ABSTRACT

Prolongation of cell survival through prevention of apoptosis is considered to be a significant factor leading to anabolic responses in bone. The current studies were carried out to determine the role of the small GTPase, RhoA, in osteoblast apoptosis, since RhoA has been found to be critical for cell survival in other tissues. We investigated the effects of inhibitors and activators of RhoA signaling on osteoblast apoptosis. In addition, we assessed the relationship of this pathway to parathyroid hormone (PTH) effects on apoptotic signaling and cell survival. RhoA is activated by geranylgeranylation, which promotes its membrane anchoring. In serum-starved MC3T3-E1 osteoblastic cells, inhibition of geranylgeranylation with geranylgeranyl transferase I inhibitors increased activity of caspase-3, a component step in the apoptosis cascade, and increased cell death. Dominant negative RhoA and Y27632, an inhibitor of the RhoA effector Rho kinase, also increased caspase-3 activity. A geranylgeranyl group donor, geranylgeraniol, antagonized the effect of the geranylgeranyl transferase I inhibitor GGTI-2166, but could not overcome the effect of the Rho kinase inhibitor. PTH 1-34, a potent anti-apoptotic agent, completely antagonized the stimulatory effects of GGTI-2166, dominant negative RhoA, and Y27632, on caspase-3 activity. The results suggest that RhoA signaling is essential for osteoblastic cell survival but that the survival effects of PTH 1-34 are independent of this pathway. *J. Cell. KEY WORDS: OSTEOLAST; RhoA; APOPTOSIS; PARATHYROID HORMONE

Anti-apoptotic actions are a mechanism through which a number of stimuli have been proposed to increase osteoblastic activity, leading to anabolic responses in bone. These anti-apoptotic factors include parathyroid hormone (PTH) [Jilka et al., 1999; Sowa et al., 2003; Jilka, 2007; Wang et al., 2007], insulin-like growth factor-I [Grey et al., 2003], endothelin [Van Sant et al., 2007], mechanical loading [Pavalko et al., 2003; Weyts et al., 2003; Bran et al., 2008], and matrix environment [Buxton et al., 2008]. Activation of protein kinase A appears to be a critical component of the anti-apoptotic response to PTH [Swarthout et al., 2002; Chen et al., 2007]. However, other signaling pathways could contribute to anti-apoptotic actions. Our previous studies had shown that PTH activates the small G protein RhoA in osteoblastic cells [Radeff et al., 2004]. RhoA signaling promotes survival in other tissues [Gallagher et al., 2004; Kobayashi et al., 2004; Reuveny et al., 2004; Stepan et al., 2004; Zhu et al., 2008]. RhoA inactivation by statins leads to apoptosis of human osteosarcoma cells [Fromiguet et al., 2006]. However, in some tissues RhoA can induce apoptosis [Wu et al., 2006; Del Re et al., 2007]. In view of these diverse

findings, we were interested in determining whether the pathway is important for survival of osteoblastic cells, and whether it plays a role in the effects of PTH to promote osteoblast survival.

RhoA signaling can be manipulated with genetic and pharmacologic tools. Translocation of RhoA to the plasma membrane and its activation are dependent upon the lipid modification, geranylgeranylation. A number of agents have been developed that inhibit geranylgeranyltransferase I and prevent the geranylgeranylation of RhoA. Exogenous geranylgeranyl groups can be provided through the donor molecule geranylgeraniol. The downstream RhoA effector Rho kinase can be inhibited pharmacologically. Actions of RhoA can also be prevented through the stable expression of a dominant negative RhoA. These tools were used to assess the importance of the pathway in MC3T3-E1 osteoblastic cells.

The findings demonstrate that RhoA, through its downstream effects, promotes survival of MC3T3-E1 osteoblastic cells. Interruption of RhoA signaling or interference with the activation of RhoA increases caspase-3 activity and cell death. The effects of interfering with the RhoA pathway could be overcome by PTH

treatment. However, blocking the pathway in the MC3T3-E1 cells did not significantly attenuate the effects of PTH, suggesting that these are independent pathways mediating osteoblast survival.

METHODS

CELL CULTURE

MC3T3-E1 pre-osteoblastic cells were obtained from RIKEN Cell Bank (Tsukuba, Japan), and maintained in α -MEM (Invitrogen, Carlsbad, CA) supplemented with 10% fetal bovine serum (FBS; Hyclone, Logan, UT) and 1% penicillin-streptomycin (Invitrogen) at 37°C, 5% CO₂. Media were replaced every three days, and the cells were subcultured weekly for use in experiments within 20 passages. For serum starvation, 0.1% bovine serum albumin (BSA; Calbiochem, San Diego, CA, fraction V) was substituted for the bovine serum. For the caspase-3 assay, cells were seeded at 250,000 cells/well on a 6-well plate. For the LIVE/DEAD assay, cells were seeded at 55,000 cells/well on a 24-well plate.

STABLE TRANSFECTION OF MC3T3-E1 CELLS

MC3T3-E1 cells were transfected with constitutive active RhoA63L, dominant negative RhoA19N, or pcDNA (empty vector-EV) using a CalPhos mammalian transfection kit (Clontech, Palo Alto, CA). The RhoA construct and pcDNA were generously provided by Dr. Said Sebt, Moffitt Cancer Center. Briefly, 5 μ g of plasmid DNA was added to 12.4 μ l of 2 M calcium solution to make 100 μ l solution A. Solution A was then added dropwise into 100- μ l 2 \times HEPES-buffered saline (Solution B) with slow vortexing to make the transfection solution. After incubation at room temperature for 20 min, the transfection solution was added dropwise to cell culture plates. After 3 h at 37°C, calcium phosphate-containing medium was removed and replaced with 2 ml fresh medium for 24 h. The stable transfectants were selected and maintained with culture medium containing 400 μ g/ml G418 (Sigma, St. Louis, MO).

TREATMENTS

To inhibit its geranylgeranylation, a process by which RhoA is modified to permit its translocation to the plasma membrane, a geranylgeranyl transferase I inhibitor, GGTI-2166, was used. This reagent was kindly provided by Dr. Said Sebt, Moffitt Cancer Center and Dr. Andrew Hamilton, Yale University. To inhibit the activity of the downstream target of RhoA, Rho kinase, the inhibitor Y-27632 (Calbiochem) was used. Geranylgeraniol (Biomol, Plymouth Meeting, PA) was used as a precursor to increase cellular geranylgeranyl pyrophosphate. bPTH 1-34 peptide (PTH 1-34) was from Bachem (Philadelphia, PA).

PROTEIN ASSAY AND CASPASE-3 ASSAY

Caspase-3 activity was measured using a caspase-3 colorimetric assay (R&D Systems, Minneapolis, MN) according to the manufacturer's instructions. At the end of the experiments, MC3T3-E1 cells and the culture media were harvested and centrifuged at 300g for 10 min. The supernatant was removed and the cell pellet was lysed by the addition of lysis buffer that was provided in the kit. The lysate was incubated on ice for 10 min. During the incubation the lysate was vortexed for 10 s twice to homogenize. At the end of

the incubation, the lysate was centrifuged at 10,000g for 1 min, and the supernatant was saved for the further experiments. The enzymatic reaction was carried out on a 96-well plate. Forty microliters of lysate, 40 μ l of reaction buffer 3 and 5 μ l of substrate (DEVD-pNA) were mixed, incubated at 37°C for 2 h, and the absorbance was read at 410 nm. After subtraction of the absorbance of reaction mix in which water was substituted for the cell lysate, the value was adjusted by the protein concentration determined with a BCA protein assay kit (Pierce, Rockford, IL).

LIVE/DEAD ASSAY

For assay of cell survival, MC3T3-E1 cells grown on 96-well plates were rinsed with phosphate-buffered saline (PBS), and stained with a LIVE/DEAD Viability/Cytotoxicity Kit (Invitrogen) according to the manufacturer's instruction. Briefly, 0.4 μ M ethidium homodimer and 0.4 μ M calcein-AM dissolved in PBS were added to the wells, and the mixture was incubated for 45 min at room temperature. Microscope images were recorded and quantification of cell numbers was achieved with a "cell counter" plug-in of Image J software.

STATISTICS

Significance was determined by analysis of variance and Tukey's post hoc test.

RESULTS

For the current investigation, two assays were used to determine the importance of RhoA for MC3T3-E1 osteoblastic cell survival. All treatments were assessed for their effects on the activity of caspase-3, a downstream effector caspase that reflects activity of both the mitochondrial and death receptor apoptotic mechanisms. However, recent work demonstrates that caspases are involved in processes in addition to apoptosis [Nhan et al., 2006] including osteoclast differentiation [Szymczyk et al., 2006], and therefore for most treatments, effects were also evaluated with a fluorescence-based LIVE/DEAD (Invitrogen) assay which is dependent on the esterase activity of live cells and the increased permeability of dead and dying cells. The assay identifies living cells based on their esterase activity, which allows them to release green fluorescent calcein from the nonfluorescent cell-permeant calcein acetoxymethylester (calcein-AM). Dead cells and dying cells are identified with the compound ethidium homodimer, which enters cells that have damaged membranes and undergoes a marked increase in red fluorescence when bound to nucleic acids. To demonstrate the effects of cell death in these assays, control experiments were carried out in which cells were subjected to serum starvation (24 h culture in medium containing 0.1% BSA) in place of culture in 10% FBS. Figure 1 shows that serum starvation of MC3T3-E1 cells resulted in increased caspase-3 activity (Fig. 1A) and increased cell death (Fig. 1B).

The Rho GTPases requires geranylgeranylation for membrane translocation and activation. This geranylgeranylation is catalyzed by the enzyme geranylgeranyl transferase I. The geranylgeranyl transferase I inhibitor GGTI-2166 increased caspase-3 activity

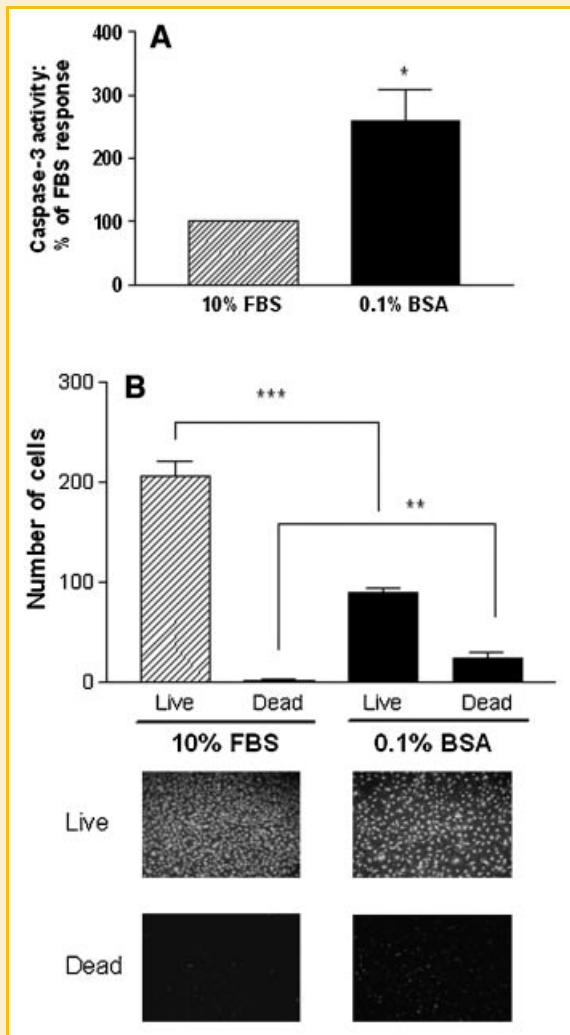

Fig. 1. Serum starvation (0.1% BSA for 24 h) increases caspase-3 activity in MC3T3-E1 cells (A) and decreases the number of live cells and increases the number of dead cells in a LIVE/DEAD assay (B) graphs and images). Values are means \pm SE of three replicates for the caspase assay and six replicates for the LIVE/DEAD assay. * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$ versus FBS.

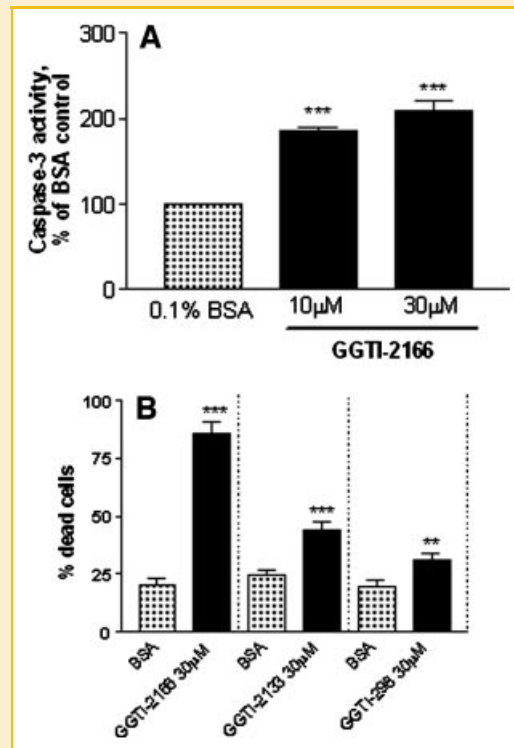

Fig. 2. Treatment of MC3T3-E1 cells for 6 h with geranylgeranyltransferase I inhibitors increases caspase-3 activity (A) and the percentage of dead cells (B). Basal caspase-3 activity in the serum-starved cells = 0.483 ± 0.090 A410 absorbance units/mg protein. Values are means \pm SE of three replicates for the caspase assay and six replicates for the LIVE/DEAD assay. ** $P < 0.01$; *** $P < 0.001$ versus BSA control.

(Fig. 2A) and cell death (Fig. 2B) in the serum-starved cells. Two other geranylgeranyl transferase I inhibitors, GGTI-2133 and GGTI-298 also increased the percent of dead cells, although they were less potent than GGTI-2166 (Fig. 2B). GGTI-2166 did not increase caspase-3 activity or cell death in the cells cultured in 10% FBS (data not shown).

Geranylgeraniol (GGOH), a precursor of geranylgeranyl pyrophosphate, increases the amount of substrate available to geranylgeranyl Rho GTPases. GGOH was able to overcome the effect of the geranylgeranyl transferase I inhibitor GGTI-2166 in both the caspase-3 assay (Fig. 3A) and the LIVE/DEAD assay (Fig. 3B). GGOH alone did not have significant effects in either assay.

The effect of GGTI-2166 to increase caspase-3 activity in the serum-starved MC3T3-E1 cells was prevented by PTH (Fig. 4A). PTH also prevented the increase in the number of dead cells resulting from treatment with GGTI-2166 (Fig. 4B).

To directly test the role of the RhoA GTPase on survival of the MC3T3-E1 cells, the cells were stably transfected with either a dominant negative RhoA construct (RhoA19N) or EV. Stable expression of the dominant negative RhoA increased caspase-3 activity and the effect was antagonized by PTH (Fig. 5).

One of the effectors of RhoA is the downstream kinase, Rho kinase. A Rho kinase inhibitor, Y27632, increased caspase-3 activity. PTH prevented the effect of the downstream inhibitor the Rho kinase inhibitor (Fig. 6A), whereas GGOH did not prevent the effect of Y27632 on caspase-3 activity (Fig. 6B).

DISCUSSION

The current studies reveal that RhoA signaling plays an important role in osteoblast survival by inhibiting osteoblast apoptosis. Apoptosis, or programmed cell death, appears to function as a limiting factor in bone formation. A number of bone anabolic agents and conditions are able to prevent osteoblast apoptosis, including PTH [Jilka et al., 1999; Sowa et al., 2003; Jilka, 2007; Wang et al., 2007], insulin-like growth factor-I [Grey et al., 2003], endothelin [Van Sant et al., 2007], mechanical loading [Pavalko et al., 2003; Weyts et al., 2003; Bran et al., 2008], and matrix environment [Buxton et al., 2008]. Thus it is important to understand the mechanisms responsible for osteoblast apoptosis. Apoptosis can be

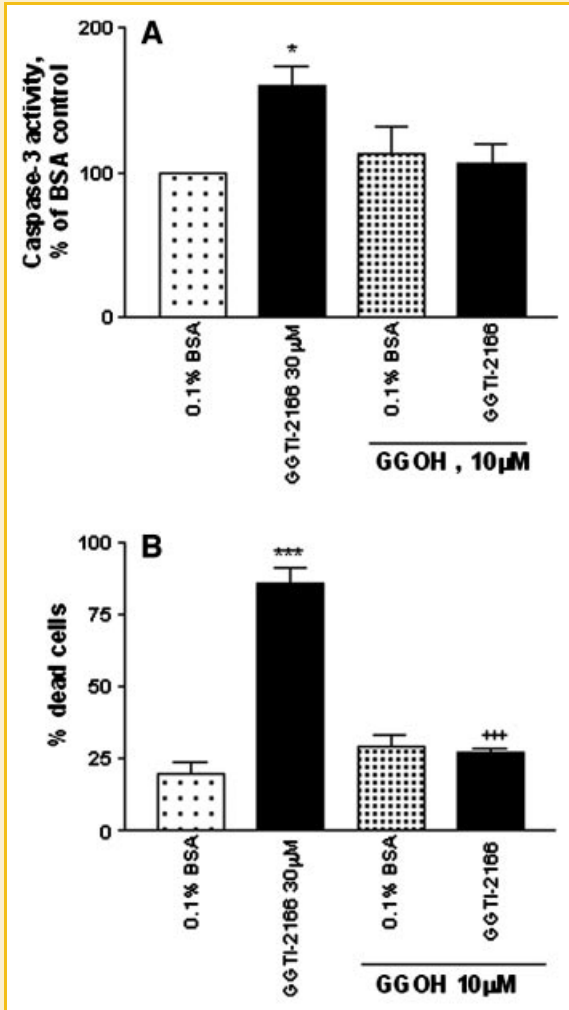

Fig. 3. Co-treatment of MC3T3-E1 cells for 6 h with geranylgeraniol (GGOH) protects against the apoptotic effect of geranylgeranyl transferase I inhibitor GGTI-2166 as shown by effects on caspase-3 activity (A) and the percentage of dead cells (B). initiated through membrane receptor-associated and mitochondrial-initiated pathways that converge and mediate their downstream effects to degrade cellular proteins and organelles through the cysteine protease caspase-3 [Hengartner, 2000]. A family of proteins, the Bcl-2 family, which contains both pro-apoptotic (e.g., Bad, Bax, Bim) and anti-apoptotic members (Bcl-2, Bcl-xl), facilitates or inhibits the process [Hengartner, 2000]. Multiple signaling intermediates, including phosphatidylinositol 3-kinase, p42/p44 MAP kinase and protein kinase A interact with various Bcl-2 family members to regulate the pathway in response to stimuli [Danilovitch et al., 2000; van de Donk et al., 2005; Sastry et al., 2006].

Rho small G proteins, molecular switches that function through binding and hydrolyzing GTP, can promote cell survival and

survival-related signaling [Gallagher et al., 2004; Kobayashi et al., 2004; Reuveny et al., 2004; Stepan et al., 2004; Zhu et al., 2008], likely through increased Bcl-2 expression [Gomez et al., 1997; Zhu et al., 2008]. Conditional knockout of RhoA or the Rho effector Rho kinase results in apoptosis of motor neurons in the spinal cord [Kobayashi et al., 2004]. The signaling pathway through which RhoA prevents apoptosis varies in different tissues. RhoA binds to the regulatory domain of mitogen-activated protein kinase kinase kinase [Gallagher et al., 2004]. The Mek/Erk pathway has been found to be crucial for anti-apoptotic effects during zebrafish embryogenesis [Zhu et al., 2008], but does not appear to be the critical pathway in AR4-2J pancreatic acinar cells [Stepan et al., 2004]. In the acinar cells and in myoblasts, survival involves the PI-3-kinase/Akt pathway [Reuveny et al., 2004; Stepan et al., 2004]. Interestingly, in some in vitro models Rho signaling promotes apoptosis [Aznar and Lacal, 2001; Wu et al., 2006; Del Re et al.,

Fig. 5. Stable expression of dominant negative RhoA in MC3T3-E1 cells increases caspase-3 activity in serum-starved cells; the effect is antagonized by 6 h treatment with PTH 1-34. Basal caspase-3 activity in the serum-starved cells = 2.31 ± 0.10 A410 absorbance units/mg protein. Values are means \pm SE of three replicates. *** $P < 0.001$ versus BSA control; + $P < 0.05$ versus dn RhoA without PTH; +++ $P < 0.001$ versus dn RhoA without PTH. EV = empty vector.

2007]. In cardiac myocytes this involves upregulation of Bax [Del Re et al., 2007].

The use of PTH as a therapeutic agent in the treatment of osteoporosis reflects its impressive effects on bone density and fracture prevention in clinical studies [Hodsman et al., 1997; Lindsay et al., 1997; Finkelstein et al., 1998; Lane et al., 1998; Neer et al., 2001] and responses in animal models [Hock et al., 1989; Dempster et al., 1993; Hodsman and Steer, 1993; Lane et al., 1996]. One of the mechanisms that is likely to be crucial to this anabolic effect is the ability of PTH to inhibit osteoblast apoptosis, resulting in increased bone formation. Signaling pathways considered to have a role in this response are p42/p44 MAP kinase [Gentili et al., 2001; Swarthout et al., 2001; Kaiser and Chandrasekhar, 2003; Chen et al., 2004] and PI-3-kinase/Akt [Gentili et al., 2002, 2003] activation. At the level of G proteins, receptor association with G α s containing heterotrimeric G proteins, leading to increased cyclic AMP and activation of protein kinase A have been strongly implicated as initiation events in the signaling [Swarthout et al., 2002; Chen et al., 2007]. Our previous studies showed that PTH treatment of osteoblastic cells could promote RhoA translocation to a cell membrane fraction and increase GTP-bound (activated) RhoA [Radeff et al., 2004]. Since both PTH and RhoA promote cell survival through MAP kinase and PI-3-kinase/Akt signaling, it was of interest to determine the interactions of PTH and agents that interfered with RhoA signaling, first to determine whether PTH could overcome the effects of inhibition of RhoA signaling, and second, whether RhoA signaling could contribute partially to the anti-apoptotic effects of PTH, that is, whether attenuation of RhoA signaling decreased the anti-apoptotic effect of PTH. The studies reported here show that PTH signaling is able to bypass or overcome

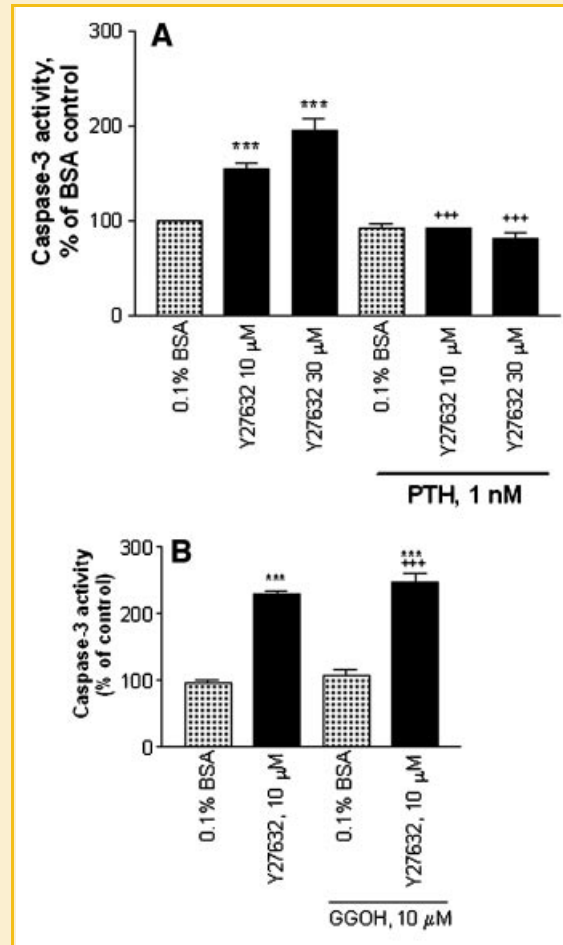

Fig. 6. Treatment of MC3T3-E1 cells for 6 h with the Rho kinase inhibitor Y27632 increases caspase-3 activity in serum starved cells; the effect is antagonized by co-treatment with PTH 1-34 (A) but not by co-treatment with geranylgeraniol (GGOH) (B). Basal caspase-3 activity in the serum-starved cells = A: 0.638 ± 0.038 A410 absorbance units/mg protein; B: 1.40 ± 0.28 A410 absorbance units/mg protein. Values are means \pm SE of two replicates for A and three replicates for B. *** $P < 0.001$ versus BSA control; +++ $P < 0.001$ versus Y27632 alone.

the inhibitory effects of GGTI-2166, Y-27632 and dominant negative RhoA. However, the effects of PTH were not antagonized by the inhibitors of the pathway. This finding differed from what we observed in earlier studies (2007 ASBMR meeting abstract # 1192), in which there was a small but significant inhibition by GGTI-2166 of the effect of PTH on caspase-3 in the MC3T3-E1 cells. The reason for this is unclear. PTH itself did not have a significant anti-apoptotic effect under basal conditions (i.e., serum starvation), except in transfected cells. The transfection procedure itself resulted in a higher basal caspase-3 activity. The role of conditions that can affect basal caspase activity on PTH-stimulated survival signaling merits further study. Also, the role of Rho signaling in the anti-apoptotic effects of other treatments affecting bone, such as endothelin, other growth factors, and mechanical stimuli, needs to be investigated. In future studies we will examine the role of the pathway in primary osteoblasts. In preliminary studies using trypan

blue uptake as an indicator of cell apoptosis, as previously applied by Jilka et al. [1998] we found that GGTI-2166 increased the percentage of neonatal mouse osteoblasts taking up trypan blue, and that this was antagonized by PTH, findings consistent with the current observations.

ACKNOWLEDGMENTS

The research described in this manuscript was supported by NIH grant AR11262 to PHS. Dr. Said Sebti, Moffitt Cancer Center and Research Institute, and Dr. Andrew Hamilton, Yale University, kindly donated the GGTI-2166 reagent. Dr. Sebti also provided the dominant negative RhoA plasmid and the pcDNA. We thank Dr. Jun Wang for his reading of the manuscript and Ms. Shirley Foster for technical support.
