THE AUTOPROTOLYSIS CONSTANT OF LIQUID ANHYDROUS HYDROGEN FLUORIDE

RUDOLF GUT

Department of Inorganic Chemistry, ETH, Universitätsstr. 6 CH - 8092 Zürich, (Switzerland)

ABSTRACT

The autoprotolysis constant of HF $K = [H^{+}][F^{-}] = 10^{-12.5}0$ (I = 0.1, KSbF₆, 0° C) has been evaluated from potentiometric titrations of solutions of H^{+} with F^{-} . The F^{-} concentrations were determined with the help of an Ag electrode acting in the presence of HCl and AgCl as a F^{-} electrode.

The earliest estimates of the autoprotolysis constant K = [H][F] * of liquid anhydrous hydrogen fluoride (AHF) were based on conductivity measurements and the first results from solutions of BF $_3$ /BF $_4$ [1] gave K $\simeq 2 \cdot 10^{-10}$ (20° C). A later estimation based on the molal conductivity of H $^+$ ($350 \text{ ohm}^{-1}\text{cm}^{-1}\text{kgmole}^{-1}$, 0° C, [2] and F $^-$ (273, 0° C, [3]) at infinite dilution in AHF [4] and on the specific conductivity of AHF ($< 1.0 \cdot 10^{-6} \text{ ohm}^{-1}\text{cm}^{-1}$, 0° C, [4]) gave K $< 2.6 \cdot 10^{-12}$ [4] as an upper limiting value. Possible variations in the assingements of values for the equivalent ionic conductances of H $^+$ and F $^-$ would result in only small shifts in the pK value. The specific conductivity is even somewhat lower than $1.0 \cdot 10^{-6} \text{ ohm}^{-1}\text{cm}^{-1}$ (25° C) [5][6]. Under the assumption that this is actually the limiting conductivity of AHF a value of pK \simeq 12 to 13 would be estimated for 0° C.

Density of AHF: 1.0005, 0° C.

^{*[],} concentrations given in mole per litre.

Another method for the elucidation of K is based on the potentiometric determination of hydrogen ion concentration in solutions of fluoride ions in AHF or vice versa. Gut and Gautschi /7] used a Pd - $\rm H_2$ electrode for the determination of $\rm [H^+]$ in solutions of the near strong acid AsF₅. However the resulting value of pK = 19.3 was much too high because of oxidation of $\rm H_2$ and reduction of As(V) at the indicator electrode surface, as was correctly stated by Devynck et al. [8].

These authors used an elegant method of stepwise combination of redox and pH equilibria of chloranil and its various protonated and/or reduced forms in a quinone electrode system to cover the entire pH range in AHF. Their evaluation of the ionic product of AHF from pF determinations in solutions of ${\rm SbF}_5$, acting as a strong acid [9][10], lead to a value of pK = 13.7. That is somewhat larger than the value reached by conductivity measurements. At least three redox- and/or protonation-constants of the chloranil system enter into such a pK evaluation and systematic errors may build up to the extent of some tenths of a logarithmic unit.

The electrode system Ag/AgCl(s)/HCl can be used for the determination of fluoride ion concentrations in SbF_5 acidified AHF solutions. Such determinations are based on the equilibrium reaction (1) [11].

$$Ag^{+} + F^{-} + HC1 \longrightarrow AgC1(s) + HF$$
 (1)
 $K_{1} = \frac{1}{[Ag1[F][HC1]}$; $\log K_{1} = 15.55^{*}$ (I = 0.1, KF, 0°C)

If [HC1] is held at a constant concentration [Ag] and [F] are inversly proportional. This permits a calibration of the electrode potential E versus pF. With [HC1] $\simeq 0.05$ pF - values up to pF $\simeq 11$ can be determined without marked dissolution of AgC1 ([Ag] $< 10^{-3}$). Sb(V) does not interfere since it does not oxidize Ag(0) [10] nor C1(-I). Thus solutions of SbF $_5$ in AHF containing dissolved HC1 and some suspended AgC1 were titrated with AHF solutions of KF. The resulting titration curves (Fig.1, Table 1) are analogous to the well known potentiometric titration

^{*} redetermined value for I = 0.1, KF, see [11].

curves of a strong acid with a strong base. The "acid" branch of such a curve follows the relation $E=E_H^{0+}+s\log[H]$. The "alkaline" branch corresponds to $E=E_F^{0-}-s\log[F]$. E^{0} values refer to the potential of the reference electrode used. The correct dependence of E and $\log[F]$ in the equation $E=E_F^{0-}-s\log[F]$ is used by us routinely as a simple check of the proper function of the whole electrode system.

For any potential E of the indicator electrode the equation

$$E = E_{H}^{o'} + s \log [H] = E_{F}^{o'} - s \log [F]$$

holds, giving

$$\frac{E_{H}^{0'} + - E_{F}^{0'}}{} = pF + pH = pK$$

on rearrangement. The calculation of $E_H^{0'}$ needs only values of [H], obtainable from the solution composition, and the corresponding E values before the pF jump. Similarly the calculation of $E_F^{0'}$ need only values of [F] and corresponding values of E after the pF jump. The constant K_1 , the amount of AgCl present and the concentration of dissolved HCl do not enter the calculation. That makes this method an extremely simple one.

Two completely independent determinations resulted in

$$pK = \frac{0.0464 - (-0.6280)}{0.0542} = 12.44_4 \pm 0.022$$

$$pK = \frac{0.0490 - (-0.6291)}{0.0542} = 12.511^{\pm} 0.045$$

giving an average of $pK_{HF} = 12.5_0 \pm 0.1$.
