The Diels Alder reaction of a glutamate derived dienophile with trans-1-methoxy-3-trimethylsilyloxy-1,3-butadiene affords a spirodienone. This, upon treatment with aqueous base leads to N-CBz-tyrosine. Optical activity is substantially maintained throughout the process.

Recently we have begun some investigations into the possibility of the chemical interconversions of α -amino acids.¹ Our long term objective in this activity is to learn to achieve such transformations within the context of a polypeptide, thus possibly modifying its biological function.

Our first success in the more limited area of interconversions of α -amino acids was the synthesis of γ -carboxyglutamate from L-glutamate via the intermediacy of pyroglutamate.² Below we wish to describe a more complex type of transformation, *i.e.* the conversion of L-glutamate to L-tyrosine.

For this purpose, we started with the readily available L-benzyl-N-CBz-pyroglutamate (**1**). We have previously described² the smooth reaction of **1** with the Brederick reagent, bisdimethyl-amino-tert-butoxymethane, to afford a nearly quantitative yield of **2**. Hydrolysis of **2** with aqueous 1N HCl-THF afforded the hydroxymethylenelactam **3**.³ The latter was converted to an E:Z mixture of α -thiophenylmethylenelactam isomers **4**^{3,4} through the action of tri-n-butylphosphine and diphenyl disulfide (THF, rt, 68% yield).⁵

Oxidation of **4** with m-chloroperoxybenzoic acid in chloroform at -23° for 2.5 hr provided a

60% yield of diastereometric sulfoxides **5**,^{3,6} which were not routinely separated for use in the next step. Diels Alder reaction of **5** with diene **6**,^{7,8,9} was accomplished by heating the mixture in benzene at reflux for 22.5 hr. Hydrolysis of the crude adduct with 2.5% acetic acid in ethyl acetate afforded, after silica gel chromatography, a 57% yield of crystalline spirodienone **7**,³ mp 109.5-111°, $[\alpha]_D = -19.8^\circ$ ($C = 1.0$, chloroform).

Treatment of **7** with 2N sodium hydroxide in tetrahydrofuran (2 mmol of hydroxide/mmol of **7**) for 24 hr followed by acidification of the derived basic material with 1N aqueous hydrochloric acid produced a nearly quantitative yield of N-CBz-tyrosine **8**, mp 92.5-94°, $[\alpha]_D = +9.0$ ($C = 0.7$, acetic acid); natural¹⁰ mp 94-98° $[\alpha]_D = +9.8^\circ$ ($C = 0.5$, acetic acid).

Proof of the optical purity of the synthetically derived **8** was provided by its conversion to optically pure L-tyrosine methyl ester. This was accomplished by treatment of **8** with an ethereal solution of diazomethane in methanol at 0° followed by catalytic transfer hydrogenolysis¹¹ (10% Pd/C, 2:1 methanol/cyclohexene) of the derived methyl ester. There was thus obtained the relatively unstable amino ester. Examination of its ¹H NMR spectrum (CDCl₃, 270 MHz) in the presence of the lanthanide shift reagent, tris [3-(trifluoromethylhydroxymethylene)-d-camphorato] europium (III) showed the L-tyrosine methyl ester to be >95% enantiomerically pure.¹²
