Tyrosine phosphorylation of p60^{c-src} induced by Zn²⁺ in rat hippocampal membranes is shown to inhibit *Src* tyrosine kinase activity. Zn²⁺ catalyzes the phosphorylation of p60^{c-src} in the membranes but does not activate autophosphorylation of p60^{c-src} immunoprecipitated with anti-*Src* monoclonal antibody. Moreover, the immunoprecipitated *Src* kinase has no Zn²⁺-induced activity in phosphorylation of exogenous substrate, enolase. Cyanogen bromide cleavage of p60^{c-src} phosphorylated in the presence of Zn²⁺ yields a 4-kDa phosphopeptide corresponding to phosphorylation of a carboxy-terminal tyrosine residue of *Src* kinase. In conclusion, hippocampal membranes contain a Zn²⁺-stimulated protein tyrosine kinase capable of regulating the p60^{c-src} activity.

Zinc: Protein phosphorylation; Phosphotyrosine; p60^{c-src}; Rat hippocampus

1. INTRODUCTION

Brain contains an abundance of the transition metal zinc, which is primarily accumulated in hippocampus. The concentration of zinc in mossy fibers of human and rat hippocampus has been estimated at 0.22–0.30 mM [1]. Zn²⁺ is actively taken up and released from the mossy fiber terminals during stimulation of nerve fiber tracts [2–4], but functional significance of these events is still not clear. We have recently observed that Zn²⁺, at concentrations 0.2 mM and greater, induces tyrosine phosphorylation of p60^{c-src} and 49-kDa protein associated with p60^{c-src} in rat hippocampal membranes [5]. A product of cellular *Src* proto-oncogene, p60^{c-src}, is highly expressed in neural tissues [6], particularly in hippocampal pyramidal cells [7]. It is a membrane-associated protein tyrosine kinase with two principal sites of tyrosine phosphorylation: Tyr⁴¹⁶ and Tyr⁵²⁷ [8,9]. Tyr⁴¹⁶ is a site of p60^{c-src} autophosphorylation in vitro [8]. Phosphorylation of Tyr⁴¹⁶ is a characteristic of activated forms of p60^{c-src} [10]. Carboxy-terminal Tyr⁵²⁷ is a major site of the in vivo p60^{c-src} phosphorylation leading to inhibition of the enzyme activity [9]. Phosphorylation of p60^{c-src} on Tyr⁵²⁷ is catalyzed by another protein tyrosine kinase(s), distinct from p60^{c-src} [11,12]. In the present study, we characterized the type of p60^{c-src} tyrosine phosphorylation induced by Zn²⁺ in hippocampal membranes.

2. MATERIALS AND METHODS

2.1. Materials

[γ -³²P]ATP (>5000 Ci/mmol) was purchased from Amersham. The anti-*Src* monoclonal antibody LAO was obtained from NCI Repository Microbiological Associates, Inc (Bethesda). Membrane fraction from rat hippocampi was prepared as described before [5].

2.2. Immunoprecipitation and assay of p60^{c-src} kinase activity

Proteins of hippocampal membranes (300 μ g) were extracted from the membranes with extraction buffer containing 50 mM Tris-HCl, pH 8.1, 0.5 M KCl, 2% Nonidet P40, 10% glycerol, 0.2 mM Na₂VO₄, 1 mM EDTA and 2 mM dithiothreitol. After incubation for 2 h at 4°C with occasional mixing, the suspension was spun for 10 min at 11,000 $\times$ g. The supernatant was incubated with 2 μ l of monoclonal antibody LAO to p60^{c-src} for 90 min on ice. Then 6 μ l of Protein A-Sepharose suspended in the extraction buffer (1:1) was added and the mixture was incubated for 30 min on ice with occasional mixing. Sepharose beads were then washed three times with the extraction buffer and once with 50 mM Tris-HCl, pH 7.4. Twenty microliters of reaction buffer containing 50 mM Tris-HCl, pH 7.4, 10 mM MgCl₂, 3 mM MnCl₂, 0.1 mM Na₂VO₄, 10 μ M [γ -³²P]ATP (50 Ci/mmol) and (or not) 0.5 mg/ml of yeast enolase (denatured with 0.1 M acetic acid for 5 min at 30°C) were added to the washed Sepharose beads and the mixture was incubated for 10 min at 30°C. The reaction was terminated by adding SDS-sample buffer and boiling. The samples were subjected to electrophoresis on 10% SDS-polyacrylamide gels followed by the alkali treatment of the gel [13], staining with Coomassie blue, drying and exposure for autoradiography. The individual labeled bands of phosphoproteins were excised from the gel and counted.

2.3. Protein phosphorylation assay

The standard reaction mixture (20 μ l) contained 50 mM HEPES-NaOH, pH 6.9, the membrane fraction proteins (1–2 mg/ml), 0.1 mM [γ -³²P]ATP (1 Ci/mmol) and 0.5 mM ZnCl₂ or 2.0 mM MnCl₂, or both 0.5 mM ZnCl₂ and 2.0 mM MnCl₂. After incubation for 10 min at 30°C, the reaction was terminated by adding SDS-sample buffer and boiling. The samples were subjected to SDS-PAGE on 10% gels followed by the alkali treatment of the gel [13], staining, drying and exposure for autoradiography.

2.4. Cyanogen bromide cleavage analysis

After phosphorylation and electrophoresis dried gel bands containing phosphorylated p60^{src} were excised and subjected to cyanogen bromide treatment by the method of Takeya et al. [14], loaded onto 18.75% SDS-polyacrylamide gel containing 6 M urea prepared as described by Kadenbach et al. [15] and analyzed by electrophoresis.

3. RESULTS AND DISCUSSION

To characterize the Zn²⁺-induced tyrosine phosphorylation of p60^{src} we compared activities of *Src* kinase from rat hippocampal membranes phosphorylated by ATP in the presence of Zn²⁺ and from the control membranes. The kinase activity was measured after immunoprecipitation with p60^{src}-specific monoclonal antibody. Autophosphorylation of p60^{src} (Fig. 1, lanes 1, 3, 5 and 7) as well as phosphorylation of enolase, the conventional exogenous substrate of p60^{src} (Fig. 1, lanes 2, 4, 6 and 8) have been studied. The activity of p60^{src} from the membranes preincubated with ZnCl₂ and nonradioactive ATP (Fig. 1, lanes 3 and 4) was reduced. With enolase as the phosphorylation substrate (Fig. 1, lane 4) the activity was as low as 31 ± 8% (*n* = 3) of the activity of p60^{src} from untreated membranes (Fig. 1, lane 2) or from the membranes prephosphorylated by MgATP (Fig. 1, lane 8) or preincubated in the presence of ZnCl₂ or ATP alone (data not shown). Reduction of the kinase activity in the autophosphorylation after prephosphorylation of p60^{src} in the presence of Zn²⁺ was not so prominent (Fig. 1, lane 3 in comparison with lanes 1 and 7). These results are in line with the known fact of the more drastic influence

Fig. 1. Tyrosine kinase activity of the immunoprecipitated p60^{src} in the autophosphorylation (lanes 1, 3, 5 and 7) and phosphorylation of enolase (lanes 2, 4, 6 and 8). Hippocampal membranes were preincubated in 50 mM HEPES-NaOH, pH 6.9, for 10 min at 30°C without ATP and bivalent cations (1, 2, 5 and 6) or with 0.1 mM ATP and 0.5 mM ZnCl₂ (3 and 4), or with 0.1 mM ATP and 1.0 mM MgCl₂ (7 and 8) before immunoprecipitation. Lanes 5 and 6 demonstrate the activity of p60^{src} from hippocampal membranes isolated in the presence of 0.1 mM Na₃VO₄ (the inhibitor of protein tyrosine phosphatases).

Fig. 2. Tyrosine kinase activity of the immunoprecipitated p60^{src} in the autophosphorylation (lanes 1 and 3) and phosphorylation of enolase (lanes 2 and 4) in the presence of 10 mM MgCl₂, 3 mM MnCl₂ and 0.01 mM [γ -³²P]ATP (1 and 2) and in the presence of 0.5 mM ZnCl₂ and 0.1 mM [γ -³²P]ATP (3 and 4). Specific radioactivity of [γ -³²P]ATP in all experiments was equal to 50 Ci/mmol.

of inhibitory tyrosine phosphorylation of p60^{src} on phosphorylation of exogenous substrates than on the autophosphorylation [16]. The activity of *Src* kinase of the membranes isolated from the hippocampi in the conditions preserving endogenous protein phosphotyrosyl (Fig. 1, lanes 5 and 6) was 62 ± 9% (*n* = 3) of that of the enzyme from the membranes isolated in the absence of a protein tyrosine phosphatase inhibitor (Fig. 1, lanes 1 and 2). These data demonstrate that Zn²⁺ induces the inhibitory phosphorylation of p60^{src} and *Src* kinase is only partially inhibited in hippocampus.

Fig. 3. Cyanogen bromide cleavage analysis of p60^{src} autophosphorylated after immunoprecipitation (lane 1) and phosphorylated in hippocampal membranes in the presence of Zn²⁺ (lane 2).

Fig. 4. Phosphorylation of $p60^{c-src}$ in hippocampal membranes in the presence of 0.5 mM $ZnCl_2$ (1), 2.0 mM $MnCl_2$ (2), or 0.5 mM $ZnCl_2$ and 2.0 mM $MnCl_2$ (3). The gel was treated with hot alkali [13] after electrophoresis to reduce the content of phosphoserine and phosphothreonine in the proteins.

Inhibitory tyrosine phosphorylation of $p60^{c-src}$ on carboxy-terminal tyrosyl is known to be catalyzed not by *Src* kinase itself but by another cellular protein tyrosine kinase(s) [11,12]. Immunoprecipitated $p60^{c-src}$ had no Zn^{2+} -induced kinase activity in the autophosphorylation (Fig. 2, lane 3) as well as in phosphorylation of enolase (Fig. 2, lane 4). Besides, there was no phosphorylation of 49-kDa protein (Fig. 2, lane 3), which was shown to be tyrosyl-phosphorylated in hippocampal membranes in the presence of Zn^{2+} and co-immunoprecipitated with $p60^{c-src}$ [5]. These results favored the suggestion that $p60^{c-src}$ and 49-kDa protein are phosphorylated in the hippocampal membranes not by $p60^{c-src}$, but by another protein tyrosine kinase, stimulated by Zn^{2+} and not co-immunoprecipitated with $p60^{c-src}$. Cyanogen bromide cleavage of the phosphorylated *Src* kinase provided an additional confirmation. The carboxy-terminal Tyr^{527} is contained within the 4-kDa peptide, but Tyr^{416} within the 10-kDa fragment after this treatment [11]. We observed that the cleavage of $p60^{c-src}$ phosphorylated by $ZnATP$ in hippocampal membranes did produce 4-kDa phosphopeptide (Fig. 3, lane 2). Control cleavage of the autophosphorylated $p60^{c-src}$ produced a 10-kDa rather than 4-kDa phosphopeptide (Fig. 3, lane 1). Based on these observations, we concluded that Zn^{2+} in hippocampal membranes activates a protein tyrosine kinase which catalyzes inhibitory phosphorylation of $p60^{c-src}$ on the carboxy-terminal tyrosine residue.

Recently, a protein tyrosine kinase, named *CSK*, that

specifically phosphorylates the negative regulatory site of $p60^{c-src}$ has been found and characterized in neonatal rat brain [17,18]. However the activity of *CSK* is maximal in the presence of Mn^{2+} and is inhibited by Zn^{2+} [17]. Phosphorylation of $p60^{c-src}$ in hippocampal membranes was lower in the presence of Mn^{2+} than in the presence of Mn^{2+} and Zn^{2+} and much lower than in the presence of Zn^{2+} alone (Fig. 4). Besides, *CSK* was reported to be a cytosolic protein [18]. So, the nature of the Zn^{2+} -activated protein tyrosine kinase catalyzing negative regulatory phosphorylation of *Src* kinase in hippocampal membranes remains unclear. The existence of the Zn^{2+} -stimulated protein tyrosine kinase capable of regulating $p60^{c-src}$ kinase activity in the membranes of hippocampal neurons makes it likely that Zn^{2+} may participate in hippocampal neurotransmission causing changes in the protein tyrosine kinase activities.

Acknowledgements: We thank G. Gacon for helpful discussions, R. Fagard for providing the antibody to $p60^{c-src}$ and Y. Ben-Ari for support of this work. A.V. Vener was the recipient of a French Ministry of Research and Technology postdoctoral fellowship.
