Received 14 September 1990

A novel low  $M_r$  GTP-binding protein cDNA was isolated from a rat megakaryocyte cDNA library with a synthetic oligonucleotide probe corresponding to an 8-amino acid sequence specific for c25KG, a GTP-binding protein previously isolated from human platelet cytosol fraction [(1989) J. Biol. Chem. 264, 17000-17005]. The cDNA has an open reading frame encoding a protein of 221 amino acids with a calculated  $M_r$  of 25068. The protein is designated as *ram* (*ras*-related gene from megakaryocyte) protein (*ram* p25). The amino acid sequence deduced from the *ram* cDNA contains the consensus sequences for GTP-binding and GTPase domains. *ram* p25 shares about 23%, 39% and 80% amino acid homology with the H-*ras*, *smg25A* and c25KG proteins, respectively. The 3.5-kb *ram* mRNA was detected abundantly in spleen cells.

Low  $M_r$  GTP-binding protein; cDNA cloning; Megakaryocyte

## 1. INTRODUCTION

There is a family of structurally homologous monomeric GTP-binding proteins with molecular weight ( $M_r$ ) ranging from 20 000 to 30 000 in mammalian cells [1]. The family contains *ARF* [2], *ral* [3,4], *rho* [5,6], *R-ras* [7], *rap* [8,9], *rab* [10-12], *rac* [13], *smg25* [14] and *ypt1* [15] proteins. These low  $M_r$  GTP-binding proteins show 30-50% homology to *ras* p21 [16]. Four of GTP-binding domains are highly conserved in all of the low  $M_r$  GTP-binding proteins. Among them, the phosphate-interacting domain, a stretch of six residues, Asp-Thr-Ala-Gly-Gln-Glu (in positions 57-62 of *K-ras* p21), is strictly conserved. The low  $M_r$  GTP-binding proteins also share biochemical properties, binding of GDP or GTP and GTPase activity, but the GTPase activity is lower compared to heterotrimeric G proteins such as  $G_s$ ,  $G_i$ ,  $G_o$  and transducin [17].

We purified two low  $M_r$  GTP-binding proteins (c21KG, c25KG) from human platelet cytosol fraction [18,19]. From the partial amino acid sequence analysis, the major component (c21KG) was found to be identical to *rap1A* protein, whereas the minor protein (c25KG) was identified as a novel low  $M_r$  GTP-binding protein. To determine its primary structure, we have attempted to clone the cDNA of c25KG. In the present studies, we have cloned from a rat megakaryocyte cDNA library a cDNA of a low  $M_r$  GTP-binding protein, which is highly homologous to but clearly distinct

from c25KG. We also describe its expression in several tissues of adult rat.

## 2. EXPERIMENTAL

### 2.1. Design and synthesis of the oligonucleotide probe

One 29-base antisense strand oligodeoxyribonucleotide probe (5' TG(T/C)TC(A/G)AA(A/G)TAIGGIATICC(A/G)TA(T/C)TT(A/G)TC3') was synthesised corresponding to the sequence Lys-Tyr-Gly-Leu-Pro-Tyr-Phe-Glu of c25KG. The oligonucleotide is a mixture of all the possible icosamers that might encode this sequence.

### 2.2. Screening of the cDNA library

Approximately  $4.0 \times 10^5$  recombinant plaques were screened by plaque hybridization [20] with the synthetic probe labeled at the 5' end with  $^{32}$ P. Hybridization was allowed to occur overnight under a low-stringency condition at 30°C in a solution containing 30% (v/v) formamide,  $5 \times$  SSC ( $1 \times$  SSC = 0.15 M NaCl/15 mM sodium citrate, pH 7.0),  $1 \times$  Denhardt's solution (0.02% bovine serum albumin/0.02% polyvinylpyrrolidone/0.02% Ficoll), 20 mM sodium phosphate (pH 7.0), 100 µg/ml of heat-denatured salmon sperm DNA, 0.1% NaDodSO<sub>4</sub>, and 10% dextran sulfate. Filters were washed twice at room temperature in  $5 \times$  SSC/0.1% NaDodSO<sub>4</sub> for 15 min before autoradiography. The positive clones were purified by successive plaque hybridization.

### 2.3. DNA sequence analysis

DNA sequencing was performed by the dideoxynucleotide chain-termination method [21] with [ $\alpha$ - $^{32}$ P]dCTP. 2'-Deoxy-7-deaza-guanosine 5'-triphosphate was used in place of dGTP [22]. For sequencing, cDNA fragments were subcloned into pUC118 vector and single-stranded templates were prepared with helper phage M13 KO7 [23].

### 2.4. RNA blot hybridization analysis

Total RNA was extracted by the guanidinium thiocyanate method [24]. RNA (25 µg) was denatured by heating at 60°C for 5 min in 2.2 M formaldehyde/50% (v/v) formamide and subjected to elec-

The hatched box at the right end indicates the poly(A) region. The arrow in the open box shows the direction of translation. The arrows under the map indicate the direction and the region of DNA sequencing.

trophoresis in a 1.2% agarose gel containing 2.2 M formaldehyde [25]. The RNA was transferred to nitrocellulose membranes. Hybridization was carried out under the high-stringency condition described above. Filters were washed twice at 42°C in  $0.1 \times$  SSC/ $0.1\%$  NaDodSO<sub>4</sub> for 1 h before autoradiography. Mouse megakaryoblastoma cell line MK8037 was kindly supplied by Dr T. Inoue (Yokohama City University School of Medicine).

### 3. RESULTS AND DISCUSSION

The cDNA library was screened under the low-stringency hybridization conditions with the synthetic 29-base probe (see section 2). On screening  $4 \times 10^5$  recombinant plaques, five positive clones were obtained. Among them, three clones had 0.8 kbp inserts, and the other two showed 0.4 kbp and 0.3 kbp inserts after *EcoRI* digestion, indicating the latter cDNA has an endogenous *EcoRI* site. Partial cDNA sequence analysis indicated that they are overlapping clones. We tentatively named them  $\lambda$ ram-1 (with 0.8 kbp insert) and  $\lambda$ ram-2 (0.7 kbp insert containing an endogenous *EcoRI* site). The restriction maps of the  $\lambda$ ram-1 and -2 inserts and the strategies for sequence determination are shown in Fig. 1.  $\lambda$ ram-1 lacked the COOH-terminal sequence corresponding to amino acid residues 192–221 of ram protein (ram p25), and  $\lambda$ ram-2 lacked the NH<sub>2</sub>-terminal sequence corresponding to amino acid residues 1–66 of ram p25. The insert of  $\lambda$ ram-1 was then used for screening of the rat megakaryocyte cDNA library under the high-stringency condition, but the full-length cDNA was not obtained.

Fig. 2 shows the nucleotide and deduced amino acid sequences of ram. The cDNA contained an open reading frame of 221 amino acids, assuming that the in-

Fig. 3. Alignment of *ram* protein sequence with other low *M<sub>r</sub>* GTP-binding proteins. The sequences of the GTP-binding proteins have been taken from the literature: c25KG [19], *H-ras* [16], *R-ras* [7], *rap1A* [8], *rap1B* [9], *rac1* [13], *ralA* [3], *rab1* [10], *smg25A* [14]. GTP-binding and GTPase regions are boxed. Effector region is boxed by dotted line. Hyphens indicate the gaps introduced for alignment. X represents unidentified residue.

initiator methionine codon is at position 1–3 and the termination codon TGA is at positions 664–666. The nucleotide sequence surrounding the first methionine codon agreed with the consensus sequence that is characteristic for the initiation codon of many eukaryotic mRNAs [26]. The calculated molecular mass of the polypeptide specified by this open reading frame (663 bp) is 25 068. The amino acid sequence corresponding to the synthetic oligonucleotide probes used for screening was partially different from the amino sequence: 2 amino acids out of 9 were different from c25KG. We screened human erythroleukemia K562 cell cDNA library by using a partial fragment of rat *ram* cDNA, and isolated two partial cDNAs of human-*ram* (data not shown). The amino acid sequence of *ram* p25 is strongly conserved between rat and human, and *ram* p25 is distinct from c25KG.

Fig. 3 compares the amino acid sequence of *ram* p25 with those of other low *M<sub>r</sub>* GTP-binding proteins. *ram* p25 shares 23%, 26%, 23%, 32%, 39% and 21% amino acid identity with *H-ras*, *ralA*, *rac1*, *rab1*, *smg25A* and *rap1A* proteins, respectively. The homologies are essentially restricted to the four GTP/GDP binding domains boxed in Fig. 3. The identity between *ram* p25 and c25KG is 80%: 40 out of 70 amino acids are matched to those of *ram* p25.

On the other hand, the sequence of *ram* at the effector domain (amino acid residues 32–42 of *H-ras* p21) is different from that of *H-ras* p21 but is almost identical with c25KG. Since this region in *H-ras* p21 is essential for its transforming activity and interaction with GAP [27,28], it is likely that *ram* protein and c25KG may share the common effector and/or GAP molecules.

It has been shown that low *M<sub>r</sub>* GTP-binding proteins have unique COOH-terminal amino acid sequences; they possess at least one cysteine near their COOH-terminal ends. It has been suggested that the cysteine residues are polyisoprenylated [29] and/or palmitoylated [30], and that these fatty acid moieties are essential for the proteins to attach to the inner surface of the plasma membrane and to exert their biological activity [16]. According to the COOH-terminal sequences, low *M<sub>r</sub>* GTP-binding proteins can be classified into four groups: one is a Cys-A-A-X group including *H-*, *K-* and *N-ras*, and *rho*, where A is an aliphatic amino acid, and X is any one. Second is a Cys-Cys group including the *ypt1*, *rab1* and *rab2*. Third is a Cys-Cys-X-X group including *ralA* and *ralB*, *H-rab5*. The last is a Cys-X-Cys group including *rab3* and 4, *H-rab3A*, -3B, and -4 and *smg25A*, -B and -C. The *ram* protein belongs to the last group. The variations in the COOH-terminal structures probably reflect diverse

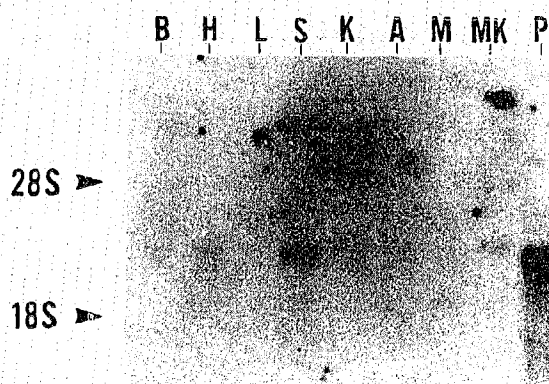

Fig. 4. Northern analysis of *ram* RNA. The following rat and mouse RNAs are in each line: brain (B), heart (H), liver (L), spleen (S), kidney (K), adrenal gland (A), skeletal muscle (M), mouse megakaryoblastoma cell line MK8057 (MK) and rat pheochromocytoma cell line PC-12 (P).

associations of the low  $M_r$  GTP-binding proteins with membranes of different organelles. As some low  $M_r$  GTP-binding proteins such as *rho*, *smg25A* and *c25KG* were purified from the cytosolic fraction [19,31,32], posttranslational modifications may regulate their location.

We examined the expression of *ram* mRNA in several rat tissues and the pheochromocytoma PC-12 cell by Northern blot analysis as shown in Fig. 4. The 260-bp *EcoRI-MluI* fragment of  $\lambda$ *ram*-2, containing the coding region of *ram* cDNA, was used as a probe. The 3.5 kb *ram* mRNA was expressed abundantly in PC-12 cells, spleen, and weakly in kidney, adrenal gland, brain, and heart. *ram* is also expressed in mouse megakaryoblastoma MK8057 cells, though the size of the mRNA is longer than that of rat. No bands were detected in liver and skeletal muscle even after a long exposure.
