### SUMMARY

The isolation of  $N_2H_5F$  from aqueous solutions is described and compared with the isolation from anhydrous hydrazine. The melting point, solubilities in various solvents and density of  $N_2H_5F$  are given.

### SYNTHESIS OF $N_2H_5F$ FROM AQUEOUS SOLUTIONS

We isolated  $N_2H_5F$  by adding  $N_2H_6F_2$  to hot, anhydrous liquid hydrazine and subsequently cooling the solution [1]. Here we describe the synthesis of  $N_2H_5F$  from aqueous solution by two different methods: a) by neutralization of hydrazine solutions with hydrofluoric acid and b) by neutralization of hydrazine solutions with solid  $N_2H_6F_2$ .

80 % hydrazine hydrate and 50 % HF were analytical grade chemicals (Riedel de Hën and Carlo Erba respectively),  $N_2H_6F_2$  was prepared by neutralization of these two reagents to pH = 2 [2]. The products were characterized by chemical analysis: hydrazine was titrated potentiometrically with potassium iodate solutions [3] and fluorine was titrated with thorium nitrate solution [4]. X-ray powder diffraction patterns were obtained using Debye-Scherrer 114.6 mm diameter camera. Conductometric measurements were performed in a polyethylene vessel using two 1.5 cm<sup>2</sup> Pt-electrodes mounted on a Teflon frame using a Teflon coated magnetic stirrer.

The neutralization reaction was carried out in a polyethylene beaker held at  $0^{\circ}\text{C}$  by ice-water bath. If the solution obtained was evaporated above room temperature,  $\text{N}_2\text{H}_6\text{F}_2$  crystallized out. In order to obtain  $\text{N}_2\text{H}_5\text{F}$  we evaporated the solutions under vacuum (10 mPa) or in a vacuum dessicator over solid  $\text{NaOH}$  at room temperature. At all the mole ratios of  $\text{HF}$  or  $1/2 \text{N}_2\text{H}_6\text{F}_2$  to  $\text{N}_2\text{H}_4$  (1:1, 1:2, 1:3) the composition of the product corresponded to  $\text{N}_2\text{H}_5\text{F}$  (found: 60.2 %  $\text{N}_2\text{H}_4$  and 37.4 %  $\text{F}$ , calculated: 61.56 %  $\text{N}_2\text{H}_4$  and 36.50 %  $\text{F}$ ). By X-ray diffraction and by conductometric analysis the product was found to contain about 5 %  $\text{N}_2\text{H}_6\text{F}_2$ . It is interesting to point out that the same product (59.9 %  $\text{N}_2\text{H}_4$  and 37.8 %  $\text{F}$ ) was obtained from anhydrous hydrazine if the conditions favoured the formation of microcrystals; large monocrystals were pure  $\text{N}_2\text{H}_5\text{F}$  with 61.0 %  $\text{N}_2\text{H}_4$  and 36.5 %  $\text{F}$ .

The synthesis of  $\text{N}_2\text{H}_5\text{F}$  is therefore possible from aqueous solutions as well as from anhydrous hydrazine. Fluoride ions can be supplied either by hydrofluoric acid or by solid  $\text{N}_2\text{H}_6\text{F}_2$ . The synthesis from aqueous solutions is, however, time consuming and yields a product contaminated by small amount of  $\text{N}_2\text{H}_6\text{F}_2$ . The synthesis in anhydrous hydrazine is faster; using solid  $\text{N}_2\text{H}_6\text{F}_2$  we can achieve a 100 % conversion of reagents. Pure  $\text{N}_2\text{H}_5\text{F}$  can only be obtained by fractional crystallization from anhydrous hydrazine, the problems being similar to those encountered in the preparation of pure  $\text{NH}_4\text{F}$ .

#### MELTING POINT OF $\text{N}_2\text{H}_5\text{F}$

$\text{N}_2\text{H}_5\text{F}$  is hygroscopic, therefore it was handled in a dry box throughout the experiments. The measurements were performed in glass and in polyethylene capillaries. Glass appears to be perfectly suitable material for the purpose. The melting point was determined in a Mettler EF 1 apparatus using a heating rate  $0.2^{\circ}\text{C}/\text{min}$  and it was found to be  $100.5 \pm 0.2^{\circ}\text{C}$ .

SOLUBILITIES OF  $\text{N}_2\text{H}_5\text{F}$ 

For the determination of solubility in aqueous solutions we used a polyethylene Landolt's pipette [5]. In contrast to pure  $\text{N}_2\text{H}_5\text{F}$  the solution reacts with glass slowly at room temperature and faster at temperatures above  $40^\circ\text{C}$  because of hydrolysis. Hydrolysis yields solid, less soluble  $\text{N}_2\text{H}_6\text{F}_2$  according to the equation:

The solubilities of  $\text{N}_2\text{H}_5\text{F}$ , which were determined by the content of  $\text{N}_2\text{H}_4$  in the solution, are given in Table 1. All the solutions were thermostated to  $\pm 0.1^\circ\text{C}$ .

TABLE 1

Solubilities of  $\text{N}_2\text{H}_5\text{F}$  in different solvents at 20 and  $40^\circ\text{C}$

Solvent	Solubility of $\text{N}_2\text{H}_5\text{F}$ in g/100 g of solution at	
	$20^\circ\text{C}$	$40^\circ\text{C}$
Water	$58.4 \pm 1.2$	$76.1 \pm 1.4$
53 % hydrazine	$24.7 \pm 1.2$	$30.7 \pm 1.5$
100 % hydrazine	$5.2 \pm 0.5$	$16.8 \pm 1.7$
$\text{CH}_3\text{OH}$	$2.6 \pm 0.1$	$3.4 \pm 0.05$
$\text{C}_2\text{H}_5\text{OH}$	$0.3 \pm 0.05$	$0.4 \pm$
$\text{CCl}_4$	insoluble	
n-hexane	insoluble	
acetone	reaction	

Glass can be used for the determination of solubilities in anhydrous hydrazine, hydrazine hydrate or organic solvents, the value being determined from the fluoride content of the solution.

The solubility of  $\text{N}_2\text{H}_5\text{F}$  is higher in water than in hydrazine; it is considerably higher than the corresponding solubility of  $\text{N}_2\text{H}_6\text{F}_2$  (e.g. 8.1 g/100 g of aqueous solution at  $20^\circ\text{C}$ )

The highest temperature dependence of solubility was found in anhydrous hydrazine; this fact was successfully utilized for the synthesis of large amounts of  $\text{N}_2\text{H}_5\text{F}$ .

#### DENSITY OF $\text{N}_2\text{H}_5\text{F}$

The density of  $\text{N}_2\text{H}_5\text{F}$  was determined picnometrically in n-hexane at  $25^\circ\text{C}$  and the average of eight measurements amounted  $1.467 \pm 0.006 \text{ g/cm}^3$ .

#### ACKNOWLEDGEMENTS

The present work was carried out with the financial support of the Research Community of Slovenia which is gratefully acknowledged. The authors wish to thank Miss B. Sedej for chemical analyses.
