Received 20 December 1991; revised version received 11 February 1992

We report here that human plasma  $\alpha_i$ -antitrypsin ( $\alpha_i$ -AT) inhibited human neutrophil  $O_2^{(i)}$  release elicited by a variety of stimulants. In comparison, the inhibitory capacities of two serine protease inhibitors, t-1-toxylamide 2-phenylethyl chloromethyl ketone (TPCK) and soybean trypsin inhibitor (SBTI), and the human recombinant  $\alpha_i$ -AT mutant,  $\alpha_i$ -AT-Arg<sup>100</sup> were in the order:  $\alpha_i$ -AT = TPCK  $\Rightarrow \alpha_i$ -AT-Arg<sup>100</sup> > SBTI when cells were stimulated with concanavalin A plus cytochalasin E. These data suggest that, in human inflammatory fluids containing relatively high concentrations of  $\alpha_i$ -AT (such as theumatoid arthritis synovial fluid). (i)  $\alpha_i$ -AT may down-regulate the inflammatory process by inhibiting the neutrophil respiratory burst and (ii) serpin oxidation by neutrophil-released reactive oxygen species is unlikely to occur.

#### 1. INTRODUCTION

Human plasma  $\alpha_1 - \alpha_2 = \text{trypsin}(\alpha_1 - AT)$  is an acute phase protein, which is synthesized in increased amounts by the liver during inflammation, and is a member of the serpin (serine protease inhibitor) superfamily of proteins (reviewed in [1]). Although  $\alpha_i$ -AT is an inhibitor of both trypsin and neutrophil clastase. neutrophil clastase is the physiological target for  $\alpha_1$ -AT. The release of neutrophil elastase has been implicated in the tissue damage associated with chronic inflammatory diseases such as pulmonary emphysema and rheumatoid arthritis [2]. Cigarette smoking is a major risk factor for pulmonary emphysema [1] and broachoalveolar lavage fluids from smokers, along with knee-joint synovial fluids from rheumatoid arthritis patients, show a reduction in anti-elastolytic activity compared with that explicted from the ap-AT concentration [3-5], containing oxidised and proteolytically fragmented forms of  $\alpha_1$ -AT [2,6,7].

Exposure of neutrophils to a variety of stimuli (including concanavalin A plus cytochalasin E) activates a membrane-bound NADPH-oxidase to catalyse the generation of the superoxide anion radical  $(O_2^{-1})$ 

Abbreviations:  $\alpha_1$ -AT,  $\alpha_1$ -antitrypsin: TPCK, t-1-tosylamide 2-phenylethyl chloromethyl ketone; SBTI, soybean trypsin inhibitor; Con A, concanavalin A; Cyto E, cytochalasin E.

Correspondence address: P.G. Winyard, Inflammation Research Group, Arthritis and Rheumatism Council Building, London Hospital Medical College, 25–29 Ashfield Street, London El 2AD, England, Fax: (44) (71) 377 7677. (reviewed in [8]). This radical species dismutes to  $H_2O_2$  which is in turn converted to hypochlorous acid (HOCl) in a reaction catalysed by neutrophil myeloperoxide. [8]. In vitro experiments have suggested that the mechanism of  $\alpha_1$ -AT inactivation involves oxidation of the reactive centre (Met<sup>158</sup>) residue by neutrophil- or macrophage-derived oxidants, such as HOCl [8,9]. However, the proteolytic inactivation of  $\alpha_1$ -AT by neutrophil collagenase [8,10,11], as well as connective tissue metal-toproteinases [12–14], may also play a role in the inactivation process.

During the course of experiments designed to study the mechanisms of  $\alpha_1$ -AT inactivation by isolated human neutrophils, we noted that the amount of detectable Os released by cells stimulated with a variety of agents (sermat-treated zymosan, calcium ionophore or concenavalin A (Con A) this establish E (Cyte E)) was lowered in the presence of  $\alpha_1$ -AT. Earlier studies, which were largely performed with Con A + Cyto E as the stimulus, showed that L-1-tosylamide 2-phonylethyl chloromethyl ketone (TPCK), soybean trypsin inhibitor (SBTI) and other serine protease inhibitors have the ability to inhibit O<sub>5</sub><sup>--</sup> production by neutrophils ([15] and references therein) and by other cell types [15,16]. Therefore, the dose-dependent inhibition by  $\alpha_1$ -AT of Con A + Cyto E-stimulated neutrophil O2 production was compared with the dose responses for TPCK, SBTI and  $\alpha_1$ -AT-Arg<sup>358</sup>. The latter is a human recombinant a<sub>1</sub>-AT variant in which the reactive centre Met<sup>358</sup> has been replaced by an arginine residue [17]. This single amino acid substitution results in a 10,000-fold decrease in anti-clastolytic activity and a 10.000-fold increase in thrombin inhibitory capacity.

# 2. MATERIALS AND METHODS

Concanavalin A (Type IV-S), cytochalasin E (from Aspergillus clavatus), cytochrome c (Type III, from horse heart), trypsin inhibitor (Type 1-S, from soybean), superoxide dismutase (from bovine erythrocytes), 1-1-tosylamide 2-phenylethyl chloromethyl ketone, calcium ionophore A 23187, zymosan A, N-succinyl-Ala-Ala-Ala pnitroanilide and clastase (Type IV, from porcine pancreas, 120 U/mg protein) were purchased from Sigma (Poole, Dorset, UK). Human plasma a -AT was obtained from Novablochem (Nottingham, UK). The purity of this preparation was >95% by SDS-PAGE. The clastase inhibitory capacity of the  $\alpha_i$ -AT batches used in these experiments was assessed by a kinetic spectrophotometric determination of the ability of a<sub>1</sub>-AT to inhibit the cleavage of a synthetic substrate for porcine pancreatic clustuse [18]. The anti-clustolytic activity of the two batches was 1.06 ± 0.10 and 1.18 ± 0.08 (mean ± 1 S.D., n = 5) mol of  $\alpha_1$ -AT required to inhibit I mol of clastase. Recombinant  $\alpha_1$ -AT-Arg<sup>136</sup>, expressed in yeast, was kindly provided by Dr. Michael Courtney, Delta Biotechnology Ltd., Nottingham, UK

Protein concentrations were determined by the Bradford assay [19]. TPCK, cytochalasin E and A 23187 were dissolved in dimethyl sulphoxide and diluted with Hanks' balanced salt solution (Gibco, Uxbridge, Middlesex, UK) immediately before use. Serum-treated zymosan was prepared according to Goldstein et al. [20].

#### 2A. Preparation of cells

Human peripheral blc od neutrophils were isolated from fresh heparinised blood obtained from healthy adult volunteers by dextran sedimentation followed by density gradient centrifugation and hypotonic lysis of the remaining red blood cells [21]. Finally, the cells were resuspended in Hanks' balanced salt solution without Phenol red, counted and diluted to a concentration of  $5\times10^\circ$  cells/ml. Cell viability was assessed by Trypan blue exclusion.

### 2.2. Measurement of Of production

Superoxide anion production was measured by superoxide dismutase inhibitable reduction of cytochrome c using a recording double beam spectrophotometer (Uvikon 860, Kontron Instruments, Watford, UK) equipped with a thermostated 6-cuvette holder.

The cells  $(5 \times 10^5)$  were pre-incubated for 3 min at 37°C with various amounts of inhibitors (TPCK, SBTI,  $\alpha_1$ -AT,  $\alpha_1$ -AT-Arg<sup>338</sup>) in Hanks' (final volume, 700  $\mu$ I). Cytochrome c (100  $\mu$ I; final concentration, 100  $\mu$ M) was added to both sample and reference cuvettes and in the sample cuvettes the neutrophils were stimulated with Con A + Cyto E (200  $\mu$ I + 100  $\mu$ I; final concentrations, 100 and 10  $\mu$ M, respectively), serum-treated zymosan (2 mg/ml, final concentration) or A23187 (30  $\mu$ M, final concentration). Both sample and reference cuvettes contained the same concentrations of cells and dimethyl sufpinoxide. The basal release of O<sub>2</sub> was automatically subtracted and the absorbance changes recorded were due solely to the Con A + Cyto E-induced respiratory burst. The reduction of cytochrome c was monitored at 550 nm at 1 min intervals for 15 min at 37°C. Six samples were monitored simultaneously, one acting as a positive control (cells +

stimulatory agents only) and one as a negative control (cells + stimulatory agents + superoxide dismutase).

The amount of  $O_2^{-1}$  produced (nmol  $O_2^{-1}/10^6$  cells) was calculated using an extinction coefficient of  $21 \times 10^8$  M<sup>-1</sup>·cm<sup>-1</sup> and plotted as a function of time after addition of stimulants to obtain the initial rate of each reaction. The inhibitory capacity was calculated as the % inhibition of the initial rate of the positive control.

## 3. RESULTS

 $\alpha_1$ -AT, TPCK and SBTI showed various degrees of inhibition of the neutrophil  $O_2^{-1}$  production elicited by serum-treated zymosan, calcium ionophore A 23187 and Con A plus Cyto E (Table I). Whatever the triggering agent, significant amounts of inhibition were obtained with both  $\alpha_1$ AT and TPCK at similar molar concentrations (11.5 and 10.0  $\mu$ M, respectively). However, for SBTI, the molar concentration required to give similar extents of inhibition was about 50-fold higher (Table I).

 $\alpha_1$ -AT at a concentration of 0.6 mg/ml (11.5  $\mu$ M) almost completely inhibited O<sub>2</sub><sup>--</sup> release from human neutrophils stimulated with Con A + Cyto E. Fig. 1 shows the results of a typical experiment. The inhibition was dose-dependent and was still significant at 0.2 mg/ml (3.8  $\mu$ M).

 $\alpha_1$ -AT-Arg<sup>358</sup> showed no effect over the effective dose range of  $\alpha_1$ -AT. At high concentrations  $\alpha_1$ -AT-Arg<sup>358</sup> produced some inhibition (115  $\mu$ M gave a 65% inhibition) (Fig. 2). Two serine protease inhibitors (TPCK and SBTI) tested showed dose-response effects similar to those previously obtained by Kitagawa and coworkers [15] (Fig. 2). The concentration range used was 0.2-10  $\mu$ M for TPCK and 100-500  $\mu$ M for SBTI. Table 11 shows the  $K_i$  values (concentration required for 50% inhibition of  $O_2$ <sup>-</sup> production) for the four serine protease inhibitors,  $\alpha_1$ -antitrypsin has a  $K_i$  lower than SBT1 and similar to TPCK.

The serine protease inhibitors tested had no cytotoxic

effect as assessed by Trypan blue exclusion tests performed at the end of activation experiments. In addition, at the concentrations used in the neutrophil experiments, none of these inhibitors possesed  $O_2$  scavenging activity in a xanthine-xanthine oxidase system coupled with the cytochrome c assay (data not shown), which also shows that the  $\alpha_1$ -AT preparation was not contaminated with superoxide dismutase.

## 4. DISCUSSION

We have shown that at sub-physiological concentrations  $\alpha_i$ -AT inhibits the oxidative burst of stimulated neutrophils. For comparison, the concentration of  $\alpha_i$ -AT in both normal human plasma and knee-joint synovial fluid from rheumatoid arthritis patients is about 3-5 mg/ml, although on average about 40% of the  $\alpha_i$ -AT in rheumatoid arthritis synovial fluid is inactive [5].

 $\alpha_1$ -AT-Arg<sup>338</sup>, which has relatively weak anti-elastase activity compared with  $\alpha_1$ -AT, only inhibited neutrophil O<sub>2</sub><sup>--</sup> production at high concentrations, suggesting that this effect was related to protease inhibitory capacity. This interpretation is further sustained by the lack of

Table II

K<sub>i</sub> (concentration required for 50% inhibition of O<sub>2</sub>\*\* production) of serine protease inhibitors in Con A + Cyto E-triggered O<sub>2</sub>\*\* release by human neutrophils. Values were calculated form Fig. 2.

O<sub>2</sub> scavenging capacity of all the inhibitors tested. In agreement with previous results [15], serine protease inhibitors which are not members of the serpin protein superfamily also inhibited neutrophil O<sub>2</sub> production. The high molecular weight inhibitor of trypsin (SBTI) and the low molecular weight inhibitor of chymotrypsin (TPCK) act by inhibiting a neutrophil plasma membrane trypsin/chymotrypsin-like protease [15].

Recently, Kilpatrick et al. [22] reported the inhibition of human neutrophil  $O_5$ —generation by  $\alpha_1$ -antichymotrypsin. These workers mention that a commercial preparation of  $\alpha_1$ -AT (Sigma) had no inhibitory effect at concentrations ranging from 0.1 to 100  $\mu$ M. This discrepancy might be accounted for by a difference in the activities of the  $\alpha_1$ -AT preparation used in this study and that used by Kilpatrick and co-workers.

In many of the earlier studies in which neutrophil/ macrophage-mediated oxidative inactivation of  $\alpha_i$ -AT was demonstrated in vitro (for example [9,23]), the concentrations of  $\alpha_i$ -AT would have been too low to significantly inhibit  $O_2^{-1}$  production. The  $\alpha_1$ -AT concentrations used in these experiments reflected the concentration range in bronchoalveolar lavage fluids (up to 100 µg/ml). However, in some inflammatory exudates the a<sub>i</sub>-AT concentration is much higher, e.g. rheumanid arthritis synovial fluid. In experiments where as the trophils were incubated with  $\alpha_i$ -AT at concentrations in this higher range, the a<sub>1</sub>-AT was either not in direct contact with the cells, e.g. compartmentalised in dialysis tubing in the presence of external, stimulated neutrophils [24] or, the  $\alpha_1$ -A't was inactivated by the addition of a supernatant which had been conditioned by stimulated neutrophils [11.25].

We conclude that, in inflammatory fluids containing relatively high concentrations of  $\alpha_1$ -AT, this serpin might play a physiological role in directly inhibiting neutrophil O. production. Although it might be argued that the stimulus mainly used in this study (Con-A + Cyto E) is not physiologically referent, other studies (see references cited 1/15)) as well as our own results obtained with serum-treated zymosan and calcium ionophore show that serine protease inhibitors inhibit neutrophil O2 production in response to a variety of stimuli. Elastase has been shown to prime neutrophil O. release elicited by different stimulants [26,27]. Our experimental system contained no added elastase to prime the system prior to stimulant addition, suggesting that  $\alpha_1$ -AT inhibited neutrophil  $O_2$ - release by inhibiting a membrane bound serine protease. However, in vivo, inhibition of elastase may be an additional mechanism by which a1-AT down-regulates the neutrophil oxidative response.

Our results also suggest that, in those inflammatory fluids where the  $\alpha_1$ -AT concentration is relatively high, the oxidation of  $\alpha_1$ -AT by neutrophil-released reactive oxygen species is unlikely to occur. However, other ceil types may mediate the oxidation of  $\alpha_1$ -AT and it is

possible that neutrophil metalloproteinases inactivate  $\alpha_1$ -AT locally, thus permitting elastase activity.
