form of this protein. Differences to a second form of S3 with lower molecular weight, which can be isolated by chromatographic procedures (H. G. Wittmann, personal communication) are under investigation and will be detailed elsewhere.

In fig.2 the result of secondary structure prediction of protein S3 by four different methods is presented. This procedure was carried out by Dr B. Wittmann-Liebold and is detailed in [24]. In the line 'PRE' of fig.2, regions for helix, extended structure and β -turns are indicated from at least three out of four methods in agreement. Based on this prediction, protein S3 was predicted to contain at least 28% helix, 12% extended structure and 15% β -turns.
